Quantum Mechanics

Yury Holubeu *

October 5, 2025

This note isn't intended for distribution. Quantum mechanics is discussed in detail. Links below show contents of solved problems and summary of special topics. Readers who have opened this note for the first time are highly recommended to read the preface.

Contents

Preface, main motivation, main tips for studying **2**

I —— Typical Quantum Mechanics in a Nutshell —— **6**

1 Main laws, methods, models **6**
1.1 Main laws and properties of QM . . . 6
1.1.1 Schrodinger, Heisenberg equations, wave function . . . 6
1.1.2 Axioms of QM, measurements . . . 11
1.1.3 Quantum operators, angular momentum . . . 16
1.1.4 Density Matrix, Basics of Open Systems, SF . . . 19
1.1.5 Relativistic quantum fields, QED: main laws . . . 19
1.1.6 Spin, spinors, γ-matrices . . . 21
1.1.7 Information, entanglement, entropy . . . 29
1.1.8 Path integral: basics . . . 30
1.2 Matrices, Algebra, Integrals, Functional Analysis, Special Functions . . . 32
1.3 Typical Methods . . . 35
1.3.1 Perturbation theories . . . 35
1.3.2 Green's function methods for QM . . . 42
1.3.3 Scattering, S-matrix, Born Approximation: Main Methods . . . 43
1.3.4 Quasiclassics . . . 50
1.3.5 Adiabatic evolution, Berry's connection, f/s variables . . . 54
1.3.6 Variational Method . . . 58
1.3.7 Solutions by special functions . . . 61
1.4 Typical Models and Systems . . . 65
1.4.1 Transitions in atoms, selection rules . . . 65
1.4.2 Multi-electron atoms, molecules: basics . . . 72
1.4.3 Many-particle condensed systems: basics . . . 78
1.4.4 Addition of two angular momenta . . . 80
1.4.5 $T \neq 0$ quantum systems, black body . . . 81
1.5 Typical models and effects . . . 82
1.5.1 Qubits, quantum computation . . . 82
1.5.2 De Broglie waves, photoelectric effect, Compton effect . . . 84
1.5.3 1D scatterings and bound states . . . 87
1.5.4 Oscillator . . . 91
1.5.5 Motion in a central field, hydrogen . . . 96
1.5.6 Fine structure, Zeeman, Stark effects . . . 101
1.5.7 Motion in magnetic field, fundamentals of magnetism . . . 110
1.5.8 Relativistic QM and QED: main models . . . 114
1.5.9 Light-matter interactions, basic quantum optics . . . 117
1.5.10 Nuclear physics: basic effects . . . 119
1.5.11 Key fundamental experiments . . . 121

II Fundamentals of Quantum Mechanics **124**

*https://yuriholubeu.github.io/, yuri.holubev@gmail.com

2 Main General Fundamentals **124**
2.1 Experimental Facts in Basis of Quantum Mechanics . . . 124
2.1.1 Quantum Tunneling . . . 124
2.2 How In General We See Quantum World? . . . 124
2.2.1 What is the Microworld And Particle? . . . 124
2.2.2 Connection of Classical and Quantum Mechanics . . . 126
2.2.3 How Do We Understand Measurement? . . . 126
2.2.4 Planck Constant (??) . . . 126
2.2.5 What Would Be If One Slightly Changed Fundamental Constants of QM (??) . 126
2.2.6 Transitions To Other Reference Frames In Quantum Mechanics (??) . . . 126
2.2.7 Idea of Matter Waves . . . 127
2.2.8 What Is Vacuum? . . . 127
2.2.9 Wave-particle duality (?) . . . 127
2.2.10 Why Do We Need Exactly a Density of Probability? . . . 129
2.2.11 How Do Interactions Occur? . . . 129
2.3 Concepts That Are Used in QM Models . . . 130
2.3.1 The Main Idea of Quantum Mechanics . . . 130
2.3.2 Time in QM: Main ideas . . . 132
2.3.3 Reference Frames in QM . . . 132
2.3.4 Idea of Operators in Quantum Mechanics . . . 132
2.3.5 Space of States (??) . . . 132
2.3.6 Concept of Path Integral (??) . . . 132
2.4 Advanced General Understanding of Quantum Mechanics . . . 132
2.4.1 The Limit of Healthy Philosophy of QM (??) . . . 134
2.4.2 Einstein's Quantum Thought Experiments . . . 134
2.4.3 Why There are Complex Numbers in QM? . . . 134
2.4.4 Determinism (??) . . . 134
2.4.5 Experiments, at which quantum mechanics breaks? (???) . . . 134
2.4.6 At Which Point Does Lifeless Micromechanics Fail? (???) . . . 135
2.4.7 Schrodinger's Cat . . . 135
2.5 Features of Interpretations of Fundamental Experiments in QM . . . 135
2.5.1 Can the photoelectric effect be explained without photons? . . . 135
2.6 Limits of Applicability of Quantum Mechanics . . . 135
2.6.1 Limits of Applicability Due to Relativistic Effects . . . 135
2.6.2 Limits of Applicability Due to Size of a System . . . 135
2.7 Operators, Wave Functions, States . . . 135
2.7.1 Wave Function . . . 135
2.7.2 Entanglement and Purity of States (??) . . . 141
2.7.3 Openness and Closeness of a Quantum System . . . 143
2.7.4 Coordinate and Momentum Operators (!!!) . . . 143
2.7.5 Coordinate and Momentum Representations . . . 144
2.7.6 De Broglie Waves and the Connection of QM with Optics (????) . . . 151
2.7.7 Wave Packet (???) . . . 151
2.7.8 Concept of Quantum Field . . . 152
2.7.9 Superposition Principle (??) . . . 152
2.7.10 Probability Current . . . 152
2.7.11 Concept of Density Matrix 1: Basics . . . 152
2.7.12 Concept of Density Matrix 1: Other Approaches . . . 155
2.7.13 How to Use QM for Many-Particle Systems? . . . 157
2.8 Other, Useful Operators . . . 157
2.8.1 Form of a Spectrum of a Particle . . . 157
2.8.2 Evolution Operator . . . 157
2.8.3 Particle Number Operator . . . 158

2.9 Concept of Measurement in QM . . . 158
2.9.1 Measurement Method . . . 158
2.9.2 Simplified Theory of Measurements . . . 162
2.9.3 Quantum Entanglement . . . 162
2.9.4 What Happens After Measurement? . . . 162
2.9.5 The Measurement Problem in Quantum Mechanics (???) . . . 162
2.9.6 Quantum Zeno Effect . . . 162
2.9.7 Other About Measurements . . . 162
2.10 Measurement in QM: Other Ideas . . . 162
2.10.1 The Perfect Measurement . . . 162
2.11 Mathematical Side of the Formalism of QM . . . 163
2.11.1 Reminder: Strict Definitions of Operators . . . 163
2.11.2 Hilbert Space . . . 164
2.11.3 Tensor Product of Hilbert Spaces . . . 165
2.12 Classical Mechanics for QM . . . 170
2.12.1 1. Classical Lagrangian Mechanics for QM . . . 171
2.12.2 2. Classical Hamiltonian Mechanics for QM 1 . . . 193
2.12.3 2. Classical Hamiltonian Mechanics for QM 2 . . . 199
2.12.4 Connection of Classical and Quantum Mechanics . . . 217

3 Formalism of Quantum Mechanics 219
3.1 Basic Principles of Quantum Mechanics . . . 219
3.1.1 Observables, States, and Dynamics . . . 219
3.1.2 Axioms of QM: Extra Discussion . . . 230
3.1.3 Heisenberg Equations . . . 230
3.2 Typical Quantization . . . 231
3.2.1 2. Quantization: Basic Method . . . 231
3.2.2 2. Quantization: Basic Models . . . 242
3.2.3 Quantization: Conceptual Questions . . . 257
3.2.4 Quantization: Advanced Features of Basic Methods . . . 258
3.2.5 Quantization by the Bohr–Sommerfeld Rule (?) . . . 264
3.3 Second Quantization . . . 264
3.3.1 Basics of Second Quantization . . . 264
3.3.2 Second Quantization: Advanced Properties, Other Questions . . . 267
3.4 Quantization: Special Methods . . . 269
3.4.1 Quantization of Constrained Systems . . . 269
3.4.2 Quantization on Manifolds and in Other Coordinates (?) . . . 269
3.4.3 Quantization of Fields and Space: Introduction . . . 269
3.5 Density Matrix Formalism of QM . . . 269
3.5.1 Evolution of a Density Matrix . . . 270
3.5.2 Density Matrix Formalism: Examples of Applications . . . 271
3.6 Schrodinger Equation . . . 271
3.6.1 Schrodinger Equation: Essential Properties for Everyone . . . 271
3.6.2 Overview of Features and Methods of Schrodinger equation . . . 273
3.6.3 Mathematics of 1D Schrödinger Equation 1 . . . 275
3.6.4 Mathematics of 1D Schrödinger Equation 2 . . . 280
3.6.5 1D Schrödinger Equation 2: Advanced Methods . . . 287
3.6.6 One-Dimensional Schrödinger Equation 3: Basic Examples . . . 307
3.6.7 Schrodinger Equation in a Rotated Frame . . . 311
3.6.8 Experimental Confirmation of Schrodinger Equation . . . 312
3.6.9 3. Angular momentum and SO(3) . . . 312
3.6.10 4. Two-body problem . . . 316
3.6.11 5. Hydrogen atom and SO(4) . . . 323
3.6.12 6. Semi-classical asymptotics - I . . . 333

3.6.13 How to guess about Schrodinger equation? . . . 340
3.6.14 Limits of Applicability of Schrodinger equation . . . 340
3.7 Heisenberg's Quantum Mechanics . . . 340

4 Other Fundamentals of Mathematical Quantum Mechanics 343
4.1 Other, Fundamental Properties of Quantum Systems . . . 343
4.1.1 Uncertainty Principle: Main Idea and Derivation . . . 343
4.1.2 Uncertainty Principle: Other Questions . . . 343
4.1.3 Concept of Coherent States . . . 344
4.1.4 Feynman-Hellmann Theorem . . . 344
4.1.5 Virial Theorem in QM . . . 345
4.1.6 Ehrenfest Theorem . . . 345
4.1.7 Variational Principle . . . 346
4.2 Special Mathematical Transformations and Their Consequences . . . 347
4.2.1 3. Weyl Relations 1 . . . 347
4.2.2 3. Weyl Relations 2 . . . 356
4.2.3 3. Weyl Relations 3: Deformation quantization . . . 367
4.3 Integration in Functional Spaces . . . 373
4.3.1 1. Gaussian measures . . . 373
4.3.2 2. Wiener measure and Wiener Integral . . . 376
4.3.3 3. Gaussian Wiener Integrals . . . 382
4.4 Fermionic Systems . . . 386
4.4.1 1. Canonical Anticommutation Relations . . . 386
4.4.2 2. Grassmann Algebras . . . 392
4.4.3 3. Graded Linear Algebra . . . 400
4.4.4 4. Path Integrals for Anticommuting Variables . . . 406
4.5 Spin, Spinors and Identical Particles . . . 414
4.5.1 Operator of Angular Momentum $\hat{j}$ (!?!!) . . . 414
4.5.2 Transformation of States Under Rotations . . . 423
4.5.3 Concept of Spin . . . 428
4.5.4 Connection of Spin with Statistics (!!????) . . . 433
4.5.5 Generalization of Spin to Spinors . . . 436
4.5.6 Other About Spin . . . 436
4.5.7 1. Spin . . . 437
4.5.8 3. System of Identical Particles . . . 440

5 Other Fundamental Questions of Quantum Mechanics 448
5.1 Established Ideas of Generalizations of Quantum Mechanics . . . 448
5.1.1 Idea of Relativistic QM . . . 448
5.1.2 Idea of QFT . . . 448
5.2 Other About the Fundamentals of Quantum Mechanics . . . 448
5.2.1 General Philosophical Features of QM . . . 448
5.2.2 Coulomb Interaction in scope of QM in Details . . . 449
5.2.3 Examples of the Inconsistency of Quantum Mechanics . . . 449
5.2.4 Bell Inequality (!!?) . . . 449
5.2.5 Experimental Verification of the Bell Inequality (!!?) . . . 449
5.2.6 On the Directions of Possible Generalizations of Quantum Mechanics . . . 449
5.2.7 On Misunderstandings of Quantum Mechanics by Physicists in General . . . 449
5.3 Other Fundamental Properties of Quantum Systems . . . 450
5.3.1 Entropy of a Quantum System . . . 450
5.3.2 Connection of Entropy and Geometry . . . 450
5.3.3 Kramers Theorem on Time Reversal(???) . . . 450
5.3.4 Time-Reversal Symmetry: Advanced Features . . . 450

III Typical Methods and Models 451

6 Main General Methods and Templates 451

6.1 Overview of Different Method for Solving Problems in QM . . . 451
6.2 Perturbation Theory: Fundamentals . . . 451
6.2.1 RS Stationary Perturbation Theory, Non-Degenerate Case . . . 451
6.2.2 RS Stationary Perturbation Theory, Degenerate Case . . . 455
6.2.3 Brillouin-Wigner Perturbation Theory . . . 459
6.2.4 RS Non-Stationary Perturbation Theory . . . 461
6.2.5 Perturbation Theory in QFT: Overview . . . 471
6.3 Perturbation theory: Well-known Special Cases and Features . . . 471
6.3.1 Perturbation Theory in the Continuous Spectrum . . . 471
6.3.2 Scattering of Charged Particles on Nuclei . . . 475
6.3.3 Perturbation of Boundary Conditions and Levels of a Deformed Nucleus . . . 476
6.3.4 Sudden Perturbations and Ionization in Decay and Nuclear Impact . . . 479
6.3.5 Collisions in Perturbation Theory: Typical Examples . . . 485
6.3.6 Perturbation Theory in the Case of Close Levels . . . 486
6.3.7 Other Perturbation Theories: Overview . . . 491
6.3.8 Other Properties of Perturbation Theories . . . 492
6.4 Harmonic Oscillator: Basics . . . 493
6.4.1 Quantization of a Harmonic Oscillator . . . 493
6.4.2 Quantization of a Harmonic Oscillator with Features . . . 498
6.4.3 Harmonic Oscillator by Takhtajan . . . 499
6.4.4 Coherent States (??) . . . 507
6.4.5 Oscillator in the Holomorphic Representation . . . 511
6.4.6 Fermionic Oscillator . . . 523
6.4.7 Moving oscillator . . . 528
6.4.8 Oscillator, Moving with $v \approx c$ . . . 528
6.4.9 Motion in a Central Field . . . 528
6.4.10 Angular Momentum Operators . . . 530
6.4.11 SO(3) Representations for the Hydrogen Atom . . . 532
6.5 Harmonic Oscillator: Advanced Ideas . . . 535
6.5.1 Overview of Applications of Harmonic Oscillator . . . 535
6.5.2 Discrete Spectrum in a Central Field . . . 535
6.5.3 Continuous Spectrum in a Central Field . . . 538
6.5.4 Hidden SO(4) Symmetry . . . 540
6.5.5 Particle in a Central-Symmetric Potential by Takhtajan . . . 546
6.5.6 Other Questions About the Central Field . . . 550
6.5.7 Central Field in Spherical and Parabolic Coordinates . . . 551
6.5.8 Non-Relativistic Hydrogen Atom . . . 551
6.6 Three-Dimensional Problem by Migdal-Krainov (?) . . . 553
6.6.1 Centrally-Symmetric Field . . . 553
6.6.2 Energy Levels in a Coulomb Field . . . 554
6.6.3 Quasi-Classical Representation of Spherical Functions . . . 555
6.6.4 Thomas-Fermi Distribution in the Atom . . . 557
6.6.5 Estimates of Nuclear Matrix Elements . . . 560
6.6.6 Non-Central Potential (???????) . . . 563
6.6.7 Quasi-Classical Scattering Problem . . . 563
6.7 Adiabatic methods . . . 565
6.7.1 Non-stationary Adiabatics . . . 566
6.7.2 Non-stationary Adiabatics by Migdal Krainov . . . 572
6.7.3 Berry's Phase: Basics . . . 577
6.7.4 Extra Understanding of Geometrical Phases 1 . . . 581
6.7.5 Extra Understanding of Geometrical Phases 2 . . . 590

6.7.6 Stationary Adiabatics . . . 600
6.7.7 Examples of Fast and Slow Subsystems by Migdal Krainov 1 . . . 603
6.7.8 Examples of Fast and Slow Subsystems by Migdal Krainov 2 . . . 611
6.7.9 Adiabatic Methods: Other Statements . . . 615
6.8 Variational methods: basics . . . 616
6.8.1 Variational methods by Tong . . . 616
6.8.2 Variational methods by Zhou . . . 616
6.8.3 Variational proof that any 2D well supports at least one bound state . . . 616
6.9 Semiclassical methods . . . 616
6.9.1 Main Semiclassical Methods . . . 616
6.9.2 Tunneling Through a Barrier . . . 637
6.9.3 Typical Examples and Details of the Semiclassical Method . . . 637
6.9.4 Semiclassical Approximation by MK (??) . . . 641
6.9.5 Time-Dependent Asymptotics by Takhtajan . . . 653
6.9.6 Time-Independent Asymptotics . . . 657
6.9.7 Bohr-Wilson-Sommerfeld Quantization Rules . . . 660
6.9.8 Other About Semiclassics . . . 661

7 Methods for Scatterings **664**
7.1 Green's Function Methods (??) . . . 664
7.1.1 Idea of GF Method . . . 664
7.1.2 Why GF Method is That Powerful? . . . 666
7.1.3 GF Method for Time-Dependent Problems? . . . 666
7.1.4 GF Method for Matrix Hamiltonians . . . 666
7.2 Scattering Theory: Perturbative Approach . . . 666
7.2.1 Concept of Scattering Cross-Section . . . 666
7.2.2 Spherical Waves of a Free Particle . . . 667
7.2.3 Expansion of the de Broglie Wave into Partial Waves . . . 669
7.2.4 Born Approximation . . . 671
7.2.5 Lippmann–Schwinger Integral Scattering Theory (??) . . . 674
7.2.6 Expansion of the S-Matrix and T-Matrix . . . 677
7.2.7 Unitarity and the Optical Theorem . . . 681
7.3 Scattering Theory: Phase Decomposition Approach . . . 681

8 Specific Methods and Templates **682**
8.1 Path Integral Formulation of QM: Basics . . . 682
8.1.1 1. Feynman Path Integral . . . 682
8.1.2 2. Symbols of the evolution operator and path integrals . . . 689
8.1.3 3. Feynman path integral for the harmonic oscillator . . . 694
8.1.4 4. Gaussian path integrals . . . 698
8.1.5 5. Regularized determinants of differential operators . . . 704
8.1.6 6. Semi-classical asymptotics - II . . . 714
8.1.7 7. Notes and references . . . 719
8.1.8 Path Integral Formalism . . . 720
8.2 Path Integral Formulation of QM: Advanced Ideas . . . 722
8.2.1 Typical Path Integral by Kiselev . . . 722
8.2.2 Source and Generating Functional . . . 739
8.2.3 Diagrams in the Kiselev Formalism . . . 751
8.2.4 Strongly Connected Diagrams by Kiselev . . . 757
8.2.5 $\mathcal{S}-$Matrix Functional . . . 764
8.3 Scattering Theory: Features, Specific Models . . . 768
8.3.1 1D delta-potential . . . 768
8.3.2 Regularization methods for δ-function potential in 2D QM . . . 768
8.3.3 2D scattering theory . . . 768

8.3.4 Formalism of 3D Scattering Theory by Takhtajan . . . 771
8.3.5 Properties of the S-Matrix for Scattering in Continuous Media (!?!??) . . . 772
8.3.6 Phase Shift Formalism and Partial Cross-Sections . . . 772
8.3.7 Scattering of Identical Particles . . . 776
8.3.8 Scattering on Coulomb Potential . . . 776
8.3.9 Illustrative Examples of Typical Scattering Models . . . 776
8.3.10 Comparison of Quantum and Classical Scattering Theories . . . 776
8.4 Analytical Properties of Physical Quantities . . . 776
8.4.1 Dependence of the Nuclear Moment of Inertia on Deformation . . . 777
8.4.2 Dependence of Sound Frequency on the Wave Vector . . . 777
8.4.3 Analytical Properties of the Wave Function . . . 778
8.4.4 Scattering Amplitude at Low Energies . . . 778
8.4.5 Analytical Properties of a Dielectric Constant . . . 779
8.4.6 Analytical Properties of a Scattering Amplitude . . . 782
8.5 Scattering theory: Other features and methods . . . 782
8.5.1 Eikonal Approximation (??) . . . 782
8.5.2 Resonances . . . 786
8.5.3 Fundamentals of Inelastic Collisions . . . 787
8.5.4 Second order Born approximation (??) . . . 788
8.5.5 Reconstruction of the potential from scattering . . . 788
8.5.6 Time Delay in Scattering . . . 788
8.5.7 $1/x^2$ potential by Essin, Griffiths (2005) 1 . . . 789
8.5.8 $1/x^2$ potential by Essin, Griffiths (2005) 2 . . . 797
8.5.9 How a Mirror Works from QM Point of View? . . . 805
8.5.10 Scattering for Systems Described by the Density Matrix . . . 805
8.5.11 Useful Integrals in Scattering Theory and Their Convergence . . . 805

9 Typical Addition of Angular Momenta 805
9.0.1 Addition of Two Momenta . . . 805
9.0.2 Wigner–Eckart Theorem . . . 813
9.0.3 Matrix Elements of Tensors by Landau (?????) . . . 824
9.0.4 6j-Symbols by Landau . . . 826
9.0.5 Matrix Elements in the Addition of Momenta by Landau (!!!) . . . 830
9.0.6 Matrix Elements for Axially Symmetric Systems by Landau . . . 832
9.0.7 Other About Addition of Momenta . . . 834

10 Other Template Models and Basic Special Method 834
10.1 Motion in a magnetic field . . . 834
10.1.1 Description of Motion in Magnetic Field by Landau (?) . . . 834
10.1.2 Landau Levels . . . 834
10.1.3 Degeneracy of Landau Levels . . . 835
10.1.4 2.1. Pauli Hamiltonian by Tahtajan . . . 835
10.1.5 2.2. Particle in a uniform magnetic field by Tahtajan . . . 836
10.1.6 Motion in magnetic field in Dirac notation . . . 837
10.2 Selection Rules . . . 842
10.3 Two- and Three-Body Problems . . . 850
10.3.1 Separation of the Center of Mass . . . 851
10.3.2 Connection with Two- and Three-Body Problem in Classical Mechanics . . . 852

11 Models of Relativistic QM and QFT 852
11.1 Basics of QFT (Ch. IV in LL4) . . . 852
11.1.1 Particle in an External Field . . . 852
11.1.2 Dirac Equation for an Electron in an External Field . . . 852
11.1.3 Expansion in Powers of $1/c$ . . . 852

11.1.4 Fine Structure of the Hydrogen Atom . . . 852
11.1.5 Motion in a Centrally Symmetric Field . . . 852
11.1.6 On Other Topics in Quantum Electrodynamics . . . 852
11.2 Introduction to Particle Physics . . . 852
11.2.1 True Overview of Modern Particle Physics . . . 853
11.2.2 Standard Model: Basic Concepts . . . 853
11.2.3 Experiments of Particle Physics: Basics . . . 853

12 Famous numerical methods **853**
12.0.1 Wolfram methods . . . 853
12.0.2 QuSpin . . . 853

IV Parts of Quantum Mechanics **854**

13 Estimations and Well-known Effects **854**
13.1 Estimates in Atomic Mechanics . . . 854
13.1.1 Estimates of Velocities and Sizes of Inner Electron Orbits in the Atom . . . 854
13.1.2 Stationary States . . . 854
13.1.3 Distribution of Electric Charge in an Atom . . . 857
13.1.4 Rutherford Formula . . . 858
13.1.5 Inapplicability of Classical Mechanics at Large Impact Parameters (!!!!!!!) . . . 859
13.1.6 Estimate of Cross Sections for Potentials Decaying Faster than Coulomb (?????) 860
13.1.7 Resonance Effects in Scattering (!!!!!) . . . 861
13.1.8 Interaction Between Atoms . . . 862
13.1.9 Ionization of Atoms . . . 862
13.1.10 Multiple Scattering . . . 863
13.2 Estimations and Effects in Quantum Electrodynamics . . . 864
13.2.1 Zero Fluctuations of the Electromagnetic Field . . . 864
13.2.2 Photoelectric Effect . . . 866
13.2.3 Lifetimes of Excited Atomic States . . . 869
13.2.4 Braking radiation (!?!?) . . . 870
13.2.5 Pair Production (!!!) . . . 872
13.2.6 Lamb Shift . . . 873
13.2.7 Divergence of Series in Quantum Electrodynamics . . . 875
13.3 Light-Matter Interactions . . . 876

14 Atomic and Nuclear Physics **876**
14.1 Radiation, Transitions in Atoms . . . 876
14.1.1 Typical radiation . . . 876
14.1.2 Taking into account special features in radiation . . . 876
14.2 Hydrogen atom with extra physics . . . 876
14.2.1 Relativistic hydrogen atom . . . 876
14.2.2 Fine Splitting and Spin–Orbit Interaction . . . 876
14.2.3 Stark Effect . . . 877
14.2.4 Zeeman effects: basics . . . 879
14.2.5 Zeeman effects: other topics . . . 886
14.2.6 Hyperfine interactions: basics . . . 887
14.2.7 Hyperfine interactions: other topics . . . 888
14.3 Fundamentals of Atomic Physics . . . 888
14.3.1 Influence of the Solid-State Lattice on the Atom (????) . . . 889
14.4 Other on Quantum Scattering Theory . . . 889
14.4.1 Gell-Mann and Low theorem . . . 889
14.4.2 Ramsauer Effect . . . 890

14.4.3 Other on Scattering Theory . . . 891
14.5 Some Methods of Collisions and Scattering . . . 891
14.5.1 Other on Elastic Collisions . . . 891
14.5.2 Other on Inelastic Collisions . . . 891
14.6 Fundamentals of Nuclear Physics . . . 891
14.7 Electronic Magnetic Resonances . . . 892

15 Open Quantum Systems, Many Particle Systems 892
15.1 Typical Models of Open Quantum Systems (?) . . . 892
15.1.1 Spin-Boson Model . . . 892
15.1.2 Interaction Representation of Open Systems . . . 893
15.1.3 Born–Markov Approximation . . . 893
15.1.4 Correlation Functions of the Environment . . . 895
15.1.5 Bloch Equations . . . 896
15.1.6 On the Spectral Density . . . 898
15.2 Suppression of Tunneling in a Two-Level System . . . 899
15.2.1 Perturbative Consideration . . . 899
15.2.2 Adiabatic Consideration . . . 899
15.2.3 Caldeira–Leggett Model . . . 901
15.2.4 Spectral Weight and Ohmic Bath (???) . . . 903
15.3 Many Particle Systems [see cond matter] . . . 904

16 Quantum Optics, Quantum Information 904
16.1 Quantum Entanglement . . . 904
16.2 Fundamentals of Quantum Information Theory . . . 904
16.2.1 Introduction to Quantum Information Theory . . . 904
16.2.2 Introduction to Quantum Computing (!!) . . . 905
16.2.3 Introduction to Quantum Computers . . . 905
16.3 Physical Realization of Ideas of Quantum Information . . . 906
16.3.1 How to initialize and read the state of a qubit? . . . 906

V Problems in Quantum Mechanics 907

17 Problems of typical parts of quantum mechanics 907
17.1 Mastering typical methods . . . 907
17.1.1 Problems about Time-Independent PT 1 . . . 907
17.1.2 Problems about Time-Independent PT 2 . . . 918
17.1.3 Problems about Time-Independent PT 3 . . . 923
17.1.4 Problems about Time-Dependent PT 1 . . . 925
17.1.5 Problems about Time-Dependent PT 2 . . . 933
17.1.6 Problems about adiabatics 1: Fun Models . . . 936
17.1.7 Problems about adiabatics 2: Template Models . . . 942
17.1.8 Problems about adiabatics 3: Specific Models . . . 946
17.1.9 Simple Problems about adiabatics in Condensed Matter . . . 952
17.1.10 Problems about adiabatics in Applications . . . 954
17.1.11 Problems about quasiclassical method 1: Easy Templates . . . 955
17.1.12 Problems about quasiclassics 1: Templates That Require Special Mathematics . . . 958
17.1.13 Problems about quasiclassical method 2 . . . 961
17.1.14 Problems about quasiclassical method 3 . . . 969
17.1.15 Problems about variational method (!?) . . . 976
17.1.16 Problems about solutions by special functions 1 . . . 976
17.1.17 Problems about solutions by special functions 2 . . . 988
17.1.18 Problems about radiation . . . 995

17.2 Analysis of Typical Models . . . 1001
17.2.1 Problems about Spin, Two-Level Systems, and Their Measurements . . . 1001
17.2.2 Problems about stationary states in potentials 1 . . . 1011
17.2.3 Problems about stationary states in potentials 2 . . . 1017
17.2.4 Problems about delta-potentials 1 . . . 1024
17.2.5 Problems about delta-potentials 2 . . . 1034
17.2.6 Problems about oscillator 1 . . . 1036
17.2.7 Problems about oscillator 2 . . . 1043
17.2.8 Problems about central field 1 . . . 1049
17.2.9 Problems about central field 2 . . . 1051
17.2.10 Problems about motion in a magnetic field 1 . . . 1057
17.2.11 Problems about motion in a magnetic field 2 . . . 1068
17.3 Basic Scatterings . . . 1076
17.3.1 Problems about Passing though a Barrier 1 . . . 1076
17.3.2 Problems about Passing though a Barrier 2 . . . 1080
17.3.3 Problems about Passing though a Barrier 3 . . . 1087
17.3.4 Problems about basic 1D scatterings 1 . . . 1094
17.3.5 Problems about basic 1D scatterings 2 . . . 1103
17.3.6 Problems about basic 1D scatterings 3 . . . 1112
17.3.7 Problems about scattering in Born approximation 1 . . . 1114
17.3.8 Problems about scattering in Born approximation 2 . . . 1128
17.3.9 Second Order Scattering in Yukawa Potential . . . 1131
17.3.10 Problems about scattering in Born approximation 3 . . . 1148
17.3.11 Problems about partial-wave analysis 1 . . . 1151
17.3.12 Problems about partial-wave analysis 2 . . . 1161
17.3.13 Advanced different problems about typical scatterings . . . 1167
17.4 Specific qeuestions and setups for scattering . . . 1190
17.4.1 Problems about low-energy scattering and resonant scattering 1 . . . 1190
17.4.2 Problems about low-energy scattering and resonant scattering 2 . . . 1200
17.4.3 Problems about low-energy scattering and resonant scattering 3 . . . 1209
17.4.4 Problems about scattering of fast particles; Eikonal approximation . . . 1215
17.4.5 Problems about scattering of particles with spin . . . 1224
17.4.6 Problems about analytic properties of the scattering amplitude . . . 1231
17.4.7 Problems about scattering on composite particles, inelastic collisions . . . 1237
17.5 Checking Basic Understanding . . . 1257
17.5.1 Questions on Understanding the Basics of Quantum Mechanics . . . 1257
17.5.2 Questions on Understanding Typical Sections of Quantum Mechanics . . . 1257
17.5.3 Questions on Understanding Typical Details . . . 1257
17.5.4 Typical Problems on Testing Knowledge of Quantum Models . . . 1258
17.5.5 Problems about Understanding States, Entanglement Measurements (???) . . . 1258
17.5.6 Short Problems on Understanding Atoms . . . 1259
17.5.7 Typical Problems on Testing Mastery of Methods . . . 1260

18 Other Problems about Basic Atomic Physics 1260
18.1 Photons, Atoms, Molecules . . . 1260
18.1.1 Problems about photons 1 . . . 1261
18.1.2 Problems about photons 2 . . . 1268
18.1.3 Problems about Special Effects in Atoms 1 . . . 1279
18.1.4 Problems about Special Effects in Atoms 2 . . . 1285
18.1.5 Basic Problems about Hydrogen Atoms 1 . . . 1288
18.1.6 Basic Problems about Hydrogen Atoms 2 . . . 1299
18.1.7 Advanced problems about atoms 1 . . . 1304
18.1.8 Advanced problems about atoms 2 . . . 1306
18.1.9 Advanced problems about atoms 3 . . . 1309

18.1.10 Advanced problems about atoms 4 . . . 1332
18.1.11 Basic problems about molecules . . . 1343
18.1.12 Advanced problems about molecules . . . 1359
18.1.13 Extra Problems about scattering 1 . . . 1366
18.1.14 Extra Problems about scattering 2 . . . 1374
18.1.15 General problems about of uncertainty and matter waves 1 . . . 1389
18.1.16 General problems about of uncertainty and matter waves 2 . . . 1394
18.1.17 General problems about of uncertainty and matter waves 3 . . . 1396
18.1.18 Basic problems about atoms in fields 1 . . . 1408
18.1.19 Basic problems about atoms in fields 2 . . . 1414
18.1.20 Basic problems about atoms in fields 3 . . . 1417
18.2 Nuclear and Particle Physics . . . 1434
18.2.1 General questions about nuclei and radioactivity . . . 1434
18.2.2 Problems about radioactivity 1 . . . 1434
18.2.3 Problems about radioactivity 2 . . . 1448
18.2.4 Problems about neutrons 1 . . . 1454
18.2.5 Problems about neutrons 2 . . . 1465
18.2.6 Problems about neutrons 3 . . . 1470
18.2.7 Problems about nuclear fission and reactors 1 . . . 1475
18.2.8 Problems about nuclear fission and reactors 2 . . . 1481
18.2.9 Problems about nuclear fission and reactors 3 . . . 1492
18.2.10 Basic Problems about Elementary Particles 1 . . . 1492
18.2.11 Basic Problems about Elementary Particles 2 . . . 1501

19 Problems about Formalism of QM 1516
19.1 Problems about Operators . . . 1516
19.1.1 Problems about Basic Quantum Operators . . . 1516
19.1.2 Problems about formalism of second quantization . . . 1522
19.1.3 Problems about Angular Momentum and Spin . . . 1522
19.1.4 Problems about Mathematical Properties of Quantum Mechanical Operators . . . 1528
19.1.5 Problems about Models of Many-Body Systems (!?!?!!) . . . 1531
19.2 Problems about Derivations of Properties . . . 1532
19.2.1 Problems about derivation of special constructions . . . 1532
19.3 Problems about Mathematical Quantum Mechanics . . . 1533
19.3.1 Problems about Mathematical Scattering . . . 1533

20 Other, Special Parts and Special Methods 1534
20.1 Deep Understanding of Quantum Mechanics . . . 1534
20.1.1 Questions about the True Understanding of Quantum Mechanics . . . 1534
20.1.2 Problems about Strict Mathematical Properties of Quantum Mechanics . . . 1535
20.1.3 Problems about Understanding the Details of the Mathematical Foundations of Quantum Mechanics . . . 1535
20.2 Special Theoretical Models . . . 1535
20.2.1 Problems about Open Systems . . . 1535
20.2.2 Problems about the Functional Integral . . . 1542
20.2.3 Problems about Instantons and Tunneling . . . 1548
20.2.4 Decay of a Metastable State (??) . . . 1556
20.3 Special Phenomena for Experiments . . . 1556
20.3.1 Problems about Blackbody Radiation and Photons . . . 1556
20.3.2 Problems about line widths and their detection 1 . . . 1567
20.3.3 Problems about line widths and their detection 2 . . . 1573
20.4 Many-Body Quantum Mechanics Problems . . . 1584
20.4.1 Problems about Addition of Momenta and Particle Identity . . . 1584
20.4.2 Simple Problems of Solid State Physics . . . 1587

20.4.3 Simple Problems of Quantum Mechanics of Gases . . . 1592
20.5 Problems of Other Parts . . . 1594
20.5.1 Typical Problems of Relativistic Quantum Mechanics . . . 1594
20.5.2 Problems about the Heisenberg Formalism (??) . . . 1603
20.6 Problems on the Foundations of Quantum Information Theory . . . 1603
20.6.1 Problems on basic quantum gates . . . 1603

VI —— Special Topics in a Nutshell —— 1609

21 Other Theories 1609
21.1 Other details of typical methods . . . 1609
21.1.1 Typical Scattering: Details . . . 1609
21.1.2 Special Scatterings . . . 1615
21.1.3 Details of typical adiabatics . . . 1618
21.1.4 Scattering: Other Details of Basic Methods . . . 1619
21.1.5 Details of typical QM methods for simple atoms . . . 1628
21.2 Typical numerical methods . . . 1631
21.2.1 On density functional theory . . . 1631
21.2.2 Typical modeling in Wolfram . . . 1633
21.3 Fundamentals of QM: details . . . 1633
21.3.1 Open quantum systems: formalism . . . 1633
21.3.2 Parameters for constructing models . . . 1635
21.3.3 The Meaning and Main Interpretations of Quantum Mechanics (???) . . . 1635
21.3.4 Constants of quantum mechanics . . . 1637
21.3.5 Other important real and thought experiments . . . 1637
21.3.6 Uncertainty Relation (????) . . . 1637
21.3.7 Other features of basics of QM . . . 1639
21.3.8 Quantum Fields and the Poincaré Group (!?!??!) . . . 1643
21.3.9 What can be and what cannot be in QM? (???) . . . 1643
21.3.10 Special Quantization Methods . . . 1644
21.4 Methods for special applications 1 . . . 1648
21.4.1 Rotations, C-, P-, T-Symmetry . . . 1648
21.4.2 Symmetries, group theory methods . . . 1650
21.4.3 Sepcial mathematical constructions by Takhtajan . . . 1650
21.4.4 Symmetries in Quantum Mechanics and Their Consequences . . . 1653
21.4.5 Absence of Hidden Variables, Bell's Theorem, EPR . . . 1653
21.4.6 Response, Polarization, Susceptibility . . . 1654
21.4.7 Generalized Functions in Quantum Mechanics . . . 1654
21.4.8 Other Useful Methods for the Schrödinger Equation . . . 1654
21.4.9 Other Estimates (!!!!) . . . 1654
21.4.10 Other methods of atomic properties . . . 1654
21.4.11 Perturbation theory in QM: other methods . . . 1655
21.5 Methods for special applications 2 . . . 1655
21.5.1 Path integral in QM: special methods . . . 1655
21.5.2 Diagrammatic Techniques (???) . . . 1656
21.5.3 Quantum information theory: Basic models . . . 1656
21.5.4 Quantum information theory: Basic theorems . . . 1657
21.5.5 Methods for open systems . . . 1657
21.5.6 Summation of many moments . . . 1659
21.5.7 Quantum chaos . . . 1660
21.5.8 On quantum noise (!!!!) . . . 1660
21.5.9 On quantum metrology and its applications . . . 1660

22 Other Models **1660**
22.1 Famous condensed matter models . . . 1660
22.1.1 Electric, thermal properties of matter . . . 1660
22.1.2 Famous Topological Models . . . 1660
22.1.3 Typical Magnetism in a Nutshell . . . 1661
22.1.4 Fundamentals of Theories of Superfluidity . . . 1661
22.1.5 Fundamentals of Theories of Superconductivity . . . 1661
22.1.6 Bound States in Condensates, Transport, Localization . . . 1661
22.2 Typical models of atomic, molecule, nuclear physics . . . 1662
22.2.1 Review of Properties of Molecules and Methods for Them . . . 1662
22.2.2 Diatomic Molecules (???) . . . 1662
22.2.3 Polyatomic Molecules: Basics . . . 1662
22.2.4 Specific models of scattering of atoms and electrons . . . 1662
22.2.5 Inelastic Collisions . . . 1663
22.2.6 The Essence of Typical Models of Elementary Particles . . . 1664
22.2.7 Estimates in Nuclear Physics . . . 1664
22.2.8 Ionizing radiation . . . 1665
22.2.9 Mass spectrometry . . . 1665
22.2.10 Structure of Atomic Nuclei . . . 1666
22.2.11 Hyperfine Structure (!?) . . . 1670
22.3 Other Quantum Phenomena . . . 1675
22.3.1 Penetration of particles through medium in a nutshell . . . 1675
22.3.2 Cosmic rays . . . 1676
22.3.3 Magnetic resonances and nuclei . . . 1676
22.3.4 Stars, atoms a Universe . . . 1677
22.4 Modifications and Generalizations of QM . . . 1678
22.4.1 SUSY QM (???) . . . 1678
22.4.2 QFT as a generalization of QM (???) . . . 1678
22.4.3 Review of Other Theoretical Modifications of QM . . . 1678

VII Introduction to Other Parts of QM **1679**

23 Experiments in Quantum Mechanics **1679**
23.1 Review of Basic Devices for Experiments in QM . . . 1679
23.2 How Exactly Basic Experiments of Quantum Mechanics Were Made? . . . 1679
23.2.1 Photoelectric Effect . . . 1680
23.2.2 Young's Double-Slit Experiment . . . 1689
23.2.3 Experiment on the Compton Effect . . . 1694
23.2.4 Davisson–Germer Experiment (?) . . . 1696
23.2.5 Franck–Hertz Experiment (??) . . . 1696
23.2.6 Thomson Experiment . . . 1697
23.2.7 Lasers . . . 1697
23.2.8 Microscopes . . . 1697

24 Advanced Established Theoretical Methods of Quantum Mechanics **1698**
24.1 More About the Path Integral . . . 1698
24.2 Space . . . 1718
24.2.1 Rotation of Euclidean Space . . . 1718
24.2.2 Wigner D-Function . . . 1730
24.2.3 Transformations of Minkowski Space . . . 1735
24.3 Quantum Chaos: Some Concepts . . . 1735
24.3.1 Concept of Quantum Chaos . . . 1736
24.3.2 Main Models of Quantum Chaos . . . 1736

24.3.3 Is the moon there when somebody looks? by Berry 1 . . . 1736
24.3.4 Is the moon there when somebody looks? by Berry 2 . . . 1738
24.3.5 Is the moon there when somebody looks? by Berry 3 . . . 1742
24.4 Other Fundamental Ideas . . . 1746
24.4.1 Wigner Function in QM (????) . . . 1746
24.5 Dirac's Quantization Method . . . 1747
24.5.1 Overview of Dirac's Quantization Method . . . 1747
24.5.2 Dirac's Lecture 1: The Hamilton Method . . . 1747
24.5.3 Dirac's Lecture 2: The Problem of Quantization . . . 1759
24.5.4 Dirac's Lecture 3: Quantization on Curved Surfaces . . . 1768
24.5.5 Dirac's Lecture 4: Quantization on Flat Surfaces . . . 1778
24.5.6 Introduction to Supersymmetric Quantum Mechanics . . . 1788
24.5.7 Quantum scars . . . 1788
24.5.8 Quantum mirage . . . 1788

25 Very Special Methods, Phenomena, Applications 1789
25.1 More on Quantum Scattering Theory . . . 1789
25.1.1 Gell-Mann and Low theorem . . . 1789
25.1.2 Coulomb Scattering in 4D by Kiselev . . . 1790
25.1.3 More on Scattering Theory . . . 1791
25.2 Quantum Chemistry . . . 1791
25.3 Many-Body Quantum Systems . . . 1791
25.4 Special Applications of Path Integral Methods . . . 1801
25.4.1 Path Integral Approach for Gravitational Lensing . . . 1801
25.4.2 Path Integral Approach for Gravitational Lensing: Background and Features . . . 1801
25.5 Introduction to Other Questions . . . 1801
25.5.1 Quantum Phenomena in Astronomy . . . 1801

26 Advanced Exotic Mathematical Methods of Quantum Mechanics 1803
26.1 Supersymmetry . . . 1803
26.1.1 Why Does One Need Supersymmetry and What Does It Give? . . . 1803
26.1.2 Supermanifolds . . . 1803
26.1.3 Equivariant Cohomology and Localization . . . 1805
26.1.4 Classical mechanics on supermanifolds . . . 1812
26.1.5 Supersymmetry . . . 1816
26.1.6 Quantum mechanics on supermanifolds . . . 1820
26.1.7 Atiyah-Singer index formula . . . 1824

27 Deeper Understanding of Quantum Mechanics 1825
27.1 Construction of Quantum Mechanics (?) . . . 1825
27.1.1 Gauges in Quantum Mechanics (??) . . . 1825
27.1.2 Ways to Combine Quantum Mechanics and Gravity . . . 1826
27.1.3 On the Construction of Quantum Mechanics Without Imaginary Numbers (???) 1827
27.1.4 Quantum Mechanics Methods in Solid-State Physics . . . 1827
27.2 How to Understand Quantum Mechanics? . . . 1827
27.2.1 Copenhagen Interpretation . . . 1827
27.2.2 Other Attempts to Construct Quantum Mechanics . . . 1830
27.3 Paradoxes . . . 1830
27.3.1 EPR . . . 1831
27.4 Deeper Understanding of Philosophy of Quantum Mechanics . . . 1831
27.4.1 Is QM Created This Way By The Way How Humans Want or By Nature? . . . 1831
27.4.2 Other Philosophical Questions . . . 1831
27.4.3 Criticism by Fock of Bohr's Views on Quantum Mechanics (!?!??!) . . . 1833
27.4.4 Universe from the Point of View of Quantum Mechanics . . . 1841

27.4.5 On the Applications of Quantum Mechanics Principles to Non-Quantum Objects 1841
27.4.6 On the Limits of Applicability of Quantum Mechanics . . . 1841
27.4.7 On the Determinism of the World . . . 1841
27.4.8 On the Possibility of Predicting Future and Past (?) . . . 1841
27.5 Some Hypothetical Projects . . . 1841
27.5.1 On Quantum Teleportation . . . 1841
27.6 Quantum Theories that are Considered to be Bad or False . . . 1843
27.6.1 Introduction to Matrix Mechanics . . . 1843
27.6.2 Other Theories . . . 1843
27.6.3 Erroneous Understandings of Quantum Mechanics . . . 1844
27.6.4 On Quantum Cosmology (??) . . . 1844
27.6.5 On Multiverses . . . 1844
27.6.6 On Hidden Variables Theory . . . 1844

VIII Appendix 1845

A Introduction and Overview of Quantum Mechanics 1845
A.1 More Motivation for Quantum Mechanics . . . 1845
A.1.1 Other General Motivation . . . 1845
A.1.2 Motivation for Sections of Quantum Mechanics . . . 1846
A.2 How Professionals in Quantum Mechanics Think? . . . 1848
A.2.1 Useless and Useful Parts of Quantum Mechanics . . . 1848
A.2.2 Approaches for Description of Quantum Phenomena . . . 1849
A.2.3 On Studying Quantum Mechanics . . . 1853
A.2.4 Ways to Earn Money by Knowing Quantum Mechanics (!!) . . . 1854
A.2.5 People, Who Are Engaged in Quantum Mechanics . . . 1854
A.2.6 Use of Quantum Mechanics in Everyday Life . . . 1854
A.2.7 Ways to Guess the Main Ideas of Quantum Mechanics . . . 1854
A.2.8 Influence of Quantum Mechanics on Worldview . . . 1855
A.2.9 Overview of Special Applications of Quantum Mechanics (???) . . . 1855
A.2.10 On Dead Ends in the Creation and Understanding of Quantum . . . 1855
A.3 Acknowledgements . . . 1855
A.4 Literature . . . 1855
A.4.1 Main Literature . . . 1856
A.4.2 Additional Literature on Basic Topics . . . 1858
A.4.3 Additional Literature on Other Topics . . . 1866
A.4.4 Articles on Special Models, Experiments and Special Methods . . . 1870

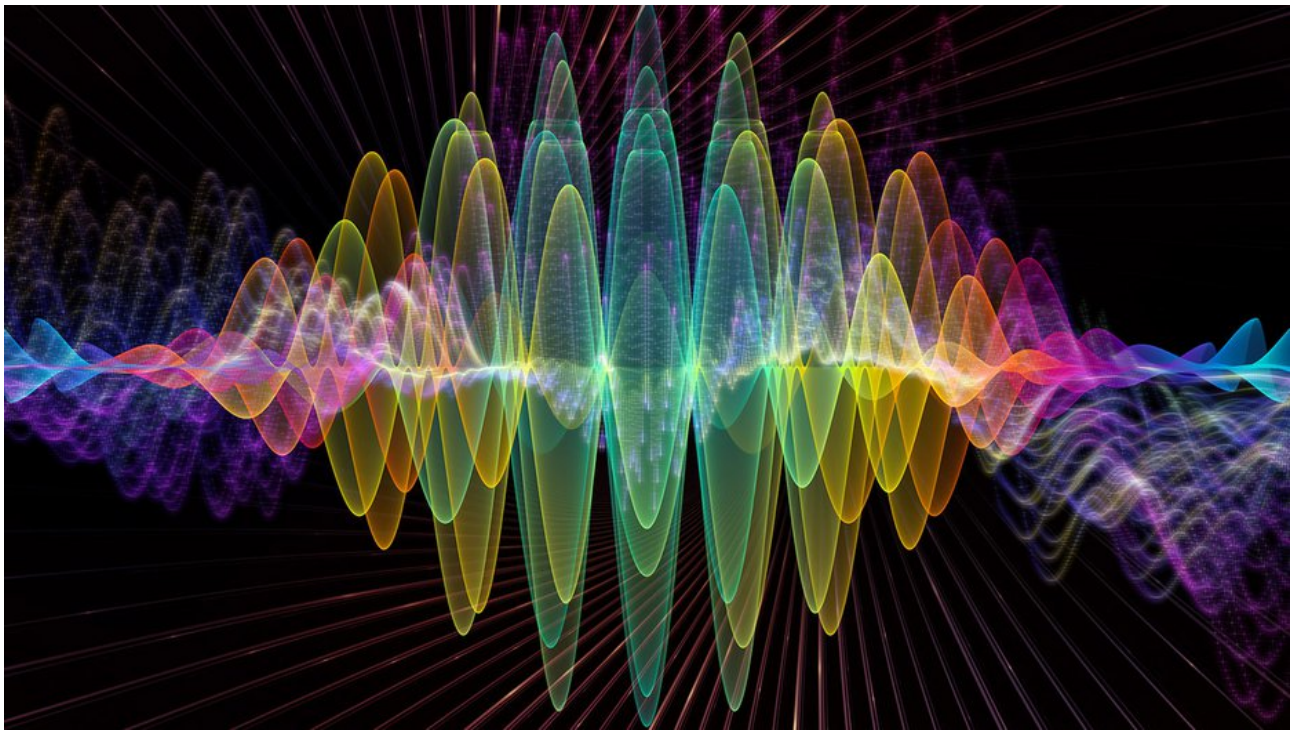
Preface, main motivation, main tips for studying



Overview of the note

Parts of the note are:
Fundamentals of Quantum Mechanics

Typical Methods and Models

Parts of Quantum Mechanics

Introduction to Other Parts of QM

The key sections are:
Perturbation Theories

Adiabatic methods

Semiclassical methods

Scattering theory: Fundamentals

Estimations and Features of Typical Models

This note contains special mathematical methods by Takhtajan, and approximate methods by Migdal, Krainov. I used the following literature.

(напишу потом качественно самое сильно мотивирующее, пока не готов писать, многие просто мотивирующие соображения - в дополнениях.)

Квантовая механика - один из самых основных предметов современной физики, без нее не следует вообще заниматься физикой, что бы человек ни делал

Да, я знаю, что можно сказать, что вот, мне по факту она не нужна, зачем ее учить? Потому что столько много предметов из нее идут! Столько много принципиально важных задач в рамках нее решаются. Да, пусть и методами, которые не обсуждаются в основном курсе квантмеха, но тем не менее. Уж слишком этот предмет важен для физики, чтобы какой-то физик мог заявить, что он профессионал, не владея основами квантмеха. К тому же, если человек умеет учиться, то это вообще не сложно.

(раскрою потом эту мысль)

Best general questions

m-ge.1 Как частица связана с волной? (!!!)

(так и не прописал четко ответ, потом пропишу)

(?? тут же про волны материи) (напряженность E, H....) и уравнения (формулы про волны) а с другой стороны: (???? формулы про частицы) Вопрос: как так получается и почему эти подходы эквивалентны?

(укажу потом ответ, пока обхожу стороной это.)

m-ge.2 Что такое измерение и как его описать?

m-ge.1 Что такое электрон?

(почему на это сложно отвечать? сформулирую свой ответ на этот вопрос)

m-ge.1 Почему атомы устойчивы?

(идейный ответ на этот вопрос именно квантовой механикой дается.)

m-ge.1 Описывая части системы, можно ли описать всю систему?

Оказывается, нет.
(тут пример Филиппова (?!!!))
(тут рассуждения и комментарии, мб еще пример приведу)

m-ge.1 Откуда берется спектр черного тела?

Best technical questions

(наберу самые лучшие - впишу, пока не уверен, какие они?)

m-te.1 I-motiv-1 Сколько будет спин параллелен полю?

Нейтрон находится в однородном магнитном поле $\mathcal{H}_0 \| z$. Определить время жизни состояния с проекцией спина на направление поля $m_s = +1/2$. Получить численное значение времени жизни для $\mathcal{H}_0 = 1$ кГс.

Указание к решению:
(напишу потом, пока в разделе с задачами это смотрю.)

m-te.2. Probability of ionization

Calculate the probability of ionization (removal of one electron from the atom) of a hydrogen atom when it collides with a neutron. Assume that momentum of neutron is given.

Указание к решению:
(напишу потом коротко суть решения, ЛЛ3 почитать нужно просто, чтобы разобраться.)
Answer:

$$W_{0k}dk = 2^8 \frac{v_{\text{n}}^2 \left(v_{\text{n}}^2 + \frac{1}{3}k^2 + \frac{1}{3}\right) e^{-\frac{2}{k}\,\text{arctg}\,\frac{2k}{v_{\text{n}}^2 - k^2 + 1}}}{\left[\left(v_{\text{n}} + k\right)^2 + 1\right]\left[\left(v_{\text{n}} - k\right)^2 + 1\right]\left[1 - e^{-2\pi/k}\right]} kdk.$$

m-te.3 (??) Что-то на момент и их сложение

Указание к решению:
(просто это типичная тема квантмеха, так что очень круто было бы это указать.)

Main tips for studying

В квантовой механике тупики в прогрессе понимания гораздо более вероятные, чем в других предметах, поэтому полезно указать особенности одного из правильных подходов к предмету.

Не занимайтесь долго вопросами о сути происходящего в квантмехе раньше времени и без повода

Очень важно забить на вопросы такого рода, потому что сил они кучу выедут, ничего не дадут. Итак полно заморочек, потом когда-то отвечу эти вопросы.

Не понимаешь волновую функцию? Ну и не важно, кто ее полностью понимает? Там вообще частица одновременно из всех координатных состояний в другое координатное состояние переходит. Это вообще не тот вопрос, которым следует заниматься, пока не прорешены задачи. И таких вопросов можно целую кучу задать.

Не циклитесь много на квантовой механике без потребности, нарешайте штук 100 задач, застабильте штук 15 ключевых тем и остальное уже по потребности доучивайте

Есть тысячи самых разных задач, большинство их, может, никто вообще не способен решить без отдельной подготовки к каждой. Они разные, разные темы есть. Не нужно требовать от себя знать всё или даже большинство тем. Так можно пару лет просто топтаться на месте, ничего в науке не достичь, деньги не заработать, ничего для мира не сделать.

Поэтому отдельно важно понимать, что пусть квантовая механика и базовый предмет, не нужно ставить целью пройти все её основы. Пара тем будет качественно отработана, минимальное количество задач будет нормально разобрано - всё, идем вперед и используем, доучиваем то, что требуется. И это абсолютно нормально не быть способным решить большинство задач, ибо альтернатива - ничего не сделать в жизни, но только набивать руку в том, что скорее всего не будет использоваться.

Конечно, важно понимать и другую мысль, что действительно нужно минимальные основы хорошо понять и если они не усвоены и если есть возможность - действительно, следует их доработать. Просто не об этом речь сейчас.

Не ведитесь на тех, кто предлагает курсы по квантовой механике, если уже прошли другой нормальный курс и нет потребности в рамках актуального проекта в ней! Такие

предложения - это предложения потоптаться на месте. Разве что если это не мировой авторитетный ученый в области квантовой механики, но даже в таком случае скорее всего правильнее отказаться от таких доп. курсов, потому что опять же, предмет большой, даже все основы изучать - слишком большое и редко применяющееся дело.

Следуйте структурному подходу

Конечно, я всегда в рамках него и работаю, но именно на квантовой механике становится понятно, что без структур начинается огромная путаница. Другие же предметы могут взяться и без структур, а вот квантовая механика в ее современной форме скорее всего в принципе не возьмется. Слишком много разных теорией, разных вопросов, разных задач, просто не вырулить, если без структур работать.

Part I
Typical Quantum Mechanics in a Nutshell

1 Main laws, methods, models

1.1 Main laws and properties of QM

1.1.1 Schrodinger, Heisenberg equations, wave function

Суть уравнения Шредингера

non-stationary: $i\hbar\frac{\partial\Psi}{\partial t} = \hat{H}\Psi,$ $\hat{H} = i\hbar\frac{\partial}{\partial t}$

stationary: $\hat{H}\left|\psi_E\right\rangle = E\left|\psi_E\right\rangle.$ e.v. of H

non-stationary: $\left|\psi_E(t)\right\rangle = \sum_n \left|n\right\rangle e^{-iE_nt/\hbar}\langle n|\psi\rangle$

stationary: $\left|\psi(t)\right\rangle = \hat{U}(t)\left|\psi_E\right\rangle \equiv e^{-i\hat{H}t/\hbar}\left|\psi_E\right\rangle = e^{-iEt/\hbar}\left|\psi_E\right\rangle$

Если задача на стационарное состояние в 1D потенциале:

1/4) Пишем уравнение Шредингера $\psi'' + \frac{2m}{\hbar^2}(E - U(x))\psi(x) = 0$; если потенциал в виде "ступенек", то пишем систему для каждой зоны.

2/4) Вводим обозначения для констант, пишем предполагаемый вид волновой функции, через сумму экспонент или гармоник.

3/4) Сшиваем по равенству логарифмичекой производной $\psi'/\psi|_1 = \psi'/\psi|_2$, получаем уравнение или систему уравнений, из нее - уровни энергии.

4/4) Доходим до ответа (??? как???)

Probability of changing the state is

$$P = \langle\psi_2|\psi_1\rangle.$$

Thus we often evaluate coefficient in front of the wavefunction and it gives the probability of changing the state. The probability of staying in the same state can be found also by subtraction from one the probability of change.

Важно следовать этому алгоритму и не скакать, потому что иначе можно запутаться, какие параметры когда появились и что требуется искать!

(?? а в импульсном предст когда удобнее???)

(тут очень коротко про задачи, вообще ниже в моделях все указания)

Свойства и частные случаи уравнения Шредингера

Типичные свойства Уравнения Шредингера

$$\psi(x) \approx \begin{cases} a_L e^{ikx} + b_L e^{-ikx}, & x \to -\infty \\ a_R e^{ikx} + b_R e^{-ikx}, & x \to +\infty \end{cases}$$

(допишу потом, в контексте задач на это)

$$\psi_k^{(+)}(x) = \begin{cases} e^{ikx} + re^{-ikx}, & x \to -\infty \\ te^{ikx}, & x \to +\infty \end{cases}, \qquad \psi_k^{(-)}(x) = \begin{cases} t'e^{-ikx}, & x \to -\infty \\ e^{-ikx} + r'e^{ikx}, & x \to +\infty \end{cases}$$

$$\begin{cases} t' &= t \\ r' &= -r^* t/t^* \end{cases} \qquad \text{(time rev sym)}$$

Об уравнении Шредингера в импульсном представлении (!?!?!??!?!?)

$$\frac{\boldsymbol{p}^2}{2m}\psi(\boldsymbol{p}) + \int \frac{d^D\boldsymbol{p}}{(2\pi)^d}\psi(\boldsymbol{p}')\, U_{\boldsymbol{p}-\boldsymbol{p}'} = E\psi(\boldsymbol{p})$$

Для перехода полезны формулы преобразования Фурье.
(напишу тут их.)

$$\langle p|U(\hat{x})|p'\rangle = \left\langle p\left|U(\hat{x})\int dx\right|x\right\rangle\langle x|p'\rangle = \int dx U(x)\langle p|x\rangle\langle x|p'\rangle = \int dx U(x)e^{-i(p-p')x} = U_{p-p'}$$

$$\langle \boldsymbol{p}|U(\hat{\boldsymbol{x}})|\psi\rangle = \langle \boldsymbol{p}|U(\hat{\boldsymbol{x}})\underbrace{\int (d\boldsymbol{p}')\,|\boldsymbol{p}'\rangle\langle\boldsymbol{p}'|}_{\hat{\mathbb{I}}}(d\boldsymbol{p}')\, U_{\boldsymbol{p}-\boldsymbol{p}'}\psi(\boldsymbol{p}')$$

$(d\boldsymbol{p}) \equiv d^d\boldsymbol{p}/(2\pi)^d$.

Useful approximations:

$$\int_0^\infty \left(\frac{\exp(-ku)}{\sqrt{1+u^2}}\right)du \approx \int_0^{1/k}\frac{du}{\sqrt{1+u^2}} = \ln\left[u+\sqrt{1+u^2}\right]\Big|_0^{1/k} = \ln\left(\frac{2}{k}\right)$$

(!! другие приближения напишу!)

(!?!?!? абзац про смысл происходящего, и почему так можно вообще делать?)

Дальше можно точно решать (????? я хз, там сумма функций часто от разных аргументов, я такое решать не умею.)
Но часто решаем приближенно.

О стационарных состояниях

Связь представления Шредингера и других представлений (???)

потом пропишу, я кстати хз, зачем оно нужно.
В Гейзенберга:
(????)
в представление взаимодействия:
(???)
на деле ни разу не использовал пока что

О выводе УШ

(тоже полезно помнить)

О влиянии геометрии на квантовую динамику (???)

(частица там вылетит из сопла, треугольник, эллипс, в чем особенности таких задач?? пропишу потом)

Энергия поперечного движения оценивается как

$$\varepsilon^{(f)}(z) \sim \frac{1}{mR^2(z)},$$

ибо $\varepsilon = \frac{1}{2m}\frac{\partial^2}{\partial^2 x}$.

(!! порешаю - пропишу.)

О неортонормированном базисе (???)

Если базисные вектора не являются ортогональными, нужно вычислить матрицу Грама для этого базиса (это матрица скалярных произведений $G_{ij} = \langle\psi_i|\psi_j\rangle$).

Характеристическое уравнение, определяющее собственные числа для неортонормированного базиса, имеет вид $\det(\hat{H} - E \cdot \hat{G}) = 0$. Найдите собственные уровни энергии в заданном приближении.

(см. задачу пока, такое пока только раз нужно было, но потом еще попрактикуюсь. крутой очень метод!)

Преобразования уравнения Шредингера в другие координаты и для решений через спецфункции

(???? из ЛЛ3 многое добавлю про это!)

В сферических

$$\Delta\phi = \frac{1}{r^2}\frac{\partial}{\partial r}r^2\frac{\partial}{\partial r}\phi$$

В цилиндрических

$$-\frac{\hbar^2}{2M}\left(\frac{\partial^2\psi}{\partial r^2} + \frac{1}{r}\frac{\partial\psi}{\partial r} + \frac{1}{r^2}\frac{\partial^2\psi}{\partial\varphi^2}\right) + U(r)\psi(r) = E\psi(r)$$

$$\psi(r,\varphi) \equiv \psi(r)e^{im\varphi} \qquad \psi''(r) + \frac{1}{r}\psi'(r) - \left(\frac{2MU(r)}{\hbar^2} + x^2 + \frac{m^2}{r^2}\right)\psi(r) = 0$$

Для связных состояний ($E < 0$), ответ, учитывающий $\psi(r \to \infty) \to 0$:

$$\psi(r > a) = AK_m(\varkappa r).$$

А в общем случае:

$$\psi(z) = A_1 I_m(z) + A_2 K_m(z)$$

$$z \gg 1 \qquad I_m(z) \approx \frac{1}{\sqrt{2\pi z}} e^z, \qquad K_m(z) \approx \sqrt{\frac{\pi}{2z}} e^{-z},$$
$$z \ll 1 \qquad I_m(z) \approx \frac{1}{m!}\left(\frac{z}{2}\right)^m, \qquad K_m(z) \approx \begin{cases} \frac{(m-1)!}{2}\left(\frac{2}{z}\right)^m, & m \neq 0 \\ \ln\frac{2}{z} - \gamma, & m = 0 \end{cases}$$

О решении через гипергеометрическую функцию ${}_2F_1(a,b;c;x)$ (!??!?!?)

$$z(1-z)f''(z) + (c-(a+b+1)z)f'(z) - abf(z) = 0, \qquad c \neq 1,\ f(0) = 1,$$
$$f(z) = C_1 {}_2F_1(a,b;c;z) + C_2 z^{1-c} {}_2F_1(b-c+1, a-c+1; 2-c; z),$$

где

(?? укажу, что это за функции тут!)

Метод применяется в задачах релятивисткой квантовой механики и скорее всего в других темах.

(какие-то основные свойства гип геом ф-ции тут для полноты добавлю)

О решении через вырожденную гипергеометрическую функцию ${}_1F_1(a,b;x)$ (!??!?!?)

$$zf''(z) + (b-z)f'(z) - af(z) = 0, \quad f(0) = 1,$$
$$f^{(2)}(z) = z^{1-b} {}_1F_1(a-b+1; 2-b; z).$$

(?? укажу, что это за функции тут!)

Например, для осциллятора именно этот метод работает!

(пока тоже не много нарешал такого еще)

волновой функции

Определение и основные свойства волновой функции

(важный абзац со смыслом ее!)

$$\int_V \Psi^* \Psi dv = 1$$

(важный абзац про то, откуда это появилось????)

Среднее наблюдаемой q:

$$\langle q \rangle = \sum_{\{q\}} q|\Psi(q)|^2 \equiv \sum_{\{q\}} q\Psi^*(q)\Psi(q) \equiv \sum_{\{q\}} q\langle\Psi|q\rangle\langle q|\Psi\rangle$$

Введем для наблюдаемой $\{q\}$ оператор $\hat{Q}$ такой, что

$$\hat{Q}|q\rangle = q|q\rangle$$

Отсюда (????) $\langle q \rangle = \sum_{\{q\}} \langle\Psi|Qq\rangle\langle q|\Psi\rangle$ и $\langle q \rangle = \langle\Psi|Q\Psi\rangle$.

(тут про то, как это было бы, если бы были открытые сист и запутанность?)

Волновые функции могут быть нормируемые на дельта-функцию, например, это так для свободной частицы в пустоте. (? а что с в.ф. в магнитном поле, уровни Ландау насколько меняют нормировку?)

Связь волновой функции с другими квантовым параметрами (!!)

энергия
матрица плотности
ток
связь волновой функции фотона ψ и напряженности поля волны $\vec{E}$
(?!!!)

О смысле и интерпретациях волновой функции и ее коллапса (??)

(тут суть этого напишу, что есть, какой смысл? подробно - раздел далеко внизу)

потоке вероятности и уравнении непрерывности (?!)

$$\begin{aligned} j(x) &= \operatorname{Re}\psi^*\hat{v}\psi \equiv \\ &\equiv -\frac{i\hbar}{2m}\left(\psi^*\nabla\psi - \psi\nabla\psi^*\right) \equiv \\ &\equiv \frac{\hbar}{m}|\psi(\boldsymbol{r})|^2\nabla\varphi \qquad\qquad \psi(\boldsymbol{r}) \equiv |\psi(\boldsymbol{r})|e^{i\varphi(\boldsymbol{r})}. \end{aligned}$$

$$\frac{\partial}{\partial t}\rho(\boldsymbol{r},t) = \frac{\partial}{\partial t}\left\{\Psi^*(\boldsymbol{r},t)\Psi(\boldsymbol{r},t)\right\} = \tfrac{\mathrm{i}}{\hbar}\left\{(\hat{H}\Psi^*)\Psi - \Psi^*(\hat{H}\Psi)\right\} \equiv -\boldsymbol{\nabla}\cdot\boldsymbol{j} \qquad \Rightarrow$$

$$\frac{\partial\rho}{\partial t} + \boldsymbol{\nabla}\cdot\boldsymbol{j} = 0.$$

$$\int\limits_V d^2r\,\mathrm{div}\,j = \oint\limits_{\partial V} j\cdot ds = 0$$

Поток вероятности через поверхность, в которой находится квантовая частица, должен быть равен нулю.

(!!! не раскрыто, как пользоваться j????? пока не знаю, ну есть это, ну и все на том... напишу потом. по идее эти формулы и используем для задач о вероятности перехода.)

О волновом пакете (???)

$$\Psi(\boldsymbol{r},t) \equiv \int \frac{d^3p}{(2\pi\hbar)^3}\tilde{\Psi}(\boldsymbol{p})e^{\frac{\mathrm{i}}{\hbar}(\boldsymbol{p}\cdot\boldsymbol{r}-Et)}$$

(??)

Proof:

$$\Psi(\boldsymbol{r},t) = \langle\boldsymbol{r}|\Psi(t)\rangle = \int\langle\boldsymbol{r}|\boldsymbol{p}\rangle\frac{d^3p}{(2\pi\hbar)^3}\langle\boldsymbol{p}|\Psi(t)\rangle$$

где (????)

$$\langle\boldsymbol{r}|\boldsymbol{p}\rangle = \Psi_{\boldsymbol{p}}(\boldsymbol{r}) = e^{\frac{\mathrm{i}}{\hbar}\boldsymbol{p}\cdot\boldsymbol{r}}, \quad \langle\boldsymbol{p}|\Psi(t)\rangle = e^{-\frac{1}{\hbar}Et}\langle\boldsymbol{p}|\Psi\rangle = e^{-\frac{1}{\hbar}Et}\tilde{\Psi}(p)$$

Для движения фронта волны: $\phi = \mathrm{const}$,

$$\boldsymbol{r}(t) = \frac{E}{p^2}\boldsymbol{p}t + \boldsymbol{r}_0 \quad \rightarrow \quad \phi = \boldsymbol{p}\cdot\boldsymbol{r}_0 + \hbar\alpha(\boldsymbol{p}) = \ \mathrm{const}.$$

$$\boldsymbol{v}_{\text{ph}} := \frac{E}{p^2}\boldsymbol{p}$$

(????)

размерностях и оценках в квантовой механике (!!!)

(тут крутые методы, скоро пропишу!)

Уравнение Гейзенберга

(мб потом напишу, пока повесит пусть, ну или удалю.)

1.1.2 Axioms of QM, measurements

(По Тахтаджаяну. Не до этого, не хочу этим заниматься, сперва уровень теормина.)

Аксиомы квантовой механики Дирака-фон Неймана. (тут же аксиома об измерении)

1. A1. С любой квантовой системой ассоциировано бесконечномерное сепарабельное комплексное гильбертово пространство $\mathscr{H}$. (В физической терминологии оно называется пространством чистых состояний.) Гильбертово пространство составной квантовой системы - это тензорное произведение гильбертовых пространств компонент системы.

2. A2. Множество наблюдаемых $\mathscr{A}$ квантовой системы $\mathscr{H}$ - это все самосопряженные операторы в $\mathscr{H}$. Подмножество $\mathscr{A}_0 = \mathscr{A} \cap \mathscr{L}(\mathscr{H})$ ограниченых наблюдаемых является векторным пространством над $\mathbb{R}$.

3. A3. Множество состояний $\mathscr{S}$ квантовой системы с гильбертовым пространством $\mathscr{H}$ состоит из всех положительных (а значит, самосопряженных) операторов M со следом $\operatorname{Tr} M = 1$. Чистые состояния это операторы проектирования (проекторы) на одномерные подпространства $\mathscr{H}$.

   Для $\psi \in \mathscr{H}, \|\psi\| = 1$, соответствующий проектор на $\mathbb{C}\psi$ обозначается P_ψ. Все остальные состояния называются смешанными состояниями.

4. A4. Процесс измерения - это сопоставление каждой наблюдаемой $A \in \mathscr{A}$ и состоянию $M \in \mathscr{S}$ вероятностную меру μ_A на $\mathbb{R}$:

   $$\mathscr{A} \times \mathscr{S} \ni (A, M) \mapsto \mu_A \in \mathscr{P}(\mathbb{R}),$$

   и она - это вероятность того, что для квантовой системы в состоянии M результат измерения наблюдаемой A принадлежит E, $E \subseteq \mathbb{R}$ - любое борелевское подмножество. То есть она в пределах: $0 \leqslant \mu_A(E) \leqslant 1$. Конкретно, для нее есть формула Борна-фон Нейиана:

   $$\mu_A(E) = \operatorname{Tr} \mathrm{P}_A(E)M, \quad E \in \mathscr{B}(\mathbb{R})$$

   Математическое ожидание (среднее значение) наблюдаемой $A \in \mathscr{A}$ в состоянии $M \in \mathscr{S}$ - это

   $$\langle A|M\rangle = \int_{-\infty}^{\infty} \lambda d\mu_A(\lambda)$$

$\mu_A(\lambda) = \mu_A((-\infty, \lambda))$ - функция распределения вероятностной меры μ_A. (???? непонятно, что значит этот интеграл???)

(???? я пока не вижу, почему именно такие аксиомы нужным нам и как они проявляются. Потом додумаю.)

(???? есть много про это теории в записи про квантовую теорию информации, там в первую очередь буду её разбирать и прописывать)

О состояниях, мерах, определениях операторов

Состояние $M \in \mathscr{S}$ - чистое, если и только если его нельзя представить в виде нетривиальной линейной комбинации в $\mathscr{S}$.

Определение. Проекторная мера на $\mathbb{R}$ - это отображение P: $\mathscr{B}(\mathbb{R}) \to \to \mathscr{L}(\mathscr{H})\sigma$-алгебры $\mathscr{B}(\mathbb{R})$ борелевских подмножеств $\mathbb{R}$ в алгебру ограниченных операторов в $\mathscr{H}$, удовлетворяющее следующим свойствам.

PM1. Для любого борелевского подмножества $E \subseteq \mathbb{R}$, оператор $\mathrm{P}(E)$ ортогональная проекция, т. е. $\mathrm{P}(E) = \mathrm{P}(E)^2$ и $\mathrm{P}(E) = \mathrm{P}(E)^*$.

PM2. $\mathrm{P}(\emptyset) = 0, \mathrm{P}(\mathbb{R}) = I$, единичный оператор в $\mathscr{H}$.

PM3 Для любого дизъюнктного объединения борелевских подмножеств

$$E. = \coprod_{n=1}^{\infty} E_n, \quad \mathrm{P}(E) = \lim_{n\to\infty} \sum_{i=1}^{n} \mathrm{P}\left(E_i\right)$$

в сильной топологии $\mathscr{L}(\mathscr{H})$.

С любой проекторной мерой P на $\mathbb{R}$ ассоциируется проекторнозначная функция

$$\mathrm{P}(\lambda) = \mathrm{P}((-\infty, \lambda)),$$

называемая проекторным разложением единицы. Она характеризуется следующими свойствами. PD1.

$$\mathrm{P}(\lambda)\mathrm{P}(\mu) = \mathrm{P}(\min\{\lambda, \mu\}).$$

PD2.

$$\lim_{\lambda\to-\infty} \mathrm{P}(\lambda) = 0, \lim_{\lambda\to\infty} \mathrm{P}(\lambda) = I.$$

PD3.

$$\lim_{\substack{\mu\to\lambda \\ \mu<\lambda}} \mathrm{P}(\mu) = \mathrm{P}(\lambda)$$

Измеримая функция f на $\mathbb{R}$ называется финитной почти везде (п. в.) по отношению к проекторной мере P, если она финитна п. в. по отношению ко всем мерам $(\mathrm{P}\psi, \psi), \psi \in \mathscr{H}$. Для сепарабельного $\mathscr{H}$ теорема фон Неймана утверждает, что для любой проекторной меры P существует $\varphi \in \mathscr{H}$, такое, что функция f финитна п. в. по отношению к P, если и только если она финитна п. в. по отношению к мере $(\mathrm{P}\varphi, \varphi)$.

Теорема Дж. фон Неймана по Тахтаджаяну. Для любого самосопряженного оператора A в гильбертовом пространстве $\mathscr{H}$ существует единственое проекторное разложение единицы $\mathrm{P}(\lambda)$, удовлетворяющее следующим свойствам.

(i)

$$D(A) = \left\{ \varphi \in \mathscr{H} : \int_{-\infty}^{\infty} \lambda^2 d(\mathrm{P}(\lambda)\varphi, \varphi) < \infty \right\},$$

и для любого $\varphi \in D(A)$

$$A\varphi = \int_{-\infty}^{\infty} \lambda d\mathrm{P}(\lambda)\varphi$$

определенный как предел сумм Римана-Стильтьеса в сильной топологии на $\mathscr{H}$. Носитель соответствующей проекторной меры P совпадает со спектром оператора A : $\lambda \in \sigma(A)$, если и только если $\mathrm{P}'_A((\lambda-\varepsilon, \lambda+\varepsilon)) \neq 0$ для любого $\varepsilon > 0$.

(ii) $\forall f \in C[\mathbb{R}]$, $f(A)$: $D(f(A)) = \left\{\varphi \in \mathscr{H} : \int_{-\infty}^{\infty} |f(\lambda)|^2 d(\mathrm{P}(\lambda)\varphi, \varphi) < \infty\right\}$, $\forall \varphi \in D(f(A))$

$$f(A)\varphi = \int_{-\infty}^{\infty} f(\lambda) d\mathrm{P}(\lambda)\varphi$$

и понимаемый, как в части (i).

$$f(A)^* = \bar{f}(A)$$

$\bar{f}$ - комплексно сопряженная функция κf, а оператор $f(A)$ ограничен, если и только если функция f ограничена на $\sigma(A)$. Для ограниченных на $\sigma(A)$ непрерывных функций f u g

$$f(A)g(A)\varphi = \int_{-\infty}^{\infty} f(\lambda)g(\lambda) d\mathrm{P}(\lambda)\varphi, \quad \varphi \in \mathscr{H}$$

(iii) Для любой измеримой функции f на $\mathbb{R}$, конечной п. в. по отночению κ проекторной мере $\mathrm{P}, f(A)$ - линейный оператор в $\mathscr{H}$, определенный, как в (ii), где интеграл для $f(A)\varphi$ теперь понимается в слабом смысле: для $\varphi \in D(f(A))$ и любого $\psi \in \mathscr{H}$

$$(f(A)\varphi, \psi) = \int_{-\infty}^{\infty} f(\lambda) d(\mathrm{P}(\lambda)\varphi, \psi)$$

- интеграл Лебега-Стильтьеса по отношению к комплексной мере. Соответствие $f \mapsto f(A)$ удовлетворяет тем же свойствам, что и в (ii), где интегралы понимаются в слабом смысле.

(iv) Ограниченный оператор B коммутирует с A, то есть $B(D(A)) \subset \subset D(A)$ и $AB = BA$ на $D(A)$, если и только если он коммутирует с $\mathrm{P}(\lambda)$ для всех λ, и, следовательно, B коммутирует с любьи оператором $f(A)$.

(v) Для любого проекторного разложения единицы $\mathrm{P}(\lambda)$ оператор A в $\mathscr{H}$, определенный, как в части (i), самосопряжен.

Canonical quantization

Квантование классических систем каноническим образом происходит за счет замены скобки пуассона переходит на коммутатор:

$$\{q, p\}_{\mathrm{P}} = 1 \quad \longrightarrow \quad [\hat{q}, \hat{p}] = \mathrm{i}\hbar$$

Покажем это.

(короче, я не уверен, как это сделать, тут пока накидывание)

Производная по времени имеет вид:

$$\frac{df}{dt} = \frac{\partial f}{\partial t} + \left\{\frac{\partial f}{\partial q}\dot{q} + \frac{\partial f}{\partial p}\dot{p}\right\}$$

$$df = \frac{\partial f}{\partial q}dq + \frac{\partial f}{\partial p}dp = 0$$

Тогда дифференциал g можно записать через дифференциал f:

$$dg = \frac{\partial g}{\partial q}dq + \frac{\partial g}{\partial p}dp = dq\left\{\frac{\partial g}{\partial q}\frac{\partial f}{\partial p} - \frac{\partial g}{\partial p}\frac{\partial f}{\partial q}\right\}\frac{1}{\partial f/\partial p}$$

$$dg = dq\{g,f\}_{\mathrm{P}}\frac{1}{\partial f/\partial p}$$

$$\delta g\delta f \simeq \{g,f\}_{\mathrm{P}}\delta q\delta p$$

$$\delta g\delta f \simeq \{g,f\}_{\mathrm{P}}\Delta\Gamma$$

$$\Delta g\Delta f \simeq |[\hat{g},\hat{f}]|$$

$$[\hat{f},\hat{g}] = \{f,g\}_{\mathrm{P}}\cdot \mathrm{i}\hbar$$

кстати, уравнение Гейзенберга тут тоже относится к этому.

$$\mathrm{i}\hbar\frac{d\hat{f}}{dt} = \mathrm{i}\hbar\frac{\partial\hat{f}}{\partial t} + [\hat{f},\hat{H}]$$

Примеры

вторичном квантовании

(очень важная тема, напишу скоро, пока в КТП, конд средах или еще где-то.)

Основные методы и формулы вторичного квантования

Примеры вторичного квантования

проективных измерениях (????)

(??? путаюсь, заново учить нужно!)

смешанности состояний и других основах (????)

(заготовка основ для кв теор инф, в ней уже они применяться будут)

О типичных заблуждениях про измерения

О гамильтонианах в квантовой механике

зависимость гамильтониана от параметра теорема Гельмана — Фейнмана:

$$\frac{\partial E_n(\lambda)}{\partial\lambda} = \int \Psi_n^*(\lambda)\frac{\partial \mathrm{H}(\lambda)}{\partial\lambda}\Psi_n(\lambda)d\tau$$

(тут строчка про применения ее (?????))

(тут формулы преобразования Гамильтониана при переходе в новую СК в случаях, если он зависит от времени или не зависит.)

(??? о неэрмитовых гамильтонианах, откуда они вообще могут взяться??? открытые системы, так просто??)

Об операторе эволюции

(самое основное про него пока тут)

$$|\psi(t)\rangle = \hat{U}(t)|\psi\rangle$$

$$\hat{U}(t) = \lim_{N\to\infty}\prod_{k=1}^{N}\hat{\mathrm{T}}\left\{e^{-\frac{\mathrm{i}}{\hbar}\hat{H}(t_k)dt}\right\} = \hat{\mathrm{T}}\left\{e^{-\int\frac{1}{\hbar}\hat{H}(t)dt}\right\},$$

$$\hat{U}(t) = \exp(-i\hat{H}t/\hbar), \qquad H \neq H(t).$$

случай дискретного спектра

(сперва методы работы с ним, потом - примеры именно моделей с ним)

способе измерений (????)

(??? пока хз, еще не уверен в ответах на это.)
(это вечный вопрос, пока не хочу на это тратить время)
(просто указания на все ответы про них, как раз 1 раздел и нужен, пока не особо думал про это)

Типичные явления с измерениями

О квантовом парадоксе Зенона

(??? впишу, как описать его?? пока см. задачу про 2х уровневую систему, там пока решил это.)

Что может быть, а чего не может быть во время измерений?

(очень много идейно важных вопросов, поэтому их тут сразу и указываю! всё это с профессионалами нужно обсуждать.)

Может ли после измерения частица остаться в том же состоянии, в котором и была до измеренеия?

другом про измерения

О принципе суперпозиции состояний

(упомянуть все-таки стоит того, но особо много писать не вижу пока смысла, когда-то потом гораздо подробнее изучу - мб тогда больше укажу тут.)

1.1.3 Quantum operators, angular momentum

Определения основных операторов и их смысл

О типичных квантовых операторах и их свойствах

$$\hat{p}\psi(x) = -i\hbar\frac{\partial\psi}{\partial x}$$

$$[x, P] = i\hbar$$

$$\hat{T}_a = e^{a\frac{\partial}{\partial x}}$$

$$\hat{T}_a|x\rangle \underset{\text{def.}}{\equiv} |x-a\rangle.$$

$$\hat{T}_a\psi(x) \underset{\text{def.}}{\equiv} \langle x|\hat{T}_a|\psi\rangle = \langle \hat{T}_a^\dagger x|\psi\rangle = \langle x+a|\psi\rangle = \psi(x+a).$$

Momentum operator in spherical coordinates

О задачах на оператор момента импульса (?)

(тоже специфика есть.)

Алгоритм вывода вида операторов

(там что-то из ур Гейзенберга получать нужно, напишу потом, есть на это задачи)
(абзац про оператор времени, там статья есть, крутая идея, но нужно подумать минимум полчаса про это. Мб еще день тренироваться в этой идеи, пробовать применять его. пока не актуально.)

Об угловом моменте

Для $H = \frac{\boldsymbol{P}^2}{2m} + V(\boldsymbol{Q})$ со сферическим $V(\boldsymbol{x}) = V(|\boldsymbol{x}|)$ операторы M_1, M_2, M_3 и M^2, - квантовые интегралы движения:

$$[H, M_1] = [H, M_2] = [H, M_3] = 0; \qquad \left[H, M^2\right] = 0. \quad \text{(integrals)}$$

$$\{M_j, P_k\}_\hbar = -\varepsilon_{jkl}P_l, \quad \{M_j, Q_k\}_\hbar = -\varepsilon_{jkl}Q_l, \quad j,k,l = 1,2,3,$$

$$M_1 = i\hbar\left(x_3\frac{\partial}{\partial x_2} - x_2\frac{\partial}{\partial x_3}\right), \quad M_2 = i\hbar\left(x_1\frac{\partial}{\partial x_3} - x_3\frac{\partial}{\partial x_1}\right), \quad M_3 = i\hbar\left(x_2\frac{\partial}{\partial x_1} - x_1\frac{\partial}{\partial x_2}\right).$$

$$\forall\psi:\ \psi(\boldsymbol{x}) = \psi(|\boldsymbol{x}|). \qquad M_1\psi = M_2\psi = M_3\psi = 0$$

$$x_1 = r\sin\vartheta\cos\varphi, \quad x_2 = r\sin\vartheta\sin\varphi, \quad x_3 = r\cos\vartheta,$$

$0 \leqslant \vartheta < \pi, 0 \leqslant \varphi < 2\pi$

$$M_1 = i\hbar\left(\sin\varphi\frac{\partial}{\partial\vartheta} + \cot\vartheta\cos\varphi\frac{\partial}{\partial\varphi}\right), \quad M_2 = -i\hbar\left(\cos\varphi\frac{\partial}{\partial\vartheta} - \cot\vartheta\sin\varphi\frac{\partial}{\partial\varphi}\right), \quad M_3 = -i\hbar\frac{\partial}{\partial\varphi}.$$

$$\boldsymbol{M}^2 = -\hbar^2\left(\frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\left(\sin\vartheta\frac{\partial}{\partial\vartheta}\right) + \frac{1}{\sin^2\vartheta}\frac{\partial^2}{\partial\varphi^2}\right),$$

$$\Delta = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) - \frac{1}{\hbar^2 r^2}\boldsymbol{M}^2$$

$$\hat{p}_r = \frac{1}{2}\left(\frac{\boldsymbol{r}}{|\hat{\boldsymbol{r}}|}\cdot\hat{\boldsymbol{p}} + \hat{\boldsymbol{p}}\cdot\frac{\boldsymbol{r}}{|\hat{\boldsymbol{r}}|}\right), \qquad \text{(Hermitian)}$$

$$\boldsymbol{p}^2\psi(\boldsymbol{r}) = \left({p_r}^2 + \frac{\boldsymbol{L}^2}{r^2}\right)\psi(\boldsymbol{r})$$

$$\hat{\boldsymbol{L}}^2 = \hat{\boldsymbol{r}}^2\hat{\boldsymbol{p}}^2 - (\hat{\boldsymbol{r}}\cdot\hat{\boldsymbol{p}})^2 + i\hbar\hat{\boldsymbol{r}}\cdot\hat{\boldsymbol{p}}$$

$$p_r = \frac{\hbar}{i}\frac{1}{r}\frac{\partial}{\partial r}r, \qquad p_r^2 = -\hbar^2\frac{1}{r}\frac{\partial^2}{\partial r^2}r, \qquad \frac{\boldsymbol{L}^2}{\hbar^2} = -r^2\nabla^2 + \frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) = -r^2\nabla^2 - \frac{r^2}{\hbar^2}p_r^2,$$

$$[p_r, r] = -i\hbar, \qquad \left[p_r, r^2\right] = -2i\hbar r, \qquad [p_r, r^n] = -ni\hbar r^{n-1},$$

$$\left[r, p_r^2\right] = 2i\hbar p_r, \qquad \left[r, p_r^3\right] = 3i\hbar p_r^2, \qquad \left[p_r, \frac{1}{r}\right] = \frac{i\hbar}{r^2}$$

$$\left[p_r, \frac{1}{r^2}\right] = \frac{2i\hbar}{r^3} \qquad \left[p_r^2, \frac{1}{r^2}\right] = -\frac{2\hbar^2}{r^4}\left(1 - 2r\frac{\partial}{\partial r}\right), \qquad \left[p_r^2, \frac{1}{r}\right] = \frac{2\hbar^2}{r^2}\frac{\partial}{\partial r}$$

$$p_x = \cos\phi p_r - \frac{\sin\phi}{r}p_\phi,$$

$$p_y = \sin\phi p_r + \frac{\cos\phi}{r}p_\phi.$$

О представлениях SO(3)

Группа вращений SO(3) - группы ортогональных матриц 3×3 с определителем 1. Она компактная группа Ли, изоморфная вещественному проективному пространству $\mathbb{RP}^3$ как гладкое многообразие. Имеется изоморфизм групп Ли $\mathrm{SO}(3) \simeq \mathrm{SU}(2)/\{\pm I\}$, SU(2) - группа Ли унитарных матриц 2×2 с определителем 1. Алгебра Ли $\mathfrak{so}(3)$ группы SO(3) - трехмерная алгебра Ли кососимметрических матриц 3×3 с базисом

$$X_1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, \quad X_2 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, \quad X_3 = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

$$[X_1, X_2] = X_3, \qquad [X_2, X_3] = X_1, \qquad [X_3, X_1] = X_2$$

Матрицы X_1, X_2, X_3 порождают соответственно однопараметрические подгруппы SO(3), состоящие из вращений вокруг координатных осей в $\mathbb{R}^3$.

Чтобы установить связь между квантовыми операторами углового момента и теорией представлений SO(3), рассмотрим регулярное представление R группы SO(3) в $\mathscr{H} = L^2(\mathbb{R}^3, d^3\boldsymbol{x})$, определенное формулой

$$(R(g)\psi)(\boldsymbol{x}) = \psi\left(g^{-1}\boldsymbol{x}\right), \quad g \in \mathrm{SO}(3), \psi \in \mathscr{H}$$

Лемма 3.1. Имеем

$$R\left(e^{u_1X_1+u_2X_2+u_3X_3}\right) = e^{-\frac{i}{\hbar}(u_1M_1+u_2M_2+u_3M_3)}$$

Все неприводимые унитарные представления R_l группы Ли SO(3) конечномерны и параметризуются неотрицательными целыми числами $l \geqslant 0$. Соответствующее неприводимое представление $\rho_l = dR_l$ алгебры Ли so(3) в $2l+1$-мерном комплексном векторном пространстве V_l можно явно описать следующим образом. Введем эрмитовы операторы $T_j = i\rho_l(X_j)$, $j = 1, 2, 3$, удовлетворяющие коммутационным соотношениям

$$[T_1, T_2] = iT_3, \quad [T_3, T_1] = iT_2, \quad [T_2, T_3] = iT_1$$

В векторном пространстве V_l есть ортонормированный базис $\{e_{lm}\}_{m=-l}^{m=l}$, такой, что

$$\begin{aligned}(T_1 - iT_2)\, e_{lm} &= -\sqrt{(l+m)(l-m+1)}e_{lm-1},\\ (T_1 + iT_2)\, e_{lm} &= -\sqrt{(l-m)(l+m+1)}e_{lm+1},\\ T_3 e_{lm} &= m e_{lm}.\end{aligned}$$

В частности, $(T_1 + iT_2)\, e_{ll} = 0$, так что V_l - модуль со старшим весом. Представление ρ_l неприводимо, и по лемме Шура

$$\boldsymbol{T}^2 = l(l+1)I_l,$$

I_l - тождественный оператор в V_l. Это можно также прямо проверить, используя (3.10) - (3.12).

Когда l - полуцелое число, т.е. $l \in \frac{1}{2} + \mathbb{Z}_{\geqslant 0}$, и $m = -l, -l+1, ..., l-1, l$, формулы (3.10) - (3.12) все еще определяют неприводимое представление ρ_l старшего веса алгебры Ли $\mathfrak{so}(3)$ размерности $2l+1$, и любое неприводимое n-мерное представление $\mathfrak{so}(3)$ изоморфно представлению ρ_l с $l = \frac{n-1}{2}$.

(?????) Для полуцелых l представления ρ_l не интегрируемы: они порождают двузначные представления SO(3), так называемые спинорные представления. Однако рассматриваемые как представления алгебры Ли $\mathfrak{su}(2) \simeq \mathfrak{so}(3), \rho_l$ соответствуют неприводимым унитарным представлениям группы Ли SU(2). Из теории представлений SU(2) следует, что при $l, l' \in \frac{1}{2}\mathbb{Z}_{\geqslant 0}$

$$V_l \otimes V_{l'} = \bigoplus_{j=|l-l'|}^{l+l'} V_j \qquad \text{(разложение Клебша-Гордона)}$$

Регулярное представление R группы SO(3) в $\mathscr{H} = L^2(\mathbb{R}^3, d^3\boldsymbol{x})$ не является неприводимым. Имеем

$$\mathscr{H} = L^2\left(S^2, d\boldsymbol{n}\right) \otimes L^2\left(\mathbb{R}_{>0}, r^2 dr\right),$$

$d\boldsymbol{n}$ - мера на S^2, индуцированная мерой Лебега на $\mathbb{R}^3$. Группа SO(3) действует вращениями на $L^2(S^2, d\boldsymbol{n})$, а на второй сомножитель она действует как тождественный оператор.

Таким образом, задача разложения регулярного представления R сводится к нахождению SO(3)-инвариантных подпространств гильбертова пространства $L^2\left(S^2, d\boldsymbol{n}\right)$. Итог:

$$L^2\left(S^2, d\boldsymbol{n}\right) = \bigoplus_{l=0}^{\infty} \mathscr{D}_l$$

$\mathscr{D}_l \simeq V_l$. (???????)

При этом изоморфизме ортонормированный базис Y_{lm} в $\mathscr{D}_l$, соответствующий базису e_{lm} в V_l, дается нормированными сферическими функциями

$$Y_{lm}(\vartheta, \varphi) = \frac{1}{\sqrt{2\pi}} e^{im\varphi} P_l^m(\cos\vartheta), \qquad m = -l, ..., l,$$

$$P_l^m(x) := (-1)^m \sqrt{\frac{(l+m)!}{(l-m)!}} \sqrt{\frac{2l+1}{2}} \frac{1}{2^l l!} \left(1-x^2\right)^{-\frac{m}{2}} \frac{d^{l-m}}{dx^{l-m}} \left(x^2-1\right)^l, \quad |x| < 1.$$

других операторах и величинах

О силе и определении величины силы (!??!??!?)

(абзац про то, как считать, с какой силой частица действует на стенки ямы???? пока остался вопрос. типа производную по энергии мб взять нужно и написать, что формализм, что только так и считаем?)

О времени и операторе времени

(1/3 страницы добавлю, смотрел статью про это, в теории подробнее напишу)

членах взаимодействия в гамильтониане (!?!?!??)

(show how to Construct quantum models!!!)

(тут член дипольного вз-я)

(тут член магнитного вз-я)

(??? какие еще есть???)

1.1.4 Density Matrix, Basics of Open Systems, SF

Density Matrix

(write what is it)

Basics of Open Systems, SF

$$\hat{\rho} = \frac{1}{Z} e^{-\beta \hat{H}}, \quad Z = \mathrm{Tr}\left(e^{-\beta \hat{H}}\right) = \sum_n e^{-\beta E_n}$$

1.1.5 Relativistic quantum fields, QED: main laws

(see note on qft and field theory for now about it)

Об разложении $S-$матрицы в диаграммный ряд

Об уравнении Дирака

$$\mathcal{S}(x,y) = \langle 0|\ \mathrm{T}(\widehat{\psi}(x)\widehat{\bar{\psi}}(y))|0\rangle = \int \frac{\mathrm{d}^4 p}{(2\pi)^4} \mathrm{e}^{-\mathrm{i}p\cdot(x-y)} \frac{\mathrm{i}}{p^2 - m^2 + \mathrm{i}0}(\not{p} + m).$$

(Абзац О выводе уравнения Дирака из представлений группы Пуанкаре)

нерелятивистском пределе в сферическом потенциале и уравнению Паули

$$(\not{\mathcal{P}} - mc)\psi = 0, \qquad \mathcal{P}_k = \mathrm{i}\hbar\partial_k - \frac{e}{c}\mathcal{A}_k$$

$$\psi(t,\boldsymbol{r}) \equiv e^{-\frac{\mathrm{i}}{\hbar}mc^2 t}\begin{pmatrix}\varphi(t,\boldsymbol{r})\\ \chi(t,\boldsymbol{r})\end{pmatrix},$$

$$\begin{pmatrix} p_0 - \frac{e}{c}\phi - mc & (\boldsymbol{\sigma}\cdot\mathcal{P}) \\ -(\boldsymbol{\sigma}\cdot\mathcal{P}) & -p_0 + \frac{e}{c}\phi - mc\end{pmatrix}\begin{pmatrix}\varphi\\ \chi\end{pmatrix} = 0$$

$$p_0 := mc + \hat{\epsilon}/c, \qquad \hat{\epsilon} := \mathrm{i}\hbar\partial_t.$$

$$\chi = -\frac{1}{1 + \frac{\hat{\epsilon} - e\phi}{2mc^2}}\frac{(\boldsymbol{\sigma}\cdot\mathcal{P})}{2mc}\varphi,$$

$$\hat{\mathcal{W}} := \left|\frac{\hat{\epsilon} - e\Phi}{2mc^2}\right| \ll 1, \qquad \chi = -(1+\hat{\mathcal{W}})\frac{(\boldsymbol{\sigma}\cdot\mathcal{P})}{2mc}\varphi$$

$$\chi \ll \varphi \qquad \text{as} \qquad \mathcal{O}(v/c),$$

Получаем действие Дирака через ψ: (??? перерешаю!)

$$c\bar{\psi}(\not{\mathcal{P}} - mc)\psi = \varphi^\dagger\{(\hat{\epsilon} - e\phi)\varphi + c(\boldsymbol{\sigma}\cdot\mathcal{P})\chi\} = \varphi^\dagger\left\{\hat{\epsilon} - e\phi - \frac{1}{2m}(\boldsymbol{\sigma}\cdot\mathcal{P})(1+\hat{\mathcal{W}})(\boldsymbol{\sigma}\cdot\mathcal{P})\right\}\varphi$$

$S_{\mathrm{NR}} = \int dt \int d^3\boldsymbol{r}\varphi^\dagger\left\{\hat{\epsilon} - e\phi - \frac{1}{2m}(\boldsymbol{\sigma}\cdot\mathcal{P})^2\right\}\varphi$, $(\boldsymbol{\sigma}\cdot\mathcal{P})^2 = \mathcal{P}^2 + \mathrm{i}\boldsymbol{\sigma}(\mathcal{P}\times\mathcal{P})$, $\mathcal{P}_\beta = -\mathrm{i}\hbar\partial_\beta - \frac{e}{c}\mathcal{A}_\beta \Rightarrow$ $(\mathcal{P}\times\mathcal{P}) = \mathrm{i}\frac{\hbar e}{c}\mathcal{H}$,

$$S_{\mathrm{Pauli}} = \int dt \int d^3\boldsymbol{r}\varphi^\dagger\left\{\hat{\epsilon} - e\phi - \frac{\mathcal{P}^2}{2m} + \frac{e\hbar}{2mc}(\boldsymbol{\sigma}\cdot\boldsymbol{\mathcal{H}})\right\}\varphi$$

$$i\hbar\frac{\partial}{\partial t}\varphi = \hat{H}_{\mathrm{Pauli}}\varphi, \qquad \hat{H}_{\mathrm{Pauli}} := \frac{\mathcal{P}^2}{2m} + e\phi - g\frac{e\hbar}{2mc}(s\cdot\mathcal{H}),$$

$s := \frac{1}{2}\sigma$, $g := 2$.

Релятивистские поправки для статического потенциала (???)

(???)

В случае $\mathcal{A} = 0$

$$ej^0 \approx e\varphi^\dagger\left\{1 + \frac{\boldsymbol{p}^2}{4m^2c^2}\right\}\varphi$$

Об уравнении Клейна-Гордона

(пока в теорполе, потом это же тут и будет)

Об уравнениях Максвелла и формул о фотонах для задач квантовой механики

(или тут, или в разделе о связке с КТП это напишу, пока тут, так проще.)

Другое о релятивистской квантовой механике

(тут обзор основных моделей и применений уравнений. подробно - в одной из следующих частях)

Уравнение Дирака для позитрона

(пока еще не разобрался полностью)
(абзац, почему не достаточно просто заменить e на -e? тонкости такие есть...)

Idea and main formulas of QED

(см. пока запись по КТП, потом сюда тоже добавлю.)

Расходимость рядов в квантовой электродинамике по МК

1.1.6 Spin, spinors, γ-matrices

Main physical properties of a spin

Спин можно определять аксиоматически:
A10 (Частицы со спином). Гильбертово пространство состояний квантовой частицы спина $s \in \left\{0, \frac{1}{2}, 1, \frac{3}{2}, ...\right\}$ - это $\mathscr{H}_S = L^2\left(\mathbb{R}^3\right) \otimes V_s$, $V_s - 2s + 1$-мерное комплексное векторное пространство неприводимого представления R_s группы Ли SU(2) спина s. Операторы спина $S = (S_1, S_2, S_3)$ даются формулой

$$S_j = i\hbar\rho_s\left(A_j\right), \quad j = 1, 2, 3,$$

A_1, A_2, A_3 - стандартные образующие алгебры Ли $\mathfrak{su}(2)$, а $\rho_s = dR_s$ - соответствующее представление $\mathfrak{su}(2)$ в V_s. Частицы с целым спином называются бозонами, а с полуцелым спином - фермионами.

Connection of a Spin and Orbital Angular Momentum

$$\boldsymbol{\mu} = \frac{q}{2mc}\mathbf{L} \qquad \text{gyromagnetic}$$

$$\boldsymbol{\mu} = g\frac{q}{2mc}\mathbf{S}$$

$$\boldsymbol{\mu} = g\mu_N\mathbf{S}, \quad \mu_N = \frac{q}{2m_pc}$$

$$g_p \approx 5.56, \quad g_n \approx -3.83$$

Построение нерелятивистских спиноров, алгебра $su(2)$, спиновые матрицы

Основные методы и формулы о спинах

Спина строится как представление алгебры $su(2)$. А именно: пусть $A_1 = -\frac{i}{2}\sigma_1$, $A_2 = -\frac{i}{2}\sigma_2$, $A_3 = -\frac{i}{2}\sigma_3$ - стандартный базис алгебры Ли su(2) - алгебры 2×2 косоэрмитовых матриц с нулевым следом, у них $[A_1, A_2] = A_3$, $[A_2, A_3] = A_1$, $[A_3, A_1] = A_2$, и пусть $\rho_{\frac{1}{2}}$ - двумерное (фундаментальное) представление $\mathfrak{su}(2)$ в $V_{\frac{1}{2}} \simeq \mathbb{C}^2$. Операторы спина даются формулами

$$S_j = i\hbar\rho_{\frac{1}{2}}(A_j), \quad j = 1, 2, 3$$

и $\rho_{\frac{1}{2}}$ называется представлением спина $\frac{1}{2}$.

В общем, представление ρ_s в $2s+1$-мерном комплексном векторном пространстве V_s называется представлением спина $s \in \frac{1}{2}\mathbb{Z}_{\geqslant 0}$. Действие операторов $T_j = i\rho_s(A_j)$ на V_s описывается формулами

$$\begin{aligned}(T_1 - iT_2)\, e_{sm} &= -\sqrt{(s+m)(s-m+1)}\, e_{sm-1}\\ (T_1 + iT_2)\, e_{sm} &= -\sqrt{(s-m)(s+m+1)}\, e_{sm+1}\\ T_3 e_{sm} &= m e_{sm}.\end{aligned}$$

(абзац про то, что орбитальный момент и спин это разные вещи (???) важный вопрос)

Целость и полуцелость спина (квантование спина)

Потому что если мы посчитаем квадрат $N^2 := s_\mp s_\pm$, то он окажется равным $\lambda_s - m_s(m_s \pm 1)$, при этом собственных векторов конечное число, отсюда и квантование.

(??а почему N^2 должен быть положительный???)

$$\begin{aligned}\boldsymbol{s}^2 = s_x^2 + s_y^2 + s_z^2 = s_+ s_- + \mathrm{i}\,[s_x, s_y] + s_z^2 = s_+ s_- - s_z + s_z^2 \equiv\\ \equiv s_- s_+ - \mathrm{i}\,[s_x, s_y] + s_z^2 = s_- s_+ + s_z + s_z^2.\end{aligned}$$

$$\begin{aligned}\langle \lambda_s, m_s | s_\mp s_\pm | \lambda_s, m_s\rangle = (s_\pm |\lambda_s, m_s\rangle)^\dagger\, s_\pm |\lambda_s, m_s\rangle = N_\pm^2(\lambda_s, m_s) \equiv\\ \equiv \left\langle \lambda_s, m_s \middle| \left(s^2 - s_z^2 \mp s_z\right)\right| \lambda_s, m_s\right\rangle = \lambda_s - m_s(m_s \pm 1).\end{aligned}$$

Поэтому

$$\begin{gathered}m_s(m_s \pm 1) \leqslant \lambda_s,\\ m_s^{\max}(m_s^{\max}+1) - m_s^{\min}\left(m_s^{\min} - 1\right) = 0,\\ m_s^{\max}(m_s^{\max}+1) - (m_s^{\max} - n)(m_s^{\max} - n - 1) = 0,\\ m_s^{\max} = \frac{n}{2}, \qquad m_s^{\min} = -\frac{n}{2}.\\ s := m_s^{\max} = \frac{n}{2},\end{gathered}$$

О спинорной метрике (???)

(чуть потренирую - и напишу, не так это нужно особо)

$$\hat\epsilon \stackrel{\text{def}}{=} \begin{pmatrix} 0 & 1\\ -1 & 0\end{pmatrix} = \mathrm{i}\sigma_2, \quad \hat\epsilon^2 = -\mathbb{1}, \quad \hat\epsilon^{-1} = \hat\epsilon^{\mathrm{T}} = -\hat\epsilon$$

$$\psi_c \stackrel{\text{def}}{=} -\hat\epsilon\psi^* = -\mathrm{i}\sigma_2\psi^*,$$

(? почему именно она?)

$$\hat{\epsilon}\circ\exp\{A\}\circ\hat{\epsilon}^{-1}=\hat{\epsilon}\circ\left(\sum_{n=0}^{\infty}\frac{1}{n!}A^n\right)\circ\hat{\epsilon}^{-1}=\sum_{n=0}^{\infty}\frac{1}{n!}\left\{\hat{\epsilon}\circ A\circ\hat{\epsilon}^{-1}\right\}^n=\exp\left\{\hat{\epsilon}\circ A\circ\hat{\epsilon}^{-1}\right\}.$$

$$\hat{R}_S=\exp\left(-\frac{\mathrm{i}}{2}\phi(\boldsymbol{\sigma}\cdot\mathcal{O})\right)$$
$$\hat{R}^*_S=\exp\left(\frac{\mathrm{i}}{2}\phi\left(\boldsymbol{\sigma}^*\cdot\mathcal{O}\right)\right).$$

(??? место додумать!)

(????) Сопряженный спинор при поворотах преобразуется также, как и обычный спинор. Поэтому скаляром будет величина

$$-\chi^\dagger\cdot\psi_c=-\bar{\chi}_{\dot{\alpha}}\bar{\psi}^{\dot{\alpha}}$$

$$\bar{\chi}_{\dot{\alpha}}=\left(\chi^\dagger\right)_{\dot{\alpha}}$$
$$\chi^\dagger=\{\chi^*\}^{\mathrm{T}}=\{\hat{\epsilon}\,(-\hat{\epsilon}\chi^*)\}^{\mathrm{T}}=\{\hat{\epsilon}\bar{\chi}\}^{\mathrm{T}}=-\bar{\chi}^{\mathrm{T}}\hat{\epsilon}$$

Поэтому

$$-\bar{\chi}\cdot\bar{\psi}=\bar{\chi}^{\mathrm{T}}\hat{\epsilon}\bar{\psi}=\bar{\chi}^{\dot{\alpha}}\epsilon_{\dot{\alpha}\dot{\beta}}\bar{\psi}^{\dot{\beta}},\quad \epsilon_{12}=1,$$

т.е. метрика $\epsilon_{\dot{\alpha}\dot{\beta}}$ в спинорных индексах с точкой совпадает с метрикой $\epsilon_{\alpha\beta}$ в спинорных индексах без точек.

спинорах

(коротко, потому что подробнее в теории поля.)

О спиральности (?????)

(!?!!!! еще раз про спин фотона подумаю, так и не понял, если мы говорим, что спин это генератор группы вращений, то что с фотоном то делать???? как представить его вращения???? мы же даже в его систему не можем перейти ведь???? пока хз)

$$\gamma^0=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&-1&0\\0&0&0&-1\end{pmatrix},\qquad \gamma^1=\begin{pmatrix}0&0&0&1\\0&0&1&0\\0&-1&0&0\\-1&0&0&0\end{pmatrix},\qquad \gamma^2=\begin{pmatrix}0&0&0&-i\\0&0&i&0\\0&i&0&0\\-i&0&0&0\end{pmatrix},$$
$$\gamma^3=\begin{pmatrix}0&0&1&0\\0&0&0&-1\\-1&0&0&0\\0&1&0&0\end{pmatrix}.\qquad I_4=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix},\quad \gamma^5\equiv i\gamma^0\gamma^1\gamma^2\gamma^3=\begin{pmatrix}0&0&1&0\\0&0&0&1\\1&0&0&0\\0&1&0&0\end{pmatrix}$$

$(\gamma^0)^\dagger=\gamma^0$
$\gamma^0\gamma^\mu\gamma^0=(\gamma^\mu)^\dagger,$

$$\gamma_\lambda\gamma^\lambda = 4,$$
$$\gamma_\lambda\gamma^\alpha\gamma^\lambda = -2\gamma^\alpha$$
$$\gamma_\lambda\gamma^\alpha\gamma^\beta\gamma^\lambda = 4g^{\alpha\beta},$$
$$\gamma_\lambda\gamma^\alpha\gamma^\beta\gamma^\gamma\gamma^\lambda = -2\gamma^\gamma\gamma^\beta\gamma^\alpha$$
$$\gamma_i\gamma^\alpha\gamma^\beta\gamma^\gamma\gamma^\delta\gamma^\lambda = 2\left(\gamma^\delta\gamma^\alpha\gamma^\beta\gamma^\gamma + \gamma^\gamma\gamma^\beta\gamma^\alpha\gamma^\delta\right)$$

For 4-vectors A, B: $\gamma_\lambda \not{A}\gamma^\lambda = -2\not{A}$ $\quad \not{A} := \gamma^\alpha A_\alpha$

$$\gamma_\lambda \not{A}\not{B}\gamma^\lambda = 4\not{A}\not{B},$$
$$\gamma_\lambda \not{A}\not{B}\not{C}\gamma^\lambda = -2\not{C}\not{B}\not{A}$$
$$\gamma_\lambda \not{A}\not{B}\not{C}\not{D}\gamma^\lambda = 2(\not{D}\not{A}\not{B}\not{C} + \not{C}\not{B}\not{A}\not{D})$$

$$\mathrm{Tr}(\not{A}\not{B}) = 4(AB)$$
$$\mathrm{Tr}(\not{A}\not{B}\not{C}\not{D}) = 4\{(AB)(CD) - (AC)(BD) + (AD)(BC)\},$$
$$\mathrm{Tr}\left(\not{A}_1\not{A}_2...\not{A}_{2n}\right) = (A_1A_2)\,\mathrm{Tr}\left(\not{A}_3...\not{A}_{2n}\right) - (A_1A_3)\,\mathrm{Tr}\left(A_2A_4...A_{2n}\right) + ... + (A_1A_{2n})\,\mathrm{Tr}\left(\not{A}_2\not{A}_3...\not{A}_{2n-1}\right).$$

$$\not{A}\not{B} = AB - \mathrm{i}\sigma^{\alpha\beta}A_\alpha B_\beta = 2AB - \not{B}\not{A},$$
$$\not{A}\not{A} = A^2; \qquad \text{if } AB = 0. \qquad \not{A}\not{B} = -\not{B}\not{A},$$

(i) For any two $n \times n$ matrices U, V we have: $\mathrm{Tr}(UV) = \mathrm{Tr}(VU)$
(ii) If $\left(\gamma^\alpha\gamma^\beta\cdots\gamma^\mu\gamma^\nu\right)$ contains an odd number of γ-matrices: $\mathrm{Tr}\left(\gamma^\alpha\gamma^\beta\cdots\gamma^\mu\gamma^\nu\right) = 0$
(iii) For a product of an even number of γ-matrices:

$$\mathrm{Tr}\left(\gamma^\alpha\gamma^\beta\right) = 4g^{\alpha\beta}, \quad \mathrm{Tr}\,\sigma^{\alpha\beta} = 0$$
$$\mathrm{Tr}\left(\gamma^\alpha\gamma^\beta\gamma^\gamma\gamma^\delta\right) = 4\left(g^{\alpha\beta}g^{\gamma\delta} - g^{\alpha\gamma}g^{\beta\delta} + g^{\alpha\delta}g^{\beta\gamma}\right),$$

(iv) For any product of γ-matrices

$$\mathrm{Tr}\left(\gamma^\alpha\gamma^\beta...\gamma^\mu\gamma^\nu\right) = \mathrm{Tr}\left(\gamma^\nu\gamma^\mu...\gamma^\beta\gamma^\alpha\right)$$

$$\mathrm{Tr}\left(\not{A}_1\not{A}_2...\not{A}_{2n}\right) = \mathrm{Tr}\left(\not{A}_{2n}...\not{A}_2\not{A}_1\right)$$

$$\mathrm{Tr}\,\gamma^5 = \mathrm{Tr}\left(\gamma^5\gamma^\alpha\right) = \mathrm{Tr}\left(\gamma^5\gamma^\alpha\gamma^\beta\right) = \mathrm{Tr}\left(\gamma^5\gamma^\alpha\gamma^\beta\gamma^\gamma\right) = 0$$
$$\mathrm{Tr}\left(\gamma^5\gamma^\alpha\gamma^\beta\gamma^\gamma\gamma^\delta\right) = -4\mathrm{i}\varepsilon^{\alpha\beta\gamma\delta}$$

$\left(\gamma^5\right)^2 = 1,$

$$\mathrm{Tr}\left(\gamma^\alpha...\gamma^\nu\right) = \mathrm{Tr}\left[\left(\gamma^5\right)^2\gamma^\alpha...\gamma^\nu\right] = \mathrm{Tr}\left(\gamma^5\gamma^\alpha...\gamma^\nu\gamma^5\right)$$

Algebra of $\mathfrak{su}(2)$ and spins

$\mathscr{H}_S = \mathscr{H} \otimes \mathbb{C}^2,$
$\Psi = \begin{pmatrix} \psi_1(\boldsymbol{x}) \\ \psi_2(\boldsymbol{x}) \end{pmatrix} \in \mathscr{H}_S, \qquad \|\Psi\|^2 = \int\limits_{\mathbb{R}^3} |\psi_1(\boldsymbol{x})|^2\, d^3\boldsymbol{x} + \int\limits_{\mathbb{R}^3} |\psi_2(\boldsymbol{x})|^2\, d^3\boldsymbol{x} < \infty.$

Каждой наблюдаемой A в $\mathscr{H}$ соответствует наблюдаемая $A \otimes I_2$ в $\mathscr{H}_S$, задаваемая 2×2 блочно-диагональной матрицей $\begin{pmatrix} A & 0 \\ 0 & A \end{pmatrix}$. Наблюдаемые вида $I \otimes S$, I - тождественный

оператор в $\mathscr{H}$, а S - самосопряженный оператор в $\mathbb{C}^2$, описывают внутренние степени свободы и коммутируют со всеми наблюдаемыми $A \otimes I_2$. Полный набор наблюдаемых в $\mathscr{H}_S$ состоит из операторов $Q_1 \otimes I_2, Q_2 \otimes I_2, Q_3 \otimes I_2$ и $I \otimes S_1, I \otimes S_2, I \otimes S_3$, Q_j - операторы координат, а S_j - операторы спина, самосопряженные операторы в $\mathbb{C}^2$ с нулевым следом, удовлетворяющие тем же коммутационным соотношениям, что и квантовые операторы углового момента,

$$[S_1, S_2] = i\hbar S_3, \quad [S_2, S_3] = i\hbar S_1, \quad [S_3, S_1] = i\hbar S_2.$$

В стандартном базисе $e_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, e_2 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$ пространства $\mathbb{C}^2$, $S_j = \frac{\hbar}{2}\sigma_j, j = 1, 2, 3$, σ_j - это матрицы Паули:

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

Тут σ_z - это с.з. на диагонали, а другие восстанавливаются из σ_+, σ_-, у которых только одна 1 на крос-диагонали.

Часто представляем $\Psi \in \mathscr{H}_S$ как функцию $\psi(\boldsymbol{x}, \sigma)$, $\boldsymbol{x} \in \mathbb{R}^3$, а $\sigma \in \{\frac{1}{2}, -\frac{1}{2}\}$, положив $\psi\left(\boldsymbol{x}, \frac{1}{2}\right) = \psi_1(\boldsymbol{x})$ и $\psi\left(\boldsymbol{x}, -\frac{1}{2}\right) = \psi_2(\boldsymbol{x})$. Каждая функция $\psi(\boldsymbol{x}, \sigma)$ является конечной линейной комбинацией функций $\psi(\boldsymbol{x})\chi(\sigma)$ - разложимых на множители элементов тензорного произведения $L^2(\mathbb{R}^3) \otimes \mathbb{C}^2$. Мы отождествляем $\mathbb{C}^2$ с комплексным векторным пространством функций $\chi : \left\{-\frac{1}{2}, \frac{1}{2}\right\} \to \mathbb{C}$, сопоставляя стандартному базису e_1, e_2 функции χ_1, χ_2, определенные формулами $\chi_1\left(\frac{1}{2}\right) = 1, \chi_1\left(-\frac{1}{2}\right) = 0$ и $\chi_2\left(\frac{1}{2}\right) = 0, \chi_2\left(-\frac{1}{2}\right) = 1$.

su(2) main properties

(see note about algebra for now!)

$$J_\pm = J_1 \pm iJ_2, \quad [J_3, J_\pm] = \pm\hbar J_\pm, \quad [J_+, J_-] = 2\hbar J_3, \quad \left[J^2, J_\pm\right] = 0$$

$$J^2 = \frac{1}{2}(J_+J_- + J_-J_+) + J_3^2, \quad J_-J_+ = J^2 - J_3(J_3 + \hbar), \quad J_+J_- = J^2 - J_3(J_3 - \hbar)$$

$$J_+|jm\rangle = \hbar\sqrt{(j-m)(j+m+1)}|j, m+1\rangle, \quad J_-|jm\rangle = \hbar\sqrt{(j+m)(j-m+1)}|j, m-1\rangle.$$

$$|jm\rangle = \sqrt{\frac{(j+m)!}{(2j)!(j-m)!}}\left(\frac{J_-}{\hbar}\right)^{j-m}|jj\rangle$$

$$\langle j'm'|\, J_3|jm\rangle = \hbar\delta_{j'j}\delta_{m'm}m$$

О матрицах Паули

$$\sigma_1 = \sigma_{\mathrm{x}} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \qquad \sigma_2 = \sigma_{\mathrm{y}} = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} \qquad \sigma_3 = \sigma_{\mathrm{z}} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

They can be restored from s_z and s_+, s_-.

$$\hat{S}_x = \frac{\hbar}{2}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \equiv \frac{\hbar}{2}[(|\uparrow\rangle\langle\downarrow|) + (|\downarrow\rangle\langle\uparrow|)]; \qquad \hat{S}_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix} \equiv \frac{i\hbar}{2}[-(|\uparrow\rangle\langle\downarrow|) + (|\downarrow\rangle\langle\uparrow|)]$$

$$\begin{aligned}\sigma_x \cos\varphi + \sigma_y \sin\varphi =& e^{-i\varphi\sigma_z/2}\sigma_x e^{i\varphi\sigma_z/2},\\ \sigma_x \sin\varphi - \sigma_y \cos\varphi =& -e^{-i\varphi\sigma_z/2}\sigma_y e^{i\varphi\sigma_z/2}.\end{aligned}$$

О $s = 1$ матрицах

$$s_x = \mathrm{i}\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix} \qquad s_y = \mathrm{i}\begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix} \qquad s_z = \mathrm{i}\begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

$$[s_i, s_j] = \mathrm{i}\varepsilon_{ijk}s_k.$$

$$s^2\,|\lambda_s, m_s\rangle = \lambda_s\,|\lambda_s, m_s\rangle\,, \quad s_z\,|\lambda_s, m_s\rangle = m_s\,|\lambda_s, m_s\rangle\,.$$

$$s_\pm = s_x \pm \mathrm{i}\ s_y$$

$$\left[s^2, s_\pm\right] = 0$$

Restore the position of two ± 1 in $\hat{s}_{s_{x,y,z}}$ by: 
$\Rightarrow$  ,

$\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} \cos\phi_z & -\sin\phi_z \\ \sin\phi_z & \cos\phi_z \end{pmatrix}\begin{pmatrix} x \\ y \end{pmatrix}$, $\quad \hat{G}(\boldsymbol{a}) \approx \mathbb{1} - \mathrm{i}\Gamma_\alpha a^\alpha, \quad \Gamma_\alpha := \mathrm{i}\lim_{\boldsymbol{a}\to 0}\frac{\partial}{\partial a^\alpha}\hat{T}(\boldsymbol{a})$.

(?? додумаю, для больших спинов такой метод не работает, а почему? вообще, укажу про большие спины тут!)

Об индексах и их позиции

(см. пока теорпол, потом сюда тоже допишу)

(???? абзац про точечный и неточечный индексы, что это и зачем???)

Wigner D-matrix basics (?)

$$D^j_{m'm}(U) = \langle jm'|\,U|jm\rangle$$

$$D^j_{mm'}(\alpha,\beta,\gamma) = \langle jm|e^{-i\alpha J_z/\hbar}e^{-i\beta J_y/\hbar}e^{-i\gamma J_z/\hbar}\,|jm'\rangle$$

$$D^j_{mm'}(\alpha,\beta,\gamma) = e^{-i\alpha m - i\gamma m'}d^j_{mm'}(\beta), \quad d^j_{mm'}(\beta) = \langle jm|e^{-i\beta J_y/\hbar}|jm\rangle$$

$$D^j_{mm'}\left(U^{-1}\right) = D^{j*}_{m'm}(U)$$

(see wiki for now)

On higher spin representations of $su(2)$

(see algebra for now.)

Спиновые матрицы плотности (from Vergeles)

Спиновые матрицы плотности необходимы при вычислении сечений и вероятностей распадов, т.к. в процессе таких вычислений приходится делать замены выражений, билинейных относительно спиновых волновых функций начальных и конечных частиц, согласно правилу

$$e_{\mathbf{k}\mu}e^*_{\mathbf{k}\nu} \longrightarrow \rho_{\mu\nu}(k), \quad u_{\pm ka}\bar{u}_{\pm kb} \longrightarrow \rho^{(\pm)}_{ab}(k) \tag{Б1}$$

где $\rho_{\mu\nu}(k)$ - спиновая матрица плотности фотона, $\rho^{(+)}_{ab}(k)\left(\rho^{(-)}_{ab}(k)\right)$ - спиновая матрица плотности электрона (позитрона), причём импульс всех этих частиц равен $\mathbf{k}$.

Фотонные спиновые матрицы плотности.

$$\rho^{\text{unpol}}_{ij} = \frac{1}{2}\left(\delta_{ij} - \frac{k_i k_j}{\mathbf{k}^2}\right), \quad \rho_{0i} = \rho_{i0} = \rho_{00} = 0 \tag{Б2}$$

$$\rho^{\mu}_{\mu} = -1 \tag{Б3}$$

$$\rho_{\mu\nu}(k) \longrightarrow \rho_{\mu\nu}(k) + (\chi_\mu k_\nu + \chi_\nu k_\mu) \tag{Б4}$$

$$\chi^\mu = \left(-\frac{1}{4\omega}, \frac{\mathbf{k}}{4\omega^2}\right) \qquad \Rightarrow \qquad \rho_{\mu\nu} = -\eta_{\mu\nu}/2 \tag{Б5}$$

В общем случае матрица плотности представляется в виде

$$\rho_{\mu\nu} = \rho^*_{\nu\mu} = \sum_{\alpha,\beta=1}^{2} \rho^{\alpha\beta} e_{\alpha\mu} e^*_{\beta\nu} \tag{Б6}$$

$$\rho^{\alpha\beta} = \rho^{\beta\alpha *} \tag{Б7}$$

$$\rho^{\alpha\beta}_{\text{unpol}} = (1/2)\delta^{\alpha\beta} \tag{Б8}$$

$$\det \rho^{\alpha\beta}_{\text{unpol}} = 1/4 \tag{Б9}$$

$$\rho^{\alpha\beta}_{\text{fully pol}} = v^\alpha v^{\beta *} \tag{В10}$$

$$\det \rho^{\alpha\beta}_{\text{fully pol}} = 0 \tag{Б11}$$

В общем случае:

$$\sum_{\alpha=1}^{2} \rho^{\alpha\alpha} = 1 \tag{Б12}$$

$$0 \leq \det \rho^{\alpha\beta} \leq 1/4 \tag{Б13}$$

$$\rho = \frac{1}{2}(1 + \boldsymbol{\xi}\boldsymbol{\sigma}), \quad \boldsymbol{\xi} = (\xi_1, \xi_2, \xi_3) \tag{Б14}$$

$$\det \rho = \frac{1}{4}\left(1 - \xi_1^2 - \xi_2^2 - \xi_3^2\right) \tag{Б15}$$

$$0 \le \xi_1^2 + \xi_2^2 + \xi_3^2 \equiv \boldsymbol{\xi}^2 \le 1 \tag{Б16}$$

Поэтому в неполяризованном случае $\xi^2 = 0$, а в полностью поляризованном $\xi^2 = 1$.

Спинорные матрицы плотности.

$$\operatorname{tr} \rho^{(\pm)}(k) = \pm 2m \tag{Б19}$$

$$(\not{k} \mp m)\rho^{(\pm)}(k) = \rho^{(\pm)}(k)(\not{k} \mp m) = 0 \tag{Б20}$$

$$\langle \mathbf{s} \rangle = \frac{1}{2\omega_k} \operatorname{tr}\left(\rho^{(\pm)}\gamma^0 \boldsymbol{\Sigma}\right) = \frac{1}{4\omega_k} \operatorname{tr}\left(\rho^{(\pm)}\gamma^5\gamma\right) \tag{Б21}$$

Матрица плотности для неполяризованного состояния получается при $\frac{1}{2}\sum\limits_{s=1,2} u_{\pm ks}\bar{u}_{\pm ks} = \not{k} \pm m$

$$\rho^{(\pm)}(k) = (1/2)(\not{k} \pm m) \tag{Б22}$$

В общем случае

$$\rho^{(\pm)}(k) = (1/2)(\not{k} \pm m)\left(1 - \gamma^5 \not{a}\right) \tag{Б23}$$

$a^\mu: \quad k_\mu a^\mu = 0 \quad \longleftrightarrow \quad \not{a}\not{k} + \not{k}\not{a} = 0$

$$\pm a^\mu = \frac{1}{2m} \operatorname{tr}\left(\rho^{(\pm)}\gamma^5\gamma^\mu\right) \tag{b25}$$

В системе покоя частицы

$$a^\mu = (0, \pm 2\langle \mathbf{s} \rangle) \tag{Б26}$$

$0 \le \langle \mathbf{s} \rangle^2 \le 1/4 \quad \Rightarrow -1 \le a^2 \le 0$

Также в сечение рассеяния следует внести дополнительный множитель 2^r, где r - суммарное число электронов, позитронов и фотонов в конечном состоянии. Этот множитель означает учёт обоих состояний спина каждой конечной частицы. (??)

других темах про спин

(просто укажу тут их, их прямо очень много, но я не буду их касаться, так что эти разделы дальше, на которые тут будет отсылка, вряд ли создам скоро.)

связи спина со статистикой

bosons: $\left[\mathfrak{a}^\dagger_\lambda(\boldsymbol{k}), \mathfrak{a}^\dagger_{\lambda'}(\boldsymbol{k}')\right] = 0 \qquad [\mathfrak{a}_\lambda(\boldsymbol{k}), \mathfrak{a}_{\lambda'}(\boldsymbol{k}')] = 0$

femions: $\left\{\mathfrak{a}^\dagger_\lambda(\boldsymbol{k}), \mathfrak{a}^\dagger_{\lambda'}(\boldsymbol{k}')\right\} = 0 \qquad \{\mathfrak{a}_\lambda(\boldsymbol{k}), \mathfrak{a}_{\lambda'}(\boldsymbol{k}')\} = 0$

(тут про вывод, почему так? (!?!???))
(тут про то, что видите ли, в КТП могут быть госты, у которых это не так.)

(see Tong!!!! просто пока это не нужно было и сейчас не нужно, пару дней подумаю - и готов буду написать)

Quantum Maps

$$\rho = \mathrm{Tr}_{\mathcal{H}_E} |\Psi\rangle\langle\Psi|$$

We would like to understand how this density matrix evolves. The state $|\Psi\rangle$ evolves by a unitary operator $U(t)$ acting on the full Hilbert space $\mathcal{H}$. The story that we are about to tell only works if, at time $t = 0$, the two systems lie in a separable state,

$$|\Psi_0\rangle = |\psi\rangle \otimes |\chi\rangle$$

This means that the original density matrix $\rho_0 = |\psi\rangle\langle\psi|$ describes a pure state on $\mathcal{H}_S$. We now look at how this density matrix evolves. We have

$$\rho(t) = \mathrm{Tr}_{\mathcal{H}_E} U(t) |\Psi_0\rangle \langle\Psi_0| U^\dagger(t) = \sum_m \langle m|U(t) |\Psi_0\rangle \langle\Psi_0| U^\dagger(t)|m\rangle$$

with $|m\rangle$ a complete basis for $\mathcal{H}_E$. This encourages us to define a set of operators on $\mathcal{H}_S$, given by

$$M_m(t) = \langle m|U(t)|\chi\rangle = \mathrm{Tr}_{\mathcal{H}_E}(U(t)|\chi\rangle\langle m|)$$

The unitarity of $U(t)$ translates into a completeness condition on the operators $M_m(t)$,

$$\sum_m M_m^\dagger(t) M_m(t) = \sum_m \langle\chi|U^\dagger(t)|m\rangle\langle m|U(t)|\chi\rangle = 1$$

We see that the original density matrix on $\mathcal{H}_S$ evolves as

$$\rho(t) = \sum_m M_m(t)\rho_0 M_m^\dagger(t)$$

Kraus Representation Theorem

$$\rho \mapsto \mathcal{L}[\rho]$$

Such a map is sometimes called a superoperator (because it maps operators to operators, rather than states to states). We will require some special properties of our map, most of which are inherited from the properties of the density matrices listed in Section 5.3

- Linearity: $\mathcal{L}[a\rho_1 + b\rho_2] = a\mathcal{L}[\rho_1] + b\mathcal{L}[\rho_2]$.
- Hermiticity Preserving: $\rho = \rho^\dagger \Rightarrow \mathcal{L}[\rho] = \mathcal{L}[\rho]^\dagger$.
- Trace Preserving: $\mathrm{Tr}\,\mathcal{L}[\rho] = \mathrm{Tr}\,\rho$.
- Complete Positivity. This one requires some explanation. It is natural to insist that the map is positive, so that $\mathcal{L}[\rho] \geq 0$ whenever $\rho \geq 0$. However, this is not sufficient. Instead, we require the stronger statement that the map $\mathcal{L} \otimes \mathbf{1}_E$ is positive on any extension of the Hilbert space $\mathcal{H}_S$ to $\mathcal{H}_S \otimes \mathcal{H}_E$. This is the statement of complete positivity. It ensures that the map $\mathcal{L} \otimes \mathbf{1}_E$ will take a valid density matrix on the composite system to another density matrix.

A superoperator obeying these conditions is called a trace preserving, completely positive (TPCP) map, with the first two conditions taken for granted. In the quantum information community, this map is referred to as a quantum channel.

The Kraus representation theorem (which we do not prove here) states that any quantum map, obeying the four conditions above, can be written as

$$\mathcal{L}[\rho] = \sum_m M_m \rho M_m^\dagger \quad \text{with} \quad \sum_m M_m^\dagger M_m = 1$$

In this framework, the M_m are called Kraus operators. They are not unique. The number of Kraus operators in the quantum map does not exceed $\dim(\mathcal{H}_S)^2$.

The Increase of Entropy in quantum systems

$$S(\rho) = -\operatorname{Tr}\rho\log\rho$$

$$\frac{dS}{dt} = -\operatorname{Tr}\left(\frac{\partial\rho}{\partial t}(1+\log\rho)\right) = -\operatorname{Tr}\left(\frac{\partial\rho}{\partial t}\log\rho\right)$$

$$\hbar\frac{dS}{dt} = -\sum_m \operatorname{Tr}\left[(L_m\rho L_m - L_m L_m\rho)\log\rho\right]$$

$$\rho = \sum_i p_i \left|\phi_i\right\rangle\left\langle\phi_i\right|$$

$$\begin{aligned}\hbar\frac{dS}{dt} &= -\sum_m\sum_i \left\langle\phi_i\right|(L_m\rho L_m - L_m L_m\rho)\left|\phi_i\right\rangle\log p_i \\ &= -\sum_m\sum_{i,j}\left\langle\phi_i\right|L_m\left|\phi_j\right\rangle\left\langle\phi_j\right|L_m\left|\phi_i\right\rangle(p_j-p_i)\log p_i \\ &= -\frac{1}{2}\sum_m\sum_{i,j}\left|\langle\phi_i|L_m|\phi_j\rangle\right|^2(p_j-p_i)(\log p_i - \log p_j)\end{aligned}$$

$$\hbar\frac{dS}{dt} \geq 0$$

(??? и что с этим делать? статфиз говорил, что нет, такого не может быть???)

1.1.8 Path integral: basics

(только самое важное, пока в КТП об этом. страницы мб 5 будет.)

Main formulas to work with a path integral

Main ideas of path integral

$$K\left(x,t;x_0,t_0\right)=\langle x|U\left(t,t_0\right)|x_0\rangle$$

$$\psi(x,t)=\int dx_0 K\left(x,t;x_0,t_0\right)\psi\left(x_0,t_0\right)$$

$$U(\epsilon)=1-\frac{i\epsilon}{\hbar}(T+V)+O\left(\epsilon^2\right)=e^{-i\epsilon T/\hbar}e^{-i\epsilon V/\hbar}+O\left(\epsilon^2\right)$$

$$U(t)=\left(e^{-i\epsilon T/\hbar}e^{-i\epsilon V/\hbar}\right)^N+O(1/N)\qquad t=N\varepsilon$$

$$K\left(x,x_0,t\right)=\lim_{N\to\infty}\int dx_1...dx_{N-1}\prod_{j=0}^{N-1}\left\langle x_{j+1}\right|e^{-i\epsilon T/\hbar}e^{-i\epsilon V/\hbar}\left|x_j\right\rangle,\quad x=x_N$$

$$\int dp\left\langle x_{j+1}\right|e^{-i\epsilon\hat{p}^2/2m\hbar}|p\rangle\langle p|e^{-i\epsilon V(\hat{x})/\hbar}\left|x_j\right\rangle=\sqrt{\frac{m}{2\pi i\epsilon\hbar}}\exp\left[\frac{i}{\hbar}\left(m\frac{\left(x_{j+1}-x_j\right)^2}{2\epsilon}-\epsilon V\left(x_j\right)\right)\right]$$

$$K\left(x,x_0,t\right)=\lim_{N\to\infty}\left(\frac{m}{2\pi i\hbar\epsilon}\right)^{N/2}\int dx_1...dx_{N-1}\exp\left[\frac{i\epsilon}{\hbar}\sum_{j=0}^{N-1}\left(m\frac{\left(x_{j+1}-x_j\right)^2}{2\epsilon^2}-V\left(x_j\right)\right)\right]$$

$$=C\int\mathcal{D}x(\tau)\exp\left(\frac{i}{\hbar}\int_0^t Ld\tau\right)$$

Semiclassical Approximation for path integral

$$\varphi\left(x_1,...,x_{N-1}\right)=\epsilon\sum_{j=0}^{N-1}\left(\frac{m}{2}\frac{\left(x_{j+1}-x_j\right)^2}{\epsilon^2}-V\left(x_j\right)\right)$$

$$\frac{\partial\varphi}{\partial x_k}=\epsilon\left(\frac{m}{\epsilon^2}\left(2x_k-x_{k+1}-x_{k-1}\right)-V'\left(x_k\right)\right),\quad\frac{\partial^2\varphi}{\partial x_k\partial x_\ell}=\frac{m}{\epsilon}Q_{k\ell}$$

$$Q_{k\ell}=\begin{pmatrix}2-c_1 & -1 & 0 & 0 & ...\\ -1 & 2-c_2 & -1 & 0 & ...\\ 0 & -1 & 2-c_3 & -1 & ...\\ \vdots & \vdots & \vdots & \vdots & \ddots\end{pmatrix},\quad c_k=\frac{\epsilon^2}{m}V''\left(x_k\right)$$

$$\lim_{N\to\infty}\varphi(\bar{x})=S\left(x,x_0,t\right)$$

$$D_{k+1}=\left(2-c_{k+1}\right)D_k-D_{k-1}$$

$$m\frac{d^2F(\tau)}{d\tau^2}=-V''(\bar{x}(\tau))F(\tau),\quad F_k=\epsilon D_k$$

$$F(0)=\lim_{\epsilon\to0}\epsilon D_0=\lim_{\epsilon\to0}\epsilon=0,\quad F'(0)=\lim_{\epsilon\to0}\left(D_1-D_0\right)=1.$$

$$F(t) = \frac{\partial x}{\partial v_i} = m\left(\frac{\partial p_i}{\partial x}\right)^{-1} = -m\left(\frac{\partial^2 S}{\partial x_0 \partial x}\right)^{-1}$$

$$K(x, x_0, t) \approx \sum_b \frac{e^{-i\mu_b \pi/2}}{\sqrt{2\pi i\hbar}} \left|\frac{\partial^2 S_b}{\partial x \partial x_0}\right|^{1/2} \exp\left(\frac{i}{\hbar} S_b(x, x_0, t)\right) \quad \text{Van Vleck}$$

(!!! see useful examples in Zhou or later in my theoretical part!)

Типичные примеры

1.2 Matrices, Algebra, Integrals, Functional Analysis, Special Functions

Функан для квантмеха

(!!! тут функан подтягивать нужно, большая тоже работа.)

Об определениях операторов

$$A \text{ Hermitian} \iff A = \overline{A^\top} \iff a_{ij} = \overline{a_{ji}}$$

$$A \text{ Unitary} \iff U^\dagger U = UU^\dagger = I$$

$$\forall \text{ Unitary } U \quad \exists \text{ Unitary } V: \qquad U = V^{-1} D V,$$

$D = \operatorname{diag}\{1, ..., 1\}$

$$\forall \text{ hermitian } A \qquad A = V^{-1} D V$$

V - унитарная матрица, а D - диагональная матрица с вещественными числами.
Например, разложение произвольной унитарной матрицы

$$U = \begin{bmatrix} \cos\rho & -\sin\rho \\ \sin\rho & \cos\rho \end{bmatrix} \begin{bmatrix} e^{i\xi} & 0 \\ 0 & e^{i\zeta} \end{bmatrix} \begin{bmatrix} \cos\sigma & \sin\sigma \\ -\sin\sigma & \cos\sigma \end{bmatrix}$$

О формулах линала для квантмеха

$\operatorname{tr}(\alpha A + \beta B) = \alpha \operatorname{tr} A + \beta \operatorname{tr} B.$
$\operatorname{tr}(AB) = \operatorname{tr}(BA) \qquad \Rightarrow \qquad \operatorname{tr}(C^{-1}AC) = \operatorname{tr} A.$
$\operatorname{tr} A = \operatorname{tr} A^{\mathrm{T}}$
$\ln\det A = \operatorname{tr}\ln A.$
$\operatorname{tr} A \otimes B = (\operatorname{tr} A)(\operatorname{tr} B).$
$\det A_{3\times 3} = \frac{1}{6}\left((\operatorname{tr} A)^3 - 3\operatorname{tr} A \cdot \operatorname{tr} A^2 + 2\operatorname{tr} A^3\right)$

$$\dim\left(\mathcal{H}^A \otimes \mathcal{H}^B\right) = \dim\mathcal{H}^A \cdot \dim\mathcal{H}^B$$
$$\operatorname{tr}(A \otimes B) = \operatorname{tr}(A) \cdot \operatorname{tr}(B)$$
$$(A \otimes B) \cdot (C \otimes D) = (AC) \otimes (BD)$$

Typical integrals for QM

$$\int dx e^{-ax^2/2} = \sqrt{\frac{2\pi}{a}}, \quad \operatorname{Re} a > 0.$$

$$\int dx e^{-ax^2/2} x^2 = \sqrt{\frac{2\pi}{a^3}}.$$

$$\int dx e^{-ax^2/2+bx} = \sqrt{\frac{2\pi}{a}} e^{b^2/2a}.$$

(complex)
$$\int d(\bar{z}, z) e^{-\bar{z}wz} = \frac{\pi}{w}, \quad \operatorname{Re} w > 0$$

$$\int d(\bar{z}, z) e^{-\bar{z}wz+\bar{u}z+\bar{z}v} = \frac{\pi}{w} e^{\bar{u}v/w}, \quad \operatorname{Re} w > 0.$$

$$\int d\mathbf{v} e^{-\mathbf{v}^T A\mathbf{v}/2} = \sqrt{\frac{(2\pi)^N}{\det A}}$$

$$\int d\mathbf{v} \exp\left(-\frac{1}{2}\mathbf{v}^T A\mathbf{v} + \mathbf{j}^T\mathbf{v}\right) = \sqrt{\frac{(2\pi)^N}{\det A}} \exp\left(\frac{1}{2}\mathbf{j}^T A^{-1}\mathbf{j}\right) \qquad \mathbf{v} \to \mathbf{v} + A^{-1}\mathbf{j}$$

(??)

$$\partial_{j_m} e^{\mathbf{j}^T A^{-1}\mathbf{j}/2} = \left(A^{-1}\mathbf{j}\right)_m e^{\mathbf{j}^T A^{-1}\mathbf{j}/2}$$

$$\int d\mathbf{v} e^{-\mathbf{v}^T A\mathbf{v}/2} v_m v_n = \sqrt{\frac{(2\pi)^N}{\det A}} A^{-1}_{mn}$$

$$\langle v_m v_n \rangle = A^{-1}_{mn}$$

$$\langle v_{i_1} \cdots v_{i_{2n}} \rangle = \sum_{\text{pairings}} A^{-1}_{i_{k_1} i_{k_2}} \ldots A^{-1}_{i^{-1}_{k_{2n-1}} i_{k_{2n}}}$$

$$\int d\left(\mathbf{v}^\dagger, \mathbf{v}\right) e^{-\mathbf{v}^\dagger A\mathbf{v}} = \frac{\pi^N}{\det A}$$

$$\int d\left(\mathbf{v}^\dagger, \mathbf{v}\right) e^{-\mathbf{v}^\dagger A\mathbf{v}+\mathbf{w}^\dagger\mathbf{v}+\mathbf{v}^\dagger\mathbf{w}'} = \frac{\pi^N}{\det A} e^{\mathbf{w}^\dagger A^{-1}\mathbf{w}'}$$

$$\langle \bar{v}_{i_1} \cdots \bar{v}_{i_n} v_{j_1} \cdots v_{j_n} \rangle = \sum_{\text{perms}} A^{-1}_{j_1 i_{P_1}} \cdots A^{-1}_{j_n i_{P_n}}$$

Stationary phase approximation

$$\int dx e^{i\varphi(x)/\kappa}$$

$$\int dx e^{i\varphi(x)/\kappa} \approx \sqrt{\frac{2\pi i\kappa}{\varphi''(\bar{x})}} e^{i\varphi(\bar{x})/\kappa} = e^{i\nu\pi/4} \sqrt{\frac{2\pi\kappa}{|\varphi''(\bar{x})|}} e^{i\varphi(\bar{x})/\kappa}, \quad \nu = \operatorname{sign}\left(\varphi''(\bar{x})\right)$$

$$\int d\mathbf{x} e^{i\varphi(\mathbf{x})/\kappa}$$

$$\nabla\varphi = 0$$

$$\int d\mathbf{x} e^{i\varphi(\mathbf{x})/\kappa} = e^{i\nu\pi/4}(2\pi\kappa)^{n/2}\left|\det\frac{\partial^2\varphi(\bar{x})}{\partial x_k \partial x_l}\right|^{-1/2} e^{i\varphi(\bar{x})/\kappa}, \quad \nu = \sum_i \operatorname{sign}(\lambda_i)$$

Typical integrals for scattering

$$\int_{-\infty}^{\infty} e^{-x^2/\beta^2}dx = \beta\sqrt{\pi}; \qquad \int_{-\infty}^{\infty} dx e^{-ax^2} = \sqrt{\frac{\pi}{a}}$$

$$\int_0^{\infty} x^2 \mathrm{e}^{-\gamma x^2}dx = \frac{1}{4\gamma}\sqrt{\frac{\pi}{\gamma}}, \qquad \int_0^{\infty} x^4 e^{-x^2}dx = \frac{3\sqrt{\pi}}{8}$$

$$\int_0^{\infty} \sqrt{x}e^{-x}dx = (1/2)! = \sqrt{\pi}/2$$

$$\int_0^{\infty} x\mathrm{e}^{-\gamma x^2}dx = \frac{1}{2\gamma}, \qquad \int_0^{\infty} x^3\mathrm{e}^{-\gamma x^2}dx = \frac{1}{2\gamma^2}, \qquad \int_0^{\infty} x^5\mathrm{e}^{-\gamma x^2}dx = \frac{1}{\gamma^3}$$

$$\int \frac{e^{-i\mathbf{q}\cdot\mathbf{r}}dV}{|\mathbf{r}+\mathbf{r}_1'-\mathbf{r}_2'|} = \frac{4\pi}{q^2}e^{i\mathbf{q}\cdot(\mathbf{r}_1'-\mathbf{r}_2')}$$

$$\int_0^{\infty} \frac{\sin x}{x^{\nu-1}}dx = \Gamma(2-\nu)\sin\frac{\pi\nu}{2} = -\frac{\pi\sin(\pi\nu/2)}{\Gamma(\nu-1)\sin\pi\nu}.$$

$$\int_{-\infty}^{\infty} \frac{e^{ikx}dk}{k^2-\kappa^2\mp i\varepsilon} = \pm i\frac{\pi}{\kappa}e^{i\pm\kappa|x|}, \qquad \int_{-\infty}^{\infty} \frac{e^{ikx}dk}{k^2+\kappa^2} = \frac{\pi}{\kappa}e^{-\kappa|x|}$$

where x and κ are real, $\kappa > 0$, and $\varepsilon > 0$ is infinitely small. Integrals are calculated using the residue theorem, by closing the integration contour in either the upper ($x > 0$) or lower ($x < 0$) complex half-plane, k.

$$\int \frac{1}{r}e^{i\mathbf{k}\cdot\mathbf{r}-\kappa r}d^3r = \frac{4\pi}{k^2+\kappa^2}, \quad \operatorname{Re}\kappa > 0$$

преобразованиях операторов

(необходимая математика тут)

О типичных преобразованиях операторов

$$[\mathrm{AB},\mathrm{C}] = \mathrm{A}[\mathrm{B},\mathrm{C}] + |\mathrm{A},\mathrm{C}|\mathrm{B}$$
$$|\mathrm{A},\mathrm{BC}| = \mathrm{B}|\mathrm{A},\mathrm{C}| + [\mathrm{A},\mathrm{B}]\mathrm{C}$$

(добавлю еще полезные формулы!)

матричных элементах операторов

(!? тут основная идея. почему такое вообще может быть?)

$$\langle n', L, M-1 \,|A_-|\, nLM\rangle = \sqrt{\frac{(L-M+1)(L+M)}{L(L+1)(2L+1)}}\,\langle n'L\|A\|nL\rangle\,,$$

$$\langle n', L, M-1 \,|A_-|\, n, L-1, M\rangle = \sqrt{\frac{(L-M+1)(L-M)}{L(2L-1)(2L+1)}}\,\langle n'L\|A\|n, L-1\rangle\,,$$

$$\langle n', L-1, M-1 \,|A_-|\, nLM\rangle = -\sqrt{\frac{(L+M-1)(L+M)}{L(2L-1)(2L+1)}}\,\langle n', L-1\|A\|nL\rangle\,.$$

$$\langle n'L'M' \,|A_+|\, nLM\rangle = \langle nLM \,|A_-|\, n'L'M'\rangle^*$$

$$\widehat{\mathbf{A}}\widehat{\mathbf{B}} = \frac{1}{2}\left(\widehat{A}_+\widehat{B}_- + \widehat{A}_-\widehat{B}_+\right) + \widehat{A}_z\widehat{B}_z$$

$$\langle n'LM|\mathbf{AB}|nLM\rangle = \frac{1}{2L+1}\sum_{n'',L''}\langle n'L\|A\|n''L''\rangle\,\langle n''L''\|B\|nL\rangle\,,$$

L'' пробегает значения $L, L\pm 1$.

(абзац про разложение тензоров и усреднение, см. зад. 28 ЛЛ3, пока такое не понял.)

Tensor operators

$|\psi\rangle \to |\psi'\rangle = U(R)|\psi\rangle$

$$A' = U(R)AU(R)^\dagger$$

$\langle\psi'|\,A'\,|\psi'\rangle = \langle\psi|A|\psi\rangle$.

$$\langle\psi'|\,\mathbf{V}\,|\psi'\rangle = R\langle\psi|\mathbf{V}|\psi\rangle$$

$$U(R)V_iU(R)^\dagger = V_jR_{ji}$$

$$[J_i, V_j] = i\hbar\epsilon_{ijk}V_k$$

rank-2 tensor oper

$$U(R)T_{ij}U(R)^\dagger = T_{kl}R_{ki}R_{lj}$$

1.3 Typical Methods

1.3.1 Perturbation theories

Нестационарная теория возмущений в невырожденном случае

$$|\psi(t)\rangle = \sum_n \psi_n(t)|n(t)\rangle, \quad |n(t)\rangle = e^{-iE_nt}|n\rangle$$

$$w_{i\to f} = \left| \int_{-\infty}^{\infty} V_{fi}(t) e^{i\omega_{fi}t} dt \right|^2 \qquad (\hbar = 1)$$

$$i\frac{\partial \psi_n}{\partial t} = \sum_m V_{nm}^{(I)}(t)\psi_m(t), \quad V_{nm}^{(I)} \equiv \langle n(t)|\hat{V}(t)|m(t)\rangle = e^{i\omega_{nm}t}V_{nm}(t), \qquad \omega_{nm} = E_n - E_m.$$

$$c_n^{(0)}(t) = \delta_{ni}$$

$$c_n^{(1)}(t) = \frac{-i}{\hbar}\int_{t_0}^{t} e^{i\omega_{ni}t'} V_{ni}\left(t'\right) dt'$$

$$c_n^{(2)}(t) = \left(\frac{-i}{\hbar}\right)^2 \sum_m \int_{t_0}^{t} dt' \int_{t_0}^{t'} dt'' e^{i\omega_{nm}t'} V_{nm}\left(t'\right) e^{i\omega_{mi}t''} V_{mi}\left(t''\right), \qquad \omega_{ni} := \frac{E_n - E_i}{\hbar}$$

Proof:

$$\hat{H} = \hat{H}_0 + \lambda V(t)$$

$$\hat{H}_0|i\rangle = E_{\mathrm{i}}^{(0)}|\mathrm{i}\rangle$$

$$|i(t)\rangle_0 = U_0\left(t,t'\right)|i\rangle = e^{-\frac{i}{\hbar}E_1^{(0)}(t-t')}|\mathrm{i}\rangle$$

$$U_0\left(t,t'\right) = e^{-\frac{\mathrm{i}}{\hbar}\hat{H}_0(t-t')}$$

$$U\left(t,t'\right) = \hat{\mathrm{T}}\exp\left\{-\frac{\mathrm{i}}{\hbar}\int_{t'}^{t}\hat{H}(t)dt\right\} \approx \mathbb{1} - \frac{\mathrm{i}}{\hbar}\lambda\int_{t'}^{t} V_I(t)\mathrm{d}t$$

$$|\mathfrak{i}(t)\rangle_I \equiv U_0^{\dagger}\left(t,t'\right)|\mathfrak{i}(t)\rangle := U_I\left(t,t'\right)|i\rangle$$

$$\mathrm{i}\hbar\frac{\partial U_I}{\partial t} = \lambda V_I U_I \qquad V_I := U_0^{\dagger} V U_0$$

(??? строчка, когда нужен второй порядок??? дорешаю ещё задачи!!!)

Вероятность переходов в единицу времени

$$w_{nm} = \frac{2\pi}{\hbar}\left|V_{mn}^{\pm}\right|^2 \delta\left(E_m - E_n \pm \hbar\omega\right) \qquad \text{(золотое правило Ферми)}$$

Работает это для периодических $\widehat{V}(t) = \widehat{V}e^{-i\omega t} + \widehat{V}^{\dagger}e^{i\omega t}$.

$$U(t,t') = \mathbb{1} - \frac{\mathrm{i}}{\hbar}\lambda\int_{t'}^{t} V_I(t)dt$$

$$\langle f\left|U_I(t,t')\right|\mathfrak{i}\rangle \approx -\lambda\frac{\mathrm{i}}{\hbar}\int_{t'}^{t}\langle f\left|V_I(t)\right|\mathfrak{i}\rangle\, dt, \quad |\mathfrak{f}\rangle \neq |\mathfrak{i}\rangle$$

$$\langle f\,|V_I(t)|\,\mathrm{i}\rangle = \left\langle f\left|U_0^\dagger(t,t')\,V(t)U_0(t,t')\right|\mathrm{i}\right\rangle = \langle f|V(t)|\mathrm{i}\rangle e^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')} \qquad \omega_{\mathrm{fi}} = \frac{1}{\hbar}\left(E_{\mathrm{f}}^{(0)} - E_{\mathrm{i}}^{(0)}\right)$$

$$A_{\mathrm{fi}} = -\lambda\frac{\mathrm{i}}{\hbar}\int\limits_{t'}^{t} V_{\mathrm{fi}}(t)e^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')}dt$$

$$W_{\mathrm{i}\to\mathrm{f}} = \frac{1}{\hbar^2}\left|\int\limits_{t'}^{t}\lambda V_{\mathrm{fi}}(t)e^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')}dt\right|^2, \qquad \frac{dW_{\mathrm{i}\to\mathrm{f}}}{d\nu} = \frac{1}{\hbar^2}\left|\int\limits_{t'}^{t}\lambda V_{\mathrm{fi}}(t)e^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')}dt\right|^2$$

Нестационарная теория возмущений в вырожденном случае

(пропишу потом, пока не работал с этим)

Rayleigh–Schrodinger time independent PT for non-degenerate case

$$\hat{H} = \hat{H}_0 + \lambda V, \quad \lambda \to 0 \qquad \hat{H}_0\left|n^{(0)}\right\rangle = E_n^{(0)}\left|n^{(0)}\right\rangle,$$

$|n\rangle = \left|n^{(0)}\right\rangle + \left|n^{(1)}\right\rangle + \ldots, \quad E_n = E_n^{(0)} + E_n^{(1)} + \ldots$

$\left|n^{(p)}\right\rangle = \sum\limits_m c_m^{(p)}\left|m^{(0)}\right\rangle$

$\omega_{nk} := E_n - E_k,$

$$E_n^{(1)} = V_{nn}, \qquad c_{m\neq n}^{(1)} = \frac{V_{mn}}{\omega_{nm}}, \qquad c_n^{(1)} = 0$$

$$E_n^{(2)} = \sum_{k\neq n}\frac{V_{nk}V_{kn}}{\omega_{nm}}, \qquad c_{m\neq n}^{(2)} = \sum_{k\neq n}\frac{V_{mk}V_{kn}}{\omega_{nk}\omega_{nm}} - \frac{V_{nn}V_{mn}}{\omega_{nm}^2}, \qquad c_n^{(2)} = -\frac{1}{2}\sum_k\frac{|V_{nk}|^2}{\omega_{kn}^2}$$

$$E_n^{(3)} = \sum_{m\neq n}\sum_{k\neq n}\frac{V_{nm}V_{mk}V_{kn}}{\omega_{nk}\omega_{nm}} - V_{nn}\sum_{m\neq n}\frac{V_{nm}V_{mn}}{\omega_{nm}^2}$$

Works if: $\qquad \dfrac{|V_{kn}|}{\Delta E_{kn}^{(0)}} \ll 1$

Proof by Landau institute:

$$\hat{H}_0\left|n^{(p)}\right\rangle + \hat{V}\left|n^{(p-1)}\right\rangle = \sum_{l=0}^{p} E_n^{(p-l)}\left|n^{(l)}\right\rangle \qquad \text{(same order)}$$

$\left|n^{(p)}\right\rangle = \sum\limits_i c_i^{(p)}\left|i^{(0)}\right\rangle \quad \Rightarrow \left\langle m^{(0)}\right|,$

$$E_m^{(0)}c_m^{(p)} + \sum_k V_{mk}c_k^{(p-1)} = E_n^{(0)}c_m^{(p)} + \sum_{l=0}^{p-1}E_n^{(p-l)}c_m^{(l)}$$

$$c_{m\neq n}^{(p)} = \frac{1}{\omega_{nm}}\left(\sum_k V_{mk}c_k^{(p-1)} - \sum_{l=0}^{p-1}E_n^{(p-l)}c_m^{(l)}\right)$$

$$m = n \quad \Rightarrow \qquad E_n^{(p)} = \sum_k V_{nk} c_k^{(p-1)} - \sum_{l=1}^{p-1} E_n^{(p-l)} c_n^{(l)}$$

We chose normalization like $\sum_{l=0}^{p} \left\langle n^{(l)} | n^{(p-l)} \right\rangle = 0$ because we want so, then

$$c_n^{(p)} + \left(c_n^{(p)}\right)^* + \sum_{l=1}^{p-1} \left\langle n^{(l)} | n^{(p-l)} \right\rangle = 0 \Rightarrow c_n^{(p)} = -\frac{1}{2} \sum_{l=1}^{p-1} \sum_k c_k^{(l)*} c_k^{(p-l)}$$

All formulas are a particular case (???).

Proof by Kiselev:

$$\left\langle n^{(0)} | n \right\rangle = 1 \qquad \left\langle n^{(0)} | n^{(p)} \right\rangle = 0$$

$$\left(\hat{H}_0 + \lambda V\right) \left\{ \left| n^{(0)} \right\rangle + \sum_{p=1}^{\infty} \lambda^p \left| n^{(p)} \right\rangle \right\} = \left(E_n^{(0)} + \sum_{p=1}^{\infty} \lambda^p \epsilon_p \right) \left\{ \left| n^{(0)} \right\rangle + \sum_{p=1}^{\infty} \lambda^p \left| n^{(p)} \right\rangle \right\}$$

$$\begin{aligned}
\lambda^0: &\quad \hat{H}_0 \left| n^{(0)} \right\rangle &&= E_n^{(0)} \left| n^{(0)} \right\rangle \\
\lambda^1: &\quad \hat{H}_0 \left| n^{(1)} \right\rangle + V \left| n^{(0)} \right\rangle &&= E_n^{(0)} \left| n^{(1)} \right\rangle + \epsilon_1 \left| n^{(0)} \right\rangle \\
&\quad \ldots &&\quad \ldots \\
\lambda^p: &\quad \hat{H}_0 \left| n^{(p)} \right\rangle + V \left| n^{(p-1)} \right\rangle &&= E_n^{(0)} \left| n^{(p)} \right\rangle + \epsilon_1 \left| n^{(p-1)} \right\rangle + \ldots + \epsilon_p \left| n^{(0)} \right\rangle .
\end{aligned}$$

$$\begin{aligned}
\epsilon_1 &= \left\langle n^{(0)} | V | n^{(0)} \right\rangle = V_{nn} \\
\epsilon_2 &= \left\langle n^{(0)} | V | n^{(1)} \right\rangle \\
&\ldots\ldots\ldots \\
\epsilon_p &= \left\langle n^{(0)} | V | n^{(p-1)} \right\rangle \\
\left| n^{(p)} \right\rangle &= \sum_{k \neq n} \left| k^{(0)} \right\rangle \left\langle k^{(0)} | n^{(p)} \right\rangle
\end{aligned}$$

$$\left\langle k^{(0)} | V | n^{(0)} \right\rangle = \left(E_n^{(0)} - E_k^{(0)} \right) \left\langle k^{(0)} | n^{(1)} \right\rangle$$

$$\ldots\ldots\ldots\ldots$$

$$\left\langle k^{(0)} | V | n^{(p-1)} \right\rangle = \left(E_n^{(0)} - E_k^{(0)} \right) \left\langle k^{(0)} | n^{(p)} \right\rangle + \epsilon_1 \left\langle k^{(0)} | n^{(p-1)} \right\rangle + \ldots + \epsilon_{p-1} \left\langle k^{(0)} | n^{(1)} \right\rangle$$

$\epsilon_0 = 0$

$$\left\langle k^{(0)} | n^{(p)} \right\rangle = \frac{1}{E_n^{(0)} - E_k^{(0)}} \left\{ V_{kn}^{(p-1)} - \epsilon_1 \left\langle k^{(0)} | n^{(p-1)} \right\rangle - \ldots - \epsilon_{p-1} \left\langle k^{(0)} | n^{(1)} \right\rangle \right\}$$

$p \geqslant 1, k \neq n, V_{kn}^{(p-1)} = \left\langle k^{(0)} | V | n^{(p-1)} \right\rangle$. From it we see a second-order correction.

Rayleigh–Schrodinger time independent PT for degenerate case

$$\hat{H}_0 \left| n^{(0)}, a \right\rangle = E^{(0)} \left| n^{(0)}, a \right\rangle, \quad a \in (\overline{1,k})$$

$$|n\rangle = \sum_{a=1}^{k} C_a \left| n^{(0)}, a \right\rangle + \sum_{p=1}^{\infty} \lambda^p \left| n^{(p)} \right\rangle$$

$$\det(\hat{V} - \epsilon) = 0 \qquad V_{ba} = \left\langle n^{(0)}, b | V | n^{(0)}, a \right\rangle$$

Proof by Kiselev:

$$\left|\tilde{n}^{(0)}, g\right\rangle, \quad \hat{V}\left|\tilde{n}^{(0)}, g\right\rangle = \epsilon_1^{(g)}\left|\tilde{n}^{(0)}, g\right\rangle,$$

$$\hat{H}_0\left|n^{(p)}, g\right\rangle + V\left|n^{(p-1)}, g\right\rangle = E_n^{(0)}\left|n^{(p)}, g\right\rangle + \epsilon_1^{(g)}\left|n^{(p-1)}, g\right\rangle + \ldots + \epsilon_p^{(g)}\left|n^{(0)}, g\right\rangle$$

Second ordeor of t-indep. RS p.th by inst. Landau: (???)

$$\hat{H}_0\left|n^{(2)}\right\rangle + \hat{V}\left|n^{(1)}\right\rangle = E_n^{(2)}\left|n^{(0)}\right\rangle + E_n^{(1)}\left|n^{(1)}\right\rangle + E_n^{(0)}\left|n^{(2)}\right\rangle$$

$\left\langle n_\alpha^{(0)}\right|$,

$$\sum_{m\neq n,\beta} \frac{V_{\alpha m}V_{m\beta}}{\omega_{nm}} c_{n,\beta}^{(0)} \equiv \sum_\beta H_{\alpha\beta}^{(\text{eff})} c_{n,\beta}^{(0)} = E_n^{(2)} c_{n,\alpha}^{(0)}, \qquad H_{\alpha\beta}^{(\text{eff})} := \sum_{m\neq n} \frac{V_{\alpha m}V_{m\beta}}{\omega_{nm}}$$

$$\det\left(\hat{H}^{(\text{eff})} - E_n^{(2)}\right) = 0$$

$$\hat{H}_0\left|n^{(2)}\right\rangle + \hat{V}\left|n^{(1)}\right\rangle = E_n^{(2)}\left|n^{(0)}\right\rangle + E_n^{(1)}\left|n^{(1)}\right\rangle + E_n^{(0)}\left|n^{(2)}\right\rangle$$

$$\sum_{m\neq n} \frac{V_{\beta m}V_{m\alpha}}{\omega_{nm}} c_{n,\alpha}^{(0)} \equiv \sum_\alpha \hat{H}_{\beta\alpha}^{(\text{eff})} c_{n,\alpha}^{(0)} = E_n^{(2)} c_{n,\beta}^{(0)}, \quad H_{\beta\alpha}^{(\text{eff})} = \sum_{m\neq n} \frac{V_{\beta m}V_{m\alpha}}{\omega_{nm}}$$

Brillouin–Wigner PT for non-degenerate case

$$H = H_0 + \lambda H_1, \qquad \lambda \in [0,1].$$

$$H_0|k\alpha\rangle = \epsilon_k|k\alpha\rangle \qquad \mathcal{H} = \bigoplus \mathcal{H}_k \qquad (\alpha \text{ - for deg.})$$

(??? examples???)

Теория возмущений в частных типичных случаях

Обзор применений и типичных частных случаев нестационарной теории возмущений

Действие возмущения в течение конечного времени.
применяем нестационарную теорию возмущений!
(!?!?!?!)

Постоянное возмущение, $\lambda V(t) = \bar{V}\theta\left(t - t'\right)$:

$$W = \left|\bar{V}_{\text{fi}}\right|^2 \left(\frac{2\sin\left[\omega_{\text{fi}}\left(t - t'\right)/2\right]}{\hbar\omega_{\text{fi}}}\right)^2$$

(добавлю очень известный график про него, см. Киселева пока что)

Периодическое возмущение,

$$\lambda V(t) = \frac{1}{\mathrm{i}}\left\{\bar{V}\mathrm{e}^{\mathrm{i}\omega(t-t')} - \bar{V}^{\dagger}\mathrm{e}^{-\mathrm{i}\omega(t-t')}\right\}, \quad \bar{V}^{\dagger} = \bar{V}, \quad V\left(t'\right) = 0$$

$$\mathrm{d}w_{\text{fi}} = \frac{1}{\hbar}\left|\bar{V}_{\text{fi}}\right|^2 2\pi\delta\left(E_{\text{f}}^{(0)} - E_{\text{i}}^{(0)} + \hbar\omega\right)\mathrm{d}\nu\left(E_{\text{f}}^{(0)}\right) \quad \text{Gold F r}$$

Мгновенное включение возмущения:

$$\lambda V(t) = \bar{V}(s), \quad t = \delta t \cdot s, \quad s \in [0,1].$$

$$\hat{H}(s) = \hat{H}_0 + \bar{V}(s)$$

$$U(\delta t) = \mathbb{1} - \frac{\mathrm{i}}{\hbar}\int_0^1 \hat{H}(s)\delta t\ \mathrm{d}s = \mathbb{1} - \frac{\mathrm{i}}{\hbar}\delta t\bar{H}$$

(это не такая простая задача, в теории подробно пропишу!??!?!)

О типичных тренировочных моделях на теорию возмущений

(особенности, которые лучше помнить - тут.)

Теория возмущений для задач про геометрические деформации (???)

(на полстраницы максимум указаний, скоро прорешаю их уже! обычная теор возмущений, просто пара еще догадок нужны!)

Теория возмущений для задач про линейный отклик (???)

Теория возмущений для энергетических уровней деформированного ядра

Частица в периодическом потенциале по МК

Overview of perturbation theories

(??? в чем ее преимущества в сравнении с РШ ТВ???)

(??? а как так вообще, что у нас разные теории возмущений? а третьей еще теории нет??)

(??? как все-таки это связано с ТВ в теормехе?? пока ее в теормехе разбирать буду.)

1.3.2 Green's function methods for QM

(пока в записи по КТП про это, потом сюда допишу в рамках квантмеха и рассеяний!)

Общий формализм пропагаторов

$$|\psi(t)\rangle = \exp\left[\frac{-i\hat{H}\,(t-t_0)}{\hbar}\right]|\psi\,(t_0)\rangle = \sum_a |a\rangle\,\langle a|\psi\,(t_0)\rangle \exp\left[\frac{-iE_a\,(t-t_0)}{\hbar}\right].$$

$$\langle\vec{x}|\psi(t)\rangle = \sum_a \langle\vec{x}|a\rangle \underbrace{\langle a|\psi\,(t_0)\rangle}_{=\int d^3x'\langle a|\vec{x}'\rangle\langle\vec{x}'|\psi(t_0)\rangle.} \exp\left[\frac{-iE_a\,(t-t_0)}{\hbar}\right].$$

$$\psi\,(\vec{x}',t) = \int d^3x K\,(\vec{x}',t;\vec{x},t_0)\,\psi\,(\vec{x},t_0) \qquad K\,(\vec{x}',t;\vec{x},t_0) := \sum_a \langle\vec{x}'|a\rangle\,\langle a|\vec{x}\rangle \exp\left[\frac{-iE_a\,(t-t_0)}{\hbar}\right].$$

$$\lim_{t\to t_0} K\,(\vec{x}',t;\vec{x},t_0) = \delta^3\,(\vec{x}'-\vec{x})\,.$$

$$G(t) \equiv \int d^3x K(x,t;x,0) = \int d^3x \sum_a \langle x|a\rangle\langle a|x\rangle e^{-iE_at/\hbar} = \sum_a \int d^3x \langle a|x\rangle\langle x|a\rangle e^{-iE_at/\hbar} =$$
$$= \sum_a \langle a|a\rangle e^{-iE_at/\hbar} = \sum_a e^{-iE_at/\hbar}.$$

$$Z = \sum_a e^{-\beta E_a} \qquad \beta \equiv 1/(kT) \to -it/\hbar$$

$$\tilde{G}(E) \equiv -\frac{i}{\hbar}\int_0^\infty dt G(t) e^{iEt/\hbar} = -\frac{i}{\hbar}\int_0^\infty dt \sum_a e^{-iE_at/\hbar} e^{iEt/\hbar}. \qquad E \to E + i\varepsilon$$

$$\tilde{G}(E) = \sum_a \frac{1}{E - E_a + i\epsilon}.$$

$$K\,(\vec{x}',t;\vec{x},t_0) = \sum_a \langle\vec{x}'|a\rangle\,\langle a|\vec{x}\rangle \exp\left[\frac{-iE_a\,(t-t_0)}{\hbar}\right] =$$
$$= \sum_a \langle\vec{x}'| \exp\left(-\frac{i\hat{H}t}{\hbar}\right)|a\rangle\langle a| \exp\left(\frac{i\hat{H}t_0}{\hbar}\right)|\vec{x}\rangle = \langle\vec{x}',t|\vec{x},t_0\rangle\,.$$

Examples of propagators

The propagator of a 1D free particle:

$$K\,(x',t;x,t_0) = \left\langle x'\left|e^{-i\hat{H}t/\hbar}\right|x\right\rangle = \int dp\,\langle x'|p\rangle\,e^{-ip^2t/2m\hbar}\langle p|x\rangle =$$
$$= \frac{1}{2\pi\hbar}\int dp \exp\left[\frac{ip\,(x'-x)}{\hbar} - \frac{ip^2\,(t-t_0)}{2m\hbar}\right] =$$
$$= \sqrt{\frac{m}{2\pi i\hbar\,(t-t_0)}} \exp\left[\frac{im\,(x'-x)^2}{2\hbar\,(t-t_0)}\right]\Theta\,(t-t_0)$$

The propagator of a 1D oscillator:

$$K\left(x,x';t\right)=\left(\frac{m\omega}{2\pi i\hbar\sin\omega t}\right)^{\frac{1}{2}}\exp\left(-\frac{m\omega\left(\left(x^2+x'^2\right)\cos\omega t-2xx'\right)}{2i\hbar\sin\omega t}\right)\qquad\text{(Mehler kernel)}$$

(там пара страниц вывода, потом словами укажу его!)

Для уравнения Клейна-Гордона

$$G(x,y)=\frac{1}{(2\pi)^4}\int d^4p\frac{e^{-ip\cdot(x-y)}}{p^2-m^2\pm i\varepsilon}\qquad\qquad p_\mu=(p_0,p),\ p^2=p_\mu p^\mu$$

Для получения решаем $\left(\Box_x+m^2\right)G(x,y)=-\delta(x-y)$, after Fourier transform, $\left(-p^2+m^2\right)G(p)=-1$, and Sokhotski-Plemelj theorem $\frac{1}{x\pm i\varepsilon}=\frac{1}{x}\mp i\pi\delta(x)$ we get (?? додумаю и допишу. тут еще путаница с метрикой, перепишу начало)

Examples of solution by a propagator

(??? write the model!)

$$\Psi(x,t)=\int\limits_0^\infty dx'e^{-\eta x'}\mathcal{K}(t,t_0|x,x')e^{-i\sigma v_F^{(\nu)}kt_0}\chi_{k,\sigma}(x')$$

$$\mathcal{K}(t,t'|x,x')=\sum_{\alpha=\pm}\int\limits_0^\infty dke^{-i\alpha\epsilon_k(t-t')}\Psi_{k,\alpha}(x)\Psi_{k,\alpha}^\dagger(x')+e^{-i\epsilon_e(t-t')}\Psi_e(x)\Psi_e^\dagger(x'),$$

Real-time dynamics in the GF formalism

(??????????????????????)
(см. раздел Галицкого)

Математика для пропагаторов

$$\prod_{n=1}^\infty\left(1-\frac{x^2}{n^2\pi^2}\right)=\frac{\sin x}{x},$$

другом про функцию Грина

О функции Грина в методе интеграла по траекториям

(займусь - пропишу это.)

1.3.3 Scattering, S-matrix, Born Approximation: Main Methods

Elementary scatterings

(I'll solve problems soon!!!)

$$\psi_k^{(+)}(x)=\begin{cases}e^{ikx}+re^{-ikx}, & x\to-\infty\\ te^{ikx}, & x\to+\infty\end{cases},\qquad\psi_k^{(-)}(x)=\begin{cases}t'e^{-ikx}, & x\to-\infty\\ e^{-ikx}+r'e^{ikx}, & x\to+\infty\end{cases}$$

$$\psi^* \Rightarrow \qquad t' = t, \quad r' = -\frac{r^* t}{t^*}$$

$|r| = |r'|$

$$j_{\text{пад}} = \frac{\hbar k}{m}, \qquad j_{\text{отр}} = \frac{\hbar k}{m}|r|^2, \qquad j_{\text{прош}} = \frac{\hbar k}{m}|t|^2$$

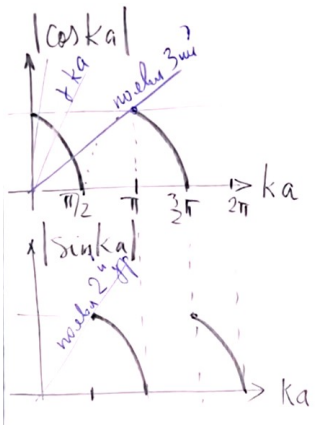
$j(x) = \text{const} \Rightarrow$

$$|r|^2 + |t|^2 = 1$$

$$R := \frac{j_{\text{отр}}}{j_{\text{пад}}} = |r|^2, \qquad T := \frac{j_{\text{прош}}}{j_{\text{пад}}} = |t|^2$$

$$R = |r|^2, \quad T = \frac{k'}{k}|t|^2, \quad R + T = 1$$

(????)



(!! скоро дорешаю, напишу, типичные задачи такого типа в общей физике)

More professional well-known methods

Born approximation

$$\left[-\frac{\hbar^2}{2m}\Delta + U(\mathbf{r})\right]\psi^+_{k_0}(\mathbf{r}) = E\psi^+_{k_0}(\mathbf{r}) \tag{XIII.1}$$

$$\psi^+_{k_0}(\mathbf{r}) \overset{r\to\infty}{\approx} e^{i\mathbf{k}_0 r} + \frac{f(\mathbf{k},\mathbf{k}_0)}{r}e^{ikr}, \quad \mathbf{k} = \frac{k_0\mathbf{r}}{r} \quad U(\mathbf{r}) \downarrow \text{ faster than } \propto 1/r \tag{XIII.2}$$

$k_0 = \sqrt{2mE/\hbar^2}$.
$\sigma = \int |f(\mathbf{k},\mathbf{k}_0)|^2 \, d\Omega_k$.

$$G^+_E(\mathbf{r},\mathbf{r}') = \frac{m}{2\pi\hbar^2|\mathbf{r}-\mathbf{r}'|}e^{ik|\mathbf{r}-\mathbf{r}'|} \tag{XIII.3}$$

$$\psi^+_{\mathbf{k}_0}(\mathbf{r}) = e^{i\mathbf{k}_0\cdot\mathbf{r}} - \frac{m}{2\pi\hbar^2}\int \frac{e^{ik|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|}U(\mathbf{r}')\,\psi^+_{\mathbf{k}_0}(\mathbf{r}')\,dV' \tag{XIII.4}$$

$$f(\mathbf{k},\mathbf{k}_0) = -\frac{m}{2\pi\hbar^2}\int e^{-i\mathbf{k}\cdot\mathbf{r}}U(r)\psi^+_{\mathbf{k}_0}(\mathbf{r})dV \tag{XIII.5}$$

First Born approximation:
$\psi^{+}_{\mathbf{k}_0} = e^{i\mathbf{k}_0\cdot\mathbf{r}}$,

$$f^B(\mathbf{q}) = -\frac{m}{2\pi\hbar^2}\tilde{U}(\mathbf{q}), \qquad \tilde{U}(\mathbf{q}) = \int e^{-i\mathbf{q}\cdot\mathbf{r}}U(\mathbf{r})dV \qquad \mathbf{q} := \mathbf{k} - \mathbf{k}_0 \tag{XIII.6}$$

$q_{\text{el}} = 2k\sin(\theta/2)$,

Борновское приближение:

$$\psi^{(1)}(\mathbf{r}) = -\frac{m}{2\pi\hbar^2}\int \frac{e^{ik|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|}U(\mathbf{r}')\,e^{i\mathbf{k}\mathbf{r}'}d\mathbf{r}'$$

$$f(\theta,\varphi) \approx -\frac{m}{2\pi\hbar^2}\int e^{-i(\mathbf{k}'-\mathbf{k})\mathbf{r}'}U(\mathbf{r}')\,d\mathbf{r}' \equiv -\frac{m}{2\pi\hbar^2}\tilde{V}_{\mathbf{k}-\mathbf{k}'}$$

$$\hat{T}_E \approx \hat{V}. \qquad \text{Born appr}$$

$\hat{T}_E := \hat{V} + \hat{V}\hat{G}_E^{(0,R)}\hat{V} + \ldots$

$$f_{\text{sp sym, 3D}}(\theta) = -\frac{m}{2\pi\hbar^2}\int d^3\mathbf{r}\; V(\mathbf{r})e^{-i(\mathbf{k}-\mathbf{k}')\mathbf{r}} = -\frac{m}{\hbar^2}\int_0^\infty drr^2V(r)\int_0^\pi e^{-i|\mathbf{k}-\mathbf{k}'|r\cos\varphi}\sin\varphi d\varphi$$

$$= -\frac{2m}{\hbar^2|\mathbf{k}-\mathbf{k}'|}\int_0^\infty drr\sin(|\mathbf{k}-\mathbf{k}'|r)V(r) = -\frac{2m}{2k\hbar^2\sin\frac{\theta}{2}}\int_0^\infty drr\sin\left(2kr\sin\frac{\theta}{2}\right)V(r)$$

valid if:

$$U_0 \ll \frac{\hbar^2}{mR^2} \quad \text{or} \quad U_0 \ll \frac{\hbar v}{R} \tag{XIII.7}$$

In the 1 Born approx. it depends only on the magnitude of momentum transfer, $\hbar q$.

$$\sigma_{3D}(E) = \int |f|^2 d\Omega = 2\pi\int_0^\pi |f|^2\sin\theta d\theta = \frac{\pi\hbar^2}{2mE}\int_0^{8mE/\hbar^2} f^2(q)dq^2 \tag{1}$$

$q := 2k\sin(\theta/2), \qquad \sin\theta d\theta = d(1-\cos\theta) = \frac{d(q^2)}{2k^2}.$

$$f^B_{3D}(q) = -\frac{2m}{\hbar^2 q}\int_0^\infty U(r)\sin(qr)rdr \tag{XIII.8}$$

$\left(k = k_0 = \sqrt{2mE/\hbar^2}\right)$

$$\langle\mathbf{r}|\hat{G}_0|\mathbf{r}'\rangle = \frac{2m}{\hbar^2}\times\begin{cases}\dfrac{1}{2ik}\exp\left(ik\left|x-x'\right|\right), & d=1\\ \dfrac{1}{4i}H_0^+\left(k\left|\mathbf{r}-\mathbf{r}'\right|\right), & d=2\\ -\dfrac{\exp\left(ik\left|\mathbf{r}-\mathbf{r}'\right|\right)}{4\pi\left|\mathbf{r}-\mathbf{r}'\right|}, & d=3\end{cases}$$

$$dN_{\text{pacc}} \equiv d\omega_{i\to f} = 2\pi\left|V_{\boldsymbol{k}-\boldsymbol{k}'}\right|^2\delta\left(\frac{k^2}{2m}-\frac{k^2}{2m}\right)\frac{d^d\boldsymbol{k}'}{(2\pi)^d} = \frac{mk'^{d-2}}{(2\pi)^{d-1}}\left|V_{\boldsymbol{k}-\boldsymbol{k}'}\right|^2\delta\left(k-k'\right)dk'd\Omega$$

Интегрируя по модулю импульса конечных состояний и деля на плотность потока частиц в падающей волне $\boldsymbol{j}_{\text{пад}} = \boldsymbol{k}/m$, получаем:

$$\frac{d\sigma}{d\Omega} = \frac{m^2 k'^{d-3}}{(2\pi)^{d-1}} \left|V_{\boldsymbol{k}-\boldsymbol{k}'}\right|^2$$

(?????)

$d = 3 \quad \Rightarrow \quad d\sigma/d\Omega = m^2 \left|V_{\boldsymbol{k}-\boldsymbol{k}'}\right|^2 / 4\pi^2 \equiv |f(\theta)|^2,$

$|\boldsymbol{k} - \boldsymbol{k}'| = 2k \sin(\theta/2),$

$$f_{\text{sp sym}}(\theta) = -\frac{m}{2\pi} \tilde{V}\left(2k \sin\frac{\theta}{2}\right),$$

Условия применимости Борновского приближения:

$$\frac{m}{\hbar^2 k} \left| \int_0^a \left(1 - e^{2ikr'}\right) U(r')\, dr' \right| \ll 1$$

Slow $\Rightarrow$ $ka \ll 1$, $1 - e^{2ikr'} \approx -2ikr'$,

$$\frac{m}{\hbar^2} \underbrace{\left| \int_0^a r' U(r')\, dr' \right|}_{\sim a^2 U_0} \sim \frac{m U_0 a^2}{\hbar^2} \ll 1 \quad \Leftrightarrow \quad U_0 \ll \frac{\hbar^2}{m a^2},$$

Fast $\Rightarrow$ $ka \gg 1$, $e^{2ikr'} \approx 0$ (oscillates),

$$\frac{m}{\hbar^2 k} \underbrace{\left| \int_0^a U(r')\, dr' \right|}_{\sim a U_0} \sim \frac{m U_0 a}{\hbar^2 k} \quad \Leftrightarrow \quad U_0 \ll \frac{\hbar^2}{m a^2} ka$$

The Born approximation is valid for high energy limit, while the phase shift analysis is useful in the low energy limit

(??? почему? Сузуки так написал)

Partial-wave analysis

For a spherically-symmetric potential,

$$f(k,\theta) = \sum_{l=0}^{\infty} (2l+1) \varphi_l(E) P_l(\cos\theta)$$

$$\varphi_l = \frac{e^{2i\delta_l} - 1}{2ik} = \frac{1}{k(\cot\delta_l - i)} \tag{XIII.9}$$

$$\delta_l(k): \qquad r R_{k,l} \approx C \sin(kr - \pi l/2 + \delta_l),$$

$$\sigma = \sum_{l=0}^{\infty} \sigma_l; \qquad \sigma_l := \frac{4\pi}{k^2}(2l+1)\sin^2\delta_l = \frac{4\pi}{k^2}(2l+1)\left(\cot^2\delta_l + 1\right)^{-1} \tag{XIII.10}$$

$$\operatorname{Im} f(E,\theta=0)=\frac{k}{4\pi}\sigma(E) \tag{XIII.11}$$

1) In the Born approximation ($\left|\delta_l^B\right| \ll 1$),

$$\delta_l^B(k)=-\frac{\pi m}{\hbar^2}\int\limits_0^\infty U(r)J_{l+1/2}^2(kr)rdr \tag{XIII.12}$$

2) In the quasi-classical approximation,

$$\delta_l^{(q)}=\int\limits_{r_0}^\infty\left\{\sqrt{k^2-\frac{2m}{\hbar^2}U(r)-\frac{(l+1/2)^2}{r^2}}-k\right\}dr+\frac{1}{2}\pi\left(l+\frac{1}{2}\right)-kr_0 \tag{XIII.13}$$

r_0 is the turning point of the motion.

$$\delta_{l\ |U(r)|\ll E}^{(q)}\approx-\int\limits_{r_0}^\infty\frac{mU(r)dr}{\hbar^2\sqrt{k^2-(l+1/2)^2/r^2}},\qquad r_0=\frac{(l+1/2)}{k} \tag{XIII.14}$$

A few examples of model scatterings

Example 1: for $V(x)=-V_0\theta(x-a/2)\theta(x+a/2)$

$$r=\frac{(k^2-q^2)\sin(qa)e^{-ika}}{(q^2+k^2)\sin(qa)+2iqk\cos(qa)},\quad t=\frac{2iqke^{-ika}}{(q^2+k^2)\sin(qa)+2iqk\cos(qa)},\quad q^2:=\frac{2mV_0}{\hbar^2}+k^2$$

Well-known special cases of scatterings

Collisions of real particles in a nutshell

(about problems like "neutron hits hydrogen atom, what will come out?")

Slow particles

For the slow particles ($kR\ll 1$), if the potential falls rapidly enough, we plug into

$$f(k,\theta)=\sum_{l=0}^\infty(2l+1)\varphi_l(E)P_l(\cos\theta)\qquad\varphi_l=\frac{e^{2i\delta_l}-1}{2ik}=\frac{1}{k\left(\cot\delta_l-i\right)}$$
$$\sigma=\sum_{l=0}^\infty\sigma_l\qquad\sigma_l=\frac{4\pi}{k^2}(2l+1)\sin^2\delta_l=\frac{4\pi}{k^2}(2l+1)\left(\cot^2\delta_l+1\right)^{-1}$$

the following:

$$k^{2l+1}\cot\delta_l=-\frac{1}{a_l}+\frac{r_lk^2}{2}+\ldots\qquad\text{(eff range expansion)} \tag{XIII.15}$$

a_l - "scattering length"; r_l - "effective interaction range".

If there are no shallow real/virtual (for $l=0$) or quasi-stationary (for $l\neq 0$) levels in the potential, then the second term involving the effective interaction range can be ignored. In this case,

$$\delta_l \approx -a_l k^{2l+1}, \quad |a_l| \leq R^{2l+1}, \quad \text{and} \quad \sigma_l \leq 4\pi(2l+1)(kR)^{4l}R^2$$

The dimensions are $[a_l] = L^{2l+1}, [r_l] = L^{1-2l}$, where L is a unit of length.

On the other hand, if the potential supports a shallow bound state with the energy $|E_l| \ll \hbar^2/mR^2$ and angular momentum, l, the scattering cross-section for the corresponding partial wave, $\sigma_l(E)$, is sharply peaked at $E \approx E_l$ (resonant scattering). Specifically, if a shallow s-level ($l = 0$) exists, then it follows that $|a_0| \gg R$ and

$$\sigma(E) \approx \sigma_{l=0}(E) \approx \frac{2\pi\hbar^2}{m}\frac{1 + r_0\kappa_0}{E + \varepsilon_0} \qquad \begin{array}{r} |E_0| = \varepsilon_0 = \hbar^2\kappa_0^2/2m \\ \kappa_0 = 1/a_0 + r_0/2a_0^2 \end{array} \tag{XIII.16}$$

This is because the poles of the partial-wave amplitude $\varphi_l(E)$ are given by $\cot\delta_l(E) = i$. Combining this with the wave-vector corresponding to a bound state $\kappa = -i\sqrt{2mE/\hbar^2}$ and taking into account $k^{2l+1}\cot\delta_l = -\frac{1}{a_l} + \frac{r_l k^2}{2} + \ldots$ for $a_0 \gg R\,(\approx r_0)$, it follows that $\kappa_0 \approx 1/a_0, \varepsilon_0 \approx \hbar^2/2ma_0^2$ to first order in $1/a_0$. The second-order term is obtained by substituting the first-order term in $k^{2l+1}\cot\delta_l = -\frac{1}{a_l} + \frac{r_l k^2}{2} + \ldots$.

If $a_0 > 0$, it follows that $\kappa_0 > 0$, and ε_0 gives the energy of a real bound state. For $a_0 < 0$, the level is virtual.

For resonant scattering with $l \neq 0$, the behavior of $\sigma_l(E)$ depend crucially on whether the energy level is real or quasi-stationary ($a_l < 0$). In the latter case, $E_l \equiv E_R - i\Gamma_R/2$ (E_R and Γ_R are the level energy and its width), from the poles of the scattering amplitude in the l-th harmonic located at $\cot\delta_l(E_l) = i$, we find:

$$E_R \equiv \frac{\hbar^2 k_R^2}{2m} \approx \frac{\hbar^2}{ma_l r_l} > 0 \qquad\qquad \Gamma_R \approx \left(\frac{2\hbar^2}{m|r_l|}\right) k_R^{2l+1}$$

[308] For a shallow level with $l \neq 0$ to exist, effective interaction range must be negative, $r_l < 0$, so that $E_R, \Gamma_R > 0$ (see Problem 13.44).

$$\sigma_l(E) \approx \frac{(2l+1)\pi}{k_R^2}\frac{\Gamma_R^2}{(E - E_R)^2 + \Gamma_R^2/4} \tag{XIII.17}$$

Fast particles and eikonal approximation

For fast particles ($kR \gg 1$ and $E \gg |U(\mathbf{r})|$), small scattering angles $\theta \leq 1/kR$,

$$f(\mathbf{k}_0, \mathbf{q}_\perp) = \frac{k}{2\pi i}\int [S(\boldsymbol{\rho}) - 1]e^{-i\mathbf{q}_\perp\cdot\boldsymbol{\rho}}d^2\rho \qquad \text{eikonal appr} \tag{XIII.18}$$

$\mathbf{q}_\perp \perp \hbar\mathbf{k}_0, \qquad q_\perp \approx q \approx k\theta;\ q_\parallel \approx k\theta^2/2)$

$$S(\boldsymbol{\rho}) = e^{2i\delta(\boldsymbol{\rho})}, \qquad \delta(\boldsymbol{\rho}) = -\frac{1}{2\hbar v}\int\limits_{-\infty}^{\infty} U(\boldsymbol{\rho}, z)dz \tag{XIII.19}$$

$$\sigma_{\text{tot}}(E) = 2\int [1 - \cos 2\delta(\boldsymbol{\rho})]d^2\rho \tag{XIII.20}$$

$$f_{\text{cntr pot}}(k,\theta) = ik \int\limits_0^\infty \left[1 - e^{2i\delta(\rho)}\right] J_0(k\rho\theta)\rho d\rho \tag{XIII.21}$$

$J_0(z)$ is the 0-order Bessel function.

Other generally important laws of scattering

Derivation of Scattering formalism by Green's function approach

(!! I'll write soon the beginning!)
eq. by Kiselev (!!!)
Lippmann-Schwinger:

$$u^{(\pm)}(\boldsymbol{x},\boldsymbol{k}) = e^{i\boldsymbol{k}\boldsymbol{x}} + \int\limits_{\mathbb{R}^3} G^{(\pm)}(\boldsymbol{x}-\boldsymbol{y},k)\ V(\boldsymbol{y})\ u^{(\pm)}(\boldsymbol{y},\boldsymbol{k})\ d^3\boldsymbol{y}$$

$$G^{(\pm)}(\boldsymbol{x},k) = -\frac{1}{4\pi}\frac{e^{\pm ikr}}{r}$$

For a general case:

$$\chi_{\mathbf{k}}(\mathbf{r}) = \langle\mathbf{r}|\chi\rangle = \langle\mathbf{r}|\hat{G}_E^{(0,R)}\hat{T}_E|\mathbf{k}\rangle = \int d\mathbf{r}'\frac{d\mathbf{k}'}{(2\pi)^d}\langle\mathbf{r}|\hat{G}_E^{(0,R)}|\mathbf{r}'\rangle\langle\mathbf{r}'|\mathbf{k}'\rangle\langle\mathbf{k}'|\hat{T}_E|\mathbf{k}\rangle =$$

$$= \int d\mathbf{r}'\frac{d\mathbf{k}'}{(2\pi)^d}\hat{G}_E^{(0,R)}(\mathbf{r},\mathbf{r}')e^{i\mathbf{k}'\mathbf{r}'}\hat{T}_E(\mathbf{k},\mathbf{k}')$$

$\hat{T}_{E\ \text{brn}} \approx \hat{V}_{\text{brn}}$,

$$\chi_{\mathbf{k}\ \text{brn}}(\mathbf{r}) = \int d\mathbf{r}'\frac{d\mathbf{k}'}{(2\pi)^d}\hat{G}_E^{(0,R)}(\mathbf{r},\mathbf{r}')e^{i\mathbf{k}'\mathbf{r}'}\langle\mathbf{k}'|\hat{V}|\mathbf{k}\rangle$$

(тут конкретно, как связано Борновское приближение и фазы? см. пока задачу Белоусова, пока это додумываю еще.)

О рассеянии тождественных частиц

(допишу пару строчек основной идеи, что имеем зависимость от спина, и используем пространственную четность в.ф. (??))

$$\psi^{(+)}(\boldsymbol{r}) \simeq \mathrm{e}^{\mathrm{i}\boldsymbol{k}\cdot\boldsymbol{r}} + (-1)^S\mathrm{e}^{-\mathrm{i}\boldsymbol{k}\cdot\boldsymbol{r}} + \frac{\mathrm{e}^{\mathrm{i}\boldsymbol{k}r}}{r}\left\{f(\theta) + (-1)^S f(\pi-\theta)\right\}$$

$$\mathrm{d}\sigma = \left|f(\theta) + (-1)^S f(\pi-\theta)\right|^2\ \mathrm{d}\Omega$$

А для учета еще спина - см. ЛЛ3.137

Например столкновене двух электронов, взаимодействующих по Кулону ($U = e^2/r$), описывается:

$$d\sigma = \left(\frac{e^2}{m_0v^2}\right)\left[\frac{1}{\sin^4(\theta/2)} + \frac{1}{\cos^4(\theta/2)} - \frac{1}{\sin^2(\theta/2)\cos^2(\theta/2)}\cos\left(\frac{e^2}{\hbar v}\ln^2\mathrm{tg}^2\frac{\theta}{2}\right)\right]do$$

$$d\sigma_{e\ll\hbar v} \approx \left(\frac{2e^2}{m_0v^2}\right)^2\frac{4-3\sin^2\theta}{\sin^4\theta}do.$$

(там специфика приближений, см. ЛЛ3.137)

Резонансное рассеяние при малых энергиях

(если притягивающий потенциал и у него уровень вблизи нуля, и особая волна падает, то могут быть приколы. Кому интересно - думайте часа 3 над параграфом Ландау. Специфика, редко такое можно встретить в теории, ну а в экпериментах - не знаю, может, такое и встречается иногда...)

1.3.4 Quasiclassics

Quasiclassics for 1D

$$\psi(x,t) = Ae^{\frac{i}{\hbar}S(x,t)} \quad \Rightarrow \quad \tfrac{1}{2m}\left(\tfrac{\partial S}{\partial x}\right)^2 + U(x) = E \quad \Rightarrow \quad S(x) = \int\limits_{x_0}^{x} p(x)dx, \quad p(x) \equiv \sqrt{2m(E-U(x))}$$

Волновые функции в 1м порядке нарушают унитарность, ведь $j(x) = \hbar p(x)/m$, а в стационарных состояниях этот поток обязан не зависеть от координат. (????) Во 2м порядке:

$$\psi(x) = c_+\psi_+(x) + c_-\psi_-(x)$$

$$\psi_\pm(x) = \frac{e^{\pm i\int\limits_{x_0}^{x} p(x)dx}}{\sqrt{p(x)}}, \qquad \text{(разрешенная о.)}$$

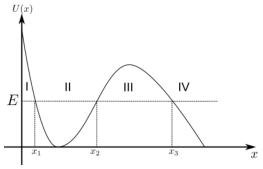
$$\psi_\pm(x) = \frac{e^{\pm\int\limits_{x_0}^{x} |p(x)|dx}}{\sqrt{|p(x)|}}, \quad |p(x)| = \sqrt{2m(U(x)-E)} \qquad \text{(запрещенная о.)}$$

$$\begin{pmatrix} c_+^{(L)} \\ c_-^{(L)} \end{pmatrix} = \hat{A}\begin{pmatrix} c_+^{(R)} \\ c_-^{(R)} \end{pmatrix}, \quad \hat{A} = \begin{pmatrix} e^{-i\pi/4}/2 & e^{i\pi/4} \\ e^{i\pi/4}/2 & e^{-i\pi/4} \end{pmatrix}$$

$$\hat{S}_{\text{cl alwd}} = \begin{pmatrix} e^{-iS} & 0 \\ 0 & e^{iS} \end{pmatrix}, \quad \hat{S}_{\text{cl forb}} = \begin{pmatrix} e^{-S_T} & 0 \\ 0 & e^{S_T} \end{pmatrix}$$

$$\begin{cases} S = \int\limits_{x_1}^{x_2} \sqrt{2m(E-U(x))}dx \\ S_T = \int\limits_{x_2}^{x_3} \sqrt{2m(U(x)-E)}dx \end{cases}$$

Идем из одной крайней области в другую, используя матрицы сшивки A и матриц перехода. Получаем уравнение из условия обнуления растущей экспонент, находим поправку к энергии (или если она мнимая - ширину уровня). Например:



$$\Rightarrow \quad c_I = \underbrace{\hat{A}^\dagger}_{x_1}\underbrace{\hat{S}_{12\text{all}}}_{II}\underbrace{\hat{A}}_{x_2}\underbrace{\hat{S}_{23\text{forb}}}_{III}\underbrace{\hat{A}^\dagger}_{x_3}c_{IV},$$

Критерии применимости:

$$\left|\frac{dp}{dx}\right| \ll p^2 \quad \Leftrightarrow \quad \left|\frac{d\lambda}{dx}\right| \ll 1 \quad \Leftrightarrow \quad m\left|\frac{\partial U/\partial x}{p^3}\right| \ll 1$$

(??????)

ВКБ-приближение пригодно для решения УШ только с аналитическими потенциалами. Однако в ряде случаев для оценки коэффициента подбарьерного прохождения $D(E)$ можно использовать и разрывный потенциал, так как интеграл в показателе экспоненты (ЕК-7.31) нечувствителен к наличию разрывов. Для рассмотрения надбарьерного отражения использование разрывных потенциалов недопустимо.

(абзац про прохождения через барьеры методами ВКБ (!??!?))

Средняя кинетическая энергия стационарного состояния в квазиклассике:

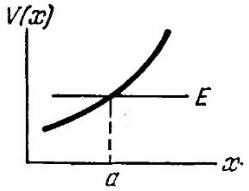
$$\bar{T} = \frac{1}{2}\frac{dE_n}{dn}\left(n + \frac{1}{2}\right).$$

(напишу строчкой, почему, я задачу решал, там подробно вывел это) Кстати, среднюю кинетическую энергию можно выразить через полную с помощью теоремы вириала.

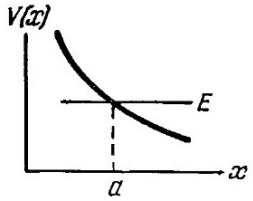
(абзац про обратную задачу)

(мб еще типичные шаблоны про это напишу!!!!)

Квазиклассическое решение справедливо лишь в далекой области от точки поворота ($V(x) = E$).



$$\psi_1 = \begin{cases} \frac{1}{\sqrt{p}} \sin\left(\frac{1}{\hbar}\int\limits_x^a p dx + \frac{\pi}{4}\right) & \text{для } x < a, \\ \frac{1}{2\sqrt{|p|}} e^{-\frac{1}{n}\int\limits_a^x |p| dx} & \text{для } x > a. \end{cases}$$



$$\psi_1 = \begin{cases} \frac{1}{\sqrt{p}} \sin\left(\frac{1}{\hbar}\int\limits_a^x p dx + \frac{\pi}{4}\right) & \text{для } x > a, \\ \frac{1}{2\sqrt{|p|}} e^{-\frac{1}{\hbar}\int\limits_x^a |p| dx} & \text{для } x < a \end{cases}$$

$$\psi = \begin{cases} \frac{1}{\sqrt{p}} e^{\pm\frac{i}{\hbar}\int\limits_x^a p dx} & x < a, \\ \frac{1}{\sqrt{|p|}} e^{\frac{1}{\hbar}\int\limits_a^x |p| dx \mp i\frac{\pi}{4}} + \frac{1}{2\sqrt{|p|}} e^{-\frac{1}{\hbar}\int\limits_a^x |p| dx \pm i\frac{\pi}{4}} & x > a. \end{cases}$$

(дальше у ГК есть еще формулы разные, их потом напишу скорее всего. может, они и не нужны, еще подумаю над задачами)

О правиле Бора-Зоммерфельда (!?!?)

$$\int\limits_{x_1}^{x_2} p(x) dx = \pi\hbar\left(n + \frac{1}{2}\right)$$

Оно получается из (!?!?!!?)

Обсудим дополнительно несколько его свойств.

- Его можно применять только для высоковозбуждённых уровней $n \gg 1$.

- Член 1/2, хоть и мал по сравнению с n - но тем не менее законен; следующие члены разложения будут начинаться с $O(1/n)$. Этот член возник из различных фаз, которые были в задаче сшивки; этот член будет другим для других типов точек остановки. (????) Поэтому часто записывают правило квантования в виде $\pi\hbar(n+\gamma)$ в правой части.

- Номер n тут в точности равен числу нулей квазиклассической волновой функции (которые могут быть только в разрешённой области), то есть полученная волновая функция описывает n-тое возбуждённое состояние.

- Для квантового гармонического осциллятора, правило квантования воспроизводит точный ответ $E = \hbar\omega\left(n+\frac{1}{2}\right)$.

Вид формулы $\oint p(x)dx = 2\pi\hbar\left(n+\frac{1}{2}\right)$ указывает, что номер уровня связан с классическим адиабатическим инвариантом. В частности, сохранения адиабатического инварианта в классической механике и адиабатическая теорема в квантовой механике оказываются связаны посредством этой формулы. (????? почему????)

О типичной математике для квазиклассики

$$\frac{d}{dx}\left(\int\limits_{a(x)}^{b(x)} f(x,t)dt\right) = f(x,b(x))\frac{d}{dx}b(x) - f(x,a(x))\frac{d}{dx}a(x) + \int\limits_{a(x)}^{b(x)}\frac{\partial}{\partial x}f(x,t)dt \quad \text{(Leibniz integr rule)}$$

Часто именно дифференцирование и позволяет сдвинуться.

(тут идея про дифф инт по энергии, вычисление его, потом обратно интегрирования, только так и можно сдвинуться.)

Интегралы часто считаются дифференцированием, а потом заменами переменных. Важно не ошибиться и в переделах интегралов тоже заменять переменные.

(?? мб по тригонометрии пару формул вставлю для этого, пока просто помню, что они очень могут понадобиться)

(можно продифф по n, так получить $\int\limits_a^b \frac{dx}{p}$)

О методе линий Стокса

(см. пока теор части про него, там для ф. Айри и для осциллятора решен он. Мутный метод на самом деле, заумный. Мы выделяем линииб Стокса и анти Стокса, где показатель экспоненты — чисто ещественный, а решения имеют не осциллирующую природу, а экспоненциально возрастающие и затухающие. Дальше у нас какой-то многошаговый обход полюсов и при этом пересечение линий Стокса. Напишу сперва в теории его, потому что место, где я читал про него очень криво его объяснило.)

О поправках к уровням энергии квазиклассикой

(1/2 страницы про такие задачи, тоже типичные формулы тут есть. см. нпр лекции Киселева)

Illustrations of WKB

Oscillator in WKB:

$$\int\limits_{x_{\min}}^{x_{\max}} dx\sqrt{2m\left(E-m^2\omega^2x^2\right)} = \frac{2mE}{m\omega}\frac{\pi}{2} = \left(n+\frac{1}{2}\right)\hbar\pi \qquad \Rightarrow \qquad E = \left(n+\frac{1}{2}\right)\hbar\omega$$

Tunneling through a barrier:

$$\psi(x) = \vec{c}_+^{(II)} e^{\int\limits_{x_2}^{x_1}|p(x)|dx} + \vec{c}_-^{(II)} e^{-\int\limits_{x_2}^{x}|p(x)|dx} \equiv \vec{c}_+^{(II)} e^{-S} e^{\int\limits_{x_1}^{x}|p(x)|dx} + \vec{c}_-^{(II)} e^{S} e^{-\int\limits_{x_1}^{x}|p(x)|dx},$$

$$S = \int\limits_{x_1}^{x_2}|p(x)|dx$$

$$\overleftarrow{c}_{II} = \hat{S}_{12}\vec{c}_{II} = \begin{pmatrix} e^{-S} & 0 \\ 0 & e^{S} \end{pmatrix}\vec{c}_{II}$$

$$c_I = \hat{A}\hat{S}_{12}\hat{A}^\dagger c_{III} = \begin{pmatrix} \frac{e^{-S}}{4} + e^{S} \\ \left(\frac{1}{4}ie^{-S} - ie^{S}\right) \end{pmatrix} t$$

$$\begin{cases} t & \approx e^{-S} \\ r & \approx -i \end{cases} \Rightarrow \begin{cases} T & \approx e^{-2S} \\ R & \approx 1 \end{cases}$$

Гамов

Tunneling out of a Trap:
(картинку Гейгера-Нейтелла добавлю)

$$\psi\left(x_\star\right) = \psi(R)e^{-S/\hbar}$$

$$S = \int\limits_{R}^{x_\star} dx'\sqrt{2m\left(\frac{\alpha}{x'}-E\right)}$$

$$S = \sqrt{\frac{2m}{E}}\pi\alpha = \frac{2\pi\alpha}{\hbar v}$$

$$T = \frac{\left|\psi\left(x_\star\right)\right|^2}{|\psi(R)|^2} = e^{-2S/\hbar}$$

$$v_0 = \sqrt{\frac{2\left(E+V_0\right)}{m}}$$

This means that the particle hits the barrier with frequency $\nu = v_0/R$. The decay rate is then $\Gamma = \nu e^{-2S/\hbar}$ and the lifetime is

$$\tau = \frac{R\sqrt{m}}{\sqrt{2\left(E+V_0\right)}}e^{2S/\hbar}$$

Quarkonium in WKB by Tong:

$$V = Cr$$

$$-\frac{\hbar^2}{2m}\left(\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{d\psi}{dr}\right) - \frac{l(l+1)}{r^2}\psi(r)\right) + Cr\psi(r) = E\psi(r)$$

$l = 0$

$\chi = r\psi$

$u = (2mC/\hbar^2)^{1/3}(r - E/C)$

$\chi(u) = \mathrm{Ai}(u)$

$\chi(r = 0) = 0\mathrm{J}$

$$\mathrm{Ai}\left(-\left(\frac{2m}{\hbar^2 C^2}\right)^{1/3} E\right) = 0$$

$y_\star = 2.34, 4.09, 5.52, 6.79, 7.94, 9.02, ...$

$E = (\hbar^2 C^2/2m)^{1/3} y_\star$

других свойствах и случаях применения квазиклассики

(?? Мигдала Крайнова дочитаю - допишу другие указания еще)

(О квазиклассике в черной дыре, как догадаться про это? см. пока Киселева про это)

(О квазиклассике в 2Д и 3Д, что там делать? пока не знаю, в водороде то работает, а вот в других моделях не 1д - видимо, слишком сложный метод, пока не знаю инструкций к нему. в теории пропишу сперва.)

1.3.5 Adiabatic evolution, Berry's connection, f/s variables

Суть нестационарной адиабатики (!?)

$$\hat{H}(t)|n(t)\rangle = E_n(t)|n(t)\rangle$$

$$\omega \ll \Delta E \Rightarrow T \gg 1/\Delta E$$

$$\psi_n(t) \equiv c_n(t) \cdot \exp\left(-i\int\limits_{t_0}^{t} E_n(\tau)d\tau\right),$$

From the sense of $\hat{H}$ one gets that for $m \neq n$ $\quad \langle n(t)\,|\partial_t|\,m(t)\rangle = -\frac{\langle n(t)|\partial_t \hat{H}|m(t)\rangle}{\omega_{nm}(t)}$,

$$c_m(T) \approx \int\limits_{t_0}^{T} \exp\left(i\int\limits_{t_0}^{t} \omega_{mn}(\tau)d\tau\right) \frac{\left\langle m(t)\left|\partial_t \hat{H}\right|n(t)\right\rangle}{\omega_{mn}(t)} dt.$$

(?? допишу чуть лучше вывод!)

Суть стационарной адиабатики, приближения Борна-Опенгеймера, быстрых и медленных переменных (!?)

$$H := \sum_\alpha \frac{\hbar^2}{2M_\alpha}\nabla_\alpha^2 + \sum_i \frac{\hbar^2}{2m}\nabla_i^2 + \frac{e^2}{4\pi\epsilon_0}\left(\sum_{i,j}\frac{1}{|\mathbf{r}_i - \mathbf{r}_j|} + \sum_{\alpha,i}\frac{Z_\alpha Z_\beta}{|\mathbf{R}_\alpha - \mathbf{R}_\beta|} - \sum_{i,\alpha}\frac{Z_\alpha}{|\mathbf{r}_i - \mathbf{R}_\alpha|}\right) \equiv$$

$$\equiv H_{\mathrm{nucl}} + H_{\mathrm{el}}$$

$$H_{\text{nucl}} = -\sum_{\alpha} \frac{\hbar^2}{2M_\alpha}\nabla_\alpha^2 + \frac{e^2}{4\pi\epsilon_0}\sum_{\alpha,i}\frac{Z_\alpha Z_\beta}{|\mathbf{R}_\alpha - \mathbf{R}_\beta|}$$

$$H_{\text{el}} = -\sum_{i} \frac{\hbar^2}{2m}\nabla_i^2 + \frac{e^2}{4\pi\epsilon_0}\left(\sum_{i,j}\frac{1}{|\mathbf{r}_i - \mathbf{r}_j|} - \sum_{i,\alpha}\frac{Z_\alpha}{|\mathbf{r}_i - \mathbf{R}_\alpha|}\right)$$

$$H_{\text{el}}\phi_n(\mathbf{r};\mathbf{R}) = \epsilon_n(\mathbf{R})\phi_n(\mathbf{r};\mathbf{R})$$

$$\Psi(\mathbf{r},\mathbf{R}) = \sum_n \Phi_n(\mathbf{R})\phi_n(\mathbf{r};\mathbf{R})$$

$$\left(H_{\text{nucl}} + H_{\text{el}}\right)\Psi = E\Psi$$

$$\sum_n \langle\phi_m| H_{\text{nucl}}\Phi_n |\phi_n\rangle + \epsilon_m(\mathbf{R})\Phi_m = E\Phi_m$$

$$\langle\phi_m| \nabla_{\mathbf{R}}^2\Phi_n |\phi_n\rangle = \sum_k \left(\delta_{mk}\nabla_{\mathbf{R}} + \langle\phi_m| \nabla_{\mathbf{R}} |\phi_k\rangle\right)\left(\delta_{kn}\nabla_{\mathbf{R}} + \langle\phi_k| \nabla_{\mathbf{R}} |\phi_n\rangle\right)\Phi_n$$

$$\sum_{k\neq n}\langle\phi_n| \nabla_{\mathbf{R}} |\phi_k\rangle\langle\phi_k| \nabla_{\mathbf{R}} |\phi_n\rangle = \sum_{k\neq n}\left|\frac{\langle\phi_n| \left(\nabla_{\mathbf{R}} H_{\text{el}}\right)|\phi_k\rangle}{\epsilon_n - \epsilon_k}\right|^2$$

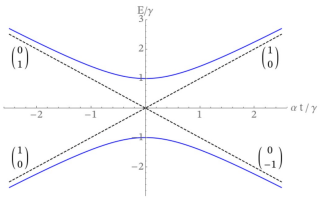
$$H_n^{\text{eff}} = -\sum_\alpha \frac{\hbar^2}{2M_\alpha}\left(\nabla_\alpha - i\mathcal{A}_{n,\alpha}\right)^2 + \frac{e^2}{4\pi\epsilon_0}\sum_{\alpha,i}\frac{Z_\alpha Z_\beta}{|\mathbf{R}_\alpha - \mathbf{R}_\beta|} + \epsilon_n(\mathbf{R})$$

(потом додумаю, в чем польза этих преобразований? см. пока Тонга)

Illustrations of adiabatics

Adiabatics in Landau-Zener:

$$\hat{H}(t) = \begin{pmatrix} \alpha t & \gamma \\ \gamma & -\alpha t \end{pmatrix},$$



$$\alpha t = \gamma\sinh\theta$$

$$E_+(\theta) = \gamma\cosh\theta, \quad |\psi_+(\theta)\rangle = \frac{1}{\sqrt{2\cosh\theta}}\begin{pmatrix} e^{\theta/2} \\ e^{-\theta/2}\end{pmatrix}$$

$$E_-(\theta) = -\gamma\cosh\theta, \quad |\psi_-(\theta)\rangle = \frac{1}{\sqrt{2\cosh\theta}}\begin{pmatrix} e^{-\theta/2} \\ -e^{\theta/2}\end{pmatrix}$$

$$c_+(+\infty) = \int_{-\infty}^{\infty}\exp\left(i\int_0^\theta \omega_{+-}(\theta)\frac{d\tau}{d\theta}d\theta\right)\frac{\langle\psi_+|\partial_\theta\hat{H}|\psi_-\rangle}{\omega_{+-}(\theta)}d\theta$$

$$\partial_\theta\hat{H} = \gamma\begin{pmatrix}\cosh\theta & 0 \\ 0 & -\cosh\theta\end{pmatrix} \Rightarrow \langle\psi_+|\partial_\theta\hat{H}|\psi_-\rangle = \gamma$$

$$\int_0^\theta \omega_{+-}(\theta)\cdot\frac{d\tau}{d\theta}d\theta = \frac{2\gamma^2}{\alpha}\int_0^\theta\cosh^2\theta d\theta = \frac{\gamma^2}{\alpha}\left(\theta + \frac{1}{2}\sinh 2\theta\right)$$

$$c_+(+\infty) \approx \int\limits_{-\infty}^{\infty} \frac{d\theta}{2\cosh\theta} \exp\left(i\frac{\gamma^2}{\alpha}\left(\theta + \frac{1}{2}\sinh 2\theta\right)\right)$$

$f(\theta) = \theta + \frac{1}{2}\sinh 2\theta$;
$f'(\theta) = 1 + \cosh 2\theta \geq 2$,
$z = \theta + \frac{1}{2}\sinh 2\theta \Rightarrow dz = d\theta(1 + \cosh 2\theta) = 2\cosh^2\theta d\theta$,

$$c_+(+\infty) = \int\limits_{-\infty}^{\infty} \frac{\exp\left(i\frac{\gamma^2}{\alpha}z\right)}{4\cosh^3\theta} dz$$

$\cosh\theta = 0 \Rightarrow \theta_k = i\pi(1/2 + k) = z_k$,

$$c_+^{(1)}(+\infty) \sim \exp\left(-\pi\gamma^2/2\alpha\right) \Rightarrow P \sim \exp\left(-\pi\gamma^2/\alpha\right)$$

Adiabatic Spin in a Magnetic Field:

$$H = -\mathbf{B}\cdot\boldsymbol{\sigma} + BM \qquad \mathbf{B} = \begin{pmatrix} B\sin\theta\cos\phi \\ B\sin\theta\sin\phi \\ B\cos\theta \end{pmatrix}$$

$$H = -B\begin{pmatrix} \cos\theta - 1 & e^{-i\phi}\sin\theta \\ e^{+i\phi}\sin\theta & -\cos\theta - 1 \end{pmatrix}$$

$$|\downarrow\rangle = \begin{pmatrix} e^{-i\phi}\sin\theta/2 \\ -\cos\theta/2 \end{pmatrix} \qquad |\uparrow\rangle = \begin{pmatrix} e^{-i\phi}\cos\theta/2 \\ \sin\theta/2 \end{pmatrix}$$

$$\mathcal{A}_\theta = -i\langle\downarrow|\frac{\partial}{\partial\theta}|\downarrow\rangle = 0 \qquad \mathcal{A}_\phi = -i\langle\downarrow|\frac{\partial}{\partial\phi}|\downarrow\rangle = -\sin^2\left(\frac{\theta}{2}\right)$$

$$\mathcal{F}_{\theta\phi} = \frac{\partial\mathcal{A}_\phi}{\partial\theta} - \frac{\partial\mathcal{A}_\theta}{\partial\phi} = -\frac{1}{2}\sin\theta$$

$$\mathcal{F}_{ij}(\mathbf{B}) = -\epsilon_{ijk}\frac{B^k}{2|\mathbf{B}|^3}$$

(?? что тут содержательного мы доказали. ввели свои обозначения, и что?)

Stationary adiabatics in hydrogen:

$$H_{\text{el}} = -\frac{\hbar^2}{2m}\nabla^2 - \frac{e^2}{4\pi\epsilon_0}\left[\frac{1}{r} + \frac{1}{|\mathbf{r} - \mathbf{R}|}\right]$$

$$\phi_\pm(\mathbf{r}) = A_\pm\left(\psi_0(\mathbf{r}) \pm \psi_0(\mathbf{r} - \mathbf{R})\right)$$

$$\psi_0 = \sqrt{\frac{1}{\pi a_0^3}}e^{-r/a_0}$$

$E_0 = -e^2/8\pi\epsilon_0 a_0$.

$$A_\pm^2 = \frac{1}{2}\left[1 \pm \int d^3r\psi_0(\mathbf{r})\psi_0(\mathbf{r} - \mathbf{R})\right]^{-1}$$

$$u(R) = \int d^3r \psi_0(\mathbf{r})\psi_0(\mathbf{r}-\mathbf{R}) = \left(1 + \frac{R}{a_0} + \frac{R^2}{3a_0^2}\right) e^{-R/a_0}$$

$$v(R) = \int d^3r \frac{\psi_0(\mathbf{r})\psi_0(\mathbf{r}-\mathbf{R})}{r} = \frac{1}{a_0}\left(1 + \frac{R}{a_0}\right) e^{-R/a_0}$$

$$w(R) = \int d^3r \frac{\psi_0(\mathbf{r})^2}{|\mathbf{r}-\mathbf{R}|} = \frac{1}{R} - \frac{1}{R}\left(1 + \frac{R}{a_0}\right) e^{-2R/a_0}$$

$$\epsilon_\pm(R) = \langle \phi_\pm | H_{\text{el}} | \phi_\pm \rangle = E_0 - 2A_\pm^2(w(R) \pm v(R))$$

$$V_\pm^{\text{eff}}(\mathbf{R}) = \frac{e^2}{4\pi\epsilon_0 R} + \epsilon_\pm(R) = \frac{e^2}{4\pi\epsilon_0}\left(\frac{1}{R} - \frac{w(R) \pm v(R)}{1 \pm u(R)}\right) + E_0$$

(??? что получили от этого???)

Adiabatic dynamics in an ellipse:

$$\psi_{N,p}(x,y) = e^{ipx} \cdot \sqrt{\frac{2}{a}} \sin\left(\frac{\pi N}{a}\left(y - \frac{a}{2}\right)\right) \qquad y \in \left(-\frac{a}{2}; \frac{a}{2}\right)$$

$E_{N,p} = \frac{p^2}{2m} + \frac{\pi^2 N^2}{2ma^2}$.

$$\psi_N^{(f)}(y,x) = \sqrt{\frac{2}{a(x)}} \sin\left[\frac{\pi N}{a(x)}\left(y - \frac{a(x)}{2}\right)\right], \quad \varepsilon_N^{(f)}(x) = \frac{\pi^2 N^2}{2ma^2(x)}$$

$$\hat{H}_{\text{eff}}^{(s)} = \frac{\hat{p}_x^2}{2m} + \frac{\pi^2 N^2}{2ma^2(x)}$$

Adiabatic dynamics in a cone:

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, a \gg b$$

$$E^{(f)} \sim \frac{1}{mb^2},$$

$$\psi_N^{(f)}(y,x) = \frac{1}{\sqrt{y(x)}} \sin\left[\frac{\pi N y}{2y(x)}(y - y(x))\right], \quad \varepsilon_N^{(f)} = \frac{\pi^2 N^2}{8my^2(x)}$$

$$\hat{H}_{\text{eff}} = \frac{\hat{p}_x^2}{2m} + \frac{\pi^2 N^2}{8my^2(x)} = \frac{\hat{p}_x^2}{2m} + \frac{\pi^2 N^2}{8mb^2}\left(1 - \frac{x^2}{a^2}\right)^{-1}$$

$$a \gg b \qquad \Rightarrow \qquad \omega_N = \frac{\pi N}{2mab} \qquad \Rightarrow \qquad E_{N,n} = \frac{\pi^2 N^2}{8mb^2} + \frac{\pi N}{2mab}\left(n + \frac{1}{2}\right)$$

Berry's phase and connection: basics

$$\gamma_n(t) := \int dt \cdot i \left\langle \psi_n(t) | \frac{\partial \psi_n(t)}{\partial t} \right\rangle \qquad - \text{ фаза Берри.}$$

(напомню тут разложение по этим амплитудам с!):

$$c_n(t) = c_n(0) \exp\left(i\gamma_n(t)\right),$$

что легко видеть, переписав $\frac{dc_n(t)}{dt} = ic_n(t) \left\langle \psi_n(t) \left| i\frac{\partial}{\partial t} \right| \psi_n(t) \right\rangle$.

Если гамильтониан зависит не явно от времени, но зависит от какого-то конечного набора параметров $R_i : \hat{H} = \hat{H}(\boldsymbol{R})$, которые, в свою очередь, как-то меняются со временем, то (????)

В свою очередь, мгновенные состояния гамильтониана тоже являются функциями этих параметров $|\psi_n\rangle = |\psi_n(\boldsymbol{R})\rangle$. Тогда выражение для фазы Берри можно переписать:

$$\gamma_n = \int dt \cdot i \langle \psi_n(\boldsymbol{R}) | \nabla_{\boldsymbol{R}} \psi_n(\boldsymbol{R}) \rangle \cdot \frac{\partial \boldsymbol{R}}{\partial t} = \int \boldsymbol{A}_n(\boldsymbol{R}) d\boldsymbol{R}, \quad \boldsymbol{A}_n(\boldsymbol{R}) = i \langle \psi_n(\boldsymbol{R}) | \nabla_{\boldsymbol{R}} \psi_n(\boldsymbol{R}) \rangle$$

$|\widetilde{n}(\boldsymbol{R})\rangle = e^{i\varphi(\boldsymbol{R})} |n(\boldsymbol{R})\rangle \Rightarrow$

$$\widetilde{\boldsymbol{A}}_n(\boldsymbol{R}) = \boldsymbol{A}_n(\boldsymbol{R}) - \nabla_{\boldsymbol{R}} \varphi(\boldsymbol{R}), \quad \widetilde{\gamma}_n = \gamma_n - \varphi(\boldsymbol{R}_f) + \varphi(\boldsymbol{R}_i)$$

Berry's phase and connection: applications and other properties

(????)

1.3.6 Variational Method

Variational method main ideas and formulas

Algorithm:

Main theory for variation by Tong:

Theorem: Consider an arbitrary state $|\psi\rangle$. The expected value of the energy obeys the inequality

$$\langle E \rangle = \langle \psi | H | \psi \rangle \geq E_0$$

(?? idea of proof?)

Now consider a family of states, $|\psi(\alpha)\rangle$, depending on some number of parameters α_i. If we like, we can relax our assumption that the states are normalised and define

$$E(\alpha) = \frac{\langle \psi(\alpha) | H | \psi(\alpha) \rangle}{\langle \psi(\alpha) | \psi(\alpha) \rangle} \qquad \text{Rayleigh-Ritz quotient}$$

$$E(\alpha) \geq E_0 \quad \text{for all } \alpha$$

The most stringent bound on the ground state energy comes from the minimum value of $E(\alpha)$ over the range of α. This, of course, obeys

$$\left. \frac{\partial E}{\partial \alpha_i} \right|_{\alpha = \alpha^\star} = 0$$

giving us the upper bound $E_0 \leq E(\alpha_*)$. This is the essence of the variational method.

Typical examples of variational method

For $H = -\frac{d^2}{dx^2} + x^4$:

$$\psi(x; \alpha) = \left(\frac{\alpha}{\pi}\right)^{1/4} e^{-\alpha x^2/2}$$

$$E(\alpha) = \sqrt{\frac{\alpha}{\pi}} \int dx \left(\alpha - \alpha^2 x^2 + x^4\right) e^{-\alpha x^2} = \frac{\alpha}{2} + \frac{3}{4\alpha^2}$$

$\alpha_\star^3 = 3,$

$$E(\alpha_\star) \approx 1.08$$

Helium Atom by perturbation theory:

$$H = \frac{\mathbf{p}_1^2}{2m} - \frac{Ze^2}{4\pi\epsilon_0}\frac{1}{r_1} + \frac{\mathbf{p}_2^2}{2m} - \frac{Ze^2}{4\pi\epsilon_0}\frac{1}{r_2} + \frac{e^2}{4\pi\epsilon_0}\frac{1}{|\mathbf{x}_1 - \mathbf{x}_2|}$$

$$\Psi(\mathbf{x}_1, \mathbf{x}_2) = \psi_{n_1,l_1,m_1}(\mathbf{x}_1)\,\psi_{n_2,l_2,m_2}(\mathbf{x}_2)$$

$$E = -Z^2\left(\frac{1}{n_1^2} + \frac{1}{n_2^2}\right)Ry$$

$$\psi_{1,0,0}(\mathbf{x}) = \sqrt{\frac{Z^3}{\pi a_0^3}}e^{-Zr/a_0} \qquad a_0 := \frac{4\pi\epsilon_0\hbar^2}{me^2} \approx 5\times 10^{-11}\ \mathrm{m}$$

$$\Delta E = \frac{e^2}{4\pi\epsilon_0}\int d^3x_1 d^3x_2 \frac{|\psi_{1,0,0}(\mathbf{x}_1)|^2\,|\psi_{1,0,0}(\mathbf{x}_2)|^2}{|\mathbf{x}_1 - \mathbf{x}_2|}$$

$|\mathbf{x}_1 - \mathbf{x}_2| = \sqrt{(\mathbf{x}_1 - \mathbf{x}_2)^2} = \sqrt{r_1^2 + r_2^2 - 2r_1 r_2\cos\theta_2}$

$$\Delta E = \frac{8\pi^2 e^2}{4\pi\epsilon_0}\left(\frac{Z^3}{\pi a_0^3}\right)^2 \int dr_1 r_1^2 e^{-2Zr_1/a_0}\int dr_2 r_2^2 e^{-2Zr_2/a_0}\int_{-1}^{+1} d(\cos\theta_2)\,\frac{1}{\sqrt{r_1^2 + r_2^2 - 2r_1 r_2\cos\theta_2}}$$
$$= \frac{5}{8}\frac{Ze^2}{4\pi\epsilon_0 a_0} = \frac{5Z}{4}Ry$$

$$E_0 \approx E + \Delta E = \left(-2Z^2 + \frac{5Z}{4}\right)Ry \approx -74.8\mathrm{eV}$$

$E_{0\mathrm{exact}} \approx -79\mathrm{eV}.$

Helium Atom by variational method:

$$\Psi(\mathbf{x}_1, \mathbf{x}_2) = \psi(\mathbf{x}_1)\,\psi(\mathbf{x}_2) \qquad \psi(\mathbf{x};\alpha) = \sqrt{\frac{\alpha^3}{\pi a_0^3}}e^{-\alpha r/a_0}$$

$$E(\alpha) = \int d^3x_1 d^3x_2 \psi^\star(\mathbf{x}_1)\,\psi^\star(\mathbf{x}_2)\,H\psi(\mathbf{x}_1)\,\psi(\mathbf{x}_2)$$

$$H_\alpha = \frac{\mathbf{p}^2}{2m} - \frac{\alpha e^2}{4\pi\epsilon_0}\frac{1}{r}$$

$$H = H_\alpha(\mathbf{p}_1, \mathbf{r}_1) + H_\alpha(\mathbf{p}_2, \mathbf{r}_2) + \frac{e^2}{4\pi\epsilon_0}\left[(\alpha - Z)\left(\frac{1}{r_1} + \frac{1}{r_2}\right) + \frac{1}{|\mathbf{x}_1 - \mathbf{x}_2|}\right]$$

$$E(\alpha) = -2\alpha^2 Ry + \frac{e^2}{4\pi\epsilon_0}\left[2(\alpha - Z)\int d^3x\frac{|\psi(\mathbf{x})|^2}{r} + \int d^3x_1 d^3x_2 \frac{|\psi(\mathbf{x}_1)|^2\,|\psi(\mathbf{x}_2)|^2}{|\mathbf{x}_1 - \mathbf{x}_2|}\right]$$

$$\int d^3x \frac{|\psi(\mathbf{x})|^2}{r} = 4\pi \frac{\alpha^3}{\pi a_0^3} \int dr r e^{-2\alpha r/a_0} = \frac{\alpha}{a_0}$$

$$\int d^3x_1 d^3x_2 \frac{|\psi(\mathbf{x}_1)|^2 |\psi(\mathbf{x}_2)|^2}{|\mathbf{x}_1 - \mathbf{x}_2|} = \frac{5\alpha}{8a_0}$$

$$E(\alpha) = \left(-2\alpha^2 + 4(\alpha - Z)\alpha + \frac{5}{4}\alpha\right) Ry$$

$\alpha_\star = Z - 5/16$.

$$E(\alpha_\star) = -2\left(Z - \frac{5}{16}\right)^2 Ry \approx -77.5\text{eV}$$

$E_0 \approx -79.0$eV.

Other about variational method

How Accurate is the Variational Method?

$$|\psi(\alpha_\star)\rangle = \frac{1}{\sqrt{1+\epsilon^2}}(|0\rangle + \epsilon|\phi\rangle)$$

where $|\phi\rangle$ is a normalised state, orthogonal to the ground state, $\langle 0|\phi\rangle = 0$, and ϵ is assumed to be small. Then our guess at the energy is

$$E(\alpha_\star) = \frac{1}{1+\epsilon^2}\left[\langle 0|H|0\rangle + \epsilon(\langle 0|H|\phi\rangle + \langle\phi|H|0\rangle) + \epsilon^2\langle\phi|H|\phi\rangle\right]$$

Importantly the terms linear in ϵ vanish. This is because $\langle\phi|H|0\rangle = E_0\langle\phi|0\rangle = 0$. We can then expand the remaining terms as

$$E(\alpha_\star) = E_0 + \epsilon^2(\langle\phi|H|\phi\rangle - E_0) + \mathcal{O}(\epsilon^2)$$

This means that if the difference from the true ground state is $\mathcal{O}(\epsilon)$, then the difference from the ground state energy is $\mathcal{O}(\epsilon^2)$. This is the reason that the variational method often does quite well.

Existence of bound state by variational Method

(потом додумаю, Тог написал, что запросто это можно устанавливать)

An Example: Existence of bound state of The Yukawa Potential

$$V(r) = -A\frac{e^{-\lambda r}}{r}$$

$$H = -\frac{\hbar^2}{2m}\nabla^2 + V(r)$$

$$\psi(\mathbf{x};\alpha) = \sqrt{\frac{\alpha^3}{\pi}}e^{-\alpha r}$$

$$E(\alpha) = \frac{\hbar^2\alpha^2}{2m} - \frac{4A\alpha^3}{(\lambda+2\alpha)^2}$$

$$\lambda < \frac{Am}{\hbar^2}$$

Upper Bound on Excited States by variation

(см. Тонга, пока не актуально. можно как-то оценить, ну и хорошо)

1.3.7 Solutions by special functions

General advice for solutions by special functions

I am not sure about this method.

Функции Бесселя $J_m(z), Y_m(z), H_m^{(1,2)}(z), I_m(z), K_m(z)$

$1d:$	e^x	e^{-x}	$\cos x$	$\sin x$	e^{ix}	e^{-ix}
$2d:$	$I_m(x)$	$K_m(x)$	$J_m(x)$	$Y_m(x)$	$H_m^{(1)}(x)$	$H_m^{(2)}(x)$

Функции Инфельда $I_m(z)$ и Макдональда $K_m(z)$

$$\psi''(z) + \frac{1}{z}\psi'(z) - \left(1 + \frac{m^2}{z^2}\right)\psi(z) = 0,$$

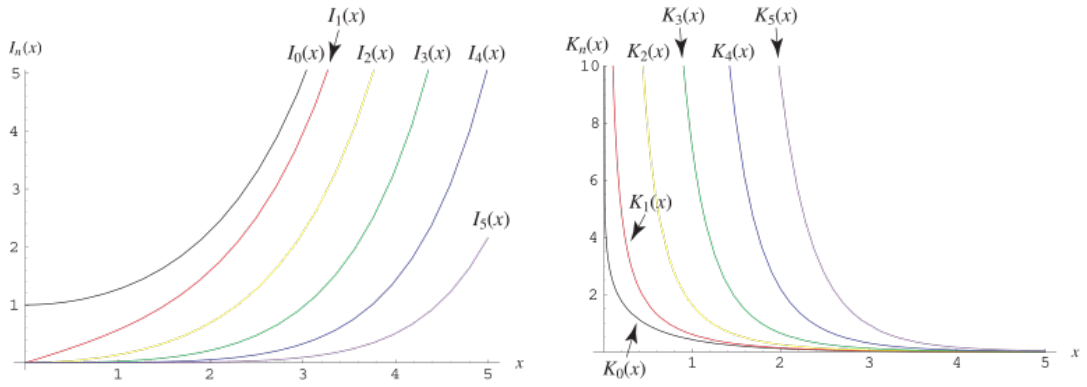
$$\psi(z) = A_1 I_m(z) + A_2 K_m(z)$$

$z \gg 1$ $\qquad I_m(z) \approx \dfrac{1}{\sqrt{2\pi z}} e^z, \qquad K_m(z) \approx \sqrt{\dfrac{\pi}{2z}} e^{-z},$

$z \ll 1$ $\qquad I_m(z) \approx \dfrac{1}{m!}\left(\dfrac{z}{2}\right)^m, \qquad K_m(z) \approx \begin{cases} \frac{(m-1)!}{2}\left(\frac{2}{z}\right)^m, & m \neq 0 \\ \ln\frac{2}{z} - \gamma, & m = 0 \end{cases}, \qquad (\gamma \approx 0.577)$

Функция $K_m(z)$ расходится в нуле, что и должно быть, поскольку W этого уравнения по формуле Лиувилля-Остроградского $\sim 1/x$.

(??)



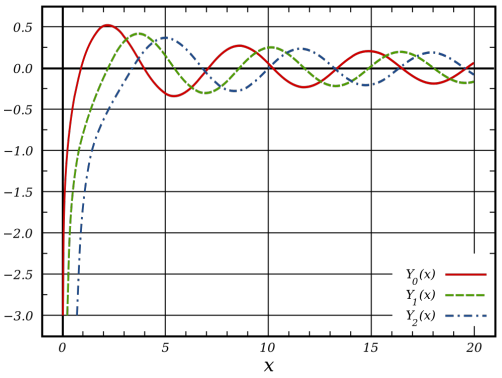
Функции Бесселя $J_m(z)$, Неймана Y_m, Ганкеля $H_m^{(1)}, H_m^{(2)}$

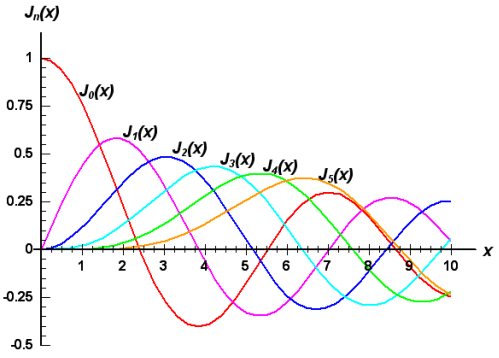
$$\psi''(z) + \frac{1}{z}\psi'(z) + \left(1 - \frac{m^2}{z^2}\right)\psi(z) = 0$$

$$\psi(z) = B_1 J_m(z) + B_2 Y_m(z) \equiv C_1 H_m^{(1)}(z) + C_2 H_m^{(2)}(z)$$

$$z \gg 1: \qquad J_m(z) \approx \sqrt{\frac{2}{\pi z}} \cos\left(z - \frac{m\pi}{2} - \frac{\pi}{4}\right), \quad Y_m(x) \approx \sqrt{\frac{2}{\pi z}} \sin\left(z - \frac{m\pi}{2} - \frac{\pi}{4}\right),$$

$$x \ll 1: \qquad J_m(z) \approx \frac{1}{m!}\left(\frac{z}{2}\right)^m, \quad Y_m(z) \approx \begin{cases} -\frac{(m-1)!}{\pi}\left(\frac{2}{z}\right)^m, & m \neq 0 \\ -\frac{2}{\pi}\left(\ln\frac{2}{z} - \gamma\right), & m = 0 \end{cases},$$





$$H_m^{(1,2)}(x) := J_m(x) \pm iY_m(x).$$

$$H_m^{(1,2)}(z) \approx \sqrt{\frac{2}{\pi z}} e^{\pm i(z - m\pi/2 - \pi/4)}, \qquad z \gg 1$$

$$H_m^{(1,2)}(z) \approx \begin{cases} \mp i\frac{(m-1)!}{\pi}\left(\frac{2}{z}\right)^m, m \neq 0 \\ \mp\frac{2i}{\pi}\left(\ln\frac{2}{z} - \gamma\right) + 1, m = 0 \end{cases} \qquad z \ll 1$$

$$K_m(x) = \frac{\pi}{2} i^{m+1} H_m^{(1)}(ix) = \frac{\pi}{2}(-i)^{m+1} H_m^{(2)}(-ix),$$

$$J_m(ix) = i^m I_m(x)$$

Hypergeometric functions (!!!)

(here def-s, see separate note about them for now)

$${}_1F_1(a, b, z) \approx \frac{\Gamma(b)}{\Gamma(a)} e^z z^{a-b} + \frac{\Gamma(b)}{\Gamma(b-a)}(-z)^{-a}$$

$F(\alpha, \beta, \gamma; z) = (1 - z)^{-\alpha} F\left(\alpha, \gamma - \beta, \gamma; \frac{z}{z-1}\right)$.

Gamma functions (!!!)

Сферические функции

$$Y_{00} = \sqrt{\frac{1}{4\pi}}; \qquad Y_{2,\pm 2} = \sqrt{\frac{15}{32\pi}} \sin^2\theta e^{\pm 2i\phi};$$

$$Y_{1,\pm 1} = \mp\sqrt{\frac{3}{8\pi}} \sin\theta e^{\pm 2i\phi}; \qquad Y^{2,\pm 1} = \mp\sqrt{\frac{15}{8\pi}} \sin\theta\cos\theta e^{\pm 21\phi};$$

$$Y_{10} = \sqrt{\frac{3}{4\pi}} \cos\theta; \qquad Y_{20} = \sqrt{\frac{5}{16\pi}}\left(3\cos^2\theta - 1\right).$$

$$\left(1-x^2\right)y''-2xy'+\left[l(l+1)-\frac{m^2}{1-x^2}\right]y=0,$$

$$l=0,1,...; \quad m=0,\pm1,...,\pm l.$$

$$P_l^{|m|}(x)=\frac{1}{2^l l!}\left(1-x^2\right)^{|m|/2}\frac{\mathrm{d}^{l+|m|}}{\mathrm{d}x^{l+|m|}}\left(x^2-1\right)^l. \qquad \text{ф Родрига}$$

$$Y_{lm}(\theta,\varphi)=\sqrt{\frac{2l+1}{4\pi}\frac{(l-|m|)!}{(l+|m|)!}}P_l^{|m|}(\cos\theta)\mathrm{e}^{\mathrm{i}m\varphi},$$

$$\left[\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\varphi^2}+l(l+1)\right]\Psi(\theta,\varphi)=0;$$

$$\left[\mathrm{i}\frac{\partial}{\partial\varphi}+m\right]\Psi(\theta,\varphi)=0$$

$$\int_0^{2\pi}\mathrm{d}\varphi\int_0^{\pi}Y^*_{l'm'}(\theta,\varphi)Y_{lm}(\theta,\varphi)\sin\theta\mathrm{d}\theta=\delta_{l'l}\delta_{m'm}$$

$$\sum_{l=0}^{\infty}\sum_{m=-l}^{l}Y^*_{lm}\left(\theta',\varphi'\right)Y_{lm}(\theta,\varphi)=\delta\left(\cos\theta'-\cos\theta\right)\delta\left(\varphi'-\varphi\right)$$

$$\cos\theta Y_{lm}(\theta,\varphi)=\sqrt{\frac{(l+1)^2-m^2}{(2l+1)(2l+3)}}Y_{l+1,m}(\theta,\varphi)+\sqrt{\frac{l^2-m^2}{(2l-1)(2l+1)}}Y_{l-1,m}(\theta,\varphi),$$

$$Y_{l,-m}=(-1)^mY^*_{lm}$$

$$\left(1-x^2\right)\frac{d^2y}{dx^2}-2x\frac{dy}{dx}+\left[n(n+1)-\frac{m^2}{1-x^2}\right]y=0$$

присоед ф Лежандра: $$P_n^m(x)=\left(1-x^2\right)^{m/2}\left(\frac{d}{dx}\right)^m P_n(x). \qquad m\in Z_+$$

$$\sum_{m'}\langle\hat{\mathbf{r}}|lm'\rangle\langle lm'|U(R)|lm\rangle=\sum_{m'}Y_{lm'}(\hat{\mathbf{r}})D^l_{m'm}(R)$$

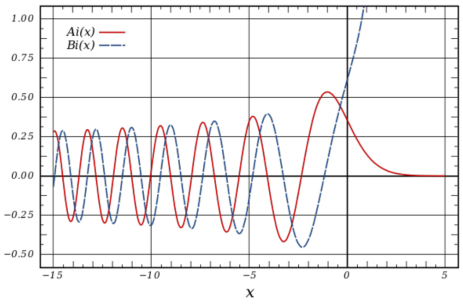
$$Y_{lm}\left(R^{-1}\hat{\mathbf{r}}\right)=\sum_{m'}Y_{lm'}(\hat{\mathbf{r}})D^l_{m'm}(R)$$

$$Y_{lm}(\hat{\mathbf{r}})=\sum_{m'}Y_{lm'}(\hat{\mathbf{z}})D^l_{m'm}\left(R^{-1}\right)$$

Функция Эйри

$$\psi''(z) - z\psi(z) = 0$$
$$\psi(z) = C_1 \operatorname{Ai}(z) + C_2 \operatorname{Bi}(z)$$

$$\operatorname{Ai}(z) \approx \begin{cases} \frac{1}{2\sqrt{\pi}} \frac{1}{z^{1/4}} \exp\left(-\frac{2}{3} z^{3/2}\right), & z \to +\infty \\ \frac{1}{\sqrt{\pi}} \frac{1}{(-z)^{1/4}} \sin\left(\frac{2}{3}(-z)^{3/2} + \frac{\pi}{4}\right), & z \to -\infty \end{cases}$$



Типично ф. Айри решает Шрёдингера с постоянной силой (eg. в $\vec{E}$=const, $U(x) = Fx$):

$$-\frac{\hbar^2}{2m}\psi''(x) + Fx\psi(x) = E\psi(x)$$

$z := \frac{x - E/F}{(\hbar^2/2mF)^{1/3}}$ Решение в классически разрешённой области решения - растущие и затухающие экспоненты.

Функция Эйри возникает естественным образом при выводе граничных условий для квазиклассического приближения (?????).

О свойствах функции Айри на комплексной плоскости и явлении Стокса (???)

Кажется естественным, что асимптотические выражения можно аналитически продолжать за пределы вещественной оси.

Однако, асимптотики не представляются однозначными функциями на комплексной плоскости - для их определения требуется проведение разрезов и выделение ветвей. В то же время сама функция Эйри, разумеется, является однозначной.

Также функция $\operatorname{Ai}(z)$ на $+\infty$ содержит одну экспоненту, а на $-\infty$ -две (в составе синуса), и одно из другого получить аналитическим продолжением невозможно. Всё это связано с так называемым явлением Стокса.

Асимптотики работают только в определённых секторах комплексной плоскости, разделённых лучами (т.н. линиями Стокса), на которых коэффициенты перед компонентами асимптотики (одна компонента содержит $\exp\left(\frac{2}{3}y^{3/2}\right)$, другая $-\exp\left(-\frac{2}{3}y^{3/2}\right)$) меняются скачком.

На этих линиях выражение в экспоненте является вещественным, так что одна из экспонент является максимально убывающей, а другая - максимально растущей.

(мб напишу потом больше, но в записи про спецфункции)

(!!! add plots here!!!!)

комплексный метод перевала

сферических функциях и полиномах Лежандра

Main selection rules

Для дипольных переходов:

$$\begin{aligned} &\Delta J = \pm 1, 0 && \text{при } J_{\text{нач}} \neq 0 \text{ и } J_{\text{кон}} \neq 0, \\ &\Delta J = \pm 1 && \text{при } J_{\text{нач}} = 0 \text{ или } J_{\text{кон}} = 0. \end{aligned}$$

Отсюда следует, что

$$\Delta m_j = \pm 1, 0$$

Переходы $J_{\text{нач}} = 0 \to J_{\text{кон}} = 0$ запрещены, поскольку в силу поперечности электромагнитных волн не может излучиться фотон с $J = 0$.

Переход с $\Delta J = 0$ при $J_{\text{нач}} \neq 0$ означает поворот вектора $\mathbf{J}$ системы на некий определенный угол.

Отсюда следует, что

$$\Delta \mathbf{S} = 0$$

Переходы с $\Delta L = 0$ невозможны для атомов, в которых испускание света связано с изменением движения всего одного электрона, в частности, для водорода и водородоподобных атомов, а также для атомов с одним электроном сверх заполненных оболочек (т. е. для атомов щелочных металлов).

Этот запрет связан с законом сохранения четности волновой функции.

Emission description from QM

For Hydrogen:

$$I_e \sim \ddot{p_e}^2 \sim \left(\sum e_i r_i\right)^2$$

$$I_\mu \sim \ddot{p_\mu}^2 \sim \left(\frac{1}{2c}\sum e_i \left[r_i v_i\right]\right)^2$$

$I_\mu \sim I_e \left(\frac{v}{c}\right)^2 \approx I_e \cdot 10^{-7}$

Example:

$$|\mathfrak{i}_{\text{at}}\rangle = |L, S; J, M_J\rangle\,, \qquad |\mathfrak{f}_{\text{at}}\rangle = |L', S'; J', M'_J\rangle\,,$$

$$A_{\mathfrak{fi}} = 2\pi\delta\left(\omega_{\mathfrak{fi}} + \omega_{\mathfrak{f}}\right)\omega_{\mathfrak{f}}\boldsymbol{\epsilon}^{*\alpha}_{\lambda_{\mathfrak{f}}}\left(\boldsymbol{k}_{\mathfrak{f}}\right)\langle\mathfrak{f}_{\text{at}}\left|\boldsymbol{d}^{\alpha}\right|\mathfrak{i}_{\text{at}}\rangle\,.$$

$$\boldsymbol{d}^{\alpha}_{\mathfrak{fi}} = \langle\mathfrak{f}_{\text{at}}\left|\boldsymbol{d}^{\alpha}\right|\mathfrak{i}_{\text{at}}\rangle\,.$$

$$\mathrm{d}w_{\mathfrak{fi}} = \frac{\left|A_{\mathfrak{fi}}\right|^2}{T}\frac{\mathrm{d}^3 k_{\mathfrak{f}}}{2\hbar\omega_{\mathfrak{f}}(2\pi)^3} = 2\pi\delta\left(\omega_{\mathfrak{fi}} + \omega_{\mathfrak{f}}\right)\omega_{\mathfrak{f}}^2\frac{\mathrm{d}^3 k_{\mathrm{f}}}{2\hbar\omega_{\mathfrak{f}}(2\pi)^3}\boldsymbol{\epsilon}^{*\alpha}_{\lambda_{\mathfrak{f}}}\boldsymbol{\epsilon}^{\beta}_{\lambda_{\mathfrak{f}}}\boldsymbol{d}^{\alpha}_{\mathfrak{fi}}\boldsymbol{d}^{*\beta}_{\mathfrak{fi}}.$$

$$\sum_{\lambda_{\mathfrak{f}}}\epsilon^{*\alpha}_{\lambda_f}\epsilon^{\beta}_{\lambda_f} = \delta^{\alpha\beta} - n^{\alpha}_{\mathfrak{f}}n^{\beta}_{\mathfrak{f}}, \qquad \boldsymbol{n}_{\mathfrak{f}} = \boldsymbol{k}_{\mathfrak{f}}/k_{\mathfrak{f}}$$

$$\sum_{\lambda_{\mathrm{f}}}\boldsymbol{\epsilon}^{*\alpha}_{\lambda_{\mathrm{f}}}\boldsymbol{\epsilon}^{\beta}_{\lambda_{\mathrm{f}}}\boldsymbol{d}^{\alpha}_{\mathrm{fi}}\boldsymbol{d}^{*\beta}_{\mathrm{fi}} = \boldsymbol{d}_{\mathrm{fi}}\cdot\boldsymbol{d}^{*}_{\mathrm{fi}} - \left(\boldsymbol{d}_{\mathrm{fi}}\cdot\boldsymbol{n}_{\mathfrak{f}}\right)\left(\boldsymbol{d}_{\mathrm{fi}}\cdot\boldsymbol{n}_{\mathfrak{f}}\right)^{*} = \left(\boldsymbol{d}_{\mathrm{fi}}\times\boldsymbol{n}_{\mathrm{f}}\right)\left(\boldsymbol{d}_{\mathrm{fi}}\times\boldsymbol{n}_{\mathrm{f}}\right)^{*} = \left|\boldsymbol{d}_{\mathrm{fi}}\right|^2\sin^2\theta$$

$$\frac{1}{\tau} = \frac{4}{3c^3}\omega_{\mathfrak{f}}^4\left|\tilde{\boldsymbol{d}}_{\mathrm{fi}}\right|^2\frac{1}{\hbar\omega_{\mathrm{f}}}$$

$$\mathcal{J}\left(\omega_{\mathfrak{f}}\right) = \frac{4}{3c^3}\omega_{\mathfrak{f}}^4\left|\tilde{\boldsymbol{d}}_{\mathfrak{fi}}\right|^2.$$

Правила отбора для дипольного момента определяются тремя фактами. Во-первых, согласно теореме Эккарта-Вигнера матричный элемент векторного оператора дипольного момента не равен нулю только в случае, если

$$|\Delta M_J| \leqslant 1, \quad |\Delta J| \leqslant 1, \quad 1 \leqslant J + J'.$$

Отсюда специально отмечаем правило запрета для переходов $0 \to 0'$: матричные элементы с $J = J' = 0$ тождественно равны нулю.

Во-вторых:

$$[S_\alpha, d_\beta] = 0, \quad \left[\boldsymbol{S}^2, d_\alpha\right] = 0,$$

$$\left\langle L', S'; J', M'_J \left| \left[\boldsymbol{S}^2, d_\alpha\right] \right| L, S; J, M_J \right\rangle = \left(S'\,(S'+1) - S(S+1)\right) \langle L', S'; J', M'_J \,|d_\alpha|\, L, S; J, M_J\rangle = 0,$$

поэтому если $\Delta S \neq 0, \quad \Delta M_S \neq 0$, то матричный элемент дипольного момента равен нулю, правило отбора по полному спину имеет вид

$$\Delta S = 0.$$

Далее, правила отбора по четности:

$$P_\mathrm{f} = -P_\mathrm{i}.$$

$$P_\mathrm{atom} = \prod_k (-1)^{l_k} = (-1)^{\sum l_k},$$

l_k - орбитальные моменты электронов в самосогласованном поле. Оно следует из свойства относительно пространственной инверсии $\hat{I}$: $\hat{I}\boldsymbol{d} = -\boldsymbol{d}\hat{I}$. Возьмем матричный элемент этого операторного равенства по конечному и начальному состояниям атома $\langle \mathfrak{f}_\mathrm{at}| \cdot |\mathfrak{i}_\mathrm{at}\rangle$ и учтем, что эти состояния, отвечающие заданным электронным конфигурациям, являются собственными для эрмитова оператора инверсии:

$$\hat{I}\,|\mathfrak{i}_\mathrm{at}\rangle = P_\mathrm{i}\,|\mathfrak{i}_\mathrm{at}\rangle\,, \qquad\qquad \langle \mathfrak{f}_\mathrm{at}|\,\hat{I} = \langle \mathfrak{f}_\mathrm{at}|\,P_\mathrm{f},$$

$$P_\mathfrak{f}\,\langle \mathfrak{f}_\mathrm{at}\,|\boldsymbol{d}|\mathfrak{i}_\mathrm{at}\rangle = -P_\mathrm{i}\,\langle \mathfrak{f}_\mathrm{at}|\boldsymbol{d}|\mathfrak{i}_\mathrm{at}\rangle\,.$$

Значит, матричный элемент дипольного момента не равен нулю, если только пространственные четности вначале и в конце противоположные:

$$P_\mathrm{f} = -P_\mathrm{i},$$

О классификации фотонов и мультипольных волнах (??)

Участвовать в атомных и ядерных процессах может лишь такое электромагнитное излучение, волновая функция которого – собственная функция операторов момента и четности. Плоская волна не имеет определенного момента и четности, однако векторный потенциал такой волны можно разложить в ряд по состояниям с определенными значениями J и P (разложения по мультиполям). Отдельные члены такого разложения будут отвечать электромагнитным волнам (фотонам) с определенными значениями момента и четности, которые могут быть поглощены атомами и ядрами.

Таким образом, задача состоит в том, чтобы перейти от поля фотонов с определенным значением импульса (h/k) к полю фотонов с определенными значениями момента и четности. Прежде чем записать разложение плоской волны по мультиполям, напомним классификацию фотонов по моменту и четности. Полный момент количества движения фотона J принимает целочисленные значения, начиная с единицы: $J = 1, 2, 3, ...$

Полный момент фотона J можно формально рассматривать как векторную сумму спинового S и орбитального L моментов ($\vec{J} = \vec{L} + \vec{S}$), причем орбитальный момент L в данном случае не что иное, как ранг сферических функций YLm, входящих в состав волновой функции фотона.

Фотоны с определенным значением J называются 2J-польными (дипольными, если J = 1; квадрупольными, если J = 2; октупольными, если J = 3 и т.д.).

Для данного J квантовое число орбитального момента L может принимать три значения: L = J+1, J, J–1 так как спин фотона S = 1.

Четность фотона P определяется правилом

$$P = (-1)^{L+1}.$$

(???) Таким образом, фотоны с одинаковым J могут иметь различные значения орбитального момента, а следовательно, и четности.

Фотоны, для которых орбитальный момент совпадает с полным, т. е. L = J, имеют четность $P = (-1)^{J+1}$ и называются магнитными (или кратко MJ) фотонами. Фотоны, для которых $L = J \pm l$, имеют четность $(\breve{}1)^J$ и называются электрическими (или EJ) фотонами.

Фотоны электрического типа, в отличие от фотонов магнитного типа, не имеют определенного значения орбитального момента. Их волновая функция является линейной комбинацией состояний с $L = J \pm 1$. (?????)

$$\mathbf{d} = \sum_i e_i \mathbf{r}_i \qquad \boldsymbol{\mu} = \frac{1}{2c} \sum_i e_i \left[\mathbf{r}_i, \mathbf{v}_i\right]$$

$$I_M = \frac{2\ddot{\mu}^2}{3c^3} \overset{\sim v^2/c^2}{\ll} I_E = \frac{2\,\ddot{\mathrm{d}}^2}{3c^3} \overset{\sim v^2/c^2}{\ll} I_Q = \frac{1}{180c^5} \dddot{Q}^2_{\alpha\beta}.$$

On Wigner–Eckart theorem (?!)

Given a tensor operator $T^{(k)}$ and two states of angular momenta j and j', there exists a constant $\left\langle j \left\| T^{(k)} \right\| j' \right\rangle$ such that for all m, m', and q,

$$\left\langle jm \left| T^{(k)}_q \right| j'm' \right\rangle = \langle j'm'kq|jm\rangle \left\langle j \left\| T^{(k)} \right\| j' \right\rangle,$$

where

- $T^{(k)}_q$ is the q-th component of the spherical tensor operator $T^{(k)}$ of rank k, [2]
- $|jm\rangle$ denotes an eigenstate of total angular momentum J^2 and its z component J_Z,
- $\langle j'm'kq|jm\rangle$ is the Clebsch-Gordan coefficient for coupling j' with k to get j,
- $\left\langle j \left\| T^{(k)} \right\| j' \right\rangle$ denotes [3] some value that does not depend on m, m', nor q and is referred to as the reduced matrix element.

(??? what is the idea of its proof????)

Examples of Wigner–Eckart theorem

Consider the position expectation value $\langle njm|x|njm\rangle$. This matrix element is the expectation value of a Cartesian operator in a spherically symmetric hydrogen-atom-eigenstate basis, which is a nontrivial problem. However, the Wigner-Eckart theorem simplifies the problem. (In fact, we could obtain the solution quickly using parity, although a slightly longer route will be taken.)

We know that x is one component of $\mathbf{r}$, which is a vector. Since vectors are rank-1 spherical tensor operators, it follows that x must be some linear combination of a rank-1 spherical tensor ${T^{(1)}}_q$ with $q \in \{-1, 0, 1\}$. In fact, it can be shown that

$$x = \frac{T^{(1)}_{-1} - T^{(1)}_1}{\sqrt{2}}, \qquad T^{(1)}_q = \sqrt{\frac{4\pi}{3}} r Y^q_1$$

and Y^m_l are spherical harmonics, which themselves are also spherical tensors of rank l. Additionally, ${T^{(1)}}_0 = z$, and

$$T^{(1)}_{\pm 1} = \mp \frac{x \pm iy}{\sqrt{2}}.$$

Therefore,

$$\begin{aligned}\langle njm|x|n'j'm'\rangle &= \left\langle njm \left| \frac{T^{(1)}_{-1} - T^{(1)}_1}{\sqrt{2}} \right| n'j'm' \right\rangle = \\ &= \frac{1}{\sqrt{2}} \left\langle nj \left\| T^{(1)} \right\| n'j' \right\rangle \left(\langle j'm'1(-1)|jm\rangle - \langle j'm'11|jm\rangle \right).\end{aligned}$$

The above expression gives us the matrix element for x in the $|njm\rangle$ basis. To find the expectation value, we set $n' = n, j' = j$, and $m' = m$. The selection rule for m' and m is $m \pm 1 = m'$ for the ${T^{(1)}}_{11}$ spherical tensors. As we have $m' = m$, this makes the ClebschGordan Coefficients zero, leading to the expectation value to be equal to zero.

$$\begin{aligned}\langle \gamma' j'm'| A_q|\gamma jm\rangle &= \langle \gamma' j'| |A\|\gamma j\rangle \langle j'm'|j1mq\rangle \\ \langle \gamma' j'm'| fA_q|\gamma jm\rangle &= \langle \gamma' j'| |fA\|\gamma j\rangle \langle j'm'|j1mq\rangle \\ \langle \gamma' j'm'| f|\gamma jm\rangle &= \delta_{m'm}\delta_{j'j} \langle \gamma' j\|f\|\gamma j\rangle .\end{aligned}$$

$$\langle \gamma' j'| |fA\|\gamma j\rangle = \sum_\Gamma \left\langle \gamma' j'| \|f||\Gamma j' \right\rangle \langle \Gamma j'\|A\|\gamma j\rangle$$

$$\langle \gamma' j'\|\mathbf{A}\cdot\mathbf{B}\|\gamma j\rangle = \sum_{\Gamma j'} \langle \gamma' j\|A\|\Gamma j'\rangle \langle \Gamma j'\|B\|\gamma j\rangle$$

$\mathbf{A}\cdot\mathbf{B} = \sum\limits_q A_q B^\dagger_q$

$$\begin{aligned}\langle \gamma' j'm'| (\mathbf{A}\cdot\mathbf{J}) J_q|\gamma jm\rangle &= \delta_{j'j}\hbar\sqrt{j(j+1)} \langle jm'|j1mq\rangle \langle \gamma' j\|\mathbf{A}\cdot\mathbf{J}\|\gamma j\rangle \\ &= \delta_{j'j}\hbar\sqrt{j(j+1)} \langle jm'|j1mq\rangle \langle \gamma' j\|A\|\gamma j\rangle \langle \gamma j\|J\|\gamma j\rangle \\ &= \delta_{j'j}\hbar^2 j(j+1) \langle jm'|j1mq\rangle \langle \gamma' j\|A\|\gamma j\rangle \\ &= \delta_{j'j}\hbar^2 j(j+1) \langle \gamma' jm'| A_q|\gamma jm\rangle\end{aligned}$$

Об излучении в рамках теории возмущений и взаимодействия с квантовым полем фотонов

$$V_{E1} = -\boldsymbol{d}\cdot\mathcal{E}(t),$$

$\boldsymbol{d} = e\sum\limits_{\text{el}} \boldsymbol{r}_{\text{el}}$.

$$\boldsymbol{\mathcal{E}}(x) = -\partial_0 \mathcal{A}(x) = \mathrm{i}\int \frac{\mathrm{d}^3k}{2(2\pi)^3}\left\{\mathrm{e}^{-\mathrm{i}\omega t}\boldsymbol{\epsilon}_\lambda(\boldsymbol{k})\mathfrak{a}_\lambda(\boldsymbol{k}) - \mathrm{e}^{\mathrm{i}\omega t}\boldsymbol{\epsilon}^*_\lambda(\boldsymbol{k})\mathfrak{a}^\dagger_\lambda(\boldsymbol{k})\right\},$$

$$\left[\mathfrak{a}_\lambda(\boldsymbol{k}), \mathfrak{a}^\dagger_{\lambda'}(\boldsymbol{k}')\right] = 2\hbar\omega(2\pi)^3\delta_{\lambda\lambda'}\delta(\boldsymbol{k}-\boldsymbol{k}'),$$

$$\hat{V}_{E1}(t) = -\mathrm{i}\int \frac{\mathrm{d}^3k}{2(2\pi)^3}\left\{\mathrm{e}^{-\mathrm{i}\omega t}\boldsymbol{d}\cdot\boldsymbol{\epsilon}_\lambda(\boldsymbol{k})\mathfrak{a}_\lambda(\boldsymbol{k}) - \mathrm{e}^{\mathrm{i}\omega t}\boldsymbol{d}\cdot\boldsymbol{\epsilon}^*_\lambda(\boldsymbol{k})\mathfrak{a}^\dagger_\lambda(\boldsymbol{k})\right\}.$$

$$\widehat{\mathbf{V}} = -\frac{e}{mc}\left(\widehat{\mathbf{A}}_{rad}\widehat{\mathbf{p}}\right) + \frac{e^2}{2mc^2}\widehat{\mathbf{A}}^2_{rad} - \mu\left(\widehat{\boldsymbol{\sigma}}\widehat{\mathcal{H}}_{rad}\right),$$

(в кулоновской калибровке), $\widehat{\mathcal{F}}_{\mathrm{rad}} = \mathrm{rot}\,\widehat{\mathbf{A}}_{\mathrm{rad}}$, e, m и μ - электрический заряд, масса и магнитный момент частицы.

Пример: E1-переход 2p → 1s в атоме водорода

$|\mathfrak{i}\rangle = |\,\mathrm{vac}\rangle|2p,m\rangle \quad \mapsto \quad \langle\boldsymbol{r}|\mathfrak{i}\rangle = |\,\mathrm{vac}\rangle\psi_{2p,m}(\boldsymbol{r}) = |\,\mathrm{vac}\rangle R_{2p}(r)y_{1,m}(\theta,\phi).$ $y_{1,\alpha}(\theta,\phi) := \sqrt{\frac{3}{4\pi}}n_\alpha,$

$|\mathfrak{f}\rangle = |\boldsymbol{k}_\mathfrak{f},\lambda_\mathfrak{f}\rangle\,|1s\rangle \quad \mapsto \quad \langle\boldsymbol{r}|\mathfrak{f}\rangle = |\boldsymbol{k}_\mathfrak{f},\lambda_\mathfrak{f}\rangle\frac{1}{\sqrt{4\pi}}R_{1s}(r).$

$$R_{1s}(r) = \frac{2}{\sqrt{a^3}}\mathrm{e}^{-r/a}, \quad R_{2p}(r) = \frac{1}{2\sqrt{6a^5}}r\mathrm{e}^{-r/2a},$$

$$A_{\mathfrak{f}\mathfrak{i}} = -\frac{\mathrm{i}}{\hbar}\int\limits_{-\infty}^{\infty}\mathrm{d}t\mathrm{e}^{\mathrm{i}\omega_{\mathfrak{f}\mathfrak{i}}t}\left\langle\mathfrak{f}\left|\hat{V}_{E1}(t)\right|\mathfrak{i}\right\rangle, \qquad \omega_{\mathfrak{f}\mathfrak{i}} := \frac{1}{\hbar}\{E_{1s}-E_{2p}\} < 0$$

$$\left\langle 1s\left|\boldsymbol{d}^\beta\right|2p,\alpha\right\rangle = \frac{1}{\sqrt{3}}\delta^{\alpha\beta}er_{\mathfrak{f}\mathfrak{i}}.$$

$$\left\langle\boldsymbol{k}_\mathfrak{f},\lambda_\mathfrak{f}\left|\mathfrak{a}^\dagger_\lambda(\boldsymbol{k})\right|\mathrm{vac}\right\rangle = 2\hbar\omega_\mathfrak{f}(2\pi)^3\delta_{\lambda_\mathfrak{f}\lambda}\delta(\boldsymbol{k}_\mathfrak{f}-\boldsymbol{k}).$$

$$\int\frac{\mathrm{d}^3k}{2(2\pi)^3}\boldsymbol{\epsilon}^{*\beta}_\lambda(\boldsymbol{k})\left\langle\boldsymbol{k}_\mathfrak{f},\lambda_\mathfrak{f}\left|\mathfrak{a}^\dagger_\lambda(\boldsymbol{k})\right|\mathrm{vac}\right\rangle = \hbar\omega_\mathfrak{f}\boldsymbol{\epsilon}^{*\beta}_{\lambda_\mathfrak{f}}(\boldsymbol{k}_\mathfrak{f}).$$

$$A_{\mathfrak{f}\mathfrak{i}} = 2\pi\delta(\omega_{\mathfrak{f}\mathfrak{i}}+\omega_\mathfrak{f})\frac{er_{\mathfrak{f}\mathfrak{i}}}{\sqrt{3}}\omega_\mathfrak{f}\epsilon^{*\alpha}_{\lambda_\mathfrak{f}}(\boldsymbol{k}_\mathfrak{f})$$

$$2\pi\delta(\omega)|_{\omega\to0} \mapsto T,$$

$T\to\infty$.

$$\mathrm{d}w_{\mathfrak{f}\mathfrak{i}} = \frac{1}{2l+1}\frac{|A_{\mathfrak{f}\mathfrak{i}}|^2}{T}\frac{\mathrm{d}^3k_\mathfrak{f}}{2\hbar\omega_\mathfrak{f}(2\pi)^3} \overset{\boldsymbol{\epsilon}^*\cdot\boldsymbol{\epsilon}=1}{=} 2\pi\delta(\omega_{\mathfrak{f}\mathfrak{i}}+\omega_\mathfrak{f})\frac{e^2r^2_{\mathfrak{f}\mathfrak{i}}}{9}\omega^2_\mathfrak{f}\frac{\mathrm{d}^3k_\mathfrak{f}}{2\hbar\omega_\mathfrak{f}(2\pi)^3},$$

$$\frac{1}{\tau} := \int\mathrm{d}w_{\mathfrak{f}\mathfrak{i}},$$

$|\boldsymbol{k}_\mathfrak{f}| = \omega_\mathfrak{f}/c, \quad \mathrm{d}^3k_\mathrm{f} = \frac{1}{c^3}\,\mathrm{d}^2\Omega\cdot\omega^2_\mathrm{f}\,\mathrm{d}\omega_\mathrm{f}$

$$\frac{1}{\tau} = \frac{2}{3c^3}\omega^4_\mathrm{f}d^2_{\mathfrak{f}\mathfrak{i}}\frac{1}{\hbar\omega_\mathrm{f}},$$

Формализм и типичные свойствах сложных атомов

Смысл и свойства термов

$$^{2S+1}L_J.$$

Определение термов

(??? потренируюсь на задачах, именно этот параграф и для задач такого типа!)

Первое правило Хунда: в первом порядке ТВ энергия атома имеет минимальное значения в состояниях с максимально возможным значением полного спина S. Если при этом возможны несколько различных значений полного орбитального момента, минимальную энергию имеют состояния с максимальным значением L.

Второе правило Хунда (о влиянии тонкого расщепления): во втором порядке ТВ минимальную энергию имеет терм с $J = |L - S|$, если электронная оболочка заполнена меньше, чем наполовину, и с $J = L + S$, если она заполнена на половину или более.

(!!! порешаю задачи!!!)

(??? почему исключения бывают??)

Определитель Слэтера

$$\Psi^F_{n_1,n_2,...,n_N}(\xi_1,\xi_2,...,\xi_N) = \frac{1}{\sqrt{N!}}\det\begin{pmatrix} \psi_{n_1}(\xi_1) & \psi_{n_2}(\xi_1) & ... & \psi_{n_N}(\xi_1) \\ \psi_{n_1}(\xi_2) & \psi_{n_2}(\xi_2) & ... & \psi_{n_N}(\xi_2) \\ \vdots & & & \vdots \\ \psi_{n_1}(\xi_N) & \psi_{n_2}(\xi_N) & ... & \psi_{n_N}(\xi_N) \end{pmatrix} \qquad \xi := \{\boldsymbol{r}, m_s\},$$

Это общий вид антисимметричной суммы произведения одночастичных волновых функций каждого электрона.

Для двух невзаимодействующих нерелятивистских частиц спиновые и координатные переменные разделяются, при этом формальное выражение имеет одинаковый вид для ферми- и бозе-частиц:

$$\Psi^F_{n_1,n_2}(\xi_1,\xi_2) = \sum_{S,M_S} C_{S,M_S}\Phi^{(S)}_{n_1,n_2}(\mathbf{r}_1,\mathbf{r}_2)\,\lambda(S,M_S).$$

$$\Phi^{(S)}_{n_1,n_2}(\mathbf{r}_1,\mathbf{r}_2) = \frac{1}{\sqrt{2}}\left(\psi_{n_1}(\mathbf{r}_1)\psi_{n_2}(\mathbf{r}_2) + (-1)^S\psi_{n_1}(\mathbf{r}_2)\psi_{n_2}(\mathbf{r}_1)\right).$$

Здесь $n_{1,2}$ - полный набор квантовых чисел одночастичных состояний (без учета спина), $\chi(S,M_S)$ - спиновая функция, описывающая состояние с определенным значением суммарного спина двух частиц S.

Приближение Хартри-Фока

Уравнения Хартри моделируют экранирование потенциальной энергии электрона «облаком» другого.

Уравнения Хартри–Фока по Zhou

Уравнения Хартри–Фока по Киселеву

(не уверен, что это хорошо объяснено тут, потом додумаю)

$$E_A\psi_A = \left\{-\frac{1}{2}\triangle_A - \frac{Z}{r_A} + \phi_B(\boldsymbol{r}_A)\right\}\psi_A,$$
$$E_B\psi_B = \left\{-\frac{1}{2}\triangle_B - \frac{Z}{r_B} + \phi_A(\boldsymbol{r}_B)\right\}\psi_B,$$
$$\phi_B(\boldsymbol{r}_A) = \int \mathrm{d}^3 r_B \frac{\rho_B(\boldsymbol{r}_B)}{|\boldsymbol{r}_A - \boldsymbol{r}_B|}, \qquad \phi_A(\boldsymbol{r}_B) = \int \mathrm{d}^3 r_A \frac{\rho_A(\boldsymbol{r}_A)}{|\boldsymbol{r}_A - \boldsymbol{r}_B|}$$
$$\rho_A(\boldsymbol{r}_A) = |\psi_A(\boldsymbol{r}_A)|^2, \qquad \rho_B(\boldsymbol{r}_B) = |\psi_B(\boldsymbol{r}_B)|^2.$$

(строчка про их идею)

Тут никак не отражено свойство тождественности электронов.

Анзац

$$\psi(\boldsymbol{r}_A, \boldsymbol{r}_B) \approx \psi_S(\boldsymbol{r}_A, \boldsymbol{r}_B) = \left\{\psi_{AB} + (-1)^S \psi_{BA}\right\}/\sqrt{2}$$

и (???? там еще обнуление одно) дает уравнения Хартри-Фока (??)

$$E_A\psi_A = \left\{-\frac{1}{2}\triangle_A - \frac{Z}{r_A} + \phi_B(\boldsymbol{r}_A)\right\}\psi_A + (-1)^S\phi(\boldsymbol{r}_A)\psi_B(\boldsymbol{r}_A),$$
$$E_B\psi_B = \left\{-\frac{1}{2}\triangle_B - \frac{Z}{r_B} + \phi_A(\boldsymbol{r}_B)\right\}\psi_B + (-1)^S\phi^*(\boldsymbol{r}_B)\psi_A(\boldsymbol{r}_B).$$

Самосогласованное поле: конфигурация электронов, термы

Основное состояние

Релятивистские поправки: электронные J-термы

Helium

(спишу у Зу потом, нужно будет - за часа 2 додумаю)

Нерелятивистская задача атома гелия

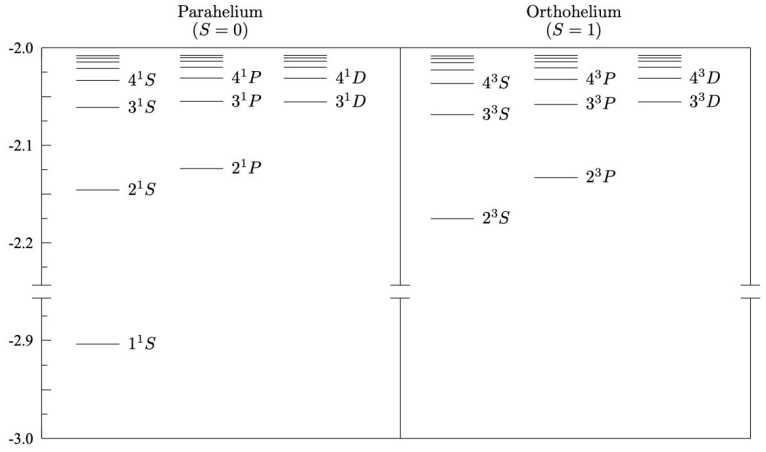
$$\hat{H}_{\mathrm{NR}} = \frac{\boldsymbol{p}_A^2}{2m} + \frac{\boldsymbol{p}_B^2}{2m} - \frac{Ze^2}{r_A} - \frac{Ze^2}{r_B} + \frac{e^2}{|\boldsymbol{r}_A - \boldsymbol{r}_B|}, \quad Z = 2,$$

$S = 0$: (para, a-sym)

$$|1,0\rangle = \frac{1}{\sqrt{2}}\left\{|+\rangle_A|-\rangle_B + |-\rangle_A|+\rangle_B\right\},$$
$$|0,0\rangle = \frac{1}{\sqrt{2}}\left\{|+\rangle_A|-\rangle_B - |-\rangle_A|+\rangle_B\right\},$$

$S = 1$: (orto, sym)

$$|1,+1\rangle = |+\rangle_A|+\rangle_B,$$
$$|1,-1\rangle = |-\rangle_A|-\rangle_B,$$



В атомных единицах (в единицах $a_{\text{Bohr}} = \hbar^2/(me^2)$, а энергия в удвоенных ридбергах $E_0 = \hbar^2/(ma^2)$, например, уровни в водороде в атомных единицах $E_n = -1/(2n^2)$).

Обменное взаимодействие

Об основных методах и уравнениях для многоэлектронного атома

Поправки к центральному потенциалу: термы

Правило интервалов Ланде. Расщепление термов вследствие спин-орбитального взаимодействия происходит с регулярными интервалами по J: разность энергий соседних термов:

$$\Delta \langle V_{ls} \rangle \equiv E\left({}^{2S+1}L_J\right) - E\left({}^{2S+1}L_{J-1}\right) = A_{LS} J \sim J. \qquad \text{(S-O interaction)}$$

(!! решу еще задачи про это!! какое обоснование этого?????)

О методе Томаса-Ферми

We consider degenerate, zero-temperature electron gas in a box of volume V, into which N electrons:

$$\frac{dN}{dk} = \frac{k^2 V}{\pi^2}$$

$$n = \frac{N}{V} = \frac{k_F^3}{3\pi^2}$$
$$k_F = \left(3\pi^2 n\right)^{1/3}.$$

$$E = \frac{\hbar^2 V k_F^5}{10 m \pi^2}$$

$$E = \frac{\hbar^2 \left(3\pi^2 N\right)^{5/3}}{10 m \pi^2} V^{-2/3}$$

$$P = \frac{\hbar^2}{15 m \pi^2} \left(3\pi^2 n\right)^{5/3}, \qquad \text{P=-d E / d V}$$

The net force per unit volume on an element of the electron fluid is the sum of $-\nabla P$ due to the pressure gradient and $\rho \mathbf{E}$ due to the electric field, where ρ is the electron charge density. These forces must balance each other in equilibrium. Since $\rho = -en$ and $\mathbf{E} = -\nabla\Phi$, where Φ is the electrostatic potential, we have the condition for hydrostatic equilibrium,

$$\nabla P = en\nabla\Phi$$

We note that the force per unit volume $-\nabla P$ will be directed outward, since the pressure must increase as we move inward, so the electrostatic force per unit volume $\rho\mathbf{E} = en\nabla\Phi$ must be directed inward. Equation (7) is augmented by the Poisson equation,

$$\nabla^2\Phi = -4\pi\rho = 4\pi ne - 4\pi Ze\delta(\mathbf{x})$$

$$\nabla P = \frac{\hbar^2}{3m}\left(3\pi^2\right)^{2/3} n^{2/3}\nabla n$$

$$\frac{\hbar^2}{3m}\left(3\pi^2\right)^{2/3} n^{-1/3}\nabla n = e\nabla\Phi$$

$$\frac{\hbar^2}{2m}\left(3\pi^2 n\right)^{2/3} = e\left(\Phi - \Phi_0\right) = e\Psi$$

$$\Psi = \Phi - \Phi_0$$

$$\frac{\hbar^2}{2m}\left(3\pi^2 n\right)^{2/3} = \frac{\hbar^2 k_F^2}{2m} = \frac{p_F^2}{2m}$$

$$\frac{p_F^2}{2m} - e\Phi = -e\Phi_0$$

(потом додумаю, см 9 страниц из университета Калифорнии, просто не до этого пока)

ротаторах (???)

(почти не решал про них)
(мб про молекулы простые тоже тут где-то будет раздел, пока не до них)

других важных свойствах атомов

О рентгеновских термах и эффекте Оже

(половину страницы добавлю, что это вообще?)

О мультипольных моментах

(см. пока ЛЛ3, пока не работал с этим, в теории сперва пропишу)

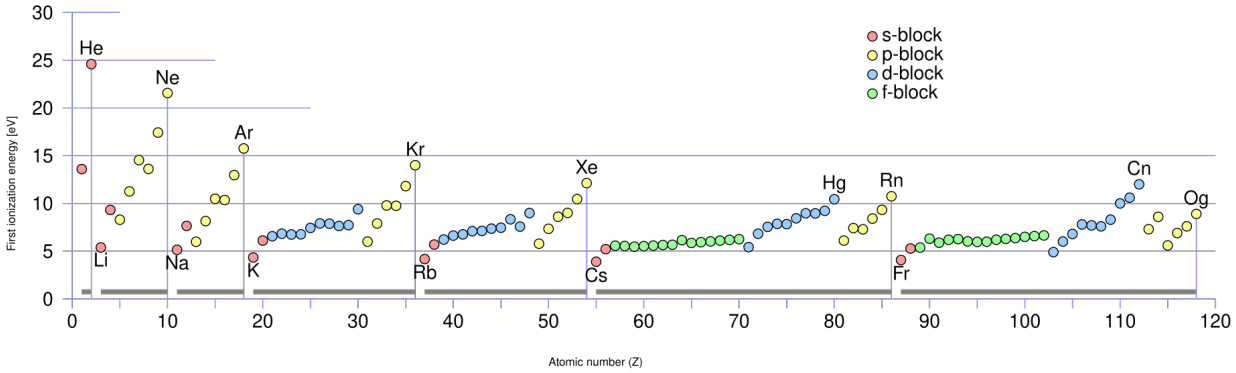
Periodic table

(просто напишу важные факты о ней для задач)

n	l	Degeneracy	N
1	0	2	2
2	0, 1	$2\times(1+3)=8$	$2+8=10$
3	0, 1, 2	$2\times(1+3+5)=18$	$2+8+18=28$
4	0, 1, 2, 3	$2\times(1+3+5+7)=32$	$2+8+18+32=60$

(см. Тонга, не уверен просто, что важные тут темы)

(см. Тонга про это, ну или много что другое)



(четкий ответ на вопрос, где нужны мультипольные моменты???)

(мб другие общие свойства из химии или таблицы менделеева добавлю)

1.4.3 Many-particle condensed systems: basics

(в статфизе и конд средах это много используется, пока там напишу, потом сюда буду переписывать)

Second quantization

$$\hat{a}_i^\dagger \left|..., n_i, ...\right\rangle = \sqrt{n_i + 1} \left|..., n_i + 1, ...\right\rangle$$
$$\hat{a}_i \left|..., n_i + 1, ...\right\rangle = \sqrt{n_i + 1} \left|..., n_i, ...\right\rangle$$

$$[\hat{a}_i, \hat{a}_j] = \hat{a}_i\hat{a}_j - \hat{a}_j\hat{a}_i = \left[\hat{a}_i^\dagger, \hat{a}_j^\dagger\right] = 0, \quad \left[\hat{a}_i, \hat{a}_j^\dagger\right] = \delta_{ij} \qquad \text{for bosons,}$$
$$\{\hat{a}_i, \hat{a}_j\} = \hat{a}_i\hat{a}_j + \hat{a}_j\hat{a}_i = \left\{\hat{a}_i^\dagger, \hat{a}_j^\dagger\right\} = 0, \quad \left\{\hat{a}_i, \hat{a}_j^\dagger\right\} = \delta_{ij} \qquad \text{for fermions.}$$

Basis transformations can be readily imported from the first quantized language

$$|\lambda\rangle = \sum_i \langle i|\lambda\rangle |i\rangle \quad \Rightarrow \quad \hat{a}_\lambda^\dagger = \sum_i \langle i|\lambda\rangle \hat{a}_i^\dagger.$$

While any orthonormal basis leads to an equally valid description of a system, one basis is rather generic as many operators find a natural definition in it: the site basis $|\mathbf{r}\rangle$:

$$\langle \mathbf{r}|i\rangle = \phi_i(\mathbf{r}) \quad |\mathbf{r}\rangle : \quad \text{particle localized at } \mathbf{r}.$$

Creation and annihilation operators in this particular basis get a special name: field operators

$$\hat{\psi}^\dagger(\mathbf{r}) = \sum_i \phi_i^*(\mathbf{r}) a_i^\dagger$$

The kinetic energy:

$$\hat{T} = \sum_{ij} t_{ij} \hat{a}_i^\dagger \hat{a}_j = \sum_{ij} \hat{a}_i^\dagger \hat{a}_j \int d\mathbf{r} \phi_i^*(\mathbf{r}) \left[-\frac{\hbar^2 \nabla^2}{2m} \right] \phi_j(\mathbf{r}) = \frac{\hbar^2}{2m} \int d\mathbf{r} \nabla \hat{\psi}^\dagger(\mathbf{r}) \nabla \hat{\psi}(\mathbf{r})$$

The potential energy:

$$U = \int d\mathbf{r} U(\mathbf{r}) \hat{\psi}^\dagger(\mathbf{r}) \hat{\psi}(\mathbf{r})$$

Two particle interactions:

$$V = \int d\mathbf{r} d\mathbf{r}' \hat{\psi}^\dagger(\mathbf{r}) \hat{\psi}^\dagger(\mathbf{r}') V(\mathbf{r} - \mathbf{r}') \hat{\psi}(\mathbf{r}) \hat{\psi}(\mathbf{r}')$$

And finally the Hamiltonian for particles interacting with a contact pseudo potential

$$H = \int d\mathbf{r} \left[\frac{\hbar^2}{2m} \nabla \hat{\psi}^\dagger(\mathbf{r}) \nabla \hat{\psi}(\mathbf{r}) + U(\mathbf{r}) \hat{\psi}^\dagger(\mathbf{r}) \hat{\psi}(\mathbf{r}) + \frac{4\pi a \hbar^2}{m} \hat{\psi}^\dagger(\mathbf{r}) \hat{\psi}^\dagger(\mathbf{r}) \hat{\psi}(\mathbf{r}) \hat{\psi}(\mathbf{r}) \right]$$

(later I'll add more from QFT and condensed matter)

Тождественные частицы, exchange interaction

$$\psi_{ab}^{(\pm)}(\vec{r}_1, \vec{r}_2) = \psi_a(\vec{r}_1) \psi_b(\vec{r}_2) \pm \psi_a(\vec{r}_2) \Psi_b(\vec{r}_1)$$
$$E^\pm = \frac{\iint \left(\Psi_{ab}^\pm\right)^* U(x_1 x_2) \Psi_{ab}^\pm dx_1 dx_2}{\iint \left(\Psi_{ab}^\pm\right)^* \Psi_{ab}^\pm dx_1 dx_2} = A \pm J$$

(????)

Young tableaux for quantum identical particles

(Ландау писал про это, ну или Тахтаджаян, см. пока их. нужно будет - впишу, пока об этом в записи по алгебре)

Examples of properties of systems of identical particles

(про задачу с 2 или 3 электронами и их симметриями)
(очень важно, указание про задачи в духе "поместим две частицы в яму"!!)

динамике многочастичных систем

(?? как ее по итогу описывать??)

задаче двух тел и разделении переменных

(потом подумаю, куда вставить. есть приложения - тут, чисто с теор т.з. вопрос большой - смещу ниже, в указания на теорию)

Основные формулы задачи двух тел

$$H = -\frac{\hbar^2}{2m_1}\Delta_1 - \frac{\hbar^2}{2m_2}\Delta_2 + V\left(\boldsymbol{x}_1 - \boldsymbol{x}_2\right),$$

$\boldsymbol{r} := \boldsymbol{r}_1 - \boldsymbol{r}_2$, $\boldsymbol{R} := \frac{m_1}{m_1+m_2} r_1 + \frac{m_2}{m_1+m_2}\boldsymbol{r}_2$,

$$\hat{H} = -\frac{\hbar^2}{2m}\Delta_r + V(\boldsymbol{r}) + \left\{-\frac{\hbar^2}{2\left(m_1+m_2\right)}\Delta_R + W(\boldsymbol{R})\right\}$$

$$\hat{H}_r = \frac{\hat{p}^2}{2m} + V(r), \quad \hat{\boldsymbol{p}} = -\mathrm{i}\hbar\nabla_r$$

$$\hat{H}_R = \frac{\hat{\boldsymbol{P}}^2}{2M} + W(\boldsymbol{R}), \quad \hat{\boldsymbol{P}} = -\mathrm{i}\hbar\boldsymbol{\nabla}_R,$$

$M = m_1 + m_2$.

$$\mathscr{H} = L^2\left(\mathbb{R}^6\right) \equiv L^2\left(\mathbb{R}^3, d^3\boldsymbol{X}\right) \otimes L^2\left(\mathbb{R}^3, d^3\boldsymbol{x}\right).$$

1.4.4 Addition of two angular momenta

Самосопряженный оператор $\boldsymbol{M}^2$ в гильбертовом пространстве $L^2\left(S^2, d\boldsymbol{n}\right)$ имеет чисто точечный спектр, состоящий из собственных значений $\hbar^2 l(l+1)$ кратностей $2l+1, l = 0, 1, 2, ...$, и разложение $L^2\left(S^2, d\boldsymbol{n}\right) = \bigoplus_{l=0}^{\infty} \mathscr{D}_l$ дает разложение по его собственным функциям:

$$\psi = \sum_{l=0}^{\infty}\sum_{m=-l}^{l} C_{lm}Y_{lm}, \qquad \forall\psi \in L^2\left(S^2, d\boldsymbol{n}\right); \qquad C_{lm} := \int_0^{2\pi}\int_0^{\pi} \psi(\vartheta,\varphi)\overline{Y_{lm}(\vartheta,\varphi)}\sin\vartheta d\vartheta d\varphi$$

(еще решу про это задачу)

Основная идея и основные формулы сложения моментов

$$\langle j_1, j_2; m_1, m_2 | j_1, j_2; j, m\rangle = (-1)^{j_1 - j_2 + m}\sqrt{2j+1}\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix}$$

$$U(\hat{\mathbf{n}}, \theta) = e^{-i\theta\hat{\mathbf{n}}\cdot(\mathbf{J}_1+\mathbf{J}_2)/\hbar} = U_1(\hat{\mathbf{n}}, \theta)U_2(\hat{\mathbf{n}}, \theta)$$

$$U\left|j_1 j_2 m_1 m_2\right\rangle = \sum_{jm}\sum_{m'} \left|jm'\right\rangle D^j_{m'm}\left\langle jm | j_1 j_2 m_1' m_2'\right\rangle$$

$$U\left|j_1 j_2 m_1 m_2\right\rangle = U_1\left|j_1 m_1\right\rangle U_2\left|j_2 m_2\right\rangle = \sum_{m_1' m_2'}\left|j_1 j_2 m_1' m_2'\right\rangle D^{j_1}_{m_1' m_1} D^{j_2}_{m_2' m_2}$$

$$D^{j_1}_{m_1 m_1'} D^{j_2}_{m_2 m_2'} = \sum_{jmm'}\left\langle j_1 j_2 m_1 m_2 | jm\right\rangle D^j_{mm'}\left\langle jm' | j_1 j_2 m_1' m_2'\right\rangle$$

Основные свойства коэффициентов Клебша-Гордана

(пойму какие основные - напишу сюда.)

(абзац, а что если больше моментов складывается? подробно - мб во 2й 1й части.)

1.4.5 $T \neq 0$ quantum systems, black body

(см. пока статфиз)

Ensembles

Bose-Einstein distribution

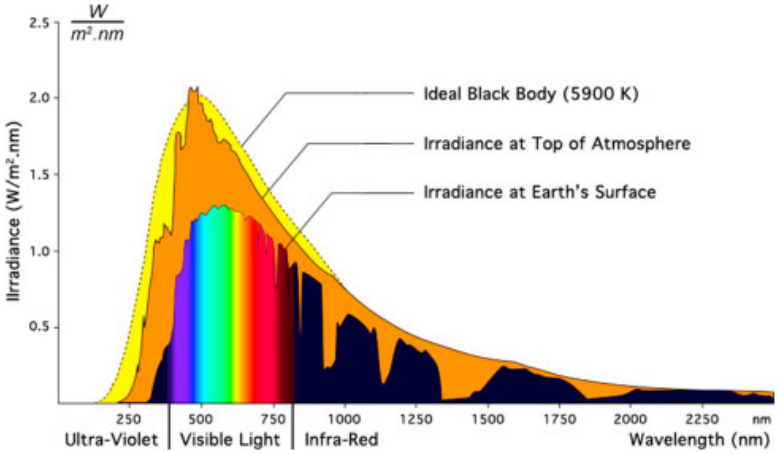
(тут всякие методы для задач, приближения, т.п.)

Fermi-Dirac distribution

(тут всякие методы для задач, приближения, т.п.)

Black body

(см статфиз пока про это, когда-то напишу и сюда. Дело 1 часа, просто не до этого)



(??? абзац, качественно почему такие пропасти в поглощении???)

Kirchhoff's law of thermal radiation:

For an arbitrary body emitting and absorbing thermal radiation in thermodynamic equilibrium, the emissivity function is equal to the absorptivity function.

or, simpler:

For a body of any arbitrary material emitting and absorbing thermal electromagnetic radiation at every wavelength in thermodynamic equilibrium, the ratio of its emissive power to its dimensionless coefficient of absorption is equal to a universal function only of radiative wavelength and temperature. That universal function describes the perfect black-body emissive power

$$\frac{B_\omega}{A_\omega} = \frac{c\rho_\omega}{4\pi}.$$

Тело, для которого $A_\omega = 1$, называется абсолютно черным; оно полностью поглощает падающее на него излучение, "перерабатывая" его в равновесное излучение с температурой, равной температуре тела. Поэтому отношение $\frac{B_\omega}{A_\omega} = \mathcal{E}_\omega$ совпадает с испускательной способностью абсолютно черного тела,

$$\mathcal{E}_\omega = \frac{c\rho_\omega}{4\pi}$$

(тут коротко напоминание формул фотометрии, потому что часто они нужны для задач излучения и определения интенсивности)

Определение, на сколько нагреется тело (?!?!)

(хз, как это сделать, но задачи про это есть, мб см. лабник.)

применении законов излучения черного тела (!!)

(есть задачи про это неочевидные, допишу про них указания)

1.5 Typical models and effects

1.5.1 Qubits, quantum computation

Осцилляции Раби

$$\hat{H} = \begin{pmatrix} E_0 + \Delta & We^{i\chi} \\ We^{-i\chi} & E_0 - \Delta \end{pmatrix}$$

$$E_\pm = E_0 \pm \sqrt{\Delta^2 + W^2}$$

$$|\psi_+\rangle = \begin{pmatrix} \cos\frac{\alpha}{2} \\ e^{-i\chi}\sin\frac{\alpha}{2} \end{pmatrix}, \quad |\psi_-\rangle = \begin{pmatrix} \sin\frac{\alpha}{2} \\ -e^{-i\chi}\cos\frac{\alpha}{2} \end{pmatrix}$$

Пусть система с гамильтонианом (1.69) при $t = 0$ находится в состоянии $|\Psi(0)\rangle = |0\rangle$, какова вероятность $P_1(t)$ обнаружить систему в состоянии $|1\rangle$ в произвольный момент времени t?

$$|\Psi(0)\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} = c_+ |\psi_+\rangle + c_- |\psi_-\rangle$$

$$c_+ = \langle\psi_+|\Psi(0)\rangle = \cos\frac{\alpha}{2}, \quad c_- = \langle\psi - |\Psi(0)\rangle = \sin\frac{\alpha}{2}$$

$$|\Psi(t)\rangle = \cos\frac{\alpha}{2} e^{-\frac{i}{\hbar}E_+ t} |\psi_+\rangle + \sin\frac{\alpha}{2} e^{-\frac{i}{\hbar}E_- t} |\psi_-\rangle$$

$$P_1(t) = \left| e^{-i\chi}\sin\frac{\alpha}{2} e^{-\frac{i}{\hbar}E_+ t}\cos\frac{\alpha}{2} - e^{-i\chi}\cos\frac{\alpha}{2} e^{-\frac{i}{\hbar}E_- t}\sin\frac{\alpha}{2} \right|^2 =$$

$$= \frac{\sin^2\alpha}{4} \left| e^{-\frac{i}{\hbar}E_+ t} - e^{-\frac{i}{\hbar}E_- t} \right|^2 = \sin^2\alpha \sin^2\left(\frac{E_+ - E_-}{2\hbar} t\right)$$

$\Omega := \frac{2\sqrt{\Delta^2+W^2}}{\hbar}$

$$P_1(t) = \frac{W^2}{\Delta^2 + W^2} \sin^2\left(\frac{\Omega t}{2}\right)$$

For the model

$$\hat{H} = \begin{pmatrix} E_0 + \Delta & We^{-i\omega t} \\ We^{i\omega t} & E_0 - \Delta \end{pmatrix}$$

$$P_1(t) = \frac{W^2}{(\Delta - \hbar\omega/2)^2 + W^2} \sin^2\left(\frac{\Omega t}{2}\right), \quad \Omega = \frac{2\sqrt{(\Delta - \hbar\omega/2)^2 + W^2}}{\hbar}$$

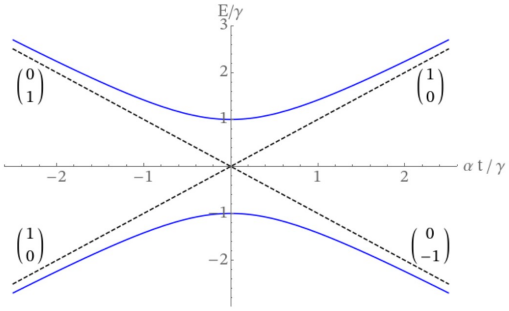
(!!! добавлю графики!!)

(см. запись по квантовой оптике с указанием на другие детали про это. также см. теор раздел, где обсужу подробно это)

Задача Ландау-Зенера

$$\hat{H} = \begin{pmatrix} \alpha t & \gamma \\ \gamma & -\alpha t \end{pmatrix}.$$

$$\psi(-\infty) \sim \begin{pmatrix} 1 \\ 0 \end{pmatrix}; \qquad P(\psi(+\infty) = |\downarrow\rangle) = ?$$



$$\alpha \gg \gamma^2 \qquad \Rightarrow \qquad P_{1\to 2} \approx \pi \frac{\gamma^2}{\alpha}. \qquad \text{big}$$

$$\alpha \ll \gamma^2 \qquad \Rightarrow \qquad P_{1\to 2} = \#e^{-\pi\gamma^2/\alpha} \qquad \text{little}$$

Proof:

$$E_+(t) = \sqrt{\gamma^2 + (\alpha t)^2}, \quad |\psi_+(t)\rangle = \frac{1}{\sqrt{2\left(\gamma^2 + (\alpha t)^2 + \alpha t\sqrt{\gamma^2 + (\alpha t)^2}\right)}} \begin{pmatrix} \sqrt{\gamma^2 + (\alpha t)^2} + \alpha t \\ \gamma \end{pmatrix}$$

$$E_-(t) = -\sqrt{\gamma^2 + (\alpha t)^2}, \quad |\psi_-(t)\rangle = \frac{1}{\sqrt{2\left(\gamma^2 + (\alpha t)^2 - \alpha t\sqrt{\gamma^2 + (\alpha t)^2}\right)}} \begin{pmatrix} \sqrt{\gamma^2 + (\alpha t)^2} - \alpha t \\ -\gamma \end{pmatrix}$$

$$\alpha t = \gamma \sinh\theta$$

$$E_+(\theta) = \gamma\cosh\theta, \quad |\psi_+(\theta)\rangle = \frac{1}{\sqrt{2\cosh\theta}} \begin{pmatrix} e^{\theta/2} \\ e^{-\theta/2} \end{pmatrix}$$

$$E_-(\theta) = -\gamma\cosh\theta, \quad |\psi_-(\theta)\rangle = \frac{1}{\sqrt{2\cosh\theta}} \begin{pmatrix} e^{-\theta/2} \\ -e^{\theta/2} \end{pmatrix}$$

Также Ландау-Зенер имеет точное решение, получаемое методом Лапласа.
(?? решу еще раз. см. записи семинаров птф, там решена она??)
(допишу скоро)

Other features of qubits and similar bits

сфере Блоха (сфере Пуанкаре) и кубитах

(просто известный теор метод, см. кв. оптику)

Qutrits

(??? I'll write something)

Quantum computation: main methods

(see note on q inform for now)

1.5.2 De Broglie waves, photoelectric effect, Compton effect

(мб что-то еще теор про это добвлю сюда, посмотрим)

Об уравнении де Бройля и длине волны де Бройля

$$\lambda \equiv \frac{h}{p} \equiv \frac{h}{mv} \equiv \frac{h}{\sqrt{2mE}}$$

(тут про смысл ее предложения!!)

комптоновской длине волны $\lambda_c = \hbar/(mc)$

Полная энергия $E = E_K + m_0c^2$ включает кинетическую энергию E_K и энергию покоя $E_0 = m_0c^2$, в терминах которых

$$\lambda = \frac{h}{p} = hc\left[E_K\left(E_K + 2m_0c^2\right)\right]^{-1/2}$$

$$p = \frac{E}{c} = \frac{\hbar\omega}{c} = \hbar k = \frac{h}{\lambda}$$

$$p_e = \frac{mc\beta}{\sqrt{1+\beta^2}}.$$

$$T_e = \hbar\omega_0 - \hbar\omega \approx \frac{hc}{\lambda^2}\Delta\lambda$$

$$T_{\max} = T_{\text{back}} = \frac{hc}{\lambda^2}2\lambda_c = \frac{2E^2}{mc^2}$$

Частица, локализованная в области с линейными размерами не более λ_{C}, согласно соотношению неопределённостей имеет квантовомеханическую неопределённость в импульсе не менее mc и неопределённость в энергии не менее mc^2, что достаточно для рождения пар частиц-античастиц с массой m. (!?!?!? почему???)

- пи-мезона: $\bar{\lambda}_{\text{C}}^{\pi} \approx 1,46 \cdot 10^{-15}$ m (характерное расстояние ядерных взаимодействий);
- W-бозона: $\bar{\lambda}_{\text{C}}^{-\text{W}} \approx 2,45 \cdot 10^{-18}$M (характерное расстояние слабых взаимодействий).

простейших столкновениях частиц

Пишем ЗСИ и ЗСЭ, подставляем энергии электронов или фотонов.
(все для общефизных задач про них!)

Об упрощенном фотоэффекте

(формула Эйштейна)
(тут обзор моделей в пару абзацев)

фотоэффекте (!!)

Суть описания фотоэффекта

(коротко все формулы про эту задачу)

О сечении фотоэффекта (!?!?)

$$\sigma = \frac{8}{3}\pi a^2 \alpha_{\text{em}} \left(\frac{4E_{\text{at}}}{\hbar\omega_{\text{i}}}\right)^{7/2}, \qquad \left(\frac{4E_{\text{at}}}{\hbar\omega_{\text{i}}}\right)^{7/2} \ll 1,$$

Proof:

$$|\mathfrak{i}\rangle = |\boldsymbol{k}_{\text{i}}, \lambda_{\text{i}}\rangle\, |\psi_{1\ \text{s}}\rangle\,, \qquad |\mathfrak{f}\rangle = |\,\text{vac}\rangle\, |\boldsymbol{k}_{\mathfrak{f}}\rangle\,.$$

$$\langle \boldsymbol{r}|\psi_{1\ \text{s}}\rangle = \frac{1}{\sqrt{\pi a^3}} \mathrm{e}^{-r/a}.$$

$$\hat{V}(t) = -\boldsymbol{d}\cdot\hat{\mathcal{E}} = -e\boldsymbol{r}\cdot\hat{\mathcal{E}}(\boldsymbol{r},t),$$

$$\mathrm{d}w_{\text{fi}} = \frac{2\pi}{\hbar^2}\delta\left(\omega_{\text{i}} + \omega_{\text{at}} - \omega_{\text{f}}\right) |V_{\text{fi}}(0)|^2 \ \mathrm{d}\nu_{\text{f}},$$

$$\mathrm{d}\nu_{\text{f}} = \frac{\mathrm{d}^3 k_{\text{f}}}{(2\pi)^3},$$

$$\hbar\omega_{\text{f}} = \frac{\hbar^2 k_f^2}{2m},$$

$$\hbar\omega_{\text{at}} = -\frac{\hbar^2}{2ma^2}$$

$$\hat{\mathcal{E}}(\boldsymbol{r}, t=0) = \int \frac{\mathrm{d}^3 k_{\mathbb{E}}}{(2\pi)^3} \frac{\mathrm{i}}{2} \left\{ \mathrm{e}^{\mathrm{i}\boldsymbol{k}\cdot\boldsymbol{r}} \boldsymbol{\epsilon}_\lambda(\boldsymbol{k}) \mathfrak{a}_\lambda(\boldsymbol{k}) - \mathrm{e}^{-\mathrm{i}\boldsymbol{k}\cdot\boldsymbol{r}} \boldsymbol{\epsilon}^*_\lambda(\boldsymbol{k}) \mathfrak{a}^\dagger_\lambda(\boldsymbol{k}) \right\}$$

$$V_{\text{fi}}(0) = -\mathrm{i}e \frac{\partial}{\partial \boldsymbol{k}_{\text{f}}} \int \mathrm{d}^3 r \mathrm{e}^{-\mathrm{i}\boldsymbol{k}_{\text{f}}\cdot\boldsymbol{r}} \frac{1}{\sqrt{\pi a^3}} \mathrm{e}^{-r/a} \mathrm{i}\hbar\omega_{\text{i}} \boldsymbol{\epsilon}_{\lambda_{\text{i}}} \mathrm{e}^{\mathrm{i}\boldsymbol{k}_{\text{i}}\cdot\boldsymbol{r}}$$

$$(qa)^2 \approx (k_{\text{f}} a)^2 \gg 1,$$

$$V_{\text{fi}}(0) \approx -2^5 \pi \hbar\omega_{\text{i}} \frac{e}{\sqrt{\pi a^3}} \left(\boldsymbol{\epsilon}_{\lambda_{\text{i}}} \cdot \boldsymbol{k}_{\mathfrak{f}}\right) \frac{a^5}{(k_{\text{f}} a)^6},$$

$$\Pi^{\alpha\beta} = \sum_{\lambda_{\text{i}}} \epsilon^\alpha_{\lambda_{\text{i}}} \left(\epsilon^\beta_{\lambda_{\text{i}}}\right)^* = \delta^{\alpha\beta} - k_{\text{i}}^\alpha k_{\text{i}}^\beta / \boldsymbol{k}_{\text{i}}^2. \qquad \left(\left(k_{\text{i}}\right)_\alpha \Pi^{\alpha\beta} = 0, \right)$$

$$\frac{1}{2}\sum_{\lambda_{\text{i}}} |V_{\mathfrak{f}\mathfrak{i}}(0)|^2 = 2^7 \pi^2 \frac{\hbar^4}{m^2} \frac{e^2}{\pi a^3} \frac{a^6}{\left(k_{\mathfrak{f}} a\right)^8} k_{\mathfrak{f}}^2 \left(1 - \frac{\left(\boldsymbol{k}_{\mathfrak{f}} \cdot \boldsymbol{k}_{\text{i}}\right)^2}{k_{\mathfrak{f}}^2 k_{\text{i}}^2}\right).$$

$$w_{\text{fi}} = \int_0^{2\pi} \mathrm{d}\phi \int_{-1}^{1} \mathrm{d}\cos\theta \cdot \left(1 - \cos^2\theta\right) \int_0^\infty \frac{k_{\text{f}}^2\, \mathrm{d}k_{\text{f}}}{(2\pi)^3} \frac{2\pi}{\hbar^2} \delta\left(\omega_{\text{i}} - \frac{\hbar k_{\text{f}}^2}{2m}\right) 2^9 \pi^2 \frac{\hbar^5 c}{m^2} \alpha_{\text{em}} \frac{a}{\left(k_{\text{f}} a\right)^6} =$$

$$= 2\pi \cdot \frac{4}{3} \cdot \frac{k_{\text{f}}^2}{(2\pi)^3} \frac{2\pi}{\hbar^2} \frac{m}{\hbar k_{\text{f}}} 2^9 \pi^2 \frac{\hbar^5 c}{m^2} \alpha_{\text{em}} \frac{a}{\left(k_{\text{f}} a\right)^6} =$$

$$= \frac{2^{10}}{3} \pi \frac{\hbar^2 c}{m} \alpha_{\text{em}} \frac{1}{\left(k_{\text{f}} a\right)^5}.$$

Полное сечение фотоэффекта σ выражается через вероятность квантового перехода в единицу времени и поток фотонов

$$j_\mathrm{i} = c \cdot 2\hbar\omega_\mathrm{i},$$

так что

$$\sigma = \frac{w_\mathrm{fi}}{j_\mathrm{i}}.$$

В рассматриваемой задаче

$$j_\mathrm{i} = c \cdot \frac{\hbar^2 k_\mathrm{f}^2}{m},$$

и

$$\sigma = \frac{2^{10}}{3}\pi a^2 \alpha_\mathrm{em} \frac{1}{(k_\mathrm{f} a)^7} = \pi a^2 \alpha_\mathrm{em} \frac{2^{10}}{3} \frac{1}{(k_\mathrm{f} a)^7}.$$

$$\sigma = \frac{8}{3}\pi a^2 \alpha_\mathrm{em} \left(\frac{4E_\mathrm{at}}{\hbar\omega_\mathrm{i}}\right)^{7/2} \qquad \frac{2^7}{(k_\mathrm{f} a)^7} = \left(\frac{4E_\mathrm{at}}{\hbar\omega_\mathrm{i}}\right)^{7/2} \ll 1,$$

(абзац про другие свойства, а также про экспериментальные результаты. пока не актуально, потом додумаю.)

О влиянии фотоэффекта на разные процессы и применениях

(отсылка ко многим задачам Овчинкина, да и вообще многие эксперименты по нему ставятся)

О других фотоэффектах

(мб допишу, пока не до этого, мб есть они, там внутренний, т.п.)

Об эффекте Комптона (!!!)

(очень годно нужно прописать)

О типичном эффекте Комптона

$$\lambda_\text{расс.} - \lambda_\text{пад.} = \Lambda_\mathrm{K}(1 - \cos\theta),$$
$$\Lambda_\mathrm{K} := \frac{h}{mc} = 2,42 \cdot 10^{-10}\text{см}.$$

Он получается из ЗСЭ и ЗСИ:

$$mc^2 + \hbar\omega_0 = \gamma mc^2 + \hbar\omega_1,$$
$$\frac{\hbar\omega_0}{c} = \gamma mv\cos\varphi + \frac{\hbar\omega_1}{c}\cos\theta$$
$$\gamma mv \sin\varphi = \frac{\hbar\omega_1}{c}\sin\theta$$

Тут считаем, что электрон покоится вначале и проецируем импульсы на две оси - так что имеем два уравнения. (???? еще раз это сделаю.)

Об обратном эффекте Комптона

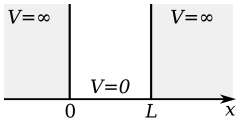
(встетилось, укажу)

О другом про эффект Комптона

1.5.3 1D scatterings and bound states

моделях связных состояний

1D wall with infinite walls



$$\psi'' + \frac{2m}{h^2}(E - U(x))\psi(x) = 0 \qquad \psi(0) = \psi(a) = 0$$

$$\psi_n(x) = \begin{cases} \sqrt{\frac{2}{a}} \sin \frac{\pi n}{a} x, & x \in \{0, a\} \\ 0, & x \notin \{0, a\} \end{cases},$$

$$k: \quad ka = \pi n, \quad n \in \mathbb{N},$$

$$E_n = \frac{\hbar^2 k^2}{2m} = \frac{\hbar^2 \pi^2 n^2}{2ma^2}.$$

$$\langle x \rangle = \int_0^a dx \psi^2(x) x = \frac{a}{2}, \qquad \rho(x) = 1/a$$

$$\langle x^2 \rangle = \int_0^a dx \psi^2(x) x^2 = \frac{a^2}{3} - \frac{a^2}{2\pi^2 n^2}$$

$$(\Delta x)^2 = \frac{a^2}{12}\left(1 - \frac{6}{\pi^2 n^2}\right), \qquad \overline{(\Delta \hat{x})^2} = \frac{a^2}{12}$$

$$(\Delta p)^2 = \langle p^2 \rangle = \langle 2mE_n \rangle = \frac{\hbar^2}{a^2}\pi^2 n^2.$$

То есть имеем просто равномерное распределение, но с квантовыми поправками, которые свои для каждого энергетического уровня.

$$(\Delta x)^2 (\Delta p)^2 = \frac{\hbar^2}{12}\left(\pi^2 n^2 - 6\right) \geqslant \frac{\hbar^2}{4},$$

$$\Delta\Gamma|_{\Delta n = 1} = \frac{d\Delta\Gamma}{dn}\Delta n \to \frac{\hbar}{2\sqrt{3}}\pi.$$

В импульсном представлении:

$$\psi_n(p) \equiv \langle p|n\rangle = \int_0^1 \langle p|x\rangle\langle x|n\rangle dx = \int_0^1 \frac{1}{\sqrt{2\pi}} e^{-ipx}\sqrt{2}\sin n\pi x dx = -i2\sqrt{\pi}\mathrm{e}^{-i\frac{(p-n\pi)}{2}} \frac{n\sin\left(\frac{p-n\pi}{2}\right)}{p^2 - (n\pi)^2}.$$

В квазиклассическом приближении ($n \gg 1$) вблизи $p = \pm n\pi$

$$|\psi_n(p)|^2 \simeq \frac{\sin^2(\varepsilon/2)}{\pi\varepsilon^2}, \qquad \int_{-\infty}^{\infty} \frac{\sin^2(\varepsilon/2)}{\pi\varepsilon^2} d\varepsilon = \frac{1}{2\pi}\int_{-\infty}^{\infty} \frac{\sin^2 x}{x^2} dx = \frac{1}{2},$$

$\varepsilon = p \pm n\pi$, что соответствует классической плотности вероятности распределения по импульсам:

$$\rho(p) = \frac{1}{2}\delta\left(p - p_n\right) + \frac{1}{2}\delta\left(p + p_n\right), \quad p_n = \sqrt{2E_n} = \pi n.$$

О типичных одномерных ямах

(по идее тут заготовка к задачам овчинкина)

В симметричной потенциальной яме $V_1 = V_2 = V$ при любых V и a всегда имеется по крайней мере один уровень. (решал про это задачу)

(тут про особенности мелкой ямы!)

О средних значениях (?!?!)

(для тривиальных задач указания)

В трехмерном пространстве при описании системы волновой функцией $\langle A \rangle = \int\limits_V |\psi|^2 A dV$, $dV = 4\pi r^2 dr$.

(?? слышал, что средние могут становиться бесконечностью, что тогда? не знаю. проверить нужно, действительно ли в тогда волновая функция в $L^2(U)$, U - область определения системы. мб всегда и окажется, что нет, она не в этой области? не знаю в общем, наверняка с этим могут быть проблемы)

О мелкой яме (!?!??!!?)

(!! словами допишу указание про потенциал)

$$U_0 \ll \hbar^2/ma^2$$

$$\frac{p^2}{2m}\psi(p) + U_p \int (dp')\,\psi(p') \approx E\psi(p)$$

$$\psi(\boldsymbol{p}) = -\frac{U_{\boldsymbol{p}}}{-E + \frac{p^2}{2m}} \int (d\boldsymbol{p}')\,\psi(\boldsymbol{p}') = -\frac{U_{\boldsymbol{p}}}{-E + \frac{p^2}{2m}},$$

$$|U_{p=0}| \int \frac{(dp)}{|E| + \frac{p^2}{2m}} \approx 1$$

$|U_{\boldsymbol{p}=0}| = -U_{\boldsymbol{p}=0}, \quad |E| = -E.$

При $d = 1$ всегда есть уровень: имеем $|U_{\boldsymbol{p}=0}| \sqrt{\frac{m}{2|E|}} = 1$, получаем

$$|E| = \frac{m}{2\hbar^2} \left| \int\limits_{-\infty}^{\infty} U(x) dx \right|^2$$

При $d = 2$ уровень мелкий, из $\int \frac{d^2p}{(2\pi)^2} \frac{1}{|E| + \frac{p^2}{2m}} = \int \frac{2\pi p dp}{4\pi^2} \frac{1}{|E| + \frac{p^2}{2m}} \approx \frac{m}{\pi} \int\limits_{\sim\sqrt{mE}}^{\sim 1/a} \frac{dp}{p} = \frac{m}{2\pi} \ln \frac{\#}{ma^2|E|}$ (???? масштаб обрезания введен???? что с расходимостью???) получаем

$$|E| = \#\frac{\hbar^2}{ma^2} \exp\left(-\frac{2\pi\hbar^2}{m} \left| \int U(r) d^2 r \right|^{-1} \right)$$

(???? непонятно откуда минус и $\hbar$ мы почему-то восстанавливаем?? что делать с $\#$?? в общем, задача точно не дорешена.)

При $d \geq 3$ связных состояний нет. Доказательство: на больших импульсах $\int \frac{(dp)}{|E| + \frac{p^2}{2m}}$ может быть обрезан на $\sim 1/a$; Имеем $\int \frac{(dp)}{|E| + \frac{p^2}{2m}} \sim ma^{2-d}$ и $U_{p=0} \sim U_0 a^d$; поэтому $\int \frac{(dp)}{|E| + \frac{p^2}{2m}} U_{p=0} \sim \frac{U_0}{\hbar^2/ma^2} \ll 1$. Сделать это выражение порядка единицы, изменяя энергию, невозможно, вот и видим, что уравнение самосогласования не имеет решений. (??????? оценку интеграла пока что не понял???? подумаю лучше про это потом.)

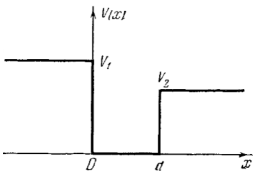
Об элементарных моделях рассеяния (!!!!)

(тут к общефизу заготовки!!!)

Рассеяние на ступеньке:

Рассеяние на яме

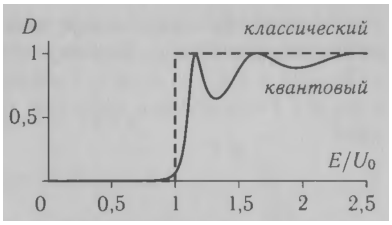
Для потенциала



(!! скоро впишу ответ!)

Надбарьерные и подбарьерные отражения (!!)

$$U(x) = \begin{cases} -U_0, & |x| < a/2 \\ 0, & |x| > a/2 \end{cases}$$



D в квантовом случае достигает $D = 1$ (классический предел) лишь при $k_1 a = \pi n,\ n = 1, 2, ...$

Proof:

$$\psi(x) = \begin{cases} e^{ikx} + Ae^{-ikx}, & x < -a/2, \\ Ce^{ik_1 x} + De^{-ik_1 x}, & |x| < a/2, \\ Be^{ikx}, & x > a/2, \end{cases} \qquad \begin{aligned} k^2 &:= \frac{2mE}{\hbar^2} > 0, \\ k_1^2 &:= \frac{2m\left(E + U_0\right)}{\hbar^2}. \end{aligned}$$

$\psi_{x=\pm a/2+0} = \psi_{x=\pm a/2-0}, \quad \psi'_{x=\pm a/2+0} = \psi'_{x=\pm a/2-0} \quad \Rightarrow$

$$A = \frac{ie^{-ika}\left(k_1^2 - k^2\right)\sin k_1 a}{2kk_1 \cos k_1 a - i\left(k_1^2 + k^2\right)\sin k_1 a}, \qquad B = \frac{2kk_1 e^{-ik_1 a}}{2kk_1 \cos k_1 a - i\left(k_1^2 + k^2\right)\sin k_1 a}.$$

$$R = \frac{\left|j_x^{\text{ref}}\right|}{\left|j_x^{\text{in}}\right|} = |A|^2 = \frac{\left(k_1^2 - k^2\right)\sin^2 k_1 a}{4k_1^2 k^2 \cos^2 k_1 a + \left(k_1^2 + k^2\right)^2 \sin^2 k_1 a} = \frac{\left(k_1^2 - k^2\right)\sin^2 k_1 a}{4k_1^2 k^2 + \left(k_1^2 - k^2\right)^2 \sin^2 k_1 a}.$$

$$D = \frac{\left|j_x^{\text{tr}}\right|}{\left|j_x^{\text{in}}\right|} = |B|^2 = \frac{4k_1^2 k^2}{4k_1^2 k^2 \cos^2 k_1 a + \left(k_1^2 + k^2\right)^2 \sin^2 k_1 a} = \frac{4k_1^2 k^2}{4k_1^2 k^2 + \left(k_1^2 - k^2\right)^2 \sin^2 k_1 a}.$$

$D + R = 1.$

$$U(x) = \begin{cases} 0, & |x| > a/2, \\ U_0, & |x| < a/2, \end{cases}$$

we take the solutions above and set $k_1^2 = \frac{2m}{\hbar^2}(E + U_0)$ осуществить замену $U_0 \to -U_0$. При $0 < E < U_0$ нужно дополнительно положить $k_1 = i\varkappa_1$, $\varkappa_1^2 = \frac{2m}{\hbar^2}(U_0 - E)$. В результате получаем

$$R = \frac{(\varkappa^2 + k^2)\,\mathrm{sh}^2\,\varkappa_1 a}{4\varkappa_1^2 k^2 + (\varkappa_1^2 + k^2)^2\,\mathrm{sh}^2\,\varkappa_1 a}, \qquad D = \frac{4\varkappa_1^2 k^2}{4\varkappa_1^2 k^2 + (\varkappa_1^2 + k^2)^2\,\mathrm{sh}^2\,\varkappa_1 a}$$

Models with δ-potentials

δ-potential

(впишу скоро, см. пока задачи)
Bound states:

$$\psi_0(p) \equiv \langle p|0\rangle = \int\limits_{-\infty}^{\infty} dx \langle p|x\rangle\langle x|0\rangle = \frac{\sqrt{\varkappa_0}}{(2\pi\hbar)^{1/2}} \int\limits_{-\infty}^{\infty} e^{-\varkappa_0|x| - \frac{ipx}{\hbar}} dx = \sqrt{\frac{2}{\pi}} \frac{(\varkappa_0\hbar)^{3/2}}{(\varkappa_0\hbar)^2 + p^2}$$

$$\psi(x) = \sqrt{\varkappa}\exp(-\varkappa|x|)$$

Scattering:

$$t = \frac{1}{1 - \frac{m\lambda}{i\hbar^2 k}}, \qquad r = \frac{1}{\frac{i\hbar^2 k}{m\lambda} - 1}.$$

$$R = |r|^2 = \frac{1}{1 + \frac{\hbar^4 k^2}{m^2\lambda^2}}, \qquad T = |t|^2 = 1 - R = \frac{1}{1 + \frac{m^2\lambda^2}{\hbar^4 k^2}}$$

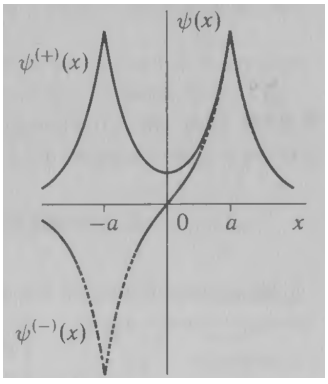
$$U(x) = -\frac{\hbar^2}{m} x_0 \delta(x)$$

Переобозначим $x^2 = \frac{2m|E|}{\hbar^2}$

$$\psi''(x) - \left(x^2 - 2x_0\delta(x)\right)\psi(x) = 0$$

$\psi(+0) = \psi(-0)$
$\psi'(+0) - \psi'(-0) = -2x_0\psi(0)$
$j(+0) = j(-0)$

Double δ-potential



$$-\frac{\hbar^2}{2m}\frac{d^2\psi(x)}{dx^2}+V(x)\psi(x)=E\psi(x) \qquad V(x)=-q\left[\delta\left(x+\frac{R}{2}\right)+\lambda\delta\left(x-\frac{R}{2}\right)\right]$$

wavefunction matching,

$$\psi(x)=Ae^{-d|x+\frac{R}{2}|}+Be^{-d|x-\frac{R}{2}|}. \quad R=2$$

$$\begin{vmatrix} q-d & qe^{-dR} \\ q\lambda e^{-dR} & q\lambda-d \end{vmatrix}=0, \qquad \text{where } E=-\frac{d^2}{2}.$$

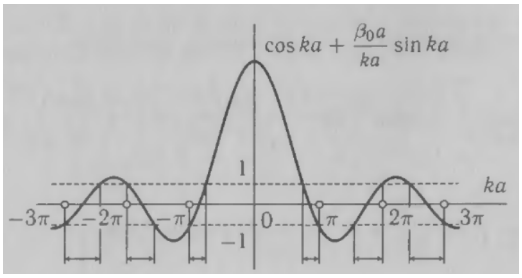
$$d_\pm(\lambda)=\frac{1}{2}q(\lambda+1)\pm\frac{1}{2}\left\{q^2(1+\lambda)^2-4\lambda q^2\left[1-e^{-2d_\pm(\lambda)R}\right]\right\}^{1/2}$$

$$d_\pm=q\left[1\pm e^{-d_\pm R}\right].$$

Moving δ-potential

Kroning-Penny model $U(x)=\sum\limits_{n=-\infty}^{\infty}\frac{\hbar^2\beta_0}{m}\delta(x-na)$

(??)



1.5.4 Oscillator

Основные формулы

$$H=-\frac{\hbar^2}{2m}\frac{d^2}{dq^2}+\frac{m\omega^2q^2}{2}=\hbar\omega\left(\hat{a}^\dagger\hat{a}+\frac{1}{2}\right)$$

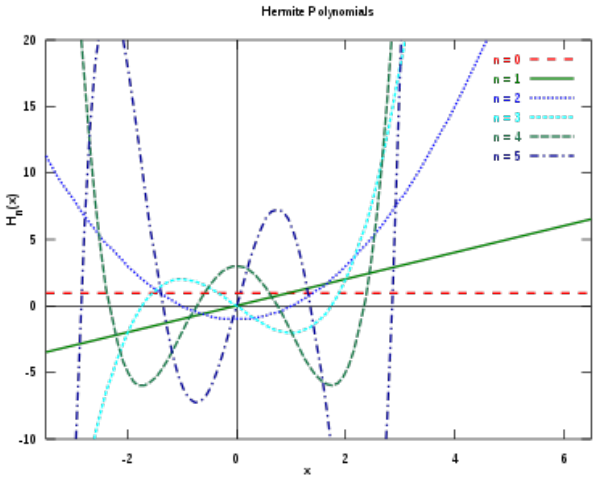
$$a=\frac{1}{\sqrt{2\omega\hbar}}(\omega Q+iP), \qquad a^*=\frac{1}{\sqrt{2\omega\hbar}}(\omega Q-iP)$$

$$\hat{x}=\sqrt{\frac{\hbar}{2m\omega}}\left(\hat{a}+\hat{a}^\dagger\right) \qquad \hat{p}=-i\sqrt{\frac{\hbar m\omega}{2}}\left(\hat{a}-\hat{a}^\dagger\right)$$

$$[a,a^*]=I$$

$$\psi_0(x) = \frac{1}{(\pi\ell^2)^{1/4}} e^{-\xi^2/2}, \qquad h_1(x) = \frac{2\xi}{(4\pi\ell^2)^{1/4}} e^{-\xi^2/2},$$
$$\psi_2(x) = \frac{2\xi^2 - 1}{(4\pi\ell^2)^{1/4}} e^{-\xi^2/2}, \qquad h_3(x) = \frac{2\xi^3 - 3\xi}{(9\pi\ell^2)^{1/4}} e^{-\xi^2/2}$$

$\omega = \sqrt{\frac{k}{m}}, \qquad \ell = \sqrt{\frac{\hbar}{m\omega}}, \qquad \xi = \frac{x}{\ell}$



$$\psi_n(q) = \sqrt[4]{\frac{m\omega}{\pi\hbar}} \frac{1}{\sqrt{2^n n!}} e^{-\frac{m\omega}{2\hbar}q^2} H_n\left(\sqrt{\frac{m\omega}{\hbar}} q\right) =$$
$$= \frac{(a^*)^n}{\sqrt{n!}} \psi_0 \equiv \frac{1}{\sqrt{n!}} \left(\frac{1}{\sqrt{2\omega\hbar}} \left(\omega q - \hbar \frac{d}{dq}\right)\right)^n \psi_0$$

Proof: $y = x\sqrt{\frac{m\omega}{\hbar}}$ и $E = \hbar\omega\left(\epsilon + \frac{1}{2}\right)$, получаем $\psi''(y) + (2\epsilon + 1 - y^2)\,\psi(y) = 0$, потом заменой $y = \sqrt{z}$,

$$4z\psi''(z) + 2\psi'(z) + (2\epsilon + 1 - z)\psi(z) = 0.$$
$$\psi(z) = \chi(z)e^{-z/2}$$
$$z\chi''(z) + \left(\frac{1}{2} - z\right)\chi'(z) + \frac{\epsilon}{2}\chi(z) = 0$$
$$\chi(z) = C_1 \cdot {}_1F_1\left(-\frac{\epsilon}{2}; \frac{1}{2}; z\right) + C_2\sqrt{z} \cdot {}_1F_1\left(-\frac{\epsilon - 1}{2}; \frac{3}{2}; z\right) \qquad b = \frac{1}{2}, a = -\frac{\epsilon}{2}$$

В общем случае ${}_1F_1 \sim e^z$, что соответствует экспоненциально растущей волновой функции и нас не устраивает, поэтому ряд должен обрываться.

(!!! подробнее про этот обрыв ряда!!!)

Осцилляторная теорема - Волновая функция n-того возбуждённого состояния содержит ровно n узлов (нулей волновой функции). Так, например, основное состояние узлов вовсе не содержит.

(??????????????)

Для a, a^* и $N = a^*a$

$$[N, a] = -a, \quad [N, a^*] = a^*, \quad [a, a^*] = I$$

(???????)

Это неприводимое унитарное представление четырехмерной разрешимой алгебры Ли $\tilde{\mathfrak{h}}$, ассоциированной с алгеброй Гейзенберга $\mathfrak{h} = \mathfrak{h}_1$: $\tilde{\mathfrak{h}}$ - алгебра Ли с образующими e, f, h, и c, e, f, c удовлетворяют соотношениям алгебры Гейзенберга $\mathfrak{h}$ и

$$[h, e] = -f, \quad [h, f] = \omega^2 e, \quad [h, c] = 0.$$

(?????)

Неприводимое интегрируемое представление ρ алгебры Гейзенберга $\mathfrak{h}$ (?????) продолжается до унитарного представления алгебры Ли $\tilde{\mathfrak{h}}$, если положить $\rho(h) = -i\omega N = \frac{P^2+\omega^2 Q^2}{2i\hbar} + \frac{i\omega}{2} I$.

В инвариантных терминах алгебра Ли $\tilde{\mathfrak{h}}$ - одномерное правое расширение алгебры Гейзенберга $\mathfrak{h}$,

$$0 \to \mathfrak{h} \to \tilde{\mathfrak{h}} \to \mathbb{R} \to 0.$$

Оно определяется $\mathfrak{h}$-значным 1-коциклом $r \in Z^1(\mathfrak{h}, \mathfrak{h})$ на алгебре Ли - дифференциальным оператором на $\mathfrak{h}$, задаваемым на образующих формулой

$$r(e) = f, \quad r(f) = -\omega^2 e, \quad r(c) = 0.$$

Конкретно, если $h \in \tilde{\mathfrak{h}}$ таково, что $\bar{h} = 1 \in \mathbb{R}$ при проекции $\tilde{\mathfrak{h}} \to \mathbb{R}$, то, отождествляя элементы $\mathfrak{h}$ с их образами при вложении $\mathfrak{h} \hookrightarrow \tilde{\mathfrak{h}}$, имеем

$$[x + \alpha h, y + \beta h] = [x, y] - \alpha r(y) + \beta r(y), \quad x, y \in \mathfrak{h}.$$

(!! из ЛШ выпишу важные формулы, уже решил задачу ту!!!)

Solution осциллятора в сферических координатах

(тут очень нетривиальные методы, потом пропишу их, пока это в задаче написано)

Об осцилляторе с n степенями свободы

$$H = -\frac{\hbar^2}{2m}\Delta + \sum_{j=1}^{n} \frac{m\omega_j^2 q_j^2}{2}$$

$$E_{n_x n_y n_z} = \frac{2n_x + 2n_y + 2n_z + 3}{2}\hbar\omega$$

$$\psi_{n_x n_y n_z} = h_{n_x}(x) h_{n_y}(y) h_{n_z}(z)$$

$$\lambda_k = \hbar\omega_1 \left(k_1 + \frac{1}{2}\right) + ... + \hbar\omega_n \left(k_n + \frac{1}{2}\right)$$

моделях с осциллятором

Часто есть какое-то возмущение зависящее от x, тогда просто расписываем его через операторы рождения, уничтожения и по теории возмущений находим поправки. Нужно только аккуратно преобразовывать их.

(!! кстати, добавлю пару заготовок преобразований сюда!)

Quantum Quench of a Harmonic Oscillator by Tong:

$$H_0 = \frac{p^2}{2m} + \frac{1}{2}\omega_0^2 x^2 = \hbar\omega_0\left(a_0^\dagger a_0 + \frac{1}{2}\right)$$

$a_0 = \frac{1}{\sqrt{2m\omega_0}}(m\omega_0 x + ip)$

$$\tau \ll \hbar/\omega_0 \qquad H = \frac{p^2}{2m} + \frac{1}{2}\omega^2 x^2 = \hbar\omega\left(a^\dagger a + \frac{1}{2}\right)$$

$$|\emptyset\rangle = \sum_{n=0}^{\infty} \alpha_{2n}|2n\rangle \qquad \alpha_{2n+2} = \sqrt{\frac{2n+1}{2n+2}}\left(\frac{\omega-\omega_0}{\omega+\omega_0}\right)\alpha_{2n}$$

We can also address more detailed questions about the dynamics. Suppose that the quench takes place at time $t = 0$. Working in the Heisenberg picture, we know that

$$\langle\emptyset|x^2(0)|\emptyset\rangle = \frac{\hbar}{2m\omega_0} \qquad \langle\emptyset|p^2(0)|\emptyset\rangle = \frac{\hbar m\omega_0}{2}$$

$$x(t) = x(0)\cos(\omega t) + \frac{p(0)}{m\omega}\sin(\omega t)$$

$$\langle\emptyset|x\left(t_2\right)x\left(t_1\right)|\emptyset\rangle = \frac{\hbar}{2m\omega}\left[e^{-i\omega(t_2-t_1)} + \frac{\left(\omega^2-\omega_0^2\right)\cos\left(\omega\left(t_2+t_1\right)\right) + \left(\omega-\omega_0\right)^2\cos\left(\omega\left(t_2-t_1\right)\right)}{2\omega\omega_0}\right]$$

The quench term not T-invariant. The state carries a memory of the traumatic event that happened during the quench.

(????)

применениях осциллятора

(абзац про квантовые поля, типа это основная модель для них)

(короткий абзац, что если действует сила, то решаем через какую-то функцию, забыл....)

Coherent states (????)

$$T(a) := e^{-ia\hat{p}}, \qquad S(b) := e^{ib\hat{x}}$$

$$(T(a)\psi)(x) = \psi(x-a), \quad (T(a)\phi)(p) = e^{-iap}\phi(p)$$
$$(S(b)\psi)(x) = e^{ibx}\psi(x), \quad (S(b)\phi)(p) = \phi(p-b)$$

$$S(b)T(a) = e^{iab}T(a)S(b)$$

$$W(a,b) := e^{i(b\hat{x}-a\hat{p})}$$

$$W(a,b) = e^{iab/2}T(a)S(b) = e^{-iab/2}S(b)T(a)$$

$$|a,b\rangle := W(a,b)|0\rangle$$

$$W(x,p) = \exp(i(p\hat{x} - x\hat{p})) = \exp\left(za^\dagger - \bar{z}a\right) \equiv D(z)$$

$$D(z) = e^{-|z|^2/2} \exp\left(za^\dagger\right) \exp(-\bar{z}a)$$

$$|z\rangle = e^{-|z|^2/2} \exp\left(za^\dagger\right)|0\rangle = e^{-|z|^2/2} \sum_{n=0}^{\infty} \frac{z^n}{\sqrt{n!}}|n\rangle.$$

$$\langle z|\hat{n}|z\rangle = \langle z|a^\dagger a|z\rangle = z^* z\langle z|z\rangle = |z|^2$$
$$\langle z|\hat{n}^2|z\rangle = \langle z|a^\dagger a a^\dagger a|z\rangle = |z|^2\langle z|aa^\dagger|z\rangle = |z|^4 + |z|^2$$
$$U(t)|z\rangle = e^{-it/2}\left|e^{-it}z\right\rangle$$

$$\langle w|z\rangle = e^{w^* z} e^{-|z|^2/2} e^{-|w|^2/2}$$

$$|\langle w|z\rangle|^2 = e^{-|w-z|^2}$$

$$\int \frac{dxdp}{2\pi}|z\rangle\langle z| = 1 \qquad \text{overcomplete}$$

$$\frac{1}{2\pi}\int dxdp e^{-|z|^2} \frac{z^n (z^*)^m}{\sqrt{n!m!}} = \int d|z|^2 e^{-|z|^2} \int \frac{d\varphi}{2\pi} \frac{z^n (z^*)^m}{\sqrt{n!m!}}$$

Coherent states are ubiquitous in nature, because they are generically produced by classically driving a harmonic oscillator:

$$x(t) = x_0(t) + \int dt' \sin(t-t')\,\theta(t-t')\,f(t')$$

$$\hat{x}(t) = \frac{\hat{a}e^{-it} + \hat{a}^\dagger e^{it}}{\sqrt{2}} + \int dt' \frac{i\theta(t-t')\,f(t')}{2}\left(e^{-i(t-t')} - e^{-i(t-t')}\right)$$

$$\hat{x}(t) = \frac{1}{\sqrt{2}}\left(\left(\hat{a} + \frac{i}{\sqrt{2}}\tilde{f}(1)\right)e^{-it} + \left(\hat{a}^\dagger - \frac{i}{\sqrt{2}}\tilde{f}(-1)\right)e^{it}\right)$$

(??!! конкретно, где они используются! примеры с формулами)

голоморфном представлении (?????)

(пока не нужно никогда было, и не усвоено еще.)

фермионном осцилляторе

Суть (??)

применения фермионного осциллятора (??)

(зачем он нужен????)

другом про осциллятор

О важности осциллятора для понимания квантования

(часто эта модель используется, так что пару абзацев напишу, как же так?)

1.5.5 Motion in a central field, hydrogen

Основное об атоме водорода

Основные формулы центрального поля и водорода

A.e. длины (боровский радиус): $a = \frac{\hbar^2}{m_e e^2} = 0,529 \cdot 10^{-8}$c.
A.e. энергии: $E_a = \frac{e^2}{a} = \frac{m_e e^4}{\hbar^2} = 27,21$ эВ.
A. e. скорости: $v_a = \frac{e^2}{\hbar} = 2,2 \cdot 10^8$ cm/c.
A. e. времени: $\tau_a = \frac{\hbar a}{e^2} = \frac{\hbar^3}{m_e e^4} = 2,42 \cdot 10^{-17}$c.
A. e. частоты: $\nu_a = \frac{m_e e^4}{\hbar^3} = 4,13 \cdot 10^{16}$c^{-1}.
A. e. напряженности электрического поля: $\varepsilon_a = \frac{e}{a^2} = 5,14 \cdot 10^9$ В/ см.

$$E_n = -\mathrm{Rg} \cdot \frac{Z^2}{n^2},$$

$\mathrm{Rg} := 2\pi\hbar c R = \frac{me^4}{2\hbar^2} = \frac{e^2}{2a_0} = 13,60$ эВ $= 2,179 \cdot 10^{-18}$ Дж,

$$E_{j,n} \approx -\frac{\mu c^2 \alpha^2}{2n^2}\left[1 + \frac{\alpha^2}{n^2}\left(\frac{n}{j+\frac{1}{2}} - \frac{3}{4}\right)\right] \qquad \text{Sommerfeld fine-str. f}$$

$$R_{10} = 2\left(\frac{Z}{a_0}\right)^{\frac{3}{2}} e^{-Zr/a_0},$$

$$R_{21} = \frac{1}{\sqrt{3}}\left(\frac{Z}{2a_0}\right)^{\frac{3}{2}}\left(\frac{Zr}{a_0}\right) e^{-Zr/2a_0}, \quad R_{20} = 2\left(\frac{Z}{2a_0}\right)^{\frac{3}{2}}\left(1 - \frac{Zr}{2a_0}\right) e^{-Zr/2a_0}$$

$$\psi_{2,1,0} = \frac{1}{4\sqrt{2\pi}a_0^{3/2}}\frac{r}{a_0}\mathrm{e}^{-r/2a_0}\cos\theta$$

$$\psi_{2,1,\pm1} = \mp\frac{1}{8\sqrt{\pi}a_0^{3/2}}\frac{r}{a_0}\mathrm{e}^{-r/2a_0}\sin\theta e^{\pm i\varphi}$$

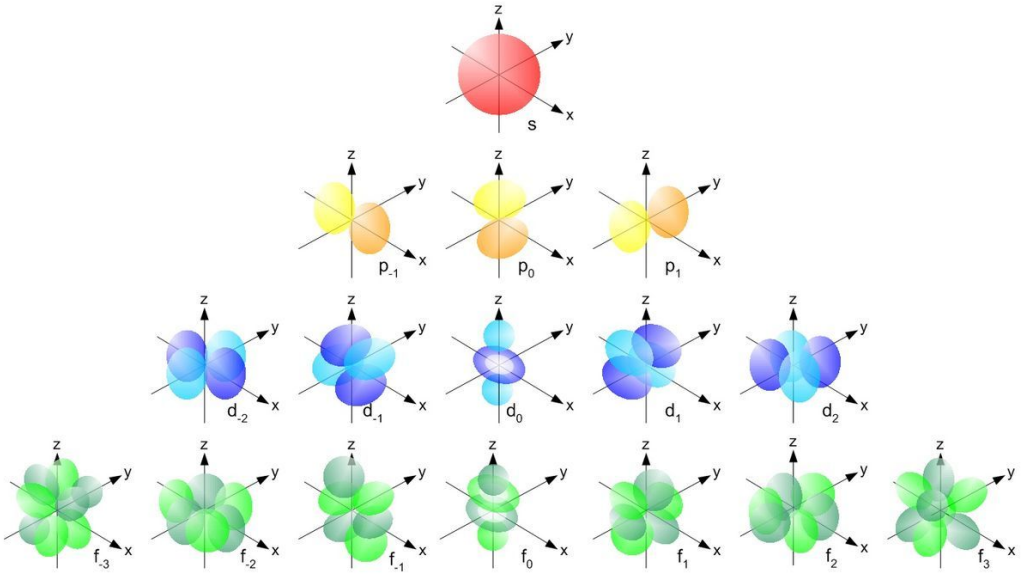
(???)

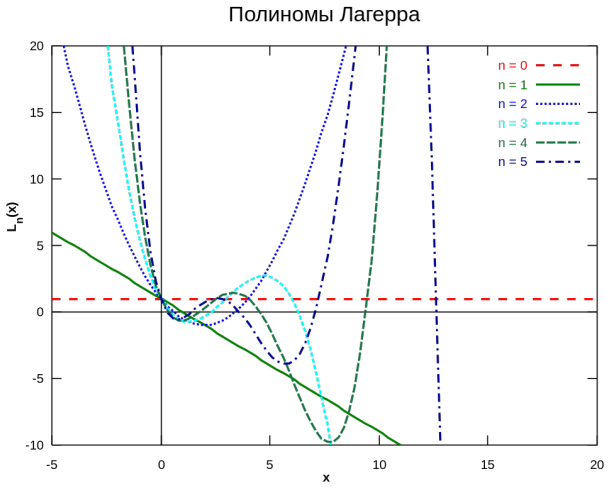
$$\mathrm{Degeneracy} = 2_{\mathrm{spin}}\sum_{l=0}^{n-1} 2l+1 = 2n^2$$

$$\psi_{n\ell m}(r,\theta,\varphi) = \sqrt{\left(\frac{2}{na_0^*}\right)^3 \frac{(n-\ell-1)!}{2n(n+\ell)!}}\mathrm{e}^{-\rho/2}\rho^\ell L_{n-\ell-1}^{2\ell+1}(\rho)Y_\ell^m(\theta,\varphi)$$

where:
- $\rho = \frac{2r}{na_0^*}$,
- a_0^* is the reduced Bohr radius, $a_0^* = \frac{4\pi\varepsilon_0\hbar^2}{\mu e^2}$,
- $L_{n-\ell-1}^{2\ell+1}(\rho)$ is a generalized Laguerre polynomial of degree $n-\ell-1$, and

- $Y_\ell^m(\theta,\varphi)$ is a spherical harmonic function of degree ℓ and order m.





(абзац словами напишу свойства)
(!!!!!!!!!!!!! абзац про вырожденность уровней!!! сразу этот вопрос и возникает!)
Считаем водород так: $\Delta\psi + \frac{2m}{\hbar^2}[E - U(r)]\psi = 0$,(??? формула для лапласиана??),

$$\frac{\hbar^2}{2m}\left[-\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\psi}{\partial r}\right) + \frac{\widehat{\mathbf{l}}^2}{r^2}\psi\right] + U(r)\psi = E\psi,$$

$\widehat{\mathbf{l}}^2 = -\left[\frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\varphi^2} + \frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\varphi}\right)\right].$

$$\widehat{p}_r\psi := -i\hbar\frac{1}{r}\frac{\partial}{\partial r}(r\psi) = -i\hbar\left(\frac{\partial}{\partial r} + \frac{1}{r}\right)\psi$$

$$\widehat{H} = \frac{1}{2m}\left(\widehat{p}_r^2 + \frac{\hbar^2\widehat{\mathbf{l}}^2}{r^2}\right) + U(r),$$

$$\psi = R(r)Y_{lm}(\theta,\varphi)$$

$\widehat{\mathbf{1}}^2 Y_{lm} = l(l+1)Y_{lm}$,

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{dR}{dr}\right) - \frac{l(l+1)}{r^2}R + \frac{2m}{\hbar^2}[E - U(r)]R = 0$$

$$R(r) = \frac{\chi(r)}{r}$$

$$\frac{d^2\chi}{dr^2} + \left[\frac{2m}{\hbar^2}(E-U) - \frac{l(l+1)}{r^2}\right]\chi = 0$$

$$U_l(r) = U(r) + \frac{\hbar^2}{2m}\frac{l(l+1)}{r^2},$$

$$R_l \approx \text{ const } \cdot r^l.$$

$$\begin{aligned}\left\langle r^{-1}\right\rangle &= 0,\\ \langle r\rangle &= \frac{a}{2}\left[3n^2 - l(l+1)\right].\\ \left\langle r^2\right\rangle &= \frac{a^2n^2}{2}\left[5n^2 + 1 - 3l(l+1)\right].\end{aligned}$$

$$\frac{s+1}{n^2}\left\langle r^s\right\rangle - a(2s+1)\left\langle r^{s-1}\right\rangle + \frac{s}{4}a^2\left\{(2l+1)^2 - s^2\right\}\left\langle r^{s-2}\right\rangle = 0 \qquad s > -2l-1 \text{ (Cramers)}$$

(??? idea of the proof???)

$\frac{\partial E_n}{\partial l} = \left\langle \frac{\partial \hat{H}}{\partial l}\right\rangle_n \quad \Rightarrow \quad -\frac{\hbar^2}{2ma^2}\frac{\partial}{\partial l}\frac{1}{(n_r+l+1)^2} = \left\langle \frac{\hbar^2}{2m}\frac{\partial}{\partial l}\frac{l(l+1)}{r^2}\right\rangle \quad \Rightarrow \quad \left\langle \frac{1}{r^2}\right\rangle = \frac{2}{a^2}\frac{1}{n^3(2l+1)}$.

Из интегрирования уравнения Шредингера (?? мб добавлю формулу, по см. Киселева):

$$|\Psi(0)|^2 = \frac{m}{2\pi\hbar^2}\langle V'\rangle.$$

(??? Тут я хз про средние, оно странно вычисляется, нужно тренироваться дальше в этом.)

При учёте движения ядра масса электрона заменяется приведённой массой электрона и ядра и тогда $R_i = \frac{R_\infty}{\frac{1+m}{M_i}}$, M_i - масса ядра атома.

разложении плоских волн

$$\begin{aligned}e^{\mathrm{i}kr\cos\theta} &= \sum_l (2l+1)P_l(\cos\theta)(-\mathrm{i})^l\frac{r^l}{2\mathrm{i}k^{l+1}}\left(\frac{1}{r}\frac{d}{dr}\right)^l\frac{1}{r}\left\{-e^{-\mathrm{i}kr} + e^{\mathrm{i}kr}\right\} \simeq\\ &\overset{r\to\infty}{\simeq} \sum_l (2l+1)P_l(\cos\theta)\frac{1}{2\mathrm{i}kr}\left\{e^{\mathrm{i}kr} - (-1)^l e^{-\mathrm{i}kr}\right\} =\\ &= \sum_l (2l+1)P_l(\cos\theta)\ \mathrm{i}^l\ \frac{\sin\left(kr - \frac{\pi}{2}l\right)}{kr}\end{aligned}$$

$$e^{i\mathbf{kr}} = 4\pi\sum_{l=0}^{\infty}\sum_{m=-l}^{l} i^l j_l(kr)Y^*_{lm}\left(\frac{\mathbf{k}}{k}\right)Y_{lm}\left(\frac{\mathbf{r}}{r}\right)$$

$$\sigma_l = \frac{\pi}{k^2}(2l+1).$$

При больших значениях l сумма прицельных площадей по интервалу Δl значений l (такому, что $1 \ll \Delta l \ll l$) равна

$$\sum_{\Delta l} \sigma_l \approx \frac{\pi}{k^2} \cdot 2l\Delta l = 2\pi \frac{l\hbar^2}{p^2}\Delta l.$$

разложении сферических волн

(тут суть пар 33 ЛЛ3)

$$\frac{1}{r}\frac{d^2(rR_{kl})}{dr^2} + k^2 R_{kl} = 0.$$

$$R_{kl} \approx 2\frac{\sin(kr - l\pi/2 + \delta_l)}{r},$$

$$R_{kl} = (-1)^l \cdot 2\frac{r^l}{k^l}\left(\frac{d}{rdr}\right)^l \frac{\sin kr}{r}$$

$$R_{kl} \equiv \sqrt{\frac{2\pi k}{r}} J_{l+1/2}(kr) = 2kj_l(kr); \qquad j_l(x) := \sqrt{\frac{\pi}{2x}} J_{l+1/2}(x)$$

$$j_0 = \frac{\sin x}{x}, \qquad j_1 = \frac{\sin x}{x^2} - \frac{\cos x}{x}, \qquad j_2 = \left(\frac{3}{x^3} - \frac{1}{x}\right)\sin x - \frac{3\cos x}{x^2}.$$

$$R^{\pm}_{kl} = (-1)^l A \frac{r^l}{k^l}\left(\frac{1}{r}\frac{d}{dr}\right)^l \frac{e^{\pm ikr}}{r} = \pm iA\sqrt{\frac{k\pi}{2r}} H^{(1,2)}_{l+1/2}(kr) \approx \frac{A}{r}\exp\left[\pm i\left(kr - \frac{\pi l}{2}\right)\right].$$

$$R^{\pm}_{kl} \approx A\frac{(2l-1)!!}{k^l} r^{-l-1}. \qquad (r \to 0)$$

Движение в центральном поле по Ландау

(см. его пар 35, там всякие спецфункции, нетривиальные методы! потом подумаю - пропишу в теорию и сюда.)

Другие общие свойства атома водорода

Водород в электрическом поле (ЛЛ.77)

$$E = -\frac{1}{2n^2} + \frac{3}{2}\mathcal{E}n(n_1 - n_2) - \frac{\mathcal{E}^2}{16}n^4\left[17n^2 - 3(n_1 - n_2)^2 - 9m^2 + 19\right]$$

(?? как понимать формулу?)

Proof:

$$\left(\frac{1}{2}\Delta + E + \frac{1}{r} - \mathcal{E}z\right)\psi = 0.$$

parabolic:
$$\frac{d}{d\xi}\left(\xi\frac{df_1}{d\xi}\right)+\left(\frac{E}{2}\xi-\frac{m^2}{4\xi}-\frac{\mathcal{E}}{4}\xi^2\right)f_1-\beta_1 f_1$$
$$\frac{d}{d\eta}\left(\eta\frac{df_2}{d\eta}\right)+\left(\frac{E}{2}\eta-\frac{m^2}{4\eta}+\frac{\mathcal{E}}{4}\eta^2\right)f_2-\beta_2 f_2,\quad \beta_1+\beta_2=1$$

(дальше словами напишу, в ЛЛ3 вывод на страницы 4)

Например, вероятность ионизации водорода считается так:
(см. задачу ЛЛ3 пар 77, пока не думал про неё особо, чуть что разберусь!)

Скрытая $SO(4)$ симметрия (??)

$$H:=\frac{\boldsymbol{P}^2}{2}-\frac{\alpha}{r},$$
$$\hat{\boldsymbol{W}}:=\frac{1}{2}(\boldsymbol{P}\times\boldsymbol{M}-\boldsymbol{M}\times\boldsymbol{P})-\frac{\alpha\boldsymbol{Q}}{r}$$ вектор Лапласа-Рунге-Ленца
$$W_j=\frac{1}{2}\varepsilon_{jkl}\left(P_kM_l+M_lP_k\right)-\frac{\alpha Q_j}{r},\quad j=1,2,3.$$

Здесь Q_i - операторы умножения на x_i, и все время подразумевается суммирование по повторяющимся индексам $1,2,3$. В силу коммутационных соотношений (3.5) имеем также

$$\boldsymbol{W}=\boldsymbol{P}\times\boldsymbol{M}-\frac{\alpha\boldsymbol{Q}}{r}-i\hbar\boldsymbol{P}=-\boldsymbol{M}\times\boldsymbol{P}-\frac{\alpha\boldsymbol{Q}}{r}+i\hbar\boldsymbol{P},$$

где слагаемое $i\hbar\boldsymbol{P}$ играет роль «квантовой поправки». Следующий результат выявляет скрытую симметрию кулоновской задачи.

Предложение 5.1. Оператор Шрёдингера H атома водорода имеет шесть квантовых интегралов движения $\boldsymbol{M}$ и $\boldsymbol{W}$,

$$[H,M_i]=[H,W_i]=0,\quad i=1,2,3,$$

удовлетворяющих условиям $\boldsymbol{W}\cdot\boldsymbol{M}=\boldsymbol{M}\cdot\boldsymbol{W}=0$ и $\boldsymbol{W}^2=\alpha^2+2H\boldsymbol{M}^2+2\hbar^2H$.

Кроме того, самосопряженные операторы $\boldsymbol{M}$ и $\boldsymbol{W}$ удовлетворяют

$$[M_j,M_k]=i\hbar\varepsilon_{jkl}M_l,\quad [W_j,M_k]=i\hbar\varepsilon_{jkl}W_l,\quad [W_j,W_k]=-2i\hbar\varepsilon_{jkl}M_lH$$

Хорошо известно из теории представлений группы Ли SO(4), что сферические гармоники - это ограничения на S^3 однородных гармонических многочленов на $\mathbb{R}^4$ степени $n-1, n\in\mathbb{N}$. Соответственно, уравнение (5.26) получается как предел $|\boldsymbol{u}|\to 1$ формулы Грина для однородных гармонических функций степени $n-1$ в единичном шаре в $\mathbb{R}^4$ с использованием потенциала двойного слоя. Это дает $\lambda=n$, чем опять устанавливается точная формула для уровней энергии атома водорода. Изоморфизм $\mathscr{H}_0\simeq L^2\left(S^3,d\Omega\right)$ следует из (5.27), а (5.23) - из разложения

$$L^2\left(S^3,d\Omega\right)\simeq\bigoplus_{l\in\frac{1}{2}\mathbb{Z}\geqslant 0}V_l\otimes V_l$$

регулярного представления SO(4) в прямую сумму неприводимых компонент. Можно также получить явный вид (5.4) собственных функций, воспользовавшись теорией представлений SO(4).

1.5.6 Fine structure, Zeeman, Stark effects

Overview of perturbations for hydrogen

The perturbations to the hydrogen energy levels, are of order:

$$\text{fine structure: } \alpha^2, \qquad \text{Lamb: } \alpha^3 \log\frac{1}{\alpha}, \qquad \text{Zeeman: } \alpha B, \qquad \text{hyperfine: } \alpha^2\frac{m_e}{m_p}$$

$$\alpha \sim 10^{-2}, \qquad m_e/m_p \sim 10^{-3},$$

(?? check this!) and the fine structure is suppressed by $O(10)$ numeric factors. The hydrogen energy levels themselves are $\sim \alpha^2 mc^2$.

In positronium there are modifications: the fine structure is still α^2, but the Lamb shift enters at the same order, since there is a tree-level diagram where the electron and positron annihilate and reappear; the Lamb shift for hydrogen is loop-level. The hyperfine splitting also enters at order α^2, so one must account for all of these effects at once.

(тут обзор, что со Штарком и Зееманом в итоге)

Поправки от тонкой структуры в случае общего центрального поля:

$$\delta V = -\frac{\boldsymbol{p}^4}{8m^3c^2} + \frac{e^2\hbar}{2m^2c^2}\frac{1}{r^3}(\boldsymbol{s}\cdot\boldsymbol{L}) + \frac{e^2\hbar^2}{2m^2c^2}\pi\delta(\boldsymbol{r}).$$

Тут первый член - кинетический, из разложения $E^2 = p^2c^2 + m^2c^4$ по c. Второй - (? от магнитного взаимодействия???) Последний член - контактный, от (???), а в случае неточечности ядра вместо дельта-функции имеем распределение заряда в ядре конечного радиуса (? решу эту модель еще раз).

Их получаем из $\hat{H} = \frac{p^2}{2m} + e\Phi - \frac{p^4}{8m^3c^2} + \frac{e\hbar}{2m^2c^2}\frac{\Phi'(r)}{r}(\boldsymbol{s}\cdot\boldsymbol{L}) + \frac{e\hbar^2}{8m^2c^2}\Delta\Phi$, где для атома водорода подставляем $\Phi = -\frac{e}{r}$, $\Phi'(r) = \frac{e}{r^2}$, и $\triangle\Phi(r) = 4\pi e\delta(\boldsymbol{r})$.

Fine structure:

$$(\Delta E)_{n,j} = \frac{(Z\alpha)^4 mc^2}{2}\left(\frac{3}{4n} - \frac{2}{2j+1}\right)\frac{1}{n^3}$$

(!!!!!!!!!!!!! тут обзор, что если такое-то есть поле, то такие-то члены в гамильтониане!!!)

Derivation of the part of corrections (?)

Relativistic Motion

$$E = \sqrt{\mathbf{p}^2c^2 + m^2c^4} \approx mc^2 + \frac{\mathbf{p}^2}{2m} - \frac{\mathbf{p}^4}{8m^3c^2} + \ldots$$

$$\Delta H = -\frac{\mathbf{p}^4}{8m^3c^2}$$

$$\langle nlm|\Delta H\,|nl'm'\rangle = 0 \quad \text{unless } l = l' \text{ and } m = m'$$

$$(\Delta E_1)_{n,l} = \langle\Delta H\rangle_{n,l}$$

$\langle \Delta H \rangle_{n,l} = \langle nlm|\Delta H|nlm\rangle$

$$\Delta H = -\frac{1}{2mc^2}[H - V(r)]^2$$

$$(\Delta E_1)_{n,l} = -\frac{1}{2mc^2}\left[E_n^2 - 2E_n\langle V(r)\rangle_{n,l} + \left\langle V(r)^2\right\rangle_{n,l}\right]$$

$\langle E\rangle = \langle T\rangle + \langle V\rangle = \frac{1}{2}\langle V\rangle$.

$$\left\langle \frac{1}{r}\right\rangle_{n,l} = -\frac{1}{Z\alpha\hbar c}\langle V\rangle_{n,l} = -\frac{1}{Z\alpha\hbar c}2E_n = \frac{Z}{a_0}\frac{1}{n^2}$$

$$\frac{\hbar^2}{2m}\frac{l(l+1)}{r^2} + \frac{\lambda}{r^2} = \frac{\hbar^2}{2m}\frac{l'(l'+1)}{r^2}$$

$$E(l') = -mc^2(Z\alpha)^2\frac{1}{2(k+l'+1)^2}$$

$n = k + l + 1$

$$E(l') = E_n + (Z\alpha)^2 mc^2\left[\frac{1}{(k+l'+1)^3}\frac{dl'}{d\lambda}\right]\Big|_{\lambda=0}\lambda + ...$$

$$= E_n + \frac{Z^2}{a_0^2}\frac{2\lambda}{n^3(2l+1)} + ...$$

$$\left\langle \frac{1}{r^2}\right\rangle_{n,l} = \frac{Z^2}{a_0^2}\frac{2}{n^3(2l+1)}$$

$$(\Delta E_1)_{n,l} = -\frac{(Z\alpha)^4 mc^2}{2}\left(\frac{n}{l+1/2} - \frac{3}{4}\right)\frac{1}{n^4}$$

Spin-Orbit Coupling and Thomas Precession

$$\mathbf{m} = -g\frac{e}{2m}\mathbf{S}$$

$$E = -\mathbf{B}\cdot\mathbf{m}$$

$$\mathbf{B} = \frac{\gamma}{c^2}\mathbf{v}\times\mathbf{E}$$

$$\Delta E = -\frac{e\gamma}{mc^2}(\mathbf{v}\times\nabla\phi)\cdot\mathbf{S} = -\frac{e}{(mc)^2}\frac{\partial\phi}{\partial r}(\mathbf{p}\times\hat{\mathbf{r}})\cdot\mathbf{S} = \frac{e}{(mc)^2}\frac{1}{r}\frac{\partial\phi}{\partial r}\mathbf{L}\cdot\mathbf{S}$$

$\mathbf{ep} = m\gamma\mathbf{v}$

$$\Delta H_{SO} = \frac{e}{(mc)^2}\frac{1}{r}\frac{\partial\phi}{\partial r}\mathbf{L}\cdot\mathbf{S}$$

(про прецессию Томаса - указание в теории поля, тут только финальные формулы пишу, ну и в паре слов смысл явления)

$$\frac{\partial\mathbf{S}}{\partial t} = \boldsymbol{\omega}_T\times\mathbf{S} \quad \text{with} \quad \boldsymbol{\omega}_{\mathrm{T}} = \frac{\mathbf{v}\times\mathbf{a}}{2\mathrm{c}^2}$$

$$\omega_T = \frac{\gamma^2}{\gamma+1}\frac{\mathbf{v}\times\mathbf{a}}{2c^2}$$

Connection of Thomas Precession and the Spin-Orbit Coupling

$$\frac{\partial \mathbf{S}}{\partial t} = \mathbf{B}\times\mathbf{S}$$

$$\frac{\partial \mathbf{S}}{\partial t} = \mathbf{B}\times\mathbf{S} + \boldsymbol{\omega}_T\times\mathbf{S}$$

$$E = \frac{e}{m}\mathbf{B}\cdot\mathbf{S} + \boldsymbol{\omega}_T\cdot\mathbf{S}$$

$$\boldsymbol{\omega}_T\cdot\mathbf{S} = \frac{e}{2mc^2}(\mathbf{v}\times\nabla\phi)\cdot\mathbf{S} = -\frac{e}{2(mc)^2}\frac{1}{r}\frac{\partial\phi}{\partial r}\mathbf{L}\cdot\mathbf{S}$$

$$\Delta H_{SO} = \frac{e}{2(mc)^2}\frac{1}{r}\frac{\partial\phi}{\partial r}\mathbf{L}\cdot\mathbf{S}$$

Computing the Spin-Orbit Energy Shift:

$$\begin{aligned}\mathbf{L}\cdot\mathbf{S}\,|n,j,m_j;l\rangle &= \frac{\hbar^2}{2}\left(j(j+1)-l(l+1)-\frac{3}{4}\right)|n,j,m_j;l\rangle \\ &= \frac{\hbar^2}{2}\begin{cases} -(l+1)\,|n,j,m_j;l\rangle & j=l-\frac{1}{2} \\ l\,|n,j,m_j;l\rangle & j=l+\frac{1}{2}\end{cases} \qquad (l\neq 0)\end{aligned}$$

$$(\Delta E_2)_{n,j;l} = \langle \Delta H_{SO}\rangle_{n,j;l}$$

$\langle \Delta H_{SO}\rangle_{n,j;l} = \langle n,j,m_j;l|\,\Delta H_{SO}\,|n,j,m_j;l\rangle$.

$$(\Delta E_2)_{n,j;l} = -\frac{Ze^2\hbar^2}{4.4\pi\epsilon_0(mc)^2}\begin{Bmatrix} -(l+1) \\ l\end{Bmatrix}\left\langle\frac{1}{r^3}\right\rangle_{n,j;l}$$

$$\tilde{p} = -i\hbar\left(\frac{\partial}{\partial r}+\frac{1}{r}\right)$$

$$\begin{aligned}H &= -\frac{\hbar^2}{2m}\left(\frac{1}{r^2}\frac{\partial}{\partial r}r^2\frac{\partial}{\partial r}\right)+\frac{\hbar^2 l(l+1)}{2mr^2}-\frac{Ze^2}{4\pi\epsilon_0 r} \\ &= \frac{\tilde{p}^2}{2m}+\frac{\hbar^2 l(l+1)}{2mr^2}-\frac{Ze^2}{4\pi\epsilon_0 r}\end{aligned}$$

$$[\tilde{p},H] = -i\hbar\left(-\frac{\hbar^2 l(l+1)}{mr^3}+\frac{Ze^2}{4\pi\epsilon_0 r^2}\right)$$

$$\left\langle\frac{1}{r^3}\right\rangle_{n,j;l} = \frac{Z}{a_0}\frac{1}{l(l+1)}\left\langle\frac{1}{r^2}\right\rangle_{n,j;l} = \left(\frac{Z}{a_0}\right)^3\frac{1}{l\left(l+\frac{1}{2}\right)(l+1)}\frac{1}{n^3} \quad (l\neq 0)$$

$$(\Delta E_2)_{n,j;l} = \frac{(Z\alpha)^4 mc^2}{4}\begin{Bmatrix} -\frac{1}{j+1} \\ \frac{1}{j}\end{Bmatrix}\frac{1}{j+\frac{1}{2}}\frac{1}{n^3}$$

$$(\Delta E_1)_{n,l} = -\frac{(Z\alpha)^4 mc^2}{2}\left(\begin{Bmatrix} \frac{1}{j+1} \\ \frac{1}{j}\end{Bmatrix}-\frac{3}{4n}\right)\frac{1}{n^3}$$

$$(\Delta E_1)_{n,l} + (\Delta E_2)_{n,j;l} = \frac{(Z\alpha)^4 mc^2}{2}\left(\frac{3}{4n} - \frac{2}{2j+1}\right)\frac{1}{n^3}$$

Считаем возмущения так:

$$\hat{\mathbf{L}}\cdot\hat{\mathbf{S}} = \frac{1}{2}\left(\hat{\mathbf{J}}^2 - \hat{\mathbf{L}}^2 - \hat{\mathbf{S}}^2\right)$$

$$\langle ls;j,m|\hat{\mathbf{L}}\cdot\hat{\mathbf{S}}|ls;j,m\rangle = \frac{\hbar^2}{2}(j(j+1) - l(l+1) - s(s+1)) =$$
$$\overset{s=1/2}{=} \frac{\hbar^2}{2}\left(j(j+1) - l(l+1) - \frac{3}{4}\right) \qquad j = l \pm 1/2$$

Zitterbewegung and the Darwin Term

$$V(\mathbf{r}) = V(\mathbf{r}_0) + \langle\Delta\mathbf{r}\rangle\cdot\frac{\partial V}{\partial\mathbf{r}} + \frac{1}{2}\langle\Delta r_i\Delta r_j\rangle\frac{\partial^2 V}{\partial r_i\partial r_j} + \ldots$$

$$\langle\Delta r_i\Delta r_j\rangle = \left(\frac{\lambda}{2}\right)^2\delta_{ij}$$

$$\Delta H_{\text{Darwin}} = \frac{\hbar^2}{8m^2c^2}\nabla^2 V \overset{1/r}{\to} \frac{Z\alpha\hbar^3}{8m^2c}4\pi\delta^3(\mathbf{r})$$

$$(\Delta E_3)_{n,l} = \langle\Delta H_{\text{Darwin}}\rangle_{n,l} = \frac{Z\alpha\hbar^3\pi}{2m^2c}\left|\psi_{nlm}(r=0)\right|^2$$

$$R_{n,l=0}(r) = -\sqrt{\left(\frac{2Z}{na_0}\right)^3\frac{(n-1)!}{2n(n!)^3}}e^{-r/na_0}L_n^1(2r/na_0)$$

$L_n^1(x) = dL_n(x)/dx$
$L_n(x) \approx n! - n!nx + \mathcal{O}(x^2)$ so that $L_n^1(0) = n!n$.

$$|\psi_{n,l=0}(0)|^2 = \frac{Z^3}{a_0^3\pi n^3}$$

$$(\Delta E_3)_{n,l} = \frac{(Z\alpha)^4 mc^2}{2}\frac{1}{n^3}\delta_{l0}$$

Derivation of fine structure from Dirac's equation together from Kiselev

Main idea:

$$E_{n,j} = mc^2\left(1 + \left(\frac{Z\alpha}{n - j - \frac{1}{2} + \sqrt{\left(j+\frac{1}{2}\right)^2 - (Z\alpha)^2}}\right)^2\right)^{-1/2}$$
$$E_{n,j} = mc^2\left(1 - (Z\alpha)^2\frac{1}{2n^2} + (Z\alpha)^4\left(\frac{3}{4n} - \frac{2}{2j+1}\right)\frac{1}{2n^3} + \ldots\right)$$

Key steps in derivation:
(спишу скоро у него, особая теория, интересная, но Тонга хватает для понимания)

Lamb shift for hydrogen atom

Consider an atom in a large cubical box of side length L:

$$\underbrace{|\mathbf{E}_k|^2 L^3}_{\text{rand class field}} \sim \underbrace{\hbar\omega_k}_{\text{vac energ}}$$

characteristic time of change: $\tau \sim 1/\omega_k$,

displsm of a particle $$\delta r \sim \frac{e\,|\mathbf{E}_k|\,\tau^2}{m} \sim \frac{e\,|\mathbf{E}_k|}{m\omega_k^2}$$

$$\langle \delta r^2 \rangle \sim \sum_{\mathbf{k}} \frac{e^2\,|\mathbf{E}_k|^2}{m^2\omega_k^4} \sim \frac{e^2\hbar}{m^2} \sum_{\mathbf{k}} \frac{1}{(L\omega_k)^3} \sim \frac{e^2\hbar}{m^2} \int d\mathbf{k} \left(\frac{L}{\hbar}\right)^3 \frac{1}{(L\omega_k)^3} \sim \frac{e^2}{m^2\hbar^2c^3} \int \frac{d\mathbf{k}}{k^3}$$

We get rid of logarithm divergence, by putting cutoffs. Modes with wavelengths larger than the atom don't affect the electron much, just pushing on it adiabatically, while modes with wavelengths smaller than the electron's Compton wavelength will instead cause new particles to spontaneously pop out of the vacuum. The ratio between these two scales is α (????), so

$$\langle \delta r^2 \rangle \sim \frac{e^2}{m^2\hbar^2c^3} \log\frac{1}{\alpha}$$

$$\frac{\Delta E}{E_n} \sim \alpha^3 \log\frac{1}{\alpha}$$

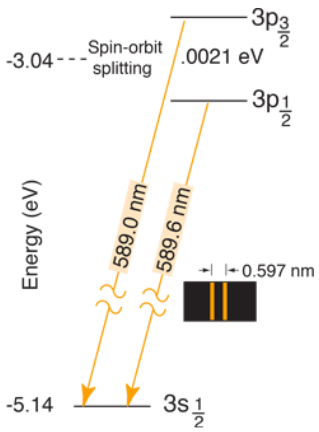
Following the same reasoning as for the Darwin term (???), this gives an energy shift of

$$\frac{\Delta E}{E_n} \sim \alpha^3 \log\frac{1}{\alpha} \qquad \text{for } \ell = 0 \text{ states.}$$

One should keep in mind that "quantum fluctuations" don't generally behave like classical stochastic ones, so in some other effects this approach does not work (????).

Об эффекте Зеемана (!!!!!)

Overview of Zeeman effects



The normal Zeeman effect is observed in systems with closed shells of electrons and arises due to lifting of the orbital degeneracy by an external magnetic field of moderate strength.

$$W_H = -\mu_H H = g m_J \mu_\mathrm{B} H,$$

уровень, отвечающий заданному J, расщепляется на $2J+1$ подуровней. Смещение уровней в единицах $\mu_\mathrm{B} H$ определяется величиной $g m_J$.

Например, жёлтый дублет натрия - переходы из $3^2P_{1/2}$ в $3^2S_{1/2}$-состояние (линия D_1), и из $3^2P_{3/2}$ - в то же $3^2S_{1/2}$-состояние (линия D_2).

Терм	L	S	J	g	m_J	gm_J
$3^2S_{1/2}$	0	1/2	1/2	2	$1/2; -1/2$	$1; -1$
$3^2P_{1/2}$	1	1/2	1/2	2/3	$1/2; -1/2$	$1/3; -1/3$
$3^2P_{3/2}$	1	1/2	3/2	4/3	$3/2; 1/2; -1/2; -3/2$	$2; 2/3; -2/3; -2$

Тут есть примеры, чуть что, в них и буду разбираться (очень подродбная теория там): https://physicspages.com/TOC%20-%20Quantum%20mechanics.html

Normal Zeeman effect (aka strong-field, aka Paschen–Back effect, aka $L+2S$ Zeeman) (!?!?!!??)

$$H = H_0^\mathrm{at} + \sum_f \left\{ \mu_0 \boldsymbol{\mathcal{H}} \cdot (\boldsymbol{l}_f + 2\boldsymbol{s}_f) + \frac{e^2}{8mc^2} \left(\boldsymbol{\mathcal{H}} \times \boldsymbol{r}_f\right)^2 \right\},$$

$$V_\mathrm{mag} = \mu_0 \mathcal{H} \cdot (\boldsymbol{L} + 2\boldsymbol{S}),$$

$$V_\mathrm{d} = \frac{e^2}{8mc^2} \sum_f \left(\boldsymbol{\mathcal{H}} \times \boldsymbol{r}_f\right)^2 = \frac{e^2 \mathcal{H}^2}{8mc^2} \sum_f r_f^2 \sin^2\theta_f$$

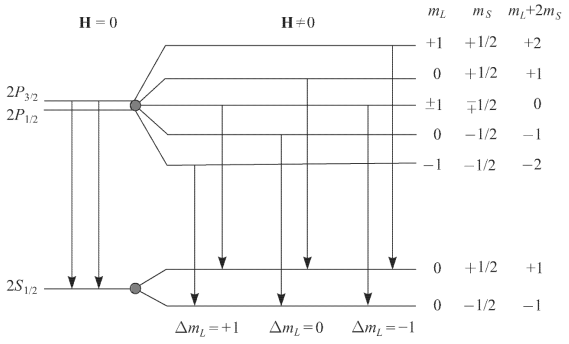
$$\widehat{H} = \widehat{H}_0 + \frac{|e|}{2mc} \mathbf{H} \sum_a [\mathbf{r}_a \widehat{\mathbf{p}}_a] + \frac{e^2}{8mc^2} \sum_a [\mathbf{H}\mathbf{r}_a]^2 + \frac{|e|\hbar}{mc} \mathbf{H}\widehat{\mathbf{S}}.$$

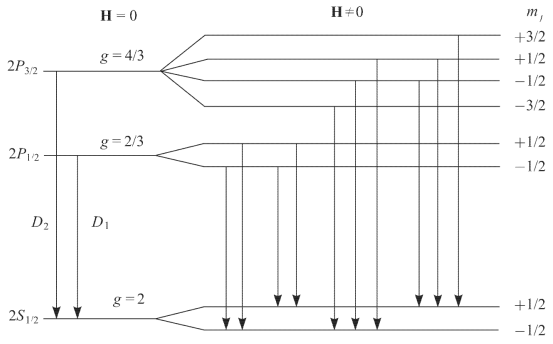
$$\widehat{H} = \widehat{H}_0 + \mu_B (\mathbf{L} + 2\widehat{\mathbf{S}})\mathbf{H} + \frac{e^2}{8mc^2} \sum_a [\mathbf{H}\mathbf{r}_a]^2$$

$$\widehat{\mu}_\mathrm{at} = -\mu_B (\widehat{\mathbf{L}} + 2\widehat{\mathbf{S}})$$

If $S = 0$, $g = 1$ (because $J = L$) and so the magnetic moment is independent of L and the upper and lower levels are split by the same amount. In this case we observe the normal Zeeman effect.

Below left - normal. right - anomalous Zeeman effects:





However, when $S \neq 0$, the value of g depends on both L and S, and so the upper and lower levels in the spectroscopic transition are split by different amounts. This is illustrated in Fig. 3.7. Note that the allowed transitions are further restricted by the angular momentum conservation selection rules, $\Delta M_J = 0$ (corresponding to emission of linearly polarized light) or $\Delta M_J = \pm 1$ (corresponding to circularly polarized light).

If the applied field is very strong, the coupling between S and L can be broken in favor of their direct coupling to the magnetic field. S and L then precess independently about the field direction. The electromagnetic field which induces the electronic transition couples only to the orbital distribution of the electrons, and so the presence of the spin does not show up in the transitions. Therefore the spectrum switches back from the anomalous to the normal Zeeman effect. This change in the spectrum is known as the Paschen-Back effect.

$$\boldsymbol{m} = -g\mu_{\mathrm{B}} M_J.$$

$$g = 1 + \frac{J(J+1) + S(S+1) - L(L+1)}{2J(J+1)}$$

$$\langle \mathbf{L} + 2\mathbf{S} \rangle = \left\langle \left(1 + \frac{\mathbf{S}\cdot\mathbf{J}}{J^2}\right)\mathbf{J} \right\rangle = \left[1 + \frac{j(j+1) - \ell(\ell+1) + s(s+1)}{2j(j+1)}\right]\langle \mathbf{J} \rangle.$$

- For one-electron atoms, some of the $2s$ states are also degenerate with the $2p$ states, as $|\ell m_\ell m_s\rangle = \left|00\tfrac{1}{2}\right\rangle$ is degenerate with $\left|10\tfrac{1}{2}\right\rangle$, and $\left|00,-\tfrac{1}{2}\right\rangle$ with $\left|10,-\tfrac{1}{2}\right\rangle$. In total, the eight $n = 2$ states are split into five energy levels, three of which have two-fold degeneracy. - We now consider the impact of fine structure, treating H_{Z} as part of the unperturbed Hamiltonian. For simplicity, we only consider the spin-orbit contribution,

$$H_{\mathrm{SO}} = f(r)\mathbf{L}\cdot\mathbf{S}, \quad f(r) = \frac{\alpha^2}{2}\frac{1}{r}\frac{dV}{dr}$$

This is the conceptually trickiest one, since it prefers the coupled basis, while we must work in the uncoupled basis $|n\ell m_\ell m_s\rangle$, where there are two-fold degeneracies.

- Using this basis is tricky because H_{SO} can modify m_ℓ and m_s values (though not ℓ values, since $[L^2, H_{\mathrm{SO}}] = 0$). However, it can only modify m_ℓ and m_s by at most one unit at a time, since

$$\mathbf{L}\cdot\mathbf{S} = \frac{1}{2}\left(L_+ S_- + L_- S_+\right) + L_z S_z$$

or by applying the Wigner-Eckart theorem. The $2p$ degenerate states differ in m_s by multiples of 2, so H_{SO} can't mix the degenerate states. Hence to calculate the first order shift, it suffices to look at its diagonal matrix elements.

- Thus, the energy shifts are

$$\Delta E = \langle n\ell m_\ell m_s |\, f(r)\mathbf{L}\cdot\mathbf{S}\,| n\ell m_\ell m_s\rangle = m_\ell m_s \langle n\ell m_\ell |\, f(r)\,| n\ell m_\ell\rangle$$

and for hydrogen we have

$$\Delta E = m_\ell m_s \frac{\alpha^2}{2}\langle n\ell 0|\frac{1}{r^3}|n\ell 0\rangle = \frac{\alpha^2}{2n^3}\frac{m_\ell m_s}{\ell(\ell+1/2)(\ell+1)}$$

In the case $\ell = 0$, the form above is indeterminate, but the energy shift is zero by similar reasoning to before.

Normal Zeeman effect (aka strong-field, aka Paschen–Back effect) from general physics

Only atoms with a total spin angular momentum = 0 show the normal Zeeman effect.

$$E = -\mu_0 \boldsymbol{m} \cdot \boldsymbol{H}$$

$$I = \frac{ev}{2\pi a} = -\frac{|e|v}{2\pi a}; \qquad A = \pi a^2.$$

$$\boldsymbol{m} = IA = \frac{eva}{2} = -\frac{|e|va}{2}.$$

$$m_\mathrm{e} va = m_l \hbar,$$
$$v = \frac{m_l \hbar}{m_\mathrm{e} a}.$$

$$\boldsymbol{m} = -\frac{e\hbar}{2m_\mathrm{e}} m_l = -\mu_\mathrm{B} m_l.$$

$$m = \mu_\mathrm{B}\sqrt{l(l+1)},$$

$$E = \mu_0 \frac{e\hbar}{2m_\mathrm{e}} m_l H = \mu_0 \mu_\mathrm{B} m_l H.$$

$$E = \mu_\mathrm{B} m_l H.$$

$$\mu_\mathrm{B} = e\hbar/2m_\mathrm{e} \sim 9.274 \times 10^{-24}\ \mathrm{J/T} = e\hbar/2m_\mathrm{e}c = 0.927 \times 10^{-20}\mathrm{erg/Oe}.$$

$$|\boldsymbol{S}| = \sqrt{s(s+1)}\hbar = \frac{\sqrt{3}}{2}\hbar$$

$$\boldsymbol{m} = -g_\mathrm{e}\mu_\mathrm{B} m_s,$$
$$m = g_\mathrm{e}\mu_\mathrm{B}\sqrt{s(s+1)}$$

$$g_\mathrm{e} = 2.002319$$

Anomalous Zeeman effect (aka weak-field, with Lande factor) from quantum mechanics

- For hydrogen, we should properly consider the Lamb shift, which is only 10 times smaller than the fine structure shifts on the $n = 2$ energy levels. However, we will ignore it for simplicity.

- In this case, we need to use the coupled basis $|n\ell j m_j\rangle$. The difficulty is that $[J^2, H_\mathrm{Z}] \neq 0$. Luckily, the fine-structure energy levels depend directly on j, in the sense that energy levels with different j are not degenerate. Hence to calculate the first-order shift, we again do not have to diagonalize any matrices, and can focus on the diagonal elements,

$$\Delta E = \langle n\ell j m_j |\, \mu_B B \left(L_z + 2S_z\right) |n\ell j m_j\rangle$$

$L_z + 2S_z = J_z + S_z,$

$$\Delta E = \mu_B B \left(m_j + \langle n\ell j m_j |\, S_z\, |n\ell j m_j\rangle\right)$$

$$\langle n\ell j m_j|\, S_z\, |n\ell j m_j\rangle = \frac{1}{j(j+1)}\, \langle n\ell j m_j|\, (\mathbf{S}\cdot\mathbf{J}) J_z\, |n\ell j m_j\rangle$$

$$\mathbf{S}\cdot\mathbf{J} = \frac{1}{2}\left(J^2 + S^2 - L^2\right)$$

$$\Delta E = g_L\,(\mu_B B)\, m_j, \quad g_L = 1 + \frac{j(j+1) + s(s+1) - \ell(\ell+1)}{2j(j+1)}$$

Об эффекте Штарка

Типичный Штарк-эффект

В $\mathcal{E} = \{0, 0, \mathcal{E}\}$, тогда

$$\hat{\mathrm{H}} = \frac{\hat{\mathrm{p}}^2}{2} - \frac{1}{r} + \mathcal{E} r\cos\theta \equiv \hat{\mathrm{H}}^{(0)} + \hat{\mathrm{V}}, \qquad (h = m = e = 1)$$

В этой СЕ величина $\mathcal{E}$ это отношение напряженности внешнего электрического поля к внутриатомному $\varepsilon_a = e/a^2 \simeq 5,14 \cdot 10^9$ В/см.

Штарк-эффект в случае близких уровней по МК

Расщепление дублета $2s_{1/2}, 2p_{1/2}$ в слабом электрическом поле в атомных единицах равно 6δ.

Рассмотрим, например, состояния $2s_{1/2}$ и $2p_{1/2}$ атома водорода. Они обладают одинаковой энергией (если не учитывать лэмбовского смещения). Расщепление такого дублетного уровня при наложении электрического поля линейно по полю и равно $E_2 - E_1 = 2\,|V_{12}|$.

Вычислим V_{12}. Для состояния $2s_{1/2}$ волновая функция равна $R_{20}(r)\frac{1}{\sqrt{4\pi}}$, а для состояния $2p_{1/2}$ равна $R_{21}\sqrt{\frac{3}{4\pi}}\cos\theta$,

$$V_{12} = -\mathscr{E}\,(R_{20}|r|R_{21})\,\frac{\sqrt{3}}{4\pi}\int \cos^2\theta d\Omega = -\frac{\mathscr{E}}{\sqrt{3}}\,(R_{20}|r|R_{21})\,.$$

Матричные элементы динольного момента для кулоновских радиальных функций табулированы. В частности, $(R_{20}|r|R_{21}) = 3\sqrt{3}$. Следовательно, $|V_{12}| = 3\delta$.

Зависимость штарковского расщепления различных компонент мультиплетного уровня от J по Ландау пар. 76:

$$\widehat{\alpha}_{ik} = a\delta_{ik} + b\left(\widehat{L}_i\widehat{L}_k + \widehat{L}_k\widehat{L}_i - \frac{2}{3}\delta_{ik}\widehat{\mathbf{L}}^2\right)$$

$$\alpha = a, \quad \beta = b\frac{3(\mathbf{JL})[2(\mathbf{JL}) - 1] - 2J(J+1)L(L+1)}{J(J+1)(2J-1)(2J+3)}$$

(???)

The Quadratic Stark Effect

$$\Delta E = e^2\mathcal{E}^2 \sum_{n=2}^{\infty} \sum_{l,m} \frac{|\langle 1,0,0|z|n,l,m\rangle\ |^2}{E_1 - E_n}$$

$$\Delta E = -4\pi\epsilon_0 C \mathcal{E}^2 a_0^3$$

$$\mathbf{P} = -\nabla_{\mathbf{E}} E$$

$$\Delta E = -\frac{1}{2}\mathbf{P}\cdot\mathbf{E}$$

$$\mathbf{P} = 2C \times 4\pi\epsilon_0 a_0^3 \mathbf{E}$$

(дочитаю Тонга скоро!!)

(см. Ландау пар 76)

$$\widehat{V} = \frac{1}{6}\frac{\partial^2\varphi}{\partial x_i \partial x_k}\widehat{Q}_{ik}$$

Изменение времени жизни $2s1/2$ водорода в электрическом поле по МК

Время жизни состояния $2s_{1/2}$ водорода на девять порядков уменьшается при наложении электрического поля $\mathscr{E} \sim \frac{1}{x_{12}\tau} \sim \frac{1}{\tau} \sim c^{-3} \sim \frac{10}{c^9}{}^3 B \sim 500b$

В атоме водорода состояние $2s_{1/2}$ имеет большое время жизни, Действительно, переход $2s_{1_{12}} \to 1s_{1/2}$ может происходить лишь с испусканием двух γ-квантов. Время жизни состояния $2s_{1/2}$ по отношению к этому переходу порядка $1/7$ сек.

Кроме того, возможен еще дипольный переход $2s_{1/2} \to 2p_{1/2}$ (энергии обоих состояний различаются из-за лэмбовского смещения). Оценим вероятность этого перехода. В (1.4) мы нашли, что вероятность динольного перехода $w \sim \omega^3/c^3$, ω-частота перехода. Разность энергий $\omega = E_{2s_{1/2}} - E_{2p_{1/2}} \sim 1/c^3$. Следовательно, $w \sim 1/c^{12}$. В атомных единицах $c \approx 137$, следовательно, $w \sim 10^{-24}$, т. е. время жизни состояния $2s_{1/2}$ по отношению к переходу $2s_{1/3} \to 2p_{1/s}$ порядка $10^{24}\tau_{\mathbf{a}_\mathrm{T}}$, $\tau_{\mathrm{ат}}$ - атомное время $\sim 10^{-10}$ сек. Итак, рассматриваемое время $\sim 10^8$ сек. Переход $2s_{1/2} \to 1s_{1/2}$ все же вероятнее, чем переход $2s_{1/2} \to 2p_{1/2}$.

При наложении внешнего поля состояние атома будет суперпозицией состояний $2s_{1/2}$ и $2p_{1/2}$. Но как только атом перейдет в состояние $2p_{1/s}$, он моментально (за время $\tau \sim 10^{-9}$ сек) совершит дипольный переход: $2p_{1/2} \to 1s_{1/2}$. Мы видим, что время жизни состояния $2s_{1/2}$ резко изменяется при наложении электрического поля.

(потом уже коротко буду все это писать)

1.5.7 Motion in magnetic field, fundamentals of magnetism

Particle in magnetic field

Основные формулы квантового движения в магнитном поле и уровней Ландау

$$H_{\mathrm{c}}(\boldsymbol{p},\boldsymbol{r}) = \frac{1}{2m}\left(\boldsymbol{p} - \frac{e}{c}\boldsymbol{A}\right)^2 + e\varphi(\boldsymbol{r})$$

$$\boldsymbol{v} = \boldsymbol{p} - \frac{e}{c}\boldsymbol{A}, \qquad \boldsymbol{v} = (v_1, v_2, v_3)$$

$$\{v_1, v_2\} = -\frac{e}{m^2 c} B_3, \quad \{v_2, v_3\} = -\frac{e}{m^2 c} B_1, \quad \{v_3, v_1\} = -\frac{e}{m^2 c} B_2,$$

$\boldsymbol{B} = (B_1, B_2, B_3)$ - компоненты $\boldsymbol{B} = \operatorname{curl} \boldsymbol{A}$. Таким образом, одновременно 3 компоненты скорости измерить нельзя.

$$\frac{1}{2m}\left[\left(\widehat{p}_x + \frac{eH}{c} y\right)^2 + \widehat{p}_y^2 + \widehat{p}_z^2\right]\psi - \frac{\mu}{s}\sigma H \psi = E\psi.$$

$$\psi = \exp\left[\frac{i}{\hbar}\left(p_x x + p_z z\right)\right] \chi(y)$$

$$\chi'' + \frac{2m}{\hbar^2}\left[\left(E + \frac{\mu\sigma}{s}H - \frac{p_z^2}{2m}\right) - \frac{m}{2}\omega_H^2 \left(y - y_0\right)^2\right]\chi = 0,$$

$$E = \left(n + \frac{1}{2}\right)\hbar\omega_H + \frac{p_z^2}{2m} - \frac{\mu\sigma}{s}H \qquad \text{Landau levels}$$

$\mu/s = -|e|\hbar/mc$,

$$E = \left(n + \frac{1}{2} + \sigma\right)\hbar\omega_H + \frac{p_z^2}{2m}$$

eig. f.: $\chi_n(y) = \dfrac{1}{\pi^{1/4} a_H^{1/2}\sqrt{2^n n!}} \exp\left(-\dfrac{(y-y_0)^2}{2a_H^2}\right) H_n\left(\dfrac{y-y_0}{a_H}\right)$. $\qquad a_H := \sqrt{\dfrac{\hbar}{m\omega_H}}$

(как и у осциллятора, с небольшим изменением обозначений)

Обсудим кратность уровней в магнитном поле. Поскольку $E = \left(n + \frac{1}{2}\right)\hbar\omega_H + \frac{p_z^2}{2m} - \frac{\mu\sigma}{s}H$ не содержит p_x, пробегающей непрерывный ряд значений, уровни энергии вырождены с непрерывной кратностью.

Кратность вырождения конечная, если движение в плоскости xy ограничено конечной площадью $S = L_x L_y$. Число различных (теперь дискретных) значений p_x в интервале Δp_x равно $(L_x/2\pi\hbar)\,\Delta p_x$. Допустимы все значения p_x, для которых центр орбиты находится внутри S (мы пренебрегаем радиусом орбиты по сравнению с большим L_y). Из условий $0 < y_0 < L_y$ имеем $\Delta p_x = eHL_y/c$. Следовательно, число состояний (для заданных n и p_z) есть $eHS/2\pi\hbar c$. Если область движения ограничена также и вдоль оси z (длиной L_z), то число возможных значений p_z в интервале Δp_z есть $(L_z/2\pi\hbar)\,\Delta p_z$ и число состояний в этом интервале есть

$$N_{\text{degen}} = \frac{eHS}{2\pi\hbar c}\frac{L_z}{2\pi\hbar}\Delta p_z = \frac{eHV}{4\pi^2\hbar^2 c}\Delta p_z.$$

И еще есть 2 за счет спинового выржождения.

Рассмотрим релятивистский электрон в МП, например, в графене (монослой графита):

$$\varepsilon_{\mathbf{p}} = v\sigma \cdot \mathbf{p} \qquad \sigma = (\sigma_x, \sigma_y)\,;\ \mathbf{p} = (p_x, p_y)$$

$$\varepsilon_n = \varepsilon_0\sqrt{|n|}\,\operatorname{sign}(n), \quad \varepsilon_0 = \hbar v\sqrt{\frac{2eH}{\hbar c}}, \quad (n = 0, \pm 1, \pm 2, \ldots)$$

n represents an electron-like ($n > 0$) or a hole-like ($n < 0$) LL index.

Вырождение каждого магнитного уровня по центру орбиты электрона такое же, как и для обычного спектра $\varepsilon_p = p^2/(2m)$, и равно eH$/(2\pi\hbar c)$. Плотность состояний в магнитном поле дается обычным соотношением:

$$g(\varepsilon) = \nu \frac{eH}{2\pi\hbar c} \sum_{n=-\infty}^{\infty} \delta\left(\varepsilon - \varepsilon_n\right) \qquad \nu := 2 \times 2 = 4$$

For massive Dirac fermions in a Bernal graphene bilayer, the LL spectrum takes the form

$$E_n = \pm\left\{\hbar\omega_c[n(n-1)]^{1/2} + E_g/2\right\}, \quad n = 0, 1, 2...$$

Here $\omega_c = eB/m^*$ is the cyclotron frequency, m^* is the effective mass of the quasiparticles, and E_g is the band gap. (from PHYS. REV. B 91, 115405 (2015))

Graphen's high-magnetic-field Landau level spectrum consists of almost equidistant groups of four-fold degenerate states at finite energy and eight zero-energy states. (see the article by Edward McCann and Vladimir I. Fal'ko: Landau level degeneracy and quantum Hall effect in a graphite bilayer)

Уравнение Шредингера в магнитном поле по Ландау

$$\mu_B = \frac{|e|\hbar}{2mc} = 0,927 \cdot 10^{-20} \frac{\text{эрг}}{\text{Гс}}.$$

$$\Delta E = \mu_B g M_J H$$
$$g = 1 + \frac{J(J+1) - L(L+1) + S(S+1)}{2J(J+1)}$$

$$\widehat{H} = \widehat{H}_0 - \widehat{\boldsymbol{\mu}}\mathbf{H} = \widehat{H}_0 - \widehat{\boldsymbol{\mu}}_z H$$

$$\bar{\mu}_z = -\frac{\partial \Delta E}{\partial H},$$

$$\bar{\mu}_z = -\mu_B g M_J.$$

$$\Delta E = \frac{e^2}{8mc^2}\sum_a \overline{[\mathbf{H}\mathbf{r}_a]^2} = \frac{e^2}{12mc^2}H^2\sum_a \overline{r_a^2}.$$

$$\chi = -\frac{e^2}{6mc^2}\sum_a \overline{r_a^2}.$$

$$\Delta E = \mu_B H\left(M_L + 2M_S\right) + A M_L M_S$$

$$\Delta E = \mu_B g_{nJ} H M_J,$$

$$\sum_n g_{nJ} M_J = \sum_{SL} g_{SLJ} M_J \qquad \Rightarrow \qquad \sum_n g_{nJ} = \sum_{SL} g_{SLJ}$$

(??? я пока так и не понял, как эффект Зеемана на магнетизм влияет?)

Спин в переменном магнитном поле по Ландау

$$\widehat{H} = -\frac{\mu}{s}\widehat{\mathbf{s}}\mathbf{H}$$

$$\widehat{H} = \sum_a \widehat{H}_a, \quad \widehat{H}_a = -\frac{\mu}{s}\mathbf{H}\widehat{\mathbf{s}}_a$$

$$i\hbar\dot{\psi}^\nu = -2\mu\mathbf{H}\widehat{\mathbf{s}}\psi^\nu.$$

$$\begin{aligned} i\hbar\dot{\psi}^1 &= -\mu H\psi^1, & \psi^1 &= c_1\exp\left(\frac{i\mu}{\hbar}\int H dt\right)\\ i\hbar\dot{\psi}^2 &= \mu H\psi^2. & \psi^2 &= c_2\exp\left(-\frac{i\mu}{\hbar}\int H dt\right). \end{aligned}$$

$$\psi^1 = e^{-i\omega t/2}\left(c_1 e^{i\Omega t/2} + c_2 e^{-i\Omega t/2}\right),$$
$$\psi^2 = 2\omega_H \sin\theta e^{i\omega t/2}\left[\frac{c_1}{\Omega + \omega + 2\omega_H\cos\theta}e^{i\Omega t/2} - \frac{c_2}{\Omega - \omega - 2\omega_H\cos\theta}e^{-i\Omega t/2}\right],$$

$\Omega := \sqrt{(\omega + 2\omega_H\cos\theta)^2 + 4\omega_H^2\sin^2\theta}.$

Плотность тока в магнитном поле по Ландау

$$\bar{H} = \int \Psi^* \left[\frac{1}{2m} \left(\widehat{\mathbf{p}} - \frac{e}{c}\mathbf{A} \right)^2 - \frac{\mu}{s}\mathbf{H}\widehat{\mathbf{s}} \right] \Psi dV$$

$$\mathbf{j} = \frac{ie\hbar}{2m} \left[(\nabla \Psi^*)\, \Psi - \Psi^* \nabla \Psi \right] - \frac{e^2}{mc}\mathbf{A}\Psi^*\Psi + \frac{\mu}{s} c \operatorname{rot} (\Psi^* \widehat{\mathbf{s}} \Psi)$$

$$\frac{\partial \rho}{\partial t} + \operatorname{div} \mathbf{j} = 0. \qquad (\rho = e|\Psi|^2)$$

$$\frac{\mu}{s} c \operatorname{rot} (\Psi^* \widehat{\mathbf{s}} \Psi) \equiv c \operatorname{rot} \mathbf{m} \qquad \mathbf{m} := \frac{\mu}{s} \Psi^* \widehat{\mathbf{s}} \Psi = \Psi^* \widehat{\mu} \Psi$$

$$\mathbf{j}_{nm} = \frac{ie\hbar}{2m} \left[(\nabla \Psi_n^*)\, \Psi_m - \Psi_n^* \nabla \Psi_m \right] - \frac{e^2}{mc}\mathbf{A}\Psi_n^*\Psi_m + \frac{\mu}{s} c \operatorname{rot} \left(\Psi_n^* \widehat{\mathbf{S}} \Psi_m \right)$$

Magnetism fundamentals

(очень коротко в контексте теории выше укажу, пока см. запись по магнетизму)

$$E_{\text{spin}} = \mu_B B s \qquad \mu_B = |e|\hbar/2m$$

Bohr's magneton $\mu_B = |e|\hbar/2m$

(!! derivation of it!)

(other important properties)

квантовом эффекте Холла

явлениях КЭД в магнитном поле

1.5.8 Relativistic QM and QED: main models

(много разных задач, выпишу указания на них потом, в теорполе уже написана теория, разберу ее скоро)

типичных моделях

О релятивистском электроне в атоме (!!!?)

The exact fine-structure formula for hydrogen (obtained from the Dirac equation without recourse to PT) is

$$E_{nj} = mc^2 \left\{ \left[1 + \left(\frac{\alpha}{n - (j + 1/2) + \sqrt{(j + 1/2)^2 - \alpha^2}} \right)^2 \right]^{-1/2} - 1 \right\},$$

which recovers mc^2, the ordinary energy levels, and the fine structure when expanded. However, at the next order additional effects appear which are not captured by the Dirac equation, such as hyperfine structure and the Lamb shift.

Proof:

$$(P - mc)\psi(x) = 0$$

$P_0 = \frac{E}{c} + \frac{e^2}{cr}, \quad \psi(x) \equiv e^{-\frac{\mathrm{i}}{\hbar}\mathrm{Et}}\psi(\boldsymbol{r}).$

$$\times(P+mc) \qquad \Rightarrow \qquad \left\{\left(p_0 + \frac{e^2}{cr}\right)^2 - \boldsymbol{p}^2 - (mc)^2 - \boldsymbol{\gamma}\cdot\boldsymbol{p}\gamma_0\frac{e^2}{cr}\right\}\psi(\boldsymbol{r}) = 0.$$

$$-\boldsymbol{\gamma}\cdot\boldsymbol{p}\gamma_0\frac{e^2}{cr} = \mathrm{i}\gamma_5\frac{\hbar^2\alpha_{\mathrm{em}}}{r^2}(\boldsymbol{\sigma}\cdot\boldsymbol{n}) \qquad \gamma\gamma_0 = -\gamma_5\boldsymbol{\sigma},\ \boldsymbol{p}\frac{1}{r} = \mathrm{i}\hbar\frac{\boldsymbol{n}}{r^2}$$

$\boldsymbol{n} := \boldsymbol{r}/r,$

$$\left\{\frac{p^2}{2m} - \frac{E}{mc^2}\frac{e^2}{r} - \frac{\hbar^2\alpha_{\mathrm{em}}}{2mr^2}\left[\alpha_{\mathrm{em}} + \mathrm{i}\gamma_5(\boldsymbol{\sigma}\cdot\boldsymbol{n})\right]\right\}\psi(\boldsymbol{r}) = \epsilon\psi(\boldsymbol{r})$$

$[\boldsymbol{l}_\alpha, (\boldsymbol{\sigma}\cdot\boldsymbol{n})] = \mathrm{i}\epsilon_{\alpha\beta\gamma}\boldsymbol{\sigma}_\beta n_\gamma, \quad [\boldsymbol{s}_\alpha, (\boldsymbol{\sigma}\cdot\boldsymbol{n})] = \mathrm{i}\epsilon_{\alpha\beta\gamma}n_\beta\boldsymbol{\sigma}_\gamma,$

$$j = l + \sigma = \mathrm{const}$$

$$\{E, j, m, l\},$$

$\Psi_\pm(\boldsymbol{r})$:

$$\left\{\frac{p^2}{2m} - \frac{E}{mc^2}\frac{e^2}{r} - \frac{\hbar^2\alpha_{\mathrm{em}}}{2mr^2}\left[\alpha_{\mathrm{em}} \pm \mathrm{i}(\boldsymbol{\sigma}\cdot\boldsymbol{n})\right]\right\}\Psi_\pm(\boldsymbol{r}) = \epsilon\Psi_\pm(\boldsymbol{r})$$

$$\Psi_\pm(\boldsymbol{r}) \equiv a_\pm\phi_{l_+}^{j,m}(\boldsymbol{r}) + b_\pm\phi_{l_-}^{j,m}(\boldsymbol{r})$$

$$\psi(\boldsymbol{r}) \quad \xrightarrow{\mathbb{P}} \quad \gamma_0\psi(-\boldsymbol{r}) = (-1)^{l+}\begin{pmatrix} a_-\phi_{l_+^j}^{j,m}(\boldsymbol{r}) - b_-\phi_{l'_-}^{j,m}(\boldsymbol{r}) \\ a_+\phi_{l_+}^{j,m}(\boldsymbol{r}) - b_+\phi_{l_-}^{j,m}(\boldsymbol{r}) \end{pmatrix}$$

Сами спиноры $\phi_{l_\pm^{j,m}}^{j,m}$ построены согласно правилам сложения двух моментов.

Поэтому

$$\boldsymbol{l}^2\phi_{l_\pm}^{j,m} = l_\pm(l_\pm+1)\,\phi_{l_\pm}^{j,m}$$

так как оператор $(\boldsymbol{\sigma}\cdot\boldsymbol{n})$ обладает отрицательной P -четностью и его квадрат равен единице, можно выбрать фазы спиноров $\phi_{l_\pm}^{j,m}$ так, чтобы

$$(\boldsymbol{\sigma}\cdot\boldsymbol{n})\phi_{l_\pm}^{j,m} = \phi_{l_\mp}^{j,m}.$$

(?????)

Значит, этот оператор смешивает состояния $\phi_{l_\pm}^{j,m}$ в уравнении (6.32), причем матрица, соответствующая вкладу орбитального движения

$$\frac{\hbar^2}{2mr^2}\left[l^2 - \alpha_{\mathrm{em}}^2 \mp \mathrm{i}\alpha_{\mathrm{em}}(\boldsymbol{\sigma}\cdot\boldsymbol{n})\right]$$

В базисе $\phi_{l_\pm}^{j,m}$ имеет вид

$$\frac{\hbar^2}{2mr^2}\begin{pmatrix} l_+(l_+1) - \alpha_{\mathrm{em}}^2 & \mp\mathrm{i}\alpha_{\mathrm{em}} \\ \mp\mathrm{i}\alpha_{\mathrm{em}} & l_-(l_-+1) - \alpha_{\mathrm{em}}^2 \end{pmatrix} = \frac{\hbar^2}{2mr^2}A$$

$$\text{e.v.} = z = \sqrt{\left(j+\frac{1}{2}\right)^2 - \alpha_{\mathrm{em}}^2}\left(\sqrt{\left(j+\frac{1}{2}\right)^2 - \alpha_{\mathrm{em}}^2} \pm 1\right) \equiv \lambda(\lambda+1)$$

$$\delta_j := j + \frac{1}{2} - \sqrt{\left(j+\frac{1}{2}\right)^2 - \alpha_{\mathrm{em}}^2}$$

$$\lambda := j \pm \frac{1}{2} - \delta_j \equiv l_\pm - \delta_j$$

Собственные значения для верхних и нижних спиноров, очевидно, совпадают, причем коэффициенты смешивания $a_\pm$ и $b_\pm$ удовлетворяют условиям построения биспиноров с заданной четностью.

В базисе собственных векторов матрицы получаем уравнение, опять имеющее вид уравнения для нерелятивистского атома водорода

$$\left\{ \frac{p_r^2}{2m} - \frac{E}{mc^2}\frac{e^2}{r} + \frac{\hbar^2}{2mr^2}\lambda(\lambda+1) \right\} u(r) = \epsilon u(r)$$

и после аналогичных случаю скалярного поля преобразований, получаем:

$$E = \frac{mc^2}{\sqrt{1 + \frac{\alpha_{em}^2}{\nu^2}}}$$

Поэтому для заданного главного квантового числа n мы имеем двукратное вырождение по орбитальному моменту l (разные значения радиального квантового числа n_r) при фиксированном значении полного момента j, если, конечно, $n > 1$ и $n > j + 1/2$, потому что В случае равенств возможны только значения $l = 0$ и $l = j - 1/2$, соответственно, при $n_r = 0$.

$$\varepsilon_{n,l} \approx -\frac{mc^2}{2n^2}\alpha_{\text{em}}^2 \left\{ 1 + \frac{\alpha_{\text{em}}^2}{n^2}\left(\frac{2n}{2j+1} - \frac{3}{4} \right) \right\}$$

Теперь значение расшепления уровней с заданным n В зависимости от j дает прекрасное согласие с экспериментами по измерению спектров в атоме водорода.

О скалярном релятивистском электроне (!?!??!?!!?!??)

$$E = \frac{mc^2}{\sqrt{1 + \frac{\alpha_{em}^2}{\nu^2}}} \qquad \text{(Enegry of bound st.)}$$

$$\mathcal{E}_{n,l} := E - mc^2 \approx -\frac{mc^2}{2n^2}\alpha_{\text{em}}^2 \left\{ 1 + \frac{\alpha_{\text{em}}^2}{n^2}\left(\frac{2n}{2l+1} - \frac{3}{4} \right) \right\}. \qquad \text{(Enegry of the bound.)}$$

Имеем снятие вырождения по l между уровнями с заданным n. Однако, эксперимент опровергает такое расщепление, например, для уровней $2s$ и $2p$, и верный результат получается с учетом спина.

Эта энергия находится из ур. Клейна-Гордона переходом к уравнению Шредингера для нерелятивистского атома водорода, но с другим зарядом и орбитальным моментом: $e^2 \mapsto \frac{E}{mc^2}e^2$; $\quad l(l+1) \mapsto \lambda(\lambda+1) = l(l+1) - \alpha_{\text{em}}^2$.

$\mathcal{A}_0(r) = -\frac{e}{r}$, $\vec{\mathcal{A}} \equiv 0$,

$$\left\{ \left(p_0 + \frac{e^2}{cr} \right)^2 - \boldsymbol{p}^2 - (mc)^2 \right\} \Phi(x) = 0, \qquad p_0 \equiv E/c$$

$$\Phi(x) \equiv \mathrm{e}^{-\frac{1}{\hbar}Et}\phi(\boldsymbol{r}), \qquad \left\{ \frac{\boldsymbol{p}^2}{2m} - \frac{E}{mc^2}\frac{e^2}{r} - \frac{e^4}{c^2}\frac{1}{2mr^2} \right\} \phi(\boldsymbol{r}) = \frac{E^2 - (mc^2)^2}{2mc^2}\phi(\boldsymbol{r}).$$

$$\phi(\boldsymbol{r}) \equiv \frac{u(r)}{r} Y_{l,m}(\theta,\varphi); \qquad \left\{ \frac{p_r^2}{2m} - \frac{E}{mc^2}\frac{e^2}{r} + \frac{\hbar^2}{2mr^2}\left(l(l+1) - \frac{e^4}{\hbar^2 c^2} \right) \right\} u(r) = \frac{E^2 - (mc^2)^2}{2mc^2} u(r),$$

$$\alpha_{\text{em}} := \frac{e^2}{\hbar c} \qquad \epsilon := \frac{E^2 - (mc^2)^2}{2mc^2}$$

$$\left\{ \frac{p_r^2}{2m} - \frac{E}{mc^2}\frac{e^2}{r} + \frac{\hbar^2}{2mr^2}\left[l(l+1) - \alpha_{\text{em}}^2 \right] \right\} u(r) = \epsilon u(r).$$

(finish writing it!!)

Это же можно получить большими преобразованиями через ряды.
(????? see my problems section and notes from KU Leuven)

О парадоксе Клейна

(тоже очень типичная тема, 1/2 страницы на это планирую, очень коротко укажу.)

О разных моделях поля Клейна-Гордона (!?!???!?!!?!??)

(абзацы тут про каждую модель, больше словами, но также основные формулы и графики приведу. почитаю ту умную книгу про них)

1.5.9 Light-matter interactions, basic quantum optics

Jaynes-Cummings model

Moving from the Schrödinger picture into the interaction picture (a.k.a. rotating frame) defined by the choice $\hat{H}_0 = \hat{H}_{\text{field}} + \hat{H}_{\text{atom}}$, we obtain

$$\hat{H}_{\text{int}}(t) = \frac{\hbar\Omega}{2}\big(\underbrace{\hat{a}\hat{\sigma}_- e^{-i(\omega_c+\omega_a)t}}_{\text{fast}} + \underbrace{\hat{a}^\dagger\hat{\sigma}_+ e^{i(\omega_c+\omega_a)t}}_{\text{fast}} + \hat{a}\hat{\sigma}_+ e^{-i(-\omega_c+\omega_a)t} + \hat{a}^\dagger\hat{\sigma}_- e^{i(-\omega_c+\omega_a)t}\big).$$

Transforming back into the Schrödinger picture,

$$\hat{H}_{\text{JC}} = \hbar\omega_c \hat{a}^\dagger\hat{a} + \hbar\omega_a \frac{\hat{\sigma}_z}{2} + \frac{\hbar\Omega}{2}\left(\hat{a}\hat{\sigma}_+ + \hat{a}^\dagger\hat{\sigma}_-\right)$$

JC model by Tong

$$H_{JC} = \frac{\hbar}{2}\begin{pmatrix} \omega_0 & ga \\ ga^\dagger & -\omega_0 \end{pmatrix} + \hbar\omega a^\dagger a$$

$$H_n = \left(n - \frac{1}{2}\right)\omega \mathbf{1}_2 + \frac{1}{2}(\omega_0 - \omega)\,\sigma^3 + \frac{1}{2}g\sqrt{n}\sigma^1$$

$$|n_+\rangle = \sin\theta|n-1,\uparrow\rangle - \cos\theta|n,\downarrow\rangle$$
$$|n_-\rangle = \cos\theta|n-1,\uparrow\rangle + \sin\theta|n,\downarrow\rangle$$

$$\tan(2\theta) = \frac{g\sqrt{n}}{\delta}, \quad \delta = \omega_0 - \omega$$

$$E_\pm = \left(n + \frac{1}{2}\right)\hbar\omega \pm \frac{1}{2}\hbar\sqrt{g^2 n + \delta^2}$$

$$|\Psi(t)\rangle = \left[e^{-iE_- t/\hbar}\sin\theta\,|n_-\rangle - e^{-iE_+ t/\hbar}\cos\theta\,|n_+\rangle\right]$$
$$P_\uparrow(t) = \frac{g^2 n}{g^2 n + \delta^2}\sin^2\left(\frac{\sqrt{g^2 n + \delta^2}}{2}t\right)$$

Death and Resurrection:

$$|\Psi\rangle = e^{-|\alpha|^2/2}e^{\alpha a^\dagger}|0,\downarrow\rangle = e^{-|\lambda|^2/2}\sum_{n=0}^{\infty}\frac{\alpha^n}{\sqrt{n!}}|n,\downarrow\rangle$$

$$|\Psi(t)\rangle = e^{-\left(|\alpha|^2 - i\omega t\right)/2}\sum_{n=0}^{\infty}\frac{\left(\alpha e^{-i\omega t}\right)^n}{\sqrt{n!}}\left[\cos\left(\frac{g\sqrt{n}t}{2}\right)|n,\downarrow\rangle + i\sin\left(\frac{g\sqrt{n}t}{2}\right)|n-1,\uparrow\rangle\right]$$

$$P_\uparrow(t) = e^{-|\alpha|^2}\sum_{n=0}^{\infty}\frac{|\alpha|^{2n}}{n!}\sin^2\left(\frac{g\sqrt{n}t}{2}\right)$$

$$P_\uparrow(t) = e^{-|\alpha|^2}\sum_{n=0}^{\infty}\frac{|\alpha|^{2n}}{n!}\left(\frac{1}{2} - \frac{1}{2}\cos(g\sqrt{n}t)\right) = \frac{1}{2} - \frac{1}{2}e^{-|\alpha|^2}\sum_{n=0}^{\infty}\frac{|\alpha|^{2n}}{n!}\cos(g\sqrt{n}t)$$

$$\frac{|\alpha|^{2n}}{n!} \approx \frac{1}{\sqrt{2\pi n}}e^{n\log|\alpha|^2 - n\log n + n} \overset{f''(n_{\max})=-1/n}{\approx} \frac{1}{\sqrt{2\pi|\alpha|^2}}e^{|\alpha|^2 - m^2/2|\alpha|^2}$$

$m = n - |\alpha|^2$.

$$P_\uparrow(t) \approx \frac{1}{2} - \frac{1}{2}\sum_{m=-\infty}^{\infty}\frac{1}{\sqrt{2\pi|\alpha|^2}}e^{-m^2/2|\alpha|^2}\cos\left(gt\sqrt{|\alpha|^2 + m}\right)$$

$$T_{\text{Rabi}} \approx \frac{2\pi}{g|\alpha|}$$

$gT\left(\sqrt{|\alpha|^2 + |\alpha|} - |\alpha|\right) \approx 2\pi$, or

$$T_{\text{collapse}} \approx \frac{4\pi}{g}$$

(!!! графики очень известные вставлю, см. пока хотя бы Тонга)

Rabi oscillations

$$\hat{H} = \begin{pmatrix} E_0 + \Delta & We^{-i\omega t} \\ We^{i\omega t} & E_0 - \Delta \end{pmatrix}$$

$$P_1(t) = \frac{W^2}{(\Delta - \hbar\omega/2)^2 + W^2} \sin^2\left(\frac{\Omega t}{2}\right), \quad \Omega = \frac{2\sqrt{(\Delta - \hbar\omega/2)^2 + W^2}}{\hbar}$$

coherent states

squeezing

manipulations of individual atoms;

системах с дискретными степенями свободы

Блоховское представление двухуровневой системы

взаимодействии двухуровневых систем с электромагнитным полем

$$\hat{V} = -\mathbf{dE}$$

$$\hat{V} = \hbar\Omega_R \left(\hat{a} + \hat{a}^+\right)\left(\hat{\sigma} + \hat{\sigma}^+\right)$$

где $\Omega_R = -\left(\mathbf{E}_0\hat{\mathbf{d}}_{eg}\right)\sin\left(\frac{\omega z}{c}\right)$ - частота Раби в поле «одного фотона», поляризованного вдоль оси x. Она играет роль константы связи ДУС и МР.

Гамильтониан Джейнса-Каммингса:

$$\hat{H} = \hbar\omega_{MP}\hat{a}^+\hat{a} + \hbar\omega_{\text{дус}}\,\hat{\sigma}^+\hat{\sigma} + \hbar\Omega_R\left(\hat{a}^+\hat{\sigma} + \hat{a}\hat{\sigma}^+\right).$$

1.5.10 Nuclear physics: basic effects

(тут указания про самые основные задачи про атомы из ЛЛ3. всё остальное - во 2й 1й части, там отдельный раздел про разные модели)

1.5.11 Key fundamental experiments

Об опыте Юнга

(конкретно, в каких параметрах установки он будет?)
Один из самых важнейших опытов квантовой механики, дающий пояснение, что такое суперпозиция состояний - это опыт Юнга

О влиянии наблюдателя

Никакого влияния наблюдателя нет, просто обычные волновые свойства света проявляются и все.
(потом напишу точнее, важное указание)

Об опытах, устанавливающих спектры атомов

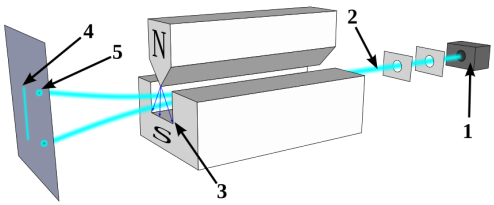
Об опыте Дэвиссона-Джермера (?)

Опыт Дэвиссона-Джермера - физический эксперимент 1927 г. по дифракции электронов.

В нем наблюдалась дифракция электронов на кристаллической решётке монокристалла.

говорят, что это с УШ связано, а также с волнами де бройля, да я хз.

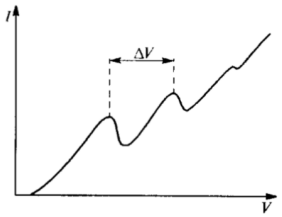
Stern–Gerlach experiment



The Franck–Hertz experiment (Nobel prize 1925)

It was the first electrical measurement to clearly show the quantum (discrete) nature of atoms.

Между катодом и анодом помещается гелий, далее увеличивая напряжение будем мерить проходящий ток. В итоге:



Proof: (??????????????)

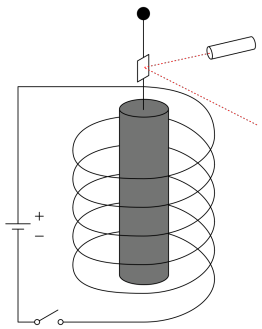
$$F = \mu_z \left(\frac{dB}{dz}\right)$$

$$V_Z = \frac{F}{m}t = \frac{F}{m}\frac{L}{V_X}$$

$$\Theta = \frac{V_Z}{V_X} = \mu_z \left(\frac{dB}{dz}\right)\frac{L}{mV_X^2} = \mu_z \left(\frac{dB}{dz}\right)\frac{L}{2T}$$

Об опыте Эйнштейна-де Гааза (????)

(???)



Об опыте Томсона?

(редко его упоминают)

Nobel experiment by Aspect, Clauser, Zeilinger

On Lenard's experiment on cathode rays (NP 1905)

for his work on cathode rays

Part II
Fundamentals of Quantum Mechanics

Обсудим основы квантовой механики.

2 Main General Fundamentals

2.1 Experimental Facts in Basis of Quantum Mechanics

(тут коротко эксперимент - и то, как он указывает на то, почему квантмех именно так мы построили в итоге.)

This is important because our philosophy is based on observations. We can't say anything without observing nature.

2.1.1 Quantum Tunneling

Main ideas

(I'll describe this phenomena)

Some models with quantum tunneling

(???)

Tunneling bullet that hits an object

(??? what is the probability that it will just tunnel through without destroying the object? I have no idea now)

Probability of fall a standing cup

(I heard that it is also can be analyzed by quantum tunneling method... I'll write later)

Other about quantum tunneling

(???)

2.2 How In General We See Quantum World?

2.2.1 What is the Microworld And Particle?

Почему нам не хватает классической механики?

What is a particle?

(I am not sure, just a concept, it is not clear, what is it and what is meant by this question?)

Short history of concept of particle

(write about ancient times, people understood it even way before modern civilizations)

Появилось это название в 30-х годах, когда единственными представите- лями рассматриваемой группы были протон, нейтрон, электрон и фотон. Эти четыре частицы служат основой для построения окружающего нас вещества и взаимодействующего с ним электромагнитного поля и назвать их элементарными было вполне естественно.

Вначале была обнаружена первая античастица — позитрон, предсказанный П. Дираком в 1928 г. Открыт позитрон был в космических лучах в 1932 г. американским физиком К. Андерсоном (1905-2005). Эта частица отличалась от электрона только знаком электрического заряда.

Окей, классической механики не хватает, но почему вообще нам нужны именно операторы?

Философия, с которыми ожидаемо направление работы с операторами

(??? почему мы так делаем??)

Почему мы в принципе можем описывать природу операторами? (???)

(пока не знаю, что ответить, можем и все... потом напишу нормальный ответ.)

Операторы - решение проблемы?

(мб)

А как мы представляем квантовый мир и как это соотносится с базовой математикой в основе квантовой механики?

(про визуализацию обсуждение, это тоже важно, потому что часто именно из визуальной идеи мы и начинаем строить теории)

Настоящие измерительные приборы тоже квантовые

Можно ли сделать мир только квантовым, не имея вообще ничего классического, так чтобы и наблюдатель был квантовым?

(вроде как нет, классический предел и классические наблюдатели у нас всегда появляются. это фундаментальный вопрос в физике)

(то, что с Кириллом обсуждали)

Что делает теорию квантовой?

(на стак эксчендже есть тоже вопрос такой, потом подумаю.)

Какая частица элементарная?

(тоже об этом тут место написать)

Почему электрон элементарный, а протон нет?

(этот вопрос типично на КТП перекидывают, я же постараюсь тут ответить, приведя опытные факты.)

Идейно, почему и как мы можем квантовой механикой описывать кварки?

(??? не знаю, остается вопрос, там же мб другая физика, состояния связанные, хз вообще, к кваркам я всегда не готов был.)

Откуда вообще возьмется потенциал, если все массивное - волновая функция и ее взаимодействия? (!?????????????????????)

2.2.2 Connection of Classical and Quantum Mechanics

(it is not clear if one is a limit of another or not? is it indeed working? we don't need to focus on quantization here and on the formalism. There are section about answering these questions from this side later. here I want to emphasis the exactly the Connection of Classical and Quantum Mechanics and tell which views of them are wrong)

2.2.3 How Do We Understand Measurement?

Обсудим подробно идею измерений.
(с формулами - ниже раздел)

Как мы меряем параметры с фундаментальной точки зрения? (???)

Как догадаться, что следует работать с собственными значениями операторов? (!??!?!)

(да не знаю, так и не понял еще, просто пользуюсь этим и все.)

2.2.4 Planck Constant (??)

(тоже могут много вопросов появиться.)

О введении постоянной планка и перехода в предел геометрической оптики (?)

Введите универсальную постоянную Планка согласно принципу соответствия классического движения частицы пределу «геометрической оптики» для волны, допускающей описание распространения лучей согласно принципу Ферма.
(Вопросы Киселева на развлечение (?!!!!!))

Теоретически, почему она постоянная?

Экспериментально, почему она постоянная?

2.2.5 What Would Be If One Slightly Changed Fundamental Constants of QM (??)

(I'll answer these questions here, if charge e is changes, if $\hbar$ is changed, if mass of electron is changed? what would be? good questions, actually)

2.2.6 Transitions To Other Reference Frames In Quantum Mechanics (??)

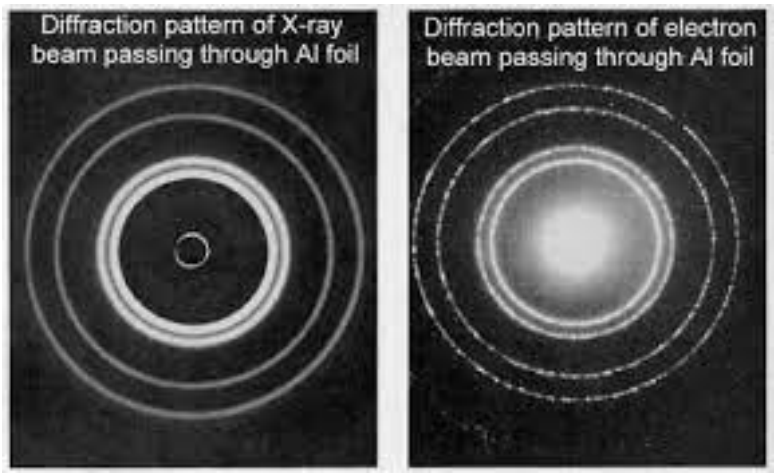
(тут же вопрос про то, как она связана с гравитацией. пока не до этого.)

Как изменится описание системы, если перейти во вращающуюся систему отсчета? (!??!!?)

(не знаю, мб много времени уйдет разобраться в этом, в механике сперва пропишу их лучше.)

2.2.7 Idea of Matter Waves

Феноменология дифракции электронов (??)



Другие свойства волн материи (????)

(есть статьи про это, пока не читал)

Волновая функция и волны материи (????)

(вроде как волновая функция даже не сразу была открыта, а уже волны какие-то материи были. так что тут про это подробнее)

О заблуждениях про волны материи

2.2.8 What Is Vacuum?

(see note on QFT, it will be first written there)

2.2.9 Wave-particle duality (?)

(тут подробно его обсуждаю)
(потом сивухина добавлю.
тут же гипотеза де Бройля: из классической механики в оптику)

Точечность частицы

Частицы всегда точечные.
(про это тут)

Почему тогда ядра не точечные?

потому что там есть нуклоны.
а почему есть нуклоны????
почему мы можем сказать, что ядра неточечные????
(остался вопрос)

Объединение корпускулярных и волновых формул в один формализм (???)

(тут формулы корпускулряных эффектов, комптон, фотоэффект)
(тут формулы волновых эффектов)
(тут общие формулы, из которых обе выше следуют.)
(??? чего еще не знаю, как это сделать???)

По киселеву

(пара слов про механику и оптику.
кстати, их отдельно тоже дописать нужно!!!) что тут типа эти вот методы нужно использовать, а не другие, там не лагранж, не еще что-то.

Из механики нам известны уравнения гамильтона, согласно которым происходит динамика нашей системы:

$$\frac{dq}{dt} = \frac{\partial H}{\partial p}, \quad \frac{dp}{dt} = -\frac{\partial H}{\partial q},$$

Что можно записать в виде уравнений на действие $S = \int\limits_{q_0,t_0}^{q,t} (pdq - Hdt)$, уравнений Гамильтона-Якоби:

$$\frac{\partial S}{\partial q} = p, \quad \frac{\partial S}{\partial t} = -H(q,p,t),$$

которые можно получить (да, они от туда?) из принципа наименьшего действия:

$$\delta S = 0$$

Предположим, что материя это волна, подчиняющаяся законам оптики.

Для такой волны $\Phi(q,t) \simeq e^{i\phi}$ фаза $\phi = \int\limits_{q_0,t_0}^{q,t}$ определяется принципом Ферма:

$$\delta\phi = 0$$

Если объект может быть и волной и частицей, то его динамика должна выводиться из одного и того же принципа. Поэтому, необходимо, чтобы принцип Ферма и принцип наименьшего действия были одним и тем же.

Таким образом, действие и угол должны выражаться друг через друга с помощью констант. Введем константу $\hbar$, имеющую размерность действия. Теперь волна материи может быть записана как

$$\Psi(q,t)_{\text{geom.optic}} \cong e^{\frac{i}{\hbar}S(q,t)}$$

И из этого следуют с одной стороны динамика с точки зрения механики, и волновые свойства.

теперь следствия (?это следствия?)

классические результаты де Бройля:

$$\lambda = \frac{2\pi}{k} = \frac{2\pi\hbar}{p}$$

(2.10 задача, потом додумаю)

удивительно, но соотношение де бройля позволяет определить относительные показатели преломления.

$$n = \frac{\lambda_1}{\lambda_2}$$

суть в том, что мы для частиц начинаем писать все то же, что мы писали для волн!!!

удивительно!

таким образом из энергии сразу получаемся длина волны: $\lambda = \frac{2\pi\hbar}{\sqrt{2mE}}$.

так что похоже что все наши волновые знания через де Бройля нами и будут пользоваться.

еще тут есть важные трюки с переходом к $\Delta\lambda$ и другим, это ниже разберем.

(и намеки на волновую функцию, введение в которую будет дальше)

дальше

$$\hat{p}_q \Psi(q,t) = \frac{\partial S(q,t)}{\partial q}\Psi(q,t) \cong -i\hbar\frac{\partial}{\partial q}e^{\frac{i}{\hbar}S(q,t)} \cong -\mathrm{i}\hbar\frac{\partial}{\partial q}\Psi(q,t)$$

$$\hat{p}_q = -\mathrm{i}\hbar\frac{\partial}{\partial q}$$

$$\frac{\partial S}{\partial t}\Psi(q,t) \cong -\mathrm{i}\hbar\frac{\partial}{\partial t}e^{\frac{1}{\hbar}S(q,t)} \cong -\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi(q,t)$$

$$\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi(q,t) = \hat{H}\left(q,\hat{p}_q,t\right)\Psi(q,t)$$

Электроны также могут описываться волной

(напишу это красиво, это удивительно вообще)

Любая материя также может описываться волной

(напишу это красиво, это удивительно вообще. хотелось бы формулу, какого размера объекты могут описываться волной?

2.2.10 Why Do We Need Exactly a Density of Probability?

(a detailed answer is here. at first studying it is better not to think about it, just use the formalism)

2.2.11 How Do Interactions Occur?

(?? не уверен в ответе, но мы описыаем просто новым членом вз-я в гамильтониане)

How to write an interaction term of atom and field?

Why for atom interaction with electric field is $\hat{V} = eE\hat{x}$?

(Это из теории поля, где разложения. См. ЛЛ3, там подробно обсуждаются вопросы вз-я атома и поля)

Нетривиальный факт, что + и - от электрона и протона учитываются именно как дипольный момент и поэтому мы имеем дипольное взаимодействие с электрическим полем.

Квадрупольные взаимодействия иногда тоже рассматриваются, например, в сверхтонкой структуре.

Can an electron interact with its own electric field?

This is something that has been considered for a long time, even before quantum theory, people tried to see if the electron's self energy could explain its mass. Unfortunately, such calculations always yield infinity for the self-energy, unless you make some assumptions about having a finite cutoff radius, which is not observed.

However, the issue reared up again in quantum electrodynamics. The electron's own electric field is made up of photons emitted from the electron itself, and the electron can absolutely interact with such photons, these are among the terms that appear in the standard perturbation theory calculations. And just as before, these types of interaction terms are infinite in size. And it was not understood for many years what to do with this result, until Feynman and Schwinger showed how to "renormalize" the parameters of the model to absorb these infinite contributions into the model parameter definitions. The procedure leaves people uneasy, but it works extremely well, and this model, Quantum Electrodynamics is now the most accurate model of anything, anywhere, ever in human history.

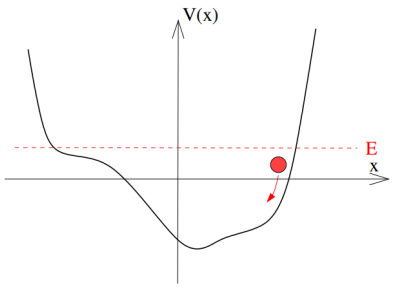
(потом продумаю!!!)

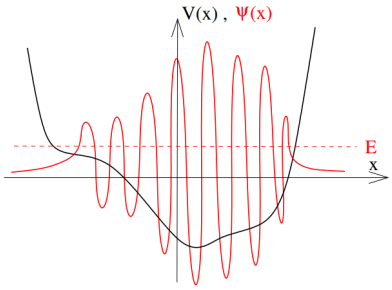
2.3 Concepts That Are Used in QM Models

2.3.1 The Main Idea of Quantum Mechanics

(тут то, что дальше во всей теории мы и применяем, с нее все и начинается.)

Сравнение классического и квантового (??)





казуальная неопределенность (??)

Подобные вероятностные характеристики имеют совершенно иную природу, не связанную с природой погрешностей прибора.

Другими словами, распределение положения точки регистрации частицы в приборе, если частица двигалась до этого свободно, без взаимодействия с системой, является распределением случайной величины, значение которой никак казуально не предопределено на каждой отдельной траектории.

Неопределённости этой случайной величинь - это новый эффект, который требует адекватного описания.

С точки зрения проблемы начальных условий следует признать, что для свободной частицы задать её координату в начальный момент времени означает задать исходную точку частицы в приборе, а значит, взаимодействие частицы с прибором должно исходно быть не равно нулю!

Напротив, в случае, если частица совершенно точно находится в заданной точке пространства, отсутствуют какие-либо данные о траектории в других точках пространства, то есть совершенно неопределено, с какой скоростью движется частица, поскольку для определения скорости необходимо получить данные о сдвиге частицы в другую точку.

Значит, если на частицу начинают действовать внешние силы, т.е. она взаимодействует с окружающей средой, положение частицы уже может быть более определенно, поскольку силы изменяют скорость частицы, то есть от них зависит сравнение характеристик движения в разных точках, но так как это положение ещё имеет ненулевую неопределённость, то и значение сил задаётся неоднозначно, силы при повторных опытах имеют флуктуации, что делает траекторию несколько неопределённой, а не абсолютно точной.

Мы видим, что неопределённости в значениях скорости и координаты частицы каким-то образом связаны казуально, но эта связь в области применимости классической механики может быть пренебрежимо малой, она существенна в квантовой механике.

В связи с вышесказанным разумнее перейти от описания эволюции системы (в данном случае, речь идёт об эволюции свободной частицы) с заданными исходными данными к описанию эволюции с заданными координатами на концах траектории: измерять координаты частицы действительно можно с любой инструментальной погрешностью.

Для свободной частицы, в отсутствие всяких сил, существуют инерциальные системы огсчёта (о них мы ещё будем разговаривать в II. 1.6), в которых частица движется поступательно и равномерно, то есть траектория является прямой линией.

В этом простейшем случае, очевидно, переход от начальных условий к данным на концах траектории является взаимно однозначнът.

При наличии сил переход к данным на концах траектории также будет взаимно однозначным, если рассматривать движение на бесконечно малом промежутке времени $t_1 - t_0 \mapsto dt \to 0$. Это справедливо и для траекторий на конечных отрезках времени, если в системе нет сингулярностей или особых симметрий.

Все другие «траектории», то есть функции $x(t)$ с теми же данными на концах не будут удовлетворять уравнениям движения с заданными начальными условиями.

Траектории, не являюшциеся решением уравнений движения, можно трактовать как траектории с другим набором сил, что влечёт за собой, конечно, и соответству ющщие изменения начальных условий, а именно, скорости в исходной точке.

В этом смысле, траектория, которая мало отличается от решения уравнений движения в заданной физической системе с фиксированными концами, получается за счёт малой флуктуации сиЛ.

Траектории с фиксированными концами: $x\left(t_0\right) = x_0, x\left(t_1\right) = x_1$, можно поставить в соответсвие число, равное единице, если эта траектория $x(t)$ является решением уравнений движения [1] в заданной физической системе, и нуль, если траектория $\bar{x}(t)$ не является решением уравнений движения.

Сконструированное нами сейчас соответствие называют динамическим функционалом достоверности траектории С:

$$\mathcal{C}[x(t)] = 1, \quad \mathcal{C}[\bar{x}(t)] = 0$$

Ясно, что при наличии нескольких частиц, которые движутся под воздействием внешних сил, динамический функционал достоверности всей системы частиц является произведением динамических функционалов достоверности для отдельных частиц:

2.3.2 Time in QM: Main ideas

(there are a lot of statements about the time, but they will be written at the last part of the note. here, there will be the most important statements)

2.3.3 Reference Frames in QM

(to know in which frame we are, we need to have photons that are coming in, but in there are a lot of models that state that something is moving, but there are no photons in that model. so, there are questions about the validity in general of these solutions. these questions I'll describe here.)

2.3.4 Idea of Operators in Quantum Mechanics

(чисто то, что используем в задачах, математика и дополнения все - в другой части.)

Суть гейзенберговского представления (???)

(укажу тут его)

The idea of spin models

(here, I'll answer this question that we have a w.f. in QM, but then later in many particle physics there are just states and action on them with on-site operators. why??? why we are so far away from Scrodinger equation??? or it is there, just the notation is fully different??)

2.3.5 Space of States (??)

Обсудим подробно пространство состояний.

2.3.6 Concept of Path Integral (??)

(intro to this method. see later parts for now with technical description of this method, or a special note about it)

2.4 Advanced General Understanding of Quantum Mechanics

$$\mathcal{C} = \prod_{i=1}^{n} \mathcal{C}_i$$

Вспомним, однако, про наличие погрешности измерения наблюдаемых характеристик частицы.

Как уже было сказано раньше, если начальные условия для координаты и скорости частицы принимают центральные значения с конечной погрешностью, то траектории из такой малой области начальных условий на малых интервалах времени будут мало отличаться от центральной траектории.

В этом случае вся «трубка» траекторий из исходной области начальных данных является эквивалентной в рамках погрешности измерений, так что для всего пучка динамический функционал достоверности траекторий в пучке равен единице.

Тем не менее, представим теперь себе ситуацию, когда

центральное значение начальных условий немного сдвинуто так, чтобы при заданной погрешности новая область начальньгх данных лишнь наполовину перекрывается с исходной областью начальных условий при той же погрешности.

Тогда динамический функционал достоверности траекторий в половине случаев принимает значение, равное единице, если траектория находится в пересечении двух областей данных, и равное нулю, если траектория находится вне исходной «трубки» траекторий.

В этом случае естественно говорить уже не о динамическом функционале достоверности траектории, а о функционале вероятности достоверности траектории $\mathcal{W}$, а в приведённом примере можно положить эту вероятность равной $\mathcal{W} = \frac{1}{2}$. Более формально, необходимо взять N_0 траекторий в области погрешности определения начальной координаты и начальной скорости и вычислить, сколько из этих траекторий попали в область фиксированных значений координаты и скорости на конце траектории N_1 за фиксированный интервал времени, и определить вероятность в зависимости от отношения $\frac{N_1}{N_0}$.

Таким образом, в общем случае, при наличии ненулевой погрешности измерений координат и скорости следует ввести функционал вероятности достоверности траектории со значениями во всем спектре от нуля до единицы: $\mathcal{W} \in [0, 1]$. Эта вероятность достоверности достигает своего максимума на решении уравнений движения с фиксированными концами траектории в заданной физической системе, то есть $\mathcal{W}$ имеет экстремум на «прямой» траектории [1]. По построению, функционал вероятности достоверности траекторий вычисляется как произведение вероятностей для независимых подсистем и подтраекторий:

$$\mathcal{W} = \prod_{i=1}^{n} \mathcal{W}_i$$

Здесь следует сделать следующее замечание: рассмотрение вероятности достоверности траекторий $\mathcal{W}$ для системы из двух тождественных частиц может привести к противоречию с принципом запрета Паули. Чтобы этого не происходило, вводится комплексная амплитуда вероятности Ψ согласно

$$\mathcal{W} = |\Psi|^2$$

При этом очевидно, что амплитуда вероятности достоверности траектории, как и сама вероятность, имеет экстремум на «прямой» траектории.

Значит, и логарифм [3] амплитуды имеет экстремум на «прямой» траектории.

Разбивая «прямую» траекторию на полтраектории, получаем

$$\ln \Psi = \sum_{i=1}^{n} \ln \Psi_i$$

Введём понятие действия S как аддитивного функционала на траектории,
пропорционального логарифму амплитуды вероятности

$$S[x(t)] = -\mathrm{i}\hbar \ln \Psi, \quad S = \sum_{i=1}^{n} S_i$$

Разбивая бесконечно малый интервал эволюции на два отрезка эволюции $dt_{12} = dt_1 + dt_2$, в силу аддитивности функционала действия находим, что $dS_{12} = dS_1 + dS_2$. На бесконечно

малом интервале действие зависит от одних и тех же значений координаты и скорости, так что при произвольном разбиении интервала условие: $dS_{12} = dS_1 + dS_2$ может быть удовлетворено, только если

$$dS = L(x, \dot{x}, t)dt$$

где функция Лагранжа $L(x, \dot{x}, t)$ зависит от определения динамических свойств физической системы.

В итоге, функционал действия на траектории задаётся в виде интеграла

$$S[x(t)] = \int_{t_0,x_0}^{t_1,x_1} L(x, \dot{x}, t)dt$$

Причём, как мы установили, на траектории, удовлетворяющей уравнениям движения, действие экстремально.

Это утверждение и составляет суть принципа экстремального действия Гамильтона, из которого мы в п. 1.3 получим уравнения движения - т.н. уравнения Эйлера-Лагранжа - для частицы (в общем случае, механической системы) с лагранжианом $L(x, \dot{x}, t)$.

2.4.1 The Limit of Healthy Philosophy of QM (??)

There are a lot of philosophers who propose to read their big books about some abstract questions in QM, listen to seminars, where they give strange statements, which are useless in a sense that one would work with QM without any problem without understanding of them. This is not the “real understanding”, which was initially proposed. Here, we will discuss this boundary between important fundamental question and waste of time, which is proposed as something very important. And this is the very big problem of quantum mechanics, one can just start thinking about such philosophical questions and come shortly to the stage when he would not be able to solve absolutely any problem. This would be just a catastrophe, so it is important to understand, which questions of QM one should postpone for a long time?

(similar things are written shortly in the section "tips for learning QM in the appendix", but here, there are informative statements about QM, and in that section, there is a focus on advice for learning)

2.4.2 Einstein’s Quantum Thought Experiments

(там как минимум на википедии есть список их, вот и обсужу их, пока не до этого)

2.4.3 Why There are Complex Numbers in QM?

(I’ll discuss this useless but interesting for a waste of time question... later!)

2.4.4 Determinism (??)

(тут про нее, уже в другом месте писал про это.)

2.4.5 Experiments, at which quantum mechanics breaks? (???)

(the most important question of quantum mechanics. since life is more than lifeless mechanics, but at what stage it emerges?)

2.4.6 At Which Point Does Lifeless Micromechanics Fail? (???)

(the most important question of quantum mechanics. since life is more than lifeless mechanics, but at what stage it emerges?)

2.4.7 Schrodinger's Cat

(I don't think that it is that important, but okay, it is a nice, fundamental topic and I still need to write it better)

2.5 Features of Interpretations of Fundamental Experiments in QM

2.5.1 Can the photoelectric effect be explained without photons?

see https://physics.stackexchange.com/questions/68147/can-the-photoelectric-effect-be-explained-without-photons, I'll think later.

2.6 Limits of Applicability of Quantum Mechanics

2.6.1 Limits of Applicability Due to Relativistic Effects

(???? write it??? if we increase speed of particles, when do we need to use different spectrum and when QM is at all not applicable?)

2.6.2 Limits of Applicability Due to Size of a System

(???? write it??? if we increase size of a system, when other effects start to play a role and when QM is at all not applicable?)

2.7 Operators, Wave Functions, States

2.7.1 Wave Function

Обсудим подробно, что такое волновая функция.

Смысл волновой функций и траектории квантового движения (!!!)

Хотя мы всегда видим только одну траекторию, никто нам не говорил, что вне измерений будет движение тоже по одной определенной траектории

как конкретно это происходит?

Что за движение частицы в точку, где она измерена, из всех точек, где ее вероятность ненулевая?

(Это звучит как самая бредовая формула в физике, но когда обсуждают смысл волновой функции, то такую формулу пишут. Тут важное обсуждение этого момента)

Свойства волновой функции

Представления волновой функции и ψ вне зависимости от представления? (?????)

Как так может быть, что есть ψ, $\psi(p)$, $\psi(x)$?
(задал этот вопрос Филиппову, так и не помню ответ, потом пропишу)
(скоро напишу ответ, но не сейчас)

That stupid notation $|\psi\rangle(x)$

(here, I'll answer, what is meant by it???? a very confusing notation)

Вероятность по волновой функции

(напишу потом, типа просто квадрат модуля. однако если у нас есть переходы, то можно брать просто скалярное произведение двух состояний, что часто делается в задачах. все, так этим и пользуюсь.)

Энергия из волновой функции (????)

(?? как это получить?)

Другие физические параметры из волновой функции

(пока не знаю.)

Нормировка волновой функции (???)

(мб сделаю большим разделом, пока лишь надеюсь, что такого раздела уже должно хватить.)

связь непрерывного и дискретного спектров через нормировку в ящике (???)

(пока хз, зачем это, потом разберу когда-то)
в итоге объем, граничные условия Борна-Кармана...

$$\psi_{\boldsymbol{p}}(\boldsymbol{r}) = \frac{1}{\sqrt{V}} e^{i\boldsymbol{p}\boldsymbol{r}}$$

хз, почему

$$\sum_{\boldsymbol{p}} \leftrightarrow \int \frac{V d^d \boldsymbol{p}}{(2\pi)^d}$$

ну и если я дойду, я начну на самом деле глубоко физику понимать.
например, можно понять, почему

$$\delta(\boldsymbol{r} - \boldsymbol{r}') \equiv \sum_{\boldsymbol{p}} \psi^*_{\boldsymbol{p}}(\boldsymbol{r}')\, \psi_{\boldsymbol{p}}(\boldsymbol{r}) \approx \int \frac{V d^d \boldsymbol{p}}{(2\pi)^d} \frac{1}{V} e^{i\boldsymbol{p}\boldsymbol{r} - i\boldsymbol{p}\boldsymbol{r}'} = \int \frac{d^d \boldsymbol{p}}{(2\pi)^d} e^{i\boldsymbol{p}(\boldsymbol{r} - \boldsymbol{r}')} = \delta(\boldsymbol{r} - \boldsymbol{r}')$$

Нормировка в случае непрерывного спектра на дельта-функцию (!?!??)

(!?!?!?? тут подробно про это напишу, важный раздел!!!)

Как и в дискретном случае, состояния, соответствующие различным собственным числам, по-прежнему ортогональны, однако они часто ненормируемы.

В непрерывном случае нормировка имеет вид: $\langle\psi_f|\psi_{f'}\rangle = c(f)\delta\left(f - f'\right)$, коэффициенты $c(f)$ могут быть любыми

Сама волновая функция через компоненты представляется

$$|\Psi\rangle = \int d\nu|\nu\rangle\Psi_\nu = \int d\nu|\nu\rangle\langle\nu|\Psi\rangle$$

Коэффициенты в общем случае можно было бы посчитать приведением скалярного произведения к виду дельта функции на коэффициент, но так никто не знает, как сделать, так что.

В данном случае нормировочные множители считаются с помощью асимптотического вида функции.

Введём произвольный масштаб λ и запишем перекрытие следующим образом

$$\int\limits_{-\infty}^{\infty} dx\psi^*_{f'}(x)\psi_f(x) = \int\limits_{-\infty}^{-\lambda} dx\psi^*_{f'}(x)\psi_f(x) + \int\limits_{\lambda}^{\infty} dx\psi^*_{f'}(x)\psi_f(x) + \int\limits_{-\lambda}^{\lambda} \psi^*_{f'}(x)\psi_f(x)dx$$

Из этого можно сделать какие-то выводы.

короче говоря, тут сказан какой-то метод про нормировку состояний непрерывного спектра, суть в том, что в разложение выше нужно подставить явный вид волновых функций, дальше выносим что угодно, что будет регулярным, так как ответ мы знаем, что он будет сингулярным.

Теперь вероятность величины быть в каком-то интервале имеет вид

$$\hat{\mathbb{P}}\left(f_1 \leq f \leq f_2\right) = \int\limits_{f_1}^{f_2} \frac{df}{c(f)}|f\rangle\langle f|$$

Плотность вероятности:

$$\rho(f)df = \langle\psi|f\rangle\langle f|\psi\rangle\frac{df}{c(f)} = |\psi(f)|^2\frac{df}{c(f)}$$

разбиение единицы имеет вид: $\hat{\mathbb{I}} = \int \frac{df}{c(f)}|f\rangle\langle f|$

В итоге наши переходы в представления делаются следующим образом:

$$\begin{cases} \psi(p) \equiv \langle p|\psi\rangle = \int dx\langle p|x\rangle\langle x|\psi\rangle \equiv \int dx e^{-ipx/\hbar}\psi(x) \\ \psi(x) \equiv \langle x|\psi\rangle = \int \frac{dp}{2\pi\hbar}\langle x|p\rangle\langle p|\psi\rangle = \int \frac{dp}{2\pi\hbar}e^{ipx/\hbar}\psi(p) \end{cases}$$

Для непрерывного спектра требования зануления одного из коэффициентов нет, из-за чего состояния непрерывного спектра двукратно вырождены

Все ли хорошо с теорией, в которой нормировка на дельта-функцию?

(?? пока вопрос остался.)

Другие свойства волновой функции

Сепарабельность и волновая функция (????)

Сепарабельность и полнота (??)

A2. Сформулируйте понятие сепарабельности и полноты пространства квантовых состояний.

Связь с квантовым полем (??)

(пока остался вопрос, ктп нужно учить)

Потенциал от волновой функции (???)

Допустим, частица описывается какой-то волновой функцией. Какой потенциал она создает для других частиц???
(не знаю, оставшийся вопрос.)

Примеры волновых функций

(из задач добавлю некоторые формулы, что типа такой потенциал например - такая функция! не вижу смысла делать структуру тут, это кругозорный параграф)
Например, волновая функция может выглядеть так:

$$\psi \propto e^{\pm ikx},$$

(где в каком-то случае $k = \sqrt{\frac{2Em}{\hbar^2}}$ (?))
Или например так:
(???)
Вот кстати их графики, чтобы прямо наглядно это представлять:
?????
а вот примеры дискретного случая:
Волновая функция свободной частицы имеет вид волны де Бройля:

$$\Psi_p(r,t) = e^{\frac{\mathrm{i}}{\hbar}(p\cdot r - Et)}$$

Общие интуитивные соображения, почему она такая, следующие:
(??)
Также ее можно найти с помощью оператора импульса, так как его действие на искомую известно:

$$\begin{aligned}\langle \boldsymbol{r}|\hat{\boldsymbol{p}}|\boldsymbol{p}\rangle &= \langle \boldsymbol{r}|\boldsymbol{p}|\boldsymbol{p}\rangle \\ \hat{\boldsymbol{p}}\Psi_{\boldsymbol{p}}(\boldsymbol{r}) &= \boldsymbol{p}\Psi_{\boldsymbol{p}}(\boldsymbol{r}) \\ -\mathrm{i}\hbar\boldsymbol{\nabla}\Psi_{\boldsymbol{p}}(\boldsymbol{r}) &= \boldsymbol{p}\Psi_{\boldsymbol{p}}(\boldsymbol{r}) \\ \Psi_{\boldsymbol{p}}(\boldsymbol{r}) &= \mathcal{N}e^{\frac{\mathrm{i}}{\hbar}\boldsymbol{p}\cdot\boldsymbol{r}}\end{aligned}$$

Равенство константы $\mathcal{N} = 1$ видно из нормировки: $\langle p'|p\rangle = (2\pi\hbar)^3\delta(p'-p) \leftrightarrow \mathcal{N}^2\int d^3r e^{\frac{\mathrm{i}}{\hbar}(p-p')\cdot r} = (2\pi\hbar)^3\delta(p'-p)$.
пример: свободная частица и волны у нас

$$\hat{H}_0 = \frac{\hat{\boldsymbol{p}}^2}{2m}$$

наблюдаемы (?)

$$\hat{\boldsymbol{p}}|\boldsymbol{p}\rangle = \boldsymbol{p}|\boldsymbol{p}\rangle, \quad \hat{H}_0|\boldsymbol{p}\rangle = \frac{\boldsymbol{p}^2}{2m}|\boldsymbol{p}\rangle$$

получили что-то заумное

$$|\boldsymbol{p}'\rangle = \int |\boldsymbol{p}\rangle \frac{d^3p}{(2\pi\hbar)^3} \langle \boldsymbol{p}|\boldsymbol{p}'\rangle$$

спустя какой-то херни

$$\langle \boldsymbol{r}|\hat{\boldsymbol{p}}|\boldsymbol{p}\rangle = \langle \boldsymbol{r}|\boldsymbol{p}|\boldsymbol{p}\rangle \quad \leftrightarrow \quad \hat{\boldsymbol{p}}\Psi_{\boldsymbol{p}}(\boldsymbol{r}) = \boldsymbol{p}\Psi_{\boldsymbol{p}}(\boldsymbol{r}) \quad \leftrightarrow$$
$$-\mathrm{i}\hbar\boldsymbol{\nabla}\Psi_{\boldsymbol{p}}(\boldsymbol{r}) = \boldsymbol{p}\Psi_{\boldsymbol{p}}(\boldsymbol{r}) \to \Psi_{\boldsymbol{p}}(\boldsymbol{r}) = \mathcal{N}e^{\frac{\mathrm{i}}{\hbar}\boldsymbol{p}\cdot\boldsymbol{r}}$$

имеем

$$\Psi_{\boldsymbol{p}}(\boldsymbol{r}) = e^{\frac{\mathrm{i}}{\hbar}\boldsymbol{p}\cdot\boldsymbol{r}}$$

вроде это волны де бройля.
потом вернусь к этому.
и потом выводы запишу.

О представлениях волновых функций (???!)

(напишу, что такие-то есть они, чтобы потом не было удивительно, что такое вообще есть)

Координатное

Импульсное

Гейзенберга координатное или импульсное

Взаимодействия

Энергетическое, операторы рождения и уничтожения

(?? кроме осциллятора это можно еще где-то ввести??)

О возможностях других представлений?

(?? оставленный вопрос, могут ли быть еще представления и как их придумать, если нужно будет.)

О волновой функции фотона или аналоге (????)

(пока думаю, что фотон ей не описывается, ну и ладно, потом напишу четко, как вместо этого можно описывать)
Связь волновой функции фотона и интенсивностью поля от него (??)

Is the concept of a wave function applicable for photons?

(maybe no, since there is QFT for it, but I don't have a good answer yet)

Детали о волновой функции

О потенциале от волновой функции (?????)

Допустим, есть две частицы. Мы говорим, что одна описывается волновой функцией в потенциале, который создается всем вокруг. Тогда если у нас есть две частицы, то ожидаемо, что они создадут тоже потенциал друг для друга. Вопрос: как так, что волновая функция создает потенциал для других частиц? Такого свойства мы не знали.

(????? не знаю ответ на этот вопрос, напишу потом)

О регулярности волновой функции в точке с особенностью потенциала

В действительности, требование на связанные состояние накладывается одно - а именно, функция в нуле (да и вообще везде) должна быть интегрируема. Это исключает возможность иметь степенные сингулярности (которые имеют функции $Y_m(z)$ и $H_m^{(1,2)}(z)$ при $m > 0$), но не исключает возможность иметь лишь логарифмическую особенность (которая имеется при $m = 0$). Аргумент, по которому эту логарифмическую особенность нужно отбросить, немного иной. С физической точки зрения поскольку потенциал в нуле вполне себе регулярен, то было бы как минимум странно иметь там сингулярность волновой функции. Математически же это связано с тем, что $\nabla^2 \ln \frac{1}{r} = 2\pi\delta(r)$ - поэтому функция Неймана, в действительности, решает задачу о двумерной дельта-яме. В исходном потенциале такой сингулярности нет, и именно по этой причине мы можем отсеять $Y_m(z)$ также и при $m = 0$.

Что происходит с волновой функцией частицы, когда она распадается на две частицы? (?????)

(напишу потом внятный ответ на этот вопрос.)

Фундаментально материя описываются квантовым полем, или волновой функцией??

(?? напишу с формулами ответ на этот вопрос, мб как раз частный случай квантового поля - случай с одной частицей?? тут основы КТП нужно знать.)

О заблуждениях и других пониманиях волновой функции

Интерпретации квантовой механике, коллапаса функций - все это в другом разделе, тут обсуждения разных соображений про то, что такое именно волновая функция.

Что может иметься в виду под несуществующими параметрами, схожими с волновой функцией?

(лень писать, ну не понимают многие это, ну и живут, просто пользуясь формулами иногда и все)

О поверхности электрона

Об электронном облаке

О шарообразности частиц

Об неверности идеи перехода многим траекториям одновременно

(типа по одной переход происходит, просто какой конкретно - разная вероятность. напишу потом)

2.7.2 Entanglement and Purity of States (??)

Обсудим подробно принцип суперпозиции.

Чистые / факторизованные

Чистые могут быть перепутанными или не перепутанными.
Чистые не перепутанные:

$$\psi_{AB} = \psi_A \otimes \psi_B$$

$$\rho_{AB} = |\psi\rangle\langle\psi| = |\varphi\rangle\langle\varphi| \otimes |\xi\rangle\langle\xi|$$

$$\rho_{AB} = \rho_A \otimes \rho_B$$

Чистые перепутанные:

$$\psi_{AB} \neq \psi_A \otimes \psi_B$$

$$\psi_{AB} = |\psi\rangle\langle\psi| \neq |\varphi\rangle\langle\varphi| \otimes |\xi\rangle\langle\xi|$$

здесь нет вообще корреляций.
(???!!! примеры??!!!)

Смешанные состояния

Смешанные не перепутанные:

$$\rho_{AB} \neq |\psi\rangle\langle\psi|$$

$$\rho^{AB} = \sum_k p_k \rho_k^A \otimes \rho_k^B,$$

где p_k - коэффициенты в выпуклой сумме.
(???!!! примеры??!!!)

сепарабельные / распутанные / не запутанные / состояния

Физический смысл незапутанных состояний в том, что если у нас есть физическая величина, состоящая из тензорного произведения величины одной части системы F и величины второй части системы G есть произведение их средних значений

$$\langle F \otimes G\rangle = \langle F\rangle \cdot \langle G\rangle.$$

Кстати, если было бы перепутанное, то $\langle F \otimes G\rangle \neq \langle F\rangle \cdot \langle G\rangle$, то ест были бы корреляции.

Другими словами, можно брать произведение результатов.

(там что я измеряю X, коллега измеряет У, мы перемножаем их и считаем матожидание)

Проверка сепарабельности делается следующими способами.
Критерий Переса-Городецких:

$$\rho_{AB}^{T_B} \geq 0 \quad \Longrightarrow \quad \text{сепарабельно}$$

$$\rho_{AB}^{T_B} \geq 0 \quad \underbrace{\Longleftarrow}_{dimH_A \cdot dimH_B \leq 6} \quad \text{сепарабельно}$$

В частности для двух кубитов, критерий Переса-Городецких утверждает, что их матрица плотности является сепарабельной тогда и только тогда, когда она остается матрицей плотности при частичном транспонировании.
(ниже где-то он доказан)

Коррелированные (классическим и квантовым образом) состояния

Коррелированные состояния - это состояния, у которых $\rho_{AB} \neq \rho_A \otimes \rho_B$.
(?? только так определяются, никак иначе?)
Есть классическая корреляция, когда можно представить в виде выпуклой суммы

$$\rho_{AB} = \sum_k p_k \rho_A^k \otimes \rho_B^k$$

Есть квантовая корреляция, когда

$$\rho_{AB} \neq \sum_k p_k \rho_A^k \otimes \rho_B^k$$

это же запутанность.
Свойства:
множество всех сепарабельных состояний для данной системы выпукло.

Запутанные состояния

Запутанность, это когда

$$\rho_{AB} \neq \sum_k p_k \rho_A^k \otimes \rho_B^k$$

Критерии:
ранг Шмидта больше 2.
(по определению его, см. разложение Шмидта.)
(?? примеры !!!)
Свойства:
множество всех квантово перепутанных состояний для данной системы не выпукло.
(?? энтропия перепутанности???)
Также есть:
максимально перепутанное состояние:
(напишу потом)

Квантовый инструмент

POVM - мера, соответствующая измерению

POVM - это мера E, которая сопоставляется каждому исходу,
удовлетворяющая $E = E^+ \geq 0$, и вероятность каждого исхода вычисляется по

$$p(i) = \mathrm{tr}(\rho E_i)$$

Теорема Озавы (?? что-то говорит)

Взаимно несмещенный базис (??!!)

Квантовый канал

Квантовый канал - это линейное, вполне положительное отображение, сохраняющее след.

(тут пояснение про вполне положительность, что за определение)

2.7.3 Openness and Closeness of a Quantum System

(introduce this concept and write what exactly is meant by it)

2.7.4 Coordinate and Momentum Operators (!!!)

(напишу четко про это потом, важные операторы, много может быть путаницы)

Radial momentum operator and angular momentum operator

(это прекрасно написано у Сузуки.)

Radial momentum operator and angular momentum operator Masatsugu Sei Suzuki Department of Physics, SUNY at Binghamton (Date: February 03, 2015)

(потом выпишу, эту теорию здесь уже представляю)

p_x, p_y as a function of p_r and p_ϕ

$$x = r\cos\phi, \quad y = r\sin\phi.$$

Дифференцирование по x связано с r и ϕ через правило цепочки:

$$\frac{\partial}{\partial x} = \frac{\partial r}{\partial x}\frac{\partial}{\partial r} + \frac{\partial \phi}{\partial x}\frac{\partial}{\partial \phi}.$$

Используем явные выражения для производных:

$$\frac{\partial r}{\partial x} = \cos\phi, \qquad \frac{\partial \phi}{\partial x} = -\frac{\sin\phi}{r}.$$

Подставляем это в правило цепочки:

$$\frac{\partial}{\partial x} = \cos\phi\frac{\partial}{\partial r} - \frac{\sin\phi}{r}\frac{\partial}{\partial \phi}.$$

Теперь оператор p_x принимает вид:

$$p_x = -i\hbar\left(\cos\phi\frac{\partial}{\partial r} - \frac{\sin\phi}{r}\frac{\partial}{\partial \phi}\right).$$

$$p_x = \cos\phi p_r - \frac{\sin\phi}{r}p_\phi.$$

The same for p_y:

$$\frac{\partial}{\partial y} = \frac{\partial r}{\partial y}\frac{\partial}{\partial r} + \frac{\partial \phi}{\partial y}\frac{\partial}{\partial \phi}.$$

Производные выражаются как:

$$\frac{\partial r}{\partial y} = \sin\phi, \quad \frac{\partial \phi}{\partial y} = \frac{\cos\phi}{r}.$$

Следовательно:

$$\frac{\partial}{\partial y} = \sin\phi \frac{\partial}{\partial r} + \frac{\cos\phi}{r}\frac{\partial}{\partial \phi}.$$

3. Оператор импульса:
Подставляем это в выражение для p_y:

$$p_y = -i\hbar\left(\sin\phi\frac{\partial}{\partial r} + \frac{\cos\phi}{r}\frac{\partial}{\partial\phi}\right).$$

4. Выражение через p_r и p_ϕ:
Подставляем определения радиального и углового операторов импульса - $p_r = -i\hbar\frac{\partial}{\partial r}$, - $p_\phi = -i\hbar\frac{\partial}{\partial\phi}$.
Получаем:

$$p_y = \sin\phi p_r + \frac{\cos\phi}{r}p_\phi.$$

2.7.5 Coordinate and Momentum Representations

(!!!!!!!!!!!!!! need to write this better!!!)

Теория импульсного представления по Тахтаджаяну

Начнем со случая одной степени свободы и рассмотрим две естественных реализации коммутационных соотношений Гейзенберга. Они определяются свойством, что один из самосопряженных операторов P и Q «диагонален» (т. е. является оператором умножения на функцию в соответствующем гильбертовом пространстве).

В координатном представлении $\mathscr{H} = L^2(\mathbb{R}, dq)$ - это L^2-пространство на конфигурационном пространстве $\mathbb{R}$с координатой q, являющемся лагранжевым подпространством пространства $\mathbb{R}^2$, определяемым уравнением $p = 0$. Положим

$$D(Q) = \left\{\varphi \in \mathscr{H} : \int\limits_{-\infty}^{\infty} q^2|\varphi(q)|^2 dq < \infty\right\}$$

и для $\varphi \in D(Q)$ определим оператор Q как «оператор умножения на q »:

$$(Q\varphi)(q) = q\varphi(q), q \in \mathbb{R}$$

оправдывая название «координатное представление». Оператор координаты Q очевидно самосопряжен, и его проекторная мера задается формулой

$$(\mathrm{P}(E)\varphi)(q) = \chi_E(q)\varphi(q)$$

где χ_E - характеристическая функция борелевского подмножества $E \subseteq \mathbb{R}$. Поэтому $\operatorname{supp} P = \mathbb{R}$ и $\sigma(Q) = \mathbb{R}$.

Напомним, что спектр самосопряженного оператора A абсолютно непрерывен, если для любого $\psi \in \mathscr{H}, \|\psi\| = 1$, вероятностная мера ν_ψ,

$$\nu_\psi(E) = (\mathrm{P}_A(E)\psi, \psi)\,, \quad E \in \mathscr{B}(\mathbb{R})$$

абсолютно непрерывна относительно меры Лебега на $\mathbb{R}$.

Лемма 2.2.

Оператор координаты Q имеет абсолютно непрерывный спектр $\mathbb{R}$, и любой ограниченный оператор B, коммутирующий cQ, является функцией от $Q, B = f(Q)cf \in L^\infty(\mathbb{R})$.

ДОКАЗАТЕЛЬСТВО.

Из (2.12) следует, что $\nu_\psi(E) = \int\limits_E |\psi(q)|^2 dq$, и это доказывает первое утверждение. Дальше, ограниченный оператор B в $\mathscr{H}$ коммутирует с Q, если и только если $B\mathrm{P}(E) = \mathrm{P}(E)B$ для всех $E \in \mathscr{B}(\mathbb{R})$, и, используя (2.12), мы получаем

$$B\left(\chi_E \varphi\right) = \chi_E B(\varphi)$$

Выбирая в (2.13) $E = E_1$ и $\varphi = \chi_{E_2}$, где E_1 и E_2 имеют конечную меру Лебега, получаем

$$B\left(\chi_{E_1} \cdot \chi_{E_2}\right) = B\left(\chi_{E_1 \cap E_2}\right) = \chi_{E_1} B\left(\chi_{E_2}\right) = \chi_{E_2} B\left(\chi_{E_1}\right),$$

так что, обозначая $f_E = B\left(\chi_E\right)$, мы получаем $\operatorname{supp} f_E \subseteq E$ и

$$f_{E_1}|_{E_1 \cap E_2} = f_{E_2}|_{E_1 \cap E_2}$$

для любых $E_1, E_2 \in \mathscr{B}(\mathbb{R})$ с конечной мерой Лебега. Таким образом, существует измеримая функция f на $\mathbb{R}$, такая, что $f|_E = f_E|_E$ для любого $E \in \mathscr{B}(\mathbb{R})$ с конечной мерой Лебега. Линейное подпространство, натянутое на все $\chi_E \in L^2(\mathbb{R})$, плотно в $L^2(\mathbb{R})$, а оператор B непрерывен, так что получаем

$$(B\varphi)(q) = f(q)\varphi(q) \quad \text{для любого } \varphi \in L^2(\mathbb{R}).$$

Поскольку B - ограниченный оператор, $f \in L^\infty(\mathbb{R})$ и $\|B\| = \|f\|_\infty$.

ЗАмечание. По теореме Шварца о ядре оператор B можно представить в виде интегрального оператора с обобщенным функциональным ядром $K\left(q, q'\right)$. Тогда из коммутативности $BQ = QB$ следует, что в смысле обобщенных функций

$$\left(q - q'\right) K\left(q, q'\right) = 0,$$

так что K «пропорционально» дельта-функции Дирака, т. е.

$$K\left(q, q'\right) = f(q)\delta\left(q - q'\right),$$

для некоторого $f \in L^\infty(\mathbb{R})$. Это рассуждение обычно приводят в учебниках физики.

ЗАМЕчАниЕ. У оператора Q нет собственных векторов - уравнение на собственные значения

$$Q\varphi = \lambda\varphi$$

не имеет решений в $L^2(\mathbb{R})$. Однако в смысле обобщенных функций это уравнение имеет для каждого $\lambda \in \mathbb{R}$ единственное (с точностью до постоянного множителя) решение $\varphi_\lambda(q) = \delta(q - \lambda)$, и эти «обобщенные собственные функции», называемые также собственными функциями непрерывного спектра, порождают ядро Шварца единичного оператора I в $L^2(\mathbb{R})$. Это отражает тот факт, что оператор Q диагонален в координатном представлении.

ЗАМЕЧАНИЕ. Нормировку собственных функций непрерывного спектра $\varphi_\lambda(q)$ можно также определить условием, что для любого $\lambda \in \mathbb{R}$ функция

удовлетворяет условию

$$\Phi_\lambda(q) = \int_{\lambda_0}^{\lambda} \varphi_\mu(q) d\mu, \quad \Phi_\lambda \in L^2(\mathbb{R})$$

$$\lim_{\Delta \to 0} \frac{1}{\Delta} \|\Phi_{\lambda+\Delta} - \Phi_\lambda\|^2 = 1.$$

Здесь $\lambda_0 \in \mathbb{R}$ фиксировано и не входит в (2.14). Действительно, в нашем случае $\Phi_\lambda = \chi_{(\lambda_0,\lambda)}$ - характеристическая функция интервала (λ_0, λ), так что $\|\Phi_{\lambda+\Delta} - \Phi_\lambda\|^2 = \Delta$. Для чистого состояния $M = P_\psi, \|\psi\| = 1$ соответствующая вероятностная мера μ_Q на $\mathbb{R}$ дается формулой

$$\mu_Q(E) = \nu_\psi(E) = \int_E |\psi(q)|^2 dq, \quad E \in \mathscr{B}(\mathbb{R}).$$

Физически это интерпретируется так, что в состоянии P_ψ с «волновой функцией» $\psi(q)$ вероятность нахождения квантовой частицы между q и $q + dq$ равна $|\psi(q)|^2 dq$. Другими словами, квадрат модуля волновой функции - это распределение вероятности координаты квантовой частицы.

Соответствующий оператор импульса P дается дифференциальным оператором

$$P = \frac{\hbar}{i} \frac{d}{dq}$$

с $D(P) = W^{1,2}(\mathbb{R})$ - пространством Соболева абсолютно непрерывных функций f на $\mathbb{R}$, таких, что f и ее производная f' (определенная п. в.) принадлежат $L^2(\mathbb{R})$. Оператор P самосопряжен, и не составляет труда проверить, что на $D = C_c^\infty(\mathbb{R})$, пространстве гладких функций на $\mathbb{R}$ с компактным носителем,

$$QP - PQ = i\hbar I.$$

Замечание. У оператора P в $\mathscr{H}$ нет собственных векторов, уравнение на собственные значения

$$P\varphi = p\varphi, p \in \mathbb{R}$$

имеет решение

$$\varphi(q) = \text{ const } \times e^{\frac{i}{\hbar} pq}$$

не принадлежащее $L^2(\mathbb{R})$. Мы увидим впоследствии, что семейство нормированных собственных функций непрерывного спектра

$$\varphi_p(q) = \frac{1}{\sqrt{2\pi\hbar}} e^{\frac{i}{\hbar} pq}$$

порождает ядро Шварца обратного к зависящему от $\hbar$ преобразованию Фурье оператора, диагонализующего оператор импульса P. В смысле обобщенных функций

$$\int_{-\infty}^{\infty} \varphi_p(q) \overline{\varphi_{p'}(q)} dq = \delta(p - p').$$

ЗАМЕчАНиЕ. Как и в случае оператора координаты, нормировку собственных функций непрерывного спектра $\varphi_p(q)$ оператора импульса можно определить условием (2.14). Действительно,

$$\Phi_p(q) = \int_{p_0}^{p} ce^{\frac{i}{\hbar}kq}dk = \frac{c\hbar}{iq}\left(e^{\frac{i}{\hbar}pq} - e^{\frac{i}{\hbar}p_0q}\right)$$

так что

$$\Phi_{p+\Delta}(q) - \Phi_p(q) = \frac{2c\hbar}{q}e^{\frac{i}{\hbar}\left(p+\frac{1}{2}\Delta\right)q}\sin\frac{\Delta q}{2\hbar}$$

Используя элементарное интегрирование, получаем

$$\frac{1}{\Delta}\left\|\Phi_{p+\Delta}(q) - \Phi_p(q)\right\|^2 = 2c^2\hbar\int_{-\infty}^{\infty}\frac{\sin^2 q}{q^2}dq = 2\pi c^2\hbar$$

так что $c = \frac{1}{\sqrt{2\pi\hbar}}$.

Предложение 2.1.

Координатное представление определяет неприводимое, унитарное, интегрируемое представление алгебры Гейзенберга.

ДокАЗАтЕЛЬство.

Чтобы показать, что координатное представление интегрируемо, положим $U(u) = e^{-iuP}$, и пусть $V(v) = e^{-ivQ}$ - соответствующая однопараметрическая группа унитарных операторов. Ясно, что $(V(v)\varphi)\psi(q) = e^{-ivq}\varphi(q)$, и из теоремы Стоуна (или из определения производной) легко выводится, что $(U(u)\varphi)(q) = \varphi(q - \hbar u)$, так что унитарные операторы $U(u)$ и $V(v)$ удовлетворяют соотношению Вейля (2.11). Такая реализация соотношения Вейля называется представлением Шрёдингера.

Для доказательства неприводимости координатного представления выберем ограниченный оператор T, коммутирующий с P и Q. По лемме 2.2$T = f(Q)$ для какого-то $f \in L^\infty(\mathbb{R})$. Дальше, из коммутативности T и P следует, что

$$TU(u) = U(u)T \quad \text{для любого} \quad u \in \mathbb{R}$$

а это эквивалентно тому, что $f(q - \hbar u) = f(q)$ для любых $q, u \in \mathbb{R}$, так что $f = \text{const}$ п. в. на $\mathbb{R}$.

В итоге координатное представление характеризуется свойством, что оператор координаты Q - это умножение на q, а оператор импульса P - это дифференцирование:

$$Q = q \quad \text{и} \quad P = \frac{\hbar}{i}\frac{d}{dq}$$

Аналогично, импульсное представление определяется свойством, что оператор импульса P - это умножение на p. А именно: пусть $\mathscr{H} = L^2(\mathbb{R}, dp)$ - гильбертово L^2-пространство на «пространстве импульсов» $\mathbb{R}$ с координатой p, являющемся лагранжевым подпространством в $\mathbb{R}^2$, определенным уравнением $q = 0$. Операторы координаты и импульса даются формулами

$$\hat{Q} = i\hbar\frac{d}{dp} \quad \text{и} \quad \hat{P} = p$$

и удовлетворяют коммутационному соотношению Гейзенберга. Как и координатное представление, импульсное представление - неприводимое, унитарное, интегрируемое представление алгебры Гейзенберга. В импульсном представлении квадрат модуля волновой функции $\psi(p)$ чистого состояния $M = P_\psi, \|\psi\| = 1$, есть распределение вероятности импульса квантовой частицы, т. е. вероятность, что квантовая частица имеет импульс, заключенный между p и $p + dp$, равна $|\psi(p)|^2 dp$.

Пусть $\mathscr{F}_\hbar : L^2(\mathbb{R}) \to L^2(\mathbb{R})$ - оператор зависящего от $\hbar$ преобразования Фурье, определенный формулой

$$\hat{\varphi}(p) = \mathscr{F}_\hbar(\varphi)(p) = \frac{1}{\sqrt{2\pi\hbar}} \int\limits_{-\infty}^{\infty} e^{-\frac{i}{\hbar}pq} \varphi(q) dq$$

Здесь интеграл понимается как предел $\hat{\varphi} = \lim_{n\to\infty} \hat{\varphi}_n$ в сильной топологии $L^2(\mathbb{R})$, где

$$\hat{\varphi}_n(p) = \frac{1}{\sqrt{2\pi\hbar}} \int\limits_{-n}^{n} e^{-\frac{i}{\hbar}pq} \varphi(q) dq$$

По теореме Планшереля $\mathscr{F}_\hbar$ - унитарный оператор в $L^2(\mathbb{R})$,

$$\mathscr{F}_\hbar \mathscr{F}_\hbar^* = \mathscr{F}_\hbar^* \mathscr{F}_\hbar = I,$$

K

$$\hat{Q} = \mathscr{F}_\hbar Q \mathscr{F}_\hbar^{-1}, \quad \hat{P} = \mathscr{F}_\hbar P \mathscr{F}_\hbar^{-1},$$

так что координатное и импульсное представления унитарно эквивалентны. В частности, поскольку оператор $\hat{P}$ очевидно самосопряжен, это мгновенно показывает, что и оператор P самосопряжен.

Для n степеней свободы координатное представление определяется заданием $\mathscr{H} = L^2\left(\mathbb{R}^n, d^n\boldsymbol{q}\right)$, где $d^n\boldsymbol{q} = dq^1 \cdots dq^n$ - мера Лебега на $\mathbb{R}^n$, и

$$\boldsymbol{Q} = \boldsymbol{q} = \left(q^1, ..., q^n\right), \quad \boldsymbol{P} = \frac{\hbar}{i}\frac{\partial}{\partial \boldsymbol{q}} = \left(\frac{\hbar}{i}\frac{\partial}{\partial q^1}, ..., \frac{\hbar}{i}\frac{\partial}{\partial q^n}\right).$$

Здесь $\mathbb{R}^n$ - конфигурационное пространство с координатами $\boldsymbol{q}$ - лагранжево подпространство $\mathbb{R}^{2n}$, определяемое уравнениями $\boldsymbol{p} = 0$. Операторы координат и импульсов самосопряжены и удовлетворяют коммутационным соотношениям Гейзенберга. Проекторные меры операторов Q^k даются формулами

$$\left(\mathrm{P}_k(E)\varphi\right)(\boldsymbol{q}) = \chi_{\lambda_k^{-1}(E)}(\boldsymbol{q})\varphi(\boldsymbol{q}),$$

где $E \in \mathscr{B}(\mathbb{R})$, а $\lambda_k : \mathbb{R}^n \to \mathbb{R}$ - каноническая проекция на k-ю компоненту, $k = 1, ..., n$. Соответственно, проекторная мера P коммутативного семейства $\boldsymbol{Q} = (Q^1, ..., Q^n)$ (см. предложение 1.3) определяется на борелевских подмножествах $\boldsymbol{E} \subseteq \mathbb{R}^n$ формулой

$$(\mathrm{P}(\boldsymbol{E})\varphi)(\boldsymbol{q}) = \chi_{\boldsymbol{E}}(\boldsymbol{q})\varphi(\boldsymbol{q}).$$

Семейство $\boldsymbol{Q}$ имеет абсолютно непрерывный совместный спектр $\mathbb{R}^n$.

Координатные операторы $Q^1, ..., Q^n$ образуют полную систему коммутирующих наблюдаемых. Это по определению означает, что ни один из этих операторов не является функцией оставшихся, и что любой ограниченный оператор, коммутирующий с $Q^1, ..., Q^n$, - функция $Q^1, ..., Q^n$, т. е. оператор умножения на $f(\boldsymbol{q})$ для какого-то $f \in L^\infty\left(\mathbb{R}^n\right)$. Доказательство дословно повторяет доказательство леммы 2.2. Для чистого состояния

$M = P_\psi, \|\psi\| = 1$, квадрат модуля $|\psi(\boldsymbol{q})|^2$ волновой функции - это плотность совместной функции распределения $\mu_{\boldsymbol{Q}}$ коммутативного семейства $\boldsymbol{Q}$, т. е. вероятность нахождения квантовой частицы в борелевском подмножестве $\boldsymbol{E} \subseteq \mathbb{R}^n$ дается формулой

$$\mu_{\boldsymbol{Q}}(\boldsymbol{E}) = \int\limits_{\boldsymbol{E}} |\psi(\boldsymbol{q})|^2 d^n\boldsymbol{q}$$

Координатное представление определяет неприводимое, унитарное, интегрируемое представление алгебры Гейзенберга $\mathfrak{h}_n$. Действительно, n параметрические группы унитарных операторов $U(\boldsymbol{u}) = e^{-i\boldsymbol{u}\boldsymbol{P}}$ и $V(\boldsymbol{v}) = e^{-iv\boldsymbol{Q}}$ описываются формулами

$$(U(\boldsymbol{u})\varphi)(\boldsymbol{q}) = \varphi(\boldsymbol{q} - \hbar\boldsymbol{u}), \quad (V(\boldsymbol{v})\varphi)(\boldsymbol{q}) = e^{-i\boldsymbol{v}\boldsymbol{q}}\varphi(\boldsymbol{q})$$

и удовлетворяют соотношениям Вейля (2.11). То же рассуждение, что и в доказательстве предложения 2.1 показывает, что это представление группы Гейзенберга $\mathbf{H}_n$, называемое представлением Шрёдингера для n степеней свободы, неприводимо. В импульсном представлении $\mathscr{H} = L^2(\mathbb{R}^n, d^n\boldsymbol{p})$, где $d^n\boldsymbol{p} = dp_1 \cdots dp_n$ - мера Лебега на $\mathbb{R}^n$, и

$$\hat{\boldsymbol{Q}} = i\hbar\frac{\partial}{\partial \boldsymbol{p}} = \left(i\hbar\frac{\partial}{\partial p_1}, ..., i\hbar\frac{\partial}{\partial p_n}\right), \quad \hat{\boldsymbol{P}} = \boldsymbol{p} = (p_1, ..., p_n).$$

Здесь $\mathbb{R}^n$ - это пространство импульсов с координатами $\boldsymbol{p}$ - лагранжево подпространство $\mathbb{R}^{2n}$, определенное уравнениями $\boldsymbol{q} = 0$.

Координатное и импульсное представления унитарно эквивалентны через преобразование Фурье. Как и в случае $n = 1$, преобразование Фурье $\mathscr{F}_\hbar : L^2(\mathbb{R}^n) \to L^2(\mathbb{R}^n)$ - это унитарный оператор, определенный формулой

$$\hat{\varphi}(\boldsymbol{p}) = \mathscr{F}_\hbar(\varphi)(\boldsymbol{p}) = (2\pi\hbar)^{-n/2} \int\limits_{\mathbb{R}^n} e^{-\frac{i}{\hbar}\boldsymbol{p}\boldsymbol{q}}\varphi(\boldsymbol{q})d^n\boldsymbol{q} =$$

$$= \lim_{N\to\infty} (2\pi\hbar)^{-n/2} \int\limits_{|\boldsymbol{q}|\leqslant N} e^{-\frac{i}{\hbar}\boldsymbol{p}\boldsymbol{q}}\varphi(\boldsymbol{q})d^n\boldsymbol{q},$$

где предел понимается в сильной топологии на $L^2(\mathbb{R}^n)$. Как в случае $n = 1$, имеем

$$\hat{Q}_k = \mathscr{F}_\hbar Q_k \mathscr{F}_\hbar^{-1}, \quad \hat{P}_k = \mathscr{F}_\hbar P_k \mathscr{F}_\hbar^{-1}, \quad k = 1, ..., n.$$

В частности, поскольку операторы $\hat{P}_1, ..., \hat{P}_n$, очевидно, самосопряжены, это мгновенно показывает, что $P_1, ..., P_n$ тоже самосопряжены.

ЗАМЕчАНиЕ. Следуя Дираку, физики обозначают вектор $\psi \in \mathscr{H}$ кетвектором $|\psi\rangle$, вектор $\varphi \in \mathscr{H}^*$ в двойственном к $\mathscr{H}$ пространстве ($\mathscr{H}^* \simeq \mathscr{H}$ - комплексный антилинейный изоморфизм) - бра-вектором $\langle\varphi|$, а их скалярное произведение - выражением $\langle\varphi|\psi\rangle$. В стандартных математических обозначениях

$$(\psi, \varphi) = \langle\varphi|\psi\rangle \quad \text{и} \quad (A\psi, \varphi) = \langle\varphi|A|\psi\rangle,$$

где A - линейный оператор. С физической точки зрения дираковские обозначения соответствуют интуиции и удобны для работы с координатным и импульсным представлениями. Обозначив как $|\boldsymbol{q}\rangle = \delta(\boldsymbol{q} - \boldsymbol{q}')$ и $|\boldsymbol{p}\rangle = (2\pi\hbar)^{-n/2}e^{\frac{i}{\hbar}pq}$ множества общих обобщенных собственных функций операторов $\boldsymbol{Q}$ и $\boldsymbol{P}$ соответственно; мы формально получаем

$$\boldsymbol{Q}|\boldsymbol{q}\rangle = \boldsymbol{q}|\boldsymbol{q}\rangle, \quad \boldsymbol{P}|\boldsymbol{p}\rangle = \boldsymbol{p}|\boldsymbol{p}\rangle$$

где операторы $\mathbf{Q}$ действуют на $\boldsymbol{q}'$, и

$$\langle \boldsymbol{q}|\psi\rangle = \int\limits_{\mathbb{R}^n} \delta\left(\boldsymbol{q}-\boldsymbol{q}'\right)\psi\left(\boldsymbol{q}'\right)d^n\boldsymbol{q}' = \psi(\boldsymbol{q}),$$

$$\langle \boldsymbol{p}|\psi\rangle = (2\pi\hbar)^{-n/2}\int\limits_{\mathbb{R}^n} e^{-\frac{i}{\hbar}\boldsymbol{p}\boldsymbol{q}}\psi(\boldsymbol{q})d^n\boldsymbol{q} = \hat{\psi}(\boldsymbol{p}),$$

так же как $\langle \boldsymbol{q}|\boldsymbol{q}'\rangle = \delta\left(\boldsymbol{q}-\boldsymbol{q}'\right), \langle \boldsymbol{p}|\boldsymbol{p}'\rangle = \delta\left(\boldsymbol{p}-\boldsymbol{p}'\right)$. Хотя в нашем изложении мы не используем дираковские обозначения, эти формулы могут помочь заинтересованному читателю «переводить» обозначения из учебников физики на стандартный математический язык.

ЗАМЕчАниЕ. Мы покажем в разделе 2.3.2, что любое лагранжево подпространство симплектического векторного пространства $\mathbb{R}^{2n}$ с канонической симплектической формой $\omega = dp \wedge d\boldsymbol{q}$ порождает интегрируемое, унитарное, неприводимое представление алгебры Гейзенберга $\mathfrak{h}_n$. Это простейший пример действительной поляризачии, определяемой для заданного симплектического многообразия $(\mathscr{M}, \omega)$ как интегрируемое распределение $\{\mathscr{L}_x\}_{x\in\mathscr{M}}$ лагранжевых подпространств $\mathscr{L}_x$ касательных пространств $T_x\mathscr{M}$. Понятие поляризации играет фундаментальную роль в геометрическом квантовании: оно позволяет построить (при определенных условиях) гильбертово пространство состояний $\mathscr{H}$, ассоциированное с классическим фазовым пространством $(\mathscr{M}, \omega)$. В линейном случае $\mathscr{M} = \mathbb{R}^{2n}$, любое лагранжево подпространство $\mathscr{L}$ в $\mathbb{R}^{2n}$ порождает действительную поляризацию через идентификацию $T_x\mathbb{R}^{2n} \simeq \mathbb{R}^{2n}$. В частности, для координатного представления $\mathscr{L}$ дается уравнением $\boldsymbol{q} = 0$, а для импульсного - уравнением $\boldsymbol{p} = 0$. Соответствующее гильбертово пространство $\mathscr{H}$ состоит из функций на $\mathbb{R}^{2n}$, постоянных на слоях поляризации.

ЗАДАчА 2.4. Приведите пример неинтегрируемого представления алгебры Гейзенберга.

ЗАДАЧА 2.5. Докажите, что существует $\varphi \in \mathscr{H} = L^2(\mathbb{R}, dq)$, такое, что векторы $\mathrm{P}(E)\varphi, E \in \mathscr{B}(\mathbb{R})$, где P - проекторная мера оператора координаты Q, плотны в $\mathscr{H}$.

ЗАДАЧА 2.6. Найдите порождающий оператор для коммутативного семейства $\boldsymbol{Q} = (Q^1, ..., Q^n)$. Есть ли у него физическая интерпретация?

ЗАДАЧА 2.7. Найдите проекторную меру коммутативного семейства $\boldsymbol{P} = (P_1, ..., P_n)$ в координатном представлении.

Interaction in coordinate and momenta representation

(??? how exactly this happens??)

Meaning of second quantization in coordinate and momenta representation

(??? that Fourier transform, what is this meaning??)
(??? how exactly this happens??)

Does a number of particle makes sense from the point of view of existence of coordinate and momenta representation

(??? the question about that Fourier transform makes from one function sum of a lot of functions, maybe 100 functions. so how many particles are there? or only coordinate representation is physical?)

Is momentum representation really useful?

(discuss this!!! I don't know, I am not convinced.)
(what if there was no momenta repr in general?)
(what if there was no momenta repr in scatteing theory?)
(what if there was no momenta repr in cond matter systems?)

2.7.10 Probability Current

(тоже про него тут всё)

2.7.11 Concept of Density Matrix 1: Basics

Приведем общие соображения про матрицу плотности и ее появление.

Density matrix by Nielsen, Chang

(write his version)

Density matrix by Tokmakoff

The density matrix or density operator is an alternate representation of the state of a quantum system for which we have previously used the wavefunction. Although describing a quantum system with the density matrix is equivalent to using the wavefunction, one gains significant practical advantages using the density matrix for certain time-dependent problemsparticularly relaxation and nonlinear spectroscopy in the condensed phase.

The density matrix is defined as the outer product of the wavefunction with its conjugate.

$$\rho(t) \equiv |\psi(t)\rangle\langle\psi(t)|$$

This implies that if you specify a state $|x\rangle$, then $\langle x|\rho|x\rangle$ gives the probability of finding a particle in the state $|x\rangle$. Its name derives from the observation that it plays the quantum role of a probability density. If you think of the statistical description of a classical observable obtained from moments of a probability distribution P, then ρ plays the role of P in the quantum case:

$$\begin{aligned}\langle A\rangle &= \int AP(A)dA \\ &= \langle\psi|A|\psi\rangle = \text{Tr}[A\rho]\end{aligned}$$

where Tr[...] refers to tracing over the diagonal elements of the matrix,

$$\mathrm{Tr}[\cdots] = \sum_a \langle a| \cdots |a\rangle$$

The last expression is obtained as follows. If the wavefunction for the system is expanded as

$$|\psi(t)\rangle = \sum_n c_n(t)|n\rangle$$

the expectation value of an operator is

$$\langle \hat{A}(t)\rangle = \sum_{n,m} c_n(t)c_m^*(t)\langle m|\hat{A}|n\rangle$$

Also, from Equation 5.1.1 we obtain the elements of the density matrix as

$$\begin{aligned}\rho(t) &= \sum_{n,m} c_n(t)c_m^*(t)|n\rangle\langle m| \\ &\equiv \sum_{n,m} \rho_{nm}(t)|n\rangle\langle m|\end{aligned}$$

We see that ρ_{nm}, the density matrix elements, are made up of the time-evolving expansion coefficients. Substituting into Equation 5.1.6 we see that

$$\begin{aligned}\langle \hat{A}(t)\rangle &= \sum_{n,m} A_{mn}\rho_{nm}(t) \\ &= \mathrm{Tr}[\hat{A}\rho(t)]\end{aligned}$$

In practice this makes evaluating expectation values as simple as tracing over a product of matrices. What information is in the density matrix elements, ρ_{nm} ? The diagonal elements $(n = m)$ give the probability of occupying a quantum state:

$$\rho_{nn} = c_n c_n^* = p_n \geq 0$$

For this reason, diagonal elements are referred to as populations. The off-diagonal elements ($n \neq m$) are complex and have a time-dependent phase factor

$$\rho_{nm} = c_n(t)c_m^*(t) = c_n c_m^* \mathrm{e}^{-i\omega_{nm}t}$$

Since these describe the coherent oscillatory behavior of coherent superpositions in the system, these are referred to as coherences.

So why would we need the density matrix? It becomes a particularly important tool when dealing with mixed states, which we take up later. Mixed states refer to statistical mixtures in which we have imperfect information about the system, for which me must perform statistical averages in order to describe quantum observables. For mixed states, calculations with the density matrix are greatly simplified. Given that you have a statistical mixture, and can

describe p_k, the probability of occupying quantum state $|\psi_k\rangle$, evaluation of expectation values is simplified with a density matrix:

$$\langle \hat{A}(t) \rangle = \sum_k p_k \langle \psi_k(t) | \hat{A} | \psi_k(t) \rangle$$
$$\rho(t) \equiv \sum_k p_k |\psi_k(t)\rangle \langle \psi_k(t)|$$
$$\langle \hat{A}(t) \rangle = \mathrm{Tr}[\hat{A}\rho(t)]$$

Evaluating expectation value is the same for pure or mixed states.

Density matrix: Other questions

(overview of many other related things to this concept)

явный пример выделения из одной системы двух подсистем

Об уравнениях открытых систем

про Линдблада чуть скажу.
мб про другие уравнения

Examples of density matrices

(четко этот пример укажу, пока что хз)

General conceptual questions about density matrix

связь с другими описаниями

с волновой функцией?
с обычной функцией распределения???
очень актуально!

О случаях применения матрицы плотности и открытых систем (?!!)

(очень важно прописать нормально, когда они нужны!!?? пока не особо применял.)
- в квантовой теории информации
(тут большое описание, насколько она важна там! достаточно в принципе важна)

Динамика систем, описываемых матрицей плотности

Динамика матрицы плотности описывается с помощью уравнения Гейзенберга:

$$\frac{\partial \hat{\rho}}{\partial t} = \frac{i}{\hbar}[\hat{\rho}(t), \hat{H}]$$

Чтобы это увидеть, нужно просто взять производную по времени от матрицы плотности: $\hat{\rho}(t) = \sum_{mn}\langle n(t)|\rho_{nm}|m(t)\rangle$. Добавка в уравнение полученное тождество уравнения Шредингера завершит доказательство:

$$i\hbar\frac{\partial\hat{\rho}}{\partial t} = \sum_{mn}\left[i\hbar\frac{\partial|n(t)\rangle}{\partial t}\rho_{nm}\langle m(t)| + i\hbar|n(t)\rangle\rho_{nm}\frac{\partial\langle m(t)|}{\partial t}\right] =$$
$$= \sum_{mn}\left[\hat{H}|n(t)\rangle\rho_{nm}\langle m(t)| - |n(t)\rangle\rho_{nm}\langle m(t)|\hat{H}\right] = [\hat{H},\hat{\rho}(t)]$$

(тут еще много про динамику можно будет добавить)

Динамика систем, описываемых матрицей плотности: Conceptual questions

основы термодинамики открытых квантовых систем

(тут общие рассуждения)
Таким образом,

$$\hat{\rho} = \frac{1}{Z}e^{-\beta\hat{H}},$$

где $Z = \mathrm{Tr}\left(e^{-\beta\hat{H}}\right) = \sum_n e^{-\beta E_n}$

(и что?)

Пример взаимодействие среды с окружением

пример: взаимодействие среды с окружением
(говорят, она для этого нужна)

Пример разделение систем на подсистемы и состояния

разделение систем на подсистемы и состояния
в простом случае, если системы разделяются, то $\rho(x,x') = \Psi(x)\Psi*(x')$ и такое состояние называется *чистым* .
что мы всегда при измеренеии можем получать смешанные состояния - супперпозицию чистых.
(?)
тема очень важная, тут как раз ответим про состояние на все вопросы.
по сути мы уже многим владеем и все можем сказать.
теперь поговорим про ЭПР
У морозова есть методичка про это, до которой скорее всего я не дойду, но она гуглится.

обзор применений открытых систем

что с ними можно описать?

2.7.12 Concept of Density Matrix 1: Other Approaches

Density matrix by Landau

(write his version)

Density matrix by Brewer Petrucione

(write their version, see note on kinetics for now)

The Density Matrix in the Interaction Picture by Tokmakoff

For the case in which we wish to describe a material Hamiltonian H_0 under the influence of an external potential $V(t)$,

$$H(t) = H_0 + V(t)$$

we can also formulate the density operator in the interaction picture, ρ_I. From our original definition of the interaction picture wavefunctions

$$|\psi_I\rangle = U_0^\dagger |\psi_S\rangle$$

We obtain ρ_I as

$$\rho_I = U_0^\dagger \rho_S U_0$$

Similar to the discussion of the density operator in the Schrödinger equation, above, the equation of motion in the interaction picture is

$$\frac{\partial \rho_I}{\partial t} = -\frac{i}{\hbar}\left[V_I(t), \rho_I(t)\right]$$

where, as before, $V_I = U_0^\dagger V U_0$. Equation 5.3.4 can be integrated to obtain

$$\rho_I(t) = \rho_I\left(t_0\right) - \frac{i}{\hbar}\int_{t_0}^{t} dt' \left[V_I\left(t'\right), \rho_I\left(t'\right)\right]$$

Repeated substitution of $\rho_I(t)$ into itself in this expression gives a perturbation series expansion

$$\begin{aligned}
\rho_I(t) &= \rho_0 - \frac{i}{\hbar}\int_{t_0}^{t} dt_2 \left[V_I\left(t_1\right), \rho_0\right] \\
&+ \left(-\frac{i}{\hbar}\right)\int_{t_0}^{t} dt_2 \int_{t_0}^{t_2} dt_1 \left[V_I\left(t_2\right), \left[V_I\left(t_1\right), \rho_0\right]\right] + \cdots \\
&+ \left(-\frac{i}{\hbar}\right)^n \int_{t_0}^{t} dt_n \int_{t_0}^{t_n} dt_{n-1} \cdots \int_{t_0}^{t_2} dt_1 \left[V_I\left(t_n\right), \left[V_I\left(t_{n-1}\right), \cdots \left[V_I\left(t_1\right), \rho_0\right]\right]\right] \\
&= \rho^{(0)} + \rho^{(1)} + \rho^{(2)} + \cdots + \rho^{(n)} + \cdots
\end{aligned}$$

Here $\rho_0 = \rho\left(t_0\right)$ and $\rho^{(n)}$ is the n^{th} -order expansion of the density matrix. This perturbative expansion will play an important role later in the description of nonlinear spectroscopy. An n^{th} order expansion term will be proportional to the observed polarization in an n^{th} -order nonlinear spectroscopy, and the commutators observed in Equation 5.3.8 are closely related to nonlinear response functions. Equation 5.3.8 can also be expressed as

$$\rho_I(t) = U_0 \rho_I(0) U_0^\dagger$$

This is the solution to the Liouville equation in the interaction picture.

2.7.13 How to Use QM for Many-Particle Systems?

(general intro to cond matter. like, okay, we know that there is a wave function, that we also can introduce creation operators, so how to describe a conductor? this is also written in the note on cond matter. I want to make this connection more explicit.)

2.8 Other, Useful Operators

(here, there are operators, which will be used, but they don't really need a special section, this section here is just for completeness, since for one it can be comfortable to have a collection of their properties in one place)

2.8.1 Form of a Spectrum of a Particle

(connect it with Noether's theorem, why it can be? seriously! why in cond matter there are different spectrums?)

2.8.2 Evolution Operator

Обсудим подробно оператор эволюции.

Типичные свойства

Согласно современному пониманию квантовой механики, любые материальные объекты состоят из частиц, которые могут быть в различных состояниях.

Состояние частицы полностью определяется амплитудой вероятности $\Psi(q)$ того, что частица имеет определенные точные значения своих наблюдаемых $\{q\}$.

Амплитуда вероятности определяет волновую сущность состояния частицы, потому также называется волновой функцией.

Переход от амплитуды вероятности к вероятности происходит просто: $w = |\psi(q)|^2$.

Поэтому суммарная вероятность всех состояний должна быть 1:

$$\sum_{\{q\}} |\psi(q, t_0)|^2 = 1$$

Есть и другие очевидные свойства волновой функции, такие как непрерывность (но не гладкости требовать не нужно), интегрируемость,

Динамика волновой функции определяется оператором эволюции $\hat{U}(t)$

$$|\Psi(t)\rangle = \hat{U}(t)|\Psi\rangle$$

При этом должна сохраняться нормировка:

$$\langle\Psi(t)|\Psi(t)\rangle = 1$$

А так как можно переходить к эрмитово сопряженному оператору как $\left\langle A^\dagger\Psi|\Phi\right\rangle = \langle\Psi|A\Phi\rangle$, то

$$\begin{aligned}\langle\Psi(t)|\Psi(t)\rangle = \langle U(t)\Psi|U(t)\Psi\rangle &= \left\langle U^\dagger(t)U(t)\Psi|\Psi\right\rangle \\ \left\langle U^\dagger(t)U(t)\Psi|\Psi\right\rangle &= \langle\Psi|\Psi\rangle \quad \leftrightarrow \quad \hat{U}^\dagger\hat{U} = \hat{1}\end{aligned}$$

Это свойство оператора эволюции называется унитарностью.

Волновая функция состояния системы эволюционирует согласно уравнению Шредингера

$$i\hbar\frac{\partial|\Psi\rangle}{\partial t} = \hat{H}|\Psi\rangle,$$

здесь $\hat{H}$ - гамильтониан, соответствующий данной системе.

Его связь с оператором эволюции легко получить, подставив в уравнение Шредингера этот оператор, и в случае гамильтониана, не зависящего от времени, имеет вид:

$$i\hbar\frac{\partial\hat{U}(t)}{\partial t} = \hat{H}\hat{U}(t) \quad \rightarrow \quad \hat{U}(t) \equiv \exp(-i\hat{H}t/\hbar)$$

Преобразования при замене базиса

При замене базиса унитарными преобразованиями $|\psi'\rangle = \hat{U}|\psi\rangle$.

1. Покажите, что гамильтониан при этом заменяется на $\hat{H}' = \hat{U}\hat{H}\hat{U}^\dagger$.

2. Последнее утверждение необходимо модифицировать, если унитарное преобразование зависит явно от времени $\hat{U} = \hat{U}(t)$. Покажите, что в таком случае гамильтониан необходимо заменить на $\hat{H}' = \hat{U}\hat{H}\hat{U}^\dagger - i\hbar\hat{U}\partial_t\hat{U}^\dagger$.

(простое свойство, потом раскрою, ничего такого нет в этом.)

Другие свойства оператора эволюции (??)

(тут многое потом связано с ним, у Киселева спишу)

Как догадаться про оператор эволюции?

2.8.3 Particle Number Operator

Обсудим подробно оператор числа частиц.

2.9 Concept of Measurement in QM

(see note on quantum information for details)

2.9.1 Measurement Method

(тут подробно отвечаю про это. мб в часть про строгий квантмех тоже добавлю, в то же время в 1й части параграф будет с сутью этого)

измерения как особенное сопоставление борелевских мер алгебре наблюдаемых

там всякое задротство
определять алгебру наблюдаемых

Парадокс Эйнштейна-Подольского-Розена

(птф 2 лекция + методичка морозова тут)

$$\hat{\rho}_{AB} = |\psi_{AB}\rangle\langle\psi_{AB}| = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

$$\hat{\rho}_A = \frac{1}{2}\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \frac{1}{2}\hat{\mathbb{I}}$$

сравним с классической: носки

$$\hat{\rho}_{AB} = \frac{1}{2}\left(\hat{\mathbb{P}}_{\uparrow\downarrow} + \hat{\mathbb{P}}_{\downarrow\uparrow}\right) = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

$$\hat{\rho}_A = \mathrm{Tr}_B\, \hat{\rho}_{AB} = \frac{1}{2}\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \frac{1}{2}\hat{\mathbb{I}}$$

Редукция фон неймана в двух словах (???)

(потом напишу)

????? Зачастую когда речь заходит об измерениях, используется механизм Фон Неймана, так что обсудим его тут.

??? после измерения $\hat{\rho}_m$????

измерение происходит по формуле??

$$\hat{\rho}_m \sum_n \mathbb{P}_n \hat{\rho} \hat{\mathbb{P}}_n \leftrightarrow \begin{pmatrix} \rho_{11} & \rho_{12} & \dots & \rho_{1n} \\ \rho_{21} & \rho_{22} & \dots & \rho_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \rho_{n1} & \rho_{n2} & \dots & \rho_{nn} \end{pmatrix} \mapsto \begin{pmatrix} \rho_{11} & 0 & \dots & 0 \\ 0 & \rho_{22} & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \dots & \rho_{nn} \end{pmatrix}$$

Такое изменение матрицы плотности является объективным результатом взаимодействия системы с измеряющим прибором.

Во-первых, мы ничего не говорили о результате измерений, узнали ли мы его или нет.

Во-вторых, оно затронет результаты последующих измерений любой другой наблюдаемой, в базисе которой матрица плотности недиагональна (т.е. которая не коммутирует с O), поэтому это — наблюдаемый эффект.

Наконец, на некоторых конкретных моделях можно аккуратно проследить, как такая диагонализация происходит в результате унитарной эволюции — взаимодействия с окружающей средой.

«Вымирание» оффдиагональных элементов матрицы плотности в результате взаимодействия с окружающей средой носит название дефазировки или декогеренции.

Важно также отметить, что эти процессы подчиняются уравнению Шрёдингера, описывающему систему «измеритель+система», и они — локальны (в смысле, не

нарушают причинность — разумеется, возмущение, вызванное взаимодействием с измерителем, не выходит за пределы светового конуса).

Наконец, как мы установили выше, оффдиагональные элементы матрицы плотности в каком-то смысле характеризуют степень «квантовости» нашей системы

поэтому мы выяснили, что в результате взаимодействия с окружающей средой, система как бы становится «классической».

Пусть теперь мы всё-таки узнали результат измерения — выяснили, что система находится в конкретном состоянии.

Матрица плотности уже диагональна, и для дальнейшего описания мы уже можем пользоваться классической интуицией.

Тогда, как и в классической статистике, мы можем учесть это знание

(говоря на языке теории вероятностей, вычислять

????

неравенство Белла

(подробно потом обсужу его)

неопределенность и измерения

откуда вообще она и как убедиться в этом?
и тут физический смысл, также ссылки на математику.
мб задачи порешаю.
еще там разные ее формы есть, например форма Вейля, через средние.
что за?
сивухин тоже про это писал много

пример измерений (??!!)

две неопределенности при измерениях??

(задача вроде из овочоса)
мы представляем себе измерение так:
при измерениях в систему вводится неконтролируемая неопределенность $\langle \Delta x_0^2 \rangle = \langle x^2 \rangle - \langle x \rangle^2$.

Далее из соотношений неопределенностей можно найти неопределенность, которая вносится в импульс:

$$\langle \Delta p_x^2 \rangle \geqslant \frac{\hbar^2}{2\langle \Delta x_0^2 \rangle} E$$

А из неопределенности импульса по формуле для равномерного движения к неопределенности в расстоянии:

$$\langle \Delta x_\tau^2 \rangle = \frac{\langle \Delta p_x^2 \rangle \tau^2}{m^2} \geqslant \frac{\hbar^2 \tau^2}{4m^2 \langle \Delta x_0^2 \rangle}$$

Получается, что спустя $\Delta\tau$ после измерения, дисперсия конечной координаты $\langle \Delta x^2 \rangle$ будет состоять из ДВУХ дисперсий:

$$\langle \Delta x^2 \rangle \geqslant \langle \Delta x_0^2 \rangle + \frac{\hbar^2 \tau^2}{4m^2 \langle \Delta x_0^2 \rangle}$$

получается, что неопределенность измерения первой координаты, таким вот образом меняет неопределенность в пути.

!! таким образом частица может смешаться при измерении на минимальное расстояние $\langle \Delta x^2 \rangle_{min} = \hbar\tau/m$
кстатиати, если у нас действует сила, то от нее смещение будет $\frac{F\tau^2}{2m}$.
таким образом ее зарегистрировать можно, если

$$\frac{F\tau^2}{2m} \geqslant \hbar\tau/m$$

так и можно узнать, какую минимальную силу за данное время можно поменить.

заметим, что за малое время на самом деле силу поменить не получится, так как ее воздействие будет не достаточное для прорыва сквозь неопределенность.

Измерение

Вероятность координаты быть в $z_1 < z < z_2$

$$P(z_1 < z < z_2) = \int int \int_{z_1}^{z_2} |\psi(x,y,z)|^2 dxdydz$$

И эту формулу следует использовать для решения, если еще есть условие на импульс, чтобы это сделать перейдем в импульсное представление: $\psi(x,p_y,z) = \int dy e^{-iyp_y/\hbar}\psi(x,y,z), \qquad \psi^*(x,p_y,z) = \int dy e^{iyp_y/\hbar}\psi^*(x,y,z).$
нам нужно

$$|\psi(x,p_y,z)|^2 = \int\int dydy e^{-i(y-y)p_y/\hbar}\psi(x,y,z)\psi^*(x,y,z)$$

По итогу имеем:

$$P(z_1 < z < z_2, p_1 < p_y < p_2) = \int \int_{p_1}^{p_2} \int_{z_1}^{z_2} |\psi(x,p_y,z)|^2 \frac{dxdp_ydz}{2\pi\hbar}$$

проблема измерений

такая есть, ее и обсудим.

обзор

хз, чуть что - на вики пойти можно.

слабые измерения (?)

ну такое ест, мб дойду.

мотивация

см вики, там статья есть

обзор

In quantum mechanics (and computation and information), weak measurements are a type of quantum measurement that results in an observer obtaining very little information about the system on average, but also disturbs the state very little.[1]

From Busch's theorem[2] the system is necessarily disturbed by the measurement. In the literature weak measurements are also known as unsharp,[3] fuzzy,[3][4] dull, noisy,[5] approximate, and gentle[6] measurements. Additionally weak measurements are often confused with the distinct but related concept of the weak value.[7]

суть

хз, пока не актуально.

2.9.2 Simplified Theory of Measurements

Условие точного измерения (Киселев,???)

Выведите необходимое и достаточное условие точного измерения наблюдаемой F в дираковских обозначениях.

(Вопросы Киселева на развлечение (?!!!!!))

2.9.3 Quantum Entanglement

весь обзор ее тут будет, ибо как раз сдали посмотрим на все, что тут есть.

типичная модель

??

квантовая запутанность на километрах с помощью дронов

(интересно, но не актуально, мб когда-то буду добавлять)

Optical-Relayed Entanglement Distribution Using Dronesas Mobile Nodes Hua-YingLiu,Xiao-HuiTian,

Статья про квантовую запутанность на киллометры, создаю параграф про это и забиваю, ибо не актуально.

2.9.4 What Happens After Measurement?

Частица остается в том же состоянии, в котором мы ее измерили, или снова становятся такие же вероятности найти ее в разных состояниях до измерения? (?????)

(??? не знаю, нужно подумать про это хорошо!)

2.9.5 The Measurement Problem in Quantum Mechanics (???)

(там часто про это говорят, напишу потом. типа вообще непонятно, что такое измерение и открытые вопросы по поводу измерения, если все только квантовое.)

2.9.6 Quantum Zeno Effect

(all about it is here, see wiki or something for now)

2.9.7 Other About Measurements

(много вопросов еще есть про это.)

2.10 Measurement in QM: Other Ideas

(see note on quantum information for details)

2.10.1 The Perfect Measurement

(there are articles about it, I'll put them to the later part, and then I'll write about it here)

2.11 Mathematical Side of the Formalism of QM

(some other really conceptually important math concepts will also have some section here)

2.11.1 Reminder: Strict Definitions of Operators

We recall the standard notation and basic facts from the theory of selfadjoint operators on Hilbert spaces. Let $\mathscr{H}$ be a separable Hilbert space with an inner product $(,)$, which is complex-linear with respect to the first argument, and let A be a linear operator in $\mathscr{H}$ with the domain $D(A) \subseteq \mathscr{H}$ - a linear subset of $\mathscr{H}$. An operator A is called closed if its graph $\Gamma(A) = \{(\varphi, A\varphi) \in \mathscr{H} \times \mathscr{H} : \varphi \in D(A)\}$ is a closed subspace in $\mathscr{H} \times \mathscr{H}$. If the domain of A is dense [1] in $\mathscr{H}$, i.e., $\overline{D(A)} = \mathscr{H}$, the domain $D(A^*)$ of the adjoint operator A^* consists of $\varphi \in \mathscr{H}$ such that there is $\eta \in \mathscr{H}$ with the property that

$$(A\psi, \varphi) = (\psi, \eta) \quad \text{for all} \quad \psi \in D(A)$$

and the operator A^* is defined by $A^*\varphi = \eta$. An operator A is called symmetric if

$$(A\psi, \varphi) = (\psi, A\varphi) \quad \text{for all} \quad \varphi, \psi \in D(A)$$

By definition, the regular set of a closed operator A with a dense domain $D(A)$ is the set $\rho(A) = \{\lambda \in \mathbb{C} | A - \lambda I : D(A) \to \mathscr{H}$ is a bijection with a bounded inverse [2]$\}$, and for $\lambda \in \rho(A)$, the bounded operator $R_\lambda(A) = (A - \lambda I)^{-1}$ is called the resolvent of A at λ. The regular set $\rho(A) \subset \mathbb{C}$ is open and its complement $\sigma(A) = \mathbb{C} \backslash \rho(A)$ is the spectrum of A. The subset $\sigma_p(A)$ of $\sigma(A)$ consisting of eigenvalues of A of finite multiplicity is called the point spectrum.

An operator A is self-adjoint (or Hermitian) if $A = A^*$. Equivalently, A is symmetric and $D(A) = D(A^*)$, and for such operators $\sigma(A) \subset \mathbb{R}$. A symmetric operator A is called essentially self-adjoint if its closure $\bar{A} = A^{**}$ is self-adjoint. For a symmetric operator A the following conditions are equivalent:
(i) A is essentially self-adjoint.
(ii) $\operatorname{Ker}(A^* + iI) = \operatorname{Ker}(A^* - iI) = \{0\}$.
(iii) $\overline{\operatorname{Im}(A + iI)} = \overline{\operatorname{Im}(A - iI)} = \mathscr{H}$.

A symmetric operator A with $D(A) = \mathscr{H}$ is bounded and self-adjoint. An operator A is positive [3] if $(A\varphi, \varphi) \geq 0$ for all $\phi \in D(A)$, which we denote by $A \geq 0$. Positive operators satisfy the Cauchy-Bunyakovski-Schwarz inequality

$$|(A\varphi, \psi)|^2 \leq (A\varphi, \varphi)(A\psi, \psi) \quad \text{for all} \quad \varphi, \psi \in D(A) \tag{0.1}$$

In particular, $(A\varphi, \varphi) = 0$ implies that $A\varphi = 0$. Every bounded positive operator is self-adjoint [4]. We denote by $\mathscr{L}(\mathscr{H})$ the $\mathbb{C}^*$-algebra of bounded linear operators on $\mathscr{H}$ with the operator norm $\| \cdot \|$ and with the antiinvolution * given by the operator adjoint. Operator $A \in \mathscr{L}(\mathscr{H})$ is called compact if it maps bounded sets in $\mathscr{H}$ into pre-compact sets [5]. The vector space $\mathscr{C}(\mathscr{H})$ of compact operators on $\mathscr{H}$ is a closed two-sided ideal [6] of the $\mathbb{C}^*$-algebra $\mathscr{L}(\mathscr{H})$.

An operator $A \in \mathscr{C}(\mathscr{H})$ is of trace class if

$$\|A\|_1 = \sum_{n=1}^{\infty} \mu_n(A) < \infty$$

[01] We consider only linear operators with dense domains.
[2] By the closed graph theorem, the last condition is redundant.

where $\mu_n(A)$ are singular values of $A : \mu_n(A) = \sqrt{\lambda_n(A)} \geq 0$, where $\lambda_n(A)$ are eigenvalues of A^*A. Equivalently, an operator $A \in \mathscr{L}(\mathscr{H})$ is of trace class if and only if for every orthonormal basis $\{e_n\}_{n=1}^{\infty}$ for $\mathscr{H}$

$$\sum_{n=1}^{\infty} |(Ae_n, e_n)| < \infty$$

Since a permutation of an orthonormal basis is again an orthonormal basis, this condition can be replaced by

$$\sum_{n=1}^{\infty} (Ae_n, e_n) < \infty$$

for every orthonormal basis $\{e_n\}_{n=1}^{\infty}$ for $\mathscr{H}$. The trace of a trace class operator A is defined by

$$\operatorname{Tr} A = \sum_{n=1}^{\infty} (Ae_n, e_n)$$

and does not depend on the choice of an orthonormal basis $\{e_n\}_{n=1}^{\infty}$ for $\mathscr{H}$. A positive operator $A \in \mathscr{L}(\mathscr{H})$ is of trace class if

$$\sum_{n=1}^{\infty} (Ae_n, e_n) < \infty$$

for some orthonormal basis $\{e_n\}_{n=1}^{\infty}$ for $\mathscr{H}$. The space $\mathscr{S}_1$ of trace class operators in $\mathscr{H}$ is a Banach algebra with the norm $\|A\|_1 = \operatorname{Tr} \sqrt{A^*A}$, and is a two-sided ideal (von Neumann-Schatten ideal) in the $\mathbb{C}^*$-algebra $\mathscr{L}(\mathscr{H})$.

The property

$$\operatorname{Tr} AB = \operatorname{Tr} BA \quad \text{for all} \quad A \in \mathscr{S}_1, B \in \mathscr{L}(\mathscr{H})$$

is called the cyclic property of the trace. If $A \in \mathscr{S}_1$, the mapping $l_A(B) = \operatorname{Tr} AB, B \in \mathscr{L}(\mathscr{H})$, is a continuous linear functional on $\mathscr{L}(\mathscr{H})$, so that $\mathscr{S}_1 \subset \mathscr{L}(\mathscr{H})^*$ - the dual Banach space to $\mathscr{L}(\mathscr{H})$. However, $\mathscr{S}_1 \neq \mathscr{L}(\mathscr{H})^*$, but rather $\mathscr{S}_1 = \mathscr{C}(\mathscr{H})^*$, and the mapping $A \mapsto l_A$ is an isomorphism of Banach spaces. Similarly, the mapping $B \mapsto l_B$ gives an isomorphism $\mathscr{L}(\mathscr{H}) = \mathscr{S}_1^*$.

An operator $A \in \mathscr{L}(\mathscr{H})$ is called a Hilbert-Schmidt operator if $AA^* \in \mathscr{S}_1$. Equivalently, an operator $A \in \mathscr{L}(\mathscr{H})$ is a Hilbert-Schmidt operator if and only if for some orthonormal basis $\{e_n\}_{n=1}^{\infty}$ for $\mathscr{H}$

$$\sum_{n=1}^{\infty} \|Ae_n\|^2 < \infty$$

The vector space $\mathscr{S}_2$ of Hilbert-Schmidt operators in $\mathscr{H}$ is a Hilbert space with the inner product $(A, B)_2 = \operatorname{Tr} AB^*$. The Hilbert-Schmidt space $\mathscr{S}_2$ is also a two-sided ideal in the $\mathbb{C}^*$-algebra $\mathscr{L}(\mathscr{H})$.

2.11.2 Hilbert Space

(статья одна тут выгружена, мб посмотрю её, точно не скоро.)

[03] Non-negative, to be precise.
[4] This is true only for complex Hilbert spaces.
[5] The sets with compact closure.
[6] Ideal $\mathscr{C}(\mathscr{H})$ is the only closed two-sided ideal of $\mathscr{L}(\mathscr{H})$.

О важности строгого подхода к гильбертовым пространствам

(почему таким подходом вообще заниматься следует?)

основы гильбертова пространства

тупая обычная теория, потом напишу

2.11.3 Tensor Product of Hilbert Spaces

(наверное, по Нохриной это я писал, потому что нигде в других местах нет этой теории.)

Теория

Пусть пространства $\mathcal{H}_1$ и $\mathcal{H}_2$ - гильбертовы. Напомним, что гильбертовым называется полное евклидово пространство, то есть пространство со скалярным произведением, полное по норме, порожденной этим скалярным произведением. Для любых $\varphi \in \mathcal{H}_1$ и $\psi \in \mathcal{H}_2$ введём объект $\varphi \otimes \psi$. Определим сумму двух таких объектов и умножение этого объекта на произвольный комплексный скаляр так, чтобы

$$\alpha(\varphi \otimes \psi) = (\alpha\varphi) \otimes \psi = \varphi \otimes (\alpha\psi)$$
$$\forall \alpha \in \mathbb{C}, \varphi \in \mathcal{H}_1, \psi \in \mathcal{H}_2;$$
$$(\varphi_1 + \varphi_2) \otimes \psi = \varphi_1 \otimes \psi + \varphi_2 \otimes \psi$$
$$\forall \varphi_{1,2} \in \mathcal{H}_1, \psi \in \mathcal{H}_2;$$
$$\varphi \otimes (\psi_1 + \psi_2) = \varphi \otimes \psi_1 + \varphi \otimes \psi_2$$
$$\forall \varphi \in \mathcal{H}_1, \psi_{1,2} \in \mathcal{H}_2.$$

Пусть θ_1 нулевой вектор в $\mathcal{H}_1, \theta_2$ нулевой вектор в $\mathcal{H}_2$. Тогда $\forall \varphi_{1,2} \in \mathcal{H}_1$ и $\psi_{1,2} \in \mathcal{H}_2$ имеем

$$\theta_1 \otimes \psi_1 + \varphi_2 \otimes \psi_2 = (\varphi_2 - \varphi_2) \otimes \psi_1 + \varphi_2 \otimes \psi_2 =$$
$$= \varphi_2 \otimes \psi_1 - \varphi_2 \otimes \psi_1 + \varphi_2 \otimes \psi_2 = \varphi_2 \otimes (\psi_1 - \psi_1 + \psi_2) =$$
$$= \varphi_2 \otimes (\theta_2 + \psi_2) = \varphi_2 \otimes \psi_2$$

точно так же

$$\varphi_1 \otimes \psi_1 + \varphi_2 \otimes \theta_2 = \varphi_1 \otimes \psi_1 + \varphi_2 \otimes (\psi_1 - \psi_1) =$$
$$= \varphi_1 \otimes \psi_1 + \varphi_2 \otimes \psi_1 - \varphi_2 \otimes \psi_1 = (\varphi_1 + \varphi_2 - \varphi_2) \otimes \psi_1 =$$
$$= (\varphi_1 + \theta_1) \otimes \psi_1 = \varphi_1 \otimes \psi_1.$$

Таким образом, обьекты $\theta_1 \otimes \psi_1$ и $\varphi_1 \otimes \theta_2$ играют роль нуля в линейном пространстве L всевозможных конечных линейных комбинаций объектов $\varphi \otimes \psi$, то есть

$$L = \left\{ \sum_{i,j=1}^{N} \alpha_{ij} \varphi_i \otimes \psi_j | N \in \mathbb{N}, \right.$$
$$\left. \alpha_{ij} \in \mathbb{C}, \varphi_1 ... \varphi_N \in \mathcal{H}_1, \psi_1 ... \psi_N \in \mathcal{H}_2 \right\}.$$

Выражения (1) - (3) вместе с определением нуля $\theta_1 \otimes \psi_1$ и $\varphi_1 \otimes \theta_2$ задают линейную структуру на множестве L.

Введем на L скалярное произведение. Для этого сначала определим произведение для объектов $\varphi \otimes \psi$ следующим образом: $\forall \varphi_{1,2} \in \mathcal{H}_1$ и $\forall \psi_{1,2} \in \mathcal{H}_2$,

$$(\varphi_1 \otimes \psi_1, \varphi_2 \otimes \psi_2) = (\varphi_1, \varphi_2)(\psi_1, \psi_2)$$

ТОГДа ДлЯ

$$\Psi = \sum_{i,j=1}^{N} \alpha_{ij} \varphi_i \otimes \psi_j \in L, \quad \text{и}$$

$$\tilde{\Psi} = \sum_{k,l=1}^{N} \beta_{kl} \tilde{\varphi}_k \otimes \tilde{\psi}_l \in L$$

определим скалярное произведение элементов L как

$$(\Psi, \tilde{\Psi}) = \sum_{i,j=1}^{N} \sum_{k,l=1}^{N} \alpha_{ij} \beta_{kl} \left(\varphi_i \otimes \psi_j, \tilde{\varphi}_k \otimes \tilde{\psi}_l \right).$$

Упражнение. Докажите корректность такого определения. Таким образом, мы получили линейное евклидово пространство.

Определение 1. Тензорным произведением $\mathcal{H}_1 \otimes \mathcal{H}_2$ двух гильбертовых пространств $\mathcal{H}_1$ и $\mathcal{H}_2$ называется пополнение множества всех возможных конечных линейных комбинаций $\varphi \otimes \psi$ по норме, порожденной скалярным произведением (7).

Если мы работаем с тензорным произведением бесконечномерных пространств, то множество всех конечных линейных комбинаций не полно. Поэтому для того, чтобы тензорное произведение было также гильбертовым пространством, необходимо 6 его пополнить. Нередко в квантовой механике работают с тензорным произведением конечномерных гильбертовых пространств, изоморфных $\mathbb{C}^n, n \in \mathbb{N}$. В этом случае конечные линейные комбинации образуют полное пространство, и процедуры пополнения не требуется. в гильбертовых $\mathcal{H}_1$ и $\mathcal{H}_2$ соответственно, то $\varphi_i \otimes \psi_j$ - ортонормированный базис в тензорном произведении $\mathcal{H}_1 \otimes \mathcal{H}_2$.

Доказательство. Базис - это полная ортогональная система. Полнота обеспечивает приближение произвольного элемента с любой точностью (по норме пространства), а ортогональность обеспечивает единственность коэффициентов разложения. Поскольку ортонормированность $\varphi_i \otimes \psi_j$ очевидна, нам нужно доказать лишь полноту. Возьмём произвольный вектор $\varphi \otimes \psi$. Вектор φ раскладывается по базису φ_i, а ψ - по ψ_j: $\varphi = \sum\limits_{i=1}^{+\infty} c_i \varphi_i$ и $\psi = \sum\limits_{j=1}^{+\infty} d_j \psi_j$. Здесь по равенству Парсеваля выполнено $\sum\limits_{i=1}^{+\infty} |c_i|^2 < +\infty$, $\sum\limits_{j=1}^{+\infty} |d_j|^2 < +\infty$ и, следовательно, верно $\sum\limits_{i,j=1}^{+\infty} |c_i d_j|^2 \leq \sum\limits_{i=1}^{+\infty} |c_i|^2 \sum\limits_{j=1}^{+\infty} |d_j|^2 < +\infty$. Значит, существует вектор $\alpha = \sum\limits_{i,j=1}^{+\infty} c_i d_j \varphi_i \otimes \psi_j$. Покажем, что

$$\left\| \varphi \otimes \psi - \sum_{i,j=1}^{M,N} c_i d_j \varphi_i \otimes \psi_j \right\| \to 0$$

при $M, N \to +\infty$. Рассмотрим следующие частичные суммы:

$$f_M = \sum_{i=1}^{M} c_i \varphi_i, \quad g_N = \sum_{j=1}^{N} d_j \psi_j$$

Тензорное произведение частичных сумм

$$f_M \otimes g_N = \sum_{i,j=1}^{M,N} c_i d_j \varphi_i \otimes \psi_j$$

Рассмотрим цепочку неравенств:

$$\|\varphi\otimes\psi - f_M\otimes g_N\| =$$
$$= \left\|\varphi\otimes\psi \pm \frac{1}{2}f_M\otimes\psi \pm \frac{1}{2}\varphi\otimes g_N - f_M\otimes g_N\right\| \leq$$
$$\leq \frac{1}{2}\|\varphi\otimes(\psi-g_N)+(\varphi-f_M)\otimes\psi+$$
$$+f_M\otimes(\psi-g_N)+(\varphi-f_M)\otimes g_N\| \leq$$
$$\leq \frac{1}{2}\left(\|\varphi\|\,\|\psi-g_N\|+\|\varphi-f_M\|\,\|\psi\|+\right.$$
$$\left.+\|f_M\|\,\|\psi-g_N\|+\|\varphi-f_M\|\,\|g_N\|\right)\to 0$$

при $M,N\to+\infty$. Пример 3. Рассмотрим тензорное произведение $\mathbb{C}^2\otimes\mathbb{C}^2$. Базисом в тензорном произведении являются в соответствии с Утверждением 2 следующие векторы:

$$\begin{pmatrix}1\\0\end{pmatrix}\otimes\begin{pmatrix}1\\0\end{pmatrix},\quad \begin{pmatrix}1\\0\end{pmatrix}\otimes\begin{pmatrix}0\\1\end{pmatrix},$$
$$\begin{pmatrix}0\\1\end{pmatrix}\otimes\begin{pmatrix}1\\0\end{pmatrix},\quad \begin{pmatrix}0\\1\end{pmatrix}\otimes\begin{pmatrix}0\\1\end{pmatrix}.$$

Как правило, гораздо удобнее работать именно с такими объектами. Тем не менее часто в физической литературе принято использовать пространства, изоморфные тензорному произведению. Напомним, что изоморфизм - это взаимно однозначное отображение на пространство. Для задания такого отображения достаточно определить отображение базисных векторов. В нашем примере пространство $\mathbb{C}^2\otimes\mathbb{C}^2$ является четырёхмерным, поэтому естественно отобразить его на $\mathbb{C}^4$. Зададим изоморфизм (изометрический) U : $\mathbb{C}^2\otimes\mathbb{C}^2\to\mathbb{C}^4$:

$$U\begin{pmatrix}1\\0\end{pmatrix}\otimes\begin{pmatrix}1\\0\end{pmatrix}=\begin{pmatrix}1\\0\\0\\0\end{pmatrix},\quad U\begin{pmatrix}1\\0\end{pmatrix}\otimes\begin{pmatrix}0\\1\end{pmatrix}=\begin{pmatrix}0\\1\\0\\0\end{pmatrix}$$

8 и так далее. Такое отображение реализует кронекерово произведение. Необходимо заметить, что оно не единственно. Более того, в нем нет необходимости - работать можно в исходном тензорном произведении пространств.

Пусть в каждом из гильбертовых пространств заданы операторы $\hat{S}$: $D(\hat{S})\to\mathcal{H}_1$ и $\hat{T}$: $D(\hat{T})\to\mathcal{H}_2$. Здесь области определения операторов $-D(\hat{S})\subset\mathcal{H}_1$ и $D(\hat{T})\subset\mathcal{H}_2$ соответственно. Тензорным произведением этих операторов называется оператор $\hat{T}\otimes\hat{S}$, действие которого для любых $\varphi\in D(\hat{S})$ и $\psi\in D(\hat{T})$ определено следующим образом: $(\hat{T}\otimes\hat{S})(\varphi\otimes\psi)=(\hat{T}\varphi)\otimes(\hat{S}\psi)$. Т.е. первый оператор действует только на первый вектор, а второй - только на второй. Соответственно, $\forall\varphi_1...\varphi_N\in D(\hat{S})$ и $\forall\psi_1...\psi_N\in D(\hat{T})$ действие оператора $\hat{S}\otimes\hat{T}$ на линейную комбинацию тензорного произведения векторов опеределно как

$$(\hat{S}\otimes\hat{T})\left(\sum_{i,j=1}^{N}a_{ij}\varphi_i\otimes\psi_j\right)=\sum_{i,j=1}^{N}a_{ij}(\hat{S}\otimes\hat{T})\,(\varphi_i\otimes\psi_j)$$

Хочется определить тензорное произведение операторов на произвольном объекте $\Psi\in\mathcal{H}_1\otimes\mathcal{H}_2$. Произвольный элемент тензорного произведения бесконечномерных пространств является пределом частичных сумм

$$\Psi=\lim_{N\to+\infty}\sum_{n=1}^{N}c_n\psi_n,$$

где $\{\psi_n\}$ - базис в сепарабельном гильбертовом пространстве. Для определения действия тензорного произведения операторов на такой объект необходимо продолжить действие по непрерывности. Но неограниченный оператор $\hat{S}$ является всюду разрывным, поэтому нельзя определить действие оператора на предел частичных сумм по непрерывности. Тем не менее если оператор $\hat{S}$ самосопряженный, то такой переход верен. Покажем это для случая, когда каждый из операторов $\hat{S}$ и $\hat{T}$ обладает только точечным спектром и, значит, базисом из собственных функций. Для сложения моментов этого достаточно.

Рассмотрим $\psi \in D(\hat{S})$. Пусть $\{\psi_n\}$ - базис из собственных 9 функций $\hat{S}$ в $\mathcal{H}_1$. Вектор ψ раскладывается по базису

$$\psi = \sum_n c_n \psi_n$$

Мы не можем напрямую записать действие оператора $\hat{S}$ на этот вектор как предел частичных сумм, на каждый член которой действует $\hat{S}$ из-за разрывности $\hat{S}$. Так как $\psi \in D(\hat{S})$, то $\hat{S}\psi \in \mathcal{H}_1$. Вектор $\hat{S}\psi$ может быть разложен по базису ψ_n:

$$\hat{S}\psi = \sum_n d_n \psi_n$$

где коэффициенты Фурье d_n определяются выражением

$$d_n = \left(\psi_n, \hat{S}\psi\right) = \left(\hat{S}\psi_n, \psi\right) = \lambda_n \left(\psi_n, \psi\right)$$

Значит,

$$\hat{S}\psi = \sum_n d_n \psi_n = \sum_n \lambda_n c_n \psi_n$$

Таким образом, мы показали, что

$$\hat{S}\psi = \sum_n \lambda_n c_n \psi_n$$

Определение 4. Тензорным произведением двух самосопряженных операторов $\hat{S} : D(\hat{S}) \to \mathcal{H}_1$ и $\hat{T} : D(\hat{T}) \to \mathcal{H}_2$, каждый из которых обладает чисто точечным спектром λ_n и μ_m и, значит, базисом из собственных функций $\{\varphi_n\}$ и $\{\psi_m\}$ соответственно, называется оператор $\hat{S} \otimes \hat{T}$, действие которого на

$$\Psi \in D(\hat{S} \otimes \hat{T}) =$$

$$= \left\{ \Psi \in \mathcal{H}_1 \otimes \mathcal{H}_2 \left| \sum_n \sum_m \right| \lambda_n \Big|^2 |\mu_m|^2 |\alpha_{nm}|^2 < +\infty \right\}$$

определяется как

$$(\hat{S} \otimes \hat{T})\Psi = \sum_n \sum_m \lambda_n \mu_m \alpha_{nm} \varphi_n \otimes \psi_m$$

Здесь вектор Ψ разложен по базису в $\mathcal{H}_1 \otimes \mathcal{H}_2$:

$$\Psi = \sum_n \sum_m \alpha_{nm} \varphi_n \otimes \psi_m$$

Область определения 10 задется очень естественным требованием, чтобы вектор $(\hat{S} \otimes \hat{T})\Psi$ лежал в пространстве $\mathcal{H}_1 \otimes \mathcal{H}_2$. Упражнение. Покажите, что $(\hat{S} \otimes \hat{T})\Psi \in \mathcal{H}_1 \otimes \mathcal{H}_2$ тогда и только тогда, когда $\Psi \in D(\hat{S} \otimes \hat{T})$, определенную выражением (10)

В дальнейшем нам понадобится более простое определение определение тензорного произведения операторов в конечномерном пространстве.

Определение 5. Тензорным произведением двух самосопряженных операторов $\hat{S}$ и $\hat{T}$ в конечномерных $\mathcal{H}_1$ и $\mathcal{H}_2$ называется оператор $\hat{S} \otimes \hat{T}$, действие которого на объект $\Psi \in \mathcal{H}_1 \otimes \mathcal{H}_2$ задается выражением (9).

Замечание 6. Пусть два симметрических оператора $\hat{S}$ и $\hat{T}$ действут на конечномерных гильбертовых пространствах $\mathbb{C}^n$ и $\mathbb{C}^m$ соответственно. Пусть в $\mathbb{C}^n$ Задан ортонормированный базис $\{\varphi_i\}, i = \overline{1,n}$, а в $\mathbb{C}^m$ - базис $\{\psi_j\}, j = \overline{1,m}$. Каждый из этих операторов в заданном базисе можно записать в виде матрицы с компонентами:

$$S_{ij} = \left(\varphi_i, \hat{S}\varphi_j\right), T_{kl} = \left(\psi_k, \hat{T}\psi_l\right)$$

Задавая на этом базисе какой-либо изометрический изоморфизм $U : \mathbb{C}^n \otimes \mathbb{C}^m \to \mathbb{C}^{n \cdot m}$, реализуемый как $\varphi_i \otimes \psi_k \cong \Psi_{s_{ik}}$, где $s = \overline{1, n \cdot m}$. Мы можем задать на $\mathbb{C}^{n \cdot m}$ оператор $\hat{W} \cong \hat{S} \otimes \hat{T}$ матрицей:

$$W_{s_{ik}s_{jl}} = \left(\Psi_{s_{ik}}, \hat{W}\Psi_{s_{jl}}\right) = \left(\varphi_i \otimes \psi_k, (\hat{S} \otimes \hat{T})\varphi_j \otimes \psi_l\right) =$$

У пражнение. Пусть изоморфизм U осуществляется как:

$$\left(\Psi_{s_{ik}}\right)_a = \left(\varphi_i\right)_b \cdot \left(\psi_k\right)_c$$

11 где $\left(\Psi_{s_{ik}}\right)_a$ это a компонента вектора $\Psi_{s_{ik}}$, а $\left(\varphi_i\right)_b$ это b компонента вектора φ_i. Здесь $b = \overline{1,n}, c = \overline{1,m}$, а $a = b + (c-1) \cdot n$. Покажите, что тензорное произведение операторов осуществляется как кронекерово произведение матриц.

Таким образом, кронекерово произведение лишь одна удобная реализация тензорного произведения, задаваемая конкретным отображением U.

Тензорное произведение гильбертовых пространств обеспечивает естественный математический аппарат для описания в квантовой механике независимых величин. Рассмотрим две наблюдаемые A и B, которым соответствуют самосопряженные операторы $\hat{A}$ и $\hat{B}$, каждый из которых действует в своем гильбертовом пространстве. Пусть величины A и B независимы. В силу структуры тензорного произведения оператор $\hat{A} \otimes \hat{B}$ имеет независимые вероятностные характеристики в состоянии $\Psi = \psi \otimes \varphi$. Например, среднее значение

$$\langle \hat{A} \otimes \hat{B} \rangle_\Psi = (\psi, \hat{A}\psi)(\varphi, \hat{B}\varphi) = \langle \hat{A} \rangle_\psi \langle \hat{B} \rangle_\varphi$$

Значит, тензорное произведение гильбертовых пространств корректно описывает совместные распределения независимых величин Пример 9. Рассмотрим пример с трехмерным изотропным осциллятором. Так как энергии колебаний по каждой из осей такой системы не зависят от колебаний по другим осям, то естественно описывать состояние трехмерного осциллятора в тензорном произведении гильбертовых пространств, каждое их которых используется для описания одномерного осциллятора. В силу того что гамильтониан распадается на сумму трех гамильтонианов одномерного осциллятора по независимым переменным, естественно записать его в виде

$$\hat{H} = \hat{H}_x \otimes \hat{E} \otimes \hat{E} + \hat{E} \otimes \hat{H}_y \otimes \hat{E} + \hat{E} \otimes \hat{E} \otimes \hat{H}_z.$$

Этот оператор действует в тензорном произведении пространств: $\mathcal{H}_1 = L^2(\mathbb{R}) \otimes L^2(\mathbb{R}) \otimes L^2(\mathbb{R})$. Базисом из собственных векторов этого гамильтониана является набор

$$\psi_{n_1} \otimes \psi_{n_2} \otimes \psi_{n_3}$$

Может быть построен так называемый естественный изоморфизм [1]$U : \mathcal{H}_1 \to \mathcal{H}_2$, где $\mathcal{H}_2 = L^2(\mathbb{R}^3)$:

$$U(\psi_{n_1} \otimes \psi_{n_2} \otimes \psi_{n_3}) \to \psi_{n_1}(x)\psi_{n_2}(y)\psi_{n_3}(z).$$

Пример 10. Тензорное произведение в линейной алгебре. Рассмотрим пространство $\mathbb{R}^3$. Определим в нем вектор как тройку чисел a_i (его координат в определенном ортонормированном базисе $\mathbf{e}_i$), которые при поворотах базисных векторов в $\mathbb{R}^3$, задаваемых матрицей R с компонентами $R_{ij}, i, j = 1, 2, 3$, преобразуются как $a'_i = R_{ij}a_j$. Тогда можно определить тензорное произведение векторов $\mathbf{a}$ и $\mathbf{b}$:

$$\mathbf{a} \otimes \mathbf{b} = \sum_{i,j=1}^{3} a_i b_j \mathbf{e}_i \otimes \mathbf{e}_j.$$

Координаты этого объекта $a_i b_j$ преобразуются как

$$a'_i b'_j = R_{il} R_{jm} a_l b_m.$$

Это пример простейшего тензора.

2.12 Classical Mechanics for QM

We assume that the reader is familiar with the basic notions from the theory of smooth (that is, C^∞) manifolds and recall here the standard notation. Unless it is stated explicitly otherwise, all maps are assumed to be smooth and all functions are assumed to be smooth and real-valued. Local coordinates $\boldsymbol{q} = (q^1, ..., q^n)$ on a smooth n-dimensional manifold M at a point $q \in M$ are Cartesian coordinates on $\varphi(U) \subset \mathbb{R}^n$, where (U, φ) is a coordinate chart on M centered at $q \in U$. For $f : U \to \mathbb{R}^n$ we denote $(f \circ \varphi^{-1})(q^1, ..., q^n)$ by $f(\boldsymbol{q})$, and we let

$$\frac{\partial f}{\partial \boldsymbol{q}} = \left(\frac{\partial f}{\partial q^1}, ..., \frac{\partial f}{\partial q^n} \right)$$

stand for the gradient of a function f at a point $\boldsymbol{q} \in \mathbb{R}^n$ with Cartesian coordinates $(q^1, ..., q^n)$. We denote by

$$\mathcal{A}^\bullet(M) = \bigoplus_{k=0}^{n} \mathcal{A}^k(M)$$

the graded algebra of smooth differential forms on M with respect to the wedge product, and by d the de Rham differential - a graded derivation of $\mathcal{A}^\bullet(M)$ of degree 1 such that df is a differential of a function $f \in \mathcal{A}^0(M) = C^\infty(M)$. Let $\mathrm{Vect}(M)$ be the Lie algebra of smooth vector fields on M with the Lie bracket [,], given by a commutator of vector fields. For $X \in \mathrm{Vect}(M)$ we denote by $\mathcal{L}_X$ and i_X, respectively, the Lie derivative along X and the inner product with X. The Lie derivative is a degree 0 derivation of $\mathcal{A}^\bullet(M)$ which commutes with d and satisfies $\mathcal{L}_X(f) = X(f)$ for $f \in \mathcal{A}^0(M)$, and the inner product is a degree -1 derivation of $\mathcal{A}^\bullet(M)$ satisfying $i_X(f) = 0$
and $i_X(df) = X(f)$ for $f \in \mathcal{A}^0(M)$. They satisfy Cartan formulas

$$\mathcal{L}_X = i_X \circ d + d \circ i_X = (d + i_X)^2$$
$$i_{[X,Y]} = \mathcal{L}_X \circ i_Y - i_Y \circ \mathcal{L}_X$$

For a smooth mapping of manifolds $f : M \to N$ we denote by $f_* : TM \to TN$ and $f^* : T^*N \to T^*M$, respectively, the induced mappings on tangent and cotangent bundles. Other notations, including those traditional for classical mechanics, will be introduced in the main text.

2.12.1 1. Classical Lagrangian Mechanics for QM

1.1. Generalized coordinates.

Classical mechanics describes systems of finitely many interacting particles [1]. A system is called closed if its particles do not interact with the outside material bodies. The position of a system in space is specified by positions of its particles and defines a point in a smooth, finite-dimensional manifold M, the configuration space of a system. Coordinates on M are called generalized coordinates of a system, and the dimension $n = \dim M$ is called the number of degrees of freedom [2].

The state of a system at any instant of time is described by a point $q \in M$ and by a tangent vector $v \in T_qM$ at this point. The basic principle of classical mechanics is the Newton-Laplace determinacy principle which asserts that a state of a system at a given instant completely determines its motion at all times t (in the future and in the past). The motion is described by the classical trajectory - a path $\gamma(t)$ in the configuration space M. In generalized coordinates $\gamma(t) = (q^1(t), ..., q^n(t))$, and corresponding derivatives $\dot{q}^i = \frac{dq^i}{dt}$ are called generalized velocities. The Newton-Laplace principle is a fundamental experimental fact confirmed by our perception of everyday experiences. It implies that generalized accelerations $\ddot{q}^i = \frac{d^2q^i}{dt^2}$ are uniquely defined by generalized coordinates q^i and generalized velocities $\dot{q}^i$, so that classical trajectories satisfy a system of second order ordinary differential equations, called equations of motion. In the next section we formulate the most general principle governing the motion of mechanical systems.
1.2. The principle of the least action. A Lagrangian system on a configuration space M is defined by a smooth, real-valued function L on $TM \times \mathbb{R}$ - the direct product of a tangent bundle TM of M and the time axis [3] called the Lagrangian function (or simply, Lagrangian). The motion of a

Lagrangian system (M, L) is described by the principle of the least action in the configuration space (or Hamilton's principle), formulated as follows.

Let

$$P(M)_{q_0,t_0}^{q_1,t_1} = \{\gamma : [t_0, t_1] \to M; \gamma(t_0) = q_0, \gamma(t_1) = q_1\}$$

be the space of smooth parametrized paths in M connecting points q_0 and q_1. The path space $P(M) = P(M)_{q_0,t_0}^{q_1,t_1}$ is an infinite-dimensional real Frchet manifold, and the tangent space $T_\gamma P(M)$ to $P(M)$ at $\gamma \in P(M)$ consists of all smooth vector fields along the path γ in M which vanish at the endpoints q_0 and q_1. A smooth path Γ in $P(M)$, passing through $\gamma \in P(M)$, is called a variation with fixed ends of the path $\gamma(t)$ in M. A variation Γ is a family $\gamma_\varepsilon(t) = \Gamma(t, \varepsilon)$ of paths in M given by a smooth map

$$\Gamma : [t_0, t_1] \times [-\varepsilon_0, \varepsilon_0] \to M$$

such that $\Gamma(t, 0) = \gamma(t)$ for $t_0 \le t \le t_1$ and $\Gamma(t_0, \varepsilon) = q_0, \Gamma(t_1, \varepsilon) = q_1$ for $-\varepsilon_0 \le \varepsilon \le \varepsilon_0$. The tangent vector

$$\delta\gamma = \left.\frac{\partial\Gamma}{\partial\varepsilon}\right|_{\varepsilon=0} \in T_\gamma P(M)$$

corresponding to a variation $\gamma_\varepsilon(t)$ is traditionally called an infinitesimal variation. Explicitly,

$$\delta\gamma(t) = \Gamma_* \left(\frac{\partial}{\partial\varepsilon}\right)(t, 0) \in T_{\gamma(t)}M, \quad t_0 \le t \le t_1,$$

[01] A particle is a material body whose dimensions may be neglected in describing its motion.
[2] Systems with infinitely many degrees of freedom are described by classical field theory.
[3] It follows from the Newton-Laplace principle that L could depend only on generalized coordinates and velocities, and on time.

where $\frac{\partial}{\partial\varepsilon}$ is a tangent vector to the interval $[-\varepsilon_0, \varepsilon_0]$ at 0 . Finally, a tangential lift of a path $\gamma : [t_0, t_1] \to M$ is the path $\gamma' : [t_0, t_1] \to TM$ defined by $\gamma'(t) = \gamma_* \left(\frac{\partial}{\partial t}\right) \in T_{\gamma(t)}M, t_0 \leq t \leq t_1$, where $\frac{\partial}{\partial t}$ is a tangent vector to $[t_0, t_1]$ at t. In other words, $\gamma'(t)$ is the velocity vector of a path $\gamma(t)$ at time t.

Definition. The action functional $S : P(M) \to \mathbb{R}$ of a Lagrangian system (M, L) is defined by

$$S(\gamma) = \int_{t_0}^{t_1} L\left(\gamma'(t), t\right) dt$$

Principle of the Least Action (Hamilton's principle). A path $\gamma \in PM$ describes the motion of a Lagrangian system (M, L) between the position $q_0 \in M$ at time t_0 and the position $q_1 \in M$ at time t_1 if and only if it is a critical point of the action functional S,

$$\left.\frac{d}{d\varepsilon}\right|_{\varepsilon=0} S\left(\gamma_\varepsilon\right) = 0$$

for all variations $\gamma_\varepsilon(t)$ of $\gamma(t)$ with fixed ends.
The critical points of the action functional are called extremals and the principle of the least action states that a Lagrangian system (M, L)
moves along the extremals [4]. The extremals are characterized by equations of motion - a system of second order differential equations in local coordinates on TM. The equations of motion have the most elegant form for the following choice of local coordinates on TM.

Definition. Let (U, φ) be a coordinate chart on M with local coordinates $\boldsymbol{q} = (q^1, ..., q^n)$. Coordinates

$$(\boldsymbol{q}, \boldsymbol{v}) = \left(q^1, ..., q^n, v^1, ..., v^n\right)$$

on a chart TU on TM, where $\boldsymbol{v} = (v^1, ..., v^n)$ are coordinates in the fiber corresponding to the basis $\frac{\partial}{\partial q^1}, ..., \frac{\partial}{\partial q^n}$ for T_qM, are called standard coordinates.
Standard coordinates are Cartesian coordinates on $\varphi_*(TU) \subset T\mathbb{R}^n \simeq \mathbb{R}^n \times \mathbb{R}^n$ and have the property that for $(q, v) \in TU$ and $f \in C^\infty(U)$,

$$v(f) = \sum_{i=1}^{n} v^i \frac{\partial f}{\partial q^i} = \boldsymbol{v}\frac{\partial f}{\partial \boldsymbol{q}}.$$

Let (U, φ) and (U', φ') be coordinate charts on M with the transition functions $F = (F^1, ..., F^n) = \varphi' \circ \varphi^{-1} : \varphi\left(U \cap U'\right) \to \varphi'\left(U \cap U'\right)$, and let $(\boldsymbol{q}, \boldsymbol{v})$ and $(\boldsymbol{q}', \boldsymbol{v}')$, respectively, be the standard coordinates on TU and TU'. We have $\boldsymbol{q}' = F(\boldsymbol{q})$ and $\boldsymbol{v}' = F_*(\boldsymbol{q})\boldsymbol{v}$, where $F_*(\boldsymbol{q}) = \left\{\frac{\partial F^i}{\partial q^j}(\boldsymbol{q})\right\}_{i,j=1}^{n}$ is a matrixvalued function on $\varphi\left(U \cap U'\right)$. Thus "vertical" coordinates $\boldsymbol{v} = (v^1, ..., v^n)$ in the fibers of $TM \to M$ transform like components of a tangent vector on M under the change of coordinates on M.
The tangential lift $\gamma'(t)$ of a path $\gamma(t)$ in M in standard coordinates on TU is $(\boldsymbol{q}(t), \dot{\boldsymbol{q}}(t)) = (q^1(t), ..., q^n(t), \dot{q}^1(t), ..., \dot{q}^n(t))$, where the dot stands for the time derivative, so that

$$L\left(\gamma'(t), t\right) = L(\boldsymbol{q}(t), \dot{\boldsymbol{q}}(t), t).$$

Following a centuries long tradition [5], we will usually denote standard coordinates by

$$(\boldsymbol{q}, \dot{\boldsymbol{q}}) = \left(q^1, ..., q^n, \dot{q}^1, ..., \dot{q}^n\right)$$

where the dot does not stand for the time derivative. Since we only consider paths in TM that are tangential lifts of paths in M, there will be no confusion [6].

Theorem 1.1. The equations of motion of a Lagrangian system (M, L) in standard coordinates on TM are given by the Euler-Lagrange equations

$$\frac{\partial L}{\partial \boldsymbol{q}}(\boldsymbol{q}(t), \dot{\boldsymbol{q}}(t), t) - \frac{d}{dt}\left(\frac{\partial L}{\partial \dot{\boldsymbol{q}}}(\boldsymbol{q}(t), \dot{\boldsymbol{q}}(t), t)\right) = 0.$$

Proof. Suppose first that an extremal $\gamma(t)$ lies in a coordinate chart U of M. Then a simple computation in standard coordinates, using integration by parts, gives

$$\begin{aligned}
0 &= \left.\frac{d}{d\varepsilon}\right|_{\varepsilon=0} S\left(\gamma_\varepsilon\right) \\
&= \left.\frac{d}{d\varepsilon}\right|_{\varepsilon=0} \int_{t_0}^{t_1} L(\boldsymbol{q}(t,\varepsilon), \dot{\boldsymbol{q}}(t,\varepsilon), t) dt \\
&= \sum_{i=1}^{n} \int_{t_0}^{t_1} \left(\frac{\partial L}{\partial q^i}\delta q^i + \frac{\partial L}{\partial \dot{q}^i}\delta \dot{q}^i\right) dt \\
&= \sum_{i=1}^{n} \int_{t_0}^{t_1} \left(\frac{\partial L}{\partial q^i} - \frac{d}{dt}\frac{\partial L}{\partial \dot{q}^i}\right) \delta q^i dt + \sum_{i=1}^{n} \left.\frac{\partial L}{\partial \dot{q}^i}\delta q^i\right|_{t_0}^{t_1}.
\end{aligned}$$

The second sum in the last line vanishes due to the property $\delta q^i\left(t_0\right) = \delta q^i\left(t_1\right) = 0, i = 1, ..., n$. The first sum is zero for arbitrary smooth functions δq^i on the interval $[t_0, t_1]$ which vanish at the endpoints. This implies that for each term in the sum the integrand is identically zero,

$$\frac{\partial L}{\partial q^i}(\boldsymbol{q}(t), \dot{\boldsymbol{q}}(t), t) - \frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^i}(\boldsymbol{q}(t), \dot{\boldsymbol{q}}(t), t)\right) = 0, \quad i = 1, ..., n.$$

Since the restriction of an extremal of the action functional S to a coordinate chart on M is again an extremal, each extremal in standard coordinates on TM satisfies Euler-Lagrange equations.

Remark. In calculus of variations, the directional derivative of a functional S with respect to a tangent vector $V \in T_\gamma P(M)$ - the Gato derivative is defined by

$$\delta_V S = \left.\frac{d}{d\varepsilon}\right|_{\varepsilon=0} S\left(\gamma_\varepsilon\right),$$

where γ_ε is a path in $P(M)$ with a tangent vector V at $\gamma_0 = \gamma$. The result of the above computation (when γ lies in a coordinate chart $U \subset M$) can be written as

$$\begin{aligned}
\delta_V S &= \int_{t_0}^{t_1} \sum_{i=1}^{n} \left(\frac{\partial L}{\partial q^i} - \frac{d}{dt}\frac{\partial L}{\partial \dot{q}^i}\right)(\boldsymbol{q}(t), \dot{\boldsymbol{q}}(t), t) v^i(t) dt \\
&= \int_{t_0}^{t_1} \left(\frac{\partial L}{\partial \boldsymbol{q}} - \frac{d}{dt}\frac{\partial L}{\partial \dot{\boldsymbol{q}}}\right)(\boldsymbol{q}(t), \dot{\boldsymbol{q}}(t), t) \boldsymbol{v}(t) dt
\end{aligned} \tag{1.1}$$

[04] The principle of the least action does not state that an extremal connecting points q_0 and q_1 is a minimum of S, nor that such an extremal is unique. It also does not state that any two points can be connected by an extremal.

[5] Used in all texts on classical mechanics and theoretical physics.

[6] We reserve the notation $(\boldsymbol{q}(t), \boldsymbol{v}(t))$ for general paths in TM.

Here $V(t) = \sum_{i=1}^{n} v^i(t) \frac{\partial}{\partial q^i}$ is a vector field along the path γ in M. Formula (1.1) is called the formula for the first variation of the action with fixed ends. The principle of the least action is a statement that $\delta_V S(\gamma) = 0$ for all $V \in T_\gamma P(M)$.

Remark. It is also convenient to consider a space $\widehat{P(M)} = \{\gamma : [t_0, t_1] \to M\}$ of all smooth parametrized paths in M. The tangent space $T_\gamma \widehat{P(M)}$ to $\widehat{P(M)}$ at $\gamma \in \widehat{P(M)}$ is the space of all smooth vector fields along the path γ in M (no condition at the endpoints). The computation in the proof of Theorem 1.1 yields the following formula for the first variation of the action with free ends:

$$\delta_V S = \int_{t_0}^{t_1} \left(\frac{\partial L}{\partial \boldsymbol{q}} - \frac{d}{dt} \frac{\partial L}{\partial \dot{\boldsymbol{q}}} \right) \boldsymbol{v} dt + \frac{\partial L}{\partial \dot{\boldsymbol{q}}} \boldsymbol{v} \Big|_{t_0}^{t_1} \tag{1.2}$$

Problem 1.1. Show that the action functional is given by the evaluation of the 1-form Ldt on $TM \times \mathbb{R}$ over the 1-chain $\tilde{\gamma}$ on $TM \times \mathbb{R}$,

$$S(\gamma) = \int_{\tilde{\gamma}} Ldt,$$

where $\tilde{\gamma} = \{(\gamma'(t), t)\,; t_0 \le t \le t_1\}$ and $Ldt\left(w, c\frac{\partial}{\partial t}\right) = cL(q, v), w \in T_{(q,v)}TM, c \in \mathbb{R}$.

Problem 1.2. Let $f \in C^\infty(M)$. Show that Lagrangian systems (M, L) and $(M, L + df)$ (where df is a fibre-wise linear function on TM) have the same equations of motion.

Problem 1.3. Give examples of Lagrangian systems such that an extremal connecting two given points (i) is not a local minimum; (ii) is not unique; (iii) does not exist.

Problem 1.4. For γ an extremal of the action functional S, the second variation of S is defined by

$$\delta^2_{V_1 V_2} S = \frac{\partial^2}{\partial \varepsilon_1 \partial \varepsilon_2} \Big|_{\varepsilon_1 = \varepsilon_2 = 0} S\left(\gamma_{\varepsilon_1, \varepsilon_2}\right)$$

where $\gamma_{\varepsilon_1, \varepsilon_2}$ is a smooth two-parameter family of paths in M such that the paths $\gamma_{\varepsilon_1, 0}$ and $\gamma_{0, \varepsilon_2}$ in $P(M)$ at the point $\gamma_{0,0} = \gamma \in P(M)$ have tangent vectors V_1 and V_2, respectively. For a Lagrangian system (M, L) find the second variation of S and verify that for given V_1 and V_2 it does not depend on the choice of $\gamma_{\varepsilon_1, \varepsilon_2}$.

1.3. Examples of Lagrangian systems. To describe a mechanical phenomena it is necessary to choose a frame of reference. The properties of the space-time where the motion takes place depend on this choice. The space-time is characterized by the following postulates [7].

Newtonian Space-Time. The space is a three-dimensional affine Euclidean space E^3. A choice of the origin $0 \in E^3$ - a reference point establishes the isomorphism $E^3 \simeq \mathbb{R}^3$, where the vector space $\mathbb{R}^3$ carries the Euclidean inner product and has a fixed orientation. The time is onedimensional - a time axis $\mathbb{R}$ - and the space-time is a direct product $E^3 \times \mathbb{R}$. An inertial reference frame is a coordinate system with respect to the origin $0 \in E^3$, initial time t_0, and an orthonormal basis in $\mathbb{R}^3$. In an inertial frame the space is homogeneous and isotropic and the time is homogeneous. The laws of motion are invariant with respect to the transformations

$$\boldsymbol{r} \mapsto g \cdot \boldsymbol{r} + \boldsymbol{r}_0, \quad t \mapsto t + t_0,$$

where $r, r_0 \in \mathbb{R}^3$ and g is an orthogonal linear transformation in $\mathbb{R}^3$. The time in classical mechanics is absolute.

The Galilean group is the group of all affine transformations of $E^3 \times \mathbb{R}$ which preserve time intervals and which for every $t \in \mathbb{R}$ are isometries in E^3. Every Galilean transformation is a composition of rotation, space-time translation, and a transformation

[7] Strictly speaking, these postulates are valid only in the non-relativistic limit of special relativity, when the speed of light in the vacuum is assumed to be infinite.

$$\boldsymbol{r} \mapsto \boldsymbol{r} + \boldsymbol{v}t, \quad t \mapsto t$$

where $v \in \mathbb{R}^3$. Any two inertial frames are related by a Galilean transformation.

Galileo's Relativity Principle. The laws of motion are invariant with respect to the Galilean group.

These postulates impose restrictions on Lagrangians of mechanical systems. Thus it follows from the first postulate that the Lagrangian L of a closed system does not explicitly depend on time. Physical systems are described by special Lagrangians, in agreement with the experimental facts about the motion of material bodies.

Example 1.1 (Free particle). The configuration space for a free particle is $M = \mathbb{R}^3$, and it can be deduced from Galileo's relativity principle that the Lagrangian for a free particle is

$$L = \frac{1}{2} m \dot{\boldsymbol{r}}^2.$$

Here $m > 0$[08] is the mass of a particle and $\dot{\boldsymbol{r}}^2 = |\dot{\boldsymbol{r}}|^2$ is the length square of the velocity vector $\dot{\boldsymbol{r}} \in T_{\boldsymbol{r}}\mathbb{R}^3 \simeq \mathbb{R}^3$. Euler-Lagrange equations give Newton's law of inertia,

$$\ddot{\boldsymbol{r}} = 0.$$

Example 1.2 (Interacting particles). A closed system of N interacting particles in $\mathbb{R}^3$ with masses $m_1, ..., m_N$ is described by a configuration space

$$M = \mathbb{R}^{3N} = \underbrace{\mathbb{R}^3 \times \cdots \times \mathbb{R}^3}_{N}$$

with a position vector $\boldsymbol{r} = (\boldsymbol{r}_1, ..., \boldsymbol{r}_N)$, where $\boldsymbol{r}_a \in \mathbb{R}^3$ is the position vector of the a-th particle, $a = 1, ..., N$. It is found that the Lagrangian is given by

$$L = \sum_{a=1}^{N} \frac{1}{2} m_a \dot{\boldsymbol{r}}_a^2 - V(\boldsymbol{r}) = T - V,$$

where

$$T = \sum_{a=1}^{N} \frac{1}{2} m_a \dot{\boldsymbol{r}}_a^2$$

is called kinetic energy of a system and $V(\boldsymbol{r})$ is potential energy. The Euler-Lagrange equations give Newton's equations

$$m_a \ddot{\boldsymbol{r}}_a = \boldsymbol{F}_a$$

where

$$\boldsymbol{F}_a = -\frac{\partial V}{\partial \boldsymbol{r}_a}$$

is the force on the a-th particle, $a = 1, ..., N$. Forces of this form are called conservative. It follows from homogeneity of space that potential energy $V(\boldsymbol{r})$ of a closed system of N interacting particles with conservative forces depends only on relative positions of the particles, which leads to the equation

[08] Otherwise the action functional is not bounded from below.

$$\sum_{a=1}^{N} \boldsymbol{F}_a = 0$$

In particular, for a closed system of two particles $\boldsymbol{F}_1 + \boldsymbol{F}_2 = 0$, which is the equality of action and reaction forces, also called Newton's third law.

The potential energy of a closed system with only pair-wise interaction between the particles has the form

$$V(\boldsymbol{r}) = \sum_{1 \le a < b \le N} V_{ab}\left(\boldsymbol{r}_a - \boldsymbol{r}_b\right)$$

It follows from the isotropy of space that $V(\boldsymbol{r})$ depends only on relative distances between the particles, so that the Lagrangian of a closed system of N particles with pair-wise interaction has the form

$$L = \sum_{a=1}^{N} \frac{1}{2} m_a \dot{\boldsymbol{r}}_a^2 - \sum_{1 \le a < b \le N} V_{ab}\left(|\boldsymbol{r}_a - \boldsymbol{r}_b|\right)$$

If the potential energy $V(\boldsymbol{r})$ is a homogeneous function of degree ρ, $V(\lambda \boldsymbol{r}) = \lambda^\rho V(\boldsymbol{r})$, then the average values $\bar{T}$ and $\bar{V}$ of kinetic energy and potential energy over a closed trajectory are related by the virial theorem

$$2\bar{T} = \rho \bar{V} \tag{1.3}$$

Indeed, let $\boldsymbol{r}(t)$ be a periodic trajectory with period $\tau > 0$, i.e., $\boldsymbol{r}(0) = \boldsymbol{r}(\tau)$, $\dot{\boldsymbol{r}}(0) = \dot{\boldsymbol{r}}(\tau)$. Using integration by parts, Newton's equations, and Euler's homogeneous function theorem, we get

$$\begin{aligned} 2\bar{T} &= \frac{1}{\tau} \int_0^\tau \sum_{a=1}^{N} m_a \dot{\boldsymbol{r}}_a^2 dt = -\frac{1}{\tau} \int_0^\tau \sum_{a=1}^{N} m_a \boldsymbol{r}_a \ddot{\boldsymbol{r}}_a dt \\ &= \frac{1}{\tau} \int_0^\tau \sum_{a=1}^{N} \boldsymbol{r}_a \frac{\partial V}{\partial \boldsymbol{r}_a} dt = \rho \bar{V} \end{aligned}$$

Example 1.3 (Universal gravitation). According to Newton's law of gravitation, the potential energy of the gravitational force between two particles with masses m_a and m_b is

$$V\left(\boldsymbol{r}_a - \boldsymbol{r}_b\right) = -G \frac{m_a m_b}{|\boldsymbol{r}_a - \boldsymbol{r}_b|},$$

where G is the gravitational constant. The configuration space of N particles with gravitational interaction is

$$M = \left\{ (\boldsymbol{r}_1, ..., \boldsymbol{r}_N) \in \mathbb{R}^{3N} : \boldsymbol{r}_a \neq \boldsymbol{r}_b \text{ for } a \neq b, a, b = 1, ..., N \right\}$$

Example 1.4 (Particle in an external potential field). Here $M = \mathbb{R}^3$ and

$$L = \frac{1}{2} m \dot{\boldsymbol{r}}^2 - V(\boldsymbol{r}, t)$$

where potential energy can explicitly depend on time. Equations of motion are Newton's equations

$$m \ddot{\boldsymbol{r}} = \boldsymbol{F} = -\frac{\partial V}{\partial \boldsymbol{r}}.$$

If $V = V(|\boldsymbol{r}|)$ is a function only of the distance $|\boldsymbol{r}|$, the potential field is called central.

Example 1.5 (Charged particle in electromagnetic field [9]). Consider a particle of charge e and mass m in $\mathbb{R}^3$ moving in a time-independent electromagnetic field with scalar and vector potentials $\varphi(\boldsymbol{r})$ and $\boldsymbol{A}(\boldsymbol{r}) = (A_1(\boldsymbol{r}), A_2(\boldsymbol{r}), A_3(\boldsymbol{r}))$. The Lagrangian has the form

$$L = \frac{m\dot{\boldsymbol{r}}^2}{2} + e\left(\frac{\dot{\boldsymbol{r}}\boldsymbol{A}}{c} - \varphi\right),$$

where c is the speed of light. The Euler-Lagrange equations give Newton's equations with the Lorentz force,

$$m\ddot{\boldsymbol{r}} = e\left(\boldsymbol{E} + \frac{\dot{\boldsymbol{r}}}{c} \times \boldsymbol{B}\right)$$

where $\times$ is the cross-product of vectors in $\mathbb{R}^3$, and

$$\boldsymbol{E} = -\frac{\partial\varphi}{\partial\boldsymbol{r}} \quad \text{and} \quad \boldsymbol{B} = \operatorname{curl}\boldsymbol{A}$$

are electric and magnetic [10] fields, respectively.

Example 1.6 (Small oscillations). Consider a particle of mass m with n degrees of freedom moving in a potential field $V(\boldsymbol{q})$, and suppose that potential energy U has a minimum at $\boldsymbol{q} = 0$. Expanding $V(\boldsymbol{q})$ in Taylor series around 0 and keeping only quadratic terms, one obtains a Lagrangian system which describes small oscillations from equilibrium. Explicitly,

$$L = \frac{1}{2}m\dot{\boldsymbol{q}}^2 - V_0(\boldsymbol{q}),$$

where V_0 is a positive-definite quadratic form on $\mathbb{R}^n$ given by

$$V_0(\boldsymbol{q}) = \frac{1}{2}\sum_{i,j=1}^{n}\frac{\partial^2 V}{\partial q^i \partial q^j}(0)q^i q^j$$

Since every quadratic form can be diagonalized by an orthogonal transformation, we can assume from the very beginning that coordinates $\boldsymbol{q} = (q^1, \ldots, q^n)$ are chosen so that $V_0(\boldsymbol{q})$ is diagonal and

$$L = \frac{1}{2}m\left(\dot{\boldsymbol{q}}^2 - \sum_{i=1}^{n}\omega_i^2\left(q^i\right)^2\right) \tag{1.4}$$

where $\omega_1, \ldots, \omega_n > 0$. Such coordinates $\boldsymbol{q}$ are called normal coordinates. In normal coordinates Euler-Lagrange equations take the form

$$\ddot{q}^i + \omega_i^2 q^i = 0, \quad i = 1, \ldots, n$$

and describe n decoupled (i.e., non-interacting) harmonic oscillators with frequencies $\omega_1, \ldots, \omega_n$.

Example 1.7 (Free particle on a Riemannian manifold). Let (M, ds^2) be a Riemannian manifold with the Riemannian metric ds^2. In local coordinates $x^1, \ldots, x^n$ on M,

$$ds^2 = g_{\mu\nu}(x)dx^\mu dx^\nu$$

where following tradition we assume the summation over repeated indices. The Lagrangian of a free particle on M is

[09] This is a non-relativistic limit of an example in classical electrodynamics.

$$L(v) = \frac{1}{2}\langle v, v\rangle = \frac{1}{2}\|v\|^2, v \in TM,$$

[10] Notation $\boldsymbol{B} = \text{rot}\,\boldsymbol{A}$ is also used.

where $\langle,\rangle$ stands for the inner product in fibers of TM given by the Riemannian metric. The corresponding functional

$$S(\gamma) = \frac{1}{2}\int_{t_0}^{t_1} \|\gamma'(t)\|^2\, dt = \frac{1}{2}\int_{t_0}^{t_1} g_{\mu\nu}(x)\dot{x}^\mu\dot{x}^\nu dt$$

is called the action functional in Riemannian geometry. The Euler-Lagrange equations are

$$g_{\mu\nu}\ddot{x}^\mu + \frac{\partial g_{\mu\nu}}{\partial x^\lambda}\dot{x}^\mu\dot{x}^\lambda = \frac{1}{2}\frac{\partial g_{\mu\lambda}}{\partial x^\nu}\dot{x}^\mu\dot{x}^\lambda,$$

and after multiplying by the inverse metric tensor $g^{\sigma\nu}$ and summation over ν they take the form

$$\ddot{x}^\sigma + \Gamma^\sigma_{\mu\nu}\dot{x}^\mu\dot{x}^\nu = 0, \quad \sigma = 1, ..., n,$$

where

$$\Gamma^\sigma_{\mu\nu} = \frac{1}{2}g^{\sigma\lambda}\left(\frac{\partial g_{\mu\lambda}}{\partial x^\nu} + \frac{\partial g_{\nu\lambda}}{\partial x^\mu} - \frac{\partial g_{\mu\nu}}{\partial x^\lambda}\right)$$

are Christoffel's symbols. The Euler-Lagrange equations of a free particle moving on a Riemannian manifold are geodesic equations.

Let ∇ be the Levi-Civita connection - the metric connection in the tangent bundle TM - and let ∇_ξ be a covariant derivative with respect to the vector field $\xi \in \text{Vect}(M)$. Explicitly,

$$(\nabla_\xi\eta)^\mu = \left(\frac{\partial\eta^\mu}{\partial x^\nu} + \Gamma^\mu_{\nu\lambda}\eta^\lambda\right)\xi^\nu, \quad \text{where} \quad \xi = \xi^\mu(x)\frac{\partial}{\partial x^\mu}, \eta = \eta^\mu(x)\frac{\partial}{\partial x^\mu}$$

For a path $\gamma(t) = (x^\mu(t))$ denote by $\nabla_{\dot\gamma}$ a covariant derivative along γ,

$$(\nabla_{\dot\gamma}\eta)^\mu(t) = \frac{d\eta^\mu(t)}{dt} + \Gamma^\mu_{\nu\lambda}(\gamma(t))\dot{x}^\nu(t)\eta^\lambda(t), \quad \text{where} \quad \eta = \eta^\mu(t)\frac{\partial}{\partial x^\mu}$$

is a vector field along γ. Formula (1.1) can now be written in an invariant form

$$\delta S = -\int_{t_0}^{t_1} \langle\nabla_{\dot\gamma}\dot\gamma, \delta\gamma\rangle\, dt$$

which is known as the formula for the first variation of the action in Riemannian geometry.

Example 1.8 (The rigid body). The configuration space of a rigid body in $\mathbb{R}^3$ with a fixed point is a Lie group $G = \text{SO}(3)$ of orientation preserving orthogonal linear transformations in $\mathbb{R}^3$. Every left-invariant Riemannian metric $\langle,\rangle onG$ defines a Lagrangian $L : TG \to \mathbb{R}$ by

$$L(v) = \frac{1}{2}\langle v, v\rangle, \quad v \in TG.$$

According to the previous example, equations of motion of a rigid body are geodesic equations on G with respect to the Riemannian metric $\langle,\rangle.Let\ \mathfrak{g} = \mathfrak{so}(3)$ be the Lie algebra of G. A velocity vector $\dot g \in T_gG$ defines the angular velocity of the body by $\Omega = (L_{g^{-1}})_*\,\dot g \in \mathfrak{g}$, where $L_g : G \to G$ are left translations on G. In terms of angular velocity, the Lagrangian takes the form

$$L = \frac{1}{2}\langle\Omega, \Omega\rangle_e$$

where $\langle , \rangle_e$ is an inner product on $\mathfrak{g} = T_eG$ given by the Riemannian metric $\langle , \rangle$. The Lie algebra $\mathfrak{g}$ - the Lie algebra of 3×3 skew-symmetric matrices has the invariant inner product $\langle u, v \rangle_0 = -\frac{1}{2} \operatorname{Tr} uv$ (the Killing form), so that $\langle \Omega, \Omega \rangle_e = \langle \boldsymbol{A} \cdot \Omega, \Omega \rangle_0$ for some symmetric linear operator $\boldsymbol{A} : \mathfrak{g} \to \mathfrak{g}$ which is positive-definite with respect to the Killing form. Such a linear operator $\boldsymbol{A}$ is called the inertia tensor of the body. The principal axes of inertia of the body are orthonormal eigenvectors e_1, e_2, e_3 of $\boldsymbol{A}$; corresponding eigenvalues I_1, I_2, I_3 are called the principal moments of inertia. Setting $\Omega = \Omega_1 e_1 + \Omega_2 e_2 + \Omega_3 e_3$[11], we get

$$L = \frac{1}{2} \left(I_1 \Omega_1^2 + I_2 \Omega_2^2 + I_3 \Omega_3^2 \right).$$

In this parametrization, the Euler-Lagrange equations become Euler's equations

$$\begin{aligned} I_1 \dot{\Omega}_1 &= (I_2 - I_3)\, \Omega_2 \Omega_3 \\ I_2 \dot{\Omega}_2 &= (I_3 - I_1)\, \Omega_1 \Omega_3 \\ I_3 \dot{\Omega}_3 &= (I_1 - I_2)\, \Omega_1 \Omega_2 \end{aligned}$$

Euler's equations describe the rotation of a free rigid body around a fixed point. In the system of coordinates with axes which are the principal axes of inertia, principal moments of inertia of the body are I_1, I_2, I_3.

Problem 1.5. Determine the motion of a charged particle in a constant uniform magnetic field. Show that if the initial velocity $v_3 = 0$ in the z-axis (taken in the direction of the field, $\boldsymbol{B} = (0, 0, B)$), the trajectories are circles of radii $r = \frac{cmv_t}{eB}$ in a plane perpendicular to the field (the xy-plane), where $v_t = \sqrt{v_1^2 + v_2^2}$ is the initial velocity in the xy-plane. The centers (x_0, y_0) of circles are given by

$$x_0 = \frac{cmv_1}{eB} + x, \quad y_0 = -\frac{cmv_2}{eB} + y$$

where (x, y) are points on a circle of radius r.

Problem 1.6. Show that the Euler-Lagrange equations for the Lagrangian $L(v) = \|v\|, v \in TM$, coincide with the geodesic equations written with respect to a constant multiple of the natural parameter.

Problem 1.7. Prove that for a particle in a potential field, discussed in Example 1.4, the second variation of the action functional, defined in Problem 1.4, is given by

$$\delta^2 S = \int_{t_0}^{t_1} \mathcal{J}\left(\delta_1 \boldsymbol{r}\right) \delta_2 \boldsymbol{r} dt$$

[11] This establishes the Lie algebra isomorphism $\mathfrak{g} \simeq \mathbb{R}^3$, where the Lie bracket in $\mathbb{R}^3$ is given by the cross-product.

where $\delta_1 \boldsymbol{r}, \delta_2 \boldsymbol{r} \in T_\gamma P\mathbb{R}^3, \gamma = \boldsymbol{r}(t)$ is the classical trajectory, $\mathcal{J} = -m\frac{d^2}{dt^2} I - \frac{\partial^2 V}{\partial \boldsymbol{r}^2}(t)$, I is the 3×3 identity matrix, and $\frac{\partial^2 V}{\partial \boldsymbol{r}^2}(t) = \left\{ \frac{\partial^2 V}{\partial \boldsymbol{r}_a \partial \boldsymbol{r}_b}(\boldsymbol{r}(t)) \right\}_{a,b=1}^{3}$. A second-order linear differential operator $\mathcal{J}$, acting on vector fields along γ, is called the Jacobi operator.

Problem 1.8. Find normal coordinates and frequencies for the Lagrangian system considered in Example 1.6 with $V_0(\boldsymbol{q}) = \frac{1}{2} a^2 \sum_{i=1}^{n} \left(q^{i+1} - q^i\right)^2$, where $q^{n+1} = q^1$.

Problem 1.9. Prove that the second variation of the action functional in Riemannian geometry is given by

$$\delta^2 S = \int_{t_0}^{t_1} \langle \mathcal{J}(\delta_1\gamma), \delta_2\gamma \rangle \, dt$$

Here $\delta_1\gamma, \delta_2\gamma \in T_\gamma PM$, $\mathcal{J} = -\nabla_{\dot\gamma}^2 - R(\dot\gamma, \cdot)\dot\gamma$ is the Jacobi operator, and R is a curvature operator - a fibre-wise linear mapping $R : TM \otimes TM \to \mathrm{End}(TM)$ of vector bundles, defined by $R(\xi,\eta) = \nabla_\eta\nabla_\xi - \nabla_\xi\nabla_\eta + \nabla_{[\xi,\eta]} : TM \to TM$, where $\xi, \eta \in \mathrm{Vect}(M)$.

Problem 1.10. Choosing the principal axes of inertia as a basis in $\mathbb{R}^3$, show that the Lie algebra isomorphism $\mathfrak{g} \simeq \mathbb{R}^3$ is given by $\mathfrak{g} \ni \begin{pmatrix} 0 & -\Omega_3 & \Omega_2 \\ \Omega_3 & 0 & \\ -\Omega_2 & \Omega_1 & -\Omega_1 \end{pmatrix} \mapsto (\Omega_1, \Omega_2, \Omega_3) \in \mathbb{R}^3$.

Problem 1.11. Show that for every symmetric $\boldsymbol{A} \in \mathrm{End}\ \mathfrak{g}$ there exists a symmetric 3×3 matrix A such that $\boldsymbol{A} \cdot \Omega = A\Omega + \Omega A$, and find A for diagonal $\boldsymbol{A}$.

Problem 1.12. Derive Euler's equations for a rigid body. (Hint: Use that $L = -\frac{1}{2}\,\mathrm{Tr}\, A\Omega^2$, where $\Omega = g^{-1}\dot g$ and $\delta\Omega = -g^{-1}\delta g\Omega + g^{-1}\delta\dot g$, and obtain the EulerLagrange equations in the matrix form $A\dot\Omega + \dot\Omega A = A\Omega^2 - \Omega^2 A$.)

1.4. Symmetries and Noether's theorem.

To describe the motion of a mechanical system one needs to solve the corresponding Euler-Lagrange equations - a system of second order ordinary differential equations for the generalized coordinates. This could be a very difficult problem. Therefore of particular interest are those functions of generalized coordinates and velocities which remain constant during the motion.

Definition. A smooth function $I : TM \to \mathbb{R}$ is called the integral of motion (first integral, or conservation law) for a Lagrangian system (M, L) if

$$\frac{d}{dt} I(\gamma'(t)) = 0$$

for all extremals γ of the action functional.

Definition. The energy of a Lagrangian system (M, L) is a function E on $TM \times \mathbb{R}$ defined in standard coordinates on TM by

$$E(\boldsymbol{q}, \dot{\boldsymbol{q}}, t) = \sum_{i=1}^{n} \dot q^i \frac{\partial L}{\partial \dot q^i}(\boldsymbol{q}, \dot{\boldsymbol{q}}, t) - L(\boldsymbol{q}, \dot{\boldsymbol{q}}, t)$$

Lemma 1.1. The energy $E = \dot{\boldsymbol{q}}\frac{\partial L}{\partial \dot{\boldsymbol{q}}} - L$ is a well-defined function on $TM \times \mathbb{R}$.

Proof. Let (U, φ) and (U', φ') be coordinate charts on M with the transition functions $F = (F^1, ..., F^n) = \varphi' \circ \varphi^{-1} : \varphi(U \cap U') \to \varphi'(U \cap U')$. Corresponding standard coordinates $(\boldsymbol{q}, \dot{\boldsymbol{q}})$ and $(\boldsymbol{q}', \dot{\boldsymbol{q}}')$ are related by $\boldsymbol{q}' = F(\boldsymbol{q})$ and $\dot{\boldsymbol{q}}' = F_*(\boldsymbol{q})\dot{\boldsymbol{q}}$ (see Section 1.2). We have $d\boldsymbol{q}' = F_*(\boldsymbol{q})d\boldsymbol{q}$ and $d\dot{\boldsymbol{q}}' = G(\boldsymbol{q}, \dot{\boldsymbol{q}})d\boldsymbol{q} + F_*(\boldsymbol{q})d\dot{\boldsymbol{q}}$ (for some matrix-valued function $G(\boldsymbol{q}, \dot{\boldsymbol{q}})$), so that

$$\begin{aligned} dL &= \frac{\partial L}{\partial \boldsymbol{q}'} d\boldsymbol{q}' + \frac{\partial L}{\partial \dot{\boldsymbol{q}}'} d\dot{\boldsymbol{q}}' + \frac{\partial L}{\partial t} dt \\ &= \left(\frac{\partial L}{\partial \boldsymbol{q}'} F_*(\boldsymbol{q}) + \frac{\partial L}{\partial \dot{\boldsymbol{q}}'} G(\boldsymbol{q}, \dot{\boldsymbol{q}}) \right) d\boldsymbol{q} + \frac{\partial L}{\partial \dot{\boldsymbol{q}}'} F_*(\boldsymbol{q}) d\dot{\boldsymbol{q}} + \frac{\partial L}{\partial t} dt \\ &= \frac{\partial L}{\partial \boldsymbol{q}} d\boldsymbol{q} + \frac{\partial L}{\partial \dot{\boldsymbol{q}}} d\dot{\boldsymbol{q}} + \frac{\partial L}{\partial t} dt. \end{aligned}$$

Thus under a change of coordinates

$$\frac{\partial L}{\partial \dot{\boldsymbol{q}}'} F_*(\boldsymbol{q}) = \frac{\partial L}{\partial \dot{\boldsymbol{q}}} \quad \text{and} \quad \dot{\boldsymbol{q}}' \frac{\partial L}{\partial \dot{\boldsymbol{q}}'} = \dot{\boldsymbol{q}} \frac{\partial L}{\partial \dot{\boldsymbol{q}}},$$

so that E is a well-defined function on TM.

Corollary 1.2. Under a change of local coordinates on M, components of $\frac{\partial L}{\partial \dot{\boldsymbol{q}}}(\boldsymbol{q}, \dot{\boldsymbol{q}}, t) = \left(\frac{\partial L}{\partial \dot{q}^1}, ..., \frac{\partial L}{\partial \dot{q}^n} \right)$ transform like components of a 1-form on M.

Proposition 1.1 (Conservation of energy). The energy of a closed system is an integral of motion.

Proof. For an extremal γ set $E(t) = E(\gamma(t))$. We have, according to the Euler-Lagrange equations,

$$\begin{aligned} \frac{dE}{dt} &= \frac{d}{dt} \left(\frac{\partial L}{\partial \dot{\boldsymbol{q}}} \right) \dot{\boldsymbol{q}} + \frac{\partial L}{\partial \dot{\boldsymbol{q}}} \ddot{\boldsymbol{q}} - \frac{\partial L}{\partial \boldsymbol{q}} \dot{\boldsymbol{q}} - \frac{\partial L}{\partial \dot{\boldsymbol{q}}} \ddot{\boldsymbol{q}} - \frac{\partial L}{\partial t} \\ &= \left(\frac{d}{dt} \left(\frac{\partial L}{\partial \dot{\boldsymbol{q}}} \right) - \frac{\partial L}{\partial \boldsymbol{q}} \right) \dot{\boldsymbol{q}} - \frac{\partial L}{\partial t} = -\frac{\partial L}{\partial t} \end{aligned}$$

Since for a closed system $\frac{\partial L}{\partial t} = 0$, the energy is conserved.

Conservation of energy for a closed mechanical system is a fundamental law of physics which follows from the homogeneity of time. For a general closed system of N interacting particles considered in Example 1.2,

$$E = \sum_{a=1}^{N} m_a \dot{\boldsymbol{r}}_a^2 - L = \sum_{a=1}^{N} \frac{1}{2} m_a \dot{\boldsymbol{r}}_a^2 + V(\boldsymbol{r}).$$

In other words, the total energy $E = T + V$ is a sum of the kinetic energy and the potential energy.

Definition. A Lagrangian $L : TM \to \mathbb{R}$ is invariant with respect to the diffeomorphism $g : M \to M$ if $L(g_*(v)) = L(v)$ for all $v \in TM$. The diffeomorphism g is called the symmetry of a closed Lagrangian system (M, L). A Lie group G is the symmetry group of (M, L) (group of continuous symmetries) if there is a left G-action on M such that for every $g \in G$ the mapping $M \ni x \mapsto g \cdot x \in M$ is a symmetry.

Continuous symmetries give rise to conservation laws.

Theorem 1.3 (Noether). Suppose that a Lagrangian $L : TM \to \mathbb{R}$ is invariant under a one-parameter group $\{g_s\}_{s \in \mathbb{R}}$ of diffeomorphisms of M. Then the Lagrangian system (M, L) admits an integral of motion I, given in standard coordinates on TM by

$$I(\boldsymbol{q}, \dot{\boldsymbol{q}}) = \sum_{i=1}^{n} \frac{\partial L}{\partial \dot{q}^i}(\boldsymbol{q}, \dot{\boldsymbol{q}}) \left(\left. \frac{dg_s^i(\boldsymbol{q})}{ds} \right|_{s=0} \right) = \frac{\partial L}{\partial \dot{\boldsymbol{q}}} \boldsymbol{a}$$

where $X = \sum_{i=1}^{n} a^i(\boldsymbol{q}) \frac{\partial}{\partial q^i}$ is the vector field on M associated with the flow g_s. The integral of motion I is called the Noether integral.

Proof. It follows from Corollary 1.2 that I is a well-defined function on TM. Now differentiating $L\left(\left(g_s\right)_*\left(\gamma'(t)\right)\right) = L\left(\gamma'(t)\right)$ with respect to s at $s = 0$ and using the Euler-Lagrange equations we get

$$0 = \frac{\partial L}{\partial \boldsymbol{q}}\boldsymbol{a} + \frac{\partial L}{\partial \dot{\boldsymbol{q}}}\dot{\boldsymbol{a}} = \frac{d}{dt}\left(\frac{\partial L}{\partial \dot{\boldsymbol{q}}}\right)\boldsymbol{a} + \frac{\partial L}{\partial \dot{\boldsymbol{q}}}\frac{d\boldsymbol{a}}{dt} = \frac{d}{dt}\left(\frac{\partial L}{\partial \dot{\boldsymbol{q}}}\boldsymbol{a}\right),$$

where $\boldsymbol{a}(t) = (a^1(\gamma(t)), ..., a^n(\gamma(t)))$.

Remark. A vector field X on M is called an infinitesimal symmetry if the corresponding local flow g_s of X (defined for each $s \in \mathbb{R}$ on some $U_s \subseteq M$) is a symmetry: $L \circ \left(g_s\right)_* = L$ on U_s. Every vector field X on M lifts to a vector field X' on TM, defined by a local flow on TM induced from the corresponding local flow on M. In standard coordinates on TM,

$$X = \sum_{i=1}^{n} a^i(\boldsymbol{q})\frac{\partial}{\partial q^i} \quad \text{and} \quad X' = \sum_{i=1}^{n} a^i(\boldsymbol{q})\frac{\partial}{\partial q^i} + \sum_{i,j=1}^{n} \dot{q}^j \frac{\partial a^i}{\partial q^j}(\boldsymbol{q})\frac{\partial}{\partial \dot{q}^i}. \tag{1.5}$$

It is easy to verify that X is an infinitesimal symmetry if and only if $dL\left(X'\right) = 0$ on TM, which in standard coordinates has the form

$$\sum_{i=1}^{n} a^i(\boldsymbol{q})\frac{\partial L}{\partial q^i} + \sum_{i,j=1}^{n} \dot{q}^j \frac{\partial a^i}{\partial q^j}(\boldsymbol{q})\frac{\partial L}{\partial \dot{q}^i} = 0. \tag{1.6}$$

Remark. Noether's theorem generalizes to time-dependent Lagrangians L: $TM \times \mathbb{R} \to \mathbb{R}$. Namely, on the extended configuration space $M_1 = M \times \mathbb{R}$ define a time-independent Lagrangian L_1 by

$$L_1(\boldsymbol{q}, \tau, \dot{\boldsymbol{q}}, \dot{\tau}) = L\left(\boldsymbol{q}, \frac{\dot{\boldsymbol{q}}}{\dot{\tau}}, \tau\right)\dot{\tau}$$

where $(\boldsymbol{q}, \tau)$ are local coordinates on M_1 and $(\boldsymbol{q}, \tau, \dot{\boldsymbol{q}}, \dot{\tau})$ are standard coordinates on TM_1. The Noether integral I_1 for a closed system (M_1, L_1) defines an integral of motion I for a system (M, L) by the formula

$$I(\boldsymbol{q}, \dot{\boldsymbol{q}}, t) = I_1(\boldsymbol{q}, t, \dot{\boldsymbol{q}}, 1).$$

When the Lagrangian L does not depend on time, L_1 is invariant with respect to the one-parameter group of translations $\tau \mapsto \tau + s$, and the Noether integral $I_1 = \frac{\partial L_1}{\partial \dot{\tau}}$ gives $I = -E$.

Noether's theorem can be generalized as follows.

Proposition 1.2. Suppose that for the Lagrangian $L : TM \to \mathbb{R}$ there exist a vector field X on M and a function K on TM such that for every path γ in M,

$$dL\left(X'\right)\left(\gamma(t)\right) = \frac{d}{dt}K\left(\gamma'(t)\right)$$

Then

$$I = \sum_{i=1}^{n} a^i(\boldsymbol{q})\frac{\partial L}{\partial \dot{q}^i}(\boldsymbol{q}, \dot{\boldsymbol{q}}) - K(\boldsymbol{q}, \dot{\boldsymbol{q}})$$

is an integral of motion for the Lagrangian system (M, L).

Proof. Using Euler-Lagrange equations, we have along the extremal γ,

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{\boldsymbol{q}}}\boldsymbol{a}\right) = \frac{\partial L}{\partial \boldsymbol{q}}\boldsymbol{a} + \frac{\partial L}{\partial \dot{\boldsymbol{q}}}\dot{\boldsymbol{a}} = \frac{dK}{dt}.$$

Example 1.9 (Conservation of momentum). Let $M = V$ be a vector space, and suppose that a Lagrangian L is invariant with respect to a one-parameter group $g_s(q) = q + sv, v \in V$. According to Noether's theorem,

$$I = \sum_{i=1}^{n} v^i \frac{\partial L}{\partial \dot{q}^i}$$

is an integral of motion. Now let (M, L) be a closed Lagrangian system of N interacting particles considered in Example 1.2. We have $M = V = \mathbb{R}^{3N}$, and the Lagrangian L is invariant under simultaneous translation of
coordinates $\boldsymbol{r}_a = (r_a^1, r_a^2, r_a^3)$ of all particles by the same vector $\boldsymbol{c} \in \mathbb{R}^3$. Thus $v = (c, ..., c) \in \mathbb{R}^{3N}$ and for every $c = (c^1, c^2, c^3) \in \mathbb{R}^3$,

$$I = \sum_{a=1}^{N} \left(c^1 \frac{\partial L}{\partial \dot{r}_a^1} + c^2 \frac{\partial L}{\partial \dot{r}_a^2} + c^3 \frac{\partial L}{\partial \dot{r}_a^3} \right) = c^1 P_1 + c^2 P_2 + c^3 P_3$$

is an integral of motion. The integrals of motion P_1, P_2, P_3 define the vector

$$\boldsymbol{P} = \sum_{a=1}^{N} \frac{\partial L}{\partial \dot{\boldsymbol{r}}_a} \in \mathbb{R}^3$$

(or rather a vector in the dual space to $\mathbb{R}^3$), called the momentum of the system. Explicitly,

$$\boldsymbol{P} = \sum_{a=1}^{N} m_a \dot{r}_a$$

so that the total momentum of a closed system is the sum of momenta of individual particles. Conservation of momentum is a fundamental physical law which reflects the homogeneity of space.

Traditionally, $p_i = \frac{\partial L}{\partial \dot{q}^i}$ are called generalized momenta corresponding to generalized coordinates q^i, and $F_i = \frac{\partial L}{\partial q^i}$ are called generalized forces. In these notations, the Euler-Lagrange equations have the same form

$$\dot{p} = F$$

as Newton's equations in Cartesian coordinates. Conservation of momentum implies Newton's third law.

Example 1.10 (Conservation of angular momentum). Let $M = V$ be a vector space with Euclidean inner product. Let $G = \mathrm{SO}(V)$ be the connected Lie group of automorphisms of V preserving the inner product, and let $\mathfrak{g} = \mathfrak{so}(V)$ be the Lie algebra of G. Suppose that a Lagrangian L is invariant with respect to the action of a one-parameter subgroup $g_s(q) = e^{sx} \cdot q$ of G on V, where $x \in \mathfrak{g}$ and e^x is the exponential map. According to Noether's theorem,

$$I = \sum_{i=1}^{n} (x \cdot q)^i \frac{\partial L}{\partial \dot{q}^i}$$

is an integral of motion. Now let (M, L) be a closed Lagrangian system of N interacting particles considered in Example 1.2. We have $M = V = \mathbb{R}^{3N}$, and the Lagrangian L is invariant under a simultaneous rotation of coordinates $\boldsymbol{r}_a$ of all particles by the same orthogonal transformation in $\mathbb{R}^3$.

Thus $x = (u, ..., u) \in \underbrace{\mathfrak{so}(3) \oplus \cdots \oplus \mathfrak{so}(3)}_{N}$, and for every $u \in \mathfrak{so}(3)$,

$$I = \sum_{a=1}^{N} \left((u \cdot \boldsymbol{r}_a)^1 \frac{\partial L}{\partial \dot{r}_a^1} + (u \cdot \boldsymbol{r}_a)^2 \frac{\partial L}{\partial \dot{r}_a^2} + (u \cdot \boldsymbol{r}_a)^3 \frac{\partial L}{\partial \dot{r}_a^3} \right)$$

is an integral of motion. Let $u = u^1 X_1 + u^2 X_2 + u^3 X_3$, where $X_1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, X_2 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, X_3 = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$ is the basis in $\mathfrak{so}(3) \simeq \mathbb{R}^3$ corresponding to the rotations about the vectors e_1, e_2, e_3 of the standard orthonormal basis in $\mathbb{R}^3$ (see Problem 1.10). We get

$$I = u^1 M_1 + u^2 M_2 + u^3 M_3,$$

where $\boldsymbol{M} = (M_1, M_2, M_3) \in \mathbb{R}^3$ (or rather a vector in the dual space to $\mathfrak{so}(3)$) is given by

$$\boldsymbol{M} = \sum_{a=1}^{N} \boldsymbol{r}_a \times \frac{\partial L}{\partial \dot{\boldsymbol{r}}_a}$$

The vector $\boldsymbol{M}$ is called the angular momentum of the system. Explicitly,

$$\boldsymbol{M} = \sum_{a=1}^{N} \boldsymbol{r}_a \times m_a \dot{\boldsymbol{r}}_a$$

so that the total angular momentum of a closed system is the sum of angular momenta of individual particles. Conservation of angular momentum is a fundamental physical law which reflects the isotropy of space.

Problem 1.13. Find how total momentum and total angular momentum transform under the Galilean transformations.

1.5. One-dimensional motion.

The motion of systems with one degree of freedom is called one-dimensional. In terms of a Cartesian coordinate x on $M = \mathbb{R}$ the Lagrangian takes the form

$$L = \frac{1}{2} m \dot{x}^2 - V(x)$$

The conservation of energy

$$E = \frac{1}{2} m \dot{x}^2 + V(x)$$

allows us to solve the equation of motion in a closed form by separation of variables. We have

$$\frac{dx}{dt} = \sqrt{\frac{2}{m}(E - V(x))}$$

so that

$$t = \sqrt{\frac{m}{2}} \int \frac{dx}{\sqrt{E - V(x)}}$$

The inverse function $x(t)$ is a general solution of Newton's equation

$$m\ddot{x} = -\frac{dV}{dx}$$

with two arbitrary constants, the energy E and the constant of integration.
Since kinetic energy is non-negative, for a given value of E the actual motion takes place in the region of $\mathbb{R}$ where $V(x) \leq E$. The points where $V(x) = E$ are called turning points. The motion which is confined between two turning points is called finite. The finite motion is periodic - the particle oscillates between the turning points x_1 and x_2 with the period

$$T(E) = \sqrt{2m}\int_{x_1}^{x_2} \frac{dx}{\sqrt{E - V(x)}}$$

If the region $V(x) \leq E$ is unbounded, then the motion is called infinite and the particle eventually goes to infinity. The regions where $V(x) > E$ are forbidden.

On the phase plane with coordinates (x, y) Newton's equation reduces to the first order system

$$m\dot{x} = y, \quad \dot{y} = -\frac{dV}{dx}$$

Trajectories correspond to the phase curves $(x(t), y(t))$, which lie on the level sets

$$\frac{y^2}{2m} + V(x) = E$$

of the energy function. The points $(x_0, 0)$, where x_0 is a critical point of the potential energy $V(x)$, correspond to the equilibrium solutions. The local minima correspond to the stable solutions and local maxima correspond to the unstable solutions. For the values of E which do not correspond to the equilibrium solutions the level sets are smooth curves. These curves are closed if the motion is finite.

The simplest non-trivial one-dimensional system, besides the free particle, is the harmonic oscillator with $V(x) = \frac{1}{2}kx^2 (k > 0)$, considered in Example 1.6. The general solution of the equation of motion is

$$x(t) = A\cos(\omega t + \alpha),$$

where A is the amplitude, $\omega = \sqrt{\frac{k}{m}}$ is the frequency, and α is the phase of a simple harmonic motion with the period $T = \frac{2\pi}{\omega}$. The energy is $E = \frac{1}{2}m\omega^2 A^2$ and the motion is finite with the same period T for $E > 0$.

Problem 1.14. Show that for $V(x) = -x^4$ there are phase curves which do not exist for all times. Prove that if $V(x) \geq 0$ for all x, then all phase curves exist for all times.

Problem 1.15. The simple pendulum is a Lagrangian system with $M = S^1 = \mathbb{R}/2\pi\mathbb{Z}$ and $L = \frac{1}{2}\dot{\theta}^2 + \cos\theta$. Find the period T of the pendulum as a function of the amplitude of the oscillations.

Problem 1.16. Suppose that the potential energy $V(x)$ is even, $V(0) = 0$, and $V(x)$ is a one-to-one monotonically increasing function for $x \geq 0$. Prove that the inverse function $x(V)$ and the period $T(E)$ are related by the Abel transform

$$T(E) = 2\sqrt{2m}\int_0^E \frac{dx}{dV}\frac{dV}{\sqrt{E - V}} \quad \text{and} \quad x(V) = \frac{1}{2\pi\sqrt{2m}}\int_0^V \frac{T(E)dE}{\sqrt{V - E}}$$

1.6. The motion in a central field and the Kepler problem. The motion of a system of two interacting particles - the two-body problem - can also be solved completely. Namely, in this case (see Example 1.2) $M = \mathbb{R}^6$ and

$$L = \frac{m_1 \dot{\boldsymbol{r}}_1^2}{2} + \frac{m_2 \dot{\boldsymbol{r}}_2^2}{2} - V\left(|\boldsymbol{r}_1 - \boldsymbol{r}_2|\right)$$

Introducing on $\mathbb{R}^6$ new coordinates

$$\boldsymbol{r} = \boldsymbol{r}_1 - \boldsymbol{r}_2 \quad \text{and} \quad \boldsymbol{R} = \frac{m_1 \boldsymbol{r}_1 + m_2 \boldsymbol{r}_2}{m_1 + m_2}$$

we get

$$L = \frac{1}{2} m \dot{\boldsymbol{R}}^2 + \frac{1}{2} \mu \dot{\boldsymbol{r}}^2 - V(|\boldsymbol{r}|)$$

where $m = m_1 + m_2$ is the total mass and $\mu = \frac{m_1 m_2}{m_1 + m_2}$ is the reduced mass of a two-body system. The Lagrangian L depends only on the velocity $\dot{\boldsymbol{R}}$ of the center of mass and not on its position $\boldsymbol{R}$. A generalized coordinate with this property is called cyclic. It follows from the Euler-Lagrange equations that generalized momentum corresponding to the cyclic coordinate is conserved. In our case it is a total momentum of the system,

$$\boldsymbol{P} = \frac{\partial L}{\partial \dot{\boldsymbol{R}}} = m \dot{\boldsymbol{R}}$$

so that the center of mass $\boldsymbol{R}$ moves uniformly. Thus in the frame of reference where $\boldsymbol{R} = 0$, the two-body problem reduces to the problem of a single particle of mass μ in the external central field $V(|\boldsymbol{r}|)$. In spherical coordinates in $\mathbb{R}^3$,

$$x = r \sin\vartheta \cos\varphi, y = r \sin\vartheta \sin\varphi, z = r \cos\vartheta$$

where $0 \leq \vartheta < \pi, 0 \leq \varphi < 2\pi$, its Lagrangian takes the form

$$L = \frac{1}{2} \mu \left(\dot{r}^2 + r^2 \dot{\vartheta}^2 + r^2 \sin^2\vartheta \dot{\varphi}^2 \right) - V(r)$$

It follows from the conservation of angular momentum $\boldsymbol{M} = \mu \boldsymbol{r} \times \dot{\boldsymbol{r}}$ that during motion the position vector r lies in the plane P orthogonal to M in $\mathbb{R}^3$. Introducing polar coordinates (r, χ) in the plane P we get $\dot{\chi}^2 = \dot{\vartheta}^2 + \sin^2\vartheta \dot{\varphi}^2$, so that

$$L = \frac{1}{2} \mu \left(\dot{r}^2 + r^2 \dot{\chi}^2 \right) - V(r)$$

The coordinate χ is cyclic and its generalized momentum $\mu r^2 \dot{\chi}$ coincides with $|\boldsymbol{M}|$ if $\dot{\chi} > 0$ and with $-|\boldsymbol{M}|$ if $\dot{\chi} < 0$. Denoting this quantity by M, we get the equation

$$\mu r^2 \dot{\chi} = M \tag{1.7}$$

which is equivalent to Kepler's second law [12]. Using (1.7) we get for the total energy

$$E = \frac{1}{2} \mu \left(\dot{r}^2 + r^2 \dot{\chi}^2 \right) + V(r) = \frac{1}{2} \mu \dot{r}^2 + V(r) + \frac{M^2}{2 \mu r^2} \tag{1.8}$$

Thus the radial motion reduces to a one-dimensional motion on the half-line $r > 0$ with the effective potential energy

$$V_{eff}(r) = V(r) + \frac{M^2}{2 \mu r^2}$$

where the second term is called the centrifugal energy. As in the previous section, the solution is given by

$$t = \sqrt{\frac{\mu}{2}} \int \frac{dr}{\sqrt{E - V_{eff}(r)}} \tag{1.9}$$

It follows from (1.7) that the angle χ is a monotonic function of t, given by another quadrature

$$\chi = \frac{M}{\sqrt{2\mu}} \int \frac{dr}{r^2\sqrt{E - V_{eff}(r)}} \tag{1.10}$$

yielding an equation of the trajectory in polar coordinates.
The set $V_{eff}(r) \leq E$ is a union of annuli $0 \leq r_{\min} \leq r \leq r_{\max} \leq \infty$, and the motion is finite if $0 < r_{\min} \leq r \leq r_{\max} < \infty$. Though for a finite motion $r(t)$ oscillates between $r_{\min}$ and $r_{\max}$, corresponding trajectories are not necessarily closed. The necessary and sufficient condition for a finite motion to have a closed trajectory is that the angle

$$\Delta\chi = \frac{M}{\sqrt{2\mu}} \int_{r_{\min}}^{r_{\max}} \frac{dr}{r^2\sqrt{E - V_{eff}(r)}}$$

is commensurable with 2π, i.e., $\Delta\chi = 2\pi\frac{m}{n}$ for some $m, n \in \mathbb{Z}$. If the angle $\Delta\chi$ is not commensurable with 2π, the orbit is everywhere dense in the annulus $r_{\min} \leq r \leq r_{\max}$. If

$$\lim_{r\to\infty} V_{eff}(r) = \lim_{r\to\infty} V(r) = V < \infty$$

the motion is infinite for $E > V$ - the particle goes to ∞ with finite velocity $\sqrt{\frac{2}{\mu}(E - V)}$.

A very important special case is when

$$V(r) = -\frac{\alpha}{r}.$$

It describes Newton's gravitational attraction ($\alpha > 0$) and Coulomb electrostatic interaction (either attractive or repulsive). First consider the case when $\alpha > 0$ - Kepler's problem. The effective potential energy is

$$V_{eff}(r) = -\frac{\alpha}{r} + \frac{M^2}{2\mu r^2}$$

and has the global minimum

$$V_0 = -\frac{\alpha^2\mu}{2M^2}$$

at $r_0 = \frac{M^2}{\alpha\mu}$. The motion is infinite for $E \geq 0$ and is finite for $V_0 \leq E < 0$. The explicit form of trajectories can be determined by an elementary integration in (1.10), which gives

$$\chi = \cos^{-1} \frac{\frac{M}{r} - \frac{M}{r_0}}{\sqrt{2\mu\,(E - V_0)}} + C.$$

Choosing a constant of integration $C = 0$ and introducing notation

$$p = r_0 \quad \text{and} \quad e = \sqrt{1 - \frac{E}{V_0}},$$

we get the equation of the orbit (trajectory)

[012] It is the statement that sectorial velocity of a particle in a central field is constant.

$$\frac{p}{r} = 1 + e\cos\chi. \tag{1.11}$$

This is the equation of a conic section with one focus at the origin. Quantity $2p$ is called the latus rectum of the orbit, and e is called the eccentricity. The choice $C = 0$ is such that the point with $\chi = 0$ is the point nearest to the origin (called the perihelion). When $V_0 \le E < 0$, the eccentricity $e < 1$ so that the orbit is the ellipse [13] with the major and minor semi-axes

$$a = \frac{p}{1-e^2} = \frac{\alpha}{2|E|}, \quad b = \frac{p}{\sqrt{1-e^2}} = \frac{|M|}{\sqrt{2\mu|E|}}. \tag{1.12}$$

Correspondingly, $r_{\min} = \frac{p}{1+e}, r_{\max} = \frac{p}{1-e}$, and the period T of elliptic orbit is given by

$$T = \pi\alpha\sqrt{\frac{\mu}{2|E|^3}}.$$

The last formula is Kepler's third law. When $E > 0$, the eccentricity $e > 1$ and the motion is infinite - the orbit is a hyperbola with the origin as

internal focus. When $E = 0$, the eccentricity $e = 1$ - the particle starts from rest at ∞ and the orbit is a parabola.

For the repulsive case $\alpha < 0$ the effective potential energy $V_{eff}(r)$ is always positive and decreases monotonically from ∞ to 0 . The motion is always infinite and the trajectories are hyperbolas (parabola if $E = 0$)

$$\frac{p}{r} = -1 + e\cos\chi$$

with

$$p = \frac{M^2}{\alpha\mu} \quad \text{and} \quad e = \sqrt{1 + \frac{2EM^2}{\mu\alpha^2}}.$$

Kepler's problem is very special: for every $\alpha \in \mathbb{R}$ the Lagrangian system on $\mathbb{R}^3$ with

$$L = \frac{1}{2}\mu\dot{\boldsymbol{r}}^2 + \frac{\alpha}{r} \tag{1.13}$$

has three extra integrals of motion W_1, W_2, W_3 in addition to the components of the angular momentum $\boldsymbol{M}$. The corresponding vector $\boldsymbol{W} = (W_1, W_2, W_3)$, called the Laplace-Runge-Lenz vector, is given by

$$\boldsymbol{W} = \dot{\boldsymbol{r}} \times \boldsymbol{M} - \frac{\alpha\boldsymbol{r}}{r}. \tag{1.14}$$

Indeed, using equations of motion $\mu\ddot{\boldsymbol{r}} = -\frac{\alpha r}{r^3}$ and conservation of the angular momentum $\boldsymbol{M} = \mu\boldsymbol{r} \times \dot{\boldsymbol{r}}$, we get

$$\begin{aligned}
\dot{\boldsymbol{W}} &= \mu\ddot{\boldsymbol{r}} \times (\boldsymbol{r} \times \dot{\boldsymbol{r}}) - \frac{\alpha\dot{\boldsymbol{r}}}{r} + \frac{\alpha(\dot{\boldsymbol{r}} \cdot \boldsymbol{r})\boldsymbol{r}}{r^3} \\
&= (\mu\ddot{\boldsymbol{r}} \cdot \dot{\boldsymbol{r}})\boldsymbol{r} - (\mu\ddot{\boldsymbol{r}} \cdot \boldsymbol{r})\dot{\boldsymbol{r}} - \frac{\alpha\dot{\boldsymbol{r}}}{r} + \frac{\alpha(\dot{\boldsymbol{r}} \cdot \boldsymbol{r})\boldsymbol{r}}{r^3} \\
&= 0.
\end{aligned}$$

Using $\mu(\dot{\boldsymbol{r}} \times \boldsymbol{M}) \cdot \boldsymbol{r} = \boldsymbol{M}^2$ and the identity $(\boldsymbol{a} \times \boldsymbol{b})^2 = \boldsymbol{a}^2\boldsymbol{b}^2 - (\boldsymbol{a} \cdot \boldsymbol{b})^2$, we get

[013] The statement that planets have elliptic orbits with a focus at the Sun is Kepler's first law.

$$W^2 = \alpha^2 + \frac{2M^2E}{\mu} \tag{1.15}$$

where

$$E = \frac{\boldsymbol{p}^2}{2\mu} - \frac{\alpha}{r}$$

is the energy corresponding to the Lagrangian (1.13). The fact that all orbits are conic sections follows from this extra symmetry of Kepler's problem.

Problem 1.17. Prove all the statements made in this section.

Problem 1.18. Show that if

$$\lim_{r\to 0} V_{eff}(r) = -\infty,$$

then there are orbits with $r_{\min} = 0$ - "fall" of the particle to the center.

Problem 1.19. Prove that all finite trajectories in the central field are closed only when

$$V(r) = kr^2, k > 0, \quad \text{and} \quad V(r) = -\frac{\alpha}{r}, \alpha > 0$$

Problem 1.20. Find parametric equations for orbits in Kepler's problem.

Problem 1.21. Prove that the Laplace-Runge-Lenz vector $\boldsymbol{W}$ points in the direction of the major axis of the orbit and that $|\boldsymbol{W}| = \alpha e$, where e is the eccentricity of the orbit.

Problem 1.22. Using the conservation of the Laplace-Runge-Lenz vector, prove that trajectories in Kepler's problem with $E < 0$ are ellipses. (Hint: Evaluate $\boldsymbol{W} \cdot \boldsymbol{r}$ and use the result of the previous problem.)

1.7. Legendre transform. The equations of motion of a Lagrangian system (M, L) in standard coordinates associated with a coordinate chart $U \subset M$ are the Euler-Lagrange equations. In expanded form, they are given by the following system of second order ordinary differential equations:

$$\begin{aligned}\frac{\partial L}{\partial q^i}(\boldsymbol{q}, \dot{\boldsymbol{q}}) &= \frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^i}(\boldsymbol{q}, \dot{\boldsymbol{q}})\right) \\ &= \sum_{j=1}^{n}\left(\frac{\partial^2 L}{\partial \dot{q}^i \partial \dot{q}^j}(\boldsymbol{q}, \dot{\boldsymbol{q}})\ddot{q}^j + \frac{\partial^2 L}{\partial \dot{q}^i \partial q^j}(\boldsymbol{q}, \dot{\boldsymbol{q}})\dot{q}^j\right), \quad i = 1, ..., n.\end{aligned}$$

In order for this system to be solvable for the highest derivatives for all initial conditions in TU, the symmetric $n \times n$ matrix

$$H_L(\boldsymbol{q}, \dot{\boldsymbol{q}}) = \left\{\frac{\partial^2 L}{\partial \dot{q}^i \partial \dot{q}^j}(\boldsymbol{q}, \dot{\boldsymbol{q}})\right\}_{i,j=1}^{n}$$

should be invertible on TU.

Definition. A Lagrangian system (M, L) is called non-degenerate if for every coordinate chart U on M the matrix $H_L(\boldsymbol{q}, \dot{\boldsymbol{q}})$ is invertible on TU.

Remark. Note that the $n \times n$ matrix H_L is a Hessian of the Lagrangian function L for vertical directions on TM. Under the change of standard coordinates $\boldsymbol{q}' = F(\boldsymbol{q})$ and $\boldsymbol{q}' = F_*(\boldsymbol{q})\boldsymbol{v}$ (see Section 1.2) it has the transformation law

$$H_L(\boldsymbol{q}, \dot{\boldsymbol{q}}) = F_*(\boldsymbol{q})^T H_L\left(\boldsymbol{q}', \dot{\boldsymbol{q}}'\right) F_*(\boldsymbol{q})$$

where $F_*(\boldsymbol{q})^T$ is the transposed matrix, so that the condition $\det H_L \neq 0$ does not depend on the choice of standard coordinates.

For an invariant formulation, consider the 1-form θ_L, defined in standard coordinates associated with a coordinate chart $U \subset M$ by

$$\theta_L = \sum_{i=1}^{n} \frac{\partial L}{\partial \dot{q}^i} dq^i = \frac{\partial L}{\partial \dot{\boldsymbol{q}}} d\boldsymbol{q}.$$

It follows from Corollary 1.2 that θ_L is a well-defined 1 -form on TM.

Lemma 1.2. A Lagrangian system (M, L) is non-degenerate if and only if the 2 -form $d\theta_L$ on TM is non-degenerate.

Proof. In standard coordinates,

$$d\theta_L = \sum_{i,j=1}^{n} \left(\frac{\partial^2 L}{\partial \dot{q}^i \partial \dot{q}^j} d\dot{q}^j \wedge dq^i + \frac{\partial^2 L}{\partial \dot{q}^i \partial q^j} dq^j \wedge dq^i \right)$$

and it is easy to see, by considering the $2n$-form $d\theta_L^n = \underbrace{d\theta_L \wedge \cdots \wedge d\theta_L}_{n}$, that the 2-form $d\theta_L$ is non-degenerate if and only if the matrix H_L is nondegenerate.

Remark. Using the 1-form θ_L, the Noether integral I in Theorem 1.3 can be written as

$$I = i_{X'}(\theta_L) \tag{1.16}$$

where X' is a lift to TM of a vector field X on M given by (1.5). It also immediately follows from (1.6) that if X is an infinitesimal symmetry, then

$$\mathcal{L}_{X'}(\theta_L) = 0. \tag{1.17}$$

Definition. Let (U, φ) be a coordinate chart on M. Coordinates

$$(\boldsymbol{p}, \boldsymbol{q}) = \left(p_1, ..., p_n, q^1, ..., q^n\right)$$

on the chart $T^*U \simeq \mathbb{R}^n \times U$ on the cotangent bundle T^*M are called standard coordinates [14] if for $(p, q) \in T^*U$ and $f \in C^\infty(U)$

$$p_i(df) = \frac{\partial f}{\partial q^i}, \quad i = 1, ..., n$$

Equivalently, standard coordinates on T^*U are uniquely characterized by the condition that $\boldsymbol{p} = (p_1, ..., p_n)$ are coordinates in the fiber corresponding to the basis $dq^1, ..., dq^n$ for T_q^*M, dual to the basis $\frac{\partial}{\partial q^1}, ..., \frac{\partial}{\partial q^n}$ for T_qM.

Definition. The 1-form θ on T^*M, defined in standard coordinates by

$$\theta = \sum_{i=1}^{n} p_i dq^i = \boldsymbol{p} d\boldsymbol{q}$$

is called Liouville's canonical 1-form.

Corollary 1.2 shows that θ is a well-defined 1 -form on T^*M. Clearly, the 1 -form θ also admits an invariant definition

[014] Following tradition, the first n coordinates parametrize the fiber of T^*U and the last n coordinates parametrize the base.

$$\theta(u) = p\left(\pi_*(u)\right), \quad \text{where} \quad u \in T_{(p,q)}T^*M,$$

and $\pi : T^*M \to M$ is the canonical projection.

Definition. A fibre-wise mapping $\tau_L : TM \to T^*M$ is called a Legendre transform associated with the Lagrangian L if

$$\theta_L = \tau_L^*(\theta)$$

In standard coordinates the Legendre transform is given by

$$\tau_L(\boldsymbol{q}, \dot{\boldsymbol{q}}) = (\boldsymbol{p}, \boldsymbol{q}), \quad \text{where} \quad \boldsymbol{p} = \frac{\partial L}{\partial \dot{\boldsymbol{q}}}(\boldsymbol{q}, \dot{\boldsymbol{q}}).$$

The mapping τ_L is a local diffeomorphism if and only if the Lagrangian L is non-degenerate.

Definition. Suppose that the Legendre transform $\tau_L : TM \to T^*M$ is a diffeomorphism. The Hamiltonian function $H : T^*M \to \mathbb{R}$, associated with the Lagrangian $L : TM \to \mathbb{R}$, is defined by

$$H \circ \tau_L = E_L = \dot{\boldsymbol{q}}\frac{\partial L}{\partial \dot{\boldsymbol{q}}} - L$$

In standard coordinates,

$$H(\boldsymbol{p}, \boldsymbol{q}) = \left(\boldsymbol{p}\dot{\boldsymbol{q}} - L(\boldsymbol{q}, \dot{\boldsymbol{q}})\right)\big|_{\boldsymbol{p}=\frac{\partial L}{\partial \dot{\boldsymbol{q}}}},$$

where $\dot{\boldsymbol{q}}$ is a function of $\boldsymbol{p}$ and $\boldsymbol{q}$ defined by the equation $\boldsymbol{p} = \frac{\partial L}{\partial \dot{\boldsymbol{q}}}(\boldsymbol{q}, \dot{\boldsymbol{q}})$ through the implicit function theorem. The cotangent bundle T^*M is called the phase space of the Lagrangian system (M, L). It turns out that on the phase space the equations of motion take a very simple and symmetric form.

Theorem 1.4. Suppose that the Legendre transform $\tau_L : TM \to T^*M$ is a diffeomorphism. Then the Euler-Lagrange equations in standard coordinates on TM,

$$\frac{d}{dt}\frac{\partial L}{\partial \dot{q}^i} - \frac{\partial L}{\partial q^i} = 0, \quad i = 1, ..., n$$

are equivalent to the following system of first order differential equations in standard coordinates on T^*M:

$$\dot{p}_i = -\frac{\partial H}{\partial q^i}, \quad \dot{q}^i = \frac{\partial H}{\partial p_i}, \quad i = 1, ..., n.$$

Proof. We have

$$\begin{aligned} dH &= \frac{\partial H}{\partial \boldsymbol{p}}d\boldsymbol{p} + \frac{\partial H}{\partial \boldsymbol{q}}d\boldsymbol{q} \\ &= \left(\boldsymbol{p}d\dot{\boldsymbol{q}} + \dot{\boldsymbol{q}}d\boldsymbol{p} - \frac{\partial L}{\partial \boldsymbol{q}}d\boldsymbol{q} - \frac{\partial L}{\partial \dot{\boldsymbol{q}}}d\dot{\boldsymbol{q}}\right)\Big|_{\boldsymbol{p}=\frac{\partial L}{\partial \dot{\boldsymbol{q}}}} \\ &= \left(\dot{\boldsymbol{q}}d\boldsymbol{p} - \frac{\partial L}{\partial \boldsymbol{q}}d\boldsymbol{q}\right)\Big|_{\boldsymbol{p}=\frac{\partial L}{\partial \dot{\boldsymbol{q}}}} \end{aligned}$$

Thus under the Legendre transform,

$$\dot{\boldsymbol{q}} = \frac{\partial H}{\partial \boldsymbol{p}} \quad \text{and} \quad \dot{\boldsymbol{p}} = \frac{d}{dt}\frac{\partial L}{\partial \dot{\boldsymbol{q}}} = \frac{\partial L}{\partial \boldsymbol{q}} = -\frac{\partial H}{\partial \boldsymbol{q}}.$$

Corresponding first order differential equations on T^*M are called Hamilton's equations (canonical equations).

Corollary 1.5. The Hamiltonian H is constant on the solutions of Hamilton's equations.

Proof. For $H(t) = H(\boldsymbol{p}(t), \boldsymbol{q}(t))$ we have

$$\frac{dH}{dt} = \frac{\partial H}{\partial \boldsymbol{q}}\dot{\boldsymbol{q}} + \frac{\partial H}{\partial \boldsymbol{p}}\dot{\boldsymbol{p}} = \frac{\partial H}{\partial \boldsymbol{q}}\frac{\partial H}{\partial \boldsymbol{p}} - \frac{\partial H}{\partial \boldsymbol{p}}\frac{\partial H}{\partial \boldsymbol{q}} = 0.$$

For the Lagrangian

$$L = \frac{m\dot{\boldsymbol{r}}^2}{2} - V(\boldsymbol{r}) = T - V, \quad \boldsymbol{r} \in \mathbb{R}^3,$$

of a particle of mass m in a potential field $V(\boldsymbol{r})$, considered in Example 1.4, we have

$$\boldsymbol{p} = \frac{\partial L}{\partial \dot{\boldsymbol{r}}} = m\dot{\boldsymbol{r}}.$$

Thus the Legendre transform $\tau_L : T\mathbb{R}^3 \to T^*\mathbb{R}^3$ is a global diffeomorphism, linear on the fibers, and

$$H(\boldsymbol{p}, \boldsymbol{r}) = (\boldsymbol{p}\dot{\boldsymbol{r}} - L)|_{\dot{\boldsymbol{r}} = \frac{\boldsymbol{p}}{m}} = \frac{\boldsymbol{p}^2}{2m} + V(\boldsymbol{r}) = T + V$$

Hamilton's equations

$$\dot{\boldsymbol{r}} = \frac{\partial H}{\partial \boldsymbol{p}} = \frac{\boldsymbol{p}}{m}$$
$$\dot{\boldsymbol{p}} = -\frac{\partial H}{\partial r} = -\frac{\partial V}{\partial \boldsymbol{r}}$$

are equivalent to Newton's equations with the force $\boldsymbol{F} = -\frac{\partial V}{\partial \boldsymbol{r}}$.

For the Lagrangian system describing small oscillators, considered in Example 1.6, we have $\boldsymbol{p} = m\dot{\boldsymbol{q}}$, and using normal coordinates we get

$$H(\boldsymbol{p}, \boldsymbol{q}) = (\boldsymbol{p}\dot{\boldsymbol{q}} - L(\boldsymbol{q}, \dot{\boldsymbol{q}}))|_{\dot{\boldsymbol{q}} = \frac{\boldsymbol{p}}{m}} = \frac{\boldsymbol{p}^2}{2m} + V_0(\boldsymbol{q}) = \frac{1}{2m}\left(\boldsymbol{p}^2 + m^2 \sum_{i=1}^{n} \omega_i^2 \left(q^i\right)^2\right).$$

Similarly, for the system of N interacting particles, considered in Example 1.2, we have $\boldsymbol{p} = (\boldsymbol{p}_1, ..., \boldsymbol{p}_N)$, where

$$\boldsymbol{p}_a = \frac{\partial L}{\partial \dot{\boldsymbol{r}}_a} = m_a\dot{\boldsymbol{r}}_a, \quad a = 1, ..., N.$$

The Legendre transform $\tau_L : T\mathbb{R}^{3N} \to T^*\mathbb{R}^{3N}$ is a global diffeomorphism, linear on the fibers, and

$$H(\boldsymbol{p}, \boldsymbol{r}) = (\boldsymbol{p}\dot{\boldsymbol{r}} - L)|_{\dot{\boldsymbol{r}} = \frac{\boldsymbol{p}}{m}} = \sum_{a=1}^{N} \frac{\boldsymbol{p}_a^2}{2m_a} + V(\boldsymbol{r}) = T + V.$$

In particular, for a closed system with pair-wise interaction,

$$H(\boldsymbol{p}, \boldsymbol{r}) = \sum_{a=1}^{N} \frac{\boldsymbol{p}_a^2}{2m_a} + \sum_{1 \le a < b \le N} V_{ab}\left(\boldsymbol{r}_a - \boldsymbol{r}_b\right).$$

In general, consider the Lagrangian

$$L = \sum_{i,j=1}^{n} \frac{1}{2} a_{ij}(\boldsymbol{q}) \dot{q}^i \dot{q}^j - V(\boldsymbol{q}), \boldsymbol{q} \in \mathbb{R}^n,$$

where $A(\boldsymbol{q}) = \{a_{ij}(\boldsymbol{q})\}_{i,j=1}^n$ is a symmetric $n \times n$ matrix. We have

$$p_i = \frac{\partial L}{\partial \dot{q}^i} = \sum_{j=1}^{n} a_{ij}(\boldsymbol{q}) \dot{q}^j, \quad i = 1, ..., n,$$

and the Legendre transform is a global diffeomorphism, linear on the fibers, if and only if the matrix $A(\boldsymbol{q})$ is non-degenerate for all $\boldsymbol{q} \in \mathbb{R}^n$. In this case,

$$H(\boldsymbol{p}, \boldsymbol{q}) = (\boldsymbol{p}\dot{\boldsymbol{q}} - L(\boldsymbol{q}, \dot{\boldsymbol{q}}))|_{\boldsymbol{p}=\frac{\partial L}{\partial \dot{\boldsymbol{q}}}} = \sum_{i,j=1}^{n} \frac{1}{2} a^{ij}(\boldsymbol{q}) p_i p_j + V(\boldsymbol{q}),$$

where $\{a^{ij}(\boldsymbol{q})\}_{i,j=1}^n = A^{-1}(\boldsymbol{q})$ is the inverse matrix.

Problem 1.23 (Second tangent bundle). Let $\pi : TM \to M$ be the canonical projection and let $T_{\mathrm{V}}(TM)$ be the vertical tangent bundle of TM along the fibers of π - the kernel of the bundle mapping $\pi_* : T(TM) \to TM$. Prove that there is a natural bundle isomorphism $i : TM \simeq T_{\mathrm{V}}(TM)$.

Problem 1.24 (Invariant definition of the 1-form θ_L). Show that $\theta_L(v) = dL\left((i \circ \pi_*)\, v\right)$, where $v \in T(TM)$.

Problem 1.25. Give an invariant proof of (1.17).

Problem 1.26. Prove that the path $\gamma(t)$ in M is a trajectory for the Lagrangian system (M, L) if and only if

$$i_{\dot{\gamma}'(t)}\left(d\theta_L\right) + dE_L\left(\gamma'(t)\right) = 0,$$

where $\dot{\gamma}'(t)$ is the velocity vector of the path $\gamma'(t)$ in TM.

Problem 1.27. Show that for a charged particle in an electromagnetic field, considered in Example 1.5,

$$\boldsymbol{p} = m\dot{\boldsymbol{r}} + \frac{e}{c}\boldsymbol{A} \quad \text{and} \quad H(\boldsymbol{p}, \boldsymbol{r}) = \frac{1}{2m}\left(\boldsymbol{p} - \frac{e}{c}\boldsymbol{A}\right)^2 + e\varphi(\boldsymbol{r}).$$

Problem 1.28. Suppose that for a Lagrangian system $(\mathbb{R}^n, L)$ the Legendre transform τ_L is a diffeomorphism and let H be the corresponding Hamiltonian. Prove that for fixed $\boldsymbol{q}$ and $\dot{\boldsymbol{q}}$ the function $\boldsymbol{p}\dot{\boldsymbol{q}} - H(\boldsymbol{p}, \boldsymbol{q})$ has a single critical point at $\boldsymbol{p} = \frac{\partial L}{\partial \dot{\boldsymbol{q}}}$.

Problem 1.29. Give an example of a non-degenerate Lagrangian system (M, L) such that the Legendre transform $\tau_L : TM \to T^*M$ is one-to-one but not onto.

2.12.2 2. Classical Hamiltonian Mechanics for QM 1

2.1. Hamilton's equations.

With every function $H : T^*M \to \mathbb{R}$ on the phase space T^*M there are associated Hamilton's equations - a first-order system of ordinary differential equations, which in the standard coordinates on T^*U has the form

$$\dot{\boldsymbol{p}} = -\frac{\partial H}{\partial \boldsymbol{q}}, \quad \dot{\boldsymbol{q}} = \frac{\partial H}{\partial \boldsymbol{p}}. \tag{2.1}$$

The corresponding vector field X_H on T^*U,

$$X_H = \sum_{i=1}^{n} \left(\frac{\partial H}{\partial p_i} \frac{\partial}{\partial q^i} - \frac{\partial H}{\partial q^i} \frac{\partial}{\partial p_i} \right) = \frac{\partial H}{\partial \boldsymbol{p}} \frac{\partial}{\partial \boldsymbol{q}} - \frac{\partial H}{\partial \boldsymbol{q}} \frac{\partial}{\partial \boldsymbol{p}}$$

gives rise to a well-defined vector field X_H on T^*M, called the Hamiltonian vector field. Suppose now that the vector field X_H on T^*M is complete, i.e., its integral curves exist for all times. The corresponding one-parameter group $\{g_t\}_{t\in\mathbb{R}}$ of diffeomorphisms of T^*M generated by X_H is called the Hamiltonian phase flow. It is defined by $g_t(p,q) = (p(t), q(t))$, where $p(t)$, $q(t)$ is a solution of Hamilton's equations satisfying $p(0) = p, q(0) = q$.

Liouville's canonical 1-form θ on T^*M defines a 2-form $\omega = d\theta$. In standard coordinates on T^*M it is given by

$$\omega = \sum_{i=1}^{n} dp_i \wedge dq^i = d\boldsymbol{p} \wedge d\boldsymbol{q}$$

and is a non-degenerate 2 -form. The form ω is called the canonical symplectic form on T^*M. The symplectic form ω defines an isomorphism J: $T^*\left(T^*M\right) \to T\left(T^*M\right)$ between tangent and cotangent bundles to T^*M. For every $(p,q) \in T^*M$ the linear mapping $J^{-1} : T_{(p,q)}T^*M \to T^*_{(p,q)}T^*M$ is given by

$$\omega\left(u_1, u_2\right) = J^{-1}\left(u_2\right)\left(u_1\right), \quad u_1, u_2 \in T_{(p,q)}T^*M$$

The mapping J induces the isomorphism between the infinite-dimensional vector spaces $\mathcal{A}^1\left(T^*M\right)$ and $\mathrm{Vect}\left(T^*M\right)$, which is linear over $C^\infty\left(T^*M\right)$. If ϑ is a 1 -form on T^*M, then the corresponding vector field $J(\vartheta)$ on T^*M satisfies

$$\omega(X, J(\vartheta)) = \vartheta(X), \quad X \in \mathrm{Vect}\left(T^*M\right)$$

and $J^{-1}(X) = -i_X\omega$. In particular, in standard coordinates,

$$J(d\boldsymbol{p}) = \frac{\partial}{\partial \boldsymbol{q}} \quad \text{and} \quad J(d\boldsymbol{q}) = -\frac{\partial}{\partial \boldsymbol{p}}$$

so that $X_H = J(dH)$.

Theorem 2.1. The Hamiltonian phase flow on T^*M preserves the canonical symplectic form.

Proof. We need to prove that $\left(g_t\right)^* \omega = \omega$. Since g_t is a one-parameter group of diffeomorphisms, it is sufficient to show that

$$\frac{d}{dt}\left(g_t\right)^* \omega \Big|_{t=0} = \mathcal{L}_{X_H}\omega = 0$$

where $\mathcal{L}_{X_H}$ is the Lie derivative along the vector field X_H. Since for every vector field X,

$$\mathcal{L}_X(df) = d(X(f)),$$

we compute

$$\mathcal{L}_{X_H}\left(dp_i\right) = -d\left(\frac{\partial H}{\partial q^i}\right) \quad \text{and} \quad \mathcal{L}_{X_H}\left(dq^i\right) = d\left(\frac{\partial H}{\partial p_i}\right)$$

so that

$$\begin{aligned}
\mathcal{L}_{X_H}\omega &= \sum_{i=1}^{n} \left(\mathcal{L}_{X_H}\left(dp_i\right) \wedge dq^i + dp_i \wedge \mathcal{L}_{X_H}\left(dq^i\right) \right) \\
&= \sum_{i=1}^{n} \left(-d\left(\frac{\partial H}{\partial q^i}\right) \wedge dq^i + dp_i \wedge d\left(\frac{\partial H}{\partial p_i}\right) \right) = -d(dH) = 0.
\end{aligned}$$

Corollary 2.2. $\mathcal{L}_{X_H}(\theta) = d\left(-H + \theta\left(X_H\right)\right)$, where θ is Liouville's canonical 1-form.

The canonical symplectic form ω on T^*M defines the volume form $\frac{\omega^n}{n!} = \frac{1}{n!}\underbrace{\omega \wedge \cdots \wedge \omega}_{n}$ on T^*M, called Liouville's volume form.

Corollary 2.3 (Liouville's theorem). The Hamiltonian phase flow on T^*M preserves Liouville's volume form.

The restriction of the symplectic form ω on T^*M to the configuration space M is 0 . Generalizing this property, we get the following notion.

Definition. A submanifold $\mathscr{L}$ of the phase space T^*M is called a *La* grangian submanifold if $\dim \mathscr{L} = \dim M$ and $\omega|_{\mathscr{L}} = 0$.

It follows from Theorem 2.1 that the image of a Lagrangian submanifold under the Hamiltonian phase flow is a Lagrangian submanifold.

Problem 2.1. Verify that X_H is a well-defined vector field on T^*M.

Problem 2.2. Show that if all level sets of the Hamiltonian H are compact submanifolds of T^*M, then the Hamiltonian vector field X_H is complete.

Problem 2.3. Let $\pi : T^*M \to M$ be the canonical projection, and let $\mathscr{L}$ be a Lagrangian submanifold. Show that if the mapping $\pi|_{\mathscr{L}} : \mathscr{L} \to M$ is a diffeomorphism, then $\mathscr{L}$ is a graph of a smooth function on M. Give examples when for some $t > 0$ the corresponding projection of $g_t(\mathscr{L})$ onto M is no longer a diffeomorphism.

2.2. The action functional in the phase space.

With every function H on the phase space T^*M there is an associated 1-form

$$\theta - Hdt = \boldsymbol{p}d\boldsymbol{q} - Hdt$$

on the extended phase space $T^*M \times \mathbb{R}$, called the Poincar-Cartan form. Let $\gamma : [t_0, t_1] \to T^*M$ be a smooth parametrized path in T^*M such that $\pi\left(\gamma\left(t_0\right)\right) = q_0$ and $\pi\left(\gamma\left(t_1\right)\right) = q_1$, where $\pi : T^*M \to M$ is the canonical projection. By definition, the lift of a path γ to the extended phase space $T^*M \times \mathbb{R}$ is a path $\sigma : [t_0, t_1] \to T^*M \times \mathbb{R}$ given by $\sigma(t) = (\gamma(t), t)$, and a path σ in $T^*M \times \mathbb{R}$ is called an admissible path if it is a lift of a path γ in T^*M. The space of admissible paths in $T^*M \times \mathbb{R}$ is denoted by $\tilde{P}\left(T^*M\right)_{q_0,t_0}^{q_1,t_1}$. A variation of an admissible path σ is a smooth family of admissible paths σ_ε, where $\varepsilon \in [-\varepsilon_0, \varepsilon_0]$ and $\sigma_0 = \sigma$, and the corresponding infinitesimal variation is

$$\delta\sigma = \left.\frac{\partial \sigma_\varepsilon}{\partial \varepsilon}\right|_{\varepsilon=0} \in T_\sigma \tilde{P}\left(T^*M\right)_{q_0,t_0}^{q_1,t_1}$$

(cf. Section 1.2). The principle of the least action in the phase space is the following statement.

Theorem 2.4 (Poincar). The admissible path σ in $T^*M \times \mathbb{R}$ is an extremal for the action functional

$$S(\sigma) = \int_\sigma (\boldsymbol{p}d\boldsymbol{q} - Hdt) = \int_{t_0}^{t_1} (\boldsymbol{p}\dot{\boldsymbol{q}} - H)dt$$

if and only if it is a lift of a path $\gamma(t) = (\boldsymbol{p}(t), \boldsymbol{q}(t))$ in T^*M, where $\boldsymbol{p}(t)$ and $\boldsymbol{q}(t)$ satisfy canonical Hamilton's equations

$$\dot{\boldsymbol{p}} = -\frac{\partial H}{\partial \boldsymbol{q}}, \quad \dot{\boldsymbol{q}} = \frac{\partial H}{\partial \boldsymbol{p}}$$

Proof. As in the proof of Theorem 1.1, for an admissible family $\sigma_\varepsilon(t) = (\boldsymbol{p}(t,\varepsilon), \boldsymbol{q}(t,\varepsilon), t)$ we compute using integration by parts,

$$\left.\frac{d}{d\varepsilon}\right|_{\varepsilon=0} S(\sigma_\varepsilon) = \sum_{i=1}^{n} \int_{t_0}^{t_1} \left(\dot{q}^i \delta p_i - \dot{p}_i \delta q^i - \frac{\partial H}{\partial q^i} \delta q^i - \frac{\partial H}{\partial p_i} \delta p_i \right) dt + \sum_{i=1}^{n} p_i \delta q^i \Big|_{t_0}^{t_1}$$

Since $\delta \boldsymbol{q}(t_0) = \delta \boldsymbol{q}(t_1) = 0$, the path σ is critical if and only if $\boldsymbol{p}(t)$ and $\boldsymbol{q}(t)$ satisfy canonical Hamilton's equations (2.1).

Remark. For a Lagrangian system (M, L), every path $\gamma(t) = (\boldsymbol{q}(t))$ in the configuration space M connecting points q_0 and q_1 defines an admissible path $\hat{\gamma}(t) = (\boldsymbol{p}(t), \boldsymbol{q}(t), t)$ in the phase space T^*M by setting $\boldsymbol{p} = \frac{\partial L}{\partial \dot{\boldsymbol{q}}}$. If the Legendre transform $\tau_L : TM \to T^*M$ is a diffeomorphism, then

$$S(\hat{\gamma}) = \int_{t_0}^{t_1} (\boldsymbol{p}\dot{\boldsymbol{q}} - H) dt = \int_{t_0}^{t_1} L(\gamma'(t), t)\, dt$$

Thus the principle of the least action in a configuration space - Hamilton's principle - follows from the principle of the least action in a phase space. In fact, in this case the two principles are equivalent (see Problem 1.28).

From Corollary 1.5 we immediately get the following result.

Corollary 2.5. Solutions of canonical Hamilton's equations lying on the hypersurface $H(\boldsymbol{p}, \boldsymbol{q}) = E$ are extremals of the functional $\int_\sigma \boldsymbol{p} d\boldsymbol{q}$ in the class of admissible paths σ lying on this hypersurface.

Corollary 2.6 (Maupertuis' principle). The trajectory $\gamma = (\boldsymbol{q}(\tau))$ of a closed Lagrangian system (M, L) connecting points q_0 and q_1 and having energy E is the extremal of the functional

$$\int_\gamma \boldsymbol{p} d\boldsymbol{q} = \int_\gamma \frac{\partial L}{\partial \dot{\boldsymbol{q}}}(\boldsymbol{q}(\tau), \dot{\boldsymbol{q}}(\tau)) \dot{\boldsymbol{q}}(\tau) d\tau$$

on the space of all paths in the configuration space M connecting points q_0 and q_1 and parametrized such that $H\left(\frac{\partial L}{\partial \dot{\boldsymbol{q}}}(\tau), \boldsymbol{q}(\tau)\right) = E$.

The functional

$$S_0(\gamma) = \int_\gamma \boldsymbol{p} d\boldsymbol{q}$$

is called the abbreviated action [15].

Proof. Every path $\gamma = \boldsymbol{q}(\tau)$, parametrized such that $H\left(\frac{\partial L}{\partial \dot{\boldsymbol{q}}}, \boldsymbol{q}\right) = E$, lifts to an admissible path $\sigma = \left(\frac{\partial L}{\partial \dot{\boldsymbol{q}}}(\tau), \boldsymbol{q}(\tau), \tau\right), a \le \tau \le b$, lying on the hypersurface $H(\boldsymbol{p}, \boldsymbol{q}) = E$.

Problem 2.4 (Jacobi). On a Riemannian manifold (M, ds^2) consider a Lagrangian system with $L(q, v) = \frac{1}{2}\|v\|^2 - V(q)$. Let $E > V(q)$ for all $q \in M$. Show that the trajectories of a closed Lagrangian system (M, L) with total energy E are geodesics for the Riemannian metric $d\hat{s}^2 = (E - V(q)) ds^2$ on M.

2.3. The action as a function of coordinates.

Consider a non-degenerate Lagrangian system (M, L) and denote by $\gamma(t; q_0, v_0)$ the solution of Euler-Lagrange equations

$$\frac{d}{dt}\frac{\partial L}{\partial \dot{\boldsymbol{q}}} - \frac{\partial L}{\partial \boldsymbol{q}} = 0$$

with the initial conditions $\gamma(t_0) = q_0 \in M$ and $\dot{\gamma}(t_0) = v_0 \in T_{q_0}M$. Suppose that there exist a neighborhood $V_0 \subset T_{v_0}M$ of v_0 and $t_1 > t_0$ such that for all $v \in V_0$ the extremals $\gamma(t; q_0, v)$, which start at time t_0 at q_0, do not intersect in the extended configuration space $M \times \mathbb{R}$ for times $t_0 < t < t_1$. Such extremals are said to form a central field which includes the extremal $\gamma_0(t) = \gamma(t; q_0, v_0)$. The existence of the central field of extremals is equivalent to the condition that for every $t_0 < t < t_1$ there is a neighborhood $U_t \subset M$ of $\gamma_0(t) \in M$ such that the mapping

$$V_0 \ni v \mapsto q(t) = \gamma(t; q_0, v) \in U_t \tag{2.2}$$

is a diffeomorphism. Basic theorems in the theory of ordinary differential equations guarantee that for t_1 sufficiently close to t_0 every extremal $\gamma(t)$ for $t_0 < t < t_1$ can be included into the central field. In standard coordinates the mapping (2.2) is given by $\dot{\boldsymbol{q}} \mapsto \boldsymbol{q}(t) = \gamma(t; \boldsymbol{q}_0, \dot{\boldsymbol{q}})$.

For the central field of extremals $\gamma(t; \boldsymbol{q}_0, \dot{\boldsymbol{q}}), t_0 < t < t_1$, we define the action as a function of coordinates and time (or, classical action) by

$$S(\boldsymbol{q}, t; \boldsymbol{q}_0, t_0) = \int_{t_0}^{t} L(\gamma'(\tau))\, d\tau$$

where $\gamma(\tau)$ is the extremal from the central field that connects $\boldsymbol{q}_0$ and $\boldsymbol{q}$. For given $\boldsymbol{q}_0$ and t_0, the classical action is defined for $t \in (t_0, t_1)$ and $\boldsymbol{q} \in \bigcup_{t_0<t<t_1} U_t$. For a fixed energy E,

$$S(\boldsymbol{q}, t; \boldsymbol{q}_0, t_0) = S_0(\boldsymbol{q}, t; \boldsymbol{q}_0, t_0) - E(t - t_0), \tag{2.3}$$

where S_0 is the abbreviated action from the previous section. Theorem 2.7. The differential of the classical action $S(\boldsymbol{q}, t)$ with fixed initial point is given by

$$dS = \boldsymbol{p}d\boldsymbol{q} - Hdt$$

where $\boldsymbol{p} = \frac{\partial L}{\partial \dot{\boldsymbol{q}}}(\boldsymbol{q}, \dot{\boldsymbol{q}})$ and $H = \boldsymbol{p}\dot{\boldsymbol{q}} - L(\boldsymbol{q}, \dot{\boldsymbol{q}})$ are determined by the velocity $\dot{\boldsymbol{q}}$ of the extremal $\gamma(\tau)$ at time t.

Proof. Let $\boldsymbol{q}_\varepsilon$ be a path in M passing through $\boldsymbol{q}$ at $\varepsilon = 0$ with the tangent vector $v \in T_{\boldsymbol{q}}M \simeq \mathbb{R}^n$, and for ε small enough let $\gamma_\varepsilon(\tau)$ be the family of extremals from the central field satisfying $\gamma_\varepsilon(t_0) = \boldsymbol{q}_0$ and $\gamma_\varepsilon(t) = \boldsymbol{q}_\varepsilon$. For the infinitesimal variation $\delta\gamma$ we have $\delta\gamma(t_0) = 0$ and $\delta\gamma(t) = \boldsymbol{v}$, and for fixed t we get from the formula for variation with the free ends (1.2) that

$$dS(\boldsymbol{v}) = \frac{\partial L}{\partial \dot{\boldsymbol{q}}}\boldsymbol{v}.$$

This shows that $\frac{\partial S}{\partial \boldsymbol{q}} = \boldsymbol{p}$. Setting $\boldsymbol{q}(t) = \gamma(t)$, we obtain

$$\frac{d}{dt}S(\boldsymbol{q}(t), t) = \frac{\partial S}{\partial \boldsymbol{q}}\dot{\boldsymbol{q}} + \frac{\partial S}{\partial t} = L,$$

so that $\frac{\partial S}{\partial t} = L - \boldsymbol{p}\dot{\boldsymbol{q}} = -H$.

Corollary 2.8. The classical action satisfies the following nonlinear partial differential equation

$$\frac{\partial S}{\partial t} + H\left(\frac{\partial S}{\partial \boldsymbol{q}}, \boldsymbol{q}\right) = 0 \tag{2.4}$$

[015] The accurate formulation of Maupertuis' principle is due to Euler and Lagrange.

This equation is called the Hamilton-Jacobi equation. Hamilton's equations (2.1) can be used for solving the Cauchy problem

$$S(\boldsymbol{q},t)|_{t=0} = s(\boldsymbol{q}), \quad s \in C^\infty(M), \tag{2.5}$$

for Hamilton-Jacobi equation (2.4) by the method of characteristics. Namely, assume the existence of the Hamiltonian phase flow g_t on T^*M and consider the Lagrangian submanifold

$$\mathscr{L} = \left\{ (\boldsymbol{p},\boldsymbol{q}) \in T^*M : \boldsymbol{p} = \frac{\partial s(\boldsymbol{q})}{\partial \boldsymbol{q}} \right\},$$

a graph of the 1 -form ds on M - a section of the cotangent bundle π: $T^*M \to M$. The mapping $\pi|_{\mathscr{L}}$ is one-to-one and for sufficiently small t the restriction of the projection π to the Lagrangian submanifold $\mathscr{L}_t = g_t(\mathscr{L})$ remains to be one-to-one. In other words, there is $t_1 > 0$ such that for all $0 \le t < t_1$ the mapping $\pi_t = \pi \circ g_t \circ (\pi|_{\mathscr{L}})^{-1} : M \to M$ is a diffeomorphism, and the extremals $\gamma(\tau, \boldsymbol{q}_0, \dot{\boldsymbol{q}}_0)$ in the extended configuration space $M \times \mathbb{R}$, where $\dot{\boldsymbol{q}}_0 = \frac{\partial H}{\partial \boldsymbol{p}}(\boldsymbol{p}_0, \boldsymbol{q}_0)$ and $(\boldsymbol{p}_0, \boldsymbol{q}_0) \in \mathscr{L}$, do not intersect. Such extremals are called the characteristics of the Hamilton-Jacobi equation.

Proposition 2.1. For $0 \le t < t_1$ the solution $S(\boldsymbol{q},t)$ to the Cauchy problem (2.4)-(2.5) is given by

$$S(\boldsymbol{q},t) = s(\boldsymbol{q}_0) + \int_0^t L(\gamma'(\tau))\, d\tau$$

Here $\gamma(\tau)$ is the characteristic with $\gamma(t) = \boldsymbol{q}$ and with the starting point $\boldsymbol{q}_0 = \gamma(0)$ which is uniquely determined by $\boldsymbol{q}$.

Proof. As in the proof of Theorem 2.7 we use formula (1.2), where now $\boldsymbol{q}_0$ depends on $\boldsymbol{q}$, and obtain

$$\frac{\partial S}{\partial \boldsymbol{q}}(\boldsymbol{q}) = \frac{\partial s}{\partial \boldsymbol{q}_0}(\boldsymbol{q}_0)\frac{\partial \boldsymbol{q}_0}{\partial \boldsymbol{q}} + \frac{\partial L}{\partial \dot{\boldsymbol{q}}}(\boldsymbol{q},\dot{\boldsymbol{q}}) - \frac{\partial L}{\partial \dot{\boldsymbol{q}}_0}(\boldsymbol{q}_0,\dot{\boldsymbol{q}}_0)\frac{\partial \boldsymbol{q}_0}{\partial \boldsymbol{q}} = \boldsymbol{p}$$

since $\frac{\partial s}{\partial \boldsymbol{q}_0}(\boldsymbol{q}_0) = \boldsymbol{p}_0 = \frac{\partial L}{\partial \dot{\boldsymbol{q}}_0}(\boldsymbol{q}_0,\dot{\boldsymbol{q}}_0)$. Setting $\boldsymbol{q}(t) = \gamma(t)$ we get

$$\frac{d}{dt}S(\boldsymbol{q}(t),t) = \frac{\partial S}{\partial \boldsymbol{q}}\dot{\boldsymbol{q}} + \frac{\partial S}{\partial t} = L(\boldsymbol{q},\dot{\boldsymbol{q}})$$

so that

$$\frac{\partial S}{\partial t} = -H(\boldsymbol{p},\boldsymbol{q})$$

and S satisfies the Hamilton-Jacobi equation.

We can also consider the action $S(\boldsymbol{q},t;\boldsymbol{q}_0,t_0)$ as a function of both variables $\boldsymbol{q}$ and $\boldsymbol{q}_0$. The analog of Theorem 2.7 is the following statement.

Proposition 2.2. The differential of the classical action as a function of initial and final points is given by

$$dS = \boldsymbol{p}d\boldsymbol{q} - \boldsymbol{p}_0 d\boldsymbol{q}_0 - H(\boldsymbol{p},\boldsymbol{q})dt + H(\boldsymbol{p}_0,\boldsymbol{q}_0)\,dt_0$$

Problem 2.5. Prove that the solution to the Cauchy problem for the HamiltonJacobi equation is unique.

2.12.3 2. Classical Hamiltonian Mechanics for QM 2

2.4. Classical observables and Poisson bracket.

Smooth real-valued functions on the phase space T^*M are called classical observables. The vector space $C^\infty(T^*M)$ is an $\mathbb{R}$-algebra - an associative algebra over $\mathbb{R}$ with a unit given by the constant function 1, and with a multiplication given by the point-wise product of functions. The commutative algebra $C^\infty(T^*M)$ is called the algebra of classical observables. Assuming that the Hamiltonian phase flow g_t exists for all times, the time evolution of every observable $f \in C^\infty(T^*M)$ is given by

$$f_t(p,q) = f(g_t(p,q)) = f(p(t),q(t)), \quad (p,q) \in TM$$

Equivalently, the time evolution is described by the differential equation

$$\begin{aligned}\frac{df_t}{dt} &= \left.\frac{df_{s+t}}{ds}\right|_{s=0} = \left.\frac{d(f_t \circ g_s)}{ds}\right|_{s=0} = X_H(f_t) \\ &= \sum_{i=1}^{n}\left(\frac{\partial H}{\partial p_i}\frac{\partial f_t}{\partial q^i} - \frac{\partial H}{\partial q^i}\frac{\partial f_t}{\partial p_i}\right) = \frac{\partial H}{\partial \boldsymbol{p}}\frac{\partial f_t}{\partial \boldsymbol{q}} - \frac{\partial H}{\partial \boldsymbol{q}}\frac{\partial f_t}{\partial \boldsymbol{p}},\end{aligned}$$

called Hamilton's equation for classical observables. Setting

$$\{f,g\} = X_f(g) = \frac{\partial f}{\partial \boldsymbol{p}}\frac{\partial g}{\partial \boldsymbol{q}} - \frac{\partial f}{\partial \boldsymbol{q}}\frac{\partial g}{\partial \boldsymbol{p}}, \quad f,g \in C^\infty(T^*M) \tag{2.6}$$

we can rewrite Hamilton's equation in the concise form

$$\frac{df}{dt} = \{H,f\} \tag{2.7}$$

where it is understood that (2.7) is a differential equation for a family of functions f_t on T^*M with the initial condition $f_t(p,q)|_{t=0} = f(p,q)$. The properties of the bilinear mapping

$$\{,\} : C^\infty(T^*M) \times C^\infty(T^*M) \to C^\infty(T^*M)$$

are summarized below.

Theorem 2.9. The mapping $\{,\}$ *satisfies the following properties.*

(i) (Relation with the symplectic form)

$$\{f,g\} = \omega(J(df), J(dg)) = \omega(X_f, X_g)$$

(ii) (Skew-symmetry)

$$\{f,g\} = -\{g,f\}$$

(iii) (Leibniz rule)

$$\{fg,h\} = f\{g,h\} + g\{f,h\}.$$

(iv) (Jacobi identity)

$$\{f,\{g,h\}\} + \{g,\{h,f\}\} + \{h,\{f,g\}\} = 0$$

for all $f,g,h \in C^\infty(T^*M)$.

Proof. Property (i) immediately follows from the definitions of ω and J in Section 2.1. Properties (ii)-(iii) are obvious. The Jacobi identity could be verified by a direct computation using (2.6), or by the following elegant argument. Observe that $\{f,g\}$ is a bilinear form in the

first partial derivatives of f and g, and every term in the left-hand side of the Jacobi identity is a linear homogenous function of second partial derivatives of f, g, and h. Now the only terms in the Jacobi identity which could actually contain second partial derivatives of a function h are the following:

$$\{f, \{g, h\}\} + \{g, \{h, f\}\} = (X_f X_g - X_g X_f)(h)$$

However, this expression does not contain second partial derivatives of h since it is a commutator of two differential operators of the first order which is again a differential operator of the first order!

The observable $\{f, g\}$ is called the canonical Poisson bracket of the observables f and g. The Poisson bracket map $\{\} :, C^\infty(T^*M) \times C^\infty(T^*M) \to C^\infty(T^*M)$ turns the algebra of classical observables $C^\infty(T^*M)$ into a Lie algebra with a Lie bracket given by the Poisson bracket. It has an important property that the Lie bracket is a bi-derivation with respect to the multiplication in $C^\infty(T^*M)$. The algebra of classical observables $C^\infty(T^*M)$ is an example of the Poisson algebra - a commutative algebra over $\mathbb{R}$ carrying a structure of a Lie algebra with the property that the Lie bracket is a derivation with respect to the algebra product.

In Lagrangian mechanics, a function I on TM is an integral of motion for the Lagrangian system (M, L) if it is constant along the trajectories. In Hamiltonian mechanics, an observable I - a function on the phase space T^*M - is called an integral of motion (first integral) for Hamilton's equations (2.1) if it is constant along the Hamiltonian phase flow. According to (2.7), this is equivalent to the condition

$$\{H, I\} = 0$$

It is said that the observables H and I are in involution (Poisson commute).

2.5. Canonical transformations and generating functions.

Definition. A diffeomorphism g of the phase space T^*M is called a canonical transformation, if it preserves the canonical symplectic form ω on T^*M, i.e., $g^*(\omega) = \omega$. By Theorem 2.1, the Hamiltonian phase flow g_t is a oneparameter group of canonical transformations.

Proposition 2.3. Canonical transformations preserve Hamilton's equations.

Proof. From $g^*(\omega) = \omega$ it follows that the mapping $J : T^*(T^*M) \to T(T^*M)$ satisfies

$$g_* \circ J \circ g^* = J. \tag{2.8}$$

Indeed, for all $X, Y \in \mathrm{Vect}(M)$ we have [16]

$$\omega(X, Y) = g^*(\omega)(X, Y) = \omega(g_*(X), g_*(Y)) \circ g$$

so that for every 1 -form ϑ on M,

$$\omega(X, J(g^*(\vartheta))) = g^*(\vartheta)(X) = \vartheta(g_*(X)) \circ g = \omega(g_*(X), J(\vartheta)) \circ g$$

which gives $g_*(J(g^*(\vartheta))) = J(\vartheta)$. Using (2.8), we get

$$g_*(X_H) = g_*(J(dH)) = J\left((g^*)^{-1}(dH)\right) = X_K,$$

where $K = H \circ g^{-1}$. Thus the canonical transformation g maps trajectories of the Hamiltonian vector field X_H into the trajectories of the Hamiltonian vector field X_K.

Remark. In classical terms, Proposition 2.3 means that canonical Hamilton's equations

$$\dot{\boldsymbol{p}} = -\frac{\partial H}{\partial \boldsymbol{q}}(\boldsymbol{p}, \boldsymbol{q}), \quad \dot{\boldsymbol{q}} = \frac{\partial H}{\partial \boldsymbol{p}}(\boldsymbol{p}, \boldsymbol{q})$$

in new coordinates $(\boldsymbol{P}, \boldsymbol{Q}) = g(\boldsymbol{p}, \boldsymbol{q})$ continue to have the canonical form

$$\dot{\boldsymbol{P}} = -\frac{\partial K}{\partial \boldsymbol{Q}}(\boldsymbol{P}, \boldsymbol{Q}), \quad \dot{\boldsymbol{Q}} = \frac{\partial K}{\partial \boldsymbol{P}}(\boldsymbol{P}, \boldsymbol{Q})$$

with the old Hamiltonian function $K(\boldsymbol{P}, \boldsymbol{Q}) = H(\boldsymbol{p}, \boldsymbol{q})$.

Consider now the classical case $M = \mathbb{R}^n$. For a canonical transformation $(\boldsymbol{P}, \boldsymbol{Q}) = g(\boldsymbol{p}, \boldsymbol{q})$ set $\boldsymbol{P} = \boldsymbol{P}(\boldsymbol{p}, \boldsymbol{q})$ and $\boldsymbol{Q} = \boldsymbol{Q}(\boldsymbol{p}, \boldsymbol{q})$. Since $d\boldsymbol{P} \wedge d\boldsymbol{Q} = d\boldsymbol{p} \wedge d\boldsymbol{q}$ on $T^*M \simeq \mathbb{R}^{2n}$, the 1-form $\boldsymbol{p}d\boldsymbol{q} - \boldsymbol{P}d\boldsymbol{Q}$ - the difference between the canonical Liouville 1-form and its pullback by the mapping g-is closed. From the Poincar lemma it follows that there exists a function $F(\boldsymbol{p}, \boldsymbol{q})$ on $\mathbb{R}^{2n}$ such that

$$\boldsymbol{p}d\boldsymbol{q} - \boldsymbol{P}d\boldsymbol{Q} = dF(\boldsymbol{p}, \boldsymbol{q}) \tag{2.9}$$

Now assume that at some point $(\boldsymbol{p}_0, \boldsymbol{q}_0)$ the $n \times n$ matrix $\frac{\partial \boldsymbol{P}}{\partial \boldsymbol{p}} = \left\{ \frac{\partial P_i}{\partial p_j} \right\}_{i,j=1}^{n}$ is non-degenerate. By the inverse function theorem, there exists a neighborhood U of $(\boldsymbol{p}_0, \boldsymbol{q}_0)$ in $\mathbb{R}^{2n}$ for which the functions $\boldsymbol{P}, \boldsymbol{q}$ are coordinate functions. The function

$$S(\boldsymbol{P}, \boldsymbol{q}) = F(\boldsymbol{p}, \boldsymbol{q}) + \boldsymbol{P}\boldsymbol{Q}$$

is called a generating function of the canonical transformation g in U. It follows from (2.9) that in new coordinates $\boldsymbol{P}, \boldsymbol{q}$ on U,

$$\boldsymbol{p} = \frac{\partial S}{\partial \boldsymbol{q}}(\boldsymbol{P}, \boldsymbol{q}) \quad \text{and} \quad \boldsymbol{Q} = \frac{\partial S}{\partial \boldsymbol{P}}(\boldsymbol{P}, \boldsymbol{q})$$

The converse statement below easily follows from the implicit function theorem.

Proposition 2.4. Let $S(\boldsymbol{P}, \boldsymbol{q})$ be a function in some neighborhood U of a point $(\boldsymbol{P}_0, \boldsymbol{q}_0) \in \mathbb{R}^{2n}$ such that the $n \times n$ matrix

$$\frac{\partial^2 S}{\partial \boldsymbol{P} \partial \boldsymbol{q}}(\boldsymbol{P}_0, \boldsymbol{q}_0) = \left\{ \frac{\partial^2 S}{\partial P_i \partial q^j}(\boldsymbol{P}_0, \boldsymbol{q}_0) \right\}_{i,j=1}^{n}$$

is non-degenerate. Then S is a generating function of a local (i.e., defined in some neighborhood of $(\boldsymbol{P}_0, \boldsymbol{q}_0)$ in $\mathbb{R}^{2n}$) canonical transformation.

Suppose there is a canonical transformation $(\boldsymbol{P}, \boldsymbol{Q}) = g(\boldsymbol{p}, \boldsymbol{q})$ such that $H(\boldsymbol{p}, \boldsymbol{q}) = K(\boldsymbol{P})$ for some function K. Then in the new coordinates Hamilton's equations take the form

$$\dot{\boldsymbol{P}} = 0, \quad \dot{\boldsymbol{Q}} = \frac{\partial K}{\partial \boldsymbol{P}} \tag{2.10}$$

and are trivially integrated:

$$\boldsymbol{P}(t) = \boldsymbol{P}(0), \quad \boldsymbol{Q}(t) = \boldsymbol{Q}(0) + t\frac{\partial K}{\partial \boldsymbol{P}}(\boldsymbol{P}(0))$$

Assuming that the matrix $\frac{\partial \boldsymbol{P}}{\partial \boldsymbol{p}}$ is non-degenerate, the generating function $S(\boldsymbol{P}, \boldsymbol{q})$ satisfies the differential equation

$$H\left(\frac{\partial S}{\partial \boldsymbol{q}}(\boldsymbol{P}, \boldsymbol{q}), \boldsymbol{q}\right) = K(\boldsymbol{P}) \tag{2.11}$$

[016] Since g is a diffeomorphism, g_*X is a well-defined vector field on M.

where after the differentiation one should substitute $\boldsymbol{q} = \boldsymbol{q}(\boldsymbol{P}, \boldsymbol{Q})$, defined by the canonical transformation g^{-1}. The differential equation (2.11) for fixed $\boldsymbol{P}$, as it follows from (2.3), coincides with the Hamilton-Jacobi equation for the abbreviated action $S_0 = S - Et$ where $E = K(\boldsymbol{P})$,

$$H\left(\frac{\partial S_0}{\partial \boldsymbol{q}}(\boldsymbol{P}, \boldsymbol{q}), \boldsymbol{q}\right) = E$$

Theorem 2.10 (Jacobi). Suppose that there is a function $S(\boldsymbol{P}, \boldsymbol{q})$ which depends on n parameters $\boldsymbol{P} = (P_1, ..., P_n)$, satisfies the Hamilton-Jacobi equation (2.11) for some function $K(\boldsymbol{P})$, and has the property that the $n \times n$ matrix $\frac{\partial^2 S}{\partial \boldsymbol{P} \partial \boldsymbol{q}}$ is non-degenerate. Then Hamilton's equations

$$\dot{\boldsymbol{p}} = -\frac{\partial H}{\partial \boldsymbol{q}}, \quad \dot{\boldsymbol{q}} = \frac{\partial H}{\partial \boldsymbol{p}}$$

can be solved explicitly, and the functions $\boldsymbol{P}(\boldsymbol{p}, \boldsymbol{q}) = (P_1(\boldsymbol{p}, \boldsymbol{q}), ..., P_n(\boldsymbol{p}, \boldsymbol{q}))$, defined by the equations $\boldsymbol{p} = \frac{\partial S}{\partial \boldsymbol{q}}(\boldsymbol{P}, \boldsymbol{q})$, are integrals of motion in involution.

Proof. Set $\boldsymbol{p} = \frac{\partial S}{\partial \boldsymbol{q}}(\boldsymbol{P}, \boldsymbol{q})$ and $\boldsymbol{Q} = \frac{\partial S}{\partial \boldsymbol{P}}(\boldsymbol{P}, \boldsymbol{q})$. By the inverse function theorem, $g(\boldsymbol{p}, \boldsymbol{q}) = (\boldsymbol{P}, \boldsymbol{Q})$ is a local canonical transformation with the generating function S. It follows from (2.11) that $H(\boldsymbol{p}(\boldsymbol{P}, \boldsymbol{Q}), \boldsymbol{q}(\boldsymbol{P}, \boldsymbol{Q})) = K(\boldsymbol{P})$, so that Hamilton's equations take the form (2.10). Since $\omega = d\boldsymbol{P} \wedge d\boldsymbol{Q}$, integrals of motion $P_1(\boldsymbol{p}, \boldsymbol{q}), ..., P_n(\boldsymbol{p}, \boldsymbol{q})$ are in involution.

The solution of the Hamilton-Jacobi equation satisfying conditions in Theorem 2.10 is called the complete integral. At first glance it seems that solving the Hamilton-Jacobi equation, which is a nonlinear partial differential equation, is a more difficult problem then solving Hamilton's equations, which is a system of ordinary differential equations. It is quite remarkable that for many problems of classical mechanics one can find the complete integral of the Hamilton-Jacobi equation by the method of separation of variables. By Theorem 2.10, this solves the corresponding Hamilton's equations.

Problem 2.6. Find the generating function for the identity transformation $\boldsymbol{P} = p, Q = q$.

Problem 2.7. Prove Proposition 2.4.

Problem 2.8. Suppose that the canonical transformation $g(\boldsymbol{p}, \boldsymbol{q}) = (\boldsymbol{P}, \boldsymbol{Q})$ is such that locally $(\boldsymbol{Q}, \boldsymbol{q})$ can be considered as new coordinates (canonical transformations with this property are called free). Prove that $S_1(\boldsymbol{Q}, \boldsymbol{q}) = F(\boldsymbol{p}, \boldsymbol{q})$, also called a generating function, satisfies

$$\boldsymbol{p} = \frac{\partial S_1}{\partial \boldsymbol{q}} \quad \text{and} \quad \boldsymbol{P} = -\frac{\partial S_1}{\partial \boldsymbol{Q}}$$

Problem 2.9. Find the complete integral for the case of a particle in $\mathbb{R}^3$ moving in a central field.

2.6. Symplectic manifolds. The notion of a symplectic manifold is a generalization of the example of a cotangent bundle T^*M.

Definition. A non-degenerate, closed 2 -form ω on a manifold $\mathscr{M}$ is called a symplectic form, and the pair $(\mathscr{M}, \omega)$ is called a symplectic manifold.

Since a symplectic form ω is non-degenerate, a symplectic manifold $\mathscr{M}$ is necessarily even-dimensional, $\dim \mathscr{M} = 2n$. The nowhere vanishing $2n$-form ω^n defines a canonical orientation on $\mathscr{M}$, and as in the case $\mathscr{M} = T^*M$, $\frac{\omega^n}{n!}$ is called Liouville's volume form. We also have the general notion of a Lagrangian submanifold.

Definition. A submanifold $\mathscr{L}$ of a symplectic manifold $(\mathscr{M}, \omega)$ is called a Lagrangian submanifold, if $\dim \mathscr{L} = \frac{1}{2} \dim \mathscr{M}$ and the restriction of the symplectic form ω to $\mathscr{L}$ is 0 .

Symplectic manifolds form a category. A morphism between $(\mathscr{M}_1, \omega_1)$ and $(\mathscr{M}_2, \omega_2)$, also called a symplectomorphism, is a mapping $f : \mathscr{M}_1 \to \mathscr{M}_2$ such that $\omega_1 = f^*(\omega_2)$. When $\mathscr{M}_1 = \mathscr{M}_2$ and $\omega_1 = \omega_2$, the notion of a symplectomorphism generalizes the notion of a canonical transformation. The direct product of symplectic manifolds $(\mathscr{M}_1, \omega_1)$ and $(\mathscr{M}_2, \omega_2)$ is a symplectic manifold

$$(\mathscr{M}_1 \times \mathscr{M}_2, \pi_1^*(\omega_1) + \pi_2^*(\omega_2))$$

where π_1 and π_2 are, respectively, projections of $\mathscr{M}_1 \times \mathscr{M}_2$ onto the first and second factors in the Cartesian product.

Besides cotangent bundles, another important class of symplectic manifolds is given by Khler manifolds [17]. Recall that a complex manifold $\mathscr{M}$ is a Khler manifold if it carries the Hermitian metric whose imaginary part is a closed (1,1)-form. In local complex coordinates $\boldsymbol{z} = (z^1, ..., z^n)$ on $\mathscr{M}$ the Hermitian metric is written as

$$h = \sum_{\alpha,\beta=1}^{n} h_{\alpha\bar{\beta}}(\boldsymbol{z}, \overline{\boldsymbol{z}}) dz^\alpha \otimes d\bar{z}^\beta.$$

Correspondingly,

$$g = \operatorname{Re} h = \frac{1}{2} \sum_{\alpha,\beta=1}^{n} h_{\alpha\bar{\beta}}(\boldsymbol{z}, \overline{\boldsymbol{z}}) \left(dz^\alpha \otimes d\bar{z}^\beta + d\bar{z}^\beta \otimes dz^\alpha \right)$$

is the Riemannian metric on $\mathscr{M}$ and

$$\omega = -\operatorname{Im} h = \frac{i}{2} \sum_{\alpha,\beta=1}^{n} h_{\alpha\bar{\beta}}(\boldsymbol{z}, \overline{\boldsymbol{z}}) dz^\alpha \wedge d\bar{z}^\beta$$

is the symplectic form on $\mathscr{M}$ (considered as a $2n$-dimensional real manifold).
The simplest compact Khler manifold is $\mathbb{C}P^1 \simeq S^2$ with the symplectic form given by the area 2 -form of the Hermitian metric of Gaussian curvature 1 - the round metric on the 2 -sphere. In terms of the local coordinate z associated with the stereographic projection $\mathbb{C}P^1 \simeq \mathbb{C} \cup \{\infty\}$,

$$\omega = 2i \frac{dz \wedge d\bar{z}}{(1 + |z|^2)^2}$$

Similarly, the natural symplectic form on the complex projective space $\mathbb{C}P^n$ is the symplectic form of the Fubini-Study metric. By pull-back, it defines symplectic forms on complex projective varieties.

The simplest non-compact Khler manifold is the n-dimensional complex vector space $\mathbb{C}^n$ with the standard Hermitian metric. In complex coordinates $\boldsymbol{z} = (z^1, ..., z^n)$ on $\mathbb{C}^n$ it is given by

$$h = d\boldsymbol{z} \otimes d\overline{\boldsymbol{z}} = \sum_{\alpha=1}^{n} dz^\alpha \otimes d\bar{z}^\alpha.$$

In terms of real coordinates $(\boldsymbol{x}, \boldsymbol{y}) = (x^1, ..., x^n, y^1, ..., y^n)$ on $\mathbb{R}^{2n} \simeq \mathbb{C}^n$, where $\boldsymbol{z} = \boldsymbol{x} + i\boldsymbol{y}$, the corresponding symplectic form $\omega = -\operatorname{Im} h$ has the canonical form

$$\omega = \frac{i}{2} d\boldsymbol{z} \wedge d\overline{\boldsymbol{z}} = \sum_{\alpha=1}^{n} dx^\alpha \wedge dy^\alpha = d\boldsymbol{x} \wedge d\boldsymbol{y}$$

[017] Needless to say, not every symplectic manifold admits a complex structure, not to mention a Khler structure.

This example naturally leads to the following definition.

Definition. A symplectic vector space is a pair (V, ω), where V is a vector space over $\mathbb{R}$ and ω is a non-degenerate, skew-symmetric bilinear form on V.

It follows from basic linear algebra that every symplectic vector space V has a symplectic basis - a basis $e^1, ..., e^n, f_1, ..., f_n$ of V, where $2n = \dim V$, such that

$$\omega\left(e^i, e^j\right) = \omega\left(f_i, f_j\right) = 0 \quad \text{and} \quad \omega\left(e^i, f_j\right) = \delta^i_j, \quad i, j = 1, ..., n.$$

In coordinates $(\boldsymbol{p}, \boldsymbol{q}) = (p_1, ..., p_n, q^1, ..., q^n)$ corresponding to this basis, $V \simeq \mathbb{R}^{2n}$ and

$$\omega = d\boldsymbol{p} \wedge d\boldsymbol{q} = \sum_{i=1}^{n} dp_i \wedge dq^i$$

Thus every symplectic vector space is isomorphic to a direct product of the phase planes $\mathbb{R}^2$ with the canonical symplectic form $dp \wedge dq$. Introducing complex coordinates $\boldsymbol{z} = \boldsymbol{p} + i\boldsymbol{q}$, we get the isomorphism $V \simeq \mathbb{C}^n$, so that every symplectic vector space admits a Khler structure.

It is a basic fact of symplectic geometry that every symplectic manifold is locally isomorphic to a symplectic vector space.

Theorem 2.11 (Darboux' theorem). Let $(\mathscr{M}, \omega)$ be a $2n$-dimensional symplectic manifold. For every point $x \in \mathscr{M}$ there is a neighborhood U of x with local coordinates $(\boldsymbol{p}, \boldsymbol{q}) = (p_1, ..., p_n, q^1, ..., q^n)$ such that on U

$$\omega = d\boldsymbol{p} \wedge d\boldsymbol{q} = \sum_{i=1}^{n} dp_i \wedge dq^i$$

Coordinates $\boldsymbol{p}, \boldsymbol{q}$ are called canonical coordinates (Darboux coordinates). The proof proceeds by induction on n with the two main steps stated as Problems 2.13 and 2.14.

A non-degenerate 2-form ω for every $x \in \mathscr{M}$ defines an isomorphism $J : T^*_x\mathscr{M} \to T_x\mathscr{M}$ by

$$\omega\left(u_1, u_2\right) = J^{-1}\left(u_2\right)\left(u_1\right), u_1, u_2 \in T_x\mathscr{M}.$$

Explicitly, for every $X \in \mathrm{Vect}(\mathscr{M})$ and $\vartheta \in \mathcal{A}^1(\mathscr{M})$ we have

$$\omega(X, J(\vartheta)) = \vartheta(X) \quad \text{and} \quad J^{-1}(X) = -i_X(\omega)$$

(cf. Section 2.1). In local coordinates $\boldsymbol{x} = (x^1, ..., x^{2n})$ for the coordinate chart (U, φ) on $\mathscr{M}$, the 2 -form ω is given by

$$\omega = \frac{1}{2} \sum_{i,j=1}^{2n} \omega_{ij}(\boldsymbol{x}) dx^i \wedge dx^j,$$

where $\{\omega_{ij}(\boldsymbol{x})\}_{i,j=1}^{2n}$ is a non-degenerate, skew-symmetric matrix-valued function on $\varphi(U)$. Denoting the inverse matrix by $\{\omega^{ij}(\boldsymbol{x})\}_{i,j=1}^{2n}$, we have

$$J\left(dx^i\right) = -\sum_{j=1}^{2n} \omega^{ij}(\boldsymbol{x}) \frac{\partial}{\partial x^j}, \quad i = 1, ..., 2n$$

Definition. A Hamiltonian system is a pair consisting of a symplectic manifold $(\mathscr{M}, \omega)$, called a phase space, and a smooth real-valued function H on $\mathscr{M}$, called a Hamiltonian. The motion of points on the phase space is described by the vector field

$$X_H = J(dH)$$

called a Hamiltonian vector field.
The trajectories of a Hamiltonian system $((\mathscr{M},\omega),H)$ are the integral curves of a Hamiltonian vector field X_H on $\mathscr{M}$. In canonical coordinates $(\boldsymbol{p},\boldsymbol{q})$ they are described by the canonical Hamilton's equations (2.1),

$$\dot{\boldsymbol{p}}=-\frac{\partial H}{\partial \boldsymbol{q}},\quad \dot{\boldsymbol{q}}=\frac{\partial H}{\partial \boldsymbol{p}}$$

Suppose now that the Hamiltonian vector field X_H on $\mathscr{M}$ is complete. The Hamiltonian phase flow on $\mathscr{M}$ associated with a Hamiltonian H is a oneparameter group $\{g_t\}_{t\in\mathbb{R}}$ of diffeomorphisms of $\mathscr{M}$ generated by X_H. The following statement generalizes Theorem 2.1.

Theorem 2.12. The Hamiltonian phase flow preserves the symplectic form.
Proof. It is sufficient to show that $\mathcal{L}_{X_H}\omega=0$. Using Cartan's formula

$$\mathcal{L}_X=i_X\circ d+d\circ i_X$$

and $d\omega=0$, we get for every $X\in \mathrm{Vect}(\mathscr{M})$,

$$\mathcal{L}_X\omega=(d\circ i_X)(\omega)$$

Since $i_X(\omega)(Y)=\omega(X,Y)$, we have for $X=X_H$ and every $Y\in\mathrm{Vect}(\mathscr{M})$ that

$$i_{X_H}(\omega)(Y)=\omega(J(dH),Y)=-dH(Y).$$

Thus $i_{X_H}(\omega)=-dH$, and the statement follows from $d^2=0$.
Corollary 2.13. A vector field X on $\mathscr{M}$ is a Hamiltonian vector field if and only if the 1 -form $i_X(\omega)$ is exact.

Definition. A vector field X on a symplectic manifold $(\mathscr{M},\omega)$ is called a symplectic vector field if the 1 -form $i_X(\omega)$ is closed, which is equivalent to $\mathscr{L}_X\omega=0$.

The commutative algebra $C^\infty(\mathscr{M})$, with a multiplication given by the point-wise product of functions, is called the algebra of classical observables. Assuming that the Hamiltonian phase flow g_t exists for all times, the time evolution of every observable $f\in C^\infty(\mathscr{M})$ is given by

$$f_t(x)=f\left(g_t(x)\right),\quad x\in\mathscr{M},$$

and is described by the differential equation

$$\frac{df_t}{dt}=X_H\left(f_t\right)$$

- Hamilton's equation for classical observables. Hamilton's equations for observables on $\mathscr{M}$ have the same form as Hamilton's equations on $\mathscr{M}=T^*M$, considered in Section 2.3. Since

$$X_H(f)=df\left(X_H\right)=\omega\left(X_H,J(df)\right)=\omega\left(X_H,X_f\right),$$

we have the following.

Definition. A Poisson bracket on the algebra $C^\infty(\mathscr{M})$ of classical observables on a symplectic manifold $(\mathscr{M},\omega)$ is a bilinear mapping $\{,\}:C^\infty(\mathscr{M})\times C^\infty(\mathscr{M})\to C^\infty(\mathscr{M})$, defined by

$$\{f,g\}=\omega\left(X_f,X_g\right),\quad f,g\in C^\infty(\mathscr{M}).$$

Now Hamilton's equation takes the concise form

$$\frac{df}{dt} = \{H, f\}, \tag{2.12}$$

understood as a differential equation for a family of functions f_t on $\mathscr{M}$ with the initial condition $f_t|_{t=0} = f$. In local coordinates $\boldsymbol{x} = (x^1, ..., x^{2n})$ on $\mathscr{M}$,

$$\{f, g\}(\boldsymbol{x}) = -\sum_{i,j=1}^{2n} \omega^{ij}(\boldsymbol{x}) \frac{\partial f(\boldsymbol{x})}{\partial x^i} \frac{\partial g(\boldsymbol{x})}{\partial x^j}.$$

Theorem 2.14. The Poisson bracket $\{,\}$ *on a symplectic manifold* $(\mathscr{M}, \omega)$ is skew-symmetric and satisfies Leibniz rule and the Jacobi identity.

Proof. The first two properties are obvious. It follows from the definition of a Poisson bracket and the formula

$$[X_f, X_g](h) = (X_g X_f - X_f X_g)(h) = \{g, \{f, h\}\} - \{f, \{g, h\}\}$$

that the Jacobi identity is equivalent to the property

$$[X_f, X_g] = X_{\{f,g\}} \tag{2.13}$$

Let X and Y be symplectic vector fields. Using Cartan's formulas we get

$$\begin{aligned} i_{[X,Y]}(\omega) &= \mathcal{L}_X (i_Y(\omega)) - i_Y (\mathcal{L}_X(\omega)) \\ &= d (i_X \circ i_Y(\omega)) + i_X d (i_Y(\omega)) \\ &= d(\omega(Y, X)) = i_Z(\omega) \end{aligned}$$

where Z is a Hamiltonian vector field corresponding to $\omega(X, Y) \in C^\infty(\mathscr{M})$. Since the 2-form ω is non-degenerate, this implies $[X, Y] = Z$, so that setting $X = X_f, Y = X_g$ and using $\{f, g\} = \omega(X_f, X_g)$, we get (2.13).

From (2.13) we immediately get the following result.

Corollary 2.15. The subspace $\mathrm{Ham}(\mathscr{M})$ of Hamiltonian vector fields on $\mathscr{M}$ is a Lie subalgebra of $\mathrm{Vect}(\mathscr{M})$. The mapping $C^\infty(\mathscr{M}) \to \mathrm{Ham}(\mathscr{M})$, given by $f \mapsto X_f$, is a Lie algebra homomorphism with the kernel consisting of locally constant functions on $\mathscr{M}$.

As in the case $\mathscr{M} = T^*M$ (see Section 2.4), an observable I - a function on the phase space $\mathscr{M}$ - is called an integral of motion (first integral) for the Hamiltonian system $((\mathscr{M}, \omega), H)$ if it is constant along the Hamiltonian phase flow. According to (2.12), this is equivalent to the condition

$$\{H, I\} = 0. \tag{2.14}$$

It is said that the observables H and I are in involution (Poisson commute). From the Jacobi identity for the Poisson bracket we get the following result.

Corollary 2.16 (Poisson's theorem). The Poisson bracket of two integrals of motion is an integral of motion.

Proof. If $\{H, I_1\} = \{H, I_2\} = 0$, then

$$\{H, \{I_1, I_2\}\} = \{\{H, I_1\}, I_2\} - \{\{H, I_2\}, I_1\} = 0.$$

It follows from Poisson's theorem that integrals of motion form a Lie algebra and, by (2.13), corresponding Hamiltonian vector fields form a Lie subalgebra in $\mathrm{Vect}(\mathscr{M})$. Since $\{I, H\} = dH(X_I) = 0$, the vector fields X_I are tangent to submanifolds $\mathscr{M}_E = \{x \in \mathscr{M} : H(x) = E\}$ - the level sets of the Hamiltonian H. This defines a Lie algebra of integrals of motion for the Hamiltonian system $((\mathscr{M}, \omega), H)$ at the level set $\mathscr{M}_E$.

Let G be a finite-dimensional Lie group that acts on a connected symplectic manifold $(\mathscr{M}, \omega)$ by symplectomorphisms. The Lie algebra $\mathfrak{g}$ of G acts on $\mathscr{M}$ by vector fields

$$X_\xi(f)(x) = \left.\frac{d}{ds}\right|_{s=0} f\left(e^{-s\xi} \cdot x\right)$$

and the linear mapping $\mathfrak{g} \ni \xi \mapsto X_\xi \in \mathrm{Vect}(\mathscr{M})$ is a homomorphism of Lie algebras,

$$[X_\xi, X_\eta] = X_{[\xi,\eta]}, \quad \xi, \eta \in \mathfrak{g}.$$

The G-action is called a Hamiltonian action if X_ξ are Hamiltonian vector fields, i.e., for every $\xi \in \mathfrak{g}$ there is $\Phi_\xi \in C^\infty(\mathscr{M})$, defined up to an additive constant, such that $X_\xi = X_{\Phi_\xi} = J\,(d\Phi_\xi)$. It is called a Poisson action if there is a choice of functions Φ_ξ such that the linear mapping $\Phi : \mathfrak{g} \to C^\infty(\mathscr{M})$ is a homomorphism of Lie algebras,

$$\{\Phi_\xi, \Phi_\eta\} = \Phi_{[\xi,\eta]}, \quad \xi, \eta \in \mathfrak{g}. \tag{2.15}$$

Definition. A Lie group G is a symmetry group of the Hamiltonian system $((\mathscr{M}, \omega), H)$ if there is a Hamiltonian action of G on $\mathscr{M}$ such that

$$H(g \cdot x) = H(x), \quad g \in G, x \in \mathscr{M}.$$

Theorem 2.17 (Noether theorem with symmetries). If G is a symmetry group of the Hamiltonian system $((\mathscr{M}, \omega), H)$, then the functions $\Phi_\xi, \xi \in \mathfrak{g}$, are the integrals of motion. If the action of G is Poisson, the integrals of motion satisfy (2.15).

Proof. By definition of the Hamiltonian action, for every $\xi \in \mathfrak{g}$,

$$0 = X_\xi(H) = X_{\Phi_\xi}(H) = \{\Phi_\xi, H\}$$

Corollary 2.18. Let (M, L) be a Lagrangian system such that the Legendre transform $\tau_L : TM \to T^*M$ is a diffeomorphism. Then if a Lie group G is a symmetry of (M, L), then G is a symmetry group of the corresponding Hamiltonian system $\left((T^*M, \omega), H = E_L \circ \tau_L^{-1}\right)$, and the corresponding G action on T^*M is Poisson. In particular, $\Phi_\xi = -I_\xi \circ \tau_L^{-1}$, where I_ξ are Noether integrals of motion for the one-parameter subgroups of G generated by $\xi \in \mathfrak{g}$.

Proof. Let X be the vector field associated with the one-parameter subgroup $\left\{e^{s\xi}\right\}_{s\in\mathbb{R}}$ of diffeomorphisms of M, used in Theorem 1.3, and let X' be its lift to TM. We have [18]

$$X_\xi = -\left(\tau_L\right)_* (X') \tag{2.16}$$

and it follows from (1.16) that $\Phi_\xi = i_{X_\xi}(\theta) = \theta\,(X_\xi)$, where θ is the canonical Liouville 1-form on T^*M. From Cartan's formula and (1.17) we get

$$d\Phi_\xi = d\left(i_{X_\xi}(\theta)\right) = -i_{X_\xi}(d\theta) + \mathcal{L}_{X_\xi}(\theta) = -i_{X_\xi}(\omega)$$

so that

$$J\,(d\Phi_\xi) = -J\left(i_{X_\xi}(\omega)\right) = X_\xi$$

and the G-action is Hamiltonian. Using (1.17) and another Cartan's formula, we obtain

$$\begin{aligned}\Phi_{[\xi,\eta]} = i_{\left[X_\xi, X_\eta\right]}(\theta) &= \mathcal{L}_{X_\xi}\left(i_{X_\eta}(\theta)\right) + i_{X_\eta}\left(\mathcal{L}_{X_\xi}(\theta)\right) \\ &= X_\xi\left(\Phi_\eta\right) = \left\{\Phi_\xi, \Phi_\eta\right\}.\end{aligned}$$

[018] The negative sign reflects the difference in definitions of X and X_ξ.

Example 2.1. The Lagrangian

$$L = \frac{1}{2}m\dot{\boldsymbol{r}}^2 - V(r)$$

for a particle in $\mathbb{R}^3$ moving in a central field (see Section 1.6) is invariant with respect to the action of the group SO(3) of orthogonal transformations of the Euclidean space $\mathbb{R}^3$. Let u_1, u_2, u_3 be a basis for the Lie algebra $\mathfrak{so}(3)$ corresponding to the rotations with the axes given by the vectors of the standard basis e_1, e_2, e_3 for $\mathbb{R}^3$ (see Example 1.10 in Section 1.4). These generators satisfy the commutation relations

$$[u_i, u_j] = \varepsilon_{ijk}u_k$$

where $i, j, k = 1, 2, 3$, and ε_{ijk} is a totally anti-symmetric tensor, $\varepsilon_{123} = 1$. Corresponding Noether integrals of motion are given by $\Phi_{u_i} = -M_i$, where

$$\begin{aligned} M_1 &= (\boldsymbol{r} \times \boldsymbol{p})_1 = r_2p_3 - r_3p_2, \\ M_2 &= (\boldsymbol{r} \times \boldsymbol{p})_2 = r_3p_1 - r_1p_3, \\ M_3 &= (\boldsymbol{r} \times \boldsymbol{p})_3 = r_1p_2 - r_2p_1 \end{aligned}$$

are components of the angular momentum vector $\boldsymbol{M} = \boldsymbol{r} \times \boldsymbol{p}$. (Here it is convenient to lower the indices of the coordinates r_i by the Euclidean metric on $\mathbb{R}^3$.) For the Hamiltonian

$$H = \frac{\boldsymbol{p}^2}{2m} + V(r)$$

we have

$$\{H, M_i\} = 0$$

According to Theorem 2.17 and Corollary 2.18, Poisson brackets of the components of the angular momentum satisfy

$$\{M_i, M_j\} = -\varepsilon_{ijk}M_k,$$

which is also easy to verify directly using (2.6),

$$\{f, g\}(\boldsymbol{p}, \boldsymbol{r}) = \frac{\partial f}{\partial \boldsymbol{p}}\frac{\partial g}{\partial \boldsymbol{r}} - \frac{\partial f}{\partial \boldsymbol{r}}\frac{\partial g}{\partial \boldsymbol{p}}$$

Example 2.2 (Kepler's problem). For every $\alpha \in \mathbb{R}$ the Lagrangian system on $\mathbb{R}^3$ with

$$L = \frac{1}{2}m\dot{r}^2 + \frac{\alpha}{r}$$

has three extra integrals of motion - the components W_1, W_2, W_3 of the Laplace-Runge-Lenz vector, given by

$$\boldsymbol{W} = \frac{\boldsymbol{p}}{m} \times \boldsymbol{M} - \frac{\alpha \boldsymbol{r}}{r}$$

(see Section 1.6). Using Poisson brackets from the previous example, together with $\{r_i, M_j\} = -\varepsilon_{ijk}r_k$ and $\{p_i, M_j\} = -\varepsilon_{ijk}p_k$, we get by a straightforward computation,

$$\{W_i, M_j\} = -\varepsilon_{ijk}W_k \quad \text{and} \quad \{W_i, W_j\} = \frac{2H}{m}\varepsilon_{ijk}M_k$$

where $H = \frac{\boldsymbol{p}^2}{2m} - \frac{\alpha}{r}$ is the Hamiltonian of Kepler's problem.
The Hamiltonian system $((\mathscr{M}, \omega), H), \dim \mathscr{M} = 2n$, is called completely integrable if it has

n independent integrals of motion $F_1 = H, ..., F_n$ in involution. The former condition means that $dF_1(x), ..., dF_n(x) \in T_x^*\mathscr{M}$ are linearly independent for almost all $x \in \mathscr{M}$. Hamiltonian systems with one degree of freedom such that dH has only finitely many zeros are completely integrable. Complete separation of variables in the Hamilton-Jacobi equation (see Section 2.5) provides other examples of completely integrable Hamiltonian systems.

Let $((\mathscr{M}, \omega), H)$ be a completely integrable Hamiltonian system. Suppose that the level set $\mathscr{M}_f = \{x \in \mathscr{M} : F_1(x) = f_1, ..., F_n(x) = f_n\}$ is compact and tangent vectors $JdF_1, ..., JdF_n$ are linearly independent for all $x \in \mathscr{M}_f$. Then by the Liouville-Arnold theorem, in a neighborhood of $\mathscr{M}_f$ there exist so-called action-angle variables: coordinates $\boldsymbol{I} = (I_1, ..., I_n) \in \mathbb{R}_+^n = (\mathbb{R}_{>0})^n$ and $\varphi = (\varphi_1, ..., \varphi_n) \in T^n = (\mathbb{R}/2\pi\mathbb{Z})^n$ such that $\omega = d\boldsymbol{I} \wedge d\varphi$ and $H = H(I_1, ..., I_n)$. According to Hamilton's equations,

$$\dot{I}_i = 0 \quad \text{and} \quad \dot{\varphi}_i = \omega_i = \frac{\partial H}{\partial I_i}, \quad i = 1, ..., n$$

so that action variables are constants, and angle variables change uniformly, $\varphi_i(t) = \varphi_i(0) + \omega_i t, i = 1, ..., n$. The classical motion is almost-periodic with the frequencies $\omega_1, ..., \omega_n$.

Problem 2.10. Show that a symplectic manifold $(\mathscr{M}, \omega)$ admits an almost complex structure: a bundle map $\mathscr{J} : T\mathscr{M} \to T\mathscr{M}$ such that $\mathscr{J}^2 = -\mathrm{id}$.

Problem 2.11. Give an example of a symplectic manifold which admits a complex structure but not a Khler structure.

Problem 2.12 (Coadjont orbits). Let G be a finite-dimensional Lie group, let $\mathfrak{g}$ be its Lie algebra, and let $\mathfrak{g}^*$ be the dual vector space to $\mathfrak{g}$. For $u \in \mathfrak{g}^*$ let $\mathscr{M} = \mathcal{O}_u$ be the orbit of u under the coadjoint action of G on $\mathfrak{g}^*$. Show that the formula

$$\omega(u_1, u_2) = u([x_1, x_2]),$$

where $u_1 = \mathrm{ad}^* x_1(u), u_2 = \mathrm{ad}^* x_2(u) \in \mathcal{O}_u$, and ad* stands for the coadjoint action of a Lie algebra $\mathfrak{g}$ on $\mathfrak{g}^*$, gives rise to a well-defined 2 -form on $\mathscr{M}$, which is closed and non-degenerate. (The 2 -form ω is called the Kirillov-Kostant symplectic form.)

Problem 2.13. Let $(\mathscr{M}, \omega)$ be a symplectic manifold. For $x \in \mathscr{M}$ choose a function q^1 on $\mathscr{M}$ such that $q^1(x) = 0$ and dq^1 does not vanish at x, and set $X = -X_{q^1}$. Show that there is a neighborhood U of $x \in \mathscr{M}$ and a function p_1 on U such that $X(q^1) = 1$ on U, and there exist coordinates $p_1, q^1, z^1, ..., z^{2n-2}$ on U such that

$$X = \frac{\partial}{\partial p_1} \quad \text{and} \quad Y = X_{p_1} = \frac{\partial}{\partial q^1}$$

Problem 2.14. Continuing Problem 2.13, show that the 2 -form $\omega - dp_1 \wedge dq^1$ on U depends only on coordinates $z^1, ..., z^{2n-2}$ and is non-degenerate.

Problem 2.15. Do the computation in Example 2.2 and show that the Lie algebra of the integrals $M_1, M_2, M_3, W_1, W_2, W_3$ in Kepler's problem at $H(\boldsymbol{p}, \boldsymbol{r}) = E$ is isomorphic to the Lie algebra $\mathfrak{so}(4)$, if $E < 0$, to the Euclidean Lie algebra $\mathfrak{e}(3)$, if $E = 0$, and to the Lie algebra $\mathfrak{so}(1, 3)$, if $E > 0$.

Problem 2.16. Find the action-angle variables for a particle with one degree of freedom, when the potential $V(x)$ is a convex function on $\mathbb{R}$ satisfying $\lim_{|x|\to\infty} V(x) = \infty$. (Hint: Define $I = \oint p dx$, where integration goes over the closed orbit with $H(p, x) = E$.)

Problem 2.17. Show that a Hamiltonian system describing a particle in $\mathbb{R}^3$ moving in a central field is completely integrable, and find the action-angle variables.

Problem 2.18 (Symplectic quotients). For a Poisson action of a Lie group G on a symplectic manifold $(\mathscr{M}, \omega)$, define the moment map $P : \mathscr{M} \to \mathfrak{g}^*$ by

$$P(x)(\xi) = \Phi_\xi(x), \xi \in \mathfrak{g}, x \in \mathscr{M},$$

where $\mathfrak{g}$ is the Lie algebra of G. For every $p \in \mathfrak{g}^*$ such that a stabilizer G_p of p acts freely and properly on $\mathscr{M}_p = P^{-1}(p)$ (such p is called the regular value of the moment map), the quotient $M_p = G_p \backslash \mathscr{M}_p$ is called a reduced phase space. Show that M_p is a symplectic manifold with the symplectic form uniquely characterized by the condition that its pull-back to $\mathscr{M}_p$ coincides with the restriction to $\mathscr{M}_p$ of the symplectic form ω.

2.7. Poisson manifolds.

The notion of a Poisson manifold generalizes the notion of a symplectic manifold.

Definition. A Poisson manifold is a manifold $\mathscr{M}$ equipped with a Poisson structure - a skew-symmetric bilinear mapping

$$\{,\} : C^\infty(\mathscr{M}) \times C^\infty(\mathscr{M}) \to C^\infty(\mathscr{M})$$

which satisfies the Leibniz rule and Jacobi identity.

Equivalently, $\mathscr{M}$ is a Poisson manifold if the algebra $\mathcal{A} = C^\infty(\mathscr{M})$ of classical observables is a Poisson algebra - a Lie algebra such that the Lie bracket is a bi-derivation with respect to the multiplication in $\mathcal{A}$ (a pointwise product of functions). It follows from the derivation property that in local coordinates $\boldsymbol{x} = \left(x^1, ..., x^N\right)$ on $\mathscr{M}$, the Poisson bracket has the form

$$\{f, g\}(\boldsymbol{x}) = \sum_{i,j=1}^{N} \eta^{ij}(\boldsymbol{x}) \frac{\partial f(\boldsymbol{x})}{\partial x^i} \frac{\partial g(\boldsymbol{x})}{\partial x^j}.$$

The 2-tensor $\eta^{ij}(\boldsymbol{x})$, called a Poisson tensor, defines a global section η of the vector bundle $T\mathscr{M} \wedge T\mathscr{M}$ over $\mathscr{M}$.

The evolution of classical observables on a Poisson manifold is given by Hamilton's equations, which have the same form as (2.12),

$$\frac{df}{dt} = X_H(f) = \{H, f\}.$$

The phase flow g_t for a complete Hamiltonian vector field $X_H = \{H, \cdot\}$ defines the evolution operator $U_t : \mathcal{A} \to \mathcal{A}$ by

$$U_t(f)(x) = f\left(g_t(x)\right), f \in \mathcal{A}.$$

Theorem 2.19. Suppose that every Hamiltonian vector field on a Poisson manifold $(\mathscr{M}, \{\},)is complete. Then for every H \in \mathcal{A}$, the corresponding evolution operator U_t is an automorphism of the Poisson algebra $\mathcal{A}$, i.e.,

$$U_t(\{f, g\}) = \{U_t(f), U_t(g)\} \quad \text{for all} \quad f, g \in \mathcal{A}. \tag{2.17}$$

Conversely, if a skew-symmetric bilinear mapping $\{\} :, C^\infty(\mathscr{M}) \times C^\infty(\mathscr{M}) \to C^\infty(\mathscr{M})$ is such that $X_H = \{H, \cdot\}$ are complete vector fields for all $H \in \mathcal{A}$, and corresponding evolution operators U_t satisfy (2.17), then $(\mathscr{M}, \{\},$ is a Poisson manifold.

Proof. Let $f_t = U_t(f), g_t = U_t(g)$, and [19] $h_t = U_t(\{f, g\})$. By definition,

$$\frac{d}{dt}\{f_t, g_t\} = \{\{H, f_t\}, g_t\} + \{f_t, \{H, g_t\}\} \quad \text{and} \quad \frac{dh_t}{dt} = \{H, h_t\}.$$

If $(\mathscr{M}, \{\},) is a Poisson manifold, then it follows from the Jacobi identity$ that

$$\{\{H, f_t\}, g_t\} + \{f_t, \{H, g_t\}\} = \{H, \{f_t, g_t\}\},$$

so that h_t and $\{f_t, g_t\}$ satisfy the same differential equation (2.12). Since these functions coincide at $t = 0$, (2.17) follows from the uniqueness theorem for the ordinary differential equations.

Conversely, we get the Jacobi identity for the functions f, g, and H by differentiating (2.17) with respect to t at $t = 0$.

Corollary 2.20. A global section η of $T\mathscr{M} \wedge T\mathscr{M}$ is a Poisson tensor if and only if

$$\mathcal{L}_{X_f}\eta = 0 \quad \text{for all} \quad f \in \mathcal{A}.$$

Definition. The center of a Poisson algebra $\mathcal{A}$ is

$$\mathcal{Z}(\mathcal{A}) = \{f \in \mathcal{A} : \{f, g\} = 0 \quad \text{for all } g \in \mathcal{A}\}$$

A Poisson manifold $(\mathscr{M}, \{,\})is called non-degenerate if the center of a$ Poisson algebra of classical observables $\mathcal{A} = C^\infty(\mathscr{M})$ consists only of locally constant functions ($\mathcal{Z}(\mathcal{A}) = \mathbb{R}$ for connected $\mathscr{M}$).

Equivalently, a Poisson manifold $(\mathscr{M}, \{\},)is non-degenerate if the Pois$ - son tensor η is non-degenerate everywhere on $\mathscr{M}$, so that $\mathscr{M}$ is necessarily an even-dimensional manifold. A non-degenerate Poisson tensor for every $x \in \mathscr{M}$ defines an isomorphism $J : T_x^*\mathscr{M} \to T_x\mathscr{M}$ by

$$\eta(u_1, u_2) = u_2(J(u_1)), u_1, u_2 \in T_x^*\mathscr{M}.$$

In local coordinates $\boldsymbol{x} = \left(x^1, ..., x^N\right)$ for the coordinate chart (U, φ) on $\mathscr{M}$, we have

$$J\left(dx^i\right) = \sum_{j=1}^{N} \eta^{ij}(\boldsymbol{x}) \frac{\partial}{\partial x^j}, \quad i = 1, ..., N$$

Poisson manifolds form a category. A morphism between $(\mathscr{M}_1, \{,\}_1)$ and $(\mathscr{M}_2, \{,\}_2)$ is a mapping $\varphi : \mathscr{M}_1 \to \mathscr{M}_2$ of smooth manifolds such that

$$\{f \circ \varphi, g \circ \varphi\}_1 = \{f, g\}_2 \circ \varphi \quad \text{for all } f, g \in C^\infty(\mathscr{M}_2)$$

A direct product of Poisson manifolds $(\mathscr{M}_1, \{,\}_1)$ and $(\mathscr{M}_2, \{,\}_2)$ is a Poisson manifold $(\mathscr{M}_1 \times \mathscr{M}_2, \{\},)$ defined by the property that natural projection maps $\pi_1 : \mathscr{M}_1 \times \mathscr{M}_2 \to \mathscr{M}_1$ and $\pi_2 : \mathscr{M}_1 \times \mathscr{M}_2 \to \mathscr{M}_2$ are Poisson mappings. For $f \in C^\infty(\mathscr{M}_1 \times \mathscr{M}_2)$ and $(x_1, x_2) \in \mathscr{M}_1 \times \mathscr{M}_2$ denote, respectively, by $f_{x_2}^{(1)}$ and $f_{x_1}^{(2)}$ restrictions of f to $\mathscr{M} \times \{x_2\}$ and $\{x_1\} \times \mathscr{M}_2$. Then for $f, g \in C^\infty(\mathscr{M}_1 \times \mathscr{M}_2)$,

$$\{f, g\}(x_1, x_2) = \left\{f_{x_2}^{(1)}, g_{x_2}^{(1)}\right\}_1(x_1) + \left\{f_{x_1}^{(2)}, g_{x_1}^{(2)}\right\}_2(x_2)$$

Non-degenerate Poisson manifolds form a subcategory of the category of Poisson manifolds.

Theorem 2.21. The category of symplectic manifolds is (anti-) isomorphic to the category of non-degenerate Poisson manifolds.

Proof. According to Theorem 2.14, every symplectic manifold carries a Poisson structure. Its non-degeneracy follows from the non-degeneracy of a symplectic form. Conversely, let $(\mathscr{M}, \{\},)be a non-degenerate Poisson$ manifold. Define the 2 -form ω on $\mathscr{M}$ by

$$\omega(X, Y) = J^{-1}(Y)(X), \quad X, Y \in \mathrm{Vect}(\mathscr{M})$$

where the isomorphism $J : T^*\mathscr{M} \to T\mathscr{M}$ is defined by the Poisson tensor η. In local coordinates $\boldsymbol{x} = \left(x^1, ..., x^N\right)$ on $\mathscr{M}$,

[019] Here g_t is not the phase flow!

$$\omega = -\sum_{1\leq i<j\leq N} \eta_{ij}(\boldsymbol{x}) dx^i \wedge dx^j$$

where $\{\eta_{ij}(\boldsymbol{x})\}_{i,j=1}^N$ is the inverse matrix to $\{\eta^{ij}(\boldsymbol{x})\}_{i,j=1}^N$. The 2 -form ω is skew-symmetric and non-degenerate. For every $f \in \mathcal{A}$ let $X_f = \{f, \cdot\}$ be the corresponding vector field on $\mathscr{M}$. The Jacobi identity for the Poisson bracket $\{,\} is equivalent to \mathcal{L}_{X_f}\eta = 0$ for every $f \in \mathcal{A}$, so that

$$\mathcal{L}_{X_f}\omega = 0.$$

Since $X_f = Jdf$, we have $\omega(X, Jdf) = df(X)$ for every $X \in \mathrm{Vect}(\mathscr{M})$, so that

$$\omega\left(X_f, X_g\right) = \{f, g\}.$$

By Cartan's formula,

$$\begin{aligned} d\omega(X,Y,Z) =& \frac{1}{3}\left(\mathcal{L}_X\omega(Y,Z) - \mathcal{L}_Y\omega(X,Z) + \mathcal{L}_Z\omega(X,Y)\right. \\ & \left. - \omega([X,Y],Z) + \omega([X,Z],Y) - \omega([Y,Z],X)\right), \end{aligned}$$

where $X, Y, Z \in \mathrm{Vect}(\mathscr{M})$. Now setting $X = X_f, Y = X_g, Z = X_h$, we get

$$\begin{aligned} d\omega\left(X_f, X_g, X_h\right) &= \frac{1}{3}\left(\omega\left(X_h, [X_f, X_g]\right) + \omega\left(X_f, [X_g, X_h]\right) + \omega\left(X_g, [X_h, X_f]\right)\right) \\ &= \frac{1}{3}\left(\omega\left(X_h, X_{\{f,g\}}\right) + \omega\left(X_f, X_{\{g,h\}}\right) + \omega\left(X_g, X_{\{h,f\}}\right)\right) \\ &= \frac{1}{3}(\{h,\{f,g\}\} + \{f,\{g,h\}\} + \{g,\{h,f\}\}) \\ &= 0. \end{aligned}$$

The exact 1 -forms $df, f \in \mathcal{A}$, generate the vector space of 1 -forms $\mathcal{A}^1(\mathscr{M})$ as a module over $\mathcal{A}$, so that Hamiltonian vector fields $X_f = Jdf$ generate the vector space $\mathrm{Vect}(\mathscr{M})$ as a module over $\mathcal{A}$. Thus $d\omega = 0$ and $(\mathscr{M}, \omega)$ is a symplectic manifold associated with the Poisson manifold $(\mathscr{M}, \{\},)$. It follows from the definitions that Poisson mappings of non-degenerate Poisson manifolds correspond to symplectomorphisms of associated symplectic manifolds.

Remark. One can also prove this theorem by a straightforward computation in local coordinates $\boldsymbol{x} = \left(x^1, ..., x^N\right)$ on $\mathscr{M}$. Just observe that the condition

$$\frac{\partial \eta_{ij}(\boldsymbol{x})}{\partial x^l} + \frac{\partial \eta_{jl}(\boldsymbol{x})}{\partial x^i} + \frac{\partial \eta_{li}(\boldsymbol{x})}{\partial x^j} = 0, \quad i,j,l = 1, ..., N$$

which is a coordinate form of $d\omega = 0$, follows from the condition

$$\sum_{j=1}^N \left(\eta^{ij}(\boldsymbol{x})\frac{\partial \eta^{kl}(\boldsymbol{x})}{\partial x^j} + \eta^{lj}(\boldsymbol{x})\frac{\partial \eta^{ik}(\boldsymbol{x})}{\partial x^j} + \eta^{kj}(\boldsymbol{x})\frac{\partial \eta^{li}(\boldsymbol{x})}{\partial x^j}\right) = 0$$

which is a coordinate form of the Jacobi identity, by multiplying it three times by the inverse matrix $\eta_{ij}(\boldsymbol{x})$ using

$$\sum_{p=1}^N \left(\eta^{ip}(\boldsymbol{x})\frac{\partial \eta_{pk}(\boldsymbol{x})}{\partial x^j} + \frac{\partial \eta^{ip}(\boldsymbol{x})}{\partial x^j}\eta_{pk}(\boldsymbol{x})\right) = 0.$$

Remark. Let $\mathscr{M} = T^*\mathbb{R}^n$ with the Poisson bracket $\{,\} given by the canon$ - ical symplectic form $\omega = d\boldsymbol{p} \wedge d\boldsymbol{q}$, where $(\boldsymbol{p}, \boldsymbol{q}) = (p_1, ..., p_n, q^1, ..., q^n)$ are coordinate functions on $T^*\mathbb{R}^n$. The non-degeneracy of the Poisson manifold $(T^*\mathbb{R}^n, \{\},)$ can be formulated as the property that the only observable $f \in C^\infty\left(T^*\mathbb{R}^n\right)$ satisfying

$$\{f, p_1\} = \cdots = \{f, p_n\} = 0, \quad \{f, q^1\} = \cdots = \{f, q^n\} = 0$$

is $f(\boldsymbol{p}, \boldsymbol{q}) = \text{const}$.

Problem 2.19 (Dual space to a Lie algebra). Let $\mathfrak{g}$ be a finite-dimensional Lie algebra with a Lie bracket $[,]$, and let $\mathfrak{g}^*$ be its dual space. For $f, g \in C^\infty(\mathfrak{g}^*)$ define

$$\{f, g\}(u) = u([df, dg]),$$

where $u \in \mathfrak{g}^*$ and $T_u^*\mathfrak{g}^* \simeq \mathfrak{g}$. Prove that $\{,\}$ *is a Poisson bracket.* (*It was introduced* by Sophus Lie and is called a linear, or Lie-Poisson bracket.) Show that this bracket is degenerate and determine the center of $\mathcal{A} = C^\infty(\mathfrak{g}^*)$.

Problem 2.20. A Poisson bracket $\{,\}$ *on* $\mathscr{M}$ restricts to a Poisson bracket $\{,\}_0$ on a submanifold $\mathscr{N}$ if the inclusion $\imath : \mathscr{N} \to \mathscr{M}$ is a Poisson mapping. Show that the Lie-Poisson bracket on $\mathfrak{g}^*$ restricts to a non-degenerate Poisson bracket on a coadjoint orbit, associated with the Kirillov-Kostant symplectic form.

Problem 2.21 (Lie-Poisson groups). A finite-dimensional Lie group is called a Lie-Poisson group if it has a structure of a Poisson manifold $(G, \{\},)$ *such that* the group multiplication $G \times G \to G$ is a Poisson mapping, where $G \times G$ is a direct product of Poisson manifolds. Using a basis $\partial_1, ..., \partial_n$ of left-invariant vector fields on G corresponding to a basis $x_1, ..., x_n$ of the Lie algebra $\mathfrak{g}$, the Poisson bracket $\{,\}$ *can be written as*

$$\{f_1, f_2\}(g) = \sum_{i,j=1}^{n} \eta^{ij}(g) \partial_i f_1 \partial_j f_2,$$

where the 2-tensor $\eta^{ij}(g)$ defines a mapping $\eta : G \to \Lambda^2\mathfrak{g}$ by $\eta(g) = \sum_{i,j=1}^n \eta^{ij}(g) x_i \otimes x_j$. Show that the bracket $\{,\}$ *equips* G with a Lie-Poisson structure if and only if the following conditions are satisfied: (i) for all $g \in G$,

$$\xi^{ijk}(g) = \sum_{l=1}^{n} \left(\eta^{il}(g) \partial_l \eta^{jk}(g) + \eta^{jl}(g) \partial_l \eta^{ki}(g) + \eta^{kl}(g) \partial_l \eta^{ij}(g) \right)$$
$$+ \sum_{l,p=1}^{n} \left(c_{lp}^i \eta^{pj}(g) \eta^{kl}(g) + c_{lp}^j \eta^{pk}(g) \eta^{il}(g) + c_{lp}^k \eta^{pi}(g) \eta^{jl}(g) \right) = 0$$

where $[x_i, x_j] = \sum_{k=1}^n c_{ij}^k x_k$; (ii) the mapping η is a group 1-cocycle with the adjoint action on $\Lambda^2\mathfrak{g}$, i.e., $\eta(g_1 g_2) = \mathrm{Ad}^{-1} g_2 \cdot \eta(g_1) + \eta(g_2), g_1, g_2 \in G$.

Problem 2.22. Show that the second condition in the previous problem trivially holds when η is a coboundary, $\eta(g) = -r + \mathrm{Ad}^{-1} g \cdot r$ for some $r = \sum_{i,j=1}^n r^{ij} x_i \otimes x_j \in \Lambda^2\mathfrak{g}$, and then the first condition is satisfied if and only if the element

$$\xi(r) = [r_{12}, r_{13} + r_{23}] + [r_{13}, r_{23}] \in \Lambda^3\mathfrak{g}$$

is invariant under the adjoint action of $\mathfrak{g}$ on $\Lambda^3\mathfrak{g}$. Here $r_{12} = \sum_{i,j=1}^n r^{ij} x_i \otimes x_j \otimes 1$, $r_{13} = \sum_{i,j=1}^n r^{ij} x_i \otimes 1 \otimes x_j$, and $r_{23} = \sum_{i,j=1}^n r^{ij} 1 \otimes x_i \otimes x_j$ are corresponding elements in the universal enveloping algebra $U\mathfrak{g}$ of a Lie algebra $\mathfrak{g}$. In particular, G is a Lie-Poisson group if $\xi(r) = 0$, which is called the classical Yang-Baxter equation.

Problem 2.23. Suppose that $r = \sum_{i,j=1}^n r^{ij} x_i \otimes x_j \in \Lambda^2\mathfrak{g}$ is such that the matrix $\{r^{ij}\}$ is non-degenerate, and let $\{r_{ij}\}$ be the inverse matrix. Show that r satisfies the classical Yang-Baxter equation if and only if the map $c : \Lambda^2\mathfrak{g} \to \mathbb{C}$, defined by $c(x, y) = \sum_{i,j=1}^n r_{ij} u^i v^j$, where $x = \sum_{i=1}^n u^i x_i, y = \sum_{i=1}^n v^i x_i$, is a non-degenerate Lie algebra 2-cocycle, i.e., it satisfies

$$c(x, [y, z]) + c(z, [x, y]) + c(y, [z, x]) = 0, \quad x, y, z \in \mathfrak{g}.$$

2.8. Hamilton's and Liouville's representations.

To complete the formulation of classical mechanics, we need to describe the process of measurement. In physics, by a measurement of a classical system one understands the result of a physical experiment which gives numerical values for classical observables. The experiment consists of creating certain conditions for the system, and it is always assumed that these conditions can be repeated over and over. The conditions of the experiment define a state of the system if repeating these conditions results in probability distributions for the values of all observables of the system.

Mathematically, a state μ on the algebra $\mathcal{A} = C^\infty(\mathscr{M})$ of classical observables on the phase space $\mathscr{M}$ is the assignment

$$\mathcal{A} \ni f \mapsto \mu_f \in \mathscr{P}(\mathbb{R}),$$

where $\mathscr{P}(\mathbb{R})$ is a set of probability measures on $\mathbb{R}$ - Borel measures on $\mathbb{R}$ such that the total measure of $\mathbb{R}$ is 1 . For every Borel subset $E \subseteq \mathbb{R}$ the quantity $0 \leq \mu_f(E) \leq 1$ is a probability that in the state μ the value of the observable f belongs to E. By definition, the expectation value of an observable f in the state μ is given by the Lebesgue-Stieltjes integral

$$\mathrm{E}_\mu(f) = \int_{-\infty}^{\infty} \lambda d\mu_f(\lambda)$$

where $\mu_f(\lambda) = \mu_f((-\infty, \lambda))$ is a distribution function of the measure $d\mu_f$. The correspondence $f \mapsto \mu_f$ should satisfy the following natural properties.

S1. $|\mathrm{E}_\mu(f)| < \infty$ for $f \in \mathcal{A}_0$ - the subalgebra of bounded observables.

S2. $\mathrm{E}_\mu(1) = 1$, where 1 is the unit in $\mathcal{A}$.

S3. For all $a, b \in \mathbb{R}$ and $f, g \in \mathcal{A}$,

$$\mathrm{E}_\mu(af + bg) = a\mathrm{E}_\mu(f) + b\mathrm{E}_\mu(g),$$

if both $\mathrm{E}_\mu(f)$ and $\mathrm{E}_\mu(g)$ exist.

S4. If $f_1 = \varphi \circ f_2$ with smooth $\varphi : \mathbb{R} \to \mathbb{R}$, then for every Borel subset $E \subseteq \mathbb{R}$,

$$\mu_{f_1}(E) = \mu_{f_2}\left(\varphi^{-1}(E)\right)$$

It follows from property **S4** and the definition of the Lebesgue-Stieltjes integral that

$$\mathrm{E}_\mu(\varphi(f)) = \int_{-\infty}^{\infty} \varphi(\lambda) d\mu_f(\lambda) \tag{2.18}$$

In particular, $\mathrm{E}_\mu\left(f^2\right) \geq 0$ for all $f \in \mathcal{A}$, so that the states define normalized, positive, linear functionals on the subalgebra $\mathcal{A}_0$.

Assuming that the functional E_μ extends to the space of bounded, piecewise continuous functions on $\mathscr{M}$, and satisfies (2.18) for measurable functions φ, one can recover the distribution function from the expectation values by the formula

$$\mu_f(\lambda) = \mathrm{E}_\mu(\theta(\lambda - f)),$$

where $\theta(x)$ is the Heavyside step function,

$$\theta(x) = \begin{cases} 1, & x > 0 \\ 0, & x \leq 0 \end{cases}$$

Indeed, let χ be the characteristic function of the interval $(-\infty, \lambda) \subset \mathbb{R}$. Using (2.18) and the definition of the Lebesgue-Stieltjes integral we get

$$\mathrm{E}_\mu(\theta(\lambda - f)) = \int_{-\infty}^{\infty} \chi(s) d\mu_f(s) = \mu_f((-\infty, \lambda)) = \mu_f(\lambda)$$

Every probability measure $d\mu$ on $\mathscr{M}$ defines the state on $\mathcal{A}$ by assigning [20] to every observable f a probability measure $\mu_f = f_*(\mu)$ on $\mathbb{R}$ - a pushforward of the measure $d\mu$ on $\mathscr{M}$ by the mapping $f : \mathscr{M} \to \mathbb{R}$. It is defined by $\mu_f(E) = \mu\left(f^{-1}(E)\right)$ for every Borel subset $E \subseteq \mathbb{R}$, and has the distribution function

$$\mu_f(\lambda) = \mu\left(f^{-1}(-\infty, \lambda)\right) = \int_{\mathscr{M}_\lambda(f)} d\mu,$$

where $\mathscr{M}_\lambda(f) = \{x \in \mathscr{M} : f(x) < \lambda\}$. It follows from the Fubini theorem that

$$E_\mu(f) = \int_{-\infty}^{\infty} \lambda d\mu_f(\lambda) = \int_{\mathscr{M}} f d\mu \tag{2.19}$$

It turns out that probability measures on $\mathscr{M}$ are essentially the only examples of states. Namely, for a locally compact topological space $\mathscr{M}$ the Riesz-Markov theorem asserts that for every positive, linear functional l on the space $C_{\mathrm{c}}(\mathscr{M})$ of continuous functions on $\mathscr{M}$ with compact support, there is a unique regular Borel measure $d\mu$ on $\mathscr{M}$ such that

$$l(f) = \int_{\mathscr{M}} f d\mu \quad \text{for all} \quad f \in C_{\mathrm{c}}(\mathscr{M})$$

This leads to the following definition of states in classical mechanics.

Definition. The set of states $\mathcal{S}$ for a Hamiltonian system with the phase space $\mathscr{M}$ is the convex set $\mathscr{P}(\mathscr{M})$ of all probability measures on $\mathscr{M}$. The states corresponding to Dirac measures $d\mu_x$ supported at points $x \in \mathscr{M}$ are called pure states, and the phase space $\mathscr{M}$ is also called the space of states [21]. All other states are called mixed states. A process of measurement in classical mechanics is the correspondence

$$\mathcal{A} \times \mathcal{S} \ni (f, \mu) \mapsto \mu_f = f_*(\mu) \in \mathscr{P}(\mathbb{R})$$

which to every observable $f \in \mathcal{A}$ and state $\mu \in \mathcal{S}$ assigns a probability measure μ_f on $\mathbb{R}$ - a push-forward of the measure $d\mu$ on $\mathscr{M}$ by f. For every Borel subset $E \subseteq \mathbb{R}$ the quantity $0 \leq \mu_f(E) \leq 1$ is the probability that for a system in the state μ the result of a measurement of the observable f is in the set E. The expectation value of an observable f in a state μ is given by (2.19).

In physics, pure states are characterized by having the property that a measurement of every observable always gives a well-defined result. Mathematically this can be expressed as follows. Let

$$\sigma_\mu^2(f) = \mathrm{E}_\mu\left((f - \mathrm{E}_\mu(f))^2\right) = \mathrm{E}_\mu\left(f^2\right) - \mathrm{E}_\mu(f)^2 \geq 0$$

be the variance of the observable f in the state μ.

Lemma 2.1. Pure states are the only states in which every observable has zero variance.

Proof. It follows from the Cauchy-Bunyakovski-Schwarz inequality that $\sigma_\mu^2(f) = 0$ if only if f is constant on the support of a probability measure $d\mu$.

In particular, a mixture of pure states $d\mu_x$ and $d\mu_y, x, y \in \mathscr{M}$, is a mixed state with

$$d\mu = \alpha d\mu_x + (1 - \alpha) d\mu_y, \quad 0 < \alpha < 1$$

[20] There should be no confusion in denoting the state and the measure by μ.

so that $\sigma_\mu^2(f) > 0$ for every observable f such that $f(x) \neq f(y)$.

For a system consisting of few interacting particles (say, a motion of planets in celestial mechanics) it is possible to measure all coordinates and momenta, so one considers only pure states. Mixed states necessarily appear for macroscopic systems, when it is impossible to measure all coordinates and momenta [22].

Remark. As a topological space, the space of states $\mathscr{M}$ can be reconstructed from the algebra $\mathcal{A}$ of classical observables. Namely, suppose for simplicity that $\mathscr{M}$ is compact. Then the $\mathbb{C}$-algebra $\mathcal{C} = C(\mathscr{M})$ of complex-valued continuous functions on $\mathscr{M}$ - the completion of the complexification of the $\mathbb{R}$-algebra $\mathcal{A}$ of classical observables with respect to the sup-norm is a commutative $\mathbb{C}^*$-algebra. This means that $C(\mathscr{M})$ is a Banach space with respect to the norm $\|f\| = \sup_{x\in\mathscr{M}} |f(x)|$, has a $\mathbb{C}$-algebra structure (associative algebra over $\mathbb{C}$ with a unit) given by the point-wise product of functions such that $\|f \cdot g\| \leq \|f\|\|g\|$, and has a complex anti-linear antiinvolution: a map $^* : \mathcal{C} \to \mathcal{C}$ given by the complex conjugation $f^*(x) = \overline{f(x)}$ and satisfying $\|f \cdot f^*\| = \|f\|^2$. Then the Gelfand-Naimark theorem asserts that every commutative $\mathbb{C}^*$-algebra $\mathcal{C}$ is isomorphic to the algebra $C(\mathscr{M})$ of continuous functions on its spectrum - the set of maximal ideals of $\mathcal{C}$ - a compact topological space with the topology induced by the weak topology on $\mathcal{C}^*$, the dual space of $\mathcal{C}$.

We conclude our exposition of classical mechanics by presenting two equivalent ways of describing the dynamics - the time evolution of a Hamiltonian system $((\mathscr{M}, \{\}), H,)withthealgebraofobservables\mathcal{A} = C^\infty(\mathscr{M})$ and the set of states $\mathcal{S} = \mathscr{P}(\mathscr{M})$. In addition, we assume that the Hamiltonian phase flow g_t exists for all times, and that the phase space $\mathscr{M}$ carries a volume form dx invariant under the phase flow [23].

Hamilton's Description of Dynamics. States do not depend on time, and time evolution of observables is given by Hamilton's equations of motion,

$$\frac{d\mu}{dt} = 0, \quad \mu \in \mathcal{S}, \quad \text{and} \quad \frac{df}{dt} = \{H, f\}, \quad f \in \mathcal{A}$$

The expectation value of an observable f in the state μ at time t is given by

$$\mathrm{E}_\mu(f_t) = \int_{\mathscr{M}} f \circ g_t d\mu = \int_{\mathscr{M}} f(g_t(x))\,\rho(x)dx$$

where $\rho(x) = \frac{d\mu}{dx}$ is the Radon-Nikodim derivative. In particular, the expectation value of f in the pure state $d\mu_x$ corresponding to the point $x \in \mathscr{M}$ is $f(g_t(x))$. Hamilton's picture is commonly used for mechanical systems consisting of few interacting particles.

Liouville's Description of Dynamics. The observables do not depend on time

$$\frac{df}{dt} = 0, \quad f \in \mathcal{A},$$

and states $d\mu(x) = \rho(x)dx$ satisfy Liouville's equation

$$\frac{d\rho}{dt} = -\{H, \rho\}, \quad \rho(x)dx \in \mathcal{S}.$$

Here the Radon-Nikodim derivative $\rho(x) = \frac{d\mu}{dx}$ and Liouville's equation are understood in the distributional sense. The expectation value of an observable f in the state μ at time t is given by

[021] The space of pure states, to be precise.

[022] Typically, a macroscopic system consists of $N \sim 10^{23}$ molecules. Macroscopic systems are studied in classical statistical mechanics.

[23] It is Liouville's volume form when the Poisson structure on $\mathscr{M}$ is non-degenerate.

$$\mathrm{E}_{\mu_t}(f) = \int_{\mathscr{M}} f(x)\rho\left(g_{-t}(x)\right) dx$$

Liouville's picture, where states are described by the distribution functions $\rho(x)$ - positive distributions on $\mathscr{M}$ corresponding to probability measures $\rho(x)dx$ - is commonly used in statistical mechanics. The equality

$$\mathrm{E}_{\mu}\left(f_t\right) = \mathrm{E}_{\mu_t}(f) \quad \text{for all} \quad f \in \mathcal{A}, \quad \mu \in \mathcal{S}$$

which follows from the invariance of the volume form dx and the change of variables, expresses the equivalence between Liouville's and Hamilton's descriptions of the dynamics.

2.12.4 Connection of Classical and Quantum Mechanics

Обсудим подробно связь квантовой механики с классической.

появление принципа наименьшего действия из функционала достоверности

(below, there is a not professional attempt to explain this connection. It is still telling us something, but I don't think, that it is a fundamental one. Also, it is useless. But this is the default answer on this question from MIPT. I also don't like, how it is written, but I don't have now a better theory)

В механике частица представляет собой точку, которая движется в пространстве под воздействием сил.

В качестве наблюдаемой величины измеряется положение частицы в пространстве, которое задаётся координатой x, а зависимость от времени - траекторией $x(t)$. Лвижение полностью детерминировано, если заданы координата и скорость частицы в начальный момент времени, а также силы во всех точках пространства на протяжении всего времени их действия.

Этот факт, известный также, как принцип детерминированности в классической механике, конечно же, нашёл своё отражение в уравнениях движения частицы.

Так например, всем известное уравнение Ньютона

$$m\ddot{x} = F(t, x, \dot{x})$$

является дифференциальным уравнением второго порядка, а значит, для постановки задачи Коши для него необходимо задать начальную координату $x\left(t_0\right) = x_0$ и начальную скорость $\dot{x}\left(t_0\right) = \dot{x}_0$. Подобное описание движения частицы под действием сил представляет собой механическую формулировку принципа причинности: всякая точка на траектории частицы возникает как следствие воздействия на частицу сил в предыдущие моменты времени при заданных начальных условиях: координате и скорости в исходный момент времени.

Здесь возникает сразу несколько вопросов.

Во-первых, с чего мы взяли, что движение частицы полностью детерминировано, если в качестве начальных условий заданы только начальные координата и скорость частицы?

На самом деле, это предположение, являющееся обобщением опытных фактов, нетривиально и лежит в основе классической механики.

Во-вторых, откуда вообще взялось уравнение Ньютона и есть ли регулярный способ получения уравнений движения для механических систем?

Конечно, можно было бы просто объявить уравнение движения в форме Ньютона опытным фактом, однако, как мы увидим дальше, уравнения движения для частиц и

полей могут быть получены из такого фундаментального принципа как вариационный принцип экстремального действия Гамильтона.

Следствием этого принципа будет уравнение Эйлера- Лагранжа, которое имеет вид

$$\frac{\partial L}{\partial x} - \frac{d}{dt}\frac{\partial L}{\partial \dot{x}} = 0$$

Очевидно, что уравнение Эйлера-Лагранжа в этом случае эквивалентно уравнению Ньютона.

Действительно,

$$\frac{d}{dt}\frac{\partial L}{\partial \dot{x}} = m\ddot{x}, \quad \frac{\partial L}{\partial x} = -\frac{\partial U}{\partial x} = F(t,x)$$

В-третьих, мы рассматриваем координаты и скорости частицы как непрерывные вещественные величины, которые в топологическом смысле определяются как множество точек с малыми окрестностями, покрывающщми область непрерывности.

Каков физический смысл этих окрестностей? Ответ на этот вопрос одновременно и прост, и сложен.

Простота в том, что в физическом смысле эти окрестности отвечают, очевидно, погрешностям измерения непрерывной величины.

В идеале окрестность может считаться бесконечно малой, но ненулевой.

Именно наличием погрешности непрерывные величины существенно отличаются от дискретных изолированных величин.

Если начальные условия для координаты и скорости частицы принимают центральные значения с конечной погрешностью, то траектории из такой малой области начальных условий могут на мальх интервалах времени либо мало отличаться от центральной траектории, либо быстро расходиться.

В последнем случае говорят, что механическая система находится в состоянии динамической неустойчивости или хаоса.

Мы ограничимся рассмотрением систем без хаоса.

Вышеупомянутая сложность в ответе на вопрос о физическом смысле окрестностей состоит в том, что неопределённость траектории может быть связана не только с инструментальной погрешностью приборов измерения наблюдаемых величин; она может иметь и казуальный характер.

Само наличие возможности задания начальных условий с инструментальной погрешностью приборов, базируется на предположении классической механики о том, что предел бесконечно малой инструментальной погрешности во всех механических системах достижим и начальные условия могут задаваться с бесконечно малой неопределённостью.

Последнее может оказаться (и оказалось в действительности при изучении этого предела в физике атомов), вообше говоря, неверным. Действительно, поставим задачу не о единичной траектории частицы, однократно зарегистрированной в измерительном приборе, а о многократных измерениях, проводимbIX одинаковыми приборами для частиц с определёнными характеристиками.

Если приборная погрешность связана с регистрацией траектории частицы, то многократная регистрация траекторий вноси’т в задачу новые характеристики.

Так, например, в случае, когда свободная частица движется с некоторой скоростью равномерно и поступательно, то есть никак не взаимодействует с приборами, положение центра системы координат в приборе для свободной частицы никак не выделено и, стало быть, является неопредёленным, оно с точки зрения взаимодействия частицы с прибором абсолIотно произвольно: если в момент регистрации частицы прибором [1] поставить в приборе реперну ю точку, которая будет измерена с инструментальной

погрешностью самого прибора, то многократные повторы регистрации дадут некую форму распределения вероятности расположения реперных точек в приборе. ’ ’то распределение будет иметь свои погрешности и другие вероятностные характеристики многократных измерений в зависимости от физики источника свободной частицы.

Other questions about connection of classical and quantum mechanics

3 Formalism of Quantum Mechanics

3.1 Basic Principles of Quantum Mechanics

3.1.1 Observables, States, and Dynamics

Quantum mechanics studies the microworld - the physical laws at an atomic scale - that cannot be adequately described by classical mechanics. The properties of the microworld are so different from our everyday experiences that it is no surprise that its laws seem to contradict the common sense. Thus classical mechanics and classical electrodynamics cannot explain the stability of atoms and molecules. Neither can these theories reconcile different properties of light, its wave-like behavior in interference and diffraction phenomena, and its particle-like behavior in photo-electric emission and scattering by free photons. The fundamental difference between the microworld and the perceived world around us is that in the microworld every experiment results in interaction with the system and thus disturbs its properties, whereas in classical physics it is always assumed that one can neglect the disturbances the measurement

brings upon a system. This imposes a limitation on our powers of observation and leads to a conclusion that there exist observables which cannot be measured simultaneously.

We will not discuss here these and other basic experimental facts, referring the interested reader to physics textbooks. Nor will we follow the historic path of the theory. Instead, we show how to formulate quantum mechanics using the general notions of states, observables, and time evolution, described in Section 2.8 in Chapter 1. There we have seen that commutativity of the algebra of observables $\mathcal{A}$ results in its realization as an algebra of functions on the topological space - the space of states - and thus brings us to the realm of classical mechanics. Therefore in order to get a realization of observables and states which is different from classical mechanics, we must assume that the $\mathbb{C}^*$-algebra associated with observables is no longer commutative. A fundamental example of a non-commutative $\mathbb{C}^*$-algebra is given by the algebra of all bounded operators on a complex Hilbert space, and it turns out that it is this algebra which plays a fundamental role in quantum mechanics!

Here we formulate the basic principles of quantum mechanics using precise mathematical language. At this point it should be noted that one can not verify directly the principles lying at the foundation of quantum mechanics. Nevertheless, the validity of quantum mechanics, whenever it is applicable, is continuously being confirmed by numerous experimental facts which perfectly agree with the predictions of the theory [7].

1.1. Mathematical formulation.

The following axioms constitute the basis of quantum mechanics.

A1. With every quantum system there is associated an infinite-dimensional separable complex Hilbert space $\mathscr{H}$, in physics terminology called the space of states [8]. The Hilbert space of a composite quantum system is a tensor product of Hilbert spaces of component systems.

A2. The set of observables $\mathscr{A}$ of a quantum system with the Hilbert space $\mathscr{H}$ consists of all self-adjoint operators on $\mathscr{H}$. The subset $\mathscr{A}_0 = \mathscr{A} \cap \mathscr{L}(\mathscr{H})$ of bounded observables is a vector space over $\mathbb{R}$.

A3. The set of states $\mathscr{S}$ of a quantum system with a Hilbert space $\mathscr{H}$ consists of all positive (and hence self-adjoint) trace class operators M with

$\operatorname{Tr} M = 1$. Pure states are projection operators onto one-dimensional subspaces of $\mathscr{H}$. For $\psi \in \mathscr{H}, \|\psi\| = 1$, the corresponding projection onto $\mathbb{C}\psi$ is denoted by P_ψ. All other states are called mixed states [9].

A4. A process of measurement is the correspondence

$$\mathscr{A} \times \mathscr{S} \ni (A, M) \mapsto \mu_A \in \mathscr{P}(\mathbb{R})$$

which to every observable $A \in \mathscr{A}$ and state $M \in \mathscr{S}$ assigns a probability measure μ_A on $\mathbb{R}$. For every Borel subset $E \subseteq \mathbb{R}$, the quantity $0 \leq \mu_A(E) \leq 1$ is the probability that for a quantum system in the state M the result of a measurement of the observable A belongs to E. The expectation value (the mean-value) of the observable $A \in \mathscr{A}$ in the state $M \in \mathscr{S}$ is

$$\langle A|M\rangle = \int_{-\infty}^{\infty} \lambda d\mu_A(\lambda)$$

where $\mu_A(\lambda) = \mu_A((-\infty, \lambda))$ is a distribution function for the probability measure μ_A.

The set of states $\mathscr{S}$ is a convex set. According to the Hilbert-Schmidt theorem on the canonical decomposition for compact self-adjoint operators, for every $M \in \mathscr{S}$ there exists an orthonormal set $\{\psi_n\}_{n=1}^N$ in $\mathscr{H}$ (finite or infinite, in the latter case $N = \infty$) such that

[07] This refers to non-relativistic phenomena at the atomic scale.

[8] The space of pure states, to be precise.

$$M = \sum_{n=1}^{N} \alpha_n P_{\psi_n} \quad \text{and} \quad \operatorname{Tr} M = \sum_{n=1}^{N} \alpha_n = 1 \tag{1.1}$$

where $\alpha_n > 0$ are non-zero eigenvalues of M. Thus every mixed state is a convex linear combination of pure states. The following result characterizes the pure states.

Lemma 1.1. A state $M \in \mathscr{S}$ is a pure state if and only if it cannot be represented as a non-trivial convex linear combination in $\mathscr{S}$.

Proof. Suppose that

$$P_\psi = aM_1 + (1-a)M_2, \quad 0 < a < 1,$$

and let $\mathscr{H} = \mathbb{C}\psi \oplus \mathscr{H}_1$ be the orthogonal sum decomposition. Since M_1 and M_2 are positive operators, for $\varphi \in \mathscr{H}_1$ we have

$$a\,(M_1\varphi, \varphi) \le (P_\psi \varphi, \varphi) = 0$$

so that $(M_1\varphi, \varphi) = 0$ for all $\varphi \in \mathscr{H}_1$ and by (0.1) we get $M_1|_{\mathscr{H}_1} = 0$. Since M_1 is self-adjoint, it leaves the complementary subspace $\mathbb{C}\psi$ invariant, and from $\operatorname{Tr} M_1 = 1$ it follows that $M_1 = P_\psi$. Therefore, $M_1 = M_2 = P_\psi$.

Explicit construction of the correspondence $\mathscr{A} \times \mathscr{S} \to \mathscr{P}(\mathbb{R})$ is based on the general spectral theorem of von Neumann, which emphasizes the fundamental role the self-adjoint operators play in quantum mechanics.

Definition. A projection-valued measure on $\mathbb{R}$ is a mapping $\mathrm{P} : \mathscr{B}(\mathbb{R}) \to \mathscr{L}(\mathscr{H})$ of the σ-algebra $\mathscr{B}(\mathbb{R})$ of Borel subsets of $\mathbb{R}$ into the algebra of bounded operators on $\mathscr{H}$, satisfying the following properties.

PM1. For every Borel subset $E \subseteq \mathbb{R}, \mathrm{P}(E)$ is an orthogonal projection, i.e., $\mathrm{P}(E) = \mathrm{P}(E)^2$ and $\mathrm{P}(E) = \mathrm{P}(E)^*$.

PM2. $\mathrm{P}(\emptyset) = 0, \mathrm{P}(\mathbb{R}) = I$, the identity operator on $\mathscr{H}$.

PM3. For every disjoint union of Borel subsets,

$$E = \coprod_{n=1}^{\infty} E_n, \quad \mathrm{P}(E) = \lim_{n\to\infty} \sum_{i=1}^{n} \mathrm{P}\,(E_i)$$

in the strong topology on $\mathscr{L}(\mathscr{H})$.

Remark. Similarly, a projection-valued measure on $\mathbb{R}^n$ is a mapping P: $\mathscr{B}\,(\mathbb{R}^n) \to \mathscr{L}(\mathscr{H})$, satisfying the same properties PM1-PM3.

It follows from PM1-PM3 that

$$\mathrm{P}\,(E_1)\,\mathrm{P}\,(E_2) = \mathrm{P}\,(E_1 \cap E_2) \quad \text{for all } E_1, E_2 \in \mathscr{B}(\mathbb{R}) \tag{1.2}$$

With every projection-valued measure P on $\mathbb{R}$ we associate a projectionvalued function

$$\mathrm{P}(\lambda) = \mathrm{P}((-\infty, \lambda)),$$

called the projection-valued resolution of the identity. It is characterized by the following properties.

PD1.

$$\mathrm{P}(\lambda)\mathrm{P}(\mu) = \mathrm{P}(\min\{\lambda, \mu\})$$

[09] In physics terminology, the operator M is called the density operator.

PD2.

$$\lim_{\lambda\to-\infty} \mathrm{P}(\lambda) = 0, \quad \lim_{\lambda\to\infty} \mathrm{P}(\lambda) = I$$

PD3.

$$\lim_{\substack{\mu\to\lambda \\ \mu<\lambda}} \mathrm{P}(\mu) = \mathrm{P}(\lambda).$$

For every $\varphi \in \mathscr{H}$ the resolution of the identity $\mathrm{P}(\lambda)$ defines a distribution function $(\mathrm{P}(\lambda)\varphi, \varphi)$ of the bounded measure on $\mathbb{R}$ (probability measure when $\|\varphi\| = 1$). By the polarization identity

$$\begin{aligned}(\mathrm{P}(\lambda)\varphi, \psi) = \frac{1}{4}\{&(\mathrm{P}(\lambda)(\varphi+\psi), \varphi+\psi) - (\mathrm{P}(\lambda)(\varphi-\psi), \varphi-\psi) \\ &+ i(\mathrm{P}(\lambda)(\varphi+i\psi), \varphi+i\psi) - i(\mathrm{P}(\lambda)(\varphi-i\psi), \varphi-i\psi)\}\end{aligned}$$

so that $(\mathrm{P}(\lambda)\varphi, \psi)$ corresponds to a complex measure on $\mathbb{R}$ - a complex linear combination of measures.

A measurable function f on $\mathbb{R}$ is said to be finite almost everywhere (a.e.) with respect to the projection-valued measure P if it is finite a.e. with respect to all measures $(\mathrm{P}\psi, \psi), \psi \in \mathscr{H}$. For separable $\mathscr{H}$ a theorem of von Neumann states that for every projection-valued measure P there exists $\varphi \in \mathscr{H}$ such that a function f is finite a.e. with respect to P if and only if it is finite a.e. with respect to the measure $(\mathrm{P}\varphi, \varphi)$.

The next statement is the celebrated general spectral theorem of von Neumann.

Theorem 1.1 (J. von Neumann). For every self-adjoint operator A on the Hilbert space $\mathscr{H}$ there exists a unique projection-valued resolution of the identity $\mathrm{P}(\lambda)$, satisfying the following properties.
(i)

$$D(A) = \left\{\varphi \in \mathscr{H} : \int_{-\infty}^{\infty} \lambda^2 d(\mathrm{P}(\lambda)\varphi, \varphi) < \infty\right\},$$

and for every $\varphi \in D(A)$

$$A\varphi = \int_{-\infty}^{\infty} \lambda d\mathrm{P}(\lambda)\varphi,$$

defined as a limit of Riemann-Stieltjes sums in the strong topology on $\mathscr{H}$. The support of the corresponding projection-valued measure P coincides with the spectrum of the operator $A : \lambda \in \sigma(A)$ if and only if $\mathrm{P}_A((\lambda-\varepsilon, \lambda+\varepsilon)) \neq 0$ for all $\varepsilon > 0$.
(ii) For every continuous function f on $\mathbb{R}$, $f(A)$ is a linear operator on $\mathscr{H}$ with a dense domain

$$D(f(A)) = \left\{\varphi \in \mathscr{H} : \int_{-\infty}^{\infty} |f(\lambda)|^2 d(\mathrm{P}(\lambda)\varphi, \varphi) < \infty\right\}$$

defined for $\varphi \in D(f(A))$ as

$$f(A)\varphi = \int_{-\infty}^{\infty} f(\lambda) d\mathrm{P}(\lambda)\varphi,$$

and understood as in part (i). The operator $f(A)$ satisfies

$$f(A)^* = \bar{f}(A)$$

where $\bar{f}$ is the complex conjugate function to f, and the operator $f(A)$ is bounded if and only if the function f is bounded on $\sigma(A)$. For bounded on $\sigma(A)$ continuous functions f and g,

$$f(A)g(A)\varphi = \int_{-\infty}^{\infty} f(\lambda)g(\lambda)d\mathrm{P}(\lambda)\varphi, \quad \varphi \in \mathscr{H}.$$

(iii) For every measurable function f on $\mathbb{R}$, finite a.e. with respect to the projection-valued measure P, $f(A)$ is a linear operator on $\mathscr{H}$ defined as in (ii), where the integral for $f(A)\varphi$ is now understood in the weak sense: for $\varphi \in D(f(A))$ and every $\psi \in \mathscr{H}$,

$$(f(A)\varphi, \psi) = \int_{-\infty}^{\infty} f(\lambda)d(\mathrm{P}(\lambda)\varphi, \psi)$$

- a Lebesgue-Stieltjes integral with respect to a complex measure. The correspondence $f \mapsto f(A)$ satisfies the same properties as in (ii), where the integrals are understood in the weak sense.
  (iv) A bounded operator B commutes with A, that is, $B(D(A)) \subset D(A)$ and $AB = BA$ on $D(A)$, if and only if it commutes with $\mathrm{P}(\lambda)$ for all λ and, therefore, B commutes with every operator $f(A)$.
  (v) For every projection-valued resolution of identity $\mathrm{P}(\lambda)$ the operator A on $\mathscr{H}$, defined as in part (i), is self-adjoint.

Using the spectral theorem, the correspondence $(A, M) \mapsto \mu_A$, postulated in A4, can be explicitly described as follows.

A5. The probability measure μ_A on $\mathbb{R}$, which defines the correspondence $\mathscr{A} \times \mathscr{S} \to \mathscr{P}(\mathbb{R})$, is given by the Born-von Neumann formula

$$\mu_A(E) = \operatorname{Tr} P_A(E)M, \quad E \in \mathscr{B}(\mathbb{R}) \tag{1.3}$$

where P_A is a projection-valued measure on $\mathbb{R}$ associated with the self-adjoint operator A.

Remark. The probability measure μ_A on $\mathbb{R}$ can be considered as a "quantum push-forward" of the state M by the observable A (cf. the discussion in Section 2.8 in Chapter 1).

From the Hilbert-Schmidt decomposition (1.1) we get

$$\mu_A(E) = \sum_{n=1}^{N} \alpha_n \left(\mathrm{P}_A(E)\psi_n, \psi_n\right) = \sum_{n=1}^{N} \alpha_n \left\|\mathrm{P}_A(E)\psi_n\right\|^2 \leq \sum_{n=1}^{N} \alpha_n = 1$$

so that indeed $0 \leq \mu_A(E) \leq 1$. Denote by $\mu_A(\lambda)$ the distribution function of the probability measure μ_A, $\mu_A(\lambda) = (\mathrm{P}_A(\lambda)\psi, \psi)$ for $M = P_\psi$.

Proposition 1.1. Suppose that an observable $A \in \mathscr{A}$ and a state $M \in \mathscr{S}$ are such that $\langle A|M\rangle < \infty$ and $\operatorname{Im} M \subseteq D(A)$. Then $AM \in \mathscr{S}_1$ and

$$\langle A|M\rangle = \operatorname{Tr} AM$$

In particular, if $M = P_\psi$ and $\psi \in D(A)$, then

$$\langle A|M\rangle = (A\psi, \psi) \quad \text{and} \quad \left\langle A^2|M\right\rangle = \|A\psi\|^2.$$

Proof. Let $\{e_n\}_{n=1}^{\infty}$ be an orthonormal basis for $\mathscr{H}$. Since

$$\mu_A(E) = \operatorname{Tr} \mathrm{P}_A(E)M = \sum_{n=1}^{\infty} \left(\mathrm{P}_A(E)Me_n, e_n\right)$$

we get for every $E \in \mathscr{B}(\mathbb{R})$,

$$\mu_A(E) = \sum_{n=1}^{\infty} \mu_n(E)$$

where μ_n are finite measures on $\mathbb{R}$ defined by $\mu_n(E) = (\mathrm{P}_A(E)Me_n, e_n)$. Since

$$\int_{\mathbb{R}} f d\mu_A = \sum_{n=1}^{\infty} \int_{\mathbb{R}} f d\mu_n$$

for every function f integrable with respect to the measure μ_A, it follows from the spectral theorem that

$$\sum_{n=1}^{\infty} (AMe_n, e_n) = \sum_{n=1}^{\infty} \int_{-\infty}^{\infty} \lambda d\mu_n(\lambda) = \int_{-\infty}^{\infty} \lambda d\mu_A(\lambda) < \infty$$

Thus $AM \in \mathscr{S}_1$ and $\langle A|M\rangle = \operatorname{Tr} AM$. In particular, when $M = P_\psi$ and $\psi \in D(A)$,

$$\langle A|M\rangle = \int_{-\infty}^{\infty} \lambda d\left(\mathrm{P}_A(\lambda)\psi, \psi\right) = (A\psi, \psi)$$

Finally, from the spectral theorem and the change of variables formula we get

$$\|A\psi\|^2 = \int_{-\infty}^{\infty} \lambda^2 d\left(\mathrm{P}_A(\lambda)\psi, \psi\right) = \int_0^{\infty} \lambda d\left(\mathrm{P}_{A^2}(\lambda)\psi, \psi\right) = \left\langle A^2|M\right\rangle$$

Corollary 1.2. If $\langle A|M\rangle, \langle A^2|M\rangle < \infty$, then $AM \in \mathscr{S}_1$ and $\langle A|M\rangle = \operatorname{Tr} AM$.

Proof. Since

$$\int_{-\infty}^{\infty} \lambda^2 d\mu_n(\lambda) \le \int_{-\infty}^{\infty} \lambda^2 d\mu_A(\lambda) = \left\langle A^2|M\right\rangle < \infty$$

we get that $e_n \in D(AM)$, and the result follows from the proof of Proposition 1.1.

Remark. It is convenient to approximate an unbounded self-adjoint operator A by bounded operators $A_n = f_n(A)$, where $f_n = \chi_{[-n,n]}$ - a characteristic function of the interval $[-n, n]$. Assuming that $\langle A|M\rangle$ exists, we have

$$\langle A|M\rangle = \int_{-\infty}^{\infty} \lambda d\mu_A(\lambda) = \lim_{n\to\infty} \int_{-n}^{n} \lambda d\mu_A(\lambda) = \lim_{n\to\infty} \langle A_n|M\rangle$$

Definition. Self-adjoint operators A and B commute if the corresponding projection-valued measures P_A and P_B commute,

$$\mathrm{P}_A(E_1)\,\mathrm{P}_B(E_2) = \mathrm{P}_B(E_2)\,\mathrm{P}_A(E_1) \quad \text{for all} \quad E_1, E_2 \in \mathscr{B}(\mathbb{R})$$

The following results, which follow from the spectral theorem, are very useful in applications.

Proposition 1.2. The following statements are equivalent.

(i) Self-adjoint operators A and B commute.

(ii) For all $\lambda, \mu \in \mathbb{C}, \operatorname{Im}\lambda, \operatorname{Im}\mu \neq 0$,

$$R_\lambda(A)R_\mu(B) = R_\mu(B)R_\lambda(A)$$

(iii) For all $u, v \in \mathbb{R}$,

$$e^{iuA}e^{ivB} = e^{ivB}e^{iuA}.$$

(iv) For all $u \in \mathbb{R}$, the operators e^{iuA} and B commute.

Slightly abusing notation [10], we will often write $[A, B] = AB - BA = 0$ for commuting self-adjoint operators A and B.

Proposition 1.3. Let $\boldsymbol{A} = \{A_1, ..., A_n\}$ be a finite set of self-adjoint, pairwise commuting operators on $\mathscr{H}$. There exists a unique projection-valued measure $\mathrm{P}_{\boldsymbol{A}}$ on the Borel subsets of $\mathbb{R}^n$ having the following properties.
(i) For every $\boldsymbol{E} = E_1 \times \cdots \times E_n \in \mathscr{B}(\mathbb{R}^n)$,

$$\mathrm{P}_{\boldsymbol{A}}(\boldsymbol{E}) = \mathrm{P}_{A_1}(E_1) ... \mathrm{P}_{A_n}(E_n).$$

(ii) In the strong operator topology,

$$A_k = \int_{\mathbb{R}^n} \lambda_k d\mathrm{P}_{\boldsymbol{A}}, \quad k = 1, ..., n$$

where λ_k is the k-th coordinate function on $\mathbb{R}^n$, $\lambda_k(x_1, ..., x_n) = x_k$.
(iii) For every measurable function f on $\mathbb{R}^n$, finite a.e. with respect to the projection-valued measure $\mathrm{P}_{\boldsymbol{A}}$, $f(A_1, ..., A_n)$ is a linear operator on $\mathscr{H}$ defined *by*

$$f(A_1, ..., A_n) = \int_{\mathbb{R}^n} f d\mathrm{P}_{\boldsymbol{A}}$$

where the integral is understood in the weak operator topology. The correspondence $f \mapsto f(A_1, ..., A_n)$ satisfies the same properties as in part (ii) of the spectral theorem.

The support of the projection-valued measure $\mathrm{P}_{\boldsymbol{A}}$ on $\mathbb{R}^n$ is called the joint spectrum of the commutative family $\boldsymbol{A} = \{A_1, ..., A_n\}$.

Remark. According to von Neumann's theorem on a generating operator, for every commutative family $\boldsymbol{A}$ of self-adjoint operators (not necessarily finite) on a separable Hilbert space $\mathscr{H}$ there is a generating operator - a self-adjoint operator R on $\mathscr{H}$ such that all operators in A are functions of R.

It seems natural that simultaneous measurement of a finite set of observables $\boldsymbol{A} = \{A_1, ..., A_n\}$ in the state $M \in \mathscr{S}$ should be described by the probability measure μ_A on $\mathbb{R}^n$ given by the following generalization of the Born-von Neumann formula:
(1.4) $\mu_{\boldsymbol{A}}(\boldsymbol{E}) = \mathrm{Tr}\left(\mathrm{P}_{A_1}(E_1) ... \mathrm{P}_{A_n}(E_n) M\right), \quad \boldsymbol{E} = E_1 \times \cdots \times E_n \in \mathscr{B}(\mathbb{R}^n)$.

However, formula (1.4) defines a probability measure on $\mathbb{R}^n$ if and only if $\mathrm{P}_{A_1}(E_1) ... \mathrm{P}_{A_n}(E_n)$ defines a projection-valued measure on $\mathbb{R}^n$. Since a product of orthogonal projections is an orthogonal projection only when the projection operators commute, we conclude that the operators $A_1, ..., A_n$ should form a commutative family. This agrees with the requirement that simultaneous measurement of several observables should be independent of the order of the measurements of individual observables. We summarize these arguments as the following axiom.

A6. A finite set of observables $\boldsymbol{A} = \{A_1, ..., A_n\}$ can be measured simultaneously (simultaneously measured observables) if and only if they form a commutative family. Simultaneous measurement of the commutative family $\boldsymbol{A} \subset \mathscr{A}$ in the state $M \in \mathscr{S}$ is described by the probability measure $\mu_{\boldsymbol{A}}$ on $\mathbb{R}^n$ given by

$$\mu_{\boldsymbol{A}}(\boldsymbol{E}) = \mathrm{Tr}\, \mathrm{P}_{\boldsymbol{A}}(\boldsymbol{E}) M, \quad \boldsymbol{E} \in \mathscr{B}(\mathbb{R}^n),$$

where P_A is the projection-valued measure from Proposition 1.3. Explicitly, $\mathrm{P}_{\boldsymbol{A}}(\boldsymbol{E}) = \mathrm{P}_{A_1}(E_1) ... \mathrm{P}_{A_n}(E_n)$ for $\boldsymbol{E} = E_1 \times \cdots \times E_n \in \mathscr{B}(\mathbb{R}^n)$. For every Borel subset $\boldsymbol{E} \subseteq \mathbb{R}^n$ the

[010] In general, for unbounded self-adjoint operators A and B the commutator $[A, B] - AB - BA$ is not necessarily closed, i.e., it could be defined only for $\varphi = 0$.

quantity $0 \le \mu_{\boldsymbol{A}}(\boldsymbol{E}) \le 1$ is the probability that for a quantum system in the state M the result of the simultaneous measurement of observables $A_1, ..., A_n$ belongs to $\boldsymbol{E}$.

The axioms A1-A6 are known as Dirac-von Neumann axioms.

Problem 1.1. Prove property (1.2).

Problem 1.2. Prove that the state M is a pure state if and only if $\operatorname{Tr} M^2 = 1$.

Problem 1.3. Prove that the Born-von Neumann formula (1.3) defines a probability measure on $\mathbb{R}$, i.e., μ_A is a σ-additive function on $\mathscr{B}(\mathbb{R})$.

Problem 1.4. Prove all the remaining statements in this section.

1.2. Heisenberg's uncertainty relations. The variance of the observable A in the state M, which measures the mean deviation of A from its expectation value, is defined by

$$\sigma_M^2(A) = \left\langle (A - \langle A|M\rangle I)^2 | M \right\rangle = \left\langle A^2 | M \right\rangle - \langle A|M\rangle^2 \ge 0$$

provided the expectation values $\langle A^2|M\rangle$ and $\langle A|M\rangle$ exist. It follows from Proposition 1.1 that for $M = P_\psi$, where $\psi \in D(A)$,

$$\sigma_M^2(A) = \|(A - \langle A|M\rangle I)\psi\|^2 = \|A\psi\|^2 - (A\psi, \psi)^2$$

Lemma 1.2. For $A \in \mathscr{A}$ and $M \in \mathscr{S}$ the variance $\sigma_M(A) = 0$ if and only if $\operatorname{Im} M$ is an eigenspace for the operator A with the eigenvalue $a = \langle A|M\rangle$. In particular, if $M = P_\psi$, then ψ is an eigenvector of A, $A\psi = a\psi$.

Proof. It follows from the spectral theorem that

$$\sigma_M^2(A) = \int_{-\infty}^{\infty} (\lambda - a)^2 d\mu_A(\lambda)$$

so that $\sigma_M(A) = 0$ if and only if the probability measure μ_A is supported at the point $a \in \mathbb{R}$, i.e., $\mu_A(\{a\}) = 1$. Since $\mu_A(\{a\}) = \operatorname{Tr} P_A(\{a\})M$ and $\operatorname{Tr} M = 1$, we conclude that this is equivalent to $\operatorname{Im} M$ being an invariant subspace for $P_A(\{a\})$, and it follows from the spectral theorem that $\operatorname{Im} M$ is an eigenspace for A with the eigenvalue a.

Generalized Heisenberg's uncertainty relations

Now we formulate generalized Heisenberg's uncertainty relations.

Proposition 1.4 (H. Weyl).

Let $A, B \in \mathscr{A}$ and let $M = P_\psi$ be the pure state such that $\psi \in D(A) \cap D(B)$ and $A\psi, B\psi \in D(A) \cap D(B)$. Then

$$\sigma_M^2(A)\sigma_M^2(B) \ge \frac{1}{4}\langle i[A, B]|M\rangle^2$$

The same inequality holds for all $M \in \mathscr{S}$, where by definition $\langle i[A, B]|M\rangle = \lim_{n\to\infty} \langle i\,[A_n, B_n]\,|M\rangle$.

Proof. Let $M = P_\psi$. Since

$$[A - \langle A|M\rangle I, B - \langle B|M\rangle I] = [A, B]$$

it is sufficient to prove the inequality

$$\left\langle A^2|M\right\rangle \left\langle B^2|M\right\rangle \ge \frac{1}{4}\langle i[A, B]|M\rangle^2.$$

We have for all $\alpha \in \mathbb{R}$,

$$\|(A+i\alpha B)\psi\|^2 = \alpha^2(B\psi,B\psi) - i\alpha(A\psi,B\psi) + i\alpha(B\psi,A\psi) + (A\psi,A\psi)$$
$$= \alpha^2\left(B^2\psi,\psi\right) + \alpha(i[A,B]\psi,\psi) + \left(A^2\psi,\psi\right) \geq 0$$

so that necessarily $4\left(A^2\psi,\psi\right)\left(B^2\psi,\psi\right) \geq (i[A,B]\psi,\psi)^2$.

The same argument works for the mixed states. Since

$$\sigma_M^2(A)\sigma_M^2(B) = \lim_{n\to\infty} \sigma_M^2\left(A_n\right)\sigma_M^2\left(B_n\right)$$

(see the remark in the previous section), it is sufficient to prove the inequality for bounded A and B. Then using the cyclic property of the trace we have for all $\alpha \in \mathbb{R}$,

$$0 \leq \operatorname{Tr}\left((A+i\alpha B)M(A+i\alpha B)^*\right) = \operatorname{Tr}((A+i\alpha B)M(A-i\alpha B))$$
$$= \alpha^2 \operatorname{Tr} BMB + i\alpha \operatorname{Tr} BMA - i\alpha \operatorname{Tr} AMB + \operatorname{Tr} AMA$$
$$= \alpha^2 \operatorname{Tr} B^2M + \alpha \operatorname{Tr}(i[A,B]M) + \operatorname{Tr} A^2M,$$

so that $4 \operatorname{Tr} A^2M \operatorname{Tr} B^2M \geq \operatorname{Tr}(i[A,B]M)^2$.

Heisenberg's uncertainty relations provide a quantitative expression of the fact that even in a pure state non-commuting observables cannot be measured simultaneously. This shows a fundamental difference between the process of measurement in classical mechanics and in quantum mechanics.

1.3. Dynamics.

The set $\mathscr{A}$ of quantum observables does not form an algebra with respect to an operator product [11]. Nevertheless, a real vector space $\mathscr{A}_0$ of bounded observables has a Lie algebra structure with the Lie bracket

$$i[A,B] = i(AB-BA), \quad A,B \in \mathscr{A}_0$$

Remark. In fact, the $\mathbb{C}^*$-algebra $\mathscr{L}(\mathscr{H})$ of bounded operators on $\mathscr{H}$ has a structure of a complex Lie algebra with the Lie bracket given by a commutator $[A,B] = AB-BA$. It satisfies the Leibniz rule

$$[AB,C] = A[B,C] + [A,C]B$$

so that the Lie bracket is a derivation of the $\mathbb{C}^*$-algebra $\mathscr{L}(\mathscr{H})$.

In analogy with classical mechanics, we postulate that the time evolution of a quantum system with the space of states $\mathscr{H}$ is completely determined by a special observable $H \in \mathscr{A}$, called a Hamiltonian operator (Hamiltonian for brevity). As in classical mechanics, the Lie algebra structure on $\mathscr{A}_0$ leads to corresponding quantum equations of motion.

Specifically, the analog of Hamilton's picture in classical mechanics (see Section 2.8 in Chapter 1) is the Heisenberg picture in quantum mechanics, where the states do not depend on time

$$\frac{dM}{dt} = 0, \quad M \in \mathscr{S}$$

and bounded observables satisfy the Heisenberg equation of motion

$$\frac{dA}{dt} = \{H,A\}_\hbar, \quad A \in \mathscr{A}_0, \tag{1.5}$$

[011] The product of two non-commuting self-adjoint operators is not self-adjoint.

where

$$\{,\}_\hbar = \frac{i}{\hbar}[,] \tag{1.6}$$

is the quantum bracket - the $\hbar$-dependent Lie bracket on $\mathscr{A}_0$. The positive number $\hbar$, called the Planck constant, is one of the fundamental constants in physics [12].

The Heisenberg equation (1.5) is well defined when $H \in \mathscr{A}_0$. Indeed, let $U(t)$ be a strongly continuous one-parameter group of unitary operators associated with a bounded self-adjoint operator H,

$$U(t) = e^{-\frac{i}{\hbar}tH}, \quad t \in \mathbb{R} \tag{1.7}$$

It satisfies the differential equation

$$i\hbar\frac{dU(t)}{dt} = HU(t) = U(t)H \tag{1.8}$$

so that the solution $A(t)$ of the Heisenberg equation of motion with the initial condition $A(0) = A \in \mathscr{A}_0$ is given by

$$A(t) = U(t)^{-1}AU(t) \tag{1.9}$$

In general, a strongly one-parameter group of unitary operators (1.7), associated with a self-adjoint operator H, satisfies differential equation (1.8) only on $D(H)$ in a strong sense, that is, applied to $\varphi \in D(H)$. The quantum dynamics is defined by the same formula (1.9), and in this sense all quantum observables satisfy the Heisenberg equation of motion (1.5). The evolution operator $U_t : \mathscr{A} \to \mathscr{A}$ is defined by $U_t(A) = A(t) = U(t)^{-1}AU(t)$, and is an automorphism of the Lie algebra $\mathscr{A}_0$ of bounded observables. This is a quantum analog of the statement that the evolution operator in classical mechanics is an automorphism of the Poisson algebra of classical observables (see Theorem 2.19 in Section 2.7 of Chapter 1).

By Stone's theorem, every strongly-continuous one-parameter group of unitary operators [13]$U(t)$ is of the form (1.7), where
$D(H) = \left\{\varphi \in \mathscr{H} : \lim_{t\to 0}\frac{U(t)-I}{t}\varphi \text{ exists } \right\}$ and $H\varphi = i\hbar\lim_{t\to 0}\frac{U(t)-I}{t}\varphi$.
The domain $D(H)$ of the self-adjoint operator H, called the infinitesimal generator of $U(t)$, is an invariant linear subspace for all operators $U(t)$.

We summarize the presented arguments as the following axiom.

A7 (Heisenberg's Picture). The dynamics of a quantum system is described by the strongly continuous one-parameter group $U(t)$ of unitary operators. Quantum states do not depend on time, $\mathscr{S} \ni M \mapsto M(t) = M \in \mathscr{S}$, and time dependence of quantum observables is given by the evolution operator U_t,

$$\mathscr{A} \ni A \mapsto A(t) = U_t(A) = U(t)^{-1}AU(t) \in \mathscr{A}.$$

Infinitesimally, the evolution of quantum observables is described by the Heisenberg equation of motion (1.5), where the Hamiltonian operator H is the infinitesimal generator of $U(t)$.

The analog of Liouville's picture in classical mechanics (see Section 2.8 in Chapter 1) is Schrodinger's picture in quantum mechanics, defined as follows.

[012] The Planck constant has a physical dimension of the action (energy $\times$ time). Its value $\hbar = 1.054 \times 10^{-27}$erg $\times$ sec, which is determined from the experiment, manifests that quantum mechanics is a microscopic theory.

[13] According to a theorem of von Neumann, on a separable Hilbert space every weakly measurable one-parameter group of unitary operators is strongly continuous.

A8 (Schrodinger's Picture). The dynamics of a quantum system is described by the strongly continuous one-parameter group $U(t)$ of unitary operators. Quantum observables do not depend on time, $\mathscr{A} \ni A \mapsto A(t) = A \in \mathscr{A}$, and time dependence of states is given by the inverse of the evolution operator $U_t^{-1} = U_{-t}$,

$$\mathscr{S} \ni M \mapsto M(t) = U_{-t}(M) = U(t)MU(t)^{-1} \in \mathscr{S}. \tag{1.10}$$

Infinitesimally, the evolution of quantum states is described by the Schrodinger equation of motion

$$\frac{dM}{dt} = -\{H, M\}_h, \quad M \in \mathscr{S} \tag{1.11}$$

where the Hamiltonian operator H is the infinitesimal generator of $U(t)$.

Proposition 1.5. Heisenberg and Schrodinger descriptions of dynamics are equivalent.

Proof. Let $\mu_{A(t)}$ and $(\mu_t)_A$ be, respectively, probability measures on $\mathbb{R}$ associated with $(A(t), M) \in \mathscr{A} \times \mathscr{S}$ and $(A, M(t)) \in \mathscr{A} \times \mathscr{S}$ according to A3-A4, where $A(t) = U_t(A)$ and $M(t) = U_{-t}(M)$. We need to show that $\mu_{A(t)} = (\mu_t)_A$. It follows from the spectral theorem that $\mathrm{P}_{A(t)} = U(t)^{-1}\mathrm{P}_A U(t)$, so that using the Born-von Neumann formula (1.3) and the cyclic property of the trace, we get for $E \in \mathscr{B}(\mathbb{R})$,

$$\begin{aligned}\mu_{A(t)}(E) &= \operatorname{Tr} \mathrm{P}_{A(t)}(E)M = \operatorname{Tr}\left(U(t)^{-1}\mathrm{P}_A(E)U(t)M\right) \\ &= \operatorname{Tr}\left(\mathrm{P}_A(E)U(t)MU(t)^{-1}\right) = \operatorname{Tr}\mathrm{P}_A(E)M(t) = (\mu_t)_A(E)\end{aligned}$$

Corollary 1.3. $\langle A(t)|M\rangle = \langle A|M(t)\rangle$.

In analogy with classical mechanics (see Section 1.4 of Chapter 1), we have the following definition.

Definition. An observable $A \in \mathscr{A}$ is a quantum integral of motion (or a constant of motion) for a quantum system with the Hamiltonian H if in Heisenberg's picture

$$\frac{dA(t)}{dt} = 0$$

It follows from Proposition 1.2 that $A \in \mathscr{A}$ is an integral of motion if and only if it commutes with the Hamiltonian H, so that, in agreement with (1.5),

$$\{H, A\}_\hbar = 0$$

This is a quantum analog of the Poisson commutativity property, given by formula (2.14) in Section 2.6 of Chapter 1.

It follows from (1.11) that the time evolution of a pure state $M = P_\psi$ is given by $M(t) = P_{\psi(t)}$, where $\psi(t) = U(t)\psi$. Since $D(H)$ is invariant under $U(t)$, the vector $\psi(t) = U(t)\psi$ satisfies the time-dependent Schrodinger equation

$$i\hbar\frac{d\psi}{dt} = H\psi \tag{1.12}$$

with the initial condition $\psi(0) = \psi$.

Definition. A state $M \in \mathscr{S}$ is called stationary for a quantum system with Hamiltonian H if in Schrodinger's picture

$$\frac{dM(t)}{dt} = 0$$

The state M is stationary if and only if $[M, U(t)] = 0$ for all t, and by Proposition 1.2 this is equivalent to

$$\{H, M\}_\hbar = 0,$$

in agreement with (1.11). The following simple result is fundamental.

Lemma 1.3. The pure state $M = P_\psi$ is stationary if and only if ψ is an eigenvector for H,

$$H\psi = \lambda\psi,$$

and in this case

$$\psi(t) = e^{-\frac{i}{\hbar}\lambda t}\psi$$

Proof. It follows from $U(t)P_\psi = P_\psi U(t)$ that ψ is a common eigenvector for unitary operators $U(t)$ for all $t, U(t)\psi = c(t)\psi, |c(t)| = 1$. Since $U(t)$ is a strongly continuous one-parameter group of unitary operators, the continuous function $c(t) = (U(t)\psi, \psi)$ satisfies the equation $c(t_1 + t_2) = c(t_1)\, c(t_2)$ for all $t_1, t_2 \in \mathbb{R}$, so that $c(t) = e^{-\frac{i}{\hbar}\lambda t}$ for some $\lambda \in \mathbb{R}$. Thus by Stone's theorem $\psi \in D(H)$ and $H\psi = \lambda\psi$.

In physics terminology, the eigenvectors of H are called bound states. The corresponding eigenvalues are called energy levels and are usually denoted by E. The eigenvalue equation $H\psi = E\psi$ is called the stationary Schrodinger equation.

Problem 1.5. Show that if an observable A is such that for every state M the expectation value $\langle A|M(t)\rangle$ does not depend on t, then A is a quantum integral of motion. (This is the definition of integrals of motion in the Schrodinger picture.)

Problem 1.6. Show that a solution of the initial value problem for the timedependent Schrodinger equation (1.12) is given by

$$\psi(t) = \int_{-\infty}^{\infty} e^{-\frac{i}{\hbar}t\lambda} d\mathrm{P}(\lambda)\psi$$

where $\mathrm{P}(\lambda)$ is the resolution of identity for the Hamiltonian H.

Problem 1.7. Let D be a linear subspace of $\mathscr{H}$, consisting of Grding vectors

$$\psi_f = \int_{-\infty}^{\infty} f(s)U(s)\psi ds, \quad f \in \mathscr{S}(\mathbb{R}), \quad \psi \in \mathscr{H}$$

where $\mathscr{S}(\mathbb{R})$ is the Schwartz space of rapidly decreasing functions on $\mathbb{R}$. Prove that D is dense in $\mathscr{H}$ and is invariant for $U(t)$ and for the Hamiltonian H. (Hint: Show that $U(t)\psi_f = \psi_{f_t} \in D$, where $f_t(s) = f(s - t)$, and deduce $H\psi_f = \frac{\hbar}{i}\psi_{f'}$.)

3.1.2 Axioms of QM: Extra Discussion

(write some ideas from some fundamental articles and from section before. again: what are they? why exactly they are as they are? this is the goal of this section)

Conceptual questions about formalism of Heisenberg equations

What does one mean if one says "dynamics of observable"?

(I am not sure)

Overview of applications of Heisenberg equations

Density matrix and open quantum systems are described by Heisenberg equations

(write that this is very used there with some short examples)
(??? by the way, I don't know, why Schrodinger's one isn't used there??? there should be a reason for it)

(??? what in QFT) is described by Heisenberg equations

(I heard about it, I don't know now)

3.2 Typical Quantization

3.2.1 2. Quantization: Basic Method

To study the quantum system one needs to describe its Hilbert space of states $\mathscr{H}$ and the Hamiltonian H - a self-adjoint operator in $\mathscr{H}$ which defines the evolution of a system. When the quantum system has a classical analog, the procedure of constructing the corresponding Hilbert space $\mathscr{H}$ and the Hamiltonian H is called quantization.

Definition of quantization

Quantization of a classical system $((\mathscr{M},\{\}),,H_c)$ with the Hamiltonian function [14]H_c is a one-to-one mapping $\mathrm{Q}_\hbar : \mathcal{A} \to \mathscr{A}$ from the set of classical observables $\mathcal{A} = C^\infty(\mathscr{M})$ to the set $\mathscr{A}$ of quantum observables - the set of self-adjoint operators on a Hilbert space $\mathscr{H}$. The map $\mathrm{Q}_\hbar$ depends on the parameter $\hbar > 0$, and its restriction to the subspace of bounded classical observables $\mathcal{A}_0$ is a linear mapping to the subspace $\mathscr{A}_0$ of bounded quantum observables, which satisfies the properties

$$\lim_{\hbar\to 0} \frac{1}{2}\mathrm{Q}_\hbar^{-1}\left(\mathrm{Q}_\hbar\left(f_1\right)\mathrm{Q}_\hbar\left(f_2\right)+\mathrm{Q}_\hbar\left(f_2\right)\mathrm{Q}_\hbar\left(f_1\right)\right)=f_1 f_2$$

and

$$\lim_{\hbar\to 0} \mathrm{Q}_\hbar^{-1}\left(\left\{\mathrm{Q}_\hbar\left(f_1\right),\mathrm{Q}_\hbar\left(f_2\right)\right\}_\hbar\right)=\{f_1,f_2\} \qquad \text{for all} \qquad f_1,f_2\in\mathcal{A}_0$$

The latter property is the celebrated correspondence principle of Niels Bohr. In particular, $H_\mathrm{c} \mapsto \mathrm{Q}_\hbar\left(H_\mathrm{c}\right) = H$ - the Hamiltonian operator for a quantum system.
Remark. In physics literature the correspondence principle is often stated in the form

$$[,] \simeq \frac{\hbar}{i}\{,\} \qquad \text{as} \qquad \hbar\to 0$$

Quantum mechanics is different from classical mechanics, so that the correspondence $f \mapsto \mathrm{Q}_\hbar(f)$ cannot be an isomorphism between the Lie algebras of bounded classical and quantum

[014] Notation H_c is used to distinguish the Hamiltonian function in classical mechanics from the Hamiltonian operator H in quantum mechanics.

observables with respect to classical and quantum brackets. It becomes an isomorphism only in the limit $\hbar \to 0$ when, according to the correspondence principle, quantum mechanics turns into classical mechanics. Since quantum mechanics provides a more accurate and refined description than classical mechanics, quantization of a classical system may not be unique.

Definition. Two quantizations $\mathrm{Q}_\hbar^{(1)}$ and $\mathrm{Q}_\hbar^{(2)}$ of a given classical system $((\mathscr{M}, \{\}), , H_c)$ are said to be equivalent if there exists a linear mapping $\mathscr{U}_\hbar : \mathcal{A} \to \mathcal{A}$ such that $\mathrm{Q}_\hbar^{(2)} = \mathrm{Q}_\hbar^{(1)} \circ \mathscr{U}_\hbar$ and $\lim_{\hbar \to 0} \mathscr{U}_\hbar = \mathrm{id}$.

For many "real world" quantum systems - the systems describing actual physical phenomena - the corresponding Hamiltonian H does not depend on a choice of equivalent quantization, and is uniquely determined by the classical Hamiltonian function H_c.

2.1. Heisenberg commutation relations.

The simplest classical system with one degree of freedom is described by the phase space $\mathbb{R}^2$ with coordinates p, q and the Poisson bracket $\{,\}, associatedwiththecanonical$ symplectic form $\omega = dp \wedge dq$. In particular, the Poisson bracket between classical observables p and q - momentum and coordinate of a particle has the following simple form:

$$\{p, q\} = 1 \tag{2.1}$$

It is another postulate of quantum mechanics that under quantization classical observables p and q correspond to quantum observables P and Q -self-adjoint operators on a Hilbert space $\mathscr{H}$, satisfying the following properties.

CR1. There is a dense linear subset $D \subset \mathscr{H}$ such that $P : D \to D$ and $Q : D \to D$.
CR2. For all $\psi \in D$,

$$(PQ - QP)\psi = -i\hbar\psi$$

CR3. Every bounded operator on $\mathscr{H}$ which commutes with P and Q is a multiple of the identity operator I.

Property CR2 is called the Heisenberg commutation relation for one degree of freedom. In terms of the quantum bracket (1.6) it takes the form

$$\{P, Q\}_\hbar = I, \tag{2.2}$$

which is exactly the same as the Poisson bracket (2.1). Property CR3 is a quantum analog of the classical property that the Poisson manifold $(\mathbb{R}^2, \{\},)$ is non-degenerate: every function which Poisson commutes with p and q is a constant (see the last remark in Section 2.7 of Chapter 1).

The operators P and Q are called, respectively, the momentum operator and the coordinate operator. The correspondence $p \mapsto P, q \mapsto Q$ with P and Q satisfying CR1-CR3 is the cornerstone for the quantization of classical systems. The validity of (2.2), as well as of quantum mechanics as a whole, is confirmed by the agreement of the theory with numerous experiments.

Remark. It is tempting to extend the correspondence $p \mapsto P, q \mapsto Q$ to all observables by defining the mapping $f(p, q) \mapsto f(P, Q)$. However, this approach to quantization is rather naive: operators P and Q satisfy (2.2) and do not commute, so that one needs to understand how $f(P, Q)$

- a "function of non-commuting variables" - is actually defined. We will address this problem of the ordering of non-commuting operators P and Q in Section 3.3.

It follows from Heisenberg's uncertainty relations (see Proposition 1.4), that for any pure state $M = P_\psi$ with $\psi \in D$,

$$\sigma_M(P)\sigma_M(Q) \geq \frac{\hbar}{2}$$

This is a fundamental result saying that it is impossible to measure the coordinate and the momentum of a quantum particle simultaneously: the more accurate the measurement of one quantity is, the less accurate the value of the other is. It is often said that a quantum particle has no observed path, so that "quantum motion" differs dramatically from the motion in classical mechanics.

It is now straightforward to consider a classical system with n degrees of freedom, described by the phase space $\mathbb{R}^{2n}$ with coordinates $\boldsymbol{p} = (p_1, ..., p_n)$ and $\boldsymbol{q} = (q^1, ..., q^n)$, and the Poisson bracket $\{,\}, associatedwiththe$ canonical symplectic form $\omega = d\boldsymbol{p} \wedge d\boldsymbol{q}$. The Poisson brackets between classical observables $\boldsymbol{p}$ and $\boldsymbol{q}$ - momenta and coordinates of a particle - have the form

$$\{p_k, p_l\} = 0, \quad \left\{q^k, q^l\right\} = 0, \quad \left\{p_k, q^l\right\} = \delta_k^l, \quad k, l = 1, ..., n. \tag{2.3}$$

Corresponding momenta and coordinate operators $\boldsymbol{P} = (P_1, ..., P_n)$ and $\boldsymbol{Q} = (Q^1, ..., Q^n)$ are self-adjoint operators that have a common invariant dense linear subset $D \subset \mathscr{H}$, and on D satisfy the following commutation relations:

$$\{P_k, P_l\}_\hbar = 0, \quad \left\{Q^k, Q^l\right\}_\hbar = 0, \quad \left\{P_k, Q^l\right\}_\hbar = \delta_k^l I, \quad k, l = 1, ..., n. \tag{2.4}$$

These relations are called Heisenberg commutation relations for n degrees of freedom. The analog of CR3 is the property that every bounded operator on $\mathscr{H}$ which commutes with all operators $\boldsymbol{P}$ and $\boldsymbol{Q}$ is a multiple of the identity operator I.

The fundamental algebraic structure associated with Heisenberg commutation relations is the so-called Heisenberg algebra.

Definition. The Heisenberg algebra $\mathfrak{h}_n$ with n degrees of freedom is a Lie algebra with the generators $e^1, ..., e^n, f_1, ..., f_n, c$ and the relations

$$\left[e^k, c\right] = 0, \quad [f_k, c] = 0, \quad \left[e^k, f_l\right] = \delta_l^k c, \quad k, l = 1, ..., n \tag{2.5}$$

The invariant definition is the following. Let (V, ω) be a $2n$-dimensional symplectic vector space considered as an abelian Lie algebra, and let $\mathfrak{g}$ be a one-dimensional central extension of V by a Lie algebra 2-cocycle given by the bilinear form ω. This means that there is an exact sequence of vector spaces

$$0 \to \mathbb{R} \to \mathfrak{g} \to V \to 0 \tag{2.6}$$

and the Lie bracket in $\mathfrak{g}$ is defined by

$$[x, y] = \omega(\bar{x}, \bar{y})c \tag{2.7}$$

where $\bar{x}, \bar{y}$ are the images in V of elements $x, y \in \mathfrak{g}$, and c is the image of 1 under the embedding $\mathbb{R} \hookrightarrow \mathfrak{g}$, called the central element of $\mathfrak{g}$. A choice of a symplectic basis $e^1, ..., e^n, f_1, ..., f_n$ for V (see Section 2.6 of Chapter 1) establishes the isomorphism $\mathfrak{g} \simeq \mathfrak{h}_n$, and relations (2.5) are obtained from the Lie bracket (2.7).

By Ado's theorem, the Heisenberg algebra $\mathfrak{h}_n$ is isomorphic to a Lie subalgebra of a matrix algebra over $\mathbb{R}$. Explicitly, it is realized as a nilpotent subalgebra of the Lie algebra $\mathfrak{gl}_{n+2}$ of $(n+2) \times (n+2)$ matrices with the elements

$$\sum_{k=1}^{n}\left(u^k f_k + v_k e^k\right) + \alpha c = \begin{pmatrix} 0 & u^1 & u^2 & ... & u^n & \alpha \\ 0 & 0 & 0 & \cdots & 0 & v_1 \\ 0 & 0 & 0 & \cdots & 0 & v_2 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 0 & v_n \\ 0 & 0 & 0 & \cdots & 0 & 0 \end{pmatrix} \tag{2.8}$$

Remark. The faithful representation $\mathfrak{h}_n \to \mathfrak{gl}_{n+2}$, given by (2.8), is clearly reducible: the subspace $V = \{\boldsymbol{x} = (x_1, ..., x_{n+2}) \in \mathbb{R}^{n+2} : x_{n+2} = 0\}$ is an invariant subspace for $\mathfrak{h}_n$ with the central element c acting by zero. However, this representation is not decomposable: the vector space $\mathbb{R}^{n+2}$ cannot be written as a direct sum of V and a one-dimensional invariant subspace for $\mathfrak{h}_n$. This explains why the central element c is not represented by a diagonal matrix with the first $n+1$ zeros, but rather has a special form given by (2.8).

Analytically, Heisenberg commutation relations (2.5) correspond to an irreducible unitary representation of the Heisenberg Lie algebra $\mathfrak{h}_n$. Recall that a unitary representation ρ of $\mathfrak{h}_n$ in the Hilbert space $\mathscr{H}$ is the linear mapping $\rho : \mathfrak{h}_n \to i\mathscr{A}$ - the space of skew-Hermitian operators in $\mathscr{H}$ such that all self-adjoint operators $i\rho(x), x \in \mathfrak{h}_n$, have a common invariant dense linear subset $D \subset \mathscr{H}$ and satisfy

$$\rho([x,y])\varphi = (\rho(x)\rho(y) - \rho(y)\rho(x))\varphi, \quad x, y \in \mathfrak{h}_n, \varphi \in D.$$

Formally applying Schur's lemma we say that the representation ρ is irreducible if every bounded operator which commutes with all operators $i\rho(x)$ is a multiple of the identity operator I. Then Heisenberg commutation relations (2.5) define an irreducible unitary representation ρ of the Heisenberg Lie algebra $\mathfrak{h}_n$ in the Hilbert space $\mathscr{H}$ by setting

$$\rho\left(f_k\right) = -iP_k, \quad \rho\left(e^k\right) = -iQ^k, \quad k = 1, ..., n, \quad \rho(c) = -i\hbar I. \tag{2.9}$$

Since the operators P^k and Q_k are necessarily unbounded (see Problem 2.1), the condition

$$P_k P_l \varphi = P_l P_k \varphi \quad \text{for all} \quad \varphi \in D$$

does not necessarily imply (see Problem 2.2) that self-adjoint operators P_k and P_l commute in the sense of the definition in Section 1.1. To avoid such "pathological" representations, we will assume that ρ is an integrable representation, i.e., it can be integrated (in a precise sense specified below) to an irreducible unitary representation of the Heisenberg group $\mathbf{H}_n$ – a connected, simply-connected Lie group with the Lie algebra $\mathfrak{h}_n$.

Explicitly, the Heisenberg group is a unipotent subgroup of the Lie algebra $\mathrm{SL}(n+2, \mathbb{R})$ with the elements

$$g = \begin{pmatrix} 1 & u^1 & u^2 & \cdots & u^n & \alpha \\ 0 & 1 & 0 & \cdots & 0 & v_1 \\ 0 & 0 & 1 & \cdots & 0 & v_2 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & v_n \\ 0 & 0 & 0 & \cdots & 0 & 1 \end{pmatrix}.$$

The exponential map $\exp : \mathfrak{h}_n \to \mathbf{H}_n$ is onto, and the Heisenberg group $\mathbf{H}_n$ is generated by two n-parameter abelian subgroups

$$\exp \boldsymbol{u}X = \exp\left(\sum_{k=1}^{n} u^k f_k\right), \quad \exp \boldsymbol{v}Y = \exp\left(\sum_{k=1}^{n} v_k e^k\right), \quad \boldsymbol{u}, \boldsymbol{v} \in \mathbb{R}^n$$

and a one-parameter center $\exp \alpha c$, which satisfy the relations

$$\exp \boldsymbol{u}X \exp \boldsymbol{v}Y = \exp(-\boldsymbol{u}\boldsymbol{v}c) \exp \boldsymbol{v}Y \exp \boldsymbol{u}X, \quad \boldsymbol{u}\boldsymbol{v} = \sum_{k=0}^{n} u^k v_k \tag{2.10}$$

Indeed, it follows from (2.5) that $[\boldsymbol{u}X, \boldsymbol{v}Y] = -\boldsymbol{u}\boldsymbol{v}\boldsymbol{c}$ is a central element, so that using the Baker-Campbell-Hausdorff formula we obtain

$$\exp \boldsymbol{u}X \exp \boldsymbol{v}Y = \exp\left(-\frac{1}{2}\boldsymbol{u}\boldsymbol{v}c\right) \exp(\boldsymbol{u}X + \boldsymbol{v}Y)$$
$$\exp \boldsymbol{v}Y \exp \boldsymbol{u}X = \exp\left(\frac{1}{2}\boldsymbol{u}\boldsymbol{v}\boldsymbol{c}\right) \exp(\boldsymbol{u}X + \boldsymbol{v}Y)$$

In the matrix realization, the exponential map is given by the matrix exponential and we get $e^{uX} = I + \boldsymbol{u}X, e^{\boldsymbol{v}Y} = I + \boldsymbol{v}Y$, and $e^{\alpha c} = I + \alpha c$, where I is the $(n+2) \times (n+2)$ identity matrix.

Let R be an irreducible unitary representation of the Heisenberg group $\mathbf{H}_n$ in the Hilbert space $\mathscr{H}$ - a strongly continuous group homomorphism $R : \mathbf{H}_n \to \mathscr{U}(\mathscr{H})$, where $\mathscr{U}(\mathscr{H})$ is the group of unitary operators in $\mathscr{H}$. By Schur's lemma, $R(e^{\alpha c}) = e^{-i\lambda\alpha} I, \lambda \in \mathbb{R}$. Suppose now that $\lambda = \hbar$, and define two strongly continuous n-parameter abelian groups of unitary operators

$$U(\boldsymbol{u}) = R(\exp \boldsymbol{u}X), \quad V(\boldsymbol{v}) = R(\exp \boldsymbol{v}Y), \quad \boldsymbol{u}, \boldsymbol{v} \in \mathbb{R}^n$$

Then it follows from (2.10) that unitary operators $U(\boldsymbol{u})$ and $V(\boldsymbol{v})$ satisfy commutation relations

$$U(\boldsymbol{u})V(\boldsymbol{v}) = e^{i\hbar\boldsymbol{u}\boldsymbol{v}} V(\boldsymbol{v})U(\boldsymbol{u}) \tag{2.11}$$

called Weyl relations. Let $\boldsymbol{P} = (P_1, ..., P_n)$ and $\boldsymbol{Q} = (Q^1, ..., Q^n)$ be, respectively, infinitesimal generators of the subgroups $U(\boldsymbol{u})$ and $V(\boldsymbol{v})$, given by the Stone theorem,

$$P_k = i\frac{\partial U(\boldsymbol{u})}{\partial u^k}\bigg|_{\boldsymbol{u}=0} \quad \text{and} \quad Q^k = i\frac{\partial V(\boldsymbol{v})}{\partial v_k}\bigg|_{\boldsymbol{v}=0}, \quad k = 1, ..., n.$$

Taking the second partial derivatives of Weyl relations (2.11) at the origin $\boldsymbol{u} = \boldsymbol{v} = 0$ and using the solution of Problem 1.7 in the previous section, we easily obtain the following result.

Lemma 2.1. Let $R : \mathbf{H}_n \to \mathscr{U}(\mathscr{H})$ be an irreducible unitary representation of the Heisenberg group $\mathbf{H}_n$ in $\mathscr{H}$ such that $R(e^{\alpha c}) = e^{-i\hbar\alpha} I$, and let $\boldsymbol{P} = (P_1, ..., P_n)$ and $\boldsymbol{Q} = (Q^1, ..., Q^n)$ be, respectively, infinitesimal generators of the strongly continuous n-parameter abelian subgroups $U(\boldsymbol{u})$ and $V(\boldsymbol{v})$.

Then formulas (2.9) define an irreducible unitary representation ρ of the Heisenberg algebra $\mathfrak{h}_n$ in $\mathscr{H}$.

The representation ρ in Lemma 2.1 is called the differential of a representation R, and is denoted by dR. The irreducible unitary representation ρ of $\mathfrak{h}_n$ is called integrable if $\rho = dR$ for some irreducible unitary representation R of $\mathbf{H}_n$.

Remark. Not every irreducible unitary representation of the Heisenberg algebra is integrable, so that Weyl relations cannot be obtained from the Heisenberg commutation relations. However, the following heuristic argument (which ignores the subtleties of dealing with unbounded operators) is commonly used in physics textbooks. Consider the case of one degree of freedom and start with

$$\{P, Q\}_\hbar = I.$$

Since the quantum bracket satisfies the Leibniz rule we have, for a "suitable" function f,

$$\{f(P), Q\}_h = f'(P).$$

In particular, choosing $f(P) = e^{-iuP} = U(u)$, we obtain

$$U(u)Q - QU(u) = \hbar u U(u) \quad \text{or} \quad U(u)QU(u)^{-1} = Q + \hbar u I.$$

This implies, for a "suitable" function g,

$$U(u)g(Q) = g(Q + \hbar u I)U(u),$$

and setting $g(Q) = e^{-ivQ} = V(v)$, we get the Weyl relation.
We will prove in Section 3.1 that all integrable irreducible unitary representations of the Heisenberg algebra $\mathfrak{h}_n$ with the same action of the central element c are unitarily equivalent. This justifies the following mathematical formulation of the Heisenberg commutation relations for n degrees of freedom.

A9 (Heisenberg's Commutation Relations). Momenta and coordinate operators $\boldsymbol{P} = (P_1, ..., P_n)$ and $\boldsymbol{Q} = (Q^1, ..., Q^n)$ for a quantum particle with n degrees of freedom are defined by formulas (2.9), where ρ is an integrable irreducible unitary representation of the Heisenberg algebra $\mathfrak{h}_n$ with the property $\rho(c) = -i\hbar I$.

Problem 2.1. Prove that there are no bounded operators on the Hilbert space $\mathscr{H}$ satisfying $[A, B] = I$.

Problem 2.2. Give an example of self-adjoint operators A and B which have a common invariant dense linear subset $D \subset \mathscr{H}$ such that $AB\varphi = BA\varphi$ for all $\varphi \in D$, but e^{iA} and e^{iB} do not commute.

Problem 2.3. Prove Lemma 2.1. (Hint: As in Problem 1.7, let D be the linear set of Grding vectors

$$\psi_f = \int_{\mathbb{R}^{2n}} f(\boldsymbol{u}, \boldsymbol{v}) U(\boldsymbol{u}) V(\boldsymbol{v}) \psi d^n\boldsymbol{u} d^n\boldsymbol{v}, \quad f \in \mathscr{S}\left(\mathbb{R}^{2n}\right), \psi \in \mathscr{H}$$

where $\mathscr{S}(\mathbb{R}^{2n})$ is the Schwartz space of rapidly decreasing functions on $\mathbb{R}^{2n}$.)

2.2. Coordinate and momentum representations.

We start with the case of one degree of freedom and consider two natural realizations of the Heisenberg commutation relation. They are defined by the property that one of the self-adjoint operators P and Q is "diagonal" (i.e., is a multiplication by a function operator in the corresponding Hilbert space).

In the coordinate representation, $\mathscr{H} = L^2(\mathbb{R}, dq)$ is the L^2-space on the configuration space $\mathbb{R}$ with the coordinate q, which is a Lagrangian subspace of $\mathbb{R}^2$ defined by the equation $p = 0$. Set

$$D(Q) = \left\{ \varphi \in \mathscr{H} : \int_{-\infty}^{\infty} q^2 |\varphi(q)|^2 dq < \infty \right\}$$

and for $\varphi \in D(Q)$ define the operator Q as a "multiplication by q operator",

$$(Q\varphi)(q) = q\varphi(q), q \in \mathbb{R}$$

justifying the name coordinate representation. The coordinate operator Q is obviously self-adjoint and its projection-valued measure is given by

$$(\mathrm{P}(E)\varphi)(q) = \chi_E(q)\varphi(q) \tag{2.12}$$

where χ_E is the characteristic function of a Borel subset $E \subseteq \mathbb{R}$. Therefore $\operatorname{supp} \mathbf{P} = \mathbb{R}$ and $\sigma(Q) = \mathbb{R}$.

Recall that a self-adjoint operator A has an absolutely continuous spectrum if for every $\psi \in \mathscr{H}, \|\psi\| = 1$, the probability measure ν_ψ,

$$\nu_\psi(E) = (\mathrm{P}_A(E)\psi, \psi), \quad E \in \mathscr{B}(\mathbb{R})$$

is absolutely continuous with respect to the Lebesgue measure on $\mathbb{R}$.

Lemma 2.2. The coordinate operator Q has an absolutely continuous spectrum $\mathbb{R}$, and every bounded operator B which commutes with Q is a function of $Q, B = f(Q)$ with $f \in L^\infty(\mathbb{R})$.

Proof. It follows from (2.12) that $\nu_\psi(E) = \int_E |\psi(q)|^2 dq$, which proves the first statement. Now a bounded operator B on $\mathscr{H}$ commutes with Q if and only if $B\mathrm{P}(E) = \mathrm{P}(E)B$ for all $E \in \mathscr{B}(\mathbb{R})$, and using (2.12) we get

$$B(\chi_E\varphi) = \chi_E B(\varphi) \tag{2.13}$$

Choosing in (2.13) $E = E_1$ and $\varphi = \chi_{E_2}$, where E_1 and E_2 have finite Lebesgue measure, we obtain

$$B(\chi_{E_1} \cdot \chi_{E_2}) = B(\chi_{E_1 \cap E_2}) = \chi_{E_1} B(\chi_{E_2}) = \chi_{E_2} B(\chi_{E_1}),$$

so that denoting $f_E = B(\chi_E)$ we get $\operatorname{supp} f_E \subseteq E$, and

$$f_{E_1}|_{E_1 \cap E_2} = f_{E_2}|_{E_1 \cap E_2}$$

for all $E_1, E_2 \in \mathscr{B}(\mathbb{R})$ with finite Lebesgue measure. Thus there exists a measurable function f on $\mathbb{R}$ such that $f|_E = f_E|_E$ for every $E \in \mathscr{B}(\mathbb{R})$ with finite Lebesgue measure. The linear subspace spanned by all $\chi_E \in L^2(\mathbb{R})$ is dense in $L^2(\mathbb{R})$ and the operator B is continuous, so that we get

$$(B\varphi)(q) = f(q)\varphi(q) \quad \text{for all} \quad \varphi \in L^2(\mathbb{R})$$

Since B is a bounded operator, $f \in L^\infty(\mathbb{R})$ and $\|B\| = \|f\|_\infty$.

Remark. By the Schwartz kernel theorem, the operator B can be represented by an integral operator with a distributional kernel $K(q, q')$. Then the commutativity $BQ = QB$ implies that, in the distributional sense,

$$(q - q')K(q, q') = 0,$$

so that K is "proportional" to the Dirac delta-function, i.e.,

$$K(q, q') = f(q)\delta(q - q')$$

with some $f \in L^\infty(\mathbb{R})$. This argument is usually given in the physics textbooks.

Remark. The operator Q has no eigenvectors - the eigenvalue equation

$$Q\varphi = \lambda\varphi$$

has no solutions in $L^2(\mathbb{R})$. However, in the distributional sense, this equation for every $\lambda \in \mathbb{R}$ has a unique (up to a constant factor) solution $\varphi_\lambda(q) = \delta(q - \lambda)$, and these "generalized eigenfunctions", also called eigenfunctions of the continuous spectrum, combine to a Schwarz kernel of the identity operator I on $L^2(\mathbb{R})$. This reflects the fact that operator Q is diagonal in the coordinate representation.

Remark. Normalization of the eigenfunctions of the continuous spectrum $\varphi_\lambda(q)$ can be also determined by the condition that for every $\lambda \in \mathbb{R}$ the function

$$\Phi_\lambda(q) = \int_{\lambda_0}^{\lambda} \varphi_\mu(q) d\mu, \quad \Phi_\lambda \in L^2(\mathbb{R})$$

satisfies

$$\lim_{\Delta \to 0} \frac{1}{\Delta} \|\Phi_{\lambda+\Delta} - \Phi_\lambda\|^2 = 1 \tag{2.14}$$

Here $\lambda_0 \in \mathbb{R}$ is fixed and does not enter (2.14). Indeed, in our case $\Phi_\lambda = \chi_{(\lambda_0,\lambda)}$ - the characteristic function of the interval (λ_0, λ) - so that $\|\Phi_{\lambda+\Delta^-} \Phi_\lambda\|^2 = \Delta$.

For a pure state $M = P_\psi, \|\psi\| = 1$, the corresponding probability measure μ_Q on $\mathbb{R}$ is given by

$$\mu_Q(E) = \nu_\psi(E) = \int_E |\psi(q)|^2 dq, \quad E \in \mathscr{B}(\mathbb{R})$$

Physically, this is interpreted that in the state P_ψ with the "wave function" $\psi(q)$, the probability of finding a quantum particle between q and $q + dq$ is $|\psi(q)|^2 dq$. In other words, the modulus square of a wave function is the probability distribution for the coordinate of a quantum particle.

The corresponding momentum operator P is given by a differential operator

$$P = \frac{\hbar}{i} \frac{d}{dq}$$

with $D(P) = W^{1,2}(\mathbb{R})$ - the Sobolev space of absolutely continuous functions f on $\mathbb{R}$ such that f and its derivative f' (defined a.e.) are in $L^2(\mathbb{R})$. The operator P is self-adjoint and it is straightforward to verify that on $D = C_c^\infty(\mathbb{R})$, the space of smooth functions on $\mathbb{R}$ with compact support,

$$QP - PQ = i\hbar I$$

Remark. The operator P on $\mathscr{H}$ has no eigenvectors - the eigenvalue equation

$$P\varphi = p\varphi, p \in \mathbb{R}$$

has a solution

$$\varphi(q) = \text{ const } \times e^{\frac{i}{\hbar} pq}$$

which does not belong to $L^2(\mathbb{R})$. We will see later that the family of normalized eigenfunctions of the continuous spectrum

$$\varphi_p(q) = \frac{1}{\sqrt{2\pi\hbar}} e^{\frac{i}{\hbar} pq}$$

combines to a Schwartz kernel of the inverse $\hbar$-dependent Fourier transform operator, which diagonalizes the momentum operator P. In the distributional sense,

$$\int_{-\infty}^{\infty} \varphi_p(q) \overline{\varphi_{p'}(q)} dq = \delta(p - p')$$

Remark. As for the case of the coordinate operator, the normalization of the eigenfunctions of the continuous spectrum $\varphi_p(q)$ of the momentum operator can be determined from the condition (2.14). Indeed,

$$\Phi_p(q) = \int_{p_0}^{p} ce^{\frac{i}{\hbar}kq} dk = \frac{c\hbar}{iq}\left(e^{\frac{i}{\hbar}pq} - e^{\frac{i}{\hbar}p_0 q}\right)$$

so that

$$\Phi_{p+\Delta}(q) - \Phi_p(q) = \frac{2c\hbar}{q} e^{\frac{i}{\hbar}(p+\frac{1}{2}\Delta)q} \sin\frac{\Delta q}{2\hbar}.$$

Using the elementary integral, we obtain

$$\frac{1}{\Delta}\left\|\Phi_{p+\Delta}(q) - \Phi_p(q)\right\|^2 = 2c^2\hbar \int_{-\infty}^{\infty} \frac{\sin^2 q}{q^2} dq = 2\pi c^2\hbar$$

so that $c = \frac{1}{\sqrt{2\pi\hbar}}$.

Proposition 2.1. The coordinate representation defines an irreducible, unitary, integrable representation of the Heisenberg algebra.

Proof. To show that the coordinate representation is integrable, let $U(u) = e^{-iuP}$ and $V(v) = e^{-ivQ}$ be the corresponding one-parameter groups of unitary operators. Clearly, $(V(v)\varphi)\psi(q) = e^{-ivq}\varphi(q)$ and it easily follows from the Stone theorem (or by the definition of a derivative) that $(U(u)\varphi)(q) = \varphi(q - \hbar u)$, so that unitary operators $U(u)$ and $V(v)$ satisfy the Weyl relation (2.11). Such a realization of the Weyl relation is called the Schrodinger representation.

To prove that the coordinate representation is irreducible, let B be a bounded operator commuting with P and Q. By Lemma 2.2, $T = f(Q)$ for some $f \in L^\infty(\mathbb{R})$. Now commutativity between T and P implies that

$$TU(u) = U(u)T \quad \text{for all} \quad u \in \mathbb{R},$$

which is equivalent to $f(q - \hbar u) = f(q)$ for all $q, u \in \mathbb{R}$, so that $f = \text{const}$ a.e. on $\mathbb{R}$.

To summarize, the coordinate representation is characterized by the property that the coordinate operator Q is a multiplication by q operator and the momentum operator P is a differentiation operator,

$$Q = q \quad \text{and} \quad P = \frac{\hbar}{i}\frac{d}{dq}.$$

Similarly, momentum representation is defined by the property that the momentum operator P is a multiplication by p operator. Namely let $\mathscr{H} = L^2(\mathbb{R}, dp)$ be the Hilbert L^2-space on the "momentum space" $\mathbb{R}$ with the coordinate p, which is a Lagrangian subspace of $\mathbb{R}^2$ defined by the equation $q = 0$. The coordinate and momentum operators are given by

$$\hat{Q} = i\hbar\frac{d}{dp} \quad \text{and} \quad \hat{P} = p$$

and satisfy the Heisenberg commutation relation. As the coordinate representation, the momentum representation is an irreducible, unitary, integrable representation of the Heisenberg algebra. In the momentum representation, the modulus square of the wave function $\psi(p)$ of a pure state $M = P_\psi$,
$\|\psi\| = 1$, is the probability distribution for the momentum of the quantum particle, i.e., the probability that a quantum particle has momentum between p and $p + dp$ is $|\psi(p)|^2 dp$.

Let $\mathscr{F}_\hbar : L^2(\mathbb{R}) \to L^2(\mathbb{R})$ be the $\hbar$-dependent Fourier transform operator, defined by

$$\hat{\varphi}(p) = \mathscr{F}_\hbar(\varphi)(p) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-\infty}^{\infty} e^{-\frac{i}{\hbar}pq}\varphi(q) dq$$

Here the integral is understood as the limit $\hat{\varphi} = \lim_{n\to\infty} \hat{\varphi}_n$ in the strong topology on $L^2(\mathbb{R})$, where

$$\hat{\varphi}_n(p) = \frac{1}{\sqrt{2\pi\hbar}} \int_{-n}^{n} e^{-\frac{i}{\hbar}pq} \varphi(q) dq$$

By Plancherel's theorem, $\mathscr{F}_\hbar$ is a unitary operator on $L^2(\mathbb{R})$,

$$\mathscr{F}_\hbar \mathscr{F}_\hbar^* = \mathscr{F}_\hbar^* \mathscr{F}_\hbar = I,$$

and

$$\hat{Q} = \mathscr{F}_\hbar Q \mathscr{F}_\hbar^{-1}, \quad \hat{P} = \mathscr{F}_\hbar P \mathscr{F}_\hbar^{-1}$$

so that coordinate and momentum representations are unitarily equivalent. In particular, since the operator $\hat{P}$ is obviously self-adjoint, this immediately shows that the operator P is self-adjoint.

For n degrees of freedom, the coordinate representation is defined by setting $\mathscr{H} = L^2(\mathbb{R}^n, d^n\boldsymbol{q})$, where $d^n\boldsymbol{q} = dq^1 \cdots dq^n$ is the Lebesgue measure on $\mathbb{R}^n$, and

$$\boldsymbol{Q} = \boldsymbol{q} = \left(q^1, ..., q^n\right), \quad \boldsymbol{P} = \frac{\hbar}{i}\frac{\partial}{\partial \boldsymbol{q}} = \left(\frac{\hbar}{i}\frac{\partial}{\partial q^1}, ..., \frac{\hbar}{i}\frac{\partial}{\partial q^n}\right)$$

Here $\mathbb{R}^n$ is the configuration space with coordinates $\boldsymbol{q}$ - a Lagrangian subspace of $\mathbb{R}^{2n}$ defined by the equations $\boldsymbol{p} = 0$. The coordinate and momenta operators are self-adjoint and satisfy Heisenberg commutation relations. Projection-valued measures for the operators Q^k are given by

$$\left(\mathrm{P}_k(E)\varphi\right)(\boldsymbol{q}) = \chi_{\lambda_k^{-1}(E)}(\boldsymbol{q})\varphi(\boldsymbol{q})$$

where $E \in \mathscr{B}(\mathbb{R})$ and $\lambda_k : \mathbb{R}^n \to \mathbb{R}$ is a canonical projection onto the k-th component, $k = 1, ..., n$. Correspondingly, the projection-valued measure P for the commutative family $\boldsymbol{Q} = (Q^1, ..., Q^n)$ (see Proposition 1.3) is defined on the Borel subsets $\boldsymbol{E} \subseteq \mathbb{R}^n$ by

$$(\mathrm{P}(\boldsymbol{E})\varphi)(\boldsymbol{q}) = \chi_{\boldsymbol{E}}(\boldsymbol{q})\varphi(\boldsymbol{q})$$

The family Q has absolutely continuous joint spectrum $\mathbb{R}^n$.
Coordinate operators $Q^1, ..., Q^n$ form a complete system of commuting observables. This means, by definition, that none of these operators is a function of the other operators, and that every bounded operator commuting with $Q^1, ..., Q^n$ is a function of $Q^1, ..., Q^n$, i.e., is a multiplication by $f(\boldsymbol{q})$
operator for some $f \in L^\infty(\mathbb{R}^n)$. The proof repeats verbatim the proof of Lemma 2.2. For a pure state $M = P_\psi, \|\psi\| = 1$, the modulus square $|\psi(\boldsymbol{q})|^2$ of the wave function is the density of a joint distribution function $\mu_{\boldsymbol{Q}}$ for the commutative family $\boldsymbol{Q}$, i.e., the probability of finding a quantum particle in a Borel subset $E \subseteq \mathbb{R}^n$ is given by

$$\mu_{\boldsymbol{Q}}(\boldsymbol{E}) = \int_{\boldsymbol{E}} |\psi(\boldsymbol{q})|^2 d^n\boldsymbol{q}.$$

The coordinate representation defines an irreducible, unitary, integrable representation of the Heisenberg algebra $\mathfrak{h}_n$. Indeed, n-parameter groups of unitary operators $U(\boldsymbol{u}) = e^{-i\boldsymbol{u}\boldsymbol{P}}$ and $V(\boldsymbol{v}) = e^{-i\boldsymbol{v}\boldsymbol{Q}}$ are given by

$$(U(\boldsymbol{u})\varphi)(\boldsymbol{q}) = \varphi(\boldsymbol{q} - \hbar\boldsymbol{u}), \quad (V(\boldsymbol{v})\varphi)(\boldsymbol{q}) = e^{-i\boldsymbol{v}\boldsymbol{q}}\varphi(\boldsymbol{q})$$

and satisfy Weyl relations (2.11). The same argument as in the proof of Proposition 2.1 shows that this representation of the Heisenberg group $\mathbf{H}_n$, called the Schrodinger representation for n degrees of freedom, is irreducible.

In the momentum representation, $\mathscr{H} = L^2(\mathbb{R}^n, d^n\boldsymbol{p})$, where $d^n\boldsymbol{p} = dp_1 \cdots dp_n$ is the Lebesgue measure on $\mathbb{R}^n$, and

$$\hat{\boldsymbol{Q}} = i\hbar\frac{\partial}{\partial \boldsymbol{p}} = \left(i\hbar\frac{\partial}{\partial p_1}, ..., i\hbar\frac{\partial}{\partial p_n}\right), \quad \hat{\boldsymbol{P}} = \boldsymbol{p} = (p_1, ..., p_n).$$

Here $\mathbb{R}^n$ is the momentum space with coordinates $\boldsymbol{p}$ - a Lagrangian subspace of $\mathbb{R}^{2n}$ defined by the equations $\boldsymbol{q} = 0$.

The coordinate and momentum representations are unitarily equivalent by the Fourier transform. As in the case $n = 1$, the Fourier transform $\mathscr{F}_\hbar$: $L^2(\mathbb{R}^n) \to L^2(\mathbb{R}^n)$ is a unitary operator defined by

$$\begin{aligned}\hat{\varphi}(\boldsymbol{p}) = \mathscr{F}_\hbar(\varphi)(\boldsymbol{p}) &= (2\pi\hbar)^{-n/2}\int_{\mathbb{R}^n} e^{-\frac{i}{\hbar}\boldsymbol{pq}}\varphi(\boldsymbol{q})d^n\boldsymbol{q} \\ &= \lim_{N\to\infty}(2\pi\hbar)^{-n/2}\int_{|\boldsymbol{q}|\le N} e^{-\frac{i}{\hbar}\boldsymbol{pq}}\varphi(\boldsymbol{q})d^n\boldsymbol{q}\end{aligned}$$

where the limit is understood in the strong topology on $L^2(\mathbb{R}^n)$. As in the case $n = 1$, we have

$$\hat{Q}_k = \mathscr{F}_\hbar Q_k \mathscr{F}_\hbar^{-1}, \quad \hat{P}_k = \mathscr{F}_\hbar P_k \mathscr{F}_\hbar^{-1}, \quad k = 1, ..., n.$$

In particular, since operators $\hat{P}_1, ..., \hat{P}_n$ are obviously self-adjoint, this immediately shows that $P_1, ..., P_n$ are also self-adjoint.

Remark. Following Dirac, physicists denote a vector $\psi \in \mathscr{H}$ by a ket vector $|\psi\rangle$, a vector $\varphi \in \mathscr{H}^*$ in the dual space to $\mathscr{H}$ ($\mathscr{H}^* \simeq \mathscr{H}$ is a complex antilinear isomorphism) by a bra vector $\langle\varphi|$, and their inner product by $\langle\varphi|\psi\rangle$. In standard mathematics notation,

$$(\psi, \varphi) = \langle\varphi|\psi\rangle \quad \text{and} \quad (A\psi, \varphi) = \langle\varphi|A|\psi\rangle,$$

where A is a linear operator. From a physics point of view, Dirac's notation is intuitive and convenient for working with coordinate and momentum representations. Denoting by $|\boldsymbol{q}\rangle = \delta(\boldsymbol{q} - \boldsymbol{q}')$ and $|\boldsymbol{p}\rangle = (2\pi\hbar)^{-n/2}e^{\frac{i}{\hbar}\boldsymbol{pq}}$ the set of generalized common eigenfunctions for the operators $\boldsymbol{Q}$ and $\boldsymbol{P}$, respectively, we formally get

$$\boldsymbol{Q}|\boldsymbol{q}\rangle = \boldsymbol{q}|\boldsymbol{q}\rangle, \quad \boldsymbol{P}|\boldsymbol{p}\rangle = \boldsymbol{p}|\boldsymbol{p}\rangle$$

where operators $\mathbf{Q}$ act on $\boldsymbol{q}'$, and

$$\begin{aligned}\langle\boldsymbol{q}|\psi\rangle &= \int_{\mathbb{R}^n}\delta(\boldsymbol{q} - \boldsymbol{q}')\,\psi(\boldsymbol{q}')\,d^n\boldsymbol{q}' = \psi(\boldsymbol{q}), \\ \langle\boldsymbol{p}|\psi\rangle &= (2\pi\hbar)^{-n/2}\int_{\mathbb{R}^n} e^{-\frac{i}{\hbar}\boldsymbol{pq}}\psi(\boldsymbol{q})d^n\boldsymbol{q} = \hat{\psi}(\boldsymbol{p}),\end{aligned}$$

as well as $\langle\boldsymbol{q}|\boldsymbol{q}'\rangle = \delta(\boldsymbol{q} - \boldsymbol{q}')$, $\langle\boldsymbol{p}|\boldsymbol{p}'\rangle = \delta(\boldsymbol{p} - \boldsymbol{p}')$. Though in our exposition we are not using Dirac's notation, these formulas would help the interested reader "translate" the notation used in physics textbooks to standard mathematics notation.

Remark. We will show in Section 3.2 that every Lagrangian subspace of the symplectic vector space $\mathbb{R}^{2n}$ with the canonical symplectic form $\omega = d\boldsymbol{p} \wedge d\boldsymbol{q}$ gives rise to an integrable, unitary, irreducible representation of the Heisenberg algebra $\mathfrak{h}_n$. This is the simplest example of the real polarization, which for a given symplectic manifold $(\mathscr{M}, \omega)$ is defined as an integrable

distribution $\{\mathscr{L}_x\}_{x\in\mathscr{M}}$ of Lagrangian subspaces $\mathscr{L}_x$ of tangent spaces $T_x\mathscr{M}$. The notion of a polarization plays a fundamental role in geometric quantization: it allows us to construct (under certain conditions) the Hilbert space of states $\mathscr{H}$ associated with the classical phase space $(\mathscr{M},\omega)$. In the linear case $\mathscr{M}=\mathbb{R}^{2n}$ every Lagrangian subspace $\mathscr{L}$ in $\mathbb{R}^{2n}$ gives rise to a real polarization by using the identification $T_x\mathbb{R}^{2n}\simeq\mathbb{R}^{2n}$. In particular, for the coordinate representation, $\mathscr{L}$ is given by the equation $\boldsymbol{q}=0$, and for the momentum representation - by the equation $\boldsymbol{p}=0$. The corresponding Hilbert $\mathscr{H}$ space consists of functions on $\mathbb{R}^{2n}$ which are constant along the fibers of the polarization.

Problem 2.4. Give an example of a non-integrable representation of the Heisenberg algebra.

Problem 2.5. Prove that there exists $\varphi\in\mathscr{H}=L^2(\mathbb{R},dq)$ such that the vectors $\mathrm{P}(E)\varphi, E\in\mathscr{B}(\mathbb{R})$, where P is a projection-valued measure for the coordinate operator Q, are dense in $\mathscr{H}$.

Problem 2.6. Find the generating operator for the commutative family $\boldsymbol{Q}=(Q^1,...,Q^n)$. Does it have a physical interpretation?

Problem 2.7. Find the projection-valued measure for the commutative family $\boldsymbol{P}=(P_1,...,P_n)$ in the coordinate representation.

3.2.2 2. Quantization: Basic Models

2.3. Free quantum particle.

A free classical particle with one degree of freedom is described by the phase space $\mathbb{R}^2$ with coordinates p,q and the Poisson bracket (2.1), and by the Hamiltonian function

$$H_{\mathrm{c}}(p,q)=\frac{p^2}{2m} \tag{2.15}$$

The Hamiltonian operator of a free quantum particle with one degree of freedom is

$$H_0=\frac{P^2}{2m}$$

and in coordinate representation is given by

$$H_0=-\frac{\hbar^2}{2m}\frac{d^2}{dq^2}$$

It is a self-adjoint operator on $\mathscr{H}=L^2(\mathbb{R},dq)$ with $D(H_0)=W^{2,2}(\mathbb{R})$ - the Sobolev space of functions in $L^2(\mathbb{R})$, whose generalized first and second derivatives are in $L^2(\mathbb{R})$.

The operator H_0 is positive with absolutely continuous spectrum $[0,\infty)$ of multiplicity two. Indeed, let $\mathfrak{H}_0=L^2(\mathbb{R}_{>0},\mathbb{C}^2;d\sigma)$ be the Hilbert space of $\mathbb{C}^2$-valued measurable functions Ψ on the semi-line $\mathbb{R}_{>0}=(0,\infty)$, which are square-integrable with respect to the measure $d\sigma(\lambda)=\sqrt{\frac{m}{2\lambda}}d\lambda$,

$$\mathfrak{H}_0=\left\{\Psi(\lambda)=\begin{pmatrix}\psi_1(\lambda)\\ \psi_2(\lambda)\end{pmatrix}:\|\Psi\|^2=\int_0^\infty\left(|\psi_1(\lambda)|^2+|\psi_2(\lambda)|^2\right)d\sigma(\lambda)<\infty\right\}.$$

It follows from the unitarity of the Fourier transform that the operator $\mathscr{U}_0:L^2(\mathbb{R},dq)\to\mathfrak{H}_0$,

$$\mathscr{U}_0(\psi)(\lambda)=\Psi(\lambda)=\begin{pmatrix}\hat{\psi}(\sqrt{2m\lambda})\\ \hat{\psi}(-\sqrt{2m\lambda})\end{pmatrix}$$

is unitary, $\mathscr{U}_0^*\mathscr{U}_0=I$ and $\mathscr{U}_0\mathscr{U}_0^*=I_0$, where I and I_0 are, respectively, identity operators in $\mathscr{H}$ and $\mathfrak{H}_0$. The operator $\mathscr{U}_0$ establishes the isomorphism $L^2(\mathbb{R},dq)\simeq\mathfrak{H}_0$, and since in the momentum representation H_0 is a multiplication by $\frac{1}{2m}p^2$ operator, the operator $\mathscr{U}_0H_0\mathscr{U}_0^{-1}$ is

a multiplication by λ operator in $\mathfrak{H}_0$.
Remark. The Hamiltonian operator H_0 has no eigenvectors - the eigenvalue equation

$$H_0\psi = \lambda\psi$$

has no solutions in $L^2(\mathbb{R})$. However, for every $\lambda = \frac{1}{2m}k^2 > 0$ this differential equation has two linear independent bounded solutions

$$\psi_k^{(\pm)}(q) = \frac{1}{\sqrt{2\pi\hbar}} e^{\pm\frac{i}{\hbar}kq}, \quad k > 0$$

In the distributional sense, these eigenfunctions of the continuous spectrum combine to a Schwartz kernel of the unitary operator $\mathscr{U}_0$, which establishes
the isomorphism between $\mathscr{H} = L^2(\mathbb{R}, dq)$ and the Hilbert space $\mathfrak{H}_0$, where H_0 acts as a multiplication by λ operator. The normalization of the eigenfunctions of the continuous spectrum is also determined by the condition (2.14):

$$\lim_{\Delta\to 0}\frac{1}{\Delta}\left\|\Psi_{k+\Delta}^{(\pm)} - \Psi_k^{(\pm)}\right\|^2 = 1, \quad \lim_{\Delta\to 0}\frac{1}{\Delta}\left(\Psi_{k+\Delta}^{(+)} - \Psi_k^{(+)}, \Psi_{k+\Delta}^{(-)} - \Psi_k^{(-)}\right) = 0$$

where $\Psi_k^{(\pm)}(q) = \int_{k_0}^k \psi_p^{(\pm)}(q)dp$.
The Cauchy problem for the Schrodinger equation for a free particle,

$$i\hbar\frac{d\psi(t)}{dt} = H_0\psi(t), \quad \psi(0) = \psi \tag{2.16}$$

is easily solved by the Fourier transform. Indeed, in the momentum representation it takes the form

$$i\hbar\frac{\partial\hat{\psi}(p,t)}{\partial t} = \frac{p^2}{2m}\hat{\psi}(p,t), \quad \hat{\psi}(p,0) = \hat{\psi}(p)$$

so that

$$\hat{\psi}(p,t) = e^{-\frac{ip^2}{2m\hbar}t}\hat{\psi}(p).$$

In the coordinate representation, the solution of (2.16) is given by

$$\psi(q,t) = \frac{1}{\sqrt{2\pi\hbar}}\int_{-\infty}^{\infty} e^{\frac{i}{\hbar}pq}\hat{\psi}(p,t)dp = \frac{1}{\sqrt{2\pi\hbar}}\int_{-\infty}^{\infty} e^{\frac{i}{\hbar}\chi(p,q,t)t}\hat{\psi}(p)dp \tag{2.17}$$

where

$$\chi(p,q,t) = -\frac{p^2}{2m} + \frac{pq}{t}.$$

Formula (2.17) describes the motion of a quantum particle, and admits the following physical interpretation. Let initial condition ψ in (2.16) be such that its Fourier transform $\hat{\psi} = \mathcal{F}_\hbar(\psi)$ is a smooth function supported in a neighborhood U_0 of $p_0 \in \mathbb{R}\backslash\{0\}, 0 \notin U_0$, and

$$\int_{-\infty}^{\infty}|\hat{\psi}(p)|^2dp = 1$$

Such states are called "wave packets". Then for every compact subset $E \subset \mathbb{R}$ we have

$$\lim_{|t|\to\infty}\int_E |\psi(q,t)|^2dq = 0 \tag{2.18}$$

Since

$$\int_{-\infty}^{\infty} |\psi(q,t)|^2 dq = 1$$

for all t, it follows from (2.18) that the particle leaves every compact subset of $\mathbb{R}$ as $|t| \to \infty$ and the quantum motion is infinite. To prove (2.18), observe that the function $\chi(p,q,t)$ - the "phase" in integral representation (2.17)

- has the property that $\left|\frac{\partial \chi}{\partial p}\right| > C > 0$ for all $p \in U_0, q \in E$ and large enough $|t|$. Integrating by parts we get

$$\begin{aligned}\psi(q,t) &= \frac{1}{\sqrt{2\pi\hbar}} \int_{U_0} e^{\frac{i}{\hbar}\chi(p,q,t)t} \hat{\psi}(p) dp \\ &= -\frac{1}{it}\sqrt{\frac{\hbar}{2\pi}} \int_{U_0} \frac{\partial}{\partial p}\left(\frac{\hat{\psi}(p)}{\frac{\partial \chi(p,q,t)}{\partial p}}\right) e^{\frac{i}{\hbar}\chi(p,q,t)t} dp\end{aligned}$$

so that uniformly on E,

$$\psi(q,t) = O\left(|t|^{-1}\right) \quad \text{as} \quad |t| \to \infty.$$

By repeated integration by parts, we obtain that for every $n \in \mathbb{N}$, uniformly on E,

$$\psi(q,t) = O\left(|t|^{-n}\right)$$

so that $\psi(q,t) = O\left(|t|^{-\infty}\right)$.

To describe the motion of a free quantum particle in unbounded regions, we use the stationary phase method. In its simplest form it is stated as follows.

The Method of Stationary Phase. Let $f, g \in C^\infty(\mathbb{R})$, where f is realvalued and g has compact support, and suppose that f has a single nondegenerate critical point x_0, i.e., $f'(x_0) = 0$ and $f''(x_0) \neq 0$. Then

$$\int_{-\infty}^{\infty} e^{iNf(x)} g(x) dx = \left(\frac{2\pi}{N|f''(x_0)|}\right)^{\frac{1}{2}} e^{iNf(x_0) + \frac{i\pi}{4}\operatorname{sgn} f''(x_0)} g(x_0) + O\left(\frac{1}{N}\right)$$

as $N \to \infty$.

Applying the stationary phase method to the integral representation (2.17) (and setting $N = t$), we find that the critical point of $\chi(p,q,t)$ is $p_0 = \frac{mq}{t}$ with $\chi''(p_0) = -\frac{1}{m} \neq 0$, and

$$\begin{aligned}\psi(q,t) &= \sqrt{\frac{m}{t}} \hat{\psi}\left(\frac{mq}{t}\right) e^{\frac{imq^2}{2\hbar t} - \frac{\pi i}{4}} + O\left(t^{-1}\right) \\ &= \psi_0(q,t) + O\left(t^{-1}\right) \quad \text{as} \quad t \to \infty\end{aligned}$$

Thus as $t \to \infty$, the wave function $\psi(q,t)$ is supported on $\frac{t}{m}U_0$ - a domain where the probability of finding a particle is asymptotically different from zero. At large t the points in this domain move with constant velocities $v = \frac{p}{m}, p \in U_0$. In this sense, the classical relation $p = mv$ remains valid in the quantum picture. Moreover, the asymptotic wave function ψ_0 satisfies

$$\int_{-\infty}^{\infty} |\psi_0(q,t)|^2 dq = \sqrt{\frac{m}{t}} \int_{-\infty}^{\infty} \left|\hat{\psi}\left(\frac{mq}{t}\right)\right|^2 dq = 1$$

and, therefore, describes the asymptotic probability distribution. Similarly, setting $N = -|t|$, we can describe the behavior of the wave function $\psi(q,t)$ as $t \to -\infty$.

Remark. We have $\lim_{|t|\to\infty}\psi(t)=0$ in the weak topology on $\mathscr{H}$. Indeed, for every $\varphi\in\mathscr{H}$ we get by Parseval's identity for the Fourier integrals,

$$(\psi(t),\varphi)=\int_{-\infty}^{\infty}\hat{\psi}(p)\overline{\hat{\varphi}(p)}e^{-\frac{ip^2t}{2m\hbar}}dp$$

and the integral goes to zero as $|t|\to\infty$ by the Riemann-Lebesgue lemma.
A free classical particle with n degrees of freedom is described by the phase space $\mathbb{R}^{2n}$ with coordinates $\boldsymbol{p}=(p_1,...,p_n)$ and $\boldsymbol{q}=(q^1,...,q^n)$, the Poisson bracket (2.3), and the Hamiltonian function

$$H_{\mathrm{c}}(\boldsymbol{p},\boldsymbol{q})=\frac{\boldsymbol{p}^2}{2m}=\frac{1}{2m}\left(p_1^2+\cdots+p_n^2\right).$$

The Hamiltonian operator of a free quantum particle with n degrees of freedom is

$$H_0=\frac{\boldsymbol{P}^2}{2m}=\frac{1}{2m}\left(P_1^2+\cdots+P_n^2\right)$$

and in the coordinate representation is

$$H_0=-\frac{\hbar^2}{2m}\Delta$$

where

$$\Delta=\left(\frac{\partial}{\partial\boldsymbol{q}}\right)^2=\left(\frac{\partial}{\partial q^1}\right)^2+\cdots+\left(\frac{\partial}{\partial q^n}\right)^2$$

is the Laplace operator [15] in the Cartesian coordinates on $\mathbb{R}^n$. The Hamiltonian H_0 is a self-adjoint operator on $\mathscr{H}=L^2\left(\mathbb{R}^n,d^n\boldsymbol{q}\right)$ with $D\left(H_0\right)=W^{2,2}\left(\mathbb{R}^n\right)$ - the Sobolev space on $\mathbb{R}^n$. In the momentum representation,

$$H_0=\frac{\boldsymbol{p}^2}{2m}$$

- a multiplication by a function operator on $\mathscr{H}=L^2\left(\mathbb{R}^n,d^n\boldsymbol{p}\right)$.

The operator H_0 is positive with absolutely continuous spectrum $[0,\infty)$ of infinite multiplicity. Namely, let $S^{n-1}=\{n\in\mathbb{R}^n:n^2=1\}$ be the $(n-1)$dimensional unit sphere in $\mathbb{R}^n$, let $d\boldsymbol{n}$ be the measure on S^{n-1} induced by the Lebesgue measure on $\mathbb{R}^n$, and let

$$\mathfrak{h}=\left\{f:S^{n-1}\to\mathbb{C}:\|f\|_{\mathfrak{h}}^2=\int_{S^{n-1}}|f(\boldsymbol{n})|^2dn<\infty\right\}$$

Let $\mathfrak{H}_0^{(n)}=L^2\left(\mathbb{R}_{>0},\mathfrak{h};d\sigma_n\right)$ be the Hilbert space of $\mathfrak{h}$-valued measurable functions [16]Ψ on $\mathbb{R}_{>0}=(0,\infty)$, square-integrable on $\mathbb{R}_{>0}$ with respect to the measure $d\sigma_n(\lambda)=(2m\lambda)^{\frac{n}{2}}\frac{d\lambda}{2\lambda}$,

$$\mathfrak{H}_0^{(n)}=\left\{\Psi:\mathbb{R}_{>0}\to\mathfrak{h},\|\Psi\|^2=\int_0^{\infty}\|\Psi(\lambda)\|_{\mathfrak{h}}^2d\sigma_n(\lambda)<\infty\right\}.$$

When $n=1,\mathfrak{H}_0^{(1)}=\mathfrak{H}_0$ - the corresponding Hilbert space for one degree of freedom. The operator $\mathscr{U}_0:L^2\left(\mathbb{R}^n,d^n\boldsymbol{q}\right)\to\mathfrak{H}_0^{(n)}$,

$$\mathscr{U}_0(\psi)(\lambda)=\Psi(\lambda),\quad\Psi(\lambda)(\boldsymbol{n})=\hat{\psi}(\sqrt{2m\lambda}\boldsymbol{n})$$

[015] It is the negative of the Laplace-Beltrami operator of the standard Euclidean metric on $\mathbb{R}^n$.

is unitary and establishes the isomorphism $L^2(\mathbb{R}^n, d^n\boldsymbol{q}) \simeq \mathfrak{H}_0^{(n)}$. In the momentum representation H_0 is a multiplication by $\frac{1}{2m}\boldsymbol{p}^2$ operator, so that the operator $\mathscr{U}_0 H_0 \mathscr{U}_0^{-1}$ is a multiplication by λ operator in $\mathfrak{H}_0^{(n)}$.

Remark. As in the case $n = 1$, the Hamiltonian operator H_0 has no eigenvectors - the eigenvalue equation

$$H_0\psi = \lambda\psi$$

has no solutions in $L^2(\mathbb{R}^n)$. However, for every $\lambda > 0$ this differential equation has infinitely many linearly independent bounded solutions

$$\psi_{\boldsymbol{n}}(\boldsymbol{q}) = (2\pi\hbar)^{-\frac{n}{2}} e^{\frac{i}{\hbar}\sqrt{2m\lambda}\boldsymbol{n}\boldsymbol{q}}$$

parametrized by the unit sphere S^{n-1}. These solutions do not belong to $L^2(\mathbb{R}^n)$, but in the distributional sense they combine to a Schwartz kernel of the unitary operator $\mathscr{U}_0$, which establishes the isomorphism between $\mathscr{H} = L^2(\mathbb{R}^n, d^n\boldsymbol{q})$ and the Hilbert space $\mathfrak{H}_0^{(n)}$, where H_0 acts as a multiplication by λ operator.

As in the case $n = 1$, the Schrodinger equation for free particle,

$$i\hbar\frac{d\psi(t)}{dt} = H_0\psi(t), \quad \psi(0) = \psi$$

is solved by the Fourier transform

$$\psi(\boldsymbol{q}, t) = (2\pi\hbar)^{-n/2} \int_{\mathbb{R}^n} e^{\frac{i}{\hbar}\left(\boldsymbol{p}\boldsymbol{q} - \frac{p^2}{2m}t\right)} \hat{\psi}(\boldsymbol{p}) d^n\boldsymbol{p}$$

For a wave packet, an initial condition ψ such that its Fourier transform $\hat{\psi} = \mathscr{F}_\hbar(\psi)$ is a smooth function supported on a neighborhood U_0 of $\boldsymbol{p}_0 \in \mathbb{R}^n\backslash\{0\}$ such that $0 \notin U_0$ and

$$\int_{\mathbb{R}^n} |\hat{\psi}(\boldsymbol{p})|^2 d^n\boldsymbol{p} = 1$$

the quantum particle leaves every compact subset of $\mathbb{R}^n$ and the motion is infinite. Asymptotically as $|t| \to \infty$, the wave function $\psi(\boldsymbol{q}, t)$ is different from 0 only when $\boldsymbol{q} = \frac{\boldsymbol{p}}{m}t, \boldsymbol{p} \in U_0$.

Problem 2.8. Find the asymptotic wave function for a free quantum particle with n degrees of freedom.

2.4. Examples of quantum systems.

Here we describe quantum systems that correspond to the classical Lagrangian systems introduced in Section 1.3 of Chapter 1. In Hamiltonian formulation, the phase space of these systems, except for the last example, is a symplectic vector space $\mathbb{R}^{2n}$ with canonical coordinates $\boldsymbol{p}, \boldsymbol{q}$ and symplectic form $\omega = d\boldsymbol{p} \wedge d\boldsymbol{q}$.

Example 2.1 (Newtonian particle). According to Section 1.7 in Chapter 1, a classical particle in $\mathbb{R}^n$ moving in a potential field $V(\boldsymbol{q})$ is described by the Hamiltonian function

$$H_{\mathrm{c}}(\boldsymbol{p}, \boldsymbol{q}) = \frac{\boldsymbol{p}^2}{2m} + V(\boldsymbol{q})$$

Assume that the Hamiltonian operator for the quantum system is given by

$$H = \frac{\boldsymbol{P}^2}{2m} + V,$$

[016] That is, for every $f \in \mathfrak{h}$ the function (f, Ψ) is measurable on $\mathbb{R}_{>0}$.

with some operator V, so that coordinate and momenta operators satisfy Heisenberg equations of motion

$$\dot{\boldsymbol{P}} = \{H, \boldsymbol{P}\}_\hbar, \dot{\boldsymbol{Q}} = \{H, \boldsymbol{Q}\}_\hbar \tag{2.19}$$

To determine V, we require that the classical relation $\dot{\boldsymbol{q}} = \frac{\boldsymbol{p}}{m}$ between the velocity and the momentum of a particle is preserved under the quantization, i.e.,

$$\dot{\boldsymbol{Q}} = \frac{\boldsymbol{P}}{m}$$

Since $\{\boldsymbol{P}^2, \boldsymbol{Q}\}_\hbar = 2\boldsymbol{P}$, it follows from (2.19) that this condition is equivalent to

$$[V, Q_k] = 0, \quad k = 1, ..., n$$

It follows from Section 2.2 that V is a function of commuting operators $Q_1, ..., Q_n$, and the natural choice [17] is $V = V(\boldsymbol{Q})$. Thus the Hamiltonian operator of a Newtonian particle is

$$H = \frac{\boldsymbol{P}^2}{2m} + V(\boldsymbol{Q})$$

in agreement with $H = H_{\mathrm{c}}(\boldsymbol{P}, \boldsymbol{Q})$[18]. In coordinate representation the Hamiltonian is the Schrodinger operator

$$H = -\frac{\hbar^2}{2m}\Delta + V(\boldsymbol{q}) \tag{2.20}$$

with the real-valued potential $V(\boldsymbol{q})$.

Remark. The sum of two unbounded, self-adjoint operators is not necessarily self-adjoint, and one needs to describe admissible potentials $V(\boldsymbol{q})$ for which H is a self-adjoint operator on $L^2(\mathbb{R}^n, d^n\boldsymbol{q})$. If the potential $V(\boldsymbol{q})$ is a real-valued, locally integrable function on $\mathbb{R}^n$, then the differential operator (2.20) defines a symmetric operator H with the domain $C_0^2(\mathbb{R}^n)$ - twice continuously differentiable functions on $\mathbb{R}^n$ with compact support. Potentials for which the symmetric operator H has no self-adjoint extensions are obviously non-physical. It may also happen that H has several self-adjoint extensions [19]. These extensions are specified by some boundary conditions at infinity and there are no physical principles distinguishing between them. The only physical case is when the symmetric operator H admits a unique self-adjoint extension, that is, when H is essentially self-adjoint. In Chapter 3 we present necessary conditions for the essential self-adjointness. Here we only mention the von Neumann criterion that if A is a closed operator and $\overline{D(A)} = \mathscr{H}$, then $H = A^*A$ is a positive self-adjoint operator.

Example 2.2 (Interacting quantum particles). In Lagrangian formalism, a closed classical system of N interacting particles on $\mathbb{R}^3$ was described in Example 1.2 in Section 1.3 of Chapter 1. In Hamiltonian formalism, it is described by the canonical coordinates $r = (\boldsymbol{r}_1, ..., \boldsymbol{r}_N)$, the canonical momenta $\boldsymbol{p} = (\boldsymbol{p}_1, ..., \boldsymbol{p}_N), \boldsymbol{r}_a, \boldsymbol{p}_a \in \mathbb{R}^3$, and by the Hamiltonian function

$$H_{\mathrm{c}}(\boldsymbol{p}, \boldsymbol{r}) = \sum_{a=1}^{N} \frac{\boldsymbol{p}_a^2}{2m_a} + V(\boldsymbol{r}) \tag{2.21}$$

where m_a is the mass of the a-th particle, $a = 1, ..., N$ (see Section 1.7 in Chapter 1). The corresponding Hamiltonian operator H in the coordinate representation has the form

$$H = -\sum_{a=1}^{N} \frac{\hbar^2}{2m_a}\Delta_a + V(\boldsymbol{r}) \tag{2.22}$$

[017] Confirmed by the agreement of the theory with the experiments.

In particular, when

$$V(\boldsymbol{r}) = \sum_{1\le a<b\le N} V\left(\boldsymbol{r}_a - \boldsymbol{r}_b\right),$$

the Schrodinger operator (2.22) describes the N-body problem in quantum mechanics. The fundamental quantum system is the complex atom, formed by a nucleus of charge Ne and mass M, and by N electrons of charge $-e$ and mass m. Denoting by $\boldsymbol{R} \in \mathbb{R}^3$ the position of the nucleus, and by $\boldsymbol{r}_1, ..., \boldsymbol{r}_N$ the positions of the electrons and assuming that the interaction is given by the Coulomb attraction, we get for the Hamiltonian function (2.21)

$$H_{\mathrm{c}}(\boldsymbol{P}, \boldsymbol{p}, \boldsymbol{R}, \boldsymbol{r}) = \frac{\boldsymbol{P}^2}{2M} + \sum_{a=1}^{N} \frac{\boldsymbol{p}_a^2}{2m} - \sum_{a=1}^{N} \frac{Ne^2}{|\boldsymbol{R} - \boldsymbol{r}_a|} + \sum_{1\le a<b\le N} \frac{e^2}{|\boldsymbol{r}_a - \boldsymbol{r}_b|},$$

where $\boldsymbol{P}$ is the canonical momentum of the nucleus. The corresponding Schrodinger operator H in the coordinate representation has the form [20]

$$H = -\frac{\hbar^2}{2M}\Delta - \sum_{a=1}^{N} \frac{\hbar^2}{2m}\Delta_a - \sum_{a=1}^{N} \frac{Ne^2}{|\boldsymbol{R} - \boldsymbol{r}_a|} + \sum_{1\le a<b\le N} \frac{e^2}{|\boldsymbol{r}_a - \boldsymbol{r}_b|}$$

In the simplest case of the hydrogen atom, when $N = 1$ and the nucleus consists of a single proton [21], the Hamiltonian is

$$H = -\frac{\hbar^2}{2M}\Delta_p - \frac{\hbar^2}{2m}\Delta_e - \frac{e^2}{|\boldsymbol{r}_p - \boldsymbol{r}_e|}$$

where $\boldsymbol{r}_p$ is the position of the proton and $\boldsymbol{r}_e$ is the position of the electron. As the first approximation, the proton can be considered as infinitely heavy, so that the hydrogen atom is described by an electron in an attractive Coulomb field $-e^2/|\boldsymbol{r}|$, where now $\boldsymbol{r} = \boldsymbol{r}_e - \boldsymbol{r}_p$. The corresponding Hamiltonian operator takes the form

$$H = -\frac{\hbar^2}{2m}\Delta - \frac{e^2}{|\boldsymbol{r}|} \tag{2.23}$$

We will solve the Schrodinger equation with this Hamiltonian H and determine its energy levels in Section 5.1 of Chapter 3.

Example 2.3 (Charged particle in an electromagnetic field). A classical particle of charge e and mass m moving in the time-independent electromagnetic field with scalar and vector potentials $\varphi(\boldsymbol{r})$ and $\boldsymbol{A}(\boldsymbol{r}), \boldsymbol{r} \in \mathbb{R}^3$, is described by the Hamiltonian function

$$H_{\mathrm{c}}(\boldsymbol{p}, \boldsymbol{r}) = \frac{1}{2m}\left(\boldsymbol{p} - \frac{e}{c}\boldsymbol{A}\right)^2 + e\varphi(\boldsymbol{r})$$

(see Problem 1.27 in Section 1.7 of Chapter 1). The corresponding classical velocity vector $\boldsymbol{v} = \{H_{\mathrm{c}}, \boldsymbol{r}\}$ is given by

$$v = p - \frac{e}{c}A$$

[018] In the special case $H_c(\boldsymbol{p}, \boldsymbol{q}) = f(\boldsymbol{p}) + g(\boldsymbol{q})$ the problem of the ordering of non-commuting operators $\boldsymbol{P}$ and $\boldsymbol{Q}$ does not arise.

[19] This is the case when the defect indices of H are equal and are non-zero.

[020] Ignoring the fact that electron has spin, see Chapter 4.

[21] In the case of hydrogen-1 or protium; it includes one or more neutrons for deuterium, tritium, and other isotopes.

and its components $\boldsymbol{v} = (v_1, v_2, v_3)$ have non-vanishing Poisson brackets:

$$\{v_1, v_2\} = -\frac{e}{m^2c}B_3, \quad \{v_2, v_3\} = -\frac{e}{m^2c}B_1, \quad \{v_3, v_1\} = -\frac{e}{m^2c}B_2,$$

where $\boldsymbol{B} = (B_1, B_2, B_3)$ are components of the magnetic field $\boldsymbol{B} = \operatorname{curl} \boldsymbol{A}$.
The Hamiltonian operator of a quantum particle is

$$H = \frac{1}{2m}\left(\boldsymbol{P} - \frac{e}{c}\boldsymbol{A}\right)^2 + e\varphi(\boldsymbol{r}) \tag{2.24}$$

- the Schrodinger operator of a charged particle in an electromagnetic field. The corresponding quantum velocity vector $\boldsymbol{V} = \{H, \boldsymbol{Q}\}_\hbar$ is given by the same formula as in the classical case,

$$V = P - \frac{e}{c}A,$$

and its components $\boldsymbol{V} = (V_1, V_2, V_3)$ have non-vanishing quantum brackets:

$$\{V_1, V_2\}_\hbar = -\frac{e}{m^2c}B_3, \qquad \{V_2, V_3\}_\hbar = -\frac{e}{m^2c}B_1, \qquad \{V_3, V_1\}_\hbar = -\frac{e}{m^2c}B_2$$

Thus in the presence of a magnetic field the three components of a quantum velocity operator no longer commute and cannot be measured simultaneously.

Example 2.4 (Free quantum particle on a Riemannian manifold). The phase space of a classical particle of mass $m = 1$ moving on a Riemannian manifold (M, g) is the cotangent bundle T^*M, and the corresponding Hamiltonian function is given by

$$H_c(\boldsymbol{p}, \boldsymbol{x}) = \frac{1}{2}g^{\mu\nu}(\boldsymbol{x})p_\mu p_\nu,$$

where $g^{\mu\nu}(\boldsymbol{x})$ is the inverse of the metric tensor $g_{\mu\nu}(\boldsymbol{x})$, and

$$(\boldsymbol{p}, \boldsymbol{x}) = \left(p_1, ..., p_n, x^1, ..., x^n\right)$$

are standard coordinates on T^*M (see Section 1.7 of Chapter 1). The Hilbert space of the quantum system is $\mathscr{H} = L^2(M, d\mu)$, where $d\mu = \sqrt{g(\boldsymbol{x})}d^n\boldsymbol{x}$, $g(\boldsymbol{x}) = \det\left(g_{\mu\nu}(\boldsymbol{x})\right)$, is the measure associated with the density of the Riemannian metric (Riemannian volume form if M is oriented). When canonical coordinates $(\boldsymbol{p}, \boldsymbol{x})$ are only locally defined on T^*M, it is not possible to construct corresponding operators $\boldsymbol{P}$ and $\boldsymbol{Q}$. Still, one can always define the Hamiltonian operator by

$$H = \frac{\hbar^2}{2}\Delta_g, \quad \text{where} \quad \Delta_g = -\frac{1}{\sqrt{g(\boldsymbol{x})}}\frac{\partial}{\partial x^\mu}\left(\sqrt{g(\boldsymbol{x})}g^{\mu\nu}\frac{\partial}{\partial x^\nu}\right) \tag{2.25}$$

is the Laplace-Beltrami operator of the Riemannian metric g on M. Note that in this case there is a non-trivial problem of the ordering of noncommuting operators in the quantization of $H_c(\boldsymbol{p}, \boldsymbol{x})$, which arises if in a
coordinate chart on M one replaces canonical coordinates $\boldsymbol{p}$ and $\boldsymbol{x}$ by $\boldsymbol{P}$ and $\boldsymbol{Q}$. The formula

$$\Delta_g = -g^{\mu\nu}(\boldsymbol{x})\frac{\partial^2}{\partial x^\mu \partial x^\nu} + g^{\mu\sigma}(\boldsymbol{x})\Gamma^\nu_{\mu\sigma}(\boldsymbol{x})\frac{\partial}{\partial x^\nu}$$

shows that local expressions defined by

$$H_c(\boldsymbol{P}, \boldsymbol{Q}) = \frac{1}{2}\left(g^{\mu\nu}(\boldsymbol{Q})P_\mu P_\nu + i\hbar g^{\mu\sigma}(\boldsymbol{Q})\Gamma^\nu_{\mu\sigma}(\boldsymbol{Q})P_\nu\right) \tag{2.26}$$

combine to a well-defined self-adjoint operator H on $\mathscr{H}$ given by (2.25). Thus even when $M = \mathbb{R}^n$ and canonical coordinates $(\boldsymbol{p}, \boldsymbol{x})$ are globally defined on $T^*\mathbb{R}^n$, the correct formula for $H_c(\boldsymbol{P}, \boldsymbol{Q})$ - the one which extends to general Riemannian manifolds - is given by (2.26), where the second term represents the "quantum correction" to the naive expression $g^{\mu\nu}(\boldsymbol{Q})P_\mu P_\nu$.

2.5. Old quantum mechanics.

The formulation of quantum mechanics presented here goes back to 1925-1927, and is due to Heisenberg, Schrodinger, Born, Jordan, and Dirac. It replaced the old quantum theory, proposed in 1913 by Bohr, which was based on Rutherford's planetary model of the atom. In the old theory, the energy levels of a one-dimensional quantum system correspond to the closed orbits of the associated classical Hamiltonian system which satisfy the Bohr-Wilson-Sommerfeld quantization rule (BWS rule)

$$\oint p dq = 2\pi\hbar \left(n + \frac{1}{2}\right)$$

where n is a non-negative integer, and integration goes over the closed orbit in the phase space $\mathbb{R}^2$. Bohr-Wilson-Sommerfeld quantization rules also apply to completely integrable Hamiltonian systems with several degrees of freedom (see Section 2.6 of Chapter 1). Namely, let $F_1 = H_c, ..., F_N$ be N independent integrals of motion in involution. The BWS quantization rules are

$$\oint_\gamma \boldsymbol{p} d\boldsymbol{q} = 2\pi\hbar \left(n_\gamma + \frac{1}{4} \operatorname{ind} \gamma\right),$$

where integration goes over all 1-cycles γ in the Lagrangian submanifold $\Lambda = \left\{(\boldsymbol{p}, \boldsymbol{q}) \in \mathbb{R}^{2N} : H_c(\boldsymbol{p}, \boldsymbol{q}) = E, F_2(\boldsymbol{p}, \boldsymbol{q}) = E_2, ..., F_N(\boldsymbol{p}, \boldsymbol{q}) = E_N\right\}$, and $\operatorname{ind} \gamma \in \mathbb{Z}$ is the so-called Maslov index of a cycle γ in Λ. In the onedimensional case the closed orbit is topologically a circle and its Maslov index is 2 . It will be shown in Section 6.3 of Chapter 3 that, in general, Bohr-Wilson-Sommerfeld quantization rules only give asymptotics of the energy levels as $\hbar \to 0$. However, for integrable systems with extra symmetry, such as the harmonic oscillator and the Kepler problem, the BWS quantization rules determine the energy levels exactly. We will show this in the next section for the harmonic oscillator, and in Section 5.1 of Chapter 3 - for the Kepler problem.

2.6. Harmonic oscillator.

The simplest classical system with one degree of freedom, besides the free particle, is the harmonic oscillator. It is described by the phase space $\mathbb{R}^2$ with the canonical coordinates p, q, and the Hamiltonian function

$$H_c(p, q) = \frac{p^2}{2m} + \frac{m\omega^2 q^2}{2} \tag{2.27}$$

(see Sections 1.5 and 1.7 in Chapter 1). Hamilton's equations

$$\dot{p} = \{H_c, p\} = -m\omega^2 q, \quad \dot{q} = \{H_c, q\} = \frac{p}{m}$$

with the initial conditions p_0, q_0 are readily solved,

$$p(t) = p_0 \cos \omega t - m\omega q_0 \sin \omega t \tag{2.28}$$

$$q(t) = q_0 \cos \omega t + \frac{1}{m\omega} p_0 \sin \omega t \tag{2.29}$$

and describe the harmonic motion. As in Section 2.6 of Chapter 1, it is convenient to introduce complex coordinates on the phase space on $\mathbb{R}^2 \simeq \mathbb{C}$,

$$z = \frac{1}{\sqrt{2\omega}}(\omega q + ip), \quad \bar{z} = \frac{1}{\sqrt{2\omega}}(\omega q - ip). \tag{2.30}$$

We have

$$\{z, \bar{z}\} = \frac{i}{m}, \quad H_{\mathrm{c}}(z, \bar{z}) = m\omega|z|^2 \tag{2.31}$$

so that Hamilton's equations decouple,

$$\dot{z} = \{H_{\mathrm{c}}, z\} = -i\omega z, \quad \dot{\bar{z}} = \{H_{\mathrm{c}}, \bar{z}\} = i\omega\bar{z}$$

and are trivially solved,

$$z(t) = e^{-i\omega t} z_0, \quad \bar{z} = e^{i\omega t}\bar{z}_0. \tag{2.32}$$

Here

$$z_0 = \frac{1}{\sqrt{2\omega}}\left(\omega q_0 + ip_0\right), \quad \bar{z}_0 = \frac{1}{\sqrt{2\omega}}\left(\omega q_0 - ip_0\right).$$

For the quantum system, the corresponding Hamiltonian operator is

$$H = \frac{P^2}{2m} + \frac{m\omega^2 Q^2}{2},$$

and in the coordinate representation $\mathscr{H} = L^2(\mathbb{R}, dq)$ it is a Schrodinger operator with a quadratic potential,

$$H = -\frac{\hbar^2}{2m}\frac{d^2}{dq^2} + \frac{m\omega^2 q^2}{2}.$$

The quantum harmonic oscillator is the simplest non-trivial quantum system, besides the free particle, whose Schrodinger equation can be solved explicitly. It appears in all problems involving quantized oscillations, namely in molecular and crystalline vibrations. The exact solution of the harmonic
oscillator, described below, has remarkable [22] algebraic and analytic properties.

Temporarily set $m = 1$ and consider the operators

$$a = \frac{1}{\sqrt{2\omega\hbar}}(\omega Q + iP), \quad a^* = \frac{1}{\sqrt{2\omega\hbar}}(\omega Q - iP) \tag{2.33}$$

which are quantum analogs of complex coordinates (2.30). The operators a and a^* are defined on $W^{1,2}(\mathbb{R}) \cap \widehat{W}^{1,2}(\mathbb{R})$, where $\widehat{W}^{1,2}(\mathbb{R}) = \mathscr{F}\left(W^{1,2}(\mathbb{R})\right)$, and it is easy to show that a^* is the adjoint operator to a and $a^{**} = a$, so that a is a closed operator. From the Heisenberg commutation relation (2.2) we get the canonical commutation relation

$$[a, a^*] = I \tag{2.34}$$

on $W^{2,2}(\mathbb{R}) \cap \widehat{W}^{2,2}(\mathbb{R})$. Indeed,

$$aa^* = \frac{P^2 + \omega^2 Q^2}{2\omega\hbar} + \frac{i\omega}{2\omega\hbar}[P, Q] = \frac{P^2 + \omega^2 Q^2}{2\omega\hbar} + \frac{1}{2}I,$$

and

$$a^* a = \frac{P^2 + \omega^2 Q^2}{2\omega\hbar} - \frac{i\omega}{2\omega\hbar}[P, Q] = \frac{P^2 + \omega^2 Q^2}{2\omega\hbar} - \frac{1}{2}I,$$

so that (2.34) holds on $W^{2,2}(\mathbb{R}) \cap \widehat{W}^{2,2}(\mathbb{R})$, where $\widehat{W}^{2,2}(\mathbb{R}) = \mathscr{F}\left(W^{2,2}(\mathbb{R})\right)$, and

$$H = \omega\hbar\left(a^*a + \frac{1}{2}I\right) = \omega\hbar\left(aa^* - \frac{1}{2}I\right).$$

In particular, it follows from the von Neumann criterion that the Hamiltonian operator H is self-adjoint.

The operators a, a^* and $N = a^*a$ satisfy the commutation relations

$$[N, a] = -a, \quad [N, a^*] = a^*, \quad [a, a^*] = I. \tag{2.35}$$

These commutation relations correspond to the irreducible unitary representation of a four-dimensional solvable Lie algebra $\tilde{\mathfrak{h}}$ associated with the Heisenberg algebra $\mathfrak{h} = \mathfrak{h}_1$, introduced in Section 2.1. Namely, $\mathfrak{h}$ is a Lie algebra with the generators e, f, h, and c, where e, f, c satisfy the relations of the Heisenberg algebra $\mathfrak{h}$, and

$$[h, e] = -f, \quad [h, f] = \omega^2 e, \quad [h, c] = 0.$$

The irreducible integrable representation ρ of the Heisenberg algebra $\mathfrak{h}$ (see (2.9) in Section 2.1) extends to a unitary representation of the Lie algebra
$\tilde{\mathfrak{h}}$ by setting

$$\rho(h) = -i\omega N = \frac{P^2 + \omega^2 Q^2}{2i\hbar} + \frac{i\omega}{2}I.$$

Remark. In invariant terms, the Lie algebra $\tilde{\mathfrak{h}}$ is a one-dimensional right extension of the Heisenberg algebra $\mathfrak{h}$,

$$0 \to \mathfrak{h} \to \tilde{\mathfrak{h}} \to \mathbb{R} \to 0$$

It is defined by the $\mathfrak{h}$-valued Lie algebra 1-cocycle $r \in Z^1(\mathfrak{h}, \mathfrak{h})$ - a derivation of $\mathfrak{h}$, given on generators by

$$r(e) = f, \quad r(f) = -\omega^2 e, \quad r(c) = 0$$

Explicitly, if $h \in \tilde{\mathfrak{h}}$ is such that $\bar{h} = 1 \in \mathbb{R}$ under the projection $\tilde{\mathfrak{h}} \to \mathbb{R}$, then identifying elements in $\mathfrak{h}$ with their images under the embedding $\mathfrak{h} \hookrightarrow \tilde{\mathfrak{h}}$, we have

$$[x + \alpha h, y + \beta h] = [x, y] - \alpha r(y) + \beta r(y), \quad x, y \in \mathfrak{h}.$$

It is due to this Lie-algebraic structure of commutation relations (2.35) that Heisenberg equations of motion for the harmonic oscillator can be solved exactly. Namely, we have

$$\dot{a} = \{H, a\}_\hbar = -i\omega a, \quad \dot{a}^* = \{H, a^*\}_\hbar = i\omega a^*,$$

so that

$$a(t) = e^{-i\omega t}a_0, \quad a^*(t) = e^{i\omega t}a_0^*.$$

Comparing with (2.32) we see that solutions of classical and quantum equations of motion for the harmonic oscillator have the same form!

Next, using commutation relations (2.35) and positivity of the operator N, we will solve the eigenvalue problem for the Hamiltonian H of the harmonic oscillator explicitly by finding its energy levels and corresponding eigenvectors. We will prove that the eigenvectors form

[022] The algebraic structure of the exact solution of the harmonic oscillator plays a fundamental role in quantum electrodynamics and in quantum field theory in general.

a complete system of vectors in $\mathscr{H}$, so that the spectrum of the Hamiltonian H is the point spectrum. This is a quantum mechanical analog of the fact that classical motion of the harmonic oscillator is always finite.

The algebraic part of the exact solution is the following fundamental result.

Proposition 2.2. Suppose that there exists a non-zero $\psi \in D(a^n) \cap D((a^*)^n)$, $n = 1, 2, ...$, such that

$$H\psi = \lambda\psi.$$

Then the following statements hold.

(i) There exists $\psi_0 \in \mathscr{H}$, $\|\psi_0\| = 1$, such that

$$H\psi_0 = \frac{1}{2}\hbar\omega\psi_0.$$

(ii) The vectors

$$\psi_n = \frac{(a^*)^n}{\sqrt{n!}}\psi_0 \in \mathscr{H}, \quad n = 0, 1, 2, ...,$$

are orthonormal eigenvectors for H with the eigenvalues $\hbar\omega\left(n + \frac{1}{2}\right)$,

$$H\psi_n = \hbar\omega\left(n + \frac{1}{2}\right)\psi_n.$$

(iii) Restriction of the operator H to the Hilbert space $\mathscr{H}_0 - a$ closed subspace of $\mathscr{H}$, spanned by the orthonormal set $\{\psi_n\}_{n=0}^{\infty}$ - is essentially self-adjoint.

Proof. Rewriting commutation relations (2.35) as

$$Na = a(N - I) \quad \text{and} \quad Na^* = a^*(N + I),$$

and putting $\lambda = \hbar\omega\left(\mu + \frac{1}{2}\right)$, we get for all $n \geq 0$,

$$Na^n\psi = (\mu - n)a^n\psi \quad \text{and} \quad N(a^*)^n\psi = (\mu + n)(a^*)^n\psi. \tag{2.36}$$

Since $N \geq 0$ on $D(N)$, it follows from the first equation in (2.36) that there exists $n_0 \geq 0$ such that $a^{n_0}\psi \neq 0$ but $a^{n_0+1}\psi = 0$. Setting $\psi_0 = \frac{a^{n_0}\psi}{\|a^{n_0}\psi\|} \in \mathscr{H}$ we get

$$a\psi_0 = 0 \quad \text{and} \quad N\psi_0 = 0 \tag{2.37}$$

Since $H = \hbar\omega\left(N + \frac{1}{2}I\right)$, this proves part (i). To prove part (ii), we use commutation relations

$$[a, (a^*)^n] = n(a^*)^{n-1}, \tag{2.38}$$

which follow from (2.34) and the Leibniz rule. Using (2.37)-(2.38), we get

$$a^*\psi_n = \sqrt{n+1}\psi_{n+1}, \quad a\psi_n = \sqrt{n}\psi_{n-1}, \tag{2.39}$$

so that

$$\|\psi_n\|^2 = \frac{1}{\sqrt{n}}(a^*\psi_{n-1}, \psi_n) = \frac{1}{\sqrt{n}}(\psi_{n-1}, a\psi_n) = \|\psi_{n-1}\|^2 = \cdots = \|\psi_0\|^2 = 1.$$

From the second equation in (2.36) it follows that $N\psi_n = n\psi_n$, so ψ_n are normalized eigenvectors of H with the eigenvalues $\hbar\omega\left(n + \frac{1}{2}\right)$. The eigenvectors ψ_n are orthogonal since the corresponding eigenvalues are distinct and the operator H is symmetric. Finally, part (iii)

immediately follows from the fact that, according to part (ii), the subspaces $\mathrm{Im}(H \pm iI)|_{\mathscr{H}_0}$ are dense in $\mathscr{H}_0$, which is the criterion of essential self-adjointness.

Remark. Since the coordinate representation of the Heisenberg commutation relations is irreducible, it is tempting to conclude, using Proposition 2.2, that $\mathscr{H}_0 = \mathscr{H}$. Namely, it follows from the construction that the linear span of vectors ψ_n - a dense subspace of $\mathscr{H}_0$ - is invariant for the operators P and Q. However, this does not immediately imply that the projection operator Π_0 onto the subspace $\mathscr{H}_0$ commutes with self-adjoint operators P and Q in the sense of the definition in Section 1.1.

Using the coordinate representation, we can immediately show the existence of the vector ψ_0 in Proposition 2.2, and prove that $\mathscr{H}_0 = \mathscr{H}$. Indeed, equation $a\psi_0 = 0$ becomes a first order linear differential equation

$$\left(\hbar\frac{d}{dq} + \omega q\right)\psi_0 = 0$$

so that

$$\psi_0(q) = \sqrt[4]{\frac{\omega}{\pi\hbar}}e^{-\frac{\omega}{2\pi}q^2},$$

and

$$\|\psi_0\|^2 = \sqrt{\frac{\omega}{\pi\hbar}}\int_{-\infty}^{\infty} e^{-\frac{\omega}{\hbar}q^2}dq = 1$$

The vector ψ_0 is called the ground state for the harmonic oscillator. Correspondingly, the eigenfunctions

$$\psi_n(q) = \frac{1}{\sqrt{n!}}\left(\frac{1}{\sqrt{2\omega\hbar}}\left(\omega q - \hbar\frac{d}{dq}\right)\right)^n\psi_0$$

are of the form $P_n(q)e^{-\frac{\omega}{2\hbar}q^2}$, where $P_n(q)$ are polynomials of degree n. The following result guarantees that the functions $\{\psi_n\}_{n=0}^{\infty}$ form an orthonormal basis in $L^2(\mathbb{R}, dq)$.

Lemma 2.3. The functions $q^n e^{-q^2}, n = 0, 1, 2, ...$, are complete in $L^2(\mathbb{R}, dq)$.

Proof. Let $f \in L^2(\mathbb{R}, dq)$ is such that

$$\int_{-\infty}^{\infty} f(q)q^n e^{-q^2}dq = 0, \quad n = 0, 1, 2, ...$$

The integral

$$F(z) = \int_{-\infty}^{\infty} f(q)e^{iqz-q^2}dq$$

is absolutely convergent for all $z \in \mathbb{C}$ and, therefore, defines an entire function. We have

$$F^{(n)}(0) = i^n\int_{-\infty}^{\infty} f(q)q^n e^{-q^2}dq = 0, \quad n = 0, 1, 2, ...$$

so that $F(z) = 0$ for all $z \in \mathbb{C}$. This implies the function $g(q) = f(q)e^{-q^2} \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ satisfies $\mathscr{F}(g) = 0$, where $\mathscr{F}$ is the "ordinary" ($\hbar = 1$) Fourier transform. Thus we conclude that $g = 0$.

The polynomials P_n are expressed through classical Hermite-Tchebyscheff polynomials H_n, defined by

$$H_n(q) = (-1)^n e^{q^2}\frac{d^n}{dq^n}e^{-q^2}, \quad n = 0, 1, 2, ...$$

Namely, using the identity

$$e^{\frac{q^2}{2}}\frac{d^n}{dq^n}e^{-q^2} = -\left(q-\frac{d}{dq}\right)\left[e^{\frac{q^2}{2}}\frac{d^{n-1}}{dq^{n-1}}e^{-q^2}\right]$$
$$= \cdots = (-1)^n\left(q-\frac{d}{dq}\right)^n e^{-\frac{q^2}{2}}$$

we obtain

$$\psi_n(q) = \sqrt[4]{\frac{\omega}{\pi\hbar}}\frac{1}{\sqrt{2^n n!}}e^{-\frac{\omega}{2\hbar}q^2}H_n\left(\sqrt{\frac{\omega}{\hbar}}q\right).$$

We summarize the obtained results as follows.

Theorem 2.1. The Hamiltonian

$$H = -\frac{\hbar^2}{2m}\frac{d^2}{dq^2} + \frac{m\omega^2 q^2}{2}$$

of the quantum harmonic oscillator with one degree of freedom is a selfadjoint operator on $\mathscr{H} = L^2(\mathbb{R}, dq)$ with the domain $D(H) = W^{2,2}(\mathbb{R}) \cap \widehat{W}^{2,2}(\mathbb{R})$. The operator H has pure point spectrum

$$H\psi_n = \lambda_n\psi_n, \quad n = 0, 1, 2, ...$$

with the eigenvalues $\lambda_n = \hbar\omega\left(n+\frac{1}{2}\right)$. Corresponding eigenfunctions ψ_n form an orthonormal basis for $\mathscr{H}$ and are given by

$$\psi_n(q) = \sqrt[4]{\frac{m\omega}{\pi\hbar}}\frac{1}{\sqrt{2^n n!}}e^{-\frac{m\omega}{2\hbar}q^2}H_n\left(\sqrt{\frac{m\omega}{\hbar}}q\right) \tag{2.40}$$

where $H_n(q)$ are classical Hermite-Tchebyscheff polynomials.

Proof. Consider the operator H defined on the Schwartz space $\mathscr{S}(\mathbb{R})$ of rapidly decreasing functions. Since the operator H is symmetric and has a complete system of eigenvectors in $\mathscr{S}(\mathbb{R})$, the subspaces $\mathrm{Im}(H \pm iI)$ are dense in $\mathscr{H}$, so that H is essentially self-adjoint. The proof that its self-adjoint closure (which we continue to denote by H) has the domain $W^{2,2}(\mathbb{R}) \cap \widehat{W}^{2,2}(\mathbb{R})$ is left to the reader.

Remark. The energy levels of the harmonic oscillator can be also obtained from the Bohr-Wilson-Sommerfeld quantization rule. Indeed, the corresponding classical orbit with the energy E is an ellipse in the phase plane
given by the equations $q(t) = A\cos(\omega t + \alpha), p(t) = -m\omega A\sin(\omega t + \alpha)$, where $E = \frac{1}{2}m\omega^2 A^2$ (see Section 1.5 in Chapter 1). Thus

$$\oint pdq = \iint dp \wedge dq = \pi m\omega A^2 = \frac{2\pi}{\omega}E,$$

and the BWS quantization rule gives the energy levels $E_n = \hbar\omega\left(n+\frac{1}{2}\right)$.

Remark. Since the energy levels of the Hamiltonian H are equidistant by $\hbar\omega$, the quantum harmonic oscillator describes the system of identical "quanta" with the energy $\hbar\omega$. The ground state $|0\rangle = \psi_0$, in Dirac's notation, is the vacuum state with no quanta present and with the vacuum energy $\frac{1}{2}\hbar\omega$, and the states $|n\rangle = \psi_n$ consist of n quanta with the energy $\hbar\omega\left(n+\frac{1}{2}\right)$. According to (2.39), the operator a^* adds one quantum to the state $|n\rangle$ and is called a creation operator, and the operator a destroys one quantum in the state $|n\rangle$ and is called an annihilation operator.

An example of the harmonic oscillator illustrates the dramatic difference between the motion in quantum mechanics and in classical mechanics. The classical motion in the potential field

$V(q) = \frac{1}{2}m\omega^2 q^2$ is finite: a particle with energy E moves in the region $|\omega q| \leq \sqrt{\frac{2E}{m}}$, whereas there is always a non-zero probability of finding a quantum particle outside the classical region. Thus for the ground state energy $E = \frac{1}{2}\hbar\omega$ this probability is

$$\int_{|q|\geq\sqrt{\frac{\hbar}{m\omega}}} |\psi_0(q)|^2 \, dq = \frac{2}{\sqrt{\pi}} \int_1^\infty e^{-x^2} dx \simeq 0.1572992070.$$

The classical harmonic oscillator with n degrees of freedom is described by the phase space $\mathbb{R}^{2n}$ with the canonical coordinates $\boldsymbol{p}, \boldsymbol{q}$, and the Hamiltonian function

$$H_{\mathrm{c}}(\boldsymbol{p}, \boldsymbol{q}) = \frac{\boldsymbol{p}^2}{2m} + \sum_{j=1}^n \frac{m\omega_j^2 q_j^2}{2},$$

where $\omega_1, ..., \omega_n > 0$ (see Sections 1.3 and 1.7 in Chapter 1).
The corresponding Hamiltonian operator is

$$H = \frac{\boldsymbol{P}^2}{2m} + \sum_{j=1}^n \frac{m\omega_j^2 Q_j^2}{2}$$

and in the coordinate representation $\mathscr{H} = L^2(\mathbb{R}^n, d^n\boldsymbol{q})$ is a Schrodinger operator with quadratic potential,

$$H = -\frac{\hbar^2}{2m}\Delta + \sum_{j=1}^n \frac{m\omega_j^2 q_j^2}{2}.$$

The Hamiltonian H is a self-adjoint operator with $D(H) = W^{2,2}(\mathbb{R}^n) \cap \widehat{W}^{2,2}(\mathbb{R}^n)$ and a pure point spectrum. The corresponding eigenfunctions

$$\psi_{\boldsymbol{k}}(\boldsymbol{q}) = \psi_{k_1}(q_1) ... \psi_{k_n}(q_n)$$

where $\boldsymbol{k} = (k_1, ..., k_n)$ and $\psi_{k_j}(q_j)$ are eigenfunctions (2.40) with $\omega = \omega_j$, form an orthonormal basis for $L^2(\mathbb{R}^n, d^n\boldsymbol{q})$. The corresponding energy levels are given by

$$\lambda_{\boldsymbol{k}} = \hbar\omega_1\left(k_1 + \frac{1}{2}\right) + \cdots + \hbar\omega_n\left(k_n + \frac{1}{2}\right)$$

The spectrum of H is simple if and only if $\hbar\omega_1, ..., \hbar\omega_n$ are linearly independent over $\mathbb{Z}$. The highest degeneracy case is $\omega_1 = \cdots = \omega_n = \omega$, when the multiplicity of the eigenvalue

$$\lambda_k = \hbar\omega \sum_{j=1}^n \left(k_j + \frac{1}{2}\right)$$

is the partition function $p_n(|\boldsymbol{k}|)$ - the number of representations of the integer $|\boldsymbol{k}| = k_1 + \cdots + k_n$ as a sum of n non-negative integers. Setting $m = 1$ and introducing the operators [23]

$$a_j = \frac{1}{\sqrt{2\omega\hbar}}(\omega Q_j + iP_j), \quad a_j^* = \frac{1}{\sqrt{2\omega\hbar}}(\omega Q_j - iP_j), \quad j = 1, ..., n \tag{2.41}$$

we get canonical commutation relations for creation and annihilation operators for n degrees of freedom,

$$[a_j, a_l] = 0, \quad \left[a_j^*, a_l^*\right] = 0, \quad [a_j, a_l^*] = \delta_{jl}I, \quad j, l = 1, ..., n, \tag{2.42}$$

which generalize relation (2.34) for the one degree of freedom. The operators a_j, a_j^* and $N_j = a_j^* a_j, j = 1, ..., n$, satisfy commutation relations

$$[N_j, a_l] = -\delta_{jl} a_l, \quad [N_j, a_l^*] = \delta_{jl} a_l^*, \quad j, l = 1, ..., n \tag{2.43}$$

In particular, the operator

$$N = \sum_{j=1}^{n} N_j = \sum_{j=1}^{n} a_j^* a_j$$

satisfies

$$[N, a_j] = -a_j, \quad \left[N, a_j^*\right] = a_j^*, \quad j = 1, ..., n,$$

and $H = \hbar\omega\left(N + \frac{n}{2} I\right)$.

Commutation relations (2.42) and (2.43) correspond to the irreducible unitary representation of the solvable Lie algebra $\tilde{\mathfrak{h}}_n$ with $3n+1$ generators e_j, f_j, h_j, and c, where e_j, f_j, c satisfy the relations in the Heisenberg algebra $\mathfrak{h}_n$, and

$$[h_j, e_l] = -\delta_{jl} f_l, \quad [h_j, f_l] = \delta_{jl}\omega_l^2 e_l, \quad [h_j, c] = 0, \quad j, l = 1, ..., n$$

Problem 2.9. Show that $\langle H|M\rangle \geq \frac{1}{2}\hbar\omega$ for every $M \in \mathscr{S}$, where H is the Hamiltonian of the harmonic oscillator with one degree of freedom.

Problem 2.10. Let $q(t) = A\cos(\omega t + \alpha)$ be the classical trajectory of the harmonic oscillator with $m = 1$ and the energy $E = \frac{1}{2}\omega^2 A^2$, and let μ_α be the probability measure on $\mathbb{R}$ supported at the point $q(t)$. Show that the convex linear combination of the measures $\mu_\alpha, 0 \leq \alpha \leq 2\pi$, is the probability measure on $\mathbb{R}$ with the distribution function $\mu(q) = \frac{\theta\left(A^2 - q^2\right)}{\pi\sqrt{A^2 - q^2}}$, where $\theta(q)$ is the Heavyside step function.

Problem 2.11. Show that when $n \to \infty$ and $\hbar \to 0$ such that $\hbar\omega\left(n + \frac{1}{2}\right) = \frac{1}{2}\omega^2 A^2$ remains fixed, the envelope of the distribution function $|\psi_n(q)|^2$ on the interval $|q| \leq A$ coincides with the classical distribution function $\mu(q)$ from the previous problem. (Hint: Prove the integral representation

$$e^{-q^2} H_n(q) = \frac{2^{n+1}}{\sqrt{\pi}} \int_0^\infty e^{-y^2} y^n \cos\left(2qy - \frac{1}{2} n\pi\right) dy$$

and derive the asymptotic formula

$$\psi_n(q) = \sqrt{\frac{2}{\pi}} \frac{1}{\sqrt[4]{A^2 - q^2}} \cos\left\{\frac{\omega}{2\hbar}\left(A^2 \sin^{-1}\frac{q}{A} + q\sqrt{A^2 - q^2} - \frac{1}{2}A^2\pi\right) + O(1)\right\}$$

when $\hbar \to 0$ and $\hbar\left(n + \frac{1}{2}\right) = \frac{1}{2}\omega A^2, |q| < A$.)

Problem 2.12. Complete the proof of Theorem 2.1.

Problem 2.13 (The N-representation theorem). Let $\psi \in \mathscr{S}(\mathbb{R})$. Show that the L^2-convergent expansion $\psi = \sum_{n=0}^{\infty} c_n \psi_n$, where $c_n = (\psi, \psi_n)$, converges in $\mathscr{S}(\mathbb{R})$. (Hint: Use $N\psi_n = n\psi_n$.)

Problem 2.14. Show that the operators $E_{ij} = a_i^* a_j, i, j = 1, ..., n$, satisfy the commutation relations of the Lie algebra $\mathrm{sl}(n, \mathbb{C})$.

3.2.3 Quantization: Conceptual Questions

О случаях применения

(пока хз)

[023] Here, using the standard Euclidean metric on $\mathbb{R}^n$, we lowered the indices for Q^j.

Все-таки, почему скобка Пуассона должна переходить в коммутатор? В чем смысл этого? (!?!??!??!?)

(потом очень подробно отвечу, смысл этого пока так себе понимаю)

How to guess the way, how does canonical quantization work?

(great question, actually.... Maybe, answer is in Kiselev's style, that we have infinitesemal algebra, so we work on this level... I'll write later)

Why there are a lot of ways of quantization?

(??? I don't know??? a good question)

How does the method of canonical quantization (or other one) is related to the picture that we had some field (smooth distribution of matter) and now we have points (quantums)?

(??? I don't know??? a good question. so the problem is that this mathematics do not give us the intuitive picture (which one naively imagines))

3.2.4 Quantization: Advanced Features of Basic Methods

2.7. Holomorphic representation and Wick symbols.

Let

$$\ell^2 = \left\{ c = \{c_n\}_{n=0}^{\infty} : \|c\|^2 = \sum_{n=0}^{\infty} |c_n|^2 < \infty \right\}$$

be the Hilbert ℓ^2-space. The choice of an orthonormal basis $\{\psi_n\}_{n=0}^{\infty}$ for $L^2(\mathbb{R}, dq)$, given by the eigenfunctions (2.40) of the Schrodinger operator for the harmonic oscillator, establishes the Hilbert space isomorphism $L^2(\mathbb{R}, dq) \simeq \ell^2$,

$$L^2(\mathbb{R}, dq) \ni \psi = \sum_{n=0}^{\infty} c_n \psi_n \mapsto c = \{c_n\}_{n=0}^{\infty} \in \ell^2$$

where

$$c_n = (\psi, \psi_n) = \int_{-\infty}^{\infty} \psi(q)\psi_n(q)dq$$

since the functions ψ_n are real-valued. Using (2.39) we get

$$a^*\psi = \sum_{n=0}^{\infty} c_n a^*\psi_n = \sum_{n=0}^{\infty} \sqrt{n+1} c_n \psi_{n+1} = \sum_{n=1}^{\infty} \sqrt{n} c_{n-1}\psi_n, \quad \psi \in D(a^*)$$

and

$$a\psi = \sum_{n=0}^{\infty} c_n a\psi_n = \sum_{n=1}^{\infty} \sqrt{n} c_n \psi_{n-1} = \sum_{n=0}^{\infty} \sqrt{n+1} c_{n+1}\psi_n, \quad \psi \in D(a)$$

so that in ℓ^2 creation and annihilation operators a^* and a are represented by the following semi-infinite matrices:

$$a = \begin{pmatrix} 0 & \sqrt{1} & 0 & 0 & \cdots \\ 0 & 0 & \sqrt{2} & 0 & \cdots \\ 0 & 0 & 0 & \sqrt{3} & \cdots \\ 0 & 0 & 0 & 0 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}, \quad a^* = \begin{pmatrix} 0 & 0 & 0 & 0 & \cdots \\ \sqrt{1} & 0 & 0 & 0 & \cdots \\ 0 & \sqrt{2} & 0 & 0 & \cdots \\ 0 & 0 & \sqrt{3} & 0 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}.$$

As a result,

$$N = a^* a = \begin{pmatrix} 0 & 0 & 0 & 0 & \cdots \\ 0 & 1 & 0 & 0 & \cdots \\ 0 & 0 & 2 & 0 & \cdots \\ 0 & 0 & 0 & 3 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}$$

so that the Hamiltonian of the harmonic oscillator is represented by a diagonal matrix,

$$H = \hbar\omega \left(N + \frac{1}{2} \right) = \operatorname{diag} \left\{ \frac{1}{2}\hbar\omega, \frac{3}{2}\hbar\omega, \frac{5}{2}\hbar\omega, \ldots \right\}$$

This representation of the Heisenberg commutation relations is called the representation by occupation numbers, and has the property that in this representation the Hamiltonian H of the harmonic operator is diagonal.

Another representation where H is diagonal is constructed as follows. Let $\mathscr{D}$ be the space of entire functions $f(z)$ with the inner product

$$(f, g) = \frac{1}{\pi} \int_{\mathbb{C}} f(z) \overline{g(z)} e^{-|z|^2} d^2 z \tag{2.44}$$

where $d^2 z = \frac{i}{2} dz \wedge d\bar{z}$ is the Lebesgue measure on $\mathbb{C} \simeq \mathbb{R}^2$. It is easy to check that $\mathscr{D}$ is a Hilbert space with the orthonormal basis

$$f_n(z) = \frac{z^n}{\sqrt{n!}}, \quad n = 0, 1, 2, \ldots$$

The correspondence

$$\ell^2 \ni c = \{c_n\}_{n=0}^{\infty} \mapsto f(z) = \sum_{n=0}^{\infty} c_n f_n(z) \in \mathscr{D}$$

establishes the Hilbert space isomorphism $\ell^2 \simeq \mathscr{D}$. The realization of a Hilbert space $\mathscr{H}$ as the Hilbert space $\mathscr{D}$ of entire functions is called a holomorphic representation. In the holomorphic representation,

$$a^* = z, \quad a = \frac{d}{dz}, \quad \text{and} \quad H = \hbar\omega \left(z \frac{d}{dz} + \frac{1}{2} \right)$$

and it is very easy to show that a^* is the adjoint operator to a. The mapping

$$\mathscr{H} \ni \psi = \sum_{n=0}^{\infty} c_n \psi_n \mapsto f(z) = \sum_{n=0}^{\infty} c_n f_n(z) \in \mathscr{D}$$

establishes the isomorphism between the coordinate and holomorphic representations. It follows from the formula for the generating function for Hermite-Tchebyscheff polynomials,

$$\sum_{n=0}^{\infty} H_n(q)\frac{z^n}{n!} = e^{2qz-z^2}$$

that the corresponding unitary operator $U : \mathscr{H} \to \mathscr{D}$ is an integral operator

$$U\psi(z) = \int_{-\infty}^{\infty} U(z,q)\psi(q)dq$$

with the kernel

$$U(z,q) = \sum_{n=0}^{\infty} \psi_n(q)f_n(z) = \sqrt[4]{\frac{m\omega}{\pi\hbar}} e^{\frac{m\omega}{2\hbar}q^2 - \left(\sqrt{\frac{m\omega}{\hbar}}q - \frac{1}{\sqrt{2}}z\right)^2} \tag{2.45}$$

Another useful realization is a representation in the Hilbert space $\overline{\mathscr{D}}$ of anti-holomorphic functions $f(\bar{z})$ on $\mathbb{C}$ with the inner product

$$(f,g) = \frac{1}{\pi}\int_{\mathbb{C}} f(\bar{z})\overline{g(\bar{z})}e^{-|z|^2}d^2z$$

given by

$$a^* = \bar{z}, \quad a = \frac{d}{d\bar{z}}.$$

Remark. Holomorphic and anti-holomorphic representations correspond to different choices of a complex polarization of the symplectic manifold $\mathbb{R}^2$. By definition, a complex polarization of a symplectic manifold $(\mathscr{M}, \omega)$ is an integrable distribution on $\mathscr{M}$ of complex Lagrangian subspaces of the complexified vector spaces $T_x\mathscr{M} \otimes_{\mathbb{R}} \mathbb{C}$. As the notion of real polarization, the notion of complex polarization plays a fundamental role in geometric quantization. In particular, holomorphic representation corresponds to the complex Lagrangian subspace in $T_x\mathbb{R}^2 \otimes_{\mathbb{R}} \mathbb{C} \simeq \mathbb{C}^2$ given by the equation $z = 0$, where z and $\bar{z}$ are complex coordinates on $\mathbb{C}^2$. (Note that here $\bar{z}$ is not a complex conjugate to z !) The equation $\bar{z} = 0$ defines a complex Lagrangian subspace which corresponds to the anti-holomorphic representation.

The anti-holomorphic representation is used to introduce the so-called Wick symbols of the operators. Namely, let A be an operator in $\overline{\mathscr{D}}$ which is a polynomial with constant coefficients in creation and annihilation operators a^* and a. Using the commutation relation (2.34), we can move all operators a^* to the left of the operators a, and represent A in the Wick normal form as follows:

$$A = \sum_{l,m} A_{lm}\,(a^*)^l\,a^m \tag{2.46}$$

By definition, the Wick symbol $A(\bar{z}, z)$ of the operator A is

$$A(\bar{z}, z) = \sum_{l,m} A_{lm}\bar{z}^l z^m \tag{2.47}$$

It is a restriction of a polynomial $A(v, z)$ in variables v and z to $v = \bar{z}$.
In order to define Wick symbols of bounded operators in $\overline{\mathscr{D}}$, we consider the family of coherent states (or Poisson vectors) $\Phi_v \in \overline{\mathscr{D}}, v \in \mathbb{C}$, defined by

$$\Phi_v(\bar{z}) = e^{v\bar{z}}, \quad z \in \mathbb{C}$$

They satisfy the properties

$$a\Phi_v = v\Phi_v \quad \text{and} \quad f(\bar{v}) = (f, \Phi_v), \quad f \in \overline{\mathscr{D}}, v \in \mathbb{C}. \tag{2.48}$$

Indeed, the first property is trivial, whereas the "reproducing property" immediately follows from the formula

$$\Phi_v(\bar{z}) = \sum_{n=0}^{\infty} f_n(v)\bar{f}_n(\bar{z}) \tag{2.49}$$

where $\bar{f}_n(\bar{z}) = \overline{f_n(z)}, n = 0, 1, 2, ...$, is the orthonormal basis for $\overline{\mathscr{D}}$.
We also have

$$(f, g) = \frac{1}{\pi}\int_{\mathbb{C}} (f, \Phi_v)\,\overline{(g, \Phi_v)}e^{-|v|^2}d^2v \tag{2.50}$$

Now for the operator A in the Wick normal form (2.46) we get, using the first property in (2.48),

$$\begin{aligned}(A\Phi_z, \Phi_{\bar{v}}) &= \sum_{l,m} A_{lm}\left((a^*)^l a^m\Phi_z, \Phi_{\bar{v}}\right) = \sum_{l,m} A_{lm}\left(a^m\Phi_z, a^l\Phi_{\bar{v}}\right)\\ &= A(v, z)\,(\Phi_z, \Phi_{\bar{v}})\,.\end{aligned}$$

Therefore,

$$A(v, z) = \frac{(A\Phi_z, \Phi_{\bar{v}})}{(\Phi_z, \Phi_{\bar{v}})} = e^{-vz}\,(A\Phi_z, \Phi_{\bar{v}})$$

since by the reproducing property, $(\Phi_z, \Phi_{\bar{v}}) = \Phi_z(v) = e^{vz}$.

Definition. The Wick symbol $A(\bar{z}, z)$ of a bounded operator A in the Hilbert space $\overline{\mathscr{D}}$ is a restriction to $v = \bar{z}$ of an entire function $A(v, z)$ in variables v and z, defined by

$$A(v, z) = e^{-vz}\,(A\Phi_z, \Phi_{\bar{v}})$$

In the next theorem, we summarize the properties of the Wick symbols.
Theorem 2.2. Wick symbols of the bounded operators on $\overline{\mathscr{D}}$ have the following properties.
(i) If $A(\bar{z}, z)$ is the Wick symbol of an operator A, then for the Wick symbol of the operator A^* we have $A^*(\bar{z}, z) = \overline{A(\bar{z}, z)}$ and

$$A^*(v, z) = \overline{A(\bar{z}, \bar{v})}$$

(ii) For $f \in \overline{\mathscr{D}}$,

$$(Af)(\bar{z}) = \frac{1}{\pi}\int_{\mathbb{C}} A(\bar{z}, v)f(\bar{v})e^{-v(\bar{v}-\bar{z})}d^2v$$

(iii) A real-analytic function $A(\bar{z}, z)$ is a Wick symbol of a bounded operator A in $\overline{\mathscr{D}}$ if and only if it is a restriction to $v = \bar{z}$ of an entire function $A(v, z)$ in variables v and z with the property that for every $f \in \overline{\mathscr{D}}$ the integral in part (ii) is absolutely convergent and defines a function in $\overline{\mathscr{D}}$.
(iv) If $A_1(\bar{z}, z)$ and $A_2(\bar{z}, z)$ are the Wick symbols of operators A_1 and A_2, then the Wick symbol of the operator $A = A_1A_2$ is given by

$$A(\bar{z}, z) = \frac{1}{\pi}\int_{\mathbb{C}} A_1(\bar{z}, v)A_2(\bar{v}, z)e^{-(v-z)(\bar{v}-\bar{z})}d^2v$$

Proof. We have

$$A^*(v,z) = e^{-vz}\,(A^*\Phi_z, \Phi_{\bar v}) = e^{-vz}\,(\Phi_z, A\Phi_{\bar v}) = e^{-vz}\overline{(A\Phi_{\bar v}, \Phi_z)} = \overline{A(\bar z, \bar v)},$$

which proves (i). To prove (ii), we use the reproducing property to get

$$(Af)(\bar z) = (Af, \Phi_z) = (f, A^*\Phi_z) = \frac{1}{\pi}\int_{\mathbb{C}} f(\bar v)\overline{(A^*\Phi_z)\,(\bar v)}e^{-|v|^2}d^2v$$

Using the reproducing property once again we have

$$(A^*\Phi_z)\,(\bar v) = (A^*\Phi_z, \Phi_v) = A^*(\bar v, z)\,(\Phi_z, \Phi_v) = \overline{e^{v\bar z}A(\bar z, v)},$$

which proves (ii). Property (iii) follows from the definition and the uniform boundness principle, which is needed to show that the operator A on $\overline{\mathscr{D}}$,
defined by the integral in (ii), is bounded. We leave the standard details to the reader. To prove (iv), by using (2.50) and (i) we get

$$\begin{aligned} A(\bar z, z) &= e^{-|z|^2}\,(A_1A_2\Phi_z, \Phi_z) = e^{-|z|^2}\,(A_2\Phi_z, A_1^*\Phi_z) \\ &= \frac{1}{\pi}\int_{\mathbb{C}} (A_2\Phi_z, \Phi_v)\,\overline{(A_1^*\Phi_z, \Phi_v)}e^{-\left(|v|^2+|z|^2\right)}d^2v \\ &= \frac{1}{\pi}\int_{\mathbb{C}} A_1(\bar z, v)A_2(\bar v, z)e^{-(v-z)(\bar v-\bar z)}d^2v \end{aligned}$$

Remark. Properties (i) and (iv) remain valid for the polynomials in a^* and a - operators of the form (2.46).

A matrix symbol $\tilde A(\bar z, z)$ of a bounded operator A in the Hilbert space $\overline{\mathscr{D}}$ is a restriction to $v = \bar z$ of an entire function $\tilde A(v, z)$ in variables v and z, defined by the following absolutely convergent series:

$$\tilde A(v,z) = \sum_{m,n=0}^{\infty} \left(A\bar f_m, \bar f_n\right) f_n(v)f_m(z) \tag{2.51}$$

The matrix and Wick symbols are related as follows.
Lemma 2.4. For a bounded operator A in the Hilbert space $\overline{\mathscr{D}}$,

$$\tilde A(v,z) = e^{vz}A(v,z)$$

Proof. Using (2.49) we get

$$\begin{aligned} \tilde A(v,z) &= \frac{1}{\pi}\sum_{m,n=0}^{\infty} f_n(v)f_m(z)\int_{\mathbb{C}} \left(A\bar f_m\right)(\bar u)f_n(u)e^{-|u|^2}d^2u \\ &= \frac{1}{\pi}\int_{\mathbb{C}} (A\Phi_z)\,(\bar u)\overline{\Phi_{\bar v}(\bar u)}e^{-|u|^2}d^2u = (A\Phi_z, \Phi_{\bar v}) = e^{vz}A(v,z) \end{aligned}$$

Changing the order of summation and integration is justified by the absolute convergence.
Corollary 2.3. If $\tilde A_1(\bar z, z)$ and $\tilde A_2(\bar z, z)$ are matrix symbols of operators A_1 and A_2, then the matrix symbol of the operator $A = A_1A_2$ is given by

$$\tilde A(\bar z, z) = \frac{1}{\pi}\int_{\mathbb{C}} \tilde A_1(\bar z, v)\tilde A_2(\bar v, z)e^{-|v|^2}d^2v$$

Proof. The proof immediately follows from part (iv) of Theorem 2.2 and Lemma 2.4.

It is straightforward to generalize these constructions to n degrees of freedom. The Hilbert space $\mathscr{D}_n$ defining the holomorphic representation is
the space of entire functions $f(\boldsymbol{z})$ of n complex variables $\boldsymbol{z} = (z_1, ..., z_n)$ with the inner product

$$(f, g) = \frac{1}{\pi^n} \int_{\mathbb{C}^n} f(\boldsymbol{z}) \overline{g(\boldsymbol{z})} e^{-|\boldsymbol{z}|^2} d^{2n}\boldsymbol{z} < \infty$$

where $|\boldsymbol{z}|^2 = z_1^2 + \cdots + z_n^2$ and $d^{2n}\boldsymbol{z} = d^2 z_1 \cdots d^2 z_n$ is the Lebesgue measure on $\mathbb{C}^n \simeq \mathbb{R}^{2n}$. The functions

$$f_m(\boldsymbol{z}) = \frac{z_1^{m_1} ... z_n^{m_n}}{\sqrt{m_1! ... m_n!}}, \quad m_1, ..., m_n = 0, 1, 2, ...$$

where $\boldsymbol{m} = (m_1, ..., m_n)$ is a multi-index, form an orthonormal basis for $\mathscr{D}_n$. Corresponding creation and annihilation operators are given by

$$a_j^* = z_j, \quad a_j = \frac{\partial}{\partial z_j}, \quad j = 1, ..., n$$

The Hilbert space $\overline{\mathscr{D}}_n$ of anti-holomorphic functions $f(\overline{\boldsymbol{z}})$ on $\mathbb{C}^n$ is defined by the inner product

$$(f, g) = \frac{1}{\pi^n} \int_{\mathbb{C}^n} f(\overline{\boldsymbol{z}}) \overline{g(\overline{\boldsymbol{z}})} e^{-|\boldsymbol{z}|^2} d^{2n}\boldsymbol{z} < \infty, \tag{2.52}$$

and the creation and annihilation operators are given by

$$a_j^* = \bar{z}_j, \quad a_j = \frac{\partial}{\partial \bar{z}_j}, \quad j = 1, ..., n.$$

The coherent states are $\Phi_{\boldsymbol{v}}(\overline{\boldsymbol{z}}) = e^{\boldsymbol{v}\overline{\boldsymbol{z}}}$, where $\boldsymbol{v}\overline{\boldsymbol{z}} = v_1\bar{z}_1 + \cdots + v_n z_n$, and satisfy the reproducing property

$$f(\overline{\boldsymbol{v}}) = (f, \Phi_{\boldsymbol{v}}), \quad f \in \overline{\mathscr{T}}_n, \quad \boldsymbol{v} \in \mathbb{C}^n$$

The Wick symbol $A(\overline{\boldsymbol{z}}, \boldsymbol{z})$ of a bounded operator A on $\overline{\mathscr{D}}_n$ is defined as a restriction to $\boldsymbol{v} = \overline{\boldsymbol{z}}$ of an entire function $A(\boldsymbol{v}, \boldsymbol{z})$ of $2n$ variables $\boldsymbol{v} = (v_1, ..., v_n)$ and $\boldsymbol{z} = (z_1, ..., z_n)$, given by

$$A(\boldsymbol{v}, \boldsymbol{z}) = e^{-\boldsymbol{v}\boldsymbol{z}} (A\Phi_{\boldsymbol{z}}, \Phi_{\overline{\boldsymbol{v}}}).$$

We have

$$(Af)(\overline{\boldsymbol{z}}) = \frac{1}{\pi^n} \int_{\mathbb{C}^n} A(\overline{\boldsymbol{z}}, \boldsymbol{v}) f(\overline{\boldsymbol{v}}) e^{-\boldsymbol{v}(\overline{\boldsymbol{v}} - \overline{\boldsymbol{z}})} d^{2n}\boldsymbol{v}, \quad f \in \overline{\mathscr{D}}_n$$

and the Wick symbol $A(\bar{z}, z)$ of the operator $A = A_1 A_2$ is given by

$$A(\bar{z}, \boldsymbol{z}) = \frac{1}{\pi^n} \int_{\mathbb{C}^n} A_1(\overline{\boldsymbol{z}}, \boldsymbol{v}) A_2(\overline{\boldsymbol{v}}, \boldsymbol{z}) e^{-(\boldsymbol{v} - \boldsymbol{z})(\overline{\boldsymbol{v}} - \overline{\boldsymbol{z}})} d^{2n}\boldsymbol{v}$$

where $A_1(\overline{\boldsymbol{z}}, \boldsymbol{z})$ and $A_2(\overline{\boldsymbol{z}}, \boldsymbol{z})$ are the Wick symbols of the operators A_1 and A_2.

The matrix symbol $\tilde{A}(\overline{\boldsymbol{z}}, \boldsymbol{z})$ of a bounded operator A on $\overline{\mathscr{D}}_n$ is defined as a restriction to $\boldsymbol{v} = \overline{\boldsymbol{z}}$ of an entire function $\tilde{A}(\boldsymbol{v}, \boldsymbol{z})$ of $2n$ variables $\boldsymbol{v} = (v_1, ..., v_n)$ and $\boldsymbol{z} = (z_1, ..., z_n)$, given by the absolutely convergent series

$$\tilde{A}(\boldsymbol{v}, \boldsymbol{z}) = \sum_{\boldsymbol{k}, \boldsymbol{m} = 0}^{\infty} \left(A\bar{f}_{\boldsymbol{k}}, \bar{f}_{\boldsymbol{m}}\right) f_{\boldsymbol{m}}(\boldsymbol{v}) f_{\boldsymbol{k}}(\boldsymbol{z})$$

where $\boldsymbol{k} = (k_1, ..., k_n), \boldsymbol{m} = (m_1, ..., m_n)$ are multi-indices, and $\bar{f}_{\boldsymbol{m}}(\overline{\boldsymbol{z}}) = \overline{f_m(\boldsymbol{z})}$. The matrix and Wick symbols of a bounded operator A are related by

$$\tilde{A}(\boldsymbol{v}, \boldsymbol{z}) = e^{\boldsymbol{v}\boldsymbol{z}} A(\boldsymbol{v}, \boldsymbol{z})$$

Remark. The anti-holomorphic representation is very useful in quantum mechanics and especially in quantum field theory, where it is called holomorphic representation (with respect to the variables $\overline{\boldsymbol{z}}$). Slightly abusing terminology, in Part 2 we will also call it holomorphic representation.

Problem 2.15. Find an explicit formula for the unitary operator establishing the Hilbert space isomorphism $\overline{\mathscr{D}}_n \simeq L^2(\mathbb{R}^n, d^n\boldsymbol{q})$.

Problem 2.16. Prove that for the bounded operator A the functions $A(\boldsymbol{v}, \boldsymbol{z})$ and $\tilde{A}(\boldsymbol{v}, \boldsymbol{z})$ are entire functions of $2n$ variables.

Problem 2.17. Let A be a trace class operator on $\overline{\mathscr{D}}_n$ with the Wick symbol $A(\bar{z}, \boldsymbol{z})$. Prove that

$$\operatorname{Tr} A = \frac{1}{\pi^n} \int_{\mathbb{C}^n} A(\bar{z}, \boldsymbol{z}) e^{-|\boldsymbol{z}|^2} d^{2n}\boldsymbol{z}$$

Problem 2.18. Show that the Wick symbol $A(\bar{z}, z)$ of the product $A = A_l ... A_1$ is given by

$$A(\bar{z}, z) = \frac{1}{\pi^l} \int_{\mathbb{C}^l} A_l(\bar{z}, z_{l-1}) ... A_1(\bar{z}_1, z) \exp\left\{ \sum_{k=1}^{l} \bar{z}_k (z_{k-1} - z_k) \right\} d^2 z_1 ... d^2 z_{l-1}$$

where $z_0 = z_l = z, \bar{z}_l = \bar{z}$, and $A_k(\bar{z}, z)$ are the Wick symbols of the operators A_k.

3.2.5 Quantization by the Bohr–Sommerfeld Rule (?)

(this also works as quantization, but currently I have no idea how this fits into the modern physic world, so it is a conceptual question, what is it?)

3.3 Second Quantization

Second quantization is conceptually important topic, thus I have a subsection about it, not subsubsection. Basically, it answers question "okay, we have Schrodinger equation, but what it there are a lot of electrons and they interact one with another with some law"? Understanding exactly of this method will allow one to use QM for something really meaningful, and not for some one-particle conceptually simple model.

3.3.1 Basics of Second Quantization

Обсудим подробно вторичное квантование

Origin of creation and annihilation operators

(we have Schrodinger equation. okay. why we are introducing operators????? answer this question!)

Second quantization as a magic teleportation of a state from one to another

(two particle just stop to exist, then new two particles appear. discuss this)

Coulomb interaction

(discuss how exchange of virtual photon looks like. this is also in the note on QFT)

вкратце теория

(левитов шитов начало)

Рассмотрим вначале систему бозе-частиц, каждая из которых может находиться в одном из состояний $\psi_i(x), i = 1, 2, ...$ Многочастичная волновая функция задается в представлении чисел заполнения, указывающем сколько частиц занимают каждое из состояний $\psi_i(x)$.

В обозначениях Дирака такие состояния могут быть записаны как $|..., N_{i-1}, N_i, N_{i+1}, ...\rangle$, где числа заполнения N_i принимают произвольные целые неотрицательные значения, $N_i = 0, 1, ...$ Канонические операторы рождения и уничтожения a_i^+ и a_i вводятся следующим образом:

$$a_i |..., N_i, N_{i+1}, ...\rangle = \sqrt{N_i} |..., N_i - 1, N_{i+1}, ...\rangle$$
$$a_i^+ |..., N_i, N_{i+1}, ...\rangle = \sqrt{N_i + 1} |..., N_i + 1, N_{i+1}, ...\rangle$$

Нетрудно проверить, что выполняются коммутационные соотношения:

$$\left[a_i, a_j^+\right] = a_i a_j^+ - a_j^+ a_i = \delta_{ij}; \quad [a_i, a_j] = \left[a_i^+, a_j^+\right] = 0$$

Далее, вводятся ψ -операторы:

$$\widehat{\psi}(x) = \sum_i \widehat{a}_i \psi_i(x); \quad \widehat{\psi}^+(x) = \sum_i \widehat{a}_i^+ \psi_i^*(x)$$

Функции $\psi_i(x)$ выбирают таким образом, чтобы они образовывали полную ортонормированную систему.

При этом коммутационные соотношения ψ -операторов оказываются следующими:

$$\left[\widehat{\psi}(x), \widehat{\psi}^+(x')\right] = \delta(x - x'), \quad \left[\widehat{\psi}(x), \widehat{\psi}(x')\right] = \left[\widehat{\psi}^+(x), \widehat{\psi}^+(x')\right] = 0$$

В случае ферми-статистики представление чисел заполнения, а также операторы рождения и уничтожения, их коммутационные соотношения и ψ -операторы вводятся сходным образом.

Остановимся на отличиях бозевского и фермиевского вторичного квантования.

Во-первых, в силу принципа Паули, числа заполнения N_i принимают всего два значения: $N_i = 0, 1$.

Поэтому канонические операторы a_i и a_i^+ действуют так:

$$a_i |..., N_i, N_{i+1}, ...\rangle = \begin{cases} |..., 0, N_{i+1}, ...\rangle & \text{при } N_i = 1 \\ 0 & \text{при } N_i = 0 \end{cases}$$
$$a_i^+ |..., N_i, N_{i+1}, ...\rangle = \begin{cases} 0 & \text{при } N_i = 1 \\ |..., 1, N_{i+1}, ...\rangle & \text{при } N_i = 0 \end{cases}$$

Во-вторых, антисимметрия многочастичного состояния по отношению к перестановке частиц приводит к антикоммутативности a_i и a_j^+ :

$$\left[a_i^+, a_j\right]_+ = a_i^+ a_j + a_j a_i^+ = \delta_{ij}, \quad [a_i, a_j]_+ = \left[a_i^+, a_j^+\right]_+ = 0$$

Для ψ -операторов (1.3) соотношения антикоммутативности выглядят так:

$$\left[\widehat{\psi}(x), \widehat{\psi}^+(x')\right]_+ = \delta(x - x'), \quad \left[\widehat{\psi}(x), \widehat{\psi}(x')\right]_+ = \left[\widehat{\psi}^+(x), \widehat{\psi}^+(x')\right]_+ = 0$$

Удобство представления вторичного квантования заключается в том, связь между одно- и многочастичной задачами на языке ψ -операторов оказывается весьма простой.

Например, нетрудно проверить, что гамильтониан системы невзаимодействующих бозе- или ферми-частиц, имеющих массу m и движущихся в потенциале $U(\mathbf{r})$, записывается так:

$$\widehat{\mathcal{H}} = \int \left(-\frac{\hbar^2}{2m} \widehat{\psi}^{+}(\mathbf{r}) \nabla^2 \hat{\psi}(\mathbf{r}) + \widehat{\psi}^{+}(\mathbf{r}) \hat{\psi}(\mathbf{r}) U(\mathbf{r}) \right) d^3 r$$

А если частицы взаимодействуют по закону $V(\mathbf{r}_1 - \mathbf{r}_2)$, то гамильтониан нужно просто дополнить членом

$$\widehat{\mathcal{H}}_{\text{int}} = \frac{1}{2} \iint \widehat{\psi}^{+}(\mathbf{r}_1) \widehat{\psi}^{+}(\mathbf{r}_2) V(\mathbf{r}_1 - \mathbf{r}_2) \widehat{\psi}(\mathbf{r}_2) \hat{\psi}(\mathbf{r}_1) d^3 r_1 d^3 r_2$$

Вторично квантованный оператор плотности частиц $\hat{\rho}(\mathbf{r}) = \widehat{\psi}^{+}(\mathbf{r}) \widehat{\psi}(\mathbf{r})$ является многочастичным эквивалентом одночастичного выражения $|\psi(\mathbf{r})|^2$ для плотности вероятности.

Интеграл от $\hat{\rho}(\mathbf{r})$, взятый по всему пространству, есть оператор полного числа частиц в системе

$$\widehat{N} = \int \widehat{\psi}^{+}(\mathbf{r}) \hat{\psi}(\mathbf{r}) d^3 r$$

Подчеркнем, что все операторы (1.8) – (1.10) в представлении вторичного квантования имеют один и тот же вид и для фермионов, и для бозонов.

Examples of second quantization

Second quantization of particle operator

Your particle density operator $n(\mathbf{x}) = \sum_\alpha \delta(\mathbf{x} - \mathbf{x}_\alpha)$ is in first-quantized form and $\hat{n}(\mathbf{x}) = \hat{\psi}^\dagger(\mathbf{x}) \hat{\psi}(\mathbf{x})$ is second-quantized.

When a general one-body operator is written in first-quantized form $J = \sum_\alpha J(\mathbf{x}_\alpha)$, the secondquantized form is:

$$\begin{aligned} \hat{J} &\equiv \sum_{rs} \langle r|J|s\rangle \hat{c}_r^\dagger \hat{c}_s \\ &= \sum_{rs} \int d\mathbf{x}' \psi_r^*(\mathbf{x}') J(\mathbf{x}') \psi_s(\mathbf{x}') \hat{c}_r^\dagger \hat{c}_s \\ &= \int d\mathbf{x}' \hat{\psi}^\dagger(\mathbf{x}') J(\mathbf{x}') \hat{\psi}(\mathbf{x}') \end{aligned}$$

The last equality follows from $\hat{\psi}(\mathbf{x}) \equiv \sum_s \psi_s(\mathbf{x}) \hat{c}_s$. In the case of the particle density operator:

$$\begin{aligned} \hat{n}(\mathbf{x}) &= \int d\mathbf{x}' \hat{\psi}^\dagger(\mathbf{x}') \delta(\mathbf{x} - \mathbf{x}') \hat{\psi}(\mathbf{x}') \\ &= \hat{\psi}^\dagger(\mathbf{x}) \hat{\psi}(\mathbf{x}) \end{aligned}$$

Please let me know if you'd like more detail on any of these steps. For somewhat relevant discussion on the relation between first and second-quantized operators, see my answer here: Second quantization. In that answer I only considered the two body interaction operator in detail. I could do the same for (simpler) one body operators if it'd be of help.

Мы понимаем, что в классической механике у нас точка, а в квантовой - волновая функция, то есть координата не определена. Как это следует из определения квантования операторов? (!??!?!?)

(додумаю, интересный и концептуально важный вопрос, но для задач это не нужно знать.)

3.3.2 Second Quantization: Advanced Properties, Other Questions

Concept of canonical transformations for second-quantized operators

Остановимся теперь на важном понятии канонического преобразования и на том, как эти преобразования выглядят в представлении вторичного квантования.

Напомним, что в классической механике канонические преобразования фазового пространства $(p, q) \to (p', q')$ вводятся с помощью скобок Пуассона $\{\ldots\}$, причем роль

этих преобразований заключается в том, что они сохраняют гамильтонову форму уравнений движения: $\dot{p} = \{p, H\}, \dot{q} = \{q, H\}$.

В квантовой механике роль скобок Пуассона переходит к коммутаторам.

(Например, в представлении Гейзенберга уравнения движения имеют вид $i\hbar\partial_t \widehat{A} = [\widehat{A}, \widehat{\mathcal{H}}].$) Поэтому каноническими называют преобразования физических величин, сохраняющие коммутационные соотношения операторов.

Как и в классической механике, канонические преобразования важны, поскольку они сохраняют форму уравнений движения.

Подобрав каноническое преобразование, часто возможно перейти от взаимодействующих частиц к невзаимодействующим квазичастицам.

Наиболее часто рассматривают линейные преобразования канонических операторов (бозонов или фермионов)

$$\tilde{a}_i = \sum_j \left(U_{ij} a_j + V_{ij} a_j^+\right), \quad \tilde{a}_i^+ = \sum_j \left(V_{ij}^* a_j + U_{ij}^* a_j^+\right)$$

называемые преобразованиями Боголюбова.

Одной из часто встречающихся задач является отыскание спектра и собственных состояний гамильтониана, квадратичного по операторам рождения и уничтожения.

Нетрудно проверить, что произвольный гамильтониан такого вида может быть приведен к диагональной форме с помощью соответствующим образом подобранного преобразования (1.11):

$$\widehat{\mathcal{H}} = \sum_{ij} h_{ij}^{(1)} a_i^+ a_j + h_{ij}^{(2)} a_i a_j + \text{h.c.} = \sum_i \varepsilon_i \tilde{a}_i^+ \tilde{a}_i + \langle 0|\widehat{\mathcal{H}}|0\rangle$$

Энергии ε_i дают спектр квазичастиц, а константа $\langle 0|\widehat{\mathcal{H}}|0\rangle$ в правой части представляет собой так называемую энергию нулевых колебаний.

Преобразования (1.11) являются каноническими, если они сохраняют коммутационные соотношения

$$[a_i, a_j]_\pm = 0, \quad \left[a_i, a_j^+\right]_\pm = \delta_{ij}$$

Соответствующие условия на матрицы U и V в (1.11) в общем случае выглядят так:

$$U_{ki} V_{kj} \pm V_{ki} U_{kj} = 0, \quad U_{ki}^* U_{kj} \pm V_{ki}^* V_{kj} = \delta_{ij}$$

где знак «+» соответствует случаю ферми-статистики, а знак -» - случаю бозестатистики.

Структура преобразований (1.11) для бозе-операторов видна уже в простейшем случае одной бозонной степени свободы (примером является квантово-механический осциллятор).

При этом U и V -не матрицы, а числа, и имеется всего два простейших однородных канонических преобразования:

$$\begin{array}{ll} \tilde{a} = \operatorname{ch}\lambda a + \operatorname{sh}\lambda a^+ & \tilde{a} = e^{i\varphi}\tilde{a} \\ \widetilde{a}^+ = \operatorname{sh}\lambda a + \operatorname{ch}\lambda a^+ & \widetilde{a}^+ = e^{-i\varphi}\widetilde{a}^+ \end{array}$$

где λ и φ -вещественные параметры.

Более обшие преобразования представляют собой произведение (композищию) преобразований (1.15).

В случае же ферми-статистики линейные канонические преобразования задаются сходным образом.

Для одной фермионной степени свободы все линейные канонические преобразования исчерпываются сопряжением, $\tilde{a} = a^+, \tilde{a}^+ = a$, и умножением на фазовый множитель, $\tilde{a} = e^{i\varphi}a^+, \tilde{a}^+ = e^{-i\varphi}a$, а преобразования более общего вида в этом случае оказываются нелинейными - см. задачу 3.

Более общие линейные преобразования возникают в системе из двух фермионов, например,

$$\begin{array}{ll} \tilde{a} = \cos\theta a - \sin\theta b^+ & \tilde{a}^+ = \cos\theta a^+ - \sin\theta b \\ \widetilde{b}^+ = \sin\theta a + \cos\theta b^+ & \tilde{b} = \sin\theta a^+ + \cos\theta b \end{array}$$

где θ -параметр.

Интересно, что первое из бозонных преобразований (1.15) есть псевдоевклидово вращение, то есть не что иное, как преобразование Лоренца с быстротой λ в двумерном пространстве -времени, в то время как для фермионов возникают преобразования вида (1.16), соответствующие вращению евклидова пространства.

Возможные канонические преобразования не исчерпываются однородными линейными преобразованиями.

Иногда бывают полезны неоднородные линейные преобразования (как в задаче 6) или даже нелинейные преобразования (см. задачу 3, а также раздел 1.4).

Часто встречаюшаяся разновидность линейных канонических преобразований фурье-преобразование ψ -операторов:

$$\widehat{\psi}(\mathbf{r}) = \int e^{i\mathbf{pr}}\widehat{a}_{\mathbf{p}}\frac{d^3p}{(2\pi)^3}, \quad \widehat{\psi}^+(\mathbf{r}) = \int e^{-i\mathbf{pr}}\widehat{a}^+_{\mathbf{p}}\frac{d^3p}{(2\pi)^3}$$

Принято выбирать нормировку операторов $\widehat{a}_{\mathbf{p}}$ и $\widehat{a}^+_{\mathbf{p}}$ так, чтобы

$$\left[\hat{a}_{\mathbf{p}_1}, \widehat{a}^+_{\mathbf{p}_2}\right]_{\pm} = (2\pi)^3\delta^{(3)}\left(\mathbf{p}_1 - \mathbf{p}_2\right)$$

Такой выбор согласуется с определениями (1.4) и (1.7).

Имеется важный для теории твердого тела круг задач, когда ψ -операторы или другие величины заданы на решетке. Фурье-преобразование (1.17) нетрудно распространить на этот случай, заметив, что если r пробегает узлы некоторой решетки, то $\mathbf{p}$ изменяется внутри периода обратной решетки (или, иначе говоря, внутри зоны Бриллюэна). Скажем, в одном измерении решетка есть $r_n = an$, а зона Бриллюэна это отрезок $-\pi/a < p < \pi/a$.

Other, conceptual questions about second quantization

О названии вторичного квантования

(почему это может быть похоже на то, что квантуем дважды???? пока не так понимаю)

О случаях применения вторичного квантования

(write that in QFT, in cond matter there are a lot of them! it is very used.)

Second quantization in density matrix formalism

(before I wrote only about the wave function, now, how to do the same if I describe the system by the density matrix? I don't know)

Is it possible to work with wave function for the models that are usually described in second quantized form?

(??? currently, I have no idea how to do it. maybe there is absolutely no sense in doing it, but even in terms of formalism, I am not sure at all, how to get back to WF formalism. I'll write it here)

How to deduce second quantization if it wasn't discovered?

(????? a very good question!!!)

How conceptually fermionic operators can appear from bosonic ones?

(??? also, it should be explained!!!)

3.4 Quantization: Special Methods

3.4.1 Quantization of Constrained Systems

(по идее просто лекции Дирака почитаю внимательно, там по идее теория, которая тут в страниц 40 должна уложиться.)

3.4.2 Quantization on Manifolds and in Other Coordinates (?)

(не знаю, есть магистерская работа про это, мб пойму когда-то)

3.4.3 Quantization of Fields and Space: Introduction

(про поля - отслыка в КТП, важное понимание для него. про пространство - отсылка в кв космологию, тоже по идее многое про это написано.)

О квантовании дираковского поля

О квантовании векторного поля

О квантовании плоского пространства (????)

О квантовании гравитации

(отдельные книги про это, так что просто коротко укажу. Скорее всего после записи отдельного это в отдельной записи.)

3.5 Density Matrix Formalism of QM

(!!! I'll write soon, since it is a very important basic concept)

3.5.1 Evolution of a Density Matrix

Evolution of a Density Matrix by Tokmakoff

The equation of motion for the density matrix follows naturally from the definition of ρ and the time-dependent Schrödinger equation.

$$\begin{aligned}\frac{\partial \rho}{\partial t} &= \frac{\partial}{\partial t}[|\psi\rangle\langle\psi|] \\ &= \left[\frac{\partial}{\partial t}|\psi\rangle\right]\langle\psi| + |\psi\rangle\frac{\partial}{\partial t}\langle\psi| \\ &= \frac{-i}{\hbar}H|\psi\rangle\langle\psi| + \frac{i}{\hbar}|\psi\rangle\langle\psi|H \\ &= \frac{-i}{\hbar}[H,\rho]\end{aligned}$$

Equation 5.2.4 is the Liouville-Von Neumann equation. It is isomorphic to the Heisenberg equation of motion, since ρ is also an operator. The solution to Equation 5.2.4 is

$$\rho(t) = U\rho(0)U^\dagger$$

This can be demonstrated by first integrating Equation 5.2.4 to obtain

$$\rho(t) = \rho(0) - \frac{i}{\hbar}\int_0^t d\tau[H(\tau),\rho(\tau)]$$

If we expand Equation 5.2.6 by iteratively substituting into itself, the expression is the same as when we substitute

$$U = \exp_+\left[-\frac{i}{\hbar}\int_0^t d\tau H(\tau)\right]$$

into Equation 5.2.5 and collect terms by orders of $H(\tau)$.

Note that Equation 5.2.5 and the cyclic invariance of the trace imply that the time-dependent expectation value of an operator can be calculated either by propagating the operator (Heisenberg) or the density matrix (Schrödinger or interaction picture):

$$\begin{aligned}\langle\hat{A}(t)\rangle &= \mathrm{Tr}[\hat{A}\rho(t)] \\ &= \mathrm{Tr}\left[\hat{A}U\rho_0U^\dagger\right] \\ &= \mathrm{Tr}\left[\hat{A}(t)\rho_0\right]\end{aligned}$$

For a time-independent Hamiltonian it is straightforward to show that the density matrix elements evolve as

$$\begin{aligned}\rho_{nm}(t) &= \langle n|\rho(t)|m\rangle \\ &= \langle n|U\,|\psi_0\rangle\,\langle\psi_0|\,U^\dagger|m\rangle \\ &= e^{-i\omega_{nm}(t-t_0)}\rho_{nm}\,(t_0)\end{aligned}$$

From this we see that populations, $\rho_{mn}(t) = \rho_{nm}\,(t_0)$, are time-invariant, and coherences oscillate at the energy splitting ω_{nm}

3.5.2 Density Matrix Formalism: Examples of Applications

(see articles about it)

3.6 Schrodinger Equation

Here, we will discuss Schrodinger equation in detail.

One can ask, why such fundamental equation is after so many theory? This is because this part focuses on fundamental quantum mechanics, and Schrodinger equation is not the only one topic from fundamental point of view. From the point of view of solving some ideologically trivial, but mathematically not so obvious problems, it is indeed the central part. This is why it is first one in the first part of this nore/

3.6.1 Schrodinger Equation: Essential Properties for Everyone

(of course, this should be rewritten. I'll do it with some little practice)

Typical method of dealing with 1D Schrodinger equation

(this is the long and extended version of what is written in the first part)
(write that we join the derivative)

Уравнение Шредингера в импульсном представлении

Чтобы записать уравнение Шрёдингера в импульсном представлении, необходимо его спроектировать на бра-вектор $\langle \boldsymbol{p}|$, то есть рассмотреть $\langle \boldsymbol{p}|\hat{H}|\psi\rangle = E\langle \boldsymbol{p}|\psi\rangle$. Кинетическая энергия в таком случае запишется тривиально -этот оператор в импульсном представлении:

$$\left\langle \boldsymbol{p} \left| \frac{\hat{p}^2}{2m} \right| \psi \right\rangle = \frac{\boldsymbol{p}^2}{2m}\psi(\boldsymbol{p})$$

Потенциальная энергия не является диагональным оператором; поэтому нам пригодятся её матричные элементы в этом базисе.

Стандартный способ перехода между представлениями - вставление "разложения единиц" по базису, в котором мы знаем как действует оператор, в данном случае - в координатном базисе:

$$\langle \boldsymbol{p}|U(\hat{x})|\boldsymbol{p}'\rangle = \langle \boldsymbol{p}|U(\hat{\boldsymbol{x}}) \underbrace{\int d\boldsymbol{x}|\boldsymbol{x}\rangle\langle \boldsymbol{x}|}_{\mathbb{1}} |\boldsymbol{p}'\rangle = \int d\boldsymbol{x}U(\boldsymbol{x})\langle \boldsymbol{p}|\boldsymbol{x}\rangle \langle \boldsymbol{x}|\boldsymbol{p}'\rangle = \int d\boldsymbol{x}U(\boldsymbol{x})e^{-i(p-p')x} = U_{\boldsymbol{p}-\boldsymbol{p}'}$$

из чего мы заключаем, что эти матричные элементы тождественно совпадают с преобразованием Фурье от потенциала.

В таком случае, потенциальная энергия записывается в импульсном представлении в следующем виде:

$$\langle \boldsymbol{p}|U(\hat{\boldsymbol{x}})|\psi\rangle = \langle \boldsymbol{p}|U(\hat{\boldsymbol{x}}) \underbrace{\int (d\boldsymbol{p}') |\boldsymbol{p}'\rangle \langle \boldsymbol{p}'|}_{\hat{\mathbb{1}}} |\psi\rangle = \int (d\boldsymbol{p}')\, U_{\boldsymbol{p}-\boldsymbol{p}'}\psi(\boldsymbol{p}'),$$

где введено удобное обозначение $(d\boldsymbol{p}) \equiv d^d\boldsymbol{p}/(2\pi)^d$. Полученный объект называется свёрткой двух функций.

(?? это та самая свертка??)

Таким образом, уравнение Шрёдингера в импульсном представлении записывается в следующем виде:

$$\frac{p^2}{2m}\psi(\boldsymbol{p}) + \int (d\boldsymbol{p}')\,\psi(\boldsymbol{p}')\,U_{p-p'} = E\psi(\boldsymbol{p})$$

Таким образом, в импульсном представлении уравнение Шрёдингера уже интегральное, и иногда его оказывается решать проще.

(?? когда??)

Обсудим методы решения его, а также пример с мелкой ямой - одним из ключевых тому примеров.

Из общих рассуждений мы понимаем, что масштаб волновой функции в координатном представлении - большой масштаб $\kappa^{-1} \gg a$ -что из соотношения неопределённостей означает, что в импульсном представлении, напротив, волновая функция $\psi(p)$ является локализованной вблизи нуля на малом масштабе $\sim \kappa$. С другой стороны, масштаб $U(\boldsymbol{x})$ -это $a \ll \kappa^{-1}$; в свою очередь, масштаб $U_{p-p'}$ -это большой масштаб a^{-1}. Благодаря большой разнице в масштабах, в свёртке $\int (d\boldsymbol{p}')\,\psi(\boldsymbol{p}')\,U_{\boldsymbol{p}-\boldsymbol{p}'}$ основной вклад в интеграл приходит с $|\boldsymbol{p}'| \lesssim \kappa$, на котором функция $U_{\boldsymbol{p}-\boldsymbol{p}'}$ меняется слабо - поэтому

приближённому уравнению:

$$\frac{p^2}{2m}\psi(\boldsymbol{p}) + U_p \int (d\boldsymbol{p}')\,\psi(\boldsymbol{p}') = E\psi(\boldsymbol{p}) \to \psi(\boldsymbol{p}) = -\frac{U_{\boldsymbol{p}}}{-E + \frac{p^2}{2m}} \int (d\boldsymbol{p}')\,\psi(\boldsymbol{p}')$$

(отметим, что поскольку мы имеем дело с ямой, то потенциал $U(x) < 0$; и поскольку мы имеем дело со связанным состоянием, то $E = -|E| < 0$).

Данное уравнение - алгебраическое, ведь в правой части стоит интеграл от волновой функции, который является константой.

Последнее упрошение можно сделать, заметив, что в произведении перед интегралом, Опять-таки, $U_{\boldsymbol{p}}$ является медленной огибающей, а $(|E| + p^2/2m)^{-1}$ - относительно быстрозатухающей функцией, посему можно вообще положить $p = 0$. Наконец, проинтегрировав получивпееся уравнения по $(d\boldsymbol{p})$ и сократив на интеграл от волновой функции, мы получаем следующее y равиежие самосогласоважия - которое является уравнением на допустимые уровни энергии:

$$|U_{p=0}| \int \frac{(d\boldsymbol{p})}{|E| + \frac{p^2}{2m}} = 1$$

Данное уравнение устроено следующим образом.

Перед интегралом стоит Фурье-компонента потенциала, которая, в меру уравнению - сделать интеграл пропорционально большим; при этом единственный параметр, Который мы можем менять -Это энергия $|E|$; и по мере уменьшения энергии, интеграл увеличивается.

Дальнейппий анализ мы будем проводить уже Для конкретного случая пространства различной размерности.

Размерность $d = 1$ При буквально нулевой энергии, этот интеграл расходится степенным образом на малых импульсах, и сходится на больших [12] -поэтому ожидается степенная зависимость от энергии.

Подбирая достаточно маленькую энергию, можно прийти к тому, что знак равенства будет иметь место.

В действительности же, этот интеграл, разумеется, считается точно:

$$|U_{p=0}| \sqrt{\frac{m}{2|E|}} = 1 \to |E| = \frac{m}{2\hbar^2} \left| \int_{-\infty}^{\infty} U(x)dx \right|^2$$

(???????)
О случаях применений уравнения Шредингера в импульсном представлении
(пока актуальный вопрос.)
(??? пару примеров добавлю)

3.6.2 Overview of Features and Methods of Schrodinger equation

(intro to like 400 pages of this note, because there are a lot of methods and properties, so an intro will be also big)

Time-Reversal Symmetry: Basics

если сопрячь УШ, то ψ^* - тоже решение.
если $H = H*$, вообще говорят, что магнитное поле может это нарушать.
комплексно сопряжем левую задачу рассеяния.
нужно искать какую-то линейную комбинацию.

$$\psi_k^{(-)}(x) \equiv \alpha\psi_k^{(+)}(x)+\beta\left(\psi_k^{(+)}(x)\right)^* = \begin{cases} \alpha\left(e^{ikx}+re^{-ikx}\right)+\beta\left(e^{-ikx}+r^*e^{ikx}\right) \equiv t'e^{-ikx}, & x\to-\infty \\ \alpha te^{ikx}+\beta t^*e^{-ikx} \equiv e^{-ikx}+r'e^{ikx} & x\to+\infty \end{cases}$$

короче, нужно прийти к этому:

$$\begin{cases} \alpha+\beta r^* = 0 \\ \alpha r+\beta = t' \\ \alpha t \quad = r' \\ \beta t^* \quad = 1 \end{cases} \to \begin{cases} \alpha = -\frac{r^*}{t^*} \\ \beta = \frac{1}{t^*} \\ \beta = \frac{1}{t^*} \end{cases}, \quad \left[\begin{array}{l} t' = t \\ r' = -r^*t/t^* \\ r' = -r^*t/t^* \\ r' = -r^*t/t^* \end{array}\right.$$

т.о.
будем рассматривать только левую задачу рассеяния, так как в правой все такое же, только фаза сдвинута.
ну, вроде мы что-то больше можем, в самом деле.

О важности симметрий в формализме Шредингера

(я хз, зачем они нужны, тут отвечу на этот вопрос)

Качественное описание решения уравнения Шредингера (??)

(там что-то много осциллирует. пока больше не могу сказать, не знаю.)

Преобразование Галилея in Schrodinger equation (?)

Нужно сделать из $\hat{H}(t) = \frac{\hat{p}^2}{2m} + V(\hat{x}-vt)$ преобразованием новый гамильтониан:

$$\hat{H}'(t) \equiv \hat{U}(t)\hat{H}(t)\hat{U}^\dagger(t) - i\hbar\hat{U}(t)\partial_t\hat{U}^\dagger(t) = \frac{\hat{p}^2}{2m} + V(\hat{x})$$

преобразование такое:

$$\hat{U} = e^{i(\frac{mv}{\hbar}\hat{x}+\frac{mv}{2\hbar}t)}\hat{T}_{-vt}$$

Понятно, что наша система отсчета должна сдвигаться, так что начнем с $\hat{U} = \hat{T}_{-vt} = e^{-vt\partial_x} = e^{-ivt\hat{p}/\hbar}$. $\hat{p}$ не меняется, так что это уже хорошо, посмотрим первую часть преобразованного Гамильтониана $\hat{U}V(x-vt)\hat{U}^\dagger$ по действию на волновую функцию:

$$\hat{T}_{-vt}V(x-vt)\hat{T}_{vt}|\psi\rangle(x) = \hat{T}_{-vt})V(x-vt)|\psi\rangle(x-vt)) = V(x)|\psi\rangle(x)$$

заметим, что все хорошо получилось потому что $\hat{T}_{-vt}$ по итогу сдвиг вернул назад. (важно понимать, что оператор действует на все, что справа от него стоит.)
Окей, все хорошо, но в гамильтониане $\hat{H}'$ появляется еще один член:

$$-i\hbar\hat{U}\partial_t\hat{U}^\dagger = -i\hbar v\hat{T}_{-vt}\hat{T}_{vt}\partial_x = -iv\hbar\partial_x = -v\hat{p}.$$

Так что над новым гамильтонианом нужно сделать какое-то преобразование...
Поищем его в общем виде $\hat{U}' = e^{i(\alpha\hat{x}+\beta t)}$.
Запишем уравнение для $\hat{H}'' = \hat{U}'\hat{H}'\hat{U}'^\dagger - i\hbar\hat{U}'\partial_t\hat{U}'^\dagger \equiv \hat{H}$, по итоге решение такое:

$$\hat{U}' = e^{i(\frac{mv}{\hbar}\hat{x}+\frac{mv}{2\hbar}t)}$$

Получается, что преобразование такое:

$$\hat{U} = e^{i(\frac{mv}{\hbar}\hat{x}+\frac{mv}{2\hbar}t)}\hat{T}_{-vt}$$

(???? где оно применяется????)

интегралы движения в представлении Шредингера

(киселев стр 41)
Интегралы получаются из теоремы Нетер (???)

$$\mathrm{i}\hbar\frac{d\hat{f}}{dt} = \mathrm{i}\hbar\frac{\partial\hat{f}}{\partial t} + [\hat{f},\hat{H}]$$

$$[\hat{f},\hat{H}] = 0$$

$$\frac{df}{dt} = -\frac{\partial H}{\partial\phi} = \{f,H\}_{\mathrm{P}}$$

согласно теореме Нётер, параметрическая замена

$$\frac{dS}{du} = \int dt\frac{d}{dt}\left(\frac{\partial L}{\partial\dot{\phi}}\frac{\partial\phi'}{\partial u}\right)$$

$$\frac{\partial\phi'}{\partial u} = 1$$

$$\frac{\partial L}{\partial\dot{\phi}} = f$$

Do we need to know mathematics of 1D Schrödinger Equation?

(currently, I don't see arguments to study it, but okay, maybe I'll understand them later and write them here)

3.6.3 Mathematics of 1D Schrödinger Equation 1

Theory

Here we describe the general properties of the Schrodinger operator for a quantum particle in $\mathbb{R}^n$ moving in a potential field. To simplify the notation, in this chapter we set $\hbar = 1$ and $m = \frac{1}{2}$, and use $\boldsymbol{x} = (x_1, ..., x_n)$ for Cartesian coordinates on $\mathbb{R}^n$. Recall (see Section 2.4 in Chapter 2) that the corresponding Schrodinger operator is given by the formal differential expression

$$H = -\Delta + V(\boldsymbol{x})$$

where $V(\boldsymbol{x})$ is a real-valued, measurable function on $\mathbb{R}^n$. Denote by

$$H_0 = -\Delta = -\left(\frac{\partial^2}{\partial x_1^2} + \cdots + \frac{\partial^2}{\partial x_n^2}\right)$$

the Schrodinger operator of a free quantum particle of mass $m = \frac{1}{2}$ on $\mathbb{R}^n$, also called the kinetic energy operator, and by V - the multiplication by $V(\boldsymbol{x})$ operator, also called the potential energy operator, so that

$$H = H_0 + V. \tag{1.1}$$

According to Section 2.3 of Chapter 2, the operator H_0 is self-adjoint and unbounded on $\mathscr{H} = L^2(\mathbb{R}^n)$, with the domain $D(H_0) = W^{2,2}(\mathbb{R}^n)$ and absolutely continuous spectrum $[0, \infty)$, and the operator V is self-adjoint and is bounded if and only if $V(\boldsymbol{x}) \in L^\infty(\mathbb{R}^n)$, when $\|V\| = \|V\|_\infty$. The sum $H_0 + V$ is not necessarily self-adjoint, and the first major mathematical problem of quantum mechanics is to characterize potentials $V(x)$ for which the formal differential expression (1.1) uniquely defines a self-adjoint operator H on $\mathscr{H}$. We start by presenting some useful criteria for the self-adjointness.

1.1. Self-adjointness.

The main result here is the Kato-Rellich theorem on perturbation of self-adjoint operators.

Definition. Let A and B be densely defined operators in $\mathscr{H}$. The operator B is smaller than A in the sense of Kato if $D(A) \subseteq D(B)$ and there exist $a, b \in \mathbb{R}$ with $a < 1$ such that for all $\psi \in D(A)$,

$$\|B\psi\| \leq a\|A\psi\| + b\|\psi\| \tag{1.2}$$

Equivalently, the operator B is smaller than A in the sense of Kato, if there exist $\alpha, \beta \in \mathbb{R}$ with $\alpha < 1$ such that for all $\psi \in D(A)$,

$$\|B\psi\|^2 \leq \alpha\|A\psi\|^2 + \beta\|\psi\|^2 \tag{1.3}$$

Kato-Rellich Theorem

If A is a self-adjoint operator with domain $D(A)$ and B is a symmetric operator smaller than A in the sense of Kato, then $H = A + B$ with $D(H) = D(A)$ is a self-adjoint operator.

Proof.

Recall that the operator H is self-adjoint if and only if $\mathrm{Im}(H + \lambda I) = \mathrm{Im}(H - \lambda I) = \mathscr{H}$ for some $\lambda \in i\mathbb{R}$, and hence for all $\lambda \in \mathbb{C}\backslash\sigma(H)$. Since $A = A^*$, for every $\lambda \in i\mathbb{R}$ we have $R_\lambda = (A - \lambda I)^{-1} \in \mathscr{L}(\mathscr{H})$ and $\mathrm{Im}\, R_\lambda = D(A)$. Now

$$H - \lambda I = (I + BR_\lambda)\,(A - \lambda I)$$

and in order to prove that $\mathrm{Im}(H - \lambda I) = \mathscr{H}$ it is sufficient to show that for $|\lambda|$ large enough $\|BR_\lambda\| < 1$, since then by Neumann series $I + BR_\lambda$ is an invertible bounded operator and $\mathrm{Im}\,(I + BR_\lambda) = \mathscr{H}$. Indeed, for all $\varphi \in \mathscr{H}$ we have the inequalities

$$\|R_\lambda\varphi\| \leq \frac{1}{|\lambda\|}\|\varphi\| \quad \text{and} \quad \|AR_\lambda\varphi\| \leq \|\varphi\|$$

which follow from the equation $\|(A-\lambda I)\psi\|^2 = \|A\psi\|^2 + |\lambda|^2\|\psi\|^2$ by setting $\varphi = (A-\lambda I)\psi$. Now using (1.2) with $\psi = R_\lambda\varphi$, we get

$$\|BR_\lambda\varphi\| \leq a\,\|AR_\lambda\varphi\| + b\,\|R_\lambda\varphi\| \leq \left(a + \frac{b}{|\lambda|}\right)\|\varphi\|,$$

so that $\|BR_\lambda\| < 1$ for large enough $|\lambda|$.

We use the Kato-Rellich criterion for the physically important case when $A = H_0$ - the Schrodinger operator of a free particle in $\mathbb{R}^3$ - and $B = V$ - the multiplication by $V(\boldsymbol{x})$ operator.

Theorem 1.2.

Let $V = V_1 + V_2$, where $V_1(\boldsymbol{x}) \in L^2(\mathbb{R}^3)$ and $V_2(\boldsymbol{x}) \in L^\infty(\mathbb{R}^3)$. Then $H = H_0 + V$ is a self-adjoint operator and $D(H) = W^{2,2}(\mathbb{R}^3)$.

Proof. It is sufficient to show that V is smaller than H_0 in the sense of Kato on $C_0^\infty(\mathbb{R}^3) \subset W^{2,2}(\mathbb{R}^3)$. Denoting by $\|\cdot\|_\infty$ the norm in $L^\infty(\mathbb{R}^3)$, for $\varphi \in C_0^\infty(\mathbb{R}^3)$ we have

$$\|V\varphi\| \leq \|V_1\|\,\|\varphi\|_\infty + \|V_2\|_\infty\,\|\varphi\|.$$

Let $h(\boldsymbol{p}) = \boldsymbol{p}^2$. Denoting by $\|\cdot\|_1$ the norm in $L^1(\mathbb{R}^3)$ and using the Fourier transform and the Cauchy-Bunyakovski-Schwarz inequality, we get

$$\begin{aligned}(2\pi)^{3/2}\|\varphi\|_\infty &= \sup_{\boldsymbol{x}\in\mathbb{R}^3}\left|\int_{\mathbb{R}^3} e^{i\boldsymbol{p}\boldsymbol{x}}\breve{\varphi}(\boldsymbol{p})d^3\boldsymbol{p}\right| \leq \|\breve{\varphi}\|_1 \\ &\leq \left\|(h+1)^{-1}\right\|\,\|(h+1)\breve{\varphi}\| \leq C(\|h\breve{\varphi}\| + \|\breve{\varphi}\|) \\ &= C\,(\|H_0\varphi\| + \|\varphi\|)\,.\end{aligned}$$

Now replace $\breve{\varphi}(\boldsymbol{p})$ by $\breve{\varphi}_r(\boldsymbol{p}) = r^3\breve{\varphi}(r\boldsymbol{p}), r > 0$. Since $\|\breve{\varphi}_r\|_\infty = \|\breve{\varphi}\|_\infty, \|\breve{\varphi}_r\|_1 = \|\breve{\varphi}\|_1, \|\breve{\varphi}_r\| = r^{3/2}\|\breve{\varphi}\|$, and $\|h\breve{\varphi}_r\| = r^{-1/2}\|h\breve{\varphi}\|$, we get

$$(2\pi)^{3/2}\|\varphi\|_\infty \le r^{-1/2}C\left(\|H_0\varphi\| + r^2\|\varphi\|\right)$$

where $r > 0$ is arbitrary. Choosing r such that $a = r^{-1/2}(2\pi)^{-3/2}C\,\|V_1\| < 1$ completes the proof.

Corollary 1.3. The Schrodinger operator of a complex atom, considered in Example 2.2 in Section 2.4 of Chapter 2, is essentially self-adjoint on $C_0^\infty\left(\mathbb{R}^{3(N+1)}\right)$.

Proof. We consider only the special case of the Hamiltonian of the hydrogen atom,

$$H = -\Delta - \frac{e^2}{r}, \quad r = |\boldsymbol{x}|.$$

Writing $V = \chi_1 V + (1-\chi_1)\,V = V_1 + V_2$, where χ_1 is the characteristic function of the unit ball $B_1 = \{x \in \mathbb{R}^3 : |x| \le 1\}$, we have $V_1(\boldsymbol{x}) \in L^2(\mathbb{R}^3)$ and $V_2(\boldsymbol{x}) \in L^\infty(\mathbb{R}^3)$.

Another useful criterion applies to real-valued potentials $V(\boldsymbol{x}) \in L^\infty_{\text{loc}}(\mathbb{R}^n)$, the space of locally bounded a.e. functions on $\mathbb{R}^n$. In this case the operator H, defined by the formal differential expression (1.1), is symmetric on $C_0^\infty(\mathbb{R}^n)$ and we have the following result.

Theorem 1.4. If $V(\boldsymbol{x}) \in L^\infty_{\text{loc}}(\mathbb{R}^n)$ is bounded from below, $V(\boldsymbol{x}) \ge C$ a.e. on $\mathbb{R}^n$, then the Schrodinger operator $H = H_0 + V$ is essentially self-adjoint on $C_0^\infty(\mathbb{R}^n)$.

In fact, a much more general statement holds.

Theorem 1.5 (Sears). Suppose that the potential $V(\boldsymbol{x}) \in L^\infty_{\text{loc}}(\mathbb{R}^n)$ for all $\boldsymbol{x} \in \mathbb{R}^n$ satisfies the condition

$$V(\boldsymbol{x}) \ge -Q(|\boldsymbol{x}|),$$

where $Q(r)$ is an increasing continuous positive function on $[0,\infty)$ such that

$$\int_0^\infty \frac{dr}{\sqrt{Q(r)}} = \infty$$

Then the Schrodinger operator $H = H_0 + V$ is essentially self-adjoint on $C_0^\infty(\mathbb{R}^n)$.

Problem 1.1. Prove the general case of Corollary 1.3 (Hint: Derive the estimate (1.3) for each term in the corresponding potential energy operator.)

Problem 1.2 (Kato's inequality). Let $\psi \in L^1_{\text{loc}}(\mathbb{R}^n)$ be such that $\Delta\psi$, defined in the distributional sense, is represented by a function in $L^1_{\text{loc}}(\mathbb{R}^n)$. Prove that in the distributional sense, $\Delta|u| \ge \operatorname{Re}\left(\frac{\overline{u}}{u}\Delta u\right)$, where it is assumed that $\frac{\overline{u(\boldsymbol{x})}}{u(\boldsymbol{x})} = 0$ if $u(\boldsymbol{x}) = 0$. (The distribution $T \in \mathscr{S}(\mathbb{R}^n)'$ is non-negative if $T(\varphi) \ge 0$ for all non-negative $\varphi \in \mathscr{S}(\mathbb{R}^n)$.)

Problem 1.3. Prove Theorem 1.4 using Kato's inequality. (Hint: Show that if $\psi \in L^2(\mathbb{R}^n)$ in the distributional sense satisfies $(-\Delta + V(\boldsymbol{x}) + C + 1)\psi = 0$, then $\psi = 0$.)

Problem 1.4. Prove that one-dimensional Schrodinger operators with unbounded below potentials $V(x) = x$ and $V(x) = -x^2$ are essentially self-adjoint on $C_0^\infty(\mathbb{R})$.

1.2. Characterization of the spectrum.

The second major mathematical problem in quantum mechanics is to describe the spectral properties of the Schrodinger operator H. Here we present some general results characterizing the spectrum of H. The first basic result is the following.

Theorem 1.6. Suppose that $V(\boldsymbol{x}) \in L^\infty_{\text{loc}}(\mathbb{R}^n)$ satisfies

$$\lim_{|x|\to\infty} V(x) = \infty$$

Then the operator H has a pure point spectrum: there exists an orthonormal basis $\{\psi_n\}_{n\in\mathbb{N}}$ for $\mathscr{H}$ consisting of eigenfunctions of H with eigenvalues $\lambda_1 \le \lambda_2 \le \cdots \le \lambda_n \le \cdots$ of finite multiplicity,

$$H\psi_n = \lambda_n \psi_n,$$

and $\lim_{n\to\infty} \lambda_n = \infty$.

Recall that the essential spectrum $\sigma_{\text{ess}}(A)$ of a self-adjoint operator A consists of all non-isolated points of $\sigma(A)$ and of eigenvalues of infinite multiplicity. The following result gives a sufficient condition for the essential spectrum of the Schrodinger operator to fill $[0,\infty)$.

Theorem 1.7. Suppose that $V = V_1 + V_2$, where $V_1(\boldsymbol{x}) \in L^q(\mathbb{R}^n), 2q \ge n$ for $n > 4$ and $q \ge 2$ for $n \le 4$[1], and $V_2(\boldsymbol{x}) \in L^\infty(\mathbb{R}^n)$ satisfies

$$\lim_{|\boldsymbol{x}|\to\infty} V_2(\boldsymbol{x}) = 0$$

Then $\sigma_{\text{ess}}(H) = [0,\infty)$, so that $\sigma(H) \cap (-\infty, 0)$ consists of isolated eigenvalues of H of finite multiplicity.

The next result gives a sufficient condition for the Schrodinger operator with decaying potential to have only negative eigenvalues.

Theorem 1.8 (Kato). Suppose that $V(\boldsymbol{x}) \in L^\infty(\mathbb{R}^n)$ and

$$\lim_{|\boldsymbol{x}|\to\infty} |\boldsymbol{x}| V(\boldsymbol{x}) = 0$$

Then the Schrodinger operator $H = H_0 + V$ has no positive eigenvalues.

Recall that the absolutely continuous spectrum and the singular spectrum of a self-adjoint operator A on $\mathscr{H}$ are defined, respectively, by $\sigma_{\text{ac}}(A) = \sigma\left(A|_{\mathscr{H}_{\text{ac}}}\right)$ and $\sigma_{\text{sc}}(A) = \sigma\left(A|_{\mathscr{H}_{\text{sc}}}\right)$, where $\mathscr{H}_{\text{ac}}$ and $\mathscr{H}_{\text{sc}}$ are closed subspaces for A defined as follows. Let P_A be the projection-valued measure for the self-adjoint operator A and let $\nu_\psi = (\mathrm{P}_A\psi, \psi)$ be the finite Borel measure on $\mathbb{R}$ corresponding to $\psi \in \mathscr{H}, \psi \ne 0$. Then $\mathscr{H}_{\text{ac}}$ consists of 0 and all $\psi \in \mathscr{H}$ such that the measure ν_ψ is absolutely continuous with respect to the Lebesgue measure on $\mathbb{R}$, and $\mathscr{H}_{\text{sc}}$ consists of 0 and all $\psi \in \mathscr{H}$ such that the measure ν_ψ is continuous singular with respect to the Lebesgue measure on $\mathbb{R}$.

Theorem 1.9. Suppose that the potential $V(\boldsymbol{x}) \in L^\infty(\mathbb{R}^n)$ for some $\varepsilon > 0$ satisfies

$$V(\boldsymbol{x}) = O\left(|\boldsymbol{x}|^{-1-\varepsilon}\right) \quad \text{as} \quad |\boldsymbol{x}| \to \infty.$$

Then the Schrodinger operator $H = H_0 + V$ has no singular spectrum and $\sigma_{\text{ac}}(H) = [0,\infty)$. Moreover, $\sigma(H) \cap (-\infty, 0)$ consists of eigenvalues of H of finite multiplicity with the only possible accumulation point at 0 .

Finally, for the physically important case $n = 3$ there is a useful estimate for the number of eigenvalues of the Schrodinger operator.

Theorem 1.10 (Birman-Schwinger). Suppose that $V(\boldsymbol{x}) \in L^\infty(\mathbb{R}^3)$ and

$$\int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \frac{|V(\boldsymbol{x})V(\boldsymbol{y})|}{|\boldsymbol{x}-\boldsymbol{y}|^2} d^3\boldsymbol{x} d^3\boldsymbol{y} < \infty.$$

Then for the total number N of eigenvalues of the Schrodinger operator $H = H_0 + V$, counted with multiplicities, we have

$$N \le \frac{1}{16\pi^2}\int_{\mathbb{R}^3}\int_{\mathbb{R}^3} \frac{|V(\boldsymbol{x})V(\boldsymbol{y})|}{|\boldsymbol{x}-\boldsymbol{y}|^2} d^3\boldsymbol{x} d^3\boldsymbol{y}.$$

[1] In the special case $n = 4$ one has $q > 2$.

Problem 1.5. Prove all results stated in this section. (Hint: See the list of references to this chapter.)

1.3. The virial theorem.

Let $H = H_0 + V$ be the Schrodinger operator whose potential is a homogeneous function on $\mathbb{R}^n$ of degree ρ, i.e., $V(a\boldsymbol{x}) = a^\rho V(\boldsymbol{x})$. The virial theorem in quantum mechanics is the relation between the expectation values of the kinetic and potential energy operators H_0 and V in the stationary state.

Theorem 1.11 (The virial theorem). Let $\psi \in \mathscr{H}, \|\psi\| = 1$, be the eigenfunction of the Schrodinger operator with the homogeneous potential of degree ρ, and let $T_0 = (H_0\psi, \psi)$ and $V_0 = (V\psi, \psi)$ be the corresponding expectation values of kinetic and potential energy operators. Then

$$2T_0 = \rho V_0.$$

Proof. It follows from the Schrodinger equation

$$-\Delta\psi + V(\boldsymbol{x})\psi = \lambda\psi$$

that

$$T_0 + V_0 = -(\Delta\psi, \psi) + (V\psi, \psi) = \lambda.$$

For every $a > 0$ the function $\psi_a(\boldsymbol{x}) = \psi(a\boldsymbol{x})$ satisfies

$$-\Delta\psi_a + a^{\rho+2}V(\boldsymbol{x})\psi_a = a^2\lambda\psi_a$$

so that by differentiating this equation with respect to a at $a = 1$ and using Euler's homogenous function theorem, we get

$$-\Delta\dot{\psi} + V(\boldsymbol{x})\dot{\psi} = \lambda\dot{\psi} + (2\lambda - (\rho+2)V(\boldsymbol{x}))\psi \tag{1.4}$$

Since $\dot{\psi} \in D(H)$ and H is self-adjoint,

$$((H - \lambda I)\dot{\psi}, \psi) = (\dot{\psi}, (H - \lambda I)\psi) = 0$$

and we obtain from (1.4) that

$$2\lambda = (\rho + 2)V_0,$$

which completes the proof.

Remark. Since energy levels of quantum systems are related to the closed orbits of corresponding classical systems, Theorem 1.11 is the quantum analog of the classical virial theorem (see Example 1.2 in Section 1.3 of Chapter 1).

Problem 1.6 (The Raleigh-Ritz principle). Prove that λ is an eigenvalue of a self-adjoint operator H with the eigenfunction ψ if and only if ψ is a critical point of the functional $F(\varphi) = ((H - \lambda I)\varphi, \varphi)$ on $D(H)$.

Problem 1.7. Derive the virial theorem from the Raleigh-Ritz principle.

О случаях, когда УШ не работает, but QM works

(I heard about it, but I forgot about it. It is something about range of definition of operators, some mathematically exotic situation)

3.6.4 Mathematics of 1D Schrödinger Equation 2

The Schrodinger operator on the real line - the one-dimensional Schrodinger operator - has the form

$$H = -\frac{d^2}{dx^2} + V(x)$$

where the real-valued potential $V(x) \in L^1_{\text{loc}}(\mathbb{R})$, the space of locally integrable functions on $\mathbb{R}$. The corresponding eigenvalue problem

$$H\psi = \lambda\psi$$

reduces to the second order ordinary differential equation

$$-y'' + V(x)y = k^2 y, \quad -\infty < x < \infty \tag{2.1}$$

where it is convenient to set $\lambda = k^2$. In this section, we will study in detail the one-dimensional Schrodinger equation (2.1) for the case when

$$\int_{-\infty}^{\infty} (1 + |x|)|V(x)|dx < \infty. \tag{2.2}$$

Condition (2.2) is a mathematical formulation of the physical statement that the potential $V(x)$ decays as $|x| \to \infty$. It allows us to compare solutions $y(x, k)$ of the Schrodinger equation (2.1) with the solutions $e^{\pm ikx}$ of the Schrodinger equation for the free quantum particle, which corresponds to the case $V = 0$ in (2.1). All results in this section hold for the real-valued potential $V(x) \in L^1_{\text{loc}}(\mathbb{R})$ satisfying (2.2); to simplify the presentation we will additionally assume that the potential $V(x)$ in (2.2) is continuous on $\mathbb{R}$.

Способы определения стационарных состояний

(соберу их тут, this is relatively easy question)

Determining other properties of 1D one-particle systems using Schrodinger equation

О нахождении среднего (!!!)

(укажу тут что-то про это, вроде просто по обычной формуле смело считаем и все.)

Typical mathematical transformations for Schrodinger equation

(важное указание, как не тратить время на них.)

When strict mathematical transformations for Schrodinger equation are essential and when one can without problems work with basic methods?

(this is the general question, after which one will understand why he should at all read about math about Shr. eq. And this is a very important question.)

2.1. Jost functions and transition coefficients.

Let

$$\sigma(x) = \int_x^\infty |V(s)|ds \quad \text{and} \quad \sigma_1(x) = \int_x^\infty \sigma(s)ds$$

Since $V \in L^1(\mathbb{R})$, we have $\lim_{x\to\infty} \sigma(x) = 0$, and using condition (2.2) and the Fubini theorem we get
$\sigma_1(x) = \int_x^\infty \int_s^\infty |V(t)|dtds = \int_x^\infty \int_x^t |V(t)|dsdt = \int_x^\infty (t-x)|V(t)|dt < \infty$, so that $\sigma \in L^1(x,\infty)$ for all $x \in \mathbb{R}$ and $\lim_{x\to\infty} \sigma_1(x) = 0$. Similarly, the functions

$$\tilde\sigma(x) = \int_{-\infty}^x |V(s)|ds \quad \text{and} \quad \tilde\sigma_1(x) = \int_{-\infty}^x \tilde\sigma(s)ds$$

satisfy $\lim_{x\to-\infty} \tilde\sigma(x) = \lim_{x\to-\infty} \tilde\sigma_1(x) = 0$. Condition (2.2) ensures that for real k the differential equation (2.1) has solutions $f_1(x,k)$ and $f_2(x,k)$,
uniquely defined by the following asymptotics:

$$f_1(x,k) = e^{ikx} + o(1) \quad \text{as} \quad x \to \infty$$
$$f_2(x,k) = e^{-ikx} + o(1) \quad \text{as} \quad x \to -\infty$$

They are called Jost solutions and play a fundamental role in the theory of a one-dimensional Schrodinger equation.

Theorem 2.1. For real k the differential equation (2.1) has solutions $f_1(x,k)$ and $f_2(x,k)$ satisfying the following properties.
(i) Estimates for $k \in \mathbb{R}$:

$$\left|e^{-ikx} f_1(x,k) - 1\right| \le \left(\sigma_1(x) - \sigma_1\left(x + \frac{1}{|k|}\right)\right) e^{\sigma_1(x)}$$
$$\left|e^{ikx} f_2(x,k) - 1\right| \le \left(\tilde\sigma_1(x) - \tilde\sigma_1\left(x - \frac{1}{|k|}\right)\right) e^{\tilde\sigma_1(x)}$$

(ii) Asymptotics as $|x| \to \infty$:

$$\lim_{x\to\infty} e^{-ikx} f_1(x,k) = 1, \lim_{x\to\infty} e^{-ikx} f_1'(x,k) = ik$$
$$\lim_{x\to-\infty} e^{ikx} f_2(x,k) = 1, \lim_{x\to-\infty} e^{ikx} f_1'(x,k) = -ik$$

(iii) Analyticity: $f_1(x,k)$ and $f_2(x,k)$ admit analytic continuation to the upper half-plane $\operatorname{Im} k > 0$, and are continuous functions on $\operatorname{Im} k \ge 0$, uniformly in x on compact subsets of $\mathbb{R}$.
(iv) The conjugation property:

$$\overline{f_1(x,k)} = f_1(x,-\bar k), \quad \overline{f_2(x,k)} = f_2(x,-\bar k), \quad \operatorname{Im} k \ge 0$$

(v) Estimates in part (i) hold for $\operatorname{Im} k \ge 0$. For $k \ne 0$,

$$\left|f_1(x,k) - e^{ikx}\right| \le \frac{e^{-\operatorname{Im} kx}}{|k|}\sigma(x)e^{\frac{1}{|k|}\sigma(x)}$$
$$\left|f_2(x,k) - e^{-ikx}\right| \le \frac{e^{\operatorname{Im} kx}}{|k|}\tilde\sigma(x)e^{\frac{1}{|k|}\tilde\sigma(x)}$$

(vi) Asymptotics as $|k| \to \infty, \operatorname{Im} k \ge 0$:

$$e^{-ikx} f_1(x,k) = 1 + O\left(|k|^{-1}\right), \quad e^{ikx} f_2(x,k) = 1 + O\left(|k|^{-1}\right)$$

Proof. It follows from the method of variation of parameters that differential equation (2.1) with the boundary condition $\lim_{x\to\infty} e^{-ikx} f_1(x,k) = 1$ is equivalent to the integral equation

$$f_1(x,k) = e^{ikx} - \int_x^\infty \frac{\sin k(x-t)}{k} V(t) f_1(t,k)\,dt \tag{2.3}$$

Setting $\varphi(x,k) = e^{-ikx} f_1(x,k)$, we get

$$\varphi(x,k) = 1 - \int_x^\infty \frac{1 - e^{-2ik(x-t)}}{2ik} V(t)\varphi(t,k)\,dt. \tag{2.4}$$

For $\operatorname{Im} k \geq 0$ the integral equation (2.4) is of Volterra type and can be solved by the method of successive approximations. Namely, we look for the solution in the form

$$\varphi(x,k) = \sum_{n=0}^{\infty} \varphi_n(x,k) \tag{2.5}$$

where $\varphi_0(x,k) = 1$ and

$$\begin{aligned}\varphi_{n+1}(x,k) &= -\int_x^\infty \frac{1 - e^{-2ik(x-t)}}{2ik} V(t)\varphi_n(t,k)\,dt \\ &= \int_x^\infty \left(\int_x^t e^{-2ik(x-s)} V(t)\varphi_n(t,k)\,ds \right) dt\end{aligned}$$

From here we conclude that for $\operatorname{Im} k \geq 0$

$$|\varphi_n(x,k)| \leq \frac{\sigma_1(x)^n}{n!}. \tag{2.6}$$

Indeed, this estimate is true for $n = 0$, and using the Fubini theorem and the induction hypothesis we get

$$\begin{aligned}|\varphi_{n+1}(x,k)| &\leq \frac{1}{n!} \int_x^\infty \left(\int_x^t |V(t)| \sigma_1(t)^n ds \right) dt \\ &= \frac{1}{n!} \int_x^\infty \left(\int_s^\infty |V(t)| \sigma_1(t)^n dt \right) ds \\ &\leq \frac{1}{n!} \int_x^\infty \sigma(s) \sigma_1(s)^n ds = \frac{\sigma_1(x)^{n+1}}{(n+1)!}\end{aligned}$$

Thus

$$|\varphi(x,k)| \leq e^{\sigma_1(x)}. \tag{2.7}$$

By the Weierstrass M-test the function $\varphi(x,k)$, defined by convergent series (2.5), is analytic for $\operatorname{Im} k > 0$. It is also continuous up to $\operatorname{Im} k = 0$ uniformly in x on compact subsets of $\mathbb{R}$.

The first estimate in part (i) now follows from (2.4) and (2.7). Namely, using $|V(t)| = -\sigma'(t)$ and integration by parts, we obtain

$$\begin{aligned}|\varphi(x,k) - 1| &\leq \int_x^\infty \left| \frac{1 - e^{-2ik(x-t)}}{2ik} \right| |V(t)| |\varphi(t,k)|\,dt \\ &\leq e^{\sigma_1(x)} \left(\int_x^{x+\frac{1}{|k|}} (t-x)|V(t)|\,dt + \frac{1}{|k|} \int_{x+\frac{1}{|k|}}^\infty |V(t)|\,dt \right) \\ &= e^{\sigma_1(x)} \left(-(t-x)\sigma(t)\Big|_x^{x+\frac{1}{|k|}} + \int_x^{x+\frac{1}{|k|}} \sigma(t)\,dt + \frac{1}{|k|} \int_{x+\frac{1}{|k|}}^\infty |V(t)|\,dt \right) \\ &= e^{\sigma_1(x)} \left(\sigma_1(x) - \sigma_1\left(x + \frac{1}{|k|} \right) \right).\end{aligned}$$

For $k = 0$ this estimate should be understood as $|\varphi(x,0) - 1| \le \sigma_1(x) e^{\sigma_1(x)}$. The function $f_1(x,k) = e^{ikx}\varphi(x,k)$ satisfies the integral equation (2.3), and (2.7) allows us to differentiate under the integral sign in (2.3). This proves that $f_1(x,k)$ satisfies the differential equation (2.1) and the first estimate in part (i). In particular, $\lim_{x\to\infty} e^{-ikx} f_1(x,k) = 1$ for $\operatorname{Im} k \ge 0$. Differentiating (2.3) and using $e^{-\operatorname{Im} k(t-x)} |\cos k(x-t)| \le 1$ for $t \ge x$ and $\operatorname{Im} k \ge 0$, we obtain

$$\left| e^{-ikx} f_1'(x,k) - ik \right| \le \int_x^\infty |V(t)| |\varphi(t,k)| dt \le \sigma(x) e^{\sigma_1(x)} \tag{2.8}$$

so that $\lim_{x\to\infty} e^{-ikx} f_1'(x,k) = ik$ for $\operatorname{Im} k \ge 0$.

The conjugation property follows from the uniqueness of the solution $f_1(x,k)$ satisfying the estimate in part (i). To prove the uniqueness, denote by $\chi(x,k)$ the homogeneous solution of the integral equation (2.4) with the property that $\alpha(x) = \sup_{x \le t < \infty} |\chi(t,k)| < \infty$ for all $x \in \mathbb{R}$. Consider the inequality

$$|\chi(x,k)| \le \int_x^\infty \left(\int_x^t |V(t)| |\chi(t,k)| ds \right) dt$$

which follows from the homogeneous form of equation (2.4). Repeating the proof of the estimate (2.6), we get $|\chi(x,k)| \le \alpha(x) \frac{\sigma_1(x)^n}{n!}$, and passing to the limit $n \to \infty$ gives $\chi(x,k) = 0$.

To prove the first estimate in part (v), consider the inequality

$$|\varphi(x,k) - 1| \le \frac{\sigma(x)}{|k|} - \frac{1}{|k|} \int_x^\infty \sigma'(t) |\varphi(t,k) - 1| dt \tag{2.9}$$

which follows from (2.4) for $k \ne 0$. Iterating (2.9) we get

$$|\varphi(x,k) - 1| \le \frac{\sigma(x)}{|k|} e^{\frac{1}{|k|}\sigma(x)}$$

The asymptotic in part (vi) follows from the estimate in part (v), which completes the proof for the solution $f_1(x,k)$. The existence and analytic properties of the solution $f_2(x,k)$ are proved similarly by considering the integral equation

$$f_2(x,k) = e^{-ikx} + \int_{-\infty}^x \frac{\sin k(x-t)}{k} V(t) f_2(t,k) dt \tag{2.10}$$

Corollary 2.2. For $\operatorname{Im} k \ge 0$ and $k \ne 0$,
$\lim_{x\to\infty} e^{-ikx} \left(\dot f_1(x,k) - ix f_1(x,k) \right) = 0$, $\quad \lim_{x\to-\infty} e^{ikx} \left(\dot f_2(x,k) + ix f_2(x,k) \right) = 0$, where the dot stands for the partial derivative with respect to k.

Proof. Differentiating (2.4) with respect to k we obtain the following integral equation for $\dot\varphi(x,k) = e^{-ikx} \left(\dot f_1(x,k) - ix f_1(x,k) \right)$:

$$\dot\varphi(x,k) = g(x,k) - \int_x^\infty \frac{1 - e^{-2ik(x-t)}}{2ik} V(t) \dot\varphi(t,k) dt,$$

where

$$g(x,k) = \frac{1}{k} \int_x^\infty (t-x) e^{-2ik(x-t)} V(t) \varphi(t,k) dt + \frac{1}{k}(1 - \varphi(x,k)).$$

It follows the estimate in part (i) of Theorem 2.1 and (2.7) that $|g(x,k)| \le \frac{2}{|k|} \sigma_1(x) e^{\sigma_1(x)}$, and repeating the proof of the estimate (2.7), we obtain that $|\dot\varphi(x,k)| \le \frac{2}{|k|} \sigma_1(x) e^{2\sigma_1(x)}$. Since $\lim_{x\to\infty} \sigma_1(x) = 0$, this proves the statement for $f_1(x,k)$. The corresponding result for $f_2(x,k)$ is proved similarly.

For real $k \neq 0$ the pairs $f_1(x,k), f_1(x,-k) = \overline{f_1(x,k)}$ and $f_2(x,k),\ f_2(x,-k) = \overline{f_2(x,k)}$ are fundamental solutions of the differential equation (2.1). Indeed, the Wronskian $W(y_1,y_2) = y_1'y_2 - y_1y_2'$ of two solutions of (2.1) does not depend on x, and we get from part (ii) that

$$W(f_1(x,k), f_1(x,-k)) = \lim_{x\to\infty} W(f_1(x,k), f_1(x,-k)) = 2ik,$$
$$W(f_2(x,k), f_2(x,-k)) = \lim_{x\to-\infty} W(f_2(x,k), f_2(x,-k)) = -2ik.$$

Therefore for such k we have

$$f_2(x,k) = a(k)f_1(x,-k) + b(k)f_1(x,k) \tag{2.11}$$

where the transition coefficients $a(k)$ and $b(k)$ are given by
(2.12) $a(k) = \frac{1}{2ik}W(f_1(x,k), f_2(x,k)), \quad b(k) = \frac{1}{2ik}W(f_2(x,k), f_1(x,-k))$, and satisfy $\overline{a(k)} = a(-k), \overline{b(k)} = b(-k)$. Similarly we find that

$$f_1(x,k) = a(k)f_2(x,-k) - b(-k)f_2(x,k) \tag{2.13}$$

Back substituting (2.13) for $f_1(x,k)$ and $f_1(x,-k)$ into (2.11), for real $k \neq 0$ we find the so-called normalization condition,

$$|a(k)|^2 = 1 + |b(k)|^2. \tag{2.14}$$

It follows from parts (iii) and (vi) of Theorem 2.1 that coefficient $a(k)$ admits analytic continuation to $\operatorname{Im} k > 0$ and

$$a(k) = 1 + O\left(|k|^{-1}\right) \quad \text{as} \quad |k| \to \infty \tag{2.15}$$

Moreover, the function $ka(k)$ is continuous in $\operatorname{Im} k \geq 0$.
Normalization condition (2.14) implies that all zeros of $a(k)$ are in the upper half-plane $\operatorname{Im} k > 0$. Let k_0 be such a zero, $a(k_0) = 0$. It follows from the first equation in (2.12) that $W(f_1(x,k_0), f_2(x,k_0)) = 0$, so that the Jost solutions $f_1(x,k_0), f_2(x,k_0)$ are linearly dependent,

$$f_1(x,k_0) = c_0 f_2(x,k_0)$$

for some $c_0 \neq 0$. It follows from part (i) of Theorem 2.1 that for $\operatorname{Im} k > 0$ the solution $f_1(x,k)$ is exponentially decaying as $x \to \infty$, and the solution $f_2(x,k)$ is exponentially decaying as $x \to -\infty$. Therefore $f_1(\cdot,k_0) \in L^2(\mathbb{R})$ is an eigenfunction of the Schrodinger operator H with the eigenvalue $\lambda_0 = k_0^2$. Since H is symmetric, its eigenvalues are real:

$$\lambda_0 \|f_1(\cdot,k_0)\|^2 = \int_{-\infty}^{\infty} (-f_1''(x,k_0) + V(x)f_1(x,k_0))\,\overline{f_1(x,k_0)}dx$$
$$= \int_{-\infty}^{\infty} f_1(x,k_0)\left(-\overline{f_1''(x,k_0)} + V(x)\overline{f_1(x,k_0)}\right)dx = \bar{\lambda}_0 \|f_1(\cdot,k_0)\|^2$$

as is easily seen by integrating by parts twice; due to part (i) of Theorem 2.1 and estimate (2.8) the boundary terms vanish as $|x| \to \infty$. Thus $k_0 = i\varkappa_0$ is pure imaginary with $\varkappa_0 > 0$ so that $\lambda_0 = -\varkappa_0^2 < 0$, and the corresponding eigenfunction $f_1(x, i\varkappa_0)$ is real-valued.

Proposition 2.1.

The function $a(k)$ in the upper half-plane $\operatorname{Im} k > 0$ has only finitely many pure imaginary simple zeros $k_l = i\varkappa_l$, and

$$\dot{a}(i\varkappa_l) = -ic_l \|f_2(\cdot, i\varkappa_l)\|^2, \quad l = 1, ..., n$$

where the dot stands for the derivative and $f_1(x, i\varkappa_l) = c_l f_2(x, i\varkappa_l)$. The function $1/a(k)$ is bounded in some neighborhood of $k = 0$ in $\operatorname{Im} k \geq 0$.

Proof. It follows from (2.14) and (2.15) that $k = 0$ is the only possible accumulation point of zeros of $a(k)$ in $\operatorname{Im} k \geq 0$. First suppose that functions $f_1(x, k)$ and $f_2(x, k)$ are linearly independent for $k = 0$. Then the continuous in $\operatorname{Im} k > 0$ function $ka(k)$ satisfies $\lim_{k\to 0} ka(k) = W(f_1(x, 0), f_2(x, 0)) \neq 0$. Therefore $a(k) \neq 0$ in some neighborhood of 0, and $a(k)$ has only finitely many zeros in $\operatorname{Im} k > 0$.

The case when $f_1(x, 0) = cf_2(x, 0), c \neq 0$, is more subtle. Suppose that there is a converging to 0 subsequence $k_n = i\varkappa_n$ of zeros of $a(k)$ in $\operatorname{Im} k > 0$. It follows from part (i) of Theorem 2.1 that there exists $A > 0$ such that for all $\varkappa \geq 0$ we have $f_1(x, i\varkappa) > \frac{1}{2}e^{-\varkappa x}$ for $x \geq A$ and $f_2(x, i\varkappa) > \frac{1}{2}e^{\varkappa x}$ for $x \leq A$, so that

$$\int_A^\infty f_1(x, i\varkappa_n) f_1(x, 0)dx, \int_{-\infty}^{-A} f_2(x, i\varkappa_n) f_2(x, 0)dx \geq \frac{1}{4\varkappa} e^{-\varkappa A}$$

Using integration by parts, we get, as before,

$$\begin{aligned}\varkappa_n^2 \int_{-\infty}^\infty f_1(x, i\varkappa_n) f_1(x, 0)dx &= \int_{-\infty}^\infty (f_1''(x, i\varkappa_n) - V(x) f_1(x, i\varkappa_n)) f_1(x, 0)dx \\ &= \int_{-\infty}^\infty f_1(x, i\varkappa_n) (f_1''(x, 0) - V(x) f_1(x, 0))\, dx = 0\end{aligned}$$

On other hand, we have

$$\begin{aligned}0 = &\int_A^\infty f_1(x, i\varkappa_n) f_1(x, 0)dx + \int_{-A}^A f_1(x, i\varkappa_n) f_1(x, 0)dx \\ &+ c \cdot c_n \int_{-\infty}^{-A} f_2(x, i\varkappa_n) f_2(x, 0)dx\end{aligned} \tag{2.16}$$

Since $f_1(x, k)$ is continuous on $\operatorname{Im} k \geq 0$, uniformly in x on the compact subsets of $\mathbb{R}$, we have

$$\lim_{n\to\infty} \int_{-A}^A f_1(x, i\varkappa_n) f_1(x, 0)dx = \int_{-A}^A f_1(x, 0)^2 dx \geq 0$$

Using

$$\lim_{n\to\infty} c \cdot c_n = c \lim_{n\to\infty} \frac{f_1(x, i\varkappa_n)}{f_2(x, i\varkappa_n)} = c\frac{f_1(x, 0)}{f_2(x, 0)} = c^2 > 0$$

we obtain from (2.16) that for large enough n,

$$0 > \frac{1}{4\varkappa_n} e^{-\varkappa_n A}.$$

This is clearly a contradiction, so $a(k)$ has only finitely many zeros. The proof of local boundness of $1/a(k)$ in this case is left to the reader.

Next, consider the differential equation (2.1) together with the equation obtained from it by differentiating with respect to k:

$$-y'' + V(x)y = k^2 y \tag{2.17}$$
$$-\dot{y}'' + V(x)\dot{y} = k^2\dot{y} + 2ky \tag{2.18}$$

Set $y = f_1(x,k)$ in equation (2.17), $y = f_2(x,k)$ in equation (2.18), and multiply (2.17) by $\dot{f}_2(x,k)$ and (2.18) by $f_1(x,k)$. Subtracting the resulting equations, we obtain

$$W\left(f_1(x,k), \dot{f}_2(x,k)\right)' = 2kf_1(x,k)f_2(x,k)$$

Similarly, setting $y = f_2(x,k)$ in (2.17), $y = f_1(x,k)$ in (2.18), cross multiplying and subtracting, we obtain

$$-W\left(\dot{f}_1(x,k), f_2(x,k)\right)' = 2kf_1(x,k)f_2(x,k)$$

Therefore

$$W\left(f_1(x,k), \dot{f}_2(x,k)\right)\Big|_{-A}^{x} = 2k\int_{-A}^{x} f_1(x,k)f_2(x,k)dx \tag{2.19}$$
$$-W\left(\dot{f}_1(x,k), f_2(x,k)\right)\Big|_{x}^{A} = 2k\int_{x}^{A} f_1(x,k)f_2(x,k)dx \tag{2.20}$$

Now suppose that $a(k_0) = 0$. We have

$$W(f_1(x,k), f_2(x,k)) = 2ika(k),$$

so that differentiating with respect to k and setting $k = k_0$ gives

$$W\left(\dot{f}_1(x,k_0), f_2(x,k_0)\right) + W\left(f_1(x,k_0), \dot{f}_2(x,k_0)\right) = 2ik_0\dot{a}(k_0).$$

Since $f_1(x,k_0) = c_0 f_2(x,k_0)$, it follows from Theorem 2.1 and Corollary 2.2 that boundary terms in (2.19)-(2.20) vanish as $A \to \infty$, and we obtain, using that $f(x,k_0)$ is real-valued:

$$\dot{a}(k_0) = -i\int_{-\infty}^{\infty} f_1(x,k_0) f_2(x,k_0)\,dx = -ic_0\|f_2(\cdot,k_0)\|^2.$$

The eigenvalues of the Schrodinger operator H are simple. Indeed, the function $f_1(x,i\varkappa)$ is a solution of the differential equation (2.1) for $\lambda = -\varkappa^2 < 0$, which decays exponentially as $x \to \infty$. Since the Wronskian of any two solutions of (2.1) is constant, the second solution of (2.1), linearly independent with $f_1(x,i\varkappa)$, is exponentially increasing as $x \to \infty$. Thus every exponentially decaying as $x \to \infty$ solution of (2.1) for $\lambda = -\varkappa^2$ is a constant multiple of $f_1(x,i\varkappa)$. In particular, this proves that the point spectrum of H is simple. This result also follows from the simplicity of zeros of the function $a(k)$ and the eigenfunction expansion theorem, proved in the next section.

Problem 2.1 (The oscillation theorem). Let $\lambda_1 = -\varkappa_1^2 < \cdots < \lambda_n = \varkappa_n^2 < 0$ be the eigenvalues of the one-dimensional Schrodinger operator H. Prove that corresponding eigenfunctions $f_1(x,i\varkappa_l)$ have exactly $l-1$ simple zeros, $l = 1,...,n$.

Problem 2.2. Prove that for $\operatorname{Im} k \geq 0$ the Jost solution $f_1(x,k)$ admits the representation

$$f_1(x,k) = e^{ikx} + \int_x^{\infty} K_1(x,t)e^{ikt}dt$$

where

$$K(x,x)=\frac{1}{2}\int_x^\infty V(t)dt \quad \text{and} \quad |K_1(x,t)|\le\frac{1}{2}\sigma\left(\frac{x+t}{2}\right)e^{\sigma_1(x)-\sigma_1\left(\frac{x+t}{2}\right)}.$$

Moreover, the kernel $K_1(x,t)$ is differentiable and

$$\left|\frac{\partial K_1}{\partial x}(x,t)+\frac{1}{4}V\left(\frac{x+t}{2}\right)\right|\le\frac{1}{2}\sigma_1(x)\sigma\left(\frac{x+t}{2}\right)e^{\sigma_1(x)},$$

with the similar inequality for $\frac{\partial K_1}{\partial t}(x,t)$. Correspondingly, for $\operatorname{Im} k\le 0$ the Jost solution $f_2(x,k)$ admits the integral representation

$$f_2(x,k)=e^{-ikx}+\int_{-\infty}^x K_2(x,t)e^{-ikt}dt$$

where the kernel $K_2(x,t)$ satisfies similar estimates. (Hint: Show that (2.3) is equivalent to the integral equation

$$K_1(x,t)=\frac{1}{2}\int_{\frac{x+t}{2}}^\infty V(s)ds+\frac{1}{2}\int_x^\infty V(s)\int_{t-(s-x)}^{t+(s-x)}K_1(s,u)duds$$

with the condition $K_1(x,t)=0$ for $t<x$, which is solved by the method of successive approximations.)

Problem 2.3. Show that transition coefficients $a(k)$ and $b(k)$ have the representations

$$a(k)=1-\frac{1}{2ik}\int_{-\infty}^\infty V(x)dx-\frac{1}{2ik}\int_0^\infty A(t)e^{ikt}dt,\quad b(k)=\frac{1}{2ik}\int_{-\infty}^\infty B(t)e^{-ikt}dt,$$

where $A(t)\in L^1(0,\infty)$ and $B(t)\in L^1(-\infty,\infty)$.

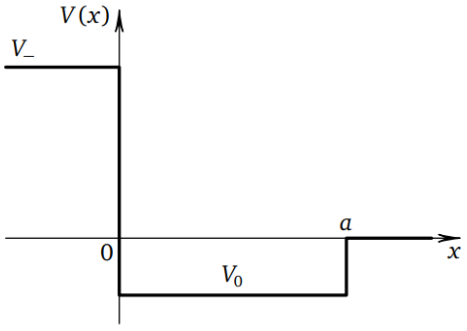
Problem 2.4. Show that for $\operatorname{Im} k>0$ the transition coefficient $a(k)$ satisfies the dispersion relation

$$a(k)=\exp\left\{\frac{1}{2\pi i}\int_{-\infty}^\infty\frac{\log\left(1+|b(p)|^2\right)}{p-k}dp\right\}\prod_{l=1}^n\frac{k-i\varkappa_l}{k+i\varkappa_l}.$$

3.6.5 1D Schrödinger Equation 2: Advanced Methods

Резонансы при одномерном движении по Киселеву (?!!????)

(из киселева стр 68)



Рассмотрим непрерывный спектр невырожденных уровней энергии в потенциале

$$V(x) = \begin{cases} V_- \to +\infty, & x < 0 \\ V_0 < 0, & 0 < x < a \\ V_+ = 0, & x > a \end{cases}$$

показанном на рис. 2.2.

По условию задачи

$$V_+ < E < V_-$$

Интервал значений координаты естественным образом разбивается на три области.

I) $x < 0$. Согласно общему рассмотрению в (5.5) решение уравнения Шрёдингера затухает на бесконечности экспоненциально, причем коэффициент затухания стремится к бесконечности:

$$x_-^2 = \frac{2m}{\hbar^2}(V_- - E) \to +\infty$$

так что при наличии в некотором интервале конечной ширины бесконечно высокого потенциала волновая функция обращается внутри этого интервала в тождественный нуль:

$$\psi_I(x) = 0, \quad x < 0$$

II) $0 < x < a$. Решение осциллирует, но поскольку по непрерывн ости волновой функции

$$\psi(0) = 0$$

решение уравнения можно выбрать с точностью до множителя вещественным, так что с учетом наличия узла в нуле

$$\psi_{II}(x) = A\sin(k_0 x), \quad \frac{\hbar^2}{2m}k_0^2 = V_0 + E$$

где связь k_0 с энергией следует из уравн ения Шредингера.

III) $x > a$. Запишем решение в виде

$$\psi_{III}(x) = e^{-\mathrm{i}kx} + Re^{\mathrm{i}kx}, \quad \frac{\hbar^2}{2m}k^2 = E$$

где первый вклад отвечает падающей из бесконечности на потенциальную яму волне, а Второй -отраженной от стенки волне.

Поскольку поток прошедшей волны равен в этой Задаче нулю, коэффициент отражения равен единице и

$$|R| = 1 \quad \to \quad R = e^{\mathrm{i}\phi}$$

Т.е. отраженная волна приобретает Дополнительную фазу рассеяния ϕ.

Для получения связи неизвестных параметров в волновой функции необходимо потребовать непрерывн ости волновой функции и ее производной в точке сшивки решений

$$\psi_{II}(a) = \psi_{III}(a), \quad \psi'_{II}(a) = \psi'_{III}(a)$$

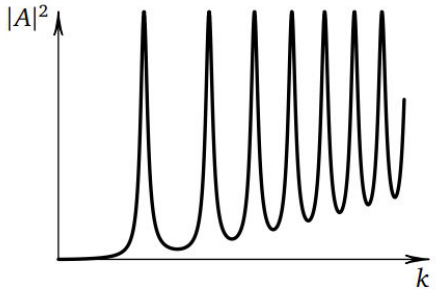
Отсюда

$$\begin{cases} A\sin(k_0 a) = \mathrm{e}^{-\mathrm{i}ka} + \mathrm{e}^{\mathrm{i}(ka+\phi)}, \\ k_0 A\cos(k_0 a) = -\mathrm{i}k\mathrm{e}^{-\mathrm{i}ka} + \mathrm{i}k\mathrm{e}^{\mathrm{i}(ka+\phi)} \end{cases} \quad \Rightarrow \quad \begin{cases} A = -2\mathrm{i}k\frac{\mathrm{e}^{-\mathrm{i}ka}}{k_0\cos(k_0 a) - \mathrm{i}k\sin(k_0 a)}, \\ \mathrm{e}^{\mathrm{i}\phi} = -\mathrm{e}^{-2\mathrm{i}ka}\frac{k_0\cos(k_0 a) + \mathrm{i}k\sin(k_0 a)}{k_0\cos(k_0 a) - \mathrm{i}k\sin(k_0 a)}. \end{cases}$$

Модуль амплитуды A, которая определяет плотность вероятности нахождения частицы в ПОТенциальной яме, задается величиной

$$|A|^2 = \frac{4k^2}{k^2 + (k_0^2 - k^2)\cos^2(k_0 a)} = \frac{4k^2}{k^2 + \frac{2m}{\hbar^2} V_0 \cos^2(k_0 a)}$$

Как видим, Квадрат модуля осциллирует в границах $0 \leqslant |A|^2 \leqslant 4$. Характерный график этой функции в зависимости от волнового вектора показан на рис. 2.3.



Пик и распределения расположены при

$$k_0 a = \frac{\pi}{2} + \pi n, \quad n \in \mathbb{N}$$

Эти пики сглаживаются, если их амплитуда мала, т.е. при

$$k^2 \gg \frac{2mV_0}{\hbar^2}$$

При обратном же соотношении пики хорошо разделены и ярко выражены.

Это имеет место при

$$k^2 \ll k_0^2 \quad \leftrightarrow \quad v \ll v_0$$

где v и v_0 -скорости дВижения волны при $x > a$ и в потенциальной яме.

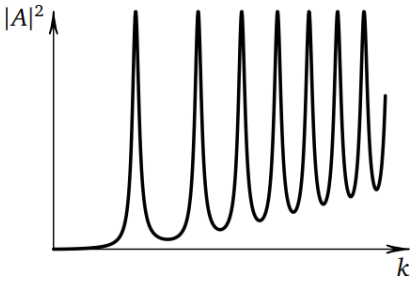


Рис. 5. Нормировка плотности вероятности обнаружить частицу в потенциальной яме в зависимости от волнового вектора падающей волны (в единицах $a = 10, -2mV_0/\hbar^2 = 200$)

Другими словами, при наличии пиков потенциальная яма выглядит глубокой для рассеивающейся частицы. С ростом энергии, естественно, потенциальная яма будет восприниматься как мелкая.

(????????)

Совершенно аналогично фаза

$$\phi = -\pi - 2ka + 2 \arctan \left[\frac{k}{k_0} \tan(k_0 a)\right]$$

вблизи пика и спытывает существенное изменение.

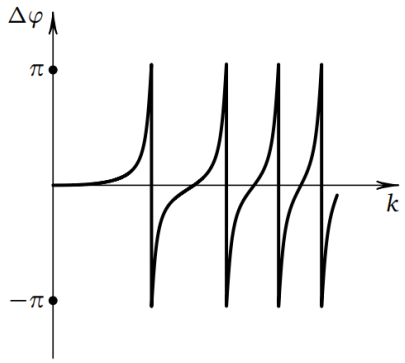
В качестве более объективной характери стики обычно рассматривают разность фаз падающей и отраженной волны, например, на границе потенциальной ямы, т.е. при $x = a$

$$\Delta\phi = 2 \arctan \left[\frac{k}{k_0} \tan(k_0 a)\right] - \pi$$

Это же значение комплексной фазы получается при умножении найденного нам и решения на фактор $\exp(\mathrm{i}2ka)$, т.е. при переопределении глобальной, не наблюдаем ой фазы волновой функции в целом.

Deeper understanding of resonances in scattering of a wall near well

Говорят, что пики амплитуды и быстрая смена фазы отвечают возбуждению резонансов в глубокой потенциальной яме. График разности фаз представлен на рис. 6, откуда видно, что вблизи пика комплексная фаза быстро меняется на 2π. Соотношение (5.45) показывает, что резонанс имеет место при условии, что в яме укладывается нечетное число четверть-волн, что в случае ямы с бесконечными стенками, т. е. потенциального ящика, соответствовало бы положению ровно посредине между стационарными уровнями энергии.



Групповая скорость волны определялась из условия стаци онарности фазы

$$\frac{\partial\phi(x,t)}{\partial p} = 0$$

так что для отраженной волны с учетом переопределения фазы, как это было сделано при выводе $\Delta\phi$

$$\phi(x,t) = px - Et + \hbar\phi, \quad p = \hbar k$$

Н

$$x = \frac{\partial E}{\partial p} t - \frac{\partial \phi}{\partial k}$$

Что можно переписать в виде

$$x = v_{\mathrm{gr}}(t - \Delta t)$$

где запаздывание по времени определим по разности фаз $\Delta\phi$

$$\Delta t = \frac{\partial\Delta\phi/\partial k}{\partial E/\partial p} = \hbar\frac{\partial\Delta\phi}{\partial E}$$

В явном виде в рассматриваемой задаче производная

$$\frac{\partial\Delta\phi}{\partial k} = \frac{2}{k^2\tan^2(k_0a)+k_0^2}\left\{\frac{ak^2}{\cos^2(k_0a)}|\frac{k_0^2-k^2}{k_0}\tan(k_0a)\right\}$$

В пике имеет значение

$$\left.\frac{\partial\Delta\phi}{\partial k}\right|_{\text{peak}} \to 2a$$

а между пиками при $\sin(k_0a)=0$

$$\frac{\partial\Delta\phi}{\partial k} \simeq 2a\frac{k^2}{k_0^2} \ll 2a$$

Эти соотношения можно проинтерпретировать следующим образом.

В классике частица проходит от одного конца ям ы до другого за время

$$\Delta t_{\text{class.}} = \frac{2a}{v_0} = m\frac{2a}{\hbar k_0}.$$

В пике, когда частицу с высокой вероятностью можно обнаружить в глубокой потенциаль- н ой яме, в квантовом случае получаем

$$\Delta t_{\text{quant.}} = m\frac{2a}{\hbar k} = m\frac{2a}{\hbar k_0}\frac{k_0}{k} \gg \Delta t_{\text{class.}}$$

Величину $\tau = \Delta t_{\text{quant.}}/4$ называют временем жизни резонанса в глубокой потенциальной ям e^4. Вне резонанса время пребывания частицы в яме даже меньше, чем в классике.

Поведение амплитуды резонанса вблизи пика

Рассмотрим поведение амплитуды резонанса вблизи пика с $k_\star \neq 0$. При этом

$$|\sin(k_0a)| \to 1, \quad \cos(k_0a) \to 0$$

так что, вводя малый параметр разложения Δk

$$k = k_\star + \Delta k, \quad \Delta k \to 0$$

находим

$$k_0 = \sqrt{\frac{2mV_0}{\hbar^2}+k^2} \to \sqrt{\frac{2mV_0}{\hbar^2}+k_\star^2+2k_\star\Delta k} \to k_0^\star + \frac{k_\star}{k_0^\star}\Delta k$$

где $k_0^\star = k_0(k_\star)$. Поскольку в пике

$$\cos(k_0^\star a) = 0, \quad k_0^\star a = \frac{\pi}{2}+\pi n$$

В окрестности пика получим

$$k_0\cos(k_0a) \to (-1)^{n+1}k_0^\star\sin\left(\frac{k_\star}{k_0^\star}a\Delta k\right) \to (-1)^{n+1}k_\star a\Delta k$$

Тогда согласно выражению для амплитуды (5.21) вблизи пика резонанса

$$A \approx -2\mathrm{i}k_\star \frac{e^{-\mathrm{i}k_\star a}}{k_0 \cos(k_0 x) - \mathrm{i}k \sin(k_0 x)} \sim \frac{1}{(-1)^{n+1} k_\star a \Delta k - (-1)^n \mathrm{i}k_\star}$$

где мы учли, что $\sin(k_0^\star a) = (-1)^n$. Выразим Δk через разн ость энергий

$$E - E_\star = \frac{\hbar^2}{2m}\left(k^2 - k_\star^2\right) = \frac{\hbar^2}{2m}(k + k_\star)\Delta k \approx \frac{\hbar^2}{m} k_\star \Delta k$$

Откуда:

$$A \sim \frac{1}{\frac{ma}{\hbar^2}(E - E_\star) + \mathrm{i}k_\star} \sim \frac{1}{(E - E_\star) + \mathrm{i}k_\star \frac{\hbar^2}{ma}}$$

Стандартная запись подобной ам пЛитуды резонанса в виде

$$A \sim \frac{1}{(E - E_\star) + \frac{i}{2}\Gamma}$$

называется приближением Брейта-Вигнера.

Величину Γ называют шириной резонанса.

Квадрат модуля амплитуды -

$$|A|^2 \sim \frac{1}{(\Delta E)^2 + \frac{1}{4}\Gamma^2}$$

так что при $\Delta E = \pm\Gamma/2$ плотность вероятности обнаружения резонанса падает вдвое. Поэтому Γ еще называют шириной на полувысоте. В рассматриваемой нами задаче

$$\Gamma = 2\frac{\hbar^2 k_\star}{ma}$$

Амплитуда Брейта-Вигнера как функция энергии представляет собой полюс в комплексной плоскости энергии при

$$E_{\text{pole}} = E_\star - \frac{\mathrm{i}}{2}\Gamma.$$

Time-dependent scattering on a wall near well (????????)

(???? I'll think later, a big advanced question)

Поэтому считают, что временная зависимость волновой функции резонанса

$$\psi \sim \mathrm{e}^{-\frac{i}{\hbar}E_{\text{pole}}\, t} = \mathrm{e}^{-\frac{i}{\hbar}E_\star t}\mathrm{e}^{-\frac{1}{2\hbar}\Gamma t}$$

имеет затухающий фактор, так что плотность вероятности падает со временем как

$$|\psi|^2 \sim \mathrm{e}^{-\frac{1}{\hbar}\Gamma t}.$$

Величину

$$\tau = \frac{\hbar}{\Gamma}$$

называют временем жизни резонанса. Тогда

$$|\psi|^2 \sim \mathrm{e}^{-t/\tau}.$$

В нашем случае

$$\tau = \frac{ma}{2\hbar k_\star},$$

что находится в полном согласии с приведенной выше интерпретацией времени запаздывания сигнала в терминах комплексной фазы за счет возбуждения резонанса.

2.2. Eigenfunction expansion.

Here we explicitly construct the resolvent kernel for the one-dimensional Schrodinger operator H, and show that it is self-adjoint with the domain consisting of functions $\psi \in L^2(\mathbb{R})$, which are twice differentiable on $\mathbb{R}$, and such that $-\psi'' + V(x)\psi \in L^2(\mathbb{R})$. Using the method of complex integration we derive the eigenfunction expansion theorem for the operator H, which generalizes the corresponding result for the operator H_0 of a free quantum particle, considered in Section 2.3 of Chapter 2.

For $\lambda \in \mathbb{C}\backslash[0,\infty)$ let

$$R_\lambda(x,y) = \begin{cases} -\frac{f_1(x,k)f_2(y,k)}{2ika(k)} & \text{if } x \geq y \\ -\frac{f_1(y,k)f_2(x,k)}{2ika(k)} & \text{if } x \leq y \end{cases} \tag{2.21}$$

where the branch of the function $k = \sqrt{\lambda}$ on $\mathbb{C}\backslash[0,\infty)$ is defined by the condition that $\operatorname{Im} k > 0$. For fixed x and y the function $R_\lambda(x,y)$ is meromorphic on $\mathbb{C}\backslash[0,\infty)$ with simple poles at $\lambda_l = -\varkappa_l^2, l = 1, ..., n$. For fixed
$\lambda \neq \lambda_l$ the function $R_\lambda(x,y) = R_\lambda(y,x)$ is continuous in x and y, and it follows from part (v) of Theorem 2.1 and (2.15) that

$$|R_\lambda(x,y)| \leq C\frac{e^{-\operatorname{Im} k|x-y|}}{|k|}, \quad C > 0. \tag{2.22}$$

The kernel $R_\lambda(x,y)$ for $\lambda \neq \lambda_l$ defines a bounded integral operator R_λ in $L^2(\mathbb{R})$ by the formula

$$\left(R_\lambda\psi\right)(x) = \int_{-\infty}^{\infty} R_\lambda(x,y)\psi(y)dy$$

Indeed, it follows from (2.22) that for $\psi \in L^2(\mathbb{R})$,

$$|k|^2 \left\|R_\lambda\psi\right\|^2 \leq C^2 \int_{-\infty}^{\infty} \left(\int_{-\infty}^{\infty} e^{-\operatorname{Im} k|x-y|}|\psi(y)|dy\right)^2 dx$$
$$= C^2 \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{-\operatorname{Im} k(|y_1|+|y_2|)} \int_{-\infty}^{\infty} \left|\psi\left(x+y_1\right)\psi\left(x+y_2\right)\right| dxdy_1dy_2$$
$$\leq 4C^2(\operatorname{Im} k)^{-2}\|\psi\|^2$$

In particular,

$$\|R_\lambda\| \le \frac{2C}{|k| \operatorname{Im} k}$$

Lemma 2.1. The operator H is self-adjoint and $R_\lambda = (H - \lambda I)^{-1}$ for $\lambda \in \mathbb{C}\setminus\{[0,\infty) \cup \{\lambda_1, ..., \lambda_n\}\}$, where I is the identity operator in $L^2(\mathbb{R})$.

Proof. Let $g \in L^2(\mathbb{R})$. As in the variation of parameters method, it follows from (2.21) that for $\lambda \in \mathbb{C}\setminus\{[0,\infty) \cup \{\lambda_1, ..., \lambda_n\}\}$ the function $y = R_\lambda g \in L^2(\mathbb{R})$ is twice differentiable a.e. on $\mathbb{R}$ and satisfies the differential equation

$$-y'' + V(x)y = \lambda y + g(x)$$

Thus $(H - \lambda I)R_\lambda = I$ and, in particular, $\operatorname{Im}(H \pm iI) = L^2(\mathbb{R})$, so that H is self-adjoint.

Let $\mathfrak{H}_0$ be the Hilbert space of $\mathbb{C}^2$-valued functions $\Phi(\lambda) = \binom{\varphi_1(\lambda)}{\varphi_2(\lambda)}$ on $[0,\infty)$ with the norm

$$\|\Phi\|_0^2 = \int_0^\infty \left(|\varphi_1(\lambda)|^2 + |\varphi_2(\lambda)|^2\right) d\sigma(\lambda)$$

where $d\sigma(\lambda) = \frac{1}{2\sqrt{\lambda}} d\lambda$ and $\sqrt{\lambda} \ge 0$ for $\lambda \ge 0$ (see Section 2.3 of Chapter 2, where one should put $\hbar = 1$ and $m = \frac{1}{2}$). For $\lambda \ge 0$ set

$$u_j(x, \sqrt{\lambda}) = \frac{1}{a(\sqrt{\lambda})} f_j(x, \sqrt{\lambda}), \quad j = 1, 2 \tag{2.23}$$

and for $\psi \in C_0^2(\mathbb{R})$ define the $\mathbb{C}^2$-valued function $\mathscr{U}\psi$ on $[0,\infty)$ with components $(\mathscr{U}\psi)_1$ and $(\mathscr{U}\psi)_2$ by

$$(\mathscr{U}\psi)_j(\lambda) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^\infty \psi(x)\overline{u_j(x, \sqrt{\lambda})} dx, \quad j = 1, 2. \tag{2.24}$$

By Proposition 2.1 the function $\mathscr{U}\psi$ is bounded at $\lambda = 0$, and for large λ using differential equation (2.1) and integration by parts we get

$$(\mathscr{U}\psi)_j(\lambda) = \frac{1}{\lambda\sqrt{2\pi}} \int_{-\infty}^\infty (-\psi''(x) + V(x)\psi(x))\, \overline{u_j(x, \sqrt{\lambda})} dx$$

which shows that $\mathscr{U}\psi \in \mathfrak{H}_0$.

Let P be the orthogonal projection on the subspace of $\mathscr{H} = L^2(\mathbb{R})$ spanned by the eigenfunctions $\psi_l(x) = f_1(x, i\varkappa_l), l = 1, ..., n$. The functions ψ_l are real-valued and orthogonal, so that for $\psi \in \mathscr{H}$

$$(P\psi)(x) = \sum_{l=1}^n \frac{1}{\|\psi_l\|^2} \psi_l(x) \int_{-\infty}^\infty \psi(y)\psi_l(y) dy$$

Theorem 2.3. The operator $\mathscr{U}$ extends to a partial isometry operator $\mathscr{U}\colon \mathscr{H} \to \mathfrak{H}_0$,

$$\mathscr{U}^*\mathscr{U} = I - P \quad \text{and} \quad \mathscr{U}\mathscr{U}^* = I_0,$$

and establishes the isomorphism $(I - P)\mathscr{H} \simeq \mathfrak{H}_0$. Here I and I_0 are, respectively, identity operators in $\mathscr{H}$ and $\mathfrak{H}_0$. For the spectrum of the corresponding Schrodinger operator H we have $\sigma(H) = \{-\varkappa_1^2, ..., -\varkappa_n^2\} \cup [0,\infty)$, and

$$\mathscr{H} = \mathscr{H}_{\text{pp}} \oplus \mathscr{H}_{\text{ac}}$$

where $\mathscr{H}_{\text{pp}} = P\mathscr{H}$ and $\mathscr{H}_{\text{ac}} = (I - P)\mathscr{H}$ are, respectively, invariant subspaces associated with pure point and absolutely continuous spectra of H. The operator $\mathscr{U} H_{\mathscr{U}^*}$ is a multiplication

by λ operator in $\mathfrak{H}_0$, so that the absolutely continuous spectrum $[0,\infty)$ of H has multiplicity two, and the operator $\mathscr{U}$ "diagonalizes" the restriction of H to the subspace $\mathscr{H}_{\rm ac}$.

Proof. To proof the relation $\mathscr{U}^*\mathscr{U} = I - P^-$ the so-called completeness relation - it is sufficient to establish the following classical eigenfunction expansion formula for $\psi \in C_0^2(\mathbb{R})$:
$\psi(x) = \frac{1}{2\pi}\int_0^\infty \left(u_1(x,k)\int_{-\infty}^\infty \psi(y)\overline{u_1(y,k)}dy + u_2(x,k)\int_{-\infty}^\infty \psi(y)\overline{u_2(y,k)}dy\right)dk$

$$+\sum_{l=1}^n \frac{1}{\|\psi_l\|^2}\psi_l(x)\int_{-\infty}^\infty \psi(y)\psi_l(y)dy \tag{2.25}$$

where all integrals are absolutely convergent, and we put $\sqrt{\lambda} = k, d\sigma(\lambda) = dk$. Indeed, assuming that (2.25) holds, we get for $\psi, \varphi \in C_0^2(\mathbb{R})$

$$\begin{aligned}(\psi,\varphi) &= \int_{-\infty}^\infty \psi(x)\overline{\varphi(x)}dx = \frac{1}{2\pi}\int_{-\infty}^\infty \overline{\varphi(x)}\left(\int_0^\infty \left(u_1(x,k)\int_{-\infty}^\infty \psi(y)\overline{u_1(y,k)}dy\right.\right.\\ &\left.\left.+u_2(x,k)\int_{-\infty}^\infty \psi(y)\overline{u_2(y,k)}dy\right)dk\right)dx + \sum_{l=1}^n \frac{1}{\|\psi_l\|^2}(\psi,\psi_l)(\psi_l,\varphi)\\ &= (\mathscr{U}\psi,\mathscr{U}\varphi)_0 + \sum_{l=1}^n \frac{1}{\|\psi_l\|^2}(\psi,\psi_l)(\psi_l,\varphi)\end{aligned}$$

where $(,)_0$ is the inner product in $\mathfrak{H}_0$, and the interchange of integrals over x and k is justified by the Fubini theorem. Thus

$$(\mathscr{U}\psi,\mathscr{U}\varphi)_0 = ((I-P)\psi,\varphi) \tag{2.26}$$

for $\psi, \varphi \in C_0^2(\mathbb{R})$, and we conclude that $\mathscr{U}$ extends to a bounded operator from $\mathscr{H}$ and $\mathfrak{H}_0$ satisfying (2.26) for all $\psi, \varphi \in \mathscr{H}$.

To prove the eigenfunction expansion formula (2.25), for $\lambda \in \mathbb{C}\backslash[0,\infty)$ set $g(x,\lambda) = (R_\lambda\psi)(x)$. The function $g(x,\lambda)$ for fixed x is meromorphic in $\lambda \in \mathbb{C}\backslash[0,\infty)$ with simple poles at $\lambda = \lambda_l, l = 1,...,n$. It follows from (2.21) and Proposition 2.1 that

$$\mathrm{Res}_{\lambda=\lambda_l} g(x,\lambda) = \frac{ic_l}{\dot{a}(i\varkappa_l)}f_2(x,i\varkappa_l)\int_{-\infty}^\infty f_2(y,i\varkappa_l)\psi(y)dy = -\frac{(\psi,\psi_l)}{\|\psi_l\|^2}\psi_l(x)$$

Since $HR_\lambda = R_\lambda H = I + \lambda R_\lambda$, we have

$$-g''(x,\lambda) + V(x)g(x,\lambda) = \psi(x) + \lambda g(x,\lambda)$$

so that

$$g(x,\lambda) = -\frac{1}{\lambda}\psi(x) + \frac{1}{\lambda}(R_\lambda\varphi)(x)$$

where $\varphi = -\psi'' + V(x)\psi \in C_0(\mathbb{R})$. From (2.22) we get

$$|(R_\lambda\varphi)(x)| \le \frac{C}{|\sqrt{\lambda}|} \quad \text{as} \quad |\lambda| \to \infty$$

so that

$$g(x,\lambda) = -\frac{1}{\lambda}\psi(x) + O\left(|\lambda|^{-3/2}\right) \quad \text{as} \quad |\lambda| \to \infty \tag{2.27}$$

It follows from Proposition 2.1 and (2.21) that

$$g(x,\lambda) = O\left(|\lambda|^{-1/2}\right) \quad \text{as} \quad \lambda \to 0 \tag{2.28}$$

For $0 < \varepsilon < 1 < N$ let $\mathcal{C} = \mathcal{C}_{\varepsilon,N}$ be the contour consisting of the following parts: (i) the arc $\mathcal{C}_\varepsilon$ of a circle $\lambda = \varepsilon e^{i\theta}, \varepsilon \le |\arg\theta| \le \pi$, oriented clockwise; (ii) the arc $\mathcal{C}_N$ of a circle $\lambda = Ne^{i\theta}, \varepsilon_N \le |\arg\theta| \le \pi$, oriented anti-clockwise, where $N\sin\varepsilon_N = \varepsilon\sin\varepsilon$; (iii) the segments $\mathcal{I}_\pm$of the straight
lines $\operatorname{Im}\lambda = \pm\varepsilon\sin\varepsilon$ which connect the boundaries of the arcs. Choose ε and N such that all poles λ_l of $g(x,\lambda)$ are inside $\mathcal{C}$, and consider the integral

$$I = \frac{1}{2\pi i}\int_{\mathcal{C}} g(x,\lambda)d\lambda$$

On one hand, by the Cauchy residue theorem

$$I = \sum_{l=1}^{n} \operatorname{Res}_{\lambda=\lambda_l} g(x,\lambda) = -\sum_{l=1}^{n} \frac{(\psi,\psi_l)}{\|\psi_l\|^2}\psi_l(x)$$

On the other hand, it follows from (2.27) and (2.28) that

$$\lim_{N\to\infty}\frac{1}{2\pi i}\int_{\mathcal{C}_N} g(x,\lambda)d\lambda = -\psi(x) \quad \text{and} \quad \lim_{\varepsilon\to 0}\frac{1}{2\pi i}\int_{\mathcal{C}_\varepsilon} g(x,\lambda)d\lambda = 0$$

Thus we obtain

$$\begin{aligned}\psi(x) - \sum_{l=1}^{n}\frac{1}{\|\psi_l\|^2}(\psi,\psi_l)\psi_l(x) &= \lim_{\varepsilon\to 0}\lim_{N\to\infty}\frac{1}{2\pi i}\left(\int_{\mathcal{I}_+} g(x,\lambda)d\lambda - \int_{\mathcal{I}_-} g(x,\lambda)d\lambda\right)\\ &= \frac{1}{2\pi i}\int_0^\infty\left(\int_{-\infty}^{\infty}\left(R_{\lambda+i0}(x,y) - R_{\lambda-i0}(x,y)\right)\psi(y)dy\right)d\lambda, \qquad (2.29)\end{aligned}$$

where

$$R_{\lambda\pm i0}(x,y) = \lim_{\varepsilon\to 0} R_{\lambda\pm i\varepsilon}(x,y)$$

To compute the difference $R_{\lambda+i0}(x,y) - R_{\lambda-i0}(x,y)$, observe that on the cut $\lambda \ge 0$ we have $\sqrt{\lambda+i0} = k \ge 0$ and $\sqrt{\lambda-i0} = -k \le 0$. It follows from (2.21) that for $x \ge y$
$R_{\lambda+i0}(x,y) - R_{\lambda-i0}(x,y) = -\frac{1}{2ik}\left(\frac{f_1(x,k)f_2(y,k)}{a(k)} + \frac{f_1(x,-k)f_2(y,-k)}{a(-k)}\right)$,
and using the equations

$$\begin{aligned}f_1(x,k) &= \frac{1}{a(-k)}f_2(x,-k) - \frac{b(-k)}{a(-k)}f_1(x,-k),\\ f_2(y,-k) &= \frac{1}{a(k)}f_1(y,k) + \frac{b(-k)}{a(k)}f_2(y,k),\end{aligned}$$

which follow from (2.11) and (2.13), we obtain

$$\begin{aligned}R_{\lambda+i0}(x,y) - R_{\lambda-i0}(x,y) &= \frac{i}{2k|a(k)|^2}\left(f_1(x,k)\overline{f_1(y,k)} + f_2(x,k)\overline{f_2(y,k)}\right)\\ &= \frac{i}{2k}\left(u_1(x,k)\overline{u_1(y,k)} + u_2(x,k)\overline{u_2(y,k)}\right)\end{aligned}$$

where $\lambda = k^2$. Substituting this into (2.29) and using the symmetry $R_\lambda(x,y) = R_\lambda(y,x)$ of the resolvent kernel, we get the eigenfunction expansion (2.25).

Let $\mathscr{U}_{\rm ac}$ be the restriction of the operator $\mathscr{U}$ to the subspace $\mathscr{H}_{\rm ac} = (I-P)\mathscr{H}$. It follows from the completeness relation that the operator $\mathscr{U}_{\rm ac}$

is an isometry, so that $\mathrm{Im}\,\mathscr{U} = \mathrm{Im}\,\mathscr{U}_{\mathrm{ac}}$ is a closed subspace of $\mathfrak{H}_0$. Thus to verify the orthogonality relation $\mathscr{U}\mathscr{U}^* = I_0$, it is sufficient to show that $\mathrm{Im}\,\mathscr{U} = \mathfrak{H}_0$. Using integration by parts we easily get that a self-adjoint operator $\mathscr{U}_{\mathrm{ac}} H \mathscr{U}_{\mathrm{ac}}^{-1}$ is a multiplication by λ operator in $\mathrm{Im}\,\mathscr{U}$ with the domain $\mathscr{U}D(H)$. Moreover,

$$\mathscr{U}R_\mu = R_\mu^{(0)}\mathscr{U}, \quad \mu \in \mathbb{C}\backslash[0,\infty),$$

where $R_\mu^{(0)}$ is the resolvent of the multiplication by λ operator in $\mathfrak{H}_0$, so that $\mathrm{Im}\,\mathscr{U}$ is an invariant subspace for $R_\mu^{(0)}$. Now it follows from Lemma 2.2 in Section 2.2 of Chapter 2 that there are Borel subsets $E_1, E_2 \subseteq [0,\infty)$ such that

$$\mathrm{Im}\,\mathscr{U} = \left\{ \tilde{\Phi} = \begin{pmatrix} \chi_{E_1}\varphi_1 \\ \chi_{E_2}\varphi_2 \end{pmatrix}, \quad \Phi = \begin{pmatrix} \varphi_1 \\ \varphi_2 \end{pmatrix} \in \mathfrak{H}_0 \right\}.$$

If, say, $E_1^{\mathrm{c}} = [0,\infty)\backslash E_1$ has positive Lebesgue measure, then for $\lambda = k^2 \in E_1^{\mathrm{c}}$ we have

$$\int_{-\infty}^{\infty} \overline{u_1(x,k)}\psi(x)dx = 0 \quad \text{for all} \quad \psi \in C_0^2(\mathbb{R}),$$

so that $u(x,k) = 0$ for all $x \in \mathbb{R}$ - a contradiction. Therefore, $\mathrm{Im}\,\mathscr{U} = \mathfrak{H}_0$.

Let $\mathscr{U}_0 : \mathscr{H} \to \mathfrak{H}_0$ be the corresponding unitary operator for the Schrodinger operator H_0 of a free particle, constructed in Section 2.3 of Chapter 2 (with $\hbar = 1$ and $m = \frac{1}{2}$), and set $U = \mathscr{U}^*\mathscr{U}_0 : \mathscr{H} \to \mathscr{H}_{\mathrm{ac}}$.

Corollary 2.4. The restriction of H to the absolutely continuous subspace $\mathscr{H}_{\mathrm{ac}}$ is unitarily equivalent to H_0,

$$H|_{\mathscr{H}_{\mathrm{ac}}} = UH_0U^{-1}.$$

Remark. In physics literature, completeness and orthogonality relations, understood in the distributional sense, are usually written as

$$\frac{1}{2\pi}\int_0^\infty \left(u_1(x,k)\overline{u_1(y,k)} + u_2(x,k)\overline{u_2(y,k)} \right) dk + \sum_{l=1}^{n} \frac{\psi_l(x)\psi_l(y)}{\|\psi_l\|^2} = \delta(x-y)$$

and

$$\frac{1}{2\pi}\int_{-\infty}^{\infty} u_j(x,k)\overline{u_k(x,p)}dx = \delta_{jk}\delta(k-p),$$

where $i,k = 1,2$ and $k,p > 0$. When transition coefficients $a(k)$ and $b(k)$ are differentiable for $k \neq 0$[2], the orthogonality relation can be derived from the identity

$$\frac{d}{dx}W\left(u_j(x,k), \overline{u_k(x,p)}\right) = \left(k^2 - p^2\right) u_j(x,k)\overline{u_k(x,p)}, \tag{2.30}$$

which immediately follows from the differential equation (2.1). Namely, consider the case $j = k = 1$ and integrate (2.30) over $[-N,N]$. Using (2.13) and asymptotics of Jost solutions, we get

[2] This is the case when $V(x)$ satisfies $\int_{-\infty}^{\infty}\left(1+|x|^2\right)|V(x)|dx < \infty$.

$$\int_{-N}^{N} u_1(x,k)\overline{u_1(x,p)}dx = \frac{1}{(k^2-p^2)\,a(k)\overline{a(p)}} W\left(f_1(x,k), \overline{f_1(x,p)}\right)\Big|_{-N}^{N}$$
$$= \frac{i}{a(k)\overline{a(p)}}\left(\frac{e^{i(k-p)N} - a(k)\overline{a(p)}e^{-i(k-p)N} + \overline{b(k)}b(p)e^{i(k-p)N}}{k-p}\right.$$
$$\left. + \frac{a(k)b(p)e^{-i(k+p)N} - \overline{b(k)a(p)}e^{i(k+p)N}}{k+p}\right) + o(1) \quad \text{as} \quad N\to\infty$$

Since $k, p > 0$, by the Riemann-Lebesgue lemma the distributional limit as $N \to \infty$ of the terms in the third line is zero. Since $a(k)$ and $b(k)$ are assumed differentiable, in the second line we can replace $\overline{a(p)}$ and $b(p)$ by $\overline{a(k)}$ and $b(k)$, respectively, since the difference goes to zero as $N \to \infty$ by the Riemann-Lebesgue lemma. Finally, using (2.14) we obtain

$$\lim_{N\to\infty}\int_{-N}^{N} u_1(x,k)\overline{u_1(x,p)}dx = 2\lim_{N\to\infty}\frac{\sin(k-p)N}{k-p} = 2\pi\delta(k-p),$$

where the last equality is the distributional form of the orthogonality relation for the Fourier transform.

Remark. The eigenfunctions of the continuous spectrum $u_j(x,\lambda)$ also satisfy the normalization condition (2.14) in Section 2.2 of Chapter 2:

$$\lim_{\Delta\to 0}\frac{1}{\Delta}\left(U_{j,k+\Delta} - U_{j,k}, U_{l,k+\Delta} - U_{l,k}\right) = \delta_{jl}, \quad j,l = 1,2$$

where

$$U_{j,k}(x) = \int_{k_0^2}^{k^2} u_j(x,\sqrt{\lambda})\frac{d\lambda}{2\sqrt{\lambda}} = \int_{k_0}^{k}\frac{f_j(x,p)}{a(p)}dp, \quad j = 1,2.$$

Remark. The qualitative structure of the spectrum of the Schrodinger operator H is determined by the structure of the level sets $H_c(p,x) = \lambda$ of the classical Hamiltonian function $H_c(p,x) = p^2 + V(x)$. Namely, condition $\lim_{|x|\to\infty} V(x) = 0$ implies that the level sets for $\lambda > 0$ are non-compact and the classical motion is unbounded in both directions, and these values of λ fill the absolutely continuous spectrum $[0,\infty)$ of H of multiplicity two. For $\lambda < 0$ the level sets are compact and classical motion is periodic. According to BWS quantization rules (see Section 2.5 in Chapter 2), the energy levels - eigenvalues of H - correspond to the closed orbits, and condition (2.2) guarantees that H has only finitely many eigenvalues.

Problem 2.5. Find the energy levels for the potential

$$V(x) = -\frac{V_0}{\cosh^2 \varkappa x}, \quad V_0 > 0.$$

In particular, show that when $V_0 = 2\varkappa^2$ there is only one eigenvalue $E = -\varkappa^2$.

Problem 2.6. Show that the operator $R_\lambda - R_\lambda^{(0)}$, where $R_\lambda^{(0)} = (H_0 - \lambda I)^{-1}$ and $\lambda \in \mathbb{C}\backslash[0,\infty)$, is of the trace class, and

$$\mathrm{Tr}\left(R_\lambda - R_\lambda^{(0)}\right) = -\frac{d}{d\lambda}\log a(\sqrt{\lambda}).$$

(Hint: Use Wronskian identities (2.19)-(2.20) from the previous section.)

2.3. S-matrix and scattering theory.

It was shown in the previous section that for potentials $V(x)$ satisfying (2.2) the operators $H = H_0 + V$ and H_0 have the same absolutely continuous spectrum. Among many partial isometry operators in $\mathscr{H}$ which establish the unitary equivalence between $H|_{\mathscr{H}_{\rm ac}}$ and H_0, there are two operators $W_\pm$of fundamental physical significance. They are defined as

$$W_\pm = \lim_{t\to\pm\infty} e^{iHt}e^{-itH_0} \tag{2.31}$$

where the limit is understood in the strong operator topology, and are called wave operators (or Mller operators). In general, the wave operators exist for a Schrodinger operator $H = H_0+V$ on $\mathbb{R}^n$ with the potential $V(\boldsymbol{q})$ decaying sufficiently fast as $|\boldsymbol{q}| \to \infty$. In this section, we will show that for potentials $V(x)$ satisfying (2.2) the limits (2.31) exist.

The wave operators satisfy the partial isometry relation

$$W_\pm^* W_\pm = I \tag{2.32}$$

Indeed, strong limits of unitary operators preserve the inner products, so that $(W_\pm\psi, W_\pm\varphi) = (\psi,\varphi)$ for all $\psi,\varphi \in \mathscr{H}$. Convergence $A_n \to A$ as $n \to \infty$ in the strong operator topology does not necessarily imply that $A_n^* \to A^*$, so that we cannot conclude that $W_\pm W_\pm^* = I$. Thus in general the wave operators are not unitary. In fact, it can be shown that $\operatorname{Im} W_\pm = \mathscr{H}_{\rm ac} = (I-P)\mathscr{H}$ or, equivalently,

$$W_\pm W_\pm^* = I - P \tag{2.33}$$

where P is the orthogonal projection on the subspace $\mathscr{H}_{\rm pp}$. Though the proof of (2.33) is rather non-trivial, it is easy to show that $\operatorname{Im} W_\pm \subseteq (I-P)\mathscr{H}$. Indeed, let $\psi \in \mathscr{H}$ be a bound state - an eigenvector for H,

$$H\psi = \lambda\psi$$

Then for every $\varphi \in \mathscr{H}$ we have

$$(W_\pm\varphi,\psi) = \lim_{t\to\pm\infty} e^{i\lambda t}\left(e^{-itH_0}\varphi,\psi\right) = 0$$

by the Riemann-Lebesgue lemma, as we have seen in Section 2.3 of Chapter 2.

Assuming that wave operators exist and satisfy (2.33), it is easy to prove that

$$f(H)W_\pm = W_\pm f(H_0) \tag{2.34}$$

for any measurable function f on $\mathbb{R}$. Indeed, according to the spectral theorem, it is sufficient to prove this property for the functions $f(\lambda) = e^{i\tau\lambda}$ for all $\tau \in \mathbb{R}$. In this case, (2.34) immediately follows from the identity

$$e^{i\tau H}e^{i(t-\tau)H}e^{-i(t-\tau)H_0} = e^{itH}e^{-itH_0}e^{i\tau H_0}$$

by passing to the limits $t \to \pm\infty$. Using (2.34) and (2.32) we conclude

$$W_\pm^* H W_\pm = H_0$$

so that restrictions of the wave operators to the subspace $\mathscr{H}_{\rm ac}$ establish the unitary equivalence between $H|_{\mathscr{H}_{\rm ac}}$ and H_0.

Remark. The physical meaning of the wave operators is the following. The one-parameter group $U(t) = e^{-itH}$ of unitary operators describes the evolution of the quantum particle moving in a short-ranged potential field. For large $|t|$ the particle with positive energy moves far

away from the center and as $|t| \to \infty$ its evolution is described by the one-parameter group $U_0(t) = e^{-itH_0}$ which corresponds to the free motion. Mathematically this is expressed by the fact that for every $\varphi_- \in \mathscr{H}$ there exists a vector $\psi \in \mathscr{H}$ such that

$$\lim_{t\to-\infty} \left\| e^{-itH}\psi - e^{-itH_0}\varphi_- \right\| = 0$$

and such a vector is given by $\psi = W_-\varphi_-$. Similarly, for every $\varphi_+ \in \mathscr{H}$ the vector $\psi = W_+\varphi_+$satisfies

$$\lim_{t\to\infty} \left\| e^{-itH}\psi - e^{-itH_0}\varphi_+ \right\| = 0$$

As a physical interpretation, orthogonality of $\operatorname{Im} W_\pm$to the subspace $\mathscr{H}_{\rm pp}$ is explained by the fact that for all times t bound states are localized near the potential center, whereas the free quantum particle goes to infinity as $|t| \to \infty$.

The wave operators are used to describe the scattering of the quantum particle by the potential center. Namely, given $\varphi_- \in \mathscr{H}$, there is $\psi = W_-\varphi_- \in \mathscr{H}$ such that the solution $\psi(t) = U(t)\psi$ of the non-stationary Schrodinger equation with Hamiltonian H and initial condition $\psi(0) = \psi$ as $t \to -\infty$ approaches the solution $\varphi_-(t) = U_0(t)\varphi_-$of the non-stationary Schrodinger equation with free Hamiltonian H_0 and initial condition $\varphi_-(0) = \varphi_-$. Since $\operatorname{Im} W_- = \operatorname{Im} W_+$, there is $\varphi_+ \in \mathscr{H}$ such that $\psi = W_+\varphi_+$and
the solution $\psi(t)$ of the non-stationary Schrodinger equation with Hamiltonian H and initial condition $\psi(0) = \psi$ as $t \to \infty$ approaches the solution $\varphi_+(t) = U_0(t)\varphi_+$of the non-stationary Schrodinger equation with free Hamiltonian H_0 and initial condition $\varphi_+(0) = \varphi_+$. The passage from the solution $\varphi_-(t)$ of the free Schrodinger equation describing the motion of quantum particle at $t = -\infty$ to the solution $\varphi_+(t)$ describing its motion at $t = \infty$ is the result of scattering of the quantum particle by a potential center. All information about the scattering is contained in the scattering operator S (also called S-matrix in physics), which relates initial and final conditions $\varphi_-$and φ_+:

$$\varphi_+ = S\varphi_-$$

From (2.32) and $\psi = W_-\varphi_- = W_+\varphi_+$we immediately get that

$$S = W_+^* W_-, \tag{2.35}$$

and from (2.32)-(2.34) we obtain that the scattering operator S is a unitary operator in $\mathscr{H}$ and commutes with the free Hamiltonian H_0:

$$S^*S = SS^* = I \quad \text{and} \quad SH_0 = H_0S$$

This is the outline of a non-stationary approach to scattering theory.
In the stationary approach to scattering theory, the wave operators $W_\pm$ and the scattering operator S are constructed as integral operators in the coordinate representation with integral kernels expressed through special solutions of the stationary Schrodinger equation. Here we present this construction for the one-dimensional Schrodinger operator considered in the previous section.

Namely, let $u_1(x,k)$ and $u_2(x,k)$ be solutions of the one-dimensional Schrodinger equation (2.1) given by (2.23), where $\sqrt{\lambda} = k > 0$. It follows from Theorem 2.1 and (2.11), (2.13) that these solutions have the following asymptotics:

$$\begin{aligned} u_1(x,k) &= s_{11}(k)e^{ikx} + o(1) && \text{as} \quad x \to \infty \\ u_1(x,k) &= e^{ikx} + s_{21}(k)e^{-ikx} + o(1) && \text{as} \quad x \to -\infty \end{aligned} \tag{2.37}$$

and

$$\begin{array}{lll} u_2(x,k) = e^{-ikx} + s_{12}(k)e^{ikx} + o(1) & \text{as} & x \to \infty \\ u_2(x,k) = s_{22}(k)e^{-ikx} + o(1) & \text{as} & x \to -\infty \end{array} \tag{2.39}$$

where

$$s_{11}(k) = s_{22}(k) = \frac{1}{a(k)}, \quad s_{12}(k) = \frac{b(k)}{a(k)}, \quad s_{21}(k) = -\frac{\overline{b(k)}}{a(k)}. \tag{2.40}$$

Solutions $u_1(x,k)$ and $u_2(x,k)$ are called scattering solutions, the function $s_{11}(k)$ is called the complex transmission coefficient, and functions $s_{12}(k)$ and
$s_{21}(k)$, respectively, are called right and left complex reflection coefficients. Correspondingly, $T = |s_{11}(k)|^2$ is called the transmission coefficient and $R = |s_{12}(k)|^2 = |s_{21}(k)|^2$ - the reflection coefficient. The 2×2 matrix

$$S(k) = \begin{pmatrix} s_{11}(k) & s_{12}(k) \\ s_{21}(k) & s_{22}(k) \end{pmatrix}$$

is called the scattering matrix. It follows from (2.14) that the scattering matrix is unitary, $S^*(k)S(k) = I$, where I is the 2×2 identity matrix, and satisfies $\overline{S(k)} = S(-k)$. In particular, unitarity of the scattering matrix implies that $T + R = 1$, which is called conservation of probability.

The physical interpretation of the solutions $u_1(x,k)$ and $u_2(x,k)$ is the following. For simplicity, suppose that the potential $V(x)$ is smooth and vanishes for $|x| > A$, so that asymptotics (2.36) and (2.38) become equalities for $x > A$, and asymptotics (2.37) and (2.39) become equalities for $x < -A$. In this case elements $s_{ij}(k)$ of the scattering matrix are smooth functions for $k \neq 0$. As in Section 2.3 of Chapter 2, let $\varphi_1(k)$ and $\varphi_2(k)$ be the wave packets: smooth functions on $(0, \infty)$ supported in some neighborhood U_0 of $k_0 > 0$. The functions, called scattering waves,

$$\psi_j(x,t) = \int_0^\infty \varphi_j(k)u_j(x,k)e^{-ik^2t}dk, \quad j = 1,2$$

are solutions of the time-dependent Schrodinger equation

$$i\frac{\partial \psi}{\partial t} = H\psi$$

In the region $|x| > A$ the solution $\psi_1(x,t)$ can be simplified as follows:

$$\begin{array}{ll} \psi_1(x,t) = \int_0^\infty \varphi_1(k)s_{11}(k)e^{ikx-ik^2t}dk, & \text{when} \quad x > A \\ \psi_1(x,t) = \int_0^\infty \varphi_1(k)\left(e^{ikx-ik^2t} + s_{21}(k)e^{-ikx-ik^2t}\right)dk, & \text{when} \quad x < -A \end{array}$$

Using the method of stationary phase (see Section 2.3 in Chapter 2) we get as $t \to -\infty$,

$$\begin{array}{ll} \psi_1(x,t) = O\left(|t|^{-1}\right), & \text{when } x > A \\ \psi_1(x,t) = \frac{1}{\sqrt{|t|}}\varphi_1\left(\frac{x}{2t}\right)e^{\frac{ix}{2}x^2 + \frac{i\pi}{4}} + O\left(|t|^{-1}\right), & \text{when } x < -A \end{array}$$

and as $t \to \infty$,

$$\begin{array}{ll} \psi_1(x,t) = \frac{1}{\sqrt{t}}\varphi_1\left(\frac{x}{2t}\right)s_{11}\left(\frac{x}{2t}\right)e^{\frac{ix^2}{4t} - \frac{i\pi}{4}} + O\left(t^{-1}\right), & \text{when} \quad x > A \\ \psi_1(x,t) = \frac{1}{\sqrt{t}}\varphi_1\left(-\frac{x}{2t}\right)s_{21}\left(-\frac{x}{2t}\right)e^{\frac{ix^2}{4t} - \frac{i\pi}{4}} + O\left(t^{-1}\right), & \text{when} \quad x < -A \end{array}$$

Assuming that the neighborhood U_0 is "sufficiently small", we see as in Section 2.3 of Chapter 2 that as $t \to -\infty$ the solution $\psi_1(x,t)$ represents a plane wave with amplitude

$|\varphi_1(k_0)|$ moving from $x=-\infty$ to the right, toward the potential center, with velocity $v=2k_0$. When $t\to\infty$, the solution $\psi_1(x,t)$ is a superposition of two plane waves: the transmitted wave with amplitude $|s_{11}(k_0)|$ times the original amplitude, located to the right of the potential center and moving toward ∞ with velocity v, and the reflected wave with amplitude factor $|s_{21}(k_0)|$, located to the left of the potential center and moving toward $-\infty$ with velocity $-v$. Corresponding transmission and reflection coefficients are $T=|s_{11}(k_0)|^2$ and $R=|s_{21}(k_0)|^2$.

Analogously, we have as $t\to-\infty$,

$$\begin{aligned}\psi_2(x,t)&=\tfrac{1}{\sqrt{|t|}}\varphi_2\left(-\tfrac{x}{2t}\right)e^{\frac{ix^2}{4t}-\frac{i\pi}{4}}+O\left(|t|^{-1}\right), &&\text{when}\quad x>A\\ \psi_2(x,t)&=O\left(|t|^{-1}\right), &&\text{when}\quad x<-A\end{aligned}$$

and as $t\to\infty$,

$$\begin{aligned}\psi_2(x,t)&=\frac{1}{\sqrt{t}}\varphi_2\left(\frac{x}{2t}\right)s_{12}\left(\frac{x}{2t}\right)e^{\frac{ix^2}{4t}-\frac{i\pi}{4}}+O\left(t^{-1}\right), &&\text{when}\quad x>A\\ \psi_2(x,t)&=\frac{1}{\sqrt{t}}\varphi_2\left(-\frac{x}{2t}\right)s_{22}\left(-\frac{x}{2t}\right)e^{\frac{ix^2}{4t}-\frac{i\pi}{4}}+O\left(t^{-1}\right), &&\text{when}\quad x<-A.\end{aligned}$$

As $t\to-\infty$, the solution $\psi_2(x,t)$ is a plane wave with amplitude $|\varphi_2(k_0)|$ moving from $x=\infty$ to the left, toward the potential center, with velocity $-v$. When $t\to\infty$, the solution $\psi_2(x,t)$ is a superposition of two plane waves: the transmitted wave with the same amplitude factor $|s_{22}(k_0)|$, located to the left of the potential center and moving toward $-\infty$ with velocity $-v$, and the reflected wave with amplitude factor $|s_{12}(k_0)|$, located to the right of the potential center and moving toward ∞ with velocity v. Formulas (2.40) show that transmission and reflection coefficients for the solution $\psi_2(x,t)$ are the same as for the solution $\psi_1(x,t)$, and are independent of the direction of travel. This is the so-called reciprocity property of the transmission coefficient.

The solutions $u_1(x,k)$ and $u_2(x,k)$ of the stationary Schrodinger equation have the property that corresponding solutions $\psi_1(x,t)$ and $\psi_2(x,t)$ of the time-dependent Schrodinger equation become the plane waves as $t\to-\infty$. In accordance with this interpretation, we denote them, respectively, by $u_1^{(-)}(x,k)$ and $u_2^{(-)}(x,k)$. Solutions of the stationary Schrodinger equation, $u_1^{(+)}(x,k)=\overline{u_2(x,k)}=u_2(x,-k)$ and $u_2^{(+)}(x,k)=\overline{u_1(x,k)}=u_1(x,-k)$, admit a similar interpretation: they correspond to the solutions of the timedependent Schrodinger equation which become the plane waves as $t\to\infty$.

Introducing

$$U_+(x,k)=\begin{pmatrix}u_1^{(+)}(x,k)\\ u_2^{(+)}(x,k)\end{pmatrix}\quad\text{and}\quad U_-(x,k)=\begin{pmatrix}u_1^{(-)}(x,k)\\ u_2^{(-)}(x,k)\end{pmatrix}$$

we get by a straightforward computation using (2.11) and (2.13) that

$$U_+(x,k)=\overline{S(k)}U_-(x,k) \tag{2.41}$$

The following result establishes equivalence between stationary and nonstationary approaches to scattering theory.

Theorem 2.5. For the one-dimensional Schrodinger operator $H=H_0+V$ with potential $V(x)$ satisfying condition (2.2) the wave operators exist and are given explicitly by

$$W_\pm=\mathscr{U}_\pm^*\mathscr{U}_0$$

Here $\mathscr{U}_\pm:\mathscr{H}\to\mathfrak{H}_0$ are the integral operators given by

$$\mathscr{U}_\pm(\psi)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}\psi(x)\overline{U_\pm(x,\sqrt{\lambda})}dx$$

and $\mathscr{U}_0 : \mathscr{H} \to \mathfrak{H}_0$ establishes the unitary equivalence between the operator H_0 in $\mathscr{H}$ and the multiplication by λ operator in $\mathfrak{H}_0$,

$$\mathscr{U}_0(\psi) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \psi(x) \begin{pmatrix} e^{-i\sqrt{\lambda}x} \\ e^{i\sqrt{\lambda}x} \end{pmatrix} dx$$

The scattering operator S in $\mathscr{H}$ and the multiplication by the scattering matrix $S(\sqrt{\lambda})$ operator in $\mathfrak{H}_0$ are unitarily equivalent:

$$S = \mathscr{U}_0^* S(\sqrt{\lambda}) \mathscr{U}_0$$

Proof. The formula for the scattering operator immediately follows from the definition of the operators $\mathscr{U}_\pm$, formula (2.41), and orthogonality relation $\mathscr{U}_- \mathscr{U}_-^* = I_0$ (see Theorem 2.3). To prove that $W_\pm = \mathscr{U}_\pm^* \mathscr{U}_0$, it is sufficient to show that for all $\Phi = \binom{\varphi_1}{\varphi_2} \in \mathfrak{H}_0$, where $\varphi_1(k)$ and $\varphi_2(k)$ are smooth functions on $(0, \infty)$ with compact support,

Indeed, setting $\chi^{(\pm)}(t) = \left(e^{-itH} \mathscr{U}_\pm^* - e^{-itH_0} \mathscr{U}_0^*\right) \Phi$, we have

$$\chi^{(\pm)}(x,t) = \frac{1}{\sqrt{2\pi}} \int_0^\infty \left(\left(u_1^{(\pm)}(x,k) - e^{ikx} \right) \varphi_1(k) + \left(u_2^{(\pm)}(x,k) - e^{-ikx} \right) \varphi_2(k) \right) e^{-ik^2 t} dk$$

and it is not difficult to estimate the integral

$$\left\| \chi^{(\pm)}(t) \right\|^2 = \int_{-\infty}^{\infty} \left| \chi^{(\pm)}(x,t) \right|^2 dx \tag{2.42}$$

as $t \to \pm\infty$. Namely, it follows from the Riemann-Lebesgue lemma that for any fixed $A > 0$ the contribution to (2.42) from the interval $[-A, A]$ goes to 0 as $t \to \pm\infty$. In integrals over $-\infty \le x \le -A$ and $A \le x \le \infty$ we replace $u_{1,2}^{(\pm)}(x,k)$ by their asymptotics (2.36)-(2.39). Using estimates in Theorem 2.1, part (v), it is easy to show that for sufficiently large A the difference can be made arbitrarily small uniformly in t. To finish the proof it remains to show that for every continuous function $\varphi(k)$ on $(0, \infty)$ with compact support the integrals

$$J_1^{(\pm)}(t) = \frac{1}{2} \int_A^\infty \left| \int_0^\infty \varphi(k) e^{\mp ikx - ik^2 t} dk \right|^2 dx$$

and

$$J_2^{(\pm)}(t) = \frac{1}{2} \int_{-\infty}^A \left| \int_0^\infty \varphi(k) e^{\pm ikx - ik^2 t} dk \right|^2 dx$$

vanish as $t \to \pm\infty$. Consider, for instance, the integral $J_1^{(+)}(t)$. Given $\varepsilon > 0$, there exists a smooth function $\eta(k)$ on $(0, \infty)$ with compact support $[\alpha, \beta]$ such that

$$\|\varphi - \eta\|_{\mathscr{H}_0}^2 < \frac{\varepsilon}{4\pi}$$

We have by the Plancherel theorem,

$$J_1^{(+)}(t) = \frac{1}{2}\int_A^\infty \left|\int_0^\infty ((\varphi(k)-\eta(k))+\eta(k))e^{-ikx-ik^2t}dk\right|^2 dx$$
$$\le \int_A^\infty \left|\int_0^\infty (\varphi(k)-\eta(k))e^{-ikx-ik^2t}dk\right|^2 dx + \int_A^\infty \left|\int_0^\infty \eta(k)e^{-ikx-ik^2t}dk\right|^2 dx$$
$$\le \int_{-\infty}^\infty \left|\int_0^\infty (\varphi(k)-\eta(k))e^{-ikx-ik^2t}dk\right|^2 dx + \int_A^\infty \left|\int_0^\infty \eta(k)e^{-ikx-ik^2t}dk\right|^2 dx$$
$$\le \frac{\varepsilon}{2} + \int_A^\infty \left|\int_0^\infty \eta(k)e^{-ikx-ik^2t}dk\right|^2 dx.$$

To estimate the remaining integral we use integration by parts to obtain

$$\int_0^\infty \eta(k)e^{-i\left(kx+k^2t\right)}dk = \int_0^\infty \frac{\eta'(k)}{i(x+2kt)}e^{-i\left(kx+k^2t\right)}dk$$

and since $\frac{|\eta'(k)|}{x+2kt} \le \frac{C}{x+2\alpha t}$ for $x, t > 0$, we have

$$\int_A^\infty \left|\int_0^\infty \eta(k)e^{-i\left(kx+k^2t\right)}dk\right|^2 dx \le C^2\int_A^\infty \frac{dx}{(x+2\alpha t)^2} = \frac{C^2}{A+2\alpha t}$$

Choosing $t > \frac{2C^2}{\alpha\varepsilon}$, we obtain $J_1^{(+)}(t) < \varepsilon$. Other integrals are treated similarly.

Corollary 2.6. The wave operators satisfy orthogonality and completeness relations $W_\pm^* W_\pm = I$ and $W_\pm W_\pm^* = I - P$.

Proof. The result of Theorem 2.3, proved for the operator $\mathscr{U} = \mathscr{U}_-$, obviously holds for the operator $\mathscr{U}_+$. Thus relations (2.32) and (2.33) follow from the corresponding orthogonality and completeness relations for the operators $\mathscr{U}_\pm$.

Remark. The orthogonality relation (2.32) is trivial once the existence of the wave operators is established. Thus Theorem 2.5 gives another proof of the orthogonality relation in Theorem 2.3.

Problem 2.7 (The Cook's criterion). In abstract scattering theory, prove that the wave operators $W_\pm$exist if for all $\varphi \in \mathscr{H}$,

$$\int_0^\infty \left\|Ve^{-itH_0}\varphi\right\| dt < \infty.$$

Problem 2.8. Find the scattering matrix $S(k)$ for the potential $V(x)$ from Problem 2.5 and show that when $V_0 = 2\varkappa^2$, the scattering matrix is diagonal.

Problem 2.9 (Quantum tunneling). Find the scattering matrix $S(k)$ for the rectangular potential barrier: $V(x) = 0$ for $x < 0$ and $x > 2a$, and $V(x) = V_0 > 0$ for $0 \le x \le 2a$. Show that when E varies from 0 to V_0, T increases from 0 to $(1 + V_0a^2)^{-1}$ - the penetration of a potential barrier by a quantum particle.

2.4. Other boundary conditions.

Here we consider two examples of the Schrodinger operator

$$H = -\frac{d^2}{dx^2} + V(x)$$

with the potential $V(x)$ having different asymptotics as $x \to \pm\infty$.

Example 2.1. Suppose that the potential $V(x)$ satisfies

$$\int_{-\infty}^{0} (1+|x|)\left|V(x)-c^2\right| dx < \infty \quad \text{and} \quad \int_{0}^{\infty} (1+|x|)|V(x)|dx < \infty$$

for some $c > 0$. The Schrodinger operator H has negative discrete spectrum, consisting of finitely many simple eigenvalues $\lambda_1 < \cdots < \lambda_n < 0$, and absolutely continuous spectrum $[0, \infty)$, which is simple for $0 < \lambda < c^2$ and is of multiplicity two for $\lambda > c^2$. This qualitative structure of the spectrum is determined by the structure of the level sets $H_c(p, x) = \lambda$ of the classical Hamiltonian function $H_c(p, x) = p^2 + V(x)$: the eigenvalues could only appear for compact level sets, when the classical motion is periodic, while the values of λ with non-compact level sets, where the classical motion is
infinite, belong to the absolutely continuous spectrum. The absolutely continuous spectrum has multiplicity one or two depending on whether the corresponding classical motion is unbounded in one or in both directions, i.e., when $0 < \lambda < c^2$ or $\lambda > c^2$.

These results can be proved using methods in Section 2.1. Namely, set $\lambda = k^2$ and define the function $k_1 = \sqrt{k^2 - c^2}$ by the condition that $\operatorname{Im} k_1 \geq 0$ for $\operatorname{Im} k \geq 0$. In particular, $\operatorname{sgn} k_1 = \operatorname{sgn} k$ for k real, $|k| > c$. The differential equation

$$-y'' + V(x)y = k^2 y \tag{2.43}$$

for real k has two linear independent solutions $f_1(x, k), f_1(x, -k) = \overline{f_1(x, k)}$, where $f_1(x, k)$ has the asymptotics

$$f_1(x, k) = e^{ikx} + o(1) \quad \text{as} \quad x \to \infty.$$

For real $k, |k| > c$, equation (2.43) also has two linear independent solutions $f_2(x, k), f_2(x, -k) = \overline{f_2(x, -k)}$, where $f_2(x, k)$ has the asymptotics

$$f_2(x, k) = e^{-ik_1 x} + o(1) \quad \text{as} \quad x \to -\infty.$$

(Actually, these solutions satisfy estimates similar to that in Theorem 2.1.) As in Section 2.1, for real $k, |k| > c$, we have

$$f_2(x, k) = a(k)f_1(x, -k) + b(k)f_1(x, k),$$

where

$$a(k) = \frac{1}{2ik} W\left(f_1(x, k), f_2(x, k)\right), \quad b(k) = \frac{1}{2ik} W\left(f_2(x, k), f_1(x, -k)\right), \tag{2.44}$$

and $a(-k) = \overline{a(k)}, b(-k) = \overline{b(k)}$. However, $W\left(f_2(x, k), f_2(x, -k)\right) = -2ik_1$, so that for real $k, |k| > c$, we have

$$f_1(x, k) = \frac{k}{k_1} a(k) f_2(x, -k) - \frac{k}{k_1} b(-k) f_2(x, k).$$

From here we obtain the normalization condition

$$|a(k)|^2 - |b(k)|^2 = \frac{k_1}{k}, \quad |k| > c.$$

For fixed x solutions $f_1(x, k)$ and $f_2(x, k)$ can be analytically continued to the upper half-plane $\operatorname{Im} k > 0$. For $-c < k < c$ solution $f_2(x, k)$ is realvalued and satisfies

$$f_2(x, k) = a(k)f_1(x, -k) + \overline{a(k)f_1(x, -k)},$$

where $a(k)$ is still given by the same formula (2.44). The function $a(k)$ does not vanish for real k and admits meromorphic continuation to the upper half-plane $\operatorname{Im} k > 0$ where it has finitely many pure imaginary simple zeros $i\varkappa_1, ..., i\varkappa_n$ which correspond to the eigenvalues $\lambda_1 = -\varkappa_1^2, ..., \lambda_n = -\varkappa_n^2$.

The absolutely continuous spectrum of the Schrodinger operator H fills $[0, \infty)$. For $0 < \lambda = k^2 < c^2$ the spectrum is simple and

$$u(x, \lambda) = \frac{1}{a(k)} f_2(x, k), \quad 0 < k < c$$

are the corresponding normalized eigenfunctions of the continuous spectrum. For $\lambda = k^2 > c^2$ the spectrum has multiplicity two and

$$u_1(x, \lambda) = \frac{1}{a(k)} f_2(x, k), \quad u_2(x, k) = \frac{k_1}{ka(k)} f_1(x, k), \quad k > c$$

are the corresponding normalized eigenfunctions of the continuous spectrum. Denoting by $\psi_l(x)$ the normalized eigenfunctions of H corresponding to the eigenvalues λ_l, we get the eigenfunction expansion theorem: for $\psi \in L^2(\mathbb{R})$,

$$\psi(x) = \sum_{l=1}^{n} C_l \psi_l(x) + \int_0^c C(k) u(x, k) dk$$
$$+ \int_c^\infty \left(C_1(k) u_1(x, k) + C_2(k) u_2(x, k) \right) dk$$

where $C_l = (\psi, \psi_l), l = 1, ..., n$, and

$$C(k) = \int_{-\infty}^{\infty} \psi(x) \overline{u(x, k)} dx, \quad C_j(k) = \int_{-\infty}^{\infty} \psi(x) \overline{u_j(x, k)} dx, \quad j = 1, 2.$$

Example 2.2. Suppose that the potential $V(x)$ grows as $x \to -\infty$ and decays as $x \to \infty$:

$$\int_a^\infty (1 + |x|) |V(x)| dx < \infty \quad \text{for all} \quad a$$

and there exists $x_0 \in \mathbb{R}$ such that the spectrum of the Sturm-Liouville problem

$$-y'' + V(x) y = \lambda y, \quad -\infty < x \le x_0, \quad \text{and} \quad y'(x_0) = 0$$

is bounded below and discrete. The latter condition is a quantitative formulation of the property $\lim_{x \to -\infty} V(x) = \infty$.

Then for every real k there exists a solution $f(x, k)$ of the differential equation (2.43) with the asymptotics

$$f(x, k) = e^{ikx} + o(1) \quad \text{as} \quad x \to \infty$$

and there is a function $s(k)$ such that

$$u(x, k) = f(x, -k) + s(k) f(x, k)$$

is square integrable over $(-\infty, a)$ for any real a. The Schrodinger operator H has simple absolutely continuous spectrum $[0, \infty)$ and discrete spectrum consisting of finitely many negative eigenvalues. Functions $u(x, k)$ are normalized eigenfunctions of the continuous spectrum and the corresponding eigenfunction expansion theorem has the following form: for every $\psi \in L^2(\mathbb{R})$,

$$\psi(x) = \sum_{l=1}^{n} C_l \psi_l(x) + \int_0^\infty C(k) u(x,k) dk$$

where $C_l = (\psi, \psi_l), l = 1, ..., n$, and

$$C(k) = \int_{-\infty}^{\infty} \psi(x) \overline{u(x,k)} dx$$

Problem 2.10. Give an explicit form of the eigenfunction expansion theorem for the potential $V(x) = e^x$.

Problem 2.11. Find energy levels for the Morse potential $V(x) = e^{-2\alpha x} - 2e^{-\alpha x}$, $\alpha > 0$.

Problem 2.12. Give an explicit form of the eigenfunction expansion theorem for the potential $V(x) = Fx$, describing the motion of a quantum particle in a homogeneous field; according to Problem 1.4, the corresponding Schrodinger operator is self-adjoint. (Hint: Solve the Schrodinger equation explicitly in the momentum representation, and express normalized eigenfunctions of the continuous spectrum in the coordinate representation in terms of Airy-Fock functions, defined in Section 6.2.)

Problem 2.13. Give an explicit form of the eigenfunction expansion theorem for the potential $V(x) = -\frac{1}{2}kx^2$, where $k > 0$ (according to Problem 1.4, the corresponding Schrodinger operator is self-adjoint).

3.6.6 One-Dimensional Schrödinger Equation 3: Basic Examples

Одномерный ящик с бесконечными стенками (?)

Найдем уровни энергии в *одномерном ящике*, то в: $V(x) = \begin{cases} 0, & 0 < x < a \\ \infty, & x < 0, x > a \end{cases}$

Волновую функцию находим, решая уравнение Шредингера с граничными условиями, энергию находим с помощью k, который квантуется из вида волновой функции и граничных условий.

Уравнение Шредингера есть:

$$\psi'' + \frac{2m}{h^2}(E - U(x))\psi(x) = 0$$

Введем $k^2 = \frac{2mE}{\hbar^2}$, внутри ямы:

$$\psi'' + k^2\psi(x) = 0,$$

Общее решение $\psi(x) = c_1 e^{ikx} + c_2 e^{-ikx}$, и при граничных условиях $\psi(0) = \psi(a) = 0$ дает:

$$\psi(x) = C_1 \sin(kx), \quad ka = \pi n, \quad n \in \mathbb{N},$$
$$E_n = \frac{\hbar^2 k^2}{2m} = \frac{\hbar^2 \pi^2 n^2}{2ma^2}.$$

и в итоге учетом нормировки волновая функция имеет вид:

$$\psi_n(x) = \begin{cases} \sqrt{\frac{2}{a}} \sin \frac{\pi n}{a} x, & 0 < x < a \\ 0, & x \leqslant 0, x \geqslant a \end{cases}$$

Заметим также, что на границах имеется скачек производной.

Посмотрим на свойства наших решений. Посчитаем дисперсию:

$$\langle x\rangle = \int\limits_0^a dx\psi^2(x)x = \frac{a}{2},$$

$$\left\langle x^2\right\rangle = \int\limits_0^a dx\psi^2(x)x^2 = \frac{a^2}{3} - \frac{a^2}{2\pi^2 n^2}$$

$$(\Delta x)^2 = \frac{a^2}{12}\left(1 - \frac{6}{\pi^2 n^2}\right)$$

Для импульса:

$$(\Delta p)^2 = \left\langle p^2\right\rangle = \langle 2mE_n\rangle = \frac{\hbar^2}{a^2}\pi^2 n^2.$$

Сравним с классическим случаем, в котором распределение равномерное, то есть $\rho(x) = 1/a$:

$$\overline{x} = \int\limits_0^a x\rho(x) = \frac{a}{2}, \quad \overline{(\Delta\hat{x})^2} = \frac{a^2}{12}$$

Видим, что в квантовом случае дисперсия другая.
(???? как так??)
Теперь можно посчитать фазовый объем. Заметим, что для любого n

$$(\Delta x)^2(\Delta p)^2 = \frac{\hbar^2}{12}\left(\pi^2 n^2 - 6\right) \geqslant \frac{\hbar^2}{4},$$

поэтому ячейка фазового пространства для одного состояния имеет

$$\Delta\Gamma|_{\Delta n=1} = \frac{d\Delta\Gamma}{dn}\Delta n \to \frac{\hbar}{2\sqrt{3}}\pi.$$

(? зачем эта ячейка? потом вернусь, отвечу, если буду понимать.)
(какие еще выводы есть???)
Волновая функция частицы в импульсном представлении:

$$\psi_n(p) \equiv \langle p|n\rangle = \int\limits_0^1 \langle p|x\rangle\langle x|n\rangle dx = \int\limits_0^1 \frac{1}{\sqrt{2\pi}}e^{-ipx}\sqrt{2}\sin n\pi x dx = -i2\sqrt{\pi}\mathrm{e}^{-i\frac{(p-n\pi)}{2}}\frac{n\sin\left(\frac{p-n\pi}{2}\right)}{p^2-(n\pi)^2}.$$

В квазиклассическом приближении ($n \gg 1$) распределение по импульсам вблизи $p = \pm n\pi$ имеет вид

$$|\psi_n(p)|^2 \simeq \frac{\sin^2(\varepsilon/2)}{\pi\varepsilon^2}, \quad \int\limits_{-\infty}^{\infty}\frac{\sin^2(\varepsilon/2)}{\pi\varepsilon^2}d\varepsilon = \frac{1}{2\pi}\int\limits_{-\infty}^{\infty}\frac{\sin^2 x}{x^2}dx = \frac{1}{2},$$

где $\varepsilon = p \pm n\pi$, что соответствует классической плотности вероятности распределения по импульсам:

$$\rho(p) = \frac{1}{2}\delta\left(p - p_n\right) + \frac{1}{2}\delta\left(p + p_n\right), \quad p_n = \sqrt{2E_n} = \pi n.$$

Фазовая плоскость, как и траектория частицы на ней, - понятие классическое, поэтому рассмотрим эту часть задачи в квазиклассическом приближении: $\hbar \to 0, n \to \infty$ при конечном hn. Фазовые объёмы для состояний с энергией $E \leqslant E_n$ и $E \leqslant E_{n+1}$ имеют вид

$$\Gamma_n = 2p_n a = 2\pi hn \quad \left(p_n = \sqrt{2mE_n} = \frac{\pi\hbar}{a}n\right),$$

$$\Gamma_{n+1} = 2p_{n+1}a = 2\pi h(n+1)$$

Следовательно, объём, приходящийся на одно квантовое состояние,

$$\Delta\Gamma_n = \Gamma_{n+1} - \Gamma_n = 2\pi\hbar.$$

Мелкая яма

Обсудим подробно мелкую яму.

Описание мелкой ямы

Критерии существования основного состояния в мелкой яме

Основное состояние в мелкой яме единственное

(подробно про этот факт, и запоминаем его.)

О моделях из дельта-потенциалов

(укажу потом методы для них и их применения, пока об этом в каталоге задач.)

Особенности моделей из дельта-потенциалов (??)

О применениях (??)

(эта модель применяется дальше или все на неё забили? если да - укажу в части ниже, где и как.)

О других типичных одномерных ямах

(по идее тут заготовка к задачам овчинкина)

Если есть возможность - интегралы считаем на компьютере

Потом уже руками. Так в разы быстрее и меньше вероятности ошибок. А тут очень часто можно фигню насчитать.

Theory from Landau

Вообще говоря, до сих пор мы обсуждали стационарные задачи.

С другой стороны, с точки зрения задачи рассеяния более логичной кажется задача нестационарная, для определения которой нам необходимо:

1.

Задать начальные условия, которые соответствуют волновому пакету, находящемуся на $x \to -\infty$ при времени $\tau \to -\infty$ и имеющему конечный импульс p_0, направленный на рассеиватель.

Примером такого волнового пакета может служить следующая волновая функция:

$$\psi\left(x, -\tau_0\right) \equiv \psi_0(x) = \frac{1}{\pi^{1/4} a^{1/2}} \exp\left(-\frac{(x+L)^2}{2a^2} + ip_0 x\right)$$

В координатном представлении она представляет собой волновой пакет ширины a вокруг точки $x = -L$, а в импульсном - волновой пакет ширины $\sim 1/a$ вокруг среднего значения k_0

2. Решить нестациониое уравнение Шрёдингера, рассмотрев эволюцию этого волнового пакета.

3. Исследовать асимптотики полученного решения при $\tau \to +\infty$, которые представляли бы пару волновых пакетов отражённый, который находится на $x \to -\infty$ и имеет импульс $-p$, и прошедший, который летит на $x \to +\infty$ и имеет импульс p

4. Наконец, вычислить вероятность отражения $R = \int\limits_{\infty}^{0} |\psi(x, \tau \to +\infty)|^2 dx$ и $T = \int\limits_{0}^{\infty} |\psi(x, \tau \to +\infty)|^2 dx$ Априори утверждение о том, что эти вероятности совпадают с вероятностями, которые мы определили в стационарной задаче рассеяния, не является очевидным.

Тем не менее, это действительно так, что мы попробуем продемонстрировать ниже, для чего мы попробуем решить нестационарное уравнение Шрёдингера в общем виде. ивателя не было, то волновой пакет тоже имелся бы, но двигался бы он правее.

Явление это носит название задержки

волнового пакета - частица может на некоторое время кзастрять в рассеивателезз.

Мы ставим своей целью найти время этой задержки.

Для решения нестационарного УШ, как обычно, необходимо разложиться по базису стационарных решений (3.32), для чего мы можем воспользоваться выведенной выше нормировкой состояний непрерывного спектра [24]:

$$\hat{\mathbb{I}} = \int\limits_{0}^{\infty} \frac{dp}{2\pi} \left(\left|\psi_p^{(+)}\right\rangle \left\langle \psi_p^{(+)}\right| + \left|\psi_p^{(-)}\right\rangle \left\langle \psi_p^{(-)}\right| \right)$$

Разложимся по базису, используя асимптотики при $x \to -\infty$

$$\psi_+(p) = \left\langle \psi_p^{(+)} | \psi_0 \right\rangle = 2^{1/2}\pi^{1/4}a^{1/2} \left[\exp\left(-\frac{1}{2}(p-p_0)^2 a^2 + i(p-p_0)L \right) + \right.$$
$$\left. + \, r^* \exp\left(-\frac{1}{2}(p+p_0)^2 a^2 - i(p+p_0)L \right) \right]^0$$

Из физической интуиции понятно, что нас интересует именно первый член, ведь он возник из асимптотики падающей волны в задаче рассеяния.

Математически же это соответствует тому, что интегрируем мы по импульсам $p > 0$, а p_0 -большой положительный импульс, поэтому второй вклад оказывается экспоненциально малым.

Ровно по этой же причине, коэффициенты разложения по $\left|\psi_p^{(-)}\right\rangle$, как и следует из нашей физической интуиции (ведь это - решение задачи рассеяния ксправа-налевож!) тоже будут экспоненциально малы и нас интересовать не будут.

Дальше мы должны решать нестационарное уравнение Шрёдингера.

Поскольку $\left|\psi_p^{(+)}\right\rangle$ эволюционируют тривиальным образом, накручивая фазу $e^{-i\varepsilon_p\tau}$, то $\psi_+(p,t) = e^{-i\varepsilon_p\tau}\psi_+(p)$. Наконец, мы должны сделать кобратное преобразование Фурье и записать:

$$\psi(x,\tau) = \int \frac{dp}{2\pi} \psi_+(p,\tau) \cdot \psi_p^{(+)}(x) =$$
$$= 2^{1/2}\pi^{1/4}a^{1/2} \int \frac{dp}{2\pi} \psi_p^{(+)}(x) \exp\left(-\frac{1}{2}(p-p_0)^2 a^2 + i(p-p_0)L \right) e^{-i\varepsilon_p(\tau+\tau_0)}$$

Мы не знаем явный вид функции $\psi_p^{(+)}(x)$, но знаем асимптотики при $x \to \pm\infty$, поэтому давайте посмотрим на асимптотики $\psi(x,\tau)$ при $x \to \pm\infty$. При этом интеграл имеет пик

вблизи $p = p_0$, поэтому все величины мы разложим вблизи этой точки и возьмём интеграл методом перевала.

При этом учтём, что амплитуды прохождения, вообще говоря, тоже зависят от импульсов, и их тоже стоит раскладывать: $t \equiv t(p) = \sqrt{T(p)}e^{i\theta_p}$. Именно из-за зависимости фазы от импульса и произойдёт в конечном итоге эффект задержки.

Итак, раскладываем ε_p и θ_p до второго порядка и берем Гауссов интеграл:

Мы не знаем явный вид функции $\psi_p^{(+)}(x)$, но знаем асимптотики при $x \to \pm\infty$, поэтому давайте посмотрим на асимптотики $\psi(x,\tau)$ при $x \to \pm\infty$. При этом интеграл имеет пик вблизи $p = p_0$, поэтому все величины мы разложим вблизи этой точки и возьмём интеграл методом перевала.

При этом учтём, что амплитуды прохождения, вообще говоря, тоже зависят от импульсов, и их тоже стоит раскладывать: $t \equiv t(p) = \sqrt{T(p)}e^{i\theta_p}$. Именно из-за зависимости фазы от импульса и произойдёт в конечном итоге эффект задержки.

Итак, раскладываем ε_p и θ_p до второго порядка и берем Гауссов интеграл:

$$\psi(x \to +\infty, \tau) \approx 2^{1/2}\pi^{1/4}a^{1/2}\int \frac{dp}{2\pi}\sqrt{T(k)}\exp\left(i\left[\theta_{p_0} + \theta'_{p_0}(p-p_0) + \frac{1}{2}\theta''_{p_0}(p-p_0)^2\right]\right)\cdot e^{ipx}$$
$$\cdot\exp\left(-\frac{1}{2}(p-p_0)^2 a^2 + i(p-p_0)L\right)\cdot\exp\left(-i\left[\varepsilon_{p_0} + \varepsilon'_{p_0}(p-p_0) + \frac{1}{2}\varepsilon''_{p_0}(p-p_0)^2\right](\tau+\tau_0)\right) =$$
$$= \frac{a^{1/2}}{\pi^{1/4}\widetilde{a}(t)}\sqrt{T(p_0)}\exp\left[-\frac{[(x+L)+\theta'(p_0)-\varepsilon'(p_0)(\tau+\tau_0)]^2}{2\widetilde{a}^2(t)} + i\cdot\text{ phase }\right]$$

где $\widetilde{a}^2(t) = a^2 - i\theta''(p_0) + i\varepsilon''(p_0)(\tau+\tau_0)$. Исследуем теперь полученное выражение:

1.

Это - гауссов волновой пакет, центр которого расположен при $x_0(\tau) = -L - \theta'(p_0) + \varepsilon'(p_0)(\tau+\tau_0) = -L + \varepsilon'(p_0)(\tau + \tau_0 - \theta'/\varepsilon')$.

Это соответствует пакету, который движется с групповой скоростью $v = \partial\varepsilon/\partial p = p/m$. Однако выражение это устроено так, будто он стартовал из точки $-L$ не в момент времени $\tau = -\tau_0$ (как было бы со свободным движением), а чуть позже, в момент времени $\tau = -\tau_0 + \theta'/\varepsilon'$. Это и есть явление задержки волнового пакета; время же задержки равно $|\Delta\tau = \theta'/\varepsilon' = \partial\theta/\partial\varepsilon$. Тут сразу же возникает важнейшее свойство фазы – ведь в силу причинности, $\Delta\tau > 0$ (частица не может прилететь к детектору раньше, чем если бы она летела баллистически!) а значит, фаза рассеяния является монотонной функцией энергии.

2.

Ширина этого пакета определяется из условия $\frac{1}{a^2(t)} = \mathrm{Re}\,\frac{1}{\widetilde{a}^2(t)} \to a^2(t) = a^2 + \frac{[\varepsilon''(p_0)(\tau+\tau_0)-\theta''(p_0)]^2}{a^2}$.

Этот эффект называется расплыванием волнового пакетаж, и связан он с наличием у спектра кривизны $^{25}\varepsilon''(p_0)$; из-за соотношения неопределённостей, в пакет всегда будут входить частицы со слегка разными импульсами, а значит - и с разными скоростями.

Поэтому со временем ширина пакета будет меняться.

3. Наконец, полное число частиц в этом пакете равно $\int\limits_{-\infty}^{\infty}|\psi(x \to +\infty, \tau)|^2 dx = T(p_0)$ - что и завершает связь стационарной и нестационарной задачи рассеяния.

Исследование асимптотики $\psi(x \to -\infty, \tau)$ проходит абсолютно аналогично -вклад при этом будет приходить от котражённой волныж re^{-ipx}, а вклад от кпадающей e^{ipx} будет экспоненциально маленьким.

3.6.7 Schrodinger Equation in a Rotated Frame

(read articles about it, I don't know yet)

3.6.8 Experimental Confirmation of Schrodinger Equation

(I'll collect some experiments here)

Догадка про УШ из эксперимента

как?

3.6.9 3. Angular momentum and SO(3)

3.1. Angular momentum operators.

In Chapter 1 (see Example 1.10 in Section 1.4) for a classical particle in $\mathbb{R}^3$ we introduced the angular momentum vector $\boldsymbol{M}_{\mathrm{c}} = \boldsymbol{x} \times \boldsymbol{p}$ with components

$$M_{\mathrm{c}1} = x_2p_3 - x_3p_2, \quad M_{\mathrm{c}2} = x_3p_1 - x_1p_3, \quad M_{\mathrm{c}3} = x_1p_2 - x_2p_1$$

According to Example 2.1 in Section 2.6 of Chapter 1, they have the following Poisson brackets with respect to the canonical Poisson structure on $T^*\mathbb{R}^3$:

(3.1) $\{M_{\mathrm{c}1}, M_{\mathrm{c}2}\} = -M_{\mathrm{c}3}, \quad \{M_{\mathrm{c}2}, M_{\mathrm{c}3}\} = -M_{\mathrm{c}1}, \quad \{M_{\mathrm{c}3}, M_{\mathrm{c}1}\} = -M_{\mathrm{c}2}.$

The square of the angular momentum $\boldsymbol{M}_{\mathrm{c}}^2 = M_{\mathrm{c}1}^2 + M_{\mathrm{c}2}^2 + M_{\mathrm{c}3}^2$ satisfies

$$\left\{\boldsymbol{M}_{\mathrm{c}}^2, M_{\mathrm{c}1}\right\} = \left\{\boldsymbol{M}_{\mathrm{c}}^2, M_{\mathrm{c}2}\right\} = \left\{\boldsymbol{M}_{\mathrm{c}}^2, M_{\mathrm{c}3}\right\} = 0$$

If the Hamiltonian function

$$H_{\mathrm{c}}(\boldsymbol{p}, \boldsymbol{x}) = \frac{\boldsymbol{p}^2}{2m} + V(\boldsymbol{x})$$

is invariant under rotations, $V(\boldsymbol{x}) = V(|\boldsymbol{x}|)$, then components of the angular momentum are the integrals of motion

$$\{H_{\mathrm{c}}, M_{\mathrm{c}1}\} = \{H_{\mathrm{c}}, M_{\mathrm{c}2}\} = \{H_{\mathrm{c}}, M_{\mathrm{c}3}\} = 0 \quad \text{and} \quad \left\{H_{\mathrm{c}}, M_{\mathrm{c}}^2\right\} = 0$$

This can also be verified directly using Poisson brackets

$$\{M_{\mathrm{c}j}, p_k\} = -\varepsilon_{jkl}p_l \quad \text{and} \quad \{M_{\mathrm{c}j}, x_k\} = -\varepsilon_{jkl}x_l, \quad i, j, k = 1, 2, 3 \tag{3.2}$$

where ε_{jkl} is a totally anti-symmetric tensor, $\varepsilon_{123} = 1$.

Correspondingly, in quantum mechanics the components of the angular momentum operator $\boldsymbol{M} = \boldsymbol{Q} \times \boldsymbol{P}$ are defined by

$$M_1 = Q_2P_3 - Q_3P_2, \quad M_2 = Q_3P_1 - Q_1P_3, \quad M_3 = Q_2P_3 - Q_3P_2$$

where $\boldsymbol{Q} = (Q_1, Q_2, Q_3)$ and $\boldsymbol{P} = (P_1, P_2, P_3)$ are, respectively, coordinate and momentum operators. Since operators Q_i and P_k commute for $i \neq k$, there is no ordering problem when defining quantum angular momentum operators. It follows from Heisenberg commutation relations that their quantum brackets are the same as the corresponding Poisson brackets (3.1):

$$\{M_1, M_2\}_\hbar = -M_3, \quad \{M_2, M_3\}_\hbar = -M_1, \quad \{M_3, M_1\}_\hbar = -M_2 \tag{3.3}$$

Equivalently,

$$[M_1, M_2] = i\hbar M_3, \quad [M_2, M_3] = i\hbar M_1, \quad [M_3, M_1] = i\hbar M_2 \tag{3.4}$$

The operator of the square of the total angular momentum $\boldsymbol{M}^2 = M_1^2 + M_2^2 + M_3^2$ satisfies

$$\left[\boldsymbol{M}^2, M_1\right] = \left[\boldsymbol{M}^2, M_2\right] = \left[\boldsymbol{M}^2, M_3\right] = 0$$

Correspondingly, for the Hamiltonian operator

$$H = \frac{\boldsymbol{P}^2}{2m} + V(\boldsymbol{Q})$$

with spherically symmetric potential $V(\boldsymbol{x}) = V(|\boldsymbol{x}|)$ operators M_1, M_2, M_3 and, therefore, $\boldsymbol{M}^2$, are quantum integrals of motion:

$$[H, M_1] = [H, M_2] = [H, M_3] = 0 \quad \text{and} \quad \left[H, M^2\right] = 0$$

This can be verified directly by using quantum brackets

$$\{M_j, P_k\}_\hbar = -\varepsilon_{jkl} P_l, \quad \{M_j, Q_k\}_\hbar = -\varepsilon_{jkl} Q_l, \quad j,k,l = 1,2,3 \tag{3.5}$$

which are the same as Poisson brackets (3.2), and follow from Heisenberg commutation relations.

In the coordinate representation $\mathscr{H} = L^2\left(\mathbb{R}^3, d^3\boldsymbol{x}\right)$ the operators of angular momentum are given by the following first order self-adjoint differential operators:

$$M_1 = i\hbar\left(x_3\frac{\partial}{\partial x_2} - x_2\frac{\partial}{\partial x_3}\right) \tag{3.6}$$

$$M_2 = i\hbar\left(x_1\frac{\partial}{\partial x_3} - x_3\frac{\partial}{\partial x_1}\right) \tag{3.7}$$

$$M_3 = i\hbar\left(x_2\frac{\partial}{\partial x_1} - x_1\frac{\partial}{\partial x_2}\right) \tag{3.8}$$

They have the property that

$$M_1\psi = M_2\psi = M_3\psi = 0$$

for any spherically symmetric smooth function $\psi(\boldsymbol{x}) = \psi(|\boldsymbol{x}|)$. In other words, angular momentum operators act only on the angle coordinates in $\mathbb{R}^3$. Namely, let

$$x_1 = r\sin\vartheta\cos\varphi, \quad x_2 = r\sin\vartheta\sin\varphi, \quad x_3 = r\cos\vartheta,$$

where $0 \le \vartheta < \pi, 0 \le \varphi < 2\pi$, be the spherical coordinates in $\mathbb{R}^3$. Explicit computation gives

$$M_1 = i\hbar\left(\sin\varphi\frac{\partial}{\partial\vartheta} + \cot\vartheta\cos\varphi\frac{\partial}{\partial\varphi}\right)$$

$$M_2 = -i\hbar\left(\cos\varphi\frac{\partial}{\partial\vartheta} - \cot\vartheta\sin\varphi\frac{\partial}{\partial\varphi}\right)$$

$$M_3 = -i\hbar\frac{\partial}{\partial\varphi}$$

Thus

$$\boldsymbol{M}^2 = -\hbar^2\left(\frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\left(\sin\vartheta\frac{\partial}{\partial\vartheta}\right) + \frac{1}{\sin^2\vartheta}\frac{\partial^2}{\partial\varphi^2}\right),$$

so that the operator $-\frac{1}{\hbar^2}\boldsymbol{M}^2$ is the spherical part of the Laplace operator in $\mathbb{R}^3$,

$$\Delta = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) - \frac{1}{\hbar^2 r^2}\boldsymbol{M}^2 \tag{3.9}$$

3.2. Representation theory of SO(3). Quantum operators of angular momentum are related with the representation theory of the rotation group SO(3) - the group of 3×3 orthogonal matrices with determinant 1.SO(3) is a compact Lie group, isomorphic to the real projective space $\mathbb{RP}^3$ as a smooth manifold. There is a Lie group isomorphism $\mathrm{SO}(3)\simeq \mathrm{SU}(2)/\{\pm I\}$, where SU(2) is a Lie group of 2×2 unitary matrices with determinant 1 .

The Lie algebra $\mathfrak{so}(3)$ of SO(3) is a three-dimensional Lie algebra of 3×3 skew-symmetric matrices, with the basis

$$X_1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, \quad X_2 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, \quad X_3 = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

The matrices X_1, X_2, X_3 correspond, respectively, to the one-parameter subgroups of SO(3) consisting of rotations about coordinate axes in $\mathbb{R}^3$. They satisfy commutation relations

$$[X_1, X_2] = X_3, \quad [X_2, X_3] = X_1, \quad [X_3, X_1] = X_2$$

which are similar to (3.4). To establish the connection between quantum angular momentum operators and representation theory of SO(3), consider the regular representation R of SO(3) in $\mathscr{H} = L^2(\mathbb{R}^3, d^3\boldsymbol{x})$, defined by

$$(R(g)\psi)(\boldsymbol{x}) = \psi\left(g^{-1}\boldsymbol{x}\right), \quad g\in \mathrm{SO}(3), \psi\in\mathscr{H}$$

Lemma 3.1. We have

$$R\left(e^{u_1X_1+u_2X_2+u_3X_3}\right) = e^{-\frac{i}{\hbar}(u_1M_1+u_2M_2+u_3M_3)}.$$

Proof. Put $\boldsymbol{uX} = u_1X_1+u_2X_2+u_3X_3$ and $\boldsymbol{uM} = u_1M_1+u_2M_2+u_3M_3$. It follows from the Stone theorem and direct computation that

$$i\hbar\frac{\partial}{\partial u_j}\bigg|_{\boldsymbol{u}=0} R\left(e^{\boldsymbol{uX}}\right) = M_j, \quad j=1,2,3$$

where self-adjoint operators M_1, M_2, M_3 are given by (3.6)-(3.8). Next, for fixed u_1, u_2, u_3, consider the following one-parameter group $U(t) = R\left(e^{t\boldsymbol{uX}}\right)$ of unitary operators in $\mathscr{H}$. By the Stone theorem, $U(t) = e^{-itA}$, where

$$A = i\frac{d}{dt}\bigg|_{t=0} U(t) = \frac{1}{\hbar}\boldsymbol{uM}$$

Remark. We have $M_j = i\hbar\rho(X_j)$, where $\rho = dR$ is the corresponding regular representation of the Lie algebra $\mathfrak{so}(3)$ in $\mathscr{H}$.

All irreducible unitary representations R_l of the Lie group SO(3) are finite-dimensional and are parametrized by non-negative integers $l\geq 0$. The corresponding irreducible representation $\rho_l = dR_l$ of the Lie algebra $\mathfrak{so}(3)$ in $2l+1$-dimensional complex vector space V_l can be explicitly described as follows. Introduce Hermitian operators $T_j = i\rho_l(X_j), j=1,2,3$, which satisfy commutation relations

$$[T_1, T_2] = iT_3, \quad [T_3, T_1] = iT_2, \quad [T_2, T_3] = iT_1$$

The vector space V_l has an orthonormal basis $\{e_{lm}\}_{m=-l}^{m=l}$ such that

$$(T_1 - iT_2)\, e_{lm} = -\sqrt{(l+m)(l-m+1)}e_{lm-1}, \tag{3.10}$$

$$(T_1 + iT_2)\, e_{lm} = -\sqrt{(l-m)(l+m+1)}e_{lm+1}, \tag{3.11}$$

$$T_3 e_{lm} = m e_{lm} \tag{3.12}$$

In particular, $(T_1 + iT_2)\, e_{ll} = 0$, so that V_l is the highest weight module. The representation ρ_l is irreducible, and we have by Schur's lemma

$$\boldsymbol{T}^2 = l(l+1)I_l,$$

where I_l is the identity operator in V_l. This can also be verified directly by using (3.10)-(3.12).

Remark. When l is a half-integer, i.e., $l \in \frac{1}{2} + \mathbb{Z}_{\geq 0}$, and $m = -l, -l+1, ..., l-1, l$, formulas (3.10)-(3.12) still define an irreducible highest weight representation ρ_l of the Lie algebra $\mathfrak{so}(3)$ of dimension $2l+1$, and every irreducible n-dimensional representation of $\mathfrak{so}(3)$ is isomorphic to the representation ρ_l with $l = \frac{n-1}{2}$. For half-integer l, representations ρ_l are not integrable: they give rise to two-valued representations of SO(3), the socalled spinor representations. However, considered as representations of the Lie algebra $\mathfrak{su}(2) \simeq \mathfrak{so}(3)$, ρ_l correspond to the irreducible unitary representations of the Lie group SU(2). It follows from the representation theory of SU(2) that for $l, l' \in \frac{1}{2}\mathbb{Z}_{\geq 0}$,

$$V_l \otimes V_{l'} = \bigoplus_{j=|l-l'|}^{l+l'} V_j, \tag{3.13}$$

the so-called Clebsch-Gordan decomposition. In physics, it corresponds to the addition of angular momenta.

The regular representation R of SO(3) in $\mathscr{H} = L^2(\mathbb{R}^3, d^3\boldsymbol{x})$ is not irreducible. We have

$$\mathscr{H} = L^2\left(S^2, d\boldsymbol{n}\right) \otimes L^2\left(\mathbb{R}_{>0}, r^2 dr\right), \tag{3.14}$$

where $d\boldsymbol{n}$ is the measure on S^2 induced by the Lebesgue measure on $\mathbb{R}^3$. The group SO(3) acts by rotations in the first factor of the tensor product (3.14), whereas in the second factor it acts as the identity operator. Thus the problem of decomposing the regular representation R reduces to finding SO(3) invariant subspaces of the Hilbert space $L^2(S^2, d\boldsymbol{n})$. The result is the orthogonal sum decomposition

$$L^2\left(S^2, d\boldsymbol{n}\right) = \bigoplus_{l=0}^{\infty} \mathscr{D}_l, \tag{3.15}$$

where $\mathscr{D}_l \simeq V_l$. Under this isomorphism, the orthonormal basis Y_{lm} in $\mathscr{D}_l$ which corresponds to the basis e_{lm} in V_l is given by the normalized spherical functions

$$Y_{lm}(\vartheta, \varphi) = \frac{1}{\sqrt{2\pi}} e^{im\varphi} P_l^m(\cos\vartheta), \quad m = -l, ..., l$$

where $P_l^m(x)$ are normalized associated Legendre polynomials,
$P_l^m(x) = (-1)^m \sqrt{\frac{(l+m)!}{(l-m)!}} \sqrt{\frac{2l+1}{2}} \frac{1}{2^l l!} (1-x^2)^{-\frac{m}{2}} \frac{d^{l-m}}{dx^{l-m}} (x^2-1)^l, \quad |x| < 1.$
The self-adjoint operator $\boldsymbol{M}^2$ in the Hilbert space $L^2(S^2, d\boldsymbol{n})$ has pure point spectrum consisting of eigenvalues $\hbar^2 l(l+1)$ of multiplicities $2l+1$, $l = 0, 1, 2, ...$, and the decomposition (3.15) gives its eigenfunction expansion: for every $\psi \in L^2(S^2, d\boldsymbol{n})$,
$\psi = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} C_{lm} Y_{lm}$, where $C_{lm} = \int_0^{2\pi} \int_0^{\pi} \psi(\vartheta, \varphi) \overline{Y_{lm}(\vartheta, \varphi)} \sin\vartheta d\vartheta d\varphi$.

Problem 3.

1. Prove all results in this section. (Hint: See the list of references to this chapter.)

3.6.10 4. Two-body problem

(???? are there are really answer here about two-body problem in QM?)

4.1. Separation of the center of mass.

Consider the Schrodinger operator for the two-body problem (see Example 2.2 in Section 2.4 in Chapter 2)

$$H = -\frac{\hbar^2}{2m_1}\Delta_1 - \frac{\hbar^2}{2m_2}\Delta_2 + V(\boldsymbol{x}_1 - \boldsymbol{x}_2)$$

Introducing

$$\boldsymbol{X} = \frac{m_1\boldsymbol{x}_1 + m_2\boldsymbol{x}_2}{m_1 + m_2} \quad \text{and} \quad \boldsymbol{x} = \boldsymbol{x}_1 - \boldsymbol{x}_2$$

the coordinate of the center of mass and the relative coordinate, we get

$$H = -\frac{\hbar^2}{2M}\Delta_{\boldsymbol{X}} - \frac{\hbar^2}{2\mu}\Delta_{\boldsymbol{x}} + V(\boldsymbol{x})$$

where $M = m_1 + m_2$ is the total mass and $\mu = \frac{m_1 m_2}{m_1 + m_2}$ is the reduced mass. The Hamiltonian operator H can be diagonalized by the method of separation of variables. Namely, consider the following decomposition of the two-body Hilbert space $\mathscr{H} = L^2(\mathbb{R}^6)$ into the tensor product of Hilbert spaces:

$$\mathscr{H} = L^2\left(\mathbb{R}^3, d^3\boldsymbol{X}\right) \otimes L^2\left(\mathbb{R}^3, d^3\boldsymbol{x}\right) \tag{4.1}$$

The operator

$$H_{\boldsymbol{X}} = -\frac{\hbar^2}{2M}\Delta_{\boldsymbol{X}} \tag{4.2}$$

acts as the identity operator in the second factor of (4.1), and the operator

$$H_{\boldsymbol{x}} = -\frac{\hbar^2}{2\mu}\Delta_{\boldsymbol{x}} + V(\boldsymbol{x}) \tag{4.3}$$

acts as the identity operator in the first factor of (4.1). For the solutions of the eigenvalue problem

$$H\psi = E\psi \tag{4.4}$$

in the product form

$$\psi(\boldsymbol{X}, \boldsymbol{x}) = \Psi(\boldsymbol{X})\psi(\boldsymbol{x}),$$

the variables are separated:

$$H_{\boldsymbol{X}}\Psi(\boldsymbol{X}) = E_1\Psi(\boldsymbol{X}) \quad \text{and} \quad H_{\boldsymbol{x}}\psi(\boldsymbol{x}) = E_2\psi(\boldsymbol{x}),$$

where $E = E_1 + E_2$. Since

$$\Psi(\boldsymbol{X}) = \left(\frac{1}{2\pi\hbar}\right)^{\frac{3}{2}} e^{\frac{i}{\hbar}\boldsymbol{kX}}, \quad \boldsymbol{k}^2 = 2ME_{\mathbf{1}}$$

the quantum two-body problem reduces to the problem of a quantum particle moving in the potential field, and is described by the Hamiltonian operator (4.3) in the Hilbert space $L^2(\mathbb{R}^3, d^3\boldsymbol{x})$.

4.2. Three-dimensional scattering theory.

Here we outline the scattering theory for the Schrodinger operator $H = -\Delta + V(\boldsymbol{x})$ (where we put $\hbar = 1$ and $\mu = \frac{1}{2}$) with rapidly decreasing potential. Specifically, assume that the bounded, real-valued function $V(\boldsymbol{x})$ on $\mathbb{R}^3$ satisfies

$$V(\boldsymbol{x}) = O\left(|\boldsymbol{x}|^{-3-\varepsilon}\right) \quad \text{as} \quad |\boldsymbol{x}| \to \infty \tag{4.5}$$

for some $\varepsilon > 0$. Then for every $k \in \mathbb{R}^3$ the Schrodinger equation

$$-\Delta\psi(\boldsymbol{x}) + V(\boldsymbol{x})\psi(\boldsymbol{x}) = k^2\psi(\boldsymbol{x}), \quad k = |\boldsymbol{k}|, \tag{4.6}$$

has two solutions $u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})$ satisfying the following asymptotics as $|\boldsymbol{x}| \to \infty$:

$$u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k}) = e^{i\boldsymbol{kx}} + f^{(\pm)}(k, \boldsymbol{\omega}, \boldsymbol{n})\frac{e^{\pm ikr}}{r} + o\left(\frac{1}{r}\right) \tag{4.7}$$

where $\boldsymbol{k} = k\boldsymbol{\omega}, \boldsymbol{x} = r\boldsymbol{n}$. Asymptotics (4.7) are called Sommerfeld's radiation conditions. To prove the existence of solutions $u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})$, one should consider the following integral equations:

$$u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k}) = c^{i\boldsymbol{kx}} + \int_{\mathbb{R}^3} G^{(\pm)}(\boldsymbol{x} - \boldsymbol{y}, k)V(\boldsymbol{y})u^{(\pm)}(\boldsymbol{y}, \boldsymbol{k})d^3\boldsymbol{y} \tag{4.8}$$

where

$$G^{(\pm)}(\boldsymbol{x}, k) = -\frac{1}{4\pi}\frac{e^{\pm ikr}}{r}.$$

Integral equations (4.8) are equivalent to the Schrodinger equation (4.6) with Sommerfeld's radiation conditions (4.7), and are called Lippman-Schwinger equations. Their analysis uses Fredholm theory and Kato's Theorem 1.8.

Solutions $u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})$ are called stationary scattering waves. They are analogous to the solutions $u_j^{(\pm)}(x, k)$ for the one-dimensional case, where the vector $\boldsymbol{\omega} \in S^2$ replaces the index $j = 1, 2$. The absolutely continuous spectrum of H fills $[0, \infty)$ and has a uniform infinite multiplicity, parametrized by the two-dimensional sphere S^2. Solutions $u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})$ are normalized eigenfunctions of the continuous spectrum. In general, the operator H has finitely many negative eigenvalues $\lambda_l < 0$ of finite multiplicities $m_l, l = 1, ..., n$.

In terms of the operators $\mathscr{U}_\pm : \mathscr{H} \to \mathscr{H}$ given by

$$\mathscr{U}_\pm(\psi)(\boldsymbol{k}) = (2\pi)^{-\frac{3}{2}} \int_{\mathbb{R}^3} \psi(\boldsymbol{x})u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})d^3\boldsymbol{x}$$

completeness and orthogonality relations take the form

$$\mathscr{U}_\pm^*\mathscr{U}_\pm = I - P, \quad \mathscr{U}_\pm\mathscr{U}_\pm^* = I,$$

where P is the orthogonal projection on the invariant subspace for the operator H associated with the pure point spectrum. Now let

$$W_\pm = \mathscr{U}_\pm^* \mathscr{U}_0,$$

where $\mathscr{U}_0 = \mathscr{F}^{-1}$ is the inverse Fourier transform. As in Section 2.3, one can prove the following result.

Theorem 4.1. The operators $W_\pm$are wave operators for the Schrodinger operator H. The corresponding scattering operator $S = W_+^* W_-$has the form

$$S = \mathscr{F} \hat{S} \mathscr{F}^{-1}$$

where $\hat{S}$ is the integral operator,

$$(\hat{S}\psi)(k, \boldsymbol{\omega}) = \psi(k, \boldsymbol{\omega}) + \frac{ik}{2\pi} \int_{S^2} f\left(k, \boldsymbol{\omega}, \omega'\right) \psi\left(k, \boldsymbol{\omega}'\right) d\boldsymbol{\omega}'$$

and $f\left(k, \boldsymbol{\omega}, \boldsymbol{\omega}'\right) = f^{(+)}\left(k, \boldsymbol{\omega}, \boldsymbol{\omega}'\right)$.
The function $f\left(k, \boldsymbol{\omega}, \boldsymbol{\omega}'\right)$ is called the scattering amplitude.
Problem 4.1. Prove that if

$$\sup_{\boldsymbol{x} \in \mathbb{R}^3} \int_{\mathbb{R}^3} |V(\boldsymbol{y})| \frac{1}{|\boldsymbol{x} - \boldsymbol{y}|} d^3\boldsymbol{y} < 4\pi$$

then the Lippman-Schwinger integral equations can be solved by Neumann series and for fixed $\boldsymbol{x}$ and $\boldsymbol{\omega}$ solutions $u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k}), \boldsymbol{k} = k\boldsymbol{\omega}$, admit analytic continuation to
the upper half-plane $\operatorname{Im} k > 0$. Show also that in this case the Schrodinger operator H has no eigenvalues.

Problem 4.2 (Born's approximation). Show that $u^{(+)}(\boldsymbol{x}, \boldsymbol{k}) = e^{i\boldsymbol{k}\boldsymbol{x}} + o(1)$ as $k \to \infty$, and deduce from this that

$$f(k, \boldsymbol{n}, \boldsymbol{\omega}) + \frac{1}{4\pi} \int_{\mathbb{R}^3} e^{ik(\boldsymbol{n}-\boldsymbol{\omega})\boldsymbol{x}} V(\boldsymbol{x}) d^3\boldsymbol{x} = o(1) \quad \text{as} \quad k \to \infty$$

uniformly on $\boldsymbol{n}, \boldsymbol{\omega} \in S^2$.
Problem 4.3. Prove unitarity of the operator $\hat{S}$ using Schrodinger equation (4.6), radiation conditions (4.7), and the Green's formula.

Problem 4.4 (The optical theorem). Show that

$$\int_{S^2} |f(k, \boldsymbol{n}, \boldsymbol{\omega})|^2 d\boldsymbol{n} = \frac{4\pi}{k} \operatorname{Im} f(k, \boldsymbol{\omega}, \boldsymbol{\omega}).$$

(Here the left-hand side is the total cross-section in direction $\boldsymbol{\omega}$ at the energy $E = k^2$.)

Problem 4.5. Let $\lambda_l = -\varkappa_l^2 < 0$ be the eigenvalues of H with multiplicities m_l, $l = 1, ..., n$. Prove that for fixed $\boldsymbol{x}$ and $\boldsymbol{\omega}$ solutions $u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})$ admit a meromorphic continuation to the upper half-plane $\operatorname{Im} k > 0$ with poles of orders m_l at $i\varkappa_l$, $l = 1, ..., n$.

Problem 4.6. Prove that the wave operators $W_\pm$exist using the non-stationary approach. (Hint: Show that when $V(\boldsymbol{x})$ satisfies (4.5), Cook's criterion, formulated in Problem 2.7, is applicable.)

4.3. Particle in a central potential.

The eigenvalue problem for the Schrodinger operator

$$H = -\frac{\hbar^2}{2\mu} \Delta + V(\boldsymbol{x})$$

simplifies, when H commutes with the SO(3)-action in $\mathscr{H} = L^2(\mathbb{R}^3, d^3\boldsymbol{x})$:

$$[H, T(g)] = 0 \quad \text{for all} \quad g \in \mathrm{SO}(3)$$

This reduces to the conditions

$$[H, M_i] = 0, \quad i = 1, 2, 3, \tag{4.9}$$

and is equivalent to the property that the potential V is spherically symmetric, $V(\boldsymbol{x}) = V(r), r = |\boldsymbol{x}|$. In particular

$$[H, M_3] = \left[H, M^2\right] = 0$$

where $M^2 = M_1^2 + M_2^2 + M_3^2$, and operators M_3 and M^2 are commuting quantum integrals of motion for the Hamiltonian H. As follows from results in Section 3.2, one can look for the solutions of the eigenvalue problem

$$H\psi = E\psi$$

satisfying

$$M_3\psi = m\psi \quad \text{and} \quad M^2\psi = \hbar^2 l(l+1)\psi, \quad m = -l, ..., l.$$

Using (3.9), we get

$$H = -\frac{\hbar^2}{2\mu r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) + \frac{\boldsymbol{M}^2}{\mu r^2} + V(r)$$

so that in accordance with the decompositions (3.14) and (3.15), we look for the solutions in the form

$$\psi(\boldsymbol{x}) = R_l(r)Y_{lm}(\boldsymbol{n}), \quad \boldsymbol{x} = r\boldsymbol{n}$$

where Y_{lm} are normalized spherical functions. Separating the variables, one gets the following ordinary differential equation for the function $R_l(r)$:

$$\frac{\hbar^2}{2\mu r^2}\frac{d}{dr}\left(r^2\frac{dR_l}{dr}\right) + \frac{\hbar^2 l(l+1)}{\mu r^2}R_l + V(r)R_l = ER_l.$$

Introducing

$$f_l(r) = rR_l(r)$$

we obtain the so-called radial Schrodinger equation

$$-\frac{\hbar^2}{2\mu}\frac{d^2 f_l}{dr^2} + \frac{\hbar^2 l(l+1)}{2\mu r^2}f_l + V(r)f_l = Ef_l \tag{4.10}$$

Since for the continuous potential $V(\boldsymbol{x})$ the solution $\psi(\boldsymbol{x})$ is also continuous, equation (4.10) should be supplemented by the boundary condition $f_l(0) = 0$.

The radial Schrodinger equation looks similar to the Schrodinger equation for a one-dimensional particle, if one introduces the so-called effective potential

$$V_{\text{eff}}(r) = V(r) + \frac{\hbar^2 l(l+1)}{2\mu r^2}$$

where the second term is called the centrifugal energy. However, since f_l is defined only for $r > 0$, equation (4.10) is equivalent to equation (2.1) with the potential satisfying $V(x) = \infty$ for $x < 0$, which describes the infinite potential barrier at $x = 0$.

Since the radial Schrodinger operators

$$H_l = -\frac{\hbar^2}{2\mu}\frac{d^2}{dr^2} + V(r) + \frac{\hbar^2 l(l+1)}{2\mu r^2}$$

are obtained from the three-dimensional Schrodinger operator

$$H = -\frac{\hbar^2}{2\mu}\Delta + V(r)$$

by separation of variables, the operators H_l with boundary condition $f_l(0) = 0$ are self-adjoint in $L^2(0,\infty)$ whenever H is a self-adjoint operator in $L^2(\mathbb{R}^3)$.

In particular, it follows from Theorem 1.9 in Section 1.2 that when the bounded potential V satisfies

$$V(r) = O\left(r^{-1-\varepsilon}\right) \quad \text{as} \quad r \to \infty$$

for some $\varepsilon > 0$, then H_l are self-adjoint operators with simple absolutely continuous spectrum filling $[0,\infty)$, and negative eigenvalues with possible accumulation point at 0 . If

$$V(r) = O\left(r^{-2-\varepsilon}\right) \quad \text{as} \quad r \to \infty,$$

then the operators H_l have only finitely many negative eigenvalues, and for l large enough have no eigenvalues at all. The same conclusion holds if

$$\int_0^\infty r|V(r)|dr < \infty \tag{4.11}$$

Such potentials $V(r)$ are called short-range potentials. Decaying at infinity potentials which do not satisfy (4.11) are called long-range potentials.

For a short-range potential $V(r)$ the differential equation (4.10) for $E \neq 0$ has two linearly independent solutions $f_l^{\pm}(r)$ satisfying the following asymptotics as $r \to \infty$:

$$f_l^{\pm}(r) = e^{\pm \varkappa r}(1 + o(1)), \tag{4.12}$$

where $\varkappa = \sqrt{-2\mu E}$ is pure imaginary, $\operatorname{Im} \varkappa > 0$ for $E > 0$, and $\varkappa > 0$ for $E < 0$. When $r \to 0$, the most singular term in the radial Schrodinger equation is given by the centrifugal energy. Since the elementary differential equation

$$f'' = \frac{l(l+1)}{r^2} f$$

has two linearly independent solutions r^{-l} and r^{l+1}, the solution $f_l(r)$ satisfying the boundary condition $f_l(0) = 0$ has the asymptotics

$$f_l(r) = Cr^{l+1} + o(1) \quad \text{as} \quad r \to 0, \tag{4.13}$$

and is uniquely determined (up to a constant). Since

$$f_l(r) = C_1 f_l^+(r) + C_2 f_l^-(r),$$

for some constants C_1 and C_2 depending on E, the differential equation (4.10) has no square-integrable solutions for $E > 0$. The corresponding solution $f_l(r)$ is bounded on $[0,\infty)$, and is an eigenfunction of the continuous spectrum. This agrees with the description in Section 1.6 of

Chapter 1, since for $E > 0$ the classical particle in the central potential $V_{\text{eff}}(r)$ goes to infinity with finite velocity. For $E < 0$ the equation $C_1(E) = 0$ determines the eigenvalues of H_l, which are simple. This also agrees with the classical picture, since classical motion is finite for $E < 0$. For a short range potential the equation $C_1(E) = 0$ has only finitely many solutions. When $V_{\text{eff}}(r) > 0$ for $r > 0$ - the case of repulsive potential - the operator H_l has no eigenvalues.

Remark. When $V(r) = 0$, the radial Schrodinger operator H_l has only simple absolutely continuous spectrum filling $[0, \infty)$. The substitution

$$f_l(r) = \sqrt{\xi} J(\xi), \quad \xi = \frac{kr}{\hbar} \quad \text{and} \quad k = |\varkappa| = \sqrt{2\mu E} > 0$$

reduces differential equation (4.10) to the Bessel equation

$$\xi^2 \frac{d^2 J}{d\xi^2} + \xi \frac{dJ}{d\xi} + \left(\xi^2 - \nu^2\right) J = 0$$

of the half-integer order $\nu = l + \frac{1}{2}$. The corresponding solution regular at 0 - the Bessel function of the first kind $J_{l+\frac{1}{2}}(\xi)$ - is given explicitly by

$$J_{l+\frac{1}{2}}(\xi) = (-1)^l \sqrt{\frac{2}{\pi\xi}} \xi^{l+1} \left(\frac{1}{\xi}\frac{d}{d\xi}\right)^l \frac{\sin\xi}{\xi}$$

and

$$J_{l+\frac{1}{2}}(\xi) = \sqrt{\frac{2}{\pi\xi}} \sin\left(\xi - \frac{l\pi}{2}\right) \quad \text{as} \quad \xi \to \infty \tag{4.14}$$

It can be shown that

$$f_{El}(r) = \sqrt{\frac{kr}{\hbar}} J_{l+\frac{1}{2}}\left(\frac{kr}{\hbar}\right)$$

satisfy the normalization condition (2.14) in Section 2.2 of Chapter 2:

$$\lim_{\Delta\to 0} \frac{1}{\Delta} \int_0^\infty \left(\int_k^{k+\Delta} f_{El}(r) d\sigma(E) \right)^2 dr = 1 \tag{4.15}$$

where $k = \sqrt{2\mu E}$ and $d\sigma(E) = \sqrt{\frac{\mu}{2E}} dE = dk$. The corresponding eigenfunction expansion theorem is the special case of the classical Fourier-Bessel transform for integer l, which generalizes the Fourier sine transform: for every $f \in L^2(0, \infty)$,

$$f(r) = \int_0^\infty c_l(E) f_{El}(r) d\sigma(E), \quad c_l(E) = \int_0^\infty f(r) f_{El}(r) dr$$

In general, for every $l = 0, 1, ...$, denote by $f_{El}(r)$ the solution of the radial Schrodinger equation (4.10) with the following asymptotics:

$$f_{El}(r) = \sqrt{\frac{2}{\pi\hbar}} \sin\left(\frac{kr}{\hbar} - \frac{l\pi}{2} + \delta_l\right) + o(1) \quad \text{as} \quad r \to \infty \tag{4.16}$$

The function $\delta_l(k), k = \sqrt{2\mu E}$, is called the phase shift. It follows from (4.14) that for the free case $\delta_l(k) = 0$. The eigenfunctions of the continuous spectrum $f_{El}(r)$ satisfy the same normalization condition (4.15) as the
eigenfunctions for the free case. The function $S_l(k) = e^{2i\delta_l(k)}$ plays the role of the scattering matrix for the radial Schrodinger operator H_l. It admits a meromorphic continuation to the upper half-plane $\operatorname{Im} k > 0$ with simple poles $k = i\varkappa_{kl} = i\sqrt{-2\mu E_{kl}}$, where E_{kl} are the eigenvalues of H_l.

Let $E_{0l} < E_{2l} < \cdots < E_{N_l-1l} < 0$ be the eigenvalues of H_l, and let $f_{jl}(r), j = 0, ..., N_l - 1$, be the corresponding normalized eigenfunctions. By the oscillation theorem, the eigenfunctions $f_{jl}(r)$ have j simple zeros in $(0, \infty)$. The functions

$$\psi_{jlm}(\boldsymbol{x}) = \frac{f_{jl}(r)}{r} Y_{lm}(\boldsymbol{n}), \quad m = -l, ..., l$$

are normalized eigenfunctions of the Schrodinger operator H with eigenvalues E_{jl}, and the functions

$$\psi_{Elm}(\boldsymbol{x}) = \frac{f_{El}(r)}{r} Y_{lm}(\boldsymbol{n}), \quad m = -l, ..., l,$$

are normalized eigenfunctions of the continuous spectrum. The corresponding eigenfunction expansion theorem for the Schrodinger operator H with spherically symmetric potential states that for every $\psi \in L^2(\mathbb{R}^3, d^3\boldsymbol{x})$,

$$\psi(\boldsymbol{x}) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \int_0^{\infty} c_{lm}(E) \psi_{Elm}(\boldsymbol{x}) d\sigma(E) + \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \sum_{j=0}^{N_l-1} c_{jlm} \psi_{jlm}(\boldsymbol{x})$$

where

$$c_{lm}(E) = \int_{\mathbb{R}^3} \psi(\boldsymbol{x}) \overline{\psi_{Elm}(\boldsymbol{x})} d^3\boldsymbol{x}, \quad c_{jlm} = \int_{\mathbb{R}^3} \psi(\boldsymbol{x}) \overline{\psi_{jlm}(\boldsymbol{x})} d^3\boldsymbol{x}.$$

Remark. In physics, it is traditional to call the parameter j in the eigenfunction $\psi_{jlm}(\boldsymbol{x})$ the radial quantum number and denote it by n_r. The parameter l is called the azimuthal quantum number, and the parameter m - the magnetic quantum number. This terminology originated from the old quantum theory, where to each value E_{kl} there corresponds a classical orbit. The parameter $n = n_r + l + 1$ is called the principal quantum number, so that $n_r = n - l - 1$ is always the number of zeros of the corresponding radial eigenfunction $f_{jl}(r)$.

Remark. In general, the eigenvalues E_{jl} of a Schrodinger operator H with spherically symmetric potential have multiplicity $2l+1$. For special potentials, due to the extra symmetry of a problem, there may be "accidental degeneracy" with respect to the azimuthal quantum number l. This is the case for the Schrodinger operator of the hydrogen atom, considered in the next section.

Problem 4.7. Prove all results stated in this section. (Hint: See the list of references to this chapter.)

Problem 4.8. Find the energy levels of a particle with angular momentum $l = 0$ in the centrally symmetric potential well $V(r) = -V_0 < 0$ when $0 < r < a$ and $V(r) = 0$ when $r > a$.

Problem 4.9. Find the spectrum of the Schrodinger operator with the potential $V(r) = ar^{-2} + br^2, a, b > 0$.

Problem 4.10. Prove that the scattering wave $u(\boldsymbol{x}, \boldsymbol{k}) = u^{(+)}(\boldsymbol{x}, \boldsymbol{k})$ in the central potential is given by

$$u(\boldsymbol{x}, \boldsymbol{k}) = \frac{1}{kr} \sqrt{\frac{\pi}{2}} \sum_{l=0}^{\infty} (2l+1) i^l e^{i\delta_l(k)} f_{El}(r) P_l(\cos\vartheta),$$

where $\boldsymbol{x} \cdot \boldsymbol{k} = kr\cos\vartheta$ and, as in Section 4.2, $\hbar = 1$ and $\mu = \frac{1}{2}$.

Problem 4.11. Using the result of the previous problem, show that

$$f(k, \boldsymbol{n}, \boldsymbol{\omega}) = f(k, \cos\vartheta) = \frac{1}{2ik} \sum_{l=0}^{\infty} (2l+1) \left(S_l(k) - 1\right) P_l(\cos\vartheta)$$

- the partial wave decomposition of the scattering amplitude - and get the following formula for the total cross-section

$$\sigma_{\text{tot}}(k) = \frac{4\pi}{k^2}\sum_{l=0}^{\infty}(2l+1)\sin^2\delta_l(k).$$

3.6.11 5. Hydrogen atom and SO(4)

Theory

The hydrogen atom is described by the long-range potential

$$V(\boldsymbol{r}) = -\frac{\alpha}{r}$$

- the Coulomb potential, where $\alpha > 0$[3]. The corresponding eigenvalue problem for the Schrodinger operator with Coulomb potential is called the Coulomb problem. Here we present its exact solution using the so-called Coulomb units $\hbar = 1, \mu = 1$, and $\alpha = 1$[4].

5.1. Discrete spectrum.

To determine the discrete spectrum, it is convenient to put $2E = -\varkappa^2 < 0$, so that the eigenvalue equation (4.10) becomes

$$f_l'' + \left(\frac{2}{r} - \frac{l(l+1)}{r^2} - \varkappa^2\right) f_l = 0. \tag{5.1}$$

Asymptotics (4.12)-(4.13) for the short-range potentials suggest that for the long-range Coulomb potential one can look for a square-integrable solution in the following form:

$$f_l(r) = r^{l+1}e^{-\varkappa r}\Lambda(r)$$

Substituting it into (5.1), we get the equation

$$\Lambda_l'' + \left(\frac{2(l+1)}{r} - 2\varkappa\right)\Lambda_l' + \left(\frac{2}{r} - \frac{2\varkappa(l+1)}{r}\right)\Lambda_l = 0, \tag{5.2}$$

which can be solved by the power series

$$\Lambda_l(r) = \sum_{k=0}^{\infty} a_k r^k \tag{5.3}$$

Substituting these power series into (5.2) yields the following recurrence relation for the coefficients a_k:

$$a_{k+1} = \frac{2\varkappa(k+l+1)-2}{(k+1)(k+2l+2)}a_k, \quad k = 1, 2, ...,$$

where $a_0 \neq 0$. The power series (5.3) converges for all $r > 0$ by the ratio test. When $\varkappa > 0$ is such that $a_k \neq 0$ for all k, we have

[3] For the hydrogen atom $\alpha = e^2$, where e is the electron charge. The case $\alpha = Ze^2$, where $Z = 2, 3, ...$, corresponds to the hydrogen ions.
[4] When $\alpha = e^2$, Coulomb units coincide with atomic units.

$$\lim_{k\to\infty}\frac{(k+1)a_{k+1}}{a_k}=2\varkappa.$$

Thus for every $\varepsilon>0$ there is N such that for $k>N$ all a_k are of the same sign, say $a_k>0$, and

$$\frac{a_{k+1}}{a_k}\geq\frac{2\varkappa-\varepsilon}{k+1}.$$

Then for $k>N$ we get

$$a_k\geq C\frac{(2\varkappa-\varepsilon)^k}{k!}$$

with some constant $C>0$ (depending on ε), and since for fixed N the sum of the first N terms in (5.3) grows like r^N as $r\to\infty$, for r large enough we obtain [5]

$$\Lambda_l(r)\geq Ce^{(2\varkappa-\varepsilon)r}-C_1r^N>C_2e^{(2\varkappa-\varepsilon)r}.$$

This proves that for such values of $\varkappa$ the function $f_l(r)$ is not squareintegrable on $(0,\infty)$. However, for the special values

$$\varkappa=\varkappa_{kl}=\frac{1}{k+l+1}$$

the power series (5.3) terminates: $\Lambda_l(r)$ becomes a polynomial $\Lambda_{kl}(r)$ of order k and $f_{kl}(r)=r^{l+1}e^{-\varkappa_{kl}r}\Lambda_{kl}(r)\in L^2(0,\infty)$. Setting $n=k+l+1$, we get an explicit formula for the eigenvalues

$$E_n=-\frac{1}{2n^2},\quad n=1,2,...$$

For fixed n the integer l varies from 0 to $n-1$, and for each l there are $2l+1$ orthogonal eigenfunctions $\frac{f_{kl}(r)}{r}Y_{lm}(n)$ with the eigenvalue E_n. Thus the overall multiplicity of the eigenvalue E_n is

$$\sum_{l=0}^{n-1}(2l+1)=n^2.$$

The eigenfunctions $f_{kl}(r)$ of the radial Schrodinger equation (5.1) corresponding to the eigenvalue E_n can be expressed in terms of classical Laguerre polynomials. Namely, for $\varkappa=\frac{1}{n}$ the substitution $x=\frac{2r}{n}$ reduces the differential equation (5.2) to

$$xQ''+(p+1-x)Q'+kQ=0$$

where $p=2l+1$ and $Q(x)=\Lambda_l(r)$. This is the differential equation satisfied by the associated Laguerre polynomials $Q_k^p(x)$, defined by [6]

$$Q_k^p(x)=e^xx^{-p}\frac{d^k}{dx^k}\left(e^{-x}x^{k+p}\right)$$

which are polynomials of order k with leading coefficient $(-1)^k$, having k zeros in $(0,\infty)$. For every p the associated Laguerre polynomials $\{Q_k^p(x)\}_{k=0}^\infty$ are orthogonal polynomials on $(0,\infty)$ with respect to the measure $e^{-x}x^pdx$, and have the property

$$\int_0^\infty e^{-x}x^{p+1}Q_k^p(x)^2dx=k!(k+p)!(2k+p+1)$$

[05] It can be shown that $\Lambda_l(r)=Ce^{2\varkappa r}(1+o(1))$ as $r\to\infty$.

The orthonormal eigenfunctions of the Schrodinger operator H for the hydrogen atom corresponding to the eigenvalue E_n have the form

$$\psi_{klm}(\boldsymbol{q}) = \frac{2}{n^2}\frac{1}{\sqrt{k!(n+l)!}}\left(\frac{2r}{n}\right)^l e^{-\frac{r}{n}} Q_k^{2l+1}\left(\frac{2r}{n}\right) Y_{lm}(\boldsymbol{n}), \tag{5.4}$$

where $n = k + l + 1, l = 0, ..., n-1$, and $m = -l, ..., l$.
Remark. Returning to the physical units $\alpha = e^2$, where e is the electron charge, we get for the energy levels of the hydrogen atom

$$E_n = -\frac{\mu e^4}{2n^2\hbar^2}$$

where μ is the reduced mass of the electron and the nucleus. In particular, the ground state energy is $E_1 = -13.6\text{eV}$; its absolute value is the ionization energy - the energy required to remove the electron from the hydrogen atom. Using Bohr's formula for the frequencies of the spectral lines

$$\hbar\omega_{mn} = E_n - E_m,$$

we get for the hydrogen atom

$$\omega_{mn} = \frac{\mu e^4}{2\hbar^3}\left(\frac{1}{n^2} - \frac{1}{m^2}\right), \quad m < n$$

When $n = 1$ and $m = 2, 3, ...$, we get classical Lyman series, $n = 2$ and $m = 3, 4, ...$ give Balmer series, and $n = 3$ and $m = 4, 5, ...$ give Paschen series. These series of spectral lines were discovered experimentally long before the formulation of quantum mechanics.

Remark. The energy levels of the hydrogen atom can also be determined from Bohr-Wilson-Sommerfeld quantization rules. Namely, in spherical coordinates (r, ϑ, φ) in $\mathbb{R}^3$ the Lagrangian of Kepler's problem takes the form (see Section 1.6 in Chapter 1)

$$L = \frac{1}{2}\mu\left(\dot{r}^2 + r^2\dot{\vartheta}^2 + r^2\sin^2\vartheta\dot{\varphi}^2\right) + \frac{\alpha}{r}$$

and the corresponding generalized momenta are

$$p_r = \mu\dot{r}, \quad p_\vartheta = \mu r^2\dot{\vartheta}, \quad p_\varphi = \mu r^2\sin^2\vartheta\dot{\varphi}.$$

The BWS quantization conditions

$$\oint p_r dr = 2\pi\hbar\left(k + \frac{1}{2}\right) \tag{5.5}$$

$$\oint p_\vartheta d\vartheta = 2\pi\left(l - m + \frac{1}{2}\right) \tag{5.6}$$

$$\oint p_\varphi d\varphi = 2\pi\hbar m \tag{5.7}$$

where integration goes over the closed orbit of the Kepler problem with the energy $E < 0$, exactly determine the energy levels $E_n, n = k + l + 1$.

Indeed, we have $p_\varphi = M_{c3}$, where $M_c = (M_{c1}, M_{c2}, M_{c3})$ is the classical angular momentum. It is constant along the orbit, so that (5.7) determines the eigenvalues of operator M_3 (see Section 3.2). To evaluate $\oint p_\vartheta d\vartheta$, we use polar coordinates (r, χ) in the orbit plane P (see

[06] Polynomials $L_n^m(x) = (-1)^m\frac{n!}{(n-m)!}Q_{n-m}^m(x)$ are also being used.

Section 1.6 in Chapter 1). Since $\dot{\chi}^2 = \dot{\vartheta}^2 + \sin^2\vartheta\dot{\varphi}^2$, along the orbit we get $p_\chi d\chi = p_\vartheta d\vartheta + p_\varphi d\varphi$, where $p_\chi = \mu r^2\dot{\chi} = |\boldsymbol{M}_{\rm c}|$. Condition (5.6) now follows from

$$\oint p_\chi d\chi = 2\pi\,|M_{\rm c}| = 2\pi\hbar\left(l+\frac{1}{2}\right) \tag{5.8}$$

which is the quantization rule for the square of total angular momentum [7]. Finally, to evaluate $\oint p_r dr$, we use equations (1.7) and (1.11) in Section 1.6

of Chapter 1 and get

$$p_r dr = \mu\dot{r}dr = \mu\frac{dr}{d\chi}\dot{\chi}dr = \frac{|M_{\rm c}|}{r^2}\left(\frac{dr}{d\chi}\right)^2 d\chi = p_\chi\frac{e^2\sin^2\chi}{(1+e\cos\chi)^2}d\chi$$

where $0 < e < 1$ is the eccentricity of the orbit. We have

$$\oint p_r dr = p_\chi\int_0^{2\pi}\frac{e^2\sin^2\chi}{(1+e\cos\chi)^2}d\chi = 2\pi p_\chi\left(\frac{1}{\sqrt{1-e^2}}-1\right)$$

as can be shown by using the substitution $z = e^{i\chi}$ and the Cauchy residue theorem [8]. It follows from equation (1.12) in Section 1.6 of Chapter 1 that

$$\sqrt{1-e^2} = \frac{|\boldsymbol{M}_{\rm c}|\,\sqrt{2|E|}}{\alpha\sqrt{\mu}}$$

and we obtain from (5.5) and (5.8),

$$|E| = -E_n = \frac{\mu\alpha^2}{2n^2\hbar^2}, \quad n = k+l+1$$

5.2. Continuous spectrum.

Set $2E = k^2$, where $k > 0$, and consider the equation

$$f_l'' + \left(\frac{2}{r} - \frac{l(l+1)}{r^2} + k^2\right) f_l = 0 \tag{5.9}$$

Substitution

$$f_l(r) = r^{l+1}e^{-ikr}F_l(r)$$

reduces (5.9) to

$$F_l'' + \left(\frac{2(l+1)}{r} - 2ik\right)F_l' + \left(\frac{2}{r} - \frac{2ik(l+1)}{r}\right)F_l = 0. \tag{5.10}$$

The solution of equation (5.10) satisfying $F_l(0) = 1$ can be explicitly written as

$$F_l(r) = F(l+1+i\lambda, 2l+2, 2ikr), \quad \lambda = \frac{1}{k}$$

where $F(\alpha,\gamma,z)$ is a confluent hypergeometric function, defined by the absolutely convergent series

[07] It gives the quantized values $\hbar^2\left(l+\frac{1}{2}\right)^2$, which for large l agree well with the eigenvalues $\hbar^2 l(l+1)$ of the operator $\boldsymbol{M}^2$.

$$F(\alpha,\gamma,z)=\sum_{n=0}^{\infty}\frac{\Gamma(\alpha+n)\Gamma(\gamma)}{\Gamma(\alpha)\Gamma(\gamma+n)}\frac{z^n}{n!}$$

for all α and $\gamma\neq 0,-1,-2,\ldots$ The confluent hypergeometric function is an entire function of the variable z and satisfies the differential equation

$$zF''+(\gamma-z)F'-\alpha F=0$$

For $\alpha=-k$ and $\gamma=p+1$, where $k,p=0,1,2,\ldots$, the confluent hypergeometric function reduces to associated Laguerre polynomials

$$Q_k^p(x)=\frac{(k+p)!}{p!}F(-k,p+1,x)$$

considered in the previous section. For $\operatorname{Re}\gamma>\operatorname{Re}\alpha>0$ the function $F(\alpha,\gamma,z)$ admits the integral representation

$$F(\alpha,\gamma,z)=\frac{\Gamma(\gamma)}{\Gamma(\alpha)\Gamma(\gamma-\alpha)}\int_0^1 t^{\alpha-1}(1-t)^{\gamma-\alpha-1}e^{zt}dt \tag{5.11}$$

obtained by the Laplace method. The confluent hypergeometric function satisfies the functional equation

$$F(\alpha,\gamma,z)=e^zF(\gamma-\alpha,\gamma,-z) \tag{5.12}$$

and has the following asymptotics as $z\to\infty$:

$$\begin{aligned}F(\alpha,\gamma,z)=\frac{\Gamma(\gamma)}{\Gamma(\gamma-\alpha)}(-z)^{-\alpha}\left(1+O\left(z^{-1}\right)\right)\\ +\frac{\Gamma(\gamma)}{\Gamma(\alpha)}e^zz^{\alpha-\gamma}\left(1+O\left(z^{-1}\right)\right)\end{aligned} \tag{5.13}$$

It follows from (5.12) that $f_l(r)=r^{l+1}e^{-ikr}F(l+1+i\lambda,2l+2,2ikr)$ is real-valued and it follows from (5.13) that the function

$$f_{El}(r)=\frac{(2k)^{l+1}}{\sqrt{2\pi}(2l+1)!}e^{\frac{\pi}{2k}}|\Gamma(l+1-i\lambda)|f_l(r) \tag{5.14}$$

has the following asymptotics as $r\to\infty$:

$$f_{El}(r)=\sqrt{\frac{2}{\pi}}\sin\left(kr+\lambda\log 2kr-\frac{l\pi}{2}+\delta_l\right) \tag{5.15}$$

where

$$\delta_l(k)=\arg\Gamma(l+1-i\lambda),\quad \lambda=\frac{1}{k}=\frac{1}{\sqrt{2E}} \tag{5.16}$$

is the phase shift. The partial S-matrix for the Coulomb problem is

$$S_l(k)=e^{2i\delta_l(k)}=\frac{\Gamma(l+1-i\lambda)}{\Gamma(l+1+i\lambda)}$$

[08] This integral was evaluated by Sommerfeld in 1916.

It admits meromorphic continuation to the upper half-plane $\operatorname{Im} k > 0$ and has simple poles at $k = i\varkappa_{jl}$, which correspond to the eigenvalues E_{kl} of the radial Schrodinger operator H_l. The radial eigenfunctions of the continuous spectrum (5.14) satisfy normalization condition (4.15).
Remark. It is instructive to compare asymptotics (5.15) for the Coulomb potential, which is long-range, with the corresponding formula (4.16) for the general short-range potential. The long range nature of the Coulomb interaction manifests itself by the extra logarithmic term $\lambda \log 2kr$ in (5.15).

The eigenfunction expansion theorem for the Schrodinger operator H of the hydrogen atom has the same form as in Section 4.3: the eigenfunctions $\psi_{klm}(\boldsymbol{x})$ are given by (5.4) where $k = 0, 1, ..., N_l = \infty$, and the eigenfunctions of the continuous spectrum are given by

$$\psi_{Elm}(\boldsymbol{x}) = \frac{f_{El}(r)}{r} Y_{lm}(\boldsymbol{n}), \quad l = 0, 1, ..., \quad m = -l, ..., l.$$

5.3. Hidden SO(4) symmetry.

As we have seen in Section 1.6 of Chapter 1, classical system with the Hamiltonian function

$$H_{\mathrm{c}}(\boldsymbol{p}, \boldsymbol{x}) = \frac{\boldsymbol{p}^2}{2m} - \frac{\alpha}{r},$$

in addition to the angular momentum $\boldsymbol{M}_{\mathbf{c}}$, has three extra integrals of motion given by the Laplace-Runge-Lenz vector

$$\boldsymbol{W}_{\mathrm{c}} = \frac{\boldsymbol{p}}{m} \times \boldsymbol{M}_{\mathrm{c}} - \frac{\alpha \boldsymbol{x}}{r}.$$

According to Example 2.2 in Section 2.6 of Chapter 1, the integrals $\boldsymbol{M}_{\mathrm{c}}$ and $\boldsymbol{W}_{\mathrm{c}}$ for the Kepler problem have the Poisson brackets

$$\{M_{\mathrm{c}j}, M_{\mathrm{c}k}\} = -\varepsilon_{jkl} M_{\mathrm{c}l}, \quad \{W_{\mathrm{c}j}, M_{\mathrm{c}k}\} = -\varepsilon_{jkl} W_{\mathrm{c}l}$$
$$\{W_{\mathrm{c}j}, W_{\mathrm{c}k}\} = 2H_{\mathrm{c}} \varepsilon_{jkl} M_{\mathrm{c}l}$$

where $j, k, l = 1, 2, 3$ and $\varepsilon_{123} = 1$.
The quantum Kepler problem is the Coulomb problem. In the coordinate representation $\mathscr{H} = L^2(\mathbb{R}^3, d^3\boldsymbol{x})$, its Hamiltonian is

$$H = \frac{\boldsymbol{P}^2}{2} - \frac{\alpha}{r}$$

where $r = |\boldsymbol{x}|$ and we put $m = 1$. The quantum Laplace-Runge-Lenz vector - the Laplace-Runge-Lenz operator $\boldsymbol{W}$ - is defined by

$$\boldsymbol{W} = \frac{1}{2}(\boldsymbol{P} \times \boldsymbol{M} - \boldsymbol{M} \times \boldsymbol{P}) - \frac{\alpha \boldsymbol{Q}}{r}$$

or in components

$$W_j = \frac{1}{2} \varepsilon_{jkl} (P_k M_l + M_l P_k) - \frac{\alpha Q_j}{r}, \quad j = 1, 2, 3$$

Here Q_i are multiplication by x_i operators, and it is always understood that there is a summation over repeated indices $1, 2, 3$. Using commutation relations (3.5), we also have

$$\boldsymbol{W} = \boldsymbol{P} \times \boldsymbol{M} - \frac{\alpha \boldsymbol{Q}}{r} - i\hbar \boldsymbol{P} = -\boldsymbol{M} \times \boldsymbol{P} - \frac{\alpha \boldsymbol{Q}}{r} + i\hbar \boldsymbol{P} \tag{5.17}$$

where the term $i\hbar \boldsymbol{P}$ plays the role of a "quantum correction". The following result reveals the hidden symmetry of the Coulomb problem.

Proposition 5.1. The Schrodinger operator H of the hydrogen atom has quantum integrals of motion $\boldsymbol{M}$ and $\boldsymbol{W}$,

$$[H, M_i] = [H, W_i] = 0, \quad i = 1, 2, 3,$$

satisfying $\boldsymbol{W} \cdot \boldsymbol{M} = \boldsymbol{M} \cdot \boldsymbol{W} = 0$ and

$$\boldsymbol{W}^2 = \alpha^2 + 2H\boldsymbol{M}^2 + 2\hbar^2 H. \tag{5.18}$$

Moreover, self-adjoint operators $\boldsymbol{M}$ and $\boldsymbol{W}$ have the following commutation relations:

$$[M_j, M_k] = i\hbar\varepsilon_{jkl}M_l, \quad [W_j, M_k] = i\hbar\varepsilon_{jkl}W_l, \quad [W_j, W_k] = -2i\hbar\varepsilon_{jkl}M_l H.$$

Proof. We know that $[H, M_j] = 0$. To prove that W_j are quantum integrals of motion, we first compute $\left[\boldsymbol{P}^2, \frac{Q_j}{r}\right]$. It follows from Heisenberg's commutation relations that

$$\left[P_j, \frac{1}{r}\right] = i\hbar\frac{Q_j}{r^3}, \tag{5.19}$$

so that using Leibniz rule and relations $r^2 = x_1^2 + x_2^3 + x_3^2$, $[M_l, r] = 0$, and $Q_j P_k - Q_k P_j = \varepsilon_{jkl}M_l$, we obtain

$$\left[\boldsymbol{P}^2, \frac{Q_j}{r}\right] = 2i\hbar\frac{Q_j}{r^3} + 2i\hbar\varepsilon_{jkl}\frac{Q_k}{r^3}M_l.$$

Now using the first equation in (5.17) and (5.19), we get

$$\begin{aligned}[H, W_j] &= \left[\frac{\boldsymbol{P}^2}{2} - \frac{\alpha}{r}, \varepsilon_{jkl}P_k M_l - \frac{\alpha Q_j}{r} - i\hbar P_j\right] \\ &= -i\alpha\hbar\frac{Q_j}{r^3} - i\alpha\hbar\varepsilon_{jkl}\frac{Q_k}{r^3}M_l + i\alpha\hbar\varepsilon_{jkl}\frac{Q_k}{r^3}M_l + i\alpha\hbar\frac{Q_j}{q^3} = 0.\end{aligned}$$

It is easy to prove the relation $\boldsymbol{W} \cdot \boldsymbol{M} = W_1M_1 + W_2M_2 + W_3M_3 = 0$. Indeed, it follows from the definition of $\boldsymbol{M}$ and commutativity of P_k and Q_l for $k \neq l$ that

$$\boldsymbol{M} \cdot \boldsymbol{P} = \boldsymbol{P} \cdot \boldsymbol{M} = \boldsymbol{M} \cdot \boldsymbol{Q} = \boldsymbol{Q} \cdot \boldsymbol{M} = 0,$$

and using the first equation in (5.17) and commutation relations for the components of the angular momentum, we immediately get $\boldsymbol{W} \cdot \boldsymbol{M} = 0$. To prove that $\boldsymbol{M} \cdot \boldsymbol{W} = 0$, one should use the second equation in (5.17).

Verification of (5.18) is more involved. We have

$$\begin{aligned}W^2 = W_j W_j &= \left(\varepsilon_{jkl}M_l P_k - \frac{\alpha Q_j}{r} + i\hbar P_j\right)\left(\varepsilon_{jmn}P_m M_n - \frac{\alpha Q_j}{r} - i\hbar P_j\right) \\ &= \varepsilon_{jkl}\left(\varepsilon_{jmn}M_l P_k P_m M_n - \alpha M_l P_k \frac{Q_j}{r} - i\hbar M_l P_k P_j\right) - \alpha\varepsilon_{jmn}\frac{Q_j}{q}P_m M_n \\ &+ \alpha^2\frac{Q_j Q_j}{r^2} + i\alpha\hbar\frac{Q_j}{r}P_j + i\hbar\varepsilon_{jmn}P_j P_m M_n - i\alpha\hbar P_j\frac{Q_j}{r} + \hbar^2 P_j P_j \\ &= \alpha^2 I + \hbar^2 P^2 + \varepsilon_{jkl}\varepsilon_{jmn}M_l P_k P_m M_n - \alpha\varepsilon_{jkl}\left(M_l P_k \frac{Q_j}{q} + \frac{Q_j}{r}P_k M_l\right) \\ &- i\alpha\hbar\left[P_j, \frac{Q_j}{r}\right]\end{aligned}$$

Since operators M_j and P_j commute, the identity $(\boldsymbol{a} \times \boldsymbol{b})^2 = \boldsymbol{a}^2\boldsymbol{b}^2 - (\boldsymbol{a} \cdot \boldsymbol{b})^2$ is still applicable and we get

$\varepsilon_{jkl}\varepsilon_{jmn}M_lP_kP_mM_n = -(\boldsymbol{M}\times\boldsymbol{P})\cdot(\boldsymbol{P}\times\boldsymbol{M}) = \boldsymbol{M}^2\boldsymbol{P}^2 - (\boldsymbol{M}\cdot\boldsymbol{P})^2 = \boldsymbol{M}^2\boldsymbol{P}^2$.
Using (5.19) we easily obtain (summation over repeated indices)

$$\left[P_j, \frac{Q_j}{r}\right] = i\hbar\left(-\frac{3}{r} + \frac{r^2}{r^3}\right) = -\frac{2i\hbar}{r}.$$

Since $[\boldsymbol{M}^2, r] = 0$ it follows from $\boldsymbol{M} = \boldsymbol{Q}\times\boldsymbol{P}$ that

$$\varepsilon_{jkl}\left(M_lP_k\frac{Q_j}{r} + \frac{Q_j}{r}P_kM_l\right) = M^2\frac{1}{r} + \frac{1}{r}M^2 = \frac{2M^2}{r}.$$

Putting everything together, we get (5.18).
It is also not difficult to establish commutation relations between M_j and W_k. Using (3.5) and properties of ε_{jkl}, we get

$$\begin{aligned}[M_j, W_k] &= \left[M_j, \varepsilon_{kmn}P_mM_n - \frac{\alpha Q_k}{r} - i\hbar P_k\right]\\ &= i\hbar\left(\varepsilon_{jmp}\varepsilon_{kmn}P_pM_n + \varepsilon_{jnp}\varepsilon_{kmn}P_mM_p\right) - i\hbar\varepsilon_{jkl}\left(\frac{\alpha Q_l}{r} + i\hbar P_l\right)\\ &= i\hbar\left(P_jM_k - M_kP_j\right) - i\hbar\varepsilon_{jkl}\left(\frac{\alpha r_l}{r} + i\hbar P_l\right) = i\hbar\varepsilon_{jkl}W_l\end{aligned}$$

Finally, to establish commutation relations between components of $\boldsymbol{W}$, we use the representations

$$\boldsymbol{W} = \boldsymbol{Q}\boldsymbol{P}^2 - \boldsymbol{P}(\boldsymbol{Q}\cdot\boldsymbol{P}) - \frac{\alpha\boldsymbol{Q}}{r} = \boldsymbol{P}^2\boldsymbol{Q} - (\boldsymbol{P}\cdot\boldsymbol{Q})\boldsymbol{P} - \frac{\alpha\boldsymbol{Q}}{r} \tag{5.20}$$

The first formula in (5.20) follows from the first formula in (5.17) by using

$$\begin{aligned}\varepsilon_{jkl}P_kM_l = \varepsilon_{jkl}\varepsilon_{lmn}P_kQ_mP_l &= \varepsilon_{jkl}\left(\varepsilon_{ljk}P_kQ_jP_k + \varepsilon_{lkj}P_kQ_kP_j\right)\\ &= P_k\left(P_kQ_j - P_jQ_k\right) = Q_j\boldsymbol{P}^2 - P_j(\boldsymbol{P}\cdot\boldsymbol{Q}) - 2i\hbar P_j\end{aligned}$$

and relation $\boldsymbol{P}\cdot\boldsymbol{Q} = \boldsymbol{Q}\cdot\boldsymbol{P} - 3i\hbar I$. The second formula in (5.20) follows from the first by using Heisenberg's commutation relations. Now we have

$$\begin{aligned}\varepsilon_{jkl}\left[W_k, W_l\right] &= 2\varepsilon_{jmn}W_mW_n\\ = 2\varepsilon_{jmn}&\left(\boldsymbol{P}^2Q_m - (\boldsymbol{P}\cdot\boldsymbol{Q})P_m - \frac{\alpha Q_m}{r}\right)\left(Q_n\boldsymbol{P}^2 - P_n(\boldsymbol{Q}\cdot\boldsymbol{P}) - \frac{\alpha Q_n}{r}\right)\\ &= 2M_j\left(-\boldsymbol{P}^2(\boldsymbol{Q}\cdot\boldsymbol{P}) + (\boldsymbol{P}\cdot\boldsymbol{Q})\boldsymbol{P}^2 + \frac{\alpha}{r}(\boldsymbol{Q}\cdot\boldsymbol{P}) - (\boldsymbol{P}\cdot\boldsymbol{Q})\frac{\alpha}{r}\right)\\ &= -2i\hbar M_j\left(\boldsymbol{P}^2 - \frac{2\alpha}{r}\right) = -4i\hbar M_jH,\end{aligned}$$

where we have used $[\boldsymbol{M}, \boldsymbol{P}\cdot\boldsymbol{Q}] = 0$ and $\left[\boldsymbol{P}\cdot\boldsymbol{Q}, \frac{1}{r}\right] = \frac{i\hbar}{r}$. This proves that $[W_k, W_l] = -2i\hbar\varepsilon_{jkl}M_jH$.

Let $\mathscr{H}_0 = \mathrm{P}_H(-\infty, 0)\mathscr{H}$, where P_H is the projection-valued measure for the Schrodinger operator H. Since self-adjoint operators M and W commute with H, the subspace $\mathscr{H}_0$ is an invariant subspace for these operators. The Schrodinger operator H is non-negative on $\mathscr{H}_0$, so that on this subspace the operator $(-2H)^{-1/2}$ is well defined. Now on $\mathscr{H}_0$ we set

$$\boldsymbol{J}^{(\pm)} = \frac{1}{2}\left(\boldsymbol{M} \pm (-2H)^{-1/2}W\right).$$

It follows from Proposition 5.1 that self-adjoint operators $J_j^{(\pm)}$on $\mathscr{H}_0$ satisfy the commutation relations

$$\left[J_j^{(\pm)}, J_k^{(\pm)}\right] = i\hbar\varepsilon_{jkl}J_l^{(\pm)}, \quad \left[J_j^{(+)}, J_k^{(-)}\right] = 0 \tag{5.21}$$

and

$$\left(\boldsymbol{J}^{(+)}\right)^2 = \left(\boldsymbol{J}^{(-)}\right)^2 = -\frac{1}{4}\left(\hbar^2 I + \frac{\alpha^2}{2H}\right). \tag{5.22}$$

Equations (5.21) are commutation relations for the generators of the Lie algebra $\mathfrak{so}(4)$, which correspond to the Lie isomorphism $\mathfrak{so}(4) \simeq \mathfrak{so}(3) \oplus \mathfrak{so}(3)$, and exhibit the hidden SO(4) symmetry of the Coulomb problem! Together with (5.22), they allow us to find the energy levels pure algebraically.

Namely, the eigenvalues of the operators $\left(\boldsymbol{J}^{(+)}\right)^2$ and $\left(\boldsymbol{J}^{(-)}\right)^2$ are, respectively, $\hbar^2 l_1\left(l_1+1\right)$ and $\hbar^2 l_2\left(l_2+1\right)$, and it follows from (5.22) that $l_1 = l_2 = l$ so that the corresponding eigenvalue of H is

$$E_n = -\frac{\alpha^2}{2\hbar^2 n^2}, \quad n = 2l+1$$

Assuming that

$$\mathscr{H}_0 \simeq \bigoplus_{l\in\frac{1}{2}\mathbb{Z}_{\geq 0}} V_l \otimes V_l \tag{5.23}$$

where summation goes over all non-negative integer and half-integer values of l, we get from the Clebsch-Gordan decomposition (3.13) that the multiplicity of the eigenvalue E_n is

$$\dim V_l \otimes V_l = \sum_{j=0}^{2l}(2j+1) = (2l+1)^2 = n^2$$

To prove the orthogonal sum decomposition (5.23), one should consider the Schrodinger equation for the hydrogen atom in the momentum representation. Using spherical coordinates in $\mathbb{R}^3$ and the elementary integral

$$\int_0^\infty \frac{\sin r}{r} dr = \frac{\pi}{2}$$

it is easy to show that for every $\psi \in \mathscr{S}\left(\mathbb{R}^3\right)$

$$\frac{1}{2\pi^2\hbar}\int_{\mathbb{R}^3}\frac{\hat{\psi}(\boldsymbol{q})}{|\boldsymbol{p}-\boldsymbol{q}|^2}d^3\boldsymbol{q} = \frac{1}{(\sqrt{2\pi\hbar})^3}\int_{\mathbb{R}^3}\frac{1}{r}\psi(\boldsymbol{x})e^{-\frac{i}{\hbar}\boldsymbol{p}\boldsymbol{x}}d^3\boldsymbol{x} \tag{5.24}$$

where $\hat{\psi} = \mathscr{F}_\hbar(\psi)$ is the $\hbar$-dependent Fourier transform [9]. Let ψ be the eigenfunction of H with the the eigenvalue $E < 0$. It follows from (5.24) that in the momentum representation the corresponding Schrodinger equation the eigenvalue equation $H\psi = E\psi$ - takes the form

$$\left(\boldsymbol{p}^2 + p_0^2\right)\hat{\psi}(\boldsymbol{p}) = \lambda\int_{\mathbb{R}^3}\frac{\hat{\psi}(\boldsymbol{q})}{|\boldsymbol{p}-\boldsymbol{q}|^2}d^3\boldsymbol{q} \tag{5.25}$$

where $p_0 = \sqrt{-2\mu E}$ and $\lambda = \frac{\alpha\mu}{p_0\hbar}$. Next, consider the homogeneous coordinates $\frac{\boldsymbol{p}}{p_0}$ in $\mathbb{R}^3$ as coordinates of the stereographic projection of the unit sphere S^3 in $\mathbb{R}^4$. Namely, denoting by $\boldsymbol{n}$ the unit vector from the origin to the north pole of S^3, we get for the point $\boldsymbol{u} \in S^3$ corresponding to $\frac{\boldsymbol{p}}{p_0} \in \mathbb{R}^3$:

$$\boldsymbol{u} = \frac{\boldsymbol{p}^2 - p_0^2}{\boldsymbol{p}^2 + p_0^2}\boldsymbol{n} + \frac{2p_0}{\boldsymbol{p}^2 + p_0^2}\boldsymbol{p}$$

For the volume form on S^3 we have

$$d\Omega = \frac{(2p_0)^3}{(\boldsymbol{p}^2+p_0^2)^3}d^3\boldsymbol{p}, \quad \int_{S^3} d\Omega = 2\pi^2$$

Using

$$|\boldsymbol{p}-\boldsymbol{q}|^2 = \frac{(\boldsymbol{p}^2+p_0^2)\,(\boldsymbol{q}^2+p_0^2)}{(2p_0)^2}|\boldsymbol{u}-\boldsymbol{v}|^2$$

where $\boldsymbol{v}\in S^3$ corresponds to $\frac{\boldsymbol{q}}{p_0}\in\mathbb{R}^3$, and introducing

$$\Psi(\boldsymbol{u}) = \frac{1}{\sqrt{p_0}}\frac{(\boldsymbol{p}^2+p_0^2)^2}{(2p_0)^2}\hat{\psi}(\boldsymbol{p})$$

we can rewrite equation (5.25) as

$$\Psi(\boldsymbol{u}) = \frac{\lambda}{2\pi^2}\int_{S^3}\frac{\Psi(\boldsymbol{v})}{|\boldsymbol{u}-\boldsymbol{v}|^2}d\Omega_{\boldsymbol{v}} \tag{5.26}$$

We also have

$$\int_{S^3}|\Psi(\boldsymbol{u})|^2 d\Omega_{\boldsymbol{u}} = \int_{\mathbb{R}^3}\frac{\boldsymbol{p}^2+p_0^2}{2p_0^2}|\hat{\psi}(\boldsymbol{p})|^2 d^3\boldsymbol{p} = \int_{\mathbb{R}^3}|\hat{\psi}(\boldsymbol{p})|^2 d^3\boldsymbol{p}. \tag{5.27}$$

Indeed, it follows from the Schrodinger equation that

$$\frac{1}{2\mu}\int_{\mathbb{R}^3}\boldsymbol{p}^2|\hat{\psi}(\boldsymbol{p})|^2 d^3\boldsymbol{p} = \frac{1}{2\mu}\int_{\mathbb{R}^3}\left|\frac{\partial\psi(\boldsymbol{x})}{\partial\boldsymbol{x}}\right|^2 d^3\boldsymbol{x} = \int_{\mathbb{R}^3}(E-V(r))|\psi(\boldsymbol{x})|^2 d^3\boldsymbol{x},$$

and by the virial theorem (see Section 1.3) we get
$\frac{1}{2\mu}\int_{\mathbb{R}^3}\left|\frac{\partial\psi(\boldsymbol{x})}{\partial\boldsymbol{x}}\right|^2 d^3\boldsymbol{x} = -\frac{1}{2\mu}\int_{\mathbb{R}^3}\Delta\psi(\boldsymbol{x})\overline{\psi(\boldsymbol{x})}d^3\boldsymbol{x} = -\frac{1}{2}\int_{\mathbb{R}^3}V(r)|\psi(\boldsymbol{x})|^2 d^3\boldsymbol{x}$, where $V(r) = -\frac{\alpha}{r}$, so that

$$\int_{\mathbb{R}^3}V(r)|\psi(\boldsymbol{x})|^2 d^3\boldsymbol{x} = 2E\int_{\mathbb{R}^3}|\psi(\boldsymbol{x})|^2 d^3\boldsymbol{x} = 2E\int_{\mathbb{R}^3}|\hat{\psi}(\boldsymbol{p})|^2 d^3\boldsymbol{p}.$$

This shows that the eigenvalue problem for the Schrodinger equation is equivalent to the eigenvalue problem for the integral equation (5.26) in $L^2(S^3, d\Omega)$. The latter is a classical problem in the theory of spherical harmonics. Namely, the function $G(\boldsymbol{u}) = -\frac{1}{4\pi^2 u^2}$, where $u = |\boldsymbol{u}|, \boldsymbol{u}\in\mathbb{R}^4$, is the fundamental solution for the Laplace operator Δ in $\mathbb{R}^4$,

$$\Delta = \frac{\partial^2}{\partial u_1^2}+\frac{\partial^2}{\partial u_2^2}+\frac{\partial^2}{\partial u_3^2}+\frac{\partial^2}{\partial u_4^2},$$

and equation (5.26) is the equation satisfied by the spherical harmonics on S^3: the eigenfunctions of the spherical part Δ_0 of the Laplace operator on $\mathbb{R}^4$, defined by

$$\Delta = \frac{1}{u^3}\frac{\partial}{\partial u}\left(u^3\frac{\partial}{\partial u}\right)+\frac{1}{u^2}\Delta_0.$$

It is well known from the representation theory of the Lie group SO(4) that spherical harmonics are restrictions to S^3 of homogeneous harmonic polynomials in $\mathbb{R}^4$ of degree $n-1, n\in$

[09] Since $\boldsymbol{x}$ is the variable in the coordinate representation, here $\boldsymbol{q}$ is another variable in the momentum representation.

$\mathbb{N}$. Correspondingly, equation (5.26) is obtained as a limit $|\boldsymbol{u}| \to 1$ of the Green's formula for the homogeneous harmonic function of degree $n-1$ in the unit ball in $\mathbb{R}^4$, by using the property of a double layer potential. This gives $\lambda = n$, which once again establishes the exact formula for the energy levels of the hydrogen atom. The isomorphism $\mathscr{H}_0 \simeq L^2(S^3, d\Omega)$ follows from (5.27), and (5.23) - from the decomposition

$$L^2\left(S^3, d\Omega\right) \simeq \bigoplus_{l \in \frac{1}{2}\mathbb{Z}_{\geq 0}} V_l \otimes V_l$$

of the regular representation of SO(4) into the direct sum of irreducible components. One can also obtain the explicit form (5.4) of the eigenfunctions by using the representation theory of SO(4). We leave all these details to the interested reader.

Remark. For $E > 0$ one should consider the subspace $\mathscr{H}_1 = \mathrm{P}_H(0,\infty)\mathscr{H}$ and define $\boldsymbol{J}^{(\pm)} = \frac{1}{2}\left(\boldsymbol{M} \pm (2H)^{-1/2}\boldsymbol{W}\right)$. Instead of (5.21), these operators satisfy commutation relations of the Lie algebra $\mathfrak{so}(3,1)$ of the Lorentz group SO(3,1). The problem of finding eigenfunctions of the continuous spectrum for the Coulomb problem can be solved by using harmonic analysis on the three-dimensional Lobachevsky space.

Problem 5.1. Show that components of angular momentum M are generators of $\mathfrak{so}(4)$ that correspond to the infinitesimal rotations in the subspace of $\mathbb{R}^4$ with coordinates $(0, \boldsymbol{p})$, and components of the Laplace-Runge-Lenz vector $\boldsymbol{W}$ correspond to the infinitesimal rotations in the $(p_0 p_1), (p_0, p_2)$, and $(p_0 p_3)$ planes in $\mathbb{R}^4$.

3.6.12 6. Semi-classical asymptotics - I

Theory

Here we describe the relation between classical and quantum mechanics by considering the behavior of the wave function $\psi(\boldsymbol{q}, t)$ - the solution of the time dependent Schrodinger equation [10]

$$i\hbar\frac{\partial\psi}{\partial t} = -\frac{\hbar^2}{2m}\Delta\psi + V(\boldsymbol{q})\psi \tag{6.1}$$

as $\hbar \to 0$. The substitution

$$\psi(\boldsymbol{q}, t) = e^{-\frac{i}{\hbar}S(\boldsymbol{q},t;\hbar)} \tag{6.2}$$

reduces (6.1) to the following non-linear partial differential equation:

$$\frac{\partial S}{\partial t} + \frac{1}{2m}\left(\frac{\partial S}{\partial \boldsymbol{q}}\right)^2 + V(\boldsymbol{q}) = \frac{i\hbar}{2m}\Delta S \tag{6.3}$$

It is remarkable that (6.3) differs from the Hamilton-Jacobi equation (2.4) for the Hamiltonian function $H_c(\boldsymbol{p}, \boldsymbol{q}) = \frac{\boldsymbol{p}^2}{2m} + V(\boldsymbol{q})$, considered in Section 2.3 of Chapter 1, only by the term in the right-hand side which is proportional to $\hbar$. Thus as $\hbar \to 0$, equations of motion in quantum mechanics turn into classical equations of motion.

For the stationary state $\psi(\boldsymbol{q}, t) = \psi(\boldsymbol{q})e^{-\frac{i}{\hbar}Et}$ the substitution (6.2) becomes

$$\psi(\boldsymbol{q}, t) = e^{-\frac{i}{\hbar}(\sigma(\boldsymbol{q};\hbar) - Et)}. \tag{6.4}$$

The corresponding non-linear partial differential equation

[10] Here it is convenient to denote Cartesian coordinates on $\mathbb{R}^n$ by $\boldsymbol{q} = (q_1, ..., q_n)$.

$$\frac{1}{2m}\left(\frac{\partial\sigma}{\partial \boldsymbol{q}}\right)^2 + V(\boldsymbol{q}) = E + \frac{i\hbar}{2m}\Delta\sigma \tag{6.5}$$

differs from the corresponding Hamilton-Jacobi equation for the abbreviated action, considered in Section 2.5 of Chapter 1, by the term proportional to $\hbar$ in the right-hand side.

In this section we consider semi-classical asymptotics: asymptotics of the partial differential equations (6.3) and (6.5) as $\hbar \to 0$. They describe the precise relation between quantum mechanics and classical mechanics, and provide a quantitative form of the correspondence principle, discussed in Section 2 of Chapter 2. In particular, using semi-classical asymptotics for the stationary Schrodinger equation, we derive Bohr-Wilson-Sommerfeld quantization rules, postulated in Section 2.5 of Chapter 2.

6.1. Time-dependent asymptotics.

Here we consider the problem of finding short-wave asymptotics - asymptotics as $\hbar \to 0$ of the solution $\psi_\hbar(q,t)$ of the Cauchy problem for the Schrodinger equation (6.1) in one dimension,

$$i\hbar\frac{\partial\psi}{\partial t} = -\frac{\hbar^2}{2m}\frac{\partial^2\psi}{\partial q^2} + V(q)\psi$$

with the initial condition

$$\psi_\hbar(q,t)|_{t=0} = \varphi(q)e^{\frac{i}{\hbar}s(q)}.$$

It is assumed that the real-valued functions $\varphi(q)$ and $s(q)$ are smooth, $s(q), \varphi(q) \in C^\infty(\mathbb{R})$, and that the "amplitude" $\varphi(q)$ has compact support. The substitution (6.2) is $\psi_\hbar(q,t) = e^{\frac{i}{\hbar}S(q,t,\hbar)}$, and differential equation (6.3) takes the form

$$\frac{\partial S}{\partial t} + \frac{1}{2m}\left(\frac{\partial S}{\partial q}\right)^2 + V(q) = \frac{i\hbar}{2m}\frac{\partial^2 S}{\partial q^2}. \tag{6.6}$$

To determine the asymptotic behavior of $S(q,t,\hbar)$ as $\hbar \to 0$, we assume that as $\hbar \to 0$

$$S(q,t,\hbar) = \sum_{n=0}^{\infty}(-i\hbar)^n S_n(q,t),$$

and substitute this expansion into (6.6). Comparing terms with the same powers of $\hbar$ we obtain that $S_0(q,t)$ satisfies the initial value problem

$$\frac{\partial S_0}{\partial t} + \frac{1}{2m}\left(\frac{\partial S_0}{\partial q}\right)^2 + V(q) = 0 \tag{6.7}$$

and

$$S_0(q,t)|_{t=0} = s(q) \tag{6.8}$$

whereas $S_1(q,t)$ satisfies the differential equation

$$\frac{\partial S_1}{\partial t} + \frac{1}{m}\frac{\partial S_0}{\partial q}\frac{\partial S_1}{\partial q} = -\frac{1}{2m}\frac{\partial^2 S_0}{\partial q^2} \tag{6.9}$$

the so-called transport equation, and

$$S_1(q,t)|_{t=0} = \varphi(q) \tag{6.10}$$

The functions $S_n(q,t)$ for $n > 1$ satisfy non-homogeneous differential equations similar to (6.9).

The initial value problem (6.7)-(6.8) is the Cauchy problem for the Hamilton-Jacobi equation with the Hamiltonian function

$$H_{\mathrm{c}}(p,q) = \frac{p^2}{2m} + V(q)$$

considered in Section 2.3 of Chapter 1. According to Proposition 2.1 in Section 2.3 of Chapter 1, the solution of (6.7)-(6.8) is given by the method of characteristics,

$$S_0(q,t) = s\left(q_0\right) + \int_0^t L\left(\gamma'(\tau)\right) d\tau \tag{6.11}$$

Here $L(q,\dot{q}) = \frac{1}{2}m\dot{q}^2 - V(q)$ is the Lagrangian function, and $\gamma(\tau)$ is the characteristic - the classical trajectory which starts at q_0 at time $\tau = 0$ with the momentum $p_0 = \frac{\partial s}{\partial q}\left(q_0\right)$, and ends at q at time $\tau = t$, where q_0 is uniquely determined by q. (We are assuming that the Hamiltonian phase flow g_t satisfies the assumptions made in Section 2.3 of Chapter 1.) It follows from Theorem 2.7 in Section 2.3 of Chapter 1 that along the characteristic,

$$\frac{\partial S_0}{\partial q}(q,t) = m\frac{d\gamma}{dt}(t)$$

so that

$$\left(\frac{\partial}{\partial t} + \frac{\partial S_0}{\partial q}\right) S_1(\gamma(t),t) = \frac{d}{dt} S_1(\gamma(t),t) \tag{6.12}$$

Now we can solve the Cauchy problem (6.9)-(6.10) for the transport equation explicitly. Consider the flow $\pi_t : \mathbb{R} \to \mathbb{R}$, defined in Section 2.3 of

Chapter 1, and denote [11] by $\gamma(Q,q;\tau)$ the characteristic connecting points q at $\tau = 0$ and $Q = \pi^t(q)$ at $\tau = t$ (under our assumptions the flow π_t is a diffeomorphism and the mapping $q \mapsto Q$ is one to one). Differentiating the equation

$$\frac{\partial S_0}{\partial Q}(Q,t) = m\frac{\partial \gamma}{\partial t}(Q,q;t)$$

with respect to q we obtain

$$\frac{\partial^2 S_0}{\partial Q^2}(Q,t)\frac{\partial Q}{\partial q} = m\frac{\partial^2 \gamma}{\partial q \partial t}(Q,q;t) = m\frac{d}{dt}\left(\frac{\partial Q}{\partial q}\right)$$

so that (6.9) can be rewritten as

$$\frac{d}{dt} S_1(Q,t) = -\frac{1}{2}\frac{d}{dt}\log\frac{\partial Q}{\partial q}$$

and using (6.10) we obtain

$$S_1(Q,t) = \varphi(q)\left|\frac{\partial Q}{\partial q}(q)\right|^{-\frac{1}{2}}$$

Therefore,

$$\psi_\hbar(Q,t) = \varphi(q)\left|\frac{\partial Q}{\partial q}(q)\right|^{-\frac{1}{2}} e^{\frac{i}{\hbar}(S(Q,q;t)+s(q))}(1+O(\hbar)) \tag{6.13}$$

where $S(Q,q;t)$ is the classical action along the characteristic that starts at q at time $\tau=0$ and ends at Q at time $\tau=t$.

The rigorous proof that (6.13) is an asymptotic expansion as $\hbar\to 0$ uses the assumptions made in Section 2.3 of Chapter 1, and is left to the interested reader. Here we just mention that asymptotics (6.13) is consistent with the conservation of probability: for any Borel subset $E\subset\mathbb{R}$,

$$\int_{E_t}|\psi_\hbar(Q,t)|^2\,dQ=\int_E|\varphi(q)|^2dq+O(\hbar)$$

as $\hbar\to 0$, where $E_t=\pi_t(E)$.

Remark. When assumptions in Section 2.3 of Chapter 1 are not satisfied, the situation becomes more complicated. Namely, in this case there may be several characteristics $\gamma_j(\tau)$ which end at Q at $\tau=t$ having q_j as their corresponding initial points. In this case,

$$\psi_\hbar(Q,t)=\sum_j\varphi\left(q_j\right)\left|\frac{\partial Q}{\partial q}\left(q_j\right)\right|^{-\frac12}e^{\frac{i}{\hbar}(S(Q,q_j;t)+s(q_j))-\frac{\pi i}{2}\mu_j}(1+O(\hbar))$$

where $\mu_j\in\mathbb{Z}$ is the Morse index of the characteristic γ_j. It is defined as the number of focal points of the phase curve $(q(\tau),p(\tau))$ with initial data

q_j and $p_j=\frac{\partial s}{\partial q}\left(q_j\right)$ with respect to the configuration space $\mathbb{R}$. It is a special case of a more general Maslov index.

The case of n degrees of freedom is considered similarly. Under the assumptions in Section 2.3 of Chapter 1, the solution $\psi_\hbar(\boldsymbol{q},t)$ of the Schrodinger equation (6.1) with the initial condition

$$\psi_\hbar(\boldsymbol{q},t)|_{t=0}=\varphi(\boldsymbol{q})e^{\frac{i}{\hbar}s(\boldsymbol{q})}$$

where real-valued functions $s(\boldsymbol{q})$ and $\varphi(\boldsymbol{q})$ are smooth and $\varphi(\boldsymbol{q})$ is compactly supported, has the following asymptotics as $\hbar\to 0$:

$$\psi_\hbar(\boldsymbol{Q},t)=\varphi(\boldsymbol{q})\left|\det\left(\frac{\partial\boldsymbol{Q}}{\partial\boldsymbol{q}}(\boldsymbol{q})\right)\right|^{-\frac12}e^{\frac{i}{\hbar}(S(\boldsymbol{Q},\boldsymbol{q};t)+s(\boldsymbol{q}))}(1+O(\hbar)).\tag{6.14}$$

6.2. Time independent asymptotics. Here we consider semi-classical asymptotics for the one-dimensional Schrodinger equation

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2}+V(x)\psi=E\psi\tag{6.15}$$

This asymptotic method is also known as the WKB method (after G. Wentzel, H. Kramers, and L. Brillouin). The substitution (6.4) is $\psi_\hbar(x)=e^{\frac{i}{\hbar}\sigma(x;\hbar)}$ and equation (6.5) takes the form

$$\frac{1}{2m}\left(\frac{d\sigma}{dx}\right)^2+V(x)=E+\frac{i\hbar}{2m}\frac{d^2\sigma}{dx^2}$$

As in the previous section, we use the expansion

$$\sigma(x,\hbar)=\sum_{n=0}^{\infty}(-i\hbar)^n\sigma_n(x)$$

and for the first two terms obtain

$$\frac{1}{2m}\sigma_0'^2=E-V(x)\quad\text{ and }\quad\sigma_0'\sigma_1'=-\frac12\sigma_0''.\tag{6.16}$$

[011] There should not be any confusion with the quantum coordinate operator Q.

Let $p(x) = \sqrt{2m(E - V(x))}$ be the classical momentum of a particle moving in a potential $V(x)$ with the energy E. The solution of the first equation in (6.16) is given by

$$\sigma_0 = \pm \int p(x)dx$$

and from the second equation in (6.16) we get

$$\sigma_1 = -\frac{1}{2}\log p$$

The wave function in the WKB approximation has the form

$$\psi_\hbar(x) = \frac{1}{\sqrt{|p(x)|}}\left(C_1 e^{\frac{i}{\hbar}\int p(x)dx} + C_2 e^{-\frac{i}{\hbar}\int p(x)dx}\right)(1 + O(\hbar)), \tag{6.17}$$

where $p(x)$ is real in the classical region $V(x) < E$, and is pure imaginary in the classically forbidden region $V(x) > E$ (see Section 1.5 of Chapter 1).

Note that the asymptotic (6.17) is valid only if $\sigma^2 \ll \hbar\sigma''$, which in the first approximation gives

$$\left|\frac{d}{dx}\left(\frac{\hbar}{p(x)}\right)\right| \ll 1.$$

Introducing the classical force $F = -\frac{dV}{dx}$, this condition can be written as

$$\frac{m\hbar F}{p^3} \ll 1 \tag{6.18}$$

Thus the WKB approximation does not work when the classical momentum $p(x)$ is small. In particular, it is not applicable near the turning points where $E = V(x)$ and, therefore, $p(x) = 0$. Let $x = a$ be a turning point. If $F_0 = F(a) \neq 0$, using the approximation $E - V(x) \simeq F_0(x - a)$ near $x = a$, one can replace (6.15) by

$$\frac{\hbar^2}{2m}\psi'' = F_0(x - a)\psi$$

This differential equation can be explicitly solved by the Laplace method. Its bounded solution is

$$\psi(x) = \Phi(\xi), \quad \xi = \left(\frac{2mF_0}{\hbar^2}\right)^{\frac{1}{3}}(a - x)$$

where $\Phi(\xi)$ is the Airy-Fock function, defined by the improper integral

$$\Phi(\xi) = \frac{1}{\sqrt{\pi}}\int_0^\infty \cos\left(\frac{1}{3}t^3 + \xi t\right)dt.$$

The large ξ asymptotics of the Airy-Fock function, obtained by the steepest descent method, are the following:

$$\Phi(\xi) = \frac{1}{2\sqrt[4]{\xi}}e^{-\frac{2}{3}\xi^{\frac{3}{2}}}\left(1 + O\left(\xi^{-\frac{3}{2}}\right)\right) \quad \text{as} \quad \xi \to \infty, \tag{6.19}$$

$$\Phi(\xi) = \frac{1}{\sqrt[4]{|\xi|}}\sin\left(\frac{2}{3}|\xi|^{\frac{3}{2}} + \frac{\pi}{4}\right)\left(1 + O\left(|\xi|^{-\frac{3}{2}}\right)\right) \quad \text{as} \quad \xi \to -\infty. \tag{6.20}$$

Using asymptotics (6.19)-(6.20) one can obtain connection formulas relating WKB approximations for classical and forbidden regions. The rigorous justification of this approach is technically rather involved and we will not present it here. Instead we highlight the simplest case when there is only one turning point $x = a$ with $F_0 > 0$, so that $x < a$ is a classically forbidden region. From (6.17) we obtain that the WKB wave function in the forbidden region $x < a$ is exponentially decaying,

$$\psi_{\mathrm{WKB}}(x) = \frac{A}{\sqrt{|p(x)|}} e^{\frac{1}{\hbar}\int_a^x |p(s)|ds},$$

whereas in the classical region $x < a$ it is oscillating, $\psi_{\mathrm{WKB}}(x) = \frac{1}{\sqrt{p(x)}}\left(C_1 e^{\frac{i}{\hbar}\int_a^x p(s)ds} + C_2 e^{-\frac{i}{\hbar}\int_a^x p(s)ds}\right) = \frac{B}{\sqrt{p(x)}}\sin\left(\frac{1}{\hbar}\int_a^x p(s)ds + \alpha\right)$.
As follows from (6.18), the WKB approximation near the turning point $x = a$ remains valid whenever $|x-a| \gg \frac{1}{2}\left(\frac{\hbar^2}{mF_0}\right)^{\frac{1}{3}}$, which is equivalent to the condition $|\xi| \gg 1$. On the other hand, when $|x-a| \ll 1$ the wave function has the asymptotic

$$\psi_\hbar(x) = C\Phi(\xi)(1 + O(\hbar))$$

To determine the unknown phase α and to find the relation between coefficients A, B, and C, we consider the domain $\frac{1}{2}\left(\frac{\hbar^2}{mF_0}\right)^{\frac{1}{3}} \ll |x-a| \ll 1$ and compare the WKB approximation for the wave function with the large ξ asymptotics of the Airy-Fock function. Namely, for $x < a$ we have $\xi \gg 1$ and

$$\frac{2}{3}\xi^{\frac{3}{2}} = \frac{2}{3\hbar}\sqrt{2mF_0}(a-x)^{\frac{3}{2}} \simeq \frac{1}{\hbar}\int_x^a |p(s)|ds, \quad \sqrt[4]{\xi} = \frac{\sqrt{|p(x)|}}{\sqrt[6]{2m\hbar F_0}}$$

Comparing (6.19) with the WKB wave function for $x < a$ we obtain that $2A = \sqrt[6]{2m\hbar F_0}C$. For $x > a$ we have $\xi \ll -1$ and

$$\frac{2}{3}|\xi|^{\frac{3}{2}} = \frac{2}{3\hbar}\sqrt{2mF_0}(x-a)^{\frac{3}{2}} \simeq \frac{1}{\hbar}\int_a^x p(s)ds, \quad \sqrt[4]{|\xi|} = \frac{\sqrt{p(x)}}{\sqrt[6]{2m\hbar F_0}}$$

Comparing (6.20) with the WKB wave function for $x < a$ we obtain that $\alpha = \frac{\pi}{4}$ and $B = \sqrt[6]{2m\hbar\overline{F_0}}C$, so that $B = 2A$. Thus for this example the WKB wave function is

$$\psi_{\mathrm{WKB}}(x) = \begin{cases} \frac{A}{\sqrt{|p(x)|}} e^{\frac{1}{\hbar}\int_a^x |p(s)|ds} & \text{when } x < a \\ \frac{2A}{\sqrt{p(x)}}\sin\left(\frac{1}{\hbar}\int_a^x p(s)ds + \frac{\pi}{4}\right) & \text{when } x > a \end{cases} \tag{6.21}$$

The case when there is only one turning point $x = b$ with $F_0 < 0$, so that $x > b$ is a classically forbidden region, reduces to the previous example by reversing the orientation $x \mapsto -x$. As the result, we obtain

$$\psi_{\mathrm{WKB}}(x) = \begin{cases} \frac{2B}{\sqrt{p(x)}}\sin\left(\frac{1}{\hbar}\int_x^b p(s)ds + \frac{\pi}{4}\right) & \text{when } x < b \\ \frac{B}{\sqrt{|p(x)|}} e^{-\frac{1}{\hbar}\int_b^x |p(s)|ds} & \text{when } x > b \end{cases} \tag{6.22}$$

Problem 6.1 (Penetration through a potential barrier). Consider a potential barrier for a given energy E - a potential $V(x)$ such that $\{x \in \mathbb{R} : V(x) > E\} = (a, b)$. Show that

$$T_{\mathrm{WKB}} = e^{-\frac{2}{\hbar}\int_a^b |p(x)|dx}.$$

Verify directly that transmission coefficient for the potential in Problem 2.9 in the semi-classical approximation is given by this formula.

Problem 6.2 (Above barrier reflection). Suppose that a potential $V(x)$ admits analytic continuation into the upper half-plane, and let E be the energy such that $E > V(x)$ for all real x. Suppose that there is only one complex x_0 such that $V(x_0) = E$. Show that in the semi-classical approximation

$$R_{\mathrm{WKB}} = e^{-\frac{4}{\hbar}\operatorname{Im}\int_a^{x0} p(x)dx},$$

where $p(x) = \sqrt{2m(E - V(x))}$ and $a \in \mathbb{R}$ (the choice of a does not change the imaginary part of the integral in the exponent). Verify directly that the reflection coefficient for the potential in Problem 2.9 in the semi-classical approximation is given by this formula.

Problem 6.3. Find transmission and reflection coefficients for the parabolic barrier - a potential $V(x) = -\frac{1}{2}kx^2$, where $k > 0$ - and verify directly that in the semi-classical approximation they satisfy, for $E < 0$ and $E > 0$, respectively, formulas in Problems 6.1 and 6.2.

6.3. Bohr-Wilson-Sommerfeld quantization rules. The WKB method allows us to determine energy levels in the semi-classical approximation. Consider, for simplicity, the finite motion of a one-dimensional particle in a potential well: in a potential $V(x)$ at the energy E such that there are two turning points a and b. The classical region is $a \le x \le b$, and the motion is periodic with the period

$$T = 2\int_a^b \frac{dx}{\dot{x}} = 2m\int_a^b \frac{dx}{p} = \sqrt{2m}\int_a^b \frac{dx}{\sqrt{E - V(x)}}.$$

The regions $x < a$ and $x > b$ are forbidden (see Section 1.5 of Chapter 1).

It follows from (6.21)-(6.22) that the WKB wave function exponentially decays in the forbidden regions $x < a$ and $x > b$. Using (6.21) we see that in the classical region the WKB wave function has the form

$$\psi_{\mathrm{WKB}}(x) = \frac{2A}{\sqrt{p(x)}}\sin\left(\frac{1}{\hbar}\int_a^x p(s)ds + \frac{\pi}{4}\right),$$

while using (6.22) we obtain

$$\begin{aligned}\psi_{\mathrm{WKB}}(x) &= \frac{2B}{\sqrt{p(x)}}\sin\left(\frac{1}{\hbar}\int_x^b p(s)ds + \frac{\pi}{4}\right)\\ &= \frac{2B}{\sqrt{p(x)}}\sin\left(\frac{1}{\hbar}\int_a^b p(s)ds + \frac{\pi}{2} - \left(\frac{1}{\hbar}\int_a^x p(s)ds + \frac{\pi}{4}\right)\right).\end{aligned}$$

These two expressions define the same function in $a \le x \le b$ if and only if there is a positive integer n such that

$$\frac{1}{\hbar}\int_a^b p(x)dx + \frac{\pi}{2} = (n+1)\pi, \tag{6.23}$$

in which case $A = (-1)^{n+1}B$. Equation (6.23), written in the form

$$\int_a^b \sqrt{2m(E - V(x))}dx = \pi\hbar\left(n + \frac{1}{2}\right)$$

determines the semi-classical energy levels. It follows from (6.21)-(6.22) that the integer n is equal to the number of zeros of the WKB wave function. In accordance with the oscillation theorem, the case $n = 0$ corresponds to the ground state, case $n = 1$ - to the next energy level state, etc.

Denoting, as in Chapters 1 and 2, coordinate x by q, we can rewrite (6.23) as

$$\oint p dq = 2\pi\hbar \left(n + \frac{1}{2}\right), \tag{6.24}$$

where integration goes over the closed classical orbit in the phase plane $\mathbb{R}^2$ with canonical coordinates p, q. Condition (6.24) is the famous Bohr-Wilson-Sommerfeld quantization rule for the case of one degree of freedom (see Section 2.5 of Chapter 2). We emphasize that, in general, the BWS quantization rule is applicable only for large n and gives the semi-classical asymptotic of energy levels E_n. However, as was shown in Section 2.6 of Chapter 2, the energy levels of the harmonic oscillator obtained by the BWS quantization rule are exact. The BWS rules are also exact for the energy levels of the hydrogen atom (see Section 5.1).

This semi-classical analysis can be generalized for quantum systems with n degrees of freedom which correspond to completely integrable classical Hamiltonian systems (see Section 2.6 of Chapter 1). Bohr-WilsonSommerfeld quantization rules take the form

$$\oint_\gamma \boldsymbol{p} d\boldsymbol{q} = 2\pi\hbar \left(n_\gamma + \frac{1}{4} \text{ ind } \gamma\right). \tag{6.25}$$

Here integration goes over all 1-cycles γ in the Lagrangian submanifold $\Lambda = \{(\boldsymbol{p}, \boldsymbol{q}) \in \mathbb{R}^{2n} : H_c(\boldsymbol{p}, \boldsymbol{q}) = E, F_2(\boldsymbol{p}, \boldsymbol{q}) = E_2, ..., F_n(\boldsymbol{p}, \boldsymbol{q}) = E_n\}$, and ind γ is the Maslov index of a cycle γ in Λ. For the action-angle variables $(\boldsymbol{I}, \boldsymbol{\varphi})$ the integration in (6.25) goes over the basic 1 -cycles on the n-torus T^n, and we obtain quantization conditions $I_i = \left(n_i + \frac{1}{2}\right)\hbar, i = 1, ..., n$.

3.6.13 How to guess about Schrodinger equation?

(conceptually important question, but few people were really thinking about it beyond "we take Hamilton-Jacobi equation"... I'll think later. from which experiment? an answer to some question of early 19's)

3.6.14 Limits of Applicability of Schrodinger equation

(discussion in details, where it does not work?)

3.7 Heisenberg's Quantum Mechanics

Обзор форамлизма Гейзенберга

(тут будут ответы на все актуальные вопросы)

Мотивация изучать представление Гейзенберга

(я пока что не знаю, нафига оно нужно, но буду пользоваться - пропишу)

Об уравнении Гейзенберга

Уравнение Гейзенберга в двух словах

Представление Гейзенберга характерно тем, что в нем эволюционируют операторы, а не волновые функции.

отличие от Шредингера

применения

актуально увидеть, что конкретно им решается?

итоговые методы

Уравнение Гейзенберга для оператора $\hat{A}_H$ в представлении гейзенберга имеет вид:

$$\frac{d}{dt}\hat{A}_H(t) = \frac{i}{\hbar}\left[\hat{H}, \hat{A}_H(t)\right] + \frac{\partial \hat{A}_H}{\partial t}$$

Переход в представление гейзенберга происходит по средством оператора эволюции:

$$\hat{F}_H(t) = \hat{U}^\dagger(t)\hat{F}\hat{U}(t)$$

вывод уравнений и способа перехода в представление Гейзенберга

(все из киселева перепишу)

Рассмотрим матричный элемент произвольного оператора $\hat{F}$ в представлении Шредингера:

$$\langle \Phi(t)|F\Psi(t)\rangle = \langle U(t)\Phi|FU(t)\Psi\rangle = \left\langle \Phi|U^\dagger(t)FU(t)\Psi\right\rangle$$

Поэтому если волновую функцию рассматривать как неизменную величину, а единственным изменяющимся объектом были бы операторы, то их эволюция определялась бы:

$$\hat{F}_H(t) = \hat{U}^\dagger(t)\hat{F}\hat{U}(t)$$

Так и происходит переход в представление Гейзенберга.

Этот переход сохраняет эрмитовость, действительно:

$$\hat{F}^\dagger = \hat{F} \quad \leftrightarrow \quad \hat{F}_H^\dagger = \left(\hat{U}^\dagger\hat{F}\hat{U}\right)^\dagger = \hat{U}^\dagger\hat{F}\hat{U} = \hat{F}_H$$

Теперь получим уравнение динамики этих операторов.

Для этого продифференцируем оператор в представлении гейзенберга по времени и домножим на константы, чтобы воспользоваться уравнением Шредингера. Получим следующее:

$$\mathrm{i}\hbar\frac{d\hat{F}_H}{dt} = \mathrm{i}\hbar\hat{U}^\dagger\frac{\partial\hat{F}}{\partial t}\hat{U} + \hat{U}^\dagger(-\hat{H}\hat{F} + \hat{F}\hat{H})\hat{U}$$

Первый член правой части равен нулю, а второй с помощью $\hat{U}^\dagger\hat{U} = 1$ можно перевести в представление Гейзенберга:

$$\hat{U}^\dagger(-\hat{H}\hat{F} + \hat{F}\hat{H})\hat{U} = \left(\hat{U}^\dagger\hat{F}\hat{U}\right)\left(\hat{U}^\dagger\hat{H}U\right) - \left(U^\dagger\hat{H}\hat{U}\right)\left(U^\dagger\hat{F}\hat{U}\right) = \left[\hat{F}_H, \hat{H}_H\right]$$

В итоге уравнение динамики имеет вид:

$$\mathrm{i}\hbar\frac{dF}{dt} = [\hat{F}_H, \hat{H}_H]$$

Посмотрим далее на свойства этого уравнения.

матричная механика

Можно записать операторы и их уравнения в матричном виде:

$$\mathrm{i}\hbar\frac{dF_{nm}}{dt} = \left\langle n \left| \left[\hat{F}_H, \hat{H}_H\right] \right| m \right\rangle$$

Если наблюдаемая не зависит от времени явно, то можно взять матричный элемент по двум состояниям:

$$\mathrm{i}\hbar\frac{dF_{nm}}{dt} = \left\langle n\hat{F}_H, \hat{H}_H m \right\rangle$$

Преобразуем коммутатор

$$\left\langle n \left| \hat{F}_H \left(\sum_k |k\rangle\langle k| \right) \hat{H}_H - \hat{H}_H \left(\sum_k |k\rangle\langle k| \right) \hat{F}_H \right| m \right\rangle = \sum_k \left(F_{nk}H_{km} - H_{nk}F_{km}\right)$$

В итоге у нас появляется уравнение матричной механики:

$$\mathrm{i}\hbar\frac{dF_{nm}}{dt} = \sum_k \left(F_{nk}H_{km} - H_{nk}F_{km}\right)$$

Если система консервативна (?)б то базис строится по собственным функциям оператора $H_{km} = E_m\delta_{km}$, тогда уравнение гейзенберга будет иметь вид:

$$\mathrm{i}\hbar\frac{dF_{nm}}{dt} = F_{nm}\left(E_n - E_m\right)$$

пример решения хотя бы чего-то уравнением Гейзенберга

Киселев предлагает записать осциллятор в представлении Гейзенберга.

но после того, как он записал, он просто забил, так что я суть так и не понял, поэтому этот раздел откладывается на потом...

$$H(q,p) = \frac{p^2}{2m} + \frac{m\omega^2 q^2}{2} \quad \rightarrow \quad E_n = \frac{1}{2m}p_{nk}p_{kn} + \frac{m\omega^2}{2}q_{nk}q_{kn}$$

$$\langle n|[\hat{q},\hat{H}]|m\rangle = \left\langle n \left| \frac{\partial H}{\partial p} \right| m \right\rangle = \left\langle n \left| \frac{\hat{p}}{m} \right| m \right\rangle = \frac{p_{nm}}{m}$$

$$i\hbar\frac{dq_{nm}}{dt} = q_{nm}\left(E_n - E_m\right) = \frac{p_{nm}}{m}$$

соотношение неопределнностей энергии время

(тут - в качестве иллюстрации методы Гейзенберга, вообще подробно это будет написано в главе про соотношение неопределенностей, наверное, в научпопе)

(стр 43 киселев)

(место мотивации, зачем оно?)

$$[\hat{A},\hat{H}] = \mathrm{i}\hbar\frac{d\hat{A}}{dt}$$

$$\Delta A\Delta E \geqslant \frac{\hbar}{2}\left|\left\langle\frac{d\hat{A}}{dt}\right\rangle\right|$$

$$\left|\left\langle\frac{d\hat{A}}{dt}\right\rangle\right| = \frac{\Delta A}{\Delta t}$$

$$\Delta E\Delta t \geqslant \frac{\hbar}{2}$$

4 Other Fundamentals of Mathematical Quantum Mechanics

(later in this section, there will be a connection with quantum information theory)

4.1 Other, Fundamental Properties of Quantum Systems

4.1.1 Uncertainty Principle: Main Idea and Derivation

Обсудим подробно соотношение неопределенностей.

Соотношение неопределенностей для операторов в общем случае (??)

(тут страничка от Киселева про это)

Соотношение неопределенностей для энергии и времени (??)

(ну такая есть, и что??)

Connection of Fourier transformation and uncertainty principle in QM

(??? are they connected? I am not sure)

О неверных пониманиях соотношения неопределенностей (??)

(??? what can be and what can't be??? these are the important questions)

Соотношение неопределенностей для операторов в общем случае (??)

О применениях соотношения неопределенностей (??)

(тоже сразу укажу, где она нужна, а где нет.)

Об экспериментальной проверке соотношения неопределенностей (???)

(как конкретно проверить, что оно на самом деле есть? хз.)

Uncertainty in Fourier transformation

Does uncertainty principle have something to do with experiment

We were taught that no, we can derive it from theory. But there should be some further experimental restrictions!
(????)
(discuss!!!)

4.1.2 Uncertainty Principle: Other Questions

(maybe I'll create a section for each paragraph here later)

Connection of uncertainty principle and other quantum laws

(a big general question)

Соотношение неопределенностей энергия-время

Обсудим подробно соотношение неопределенностей энергия-время.
(думаю, это заслуживает отдельного раздела, тут много сложностей)

Experimental Confirmation of Uncertainty Principle

(??? I'll read something about it later)

How a wave packet moves? If there is no fixed coordinate and momenta, then how to see it?

Can at all there be a wave packet? We can't imagine it, since typical wave packet has a fixed momenta, which can't be.
(??? right?)

Can we change uncertainty to the momenta or to coordinate?

(discuss this question about a particle, that how many operators correspond to it? why in the QFT we solve for only one plane wave for the electron? the reason is (maybe!!???) that we can go to the momenta representation and if we don't know anything about coordinate, then it will 100% be fine. is it a good argument?????????????? think about it!!!!)

4.1.3 Concept of Coherent States

(скоро разберусь, пока не вижу еще)

Concept

(it is written in many books, by the way)

Applications of coherent states

(it is written in many books, by the way)

4.1.4 Feynman-Hellmann Theorem

(пока не отработал, нужно доделывать!)

Суть теоремы Фейнмана-Хеллмана

Известно, что среднее значение

$$\frac{\partial f_n}{\partial \lambda} = \left\langle n \left| \frac{\partial \hat{f}}{\partial \lambda} \right| n \right\rangle, \quad \hat{f}|n\rangle = f_n|n\rangle$$

$$\frac{\partial f_n}{\partial \lambda} = \frac{\partial}{\partial \lambda}\langle n|\hat{f}|n\rangle = \left\langle n \left| \frac{\partial \hat{f}}{\partial \lambda} \right| n \right\rangle + \left(\frac{\partial}{\partial \lambda}\langle n|\right)\hat{f}|n\rangle + \left\langle n \left| \hat{f}\left(\frac{\partial}{\partial \lambda}|n\rangle\right)\right.\right.$$

$$\frac{\partial f_n}{\partial \lambda} = \left\langle n \left| \frac{\partial \hat{f}}{\partial \lambda} \right| n \right\rangle + f_n\left(\frac{\partial}{\partial \lambda}\langle n|\right)|n\rangle + f_n\left\langle n \left| \left(\frac{\partial}{\partial \lambda}|n\rangle\right)\right.\right. = \left\langle n \left| \frac{\partial \hat{f}}{\partial \lambda} \right| n \right\rangle + f_n\frac{\partial}{\partial \lambda}\langle n|n\rangle$$

$$\hat{H} = \hat{T} + \hat{V} = -\frac{\hbar^2}{2m}\Delta + V(\boldsymbol{r})$$

$$\frac{\partial E_n}{\partial \lambda} = 0$$

$$\frac{\partial E_n}{\partial \lambda} = \left\langle n \left| \frac{\partial \hat{H}}{\partial \lambda} \right| n \right\rangle \Bigg|_{\lambda=1}$$

$$\left.\frac{\partial \hat{H}}{\partial \lambda}\right|_{\lambda=1} = 2\frac{\hbar^2}{2m}\frac{1}{\lambda^3}\Delta' + \left.\frac{\partial V(\lambda \boldsymbol{r})}{\partial \lambda \boldsymbol{r}'}\frac{\partial \lambda \boldsymbol{r}'}{\partial \lambda}\right|_{\lambda=1} = -2\hat{T} + \boldsymbol{r}\frac{\partial V(\boldsymbol{r})}{\partial \boldsymbol{r}}$$

$$\left.\frac{\partial \hat{H}}{\partial \lambda}\right|_{\lambda=1} = 2\frac{\hbar^2}{2m}\frac{1}{\lambda^3}\Delta' + \left.\frac{\partial V(\lambda \boldsymbol{r})}{\partial \lambda \boldsymbol{r}'}\frac{\partial \lambda \boldsymbol{r}'}{\partial \lambda}\right|_{\lambda=1} = -2\hat{T} + \boldsymbol{r}\frac{\partial V(\boldsymbol{r})}{\partial \boldsymbol{r}}$$

О применениях соотношения Фейнмана-Хеллмана

(потом напишу, пока не очень применял)

Сила действующая на стенку, пользуясь теоремой Ф-Х (???)

(потом напишу)

Как догадаться про это?

4.1.5 Virial Theorem in QM

(нужно будет - пропишу тут)

4.1.6 Ehrenfest Theorem

(???)

мотивация и обзор

Теорема Эренфеста в двух словах

Важно понимать, что квантование происходит так, что в среднем квантовая система за счет канонического квантования ведет себя так, как классическая.

(что такое "в среднем"??? тут подробно объяснять это нужно)

Это же отражает теорема Эрнфеста. На языке формул в формализме Гамильтона можно записать:

$$\frac{d\langle \hat{q} \rangle}{dt} = \left\langle \frac{\partial H}{\partial p} \right\rangle, \quad \frac{d\langle \hat{p} \rangle}{dt} = -\left\langle \frac{\partial H}{\partial q} \right\rangle$$

$$\mathrm{i}\hbar \frac{d\langle \hat{q} \rangle}{dt} = \langle [\hat{q}, \hat{H}] \rangle = \mathrm{i}\hbar \langle \{q, H\}_{\mathrm{P}} \rangle = \mathrm{i}\hbar \left\langle \frac{\partial H}{\partial p} \right\rangle$$

$$\mathrm{i}\hbar \frac{d\langle \hat{p} \rangle}{dt} = \langle [\hat{p}, \hat{H}] \rangle = \mathrm{i}\hbar \langle \{p, H\}_{\mathrm{P}} \rangle = -\mathrm{i}\hbar \left\langle \frac{\partial H}{\partial q} \right\rangle$$

(суть? применения?)

О применениях теоремы Эрнфеста

(укажу, когда она нужна, пока что не пользовался ни разу и не до неё)
(укажу связи с другими местами, где она используется)

Другое о квантовании

Пространственное квантование (???????????)

(зависла теория общефиза, потом посмотрю.)
Энергия физической системы в зависимости от формы потенциальной кривой может иметь либо непрерывный, либо дискретный спектр.

Как догадаться про это?

4.1.7 Variational Principle

(метод пробных функций для атома гелия тоже тут)

Теория

Если бы действие для динамики волновой функции существовало и имело вид

$$S = \int d^3 r dt \Psi^\dagger(\boldsymbol{r}, t) \left\{ \mathrm{i}\hbar \frac{\partial}{\partial t} - \hat{H} \right\} \Psi(\boldsymbol{r}, t)$$

То с помощью вариации можно было бы получить уравнение Шредингера.
Считая $\Psi, \Psi^\dagger$ независимыми, запишем уравнение Эйлера-Лагранжа:

$$\frac{\delta S}{\delta \Psi^\dagger} = 0 \leftrightarrow \frac{\partial \mathcal{L}}{\partial \Psi^\dagger} = 0 \to \mathrm{i}\hbar \frac{\partial}{\partial t} \Psi - \hat{H}\Psi = 0$$
$$\frac{\delta S}{\delta \Psi} = 0 \leftrightarrow \frac{\partial \mathcal{L}}{\partial \Psi} - \frac{\partial}{\partial t} \frac{\partial \mathcal{L}}{\partial \dot{\Psi}} = 0 \to -\Psi^\dagger \hat{H} - \mathrm{i}\hbar \frac{\partial}{\partial t} \Psi^\dagger = 0$$

Другое о вариационном принципе

Почему не очевиден вариационный принцип (??)

(оставшийся вопрос)

О случаях применения вариационного принципа (???)

Заготовки для применения вариационного принципа

Мы только что нашли принцип, из которого можно вывести уравнение Шредингера, посмотрим, что же еще можно из него вывести?
(вроде бы в атоме гелия про него есть примеры)

приближенные оценки энергии стационарных состояний

Вариационный принцип полезен для нахождения энергии стационарных состояний в классе пробных функций.
(алгоритм такой-то)
Покажем на примере, как это происходит:

$$\Psi(q) \simeq e^{-\frac{q^2}{2\sigma^2}}$$

$$\hat{H}\Psi(q) = -\frac{\hbar^2}{2m}\Psi''(q) + \frac{m\omega^2 q^2}{2}\Psi(q)$$

$$N = \int\limits_{-\infty}^{\infty} dq|\Psi(q)|^2 = \int\limits_{-\infty}^{\infty} dq e^{-\frac{q^2}{\sigma^2}} = \left\{ \int\limits_{-\infty}^{\infty} dq dq' e^{-\frac{q^2+q'^2}{\sigma^2}} \right\}^{1/2}$$

$$N = \left\{ \int\limits_{0}^{2\pi} d\varphi \int\limits_{0}^{\infty} r dr e^{-\frac{r^2}{\sigma^2}} \right\}^{1/2} = \sqrt{\pi\sigma^2}$$

$$S_{\text{stat.}} = \frac{1}{\sigma\sqrt{\pi}} \int\limits_{\text{infty}}^{\infty} dq \cdot e^{-\frac{q^2}{\sigma^2}} \left\{ E - \frac{\hbar^2}{2m\sigma^2} - \frac{q^2}{2}\left[m\omega^2 - \frac{\hbar^2}{m\sigma^4} \right] \right\} = E - \frac{\hbar^2}{2m\sigma^2} - \frac{\sigma^2}{4}\left[m\omega^2 - \frac{\hbar^2}{m\sigma^4} \right]$$

$$S'_{\text{stat.}} = \frac{\hbar^2}{4m\sigma^4} - \frac{m\omega^2}{4} = 0, \quad \rightarrow \quad \sigma^2 = \frac{\hbar}{m\omega}$$

$$H = \tfrac{1}{2}\hbar\omega$$
$$S''_{\text{stat.}} = -\tfrac{\hbar^2}{2m\sigma^6} < 0$$

Как догадаться про это?

(????)

4.2 Special Mathematical Transformations and Their Consequences

4.2.1 3. Weyl Relations 1

Let R be an irreducible unitary representation of the Heisenberg group $\mathbf{H}_n$ in Hilbert space $\mathscr{H}$. It follows from Schur's lemma that $R\left(e^{\alpha c}\right) = e^{i\hbar\alpha} I$ for some $\hbar \in \mathbb{R}$, where I is the identity operator on $\mathscr{H}$. If $\hbar = 0$, the n-parameter abelian groups of unitary operators $U(\boldsymbol{u}) = R\left(e^{\boldsymbol{u}X}\right)$ and $V(\boldsymbol{v}) = R\left(e^{\boldsymbol{v}\boldsymbol{Y}}\right)$ commute, so using Schur's lemma once again we conclude that there exist $\boldsymbol{p}, \boldsymbol{q} \in \mathbb{R}^n$ such that $U(\boldsymbol{u}) = e^{-i\boldsymbol{u}\boldsymbol{p}} I$ and $V(\boldsymbol{v}) = e^{-i\boldsymbol{v}\boldsymbol{q}} I$. Therefore, in this case the irreducible representation R is one-dimensional and is parametrized by a vector $(\boldsymbol{p}, \boldsymbol{q}) \in \mathbb{R}^{2n}$. When $\hbar \neq 0$, unitary operators $U(\boldsymbol{u})$ and $V(\boldsymbol{v})$ satisfy the Weyl relations

$$U(\boldsymbol{u})V(\boldsymbol{v}) = e^{i\hbar\boldsymbol{u}\boldsymbol{v}} V(\boldsymbol{v})U(\boldsymbol{u}) \tag{3.1}$$

which admit the Schrodinger representation, introduced in Section 2.2. It turns out that every unitary irreducible representation of the Heisenberg group $\mathbf{H}_n$ is unitarily equivalent either to a one-dimensional representation with parameters $(\boldsymbol{p}, \boldsymbol{q}) \in \mathbb{R}^{2n}$, or to the Schrodinger representation with some $\hbar \neq 0$. The physically meaningful case corresponds to $\hbar > 0$, and representation with $-\hbar$ is given by the operators $U^{-1}(\boldsymbol{u}) = U(-\boldsymbol{u})$ and $V(\boldsymbol{v})$.

3.1. Stone-von Neumann theorem.

Here we prove the following fundamental result.

Theorem 3.1 (Stone-von Neumann theorem). Every irreducible unitary representation of the Weyl relations for n degrees of freedom,

$$U(\boldsymbol{u})V(\boldsymbol{v}) = e^{i\hbar \boldsymbol{u}\boldsymbol{v}}V(\boldsymbol{v})U(\boldsymbol{u})$$

is unitarily equivalent to the Schrodinger representation.

Proof. It is sufficient to consider $n = 1$, the general case $n > 1$ is treated similarly. Set

$$S(u, v) = e^{-\frac{i\hbar uv}{2}}U(u)V(v)$$

The unitary operator $S(u, v)$ satisfies

$$S(u, v)^* = S(-u, -v) \tag{3.2}$$

and it follows from the Weyl relation that

$$S(u_1, v_1)\, S(u_2, v_2) = e^{\frac{i\hbar}{2}(u_1v_2 - u_2v_1)} S(u_1 + u_2, v_1 + v_2) \tag{3.3}$$

Define a linear map $W : L^1(\mathbb{R}^2) \to \mathscr{L}(\mathscr{H})$, called the Weyl transform, by

$$W(f) = \frac{1}{2\pi}\int_{\mathbb{R}^2} f(u, v)S(u, v)dudv$$

Here the integral is understood in the weak sense: for every $\psi_1, \psi_2 \in \mathscr{H}$,

$$(W(f)\psi_1, \psi_2) = \frac{1}{2\pi}\int_{\mathbb{R}^2} f(u, v)\,(S(u, v)\psi_1, \psi_2)\, dudv$$

The integral is absolutely convergent for all $\psi_1, \psi_2 \in \mathscr{H}$, and defines a bounded operator $W(f)$ satisfying

$$\|W(f)\| \leq \frac{1}{2\pi}\|f\|_{L^1}$$

The Weyl transform has the following properties.

WT1. For $f \in L^1(\mathbb{R}^2)$,

$$W(f)^* = W(f^*)$$

where

$$f^*(u, v) = \overline{f(-u, -v)}$$

WT2. For $f \in L^1(\mathbb{R}^2)$,

$$S(u_1, v_1)\, W(f) S(u_2, v_2) = W(\tilde{f})$$

where

$$\tilde{f}(u, v) = e^{\frac{i\hbar}{2}\{(u_1-u_2)v-(v_1-v_2)u+u_1v_2-u_2v_1\}} f(u - u_1 - u_2, v - v_1 - v_2)\,.$$

WT3. $\operatorname{Ker} W = \{0\}$

WT4. For $f_1, f_2 \in L^1(\mathbb{R}^2)$,

$$W(f_1)\, W(f_2) = W(f_1 *_\hbar f_2)\,,$$

where

$$(f_1 *_\hbar f_2)(u,v) = \frac{1}{2\pi}\int_{\mathbb{R}^2} e^{\frac{i\hbar}{2}(uv'-u'v)} f_1(u-u', v-v')\, f_2(u',v')\, du'dv'.$$

The first two properties follow from the definition and (3.2) and (3.3). To prove WT3, suppose that $W(f)=0$. Then for every $\psi_1, \psi_2 \in \mathscr{H}$ and all $u', v' \in \mathbb{R}$ we have

$$\begin{aligned} 0 &= (W(f) S(u',v')\,\psi_1, S(u',v')\,\psi_2) \\ &= \frac{1}{2\pi}\int_{\mathbb{R}^2} e^{i\hbar(uv'-u'v)} f(u,v)\,(S(u,v)\psi_1, \psi_2)\, dudv. \end{aligned}$$

Therefore $f(u,v)\,(S(u,v)\psi_1,\psi_2)=0$ a.e. on $\mathbb{R}^2$, so that $f=0$.
To prove WT4, we compute

$$\begin{aligned} (W(f_1)W(f_2)\psi_1,\psi_2) &= (W(f_2)\psi_1, W(f_1)^*\psi_2) \\ &= \frac{1}{2\pi}\int_{\mathbb{R}^2} f_2(u_2,v_2)\,(S(u_2,v_2)\psi_1, W(f_1)^*\psi_2)\, du_2dv_2 \\ &= \frac{1}{2\pi}\int_{\mathbb{R}^2} f_2(u_2,v_2)\,(W(f_1)S(u_2,v_2)\psi_1, \psi_2)\, du_2dv_2 \\ &= \frac{1}{(2\pi)^2}\int_{\mathbb{R}^2}\int_{\mathbb{R}^2} f_1(u_1-u_2, v_1-v_2)\, f_2(u_2,v_2)\,. \\ &\quad \cdot e^{\frac{i\hbar}{2}(u_1v_2-u_2v_1)}\,(S(u_1,v_1)\psi_1,\psi_2)\, du_1dv_1du_2dv_2 \\ &= \frac{1}{2\pi}\int_{\mathbb{R}^2} (f_1 *_\hbar f_2)(u,v)\,(S(u,v)\psi_1,\psi_2)\, dudv. \end{aligned}$$

We have $f_1 *_\hbar f_2 \in L^1(\mathbb{R}^2)$, and it follows from the associativity of the operator product and property WT3 that the linear mapping

$$*_\hbar : L^1(\mathbb{R}^2) \times L^1(\mathbb{R}^2) \to L^1(\mathbb{R}^2)$$

defines a new associative product on $L^1(\mathbb{R}^2)$,

$$f_1 *_\hbar (f_2 *_\hbar f_3) = (f_1 *_\hbar f_2) *_\hbar f_3 \text{ for all } f_1, f_2, f_3 \in L^1(\mathbb{R}^2).$$

When $\hbar = 0$, the product $*_\hbar$ becomes the usual convolution product on $L^1(\mathbb{R}^2)$.

For every non-zero $\psi \in \mathscr{H}$ denote by $\mathscr{H}_\psi$ the closed subspace of $\mathscr{H}$ spanned by the vectors $S(u,v)\psi$ for all $u, v \in \mathbb{R}$. The subspace $\mathscr{H}_\psi$ is invariant for all operators $U(u)$ and $V(v)$. Since the representation of the Weyl relation is irreducible, $\mathscr{H}_\psi = \mathscr{H}$.

There is a vector $\psi_0 \in \mathscr{H}$ for which all inner products of the generating vectors $S(u,v)\psi_0$ of $\mathscr{H}_{\psi_0}$ can be explicitly computed. Namely, let

$$f_0(u,v) = \hbar e^{-\frac{\hbar}{4}(u^2+v^2)}$$

and set

$$W_0 = W(f_0)$$

Then $W_0^* = W_0$ and

$$W_0 S(u,v) W_0 = e^{-\frac{\hbar}{4}(u^2+v^2)} W_0.$$

In particular, $W_0^2 = W_0$, so that W_0 is an orthogonal projection. Indeed, using WT4, we have

$$W_0 S(u,v) W_0 = W\left(f_0 *_\hbar \tilde{f}_0\right)$$

where

$$\tilde{f}_0(u',v') = e^{\frac{i\hbar}{2}(uv'-u'v)} f_0(u'-u, v'-v)$$

By "completing the square" we obtain

$$\left(f_0 * \hbar\tilde{f}_0\right)(u',v') = \hbar e^{-\frac{\hbar}{4}\left(u^2+v^2+u'^2+v'^2\right)} I(u',v')$$

where

$$I(u',v') = \frac{\hbar}{2\pi}\int_{\mathbb{R}^2} e^{-\frac{\hbar}{2}\left\{(u''-u-u'+iv+iv')^2+(v''-v-v'-iu-iu')^2\right\}} du''dv''$$

Shifting contours of integration to $\operatorname{Im} u'' = -v-v', \operatorname{Im} v'' = u+u'$ and substituting $\xi = u''-u-u'+iv+iv', \eta = v''-v-v'-iu-iu'$, we get

$$I(u',v') = \frac{\hbar}{2\pi}\int_{\mathbb{R}^2} e^{-\frac{\hbar}{2}\left(\xi^2+\eta^2\right)} d\xi d\eta = 1$$

Now let $\mathscr{H}_0 = \operatorname{Im} W_0$ - a non-zero closed subspace of $\mathscr{H}$ by property WT3.
For every $\psi_1, \psi_2 \in \mathscr{H}_0$ we have $W_0\psi_1 = \psi_1, W_0\psi_2 = \psi_2$, and

$$\begin{aligned}
\left(S(u_1,v_1)\psi_1, S(u_2,v_2)\psi_2\right) &= \left(S(u_1,v_1) W_0\psi_1, S(u_2,v_2) W_0\psi_2\right) \\
&= \left(W_0 S(-u_2,-v_2) S(u_1,v_1) W_0\psi_1, \psi_2\right) \\
&= e^{\frac{i\hbar}{2}(u_1v_2-u_2v_1)}\left(W_0 S(u_1-u_2, v_1-v_2) W_0\psi_1, \psi_2\right) \\
&= e^{\frac{i\hbar}{2}(u_1v_2-u_2v_1)-\frac{\hbar}{4}\left\{(u_1-u_2)^2+(v_1-v_2)^2\right\}}\left(W_0\psi_1, \psi_2\right) \\
&= e^{\frac{i\hbar}{2}(u_1v_2-u_2v_1)-\frac{\hbar}{4}\left\{(u_1-u_2)^2+(v_1-v_2)^2\right\}}\left(\psi_1, \psi_2\right)
\end{aligned}$$

This implies that the subspace $\mathscr{H}_0$ is one-dimensional. Indeed, for every $\psi_1, \psi_2 \in \mathscr{H}_0$ such that $(\psi_1, \psi_2) = 0$, we have that the corresponding subspaces $\mathscr{H}_{\psi_1}$ and $\mathscr{H}_{\psi_2}$ are orthogonal. Since $\mathscr{H}_\psi = \mathscr{H}$ for every non-zero ψ, at least one of the vectors ψ_1, ψ_2 is 0 . Let $\mathscr{H}_0 = \mathbb{C}\psi_0, \|\psi_0\| = 1$, and set

$$\psi_{\alpha,\beta} = S(\alpha,\beta)\psi_0, \quad \alpha,\beta \in \mathbb{R}.$$

The closure of the linear span of the vectors $\psi_{\alpha,\beta}$ for all $\alpha,\beta \in \mathbb{R}$ is $\mathscr{H}$. We have

$$\left(\psi_{\alpha,\beta}, \psi_{\gamma,\delta}\right) = e^{\frac{i\hbar}{2}(\alpha\delta-\beta\gamma)-\frac{\hbar}{4}\left\{(\alpha-\gamma)^2+(\beta-\delta)^2\right\}}$$

and

$$S(u,v)\psi_{\alpha,\beta} = e^{\frac{i\hbar}{2}(u\beta-v\alpha)}\psi_{\alpha+u,\beta+v}.$$

Next we consider the Schrodinger representation of the Weyl relation in $L^2(\mathbb{R}, dq)$:

$$\begin{aligned}
(\mathrm{U}(u)\varphi)(q) &= \varphi(q-\hbar u) \\
(\mathrm{V}(v)\varphi)(q) &= e^{-ivq}\varphi(q) \\
(\mathrm{S}(u,v)\varphi)(q) &= e^{\frac{i\hbar}{2}uv-ivq}\varphi(q-\hbar u)
\end{aligned}$$

For the corresponding operator W_0 we have

$$
\begin{aligned}
\left(\mathbf{W}_0\varphi\right)(q) &= \frac{\hbar}{2\pi}\int_{\mathbb{R}^2} e^{-\frac{\hbar}{4}\left(u^2+v^2\right)} e^{\frac{i\hbar}{2}uv-ivq}\varphi(q-\hbar u)dudv \\
&= \sqrt{\frac{\hbar}{\pi}}\int_{-\infty}^{\infty} e^{-\frac{\hbar}{4}\left\{u^2+\left(u-\frac{2}{\hbar}q\right)^2\right\}}\varphi(q-\hbar u)du \\
&= \frac{1}{\sqrt{\hbar\pi}}\int_{-\infty}^{\infty} e^{-\frac{1}{2\hbar}\left(q^2+q'^2\right)}\varphi\left(q'\right)dq',
\end{aligned}
$$

so that W_0 is a projection onto the one-dimensional subspace of $L^2(\mathbb{R},dq)$ spanned by the Gaussian exponential $\varphi_0(q)=\frac{1}{\sqrt[4]{\pi\hbar}}e^{-\frac{1}{2\hbar}q^2}$, $\|\varphi_0\|=1$. Let

$$\varphi_{\alpha,\beta}=\mathrm{S}(\alpha,\beta)\varphi_0.$$

Since the Schrodinger representation is irreducible, the closed subspace spanned by the functions $\varphi_{\alpha,\beta}$ for all $\alpha,\beta\in\mathbb{R}$ is the whole Hilbert space $L^2(\mathbb{R},dq)$. (This also follows from the completeness of Hermite-Tchebyscheff functions, since $\varphi_{\alpha,\beta}(q)=\frac{1}{\sqrt[4]{\pi\hbar}}e^{\frac{i\hbar}{2}\alpha\beta-i\beta q-\frac{1}{2\hbar}(q-\hbar\alpha)^2}$.) We have

$$\left(\varphi_{\alpha,\beta},\varphi_{\gamma,\delta}\right)=e^{\frac{i\hbar}{2}(\alpha\delta-\beta\gamma)-\frac{\hbar}{4}\left\{(\alpha-\gamma)^2+(\beta-\delta)^2\right\}}$$

and

$$\mathrm{S}(u,v)\varphi_{\alpha,\beta}=e^{\frac{i\hbar}{2}(u\beta-v\alpha)}\varphi_{\alpha+u,\beta+v}.$$

For $\psi=\sum_{i=1}^n c_i\psi_{\alpha_i,\beta_i}\in\mathscr{H}$ define

$$\mathscr{U}(\psi)=\sum_{i=1}^n c_i\varphi_{\alpha_i,\beta_i}\in L^2(\mathbb{R},dq)$$

Since inner products between the vectors $\psi_{\boldsymbol{\alpha},\beta}$ coincide with the inner products between the vectors $\varphi_{\alpha,\beta}$, we have

$$\|\mathscr{U}(\psi)\|_{L^2}^2=\|\psi\|_{\mathscr{H}}^2,$$

so that $\mathscr{U}$ is a well-defined unitary operator between the subspaces spanned by the vectors $\{\psi_{\alpha,\beta}\}_{\alpha,\beta\in\mathbb{R}}$ and $\{\varphi_{\alpha,\beta}\}_{\alpha,\beta\in\mathbb{R}}$. Thus $\mathscr{U}$ extends to the unitary operator $\mathscr{U}:\mathscr{H}\to L^2(\mathbb{R},dq)$ and

$$\mathscr{U}\,S(\alpha,\beta)=\mathrm{S}(\alpha,\beta)\mathscr{U}\quad\text{ for all }\quad\alpha,\beta\in\mathbb{R}.$$

Lemma 2.1 in Section 2.1 is now an easy corollary of the Stone-von Neumann theorem.

Corollary 3.2. The self-adjoint generators $\boldsymbol{P}=(P_1,...,P_n)$ and $\boldsymbol{Q}=(Q^1,...,Q^n)$ of the n-parameter abelian groups of unitary operators $U(\boldsymbol{u})$ and $V(\boldsymbol{v})$ satisfy Heisenberg commutation relations.

Proof. It follows from the Stone theorem that in the Schrodinger representation the generators $\boldsymbol{P}$ and $\boldsymbol{Q}$ are momenta and coordinate operators.

Remark. For n degrees of freedom

$$S(\boldsymbol{u},\boldsymbol{v})=e^{-\frac{i\hbar}{2}\boldsymbol{uv}}U(\boldsymbol{u})V(\boldsymbol{v})=e^{-\frac{i\hbar}{2}\boldsymbol{uv}}e^{-i\boldsymbol{uP}}e^{-i\boldsymbol{vQ}}$$

and formally using the Baker-Campbell-Hausdorff formula, we get

$$S(\boldsymbol{u},\boldsymbol{v})=e^{-i(\boldsymbol{uP}+\boldsymbol{vQ})}\tag{3.4}$$

Thus the Weyl transform

$$W(f) = \frac{1}{(2\pi)^n} \int_{\mathbb{R}^{2n}} f(\boldsymbol{u}, \boldsymbol{v}) e^{-i(\boldsymbol{uP}+\boldsymbol{vQ})} d^n\boldsymbol{u} d^n\boldsymbol{v}$$

can be considered as a non-commutative Fourier transform - an operatorvalued generalization of the "ordinary" Fourier transform

$$\hat{f}(\boldsymbol{p}, \boldsymbol{q}) = \frac{1}{(2\pi)^n} \int_{\mathbb{R}^{2n}} f(\boldsymbol{u}, \boldsymbol{v}) e^{-i(\boldsymbol{up}+\boldsymbol{vq})} d^n\boldsymbol{u} d^n\boldsymbol{v}$$

Remark. The Stone-von Neumann theorem is a very strong result. In particular, it implies that creation and annihilation operators for n degrees of freedom,

$$\boldsymbol{a} = \frac{1}{\sqrt{2\hbar}}(\boldsymbol{Q} + i\boldsymbol{P}), \quad \boldsymbol{a}^* = \frac{1}{\sqrt{2\hbar}}(\boldsymbol{Q} - i\boldsymbol{P})$$

where $\boldsymbol{P}$ and $\boldsymbol{Q}$ are the corresponding generators [24] satisfying Heisenberg commutation relations, are unitarily equivalent to the corresponding operators in the Schrodinger representation. Thus there always exists a ground state - a vector $\psi_0 \in \mathscr{H}$, annihilated by the operators $\boldsymbol{a} = (a_1, ..., a_n)$. The corresponding statement no longer holds for quantum systems with infinitely many degrees of freedom, described by quantum field theory, where one needs to postulate the existence of the ground state (the "physical vacuum").

The Weyl transform in the Schrodinger representation $\mathscr{H} = L^2(\mathbb{R}^n, d^n\boldsymbol{q})$ can be described explicitly as a bounded operator with an integral kernel. Namely,

$$(S(\boldsymbol{u}, \boldsymbol{v})\psi)(\boldsymbol{q}) = e^{\frac{i\hbar}{2}\boldsymbol{uv} - i\boldsymbol{vq}} \psi(\boldsymbol{q} - \hbar\boldsymbol{u}), \quad \psi \in L^2(\mathbb{R}^n, d^n\boldsymbol{q}) \tag{3.5}$$

and for $\psi_1, \psi_2 \in L^2(\mathbb{R}^n, d^n\boldsymbol{q})$ and $f \in L^1(\mathbb{R}^{2n}) \cap L^2(\mathbb{R}^{2n})$ we have

$$\begin{aligned}(W(f)\psi_1, \psi_2) &= \frac{1}{(2\pi)^n} \int_{\mathbb{R}^{2n}} f(\boldsymbol{u}, \boldsymbol{v}) \left(S(\boldsymbol{u}, \boldsymbol{v})\psi_1, \psi_2\right) d^n\boldsymbol{u} d^n\boldsymbol{v} \\ = \frac{1}{(2\pi)^n} \int_{\mathbb{R}^{2n}} &\left(\int_{\mathbb{R}^n} e^{\frac{i\hbar}{2}\boldsymbol{uv} - i\boldsymbol{vq}} f(\boldsymbol{u}, \boldsymbol{v}) \psi_1(\boldsymbol{q} - \hbar\boldsymbol{u}) \overline{\psi_2(\boldsymbol{q})} d^n\boldsymbol{q} \right) d^n\boldsymbol{u} d^n\boldsymbol{v} \\ &= \int_{\mathbb{R}^n} \left(\int_{\mathbb{R}^n} K(\boldsymbol{q}, \boldsymbol{q}') \psi_1(\boldsymbol{q}') d^n\boldsymbol{q}' \right) \overline{\psi_2(\boldsymbol{q})} d^n\boldsymbol{q}\end{aligned}$$

where

$$K(\boldsymbol{q}, \boldsymbol{q}') = \frac{1}{(2\pi\hbar)^n} \int_{\mathbb{R}^n} f\left(\frac{\boldsymbol{q} - \boldsymbol{q}'}{\hbar}, \boldsymbol{v}\right) e^{-\frac{i}{2}(\boldsymbol{q}+\boldsymbol{q}')\boldsymbol{v}} d^n\boldsymbol{v} \tag{3.6}$$

The interchange of the order of integrations is justified by the Fubini theorem. Thus $W(f)$ is an integral operator with the integral kernel $K(\boldsymbol{q}, \boldsymbol{q}')$,

$$(W(f)\psi)(\boldsymbol{q}) = \int_{\mathbb{R}^n} K(\boldsymbol{q}, \boldsymbol{q}') \psi(\boldsymbol{q}') d^n\boldsymbol{q}', \quad \psi \in L^2(\mathbb{R}^n, d^n\boldsymbol{q}).$$

By the Plancherel theorem,

$$\int_{\mathbb{R}^{2n}} |K(\boldsymbol{q}, \boldsymbol{q}')|^2 d^n\boldsymbol{q} d^n\boldsymbol{q}' = \int_{\mathbb{R}^{2n}} |f(\boldsymbol{u}, \boldsymbol{v})|^2 d^n\boldsymbol{u} d^n\boldsymbol{v}$$

so that $W(f)$ is a Hilbert-Schmidt operator on $\mathscr{H}$. The linear subspace $L^1(\mathbb{R}^{2n}) \cap L^2(\mathbb{R}^{2n})$ is dense in $L^2(\mathbb{R}^{2n})$ and the Weyl transform extends to the isometry $W : L^2(\mathbb{R}^{2n}) \to \mathscr{S}_2$, where $\mathscr{S}_2$ is the Hilbert space of HilbertSchmidt operators on $\mathscr{H} = L^2(\mathbb{R}^n, d^n\boldsymbol{q})$. Since every

Hilbert-Schmidt operator on $\mathscr{H}$ is a bounded operator with the integral kernel in $L^2(\mathbb{R}^{2n})$, the mapping W is onto. Thus we have proved the following result.

Lemma 3.1. The Weyl transform W defines the isomorphism $L^2(\mathbb{R}^{2n}) \simeq \mathscr{S}_2$.

Problem 3.

1. Let $\boldsymbol{P} = (P_1, ..., P_n)$ and $\boldsymbol{Q} = (Q_1, ..., Q_n)$ be self-adjoint operators [25] on $\mathscr{H}$ satisfying Heisenberg commutation relations (2.4) on some dense domain D in $\mathscr{H}$, and such that the symmetric operator $H = \sum_{k=1}^{n}(P_k^2 + Q_k^2)$, defined on D, is essentially self-adjoint. Also suppose that every bounded operator which commutes with $\boldsymbol{P}$ and $\boldsymbol{Q}$ is a multiple of the identity operator in $\mathscr{H}$. Prove that $\boldsymbol{P}$ and $\boldsymbol{Q}$ are unitarily equivalent to momenta and coordinate operators in the Schrodinger representation. (Hint: By the Stone-von Neumann theorem, it is sufficient to show that $\boldsymbol{P}$ and $\boldsymbol{Q}$ define an integrable representation of the Heisenberg algebra. One can also prove this result directly by using commutation relations between the operators $H, a^*, \boldsymbol{a}$ and the arguments in Section 2.6. This would give another proof of the Stone-von Neumann theorem.)

Problem 3.

2. Prove formula (3.4).

3.2. Invariant formulation.

Here we present a coordinate-free description of the Schrodinger representation. Let (V, ω) be a finite-dimensional symplectic vector space, $\dim V = 2n$. Recall that (see Section 2.1) the Heisenberg algebra $\mathfrak{g} = \mathfrak{g}(V)$ is a one-dimensional central extension of the abelian Lie algebra V by the skew-symmetric bilinear form ω. As a vector space,

$$\mathfrak{g} = V \oplus \mathbb{R}c$$

with the Lie bracket

$$[u + \alpha c, v + \beta c] = \omega(u, v)c, \quad u, v \in V, \quad \alpha, \beta \in \mathbb{R}$$

Every Lagrangian subspace ℓ of V defines an abelian subalgebra $\ell \oplus \mathbb{R}c$ of g. A Lagrangian subspace ℓ' is complementary to ℓ in V if $\ell \oplus \ell' = V$. A choice of the complementary Lagrangian subspace ℓ' to ℓ establishes the isomorphism

$$\mathfrak{g}/(\ell \oplus \mathbb{R}c) \simeq \ell'$$

The Heisenberg group $G = G(V)$ is a connected and simply-connected Lie group with the Lie algebra $\mathfrak{g}$. By the exponential map, $G \simeq V \oplus \mathbb{R}c$ as a manifold, with the group law

$$\exp(v_1 + \alpha_1 c)\exp(v_2 + \alpha_2 c) = \exp\left(v_1 + v_2 + \left(\alpha_1 + \alpha_2 + \frac{1}{2}\omega(v_1, v_2)\right)c\right)$$

where $v_1, v_2 \in V, \alpha_1, \alpha_2 \in \mathbb{R}$. A choice of the symplectic basis for V establishes the isomorphism $G(V) \simeq \mathbf{H}_n$ with the matrix Heisenberg group defined in Section 2.1. The volume form

[024] Here it is convenient to lower the indices by the Euclidean metric on $\mathbb{R}^n$ and use $Q = (Q_1, ..., Q_n)$.

$d^{2n}\boldsymbol{v} \wedge dc$, where $d^{2n}\boldsymbol{v} \in \Lambda^{2n}V^*$ is a volume form on V and V^* is the dual vector space to V, defines a bi-invariant Haar measure on G. Every Lagrangian subspace ℓ defines an

abelian subgroup $L = \exp(\ell \oplus \mathbb{R}c)$ of G, and a choice of the complementary Lagrangian subspace ℓ' establishes the isomorphism

$$G/L \simeq \ell'. \tag{3.7}$$

The isomorphism $\Lambda^{2n}V^* \simeq \Lambda^n\ell^* \wedge \Lambda^n\ell'^*$ gives rise to the volume form $d^n\boldsymbol{v}'$ on ℓ' and defines a measure dg on the homogeneous space G/L. The measure dg is invariant under the left G-action and does not depend on the choice of ℓ'.

For a given $\hbar \in \mathbb{R}$, the function $\chi : L \to \mathbb{C}$,

$$\chi(\exp(v + \alpha c)) = e^{i\hbar\alpha}, \quad v \in V, \alpha \in \mathbb{R},$$

defines a one-dimensional unitary character of L,

$$\chi(l_1 l_2) = \chi(l_1)\chi(l_2), \quad l_1, l_2 \in L.$$

Definition. The Schrodinger representation S_ℓ of the Heisenberg group $G(V)$, associated with a Lagrangian subspace ℓ of V, is a representation of G induced by the one-dimensional representation χ of the corresponding abelian Lie group L,

$$S_\ell = \mathrm{Ind}_L^G \chi.$$

By definition of the induced representation, the Hilbert space $\mathscr{H}_\ell$ of the representation S_ℓ consists of measurable functions $f : G \to \mathbb{C}$ satisfying the property

$$f(gl) = \chi(l)^{-1} f(g), \quad g \in G, l \in L,$$

and such that

$$\|f\|^2 = \int_{G/L} |f(g)|^2 dg < \infty.$$

Corresponding unitary operators $S_\ell(g), g \in G$, are defined by the left translations,

$$(S_\ell(g)f)(g') = f\left(g^{-1}g'\right), \quad f \in \mathscr{H}_\ell, g \in G.$$

In particular,

$$(S_\ell(\exp \alpha c)f)(g) = f(\exp(-\alpha c)g) = f(g\exp(-\alpha c)) = e^{i\hbar\alpha} f(g),$$

so that $S_\ell(\exp \alpha c) = e^{i\hbar\alpha} I$, where I is the identity operator on $\mathscr{H}_\ell$.

For every Lagrangian subspace ℓ of V, the representation S_ℓ is unitarily equivalent to the Schrodinger representation. This can be explicitly shown as follows. By (3.7), a choice of a complementary Lagrangian subspace ℓ' gives rise to the unique decomposition $g = \exp v' \exp(v + \alpha c)$, and for $f \in \mathscr{H}_\ell$ we get

$$f(g) = f(\exp v' \exp(v + \alpha c)) = e^{-i\hbar\alpha} f(\exp v'), \quad v \in \ell, v' \in \ell', \alpha \in \mathbb{R}.$$

Thus every $f \in \mathscr{H}_\ell$ is completely determined by its restriction to $\exp \ell' \simeq \ell'$, and the mapping $\mathscr{U}_\ell : \mathscr{H}_\ell \to L^2(\ell', d^n\boldsymbol{v}')$, defined by

[025] See previous footnote.

$$\mathscr{U}_\ell(f)\,(v') = f\left(\exp\frac{1}{\hbar}v'\right), \quad v' \in \ell',$$

is the isomorphism of Hilbert spaces. For the corresponding representation $\mathrm{S}_\ell = \mathscr{U}_\ell S_\ell \mathscr{U}_\ell^{-1}$ in $L^2\,(\ell', d^n v')$ we have

$$\begin{aligned}(\mathrm{S}_\ell(\exp v)\psi)\,(v') &= e^{i\omega(v,v')}\psi\,(v'), \quad v \in \ell, v' \in \ell' \\ (\mathrm{S}_\ell\,(\exp u')\,\psi)\,(v') &= \psi\,(v' - \hbar u'), \quad u', v' \in \ell'\end{aligned}$$

Let $e^1, ..., e^n, f_1, ..., f_n$ be the symplectic basis for V such that

$$\ell = \mathbb{R}e^1 \oplus \cdots \oplus \mathbb{R}e^n \quad \text{and} \quad \ell' = \mathbb{R}f_1 \oplus \cdots \oplus \mathbb{R}f_n$$

and let $(\boldsymbol{p}, \boldsymbol{q}) = (p_1, ..., p_n, q^1, ..., q^n)$ be the corresponding coordinates in V (see Section 2.6 in Chapter 1). Then $L^2\,(\ell', d^n\boldsymbol{v}') \simeq L^2\,(\mathbb{R}^n, d^n\boldsymbol{q})$ and

$$\mathrm{S}_\ell(\exp \boldsymbol{u}X) = U(\boldsymbol{u}) \quad \text{and} \quad \mathrm{S}_\ell(\exp \boldsymbol{v}Y) = V(\boldsymbol{v})$$

where $\boldsymbol{u}X = \sum_{k=1}^n u^k f_k, \boldsymbol{v}Y = \sum_{k=1}^n v_k e^k$, and $U(\boldsymbol{u}) = e^{-i\boldsymbol{u}\boldsymbol{P}}, V(\boldsymbol{v}) = e^{-i\boldsymbol{v}Q}$ are, respectively, n-parameter groups of unitary operators corresponding to momenta and coordinate operators $\boldsymbol{P}$ and $\boldsymbol{Q}$.

The mapping $*_\hbar$ - the new associative product on $L^1\,(\mathbb{R}^{2n})$ introduced in the last section - can also be described in invariant terms. Let $B_\hbar = G/\Gamma_\hbar$ be the quotient group, where $\Gamma_\hbar = \left\{\exp\left(\frac{2\pi n}{\hbar}c\right) \in G \middle|\ n \in \mathbb{Z}\right\}$ is a discrete central subgroup in G, and let $db = d^{2n}v \wedge d^*\alpha$ be the left-invariant Haar measure on $B_\hbar$, where $d^*\alpha$ is the normalized Haar measure on the circle $\mathbb{R}/\frac{2\pi}{\hbar}\mathbb{Z}$. The Banach space $L^1\,(B_\hbar, db)$ has an algebra structure with respect to the convolution:

$$(\varphi_1 *_{B_\hbar} \varphi_2)\,(b) = \int_{B_\hbar} \varphi_1\,(b_1)\,\varphi_2\left(b_1^{-1}b\right) db_1, \quad \varphi_1, \varphi_2 \in L^1\,(B_\hbar, db)$$

The correspondence

$$L^1\left(V, d^{2n}\boldsymbol{v}\right) \ni f(v) \mapsto \varphi(\exp(v + \alpha c)) = e^{-i\hbar\alpha} f(v) \in L^1\,(B_\hbar, db)$$

defines the inclusion map $L^1\,(V, d^{2n}\boldsymbol{v}) \hookrightarrow L^1\,(B_\hbar, db)$, and the image of $L^1\,(V, d^{2n}\boldsymbol{v})$ is a subalgebra of $L^1\,(B_\hbar, db)$ under the convolution. We have for $f_1, f_2 \in L^1\,(V, d^{2n}v)$,

$$\begin{aligned}(\varphi_1 *_{B_\hbar} \varphi_2)\,(\exp v) &= \int_{B_\hbar} \varphi_1(\exp(u + \alpha c))\varphi_2(\exp(-u - \alpha c)\exp v) d^{2n}\boldsymbol{v} d^*\alpha \\ &= \int_V \varphi_1(\exp u)\varphi_2\left(\exp(v - u)\exp\left(-\frac{1}{2}\omega(u, v)c\right)\right) d^{2n}\boldsymbol{v} \\ &= \int_V f_1(u) f_2(v - u) e^{\frac{i\hbar}{2}\omega(u,v)} d^{2n}\boldsymbol{v} \\ &= (f_1 *_\hbar f_2)\,(v), \quad v \in V\end{aligned}$$

Problem 3.

3. Prove that the Weyl transform is the restriction to $L^1\,(V, d^{2n}\boldsymbol{v})$ of the mapping

$$L^1\,(B_\hbar, db) \ni \varphi \mapsto \int_{B_\hbar} \varphi(b) S_\ell(b) db \in \mathscr{L}\,(\mathscr{H}_\ell)\,.$$

Problem 3.

4. Let ℓ_1, ℓ_2, ℓ_3 be Lagrangian subspaces of V. Define the triple Maslov index $\tau(\ell_1, \ell_2, \ell_3)$ as a signature of the quadratic form Q on $\ell_1 \oplus \ell_2 \oplus \ell_3$, defined by

$$Q(x_1, x_2, x_3) = \omega(x_1, x_2) + \omega(x_2, x_3) + \omega(x_3, x_1).$$

For Lagrangian subspaces ℓ_1, ℓ_2 of V let $\mathscr{F}_{\ell_2,\ell_1}$ be the unitary operator establishing the Hilbert space isomorphism $\mathscr{H}_{\ell_1} \simeq \mathscr{H}_{\ell_2}$ and intertwining representations S_{ℓ_1} and S_{ℓ_2},

$$\mathscr{F}_{\ell_2,\ell_1} S_{\ell_1}(g) = S_{\ell_2}(g) \mathscr{F}_{\ell_2,\ell_1}, \quad g \in G.$$

Prove that $\mathscr{F}_{\ell_1,\ell_3} \mathscr{F}_{\ell_3,\ell_2} \mathscr{F}_{\ell_2,\ell_1} = e^{-\pi i \tau(\ell_1,\ell_2,\ell_3)} I_1$, where I_1 is the identity operator in $\mathscr{H}_{\ell_1}$.

Problem 3.

5. Let $\mathrm{Sp}(V)$ be the symplectic group of (V, ω) - the subgroup of $\mathrm{GL}(V)$, preserving the symplectic form ω. The group $\mathrm{Sp}(V)$ acts as a group of automorphisms of the Heisenberg group G by the formula $h \cdot \exp(v + \alpha c) = \exp(h \cdot v + \alpha c), h \in \mathrm{Sp}(V), v \in V$. Let R be an irreducible unitary representation of G in the Hilbert space $\mathscr{H}$. Show that there exist unitary operators $U(h)$, defined up to multiplication by complex numbers of modulus 1, such that

$$U(h) R(g) U(h)^{-1} = R(h \cdot g), \quad h \in \mathrm{Sp}(V), \quad g \in G,$$

and that U defines a projective unitary representation of $\mathrm{Sp}(V)$ in $\mathscr{H}$, called the Shale-Weil representation. Find a realization of the Hilbert space $\mathscr{H}$ such that the 2-cocycle of the Shale-Weil representation is explicitly computed in terms of the Maslov index.

4.2.2 3. Weyl Relations 2

3.3. Weyl quantization

The Weyl transform, introduced in Section 3.1, defines a quantization of classical systems associated with the phase space $\mathbb{R}^{2n}$ with coordinates $\boldsymbol{p} = (p_1, ..., p_n), \boldsymbol{q} = (q^1, ..., q^n)$, and the Poisson bracket $\{,\} associated with the canonical symplectic form \omega = d\boldsymbol{p} \wedge d\boldsymbol{q}$. Let

$$\Phi = W \circ \mathscr{F}^{-1} : \mathscr{S}\left(\mathbb{R}^{2n}\right) \to \mathscr{L}(\mathscr{H})$$

where W is the Weyl transform and $\mathscr{F}^{-1}$ is the inverse Fourier transform, be the linear mapping of the Schwartz space $\mathscr{S}(\mathbb{R}^{2n})$ of complex-valued functions of rapid decay on $\mathbb{R}^{2n}$ into the Banach space of bounded operators $\mathscr{L}(\mathscr{H})$ on $\mathscr{H} = L^2(\mathbb{R}^n, d^n\boldsymbol{q})$. It is given explicitly by the integral

$$\Phi(f) = \frac{1}{(2\pi)^n} \int_{\mathbb{R}^{2n}} \check{f}(\boldsymbol{u}, \boldsymbol{v}) S(\boldsymbol{u}, \boldsymbol{v}) d^n\boldsymbol{u} d^n\boldsymbol{v}$$

understood as a limit of Riemann sums in the uniform topology on $\mathscr{L}(\mathscr{H})$, where

$$\check{f}(\boldsymbol{u}, \boldsymbol{v}) = \mathscr{F}^{-1}(f)(\boldsymbol{u}, \boldsymbol{v}) = \frac{1}{(2\pi)^n} \int_{\mathbb{R}^{2n}} f(\boldsymbol{p}, \boldsymbol{q}) e^{i(\boldsymbol{up}+\boldsymbol{vq})} d^n\boldsymbol{p} d^n\boldsymbol{q}$$

and $S(\boldsymbol{u}, \boldsymbol{v}) = e^{-\frac{i\hbar}{2}\boldsymbol{uv}} U(\boldsymbol{u}) V(\boldsymbol{v})$. It follows from (3.6) that $\Phi(f)$ is an integral operator: for every $\psi \in L^2(\mathbb{R}^n, d^n\boldsymbol{q})$,

$$(\Phi(f)\psi)(\boldsymbol{q}) = \int_{\mathbb{R}^n} K(\boldsymbol{q},\boldsymbol{q}')\,\psi(\boldsymbol{q}')\,d^n\boldsymbol{q}'$$

where

$$\begin{aligned} K(\boldsymbol{q},\boldsymbol{q}') &= \frac{1}{(2\pi\hbar)^n}\int_{\mathbb{R}^n} \check{f}\left(\frac{\boldsymbol{q}-\boldsymbol{q}'}{\hbar},\boldsymbol{v}\right) e^{-\frac{i}{2}\boldsymbol{v}(\boldsymbol{q}+\boldsymbol{q}')} d^n\boldsymbol{v} \\ &= \frac{1}{(2\pi\hbar)^n}\int_{\mathbb{R}^n} f\left(\boldsymbol{p},\frac{\boldsymbol{q}+\boldsymbol{q}'}{2}\right) e^{\frac{i}{\hbar}\boldsymbol{p}(\boldsymbol{q}-\boldsymbol{q}')} d^n\boldsymbol{p} \end{aligned}$$

Since the Schwartz space is self-dual with respect to the Fourier transform, $K \in \mathscr{S}(\mathbb{R}^n\times\mathbb{R}^n) \subset L^2(\mathbb{R}^n\times\mathbb{R}^n)$, so that $\Phi(f)$ is a Hilbert-Schmidt operator. Using the property $S(\boldsymbol{u},\boldsymbol{v})^* = S(-\boldsymbol{u},-\boldsymbol{v})$ we get

$$\Phi(f)^* = \Phi(\bar{f})$$

so that classical observables - real-valued functions on $\mathbb{R}^{2n}$, correspond to quantum observables - self-adjoint operators in $\mathscr{H}$. It follows from the property WT3 in Section 3.1 that the mapping Φ is injective; its image $\operatorname{Im}\Phi$ and the inverse mapping Φ^{-1} are explicitly described as follows.

Proposition 3.1. The subspace $\operatorname{Im}\Phi \subset \mathscr{L}(\mathscr{H})$ consists of operators $B \in \mathscr{S}_1$ such that corresponding functions $g(\boldsymbol{u},\boldsymbol{v}) = \hbar^n \operatorname{Tr}(BS(\boldsymbol{u},\boldsymbol{v})^{-1})$ belong to the Schwartz class $\mathscr{S}(\mathbb{R}^{2n})$; in this case $W(g) = B$. The inverse mapping $\Phi^{-1} = \mathscr{F}\circ W^{-1}$ is given by the Weyl's inversion formula

$$\check{f}(\boldsymbol{u},\boldsymbol{v}) = \hbar^n \operatorname{Tr}\left(\Phi(f)S(\boldsymbol{u},\boldsymbol{v})^{-1}\right), \quad f \in \mathscr{S}\left(\mathbb{R}^{2n}\right)$$

Proof. First consider the case $n = 1$. Let

$$H = \frac{P^2+Q^2}{2}$$

be the Hamiltonian of the harmonic oscillator with $m = 1$ and $\omega = 1$. According to Theorem 2.1, the operator H has a complete orthonormal system of real-valued eigenfunctions $\psi_n(q)$, given by Hermite-Tchebyscheff functions, with the eigenvalues $\hbar\left(n+\frac{1}{2}\right)$, so that the inverse operator $H^{-1} \in \mathscr{S}_2$. The operator $H\Phi(f)$ is an integral operator with the kernel $\frac{1}{2}\left(-\hbar^2\frac{\partial^2}{\partial q^2} + q^2\right)K(q,q')$, which is a Schwartz class function on $\mathbb{R}^2$, so that $H\Phi(f) \in \mathscr{S}_2$. The operator

$$\Phi(f) = H^{-1}H\Phi(f)$$

is a product of Hilbert-Schmidt operators and, therefore, is of trace class. Using the orthonormal basis $\{\psi_n(q)\}_{n=0}^{\infty}$ for $\mathscr{H} = L^2(\mathbb{R})$, we get

$$K(q,q') = \sum_{m,n=0}^{\infty} c_{mn}\psi_n(q)\psi_m(q') \tag{3.8}$$

where

$$c_{mn} = \int_{\mathbb{R}^2} K(q,q')\,\psi_n(q)\psi_m(q')\,dqdq'$$

and the series (3.8) converges in $L^2(\mathbb{R}^2)$. Since $K \in \mathscr{S}(\mathbb{R}^2)$, it follows from the N-representation theorem (see Problem 2.13) that this series is also convergent in the $\mathscr{S}(\mathbb{R}^2)$ topology. It is this fact which allows us to set $q' = q$ in (3.8) and to get the expansion

$$K(q,q)=\sum_{m,n=0}^{\infty}c_{mn}\psi_n(q)\psi_m(q)$$

which converges in $\mathscr{S}(\mathbb{R})$. Thus we obtain

$$\operatorname{Tr}\Phi(f)=\sum_{n=0}^{\infty}(\Phi(f)\psi_n,\psi_n)=\sum_{n=0}^{\infty}c_{nn}=\int_{-\infty}^{\infty}K(q,q)dq$$

where the interchange of orders of summation and integration is legitimate.
The general case $n>1$ is similar. We consider the operator

$$H=\frac{\boldsymbol{P}^2+\boldsymbol{Q}^2}{2}$$

and use the fact that operators $H^n\Phi(f)$ and H^{-n} are Hilbert-Schmidt. To prove the formula

$$\operatorname{Tr}\Phi(f)=\int_{\mathbb{R}^n}K(\boldsymbol{q},\boldsymbol{q})d^n\boldsymbol{q}$$

we expand the kernel $K(\boldsymbol{q},\boldsymbol{q}')$ using the orthonormal basis $\{\psi_{\boldsymbol{k}}(\boldsymbol{q})\}_{\boldsymbol{k},=0}^{\infty}$ for $L^2(\mathbb{R}^n)$, where

$$\psi_{\boldsymbol{k}}(\boldsymbol{q})=\psi_{k_1}(q_1)\cdots\psi_{k_n}(q_n),\quad \boldsymbol{k}=(k_1,...,k_n)$$

From the explicit form of the kernel K we get

$$\operatorname{Tr}\Phi(f)=\frac{1}{(2\pi\hbar)^n}\int_{\mathbb{R}^n}\int_{\mathbb{R}^n}\check{f}(0,\boldsymbol{v})e^{-i\boldsymbol{vq}}d^n\boldsymbol{v}d^n\boldsymbol{q}=\hbar^{-n}\check{f}(0,0)\tag{3.9}$$

which gives the inversion formula for $\boldsymbol{u}=\boldsymbol{v}=0$. To get the inversion formula for all $\boldsymbol{u},\boldsymbol{v}\in\mathbb{R}^n$, it is sufficient to apply (3.9) to the function $f_{uv}=\mathscr{F}\left(\check{f}_{u,v}\right)$, where

$$\check{f}_{\boldsymbol{u},\boldsymbol{v}}(\boldsymbol{u}',\boldsymbol{v}')=\check{f}(\boldsymbol{u}+\boldsymbol{u}',\boldsymbol{v}+\boldsymbol{v}')\,e^{\frac{i\hbar}{2}(\boldsymbol{v}'\boldsymbol{u}-\boldsymbol{u}'\boldsymbol{v})}$$

and to use $S(\boldsymbol{u},\boldsymbol{v})^{-1}=S(\boldsymbol{u},\boldsymbol{v})^*=S(-\boldsymbol{u},-\boldsymbol{v})$ and the property WT2 in Section 3.1,

$$W(\check{f})S(-\boldsymbol{u},-\boldsymbol{v})=W\left(\check{f}_{\boldsymbol{u},\boldsymbol{v}}\right)$$

To complete the proof, we need to show that $\operatorname{Im}\Phi$ consists of all $B\in\mathscr{S}_1$ with the property that the function $g(\boldsymbol{u},\boldsymbol{v})=\hbar^n\operatorname{Tr}\left(BS(\boldsymbol{u},\boldsymbol{v})^{-1}\right)$ belongs to the Schwartz class. By the inversion formula,

$$g(\boldsymbol{u},\boldsymbol{v})=\hbar^n\operatorname{Tr}\left(\Phi(f)S(\boldsymbol{u},\boldsymbol{v})^{-1}\right)$$

where $f=\mathscr{F}(g)$, so it is sufficient to prove that if

$$\operatorname{Tr}\left(BS(\boldsymbol{u},\boldsymbol{v})^{-1}\right)=0$$

for all $\boldsymbol{u},\boldsymbol{v}\in\mathbb{R}^n$, then $B=0$. Indeed, multiplying by $\overline{f(\boldsymbol{u},\boldsymbol{v})}$ and integrating, we get

$$\operatorname{Tr}BW(f)^*=0$$

for all $f\in\mathscr{S}(\mathbb{R}^{2n})$. Since Schwartz class functions are dense in $L^2(\mathbb{R}^{2n})$, by Lemma 3.1 we get $\operatorname{Tr}BB^*=0$ and, therefore, $B=0$.

Corollary 3.3.

$$\operatorname{Tr}\Phi(f)=\frac{1}{(2\pi\hbar)^n}\int_{\mathbb{R}^{2n}}f(\boldsymbol{p},\boldsymbol{q})d^n\boldsymbol{p}d^n\boldsymbol{q}$$

Remark. By the Schwartz kernel theorem, the operator $S(\boldsymbol{u},\boldsymbol{v})$ is an integral operator with the distributional kernel

$$e^{\frac{i\hbar}{2}\boldsymbol{u}\boldsymbol{v}-i\boldsymbol{v}\boldsymbol{q}}\delta\left(\boldsymbol{q}-\boldsymbol{q}'-\hbar\boldsymbol{u}\right)$$

so that

$$\operatorname{Tr} S(\boldsymbol{u},\boldsymbol{v})=\left(\frac{2\pi}{\hbar}\right)^{n}\delta(\boldsymbol{u})\delta(\boldsymbol{v})$$

Thus, as is customary in physics texts,

$$\operatorname{Tr}\Phi(f)=\hbar^{-n}\int_{\mathbb{R}^n}\check{f}(\boldsymbol{u},\boldsymbol{v})\delta(\boldsymbol{u})\delta(\boldsymbol{v})d^n\boldsymbol{u}d^n\boldsymbol{v}=\hbar^{-n}\check{f}(0,0)$$

Let $\mathcal{A}_0=\mathscr{S}\left(\mathbb{R}^{2n},\mathbb{R}\right)\subset\mathcal{A}$ be the subalgebra of classical observables on $\mathbb{R}^{2n}$ of rapid decay, and let $\mathscr{A}_0=\mathscr{A}\cap\mathscr{L}(\mathscr{H})$ be the space of bounded quantum observables.

Proposition 3.2. The mapping $\mathcal{A}_0\ni f\mapsto\Phi(f)\in\mathscr{A}_0$ is a quantization, i.e., it satisfies

$$\lim_{\hbar\to0}\frac{1}{2}\Phi^{-1}\left(\Phi\left(f_1\right)\Phi\left(f_2\right)+\Phi\left(f_2\right)\Phi\left(f_1\right)\right)=f_1f_2$$

and the correspondence principle

$$\lim_{\hbar\to0}\Phi^{-1}\left(\left\{\Phi\left(f_1\right),\Phi\left(f_2\right)\right\}_\hbar\right)=\left\{f_1,f_2\right\},\quad f_1,f_2\in\mathcal{A}_0$$

where

$$\left\{\Phi\left(f_1\right),\Phi\left(f_2\right)\right\}_\hbar=\frac{i}{\hbar}\left[\Phi\left(f_1\right),\Phi\left(f_2\right)\right]\quad\text{and}\quad\left\{f_1,f_2\right\}=\frac{\partial f_1}{\partial\boldsymbol{p}}\frac{\partial f_2}{\partial\boldsymbol{q}}-\frac{\partial f_1}{\partial\boldsymbol{q}}\frac{\partial f_2}{\partial\boldsymbol{p}}$$

are, respectively, the quantum bracket and the Poisson bracket.

Proof. In terms of the product $*_\hbar$ introduced in Section 3.1 we have

$$\Phi^{-1}\left(\Phi\left(f_1\right)\Phi\left(f_2\right)\right)=\mathscr{F}\left(\check{f}_1*_\hbar\check{f}_2\right)$$

and it follows from the property WT4 that

$$\Phi^{-1}\left(\Phi\left(f_1\right)\Phi\left(f_2\right)\right)(\boldsymbol{p},\boldsymbol{q})=\frac{1}{(2\pi)^{2n}}\int_{\mathbb{R}^{2n}}\int_{\mathbb{R}^{2n}}\check{f}_1\left(\boldsymbol{u}_1,\boldsymbol{v}_1\right)\check{f}_2\left(\boldsymbol{u}_2,\boldsymbol{v}_2\right)\cdot e^{\frac{i\hbar}{2}(\boldsymbol{u}_1\boldsymbol{v}_2-\boldsymbol{u}_2\boldsymbol{v}_1)-i(\boldsymbol{u}_1+\boldsymbol{u}_2)\boldsymbol{p}-i(\boldsymbol{v}_1+\boldsymbol{v}_2)\boldsymbol{q}}\boldsymbol{d}^n\boldsymbol{u}_1d^n\boldsymbol{u}_2d^n\boldsymbol{v}_1d^n\boldsymbol{v}_2\tag{3.10}$$

Using the expansion

$$e^{\frac{i\hbar}{2}(\boldsymbol{u}_1\boldsymbol{v}_2-\boldsymbol{u}_2\boldsymbol{v}_1)}=1+\frac{i\hbar}{2}\left(\boldsymbol{u}_1\boldsymbol{v}_2-\boldsymbol{u}_2\boldsymbol{v}_1\right)+O\left(\hbar^2\left(\boldsymbol{u}_1\boldsymbol{v}_2-\boldsymbol{u}_2\boldsymbol{v}_1\right)^2\right)$$

as $\hbar\to0$, and the basic properties of the Fourier transform,

$$\mathscr{F}(\boldsymbol{u}\check{f}(\boldsymbol{u},\boldsymbol{v}))=i\frac{\partial f}{\partial\boldsymbol{p}}(\boldsymbol{p},\boldsymbol{q})\quad\text{and}\quad\mathscr{F}(\boldsymbol{v}\check{f}(\boldsymbol{u},\boldsymbol{v}))=i\frac{\partial f}{\partial\boldsymbol{q}}(\boldsymbol{p},\boldsymbol{q})$$

we get from (3.10) that as $\hbar\to0$,

$$\Phi^{-1}\left(\Phi\left(f_1\right)\Phi\left(f_2\right)\right)(\boldsymbol{p},\boldsymbol{q})=\left(f_1f_2\right)(\boldsymbol{p},\boldsymbol{q})-\frac{i\hbar}{2}\left\{f_1,f_2\right\}(\boldsymbol{p},\boldsymbol{q})+O\left(\hbar^2\right)$$

Using skew-symmetry of the Poisson bracket completes the proof.

The quantization associated with the mapping $\Phi=W\circ\mathscr{F}^{-1}$ is called the Weyl quantization.

The correspondence $f \mapsto \Phi(f)$ can be easily extended to the vector space $\widehat{L^1(\mathbb{R}^{2n})}$ - the image of $L^1(\mathbb{R}^{2n})$ under the Fourier transform, which is a subspace of $C(\mathbb{R}^{2n})$. More generally, for $f \in \mathscr{S}(\mathbb{R}^{2n})'$ - the space of tempered distributions on $\mathbb{R}^{2n}$ - the corresponding kernel

$$K(\boldsymbol{q}, \boldsymbol{q}') = \frac{1}{(2\pi\hbar)^n} \int_{\mathbb{R}^n} f\left(\boldsymbol{p}, \frac{\boldsymbol{q}+\boldsymbol{q}'}{2}\right) e^{\frac{i}{\hbar}\boldsymbol{p}(\boldsymbol{q}-\boldsymbol{q}')} d^n\boldsymbol{p} \tag{3.11}$$

considered as a tempered distribution on $\mathbb{R}^n \times \mathbb{R}^n$, is a Schwartz kernel of the linear operator

$$\Phi(f) : \mathscr{S}(\mathbb{R}^n) \to \mathscr{S}(\mathbb{R}^n)'$$

In particular, the constant function $f = 1$ corresponds to the identity operator I with $K(\boldsymbol{q}, \boldsymbol{q}') = \delta(\boldsymbol{q} - \boldsymbol{q}')$. In terms of the kernel $K(\boldsymbol{q}, \boldsymbol{q}')$ the Weyl inversion formula takes the form

$$f(\boldsymbol{p}, \boldsymbol{q}) = \int_{\mathbb{R}^n} K\left(\boldsymbol{q} - \frac{1}{2}\boldsymbol{v}, \boldsymbol{q} + \frac{1}{2}\boldsymbol{v}\right) e^{\frac{i}{\hbar}\boldsymbol{v}\boldsymbol{v}} d^n\boldsymbol{v} \tag{3.12}$$

The distribution $f(\boldsymbol{p}, \boldsymbol{q})$ defined by (3.12) is called the Weyl symbol of the operator in $L^2(\mathbb{R}^n, d^n\boldsymbol{q})$ with the Schwartz kernel $K(\boldsymbol{q}, \boldsymbol{q}')$.

Examples below describe classes of distributions f such that the operators $\Phi(f)$ are essentially self-adjoint unbounded operators on the domain $\mathscr{S}(\mathbb{R}^n) \subset L^2(\mathbb{R}^n, d^n\boldsymbol{q})$.

Example 3.1. Let $f = f(\boldsymbol{q}) \in L^p(\mathbb{R}^n)$ for some $1 \leq p \leq \infty$, or let f be a polynomially bounded function as $|\boldsymbol{q}| \to \infty$. In the distributional sense,

$$\check{f}(\boldsymbol{u}, \boldsymbol{v}) = (2\pi)^{n/2} \delta(\boldsymbol{u}) \check{f}(\boldsymbol{v})$$

so that

$$\begin{aligned} K(\boldsymbol{q}, \boldsymbol{q}') &= \frac{1}{(\hbar\sqrt{2\pi})^n} \int_{\mathbb{R}^n} \delta\left(\frac{\boldsymbol{q} - \boldsymbol{q}'}{\hbar}\right) \check{f}(\boldsymbol{v}) e^{-\frac{i}{2}\boldsymbol{v}(\boldsymbol{q}+\boldsymbol{q}')} d^n\boldsymbol{v} \\ &= \delta(\boldsymbol{q} - \boldsymbol{q}') f\left(\frac{\boldsymbol{q}+\boldsymbol{q}'}{2}\right) = f(\boldsymbol{q}) \delta(\boldsymbol{q} - \boldsymbol{q}'). \end{aligned}$$

Thus the operator $\Phi(f)$ is a multiplication by $f(\boldsymbol{q})$ operator on $L^2(\mathbb{R}^n)$. In particular, coordinates $\boldsymbol{q}$ in classical mechanics correspond to coordinate operators $\boldsymbol{Q}$ in quantum mechanics. Similarly, if $f = f(\boldsymbol{p})$, then $\Phi(f) = f(\boldsymbol{P})$. In particular, momenta $\boldsymbol{p}$ in classical mechanics correspond to the momenta operators $\boldsymbol{P}$ in quantum mechanics.

Example 3.2. Let

$$H_{\mathrm{c}} = \frac{\boldsymbol{p}^2}{2m} + V(\boldsymbol{q})$$

be the Hamiltonian function in classical mechanics. Then $H = \Phi(H_c)$ is the corresponding Hamiltonian operator in quantum mechanics,

$$H = \frac{\boldsymbol{P}^2}{2m} + V(\boldsymbol{Q})$$

In Chapter 3 we give necessary conditions for the operator H to be essentially self-adjoint.

Example 3.3. Here we find $f \in \mathscr{S}(\mathbb{R}^{2n})'$ such that

$$\Phi(f) = P_\psi$$

- a pure state P_ψ, where $\psi \in L^2(\mathbb{R}^n), \|\psi\| = 1$. The projection P_ψ is an integral operator with the kernel $\psi(\boldsymbol{q})\overline{\psi(\boldsymbol{q}')}$, and we get from (3.11),

$$\frac{1}{(2\pi\hbar)^n}\int_{\mathbb{R}^n} f\left(\boldsymbol{p},\frac{\boldsymbol{q}+\boldsymbol{q}'}{2}\right)e^{\frac{i}{\hbar}\boldsymbol{p}(\boldsymbol{q}-\boldsymbol{q}')}d^n\boldsymbol{p}=\psi(\boldsymbol{q})\overline{\psi\left(\boldsymbol{q}'\right)}.$$

Introducing $\boldsymbol{q}_+=\frac{1}{2}\left(\boldsymbol{q}+\boldsymbol{q}'\right),\boldsymbol{q}_-=\frac{1}{2}\left(\boldsymbol{q}-\boldsymbol{q}'\right)$, we obtain

$$\check{f}\left(\frac{2\boldsymbol{q}_-}{\hbar},\boldsymbol{v}\right)=\hbar^n\int_{\mathbb{R}^n}\psi\left(\boldsymbol{q}_-+\boldsymbol{q}_+\right)\overline{\psi\left(\boldsymbol{q}_+-\boldsymbol{q}_-\right)}e^{i\boldsymbol{v}\boldsymbol{q}_+}d^n\boldsymbol{q}_+,$$

or

$$\check{f}(\boldsymbol{u},\boldsymbol{v})=\hbar^n\int_{\mathbb{R}^n}\psi\left(\boldsymbol{q}+\frac{1}{2}\hbar\boldsymbol{u}\right)\overline{\psi\left(\boldsymbol{q}-\frac{1}{2}\hbar\boldsymbol{u}\right)}e^{i\boldsymbol{v}\boldsymbol{q}}d^n\boldsymbol{q}.$$

Assuming that ψ does not depend on $\hbar$, we get in accordance with Corollary 3.3,

$$\check{\rho}(\boldsymbol{u},\boldsymbol{v})=\lim_{\hbar\to 0}\frac{1}{(2\pi\hbar)^n}\check{f}(\boldsymbol{u},\boldsymbol{v})=\frac{1}{(2\pi)^n}\int_{\mathbb{R}^n}|\psi(\boldsymbol{q})|^2e^{i\boldsymbol{v}\boldsymbol{q}}d^n\boldsymbol{v}.$$

Thus in the classical limit $\hbar\to 0$ the pure state P_ψ in quantum mechanics becomes a mixed state in classical mechanics, given by a probability measure $d\mu=\rho(\boldsymbol{p},\boldsymbol{q})d^n\boldsymbol{p}d^n\boldsymbol{q}$ on $\mathbb{R}^{2n}$ with the density

$$\rho(\boldsymbol{p},\boldsymbol{q})=\delta(\boldsymbol{p})|\psi(\boldsymbol{q})|^2$$

It describes a classical particle at rest ($\boldsymbol{p}=0$) with the distribution of coordinates given by the probability measure $|\psi(\boldsymbol{q})|^2d^n\boldsymbol{q}$ on $\mathbb{R}^n$. When $\psi(\boldsymbol{q})=e^{\frac{i}{\hbar}\boldsymbol{p}_0\boldsymbol{q}}\varphi(\boldsymbol{q})$, where $\varphi(\boldsymbol{q})$ does not depend on $\hbar$, the corresponding density is $\rho(\boldsymbol{p},\boldsymbol{q})=\delta\left(\boldsymbol{p}-\boldsymbol{p}_0\right)|\varphi(\boldsymbol{q})|^2$.

Remark. The Weyl quantization can be considered as a way of defining a function $f(\boldsymbol{P},\boldsymbol{Q})$ of non-commuting operators $\boldsymbol{P}=(P_1,...,P_n)$ and $\boldsymbol{Q}=(Q^1,...,Q^n)$ by setting

$$f(\boldsymbol{P},\boldsymbol{Q})=\Phi(f)$$

In particular, if $f(\boldsymbol{p},\boldsymbol{q})=g(\boldsymbol{p})+h(\boldsymbol{q})$, then

$$f(\boldsymbol{P},\boldsymbol{Q})=g(\boldsymbol{P})+h(\boldsymbol{Q})$$

For $f(\boldsymbol{p},\boldsymbol{q})=\boldsymbol{p}\boldsymbol{q}=p_1q^1+\cdots+p_nq^n$ we get, using (3.11),

$$f(\boldsymbol{P},\boldsymbol{Q})=\frac{\boldsymbol{P}\boldsymbol{Q}+\boldsymbol{Q}\boldsymbol{P}}{2}$$

This shows that the Weyl quantization symmetrizes products of the noncommuting factors $\boldsymbol{P}$ and $\boldsymbol{Q}$. In general, let f be a polynomial function,

$$f(\boldsymbol{p},\boldsymbol{q})=\sum_{|\alpha|,|\beta|\leq N}c_{\alpha\beta}\boldsymbol{p}^\alpha\boldsymbol{q}^\beta, \tag{3.13}$$

where for the multi-indices $\alpha=(\alpha_1,...,\alpha_n)$ and $\beta=(\beta_1,...,\beta_n)$,

$$\boldsymbol{p}^\alpha=p_1^{\alpha_1}...p_n^{\alpha_n},\quad \boldsymbol{q}^\beta=\left(q^1\right)^{\beta_1}...\left(q^n\right)^{\beta_n}$$

and $|\alpha|=\alpha_1+\cdots+\alpha_n,\quad |\beta|=\beta_1+\cdots+\beta_n$. Using (3.11), we get the following formula

$$\Phi(f)=\sum_{|\alpha|,|\beta|\leq N}c_{\alpha\beta}\,\mathrm{Sym}\left(\boldsymbol{P}^\alpha\boldsymbol{Q}^\beta\right) \tag{3.14}$$

Here $\mathrm{Sym}\left(\boldsymbol{P}^\alpha\boldsymbol{Q}^\beta\right)$ is a symmetric product, defined by

$$(\boldsymbol{uP}+\boldsymbol{vQ})^k=\sum_{|\alpha|+|\beta|=k}\frac{k!}{\alpha!\beta!}\boldsymbol{u}^\alpha\boldsymbol{v}^\beta\,\mathrm{Sym}\left(\boldsymbol{P}^\alpha\boldsymbol{Q}^\beta\right) \tag{3.15}$$

where $\boldsymbol{uP}+\boldsymbol{vQ}=u^1P_1+\cdots+u^nP_n+v_1Q^1+\cdots+v_nQ^n$ and

$$\alpha!=\alpha_1!...\alpha_n!,\quad \beta!=\beta_1!...\beta_n!$$

Remark. In addition to the Weyl quantization Φ, consider also the mappings $\Phi_1:\mathscr{S}\left(\mathbb{R}^{2n}\right)\to\mathscr{L}(\mathscr{H})$ and $\Phi_2:\mathscr{S}\left(\mathbb{R}^{2n}\right)\to\mathscr{L}(\mathscr{H})$, defined by

$$\Phi_1(f)=\frac{1}{(2\pi)^n}\int_{\mathbb{R}^{2n}}\check{f}(\boldsymbol{u},\boldsymbol{v})e^{\frac{i\hbar}{2}\boldsymbol{uv}}S(\boldsymbol{u},\boldsymbol{v})d^n\boldsymbol{u}d^n\boldsymbol{v}$$

and

$$\Phi_2(f)=\frac{1}{(2\pi)^n}\int_{\mathbb{R}^{2n}}\check{f}(\boldsymbol{u},\boldsymbol{v})e^{-\frac{i\hbar}{2}\boldsymbol{uv}}S(\boldsymbol{u},\boldsymbol{v})d^n\boldsymbol{u}d^n\boldsymbol{v}$$

where $\check{f}=\mathscr{F}^{-1}(f)$ is the inverse Fourier transform. Though Φ_1 and Φ_2 no longer map $\mathcal{A}_0$ into the real vector space $\mathscr{A}_0$ of bounded quantum observables, they satisfy all the properties in Proposition 3.2. It follows from (3.5) that for $f\in\mathscr{S}\left(\mathbb{R}^{2n}\right)$ the operators $\Phi_1(f)$ and $\Phi_2(f)$ are integral operators with the integral kernels

$$K_1\left(\boldsymbol{q},\boldsymbol{q}'\right)=\frac{1}{(2\pi\hbar)^n}\int_{\mathbb{R}^n}f\left(\boldsymbol{p},\boldsymbol{q}'\right)e^{\frac{i}{\hbar}\boldsymbol{p}(\boldsymbol{q}-\boldsymbol{q}')}d^n\boldsymbol{p}$$

and

$$K_2\left(\boldsymbol{q},\boldsymbol{q}'\right)=\frac{1}{(2\pi\hbar)^n}\int_{\mathbb{R}^n}f(\boldsymbol{p},\boldsymbol{q})e^{\frac{i}{\hbar}\boldsymbol{p}(\boldsymbol{q}-\boldsymbol{q}')}d^n\boldsymbol{p}$$

respectively. As in the case of the Weyl quantization, these formulas extend the mappings $f\mapsto\Phi_1(f)$ and $f\mapsto\Phi_2(f)$ of the space $\mathscr{S}\left(\mathbb{R}^{2n}\right)'$ of tempered distributions on $\mathbb{R}^{2n}$. In particular, if $f(\boldsymbol{p},\boldsymbol{q})$ is a polynomial function (3.13), then

$$\Phi_1(f)=\sum_{|\alpha|,|\beta|\leq N}c_{\alpha\beta}\boldsymbol{P}^\alpha\boldsymbol{Q}^\beta \tag{3.16}$$

and

$$\Phi_2(f)=\sum_{|\alpha|,|\beta|\leq N}c_{\alpha\beta}\boldsymbol{Q}^\beta\boldsymbol{P}^\alpha. \tag{3.17}$$

Therefore the mapping $f\mapsto\Phi_1(f)$ is called the pq-quantization, and the mapping $f\mapsto\Phi_2(f)$ - the $\boldsymbol{qp}$-quantization. Corresponding inversion formulas are

$$f(\boldsymbol{p},\boldsymbol{q})=\int_{\mathbb{R}^n}K_1(\boldsymbol{q}-\boldsymbol{v},\boldsymbol{q})e^{\frac{i}{\hbar}\boldsymbol{pv}}d^n\boldsymbol{v} \tag{3.18}$$

and

$$f(\boldsymbol{p},\boldsymbol{q})=\int_{\mathbb{R}^n}K_2(\boldsymbol{q},\boldsymbol{q}+\boldsymbol{v})e^{\frac{i}{\hbar}\boldsymbol{pv}}d^n\boldsymbol{v} \tag{3.19}$$

The distribution $f(\boldsymbol{p},\boldsymbol{q})$ defined by (3.18) is called the $\boldsymbol{pq}$-symbol of an operator with the Schwartz kernel $K_1\left(\boldsymbol{q},\boldsymbol{q}'\right)$, and the distribution $f(\boldsymbol{p},\boldsymbol{q})$ defined by (3.19) - the $\boldsymbol{qp}$-symbol of an operator with the Schwartz kernel $K_2\left(\boldsymbol{q},\boldsymbol{q}'\right)$. The $\boldsymbol{qp}$-symbols are commonly used in the theory of pseudodifferential operators. It follows from (3.18) and (3.19) that if $f(\boldsymbol{p},\boldsymbol{q})$ is a $\boldsymbol{pq}$-symbol of the operator $\Phi_1(f)$, then $\overline{f(\boldsymbol{p},\boldsymbol{q})}$ is a $\boldsymbol{qp}$-symbol of the adjoint operator $\Phi_1(f)^*$.

Problem 3.

6. Prove formula (3.14).

Problem 3.

7. Prove formulas (3.16)-(3.17).

Problem 3.

8. Prove that Weyl, pq, and $\boldsymbol{qp}$-quantizations are equivalent. (Hint: Find the relations between Weyl, $\boldsymbol{pq}$, and $\boldsymbol{qp}$-symbols of a given operator.)

3.4. The $\star$-product.

The Weyl quantization $\Phi : \mathscr{S}(\mathbb{R}^{2n}) \to \mathscr{L}(\mathscr{H})$, studied in the previous section, defines a new bilinear operation

$$\star_\hbar : \mathscr{S}\left(\mathbb{R}^{2n}\right) \times \mathscr{S}\left(\mathbb{R}^{2n}\right) \to \mathscr{S}\left(\mathbb{R}^{2n}\right)$$

on $\mathscr{S}(\mathbb{R}^{2n})$ by the formula

$$f_1 \star_\hbar f_2 = \Phi^{-1}\left(\Phi\left(f_1\right)\Phi\left(f_2\right)\right).$$

This operation is called the $\star$-product [26]. According to (3.10),

$$\left(f_1 \star_\hbar f_2\right)(\boldsymbol{p},\boldsymbol{q}) = \frac{1}{(2\pi)^{2n}} \int_{\mathbb{R}^{2n}} \int_{\mathbb{R}^{2n}} \check{f}_1(\boldsymbol{u}_1,\boldsymbol{v}_1)\, \check{f}_2(\boldsymbol{u}_2,\boldsymbol{v}_2)\, . \tag{3.20}$$
$$. \, e^{\frac{i\hbar}{2}(\boldsymbol{u}_1\boldsymbol{v}_2 - \boldsymbol{u}_2\boldsymbol{v}_1) - i(\boldsymbol{u}_1+\boldsymbol{u}_2)\boldsymbol{p} - i(\boldsymbol{v}_1+\boldsymbol{v}_2)\boldsymbol{q}} d^n\boldsymbol{u}_1 d^n\boldsymbol{u}_2 d^n\boldsymbol{v}_1 d^n\boldsymbol{v}_2.$$

The *-product on $\mathscr{S}(\mathbb{R}^{2n})$ has the following properties.

1. Associativity:

$$f_1 \star_\hbar (f_2 \star_\hbar f_3) = (f_1 \star_\hbar f_2) \star_\hbar f_3.$$

2. Semi-classical limit:

$$\left(f_1 \star_\hbar f_2\right)(\boldsymbol{p},\boldsymbol{q}) = \left(f_1 f_2\right)(\boldsymbol{p},\boldsymbol{q}) - \frac{i\hbar}{2}\left\{f_1, f_2\right\}(\boldsymbol{p},\boldsymbol{q}) + O\left(\hbar^2\right) \text{ as } \hbar \to 0$$

3. Property of the unit:

$$f \star_\hbar \mathbf{1} = \mathbf{1} \star_\hbar f,$$

where 1 is a function which identically equals 1 on $\mathbb{R}^{2n}$.

4. The cyclic trace property:

$$\tau\left(f_1 \star_\hbar f_2\right) = \tau\left(f_2 \star_\hbar f_1\right)$$

where the $\mathbb{C}$-linear map $\tau : \mathscr{S}\left(\mathbb{R}^{2n}\right) \to \mathbb{C}$ is defined by

$$\tau(f) = \frac{1}{(2\pi\hbar)^n} \int_{\mathbb{R}^{2n}} f(\boldsymbol{p}, \boldsymbol{q}) d^n\boldsymbol{p} d^n\boldsymbol{q}$$

Property 1 follows from the corresponding property for the product $*_\hbar$ (see Section 3.1), property 2 follows from Proposition 3.2, and properties 3 and 4 directly follow from the definition (3.20). The complex vector space $\mathscr{S}\left(\mathbb{R}^{2n}\right) \oplus \mathbb{C}1$ with the bilinear operation $\star_\hbar$ is an associative algebra over $\mathbb{C}$ with unit 1 and the cyclic trace τ, satisfying the correspondence principle,

$$\lim_{\hbar\to 0} \frac{i}{\hbar}\left(f_1 \star_\hbar f_2 - f_2 \star_\hbar f_1\right) = \{f_1, f_2\}\,.$$

Consider the tensor product of Hilbert spaces

$$L^2\left(\mathbb{R}^{2n}\right) \otimes L^2\left(\mathbb{R}^{2n}\right) \simeq L^2\left(\mathbb{R}^{2n} \times \mathbb{R}^{2n}\right)$$

and define the unitary operator $\boldsymbol{U}_1$ on $L^2\left(\mathbb{R}^{2n}\right) \otimes L^2\left(\mathbb{R}^{2n}\right)$ by

$$\boldsymbol{U}_1 = e^{-\frac{i\hbar}{2}\left(\frac{\partial}{\partial \boldsymbol{p}} \otimes \frac{\partial}{\partial \boldsymbol{q}}\right)}$$

where

$$\frac{\partial}{\partial \boldsymbol{p}} \otimes \frac{\partial}{\partial \boldsymbol{q}} = \sum_{k=1}^{n} \frac{\partial}{\partial p_k} \otimes \frac{\partial}{\partial q^k}$$

It follows from the theory of Fourier transform that for $f_1, f_2 \in \mathscr{S}\left(\mathbb{R}^{2n}\right)$,

$$\left(\boldsymbol{U}_1\left(f_1 \otimes f_2\right)\right)\left(\boldsymbol{p}_1, \boldsymbol{q}_1, \boldsymbol{p}_2, \boldsymbol{q}_2\right) = \frac{1}{(2\pi)^{2n}} \int_{\mathbb{R}^{2n}} \int_{\mathbb{R}^{2n}} \check{f}_1\left(\boldsymbol{u}_1, \boldsymbol{v}_1\right) \check{f}_2\left(\boldsymbol{u}_2, \boldsymbol{v}_2\right).$$
$$\cdot e^{\frac{i\hbar}{2}\boldsymbol{u}_1\boldsymbol{v}_2 - i\boldsymbol{u}_1\boldsymbol{p}_1 - i\boldsymbol{u}_2\boldsymbol{p}_2 - i\boldsymbol{v}_1\boldsymbol{q}_1 - i\boldsymbol{v}_2\boldsymbol{q}_2} d^n\boldsymbol{u}_1 d^n\boldsymbol{u}_2 d^n\boldsymbol{v}_1 d^n\boldsymbol{v}_2$$

Similarly, defining the unitary operator $\boldsymbol{U}_2$ on $L^2\left(\mathbb{R}^{2n}\right) \otimes L^2\left(\mathbb{R}^{2n}\right)$ by

$$\boldsymbol{U}_2 = e^{-\frac{i\hbar}{2}\left(\frac{\partial}{\partial \boldsymbol{q}} \otimes \frac{\partial}{\partial p}\right)}$$

we get

$$\left(\boldsymbol{U}_2\left(f_1 \otimes f_2\right)\right)\left(\boldsymbol{p}_1, \boldsymbol{q}_1, \boldsymbol{p}_2, \boldsymbol{q}_2\right) = \frac{1}{(2\pi)^{2n}} \int_{\mathbb{R}^{2n}} \int_{\mathbb{R}^{2n}} \check{f}_1\left(\boldsymbol{u}_1, \boldsymbol{v}_1\right) \check{f}_2\left(\boldsymbol{u}_2, \boldsymbol{v}_2\right)$$
$$\cdot e^{\frac{i\hbar}{2}\boldsymbol{u}_2\boldsymbol{v}_1 - i\boldsymbol{u}_1\boldsymbol{p}_1 - i\boldsymbol{u}_2\boldsymbol{p}_2 - i\boldsymbol{v}_1\boldsymbol{q}_1 - \boldsymbol{v}_2\boldsymbol{q}_2} d^n\boldsymbol{u}_1 d^n\boldsymbol{u}_2 d^n\boldsymbol{v}_1 d^n\boldsymbol{v}_2$$

Finally, define the unitary operator $\boldsymbol{U}_\hbar$ on $L^2\left(\mathbb{R}^{2n}\right) \otimes L^2\left(\mathbb{R}^{2n}\right)$ by

$$\boldsymbol{U}_\hbar = \boldsymbol{U}_1\boldsymbol{U}_2^{-1} = e^{-\frac{i\hbar}{2}\left(\frac{\partial}{\partial \boldsymbol{p}} \otimes \frac{\partial}{\partial \boldsymbol{q}} - \frac{\partial}{\partial \boldsymbol{q}} \otimes \frac{\partial}{\partial \boldsymbol{p}}\right)}$$

and denote by $m : \mathscr{S}\left(\mathbb{R}^{2n}\right) \otimes \mathscr{S}\left(\mathbb{R}^{2n}\right) \to \mathscr{S}\left(\mathbb{R}^{2n}\right)$ the point-wise product of functions, $\left(m\left(f_1 \otimes f_2\right)\right)\left(\boldsymbol{p}, \boldsymbol{q}\right) = f_1(\boldsymbol{p}, \boldsymbol{q}) f_2(\boldsymbol{p}, \boldsymbol{q})$. Then the $\star$-product can be written in the following concise form:

$$f_1 \star_\hbar f_2 = \left(m \circ \boldsymbol{U}_\hbar\right)\left(f_1 \otimes f_2\right). \tag{3.21}$$

[026] Also called Moyal product in physics.

In analogy with the Poisson bracket $\{,\} on \mathbb{R}^{2n}$ associated with the canonical symplectic form $\omega = d\boldsymbol{p} \wedge d\boldsymbol{q}$,

$$\{f_1, f_2\} = \frac{\partial f_1}{\partial \boldsymbol{p}} \frac{\partial f_2}{\partial \boldsymbol{q}} - \frac{\partial f_1}{\partial \boldsymbol{q}} \frac{\partial f_2}{\partial \boldsymbol{p}}$$

we introduce the notation

$$\{\overset{\otimes}{,}\} = \frac{\partial}{\partial \boldsymbol{p}} \otimes \frac{\partial}{\partial \boldsymbol{q}} - \frac{\partial}{\partial \boldsymbol{q}} \otimes \frac{\partial}{\partial \boldsymbol{p}} = \frac{\partial^2}{\partial \boldsymbol{p}_1 \partial \boldsymbol{q}_2} - \frac{\partial^2}{\partial \boldsymbol{q}_1 \partial \boldsymbol{p}_2}.$$

Then it follows from the theory of Fourier transform that formula (3.21) for the $*$-product can be rewritten as

$$\left(f_1 \star_\hbar f_2\right)(\boldsymbol{p}, \boldsymbol{q}) = \left(e^{-\frac{i\hbar}{2}\{\overset{\otimes}{P}\}} f_1\left(\boldsymbol{p}_1, \boldsymbol{q}_1\right) f_2\left(\boldsymbol{p}_2, \boldsymbol{q}_2\right) \right)\Big|_{\substack{\boldsymbol{p}_1=\boldsymbol{p}_2=\boldsymbol{p} \\ \boldsymbol{q}_1=\boldsymbol{q}_2=\boldsymbol{q}}}. \tag{3.22}$$

Thus we have shown that on $\mathscr{S}\left(\mathbb{R}^{2n}\right)$ the $\star$-product can be equivalently defined by (3.20), or by (3.21) and (3.22). The latter representation has the advantage that the formal expansion of the exponential $e^{-\frac{i\hbar}{2}\{\overset{\otimes}{,}\}}$ into the power series gives the asymptotic expansion of the $\star$-product as $\hbar \to 0$. Namely, define the bidifferential operators

$$B_k : \mathscr{S}\left(\mathbb{R}^{2n}\right) \otimes \mathscr{S}\left(\mathbb{R}^{2n}\right) \to \mathscr{S}\left(\mathbb{R}^{2n}\right)$$

by $B_k = m \circ \{\overset{\otimes}{,}\}^k$ for $k \geq 1$ and $B_0 = m$.

Lemma 3.2. For every $f_1, f_2 \in \mathscr{S}\left(\mathbb{R}^{2n}\right)$ and $l \in \mathbb{N}$ there is $C > 0$ such that for all $\boldsymbol{p}, \boldsymbol{q} \in \mathbb{R}^{2n}$

$$\left| \left(f_1 \star_\hbar f_2\right)(\boldsymbol{p}, \boldsymbol{q}) - \sum_{k=0}^{l} \frac{(-i\hbar)^k}{2^k k!} B_k\left(f_1, f_2\right)(\boldsymbol{p}, \boldsymbol{q}) \right| \leq C\hbar^{l+1} \quad \text{as} \quad \hbar \to 0$$

Succinctly,

$$\left(f_1 \star_\hbar f_2\right)(\boldsymbol{p}, \boldsymbol{q}) = \sum_{k=0}^{\infty} \frac{(-i\hbar)^k}{2^k k!} B_k\left(f_1, f_2\right)(\boldsymbol{p}, \boldsymbol{q}) + O\left(\hbar^\infty\right). \tag{3.23}$$

Proof. Expanding the exponential function $e^{\frac{i\hbar}{2}(\boldsymbol{u}_1 \boldsymbol{v}_2 - \boldsymbol{u}_2 \boldsymbol{v}_1)}$ into the power series and repeating the proof of Proposition 3.2 gives the result.

Finally, we get another integral representation for the $\star$-product. Applying the Fourier inversion formula to the integral over $d^n\boldsymbol{u}_1 d^n\boldsymbol{v}_1$ in (3.20), we get

$$\begin{aligned}
\left(f_1 \star_\hbar f_2\right)(\boldsymbol{p}, \boldsymbol{q}) &= \frac{1}{(2\pi)^n} \int_{\mathbb{R}^{2n}} f_1\left(\boldsymbol{p} - \frac{\hbar}{2}\boldsymbol{v}_2, \boldsymbol{q} + \frac{\hbar}{2}\boldsymbol{u}_2\right) \check{f}_2\left(\boldsymbol{u}_2, \boldsymbol{v}_2\right) \\
&= \frac{1}{(2\pi)^{2n}} \int_{\mathbb{R}^{2n}} \int_{\mathbb{R}^{2n}} f_1\left(\boldsymbol{p} - \frac{\hbar}{2}\boldsymbol{v}_2, \boldsymbol{q} + \frac{\hbar}{2}\boldsymbol{u}_2\right) f_2\left(\boldsymbol{p}_2, \boldsymbol{q}_2\right) \\
&\quad \cdot e^{-i\boldsymbol{u}_2\boldsymbol{p} - i\boldsymbol{v}_2\boldsymbol{q}} d^n\boldsymbol{u}_2 d^n\boldsymbol{v}_2 - i\boldsymbol{v}_2\boldsymbol{q} + i\boldsymbol{u}_2\boldsymbol{p}_2 + i\boldsymbol{v}_2\boldsymbol{q}_2 \\
&\quad d^n\boldsymbol{p}_2 d^n\boldsymbol{q}_2 d^n\boldsymbol{u}_2 d^n\boldsymbol{v}_2
\end{aligned}$$

and changing variables $\boldsymbol{p}_1 = \boldsymbol{p} - \frac{\hbar}{2}\boldsymbol{v}_2, \boldsymbol{q}_1 = \boldsymbol{q} + \frac{\hbar}{2}\boldsymbol{u}_2$, we obtain

$$\begin{aligned}
\left(f_1 \star_\hbar f_2\right)(\boldsymbol{p}, \boldsymbol{q}) &= \frac{1}{(\pi\hbar)^{2n}} \int_{\mathbb{R}^{2n}} \int_{\mathbb{R}^{2n}} f_1\left(\boldsymbol{p}_1, \boldsymbol{q}_1\right) f_2\left(\boldsymbol{p}_2, \boldsymbol{q}_2\right). \\
&\quad \cdot e^{\frac{2i}{\hbar}(\boldsymbol{p}_1\boldsymbol{q} - \boldsymbol{p}\boldsymbol{q}_1 + \boldsymbol{q}_1\boldsymbol{p}_2 - \boldsymbol{q}_2\boldsymbol{p}_1 + \boldsymbol{p}\boldsymbol{q}_2 - \boldsymbol{p}_2\boldsymbol{q})} d^n\boldsymbol{p}_1 d^n\boldsymbol{q}_1 d^n\boldsymbol{p}_2 d^n\boldsymbol{q}_2.
\end{aligned}$$

Let $\triangle$ be a Euclidean triangle (a 2 -simplex) in the phase space $\mathbb{R}^{2n}$ with the vertices $(\boldsymbol{p},\boldsymbol{q}),(\boldsymbol{p}_1,\boldsymbol{q}_1)$, and $(\boldsymbol{p}_2,\boldsymbol{q}_2)$. It is easy to see that

$$\boldsymbol{p}_1\boldsymbol{q}-\boldsymbol{p}\boldsymbol{q}_1+\boldsymbol{q}_1\boldsymbol{p}_2-\boldsymbol{q}_2\boldsymbol{p}_1+\boldsymbol{p}\boldsymbol{q}_2-\boldsymbol{p}_2\boldsymbol{q}=2\int_{\triangle}\omega$$

which is twice the symplectic area of $\triangle$ - the sum of oriented areas of the projections of $\triangle$ onto two-dimensional planes $(p_1,q^1),...,(p_n,q^n)$. Thus we have the final formula

$$\begin{aligned}(f_1\star_\hbar f_2)(\boldsymbol{p},\boldsymbol{q})=\frac{1}{(\pi\hbar)^{2n}}\int_{\mathbb{R}^{2n}}\int_{\mathbb{R}^{2n}}f_1(\boldsymbol{p}_1,\boldsymbol{q}_1)\,f_2(\boldsymbol{p}_2,\boldsymbol{q}_2)\\ \cdot e^{\frac{4i}{\hbar}\int_{\triangle}\omega}d^n\boldsymbol{p}_1d^n\boldsymbol{q}_1d^n\boldsymbol{p}_2d^n\boldsymbol{q}_2\end{aligned}\tag{3.24}$$

which is a composition formula for the Weyl symbols.
Remark. It is instructive to compare formulas (3.23) and (3.24). The latter formula represents the $\star$-product on $\mathscr{S}(\mathbb{R}^{2n})$ as an absolutely convergent integral, and is equivalent to the Weyl quantization. The former formula is an asymptotic expansion of the $\star$-product as $\hbar\to 0$, and does not capture all properties of the Weyl quantization. In general, the power series in (3.23) diverges; for polynomial functions this series becomes a finite sum and gives a formula for the $\star$-product of polynomials.

Problem 3.

9 (Composition formula for $\boldsymbol{pq}$-symbols). Let $f_1(\boldsymbol{p},\boldsymbol{q})$ and $f_2(\boldsymbol{p},\boldsymbol{q})$ be, respectively, the $\boldsymbol{pq}$-symbols of the operators $\Phi_1(f_1)$ and $\Phi_1(f_2)$. Show that the pq-symbol of the operator $\Phi_1(f_1)\Phi_1(f_2)$ is given by

$$f(\boldsymbol{p},\boldsymbol{q})=\frac{1}{(2\pi h)^n}\int_{\mathbb{R}^{2n}}f_1(\boldsymbol{p},\boldsymbol{q}_1)\,f_2(\boldsymbol{p}_1,\boldsymbol{q})\,e^{\frac{i}{\hbar}(\boldsymbol{p}-\boldsymbol{p}_1)(\boldsymbol{q}-\boldsymbol{q}_1)}d^n\boldsymbol{p}_1d^n\boldsymbol{q}_1.$$

(Hint: Use the formula for $(m\circ\boldsymbol{U}_1^2)(f_1\otimes f_2)$.)

Problem 3.

10 (Composition formula for $\boldsymbol{qp}$-symbols). Let $f_1(\boldsymbol{p},\boldsymbol{q})$ and $f_2(\boldsymbol{p},\boldsymbol{q})$ be, respectively, the $\boldsymbol{qp}$-symbols of the operators $\Phi_2(f_1)$ and $\Phi_2(f_2)$. Show that the qp-symbol of the operator $\Phi_2(f_1)\Phi_2(f_2)$ is given by

$$f(\boldsymbol{p},\boldsymbol{q})=\frac{1}{(2\pi\hbar)^n}\int_{\mathbb{R}^{2n}}f_1(\boldsymbol{p}_1,\boldsymbol{q})\,f_2(\boldsymbol{p},\boldsymbol{q}_1)\,e^{-\frac{i}{\hbar}(\boldsymbol{p}-\boldsymbol{p}_1)(\boldsymbol{q}-\boldsymbol{q}_1)}d^n\boldsymbol{p}_1d^n\boldsymbol{q}_1$$

(Hint: Use the formula for $\left(m\circ\boldsymbol{U}_2^{-2}\right)(f_1\otimes f_2)$.)

Problem 3.

11. Using (3.24) prove that the $\star$-product is associative.

Problem 3.

12. For classical observable $f(\boldsymbol{p},\boldsymbol{q})$ define the $\star$-exponential (the analog of the evolution operator) by

$$\exp_\star f = \sum_{n=0}^{\infty} \frac{\hbar^{-n}}{n!} \underbrace{f \star_\hbar f \star_\hbar \cdots \star_\hbar f}_{n}.$$

Compute $\exp_\star(-itH_{\rm c})$, where $H_{\rm c}(\boldsymbol{p},\boldsymbol{q})$ is the Hamiltonian function (2.27) of the harmonic oscillator.

4.2.3 3. Weyl Relations 3: Deformation quantization

3.5. Deformation quantization.

Here we consider the quantization procedure from a formal algebraic point of view as the deformation theory of associative algebras. Let $\mathcal{A}$ be a $\mathbb{C}$-algebra (or an associative algebra with unit over a field k of characteristic zero) with a bilinear multiplication map $m_0 : \mathcal{A} \otimes_{\mathbb{C}} \mathcal{A} \to \mathcal{A}$, which we will abbreviate as $a \cdot b = m_0(a,b)$. Denote by $\mathbb{C}[[t]]$ the ring of formal power series in t with coefficients in $\mathbb{C}$,

$$\mathbb{C}[[t]] = \left\{ \sum_{n=0}^{\infty} a_n t^n : a_n \in \mathbb{C} \right\},$$

and let

$$\mathcal{A}_t = \mathbb{C}[[t]] \otimes_{\mathbb{C}} \mathcal{A}$$

be the $\mathbb{C}[[t]]$-algebra of formal power series in t with coefficients in $\mathcal{A}$. The multiplication in $\mathcal{A}_t$ is a $\mathbb{C}[[t]]$-bilinear extension of the multiplication in $\mathcal{A}$, which we continue to denote by m_0. The algebra $\mathcal{A}_t$ is $\mathbb{Z}$-graded,

$$\mathcal{A}_t = \bigoplus_{n=0}^{\infty} A_n,$$

where $A_n = t^n \mathcal{A}$, so that $A_m \cdot A_m \subset A_{m+n}$.

Definition. A formal deformation of a $\mathbb{C}$-algebra $\mathcal{A}$ with a multiplication m_0 is an associative algebra $\mathcal{A}_t$ over the ring $\mathbb{C}[[t]]$ with a $\mathbb{C}[[t]]$-bilinear multiplication map $m_t : \mathcal{A}_t \otimes_{\mathbb{C}[[t]]} \mathcal{A}_t \to \mathcal{A}_t$ such that

$$m_t(a,b) = a \cdot b + \sum_{n=1}^{\infty} t^n m_n(a,b)$$

for all $a, b \in \mathcal{A}$, where $m_n : \mathcal{A} \otimes_{\mathbb{C}} \mathcal{A} \to \mathcal{A}$ are bilinear mappings.
It follows from $\mathbb{C}[[t]]$-bilinearity of m_t that the associativity condition is equivalent to

$$m_t\left(m_t(a,b),c\right) = m_t\left(a, m_t(b,c)\right) \tag{3.25}$$

for all $a, b, c \in \mathcal{A}$.

Definition. Two formal deformations m_t and $\tilde{m}_t$ of a $\mathbb{C}$-algebra $\mathcal{A}$ are equivalent if there is a $\mathbb{C}[[t]]$-linear mapping $F_t : \mathcal{A}_t \to \mathcal{A}_t$ such that
(i) for every $a \in \mathcal{A}$,

$$F_t(a) = a + \sum_{n=1}^{\infty} t^n f_n(a)$$

where $f_n : \mathcal{A} \to \mathcal{A}$ are linear mappings;
(ii) for all $a, b \in \mathcal{A}$,

$$F_t\left(\tilde{m}_t(a,b)\right) = m_t\left(F_t(a), F_t(b)\right)$$

The bilinear maps m_n satisfy infinitely many relations which are obtained by expanding (3.25) into formal power series in t. The first two of them, arising from comparing the coefficients at t and t^2, are

$$a \cdot m_1(b,c) - m_1(a \cdot b, c) + m_1(a, b \cdot c) - m_1(a,b) \cdot c = 0,$$

and

$$\begin{aligned} a \cdot m_2(b,c) - m_2(a \cdot b, c) + m_2(a, b \cdot c) - m_2(a,b) \cdot c \\ = m_1\left(m_1(a,b), c\right) - m_1\left(a, m_1(b,c)\right). \end{aligned}$$

In general

$$\begin{aligned} a \cdot m_n(b,c) - m_n(a \cdot b, c) + m_n(a, b \cdot c) - m_n(a,b) \cdot c \\ = \sum_{j=1}^{n-1} \left(m_j\left(m_{n-j}(a,b), c\right) - m_j\left(a, m_{n-j}(b,c)\right)\right). \end{aligned}$$

The main tool for understanding these equations and studying the deformation theory of associative algebras is the Hochschild cohomology. Namely, let M be an $\mathcal{A}$-bimodule, i.e., a left and right module for the $\mathbb{C}$-algebra $\mathcal{A}$.

Definition. The Hochschild cochain complex $C^\bullet(\mathcal{A}, M)$ of a $\mathbb{C}$-algebra $\mathcal{A}$ with coefficients in $\mathcal{A}$-bimodule M is defined by the cochains

$$\mathbb{C}^n(\mathcal{A}, M) = \mathrm{Hom}_{\mathbb{C}}\left(\mathcal{A}^{\otimes n}, M\right)$$

i.e., n-linear maps $f\left(a_1, ..., a_n\right)$ on $\mathcal{A}$ with values in M, and the differential $d_n : C^n(\mathcal{A}, M) \to C^{n+1}(\mathcal{A}, M)$,

$$\begin{aligned} \left(d_n f\right)\left(a_1, a_2, ..., a_{n+1}\right) =& a_1 \cdot f\left(a_2, ..., a_{n+1}\right) \\ &+ \sum_{j=1}^{n} (-1)^j f\left(a_1, ..., a_{j-1,}, a_j \cdot a_{j+1}, a_{j+2}..., a_{n+1}\right) \\ &+ (-1)^{n+1} f\left(a_1, ..., a_n\right) \cdot a_{n+1} \end{aligned}$$

We have $d^2 = 0$, i.e., $d_{n+1} \circ d_n = 0$, and the cohomology $H^\bullet(\mathcal{A}, M)$ of the complex $(\mathrm{C}^\bullet(\mathcal{A}, M), d)$,

$$H^n(\mathcal{A}, M) = \ker d_n / \operatorname{Im} d_{n-1}$$

is called the Hochschild cohomology of the algebra $\mathcal{A}$ with coefficients in the $\mathcal{A}$-bimodule M.

In the deformation theory of associative algebras we have the simplest non-trivial case $M = \mathcal{A}$ with the left and right $\mathcal{A}$-actions given by the multiplication map. The associativity equation (3.25) can be written as

$$(d_2 m_1)(a,b,c) = 0$$
$$(d_2 m_n)(a,b,c) = \sum_{j=1}^{n-1} \left(m_j\left(m_{n-j}(a,b),c\right) - m_j\left(a, m_{n-j}(b,c)\right)\right), \quad a,b,c \in \mathcal{A}$$

It is quite remarkable that the Hochschild cochain complex $C^\bullet(\mathcal{A},\mathcal{A})$ carries an additional structure of a graded Lie algebra, which plays a fundamental
role in studying the associativity equation (3.25). Namely, for $f \in \mathrm{C}^m(\mathcal{A},\mathcal{A})$ and $g \in \mathbb{C}^n(\mathcal{A},\mathcal{A})$ let

$$(f \circ g)(a_1, ..., a_{m+n-1})$$
$$= \sum_{j=0}^{m-1} (-1)^j f\left(a_1, ..., a_j, g\left(a_{j+1}, ..., a_{j+n}\right), a_{j+n+1}, ..., a_{m+n-1}\right),$$

and define

$$[f,g]_G = f \circ g - (-1)^{(m-1)(n-1)} g \circ f.$$

The linear mapping $[,]_G : \mathrm{C}^m(\mathcal{A},\mathcal{A}) \times \mathrm{C}^n(\mathcal{A},\mathcal{A}) \to \mathbb{C}^{m+n-1}(\mathcal{A},\mathcal{A})$ satisfies $[f,g]_G = -(-1)^{(m-1)(n-1)}[g,f]_G$, and is called the Gerstenhaber bracket [27]. Considering the restriction of a multiplication m_t to $\mathcal{A} \otimes_{\mathbb{C}} \mathcal{A}$ as formal power series in t with coefficients in $C^\bullet(\mathcal{A},\mathcal{A})$ and using the Gerstenhaber bracket, we can rewrite (3.25) in the succinct form:

$$[m_t, m_t]_G = 0. \tag{3.26}$$

Let $\mathcal{A}$ be a commutative $\mathbb{C}$-algebra, and let $\mathcal{A}_t$ be a formal deformation of $\mathcal{A}$. Define the bilinear map $\{\} :, \mathcal{A} \otimes \mathbb{C}\mathcal{A} \to \mathcal{A}$ by

$$\{a,b\} = m_1(a,b) - m_1(b,a), \quad a,b \in \mathcal{A} \tag{3.27}$$

Lemma 3.3. *A formal deformation $\mathcal{A}_t$ of a commutative $\mathbb{C}$-algebra $\mathcal{A}$ equips $\mathcal{A}$ with a Poisson algebra structure with the bracket $\{,\}$.*

Proof. Consider the equation $d\mu_1(a,b,c) = 0$. Subtracting from it the equation with a and c interchanged, and using the commutativity of $\mathcal{A}$, we obtain

$$\{a \cdot b, c\} - \{a, b \cdot c\} = a \cdot \{b,c\} - c \cdot \{a,b\}.$$

Interchanging b and c, we get

$$\{a \cdot c, b\} - \{a, b \cdot c\} = a \cdot \{c,b\} - b \cdot \{a,c\}$$

and interchanging further a and c, we obtain

$$\{a \cdot c, b\} - \{c, a \cdot b\} = c \cdot \{a,b\} - b \cdot \{c,a\}.$$

Adding the first and third equations and subtracting the second equation gives

$$\{a \cdot b, c\} = a \cdot \{a,c\} + b \cdot \{a,c\}$$

so that the skew-symmetric cochain $\{,\} \in C^2(\mathcal{A},\mathcal{A})$ satisfies the Leibniz rule. To prove the Jacobi identity, observe that

$$\{a,b\} = \frac{m_t(a,b) - m_t(b,a)}{t} \bmod t\mathcal{A}_t. \tag{3.28}$$

Using associativity condition (3.25) (associativity modulo $t^2\mathcal{A}_t$ is sufficient) we get

$$\begin{gathered}\{\{a,b\},c\} + \{\{c,a\},b\} + \{\{b,c\},a\} = \frac{1}{t^2}\left(\left(m_t\left(m_t(a,b) - m_t(b,a)\right),c\right)\right.\\ -m_t\left(c, m_t(a,b) - m_t(b,a)\right) + m_t\left(m_t(c,a) - m_t(a,c),b\right)\\ -m_t\left(b, m_t(c,a) - m_t(a,c)\right) + m_t\left(m_t(b,c) - m_t(c,b),a\right)\\ \left.-m_t\left(a, m_t(b,c) - m_t(c,b)\right)\right) \bmod t\mathcal{A}_t = 0\end{gathered}$$

This result motivates the following definition.

Definition. A deformation quantization of a Poisson algebra $(\mathcal{A},\{\},)with$ the commutative product $m_0 : \mathcal{A}\otimes_{\mathbb{C}}\mathcal{A}\to\mathcal{A}$ is a formal deformation $\mathcal{A}_t$ of an algebra $\mathcal{A}$ such that the multiplication map m_t satisfies (3.28).

By Lemma 3.3, every formal deformation $\mathcal{A}_t$ of a commutative algebra $\mathcal{A}$ is a deformation quantization of the Poisson algebra $(\mathcal{A},\{\},)withthe$ Poisson bracket given by (3.27).

According to Lemma 3.2, a deformation quantization of the Poisson algebra $(\mathscr{S}(\mathbb{R}^{2n}),\{\},)$, where the Poisson bracket is associated with the canonical symplectic form $\omega = d\boldsymbol{p}\wedge d\boldsymbol{q}$, is the algebra $\mathscr{S}(\mathbb{R}^{2n})[[t]]$, where $t = -i\hbar$ and $\hbar$ is considered as a formal parameter, and the multiplication map is given by the $\star$-product. The following statement is a formal algebraic analog of the representation (3.22) for the $\star$-product.

Theorem 3.4 (Universal deformation). Let $\mathcal{A}$ be a commutative $\mathbb{C}$-algebra with the multiplication map m_0, and let φ_1 and φ_2 be two commuting derivations of $\mathcal{A}$, i.e., linear maps $\varphi_1,\varphi_2 : \mathcal{A}\to\mathcal{A}$ satisfying Leibniz rule and

$$\varphi_1\circ\varphi_2 = \varphi_2\circ\varphi_1.$$

Then

$$\{a,b\} = \varphi_1(a)\cdot\varphi_2(b) - \varphi_2(a)\cdot\varphi_1(b),\quad a,b\in\mathcal{A},$$

defines a Poisson bracket on $\mathcal{A}$, and the formula

$$m_t = m_0\circ e^{t\Phi},\quad \Phi = \varphi_1\otimes\varphi_2$$

called the universal deformation formula, gives a deformation quantization of the Poisson algebra $(\mathcal{A},\{\},)$.

Proof. The Jacobi identity for the bracket $\{,\}follows fromthecommu$ - tativity of the derivations φ_1 and φ_2. To show that $\mathcal{A}_t$ is a deformation quantization of the Poisson algebra $(\mathcal{A},\{,\}),weneedtoverifytheasso$ - ciativity condition (3.25) for the map m_t. Let $\Delta : \mathcal{A}\to\mathcal{A}\otimes\mathbb{C}\mathcal{A}$ be the coproduct map,

$$\Delta(a) = a\otimes 1 + 1\otimes a,\quad a\in\mathcal{A}$$

It extends to a $\mathbb{C}$-linear mapping from $\mathrm{Hom}_{\mathbb{C}}(\mathcal{A},\mathcal{A})$ to $\mathrm{Hom}_{\mathbb{C}}(\mathcal{A}^{\otimes 2},\mathcal{A}^{\otimes 2})$, which we continue to denote by Δ, and

$$\Delta(\varphi) = \varphi\otimes\mathrm{id} + \mathrm{id}\otimes\varphi,\quad \varphi\in\mathrm{Hom}_{\mathbb{C}}(\mathcal{A},\mathcal{A}).$$

[027] Together with the cup product of cochains, the Gerstenhaber bracket equips $C^*(\mathcal{A},\mathcal{A})$ with the structure of a Gerstenhaber algebra.

To prove (3.25), we observe that the Leibniz rule and the binomial formula yield the following identity for a derivation φ of $\mathcal{A}$:

$$e^{t\varphi} \circ m_0 = m_0 \circ e^{t\Delta(\varphi)}.$$

Using commutativity of φ_1 and φ_2, we obtain

$$\begin{aligned} m_t\left(a, m_t(b,c)\right) &= m_0\left(e^{t\Phi}\left(a \otimes m_0\left(e^{t\Phi}(b\otimes c)\right)\right)\right) \\ &= \left(m_0 \circ (\mathrm{id}\otimes m_0)\right)\left(e^{t(\mathrm{id}\otimes\Delta)(\Phi)} e^{t\mathrm{id}\otimes\Phi}(a\otimes b\otimes c)\right) \\ &= \left(m_0 \circ (\mathrm{id}\otimes m_0)\right)\left(e^{t(\mathrm{id}\otimes\Delta)(\Phi)+t\mathrm{id}\otimes\Phi}(a\otimes b\otimes c)\right) \end{aligned}$$

where $(\mathrm{id}\otimes\Delta)(\Phi) = \varphi_1 \otimes \Delta(\varphi_2) \in \mathcal{A}^{\otimes 3}$. Similarly,

$$m_t\left(m_t(a,b),c\right) = \left(m_0 \circ (m_0\otimes \mathrm{id})\right)\left(e^{t(\Delta\otimes\mathrm{id})(\Phi)+t\Phi\otimes\mathrm{id}}(a\otimes b\otimes c)\right)$$

where $(\Delta\otimes\mathrm{id})(\Phi) = \Delta(\varphi_1)\otimes\varphi_2 \in \mathcal{A}^{\otimes 3}$. Since $m_0\circ(\mathrm{id}\otimes m_0) = m_0\circ(m_0\otimes\mathrm{id})$, the associativity of the multiplication m_t is equivalent to

$$(\Delta\otimes\mathrm{id})(\Phi) + \Phi\otimes\mathrm{id} = (\mathrm{id}\otimes\Delta)(\Phi) + \mathrm{id}\otimes\Phi,$$

which is obviously satisfied since $\Phi = \varphi_1\otimes\varphi_2$.
In general, $2n$ pair-wise commuting derivations φ_i on a commutative algebra $\mathcal{A}$ define a Poisson bracket on $\mathcal{A}$,

$$\{a,b\} = \sum_{i=1}^{n}\left(\varphi_i(a)\cdot\varphi_{i+n}(b) - \varphi_{i+n}(a)\cdot\varphi_i(b)\right),$$

and deformation quantization of the corresponding Poisson algebra $(\mathcal{A},\{\},$ is given by the universal deformation formula

$$m_t = m_0 \circ e^{t\sum_{i=1}^{n}(\varphi_i\otimes\varphi_{i+n} - \varphi_{i+n}\otimes\varphi_i)}.$$

A deformation quantization of a Poisson manifold $(\mathscr{M},\{\},)(see Sec$ - tion 2.7 in Chapter 1) is, by definition, a deformation quantization of the corresponding Poisson algebra of classical observables $(C^\infty(\mathscr{M}),\{\},)$ with the property that the linear maps $m_n, n\geq 1$, are bidifferential operators [28]. The formal power series expansion (3.22) of the $\star$-product is a deformation quantization of the Poisson manifold $(\mathbb{R}^{2n},\{\},)$, where the Poisson bracket corresponding to the canonical symplectic form $\omega = d\boldsymbol{p}\wedge d\boldsymbol{q}$.

Problem 3.

13. Show that $C^\bullet(\mathcal{A},\mathcal{A})$ is a graded Lie algebra with respect to the Gerstenhaber bracket, i.e., that $[,]_G$ satisfies the graded Jacobi identity

$$(-1)^{(m-1)(p-1)}[f,[g,h]] + (-1)^{(n-1)(p-1)}[h,[f,g]] + (-1)^{(m-1)(n-1)}[g,[h,f]] = 0$$

for all $f\in C^m(\mathcal{A},\mathcal{A}), g\in C^n(\mathcal{A},\mathcal{A}), h\in C^p(\mathcal{A},\mathcal{A})$.

Problem 3.

14. Verify that $d_n f = [f,m_0]_G$, where $f\in\mathbb{C}^n(\mathcal{A},\mathcal{A})$ and d_n is the Hochschild differential.

[028] This property ensures that the unit in Poisson algebra is preserved under the deformation.

Problem 3.

15. Show that deformation quantizations associated with Weyl, pq, and ***qp***-quantizations are equivalent. (In fact, all deformation quantizations of the canonical Poisson manifold $(\mathbb{R}^{2n}, \{,\})$*areequivalent.*)

Problem 3.

16. Let $\mathfrak{g}$ be a finite-dimensional Lie algebra with a basis $x_1, ..., x_n$, and let $\mathfrak{g}^*$ be its dual space equipped with the Lie-Poisson bracket $\{,\}$(*seeProblem* 2.20 in Section 2.7 of Chapter 1). For $u \in \mathfrak{g}^*$ and $x = \sum_{i=1}^n \xi^i x_i, y = \sum_{i=1}^n \eta^i x_i \in \mathfrak{g}$ let

$$e^{u\left(\frac{1}{t}\log e^{tx}e^{ty}-x-y\right)} = \sum_{\alpha,\beta} a_{\alpha\beta}(u,t)\xi^\alpha\eta^\beta,$$

where $\xi^\alpha = (\xi^1)^{\alpha_1} ... (\xi^n)^{\alpha_n}, \eta^\beta = (\eta^1)^{\beta_1} ... (\eta^n)^{\beta_n}$, be the formal group law the "Baker-Campbell-Hausdorff series". Show that the product

$$m_t(f_1, f_2) = \sum_{\alpha,\beta} a_{\alpha\beta}(u,t) D^\alpha f_1(u) D^\beta f_2(u), \quad f_1, f_2 \in C^\infty(\mathfrak{g}^*)$$

where for a multi-index $\alpha = (\alpha_1, ..., \alpha_n)$ and $f \in C^\infty(\mathfrak{g}^*), D^\alpha f = \frac{\partial^{\alpha_1+\cdots+\alpha_n} f}{\partial u_1^{\alpha_1} ... \partial u_n^{\alpha_n}}$, gives a deformation quantization of the Poisson manifold $(\mathfrak{g}^*, \{,\})$.

Problem 3.

17. Let $(G, \{\},)$*beaLie* $-$ *Poissongroup, where*$\eta(g) = -r + \mathrm{Ad}^{-1}g \cdot r$ and non-degenerate r satisfies the classical Yang-Baxter equation (see Problems $2.21 - 2.23$ in Section 2.7 of Chapter 1). Using Baker-Campbell-Hausdorff series for the Lie algebra $\tilde{g}$ - the one-dimensional central extension of $\mathfrak{g}$ by the 2 -cocycle c (see Problem 2.23 in Section 2.7 of Chapter 1), show that there exists an element $F \in (U\mathfrak{g} \otimes U\mathfrak{g})[[t]]$ of the form $F = 1 - \frac{1}{2}tr + O(t^2)$, satisfying

$$(\Delta \otimes \mathrm{id})(F)(F \otimes 1) = (\mathrm{id} \otimes \Delta)(F)(1 \otimes F)$$

where Δ is the standard coproduct in $U\mathfrak{g}$.

Problem 3.

18. Let F_L and F_R be the images of F and F^{-1} under the identifications of the universal enveloping algebra $U\mathfrak{g}$ with the algebras of left and rightinvariant differential operators on G (see Problem 2.21 in Section 2.7 of Chapter 1), and let $\mathscr{F} = F_L \circ F_R$. Show that the product $m_t = m_0 \circ \mathscr{F}$ gives a deformation quantization of the Poisson-Lie group $(G, \{,\})$*suchthat*

$$\Delta \circ m_t = (m_t \otimes m_t) \circ \Delta,$$

where Δ is the standard coproduct on functions on $G, \Delta(f)(g_1, g_2) = f(g_1 g_2), f \in C^\infty(G)$. The Hopf algebra $(C^\infty(G), m_t, \Delta, S)$, where S is the standard antipode on $G, S(f)(g) = f(g^{-1})$, is called the quantum group corresponding to the Poisson-Lie group G, and is denoted by $G_q, q = e^t$.

Problem 3.

19. Let $R = \sigma\left(F^{-1}\right) F \in (U\mathfrak{g} \otimes U\mathfrak{g})[[t]]$, where σ is a permutation - an involution of $U\mathfrak{g} \otimes U\mathfrak{g}$, defined by $\sigma(a \otimes b) = b \otimes a, a, b \in U\mathfrak{g}$. Show that $R = 1 - tr + O\left(t^2\right)$ and satisfies the quantum Yang-Baxter equation

$$R_{12}R_{13}R_{23} = R_{23}R_{13}R_{12}$$

(see Problem 2.22 in Section 2.7 in Chapter 1 for notation).

4.3 Integration in Functional Spaces

(maybe later I'll put it to the section of methods)

In the previous chapter we studied the propagator $K\left(\boldsymbol{q}', t; \boldsymbol{q}, 0\right)$ - the integral kernel of the evolution operator $U(t) = e^{-\frac{i}{\hbar}tH}$ - by using its representation by the Feynman path integral. Here we replace the physical time t by the Euclidean time -it, and study the integral kernel of the semigroup $e^{-\frac{1}{\hbar}tH}$ for $t > 0$ by using its representation by the Wiener integral.

4.3.1 1. Gaussian measures

Here we consider the simplest example of Gaussian measures, which are naturally defined for finite-dimensional and infinite-dimensional vector spaces, and are used in many areas of analysis and probability theory. The basic result of the Gaussian integration - the Wick theorem - is the main tool of the perturbation expansion in quantum mechanics and quantum field theory, conveniently expressed through Feynman diagrams.

1.1. Finite-dimensional case.

Let A be a positive-definite, real symmetric $n \times n$ matrix. A basic formula of Gaussian integration is

$$\int_{\mathbb{R}^n} e^{-\frac{1}{2}(A\boldsymbol{q},\boldsymbol{q})} d^n\boldsymbol{q} = \sqrt{\frac{(2\pi)^n}{\det A}} \tag{1.1}$$

(see Lemma 3.1 in Section 3.1 of Chapter 5). The corresponding Gaussian measure associated with the matrix A is a probability measure μ_A on $\mathbb{R}^n$, defined by

$$d\mu_A(\boldsymbol{q}) = \sqrt{\frac{\det A}{(2\pi)^n}} e^{-\frac{1}{2}(A\boldsymbol{q},\boldsymbol{q})} d^n\boldsymbol{q}. \tag{1.2}$$

The measure μ_A is a mean-zero probability measure on $\mathbb{R}^n$ with the covariance $G = A^{-1}$. When $A = I_n$ - the $n \times n$ identity matrix - the corresponding measure is denoted by μ_n.

As follows from Lemma 3.1 in Section 3.1 of Chapter 5,

$$\int_{\mathbb{R}^n} e^{(\boldsymbol{p},\boldsymbol{q})} d\mu_A(\boldsymbol{q}) = e^{\frac{1}{2}(G\boldsymbol{p},\boldsymbol{p})}, \tag{1.3}$$

and by analytic continuation,

$$\int_{\mathbb{R}^n} e^{i(\boldsymbol{p},\boldsymbol{q})} d\mu_A(\boldsymbol{q}) = \lim_{R\to\infty} \int_{\|\boldsymbol{q}\|\le R} e^{i(\boldsymbol{p},\boldsymbol{q})} d\mu_A(\boldsymbol{q}) = e^{-\frac{1}{2}(G\boldsymbol{p},\boldsymbol{p})}. \tag{1.4}$$

The function $(2\pi)^{-\frac{n}{2}} e^{-\frac{1}{2}\langle G\boldsymbol{p},\boldsymbol{p}\rangle}$ is a Fourier transform of the measure μ_A.

Theorem 1.1 (Wick theorem). $\int_{\mathbb{R}^n} (\boldsymbol{v}_1,\boldsymbol{q}) \dots (\boldsymbol{v}_N,\boldsymbol{q})\, d\mu_A(\boldsymbol{q}) = \begin{cases} 0, & N \text{ is odd}, \\ \sum (G\boldsymbol{v}_{i_1},\boldsymbol{v}_{i_2}) \dots \left(G\boldsymbol{v}_{i_{N-1}},\boldsymbol{v}_{i_N}\right), & N \text{ is even}, \end{cases}$, where the sum goes over all possible pairings $(i_1,i_2),\dots,(i_{N-1},i_N)$ - all partitions in pairs of the set $\{1,2,\dots,N\}$.

Proof. Applying to (1.3) the directional derivative along the vector $\boldsymbol{v} \in \mathbb{R}^n$ - the differential operator

$$\partial_{\boldsymbol{v}} = \boldsymbol{v}\frac{\partial}{\partial \boldsymbol{p}} = \sum_{k=1}^{n} v_k \frac{\partial}{\partial p_k}$$

(differentiation under the integral sign is clearly legitimate), we obtain

$$\int_{\mathbb{R}^n} (\boldsymbol{v},\boldsymbol{q}) e^{(\boldsymbol{p},\boldsymbol{q})} d\mu_A(\boldsymbol{q}) = (G\boldsymbol{v},\boldsymbol{p}) e^{\frac{1}{2}(G\boldsymbol{p},\boldsymbol{p})}. \tag{1.5}$$

Setting here $\boldsymbol{p} = 0$ we get

$$\int_{\mathbb{R}^n} (\boldsymbol{v},\boldsymbol{q}) d\mu_A(\boldsymbol{q}) = 0,$$

while applying to (1.5) another $\partial_{\boldsymbol{v}'}$ and setting $\boldsymbol{p} = 0$ afterwards, we obtain

$$\int_{\mathbb{R}^n} (\boldsymbol{v},\boldsymbol{q})\,(\boldsymbol{v}',\boldsymbol{q})\, d\mu_A(\boldsymbol{q}) = (G\boldsymbol{v},\boldsymbol{v}')\,. \tag{1.6}$$

To get the general result, we differentiate (1.3) N times along the vectors $\boldsymbol{v}_1,\dots,\boldsymbol{v}_N$ and set $\boldsymbol{p} = 0$.

Problem 1.1. Let $\boldsymbol{v}_i, \boldsymbol{w}_j \in \mathbb{R}^n$ be such that $(A\boldsymbol{v}_i,\boldsymbol{w}_j) = 0, i,j = 1,\dots,N$, and let F and H be bounded measurable functions on $\mathbb{R}^N$. Show that the functions $f(\boldsymbol{q}) = F\left((\boldsymbol{v}_1,\boldsymbol{q}),\dots,(\boldsymbol{v}_N,\boldsymbol{q})\right)$ and $h(\boldsymbol{q}) = H\left((\boldsymbol{w}_1,\boldsymbol{q}),\dots,(\boldsymbol{w}_N,\boldsymbol{q})\right)$ satisfy

$$\int_{\mathbb{R}^n} f(\boldsymbol{q})h(\boldsymbol{q})d\mu_A(\boldsymbol{q}) = \int_{\mathbb{R}^n} f(\boldsymbol{q})d\mu_A(\boldsymbol{q}) \int_{\mathbb{R}^n} h(\boldsymbol{q})d\mu_A(\boldsymbol{q}).$$

1.2. Infinite-dimensional case.

Let $\mathscr{V} = \mathbb{R}^\infty$ be the Cartesian product of countably many copies of $\mathbb{R}$ equipped with the Tychonoff topology, and let

$$\mathscr{H} = \ell^2(\mathbb{R}) = \left\{ x = \{x_i\}_{i=1}^{\infty} \in \mathscr{V} : \|x\|^2 = \sum_{i=1}^{\infty} x_i^2 < \infty \right\}$$

be the real Hilbert space with the scalar product $(x,y) = \sum_{i=1}^{\infty} x_i y_i$. In particular, the Hilbert space $\mathscr{H}$ contains all elements of finite support: the elements $x \in \mathscr{V}$ such that $x_i = 0$ for sufficiently large i.

The Gaussian measure μ on $\mathscr{V}$ is defined by the direct product of the Gaussian measures μ_1,

$$\mu = \mu_\infty = \mu_1 \times \mu_1 \times \dots \times \mu_1 \times \dots$$

More precisely, the measure μ is defined as follows. Let $\mathscr{C}$ be the set of cylindrical subsets of $\mathscr{V}$: $C \in \mathscr{C}$ if $C = p_n^{-1}(E_1 \times \cdots \times E_n)$ for some n, where $p_n : \mathscr{V} \to \mathbb{R}^n$ is the projection on the Cartesian product of the first n factors, and $E_1, ..., E_n$ are Borel subsets of $\mathbb{R}$. Then we set

$$\mu(C) = \mu_1(E_1) ... \mu_1(E_n),$$

and extend μ to the whole σ-algebra generated by $\mathscr{C}$ by using the Kolmogoroff extension theorem. In particular, if $F(x) = f(x_1, ..., x_n)$, where f is a bounded measurable function on $\mathbb{R}^n$, then

$$\int_{\mathscr{V}} F d\mu = \int_{\mathbb{R}^n} f d\mu_n \tag{1.7}$$

Equivalently, the Gaussian measure μ is characterized by the following property.

Lemma 1.1. The measure μ is a unique probability measure on $\mathscr{V}$ such that for all $v \in \mathscr{V}$ with finite support,

$$\int_{\mathscr{Y}} e^{i(v,x)} d\mu(x) = e^{-\frac{1}{2}\|v\|^2}$$

Proof. The proof immediately follows from (1.4), since measures μ_n are uniquely determined by their Fourier transforms.

Remark. The Gaussian measure μ can be heuristically represented by

$$d\mu = (2\pi)^{-\infty} e^{-\frac{1}{2}\|x\|^2} \prod_{i=1}^{\infty} dx_i$$

Here the "divergent to 0 " product $(2\pi)^{-\infty} e^{-\frac{1}{2}\|x\|^2}$ " compensates the "divergent to ∞ " product $\prod_{i=1}^{\infty} dx_i$.

Now for $\alpha = \{\alpha_i\} \in \mathscr{V}$ let

$$\mathscr{H}_\alpha = \left\{ x \in \mathscr{V} : \sum_{i=1}^{\infty} \alpha_i^2 x_i^2 < \infty \right\}.$$

The following result is a version of Kolmogoroff's celebrated 0-1 law in probability theory.

Proposition 1.1.

$$\mu(\mathscr{H}_\alpha) = \begin{cases} 0 & \text{if } \alpha \notin \mathscr{H} \\ 1 & \text{if } \alpha \in \mathscr{H}. \end{cases}$$

In particular, $\mu(\mathscr{H}) = 0$.

Proof. Let χ_α be the characteristic function of the set $\mathscr{H}_\alpha \subset \mathscr{V}$,

$$\chi_\alpha(x) = \lim_{\varepsilon \to 0} \lim_{n \to \infty} \exp\left\{ -\varepsilon^2 \sum_{i=1}^{n} \alpha_i^2 x_i^2 \right\}.$$

Twice applying the dominated convergence theorem, we get

$$\begin{aligned} \mu(\mathscr{H}_\alpha) &= \int_{\mathscr{Y}} \chi_\alpha d\mu = \lim_{\varepsilon \to 0} \lim_{n \to \infty} \int_{\mathbb{R}^n} \exp\left\{ -\varepsilon^2 \sum_{i=1}^{n} \alpha_i^2 x_i^2 \right\} d\mu_n(x) \\ &= \lim_{\varepsilon \to 0} \lim_{n \to \infty} \prod_{i=1}^{n} \left(1 + \varepsilon^2 \alpha_i^2\right)^{-1/2}, \end{aligned}$$

and the product $\prod_{i=1}^{\infty} (1 + \varepsilon^2 \alpha_i^2)$ is convergent if and only if $\alpha \in \mathscr{H}$.

Remark. For $v \in \mathscr{H}$ let $v^{(n)} = (v_1, ..., v_n, 0, 0, ...)$. It follows from (1.6) that

$$\int_{\mathscr{Y}} \left(v^{(n)}, x\right)^2 d\mu(x) = \left\|v^{(n)}\right\|^2,$$

so that the sequence of functions $F_n(x) = \left(v^{(n)}, x\right), x \in \mathscr{V}$, is a Cauchy sequence in $L^2(\mathscr{V}, d\mu)$, and it converges in L^2 to the function $F(x)$. Abusing notation, we write $F(x) = (v, x) \in L^2(\mathscr{V}, d\mu)$. Thus though $\mu(\mathscr{H}) = 0$, Lemma 1.1 and, consequently, Wick's theorem, hold for $v \in \mathscr{H}$.

Problem 1.2. Prove that there is no probability measure μ on $\mathscr{H}$ such that $\mu(C) = \mu_n(E)$ for every cylindrical subset $C = p_n^{-1}(E)$ of $\mathscr{H}$, where $p_n : \mathscr{H} \to \mathbb{R}^n$ is the natural projection, and E is a Borel subset of $\mathbb{R}^n$. However, show that there exists a finitely-additive, non-negative function ν on cylindrical subsets of $\mathscr{H}$ satisfying this property.

Problem 1.3. Show that the formula

$$\nu\left(\{x \in \mathscr{V} : x_1 \in I_1, ..., x_n \in I_n\}\right) = \prod_{k=1}^{n} \mu_1\left(kI_k\right)$$

where $kI_k = (k\alpha_k, k\beta_k)$ for $I_k = (\alpha_k, \beta_k) \subseteq \mathbb{R}$, defines a probability measure ν on $\mathscr{V}$ such that $\nu(\mathscr{H}) = 1$.

4.3.2 2. Wiener measure and Wiener Integral

2.1. Definition of the Wiener measure.

Here we define the probability measure on the space $\mathscr{C} = C\left([0, \infty), \mathbb{R}^n; 0\right)$ of parametrized continuous paths in $\mathbb{R}^n$ starting at the origin, called the Wiener measure. It is related to the Brownian motion: the diffusion process in $\mathbb{R}^n$ with diffusion coefficient $D > 0$, which is described by the probability density

$$P\left(\boldsymbol{q}', \boldsymbol{q}; t\right) = (4\pi D t)^{-\frac{n}{2}} e^{-\frac{(\boldsymbol{q}-\boldsymbol{q}')^2}{4Dt}} \tag{2.1}$$

that a particle with initial certainty of being at point $\boldsymbol{q} \in \mathbb{R}^n$ is diffused in time t to point $\boldsymbol{q}' \in \mathbb{R}^n$.

It will be convenient to compactify $\mathbb{R}^n$ by adding a point at infinity, $\widehat{\mathbb{R}}^n = \mathbb{R}^n \cup \{\infty\} \simeq S^n$. Let

$$\Omega = \prod_{0 \le t < \infty} \widehat{\mathbb{R}}^n$$

be the Cartesian product of copies of $\widehat{\mathbb{R}}^n$ parametrized by $\mathbb{R}_{\ge 0}$. Equipped with the Tychonoff topology, Ω is a compact topological space - the space of all parametrized paths in $\widehat{\mathbb{R}}^n$. For every partition $\boldsymbol{t}_m = \{0 \le t_1 \le \cdots \le t_m\}$ and every $F \in C(\underbrace{\mathbb{R}^n \times \cdots \times \widehat{\mathbb{R}}^n}_{m})$, define $\varphi \in C(\Omega)$ by

$$\varphi(\gamma) = F\left(\gamma\left(t_1\right), ..., \gamma\left(t_m\right)\right) \quad \text{for all} \quad \gamma \in \Omega$$

We denote by $C_{\text{fin}}(\Omega)$ the subspace of $C(\Omega)$ spanned by the functions φ for all partitions $\boldsymbol{t}_m$ and for all continuous functions F. Define a linear functional l on $C_{\text{fin}}\left(\Omega\right)$ by the following formula:

$$l(\varphi) = \int_{\mathbb{R}^n} ... \int_{\mathbb{R}^n} F\left(\boldsymbol{q}_1, ..., \boldsymbol{q}_m\right) P\left(\boldsymbol{q}_m, \boldsymbol{q}_{m-1}; t_m - t_{m-1}\right) ... \tag{2.2}$$
$$...P\left(\boldsymbol{q}_1, 0; t_1\right) d^n\boldsymbol{q}_1 ... d^n\boldsymbol{q}_m$$

It follows from the semi-group property

$$\int_{\mathbb{R}^n} P(\boldsymbol{q}', \boldsymbol{q}_1; t' - t_1) P(\boldsymbol{q}_1, \boldsymbol{q}; t_1 - t) d^n \boldsymbol{q}_1 = P(\boldsymbol{q}', \boldsymbol{q}; t' - t)$$

(also called Kolmogoroff's equation in probability theory) that the functional l is well defined. The functional l is positive: $l(\varphi) \geq 0$ for $\varphi \geq 0$, satisfies $l(1) = 1$, and

$$|l(\varphi)| \leq \|\varphi\|_\infty = \sup_{\gamma \in \Omega} |\varphi(\gamma)|.$$

The subspace $C_{\text{fin}}(\Omega)$ separates points in Ω and $1 \in C_{\text{fin}}(\Omega)$, so that by the Stone-Weierstrass theorem $C_{\text{fin}}(\Omega)$ is dense in $C(\Omega)$. Now the functional l has a unique extension to a continuous positive linear functional on $C(\Omega)$ with norm 1, and by the Riesz-Markoff theorem, there exists a unique regular Borel measure μ_W on Ω with $\mu_W(\Omega) = 1$ such that

$$l(\varphi) = \int_\Omega \varphi d\mu_W$$

The measure μ_W is called the Wiener measure. The integral over the Wiener measure is called the Wiener integral.

Remark. The Riesz-Markoff theorem provides a natural way of defining measures in various problems of functional analysis. In general, it ensures the existence of a Baire measure — a measure defined on the σ-algebra of Baire sets. However, for compact spaces a Baire measure has a unique extension to a regular Borel measure - a measure defined on the σ-algebra generated by all open subsets. A Borel measure μ is regular, if for every Borel set $E \subseteq \Omega$,

$$\mu(E) = \begin{cases} \inf \mu(U), & E \subseteq U, U \text{ is open,} \\ \sup \mu(K), & K \subseteq E, K \text{ is compact and Borel.} \end{cases}$$

The space Ω is "so large" that its σ-algebras of Baire and Borel sets are different.

Proposition 2.1. The Wiener measure μ_W is supported on continuous paths starting at the origin, i.e., $\mu_W(\mathscr{C}) = 1$.

Replacing the probability density $P(\boldsymbol{q}_1, 0; t_1)$ by $P(\boldsymbol{q}_1, \boldsymbol{q}_0; t_1)$ in definition (2.2), for a fixed $\boldsymbol{q}_0 \in \mathbb{R}^n$ we obtain a Wiener measure $\mu_{\boldsymbol{q}_0}$, which is supported on the space $\mathscr{C}_{\boldsymbol{q}_0} = C([0, \infty), \mathbb{R}^n; \boldsymbol{q}_0)$ of continuous paths in $\mathbb{R}^n$ that start at $\boldsymbol{q}_0$.

Remark. The support of the Wiener measure μ_W can be characterized more precisely as follows. For $0 < \alpha \leq 1$ let Ω_α be the subspace of Ω of Hlder continuous paths of order α:

$$\Omega_\alpha = \left\{ \gamma \in \Omega : \sup_{t, t' \geq 0} \frac{\|\gamma(t) - \gamma(t')\|}{|t - t'|^\alpha} < \infty \right\}.$$

Then

$$\mu_W(\Omega_\alpha) = \begin{cases} 1, & \text{if } 0 < \alpha < \frac{1}{2} \\ 0, & \text{if } \frac{1}{2} \leq \alpha \leq 1 \end{cases}$$

Remark. It seems natural to define Wiener measure by the following construction. Set for simplicity $n = 1$, and for every partition $\boldsymbol{t}_m = \{0 \leq t_1 \leq \cdots \leq t_m\}$ and intervals $(\alpha_1, \beta_1), ..., (\alpha_m, \beta_m)$, define the measure of a cylindrical set

$$C_t = \{\gamma \in \Omega : \alpha_1 < \gamma(t_1) < \beta_1, ..., \alpha_m < \gamma(t_m) < \beta_m\}$$

by the formula

$$\mu\left(C_{\boldsymbol{t}}\right)=\int_{\alpha_1}^{\beta_1}...\int_{\alpha_m}^{\beta_m}P\left(q_m,q_{m-1};t_m-t_{m-1}\right)...P\left(q_1,0;t_1\right)dq_1...dq_m \tag{2.3}$$

By the Kolmogoroff extension theorem and the semi-group property, μ extends to a measure on the σ-algebra generated by the cylindrical subsets of Ω, which we continue to denote by μ. However, the set $\mathscr{C}$ of continuous paths starting at 0 turns out to be non-measurable! Specifically, one can show that

$$\mu_*(\mathscr{C})=0 \quad \text{and} \quad \mu^*(\mathscr{C})=1$$

where $\mu_*(E)$ and $\mu^*(E)$ denote, respectively, the inner and outer measures of the subset $E\subseteq\Omega$. To remedy this situation, one should from the beginning define cylindrical sets C_t as consisting of continuous paths only, and define $\mu\left(C_{\boldsymbol{t}}\right)$ by the same formula as above. Then the measure μ extends to a σ algebra generated by cylindrical subsets of $\mathscr{C}$, and coincides with the Wiener measure μ_W.

Remark. The same formula (2.3) can be used to define the Wiener measure on the space $C([0,\pi],\mathbb{R};0)$ of continuous functions on the interval $[0,\pi]$ which vanish at $t=0$; in this case $\boldsymbol{t}_m$ is a partition of $[0,\pi]$. This is the classical definition of the Wiener measure given by Wiener himself.

The following result will be used for representing the integral kernel of the one-parameter semigroup $e^{-\frac{1}{\hbar}tH}$ for $t>0$ by the Wiener integral.

Proposition 2.2. Let the real-valued function $V\in C\left(\mathbb{R}^n\right)$ be bounded below. Then for every $t\geq 0$ the function $\mathcal{F}_t:\mathscr{C}\to\mathbb{R}$, defined by

$$\mathcal{F}_t(\gamma)=e^{-\int_0^t V(\gamma(\tau))d\tau}$$

is integrable with respect to the Wiener measure, and

$$\int_{\mathscr{C}}\mathcal{F}_t d\mu_W=\lim_{N\to\infty}\int_{\mathbb{R}^n}...\int_{\mathbb{R}^n}\exp\left\{-\sum_{k=1}^{N}V\left(\boldsymbol{q}_k\right)\Delta t\right\}P\left(\boldsymbol{q}_N,\boldsymbol{q}_{N-1};\Delta t\right)...$$
$$...P\left(\boldsymbol{q}_1,0;\Delta t\right)d^n\boldsymbol{q}_1...d^n\boldsymbol{q}_N,\quad \Delta t=\frac{t}{N}$$

Proof. For $\gamma\in\mathscr{C}$,

$$\int_0^t V(\gamma(\tau))d\tau=\lim_{N\to\infty}\sum_{k=1}^{N}V\left(\gamma\left(t_k\right)\right)\Delta t$$

where $t_k=k\Delta t$. Since by definition every function $\sum_{k=1}^{N}V\left(\gamma\left(t_k\right)\right)\Delta t$ is measurable with respect to the Wiener measure on $\mathscr{C}$, the function $\mathcal{F}_t$ is measurable as a point-wise limit of a sequence of measurable functions. The function $\mathcal{F}_t$ is bounded and, therefore, is integrable on $\mathscr{C}$ with respect to the Wiener measure. Finally, by the dominated convergence theorem,

$$\int_{\mathscr{C}}\mathcal{F}_t d\mu_W=\lim_{N\to\infty}\int_{\mathscr{C}}\exp\left\{-\sum_{k=1}^{N}V\left(\gamma\left(t_k\right)\right)\Delta t\right\}d\mu_W(\gamma)$$

and the result follows from (2.2).

Remark. Note the limit in Proposition 2.2 exists because the function $\mathcal{F}_t$ is integrable, and not the other way around. This is similar to an elementary calculus argument that the limit

$$\lim_{n\to\infty}\left(1+\frac{1}{2}+\cdots+\frac{1}{n}-\log n\right)$$

exists because the integral

$$\int_0^1 \left(\frac{1}{x} - \left[\frac{1}{x}\right]\right) dx$$

is convergent. Here $[x]$ stands for the largest integer not greater than x.

Problem 2.1. Prove all statements about the support of Wiener measure.

Problem 2.2. Construct the Wiener measure by defining it on the cylindrical subsets of $\mathscr{C}$ by formula (2.3).

Problem 2.3. Prove that the Wiener measure μ_W on $C([0,\pi],\mathbb{R};0)$ for $D = \frac{1}{4}$ actually coincides with the measure ν defined in Problem 1.3. (Hint: Show that the mapping $\gamma(t) \mapsto \gamma(t)-\gamma(0)$ establishes the isomorphism between the space of $\hat{C}([0,\pi],\mathbb{R})$ of functions orthogonal to 1 and $C([0,\pi],\mathbb{R};0)$, and use the Fourier sine coefficients for the embedding $\hat{C}([0,\pi],\mathbb{R}) \hookrightarrow \mathscr{V}$.)

2.2. Conditional Wiener measure and Feynman-Kac formula. Let

$$\Omega_{\boldsymbol{q},\boldsymbol{q}'} = \left\{\boldsymbol{\gamma} \in \prod_{t\le\tau\le t'} \widehat{\mathbb{R}}^n : \boldsymbol{\gamma}(t) = \boldsymbol{q}, \boldsymbol{\gamma}(t') = \boldsymbol{q}'\right\}$$

be the space of all parametrized paths in $\widehat{\mathbb{R}}^n$ which start at $\boldsymbol{q} \in \mathbb{R}^n$ at time t and end at $\boldsymbol{q}' \in \mathbb{R}^n$ at t', and let $\mathscr{C}_{\boldsymbol{q},\boldsymbol{q}'}$ be the corresponding subspace of continuous paths. The conditional Wiener measure $\mu_{\boldsymbol{q},\boldsymbol{q}'}$ on $\Omega_{\boldsymbol{q},\boldsymbol{q}'}$ is defined
similarly. We replace a positive linear functional l on $C(\Omega)$ by a positive linear functional $l_{\boldsymbol{q},\boldsymbol{q}'}$ on $C(\Omega_{\boldsymbol{q},\boldsymbol{q}'})$, which for $\varphi \in C_{\text{fin}}(\Omega_{\boldsymbol{q},\boldsymbol{q}'})$ is defined by

$$l_{\boldsymbol{q},\boldsymbol{q}'}(\varphi) = \int_{\mathbb{R}^n} ... \int_{\mathbb{R}^n} F(\boldsymbol{q}_1,...,\boldsymbol{q}_m) P(\boldsymbol{q}',\boldsymbol{q}_m;t'-t_m) ...$$
$$...P(\boldsymbol{q}_1,\boldsymbol{q};t_1-t)\, d^n\boldsymbol{q}_1...d^n\boldsymbol{q}_m$$

where $t \le t_1 \le \cdots \le t_m \le t'$ and $\varphi(\gamma) = F(\gamma(t_1),...,\gamma(t_m))$. Then

$$l_{\boldsymbol{q},\boldsymbol{q}'}(\varphi) = \int_{\Omega_{\boldsymbol{q},\boldsymbol{q}'}} \varphi d\mu_{\boldsymbol{q},\boldsymbol{q}'}$$

As in the case of the Wiener measure μ_W, the conditional Wiener measure $\mu_{\boldsymbol{q},\boldsymbol{q}'}$ is supported on continuous paths and

$$\mu_{\boldsymbol{q},\boldsymbol{q}'}(\mathscr{C}_{\boldsymbol{q},\boldsymbol{q}'}) = P(\boldsymbol{q}',\boldsymbol{q};t'-t)$$

Let

$$H = H_0 + V = \frac{\boldsymbol{P}^2}{2m} + V(\boldsymbol{Q})$$

be the Schrodinger operator on $L^2(\mathbb{R}^n, d^n\boldsymbol{q})$ with continuous, real-valued and bounded below potential $V(\boldsymbol{q})$. Denote by $L_\hbar(\boldsymbol{q}',t';\boldsymbol{q},t), t' > t$, the heat kernel - the integral kernel of the diffusion operator $e^{-\frac{t'-t}{\hbar}H}$. Here is the main result of this section.

Theorem 2.1 (Feynman-Kac formula).

$$L_\hbar(\boldsymbol{q}',t';\boldsymbol{q},t) = \int_{\mathscr{C}_{\boldsymbol{q},\boldsymbol{q}'}} e^{-\frac{1}{\hbar}\int_t^{t'} V(\gamma(\tau))d\tau} d\mu_{\boldsymbol{q},\boldsymbol{q}'}(\boldsymbol{\gamma})$$

where $\mu_{\boldsymbol{q},q'}$ is the conditional Wiener measure.

Proof. We have by the Lie-Kato-Trotter product formula

$$e^{-\frac{1}{\hbar}TH} = \lim_{N\to\infty}\left(e^{-\frac{\Delta t}{\hbar}H_0}e^{-\frac{\Delta t}{\hbar}V}\right)^N, \quad \Delta t = \frac{T}{N}$$

where $T = t'-t$. Let $L_\hbar^{(N)}(\boldsymbol{q}', t'; \boldsymbol{q}, t)$ be the integral kernel of the operator $\left(e^{-\frac{\Delta t}{\hbar}H_0}e^{-\frac{\Delta t}{\hbar}V}\right)^N$. Computing it as in Section 1.3 of Chapter 5, and using the definition of the conditional Wiener measure we obtain

$$L_\hbar^{(N)}(\boldsymbol{q}', t'; \boldsymbol{q}, t) = \int_{\mathscr{C}_{\boldsymbol{q},\boldsymbol{q}'}} \exp\left\{-\frac{1}{\hbar}\sum_{k=1}^{N} v\left(\gamma\left(t_k\right)\right)\Delta t\right\} d\mu_{\boldsymbol{q},\boldsymbol{q}'}(\gamma)$$

Evaluating the limit $N \to \infty$ by the dominated convergence theorem completes the proof.
Using the conditional Wiener measure it is easy to define a measure μ_W^{loop} on the space

$$\mathcal{L} = \left\{\gamma \in \prod_{t\le\tau\le t'} \widehat{\mathbb{R}}^n : \gamma(t) = \gamma\left(t'\right)\right\}$$

of free parametrized loops in $\widehat{\mathbb{R}}^n$. Namely, the space $\mathcal{L}$ is a disjoint union over $\boldsymbol{q} \in \widehat{\mathbb{R}}^n$ of the spaces $\Omega_{\boldsymbol{q},\boldsymbol{q}}$ of the parametrized loops based at $\boldsymbol{q} \in \widehat{\mathbb{R}}^n$. By definition, a function $\varphi : \mathcal{L} \to \mathbb{C}$ is called integrable, if its restrictions $\varphi|_{\Omega_{q,q}}$ are measurable with respect to $\mu_{\boldsymbol{q},\boldsymbol{q}}$ for all $\boldsymbol{q} \in \mathbb{R}^n$, and if the function $\int_{\Omega_{q,\boldsymbol{q}}} \varphi d\mu_{\boldsymbol{q},\boldsymbol{q}} : \mathbb{R}^n \to \mathbb{C}$ is Lebesgue integrable on $\mathbb{R}^n$. Then

$$\int_{\mathcal{L}} \varphi d\mu_W^{\text{loop}} = \int_{\mathbb{R}^n}\int_{\Omega_{\boldsymbol{q},\boldsymbol{q}}} \varphi d\mu_{\boldsymbol{q},\boldsymbol{q}} d^n\boldsymbol{q} \tag{2.4}$$

Suppose that the Schrodinger operator $H = H_0 + V$ with continuous, real-valued, and bounded below potential $V(\boldsymbol{q})$ has a pure point spectrum, and that $e^{-\frac{T}{\hbar}H}$ is of trace class [1]. The following result is a useful corollary of the Feynman-Kac formula.

Corollary 2.2.

$$\operatorname{Tr} e^{-\frac{T}{\hbar}H} = \int_{\mathcal{L}} e^{-\frac{1}{\hbar}\int_0^T V(\gamma(t))dt} d\mu_W^{\text{loop}}(\gamma)$$

Proof. The heat kernel $L_\hbar(\boldsymbol{q}', T; \boldsymbol{q}, 0)$ - the integral kernel of the trace class operator $e^{-\frac{T}{\hbar}H}$ - is a continuous function of $\boldsymbol{q}$ and $\boldsymbol{q}'$, so that by the theorem [2] that "the operator trace equals the matrix trace", used in Sections $5.1 - 5.2$ of Chapter 5, we get

$$\operatorname{Tr} e^{-\frac{T}{\hbar}H} = \int_{\mathbb{R}^n} L_\hbar(\boldsymbol{q}, T; \boldsymbol{q}, 0) d^n\boldsymbol{q}$$

The result now follows from the Feynman-Kac formula and equation (2.4).
Remark. The Wiener measure on the loop space

$$\mathcal{L} = \{\gamma \in C([0,T], \mathbb{R}) : \gamma(0) = \gamma(T)\}$$

in terms of the Fourier coefficients

$$\gamma(t) = \sum_{n=-\infty}^{\infty} c_n e^{\frac{2\pi i n t}{T}}, \quad \bar{c}_n = c_{-n}$$

can be expressed as follows:

$$d\mu_W^{\text{loop}} = \sqrt{\frac{m}{2\pi\hbar T}} dc_0 \prod_{n=1}^{\infty} \left(\frac{m}{\pi\hbar T}\right) (2\pi n)^2 e^{-\frac{m}{\hbar T}(2\pi n)^2 |c_n|^2} d^2 c_n \tag{2.5}$$

In particular,

$$\int_{\mathcal{L}} f(\gamma) d\mu_W^{\text{loop}}(\gamma) = \sqrt{\frac{m}{2\pi\hbar T}} \int_{-\infty}^{\infty} \left(\int_{\mathcal{L}_0} f(x, \gamma_0)\, d\mu_W^{\text{loop}}(\gamma_0) \right) dx \tag{2.6}$$

Here $\mathcal{L}_0$ is the space of loops γ_0 with $c_0 = 0$, and $\mathcal{L} = \mathbb{R} \times \mathcal{L}_0$ according to the decomposition $\gamma = x + \gamma_0$, where $\int_0^T \gamma_0(t) dt = 0$ so that $x = c_0(\gamma)$.

Problem 2.4. Deduce from the Feynman-Kac formula that for every $\psi \in L^2(\mathbb{R}^n)$,

$$\left(e^{-\frac{1}{\hbar}T(H_0+V)}\psi\right)(\boldsymbol{q}) = \int_{\mathscr{C}_{\boldsymbol{q}}} \psi(\gamma(t)) e^{-\frac{1}{\hbar}\int_0^T V(\gamma(t))dt} d\mu_{\boldsymbol{q}}(\gamma).$$

Problem 2.5. Prove formula (2.5) and deduce (2.6) from it. (Hint: Use Problem 2.3.)

2.3. Relation between Wiener and Feynman integrals. It is very instructive to compare Feynman and Wiener integrals. Heuristically, the conditional Wiener measure can be written as

$$\mathscr{D}\boldsymbol{q}_W = e^{-\frac{m}{2\hbar}\int_t^{t'} \dot{\boldsymbol{q}}^2 d\tau} \mathscr{D}_\hbar \boldsymbol{q} \tag{2.7}$$

where

$$\mathscr{D}_\hbar \boldsymbol{q} = \lim_{N\to\infty} \left(\frac{m}{2\pi\hbar\Delta t}\right)^{\frac{N}{2}} \prod_{k=1}^{N-1} d^n \boldsymbol{q}_k. \tag{2.8}$$

Of course, neither the "measure" $\mathscr{D}_\hbar \boldsymbol{q}$ exists: the infinite product (2.8) is divergent, nor the trajectory $\gamma = \boldsymbol{q}(\tau)$ is, in general, differentiable: the integral $\int_t^{t'} \dot{\boldsymbol{q}}^2 d\tau$ is divergent. However, due to the presence of a negative sign in the exponential, we have the indeterminate form "infinity over infinity", and the resulting expression (2.7) can be given a precise meaning as the Wiener measure. The corresponding "measure" for the Feynman path integral is obtained by replacing $\hbar$ by $i\hbar$ in (2.7)-(2.8), and the exponential factor no longer compensates for the divergence of $\mathscr{D}_{i\hbar}\boldsymbol{q}$, since it is a complex number of modulus 1 for a differentiable trajectory, and has no meaning for a non-differentiable one.

However, as we have seen in Sections 1.3-1.4 of Chapter 5, the Feynman path integral allows us to represent the propagator of a quantum particle in a profound way, which shows a deep relation between quantum and classical mechanics. Namely,

$$K_\hbar(\boldsymbol{q}', t'; \boldsymbol{q}, t) = \int_{\substack{\boldsymbol{q}(t')=q' \\ \boldsymbol{q}(t)=\boldsymbol{q}}} e^{\frac{i}{\hbar}S(\gamma)} \mathscr{D}_{i\hbar}\boldsymbol{q},$$

where $S(\gamma) = \int_t^{t'} L(\boldsymbol{q}, \dot{\boldsymbol{q}}) d\tau$ is the action functional evaluated on a trajectory $\boldsymbol{\gamma} = \boldsymbol{q}(\tau)$, and $L(\boldsymbol{q}, \dot{\boldsymbol{q}}) = \frac{1}{2}m\dot{\boldsymbol{q}}^2 - V(\boldsymbol{q})$ is the corresponding Lagrangian function. One also can formally rewrite the Wiener integral for the integral kernel $L_\hbar(\boldsymbol{q}', t'; \boldsymbol{q}, t)$ - the Feynman-Kac formula - in a similar form,

$$L_\hbar(\boldsymbol{q}', t'; \boldsymbol{q}, t) = \int_{\substack{\boldsymbol{q}(t')=q' \\ \boldsymbol{q}(t)=\boldsymbol{q}}} e^{-\frac{1}{\hbar}\int_t^{t'} E(\boldsymbol{q},\boldsymbol{q})d\tau} \mathscr{D}_\hbar \boldsymbol{q}$$

[01] This is the case when $V(\boldsymbol{q}) \to \infty$ as $\boldsymbol{q} \to \infty$ "fast enough", i.e., $V(q) \geq C\|\boldsymbol{q}\|^2$.

[2] See Section 7 of Chapter 5 for the reference.

where $E(\boldsymbol{q},\dot{\boldsymbol{q}}) = \frac{1}{2}m\dot{\boldsymbol{q}}^2 + V(\boldsymbol{q})$ is the energy function. However, in this representation we no longer see the presence of the corresponding action functional, and connection with the classical mechanics is lost.

The precise relation between Wiener and Feynman integrals for a quantum particle is the following. As in the case of the Feynman-Kac formula, suppose that the real-valued potential $V(\boldsymbol{q}) \in C(\mathbb{R}^n)$ is bounded below. Using the Lie-Kato-Trotter formula, it is easy to show that the heat kernel $L_\hbar(\boldsymbol{q}',t';\boldsymbol{q},t)$, defined for $\hbar > 0$, admits an analytic continuation into the half-plane $\operatorname{Re}\hbar > 0$. Then

$$K_\hbar(\boldsymbol{q}',t';\boldsymbol{q},t) = \lim_{\varepsilon\to 0^+} L_{i\hbar+\varepsilon}(\boldsymbol{q}',t';\boldsymbol{q},t) \tag{2.9}$$

Remark. Let f be a smooth bounded function on $\mathbb{R}$ such that $f'(x) = O(|x|^{-1})$ as $|x| \to \infty$. The Gaussian integral $\int_{-\infty}^{\infty} f(x)e^{-x^2}dx$ is absolutely convergent, whereas the integral $\int_{-\infty}^{\infty} f(x)e^{ix^2}dx$ is only conditionally convergent. The formula

$$\int_{-\infty}^{\infty} f(x)e^{ix^2}dx = \lim_{\varepsilon\to 0^+}\int_{-\infty}^{\infty} f(x)e^{(i-\varepsilon)x^2}dx$$

interprets it as the limit $\varepsilon \to 0$ of an integral with respect to the complexvalued Gaussian measure $e^{(i-\varepsilon)x^2}dx$. It is tempting to extend this interpretation to Wiener integrals, and for a complex diffusion coefficient D with $\operatorname{Re} D > 0$ to define a complex-valued Wiener measure by the same formula (2.2). However, a theorem of Cameron states that the linear functional l, defined by an analog of (2.2) for $\operatorname{Re} D > 0$, is no longer bounded on $C_{\text{fin}}(\Omega)$, so that this approach does not work.

Problem 2.6. Let l be the functional on $C_{\text{fin}}(\Omega)$ defined by (2.2) where $P(\boldsymbol{q}',\boldsymbol{q},t)$ is given by (2.1) with $\operatorname{Re} D \geq 0$.
(i) Prove that when $\operatorname{Re} D = 0$,

$$\sup_{t\geq 0, F\in C(\hat{\mathbb{R}})}\{|l(\varphi)| : \|\varphi\|_\infty = 1, \varphi(\gamma) = F(\gamma(t))\} = \infty.$$

(ii) Prove that when $\operatorname{Re} D > 0$,

$$\sup_{\boldsymbol{t}_m, F\in C(\mathbb{R}^m)}\{|l(\varphi)| : \|\varphi\|_\infty = 1, \varphi(\gamma) = F(\gamma(t_1),...,\gamma(t_m))\} = \left(\frac{|D|}{\operatorname{Re} D}\right)^m.$$

4.3.3 3. Gaussian Wiener Integrals

In Section 4 of Chapter 5 we evaluated Gaussian Feynman integrals in terms of the regularized determinants of corresponding differential operators. Here we consider the same problem for Gaussian Wiener integrals.

3.1. Dirichlet boundary conditions.

Let

$$A = -D^2 + u(t), \quad D = \frac{d}{dt},$$

where $u \in C^1([0,T])$, be the Sturm-Liouville operator on the interval $[0,T]$ with Dirichlet boundary conditions. The following result is fundamental.

Theorem 3.1. Suppose that $u(t) \geq 0$. Then

$$\int_{\mathscr{C}_{0,0}} e^{-\frac{m}{2\hbar}\int_0^T u(t)y^2(t)dt} d\mu_{0,0}(y) = \sqrt{\frac{m}{\pi\hbar \det A}}$$

Proof. Using Proposition 2.2 and finite-dimensional Gaussian integration formula (1.1), we get

$$\int_{\mathscr{C}_{0,0}} e^{-\frac{m}{2\hbar}\int_0^T u(t)y^2(t)dt} d\mu_{0,0}(y) = \lim_{n\to\infty} \left(\frac{m}{2\pi\hbar\Delta t}\right)^{\frac{n}{2}} \int \ldots \int$$
$$\exp\left\{-\frac{m}{2\hbar\Delta t}\sum_{k=0}^{n-1}\left(\left(y_{k+1}-y_k\right)^2 + u\left(t_k\right)\left(\Delta t\right)^2 y_k^2\right)\right\}\prod_{k=1}^{n-1} dy_k$$
$$= \lim_{n\to\infty}\sqrt{\frac{m}{2\pi\hbar\Delta t \det A_{n-1}}}$$

(cf. the proof of Proposition 3.1 in Section 3.2 of Chapter 5). Here $y_0 = y_n = 0, t_k = k\Delta t, \Delta t = \frac{T}{n}$, and

$$A_{n-1} = \begin{pmatrix} a_1 & -1 & 0 & \cdots & 0 & 0 \\ -1 & a_2 & -1 & \cdots & 0 & 0 \\ 0 & -1 & a_3 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & a_{n-2} & -1 \\ 0 & 0 & 0 & \cdots & -1 & a_{n-1} \end{pmatrix}$$

where $a_k = 2 + u\left(t_k\right)\left(\Delta t\right)^2, k = 1, \ldots, n-1$. Let $y_k^{(n)}$ be Δt times the principal minor of order $k-1$ of the matrix A_{n-1} corresponding to its upper-left corner, so that $y_n^{(n)} = \Delta t \det A_{n-1}$. The sequence $y_k^{(n)}$ satisfies the initial conditions

$$y_2^{(n)} = 2\Delta t + O\left(\left(\Delta t\right)^3\right), \quad y_3^{(n)} = 3\Delta t + O\left(\left(\Delta t\right)^3\right)$$

and expanding the order k determinant $y_{k+1}^{(n)}$ with respect to the last row, we obtain the recurrence relation

$$y_{k+1}^{(n)} + y_{k-1}^{(n)} - 2y_k^{(n)} = u\left(t_k\right)\left(\Delta t\right)^2 y_k^{(n)}, \quad k = 3, \ldots, n-1$$

Since

$$\lim_{k,n\to\infty} u\left(t_k\right) = u(t) \quad \text{when} \quad \lim_{k,n\to\infty} t_k = t$$

it follows from the method of finite-differences for solving initial value problem for ordinary differential equations that

$$\lim_{k,n\to\infty} y_k^{(n)} = y(t)$$

where $y(t)$ is the solution of the differential equation

$$-y'' + u(t)y = 0$$

with the initial conditions

$$y(0) = \lim_{n\to\infty} y_2^{(n)} = 0, \quad y'(0) = \lim_{n\to\infty} \frac{y_3^{(n)} - y_2^{(n)}}{\Delta t} = 1$$

Using Theorem 5.1 in Section 5.1 of Chapter 5, we finally obtain

$$\lim_{n\to\infty} \Delta t \det A_{n-1} = \lim_{n\to\infty} y_n^{(n)} = y(T) = \frac{1}{2}\det{}' A$$

Remark. The same computation also works for Feynman path integrals, and gives a rigorous proof of the formula

$$\int_{\left\{\begin{array}{l} y(T)=0 \\ y(0)=0 \end{array}\right\}} e^{\frac{im}{2\hbar}\int_0^T \left(\dot{y}^2 - u(t)y^2\right)dt} \mathscr{D}y = \sqrt{\frac{m}{\pi i\hbar \det A}}$$

where $A = -D^2 - u(t)$ is a positive-definite operator (see Section 6.1 of Chapter 5). In particular, the coefficient $c_{m,\hbar}$ from Section 4 of Chapter 5 is indeed equal to $\sqrt{\frac{m}{\pi i\hbar}}$.

3.2. Periodic boundary conditions. Let $A = -D^2 + u(t)$, where $u \in C^1([0,T])$, be the Sturm-Liouville operator on the interval $[0,T]$ with periodic boundary conditions. Here we prove the following analog of Theorem 3.1.

Theorem 3.2. Suppose that $u(t) > 0$. Then

$$\int_{\mathcal{L}} e^{-\frac{m}{2\hbar}\int_0^T u(t)y^2(t)dt} d\mu_W^{\text{loop}}(y) = \frac{1}{\sqrt{\det A}}$$

where $\mathcal{L}$ is the space of free loops in $\mathbb{R}$ parametrized by the interval $[0,T]$.

Proof. As in the proof of Theorem 3.1, we have

$$\int_{\mathcal{L}} e^{-\frac{m}{2\hbar}\int_0^T u(t)y^2(t)dt} d\mu_W^{\text{loop}}(y) = \lim_{n\to\infty} \left(\frac{m}{2\pi\hbar\Delta t}\right)^{\frac{n}{2}} \int\cdots\int$$
$$\exp\left\{-\frac{m}{2\hbar\Delta t}\sum_{k=0}^{n-1}\left(\left(y_{k+1}-y_k\right)^2 + u\left(t_k\right)\left(\Delta t\right)^2 y_k^2\right)\right\}\prod_{k=1}^{n} dy_k$$
$$= \lim_{n\to\infty} \frac{1}{\sqrt{\det A_n}}$$

Here $y_0 = y_n$ and A_n is the following $n \times n$ matrix:

$$A_n = \begin{pmatrix} a_0 & -1 & 0 & \cdots & 0 & -1 \\ -1 & a_1 & -1 & \cdots & 0 & 0 \\ 0 & -1 & a_2 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & a_{n-2} & -1 \\ -1 & 0 & 0 & \cdots & -1 & a_{n-1} \end{pmatrix}$$

where $a_k = 2 + u\left(t_k\right)\left(\Delta t\right)^2, k = 0, 1, ..., n-1$. We compute $\det A_n$ by the following elegant argument. First, note that the real λ is an eigenvalue of A_n if only if the difference equation

$$-\left(y_{k+1} + y_{k-1} - 2y_k\right) + u\left(t_k\right)\left(\Delta t\right)^2 y_k = \lambda y_k, \quad k = 0, ..., n-1 \tag{3.1}$$

with initial conditions y_{-1} and y_0 has a "periodic solution" - a solution $\{y_k\}_{k=1}^n$ satisfying $y_{n-1} = y_{-1}$ and $y_n = y_0$. For given λ denote by $v_k^{(1)}(\lambda)$ and $v_k^{(2)}(\lambda)$ solutions of (3.1) with the corresponding initial conditions $v_{-1}^{(1)}(\lambda) = 1, v_0^{(1)}(\lambda) = 0$ and $v_{-1}^{(2)}(\lambda) = 0, v_0^{(2)}(\lambda) = 1$, and put

$$T_n(\lambda) = \begin{pmatrix} v_{n-1}^{(1)}(\lambda) & v_{n-1}^{(2)}(\lambda) \\ v_n^{(1)}(\lambda) & v_n^{(2)}(\lambda) \end{pmatrix}$$

It is easy to show that the discrete analog of the Wronskian $v_{k-1}^{(1)}(\lambda)v_k^{(2)}(\lambda)$ - $v_k^{(1)}(\lambda)v_{k-1}^{(2)}(\lambda)$ does not depend on k, so that $\det T_n(\lambda) = 1$. Since every solution y_k of the initial value problem for (3.1) is a linear combination of the solutions $v_k^{(1)}(\lambda)$ and $v_k^{(2)}(\lambda)$, we have

$$\begin{pmatrix} y_{n-1} \\ y_n \end{pmatrix} = T_n(\lambda) \begin{pmatrix} y_{-1} \\ y_0 \end{pmatrix}$$

From here we conclude that λ is an eigenvalue of the matrix A_n if and only if $\det(T_n(\lambda) - I_2) = 0$, and the multiplicity of λ is the multiplicity of a root of this algebraic equation. Since

$$v_{n-1}^{(1)}(\lambda) = O\left(\lambda^{n-1}\right), \quad v_n^{(2)}(\lambda) = (-\lambda)^n + O\left(\lambda^{n-1}\right) \quad \text{as} \quad \lambda \to \infty$$

we obtain

$$\det(A_n - \lambda I_n) = -\det(T_n(\lambda) - I_2) = v_{n-1}^{(1)}(\lambda) + v_n^{(2)}(\lambda) - 2.$$

It remains to compute $\lim_{n\to\infty} \det(A_n - \lambda I_n)$. Denote by $y_k^{(1)}(\lambda)$ and $y_k^{(2)}(\lambda)$, correspondingly, two solutions of the difference equation (3.1) with the initial conditions $y_{-1}^{(1)}(\lambda) = y_0^{(1)}(\lambda) = 1$ and $y_{-1}^{(2)}(\lambda) = 0, y_0^{(2)}(\lambda) = \Delta t$. We have

$$v_k^{(1)}(\lambda) = y_k^{(1)}(\lambda) - \frac{1}{\Delta t} y_k^{(2)}(\lambda) \quad \text{and} \quad v_k^{(2)}(\lambda) = \frac{1}{\Delta t} y_k^{(2)}(\lambda)$$

so that

$$\det(A_n - \lambda I_n) = y_{n-1}^{(1)}(\lambda) + \frac{y_n^{(2)}(\lambda) - y_{n-1}^{(2)}(\lambda)}{\Delta t} - 2 \tag{3.2}$$

Now it follows from the method of finite differences that

$$\lim_{k,n\to\infty} y_k^{(1)}(\lambda) = y_1(t,\lambda), \quad \lim_{k,n\to\infty} y_k^{(2)}(\lambda) = y_2(t,\lambda) \tag{3.3}$$

as $\lim_{k,n\to\infty} t_k = t$, where $y_{1,2}(t,\lambda)$ are two solutions of the differential equation

$$-y'' + u(t)y = \lambda y$$

with the initial conditions $y_1(0,\lambda) = 1, y_1'(0,\lambda) = 0$ and $y_2(0,\lambda) = 0$, $y_2'(0,\lambda) = 1$. Using (3.2)-(3.3) and Theorem 5.2 in Section 5.2 of Chapter 5, we finally obtain

$$\lim_{n\to\infty} \det(A_n - \lambda I_n) = y_1(T,\lambda) + y_2'(T,\lambda) - 2 = \det(A - \lambda I).$$

Example 3.1. Corollary 2.2 and Theorem 3.2 can be used to compute $\operatorname{Tr} e^{-\frac{1}{\hbar}TH}$ for the harmonic oscillator $H = \frac{1}{2m}(P^2 + m^2\omega^2 Q^2)$. We have

$$\operatorname{Tr} e^{-\frac{1}{\hbar}TH} = \frac{1}{\sqrt{\det A_{i\omega}}}$$

where $A_{i\omega} = -D^2 + \omega^2$, and by formula (5.20) in Section 5.2 of Chapter 5,

$$\operatorname{Tr} e^{-\frac{1}{\hbar}TH} = \frac{1}{2\sinh\frac{\omega T}{2}} \tag{3.4}$$

Of course, since the eigenvalues are $E_n = \hbar\omega\left(n + \frac{1}{2}\right)$, we can get the same result by using geometric series

$$\operatorname{Tr} e^{-\frac{1}{\hbar}TH} = \sum_{n=0}^{\infty} e^{-\frac{1}{\hbar}TE_n} = e^{-\frac{\omega T}{2}} \sum_{n=0}^{\infty} e^{-\omega Tn} = \frac{1}{2\sinh\frac{\omega T}{2}}.$$

Similar results hold for the general second order differential operator $A = -D^2 + v(t)D + u(t)$ on the interval $[0, T]$ with periodic boundary conditions.

Theorem 3.3. Suppose that $\det A > 0$, where $A = -D^2 + v(t)D + u(t)$. Then

$$\int_{\mathcal{L}} e^{-\frac{m}{2\hbar}\int_0^T \left(v(t)\dot{y}(t)y(t) + u(t)y^2(t)\right)dt} d\mu_W^{\text{loop}}(y) = \frac{1}{\sqrt{\det A}}$$

Example 3.2. Let $A = -D^2 + \omega D$. It follows from Theorem 3.3 and (2.6) that for $\varepsilon > 0$

$$\begin{aligned}
\frac{1}{\sqrt{\det(A + \varepsilon I)}} &= \int_{\mathcal{L}} e^{-\frac{m}{2\hbar}\int_0^T \left(\omega\dot{y}(t)y(t) + \varepsilon y^2(t)\right)dt} d\mu_W^{\text{loop}}(y) \\
&= \sqrt{\frac{m}{2\pi\hbar T}} \int_{-\infty}^{\infty} e^{-\frac{mT}{2\hbar}\varepsilon x^2} dx \int_{\mathcal{L}_0} e^{-\frac{m}{2\hbar}\int_0^T \left(\omega\dot{y}_0(t)y_0(t) + \varepsilon y_0^2(t)\right)dt} d\mu_W^{\text{loop}}(y_0) \\
&= \frac{1}{T\sqrt{\varepsilon}} \int_{\mathcal{L}_0} e^{-\frac{m}{2\hbar}\int_0^T \left(\omega\dot{y}_0(t)y_0(t) + \varepsilon y_0^2(t)\right)dt} d\mu_W^{\text{loop}}(y_0)
\end{aligned}$$

where we have used the decomposition $y(t) = x + y_0(t)$, $\int_0^T y_0(t)dt = 0$. Here $\mathcal{L}_0$ is the subset of the free loop space $\mathcal{L}$ which consists of loops with zero constant term in the Fourier series expansion. Using Corollary 5.4 in Section 5.2 of Chapter 5, we obtain

$$\begin{aligned}
\int_{\mathcal{L}_0} e^{-\frac{m}{2\hbar}\int_0^T \omega\dot{y}_0(t)y_0(t)dt} d\mu_W^{\text{loop}}(y_0) &= \lim_{\varepsilon\to 0} \frac{T\sqrt{\varepsilon}}{\sqrt{\det(A + \varepsilon I)}} = \frac{T}{\sqrt{\det' A}} \\
&= \left(\frac{\frac{\omega T}{2}}{\sinh\frac{\omega T}{2}}\right)^{\frac{1}{2}} \qquad (3.5)
\end{aligned}$$

We will use this result in Section 2.2 of Chapter 8.

Problem 3.

1. Derive formula (3.4) using (2.5).

Problem 3.

2. Prove Theorem 3.3.

4.4 Fermionic Systems

(maybe later I'll put it to the section of methods)

4.4.1 1. Canonical Anticommutation Relations

1.1. Motivation.

In Sections 2.6 and 2.7 of Chapter 2 we have shown that the Hilbert space $\mathscr{H} \simeq L^2(\mathbb{R}, dq)$ of a one-dimensional quantum particle can be described in terms of the creation and annihilation operators. Namely, the operators [1]

$$a^* = \frac{1}{\sqrt{2\hbar}}(Q - iP) \quad \text{and} \quad a = \frac{1}{\sqrt{2\hbar}}(Q + iP)$$

satisfy the canonical commutation relation

$$[a, a^*] = I$$

on $W^{2,2}(\mathbb{R}) \cap \hat{W}^{2,2}(\mathbb{R})$, and the vectors

$$\psi_k = \frac{(a^*)^k}{\sqrt{k!}}\psi_0, \quad k = 0, 1, 2, ...$$

where $\psi_0(q) = (\pi\hbar)^{-\frac{1}{4}} e^{-\frac{1}{2\hbar}q^2} \in \mathscr{H}$ satisfies $a\psi_0 = 0$, form an orthonormal basis for $\mathscr{H}$. The corresponding operator $N = a^*a$ is self-adjoint and has an integer spectrum,

$$N\psi_k = k\psi_k, \quad k = 0, 1, 2, ...$$

Similarly, for several degrees of freedom $\mathscr{H} \simeq L^2(\mathbb{R}^n, d^n\boldsymbol{q})$, the creation and annihilation operators are given by

$$a_k^* = \frac{1}{\sqrt{2\hbar}}(Q_k - iP_k) \quad \text{and} \quad a_k = \frac{1}{\sqrt{2\hbar}}(Q_k + iP_k), \quad k = 1, ..., n \tag{1.1}$$

and satisfy canonical commutation relations

$$[a_k, a_l] = [a_k^*, a_l^*] = 0 \quad \text{and} \quad [a_k, a_l^*] = \delta_{kl} I, \quad k, l = 1, ..., n. \tag{1.2}$$

The ground state, the vector $\psi_0(\boldsymbol{q}) = (\pi\hbar)^{-\frac{n}{4}} e^{-\frac{1}{2\hbar}q^2} \in \mathscr{H}$, has the property

$$a_k\psi_0 = 0, \quad k = 1, ..., n$$

and the vectors

$$\psi_{k_1,...,k_n} = \frac{(a_1^*)^{k_1} ... (a_n^*)^{k_n}}{\sqrt{k_1!...k_n!}}\psi_0, \quad k_1, ..., k_n = 0, 1, 2, ...$$

form an orthonormal basis for $\mathscr{H}$. The operator $N = \sum_{k=1}^n a_k^* a_k$ is selfadjoint and has an integer spectrum:

$$N\psi_{k_1,...,k_n} = (k_1 + \cdots + k_n)\,\psi_{k_1,...,k_n}$$

and the Hilbert space $\mathscr{H}$ decomposes into the direct sum of invariant subspaces

$$\mathscr{H} = \bigoplus_{k=0}^{\infty} \mathscr{H}_k \tag{1.3}$$

- the eigenspaces for the operator N.

However spin operators, introduced in Chapter 4, satisfy algebraic relations of different type. Namely, consider the operators $\sigma_\pm = \frac{2}{\hbar}S_\pm = \frac{2}{\hbar}(S_1 \pm iS_2)$, where S_1 and S_2 are spin operators of a quantum particle of spin $\frac{1}{2}$ (see Section 1.1 of Chapter 4). Using the explicit representation of spin operators by Pauli matrices, we get

[01] Here in comparison with Section 2.6 of Chapter 2 we put $\omega = 1$.

$$\sigma_- = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad \sigma_+ = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

The operators $\sigma_\pm$are nilpotent, $\sigma_\pm^2 = 0$, and satisfy the anticommutation relation

$$\sigma_+\sigma_- + \sigma_-\sigma_+ = I_2$$

where I_2 is the identity operator in $\mathbb{C}^2$. Introducing the notion of an anticommutator of two operators,

$$[A, B]_+ = AB + BA$$

we see that the operators $a = \sigma_-$and $a^* = \sigma_+$satisfy canonical anticommutation relations

$$[a, a]_+ = [a^*, a^*]_+ = 0 \quad \text{and} \quad [a, a^*]_+ = I_2.$$

The vector $e_0 = \binom{0}{1}$ has the property $ae_0 = 0$, and together with the vector $a^*e_0 = \binom{1}{0}$ they form an orthonormal basis of $\mathbb{C}^2$. The matrix

$$N = a^*a = \frac{1}{2}(\sigma_3 + I_2) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$$

has eigenvectors e_0 and a^*e_0 with eigenvalues 0 and 1 . Thus in complete analogy with the previous discussion, we say that a and a^* are fermion creation and annihilation operators for the case of one degree of freedom. The Hilbert space of a Fermi particle is $\mathscr{H} = \mathbb{C}^2$, and the vector e_0 is the ground state.

It is straightforward to generalize this construction to the case of several degrees of freedom. Namely, canonical anticommutation relations have the form

$$[a_k, a_l]_+ = [a_k^*, a_l^*]_+ = 0 \quad \text{and} \quad [a_k, a_l^*]_+ = \delta_{kl} I, \quad k, l = 1, ..., n, \tag{1.4}$$

where I is the identity operator, and creation operators a_j^* are adjoint to annihilation operators a_j in the fermion Hilbert space $\mathscr{H}_F$. Canonical anticommutation relations (1.4) can be realized in the Hilbert space $\mathscr{H}_F = (\mathbb{C}^2)^{\otimes n} = \mathbb{C}^{2^n}$ as follows:

$$a_k = \underbrace{\sigma_3 \otimes \cdots \otimes \sigma_3}_{k-1} \otimes a \otimes I_2 \otimes \cdots \otimes I_2, \tag{1.5}$$

$$a_k^* = \underbrace{\sigma_3 \otimes \cdots \otimes \sigma_3}_{k-1} \otimes a^* \otimes I_2 \otimes \cdots \otimes I_2, \tag{1.6}$$

$k = 1, ..., n$. The ground state, the vector $\psi_0 = e_0 \otimes \cdots \otimes e_0 \in \mathscr{H}_F$, satisfies

$$a_k\psi_0 = 0, \quad k = 1, ..., n, \tag{1.7}$$

and the vectors

$$\psi_{k_1,...,k_n} = (a_1^*)^{k_1} ... (a_n^*)^{k_n} \psi_0, \quad k_1, ..., k_n = 0, 1, \tag{1.8}$$

form an orthonormal basis for $\mathscr{H}_F$. The operator

$$N = \sum_{k=1}^{n} a_k^* a_k$$

is self-adjoint and has an integer spectrum:

$$N\psi_{k_1,...,k_n} = (k_1 + \cdots + k_n)\,\psi_{k_1,...,k_n},$$

and the Hilbert space $\mathscr{H}_F$ decomposes into the direct sum of invariant subspaces

$$\mathscr{H}_F = \bigoplus_{k=0}^{n} \mathscr{H}_k \tag{1.9}$$

- the eigenspaces of N.

Remark. The fermion Hilbert space $\mathscr{H}_F$ is isomorphic to the spin part of the Hilbert space of n quantum particles of spin $\frac{1}{2}$, discussed in Section 3.1 of Chapter 4. The corresponding fermion creation and annihilation operators can also be used for describing spin degrees of freedom. The fundamental importance of the fermion and boson Hilbert spaces - $\mathscr{H}_F = (\mathbb{C}^2)^{\otimes n}$ and
$\mathscr{H}_B = L^2(\mathbb{R}^n, d^n\boldsymbol{q})$ - manifests itself in quantum field theory, which formally corresponds to the case $n = \infty$, and describes quantum systems with infinitely many degrees of freedom.

Lemma 1.1. Realization (1.5)-(1.6) of canonical anticommutation relations in the fermion Hilbert space $\mathscr{H}_F$ is irreducible: every operator in $\mathscr{H}_F$, which commutes with all creation and annihilation operators a_k^* and a_k, is a multiple of the identity operator.

Proof. It is sufficient to show that if $\{0\} \neq V \subseteq \mathscr{H}_F$ is an invariant subspace for all operators a_k and a_k^*, then $V = \mathscr{H}_F$. Indeed, every non-zero $\psi \in V$ can be written in the form

$$\psi = \sum_{k_1,...,k_n=0,1} c_{k_1,...,k_n}\psi_{k_1,...,k_n}$$

and let $c_{k_1,...,k_n}\psi_{k_1,...,k_n}$ be any of its non-zero components with maximal degree $k_1+\cdots+k_n$. Using canonical anticommutation relations and (1.7), we obtain

$$a_n^{k_n}...a_1^{k_1}\psi = c\psi_0, \quad c = c_{k_1,...,k_n} \neq 0$$

so that $\psi_0 \in V$. Applying creation operators to ψ_0, we get $V = \mathscr{H}_F$.
Remark. The realization of canonical anticommutation relations in the fermion Hilbert space $\mathscr{H}_F$ is analogous to the representation by the occupation numbers of canonical commutation relations, discussed in Section 2.7 of Chapter 2, and is called representation by the occupation numbers for fermions. It should be emphasized that the algebraic structure of the former relations allows their realization in a finite-dimensional Hilbert space, while the algebraic structure of the latter relations warrants the infinitedimensional Hilbert space.

Analogously to (1.1), coordinate and momentum operators for fermions are defined by

$$Q_k = \sqrt{\frac{\hbar}{2}}\,(a_k + a_k^*), \quad P_k = -i\sqrt{\frac{\hbar}{2}}\,(a_k - a_k^*), \quad k = 1, ..., n. \tag{1.10}$$

As follows from (1.4), they satisfy the following anticommutation relations:

$$[Q_k, Q_l]_+ = [P_k, P_l]_+ = \hbar\delta_{kl}I \quad \text{and} \quad [P_k, Q_l]_+ = 0, \quad k, l = 1, ..., n \tag{1.11}$$

- a fermion analog of Heisenberg commutations relations, introduced in Section 2.1 of Chapter 2. The following result is a fermion analog of the Stone-von Neumann theorem from Section 3.1 of Chapter 2.

Theorem 1.1. Every irreducible finite-dimensional representation of canonical anticommutation relations is unitarily equivalent to the representation by occupation numbers in the fermion Hilbert space $\mathscr{H}_F$.

Proof. Let V be the Hilbert space which realizes the irreducible representation of canonical anticommutation relations (1.4). First of all, there is $\varphi_0 \in V, \|\varphi_0\| = 1$, such that

$$a_1\varphi_0 = \cdots = a_n\varphi_0 = 0$$

Indeed, choose any non-zero $\varphi \in V$; if $a_1\varphi \neq 0$, replace it by the vector $a_1\varphi$, which obviously satisfies $a_1(a_1\varphi_1) = 0$. If $a_2(a_1\varphi) \neq 0$, replace it by $a_2a_1\varphi$, which is annihilated by a_1 and a_2, etc. In finitely many steps we arrive at a non-zero vector $\tilde{\varphi}$ annihilated by the operators $a_1, ..., a_n$, and $\varphi_0 = \tilde{\varphi}/\|\tilde{\varphi}\|$. Now consider the subspace V_0 of V, spanned by the vectors

$$\varphi_{k_1,...,k_n} = (a_1^*)^{k_1} ... (a_n^*)^{k_n} \varphi_0, \quad k_1, ..., k_n = 0, 1$$

It follows from (1.4) that V_0 is an invariant subspace for all operators a_k and a_k^*, so that $V_0 = V$. Since operators a_k^* and a_k are adjoint with respect to the inner product in V, it is easy to see, again using canonical anticommutation relations (1.4), that vectors $\varphi_{k_1,...,k_n}$ form an orthonormal basis for V. The mapping $V \ni \varphi_{k_1,...,k_n} \mapsto \psi_{k_1,...,k_n} \in \mathscr{H}_F$ establishes the Hilbert space isomorphism $V \simeq \mathscr{H}_F$.

Problem 1.1. Express the spin operators $S_j^{(k)}$ of the k-th particle in the system of n spin $\frac{1}{2}$ particles (see Section 3.1 of Chapter 4) in terms of fermion creation and annihilation operators in $\mathscr{H}_F$.

1.2. Clifford algebras. We have seen in Section 2.1 of Chapter 2 that the Heisenberg Lie algebra is the fundamental mathematical structure associated with canonical commutation relations. Similarly, the fundamental mathematical structure associated with the canonical anticommutation relations is Clifford algebra.

Let V be a finite-dimensional vector space over the field k of characteristic zero, and let $Q : V \to k$ be a symmetric non-degenerate quadratic form on V, i.e., $Q(v) = \Phi(v, v), v \in V$, where $\Phi : V \otimes_k V \to k$ is a symmetric non-degenerate bilinear form. The pair (V, Q) is called quadratic vector space.

Definition. A Clifford algebra $C(V, Q) = C(V)$ associated with a quadratic vector space (V, Q) is a k-algebra generated by the vector space V with relations

$$v^2 = Q(v) \cdot 1, \quad v \in V$$

Equivalently, Clifford algebra is defined as a quotient algebra

$$C(V) = T(V)/J$$

where J is a two-sided ideal in the tensor algebra $T(V)$ of V, generated by the elements $u \otimes v + v \otimes u - 2\Phi(u, v) \cdot 1$ for all $u, v \in V$, and 1 is the unit
in $T(V)$. In terms of a basis $\{e_i\}_{i=1}^n$ of V, the Clifford algebra $C(V)$ is a k-algebra with the generators $e_1, ..., e_n$, satisfying the relations

$$[e_i, e_j]_+ = e_ie_j + e_je_i = 2\Phi(e_i, e_j) \cdot 1, \quad i, j = 1, ..., n$$

When $k = \mathbb{C}$ (or any algebraically closed field of characteristic zero), there always exists an orthonormal basis for V - a basis $\{e_i\}_{i=1}^n$ such that $\Phi(e_i, e_k) = \delta_{ik}$. In this case for every dimension n there is one (up to an isomorphism) Clifford algebra C_n with generators $e_1, ..., e_n$ and relations

$$e_i e_j + e_j e_i = 2\delta_{ij} \cdot 1, \quad i, k = 1, ..., n.$$

Remark. If $k = \mathbb{R}$, there exist non-negative integers $p + q = n$ and an isomorphism $V \simeq \mathbb{R}^n$ such that

$$Q(\boldsymbol{x}) = x_1^2 + \cdots + x_p^2 - x_{p+1}^2 - \cdots - x_n^2, \quad \boldsymbol{x} \in \mathbb{R}^n$$

This classifies Clifford algebras over $\mathbb{R}$.

Definition. A left module S for a Clifford algebra $C(V)$ is a finite-dimensional k-vector space S with the linear map $\rho : C(V) \otimes S \to S$ such that

$$\rho(ab \otimes s) = \rho(a \otimes \rho(b \otimes s))$$

for all $a, b \in C(V)$ and $s \in S$.

The fermion Hilbert space $\mathscr{H}_F$, introduced in the previous section, is an irreducible C_{2n}-module. Indeed, it follows from canonical anticommutation relations (1.4) that self-adjoint operators

$$\gamma_{2k-1} = a_k + a_k^*, \tag{1.12}$$

$$\gamma_{2k} = -i\,(a_k - a_k^*)\,, \quad k = 1, ..., n, \tag{1.13}$$

satisfy the relations

$$\gamma_\mu \gamma_\nu + \gamma_\nu \gamma_\mu = 2\delta_{\mu\nu} I, \quad \mu, \nu = 1, ..., 2n \tag{1.14}$$

where I is the identity operator in $\mathscr{H}_F$. We define the action of the Clifford algebra C_{2n} on $\mathscr{H}_F$ by setting

$$\rho(1) = I \quad \text{and} \quad \rho\,(e_\mu) = \gamma_\mu, \quad \mu = 1, ..., 2n,$$

and extending it to a $\mathbb{C}$-algebra homomorphism $\rho : C_{2n} \to \mathrm{End}\,(\mathscr{H}_F)$. Relations (1.14) show that the map ρ admits such an extension.

Proposition 1.1. The homomorphism $\rho : C_{2n} \to \mathrm{End}\,(\mathscr{H}_F)$ is a $\mathbb{C}$-algebra isomorphism.

Proof. It follows from Lemma 1.1 that the representation ρ is irreducible: every operator in $\mathscr{H}_F$ which commutes with all elements of the $\mathbb{C}$-algebra $\rho\,(C_{2n})$ is a multiple of the identity operator. Then by Wedderburn's theorem $\rho\,(C_{2n}) = \mathrm{End}\,(\mathscr{H}_F)$, and since $\dim C_{2n} = 2^{2n} = \dim \mathrm{End}\,(\mathscr{H}_F)$, the map ρ is an isomorphism.

Remark. The structure of a Clifford algebra with an odd number of generators is different. Thus the mapping $\rho\,(e_k) = \sigma_k$, where $\sigma_k, k = 1, 2, 3$, are Pauli matrices (see Section 1 of Chapter 4), defines an irreducible representation of C_3 in $\mathscr{H}_F = \mathbb{C}^2$. However, in this case $C_3 \simeq \mathrm{End}\,(\mathbb{C}^2) \otimes \mathbb{C}[\varepsilon]$, where $\varepsilon = ie_1e_2e_3$ and satisfies $\varepsilon^2 = 1$.

We define the chirality operator by $\Gamma = e^{\pi i N}$, where $N = \sum_{j=1}^n a_j^* a_j$. Since the operator N has an integral spectrum, $\Gamma^2 = I$. Moreover, we have

$$[\Gamma, \gamma_\mu]_+ = 0, \quad \mu = 1, ..., 2n. \tag{1.15}$$

Indeed, as follows from (1.4),

$$N a_j^* = a_j^*(N + I) \quad \text{and} \quad N a_j = a_j(N - I),$$

so that

$$e^{\pi i N} a_j^* = a_j^* e^{\pi i (N+I)} = -a_j^* e^{\pi i N} \quad \text{and} \quad e^{\pi i N} a_j = a_j e^{\pi i (N-I)} = -a_j e^{\pi i N}$$

Thus Γ anticommutes with all a_j, a_j^*, and hence with all γ_μ. Since $\Gamma^2 = I$, the operators

$$P_\pm = \frac{1}{2}(I \pm \Gamma)$$

are orthogonal projection operators and we have a decomposition

$$\mathscr{H}_F = \mathscr{H}_F^+ \oplus \mathscr{H}_F^{--}$$

into the subspaces of positive and negative chirality spinors. It follows from (1.15) that

$$\gamma_\mu \left(\mathscr{H}_F^+\right) = \mathscr{H}_F^-, \quad \mu = 1, ..., 2n.$$

Also, since $e^{\pi i a_j^* a_j} = I - 2a_j^* a_j = -i\gamma_{2j-1}\gamma_{2j}$, we have

$$\Gamma = (-i)^n \gamma_1 ... \gamma_{2n}.$$

Remark. When $n = 2, 4 \times 4$ matrices $\gamma_1, \gamma_2, \gamma_3, \gamma_4$ are celebrated Dirac gamma matrices (for the Euclidean metric on $\mathbb{R}^4$), and $\Gamma = \gamma_5$.

Problem 1.2. Show that the definition of a Clifford algebra $C(V)$ is compatible with the field change: if $k \subset K$ is a field extension and $V_K = K \otimes_k V_k$, then

$$C(V_K) = K \otimes_k C(V_k).$$

Problem 1.3. Let $\mathbb{C} \cdot 1 = C^0 \subset C^1 \subset \cdots \subset C^n = C(V)$ be the natural filtration of a Clifford algebra $C(V)$, where C^r is spanned by the elements $v_1 ... v_s, s \leq r$. Let

$$C^{\mathrm{gr}}(V) = \bigoplus_{k=1}^{n} C^k / C^{k-1}$$

be the associated graded algebra. Show that the skew-symmetrizer map

$$v_1 \wedge \cdots \wedge v_r \mapsto \frac{1}{r!} \sum_{\sigma \in \mathrm{Sym}_r} (-1)^{\varepsilon(\sigma)} v_{\sigma(1)} ... v_{\sigma(r)}$$

establishes a $\mathbb{Z}$-graded algebra isomorphism $\Lambda^\bullet(V) \simeq C^{gr}(V)$, where $\Lambda^\bullet(V)$ is the exterior algebra of V.

Problem 1.4. Formulate and prove the analog of Proposition 1.1 for Clifford algebras with an odd number of generators.

4.4.2 2. Grassmann Algebras

Grassmann algebras - algebras with anticommuting generators - are necessary for the semi-classical description of fermions. The corresponding mathematical definition is the following.

Definition. A Grassmann algebra with n generators is a $\mathbb{C}$-algebra Gr_n with the generators $\theta_1, ..., \theta_n$ satisfying the relations

$$\theta_i \theta_j + \theta_j \theta_i = 0, \quad i, j = 1, ..., n$$

In particular, these relations imply that generators of a Grassmann algebra are nilpotent: $\theta_1^2 = \cdots = \theta_n^2 = 0$. Equivalently,

$$\mathrm{Gr}_n = \mathbb{C}\langle \theta_1, ..., \theta_n \rangle / J$$

- a quotient of a free $\mathbb{C}$-algebra $\mathbb{C}\langle\theta_1, ..., \theta_n\rangle$, generated by $\theta_1, ..., \theta_n$, by the two-sided ideal J generated by the elements $\theta_i\theta_j + \theta_j\theta_i, i, j = 1, ..., n$.
  Remark. It follows from (1.11) that in the semi-classical limit $\hbar \to 0$ fermion operators P_k and $Q_k, k = 1, ..., 2n$, satisfy the defining relations of Grassmann algebra Gr_{2n}.

Comparison with the polynomial algebra

$$\mathbb{C}[x_1, ..., x_n] = \mathbb{C}\langle x_1, ..., x_n\rangle / I$$

- a quotient of a free $\mathbb{C}$-algebra $\mathbb{C}\langle x_1, ..., x_n\rangle$ by the two-sided ideal generated by the elements $x_ix_j - x_jx_i, i, j = 1, ..., n$ - shows that the Grassmann algebra Gr_n can also be considered as a polynomial algebra in anticommuting variables $\theta_1, ..., \theta_n$. In what follows we will always use Roman letters for commuting variables and Greek letters for anticommuting variables, so that

$$\mathrm{Gr}_n = \mathbb{C}[\theta_1, ..., \theta_n].$$

Needless to say, the polynomial algebra $\mathbb{C}[x_1, ..., x_n]$ is isomorphic to the symmetric algebra of the vector space spanned by $x_1, ..., x_n$, and the Grassmann algebra $\mathbb{C}[\theta_1, ..., \theta_n]$ is isomorphic to the exterior algebra $\Lambda^\bullet V$ of the vector space $V = \mathbb{C}\theta_1 \oplus \cdots \oplus \mathbb{C}\theta_n$ with the basis $\theta_1, ..., \theta_n$.

The Grassmann algebra Gr_n is a complex vector space of dimension 2^n and is $\mathbb{Z}$-graded: it admits a decomposition

$$\mathrm{Gr}_n = \bigoplus_{k=0}^{n} \mathrm{Gr}_n^k \tag{2.1}$$

into homogeneous components Gr_n^k of degree k and dimension $\binom{n}{k}, k = 0, ..., n$, where $\mathrm{Gr}_n^0 = \mathbb{C} \cdot 1$. Namely, denote by $|\cdot|$ the degree of homogeneous elements in the Grassmann algebra, $|\alpha| = k$ for $\alpha \in \mathrm{Gr}_n^k$. Then multiplication in Gr_n satisfies $\mathrm{Gr}_n^k \cdot \mathrm{Gr}_n^l \subset \mathrm{Gr}_n^{k+l}$, where $\mathrm{Gr}_n^{k+l} = 0$ if $k + l > n$, and is graded-commutative:

$$\alpha\beta = (-1)^{|\alpha||\beta|}\beta\alpha \tag{2.2}$$

for homogenous elements $\alpha, \beta \in \mathrm{Gr}_n$. The elements of the Grassmann algebra Gr_n of even degree are called even elements, and those of odd degree odd elements.

2.1. Realization of canonical anticommutation relations.

The Grassmann algebra provides us with the explicit representation of canonical anticommutation relations by multiplication and differentiation operators, which is analogous to the holomorphic representation for canonical commutation relations (see Section 2.7 of Chapter 2). Namely, let

$$\partial_i = \frac{\partial}{\partial\theta_i} : \mathrm{Gr}_n \to \mathrm{Gr}_n$$

be left partial differentiation operators, defined on homogeneous monomials $\theta_{i_1}...\theta_{i_k}$ by

$$\frac{\partial}{\partial\theta_i}\theta_{i_1}...\theta_{i_k} = \sum_{l=1}^{k}(-1)^{l-1}\delta_{ii_l}\theta_{i_1}...\check{\theta}_{i_l}...\theta_{i_k}$$

where $\check{\theta}_{i_l}$ denotes the omission of the factor θ_{i_l}. The differentiation operators are of degree -1 and satisfy the graded Leibniz rule,

$$\frac{\partial}{\partial\theta_i}(\alpha\beta) = \frac{\partial\alpha}{\partial\theta_i}\beta + (-1)^{|\alpha|}\alpha\frac{\partial\beta}{\partial\theta_i}.$$

Remark. One can also introduce right partial differentiation operators by

$$(\theta_{i_1}...\theta_{i_k})\,\frac{\partial}{\partial\theta_i} = \sum_{l=1}^{k}(-1)^{k-l}\delta_{ii_l}\theta_{i_1}...\check{\theta}_{i_l}...\theta_{i_k},$$

which satisfy the following graded Leibniz rule:

$$(\alpha\beta)\frac{\partial}{\partial\theta_i} = \alpha\left(\beta\frac{\partial}{\partial\theta_i}\right) + (-1)^{|\beta|}\left(\alpha\frac{\partial}{\partial\theta_i}\right)\beta.$$

To distinguish between the left and right partial derivatives of $f \in \mathrm{Gr}_n$, we will denote them, respectively, by $\frac{\partial}{\partial\theta_i}f$ and $f\frac{\partial}{\partial\theta_i}$.

As a complex vector space, Grassmann algebra Gr_n carries a standard inner product defined by the property that homogeneous monomials $\theta_{i_1}...\theta_{i_k}$, for all $1 \le i_1 < \cdots < i_k \le n$, form an orthonormal basis,

$$(\theta_{i_1}...\theta_{i_k}, \theta_{j_1}...\theta_{j_l}) = \delta_{kl}\delta_{i_1j_1}...\delta_{i_kj_k}. \tag{2.3}$$

By checking on homogeneous monomials, it is elementary to verify that

$$(\partial_i f, g) = \left(f, \hat{\theta}_i g\right), \quad f, g \in \mathrm{Gr}_n$$

where $\hat{\theta}_i$ are left-multiplication by θ_i operators in Gr_n, so that $\hat{\theta}_i = \partial_i^*$. It is also easy to verify that the operators $\hat{\theta}_i$ and ∂_i satisfy the anticommutation relations

$$\left[\hat{\theta}_i, \hat{\theta}_j\right]_+ = [\partial_i, \partial_j]_+ = 0 \quad \text{and} \quad \left[\hat{\theta}_i, \partial_j\right]_+ = \delta_{ij}I, \quad i, j = 1, ..., n$$

where I is an identity operator in Gr_n. Thus we have the following result.

Proposition 2.1. The assignment

$$\mathscr{H}_F \ni \psi_{k_1,...,k_n} \mapsto \theta_1^{k_1}...\theta_n^{k_n} \in \mathrm{Gr}_n$$

establishes an isomorphism $\mathscr{H}_F \simeq \mathrm{Gr}_n$ between the fermion Hilbert space of n identical particles, and the vector space of the Grassmann algebra with n generators. It preserves decompositions (1.9) and (2.1) and has the property that

$$a_i^* \mapsto \hat{\theta}_i \quad \text{and} \quad a_i \mapsto \frac{\partial}{\partial\theta_i}, \quad i = 1, ..., n.$$

Using Proposition 2.1, it is also very easy to verify that the representation of canonical anticommutation relations in the fermion Hilbert space $\mathscr{H}_F$ is irreducible. Indeed, suppose that $B \in \mathrm{End}\,(\mathrm{Gr}_n)$ commutes with all operators $\hat{\theta}_i$ and ∂_i. Then

$$\partial_i(B(1)) = B\,(\partial_i(1)) = 0, \quad i = 1, ..., n.$$

The only solution of the equations $\partial_1 f = \cdots = \partial_n f = 0$ is $f = c \cdot 1$, so that $B(1) = c \cdot 1$. Since B commutes with all creation operators $\hat{\theta}_i$, we obtain $B = cI$.

Remark. We will show in Section 2.3 that by using the notion of Berezin integral, the inner product (2.3) in Gr_n can be written in a form (2.11), which is similar to the definition of the inner product in the holomorphic representation, given by formula (2.52) in Section 2.7 of

Chapter 2.
2.2. Differential forms. An algebra of differential forms in anticommuting variables $\theta_1, ..., \theta_n$ is a $\mathbb{C}$-algebra $\Omega_n^\bullet$ with odd generators $\theta_1, ..., \theta_n$ and even generators $d\theta_1, ..., d\theta_n$ satisfying relations

$$\theta_i \cdot d\theta_j = d\theta_j \cdot \theta_i, \quad i, j = 1, ..., n$$

Equivalently, $\Omega_n^\bullet$ is a symmetric tensor product over $\mathbb{C}$ of Grassmann algebra Gr_n and polynomial algebra $\mathbb{C}[d\theta_1, ..., d\theta_n]$, and every $\omega \in \Omega_n^\bullet$ can be uniquely written as

$$\omega = \sum_{k=0}^{\infty} f_k (d\theta_1)^{k_1} \cdots (d\theta_n)^{k_n}, \quad f_k \in \mathrm{Gr}_n \tag{2.4}$$

where $\boldsymbol{k} = (k_1, ..., k_n)$ is a multi-index and $f_{\boldsymbol{k}} = 0$ for all $\boldsymbol{k}$, except finitely many. By definition, the degree $|\omega_{\boldsymbol{k}}|$ of a homogeneous component $\omega_{\boldsymbol{k}} = f_k (d\theta_1)^{k_1} \cdots (d\theta_n)^{k_n} \in \Omega_n^\bullet$ is $|f_k|$, the degree of $f_k \in \mathrm{Gr}_n$.

Remark. It is instructive to compare the algebra $\Omega_n^\bullet$ with the algebra of polynomial differential forms on $\mathbb{C}^n$. On the one hand, $\Omega_n^\bullet$ is an infinitedimensional algebra in commuting variables $d\theta_1, ..., d\theta_n$ with coefficients in a finite-dimensional algebra Grassmann algebra $\mathbb{C}[\theta_1, ..., \theta_n]$. On the other hand, the algebra of differential forms in commuting variables $x_1, ..., x_n$ is a finite-dimensional algebra in anticommuting variables $dx_1, ..., dx_n$ with coefficients in an infinite-dimensional polynomial algebra $\mathbb{C}[x_1, ..., x_n]$.

The analog of the exterior (de Rham) differential on the algebra $\Omega_n^\bullet$ is the mapping $d : \Omega_n^\bullet \to \Omega_n^\bullet$, defined by

$$d\omega = \sum_{k=0}^{\infty} \sum_{i=1}^{n} \frac{\partial f_k}{\partial \theta_i} d\theta_i (d\theta_1)^{k_1} \cdots (d\theta_n)^{k_n}, \quad f_k \in \mathrm{Gr}_n$$

where ω is given by (2.4). It can also be written as $d = \sum_{i=1}^n d\theta_i \partial_i$, where it is understood that $\partial_i (d\theta_j) = 0$ for all $i, j = 1, ..., n$.

Lemma 2.1. The exterior differential d on $\Omega_n^\bullet$ satisfies the graded Leibniz rule,

$$d(\omega_1 \omega_2) = d\omega_1 \omega_2 + (-1)^{|\omega_1|} \omega_1 d\omega_2$$

for homogeneous ω_1, and is nilpotent, $d^2 = 0$.
Proof. The graded Leibniz rule for d follows from the corresponding property of partial differentiation operators ∂_i. The property $d^2 = 0$ follows from the commutativity of "differentials" $d\theta_i$ and anticommutativity of the partial derivatives ∂_i.

The next result is an analog of the Poincar lemma for differential forms in anticommuting variables.

Lemma 2.2. Suppose that $\omega \in \Omega_n^\bullet$ is closed, $d\omega = 0$. Then ω is exact: there is $\eta \in \Omega_n^\bullet$ such that $\omega = d\eta$.

Definition. A 2 -form $\omega \in \Omega_n^\bullet$,

$$\omega = \frac{1}{2} \sum_{i,j=1}^{n} \omega^{ij} d\theta_i d\theta_j, \quad \omega^{ij} = \omega^{ji} \in \mathrm{Gr}_n \tag{2.5}$$

is called a symplectic form on a Grassmann algebra if it is closed, $d\omega = 0$, and is nondegenerate: the $n \times n$ symmetric matrix $\{\omega^{ij}\}_{i,j=1}^n$ is invertible in Gr_n.

In particular, the 2 -form ω with constant coefficients $\omega^{ij} \in \mathbb{C}$ is always closed, and ω is symplectic if and only if the matrix $\{\omega^{ij}\}_{i,j=1}^n$ is nondegenerate. Since every quadratic form over $\mathbb{C}$ can be written as a sum of squares, we can always assume that generators $\theta_1, ..., \theta_n$ are chosen such that the symplectic form ω with constant coefficients has a canonical form

$$\omega = \frac{1}{2}\sum_{i=1}^{n} d\theta_i d\theta_i. \tag{2.6}$$

With every symplectic form (2.5) there is an associated Poisson bracket on Grassmann algebra, defined by

$$\{f,g\} = \sum_{i,j=1}^{n} \left(f\frac{\partial}{\partial\theta_i}\right)\omega_{ij}\left(\frac{\partial}{\partial\theta_j}g\right), \quad f,g \in \mathrm{Gr}_n \tag{2.7}$$

where $\{\omega_{ij}\}_{i,j=1}^{n}$ is the inverse matrix to $\{\omega^{ij}\}_{i,j=1}^{n}$, and we are using notation for the left and right partial differentiation operators, introduced in the previous section. The following result - an analog of Theorem 2.9 in Section 2.4 of Chapter 1 - is fundamental for formulating Hamiltonian mechanics for the systems with anticommuting variables, which we will discuss in Chapter 8.

Proposition 2.2. Suppose that all coefficients ω^{ij} of a closed symplectic form ω are even. Then the Poisson bracket map

$$\{,\} : \mathrm{Gr}_n \times \mathrm{Gr}_n \to \mathrm{Gr}_n$$

satisfies the following properties.

(i) (Graded skew-symmetry)

$$\{f,g\} = -(-1)^{|f||g|}\{g,f\}.$$

(ii) (Graded Leibniz rule)

$$\{fg,h\} = f\{g,h\} + (-1)^{|f||g|}g\{f,h\}.$$

(iii) (Graded Jacobi identity)

$$\{f,\{g,h\}\} + (-1)^{|f|(|g|+|h|)}\{g,\{h,f\}\} + (-1)^{|h|(|f|+|g|)}\{h,\{f,g\}\} = 0$$

for all $f,g,h \in \mathrm{Gr}_n$.

Proof. Part (i) follows from (2.2), the property

$$\frac{\partial}{\partial\theta_i}f = -(-)^{|f|}f\frac{\partial}{\partial\theta_i}$$

and the condition that coefficients ω^{ij} are even. The graded Leibniz rule follows from the corresponding property of right partial differentiation operators. The graded Jacobi identity for the Poisson bracket

$$\{f,g\} = \sum_{i=1}^{n}\left(f\frac{\partial}{\partial\theta_i}\right)\left(\frac{\partial}{\partial\theta_i}g\right)$$

which corresponds to the canonical symplectic form (2.6), can be verified by a direct computation. The proof of a general case is left to the reader.

Problem 2.1. Complete the proof of Lemma 2.1.

Problem 2.2. Prove Lemma 2.2.

Problem 2.3. Complete the proof of Proposition 2.2.

2.3. Berezin integral. There is a principal difference between differential forms in commuting and in anticommuting variables. The former can be differentiated and integrated, and the differential and integral are related by the Stokes' formula. However, the latter can only be differentiated. Still, there is an analog of the integration over anticommuting variables.

Definition. The integral on a Grassmann algebra Gr_n with an ordered set of generators $\theta_1, ..., \theta_n$ (Berezin integral) is a linear functional $B : \mathrm{Gr}_n \to \mathbb{C}$, defined by

$$B(f) = f^{12...n}$$

where

$$f = \sum_{k=0}^{n} \sum_{1 \le i_1 < \cdots < i_k \le n} f^{i_1 ... i_k} \theta_{i_1} ... \theta_{i_k} \in \mathrm{Gr}_n$$

It is traditional to write the Berezin integral in the form

$$B(f) = \int f(\boldsymbol{\theta}) d\theta_1 ... d\theta_n$$

where $\boldsymbol{\theta} = (\theta_1, ..., \theta_n)$, as if $f = f(\theta_1, ..., \theta_n)$ was actually a "function of anticommuting variables". It follows from the definition of partial differentiation operators that

$$\int f(\boldsymbol{\theta}) d\theta_1 ... d\theta_n = \frac{\partial}{\partial \theta_n} ... \frac{\partial}{\partial \theta_1} f$$

which implies

$$\int \frac{\partial}{\partial \theta_i} f(\boldsymbol{\theta}) d\theta_1 ... d\theta_n = 0.$$

This leads to the following integration by parts formula for the Berezin integral:

$$\int f(\boldsymbol{\theta}) \left(\frac{\partial}{\partial \theta_i} g \right) (\boldsymbol{\theta}) d\theta_1 ... d\theta_n = \int \left(f \frac{\partial}{\partial \theta_i} \right) (\boldsymbol{\theta}) g(\boldsymbol{\theta}) d\theta_1 ... d\theta_n$$

for homogeneous $f, g \in \mathrm{Gr}_n$.

Remark. The Berezin integral is not an integral in the sense of integration theory. It is defined as a linear functional on a Grassmann algebra Gr_n and it depends on the ordering of the generators $\theta_1, ..., \theta_n$ of Gr_n, which is symbolized by $d\theta_1 ... d\theta_n$. For each $\sigma \in \mathrm{Sym}_n$,

$$\int f(\boldsymbol{\theta}) d\theta_1 ... d\theta_n = (-1)^{\varepsilon(\sigma)} \int f(\boldsymbol{\theta}) d\theta_{\sigma(1)} ... d\theta_{\sigma(n)}$$

where $\varepsilon(\sigma)$ is the parity of a permutation σ.

Remark. Using the embeddings $\mathrm{Gr}_k \subset \mathrm{Gr}_n$ for $k \le n$, physicists usually define the Berezin integral as a "repeated integral" starting from the following "one-dimensional integrals":

$$\int d\theta_i = 0, \quad \int \theta_i d\theta_i = 1, \quad i = 1, ..., n$$

Lemma 2.3 (Change of variables for Berezin integral). Let $\theta_1, ..., \theta_n$ and $\tilde{\theta}_1, ..., \tilde{\theta}_n$ be two sets of generators of the Grassmann algebra Gr_n, related by $\theta_i = \sum_{j=1}^{n} a_{ij} \tilde{\theta}_j$, where the $n \times n$ matrix $A = \{a_{ij}\}_{i,j=1}^{n}$ is non-degenerate. Then

$$\int f(\boldsymbol{\theta}) d\theta_1 ... d\theta_n = \frac{1}{\det A} \int \tilde{f}(\tilde{\boldsymbol{\theta}}) d\tilde{\theta}_1 ... d\tilde{\theta}_n$$

where $\tilde{f}(\tilde{\boldsymbol{\theta}}) = f(\boldsymbol{\theta}) = f\left(\sum_{j=1}^{n} a_{1j} \tilde{\theta}_j, ..., \sum_{j=1}^{n} a_{nj} \tilde{\theta}_j \right)$.

Proof. By multi-linear algebra, $\tilde{f}^{12...n} = f^{12...n} \det A$.

Remark. According to the lemma, the "density" $d\theta_1 ... d\theta_n$ has the transformation law

$$d\theta_1 ... d\theta_n = \frac{1}{\det A} d\tilde{\theta}_1 ... d\tilde{\theta}_n \tag{2.8}$$

under the change of variables $\theta_i = \sum_{j=1}^n a_{ij}\tilde{\theta}_j$. This differs from the usual change of variables formula for the Lebesgue integral

$$\int_{\mathbb{R}^n} f(x_1, ..., x_n)\, dx_1 ... dx_n = |\det A| \int_{\mathbb{R}^n} \tilde{f}(y_1, ..., y_n)\, dy_1 ... dy_n \tag{2.9}$$

or $dx_1 ... dx_n = |\det A| dy_1 ... dy_n$, where $x_i = \sum_{j=1}^n a_{ij} y_j$. Of course, the Berezin integral is rather a multiple derivative than an integral with respect to a measure, which explains this profound difference.

Let $A = \{a_{ij}\}_{i,j=1}^n$ be an $n \times n$ skew-symmetric matrix. For even $n = 2m$ its Pfaffian $\mathrm{Pf}(A)$ is defined by

$$\mathrm{Pf}(A) = \frac{1}{m! 2^m} \sum_{\sigma \in \mathrm{Sym}_n} (-1)^{\varepsilon(\sigma)} a_{\sigma(1)\sigma(2)} ... a_{\sigma(n-1)\sigma(n)},$$

where $\varepsilon(\sigma)$ is the parity of a permutation σ. By definition, $\mathrm{Pf}(A) = 0$ when n is odd.

Proposition 2.3 (Gaussian integration for anticommuting variables). Let $A = \{a_{ij}\}_{i,j=1}^n$ be an $n \times n$ skew-symmetric matrix. Then
(i)

$$\int \exp\left\{\frac{1}{2} \sum_{i,j=1}^n a_{ij}\theta_i\theta_j\right\} d\theta_1 ... d\theta_n = \mathrm{Pf}(A)$$

(ii) For any non-degenerate $n \times n$ matrix C

$$\mathrm{Pf}\left(CAC^t\right) = \mathrm{Pf}(A) \det C$$

(iii)

$$\mathrm{Pf}(A)^2 = \det A$$

Proof. Part (i) obviously holds for odd n since the integrand is an even element of Gr_n. By the definition of the Pfaffian, we get for $n = 2m$,

$$\frac{1}{m! 2^m} \left(\sum_{i,j=1}^n a_{ij}\theta_i\theta_j\right)^m = \mathrm{Pf}(A)\theta_1 ... \theta_n$$

and expanding the exponent into power series, we obtain

$$\int \exp\left\{\frac{1}{2} \sum_{i,j=1}^n a_{ij}\theta_i\theta_j\right\} d\theta_1 ... d\theta_n = \mathrm{Pf}(A) \int \theta_1 ... \theta_n d\theta_1 ... d\theta_n = \mathrm{Pf}(A)$$

Part (ii) follows from part (i) and Lemma 2.3. Part (iii) is a classical result, which can be proved by the Berezin integral as follows. Suppose first that A is real-valued. There exists an orthogonal matrix C with determinant 1 such that

$$CAC^{-1} = \begin{pmatrix} 0 & \lambda_1 & \cdots & 0 & 0 \\ -\lambda_1 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & \lambda_m \\ 0 & 0 & \cdots & -\lambda_m & 0 \end{pmatrix}$$

is a block-diagonal matrix. Using part (ii) with this matrix C, we obtain

$$\mathrm{Pf}(A) = \int e^{\lambda_1\tilde\theta_1\tilde\theta_2+\cdots+\lambda_m\tilde\theta_{2m-1}\tilde\theta_{2m}} d\tilde\theta_1 ... d\tilde\theta_{2m} = \lambda_1 ... \lambda_m$$

so that $\mathrm{Pf}(A)^2 = \det A$. This relation holds for complex-valued A, since both sides are polynomials in variables $a_{ij}, 1 \le i < j \le n$, which coincide for real a_{ij}.

For a Grassmann algebra $\mathrm{Gr}_{2n} = \mathbb{C}\left[\theta_1, ..., \theta_n, \bar\theta_1, ..., \bar\theta_n\right]$ with $2n$ generators denote by $\int d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} = \int d\theta_1 d\bar\theta_1 ... d\theta_n d\bar\theta_n$ the corresponding Berezin integral,

$$\int f(\boldsymbol{\theta}, \overline{\boldsymbol{\theta}}) d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} = \frac{\partial}{\partial\bar\theta_n}\frac{\partial}{\partial\theta_n} ... \frac{\partial}{\partial\bar\theta_1}\frac{\partial}{\partial\theta_1} f, \quad f \in \mathbb{C}\left[\theta_1, ..., \theta_n, \bar\theta_1, ..., \bar\theta_n\right].$$

Lemma 2.4. For any $n \times n$ matrix $A = \{a_{ij}\}_{i,j=1}^n$,

$$\int \exp\left\{\sum_{i,j=1}^n a_{ij}\theta_i\bar\theta_j\right\} d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} = \det A$$

Proof. It follows from the definition of a matrix determinant that

$$\frac{1}{n!}\left(\sum_{i,j=1}^n a_{ij}\theta_i\bar\theta_j\right)^n = \det A \theta_1\bar\theta_1 ... \theta_n\bar\theta_n \tag{2.10}$$

Definition. An involution on a Grassmann algebra Gr_n over $\mathbb{C}$ is a complex anti-linear mapping $\mathrm{Gr}_n \ni f \mapsto f^* \in \mathrm{Gr}_n$ satisfying $(f^*)^* = f$ and $(fg)^* = g^* f^*$ for all $f, g \in \mathrm{Gr}_n$.

The Grassmann algebra $\mathbb{C}\left[\theta_1, ..., \theta_n, \bar\theta_1, ..., \bar\theta_n\right]$ has a natural involution defined on generators by $(\theta_1)^* = \bar\theta_1, \left(\bar\theta_1\right)^* = \theta_1, ..., (\theta_n)^* = \bar\theta_n, \left(\bar\theta_n\right)^* = \theta_n$. In particular, for

$$f(\boldsymbol{\theta}) = \sum_{k=0}^n \sum_{1\le i_1<\cdots<i_k\le n} f^{i_1...i_k}\theta_{i_1}...\theta_{i_k} \in \mathrm{Gr}_n \subset \mathrm{Gr}_{2n}$$

we have

$$f(\boldsymbol{\theta})^* = \overline{f(\boldsymbol{\theta})} = \sum_{k=0}^n \sum_{1\le i_1<\cdots<i_k\le n} \overline{f^{i_1...i_k}}\bar\theta_{i_k}...\bar\theta_{i_1} \in \mathrm{Gr}_{2n}$$

The next lemma expresses the inner product on the Grassmann algebra Gr_n, introduced in Section 2.1, in terms of the Berezin integral.

Lemma 2.5. The standard inner product (2.3) on the Grassmann algebra $\mathrm{Gr}_n = \mathbb{C}[\theta_1, ..., \theta_n]$ is given by the following Berezin integral over the Grassmann algebra $\mathrm{Gr}_{2n} = \mathbb{C}\left[\theta_1, ..., \theta_n, \bar\theta_1, ..., \bar\theta_n\right]$:

$$(f_1, f_2) = \int f_1(\boldsymbol{\theta})\overline{f_2(\boldsymbol{\theta})} e^{-\overline{\boldsymbol{\theta}}\boldsymbol{\theta}} d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} \tag{2.11}$$

where $\overline{\boldsymbol{\theta}}\boldsymbol{\theta} = \bar\theta_1\theta_1 + \cdots + \bar\theta_n\theta_n$.

Proof. Put $f_1(\boldsymbol{\theta}) = \theta_{i_1}...\theta_{i_k}$ and $f_2(\boldsymbol{\theta}) = \theta_{j_1}...\theta_{j_l}$. It is clear that the integral (2.11) is 0, unless $k = l$ and $i_1 = j_1, ..., i_k = j_k$, in which case we have

$$\begin{aligned}(\theta_{i_1}...\theta_{i_k}, \theta_{i_1}...\theta_{i_k}) &= \int \theta_{i_1}...\theta_{i_k}\bar\theta_{i_k}...\bar\theta_{i_1} e^{-\left(\bar\theta_1\theta_1+\cdots+\bar\theta_n\theta_n\right)} d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} \\ &= \int \theta_1...\theta_n\bar\theta_n...\bar\theta_1 d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} \\ &= \int \theta_1\bar\theta_1...\theta_n\bar\theta_n d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} = 1\end{aligned}$$

The following result was already stated in Section 2.1. Lemma 2.5 allows us to prove it in a way that is reminiscent of a holomorphic representation (see Section 2.7 of Chapter 2).

Corollary 2.1. The operators ∂_i and $\hat{\theta}_i, i = 1, ..., n$, are adjoint with respect to the inner product on Gr_n.

Proof. Using Lemma 2.5, formulas $\partial_i \overline{f(\boldsymbol{\theta})} = 0, \partial_i e^{-\overline{\boldsymbol{\theta}}\boldsymbol{\theta}} = \bar{\theta}_i e^{-\overline{\boldsymbol{\theta}}\boldsymbol{\theta}}$, and the integration by parts formula, we obtain

$$\begin{aligned}(\partial_i f_1, f_2) &= \int \partial_i f_1(\boldsymbol{\theta}) \overline{f_2(\boldsymbol{\theta})} e^{-\overline{\boldsymbol{\theta}}\boldsymbol{\theta}} d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} \\ &= -(-1)^{|f_1|+|f_2|} \int f_1(\boldsymbol{\theta}) \overline{f_2(\boldsymbol{\theta})} \bar{\theta}_i e^{-\overline{\boldsymbol{\theta}}\boldsymbol{\theta}} d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} \\ &= -(-1)^{|f_1|+|f_2|} \int f_1(\boldsymbol{\theta}) \overline{\theta_i f_2(\boldsymbol{\theta})} e^{-\overline{\boldsymbol{\theta}}\boldsymbol{\theta}} d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} \\ &= \left(f_1, \hat{\theta}_i f_2\right),\end{aligned}$$

since the last integral and $(f_1, \hat{\theta}_i f_2)$ are both 0 unless $|f_1| + |f_2|$ is odd.

Problem 2.4. Evaluate the Berezin integral

$$\int \exp\left\{\frac{1}{2}\sum_{i,j=1}^{n} a_{ij}\theta_i\theta_j + \sum_{k=1}^{n} \eta_k\theta_k\right\} d\theta_1 ... d\theta_n$$

where $\eta_1, ..., \eta_n$ are Grassmann variables.

Problem 2.5. Prove formula (2.10).

Problem 2.6. Prove that

$$\int f(\boldsymbol{\theta}) e^{-\overline{\boldsymbol{\theta}}\boldsymbol{\theta}} d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} = f(0)$$

- the constant term of expansion of $f(\boldsymbol{\theta})$ into the sum of monomials in $\mathbb{C}[\theta_1, ..., \theta_n]$.

4.4.3 3. Graded Linear Algebra

3.1. Graded vector spaces and superalgebras.

The notions of graded vector spaces and superalgebras, introduced in this section, allow us to consider commuting and anticommuting variables on the same footing.

Definition. A $\mathbb{Z}/2\mathbb{Z}$ graded vector space (graded vector space for brevity, or super vector space) over $\mathbb{C}$ is a vector space W with a decomposition

$$W = W^0 \oplus W^1$$

into even and odd subspaces. The elements in $W^0 \cup W^1 \backslash \{0\}$ are called homogeneous and the parity is a map $|\cdot| : W^0 \cup W^1 \backslash \{0\} \to \{0, 1\}$ such that $|w| = 0$ for $w \in W^0$ and $|w| = 1$ for $w \in W^1$.

We reserve the notation V for ordinary (even) vector spaces, denoting graded vector spaces by W. If W is finite-dimensional, we define graded dimension as a pair $(\dim W^0, \dim W^1)$, usually denoted by $n_0|n_1$, where $n_i = \dim W^i, i = 0, 1$. When $W^0 = \mathbb{C}^p$ and $W^1 = \mathbb{C}^q$, the corresponding graded vector space W is denoted by $\mathbb{C}^{p|q}$. A fermion Hilbert space $\mathscr{H}_F$ is a graded vector space with the even and odd subspaces given by decomposition (1.9):

$$\mathscr{H}_F^0 = \bigoplus_{k \text{ even}} \mathscr{H}_k, \quad \mathscr{H}_F^1 = \bigoplus_{k \text{ odd}} \mathscr{H}_k$$

The graded dimension of $\mathscr{H}_F$ is $2^{n-1}|2^{n-1}$.
Direct sums and tensor products of graded vector spaces are defined in the same way as for ordinary vector spaces. For the direct sums the homogeneous subspaces are defined by

$$(W_1 \oplus W_2)^k = W_1^k \oplus W_2^k, \quad k = 0, 1,$$

and for the tensor products they are defined as

$$(W_1 \otimes W_2)^k = \bigoplus_{i+j=k} W_1^i \otimes W_2^j, \quad k = 0, 1$$

The difference between ordinary and graded vector spaces becomes transparent in the definition of the corresponding tensor categories. Namely, the associativity morphism

$$c_{W_1W_2W_3} : W_1 \otimes (W_2 \otimes W_3) \to (W_1 \otimes W_2) \otimes W_3$$

for graded vector spaces is defined by the same formula

$$c_{W_1W_2W_3}\,(w_1 \otimes (w_2 \otimes w_3)) = (w_1 \otimes w_2) \otimes w_3$$

as in the case of ordinary vector spaces, whereas the commutativity morphism

$$\sigma_{W_1W_2} : W_1 \otimes W_2 \to W_2 \otimes W_1$$

is defined for the homogeneous elements by

$$\sigma_{W_1W_2}\,(w_1 \otimes w_2) = (-1)^{|w_1||w_2|} w_2 \otimes w_1$$

The tensor algebra $T(W)$ of a graded vector space W is defined using the associativity morphism. However the exterior algebra $\Lambda^\bullet W$ and symmetric algebra $\mathrm{Sym}(W)$ of W are defined as quotient algebras of $T(W)$ by using the commutativity morphism. Namely,

$$\mathrm{Sym}(W) = T(W)/I,$$

where I is the two-sided ideal in $T(W)$ generated by $w_1 \otimes w_2 - \sigma\,(w_2 \otimes w_1)$, $w_1, w_2 \in W$, and

$$\Lambda^\bullet(W) = T(W)/J,$$

where J is the two-sided ideal in $T(W)$ generated by $w_1 \otimes w_2 + \sigma\,(w_2 \otimes w_1)$, $w_1, w_2 \in W$. Here $\sigma = \sigma_{W,W}$ is the commutativity morphism.

Definition. Let $W = W^0 \oplus W^1$ be a graded vector space. A parity-reversed vector space ΠW is a graded vector space with $(\Pi W)^0 = W^1$ and $(\Pi W)^1 = W^0$.

It immediately follows from the definitions that for even vector space V

$$\mathrm{Sym}(\Pi V) = \Lambda^\bullet(V) \quad \text{and} \quad \Lambda^\bullet(\Pi V) = \mathrm{Sym}(V) \tag{3.1}$$

Definition. A superalgebra over $\mathbb{C}$ is a graded vector space $A = A^0 \oplus A^1$ with a $\mathbb{C}$-algebra structure such that $1 \in A^0$ and

$$A^0 \cdot A^0 \subset A^0, \quad A^0 \cdot A^1 \subset A^1, \quad A^1 \cdot A^1 \subset A^0$$

A superalgebra A is a commutative superalgebra if

$$a \cdot b = (-1)^{|a||b|} b \cdot a$$

for homogeneous elements $a, b \in A$.
An even superalgebra A is just an ordinary $\mathbb{C}$-algebra.

Definition. A left (super) module for a superalgebra A is a graded vector space M with the linear map

$$A \otimes M \ni a \otimes m \mapsto a \cdot m \in M$$

such that $|a \cdot m| = (|a| + |m|) \bmod 2$ for homogeneous $a \in A$ and $m \in M$, and $ab \cdot m = a \cdot (b \cdot m)$ for all $a, b \in A$ and $m \in M$.

Problem 3.

1. Let $\sigma \in \mathrm{Sym}_n$. Show that the isomorphism

$$W_1 \otimes \cdots \otimes W_n \simeq W_{\sigma^{-1}(1)} \otimes \cdots \otimes W_{\sigma^{-1}(n)},$$

induced by the commutativity morphism of graded vector spaces, is well defined does not depend on the representation of σ as a product of transpositions in Sym_n.

Problem 3.

2. Show that for a graded vector space W the algebras $\mathrm{Sym}(W)$ and $\Lambda^\bullet(W)$ are superalgebras.

3.2. Examples of superalgebras.

Example 3.1 (Tensor algebra). The tensor algebra

$$T(V) = \bigoplus_{k=0}^{\infty} V^{\otimes k}, \quad V^0 = \mathbb{C} \cdot 1,$$

of an even vector space V is a superalgebra. The multiplication is given by the tensor product, and even and odd subspaces - by

$$T(V)^0 = \bigoplus_{k \text{ even}} V^{\otimes k}, \quad T(V)^1 = \bigoplus_{k \text{ odd}} V^{\otimes k}.$$

Example 3.2 (Symmetric algebra). The symmetric algebra $\mathrm{Sym}(V)$ of an even vector space V is a commutative algebra. A choice of a basis $x_1, ..., x_n$ of V establishes the isomorphism $\mathrm{Sym}(V) \simeq \mathbb{C}[x_1, ..., x_n]$ - a polynomial algebra in commuting variables $x_1, ..., x_n$.

Example 3.3 (Exterior algebra). The exterior algebra $\Lambda^\bullet V$ of an even vector space V is a commutative superalgebra, with multiplication given by the wedge product; the even and odd subspaces are images of the corresponding subspaces of $T(V)$ under the surjective mapping

$$T(V) \to \Lambda^\bullet V = T(V)/J$$

where J is the two-sided ideal in $T(V)$, generated by the elements $u \otimes v + v \otimes u$, $u, v \in V$. According to (3.1), $\Lambda^\bullet(V) = \mathrm{Sym}(\Pi V)$. The choice of a basis $\theta_1, ..., \theta_n$ of the odd vector space ΠV establishes the isomorphism

$$\Lambda^\bullet(V) \simeq \mathbb{C}\left[\theta_1, ..., \theta_n\right].$$

Here $\mathbb{C}\left[\theta_1, ..., \theta_n\right]$ is the Grassmann algebra - a polynomial algebra in anticommuting variables $\theta_1, ..., \theta_n$.

Example 3.4 (Algebra of differential forms). Let M be an n-dimensional manifold. The graded algebra $\mathcal{A}^\bullet(M)$ of smooth differential forms on M is a commutative superalgebra.

Example 3.5 (Clifford algebra). The Clifford algebra $C(V)$ of a quadratic vector space (V, Q) is a superalgebra, with the multiplication and grading descending from the tensor algebra $T(V)$ under the surjective mapping

$$T(V) \to \Lambda^\bullet V = T(V)/J,$$

where now J is the two-sided ideal in $T(V)$, generated by the elements $u \otimes v + v \otimes u - 2\Phi(u, v) \cdot 1, u, v \in V$. The natural map $V \hookrightarrow C(V)$ is injective, and V is identified with its image in $C(V)$. The elements of V are odd in $C(V)$. The fermion Hilbert space $\mathscr{H}_F$ is a left supermodule for C_{2n}, and the $\mathbb{C}$-algebra isomorphism $\rho : C_{2n} \to \mathrm{End}\left(\mathscr{H}_F\right)$ (see Proposition 1.1) is an isomorphism of superalgebras.

Example 3.6 (Graded matrix algebra). Let W be a graded vector space. The vector space $\mathrm{End}(W)$ of all endomorphisms of W is a graded vector space: the even subspace consists of all endomorphisms which preserve the grading in W, and the odd subspace consists of those which reverse the grading. The vector space $\mathrm{End}(W)$ is a superalgebra with the product given by the composition of endomorphisms, and W is a module for $\mathrm{End}(W)$. When $W = \mathbb{C}^{p|q}$, the superalgebra $\mathrm{End}(W)$ is usually denoted by $\mathrm{Mat}(p|q)$. Its elements can be conveniently represented by 2×2 block matrices

$$A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}$$

where A_{11}, A_{12}, A_{21}, and A_{22} are, respectively, matrices of orders $p \times p, p \times q$, $q \times p$, and $q \times q$. The even and odd elements of $\mathrm{Mat}(p|q)$ are, respectively, block-diagonal and anti-diagonal matrices $\begin{pmatrix} A_{11} & 0 \\ 0 & A_{22} \end{pmatrix}$ and $\begin{pmatrix} 0 & A_{12} \\ A_{21} & 0 \end{pmatrix}$.

Example 3.7 (Lie superalgebra). A graded vector space $\mathfrak{g}$ is called a Lie superalgebra (or, super Lie algebra) if it carries a Lie superbracket - a linear mapping $[\,] :, \mathfrak{g} \otimes \mathfrak{g} \to \mathfrak{g}$ satisfying the following properties.

(i) (Super skew-symmetry)

$$[x, y] = -(-1)^{|x||y|}[y, x]$$

for homogeneous $x, y \in \mathfrak{g}$.

(ii) (Super Jacobi identity)

$$[x, [y, z]] + (-1)^{|x|(|y|+|z|)}[y, [z, x]] + (-1)^{|z|(|x|+|y|)}[z, [x, y]] = 0$$

for homogeneous $x, y, z \in \mathfrak{g}$.

According to Proposition 2.2, a Grassmann algebra Gr_n with a Poisson bracket (2.7) is a Lie superalgebra.

Corresponding to classical simple Lie algebras there are associated Lie superalgebras.

Problem 3.

3. Verify all the statements in this section.

Problem 3.

4. Show that a superalgebra A carries a Lie superalgebra structure with a Lie superbracket defined by

$$[a, b] = ab - (-1)^{|a||b|}ba$$

for homogeneous $a, b \in A$.

3.3. Supertrace and Berezinian. Let $\mathcal{A} = \mathcal{A}^0 \oplus \mathcal{A}^1$ be a commutative superalgebra. We have the following general notion of a graded matrix algebra.

Definition. A graded matrix algebra with coefficients in $\mathcal{A}$ is a superalgebra $\mathrm{Mat}_{\mathcal{A}}(p|q)$ of 2×2 block-matrices

$$A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}$$

where A_{11}, A_{12}, A_{21}, and A_{22} are, respectively, matrices of orders $p \times p$, $p \times q$, $q \times p$, and $q \times q$ with elements in $\mathcal{A}$. The element $A \in \mathrm{Mat}_{\mathcal{A}}(p|q)$ is even if corresponding matrices A_{11} and A_{22} consist of even elements of $\mathcal{A}$, and matrices A_{12} and A_{21} consist of odd elements of $\mathcal{A}$. The element $A \in \mathrm{Mat}_{\mathcal{A}}(p|q)$ is odd if matrices A_{11} and A_{22} consist of odd elements of $\mathcal{A}$, and A_{12} and A_{21} consist of even elements of $\mathcal{A}$. The graded vector space $\mathrm{Mat}_{\mathcal{A}}(p|q)$ is a superalgebra with the product given by the matrix multiplication.

The algebra $\mathrm{Mat}(p|q)$ in Example 3.6 corresponds to the case $\mathcal{A} = \mathbb{C}$; another interesting example is when $\mathcal{A}$ is a Grassmann algebra.

It is quite remarkable that such basic notions of linear algebra as trace and determinant admit non-trivial generalizations for graded matrix algebras.

Definition. A supertrace on a graded matrix algebra is a linear mapping $\mathrm{Tr}_s : \mathrm{Mat}_{\mathcal{A}}(p|q) \to \mathcal{A}$, defined by

$$\mathrm{Tr}_s A = \mathrm{Tr}\, A_{11} - (-1)^{|A|}\,\mathrm{Tr}\, A_{22}, \quad A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} \in \mathrm{Mat}_{\mathcal{A}}(p|q)$$

where Tr is the ordinary matrix trace.

Proposition 3.1 (The cyclic property of the supertrace).

$$\mathrm{Tr}_s AB = (-1)^{|A||B|}\,\mathrm{Tr}_s BA, \quad A, B \in \mathrm{Mat}_{\mathcal{A}}(p|q).$$

Proof. We check only the case when both 2×2 block-matrices A and B are even elements of $\mathrm{Mat}_{\mathcal{A}}(p|q)$. Other cases are treated similarly and are left to the reader. We have, using the cyclic property of the trace,

$$\begin{aligned} \mathrm{Tr}_s AB &= \mathrm{Tr}\,(A_{11}B_{11} + A_{12}B_{21}) - \mathrm{Tr}\,(A_{21}B_{12} + A_{22}B_{22}) \\ &= \mathrm{Tr}\,(B_{11}A_{11} - B_{21}A_{12}) - \mathrm{Tr}\,(-B_{12}A_{21} + B_{22}A_{22}) = \mathrm{Tr}_s BA. \end{aligned}$$

The superalgebra $\mathrm{End}\,(\mathscr{H}_F)$ corresponds to the case $\mathcal{A} = \mathbb{C}$ and is isomorphic to $\mathrm{Mat}\,(2^{n-1}|2^{n-1})$. The supertace on $\mathrm{End}\,(\mathscr{H}_F)$ is given by

$$\mathrm{Tr}_s\, A = \mathrm{Tr}\, A_{11} - \mathrm{Tr}\, A_{22} = \mathrm{Tr}\, A\Gamma, \quad A \in \mathrm{End}\,(\mathscr{H}_F)\,, \tag{3.2}$$

where Γ is the chirality operator (see Section 1.2). It has the following 2×2 block-matrix form:

$$\Gamma = \begin{pmatrix} I & 0 \\ 0 & -I \end{pmatrix},$$

where I stands for the identity operator in $\mathscr{H}_F^0$ and $\mathscr{H}_F^1$.
It is a non-trivial problem to define a superdeterminant - a natural analog of the determinant for graded matrix algebras, which is multiplicative and generalizes the rule $\det e^A = e^{\mathrm{Tr}\, A}$. The corresponding notion, which is defined only for invertible $A \in \mathrm{Mat}_{\mathcal{A}}(p|q)$, was introduced by F.A. Berezin. It is now commonly called Berezinian and is denoted by $\mathrm{Ber}(A)$.

Consider first the case of even diagonal $A = \begin{pmatrix} A_{11} & 0 \\ 0 & A_{22} \end{pmatrix}$. The relation

$$\mathrm{Ber}\left(e^A\right) = e^{\mathrm{Tr}_s\, A}$$

defines the Berezinian by

$$\mathrm{Ber}(A) = \det A_{11} \det A_{22}^{-1}.$$

Thus in this case the even $q \times q$ matrix A_{22} is necessarily invertible, i.e., $\det A_{22}$ is an invertible element of the commutative algebra $\mathcal{A}^0$, so that the inverse matrix A_{22}^{-1} exists. Now consider the general even $A \in \mathrm{Mat}_{\mathcal{A}}(p|q)$, and suppose that A_{22} is invertible. It is easy to verify the following analog of the Gauss decomposition:

$$\begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} = \begin{pmatrix} I_p & A_{12}A_{22}^{-1} \\ 0 & I_q \end{pmatrix} \begin{pmatrix} A_{11} - A_{12}A_{22}^{-1}A_{21} & 0 \\ 0 & A_{22} \end{pmatrix} \begin{pmatrix} I_p & 0 \\ A_{22}^{-1}A_{21} & I_q \end{pmatrix},$$

where I_p and I_q are, respectively $p \times p$ and $q \times q$ identity matrices. This justifies the following definition.

Definition. Let $A \in \mathrm{Mat}_{\mathcal{A}}(p|q)$ be even and such that the corresponding even $q \times q$ matrix A_{22} is invertible. Then the Berezinian (superdeterminant) of A is given by

$$\mathrm{Ber}(A) = \det\left(A_{11} - A_{12}A_{22}^{-1}A_{21}\right) \det A_{22}^{-1}.$$

Assuming that the $p \times p$ matrix A_{11} is invertible, we get the decomposition

$$\begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} = \begin{pmatrix} I_p & 0 \\ A_{21}A_{11}^{-1} & I_q \end{pmatrix} \begin{pmatrix} A_{11} & 0 \\ 0 & A_{22} - A_{21}A_{11}^{-1}A_{12} \end{pmatrix} \begin{pmatrix} I_p & A_{11}^{-1}A_{12} \\ 0 & I_q \end{pmatrix},$$

which suggests that also

$$\mathrm{Ber}(A) = \det A_{11} \det\left(A_{22} - A_{21}A_{11}^{-1}A_{12}\right)^{-1}.$$

It is a fundamental fact that for even invertible $A \in \mathrm{Mat}_{\mathcal{A}}(p|q)$ these two formulas for the Berezinian coincide.

Theorem 3.1. Let

$$A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}$$

be an even element of $\mathrm{Mat}_{\mathcal{A}}(p|q)$. Then
(i) A is invertible if and only if the matrices A_{11} and A_{22} are invertible.
(ii) For invertible $A, \mathrm{Ber}(A)$ is an invertible element of $\mathcal{A}^0$ satisfying
$\mathrm{Ber}(A) = \det\left(A_{11} - A_{12}A_{22}^{-1}A_{21}\right)\det A_{22}^{-1} = \det A_{11}\det\left(A_{22} - A_{21}A_{11}^{-1}A_{12}\right)^{-1}$ and

$$\mathrm{Ber}\left(A^{-1}\right) = \mathrm{Ber}(A)^{-1}$$

(iii) If even $A, B \in \mathrm{Mat}_{\mathcal{A}}(p|q)$ are invertible, then

$$\mathrm{Ber}(AB) = \mathrm{Ber}(A)\,\mathrm{Ber}(B)$$

Problem 3.

5. Complete the proof of Proposition 3.1.

Problem 3.

6. Prove Theorem 3.1.

4.4.4 4. Path Integrals for Anticommuting Variables

4.1. Wick and matrix symbols.

Here we describe the calculus of Wick and matrix symbols of operators in the fermion Hilbert space $\mathscr{H}_F$, which is analogous to the treatment of Wick and matrix symbols in the holomorphic representation in Section 2.7 of Chapter 2. As well as in the bosonic case, it is a tradition to work in anti-holomorphic representation by using $\mathscr{H}_F = \mathbb{C}\left[\bar{\theta}_1, ..., \bar{\theta}_n\right]$ as the fermion Hilbert space with the annihilation and creation operators

$$a_k = \hat{\bar{\theta}}_k \quad \text{and} \quad a_k^* = \frac{\partial}{\partial\bar{\theta}_k}, \quad k = 1, ..., n \tag{4.1}$$

The inner product (2.11) takes the form

$$(f_1, f_2) = \int f_1(\overline{\boldsymbol{\theta}})\overline{f_2(\overline{\boldsymbol{\theta}})}e^{-\boldsymbol{\theta}\overline{\boldsymbol{\theta}}}d\overline{\boldsymbol{\theta}}d\boldsymbol{\theta} \tag{4.2}$$

and the monomials

$$f_I(\overline{\boldsymbol{\theta}}) = \bar{\theta}_{i_1}...\bar{\theta}_{i_k}, \quad 1 \le i_1 < \cdots < i_k \le n$$

parametrized by subsets $I = \{i_1, ..., i_k\} \subseteq \{1, ..., n\}$, form an orthonormal basis in $\mathscr{H}_F$.

Definition. A matrix symbol of an operator $A : \mathscr{H}_F \to \mathscr{H}_F$ is an element $\tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) \in \mathbb{C}\left[\bar{\theta}_1, ..., \bar{\theta}_n, \theta_1, ..., \theta_n\right]$, defined by

$$\begin{aligned}\tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) &= \sum_{I,J}(Af_J, f_I)\, f_I(\overline{\boldsymbol{\theta}})\overline{f_J(\overline{\boldsymbol{\theta}})} \\ &= \sum_{I,J}(Af_J, f_I)\,\bar{\theta}_{i_1}...\bar{\theta}_{i_k}\theta_{j_l}...\theta_{j_1}\end{aligned}$$

Here summation goes over all subsets $I = \{i_1, ..., i_k\}$ and $J = \{j_1, ..., j_l\}$ of the set $\{1, ..., n\}$, and as in Section 2.3, we denote by $\overline{f(\overline{\boldsymbol{\theta}})}$ a natural involution on the Grassmann algebra $\mathbb{C}\left[\bar{\theta}_1, ..., \bar{\theta}_n, \theta_1, ..., \theta_n\right]$,

$$\overline{f_J(\overline{\boldsymbol{\theta}})} = \theta_{j_l}...\theta_{j_1} \quad \text{for} \quad f_J(\overline{\boldsymbol{\theta}}) = \bar{\theta}_{j_1}...\bar{\theta}_{j_l}.$$

According to Proposition 1.1, $C_{2n} \simeq \mathrm{End}\,(\mathscr{H}_F)$, so that every operator $A : \mathscr{H}_F \to \mathscr{H}_F$ can be uniquely represented in a Wick normal form as follows:

$$A = \sum_{I,J} K_{IJ} a^*_{i_1}...a^*_{i_k} a_{j_1}...a_{j_l}.$$

Definition. A Wick symbol of an operator $A : \mathscr{H}_F \to \mathscr{H}_F$ is an element $A(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) \in \mathbb{C}\left[\bar{\theta}_1, ..., \bar{\theta}_n, \theta_1, ..., \theta_n\right]$, defined by

$$A(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) = \sum_{I,J} K_{IJ} \bar{\theta}_{i_1}...\bar{\theta}_{i_k} \theta_{j_1}...\theta_{j_l}$$

Remark. The definition of matrix and Wick symbols in the fermion case repeats verbatim the corresponding definition for the bosonic case in Section 2.7 of Chapter 2. Note, however, that in the fermion case the product $\theta_{j_l}...\theta_{j_1}$ in the definition of the matrix symbol has reverse ordering, as is required by the inner product (4.2) in $\mathbb{C}\left[\bar{\theta}_1, ..., \bar{\theta}_n\right]$.

To matrix and Wick symbols $\tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})$ and $A(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})$ of an operator A one canonically associates elements $\tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\alpha}), A(\overline{\boldsymbol{\theta}}, \boldsymbol{\alpha})$ and $\tilde{A}(\overline{\boldsymbol{\alpha}}, \boldsymbol{\theta}), A(\overline{\boldsymbol{\alpha}}, \boldsymbol{\theta})$ in the larger Grassmann algebra

$$\mathbb{C}[\boldsymbol{\alpha}, \overline{\boldsymbol{\alpha}}, \boldsymbol{\theta}, \overline{\boldsymbol{\theta}}] = \mathbb{C}\left[\alpha_1, ..., \alpha_n, \bar{\alpha}_1, ..., \bar{\alpha}_n, \theta_1, ..., \theta_n \bar{\theta}_1, ..., \bar{\theta}_n\right]$$

by replacing, correspondingly, θ_i by α_i and $\bar{\theta}_i$ by $\bar{\alpha}_i$. The incomplete Berezin integral $\int d\boldsymbol{\alpha} d\overline{\boldsymbol{\alpha}}$ on $\mathbb{C}[\boldsymbol{\alpha}, \overline{\boldsymbol{\alpha}}, \boldsymbol{\theta}, \overline{\boldsymbol{\theta}}]$ is defined by

$$\int f d\boldsymbol{\alpha} d\overline{\boldsymbol{\alpha}} = \frac{\partial}{\partial \bar{\alpha}_n} \frac{\partial}{\partial \alpha_n} \cdots \frac{\partial}{\partial \bar{\alpha}_1} \frac{\partial}{\partial \alpha_1} f, \quad f \in \mathbb{C}[\boldsymbol{\alpha}, \overline{\boldsymbol{\alpha}}, \boldsymbol{\theta}, \overline{\boldsymbol{\theta}}],$$

and has the property

$$\int h(\boldsymbol{\theta}, \overline{\boldsymbol{\theta}}) g(\boldsymbol{\alpha}, \overline{\boldsymbol{\alpha}}) d\boldsymbol{\alpha} d\overline{\boldsymbol{\alpha}} = h(\boldsymbol{\theta}, \overline{\boldsymbol{\theta}}) \int g(\boldsymbol{\alpha}, \overline{\boldsymbol{\alpha}}) d\boldsymbol{\alpha} d\overline{\boldsymbol{\alpha}} \tag{4.3}$$

We will also use the incomplete Berezin integral $\int d\overline{\boldsymbol{\theta}} d\boldsymbol{\theta}$, defined by

$$\int f d\overline{\boldsymbol{\theta}} d\boldsymbol{\theta} = \frac{\partial}{\partial \theta_n} \frac{\partial}{\partial \bar{\theta}_n} \cdots \frac{\partial}{\partial \theta_1} \frac{\partial}{\partial \bar{\theta}_1} f, \quad f \in \mathbb{C}[\boldsymbol{\alpha}, \overline{\boldsymbol{\alpha}}, \boldsymbol{\theta}, \overline{\boldsymbol{\theta}}].$$

As follows from the proof of Corollary 2.1,

$$\int (a^*_k f_1)\, \overline{f_2} e^{-\boldsymbol{\theta}\overline{\boldsymbol{\theta}}} d\overline{\boldsymbol{\theta}} d\boldsymbol{\theta} = -(-1)^{|f|_1 + |f_2|} \int f_1 \overline{(a_k f_2)} e^{-\boldsymbol{\theta}\overline{\boldsymbol{\theta}}} d\overline{\boldsymbol{\theta}} d\boldsymbol{\theta} \tag{4.4}$$

where operators a^*_k and a_k are given by (4.1), and $f_1, f_2 \in \mathbb{C}[\boldsymbol{\alpha}, \overline{\boldsymbol{\alpha}}, \boldsymbol{\theta}, \overline{\boldsymbol{\theta}}]$.
The next result shows that the matrix symbol of an operator A in $\mathscr{H}_F$, which is just a $2^n \times 2^n$ matrix, can be considered as an integral kernel in anticommuting variables!

Lemma 4.1. Let $\tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})$ be the matrix symbol of an operator A in $\mathscr{H}_F$. Then for every $f(\overline{\boldsymbol{\theta}}) \in \mathscr{H}_F$,

$$(Af)(\overline{\boldsymbol{\theta}}) = \int \tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\alpha}) f(\overline{\boldsymbol{\alpha}}) e^{-\overline{\boldsymbol{\alpha}}\boldsymbol{\alpha}} d\boldsymbol{\alpha} d\overline{\boldsymbol{\alpha}} \tag{4.5}$$

Proof. It is sufficient to verify (4.5) for $f = f_K$, where $K = \{k_1, ..., k_m\} \subseteq \{1, ..., n\}$. Using (4.3) and Lemma 2.5, we get

$$\int \tilde{A}(\overline{\boldsymbol{\theta}},\boldsymbol{\alpha})f_K(\overline{\boldsymbol{\alpha}})e^{-\overline{\boldsymbol{\alpha}}\boldsymbol{\alpha}}d\boldsymbol{\alpha}d\overline{\boldsymbol{\alpha}} = \sum_{I,J}\left(Af_J,f_I\right)f_I(\overline{\boldsymbol{\theta}})\int \overline{f_J(\overline{\boldsymbol{\alpha}})}f_K(\overline{\boldsymbol{\alpha}})e^{-\overline{\boldsymbol{\alpha}}\boldsymbol{\alpha}}d\boldsymbol{\alpha}d\overline{\boldsymbol{\alpha}}$$
$$= \sum_{I}\left(Af_K,f_I\right)f_I(\overline{\boldsymbol{\theta}}) = \left(Af_K\right)(\overline{\boldsymbol{\theta}})$$

Next, we introduce Grassmann analogs of the coherent states (see Section 2.7 of Chapter 2). Put

$$\Phi_{\boldsymbol{\alpha}}(\overline{\boldsymbol{\theta}}) = e^{\overline{\boldsymbol{\theta}}\boldsymbol{\alpha}} = \sum_I f_I(\overline{\boldsymbol{\theta}})\overline{f_I(\overline{\boldsymbol{\alpha}})} \quad \text{and} \quad \tilde{\Phi}_{\boldsymbol{\alpha}}(\boldsymbol{\theta}) = e^{-\overline{\boldsymbol{\theta}}\boldsymbol{\alpha}} = \sum_I \overline{f_I(\overline{\boldsymbol{\alpha}})}f_I(\overline{\boldsymbol{\theta}})$$

As in the bosonic case, elements $\Phi_{\boldsymbol{\alpha}}, \tilde{\Phi}_{\boldsymbol{\alpha}} \in \mathbb{C}[\boldsymbol{\alpha},\overline{\boldsymbol{\alpha}},\boldsymbol{\theta},\overline{\boldsymbol{\theta}}]$ satisfy

$$a_k\Phi_{\boldsymbol{\alpha}} = \alpha_k\Phi_{\boldsymbol{\alpha}} \quad \text{and} \quad a_k\tilde{\Phi}_{\boldsymbol{\alpha}} = -\alpha_k\tilde{\Phi}_{\boldsymbol{\alpha}}, \quad k = 1,...,n \tag{4.6}$$

It is very easy to express the matrix symbol of an operator in terms of the coherent states.

Lemma 4.2. Let $\tilde{A}(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha})$ be the matrix symbol of an operator A in $\mathscr{H}_F$. Then

$$\tilde{A}(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha}) = \left(A\Phi_{\boldsymbol{\alpha}},\tilde{\Phi}_{\boldsymbol{\alpha}}\right)$$

Proof. The proof is a straightforward computation (cf. the proof of Lemma 2.4 in Section 2.7 of Chapter 2):

$$\tilde{A}(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha}) = \sum_{I,J}\left(Af_J,f_I\right)f_I(\overline{\boldsymbol{\alpha}})\overline{f_J(\overline{\boldsymbol{\alpha}})}$$
$$= \sum_{I,J}\left(Af_J\overline{f_J(\overline{\boldsymbol{\alpha}})},\overline{f_I(\overline{\boldsymbol{\alpha}})}f_I\right) = \left(A\Phi_{\boldsymbol{\alpha}},\tilde{\Phi}_{\boldsymbol{\alpha}}\right)$$

The next result is an exact analog of Lemma 2.4 in Section 2.7 of Chapter 2.

Lemma 4.3. The matrix and Wick symbols of an operator A in $\mathscr{H}_F$ are related by

$$\tilde{A}(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha}) = e^{\overline{\boldsymbol{\alpha}}\boldsymbol{\alpha}}A(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha})$$

Moreover, $\tilde{A}(\overline{\boldsymbol{\alpha}},\boldsymbol{\theta}) = e^{\overline{\boldsymbol{\alpha}}\boldsymbol{\theta}}A(\overline{\boldsymbol{\alpha}},\boldsymbol{\theta})$ and $\tilde{A}(\overline{\boldsymbol{\theta}},\boldsymbol{\alpha}) = e^{\overline{\boldsymbol{\theta}}\boldsymbol{\alpha}}A(\overline{\boldsymbol{\theta}},\boldsymbol{\alpha})$.

Proof. As follows from the definition of coherent states,

$$\left(\Phi_{\boldsymbol{\alpha}},\tilde{\Phi}_{\boldsymbol{\alpha}}\right) = e^{\overline{\boldsymbol{\alpha}}\boldsymbol{\alpha}}$$

Now representing the operator A in a Wick normal form and using properties (4.4) and (4.6), we obtain

$$\left(A\Phi_{\boldsymbol{\alpha}},\tilde{\Phi}_{\boldsymbol{\alpha}}\right) = \sum_{I,J}K_{IJ}\left(a^*_{i_1}...a^*_{i_k}a_{j_1}...a_{j_l}\Phi_{\boldsymbol{\alpha}},\tilde{\Phi}_{\boldsymbol{\alpha}}\right)$$
$$= \sum_{I,J}(-1)^{kl+k}K_{IJ}\left(a_{j_1}...a_{j_l}\Phi_{\boldsymbol{\alpha}},a_{i_k}...a_{i_1}\tilde{\Phi}_{\boldsymbol{\alpha}}\right)$$
$$= \sum_{I,J}(-1)^{kl}K_{IJ}\left(\alpha_{j_1}...\alpha_{j_l}\Phi_{\boldsymbol{\alpha}},\alpha_{i_k}...\alpha_{i_1}\tilde{\Phi}_{\boldsymbol{\alpha}}\right)$$
$$= \sum_{I,J}(-1)^{kl}K_{IJ}\alpha_{j_1}...\alpha_{j_l}\bar{\alpha}_{i_1}...\bar{\alpha}_{i_k}\left(\Phi_{\boldsymbol{\alpha}},\tilde{\Phi}_{\boldsymbol{\alpha}}\right)$$
$$= A(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha})\left(\Phi_{\boldsymbol{\alpha}},\tilde{\Phi}_{\boldsymbol{\alpha}}\right) = e^{\overline{\boldsymbol{\alpha}\alpha}}A(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha})$$

The same computation, after replacing $\Phi_{\boldsymbol{\alpha}}$ by Φ_θ, or $\tilde{\Phi}_{\boldsymbol{\alpha}}$ by $\tilde{\Phi}_\theta$, proves the remaining two formulas.

Thus we have shown that $2^n \times 2^n$ matrices - operators in the fermion Hilbert space $\mathscr{H}_F$ - can be considered as integral operators in anticommuting variables with the integral kernels given by matrix or Wick symbols. The next result is an exact analog of Theorem 2.2 in Section 2.7 of Chapter 2, and establishes the calculus of symbols for operators in $\mathscr{H}_F$.

Theorem 4.1. Let A_1 and A_2 be operators in $\mathscr{H}_F$ with matrix symbols $\tilde{A}_1(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})$ and $\tilde{A}_2(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})$ and Wick symbols $A_1(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})$ and $A_2(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})$. Then the following formulas hold.
(i) The matrix and Wick symbols of the operator $A = A_1 A_2$ are given by

$$\tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) = \int \tilde{A}_1(\overline{\boldsymbol{\theta}}, \boldsymbol{\alpha}) \tilde{A}_2(\overline{\boldsymbol{\alpha}}, \boldsymbol{\theta}) e^{-\overline{\boldsymbol{\alpha}}\boldsymbol{\alpha}} d\boldsymbol{\alpha} d\overline{\boldsymbol{\alpha}}$$

$$A(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) = \int A_1(\overline{\boldsymbol{\theta}}, \boldsymbol{\alpha}) A_2(\overline{\boldsymbol{\alpha}}, \boldsymbol{\theta}) e^{-(\overline{\boldsymbol{\theta}} - \overline{\boldsymbol{\alpha}})(\boldsymbol{\theta} - \boldsymbol{\alpha})} d\boldsymbol{\alpha} d\overline{\boldsymbol{\alpha}}$$

(ii) The trace and supertrace of an operator A in $\mathscr{H}_F$ are given by

$$\operatorname{Tr} A = \int \tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) e^{-\boldsymbol{\theta}\overline{\boldsymbol{\theta}}} d\overline{\boldsymbol{\theta}} d\boldsymbol{\theta} = \int A(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) e^{-2\boldsymbol{\theta}\overline{\boldsymbol{\theta}}} d\overline{\boldsymbol{\theta}} d\boldsymbol{\theta}$$

$$\operatorname{Tr}_s A = \int \tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) e^{-\overline{\boldsymbol{\theta}}\boldsymbol{\theta}} d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} = \int A(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}}$$

Proof. Part (i) for matrix symbols is proved by the following straightforward computation:

$$\begin{aligned}
&\int \tilde{A}_1(\overline{\boldsymbol{\theta}}, \boldsymbol{\alpha}) \tilde{A}_2(\overline{\boldsymbol{\alpha}}, \boldsymbol{\theta}) e^{-\overline{\boldsymbol{\alpha}}\boldsymbol{\alpha}} d\boldsymbol{\alpha} d\overline{\boldsymbol{\alpha}} \\
&= \sum_{I,J} \sum_{K,L} (A_1 f_J, f_I) (A_2 f_L, f_K) \int f_I(\overline{\boldsymbol{\theta}}) \overline{f_J(\overline{\boldsymbol{\alpha}})} f_K(\overline{\boldsymbol{\alpha}}) \overline{f_L(\overline{\boldsymbol{\theta}})} e^{-\overline{\boldsymbol{\alpha}}\boldsymbol{\alpha}} d\boldsymbol{\alpha} d\overline{\boldsymbol{\alpha}} \\
&= \sum_{I,J,L} (A_1 f_J, f_I) (A_2 f_L, f_J) f_I(\overline{\boldsymbol{\theta}}) \overline{f_L(\overline{\boldsymbol{\theta}})} \\
&= \sum_{I,J,L} (A_2 f_L, f_J) (f_J, A_1^* f_I) f_I(\overline{\boldsymbol{\theta}}) \overline{f_L(\overline{\boldsymbol{\theta}})} \\
&= \sum_{I,L} (A_2 f_L, A_1^* f_I) f_I(\overline{\boldsymbol{\theta}}) \overline{f_L(\overline{\boldsymbol{\theta}})} = \sum_{I,L} (A_1 A_2 f_L, f_I) f_I(\overline{\boldsymbol{\theta}}) \overline{f_L(\overline{\boldsymbol{\theta}})} \\
&= \tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})
\end{aligned}$$

The corresponding formula for the Wick symbols now follows from Lemma 4.3. The proof of part (ii) is also straightforward. We have

$$\begin{aligned}
\int \tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) e^{-\boldsymbol{\theta}\overline{\boldsymbol{\theta}}} d\overline{\boldsymbol{\theta}} d\boldsymbol{\theta} &= \sum_{I,J} (A f_J, f_I) \int f_I(\overline{\boldsymbol{\theta}}) \overline{f_J(\overline{\boldsymbol{\theta}})} e^{-\boldsymbol{\theta}\overline{\boldsymbol{\theta}}} d\overline{\boldsymbol{\theta}} d\boldsymbol{\theta} \\
&= \sum_I (A f_I, f_I) = \operatorname{Tr} A
\end{aligned}$$

Similarly,

$$\begin{aligned}
\int \tilde{A}(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) e^{-\overline{\boldsymbol{\theta}}\boldsymbol{\theta}} d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} &= \sum_{I,J} (A f_J, f_I) \int f_I(\overline{\boldsymbol{\theta}}) \overline{f_J(\overline{\boldsymbol{\theta}})} e^{-\overline{\boldsymbol{\theta}}\boldsymbol{\theta}} d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} \\
&= \sum_I (-1)^{|I|} (A f_I, f_I) = \operatorname{Tr}_s A
\end{aligned}$$

where $|I|$ denotes the cardinality of the subset $I \subseteq \{1, ..., n\}$. Corresponding formulas for the Wick symbol follow from Lemma 4.3.

Problem 4.1. Verify directly all results in this section for the simplest case of one degree of freedom, when $\mathscr{H}_F = \mathbb{C}^2$.

Problem 4.2. Show that the Wick symbol of the product $A = A_l ... A_1$ is given by

$$A(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}) = \int \cdots \int A_l \left(\overline{\boldsymbol{\theta}}, \boldsymbol{\alpha}_{l-1}\right) ... A_1 \left(\overline{\boldsymbol{\alpha}}_1, \boldsymbol{\theta}\right) \exp\left\{\sum_{k=1}^{l-1} \overline{\boldsymbol{\alpha}}_k \left(\boldsymbol{\alpha}_{k-1} - \boldsymbol{\alpha}_k\right) + \overline{\boldsymbol{\theta}} \left(\boldsymbol{\alpha}_{l-1} - \boldsymbol{\theta}\right)\right\}$$
$$d\boldsymbol{\alpha}_1 d\overline{\boldsymbol{\alpha}}_1 ... d\boldsymbol{\alpha}_{l-1} d\overline{\boldsymbol{\alpha}}_{l-1}$$

where $\boldsymbol{\alpha}_0 = \boldsymbol{\theta}$ and $A_k(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})$ are the Wick symbols of the operators A_k.

Problem 4.3. Prove that the Wick symbol $\Gamma(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})$ of the chirality operator Γ is $e^{-2\bar{\theta}\theta}$.

4.2. Path integral for the evolution operator. Let H be a Hamiltonian of a system of n fermions - an operator in $\mathscr{H}_F$ with the Wick symbol $H(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})$. Here we express the Wick symbol $U(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}; T)$ of the evolution operator $U(T) = e^{-iTH}$ by using the path integral over Grassmann variables. Our exposition will be parallel to that in Section 2.4 of Chapter 5, with obvious simplification due to the fact that fermion Hilbert space $\mathscr{H}_F$ is finitedimensional. Namely, the following elementary result replaces assumption (2.11), made in Section 2.4 of Chapter 5.

Lemma 4.4. Let $\tilde{U}(\Delta t)$ be the operator with the Wick symbol $e^{-iH(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta})\Delta t}$. Then

$$U(T) = \lim_{N \to \infty} \tilde{U}(\Delta t)^N, \quad \text{where} \quad \Delta t = \frac{T}{N}.$$

Proof. The Wick symbol of the operator $R(\Delta t) = I - i\hat{H}\Delta t - \tilde{U}(\Delta t)$ is a polynomial in Δt with Grassmann algebra coefficients, which starts with the term $(\Delta t)^2$. It is easy to see that $\|R(\Delta t)\| \leq c(\Delta t)^2$ for some $c > 0$, and

$$U(T) = \lim_{N \to \infty} (I - iH\Delta t)^N = \lim_{N \to \infty} (U(\Delta t) + R(\Delta t))^N = \lim_{N \to \infty} \tilde{U}(\Delta t)^N$$

Using the formula for the composition of Wick symbols (see Theorem 4.1 and Problem 4.2), we can represent the Wick symbol $U_N(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}; T)$ of the operator $\tilde{U}(\Delta t)^N$ as an $(N-1)$-fold Berezin integral. Namely, consider the anticommuting variables $\boldsymbol{\alpha}_k = \{\alpha_k^1, ..., \alpha_k^n\}, \overline{\boldsymbol{\alpha}}_k = \{\bar{\alpha}_k^1, ..., \bar{\alpha}_k^n\}, k = 1, ..., N-1$ - generators of the Grassmann algebra with involution – and denote $\overline{\boldsymbol{\alpha}}_k \boldsymbol{\alpha}_k = \sum_{l=1}^n \bar{\alpha}_k^l \alpha_k^l$, etc. Then

$$U_N(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}; T) = \int \cdots \int \exp\left\{\sum_{k=1}^{N} \left(\overline{\boldsymbol{\alpha}}_k \left(\boldsymbol{\alpha}_{k-1} - \boldsymbol{\alpha}_k\right) + \overline{\boldsymbol{\theta}} \left(\boldsymbol{\alpha}_N - \boldsymbol{\theta}\right)\right.\right.$$
$$\left.\left. -iH\left(\overline{\boldsymbol{\alpha}}_k, \boldsymbol{\alpha}_{k-1}\right)\Delta t\right)\right\} \prod_{k=1}^{N-1} d\boldsymbol{\alpha}_k d\overline{\boldsymbol{\alpha}}_k$$

where $\boldsymbol{\alpha}_0 = \boldsymbol{\theta}$, and we put $\overline{\boldsymbol{\alpha}}_N = \overline{\boldsymbol{\theta}}$. It follows from Lemma 4.4 that

$$U(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}; T) = \lim_{N \to \infty} U_N(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}; T) = \lim_{N \to \infty} \int \cdots \int \tag{4.7}$$

$$\exp\left\{\sum_{k=1}^{N} \left(\overline{\boldsymbol{\alpha}}_k \left(\boldsymbol{\alpha}_{k-1} - \boldsymbol{\alpha}_k\right) + \overline{\boldsymbol{\theta}} \left(\boldsymbol{\alpha}_N - \theta\right) - iH\left(\overline{\boldsymbol{\alpha}}_k, \boldsymbol{\alpha}_{k-1}\right)\Delta t\right)\right\} \prod_{k=1}^{N-1} d\boldsymbol{\alpha}_k d\overline{\boldsymbol{\alpha}}_k$$

This formula looks exactly the same as the corresponding formula (2.13) for the Wick symbol of the evolution operator in Section 2.4 of Chapter 5! Accordingly, we interpret the

limit $N \to \infty$ as the following Feynman path integral for Grassmann variables (or Grassmann path integral):

$$U(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}; T) = \int_{\substack{\overline{\boldsymbol{\alpha}}(T)=\overline{\boldsymbol{\theta}} \\ \boldsymbol{\alpha}(0)=\boldsymbol{\theta}}} e^{i\int_0^T (i\overline{\boldsymbol{\alpha}}\dot{\boldsymbol{\alpha}} - H(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha}))dt + \overline{\boldsymbol{\theta}}(\boldsymbol{\alpha}(T)-\boldsymbol{\theta})} \mathscr{D}\boldsymbol{\alpha}\mathscr{D}\overline{\boldsymbol{\alpha}}. \tag{4.8}$$

Here the "integration" goes over all functions $\boldsymbol{\alpha}(t), \overline{\boldsymbol{\alpha}}(t)$ with anticommuting values [2] on the interval $[0, T]$, satisfying boundary conditions $\boldsymbol{\alpha}(0) = \boldsymbol{\theta}$, $\overline{\boldsymbol{\alpha}}(T) = \overline{\boldsymbol{\theta}}$, and

$$\mathscr{D}\boldsymbol{\alpha}\mathscr{D}\overline{\boldsymbol{\alpha}} = \prod_{0\le t\le T} d\boldsymbol{\alpha}(t) d\overline{\boldsymbol{\alpha}}(t) = \lim_{N\to\infty} \prod_{k=1}^{N-1} d\boldsymbol{\alpha}_k d\overline{\boldsymbol{\alpha}}_k.$$

As in Section 2.4 of Chapter 5, for $0 < t < T$ variables $\overline{\boldsymbol{\alpha}}(t)$ are conjugated to $\boldsymbol{\alpha}(t)$ with respect to the Grassmann algebra involution, while $\overline{\boldsymbol{\alpha}}(0)$ and $\boldsymbol{\alpha}(T)$ - also variables of integration - are not conjugated to the boundary values $\boldsymbol{\alpha}(0) = \boldsymbol{\theta}, \overline{\boldsymbol{\alpha}}(T) = \overline{\boldsymbol{\theta}}$.

Remark. It should be emphasized that the only rigorous meaning of the Grassmann path integral (4.8) is the limit of multiple Berezin integrals in (4.7). However, as we have seen already in Chapter 5, it is very useful to pretend that the path integral has an independent definition, and formally work with it as if it was an actual integral.

Using Theorem 4.1, it is easy to express the supertrace of the evolution operator $U(T)$ - an operator in a finite-dimensional Hilbert space $\mathscr{H}_F$ as a Grassmann path integral. We have

$$\begin{aligned}\operatorname{Tr}_s e^{-iTH} &= \lim_{N\to\infty} \int U_N(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}; T) d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} = \lim_{N\to\infty} \int \cdots \int \exp\{\overline{\boldsymbol{\theta}}(\boldsymbol{\alpha}(T) - \boldsymbol{\theta}) \\ &+ \sum_{k=1}^{N} \left(\overline{\boldsymbol{\alpha}}_k (\boldsymbol{\alpha}_{k-1} - \boldsymbol{\alpha}_k) - iH(\overline{\boldsymbol{\alpha}}_k, \boldsymbol{\alpha}_{k-1})\Delta t\right)\Bigg\} \prod_{k=1}^{N-1} d\boldsymbol{\alpha}_k d\overline{\boldsymbol{\alpha}}_k d\boldsymbol{\theta} d\overline{\boldsymbol{\theta}} \\ &= \int_{\substack{\overline{\boldsymbol{\alpha}}(0)=\overline{\boldsymbol{\alpha}}(T) \\ \boldsymbol{\alpha}(0)=\boldsymbol{\alpha}(T)}} e^{i\int_0^T (i\overline{\boldsymbol{\alpha}}\dot{\boldsymbol{\alpha}} - H(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha}))dt} \mathscr{D}\boldsymbol{\alpha}\mathscr{D}\overline{\boldsymbol{\alpha}}\end{aligned}$$

- a Grassmann path integral with periodic boundary conditions. Here periodic boundary conditions emerge from $\boldsymbol{\alpha}_0 = \boldsymbol{\theta}$ and $\overline{\boldsymbol{\alpha}}_N = \overline{\boldsymbol{\theta}}$ in the same way as in Section 2.4 of Chapter 5. Namely, since $\overline{\boldsymbol{\theta}}$ and $\boldsymbol{\theta}$ are now variables of integration, the identity (2.17) in Section 2.4 of Chapter 5, which is valid in the case of anticommuting variables as well, ensures that $\boldsymbol{\alpha}_N = \boldsymbol{\theta}$ and $\overline{\boldsymbol{\alpha}}_0 = \overline{\boldsymbol{\theta}}$. Denoting by $\boldsymbol{\Lambda}$ the corresponding "Grassmann loop space" - the space of all functions with anticommuting values $\boldsymbol{\alpha}(t)$ and $\overline{\boldsymbol{\alpha}}(t)$ conjugated with respect to the Grassmann algebra involution and satisfying periodic boundary conditions $\boldsymbol{\alpha}(0) = \boldsymbol{\alpha}(T)$ and $\overline{\boldsymbol{\alpha}}(0) = \overline{\boldsymbol{\alpha}}(T)$ - we can rewrite the previous formula as

$$\operatorname{Tr}_s e^{-iTH} = \int_{\boldsymbol{\Lambda}} e^{i\int_0^T (i\overline{\boldsymbol{\alpha}}\dot{\boldsymbol{\alpha}} - H(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha}))dt} \mathscr{D}\boldsymbol{\alpha}\mathscr{D}\overline{\boldsymbol{\alpha}}$$

Replacing the physical time t by the Euclidean time $-it$ and T by $-iT$, we get the Grassmann integral representation for the Wick symbol of the operator $U(-iT) = e^{-TH}$,

$$U(\overline{\boldsymbol{\theta}}, \boldsymbol{\theta}; -iT) = \int_{\substack{\overline{\boldsymbol{\alpha}}(T)=\overline{\boldsymbol{\theta}} \\ \boldsymbol{\alpha}(0)=\boldsymbol{\theta}}} e^{-\int_0^T (\overline{\boldsymbol{\alpha}}\dot{\boldsymbol{\alpha}} + H(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha}))dt} \mathscr{D}\boldsymbol{\alpha}\mathscr{D}\overline{\boldsymbol{\alpha}},$$

and for the supertrace,

[02] For every $0 \le t \le T$ there is a copy of the independent Grassmann algebra with generators $\alpha^1(t), ..., \alpha^n(t), \bar{\alpha}^1(t), ..., \bar{\alpha}^n(t)$.

$$\mathrm{Tr}_s\, e^{-TH} = \int_{\boldsymbol{\Lambda}} e^{-\int_0^T (\overline{\boldsymbol{\alpha}}\dot{\boldsymbol{\alpha}} + H(\overline{\boldsymbol{\alpha}},\boldsymbol{\alpha}))dt} \mathscr{D}\boldsymbol{\alpha}\mathscr{D}\overline{\boldsymbol{\alpha}} \tag{4.9}$$

Problem 4.4. Express the matrix symbol of the evolution operator as the Grassmann path integral.

Problem 4.5. Show that

$$\mathrm{Tr}\, e^{-TH} = \int_{\substack{\overline{\boldsymbol{\alpha}}(0)=-\overline{\boldsymbol{\alpha}}(T)\\ \boldsymbol{\alpha}(0)=-\boldsymbol{\alpha}(T)}} e^{-\int_0^T (\overline{\boldsymbol{\alpha}}\dot{\boldsymbol{\alpha}} + H(\bar{\alpha},\boldsymbol{\alpha}))dt} \mathscr{D}\boldsymbol{\alpha}\mathscr{D}\overline{\boldsymbol{\alpha}}$$

- the Grassmann path integral with anti-periodic boundary conditions.

4.3. Gaussian path integrals over Grassmann variables. For simplicity, here we consider only the case $n = 1$. As in Section 5.3 of Chapter 5, for $u(t) \in C^1([0,T],\mathbb{R})$ we put

$$u_0 = \frac{1}{T}\int_0^T u(t)dt \quad \text{and} \quad D = \frac{d}{dt}$$

and consider on the interval $[0,T]$ the first-order differential operator $D+\, u(t)$ with periodic boundary conditions. The following result evaluates the simplest Gaussian path integral for Grassmann variables.

Theorem 4.2. We have

$$\int_\Lambda e^{-\int_0^T (\bar{\alpha}\dot{\alpha} + u(t)\bar{\alpha}\alpha)dt} \mathscr{D}\alpha\mathscr{D}\bar{\alpha} = \det(D + u(t)) = 1 - e^{-u_0 T}.$$

Proof. Using Lemma 2.4, we get

$$\begin{aligned}
&\int_\Lambda e^{-\int_0^T (\bar{\alpha}\dot{\alpha} + u(t)\bar{\alpha}\alpha)dt} \mathscr{D}\alpha\mathscr{D}\bar{\alpha} \\
&= \lim_{N\to\infty} \int\cdots\int e^{\sum_{k=1}^N (\bar{\alpha}_k(\alpha_{k-1}-\alpha_k) - u(t_k)\bar{\alpha}_k\alpha_{k-1}\Delta t)} \prod_{k=1}^N d\alpha_k d\bar{\alpha}_k \\
&= \lim_{N\to\infty} \det A_N
\end{aligned}$$

Here $\alpha_0 = \alpha_N, \bar{\alpha}_0 = \bar{\alpha}_N, t_k = k\Delta t$, and A_N is the following $N \times N$ matrix:

$$A_N = \begin{pmatrix} 1 & 0 & 0 & \cdots & 0 & b_N \\ b_1 & 1 & 0 & \cdots & 0 & 0 \\ 0 & b_2 & 1 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & 0 \\ 0 & 0 & 0 & \cdots & b_{N-1} & 1 \end{pmatrix},$$

where $b_k = -1 + u\,(t_k)\,\Delta t$. We have

$$\det A_N = 1 - (-1)^N \prod_{k=1}^N b_k = 1 - \prod_{k=1}^N (1 - u\,(t_k)\,\Delta t)$$

so that

$$\lim \det A_N = 1 - e^{-\int_0^T u(t)dt} = 1 - e^{-u_0 T}$$

Using Proposition 5.3 in Section 5.3 of Chapter 5 completes the proof.

Example 4.1 (The fermion harmonic oscillator). The fermion analog of the harmonic oscillator is the Hamiltonian

$$H = \frac{1}{2}\omega\left(a^*a - aa^*\right) = \omega\left(a^*a - \frac{1}{2}I\right) = \omega\left(N - \frac{1}{2}I\right),$$

where a^* and a are creation and annihilation operators in the one fermion Hilbert space $\mathscr{H}_F = \mathbb{C}^2$ (see Section 1.1). The Wick symbol H is $H(\bar{\alpha}, \alpha) = \omega\left(\bar{\alpha}\alpha - \frac{1}{2}\right)$. Now using (4.9) and Theorem 4.2, we obtain

$$\begin{aligned}\operatorname{Tr}_s e^{-TH} &= \int_\Lambda e^{-\int_0^T (\bar{\alpha}\dot{\alpha} + H(\bar{\alpha},\alpha))dt}\mathscr{D}\alpha\mathscr{D}\bar{\alpha} \\ &= e^{\frac{\omega T}{2}}\int_\Lambda e^{-\int_0^T(\bar{\alpha}\dot{\alpha}+\omega\bar{\alpha}\alpha)dt}\mathscr{D}\alpha\mathscr{D}\bar{\alpha} = e^{\frac{\omega T}{2}}\left(1 - e^{-\omega T}\right) = 2\sinh\frac{\omega T}{2}.\end{aligned}$$

Of course, the same result can be obtained directly since e^{-TH} is just a 2×2 matrix with eigenvalues $e^{\frac{\omega T}{2}}$ and $e^{-\frac{\omega T}{2}}$ which correspond, respectively, to the eigenspaces $\mathscr{H}_F^0$ and $\mathscr{H}_F^1$. Thus

$$\operatorname{Tr}_s e^{-TH} = e^{\frac{\omega T}{2}} - e^{-\frac{\omega T}{2}} = 2\sinh\frac{\omega T}{2}$$

Remark. We have the following analog of formula (2.6) of Chapter 6 for path integrals over Grassmann variables:

$$\int_\Lambda f(\alpha,\bar{\alpha})\mathscr{D}\alpha\mathscr{D}\bar{\alpha} = \int\left(\int_{\Lambda_0} f(\beta,\theta;\bar{\beta},\bar{\theta})\mathscr{D}\beta\mathscr{D}\bar{\beta}\right)d\theta d\bar{\theta} \tag{4.10}$$

where

$$\alpha(t) = \theta + \beta(t) \quad \text{and} \quad \int_0^T \beta(t)dt = 0$$

and Λ_0 is the space of Grassmann loops $\beta(t), \bar{\beta}(t)$ with zero constant term.

Example 4.2. Using formula (4.10) and Theorem 4.2, we get

$$\begin{aligned}\det(D+\omega) &= \int_\Lambda e^{-\int_0^T(\bar{\alpha}\dot{\alpha}+\omega\bar{\alpha}\alpha)dt}\mathscr{D}\alpha\mathscr{D}\bar{\alpha} \\ &= \int e^{-\omega T\bar{\theta}\theta}d\theta d\bar{\theta}\int_{\Lambda_0} e^{-\int_0^T(\bar{\beta}\dot{\beta}+\omega\bar{\beta}\beta)dt}\mathscr{D}\beta\mathscr{D}\bar{\beta} = \omega T\int_{\Lambda_0} e^{-\int_0^T(\bar{\beta}\dot{\beta}+\omega\bar{\beta}\beta)dt}\mathscr{D}\beta\mathscr{D}\bar{\beta},\end{aligned}$$

so that

$$\int_{\Lambda_0} e^{-\int_0^T \bar{\beta}\dot{\beta}dt}\mathscr{D}\beta\mathscr{D}\bar{\beta} = \lim_{\omega\to 0}\frac{\det(D+\omega)}{\omega T} = \lim_{\omega\to 0}\frac{1-e^{-\omega T}}{\omega T} = 1$$

Equivalently,

$$\int_{\Lambda_0} e^{-\int_0^T \bar{\beta}\dot{\beta}dt}\mathscr{D}\beta\mathscr{D}\bar{\beta} = \frac{1}{T}\det{}' D \tag{4.11}$$

where $\det' D = T$ (see Proposition 5.3 in Section 5.3 of Chapter 5). Introducing

$$\theta_1(t) = \frac{1}{\sqrt{2}}(\beta(t) + \bar{\beta}(t)), \quad \theta_2(t) = \frac{1}{i\sqrt{2}}(\beta(t) - \bar{\beta}(t)),$$

so that $\bar{\theta}_j(t) = \theta_j(t), j = 1, 2$, we can rewrite (4.11) as

$$\int_{\Lambda_0} e^{-\frac{1}{2}\int_0^T (\theta_1\dot\theta_1+\theta_2\dot\theta_2)dt}\mathscr{D}\theta_1\mathscr{D}\theta_2 = \frac{1}{T}\det{}' D = 1$$

Since $\mathrm{Pf}'(D) = \sqrt{\det{}' D} = \sqrt{T}$, we have

$$\int_{\Lambda_0(\mathbb{R})} e^{-\frac{1}{2}\int_0^T \theta\dot\theta dt}\mathscr{D}\theta = \frac{1}{\sqrt{T}}\mathrm{Pf}'(D) = 1. \tag{4.12}$$

Here the domain of integration $\Lambda_0(\mathbb{R})$ consists of all functions $\theta(t)$ with values in the Grassmann algebra over $\mathbb{R}$, which have zero constant term and satisfy periodic boundary conditions $\theta(0) = \theta(T)$. We will use formulas (4.10) and (4.12) in Section 2.2 of Chapter 8.

Problem 4.6. Show that

$$\int_{\substack{\bar\alpha(0)=-\bar\alpha(T)\\ \alpha(0)=-\alpha(T)}} e^{-\int_0^T(\bar\alpha\dot\alpha+u(t)\bar\alpha\alpha)dt}\mathscr{O}\alpha\mathscr{D}\bar\alpha = 1 + e^{-u_0 T}$$

- the regularized determinant of the operator $D+u(t)$ on $[0,T]$ with anti-periodic boundary conditions.

Problem 4.7. For the fermion harmonic oscillator verify that $\mathrm{Tr}\, e^{-TH} = 2\cosh\frac{\omega T}{2}$ directly, and also by using results of Problems 4.5 and 4.6.

Problem 4.8. Prove formula (4.10). (Hint: Follow the proof of Theorem 4.2, and use the decomposition $\alpha_k = \theta + \beta_k$, where $\beta_0 = \beta_N$ and $\sum_{k=1}^N \beta_k = 0$.)

Problem 4.9. Give a direct proof of formula (4.12).

4.5 Spin, Spinors and Identical Particles

Обсудим подробно спин и спиноры.

4.5.1 Operator of Angular Momentum $\hat j$ (!?!!)

(по идее тут вся теория по нему и будет.)

Оператор момента в двух словах

(еще потренировать нужно)

Основные формулы (??)

оператор момента импульса водится как

$$L_x = -i\hbar\partial\phi,$$

что очень схоже с оператором импульса

$$\mathbf{L} = -i[\mathbf{r}\times\boldsymbol{\partial}] = -i\left(\mathbf{e}_\varphi\frac{\partial}{\partial\vartheta} - \mathbf{e}_\theta\frac{1}{\sin\vartheta}\frac{\partial}{\partial\varphi}\right)$$

Можно складывать моменты

(тут укажу коротко эту теорию, подробно - ниже)

Коэффициенты Клебша—Гордана $C^{JM}_{l_1m_1j_2m_2}$, являющиеся коэффициентами векторного сложения, осуществляют разложение приводимых представлений группы вращений на неприводимые.

Все остальные коэффициенты векторного сложения могут быть представлены в виде сумм произведений коэффициентов Клебша—Гордана.

Все это определяет их широкое использование в квантовой теории углового момента.

Суть вывода (??)

(пока суть не так глубоко понял, почему именно такими повышающими, понижающими операторами работаем.)

Обзор применений оператора момента импульса

(вроде в атомах и разных моделях, укажу потом конкретно)

Мы хотим описывать радиальные движения одной частицы вокруг другой, поэтому вводим угловой момент

Вывод оператора момента

И поэтому нам известно, что

$$\left[\hat{\boldsymbol{j}}_\alpha, \hat{\boldsymbol{j}}_\beta\right] = \mathrm{i}\epsilon_{\alpha\beta\gamma}\hat{\boldsymbol{j}}_\gamma; \quad \left[\hat{\boldsymbol{j}}_\alpha, \hat{\boldsymbol{j}}^2\right] = 0; \quad \left[\hat{\boldsymbol{j}}_\alpha, \hat{\boldsymbol{p}}^2\right] = 0; \quad \left[\hat{\boldsymbol{j}}_\alpha, \hat{\boldsymbol{p}}_\beta\right] = \mathrm{i}\epsilon_{\alpha\beta\gamma}\hat{\boldsymbol{p}}_\gamma;$$

Кроме того, если энергия является скаляром, то

$$\left[\hat{\boldsymbol{j}}_\alpha, \hat{H}\right] = 0$$

Составим из взаимнокомутирующих операторов полный набор наблюдаем, например, такой:

$$\hat{H}, \hat{j}^2, \hat{\boldsymbol{p}}^2, \hat{\boldsymbol{j}}_z$$

Действительно, все эти операторы коммутируют, так что они могут быть измерены точно совместно, т.е.

они имеют общие собственные векторы состояния.

Важно подчеркнуть, что компоненты момента импульса, вообще говоря, не могут быть измерены точно совместно, так как их коммутатор не равен нулю.

Исключение составляет случай

$$\hat{\boldsymbol{j}}_\alpha|\Psi\rangle \equiv 0$$

т.е.

если орбитальный и спиновый момент импульса тождествен но равны нулю в данном состояни и.

Рассмотрим задачу на собственные значения к вадрата импульса и одной из его ком по- нент, Для определенности компоненты по оси z:

$$\hat{\boldsymbol{j}}^2|\lambda,\mu\rangle = \lambda|\lambda,\mu\rangle$$
$$\hat{\boldsymbol{j}}_z|\lambda,\mu\rangle = \mu|\lambda,\mu\rangle$$

выполнено условие вырождения: оператор $\hat{\boldsymbol{j}}^2$ коммутирует со всеми компонентами $\boldsymbol{j}$, но эти компоненты не коммутируют друг с другом.

Введем операторы

$$\hat{j}_\pm = \hat{\boldsymbol{j}}_x \pm \mathrm{i}\hat{\boldsymbol{j}}_y, \quad \hat{j}_- = \hat{j}_+^\dagger, \quad \left[\hat{j}_\pm \cdot \hat{\boldsymbol{j}}^2\right] = 0$$

Тогда легко видеть, что

$$\hat{j}_+\hat{j}_- = \hat{j}_x^2 + \hat{j}_y^2 - \mathrm{i}\left(\hat{j}_x\hat{j}_y - \hat{j}_y\hat{j}_x\right) = \hat{j}_x^2 + \hat{j}_y^2 - \mathrm{i}\left[\hat{j}_x, \hat{j}_y\right] = \hat{j}_x^2 + \hat{j}_y^2 + \hat{j}_z$$

и аналогично

$$\hat{j} - \hat{j}_+ = \hat{j}_x^2 + \hat{j}_y^2 - \hat{j}_z$$

В итоге,

$$\hat{\boldsymbol{j}}^2 = \frac{1}{2}\left(\hat{j}_+\hat{j}_- + \hat{j}_-\hat{j}_+\right) + \hat{j}_z^2$$

Коммутатор этих операторов с компонентой $\hat{j}_z$ легко вычисляется

$$\left[\hat{j}_z, \hat{j}_\pm\right] = \left[\hat{j}_z, \hat{j}_x \pm \mathrm{i}\hat{j}_y\right] = \mathrm{i}\hat{j}_y \pm \mathrm{i}\left(-\mathrm{i}\hat{j}_x\right) = \pm\hat{j}_\pm$$

Это позволяет установить, что векторы $\hat{j}_\pm|\lambda,\mu\rangle$ также являются собственным и векторами Заданной пары наблюдаемых:

$$\hat{j}_z\hat{j}_\pm|\lambda,\mu\rangle = \hat{j}_\pm\left(\hat{j}_z \pm 1\right)|\lambda,\mu\rangle = (\mu\pm 1)\hat{j}_\pm|\lambda,\mu\rangle$$

$$\hat{j}_\pm|\lambda,\mu\rangle = \mathcal{N}_\pm(\lambda,\mu)|\lambda,\mu\pm 1\rangle$$

где нормировочные множители $\mathcal{N}_\pm$ легко определить, взяв модуль каждого из состояний:

$$\left\langle\lambda,\mu\left|\hat{j}_-\hat{j}_+\right|\lambda,\mu\right\rangle = \left\langle\lambda,\mu\left|\left(\hat{j}^2 - \hat{j}_z^2 - \hat{j}_z\right)\right|\lambda,\mu\right\rangle = \lambda - \mu^2 - \mu \geqslant 0$$

и аналогично

$$\left\langle\lambda,\mu\left|\hat{j}_+\hat{j}_-\right|\lambda,\mu\right\rangle = \left\langle\lambda,\mu\left|\left(\hat{j}^2 - \hat{j}_z^2 + \hat{j}_z\right)\right|\lambda,\mu\right\rangle = \lambda - \mu^2 + \mu \geqslant 0$$

откуда

$$\hat{j}_\pm|\lambda,\mu\rangle = \sqrt{\lambda - \mu(\mu\pm 1)}|\lambda,\mu\pm 1\rangle$$

Также, как и в случае гармонического осциллятора, использование повышающего и понижающего операторов позволяет провести квантование спектра собственных значений пары $\left\{\hat{\boldsymbol{j}}^2, \hat{j}_z\right\}$ с помощью условия неотрицательности нормы вектора состояния.

В самом деле, повышающий оператор переводит $\mu \to \mu + 1$ и изменяет норм у вектора

$$\mathcal{N}^2 \to \mathcal{N}^2[\lambda - \mu(\mu+1)] \geqslant 0$$

Для того чтобы норма вектора состояния после многократного действия повышающего оператора оставалась положительно определенной, необходимо чтобы цепочка многократного повышения прервалась, т.е. чтобы существовал старший вектор состояния:

$$\hat{j}_+\,|\lambda,\mu_\lambda\rangle = 0, \quad \lambda = \mu_\lambda\,(\mu_\lambda + 1)$$

Составим цепочку состояний, многократно действуя на старший вектор понижающим оператором,

$$|\lambda,\mu_\lambda\rangle\,, \quad \hat{j}_-\,|\lambda,\mu_\lambda\rangle\,, \ldots$$

с собственным и значениям и проекции

$$\mu_\lambda, \quad \mu_\lambda - 1, \ldots$$

Для того чтобы норма векторов в этой цепочке состояний оставалась положительно определенной, необходимо, чтобы она оборвалась, т.е. существовал бы младший вектор:

$$\hat{j}_-\,|\lambda,\nu_\lambda\rangle = 0, \quad \lambda = \nu_\lambda\,(\nu_\lambda - 1)$$

но при этом мы получаем собствен ное значение для младшего вектора путем целого конечного числа шагов из собственного значения для старшего вектора:

$$\nu_\lambda = \mu_\lambda - n, \quad n \in \mathbb{N}$$

Собственное значение λ оператора $\hat{\boldsymbol{j}}^2$ при действии повышающего и понижающего операторов не изменяется (соответствующий ком мутатор равен нулю), так что согласно (8.7), (8.8) имеет место тождество

$$\mu_\lambda\,(\mu_\lambda+1)=(\mu_\lambda-n)\,(\mu_\lambda-n-1)$$

с единствен ным решением

$$\mu_\lambda=\frac{1}{2}n$$

вектора $\mu_\lambda=j$, так что

$$\begin{aligned}\hat{\boldsymbol{j}}^2|j,m\rangle&=j(j+1)|j,m\rangle\\ \hat{j}_z|j,m\rangle&=m|j,m\rangle\\ \hat{j}_+|j,j\rangle&=0\\ \hat{j}_-|j,-j\rangle&=0\end{aligned}$$

причем количество состояний с заданным j равно числу шагов от старшего вектора к младшем у $n=2j$ плюс 1 начальное состояние построения цепочки (старший вектор). т.е. вырождение $\hat{\boldsymbol{j}}^2$ по числу проекций есть

$$k=2j+1$$

где $\{j,m\}$ - полуцелые числа,

$$j=\frac{1}{2}(k-1),\quad k\in\mathbb{N},\quad j\leqslant m\leqslant -j$$

и k -кратность вырождения $\hat{\boldsymbol{j}}^2$. В частности, при $k=1$ имеем $\boldsymbol{j}\equiv 0$.

Кроме того, мы нашли, что матричные элементы повышающего и понижающего операторов задаются формулам и

$$\left\langle j,n\left|\hat{j}_\pm\right|j,m\right\rangle=\sqrt{j(j+1)-m(m\pm1)}\delta_{n,m\pm1}$$

оператор момента в сферических координатах

(выделю потом суть)

Выразим компоненты орбитального момента в полярных координатах.

Например,

$$\hat{l}_z=\boldsymbol{e}_z\cdot\boldsymbol{l}=-\mathrm{i}\boldsymbol{e}_z\cdot[\boldsymbol{r},\boldsymbol{\nabla}]$$

где векторное произведение запишем в полярных координатах

$$[\boldsymbol{r},\boldsymbol{\nabla}]=\boldsymbol{e}_\theta\epsilon_{\theta r\phi}r\frac{\partial}{\partial\ell_\phi}+\boldsymbol{e}_\phi\epsilon_{\phi r\theta}r\frac{\partial}{\partial\ell_\theta}$$

правой тройки базисных векторов

$$\epsilon_{r\theta\phi}=1$$

Отсюда для z -той компоненты находим

$$\hat{l}_z=-\mathrm{i}\frac{\partial}{\partial\phi}$$

Оставшиеся компоненты принимают вид:

$$\begin{aligned}\hat{l}_x&=+\mathrm{i}\sin\phi\frac{\partial}{\partial\theta}+\mathrm{i}\cos\phi\,\mathrm{ctg}\,\theta\frac{\partial}{\partial\phi}\\ \hat{l}_y&=-\mathrm{i}\cos\phi\frac{\partial}{\partial\theta}+\mathrm{i}\sin\phi\,\mathrm{ctg}\,\theta\frac{\partial}{\partial\phi}\end{aligned}$$

откуда

$$\hat{l}_{\pm} = e^{\pm \mathrm{i}\phi}\left(\pm\frac{\partial}{\partial\theta} + \mathrm{i}\,\mathrm{ctg}\,\theta\frac{\partial}{\partial\phi}\right)$$

Как видим, компоненты орбитального момента зависят только от углов.

Для справок приведем также вид оператора квадрата орбитального момента в угловых переменных

$$\hat{\boldsymbol{l}}^2 = -\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right) - \frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\phi^2}$$

Собственные функции

$$\hat{\boldsymbol{l}}^2 Y_{l,m}(\theta,\phi) = l(l+1)Y_{l,m}(\theta\phi)$$
$$\hat{l}_z Y_{l,m}(\theta,\phi) = mY_{l,m}(\theta,\phi)$$

нормированные на единицу,

$$\int\limits_{-1}^{1} d\cos\theta \int\limits_{0}^{2\pi} d\phi Y^*_{l,m}(\theta,\phi)Y_{l,m}(\theta,\phi) = 1$$

называются сферическими гармониками.

В угловых переменных уравнение на собственные значения для проекции момента на ось z

$$\hat{l}_z Y_{l,m}(\theta,\phi) = -\mathrm{i}\frac{\partial}{\partial\phi}Y_{l,m}(\theta,\phi) = mY_{l,m}(\theta,\phi)$$

Легко интегрируется при разделении переменных, так что

$$Y_{l,m}(\theta,\phi) = e^{\mathrm{i}m\phi}Y_{l,m}(\theta)$$

Функции $Y_{l,m}(\theta)$ проше всего найти, используя повышающий оператор, который зануляет старший вектор:

$$\hat{l}_+ Y_{l,l}(\theta,\phi) = 0$$

откуда

$$\frac{\partial}{\partial\theta}Y_{l,l}(\theta) - l\,\mathrm{ctg}\,\theta Y_{l,l}(\theta) = 0$$

с решением

$$Y_{l,l}(\theta,\phi) = C_l \sin^l\theta e^{\mathrm{i}l\phi}$$

гДе нормировоч ную константу C_l определим, взяв интеграл

$$I_l = \int\limits_{-1}^{1} d\cos\theta \int\limits_{0}^{2\pi} d\phi \sin^{2l}(\theta)$$

Проведем и нтегрирование по частям:

$$I_l = 2\pi\int\limits_{-1}^{1}\sin^{2l}\theta d\cos\theta = -2\pi 2l\int\limits_{\pi}^{0}\cos\theta\sin^{2l-1}\theta\cos\theta d\theta = 2l\left[\tilde{I}_{l-1} - \tilde{I}_l\right]$$

где после переворота пределов интегрирован ия мы ввели

$$\tilde{I}_l = 2\pi\int\limits_{0}^{\pi}\sin^{2l+1}\theta d\theta$$

Для этого интеграла аналогично находим

$$\tilde{I}_l = -2\pi \int_0^\pi \sin^{2l}\theta d\cos\theta = 2l \int_0^\pi \cos^2\theta \sin^{2l-1} d\theta = 2l\left[\tilde{I}_{l-1} - \tilde{I}_l\right]$$

Получаем рекуррентное соотношение

$$\tilde{I}_l = \frac{2l}{2l+1}\tilde{I}_{l-1} = \frac{2^2 l^2}{(2l)(2l+1)}\tilde{I}_{l-1}, \quad l \in \mathbb{N}$$

причем

$$\tilde{I}_0 = 4\pi$$

и следовательно,

$$\tilde{I}_l = \frac{2^{2l}(l!)^2}{(2l+1)!}4\pi$$

Отсюда

$$I_l = 2l\left[\frac{2l+1}{2l}\tilde{I}_l - \tilde{I}_l\right] = \tilde{I}_l$$

сферические функции

(Перенесу в дополнения потом!!! сюда пару строк добавлю и все)

Сферическая функция для старшего вектора -

$$Y_{l,l}(\theta,\phi) = (-1)^l \sqrt{\frac{(2l+1)!}{4\pi}}\frac{1}{2^l l!}\sin^l\theta e^{\mathrm{i}l\phi}$$

где фактор $(-1)^l$ определяет общепринятое соглашение о фазе. Она нормирована на единицу.

Сферические гармоники с меньшими значениями проекции момента получаются действием понижающего оператора.

$$\hat{l}_-|l,l\rangle = \sqrt{l(l+1)-l(l-1)}|l,l-1\rangle = \sqrt{2l}|l,l-1\rangle$$
$$\hat{l}_-|l,l-1\rangle = \sqrt{l(l+1)-(l-1)(l-2)}|l,l-2\rangle = \sqrt{2(2l-1)}|l,l-2\rangle$$

так что

$$\hat{l}_-^2|l,l\rangle = \sqrt{2l(2l-1)2}|l,l-2\rangle$$
$$\hat{l}_-|l,l-2\rangle = \sqrt{l(l+1)-(l-2)(l-3)}|l,l-3\rangle = \sqrt{3(2l-2)}|l,l-3\rangle$$

или

$$\hat{l}_-^3|l,l\rangle = \sqrt{2l(2l-1)(2l-2)2\cdot 3}|l,l-3\rangle$$

по индукции

$$|l,l-m\rangle = \sqrt{\frac{(2l-m)!}{(2l)!m!}}\hat{l}_-^m|l,l\rangle$$

В частности,

$$Y_{l,0}(\theta,\phi) = \frac{1}{\sqrt{(2l)!}}\hat{l}_-^l Y_{l,l}(\theta,\phi)$$

В явном виде

$$\hat{l}_- Y_{l,m}(\theta,\phi) = e^{-\mathrm{i}\phi}\left(-\frac{\partial}{\partial\theta} + \mathrm{i}\,\mathrm{ctg}\,\theta\frac{\partial}{\partial\phi}\right)e^{\mathrm{i}m\phi}Y_{l,m}(\theta) =$$

$$e^{\mathrm{i}(m-1)\phi}\left(-\frac{\partial}{\partial\theta}-m\operatorname{ctg}\theta\right)Y_{l,m}(\theta)=e^{\mathrm{i}(m-1)\phi}\left(\frac{1}{(\sin\theta)^{m-1}}\frac{\partial}{\partial\cos\theta}\sin^m\theta\right)Y_{l,m}(\theta)$$

Отсюда получаем

$$\hat{l}_-^l Y_{l,l}(\theta,\phi)=\frac{\partial^l}{\partial\cos\theta^l}\sin^l\theta Y_{l,l}(\theta)=C_l\frac{\partial^l}{\partial\cos\theta^l}\sin^{2l}\theta$$

Собирая множители,

$$Y_{l,0}(\theta,\phi)=\sqrt{\frac{2l+1}{4\pi}}\frac{(-1)^l}{2^l l!}\frac{d^l}{d\cos\theta^l}\sin^{2l}\theta$$

Согласно стандартному определению полижомами Лежсаждра называют функци и

$$P_l(\xi)\stackrel{\text{def}}{=}\frac{(-1)^l}{2^l l!}\frac{d^l}{d\xi^l}\left(1-\xi^2\right)^l$$

Н

$$Y_{l,0}(\theta,\phi)=\sqrt{\frac{2l+1}{4\pi}}P_l(\cos\theta)$$

Так как сферические гармоники, являющиеся собственным и векторами, ортогональны и нормированы на единицу, для полиномов Лежандра автоматически находим

$$\int\limits_{-1}^{1}d\xi P_l(\xi)P_{l'}(\xi)=\frac{2}{2l+1}\delta_{ll'}$$

Кроме того отмети м следующее свойство этих полиномов

$$P_l(1)=1$$

Что следует из того, что ненулевой вклад при $\xi=1$ дает лишь слагаемое с н улевой степен ью фактора $(1-\xi^2)$, и поэтому нужно многократно дифференцировать лишь степень этого фактора, что и при водит к сокращению численного множителя в (8.21)

Состояния $Y_{l,m}(\theta,\phi)$ с $m>0$ обычно находят с помощью действия повышающего опе-

$$\begin{aligned}\hat{l}_+Y_{l,m}(\theta,\phi)=&e^{\mathrm{i}\phi}\left(\frac{\partial}{\partial\theta}+\mathrm{i}\operatorname{ctg}\theta\frac{\partial}{\partial\phi}\right)e^{\mathrm{i}m\phi}Y_{l,m}(\theta)=\\&=-e^{\mathrm{i}(m+1)\phi}\left\{(\sin\theta)^{m+1}\frac{\partial}{\partial\cos\theta}\frac{1}{\sin^m\theta}\right\}Y_{l,m}(\theta)=\\&=\sqrt{l(l+1)-m(m+1)}Y_{l,m}(\theta,\phi)\\\hat{l}_+^mY_{l,0}(\theta)=&e^{\mathrm{i}m\phi}(-1)^m\sqrt{\frac{2l+1}{4\pi}}\sin^m\theta\frac{d}{d\cos\theta^m}P_l(\theta)\end{aligned}$$

а с другой

(???)

В итоге,

$$Y_{l,m}(\theta,\phi)=e^{\mathrm{i}m\phi}(-1)^m\sqrt{\frac{2l+1}{4\pi}\frac{(l-m)!}{(l+m)!}}P_{l,m}(\cos\theta),\quad 0\leqslant m\leqslant l$$

Основы квантового момента импульса по общей физике

(добавлю киселева или Ландау, тут важная теория все-таки)

В то же время другая физическая величина — момент импульса L — для любой системы может принимать только определенный, дискретный ряд значений.

Момент импульса характеризует вращательное (угловое) движение.

При изучении такого движения удобно пользоваться полярной системой координат (рис. 6.1).

в этой системе положение точки характеризуется расстоянием r от начала отсчета, полярным углом θ между полярной осью z и радиусом-вектором $\mathbf{r}$ и азимутальным углом φ, отсчитываемым в плоскости xy от оси x.

волновая функция ψ_{lz}, описываюшая состояние с определенным значен ием проекции l_z на ось z аналогична плоской волне де бройля $\exp\left[i\left(p_x/\hbar\right)z\right]$: роль координаты играет азимутальный угол φ (угол поворо

(????)

случае, если $L_z/\hbar$ принимает целочисленные значения.

Следовательно, L_z, в отличие от проекции импульса p_z, может принимать только дискретные значения:

$$L_z = m_l\hbar, \qquad \text{где} \qquad m_l = 0, \pm1, \pm2, ...$$

Таким образом, проекция момента импульса на любую ось Квантуется и равна целому числу постоянных Планка (на рис. 6.2 дано схематическое изображение квантования проекции l_z момента импульса $\mathbf{l}$ на ось z).

квантование проекции момента означает, что вектор квантового момента импульса не может иметь произвольного направления по отношению к любому фиксированному направлению в пространстве.

этот факт получил название пространственного квантования.

оно выглядит крайне необычно: поскольку направление оси z можно выбрать пройзвольно, то проекции момента на два различных направления (z и z') квантуются одинаково.

возможные значения проекции момента на оси x и y также определяются формулой (6.3).

Может показаться, что квантование проекции L_z приводит к тому, что вектор L составляет лишь определенные углы с осью, как это схематично показано на рис. 6.2.

Однако полученный результат имеет совсем другой смысл.

Формула (6.3) показывает, что при измерении проекции момента импульса мы в результате опыта обязательно получим число, являющееся кратным $\hbar$.

Однако значение L_z до этого вовсе не должно быть равно целому числу $\hbar$.

До и после опыта ψ -функции вовсе не обязаны совпадать.

Мы вправе лишь утверждать, что ψ -функция состояния, имевшегося до опыта, т. е. ψ -функция любого физического состояния, может быть представлена в виде суперпозиции собственных решений:

$$\psi = \sum_m c_m\psi_m = \sum_m c_m\frac{1}{\sqrt{2\pi}}e^{im\varphi}$$

где множитель $1/\sqrt{2\pi}$ возникает как результат нормировки фунКций ψ_m.

Система, описываемая такой ψ -функцией, не обладает определенной проекцией момента L.

Вектор $\mathbf{L}$ может быть направлен произвольным образом, но при измерении L_z всегда будет найдено какое-то одно из m значений, входящих в сумму (6.4).

Вероятность найти значение $L_z = m\hbar$ определяется, как всегда, величиной $|c_m|^2$.

Может показаться, что квантование проекции L_z приводит к тому, что вектор L составляет лишь определенные углы с осью, как это схематично показано на рис. 6.2.

Однако полученный результат имеет совсем другой смысл.

Формула (6.3) показывает, что при измерении проекции момента импульса мы в результате опыта обязательно получим число, являющееся кратным $\hbar$.

Однако значение L_z до этого вовсе не должно быть равно целому числу $\hbar$.

До и после опыта ψ -функции вовсе не обязаны совпадать.

Мы вправе лишь утверждать, что ψ -функция состояния, имевшегося до опыта, т. е. ψ -функция любого физического состояния, может быть представлена в виде суперпозиции собственных решений:

$$\psi = \sum_m c_m \psi_m = \sum_m c_m \frac{1}{\sqrt{2\pi}} e^{im\varphi}$$

где множитель $1/\sqrt{2\pi}$ возникает как результат нормировки функций ψ_m.

Система, описываемая такой ψ -функцией, не обладает определенной проекцией момента L.

Вектор $\mathbf{L}$ может быть направлен произвольным образом, но при измерении L_z всегда будет найдено какое-то одно из m значений, входящих в сумму (6.4).

Вероятность найти значение $L_z = m\hbar$ определяется, как всегда, величиной $|c_m|^2$.

ва сталкиваемся с действием квантовомеханического принципа неопределенностей.

Проекция момента не может быть больше его абсолютного значения.

Поэтому при фиксированной величине модуля момента возможные значения числа m_l ограничены сверху числом l. Если l задано, то проекция момента может принимать $2l+1$ значений. Найдем возможные значения момента импульса. Средние значения проекций L_x, L_y и L_z, как и любых других величин, могут иметь в данном состоянии определенные значения.

Если никаких предварительных операций для фиксации проекции момента на

какое-либо направление не производилось (нет выделенной поляризации частиц), то все направления равноправны и средние значения квадратов проекций момента импульса одинаковы:

$$\left\langle L_x^2 \right\rangle = \left\langle L_y^2 \right\rangle = \left\langle L_z^2 \right\rangle$$

Это утверждение вместе с правилом квантования проекции момента (6.3) позволяет определить возможные значения квадрата момента импульса.

Среднее значение квадрата момента, как и в классической механике, равно сумме средних значений квадратов проекций.

Учитывая равенство (6.5), получим

$$\left\langle \mathbf{L}^2 \right\rangle = \left\langle L_x^2 \right\rangle + \left\langle L_y^2 \right\rangle + \left\langle L_z^2 \right\rangle = 3 \left\langle L_z^2 \right\rangle$$

При любой ориентации момента его квадрат имеет одну и ту же величину.

Следовательно,

$$L^2 = \left\langle \mathbf{L}^2 \right\rangle = 3 \left\langle L_z^2 \right\rangle$$

Все значения L_z равновероятны, если никакого отбора по возможным состояниям не производилось.

Поэтому среднее значение $\langle L_z^2 \rangle$ равно сумме всех $2l+1$ возможных значений $\langle L_z^2 \rangle$ от $l\hbar$ до - $\hbar$, деленной на их полное число:

$$\left\langle L_z^2 \right\rangle = \hbar^2 \frac{l^2 + (l-1)^2 + \cdots + (-l)^2}{2l+1} = \frac{2\hbar^2}{2l+1} \left(1^2 + 2^2 + 3^2 + \cdots + l^2\right) =$$
$$= \frac{2\hbar^2}{2l+1} \frac{l(l+1)(2l+1)}{6} = \frac{\hbar^2}{3} l(l+1)$$

Здесь мы использовали известное выражение для суммы квадратов целых чисел от 1 до l.

Подставив полученное значение $\langle L_z^2 \rangle$ в (6.6), найдем

$$L^2 = \hbar^2 l(l+1)$$

Равенство (6.8) определяет закон квантования квадрата момента импульса, т. е. его длину.

Число m_l, от которого зависят значения проекции момента, называется магнитным квантовым числом.

Этот термин обусловлен тем, что, как мы увидим в дальнейшем, проекция магнитного момента, создаваемого движением заряженной частицы, пропорциональна проекции момента импульса этой частицы, определяемого числом m_l.

Максимальное значение магнитного квантового числа $m_{\max} = l$, а минимальное $m_{\min} = -l$.

Число l определяющее возможные значения квадрата момента, называется орбитальным квантовым числом.

Отметим еще одно отличие квантового момента от классического.

Максимальное значение проекции квантового момента $\hbar l$ не равно модулю момента $\hbar\sqrt{l(l+1)}$, а меньше его.

Мы уже подчеркивали, что в силу соотношения неопределенностей у микрочастицы не могут быть одновременно известны проекции момента на две различные оси.

Зафиксировав состояние с определенным L_z, мы вносим неопределенность в проекции L_x и L_y.

В квантовой механике задание L^2 и одной из проекций момента импульса полностью определяет вращательное состояние тела.

Как догадаться про это?

4.5.2 Transformation of States Under Rotations

Суть (!?!?!?!?)

(очень важно, в 1ю напишу!!!)

7.2.1. Преобразование состояний.

Как мы знаем, в классическом пределе малых флуктуаций волновая функция состояния, амплитуда вероятности, переходит в волну материи, фаза которой пропорциональна классическому действию для корпускул, которые движутся по лучам согласно законам геометрической оптики. Однако пример поля - электромагнитные волны показывает, что амплитуда волны обладает еще и такой характеристикой, как поляризация. Действительно, электрическое и магнитное поля являются векторами. Следовательно, амплитуда вероятности при квантовании будет характеризоваться не только своими модулем и фазой, зависящими от координат и импульсов, но и поляризацией. Поэтому частицы, составляющие, например, электромагнитное поле в квантовой механике, кроме координаты и импульса имеют еще и наблюдаемую величину λ, которая в классике соответствует поляризации волн. Для частиц с поляризацией базисом состояний может служить набор векторов с определенными значениями координаты частицы и ее поляризации $|\boldsymbol{r}, \lambda\rangle$ Тогда состоянию $|\Psi\rangle$ соответствует волновая функция

$$\langle \boldsymbol{r}, \lambda | \Psi \rangle = \Psi_\lambda(\boldsymbol{r}).$$

Особенностью преобразования квантовых состояний при вращениях является определение закона преобразования поляризаций частиц.

Скалярные частицы.

Скалярными называются частицы, у которых нет поляризации, так что имеет место стандартное определение преобразований состояния при вращениях:

$$\left\langle \boldsymbol{r}^{\phi}|\Psi^{\phi}\right\rangle = \langle \boldsymbol{r}|\Psi\rangle, \quad \Psi^{\phi}\left(\boldsymbol{r}^{\phi}\right) = \Psi(\boldsymbol{r}),$$

где

$$\hat{R}|\Psi\rangle = \left|\Psi^{\phi}\right\rangle, \quad \hat{R}|\boldsymbol{r}\rangle = \left|\boldsymbol{r}^{\boldsymbol{\phi}}\right\rangle = \left|\mathcal{R}^{\mathrm{T}}\boldsymbol{r}\right\rangle$$

где $\mathcal{R}$ - матрица поворотов в классике. Отсюда можно также записать

$$\Psi^{\phi}(\boldsymbol{r}) = \Psi(\mathcal{R}\boldsymbol{r}),$$

поскольку

$$\Psi^{\phi}(\boldsymbol{r}) = \langle \boldsymbol{r}|(\hat{R}|\Psi\rangle) = \left(\hat{R}^{\dagger}|\boldsymbol{r}\rangle\right)^{\dagger}|\Psi\rangle = (|\mathcal{R}\boldsymbol{r}\rangle)^{\dagger}|\Psi\rangle = \mathrm{e}^{\frac{i}{\hbar}\hat{\boldsymbol{L}}\cdot\boldsymbol{\phi}}\Psi(\boldsymbol{r})$$

есть не что иное, как координатное представление оператора вращений, где

$$\hat{\boldsymbol{L}} = -\mathrm{i}\hbar(\boldsymbol{r}\times\boldsymbol{\nabla})$$

В итоге

$$\Psi^{\phi}(\boldsymbol{r}) = \mathrm{e}^{\frac{i}{\hbar}\hat{\boldsymbol{L}}\cdot\boldsymbol{\phi}}\Psi(\boldsymbol{r}) = \Psi(\mathcal{R}\boldsymbol{r}).$$

В справедливости этого тождества можно убедиться прямыми вычислениями. Например, при $\phi \to 0$ инфинитезимально находим

$$\{1 + \boldsymbol{\phi}\cdot(\boldsymbol{r}\times\boldsymbol{\nabla})\}\Psi(\boldsymbol{r}) = \Psi(\boldsymbol{r} - \boldsymbol{r}\times\boldsymbol{\phi}),$$

и, переставляя порядок вычисления смешанного произведения слева, получаем верное тождество

$$\Psi(\boldsymbol{r}) - (\boldsymbol{r}\times\boldsymbol{\phi})\cdot\boldsymbol{\nabla}\Psi(\boldsymbol{r}) = \Psi(\boldsymbol{r} - \boldsymbol{r}\times\boldsymbol{\phi}).$$

Векторные частицы.

Векторными называются частицы, состояние которых характеризуются и координатой и единичным вектором поляризации ϵ. Независимых поляризаций может быть несколько, так что их можно нумеровать маркером λ, и поэтому волновая функция векторной частицыВектор:

$$\langle \boldsymbol{r}, \epsilon_{\lambda}|\Psi\rangle = \boldsymbol{\Psi}_{\lambda}(\boldsymbol{r}) \quad \text{или} \quad \langle \boldsymbol{r}, \boldsymbol{\epsilon}|\Psi\rangle = \boldsymbol{\epsilon}\cdot\boldsymbol{\Psi}(\boldsymbol{r}).$$

Вектор поляризации при вращениях преобразуется так же, как координата, так что

$$\hat{R}|\boldsymbol{r}, \boldsymbol{\epsilon}\rangle = \left|\boldsymbol{r}^{\boldsymbol{\phi}}, \boldsymbol{\epsilon}^{\boldsymbol{\phi}}\right\rangle = \left|\mathcal{R}^{\mathrm{T}}\boldsymbol{r}, \mathcal{R}^{\mathrm{T}}\boldsymbol{\epsilon}\right\rangle.$$

В силу унитарности оператора вращений

$$\hat{R}\hat{R}^{\dagger} = \mathbb{1}$$

по-прежнему имеет место тождество

$$\left\langle \boldsymbol{r}^{\boldsymbol{\phi}}, \boldsymbol{\epsilon}^{\boldsymbol{\phi}}|\Psi^{\boldsymbol{\phi}}\right\rangle = \langle \boldsymbol{r}, \boldsymbol{\epsilon}|\Psi\rangle.$$

Отсюда

$$\left(\mathcal{R}^{\mathrm{T}}\boldsymbol{\epsilon}\right)\cdot\boldsymbol{\Psi}^{\boldsymbol{\phi}}\left(\mathcal{R}^{\mathrm{T}}\boldsymbol{r}\right) = \boldsymbol{\epsilon}\cdot\boldsymbol{\Psi}(\boldsymbol{r})$$

или после использования равенства

$$\left(\mathcal{R}^{\mathrm{T}}\epsilon\cdot\Psi^{\phi}\right)=\mathcal{R}^{\mathrm{T}}_{\lambda\rho}\epsilon_{\rho}\Psi^{\phi}_{\lambda}=\epsilon_{\rho}\mathcal{R}_{\rho\lambda}\Psi^{\phi}_{\lambda}=\epsilon\cdot\left(\mathcal{R}\Psi^{\phi}\right)$$

и подходящей замены переменных $r\to\mathcal{R}r$ получаем

$$\mathcal{R}\Psi^{\phi}(r)=\Psi(\mathcal{R}r)\Leftrightarrow\Psi^{\phi}(r)=\mathcal{R}^{\mathrm{T}}\Psi(\mathcal{R}r),$$

или в тензорной записи

$$\boldsymbol{\Psi}^{\phi}_{\lambda}(\boldsymbol{r})=\mathcal{R}^{\mathrm{T}}_{\lambda\mu}\boldsymbol{\Psi}_{\rho}(\mathcal{R}\boldsymbol{r}),$$

где согласно (7.27) преобразование аргумента функции сводится к действию оператора орбитальных вращений,

$$\Psi_{\rho}(\mathcal{R}r)=\mathrm{e}^{\frac{i}{\hbar}\hat{L}\cdot\phi}\Psi_{\rho}(\boldsymbol{r}),$$

и

$$\Psi^{\phi}_{\lambda}(r)=\mathcal{R}^{\mathrm{T}}_{\lambda\rho}\mathrm{e}^{\dot{j}\hat{L}\cdot\phi}\Psi_{\rho}(\boldsymbol{r}),$$

Матрица поворотов нам известна, так как она определяется поворотами координат. Для бесконечно малых преобразований в (7.33) положим, что

$$\mathcal{R}^{\mathrm{T}}=\mathbb{1}+\mathrm{i}(\boldsymbol{\phi}\cdot\hat{\boldsymbol{s}}),$$

где векторная (3×3)-матрица $\hat{\boldsymbol{s}}$ определяется из равенства линейных по углу правых и левых частей равенства

$$\mathcal{R}^{\mathrm{T}}_{\alpha\beta}=\delta_{\alpha\beta}+\epsilon_{\alpha\beta\gamma}\phi^{\gamma}=\delta_{\alpha\beta}+\mathrm{i}\left(s_{\gamma}\right)_{\alpha\beta}\phi^{\gamma}.$$

Поэтому

$$\left(\hat{s}_{\gamma}\right)_{\alpha\beta}=-\mathrm{i}\epsilon_{\alpha\beta\gamma}.$$

Эта матрица эрмитова:

$$\left(\hat{\boldsymbol{s}}^{\dagger}_{\gamma}\right)_{\alpha\beta}=\left(\hat{\boldsymbol{s}}^{*}_{\gamma}\right)_{\beta\alpha}=\left(\hat{\boldsymbol{s}}_{\gamma}\right)_{\alpha\beta},$$

здесь мы использовали антисимметрию тензора Леви-Чивиты. Покажем, что для этой матрицы имеют место соотношения коммутации

$$[\hat{\boldsymbol{s}}_{\alpha},\hat{\boldsymbol{s}}_{\beta}]=\mathrm{i}\epsilon_{\alpha\beta\gamma}\hat{\boldsymbol{s}}_{\gamma}.$$

В самом деле, слева в этой формуле стоит матричное выражение с индексами

$$\begin{aligned}&\{\mu,\lambda\}\\&(-\mathrm{i})^2\left(\epsilon_{\alpha\mu\nu}\epsilon_{\beta\nu\lambda}-\epsilon_{\beta\mu\nu}\epsilon_{\alpha\nu\lambda}\ \right)=\\&\quad=\delta_{\alpha\beta}\delta_{\mu\lambda}-\delta_{\alpha\lambda}\delta_{\mu\beta}-\delta_{\alpha\beta}\delta_{\mu\lambda}+\delta_{\alpha\mu}\delta_{\beta\lambda}=\delta_{\alpha\mu}\delta_{\beta\lambda}-\delta_{\alpha\lambda}\delta_{\mu\beta}.\end{aligned}$$

Справа же имеем

$$\mathrm{i}(-\mathrm{i})\epsilon_{\alpha\beta\gamma}\epsilon_{\gamma\mu\lambda}=\delta_{\alpha\mu}\delta_{\beta\lambda}-\delta_{\alpha\lambda}\delta_{\mu\beta},$$

и тождество доказано. В матричных обозначениях для конечных вращений находим

$$\mathcal{R}^{\mathrm{T}}(\phi)=\mathrm{e}^{\mathrm{i}\hat{\boldsymbol{\beta}}\cdot\boldsymbol{\phi}}.$$

В итоге, преобразование волновой функции частицы с вектором поляризации (7.31) эквивалентно

$$\Psi^{\phi}(r)=\mathrm{e}^{\frac{i}{\hbar}(\hat{L}+\hat{S})\cdot\phi}\Psi(r),$$

где матричный оператор размерности действия

$$\hat{\boldsymbol{S}} = \hbar \hat{\boldsymbol{s}}$$

называется спином векторной частицы, а сумма

$$\hat{\boldsymbol{J}} = \hat{\boldsymbol{L}} + \hat{\boldsymbol{S}}$$

- полным моментом импульса частицы. В принятых обозначениях преобразованная при вращениях волновая функция выражается через исходную волновую функцию действием оператора вращений с генератором полного момента количества движения

$$\Psi^{\phi}(r) = \mathrm{e}^{\frac{1}{\hbar}\cdot\hat{J}\cdot\phi}\Psi(r),$$

так что физический смысл оператора спина, возникающего из-за введения поляризации волновой функции, есть собственный момент количества движения частицы.

Так как в координатном представлении дифференциальный оператор орбитального момента коммутирует с постоянной матрицей спина

$$\left[\hat{\boldsymbol{L}}_{\alpha}, \hat{\boldsymbol{S}}_{\beta}\right] = 0,$$

а коммутационные соотношения для спиновой матрицы идентичны соотношениям для орбитального момента, для полного момента импульса [1] получаем

$$\left[\hat{\boldsymbol{J}}_{\alpha}, \hat{\boldsymbol{J}}_{\beta}\right] = \mathrm{i}\hbar\epsilon_{\alpha\beta\gamma}\hat{\boldsymbol{J}}_{\gamma},$$

которые совпадают с коммутационными соотношениями как орбитального момента, так и спина.

Зададимся вопросом: является ли случай векторной частицы единственным примером, когда у частицы может быть поляризация? Кроме вектора, который представляет собой тензор первого ранга, существуют и тензоры второго ранга и тензоры высших рангов. Но тогда как описываются преобразования волновых функций таких полей при поворотах в евклидовом пространстве? И каков допустимый спектр поляризаций частиц?

Операторное квантование момента количества движения согласно коммутационным соотношениям (7.42) позволит нам определить допустимые значения момента количества движения, т.е. найти базис волновых функций в отношении их преобразований при поворотах и построить схему описания квантовых состояний с различными значениями спина и орбитального момента.

Преобразование операторов.

Согласно общей схеме при каноническом квантовании оператор вращений в квантовой механике имеет генератор так что

$$\hat{\boldsymbol{\Gamma}} = \frac{1}{\hbar}\hat{\boldsymbol{L}},$$

$$\hat{R} = \mathrm{e}^{\frac{\mathrm{i}}{\hbar}\hat{L}\cdot\phi}.$$

Для операторов, построенных из координат и импульсов, преобразование имеет вид

$$\hat{F}_{\phi} = \hat{R}\hat{F}\hat{R}^{\dagger} = \mathcal{R}(\hat{F}).$$

Рассмотрим два важнейших случая. 1. Скалярная наблюдаемая C. В классической механике скалярные величины не преобразуются при вращениях. Поэтому

$$\mathcal{R}(C) = C.$$

Значит, и в квантовой механике скалярная наблюдаемая не преобразуется при действии оператора вращений

$$\hat{C}_\phi = \hat{C}.$$

Подставляя в (7.44) инфинитезимальный оператор вращений

$$\hat{R} = \mathbb{1} + \frac{\mathrm{i}}{\hbar}\hat{\boldsymbol{L}} \cdot \phi, \quad \phi \to 0,$$

находим коммутатор оператора орбитального момента с произвольной скалярной наблюдаемой

$$[\hat{\boldsymbol{L}}, \hat{\boldsymbol{C}}] = 0.$$

2. Векторная наблюдаемая $\boldsymbol{A}$. В классической механике векторные величины преобразуются так же, как и координаты:

$$A^\phi_\alpha = \mathcal{R}_{\alpha\beta} A_\beta,$$

так что квантовый векторный оператор преобразуется при вращениях как

$$\hat{\boldsymbol{A}}^\phi_\alpha = \hat{R}\hat{\boldsymbol{A}}_\alpha \hat{R}^\dagger = \mathcal{R}_{\alpha\beta}\hat{\boldsymbol{A}}_\beta.$$

Для бесконечно малых поворотов в правой стороне (7.49) получаем

$$\mathcal{R}_{\alpha\beta}\hat{\boldsymbol{A}}_\beta \approx \hat{\boldsymbol{A}}_\alpha - \epsilon_{\alpha\beta\gamma}\hat{\boldsymbol{A}}_\beta \boldsymbol{\phi}_\gamma, \quad \phi \to 0,$$

в то время как

$$\hat{R}\hat{\boldsymbol{A}}_\alpha \hat{R}^\dagger \approx \hat{\boldsymbol{A}}_\alpha + \frac{\mathrm{i}}{\hbar}\left[\hat{\boldsymbol{L}}_\gamma \boldsymbol{\phi}_\gamma, \hat{\boldsymbol{A}}_\alpha\right].$$

Сравнивая два предыдущих выражения, находим

$$\left[\hat{\boldsymbol{L}}_\gamma, \hat{\boldsymbol{A}}_\alpha\right] = \mathrm{i}\hbar\epsilon_{\alpha\beta\gamma}\hat{\boldsymbol{A}}_\beta,$$

так что после переобозначения индексов суммирования получаем общее выражение для коммутатора мамента цмпульса с векторной наблюдаемой:

$$\left[\hat{\boldsymbol{L}}_\alpha, \hat{\boldsymbol{A}}_\beta\right] = \mathrm{i}\hbar\epsilon_{\alpha\beta\gamma}\hat{\boldsymbol{A}}_\gamma.$$

Обычно определяют безразмерный векторный оператор

$$\hat{\boldsymbol{l}} = \frac{1}{\hbar}\hat{\boldsymbol{L}},$$

так что, в частности, из (7.50) следуют коммутационные соотношения для оператора момента импульса

$$\left[\hat{\boldsymbol{l}}_\alpha, \hat{\boldsymbol{l}}_\beta\right] = \mathrm{i}\epsilon_{\alpha\beta\gamma}\hat{\boldsymbol{l}}_\gamma.$$

Последнее равенство можно также установить посредством выкладок в явном виде, пользуясь выражением для оператора

$$\hat{\boldsymbol{L}}_\alpha = \epsilon_{\alpha\beta\gamma}\hat{\boldsymbol{r}}_\beta\hat{\boldsymbol{p}}_\gamma.$$

Важным приложением общих результатов являются коммутационные соотношения генераторов поворотов с квадратом момента импульса

$$\left[\hat{\boldsymbol{l}}_\alpha, \hat{\boldsymbol{l}}^2\right] = 0,$$

как и должно быть для скалярного оператора $\hat{l}^2$.

Как догадаться про это?

4.5.3 Concept of Spin

Суть (!?)

(в 1ю продублирую.)

Спин по Киселеву

Рассмотрим собственный момент импульса частицы, спин, $s = \frac{1}{2}$. В этом случае соответствующая спиновая матрица представляется в виде

$$\hat{\boldsymbol{s}} = \frac{1}{2}\hat{\boldsymbol{\sigma}},$$

где $\boldsymbol{\sigma}$ - матрицы Паули [1]. Найдем явный вид матриц Паули, используя общие выражения для матричных элементов момента импульса (8.9), (8.11). Базис спиновых состояний для краткости обозначений записывают как

$$\left|\frac{1}{2}, +\frac{1}{2}\right\rangle = |+\rangle, \quad \left|\frac{1}{2}, -\frac{1}{2}\right\rangle = |-\rangle,$$

причем это-собственные векторы проекции спина

$$\hat{s}_z|+\rangle = \frac{1}{2}|+\rangle, \quad \hat{s}_z|-\rangle = -\frac{1}{2}|-\rangle.$$

Следовательно, эта матрица в рассматриваемом базисе имеет диагональный вид

$$\hat{\boldsymbol{s}}_z = \frac{1}{2}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Согласно (8.11) ненулевые матричные элементы повышающего и понижающего операторов

$$\langle + |\hat{s}_+| - \rangle = \sqrt{\frac{1}{2}\left(\frac{1}{2}+1\right) - (-1)\frac{1}{2}\left(-\frac{1}{2}+1\right)} = 1,$$

$$\langle - |\hat{s}_-| + \rangle = (\langle + |\hat{s}_+| - \rangle)^\dagger = 1,$$

откуда

$$\hat{\boldsymbol{s}}_+ = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \hat{\boldsymbol{s}}_- = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}.$$

Тогда

$$\hat{\boldsymbol{s}}_x = \frac{1}{2}\left(\hat{\boldsymbol{s}}_+ + \hat{\boldsymbol{s}}_-\right) = \frac{1}{2}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

и

$$\hat{\boldsymbol{s}}_y = \frac{1}{2\mathrm{i}}\left(\hat{\boldsymbol{s}}_+ - \hat{\boldsymbol{s}}_-\right) = \frac{1}{2}\begin{pmatrix} 0 & -\mathrm{i} \\ \mathrm{i} & 0 \end{pmatrix}.$$

Поэтому сигма-матрицы Паули - это

$$\hat{\boldsymbol{\sigma}}_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \hat{\boldsymbol{\sigma}}_y = \begin{pmatrix} 0 & -\mathrm{i} \\ \mathrm{i} & 0 \end{pmatrix}, \quad \hat{\boldsymbol{\sigma}}_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Поскольку частица со спином $\frac{1}{2}$, которую называют спинором, обладает двумя поляризациями [1]

$$|\mathfrak{e}_1\rangle = |+\rangle, \quad |\mathfrak{e}_2\rangle = |-\rangle, \quad |\mathfrak{e}_\alpha\rangle, \quad \alpha = \{1, 2\},$$

можно определить состояие поляризаций как

$$\langle\theta| = \langle\mathfrak{e}_\alpha|\,\theta^\alpha,$$

так что волновая функция нерелятивистского спинора [2]

$$\langle \boldsymbol{r}, \mathfrak{e}_\alpha|\Psi\rangle = \psi_\alpha(\boldsymbol{r})$$

- это так называемый двухкомпонентный спинор Паули, которой преобразуется как контрвариантный вектор двумерного пространства спиноров, и его по договоренности обычно трактуют в матричной записи как столбец. При поворотах спинор преобразуется согласно

$$\psi^\phi_\alpha(\boldsymbol{r}) = \left\{\mathrm{e}^{\mathrm{i}\hat{\mathbf{s}}\cdot\boldsymbol{\phi}}\right\}^{\cdot\beta}_{\alpha}\psi_\beta\left(\boldsymbol{r}^\phi\right),$$

где мы указали матричные индексы в явном виде, и, при этом, указали порядок следования индексов в матричном умножении с помощью символа - Так как по построению

$$\langle \boldsymbol{r}, \theta|\Psi\rangle = \theta^\alpha\psi_\alpha(\boldsymbol{r})$$

- инвариант при вращениях, спинор поляризации θ^α (строка) преобразуется как

$$\theta^\beta = \theta^\alpha_\phi\left\{\mathrm{e}^{\mathrm{i}\hat{\mathbf{s}}\cdot\boldsymbol{\phi}}\right\}^{\bullet\beta}_{\alpha} \Leftrightarrow \theta^\beta_\phi = \theta^\alpha\left\{\mathrm{e}^{-\mathrm{i}\hat{\mathbf{s}}\cdot\boldsymbol{\phi}}\right\}^{\bullet\beta}_{\alpha}.$$

В матричных обозначениях

$$\psi^\phi(\boldsymbol{r}) = \hat{R}_S\cdot\psi(\mathcal{R}\boldsymbol{r}), \quad \theta_{\boldsymbol{\phi}} = \theta\cdot\hat{R}^\dagger_S, \quad \hat{R}_S = \mathrm{e}^{\mathrm{i}\hat{\mathbf{s}}\cdot\boldsymbol{\phi}}$$

причем ψ_α - контрвектор двумерного спинорного пространства, который преобразуется матрицей $\hat{R}_S$, а θ^α - ковектор, который преобразуется обратной матрицей $\hat{R}^{-1}_S = \hat{R}^\dagger_S$.

Для вычисления матричной экспоненты установим два факта:

1) коммутационные соотношения

$$[\hat{\boldsymbol{\sigma}}_a, \hat{\boldsymbol{\sigma}}_b] = 2\mathrm{i}\epsilon_{abc}\hat{\boldsymbol{\sigma}}_c$$

следуют из коммутационных соотношений для момента импульса;

2) антикоммутационные соотношения

$$\{\hat{\sigma}_a, \hat{\sigma}_b\} \stackrel{\mathrm{def}}{=} \hat{\sigma}_a\hat{\sigma}_b + \hat{\sigma}_b\hat{\sigma}_a = 2\delta_{ab}$$

устанавливаются прямыми вычислениями произведений матриц Паули.

Поскольку

$$\hat{\boldsymbol{\sigma}}_a\hat{\boldsymbol{\sigma}}_b = \frac{1}{2}\left[\hat{\boldsymbol{\sigma}}_a, \hat{\boldsymbol{\sigma}}_b\right] + \frac{1}{2}\left\{\hat{\boldsymbol{\sigma}}_a, \hat{\boldsymbol{\sigma}}_b\right\},$$

находим

$$\hat{\boldsymbol{\sigma}}_a\hat{\boldsymbol{\sigma}}_b = \mathrm{i}\epsilon_{abc}\hat{\boldsymbol{\sigma}}_c + \delta_{ab}.$$

Домножая это тождество на векторы $\boldsymbol{a}_a$ и $\boldsymbol{b}_b$, получаем

$$(\boldsymbol{a}\cdot\hat{\boldsymbol{\sigma}})(\boldsymbol{b}\cdot\hat{\boldsymbol{\sigma}}) = \mathrm{i}(\boldsymbol{a}\times\boldsymbol{b})\cdot\hat{\boldsymbol{\sigma}} + \boldsymbol{a}\cdot\boldsymbol{b},$$

где справа стоит векторное произведение векторов. В частности,

$$(\boldsymbol{\phi}\cdot\hat{\boldsymbol{\sigma}})^2 = \boldsymbol{\phi}^2.$$

Тогда в экспоненте оператора вращений

$$\mathrm{e}^{\mathrm{i}\hat{\boldsymbol{s}}\cdot\boldsymbol{\phi}} = \sum_{n=0}^{\infty} \frac{\mathrm{i}^n}{2^n n!} (\phi \cdot \hat{\boldsymbol{\sigma}})^n$$

четные степени разложения пропорциональны единичной матрице, а нечетные-оператору

$$(\phi \cdot \hat{\boldsymbol{\sigma}}) = |\boldsymbol{\phi}|(\boldsymbol{e} \cdot \hat{\boldsymbol{\sigma}}) = (\boldsymbol{\phi} \cdot \boldsymbol{e})(\boldsymbol{e} \cdot \hat{\boldsymbol{\sigma}}),$$

где $\boldsymbol{e}$-единичный вектор вдоль оси поворота. Тогда суммирование четных и нечетных степеней дает

$$\mathrm{e}^{\mathrm{i}\hat{\boldsymbol{s}}\cdot\boldsymbol{\phi}} = \cos\left(\frac{1}{2}(\boldsymbol{\phi}\cdot\boldsymbol{e})\right) + \mathrm{i}(\boldsymbol{e}\cdot\hat{\boldsymbol{\sigma}})\sin\left(\frac{1}{2}(\boldsymbol{\phi}\cdot\boldsymbol{e})\right).$$

При повороте вокруг оси на угол $2\pi = (\boldsymbol{\phi}\cdot\boldsymbol{e})$ получаем $\boldsymbol{r}^{\phi} = r$ и

$$\mathrm{e}^{\mathrm{i}\hat{\boldsymbol{s}}\cdot\phi}\big|_{2\pi} = -1.$$

Значит,

$$\psi_\alpha(\boldsymbol{r})\big|_{2\pi} = -\psi_\alpha(\boldsymbol{r}),$$

т. е. волновая функция спинора меняет знак после поворота на угол 2π. Это свойство, очевидно, является общим для всех частиц с полуцелым спином, которые называются фермионами.

Спиновая метрика (?)

Введем вещественную матрицу $\hat{\epsilon}$,

$$\hat{\epsilon} \overset{\text{def}}{=} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} = \mathrm{i}\sigma_2, \quad \hat{\epsilon}^2 = -1, \quad \hat{\epsilon}^{-1} = \hat{\epsilon}^{\mathrm{T}} = -\hat{\epsilon},$$

и определим сопряженный к спинору ψ спинор ψ_c с помощью комплексного сопряжения и матричного умножения,

$$\psi_c \overset{\text{def}}{=} -\hat{\epsilon}\psi^* = -\mathrm{i}\sigma_2\psi^*,$$

а затем рассмотрим, как как он преобразуется при поворотах,

$$\psi_c^{\phi} = -\hat{\epsilon}\left(\hat{R}_S\psi\right)^* = \hat{\epsilon}\hat{R}_S^*\hat{\epsilon}^{-1}\left(-\hat{\epsilon}\psi^*\right). = \hat{\epsilon}\hat{R}_S^*\hat{\epsilon}^{-1}\psi_c,$$

Значит, нам необходимо найти матрицу $\hat{\epsilon}\hat{R}_S^*\hat{\epsilon}^{-1}$. При этом, матрица поворотов спиноров $\hat{R}_S$ имеет вид экспоненты (9.13). В общем случае, так как $\hat{\epsilon}\circ\hat{\epsilon}^{-1} = \mathbb{1}$, разложение экспоненты от матрицы в ряд Тейлора приводит к

$$\hat{\epsilon}\circ\exp\{A\}\circ\hat{\epsilon}^{-1} = \hat{\epsilon}\circ\left(\sum_{n=0}^{\infty}\frac{1}{n!}A^n\right)\circ\hat{\epsilon}^{-1} = \sum_{n=0}^{\infty}\frac{1}{n!}\left\{\hat{\epsilon}\circ A\circ\hat{\epsilon}^{-1}\right\}^n = \exp\left\{\hat{\epsilon}\circ A\circ\hat{\epsilon}^{-1}\right\}.$$

В случае матрицы поворотов

$$\hat{R}_S = \exp\left(\frac{\mathrm{i}}{2}\phi(\boldsymbol{\sigma}\cdot\boldsymbol{e})\right),$$

так что

$$\hat{R}_S^* = \exp\left(-\frac{\mathrm{i}}{2}\phi\left(\boldsymbol{\sigma}^*\cdot\boldsymbol{e}\right)\right).$$

Для вычисления $\hat{\epsilon} \circ \boldsymbol{\sigma}^* \circ \hat{\epsilon}^{-1}$ заметим, что матрицы σ_x, σ_z симметричные и вещественные, так что

$$\sigma_x^* = \sigma_x^{\mathrm{T}} = \sigma_x, \quad \sigma_z^* = \sigma_z^{\mathrm{T}} = \sigma_z,$$

а матрица σ_y чисто мнимая и антисимметричная, так что

$$\sigma_y^* = \sigma_y^{\mathrm{T}} = -\sigma_y.$$

Поэтому в силу

$$\sigma_x\hat{\epsilon} = -\hat{\epsilon}\sigma_x, \quad \sigma_z\hat{\epsilon} = -\hat{\epsilon}\sigma_z, \quad \sigma_y\hat{\epsilon} = \hat{\epsilon}\sigma_y,$$

получаем

$$\hat{\epsilon} \circ \boldsymbol{\sigma}^* \circ \hat{\epsilon}^{-1} = \hat{\epsilon} \circ \boldsymbol{\sigma}^{\mathrm{T}} \circ \hat{\epsilon}^{-1} = -\boldsymbol{\sigma}.$$

Значит,

$$\hat{\epsilon}\hat{R}_S^*\hat{\epsilon}^{-1} = \hat{\epsilon}\exp\left(-\frac{\mathrm{i}}{2}\phi\,(\sigma^* \cdot \boldsymbol{e})\right)\hat{\epsilon}^{-1} = \exp\left(-\frac{\mathrm{i}}{2}\phi\left(\hat{\epsilon}\boldsymbol{\sigma}^*\hat{\epsilon}^{-1} \cdot \boldsymbol{e}\right)\right) = \hat{R}_S,$$

и аналогично,

$$\hat{\epsilon}\hat{R}_S^{\mathrm{T}}\hat{\epsilon}^{-1} = \hat{\epsilon}\exp\left(\frac{\mathrm{i}}{2}\phi\left(\boldsymbol{\sigma}^{\mathrm{T}} \cdot \boldsymbol{e}\right)\right)\hat{\epsilon}^{-1} = \exp\left(\frac{\mathrm{i}}{2}\phi\left(\hat{\epsilon}\boldsymbol{\sigma}^{\mathrm{T}}\hat{\epsilon}^{-1} \cdot \boldsymbol{e}\right)\right) = \hat{R}_S^\dagger = \hat{R}_S^{-1}.$$

Напомним, что при использовании матричного умножения контравариантные спиноры ψ_α, которые при матричной записи можно по договоренности считать столбцами $\psi_\alpha\bullet$, преобразуются матрицами $\hat{R}_S$, а ковариантные спиноры ψ^α, которые можно считать строками $\psi^{\bullet\alpha}$, преобразуются обратными матрицами $\hat{R}_S^{-1}$. При этом, R_S - это унитарная матрица:

$$R_S \cdot R_S^\dagger = \mathbb{1}, \quad R_S^\dagger = R_S^{-1},$$

и поэтому эрмитово сопряженный спинор преобразуется как ковариантный. Говорят, что соотношение (9.25) устанавливает эквивалентность транспонированного представления группы поворотов спиноров эрмитово сопряженному представлению этой группы или, в данном случае, еще и эквивалентность транспонированного контравариантного представления ковариантному, а соотношение (9.24) - эквивалентность комплексно сопряженного представления контравариантному спинорному представлению. Итак, при поворотах

$$\psi_c^\phi = \hat{R}_S\psi_c,$$

где мы воспользовались соотношением (9.24). Значит, этот спинор при поворотах преобразуется также, как и сам спинор ψ. Поэтому произведение двух любых спиноров

$$\psi_c^\dagger\chi = \left(-\hat{\epsilon}\psi^*\right)^\dagger\chi = \psi^{\mathrm{T}}(-\hat{\epsilon})^\dagger\chi = \psi^{\mathrm{T}}\hat{\epsilon}\chi = \psi_\alpha\hat{\epsilon}^{\alpha\beta}\chi_\beta$$

является скаляром, т.е. инвариантом группы поворотов спиноров. Значит, формула определяет скалярное произведение двух спиноров. Поэтому согласно общему представлению о метрическом тензоре как о квадратичной инвариантной линейной функции $\hat{\epsilon}^{\alpha\beta}$ - полностью антисимметричный ковариантный тензор второго ранга в двумерном пространстве:

$$\epsilon^{\alpha\beta} = -\epsilon^{\beta\alpha}, \quad \epsilon^{12} = 1.$$

В терминах метрики скалярное произведение двух произвольных спиноров ψ и χ

$$\psi \cdot \chi = \epsilon^{\alpha\beta}\psi_\alpha\chi_\beta.$$

Метрика определяет ковариантные спиноры с верхними индексами

$$\chi^\alpha = \epsilon^{\alpha\beta}\chi_\beta,$$

так что скалярное произведение

$$\psi \cdot \chi = \psi_\alpha \chi^\alpha = -\psi^\beta \chi_\beta.$$

Обратная метрика $\epsilon_{\alpha\beta}$ определяется согласно

$$\epsilon_{\alpha\gamma}\epsilon^{\gamma\beta} = \delta^\beta_\alpha.$$

Очевидно,

$$\epsilon_{\alpha\beta} = -\epsilon_{\beta\alpha}, \quad \epsilon_{12} = -1.$$

Определенный выше спинор ψ_c обозначают также спинором с чертой, который имеет нижний индекс с точкой, так как он преобразуется по представлению, эквивалентному представлению, которое действует в комплексно сопряженном спинорном пространстве:

$$\bar{\psi}^{\dot\alpha} \stackrel{\text{def}}{=} (-\hat\epsilon\psi^*)^{\dot\alpha}$$

Как мы показали, этот спинор при поворотах преобразуется также, как и обычный спинор. Поэтому скаляром будет величина (см. знаки в (9.27))

$$-\chi^\dagger \cdot \psi_c = -\bar\chi^{\dot\alpha}\bar\psi_{\dot\alpha},$$

где мы ввели обозначение для спинора с чертой и с верхним индексом с точкой как эрмитово сопряженного к обычному спинору-столбцу:

$$\bar\chi^{\dot\alpha} = \left(\chi^\dagger\right)^{\dot\alpha}.$$

Элементарно

$$\chi^\dagger = \{\chi^*\}^{\mathrm{T}} = \{\hat\epsilon\,(-\hat\epsilon\chi^*)\}^{\mathrm{T}} = \{\hat\epsilon\bar\chi\}^{\mathrm{T}} = -\bar\chi^{\mathrm{T}}\hat\epsilon.$$

Поэтому

$$-\bar\chi\cdot\bar\psi = \bar\chi^{\mathrm{T}}\hat\epsilon\bar\psi = \bar\chi_{\dot\alpha}\epsilon^{\dot\alpha\dot\beta}\bar\psi_{\dot\beta}, \quad \epsilon^{12} = 1$$

т.е. метрика $\epsilon^{\dot\alpha\dot\beta}$ в спинорных индексах с точкой совпадает с метрикой $\epsilon^{\alpha\beta}$ в спинорных индексах без точек.

Метрика остается инвариантной при поворотах спиноров. Действительно, справедливо соотношение изометрии:

$$\hat R_S^{\mathrm{T}}\hat\epsilon\hat R_S = -\hat R_S^{\mathrm{T}}\hat\epsilon^{-1}\hat R_S = \hat\epsilon\left(\hat\epsilon\hat R_S^{\mathrm{T}}\hat\epsilon^{-1}\right)\hat R_S = \hat\epsilon\hat R_S^\dagger\hat R_S = \hat\epsilon,$$

где мы воспользовались тождеством (9.25). Группа инвариантности спинорной метрики с $\det\hat R_S = 1$ называется специальной унитарной группой на двухкомпонентных спинорах: $SU(2)$. Это трехпараметрическая группа.

Мы исследовали алгебру генераторов группы при построении поворотов спиноров. Эта алгебра совпадает с алгеброй генераторов группы поворотов трехмерного евклидова пространства $SO(3)$. Тем не менее, сами группы отличаются, так как в $SU(2)$ допустимы и полуцелые собственные значения генератора s_z, а в $SO(3)$ - только целые значения s_z. Это особенно ярко проявляется при проведенном выше рассмотрении поворота на угол 2π: для спиноров этот поворот дает фактор -1, а для бозонов, полей с целым значением спина, - фактор $+1$. Другими словами, ядро гомоморфизма $SU(2)$ на $SO(3)$, т.е. праобраз единицы, - это дискретная группа $\mathbb{Z}_2$, состоящая из 2х элементов $\{1,-1\}$. В математике имеет место утверждение: представления алгебры Ли реализуют представления универсальной накрывающей группы. В рассмотренном случае, исходная группа Ли - группа поворотов 3-мерного евклидова пространства $SO(3)$, представления

её алгебры эо(3) реализуют представления группы, которая является универсальной накрывающей группой для $SO(3)$, это - группа $SU(2)$. Физический смысл этого утверждения мы указали: для представлений группы $SU(2)$, универсальной накрывающей группы $SO(3)$, допустимы полуцелые значения спина, в отличие от представлений самой группы $SO(3)$, для которой допустимы только целые значения сiлина.

Само существование полей с полуцелым спином возможно, но оно не следует, вообще говоря, из группы поворотов евклидова пространства. Факт такого существования - экспериментальный. Подчеркнем, что спинорная метрика задает инвариант

$$\psi \cdot \psi = \psi_\alpha \epsilon^{\alpha\beta} \psi_\beta = \psi_{(1)}\psi_{(2)} - \psi_{(2)}\psi_{(1)},$$

и это инвариант обратился бы в нуль [1], если бы спиноры описывались обычными комплексными числами! Этот факт напрямую связан с тем, что спиноры - частный случай фермионов с полуцелым спином, для которых имеет место принцип запрета Паули. Из принципа запрета Паули, как мы узнаем (см. стр. 158 раздел 9.3), следует, что перестановка наблюдаемых параметров тождественных фермионов, в данном случае, перестановка номеров поляризации (проекции спина на ось z) в амплитуде вероятности должна сопровождаться сменой знака амплитуды. В частности, следует положить, что

$$\psi_{(1)}\psi_{(2)} = -\psi_{(2)}\psi_{(1)},$$

что в математике называют алгеброй Грассмана, а сами числа с такими свойствами - грассмановыми переменными. Укажем лишь, что в релятивистской теории устанвливается связь спина со статистикой: собственное значение оператора перестановок тождественных частиц равно $+1$ для частиц с целым спином (бозонов) и -1 для для частиц с полуцелым спинов (фермионов). Тогда становится понятным, почему метрика пространства как инвариантная квадратичная форма на вещественных векторах симметрична, а метрика спинорного пространства на грассмановых спинорах антисимметрична.

Как догадаться про это?

4.5.4 Connection of Spin with Statistics (!!????)

Подробно обсудим связь спина со статистикой.

Суть

Доказательство на пальцах

(?? как это на интуитивном уровне доказать?)

Типичная теория

РассМоТриМ ДВа тождественных фермиона.
Их волновая функция -

$$\left\langle \boldsymbol{r}_1, \theta^\alpha_{(1)}, n_1; \boldsymbol{r}_2, \theta^\beta_{(2)}, n_2 | \Psi \right\rangle = \psi^{(n_1,n_2)}_{\alpha\beta}\left(\boldsymbol{r}_1, \boldsymbol{r}_2\right)$$

где мы указали возможные многомерные квантовые числа (n_1, n_2), не связанные со спинорНыми характеристикам и.

После поворота на угол 2π координаты первой частицы r_1 и ее

$$\psi_{\alpha\beta}^{(n_1,n_2)}\left(\boldsymbol{r}_1,\boldsymbol{r}_2\right)\overset{\mathcal{R}_1(2\pi)}{\longrightarrow}\psi_{\alpha\beta}^{\mathcal{R}_1(n_1,n_2)}\left(\boldsymbol{r}_1,\boldsymbol{r}_2\right)=-\psi_{\alpha\beta}\left(\boldsymbol{r}_1,\boldsymbol{r}_2\right)$$

Подобное отличие в фазе волновой функции фермионов после вращения на угол 2π мо-
си туацию, когда квантовые числа двух ферм ионов тождествен но совпадают:

$$\boldsymbol{r}_1=\boldsymbol{r}_2=\boldsymbol{r},\quad \theta_{(1)}^{\alpha}=\theta_{(2)}^{\beta}=\theta^1,\quad n_1=n_2=n$$

т.е., Другим и словами, поместим тождественные частицы с одним и тем же набором знаЧений наблюдаемых величин в одну точку пространства.

В полной аналогии с выводом ДОПустимых значений квантованного орбитального момента потребуем выполнение следующего принци па: если состояния каждой из двух тождественных частиц не отличи мы, то вращение одной из них на угол 2π не наблюдаемо, т.е.

Должно приводить к тождественному преобразован ию состояния.

По сути, речь идет о вращении одной части цы отгиосителъио сТН, В одн ой точке), то такое вращение не имеет физического смысла, т.е.

не наблюдаемо.

Следовательно, исходная волновая функция

$$\psi_{11}^{(n,n)}(\boldsymbol{r},\boldsymbol{r})$$

ДОЛжна тождественно совпадать с волновой фун кцией после вращения координат одной из Частиц на угол 2π :

$$\psi_{11}^{(n,n)}\left(\mathbf{r},\mathbf{r}'\right)=-\psi_{11}^{(n,n)}(\mathbf{r},\boldsymbol{r})\equiv 0$$

Что ДОСтигается только в случае равенства нулю волновой функци и тождественных фер- . Этот прин цип автоматически удовлетворяется, если волновую функцию тождественных

$$\psi_{\alpha\beta}^{A(n_1,n_2)}\left(\boldsymbol{r}_1,\boldsymbol{r}_2\right)=\frac{1}{\sqrt{2}}\left\{\psi_{\alpha\beta}^{(n_1,n_2)}\left(\boldsymbol{r}_1,\boldsymbol{r}_2\right)-\psi_{\beta\alpha}^{(n_2,n_1)}\left(\boldsymbol{r}_2,\boldsymbol{r}_1\right)\right\}$$

так как она обращается в нуль, если квантовые состояния фермионов тождественны

А нтисим метризованная волновая функция Двух фермионов являет собой пример обшего принципа, возникающего в Квантовой механике с тождествен ными частицами.

В самом деле, физическая система из тождествен ных частиц не изменится, если поменять местами пару этих части ц.

В квантовой механике это утвержден ие означает, что состояиие системъе

$$\left|\Psi:\{Q_1,Q_2,...\}\right\rangle=\lambda\left|\Psi:\{Q_2,Q_1,...\}\right\rangle,\quad |\lambda|=1$$

где $\{Q_1,Q_2,...\}$ -полный набор наблюдаемых для частиц $\{1,2,...\}$.В этом уравнени и MbI ТребуеМ, Чтобы при перестановке квантовых чисел первой и второй частиц вектор состояния остался прежним с точ ностью до фазового множителя (норм ировка остается без.

изменения).

Если ввести оператор перестановок

$$\hat{\delta}_{1\leftrightarrow 2}\left|\Psi:\{Q_1,Q_2,...\}\right\rangle=\left|\Psi:\{Q_2,Q_1,...\}\right\rangle$$

то (9.28) есть ни что и ное, как уравнение на собствен ные значения для.

Двукратное при- менение перестановки возвращает систему к исходному состоян ию:

$$\hat{\mathcal{S}}\hat{\mathcal{S}} = 1$$

ОТКуда немедлен но следует, что спектр собствен ных значений оператора перестановок тождественных частиц

$$\lambda^2 = 1 \leftrightarrow \quad \lambda = \pm 1$$

Поскольку перестановки не изменяют н ИКаких наблюдаем ых харак тери стик систем ы ТОЖДественных частиц, оператор перестановок ком мутирует со всеми наблюдаемы ми

$$[\hat{\mathrm{S}}, \hat{H}] = [\hat{\mathrm{S}}, \hat{\boldsymbol{p}}] = [\hat{\mathrm{s}}, \hat{\boldsymbol{j}}] = ... = 0$$

Числа двух тождественных частиц совпадают.

Как мы видели, это имеет место Для ферм иОНОВ -частиц с полуцелым сп ином.

В этом случае

$$\lambda = e^{2\pi i s}$$

где s -значение сп ина каждой из тождественных частиц.

Эта форм ула, полученная для Полуцелых значений спина частиц, остается справедлива и для целых значен ий спина, Т.е.

Для бозонов, которые, таким образом, и меют сим метризованные по перестановкам волновые функции.

Именно, в природе не наблюдаются псевдо-бозоны целого спина с антисимметричным и по перестановкам волновыми функциями.

Тем не менее, поля так их частиц используются Для вспомогательных целей в квантовой теории поля для наиболее наглядной форм ули ровк и некоторых прин ципов сим метрии.

Поля псевдо-бозонов называют "гостам и" (от ан глийского ghost, Что значит "дух") или просто "духами".

При этом, ОДн ако, полагаЮт, что число духов в начальном и конечном состоянии равно нулю, т.е.

В полный набор наблюдаемых включают число ДУхов, тождественно равн ое нулю.

Подчеркнем, что рассмотренная связь спина со стати стикой возникла благодаря пространственной вращательной симметрии для спиноров, т.е.

благодаря группе $SU(2)$. ОДнако это не знач ит, что присутствие какой-либо Другой си мметри и со спинорами в группе $SU(2)$ так же неми нуемо при ведет к антисимметризации волновых функций.

Например, в стандартную модель взаимодействий элементарн ых части ц включено скалярное, а следоВательно, бозонн ое, поле со спином 0, которое является спи нором по калибровочной гр уппе $SU(2)$. Как мы показали, нали чие калибровоч ной группы сим метрии отвечает сохранени ю Заряда, который в данном случае - заряд частицы в слабом взаимодействии.

Эта калиброВОЧная группа никак не связана с пространственными вращениям и, и поэтом у она не означает введения каких-либо дополни тельн ых ограни чений на волновую функци ю, связанн ых с сим метрией по перестановкам.

Такие группы, не связанные с вращениям и пространства, называются группами внутрен ней си мм етри и.

Генераторы таких гр упп, следовательно, Коммутируют с генераторами вращений и трансляций

Элементарное объяснение принципа Паули

(потом еще раз посмотрю.)

Принцип тождественности частиц на языке волновых функций означает, что волновые функции системы частиц, получающиеся друг из друга перестановкой пар одинаковых частиц, могут отличаться только несущественным множителем e^{if}, где f -вещественное число.

Добавление этого множителя не меняет ни плотности вероятности $|\psi|^2$ обнаружения частиц, ни средних значений физических величин.

Если сделать перестановку частицы еще раз, то получится функция, отличающаяся от исходной множителем e^{2if}.

Так как при этом система возвращается в исходное состояние, то $e^{2if} = 1$ и $e^{if} = \pm 1$.

Следовательно, перестановка пары частиц местами либо оставляет волновую функцию неизменной, либо меняет ее знак.

Как догадаться про это?

4.5.5 Generalization of Spin to Spinors

Обсудим спиноры как обобщение спина. Подробно спиноры обсудим или в дополнениях или в теории поля.

4.5.6 Other About Spin

О бытовых аналогиях (?)

(укажу их потом тут.)

О моделях со спинами

О моделях со спинами

(????)

О твердотельных моделях со спинами

(тут их укажу, их полно)

пример: Дублетная структура спектральных линий натрия

итак, подумаем, если у нас атом излучает две близкие спектральные линии, как это можно объяснить?

(попробовать по бору это сделать)
и как это мы объясним????

пример: периодичность таблицы менделеева

(потом как-то с помощью спина это нужно объяснить. я ведь теоретик.
так что нужно думать над этой теорией.
как ее построить? как очевидно может быть, что это именно спин спасет ситуацию?)

О спиновой метрике (???)

(потом мб добавлю этот раздел, пока хз, нужен ли.)

4.5.7 1. Spin

1.1. Spin operators.

So far we have been tacitly assuming that the Hilbert space for a quantum particle is $\mathscr{H} = L^2(\mathbb{R}^3, d^3\boldsymbol{x})$. Based on this assumption, in Section 5.1 of Chapter 3 we have found the energy levels of the hydrogen atom. In particular, in the ground state the third component M_3 of the quantum angular momentum operator M has eigenvalue 0 . However, the famous Stern-Gerlach experiment has shown that the electron in the hydrogen atom also has a "magnetic angular momentum", whose third component in the ground state may take two values which differ by a sign. Therefore in addition to the "mechanical angular momentum" operator $\boldsymbol{M}$ with components M_1, M_2, M_3, the electron also has the "internal angular momentum" operator S with components S_1, S_2, S_3, called spin. The spin describes internal degrees of freedom of the electron and is independent of its position in the space [1]. The Hilbert space of states of the electron is $\mathscr{H}_S = \mathscr{H} \otimes \mathbb{C}^2$, i.e., it has twice as many states than a spinless particle. The Hilbert space $\mathscr{H}_S$ consists of two-component vector-valued functions on $\mathbb{R}^3$,

$$\Psi = \begin{pmatrix} \psi_1(\boldsymbol{x}) \\ \psi_2(\boldsymbol{x}) \end{pmatrix} \in \mathscr{H}_S,$$

where

$$\|\Psi\|^2 = \int_{\mathbb{R}^3} |\psi_1(\boldsymbol{x})|^2 \, d^3\boldsymbol{x} + \int_{\mathbb{R}^3} |\psi_2(\boldsymbol{x})|^2 \, d^3\boldsymbol{x} < \infty.$$

To every observable A in $\mathscr{H}$ there corresponds an observable $A \otimes I_2$ in $\mathscr{H}_S$, given by the 2×2 block-diagonal matrix $\begin{pmatrix} A & 0 \\ 0 & A \end{pmatrix}$. Observables of the form $I \otimes S$, where I is the identity operator in $\mathscr{H}$ and S is a self-adjoint operator in $\mathbb{C}^2$, describe the inner degrees of freedom and commute with all observables $A \otimes I_2$. The complete set of the observables in $\mathscr{H}_S$ consists of the operators $Q_1 \otimes I_2, Q_2 \otimes I_2, Q_3 \otimes I_2$ and $I \otimes S_1, I \otimes S_2, I \otimes S_3$, where Q_j are coordinate operators, and S_j are spin operators - traceless self-adjoint operators in $\mathbb{C}^2$, satisfying the same commutation relations as the quantum operators of the angular momentum,

$$[S_1, S_2] = i\hbar S_3, \quad [S_2, S_3] = i\hbar S_1, \quad [S_3, S_1] = i\hbar S_2$$

In terms of the standard basis $e_1 = \binom{1}{0}, e_2 = \binom{0}{1}$ of $\mathbb{C}^2, S_j = \frac{\hbar}{2}\sigma_j, j = 1, 2, 3$, where σ_j are the so-called Pauli matrices

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

which are commonly used in physics. It is also convenient to represent $\Psi \in \mathscr{H}_S$ as a function $\psi(\boldsymbol{x}, \sigma)$ of two variables, where $\boldsymbol{x} \in \mathbb{R}^3$ and σ takes two values $\frac{1}{2}$ and $-\frac{1}{2}$, by setting

[01] The spin is a pure quantum effect which is absent in classical mechanics.

$\psi\left(\boldsymbol{x}, \frac{1}{2}\right) = \psi_1(\boldsymbol{x})$ and $\psi\left(\boldsymbol{x}, -\frac{1}{2}\right) = \psi_2(\boldsymbol{x})$. Every function $\psi(\boldsymbol{x}, \sigma)$ is a finite linear combination of the functions $\psi(\boldsymbol{x})\chi(\sigma)$ the decomposable elements of the tensor product $L^2(\mathbb{R}^3) \otimes \mathbb{C}^2$. Here we are identifying $\mathbb{C}^2$ with the complex vector space of functions $\chi : \left\{-\frac{1}{2}, \frac{1}{2}\right\} \to \mathbb{C}$ by assigning to the standard basis e_1, e_2 the functions χ_1, χ_2, defined by $\chi_1\left(\frac{1}{2}\right) = 1, \chi_1\left(-\frac{1}{2}\right) = 0$ and $\chi_2\left(\frac{1}{2}\right) = 0, \chi_2\left(-\frac{1}{2}\right) = 1$. This identification is also commonly used in physics.

In this notation the operator S_3 becomes a multiplication by $\hbar\sigma$ operator,

$$S_3\psi(\boldsymbol{x}, \sigma) = \hbar\sigma\psi(\boldsymbol{x}, \sigma)$$

and

$$S_1\psi(\boldsymbol{x}, \sigma) = \hbar|\sigma|\psi(\boldsymbol{x}, -\sigma), \quad S_2\psi(\boldsymbol{x}, \sigma) = -i\hbar\sigma\psi(\boldsymbol{x}, -\sigma)$$

Here and in what follows we will always assume that spin operators act only on the variable σ, and will often write S_j instead of $I \otimes S_j$. The operator $\boldsymbol{S}^2 = S_1^2 + S_2^2 + S_3^2$ is called the square of the total spin operator, and $\boldsymbol{S}^2 = \hbar^2 s(s+1)I_2$, where $s = |\sigma| = \frac{1}{2}$ is a total spin. In physics terminology, the electron has spin $\frac{1}{2}$.

1.2. Spin and representation theory of SU(2)

Mathematical interpretation of spin is provided by the representation theory of the Lie algebra $\mathfrak{su}(2)$, discussed in Section 3.2 of Chapter 3. Namely, let

$$A_1 = \frac{i}{2}\sigma_1, \quad A_2 = -\frac{i}{2}\sigma_2, \quad A_3 = -\frac{i}{2}\sigma_3$$

be the standard basis of the Lie algebra $\mathfrak{su}(2) - 2 \times 2$ traceless skewHermitian matrices satisfying commutation relations

$$[A_1, A_2] = A_3, \quad [A_2, A_3] = A_1, \quad [A_3, A_1] = A_2$$

and let $\rho_{\frac{1}{2}}$ be the two-dimensional (fundamental) representation of $\mathfrak{su}(2)$ in $V_{\frac{1}{2}} \simeq \mathbb{C}^2$. The spin operators are given by

$$S_j = i\hbar\rho_{\frac{1}{2}}(A_j), \quad j = 1, 2, 3,$$

and $\rho_{\frac{1}{2}}$ is called the representation of spin $\frac{1}{2}$. In general, representation ρ_s in the $2s+1$-dimensional complex vector space V_s is called the representation of spin $s \in \frac{1}{2}\mathbb{Z}_{\geq 0}$. The action of operators $T_j = i\rho_s(A_j)$ in V_s is described by formulas (3.10)-(3.12) in Section 3.2 of Chapter 3 (where l is replaced by s). There is another explicit realization of the representation ρ_s in the vector space $\mathscr{P}_s$ of polynomials $f(z)$ of degree not greater than $2s$. Namely, the mapping

$$e_{sm} \mapsto \frac{z^{s+m}}{\sqrt{(s+m)!(s-m)!}}, \quad m = -s, -s+1, ..., s-1, s$$

establishes the isomorphism between the vector space V_s with the inner product determined by the orthonormal basis e_{sm}, and the vector space $\mathscr{P}_s$ with the inner product

$$(f, g) = \frac{(2s+1)!}{\pi}\int_{\mathbb{C}} \frac{f(z)\overline{g(z)}}{(1+|z|^2)^{2s+2}} d^2z, \quad f, g \in \mathscr{P}_s \tag{1.1}$$

Corresponding operators $T_j = i\rho_s(A_j)$ in $\mathscr{P}_s$ are given by

$$T_1 - iT_2 = \frac{d}{dz}, \quad T_1 + iT_2 = z^2\frac{d}{dz} - 2sz, \quad T_3 = z\frac{d}{dz} - s \tag{1.2}$$

It is easy to verify that T_1, T_2, T_3 are Hermitian operators with respect to the inner product (1.1). Representation ρ_s of the Lie algebra $\mathfrak{su}(2)$ is integrable, $\rho_s = dR_s$, where R_s is an irreducible unitary representation of the Lie group SU(2), defined by

$$R_s(g)(f)(z) = (\bar{\beta}z + \alpha)^{2s} f\left(\frac{\bar{\alpha}z - \beta}{\bar{\beta}z + \alpha}\right), \quad g = \begin{pmatrix} \alpha & \beta \\ -\bar{\beta} & \bar{\alpha} \end{pmatrix} \in \mathrm{SU}(2), \quad f \in \mathscr{P}_s.$$

Remark. The spin $\frac{1}{2}$ representation $R_{\frac{1}{2}}$ in $\mathbb{C}^2$ can also be explicitly described as

$$R_{\frac{1}{2}}(g)\boldsymbol{z} = \begin{pmatrix} \alpha & \beta \\ -\bar{\beta} & \bar{\alpha} \end{pmatrix} \begin{pmatrix} z_1 \\ z_2 \end{pmatrix}, \quad \boldsymbol{z} = \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} \in \mathbb{C}^2$$

and is called the fundamental representation.

Remark. Representation R_s of SU(2) can be lifted to a family of representations of the general unitary group U(2) acting in the same vector space $\mathscr{P}_s$. Namely, every $g \in \mathrm{U}(2)$ can be written as $g = \alpha g_0$, where $\alpha^2 = \det g$ and is determined up to a sign, and $g_0 \in \mathrm{SU}(2)$. Then for every integer l with the property that $2s + l$ is even, the formula

$$R_{l,s}(g) = \alpha^l R_s(g_0)$$

defines an irreducible unitary representation of U(2) in $\mathscr{P}_s$. The condition that $\frac{l}{2} + s$ is an integer ensures that $R_{l,s}$ does not depend on the choice of a sign in the definition of α. The representation $R_{l,s}$ is the highest weight representation of U(2) with the dominant weights $\lambda_1 = \frac{l}{2} + s \geq \lambda_2 = \frac{l}{2} - s$, $\lambda_1 + \lambda_2 = l$. We will denote the corresponding U(2)-module as $V_{\lambda,l}$, where $\lambda = (\lambda_1, \lambda_2)$ is a dominant weight with $\lambda_1 + \lambda_2 = l$. As an SU(2)-module, $V_{\lambda,l} = V_s$, where $s = \frac{1}{2}(\lambda_1 - \lambda_2)$.

Returning to the basic principles of quantum mechanics, formulated in Section 1 of Chapter 2, we now extend the first postulate A1 to the case of particles with spin.

A10 (Particles with Spin). The Hilbert space of states for a quantum particle of a spin $s \in \left\{0, \frac{1}{2}, 1, \frac{3}{2}, ...\right\}$ is

$$\mathscr{H}_S = L^2\left(\mathbb{R}^3\right) \otimes V_s$$

where V_s is a $2s + 1$-dimensional complex vector space of the irreducible representation R_s of the Lie group SU(2) of spin s. The spin operators $\boldsymbol{S} = (S_1, S_2, S_3)$ are given by

$$S_j = i\hbar\rho_s(A_j), \quad j = 1, 2, 3$$

where A_1, A_2, A_3 are standard generators of the Lie algebra $\mathfrak{su}(2)$ and $\rho_s = dR_s$ is the corresponding representation of $\mathfrak{su}(2)$ in V_s. Particles with integer spin are called bosons, and particles with half-integer spin are called fermions.

As in the case of spin $\frac{1}{2}$, it will be convenient to represent $\Psi \in \mathscr{H}_S$ as a function $\psi(\boldsymbol{x}, \sigma)$ of two variables, where $\boldsymbol{x} \in \mathbb{R}^3$ and the variable σ takes $2s+1$ values from the set $\{-s, -s+1, ..., s-1, s\}$. For a given σ, the function $\psi(\boldsymbol{x}, \sigma)$ is the k-th component, $k = s - \sigma + 1$, of the $2s + 1$-dimensional vector $\Psi(\boldsymbol{x})$. Every function $\psi(\boldsymbol{x}, \sigma)$ is a finite linear combination of the functions $\psi(\boldsymbol{x})\chi(\sigma)$ - the decomposable elements of the tensor product $L^2(\mathbb{R}^3) \otimes \mathbb{C}^{2s+1}$, where we are identifying $\mathbb{C}^{2s+1}$ with the complex vector space of functions $\chi : \{-s, -s+1, ..., s-1, s\} \to \mathbb{C}$ by assigning to the elements e_k of the standard basis $e_1, ..., e_{2s+1}$ the functions χ_k, defined by $\chi_k(s + 1 - k) = 1$ and being 0 otherwise.

The complete set of observables for a quantum particle of spin s consists of position operators $Q_1 \otimes I_{2s+1}, Q_2 \otimes I_{2s+1}, Q_3 \otimes I_{2s+1}$, where I_{2s+1} is the identity operator in V_s, and spin operators $I \otimes S_1, I \otimes S_2, I \otimes S_3$. The total angular momentum operators $\boldsymbol{J} = (J_1, J_2, J_3)$ in $\mathscr{H}_S$ are self-adjoint operators in $\mathscr{H}_S$ given by

$$\boldsymbol{J} = \boldsymbol{M} \otimes I_{2s+1} + I \otimes \boldsymbol{S}$$

They satisfy the same commutation relations as the spin operators,

$$[J_1, J_2] = i\hbar J_3, \quad [J_2, J_3] = i\hbar J_1, \quad [J_3, J_1] = i\hbar J_2$$

As angular momentum operators $\boldsymbol{M}$ (see Lemma 3.1 in Section 3.2 of Chapter 3), the total angular momentum operators $\boldsymbol{J}$ are associated with the unitary representation of the Lie group SU(2) in the Hilbert space $\mathscr{H}_S = L^2(\mathbb{R}^3, d^3\boldsymbol{x}) \otimes V_s$. Namely, let R be the unitary representation of SU(2) in $\mathscr{H} = L^2(\mathbb{R}^3, d^3x)$ corresponding to the adjoint representation of SU(2) in $\mathfrak{su}(2) \simeq \mathbb{R}^3$,

$$(R(g)\psi)(\boldsymbol{x}) = \psi\left(\operatorname{Ad} g^{-1}\boldsymbol{x}\right), \quad g \in \mathrm{SU}(2), \quad \psi \in \mathscr{H}$$

where

$$(\operatorname{Ad} g\boldsymbol{x}) \cdot \boldsymbol{\sigma} = g(\boldsymbol{x} \cdot \boldsymbol{\sigma})g^{-1}, \quad \boldsymbol{x} \cdot \boldsymbol{\sigma} = x_1\sigma_1 + x_2\sigma_2 + x_3\sigma_3$$

Lemma 1.1. We have

$$(R \otimes R_S)\left(e^{a_1A_1 + a_2A_2 + a_3A_3}\right) = e^{-\frac{i}{\hbar}(a_1J_1 + a_2J_2 + a_3J_3)}$$

where $\boldsymbol{a} = (a_1, a_2, a_3) \in \mathbb{R}^3$.

Problem 1.1. Derive formulas (1.2) and show that operators T_1, T_2, T_3 are Hermitian with respect to the inner product (1.1).

Problem 1.2. Prove Lemma 1.1.

4.5.8 3. System of Identical Particles

Consider the quantum system of N particles of spins $s_1, ..., s_N$. According to the basic principles of quantum mechanics, the Hilbert space of states of the system is given by

$$\mathscr{H}_N = \mathscr{H}_{S_1} \otimes \cdots \otimes \mathscr{H}_{S_N} = \underbrace{L^2\left(\mathbb{R}^3\right) \otimes \cdots \otimes L^2\left(\mathbb{R}^3\right)}_{N} \otimes V_{s_1} \otimes \cdots \otimes V_{s_N}$$

In terms of the variables $\boldsymbol{\xi}_i = (\boldsymbol{x}_i, \sigma_i)$, where $\boldsymbol{x}_i \in \mathbb{R}^3$ and $\sigma_i \in \{-s_i, -s_i + 1, ..., s_i - 1, s_i\}$, the total wave function of the system can be written as $\Phi(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N)$. The total wave function is a finite linear combination of the product functions

$$\Phi(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N) = \Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)\,\chi(\sigma_1, ..., \sigma_N)$$

where $\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N) \in L^2\left(\mathbb{R}^{3N}\right)$ is a coordinate part, and $\chi(\sigma_1, ..., \sigma_N)$ is a spin part of the total wave function. The spin part, in accordance with the tensor product structure $V_{s_1} \otimes \cdots \otimes V_{s_N}$, is a finite linear combination of the products $\chi_{k_1}(\sigma_1) ... \chi_{k_N}(\sigma_N)$ of functions χ_k, defined in Section 1.

The Hamiltonian of the system of N-particles (without the spin interaction) in the coordinate representation has the form

$$H_N = -\sum_{i=1}^{N} \frac{\hbar^2}{2m_i}\Delta_i + \sum_{i=1}^{N} V_i(\boldsymbol{x}_i) + \sum_{1 \le i < k \le N} V_{ik}(\boldsymbol{x}_i - \boldsymbol{x}_k),$$

where the first term is the operator of kinetic energy of the system of N particles, the second term describes the interaction of the particles with the external field, and the last term

describes their pair-wise interaction. Note that though the Hamiltonian H_N acts only on the coordinate part $\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$ of the total wave function, the physical properties of the system do depend on the spins of the particles.

3.1. The symmetrization postulate. For the system of N identical particles of mass m and spin s the corresponding Hilbert space is

$$\mathscr{H}_N = L^2\left(\mathbb{R}^{3N}\right) \otimes V_s^{\otimes N} \tag{3.1}$$

The irreducible representation R_s of the Lie group $\mathrm{SU}(2)$ in the vector space V_s naturally defines a representation $R_s^{\otimes N}$ in $V_s^{\otimes N}$,

$$R_s^{\otimes N}(g)\,(v_1 \otimes \cdots \otimes v_N) = R_s(g)v_1 \otimes \cdots \otimes R_s(g)v_N, \quad g \in \mathrm{SU}(2)$$

The corresponding representation $\rho_s^{\otimes N}$ of the Lie algebra $\mathfrak{su}(2)$ is given by

$$\rho_s^{\otimes N}(x)\,(v_1 \otimes \cdots \otimes v_N) = \sum_{k=1}^{N} v_1 \otimes \cdots \otimes \rho_s(x)v_k \otimes \cdots \otimes v_N, \quad x \in \mathfrak{su}(2).$$

The total spin operators $\boldsymbol{S} = (S_1, S_2, S_3)$ of the system of N identical particles are given by

$$S_j = i\hbar\rho_s^{\otimes N}(A_j) = \sum_{k=1}^{N} S_j^{(k)}, \quad j = 1, 2, 3 \tag{3.2}$$

Here $S_j^{(k)} = I_{2s+1} \otimes \cdots \otimes i\hbar\rho_s(A_j) \otimes \cdots \otimes I_{2s+1}$ are the spin operators of the k-th particle; they act non-trivially only in the k-th factor of the tensor product $V_s^{\otimes N}$.

Representations $R_s^{\otimes N}$ and $\rho_s^{\otimes N}$ are reducible and contain all representations V_l with spins $l \in \frac{1}{2}\mathbb{Z}_{\geq 0}$ such that $sN - l$ are non-negative integers. Indeed, the square S^2 of the total spin operator has the form

$$S^2 = S_1^2 + S_2^2 + S_3^2 = S_-S_+ + S_3(S_3 + I)$$

where $S_\pm = S_1 \pm iS_2$ and I here is the identity operator in $V_s^{\otimes N}$. It is easy to see from (3.2) that the eigenvalues of the operator S_3 are $-\hbar sN$, $\hbar(-sN+1), ..., \hbar(sN-1), \hbar sN$. Now by Schur's lemma, restriction of S^2 to the irreducible representation V_l is $\hbar^2 l(l+1)$ times the identity operator in V_l. Since V_l contains a highest weight vector which is annihilated by the operator $S_+$and is an eigenvector of the operator S_3 with eigenvalue $\hbar l$, we conclude that $V_s^{\otimes N}$ contains all irreducible representations with spins $l \in \frac{1}{2}\mathbb{Z}_{\geq 0}$ such that $sN - l$ are non-negative integers. The problem of determining the multiplicities with which representations V_l appear in the decomposition $V_s^{\otimes N}$ into the direct sum of irreducible representations will be discussed below. It plays a fundamental role in classifying the energy levels of the system of N identical particles of spin s.

There is also a natural action of the symmetric group Sym_N on N elements on $\mathscr{H}_N$, given by

$$P_\pi\Phi(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N) = \Phi\left(\boldsymbol{\xi}_{\pi^{-1}(1)}, ..., \boldsymbol{\xi}_{\pi^{-1}(N)}\right), \quad \pi \in \mathrm{Sym}_N.$$

The corresponding Hamiltonian in this case has the form

$$H_N = -\frac{\hbar^2}{2m}\sum_{i=1}^{N}\Delta_i + \sum_{i=1}^{N} V_{\mathrm{ext}}(\boldsymbol{x}_i) + \sum_{1 \leq i < k \leq N} V_{\mathrm{int}}(\boldsymbol{x}_i - \boldsymbol{x}_k), \tag{3.3}$$

and commutes with the Sym_N-action:

$$[H_N, P_\pi] = 0 \quad \text{for all} \quad \pi \in \mathrm{Sym}_N$$

Thus the operator H_N can be restricted to the Sym_N-invariant subspaces of $\mathscr{H}$, in particular to the subspace $\mathscr{H}_N^{(\mathrm{S})}$ of totally symmetric functions $\Phi(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N)$,

$$P_\pi \Phi = \Phi \quad \text{for all} \quad \pi \in \mathrm{Sym}_N$$

and to the subspace $\mathscr{H}_N^{(\mathrm{A})}$ of totally anti-symmetric functions $\Phi(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N)$,

$$P_\pi \Phi = (-1)^{\varepsilon(\pi)} \Phi \quad \text{for all} \quad \pi \in \mathrm{Sym}_N$$

where $\varepsilon(\pi)$ is the parity of a permutation π.

In classical mechanics, it is possible to label the identical particles (say by the integers $1, 2, ..., N$), and to trace the trajectory of each labeled particle separately. It follows from the Heisenberg uncertainty relations that in quantum mechanics it is impossible to trace the time evolution of labeled particles separately. In other words, in quantum mechanics identical particles are truly "indistinguishable", so that the Hilbert space (3.1) contains "too many states". It is another postulate of quantum mechanics which specifies "correct" Hilbert space of states for the system of identical particles.

A11 (The Symmetrization Postulate). The Hilbert space of states for the system of N identical particles of spin s is the totally symmetric subspace $\mathscr{H}_N^{(\mathrm{S})}$ of the N-fold tensor product $\left(L^2(\mathbb{R}^3) \otimes V_s\right)^{\otimes N}$ for the case of bosons (particles with integer spin), and is the totally anti-symmetric subspace $\mathscr{H}_N^{(\mathrm{A})}$ for the case of fermions (particles with half-integer spin).

Remark. The symmetrization postulate implies the Pauli exclusion principle, which states that no two fermions can occupy the same state. The Pauli exclusion principle is fundamental for atomic and molecular physics, and for the whole body of chemistry.

For the case of identical particles of spin 0 it follows from the symmetrization postulate that the corresponding Hilbert space $\mathscr{H}_N^{(\mathrm{S})}$ is the subspace of all totally symmetric functions $\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$ in $L^2\left(\mathbb{R}^{3N}\right)$, and in order to find the energy levels of the system, one needs to solve the Schrdinger equation

$$H_N \Psi = E_N \Psi \tag{3.4}$$

only in the totally symmetric subspace $\mathscr{H}_N^{(\mathrm{S})}$ of $\mathscr{H}_N$. Solutions of the eigenvalue problem (3.4) that do not belong to this subspace have no physical interpretation.

For the spin $\frac{1}{2}$ particles the situation is different: the symmetry properties of the coordinate part of the total wave function depend on the symmetry properties of the corresponding spin part. Consider first the simple example of a system of two electrons. In this case we have the direct sum decomposition of Hilbert spaces,

$$\mathscr{H}_2 = \mathscr{H}_2^{(\mathrm{S})} \oplus \mathscr{H}_2^{(\mathrm{A})},$$

which immediately follows from the representation

$$\Phi(\boldsymbol{\xi}_1, \boldsymbol{\xi}_2) = \frac{1}{2}\left(\Phi(\boldsymbol{\xi}_1, \boldsymbol{\xi}_2) + \Phi(\boldsymbol{\xi}_2, \boldsymbol{\xi}_1)\right) + \frac{1}{2}\left(\Phi(\boldsymbol{\xi}_1, \boldsymbol{\xi}_2) - \Phi(\boldsymbol{\xi}_2, \boldsymbol{\xi}_1)\right).$$

Using the identity

$$\begin{aligned}
&\Psi(\boldsymbol{x}_1, \boldsymbol{x}_2)\chi(\sigma_1, \sigma_2) - \Psi(\boldsymbol{x}_2, \boldsymbol{x}_1)\chi(\sigma_2, \sigma_1) \\
&= \frac{1}{2}\left(\Psi(\boldsymbol{x}_1, \boldsymbol{x}_2) + \Psi(\boldsymbol{x}_2, \boldsymbol{x}_1)\right)\left(\chi(\sigma_1, \sigma_2) - \chi(\sigma_2, \sigma_1)\right) \\
&+ \frac{1}{2}\left(\Psi(\boldsymbol{x}_1, \boldsymbol{x}_2) - \Psi(\boldsymbol{x}_2, \boldsymbol{x}_1)\right)\left(\chi(\sigma_1, \sigma_2) + \chi(\sigma_2, \sigma_1)\right),
\end{aligned}$$

we can represent $\mathscr{H}_2^{(\mathrm{A})}$ as a direct sum of Hilbert spaces

$$\mathscr{H}_2^{(\mathrm{A})} = \mathfrak{S}_0 \oplus \mathfrak{S}_1,$$

where

$$\mathfrak{S}_0 = \left(L^2\left(\mathbb{R}^3\right) \otimes L^2\left(\mathbb{R}^3\right)\right)^{(\mathrm{S})} \otimes \wedge^2\mathbb{C}^2$$

consists of finite linear combinations of the product functions $\Phi\left(\boldsymbol{\xi}_1, \boldsymbol{\xi}_2\right) = \Psi\left(\boldsymbol{x}_1, \boldsymbol{x}_2\right)\chi\left(\sigma_1, \sigma_2\right)$, where $\Psi\left(\boldsymbol{x}_1, \boldsymbol{x}_2\right) \in L^2\left(\mathbb{R}^3\right) \otimes L^2\left(\mathbb{R}^3\right)$ is symmetric and $\chi\left(\sigma_1, \sigma_2\right) \in \wedge^2\mathbb{C}^2$ is anti-symmetric, and

$$\mathfrak{S}_1 = \left(L^2\left(\mathbb{R}^3\right) \otimes L^2\left(\mathbb{R}^3\right)\right)^{(\mathrm{A})} \otimes \mathrm{Sym}^2\,\mathbb{C}^2$$

consists of finite linear combinations of the product functions where $\Psi\left(\boldsymbol{x}_1, \boldsymbol{x}_2\right)$ is anti-symmetric and $\chi\left(\sigma_1, \sigma_2\right)$ is symmetric. The vector space $\wedge^2\mathbb{C}^2$ is onedimensional and is spanned by the function χ_{00}, which corresponds to the vector

$$\frac{1}{\sqrt{2}}\left(e_1 \otimes e_2 - e_2 \otimes e_1\right) \in \mathbb{C}^2 \otimes \mathbb{C}^2$$

and the vector space $\mathrm{Sym}^2\,\mathbb{C}^2$ is three-dimensional and is spanned by the functions $\chi_{11}, \chi_{10}, \chi_{1-1}$, which correspond to the vectors

$$e_1 \otimes e_1, \quad \frac{1}{\sqrt{2}}\left(e_1 \otimes e_2 + e_2 \otimes e_1\right), \quad e_2 \otimes e_2 \in \mathbb{C}^2 \otimes \mathbb{C}^2$$

Comparing the decomposition

$$\mathbb{C}^2 \otimes \mathbb{C}^2 = \wedge^2\mathbb{C}^2 \oplus \mathrm{Sym}^2\,\mathbb{C}^2$$

with the Clebsch-Gordan decomposition

$$V_{\frac{1}{2}} \otimes V_{\frac{1}{2}} = V_0 \oplus V_1,$$

discussed in Section 3.2 of Chapter 3, we see that ${}^2\wedge^2\mathbb{C}^2 = V_0$ and $\mathrm{Sym}^2\,\mathbb{C}^2 = V_1$. In physics terminology, V_0 is the spin singlet space, and V_1 is the spin triplet space. We summarize the obtained results in the following statement.

Proposition 3.1. For a system of two identical particles of spin $\frac{1}{2}$ the total wave function of spin 0 has the form $\Psi\left(\boldsymbol{x}_1, \boldsymbol{x}_2\right)\chi_{00}\left(\sigma_1, \sigma_2\right)$, where $\Psi\left(\boldsymbol{x}_1, \boldsymbol{x}_2\right)$ is symmetric and satisfies the Schrdinger equation (3.4). The total wave function of spin 1 has the form $\Psi\left(\boldsymbol{x}_1, \boldsymbol{x}_2\right)\chi_{1m}\left(\sigma_1, \sigma_2\right)$, where $m = -1, 0, 1$, and $\Psi\left(\boldsymbol{x}_1, \boldsymbol{x}_2\right)$ is anti-symmetric and satisfies the Schrdinger equation (3.4).

Remark. The coordinate part $\Psi\left(\boldsymbol{x}_1, \boldsymbol{x}_2\right)$ of the total wave function has the usual probabilistic interpretation. Thus for a simple example of a system of two electrons with $V_{\mathrm{int}}(\boldsymbol{x}) = 0$, the coordinate part of the total wave function has the form

$$\Psi\left(\boldsymbol{x}_1, \boldsymbol{x}_2\right) = \frac{1}{\sqrt{2}}\left(\psi_1\left(\boldsymbol{x}_1\right)\psi_2\left(\boldsymbol{x}_2\right) \pm \psi_1\left(\boldsymbol{x}_2\right)\psi_2\left(\boldsymbol{x}_1\right)\right)$$

where $\psi_1(\boldsymbol{x})$ and $\psi_2(\boldsymbol{x})$ are two one-electron coordinate wave functions, the plus sign refers to the spin singlet state, and the minus sign refers to the spin triplet state. The corresponding probability density is

$$\begin{aligned}\left|\Psi\left(\boldsymbol{x}_1, \boldsymbol{x}_2\right)\right|^2 d^3\boldsymbol{x}_1 d^3\boldsymbol{x}_2 = \tfrac{1}{2}\Big(&\left|\psi_1\left(\boldsymbol{x}_1\right)\right|^2\left|\psi_2\left(\boldsymbol{x}_2\right)\right|^2 + \left|\psi_1\left(\boldsymbol{x}_2\right)\right|^2\left|\psi_2\left(\boldsymbol{x}_1\right)\right|^2 \\ &\pm 2\,\mathrm{Re}\left(\psi_1\left(\boldsymbol{x}_1\right)\psi_2\left(\boldsymbol{x}_2\right)\overline{\psi_1\left(\boldsymbol{x}_2\right)\psi_2\left(\boldsymbol{x}_1\right)}\right)\Big) d^3\boldsymbol{x}_1 d^3\boldsymbol{x}_2\end{aligned}$$

where the last term is called the exchange energy. It follows from this formula that when two electrons are in a spin triplet state, there is a zero probability of finding them at the same point $\boldsymbol{x} \in \mathbb{R}^3$. However, when electrons are in a spin singlet state, there is a non-zero probability of finding them at the same point in space, which is due to the exchange energy.

Consider now the system of N particles of spin $\frac{1}{2}$. In this case the total wave function $\Phi(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N) \in \mathscr{H}_N^{(\mathrm{A})}$ satisfies

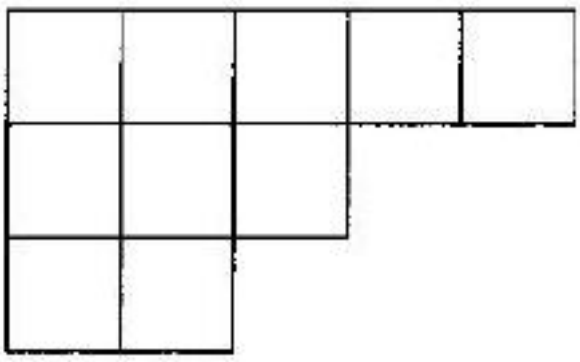
$$H_N \Phi = E_N \Phi \quad \text{and} \quad S^2 \Phi = s(s+1)\Phi \tag{3.5}$$

and describes the bound state with total spin s, where $\frac{1}{2}N - s$ is a nonnegative integer. It seems natural to assume that if one finds a coordinate wave function $\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$ satisfying (3.4), and a spin wave function $\chi(\sigma_1, ..., \sigma_N)$ which is the eigenfunction of S^2, then the total wave function $\Phi(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N)$ can be obtained by the anti-symmetrization:

$$\Phi(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N) = \sum_{\pi \in \mathrm{Sym}_N} (-1)^{\varepsilon(\pi)} \Psi\left(\boldsymbol{x}_{\pi(1)}, ..., \boldsymbol{x}_{\pi(N)}\right) \chi\left(\sigma_{\pi(1)}, ..., \sigma_{\pi(N)}\right)$$

However, it may happen that for a coordinate wave function $\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$ satisfying (3.4), the corresponding total wave function $\Phi(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N)$ is identically zero! The requirement that the total wave function $\boldsymbol{\Phi}(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N)$ is not identically zero determines admissible symmetry properties of the coordinate wave function $\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$, which are described by the irreducible representations of the symmetric group Sym_N.

3.2. Young diagrams and representation theory of Sym_N. The number of irreducible representations of the symmetric group Sym_N is the number of its conjugacy classes, which in turn is the number of partitions $\lambda = (\lambda_1, ..., \lambda_n)$ of $N : N = \lambda_1 + \cdots + \lambda_n$, where $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n \geq 1$. Denote by $\mathrm{Par}(N)$ the set of all partitions of N. To each partition $\lambda \in \mathrm{Par}(N)$ there is an irreducible representation G_λ of Sym_N, constructed as follows. Let Y_λ be the Young diagram associated with $\lambda \in \mathrm{Par}(N)$ - a collection of N boxes arranged into n left-justified rows, with the first row containing λ_1 boxes, the second row containing λ_2 boxes, etc. Thus the diagram



corresponds to the partition $10 = 5 + 3 + 2$. A Young tableau A associated with the Young diagram Y_λ is an assignment of N integers $1, 2, ..., N$ to the N boxes such that each box gets a different integer; denote by $\mathfrak{T}_\lambda$ the set of all Young tableaux associated with the partition $\lambda \in \mathrm{Par}(N)$. A canonical Young tableau $A_\lambda \in \mathfrak{T}_\lambda$ is obtained by numbering the boxes consecutively along the rows from left to right. For a Young tableau $A \in \mathfrak{T}_\lambda$, say the canonical one, define two subgroups of Sym_N:

$$\mathrm{Row}(A) = \{\pi \in \mathrm{Sym}_N : \pi \text{ preserves the rows of } A\}$$
$$\mathrm{Col}(A) = \{\pi \in \mathrm{Sym}_N : \pi \text{ preserves the columns of } A\}$$

[02] This can also be verified directly by checking the action of total spin operators.

Now let $\mathfrak{A} = \mathbb{C}\mathbb{S}\curvearrowright\!\!\succ_N$ be the group algebra of Sym_N - a complex vector space with the basis $\{e_\pi\}_{\pi\in\mathrm{Sym}_N}$ and the multiplication map defined by $e_{\pi_1}\cdot e_{\pi_2} = e_{\pi_1\pi_2}$. Denote by R the regular representation of Sym_N in $\mathfrak{A}$, defined by

$$R(\pi)x = e_\pi \cdot x, \quad x \in \mathfrak{A}.$$

With a given Young tableau A one can associate two elements in the group algebra $\mathfrak{A}$: the row symmetrizer

$$\mathrm{R}_A = \sum_{\pi\in\mathrm{Row}(A)} \pi,$$

and the column anti-symmetrizer

$$\mathrm{C}_A = \sum_{\pi\in\mathrm{Col}(A)} (-1)^{\varepsilon(\pi)}\pi.$$

Define the Young symmetrizer by

$$\Pi_A = \mathrm{C}_A\mathrm{R}_A \in \mathfrak{A},$$

and consider the left Sym_N-module ${}^3G_\lambda = \mathfrak{A}\cdot\Pi_A$, and the representation $T_\lambda : \mathrm{Sym}_N \to \mathrm{End}\, G_\lambda$, where Sym_N acts by left multiplication. The following result is fundamental.

Theorem 3.1. Each T_λ is an irreducible representation of Sym_N, and representations T_λ and T_μ are not isomorphic if $\lambda \neq \mu$. The dimension of the representation T_λ is given by the Frobenius formula

$$d_\lambda = \frac{N!}{l_1!...l_n!}\prod_{i<j}(l_i - l_j), \quad l_i = \lambda_i + n - i, \quad i = 1, ..., n,$$

and $\Pi_A^2 = d_\lambda\Pi_A$. Every irreducible representation of Sym_N is isomorphic to the representation T_λ for some partition $\lambda \in \mathrm{Par}(N)$.

Remark. It follows from the representation theory of finite groups that

$$R = \bigoplus_{\lambda\in\mathrm{Par}(N)} d_\lambda G_\lambda \quad \left(\mathfrak{A} = \bigoplus_{\lambda\in\mathrm{Par}(N)} \mathrm{End}\ G_\lambda \text{ as algebras}\right),$$

so that

$$N! = \sum_{\lambda\in\mathrm{Par}(N)} d_\lambda^2.$$

There is another expression for dimensions d_λ as a product over the boxes of the Young diagram Y_λ, given by the so-called hook-length formula.

Remark. One can explicitly construct the bases in the subspaces G_λ by the following procedure. Let A be the standard Young tableau for a partition $\lambda \in \mathrm{Par}(N)$: a Young tableau with the condition that in each row of Y_λ, the numbers in the boxes are strictly increasing from left to right, and in each column – strictly increasing from top to bottom. Let $\pi \in \mathrm{Sym}_N$ be the unique permutation such that $A = \pi(A_\lambda)$ and put $e_A = \Pi_A e_\pi$. Then the vectors e_A, where A runs through all standard Young tableaux for the partition λ, form a basis of G_λ. In other words, the basis elements are obtained by successive symmetrization on the rows of Y_λ with a subsequent anti-symmetrization on the columns.

[03] Another choice of a Young tableau $A \in \mathfrak{T}_\lambda$ gives a Sym_N-module equivalent to G_λ.

The partition $\lambda = (N)$ corresponds to the Young diagram with only one row and produces the trivial representation of Sym_N. The partition $\lambda = (1, ..., 1)$ corresponds to the transposed Young diagram - a diagram with only one column - and produces another one-dimensional representation, the alternating representation $\pi \mapsto (-1)^{\varepsilon(\pi)}$. In general, let $\lambda' = (\lambda'_1, ..., \lambda'_m)$ be the partition conjugated to the partition λ, which is defined by transposing the Young diagram Y_λ by interchanging the rows and columns (λ'_i is the number of terms in the partition λ which are greater than or equal to i). Then

$$T_{\lambda'} = T_\lambda \otimes T_{(1,...,1)} \tag{3.6}$$

Other partitions correspond to the symmetries of mixed type.
The next result will play a crucial role in determining the symmetry properties of coordinate wave functions.

Proposition 3.2. The tensor product $T_\lambda \otimes T_\mu$ contains the trivial representation of Sym_N if and only if $\mu = \lambda$, in which case it has multiplicity one. In terms of a basis $\{e_i\}_{i=1}^{d_\lambda}$ in G_λ such that the representation T_λ is given by orthogonal $d_\lambda \times d_\lambda$ matrices $t_\lambda(\pi)_{ij}$,

$$T_\lambda(\pi)e_i = \sum_{j=1}^{d_\lambda} t_\lambda(\pi)_{ji} e_j, \quad i = 1, ..., d_\lambda$$

the one-dimensional subspace of the trivial representation is spanned by the vector $\sum_{i=1}^{d_\lambda} e_i \otimes e_i \in G_\lambda \otimes G_\lambda$. Correspondingly, the tensor product $T_\lambda \otimes T_\mu$ contains the alternating representation of Sym_N if and only if $\mu = \lambda'$, in which case it has multiplicity one. In terms of a basis $\{e'_i\}_{i=1}^{d_\lambda}$ in $G_{\lambda'}$ such that the representation $T_{\lambda'}$ is given by the matrices $t_{\lambda'}(\pi)_{ij} = (-1)^{\varepsilon(\pi)} t_\lambda(\pi)_{ij}$, the one-dimensional subspace of the alternating representation is spanned by the vector $\sum_{i=1}^{d_\lambda} e_i \otimes e'_i \in G_\lambda \otimes G_{\lambda'}$.
Problem 3.1. Prove all the statements in this section. (Hint: See the list of references to this chapter).
3.3. Schur-Weyl duality and symmetry of the wave functions. In addition to the diagonal action of the Lie group SU(2) in the tensor product $(\mathbb{C}^2)^{\otimes N}$, discussed in Section 3.1, there is also a left action of a symmetric group Sym_N by permuting factors [4]:

$$T(\pi)\,(v_1 \otimes \cdots \otimes v_N) = v_{\pi^{-1}(\mathbf{1})} \otimes \cdots \otimes v_{\pi^{-1}(N)}, \quad \pi \in \mathrm{Sym}_N$$

For every partition $\lambda \in \mathrm{Par}(N)$ denote by Π_λ the Young symmetrizer corresponding to the canonical Young tableau A_λ, and by $S_\lambda \mathbb{C}^2$ the image of the operator $T(\Pi_\lambda)$ in $(\mathbb{C}^2)^{\otimes N}$. The subspace $S_\lambda \mathbb{C}^2$ is zero-dimensional when the Young diagram Y_λ has more than two rows, and is an irreducible U(2)-module, called the Weyl module, when the Young diagram Y_λ has one or two rows. For the partition $\lambda = (N)$ the Weyl module $S_\lambda \mathbb{C}^2 = \mathrm{Sym}^N \mathbb{C}^2$ and is isomorphic to the highest weight module $V_{\lambda,N}$ with the dominant weight $(N, 0)$, defined in Section 1.2. For the partition $\lambda = (\lambda_1, \lambda_2)$ the Weyl module $S_\lambda \mathbb{C}^2$ is isomorphic to the highest weight module $V_{\lambda,N}$ with the dominant weight λ.

Remark. This construction is a special case of the general construction given by H . Weyl, which applies to the symmetric group action in the tensor product $V^{\otimes N}$, where V is a finite-dimensional vector space. The Weyl modules $S_\lambda V$ associated with the Young diagram Y_λ are zero-dimensional when the number of rows is greater than $n = \dim V$, and are isomorphic to the highest weight modules of $\mathrm{GL}(V)$ with the dominant weight λ when the number of rows is less than or equal to n. The association $V \mapsto S_\lambda V$ is called the Schur functor.

The following result, the Schur-Weyl duality, establishes explicit pairing between irreducible representations of U(2) and Sym_N that appear in the decomposition of the representation of $\mathrm{SU}(2) \times \mathrm{Sym}_N$ in $(\mathbb{C}^2)^{\otimes N}$ into the irreducible components.

Theorem 3.2 (Schur-Weyl duality). There is a direct sum decomposition into irreducible components of the representation $R_{\frac{1}{2}}^{\otimes N} \times T$:

$$\left(\mathbb{C}^2\right)^{\otimes N} = \bigoplus_{\lambda \in \mathrm{Par}(N,2)} S_\lambda \mathbb{C}^2 \otimes G_\lambda$$

where $\mathrm{Par}(N,2)$ is the set of partitions of N with number of terms less than or equal to 2 . Setting $\lambda_1 = \frac{N}{2} + s, \lambda_2 = \frac{N}{2} - s$ (cf. Section 1.2), from the Frobenius formula we obtain

$$d_\lambda = \dim G_\lambda = \binom{N}{\frac{N}{2} - s} - \binom{N}{\frac{N}{2} - s - 1}. \tag{3.7}$$

Now return to the main problem of finding total wave functions satisfying (3.5). It follows from the Schur-Weyl duality that there are $(2s+1)d_\lambda$ linear independent spin wave functions $\chi_{mj}(\sigma_1, ..., \sigma_N)$ of spin s satisfying

$$S^2 \chi_{mj} = s(s+1)\chi_{mj} \quad \text{and} \quad S_3 \chi_{mj} = m\chi_{mj} \tag{3.8}$$

where $m = -s, -s+1, ..., s-1, s$ and $j = 1, ..., d_\lambda$. Here d_λ corresponds to the partition $\lambda = \left(\frac{N}{2} + s, \frac{N}{2} - s\right)$ (or $\lambda = (N)$ for $s = \frac{N}{2}$) and is given by (3.7). The spin s representation ρ_s of $\mathrm{SU}(2)$ acts on the index m of the spin wave function $\chi_{mj}(\sigma_1, ..., \sigma_N)$, and the representation T_λ of Sym_N acts on the index j. The total wave function has the form

$$\Phi_m(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N) = \sum_{j=1}^{d_\lambda} \Psi_j(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)\, \chi_{mj}(\sigma_1, ..., \sigma_N) \tag{3.9}$$

where $m = -s, ..., s$. It follows from Proposition 3.2 that the total wave function $\Phi_m(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N)$ is totally anti-symmetric if and only if the coordinate wave functions $\Psi_j(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$ transform according to the conjugated representation $T_{\lambda'}$ of Sym_N,

$$(P_\pi \Psi_i)(\boldsymbol{x}_1, ..., \boldsymbol{x}_N) = \sum_{j=1}^{d_\lambda} t_{\lambda'}(\pi)_{ji} \Psi_j(\boldsymbol{x}_1, ..., \boldsymbol{x}_N), \quad i = 1, ..., d_\lambda \tag{3.10}$$

We summarize these results as follows.

Theorem 3.3. Coordinate wave functions $\Psi_j(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$ associated with the total wave function of spin s of a system of N identical particles of spin $\frac{1}{2}$ are those solutions of the N-particle Schrdinger equation (3.4) that transform according to the representation $T_{\lambda'}$ of the symmetric group Sym_N, where λ' is a conjugated partition to $\lambda = \left(\frac{N}{2} + s, \frac{N}{2} - s\right)$. The spin wave functions $\chi_{mj}(\sigma_1, ..., \sigma_N)$ satisfy (3.8), and corresponding total wave functions $\Phi_m(\boldsymbol{\xi}_1, ..., \boldsymbol{\xi}_N)$ are given by (3.9). In general, for a given energy level E there are $2s+1$ linearly independent total wave functions of spin s, $0 \le s \le \frac{N}{2}$, and $\frac{N}{2} - s$ is an integer.

Remark. For the highest value of total spin $s = \frac{N}{2}$ the coordinate wave function $\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$ is totally anti-symmetric. Since $(N)' = (1, ..., 1) \notin \mathrm{Par}(N,2)$ when $N > 2$, coordinate wave function for the case $N > 2$ is never totally symmetric.

Using explicit description of the Young symmetrizer in the previous section, we obtain the following result.

Corollary 3.4 (V.A. Fock). The coordinate wave function $\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$ associated with the total wave function of spin s is characterized by the following symmetry properties.

(i) $\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$ is anti-symmetric with respect to the group of arguments $\boldsymbol{x}_1, ..., \boldsymbol{x}_k, k = \frac{N}{2} + s$.

(ii) $\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$ is anti-symmetric with respect to the group of arguments $\boldsymbol{x}_{k+1}, ..., \boldsymbol{x}_N$.

(iii) $\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N)$ satisfies

[04] It moves the vector in the i-th place of the tensor product to the $\pi(i)$-th place.

$\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N) = \sum_{i=1}^{k} \Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_{i-1}, \boldsymbol{x}_{k+1}, \boldsymbol{x}_{i+1}, ..., \boldsymbol{x}_k, \boldsymbol{x}_i, \boldsymbol{x}_{k+2}, ..., \boldsymbol{x}_N)$.
The case of N identical particles of arbitrary spin s is treated similarly. The symmetry properties of coordinate wave functions can be obtained by using Schur-Weyl duality for the action of $\mathrm{U}(l) \times \mathrm{Sym}_N$ in $\mathbb{C}^l$, where $l = 2s + 1$. It has the form

$$\left(\mathbb{C}^l\right)^{\otimes N} = \bigoplus_{\lambda \in \mathrm{Par}(N,l)} S_\lambda \mathbb{C}^l \otimes G_\lambda,$$

where $\mathrm{Par}(N, l)$ is the set of partitions of N with number of terms less than or equal to l, and $S_\lambda \mathbb{C}^l$ is the Weyl module corresponding to the highest weight representation of $\mathrm{U}(l)$ with the dominant weight λ.

Problem 3.2. Prove Corollary 3.4.

Problem 3.3 (One-electron approximation). Suppose that $V_{\text{int}}(\boldsymbol{x}) = 0$, and let $\psi_1(\boldsymbol{x}), ..., \psi_k(\boldsymbol{x}), k \geq \frac{N}{2}$, be the one-electron wave functions: eigenfunctions of the one-electron Schrdinger operator H_1 (see (3.4)). Show that the coordinate wave function

$$\Psi(\boldsymbol{x}_1, ..., \boldsymbol{x}_N) = \begin{vmatrix} \psi_1(\boldsymbol{x}_1) & ... & \psi_1(\boldsymbol{x}_k) \\ ... & ... & ... \\ \psi_k(\boldsymbol{x}_1) & ... & \psi_k(\boldsymbol{x}_k) \end{vmatrix} \begin{vmatrix} \psi_1(\boldsymbol{x}_{k+1}) & ... & \psi_1(\boldsymbol{x}_N) \\ ... & ... & ... \\ \psi_{N-k}(\boldsymbol{x}_{k+1}) & ... & \psi_{N-k}(\boldsymbol{x}_N) \end{vmatrix},$$

where $|\cdots|$ stands for the matrix determinant, satisfy the symmetry properties in Corollary 3.4.

5 Other Fundamental Questions of Quantum Mechanics

5.1 Established Ideas of Generalizations of Quantum Mechanics

5.1.1 Idea of Relativistic QM

(intro to rel QM, not focused on models, since they are in the next part)

5.1.2 Idea of QFT

(intro to this generalization of QM, see special note about it)

5.2 Other About the Fundamentals of Quantum Mechanics

5.2.1 General Philosophical Features of QM

Почему у частиц одни параметры квантуются (принимают разные значения с разной вероятностью), а другие нет?

Например, закон взаимодействия - один и тот же, потенциалы - для моделей - одни и те же, а координата и импульсы - да самые разные с плотностью вероятности, которая подчиняется уравнению Шредингера.

почему именно так?

почему другие параметры тоже не принимали бы разные значения с разной вероятностью?

что если заряд бы тоже был разный?

или потенциал разный? (причем не от беспорядка, а от просто какой-то квантовости природы потенциала)

5.2.2 Coulomb Interaction in scope of QM in Details

(discuss how exactly a particle is throwing a virtual photon to another one. this is written in QFT now. See Zi's book about it. a big big question!!!)

5.2.3 Examples of the Inconsistency of Quantum Mechanics

(Севрин там пару привел, тут потом напишу их)

Ненулевая вероятность частицы появиться вне светового конуса

(пропишу этот вывод)

Отрицательная норма действия оператора рождения (???)

(пропишу этот вывод, Севрин на лекции сказал, не так это и важно, но интересно.)

5.2.4 Bell Inequality (!!?)

Обсудим подробно неравенство Белла
(популярно про него из первой части, ибо часто про это поговорить хочется. тут многое можно сказать)

Вывод

Пример применения

О популярных интерпретациях

Как догадаться про это?

5.2.5 Experimental Verification of the Bell Inequality (!!?)

(!! тут Нобелевская премия за это!!)
(см. Experimental Realization of Einstein-Podolsky-Rosen-Bohm Gedankenexperiment: A New Violation of Bell's Inequalities Alain Aspect, Philippe Grangier, and Gdrard Roger. пока все равно не разбираюсь в этом, пока хз.)

5.2.6 On the Directions of Possible Generalizations of Quantum Mechanics

(это раздел про основы, так что тоже укажем, что вообще как можно было бы модифицировать. конкретно модификации - или в конце записи или в отдельной папке с теорфизическими теориями)

5.2.7 On Misunderstandings of Quantum Mechanics by Physicists in General

Часто можно встретить людей, не понимающих, что такое квантовая механика. Таким людям правильнее уволится и вообще не заниматься физикой. А я помню заблуждения в типичных шаблонах их рассказов.
(напишу потом их, потом мб сделаю большой список, но рыться в этом вообще не актуально, лучше другими делами 100 другими делами заниматься, чем думать про неверные понимания)

Об заблуждении про электронное облако

Об заблуждении про существование размеров элементарной частицы

5.3 Other Fundamental Properties of Quantum Systems

5.3.1 Entropy of a Quantum System

5.3.2 Connection of Entropy and Geometry

(?? I'll lean it someday later, maybe)

5.3.3 Kramers Theorem on Time Reversal(???)

Суть

In quantum mechanics, the Kramers' degeneracy theorem states that for every energy eigenstate of a time-reversal symmetric system with halfinteger total spin, there is another eigenstate with the same energy related by time-reversal. In other words, the degeneracy of every energy level is an even number if it has half-integer spin. The theorem is named after Dutch physicist H. A. Kramers. In theoretical physics, the time reversal symmetry is the symmetry of physical laws under a time reversal transformation:

$$T : t \mapsto -t$$

If the Hamiltonian operator commutes with the time-reversal operator, that is

$$[H, T] = 0$$

then, for every energy eigenstate $|n\rangle$, the time reversed state $T|n\rangle$ is also an eigenstate with the same energy. These two states are sometimes called a Kramers pair [1] In general, this time-reversed state may be identical to the original one, but that is not possible in a half-integer spin system: since time reversal reverses all angular momenta, reversing a half-integer spin cannot yield the same state (the magnetic quantum number is never zero).

Обзор применений (???)

(слышал, но не знаю, зачем она)

5.3.4 Time-Reversal Symmetry: Advanced Features

(people are really fascinating with this topic, I don't know why, but I am assured that there are a lot of things to write about it)

6.1 Overview of Different Method for Solving Problems in QM

(general ideas about what can be done and when it is a good idea to use this method?)

PT

Adiabatics

Averaging (extra integration)

(???? discuss how good this method is??? a problem about anisotropic spectrum is solved by it)

6.2 Perturbation Theory: Fundamentals

Обсудим подробно теорию возмущений.

6.2.1 RS Stationary Perturbation Theory, Non-Degenerate Case

Обсудим подробно стационарную теорию возмущений. By "RS" I mean Rayleigh-Schrodinger, since there are also other perturbation theories.

Стационарная теория возмущений в невырожденном случае

Вывод формул

Пусть известны точные решения стационарного уравнения с гамильтонианом $\hat{H}_0$:

$$\hat{H}_0 \left|n^{(0)}\right\rangle = E_n^{(0)} \left|n^{(0)}\right\rangle,$$

где $\left|n^{(0)}\right\rangle$ - невырожденные состояния дискретного спектра с энергией $E_n^{(0)}$. Рассмотрим спектральную задачу с гамильтонианом

$$\hat{H} = \hat{H}_0 + \lambda V, \quad \lambda \to 0,$$

где возмущение V не зависит от времени, так же как и исходный гамильтониан $\hat{H}_0$. В силу предельного перехода $\lambda \to 0$ будем полагать, что базис гильбертова пространства $\left|n^{(0)}\right\rangle$ полон и в гильбертовом пространстве и в задаче с возмущением. Это предположение является центральным в теории возмущений! Если оно a posteriori оказывается неверным, то теория возмущений теряет всякий смысл. (????? why?????)

Нас будет интересовать только дискретный спектр в задаче с возмущением, так как в силу центрального предположения применимости теории возмущений, области непрерывного спектра в задаче с возмущением и без него совпадают, а дискретные же уровни энергии могут смещаться. (????? why?????)

Будем искать собственные значения

$$\hat{H}|n\rangle = E_n|n\rangle$$

в виде ряда по $\lambda \to 0$:

$$E_n = E_n^{(0)} + \sum_{p=1}^{\infty} \lambda^p \epsilon_p,$$

где ϵ_p-поправка p-го порядка. Собственные векторы состояний также можно записать в виде ряда

$$|n\rangle = \left|n^{(0)}\right\rangle + \sum_{p=1}^{\infty} \lambda^p \left|n^{(p)}\right\rangle.$$

Однако собственные состояния гамильтониана допускают несингулярное преобразование

$$|n\rangle \mapsto f(\lambda)|n\rangle, \quad f(0) = 1.$$

Поэтому для того, чтобы разложение состояния в ряд по λ было однозначным, необходимо зафиксировать амплитуду вероятности одного из базисных векторов исходного гильбертова пространства, например, $\left|n^{(0)}\right\rangle$. (????? why?????)

Here, we will be building our PT with by using the condition

$$\left\langle n^{(0)}|n\right\rangle = 1.$$

This is not the only way. One can take another condition (??? did I wrote it below???).

Подставляя сюда $|n\rangle = \left|n^{(0)}\right\rangle + \sum\limits_{p=1}^{\infty} \lambda^p \left|n^{(p)}\right\rangle$ и рассматривая его последовательно в каждом порядке, находим, что

$$\left\langle n^{(0)}|n^{(p)}\right\rangle = 0,$$

т. е. каждая поправка к состоянию не содержит вклада $\left|n^{(0)}\right\rangle$ и, следовательно, ортогональна исходному невозмущенному состоянию. Note, that here n is the selected level, in which we are interested. We don't consider here other levels at all.

Конечно, выбор условия однозначности в форме (15.6) приводит к собственному вектору, норма которого, вообще говоря, отлична от единицы, но эта проблема легко решается последовательно в любом заданном наперед порядке по λ. (??? how exactly??)

Подставляя разложения в $\hat{H}|n\rangle = E_n|n\rangle$, находим

$$\left(\hat{H}_0 + \lambda V\right)\left\{\left|n^{(0)}\right\rangle + \sum_{p=1}^{\infty} \lambda^p \left|n^{(p)}\right\rangle\right\} = \left(E_n^{(0)} + \sum_{p=1}^{\infty} \lambda^p \epsilon_p\right)\left\{\left|n^{(0)}\right\rangle + \sum_{p=1}^{\infty} \lambda^p \left|n^{(p)}\right\rangle\right\},$$

так что последовательно в каждом порядке по λ получаем рекуррентную систему уравнений:

$$\begin{aligned}
&\lambda^0 : \hat{H}_0 \left|n^{(0)}\right\rangle = E_n^{(0)} \left|n^{(0)}\right\rangle, \\
&\lambda^1 : \hat{H}_0 \left|n^{(1)}\right\rangle + V \left|n^{(0)}\right\rangle = E_n^{(0)} \left|n^{(1)}\right\rangle + \epsilon_1 \left|n^{(0)}\right\rangle, \\
&\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \\
&\lambda^p : \hat{H}_0 \left|n^{(p)}\right\rangle + V \left|n^{(p-1)}\right\rangle = E_n^{(0)} \left|n^{(p)}\right\rangle + \epsilon_1 \left|n^{(p-1)}\right\rangle + \ldots + \epsilon_p \left|n^{(0)}\right\rangle.
\end{aligned}$$

Пользуясь ортогональностью поправок и состояния $\left|n^{(0)}\right\rangle$ и исходным уравнением $\left\langle n^{(0)}\right| \hat{H}_0 = \left\langle n^{(0)}\right| E_n^{(0)}$, возьмем проекцию уравнений выше на это состояние: $\left\langle n^{(0)}|\cdot\right\rangle$, так что

$$\begin{aligned}
&\epsilon_1 = \left\langle n^{(0)}|V|n^{(0)}\right\rangle = V_{nn},\\
&\epsilon_2 = \left\langle n^{(0)}|V|n^{(1)}\right\rangle,\\
&\ldots\ldots\ldots\ldots\ldots\ldots\\
&\epsilon_p = \left\langle n^{(0)}|V|n^{(p-1)}\right\rangle,
\end{aligned}$$

т. е. опять-таки рекуррентную схему вычисления поправок к энергии, если известны поправки к состоянию.

Поправки к состоянию в силу их ортогональности к уровню $\left|n^{(0)}\right\rangle$ в базисе исходной задачи раскладываются в виде

$$\left|n^{(p)}\right\rangle = \sum_{k\neq n} \left|k^{(0)}\right\rangle \left\langle k^{(0)}|n^{(p)}\right\rangle,$$

(?? not fully sure, why here $k \neq n$?? of course, if $k = n$, then we will have $|n^{(0)}\rangle$, which is not in order we want, but is there a derivation of this formula??) At this point, we start working with not only the needed state $\left|n^{(0)}\right\rangle$, but with any other.

Амплитуды разложения легко найти, проецируя уравнения

$$\begin{aligned}
&\lambda^0 : \hat{H}_0 \left|n^{(0)}\right\rangle = E_n^{(0)} \left|n^{(0)}\right\rangle,\\
&\lambda^1 : \hat{H}_0 \left|n^{(1)}\right\rangle + V \left|n^{(0)}\right\rangle = E_n^{(0)} \left|n^{(1)}\right\rangle + \epsilon_1 \left|n^{(0)}\right\rangle,\\
&\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\\
&\lambda^p : \hat{H}_0 \left|n^{(p)}\right\rangle + V \left|n^{(p-1)}\right\rangle = E_n^{(0)} \left|n^{(p)}\right\rangle + \epsilon_1 \left|n^{(p-1)}\right\rangle + \ldots + \epsilon_p \left|n^{(0)}\right\rangle.
\end{aligned}$$

на состояния базиса $\left\langle k^{(0)}|\cdot\right\rangle$:

$$\begin{aligned}
\left\langle k^{(0)}|V|n^{(0)}\right\rangle &= \left(E_n^{(0)} - E_k^{(0)}\right) \left\langle k^{(0)}|n^{(1)}\right\rangle,\\
\left\langle k^{(0)}|V|n^{(p-1)}\right\rangle &= \left(E_n^{(0)} - E_k^{(0)}\right) \left\langle k^{(0)}|n^{(p)}\right\rangle + \epsilon_1 \left\langle k^{(0)}|n^{(p-1)}\right\rangle + \ldots + \epsilon_{p-1} \left\langle k^{(0)}|n^{(1)}\right\rangle.
\end{aligned}$$

Now, we plug out term $\left\langle k^{(0)}|n^{(p)}\right\rangle$ after term for increasing p, and we see that for p-th term, the general formula holds:

$$\left\langle k^{(0)}|n^{(p)}\right\rangle = \frac{1}{E_n^{(0)} - E_k^{(0)}} \left\{ V_{kn}^{(p-1)} - \epsilon_1 \left\langle k^{(0)}|n^{(p-1)}\right\rangle - \ldots - \epsilon_{p-1} \left\langle k^{(0)}|n^{(1)}\right\rangle \right\},$$

где $p \geqslant 1, k \neq n,\ V_{kn}^{(p-1)} := \left\langle k^{(0)}|V|n^{(p-1)}\right\rangle$.

So, we got formula for $\left\langle k^{(0)}|n^{(p)}\right\rangle$, which will be immediately used in calculation of energy shift by $\epsilon_p = \left\langle n^{(0)}|V|n^{(p-1)}\right\rangle$.

In particular,

$$\left|n^{(1)}\right\rangle = \sum_{k\neq n} \frac{V_{kn}}{E_n^{(0)} - E_k^{(0)}} \left|k^{(0)}\right\rangle,$$

откуда

$$\epsilon_2 = \sum_{k\neq n} \frac{V_{nk} V_{kn}}{E_n^{(0)} - E_k^{(0)}},$$

и в силу $V_{nk} = \langle n^{(0)}|V|k^{(0)}\rangle = \langle k^{(0)}|V|n^{(0)}\rangle^* = V_{kn}^*$,

$$\epsilon_2 = \sum_{k\neq n} \frac{|V_{kn}|^2}{E_n^{(0)} - E_k^{(0)}}.$$

Отсюда, в частности, следует, что для основного состояния с наименьшей энергией $E_n^{(0)} - E_k^{(0)} < 0$ поправка второго порядка всегда отрицательна, если не равна нулю.

Подчеркнем, что ведущая поправка к энергии уровня задается средним значением возмущения. По смыслу теории возмущений поправки высших порядков становятся существенны, если поправки низшего порядка обращаются в нуль или необходимо получить значение с высокой точностью.

Условия применимости стационарной теории возмущений

(укажу то, что вначале Киселев писал.)

Необходимым условием применимости теории возмущений является сходимость рядов для энергий и собственных состояний системы с $\hat{H} = \hat{H}_0 + \lambda V$. Мы установили, что поправки к состояниям строятся по степеням малого отношения матричного элемента возмущения к инкременту уровней в исходной системе

$$\frac{|V_{kn}|}{\Delta E_{kn}^{(0)}} \ll 1.$$

Значит, возмущение можно считать малым, если его характерная величина, т. е. модуль его матричных элементов между векторами стационарных состояний невозмущенной задачи, отвечающими различным уровням энергии, существенно меньше типичного расстояния между этими уровнями. С физической точки зрения это означает, что возмущение не приводит к «перекрытию уровней исходной системы. В этом случае вклад высших поправок к состояниям подавлен степенями этого малого параметра, так что из выражения для поправок к энергии (15.9) следует, что и они также подавлены в зависимости от порядка p теории возмущений.

О случаях применения стационарной теории возмущений в невырожденном случае

Of course, mathematically - when we have a non-degenerate system, where there is no dynamics, just a complicated Hamiltonian. But when does it happens most often physically?

(?I'll write later)

О случаях неполного базиса, когда теория возмущений неприменима (???)

(Киселев сказал, что тогда смысла в ней нет, я пока что не понимаю, почему и когда такое может быть???)

Suppose we have system with two small perturbative terms. Поправки любых порядков от двух малых возмущений равны сумме поправок от каждого возмущения поотдельности

We always believe that this is so. But I want to also prove it.

(??? I haven't proven it yet, I don't have time to it and I am not sure, if there will be some problems with it.)

Особенности стационарной теории возмущений для типичных задач

(тут указания про задачи.)

О стационарной теории возмущений для осциллятора

(!!!! про операторы рождения и уничтожения написать нормально, пока слабая про них теория, а тут они очень нужны!!! особенно их преобразования!)

(!!! тут заготовки преобразований операторов рождения и уничтожения, типичная ситуация, что приходится они них полиномы брать!)

(!! важно не переставлять лихо N и a a крест, потому что за счет них N становится другой!!! это приводит к ошибкам, напишу там про это.)

О стационарной теории возмущений для бесконечно глубокой потенциальной ямы

О стационарной теории возмущений для конечной потенциальной ямы (!?!??!!??!?!?)

(вот тут прямо я хз, как делать, опыта нет.)

О стационарной теории возмущений для возмущения вида дельта-потенциала (!?!??!!??!?!?)

(вот тут прямо я хз, как делать, опыта нет. она вообще применима для этого случая?)

Математические указания для работы с теорией возмущений (!?!?)

(это важно, без этого ничего не сделаешь, упершись только в математику.)

Как догадаться про RS PT?

(??? left question)

6.2.2 RS Stationary Perturbation Theory, Degenerate Case

Стационарная теория возмущений в вырожденном случае

(с этим пока что не освоился.)

Вывод формул

Если уровень исходной системы $E_n^{(0)}$ является вырожденным и кратность его вырождения равна k, то предел $\lambda \to 0$ в системе с возмущением также можно определить однозначно, фиксировав вклад ортонормированных базисных собственных векторов в k-мерном подпространстве с энергией $E_n^{(0)}$

$$\hat{H}_0 \left|n^{(0)}, a\right\rangle = E^{(0)} \left|n^{(0)}, a\right\rangle, \quad a \in \{\overline{1,k}\}, \quad \left\langle n^{(0)}, b | n^{(0)}, a\right\rangle = \delta_{ab},$$

в состояние

$$|n\rangle = \sum_{a=1}^{k} C_a \left|n^{(0)}, a\right\rangle + \sum_{p=1}^{\infty} \lambda^p \left|n^{(p)}\right\rangle,$$

т. е. задав «вектор» $C_a = \langle n^{(0)}, a|n\rangle$.

Отсюда опять следует, что поправки по построению ортогональны подпространству состояний с энергией $E_n^{(0)}$.

Используя разложение в ряд энергии и состояния, в полной аналогии с невырожденным случаем в первом порядке по λ находим

$$\hat{H}_0 \left|n^{(1)}\right\rangle + V \sum_{a=1}^{k} C_a \left|n^{(0)}, a\right\rangle = E_n^{(0)} \left|n^{(1)}\right\rangle + \epsilon_1 \sum_{a=1}^{k} C_a \left|n^{(0)}, a\right\rangle .$$

Проецируя это уравнение на $\langle n^{(0)}, b|\cdot\rangle$ с учетом уравнения на собственные значения гамильтониана $\hat{H}_0$ и ортогональности поправок ведущему вкладу за счет $\left|n^{(0)}, b\right\rangle$, получаем уравнение

$$\sum_{a=1}^{k} \{V_{ba} - \epsilon_1 \delta_{ba}\} C_a = 0, \quad V_{ba} = \langle n^{(0)}, b|V|n^{(0)}, a\rangle ,$$

которое говорит о том, что вектор C_a является собственным для эрмитовой матрицы V_{ab}, и его собственное значение ϵ_1 дает величину ведущей поправки к энергии этого состояния. Секулярное уравнение для матрицы $\|\hat{V}\|_{ba} = V_{ba}$ в подпространстве собственных состояний энергии $E_n^{(0)}$

$$\det(\hat{V} - \epsilon) = 0$$

имеет k собственных значений, которые, вообще говоря, тоже могут быть вырождены. Выбирая значения C_a в виде собственных векторов матрицы $\hat{V}$, находим «правильные» функции ведущего приближения

$$\left|\tilde{n}^{(0)}, g\right\rangle , \quad \hat{V} \left|\tilde{n}^{(0)}, g\right\rangle = \epsilon_1^{(g)} \left|\tilde{n}^{(0)}, g\right\rangle ,$$

где g нумерует собственные значения матрицы $\hat{V}$. Поскольку правильные функции составляют ортогональный базис, задача нахождения высших поправок теперь сводится к решению тех же рекуррентных соотношений, что и в невырожденном случае, для каждого из собственных векторов матрицы $\hat{V}$:

$$\hat{H}_0 \left|n^{(p)}\right\rangle + V \left|n^{(p-1)}\right\rangle = E_n^{(0)} \left|n^{(p)}\right\rangle + \epsilon_1^{(g)} \left|n^{(p-1)}\right\rangle + ... + \epsilon_p^{(g)} \left|n^{(0)}, g\right\rangle .$$

Дальнейшее построение повторяет рассмотрение невырожденного случая. При этом поправки к состояниям могут включать в себя и вырожденные состояния уровней энергии исходного гамильтониана, отличных от рассматриваемого уровня $E_n^{(0)}$.

О случаях применения стационарной теории возмущений в вырожденном случае (???)

Важно понимать, какие модели могут иметь вырождение, чтобы потом оно снималось возмущением.

(?? и какие же??)

В более чем 1-мерном осцилляторе, оказывается, применяется.

Второй порядок вырожденной теории возмущений

Разумеется, может быть ситуация, в которой возмущение не снимается в первом порядке (или снимается лишь частично) - в таком случае нужно двигаться дальше. Опять-таки, мы используем уравнение (5.3):

$$\hat{H}_0 \left|n^{(2)}\right\rangle + \hat{V} \left|n^{(1)}\right\rangle = E_n^{(2)} \left|n^{(0)}\right\rangle + E_n^{(1)} \left|n^{(1)}\right\rangle + E_n^{(0)} \left|n^{(2)}\right\rangle$$

Тут мы ограничимся лишь поправкой второго порядка к уровням энергии, поэтому спроецируем сразу это уравнение на $\left\langle n_\alpha^{(0)}\right|$:

$$\sum_{m\neq n,\beta}\frac{V_{\alpha m}V_{m\beta}}{\omega_{nm}}c_{n,\beta}^{(0)}\equiv\sum_{\beta}H_{\alpha\beta}^{(\text{eff})}c_{n,\beta}^{(0)}=E_n^{(2)}c_{n,\alpha}^{(0)},\quad H_{\alpha\beta}^{(\text{eff})}=\sum_{m\neq n}\frac{V_{\alpha m}V_{m\beta}}{\omega_{nm}}$$

Полученное уравнение, как и в первом порядке, устроено в точности как уравнение Шрёдингера, спроецированное на вырожденное подпространство, но с эффективным гамильтонианом $H^{(\text{eff})}$ (который раньше попросту совпадал с $\hat{V}$). Поступать с ним нужно точно так же - если вырождение не было снято в первом порядке, то поправки второго порядка определяются секулярным уравнением $\det\left(\hat{H}^{(\text{eff})}-E_n^{(2)}\right)=0$, а правильные волновые функции ведущего приближения будут соответствовать этим уровням энергии.

Про эффективный гамильтониан можно думать, как про вклад виртуальных переходов с одного из уровней вырожденного подпространства $E_\alpha^{(0)}$ на невырожденный уровень $E_m^{(0)}$ и обратно на уровень $E_\beta^{(0)}$, принадлежащий тому же вырожденному подпространству $\left(E_\alpha^{(0)}=E_\beta^{(0)}\right)$, но не обязательно являющийся тем же состоянием (только для $\alpha=\beta$).

О случаях применения стационарной теории возмущений в вырожденном случае во втором порядке (???)

(вообще хз, ни разу не применял, но по идее могло бы такое понадобиться.)

Задача с двумя уровнями

Рассмотрим задачу с только два уровнями с гамильтонианом $\hat{H}_0+\lambda V$. Решение представляется в виде разложения

$$|\psi\rangle=c_1|1\rangle+c_2|2\rangle,$$

где эти состояния такие, что $\hat{H}_0|1\rangle=E_1^{(0)}|1\rangle$, $\hat{H}_0|2\rangle=E_2^{(0)}|2\rangle$. Подставим в уравнение $\hat{H}|\psi\rangle=E|\psi\rangle$, получим:

$$H_{11}c_1+\lambda V_{12}c_2=Ec_1$$
$$H_{22}c_2+\lambda V_{21}c_1=Ec_2$$

или в матричном виде

$$\begin{pmatrix}H_{11}&\lambda V_{12}\\ \lambda V_{12}^*&H_{22}\end{pmatrix}\begin{pmatrix}c_1\\c_2\end{pmatrix}=E\begin{pmatrix}c_1\\c_2\end{pmatrix},$$

т. е. уравнение на собственные значения матрицы 2×2.

(??? тут можно лучше написать. Судя по всему, возмущение кросдиагональное предполагается, окей. потом напишу лучше.)

Решаем:

$$\det\{\hat{H}-E\}=\left[\frac{1}{2}\left(H_{11}+H_{22}\right)-E\right]^2-\frac{1}{4}\left(H_{11}-H_{22}\right)^2-\lambda^2\left|V_{12}\right|^2=0.$$

Решения этого уравнения

$$E_\pm=\frac{1}{2}\left(H_{11}+H_{22}\right)\pm\sqrt{\frac{1}{4}\left(H_{11}-H_{22}\right)^2+\lambda^2\left|V_{12}\right|^2}$$

суть искомые значения энергии стационарных состояний, а соответствующие состояния в исходном базисе удобно выразить в виде унитарного поворота

$$|\psi_+\rangle = \mathrm{e}^{\mathrm{i}\phi/2}\sin\frac{\alpha}{2}|1\rangle + \mathrm{e}^{-\mathrm{i}\phi/2}\cos\frac{\alpha}{2}|2\rangle,$$
$$|\psi_-\rangle = \mathrm{e}^{\mathrm{i}\phi/2}\cos\frac{\alpha}{2}|1\rangle - \mathrm{e}^{-\mathrm{i}\phi/2}\sin\frac{\alpha}{2}|2\rangle$$

где мы ввели фазу ϕ матричного элемента $V_{12} = |V_{12}|\,\mathrm{e}^{\mathrm{i}\,\phi}$ и угол поворота α, так что

$$\operatorname{tg}\frac{\alpha}{2} = -\frac{\lambda\,|V_{12}|}{\frac{1}{2}\,(H_{11}-H_{22}) - \sqrt{\frac{1}{4}\,(H_{11}-H_{22})^2 + \lambda^2\,|V_{12}|^2}},$$

откуда

$$\operatorname{tg}\alpha = -\frac{2\lambda\,|V_{12}|}{H_{11}-H_{22}}.$$

В эти выражения входят значения диагональных матричных элементов гамильтониана

$$H_{11} = E_1^{(0)} + \lambda V_{11}, \quad H_{22} = E_2^{(0)} + \lambda V_{22},$$

которые при $E_1^{(0)} \neq E_2^{(0)}$ получались бы в стационарной теории возмущений в ведущем порядке по $\lambda \to 0$ без учета смешивания исходных состояний, в случае, когда точное решение (15.27) можно разложить до второго порядка по малому отношению

$$\left|\frac{\lambda V_{12}}{H_{11}-H_{22}}\right| \ll 1$$

При достаточно большой константе связи возмущения λ поведение собственных значений гамильтониана $E_\pm$, описываемое (15.27), будет качественно отличаться от поведения ведущего приближения в (15.30). Например, при некоторых фиксированных $E_1^{(0)} \neq E_2^{(0)}, V_{11} > 0, V_{22} < 0$ и $V_{12} \neq 0$ зависимость от λ для диагональных элементов гамильтониана и его собственных значений проиллюстрирована на рис. 26.

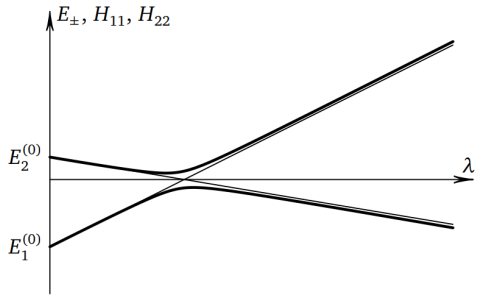

Figure 6.1: Зависимость собственных значений гамильтониана $E_\pm$(жирные линии) и диагональных элементов H_{11}, H_{22} (тонкие линии) от константы связи возмущения λ

Как видим, возмущение может быть настолько сильным, что в ведущем приближении диагональные матричные элементы имеют точку пересечения. Однако точное решение показывает, что истинные значения собственных значений гамильтониана не пересекаются. Поскольку допустимая область изменения угла $\alpha \in [0, \pi]$, собственные состояния гамильтониана являются смешанными за исключением исходной задачи с $\lambda = 0$ и при $\alpha \to \pi$, если $|V_{12}| \ll |V_{11} - V_{22}|$ и $\lambda \to \infty$, когда состояния $|1\rangle$ и $|2\rangle$ меняются местами: первое имеет большую энергию, чем второе.

Задача с двумя уровнями находит применение не только в случае, например, двух спиновых состояний для частицы со спином 1/2, но и в таких ситуациях, когда энергетическая щель между парой низших уровней энергии и их возбуждениями достаточно велика, чтобы можно было пренебречь вкладами от высших поправок от возбужденных состояний, в то время как эффекты смешивания за счет введения V велики и не могут быть рассмотрены как малые поправки в системе двух низших состояний.

О применениях (!??!)

(мб их много, укажу там потом.)

О случае, если два уровня вырождены (??)

(?? мы же решали только для одного вырожденного уровня, да? или все норм, просто то, на котором мы находились, расщепляется и все? а другие не будут расщепляться??? наверное, нет, все не норм.)

Математические указания для работы с (!?!?)

(это важно, без этого ничего не сделаешь, упершись только в математику.)

О деталях (!????!?!?!)

(тут вопросы, на которые пока я не нашел ответ. ну и не так важно.)

теория возмущений для перехода в основное состояние (??)

. Вообще у нас энергия уходит в фотон ведь? То есть это же теория излучения??? . В общем, как считать такие переходы??? Если волновая функция в основном - ноль, так что туда вообще не может перейти частица. .

теория возмущений при переходе к вырожденному уровню энергии (??)

Например, в осцилляторе переходы между ненулевыми уровнями.

Переход вырожденного случая в невырожденный случай (?!?!??!)

(остался вопрос, как этот преход происходит??? там же не супер мгновенно, а хотя бы какая-то плавность расщепления уровней должна быть??? пока не могу вывести эту плавность, одна и вторая теория есть, все, больше ничего. потом опишу этот переход.)

6.2.3 Brillouin-Wigner Perturbation Theory

Overview and derivation

(here are two pages by K. Ingersent)

Brillouin-Wigner (BW) perturbation theory is less widely used than the Rayleigh-Schrödinger (RS) version. At first order in the perturbation, the two theories are equivalent. However, BW perturbation theory extends more easily to higher orders, and avoids the need for separate treatment of non-degenerate and degenerate levels.

- Assume that we know the stationary states of the unperturbed Hamiltonian H_0, namely the kets $|n\rangle$ satisfying $H_0|n\rangle = \varepsilon_n|n\rangle$. For each unperturbed state, we can define a projection operator

$$Q_n = I - |n\rangle\langle n| = \sum_{m\neq n} |m\rangle\langle m|$$

Using the spectral representation $H_0 = \sum_n \varepsilon_n|n\rangle\langle n|$, one can see that $[H_0, Q_n] = 0$.

- Let us write the perturbed eigenproblem in the form

$$(E_n - H_0)\,|\psi_n\rangle = H_1\,|\psi_n\rangle\,.$$

Acting with Q_n from the left, and taking advantage of $[H_0, Q_n] = 0$,

$$Q_n\,|\psi_n\rangle = R_n H_1\,|\psi_n\rangle$$

where

$$R_n = (E_n - H_0)^{-1}\,Q_n = Q_n\,(E_n - H_0)^{-1}$$

which has a spectral representation

$$R_n = \sum_{m\neq n} \frac{|m\rangle\langle m|}{E_n - \varepsilon_m}$$

Note that R_n is not a projection operator because $R_n^2 \neq R_n$.

- Adopting the usual convention $\langle n \mid \psi_n\rangle = 1$, we can write

$$|\psi_n\rangle = |n\rangle + Q_n\,|\psi_n\rangle = |n\rangle + R_n H_1\,|\psi_n\rangle\,.$$

Assuming that H_1 is small, this equation can be solved iteratively in powers of H_1. The wave function correct through order j, $\left|\psi_n^{(j)}\right\rangle$, can be obtained from Eq. (2) by inserting $\left|\psi_n^{(j-1)}\right\rangle$ on the right-hand side:

$$\begin{aligned}
\left|\psi_n^{(0)}\right\rangle &= |n\rangle \\
\left|\psi_n^{(1)}\right\rangle &= |n\rangle + R_n H_1|n\rangle \\
\left|\psi_n^{(2)}\right\rangle &= |n\rangle + R_n H_1|n\rangle + (R_n H_1)^2\,|n\rangle \\
&\quad \text{etc}
\end{aligned}$$

In other words,

$$|\psi_n\rangle = \sum_{j=0}^{\infty} (R_n H_1)^j\,|n\rangle \equiv (1 - R_n H_1)^{-1}\,|n\rangle$$

where the first equality serves to define $(1 - R_n H_1)^{-1}$. Substituting the spectral representation of R_n into Eq. (3), we obtain

$$\begin{aligned}|\psi_n\rangle =& |n\rangle + \sum_{m\neq n} |m\rangle \frac{\langle m|H_1|n\rangle}{E_n - \varepsilon_m} + \sum_{m\neq n}\sum_{l\neq n} |m\rangle \frac{\langle m|H_1|l\rangle\langle l|H_1|n\rangle}{(E_n - \varepsilon_m)(E_n - \varepsilon_l)} \\ &+ \sum_{m\neq n}\sum_{l\neq n}\sum_{k\neq n} |m\rangle \frac{\langle m|H_1|l\rangle\langle l|H_1|k\rangle\langle k|H_1|n\rangle}{(E_n - \varepsilon_m)(E_n - \varepsilon_l)(E_n - \varepsilon_k)} + \ldots\end{aligned}$$

- We can obtain E_n by applying $\langle n|$ to Eq. (1):

$$(E_n - \varepsilon_n)\langle n \mid \psi_n\rangle = \langle n|H_1|\psi_n\rangle$$

Since $\langle n \mid \psi_n\rangle = 1$,

$$E_n = \varepsilon_n + \langle n|H_1|\psi_n\rangle$$

or, making use of Eq. (4),

$$\begin{aligned}E_n =& \varepsilon_n + \langle n|H_1|n\rangle + \sum_{m\neq n} \frac{\langle n|H_1|m\rangle\langle m|H_1|n\rangle}{E_n - \varepsilon_m} \\ &+ \sum_{m\neq n}\sum_{l\neq n} \frac{\langle n|H_1|m\rangle\langle m|H_1|l\rangle\langle l|H_1|n\rangle}{(E_n - \varepsilon_m)(E_n - \varepsilon_l)} \\ &+ \sum_{m\neq n}\sum_{l\neq n}\sum_{k\neq n} \frac{\langle n|H_1|m\rangle\langle m|H_1|l\rangle\langle l|H_1|k\rangle\langle k|H_1|n\rangle}{(E_n - \varepsilon_m)(E_n - \varepsilon_l)(E_n - \varepsilon_k)} + \ldots\end{aligned}$$

Advantages and disadvantages

- The BW formulation has the advantages that the expressions given in Eqs (4) and (6) are much simpler than those produced by RS perturbation theory, and there is no need to devise a special treatment of degeneracies $\varepsilon_m = \varepsilon_n$. A disadvantage of the BW approach is that the perturbed energy appears on the righthand side of Eq. (6). This is therefore really a polynomial equation for E_n, which can be nontrivial to solve.

One has to weigh up the pros and cons of the BW and RS methods in deciding which one to use for a particular problem.

(?? maybe one day I'll understand it)

6.2.4 RS Non-Stationary Perturbation Theory

Нестационарная теория возмущений по Киселеву

Постановка задачи

При введении возмущения, зависящего от времени,

$$\hat{H} = \hat{H}_0 + \lambda V(t),$$

полагают, что в начальный момент времени t' имеем $V(t') = 0$. We are interested in determining the dynamics after the appearance of the potential.

Пусть до «включения» возмущения система находилась в одном из стационарных состояний гамильтониана $\hat{H}_0$:

$$\hat{H}_0|\mathrm{i}\rangle = E_{\mathrm{i}}^{(0)}|\mathrm{i}\rangle$$

так что $|\mathrm{i}\rangle$ - начальное (initial) состояние эволюции, которое определяет

$$|\mathrm{i}(t)\rangle_0 = U_0\left(t,t'\right)|\mathrm{i}\rangle = \mathrm{e}^{-\frac{\mathrm{i}}{\hbar}E_{\mathrm{i}}^{(0)}(t-t')}|\mathrm{i}\rangle,$$

где оператор эволюции для исходного гамильтониана $U_0\left(t,t'\right) = \mathrm{e}^{-\frac{1}{\hbar}\hat{H}_0(t-t')}$. При включении возмущения, зависящего от времени, оператор эволюции в общем виде принимает вид "Т-экспоненты":

$$U\left(t,t'\right) = \hat{\mathrm{T}}\exp\left\{-\frac{\mathrm{i}}{\hbar}\int\limits_{t'}^{t}\hat{H}(t)\mathrm{d}t\right\}$$

и удовлетворяет уравнению

$$i\hbar\frac{\partial U}{\partial t} = \hat{H}U,$$

И $U\left(t',t'\right) = 1$. Состояние в момент времени $t-$

$$|\mathrm{i}(t)\rangle = U\left(t,t'\right)|\mathrm{i}\rangle.$$

Представление взаимодействия

Рассмотрим эволюцию в базисе состояний "представления взаимодействия":

$$|\mathrm{i}(t)\rangle_I = U_0^{\dagger}\left(t,t'\right)|\mathrm{i}(t)\rangle \overset{\mathrm{def}}{=} U_I\left(t,t'\right)|\mathrm{i}\rangle$$

откуда

$$U\left(t,t'\right) = U_0\left(t,t'\right)U_I\left(t,t'\right).$$

Если возмущение малó, то состояние $|\mathrm{i}(t)\rangle_I$ мало отличается от начального $|\mathrm{i}\rangle$. Подставляя $U\left(t,t'\right) = U_0\left(t,t'\right)U_I\left(t,t'\right)$ в уравнение $i\hbar\frac{\partial U}{\partial t} = \hat{H}U$, находим

$$\mathrm{i}\hbar\frac{\partial U}{\partial t} = \mathrm{i}\hbar\frac{\partial U_0}{\partial t}U_I + U_0\mathrm{i}\hbar\frac{\partial U_I}{\partial t} = \hat{H}_0U_0U_I + U_0\mathrm{i}\hbar\frac{\partial U_I}{\partial t},$$

видим что вклад с $\hat{H}_0$ с обеих сторон уравнения сокращается. После умножения уравнения слева на $U_0^{\dagger}$ с учетом унитарности оператора эволюции $U_0^{\dagger}U_0 = \mathbb{1}$ получаем

$$\mathrm{i}\hbar\frac{\partial U_I}{\partial t} = \lambda V_I U_I$$

где потенциал в представлении взаимодействия

$$V_I = U_0^{\dagger}VU_0.$$

Разложение в ряд по λ решения уравнения для оператора эволюции в представлении взаимодействия

$$U_I\left(t,t'\right) = \hat{\mathrm{T}}\exp\left\{-\frac{\mathrm{i}}{\hbar}\lambda\int\limits_{t'}^{t}V_I(t)\mathrm{d}t\right\}$$

дает построение последовательных приближений по степеням константы связи $\lambda \to 0$.

Ведущее приближение

В первом порядке по λ

$$U_I(t,t') = \mathbb{1} - \frac{\mathrm{i}}{\hbar}\lambda \int\limits_{t'}^{t} V_I(t)\mathrm{d}t.$$

Пусть $|f\rangle$ - состояние из спектра исходного гамильтониана, причем $|f\rangle \neq |i\rangle$.В момент времени t эволюция этого состояния с помощью исходного оператора эволюции дает $|\mathfrak{f}(t)\rangle_0 = U_0(t,t')|\mathfrak{f}\rangle$. Значит, амплитуда вероятности найти начальное состояние в момент времени t в конечном (final) состоянии $|f(t)\rangle_0$ в ведущем порядке по константе связи равна

$$A_{\mathrm{fi}} = 0\langle \mathrm{f}(t)|\mathrm{i}(t)\rangle = \left\langle \mathrm{f}\left| U_0^{\dagger}U_0U_I \right| \mathrm{i}\right\rangle = \langle \mathrm{f}|U_I(t,t')|\,\mathrm{i}\rangle \approx -\lambda\frac{\mathrm{i}}{\hbar}\int\limits_{t'}^{t}\langle \mathrm{f}|V_I(t)|\,\mathrm{i}\rangle\,\mathrm{d}t.$$

Для матричного элемента, очевидно, имеем

$$\langle \mathrm{f}|V_I(t)|\,\mathrm{i}\rangle = \left\langle \mathrm{f}\left| U_0^{\dagger}(t,t')\,V(t)U_0(t,t')\right| \mathrm{i}\right\rangle = \langle \mathrm{f}|V(t)|\mathrm{i}\rangle \mathrm{e}^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')},$$

где

$$\langle \mathrm{f}|V(t)|\mathrm{i}\rangle = V_{\mathrm{fi}}(t)$$

есть матричный элемент возмущения, и частота «перехода»

$$\omega_{\mathrm{fi}} = \frac{1}{\hbar}\left(E_{\mathrm{f}}^{(0)} - E_{\mathrm{i}}^{(0)}\right).$$

Если конечное состояние находится в дискретном спектре, то, возводя в квадрат модуль амплитуды

$$A_{\mathrm{fi}} = -\lambda\frac{\mathrm{i}}{\hbar}\int\limits_{t'}^{t} V_{\mathrm{fi}}(t)\mathrm{e}^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')}\mathrm{d}t,$$

получаем вероятность перехода из начального состояния в конечное

$$W_{\mathrm{i}\to\mathrm{f}} = \frac{1}{\hbar^2}\left|\int\limits_{t'}^{t}\lambda V_{\mathrm{fi}}(t)\mathrm{e}^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')}\mathrm{d}t\right|^2,$$

а в случае непрерывного спектра в конечном состоянии со спектральным параметром ν - плотность вероятности

$$\frac{\mathrm{d}W_{\mathrm{i}\to\mathrm{f}}}{\mathrm{d}\nu} = \frac{1}{\hbar^2}\left|\int\limits_{t'}^{t}\lambda V_{\mathrm{fi}}(t)\mathrm{e}^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')}\mathrm{d}t\right|^2,$$

где состояния нормированы стандартным способом: $\langle\nu'|\nu\rangle = \delta(\nu'-\nu)$.

General, important questions about non-stationary RS PT

How to guess the approach to derive the non-stationary RS PT?

(??? I'll answer later)

О хронологической экспоненте

(?? где раздел, который чисто ей и посвящен??)

Введем хронологическое произведение операторов, которое часто называют также T-упорядоченным произведением операторов, или просто T-произведением. Для бозе-операторов

$$\mathrm{T}\widehat{A}(x)\widehat{B}(x') = \begin{cases} \widehat{A}(x)\widehat{B}(x') & \text{если } t > t' \\ \widehat{B}(x')\,\hat{A}(x) & \text{если } t < t' \end{cases}$$

а для ферми-операторов

$$\mathrm{T}\widehat{A}(x)\widehat{B}(x') = \begin{cases} \widehat{A}(x)\hat{B}(x') & \text{при } t > t' \\ -\widehat{B}(x')\,\widehat{A}(x) & \text{при } t < t' \end{cases}$$

(??? и почему это так???)

Relation of non-stationary PT and scattering theory

(write how exactly it is used there)

Relation of non-stationary PT and Dyson's series
(???? how they are related???)

Why does a state within a continuum have to be treated with time-dependent PT?

(???)

The point is that the state generally gets "lost" into the continuum, i.e. the true energy eigenstates have zero overlap with the original unperturbed state. For example, if we prepare an atom in an excited state but allow it to radiate into vacuum (thus introducing a continuum of states of the electromagnetic field), then no matter how we prepare the atom, the long-term probability of occupancy of the state is zero. This is true no matter how weak the perturbation is, making time-independent PT useless. (??????)

Математические указания для работы с нестационарной теорией возмущений (!?!?)

Во время использования ТВ постоянно возникают проблемы с интегралами или матрицами, так что приведем тут обзор самых основных методов по решению таких проблем.

(?? как брать эти интегралы????)

Постоянное возмущение

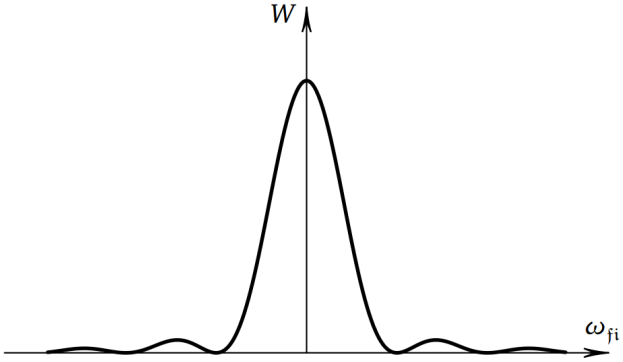
Если

$$\lambda V(t) = \bar{V}\theta(t - t'),$$

то квадрат модуля амплитуды $W_{\mathrm{i}\to\mathrm{f}} = \frac{1}{\hbar^2}\left|\int\limits_{t'}^{t} \lambda V_{\mathrm{fi}}(t)\mathrm{e}^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')}\mathrm{d}t\right|^2$ равен

$$W = \left|\bar{V}_{\mathrm{fi}}\right|^2 \left(\frac{2\sin\left[\omega_{\mathrm{fi}}(t - t')/2\right]}{\hbar\omega_{\mathrm{fi}}}\right)^2,$$

характерное поведение которого на конечных временах показано на рис. 27.



Значит, постоянное возмущение с ненулевыми недиагональными матричными элементами по состояниям исходного гамильтониана за конечное время Δt приводит к переходам с частотой

$$\Delta t \cdot \omega_{\mathrm{fi}} \lesssim 1,$$

в то время как переходы с другими частотами подавлены. Если трактовать измерение спектра системы как введение малого возмущения, то, как видим, только бесконечно длительное наблюдение за стационарным состоянием позволяет избежать возбуждения других состояний, и при конечном времени измерения всегда возникает неопределенность энергии за счет переходов на другие уровни, причем имеет место соотношение неопределенности время-энергия.

При $t' \to -\infty, t \to +\infty$ возмущение действует бесконечно долго, так что амплитуда перехода

$$-\frac{\mathrm{i}}{\hbar}\bar{V}_{\mathrm{fi}} 2\pi\delta\left(\omega_{\mathrm{fi}}\right)$$

и она формально обращается в нуль при $\omega_{\mathrm{fi}} \neq 0$ на фоне вклада начального состояния, в то время как

$$2\pi\delta(\omega)\big|_{\omega\to 0} = \int\limits_{t'\to-\infty}^{t\to+\infty} \mathrm{e}^{\mathrm{i}\omega t}\,\mathrm{d}t\Bigg|_{\omega\to 0} = (t-t') \to \infty,$$

и мы получаем поправку к эволюции за счет смещения уровня

$$E_{\mathrm{i}} = E_{\mathrm{i}}^{(0)} + \bar{V}_{\mathrm{ii}},$$

так как

$$U_0\left(t,t'\right) U_I\left(t,t'\right) \mapsto \exp\left\{-\frac{\mathrm{i}}{\hbar}\left(E_{\mathrm{i}}^{(0)} + \bar{V}_{\mathrm{ii}}\right)\left(t-t'\right)\right\}.$$

При конечных временах и $\omega_{\mathrm{fi}}(t-t') \gg 1$ амплитуда перехода равна

$$A_{\mathrm{fi}} = -\frac{1}{\hbar\omega_{\mathrm{fi}}}\bar{V}_{\mathrm{fi}}\left\{1 - \mathrm{e}^{-\mathrm{i}\omega_{\mathrm{fi}}(t-t')}\right\}\mathrm{e}^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')}.$$

Заметим, что в представлении взаимодействия матричные элементы операторов отличаются от матричных элементов по состояниям в представлении Гейзенберга, которое фактически используется в стационарной теории возмущений:

$$\left\langle \mathrm{f}\left|U_0^{\dagger}\left(t,t'\right)\hat{F}U_0\left(t,t'\right)\right|\mathrm{i}\right\rangle = \mathrm{e}^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')}\langle \mathrm{f}|\hat{F}|\mathrm{i}\rangle,$$

что, естественно, никак не сказывается на вероятности, определяемой модулем амплитуды.

Поэтому вычисленная нами выше амплитуда может быть связана с амплитудой смешивания стационарных состояний $\tilde{A}_{\mathrm{fi}}$ согласно

$$A_{\mathrm{fi}} = \mathrm{e}^{\mathrm{i}\omega_{\mathrm{fi}}(t-t')}\tilde{A}_{\mathrm{fi}},$$

где уже

$$\tilde{A}_{\mathrm{fi}} = -\frac{1}{\hbar\omega_{\mathrm{fi}}}\bar{V}_{\mathrm{fi}}\left\{1-\mathrm{e}^{-\mathrm{i}\omega_{\mathrm{fi}}(t-t')}\right\},$$

и это-величина, которая сильно осциллирует при малом изменении интервала времени, и значит, имеет смысл взять ее среднее значение по периоду, так что экспонента «выпадает», и в среднем амплитуда не зависит от времени:

$$\bar{A}_{\mathrm{fi}} = -\frac{\bar{V}_{\mathrm{fi}}}{\hbar\omega_{\mathrm{fi}}} = \frac{\bar{V}_{\mathrm{fi}}}{E_{\mathrm{i}}^{(0)}-E_{\mathrm{f}}^{(0)}},$$

что, конечно, воспроизводит результат стационарной теории возмущений для амплитуды примеси к начальному состоянию. Поэтому критерий применимости теории возмущений в этом случае остается без изменений.

Итак, мы убедились, что подстановка постоянного возмущения согласуется с теорией возмущений в стационарном случае.

Периодическое возмущение

(?? тут же ведь и золотое правило Ферми)

Рассмотрим периодическое возмущение, равное нулю при $t = t'$,

$$\lambda V(t) = \frac{1}{\mathrm{i}}\left\{\bar{V}\mathrm{e}^{\mathrm{i}\omega(t-t')} - \bar{V}^{\dagger}\mathrm{e}^{-\mathrm{i}\omega(t-t')}\right\}, \quad \bar{V}^{\dagger} = \bar{V}, \quad V(t') = 0,$$

Амплитуда согласно общему выражению (15.40) принимает вид интерференции двух вкладов

$$A_{\mathrm{fi}} = -\mathrm{i}\left\{\frac{\bar{V}_{\mathrm{fi}}}{\hbar(\omega_{\mathrm{fi}}+\omega)}\left(1-\mathrm{e}^{\mathrm{i}(\omega_{\mathrm{fi}}+\omega)(t-t')}\right) - \frac{\bar{V}_{\mathrm{fi}}^{\dagger}}{\hbar(\omega_{\mathrm{fi}}-\omega)}\left(1-\mathrm{e}^{\mathrm{i}(\omega_{\mathrm{fi}}-\omega)(t-t')}\right)\right\},$$

формальный анализ каждого из которых вполне аналогичен рассмотрению постоянного возмущения, но физические выводы существенно отличаются.

Так, во-первых, при $|(\omega_{\mathrm{fi}} \pm \omega)(t-t')| \gg 1$ сильно осциллирующие со временем экспоненты в среднем «вымирают», и амплитуда

$$A_{\mathrm{fi}} \approx \mathrm{i}\frac{2\omega\bar{V}_{\mathrm{fi}}}{\hbar(\omega_{\mathrm{fi}}^2-\omega^2)}.$$

Она мала вдали от резонанса $\omega_{\mathrm{fi}}^2 - \omega^2 = 0$, так как $|\omega_{\mathrm{fi}}^2 - \omega^2| \sim \omega^2$ и $\left|\bar{V}_{\mathrm{fi}}\right| \ll \hbar\omega$. Во-вторых, при $\omega_{\mathrm{fi}} \pm \omega \to 0$ имеет место резонанс, который мы рассмотрим при длительном действии возмущения: $t' \to -\infty, t \to +\infty$. Тогда интегрирование в (15.40) дает

$$A_{\mathrm{fi}} = \frac{\mathrm{i}}{\hbar}\bar{V}_{\mathrm{fi}}\left\{2\pi\delta(\omega_{\mathrm{fi}}+\omega) - 2\pi\delta(\omega_{\mathrm{fi}}-\omega)\right\}.$$

Считая частоту возмущения положительной по определению, заключаем, что один из вкладов отличен от нуля, если только, когда имеет место возбуждение уровня $\omega_{\mathrm{fi}} = \omega$ - вынужденное поглощение энергии квантовой системой за счет возмущения, $E_{\mathrm{f}} = E_{\mathrm{i}} + \hbar\omega$, либо когда происходит переход с вышележащего уровня на нижележащий $\omega_{\mathrm{fi}} = -\omega$

- вынужденное излучение энергии квантовой системой, $E_\mathrm{f} = E_\mathrm{i} - \hbar\omega$. При этом мы установили, что амплитуды индуцированного поглощения и излучения по модулю равны друг другу. В случае излучения, например,

$$|A_\mathrm{fi}|^2 = \frac{1}{\hbar^2}\left|\bar{V}_\mathrm{fi}\right|^2 2\pi\delta\left(\omega_{fi}+\omega\right)2\pi\delta\left(\omega_\mathrm{fi}+\omega\right)\Big|_{\omega_\mathrm{fi}+\omega\to 0} = \frac{1}{\hbar^2}\left|\bar{V}_\mathrm{fi}\right|^2 2\pi\delta\left(\omega_\mathrm{fi}+\omega\right)\left(t-t'\right),$$

где мы опять воспользовались выражением для дельта-функции от частоты при нулевом значении аргумента через полный временной интервал действия возмущения. Поэтому имеет смысл говорить о вероятности (плотности вероятности) перехода системы за единичное время:

$$w_\mathrm{fi} = \frac{\mathrm{d}\left|A_\mathrm{fi}\right|^2}{\mathrm{d}t} = \frac{1}{\hbar}\left|\bar{V}_\mathrm{fi}\right|^2 2\pi\delta\left(E_\mathrm{f}^{(0)} - E_\mathrm{i}^{(0)} + \hbar\omega\right),$$

причем мы внесли $\hbar$ под знак дельта-функции. Если конечное состояние находится в непрерывном спектре со спектральным параметром $\nu = \nu\left(E_f^{(0)}\right)$, то получаем «золотое правило Ферми» для дифференциальной вероятности перехода за единичное время:

$$\mathrm{d}w_\mathrm{fi} = \frac{1}{\hbar}\left|\bar{V}_\mathrm{fi}\right|^2 2\pi\delta\left(E_\mathrm{f}^{(0)} - E_\mathrm{i}^{(0)} + \hbar\omega\right)\mathrm{d}\nu\left(E_\mathrm{f}^{(0)}\right)$$

где $\mathrm{d}\nu\left(E_\mathrm{f}^{(0)}\right)$ - дифференциальная плотность состояний с заданной энергией конечного состояния.

Подчеркнем, что согласно формулам (15.49), (15.50) бесконечно длительное воздействие периодического возмущения приводит к точному закону сохранения энергии для уровней исходной системы в смысле квантового характера поглощения и излучения энергии.

Периодическое возмущение: Details and related concepts

Золотое правило Ферми: More discussion

$$dw_\mathrm{fi} = \frac{1}{\hbar}\left|\bar{V}_\mathrm{f}\right|^2 2\pi\delta\left(E_\mathrm{f}^{(0)} - E_\mathrm{i}^{(0)} + \hbar\omega\right)d\nu\left(E_\mathrm{f}^{(0)}\right)$$

(just tell again and more, what is the sense and how to work with it, because it is an important rule)

Золотое правило ферми at the second order

(?????. нужно будет - освоюсь с этим)

О ширине распада (???)

(?? зачем оно тут написано вообще??)

Если вычислить интегральную вероятность перехода из одного состояния в другое за единицу времени $w_{fi} = \int \mathrm{d}w_\mathrm{fi}$, то можно ввести величину τ с размерностью времени $w_\mathrm{fi} = \frac{1}{\tau}$.

Тогда, если рассмотреть распад в ансамбле из N идентичных квантовых систем в момент времени t, то за время $\mathrm{d}t$ вероятность распада

$$-\frac{\mathrm{d}N(t)}{N(t)} = \frac{\mathrm{d}t}{\tau},$$

что легко интегрируется, и

$$N(t) = N_0 \mathrm{e}^{-\frac{1}{\tau}}.$$

Согласно этому уравнению τ называют временем жизни системы, если имеет место индуцированное излучение и распад, или временем возбуждения, если происходит не распад, а вынужденное поглощение (в этом случае число систем в ансамбле с исходным состоянием также экспоненциально убывает). При этом совершенно ясно, что по прошествии времени τ вероятность индуцированного излучения или поглощения становится близка к единице. Поэтому логично считать критерием применимости теории возмущений для периодического возмущения не малость вероятности перехода за время наблюдения, а несколько иной показатель. Именно, единственным условием, которое должно с необходимостью выполняться в ходе вывода выражения для вероятности перехода в единицу времени, будет достаточная длительность воздействия возмущения, много большая, чем период колебаний возмущения. Этого всегда можно достичь, если только время жизни уровня много больше периода колебаний возмущения:

$$\tau \gg \frac{1}{\omega}$$

Поскольку в резонансе частота колебаний связана с разностью энергий уровней соотношением $\hbar\omega = |\hbar\omega_{\mathrm{fi}}| = \left|E_{\mathrm{f}}^{(0)} - E_{\mathrm{i}}^{(0)}\right| = \Delta E$, условие применимости расчета вероятности перехода за счет периодического возмущения (15.54) можно представить в виде

$$\Gamma \ll \Delta E,$$

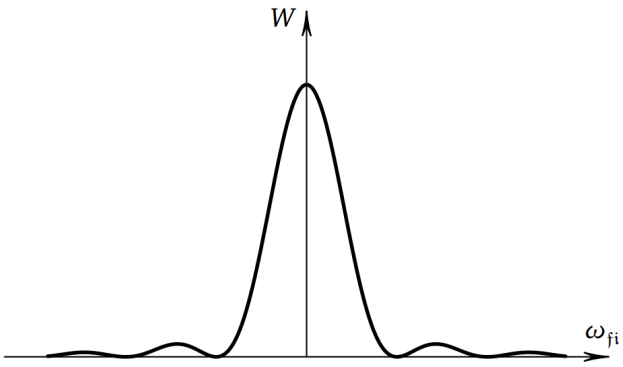
где

$$\Gamma = \frac{\hbar}{\tau}$$

называют шириной перехода.

В задаче с постоянным возмущением мы видели, что дельта-функция, отвечающая закону сохранения энергии, возникает в пределе бесконечно длительного воздействия возмущения. В случае же конечного времени воздействия имеется конечная ширина распределения по энергии, которая связана с временем воздействия соотношением неопределенности время-энергия.

Этот вывод, очевидно, остается справедлив и для периодического возмущения: просто центр распределения на рис. 27 смещается с нуля к величине $\Delta E/\hbar$.



Поскольку характерное время перехода равно τ, соответствующая неопределенность в значении энергии перехода есть $\hbar/\tau = \Gamma$. Поэтому, например, ширина перехода определяет в процессе вынужденного излучения точность определения энергии распадающегося уровня, т. е. ширину уровня.

Другое условие применимости теории возмущений - сходимость ряда по константе связи λ. Степень сходимости можно установить, только вычислив следующую по λ поправку к ширине перехода $\Gamma^{(2)}$ и убедившись, что $\Gamma^{(2)} \ll \Gamma$.

Мгновенное включение возмущения

(??? here, there is a very special theory, and I'll think more about it later again)

При рассмотрении постоянного возмущения мы полагали, что в момент включения возмущения от нулевого значения до $\bar{V}$ состояние системы точно совпадало с одним из квантовых уровней невозмущенной, исходной системы с гамильтонианом $\hat{H}_0$. Однако это предположение нуждается в более детальном исследовании, так как необходимо установить точность такого приближения, учитывая фактическую конечность интервала времени изменения потенциала, и обсудить возможную связь с соотношением неопределенности время-энергия.

Для простоты обозначений будем считать, что в начальный момент времени $t' = 0$ возмущение быстро возрастает от нуля до величины $\bar{V}$ за малое время δt:

$$\lambda V(t) = \bar{V}(s), \quad t = \delta t \cdot s, s \in [0, 1].$$

Гамильтониан как функция параметра s равен

$$\hat{H}(s) = \hat{H}_0 + \bar{V}(s).$$

Оператор эволюции в первом приближении по малому $\delta t-$

$$U(\delta t) = \mathbb{1} - \frac{\mathrm{i}}{\hbar} \int\limits_0^1 \hat{H}(s)\delta t \, \mathrm{d}s = \mathbb{1} - \frac{\mathrm{i}}{\hbar}\delta t \bar{H},$$

где мы ввели «среднее значение» гамильтониана

$$\bar{H} = \int\limits_0^1 \hat{H}(s)\mathrm{d}s.$$

Теперь сразу видно, что

$$\lim_{\delta t \to 0} U(\delta t) = \mathbb{1},$$

т. е. при мгновенном изменении потенциала начальное состояние действительно не изменяется.

Вычислим вероятность найти систему в момент времени δt в состоянии, отличном от начального:

$$w = \sum_{\mathbf{f} \neq \mathrm{i}} |\langle \mathbf{f}|U(\delta t)|\mathrm{i}\rangle|^2 = \sum_{\mathbf{f} \neq \mathrm{i}} \left\langle \mathrm{i} \left| U^\dagger(\delta t) \right| \mathbf{f} \right\rangle \langle \mathbf{f}|U(\delta t)|\mathrm{i}\rangle.$$

(???? tell better, why do we use exactly this approach???)

В силу полноты базиса

$$\sum_{\mathrm{f} \neq \mathrm{i}} |\mathrm{f}\rangle\langle \mathrm{f}| = \mathbb{1} - |\mathrm{i}\rangle \left\langle \mathrm{i} \right| = \bar{P}_\mathrm{i}, \quad \bar{P}_\mathrm{i} \left| \mathrm{i} \right\rangle = 0, \quad \langle \mathrm{i}|\bar{P}_\mathrm{i} = 0, \quad \bar{P}_\mathrm{i}^2 = \bar{P}_\mathrm{i}, \quad \bar{P}_\mathrm{i}^\dagger = \bar{P}_\mathrm{i},$$

здесь $\bar{P}_\mathrm{i}$ это проектор на пространство, ортогональное исходному состоянию $|\mathrm{i}\rangle$, так что

$$w = \left\langle \mathrm{i} \left| U^\dagger(\delta t) \bar{P}_\mathrm{i} U(\delta t) \right| \mathrm{i} \right\rangle.$$

В ведущем приближении использование ортогональности дает

$$\langle \mathrm{i}|U^\dagger(\delta t)\bar{P}_\mathrm{i} = \frac{\mathrm{i}}{\hbar}\delta t \left\langle \mathrm{i}\right|\bar{H}\bar{P}_\mathrm{i}, \quad \bar{P}_\mathrm{i}U(\delta t)\left|\,\mathrm{i}\right\rangle = -\frac{\mathrm{i}}{\hbar}\delta t\bar{P}_\mathrm{i}\bar{H}|\mathrm{i}\rangle,$$

и значит,

$$w = \frac{1}{\hbar^2}(\delta t)^2 \left\langle \mathrm{i}\right|\bar{H}\bar{P}_\mathrm{i}\bar{H}\left|\,\mathrm{i}\right\rangle = \frac{1}{\hbar^2}(\delta t)^2 \left\{\langle \mathrm{i}|\bar{H}\bar{H}|\mathrm{i}\rangle - \langle \mathrm{i}|\bar{H}|\mathrm{i}\rangle^2\right\}.$$

Но выражение в фигурных скобках есть не что иное, как квадрат флуктуации $\delta\bar{H}$ среднего значения гамильтониана,

$$w = \frac{1}{\hbar^2}(\delta t \cdot \delta\bar{H})^2,$$

поэтому вероятность возбуждения состояний, отличных от начального, пренебрежимо мала, $w \ll 1$, если

$$\delta t \cdot \delta\bar{H} \ll \hbar$$

Ясно, что флуктуация среднего значения гамильтониана $\delta\vec{H} \sim \delta E$ определяется величиной малого возмущения $\delta E \sim V$.

Мгновенное включение возмущения: Related concepts

Relation to time-energy uncertainty

(????????????? is it related or not???)

Согласно соотношению неопределенности время-энергия при флуктуации энергии на величину δE состояние, а значит, его волновая функция существенно, т. е. физически значимо, изменится за время

$$\Delta t \geqslant \frac{\hbar}{\delta E}$$

Таким образом, включение возмущения можно считать мгновенным, если состояние не успевает измениться за время δt,

$$\delta t \ll \Delta t \sim \frac{\hbar}{\delta\bar{H}},$$

т. е. интервал времени для инициации возмущения много меньше характерного времени изменения волновой функции за счет изменения энергии.

О нестационарной теории возмущений в вырожденном случае (???)

(вопрос, что делать в этом случае? пока не знаю, потом подумаю.)

Typical illustrative examples of non-stationary PT

О возбуждении осциллятора

Если действует на осциллятор $F\hat{x}e^{-t^2/\tau^2}$, то

$$V_{nm}(t) = -Fe^{-t^2/\tau^2}\langle n|\hat{x}|m\rangle = -\frac{Fe^{-t^2/\tau^2}}{\sqrt{2m\omega}} \cdot \begin{cases} \sqrt{n}, & m = n-1 \\ \sqrt{n+1}, & m = n+1 \end{cases}$$

А формула второго порядка для перехода в состояния, невозможные по первому

$$\partial_t\psi_2^{(2)}(t) = -i\int\limits_{-\infty}^{t} d\tau_1 V_{21}^{(I)}(\tau_1)\,\psi_1^{(1)}(\tau_1) = (-i)^2\int\limits_{-\infty}^{t} d\tau_1 V_{21}^{(I)}(\tau_1)\int\limits_{-\infty}^{\tau_1} d\tau_2 V_{10}^{(I)}(\tau_2)$$

(вроде этого достаточно для задачи, потом проверю, пока не понял теорию возмущений еще)

6.2.5 Perturbation Theory in QFT: Overview

Perturbation theory is so popular and so very powerful, because it is applied in QFT. It is a topic for a whole section, but here we will discuss just main ideas and applications.

(???I'll write it here after I write it in the note of QFT)

6.3 Perturbation theory: Well-known Special Cases and Features

6.3.1 Perturbation Theory in the Continuous Spectrum

Рассмотрим задачу рассеяния в случае, когда к рассеивающему потенциалу добавляется малый возмущающий потенциал. Найдем изменение амплитуды рассеяния по теории возмущений.

Scattering on a finite nuclei

В качестве примера изучим рассеяние заряженных частиц на атомных ядрах и вычислим добавку к амплитуде кулоновского рассеяния из-за конечности ядра.

Пусть гамильтониан системы равен

$$H = H_0 + H',$$

где H' - малая добавка, причем известно решенне задачи с гамильтонианом H_0:

$$H_0\varphi_p = E_p\varphi_p.$$

Граничные условия, налагаемые на φ_p в случае задачи рассеяния (непрерывный спектр), могут быть двух типов:

$$\varphi_p^{\pm} \longrightarrow e^{ipr} + \frac{f_{\pm}}{r}e^{\pm ipr}.$$

Из них физический смысл имеют лишь функции φ_p^+, соответствующее расходящейся сферической волне, однако для вспомогательных целей бывают удобны и Φ_p. Каждая из систем функций φ_p^+ или φ_p^- является полной ортогональной системой, т. е.

$$\int \varphi_p^{+*}\varphi_{p'}^{+}dr = \int \varphi_p^{-*}\varphi_{p'}dr = (2\pi)^3\delta\left(p - p'\right)$$

Требуется найти решение уравнения Шредингера

$$H\Psi_p = E_p\Psi_p,$$

или

$$\left(H_0 - E_p\right)\Psi_p = -H'\Psi_p.$$

Решение уравнения (2.1) будем искать в виде суммы решения невозмущенной задачи $(H_0 - E_p)\Psi_p = 0$, т. е. φ_p^+, и добавки, которую удобно разложить по собственным функциям φ_p^- невозмущенной задачи, т. е.

$$\Psi_p = \varphi_p^+ + \int \frac{dp'}{(2\pi)^3}C_{pp'}\varphi_{p'}$$

(можно было бы сделать разложение и по φ_p^+, но мы увидим далее, что разложение по функциям φ_p^- удобнее).

Для того чтобы описывать рассеяние, Ψ_p должна удовлетворять граничному условию

$$\Psi_p \underset{r\to\infty}{} e^{ipr} + \frac{f}{r} e^{ipr}.$$

Функция φ_p^+ удовлетворяет этому условиют

$$\varphi_p^+ \underset{r\to\infty}{\longrightarrow} e^{ipr} + \frac{f_0}{r} e^{ipr}$$

(f_0 - амплитуда рассеяния невозмущенной задачи). Поэтому должно быть

$$\int \frac{dp'}{(2\pi)^3} C_{pp'} \varphi_{p'} \underset{r\to\infty}{\longrightarrow} \frac{f_1}{r} e^{ipr}.$$

Определим $C_{pp'}$. Умножим (2.1) слева на $\varphi_{p'}^{-*}$. Учитывая $I_0 \varphi_{p'} = E_{p'} \varphi_{p'}^-$и интегрируя по T, получаем

$$(E_{p'} - E_p) \int \varphi_{p'}^{-*} \Psi_p dr = -\int \varphi_{p'}^{-*} H' \Psi_p dr$$

или, сокращенно,

$$(E_{p'} - E_p) (\varphi_{p'} (\Psi_p) = - (\varphi_{p'} |H'| \Psi_p)$$

При $|\boldsymbol{p}| \neq |\boldsymbol{p}'|$ согласно (2.2) получаем

$$\left(\varphi_{p'}^- | \Psi_p\right) = \left(\varphi_{p'}^- | \varphi_p^+\right) + \int \frac{dp''}{(2\pi)^3} C_{pp''} \left(\varphi_{p'}^- | \varphi_{p''}^-\right) = \int \frac{dp''}{(2\pi)^3} C_{pp''} \delta\left(p' - p''\right) (2\pi)^3 = C_{pp'}$$

Здесь использовано то, что при $|p| \neq |p'|$ функции $\varphi_{p'}$ и φ_p^+ортогональны. Из (2.4) находим:

$$C_{pp'} = \frac{(\varphi_{\bar{p}'} |H'| \Psi_p)}{E_p - E_{p'}}.$$

Следовательно,

$$\Psi_p = \varphi_p^+ + \int \frac{dp'}{(2\pi)^3} \frac{\left(\varphi_{p'}^- |H'| \Psi_p\right)}{E_p - E_{p'}} \varphi_{p'}^-$$

Интегральное уравнение (2.5) эквивалентно дифференциальному уравнению (2.1). Запись уравнения для Ψ_p в интегральной форме имеет то преимущество, что в этой форме удобно получать последовательные приближения. Именно:

$$\begin{aligned}
\Psi_p^{(0)} &= \varphi_p^+, \\
\Psi_p^{(1)} &= \int \frac{dp'}{(2\pi)^3} \frac{\left(\varphi_{p'} |H'| \varphi_p^+\right)}{E_p - E_{p'}} \varphi_{p'}^- \\
\Psi_p^{(2)} &= \int \frac{dp'}{(2\pi)^3} \frac{\left(\varphi_{p'} |H'| \Psi_p^{(1)}\right)}{E_p - E_{p'}} \varphi_{p'}^-
\end{aligned}$$

и т. д.

Подынтегральное выражение (2.5) [или (2.6)] имеет особую точку при $|\boldsymbol{p}| = |p'|$. Мы увидим, что способ обхода особой точки определяет асимптотический вид Ψ_p, т. е. ставит граничные условия. Мы покажем, что именно указанный на рис. 17 способ обхода (а не обход сверху и не интеграл в смысле главного значения) дает граничные условия (2.3).

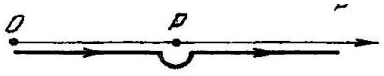


Рис. 17.

Перейдем к вычислению интеграла в выражении (2.6) для $\Psi_{p'}$ ири $r \longrightarrow \infty$. Функция $\varphi^-_{p'}$при $r \to \infty$ имеет вид

$$\varphi_{\overrightarrow{p}} \overrightarrow{r \to \infty} e^{ip'rx} + \frac{f_i^-}{r} e^{-ip'r},$$

где

$$x = \cos \angle (p'r)\,.$$

Первое слагаемое этого выражения приводит к интегралу в (2.6) вида

$$\int\limits_{-1}^{1} F(x) e^{tp'rx} dx.$$

Интегрируя по частям, имеем

$$\int\limits_{-1}^{1} F(x) e^{ip'rx} dx = \frac{1}{ip'r} e^{ip'rx} F(x)\Big|_{-1}^{1} - \frac{1}{ip'r} \int\limits_{-1}^{1} e^{ip'rx} \frac{dF}{dx} dx \underset{r\to\infty}{\approx} \frac{F(1)e^{ip'r} - F(-1)e^{-ip'r}}{ip'r}.$$

Гокажем, что часть этого выражения, содержащая $e^{-ip'r}$, исчезает в пределе $r \longrightarrow \infty$ при интегрировании по dp'. Нужно оценить интеграл

$$\frac{1}{r} \int\limits_{\Omega} \frac{dp'}{E_p - E_{p'}} e^{-ip'r} \Phi\,(p')\,.$$

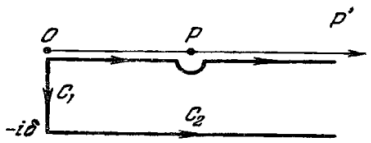

Рис. 18.

Контур интегрирования изображен на рис. 17. Заменим контур интегрирования на $C_1 + C_2$ (рис. 18), взяв δ достаточно малым, чтобы между старым и новым контуром не было особых точек. Тогда величина интеграла (2.7) не изменится. $= e^{-i\xi r} \cdot e^{-\hat{\partial} r}$ иле по $C_2 p' = \xi - i\delta, \quad \delta > 0$, поэтому $e^{-ip'r} =$ (2.7), и, следовательно, при $r \longrightarrow \infty$ весь интеграл по C_2 экспоненциально мал. На участке $C_1 p' = -it$, и получается интеграл

$$\frac{1}{r} \int\limits_{0}^{\delta} \frac{e^{-rt}}{E_p - E_{it}} (\mathrm{D}(t) dt.$$

При $r \longrightarrow \infty$ интервал для t, существенный в подынтегральном выражении (2.8), порядка $[0, 1/r]$, следовательно, E_{it} мало в этом интервале, $E_{it} \ll E_p$. Поэтому интеграл (2.8) порядка $\frac{1}{r} \int\limits_0^\delta e^{-rt} dt \sim \frac{1}{r^2}$, т. е. мал степенным образом.

По тем же соображениям мала степенным образом и часть интеграла в (2.6), содержащая слагаемое $\frac{f_i^-}{r} e^{-ip'\tau}$ асимптотического выражения для $\varphi_{p'}$. В этом и состоит преимущество базисных функций φ_p^- по сравнению с φ_p^+.

Следовательно, в (2.6) остается лишь интеграл с $e^{ip'r}$. Для его вычисления выбираем контур, изображенный на рис. 19.

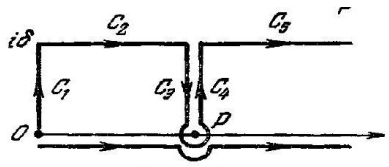

Рис. 19.

Как и для интеграла с $e^{-ip'r}$, в этом случае интеграл по C_2+C_5 будет экспоненциально мал, а по C_1 - мал степенным образом. Интегралы по C_3 и C_4 взаимно уничтожатся. Следовательно, весь интеграл сводится к вычету в точке $p'=p$:

$$\Psi_p = \varphi_p^+ + 2\pi i \frac{2\pi p'^2}{(2\pi)^3} \cdot \frac{\left(\varphi_{p'}!H'|\varphi_p^+\right)}{dE_p/dp} \frac{e^{ip'r}}{ip'r},$$

где $p' = p\frac{r}{r}$. Окончательно:

$$\Psi_p = \varphi_p^+ - \frac{p}{2\pi v}\left(\varphi_{p'}\left|H'\right|\varphi_p^+\right)\Big|_{p'=p\frac{r}{r}} \cdot \frac{e^{ipr}}{r}.$$

Итак, Ψ_p имеет нужную асимптотику:

$$\Psi_p = e^{ipr} + \frac{(f_0+f_1)}{r} e^{ipr},$$

причем

$$f_1 = -\frac{p}{2\pi v}\left(\varphi_{p'}^-\left|H'\right|\varphi_p^+\right)\Big|_{p'=p\frac{r}{r}}$$

Для нерелятивистских частиц можно заменить $p/v = m$.

В случае свободного движения φ_p^+и $\varphi_{\bar{p}}^-$- плоские волны, $f_0 = 0$, и мы получаем амплитуду рассеяния в так называсмом борновском приближении:

$$f_1 = -\frac{p}{2\pi v}\int HI'(r')\, e^{iqr'}dr',$$

где

$$q = p - p\frac{r}{r}$$

передаваемый импульс при рассеянии: $|q| = 2p\sin\frac{\theta}{2}$, а θ - угол рассеяния.

критерий применимости теории возмущений в непрерывном спектре

Найдем критерий применимости теории возмущений в непрерывном спектре. Принцип отыскания критерия любого приближенного расчета состоит в том, что приближенно вычисленная физическая величина должна быть велика по сравнению с поправко к ней от следующего порядка приближения.

В рассматриваемом случае дополнительная амплитуда рассеяния равна

$$-\frac{m}{2\pi}\int \varphi_{p'} H' \Psi_p dr'$$

В первом порядке теории возмуценин $\Psi_p = \varphi_p^+$и

$$f_1 = -\frac{m}{2\pi}\int \varphi_{p'} H' \varphi_p^+ dr'$$

Во втором порядке теории возмущений

$$f_2 = -\frac{m}{2\pi}\int \varphi_p \overline{p'} H' \Psi_p^{(1)} dr' \sim m\int \varphi_{p'} H' \frac{f_1}{r'} e^{ipr'} dr'$$

Условие $f_2/f_1 \ll 1$ служит критерием применимости решения в рассматриваемой задаче.

Iусть a - порядок величины области пространства, в которой возмущаюшее поле $H'(r)$ заметно отлично от нуля. Рассмотрим сначала случай $pa \leqslant 1$. Тогда функции $\varphi_p^{\pm}(a)$ по порядку величины равны единице. Следовательно, амплитуда f_1 порядка $H'(a)a^3$ и слабо зависит от угла рассеяния. Поэтому $f_2/f_1 \sim H' f_1 a^2/f_1 \sim H' a^2$ и критерий теории возмущений имеет вид

$$H' a^2 \ll 1$$

Рассмотрим теперь случай $pa \geqslant 1$. Более подробно этот случай исследован в 3.1. Рассеяние в этом предельном случае больших энергий резко анизотропно и направлено вперед. Действительно, в выражении (2.9) величина

$$\varphi_{p'}^{*}\varphi_p^{+} \sim e^{iqr} \sim e^{ipa\sin\frac{\theta}{2}}$$

сильно осциллирует при $pa \gg 1$ для всех углов рассеяния θ, кроме $\theta \leqslant 1/pa \ll 1$. Для углов рассеяния $\theta \leqslant 1/pa$ величина $\varphi_{p'}^{-*}(a)\varphi_p^{+}(a)$ по порядку величины равна 1 и амплитуда рассеяния имеет оценку

$$f_1(\theta) \underset{\theta\leq 1/pa}{\sim} H'(a)a^3$$

Для углов $\theta \gg 1/pa$ амплигуда $f_1(\theta)$ сущиествнно уменьиается нз-3а осцилляцни волновых функций $\varphi_p^{\pm}$.

6.3.2 Scattering of Charged Particles on Nuclei

Рассеяние заряженных частиц на атомном ядре

В качестве примера рассмотрим рассеяние заряженных частиц (электронов или μ имезонов) на атомном ядре. Будем считать, что заряд ядра равномерно распределен по его объему. Тогда потенциальная энергия частицы:

$$V = \begin{cases} -\frac{Z}{R}\left(\frac{3}{2} - \frac{1}{2}\frac{r^2}{R^2}\right), & 0 < r < R \\ -\frac{Z}{r} & , \quad r > R. \end{cases}$$

Здесь Z - заряд ядра, R - радиус ядра. Следовательно,возмущение имеет вид

$$H' = \begin{cases} -\frac{Z}{R}\left(\frac{3}{2} - \frac{1}{2}\frac{r^2}{R^2}\right) + \frac{Z}{r}, & 0 < r < R \\ 0 & r > R. \end{cases}$$

Согласно (2.9) дополнительная амплитуда рассеяния равнз

$$f_1 = -\frac{1}{2\pi}\int \varphi_{p'}^{-*} H' \varphi_p^{+} dr \approx -\frac{1}{2\pi}\varphi_{p^*}{}^{*}(0)\varphi_p^{+}(0)\int H' dr$$

Действительно, H' изменяется на расстоянии порядка R, а φ_p - на расстоянии порядка $1/p$. Для не слишком больших скоростей элегтронов $pR \ll 1$ (в атомных единицах $R \leq 10^{-4}$). Гоэтому в зыражении для f_1 функции $\varphi_{p'}^{-}$и φ_p^{+} можно выносить из-под знака интеграла в точке $r = 0$.

Вычисление дает

$$\int H' dr = \frac{2\pi Z R^2}{5}.$$

Следовательно,

$$f_1 = -\frac{ZR^2}{5}\varphi_p^{-*}(0)\varphi_p^{+}(0).$$

Кулоновские нерелятивистские волновые функции $\varphi_p^{\pm}(0)$ равны:
для поля отталкивания:

$$\varphi_p^{\pm}(0) = \frac{1}{\sqrt{(2\pi)^3}} e^{-\pi/2p}\Gamma\left(1 \pm \frac{i}{p}\right),$$

для поля притяжения

$$\varphi_p^{\pm}(0) = \frac{1}{\sqrt{(2\pi)^3}} \epsilon^{\pi/2p}\Gamma\left(1 \mp \frac{i}{p}\right),$$

где $\Gamma\left(1 \pm \frac{i}{p}\right)$ - гамма-функция. Окончательно получаем:

$$f_1 = -\frac{1}{80\pi^3}\frac{ZR^2}{a_0} e^{\pm 2\pi/p}\Gamma^2\left(1 \pm \frac{i}{p}\right),$$

где знак минус относится к потенциалу отталкивания, а плюс - к потенциалу притяжения; a_0-боровский радиус.

Дифференциальное сечение рассеяния $d\sigma/d\Omega$ равно

$$d\sigma/d\Omega = |f_0 + f_1|^2,$$

где f_0 - амплитуда кулоновского рассеяния. Поскольку f_1 не зависит от угла рассеяния, а f_0 убывает с увеличением угла рассеяния, то учет конечности ядра существен при больших углах рассеяния.

Критерий применимости теории возмущений в этом случае ($pR \ll 1$)-это $H'R^2 \ll 1$ или $2R^2 \ll 1$; он выполняется для всех реальных ядер.

Мы не интересовались рассеянием налетающей частицы на атомных электронах. Амплитуды такого рассеяния можно вычислить, зная атомный форм-фактор. При не слишком малых углах рассеяния влиянием атомных электронов можно пренебречь.

6.3.3 Perturbation of Boundary Conditions and Levels of a Deformed Nucleus

Теория

В этом разделе рассматривается случай, когда возмущение наложено на граничные условия. Преобразованне координат позволяет привести граничные условия к невозмущенному виду. Однако оно изменяет выражение для гамильтониана системы. Это изменение гамильтониана и есть возмущающий потенциал, влияние которого можно рассмотреть с помощью обычной теории возмущений. Теория поясняется на примере расчета одночастичных энергетических уровней деформированного ядра.

Пусть нам известно решение стационарной (или нестационарноӈ) задачи с гамильтонианом $H(x)$ и граничным условием на некоторой поверхности S_0:

$$\alpha\Psi + \beta\Psi'|_{S_0} = 0.$$

Требуется найти решение задачи с тем же гамильтонианом $H(x)$, но с граничным условием

$$\alpha\Psi + \beta\Psi'|_S = 0,$$

причем поверхность S близка к S_0 (эта близость и есть малый параметр в задаче). Для рсшсния задачи следует найти такое преобразование координат $x_i = f_i\left(x'_j\right)$, что $S(x) = S_0\left(x'\right)$, Т. е. в новых переменных уравнение поверхности ирежнее. Иными словами, если уравнение поверхности S_0 есть $\Phi_0\left(x_j\right) = 0$, а $S - \Phi\left(x_j\right) = 0$, то должно быть

$$\Phi\left(f_i\left(x'_j\right)\right) = \Phi_0\left(x'_j\right).$$

Гамильтониан $H\left(x_i\right) = H\left(f_i\left(x'_j\right)\right)$ в новых переменных изменяется. Мы можем запииать его в виде

$$H\left(x'_j\right) + H'\left(x'_i\right),$$

где $H'\left(x'_j\right) = H\left(f_i\left(x'_j\right)\right) - H\left(x'_j\right)$ и есть возмунение. Далее применгма уже обытная тсорня возмущений.

Энергетические уровни деформированного ядра

Пусть известны стационарные уровни энергии в сферическом ящике, а нужно найти их в эллипсоидальном ящике (стенки считаем бесконечно высокими). Уравнение поверхности S_0 имеет вид

$$\Phi_0\left(x_j\right) = 0: \quad \sum_{i=1}^{3} x_i^2 - R^2 = 0,$$

а уравнение поверхности S есть

$$\Phi\left(x_j\right) = 0: \quad \sum_{j=1}^{3} \frac{x_j^2}{a_j^2} - 1 = 0.$$

Введем новые переменные:

$$x_j = \frac{a_j x'_i}{R}.$$

Тогда $\Phi\left(f_i\left(x'_j\right)\right) = \Phi_0\left(x'_j\right)$. При этом изменяется оператор кинетической энергии частицы:

$$T\left(x_i\right) = -\frac{1}{2M}\sum_{i=1}^{3}\frac{\partial^2}{\partial x_i^2} = -\frac{R^2}{2M}\sum_{i=1}^{3}\frac{1}{a_i^2}\frac{\partial^2}{\partial x_i'^2}.$$

Следовательно, возмущение имеет вид

$$H'\left(x'_i\right) = -\frac{1}{2M}\sum_{i=1}^{3}\left(\frac{a^2}{R^2} - 1\right)\frac{\partial^2}{\partial x_i'^2}.$$

Оно малб, если все a_i близки к R.

Рассмотрим эллипсопда.тьную деформацию ядра, считая эллипсоид двухосным (с полуосями a и b). Параметром деформации называется величина

$$\beta = 2\frac{a-b}{a+b}.$$

Считаем, что объем ядра не меняется при его деформации, т. е. $ab^2 = R^3$. Если написать $a = R(1+\delta), b = R\,(1-\delta_1)$, где $\delta, \delta_1 \ll 1$, то в первом приближении из $ab^2 = R^3$ получим $\delta - 2\delta_1 = 0$, т. е.

$$\beta = 2\frac{R\,(1+2\delta_1) - R\,(1-\delta_1)}{2R} \approx 3\delta_1,$$

или

$$a \approx R\left(1 + \frac{2}{3}\beta\right)$$
$$b \approx R\left(1 - \frac{1}{3}\beta\right)$$

Тогда возмущение H' принимает следующий вид:

$$H' = -\frac{1}{2M}\left\{\left[\frac{R^2}{R^2\left(1+\frac{2}{3}\beta\right)^2} - 1\right]\frac{\partial^2}{\partial z^2} + \left[-\frac{R^2}{R^2\left(1-\frac{1}{3}\beta\right)^2} - 1\right]\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right)\right\} \approx$$
$$\approx -\frac{\beta}{3M}\left(\Delta - 3\frac{\partial^2}{\partial z^2}\right).$$

Пусть ε^0_{nlj} - энергия частиц без учета деформации ядер (от магнитного квантового числа она не зависит в силу сферической симметрии поля). С учетом деформации в первом порядке теории возмущений получаем

$$\varepsilon_{nljm} = \varepsilon^0_{nlj} + \left(\varphi^{(0)}_{nljm}\,|H'|\,\varphi^{(0)}_{nljm}\right).$$

В результате расıета находим

$$\varepsilon_{nljm} = \varepsilon^0_{nlj}\left[1 + \beta\left(\frac{m^2}{j(j+1)} - \frac{1}{3}\right)\right].$$

Зависимость ε_{nljm} от β схсматически изображенана рис. 20.

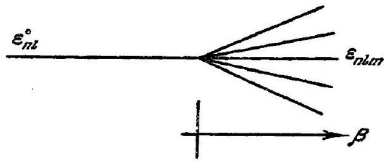

Рис. 20.

Заметим, что $\frac{1}{2j+1}\sum_{nijm} = \varepsilon^0_{nlj}$, т. е. центр тяжести мультиплета не смещается при деформации ядра.

3 ад ач а. Вычислить ε_{nln} В квазиклассицеском приближении.

6.3.4 Sudden Perturbations and Ionization in Decay and Nuclear Impact

Теория

В рассматриваемых до сих пор примерах малым пара. метром задачи было относительное изменение гамильтониана системы. Изучим случай, когда малым параметром является время действия возмущения, но само возмущение не мало.

Ионизация при β-распаде-один из примеров такого возмущения. В этом случае скорость β-распадного электрона много больше скоростей атомных электронов. Поэтому изменение заряда ядра-внезапное событие для них. Другой пример-ионизация при ударе быстрой частицы о ядро. В этом случае внезапным событием для атомных электронов служит отдача ядра.

Рассмотрим систему, волновая функция которой подчиняется уравнению Шредингера $i\frac{\partial\Psi}{\partial t} = H\Psi$ с гамильтонианом

$$H = \begin{cases} H_1(r), & t < 0, \\ H_2(r), & t > \tau. \end{cases}$$

Предположим, что гамильтониан системы сильно изменяется за короткое время τ. Введем полную систему функциія гамильтониана H_2:

$$H_2\varphi_n^{(2)} = \varepsilon_n^{(2)}\varphi_n^{(2)}$$

и разложим реиение задачи Ψ по функіиям $\Phi_n^{(2)}$:

$$\Psi(t) = \sum_n a_n(t)\varphi_n^{(2)}e^{-i\varepsilon_n^{(2)}t}$$

Запишем гамильтониан H в виде $H = H_2 + (H - H_2) = H_2 + V$. Тогда

$$i\frac{\partial\Psi}{\partial t} = i\sum_n \varphi_n^{(2)}e^{-i\varepsilon_n^{(2)}t}\left(\frac{da_n}{dt} - i\varepsilon_n^{(2)}a_n\right)$$
$$H\Psi = \sum_n a_n(t)e^{-i\varepsilon_n^{(2)}t}\left(\varepsilon_n^{(2)}\varphi_n^{(2)} + V\varphi_n^{(2)}\right)$$

откуда

$$i\frac{da_n}{dt} = \sum_m V_{nm}e^{-i\left[\varepsilon_m^{(2)} - \varepsilon_n^{(2)}\right]t}a_m(t).$$

Этот результат мог быть получен и без вычислений. Если временно обозначить $b_n(t) = a_n(t)e^{-i\varepsilon_n^{(2)}t}$, то фактически разложение $\Psi(t) = \sum\limits_n b_n(t)\varphi_n^{(2)}$ означает переход от координатного к энергетическому представлению гамильтониана H_2. Уравнение Шредингера в новом представлении имеет такой вид:

$$i\frac{\partial b_n}{\partial t} = \sum_m \left[\varepsilon_n^{(2)}\delta_{nm} + V_{nm}\right]b_m$$

откуда сразу же получаем уравнение (2.11).

Интегрируя полученное уравнение, имеем

$$a_n(t) - a_n(0) = -i\sum_m \int_0^t V_{nm}a_m(t)e^{-i\left[\varepsilon_m^{(2)} - \varepsilon_n^{(2)}\right]t}$$

Матричный элемент V_{nm} обращается в нуль при $t \gg \tau$. Предположим, что $\left(\varepsilon_n^{(2)} - \varepsilon_m^{(2)}\right)\tau \ll 1$. Тогда экспонента под интегралом приближенно равна единице. Следовательно, для того чтобы пользоваться последовательными приближениями, должно выполняться условие $V\tau \ll 1$ (возмущение не является малым, но оно действует короткое время).

В нулевом приближении из (2.12) имеем $a_n^{(0)}(t) = a_n(0)$. Заменяя в правой части уравнения (2.12) в первом приближении $a_m(t)$ на $a_m(0)$, получим

$$a_n^{(1)}(t) = -i\sum_m \int_0^t \left(\varphi_n^{(2)}|V|\varphi_m^{(2)}\right) a_m(0)dt$$

Так как

$$\sum_m a_m(0)\varphi_m^{(2)} = \Psi(0),$$

то в первом приближении находим

$$a_n^{(1)}(t) = -i\int_0^t \left(\varphi_n^{(2)}|V|\Psi(0)\right) dt.$$

Предположим, что начальное состояние $\Psi(0)$ было одной из собственных функций H_1, т. е.

$$\Psi(0) = \varphi_{n_0}^{(1)} = \sum a_n(0)\varphi_n^{(2)}.$$

Следовательно, $a_n(0) = \left(\varphi_{n_0}^{(1)}|\varphi_n^{(2)}\right)$. Итак, в нулевом приближении вероятность перехода в состояние $\varphi_n^{(2)}$ есть

$$W_{nn_0} = \left|\left(\varphi_{n_0}^{(1)}|\varphi_n^{(2)}\right)\right|^2.$$

В пространстве векторов $\Psi(t)$ с базисом φ_n внезапное возмущение соответствует сильному изменению базиса: $\varphi_n^{(1)} \longrightarrow \varphi_n^{(2)}$, при малом изменении волновой функции: $\Psi(t) \approx \Psi(0)$.

Ионизация атомов при β-распаде

Расчет ионизации атома при β-распаде сильно упрощается, если использовать тот факт, что скорость β-распадного электрона много больше скоростей атомных электронов. Покажем, что ионизация вызывается изменением заряда ядра, а непосредственным взаимодействием атомного и β-распадного электронов можно пренебречь.

Сначала оценим вероятность электронного перехода, вызываемого непосредственным взаимодействием. Согласно теории возмущений она равна

$$W = \frac{1}{\hbar}\left|\int_0^\infty V_{nn_0}e^{i\omega_{nn_0}t}dt\right|^2.$$

Здесь V_{nn_0} - матричный элемент энергии взаимодействия, а ω_{nn_0} - частота перехода.

Оценим это выражение. Величина ω_{nn_0} имеет порядок атомных частот. Время пролета β-распадного электрона τ много меньше атомных периодов, т. е. $\omega_{nn_0}\tau \ll 1$. Поэтому в (2.14) можно заменить $e^{i\omega_{nn_0}t} \longrightarrow 1$. Взаимодействие $V\beta$-электрона атомным электроном

имеет порядок величины e^2/a, где a - величина порядка атомных размеров. Так как при β-распаде электрон вылетает из атома со скоростью порядка скорости света c, то время вылета $\tau \sim a/c$. Следовательно, вероятность W имеет оценку:

$$W \sim \frac{1}{\hbar^2} V^2 \tau^2 \sim \frac{1}{\hbar^2} \left(\frac{e^2}{a} \frac{a}{c} \right)^2 \sim \left(\frac{e^2}{\hbar c} \right)^2 \ll 1.$$

Вычислим теперь вероятность ионизации вследствие изменения заряда ядра. Как мы только что видели, волновая функция атомных электронов мало меняется за время вылета β-распадного электрона. Поэтому вероятность ионизации электрона, находившегося в состоянии Ψ_0^Z в поле ядра с зарядом Z, согласно (2.13) равна

$$W_{0,E} = \left| \left(\Psi_0^Z | \Psi_E^{Z+1} \right) \right|^2.$$

Здесь Ψ_E^{Z+1} - волновая функция вылетевшего электрона с энергией $E > 0$ в поле ядра с зарядом $Z + 1$. Полная вероятность ионизации из-за изменения заряда ядра равна

$$W_0 = \int_0^\infty W_{0,E} dE.$$

Оценим (2.16). Для этого разложим функцию $f(Z_1, Z_2) = \left(\Psi_0^{Z_1} | \Psi_E^{Z_2} \right)$ в ряд по разности $Z_1 - Z_a$:

$$f(Z_1, Z_2) \approx \left(\Psi_0^{Z_1} | \Psi_E^{Z_1} \right) + (Z_1 - Z_2) \left. \frac{\partial f}{\partial Z_1} \right|_{z_1 = z_2} = (Z_1 - Z_2) \left. \frac{\partial f}{\partial Z_1} \right|_{Z_1 = z_2}.$$

Производная $\left. \frac{\partial f}{\partial Z_1} \right|_{Z_1 = Z_2} = \left(\Psi_E^{Z_1} | \frac{\partial \Psi_0^{Z_1}}{\partial Z_1} \right) \sim \frac{1}{Z_1}$. Следовательно, $\left(\Psi_0^{Z_1} | \Psi_E^{Z_2} \right) \sim \frac{Z_1 - Z_2}{Z_1} = \frac{1}{Z_1}$, т.е.

$$W_0 \sim \frac{1}{Z^2}.$$

Итак, относительное влияние непосредственного взаимодействия имеет порядок величины

$$\left(\frac{Ze^2}{\hbar c} \right)^2 = \left(\frac{Z}{137} \right)^2 \ll 1.$$

Оно выполняется для всех ядер, кроме самых тяжелых.

Из (2.14) можно сделать заключение о правилах отбора для рассматриваемого процесса. В случае ионизации внутренних оболочек самосогласованное поле, в котором движется электрон, можно считать сферически симметричным, следовательно, $\Psi = R_{nl}(r) Y_{lm}(\theta, \varphi)$. Подставляя это Ψ в (2.14), получим правила отбора:

$$l_1 = l_2, \quad m_1 = m_2.$$

Для наружных оболочек эффективный заряд Z, действующий на атомные электроны, порядка 1. Следовательно, согласно (2.17) и вероятность ионизации $W_k \sim 1$. Это подтверждается экспериментами по накоплению положительных ионов при $\beta\pm$-распаде, Вероятность ионизации можно вычислить до конца для K - и L-оболочек. В этих случаях существенна область вболизи ядра, где функции Ψ_0^Z и Ψ_E^{Z+1} можно считать водородоподобными (пользование водородоподобными функциями вносит погрешность порядка $1/Z$).

Вероятность ионизации быстро убывает, когда энергия вылетающего электрона становится много больше потенциала ионизации. Действительно, в этом случае функция

Ψ_E^{Z+1} много раз осциллирует на атомных размерах ининтеграл (2.15) мал. Таким образом, вылетающие электроны имеют энергию между нулем и величиной порядка потенциала ионизации.

Получим вероятность ионизации для K-электрона, когда энергия вылетающего атомного электрона много больше потенциала ионизации. Радиальная волновая функция R_E^{Z+1} при больших энергиях должна совпадать с радиальной функцией свободной частицы:

$$R_E^{Z+1} \sim \frac{1}{r}\sqrt{\frac{\overline{2}}{\pi k}}\sin kr.$$

$E \to \infty$

Здесь $k = \sqrt{2E}$. Функция R_E нормирована на интервал энергий

$$\int\limits_0^\infty R_E R_E \cdot r^2 dr = \delta\left(E - E'\right).$$

Следовательно,

$$W_{1E} = \left|\int\limits_0^\infty R_1^Z R_E^{Z+1} r^2 dr\right|^2_{E\to\infty} \approx \frac{2}{\pi k}\left|\int\limits_0^\infty R_1^Z \sin krr dr\right|^2$$

Для K-электрона $R_1^Z = 2Z^{3/2}e^{-Zr}$. Следовательно, нужно вычислить интеграл $I = \int\limits_0^\infty re^{-Zr}\sin krdr\mathrm{np}k \longrightarrow \infty$. Интегрируя его по частям, получаем $I \approx 2Z/k^3$ (интеграл вычпслялся в 1.1, стр. 19, и на стр. 53).

Итак, при $E \geqslant Z^2$ вероятность ионизации K-электрона приближенно равна:

$$W_{1E} \approx \frac{8Z^3}{\pi k}\left(\frac{2Z}{k^3}\right)^2 = \frac{32}{\pi}\frac{Z^5}{k^7} \text{ или } \underset{E\to\infty}{W_{1E}} \approx \frac{2\sqrt{2}}{\pi}\frac{Z^5}{E^{7/2}}.$$

Ионизация атомов при ядерных реакциях

При ядерных столкновениях с большой передачей энергии должна пронсходить ионизация атомов отдачи. Если скорость, приобретенная ядром, невелика, то ядро успевает увлечь электроны, и ионизация происходит только в наружных, слабо связанных оболочках. Наоборот, при больших скоростях ядро вылетает из оболочки, не увлекая ее за собой.

Вычислим вероятность ионизации при ударе нейтрона о ядро. Времь! соударения нейтрона с ядром $\tau \sim R/v_\mathrm{f}$, где R - радиус ядра, $v_\mathrm{н}$ - скорость нейтрона. Это время много меньше электронных периодов τ. ГПоэтому за время столкновения электронная волновая функция практически не меняется.

Если обозначить через v_s скорость, приобретенную ядром, то смещение l ядра за время соударения имеет порядок величины $l \sim v_\mathrm{g}\tau \sim \frac{v_\mathrm{G}}{v}R \sim \frac{M_\mathrm{H}}{M_\mathrm{g}}R < R$, т. е. l много меньше размеров электронной оболочки. Следовательно, ядро практически не смещается за время удара.

Перейдем к системе координат, в которой ядро после соударения покоится. Тогда волновая функция начального состояния преобразуется в выражеиие

$$\Psi_0 \longrightarrow e^{iv_0\Sigma r_i}\Psi_0\left(r_1, r_2, \ldots\right),$$

где ϑ - скорость отдачи ядра. Это выражение проще всего получить, разлагая Ψ_0-функцию по плоским волнам и сдвигая каждый из импульсов этих волн на величинну

σ. Пусть $\Psi_1(\boldsymbol{r}_1, \tau_2, \ldots)$ обозначает конечное состояние атома. Вероятность возбуждения согласно (2.13) равна

$$W = \left|\left(\Psi_1 \left| e^{iv_1 \Sigma r_i} \right| \Psi_0\right)\right|^2.$$

Критерий применимости этой формулы: $\tau \ll \tau$. Его можно записать также в виде $\frac{R}{v} \ll \frac{a}{v_э}$ или $v \gg \frac{R}{a} v_э$, где a - величина порядка размеров изучаемой оболочки.

Из выражения (2.18) можно гоолучит формулу для вероятности перехода одного фиксированного электрона. Так как взанмодействне между электронами мало по сравнению с полем ядра при $Z \gg 1$, то

$$W = W_1 W_2,$$

где W_1 - вероятность перехода рассматрнваемого электрона, а W_2 - вероятность возбуждения всех остальных электронов.

Суммируя по всем конечным состояниям, получим $\sum\limits_1 W_1 = 1, \sum\limits_2 W_2 = 1$. Следовательно, вероятность перехода рассматриваемого электрона из состояния ψ_0 в состояние ψ_n ра ВНа

$$W = W_1 \sum_2 W_2 = 1 \int \psi_n e^{i\psi_1 r} \psi_0 dr \Bigg|^2$$

Если скорость ядра много меньшге скорости электрона но $\boldsymbol{v} \gg v_a \frac{R}{a}\big)$, то экспоненту в (2.19) можно разложить в ряд. Нулевой член разложения исчезает из-за ортогональности функций Ψ_0 и Ψ_n. Пусть скорость v_{nuc} направлена по оси $\boldsymbol{z}$. Тогда

$$W = v_a^2 \left|(\Psi_n|z|\Psi_0)\right|^2.$$

Наоборот, если $v_a \geqslant v_3$, то экспонента $e^{iv\Sigma r_i}$ в (2.18) [или (2.19)] быстро осциллирует. Следовательно, вероятность перехода W не мала, только если $\Psi_1 \sim e^{-iw\Sigma r_i}$, т. е., когда электроны в новой системе движутся со скоростью - $\boldsymbol{r}_я$ В лабораторной системе координат это соответствует тому, что электронная оболочка не увлекается ядром при ударе.

Если скорость ядра $\boldsymbol{v}$ больше скорости внешних электронов, но меньше скорости внутренних электронов, т. е. $1 < v_я < Z$, то внутренние оболочки атома увлекаются ядром, а наружные - нет. Заряд получающегося иона равен по порядку величины числу электронов на наружных оболочках.

Такне соображения позволяют оценить заряд осколков при делении. Заряд определяется как чнсло электронов со скоростями, менышими чем скорость осколка (см. стр. 85).

Для атома водорода и для внутренних оболочек другнх атомов вычисления можно довести до конца. Вероятность ионизации и возбуждения для этих случаев приводится в задачах.

Оценим полную вероятность возбуждения и ионизации W при $v \ll 1$.Π_3(2.20) находим

$$W = C_1 v_{r_3}^2$$

где C_1 - число порядка единицы. Из решения задачи 6 следует, что вероятность атому водорода остаться в основном соттоянии равна

$$W_{00} = \frac{1}{\left(1 + \frac{1}{4} v_9^2\right)^4}.$$

Отсюда находим, что для атома водорода $C_1 = 1$.

Передача энергии при вылете кванта из ядра молекулы (эффект Мёссбауэра)

Предположим, что квант с энергией $\hbar\omega$ вылетает из ядра, входящего в молекулу. Если ω мало, то молекула получает слабый толчок и воспринимает отдачу как единое целое. Если $\hbar\omega$ велико, то ядро вылетает из молекулы происходит возбуждение системы (те же соображения применимы и к металлам: при малом ω отдачу воспринимает вся кристаллическая решетка).

Оценим время вылета τ кванта из ядра; τ - это время пролета пакета радиуса $\lambda = c/\omega$ через область ядра, т. е. $\tau \sim \lambda/c = 1/\omega$. Эта оценка неверна при $\lambda < R$, где R - радиус ядра, т. е. при $\omega > c/R \sim 137 \cdot 10^4 .27$ зв ~ 0 Мэв.

Время τ ничтожно по сравнению с временами, характеризующими колебания и вращения молекулы. Следовательно, Ψ-функция молекулы не успевает измениться за время вылета кванта. Задача напоминает задачу об ионизации при ядерных реакциях. Волновая функция молекулы в начальный момент после испускания кванта имеет вид

$$\Psi' = \Psi\left(r_1, r_2, ...\right) e^{iMvr_1},$$

где v - скорость отдачи, r_1 - радиус-вектор ядра, из которого вылетел квант, M - масса атома. Функция Ψ описывает основное состояние молекулы. Вероятность того, что молекула останется невозбужденного, равна

$$W_0 = \left|\left(\Psi_0 \left| e^{iMvr_1} \right| \Psi_0\right)\right|^2.$$

Если $Mvr_1 \ll 1$, то $W_0 \sim 1$, т. е. отдача воспринимается всей молекулой, возбуждения нет. Оценим частоту γ-квана ω, начиная с которой возбуждаются колебательные степени свободы молекулы. Как мы увидияi, амплитуда колебаний чмеет порядок величины $1/\sqrt[4]{M}$. Поэтому в (2.21)$r_1 \sim 1/\sqrt[4]{M}$. Следовательно, для того чтобы колебания не возбуждались, должно быть $Mv\frac{1}{\sqrt[4]{M}} \ll 1$. Так как импульс ядра $p_{\text{и}} = Mv$ равен импульсу кванта $\hbar\omega/c$, это условие означает, что $\hbar\omega/c \ll \sqrt[4]{M}$, чли $\omega \ll 137\sqrt[4]{M}$ (в атомных единицах ; в эв:

$$\omega \ll 137\sqrt[4]{100 \cdot 1840} \cdot 27 \ \ni \approx \sim 70\kappa \ni \ э$$

(здесь взято ядро с $A \sim 100$).

Критерий применимостя (2.21):

$$\hbar\omega \gg \hbar\omega_{\text{кол}} \ \sim 1/\sqrt{M} \sim \frac{27}{\sqrt{100 \cdot 1840}} \sim 0,06 \geqslant 6,$$

где $\omega_{\text{кол}}$ - колебательная частота молекулы.

Оненим теперь частоту кванта, начиная с которой возбуждаются вращательные стенени свободы молекулы. Для элого рассмотрим плоский ротатор. Его волновая функция $\psi_m = e^{im+\varphi}$, Вероятность перехода из состояния ψ_0 В состояние ψ_m согласно (2.21) равна

$$w_{m0} = \left|\int \Psi_m e^{iMvr} \psi_0 dr\right|^2 \sim \left|\int_0^{2\pi} e^{im\hbar\varphi + iMva\cos\varphi} d\varphi\right|^2$$

где a - величина порядка размеров молекулы.

Следовательно, для того цтобы вращательнье уровни не возбуждались, необходимо, чтобы момент колнчества движения $\sim$ M?a, сообиценный молекуле квантом, был много меньше момента количества двнжения ротатора m$\hbar$. В эпом случае из (2.22) находим $w_{m0} \ll_{m\neq 0} 1$. Для наинизшего возбуiкдения ($m = 1$) получасм

$$Mva \leqslant h \quad \text{или} \quad \frac{h\omega}{c} a \leqslant h,$$

откуда $h\omega \ll c = 137 \cdot 27$ эв ~ 4 кэв.

6.3.5 Collisions in Perturbation Theory: Typical Examples

(?? maybe I'll move later it to the section on atomic physics, but currently I am fine that it is here)

MK-ch2.3.1

Убедиться в том, что отдача ядра не существенна для ионизации атома при β-распаде.

MK-ch2.3.2

Вычислить вероятность возбуждения K-электрона при β-распаде в состояние дискретного спектра с главным квантовым числом n и вероятность того, что электрон останется в s-состоянии ($Z \gg 1$).

О т в г.

$$W_{1n}^{n\neq 1} = 2^6 \frac{(n-1)^{2n-4}}{(n+1)^{2n+4}} n^5 \frac{1}{Z^2}, \quad W_{11} = 1 - \frac{3}{4}\frac{1}{Z^2}.$$

MK-ch2.3.3

Используя метод Томаса - Ферми, оценить заряд осколков при делении ядра, считая его равным числу электронов со скоростью, меньшей скорости осколков.

О т в е Т.

$$Z_{\text{оск}} \sim 8.$$

MK-ch2.3.4

Найти вероятность перехода K-электрона при β-распаде в состояние непрерывного спектра с энергией E и полную вероятность ионизации ($Z \gg 1$).

О т в е г.

$$W_{1E} = 2^7 \frac{e^{-\frac{4Z}{k} \operatorname{arctg} \frac{k}{Z}}}{\left(1 + \frac{k^2}{Z^2}\right)^4 \left(1 - e^{-\frac{2\pi Z}{k}}\right)} \frac{1}{Z^2}, \quad W_1 = \frac{0,32}{Z^2}.$$

MK-ch2.3.5

Оценить ионизацию атома из-за магнитного взаимодействия налетающего нейтрона с электроном.

Or в е г.

$$\frac{W_{\text{MarH}}}{W} \leqslant \left|\frac{V_{\text{MarH}}\tau}{v_{\text{H}}}\right|^2 \sim \left|\frac{\mu_{\text{H}} u_3}{a^3}\frac{R}{v_{\text{H}}^2}\right|^2 \ll \left|\frac{1}{M_{\text{H}}c^2}\frac{1}{R}\right|^2 \sim 10^{-7}.$$

MK-ch2.3.6

Определить вероятность того, что при ударе нейтрона о ядро атома водорода электрон останется в основном состоянии.

О т в Т

$$W_{11} = \frac{1}{\left(1 + \frac{1}{4}v_\Omega^2\right)^4}.$$

MK-ch2.3.7

Вычислить вероятность ионизации атома водорода при столкновении его с нейтроном.

О т в r.

$$W_{0k}dk = 2^8 \frac{v_g^2\left(v_g^2 + \frac{1}{3}k^2 + \frac{1}{3}\right)e^{-\frac{2}{k}\operatorname{arctg}\frac{2k}{v_g^2-k^2+1}}}{\left[(v_s+k)^2+1\right]\left[(v_n-k)^2+1\right]\left[1-e^{-2\pi/k}\right]}kdk.$$

Вычислить полную вероятность ионизации атома водорода при столкновении его с нейтроном, когда скорость ядра много меньше скорости электрона.

Or B e T.

$$W_1 = 0,28v_s^2$$

6.3.6 Perturbation Theory in the Case of Close Levels

Теория

(??? отсюда пока ничего не усвоил, но вроде как тут все просто)

Рассмотрим систему с двумя близкими уровнями, на которую наложено возмущение (случай большего числа близких уровней внесет лищь алгебраические усложнения). Пусть возмущение достаточно мало́, так что можно пренебречь примесью состояний с далекими энергиями, между тем как состояния с близкими энергиями смешиваются сильно.

Решение уравнения Шредингера

$$(H_0 + H')\,\Psi == E\Psi,$$

где H' - возмущение, следует искать в виде суперпозиции состояний, соответствующих близким уровням:

$$\Psi = C_1\Psi_1 + C_2\Psi_2,$$

причем функции $\Psi_{1,2}$ удовлетворяют невозмущенному уравнению

$$H_0\Psi_{1,2} = \varepsilon_{1,2}\Psi_{1,2.}$$

Коэффициенты C_1, C_2 в (2.72) имеют одинаковый порядок величины.

Найдем энергетические уровни возмущенной системы. Для этого запишем уравнение Шредингера в представлении C_1, C_2 :

$$\left.\begin{aligned}(E-\varepsilon_1)\,C_1 &= H'_{11}C_1 + H'_{12}C_2,\\ (E-\varepsilon_2)\,C_2 &= H'_{21}C_1 + H'_{22}C_2.\end{aligned}\right\}$$

Коэффициенты C_1, C_2 отличны от нуля, если детерминант системы (2.73) равен нулю, т. е.

$$\begin{vmatrix} E-\varepsilon_1-H'_{11} & -H'_{12} \\ -H'_{21} & E-\varepsilon_2-H'_{22} \end{vmatrix} = 0.$$

Из (2.74) получаем

$$(E-\varepsilon_1-H'_{11})(E-\varepsilon_2-H'_{22}) - |H'_{12}|^2 = 0,$$

откуда

$$E = \frac{\varepsilon_1+\varepsilon_2+H'_{11}+H'_{22}}{2} \pm \sqrt{\frac{(\varepsilon_1+\varepsilon_2+H'_{11}+H'_{22})^2}{4} - (\varepsilon_1+H'_{11})(\varepsilon_2+H'_{22}) + |H'_{12}|^2}.$$

Обозначая $\varepsilon_1 + H'_{11} = \tilde{\varepsilon}_1, \varepsilon_2 + H'_{22} = \tilde{\varepsilon}_2$, окончательно находим

$$E = \frac{\tilde{\varepsilon}_1+\tilde{\varepsilon}_2}{2} \pm \frac{1}{2}\sqrt{(\tilde{\varepsilon}_1-\tilde{\varepsilon}_2)^2 + 4|H'_{12}|^2}.$$

В случае применимости обычной теории возмущений: $|H'_{12}| \ll |\varepsilon_1 - \varepsilon_2|$, из (2.75) получаем

$$E \approx \frac{1}{2}\left\{\tilde{\varepsilon}_1+\tilde{\varepsilon}_2 \pm \left[(\tilde{\varepsilon}_1-\tilde{\varepsilon}_2) + \frac{2|H'_{12}|^2}{\tilde{\varepsilon}_1-\tilde{\varepsilon}_2}\right]\right\},$$

или

$$E^{(1)} \approx \varepsilon_1 + H'_{11} + \frac{|H'_{12}|^2}{\varepsilon_1-\varepsilon_2},$$
$$E^{(2)} \approx \varepsilon_2 + H'_{22} - \frac{|H'_{12}|^2}{\varepsilon_1-\varepsilon_2},$$

что и следовало ожидать. При $H' \longrightarrow 0$ величина $E^{(1)} \to \varepsilon_1$, а $E^{(2)} \to \varepsilon_2$. Наоборот, в случае $\varepsilon_1 = \varepsilon_2 = \varepsilon$ из (2.75) имеем

$$E = \varepsilon + \frac{H'_{11}+H'_{22}}{2} \pm |H'_{12}|.$$

Заметим, что если для какоголибо возмущения, зависящего от - ξ параметра, $H'_{12} \neq 0$, то уровни $E^{(1)}$ $E^{(2)}$, как функции параметра хи не пересекаются, так как в (2.75) $\sqrt{(\tilde{\varepsilon}_1-\tilde{\varepsilon}_2)^2 + 4|H_{12}|^2} > 0$. Уровни энергии при этом имеют вид, изображенный на рис. 22.

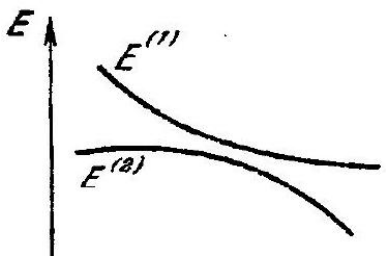

Рис. 22.
(????? подумаю про это больше, пока не очень понял)

Частица в периодическом потенциале

Рассмотрим, как изменяется движение свободной частицы при наложении периодического возмущения

$$V = V_0 \left(e^{ikx} + e^{-ikx}\right).$$

Волновая функция невозмущенной задачи имеет вид $\Psi_p = e^{ipx}$. Среднее значение V по любому невозмущенному состоянию равно нулю, а отличны от нуля лишь матричные элементы $V_{p,p-k} = V_{p,p+k} = V_0$ (длину ямы считаем равной 1). В обычной теории возмущений сдвиг энергетических уровней равен

$$E_p = \varepsilon_p + \frac{V_0^2}{\varepsilon_p - \varepsilon_{p-k}} + \frac{V_0^2}{\varepsilon_p - \varepsilon_{p+k}},$$

где $\varepsilon_p = p^2/2M$. Однако это выражение применимо лишь в случае $V_0 \ll |\varepsilon_p - \varepsilon_{p-k}|$, т. е. когда p не близко $\kappa \pm k/2$. (!?!?!??! поч?? переучу!)

Если $p \to k/2$, то состояния Ψ_p и Ψ_{p-k} имеют близкие энергии, и волновую функцию частицы нужно искать в виде

$$\Psi = C_1\Psi_p + C_2\Psi_{p-k}$$

(при $p \to -k/2 \quad \Psi = C_1\Psi_\mu + C_2\Psi_{p+k}$). Из
(2.75) для собственных значений энергии получаем выражение:

$$E_p = \frac{\varepsilon_p + \varepsilon_{p-k}}{2} \neq \sqrt{\frac{\left(\varepsilon_p - \varepsilon_{p-k}\right)^2}{4} + V_0^2}$$

Выбор знака в (2.77) определяется тем условием, чтобы при $|\varepsilon_p - \varepsilon_{p-k}| \gg V_0$ энергия E_p стремилась к ε_p. Так как при $p < k/2$ величина $\sqrt{\left(\varepsilon_p - \varepsilon_{p-k}\right)^2} = |\varepsilon_p - \varepsilon_{p-k}| = \varepsilon_{p-k} - \varepsilon_p$, а при $p > k/2\sqrt{\left(\varepsilon_p - \varepsilon_{p-k}\right)^2} = \varepsilon_p - \varepsilon_{p-k}$, то для $p < k/2$ в (2.77) нужно взять один знак корня, а при $p > k/2$ - другой.

Для E_p получается разрывная кривая, изображенная на рис. 23.

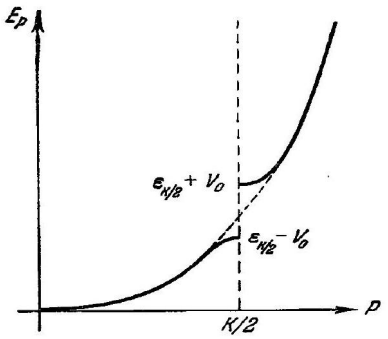

Рис. 23.

При этом величина разрыва равна $E_{k/2+0} - E_{k/2-0} = 2V_0$.

Таким образом, при наложении периодического потенциала в спектре свободных частиц появляется щель (!!!! укажу это в 1 части!!!), Отсюда понятно возникновение запрещенных зон в металлах для электронов (правда, там нужно рассматривать трехмерный случай).

Кз (2.77) следует, что $\left.\frac{dE}{dp}\right|_{p=k/2} = 0$, т. е. групповая скорость тастицы на краю зоны ($p = k/2$) равна нулю. Это соответствует тому, что на краю зонь волновая функция частицы есть стоячая, а не бегущая волна.

Штарк-эффект в случае близких уровней

Рассмотрим систему с двумя близкими уровнями, на которую наложено однородное электрическое поле $V(x) =$. Определим, как изменяется энергия системы в этом поле. Среднее значение V по любому состоянию с определенной четностью равно нулю (дипольный момент $d_x = \int \Psi^*_\lambda(r) x \Psi_\lambda(r) dr$ при замене переменной интегрирования $r \to -r$ переходит в $-d_x$, т. е. $d_x = 0$). Для энергетических уровней системы в поле $E_{1,2}$ получаем:

$$E_{1,2} = \frac{\varepsilon_1 + \varepsilon_2}{2} \pm \sqrt{\frac{(\varepsilon_1 - \varepsilon_2)^2}{4} + |V_{12}|^2}.$$

Рассмотрим, например, состояния $2s_{1/2}$ и $2p_{1/2}$ атома водорода. Они обладают одинаковой энергией (если не учитывать лэмбовского смещения). Расщепление такого дублетного уровня при наложении электрического поля линейно по полю и равно $E_2 - E_1 = 2\,|V_{12}|$.

Вычислим V_{12}. Для состояния $2s_{1/2}$ волновая функция равна $R_{20}(r)\frac{1}{\sqrt{4\pi}}$, а для состояния $2p_{1/2}$ равна $R_{21}\sqrt{\frac{3}{4\pi}}\cos\theta$. $R_{nl}(r)$ - радиальные кулоновские функции. Следовательно, $V_{12} = -\delta\,(R_{20}|r|R_{21})\,\frac{\sqrt{3}}{4\pi}\int \cos^2\theta d\Omega = -\frac{\delta}{\sqrt{3}}\,(R_{20}|r|R_{21})$.

Матричные элементы динольного момента для кулоновских радиальных функций табулированы. В частности, $(R_{20}|r|R_{21}) = 3\sqrt{3}$. Следовательно, $|V_{12}| = 30°$.

Итак, расщепление дублета $2s_{1/2}, 2p_{1/2}$ в слабом электрическом поле в атомных единицах равно 6&.

Заметим, что уровень $2p_{s/2}$ имеет ту же четность, "ito и $2p_{1/2}$. Поэтому $\int \Psi_{2p_{3/2}} x \Psi_{2p_{1/2}} dr = 0$. Следовательно, эти уровни в нашем линейном по полю приближении не расщепляются. Для их расщепления нужно рассматривать суперпозицию трех состояний $-2s_{1/2}, 2p_{1/2}, 2p_{z/2}$.

Для всех других атомов, кроме атома водорода, расщепление термов квадратично по полю: $E = E_0 + \frac{1}{2}\ \propto^2$. Действительно, уровни сложных атомов не вырождены относительно орбитального квантового числа l, т. е. нет состояний с близкими энергиями, которые перемешивались бы в слабом электрическом поле.

Изменение времени жизни состояния $2s_{1/2}$ атома водорода во внешнем электридеском поле

B атоме водорода состояние $2s_{1/2}$ имеет большое время жизни. Действительно, переход $2s_{1_{12}} \to 1s_{1/2}$ может происходить лишь с испусканием двух γ-квантов. Время жизни состояния $2s_{1/2}$ по отношению к этому переходу порядка 1/7 сек. Кроме того, возможен еще дипольный переход $2s_{1/2} \to 2p_{1/2}$ (энергии обоих состояний различаются из-за лэмбовского сменения). Оценим вероятность этого перехода.

В (1.4) мы нашли, что вероятность дипольного перехода w $\sim \omega^3/c^3$, где ω-частота перехода. Разность энергий $\omega = E_{2s_{1/2}} - E_{2p_{1/2}}$ имеет порядок $1/c^3$ (см. стр. 63). Следовательно, w $\sim 1/c^{12}$. В атомных единицах $c \approx 137$, следовательно, $\nsim 10^{-24}$, т. е. время жизни состояния $2s_{1/2}$ по отношению к переходу $2s_{1/2} \to 2p_{1/2}$ порядка $10^{24}\tau$, где $\tau_{\text{ат}}$ - атомное время $\sim 10^{-16}$ сек. Utак, рассматриваемое время $\sim 10^8$ сек. Мы видим, что переход $2s_{1/2} \to 1s_{1/2}$ все же веронтнее, чем переход $2s_{1/2} \to 2p_{1/2}$.

При наложении вненнего поля состояние атома будет суперпозицией состояний $2s_{1/2}$ и $2p_{1/2}$. Но как только атом перейдет в состояние $2p_1/2$ он моментально (за время $\tau \sim 10^{-9}$ сек) совершит дипольный переход: $2p_{1/2} \to 1s_{1/2}$. Мы видим, что время жизни состояния 25%/2 резко изменяется при наложении электрического поля. Итак, будем считать $\Psi =$

$C_1 e^{-i\varepsilon_1 t}\psi_1 + C_2 e^{-i\varepsilon_2 t}\psi_2$, где индекс 1 соответствует состоянию $2s_{1/2}$, а индекс $2-2p_{1/2}$. Для величин C_1, C_2 имеем уравнения

$$i\dot{C}_1 = V_{12}C_2 \exp\left[i\left(\varepsilon_1 - \varepsilon_2\right)t\right]$$
$$i\dot{C}_2 = -i\frac{1}{\tau}C_2 + V_{21}C_1 \exp\left[-i\left(\varepsilon_1 - \varepsilon_2\right)t\right]$$

Здесь $V = -6x$. Матричные элементы $V_{11} = V_{22} = 0$. Затухания состояния $2s_{1/2}$ со временем $\sim 1/7$ сек не учитываем. Даже в отсутствие внешнего поля C_2 не является постоянной: $C_2^{(0)} \sim \exp(-t/\tau)$ из-за взаимодействия с полем излучения. Здесь т имеет порядок времени жизни дипольного состояния ($\tau \sim 10^{-9}$ сек). $C_1^{(0)}$ считаем постоянной, поскольку время затухания состояния $2s_{1/2}$ очень велико. Обозначим $C \equiv C_2 \exp\left(i\varepsilon_{12}t\right)$, где $\varepsilon_{12} \equiv \varepsilon_1 - \varepsilon_2$ - лэмбовское сменение. Тогда из (2.79) имеем:

$$i\dot{C}_1 = V_{12}C, \quad i\dot{C} = V_{21}C_1 - \left(\varepsilon_{12} + i/\tau\right)C.$$

Исключая C_1, получтем $\ddot{C} + \left(-i\varepsilon_{12} + \frac{1}{\tau}\right)\dot{C} + \left|V_{12}^2\right|^2 = 0$. Ищем решение уравнения в виде $C = Ae^{i\omega t}$. Тогда получаем

$$\omega^2 - \omega\left(\frac{i}{\tau} + \varepsilon_{12}\right) - \left|V_{12}\right|^2 = 0,$$

что дает два комплексных корня для ω, причем $\varepsilon_{12} \sim 1/\tau$. В начальный момент времени $C_1(t=0) = 1, C(t=0) = 0$. Начальное условие для C будет выполнено, если искать C в виде $C = a\left[\exp\left(i\omega^{(1)}t\right) - \exp\left(i\omega^{(2)}t\right)\right]$. Из (2.80) находим

$$C_1 = \frac{i\dot{C} + \left(\varepsilon_{12} + i/\tau\right)C}{V_{21}} = \frac{a}{V_{21}}\left\{\left(\frac{i}{\tau} + \varepsilon_{12} - \omega^{(1)}\right)\exp\left(i\omega^{(1)}t\right) + \left(\frac{i}{\tau} - \varepsilon_{12} + \omega^{(2)}\right)\exp\left(i\omega^{(2)}t\right)\right\}.$$

Величина a определяется из условия $C_1(t=0) = 1$:

$$a = V_{21}\left(\frac{2i}{\tau} + \omega^{(2)} - \omega^{(1)}\right)^{-1}.$$

Из уравнения (2.81.) найдем частоты $\omega^{(1)}, \omega^{(2)}$;

$$\omega = \frac{1}{2}\left(\varepsilon_{12} + \frac{i}{\tau}\right) \pm \sqrt{\frac{1}{4}\left(\varepsilon_{12} + \frac{i}{\tau}\right)^2 + \left|V_{12}\right|^2}.$$

Рассмотрим случай $|V_{12}| \ll 1/\tau$. Тогда из (2.82)

$$\omega^{(1)} \approx \varepsilon_{12} + \frac{i}{\tau}, \quad \omega^{(2)} \approx \frac{V_{12}^2}{\varepsilon_{12}^2 + \frac{1}{\tau^2}}\frac{t}{\tau}.$$

Следовательно, состояние $2s_{1/2}$ имеет в этом случае очень большое время жизни $\sim 1/\left|V_{12}\right|^2\tau$.

Рассмотрим теперь противоположный предельный случай, когда наложенное поле столь велико, что $|V_{12}| \gg 1/\tau$. Тогда

$$\omega^{(1.2)} \approx \frac{1}{2}\left(\varepsilon_{12} + \frac{i}{\tau}\right) \pm \left|V_{12}\right| \pm \frac{1}{8\left|V_{12}\right|}\left(\varepsilon_{12} + \frac{i}{\tau}\right)^2$$

и время затухания C_1 становится равным по порядку величины времени жизни дипольного состояния τ.

Итак, время жизни состояния $2s_{1/2}$ атома водорода чрезвычайно сильно (на девять порядков) уменьшается при наложении электрического поля порядка $\mathscr{E} \sim \frac{1}{x_{12}\tau} \sim \frac{1}{\tau} \sim c^{-3} \sim \frac{10^9}{c^3} - B \sim 500B$.

6.3.7 Other Perturbation Theories: Overview

(нужно будет - поразбираю некоторые! пока для меня это просто есть и все, пока не работал с ними почти никак или вообще никак.)

On Schrieffer–Wolff transformation (????)

(так оказывается можно делать, см. вики мб. пока ничего не знаю.)

Суть

In quantum mechanics, the Schrieffer-Wolff transformation is a unitary transformation used to perturbatively diagonalize the system Hamiltonian to first order in the interaction. As such, the Schrieffer-Wolff transformation is an operator version of second-order perturbation theory. The Schrieffer-Wolff transformation is often used to project out the high energy excitations of a given quantum many-body Hamiltonian in order to obtain an effective low energy model.[1] The Schrieffer-Wolff transformation thus provides a controlled perturbative way to study the strong coupling regime of quantum-many body Hamiltonians. Although commonly attributed to the paper in which the Kondo model was obtained from the Anderson impurity model by J.R. Schrieffer and P.A. Wolff., [2] Joaquin Mazdak Luttinger and Walter Kohn used this method in an earlier work about non-periodic $k \cdot p$ perturbation theory. [3] Using the Schrieffer-Wolff transformation, the high energy charge excitations present in Anderson impurity model are projected out and a low energy effective Hamiltonian is obtained which has only virtual charge fluctuations. For the Anderson impurity model case, the Schrieffer-Wolff transformation showed that the Kondo model lies in the strong coupling regime of the Anderson impurity model.

см мб то, что гуглится: Bravyi, Sergey, DiVincenzo, David P, см. сп. літературы.

Derivation

Consider a quantum system evolving under the time-independent Hamiltonian operator H of the form:

$$H = H_0 + V$$

where H_0 is a Hamiltonian with known eigenstates $|m\rangle$ and corresponding eigenvalues E_m, and where V is a small perturbation. Moreover, it is assumed without loss of generality that V is purely off-diagonal in the eigenbasis of H_0, i.e., $\langle m|V|m\rangle = 0$ for all m. Indeed, this situation can always be arranged by absorbing the diagonal elements of V into H_0, thus modifying its eigenvalues to $E'_m = E_m + \langle m|V|m\rangle$. The Schrieffer-Wolff transformation is a unitary transformation which expresses the Hamiltonian in a basis (the "dressed" basis) where it is diagonal to first order in the perturbation V. This unitary transformation is conventionally written as:

$$H' = e^S H e^{-S}$$

When V is small, the generator S of the transformation will likewise be small. The transformation can then be expanded in S using the BakerCampbell-Haussdorf formula

$$H' = H + [S, H] + \frac{1}{2}[S, [S, H]] + \ldots$$

Here, $[A, B]$ is the commutator between operators A and B. In terms of H_0 and V, the transformation becomes

$$H' = H_0 + V + [S, H_0] + [S, V] + \frac{1}{2}[S, [S, H_0]] + \frac{1}{2}[S, [S, V]] + \ldots$$

The Hamiltonian can be made diagonal to first order in V by choosing the generator S such that

$$V + [S, H_0] = 0$$

This equation always has a definite solution under the assumption that V is off-diagonal in the eigenbasis of H_0. Substituting this choice in the previous transformation yields:

$$H' = H_0 + \frac{1}{2}[S, V] + O\left(V^3\right)$$

Overview of applications of Schrieffer–Wolff transformation (????)

(?? in condensed matter, in SC. but I'll learn it later)

k·p perturbation theory (??)

(см. вики)

In solid-state physics, the k·p perturbation theory is an approximated semi-empirical approach for calculating the band structure (particularly effective mass) and optical properties of crystalline solids.[1][2][3] It is pronounced "k dot p", and is also called the k·p method. This theory has been applied specifically in the framework of the Luttinger–Kohn model (after Joaquin Mazdak Luttinger and Walter Kohn), and of the Kane model (after Evan O. Kane).

6.3.8 Other Properties of Perturbation Theories

Let's discuss features of perturbation theories, which are 100% not needed to know for basic understanding.

Двойные переходы в рамках теории возмущений (?????)

Допустим, система находится на одном уровне. Она может перейти на второй в рамках 1го порядка ТВ. Дальше с него в рамках 2го порядка она может вернуться на 1-й. Может ли эта вероятность перехода во 2м порядке повлиять на суммарную вероятность остаться в 1м состоянии? Или же вероятность остаться во 2м порядке такая же, как и без учета этого перехода?

(не знаю, мб нет, потому что квантмех так устроен, что у нас только 1 переход между измерениями. Это тот вопрос, который нужно задать настоящим профессионалам.)

Connection of PT method in quantum and classical mechanics

(?? first, I'll write it in classical mechanics)

Connection of PT method in quantum mechanics and in differential equations

(PT is also a typical method for diff eq. so, is it the same as here??)

6.4 Harmonic Oscillator: Basics

Изучим подробно гармонический осциллятор.

6.4.1 Quantization of a Harmonic Oscillator

мотивация

гармонический осциллятор - одна из самых распространенных моделей квантовой механики.

На основе ее и поля квантуются, и показывается, как операторы рождения и уничтожения вводятся (и что еще?) и что только ни делается.

Разберем здесь эту модель.

вкратце теория

Выпишем тезисно все выводы, которые дальше будем получать.

В квантовой механике координатам a и a^* соответствует какая-то пара операторов $\hat{a}$ и $\hat{a}^\dagger$. Константу C удобно выбрать так, чтобы операторы получились безразмерными, что соответствует следующему выбору:

$$\begin{cases} \hat{a} = \frac{1}{\sqrt{2}}(\hat{X} + i\hat{P}) = \sqrt{\frac{m\omega}{2\hbar}}\hat{x} + \frac{i}{\sqrt{2\hbar m\omega}}\hat{p} \\ \hat{a}^\dagger = \frac{1}{\sqrt{2}}(\hat{X} - i\hat{P}) = \sqrt{\frac{m\omega}{2\hbar}}\hat{x} - \frac{i}{\sqrt{2\hbar m\omega}}\hat{p} \end{cases}, \quad \begin{cases} \hat{x} = \sqrt{\frac{\hbar}{2m\omega}}\left(\hat{a} + \hat{a}^\dagger\right) \\ \hat{p} = -i\sqrt{\frac{\hbar m\omega}{2}}\left(\hat{a} - \hat{a}^\dagger\right) \end{cases}$$

(выбор фазы остаётся произвольным - скажем, операторы $\hat{a}e^{i\varphi}$ и $\hat{a}^\dagger e^{-i\varphi}$ ничем не хуже). Наконец, можно выразить через эти операторы также и гамильтониан.

Тривиальной подстановкой, получаем:

$$\hat{H} = \hbar\omega\left(\hat{a}^\dagger\hat{a} + \frac{1}{2}\right)$$

рассмотрим частицу в потенциале $U = m\omega^2 x^2/2$

для него есть функция Гаусса

$$\psi_0(x) = \sqrt[4]{\frac{m\omega}{\pi\hbar}}e^{-\frac{X^2}{2(\hbar/nm\omega)}}$$

волновая функция:

$$\psi_n(x) = e^{-\frac{X^2}{2(\hbar/nm\omega)}}H_n(x)$$

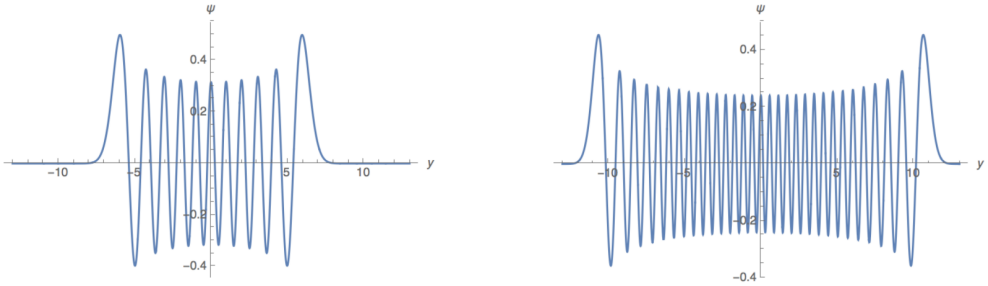

Figure 6.2: Состояния 20-го и 60-го номера по Тонгу

The 3d Harmonic Oscillator

(пока по Тонгу)

The harmonic oscillator provides a particularly simple example of the 3d Schrödinger equation because we can solve it in either Cartesian or polar coordinates. In Cartesian coordinates, the Hamiltonian is

$$\hat{H} = -\frac{\hbar^2}{2m}\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}\right) + \frac{1}{2}m\omega^2\left(x^2 + y^2 + z^2\right)$$

We see that the Hamiltonian just decomposes into three copies of the 1d harmonic oscillator: one for each direction. This means that we can just read off the energy spectrum from our earlier result (2.29). The spectrum of the 3d harmonic oscillator is given by

$$E = \hbar\omega\left(\frac{3}{2} + N\right)$$

where

$$N = n_1 + n_2 + n_3 \quad , n_i = 0, 1, 2, ...$$

All of the subtleties lie in the degeneracy of the spectrum. The ground state has energy $E = \frac{3}{2}\hbar\omega$ and is unique. But there are three excited states with energy $E = \frac{5}{2}\hbar\omega$ associated to exciting the harmonic oscillator in the x, y or z direction. There are then 6 states with energy $E = \frac{7}{2}\hbar\omega$, because we could excite one oscillator twice or two oscillators once each. In general, the degeneracy of the N^{th} level is $\frac{1}{2}(N+1)(N+2)$. How does this look in polar coordinates? It's best to work with the form of the Schrödinger equation (4.13) which is now

$$-\frac{\hbar^2}{2mr^2}\frac{d}{dr}\left(r^2\frac{dR}{dr}\right) + \left(\frac{1}{2}m\omega^2 r^2 + \frac{l(l+1)\hbar^2}{2mr^2}\right)R = ER$$

We're now awash with various constants and life will be easier if we can get rid of a few. We make the same scaling (2.22) that we used for the 1 d oscillator,

$$y = \sqrt{\frac{m\omega}{\hbar}}r \quad \text{and} \quad \tilde{E} = \frac{2E}{\hbar\omega}$$

The Schrödinger equation then becomes

$$\frac{1}{y^2}\frac{d}{dy}\left(y^2\frac{dR}{dy}\right) - \left(y^2 + \frac{l(l+1)}{y^2}\right)R = -\tilde{E}\psi$$

We're going to solve it using the same kind of polynomial expansion that we used for the 1 d harmonic oscillator. First, look at the large distance $y \to \infty$ behaviour. Here the dominant terms are

$$\frac{d^2R}{dy^2} - y^2R \approx 0 \quad \Longrightarrow \quad R \approx e^{-y^2/2} \quad \text{as } y \to \infty$$

Next, look at the behaviour near the origin $y \ll 1$. Here the dominant terms in the equation are

$$\frac{d^2R}{dy^2} + \frac{2}{y}\frac{dR}{dy} - \frac{l(l+1)}{y^2}R \approx 0 \quad \text{for } y \ll 1$$

If we make the power-law ansatz $R \sim y^\alpha$, we find

$$\alpha(\alpha-1) + 2\alpha - l(l+1) = 0 \quad \Longrightarrow \quad R \sim y^l \text{ as } y \to 0$$

Here we've discarded the second solution $\alpha = -(l+1)$ on the grounds that the resulting wavefunction diverges at the origin. Putting this together, our ansatz for the general solution is

$$R(y) = y^l h(y) e^{-y^2/2}$$

where we take

$$h(y) = \sum_{k=0}^{\infty} a_k y^k$$

At this stage we've got a little bit of algebra to do, plugging our ansatz into the Schrödinger equation (4.16). Once the dust settles, you'll find the result

$$\sum_{k=0}^{\infty} a_k \left(k(2l+k+1)y^{l+k-2} + (\bar{E} - (2l+2k+3))y^{l+k} \right) = 0$$

We start our recursion relation by setting

$$a_0 = 1$$

This is just the statement that the small y behaviour is indeed $R \sim y^l$ rather than some higher power. Now note that the first term in our equation will have term proportional to $a_1 y^{l-1}$. But there's nothing to cancel this in the second term. This means that we must set

$$a_1 = 0$$

As we'll see, our recursion relation will then set $a_k = 0$ for all odd k. To find this recursion relation, we shift the summation variable $k \to k+2$ in the first term in (4.18) so that all terms have the same power of y^{l+k},

$$\left[\sum_{k=0}^{\infty} a_{k+2}(k+2)(2l+k+3) + \sum_{k=0}^{\infty} a_k(\bar{E} - (2l+2k+3)) \right] y^{l+k} = 0$$

For this to hold for all y, we must have the following recursion relation

$$a_{k+2} = \frac{\bar{E} - (2l+2k+3)}{(k+2)(2l+k+3)} a_k$$

At this stage, the argument is the same as we used for the 1d harmonic oscillator. If the recursion relation fails to terminate then $a_{k+2} \to 2a_k/k$ for large k, but that's bad: it messes up the $e^{-y^2/2}$ behaviour at large y and turns it into a non-normalisable $e^{+y^2/2}$ behaviour. This means that we must find solutions where the recursion relation terminates. This immediately allows us to read off the energy. If we are to have $a_{2q+2} = 0$ (recall that all a_k for odd k already vanish) then the energy of the state must be

$$E = \hbar\omega \left(\frac{3}{2} + l + 2q \right) \quad l, q = 0, 1, 2, ...$$

Let's compare this to our Cartesian result (4.15). Clearly they agree, but the extra work we did in polar coordinates brings more information: it tells us how the energy depends on the total angular momentum l. In particular, the lowest energy state with angular momentum l has $E = \hbar\omega\left(\frac{3}{2} + l\right)$.

Вырождение пространственного осциллятора (!?!?)

We also have a better understanding of the degeneracy of states. When N is even, the states with energy $E = \hbar\omega\left(\frac{1}{2} + N\right)$ comprise of all even angular momentum states $l = 0, 2, 4, ..., N$. Since there are $2l + 1$ states (4.14) associated to each angular momentum l, the total number of states at level N must be

Total Degeneracy $= \sum_{k=0}^{N/2} 4k + 1 = N\left(\frac{N}{2} + 1\right) + \frac{N}{2} + 1 = \frac{1}{2}(N + 1)(N + 2)$ which agrees with the count from the Cartesian calculation. Similarly, when N is odd the states at energy $E = \hbar\omega\left(\frac{1}{2} + N\right)$ comprise of all odd angular momentum states $l = 1, 3, 5, ..., N$: again, the total count is $\frac{1}{2}(N + 1)(N + 2)$.

Вырождение трехмерного осциллятора

(типичная заготовка, важно разбираться, потом напишу нормально. пока достаточно неплохо в интернете написано.)

Частица массы m_0 движется в трехмерном потенциальном поле

$$U(x, y, z) = \frac{k}{2}\left(x^2 + y^2 + z^2\right),$$

Решение: Поскольку движение частицы вдоль осей x, y и z происходит независимо, то будем искать волновую функцию в виде произведения

$$\psi_2(y) \cdot \psi_3(z) \cdot \frac{d^2\psi_1(x)}{dx^2} + \psi_1(x) \cdot \psi_3(z)\frac{d^2\psi_2(y)}{dy^2} + \psi_1(x) \cdot \psi_2(y) \cdot \frac{d^2\psi_3(z)}{dz^2}$$

$$+\frac{2m_0}{\hbar^2}[E - U(x, y, z)]\psi_1(x) \cdot \psi_2(y) \cdot \psi_3(z) = 0.$$

Разделив это уравнение на $\psi(x, y, z)$ и используя данный в условии задачи вид зависимости $U(x, y, z)$, приходим к соотношению

$$\left[\frac{1}{\psi_1(x)} \cdot \frac{d^2\psi_1(x)}{dx^2} - \frac{2m_0}{\hbar^2} \cdot \frac{kx^2}{2}\right] + \left[\frac{1}{\psi_2(y)} \cdot \frac{d^2\psi_2(y)}{dy^2} - \frac{2m_0}{\hbar^2} \cdot \frac{ky^2}{2}\right] +$$
$$+ \left[\frac{1}{\psi_3(z)} \cdot \frac{d^2\psi_3(z)}{dz^2} - \frac{2m_0}{\hbar^2} \cdot \frac{kz^2}{2}\right] = -\frac{2m_0}{\hbar^2}E.$$

функкцей только координаты Z. Поскольку их сумма равна постоянной величине, то каждое из этих слагаемых также должно равняться постоянной величине

$$\frac{1}{\psi_1(x)} \cdot \frac{d^2\psi_1(x)}{dx^2} - \frac{2m_0}{\hbar^2} \cdot \frac{kx^2}{2} = -\frac{2m_0}{\hbar^2}E_1$$
$$\frac{1}{\psi_2(y)} \cdot \frac{d^2\psi_2(y)}{dy^2} - \frac{2m_0}{\hbar^2} \cdot \frac{ky^2}{2} = -\frac{2m_0}{\hbar^2}E_2$$

нам уже известны (см. (4.81), (4.83)).

n_2un_3

$$\psi_{x_1,x_2,x_3}(x, y, z) = \psi_{x_1}(x) \cdot \psi_{x_i}(y) \cdot \psi_{x_3}(z),$$
$$n_1, n_2, n_3 = 0, 1, 2, 3, ...$$

Для энераии трехмерного гармонического осциллятора получаем следующее выражение

$$E_n = \hbar\omega_0\left(n + \frac{3}{2}\right)$$

где $n = n_1 + n_2 + n_3, n = 0, 1, 2, 3, ...$

Найдем кратность вырождения n - го энергетического уровня трехмерного гармонического осциллятора. Дпя заданного значения n кратность вырождения уровня равна числу возможных перестановок трех чисел n_1. n_2 и n_3, сумма которых раена n. Найдем сначала число перестановок при фиксированном значении n_1. Оно, как легко видеть, равно числу возможных значений n_2 (или, что то же самое, n_3). Число n_2 при заданном n_1 может меняться в пределах от одо $(n - n_1)$, т.е. принимает $n - n_1 + 1$ значение. Следовательно, число перестановок при фиксированном n_1 равно $n - n_1 + 1$. Суммируя это выражение по n_1, находим кратность вырождения n-го уровня K_n

$$K_n = \sum_{n_1=0}^{n} (n - n_1 + 1) = \frac{(n+1)(n+2)}{2}.$$

Основное состояние трехмерного гармонического осциллятора ($n = 0$) оказывается невырожденным, $K_0 = 1$. Первое возбужденное состояние ($n = 1$) имеет кратность вырождения $K_1 = 3$, ему соответствуют тройки квантовых чисел (100), (010), (001)

(ну и поэтому на осциллятор есть задачи с применением вырожденной теории возмущений.)

точное решение

(птф, пока просто скрины)

Поучительно будет рассмотреть вырожденную гипергеометрическую функцию на примере простого гармонического осциллятора - частицы в потенциале $U(x) = \frac{m\omega^2 x^2}{2}$.

Поскольку потенциальная энергия $U(x \to \pm\infty) \to \infty$, то в этом потенциале нет непрерывного спектра, а только дискретный.

Переходя к безразмерной координате $y = x\sqrt{\frac{m\omega}{\hbar}}$ и вводя безразмерную энергию согласно $E = \hbar\omega\left(\epsilon + \frac{1}{2}\right)$, мы получаем уравнение Шрёдингера в виде:

$$\psi''(y) + \left(2\epsilon + 1 - y^2\right)\psi(y) = 0$$

Сделаем замену координат $z = y^2 \to y = \sqrt{z}$:

$$\frac{d\psi}{dy} = 2\sqrt{z}\frac{d\psi}{dz}, \quad \frac{d^2\psi}{dy^2} = 2\sqrt{z}\frac{d}{dz}\left(2\sqrt{z}\frac{d\psi}{dz}\right) = 4z\psi''(z) + 2\psi'(z)$$

$$4z\psi''(z) + 2\psi'(z) + (2\epsilon + 1 - z)\psi(z) = 0$$

Мы получили уравнение с линейными коэффициентами, значит, его можно привести к ${}_1F_1$.

Стандартный способ такой процедуры - это выделение асимптотик.

В частности, при $z \to \infty$, асимптотический вид уравнения выглядит как

$$4z\psi''(z) - z\psi(z) = 0 \to \psi(z) \approx e^{-z/2}.$$

Поэтому мы сделаем подстановку $\psi(z) = \chi(z)e^{-z/2}$; получаем:

$$z\chi''(z) + \left(\frac{1}{2} - z\right)\chi'(z) + \frac{\epsilon}{2}\chi(z) = 0$$

В нашем конкретном случае $b = \frac{1}{2}, a = -\frac{\epsilon}{2}$, и поэтому общее решение уравнения записывается следующим образом:

$$\chi(z) = C_1 \cdot {}_1F_1\left(-\frac{\epsilon}{2}; \frac{1}{2}; z\right) + C_2\sqrt{z} \cdot {}_1F_1\left(-\frac{\epsilon - 1}{2}; \frac{3}{2}; z\right)$$

В общем случае ${}_1F_1 \sim e^z$, что соответствует экспоненциально растущей волновой функции и нас не устраивает, поэтому ряд должен обрываться.

Имеются две альтернативы: что, конечно, исчерпывает все решения задачи о простом гармоническом осцилляторе.

Для справки приведём связь написанных тут гипергеометрических функций с полиномами Эрмита и нормированными волновыми функциями:

(????)

6.4.2 Quantization of a Harmonic Oscillator with Features

возбуждения под действием $-F\hat{x}c^{-t^2}$

Рассмотрим задачу об возбуждении гармонического осциллятора под действием силы, которая действует в течении конечного времени:

$$\hat{H} = \frac{\hat{p}^2}{2m} + \frac{m\omega^2\hat{x}^2}{2} - F\hat{x}c^{-t^2/\tau^2}$$

Допустим, при $t \to -\infty$ мы находились в основном состоянии осциллятора $|i\rangle = |0\rangle$;

ищем мы вероятность перехода в первое и второе возбуждённые состояния.

Определим, какие матричные элементы возмущения вообще отличны от нуля.

Используя лестничные операторы, мы видим, что отличны от нуля только переходы между соседними уровнями:

$$V_{nm}(t) = -Fe^{-t^2/\tau^2}\langle n|\hat{x}|m\rangle = -\frac{Fe^{-t^2/\tau^2}}{\sqrt{2m\omega}} \cdot \begin{cases} \sqrt{n}, & m = n-1 \\ \sqrt{n+1}, & m = n+1 \end{cases}$$

В частности, в первом порядке теории возмущений переход происходит только в первое возбуждённое состояние, разница энергий которых равна $\omega_{10} = \omega$:

$$w_{0\to 1} = \left| -\frac{F}{\sqrt{2m\omega}} \int\limits_{-\infty}^{\infty} e^{-t^2/\tau^2} e^{i\omega t} dt \right|^2 = \frac{\pi F^2 \tau^2}{2m\omega} e^{-\omega^2\tau^2/2}$$

Требуя малость поправки, мы приходим к выводу, что теория возмущений работает по параметру $F^2\tau^2/m\omega \ll 1$ либо $\omega\tau \gg 1$ Чтобы найти вероятность перехода во второе возбуждённое состояние, первого порядка теории возмущений недостаточно, и нужно решить уравнение (5.32) точнее.

Во втором приближении, получаем:

$$\partial_t \psi_2^{(2)}(t) = -i \int\limits_{-\infty}^{t} d\tau_1 V_{21}^{(I)}(\tau_1)\, \psi_1^{(1)}(\tau_1) = (-i)^2 \int\limits_{-\infty}^{t} d\tau_1 V_{21}^{(I)}(\tau_1) \int\limits_{-\infty}^{\tau_1} d\tau_2 V_{10}^{(I)}(\tau_2)$$

а значит, искомая вероятность равна:

$$w_{0\to 2} = \left| \int\limits_{-\infty}^{\infty} d\tau_1 V_{21}(\tau_1)\, e^{i\omega\tau_1} \int\limits_{-\infty}^{\tau_1} d\tau_2 V_{10}(\tau_2)\, e^{i\omega\tau_2} \right|^2 =$$

$$= \frac{2F^4}{(2m\omega)^2} \left| \int\limits_{-\infty}^{\infty} d\tau_1 e^{-\tau_1^2/\tau^2 + i\omega\tau_1} \int\limits_{-\infty}^{\tau_1} d\tau_2 e^{-\tau_2^2/\tau^2 + i\omega\tau_2} \right|^2$$

Можно заметить, что стоящий тут интеграл равен половине такого же интеграла, но с бесконечными пределами $\int\limits_{-\infty}^{\infty} d\tau_1 \int\limits_{-\infty}^{\infty} d\tau_2$ благодаря чему мы можем сразу выписать для него результат:

$$w_{0\to 2} = \frac{\pi^2 F^4 \tau^4}{8m^2\omega^2} e^{-\omega^2\tau^2}$$

Полученный результат оказался параметрически меньше $w_{0\to 1}$, поскольку он связан со вторым порядком теории возмущений.

Математические указания для работы с осциллятором (!?!?)

(это важно, без этого ничего не сделаешь, упершись только в математику.)

применение модели гармонического осциллятора

(укажу потом????)

6.4.3 Harmonic Oscillator by Takhtajan

Простейшая классическая система с одной степенью свободы, за исключением свободной частицы, - это гармонический осциллятор. Он описывается фазовым пространством $\mathbb{R}^2$ с каноническими координатами p, q и функцией Гамильтона

$$H_{\mathrm{c}}(p,q) = \frac{p^2}{2m} + \frac{m\omega^2 q^2}{2}$$

(см. разделы 1.1.5 и 1.1.7 главы 1). Уравнения Гамильтона

$$\dot{p} = \{H_{\mathrm{c}}, p\} = -m\omega^2 q, \quad \dot{q} = \{H_{\mathrm{c}}, q\} = \frac{p}{m}$$

с начальными условиями p_0, q_0 легко решаются:

$$p(t) = p_0 \cos\omega t - m\omega q_0 \sin\omega t$$
$$q(t) = q_0 \cos\omega t + \frac{1}{m\omega} p_0 \sin\omega t$$

и описывают гармоническое движение. Как и в разделе 1.2.6 главы 1, удобно ввести комплексные координаты на фазовом пространстве $\mathbb{R}^2 \simeq \mathbb{C}$,

$$z = \frac{1}{\sqrt{2\omega}}(\omega q + ip), \quad \bar{z} = \frac{1}{\sqrt{2\omega}}(\omega q - ip)$$

Имеем

$$\{z, \bar{z}\} = \frac{i}{m}, \quad H_{\mathrm{c}}(z,\bar{z}) = m\omega|z|^2$$

так что уравнения Гамильтона разделяются:

$$\dot{z} = \{H_{\mathrm{c}}, z\} = -i\omega z, \quad \dot{\bar{z}} = \{H_{\mathrm{c}}, \bar{z}\} = i\omega\bar{z}$$

и тривиально решаются:

$$z(t) = e^{-i\omega t} z_0, \quad \bar{z} = e^{i\omega t}\bar{z}_0$$

Здесь

$$z_0 = \frac{1}{\sqrt{2\omega}}\left(\omega q_0 + ip_0\right), \quad \bar{z}_0 = \frac{1}{\sqrt{2\omega}}\left(\omega q_0 - ip_0\right)$$

Для квантовой системы соответствующий оператор Гамильтона - это

$$H = \frac{P^2}{2m} + \frac{m\omega^2 Q^2}{2}$$

и в координатном представлении $\mathscr{H} = L^2(\mathbb{R}, dq)$ - это оператор Шрёдингера с квадратичным потенциалом,

$$H = -\frac{\hbar^2}{2m}\frac{d^2}{dq^2} + \frac{m\omega^2 q^2}{2}$$

Квантовый гармонический осциллятор - простейшая нетривиальная квантовая система, за исключением свободной частицы, у которой явно решается уравнение Шрёдингера. Он появляется во всех задачах, связанных с квантованными колебаниями, то есть в молекулярных и кристаллических вибрациях. Точное решение гармонического осциллятора, описываемое ниже, обладает замечательными [24] алгебраическими и аналитическими свойствами.

На время положим $m = 1$ и рассмотрим операторы

$$a = \frac{1}{\sqrt{2\omega\hbar}}(\omega Q + iP), \quad a^* = \frac{1}{\sqrt{2\omega\hbar}}(\omega Q - iP)$$

являющиеся квантовыми аналогами комплексных координат (2.30). Операторы a и a^* определены на $W^{1,2}(\mathbb{R}) \cap \widehat{W^{1,2}}(\mathbb{R})$, где $\widehat{W}^{1,2}(\mathbb{R}) = \mathscr{F}\left(W^{1,2}(\mathbb{R})\right)$, и легко показать, что a^* - сопряженный оператор к a и $a^{**} = a$, так что a - замкнутый оператор. Из коммутационных соотношений Гейзенберга (2.2) мы получаем каноническое коммутачионное соотношение

$$[a, a^*] = I$$

на $W^{2,2}(\mathbb{R}) \cap \widehat{W}^{2,2}(\mathbb{R})$. Действительно

$$aa^* = \frac{P^2 + \omega^2 Q^2}{2\omega\hbar} + \frac{i\omega}{2\omega\hbar}[P, Q] = \frac{P^2 + \omega^2 Q^2}{2\omega\hbar} + \frac{1}{2}I,$$

и

$$a^*a = \frac{P^2 + \omega^2 Q^2}{2\omega\hbar} - \frac{i\omega}{2\omega\hbar}[P, Q] = \frac{P^2 + \omega^2 Q^2}{2\omega\hbar} - \frac{1}{2}I$$

так что (2.34) выполняется на $W^{2,2}(\mathbb{R}) \cap \widehat{W}^{2,2}(\mathbb{R})$, где $\widehat{W}^{2,2}(\mathbb{R}) = \mathscr{F}\left(W^{2,2}(\mathbb{R})\right)$, и

$$H = \omega\hbar\left(a^*a + \frac{1}{2}I\right) = \omega\hbar\left(aa^* - \frac{1}{2}I\right).$$

В частности, из критерия фон Неймана следует, что оператор Гамильтона H самосопряжен.

[24] Алгебраическая структура точного решения гармонического осциллятора играет фундаментальную роль в квантовой электродинамике и вообще в квантовой теории поля. Операторы a, a^* и $N = a^*a$ удовлетворяют коммутационным соотношениям

$$[N, a] = -a, \quad [N, a^*] = a^*, \quad [a, a^*] = I.$$

Эти коммутационные соотношения соответствуют неприводимому унитарному представлению четырехмерной разрешимой алгебры Ли $\tilde{\mathfrak{h}}$, ассоциированной с алгеброй

Гейзенберга $\mathfrak{h} = \mathfrak{h}_1$, введенной в разделе 2.2.1. А именно: $\tilde{h}$ - алгебра Ли с образующими e, f, h, и c, где e, f, c удовлетворяют соотношениям алгебры Гейзенберга $\mathfrak{h}$ и

$$[h, e] = -f, \quad [h, f] = \omega^2 e, \quad [h, c] = 0.$$

Неприводимое интегрируемое представление ρ алгебры Гейзенберга $\mathfrak{h}$ (см. (2.9) в разделе 2.2.1) продолжается до унитарного представления алгебры Ли $\tilde{\mathfrak{h}}$, если положить

$$\rho(h) = -i\omega N = \frac{P^2 + \omega^2 Q^2}{2i\hbar} + \frac{i\omega}{2} I$$

ЗАМЕЧАНИЕ. В инвариантных терминах алгебра Ли $\tilde{\mathfrak{h}}$ - одномерное праве расширение алгебры Гейзенберга $\mathfrak{h}$,

$$0 \to \mathfrak{h} \to \tilde{\mathfrak{h}} \to \mathbb{R} \to 0$$

Оно определяется $\mathfrak{h}$-значным 1-коциклом $r \in Z^1(\mathfrak{h}, \mathfrak{h})$ на алгебре Ли - дифференциальным оператором на $\mathfrak{h}$, задаваемым на образующих формулой

$$r(e) = f, \quad r(f) = -\omega^2 e, \quad r(c) = 0$$

Конкретно, если $h \in \tilde{\mathfrak{h}}$ таково, что $\bar{h} = 1 \in \mathbb{R}$ при проекции $\tilde{\mathfrak{h}} \to \mathbb{R}$, то, отождествляя элементы $\mathfrak{h}$ с их образами при вложении $\mathfrak{h} \hookrightarrow \tilde{\mathfrak{h}}$, имеем

$$[x + \alpha h, y + \beta h] = [x, y] - \alpha r(y) + \beta r(y), \quad x, y \in \mathfrak{h}.$$

Как раз благодаря этой Ли-алгебраической структуре коммутационных соотношений (2.35), уравнения движения Гейзенберга для гармонического осциллятора точно решаются. А именно: мы имеем

$$\dot{a} = \{H, a\}_\hbar = -i\omega a, \quad \dot{a}^* = \{H, a^*\}_\hbar = i\omega a^*$$

так что

$$a(t) = e^{-i\omega t} a_0, \quad a^*(t) = e^{i\omega t} a_0^*$$

Сравнивая с (2.32), видим, что решения классических и квантовых уравнений движения гармонического осциллятора имеют один и тот же вид! Далее, используя коммутационные соотношения (2.35) и положительность оператора N, мы решим задачу на собственные значения гамильтониана H гармонического осциллятора, в явном виде определив его уровни энергии и соответствующие собственные вектора. Мы докажем, что собственные вектора образуют полную систему векторов в $\mathscr{H}$, так что спектр гамильтониана H является точечным. Это квантово-механический аналог того факта, что классическое движение гармонического осциллятора всегда финитно.

Алгебраическая часть точного решения состоит из следующего фундаментального результата.

Предложение 2.2.

Допустим, что существует ненулевое $\psi \in D(a^n) \cap \cap D((a^*)^n), n = 1, 2, ...$, такое, что

$$H\psi = \lambda\psi$$

Тогда выполняются следующие утверждения.

(i) Существует $\psi_0 \in \mathscr{H}, \|\psi_0\| = 1$, такое, что

$$H\psi_0 = \frac{1}{2}\hbar\omega\psi_0$$

(ii) Векторы

$$\psi_n = \frac{(a^*)^n}{\sqrt{n!}}\psi_0 \in \mathscr{H}, \quad n = 0, 1, 2, ...,$$

ортонормальные собственные векторы H с собственными значениями $\hbar\omega\left(n + \frac{1}{2}\right)$

$$H\psi_n = \hbar\omega\left(n + \frac{1}{2}\right)\psi_n$$

(iii) Ограничение оператора H на гильбертово пространство $\mathscr{H}_0$ - замкнутое подпространство $\mathscr{H}$, натянутое на ортонормальное множество $\{\psi_n\}_{n=0}^{\infty}$ - самосопряжено в существенном.

ДОКАЗАТЕЛЬСТВО.

Переписывая коммутационные соотношения (2.35) как

$$Na = a(N - I) \quad \text{и} \quad Na^* = a^*(N + I)$$

и положив $\lambda = \hbar\omega\left(\mu + \frac{1}{2}\right)$, получаем для всех $n \geqslant 0$

$$Na^n\psi = (\mu - n)a^n\psi \quad \text{и} \quad N\left(a^*\right)^n\psi = (\mu + n)\left(a^*\right)^n\psi$$

Поскольку $N \geqslant 0$ на $D(N)$, из первого уравнения в (2.36) следует, что существует $n_0 \geqslant 0$, такое, что $a^{n_0}\psi \neq 0$, но $a^{n_0+1}\psi = 0$. Положив $\psi_0 = \frac{a^{n_0}\psi}{\|a^{n_0}\psi\|} \in \mathscr{H}$, получаем

$$a\psi_0 = 0 \quad \text{и} \quad N\psi_0 = 0$$

Поскольку $H = \hbar\omega\left(N + \frac{1}{2}I\right)$, это доказывает часть (i). Для доказательства части (ii) воспользуемся коммутационными соотношениями

$$[a, (a^*)^n] = n\,(a^*)^{n-1}$$

которые следуют из (2.34) и правила Лейбница. Используя (2.37)- (2.38), получаем

$$a^*\psi_n = \sqrt{n+1}\psi_{n+1}, \quad a\psi_n = \sqrt{n}\psi_{n-1},$$

так что

$$\begin{aligned}\|\psi_n\|^2 &= \frac{1}{\sqrt{n}}\left(a^*\psi_{n-1}, \psi_n\right) = \\ &= \frac{1}{\sqrt{n}}\left(\psi_{n-1}, a\psi_n\right) = \|\psi_{n-1}\|^2 = ... = \|\psi_0\|^2 = 1.\end{aligned}$$

Из второго уравнения в (2.36) следует, что $N\psi_n = n\psi_n$, поэтому ψ_n - нормализованные собственные векторы H с собственными значениями $\hbar\omega\left(n + \frac{1}{2}\right)$. Собственные векторы ψ_n ортогональны, поскольку соответствующие собственные значения различны, а оператор H симметрический. Наконец, часть (iii) мгновенно следует из того факта, что, согласно части (ii), подпространства $\mathrm{Im}(H \pm iI)|_{\mathscr{H}_0}$ плотны в $\mathscr{H}_0$, что является критерием самосопряженности в существенном.

ЗАМЕЧАНИЕ. Поскольку координатное представление коммутационных соотношений Гейзенберга неприводимо, заманчиво заключить, используя предложение

2.2, что $\mathscr{H}_0 = \mathscr{H}$. А именно: из построения следует, что линейная оболочка векторов ψ_n - плотное подпространство в $\mathscr{H}_0$ - инвариантна относительно операторов P и Q. Однако из этого не следует сразу, что оператор Π_0 проекции на подпространство $\mathscr{H}_0$ коммутирует с самосопряженными операторами P и Q в смысле определения в разделе 2.1.1.

Используя координатное представление, можно мгновенно показать существование вектора ψ_0 в предложении 2.2 и доказать, что $\mathscr{H}_0 = \mathscr{H}$. Действительно, уравнение $a\psi_0 = 0$ превращается в линейное дифференциальное уравнение первого порядка:

$$\left(\hbar\frac{d}{dq} + \omega q\right)\psi_0 = 0$$

так что

$$\psi_0(q) = \sqrt[4]{\frac{\omega}{\pi\hbar}}e^{-\frac{\omega}{2\hbar}q^2}$$

и

$$\|\psi_0\|^2 = \sqrt{\frac{\omega}{\pi\hbar}}\int\limits_{-\infty}^{\infty} e^{-\frac{\omega}{\hbar}q^2}dq = 1.$$

Вектор ψ_0 называется основным состоянием гармонического осциллятора. Соответственно, собственные функции

$$\psi_n(q) = \frac{1}{\sqrt{n!}}\left(\frac{1}{\sqrt{2\omega\hbar}}\left(\omega q - \hbar\frac{d}{dq}\right)\right)^n\psi_0$$

имеют вид $P_n(q)e^{-\frac{\omega}{2\hbar}q^2}$, где $P_n(q)$ - многочлены степени n. Следующий результат показывает, что функции $\{\psi_n\}_{n=0}^{\infty}$ образуют ортонормальный базис в $L^2(\mathbb{R}, dq)$.

Лемма 2.3. Функции $q^n e^{-q^2}, n = 0, 1, 2, ...$, полны в $L^2(\mathbb{R}, dq)$.

ДОКАЗАТЕЛЬСТвО.

Пусть $f \in L^2(\mathbb{R}, dq)$ таково, что

$$\int\limits_{-\infty}^{\infty} f(q)q^n e^{-q^2}dq = 0, \quad n = 0, 1, 2, ...$$

Интеграл

$$F(z) = \int\limits_{-\infty}^{\infty} f(q)e^{iqz-q^2}dq$$

абсолютно сходится для всех $z \in \mathbb{C}$ и поэтому определяет целую функцию. Имеем

$$F^{(n)}(0) = i^n\int\limits_{-\infty}^{\infty} f(q)q^n e^{-q^2}dq = 0, \quad n = 0, 1, 2, ...$$

так что $F(z) = 0$ для всех $z \in \mathbb{C}$. Из этого следует, что функция $g(q) = f(q)e^{-q^2} \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ удовлетворяет условию $\mathscr{F}(g) = 0$, где $\mathscr{F}$ «обычное» ($\hbar = 1$) преобразование Фурье. Таким образом, мы заключаем, что $g = 0$. Многочлены P_n выражаются через классические многочлены Эрмита-Чебышева H_n, определяемые формулой

$$H_n(q) = (-1)^n e^{q^2} \frac{d^n}{dq^n} e^{-q^2}, \quad n = 0, 1, 2, ...$$

А именно: используя тождество

$$e^{\frac{q^2}{2}} \frac{d^n}{dq^n} e^{-q^2} = -\left(q - \frac{d}{dq}\right)\left[e^{\frac{q^2}{2}} \frac{d^{n-1}}{dq^{n-1}} e^{-q^2}\right] =$$
$$= ... = (-1)^n \left(q - \frac{d}{dq}\right)^n e^{-\frac{q^2}{2}}$$

получаем

$$\psi_n(q) = \sqrt[4]{\frac{\omega}{\pi\hbar}} \frac{1}{\sqrt{2^n n!}} e^{-\frac{\omega}{2\hbar}q^2} H_n\left(\sqrt{\frac{\omega}{\hbar}} q\right).$$

Подытожим полученные результаты следующим образом.

Th.

2.1. Гамильтониан

$$H = -\frac{\hbar^2}{2m}\frac{d^2}{dq^2} + \frac{m\omega^2 q^2}{2}$$

квантового гармонического осциллятора с одной степенью свободы является самосопряженным оператором в $\mathscr{H} = L^2(\mathbb{R}, dq)$ с областью определения $D(H) = W^{2,2}(\mathbb{R}) \cap \widehat{W}^{2,2}(\mathbb{R})$. Оператор H имеет чисто точечный спектр

$$H\psi_n = \lambda_n \psi_n, \quad n = 0, 1, 2, ...,$$

с собственными значениями $\lambda_n = \hbar\omega\left(n + \frac{1}{2}\right)$. Соответствующие собственные функции ψ_n образуют ортонормальный базис Н и даются формулами

$$\psi_n(q) = \sqrt[4]{\frac{m\omega}{\pi\hbar}} \frac{1}{\sqrt{2^n n!}} e^{-\frac{m\omega}{2\hbar}q^2} H_n\left(\sqrt{\frac{m\omega}{\hbar}} q\right)$$

где $H_n(q)$ - классические многочлены Эрмита-Чебытева.

ДОКАЗАТЕЛЬСТВО.

Рассмотрим оператор H, определенный в пространстве Шварца $\mathscr{S}(\mathbb{R})$ быстро убывающих функций. Поскольку оператор H симметрический и имеет полную систему собственных векторов в $\mathscr{S}(\mathbb{R})$, подпространство $\mathrm{Im}(H \pm iI)$ плотно в $\mathscr{H}$, так что H самосопряжен в существенном. Доказательство того, что его самосопряженное замыкание (которое мы попрежнему будем обозначать как H) имеет областью определения пространство $W^{2,2}(\mathbb{R}) \cap \widehat{W}^{2,2}(\mathbb{R})$, остается читателю.

ЗАМЕЧАНИЕ. Уровни энергии гармонического осциллятора можно также получить из правила квантования Бора-Вильсона - Зоммерфельда. Действительно, соответствующая классическая орбита с энергией E - эллипс в фазовой плоскости, задаваемый уравнениями $q(t) = A\cos(\omega t + \alpha)$, $p(t) = -m\omega A \sin(\omega t + \alpha)$, где $E = \frac{1}{2}m\omega^2 A^2$ (см. раздел 1.1.5 главы 1). Таким образом,

$$\oint p dq = \iint dp \wedge dq = \pi m\omega A^2 = \frac{2\pi}{\omega} E$$

и по правилу квантования ББЗ получаются уровни энергии $E_n = \hbar\omega\left(n + \frac{1}{2}\right)$.

ЗАмЕчАниЕ. Поскольку уровни энергии Гамильтона H эквидистантны с интервалом $\hbar\omega$, квантовый гармонический осциллятор описывает систему одинаковых «квантов» с энергией $\hbar\omega$. Основное состояние $|0\rangle = \psi_0$ в дираковских обозначениях - это вакуумное состояние, когда никаких квантов нет и вакуумная энергия равна $\frac{1}{2}\hbar\omega$, а состояния $|n\rangle = \psi_n$ состоят из n квантов с энергией $\hbar\omega\left(n+\frac{1}{2}\right)$. Согласно (2.39) оператор a^* добавляет состоянию $|n\rangle$ один квант, и он называется оператором рождения, а оператор a уничтожает в состоянии $|n\rangle$ один квант и называется оператором уничтожения.

Пример гармонического осциллятора - иллюстрация того, насколько отличается движение в квантовой механике от движения в классической механике. Классическое движение в потенциальном поле $V(q) = \frac{1}{2}m\omega^2q^2$ финитно: частица с энергией E движется в области $|\omega q| \leqslant \sqrt{\frac{2E}{m}}$, тогда как для квантовой частицы всегда есть ненулевая вероятность обнаружиться за пределами классической области. Так, для энергии $E = \frac{1}{2}\hbar\omega$ основного состояния эта вероятность равна

$$\int\limits_{|q|\geqslant\sqrt{\frac{\hbar}{m\omega}}} |\psi_0(q)|^2\,dq = \frac{2}{\sqrt{\pi}}\int\limits_1^\infty e^{-x^2}dx \simeq 0,1572992070.$$

Классический гармонический осциллятор с n степенями свободы описывается фазовым пространством $\mathbb{R}^{2n}$ с каноническими координатами $\boldsymbol{p},\boldsymbol{q}$ и функцией Гамильтона

$$H_{\mathrm{c}}(\boldsymbol{p},\boldsymbol{q}) = \frac{\boldsymbol{p}^2}{2m} + \sum_{j=1}^n \frac{m\omega_j^2q_j^2}{2}$$

где $\omega_1,...,\omega_n > 0$ (см. разделы 1.1.3 и 1.1.7 главы 1).

Соответствующий оператор Гамильтона есть

$$H = \frac{\boldsymbol{P}^2}{2m} + \sum_{j=1}^n \frac{m\omega_j^2Q_j^2}{2}$$

в координатном представлении $\mathscr{H} = L^2\left(\mathbb{R}^n, d^n\boldsymbol{q}\right)$ это оператор Шрёдингера с квадратичным потенциалом,

$$H = -\frac{\hbar^2}{2m}\Delta + \sum_{j=1}^n \frac{m\omega_j^2q_j^2}{2}$$

Гамильтониан H - самосопряженный оператор с $D(H) = W^{2,2}\left(\mathbb{R}^n\right) \cap \cap\widehat{W}^{2,2}\left(\mathbb{R}^n\right)$ с чисто точечным спектром. Соответствующие собственные функции

$$\psi_{\boldsymbol{k}}(\boldsymbol{q}) = \psi_{k_1}\left(q_1\right)...\psi_{\boldsymbol{k}_n}\left(q_n\right)$$

где $\boldsymbol{k} = (k_1,...,k_n)$ и $\psi_{k_j}\left(q_j\right)$ - это собственные функции (2.40)с$\omega = \omega_j$, образуют ортонормальный базис в $L^2\left(\mathbb{R}^n, d^n\boldsymbol{q}\right)$. Соответствующие уровни энергии даются формулами

$$\lambda_k = \hbar\omega_1\left(k_1+\frac{1}{2}\right) + ... + \hbar\omega_n\left(k_n+\frac{1}{2}\right)$$

Спектр H является простым, если и только если $\hbar\omega_1,...,\hbar\omega_n$ линейно независимы над $\mathbb{Z}$. Самый вырожденный случай $-\omega_1 = ... = \omega_n = \omega$, тогда кратность собственного значения

$$\lambda_k = \hbar\omega\sum_{j=1}^n\left(k_j+\frac{1}{2}\right)$$

это статистическая сумма $p_n(|\boldsymbol{k}|)$, т. е. число представлений целого числа $|\boldsymbol{k}| = k_1 + ... + k_n$ в виде суммы n неотрицательных целых чисел. Положив $m = 1$ и вводя операторы [25]

$$a_j = \frac{1}{\sqrt{2\omega\hbar}}\left(\omega Q_j + iP_j\right),$$
$$a_j^* = \frac{1}{\sqrt{2\omega\hbar}}\left(\omega Q_j - iP_j\right),$$

получаем канонические коммутационные соотношения операторов рождения и уничтожения для n степеней свободы:

$$[a_j, a_l] = 0, \quad \left[a_j^*, a_l^*\right] = 0, \quad [a_j, a_l^*] = \delta_{jl} I, \quad j, l = 1, ..., n,$$

обобщающие соотношение (2.34) для одной степени свободы. Операторы a_j, a_j^* и $N_j = a_j^* a_j, j = 1, ..., n$, удовлетворяют коммутационным соотношениям

$$[N_j, a_l] = -\delta_{jl} a_l, \quad [N_j, a_l^*] = \delta_{jl} a_l^*, \quad j, l = 1, ..., n.$$

В частности, оператор

$$N = \sum_{j=1}^{n} N_j = \sum_{j=1}^{n} a_j^* a_j$$

удовлетворяет соотношениям

$$[N, a_j] = -a_j, \quad \left[N, a_j^*\right] = a_j^*, \quad j = 1, ..., n,$$

и $H = \hbar\omega\left(N + \frac{n}{2} I\right)$.

Коммутационные соотношения (2.42) и (2.43) соответствуют неприводимому унитарному представлению разрешимой алгебры Ли $\tilde{\mathfrak{h}}_n$ с $3n + 1$ образующими e_j, f_j, h_j и c, где e_j, f_j, c удовлетворяют соотношениям алгебры Гейзенберга $\mathfrak{h}_n$, и

$[h_j, e_l] = -\delta_{jl} f_l, \quad [h_j, f_l] = \delta_{jl}\omega_l^2 e_l, \quad [h_j, c] = 0, \quad j, l = 1, ..., n.$

ЗАДАчА 2.9. Покажите, что $\langle H|M\rangle \geqslant \frac{1}{2}\hbar\omega$ для любого $M \in \mathscr{S}$, где H - гамильтониан гармонического осциллятора с одной степенью свободы.

[25] Здесь мы, используя стандартную евклидову метрику на $\mathbb{R}^n$, опустили индексы у Q^j. ЗАДАЧА 2.10. Пусть $q(t) = A\cos(\omega t + \alpha)$ - классическая траектория гармонического осциллятора с $m = 1$ и энергией $E = \frac{1}{2}\omega^2 A^2$, и пусть μ_α - вероятностная мера на $\mathbb{R}$, сконцентрированная в точке $q(t)$. Покажите, что выпуклая линейная комбинация мер $\mu_\alpha, 0 \leqslant \alpha \leqslant 2\pi$, является вероятностной мерой на $\mathbb{R}$ с функцией распределения $\mu(q) = \frac{\theta\left(A^2 - q^2\right)}{\pi\sqrt{A^2 - q^2}}$, где $\theta(q)$ - функция Хевисайда.

ЗАДАчА 2.11. Покажите, что когда $n \to \infty$ и $\hbar \to 0$, так что $\hbar\omega\left(n + \frac{1}{2}\right) = \frac{1}{2}\omega^2 A^2$ остается постоянным, огибающая функции распределения $|\psi_n(q)|^2$ на интервале $|q| \leqslant A$ совпадает с классической функцией распределения $\mu(q)$ из предыдущей задачи. (Указание: докажите, что существует интегральное представление

$$e^{-q^2} H_n(q) = \frac{2^{n+1}}{\sqrt{\pi}} \int_0^\infty e^{-y^2} y^n \cos\left(2qy - \frac{1}{2} n\pi\right) dy$$

и выведите асимптотическую формулу

$\psi_n(q) = \sqrt{\frac{2}{\pi}} \frac{1}{\sqrt[4]{A^2 - q^2}} \cos\left\{\frac{\omega}{2\hbar}\left(A^2 \sin^{-1}\frac{q}{A} + q\sqrt{A^2 - q^2} - \frac{1}{2}A^2\pi\right) + O(1)\right\}$

при $\hbar \to 0$ и $\hbar\left(n + \frac{1}{2}\right) = \frac{1}{2}\omega A^2, |q| < A$.)

ЗАДАЧА 2.12. Завершите доказательство теоремы 2.1.

ЗАДАЧА 2.13 (ТЕОРЕМА ОБ N-ПРЕДСТАвЛЕНИИ). Пусть $\psi \in \mathscr{S}(\mathbb{R})$. Покажите, что сходящееся в L^2 разложение $\psi = \sum_{n=0}^{\infty} c_n \psi_n$, где $c_n = (\psi, \psi_n)$, сходится в $\mathscr{S}(\mathbb{R})$. (Указание: воспользуйтесь тем, что $N\psi_n = n\psi_n$.)

ЗАДАчА 2.14. Покажите, что операторы $E_{ij} = a_i^* a_j, i, j = 1, ..., n$, удовлетворяют коммутационным соотношениям алгебры Ли $\mathrm{sl}(n, \mathbb{C})$.

6.4.4 Coherent States (??)

(об этом в главе про операторы также многое сказано)

Теория по Киселеву

Соотношение неопределенностей для двух наблюдаемых $\hat{A}$ и $\hat{B}$ минимизируется, если в гильбертовом пространстве квантовых состояний существует такое состояние $|\Psi\rangle$, что верно (см. (1.24)-(1.25))

$$(\hat{A} - \bar{A})|\Psi\rangle = \mathrm{i}\gamma(\hat{B} - \bar{B})|\Psi\rangle, \quad \gamma \in \mathbb{R}$$

где

$$\gamma = -2\mathrm{i}\frac{(\Delta A)^2}{\langle[\hat{A}, \hat{B}]\rangle} \Rightarrow |\gamma| = \frac{\Delta A}{\Delta B}$$

Для операторов $\hat{\mathcal{Q}}$ и $\hat{\mathcal{P}}$ согласно уравнению (1.24), где $\hat{A} \mapsto \hat{\mathcal{Q}}$ и $\hat{B} \mapsto \hat{\mathcal{P}}$, введем состояние $|\alpha\rangle$ в координатном представлении $\langle\mathcal{Q}|\alpha\rangle \equiv \psi_\alpha(\mathcal{Q})$, которое минимизирует соотношение неопределенностей со средними значениями $\langle\mathcal{Q}\rangle \equiv \langle\alpha|\mathcal{Q}|\alpha\rangle \equiv \mathcal{Q}_0$ и $\langle\mathcal{P}\rangle \equiv \langle\alpha|\mathcal{P}|\alpha\rangle \equiv \mathcal{P}_0$, и, следовательно,

$$(\mathcal{Q} - \mathcal{Q}_0)\,\psi_\alpha(\mathcal{Q}) = \mathrm{i}\gamma\left(-\mathrm{i}\frac{\partial}{\partial\mathcal{Q}} - \mathcal{P}_0\right)\psi_\alpha(\mathcal{Q}) \Leftrightarrow$$

$$\Leftrightarrow \left(\mathcal{Q} - \gamma\frac{\partial}{\partial\mathcal{Q}}\right)\psi_\alpha(\mathcal{Q}) = (\mathcal{Q}_0 - \mathrm{i}\gamma\mathcal{P}_0)\,\psi_\alpha(\mathcal{Q})$$

Это обыкновенное дифференциальное уравнение легко решается в общем виде, так как

$$\frac{\mathrm{d}\psi_\alpha}{\psi_\alpha} = \mathrm{d}\mathcal{Q}\frac{1}{\gamma}\,(\mathcal{Q} - \mathcal{Q}_0 + \mathrm{i}\gamma\mathcal{P}_0)$$

откуда

$$\psi_\alpha(\mathcal{Q}) = \psi_0 \mathrm{e}^{\frac{(\mathcal{Q}-\mathcal{Q}_0)^2}{2\gamma} + \mathrm{i}\mathcal{P}_0\mathcal{Q}},$$

и с учетом

$$\gamma = -2\mathrm{i}\frac{(\Delta\mathcal{Q})^2}{\langle[\hat{\mathcal{Q}}, \hat{\mathcal{P}}]\rangle} = -2(\Delta\mathcal{Q})^2$$

находим

$$\psi_\alpha(\mathcal{Q}) = \psi_0 \mathrm{e}^{-\frac{(\mathcal{Q}-\mathcal{Q}_0)^2}{4(\Delta\mathcal{Q})^2} + \mathrm{i}\mathcal{P}_0\mathcal{Q}}$$

Решение уравнения (6.29) является нормируемым и, следовательно, принадлежит гильбертову пространству только при $\gamma < 0$, и в этом случае говорят, что это решение - сжатое состояние (squeezed state) [1] для координаты, если $|\gamma| < 1$, или для импульса, если $|\gamma| > 1$. Особый случай при $\gamma = -1$ мы рассмотрим более подробно.

Итак, в общем случае соотношение неопределенностей координата-импульс минимизируется на волновых функциях гауссова типа с учетом наличия ненулевого среднего импульса, что приводит к стандартному множителю в виде волны де Бройля с фазой, зависящей от координаты и среднего значения импульса.

Для произвольной системы мы можем изготовить состояние гауссова типа, которое минимизирует соотношение неопределенностей координата-импульс в начальный момент времени. Но это не значит, что составленный таким образом волновой пакет сохранит это свойство минимизации в ходе эволюции: волновой пакет может расплыться, причем зависимость произведения дисперсий от времени определяется как гамильтонианом физической системы, так и параметрами начального состояния. Особый интерес представляют системы, для которых можно в явном виде построить динамически устойчивые волновые функции, минимизирующие соотношение неопределенностей координата-импульс во все моменты времени!

Итак, расплывание волнового пакета, минимизирующего соотношение неопределенностей координата-импульс, зависит, во-первых, от величины параметра γ, который входит в уравнение (6.29) и связан с параметром сжатия [1]

$$|\zeta| \stackrel{\text{def}}{=} -\frac{1}{2}\ln(-\gamma),$$

а во-вторых, от гамильтониана системы, задающего эволюцию волнового пакета.

Квантовые состояния, представляющие из себя нерасплывающиеся со временем гауссовы волновые пакеты, в максимальной степени соответствуют движению исходной классической системы. Именно такие квантовые состояния могут быть построены для физической системы с гамильтонианом гармонического осциллятора и называются когерентными: значение произведения дисперсий координаты и импульса минимально и не изменяется в ходе эволюции. Этого условия, в принципе, достаточно, чтобы, рассматривая эволюцию во времени дисперсии координаты и дисперсии импульса, точно построить когерентное состояние, но мы подойдем к этому вопросу менее формально и найдем основное уравнение когерентного состояния из описания состояний осциллятора.

Задача 3.1. Гармонический осциллятор в начальный момент времени находится в состоянии $|\alpha(\gamma)\rangle$, минимизирующем соотношение неопределенности координатаимпульс в осцилляторных единицах:

$$(\hat{\mathcal{Q}} - \mathrm{i}\gamma\hat{\mathcal{P}})|\alpha(\gamma)\rangle = (\langle\mathcal{Q}\rangle - \mathrm{i}\gamma\langle\mathcal{P}\rangle)|\alpha(\gamma)\rangle, \quad \gamma < 0.$$

Найдите значение параметра γ, при котором исходный волновой пакет не расплывается, т.е. флуктуации координаты и импульса остаются постоянными. Hits: - Используя исходное уравнение для состояния и коммутационные соотношения, запишите уравнение для бра-вектора состояния $\langle\alpha(\gamma)|$. Вычислите средние значения операторов $(\hat{\mathcal{Q}}-\mathrm{i}\gamma\hat{\mathcal{P}})(\hat{\mathcal{Q}}-\mathrm{i}\gamma\hat{\mathcal{P}})$ и $(\hat{\mathcal{Q}}+\mathrm{i}\gamma\hat{\mathcal{P}})(\hat{\mathcal{Q}}-\mathrm{i}\gamma\hat{\mathcal{P}})$ и получите дисперсии координаты и импульса, $(\Delta\mathcal{Q})^2$ и $(\Delta\mathcal{P})^2$ в начальный момент времени в теминах параметра γ. - Используя уравнение Гейзенберга и теорему Эренфеста для осциллятора, вычислите производные по времени

$$\frac{\mathrm{d}}{\mathrm{d}t}(\Delta\mathcal{Q})^2, \quad \frac{\mathrm{d}}{\mathrm{d}t}(\Delta\mathcal{P})^2$$

в начальный момент времени. - Вычислите вторые производные по времени

$$\frac{\mathrm{d}^2}{\mathrm{d}t^2}(\Delta\mathcal{Q})^2, \quad \frac{\mathrm{d}^2}{\mathrm{d}t^2}(\Delta\mathcal{P})^2$$

в начальный момент времени. - Найдите значение γ, при котором вторые производные тождественно обращаются в нуль в начальный момент времени. - Покажите, что все высшие производные в начальный момент времени также равны нулю.

Заметим, что стационарное вакуумное состояние осциллятора $\psi_0(\mathcal{Q})$ с энергией $E_0 = \hbar\omega/2$ является гауссовым волновым пакетом с

$$(\Delta\mathcal{Q})^2 = \frac{1}{2} \Rightarrow \gamma = -1.$$

В силу стационарности этого состояния, эволюция сводится к элементарной зависимости от времени в виде множителя $\mathrm{e}^{-\mathrm{i}E_0 t/\hbar}$,

$$\psi_0(t, \mathcal{Q}) = \mathrm{e}^{-\mathrm{i}\omega t/2}\psi_0(\mathcal{Q}),$$

а значит, волновой пакет остается гауссовым, и эта гауссова форма зависимости от координаты $\mathcal{Q}$ не изменяется со временем, и стало быть, свойство минимизации является динамически устойчивым. Это позволяет нам определить, по отношению к какому значению параметра γ состояния осциллятора, минимизирующие соотношение неопределенностей координата-импульс, являются сжатыми. Мы полагаем $\gamma_0 = -1$, как у вакуума - состояния с нулевым числом квантов энергии. При $\gamma = -1$ уравнение (6.30) перепишется в виде

$$\left(\mathcal{Q} + \frac{\partial}{\partial\mathcal{Q}}\right)\psi_\alpha(\mathcal{Q}) = (\mathcal{Q}_0 + \mathrm{i}\mathcal{P}_0)\,\psi_\alpha(\mathcal{Q})$$

Учитывая явное выражение для оператора $\hat{a}$ в представлении наблюдаемой координаты $\{\mathcal{Q}\}$, находим

$$\hat{a}\psi_\alpha(\mathcal{Q}) = \alpha\psi_\alpha(\mathcal{Q}), \quad \alpha = \frac{1}{\sqrt{2}}\left(\mathcal{Q}_0 + \mathrm{i}\mathcal{P}_0\right).$$

В обозначениях Дирака уравнение (6.32) может быть представлено как уравнение на собственные значения оператора уничтожения квантов

$$\hat{a}|\alpha\rangle = \alpha|\alpha\rangle$$

причем комплексное собственное значение имеет вполне определенный физический смысл: с точностью до фактора $\sqrt{2}$ вещественная часть собственного значения есть среднее значение координаты осциллятора, а мнимая часть среднее значение импульса.

Кроме того, вычисляя квадрат вектора состояния (6.34), находим, с одной стороны,

$$(\hat{a}|\alpha\rangle)^\dagger\hat{a}|\alpha\rangle = \left\langle\alpha\left|\hat{a}^\dagger\hat{a}\right|\alpha\right\rangle = \langle\alpha|\hat{N}|\alpha\rangle,$$

а с другой-

$$(\hat{a}|\alpha\rangle)^\dagger\hat{a}|\alpha\rangle = |\alpha|^2\langle\alpha|\alpha\rangle = |\alpha|^2,$$

где мы учли нормировку состояния на единицу. Значит,

$$\langle N\rangle = |\alpha|^2,$$

т. е. среднее число квантов в таком состоянии определяется квадратом модуля собственного значения оператора уничтожения.

Покажем теперь, что сжатые состояния, заданные уравнением (6.34), с коэффициентом сжатия $|\zeta| = 0$ или $\gamma = -1$, являются когерентными, т. е. они остаются сжатыми с тем же коэффициентом сжатия в ходе эволюции с гамильтонианом гармонического осциллятора.

Разложение по базису

Коммутатор оператора уничтожения с гамильтонианом

$$[\hat{H}, \hat{a}] = \hbar\omega \left[\hat{a}^\dagger \hat{a}, \hat{a}\right] = -\hbar\omega \left[\hat{a}, \hat{a}^\dagger\right] \hat{a} = -\hbar\omega\hat{a}$$

не обращается в нуль (за исключением среднего значения для вакуумного состояния). Поэтому энергия в состоянии $|\alpha\rangle$ флуктуирует вблизи своего среднего значения, определенного согласно (6.35) : $\langle E\rangle = \hbar\omega(\langle N\rangle + 1/2)$. Разложим это состояние по базису стационарных фоковских состояний

$$|\alpha\rangle = \sum_n C_n(\alpha)|n\rangle$$

У множим это разложение на бра-вектор $\langle n|$ и учтём уравнения на собственные значения

$$C_n(\alpha) = \langle n|\alpha\rangle = \frac{1}{\alpha}\langle n|\hat{a}\alpha\rangle = \frac{1}{\alpha}\left\langle \hat{a}^\dagger n|\alpha\right\rangle,$$

где мы воспользовались также определением операции эрмитова сопряжения оператора. По построению

$$\hat{a}^\dagger|n\rangle = \sqrt{n+1}|n+1\rangle$$

так что получаем рекуррентное соотношение

$$\alpha C_n(\alpha) = \sqrt{n+1}C_{n+1}(\alpha)$$

которое можно разрешить в явном виде:

$$C_n(\alpha) = \frac{\alpha^n}{\sqrt{n!}}C_0(\alpha)$$

Разложение принимает вид

$$|\alpha\rangle = C_0(\alpha)\sum_n \frac{\alpha^n}{\sqrt{n!}}|n\rangle = C_0(\alpha)\sum_n \frac{\left(\alpha\hat{a}^\dagger\right)^n}{n!}|0\rangle = C_0(\alpha)\mathrm{e}^{\alpha\hat{a}^\dagger}|0\rangle$$

где мы использовали соотношение

$$|n\rangle = \frac{\left(\hat{a}^\dagger\right)^n}{\sqrt{n!}}|0\rangle$$

Коэффициент $C_0(\alpha)$ можно определить из условия единичной нормировки состояния (6.36)

$$\langle\alpha|\alpha\rangle = |C_0(\alpha)|^2\sum_n \frac{(\alpha^*\alpha)^n}{n!} = 1,$$

где мы учли ортонормированность стационарных состояний. Отсюда

$$|C_0(\alpha)|^2\,\mathrm{e}^{|\alpha|^2} = 1 \Rightarrow C_0(\alpha) = \mathrm{e}^{-\frac{|\alpha|^2}{2}},$$

когерентные состояния - фундаментальное понятие

(?? почему???)

Applications of coherent states

(there are a lot of them, see note on q opt for now about them, I'll write later)

6.4.5 Oscillator in the Holomorphic Representation

Зачем нужно голоморфное представление? (?????)

(this is a important question for understanding this topic, I'll think about it later)

Осциллятор в голоморфном представлении по Киселеву (??)

Наряду с задачей нахождения амплитуды вероятности перехода из точки в точку, можно поставить другую задачу: в зависимости от времени вычислить амплитуду вероятности перехода между фоковскими состояниями или, в самом общем виде, из одного когерентного состояния в другое. Тогда вместо координатного и импульсного представлений нужно использовать базис когерентных состояний $|\alpha\rangle$ с комплексным параметром $\alpha \in \mathbb{C}$, или, как говорят, рассмотреть задачу в пространстве Баргмана-Фока:

$$\hat{a}|\alpha\rangle = \alpha|\alpha\rangle, \quad \int |\alpha\rangle \frac{\mathrm{d}\bar{\alpha}\mathrm{d}\alpha}{2\pi\mathrm{i}}\langle\alpha| = \mathbb{1}, \quad \langle\alpha'|\alpha\rangle = \exp\left\{-\frac{\bar{\alpha}'\alpha'}{2} - \frac{\bar{\alpha}\alpha}{2} + \bar{\alpha}'\alpha\right\}.$$

Для построения интеграла по траекториям в голоморфном представлении, как теперь понятно из проведенного выше общего анализа, необходимо рассмотреть оператор эволюции на k-м шаге разбиения интервала времени от t' до t''

$$\hat{U}\left(t_k + \mathrm{d}t, t_k\right) = \int |\alpha_{k+1}\rangle \frac{\mathrm{d}\bar{\alpha}_{k+1}\ \mathrm{d}\alpha_{k+1}}{2\pi\mathrm{i}} \left\langle \alpha_{k+1} \left| \hat{U}\left(t_k + \mathrm{d}t, t_k\right) \right| \alpha_k \right\rangle \frac{\mathrm{d}\bar{\alpha}_k\ \mathrm{d}\alpha_k}{2\pi\mathrm{i}} \langle\alpha_k| .$$

С точностью до членов второго порядка малости по шагу эволюции $\mathrm{d}t \to 0$ матричный элемент оператора эволюции

$$\left\langle \alpha_{k+1} \left| \hat{U}\left(t_k + \mathrm{d}t, t_k\right) \right| \alpha_k \right\rangle = \left\langle \alpha_{k+1} \left| \mathbb{1} - \frac{\mathrm{i}}{\hbar}\hat{H}\left(\hat{a}^\dagger, \hat{a}, t_k\right)\mathrm{d}t \right| \alpha_k \right\rangle$$

где необходимо вычислить матричный элемент гамильтониана, используя выражение для гамиьлтониана через операторы рождения и уничтожения, действие которых на квантовые состояния определены соответственно для бра- и кет-векторов, и мы найдем,

$$\left\langle \alpha_{k+1} \left| \hat{H}\left(\hat{a}^\dagger, \hat{a}, t_k\right) \right| \alpha_k \right\rangle = \mathcal{H}\left(\bar{\alpha}_{k+1}, \alpha_k, t_k\right) \langle\alpha_{k+1}|\alpha_k\rangle$$

если гамильтониан, как говорят, нормально упорядочен: все операторь рождения стоят слева от операторов уничтожения. В этом случае действие операторов уничтожения на кет-вектор когерентного состояния дает собственные значения

$$\hat{a}\,|\alpha_k\rangle = \alpha_k\,|\alpha_k\rangle$$

и аналогично для бра-векторов

$$\langle\alpha_{k+1}|\,\hat{a}^\dagger = \langle\alpha_{k+1}|\,\bar{\alpha}_{k+1}$$

Например, для свободного осциллятора

$$\hat{H}_0 = \hbar\omega_0\hat{a}^\dagger\hat{a} + \frac{1}{2}\hbar\omega_0$$

и

$$\left\langle \alpha_{k+1} \left| \hat{H}_0 \right| \alpha_k \right\rangle = \left\{\hbar\omega_0\bar{\alpha}_{k+1}\alpha_k + \frac{1}{2}\hbar\omega_0\right\}\langle\alpha_{k+1}|\alpha_k\rangle$$

Тогда

$$\left\langle \alpha_{k+1} \left| \hat{U}\left(t_k + \mathrm{d}t, t_k\right) \right| \alpha_k \right\rangle = \left\langle \alpha_{k+1} \left| \mathbb{1} - \frac{\mathrm{i}}{\hbar} \hat{H}\left(\hat{a}^\dagger, \hat{a}, t_k\right) \mathrm{d}t \right| \alpha_k \right\rangle =$$
$$= \langle \alpha_{k+1} | \alpha_k \rangle \left\{ 1 - \frac{\mathrm{i}}{\hbar} \mathcal{H}\left(\bar{\alpha}_{k+1}, \alpha_k, t_k\right) \mathrm{d}t \right\} =$$
$$= \langle \alpha_{k+1} | \alpha_k \rangle \exp\left\{ -\frac{\mathrm{i}}{\hbar} \mathcal{H}\left(\bar{\alpha}_{k+1}, \alpha_k, t_k\right) \mathrm{d}t \right\}$$

Матричный элемент $\langle \alpha_{k+1} | \alpha_k \rangle$ был определен при построении когерентных состояний осциллятора:

$$\langle \alpha_{k+1} | \alpha_k \rangle = \exp\left\{ -\frac{\bar{\alpha}_{k+1}\alpha_{k+1}}{2} - \frac{\bar{\alpha}_k \alpha_k}{2} + \bar{\alpha}_{k+1}\alpha_k \right\}$$

который можно представить в виде

$$\langle \alpha_{k+1} | \alpha_k \rangle = \exp\left\{ \frac{1}{2}\left(\bar{\alpha}_{k+1} - \bar{\alpha}_k\right)\alpha_k - \frac{1}{2}\bar{\alpha}_{k+1}\left(\alpha_{k+1} - \alpha_k\right) \right\}.$$

Поскольку множества точек $\{\bar{\alpha}_k, \alpha_k\}$ по построению соответствуют траекториям $\{\bar{\alpha}(t), \alpha(t)\}$, естественно ввести скорости изменения параметров траекторий

$$\left(\bar{\alpha}_{k+1} - \bar{\alpha}_k\right) = \dot{\bar{\alpha}}\left(t_k\right) \mathrm{d}t, \quad \left(\alpha_{k+1} - \alpha_k\right) = \dot{\alpha}\left(t_k\right) \mathrm{d}t$$

Значит,

$$\langle \alpha_{k+1} | \alpha_k \rangle = \exp\left\{ \frac{1}{2}\left[\dot{\bar{\alpha}}\left(t_k\right)\alpha\left(t_k\right) - \bar{\alpha}\left(t_k\right)\dot{\alpha}\left(t_k\right)\right] \mathrm{d}t \right\}$$

Таким образом, бесконечно малый шаг эволюции

$$\hat{U}\left(t_k + \mathrm{d}t, t_k\right) = \int |\alpha_{k+1}\rangle \frac{\mathrm{d}\bar{\alpha}_{k+1}\, \mathrm{d}\alpha_{k+1}}{2\pi\mathrm{i}} \left\langle \alpha_{k+1} \left| \hat{U}\left(t_k + \mathrm{d}t, t_k\right) \right| \alpha_k \right\rangle \frac{\mathrm{d}\bar{\alpha}_k\, \mathrm{d}\alpha_k}{2\pi\mathrm{i}} \langle \alpha_k |$$

представим в виде

$$\hat{U}\left(t_k + \mathrm{d}t, t_k\right) = \int |\alpha_{k+1}\rangle \frac{\mathrm{d}\bar{\alpha}_{k+1}\, \mathrm{d}\alpha_{k+1}}{2\pi\mathrm{i}} \frac{\mathrm{d}\bar{\alpha}_k\, \mathrm{d}\alpha_k}{2\pi\mathrm{i}} \langle \alpha_k | \times$$
$$\times \exp\left\{ \frac{\mathrm{i}}{\hbar} \mathrm{d}t \left[-\frac{\mathrm{i}\hbar}{2}\left[\dot{\bar{\alpha}}\left(t_k\right)\alpha\left(t_k\right) - \bar{\alpha}\left(t_k\right)\dot{\alpha}\left(t_k\right)\right] - \mathcal{H}\left(\bar{\alpha}\left(t_k\right), \alpha\left(t_k\right), t_k\right) \right] \right\}$$

а на конечном интервале времени

$$\hat{U}\left(t'', t'\right) = \lim_{N\to\infty} \int \frac{\mathrm{d}\bar{\alpha}_N\, \mathrm{d}\alpha_N}{2\pi\mathrm{i}} \frac{\mathrm{d}\bar{\alpha}_1\, \mathrm{d}\alpha_1}{2\pi\mathrm{i}} |\alpha_N\rangle \langle \alpha_1 | \int \prod_{k=2}^{N-1} \frac{\mathrm{d}\bar{\alpha}_k\, \mathrm{d}\alpha_k}{2\pi\mathrm{i}} \times$$
$$\times \exp\left\{ \frac{\mathrm{i}}{\hbar} \int_{t'}^{t''} \mathrm{d}t \left[-\frac{\mathrm{i}\hbar}{2}[\dot{\bar{\alpha}}(t)\alpha(t) - \bar{\alpha}(t)\dot{\alpha}(t)] - \mathcal{H}(\bar{\alpha}(t), \alpha(t), t) \right] \right\}$$

где интегрирование по времени дает действие на траектории в классической механике. В самом деле, вклад

$$\int p(t)\dot{q}(t)\mathrm{d}t$$

можно после интегрирования по частям представить как

$$\frac{1}{2}\int [p(t)\dot{q}(t) - q(t)\dot{p}(t)]\mathrm{d}t$$

Тогда стандартная замена переменных

$$q(t) = \sqrt{\frac{\hbar}{m\omega_0}}\frac{1}{\sqrt{2}}[\bar{\alpha}(t) + \alpha(t)], \quad p(t) = \sqrt{\hbar m\omega_0}\frac{\mathrm{i}}{\sqrt{2}}[\bar{\alpha}(t) - \alpha(t)]$$

после приведения подобных членов дает

$$\frac{1}{2}\int [p(t)\dot{q}(t) - q(t)\dot{p}(t)]\mathrm{d}t = -\int \mathrm{d}t\frac{\mathrm{i}\hbar}{2}[\dot{\bar{\alpha}}(t)\alpha(t) - \bar{\alpha}(t)\dot{\alpha}(t)].$$

Из 13.53 в пределе $N \to \infty$ получаем интеграл по траекториям в представлении когерентных состояний

$$\hat{U}\left(t'', t'\right) = \int \frac{\mathrm{d}\bar{\alpha}\left(t''\right)\mathrm{d}\alpha\left(t''\right)}{2\pi\mathrm{i}}\frac{\mathrm{d}\bar{\alpha}\left(t'\right)\mathrm{d}\alpha\left(t'\right)}{2\pi\mathrm{i}}\left|\alpha\left(t''\right)\right\rangle\left\langle\alpha\left(t'\right)\right| \int \mathcal{D}\bar{\alpha}\mathcal{D}\alpha \cdot \mathrm{e}^{\frac{\mathrm{i}}{\hbar}S(t'',t')},$$

где действие на траектории

$$S\left(t'', t'\right) = \int_{t'}^{t''} \mathrm{d}t\left[-\frac{\mathrm{i}\hbar}{2}[\dot{\bar{\alpha}}(t)\alpha(t) - \bar{\alpha}(t)\dot{\alpha}(t)] - \mathcal{H}(\bar{\alpha}(t), \alpha(t), t)\right].$$

Так же, как в координатно-импульсном представлении континуального интеграла интегрирование в фазовом пространстве по траектории импульса было независимым от интегрирования по траектории координаты (импульс не определяется скоростью!), в голоморфном представлении траектории $\bar{\alpha}(t)$ и $\alpha(t)$ не связаны комплексным сопряжением, а являются независимыми однопараметрическими кривыми в двух комплексных плоскостях z и $w : z$ для α и w для $\bar{\alpha}$.

Ядро оператора. Для определения голоморфного представления оператора $\hat{A}$ запишем:

$$\hat{A} = \int \left|\alpha_{\text{out}}\right\rangle \frac{\mathrm{d}\bar{\alpha}_{\text{out}}\,\mathrm{d}\alpha_{\text{out}}}{2\pi\mathrm{i}}\left\langle\alpha_{\text{out}}\left|\hat{A}\right|\alpha_{\text{in}}\right\rangle \frac{\mathrm{d}\bar{\alpha}_{\text{in}}\,\mathrm{d}\alpha_{\text{in}}}{2\pi\mathrm{i}}\left\langle\alpha_{\text{in}}\right|,$$

причем матричный элемент можно определить с помощью полного набора собственных состояний энергии для осциллятора

$$\left\langle\alpha_{\text{out}}\left|\hat{A}\right|\alpha_{\text{in}}\right\rangle = \sum_{n,m}\left\langle\alpha_{\text{out}}\left|n\right\rangle\right\langle n|\hat{A}|m\rangle\left\langle m|\alpha_{\text{in}}\right\rangle = \\ = \sum_{n,m}\frac{\bar{\alpha}_{\text{out}}^n}{\sqrt{n!}}A_{nm}\frac{\alpha_{\text{in}}^m}{\sqrt{m!}}\cdot\exp\left\{-\frac{\bar{\alpha}_{\text{out}}\,\alpha_{\text{out}}}{2} - \frac{\bar{\alpha}_{\text{in}}\alpha_{\text{in}}}{2}\right\},$$

где мы стандартно ввели матричные элементы оператора $A_{nm} = \langle n|\hat{A}|m\rangle$ и воспользовались голоморфным представлением для волновых функций собственных состояний энергии осциллятора. Поэтому голоморфное ядро оператора определяют в полной аналогии с волновыми функциями

$$\mathcal{A}\left(\bar{\alpha}_{\text{out}}, \alpha_{\text{in}}\right) = \left\langle\alpha_{\text{out}}\left|\hat{A}\right|\alpha_{\text{in}}\right\rangle \cdot \mathrm{e}^{\frac{\bar{\alpha}_{\text{Out}}\,\alpha_{\text{out}}}{2} + \frac{\bar{\alpha}_{\text{in}}\alpha_{\text{in}}}{2}} = \sum_{n,m}\frac{\bar{\alpha}_{\text{out}}^n}{\sqrt{n!}}A_{nm}\frac{\alpha_{\text{in}}^m}{\sqrt{m!}},$$

и оно действительно, как мы только что показали, является функцией только от $\bar{\alpha}_{\text{out и}}\,\alpha_{\text{in}}$ и не зависит от переменных, комплексно сопряженных к ним!

В частности, голоморфное ядро оператора эволюции имеет вид

$$\mathcal{U}\left(\bar{\alpha}_{\text{out}}\,,\alpha_{\text{in}}\right)=\int\mathcal{D}\bar{\alpha}\mathcal{D}\alpha\cdot\mathrm{e}^{\frac{\mathrm{i}}{\hbar}S(t'',t')}\cdot\mathrm{e}^{\frac{\bar{\alpha}_{\text{out}}\,\alpha_{\text{out}}}{2}+\frac{\bar{\alpha}_{\text{in}}\alpha_{\text{in}}}{2}},$$

где граничные условия задаются равенствами

$$\bar{\alpha}_{\text{out}}\,=\bar{\alpha}\left(t''\right),\quad\alpha_{\text{in}}=\alpha\left(t'\right)$$

Для рассмотрения граничных условий при наличии источников мы будем полагать, что $t'\to-\infty$ и $t''\to+\infty$, а сами источники отличны от нуля только при конечных временах (или достаточно быстро стремятся к нулю на временной бесконечности). Тогда состояния осциллятора в бесконечном прошлом и бесконечном будущем представимы в базисе собственных векторов энергии свободного осциллятора, т. е. в базисе с заданным числом квантов в начальном и конечном состоянии эволюции. тот базис определяет асимптотическое пространство состояний, а матричнье элементы оператора эволюции

$$\mathcal{S}_{nm}=\left\langle n\left|\hat{U}\left(t'',t'\right)\right|m\right\rangle\Big|_{j=0},\quad t'\to-\infty,t''\to+\infty$$

называют элементами «S-матрицы». Напомним, что гипотеза существования асимптотических состояний является ключевой при формулировке квантовой теории взаимодействующих полей, и фактически она может быть обоснована только после нахождения точного решения динамических уравнений теории, что на практике редко представляется возможным для реальных физических ситуаций, предоставленных нам природой [имеются искусственные примеры точных решений, например, электродинамика частицы с половинным спином в одном пространственном измерении (модель Швингера)]. Математически строго этот вопрос рассматривается в рамках аксиоматического подхода 1. S-матрица не является уже, вообще говоря, диагональной, так как при наличии взаимодействия количество квантов разного сорта (если осцилляторов несколько) может изменяться (поглощаться и излучаться). Особый случай вакуум. Мыл будем считать, что вакуум стабияен. Это означает, что в ходе эволюции вакуум переходит в себя с вероятностью, равной единице, а значит, модуль амплитуды перехода равен единице:

$$\left|\left\langle 0\left|\hat{U}\left(t'',t'\right)\right|0\right\rangle\right|=1,\quad t'\to-\infty,t''\to+\infty$$

Другими словами, эволюция вакуума сводится к введению фазового множителя, который вообще зависит от источников как функционал, и этот фактор обычно полагают равным единице в отсутствие источников [2], Поэтому для

[1] См., например, Боголюбов Н. Н., Логунов А. А., Оксак А. И., Тодо р о в И. Т. Общие принципы квантовой теории поля. М.: Наука, 1987).

2 то означает, что мы производим сдвиг энергии вакуума: $E_0=\frac{1}{2}\hbar\omega_0\to E_{\text{vac}}=0$, - так что она принимается равной нулю. вакуума

$$|\text{ out }\rangle=\hat{U}|\text{ in }\rangle=\mathrm{e}^{\frac{\mathrm{i}}{\hbar}G[j]}|\text{ in }\Big\rangle,\quad|\text{ in }\Big\rangle=|0\rangle$$

т. е. состояния «in» и «out» совпадают с точностью до фазы, которую мы определим позже с помощью введения нового понятия - производящего функционала связных функций Грина $G[j]$. Значит,

$$\langle\text{out}|=\langle\text{in}\,|\hat{U}^{\dagger}$$

Поэтому Т-произведения операторов, которые выражаются через интеграл по траекториям, при $t_1>t_2$

$$\left\langle \text{ out } \left| \hat{U}\hat{F}_H\left(t_1\right)\hat{G}_H\left(t_2\right) \right| \text{ in } \right\rangle = \left\langle \text{ in } \left| \hat{F}_H\left(t_1\right)\hat{G}_H\left(t_2\right) \right| \text{ in } \right\rangle$$

Элементы $\mathcal{S}$-матрицы можно выразить через производные голоморфного ядра оператора эволюции при нулевых источниках, поскольку

$$\mathcal{U}\left(\bar{\alpha}_{\text{out}}\,,\alpha_{\text{in}}\right) = \sum_{n,m} \frac{\bar{\alpha}_{\text{out}}^n}{\sqrt{n!}} U_{nm} \frac{\alpha_{\text{in}}^m}{\sqrt{m!}}$$

так что

$$\begin{aligned}\mathcal{S}_{nm} &= \frac{1}{\sqrt{n!m!}}\,\frac{\partial^{n+m}}{\partial\bar{\alpha}_{\text{out}}^n\,\partial\alpha_{\text{in}}^m}\mathcal{U}\left(\bar{\alpha}_{\text{out}}\,,\alpha_{\text{in}}\right)\Big|_{\bar{\alpha}_{\text{out}}=\alpha_{\text{in}}=0} = \\ &= \frac{1}{\sqrt{n!m!}}\frac{\partial^{n+m}}{\partial\bar{\alpha}_{\text{out}}^n\,\partial\alpha_{\text{in}}^m}\int \mathcal{D}\bar{\alpha}\mathcal{D}\alpha\cdot \mathrm{e}^{\frac{\mathrm{i}}{\hbar}S(t'',t')}\cdot \mathrm{e}^{\frac{\bar{\alpha}_{\text{Out}}\,\alpha_{\text{out}}}{2}+\frac{\bar{\alpha}_{\text{in}}\alpha_{\text{in}}}{2}}\Big|_{\bar{\alpha}_{\text{out}}=\alpha_{\text{in}}=0}.\end{aligned}$$

При расчете переходов из вакуума в вакуум дополнительные множители исчезают, а $\alpha_{\text{in}}\,,\bar{\alpha}_{\text{out}}\,\to 0$

$$\langle 0|\hat{U}|0\rangle = \mathcal{U}(0,0)$$

и при наличии источников так же.

При переходе «вакуум-вакуум» матричный элемент оператора эволюции выражается через интеграл по траекториям

$$\left\langle 0\left|\hat{U}\left(t'',t'\right)\right|0\right\rangle = \int \mathcal{D}\bar{\alpha}\mathcal{D}\alpha\cdot \mathrm{e}^{\frac{\mathrm{i}}{\hbar}S(t'',t')},\quad t'\to-\infty, t''\to+\infty.$$

При этом начальные данные отвечают $\alpha\left(t'\right) = \alpha_{\text{in}} \equiv 0$, а конечные данные $\bar{\alpha}\left(t''\right) = \bar{\alpha}_{\text{out}} \equiv 0$. Важно подчеркнуть, что α_{in} является собственным значением для оператора уничтожения квантов в начальном состоянии, и при бесконечно малом шаге эволюции от исходного состояния в выражении для матричного элемента оператора эволюции не возникает сопряженное собственное значение $\bar{\alpha}_{\text{in}}$, а в это выражение входит независимая величина $\bar{\alpha}\left(t'+\mathrm{d}t\right)$. И аналогично $\bar{\alpha}_{\text{out}}$ - это собственное значение для оператора рождения, который действует на бра-вектор конечного состояния, и в выражении для матричного элемента оператора эволюции не возникает собственное значение α_{out} . Другими словами, у нас есть две комплексные плоскости с траекториями $\alpha(t)$ и $\bar{\alpha}(t)$, и для этих траекторий зафиксированы начальная точка $\alpha\left(t'\right) = \alpha_{\text{in}}$ на плоскости $\alpha(t)$ и конечная точка $\bar{\alpha}\left(t''\right) = \bar{\alpha}_{\text{out}}$ на плоскости $\bar{\alpha}(t)$.

Модъ. Поскольку в голоморфном представлении состояния с заданным числом квантов являются собственными векторами оператора рождения с собственными значениями $\bar{\alpha}$:

$$\hat{a}^\dagger\psi_n(\bar{\alpha}) = \bar{\alpha}\psi_n(\bar{\alpha})$$

зависимость от времени параметров $\bar{\alpha}$ повторяет зависимость от времени оператора рождения

$$\hat{a}^\dagger(t) = \mathrm{e}^{\mathrm{i}\omega_0 t}\hat{a}^\dagger \Rightarrow \bar{\alpha}(t) = \mathrm{e}^{\mathrm{i}\omega_0 t}\bar{\alpha},\quad \alpha(t) = \mathrm{e}^{-\mathrm{i}\omega_0 t}\alpha$$

так что с учетом граничных условий $\bar{\alpha}\left(t''\right) = \bar{\alpha}_{\text{out}}\,,\alpha\left(t'\right) = \alpha_{\text{in}}$ находим

- при $t\to t''$, т. е. в асимптотическом будущем 1,

$$q(t) = x_0[\bar{\alpha}(t) + \alpha(t)] \to x_0 \left[\mathrm{e}^{-\mathrm{i}\omega_0 t}\alpha + \mathrm{e}^{\mathrm{i}\omega_0(t-t'')}\bar{\alpha}_{\mathrm{out}} \right]$$

с учетом $\bar{\alpha}_{\mathrm{out}} \to 0$ означает, что

$$q(t) \to x_0 \mathrm{e}^{-\mathrm{i}\omega_0 t}\alpha$$

т. е. в асимптотическом будущем распространяются только положительночастотные моды [2]

- при $t \to t'$, т. е. в асимптотическом прошлом [3]

$$q(t) = x_0[\bar{\alpha}(t) + \alpha(t)] \to x_0 \left[\mathrm{e}^{-\mathrm{i}\omega_0(t-t')}\alpha_{\mathrm{in}} + \mathrm{e}^{\mathrm{i}\omega_0 t}\bar{\alpha} \right]$$

с учетом $\alpha_{\mathrm{in}} \to 0$ означает, что

$$q(t) \to x_0 \mathrm{e}^{\mathrm{i}\omega_0 t}\bar{\alpha}$$

т. е. в асимптотическом прошлом распространяются только отрицательночастотные моды.

ти граничные условия позволят однозначно определить двухточечную функцию Грина для осциллятора при переходе «вакуум-вакуум», когда асимптотическое прошлое и будущее стремятся в бесконечность.

[1] Для краткости обозначим $x_0 = \sqrt{\hbar/\left(2m\omega_0\right)}\Big)$, так что само выражение в будущем отвечает матричному элементу оператора координаты по бра-состоянию $\langle \bar{\alpha}_{\mathrm{out}} \,|$ и по кетсостоянию на промежуточной стадии эволюции $|\alpha\rangle$.

[2] Наименование моды проистекает из вида зависимости волновой функции стационарного состояния от времени, которая задается зависящим от времени множителем $\exp(-\mathrm{i}Et/\hbar) = \exp(-\mathrm{i}\omega t)$, где энергия стационарного состояния $E = \hbar\omega$, так что положительная энергия отвечает положительной частоте, а экспоненциальный множитель имеет в своем аргументе отрицательный знак перед мнимой единицей.

[3] Рассматриваем решение для осциллятора, пропорциональное матричному элементу координаты между бра-состоянием на промежуточной стадии эволюции $\langle\alpha|$ и начальным кет-состоянием $|\alpha_{\mathrm{in}}\rangle$. Лекция 14 (дополнительная)

Континуальный интеграл при наличии источника, уравнения Швингера-Дайсона, производящие функционалы амплитуды $Z[j]$ и функций Грина $G[j]$, решение для осциллятора, причинный пропагатор Фейнмана и обход полюсов, теорема Вика, спаривания, 4-точка для осциллятора, теория возмущений и многоточечные корреляторы, диаграммы Фейнмана для трехточечного коррелятора в модели «лямбда-фи-в-кубе» в ведущем приближении, внешние и внутренние линии, вершины, компонентя связности диаграммы, диаграммы для многоточечных функций и источников, связные функции Грина, квантовый аналог классической траектории, преобразование Лежандра и квантовое эффективное действие, усеченные вершинные функции и диаграммы Фейнмана для уравнения Швингера-Дайсона в модели «лямбда-фи-в-четвертой», одночастичная неприводимость диаграмм в методе Коулмена-Вайнберга, связь числа петель с числом вершин и внутренних линий на связной диаграмме, разложение связных функций Грина по петлям и по степеням $\hbar$, графическое представление редукционных формул, пример введения взаимодействия осцилляторов.

7. Голоморфное представление и виковские символы

Рассмотрим гильбертово пространство

$$\ell^2 = \left\{ c = \{c_n\}_{n=0}^{\infty} : \|c\|^2 = \sum_{n=0}^{\infty} |c_n|^2 < \infty \right\}$$

последовательностей с суммируемым квадратом. Выбором ортонормального базиса $\{\psi_n\}_{n=0}^{\infty}$ в $L^2(\mathbb{R}, dq)$, состоящего из собственных функций (2.40) оператора Шрёдингера гармонического осциллятора, устанавливается изоморфизм гильбертовых пространств $L^2(\mathbb{R}, dq) \simeq \ell^2$

$$L^2(\mathbb{R}, dq) \ni \psi = \sum_{n=0}^{\infty} c_n \psi_n \mapsto c = \{c_n\}_{n=0}^{\infty} \in \ell^2$$

где

$$c_n = (\psi, \psi_n) = \int_{-\infty}^{\infty} \psi(q)\psi_n(q)dq$$

поскольку функции ψ_n вещественнозначны. Используя (2.39), получаем

$$a^*\psi = \sum_{n=0}^{\infty} c_n a^* \psi_n = \sum_{n=0}^{\infty} \sqrt{n+1} c_n \psi_{n+1} = \sum_{n=1}^{\infty} \sqrt{n} c_{n-1} \psi_n, \quad \psi \in D\left(a^*\right)$$

и

$$a\psi = \sum_{n=0}^{\infty} c_n a \psi_n = \sum_{n=1}^{\infty} \sqrt{n} c_n \psi_{n-1} = \sum_{n=0}^{\infty} \sqrt{n+1} c_{n+1} \psi_n, \quad \psi \in D(a)$$

так что в пространстве ℓ^2 операторы рождения и уничтожения a^* и a представлены следующими полубесконечными матрицами:

$$a = \begin{pmatrix} 0 & \sqrt{1} & 0 & 0 & \cdots \\ 0 & 0 & \sqrt{2} & 0 & \cdots \\ 0 & 0 & 0 & \sqrt{3} & \cdots \\ 0 & 0 & 0 & 0 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}, \quad a^* = \begin{pmatrix} 0 & 0 & 0 & 0 & \cdots \\ \sqrt{1} & 0 & 0 & 0 & \cdots \\ 0 & \sqrt{2} & 0 & 0 & \cdots \\ 0 & 0 & \sqrt{3} & 0 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}.$$

В результате

$$N = a^* a = \begin{pmatrix} 0 & 0 & 0 & 0 & \cdots \\ 0 & 1 & 0 & 0 & \cdots \\ 0 & 0 & 2 & 0 & \cdots \\ 0 & 0 & 0 & 3 & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ddots \end{pmatrix}$$

так что гамильтониан гармонического осциллятора представлен диагональной матрицей

$$H = \hbar\omega \left(N + \frac{1}{2} \right) = \operatorname{diag} \left\{ \frac{1}{2}\hbar\omega, \frac{3}{2}\hbar\omega, \frac{5}{2}\hbar\omega, \ldots \right\}$$

Это представление коммутационных соотношений Гейзенберга называется представлением чисел заполнения и обладает тем свойством, что в нем гамильтониан H гармонического осциллятора диагонален.

Другое представление, в котором H диагонален, строится так. Пусть $\mathscr{D}$ - пространство целых функций $f(z)$ со скалярным произведением

$$(f,g)=\frac{1}{\pi}\int\limits_{\mathbb{C}} f(z)\overline{g(z)}e^{-|z|^2}d^2z$$

где $d^2z=\frac{i}{2}dz\wedge d\bar{z}$ - мера Лебега на $\mathbb{C}\simeq\mathbb{R}^2$. Легко проверить, что $\mathscr{D}$ - гильбертово пространство с ортонормальным базисом

$$f_n(z)=\frac{z^n}{\sqrt{n!}},\quad n=0,1,2,...$$

Соответствие

$$\ell^2\ni c=\{c_n\}_{n=0}^{\infty}\mapsto f(z)=\sum_{n=0}^{\infty}c_nf_n(z)\in\mathscr{D}$$

изоморфизм гильбертовых пространств $\ell^2\simeq\mathscr{D}$. Реализация гильбертова пространства $\mathscr{H}$ в виде гильбертова пространства $\mathscr{D}$ целых функций называется голоморфным представлением. В голоморфном представлении

$$a^*=z,\quad a=\frac{d}{dz},\qquad \text{и}\qquad H=\hbar\omega\left(z\frac{d}{dz}+\frac{1}{2}\right)$$

и очень легко показать, что a^* - оператор, сопряженный к a. Отображением

$$\mathscr{H}\ni\psi=\sum_{n=0}^{\infty}c_n\psi_n\mapsto f(z)=\sum_{n=0}^{\infty}c_nf_n(z)\in\mathscr{D}$$

устанавливается изоморфизм между координатным и голоморфным представлениями. Из формулы для производящей функции многочленов Эрмита-Чебышева,

$$\sum_{n=0}^{\infty}H_n(q)\frac{z^n}{n!}=e^{2qz-z^2}$$

следует, что соответствующий унитарный оператор $U:\mathscr{H}\to\mathscr{D}$ - это интегральный оператор

$$U\psi(z)=\int\limits_{-\infty}^{\infty}U(z,q)\psi(q)dq$$

с ядром

$$U(z,q)=\sum_{n=0}^{\infty}\psi_n(q)f_n(z)=\sqrt[4]{\frac{m\omega}{\pi\hbar}}e^{\frac{m\omega}{2\hbar}q^2-\left(\sqrt{\frac{m\omega}{\hbar}}q-\frac{1}{\sqrt{2}}z\right)^2}$$

Другая полезная реализация - представление в гильбертовом пространстве $\overline{\mathscr{D}}$ антиголоморфных функций $f(\bar{z})$ на $\mathbb{C}$ со скалярным произведением

задаваемое формулами

$$(f,g)=\frac{1}{\pi}\int\limits_{\mathbb{C}} f(\bar{z})\overline{g(\bar{z})}e^{-|z|^2}d^2z$$

$$a^* = \bar{z}, \quad a = \frac{d}{d\bar{z}}$$

ЗАМЕЧАНИЕ. Голоморфное и антиголоморфное представления соответствуют разным выборам комплексной поляризации симплектического многообразия $\mathbb{R}^2$. По определению комплексная поляризация симплектического многообразия $(\mathscr{M}, \omega)$ - это интегрируемое распределение на $\mathscr{M}$ комплексных лагранжевых подпространств комплексифицированных векторных пространств $T_x\mathscr{M} \otimes_{\mathbb{R}} \mathbb{C}$. Как и понятие вещественной поляризации, понятие комплексной поляризации играет фундаментальную роль в геометрическом квантовании. В частности, голоморфное представление соответствует комплексному лагранжеву подпространству в $T_x\mathbb{R}^2 \otimes_{\mathbb{R}} \mathbb{C} \simeq \mathbb{C}^2$, заданному уравнением $z = 0$, где z и $\bar{z}$ - комплексные координаты на $\mathbb{C}^2$. (Заметим, что здесь $\bar{z}$ не является комплексно сопряженным к z !) Уравнение $\bar{z} = 0$ определяет комплексное лагранжево подпространство, соответствующее антиголоморфному представлению.

Антиголоморфное представление используется для введения так называемых виковских символов операторов. А именно: пусть A - оператор в $\overline{\mathscr{D}}$, являющийся многочленом с постоянными коэффициентами в операторах рождения и уничтожения a^* и a. Используя коммутационное соотношение (2.34), можно перетащить все операторы a^* налево от операторов a и представить A в виковской нормальной форме следующим образом:

$$A = \sum_{l,m} A_{lm} \left(a^*\right)^l a^m$$

По определению виковский символ $A(\bar{z}, z)$ оператора A - это

$$A(\bar{z}, z) = \sum_{l,m} A_{lm} \bar{z}^l z^m$$

Это ограничение многочлена $A(v, z)$ в переменных v и z на $v = \bar{z}$.

Чтобы определить виковские символы ограниченных операторов в $\overline{\mathscr{D}}$, рассмотрим семейство когерентных состояний (или векторов Пуассона) $\Phi_v \in \overline{\mathscr{D}}, v \in \mathbb{C}$, определенных формулой

$$\Phi_v(\bar{z}) = e^{v\bar{z}}, \quad z \in \mathbb{C}.$$

Они удовлетворяют свойствам

$$a\Phi_v = v\Phi_v \quad \text{и} \quad f(\bar{v}) = (f, \Phi_v), \quad f \in \overline{\mathscr{D}}, v \in \mathbb{C}.$$

Действительно, первое свойство тривиально, тогда как «воспроизводящее свойство» мгновенно следует из формулы

$$\Phi_v(\bar{z}) = \sum_{n=0}^{\infty} f_n(v) \bar{f}_n(\bar{z}),$$

где $\bar{f}_n(\bar{z}) = \overline{f_n(z)}, n = 0, 1, 2, ...,$ - ортонормальный базис $\overline{\mathscr{D}}$.

Имеем также

$$(f, g) = \frac{1}{\pi} \int_{\mathbb{C}} (f, \Phi_v) \overline{(g, \Phi_v)} e^{-|v|^2} d^2 v$$

Дальше, для оператора A в виковской нормальной форме (2.46) получаем, используя первое свойство в (2.48),

$$(A\Phi_z, \Phi_{\bar{v}}) = \sum_{l,m} A_{lm} \left((a^*)^l a^m \Phi_z, \Phi_{\bar{v}} \right) = \sum_{l,m} A_{lm} \left(a^m \Phi_z, a^l \Phi_{\bar{v}} \right) =$$
$$= A(v,z) \left(\Phi_z, \Phi_{\bar{v}} \right).$$

Поэтому

$$A(v,z) = \frac{(A\Phi_z, \Phi_{\bar{v}})}{(\Phi_z, \Phi_{\bar{v}})} = e^{-vz} \left(A\Phi_z, \Phi_{\bar{v}} \right),$$

так как из воспроизводящего свойства следует, что $(\Phi_z, \Phi_{\bar{v}}) = \Phi_z(v) = e^{vz}$.

Определение. Виковский символ $A(\bar{z}, z)$ ограниченного оператора A в гильбертовом пространстве $\bar{D}$ является ограничением на подпространство $v = \bar{z}$ целой функции $A(v,z)$ в переменных v и z, определенной формулой

$$A(v,z) = e^{-vz} \left(A\Phi_z, \Phi_{\bar{v}} \right).$$

В следующей теореме мы перечислим основные свойства виковских символов.

Th. 2.2.

Виковские символы ограниченных операторов в $\overline{\mathscr{D}}$ обладают следующими свойствами.

(i) Если $A(\bar{z}, z)$ - виковский символ оператора A, то для виковского символа оператора A^* имеем $A^*(\bar{z}, z) = \overline{A(\bar{z}, z)}u$

$$A^*(v,z) = \overline{A(\bar{z}, \bar{v})}$$

(ii) Для $f \in \overline{\mathscr{D}}$

$$(Af)(\bar{z}) = \frac{1}{\pi} \int\limits_{\mathbb{C}} A(\bar{z}, v) f(\bar{v}) e^{-v(\bar{v}-\bar{z})} d^2 v$$

(iii) Вещественно-аналитическая функция $A(\bar{z}, z)$ является виковским символом ограниченного оператора A в $\overline{\mathscr{D}}$, если и только если она есть ограничение на подпространство $v = \bar{z}$ целой функции $A(v,z)$ в переменных v и z со свойством, что для любого $f \in \mathscr{D}$ интеграл в части (ii) абсолютно сходится и определяет функцию в $\overline{\mathscr{D}}$.

(iv) Если $A_1(\bar{z}, z)$ и $A_2(\bar{z}, z)$ - виковские символы операторов A_1 и A_2, то виковский символ оператора $A = A_1 A_2$ задается формулой

$$A(\bar{z}, z) = \frac{1}{\pi} \int\limits_{\mathbb{C}} A_1(\bar{z}, v) A_2(\bar{v}, z) e^{-(v-z)(\bar{v}-\bar{z})} d^2 v$$

ДОКАЗАТЕЛЬСТВО.

Имеем

$$A^*(v,z) = e^{-vz} \left(A^* \Phi_z, \Phi_{\bar{v}} \right) = e^{-vz} \left(\Phi_z, A\Phi_{\bar{v}} \right) = e^{-vz} \overline{(A\Phi_{\bar{v}}, \Phi_z)} = \overline{A(\bar{z}, \bar{v})}$$

что доказывает (i). Для доказательства (ii) воспользуемся воспроизводящим свойством и получим

$$(Af)(\bar{z}) = (Af, \Phi_z) = (f, A^* \Phi_z) = \frac{1}{\pi} \int\limits_{\mathbb{C}} f(\bar{v}) \overline{\left(A^* \Phi_z \right)(\bar{v})} e^{-|v|^2} d^2 v$$

Еще раз используя воспроизводящее свойство, получаем

$$\left(A^*\Phi_z\right)(\bar{v}) = \left(A^*\Phi_z, \Phi_v\right) = A^*(\bar{v}, z)\left(\Phi_z, \Phi_v\right) = \overline{e^{v\bar{z}}A(\bar{z}, v)}$$

что доказывает (ii). Свойство (iii) следует из определения и принципа равномерной ограниченности, который нужен, чтобы показать, что оператор A в $\bar{D}$, определенный интегралом в (ii), ограничен. Рутинные подробности остаются читателю. Чтобы доказать (iv), используя (2.50) и (i), мы получаем

$$\begin{aligned} A(\bar{z}, z) &= e^{-|z|^2}\left(A_1A_2\Phi_z, \Phi_z\right) = e^{-|z|^2}\left(A_2\Phi_z, A_1^*\Phi_z\right) = \\ &= \frac{1}{\pi}\int\limits_{\mathbb{C}}\left(A_2\Phi_z, \Phi_v\right)\overline{\left(A_1^*\Phi_z, \Phi_v\right)}e^{-\left(|v|^2+|z|^2\right)}d^2v = \\ &= \frac{1}{\pi}\int\limits_{\mathbb{C}}A_1(\bar{z}, v)A_2(\bar{v}, z)e^{-(v-z)(\bar{v}-\bar{z})}d^2v. \end{aligned}$$

ЗАмЕчАниЕ. Свойства (i) и (iv) остаются верными для многочленов от a^* и a - операторов вида (2.46).

Матричный символ $\tilde{A}(\bar{z}, z)$ ограниченного оператора A в гильбертовом пространстве $\overline{\mathscr{D}}$ - это ограничение на подпространство $v = \bar{z}$ целой функции $A(v, z)$ в переменных v и z, определенной следующим абсолютно сходящимся рядом:

$$\tilde{A}(v, z) = \sum_{m,n=0}^{\infty}\left(A\bar{f}_m, \bar{f}_n\right)f_n(v)f_m(z).$$

Матричный и виковский символы связаны следующим образом.

Лемма 2.4.

Для ограниченного оператора A в гильбертовом пространстве $\overline{\mathscr{D}}$

$$\tilde{A}(v, z) = e^{vz}A(v, z)$$

ДОКАЗАТЕЛЬСтвО.

Используя (2.49), получаем

$$\begin{aligned} \tilde{A}(v, z) &= \frac{1}{\pi}\sum_{m,n=0}^{\infty}f_n(v)f_m(z)\int\limits_{\mathbb{C}}\left(A\bar{f}_m\right)(\bar{u})f_n(u)e^{-|u|^2}d^2u = \\ &= \frac{1}{\pi}\int\limits_{\mathbb{C}}\left(A\Phi_z\right)(\bar{u})\overline{\Phi_{\bar{v}}(\bar{u})}e^{-|u|^2}d^2u = \left(A\Phi_z, \Phi_{\bar{v}}\right) = e^{vz}A(v, z). \end{aligned}$$

Перестановка суммирования и интегрирования корректна в виду абсолютной сходимости.

Следствие 2.3.

Если $\tilde{A}_1(\bar{z}, z)$ и $\tilde{A}_2(\bar{z}, z)$ - матричные символы операторов A_1 и A_2, то матричный символ оператора $A = A_1A_2$ дается формулой

$$\tilde{A}(\bar{z}, z) = \frac{1}{\pi}\int\limits_{\mathbb{C}}\tilde{A}_1(\bar{z}, v)\tilde{A}_2(\bar{v}, z)e^{-|v|^2}d^2v$$

ДОКАЗАТЕЛЬСТВО.

Доказательство мгновенно следует из части (iv) теоремы 2.2 и леммы 2.4.

Эти построения, очевидно, обобщаются на случай n степеней свободы. Гильбертово пространство $\mathscr{D}_n$, определяющее голоморфное представление, это пространство целых функций $f(\boldsymbol{z})$ от n комплексных переменных $\boldsymbol{z} = (z_1, ..., z_n)$ со скалярным произведением

$$(f, g) = \frac{1}{\pi^n} \int\limits_{\mathbb{C}^n} f(\boldsymbol{z})\overline{g(\boldsymbol{z})} e^{-|\boldsymbol{z}|^2} d^{2n}\boldsymbol{z} < \infty$$

где $|\boldsymbol{z}|^2 = z_1^2 + \cdots + z_n^2$ и $d^{2n}\boldsymbol{z} = d^2 z_1 \cdots d^2 z_n$ - мера Лебега на $\mathbb{C}^n \simeq \mathbb{R}^{2n}$. Функции

$$f_{\boldsymbol{m}}(\boldsymbol{z}) = \frac{z_1^{m_1} ... z_n^{m_n}}{\sqrt{m_1! ... m_n!}}, \quad m_1, ..., m_n = 0, 1, 2, ...$$

где $\boldsymbol{m} = (m_1, ..., m_n)$ - мультииндекс, образуют ортонормальный базис в $\mathscr{D}_n$. Соответствующие операторы рождения и уничтожения даются формулами

$$a_j^* = z_j, \quad a_j = \frac{\partial}{\partial z_j}, \quad j = 1, ..., n.$$

Гильбертово пространство $\overline{\mathscr{D}}_n$ антиголоморфных функций $f(\overline{\boldsymbol{z}})$ на $\mathbb{C}^n$ определяется скалярным произведением

$$(f, g) = \frac{1}{\pi^n} \int\limits_{\mathbb{C}^n} f(\overline{\boldsymbol{z}})\overline{g(\overline{\boldsymbol{z}})} e^{-|\boldsymbol{z}|^2} d^{2n} z < \infty$$

и операторы рождения и уничтожения даются формулами

$$a_j^* = \bar{z}_j, \quad a_j = \frac{\partial}{\partial \bar{z}_j}, \quad j = 1, ..., n.$$

Когерентные состояния - это $\Phi_{\boldsymbol{v}}(\overline{\boldsymbol{z}}) = e^{\boldsymbol{v}\overline{\boldsymbol{z}}}$, где $\boldsymbol{v}\overline{\boldsymbol{z}} = v_1\bar{z}_1 + \cdots + v_n z_n$, они удовлетворяют воспроизводящему свойству

$$f(\bar{v}) = (f, \Phi_{\boldsymbol{v}}), \quad f \in \overline{\mathscr{D}}_n, \quad v \in \mathbb{C}^n$$

Виковский символ $A(\overline{\boldsymbol{z}}, \boldsymbol{z})$ ограниченного оператора A в $\overline{\mathscr{D}}_n$ определяется как ограничение на подпространство $\boldsymbol{v} = \overline{\boldsymbol{z}}$ целой функции $A(\boldsymbol{v}, \boldsymbol{z})$ от $2n$ переменных $\boldsymbol{v} = (v_1, ..., v_n)$ и $\boldsymbol{z} = (z_1, ..., z_n)$, заданной формулой

$$A(\boldsymbol{v}, \boldsymbol{z}) = e^{-\boldsymbol{v}\boldsymbol{z}} (A\Phi_{\boldsymbol{z}}, \Phi_{\overline{\boldsymbol{v}}})$$

Имеем

$$(Af)(\overline{\boldsymbol{z}}) = \frac{1}{\pi^n} \int\limits_{\mathbb{C}^n} A(\overline{\boldsymbol{z}}, \boldsymbol{v}) f(\overline{\boldsymbol{v}}) e^{-\boldsymbol{v}(\overline{\boldsymbol{v}} - \overline{\boldsymbol{z}})} d^{2n}\boldsymbol{v}, \quad f \in \overline{\mathscr{D}}_n$$

и виковский символ $A(\overline{\boldsymbol{z}}, \boldsymbol{z})$ оператора $A = A_1 A_2$ дается формулой

$$A(\overline{\boldsymbol{z}}, \boldsymbol{z}) = \frac{1}{\pi^n} \int\limits_{\mathbb{C}^n} A_1(\overline{\boldsymbol{z}}, \boldsymbol{v}) A_2(\overline{\boldsymbol{v}}, \boldsymbol{z}) e^{-(\boldsymbol{v} - \boldsymbol{z})(\overline{\boldsymbol{v}} - \overline{\boldsymbol{z}})} d^{2n}\boldsymbol{v}$$

где $A_1(\bar{z}, z)$ и $A_2(\bar{z}, z)$ - виковские символы операторов A_1 и A_2.

Матричный символ $\tilde{A}(\overline{\boldsymbol{z}}, \boldsymbol{z})$ ограниченного оператора A в $\overline{\mathscr{D}}_n$ определяется как ограничение на подпространство $\boldsymbol{v} = \overline{\boldsymbol{z}}$ целой функции $\tilde{A}(\boldsymbol{v}, \boldsymbol{z})$ от $2n$ переменных $\boldsymbol{v} = (v_1, ..., v_n)$ и $\boldsymbol{z} = (z_1, ..., z_n)$, заданной абсолютно сходящимся рядом

$$\tilde{A}(\boldsymbol{v}, \boldsymbol{z}) = \sum_{\boldsymbol{k},\boldsymbol{m}=0}^{\infty} \left(A\bar{f}_{\boldsymbol{k}}, \bar{f}_{\boldsymbol{m}}\right) f_{\boldsymbol{m}}(\boldsymbol{v}) f_{\boldsymbol{k}}(\boldsymbol{z})$$

где $\boldsymbol{k} = (k_1, ..., k_n), \boldsymbol{m} = (m_1, ..., m_n)$ - мультииндексы и $\bar{f}_{\boldsymbol{m}}(\overline{\boldsymbol{z}}) = \overline{f_m(\boldsymbol{z})}$. Матричный и виковский символы ограниченного оператора A связаны формулой

$$\tilde{A}(\boldsymbol{v}, \boldsymbol{z}) = e^{\boldsymbol{v}\boldsymbol{z}} A(\boldsymbol{v}, \boldsymbol{z})$$

ЗАмЕЧАНИЕ. Антиголоморфное представление очень полезно в квантовой механике и особенно в квантовой теории поля, в которой оно называется голоморфным представлением (относительно переменных $\bar{z}$). Слегка злоупотребляя терминологией, в части 2 мы тоже будем называть его голоморфным представлением. ЗАДАЧА 2.15. Найдите явную формулу для унитарного оператора, осуществляющего изоморфизм гильбертовых пространств $\overline{\mathscr{D}}_n \simeq L^2\left(\mathbb{R}^n, d^n q\right)$.

ЗАДАчА 2.16. Докажите, что для ограниченного оператора A функции $A(\boldsymbol{v}, \boldsymbol{z})$ и $\tilde{A}(\boldsymbol{v}, \boldsymbol{z})$ являются целыми функциями от $2n$ переменных.

ЗАДАЧА 2.17. Пусть A - оператор в $\overline{\mathscr{D}}_n$ со следом и $A(\overline{\boldsymbol{z}}, \boldsymbol{z})$ - его виковский символ. Докажите, что

$$\operatorname{Tr} A = \frac{1}{\pi^n} \int\limits_{\mathbb{C}^n} A(\overline{\boldsymbol{z}}, \boldsymbol{z}) e^{-|\boldsymbol{z}|^2} d^{2n}\boldsymbol{z}$$

ЗАДАчА 2.18. Покажите, что виковский символ $A(\bar{z}, z)$ произведения $A = A_l ... A_1$ дается формулой

$$A(\bar{z}, z) = \\ = \frac{1}{\pi^l} \int\limits_{\mathbb{C}^l} A_l\left(\bar{z}, z_{l-1}\right) ... A_1\left(\bar{z}_1, z\right) \exp\left\{\sum_{k=1}^{l} \bar{z}_k \left(z_{k-1} - z_k\right)\right\} d^2 z_1 ... d^2 z_{l-1},$$

где $z_0 = z_l = z, \bar{z}_l = \bar{z}$ и $A_k(\bar{z}, z)$ - виковские символы операторов A_k.

6.4.6 Fermionic Oscillator

(пока только тут теория, потом мб в отдельной записи подробнее буду рассматривать.)

применения фермионного осциллятора (!?!)

(обсудим примеры, зачем он нужен? пока не за чем, поэтому и не занимался им!)
(?? мб в КТП он нужен, там про него что-то еще записано было.)

Фермионный осциллятор используется для описания фермионных полей.
(??)

вкратце описание фермионного осциллятора

грассмановы переменные

Напомним, какими свойствами обладают грассмановы переменные.

Обобщение осциллятора на случай фермионных квантов нетрудно построить в уже изложенном формализме с операторами рождения и уничтожения.

Действительно, предположим, что мы рассматриваем фермион с заданной проекцией спина на ось z и фиксированным набором неспиновых квантовых чисел.

Теперь уже число квантов

$$\hat{n} = \hat{a}^\dagger \hat{a}$$

должно иметь спектр собственных значений

$$n = \{0, 1\}$$

так как согласно принципу запрета Паули в состоянии с фиксированным набором квантовых чисел может находится максимум один квант.

Значит, у фермионного осциллятора базис образуют только два кет-вектора

$$|0\rangle, \quad |1\rangle$$

Для этого необходимо, чтобы действие повышающего оператора на вектор состояния $|1\rangle$ не приводило к возникновению нового состояния:

$$\hat{a}^\dagger |1\rangle = 0$$

Но это есть не что иное, как уравнение на старший вектор. В то же время верно и определение вакуума

$$\hat{a}|0\rangle = 0$$

что, очевидно, можно трактовать как уравнение на младший вектор. В итоге мы имеем квантовую систему с двумя уровнями со старшим и младшим векторами состояний. Такая квантовая систем уже была нами построена-это, по сути, спинор. В ней операторы представляются в базисе (7.7) как матрицы 2×2. Легко провести

следующее отождествление

$$\hat{n} = \frac{1}{2} + \hat{s}_z$$

так как в заданном базисе оператор числа квантов диагонален по построению, как и матрица $\hat{s}_z$ с собственными значениями $\left\{\frac{1}{2}, -\frac{1}{2}\right\}$, откуда

$$\hat{n} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$$

так что

$$\hat{n} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \hat{n} \begin{pmatrix} 0 \\ 1 \end{pmatrix} = 0$$

и состояния представлены столбцами

$$|1\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad |0\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

Аналогично повышающий и понижающий операторы становятся операторами рождения и уничтожения:

$$\hat{a}^\dagger = \hat{s}_+, \quad \hat{a} = \hat{s}_-$$

Для них имеет место антикоммутационное соотношение

$$\left\{\hat{a}, \hat{a}^\dagger\right\} = \left\{\left(\hat{s}_x - i\hat{s}_y\right), \left(\hat{s}_x + \mathrm{i}\hat{s}_y\right)\right\} = \left\{\hat{s}_x, \hat{s}_x\right\} + \left\{\hat{s}_y, \hat{s}_y\right\} = 1$$

Значит, для фермионного осциллятора

$$\left\{\hat{a}, \hat{a}^\dagger\right\} = 1$$

сравнение гамильтонианов бозонной и фермионной частиц (???)

Сравним запись для гамильтонианов у бозонной и фермионной частиц.

Именно, у гармонического осциллятора переход от операторов координаты и импульса к операторам рождения и уничтожения квантов приводил к

$$\hat{H}_b = \hbar\omega \frac{1}{2}\left(\hat{a}_b^\dagger \hat{a}_b + \hat{a}_b \hat{a}_b^\dagger\right)$$

и использование стандартного коммутатора $\hat{a}_b \hat{a}_b^\dagger - \hat{a}_b^\dagger \hat{a}_b = 1$ давал

$$\hat{H}_b = \hbar\omega \left(\hat{a}_b^\dagger \hat{a}_b + \frac{1}{2}\right)$$

У фермионных полей возникает вклад вида

$$\hat{H} = \hbar\omega \frac{1}{2}\left(\hat{a}^\dagger \hat{a} - \hat{a}\hat{a}^\dagger\right)$$

и использование стандартного антикоммутатора $\hat{a}\hat{a}^\dagger + \hat{a}^\dagger \hat{a} = 1$ дает

$$\hat{H} = \hbar\omega \left(\hat{a}_b^\dagger \hat{a}_b - \frac{1}{2}\right)$$

Только антикоммутационные соотношения для операторов рождения и уничтожения в этом случае гарантируют, что спектр энергии ограничен снизу и система не проваливается в бесконечность, испуская море энергии.

Интересно отметить, что в случае, если характеристики каждой бозонной моды совпадают с характеристиками такой же фермионной моды, вклад вакуумных между числом бозонных и фермионных вакуумных мод называтот индексом Виттена (имеются примеры даже суперсимметричных теории поля, в которых индекс Виттена отличен от нуля). Симметрия между бозонными и фермионными партнерами называется суперсимметрией.

Возникновение суперсимметрии мы рассмотрим чуть ниже.

А сейчас обратимся к вопросу об описании фермионных мод в терминах когерентных состояний.

Это позволит нам увидеть полную идентичность записи для базиса когерентных состояний у бозонных и фермионных мод с той лишь разницей,

что амплитуды бозонных мод - комплексные числа,

а амплитуды фермионных мод - грассамановы переменные.

Когерентные состояния определяются по-прежнему:

$$\hat{a}|\,\mathrm{th}\rangle = \mathrm{th}\,|\,\mathrm{th}\rangle$$

где необходимо осторожно обращаться с числами нового типа th, свойства которых мы выясним при построении голоморфного представления.

Разложим когерентные состояния по базису.

Для этого рассмотрим

$$\langle 0|\hat{a}|\,\mathrm{th}\rangle = \left(\hat{a}^\dagger|0\rangle\right)^\dagger |\,\mathrm{th}\rangle = \langle 1|\,\mathrm{th}\rangle$$

откуда с учетом условия когерентности (7.15) находим

$$C_1 = \langle 1|\,\mathrm{th}\rangle = \mathrm{th}\langle 0|\,\mathrm{th}\rangle = \mathrm{th}\, C_0$$

Так как разложение включает в себя только два члена,

$$|\,\mathrm{th}\rangle = C_0(|0\rangle + \mathrm{th}\,|1\rangle)$$

Нормировка на единицу дает

$$\langle \mathrm{th}\,|\,\mathrm{th}\rangle = |C_0|^2\,(1 + \bar{\mathrm{th}}\,\mathrm{th}), \quad \bar{\mathrm{th}} = \mathrm{th}^\dagger$$

Кроме того, из соотношений $\left\langle \mathrm{th}\left|\hat{a}^\dagger\hat{a}\right|\mathrm{th}\right\rangle = \bar{\mathrm{th}}\,\mathrm{th}\langle \mathrm{th}\,|\,\mathrm{th}\rangle = \bar{\mathrm{th}}\,\mathrm{th}$, а также

$$\hat{a}|\,\mathrm{th}\rangle = C_0\,\mathrm{th}\,|0\rangle$$

следует, что

$$\left\langle \mathrm{th}\left|\hat{a}^\dagger\hat{a}\right|\mathrm{th}\right\rangle = |C_0|^2\,\bar{\mathrm{th}}\,\mathrm{th} = \bar{\mathrm{th}}\,\mathrm{th}$$

Поэтому в согласии с условием нормировки найдем

$$|C_0|^2\,(1 + \bar{\mathrm{th}}\,\mathrm{th}) = |C_0|^2 + \bar{\mathrm{th}}\,\mathrm{th} = 1$$

Т. е.

$$|C_0|^2 = 1 - \bar{\mathrm{th}}\,\mathrm{th}$$

а также

$$|C_0|^2\,(1 + \bar{\mathrm{th}}\,\mathrm{th}) = (1 - \bar{\mathrm{th}}\,\mathrm{th})(1 + \bar{\mathrm{th}}\,\mathrm{th}) = 1$$

и, следовательно,

$$(\bar{\mathrm{th}}\,\mathrm{th})^2 = 0$$

а значит, и все высшие степени $\bar{\mathrm{th}}\,\mathrm{th}$ обращаются в нуль.

Голоморфное представление (???)

Разложение по базису позволяет построить голоморфное представление в полной аналогии со случаем бозонного осциллятора. Действительно, определим базисные голоморфные функции согласно

$$\langle n|\,\mathrm{th}\rangle = C_0\psi_n^*(\bar{\mathrm{th}}), \quad n = \{0, 1\}$$

Значит,

$$\psi_0(\bar{\mathrm{th}}) = 1, \quad \psi_1(\bar{\mathrm{th}}) = \bar{\mathrm{th}}$$

Отсюда получаем голоморфные представления операторов. Для оператора рождения имеем

$$\hat{a}^\dagger\psi_0(\bar{\mathrm{th}}) = \psi_1(\bar{\mathrm{th}}) \to \hat{a}^\dagger = \bar{\mathrm{th}}$$

Однако, поскольку

$$\hat{a}^\dagger\psi_1(\bar{\mathrm{th}}) = 0$$

получаем необычное свойство числа $\bar{\mathrm{th}}$:

$$\bar{\mathrm{th}}^2 = 0 \leftrightarrow \{\bar{\mathrm{th}}, \bar{\mathrm{th}}\} = 0$$

Взяв эрмитово сопряжение, находим также

$$\{\mathrm{th}, \mathrm{th}\} = 0$$

Собственные значения оператора уничтожения для фермионного осциллятора можно умножать на числа и складывать, так что из соотношений $\mathrm{th}_1^2 = \mathrm{th}_2^2 = 0$ следует, что и собственное число $\mathrm{th}_1 + \mathrm{th}_2$ обладает тем же свойством:

$$(\mathrm{th}_1 + \mathrm{th}_2)^2 = 0 \rightarrow \quad \{\mathrm{th}_1, \mathrm{th}_2\} = \mathrm{th}_1\,\mathrm{th}_2 + \mathrm{th}_2\,\mathrm{th}_1 = 0$$

а значит, перестановка двух собственных чисел происходит со сменой знака. В частности,

$$\mathrm{th}\,\bar{\mathrm{th}} = -\bar{\mathrm{th}}\,\mathrm{th}$$

Для оператора уничтожения

$$\hat{a}\psi_1(\bar{\mathrm{th}}) = \psi_0(\bar{\mathrm{th}}) \rightarrow \hat{a} = \frac{\partial}{\partial\bar{\mathrm{th}}}$$

откуда автоматически

$$\hat{a}\psi_0(\bar{\mathrm{th}}) = 0$$

как и должно быть. Для операторов рождения и уничтожения в голоморфном представлении справедливы антикоммутационные соотношения

$$\left\{\hat{a}, \hat{a}^\dagger\right\} = 1$$

так как на базисных функциях действительно легко вычислить с учетом антикоммутационных соотношений для переменной $\bar{\mathrm{th}}$

$$\left\{\hat{a}, \hat{a}^\dagger\right\}\psi_0(\bar{\mathrm{th}}) = 1 = \psi_0(\bar{\mathrm{th}})$$

и

$$\left\{\hat{a}, \hat{a}^\dagger\right\}\psi_1(\bar{\mathrm{th}}) = \bar{\mathrm{th}} = \psi_1(\bar{\mathrm{th}})$$

С учетом того, что все функции от th и $\bar{\mathrm{th}}$ разлагаются в ряд только до линейных по каждой из переменных членов, можно записать, что

$$1 + \bar{\mathrm{th}}\,\mathrm{th} = e^{\bar{\mathrm{th}}\,\mathrm{th}}$$

откуда

$$|C_0|^2 = e^{-\bar{\mathrm{th}}\,\mathrm{th}}$$

т. е. имеет место прежнее выражение для вклада вакуума в когерентное состояние. Условие полноты когерентных состояний запишем в виде

$$\int \mathrm{d}\bar{\mathrm{th}}\mathrm{d}\,\mathrm{th}\,|\,\mathrm{th}\rangle\langle\mathrm{th}\,|\,| = 1$$

где необходимо определить правила интегрирования так, чтобы выполнялись соотношения ортонормированности базисных векторов. Именно,

$$\int \mathrm{d}\bar{\mathrm{th}}\mathrm{d}\,\mathrm{th}\langle n|\,\mathrm{th}\rangle\langle\mathrm{th}\,|m\rangle = \delta_{nm}, \quad n, m = \{0, 1\}$$

Интеграл можно переписать с помощью голоморфных волновых функций как

$$\int \mathrm{d}\bar{\mathrm{th}}\mathrm{d}\,\mathrm{th}\,e^{-\bar{\mathrm{th}}\,\mathrm{th}}\psi_n^*(\bar{\mathrm{th}})\psi_m(\bar{\mathrm{th}})$$

и в матричном виде получить равенство

$$\int \mathrm{d}\bar{\mathrm{th}}\mathrm{d}\,\mathrm{th}\, e^{-\mathrm{t}\bar{\mathrm{h}}\,\mathrm{th}} \begin{pmatrix} 1 & \mathrm{t}\bar{\mathrm{h}} \\ \mathrm{th} & \mathrm{th}\,\mathrm{t}\bar{\mathrm{h}} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Справедливость этого равенства имеет место, если принять следующие правила интегрирования:

$$\int \mathrm{d}\,\mathrm{th} = \int \mathrm{d}\mathrm{t}\bar{\mathrm{h}} = 0$$
$$\int \mathrm{th}\,\mathrm{d}\,\mathrm{th} = \int \mathrm{t}\bar{\mathrm{h}}\mathrm{d}\mathrm{t}\bar{\mathrm{h}} = 1$$

а также антикоммутативность переменных

$$\{\mathrm{th}, \mathrm{t}\bar{\mathrm{h}}\} = 0$$

и их дифференциалов. Совокупность соотношений антикоммутативности (7.19),(7.20),(7.27) и правила интегрирования (7.25),(17.26) полностью определяют алгебру переменных грассмана или грассмановы преемменные.

голоморфное представление для когерентных состояний фермионов, очевидно, формально повторяет построения в пространстве Баргмана-Фока для бозонных состояний. Стало быть, для вторично квантованного фермионного поля легко записать и решеточную аппроксимацию интеграла Фейнмана в полной аналогии с бозонными полями, используя амплитуды положительно и отрицательно частотных мод в каждом узле решетки импульсного пространства.

Другое о фермионном осцилляторе

примеры применения в КТП

скоро напишу наверное.
вроде бы грассмановы переменные очень много где используются (????)
В вейлевских спинорах это встречается

Сравнение с бозонным осциллятором

6.4.7 Moving oscillator

(порешаю потом задачу)

6.4.8 Oscillator, Moving with $v \approx c$

(тут вопросы про то, как он связан с сокращением длины)

6.4.9 Motion in a Central Field

(мб в другое место вставлю, тут продолб большой, что все еще нет четких методов про это. пока только этот раздел, потом напишу больше и лучше!!!)

Квантовая модель движения в центральном поле по Ландау

(из Ландау скопированы формулы, текст копироваться не хочет)
Одной частице, - аналогично тому, Как это может быть сде.тано

$$\hat{H} = -\frac{\hbar^2}{2m_1}\Delta_1 - \frac{\hbar^2}{2m_2}\Delta_2 + U(r)$$

$$\mathbf{r} = \mathbf{r}_2 - \mathbf{r}_1, \quad \mathbf{R} = \frac{m\mathbf{r}_1 + m_2\mathbf{r}_2}{m_1 + m_2}$$

$$\hat{H} = -\frac{\hbar^2}{2\,(m_1 + m_2)}\Delta_R - \frac{\hbar^2}{2m}\Delta + U(r)$$

$$\Delta\psi + \frac{2m}{\hbar^2}[E - U(r)]\psi = 0$$

Воспользовавшись известным выражением для оператора Лапласа $32]

движение в центрально-симметричном поле в сферических координатах, напишем это уравнение в виде

$$\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\psi}{\partial r}\right) + \frac{1}{r^2}\left[\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial\psi}{\partial\theta}\right) + \frac{1}{\sin^2\theta}\frac{\partial^2\psi}{\partial\varphi^2}\right] + \frac{2m}{\hbar^2}[E - U(r)]\psi = 0$$

если ввести оператор квадрата момента, то мы получим

$$\frac{\hbar^2}{2m}\left[-\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\psi}{\partial r}\right) + \frac{\hat{\mathrm{Im}ath}^2}{r^2}\psi\right] + U(r)\dot{\psi} = E\psi$$

Заданнем значений l и m оп ределяется угловая зависымость ВОл- Hin (32,6) В ВН Ze

$$\psi = R(r)Y_{lm}(\theta, \varphi)$$

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{dR}{dr}\right) - \frac{l(l+1)}{r^2}R + \frac{2m}{\hbar^2}[E - U(r)]R = 0$$

Это уравнение не содержит вовсе значения $l_2 = m$, что соответст- по направ.тениям момента.

Займемся исследованнем радиальной части волновых функцнй.

Подстановкой

$$R(r) = \frac{\chi(r)}{r}$$

$$\frac{d^2\chi}{dr^2} + \left[\frac{2m}{\hbar^2}(E - U) - \frac{l(l+1)}{r^2}\right]\chi = 0$$

В нуле:

$$\chi(0) = 0$$

В действительности это условне сохраняется (см. $35) также М Для поля, обращающегося при $r \to 0$ В бесконечность.

Уравненне (32,10) по форме совпадает с уравнением ШГредингера дл одномерного движения в поле с потенциальной энергией

$$U_l(r) = U(r) + \frac{\hbar^2}{2m}\frac{l(l+1)}{r^2}$$

равной сумме энергии $U(r)$, и члена

$$\frac{\hbar^2 l(l+1)}{2mr^2} = \frac{\hbar^2\mathbf{2}^2}{2mr^2}$$

Сферические волны по Ландау

(пар 33 ландау)

$$\psi_p = \text{const} \cdot e^{\frac{i}{\hbar}pr}$$

описывает стационарное состояние, в котором свободная частица обладает определенным импульсом p (и энергией $E = p^2/2m$) Рассмотрим теперь такие стационарные состояния свободной Частицы, В Которых она обладает, наряду с энергией, Определенными величиной и проекцией момента.

Вместо энергии нам будет удобно ввести волновой вектор

$$k = \frac{p}{\hbar} = \frac{\sqrt{2mE}}{\hbar}$$

имеет вид

$$\psi_{klm} = R_{kl}(r)Y_{lm}(\theta, \varphi)$$

где радиальная функция определяется уравнением

$$R''_{kl} + \frac{2}{r}R_{kl} + \left[k^2 - \frac{l(l+1)}{r^2}\right]R_{kl} = 0$$

(уравнение (32,8) без $U(r)$). Волновые функции ψ_{klm}, относящиеся К непрерывному (по k) спектру, удовлетворяют условиям нормировки и взаимной ортогональности:

$$\int \psi^*_{k'l'm'}\psi_{klm}dV = \delta_{ll'}\delta_{mm'}\delta\left(\frac{k'-k}{2\pi}\right)$$

(и тут куча деталей, позже их буду писать)

6.4.10 Angular Momentum Operators

(it was written before, I'll check and then or delete, or move to the previous part)

Теория

В главе 1 (см. пример 1.10 в разделе 1.1.4) мы ввели для классической частицы в $\mathbb{R}^3$ вектор углового момента $\boldsymbol{M}_{\text{c}} = \boldsymbol{x} \times \boldsymbol{p}$ с компонентами

$$M_{\text{c}1} = x_2p_3 - x_3p_2, \quad M_{\text{c}2} = x_3p_1 - x_1p_3, \quad M_{\text{c}3} = x_1p_2 - x_2p_1$$

Согласно примеру 2.1 в разделе 1.2.6 главы 1, у них следующие скобки Пуассона в канонической пуассоновой структуре на $T^*\mathbb{R}^3$:

$$\{M_{c1}, M_{c2}\} = -M_{c3},$$
$$\{M_{c2}, M_{c3}\} = -M_{c1},$$
$$\{M_{c3}, M_{c1}\} = -M_{c2}.$$

Квадрат углового момента $M_c^2 = M_{c1}^2 + M_{c2}^2 + M_{c3}^2$ удовлетворяет условию

$$\{\boldsymbol{M}_c^2, M_{c1}\} = \{\boldsymbol{M}_c^2, M_{c2}\} = \{\boldsymbol{M}_c^2, M_{c3}\} = 0.$$

Если функция Гамильтона

$$H_c(\boldsymbol{p}, \boldsymbol{x}) = \frac{\boldsymbol{p}^2}{2m} + V(\boldsymbol{x})$$

инвариантна при вращениях, $V(\boldsymbol{x}) = V(|\boldsymbol{x}|)$, то компоненты углового момента являются интегралами движения:

$$\{h_c, M_{c1}\} = \{H_c, M_{c2}\} = \{H_c, M_{c3}\} = 0 \quad \text{и} \quad \{H_c, M_c^2\} = 0.$$

Это также можно проверить прямо, используя скобки Пуассона

$$\{M_{cj}, p_k\} = -\varepsilon_{jkl} p_l \quad \text{и} \quad \{M_{cj}, x_k\} = -\varepsilon_{jkl} x_l, \quad i, j, k = 1, 2, 3,$$

где ε_{jkl} - полностью антисимметрический тензор, $\varepsilon_{123} = 1$.

В свою очередь, в квантовой механике компоненты оператора углового момента $\boldsymbol{M} = \boldsymbol{Q} \times \boldsymbol{P}$ определяются формулами

$$M_1 = Q_2 P_3 - Q_3 P_2, \quad M_2 = Q_3 P_1 - Q_1 P_3, \quad M_3 = Q_2 P_3 - Q_3 P_2,$$

где $\boldsymbol{Q} = (Q_1, Q_2, Q_3)$ и $\boldsymbol{P} = (P_1, P_2, P_3)$ - соответственно, операторы координаты и импульса. Поскольку операторы Q_i и P_k коммутируют при $i \neq k$, проблемы упорядочивания при определении операторов квантового углового момента не возникает. Из коммутационных соотношений Гейзенберга следует, что их квантовые скобки устроены также, как и соответствующие скобки Пуассона (3.1):

$$\{M_1, M_2\}_\hbar = -M_3, \quad \{M_2, M_3\}_\hbar = -M_1, \quad \{M_3, M_1\}_\hbar = -M_2.$$

Эквивалентно,

$$[M_1, M_2] = i\hbar M_3, \quad [M_2, M_3] = i\hbar M_1, \quad [M_3, M_1] = i\hbar M_2.$$

Оператор квадрата полного углового момента $\boldsymbol{M}^2 = M_1^2 + M_2^2 + M_3^2$ удовлетворяет уравнению

$$\big[\boldsymbol{M}^2, M_1\big] = \big[\boldsymbol{M}^2, M_2\big] = \big[\boldsymbol{M}^2, M_3\big] = 0.$$

Соответственно, для оператора гамильтониана

$$H = \frac{\boldsymbol{P}^2}{2m} + V(\boldsymbol{Q})$$

со сферически симметрическим потенциалом $V(\boldsymbol{x}) = V(|\boldsymbol{x}|)$ операторы M_1, M_2, M_3, а поэтому и $\boldsymbol{M}^2$, - квантовые интегралы движения:

$$[H, M_1] = [H, M_2] = [H, M_3] = 0 \quad \text{и} \quad \big[H, M^2\big] = 0.$$

Это можно прямо проверить, используя квантовые скобки

$$\{M_j, P_k\}_\hbar = -\varepsilon_{jkl} P_l, \quad \{M_j, Q_k\}_\hbar = -\varepsilon_{jkl} Q_l, \quad j,k,l = 1,2,3,$$

которые устроены так же, как скобки Пуассона (3.2), что следует из коммутационных соотношений Гейзенберга.

В координатном представлении $\mathscr{H} = L^2(\mathbb{R}^3, d^3\boldsymbol{x})$ операторы углового момента задаются следующими самосопряженными дифференциальными операторами первого порядка:

$$\begin{aligned} M_1 &= i\hbar\left(x_3\frac{\partial}{\partial x_2} - x_2\frac{\partial}{\partial x_3}\right), \\ M_2 &= i\hbar\left(x_1\frac{\partial}{\partial x_3} - x_3\frac{\partial}{\partial x_1}\right), \\ M_3 &= i\hbar\left(x_2\frac{\partial}{\partial x_1} - x_1\frac{\partial}{\partial x_2}\right). \end{aligned}$$

Они обладают свойством, что

$$M_1\psi = M_2\psi = M_3\psi = 0$$

для любой сферически симметричной гладкой функции $\psi(\boldsymbol{x}) = \psi(|\boldsymbol{x}|)$. Иными словами, операторы углового момента действуют только на угловые координаты на $\mathbb{R}^3$. То есть пусть

$$x_1 = r\sin\vartheta\cos\varphi, \quad x_2 = r\sin\vartheta\sin\varphi, \quad x_3 = r\cos\vartheta,$$

где $0 \leqslant \vartheta < \pi, 0 \leqslant \varphi < 2\pi$ - сферические координаты на $\mathbb{R}^3$. Явное вычисление дает

$$\begin{aligned} M_1 &= i\hbar\left(\sin\varphi\frac{\partial}{\partial\vartheta} + \cot\vartheta\cos\varphi\frac{\partial}{\partial\varphi}\right) \\ M_2 &= -i\hbar\left(\cos\varphi\frac{\partial}{\partial\vartheta} - \cot\vartheta\sin\varphi\frac{\partial}{\partial\varphi}\right) \\ M_3 &= -i\hbar\frac{\partial}{\partial\varphi} \end{aligned}$$

Таким образом,

$$M^2 = -\hbar^2\left(\frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\left(\sin\vartheta\frac{\partial}{\partial\vartheta}\right) + \frac{1}{\sin^2\vartheta}\frac{\partial^2}{\partial\varphi^2}\right)$$

так что оператор $-\frac{1}{\hbar^2}\boldsymbol{M}^2$ - сферическая часть оператора Лапласа на $\mathbb{R}^3$:

$$\Delta = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) - \frac{1}{\hbar^2 r^2}M^2.$$

6.4.11 SO(3) Representations for the Hydrogen Atom

Теория

Квантовые операторы углового момента связаны с теорией представлений группы вращений SO(3) - группы ортогональных матриц 3×3с определителем 1.SO(3) - компактная группа Ли, изоморфная вещественному проективному пространству $\mathbb{RP}^3$ как гладкое многообразие. Имеется изоморфизм групп Ли $\mathrm{SO}(3) \simeq \mathrm{SU}(2)/\{\pm I\}$, где SU(2) -

группа Ли унитарных матриц 2×2 с определителем 1. Алгебра Ли so(3) группы SO(3) - трехмерная алгебра Ли кососимметрических матриц 3×3 с базисом

$$X_1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, \quad X_2 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, \quad X_3 = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Матрицы X_1, X_2, X_3 порождают соответственно однопараметрические подгруппы SO(3), состоящие из вращений вокруг координатных осей в $\mathbb{R}^3$. Они удовлетворяют коммутационным соотношениям

$$[X_1, X_2] = X_3, \quad [X_2, X_3] = X_1, \quad [X_3, X_1] = X_2,$$

подобным (3.4).

Чтобы установить связь между квантовыми операторами углового момента и теорией представлений SO(3), рассмотрим регулярное представление R группы SO(3) в $\mathscr{H} = L^2(\mathbb{R}^3, d^3\boldsymbol{x})$, определенное формулой

$$(R(g)\psi)(\boldsymbol{x}) = \psi\left(g^{-1}\boldsymbol{x}\right), \quad g \in \mathrm{SO}(3), \psi \in \mathscr{H}$$

Лемма 3.1.

Имеем

$$R\left(e^{u_1X_1+u_2X_2+u_3X_3}\right) = e^{-\frac{i}{\hbar}(u_1M_1+u_2M_2+u_3M_3)}$$

Proof.

Положим $\boldsymbol{uX} = u_1X_1 + u_2X_2 + u_3X_3$ и $\boldsymbol{uM} = u_1M_1 + u_2M_2 + u_3M_3$. Из теоремы Стоуна и прямого вычисления следует, что

$$i\hbar\frac{\partial}{\partial u_j}\bigg|_{u=0} R\left(e^{u\boldsymbol{X}}\right) = M_j, \quad j = 1, 2, 3$$

где самосопряженные операторы M_1, M_2, M_3 даны формулами (3.6)-(3.8). Теперь для фиксированных u_1, u_2, u_3 рассмотрим однопараметрическую группу $U(t) = R\left(e^{tuX}\right)$ унитарных операторов в $\mathscr{H}$. По теореме Стоуна $U(t) = e^{-itA}$, где

$$A = i\frac{d}{dt}\bigg|_{t=0} U(t) = \frac{1}{\hbar}\boldsymbol{uM}$$

ЗАмЕчАНИЕ. Имеем $M_j = i\hbar\rho(X_j)$, где $\rho = dR$ - соответствующее регулярное представление алгебры Ли $\mathfrak{so}(3)$ в $\mathscr{H}$.

Все неприводимые унитарные представления R_l группы Ли SO(3) конечномерны и параметризуются неотрицательными целыми числами $l \geqslant 0$. Соответствующее неприводимое представление $\rho_l = dR_l$ алгебры Ли $\mathfrak{so}(3)$ в $2l+1$ - мерном комплексном векторном пространстве V_l можно явно описать следующим образом. Введем эрмитовы операторы $T_j = i\rho_l(X_j)$, $j = 1, 2, 3$, удовлетворяющие коммутационным соотношениям

$$[T_1, T_2] = iT_3, \quad [T_3, T_1] = iT_2, \quad [T_2, T_3] = iT_1$$

В векторном пространстве V_l есть ортонормированный базис $\{e_{lm}\}_{m=-l}^{m=l}$, такой, что

$$(T_1 - iT_2)\, e_{lm} = -\sqrt{(l+m)(l-m+1)}e_{lm-1}$$
$$(T_1 + iT_2)\, e_{lm} = -\sqrt{(l-m)(l+m+1)}e_{lm+1}$$
$$T_3 e_{lm} = m e_{lm}.$$

В частности, $(T_1 + iT_2)\, e_{ll} = 0$, так что V_l - модуль со старшим весом. Представление ρ_l неприводимо, и по лемме Шура

$$\boldsymbol{T}^2 = l(l+1)I_l$$

где I_l - тождественный оператор в V_l. Это можно также прямо проверить, используя (3.10) − (3.12).

ЗАмЕчАниЕ. Когда l - полуцелое число, т.е. $l \in \frac{1}{2} + \mathbb{Z}_{\geqslant 0}$, и $m = -l, -l+1, ..., l-1, l$, формулы (3.10) − (3.12) все еще определяют неприводимое представление ρ_l старшего веса алгебры Ли $\mathfrak{so}(3)$ размерности $2l+1$, и любое неприводимое n-мерное представление $\mathfrak{so}(3)$ изоморфно представлению $\rho_l cl = \frac{n-1}{2}$. Для полуцелых l представления ρ_l не интегрируемы: они порождают двузначные представления SO(3), так называемые спинорныеб представления. Однако рассматриваемые как представления алгебры Ли $\mathfrak{su}(2) \simeq \mathfrak{so}(3), \rho_l$ соответствуют неприводимым унитарным представлениям группы Ли SU(2). Из теории представлений SU(2) следует, что при $l, l' \in \frac{1}{2}\mathbb{Z}_{\geqslant 0}$

$$V_l \otimes V_{l'} = \bigoplus_{j=|l-l'|}^{l+l'} V_j$$

это так называемое разложение Клебша-Гордона. В физике оно соответствует сложению угловых моментов.

Регулярное представление R группы SO(3) в $\mathscr{H} = L^2(\mathbb{R}^3, d^3x)$ не является неприводимым. Имеем

$$\mathscr{H} = L^2\left(S^2, dn\right) \otimes L^2\left(\mathbb{R}_{>0}, r^2 dr\right)$$

где dn - мера на S^2, индуцированная мерой Лебега на $\mathbb{R}^3$. Группа SO(3) действует вращениями на первом сомножителе тензорного произведения (3.14), тогда как она действует на второй сомножитель как тождественный оператор. Таким образом, задача разложения регулярного представления R сводится к нахождению SO(3)-инвариантных подпространств гильбертова пространства $L^2(S^2, d\boldsymbol{n})$. Итог - разложение в ортогональную сумму

$$L^2\left(S^2, dn\right) = \bigoplus_{l=0}^{\infty} \mathscr{D}_l$$

где $\mathscr{D}_l \simeq V_l$. При этом изоморфизме ортонормированный базис Y_{lm} в $\mathscr{D}_l$, соответствующий базису e_{lm} в V_l, дается нормированными сферическими функциями

$$Y_{lm}(\vartheta, \varphi) = \frac{1}{\sqrt{2\pi}} e^{im\varphi} P_l^m(\cos\vartheta), \quad m = -l, ..., l$$

где $P_l^m(x)$ - нормированные присоединенные полиномы Лежандра,

$P_l^m(x) = (-1)^m \sqrt{\frac{(l+m)!}{(l-m)!}} \sqrt{\frac{2l+1}{2}} \frac{1}{2^l l!} \left(1-x^2\right)^{-\frac{m}{2}} \frac{d^{l-m}}{dx^{l-m}} \left(x^2-1\right)^l, .|x| < 1$

Самосопряженный оператор M^2 в гильбертовом пространстве $L^2(S^2, d\boldsymbol{n})$ имеет чисто точечный спектр, состоящий из собственных значений $\hbar^2 l(l+1)$ кратностей $2l+1, l = 0, 1, 2, ...$, и разложение (3.15) дает разложение по его собственным функциям: для любого $\psi \in L^2(S^2, d\boldsymbol{n})$

$$\psi = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} C_{lm} Y_{lm}, \quad \text{где } C_{lm} = \int_0^{2\pi} \int_0^{\pi} \psi(\vartheta, \varphi) \overline{Y_{lm}(\vartheta, \varphi)} \sin\vartheta d\vartheta d\varphi$$

ЗАдАЧА 3.1. Докажите все результаты этого раздела. (Указание: см. литературу к этой главе.)

6.5 Harmonic Oscillator: Advanced Ideas

6.5.1 Overview of Applications of Harmonic Oscillator

(surprisingly, there are a lot of applications. I'll discuss them here)

6.5.2 Discrete Spectrum in a Central Field

Теория по Тахтаджаяну

Атом водорода описывается дальнодействующим потенциалом

$$V(\boldsymbol{r}) = -\frac{\alpha}{r}$$

кулоновским потенциалом, где $\alpha > 0$[3]. Соответствующая задача о собственных значениях для оператора Шрёдингера с кулоновским потенциалом называется кулоновской задачей. Здесь мы представим ее точное решения, используя так называемые кулоновские единицы $\hbar = 1, \mu = 1$, и $\alpha = 1$[4].

Чтобы определить дискретный спектр, удобно положить $2E = -\varkappa^2 < 0$, так что уравнение на собственные значения (4.10) превращается в

$$f_l'' + \left(\frac{2}{r} - \frac{l(l+1)}{r^2} - \varkappa^2\right) f_l = 0.$$

Асимптотики (4.12) - (4.13) для короткодействующих потенциалов наводят на мысль, что для дальнодействующего кулоновского потенциала можно искать решение с интегрируемым квадратом в следующем виде:

$$f_l(r) = r^{l+1} e^{-\varkappa r} \Lambda(r).$$

Подставив это в (5.1), получаем уравнение

$$\Lambda_l'' + \left(\frac{2(l+1)}{r} - 2\varkappa\right)\Lambda_l' + \left(\frac{2}{r} - \frac{2\varkappa(l+1)}{r}\right)\Lambda_l = 0,$$

которое можно решить с помощью степенного ряда

$$\Lambda_l(r) = \sum_{k=0}^{\infty} a_k r^k$$

Подстановка этого степенного ряда в (5.2) дает следующее рекуррентное соотношение для коэффициентов a_k:

$$a_{k+1} = \frac{2\varkappa(k+l+1) - 2}{(k+1)(k+2l+2)} a_k, \quad k = 1, 2, ...,$$

[3] Для атома водорода $\alpha = e^2$, где e - заряд электрона. Случай $\alpha = Ze^2$, где $Z = 2, 3, ...$, соответствует ионам водорода.

[4] Когда $\alpha = e^2$, кулоновские единицы совпадают с атомными единицами. где $a_0 \neq 0$. Степенной ряд (5.3) сходится при всех $r > 0$ по признаку сходимости Даламбера. Когда $\varkappa > 0$ таково, что $a_k \neq 0$ для любого k, имеем

$$\lim_{k\to\infty}\frac{(k+1)a_{k+1}}{a_k}=2\varkappa.$$

Таким образом, для любого $\varepsilon>0$ существует N, такое, что при $k>N$ все a_k одного знака, скажем $a_k>0$, и

$$\frac{a_{k+1}}{a_k}\geqslant\frac{2\varkappa-\varepsilon}{k+1}$$

Тогда при $k>N$ получаем

$$a_k\geqslant C\frac{(2\varkappa-\varepsilon)^k}{k!}$$

с некоторой константой $C>0$ (зависящей от ε), и поскольку для фиксированного N сумма первых N членов в (5.3) растет как r^N при $r\to\infty$, для достаточно большого r получаем [5]

$$\Lambda_l(r)\geqslant Ce^{(2\varkappa-\varepsilon)r}-C_1r^N>C_2e^{(2\varkappa-\varepsilon)r}.$$

Этим доказывается, что для таких значений $\varkappa$ функция $f_l(r)$ не интегрируема с квадратом на $(0,\infty)$. Однако для особых значений

$$\varkappa=\varkappa_{kl}=\frac{1}{k+l+1}$$

степенной ряд (5.3) обрывается: $\Lambda_l(r)$ превращается в многочлен $\Lambda_{kl}(r)$ порядка k и $f_{kl}(r)=r^{l+1}e^{-\varkappa_{kl}r}\Lambda_{kl}(r)\in L^2(0,\infty)$. Положив $n=k+l+1$, получаем явную формулу для собственных значений

$$E_n=-\frac{1}{2n^2},\quad n=1,2,...$$

Для фиксированного n целое число l изменяется от 0 до $n-1$, и для каждого l имеется $2l+1$ ортогональных собственных функций $\frac{f_{kl}(r)}{r}Y_{lm}(\boldsymbol{n})$ с собственным значением E_n. Таким образом, полная кратность собственного значения E_n равна

$$\sum_{l=0}^{n-1}(2l+1)=n^2.$$

[5] Можно показать, что $\Lambda_l(r)=Ce^{2\varkappa r}(1+o(1))$ при $r\to\infty$. Собственные функции $f_{kl}(r)$ радиального уравнения Шрёдингера (5.1), соответствующие собственному значению E_n, можно выразить в терминах классических многочленов Лагерра. А именно: при $\varkappa=\frac{1}{n}$ подстановка $x=\frac{2r}{n}$ сводит дифференциальное уравнение (5.2) к

$$xQ''+(p+1-x)Q'+kQ=0,$$

где $p=2l+1$ и $Q(x)=\Lambda_l(r)$. Это - дифференциальное уравнение, которому удовлетворяют обобщенные многочлены Лагерра $Q_k^p(x)$, определенные формулой

$$Q_k^p(x)=e^xx^{-p}\frac{d^k}{dx^k}\left(e^{-x}x^{k+p}\right),$$

это многочлены степени k со старшим коэффициентом $(-1)^k$, у которых имеется k нулей в промежутке $(0,\infty)$. Для каждого p обобщенные многочлены Лагерра $\{Q_k^p(x)\}_{k=0}^{\infty}$ - это ортогональные по мере $e^{-x}x^pdx$ многочлены на $(0,\infty)$ со свойством

$$\int_0^\infty e^{-x}x^{p+1}Q_k^p(x)^2dx = k!(k+p)!(2k+p+1).$$

Ортонормированные собственные функции оператора Шрёдингера H для атома водорода, соответствующие собственному значению E_n, имеют вид

$$\psi_{klm}(\boldsymbol{q}) = \frac{2}{n^2}\frac{1}{\sqrt{k!(n+l)!}}\left(\frac{2r}{n}\right)^l e^{-\frac{r}{n}}Q_k^{2l+1}\left(\frac{2r}{n}\right)Y_{lm}(\boldsymbol{n})$$

где $n = k+l+1, l = 0,...,n-1$, и $m = -l,...,l$.

ЗАМЕчАниЕ. Возвращаясь к физическим единицам $\alpha = e^2$, где e - заряд электрона, получаем для уровней энергии атома водорода

$$E_n = -\frac{\mu e^4}{2n^2\hbar^2}$$

где μ - приведенная масса электрона и ядра. В частности, энергия основного состояния $-E_1 = -13,6\text{eV}$; ее абсолютная величина - это энергия

[6] Также используются многочлены $L_n^m(x) = (-1)^m\frac{n!}{(n-m)!}Q_{n-m}^m(x)$. ионизачии - энергия, необходимая, чтобы удалить электрон из атома водорода. Используя формулу Бора для частот спектральных линий

$$\hbar\omega_{mn} = E_n - E_m$$

получаем для атома водорода

$$\omega_{nm} = \frac{\mu e^4}{2\hbar^3}\left(\frac{1}{n^2}-\frac{1}{m^2}\right), \quad n < m.$$

При $n = 1$ и $m = 2,3,...$ получаем классическую серию Лаймана, $n = 2$ и значения $m = 3,4,...$ дают серию Балмера, тогда как $n = 3$ и $m = 4,5,...$ - серию Пашена. Эти серии спектральных линий были открыты экспериментально задолго до того, как была сформулирована квантовая механика.

ЗАМЕЧАНИЕ. Уровни энергии атома водорода можно также определить из правил квантования Бора-Вильсона-Зоммерфельда. А именно: в сферических координатах (r,ϑ,φ) на $\mathbb{R}^3$ лагранжиан задачи Кеплера принимает вид (см. раздел 1.1.6 главы 1)

$$L = \frac{1}{2}\mu\left(\dot r^2 + r^2\dot\vartheta^2 + r^2\sin^2\vartheta\dot\varphi^2\right) + \frac{\alpha}{r},$$

и соответствующие обобщенные импульсы - это

$$p_r = \mu\dot r, \quad p_\vartheta = \mu r^2\dot\vartheta, \quad p_\varphi = \mu r^2\sin^2\vartheta\dot\varphi.$$

Условия квантования БВЗ

$$\oint p_r dr = 2\pi\hbar\left(k+\frac{1}{2}\right)$$
$$\oint p_\vartheta d\vartheta = 2\pi\left(l-m+\frac{1}{2}\right)$$
$$\oint p_\varphi d\varphi = 2\pi\hbar m$$

в которых интегрирование ведется по замкнутой орбите задачи Кеплера с энергией $E < 0$, точно определяют уровни энергии $E_n, n = k+l+1$.

Действительно, имеем $p_\varphi = M_{c3}$, где $\boldsymbol{M}_c = (M_{c1}, M_{c2}, M_{c3})$ - классический угловой момент. Он постоянен на орбите, так что уравнение (5.7) определяет собственные значения оператора M_3 (см. раздел 3.3.2). Для вычисления $\oint p_\vartheta d\vartheta$ воспользуемся полярными координатами (r, χ) в плоскости орбиты P (см. раздел 1.1.6 главы 1). Поскольку $\dot\chi^2 = \dot\vartheta^2 + \sin^2\vartheta\dot\varphi^2$, на орбите получаем $p_\chi d\chi = p_\vartheta d\vartheta + p_\varphi d\varphi$, где $p_\chi = \mu r^2\dot\chi = |\boldsymbol{M}_c|$. Условие (5.6) теперь следует из равенства

$$\oint p_\chi d\chi = 2\pi\,|\boldsymbol{M}_c| = 2\pi\hbar\left(l + \frac{1}{2}\right)$$

то есть из правила квантования квадрата полного углового момента [7]. Наконец, чтобы вычислить $\oint p_r dr$, воспользуемся уравнениями (1.7) и (1.11) из раздела 1.1.6 главы 1 и получим, что

$$p_r dr = \mu\dot r dr = \mu\frac{dr}{d\chi}\dot\chi dr = \frac{|\boldsymbol{M}_c|}{r^2}\left(\frac{dr}{d\chi}\right)^2 d\chi = p_\chi\frac{e^2\sin^2\chi}{(1+e\cos\chi)^2}d\chi$$

где $0 < e < 1$ - эксцентриситет орбиты. Имеем

$$\oint p_r dr = p_\chi\int_0^{2\pi}\frac{e^2\sin^2\chi}{(1+e\cos\chi)^2}d\chi = 2\pi p_\chi\left(\frac{1}{\sqrt{1-e^2}} - 1\right),$$

что может быть показано с помощью подстановки $z = e^{i\chi}$ и теоремы Коши о вычетах [8]. Из уравнения (1.12) в разделе 1.1.6 главы 1 следует, что

$$\sqrt{1-e^2} = \frac{|\boldsymbol{M}_c|\,\sqrt{2|E|}}{\alpha\sqrt{\mu}}$$

и из (5.5) и (5.8) получаем

$$|E| = -E_n = \frac{\mu\alpha^2}{2n^2\hbar^2}, \quad n = k + l + 1.$$

[7] Это равенство дает квантованные значения $\hbar^2\left(l+\frac{1}{2}\right)^2$, при больших l хорошо согласующиеся с собственными значениями $\hbar^2 l(l+1)$ оператора M^2.

[8] Этот интеграл был вычислен Зоммерфельдом в 1916 г.

6.5.3 Continuous Spectrum in a Central Field

Теория по Тахтаджаяну

Положим $2E = k^2$, где $k > 0$, и рассмотрим уравнение

$$f_l'' + \left(\frac{2}{r} - \frac{l(l+1)}{r^2} + k^2\right) f_l = 0.$$

Подстановкой

$$f_l(r) = r^{l+1}e^{-ikr}F_l(r)$$

уравнение (5.9) сводится к

$$F_l'' + \left(\frac{2(l+1)}{r} - 2ik\right)F_l' + \left(\frac{2}{r} - \frac{2ik(l+1)}{r}\right)F_l = 0.$$

Решение уравнения (5.10), удовлетворяющее условию $F_l(0) = 1$, можно в явном виде записать как

$$F_l(r) = F(l+1+i\lambda, 2l+2, 2ikr), \quad \lambda = \frac{1}{k},$$

где $F(\alpha,\gamma,z)$ - вырожденная гипергеометрическая функция, определенная абсолютно сходящимся рядом

$$F(\alpha,\gamma,z) = \sum_{n=0}^{\infty} \frac{\Gamma(\alpha+n)\Gamma(\gamma)}{\Gamma(\alpha)\Gamma(\gamma+n)} \frac{z^n}{n!}$$

для всех α и $\gamma \neq 0, -1, -2, ...$ Вырожденная гипергеометрическая функция является целой функцией от переменной z и удовлетворяет дифференциальному уравнению

$$zF'' + (\gamma - z)F' - \alpha F = 0.$$

При $\alpha = -k$ и $\gamma = p+1$, где $k, p = 0, 1, 2, ...$, вырожденная гипергеометрическая функция сводится к обобщенным многочленам Лагерра:

$$Q_k^p(x) = \frac{(k+p)!}{p!} F(-k, p+1, x),$$

рассмотренным в предыдущем разделе. При $\operatorname{Re}\gamma > \operatorname{Re}\alpha > 0$ функция $F(\alpha,\gamma,z)$ допускает интегральное представление

$$F(\alpha,\gamma,z) = \frac{\Gamma(\gamma)}{\Gamma(\alpha)\Gamma(\gamma-\alpha)} \int_0^1 t^{\alpha-1}(1-t)^{\gamma-\alpha-1} e^{zt} dt$$

получаемое по методу Лапласа. Вырожденная гипергеометрическая функция удовлетворяет функциональному уравнению

$$F(\alpha,\gamma,z) = e^z F(\gamma-\alpha, \gamma, -z)$$

и имеет следующую асимптотику при $z \to \infty$:

$$F(\alpha,\gamma,z) = \frac{\Gamma(\gamma)}{\Gamma(\gamma-\alpha)}(-z)^{-\alpha}\left(1 + O\left(z^{-1}\right)\right) + \frac{\Gamma(\gamma)}{\Gamma(\alpha)} e^z z^{\alpha-\gamma}\left(1 + O\left(z^{-1}\right)\right).$$

Из (5.12) следует, что функция $f_l(r) = r^{l+1}e^{-ikr}F(l+1+i\lambda, 2l+ \ +2, 2ikr)$ вещественнозначна, а из (5.13) следует, что функция

$$f_{El}(r) = \frac{(2k)^{l+1}}{\sqrt{2\pi}(2l+1)!} e^{\frac{\pi}{2k}} |\Gamma(l+1-i\lambda)| f_l(r)$$

имеет следующую асимптотику при $r \to \infty$:

$$f_{El}(r) = \sqrt{\frac{2}{\pi}} \sin\left(kr + \lambda \log 2kr - \frac{l\pi}{2} + \delta_l\right) + o(1),$$

где

$$\delta_l(k) = \arg\Gamma(l+1-i\lambda), \quad \lambda = \frac{1}{k} = \frac{1}{\sqrt{2E}}$$

фазовый сдвиг. Частичная S-матрица для кулоновской задачи - это

$$S_l(k) = e^{2i\delta_l(k)} = \frac{\Gamma(l+1-i\lambda)}{\Gamma(l+1+i\lambda)}.$$

Она допускает мероморфное продолжение в верхнюю полуплоскость $\operatorname{Im} k > 0$ и имеет простые полюса в точках $k = i\varkappa_{jl}$, соответствующих собственным значениям E_{kl}

радиального оператора Шрёдингера H_l. Радиальные собственные функции непрерывного спектра (5.14) удовлетворяют условию нормировки (4.15).

ЗАМЕЧАНИЕ. Поучительно сравнить асимптотику (5.15) для кулоновского потенциала, являющегося дальнодействующим, с соответствующей формулой (4.16) для общего короткодействующего потенциала. Дальнодействующая природа кулоновского взаимодействия проявляется в добавочном логарифмическом члене $\lambda \log 2kr$ в (5.15).

Теорема о разложении по собственным функциям для оператора Шрёдингера H атома водорода имеет такой же вид, как и в разделе 3.4.3: собственные функции $\psi_{klm}(\boldsymbol{x})$ даются формулой (5.4), где $k = 0, 1, ..., N_l = \infty$, а собственные функции непрерывного спектра даются формулой

$$\psi_{Elm}(\boldsymbol{x}) = \frac{f_{El}(r)}{r} Y_{lm}(\boldsymbol{n}), \quad l = 0, 1, ..., \quad m = -l, ..., l$$

6.5.4 Hidden SO(4) Symmetry

Теория в центральном поле по Тахтаджаяну

Как мы видели в разделе 1.1.6 главы 1, у классической системы с функцией Гамильтона

$$H_{\mathrm{c}}(\boldsymbol{p}, \boldsymbol{x}) = \frac{p^2}{2m} - \frac{\alpha}{r}$$

вдобавок к угловому моменту M_{c} есть три добавочных интеграла движения, которые даются вектором Лапласа - Рунге - Ленца

$$\boldsymbol{W}_{\mathrm{c}} = \frac{\boldsymbol{p}}{m} \times M_{\mathrm{c}} - \frac{\alpha \boldsymbol{x}}{\boldsymbol{r}}$$

Согласно примеру 2.2 из раздела 1.2.6 главы 1, интегралы M_{c} и W_{c} для задачи Кеплера имеют скобки Пуассона:

$$\{M_{\mathrm{c}j}, M_{\mathrm{ck}}\} = -\varepsilon_{jkl} M_{\mathrm{cl}}, \quad \{W_{\mathrm{c}j}, M_{\mathrm{ck}}\} = -\varepsilon_{jkl} W_{\mathrm{cl}},$$
$$\{W_{\mathrm{c}j}, W_{\mathrm{ck}}\} = 2H_{\mathrm{c}} \varepsilon_{jkl} M_{\mathrm{cl}},$$

где $j, k, l = 1, 2, 3$ и $\varepsilon_{123} = 1$.

Квантовая задача Кеплера - это кулоновская задача. В координатном представлении $\mathscr{H} = L^2(\mathbb{R}^3, d^3x)$ ее гамильтониан - это

$$H = \frac{\boldsymbol{P}^2}{2} - \frac{\alpha}{r}$$

где $r = |\boldsymbol{x}|$, и мы положили $m = 1$. Квантовый вектор Лапласа-РунгеЛенца - оператор Лапласа-Рунге - Ленца W - определяется формулой

$$\boldsymbol{W} = \frac{1}{2}(\boldsymbol{P} \times \boldsymbol{M} - \boldsymbol{M} \times \boldsymbol{P}) - \frac{\alpha \boldsymbol{Q}}{r}$$

или Покомпонентно -

$$W_j = \frac{1}{2} \varepsilon_{jkl} (P_k M_l + M_l P_k) - \frac{\alpha Q_j}{r}, \quad j = 1, 2, 3$$

Здесь Q_i - операторы умножения на x_i, и все время подразумевается суммирование по повторяющимся индексам 1, 2, 3. В силу коммутационных соотношений (3.5) имеем также

$$W = P \times M - \frac{\alpha Q}{r} - i\hbar P = -M \times P - \frac{\alpha Q}{r} + i\hbar P$$

где слагаемое $i\hbar \boldsymbol{P}$ играет роль «квантовой поправки». Следующий результат выявляет скрытую симметрию кулоновской задачи.

Предложение 5.1.

Оператор Шрёдингера H атома водорода имеет шесть квантовых интегралов движения $\boldsymbol{MW}$,

$$[H, M_i] = [H, W_i] = 0, \quad i = 1, 2, 3$$

удовлетворяющих условиям $\boldsymbol{W} \cdot \boldsymbol{M} = \boldsymbol{M} \cdot \boldsymbol{W} = 0$ и

$$\boldsymbol{W}^2 = \alpha^2 + 2HM^2 + 2\hbar^2 H$$

Кроме того, самосопряженные операторы $\boldsymbol{M}$ и $\boldsymbol{W}$ уовлетворяют следуючим коммутачионным соотношениям:
$[M_j, M_k] = i\hbar\varepsilon_{jkl}M_l, \quad [W_j, M_k] = i\hbar\varepsilon_{jkl}W_l, \quad [W_j, W_k] = -2i\hbar\varepsilon_{jkl}M_l H$

Proof.

Мы знаем, что $[H, M_j] = 0$. Чтобы доказать, что W_j - квантовые интегралы движения, сперва вычислим $\left[\boldsymbol{P}^2, \frac{Q_j}{r}\right]$. Из коммутационных соотношений Гейзенберга следует, что

$$\left[P_j, \frac{1}{r}\right] = i\hbar\frac{Q_j}{r^3}$$

так что, используя правила Лейбница и соотношения $r^2 = x_1^2 + x_2^3 + x_3^2$, $[M_l, r] = 0$ и $Q_j P_k - Q_k P_j = \varepsilon_{jkl}M_l$, получаем

$$\left[\boldsymbol{P}^2, \frac{Q_j}{r}\right] = 2i\hbar\frac{Q_j}{r^3} + 2i\hbar\varepsilon_{jkl}\frac{Q_k}{r^3}M_l$$

Теперь, воспользовавшись первым уравнением в (5.17) и уравнением (5.19), получаем

$$\begin{aligned}[H, W_j] &= \left[\frac{\boldsymbol{P}^2}{2} - \frac{\alpha}{r}, \varepsilon_{jkl}P_k M_l - \frac{\alpha Q_j}{r} - i\hbar P_j\right] = \\ &= -i\alpha\hbar\frac{Q_j}{r^3} - i\alpha\hbar\varepsilon_{jkl}\frac{Q_k}{r^3}M_l + i\alpha\hbar\varepsilon_{jkl}\frac{Q_k}{r^3}M_l + i\alpha\hbar\frac{Q_j}{q^3} = 0\end{aligned}$$

Легко доказать соотношение $\boldsymbol{W} \cdot \boldsymbol{M} = W_1M_1 + W_2M_2 + W_3M_3 = 0$. Действительно, из определения M и коммутативности P_k и Q_l при $k \neq l$ следует, что

$$\boldsymbol{M} \cdot \boldsymbol{P} = \boldsymbol{P} \cdot \boldsymbol{M} = \boldsymbol{M} \cdot \boldsymbol{Q} = \boldsymbol{Q} \cdot \boldsymbol{M} = 0$$

и, используя первое уравнение в (5.17) и коммутационные соотношения для компонент углового момента, немедленно получаем, что $\boldsymbol{W} \cdot \boldsymbol{M} = 0$. Чтобы доказать, что $M \cdot W = 0$, надо воспользоваться вторым уравнением в (5.17).

Проверка условия (5.18) требует большей работы. Имеем

$$\begin{aligned}\boldsymbol{W}^2 = W_j W_j = \\ = \left(\varepsilon_{jkl} M_l P_k - \frac{\alpha Q_j}{r} + i\hbar P_j\right)\left(\varepsilon_{jmn} P_m M_n - \frac{\alpha Q_j}{r} - i\hbar P_j\right) = \\ = \varepsilon_{jkl}\left(\varepsilon_{jmn} M_l P_k P_m M_n - \alpha M_l P_k \frac{Q_j}{r} - i\hbar M_l P_k P_j\right) - \\ - \alpha\varepsilon_{jmn}\frac{Q_j}{q} P_m M_n + \alpha^2 \frac{Q_j Q_j}{r^2} + i\alpha\hbar\frac{Q_j}{r} P_j + i\hbar\varepsilon_{jmn} P_j P_m M_n - \\ - i\alpha\hbar P_j \frac{Q_j}{r} + \hbar^2 P_j P_j = \\ = \alpha^2 I + \hbar^2 P^2 + \varepsilon_{jkl}\varepsilon_{jmn} M_l P_k P_m M_n - \\ - \alpha\varepsilon_{jkl}\left(M_l P_k \frac{Q_j}{q} + \frac{Q_j}{r} P_k M_l\right) - i\alpha\hbar\left[P_j, \frac{Q_j}{r}\right].\end{aligned}$$

Поскольку операторы M_j и P_j коммутируют, тождество $(\boldsymbol{a}\times\boldsymbol{b})^2 = \boldsymbol{a}^2\boldsymbol{b}^2$ - $-(a\cdot b)^2$ по-прежнему применимо, и мы получаем, что

$\varepsilon_{jkl}\varepsilon_{jmn} M_l P_k P_m M_n = -(\boldsymbol{M}\times\boldsymbol{P})\cdot(\boldsymbol{P}\times\boldsymbol{M}) = \boldsymbol{M}^2\boldsymbol{P}^2 - (\boldsymbol{M}\cdot\boldsymbol{P})^2 = \boldsymbol{M}^2\boldsymbol{P}^2$. Используя (5.19), легко находим (суммирование по повторяющимся индексам), что

$$\left[P_j, \frac{Q_j}{r}\right] = i\hbar\left(-\frac{3}{r} + \frac{r^2}{r^3}\right) = -\frac{2i\hbar}{r}$$

Поскольку $[\boldsymbol{M}^2, r] = 0$, из равенства $\boldsymbol{M} = \boldsymbol{Q}\times\boldsymbol{P}$ следует, что

$$\varepsilon_{jkl}\left(M_l P_k \frac{Q_j}{r} + \frac{Q_j}{r} P_k M_l\right) = M^2\frac{1}{r} + \frac{1}{r}M^2 = \frac{2M^2}{r}$$

Собирая все вместе, получаем (5.18).

Нетрудно также установить коммутационные соотношения между M_j и W_k. Используя (3.5) и свойства ε_{jkl}, получаем

$$\begin{aligned}[M_j, W_k] = \left[M_j, \varepsilon_{kmn} P_m M_n - \frac{\alpha Q_k}{r} - i\hbar P_k\right] = \\ = i\hbar\left(\varepsilon_{jmp}\varepsilon_{kmn} P_p M_n + \varepsilon_{jnp}\varepsilon_{kmn} P_m M_p\right) - i\hbar\varepsilon_{jkl}\left(\frac{\alpha Q_l}{r} + i\hbar P_l\right) = \\ = i\hbar\left(P_j M_k - M_k P_j\right) - i\hbar\varepsilon_{jkl}\left(\frac{\alpha r_l}{r} + i\hbar P_l\right) = i\hbar\varepsilon_{jkl} W_l\end{aligned}$$

Наконец, чтобы установить коммутационные соотношения между компонентами W, воспользуемся представлениями

$$\boldsymbol{W} = \boldsymbol{Q}\boldsymbol{P}^2 - \boldsymbol{P}(\boldsymbol{Q}\cdot\boldsymbol{P}) - \frac{\alpha\boldsymbol{Q}}{r} = \boldsymbol{P}^2\boldsymbol{Q} - (\boldsymbol{P}\cdot\boldsymbol{Q})\boldsymbol{P} - \frac{\alpha\boldsymbol{Q}}{r}$$

Первая формула в (5.20) следует из первой формулы в (5.17), если воспользоваться соотношениями

$$\begin{aligned}\varepsilon_{jkl} P_k M_l = \varepsilon_{jkl}\varepsilon_{lmn} P_k Q_m P_l = \varepsilon_{jkl}\left(\varepsilon_{ljk} P_k Q_j P_k + \varepsilon_{lkj} P_k Q_k P_j\right) = \\ = P_k\left(P_k Q_j - P_j Q_k\right) = Q_j\boldsymbol{P}^2 - P_j(\boldsymbol{P}\cdot\boldsymbol{Q}) - 2i\hbar P_j\end{aligned}$$

и соотношением $\boldsymbol{P}\cdot\boldsymbol{Q} = \boldsymbol{Q}\cdot\boldsymbol{P} - 3i\hbar I$. Вторая формула в (5.20) следует из первой в силу коммутационных соотношений Гейзенберга. Дальше имеем

$$\varepsilon_{jkl}\,[W_k, W_l] = 2\varepsilon_{jmn} W_m W_n =$$
$$= 2\varepsilon_{jmn}\left(\boldsymbol{P}^2 Q_m - (\boldsymbol{P}\cdot\boldsymbol{Q})P_m - \frac{\alpha Q_m}{r}\right)\left(Q_n \boldsymbol{P}^2 - P_n(\boldsymbol{Q}\cdot\boldsymbol{P}) - \frac{\alpha Q_n}{r}\right) =$$
$$= 2M_j\left(-\boldsymbol{P}^2(\boldsymbol{Q}\cdot\boldsymbol{P}) + (\boldsymbol{P}\cdot\boldsymbol{Q})\boldsymbol{P}^2 + \frac{\alpha}{r}(\boldsymbol{Q}\cdot\boldsymbol{P}) - (\boldsymbol{P}\cdot\boldsymbol{Q})\frac{\alpha}{r}\right) =$$
$$= -2i\hbar M_j\left(\boldsymbol{P}^2 - \frac{2\alpha}{r}\right) = -4i\hbar M_j H$$

где были использованы равенства $[\boldsymbol{M}, \boldsymbol{P}\cdot\boldsymbol{Q}] = 0$ и $\left[\boldsymbol{P}\cdot\boldsymbol{Q}, \frac{1}{r}\right] = \frac{i\hbar}{r}$. Это доказывает, что $[W_k, W_l] = -2i\hbar\varepsilon_{jkl} M_j H$.

Пусть $\mathscr{H}_0 = \mathrm{P}_H(-\infty, 0)\mathscr{H}$, где P_H - проекторная мера для оператора Шрёдингера H. Поскольку самосопряженные операторы $\boldsymbol{M}$ и $\boldsymbol{W}$ коммутируют с H, подпространство $\mathscr{H}_0$ - инвариантное подпространство для этих операторов. Оператор Шрёдингера H неотрицателен на $\mathscr{H}_0$, так что на этом пространстве корректно определен оператор $(-2H)^{-1/2}$. Далее, на $\mathscr{H}_0$ положим

$$\boldsymbol{J}^{(\pm)} = \frac{1}{2}\left(\boldsymbol{M} \pm (-2H)^{-1/2}\boldsymbol{W}\right)$$

Из предложения 5.1 следует, что самосопряженные операторы $J_j^{(\pm)}$на $\mathscr{H}_0$ удовлетворяют коммутационным соотношениям

$$\left[J_j^{(\pm)}, J_k^{(\pm)}\right] = i\hbar\varepsilon_{jkl} J_l^{(\pm)}, \quad \left[J_j^{(+)}, J_k^{(-)}\right] = 0$$

и

$$\left(J^{(+)}\right)^2 = \left(J^{(-)}\right)^2 = -\frac{1}{4}\left(\hbar^2 I + \frac{\alpha^2}{2H}\right).$$

Уравнения (5.21) - это коммутационные соотношения для образующих алгебры Ли $\mathfrak{so}(4)$, что соответствует изоморфизму алгебр Ли $\mathfrak{so}(4) \simeq \mathfrak{so}(3) \oplus \mathfrak{so}(3)$ и чем демонстрируется скрытая SO(4) симметрия кулоновской задачи! Вместе с (5.22) они позволяют найти уровни энергии чисто алгебраически.

А именно: собственные значения операторов $\left(J^{(+)}\right)^2$ и $\left(J^{(-)}\right)^2$ - это соответственно $\hbar^2 l_1\,(l_1+1)$ и $\hbar^2 l_2\,(l_2+1)$, и из (5.22) следует, что $l_1 = l_2 = l$, так что соответствующее собственное значение H - это

$$E_n = -\frac{\alpha^2}{2\hbar^2 n^2}, \quad n = 2l+1$$

Предполагая, что

$$\mathscr{H}_0 \simeq \bigoplus_{l\in\frac{1}{2}\mathbb{Z}_{\geqslant 0}} V_l \otimes V_l,$$

где суммирование происходит по всем неотрицательным целым и полуцелым значениям l, получаем из разложения Клебша-Гордона (3.13), что кратность собственного значения E_n - это

$$\dim V_l \otimes V_l = \sum_{j=0}^{2l}(2j+1) = (2l+1)^2 = n^2$$

Для доказательства ортогонального разложения (5.23) надо рассмотреть уравнение Шрёдингера для атома водорода в импульсном представлении. Используя сферические координаты в $\mathbb{R}^3$ и элементарный интеграл

$$\int_0^\infty \frac{\sin r}{r} dr = \frac{\pi}{2}$$

легко показать, что для любого $\psi \in \mathscr{S}(\mathbb{R}^3)$

$$\frac{1}{2\pi^2\hbar} \int_{\mathbb{R}^3} \frac{\hat{\psi}(\boldsymbol{q})}{|\boldsymbol{p}-\boldsymbol{q}|^2} d^3\boldsymbol{q} = \frac{1}{(\sqrt{2\pi\hbar})^3} \int_{\mathbb{R}^3} \frac{1}{r} \psi(\boldsymbol{x}) e^{-\frac{i}{\hbar}\boldsymbol{p}\boldsymbol{x}} d^3\boldsymbol{x}$$

где $\hat{\psi} = \mathscr{F}_\hbar(\psi)$ - зависящее от $\hbar$ преобразование Фурье [9].

Пусть ψ - собственная функция H с собственным значением $E < 0$. Из (5.24) следует, что в импульсном представлении соответствующее уравнение Шрёдингера - уравнение на собственные значения $H\psi = E\psi$ - принимает вид

$$\left(\boldsymbol{p}^2 + p_0^2\right) \hat{\psi}(\boldsymbol{p}) = \lambda \int_{\mathbb{R}^3} \frac{\hat{\psi}(\boldsymbol{q})}{|\boldsymbol{p}-\boldsymbol{q}|^2} d^3\boldsymbol{q}$$

где $p_0 = \sqrt{-2\mu E}$ и $\lambda = \frac{\alpha\mu}{p_0\hbar}$. Дальше рассмотрим однородные координаты $\frac{p}{p_0}$ в $\mathbb{R}^3$ как координаты стереографической проекции единичной сферы S^3 в $\mathbb{R}^4$. А именно: обозначив как n единичный вектор из начала координат в северный полюс S^3, получим для точки $u \in S^3$, соответствующей $\frac{\boldsymbol{p}}{p_0} \in \mathbb{R}^3$

$$u = \frac{p^2 - p_0^2}{p^2 + p_0^2}\boldsymbol{n} + \frac{2p_0}{p^2 + p_0^2}\boldsymbol{p}$$

[9] Поскольку $\boldsymbol{x}$ - переменная в координатном представлении, здесь $\boldsymbol{q}$ - другая переменная в импульсном представлении. Для формы объема на S^3 имеем

$$d\Omega = \frac{(2p_0)^3}{\left(\boldsymbol{p}^2 + p_0^2\right)^3} d^3\boldsymbol{p}, \quad \int_{S^3} d\Omega = 2\pi^2$$

Используя равенство

$$|\boldsymbol{p}-\boldsymbol{q}|^2 = \frac{\left(\boldsymbol{p}^2 + p_0^2\right)\left(\boldsymbol{q}^2 + p_0^2\right)}{(2p_0)^2} |\boldsymbol{u}-\boldsymbol{v}|^2,$$

где $\boldsymbol{v} \in S^3$ соответствует $\frac{\boldsymbol{q}}{p_0} \in \mathbb{R}^3$, и вводя

$$\Psi(\boldsymbol{u}) = \frac{1}{\sqrt{p_0}} \frac{\left(\boldsymbol{p}^2 + p_0^2\right)^2}{(2p_0)^2} \hat{\psi}(\boldsymbol{p}),$$

можно переписать уравнение (5.25) как

$$\Psi(\boldsymbol{u}) = \frac{\lambda}{2\pi^2} \int_{S^3} \frac{\Psi(\boldsymbol{v})}{|\boldsymbol{u}-\boldsymbol{v}|^2} d\Omega_{\boldsymbol{v}}$$

Имеем также

$$\int_{S^3} |\Psi(\boldsymbol{u})|^2 d\Omega_{\boldsymbol{u}} = \int_{\mathbb{R}^3} \frac{\boldsymbol{p}^2 + p_0^2}{2p_0^2} |\hat{\psi}(\boldsymbol{p})|^2 d^3\boldsymbol{p} = \int_{\mathbb{R}^3} |\hat{\psi}(\boldsymbol{p})|^2 d^3\boldsymbol{p}.$$

Действительно, из уравнения Шрёдингера следует, что

$$\frac{1}{2\mu}\int\limits_{\mathbb{R}^3}\boldsymbol{p}^2|\hat{\psi}(\boldsymbol{p})|^2d^3\boldsymbol{p}=\frac{1}{2\mu}\int\limits_{\mathbb{R}^3}\left|\frac{\partial\psi(\boldsymbol{x})}{\partial\boldsymbol{x}}\right|^2d^3\boldsymbol{x}=\int\limits_{\mathbb{R}^3}(E-V(r))|\psi(\boldsymbol{x})|^2d^3\boldsymbol{x},$$

и по теореме о вириале (см. раздел 3.1.3) получаем

$$\frac{1}{2\mu}\int\limits_{\mathbb{R}^3}\left|\frac{\partial\psi(\boldsymbol{x})}{\partial\boldsymbol{x}}\right|^2d^3\boldsymbol{x}=-\frac{1}{2\mu}\int\limits_{\mathbb{R}^3}\Delta\psi(\boldsymbol{x})\overline{\psi(\boldsymbol{x})}d^3\boldsymbol{x}=-\frac{1}{2}\int\limits_{\mathbb{R}^3}V(r)|\psi(\boldsymbol{x})|^2d^3\boldsymbol{x},$$

где $V(r)=-\frac{\alpha}{r}$, так что

$$\int\limits_{\mathbb{R}^3}V(r)|\psi(\boldsymbol{x})|^2d^3\boldsymbol{x}=2E\int\limits_{\mathbb{R}^3}|\psi(\boldsymbol{x})|^2d^3\boldsymbol{x}=2E\int\limits_{\mathbb{R}^3}|\hat{\psi}(\boldsymbol{p})|^2d^3\boldsymbol{p}.$$

Это показывает, что задача о собственных значениях уравнения Шрёдингера эквивалентна задаче о собственных значениях интегрального уравнения (5.26) на $L^2\left(S^3,d\Omega\right)$. Последняя - классическая задача теории сферических гармоник. А именно: функция $G(u)=-\frac{1}{4\pi^2u^2}$, где $u=|\boldsymbol{u}|$, $u\in\mathbb{R}^4$, - фундаментальное решение оператора Лапласа Δ на $\mathbb{R}^4$:

$$\Delta=\frac{\partial^2}{\partial u_1^2}+\frac{\partial^2}{\partial u_2^2}+\frac{\partial^2}{\partial u_3^2}+\frac{\partial^2}{\partial u_4^2}$$

а уравнение (5.26) - уравнение, которому удовлетворяют сферические гармоники на S^3: собственные функции сферической части Δ_0 оператора Лапласа на $\mathbb{R}^4$, определенного формулой

$$\Delta=\frac{1}{u^3}\frac{\partial}{\partial u}\left(u^3\frac{\partial}{\partial u}\right)+\frac{1}{u^2}\Delta_0$$

Хорошо известно из теории представлений группы Ли $SO(4)$, что сферические гармоники - это ограничения на S^3 однородных гармонических многочленов на $\mathbb{R}^4$ степени $n-1,n\in\mathbb{N}$. Соответственно, уравнение (5.26) получается как предел $|u|\to1$ формулы Грина для однородных гармонических функций степени $n-1$ в единичном шаре в $\mathbb{R}^4$ с использованием потенциала двойного слоя. Это дает $\lambda=n$, чем опять устанавливается точная формула для уровней энергии атома водорода. Изоморфизм $\mathscr{H}_0\simeq L^2\left(S^3,d\Omega\right)$ следует из (5.27), а (5.23) - из разложения

$$L^2\left(S^3,d\Omega\right)\simeq\bigoplus_{l\in\frac{1}{2}\mathbb{Z}_{\geqslant0}}V_l\otimes V_l$$

регулярного представления SO(4) в прямую сумму неприводимых компонент. Можно также получить явный вид (5.4) собственных функций, воспользовавшись теорией представлений SO(4). Мы оставляем все эти детали заинтересованному читателю.

ЗАМЕЧАНИЕ. При $E>0$ надо рассмотреть подпространство $\mathscr{H}_1=\mathrm{P}_H(0,\infty)\mathscr{H}$ и определить $\boldsymbol{J}^{(\pm)}=\frac{1}{2}\left(\boldsymbol{M}\pm(2H)^{-1/2}\boldsymbol{W}\right)$. Вместо (5.21) эти операторы удовлетворяют коммутационным соотношениям алгебры Ли $\mathfrak{so}(3,1)$ группы Лоренца SO(3,1). Задачу нахождения собственных функций непрерывного спектра для кулоновской задачи можно решить, используя гармонический анализ на трехмерном пространстве Лобачевского. ЗАДАЧА 5.1. Покажите, что компоненты углового момента $\boldsymbol{M}$ - образующие $\mathfrak{so}(4)$, соответствующие бесконечно малым вращениям в подпространстве $\mathbb{R}^4$ с координатами $(0,\boldsymbol{p})$, а компоненты вектора ЛапласаРунге-Ленца $\boldsymbol{W}$ соответствуют бесконечно малым вращениям в плоскостях (p_0p_1), (p_0p_2) и (p_0p_3) в $\mathbb{R}^4$.

6.5.5 Particle in a Central-Symmetric Potential by Takhtajan

Задача на собственные значения для оператора Шрёдингера

$$H = -\frac{\hbar^2}{2\mu}\Delta + V(\boldsymbol{x})$$

упрощается, когда H коммутирует с действием SO(3) на $\mathscr{H} = L^2\left(\mathbb{R}^3, d^3\boldsymbol{x}\right)$:

$$[H, T(g)] = 0 \quad \text{для любого } g \in \mathrm{SO}(3).$$

Это сводится к условиям

$$[H, M_i] = 0, \quad i = 1, 2, 3,$$

и эквивалентно свойству, что потенциал V сферически симметричен, $V(\boldsymbol{x}) = V(r), r = |\boldsymbol{x}|$. В частности,

$$[H, M_3] = \left[H, M^2\right] = 0$$

где $M^2 = M_1^2 + M_2^2 + M_3^2$, а операторы M_3 и M^2 - коммутирующие интегралы движения для гамильтониана H. Как следует из результатов раздела 3.3.2, можно искать решения задачи на собственные значения

$$H\psi = E\psi$$

удовлетворяющие условию

$$M_3\psi = m\psi \quad \text{и} \quad M^2\psi = \hbar^2 l(l+1)\psi, \quad m = -l, ..., l$$

Используя (3.9), получаем

$$H = -\frac{\hbar^2}{2\mu r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) + \frac{M^2}{\mu r^2} + V(r)$$

так что в согласии с разложениями (3.14) и (3.15) мы ищем решения в виде

$$\psi(\boldsymbol{x}) = R_l(r)Y_{lm}(\boldsymbol{n}), \quad \boldsymbol{x} = r\boldsymbol{n}$$

где Y_{lm} - нормированные сферические функции. Разделяя переменные, получаем следующее обыкновенное дифференциальное уравнение на функцию $R_l(r)$:

$$\frac{\hbar^2}{2\mu r^2}\frac{d}{dr}\left(r^2\frac{dR_l}{dr}\right) + \frac{\hbar^2 l(l+1)}{\mu r^2}R_l + V(r)R_l = ER_l$$

ВвОдЯ

$$f_l(r) = rR_l(r)$$

получаем так называемое радиальное уравнение Шрёдингера:

$$-\frac{\hbar^2}{2\mu}\frac{d^2 f_l}{dr^2} + \frac{\hbar^2 l(l+1)}{2\mu r^2}f_l + V(r)f_l = Ef_l.$$

Поскольку для непрерывного потенциала $V(\boldsymbol{x})$ решение $\psi(\boldsymbol{x})$ также непрерывно, уравнение (4.10) следует дополнить граничным условием $f_l(0) = 0$. Радиальное уравнение Шрёдингера выглядит аналогичным уравнению Шрёдингера для одномерной частицы, если ввести так называемый эффективный потенциал

$$V_{\text{eff}}(r) = V(r) + \frac{\hbar^2 l(l+1)}{2\mu r^2}$$

в котором второе слагаемое называется центробежной энергией. Однако, поскольку f_l определено только при $r > 0$, уравнение (4.10) эквивалентно уравнению (2.1) с потенциалом, удовлетворяющим условию $V(x) = \infty$ при $x < 0$, описывающим бесконечный потенциальный барьер при $x = 0$.

Поскольку радиальные операторы Шрёдингера

$$H_l = -\frac{\hbar^2}{2\mu}\frac{d^2}{dr^2} + V(r) + \frac{\hbar^2 l(l+1)}{2\mu r^2}$$

получаются из трехмерного оператора Шрёдингера

$$H = -\frac{\hbar^2}{2\mu}\Delta + V(r)$$

разделением переменных, операторы H_l самосопряжены в $L^2(0,\infty)$, если H - самосопряженный оператор в $L^2(\mathbb{R}^3)$. Оператор H_0 следует дополнить граничным условием $f_0(0) = 0$, тогда как в случае $l > 0$ никаких граничных условий не требуется. В частности, из теоремы 1.9 в разделе 3.1.2 следует, что если ограниченный потенциал V удовлетворяет условию

$$V(r) = O\left(r^{-1-\varepsilon}\right) \quad \text{при} \quad r \to \infty$$

для некоторого $\varepsilon > 0$, то H_l - самосопряженные операторы с простым абсолютно непрерывным спектром, заполняющим $[0,\infty)$, и отрицательными собственными значениями с возможной точкой сгущения в нуле. Если

$$V(r) = O\left(r^{-2-\varepsilon}\right) \quad \text{при} \quad r \to \infty$$

то у операторов H_l конечно число отрицательных собственных значений, а при достаточно больших l собственных значений вообще нет. Такое же заключение верно, если

$$\int_0^\infty r|V(r)|dr < \infty$$

Такие потенциалы $V(r)$ называются короткодействующими потенциалами. Затухающие на бесконечности потенциалы, не удовлетворяющие (4.11), называются дальнодействуючими потенциалами. Для короткодействующего потенциала $V(r)$ дифференциальное уравнение (4.10) при $E \neq 0$ имеет два линейно независимых решения $f_l^{\pm}(r)$, удовлетворяющих следующим асимптотикам при $r \to \infty$:

$$f_l^{\pm}(r) = e^{\pm \varkappa r}(1 + o(1)),$$

где $\varkappa = \sqrt{-2\mu E}$ чисто мнимое, $\operatorname{Im}\varkappa > 0$ при $E > 0$ и $\varkappa > 0$ при $E < 0$. Когда $r \to 0$, наиболее сингулярный член в радиальном уравнении Шрёдингера дается центробежной энергией. Поскольку элементарное дифференциальное уравнение

$$f'' = \frac{l(l+1)}{r^2} f$$

имеет два линейно независимых решения r^{-l} и r^{l+1}, решение $f_l(r)$, удовлетворяющее граничному условию $f_l(0) = 0$, имеет асимптотику

$$f_l(r) = Cr^{l+1} + o(1) \quad \text{при} \quad r \to 0$$

и однозначно определено (с точностью до константы). Поскольку

$$f_l(r) = C_1 f_l^+(r) + C_2 f_l^-(r)$$

для некоторых констант C_1 и C_2, зависящих от E, у дифференциального уравнения (4.10) нет решений с интегрируемым квадратом при $E > 0$. Соответствующее решение $f_l(r)$ ограничено на $[0, \infty)$ и является собственной функцией непрерывного спектра. Это согласуется с описанием в разделе 1.1.6 главы 1, поскольку при $E > 0$ классическая частица в центральном потенциале $V_{\text{eff}}(r)$ уходит на бесконечность с конечной скоростью. При $E < 0$ уравнение $C_1(E) = 0$ определяет собственные значения H_l, которые просты. Это тоже согласуется с классической картиной, поскольку классическое движение финитно при $E < 0$. Для короткодействующего потенциала уравнение $C_1(E) = 0$ имеет лишь конечное число решений. Когда $V_{\text{eff}}(r) > 0$ при $r > 0$ - случай отталкивающего потенциала, у оператора H_l нет собственных значений.

ЗАмЕчАНиЕ. Когда $V(r) = 0$, радиальный оператор Шрёдингера H_l имеет только простой абсолютно непрерывный спектр, заполняющий $[0, \infty)$. Подстановка

$$f_l(r) = \sqrt{\xi} J(\xi), \quad \xi = \frac{kr}{\hbar} \quad \text{и} \quad k = |\varkappa| = \sqrt{2\mu E} > 0$$

сводит дифференциальное уравнение (4.10) к уравнению Бесселя

$$\xi^2 \frac{d^2 J}{d\xi^2} + \xi \frac{dJ}{d\xi} + \left(\xi^2 - \nu^2\right) J = 0$$

полуцелого порядка $\nu = l + \frac{1}{2}$. Соответствующее решение, регулярное в нуле, - функция Бесселя первого рода $J_{l+\frac{1}{2}}(\xi)$ - явно дается формулами

$$J_{l+\frac{1}{2}}(\xi) = (-1)^l \sqrt{\frac{2}{\pi\xi}} \xi^{l+1} \left(\frac{1}{\xi}\frac{d}{d\xi}\right)^l \frac{\sin\xi}{\xi}$$

и

$$J_{l+\frac{1}{2}}(\xi) = \sqrt{\frac{2}{\pi\xi}} \sin\left(\xi - \frac{l\pi}{2}\right) + O\left(\xi^{-1}\right) \quad \text{при} \quad \xi \to \infty$$

Можно показать, что

$$f_{El}(r) = \sqrt{\frac{kr}{\hbar}} J_{l+\frac{1}{2}}\left(\frac{kr}{\hbar}\right)$$

удовлетворяют условию нормировки (2.14) из раздела 2.2.2 главы 2:

$$\lim_{\Delta\to 0} \frac{1}{\Delta} \int_0^\infty \left(\int_k^{k+\Delta} f_{El}(r) d\sigma(E) \right)^2 dr \equiv 1$$

где $k = \sqrt{2\mu E}$ и $d\sigma(E) = \sqrt{\frac{\mu}{2E}} dE = dk$. Соответствующая теорема о разложении по собственным функциям - особый случай классического преобразования Фурье-Бесселя для целого l, обобщающего синусоидальное преобразование Фурье: для любого $f \in L^2(0, \infty)$

$$f(r) = \int_0^\infty c_l(E) f_{El}(r) d\sigma(E), \quad c_l(E) = \int_0^\infty f(r) f_{El}(r) dr$$

В общем случае для любого $l = 0, 1, ...$, обозначим как $f_{El}(r)$ решение радиального уравнения Шрёдингера (4.10) со следующей асимптотикой:

$$f_{El}(r) = \sqrt{\frac{2}{\pi\hbar}} \sin\left(\frac{kr}{\hbar} - \frac{l\pi}{2} + \delta_l\right) + o(1) \quad \text{при} \quad r \to \infty$$

Функция $\delta_l(k), k = \sqrt{2\mu E}$, называется фазовым сдвигом. Из (4.14) следует, что для случая свободного движения $\delta_l(k) = 0$. Собственные функции непрерывного спектра $f_{El}(r)$ удовлетворяют тому же условию нормировки (4.15), что и собственные функции для случая свободного движения. Функция $S_l(k) = e^{2i\delta_l(k)}$ играет роль матрицы рассеяния для радиального оператора Шрёдингера H_l. Она допускает мероморфное продолжение в верхнюю полуплоскость $\operatorname{Im} k > 0$ с простыми полюсами $k = i\varkappa_{kl} = i\sqrt{-2\mu E_{kl}}$, где E_{kl} - собственные значения H_l.

Пусть $E_{0l} < E_{2l} < \cdots < E_{N_l-1l} < 0$ - собственные значения H_l, и пусть $f_{jl}(r), j = 0, ..., N_l - 1$, - соответствующие нормированные собственные функции. По теореме о колебаниях собственные функции $f_{jl}(r)$ имеют j простых нулей на $(0, \infty)$. Функции

$$\psi_{jlm}(\boldsymbol{x}) = \frac{f_{jl}(r)}{r} Y_{lm}(\boldsymbol{n}), \quad m = -l, ..., l$$

это нормированные собственные функции оператора Шрёдингера H с собственными значениями E_{jl}, а функции

$$\psi_{Elm}(\boldsymbol{x}) = \frac{f_{El}(r)}{r} Y_{lm}(\boldsymbol{n}), \quad m = -l, ..., l$$

это нормированные собственные функции непрерывного спектра. Соответствующая теорема о разложении по собственным функциям для оператора Шрёдингера H со сферически симметричным потенциалом утверждает, что для любого $\psi \in L^2(\mathbb{R}^3, d^3\boldsymbol{x})$

$$\psi(\boldsymbol{x}) = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \int_0^{\infty} c_{lm}(E)\psi_{Elm}(\boldsymbol{x}) d\sigma(E) + \sum_{l=0}^{\infty} \sum_{m=-l}^{l} \sum_{j=0}^{N_l-1} c_{jlm}\psi_{jlm}(\boldsymbol{x})$$

где

$$c_{lm}(E) = \int_{\mathbb{R}^3} \psi(\boldsymbol{x})\overline{\psi_{Elm}(\boldsymbol{x})} d^3\boldsymbol{x}, \quad c_{jlm} = \int_{\mathbb{R}^3} \psi(\boldsymbol{x})\overline{\psi_{jlm}(\boldsymbol{x})} d^3\boldsymbol{x}.$$

ЗАМЕЧАНИЕ. В физике параметр j собственной функции $\psi_{jlm}(\boldsymbol{x})$ традиционно называется радиальным квантовым числом и обозначается n_r. Параметр l называется азимутальным квантовым числом, а параметр m - магнитным квантовым числом. Эта терминология происходит из старой квантовой теории, в которой каждому значению E_{kl} соответствует классическая орбита. Параметр $n = n_r + l + 1$ называется главным квантовым числом, так что $n_r = n - l - 1$ - всегда количество нулей соответствующей радиальной собственной функции $f_{jl}(r)$.

ЗАМЕЧАНИЕ. В общем случае собственные значения E_{jl} оператора Шрёдингера H со сферически симметричным потенциалом имеют кратность $2l + 1$. Для особых потенциалов, благодаря дополнительным симметриям задачи, могут возникать «случайные вырождения» относительно азимутального квантового числа l. Таков случай оператор Шрёдингера атома водорода, который мы будем рассматривать в следующем разделе.

ЗАдАЧА 4.7. Докажите все результаты, приведенные в этом разделе. (Указание: см. литературу к этой главе.)

ЗАдАЧА 4.8. Найдите уровни энергии частицы с угловым моментом $l = 0$ в центрально-симметричной потенциальной яме $V(r) = -V_0 < 0$ при $0 < r < a$ и $V(r) = 0$ при $r > a$.

ЗАдАЧА 4.9. Найдите спектр оператора Шрёдингера с потенциалом $V(r) = ar^{-2} + br^2, a, b > 0$.

ЗАДАЧА 4.10. Докажите, что рассеянная волна $u(\boldsymbol{x}, \boldsymbol{k}) = u^{(+)}(\boldsymbol{x}, \boldsymbol{k})$ в центрально-симметричном потенциале дается формулой

$$u(\boldsymbol{x}, \boldsymbol{k}) = \frac{1}{kr}\sqrt{\frac{\pi}{2}}\sum_{l=0}^{\infty}(2l+1)i^l e^{i\delta_l(k)} f_{El}(r)P_l(\cos\vartheta)$$

где $\boldsymbol{x}\cdot\boldsymbol{k} = kr\cos\vartheta$ и, как в разделе 3.4.2, $\hbar = 1$, а $\mu = \frac{1}{2}$.

ЗАдАЧА 4.11. Используя результат предыдущей задачи, покажите, что

$$f(k, \boldsymbol{n}, \boldsymbol{\omega}) = f(k, \cos\vartheta) = \frac{1}{2ik}\sum_{l=0}^{\infty}(2l+1)\left(S_l(k) - 1\right)P_l(\cos\vartheta)$$

разложение амплитуды рассеяния по парчиальным волнам, и получите следующую формулу для полного сечения:

$$\sigma_{\text{tot}}\,(k) = \frac{4\pi}{k^2}\sum_{l=0}^{\infty}(2l+1)\sin^2\delta_l(k)$$

6.5.6 Other Questions About the Central Field

Падение частицы на центр по Ландау

(ну да, тут отдельно это можно исследовать, а мне так лень...)

Для выяснения некоторых особенностей квантовомеханического движения полезно изучить случай, не имеющий, правда, непосредственного физического смысла,- движение частицы в поле с потенциальной энергией, обращающейся в некоторой точке (начале координат) в бесконечность по закону $U(r) \approx -\beta/r^2(\beta > 0)$; вид поля вдали от начала координат нас не будет интересовать. Мы видели в §18, что этот случай - как раз промежуточный между теми, когда имеются обычные стационарные §35 ПАДЕНИЕ ЧАСТИЦЫ НА ЦЕНТР 151 состояния, и случаями, когда происходит «падение» частицы в начало координат.

Вблизи начала координат уравнение Шредингера в рассматриваемом случае будет следующим:

$$R'' + \frac{2}{r}R' + \frac{\gamma}{r^2}R = 0$$

($R(r)$ - радиальная часть волновой функции), где введена постоянная

$$\gamma = \frac{2m\beta}{\hbar^2} - l(l+1)$$

и опущены все члены более низкого порядка по $1/r$; значение энергии E предполагается конечным, и потому соответствующий член в уравнении тоже опущен.

Ищем R в виде $R \sim r^s$; тогда получаем для s квадратное уравнение

Так в итоге, если частица падает на центр, то она там и останется что ли? (????)

(пока хз.)

6.5.7 Central Field in Spherical and Parabolic Coordinates

(лл3, там приводится это.)

Движение в кулоновском поле (сферические координаты) по Ландау

Движение в кулоновском поле (параболические координаты) по Ландау

Особенности квантового движения

В отличие от классической механики движение не плоское (????)

6.5.8 Non-Relativistic Hydrogen Atom

Обсудим подробно нерелятивистский атом водорода.
(очень скоро напишу нормально!)

Атом водорода в двух словах

(тут вся самая суть с формулами)

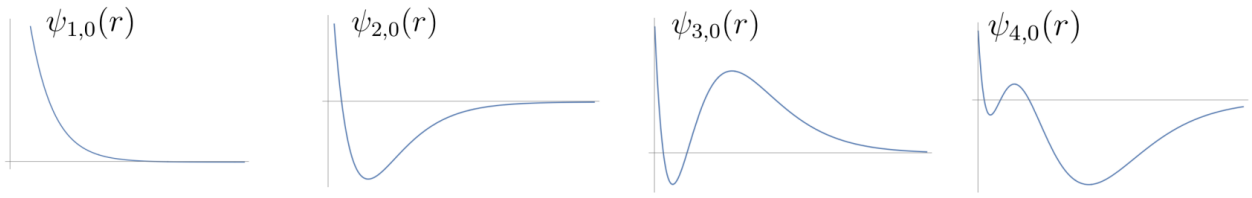

Figure 6.3: The (un-normalised) s-wave states for n = 1, 2, 3 and 4. The functions are plotted on the same range along the x-axis, although the y-axis range varies. Although it's not obvious from these plots, all wavefunctions approach a finite value at x = 0.

Модель нерелятивистского атома водорода

(тут подробно)
Кулоновский потенциал притяжения электрона и протона в атоме водорода в пренебрежении (?) имеет вид

$$V(r) = -\frac{e^2}{r}$$

Поэтому стационарное уравнение Шредингера имеет решения, которые разлагаются по ба
(???).
$\hat{H}$ -энергия стационарного уравнения Шредингера для радиального движения

$$-\frac{\hbar^2}{2m}u'' + \left\{-\frac{e^2}{r} + \frac{\hbar^2 l(l+1)}{2mr^2}\right\} u = Eu$$

так что радиальная волновая функция

$$R_l^E(r) = \frac{1}{r}u(r)$$

где $u(r) \sim r^{l+1}, \quad r \to 0,$

(???)

$$m = \frac{m_e m_p}{m_e + m_p}$$

(??)

сферическими гармониками

$$\hat{\boldsymbol{l}}^2 Y_{l,m}(\theta, \phi) = l(l+1) Y_{l,m}(\theta, \phi)$$

и

$$\hat{\boldsymbol{l}}_z Y_{l,m}(\theta, \phi) = m Y_{l,m}(\theta, \phi)$$

4.P - четность с собственным и Значен иям и

$$\lambda_P = (-1)^l$$

Для полного определения волновой функции стационарного состояния

$$\Psi_{l,m}(\boldsymbol{r}) = R_l^E(r) Y_{l,m}(\theta, \phi)$$

необходимо решить радиальное уравнение (11.2)

с эффективным потенциалом, учитывающим вклад орбитального движения, как показано на рис.

количественные выводы из модели атома водорода

??? сколько там всего уровней энергии? как решаем УШ для них?
это такие, которые состоят из двух частиц и связаны только электрическими силами.
это He^+, Li^+, Be^{+++}, я вообще хз, почему они сюда относятся, потом пойму.

качественный вид волновых функций атома водорода

Приведем визуальное представление волновых функций
(как же давно уже хочу дойти сюда!!!)

модель атома водорода в 2D

Определим уровни энергии, кратности их вырождения, стационарные волновые функции для двумерной частицы, движущейся в притягивающем потенциале $U(r) = \frac{e^2}{r}$.

Уравнение Шредингера для этой модели имеет вид

$$u''_{rr} + \frac{1}{r} u'_r + \frac{1}{r^2} u''_{\phi\phi} - 2M \left(-\frac{e^2}{r} + E \right) u = 0;$$

где $E > 0$.

ищем решение в виде $u(r, \phi) = \psi(r) e^{im\phi}$, где $m \in Z$,

$$r\psi''_{rr} + \psi'_r + \left(2Me^2 - 2MEr - \frac{m^2}{r} \right) \psi = 0$$

Если $\psi(r) = f(r) r^a$, то

$$r^{a+1} f'' + (2a+1) r^a f' + \left(a^2 r^{a-1} - m^2 r^{a-1} + 2Me^2 r^a - 2MEr^{a+1} \right) f = 0$$

положим $a = m$, тогда

$$rf'' + (2m+1)f' + \left(2Me^2 - 2MEr\right) f = 0$$

и также $f(r) = F(r)e^{br}$, получаем

$$rF'' + (2br + (2m+1))F' + \left(b^2 r + (2m+1)b + 2Me^2 - 2MEr\right) F = 0$$

видим, что польза есть от $b = -\sqrt{2ME}$, получаем

$$rF'' + (-2\sqrt{2ME}r + (2m+1))F' + \left(-(2m+1)\sqrt{2ME} + 2Me^2\right) F = 0$$

$$F(r) =_1 F_1\left(-\frac{\left(-(2m+1)\sqrt{2ME} + 2Me^2\right)}{2\sqrt{2ME}}, 2m+1, 2\sqrt{2ME}r\right)$$

В итоге

$$\psi(r) = r^m e_1^{-\sqrt{2ME}r} F_1\left(-\frac{\left(-(2m+1)\sqrt{2ME} + 2Me^2\right)}{2\sqrt{2ME}}, 2m+1, 2\sqrt{2ME}r\right)$$

для конечности волновой функции необходимо, чтобы $\frac{\left(-(2m+1)\sqrt{2ME}+2Me^2\right)}{2\sqrt{2ME}} = n$ в итоге m кратно вырожденные уровни:

$$E = \frac{M}{2}\frac{e^4}{\left(n + \left(m + \frac{1}{2}\right)\right)^2}$$

Обзор применений методов описания атома водорода в других задачах и науках (??)

(укажу, где будет она нужна)

6.6 Three-Dimensional Problem by Migdal-Krainov (?)

6.6.1 Centrally-Symmetric Field

Рассмотрим квазиклассическое движенне в центральносимметричном поле. Переменные $0, \varphi$ в этом случае отделяются от перємной r:

$$\Psi_{nlm} = R_{nl}(r)Y_{lm}(\theta, \varphi).$$

Расснотрим сначала радиäльную часть волновой функции. Введем функцно

$$u_{nl}(r) = rR_{nl}(r).$$

From ограниченности $R_{ni}(r)$ при $r = 0$ следует, что $u_{ni}(0) = 0$. Дла u_{nl}, как нзвестно, получается одномерное уравнение

$$u''_{nl} + k^2_{nl} u_{nl} = 0$$

где

$$k^2_{nl} = 2\left[\varepsilon_{nl} - V(r) - \frac{l(l+1)}{2r^2}\right].$$

Условие $u_{n2}(0) = 0$ соответствует в одномерной задаче бесконечной потенциальной стенке в начале координат.

Прн увеличении l и заданном $V(r)$ яма на рис. 28 сталовится все мельче и в конце концов исчезает, т. е. при достаточио большом l система не будет обладать дйсретныни уровнпми. Значениям $\varepsilon_{nl} > 0$ соответствует сплоціной спектю.

6.6.2 Energy Levels in a Coulomb Field

Найдем уровни энергии в кулоновском поле. Условие квантования имеет вид (при $l \neq 0$, рнс. 28,б)

$$\int_{r_{\min}}^{\max_{\max}} \sqrt{2\left(E_n + \frac{Z}{r} - \frac{(l+1/2)^2}{2r^2}\right)} dr = \left(n_r + \frac{1}{2}\right)\pi.$$

Здесь n_r - радиальное квантовое число, $r_{\min}, r_{\max}$ - квазиклассические точки поворота. Мы заменили в центробежном потенциале $l(l+1) \to (l+1/2)^2$. Тогда квазиклассическая функция имеет фазу на бесконечности, совпадающую с точным решением, между тем как другие величины от такой замены практически не меняются. Интеграл в левой части приведенного выше условия равен

Следовательно,

$$\frac{Z\pi}{\sqrt{-2E_n}} - \left(l + \frac{1}{2}\right)\pi.$$

$$E_n = -\frac{Z^2}{2n^2},$$

где $n = n_r + l + 1$ - главное квантовое число.

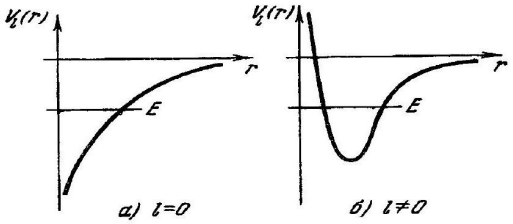

Рис. 28.

При $l = 0$ (рис. $28, a$) левая точка поворота $r_{\min} = 0$ и совпадает с особой точкой уравнения, т. е. в области левой точки поворота потенциал нельзя заменить прямой линией, как мы делали выше. Поэтому условие сшивки на левом краю изменится.

Для нахождения энергетических уровней при $l = 0$ нужно найти точное решение вблизи особой точки и сшить его с квазиклассическим решением вдали от нее.

Для больших квантовых чисел (т. е. энергий, близких к нулю), волновая функция в кулоновском поле с $l = 0$ имеет вид *)

$$R_{n0} = a_1 Z^{3/2} \frac{J_1\left(\sqrt{8Z_r}\right)}{\sqrt{Zr}},$$

где a_1 - нормировочный коэффициент. При $r \geqslant 1/Z$ отсюда находим

$$R_{n0} = a_1 \frac{\cos(\sqrt{8Zr} - 3/4\pi)}{r^{3/4}}.$$

С другой стороны, для R_{n0} можно написать квазиклассическое решение

$$R_{n0} = a_2 \frac{\cos\left(\int\limits_0^r p_r dr - C_1\pi\right)}{r\sqrt{p_r}} = a_2 \frac{\cos\left(\sqrt{8Zr} - C_1\pi\right)}{r\sqrt{p_r}}.$$

Таким образом, здесь появляется фаза $C_1\pi = \frac{3}{4}\pi$ вместо $\frac{1}{4}\pi$ в обычном случае. Функция R_{n0} может быть также записана в виде

$$R_{n0} = a_3 \frac{\cos\left(\int\limits_r^{r^{\max}} p_r dr - \pi/4\right)}{r\sqrt{p_r}}.$$

Здесь $r_{\max}$ - правая точка новорота. Из условия однозначности, так же как и в 3.1, получаем правило квантования

$$\int\limits_0^{r_{\max}} p_r dr = (n_r + 1)\,\pi = n\pi,$$

где n-главное квантовое число.

Вычисление интеграла даст

$$E_n = -\frac{Z^2}{2n^2}.$$

Как мы видим, в этом случае квазиклассическое приближение (так же как и в случае осциллятора) дает точные уровни энергий.

6.6.3 Quasi-Classical Representation of Spherical Functions

Для вычисления матричных элементов физических величин при больших угловых моментах l удобно использовать квазиклассическое представление для сферической функции:

$$Y_{lm}(\theta, \varphi) = \frac{1}{\sqrt{2\pi}} P_{lm}(\cos\theta) e^{imp}.$$

Здесь $P_{lm}(x)$ - присоединенный полином Jeeандра, удовлетворяющий уравнению

$$\frac{d}{dx}\left[\left(1 - x^2\right)\frac{dP_{L_m}}{dx}\right] + \left[l(I+1) - \frac{m^2}{1-x^2}\right] P_{tm} = 0.$$

Введем функцию $\vartheta_{lm}(x)$:

$$P_{lm}(x) = \frac{1}{\sqrt{1-x^2}} \vartheta_{lm}(x).$$

Тогда для $\vartheta_{tm}(x)$ имеем

$$\left(1 - x^2\right)\vartheta''_{lm}(x) + \left[l(l+1) - \frac{m^2+1}{1-x^2}\right]\vartheta_{lm}(x) = 0.$$

Решение этого уравнения с точностью порядка $1/l^2$ может быть найдено в квазиклассическом виде

$$\theta_{lm}(x) = \frac{a}{\sqrt{k}} \cos\left(\int\limits_{x_1}^{x} k dx - \frac{\pi}{4}\right),$$

где

$$k^2(x) = \frac{1}{1-x^2}\left[\left(l+\frac{1}{2}\right)^2 - \frac{m^2}{1-x^2}\right].$$

В точках $x_{1,2}$ величина $k(x)$ обращается в нуль, т.е.

$$x_{1,2} = \mp\sqrt{1-\frac{m^2}{(l+1/2)^2}}.$$

Мы заменили здесь $l(l+1) \longrightarrow (l+1/3)^2$, имея в виду, что квазиклассическое приближение применияо с точностью до $1/t^2$ (а не $1/l$; см. 3.1).

Коэффициент a определяется из условня нормировки присоединенных полиномов Лежандра:

$$int_{-1}^{1} P_{lm}^2(x)dx = 1,$$

т.е.

Вычислим

$$\int_{x_1}^{x_2^2}\int_{x_1}^{x_2}\frac{1}{1-x^2}\frac{dx}{k} = 1 = \frac{a^2}{2}\frac{1}{l+\frac{1}{2}}\frac{\partial}{\partial l}\int_{x_1}^{x_2} kdx.$$

$$\int_{x_1}^{x_2}\sqrt{\frac{1}{(1-x^2)}\left[\left(l+\frac{1}{2}\right)^2 - \frac{m^2}{1-x^2}\right]}dx = \left(l-|m|+\frac{1}{2}\right)\pi.$$

Этот результат следовало ожидать, так ікак число узлов $P_{tm}(x)$, как известно, равно $l-|m|$. Из (3.25) находим

$$\frac{\partial}{\partial l}\int_{x_1}^{x_2} kdx = \pi$$

Следовательно,

$$a^2 = \frac{2l+1}{\pi}.$$

Окончательно имеем

$$P_{lm}(x) \underset{x_1<x<x_2}{=} \sqrt{\frac{2l-1}{\pi}}\frac{1}{\sqrt{1-x^2}}\frac{1}{\sqrt{k}}\cos\left(\int_{x_1}^{x} kdx - \frac{\pi}{4}\right),$$

где

$$k = \frac{1}{\sqrt{1-x^2}}\pi\sqrt{\left(l+\frac{1}{2}\right)^2 - \frac{m^2}{1-x^2}}$$

Квазиклассическое представление сферических функций позволяет приближенно вычислять суммы вида

$$I_l(\theta) = \sum_{m=-t}^{l} |Y_{lm}(\theta,\varphi)|^2\,\Phi(m).$$

Действительно, используя условие квантования (3.25) и заменяя суммирование интегрированием, получаем

$$I_l(\theta) = \frac{l+1/2}{2\pi^2} \int\limits_{-(l+1/2)|\sin\theta|}^{(l+1/2)|\sin\theta|} \frac{\Phi(m)dm}{(l+2)\sin\theta\sqrt{1-\frac{m^2}{(l+1/2)^2\sin^2\theta}}} =$$

$$= \frac{l+1/2}{2\pi^2} \int\limits_{-1}^{1} \frac{dt}{\sqrt{1-t^2}} \Phi[t(l+1/2)\sin\theta].$$

В частности, для $\Phi(m) = 1, m^2, m^4$ находим

$$\sum_{m=-l}^{l} |Y_{lm}|^2 = \frac{l+1/2}{2\pi^2} \int\limits_{-1}^{1} \frac{dt}{\sqrt{1-t^2}} = \frac{2l+1}{4\pi},$$

$$\sum_{m=-l}^{l} |Y_{lm}|^2 m^2 = \frac{l+1/2}{2\pi^2} \int\limits_{-1}^{1} \frac{dt}{\sqrt{1-t^2}} t^2 (l+1/2)^2 \sin^2\theta = \frac{(l+1/2)^3}{4\pi} \sin^2\theta.$$

$$\sum_{m=-l}^{l} |Y_{lm}|^2 m^4 = \frac{l+1/2}{2\pi^2} \int\limits_{-1}^{1} \frac{dt}{\sqrt{1-t^2}} t^4 (l+1/2)^4 \sin^4\theta = \frac{3(l+1/2)^5}{16\pi} \sin^4\theta.$$

6.6.4 Thomas-Fermi Distribution in the Atom

Для потенциала V атома можно написать следующее электростатическое уравнение:

$$\Delta V = -4\pi\rho,$$

где ρ - плотность заряда электронов в данной точке. Это уравнение приближенное, так как на самом деле мы имеем многочастичную задачу - ядро и Z электронов - и потенциал

$$V(\boldsymbol{r}, \boldsymbol{r}_i) = -\frac{Z}{r} + \sum_{i=1}^{Z} \frac{1}{|\boldsymbol{r} - \boldsymbol{r}_i|}$$

есть оператор, а не число, т. е. V зависит от электронных координат, в то время как ρ, очевидно, нет. Следовательно, потенциал, используемый в (3.26), есть значение истинного потенциала, усредненное по движению электронов.

Поскольку частиц много, то отклонения $V(\boldsymbol{r}, \boldsymbol{r}_i)$ от $V(\boldsymbol{r})$ будут в среднем малы (хотя формально $V(\boldsymbol{r}, \boldsymbol{r}_i)$ может принимать любые значения). У равнение Шредингера с таким усредненным потенциалом имеет вид

$$\Delta\Psi + 2(E - V)\Psi = 0,$$

причем потенциал V можно сiитать сферически-симметричным (сферическая симметрия может нарушаться лишь за счет наружных электронов или незаполненных оболочек). Тогда $\Psi_{nlm} = \frac{u_{nl}(r)}{r} Y_{lm}$, причем для $u_{nl}(r)$ имеем уравнение

$$u''_{nl} + k^2_{nl} u_{nl} = 0,$$

где

$$k^2_{nl} = 2\left[E - V(r) - \frac{l(l+1)}{2r^2}\right].$$

Функция u_{nl} удовлетворяет граничным условиям

$$u_{nl}(0) = 0, \quad \lim_{r\to\infty} u_{nl}(r) = 0$$

и нормирована следующим образом:

$$\int_0^\infty u_{nl}^2 dr = 1.$$

(функцию $u_{n\mathrm{Im}ath}$ можно считать вещественной). Плотность заряда электронов равна (как и всюду, $e = \hbar = m = 1$)

$$\rho = -2\sum_{nlm} |\Psi_{nlm}|^2 = -2\sum_{nlm} \frac{u_{nl}^2}{r^2} |Y_{lmn}|^2 .$$

Суммирование по m с учетом соотношения (стр. 140)

$$\sum_{m=-l}^{t} |Y_{lm}|^2 = \frac{2l+1}{4\pi}$$

приводит к выражению

$$\rho(r) = -2\sum \frac{u_{nl}^3(r)}{r^2}\frac{2l+1}{4\pi}.$$

В квазиклассическом приближении радиальная волновая функция имеет вид

$$u_{nl}(r) = \frac{a_{nl}}{\sqrt{k_{nl}}} \cos\left(\int_{r_1}^{r} k_{nl}dr - \frac{\pi}{4}\right),$$

где

$$k_{nl}^2(r) = E_{nt} - V(r) - \frac{(l+1/2)^2}{2r^2}, a_{nl}^2 \approx \frac{2}{\pi}\frac{\partial E_{nl}}{\partial n}.$$

Уровни энергии E_{nt} находятся из иравила кваитовация Бора

$$\int_{r_2}^{r_3} k_{ni}dr = \left(n + \frac{1}{2}\right)\pi.$$

При $l = 0$ вместо $n + 1/2$ в соотношении (3.31) нужно написать n (см. стр. 137). Из (3.29) и (3.30) получаем

$$\rho(r) = -\frac{1}{2\pi}\sum_{nl} \frac{a_{nl}^2}{k_{nl}r^2}(2l+1)\cos^2\left(\int_{r_1}^{r} k_{nl}dr - \frac{\pi}{4}\right).$$

В квазиклассическом приближении можно заменить средпее значение квадрата косинуса на 1/2. Из (3.32) имеем

$$\rho(r) = -\frac{1}{2\pi^2}\sum_{nl} \frac{\partial E_n t}{\partial n}\frac{2l+1}{r^2}\frac{1}{k_{nl}}.$$

От суммирования по n в (3.33) перейдем к интегрированию при фиксированном l; так как

$$\sum_n \frac{\partial E_{nl}}{\partial n}(...) \to \int \frac{\partial E_{nl}}{\partial n} dn(...) \to \int dE(...),$$

ТО

$$\sum_n \frac{\partial E_{nl}}{\partial n}\frac{1}{k_{nl}} = \int \frac{dE}{k_{nl}} = \int \frac{dE}{\sqrt{2\left(E - V_l\right)}} = \sqrt{2\left(E - \bar{V}_l\right)}\Big|_{E_{\min}}^{0},$$

где $E_{\min} = V_l$ (при $E > V_l$ волновая функцня имеет вид $\cos\left(\int kdr - \frac{\pi}{4}\right)$, а при $E < V_t$ она затухает экспоненциально и вкладом этоff части в $\rho(r)$ можно иренебречь). Поэтому выражение (3.33) можно запнсать в виде

$$\rho(r) = -\frac{1}{2\pi^2}\sum_l \frac{2l+1}{r^2}\sqrt{-2V_l}.$$

Так как $V_l = V + \frac{1}{2r^2}\left(l + \frac{1}{2}\right)^2$, то $\frac{dV_l}{dl} = \frac{2l\cdot -1}{r^2}$, так что (3.34) принимает вид

$$\rho(r) = -\frac{1}{\pi^2}\sum_l \frac{dV_l}{dl}\sqrt{-2V_l} = -\frac{1}{\pi^2}\int \sqrt{-2V_l}c'V_l =$$

$$= -\frac{2}{3\cdot 2\pi^2}\left(-2V_t\right)^{3/2}\Big|_{V_{\min}}^{V_{l_{\max}}}.$$

$V_{l_{\min}}$ соответствует $l = 0, V_{l_{\min}} = V$. Величина $V_{l_{\max}}(r) = 0$. Для состояний с бОльшими l точка r находится в классически недоступной области, и такие состояния вносят экспоненциально малый вклад в плотность в точке r (рис. 29). Итак,

$$\rho(r) = \frac{1}{3\pi^2}(-2V)^{3/2}.$$

Обозначая $-V \equiv \varphi$, запишем уравнение Пуассона (3.26: с учетом (3.36) в следующем виде:

$$\Delta\varphi = 4\pi\rho = \frac{8\sqrt{2}}{3\pi}\varphi^{3/s} = C\varphi^{3/2},$$

где $C \equiv 8\sqrt{\bar{2}}/3\pi$. Это - так называемое уравнение Томаса-Ферми. Рис. 29. Если $r \longrightarrow 0$, то $\varphi \longrightarrow Z/r$ - потенциал ядра. Целесообразно заменить $\varphi(r) = Z\chi(r)/r$ с граничным условием $\chi(0) = 1$.В сферических координатах

$$\Delta\varphi = \frac{1}{r}\frac{d^2}{dr^2}(r\varphi) = \frac{1}{r}\frac{d^2}{dr^2}(Z\chi),$$

следовательно, из (3.37) имеем

$$\frac{Z}{r}\chi''(r) = C\frac{Z^{3/2}}{r^{3/2}}\chi^{3/2},$$

или

$$\chi''(r) = C\frac{Z^{1/2}}{r^{1/2}}\chi^{3/2}.$$

Введем новую переменную $x = \alpha Z^{1/s}$ (α выберем позже) с целью получить универсальное уравнение для функции χ. Тогда из (3.39) находим

$$\alpha^2 Z^{2/3}\chi'' = CZ^{1/2}\frac{1}{x^{1/2}}\alpha^{1/z}Z^{1/a}\chi^{3/2},$$

или, если выбрать $C = \alpha^{3/2}$, т. е. $\alpha = \left(\frac{8\sqrt{2}}{3\pi}\right)^{2/s}$, то окончательно находим

$$\left.\begin{array}{c} \frac{d^2\chi}{dx^2} = \frac{1}{V\bar{x}}\chi^{3/2}, \\ \chi(\infty) = 0, \quad \chi(0) = 1. \end{array}\right\}$$

Уравнение (3.40) решается численно (в 1.1 дано приближенное его решение). Решение его определяет распределение плотности электронов. Характерный радиус этого распределения в безразмерных единицах $x \sim 1$, следовательно, в обычных единицах $a^Z_{\text{Т.-Ф. }\sim a_0/\sqrt[3]{Z}}$. На этом расстоянии находится большинство электронов. Полученный результат совпадает с приближенной оценкой, приведенной на стр. 38. Уравнение (3.40) справедливо в той области атома, где применимо квазиклассическое приближение.

Граница применимости распределения Томаса-Ферми (????)

Начиная с каких и до каких расстояний применимо распределение Томаса - Ферми? (??? не знаю????)

Ответ: $r_{\min} \sim 1/Z, \quad r_{\max} \sim 1.$

(???? а можно конкретно, что не то, если мы на других расстояниях будем его использовать????)

6.6.5 Estimates of Nuclear Matrix Elements

(???? это тренировать еще нужно, не отработал использование этих оценок)

Основные методы

В теории ядра часто приходится вычислять различные суммы матричных элементов. Рассмотрим, какие матричные элементы вносят наибольший вклад в такие суммы.

Пусть $U(r)$ - величина, заметно изменяющаяся на расстояниях порядка радиуса ядра. Оценим квазиклассический матричный элемент $U_{\lambda_1\lambda_2} = (\varphi_{\lambda_1} U \varphi_{\lambda_2})$, где φ_λ - волновая функция нуклона в самосогласованном поле, создаваемом всеми остальными нуклонами ядра, λ - совокупность квантовых чисел, описывающих состояние нуклона.

Рассмотрим сначала сферическое ядро. Тогда $\lambda \equiv n, j, l, m$, где n - радиальное, l - орбитальное и m - магнитное квантовые числа, $j = l \pm \frac{1}{2}$. Покажем, что соседние уровни в сферическом ядре не комбинируют (????) между собой, т. е. дают малое значение матричного элемента $U_{\lambda_1\lambda_2}$.

Предварительно оценим расстояние между соседними уровнями. В деформированном ядре уровни с различными проекциями момента на ось симметрии расщеплены, поэтому если A - число нуклонов в ядре, а ε_F - энергия Ферми, т. е. энергетическое расстояние от дна самосогласованной ямы до места заполнения последних нуклонов, то среднее расстояние между одночастичными уровнями имеет порядок

$$\Delta E \sim \varepsilon_F / A.$$

Величина ε_F не зависит от A с той точностью, с которой постоянна плотность n ядерного вещества. Действительно, в системе, которая удерживается силами, действующими между ее частицами, радиус действия сил и среднее расстояние между частицами имеют одинаковый порядок величины. Поэтому все величины, характеризующие ядро, можно выразить с помощью размерных оценок друг через друга (!???). В частности,

$$\varepsilon_F \sim n^{2/3} \qquad (M = \hbar = 1).$$

В сферическом ядре существует вырождение по проекции углового момента с кратностью порядка величины углового момента

$$l \sim p_F R,$$

где R - радиус ядра, а p_F - импульс нуклона на границе ферми. Так как $R = r_0 A^{1/3}$, где r_0-величина порядка среднего расстояния между нуклонами, то $p_F R = p_F r_0 A^{1/2} \sim A^{1/s}$. Следовательно, среднее расстояние между ближайшими уровнями сферического ядра имеет порядок величины

$$\Delta E \sim \varepsilon_F / A^{2/3}.$$

Расстояние между уровнями с разными радиальными квантовыми числами

Оценим сначала расстояние между уровнями, отличающимися лишь радиальными квантовыми числами n, причем $\delta n \sim 1$. Для этого продифференцируем по n условие квантования Бора $\int p_r dr = n$, где p_r - радиальный импульс. Получаем:

$$1 = \int \frac{\partial p_r}{\partial n} dr = \int \frac{\partial p_r}{\partial \varepsilon_{nl}} \frac{\partial \varepsilon_{nl}}{\partial n} dr \sim \frac{\partial \varepsilon_{nl}}{\partial n} \int \frac{dr}{v} \sim \frac{\partial \varepsilon_{nl}}{\partial n} \frac{R}{v},$$

где ε_{nt} - уровень энергии, а $v = \frac{\partial \varepsilon_{nl}}{\partial p_r}$ - скорость нуклона. Отсюда

$$\frac{\partial \varepsilon_{nt}}{\partial n} \sim \frac{v}{R} = \frac{v}{r_0 A^{1/3}} \sim \frac{p_F v}{A^{1/3}} \sim \frac{\varepsilon_F}{A^{1/3}}.$$

Расстояние между уровнями с разными орбитальными квантовыми числами

Оценим теперь расстояние между уровнями, отличающимися лишь орбитальными квантовыми числами l, причем $\delta l \sim 1$. Для этого продифференцируем по l соотношение $\int p_r dr = n$, учитывая, что $p_r = \sqrt{2\left[\varepsilon_{nl} - V(r) - \frac{(l+1/2)^2}{2r^2}\right]}$.

Здесь $V(r)$-потенциальная энергия нуклона. Получаем:

$$\int \frac{dr}{p_r} \left(\frac{\partial \varepsilon_{nl}}{\partial l} - \frac{l}{r^2} \right) = 0,$$

Т. е.

$$\frac{\partial \varepsilon_{nl}}{\partial l} \int\limits_{r_{\min}}^{R} \frac{dr}{p_r} \sim l \int\limits_{r_{\min}}^{R} \frac{dr}{r^2 p_r},$$

где $r_{\min}$ находится из условия $p_r = 0$, т. е. $r_{\min} \sim l/p_F$. В интеграле $\int\limits_{r_{\min}}^{R} \frac{dr}{p_r}$ существенна вся область интегрирования, поэтому мы его оцениваем как R/v (?? видимо, считаем массу равной 1???). А в интеграле $\int\limits_{r_{\min}}^{R} \frac{dr}{r^2 p_r}$ основной вклад вносится областью вблизи $r_{\min}$, поэтому его оценка $1/(r_{\min} p_F) \sim 1/l$. Итак, $\frac{\partial \varepsilon_{nl}}{\partial l} \cdot \frac{R}{v} \sim l \frac{1}{l} = 1$, т. е.

$$\frac{\partial \varepsilon_{nl}}{\partial l} \sim \varepsilon_F / A^{1/3}.$$

Таким образом, мы получили, что

$$\frac{\partial \varepsilon_{nl}}{\partial n} \sim \frac{\partial \varepsilon_{nl}}{\partial l} \sim \varepsilon_F A^{-1/3}.$$

Поэтому уровень сферического ядра, ближайший к данному, т. е. отстоящий от него на расстоянии $\varepsilon_F/A^{2/3}$, получается, как правило, за счет больших изменений δn и δl, так чтобы величина

$$\delta\varepsilon_{nl} = \frac{\partial\varepsilon_{nl}}{\partial n}\delta n + \frac{\partial\varepsilon_{nt}}{\partial l}\delta l$$

была минимальна. Для этого нужно выбрать $\delta n, \delta l \sim A^{1/3}$. Следовательно, ближайшие уровни сферического ядра, как правило, сильно отличаются по числу узлов радиальной и угловой части волновой функции, а потому дают малое значение матричного элемента $U_{\lambda_1\lambda_3}$.

Состояния с энергнями $|\varepsilon_{\lambda_1} - \varepsilon_{\lambda_2}| \gg \varepsilon_F/A^{1/s}$ также дают малое значение $U_{\lambda_1\lambda_2}$, так как функции $\varphi\lambda_1$ и $\varphi\lambda_2$ сильно различаются по числу узлов.

Итак, матричный элемент $U_{\lambda_1\lambda_2}$ заметно отличен от нуля для $\lambda_1 = \lambda_2$ (если он при этом не равен строго нулю из-за правил отбора) и для $|\varepsilon_{\lambda_1} - \varepsilon_{\lambda_2}| \sim \varepsilon_F A^{-1/3}$, когда числа узлов функций $\varphi\lambda_1$ и $\varphi\lambda_2$ мало различаются.

Об оценках уровней деформированных ядер

Все сказанное выше о комбинирующик (?) уровнях остается в силе и для деформированного ядра, если оператор U меняет квантовые числа n и l. Если же U меняет лишь магнитное квантовое число m (например, оператор углового момента), то комбинируют уровни с соседними m, принадлежащие одному мультиплету nl. Оценим расстояние между ними. Выше (см. стр. 75) было показано, что в первом порядке теории возмущений расщепление уровней определяется соотношением

$$\varepsilon_{ntm} = \varepsilon_{nl} + \varepsilon_{nl}\beta\left(\frac{m^2}{l^2} - \frac{1}{3}\right),$$

где β-величина деформации. Следовательно,

$$\frac{\partial\varepsilon_{ntm}}{\partial m} \sim \varepsilon_{nl}\beta\frac{m}{l^2} \sim \varepsilon_F\beta A^{-1/3},$$

т. е. в этом случае могут комбинировать и близкие уровни (при малых β).

(??? хз, как например это оценивать на практике, ни одного примера не соображу???)

Иллюстрация и примеры оценок в ядерной физике (?????)

(пока не применял этот параграф, потом применю его.)

(??? что-то подозреваю, что у МК бесполезный параграф, потому что с Чармонием задачу нихрена я не могу решить этими формулами. Другую теорию буду писать скорее всего тут еще)

(??? что с Е ферми делать??? мы же не знаем его для ядра??)

Граница применимости таких оценок в ядерной физике (?????)

(??? я хз, для двухчастичных состояний она применима или нет???? мб и нет. не понимаю это пока что.)

Об идее оценивать через $E = mc^2$ и формулу Бора $E_n = -\frac{\alpha}{n^2}$ (???)

(?? хз, так в каких-то вузах предлагают.)

6.6.6 Non-Central Potential (???????)

Основные методы

Рассмотрим более общий случай, когда переменные не разделяются, и построим в этом случае квазиклассическое решение. Ищем решение уравнения

$$\Delta\Psi\Psi + k^2\Psi = 0$$

в виде $\Psi = Ae^{iS}$ Тогда

$$\nabla\Psi = (\nabla A + iA\nabla S)e^{iS},$$

$$\Delta\Psi = \left(\Delta A + 2i\nabla A\nabla S + iA\Delta S - A(\nabla S)^2\right)e^{is}.$$

Следовательно,

$$\Delta A + 2i\nabla A\nabla S - A(\nabla S)^2 + iA\Delta S + k^2 A = 0.$$

Разделяя действительную и мнимую части, из (3.41) получаем два уравнения

$$\Delta A + k^2 A = A(\nabla S)^2,$$

$$2\nabla A\nabla S + A\Delta S = 0.$$

Уравнение $2\nabla A\nabla S + A\Delta S = 0$ означает закон сохранения тока частиц. Действительно,

$$j = \frac{1}{2}\left(\Psi^*\nabla\Psi - \Psi\nabla\Psi^*\right) = \frac{1}{2i}\left[Ae^{-iS}\nabla\left(Ae^{iS}\right) - Ae^{iS}\left(\nabla Ae^{-iS}\right)\right] = A^2\nabla S$$

и

$$\operatorname{div} j = \nabla\left(A^2\nabla S\right) = A^2\Delta S + 2\nabla A\nabla S\cdot A = 0.$$

Следовательно, вдоль линии тока

$$j_1 d\sigma_1 = j_2 d\sigma_2,$$

где $d\sigma_1$ и $d\sigma_2$ - нормальные элементы площади трубки тока.

Если $\Delta A/A \ll k^2$, то из $\Delta A + k^2 A = A(\nabla S)^2$ следует уравнение Гамильтона-Якоби для S:

$$2[E - V(r)] = (\nabla S)^2.$$

6.6.7 Quasi-Classical Scattering Problem

Построим квазиклассическую волновую функцию для задачи рассеяния. Гредварительно заметим, что уравнение (3.45) содержит не одно решение: в любую точку в $+\infty$, куда устремляются частицы после рассеяния, частица может прийти по меньшей мере двумя путями. Это изображено на рис. 31.

(??????????? тут рисунок, который я вообще не понимаю)

Здесь 1 и 2 - две точки фронта плоской падающей волны.

Поэтому на основе принципа суперпозиции вместо решения $\Psi = Ae^{iS}$ мы должны потребовать $\Psi = \sum_i A_i e^{iS_l}$, где сумма берется по всем классическим траекториям, соединяющим рассматриваемые точки.

Предположим для простоты, что есть только две траектории, соединяющие фронты падающей и рассеянной волн на бесконечности. Вдоль траектории I, которая 'проходит втали от центра рассеяния, трубка тока параллельна оси x; A и ∇S постоянны, причем

$\nabla S = p_0$. Можно положить, что значение Ц-функции в каждой точке фронта падающей волны равно 1. Поэтому $A_1 = A_2 = 1$. Следовательно,

$$\Psi_1 = \exp\left[i\int\limits_{-L}^{x} p_0 dx\right] = \exp\left(ip_0 x + ip_0 L\right),$$

где L - пока произвольное число. Найдем второе решение Ψ_2. Вдоль второй трубки тока $A^2 \nabla S d\sigma = \text{const}$. На $-\infty$ имеем $A_2 = 1, \nabla S = p_0, d\sigma = \rho d\rho d\varphi$, где ρ - прицельный параметр. Следовательно,

$$p_0 \rho d\rho d\varphi = A_2^2 p_0 r^2 d\Omega.$$

Тогда

$$\Psi_2 \underset{r\to\infty}{\to} A_2 e^{iS_2} = \sqrt{\frac{\rho d\rho d\varphi}{r^2 d\Omega}} \exp\left[i\int\limits_{-L}^{r} pdl\right],$$

а полное решение задачи имеет вид

$$\Psi \underset{r\to\infty}{\to} \exp\left(ip_0 x + ip_0 L\right) + \sqrt{\frac{\rho d\rho d\varphi}{r^2 d\Omega}} \exp\left[i\int\limits_{-L}^{r} pdl\right].$$

Умножим правую часть этого равенства на постоянный множитель $e^{-ip_0 L}$:

$$\Psi \underset{r\to\infty}{\longrightarrow} e^{ip_0 x} + \sqrt{\frac{\rho d\rho d\varphi}{r^2 d\Omega}} \exp i\left[p_0 r + \int\limits_{-L}^{r} pdl - \int\limits_{-L}^{r} p_0 dl - p_0 L\right],$$

или $\Psi \underset{r\to\infty}{\to} e^{ip_0 x} + \frac{f}{r} e^{ip_0 r}$, где $f = \sqrt{\left(\frac{d\sigma}{d\Omega}\right)_{K\pi}} e^{i\Phi}, \Phi \equiv \int\limits_{-\infty}^{\infty} pdl - \int\limits_{-\infty}^{\infty} p_0 dl_0$. Траектории l и l_0 изображены на рис. 32.

(добавлю потом его)

О рассеянии с точками, где квазиклассика неприменима

В выражении (3.49) фактически существенное значение имеют точки вблизи центра рассеяния. Выражение (3.49) требует уточнения в том случае, когда классическаи траектория проходит вблизи точек, где квазиклассика неприменима. Совокупность таких точек образует поверхность, называемую каустикой. Каустика отделяет область, доступную для классического движения, от недоступной. Например, для отталкивательного кулоновского потенцнала каустика имеет вид параболоида враіцения. В случае притягивательного кулоновского потенциала она предстазляет собой прямую линию, идущую от liентра рассеяния к $+\infty$.

Найдем, как меняется фаза волновой функции вблизи касания траектории с каустикой. Разложим движение частицы на два движения: перпендикулярно касательной к каустике и вдоль касательной. Движение в перпендикулярном направлении аналогично квазиклассическому отражению от точки поворота в одномерной задаче. При этом разность фаз падающей н отраженной волны, как мы видели, равна $\pi/4 - (-\pi/4) = \pi/2$. При движении вдоль касательной к каустике изменения фазы не происходит. Следовательно, вместо (3.49) для Φ получается следующее выражение:

$$\Phi = \int\limits_{-\infty}^{\infty} pdl - \int\limits_{-\infty}^{\infty} p_0 dl_0 + iv\frac{\pi}{2},$$

где v - число точек касания с каустикой. В случае кулоновского ногенциала $v = 1$.

Сечение рассеяния протона на атоме водорода

При рассмотрении задачи о перезарядке (см. стр. 103 (???)) было получено, что амплитуда рассеяния $f_1 = 1/2\,(f_s + f_a)$, а амплитуда перезарядки $f_2 = 1/2\,(f_s - f_a)$, где f_s, f_a - амплитуды соответственно симметричного и антисимметричного рассеяния.

Потенциал V_s мало отличается от V_a, поэтому классическое сечение можно считать одинаковым для V_s и V_u, между тем как фазы Φ_s и Φ_a могут сильно различаться. Действительно, $\mathfrak{D}_s, \mathscr{D}_a$ - очень большие числа, поэтому и $\Phi_s - \Phi_a$ может быть велико.

Следовательно, согласно (3.48)

$$f_1 = \frac{1}{2}\sqrt{\left(\frac{d\sigma}{d\Omega}\right)_\pi}\left(e^{i\Phi_s} + e^{i\Phi_a}\right), f_2 = \frac{1}{2}\sqrt{\left(\frac{d\sigma}{d\Omega}\right)_\Omega}\left(e^{i\Phi_s} - e^{i\Phi_a}\right).$$

Сечение перезарядки равно

$$\left(\frac{d\sigma}{d\Omega}\right)_{\text{перез}} = |f|^2 = \frac{1}{4}\left(\frac{d\sigma}{d\Omega}\right)_{\text{cl}}\left|e^{i\Phi_s} - e^{i\Phi_a}\right|^2 = \left(\frac{d\sigma}{d\Omega}\right)_{\text{cl}}\sin^2\frac{1}{2}\left(\Phi_s - \Phi_a\right)^\circ.$$

Так как

$$\Phi \equiv \int\limits_{-\infty}^{\infty} pdl - \int\limits_{-\infty}^{\infty} p_0 dl_0$$

то

$$\Phi_s - \Phi_a = \int\limits_{-\infty}^{\infty}\left(p_s - p_a\right)dl \approx \int\limits_{-\infty}^{\infty}\frac{m_1\left(V_s - V_a\right)}{p}dl \approx \frac{1}{v_0}\int\limits_{-\infty}^{\infty}\left(V_s - V_a\right)dl,$$

где m_1 - масса, а v_0 - скорость протона.

Рассеяние на малые углы

Рассмотрим рассеяние на малые углы. Обозначим $V_s - V_a \equiv V$. Тогда для сечения перезарядки получаем следующее выражение:

$$\left(\frac{d\sigma}{d\Omega}\right)_{\text{перез}} = \left(\frac{d\sigma}{d\Omega}\right)_{\text{кл}}\sin^2\left[\frac{1}{2v_0}\int\limits_{-\infty}^{\infty} V\left(\sqrt{\rho^2 + x^2}\right)dx\right],$$

Здесь ρ - прицельный параметр. Это выражение совпадает с сечением, полученным в (2.4). Для сечения рассеяния получаем

$$\left(\frac{d\sigma}{d\Omega}\right)_{\text{расс}} = \left(\frac{d\sigma}{d\Omega}\right)_{\text{кл}}\cdot\cos^2\left[\frac{1}{2v_0}\int\limits_{-\infty}^{\infty} V\left(\sqrt{\rho^2 + x^2}\right)dx\right] =$$

$$= \frac{1}{2}\left(\frac{d\sigma}{d\Omega}\right)_{\text{кл}} - \frac{1}{2}\left(\frac{d\sigma}{d\bar{\Omega}}\right)_{\text{кл}}\cdot\cos\left[\frac{1}{v_0}\int\limits_{-\infty}^{\infty} V\left(\sqrt{\rho^2 + x^2}\right)dx\right].$$

Таким образом, наряду с обычным классическим рассеянием получаются квантовомеханические осцилляции сечения рассеяния как функции угла отклонения.

6.7 Adiabatic methods

Обсудим подробно адиабатические методы.

6.7.1 Non-stationary Adiabatics

Statement of the problem in scope of non-stationary adiabatics

Пусть гамильтониан системы адиабатически - очень медленно - меняется во времени, $\hat{H} = \hat{H}(t)$. Мы будем интересоваться тем, как устроено решение нестационарного уравнения Шрёдингера:

$$i\frac{d}{dt}|\psi(t)\rangle = \hat{H}(t)|\psi(t)\rangle$$

В принципе адиабатичность изменения параметров подразумевает предельный случай - параметры меняются бесконечно медленно.

Естественно, в реальных задачах бесконечно медленно параметры менять невозможно, и поэтому всегда имеется некий характерный масштаб времени T, определяющий скорость изменения параметров, и адиабатичность означает, что этот масштаб времени - большой. Но с чем его нужно сравнивать? Для этого предлагается привлечь интуицию, приходящую от нестационарной теории возмущений. Если имеется возмущение, которое зависит от времени периодически, то имеются переходы между состояниями, причём состояния разнесены по энергии на ω -частоту этого возмущения. Всякое непериодическое возмущение, в свою очередь, можно расписать в интеграл Фурье и представить как комбинацию периодических; в нашем случае, характерные частоты преобразования Фурье определяются из соотношения неопределённостей, $\omega \sim \frac{1}{T}$ (тем самым, частоты очень маленькие).

Теперь можно более чётко сформулировать критерий адиабатичности: частоты должно быть недостаточно для обеспечения переходов,

$$\omega \ll \Delta E \to T \gg \frac{1}{\Delta E},$$

where ΔE -типичное расстояние между соседними уровнями энергии системы, level spacing.

Уровни энергии в случае гамильтониана, зависяшего от времени - понятие бессмысленное, но если мы имеем дело с адиабатикой, то подразумеваются мгновенные уровни энергии гамильтониана - диагонализация гамильтониана в каждый конкретный момент времени:

$$\hat{H}(t)|n(t)\rangle = E_n(t)|n(t)\rangle$$

Ещё раз подчеркнём, что $|\psi_n(t)\rangle$ ни в коем случае не являются решениями нестационарного уравнения Шурёдингера! (?????? why?????)

Пусть теперь в начальный момент времени $t = 0$ мы «посадили» частицу в одно из собственных состояний гамильтониана $|\psi(0)\rangle = |\psi_n(0)\rangle$. Вышеприведённые рассуждения позволяют нам заключить, что в адиабатическом пределе $T \to \infty$ состояние системы в произвольный момент времени t будет $|\psi(t)\rangle \propto |\psi_n(t)\rangle$ (с точностью до фазового множителя) то есть волновая функция будет следовать мгновенному состоянию данного гамильтониана. This is the main philosophy of adiabatic method.

Это утверждение напрямую связано с сохранением адиабатического инварианта в классической механике. (??? see quasiclassics, why???)

We also assume that change of the energy level is occurring after the evolution. Not like a particle can be measured ones it locates at a new level. This is the big question about measurement, and we are not touching it here. Change of the state in scope of the adiabatic method happens only by change of coefficients and this is what we are dealing with. Thus it is only an approximate method for toy models and in real life, there are a lot of interactions in the intermediate dynamics which are not taken into account.

Derivation of general formulas of non-stationary adiabatics

Выведем все нужные формулы нестационарной адиабатики.

Поскольку мгновенные собственные состояния гамильтониана образуют базис, разложим волновую функцию: $|\psi(t)\rangle = \sum\limits_m \psi_m(t)\,|m(t)\rangle$, подставим в уравнение Шрёдингера:

$$i\partial_t \sum_m \psi_m(t)\,|m(t)\rangle = \sum_m E_m(t)\psi_m(t)\,|m(t)\rangle$$

$$i\sum_m \left(\partial_t\psi_m(t)|m(t)\rangle + \psi_m(t)\partial_t|m(t)\rangle\right) = \sum_m E_m(t)\psi_m(t)|m(t)\rangle.$$

Подставим

$$\psi_m(t) = c_m(t)\cdot\exp\left(-i\int\limits_{t_0}^{t} E_m(\tau)d\tau\right),$$

где $\int\limits_{t_0}^{t} E_n(\tau)d\tau$ - так называемая динамическая фаза.

(why exactly we substitute this? answer is in the derivation below, but I'd like to also write words)

Получим

$$i\sum_m\left(\partial_t\left[c_m(t)e^{\left(-i\int\limits_{t_0}^{t}E_m(\tau)d\tau\right)}\right]|m(t)\rangle + c_m(t)e^{\left(-i\int\limits_{t_0}^{t}E_m(\tau)d\tau\right)}\partial_t|m(t)\rangle\right) =$$

$$=i\sum_m\left(\partial_t c_m(t)\cdot e^{-i\int\limits_{t_0}^{t}E_m(\tau)d\tau}|m(t)\rangle + c_m(t)\partial_t e^{-i\int\limits_{t_0}^{t}E_m(\tau)d\tau}|m(t)\rangle + c_m(t)e^{-i\int\limits_{t_0}^{t}E_m(\tau)d\tau}\partial_t|m(t)\rangle\right) =$$

$$=i\sum_m \partial_t c_m(t)\cdot e^{-i\int\limits_{t_0}^{t}E_m(\tau)d\tau}|m(t)\rangle + \sum_m E_m(t)c_m(t)e^{-i\int\limits_{t_0}^{t}E_m(\tau)d\tau}|m(t)\rangle +$$

$$+ i\sum_m c_m(t)e^{\left(-i\int\limits_{t_0}^{t}E_m(\tau)d\tau\right)}\partial_t|m(t)\rangle \equiv$$

$$\equiv \sum_m E_m(t)c_m(t)e^{\left(-i\int\limits_{0}^{t}E_m(\tau)d\tau\right)}|m(t)\rangle.$$

Сокращаем слагаемое справа с одним из левой части, получаем уравнение:

$$i\sum_m \partial_t c_m(t)\cdot e^{\left(-i\int\limits_{t_0}^{t}E_m(\tau)d\tau\right)}|m(t)\rangle + i\sum_m c_m(t)e^{\left(-i\int\limits_{t_0}^{t}E_m(\tau)d\tau\right)}\partial_t|m(t)\rangle = 0$$

Спроецируем на бра-вектор $\langle n(t)|$, и пользуясь $\langle n(t)|m(t)\rangle = \delta_{nm}$, получим

$$i\partial_t c_n(t)\cdot e^{\left(-i\int\limits_{t_0}^{t}E_n(\tau)d\tau\right)} + i\sum_m c_m(t)e^{\left(-i\int\limits_{t_0}^{t}E_m(\tau)d\tau\right)}\langle n(t)\partial_t|m(t)\rangle = 0,$$

тогда окончательно

$$\frac{dc_n(t)}{dt} = -\sum_m c_m(t)e^{-i\int\limits_{t_0}^{t}\omega_{mn}(\tau)d\tau}\langle n(t)\partial_t|m(t)\rangle,$$

где введено стандартное обозначение $\omega_{mn} = E_m - E_n$.

Правая часть этого уравнения мала. она содержит производные по времени мгновенного базиса, который меняется на больших временных масштабах $t \sim T$. (?? check!!!) Поэтому это уравнение уже приспособлено для решения его методом последовательных приближений.

Пусть в начальный момент времени мы находились в каком-то состоянии $|n\rangle$, то есть $c_n(0) = 1$. Найдем амплитуду перехода в $|m\rangle$ за конечное время $c_m(t)$, где $m \neq n$.

Приведём наивную оценку, которая продемонстрирует явно, что $c_m(t)$ мал в меру адиабатичности. Для оценки $\left(\sum_m c_m(t) e^{-i\int_{t_0}^{t} \omega_{mn}(\tau)d\tau} \langle n(t)\partial_t|m(t)\rangle \right)$ продифференцируем по t уравнение $\hat{H}(t)|m(t)\rangle = E_m(t)|m(t)\rangle$, спроецируем его на $\langle n(t)|$ и воспользуемся $\langle n(t)|m(t)\rangle = \delta_{nm}$:

$$\partial_t \hat{H} \cdot |m(t)\rangle + \hat{H}\partial_t|m(t)\rangle = \partial_t E_m|m(t)\rangle + E_m\partial_t|m(t)\rangle$$

$$\langle n(t)|\partial_t\hat{H}|m(t)\rangle + (\langle n(t)|\hat{H})\partial_t|m(t)\rangle = \partial_t E_m\langle n(t)|m(t)\rangle + E_m\langle n(t)|\partial_t|m(t)\rangle$$

$$\langle n(t)|\partial_t\hat{H}|m(t)\rangle = \partial_t E_n\delta_{nm} + (E_m(t) - E_n(t))\,\langle n(t)\,|\partial_t|\,m(t)\rangle$$

получим:

$$\langle n(t)\,|\partial_t|\,m(t)\rangle = -\frac{\langle n(t)|\partial_t\hat{H}|m(t)\rangle}{\omega_{nm}(t)}, \quad m \neq n$$

Производная гамильтониана уже явно содержит параметр $1/T$ (!?! укажу про это выше), а в знаменателе оказался level spacing ω_{nm}, поэтому

$$\left(\sum_m c_m(t) e^{-i\int_{t_0}^{t} \omega_{mn}(\tau)d\tau} \langle n(t)\partial_t|m(t)\rangle \right) \sim \frac{1}{\omega_{nm}T} \ll 1.$$

(потом еще про это подумаю, пока не полностью владею такими оценками.)

First order approximation of non-stationary adiabatics

So, at this moment we are developing formulas for a general problem

$$i\frac{d}{dt}|\psi(t)\rangle = \hat{H}(t)|\psi(t)\rangle.$$

We decomposed the functions into basis vectors $|\psi(t)\rangle = \sum_m \psi_m(t)\,|m(t)\rangle$, and each coefficient of the decomposition, we parameterize by $c_m(t)$ as

$$\psi_m(t) = c_m(t) \cdot \exp\left(-i\int_{t_0}^{t} E_m(\tau)d\tau \right).$$

we got that they are changing according to

$$\frac{dc_n(t)}{dt} = -\sum_m c_m(t) e^{-i\int_{t_0}^{t} \omega_{mn}(\tau)d\tau} \langle n(t)\partial_t|m(t)\rangle.$$

Рассматривая теперь ведущее приближение для $c_m(t)$, оставим только один член в этой формуле. This is a very important approximation.

(???? why other states m in the formula $\sum_m$ will give much less contribution. Currently I don't see it.)

Now, we substitute $\langle n(t)\,|\partial_t|\,m(t)\rangle = -\frac{\langle n(t)|\partial_t \hat{H}|m(t)\rangle}{\omega_{nm}(t)}$ and get

$$c_m(T) \approx \int\limits_{t_0}^{T} \exp\left(i\int\limits_{t_0}^{t}\omega_{mn}(\tau)d\tau\right)\frac{\left\langle m(t)\left|\partial_t\hat{H}\right|n(t)\right\rangle}{\omega_{mn}(t)}dt,$$

where $|n(t)\rangle$ is the only one state to which particle can travel. Это выражение, в действительности, представляет собой интеграл типа «медленная огибающая на быстроосциллирующий фактор». Такого рода интегралы, как правило, содержат экспоненциальную малость, что мы и продемонстрируем на примере следующей задачи.

So, totally, we can work with adiabatic methods with equation with $\partial_t|m(t)\rangle$ or with $\partial_t\hat{H}$. It depends on what is more comfortable.

Задача Ландау-Зенера методами нестационарной адиабатики

Обсудим задачу Ландау-Зенера как типичный пример нестационарной адиабатики. Поскольку параметр адиабатичности $\frac{1}{\omega_{nm}T} \ll 1$ явно содержит level spacing $\omega_{nm} = \omega_{nm}(t)$, больше всего переходы между различными состояниями будут происходить, между парой уровней, которые максимально сближаются. Поэтому такую ситуацию можно сформулировать в достаточно общем виде как чисто двухуровневую задачу. Такая задача носит название задачи Ландау-Зенера, и описывается следующим гамильтонианом:

$$\hat{H}(t) = \begin{pmatrix} \alpha t & \gamma \\ \gamma & -\alpha t \end{pmatrix}$$

Задача Ландау-Зенера адиабатическим методом

Для системы с

$$\hat{H}(t) = \begin{pmatrix} \alpha t & \gamma \\ \gamma & -\alpha t \end{pmatrix}$$

Найдем мгновенные собственные состояния:

$$E_+(t) = \sqrt{\gamma^2+(\alpha t)^2}, \qquad |\psi_+(t)\rangle = \frac{1}{\sqrt{2\left(\gamma^2+(\alpha t)^2+\alpha t\sqrt{\gamma^2+(\alpha t)^2}\right)}}\begin{pmatrix} \alpha t+\sqrt{\gamma^2+(\alpha t)^2}\end{pmatrix}\\ \gamma \end{pmatrix}$$

$$E_-(t) = -\sqrt{\gamma^2+(\alpha t)^2}, \quad |\psi_-(t)\rangle = \frac{1}{\sqrt{2\left(\gamma^2+(\alpha t)^2-\alpha t\sqrt{\gamma^2+(\alpha t)^2}\right.}}\begin{pmatrix} \alpha t-\sqrt{\gamma^2+(\alpha t)^2} \\ \gamma \end{pmatrix}$$

(Check it!)

We introduce $\alpha t = \gamma\sinh\theta$ and get:

$$E_+(\theta) = \gamma\cosh\theta, \qquad |\psi_+(\theta)\rangle = \frac{1}{\sqrt{2\cosh\theta}}\begin{pmatrix} e^{\theta/2} \\ e^{-\theta/2}\end{pmatrix}$$

$$E_-(\theta) = -\gamma\cosh\theta, \qquad |\psi_-(\theta)\rangle = \frac{1}{\sqrt{2\cosh\theta}}\begin{pmatrix} e^{-\theta/2} \\ -e^{\theta/2}\end{pmatrix}$$

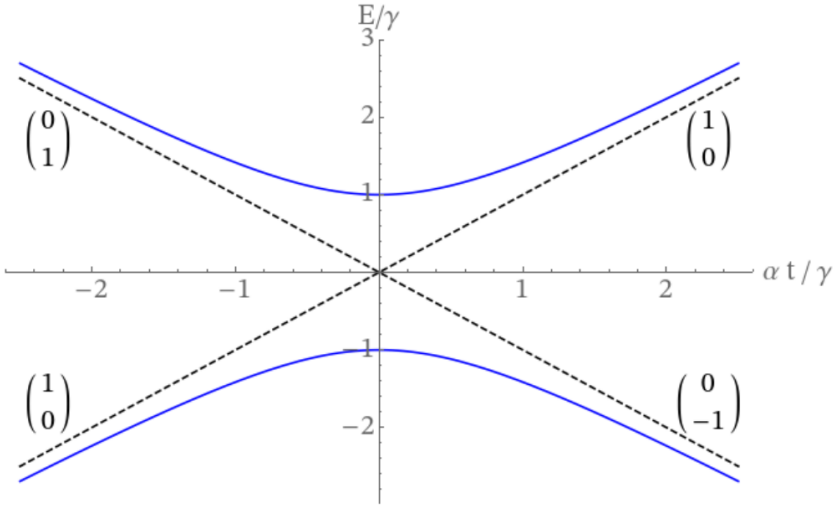

Figure 6.4: Уровни в задаче Ландау-Зенера (?? I think, here it it typo, there should not be -1 at the low part)

Пусть в момент времени $t \to -\infty$ мы находились на верхней ветке, то есть $|\psi_+(-\infty)| = 1$ и $|\psi_-(-\infty)| = 0$. Note that here ψ-s are coefficients in the original basis, where the Hamiltonian is not diagonal. Мы интересуемся вероятностью перехода в результате адиабатической эволюции на нижнюю ветку, которая определяется по формуле

$$P = |\psi_-(+\infty)|^2 .$$

Proof.

$$P = |\langle\downarrow||\psi(+\infty)\rangle|^2 = |(\langle\downarrow|)(\psi_-(+\infty)|\downarrow\rangle + \psi_+(+\infty)|\uparrow\rangle)|^2 = |\psi_-(+\infty)|^2$$

so it is equal to this coefficient.

□

Выделим параметр адиабатичности $\frac{1}{\omega_{nm}T} \ll 1$. Если уровни находятся достаточно далеко по энергии, то переходов не будет - поэтому масштаб времени T, который входи't в критерий адиабатичности, определяется из условия достаточной близости уровней: $\alpha T \sim \gamma \to T \sim \frac{\gamma}{\alpha}$. С другой стороны, масштаб расстояния между уровнями при этом равен γ. Поэтому адиабатическое приближение соответствует случаю, когда $\gamma^2 \gg \alpha$

(??? Think about this more!!)

We use $c_m(T) \approx \int\limits_{t_0}^{T} \exp\left(i \int\limits_{t_0}^{t} \omega_{mn}(\tau)d\tau\right) \frac{\langle m(t)|\partial_t \hat{H}|n(t)\rangle}{\omega_{mn}(t)} dt$ for our case:

$$c_+(+\infty) = \int\limits_{-\infty}^{\infty} \exp\left(i \int\limits_{0}^{\theta} \omega_{+-}(\theta)\frac{d\tau}{d\theta}d\theta\right) \frac{\left\langle \psi_+ \left| \partial_\theta \hat{H} \right| \psi_- \right\rangle}{\omega_{+-}(\theta)} d\theta$$

(??! про переход к параметру еще подумаю.)

Здесь:

$$\partial_\theta \hat{H} = \gamma \begin{pmatrix} \cosh\theta & 0 \\ 0 & -\cosh\theta \end{pmatrix}$$

$$\langle\psi_+|\partial_\theta \hat{H}|\psi_-\rangle = \gamma$$

(!??! ниже не додумывал математику, потом еще раз проверю.)

Входящие сюда искомые величины равны:

$$\langle\psi_-(\theta)\left|\frac{\partial\hat{H}}{\partial\theta}\right|\psi_+(\theta)\rangle = \frac{1}{2\cosh\theta}\left(e^{-\theta/2}-e^{\theta/2}\right)\begin{pmatrix}\gamma\cosh\theta & 0\\ 0 & -\gamma\cosh\theta\end{pmatrix}\begin{pmatrix}e^{\theta/2}\\ e^{-\theta/2}\end{pmatrix} = \gamma$$

и

$$\int\limits_0^t \omega_{+-}(\tau)d\tau = 2\frac{\gamma^2}{\alpha}\int\limits_0^\theta \cosh^2\theta d\theta = \frac{\gamma^2}{\alpha}\left[\theta+\frac{1}{2}\sinh 2\theta\right]$$

и искомая амплитуда даётся интегралом:

$$c_-^{(1)}(\infty) = \int\limits_{-\infty}^{\infty}\frac{\exp\left(-i\frac{\gamma^2}{\alpha}\left(\theta+\frac{1}{2}\sinh 2\theta\right)\right)}{2\cosh\theta}d\theta$$

Вычисление интеграла для численного ответа.

(пока так и не тренировал и не смотрел.)
Вычислим

$$c_-^{(1)}(\infty) = \int\limits_{-\infty}^{\infty}\frac{\exp\left(-i\frac{\gamma^2}{\alpha}\left(\theta+\frac{1}{2}\sinh 2\theta\right)\right)}{2\cosh\theta}d\theta.$$

Перед нами - классический пример интеграла вида «быстро-осциллирующая функция + медленная огибающая». Интегралы такого вида берутся методом стационарной фазы, или более общо - методом перевала. В данном конкретном случае, фаза $f(\theta)=\theta+\frac{1}{2}\sinh 2\theta$ и $f'(\theta)=1+\cosh 2\theta\geq 2$, поэтому точек стационарной фазы на вещественной оси нет. Тут мы не будем гоняться за точностью оценки, а выделим лишь ведущую экспоненциальную асимптотику интеграла. Для этого мы можем сделать так, чтобы в экспоненте стояла линейная функция, перейдя к интегралу по $z=\theta+\frac{1}{2}\sinh 2\theta \to dz = d\theta(1+\cos 2\theta) = 2\cosh^2\theta d\theta$, и переписав интеграл в виде:

$$c_-^{(1)}(\infty) = \int\limits_{-\infty}^{\infty}\frac{\exp\left(-i\frac{\gamma^2}{\alpha}z\right)}{4\cosh^3\theta}dz$$

Теперь мы можем применить лемму Жордана, замкнув контур интегрирования в нижней полуплоскости (где экспонента затухает), и сведя его к вычетам в полюсах, которые определяются из уравнения $\cosh\theta=0\to\theta_k=-i\frac{\pi}{2}(1+2k)=z_k$. Беря только полюс с $k=0$, и оставляя только экспоненту, мы получаем ответ:

$$c_-^{(1)}(\infty)\sim e^{-\pi\gamma^2/2\alpha}\to P\sim e^{-\pi\gamma^2/\alpha}$$

Comments about Landau-Zener problem

- Во-первых, ответ получился экспоненциально мал, что и обосновывает адиабатическое приближение. Действительно, переходы в другие состояния практически отсутствуют! Это утверждение весьма общего характера: глядя на уравнение $i\partial_t c_n(t) = -i\sum_m \exp\left(i\int_{t_0}^t\omega_{nm}(\tau)d\tau\right)\langle n(t)|\partial_t|m(t)\rangle c_m(t)$, мы понимаем, что поправка всегда будет устроена как быстро-осциллирующая функция (связанная с динамической фазой) + медленная огибающая (связанная с медленной зависимостью мгновенных

стационарных волновых функций), а интегралы такого вида, как правило, действительно содержат экспоненциальную малость.

(???)

- Во-вторых, следует сделать комментарий по поводу того, почему мы не стали оценивать предэкспоненту. Дело в том, что если сделать вторую итерацию адиабатического приближения, то поправка окажется малой с той же экспонентой и не будет содержать малости по сравнению с первой. В данном случае это означает, что адиабатическое приближение позволяет правильно определить показатель экспоненты, но предэкспонента находится за пределами её точности.

(????)

- В-третьих, показатель экспоненты в более или менее общем виде можно определить, используя метод перевала. Действительно, для этого достаточно определить комплексную точку перевала, условие на которую, в действительности, очень просто: $\omega_{mn}(t_0) = 0$ (в нашем случае это соответствует $t = -i\frac{\gamma}{\alpha}$), и тогда вероятность перехода дастся интегралом $P \sim \exp\left(-2\,\mathrm{Im}\int^{t_0}\omega_{mn}(t)dt\right)$

Более того, точно такое же выражение возникает при изучении вопроса о сохранении адиабатического инварианта в классической механике, что подчёркивает сходство этих двух задач.

- Наконец, as it is well-known, задача Ландау-Зенера решается абсолютно точно и без адиабатического приближения, и ответ в ней оказывается точно равен этой экспоненте: $P = e^{-\pi\gamma^2/\alpha}$.

Описание геометрии для нестационарной адиабатики (!?)

(на это есть задачи, важная идея, потом опишу.)

6.7.2 Non-stationary Adiabatics by Migdal Krainov

Теория

В этом разделе рассматривается случай, когда возмущение, действуюшее на квантовомеханическую систему, медленно меняется со временем. При этом система успевает псрестраиваться вслед за медленным изменением параметров. Такие возмушения называюотся адиабатическими.

В случае адиабатических возмущений удобно искать решение уравнения Шредингера в виде суперпозиции стационарных собственных функций, вычисленных при произвольных, но фиксированных значениях параметров.

Предположим, что гамильтониан $H(x,\xi)$ зависит от медленно меняющегося параметра ξ. Введем собственныс фугкции $\varphi_m(x,\xi)$ гамильтониана $H(x,\xi)$, в которых значение ξ зафик сировано:

$$H(x,\xi)\varphi_m(x,\xi) = \varepsilon_m(\xi)\varphi_m(x,\xi).$$

Будем искать решение уравнения Ц иедингера

$$i\frac{\partial\Psi}{\partial t} = H\Psi$$

В виде

$$\Psi = \sum_m a_m(t)\varphi_m(x,\xi)\exp\left\{-i\int\limits_{-\infty}^{t}\varepsilon_m(\xi)dt\right\}$$

Подставляя (2.25) в (2.24), находим

$$i\sum_m \exp\left\{-i\int\limits_{-\infty}^{t}\varepsilon_m(\xi)dt\right\}\left(\tfrac{da_m}{dt} - i\varepsilon_m a_m + a_m\xi\tfrac{\partial}{\partial\xi}\right)\varphi_m(x,\xi) =$$

$$= \sum_m \exp\left\{-i\int\limits_{-\infty}^{t}\varepsilon_m(\xi)dt\right\}\varepsilon_m\varphi_m(x,\xi),$$

откуда

$$\tfrac{da_n}{dt} + \sum_m\left(\varphi_n|\tfrac{\partial\varphi_m}{\partial\xi}\right)\dot\xi a_m\exp\left\{-i\int\limits_{-\infty}^{t}(\varepsilon_m-\varepsilon_n)\,dt\right\} = 0.$$

Уравнение (2.26) эквивалентно исходному Уравнению Шредингера (2.24). В отличие от (2.24), оно удобно для нахождения последовательных приближений при малых???? Именно,

$$a_n^{(0)}(t) = a_n(-\infty),$$

$$a_n^{(1)}(t) = -\int\limits_{-\infty}^{t}dt'\sum_m\left(\varphi_n|\frac{\partial\varphi_m}{\partial\xi}\right)\xi\times a_m(0)\exp\left\{-i\int\limits_{-\infty}^{t'}(\varepsilon_m-\varepsilon_n)\,dt'\right\}$$

Н Т. д. Выразим $\left(\varphi_n|\frac{\partial\varphi_m}{\partial\xi}\right)$ через матричный элемент гамильтониана H. Дифференцируя соотношение (2.23) по параметру?, находим

$$\frac{\partial H}{\partial\xi}\varphi_m + H\frac{\partial\varphi_m}{\partial\xi} = \frac{d\varepsilon_m}{d\xi}\varphi_m + \varepsilon_m\frac{d\varphi_m}{d\xi}$$

Умножая это равенство на φ_n слева и интегрируя по $\boldsymbol{x}$, получаем

$$\left(\varphi_n\left|\frac{\partial H}{\partial\xi}\right|\varphi_m\right) + \varepsilon_n\left(\varphi_n|\frac{\partial\varphi_m}{\partial\xi}\right) = \frac{d\varepsilon_m}{d\xi}\delta_{nm} + \varepsilon_m\left(\varphi_n|\frac{\partial\varphi_m}{\partial\xi}\right).$$

откуда

$\left(\varphi_n|\frac{\partial\varphi_m}{\partial\xi}\right)_{n\neq m} = \frac{\left(\varphi_n\left|\frac{\partial H}{\partial\xi}\right|\varphi_m\right)}{\varepsilon_m-\varepsilon_n}$, $\left(\varphi_n\left|\frac{\partial H}{\partial\xi}\right|\varphi_n\right) = \frac{d\varepsilon_n}{d\xi}$. Будем предполагать, что собственные состояния φ_n не вырождены. Тогда волновые функции φ_n можно выбрать вещественными, и, следовательно, диагоналыный матричный элемент

$$\left(\varphi_n|\frac{\partial\varphi_n}{\partial\xi}\right) = \frac{1}{2}\frac{\partial}{\partial\xi}\int\varphi_n^2 dr = 0.$$

Подставляя (2.28) в (2.27), получаем

$$a_n^{(1)}(t) = -\int\limits_{-\infty}^{t}dt'\sum_m\frac{\left(\varphi_n\left|\frac{\partial H}{\partial\xi}\right|\varphi_m\right)\dot\xi}{\varepsilon_m-\varepsilon_n}\times a_m(-\infty)\exp\left\{-i\int\limits_{-\infty}^{t'}(\varepsilon_m-\varepsilon_n)\,dt'\right\}.$$

Штрих в сумме по m означает, что в него нет диагональных членов.

Критерий применимости адиабатической теории возмущений состоит в том, чтобы изменение гамильтониана за время порядка обратных частот системы было малым по сравнению с энергиями, соответствующими этим частотам.

Критерий применимости легко получить, если оценить отношение поправки $a_n^{(2)}(t)$ к амплитуде $a_n^{(1)}(t)$: учитывая (2.29), находнм

$$\frac{a_n^{(2)}}{a_n^{(1)}} \sim \frac{\partial H}{\partial t} \frac{1}{(\varepsilon_m - \varepsilon_n)^2}.$$

Как видно из (??), отдельного рассмотрения требует случай, когда при некоторых значениях параметров ξ уровни энергии пересекаптся. В этом случае волновую функцию следует искать в виде суперпозиции состояний, соответствующих этим пересекающимся термам.

Покажем, что если обратные собственные частоты систе.мы ω_{mn}^{-1} много меньше временн τ, которое существенно изменяется гамильтониан системы, то эта система, как правило, будет возбуждаться эксионенциально слабо. Действительно, выражение (2.29) для амплитуды персхода $a_n^{(1)}(t)$ сводитсл к фурье-компонентам от функций $\frac{\left(\varphi_n \left| \frac{\partial H}{\partial \xi} \right| \varphi_m\right)\dot{\xi}}{\varepsilon_n - \varepsilon_m}$.

Ранее (см, 1.1) мы видели, что такие фурье- компоненты при $\omega_{mn}\tau \geqslant 1$ экспоненциально малы ($\sim e^{-\omega_{m\mathrm{I}math}\tau}$), ссли Эти функции или их производные не имеют особенностей fa велественной оси.

Как мы видели (см. стр. 53), кулоновские волновые функции имеют особенности на вещественной оси. Поэтому, иапример, вероптиость ионизации атома пролетающей медленной частицей мала степенным образом, а не экспоненциальнО.

MK-ch2.4.1

Используя соотношение (2.28), вычислить $\frac{\bar{1}}{r^2}$ для центральио-симметричного движения.

О т в е т.

$$\frac{T}{r^2} = \frac{1}{l++^1/2} \left(\frac{\partial E}{\partial l}\right)_{n_r}.$$

Захват электрона протоном (перезарядка)

Применим адиабатическуго теориоо возмуцений к задаче о перезарядке при пролете мелленного протона мимо атома водорода. Предположим, что скорость протона много меньше атомнон скорости. Тогда можно применять адиабатнческое прибпижжение.

Кроме того, предположим, что энергия налетающего протона много больше атомной. Тогда можно считать движение гротона заданным.

Гамильтониан системы имеет вид

$$H = T_e - \frac{1}{\left|r - \frac{1}{2}R\right|} - \frac{1}{\left|r + \frac{1}{2}R\right|} + \frac{1}{R}$$

где R - расстоянис между протонами, которое мы будем считать заданной функцией времени; r-координата электрона, T_e - кинетическая энергия электрона.

Гамильтониан H симметричен относительно перестановки налетающего и покоящегося протонов. Такая перестановка эквивалентиа замене $\boldsymbol{r} \longrightarrow - \longrightarrow$. Следовательно, можно ввести синметричные и антисимметричные относительно этой перестановкı соственные функции гамильтониана H : $\varphi_n^s(r,R)$ и $\varphi_n^a(r,R)$. Будем считать, что сначала электрон находился около протона, имеющего координату $R/2$. Тогда волновая функция электрона имеет вид

$$\varphi = \varphi_{n_0}^Q \left(r - \frac{1}{2}R\right),$$

где $\varphi^Q_{n_0}$ - кулоновская волновая функция для состояния n_0.

После рассеяния атом водорода с большой вероятностью останется в состоянии $\varphi^Q_{n_0}$. Действительно, для возбуждения нужна компонента Фурье с частотой, равной энергии возбуждения, $\omega_{nn_0} = \varepsilon_n - \varepsilon_{n_0}$. При медленном пролете, когда время пролета велико по сравнению с обратной частотой $\omega^{-1}_{nn_0}$, компонента Фурье с частотой ω_{nn_0} очень мала и возбуждения не происходит.

Однако электрон может перейти к другому протону. Это явление называется перезарядкой. Критерий адиабатичности (2.30) здесь не выполняется. В самом деле, когда протоны находятся на большом расстоянии друг от друга, волновая Функция электрона равна $\varphi^Q_{n_\bullet}\left(r - \frac{1}{2}R\right)$, если он находится у одного протона, и $\varphi^Q_{n_0}\left(r + \frac{1}{2}R\right)$, - если у другого. Из этих двух функций можно составить симметричную п антисимметричную комбинации $\varphi^s_{n_0}$ и $\varphi^a_{n_0}$. Оба состояния отвечают одной и той же энергии. Следовательно, мы имеем дело с пересечением уровней.

Поэтому решение уравнения Шредингера

$$i\frac{\partial \Psi}{\partial t} = H\Psi$$

следует искать в виде суперпозиции этих двух состояний $\varphi^s_{n_0}$ и $\varphi^a_{n_0}$, после чего нужно применять адиабатическую теорию возмущений. Итак,

$$\Psi = C^s(t)\varphi^s_{n_0}(\boldsymbol{r}, \boldsymbol{R}) \exp\left(-i\int\limits_{-\infty}^{t} \varepsilon^s dt\right) + C^a(t)\varphi^a_{n_0}(\boldsymbol{r}, R) \exp\left(-i\int\limits_{-\infty}^{t} \varepsilon^a dt\right).$$

Подставляя (2.32) в (2.31), получаем

$$\left\{\frac{dC^s}{dt}\varphi^s_{n_0}(\boldsymbol{r}, R) + C^s\frac{dR}{dt}\frac{\partial \varphi^s_{n_0}(\boldsymbol{r}, R)}{\partial R}\right\} \exp\left(-i\int\limits_{-\infty}^{t} \varepsilon^s dt\right) +$$

$$+ \left\{\frac{dC^a}{dt}\varphi^a_{n_0}(\boldsymbol{r}, R) + C^a\frac{dR}{dt}\frac{\partial \varphi^a_{n_0}(\boldsymbol{r}, R)}{\partial R}\right\} \exp\left(-i\int\limits_{-\infty}^{t} \varepsilon^a dt\right) = 0.$$

(2.33)

Умножим (2.33) на $\varphi^s_{n_0}$ и проинтегрируем по координате $\boldsymbol{r}$, пользуясь ортогональностью функций $\varphi^s_{n_0}$ и $\varphi^a_{n_0}$:

$$\left\{\frac{dC^s}{dt} + C^s\frac{dR}{dt}\left(\varphi^s_{n_0}|\frac{\partial \varphi^s_{n_0}}{\partial R}\right)\right\} \exp\left(-i\int\limits_{-\infty}^{t} \varepsilon^s dt\right) = -C^a\frac{dR}{dt}\left(\varphi^s_{n_0}|\frac{\partial \varphi^a_{n_0}}{\partial R}\right) \exp\left(-i\int\limits_{-\infty}^{t} \varepsilon^a dt\right).$$

Если нуклоны находятся далеко друг от друга, то

$$\varphi^{s,a}_n(\boldsymbol{r}, \boldsymbol{R}) \underset{R\to\infty}{\longrightarrow} \frac{1}{\sqrt{2}}\left[\varphi^Q_n\left(r - \frac{1}{2}R\right) \pm \varphi^Q_n\left(r + \frac{1}{2}R\right)\right].$$

Учитывая (2.35), из (2.34) в нулевом приближении получаем

$$C^s = C^s(t = -\infty) = \frac{1}{\sqrt{2}}, \quad C^a = C^a(t = -\infty) = \frac{1}{\sqrt{2}}$$

(это соответствует электрону, находящемуся в момент времени у протона с координатой $R/2$).

При этих значениях C^s, C^a из (2.32) получаем

$$\Psi|_{t\to\infty} = \frac{1}{\sqrt{2}} \exp\left(-i\int\limits_{-\infty}^{\infty} \varepsilon^s dt\right) \times$$
$$\times \frac{\varphi^Q_{n_0}\left(r-\frac{1}{2}R\right)+\varphi^Q_{n_0}\left(r+\frac{1}{2}R\right)}{V\overline{2}} + \frac{1}{\sqrt{2}} \exp\left(-i\int\limits_{-\infty}^{\infty} \varepsilon^a dt\right) \times$$
$$\times \frac{\varphi^Q_{n_0}\left(r-\frac{1}{2}R\right)-\varphi^Q_{n_0}\left(r+\frac{1}{2}R\right)}{\sqrt{2}} = \frac{1}{2}\left(\exp\left(-i\int\limits_{-\infty}^{\infty} \varepsilon^s dt\right) + \right.$$
$$\left. + \exp\left(-i\int\limits_{-\infty}^{\infty} \varepsilon^a dt\right)\right) \varphi^Q_{n_0}\left(r-\frac{1}{2}R\right) + \frac{1}{2}\left(\exp\left(-i\int\limits_{-\infty}^{\infty} \varepsilon^s dt\right) - \right.$$
$$\left. - \exp\left(-i\int\limits_{-\infty}^{\infty} \varepsilon^a dt\right)\right) \varphi^Q_{n_0}\left(r+\frac{1}{2}R\right).$$

Первое слагаемое здесь соответствует обычному рассеянию, а второе - перезарядке. Квадрат модуля коэффициента при $\varphi^Q_{n_0}\left(p+\frac{1}{2}R\right)$ дает вероятность перезарядки

$$W(\rho) = \left|\sin\left(\frac{1}{2}\int\limits_{-\infty}^{\infty}\left(\varepsilon^a-\varepsilon^s\right)dt\right)\right|^2 = \left|\sin\left(\int\limits_{0}^{\infty}\left(\varepsilon^a-\varepsilon^s\right)dt\right)\right|^2,$$

где ρ - прицельный параметр.

Мы считаем, что величины $\varepsilon^a(R)$ и $\varepsilon^s(R)$ известны из рсшения задачи с неподвижными ядрами. Предполагая траекторию налетающей частицы прямолинейной, заменим интегрирование по t интегрированием по R. Так как $R^2 = \rho^2 + v^2t^2$, то

$$dt = \frac{1}{v}\frac{RdR}{\sqrt{R^2-\rho^2}}.$$

Обозначая $\varepsilon^a(R) - \varepsilon^s(R) \equiv \Phi(R)$, из (2.36) находим

$$W(\rho) = \left|\sin\left(\frac{1}{v}\int\limits_{i}^{\infty}\Phi(R)\frac{RdR}{\sqrt{R^2-\rho^2}}\right)\right|^2.$$

Рассмотрим прицельные расстояния $\rho \sim 1$. Тогда расстояния между частицами, существенные при взаимодействии, также порядка 1. Следовательно, весь интеграл в (2.37) порядка 1. Поскольку $v \ll 1$, то выражение для $W(\rho)$ сильно меняется при малом изменении ρ. Усредним (2.37) по некоторому интервалу значений ρ, малому по сравнению с ρ:

$$\bar{W} = \sqrt{\left|\sin\left(\frac{1}{v}\int\limits_{\rho}^{\infty}\Phi(R)\frac{RdR}{\sqrt{R^2-\rho^2}}\right)\right|^2} = \frac{1}{2},$$

т. е. перезарядка будет в половине всех случаев. Рассмотрим теперь вероятность перезарядки при $\rho \gg 1$. Как можно показать), при больших расстояниях между протонами разность энергий симметричного и антисимметричного состояний равна

$$\varepsilon^a(R) - \varepsilon^s(R) \underset{R\to\infty}{\approx} \frac{4}{e} R e^{-R}.$$

Поэтому при $\rho \gg 1$ получаем

$$\begin{aligned} F(\rho) &\equiv \frac{1}{v}\int\limits_0^\infty \Phi(R)\frac{RdR}{\sqrt{R^2-\rho^2}} = \frac{4}{ev}\int\limits_\rho^\infty \frac{R^2 e^{-R}}{\sqrt{R^2-\rho^2}}dR = \\ &= \frac{4\rho^2}{ev}\int\limits_1^\infty \frac{x^2 e^{-\rho x}}{\sqrt{x^2-1}}dx = \frac{4\rho^2 e^{-p}}{ev}\int\limits_0^\infty \frac{(z+1)^2 dz}{\sqrt{2(z+2)}} e^{-pz} \approx \\ &\approx \frac{4\rho^2}{ev} e^{-p}\frac{1}{\sqrt{2}}\int\limits_0^\infty z^{-1/2} e^{-\rho z} dz = \frac{4\rho^2}{ev} e^{-\rho}\frac{1}{\sqrt{2}}\frac{1}{\sqrt{\rho}}\Gamma\left(\frac{1}{2}\right) = \\ &= \frac{\pi\sqrt{2}}{ev}\rho^{3/2} e^{-\rho}. \end{aligned}$$

Мы видим, что $F(\rho) \ll 1$ при $\rho \gg \rho_1 \sim \ln 1/0$. Следовательно,

$$W = |\sin F(\rho)|^2 \approx F^2(\rho) = \frac{2\pi^2}{e^2 v^2}\rho^3 e^{-2\rho}.$$

Таким образом, при $\rho \ll \rho_1$ величина $F(\rho) \gg 1$, а при $\rho \geqslant \rho_1$ величина $F(\rho) \ll 1$.
Теперь оценим полное сечение перезарядки

$$\sigma = \int\limits_0^\infty \sin^2 F(\rho)\cdot 2\pi\rho d\rho.$$

По порядку величины получаем

$$\sigma = \int\limits_0^{\Gamma_1} \frac{1}{2} 2\pi\rho d\rho = \frac{1}{2}\pi_{\rho_1}^2 \sim \frac{1}{2}\pi \ln^2\frac{1}{v}.$$

Таким образом, при малых скоростях v ссчение перезарядки много болише геометрического сечения.

6.7.3 Berry's Phase: Basics

Appearance of Berry's Phase

При переходе под влиянием адиабатического изменения параметров гамильтониана в другие состояния экспоненциально редки, что следует из эволюции коэффициентов $c_{m\neq n}$. Теперь перейдём к обсуждению эволюции самого коэффициента c_n. При этом достаточно очевидно, что ничего кроме «накручивания» фазы с коэффициентом происходить не может. (???? why???)

Итак, уравнение $i\partial_t c_n(t) = -i\sum_m \exp\left(i\int_{t_0}^t \omega_{nm}(\tau)d\tau\right)\langle n(t)|\partial_t|m(t)\rangle c_m(t)$, с $m = n$ записывается и тривиально интегрируется:

$$\frac{dc_n(t)}{dt} = ic_n(t)\left\langle \psi_n(t)\left| i\frac{\partial}{\partial t}\right|\psi_n(t)\right\rangle$$

поэтому:

$$c_n(t) = c_n(0)\exp\left(i\gamma_n(t)\right),$$

где так называемая фаза Бери есть:

$$\gamma_n(t) := \int dt \cdot i \left\langle \psi_n(t) | \frac{\partial \psi_n(t)}{\partial t} \right\rangle$$

Свойства фазы Берри (???)

Исследуем полученный объект.

Фаза Берри действительно фаза.

Убедимся, что это действительно фаза - а именно, что эта величина вещественная.

Сделать это просто, дифференцируя условие нормировки мгновенных стационарных состояний:

$$0 = \partial_t \langle n(t)|n(t)\rangle = \left(\partial_t \langle n(t)|\right)|n(t)\rangle + \langle n(t)\,|\partial_t|\,n(t)\rangle = 2\,\mathrm{Re}\left(\langle n(t)\,|\partial_t|\,n(t)\rangle\right)$$

поэтому

$$\langle n(t)\,|i\partial_t|\,n(t)\rangle \in \mathbb{R}$$

Formula of a Berry's phase in terms of Berry's connection

Мы можем рассмотреть случай, когда гамильтониан зависит не явно от времени, но зависит от какого-то конечного набора параметров R_i : $\hat{H} = \hat{H}(\boldsymbol{R})$, которые, в свою очередь, как-то меняются со временем - описывают некоторую траекторию $\boldsymbol{R}(t)$ в пространстве параметров.

В свою очередь, мгновенные состояния гамильтониана тоже являются функциями этих параметров $|\psi_n\rangle = |\psi_n(\boldsymbol{R})\rangle$. Тогда выражение для фазы Берри можно переписать:

$$\gamma_n = \int dt \cdot i \,\langle \psi_n(\boldsymbol{R})|\nabla_{\boldsymbol{R}}\psi_n(\boldsymbol{R})\rangle \cdot \frac{\partial \boldsymbol{R}}{\partial t} = \int \boldsymbol{A}_n(\boldsymbol{R}) d\boldsymbol{R}, \quad \boldsymbol{A}_n(\boldsymbol{R}) = i\,\langle \psi_n(\boldsymbol{R})|\nabla_{\boldsymbol{R}}\psi_n(\boldsymbol{R})\rangle$$

Это - криволинейный интеграл.

Величина $\boldsymbol{A}(\boldsymbol{R})$ носит название связности Берри и является вектором, живущем в томже пространстве параметров.

В такой записи видно следующее немаловажное свойство: фаза Берри не зависит от того, *как* именно мы меняем параметры $\boldsymbol{R}(t)$ (лишь бы это было адиабатически) - но зависит только от вида самой траектории в пространстве параметров.

Из-за этого фундаментального свойства фазу Берри называют также геометрической фазой.

Berry's phase is not gauge invariant

Связность и фаза Берри не являются калибровочно-инвариантными величинами.

Априори выбор фазы собственных состояний $|\psi_n(R)\rangle$ произволен - мы лишь требуем, чтобы оно было собственным для гамильтониана $\hat{H}(\boldsymbol{R})$. Вместо набора состояний можно выбрать любой другой $-\left|\widetilde{\psi}_n(\boldsymbol{R})\right\rangle = e^{i\chi(\boldsymbol{R})}\,|\psi_n(\boldsymbol{R})\rangle$ (это называется калибровочным преобразованием); формулы для связности и фазы изменятся:

$$\widetilde{\boldsymbol{A}}_n(\boldsymbol{R}) = \boldsymbol{A}_n(\boldsymbol{R}) - \nabla\chi, \quad \widetilde{\gamma}_n = \gamma_n - \chi\left(\boldsymbol{R}_f\right) + \chi\left(\boldsymbol{R}_i\right)$$

Where is the meaning of Berry's phase?

(????? don't know)

Is Berry's phase really important?

(????? don't know. I don't see why it is important, but there are many books that deal with it. But this is the minority, anyway)

Applications in topological materials (???)

(???? there are thousands articles about it, I'll write an overview here)

Where does Berry's phase is also used?

(??? write answer to it, currently, i don't know. And how exactly??)

О применениях во вращающихся спиновых системах в магнитном поле (??)

(???)

О применениях в эффекте Холла (???)

(??? как догадаться, что эффект Холла может быть объяснен с ней?)
(На ютубе хорошо объяснено.)

Experimental confirmation of Berry's phase

This was the first experiment to confirm the prediction of Berry. It was purposed by R.Y. Chiao and Y.S. Wu [10] in 1986 and this year yet realized by A. Tomita and R.Y. Chiao [6]. The photon's spin vector, which points either along the direction in which it is traveling or in the opposite direction, can be easily turned by changing the direction of travel. In [10] and [6], it is done with a coiled optical fibre.

[6] A. Tomita, R. Y. Chiao, "Observation of Berry's topological phase by use of an optical fibre", Phys. Rev. Lett. 57 (1986) 937-940.

[10] R.Y. Chiao and Y.S. Wu, "Manifestations of Bery's topological phase for the photon", Phys. Rev. Lett. 57 (1986) 933-936.

(this is really interesting, but no time for it now)

Спин в магнитном поле как пример адиабатических методов

Классическая задача, иллюстрирующая фазу Берри - задача о движении спина $\frac{1}{2}$ в медленно меняющемся магнитном поле.

Гамильтониан системы имеет следующий вид:

$$\hat{H}(\boldsymbol{B}) = -\boldsymbol{B} \cdot \hat{\boldsymbol{\sigma}}$$

где $\hat{\sigma} = (\hat{\sigma}_x, \hat{\sigma}_y, \hat{\sigma}_z)$ -матрицы Паули.

Основное состояние системы соответствует спину, поляризованному вдоль поля.

Если теперь поле заставить пройти замкнутый цикл (при этом наш спин адиабатически будет следить за полем, в силу адиабатической теоремы), то в конце мы получим исходное состояние.

Изучим, как устроена фаза Берри для данной задачи.

Изучать её мы будем в сферических координатах: $B = (B\sin\theta\cos\varphi, B\sin\theta\sin\varphi, B\cos\theta)$. Сперва нам требуется найти мгновенные собственные состояния гамильтониана:

$$\hat{H} = -B\begin{pmatrix} \cos\theta & \sin\theta e^{-i\varphi} \\ \sin\theta e^{i\varphi} & -\cos\theta \end{pmatrix}, \quad \begin{cases} E_+ = +B, & |\psi_+\rangle = \begin{pmatrix} \sin\frac{\theta}{2} \\ -e^{i\varphi}\cos\frac{\theta}{2} \end{pmatrix} \\ E_- = -B, & |\psi_-\rangle = \begin{pmatrix} \cos\frac{\theta}{2} \\ e^{i\varphi}\sin\frac{\theta}{2} \end{pmatrix} \end{cases}$$

Ключевых параметра тут 2 -углы θ и φ (имеются в виду параметры, задающие вектор R; изменение длины B, как мы видим, на волновые функции не влияет никак).

Поэтому у связности Берри будет две компоненты:

$$A_\theta^{(-)} = i\left\langle \psi_- | \frac{\partial\psi_-}{\partial\theta} \right\rangle = 0, \quad A_\varphi^{(-)} = i\left\langle \psi_- | \frac{\partial\psi_-}{\partial\varphi} \right\rangle = -\sin^2\frac{\theta}{2} = -\frac{1}{2}(1-\cos\theta)$$

и поэтому для любой замкнутой эволюции фаза Берри будет иметь вид:

$$\gamma_- = -\frac{1}{2}\oint(1-\cos\theta)d\varphi = -\frac{1}{2}\Omega$$

В действительности же, этот интеграл в точности равен телесному углу, который заметает замкнутая траектория на единичной сфере.

Проще всего это продемонстрировать в простом случае $\theta = \text{const} \to \gamma = -\pi(1-\cos\theta)$; в то время как телесный угол равен $2\pi(1-\cos\theta)$. Это - демонстрация того факта, что фаза Берри является геометрической фазой, в данной задаче она определяется чисто геометрической характеристикой траектории.

Сделаем ещё несколько замечаний: Телесный угол ориентирован - если изменить направление обхода контура, то поменяется и знак Ω.

Можно выбрать как телесный угол «внутри» контура Ω, так и телесный угол «вне» контура, $4\pi-(-\Omega)$ -при этом знак Ω поменяется из-за неправильного направления обхода.

Очевидно, что полученные фазы Берри отличаются на 2π -что не является большой проблемой, ведь это фаза.

Этот результат достаточно просто обобщается на произвольный спин S (не $\frac{1}{2}$) и на состояние с произвольной проекцией $M \in [-S, S]$ на направление магнитного поля - ответ записывается как $\gamma_M = M\Omega$. Поскольку M бывает либо полуцелым, либо цельм, то проблем с неоднозначностью фазы не возникает:

утверждение про калибровочную неинвариантность связаности Берри можно тут продемонстрировать явно.

Действительно, можно выбрать волновую функцию, скажем, в чуть ином виде: $\left|\widetilde{\psi}_-\right\rangle = \begin{pmatrix} e^{-i\varphi}\cos\frac{\theta}{2} \\ \sin\frac{\theta}{2} \end{pmatrix}$.

Это изменит и выражение для связности Берри, $\widetilde{A}_\varphi^{(-)} = \frac{1}{2}(1+\cos\theta)$. Однако выражение для интеграла от фазы по замкнутому контиуру при этом не изменится (разумеется, по модулю 2π).

Наконец, отметим, что в современной физике конденсированного состояния к фазе Берри проявляется огромный интерес, связанный с её применениями при исследовании топологических изоляторов.

В них фаза Берри играет ключевую роль, и именно в связи с ней эти вещества проявляются нетривиальные (топологические) свойства.

6.7.4 Extra Understanding of Geometrical Phases 1

(this theory is for applications and for connection with condensed matter, I'll later write it better, since topology is popular in condensed matter)

Introduction by Michael El-Batanouny

Known derivation in another formalism

In this chapter, we need to develop the formalism of Berry's geometric quantum phase. It is a manifestation of cyclic, adiabatic time evolution of Hamiltonians $\mathcal{H}[\eta(t)]$ controlled by a time-dependent, multidimensional parameter $\eta(t)$. For example, the parameter may determine variations in external magnetic and electric fields, or ionic coordinates in the Born-Oppenheimer approximation. It could also be, as we will need later, the crystal momentum $\mathbf{k}$ in a Brillouin zone. In general, η is defined on an n-dimensional parameter space $\eta(t) \equiv \{\eta_1(t), \eta_2(t), ..., \eta_n(t)\}$.$\mathcal{H}(\eta)$ and its energy spectrum $\varepsilon_\mu(\eta)$ depend smoothly on the parameter η.

For simplicity, we consider a quantum-mechanical system with a discrete and nondegenerate energy spectrum, with the proviso that no energy level crossing occurs during time evolution. As we have learned, for such systems the adiabatic theorem in quantum mechanics surmises that for a slowly changing Hamiltonian, the system remains in its evolving, time-dependent ground- or eigen-state. But, as revealed by Michael Berry in 1983, this is actually very incomplete [27, 159]. To understand the rationale behind this assertion, we consider the slow time variation of a Hamiltonian through its dependence on a parameter $\eta(t)$. We seek solutions for the Schrödinger equation

$$i\frac{\partial\psi(t)}{\partial t} = \mathcal{H}[\eta(t)]\psi(t), \quad \psi(t) \in \mathbb{H}$$

For adiabatic time evolution, we write the general solution of the Schrödinger equation as

$$\psi(t) = \sum_\mu c_\mu(t)|\mu, \eta(t)\rangle.$$

Substituting in (10.1), we get the following equation for the coefficients

$$\dot{c}_\mu(t) = -i\varepsilon_\mu(t)c_\mu(t) - \sum_v c_v(t)\left\langle \mu, \eta(t)\left|\partial_t\right|v, \eta(t)\right\rangle .$$

Thus, if we start with a certain $c_\mu(0) = 1, c_\nu(0) = 0, \forall\nu \neq \mu$, the adiabatic assumption is approximately fulfilled when $\langle \mu, \boldsymbol{\eta}(t)\left|\partial_t\right| v, \boldsymbol{\eta}(t)\rangle$ are small for $v \neq \mu$. We can show, by substituting in the eigenvalue equation

$$\mathcal{H}(t)|v, \boldsymbol{\eta}(t)\rangle = \varepsilon_v(t)|v, \boldsymbol{\eta}(t)\rangle,$$

that this matrix element can be expressed as

$$\left\langle \mu, \boldsymbol{\eta}(t)\left|\partial_t\right| v, \boldsymbol{\eta}(t)\right\rangle = \frac{\left\langle \mu, \boldsymbol{\eta}(t)\left|\partial_t\mathcal{H}(t)\right| v, \boldsymbol{\eta}(t)\right\rangle}{\varepsilon_v(t) - \varepsilon_\mu(t)} \ll 1 \quad \text{adiabatic assumption.}$$

Under the adiabatic assumption, we can directly solve (10.3) for $c_\mu(t)$ by integration, and obtain

$$\begin{aligned}
c_\mu(t) &= e^{-i\int_0^t d\tau \varepsilon_\mu(\tau)} e^{i\int_0^t d\tau i\langle \mu,\eta(\tau)|\partial_\tau|\mu,\eta(\tau)\rangle} = e^{i\alpha_{\rm dyn}(t)} e^{i\gamma(t)} \\
\psi(t) &= e^{i\alpha_{\rm dyn}(t)} e^{i\gamma(t)} |\mu,\eta(t)\rangle \\
\gamma &= \int_0^t d\tau i \left\langle \mu,\eta(\tau)\right| \left|\partial_\tau\right| \mu,\eta(\tau)\rangle = \int_0^t d\tau i \left\langle \mu,\eta(\tau)\right| \left|\nabla_\eta\right| \mu,\eta(\tau)\rangle \cdot \frac{d\eta}{d\tau} \\
&= \int_{\eta(0)}^{\eta(t)} i \left\langle \mu,\eta\right| \left|\nabla_\eta\right| \mu,\eta\rangle \cdot d\eta.
\end{aligned}$$

where the phase α arises from the usual dynamics, but γ is a manifestation of geometric aspects of the system evolution.

What Michael Berry demonstrated was that when the Hamiltonian evolves adiabatically around a closed loop C in η-space, with $n > 1$, an irreducible geometric phase γ relative to the initial state may emerge, namely, γ was coined Berry's phase by Barry Simon in 1983 [167], where he revealed the intimate connection between Berry's phase and holonomy on a line bundle.

10.1.1 Berry's Vector Potential, Field, and Flux

We find that the formulation becomes very easy to visualize when η is a three-dimensional parameler where ordinary vector calculus can be invoked. Here, we say that for a nondegenerate state, the only freedom in the choice of reference functions is a local phase

$$\psi(\eta) \to e^{i\theta(\eta)}\psi(\eta).$$

Under this modification, $\mathcal{A}$ in (10.6) changes by a gradient

$$\mathcal{A} \to \mathcal{A} + \nabla_\eta \theta,$$

a gauge transformation reminiscent of the vector potential in electrodynamics, and $\mathcal{A}$ is sometimes referred to as Berry's vector potential. So the integrals of $\mathcal{A}$ around closed loops C

$$\oint_C \mathcal{A} \cdot d\boldsymbol{\ell}_\eta$$

will be gauge invariant. We can use Stokes, theorem and write

$$\gamma = \oint_C \mathcal{A} \cdot d\eta \mod 2\pi = \iint_{S(C)} \mathcal{F} \cdot d\mathbf{S}_\eta \bmod 2\pi,$$

where $d\mathbf{S}_\eta$ denotes the area element in η space, and the integral is performed over any surface bounded by the closed contour C. Again, by analogy with electrodynamics, $\mathcal{F}$ is sometimes called the Berry field, and is defined as

$$\begin{aligned}
\mathcal{F} &= \nabla_\eta \times \mathcal{A} \\
\mathcal{F}_{\alpha\beta} &= \partial_\alpha \mathcal{A}_\beta - \partial_\beta \mathcal{A}_\alpha = -2\mathrm{Im}\left\langle \partial_\alpha \psi(\eta) | \partial_\beta \psi(\eta)\right\rangle.
\end{aligned}$$

Thus, this mathematical structure has evoked analogies with classical electromagnetism. We can envision $\mathcal{A}$ as abstract vector potential in parameter space, and $\mathcal{F}$ as a magnetic field.

Following this analogy, we surmise from (10.8) that Berry's phase γ is akin to a flux through the surface $\mathbf{S}$. We recall that a vector potential has considerable gauge arbitrariness, and has no physical meaning, while its loop integral is indeed gauge invariant and observable.

The set of phase factors $e^{i\theta(\eta)}$ form the group $U(1)$ of unitary 1×1 matrices. We therefore have a gauge theory with gauge (symmetry) group $U(1)$ and gauge potential $\mathbf{A}(\eta)$

The loop integral of the Berry potential, the Berry phase γ, is nontrivial in two cases:

- Curl $\mathcal{A}$ is nonzero.
- The curl is zero but the curve C is not in a simply connected domain.

We can invoke a generalized Stokes' theorem in any dimension of η parameter space, when C is the boundary of a surface $\mathbf{S}(C)$ in a simply connected domain, and the curl of $\mathcal{A}$ is regular on $\mathbf{S}(\mathcal{C})$.

$\mathcal{A}$ as a Berry Connection by Michael El-Batanouny

Now, we shall recast $\mathcal{A}$ as a topological geometric structure. We first note that the unitarity of time evolution preserves the scalar product, allowing the family of Hamiltonians $\mathcal{H}(\boldsymbol{\eta})$ to share the Hilbert space HI, and normalized state vectors to remain normalized and confined to the sphere $\mathbb{S}^{2\mathcal{N}+1}$. Consequently, the projected physical-state manifold $\mathbb{P}(\mathbb{H})$ continues to be the base manifold of the principal line bundle $\mathbb{E}$, with the fiber $\mathbb{F}$ being the unitary group $U(1)$.$\mathbb{P}(\mathbb{H})$ is homeomorphic with η.

We still focus on the spectrum of discrete, isolated, and nondegenerate eigenvalues $\varepsilon_\mu(\eta)$ with corresponding normalized eigenkets $\psi_\mu(\eta)$.[1] We recall that the set of equivalent normalized eigenkets $e^{i\phi}\psi(\eta) = \psi(\phi, \eta)$ form a ray, and share the projection $\pi = |\psi(\eta)\rangle\langle\psi(\eta)| \in \mathbb{P}(\mathbb{H})$. The adiabatic time dependence of $\mathcal{H}$ amounts to traversing a curve $t \to \eta(t)$ in η at adiabatically slow velocity. We also note that a cyclic evolution, $\eta(0) = \eta(T)$, is uniquely associated with a loop $\mathcal{C}(\eta)$ in η, or in $\mathbb{P}(\mathbb{H})$.

From another perspective, we can envision that time evolution produces a path in the total space $\mathbb{E}$. The corresponding path in the space of physical states $\mathbb{P}(\mathbb{H}) \simeq \eta$ is obtained by a π projection of the path in $\mathbb{E}$ onto the base manifold. In the cyclic evolutions we are interested in, we find that the system terminates in the initial physical state, and the paths are represented by closed curves in η. Closed paths in η may correspond to closed or open paths in $\mathbb{E}$. In a cyclic evolution, an open path in $\mathbb{E}$ means that a state vector terminates on the same initial fiber, but it lands on another state vector that differs from the initial state vector by an overall phase.

$U(1)$ A Transition Functions and Gauge Transformations

We note that, in general, each wavefunction $\psi(\eta)$ can be chosen to be smooth only over patches of η, but not necessarily over the whole of η. In other words, the set of state vectors $\psi(\phi, \eta)$ form a smooth section over each patch $\mathbb{U} \subset \eta$. For two overlapping patches $\mathbb{U}_1 \cap \mathbb{U}_2 \neq \emptyset$, with sets of smooth functions $\psi^{(1)}(\eta)$ and $\psi^{(2)}(\eta)$, respectively, we know that for any $\eta \in \mathbb{U}_1 \cap \mathbb{U}_2$ the corresponding functions share the same ray above η, and can differ only by a complex phase, $\theta(\boldsymbol{\eta}), e^{i\theta(\eta)} \in U(1)$, namely,

$$\psi^{(2)}(\eta) = e^{i\theta(\eta)}\psi^{(1)}(\eta),$$

which is just a gauge transformation. Both $\psi^{(1)}(\eta)$ and $\psi^{(2)}(\eta)$ constitute a possible set of instantaneous solutions, and the freedom in choice of either one or another manifests the gauge freedom. The corresponding group that is used to formulate the condition of the gauge freedom is called the gauge group. In our case, the gauge group is $U(1)$.

10.2.1 Construction of the Berry Connection

Before constructing the connection [34], which is associated with the horizontal subspace, we shall identify the vertical subspace, or the vertical direction. We recall that the fibers are generated by the action of the group $U(1)$ on the physical states of the base manifold $\mathbb{P}(\boldsymbol{\eta})$

$$\psi(\phi, \boldsymbol{\eta}) = e^{i\phi}\psi(\boldsymbol{\eta}), \quad \psi(\boldsymbol{\eta}) \in \mathbb{P}(\boldsymbol{\eta})$$

This means that the normalized states of a fiber differ by a phase from each other, and, thus, point in the same direction - the vertical direction generated by the $U(1)$ action.

Since the line bundle is embedded in a complex vector space, a natural way to construct the connection (a horizontal subspace) is to use the corresponding metric, the scalar product. We can decompose the tangent vectors

$$\frac{d\psi(\phi(t), \boldsymbol{\eta}(t))}{dt} = \partial_t \psi(\phi(t), \boldsymbol{\eta}(t)) \in TE$$

to the curve $\psi(\phi(t), \eta(t)) \in \mathbb{E}$, with the aid of the scalar product, into vertical and horizontal components, as

$$\begin{aligned} \frac{d\psi(\phi(t), \eta(t))}{dt} &= \langle \psi(\phi(t), \eta(t)) | \partial_t \psi(\phi(t), \eta(t)) \rangle \, |\psi(\phi(t), \eta(t))\rangle \\ &\quad + |h_\psi(t)\rangle \text{ (horizontal component)} \\ \langle \psi(\phi(t), \eta(t)) | h_\psi(t) \rangle &= 0, \quad \text{parallel transport} \end{aligned}$$

To evaluate the connection explicitly, we need to consider a local patch $\mathbb{U} \subset \eta$ and the region of $\mathbb{E}$ over $\mathbb{U}$. Since tangent vectors in TE are produced by the operator d/dt, we split it into vertical and horizontal operators as

$$\frac{d}{dt} = a_v \frac{\partial}{\partial \phi} + \sum_\alpha b_h^\alpha D_\alpha = a_v \frac{\partial}{\partial \phi} + \sum_\alpha b_h^\alpha \left[\frac{\partial}{\partial \eta^\alpha} + \mathcal{A}_\alpha \frac{\partial}{\partial \phi} \right],$$

where the first term corresponds to the vertical subspace, since it clearly depends only on variations in the phase ϕ. We therefore write

$$\begin{aligned} \langle \psi(\phi(t), \boldsymbol{\eta}(t)) | \partial_t \psi(\phi(t), \boldsymbol{\eta}(t)) \rangle \, |\psi(\phi(t), \boldsymbol{\eta}(t))\rangle &= a_v \frac{\partial}{\partial \phi} |\psi(\phi(t), \boldsymbol{\eta}(t))\rangle \\ |h_\psi\rangle = \sum_\alpha b_h^\alpha D_\alpha |\psi(\phi(t), \boldsymbol{\eta}(t))\rangle & \end{aligned}$$

and, according to (10.11), we obtain

$$\langle \psi(\phi(t), \eta(t)) \, | b_h^\alpha D_\alpha | \, \psi(\phi(t), \boldsymbol{\eta}(t)) \rangle = 0.$$

Since b_h^α is arbitrary, we find that

$$\left\langle \psi(\phi(t), \boldsymbol{\eta}(t)) \left| \frac{\partial}{\partial \eta^\alpha} + \mathcal{A}_\alpha \frac{\partial}{\partial \phi} \right| \psi(\phi(t), \boldsymbol{\eta}(t)) \right\rangle = 0.$$

Using the fact that $|\psi(\phi(t), \eta(t))\rangle$ is normalized, and that

$$\frac{\partial}{\partial \phi} |\psi(\phi(t), \boldsymbol{\eta}(t))\rangle = \frac{\partial}{\partial \phi} e^{i\phi} \psi(\eta) = i |\psi(\phi(t), \eta(t))\rangle,$$

we obtain

$$\mathcal{A}_\alpha \left\langle \psi(\phi(t),\boldsymbol{\eta}(t)) \left| \frac{\partial}{\partial \phi} \right| \psi(\phi(t),\boldsymbol{\eta}(t)) \right\rangle = i\mathcal{A}_\alpha \langle \psi(\phi(t),\boldsymbol{\eta}(t)) | \psi(\phi(t),\boldsymbol{\eta}(t)) \rangle$$
$$= - \left\langle \psi(\phi(t),\boldsymbol{\eta}(t)) \left| \frac{\partial}{\partial \eta^\alpha} \right| \psi(\phi(t),\boldsymbol{\eta}(t)) \right\rangle$$

or

$$\mathcal{A}_\alpha = i \left\langle \psi(\phi(t),\boldsymbol{\eta}(t)) \left| \frac{\partial}{\partial \eta^\alpha} \right| \psi(\phi(t),\boldsymbol{\eta}(t)) \right\rangle .$$

The connection $\mathcal{A}$ is then given by the one-form

$$\mathcal{A} = \sum \mathcal{A}_\alpha d\eta^\alpha = i\langle \psi(\phi(t),\eta(t)) | d | \psi(\phi(t),\eta(t)) \rangle$$

defined on the line bundle in terms of the covariant derivative $\nabla_{\boldsymbol{\eta}}$. Thus, $\mathcal{A}$ is also referred to as the Berry connection. [2]

The horizontal lift

With the construction of the connection in hand, we proceed to define the horizontal lift. The horizontal lift involves lifting the tangent vectors to the curve in η up along the fibers and orienting them such that they are horizontal. Consequently, for $|\psi(\phi,\eta)\rangle$ to be a horizontal lift, the vertical part of $|\partial_t \psi(\phi,\eta)\rangle$ must vanish

$$\langle \psi(\phi,\eta) | \partial_t \psi(\phi,\eta) \rangle = 0.$$

This condition is called the horizontal lift equation or the equation for parallel transport. We have invoked the notion of parallel transport in the line bundle $\mathbb{E}$ in a manner completely analogous to the way an ordinary covariant derivative on a smooth manifold defines parallel transport in the tangent bundle of the smooth base. As we will show, the twisting of this line bundle affects the phase of quantum mechanical wave functions.

In bundle language, $|\psi(\phi,\eta)\rangle$ can be considered as a local section of the fiber bundle, namely, a continuous mapping of a patch $\mathbb{U} \subset \eta$ into the fibers above $\mathbb{U}$. A change to a different patch $\mathbb{U}' \subset \eta$ corresponds to a change in the section

$$|\psi(\phi(\boldsymbol{\eta}),\boldsymbol{\eta})\rangle \to |\psi\left(\phi'(\boldsymbol{\eta}),\boldsymbol{\eta}\right)\rangle$$
$$|\psi\left(\phi'(\boldsymbol{\eta}),\boldsymbol{\eta}\right)\rangle = e^{i\theta(\eta)} |\psi(\phi,\eta)\rangle$$

This means that the connection transforms as

$$\mathcal{A}'_\alpha = \mathcal{A}_\alpha - \frac{\partial \theta(\eta)}{\partial \eta^\alpha},$$

a gauge transformation. We note that a local section, being a section over a single patch, maps a closed path in η, with $\eta(T) = \eta(0), 0 \le t \le T$, into a closed path in $\mathbb{E}$. We will denote the closed path in $\mathbb{E}$ as $|\psi(\eta(t))\rangle$, with $|\psi(\eta(T))\rangle = |\psi(\eta(0))\rangle$. A gauge transformation gives a different closed path in $\mathbb{E}$,

$$|\psi_\theta(\eta(t))\rangle = e^{i\theta(t)} |\psi(\eta(t))\rangle.$$

In order for $|\psi_\theta(\eta(t))\rangle$ to be closed, the function θ must satisfy

$$\theta(T) = \theta(0) + 2n\pi$$

with n integer.

10.2.2 Holonomy and Berry's Phase

We will now evaluate the holonomy produced by the horizontal lift of a closed curve in η with respect to the connection we previously derived (see Figure 10.1). We denote the horizontal lift by $|\psi_h(\eta(t))\rangle$. By definition, the tangent vectors to the curve $|\psi_h(\eta(t))\rangle$ must be horizontal. According to (10.10), this means

$$\langle\psi_h(\phi,\eta)|\partial_t\psi_h(\eta(t))\rangle = 0.$$

We can express the open path $|\psi_h(\boldsymbol{\eta}(t))\rangle$ in $\mathbb{E}$ in terms of a closed path $|\psi(\phi(t),\boldsymbol{\eta}(t))\rangle$ in $\mathbb{E}$ as

$$\begin{aligned}
|\psi_h(\eta(t))\rangle &= e^{i\xi(t)}|\psi(\phi(t),\eta(t))\rangle \\
|\psi(\phi(T),\eta(T))\rangle &= |\psi(\phi(0),\eta(0))\rangle, \quad \phi(T) = \phi(0) + 2n\pi \\
|\psi_h(\eta(T))\rangle &= e^{i[\xi(T)-\xi(0)]}\,|\psi_h(\eta(0))\rangle\,.
\end{aligned}$$

Setting $\gamma = \xi(T) - \xi(0)$, substituting (10.17) into (10.16) and integrating, we obtain

$$\begin{aligned}
\langle\psi_h(\phi,\eta)|\partial_t\psi_h(\eta(t))\rangle =& i\xi(t)\langle\psi(\phi(t),\eta(t))|\psi(\phi(t),\eta(t))\rangle \\
&+ \langle\psi(\phi(t),\eta(t))|\psi(\phi(t),\eta(t))\rangle \\
\xi(t) =& i\langle\psi(\phi(t),\eta(t))|\psi(\phi(t),\eta(t))\rangle \\
\gamma =& i\int_0^T dt\,\langle\psi(\phi,\eta(t))|\partial_t\psi(\phi,\eta(t))\rangle
\end{aligned}$$

The tangent vector $|\dot{\psi}(\phi(t),\eta(t))\rangle$ is given by

$$\frac{d}{dt}|\psi(\phi(t),\boldsymbol{\eta}(t))\rangle = \dot{\phi}\frac{\partial|\psi(\phi(t),\eta(t))\rangle}{\partial\phi} + \sum_\alpha \dot{\eta}^\alpha \frac{\partial|\psi(\phi,\boldsymbol{\eta}(t))\rangle}{\partial\eta^\alpha}$$

and we write

$$\begin{aligned}
\gamma =& i\int_0^T dt\dot{\phi}\left\langle\psi(\phi,\eta(t))\left|\frac{\partial}{\partial\phi}\right|\psi(\phi,\eta(t))\right\rangle \\
&+ i\int_0^T dt\eta^\mu\left\langle\psi(\phi,\eta(t))\left|\frac{\partial}{\partial\eta^\mu}\right|\psi(\phi,\eta(t))\right\rangle \\
=& -\int_{\phi(0)}^{\phi(T)} d\phi + i\int_{\eta^\mu(0)}^{\eta^\mu(T)} d\eta^\mu\left\langle\psi(\eta)\left|\frac{\partial}{\partial\eta^\mu}\right|\psi(\eta)\right\rangle \\
=& -2n\pi + \oint_{\mathcal{C}}\langle\psi(\eta)|d|\psi(\eta)\rangle = -2n\pi + \oint_{\mathcal{C}}\mathcal{A} = \gamma(\mathcal{C}),
\end{aligned}$$

where $\mathcal{C}$ is the closed path in $\eta\cdot\langle\psi(\eta)|d|\psi(\eta)\rangle$ is purely imaginary, since for normalized states $|\psi(\eta)\rangle$

$$\begin{aligned}
\frac{\partial}{\partial\eta^\mu}\langle\psi(\eta)|\psi(\eta)\rangle = 0 &= \left\langle\psi(\eta)|\frac{\partial}{\partial\eta^\mu}\psi(\eta)\right\rangle + \left\langle\frac{\partial}{\partial\eta^\mu}\psi(\eta)|\psi(\eta)\right\rangle \\
&= 2\,\mathrm{Re}\left\langle\psi(\eta)|\frac{\partial}{\partial\eta^\mu}\psi(\eta)\right\rangle
\end{aligned}$$

10.2.3 The Berry Curvature

If the base η is simply connected, then expression (10.18) for the Berry phase can be rewritten as a surface integral of the local curvature form. Using Stokes' theorem, we write

$$\gamma(\mathcal{C}) = \int\limits_{S(\mathcal{C})} \mathcal{F} \cdot d\mathbf{S},$$

where $S(\mathcal{C})$ is an arbitrary submanifold, of dimension $n-1$, bounded by $\mathcal{C}$, namely, $\delta\mathbf{S} = \mathcal{C}$, and

$$\mathcal{F} = d\mathcal{A} = -\eta\langle d\psi(\eta)|d\psi(\eta)\rangle \quad \text{two-form}$$

is the Berry curvature. In local coordinates on η it is given by the two-form

$$\begin{aligned}\mathcal{F} &= \frac{1}{2}\mathcal{F}_{ij} d\eta_i \wedge d\eta_j \\ \mathcal{F}_{ij} &= -\mathrm{Im}\left(\langle\partial_i\psi|\partial_j\psi\rangle - \langle\partial_j\psi|\partial_i\psi\rangle\right).\end{aligned}$$

If the base η is not simply connected, then the expression for the Berry phase as surface integral (10.19) is valid only for those curves that are contractible to a point. Berry's Curvature in Terms of Hamiltonian Derivatives: Hidden Physics With

$$\mathcal{F}_n(\eta) = -\mathrm{Im}\,\langle d\psi_n(\eta)|d\psi_n(\eta)\rangle$$

we insert the identity operator, $\mathbb{I} = \sum_m |\psi_m\rangle\langle\psi_m|$, and we obtain

$$\begin{aligned}\mathcal{F}_n(\boldsymbol{\eta}) &= -\mathbf{3}\sum_m \langle d\psi_n(\boldsymbol{\eta})|\psi_m(\eta)\rangle \wedge \langle\psi_m(\boldsymbol{\eta})|d\psi_n(\eta)\rangle \\ &= -3\sum_{m\neq n} \langle d\psi_n(\boldsymbol{\eta})|\psi_m(\eta)\rangle \wedge \langle\psi_m(\eta)|d\psi_n(\eta)\rangle\end{aligned}$$

where the sum excludes $m = n$ since $\langle\psi_n(\eta)|d\psi_n(\eta)\rangle$ is purely imaginary. An important consequence of (10.22) is that the sum of Berry curvatures of all the eigenstates of the Hamiltonian is zero. If we consider Hamiltonians with discrete spectra along a closed path C, and sum over Berry's phases of all eigenstates, we obtain

$$\sum_n \mathcal{F}_n(\eta) = 0,$$

which follows from (10.22), since

$$\begin{aligned}\mathcal{F}_n^{ij}(\eta) &= -\,\mathrm{Im}\sum_{m\neq n}\left(\langle\partial_i\psi_n(\eta)|\psi_m(\eta)\rangle\langle\psi_m(\eta)|\partial_j\psi_n(\eta)\rangle - (i \rightleftharpoons j)\right) \\ &= -\frac{1}{2}\mathrm{Im}\sum_{m\neq n}\left(\langle\partial_i\psi_n(\eta)|\psi_m(\eta)\rangle\langle\psi_m(\eta)|\partial_j\psi_n(\eta)\rangle\right. \\ &\quad \left. + \langle\partial_j\psi_m(\eta)|\psi_n(\eta)\rangle\langle\psi_n(\eta)|\partial_i\psi_m(\eta)\rangle - (i \rightleftharpoons j)\right)\end{aligned}$$

since $\langle\partial_i\psi_n(\eta)|\psi_m(\eta)\rangle = -\langle\psi_n(\eta)|\partial_i\psi_m(\eta)\rangle$. It is clear then that

$$\sum_n \mathcal{F}_n^{ij}(\eta) = 0$$

since the sum is both symmetric and antisymmetric in i and j. Applying the exterior derivative d to the eigenvalue equation

$$\mathcal{H}(\boldsymbol{\eta})\,|\psi_n(\boldsymbol{\eta})\rangle = E_n(\boldsymbol{\eta})\,|\psi_n(\boldsymbol{\eta})\rangle$$

yields

$$d\mathcal{H}(\boldsymbol{\eta})\,|\psi_n(\boldsymbol{\eta})\rangle + \mathcal{H}(\boldsymbol{\eta})d\,|\psi_n(\eta)\rangle = dE_n(\boldsymbol{\eta})\,|\psi_n(\boldsymbol{\eta})\rangle + E_n(\boldsymbol{\eta})d\,|\psi_n(\boldsymbol{\eta})\rangle$$

and projecting onto $\langle\psi_m(\eta)|$, we get

$$\langle\psi_m(\eta)|d\mathcal{H}(\boldsymbol{\eta})|\psi_n(\eta)\rangle = (E_n(\eta) - E_m(\eta))\,\langle\psi_m(\eta)|d\psi_n(\eta)\rangle$$

or

$$\langle\psi_m(\eta)|d\psi_n(\eta)\rangle = \frac{\langle\psi_m(\eta)|d\mathcal{H}(\eta)|\psi_n(\eta)\rangle}{E_n(\eta) - E_m(\eta)}, \quad m \neq n$$

and

$$\mathcal{F}_n(\eta) = -\ni \sum_{m\neq n} \frac{\langle\psi_n(\eta)|d\mathcal{H}(\eta)|\psi_m(\eta)\rangle \wedge \langle\psi_m(\eta)|d\mathcal{H}(\eta)|\psi_n(\eta)\rangle}{(E_n(\eta) - E_m(\eta))^2}$$

We note that $\mathcal{F}_n$ becomes infinite at some $\eta - \eta^*$, if $E_n(\eta^*) - E_m(\eta^*)$, a δ-function like singularity that heralds the presence of a fictitious field source. We discern that the source is static; for example, it may manifest the nature of a magnetic monopole rather than currents.

We can surmise that wherever the ground state is degenerate, the curvature becomes ill defined and singular. In such a situation, the vicinity of the singularity must be excluded, which leads to a domain that is not simply connected.

Finally, (10.24) has the advantage that it is free of wavefunction differentiation, therefore it can be evaluated under any gauge choice. This property is particularly useful for numerical calculations, in which the condition of a smooth phase choice of the eigenstates is not guaranteed in standard diagonalization procedures. Isolated Degeneracies and Diabolical Points We consider a quantum system parameterized by $\eta = \{\eta_1, ..., \eta_n)$, and assume that for some point η^* two energy eigenvectors $\psi_1(\eta^*)$ and $\psi_2(\eta^*)$ are degenerate, with energy $E^* = E(\eta^*)$. Near the degeneracy point η^*, we may approximate the system as a two-level one, and write its Hamiltonian as

$$\mathcal{H} = \begin{pmatrix} \mathcal{H}_{11}(\eta) & \mathcal{H}_{12}(\eta) \\ \mathcal{H}_{12}^*(\eta) & \mathcal{H}_{22}(\eta) \end{pmatrix}$$

with eigenvalues

$$E_\pm = \frac{\mathcal{H}_{11} + \mathcal{H}_{22}}{2} \pm \sqrt{\left(\frac{\mathcal{H}_{11} - \mathcal{H}_{22}}{2}\right)^2 + |\mathcal{H}_{12}|^2}\,.$$

$$(\mathcal{H}_{11} - \mathcal{H}_{22})^2 + 4\,|\mathcal{H}_{12}|^2 = 0, \quad \mathcal{H}_{11} = \mathcal{H}_{22}, \quad \mathrm{Re}\mathcal{H}_{12} = {}_3\mathcal{H}_{12} = 0.$$

At η^*,

These three constraints define an $(n-3)$-dimensional submanifold in η. If $n = 3$, then the degeneracy defines an isolated point in η.

For a system with time-reversal symmetry, the Hamiltonian $\mathcal{H}$ is real and $\mathrm{Im}\mathcal{H}_{12} = 0$. Hence, the subspace of degenerate points defines an $(n-2)$-dimensional submanifold of η. This behavior was recognized by von Neumann and Wigner [189]. Note that if we introduce the three parameters

$$u = \frac{1}{2}\,(\mathcal{H}_{11} - \mathcal{H}_{22})\,, \quad v = \mathrm{Re}\mathcal{H}_{12}, \quad w = \mathrm{Im}\mathcal{H}_{12},$$

then the eigenenergies in the vicinity of the degeneracy take a double-cone profile, as shown in Figure 10.2, with its apex at the degeneracy point, namely

$$E = E^* \pm \sqrt{u^2 + v^2 + w^2}$$

The double cone is called a diabolo (after a spinning toy of the same shape). The apex of this cone is called a diabolical point. [3]

10.2.4 Berry's Quantized Flux and Topological Invariant

The flux of Berry's curvature through a surface $\mathbf{S}$ remains a bona fide physical quantity on closed surfaces, such as a sphere or a torus, in which case the closed contour C becomes the empty set. The remarkable feature in this case is that the flux is quantized. For pedagogical reasons, we will consider the simple case of a sphere in three dimensions, $\mathbf{S} \equiv \mathbb{S}^2$. For regular and divergence-free curvature on the closed surface $\mathbb{S}^2$,

$$\int_{\mathbb{S}^2} \mathcal{F}(\eta) \cdot d\mathbf{S}$$

represents the flux of $\mathcal{F}$ across $\mathbb{S}^2$. The flux quantization is then expressed as

$$\mathcal{C}_1 = \frac{1}{2\pi} \int_{\mathbb{S}^2} \mathcal{F}(\boldsymbol{\eta}) \cdot d\mathbf{S},$$

where $\mathcal{C}_1$ is an integer $\in \mathbb{Z}$, called the Chern number of the first class. To demonstrate that $\mathcal{C}_1 \in \mathbb{Z}$, we shall assume that $\mathcal{F}(\eta)$ is singular at $\eta = 0$, and that $\mathbb{S}^2$ is the spherical surface centered at the origin (see Figure 10.3).

We cut this surface at the equator, $\eta_z = 0$, and consider the flux across the two open surfaces

$$\int_{\mathbb{S}^2} \mathcal{F}(\boldsymbol{\eta}) \cdot d\mathbf{S} = \int_{S_+} \mathcal{F}(\boldsymbol{\eta}) \cdot d\mathbf{S} + \int_{S_-} \mathcal{F}(\boldsymbol{\eta}) \cdot d\mathbf{S}$$

We notice that $C_+ = C_- = C$, but the surface normals $\hat{\mathbf{n}}$ have opposite orientations. From Stokes' theorem, we get

$$\int_{S_\pm} \mathcal{F}(\boldsymbol{\eta}) \cdot d\mathbf{S} = \pm \int_C \mathcal{A}_\pm(\boldsymbol{\eta}) \cdot d\eta$$

$$\int_{\mathbb{S}^2} \mathcal{F}(\boldsymbol{\eta}) \cdot d\mathbf{S} = \int_C \mathcal{A}_+(\eta) \cdot d\eta - \int_C \mathcal{A}_(\eta) \cdot d\eta$$

The upper and lower Berry connections $\mathcal{A}_\pm(\eta)$ may only differ by a gauge transformation. Since the right-hand side (rhs) of (10.26) is the difference of two Berry phases on the same path, it is necessarily an integer multiple of 2π.

The Chern number turns out to be a robust topological invariant, and is associated with observable phenomena, such as the integer quantum Hall effect. More recently, other topological invariants have emerged, such as the $\mathbb{Z}_2$, which classifies time-reversal symmetric insulators into disjoint trivial and topological types.

As we have outlined, the integrand $\mathcal{F}$ is the curl of the Berry connection $\mathcal{A}$, and, in general, $\mathcal{A}$ may not be a single-valued function globally on $\mathbb{S}^2$, but only on local patches, as will be described in example 1.

6.7.5 Extra Understanding of Geometrical Phases 2

10.3 Pedagogical Example 1: A Two-Level System

Pedagogically, studying this system accomplishes two goals. First, it is a simple model that demonstrates the basic concepts outlined earlier in this chapter, and reveals several important properties of the Berry phase. Second, it will emerge, in different physical guises, in the following chapters. The generic Hamiltonian of a two-level system takes the form

$$\mathcal{H} = -\mathbf{d}\cdot\boldsymbol{\sigma},$$

where σ represents the Pauli matrices and $\mathbf{d}\in\mathbb{R}^3$ vector space. [4] We parametrize $\mathbf{d}$ by its polar and azimuthal angles θ and φ as

$$\mathbf{d} = d\hat{\mathbf{n}}, \quad \hat{\mathbf{n}} = (\sin\theta\cos\varphi, \sin\theta\sin\varphi, \cos\theta).$$

The two eigenstates, with energies $\pm d$, are

$$|\psi_+(\mathbf{d})\rangle = \begin{pmatrix} \cos(\theta/2) \\ e^{i\varphi}\sin(\theta/2) \end{pmatrix} \quad |\psi_-(\mathbf{d})\rangle = \begin{pmatrix} -\sin(\theta/2) \\ e^{i\varphi}\cos(\theta/2) \end{pmatrix}.$$

We notice that the norm d does not affect the eigenvectors. Therefore, the parameter space is a two-sphere $\mathbb{S}^2$.

10.3.1 Patches and Transition Functions

We now choose two different gauges to write the ground state $|\psi_-(\mathbf{d})\rangle$:

$$\left|\psi_-^U\right\rangle = \begin{pmatrix} -\sin(\theta/2) \\ e^{i\varphi}\cos(\theta/2) \end{pmatrix} \quad \text{or} \quad \left|\psi_-^L\right\rangle = \begin{pmatrix} -e^{-i\varphi}\sin(\theta/2) \\ \cos(\theta/2) \end{pmatrix}.$$

Both states $\left|\psi_-^U\right\rangle$ and $\left|\psi_-^L\right\rangle$ describe the ground state. However, $\left|\psi_-^U\right\rangle$ is ill defined (singular) at $\theta=\pi$ (it displays a vortex at the south-pole $\Rightarrow$ value of φ ill defined), while $\left|\psi_-^L\right\rangle$ is singular at the north-pole. Thus, we have to introduce two patches on the sphere, shown in Figure 10.4, to obtain a smooth parameterization of the instantaneous eigenstates. Other gauges yield the singularity at a different point on the sphere, but a singularity is unavoidable. It is impossible to find a gauge that yields a smooth, nonsingular connection over the whole closed surface. Such singularity, often called obstruction, can be moved but not removed..[5] However, we can glue these two patches together via a gluing phase

$$\left|\psi_-^U\right\rangle = e^{it(\varphi)}\left|\psi_-^L\right\rangle \quad t(\varphi)=\varphi$$

along the equator.

10.3.2 Berry Connection, Curvature, and Phase

We now calculate the Berry connection and curvature for ψ_-^U and ψ_-^L

$$\nabla\left|\psi_-^U\right\rangle = -\frac{1}{d}\begin{pmatrix} \frac{1}{2}\cos\frac{\theta}{2} \\ \frac{1}{2}e^{i\phi}\sin\frac{\theta}{2} \end{pmatrix}\hat{\vartheta} + \frac{1}{d\sin\theta}\begin{pmatrix} 0 \\ ie^{i\phi}\cos\frac{\theta}{2} \end{pmatrix}\hat{\boldsymbol{\varphi}}$$

Hence

$$\begin{aligned}\left\langle\psi_-^U|\nabla\psi_-^U\right\rangle &= \frac{1}{2d}\left[\sin\frac{\theta}{2}\cos\frac{\theta}{2}\hat{\boldsymbol{\theta}} - \sin\frac{\theta}{2}\cos\frac{\theta}{2}\hat{\boldsymbol{\theta}} + 2i\frac{\cos^2(\theta/2)}{\sin\theta}\hat{\varphi}\right] \\ &= i\frac{2\cos^2(\theta/2)}{d\sin\theta}\hat{\varphi} = i\frac{1}{d}\cot\frac{\theta}{2}\hat{\varphi}\end{aligned}$$

and

$$\nabla \times \left\langle \psi_-^U | \nabla \psi_-^U \right\rangle = \frac{1}{d \sin\theta} \frac{\partial}{\partial \theta} \left[\sin\theta \frac{i \cos^2(\theta/2)}{d \sin\theta} \right] \hat{\mathbf{n}} = -i \frac{1}{2d^2} \hat{\mathbf{n}}.$$

We obtain

$$\mathcal{A} = \frac{1}{d} \hat{\varphi} \times \begin{cases} \cot(\vartheta/2) & \left| \psi_-^U \right\rangle \quad \text{singular at } \theta = 0, \\ \tan(\theta/2) & \left| \psi_-^L \right\rangle \quad \text{singular at } \theta = \pi, \end{cases}$$

$$\mathcal{F} = \frac{1}{2d^2} \hat{\mathbf{n}}.$$

The curvature is gauge invariant, while the connection is gauge dependent. The curvature for the upper state $|\psi_+(\mathbf{d})\rangle$ is $\mathcal{F} = -\frac{1}{2d^2}\hat{\mathbf{n}}$. Thus, parallel transport of the eigenstates $|\psi_-(\mathbf{d})\rangle$ and $|\psi_+(\mathbf{d})\rangle$ over the same loop in parameter space rotates them in opposite directions (Berry phases have opposite signs). They exhibit a twist akin to the Möbius strip.

One- and Two-Form Approach

Alternatively, we can use the one-form expression for the connection and

$$\begin{aligned} \mathcal{A} &= i \langle \psi | d\psi \rangle \\ &= i \langle \psi | \partial_\theta \psi \rangle \, d\theta + i \langle \psi | \partial_\varphi \psi \rangle \, d\varphi \\ \frac{\partial \psi_-}{\partial \theta} &= - \begin{bmatrix} (\cos\theta)/2 \\ e^{i\varphi}(\sin\theta)/2 \end{bmatrix}, \quad \frac{\partial \psi_-}{\partial \varphi} = \begin{bmatrix} 0 \\ ie^{i\varphi}(\cos\theta)/2 \end{bmatrix} \\ \frac{\partial \psi_+}{\partial \theta} &= \begin{bmatrix} -(\sin\theta)/2 \\ e^{i\varphi}(\cos\theta)/2 \end{bmatrix}, \quad \frac{\partial \psi_+}{\partial \varphi} = \begin{bmatrix} 0 \\ ie^{i\varphi}(\sin\theta)/2 \end{bmatrix} \end{aligned}$$

to obtain

$$\begin{aligned} \mathcal{A}_+ &= \langle \psi_+ | d\psi_+ \rangle = -\frac{1}{2}(1 - \cos\theta) d\varphi \\ \mathcal{A}_- &= \langle \psi_- | d\psi_- \rangle = -\frac{1}{2}(1 + \cos\theta) d\varphi \end{aligned}$$

The corresponding Berry curvature is

$$\begin{aligned} \mathscr{F}_{\theta\varphi} &= (\partial_\theta \mathcal{A}_\varphi - \partial_\varphi \mathcal{A}_\theta) \, d\theta \wedge d\varphi \\ \mathcal{F}^+_{\theta\varphi} &= -\frac{1}{2} \sin\theta d\theta \wedge d\varphi \\ \mathcal{F}^-_{\theta\varphi} &= \frac{1}{2} \sin\theta d\theta \wedge d\varphi \\ \mathcal{F}^+_{\theta\varphi} + \mathcal{F}^-_{\theta\varphi} &= 0 \end{aligned}$$

and the Chern numbers are

$$\mathcal{C}_\pm = \mp \frac{1}{2\pi} \int_{S^2} d\theta \sin\theta d\phi \frac{1}{2} = \mp 1.$$

In the integration of the Berry curvature over the parameters (θ, φ), we did not include an additional $\sin\theta$ factor that is required for a sphere. This is because we were not integrating over the surface of a sphere, but over a parameter domain shown in the figure. Here, the parameter space has the topology of a sphere $\mathbb{S}^2$, but not its metric. However, we should also note that

$$\mathcal{F}^\pm_{\theta\varphi} = \mp \frac{1}{2} \sin\theta d\theta \wedge d\varphi = \mp \frac{1}{2d^2} (dd\theta)(d \sin\theta d\varphi) \hat{\mathbf{d}}.$$

10.3.3 The Monopole: Degeneracy, Singularity, and Obstruction

If we write the curvature as $\mathcal{F} = \frac{g}{2d^2}\hat{\mathbf{n}}$, we find that it has the form of a magnetic monopole field of strength g at the origin, namely,

$$\frac{1}{2\pi}\int_{\mathbb{S}^2} \mathcal{F}\cdot d\mathbf{S} = g.$$

The corresponding Berry potential $\mathcal{A}$ also shows monopole behavior at $\mathbf{d} \equiv \mathbf{B} = 0$. As expected, the vanishing of the Hamiltonian at $d = 0$ ushers a doubly degenerate state - a singularity (see Figure 10.5).

We note that integrating over the solid angle $\Delta\Omega$ subtended by $\Delta\mathbf{S}$ yields a Berry phase $\gamma = g\Delta\mathbf{\Omega}/2$ proportional to half the subtended solid angle.

In fact, g cannot take arbitrary values: we calculate the Berry phase along a path C that does not contain the south pole

$$\gamma(C) = \oint_C \mathcal{A}\cdot d\ell = \int_{\Sigma(C)} \mathcal{F}\cdot d\mathbf{S} = \frac{g}{2}\Omega(\Sigma) \bmod 2\pi,$$

where $\Omega(\Sigma)$ is the solid angle subtended by the surface Σ that contains the north pole. If we now choose the surface $\tilde{\Sigma} = \mathbb{S}^2 - \Sigma$

$$\gamma(C) = -\int_{\tilde{\Sigma}(C)} \mathcal{F}\cdot d\mathbf{S} = -\frac{g}{2}(4\pi - \Omega(\Sigma)) \bmod 2\pi = \frac{g}{2}\Omega(\Sigma) \bmod 2\pi,$$

we find that $g \in \mathbb{Z}$. This integer measures the strength of the singularity (magnetic monopole), which resides in a site inaccessible to the quantum system. With this simple yet pedagogical procedure, we can ascertain that a nonvanishing Chern number $\mathcal{C}$ is intrinsically linked to the inability to choose a smooth gauge. In other words, only if we have to choose several patches that we glue together with a gauge transformation can $\mathcal{C}$ be nonzero.

10.4 Pedagogical Example 2: Molecular Aharonov-Bohm Effect

In this example, we consider the quantum motion of the combined electronic and ionic components of a molecule. Here, the slow motion of the ions presents an adiabatic time evolution of the electronic motion and allows the application of the Born-Oppenheimer approximation (BOA).

(???? this is a big chapter with many details, maybe I'll move it to cond matter later)

10.4.1 The Effective Ionic Hamiltonian

We start from the complete Hamiltonian $\mathcal{H}$ of an isolated $\mathcal{N}$-atom molecular system, and explicitly separate the ionic kinetic energy

$$\mathcal{H}(\mathbf{X},[\mathbf{x}]) = \frac{1}{2}\sum_{j=1}^{\mathcal{N}}\frac{\mathbf{P}_j^2}{2M_j} + \mathcal{H}_e(\mathbf{X},[\mathbf{x}]) + E_{\text{elastic}}(\mathbf{X})$$

where $[\mathbf{x}]$ denotes the electronic degrees of freedom, and $\mathbf{X} = [\mathbf{X}_1, ..., \mathbf{X}_j, ..., \mathbf{X}_{\mathcal{N}}]$ represents the ionic positions, with $\mathbf{X}_j$ the position vector of ion j.$\mathbf{P}_j = -i\hbar\nabla_{\mathbf{x}_j}$ is the canonical momentum conjugate to $\mathbf{X}_j$, and M_j the mass of ion j. Eelastic is the ionic elastic energy for the configuration $\mathbf{X}$.

We invoke the BOA by initially ignoring the ionic kinetic energy, and applying the adiabatic approximation, where the coupling between different electronic states can be neglected. Thus, the slowly varying $3\mathcal{N}$-dimensional ionic position vector $\mathbf{X}$ in $\mathcal{H}(\mathbf{X},[\mathbf{x}])$ is demoted to a classical parameter and identified with the slow parameter η. Moreover, we use the BOA ansatz and write the eigenfunctions of (10.28), $|\Psi(\mathbf{X},[\mathbf{x}])\rangle$, as the product $\langle[\mathbf{x}]|\xi(\mathbf{X})\rangle\chi(\mathbf{X})$, where ξ and χ denote the electronic and ionic wavefunction, respectively. We start with solving the electronic eigenvalue problem

$$\mathcal{H}_e(\mathbf{X},[\mathbf{x}])\,|\xi_n(\mathbf{X},[\mathbf{x}])\rangle = E_n(\mathbf{X})\,|\xi_n(\mathbf{X},[\mathbf{x}])\rangle$$

and determine the ground-state energy $E_0(\mathbf{X})$ and wavefunction $|\xi_0(\mathbf{X},[\mathbf{x}])\rangle$. Our goal is then to construct an effective Schrödinger equation for the ionic wavefunction $\chi(\mathbf{X})$ by integrating out the electronic degrees of freedom. We first consider the action of the canonical ionic momentum $\mathbf{P}$ on the product ansatz

$$\mathbf{P}|\xi(\mathbf{X},[\mathbf{x}])\rangle\chi(\mathbf{X}) = -i\hbar|\xi(\mathbf{X},[\mathbf{x}])\rangle\nabla_{\mathbf{X}}\chi(\mathbf{X}) - i\hbar\,|\nabla_{\mathbf{X}}\xi(\mathbf{X},[\mathbf{x}])\rangle\,\chi(\mathbf{X}).$$

We integrate over the electronic degrees of freedom by acting on both sides with $\langle\xi(\mathbf{X},[\mathbf{x}])|$. We obtain the effective ionic kinematic momentum Π acting on $\chi(\mathbf{X})$

$$\Pi\chi(\mathbf{X}) = [\mathbf{P} - i\hbar\,\langle\xi(\mathbf{X},[\mathbf{x}])|\nabla_{\mathbf{X}}\xi(\mathbf{X},[\mathbf{x}])\rangle\,\chi\chi(\mathbf{X}),$$

where Berry's connection is clearly recognizable. The electronic eigenvalue $E_0(\mathbf{X})$ of the ground state plays the role of a scalar potential for ionic motion. The effective Hamiltonian acting on $\chi(\mathbf{X})$ is given by

$$\mathcal{H}_{\text{eff}} = \frac{1}{2}\sum_j \frac{1}{M_j}\mathbf{\Pi}_j^2 + E_0(\mathbf{X}) + E_{\text{elastic}}\,(\mathbf{X}).$$

10.4.2 A Simple Example: The Trimer Molecule

The smallest molecular system that exhibits molecular Aharonov-Bohm effect is a trimer, with ionic coordinates $\mathbf{X} = (\mathbf{X}_1, \mathbf{X}_2, \mathbf{X}_3)$. The simplest trimers, which we consider here, are of course the homonuclear ones, where symmetry plays a major role.

Structure of the Ground State

We focus on a trimer of monovalent atoms, such as H_3 or Na_3, where the occupied valence orbitals, $|A\rangle, |B\rangle$, and $|C\rangle$, are s-like.

We start with the molecule in the equilateral configuration of Figure 10.6, with $\mathcal{D}_{3\,\text{h}}$ symmetry. [7] Two of the valence electrons occupy a totally symmetric orbital (A_{1g} symmetry)

$$\left|\phi_{\text{A}_1\ \text{g}}\right\rangle = \frac{1}{\sqrt{3}}[|A\rangle + |B\rangle + |C\rangle].$$

The remaining unpaired electron occupies the next available orbital, which has E_{g} symmetry and is doubly degenerate. [8] In a simple tight-binding scheme, a possible basis is the two-dimensional manifold

$$\left|\phi^1_{\text{E}_\text{g}}\right\rangle = \frac{1}{\sqrt{2}}[|B\rangle - |C\rangle], \quad \left|\phi^2_{\text{E}_\text{g}}\right\rangle = \frac{1}{\sqrt{6}}[2|A\rangle - |B\rangle - |C\rangle].$$

These orbitals are shown in Figure 10.7. The fact that the Hamiltonian is time reversal invariant and the wavefunctions vanish at infinity guarantees that the orbitals may always be chosen as real.

When we distort the molecule from its equilateral configuration, the doublet is linearly split, and one of the two E_g components becomes energetically favored. The molecule is said

to undergo a Jahn-Teller distortion, where the electronic ground state in the BOA becomes nondegenerate.

The $E \otimes \varepsilon$ Jahn-Teller Problem

We shall start our study of this effect with describing the motion of the ions under $\mathcal{D}_{3\ \mathrm{h}}$ symmetry. We find three symmetry-adapted (normal) modes for small oscillations of the trimer molecule, shown in Figure 10.8:

(i) A breathing mode of A_{1g} symmetry. It is totally symmetric and cannot remove the electronic doublet degeneracy

(ii) An E_{g} doubly degenerate mode. It can lift the electronic degeneracy, and is compatible with coupling to the electronic doublet and engendering invariant terms in the Hamiltonian, linear in the symmetry-adapted displacements. The vibrational doublet, in fact, drives the dynamical Jahn-Teller effect [9].

The ionic motion lifts the electronic degeneracy. This fulfills the assertion of the Jahn-Teller theorem that in the presence of electronic degeneracy, there should be distorted ionic configurations of lower energy than the symmetric one.

Solving the One-Electron Problem

Within the Born-Oppenheimer procedure, we write

$$\Psi([\mathbf{x}], \mathbf{X}) = \chi(\mathbf{X})\xi([\mathbf{x}], \mathbf{X}))$$

and we initially neglect the ionic kinetic and elastic energies in $\mathcal{H}$. The remaining component is the electronic Hamiltonian having the form

$$\mathcal{H}_e(\mathbf{X}, \mathbf{x}) = T_e + V(\mathbf{X}, \mathbf{x})$$

for the one-electron case. T_ε is the electronic kinetic energy. The electron-ion potential V is expressed in terms of the "parametric" ionic positions $\mathbf{X}$ and the one-electron degrees of freedom $\mathbf{x}$.

For infinitesimal vibrational displacements, $\mathbf{X} = \mathbf{X}_0 + \Delta\mathbf{X}$, where $\mathbf{X}_0$ represents the equilibrium configuration with $\mathcal{D}_{3\ \mathrm{h}}$ symmetry. We expand the potential V to linear terms in $\Delta\mathbf{X}$:

$$\mathcal{H}_e(\mathbf{X}, \mathbf{x}) \simeq T_e + V\left(\mathbf{X}_0, \mathbf{x}\right) + \nabla_{\mathbf{X}} V|_{\mathbf{X}=\mathbf{X}_0} \cdot \Delta\mathbf{X}$$

As we have shown in Chapter 6, we carry out a unitary transformation to normal (or symmetry-adapted) coordinates $\mathbf{X} \to \mathbf{Q}$, and obtain

$$\begin{aligned}\mathcal{H}_e(\mathbf{Q}, \mathbf{x}) &= T_e + V\left(\mathbf{X}_0, [\mathbf{x}]\right) + \sum_\alpha \nabla_{\mathbf{Q}_\alpha} V \cdot \mathbf{Q}_\alpha \\ &= T_e + V\left(\mathbf{X}_0, \mathbf{x}\right) + \sum_\alpha \sum_{\ell=1}^{d_\alpha} K_{\alpha\ell} Q_\alpha^\ell = \mathcal{H}_e^{(0)} + \mathcal{H}'\end{aligned}$$

where $\mathbf{Q}_\alpha$ is a normal mode coordinate belonging to the irreducible representation (irrep) α and d_α is the irrep dimension, or its degeneracy. In the trimer case, the relevant irrep is E_g with $d_{\mathrm{E}_8} = 2$, yielding

$$\begin{aligned}\mathcal{H}_e &= \frac{\mathbf{p}^2}{2m_e} + V\left(\mathbf{x}; \mathbf{X}_0\right) + \mathcal{V}_1(\mathbf{x})Q_1 + \mathcal{V}_2(\mathbf{x})Q_2 \\ &= \mathcal{H}_e^{(0)} + \mathcal{V}_1(\mathbf{x})Q_1 + \mathcal{V}_2(\mathbf{x})Q_2\end{aligned}$$

where we dropped the subscript E_g. Diagonalization of $\mathcal{H}_e^{(0)}$ yields the solutions $|\xi_j\left(\mathbf{X}_0, \mathbf{x}\right)\rangle$ of the adiabatic electronic problem for the equilateral ionic configuration. However, since $\mathcal{H}_e^{(0)}$ has

the $\mathcal{D}_{3\ \mathrm{h}}$ symmetry, the ground-state wavefunction is still expressed in terms of an $A_{1\ \mathrm{g}}$ singlet and an E_{g} doublet: $\left|\phi_{\mathrm{A}_{1\ \mathrm{g}}}\right\rangle, \left|\phi^1_{\mathrm{E}_g}\right\rangle, \left|\phi^2_{\mathrm{E}_g}\right\rangle$.

Treating the interaction as a degenerate perturbation problem, we evaluate the matrix elements as 10

$$\left\langle\phi^1|\mathcal{V}(\mathbf{x})|\phi^1\right\rangle = -K, \quad \left\langle\phi^2|\mathcal{V}(\mathbf{x})|\phi^2\right\rangle = K, \quad \left\langle\phi^1|\mathcal{V}(\mathbf{x})|\phi^2\right\rangle = \left\langle\phi^2|\mathcal{V}(\mathbf{x})|\phi^1\right\rangle = K,$$

where we again dropped the subscript E_g. Expressing the electron eigenket in the form

$$\xi'(\mathbf{x},\mathbf{Q}) = A_1(\mathbf{Q})\phi^1(\mathbf{x},\mathbf{Q}) + A_2(\mathbf{Q})\phi^2(\mathbf{x},\mathbf{Q})$$

we obtain

$$\begin{pmatrix} -KQ_1 & KQ_2 \\ KQ_2 & KQ_1 \end{pmatrix} \Rightarrow \mathcal{E}_\pm = \pm K\sqrt{Q_1^2+Q_2^2}$$

Next, we transform the coordinates in $Q_1 - Q_2$ parameter space to polar form (Q,φ):

$$Q_1 = Q\cos\varphi, \text{ and } Q_2 = Q\sin\varphi$$

as shown in Figure 10.9, and obtain

$$KQ\begin{pmatrix} -\cos\varphi & \sin\varphi \\ \sin\varphi & \cos\varphi \end{pmatrix} = KQ\left(\sin\varphi\sigma_x - \cos\varphi\sigma_z\right),$$

where σ_x and σ_z are the Pauli matrices. The eigenenergies become

$$\mathcal{E}_\pm = \pm KQ.$$

The rhs of (10.32) shows that the coupling to the vibronic modes in the electronic problem can be mapped onto a spin- 1/2 problem. We can then write the eigenkets as

$$\begin{cases} |\xi_-\rangle = \frac{1}{\sqrt{2}}\left[\cos(\varphi/2)\,|\phi^1\rangle - \sin(\varphi/2)\,|\phi^2\rangle\right] \\ |\xi_+\rangle = \frac{1}{\sqrt{2}}\left[\sin(\varphi/2)\,|\phi^1\rangle + \cos(\varphi/2)\,|\phi^2\rangle\right] \end{cases}$$

The eigenkets $|\xi_\pm\rangle$are real and double-valued in the angle φ. We find that although the Hamiltonian is periodic in φ, the electronic wavefunctions are antiperiodic:

$$|\xi_\pm(2\pi)\rangle = -\,|\xi_\pm(0)\rangle\,.$$

We can also view the sign change in the electronic eigenstates, as a result of varying the angle φ along a closed loop encircling the origin in the ionic configuration parameter space, shown in Figure 10.9, a possible holonomy. This behavior is demonstrated in Figure 10.10. As we will see, this is characteristic of a cyclic pseudorotation.

The sign change in the state of a two-level (fermionic) system under a 2π rotation, referred to as spinor behavior, [11] was known since the early days of quantum mechanics, but we shall show that Berry's formulation brings a new insight, namely, a special case of the geometric phase. However, to start with, the reality of the wavefunctions leads to the vanishing of Berry's geometric vector potential, $(\xi_\pm\,|\nabla_Q|\,\xi_\pm\rangle = 0$.

(??? there was a cool picture here with triangles....)

The double-valued eigenstates of (10.33) may appear disturbing and unphysical. However, this problem can be remedied in two ways. We can apply a gauge transformation that renders the wavefunctions complex, but single-valued. Or, we require that the ionic wavefunction be quantized using antiperiodic boundary conditions. Note that the eigenstate of the total molecular system, $\Psi(\mathbf{x},\mathbf{Q})$, must be single-valued, of which the electronic term is only one factor.

10.4.3 Molecular A haronov-Bohm effect (MABE)

Before describing the molecular Aharonov-Bohm effect, we will briefly describe the original Aharonov-Bohm effect (ABE) [6], for the sake of clarity and completeness. The Aharonov-Bohm Effect In the simplest description of the Aharonov-Bohm effect, an electron is placed outside a solenoid with infinite extension in the z-direction (see Figure 10.11). The region inside the solenoid is inaccessible to the electron. For simplicity, we consider the case where the electron is confined to a circular rail of radius a, in the $x-y$ plane, as shown in figure. If the magnetic flux through the solenoid is Φ, then the vector potential at the rail will be

$$A_\varphi = \frac{\Phi}{2\pi a}.$$

The corresponding Hamiltonian is

$$\mathcal{H} = \frac{\hbar^2}{2m_e}\left(\frac{i}{a}\frac{d}{d\varphi} + \frac{e}{\hbar c}A_\varphi\right)^2 = -\frac{\hbar^2}{2m_e}\left(\frac{d}{d\varphi} - i\frac{\Phi}{\Phi_0}\right)^2,$$

where $\Phi_0 = 2\pi\hbar c/e = hc/e$ is the flux quantum. The single-valued eigenfunctions satisfying periodic boundary conditions are $\psi(\varphi) \propto \exp[i\ell\varphi], \ell$ integer, with eigenenergies

$$E_\ell = \frac{h^2}{2m_e a^2}\left(\ell + \frac{\Phi}{\Phi_0}\right)^2$$

which clearly demonstrates that the energy quantization may have a noninteger quantum number whose value depends on the solenoid flux! Moreover, we note that for Φ not equal to integer multiples of Φ_0, energies for ℓ values that have the same magnitude but differ in sign are not degenerate. The canonical and kinematic angular momenta differ, so that clockwise and counterclockwise directions have different speeds for a given value of $|\ell|$. The reason is that the vector field $\mathbf{A}$ causes the phase of the electron wavefunction to change as the wave circulates on the ring. To satisfy the boundary condition, this phase change, in turn, results in higher or lower kinematic momentum.

The key to the Aharonov-Bohm effect is the vector potential $\mathbf{A}(\mathbf{x})$. Outside the solenoid $\mathbf{B} = \nabla \wedge \mathbf{A} = 0$, but $\mathbf{A} \neq 0$ because for any closed loop surrounding the solenoid we have a nonzero integral

$$\oint_C \mathbf{A} \cdot d\boldsymbol{\ell} = \int_{\substack{\text{including}\\ \text{solenoid}}} \mathbf{B} \cdot d\mathbf{s} = \Phi$$

Thus, locally, $\nabla \wedge \mathbf{A} = 0$ means that the vector potential is a gradient of some function, and we may gauge it away

$$\mathbf{A}(\mathbf{x}) \to \tilde{\mathbf{A}}(\mathbf{x}) = \mathbf{A}(\mathbf{x}) - \nabla\xi(\mathbf{x}) = 0$$

but, globally, no single-valued $\xi(\mathbf{x})$ can gauge away the vector potential. [12]

To bring out the physics behind the ABE, we consider an electron beam being split at $\mathbf{x}$, and the two components travel along paths 1 and 2, of equal lengths, as shown in Figure 10.12. When they recombine at $\mathbf{x}'$, they have acquired different phases. We have two separate and

different gauge transforms $-\xi_1(\mathbf{x})$ that gauges away $\mathbf{A}(\mathbf{x})$ along path 1, and $\xi_2(\mathbf{x})$ that gauges away $\mathbf{A}(\mathbf{x})$ along path 2:

$$\Delta\xi|_{\text{path1}} - \Delta\xi|_{\text{path2}} = \oint_{\text{cloosed}} \mathbf{A}\cdot d\boldsymbol{\ell} = \Phi.$$

Gauge Transformation of Electronic States For pedagogical reasons, we shall use a gauge transformation to remove the doublevaluedness, and we write

$$|\xi_{\pm}(\mathbf{Q},\mathbf{x})\rangle \to \exp(i\varphi/2)\,|\xi_{\pm}(\mathbf{Q},\mathbf{x})\rangle$$

Such a transformation requires the addition of a gauge potential to the Hamiltonian. As we will show, the present case requires the introduction of a vector potential

$$\nabla \to \nabla - i(\hat{\varphi}/2Q)$$

This vector potential gives rise to a fictitious magnetic field (a flux tube) confined to the origin. Consequently, the $E\otimes\varepsilon$ system may be regarded as an analog of the AharonovBohm effect. Indeed, Mead has dubbed this the molecular Aharonov-Bohm effect [128]. As in BOA, the eigenstates acquire a phase γ from the vector potential.

- Berry's connection and phase

We start with calculating Berry's connection for the single-valued $\xi(\mathbf{Q},\mathbf{x})$ of (10.34). With $\nabla_Q = \left(\frac{\partial}{\partial Q}, \frac{1}{Q}\frac{\partial}{\partial\varphi}\right)$, we find

$$\begin{aligned}\nabla_Q\,|\xi_-\rangle &= \frac{\hat{\varphi}}{Q}\frac{\partial}{\partial\varphi}\left[e^{i\varphi/2}\left(-\sin\frac{\varphi}{2}\,|\phi^1\rangle + \cos\frac{\varphi}{2}\,|\phi^2\rangle\right)\right]\\ &= \frac{\hat{\varphi}}{2Q}e^{i\varphi/2}\left[i\,|\xi_-\rangle - |\xi_+\rangle\right]\end{aligned}$$

which yields

$$\langle\xi_-|\nabla\xi_-\rangle = \left[0, \frac{i}{2Q}\right] \Rightarrow \mathcal{A}_Q = i\,\langle\xi_-|\nabla\xi_-\rangle = -\frac{1}{2Q}\hat{\varphi}$$

and Berry's phase $\gamma_A(C)$ is given by

$$\gamma_A(C) = \oint_C \mathcal{A}_Q\cdot d\mathbf{l}_Q = \int_0^{2\pi}\left(-\frac{1}{2Q}\right)Q d\varphi = -\pi.$$

Quantization of Ionic Motion: Pseudorotations

- Effective scalar potential

Having determined the electronic energy contribution to be $\mathcal{E}_{\pm} = \pm KQ$, we now turn to the vibrational (slow motion) problem. The elastic energy of the vibration modes Q_1 and Q_2 is

$$E_{\text{elastic}}\,(\mathbf{Q}) = \frac{\kappa}{2}\left(Q_1^2 + Q_2^2\right) = \frac{\kappa}{2}Q^2,$$

where the two modes have the same effective spring constant κ since they are degenerate. The potential energy experienced by the molecular ion system becomes

$$\frac{\kappa}{2}Q^2 - KQ,$$

with $Q \geq 0$ in polar coordinates. This is just the Born-Oppenheimer surface of the JahnTeller split doublet shown in Figure 10.13:

- It is a double-valued function.

- It has a degeneracy at $Q = 0$ (the point of zero distortion), together with a conical intersection.

- The double cone is just a diabolo, and the degeneracy point a diabolical.

- Near the origin, the adiabatic approximation breaks down, and the origin becomes a singularity of the Born-Oppenheimer procedure.

- The domain of Q is not simply connected, because of the singularity at the origin (an obstacle).

- The lowest sheet has a continuum of minima, a circular valley of radius $Q_0 = K/\kappa$, $E_- = -K^2/2K$, where a classical particle travels freely.

Nothing exotic happens if the ionic motion can be considered as classic; but when we quantize the ionic degrees of freedom, Berry's connection arising from the gauge transformation in the electronic wavefunction gives rise to half-order quantum numbers. The ionic system becomes fermionic!

- The eigenvalue problem

Substituting the total eigenket

$$|\Psi(\mathbf{r}, \mathbf{Q})\rangle = \chi(\mathbf{Q}) \, |\xi_-\rangle$$

in the eigenvalue equation and setting $\kappa = \mu\omega_Q^2$, where μ is the mode effective mass, we obtain

$$\left[\frac{\mathbf{P}^2}{2\mu} + \left(\frac{\mu\omega_Q^2}{2}Q^2 - KQ\right)\right] \times |\xi_-\rangle = E\chi \, |\xi_-\rangle$$

or $|\xi_-\rangle \, \frac{\mathbf{P}^2}{2\mu}\chi + i\hbar\nabla_Q \, |\xi_-\rangle \cdot \left(\frac{\mathbf{P}}{\mu}\chi\right) - \frac{\hbar^2}{2\mu}\chi\nabla_Q^2 \, |\xi_-\rangle + \left(\frac{\mu\omega_Q^2}{2}Q^2 - KQ\right)\chi \, |\xi_-\rangle = E_\chi \, |\xi_-\rangle$. Eliminating the electronic degrees of freedom, we get

$$\frac{\mathbf{P}^2}{2\mu}\chi + i\hbar \, \langle \xi_- \, |\nabla_Q| \, \xi_- \rangle \cdot \left(\frac{\mathbf{P}}{\mu}\chi\right) - \frac{\hbar^2}{2\mu} \, \langle \xi_- \, |\nabla_Q^2| \, \xi_- \rangle \, \chi + \left(\frac{\mu\omega_Q^2}{2}Q^2 - KQ\right)\chi = E\chi.$$

If we determine $\langle \xi_- \, |\nabla_Q^2| \, \xi_- \rangle$by operating on (10.35) with ∇_Q, we get

$$\langle \xi_- \, |\nabla_Q^2| \, \xi_- \rangle = \langle \xi_- \, |\nabla_Q \cdot \nabla_Q| \, \xi_- \rangle = \frac{1}{2Q^2}\frac{\partial}{\partial\varphi}e^{i\varphi/2} \left[i \, |\xi_-\rangle - |\xi_+\rangle\right] = -\frac{1}{2Q^2}.$$

Using the relations

$$\mathcal{A}_Q = i \, \langle \xi_- | \nabla \xi_- \rangle = -\frac{1}{2Q}\hat{\varphi}, \quad \nabla_Q = \left(\frac{\partial}{\partial Q}, \frac{1}{Q}\frac{\partial}{\partial\varphi}\right), \quad \nabla_Q^2 = \nabla_Q^2 + \frac{1}{Q^2}\frac{\partial^2}{\partial\varphi^2}$$

in (10.36), we obtain

$$\left[-\frac{\hbar^2}{2\mu}\nabla_{\mathbf{Q}}^2 + \frac{\hbar^2}{2\mu}\frac{1}{Q^2}\left(i\frac{\partial}{\partial\varphi}\right) + \frac{\hbar^2}{4\mu Q^2} + \left(\frac{\mu\omega_Q^2}{2}Q^2 - KQ\right)\right]\chi(\mathbf{Q}) =$$

$$\left[-\frac{\hbar^2}{2\mu}\nabla_Q^2 + \frac{\hbar^2}{2\mu Q^2}\left(-\frac{\partial^2}{\partial\varphi^2} + i\frac{\partial}{\partial\varphi}\right) + \frac{\hbar^2}{4\mu Q^2} + \left(\frac{\mu\omega_Q^2}{2}Q^2 - KQ\right)\right]\chi(\mathbf{Q}) =$$

$$\left[-\frac{\hbar^2}{2\mu}\nabla_Q^2 + \frac{\hbar^2}{2\mu Q^2}\left(i\frac{\partial}{\partial\varphi} + \frac{1}{2}\right)^2 + \frac{\hbar^2}{8\mu Q^2} + \left(\frac{\mu\omega_Q^2}{2}Q^2 - KQ\right)\right]\chi(\mathbf{Q}) = E\chi(\mathbf{Q})$$

- Quantized angular motion in Q-space: pseudorotations

Since χ has to be single-valued and periodic in φ, we set

$$\chi(\mathbf{Q}) = \eta(Q)e^{im\varphi}$$

so that the second term in (10.37) becomes

$$\frac{\hbar^2}{2\mu Q^2}\left(m-\frac{1}{2}\right)^2 = \frac{\ell^2\hbar^2}{2\mu Q^2}, \quad |\ell| = 1/2, 3/2, 5/2, ...$$

The pseudorotation term is obviously an ionic rotor in Q-space. But the angular energy is characterized by a half-integer quantum number ℓ, instead of the integer quantum number m. The lowest state with $\ell = \pm 1/2$ is an orbital doublet. This feature can be considered a manifestation of Berry's phase, which arises because we insisted that the electronic wavefunction be single-valued in Q-space!

The spectrum of (10.38) has the same structure as in ABE, if we identify the inaccessible flux Φ with half a flux quantum Φ_0, sometimes referred to as a π flux. There is no magnetic field in this problem; the flux is purely topological and can be regarded as an obstruction, since the ionic path cannot be contracted without crossing a degeneracy point. [13]

- Radial motion in Q-space

To complete the analysis of the molecular Aharonov-Bohm phenomenon, we consider here the radial motion. With

$$\nabla_Q^2 = \frac{1}{Q}\frac{\partial}{\partial Q}\left(Q\frac{\partial}{\partial Q}\right)$$

we write (10.37) in the form

$$\left[\frac{1}{Q}\frac{\partial}{\partial Q}\left(Q\frac{\partial}{\partial Q}\right) - \frac{A}{Q^2} - \left(\frac{\mu\omega_Q}{\hbar}\right)^2\left(Q-\frac{K}{\mu\omega_Q^2}\right)^2 + \frac{K^2}{\hbar^2\omega_Q^2} + \frac{2\mu E}{\hbar^2}\right]\eta(Q) = 0$$

where $A = \frac{\hbar^2}{2\mu Q^2}\left[\left(m-\frac{1}{2}\right)^2 + \frac{1}{4}\right]$ If we replace $\left(Q-\frac{K}{\mu\omega^2}\right)^2$ by Q^2, we have the radial equation of the isotropic twodimensional harmonic oscillator! Hence, (10.39) is the radial equation of a displaced isotropic oscillator, where the low-lying wavefunctions are centered on the potential minimum $Q_0 = \frac{K}{\mu\omega_Q^2}$, and concentrated in its trough. For these low-lying states, we can write

$$Q - \frac{K}{\mu\omega^2} = \Delta Q \Rightarrow \frac{\partial}{\partial \Delta Q} = \frac{\partial}{\partial Q}$$

with $\Delta Q \ll Q_0$. This allows us to set $Q \simeq Q_0$ in the first two terms of (10.39), so that (10.39) reduces to

$$\left[\frac{\partial^2}{\partial \Delta Q^2} - \left(\frac{\mu\omega_Q}{\hbar}\right)^2\Delta Q^2 + \frac{2\mu E'}{\hbar^2}\right]\eta(\Delta Q) = 0$$

which is just the equation of the one-dimensional harmonic oscillator. To visualize the behavior of this system, we first establish the analogy between the isotropic oscillator and circularly polarized light: in the latter, we have two oscillating linear electric fields that are spatially orthogonal; in the former, we have x and y oscillators. In the present system, we have two normal modes Q^1 and Q^2 that perform circular motion in $Q^1 - Q^2$ space. In real space, we have instantaneous linear superpositions of the two modes according to $Q^1 = Q\cos\varphi(t)$ and $Q^2 = Q\sin\varphi(t)$.

The vibrorotations, or pseudorotations, are depicted in Figure 10.14, with the degeneracy point represented by the equilateral triangle, and its morphing into pseudorotational distortions appears around the closed circular path.

О связи фазы Берри с дифференциальной геометрией

(тоже пропишу потом, иногда такой возникает вопрос)

Aharonov-Anandan Phase

Y. Aharonov and J. Anandan, "Phase change during a cyclic quantum evolution", Phys. Rev. Lett. 58 (1987) 1593-1596.

In 1987, Aharonov and Anandan [3] considered cyclic evolutions that are not restricted by an adiabatic condition and purposed an generalization of Berry's phase. This generalization is very important, because the adiabatic condition is never exactly fulfilled for real evolutions.

(??? If I need, I'll study it.)

6.7.6 Stationary Adiabatics

Метод Борна-Оппенгеймера

Постановка задачи для молекулы

Пусть гамильтониан квантовомеханической системы зависит от параметров, которые сами представляют собой квантомеханические степени свободы, которые тоже необходимо рассматривать с точки зрения стационарного уравнения Шрёдингера. Предположим, что в системе имеются «быстрые» степени свободы x_f и медленные» степени свободы x_s, то есть

$$\hat{H} = \hat{H}_s\left(\boldsymbol{x}_s\right) + \hat{H}_f\left(\boldsymbol{x}_f, \boldsymbol{x}_s\right)$$

то есть представляет собой сумму гамильтониана быстрой подсистемы $\hat{H}_f\left(x_f, x\right)$ (куда включено в том числе и её взаимодействие с медленной), который зависит от конкретного положения медленной как от параметров, и гамильтониана медленной подсистемы.

Каноническим примером, для которого впервые был развит адиабатический метод, является задача о квантовомеханическом описании молекулы. Молекула состоит из атомарных $x_s = \{R_i\}_{i=1}^{N_n}$ и электронных $x_f = \{r_i\}_{i=1}^{N_s}$ степеней свободы. Поскольку атомы в тысячи раз тяжелее электронов, то их квантомеханическое движение медленное, а движение электронов - быстрое.

Для молекулы гамильтониан нредставляет собой сумму кинетических энергий всех атомов и электронов, а также попарных Кулоновских энергий взаимодействия.

Разбиение гамильтониана в таком случае естественно следующее:

$$\hat{H}_s\left(\{\boldsymbol{R}_i\}\right) = \sum_{i=1}^{N_n} \frac{-\nabla^2_{\boldsymbol{R}_i}}{2M_i} + \sum_{i<j} \frac{Z_i Z_j e^2}{|\boldsymbol{R}_i - \boldsymbol{R}_j|}$$

$$\hat{H}_f\left(\{r_i\}, \{\boldsymbol{R}_j\}\right) = \sum_{i=1}^{N_e} \frac{-\nabla^2_{r_i}}{2m} + \sum_{i<j} \frac{e^2}{|\boldsymbol{r}_i - \boldsymbol{r}_j|} - \sum_{i=1}^{N_n}\sum_{j=1}^{N_e} \frac{Z_i e^2}{|\boldsymbol{R}_i - \boldsymbol{r}_j|}$$

О случаях, когда нужно учитывать квантовополевые эффекты атомов (?!?!?)

(то есть когда такая задача не работает?)

О случаях, когда нужно расчитать характеристики для конечной температуры (?!?!?)

(решаем при нулевой, дальше добавляем её как-то? методом Монте Карло что ли, отдав прогеру?)

адиабатическое разделение переменных

Логика метода очень сильно перекликается с нестационарной адиабатикой, разобранной ранее.

Если имеется сильное разделение временных масштабов, на которых «живут» различные подсистемы, то можно считать, что для «быстрой» подсистемы, «медленная» практически покоится.

Поэтому разумно решать для неё стационарное уравнение Шрёдингера, считая положение быстрой системы просто как параметр:

$$\hat{H}_f(x_f, x_s)\left|\psi_n^{(f)}(x_s)\right\rangle = \varepsilon_n^{(f)}(x_s)\left|\psi_n^{(f)}(x_s)\right\rangle$$

Таким образом мы находим полный набор состояний «быстрой» подсистемы $\psi_n^{(f)}(x_f, \{x_s\})$ и набор уровней энергии $\varepsilon_n^{(f)}(\boldsymbol{x}_s)$. Теперь, следуя логике нестационарной адиабатики, если «медленная» подсистема будет испытывать движение, то «быстрая» будет следовать мгновенным уровням энергии.

Таким образом, энергия $\varepsilon_n^{(f)}(\boldsymbol{x}_s)$ выступит в роли эффективной потенциальной энергии для движения медленной подсистемы.

Таким образом, после этого мы можем решить уравнение Шрёдингера для быстрой подсистемы, и тем самым завершая решение задачи.

Теперь схему конкретней.

Мы будем искать полное решение задачи в виде разложения по «мгновенным» собственным состояниям «быстрого» гамильтониана:

$$\Psi(x_f, x_s) = \sum u_n(x_s)\,\psi_n^{(f)}(x_f, \{x_s\})$$

Если мы сделаем такую подстановку в полное уравнение Шрёдингера, и спроецируем его на бра-вектор $\left\langle\psi_n^{(f)}\right|$, то мы получим следующее уравнение:

$$\sum_m \hat{H}_{nm}(x_s)\,u_m(x_s) + \varepsilon_n^{(f)}(x_s)\,u_n(x_s) = Eu_n(x_s), \quad \hat{H}_{nm}(x_s) = \left\langle\psi_n^{(f)}(x_s)\left|\hat{H}_s(x_s)\right|\psi_m^{(f)}(x_s)\right\rangle$$

Несмотря на внешнюю схожесть, $\hat{H}_{nm}(x_s)$ не является матричным элементом какого-то оператора, ведь функции $|\psi_n^{(f)}\rangle$ относятся к гильбертовому пространству быстрой подсистемы, а $\hat{H}_s$ -оператор, действующий на медленные степени свободы; поэтому $\hat{H}_{nm}(\boldsymbol{x}_s)$ остаётся оператором, действующим на медленные степени свободы.

С другой стороны, $\hat{H}_s(x_s)$ может содержать операторы типа градиентов по x_s и в этом смысле будет действовать на волновые функции $\left|\psi_m^{(f)}(\boldsymbol{x}_s)\right\rangle$ просто как дифференцирование по соответствующему параметру - именно поэтому $\hat{H}_{nm}(\boldsymbol{x}_s)$, вообще говоря, отлично от $\hat{H}_s(x_s)\,\delta_{nm}$. Однако в первом приближении его можно таковым считать, поскольку дифференцирование «быстрой» волновой функции по параметрам медленной системы, вообще говоря, содержит малость по параметру $\omega_{nm}^{(f)} \gg \omega_{nm}^{(s)}$(как будет показано нижу) -поэтому в ведущем приближении:

$$\left[\hat{H}_s(x_s) + \varepsilon_n^{(f)}(x_s)\right]u_n(x_s) = Eu_n(x_s)$$

Это и есть основное уравнение в адиабатическом приближении, и именно оно было озвучено ранее.

Разберём теперь поподробнее, на чём основываются сделанные приближения.

Переходы на другие состояния

До сих пор всё было точно, и полученное уравнение полностью эквивалентно исходному уравнению Шрёдингера.

Однако теперь, следуя логике из разобранной ранее нестационарной адиабатики, мы можем начать делать приближения.

Первое приближение заключается в том, что, как и ранее, если расстояние между соседними уровнями быстрой системы большое, то возбуждаться эти уровни не будут- что соответствует малости $\hat{H}_{n\neq m}$. Поступим в полной аналогии с нестационарной адиабатикой, когда мы оценивали выражение $\langle\psi_n|\partial_t\psi_m\rangle$:

$$\left\langle \psi_n^{(f)} \left| \left[\hat{H}_f\left(\boldsymbol{x}_f, \boldsymbol{x}_s\right), \hat{H}_s\left(\boldsymbol{x}_s\right) \right] \right| \psi_m^{(f)} \right\rangle \equiv \varepsilon_n^{(f)}\left(\boldsymbol{x}_s\right) \hat{H}_{nm}\left(\boldsymbol{x}_s\right) - \hat{H}_{nm}\left(\boldsymbol{x}_s\right) \varepsilon_m^{(f)}\left(\boldsymbol{x}_s\right)$$

Опять подчеркнём, что $\hat{H}_s\left(x_s\right)$ может содержать градиенты, действующие на x_s, и в этом смысле не коммутирует с $\varepsilon_n^{(f)}\left(\{x_s\}\right)$. Однако, если расстояние между уровнями достаточно большое $\omega_{nm}^{(f)} \gg \omega_{nm}^{(s)}$, то членом с коммутатором можно пренебречь и написать следующую оценку:

$$\hat{H}_{nm}\left(\boldsymbol{x}_s\right) \simeq \frac{\left\langle \psi_n^{(f)} \left| \left[\hat{H}_f\left(\boldsymbol{x}_f, \boldsymbol{x}_s\right), \hat{H}_s\left(\boldsymbol{x}_s\right) \right] \right| \psi_m^{(f)} \right\rangle}{\omega_{nm}^{(f)}\left(\boldsymbol{x}_s\right)}, \quad n \neq m$$

(сравните с формулой (5) предыдущего семинара.

Она была точной, в то время как тут мы пренебрегли коммутатором $\left[\hat{H}_{nm}\left(\boldsymbol{x}_s\right), \varepsilon_m^{(f)}\left(\boldsymbol{x}_s\right)\right]\Big)$. Опять-таки, покуда в системе нет вырождения или близких уровней, то оффдиагональными элементами $\hat{H}_{n\neq m}$ в ведущем порядке можно пренебречь.

Наконец, такая форма демонстрирует ещё один смысл адиабатического приближения.

Мы знаем, что если такой коммутатор равен нулю, то это означает, что в задаче разделяются переменные - достаточно независимо диагонализовать оба гамильтониана, и задача будет решена.

В этом смысле, стационарное адиабатическое приближение - это просто приближённое разделение переменных.

Диагональные элементы

Теперь разберёмся с диагональными элементами- на примере задачи Борна-Оппенгеймера, где интересующая нас часть гамильтониана, которая может действовать на параметр x_s, происходит просто из кинетической энергии $\hat{H}_s\left(\boldsymbol{x}_s\right) = \frac{\hat{p}_s^2}{2M}$. Тогда:

$$\left\langle \psi_n^{(f)} \left| \hat{p}_s^2 \right| \psi_n^{(f)} \right\rangle = \hat{p}_s^2 - 2 \cdot \boldsymbol{A}_n\left(\boldsymbol{x}_s\right) \hat{p}_s - \left\langle \psi_n^{(f)} | \nabla_s^2 \psi_n^{(f)} \right\rangle$$

где введена кривизна Берри (сравните с формулой (20) предыдущего семинара):

$$\boldsymbol{A}_n\left(\boldsymbol{x}_s\right) = i \left\langle \psi_n^{(f)}\left(\boldsymbol{x}_s\right) | \nabla_s \psi_n^{(f)}\left(\boldsymbol{x}_s\right) \right\rangle$$

Последнее слагаемое можно преобразовать:

$$\begin{aligned}\left\langle \psi_n^{(f)}|\nabla_s^2\psi_n^{(f)}\right\rangle &= -i\nabla_s A_n\left(x_s\right) - \left\langle \nabla_s\psi_n^{(f)}|\nabla_s\psi_n^{(f)}\right\rangle = \\ &= -i\nabla_s A_n\left(x_s\right) + \sum_k \left\langle \psi_n^{(f)}|\nabla_s\psi_k^{(f)}\right\rangle \left\langle \psi_k^{(f)}|\nabla_s\psi_n^{(f)}\right\rangle = \\ &= -i\nabla_s A_n\left(x_s\right) - A_n^2\left(x_s\right) + \sum_{k\neq n} \left\langle \psi_n^{(f)}|\nabla_s\psi_k^{(f)}\right\rangle \left\langle \psi_k^{(f)}|\nabla_s\psi_n^{(f)}\right\rangle\end{aligned}$$

Замечательно тут то, что первые два слагаемых, совместно с первыми двумя слагаемыми исходного выражения, собираются просто в комбинацию $\left(-i\nabla_s - A_n\left(x_s\right)\right)^2$. Последнее же слагаемое переписьвается как обычно через производные гамильтониана, и даст зависящую от координат добавку к эффективному гамильтониану медленной подсистемы.

Окончательно:

$$\left\langle \psi_n^{(f)}\left(\boldsymbol{x}_s\right)\left|\hat{\boldsymbol{p}}_s^2\right|\psi_n^{(f)}\left(\boldsymbol{x}_s\right)\right\rangle \equiv \left(\hat{\boldsymbol{p}}_s - \boldsymbol{A}_n\left(\boldsymbol{x}_s\right)\right)^2 + \sum_{k\neq n} \frac{\left|\left\langle \psi_n^{(f)}\left|\frac{\partial \hat{H}_f}{\partial \boldsymbol{x}_s}\right|\psi_k^{(f)}\right\rangle\right|^2}{\left(\omega_{nk}^{(f)}\left(\boldsymbol{x}_s\right)\right)^2}$$

Мь получили, что диагональный элемент $\hat{H}_{nn}\left(\boldsymbol{x}_s\right)$ в главном порядке действительно совпадает с просто $\hat{H}_s\left(x_s\right)$. Однако отличие заключается в дополнительном вкладе от фазы Берри, которая войдёт в эффективный гамильтониан медленных степеней свободы, и дополнительный вклад, являющийся просто добавкой к эффективной потенциальной энергии $\varepsilon_n^{(f)}\left(\boldsymbol{x}_s\right)$. Отметим, что его ещё можно переписать следующим образом:

$$\delta\varepsilon_n^{(f)}\left(\boldsymbol{x}_s\right) = \frac{1}{2M}\sum_{k\neq n} \boldsymbol{A}_{nk}\boldsymbol{A}_{kn}, \quad \boldsymbol{A}_{nk} = i\left\langle \psi_n^{(f)}\left(\boldsymbol{x}_s\right)|\nabla_s|\,\psi_k^{(f)}\left(\boldsymbol{x}_s\right)\right\rangle$$

Кривизна Берри входит в точности как обычный электромагнитный вектор-потенциал.

Любопытно, что он может модифицировать классические уравнения движения, добавив в них эффективное «магнитное поле», и вообще это некий нетривиальнь̆й топологический вклад в движение медленной подсистемы, который приходит от нетривиальной структуры «быстрых» волновых функций.

О случаях применения метода Борна-Опенгеймера (!??!)

О применениях в задачах про молекулы (!?!?!?)

(просто говорим, что переменные разделяются. серьезно, в этом и вся суть??? а иначе как бы было???)

Не может ли такое быть, что быстрая система влияет на медленную систему, как в маятнике Кпицы?

(вроде как мы фиксируем медленную систему и изучам быструю в ней, а может ли быть, что такой подход не работает, пусть и система явно делится на две такие части? Не знаю пока.)

6.7.7 Examples of Fast and Slow Subsystems by Migdal Krainov 1

Theory

Рассмотрим две подсистемы, одна из которых характеризуется большими, а другая - малыми частотами. Взаимодействие между подсистемами не предполагаетея малым.

Пусть ξ - совокупность координат медленной подсистемы. Гамильтониан всей системы имеет вид

$$H = H_1(x, \xi) + H_2(\xi),$$

где H_1 включает гамильтониан быстрой подсистемы и ее взаимодействие медленной подсистемой.

В предыдущем разделе мы считали, что движение медленной подсистемы классично: мы задавали траекторию $\xi = \xi(t)$ и вводили скорость ξ. Теперь это не будет предполагаться.

Введем систему собственных функций гамильтониана H_1:

$$H_1(x, \xi)\varphi_n(x, \xi) = \varepsilon_n(\xi)\varphi_n(x, \xi),$$

как это делалось и ранее. Решение всей задачи

$$H\Psi_\lambda = E_\lambda \Psi_\lambda$$

ищем в виде

$$\Psi_\lambda = \sum_{n'} u_{n'\lambda}(\xi)\varphi_{n'}(x, \xi).$$

Подставляя (2.40) в (2.39), имеем

$$(H_1 + H_2)\sum_n u_{n'\lambda}(\xi)\varphi_{n'}(x, \xi) = E_\lambda \sum_{n'} u_{n'\lambda}(\xi)\varphi_{n'}(x, \xi).$$

Умножим это равенство слева на $\varphi_n^*(x, \xi)$ и проинтегрируем по x, пользуясь ортогональностью функций $\varphi_n(x, \xi)$:

$$\int \varphi_n^*(x, \xi)\varphi_{n'}(x, \xi)dx = \delta_{nn'}$$

Получаем

$$(\varepsilon_n - E_\lambda)\, u_{n\lambda} + \int \varphi_n^* H_2 \sum_{n'} u_{n'\lambda}\varphi_{n'} dx = 0.$$

При этом для простоты предположено, что H_1 коммутирует с ξ. Далее, так как

$$H_2 u_{n'\lambda}\varphi_{n'} = \varphi_{n'} H_2 u_{n'\lambda} + [H_2, \varphi_{n'}]\, u_{n'\lambda},$$

то

$$(\varepsilon_n - E_\lambda)\, u_{n\lambda} + H_2 u_{n\lambda} = -\sum_{n'} \int \varphi_n'' \,[H_2, \varphi_{n'}]\, dx \cdot u_{n'\lambda}$$

Это соотношение аналогично соответствуюнему выражению в предыдущем разделе, только $i\xi^\circ \frac{\partial \varphi_n}{\partial \xi} = i\frac{d\varphi_n}{dt}$ заменяется коммутатором $[\mathrm{H}_2, \varphi_n]$.

В соотношении (2.41) можно перенести член с $n' = n$ налево:

$$\left\{ H_2 - \left(E_\lambda - \varepsilon_n - \int \varphi_n^* \,[H_2, \varphi_n]\, dx \right) \right\} u_{n\lambda} = -\sum_{n' \neq n} \int \varphi_n^* \,[H_2, \varphi_{n'}]\, dx \cdot u_{n'\lambda}$$

Это уравнение удобно для применения метода последовательных приближений. В нулевом приближении получаем уравнение

$$\left\{[H_2(\xi) - [E_\lambda - \varepsilon_n(\xi)]\right\} u^{(0)}_{n\lambda}(\xi) = 0.$$

Мы видим, что энергия быстрой подсистемы играет роль потенциальной энергии в эффективном гамильтониане меділенной подсистемы.

Колебательные уровни энергии молекулы

Оценим энергию колебаний молекулы. Для простоты мы напишем все выражения для иона молекулы водорода, хотя результаты без труда переносятся и на более сложные молекулы. Гамильтониан иона молекулы водорода имеет вид (в атомных единицах)

$$H = -\frac{1}{2}\Delta_r - \frac{1}{\left|r - \frac{1}{2}R\right|} - \frac{1}{\left|r + \frac{1}{2}R\right|} + \frac{1}{R} - \frac{1}{M}\Delta_R$$

Здесь M - масса протона, F-координата электрона, $\pm\frac{1}{2}R$ - координаты протонов (рис. 21). Ядра образуют медлениуг подсистему, а эпектрон - быструю. В обозначениях теории, развитой выше, примем за $H_1(x, \xi)$ гамильтониан

$$H_1(r, R) = -\frac{1}{2}\Delta_r - \frac{1}{\left|r - \frac{1}{2}R\right|} - \frac{1}{\left|r + \frac{1}{2}R\right|} + \frac{1}{R}$$

и за $H_2(\xi)$ гамильтониан

$$H_2(R) = -\frac{1}{M}\Delta_R$$

(конечно, 1/R можно было бы перенести в H_2). Введем

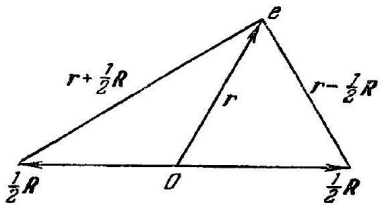

Рис. 21. Функцииг $\varphi_n(r, R)$, удовлетворяющие уравнению

$$H_1\varphi_n\{r, R) = \\ = \varepsilon_n(R)\varphi_n(r, R).$$

Они соответствуіот собственным функциям электрона при. фиксированном расстоянии между ядрами. Решение уравнения Шредингера с гамильтонианом Н имеет вид (см. стр. 94)

$$\Psi_\lambda = \sum_{n\nu} C^{n\nu}_\lambda \chi_{n\nu}(R)\varphi_n(r, R)$$

причем фупкиии $\chi_{n\nu}$ удовлетворнот уравнению

$$\left\{-\frac{1}{M}\Delta_R + \varepsilon_n(R)\right\}\chi_{n\nu}(R) = \omega_{n\nu}\chi_{n\nu}(R).$$

Ядра молекулы колеблются около некоторого среднего положения. Эти колебания имеют малую амплитуду. Поэтому для $\varepsilon_n(R)$ можно написать следующее приближенное выражение:

$$\varepsilon_n(R) \approx \varepsilon_n(R_0) + \frac{1}{2}\left(\frac{d^2\varepsilon_n}{dR^2}\right)_{R=R_0} \cdot (R-R_0)^2 .$$

Подставляя По $\varepsilon_n(R)$ в уравнение (2.44), получаем уравпоние Шредингера для трехмерного осциллятора. Следовательно, колсбателыные уровнц молекулы имеют вид

$$E_\lambda = \omega_{n\nu} = e_n(P_0) + \left(v + \frac{1}{2}\right)\omega_0,$$

гдє ω_0-частота классического осциллятора.

Найдем зависиность ω_0 от массы молекулы,

Из соотношения

$$\frac{1}{2}M\omega_0^2 (R-R_0)^2 = \frac{1}{2}\left(\frac{d^2\varepsilon_n}{dR^2}\right)_{R=R_0} \cdot (R-R_0)^2$$

вытекает, что

$$\omega_0 = \sqrt{\frac{1}{M}\left(\frac{d^2\varepsilon_n}{dR^2}\right)_{R=R_0}}.$$

Так как в атомных единицах электронные уровни $\varepsilon_n \sim 1$ и размеры молекулы $R_0 \sim 1$, то $\frac{d^2\varepsilon_n}{dR^2} \sim 1$ и, следовательно,

$$\omega_0 \sim \frac{1}{\sqrt{M}}.$$

Поскольку частоты электронных переходов $\omega_\pi \geqslant 1$, то мы Видим, ЧТО $\omega_0 \ll \omega_{9\pi}$.

Оценим амплитуду колебаний ядер. В основном состоянии осциллятора средние значения кинетической и потенциальной энергии совпадают: $\bar{T} = \bar{U} = E_0/2$ (E_0 - полная энергия), т. е.

$$\frac{1}{2}\left(\frac{d^2\varepsilon_n}{dR^2}\right)_{R=R_0} \cdot \overline{(R-R_0)^2} = \frac{1}{4}\omega_0.$$

Так как $\omega_0 \sim \sqrt{1/M}$, то величина среднего квадратичного отклонения ядра от положения равновесия имеет оценку

$$\sqrt{\overline{(R-R_0)^2}} \sim \frac{1}{\sqrt[4]{M}} \ll 1.$$

Покажем, что коэффициенты $C_\lambda^{n\nu}$ в выражении $\Psi_\lambda = \sum_{n\nu} C_\lambda^{n\nu}\chi_{n\nu}(R)\varphi_n(r,R)$, определяемые уравнением (2.42), можно вычислять методом последовательных приближений. Для этого оценим правую часть (2.42). Раскрывая коммутатор, получим члены следующего вида:

$$\left(\frac{1}{M}\chi_{n\nu}\varphi_n \Big| \frac{d\varphi_{n'}}{dR}\frac{d\chi_{n'}v'}{dR}\right), \quad \left(\frac{1}{M}\chi_{n\nu}\varphi_n \Big| \frac{d^2\varphi_{n'}}{dR^2}\chi_{n'v'}\right),$$

(члены вида $\left(\frac{1}{M}\chi_n, \varphi_n \Big| \varphi_{n'}\frac{d^2\chi_{n'v'}}{dR^2}\right)$ равны нулю). Оценим производные функции $\chi_{n\nu}$:

$$\frac{d\chi_{n_\nu}}{dR} \sim \frac{\gamma_{n_\nu}}{\sqrt{(R-R_0)^2}} \sim \sqrt[4]{(M}x_{n\nu}.$$

Поэтому из написанных двух типов членов самым большим будет первый: он порядка $1/\sqrt[4]{M^3}$. Итак, мы обосновали метод итераций в рассматриваемой задаче; каждая следующая итерация в $\sqrt[4]{M^3}$ раз меньше предыдущей.

кроме колебательных уровней, молекулы имеют также вращательные уровни. Частоты этих уровней обратно пропорциональны моменту инерции молекулы, т. е.

$$\omega_{\text{вран}} \sim 1/M.$$

Таким образом, электронные, колебательные и вращательные частоты находятся в следующем соотношении друг к другу:

$$\omega_{\text{вращ}} : \omega_{\text{кол}} : \omega_{\pi} = 1 : \sqrt{M} : M.$$

Возбуждение ядерных дипольных уровней быстрой частицей

Рассмотрим задачу о возбуждении атомного ядра при пролете мимо него быстрой заряженной частицы. В данном случае быстрая подсистема (налетающая частица) имеет сплошной спектр, а медленная (атомное ядро) - дискретный. Найдем решение, пользуясь адиабатической теорией возмущений. Для примснимости адиабатического приближения необходимо, чтобы время пролета частицы было мало гіо сравнению с существенными обратными частотами системы.

Сначала получим общне формулы для применения адиабатического приближения к задаче рассеяния. Введем собственные функции $\varphi_p(r, \xi_i)$ гамильтониана быстрой подсистемы $H_1 = T_r + V(r, \xi_i)$, где T_r - кинетическая энергия частицы, а $V(r, \xi_i)$ - ее взаимодействие с медленной подсистемой; ξ_i координаты медленной, r - быстрой подсистемы.

Таким образом, функции φp удовлетворяют уравнению

$$H_1 \varphi_p(r, \xi_i) = \varepsilon_p \varphi_p(r, \xi_i)$$

Энергия частицы $\varepsilon_p = p^2/2M$, т. е. не зависит от ξ_i, в отличне от случая дискретного спектра.

Ищем решение (2.45), имеющее асимптотический вид:

$$\varphi_{p\to\infty} \to e^{ipr} + \frac{f(\vartheta, \xi_i)}{r} e^{ipr}.$$

Поскольку ε_p не зависит от ξ_i, то уравнение для волновой функции медленной подсистемы (т. е. для ядра) будет таким же, как и без ε_p (только со сдвинутыми на ε_p собственными значениями):

$$H_2 \chi_n(\xi_i) = \omega_n \chi_n(\xi_i).$$

Ищем решение задачи в виде

$$\Psi_{pn} = \sum_n \int \frac{dp'}{(2\pi)^3} C_{pn}^{p'n'} \varphi_{p'} \chi_{n'}$$

причем коэффициенты $C_{pn}^{p'n'}$ подчиняются уравнению (см. (2.42))

$$(\omega_n - E_{p_0 n_0}) C_{p_n}^{p_0 n_0} = -\sum_{n'} \int \frac{dp'}{(2\pi)^3} (\varphi_p \chi_n [H_2, \varphi_{p'}] \chi_{n'}) C_{p_n}^{p'n'}.$$

Это уравиение можно решать последовательными приближениями. Пусть в начальный момент времени ($t = -\infty$) система находилась в состоянии ($\boldsymbol{p}_0, \boldsymbol{n}_0 \equiv 0$). Тогда в нулевом приближении

$$\Psi_{p_0 0}^{(0)} = C_0 \varphi_{p_0} x_0.$$

Точное решение должно иметь асимптотический вид:

$$\Psi \underset{r\to\infty}{\longrightarrow} e^{ip_0 r}\chi_0(\xi_i) + \frac{1}{r}\sum_n f_n(\vartheta) e^{ip_n r}\chi_n(\xi_i).$$

3 Зесь импульс p_n определяется законом сохранения энергии:

$$\varepsilon_{p_n} + \omega_n = \varepsilon_{p_0} + \omega_0.$$

Пренебрегая изменением энергии частицы, получим

$$\Psi \underset{r\to\infty}{\to} e^{ip_0 r}\chi_0(\xi_i) + \frac{e^{ip_0 r}}{r}\sum_n f_n(\vartheta)\chi_n(\xi_i).$$

Сравним с этим выражением асимптотический вид приближенного ренения $\Psi_{p_0\theta}^{(0)}$. Согласно (2.46) имеем

$$\Psi_{p_0 0}^{(0)} \underset{r\to\infty}{\longrightarrow} C_0\left(e^{ip_0 r}\chi_0(\xi_i) + \frac{e^{ip_0 r}}{r} f(\vartheta, \xi_i)\chi_0(\xi_i)\right) =$$
$$= C_0\left(e^{ip_0 r}\chi_0(\xi_i) + \frac{e^{ip_0 r}}{r}\sum_n (\chi_n f \chi_0)\chi_n\right).$$

Из сравнения (2.47) и (2.48) находим C_0 и амплитуды упругого и неупругого рассеяния:

$$C_0 = 1,$$
$$f_0(\vartheta) = (\chi_0(\xi_i)|f(\vartheta, \xi_i)|\chi_0(\xi_i))$$
$$f_n(\vartheta) = (\chi_n(\xi_i)|f(\vartheta, \xi_i)|\chi_0(\xi_i))$$

Используем полученные результаты для вычисления сечения возбуждения ядерных дигольных уровней быстрой заряженной частицей. Кулоновское взаимодействие пролетающей частицы с нуклонами ядра имеет вид (Z_1 - заряд частицы, Z_2 - заряд ядра):

$$V = Z_1\sum_i \frac{1}{|r - r_i|} = \frac{Z_1 Z_2}{r} + Z_1\frac{dr}{r^3} + ...$$

где d-динольный момент ядра. Этот потенциал можно представить в виде кулоновского, но со сдвинутым началом:

$$V \approx \frac{Z_1 Z_2}{\left|r - \frac{1}{Z_2}a\right|}$$

Для этого нужно, чтобы величина $a = d/Z_2$ была мала по сравнениио с существеными r, т. е. по сравнения с прицельным параметром $\rho : a \ll \rho$.

Следовательно, волновые функции φ_p будут кулоновскими волновыми функциями со сдвинутым аргументом:

$$\varphi_p(r, \xi_i) = \varphi_p^Q\left(r - \frac{1}{Z_2}d\right)\psi(\xi_i).$$

Выберем $\gamma(\xi_i)$ так, чтобы p имела асимптотический вид (2.46) :

$$\varphi_p(r,\xi_i) \underset{r\to\infty}{\to} \left\{\exp\left[ip\left(r-\frac{1}{Z_2}d\right)\right]+\frac{fQ(\vartheta)}{r}\exp\left[ip|r-\frac{1}{Z_2}d\right]\right\}\gamma(\xi_i),$$

где fQ - амплитуда кулоновского рассеяния. Для совпадения с (2.46) следует взять $\gamma(\xi_i) = e^{ipa}/Z_2$. Тогда

$$\varphi_p(r,\xi_i) \underset{r\to\infty}{\longrightarrow} e^{ipr}+\frac{e^{ipr}}{r}fQ(\vartheta)\exp\left[ip\left|r-\frac{1}{Z_2}d\right|+ipd\frac{1}{Z_2}-ipr\right]$$

Так как $\left|r-\frac{1}{Z_2}d\right| \approx r-\frac{1}{Z_2}\frac{dr}{r}$, то

$$\varphi_p(r,\xi_i) \underset{r\to\infty}{\longrightarrow} e^{ipr}+\frac{e^{ipr}}{r}fQ(\vartheta)\exp\left[iqd\frac{1}{Z_2}\right],$$

где $\boldsymbol{q} \equiv \boldsymbol{p}-\frac{\boldsymbol{p}}{r}r$ - векор, характеризубощий изменение импульса налетающей частицы цри столкновении. Поэтому согласно (2.49)

$$f_n(\vartheta) = f^Q(\vartheta)\left(x_n\left|\exp\left(iqd\frac{1}{Z_2}\right)\right|x_0\right).$$

Здесь f^Q - амплитуда кулоновского рассеяния.

Заметим, что сумма сечений для всех возбуждений равна

$$\sum_n |f_n(\vartheta)|^2 = \sum_n\left(x_0\left|\exp\left(-iqd\frac{1}{Z_2}\right)\right|\chi_n\right)\times\left(x_n\left|\exp\left(iqa\frac{1}{Z_2}\right)\right|x_0\right)\left|f^Q(\vartheta)\right|^2 = \left|f^Q(\vartheta)\right|^2,$$

т. е. равна сечению кулоновского рассеяния.

Если угол отклонения ϑ мал (малый переданный импульс), то из (2.50) получаем формулу теории возмущений:

$$f_n(\boldsymbol{\vartheta}) \approx f^Q(\boldsymbol{\vartheta})\left(\chi_n\left|\frac{i}{Z_2}qd\right|\chi_0\right),$$

амплитуда возбуждения пропорциональна дипольному матричному элементу.

Рассеяние протона на атоме водорода (перезарядка)

Рассмотрим рассеяние протона на атоме водорода, когда скорость протона много меньше скорости атомного электрона. В противоположность предыдущему случаю здесь дискретна быстрая подсистема, а у медленной подсистемы непрерывный спектр. Гамильтониан системы имеет вид

$$H = T_r-\frac{1}{\left|r-\frac{1}{2}R\right|}-\frac{1}{\left|r+\frac{1}{2}R\right|}+\frac{1}{R}-\frac{1}{M}\Delta_R.$$

В разделе 2.4 мы рассм атривали R как заданную функцию времени. Теперь мы рассматриваем налетающий протон и атом водорода как две взаимодействующие квантовомеханические системы.

Гамильтониан H симметричен к перестановке налетающей и покоящейся частиц ($\boldsymbol{r} \longrightarrow -\boldsymbol{r}$). Поэтому можно ввести симметричные и ағітисимметричные функции $\varphi_n^s(r,R)$ и $\varphi_n^a(r,R)$. Если нуклоны находятся далеко друг от друга, то электрон может находиться около одного либо около другого протона, и, следовательно,

$$\varphi_n^{s,a}(r,R) \underset{R\to\infty}{\longrightarrow} \frac{1}{\sqrt{2}}\left[\varphi_n^Q\left(r-\frac{1}{2}R\right)\pm\varphi_n^Q\left(r+\frac{1}{2}R\right)\right]$$

где в правой части стоят волновые функции атома водорода.

Предположим, что при сближении ядер не происходит пересечения термов. Тогда можно классифицировать их по тем состояниям, из которых они образовались.

Будем считать, что сначала электрон был около протона с координатой $R/2$, т. е. его волновая функция имеет вид

$$\varphi = \varphi^Q_{n_0}\left(r - \frac{1}{2}R\right).$$

Гамильтониан медленной подсистемы равен

$$H_2(R) = -\frac{1}{M}\Delta_R,$$

а его собственные функцни находятся из уравнения

$$\left[-\frac{1}{M}\Delta_R + \varepsilon^{s,a}_n(R)\right]\chi^{s,a}_{pn}(R) = E_p\chi^{s,a}_{pn}(R)$$

и имеют асимптотический вид

$$X^{s,a}_{pn}(R) \underset{R\to\infty}{\longrightarrow} e^{ipR} + \frac{f^{s,a}_n}{R}e^{ipR}.$$

В нулевом приближении решение задачи имеет вид (см. стр. 94)

$$\Psi_\lambda = C^{\lambda s}_{np}\varphi^s_n(r,R)\chi^s_{pn}(R) + C^{\lambda a}_{np}\varphi^a_n(r,R)\chi^a_{pn}(R)$$

Коэффициенты $C^{\lambda s}_{np}$ и $C^{\lambda a}_{np}$ определяются из асимптотического вида Ψ_λ :

$$\Psi_\lambda \underset{R\to\infty}{\to} \varphi^Q_{n_0}\left(r - \frac{1}{2}R\right)e^{ip_0R} + \left[f_1\varphi^Q_{n_0}\left(r - \frac{1}{2}R\right) + f_2\varphi^Q_{n_0}\left(r + \frac{1}{2}R\right)\right]\frac{e^{ip_0R}}{R},$$

где f_1 - амплитуда упругого рассеяния, а $f_2 \to$ амплитуда перезарядки.

Чтобы обеспечить асимптотический вид (2.53), нужно считать в (2.52)$p = p_0$ и $n = n_0$. Тогда волновая функцня (2.52) становится равной

$$\Psi_\lambda = C^s\varphi^s_{\pi_0}(r,R)\chi^s_{p_0n_0}(R) + C^a\varphi^a_{n_0}(r,R)\chi^a_{p_0n_0}(R)$$

и имеет асимптотический вид

$$\Psi_\lambda \underset{R\to\infty}{\longrightarrow} e^{ip_0R}\left(C^s\varphi^s_{n_0} + C^a\varphi^a_{n_0}\right) + \frac{1}{R}e^{ip_0R}\left(f^sC^s\varphi^s_{n_0} + f^aC^a\varphi^a_{n_0}\right)\cdot \quad (2.54)$$

Выражения (2.53) и (2.54) должны совпадать, т. е. нужно потребовать

$$C^s = C^a = \frac{1}{\sqrt{2}}.$$

Тогда из (2.54) находим

$$\begin{aligned}\frac{f^s\varphi^s_{n_0} + f^a\varphi^a_{n_0}}{\sqrt{2}} = \frac{1}{2}\Bigg\{f^s\left[\varphi^Q_{n_0}\left(r - \frac{1}{2}R\right) + \varphi^Q_{n_0}\left(r + \frac{1}{2}R\right)\right] + \\ + f^a\left[\varphi^Q_{n_0}\left(r - \frac{1}{2}R\right) - \varphi^Q_{n_0}\left(r + \frac{1}{2}R\right)\right]\Bigg\} = \\ = f_1\varphi^Q_{n_0}\left(r - \frac{1}{2}R\right) + f_2\varphi^Q_{n_0}\left(r + \frac{1}{2}R\right),\end{aligned}$$

Т. е.

$$f_1 = \frac{f_i^s + f^a\rfloor}{2}, \quad f_2 = \frac{f_1^s - f^a}{2}.$$

Таким образом, для нахождения амплитуды перезарядки f_2 и амплитуды упругого рассеяния f_1 необходимо вычислить амплитуды f^s и f^a. Чтобы найти их, нужно решить уравнение

$$\left[-\frac{1}{M}\Delta_R + \varepsilon_n^{s_n,a}(R)\right]\chi_{pn}^{s,a} = E_p\chi_{pn}^{s_s a}$$

с величинами $\boldsymbol{\varepsilon}_n^{s,a}(R)$, которые определяются из решения задачи об электроне в поле двух центров. В дальнейшем (стр. 151) мы найдем решение этой задачи в квазиклассическом приближении.

6.7.8 Examples of Fast and Slow Subsystems by Migdal Krainov 2

Рождение мягких квантов при рассеянии («инфракрасная катастрофа»)

Рассмотрим задачу о рождении мягких квантов при рассеянии частицы на ядре. Будем предполагать частицу нерелятивистской. Гамильтониан системы имеет вид

$$H = T + V - \frac{1}{c}pA + H_r.$$

Здесь T - кинетическая энергия частицы, V - рассеивающий потенциал, - $\frac{1}{c}pA$ - взаимодействие частицы с полем квантов, H_γ - гамильтониан поля квантов.

Предположим, что энергия квантов много меньше энергии частицы. Тогда движение частицы можно считать заданным и рассматривать только ту часть гамильтониана, которая содержит операторы, действующие на $\boldsymbol{\psi}$-функцию квантов. Гамильтониан γ-квантов за время столкновения, которое будем считать малым, меняется от величины $H_0 = H_\gamma - \frac{1}{c}p_0A$ до столкновения к величине $H_1 = H_\Upsilon - \frac{1}{c}p_1A$ после столкновения. Перейдем в систему координат, в которой частица до рассеяния покоилась. Тогда

$$H_0 = H_\gamma, \quad H_1 = H_\gamma - \frac{1}{c}qA,$$

где $q = p_1 - p_0$ - изменение импульса частицы в результате столкновения.

Возмущение $-\frac{1}{c}qA$ для малых частот становится большим, так как $A_{k\omega} \sim 1/\sqrt{\omega}$. Поэтому мы не будем пользоваться теорией возмущений, а используем только внезапность изменения гамильтониана γ-квантов.

Введем собственные фуикции χ_n гамильтониана H_0 и χ_n' гамильтоннана H_1. Предположим, что до столкновения система γ-квантов находилась в состоянии χ_0 Ввиду внезапности столкновения волновая функция системы χ_0 практически не изменяется. Следовательно, амплитуда перехода в состояние χ_n' равна $(\chi_n'|\chi_0)$ (см - стр. 75).

Представим гамильтониан электромагнитного поля $H_\gamma = \int\left(\frac{1}{8\pi c^2}\dot{A}^2 + \frac{1}{8\pi}(\mathrm{rot}\,A)^2\right)dr$ в виде суммы гамильтонианов отдельных осцилляторов поля. Для этого запишем векторный потенциал A в виде

$$A = \sum_{k\lambda}\sqrt{2\pi c^2}\eta_{k\lambda}\left(q_{k\lambda}\exp\left(ikr - i\omega_{k\lambda}t\right) + q_{k\lambda}^*\exp\left(-ikr + i\omega_{k\lambda}t\right)\right)$$

Здесь k - волновой вектор, λ - поляризация, $\omega_{k\lambda}$ - энергия квантов, $\eta_{k\lambda}$ - единичный вектор поляризации. Обозначая

$$q = Q + \frac{i}{\omega}P, q^* = Q - \frac{i}{\omega}P$$

и подставляя в H_γ, получим

$$H_r = \sum_{k\lambda} \frac{1}{2}\left(P^2 + \omega^2 Q^2\right)_{k\lambda}$$

В случае мягких квантов экспоненту e^{ikr} можно заменить единицей. Будем считать временны́е множители $\exp(\pm i\omega_{k\lambda}t)$ включенными в $q_{k\lambda}, q^*_{k\lambda}$. Опустим далее для простоты индексы $k\lambda$ при $q_{k\lambda}, q^*_{k\lambda}$. Тогда

$$A = \sum \sqrt{2\pi c^2}\eta \cdot 2Q.$$

(!?!??!!? подумаю еще про эту формулу???)

Гамильтониан квантов H_1 имеет вид

$$H_1 = \sum \left\{ \frac{1}{2}\left(P^2 + \omega^2 Q^2\right) - 2\sqrt{2\pi}(\eta g)Q \right\}.$$

Представим его в виде суммы осцилляторных гамильтонианов со смещенной координатой:

$$H_1 = \sum \left\{ \frac{1}{2}P^2 + \frac{1}{2}\omega^2(Q-\delta)^2 + \frac{1}{2}\omega^2\delta^2 \right\},$$

где $\delta = \frac{2\sqrt{2\pi}}{\omega^2}(\eta \boldsymbol{q})$.

Следовательно, волновые функции после столкновения $\chi'_n(Q)$ имеют вид осцилляторных функций, но со смещенной координатой:

$$\chi'_n(Q) = \chi_n(Q-\delta).$$

Таким образом, амплитуда перехода в состояние $x_n^{\dot{n}}$ имеет вид

$$C_n = \int \chi_n(Q-\delta)\chi_0(Q)dQ.$$

Предельные случаи

Рассмотрим сначала два предельных случая - малые и большие δ по сравнению с амплитудой нулевых колебанй. Если δ мало, то из $C_n = \int \chi_n(Q-\delta)\chi_0(Q)dQ$ /следует

$$C_n \approx -\delta \int \frac{\partial \chi_n}{\partial Q}\chi_0 dQ = i\delta(P)_{0n}$$

где P - оператор импульса. Он имеет отличные от нуля матричные элементы лишь для изменения числа квантов на единицу: $(P)_{01} = \frac{1}{2}\sqrt{\omega}$. Поэтому вероятность испускания одного кванта равна $w_1 = \frac{1}{4}\omega\delta^2 = \frac{2\pi}{\omega^3}(\eta q)^2\cdot$ Эта формула совпадает с результатом обычной теории возмущений.

Оценим матричный элемент $C_n = \int x_n(Q-\delta)\chi_0(Q)dQ$, когда смещение δ много больше амплитуды колебаний осциллятора. Для этого воспользуемся квазиклассическим выражением для функции x_n (см. 1.1 и 3.1) :

$$\chi_n(Q) = \frac{a_n}{\sqrt[4]{E_n - 1/2Q^2}} \cos\left(\int \sqrt{E_n - 1/2Q^2}dQ - \frac{\pi}{4}\right)$$

Для простоты здесь частота осциллятора ω взята равной единице. Результаты легко переносятся на случай $\omega \neq 1$. Нормировочный множитель a_n порядка единицы. Действительно,

$$1 = \int x_n^2 dQ \sim \frac{a_n^2}{\sqrt{E_n}} l_n \sim \frac{a_n^2}{\sqrt{E_n}}\frac{\sqrt{E_n}}{\omega}$$

Поэтому

$$C_n \sim \int \frac{\exp(-Q^2)}{\sqrt[4]{E_n - 1/2(Q-\delta)^2}} \cos\left(\int \sqrt{E_n - \frac{1}{2}(Q-\delta)^2} dQ - \frac{\pi}{4}\right) dQ$$

Так как величина δ, по предположению, много больше амплитуды нулевых колебаний, то можно под знаком корня в (2.65) пренебречь членом $Q^2/2$. Обозначим $E_n - \delta^2/2 \equiv \Delta E$ и заменим переменную интегрирования $Q : \Delta E/\delta + Q = x$. Тогда из (2.65) находим:

$$C_n \sim \int_0^\infty \frac{\cos\left(\delta^{1/2} x^{2/2}\right)}{\sqrt[4]{\delta x}} \exp\left(-x^2 + 2x\frac{\Delta E}{\delta}\right) dx \exp\left[-\left(\frac{\Delta E}{\delta}\right)^2\right]$$

Значения x, существенные в этом интеграле, соответствуют аргументу косинуса порядка единицы, т. е. имеют порядок величины $x \sim \delta\delta^{-1/2}$. Поэтому

$$C_n \sim \frac{1}{\sqrt[4]{\delta}} \frac{1}{\sqrt[12]{\delta}} \delta^{-1/3} \exp\left[-\left(\frac{\Delta E}{\delta}\right)^2\right] \sim \frac{1}{\sqrt{\delta}} \exp\left[-\left(\frac{\Delta E}{\delta}\right)^2\right],$$

$$|C_n|^2 \sim \frac{1}{\delta} \exp\left[-2\left(\frac{\Delta E}{\delta}\right)^2\right].$$

Таким образом, распределение вероятности испускания квантов имеет вид гауссовой кривой с максимумом $w_{\max} \sim 1/\delta$ и шириной $\Delta E \sim \delta$ около значения $E = \delta^2/2$. Это значение, как нетрудно видеть, совпадает с энергией классического осциллятора, начало координат которого внезапно сдвинуто на величину δ.

Случай произвольных δ

Теперь перейдем к вычислению C_n для произвольных δ. Вычислим сначала вероятность того, что не будет рождено ни одного кванта данного типа, т. е.

$$w_0 = \left|\int x_0(Q-\delta) x_0(Q) dQ\right|^2.$$

Так как волновая функция основного состояния осциллятора имеет вид

$$x_0(Q) = \sqrt[4]{\frac{\omega}{\pi}} \exp\left(-\frac{1}{2}\omega Q^2\right),$$

то

$$w_0 = \left|\sqrt{\frac{\omega}{\pi}} \int_{-\infty}^{\infty} \exp\left(-\omega Q^2 - \frac{1}{2}\omega\delta^2 + \omega Q\delta\right) dQ\right|^2 =$$

$$= \exp\left(-\frac{1}{4}\omega\delta^2\right) = \exp\left[-\frac{2\pi}{\omega^3}(q\eta)^2\right].$$

Восстановим теперь значки $\boldsymbol{k}, \lambda$. Тогда

$$\mathbf{0}_0^{k\lambda} = \exp\left[-\frac{2\pi}{\omega_{k\lambda}^3}\left(q\eta_{k\lambda}\right)^2\right]$$

- вероятность того, что не будет излучен ни один квант k, λ.

Вероятность того, что вообще не родится ни одного кванта ни в каком состоянии, равна

$$W_0 = \prod_{k\lambda} w_0^{k\lambda} = \exp\left[-\sum_{k\lambda} \frac{2\pi}{\omega_{k\lambda}^3} \left(q\eta_{k\lambda}\right)^2\right].$$

Для вычисления W_0 нужно найти сумму

$$\sum_{k\lambda} \frac{2\pi}{\omega_{k\lambda}^3} \left(q\eta_{k\lambda}\right)^2 = \sum_{\lambda} 2\pi \left(q\eta_{k\lambda}\right)^2 \int \frac{\omega^2 d\omega d\Omega}{(2\pi)^3 c^3 \omega^3}.$$

Мы видим, что при малых частотах это выражение логарифмически расходится. Следовательно, (???? как это следует?? разве не должна быть бесконечная вероятность????) $W_0 = 0$, т. е. любое торможение всегда будет сопровождаться излучением мягких квантов.

Вычислим матричный элемент $C_n = \int \chi_n(Q-\delta)\chi_0(Q)dQ$ для произвольных n. Осцилляторная волновая функция $\chi_n(Q)$ имеет вид

$$\chi_n(Q) = \sqrt[4]{\frac{\omega}{\pi}} \frac{1}{\sqrt{2^2 n!}} \exp\left(-\frac{1}{2}\omega Q^2\right) H_n(\sqrt{\omega}Q)$$

где H_n - полиномы Эрмита. Поэтому

$$C_n = \frac{\sqrt{\omega}}{\sqrt{\pi 2^n n1}} \int \exp\left[-\frac{1}{2}\omega Q^2 - \frac{1}{2}\omega(Q-\delta)^2\right] H_n(\sqrt{\omega}Q)dQ.$$

Этот интеграл легко вычислить, используя производящие функции полиномов Эрмита

$$\exp\left(-t^2 + 2t\xi\right) = \sum_{n=0}^{\infty} \frac{t^n}{n!} H_n(\xi).$$

В результате получается

$$C_n = \frac{\alpha^n}{\sqrt{n!}} \exp\left(-\frac{1}{2}\alpha^2\right),$$

где $\alpha^2 = \frac{1}{4}\omega\delta^2 = \frac{2\pi}{\omega^3}(q\eta)^2$.

Вероятность испускания квантов с различными $k\lambda$ равна произведению квадратов выражений $C_n = \frac{\alpha^n}{\sqrt{n!}} \exp\left(-\frac{1}{2}\alpha^2\right)$, т. е.

$$W = \exp\left[-\sum_{k\lambda} \alpha_{k\lambda}^2\right] \prod_{k\lambda} \frac{\left(\alpha_{k\lambda}\right)^{2n} k\lambda}{(n_{k\lambda})!}.$$

Найдем среднее число квантов, излученных при торможении:

$$\bar{n}_{k\lambda} = \sum_{n_{k\lambda}} n_{k\lambda} w_n^{k\lambda} = \exp\left[-\alpha_{k\lambda}^2\right] \sum_{n_{k\lambda}} \frac{\left(\alpha_{k\lambda}\right)^{2n} k\lambda}{(n_{k\lambda})!} n_{k\lambda} =$$

$$= \exp\left[-\alpha_{k\lambda}^2\right] \sum_{n_{k\lambda}} \frac{\alpha_{k\lambda}^2}{(n_{k\lambda}-1)!} \left(\alpha_{k\lambda}\right)^2 \left(n_{k\lambda}^{-1}\right) = \alpha_{k\lambda}^2 = \frac{2\pi}{\omega_{k\lambda}^3} \left(q\eta_{k\lambda}\right)^2.$$

Таким образом, для вероятности испускания n квантов тина $\boldsymbol{k}, \lambda$ мы получаем следующую формулу:

$$w_n^{k\lambda} = \frac{\left(\bar{n}_{k\lambda}\right)^n k\lambda}{(n_{k\lambda})!} \exp\left(-\bar{n}_{k\lambda}\right).$$

Она совпадает с распределением Пуассона.

Вероятность испускания одного кванта данного типа, как видно из $w_n^{k\lambda} = \frac{(\bar{n}_{k\lambda})^n k\lambda}{(n_{k\lambda})!} \exp(-\bar{n}_{k\lambda})$, равна

$$\boldsymbol{w}_1^{k\lambda} = \bar{n}_{k\lambda} \exp(-\bar{n}_{k\lambda}).$$

При $\bar{n}_{k\lambda} \ll 1$ получаем $w_1^{k\lambda} \approx \bar{n}_{k\lambda}$. Это выражение совпадает с результатом обычной теории возмущений. (?????)

Из (2.68) мы видим, что сечение чисто упругого рассеяния строго равняется нулю. На опыте под упругим рассеянием понимают рассеяние, при котором энергия излученных квантов меньше некоторой величины E_1, которая определяется точностью измерения. Наблюдаемое сечение рассеяния равно

$$\sigma_{\text{набл}} = \sigma_0 W_0'.$$

Здесь σ_0 - вычисленное сечение упругого рассеяния без учета излучения, W_0' - вероятность того, что не излучено ни одного кванта с энергией, большей E_1. Как мы видели,

$$W_0' = \exp\left[-\int_{E_1}^{E} \frac{2\pi}{\omega^3} (q\eta_{k\lambda})^2 \frac{\omega^2 d\omega}{c^3(2\pi)^3}\right] = \exp\left[-2\pi \frac{2}{3} \frac{1}{(2\pi)^3} \frac{q^2}{c^3} \ln \frac{E}{E_1}\right].$$

В качестве верхнего предела мы взяли энергию электрона, хотя предположение о мягкости квантов нарушается уже при меньших энергиях. Если $\ln(E/E_1)$ достаточно велико, то это внесет малую ошибку.

Сечение излучения произвольного числа квантов любого типга равно

$$\sigma = \sigma_0 \sum_n W_n = \sigma_0$$

Если бы мы пользовались теорией возмущений, то получилось **b**

$$w_1^{k\lambda} = \frac{2\pi}{\omega_{k\lambda}^3} (q\eta_{k\lambda})^2,$$

$$W_1 = \sum_{k\lambda} w_1^{k\lambda} = \frac{2\pi \cdot 2q^2}{(2\pi)^3 c^3} \int_0^E \frac{d\omega}{\omega},$$

т.е. выражение, расходящееся на нижнем пределе. Эта расходимость, связанная с незаконным применением теории возмущений, называется инфракрасной расходимостью («инфракрасной катастрофой»).

(?!?!?? еще раз продумаю все это!!!!!)

6.7.9 Adiabatic Methods: Other Statements

Как догадаться про адиабатические методы?

(потом продумаю, пока есть просто предположения)

What if one takes into account "measurements" at the intermediate stage?

In adiabatics, we assume that change of the energy level is occurring after the evolution. Not like a particle can be measured ones it locates at a new level. This is the big question about measurement, and we are not touching it here. Change of the state in scope of the adiabatic

method happens only by change of coefficients and this is what we are dealing with. Thus it is only an approximate method for toy models and in real life, there are a lot of interactions in the intermediate dynamics which are not taken into account.

(???? but how to take into account that a particle can be measured at the intermediate stage of dynamics??? Maybe, it is related to Quantum Zeno effect?)

6.8 Variational methods: basics

6.8.1 Variational methods by Tong

(его читал, впишу, очень хорошее объяснение)

6.8.2 Variational methods by Zhou

(его читал, впишу, очень хорошее объяснение)

$$
\begin{aligned}
\Delta E= & \frac{8\pi^2 e^2}{4\pi\epsilon_0}\left(\frac{Z^3}{\pi a_0^3}\right)^2 \int dr_1 r_1^2 e^{-2Zr_1/a_0} \int dr_2 r_2^2 e^{-2Zr_2/a_0} \int\limits_{-1}^{+1} d\left(\cos\theta_2\right) \frac{1}{\sqrt{r_1^2+r_2^2-2r_1r_2\cos\theta_2}} \\
= & -\frac{2\pi e^2}{\epsilon_0}\left(\frac{Z^3}{\pi a_0^3}\right)^2 \int dr_1 r_1^2 e^{-2Zr_1/a_0} \int dr_2 r_2^2 e^{-2Zr_2/a_0} \frac{\sqrt{\left(r_1-r_2\right)^2}-\sqrt{\left(r_1+r_2\right)^2}}{r_1r_2} \\
= & -\frac{2\pi e^2}{\epsilon_0}\left(\frac{Z^3}{\pi a_0^3}\right)^2 \int dr_1 r_1^2 e^{-2Zr_1/a_0} \int dr_2 r_2^2 e^{-2Zr_2/a_0} \frac{|r_1-r_2|-|r_1+r_2|}{r_1r_2} \\
= & \frac{8\pi e^2}{\epsilon_0}\left(\frac{Z^3}{\pi a_0^3}\right)^2 \int\limits_{r_2}^{\infty} dr_1 r_1 e^{-2Zr_1/a_0} \int\limits_0^{\infty} dr_2 r_2^2 e^{-2Zr_2/a_0} \\
= & \frac{8\pi e^2}{\epsilon_0}\left(\frac{Z^3}{\pi a_0^3}\right)^2 \int\limits_0^{\infty} dr_2 r_2^2 \left(\frac{a_0 r_2}{2Z}+\frac{a_0^2}{4Z^2}\right) e^{-4Zr_2/a_0} \\
= & \frac{5}{8}\frac{Ze^2}{4\pi\epsilon_0 a_0} = \frac{5Z}{4}Ry
\end{aligned}
$$

6.8.3 Variational proof that any 2D potential well supports at least one bound state by Yang, de Llano

(такое пока сам я не могу сделать, нужно будет - поучусь у них этому, небольшая статья)

6.9 Semiclassical methods

Обсудим подробно квазиклассику (или ВКБ методы, JWKB, WKB).

6.9.1 Main Semiclassical Methods

(по идее это в 1ю часть перенесу)

итоговые методы

вроде бы тут дело в том, что мы хотим научиться приближенно решать некоторые типичные диффуры в классических, то есть больших по сравнению с $\hbar$, масштабах.

(??)

Здесь волновая функция представлена как показательная функция, квазиклассически расширенная, а затем или амплитуда, или фаза медленно изменяются.

$$\frac{1}{2m}\left(\frac{\partial S}{\partial x}\right)^2 + U(x) = E \to S(x) = \int\limits_{x_0}^{x} p(x)dx, \quad p(x) = \sqrt{2m(E-U(x)}$$

Решения этого уравнения буквально соответствуют классическому действию как функции координат.

Однако, несложно Вычислить поток на такой волновой функции, мы получим $j(x) = \hbar p(x)/m$ - а в стационарных состояниях этот поток обязан не зависеть от координат.

Поэтому необходим учёт следующего порядка, который восстанавливает унитарность.

Тем самым, общий вид волновой функции в квазиклассическом приближении имеет вид (тут и дальше мы положили $\hbar = 1$):

$$\psi_{\pm}(x) = \frac{e^{\pm i\int\limits_{x_0}^{x} p(x)dx}}{\sqrt{p(x)}}, \quad \psi(x) = c_+\psi_+(x) + c_-\psi_-(x)$$

$$\psi_{\pm}(x) = \frac{c_{\pm}}{\sqrt{|p(x)|}} e^{\pm\int\limits_{x_0}^{x}|p(x)|dx}|, \quad |p(x)\,| = \sqrt{2m(U(x)-E)}$$

$$\left|\frac{dp}{dx}\right| \ll p^2 \leftrightarrow \left|\frac{d\lambda}{dx}\right| \ll 1 \leftrightarrow m\left|\frac{\partial U/\partial x}{p^3}\right| \ll 1$$

Алгоритм вывода правил Бора-Зоммерфельда (!?!?!??!)

(часто это нужно, я пока хз.)

сшивка

$$x < x_0 \to z < 0: \quad p(z) = \sqrt{-z}, \quad S(z) = \int\limits_0^z p(z)dz = -\frac{2}{3}(-z)^{3/2},$$

$$\psi_{\pm}(z) = \frac{1}{(-z)^{1/4}}\exp\left(\mp\frac{2}{3}i(-z)^{3/2}\right)$$

$$x > x_0 \to z > 0, \quad |p(z)| = \sqrt{z}, \quad \tilde{S}(z) = \int\limits_0^z |p(z)|dz = \frac{2}{3}z^{3/2}$$

$$\psi_{\pm}(z) = \frac{1}{z^{1/4}}\exp\left(\pm\frac{2}{3}z^{3/2}\right)$$

$$-\psi''(z) + z\psi(z) = 0 \to \psi(z) = C_1\,\mathrm{Ai}(z) + C_2\,\mathrm{Bi}(z)$$

$$\mathrm{Ai}(|z|\gg 1)\approx\begin{cases}\frac{1}{2\sqrt{\pi}z^{1/4}}\exp\left(-\frac{2}{3}z^{3/2}\right), & z>0,\\ \frac{1}{\sqrt{\pi}(-z)^{1/4}}\sin\left(\frac{2}{3}(-z)^{3/2}+\frac{\pi}{4}\right) & z<0\end{cases},$$

$$\mathrm{Bi}(|z|\gg 1)\approx\begin{cases}\frac{1}{\sqrt{\pi}z^{1/4}}\exp\left(\frac{2}{3}z^{3/2}\right), & z>0\\ \frac{1}{\sqrt{\pi}(-z)^{1/4}}\cos\left(\frac{2}{3}(-z)^{3/2}+\frac{\pi}{4}\right), & z<0\end{cases}$$

Метод WKB в комплексной плоскости (!?!)

(связь с компланом, да! тут еще линии Стокса, которые не шарю.)
(!!! в 1ю часть многое перенесу, важные, типичные темы!!!)

Преобразование уравнения Шредингера и классический его предел по Киселеву

Согласно принципу соответствия у квантовой системы должен существовать классический предел, в котором дисперсии физических величин малы при рассмотрении динамики их средних значений. Как мы отмечали, такой предел обычно имеет место при больших квантовых числах $n\to\infty$, когда дисперсией можно пренебречь. Принцип соответствия использовался при построении основных операторов физических величин в приближении геометрической оптики, которая как раз дает предельный случай волновой механики, когда пренебрежение эффектами интерференции позволяет говорить о траектории корпускул, составляющих свет.

Другой аспект принципа соответствия открывается, если взглянуть на соотношение неопределенностей физических наблюдаемых $\hat{A}$ и $\hat{B}$:

$$\Delta A\cdot\Delta B\geqslant\frac{\hbar}{2}|\langle\hat{C}\rangle|.$$

Можно считать, что флуктуации наблюдаемых малы, если

$$\hbar\to 0.$$

Кроме того, дискретность спектра физической величины, как мы видели, связана с конечностью значения постоянной Планка, так что этой дискретностью можно пренебречь, если верно (12.1). Конечно, это условие является лишь необходимым, но не достаточным (знак неравенства в соотношении неопределенностей). Тем не менее, исследование предела (12.1) позволяет установить и достаточные признаки применимости классического описания и приближений к нему.

Запишем волновую функцию как

$$\Psi(\boldsymbol{r},t)=A(\boldsymbol{r},t)\mathrm{e}^{\frac{i}{\hbar}S(\boldsymbol{r},t)},$$

где $A(\boldsymbol{r},t),S(\boldsymbol{r},t)\in\mathbb{R}$ т.е. в виде вещественной амплитуды A и фазы S.

Сперва вычислим

$$\Delta\Psi=\nabla^2\Psi=\boldsymbol{\nabla}\cdot\left\{\mathrm{e}^{\frac{\mathrm{i}}{\hbar}S(\boldsymbol{r},t)}\boldsymbol{\nabla}A+\frac{\mathrm{i}}{\hbar}A\mathrm{e}^{\frac{\mathrm{i}}{\hbar}S(\boldsymbol{r},t)}\nabla S\right\}=$$
$$=\mathrm{e}^{\frac{\mathrm{i}}{\hbar}S(\boldsymbol{r},t)}\left\{2\frac{\mathrm{i}}{\hbar}\boldsymbol{\nabla}S\cdot\nabla A+\Delta A-\frac{1}{\hbar^2}A(\boldsymbol{\nabla}S)^2+\frac{\mathrm{i}}{\hbar}A\triangle S\right\},$$

и также

$$\frac{\partial}{\partial t}\Psi=\left\{\frac{\partial A}{\partial t}+\frac{\mathrm{i}}{\hbar}A\frac{\partial S}{\partial t}\right\}\mathrm{e}^{\frac{i}{\hbar}S(r,t)},$$

Подставим это в уравнение Шрёдингера $\mathrm{i}\hbar\frac{\partial}{\partial t}\Psi = -\frac{\hbar^2}{2m}\triangle\Psi + V\Psi$, возьмем мнимую и вещественную части, находим

$$\hbar\frac{\partial A}{\partial t} = -\frac{\hbar}{2m}\{2\nabla S\cdot\nabla A + A\triangle S\}$$
$$-A\frac{\partial S}{\partial t} = -\frac{\hbar^2}{2m}\triangle A + \frac{A}{2m}(\nabla S)^2 + VA.$$

Запишем их в виде

$$\frac{\partial A}{\partial t} + \frac{1}{m}\nabla S\cdot\nabla A + \frac{A}{2m}\triangle S = 0,$$
$$\frac{\partial S}{\partial t} + \frac{1}{2m}(\nabla S)^2 + V = \frac{\hbar^2}{2m}\frac{\triangle A}{A}$$

(ниже - в 1 часть дублирую!)

Найдем

$$j = -\frac{\mathrm{i}\hbar}{2m}\left\{\Psi^*\nabla\Psi - (\nabla\Psi)^*\Psi\right\} = \frac{A^2}{m}\nabla S$$

и

$$\operatorname{div} j = \nabla\cdot j = \frac{2}{m}A\nabla S\cdot\nabla A + \frac{A^2}{m}\triangle S.$$

Поэтому, домножая $\frac{\partial A}{\partial t} + \frac{1}{m}\nabla S\cdot\nabla A + \frac{A}{2m}\triangle S = 0$ на $2A$, получаем

$$2A\frac{\partial A}{\partial t} + \operatorname{div} j = 0$$

и с учетом того, что

$$\rho = |\Psi|^2 = A^2,$$

находим, что это уравнение сводится к уравнению непрерывности

$$\frac{\partial\rho}{\partial t} + \operatorname{div} j = 0.$$

(???? почему это не в самом начале, тривиальные вещи!!!)

Второе уравнение из уравнения Шредингера $\frac{\partial S}{\partial t} + \frac{1}{2m}(\nabla S)^2 + V = \frac{\hbar^2}{2m}\frac{\triangle A}{A}$ при $\hbar\to 0$ сводится к уравнению Гамильтона-Якоби:

$$\frac{\partial S}{\partial t} + \frac{1}{2m}(\nabla S)^2 + V = 0.$$

Как и следовало ожидать, мы пришли к классическому пределу уравнения Шрёдингера. При этом комплексная фаза волны $S/\hbar$ удовлетворяет принципу Ферма.

(?? почему???)

Для стационарного состояния $\frac{\partial\rho}{\partial t} = 0, \frac{\partial S}{\partial t} = -E$ имеем из $\frac{\partial A}{\partial t} + \frac{1}{m}\nabla S\cdot\nabla A + \frac{A}{2m}\triangle S = 0$ уравнение

$$(\nabla S)^2 - 2m(E-V) = \hbar^2\frac{\Delta A}{A}$$

вместе с уравнением нулевой дивергенции потока вероятности.

Классический импульс есть:

$$p^2 \equiv 2m(E-V) \equiv \left(\frac{\hbar}{\lambda}\right)^2.$$

(тоже укажу это лучше в 1 части)

Поэтому

$$(\nabla S)^2 = \frac{\hbar^2}{\lambda^2}\left(1 + \lambda^2 \frac{\Delta A}{A}\right).$$

Следовательно, классическое приближение применимо, если

$$\lambda^2 \frac{\Delta A}{A} \ll 1.$$

Тогда имеет место уравнение для волнового фронта в геометрической оптике:

$$(\nabla \Phi)^2 = \frac{1}{\lambda^2}, \quad \Phi = \frac{1}{\hbar} S.$$

(с ним в оптике нужно лучше разобраться!)

Метод JWKB по Киселеву

Метод JWKB состоит в решении уравнений из уравнения Шрёдингера

$$\frac{\partial A}{\partial t} + \frac{1}{m}\nabla S \cdot \nabla A + \frac{A}{2m}\triangle S = 0,$$
$$\frac{\partial S}{\partial t} + \frac{1}{2m}(\nabla S)^2 + V = \frac{\hbar^2}{2m}\frac{\triangle A}{A}$$

в виде рядов по $\hbar$.

Нулевое приближение

Первое для стационарных состояний есть

$$2S'A' + AS'' = 0,$$

где штрих означает дифференцирование по координате частицы x. Из него:

$$A(x) = \frac{C}{\sqrt{S'(x)}}.$$

Значит, амплитуда волновой функции однозначно (с точностью до нормировки C) задается ее фазой.

Второе уравнение

$$(\nabla S)^2 - 2m(E - V) = \hbar^2 \frac{\Delta A}{A}$$

решается с подстановкой $A(x) = \frac{C}{\sqrt{S'(x)}}$, при которой $A' = -\frac{S''}{2\sqrt{(S')^3}}$, $A'' = \frac{3(S'')^2}{4\sqrt{(S')^5}} - \frac{S'''}{2\sqrt{(S')^3}}$

Получим

$$(S')^2 - 2m(E - V) = \frac{\hbar^2}{4(S')^2}\left\{3(S'')^2 - 2S'S'''\right\}.$$

Отсюда следует, что фаза раскладывается в ряд по степеням $\hbar^2$:

$$S = S_0 + \hbar^2 S_2 + \hbar^4 S_4 + ...$$

Поскольку волновую функцию можно теперь записать как

$$\Psi(x) = \exp\left\{\frac{\mathrm{i}}{\hbar}S(x) + \ln A(x)\right\} = C\exp\left\{\frac{\mathrm{i}}{\hbar}S(x) - \frac{1}{2}\ln S'\right\}$$

ясно, что разложение фазы приводит и к разложению амплитуды по степеням $\hbar^2$, а вещественного аргумента экспоненты - по нечетным степеням $\hbar$.

(!! в 1ю часть укажу это тоже, типичные свойства!!!)

Решаем методом итераций. Нулевая итерация:

$$\{S_0'(x)\}^2 = p^2(x), \quad p^2 = 2m[E - V(x)],$$

причем необходимо выполнение условия вещественности фазы, так что $p^2(x) \geqslant 0, E \geqslant V(x)$.

Это значит, что пока нулевая итерация справедлива только в области, доступной для классической частицы. При этом

$$p(x) = \pm\sqrt{2m[E - V(x)]},$$

и возможно существование двух линейно независимых решений (в зависимости от значения энергии в согласии с общими свойствами решений одномерного уравнения Шрёдингера).

Решение уравнения имеет стандартный вид координатной части действия классической частицы:

$$S_0(x) = \int p \, \mathrm{d}x$$

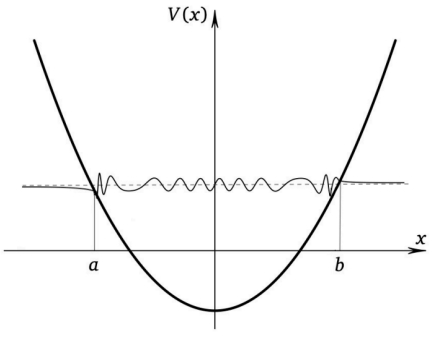
С учетом вклада энергии в комплексную фазу стационарного состояния

$$S_0(x,t) = \int p \, \mathrm{d}x - E \, \mathrm{d}t$$

получаем волновую функцию в классическом пределе

$$\Psi(x,t) = C \exp\left\{\frac{\mathrm{i}}{\hbar} S_0(x,t)\right\} = C \exp\left\{\frac{\mathrm{i}}{\hbar} \int p \, \mathrm{d}x - E \, \mathrm{d}t\right\}$$

В итоге фаза волновой функции осциллирует в области, доступной для классической частицы, например, между точками поворота, как показано на рис. 13.



Осциллирующее поведение волновой функции в этой области показано волнистой кривой, а в запрещенной для классического движения области пси-функция убывает экспоненциально. Продолжение в классически недоступную область. Заметим, что выведенная нами пара уравнений не изменится, если получать их, выделяя не мнимую и вещественную части в уравнении Шрёдингера, а вклады в виде четной и нечетной функций по $\hbar$.

В самом деле, считая, что A и S-четные функции по $\hbar$, опять приходим к (12.3) и (12.1). Значит, нулевая итерация в классически запрещенной области координаты дает решение в виде

$$\Psi(x) = C_1 \mathrm{e}^{+\frac{1}{r}} \int \sqrt{2m[V(x)-E]}\mathrm{d}x + C_2 \mathrm{e}^{-\frac{1}{r}} \int \sqrt{2m[V(x)-E]}\mathrm{d}x,$$

причем C_1, C_2 зависят от налагаемых на волновую функцию граничных условий.

Например, на рис. выше волновая функция должна экспоненциально убывать на бесконечности, так что поведение при $x \to +\infty$ требует $C_1 = 0$.

(?!?! выделю ключевые формулы потом, пока их так себе вижу.)

Квазиклассическое приближение

Учтем линейный по $\hbar$ вклад в аргумент экспоненты для волновой функции, т.е. подставим выражение для функции A через S_0. Тогда

$$\Psi(x) = \frac{C}{\sqrt{p(x)}} \exp\left\{\frac{\mathrm{i}}{\hbar}\int p(x)\mathrm{d}x\right\},$$

где импульс $p(x) = \sqrt{2m[E-V(x)]}$ уже комплекснозначная двулистная функция, т.е. имеется пара решений уравнений Шрёдингера в квазиклассическом приближении. При этом необходимо помнить, что граничные условия, а именно наличие классического финитного движения при заданной энергии, могут приводить к фиксированной суперпозиции этих решений, так как при финитном движении в одномерном случае состояние энергии невырождено.

Для первой итерации, дающей квадратичный по $\hbar$ вклад в S, имеем

$$\left(S_0' + \hbar^2 S_2'\right)^2 \approx p^2(x) + \frac{\hbar^2}{4\left(S_0'\right)^2}\left\{3\left(S_0''\right)^2 - 2S_0'S_0'''\right\}.$$

Поскольку с заданной точностью до $\hbar^2$

$$\left(S_0' + \hbar^2 S_2'\right)^2 \approx \left(S_0'\right)^2 + 2\hbar^2 S_0'S_2'$$

и $S_0' = p(x)$, получаем

$$S_2' = \frac{1}{8p^3}\left\{3\left(p'\right)^2 - 2pp''\right\}.$$

Условия применимости квазиклассики

Чтобы нулевая итерация для S_0 была хорошим приближением, необходимо выполнения условия $\hbar^2\left|S_2'\right| \ll \left|S_0'\right|$, то есть

$$\left|\frac{\hbar^2}{p^3}\left(p'\right)^2\right| \ll |p| \qquad \to \qquad \left|\frac{\hbar}{p}\frac{p'}{p}\right| \ll 1,$$
$$\left|\frac{\hbar^2}{p^3}p''p\right| \ll |p| \qquad \to \qquad \left|\frac{\hbar^2}{p^2}\frac{p''}{p}\right| \ll 1.$$

Величина

$$p'\frac{\hbar}{p} = p'\lambda\!\!\!^{-} = \delta p$$

есть изменение импульса на расстоянии в длину волны в первом порядке. Поэтому разложение по $\hbar$ оправдано, если

$$\left|\frac{\delta p}{p}\right| \ll 1,$$

т.е. если относительное изменение импульса на длине волны пренебрежимо мало в первом порядке.

Условие $\left|\frac{\hbar^2}{p^2}\frac{p''}{p}\right| \ll 1$ дает

$$\left|\frac{\delta^2 p}{p}\right| \ll 1, \quad \delta^2 p \sim p''\lambda\!\!\!^{-2},$$

т.е. относительное изменение импульса на длине волны должно быть пренебрежимо мало и во втором порядке.

С учетом

$$p = \frac{\hbar}{\lambda\!\!\!^{-}}, \quad \frac{p'}{p} = -\frac{\lambda\!\!\!^{-\prime}}{\lambda\!\!\!^{-}}$$

условия применимости квазиклассического приближения можно записать в виде

$$|\lambda\!\!\!^{-\prime}| \ll 1, \quad |\lambda\!\!\!^{-\prime\prime}\lambda\!\!\!^{-}| \ll 1,$$

что, по сути, означает, что относительное изменение длины волны на расстоянии в длину волны в первом и втором порядке должно быть пренебрежимо мало.

Условие $|\lambda\!\!\!^{-\prime}| \ll 1$ можно также переформулировать так: если ℓ - интервал, на котором потенциал изменяется настолько существенно, что изменение длины волны сравнимо с длиной волны, то

$$|\lambda\!\!\!^{-\prime}| \sim \frac{\lambda\!\!\!^{-}}{\ell}$$

откуда сразу находим

$$\frac{\lambda}{\ell} \ll 1,$$

а значит, существенное изменение потенциала в условиях применимости квазиклассики происходит на расстояниях ℓ, в которые укладывается большое число длин волн. Другими словами, потенциал должен изменяться достаточно медленно.

(?? еще раз потом посмотрю, почему именно медленно???? пока еще не разобрался.)

Кроме того, используя явный вид функции $p(x)$, запишем

$$p' = -\frac{2mV'}{2p} = \frac{m}{p}F,$$

где $F = -V'$ - сила, действующая на частицу. Тогда

$$\frac{\hbar}{p}F \approx \delta x \cdot F \sim \delta A$$

есть работа, совершаемая силой на расстоянии $\delta x = \hbar/p = \lambda$, т.е. на длине волны.

С учетом $T_{\text{kin}} = \frac{p^2}{2m}$, условие применимости квазиклассики в первом порядке принимает вид

$$\left|\frac{\delta A}{T_{\text{kin}}}\right| \ll 1,$$

т.е. работа, совершаемая силой на длине волны, должна быть пренебрежимо мала в сравнении с кинетической энергией частицы. Поэтому ясно, что вблизи точек поворота, где кинетическая энергия и импульс стремятся к нулю, а сила остается отличной от нуля, квазиклассическое приближение неприменимо.

Плотность потока вероятности в квазиклассике по Киселеву

Подставим в $j = -\frac{i\hbar}{2m}\left\{\psi^*\psi' - (\psi')^*\psi'\right\}$ выражение $\Psi_\pm(x) = \frac{C_\pm}{\sqrt{p(x)}}\exp\left\{\pm\frac{\mathrm{i}}{\hbar}\int\limits_{x_0}^{x} p(x)\mathrm{d}x\right\}$, у которой $\psi' = \frac{C_\pm}{\sqrt{p(x)}}\left(-\frac{1}{2}\frac{p'(x)}{p(x)} \pm \frac{\mathrm{i}}{\hbar}p(x)\right)\exp\left\{\pm\frac{\mathrm{i}}{\hbar}\int\limits_{x_0}^{x} p(x)\mathrm{d}x\right\} \approx \pm\frac{\mathrm{i}}{\hbar}p(x)\frac{C_\pm}{\sqrt{p(x)}}\exp\left\{\pm\frac{\mathrm{i}}{\hbar}\int\limits_{x_0}^{x} p(x)\mathrm{d}x\right\}$. Учтено, что согласно критерию применимости $\left|\frac{\hbar^2}{p^2}\frac{p''}{p}\right| \ll 1$, имеем $-\frac{1}{2}\frac{p'(x)}{p(x)} \pm \frac{\mathrm{i}}{\hbar}p(x) \approx \pm\frac{\mathrm{i}}{\hbar}p(x)$.

Получаем

$$j\left[\psi_\pm\right] \approx \pm\frac{|C_\pm|^2}{m}.$$

Это значит, что частица, которая согласно квазиклассическому приближению (12.25) имеет волновую функцию ψ_+, движется по направлению оси координат, а ψ_- - в обратном направлении.

Подчеркнем, что в выражение для потока вероятности в квазиклассическом приближении (12.26) формально уже не входит зависимость от импульса как функции координат: постоянные $C_\pm$ могут быть заданы из соображений, связанных с постановкой задачи.

Для сравнения, у свободной нерелятивистской частицы импульс $p(x) = p > 0$ не зависит от координат, так что квазиклассическое выражение для волновой функции (12.25) является точным, а постоянные $C_\pm$выбираются из соображений нормировки волны де Бройля так, что $C_\pm/\sqrt{p} = 1$, и тогда получается стандартный вывод, что поток вероятности свободной нерелятивистской частицы в волне де Бройля задается скоростью движения частицы.

(??? где нужна эта формула??)

Условия отражения, сшивка решений в точках поворота по Киселеву

Вблизи точек поворота вместо квазиклассического приближения необходимо точно решить уравнение Шрёдингера. Тогда

$$E - V(x) \approx E - V(a) - V'(a)(x-a) = F(a)(x-a),$$

где в точке поворота $V(a) = E$, и мы приходим к уравнению Шрёдингера для частицы, на которую действует постоянная сила $F(a)$. Точное решение выражается через спецфункцию Эйри, которую необходимо затем сшить с квазиклассическим приближением возле точки поворота. Результат такого строгого рассмотрения в точности согласуется с более наглядным методом сшивки квазиклассических решений вблизи точки поворота, который мы и приведем ниже. По сути, речь идет об отражении частицы от потенциального барьера в квазиклассическом приближении.

Пусть слева от точки поворота $x = a$ расположена недоступная для классической частицы область вплоть до $x \to -\infty$. Волновая функция при $x < a$ есть

$$\Psi(x) = \frac{C}{2}\frac{1}{\sqrt[4]{2mV'(a)(x-a)}}\exp\left\{\frac{1}{\hbar}\int\limits_{a}^{x}\sqrt{2mV'(a)(x-a)}\mathrm{d}x\right\},$$

где

$$V'(a) < 0,$$

так что аргументы корней положительны. Как функция комплексной переменной x выражение ((12.27) является четырехлистной функцией с разрезом, который начинается в точке поворота a и направлен по вещественной оси в сторону $x > a$. Арифметическое значение корней в формуле (12.27) в области, недоступной для классической частицы, отвечает выбранному граничному условию с затуханием волновой функции вглубь области, не доступной для частицы в рамках классической механики, $x < a$.

Покажем, что выражение (12.27) отвечает асимптотическому поведению волновой функции, которую возле точки поворота можно найти точно, решая стационарное уравнение Шрёдингера с линейным потенциалом

$$V(x) = E + V'(a)(x-a), \quad V(a) = E, \quad V'(a) < 0,$$

если перейти от точного решения в область, где становится применима квазиклассика. Уравнение Шрёдингера с линейным потенциалом (12.28)

$$\frac{\hat{p}^2}{2m}|\Psi\rangle + V(\hat{x})|\Psi\rangle = E|\Psi\rangle$$

можно записать в импульсном представлении для $\tilde{\Psi}(p) = \langle p|\Psi\rangle$, если ввести оператор

$$\hat{y} = \widehat{x-a} = \mathrm{i}\hbar\frac{\mathrm{d}}{\mathrm{d}p},$$

откуда

$$\frac{p^2}{2m}\tilde{\Psi}(p) + V'(a)\mathrm{i}\hbar\frac{\mathrm{d}\bar{\Psi}(p)}{\mathrm{d}p} = 0.$$

Точное решение этого уравнения находится элементарно, так как

$$\frac{\mathrm{d}\bar{\Psi}}{\tilde{\Psi}t} = \frac{\mathrm{i}}{\hbar}\frac{p^2}{2mV'(n)}\mathrm{d}p \to \ln\tilde{\Psi} = \frac{\mathrm{i}}{\hbar}\frac{p^3}{6mV'(a)} + \text{ const.}$$

Значит,

$$\tilde{\Psi}(p) = \tilde{\Psi}_0 \exp\left\{\frac{i}{\hbar}\frac{p^3}{6mV'(a)}\right\}.$$

Поэтому волновую функцию в координатном представлении можно найти, взяв обратное преобразование Фурье,

$$\Psi(x) = \Psi_A(y)|_{y=x-a} = \tilde{\Psi}_0\int\frac{\mathrm{d}p}{2\pi\hbar}\exp\left\{\frac{\mathrm{i}}{\hbar}\left(yp + \frac{p^3}{6mV'(a)}\right)\right\}\Bigg|_{y=x-a}.$$

Иными словами,

$$\Psi(x) = \tilde{\Psi}_0\int\frac{\mathrm{d}p}{2\pi\hbar}\mathrm{e}^{\varphi(p)}, \quad \varphi(p) = \frac{\mathrm{i}}{\hbar}\left\{(x-a)p + \frac{p^3}{6mV'(a)}\right\}.$$

Вещественная специальная функция, заданная в (12.32), при условии затухания вглубь потенциального барьера называется функцией Эйри. Найдем экстремум функции $\varphi(p)$, вычислив производную

$$\varphi'(p) = \frac{\mathrm{i}}{\hbar}\left\{(x-a) + \frac{p^2}{2mV'(a)}\right\}.$$

Точка экстремума $p = p(x)$,

$$\frac{p(x)^2}{2m} = -V'(a)(x-a) = E - V(x),$$

расположена при $p^2(x) < 0$, если $x < a$. Поскольку

$$\varphi''(p) = \frac{\mathrm{i}}{\hbar}\frac{p}{mV'(a)},$$

получаем разложение функции $\varphi(p)$ возле точки экстремума $p(x)$ с точностью до членов второго порядка малости где $\varphi(p) = \varphi(p(x)) + \frac{1}{2}(p-p(x))^2\varphi''(p(x)) + \mathcal{O}\left((p-p(x))^3\right)$,

$$\begin{aligned}
&\varphi(p(x)) = \frac{\mathrm{i}}{\hbar}(x-a)p(x)\left\{1 + \frac{p^2(x)}{6mV'(a)(x-a)}\right\} = \\
&= \frac{\mathrm{i}}{\hbar}(x-a)p(x)\left\{1 - \frac{1}{3}\right\} = \frac{\mathrm{i}}{\hbar}(x-a)p(x) \\
&\text{a } \varphi''(p(x)) = \frac{\mathrm{i}}{\hbar}\frac{p(x)}{mV'(a)} = \frac{1}{\hbar}\frac{1}{mV'(a)}\sqrt{2mV'(a)(x-a)},
\end{aligned}$$

где мы выбрали значение

$$p(x) = -\mathrm{i}\sqrt{2mV'(a)(x-a)}, \quad x < a,$$

и поэтому

$$\varphi''(p(x)) < 0, \quad x < a.$$

Это значит, что в интеграле (12.32) при $x < a$ подынтегральное выражение ведет себя гауссовым образом, а поправки в разложении функции (12.34) приводят к малым поправкам к значению интеграла

$$\begin{aligned}
\int \frac{\mathrm{d}p}{2\pi\hbar}\mathrm{e}^{\varphi(p)} &\approx \mathrm{e}^{\varphi(p(x))}\int \frac{\mathrm{d}p}{2\pi\hbar}\exp\left\{\frac{1}{2}(p-p(x))^2\varphi''(p(x))\right\} = \\
&= \frac{1}{2\pi\hbar}\mathrm{e}^{\varphi(p(x))}\sqrt{-\frac{2\pi}{\varphi''(p(x))}} = \mathrm{e}^{\varphi(p(x))}\sqrt{\frac{mV'(a)}{2\pi\hbar}}\frac{1}{\sqrt[4]{2mV'(a)(x-a)}}
\end{aligned}$$

Заметим теперь, что с выбранным нами значением экстремальной точки (12.37) интеграл от импульса в точности совпадает с найденным нами выражением для значения функции $\varphi(p)$ в экстремальной точке (12.35),

$$\begin{aligned}
&\frac{1}{\hbar}\int_a^x \sqrt{2mV'(a)(x-a)}\mathrm{d}x = \frac{1}{\hbar}\sqrt{-2mV'(a)}\int_a^x (a-x)^{\frac{1}{2}}\,\mathrm{d}x = \\
&= -\frac{2}{3}\frac{1}{\hbar}\sqrt{-2mV'(a)}(a-x)^{\frac{3}{2}} = \frac{2}{3}(x-a)\sqrt{2mV'(a)(x-a)} = \\
&= \frac{i}{\hbar}(x-a)p(x)\frac{2}{3} = \varphi(p(x)).
\end{aligned}$$

Таким образом, мы показали, что вычисление асимптотики точного решения уравнения Шрёдингера с линейным потенциалом возле точки поворота воспроизводит волновую функцию квазиклассического приближения в области, где эта функция затухает вглубь потенциального барьера (12.27).

Интересно рассмотреть вопрос о поправке к полученной асимптотике. Для этого нужно вычислить третью производную

$$\varphi'''(p) = \frac{\mathrm{i}}{\hbar}\frac{1}{mV'(a)},$$

так что поправки в подынтегральном выражении могут быть представлены в виде ряда

$$\exp\left\{\frac{1}{3!}\varphi'''(p(x))(p-p(x))^3\right\} = 1 + \left\{\frac{1}{3!}\varphi'''(p(x))(p-p(x))^3\right\} + \\ + \frac{1}{2!}\left\{\frac{1}{3!}\varphi'''(p(x))(p-p(x))^3\right\}^2 + \ldots$$

Значит, гауссов интеграл приобретает поправки в виде

$$\int \mathrm{d}p \mathrm{e}^{\phi(p)} = \mathrm{e}^{\phi(p(x))} \int \mathrm{d}p \exp\left\{-\frac{1}{2}\frac{(p-p(x))^2}{\delta p^2}\right\} \times \\ \times \left(1 + \left\{\frac{1}{3!}\varphi'''(p(x))(p-p(x))^3\right\} + \frac{1}{2!}\left\{\frac{1}{3!}\varphi'''(p(x))(p-p(x))^3\right\}^2 + \ldots\right) = \\ = \mathrm{e}^{\phi(p(x))} \int \mathrm{d}p \exp\left\{-\frac{1}{2}\frac{(p-p(x))^2}{\delta p^2}\right\} \left(1 + \frac{1}{2!}\left\{\frac{1}{3!}\varphi'''(p(x))(p-p(x))^3\right\}^2 + \ldots\right),$$

где мы исключили нулевой вклад от третьей степени по импульсу, так как нечетные степени в гауссовом интеграле обращаются в нуль в силу свертки четной функции с нечетной. Вклад шестой степени легко найти, если заметить, что гауссов интеграл

$$\int \mathrm{d}p \exp\left\{-\frac{1}{2}\frac{(p-p(x))^2}{\delta p^2}\right\} = \sqrt{2\pi\delta p^2}$$

а

$$\int \mathrm{d}p \exp\left\{-\frac{1}{2}\frac{(p-p(x))^2}{\delta p^2}\right\} (p-p(x))^2 = \delta p^2 \sqrt{2\pi\delta p^2},$$

и это дисперсия гауссова распределения, умноженная на нормировочный множитель. Значит,

$$\int \mathrm{d}p \exp\left\{-\frac{1}{2}\frac{(p-p(x))^2}{\delta p^2}\right\} (p-p(x))^6 = \\ = 2^2 \frac{\partial}{\partial 1/\delta p^2}\frac{\partial}{\partial 1/\delta p^2} \int \mathrm{d}p \exp\left\{-\frac{1}{2}\frac{(p-p(x))^2}{\delta p^2}\right\} (p-p(x))^2 = \\ = 4\frac{\partial}{\partial 1/\delta p^2}\frac{\theta}{\partial 1/\delta p^2}\left(\delta p^2\sqrt{2\pi\delta p^2}\right) = 15\left(\delta p^2\right)^3\sqrt{2\pi\delta p^2}.$$

Поэтому

$$\int \mathrm{d}p \mathrm{e}^{\phi(p)} \approx \mathrm{e}^{\phi(p(x))}\sqrt{2\pi\delta p^2}\left\{1 + \frac{1}{2!}\left\{\frac{1}{3!}\varphi'''(p(x))\right\}^2 15\left(\delta p^2\right)^3\right\}.$$

В этом выражении

$$\delta p^2 = -\frac{1}{\varphi''(p(x))} = -\left(\frac{\mathrm{i}}{\hbar}\frac{p(x)}{mV'(a)}\right)^{-1} = -\hbar m V'(a)\frac{1}{\sqrt{2mV'(a)(x-a)}},$$

как это и необходимо для квазиклассического выражения для волновой функции

$$\Psi(x) = \frac{C}{\sqrt{p(x)}}\exp\left\{\frac{1}{\hbar}\int\limits_a^x |p(x)|\mathrm{d}x\right\}$$

а подстановка $\varphi'''(p(x))$ из (12.38) приводит к поправке в виде

$$\Psi(x) \mapsto \Psi(x)\left(1+\frac{5}{24}\frac{1}{\hbar^2}mV'(a)\left(\frac{\hbar}{\sqrt{2mV'(a)(x-a)}}\right)^3\right) = \\ = \Psi(x)\left(1+\frac{5}{24}\frac{\hbar}{|p(x)|}V'(a)\frac{1}{|p^2(x)|/m}\right).$$

Из этого выражения видно, что безразмерная поправка к волновой функции казиклассического приближения имеет следующий порядок по постоянной Планка с чертой $\hbar$. Эта поправка мала в области применимости квазиклассики, так как определяется отношением работы сил на длине волны к кинетической энергии,

$$\left|\frac{\hbar}{|p(x)|}V'(a)\frac{1}{|p^2(x)|/m}\right| \sim \left|\lambda F\frac{1}{T_{\text{kin}}}\right| \sim \left|\frac{\delta A}{T_{\text{kin}}}\right| \ll 1.$$

Таким образом, мы убедились, что вычисление асимптотики точного решения уравнения Шрёдингера с линейным потенциалом согласуется с квазикласическим приближением и методом JWKB с вычислением рядов по $\hbar$.

Совершенно ясно, что теперь нужно найти асимптотическое поведение точного решения уравнения Шрёдингера с линейным потенциалом возле точки поворота перед потенциальным барьером при $x > a$. В этой области условие на экстремум (12.33) имеет два решения на разных берегах разреза в комплексной плоскости импульса: напомним, что разрез направлен по оси x от $x = a$, т.е. от точки поворота в сторону от барьера в область, доступную для частицы в классической механике.

Теперь, во-первых, интеграл будет вычисляться как сумма двух вкладов в экстремальных точках,

во-вторых, вместо гауссова интеграла возникнут интегралы возле стационарных точек комплексной фазы, так как выражения для функции $\varphi(p)$ и ее второй производной в экстремальной точке: (12.35) и (12.36), - становятся чисто мнимыми.

И наконец, в-третьих, нет никакой нужды повторять проведенные нами для случая гауссова интеграла выкладки, поскольку асимптотика интегралов со стационарной фазой вычисляется аналитическим продолжением результатов, полученных для гауссовых интегралов! Значит, нужно вычислить аналитическое продолжение выражения (12.27) на 2 берега разреза в комплексной области импульса и сложить два этих вклада в волновую функцию в координатном представлении, так как интеграл есть сумма ведущих вкладов, в данном случае, вкладов возле точек стационарной фазы. Совершпм переход в классически доступную область $x > a$ по двум контурам в комплексной плоскости x, как показано на рис. 14, так, чтобы оставаться вдали от точки поворота в области применимости квазиклассического приближения. Рис. 14. Контуры обхода точки поворота Для этого сделаем замену переменных

$$x - a = -\rho e^{i\phi}, \quad \rho = \text{ const } > 0,$$

где для контура с отрицательной мнимой частью координаты

$$0 \leqslant \phi \leqslant \pi$$

а для контура с положительной мнимой частью координаты

$$0 \geqslant \phi \geqslant -\pi$$

При таком обходе точки поворота с помощью аналитического продолжения (12.27) соответственно получаем пару вкладов при $x > a$

$$\Psi_1(x) = \frac{C}{2}\frac{\mathrm{e}^{-1\pi/4}}{\sqrt{p(x)}}\exp\left\{\frac{\mathrm{i}}{\hbar}\int\limits_a^x p(x)\mathrm{d}x\right\}$$
$$\Psi_2(x) = \frac{C}{2}\frac{\mathrm{e}^{\mathrm{i}\pi/4}}{\sqrt{p(x)}}\exp\left\{-\frac{\mathrm{i}}{\hbar}\int\limits_a^x p(x)\mathrm{d}x\right\}$$

где уже

$$p(x) = \sqrt{2\pi n\,(-V'(a)\rho)} = \sqrt{2m[E - V(x)]}, \quad x > a, \quad E > V(x),$$

- вещественная функция импульса. Решения $\Psi_{1,2}(x)$ представляют собой пару линейно независимых квазиклассических решений в области, доступной для классической частицы, которые мы уже заранее знаем в общем виде с точностью до комплексных констант в предэкспоненияльных множителях. Но

теперь рассмотренная нами процедура обхода точки поворота по контурам рис. 14, исходя из заданного вида (12.27), позволила однозначно определить связь предэкспоненциальных множителей с исходной константой C в формуле (12.27). Два контура отвечают переходу к разным берегам разреза, который идет от точки поворота a вдоль луча $x > a$. В квантовой механике берется суперпозиция этих двух линейно независимых решений. Поскольку задача одномерная и волновая функция обращается в нуль при $x \to -\infty$, спектр является невырожденным, и при вещественном значении константы C в формуле (12.27) вещественная при $x < a$ волновая функция будет вещественной и при $x > a$. Это требование при $x > a$ дает решение $\Psi_1(x) + \Psi_2(x)$, которое согласуется с описанным обходом точки поворота в комплексной плоскости, либо $\mathrm{i}\ \Psi_1(x) - \mathrm{i}\Psi_2(x)$, которое не согласуется с асимптотическим поведением точного решения уравнения Шрёдингера волизи точки поворота при условии затухания волновой функции вглубь потенциального барьера. Другими словами, мы не только знаем, что решение в классически доступной области будет вещественным, а из точного решения возле точки поворота мы знаем и модуль амплитуды этого решения, и фазы, которые в области применимости квазиклассики однозначно дают $\Psi_1(x) + \Psi_2(x)$, исходя из метода нахождения асимттотического поведения интеграла Фурье способом аналитического продолжения из области гауссова перевала к точкам стационарной фазы. В итоге

$$\Psi(x)_{x>a} = \Psi_1(x) + \Psi_2(x) = \frac{C}{\sqrt{p(x)}}\cos\left\{\frac{1}{\hbar}\int\limits_a^x p(x)\mathrm{d}x - \frac{\pi}{4}\right\}.$$

Таким образом, поскольку волны Ψ_2 и Ψ_1 в (12.42) и (12.41) можно соответственно рассматривать как падающую на потенциальный барьер волну и отраженную от него волну (см. раздел 12.3 и формулу для потока вероятности (12.26)), при отражении от классически недоступной области потенциала возникает относительная фаза волн $^1\frac{\pi}{2}$. Точнее, отраженная от потенциального барера волна отстает по фазе на $\frac{\pi}{2}$ от падающей на потенциальный барьер волны. И этот вывод не зависит от того, как расположен барьер, справа или слева от области, доступной для частицы в классической механике. Важно лишь, что в глубине потенциального барьера у потенциала нет сингулярных точек.

Совершенно аналогично при отражении от потенциального барьера справа при $x = b$

затухающая волновая функция в классически недоступной области

$$\Psi(x)_{x>b} = \frac{C}{2}\frac{1}{\sqrt{|p(x)|}}\exp\left\{\frac{1}{\hbar}\int\limits_x^b |p(x)|\mathrm{d}x\right\}$$

переходит в

$$\Psi(x)_{x<b} = \frac{C}{\sqrt{p(x)}}\cos\left\{\frac{1}{\hbar}\int\limits_x^b p(x)\mathrm{d}x - \frac{\pi}{4}\right\}.$$

Снова убеждаемся, что фаза падающей на потенциальный барьер волны на $\frac{\pi}{2}$ больше фазы отраженной волны.

Подчеркнем для примера сингулярного поведения потенциала, что в случае отражения от бесконечно высокого в точке поворота, непроницаемого потенциального барьера конечной ширины волновая функция должна обращаться в нуль в точке поворота, так что, например, если $V(x<a) = +\infty$, ТО

$$\Psi(x)_{x>a} = \frac{C}{\sqrt{p(x)}}\cos\left\{\frac{1}{\hbar}\int\limits_a^x p(x)\mathrm{d}x \pm \frac{\pi}{2}\right\}$$

и относительная фаза падающей и отраженной волн равна $\pm\pi$, т.е. вдвое болыше, чем в случае потенциального барьера конечной высоты в точках поворота, отличных от бесконечности. Подчеркнем, что в случае бесконечно высокого непроницаемого барьера импульс $p(x)$ отличен от нуля бесконечно близко к точке поворота a, так что $p(a+0) = p_0 > 0$, так что квазиклассикой можно воспользоваться вплоть до самой точки поворота, если, конечно, при $x > a$ выполняется критерий применимости квазиклассики, т.е. потенциал и, следовательно, импульс меняются достаточно медленно на длине волны, и установить вполне обоснованно условие $\Psi(a+0) = 0$, которое приводит к (12.46)

Правило квантования Бора–Зоммерфельда по Киселеву

Рассмотрим параболическую потенциальную яму, изображенную на рис. 13. Согласно полученным нами условиям сшивки решения внутри ямы с затухающими на бесконечности решениями получаем

$$\Psi(x)_{x>a} = \frac{C}{\sqrt{p(x)}}\cos\left\{\frac{1}{\hbar}\int\limits_a^x p(x)\mathrm{d}x - \frac{\pi}{4}\right\}$$

Н

$$\Psi(x)_{x<b} = \frac{\tilde{C}}{\sqrt{p(x)}}\cos\left\{\frac{1}{\hbar}\int\limits_x^b p(x)\mathrm{d}x - \frac{\pi}{4}\right\},$$

где C и $\tilde{C}$ - пормировотные копстапты для решспий, затухающих соответственно при $x \to \mp\infty$. Эти выражения должны быть тождественно равны друг другу, так как они описывают волновую функцию внутри классически доступной для частицы области. Значит,

$$\frac{C}{\sqrt{p(x)}}\cos\left\{\frac{1}{\hbar}\int\limits_a^x p(x)\mathrm{d}x - \frac{\pi}{4}\right\} = \frac{\tilde{C}}{\sqrt{p(x)}}\cos\left\{\frac{1}{\hbar}\int\limits_x^b p(x)\mathrm{d}x - \frac{\pi}{4}\right\}.$$

Это равенство имеет место, если, во-первых, амплитуды косинусов равны по модулю:

$$|C| = |\tilde{C}|,$$

а во-вторых, зависящие от координат фазы косинусов совпадают с точностью до знака и сдвига на πn:

$$\frac{1}{\hbar}\int_a^x p(x)\mathrm{d}x - \frac{\pi}{4} = \pm\left\{\frac{1}{\hbar}\int_x^b p(x)\mathrm{d}x - \frac{\pi}{4}\right\} + \pi n, \quad n \in \mathbb{Z}.$$

Знак «плюс» дает

$$\frac{1}{\hbar}\int_a^x p(x)\mathrm{d}x + \frac{1}{\hbar}\int_b^x p(x)\mathrm{d}x = \pi n,$$

так что слева стоит функция от x, а справа - постоянная: это уравнение не имеет решений ($p(x) \equiv 0$ не имеет физического смысла). Взяв знак «минус», находим

$$\frac{1}{\hbar}\int_a^b p(x)\mathrm{d}x = \pi\left(n + \frac{1}{2}\right).$$

Здесь интеграл берется по полупериоду движения классической частицы в потенциальной яме. Переходя к интегрированию по полному периоду, находим правило квантования Бора-Зоммерфельда:

$$\oint p(x)\mathrm{d}x = 2\pi\hbar\left(n + \frac{1}{2}\right), \quad n \in \{0 \cup \mathbb{N}\}.$$

Интеграл по циклу есть не что иное, как адиабатический инвариант фазовый объем внутри траектории. Поэтому квазиклассическое квантование связанных состояний частицы показывает, что квантовое число n задает число ячеек фазового пространства $\Delta\Gamma = 2\pi\hbar$, приходящихся на данное стационарное состояние (с точностью до вклада основного состояния). Ясно, что фазовый объем равен целому числу ячеек только при некоторых дискретных значениях энергии частицы.

Поскольку критерием применимости квазиклассического приближения является условие медленного изменения потенциала, это означает, что между точками поворота в потенциальной яме должно укладываться большое количество длин волн, т.е. число колебаний n в формуле (12.65) должно

быть много большим единицы: $n \gg 1$. Тогда возникает естественный вопрос о превышении точности, так как

Однако добавка одной второй имеет следующий смысл: при вычислении следующего порядка по $\hbar^2$ в методе JWKB поправка может оказаться сравнимой с вкладом $\frac{1}{2}$ в ведущем приближении, так что выражение в правой части (12.65) вполне правомерно и просто необходимо в рамках заданного порядка по.

Об обобщениях (????)

Отметим также, что в потенциалах общего вида правая часть (12.65) может принимать другое значение:

$$2\pi\hbar\left(n + \frac{1}{2}\right) \mapsto 2\pi\hbar\left(n + \gamma_M\right),$$

где γ_M носит имя «индекс Маслова».

При выводе $\gamma_M = \frac{1}{2}$ мы предполагали, что волновая функция вне области, доступной для классической частицы плавно убывает до нуля на бесконечности. Однако это становится неверно, если имеется, например, непроницаемый потенциальный барьер, расположенный на конечном расстоянии от потенциальной ямы, или сам потенциал сингулярен в конечном числе точек с ограниченными координатами. Тогда наше предположение о характере убывания волновой функции вне потенциальной ямы может оказаться неверным, и индекс Маслова принимает значение, отличное от $\frac{1}{2}$. К примеру, радиальное движение в центральном потенциале с учетом вклада центробежных сил отвечает случаю, когда и эффективный потенциал сингулярен как $1/r^2$, и движение ограничено областью $r \geqslant 0$. Поэтому квазиклассическое приближение для радиального движения в центральном потенциале существенно корректируется за счет индекса Маслова: это станет ясно при рассмотрении задачи рассеяния.

В более общем случае, когда у потенциала есть несколько потенциальных ям и потенциальных бареров условие квантования Бора-Зоммерфельда легко вывести, используя метод transfer-matrix, который мы подробно описали в параграфе на стр. 209. Ясно также, что рассмотренный нами вывод в случае одной потенциальной ямы и двух точек поворота вполне согласуется с методом transfer-matrix, а индекс Маслова для сингулярных потенциалов легко вводится в матрицу фазовых сдвигов (12.55) в соответствующих точках поворота.

Плотность состояний по Киселеву

Продифференцируем формулу квантования Бора-Зоммерфельда по энергии

$$\oint \frac{\partial p}{\partial E}\, \mathrm{d}x = 2\pi\hbar \frac{\partial n}{\partial E}.$$

Здесь, очевидно, $\frac{\partial n}{\partial E}$ - плотность спектра состояний по энергии, а $\frac{\partial E}{\partial p} = v$ - скорость движения частицы. Так как $\mathrm{d}x = v\, \mathrm{d}t$, интеграл по периоду сводится к

$$\oint \frac{\mathrm{d}x}{v(x)} = \oint \mathrm{d}t = T,$$

т.е. он равен периоду движения классической частицы. Отсюда

$$\frac{\partial E}{\partial n} = \frac{2\pi\hbar}{T} = \hbar\omega,$$

и плотность состояний определяется круговой частотой движения $\omega = 2\pi/T$. Эта частота не зависит от энергии у гармонического осциллятора, так что квазиклассика воспроизводит точный результат для разности энергий между двумя соседними уровнями:

$$\Delta E = \frac{\partial E}{\partial n}\Delta n\bigg|_{\Delta n=1} = \hbar\omega.$$

В произвольном потенциале частота движения и расщепление между уровнями связанных состояний зависят от энергии.

Нормировка

При нормировке волновой функции связанного состояния в квазиклассическом приближении необходимо учесть два факта: 1) плотность вероятности обнаружить частицу вне классически доступной области пренебрежимо мала (экспоненциально

подавлена); 2) само приближение справедливо лишь при $n \gg 1$, т.е. когда число волн между точками поворота велико (в противном случае длина волны заведомо сильно изменялась бы за период колебаний от бесконечности в точке поворота до конечного значения внутри допустимого интервала координат). Значит,

$$\int\limits_{-\infty}^{+\infty} |\Psi(x)|^2 \, \mathrm{d}x \approx \int\limits_{a}^{b} |\Psi(x)|^2 \, \mathrm{d}x = |C|^2 \int\limits_{a}^{b} |\cos\{\cdot\}|^2 \frac{\mathrm{d}x}{p(x)}.$$

Здесь под косинусом стоит фаза, которая совершает большое количество колебаний n, а амплитуда этих колебаний, обратно пропорциональная импульсу, по условию применимости квазиклассики медленно меняется. Значит, квадрат косинуса можно заменить его средним за период колебания:

$$\cos^2\{\cdot\} \to \frac{1}{2}.$$

Тогда с учетом $\mathrm{d}x = v \, \mathrm{d}t$ и $p = mv$ нормировка

$$\int\limits_{-\infty}^{+\infty} |\Psi(x)|^2 \, \mathrm{d}x \approx \frac{|C|^2}{2m} \int\limits_{a}^{b} \mathrm{d}t = \frac{|C|^2}{4m} T,$$

где опять T - полный период движения частицы в связанном состоянии. Волновая функция нормирована на единичную вероятность, так что

$$|C|^2 = \frac{4m}{T}.$$

Возмущение (!?!??!??!)

(!!! вроде это самое главное, потому что на эти формулы и решаются задачи!!!)

Рассмотрим задачу квазиклассического квантования связанных состояний системы с гамильтонианом

$$\hat{H} = \frac{\hat{p}^2}{2m} + V_0(x) + \delta V(x)$$

с малым возмущением $\delta V \ll V_0$ в смысле малого отличия интегралов от функций V_0 и $V_0 + \delta V$ на разумных конечных интервалах координаты. Будем считать, что решение задачи с гамильтонианом

$$\hat{H}_0 = \frac{\hat{r}^2}{2m} + V_0(x)$$

известно, так чтп

$$\oint p_0^E(x) \mathrm{d}x = 2\pi\hbar \left(n + \frac{1}{2}\right),$$

где, естественно,

$$p_0^E(x) = \sqrt{2m\,[E_n - V_0(x)]},$$

и интеграл берется между точками поворота (a, b). В задаче с возмущением правило квантования Бора-Зоммерфельда дает

$$\oint p^{E+\delta E}(x) \mathrm{d}x = 2\pi\hbar \left(n + \frac{1}{2}\right),$$

где импульс

$$p^{E+\delta E}(x) = \sqrt{2m\,[E_n + \delta E_n - V_0(x) - \delta V(x)]}.$$

Здесь $E_n + \delta E_n = \tilde{E}_n$ - значение уровня энергии в потенциале с возмущением, и мы полагаем, что δE - малая поправка. Пределы интегрирования, конечно, несколько меняются: $(a + \delta a, b + \delta b)$, - но вклад вблизи точек поворота в квазиклассике пренебрежимо мал, так что в (12.73) и (12.75) мы будем полагать пределы интегрирования одинаковыми (в рамках ведущего приближения это оправдаНО).

Вычтем (12.73) из (12.75) при фиксированном n. Тогда имеем

$$\oint \left\{ p^{E+\delta E}(x) - p_0^E(x) \right\} \mathrm{d}x = 0.$$

Выражение для импульса можно разложить по малому возмущению энергии и потенциала:

$$\begin{aligned} p^{E+\delta E}(x) &= \sqrt{2m\left[E_n + \delta E_n - V_0(x) - \delta V(x)\right]} = \\ &= \sqrt{2m\left[E_n - V_0(x)\right]\left\{1 + \frac{\delta E_n - \delta V}{E_n - V_0(x)}\right\}} \approx p_0 + \frac{m}{p_0}\left[\delta E_n - \delta V\right]. \end{aligned}$$

Значит,

$$\delta E_n \oint \frac{\mathrm{d}x}{p_0} = \oint \frac{\mathrm{d}x}{p_0} \delta V(x)$$

Переходя к интегралу по времени, находим

$$\delta E_n = \frac{1}{T} \int\limits_0^T \mathrm{d}t \delta V[x(t)],$$

или

$$\delta E_n = \frac{m}{T} \oint \frac{\mathrm{d}x}{p_0(x)} \delta V(x).$$

Первая из этих формул показывает, что среднее значение возмущения за период определяет сдвиг энергии связанного состояния, а вторая дает практический рецепт расчета этого сдвига.

Критерий применимости квазиклассики

Проведенное рассмотрение расчета поправки к энергии стационарного состояния за счет возмущения в квазиклассическом приближении следует считать справедливым только в том случае, если, прежде всего, изменение волновой функции $\delta\psi$ в задаче с возмущением в некотором смысле мало по сравнению с самой волновой функцией ψ_0 в исходной задаче: $|\delta\psi| = |\psi - \psi_0| \ll |\psi_0|$. Так, потребуем, чтобы в ходе временнОй эволюции, выраженной в волновой функции фактором $\exp\{-\mathrm{i}Et/\hbar\}$, за время периода колебаний частицы в потенциальной яме T была мала поправка к волновой функции за счет разности энергий:

$$\left| \mathrm{e}^{-\frac{1}{\hbar}ET} - \mathrm{e}^{-\frac{1}{\hbar}E_0 T} \right| \ll 1 \leftrightarrow \left| \mathrm{e}^{-\frac{1}{\hbar}\delta E \cdot T} - 1 \right| \ll 1.$$

Последнее возможно, только если фаза под знаком экспоненты мала по сравнению с 2π, т.е. [1]

$$\left| \frac{\delta E \cdot T}{\hbar} \right| \ll 2\pi \leftrightarrow |\delta E| \ll \hbar\omega,$$

где стандартным образом фазовая частота $\omega = 2\pi/T$. Как мы показали, величина поправки к энергии определяется средним значением возмущения на классической

траектории с энергией уровня в системе без возмущения: $\delta E = \langle \delta V \rangle$, в то время как $\hbar\omega$ задает инкремент в дискретном спектре энергий системы ΔE. Поэтому критерий применимости теории возмущений в квазиклассическом случае (12.81) можно записать в виде

$$|\langle \delta V \rangle| \ll |\Delta E|.$$

Таким образом, теория возмущений применима при условии малости возмущения по сравнению с разностью энергий между соседними стационарными уровнями.

При выводе критерия применимости методом рассмотрения временного фактора волновой функции мы по сути полагали, что в некоторой точке

пространства в области, доступной для классической частицы и удаленной от точек поворота, где квазиклассика заведомо неприменима, пространственные волновые функции в задаче с возмущением и без возмущения практически совпадают, что и позволило рассмотреть лишь разность временных факторов. Но для этого необходимо, чтобы и пространственная зависимость этих волновых функция мало отличалась друг от друга. Поэтому запишем более подробно вид координатной зависимости волновой функции в квазиклассике, используя разложение импульса по малым поправкам при наличии возмущения:

$$\exp\left\{\frac{\mathrm{i}}{\hbar}\int p(x)\mathrm{d}x\right\} \simeq \exp\left\{\frac{\mathrm{i}}{\hbar}\int p_0(x)\mathrm{d}x\right\}\exp\left\{\frac{\mathrm{i}m}{\hbar}\int \frac{\mathrm{d}x}{p_0(x)}(\delta E - \delta V(x))\right\}.$$

Как мы уже установили, переход к временной зависимости на траектории дает

$$m\int\limits_{t_0}^{t}\frac{\mathrm{d}x}{p_0(x)} = t - t_0, \quad m\int\limits_{t_0}^{t}\delta V(x)\frac{\mathrm{d}x}{p_0(x)} = \langle \delta V(t)\rangle \cdot (t - t_0)\,,$$

где, конечно, время на верхнем пределе интегрирования параметрически зависит от координаты, $t = t(x)$. Значит, координатная зависимость волновой функции в задаче с возмущением может быть представлена в виде

$$\psi(x) = \psi_0(x)\exp\left\{\frac{\mathrm{i}}{\hbar}\delta E\cdot(t-t_0) - \frac{\mathrm{i}}{\hbar}\langle\delta V(t)\rangle\cdot(t-t_0)\right\},$$

причем первое слагаемое под знаком экспоненты по сути повторяет поправку во временном факторе за счет малого сдвига энергии стационарного состояния, и мы знаем, что возникающей за счет него фазой за период колебаний можно пренебречь. Поэтому критерий применимости теории возмущений, учитывающий малое отличие пространственной зависимости волновой функции в задаче с возмущением от зависимости исходной волновой функции, можно представить в виде

$$|\psi(x) - \psi_0(x)| \ll |\psi_0(x)| \leftrightarrow \left|\mathrm{e}^{\hbar\langle\delta V(t)\rangle\cdot(t-t_0)} - 1\right| \ll 1,$$

что опять же справедливо, только если на всем периоде колебаний набегающая фаза мала по сравнению с 2π, т.е.

$$\left|\frac{\langle\delta V(T)\rangle\cdot T}{\hbar}\right| \ll 2\pi \leftrightarrow |\langle\delta V\rangle| \ll |\Delta E| = \hbar\omega.$$

В итоге и рассмотрение пространственной зависимости волновых функций приводит к тому же критерию теории возмущений в квазиклассике: характерные значения возмущения на интервале классического движения частицы должны быть существенно меньше разности энергий между соседними уровнями. При этом не следует, конечно,

забывать и о критерии применимости самого квазиклассического приближения, а именно об условии большого числа колебаний за период движения между точками поворота: $n \gg 1$.

Еще более наглядно критерий применимости теории возмущений в квазиклассике можно представить, если определить при больших квантовых числах малую вариацию номера уровня δn:

$$\delta E_n = \frac{\mathrm{d}E_n}{\mathrm{d}n}\delta n,$$

где $\mathrm{d}E_n/\mathrm{d}n$ - обратная плотность состояний в спектре энергии, посредством которой расстояние между двумя соседними уровнями можно вычислить как

$$\Delta E = \frac{\mathrm{d}E_n}{\mathrm{d}n}\Delta n \quad \text{при } \Delta n = 1.$$

Тогда условие применимости теории возмущений $\Delta E \gg |\delta E_n|$ представится в виде

$$|\delta n| \ll 1,$$

т.е. возмущение эффективно сводится к малому сдвигу номера квантового состояния в задаче без возмущения, так что не происходит перекрытия с соседними уровнями.

Случаи применимости.

(Киселев даже для черных дыр видел применение, напишу потом.)
(??? даже для эл поз пар!!!! жесть вообще.)

Как догадаться про квазиклассику?

(this is a important question for understanding this topic, I'll think about it later))

5. Введение в квазиклассические методы или "старая квантовая механика" по Тахтаджаяну

Представленная выше формулировка квантовой механики восходит к 1925 - 1927-м годам и принадлежит Гейзенбергу, Шрёдингеру, Борну, Йордану и Дираку. Она заменила старую квантовую теорию, предложенную Бором в 1913-м году, базировавшуюся на планетарной модели атома Резерфорда. В старой теории уровни энергии одномерной квантовой системы соответствуют замкнутым орбитам ассоциированной классической гамильтоновой системы, удовлетворяющим правилу квантования Бора-Вильсона-Зоммерфельда (правилу БВЗ):

$$\oint p dq = 2\pi\hbar\left(n + \frac{1}{2}\right)$$

где n - неотрицательное целое число, и интегрирование ведется по замкнутой орбите в фазовом пространстве $\mathbb{R}^2$. Правила квантования Бора-Вильсона - Зоммерфельда применяются и к вполне интегрируемым гамильтоновым системам с несколькими степенями свободы (см. раздел 1.2.6 главы 1). А именно: пусть $F_1 = H_\mathrm{c}, ..., F_N - N$ независимых интегралов движения в инволюции. Правила квантования БВЗ - это

$$\oint_\gamma \boldsymbol{p} d\boldsymbol{q} = 2\pi\hbar\left(n_\gamma + \frac{1}{4}\,\mathrm{ind}\,\gamma\right),$$

где интегрирование ведется по всем 1-циклам γ в лагранжевом подмногообразии $\Lambda = \{(\boldsymbol{p},\boldsymbol{q}) \in \mathbb{R}^{2N} : H_\mathrm{c}(\boldsymbol{p},\boldsymbol{q}) = E, F_2(\boldsymbol{p},\boldsymbol{q}) = E_2, ..., F_{\boldsymbol{N}}(\boldsymbol{p},\boldsymbol{q}) = \ = E_N\}$, $\mathrm{ind}\ \gamma \in \mathbb{Z}$ - так

называемый индекс Маслова цикла γ в Λ. В одномерном случае замкнутая орбита - топологически круг, и ее индекс Маслова равен 2. В разделе 3.6.3 главы 3 будет показано, что, вообще говоря, правила квантования Бора-Вильсона - Зоммерфельда дают только асимптотику уровней энергии при $\hbar \to 0$. Однако для интегрируемых систем с дополнительной симметрией, таких как гармонический осциллятор или задача Кеплера, правила квантования БВЗ определяют уровни энергии точно. Мы покажем это в следующем разделе для гармонического осциллятора и в разделе 3.5.1 главы 3 для задачи Кеплера.

6.9.2 Tunneling Through a Barrier

(all about it here)

Model of a tunneling

(write that well-known theory, it should be already written on some of the pages)

Special cases of a tunneling

Tunnelling of a composite particle in presence of a magnetic field

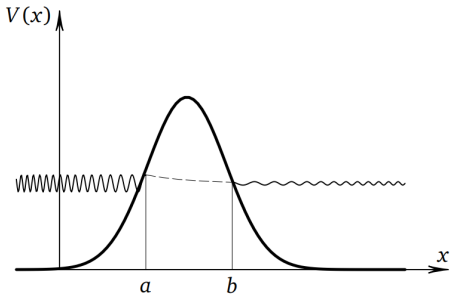
(there is an article with such a title. I'll learn it later, currently, I don't know how to describe it?)

6.9.3 Typical Examples and Details of the Semiclassical Method

(тут для задач особенности и задротские мелочи.)

Потенциальный барьер квазиклассикой

Рассмотрим задачу, в которой на потенциальный барьер с конечной силой возврата в точках поворота для классической частицы ограниченной энергии, т.е. фактически конечной высоты на конечном отрезке координат, в интервале $a < x < b$ слева падает и отражается волна. В этом случае экспоненциальное затухание волны в классически недоступной области потенциального барьера приводит к конечной, отличной от нуля волновой функции и в области $x > b$, где появляется уходящая на бесконечность волна, прошедшая через барьер (см. рис. 17).



Волновая функция

$$\Psi(x)_{x>b} - \frac{C}{\sqrt{p(x)}} \exp\left\{\frac{\mathrm{i}}{\hbar}\int_b^x p(x)\mathrm{d}x\right\}$$

имеет асимптотику прошедшей через барьер волны с потоком, направленным в положительном направлении x. Пользуясь методом сшивки решений в квазиклассическом приближении, описанным в предыдущем разделе, мы получим в области $a < x < b$ суперпозицию экспоненциально падающего и растущего с ростом x вкладов. Оба вклада нормированы так, чтобы при

обходе в комплексной плоскости точки поворота $x = b$ предэкспоненциальный множитель был бы задан одной и той же константой C в (12.87). Значит, в области $a < x < b$ возле $x = a$ в рамках погрешности самого квазиклассического приближения следует пренебречь тем вкладом, который экспоненциально подавлен, так как его учет означал бы превышение точности метода расчета. Поэтому, делая подстановку $p(x) \mapsto \mathrm{i}|p(x)|$, находим

$$\Psi(x)_{a<x<b} = \frac{C}{\sqrt{|p(x)|}} \mathrm{e}^{-\mathrm{i}\pi/4} \exp\left\{ -\frac{1}{\hbar} \int\limits_b^x |p(x)| \mathrm{d}x \right\} =$$

$$= \frac{C}{\sqrt{|p(x)|}} \mathrm{e}^{-\mathrm{i}\pi/4} \exp\left\{ -\frac{1}{\hbar} \int\limits_a^x |p(x)| \mathrm{d}x + \frac{1}{\hbar} \int\limits_a^b |p(x)| \mathrm{d}x \right\} \to$$

$$\to \quad \Psi(x)_{a<x<b} = \frac{\tilde{C}}{\sqrt{|p(x)|}} \exp\left\{ \frac{1}{\hbar} \int\limits_x^a |p(x)| \mathrm{d}x \right\},$$

$$\text{где } \tilde{C} = C \mathrm{e}^{-\mathrm{i}\pi/4} \exp\left\{ \frac{1}{\hbar} \int\limits_a^b |p(x)| \mathrm{d}x \right\}.$$

Эта волновая функция повторяет ситуацию, которая отвечает отражению волны от потенциального барьера, который находится справа от области, доступной для классической частицы при $x = a$, с затуханием волновой функции вглубь потенциального барьера, так что волновая функция слева от барьера должна вести себя как

$$\Psi(x)_{x<a} = \frac{\bar{C}}{\sqrt{p(x)}} 2 \cos\left\{ \frac{1}{\hbar} \int\limits_x^a p(x) \mathrm{d}x - \frac{\pi}{4} \right\}.$$

Коэффициент прохождения потенциального барьера $\mathcal{T}$ определяется отношением потоков вероятности в прошедшей и падающей волнах:

$$j_{\text{out}} = j_{x>b} = \frac{|C|^2}{p} \frac{p}{m} = \frac{|C|^2}{m},$$

и здесь при вычислении потока в волне дифференцируется только экспонента, а предэкспоненциальный множитель в квазиклассике изменяется очень медленно, т.е. выносится из-под знака дифференцирования, а после представления косинуса в области $x < a$ в виде суммы двух экспонент с падающей и отраженной волнами, получаем

$$j_{\text{in}} = \frac{|\tilde{C}|^2}{m},$$

так ЧТО [1]

$$\mathcal{T} = \left| \frac{C}{\tilde{C}} \right|^2 = \exp\left\{ -\frac{2}{\hbar} \int\limits_a^b |p(x)| \mathrm{d}x \right\}.$$

Отметим, что в квазиклассике коэффициент отражения тождественно равен единице (разложение косинуса на две экспоненты с одинаковыми амплитудами). Это не противоречит наличию ненулевого коэффициента прохождения, так как он экспоненциально подавлен, так что в разности $1-\mathcal{T}$ сохранение второго члена являлось бы превышением точности. Экспоненциальное подавление обусловлено условием достаточной ширины барьера, так как ширина должна превосходить несколько длин волн для применимости квазиклассики вдали от точек поворота:

$$\frac{1}{\hbar}\int\limits_a^b |p(x)|\mathrm{d}x \gg \pi \leftrightarrow \int\limits_a^b \frac{\mathrm{d}x}{\lambda} \gg \pi \to \frac{b-a}{\lambda} = \frac{\ell}{\lambda} \gg 1$$

где $\ell = b-a$ - характерная длина, на которой потенциал существенно изменился, что находится в согласии с общим условием применимости квазиклассики: длина волны существенно меняется на расстояниях, много больших длины волны, $\lambda/\ell \ll 1$.

Строго говоря, при выводе коэффициента прохождения потенциального барьера, т.е. при рассмотрении эффекта туннелирования, для применимости квазиклассического приближения необходимо, чтобы потенциал достаточно плавно вел себя вблизи точек поворота, так что, например, для потенциала на рис. 18 в области $0 < x < a$ нужно уже использовать точное решение уравнения Шрёдингера. Это, однако, сказывается только на предэкспоненциальном множителе в коэффициенте прохождения (12.89), который становится отличным от единицы [2]. Поэтому по-прежнему

$$\mathcal{T} \sim \exp\left\{-\frac{2}{\hbar}\int\limits_a^b |p(x)|\mathrm{d}x\right\}.$$

Туннельный эффект был использован Гамовым для объяснения закономерностей α-распада квазистационарных состояний ядер в соответствии с расчетом коэффициента прохождения в потенциале типа рис. 18, где притяжение (яма) обусловлено короткодействующими ядерными силами, а отталкивание-кулоновским взаимодействием положительного ядра и α-частицы.

Рис. 18.

Квазистационарное состояние в потенциальной яме и проникновение волны через потенциальный барьер В этой связи заметим, что квазистационарными состояниями называют долгоживущие резонансы, возникающие в процессах рассеяния, о которых мы упоминали в лекции 5. К теории рассеяния и распадам квазистационарных состояний мы обратимся несколько позднее во второй части курса. Здесь же укажем на то, что резонансы могут образовываться как при упругом рассеянии, когда начальное и конечное состояния описываются одним и тем же набором частиц, так и при неупругом, когда набор частиц изменяется. Долгое время жизни резонанса позволяет рассматривать его безотносительно к процессу его происхождения, а задачи описания квазистационарных состояний составляют отдельный класс, который мы не рассматриваем в этом курсе.

Флуктуации и виртуальные частицы

Физический смысл туннельного эффекта становится более ясным, если ввести понятие виртуальных частиц. В области потенциальной энергии, недоступной для классических частиц, имеют место существенные флуктуации, обусловленные тем, что операторы кинетической и потенциальной энергии по отдельности не коммутируют с

гамильтонианом:

$$[T(\boldsymbol{p}),\hat{H}]=\left[\frac{\boldsymbol{p}^2}{2m},V(\boldsymbol{r})\right]=\frac{1}{2m}(\boldsymbol{p}[\boldsymbol{p},V(\boldsymbol{r})]+[\boldsymbol{p},V(\boldsymbol{r})]\boldsymbol{p})=$$
$$=-\frac{\hbar^2}{2m}\Delta V(\boldsymbol{r})-\frac{\mathrm{i}\hbar}{m}\{\boldsymbol{\nabla}V(\boldsymbol{r})\}\cdot\boldsymbol{p}$$

и $[V(\boldsymbol{r}),\hat{H}]=-[T(\boldsymbol{p}),\hat{H}]\neq 0$, так что значения кинетической и потенциальной энергии имеют неопределенности в случае стационарного состояния с точно заданной энергией.

Этими флуктуациями можно пренебречь в области, доступной для классической частицы, потому что $-\nabla V=\boldsymbol{F}$ - сила, действующая на частицу, и второе слагаемое в коммутаторе (12.90) имеет порядок

$$\frac{\hbar}{m}\{\nabla V(\boldsymbol{r})\}\cdot\boldsymbol{p}\simeq\frac{\hbar Fp}{m}\sim F\cdot\frac{\hbar}{p}\frac{p^2}{m}\sim\delta A\cdot T_{\mathrm{kin}}\,,$$

где, как и выше, δA - работа силы на длине волны. Эта работа совершается за характерное время

$$\delta t\sim\frac{\lambda}{v}\sim\frac{\hbar}{p}\cdot\frac{m}{p}\sim\frac{\hbar}{T_{\mathrm{kin}}}.$$

Первое слагаемое в коммутаторе (12.90) также связано с работой на длине волны, если учесть поправку к значению силы на длине волны $\delta F\sim F'\lambda$,

$$-\frac{\hbar^2}{2m}\Delta V=\frac{\hbar^2}{2m}\nabla\cdot\boldsymbol{F}\simeq\frac{p^2}{2m}\frac{\hbar^2}{p^2}F'\sim T_{\mathrm{kin}}\,(\lambda\delta F)\sim T_{\mathrm{kin}}\,\delta' A.$$

Поскольку коммутатор с гамильтонианом определяет производную оператора по времени, для флуктуаций за время δt(12.91) находим

$$\mathrm{i}\hbar\frac{\delta T_{\mathrm{kin}}}{\delta t}\sim[T,\hat{H}]\to T_{\mathrm{kin}}\ \cdot\delta T_{\mathrm{kin}}\ \sim\delta A\cdot T_{\mathrm{kin}}\,,$$

а значит, согласно условию применимости квазиклассического приближения

$$\frac{\delta T_{\mathrm{kin}}}{T_{\mathrm{kin}}}\sim\frac{\delta A}{T_{\mathrm{kin}}}\ll 1,$$

и флуктуациями как кинетической, так и потенциальной энергии в классически доступной области необходимо пренебречь. Поэтому можно проводить рассуждения в терминах импульса, зависящего от потенциальной энергии, как мы это делали при построении квазиклассического приближения.

Ситуация коренным образом меняется в области, недоступной для классической частицы, когда понятия кинетической и потенциальной энергии плохо определены по отдельности. Итак, имеется вероятность такой флуктуации потенциальной энергии, при которой частица может проникнуть в классически недоступную область с некоторым положительным значением кинетической энергии. Эта вероятность в квазиклассике определяется коэффициентом прохождения

$$w\sim\mathrm{e}^{-2\frac{S}{\hbar}},$$

где S - действие, зависящее от координаты частицы в глубине потенциального барьера. Частицы, проникающие под барьер за счет флуктуаций потенциальной и кинетической энергии, называют виртуалвными. Таким образом, при наличии внешнего поля его потенциал испытывает флуктуации, приводящие κ распространению виртуальных

частиц. Если внешнее поле меняется, скажем, адиабатически в зависимости от времени или расстояния, то виртуальные частицы могут попасть в классически доступную область, т.е. наблюдаться, как это имеет место при прохождении через потенциальный барьер: если потенциал медленно уменьшается ниже значения полной энергии в некоторой области пространства, то в ней наблюдается туннельный эффект - виртуальные частицы за счет флуктуаций проходят барьер и регистрируются в классически доступной области как реальные.

Метод квазиклассики как способ учета возмущений (!?!?)

(важно обсудить это, если это применять, то по идее метод будет равносилен теории возмущений!)

Связь квазиклассики и теории возмущений (!??!?!!?)

(вопрос: как связаны эти два метода??? и как имея решение одним методом переписать его другим методом? пока слабо связь вижу, там - разложения, тут - приближенное решение. хз пока что.)

6.9.4 Semiclassical Approximation by MK (??)

В этой главе мы рассмотрим в одномерном и трехмерном случаях приближенный метод решения волнового уравнения, когда потенциал медленно изменяется на длине волны частицы. С простейшим случаем такого приближения мы познакомились в 1.1.

Одномерная задача

Напишем уравнение Шрсдингера в виде

$$\varphi'' + k^2(x)\varphi = 0$$

где

$$k^2(x) = 2[E - V(x)].$$

(считаем $\hbar = M = 1$). Пусть потенциил $V(x)$ достаточно медленно меняется с изменением координаты, так что

$$kl \geqslant 1,$$

где l - длина, на которой существенно меняется $V(x)$.

Тогда можно найти приближенное решение (3.1). Ишем решение (3.1) в виде $\varphi = Ae^{is}$, где A и S-действительные функции координаты. Имеем $\varphi' = e^{iS}\left(A' + iS'^2A\right)$ и $\varphi'' = e^{iS}\left(A'' + 2iS'A' + iS''A - S'^2A\right)$. Из (3.1) имеем

$$A'' + 2iA'S' - iS''A - S'^2A + k^2A = 0.$$

Отделяя вещественную часть от мнимой, получаем два соотношения:

$$A'' + S'^2A + k^2A = 0$$
$$S''A + 2A'S' = 0$$

Перепиинем
Отсюца (3.4)
в виде $\frac{A'}{A} = -\frac{S''}{2S'}$.

$$A = \frac{a}{\sqrt{S'}},$$

где a - постоянная величина. 13 (3.3) имеем

$$(S')^2 = k^2 + \frac{A''}{A}.$$

Так как k меняется суицественно на длине l, то и S', а следовательно, и A меняются существенно на той же длине. Поэтому $A''/A \sim 1/l^2$, т. е. $A''/k^2A \sim 1/(kl)^2 < 1$, и в первом приближении можно считать $(S')^2 = k^2$.

Тогда решение задачи имеет вид

$$\varphi(x) = \frac{a}{\sqrt{r}(x)} \exp\left[-i \int\limits_{x_1}^{x} k dx\right].$$

Это относится к случаю $E > V$, когда k вещественно. В случас $E < V$ решение будет содержать растущую и затухающую экспоненты, т. е.

$$\varphi(x) = A \exp\left[\pm \int\limits_{x_2}^{x} |k| dx\right],$$

где $A = a/\sqrt{|k|}$. Мы получили первое приближение в разложении по степеням величины $1/(kl)^2$. Ясно, как получать и следуюиие приближения. Оказывается, что получаюнийся при этом ряд по степеням параметра $1/(kl)^2$ асимптотический, а не обычный.

3 а ача. Показать, что при приближенной оценке производной от квазиклассической функции нужно дифференцировать лиив эксионенту.

Асимптотические ряды

Напомним, что такое асимнтотический ряд. Пусть

$$s_n = \sum_{v=0}^{n} \frac{a_\nu}{z^\nu}$$

- тастичная сумма ряла. Пусть при фиксированном z и $n \longrightarrow \infty$ величина $s_n \longrightarrow \infty$, но при фиксированном n и $z \longrightarrow \infty$ сумма s_n все лучшее и лучше аптроксимирует некоторую функцию $f(z)$, т. є.

$$\lim_{z\to\infty} z^n \left[s_n(z) - f(z)\right] = 0$$

Тогда говорят, что s_n есть асимптотическое представление $f(z)$. Это не есть ряд в обычном смысле этого слова, так как s_n расходится. Но из него можно извлечь сведения о функции $f(z)$, так как при $z \longrightarrow \infty$ он хорошо представляет эту функцию.

Построим $s_n(z)$ по заданноЙ $f(z)$. Величина s_0 равна a_0, следовательно, $a_0 = f(\infty)$. Величина $s_1 = a_0 + a_1/z$, тогда

$$\lim_{z\to\infty} z\left(a_0 + \frac{a_1}{z} - f(z)\right) = 0,$$

Т. е.

$$a_1 = \lim_{z\to\infty} z\,[f(z) - a_0] = \lim_{z\to\infty} z[f(z) - f(\infty)].$$

Аналогичным образом находятся все коэффициенты a_n.

Однако восстановить обратно функцию по ее асимптотическому представлению нельзя. Например, пусть $f(z) = e^{-z}$, тогда

$$a_0 = 0, \quad a_1 = \lim_{z\to\infty} ze^{-z} = 0, \quad a_2 = a_3 = ... = a_n = 0.$$

Следовательно, весь асимптотический ряд равен нулю для функции e^{-z}. Итак, функции $f(z)$ и $f(z) + e^{-z}$ имеют одиінаковые асимптотические представления.

Обозначим $z \equiv (kl)^2$. Оказывается, что квазиклассическое решение

$$\varphi_{\text{квазнкл}}\,(x) \approx \sum_{\nu=0}^{n} \frac{a_\nu(x)}{z^\nu}$$

есть асимптотический ряд, т. е. расходящийся при $n \to \infty$. Однако при $z \longrightarrow \infty$ величина $a_0(x)$ сколь угодно хорошо представляет функцию $\varphi(x)$ (точное решение).

Пусть, далее, z фиксировано. При $n \longrightarrow \infty$ ряд (3.6) расходится. Следовательно, при любом z есть оптимальное число членов $n(z)$, которое наилучшим образом описывает функцию $\varphi(x)$. Мы будем пользоваться только нулевым членом этого ряда. Следующие приближения не обязательно должны улучшить, они могут и ухудшить решение.

Поскольку квазиклассическое приближение есть асимптотический ряд по степеням параметра $1/(kl)^2$, в нем теряются эффекты, экспоненциально малые при больших значениях этого параметра.

Сиивание квазиклассических функций

В этом разделе мы найдем, как нужно сшивать квазиклассическую волновую функцию φ в области, доступной для классического движения, с φ в запреценной области. Для определенности предположим, что потенциальная энергия частицы имеет вид, изображенный на рис. 24 (начало координат взято в точке, где $V(x) = E$).

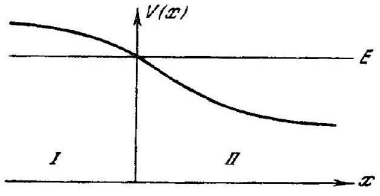


Рис. 24.

Квазиклассическое решение в области II (классически цоступной) согласно (3.5) имеет вид

$$\varphi = \frac{a_1}{\sqrt{k}} \exp\left(i\int_0^x k dx\right) + \frac{a_2}{\sqrt{k}} \exp\left(-i\int_0^x k dx\right),$$

а в области I (классически недостуінон)

$$\varphi = \frac{b_1}{\sqrt{|k|}} \exp\left(\int_x^0 |k| dx\right) + \frac{b_2}{\sqrt{|k|}} \exp\left(-\int_x^0 |k| dx\right)$$

Если бы квазиклассическое решение было аналитическо й функиий x в окрестности $x = 0$, то для нахождения соотношений между a_1, a_2 и b_1, b_2 нужно было бы аналитически продолжить это рсшение нз II в I (при этом экспоненты в (3.7) просто перешли бы в эксионенты (3.8)).

Правда, по вещественной оси нельзя было бы двигаться, так как в окрестности $x = 0$ квазиклассика негриленима ($k(0) = 0$, поэтому условие $kl \geqslant 1$ не вынолняется). Эту трудность можно было бы преодолеть, обойдя точку $x = 0$ в комнлексной плоскости по дуге достаточно большого радиуса (где применима квазиклассика).

Однако такое аналитическое продолжение дает, как мы увидим, неправильный результат.

Оказывается, что при таком обходе обязательно пере секаются линии (они называются линиями Стокса), где портится аналитическое продолжение. Поэтому такой способ нужно применять осторожно. Ниже мы покажем, как это сделать.

Дрругой возможный путь состоит в том, чтобы искать точное решение задачи вблизи $x = 0$, считая потенциал прямолинейным. Это решенне описывается так называемой функцией Эйри. Затем нужно сшить точное решение с квазиклассическим при $x > 0$ и $x < 0$.

Разумеется, так можно поступать только зная, что квазиклассическое піриближение становится применимым на расстояниях от точки поворота, малых по сравнению с расстоянием, на котором потенциал существенно отклоняется от прямолинейного. Покажем, что при большом параметре квазиклассичности ($k^2l^2 \gg 1$) это действительно так.

Разложим для этого потенциал $V(x)$ вблизи $x = 0$ в ряд: $V(x) \approx E + V'(0)x$. Тогда импульс $k(x) = \sqrt{-2V'(0)x} \equiv \alpha\sqrt{x}$. Оценим величину α : $\alpha \sim \sqrt{|V'(0)|} \sim \sqrt{\frac{V(0)}{l}} \sim \frac{k_0}{g}$, где $k_0 = \sqrt{2E}$, а l - длина, на которой существенно меняется потенциал $V(x)$. Итак, в окрестности точки $x = 0$ величина $k(x) \sim k_0\sqrt{\frac{x}{l}}$. Чтобы квазиклассическое приближение было применимо, нужно отони от точки $x = 0$ на такое расстояние, чтобы $d\left(\frac{1}{k}\right)/dx \ll 1$ или $\frac{\sqrt{l}}{k_0\sqrt{x^3}} \ll 1$. Отсюда находим: $x \gg l/\left(k_0 l\right)^{2/3}$. Так как $k_0 l \gg 1$, то можно выбрать такое x_1, Что

$$\frac{l}{\left(k_0 l\right)^{2/s}} \leqslant x_1 \ll l.$$

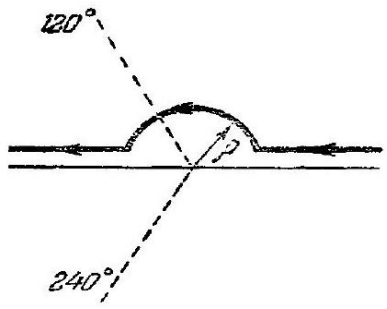
На расстояниях $\sim x_1$, с одной стороны, уже годится квазиклассическое приближение, а с другой, - нотенциал все еще можно считать прямолинейным.

Сшивка с помощью функций Эйри для потенциала, изображенного нар рис. 24, имеет вид)

$$\frac{1}{\sqrt{k}}\exp\left[i\int\limits_0^x k dx - \frac{\pi}{4}\right] \to \frac{1}{i\sqrt{|k|}}\exp\left[\int\limits_x^0 |h|dx\right] + \frac{1}{2\sqrt{|k|}}\exp\left[-\int\limits_x^0 |h|dx\right],$$

$$\frac{1}{\sqrt{k}}\exp\left[-i\int\limits_0^x k dx + \frac{\pi}{4}\right] \to \frac{-1}{i\sqrt{|k|}}\exp\left[\int\limits_x^0 |k|dx\right] + \frac{1}{2\sqrt{|k|}}\overline{|xp}\left[-\int\limits_x^0 |k|dx\right]$$

Сейчас мы получнм эти соотнонения, не прибегая к рункциям Эйрг. Выберем радиус обхода ρ порядка x_1 (рис. 25).



Тогда можно пользоваться квазнклассическим приближением и в то же время считать потенциал прямолинейным. Татк как при этом $k(x) = \alpha x^{1/2}$, то $\int\limits_0^x /2dx = \frac{2}{3}\alpha x^3/$В комплексной плоскости $x = \rho e^{i\varphi}$ и Prc. 25. $\int\limits_0^x k dx = \frac{2}{3}\alpha\rho^{3/2}\exp\left(\frac{3}{2}i\rho\right)$.

Поэтому

$\frac{1}{\sqrt{i2}}\exp\left[i\int\limits_0^i k dx\right] = \frac{1}{\sqrt{\alpha\omega^2/2}}e^{-i\frac{\varphi}{4}}\exp\left[\frac{2}{3}\alpha\rho^{3/2}\left(i\cos\frac{3}{2}\varphi - \sin\frac{3}{2}\varphi\right)\right]$

По mepe обхода контура Lo тех пор, пока $\varphi < \frac{2\pi}{3}$, $\sin\frac{3}{2}\varphi$ полоинтелен, а выражение (3.10) содержит затухающую экспоненту. Если $\varphi > \frac{2\pi}{3}$, то (3.10) содержит растущую экспоненту. Как только появпяется растущая эксионеита, все слагаемые, содержаиие убывающую экспоненту, не допжнь! учитываться, поскольку квазиклассическое приблужение, будучн аснмптотическим представлением, имеет по параметру квазнклассичности степенныio $\left(\sim\frac{1}{k^2l^2}\right)$, а не экспоненциальную точность.

При движении по окружности радиуса ρ в верхней по$i\frac{2}{3}\alpha x^3/2$

луплоскости выражение e переходит сначала в убывающщю экспоненту, а затем после пересечеция линии $\varphi = \frac{2\pi}{3}$ - в растущую экспоненту; как только появнлась растуцая экспонента, из-за неточности квазиклассического приближения возникает экспоненциально малая ошибка. Поэтому аналнтическоепродолжение позволяет найти коэфд-. фициент только при растуцей экспоненте.

Получанм

$$\frac{1}{\sqrt{k}}\exp\left[i\int\limits_0^x \dot{k}dx - \frac{\pi}{4}\right] \to \frac{1}{i\sqrt{|k|}}\exp\left[\int\limits_x^0 |k|dx\right].$$

При этом мы потеряли слагаемое, экспонениіально малое Ilo сравнению с правой частью (3.11).

При обходе точки $x = 0$ снизу функция (3.11) переходит сначала в растуцую эксионенту, а затем после пересечения линин

$$\mathscr{Q} = -\frac{2\pi}{3}$$

в убъвающчюо.

Iотерянная из-занеточности квазнклассического приближения в области $-\frac{2\pi}{3} < \varphi < 0$ экспоненциально malая добавка после перехода в область $-\pi < \varphi < -\frac{2\pi}{3}$ превращается в экспоненциально большой член, которьй такин образом теряется. Следовательно, такнм путем мы не можем получить правильное значение коэффициента при убывающей экспоненте. Как его получить? Предположим, что в классически недоступной области (при $V > E$ есть только затухающая экспонента:

$$\frac{1}{\sqrt{|k|}}\exp\left[-\int\limits_x^0 |k|dx\right]$$

Общее решение при $V < E$ имеет вид.

$$\frac{C_1}{\sqrt{\tilde{k}}}\exp\left[i\int\limits_0^x kdx - i\varphi_1\right] + \frac{C_2}{\sqrt{k}}\exp\left[-i\int\limits_0^x kdx + i\varphi_2\right]$$

Найдем C_1, C_2 и φ_1, φ_2. Для этого продіолжим аналитически (3.12) в область $x > 0$. Аналитическое продолжение через верхнюю полуплоскость имеет вид

$$\frac{1}{\sqrt{|k|}}\exp\left[-\int\limits_x^0 |k|dx\right] \to$$
$$\longrightarrow \frac{\exp[i\pi/4]}{\sqrt{\alpha\rho^{1/2}\exp(i\varphi/2)}}\exp\left[\frac{2}{3}\alpha\rho^{1/2}\left(\sin\frac{3}{2}\varphi - i\cos\frac{3}{2}\varphi\right)\right].$$

При $\varphi = 0$ получаем второе слагаемое (3.13), причем $\varphi_2 = -\pi/4, C_2 = 1$. Аналитически продолжая через нижнюю полуплоскость, мы получили бы первое слагаемое (3.13) со значениями

$$\varphi_1 = \varphi_2 = -\pi/4$$
$$C_1 = C_2 = 1$$

Каждый раз второе слагаемое теряется из-за экспоненциально малой ошибки в той области, где функция экспоненциально велика. Таким образом, имеем

$$\frac{1}{\sqrt{|k|}}\exp\left[-\int\limits_x^0 |k|dx\right] \to \frac{2}{\sqrt{k}}\cos\left(\int\limits_0^x kdx - \frac{\pi}{4}\right)$$

в согласии с (3.9).

Условие квантования

Квазиклассическое решение уравнения Шредингера в классически доступной области ($x_1 < x < x_2$; рис. 26) можно записать двумя способами: один раз - сшивая осциллирующее решение с затухающим в точке x_1, а другой раз - в точке x_2. Требование совпадения этих двух функций и даст нам условие квантования.

Первое из решений имеет вид

$$\varphi_1 = \frac{a_1}{\sqrt{k}}\cos\left(\int\limits_{x_1}^x kdx - C_1\pi\right),$$

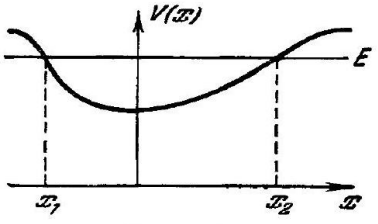


Рис. 26.

где $C_1\pi -$, которая возникает при сшивке с затухающей экспоиентой для $x < x_1$. В тех случаях, когда потенциал в окрестности точки x_1 имеет линейный ход, получается, как мы видели, $C_1 = 1/4$.

Второе из решений имеет вид

$$\varphi_2 = \frac{a_2}{V/k} \cos\left(\int_x^{x_2} k dx - C_2\pi\right).$$

Условие совпадения решений даст

$$\int_{x_1}^{x_2} k dx = (n + C_1 + C_2)\,\pi$$

(при этом $a_1 = a_2(-1)^n$).

Нетрудно видеть, что $\cos\left(\int_{x_1}^{x} k dx - C_1\pi\right)$ проходит через нуль n раз, т. е. n-число узлов волновой функции в интервале $[x_1, x_2]$.

Проверим правило квантования (3.14) (так называемое правило квантования Бора) на примере одномерной прямоугольной ямы с бесконечно высокими стенками. Так как волновая функция должна обращаться в нуль как на левой, так и на правой границах, то $C_1 = C_2 = 1/2$. Получаем

$$\int_{x_1}^{x_2} k_n dx = k_n L = (n-1)\pi, \quad E_n = \frac{1}{2}k_n^2 = \frac{\pi^2}{2L^2}(n+1)^2,$$

где L - длина ямы. Наинизшему состоянию соответствует число узлов $n = 0$.

В наиболее частом слуцае, когда потенциал имеет линейный ход как вблизн x_1, так и вблизи x_2, получаем правило квантования

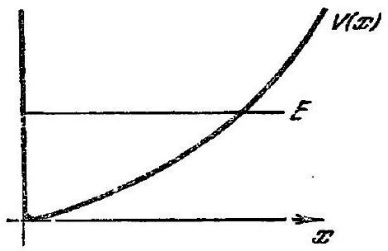

Рис. 27.

$$\int_{x_1}^{x_2} k dx = \left(n + \frac{1}{2}\right)\pi.$$

Мы увидим ниже (стр. 137), что применение квазиклассического приближения для радиальной кулоновской функции при $l = 0$ дает $C_1 = 3/4, \quad C_2 = 1/4$ а при $l \neq 0 \quad C_1 = C_2 = 1/4$.

3 ад ч а. Показать, что для потенциала, нзображенного на рис. 27, условие квантования имеет вид

$$\int_{x_1}^{x_2} k dx = \left(n + \frac{3}{4}\right)\pi.$$

Точность кваєинлассического приблинения

Едйнственное приближение, которое мы делали при выводе наших формул, состояло в отбрасывании слагаемого

$$\frac{A''}{k^2 A} \sim \frac{A/l^2}{k^2 A} \sim \frac{1}{(kl)^2}.$$

Дlя оценки kl заметим, что

$$\int k dr \sim kl \sim n\pi,$$

где n - число узлов. Следовательно, квазиклассическое прин ближение справедливо. с точностью до $1/\pi^2 n^2$ (а не $1/n$). Ɣimенно поэтому в правиле квантования Бора законно сохранять добавку $1/2$ кислу узлов , которая иредставляет собон(??) поправку $\sim 1/n$.

Нормяровка квазиклассических функций

Сунественший вклад в пориировопный интеграл внесет лишь область $x_1 < x < x_2$ (см. рис. 26), так как вне ее волновая функция экспоненциально затухает. При $x_1 < x < x_2$ волновая функция

$$\varphi_n = \frac{a}{\sqrt{\dot{\alpha}}} \cos\left(\int_{x_1}^{x} k dx - \frac{\pi}{4}\right)$$

следовательно,

$$\int |\varphi_n|^2 dx = 1 \approx \int_{x_1}^{x_2} \frac{a^2}{h} \cos^2 \Phi dx$$

где

$$D = \int_{x_1}^{x} k dx - \frac{\pi}{4}$$

Гри $E = E_n$ волновая функция φ_n имеет n узлов в области $[x_1, x_2]$, так как $\int_{x_1}^{x_2} kax$ изменяется от нуля до $(n + 1/2)\pi$ и cos Φ будет n раз обраныться в нуль. Если n велико, то фаза D - большое число.

Далее, $\cos^2 \mathrm{D} = \frac{1}{2} + \frac{1}{2}\cos 2\mathrm{D}$. Второе слагаемое много раз изменяет знак и поэтому внесет малый вклады. Следовательно,

$$1 \approx \frac{a^2}{2} \int_{x_1}^{x_2} \frac{dx}{k} = \frac{a^2}{2}\frac{T}{2},$$

где T-период классиического движения. Мтак,

$$\alpha^2 = -\frac{4}{T} = \frac{2}{\pi}\omega,$$

где ω - частота колебаний в соответствующей классической задаче. Таким образом,

$$\varphi_n = \sqrt{\frac{2\omega}{\pi k}} \cos\left(\int_{x_1}^{x} k dx - \frac{\pi}{4}\right).$$

3 адача. Оценить вклад в нормировочный множитель от классически недоступной области. О т в т.

$$1/(\pi n)^{1/3}$$

Принцип соответствия

Из правила квантования (3.9), дифференцированием по n получаем

$$\pi = \frac{d\varepsilon_n}{dn} \int_{x_1}^{x_3} \frac{dx}{k} = \frac{d\varepsilon_n}{dn} \frac{\pi}{\omega},$$

откуда

$$\frac{d\varepsilon_n}{dn} = \omega$$

Это соотношение называется принципом соответствия: при больших квантовых числах разность соседних уровней энергии равна классической частоте движения.

Средняя кинетическая энергия

Выразим среднюю кинетическую энергию частицы при квазиклассическом движении через ее иолную энергию:

$$\bar{T} = \frac{1}{2}\int \varphi_n^* \hat{p}^2 \varphi_n \, dx = -\frac{1}{2}\int \varphi_n^* \frac{d^2}{dx^2} \varphi_n \, dx \approx \frac{1}{2}\int \varphi_n^* k^2 \varphi_n \, dx.$$

3 десь величина k - число, а не оператор. Дифференцированне $1/\sqrt{k}$ в $\varphi_n = \frac{a}{\sqrt{k}} \cos\left(\int_{x_1}^{x} k dx - \frac{\pi}{4}\right)$ вносит малый вклад в $\bar{T}$. Используя (3.16), получим

$$\bar{T} = \frac{a^2}{2} \int_{x_1}^{x_2} k^2 \frac{1}{k} \cos^2 \Phi dx = \frac{a^2}{4} \int_{x_1}^{x_2} k dx =$$
$$= \frac{a^2}{4}\left(n + \frac{1}{2}\right)\pi = \frac{1}{2}\left(n + \frac{1}{2}\right)\frac{d\varepsilon_n}{dn}.$$

В случае кулоновского потенциала при $l = 0$ условие квантования не содержит $1/2$ и

$$\bar{T} = \frac{1}{2} n \frac{d\varepsilon_n}{dn}.$$

Если принять во внимание теорему вириала

$$\bar{T} = \frac{1}{2}\overline{x\frac{dV}{dx}},$$

то из (3.17) и (3.19) можно найти собственные значения энергии в квазиклассическом случае. Например, для осциллятора $V \sim x^2$ и $\overline{x\frac{dV}{dx}} = 2\bar{T}$, т. е. $\bar{T} = \bar{V}$. Следовательно,

$$\left(n + \frac{1}{2}\right)\frac{d\varepsilon_n}{dn} = \varepsilon_n.$$

Решая это уравнение, получим $\varepsilon_n = C(n+1/2)$. Из принципа соответствия следует, что $C = \omega$ - частоте классического движения, следовательно, $\varepsilon_n = (n + {}^1/2)\,\omega$. Д алее, для кулоновского потенциала при $l = 0$ из (3.18) и (3.19): $\bar{T} = -1/2\bar{V} = \frac{1}{2}n\frac{d\varepsilon_n}{dn}, \varepsilon_n = \bar{T} - 2\bar{T} = -\bar{T} = -\frac{1}{2}n\frac{d\varepsilon_n}{dn}$.Ре - шение этого уравнения есть $\varepsilon_n = C/n^2$. Мы видели (стр. 36), что из принципа соответствия следует $C = -1/2$.

Связь квазиклассических матричных элементов с компонентами Фурье классического движения

Свяжем матричный элемент $\int \varphi_n^* U(x)\varphi_n dx$ одномерной задачи с компонентой Фурье от классической величины $U[x(t)]$ (например, дипольный матричный элемент

$$\int \varphi_n^* x \varphi_n dx$$

можно связать с компонентой Фурье классической координнаты движения $x(t)$).

Пусть n' не очень снльно отличаются друг от друга, именно,

$$\frac{|n'-n|}{n} \ll 1, \quad n \geqslant 1, \quad n' \geqslant 1.$$

тогда матричный элемент
$U_{nn'} = \int \varphi_n^* U \varphi_{n'} dx = a_n a_{n'} \int \frac{U}{\sqrt{kk'}} \cos\Phi_n \cos\Phi_{n'} dx =$

$$= a_n^2 \int U\left[\cos\left(\Phi_n - \Phi_{n'}\right) + \cos\left(\Phi_n + \Phi_{n'}\right)\right]\frac{dx}{2k}.$$

Так как Φ_n и Φ_n в велики, то второе слагаемое в подынтегральном выражелии можно отбросить из-за сильной осцилляции $\cos\left(\Phi_n + \Phi_{n'}\right)$. Следовательно,

$$U_{nn'} = \frac{a_n^2}{2}\int\limits_{x_1}^{x_2} U(x)\cos\left(\phi_n - \mathrm{i}_{n'}\right)\frac{dx}{v}.$$

Так как
$\Phi_n - \lesseqgtr_{n'} = \int\limits_{x_{ib}}^{x} t_n dx - \int\limits_{x'_{ib}}^{x} k_{n'} dx \approx \int\limits_{x_{ii}}^{x} \frac{d_{ni}}{i_n}\left(\varepsilon_n - \varepsilon_{n2'}\right) =$

$$= \frac{d\varepsilon_n}{dn}\left(n - n'\right)\int\limits_{x_i}^{x}\frac{dx}{v} = \frac{d\varepsilon_n}{dn}\left(n-n'\right)t,$$

ТО

$$U_{nn} = \frac{2}{T}\int\limits_0^{T/2} U[xt]\Bigg]\cos\frac{2\pi\left(n-n'\right)t}{T}dt.$$

Итак, матричный элемент величины $U(x)$ в квазиклассическом приближении равен фууре-компоненте величины $U[x(t)]$.

Критерйй применимости теории возмуаений расqета не слинком налых величин

При возмущении -го состояния дискретного сиектра критерий применимости теории возмущений имеет вид $H' < E_{nm}$, гпе H' - матричный элсмент возмущения, а $E_{nm} = E_n - E_m$. Здесь E_n и E_m означают ближайшие уровни, для которьх матричный элемент H'_{nm} не мал. Так как

$$E_{nm} \sim \frac{dE_n}{dn} \sim \frac{E_n}{n},$$

где n-число узлов волновой функции, то это условие сводится к

$$\frac{H'}{E_n} n \ll 1.$$

В квазиклассическом случае $n \gg 1$, и это условие.может не выполняться. Покажем, что для вычисления не слишком малых величин его можно заменить более мягким условием:

$$\frac{H'}{E_n} \leqslant 1.$$

Для доказательства этого утверждения рассмотрим матричный элемент $U_{nm} = (\varphi_n|U|\varphi_{mn})$. ГIусть $U(x)$ - плавная функция. Тогда $U_{nm} \neq 0$, лиць когда n и m мало отличаюгся друг. от друга (иначе у подынтегральной функции будет много узлов). Воспользовазцись квазиклассическими волновыми функіцияи, полугаем

$U_{nm} \approx \frac{a_n a_{in}}{2} \int U(x) \frac{dx}{\sqrt{k_n k_m}} \{\cos(\Phi_n - \Phi_m) + \cos(\Phi_n + \Phi_m)\}$.

Второе слагаемое в подынтегральном выражении для U_{nm} осциллирует $n + m$ раз, поэтому его вкладом можно пренебречь. Следовательно,

$$U_{nm} \approx \frac{a_n a_m}{2} \int U(x) \frac{\cos(\Phi_n - \Phi_m)}{\sqrt{k_n k_m}} dx.$$

Пусть теперь к потенциалу $V(x)$ добавляется малая величина $H'(x)$. Так как $k_n = \sqrt{2[E_n - V(x)]}$, то

$$\Delta k_n = \sqrt{2[E_n - V(x) - H'(x)]} - \sqrt{2[E_n - V(x)]} \sim \frac{H'}{k_n},$$

следовательно, $\Delta k_n/k_n \sim H'/k_n^2 \sim H'/E_n$, если V не близко к E_n (иначе квазнклассика неприменима). Следовательно, условиее $\Delta k_n/k_n \ll 1$ эквивалентно $H'/E_n \ll 1$, Т. е. изменением k можно пренебречь при вынолнении условия (3.21). При вычислении фазы $\Phi_n = \int\limits_{x_1}^{x} k_{nz} dx - \frac{\pi}{4}$ этого нельзя делать, так как $\delta\Phi_n \approx \int\limits_{x_1}^{x} \delta k_n dx \approx \int \frac{H'}{E_n} k_n dx \sim \frac{H'}{E_n} n$, где n-число узлов. Поэтому условие $\delta\Phi_n \ll 1$ означает $\frac{H'}{E_n} n \ll 1$; отсюда и возник критерий теории возмущений.

Однако мы видим, что для вычисления величин, содержащих $\Phi_n - \Phi_m$, причем $|n-m| \sim 1$, изменение разности Фаз имеет порядок

$$\delta\left(\bar{\Phi}_n - \Phi_m\right) \sim \frac{H'}{E_n}(n-m) \sim \frac{H'}{E_n}.$$

Следовательно, изменение больших матричных элементов U_{nm} гпри возмуцении потенциала на величину $H'(x)$ определяется условием $H'/E_n \ll 1$, что и нужно было показать.

Если $|n - m|$ не мало, то изучаемый матричный элемент мал из-за осцилляций $\cos(\Phi_n - \Phi_m)$.

Выясним, как изменяется квазиклассическая волновая функция $\Psi = Ae^{is}$ при добавлении малой величины $H'(x)$ к потенциалу $V(x)$. Мзменение A определяется величиной H'/E, поскольку $A \sim 1/\sqrt{k}$, а $\Delta k/k \sim H'/E$, как уже было найдено. Но $S = \int k dl$, поэтому $\delta S \sim n\frac{H'}{E}$, так что δS может быть и больне 1, хотя $H'/E \ll 1$. Мзменение Ψ при добавлении H' равно:

$$\delta\Psi \approx \Psi e^{i\delta S} \approx \Psi \exp\left(-\int \frac{H' dx}{k}\right)$$

Возмущение, вызываемое деформацией ядра, не удовлетворяет критерию (3.20), но критерий (3.21) выполняется. Поэтому для вычисления не очень малых величин можно пользоваться теорией возмущении (стр. 74).

Надбарьерное отражение

Решим задачу об отражении частицы при движении с энергией, больцей высоты барьера, так что везде выполняется критерий квазиклассического приближеция. Легко увидеть, что ни в каком приближении по параметру квази- классичности $1/(kl)^2$ не возникает отраженной волны. Действительно, квазиклассическое приближение, соответствующее идуцей направо волне, имеет вид

$$A \exp\left[i \int_{x_1}^{x} \sqrt{k^2 + A''/A} dx \right].$$

Разлагая это решение по степеням A''/A, получим всюду только волны, идушие вправо.

Причина этого результата в том, что коэффициент отражения экспоненциально падает с увеличением $(kl)^2$, между тем как квазиклассическое решение есть асимптотический ряд и экспоненциально малые добавки в нем полностью теряются.

Lелесообразно искать решение уравнения Шредингера

$$\Psi' + k^2(x)\Psi = 0$$

В Виде

$$\Psi = \sqrt{\frac{k_0}{k}} \exp\left(i \int_{-\infty}^{x} k dx \right) + \varphi$$

где φ - малая добавка, содержашая отраженнуго волну.

Тогда получаем

$$\varphi'' + k^2 \varphi = f(x)$$

rale

$$f(x) = -A'' \exp\left[i \int_{-\infty}^{x} k dx \right]$$

Выразим решение этого неоднородного уравнения через два решения соответствующего однородного уравнения Ψ_1 и Ψ_2(Ψ_1 и Ψ_2 $\rightarrow$ волны, идущие соответственно вправо и влево):

где

$$\varphi = \frac{1}{\Delta} \left\{ \Psi_1 \int^{x} \Psi_2 f dx - \Psi_2 \int_{1}^{x} \Psi_1 f dx \right\}$$

$$\Delta = \Psi_1' \Psi_2 - \Psi_1 \Psi_2' = \text{ const}$$

- онределитель Вронского.

Цтак, решение уравнения LЦредингера (3.23) имеет вид

$$\Psi(x) = \sqrt{\frac{\widehat{k_0}}{k}} \exp\left[i \int\limits_{-\infty}^{x} k dx\right] +$$

$$+ \frac{1}{\Delta}\left\{\Psi_1 \int\limits_{-\infty}^{x} \Psi_2 f dx - \Psi_2 \int\limits_{-\infty}^{x} \Psi_1 f dx\right\}.$$

Пределы интегрирования определяются из следующих соображений: при $x \longrightarrow \infty$ должна оставаться только волна, идущая вправо; это обеспечивается функцией Ψ_1. I1ри $x \to -\infty$ функция $\varphi(-\infty)$ должна содержать только отраженную волну. Действительно, при указанном выборе нижнего предела

$$\Psi(x) \underset{x\to-\infty}{=} e^{ik_0 x + i\alpha} + \frac{1}{\Delta} e^{-ik_0 x} \int\limits_{-\infty}^{\infty} \Psi_1 f dx.$$

Так как $\Delta = \text{const}$, можно вычислить Δ при $x \longrightarrow \infty$. Функция $\Psi_1 \longrightarrow e^{ik_0 x}$, а функция Ψ_2 в силу малого коэффициента отражения приближенно стремится к $e^{-ik_0 x + i\alpha}$. Отсюда $|\Delta| = 2k_0$.

Таким образом, коэффициент отраяения

$$R = \left|\frac{1}{\Delta} \int\limits_{-\infty}^{\infty} \Psi_1 f dx\right|^2 = \left|\frac{1}{2k_0} \int\limits_{-\infty}^{\infty} \Psi_1 f dx\right|^2.$$

Заметим, что в (3.24) не используется квазиклассическое приближение.

Если $V \ll E$, то из (3.24) получается обычная формула теории возмущений. Действительно, величина $A' = -\frac{\sqrt{k_0}}{2\sqrt{k^3}} k'$. Так как $k = \sqrt{2(E-V)}$, то $k' = -V'/k$, следовательно, $f = -A'' e^{iS} \approx \frac{V''}{2k_0^2} e^{ik_0 x + i\alpha}$ и

$$R = \left|\frac{1}{4k_0^3} \int\limits_{-\infty}^{\infty} V'' e^{2ik_v x} dx\right|^2.$$

Iинтегрируя дважділ по частим, попучим выражение для коэффициента отражения, совиадающее стем, что получается по теории возмущений

$$R = \left|\frac{1}{k_0} \int\limits_{-\infty}^{\infty} V e^{2ik_0 x} dx\right|^2.$$

Величина R определяется поведением $\Psi_1 f$ в окрестности ближайшєй к вещественной оси особой точки.

6.9.5 Time-Dependent Asymptotics by Takhtajan

Здесь мы опишем соотношение между классической и квантовой механикой, рассмотрев поведение волновой функции $\psi(\boldsymbol{q}, t)$ - решения зависящего от времени уравнения Шрёдингера [10]

$$i\hbar \frac{\partial \psi}{\partial t} = -\frac{\hbar^2}{2m} \Delta\psi + \dot{V}(\boldsymbol{q})\psi$$

при $\hbar \to 0$. Подстановка

$$\psi(\boldsymbol{q}, t) = e^{-\frac{i}{\hbar} S(\boldsymbol{q}, t; \hbar)}$$

сводит (6.1) к следующему нелинейному уравнению в частных производных:

$$\frac{\partial S}{\partial t} + \frac{1}{2m} \left(\frac{\partial S}{\partial \boldsymbol{q}} \right)^2 + V(\boldsymbol{q}) = \frac{i\hbar}{2m} \Delta S$$

Замечательно, что (6.3) отличается от уравнения Гамильтона- Якоби (2.4) для функции Гамильтона $H_c(\boldsymbol{p}, \boldsymbol{q}) = \frac{\boldsymbol{p}^2}{2m} + V(\boldsymbol{q})$, рассмотренной в разделе 1.2.3 главы 1, только слагаемым в правой части, пропорциональным $\hbar$. Таким образом, при $\hbar \to 0$ уравнения движения квантовой механики переходят в классические уравнения движения.

Для стационарного состояния $\psi(\boldsymbol{q}, t) = \psi(\boldsymbol{q}) e^{-\frac{i}{\hbar} Et}$ подстановка (6.2) превращается в

$$\psi(\boldsymbol{q}, t) = e^{-\frac{i}{\hbar} (\sigma(\boldsymbol{q}; \hbar) - Et)}$$

Соответствующее нелинейное уравнение в частных производных:

$$\frac{1}{2m} \left(\frac{\partial \sigma}{\partial \boldsymbol{q}} \right)^2 + V(\boldsymbol{q}) = E + \frac{i\hbar}{2m} \Delta \sigma$$

отличается от соответствующего уравнения Гамильтона-Якоби для укороченного действия, рассмотренного в разделе 1.2.5 главы 1, пропорциональным $\hbar$ слагаемым в правой части.

[10] Здесь будет удобно обозначать декартовы координаты на $\mathbb{R}^n$ как $\boldsymbol{q} = (q_1, ..., q_n)$. В этом разделе мы рассмотрим квазиклассическую асимптотику: асимптотики уравнений в частных производных (6.3) и (6.5) при $\hbar \to 0$. Они описывают точное соотношение между квантовой и классической механикой и представляют количественную форму принципа соответствия, обсуждавшегося в разделе 2.2 главы 2. В частности, используя квазиклассическую асимптотику стационарного уравнения Шрёдингера, мы выведем правила квантования Бора- Вильсона - Зоммерфельда, которые были постулированы в разделе 2.2.5 главы 2.

Theory

Здесь мы рассмотрим задачу нахождения коротковолновой асимптотики - асимптотики при $\hbar \to 0$ решения $\psi_\hbar(q, t)$ задачи Коши для одномерного уравнения Шрёдингера (6.1),

$$i\hbar \frac{\partial \psi}{\partial t} = -\frac{\hbar^2}{2m} \frac{\partial^2 \psi}{\partial q^2} + V(q)\psi$$

с начальным условием

$$\psi_\hbar(q, t)|_{t=0} = \varphi(q) e^{\frac{i}{\hbar} s(q)}$$

Предполагается, что вещественнозначные функции $\varphi(q)$ и $s(q)$ - гладкие, $s(q), \varphi(q) \in C^\infty(\mathbb{R})$ и что у «амплитуды» $\varphi(q)$ компактный носитель. Подстановка (6.2) - это $\psi_\hbar(q, t) = e^{\frac{i}{\hbar} S(q, t, \hbar)}$, и дифференциальное уравнение (6.3) принимает вид

$$\frac{\partial S}{\partial t} + \frac{1}{2m} \left(\frac{\partial S}{\partial q} \right)^2 + V(q) = \frac{i\hbar}{2m} \frac{\partial^2 S}{\partial q^2}$$

Чтобы определить асимптотическое поведение $S(q, t, \hbar)$ при $\hbar \to 0$, предположим, что при $\hbar \to 0$

$$S(q,t,\hbar)=\sum_{n=0}^{\infty}(-i\hbar)^n S_n(q,t),$$

и подставим это разложение в (6.6). Сравнивая члены с одинаковыми степенями $\hbar$, получим, что $S_0(q,t)$ удовлетворяет задаче с начальными условиями

$$\frac{\partial S_0}{\partial t}+\frac{1}{2m}\left(\frac{\partial S_0}{\partial q}\right)^2+V(q)=0$$

И

$$S_0(q,t)|_{t=0}=s(q)$$

где $S_1(q,t)$ удовлетворяет дифференциальному уравнению

$$\frac{\partial S_1}{\partial t}+\frac{1}{m}\frac{\partial S_0}{\partial q}\frac{\partial S_1}{\partial q}=-\frac{1}{2m}\frac{\partial^2 S_0}{\partial q^2}$$

так называемому транспортному уравнению, и

$$S_1(q,t)|_{t=0}=\log\varphi(q)$$

Функции $S_n(q,t)$ при $n>1$ удовлетворяют неоднородным дифференциальным уравнениям, подобным (6.9).

Задача с начальными условиями (6.7) - (6.8) - это задача Коши для уравнения Гамильтона - Якоби с функцией Гамильтона

$$H_c(p,q)=\frac{p^2}{2m}+V(q)$$

рассмотренной в разделе 1.2.3 главы 1. Согласно предложению 2.1 в разделе 1.2.3 главы 1, решение уравнений (6.7) – (6.8) получается методом характеристик:

$$S_0(q,t)=s\left(q_0\right)+\int_0^t L\left(\gamma'(\tau)\right)d\tau$$

Здесь $L(q,\dot q)\doteq\frac{1}{2}m\dot q^2-V(q)$ - функция Лагранжа, а $\gamma(\tau)$ - характеристика, классическая траектория, начинающаяся в точке q_0 в момент времени $\tau=0$ с импульсом $p_0=\frac{\partial s}{\partial q}\left(q_0\right)$ и заканчивающаяся в точке q в момент $\tau=t$, где q_0 однозначно определяется из q. (Мы предполагаем, что гамильтонов фазовый поток g_t удовлетворяет предположениям, сделанным в разделе 1.2.3 главы 1.) Из теоремы 2.7 в разделе 1.2.3 главы 1 следует, что на характеристике

$$\frac{\partial S_0}{\partial q}(q,t)=m\frac{d\gamma}{dt}(t)$$

так что

$$\left(\frac{\partial}{\partial t}+\frac{1}{m}\frac{\partial S_0}{\partial q}\frac{\partial}{\partial q}\right)S_1(\gamma(t),t)=\frac{d}{dt}S_1(\gamma(t),t)$$

Тепіерь мы можем решить задачу Коши (6.9) – (6.10) для транспортного уравнения явным образом. Рассмотрим поток $\pi_t:\mathbb{R}\to\mathbb{R}$, определенный в разделе 1.2.3 главы 1, и обозначим [11] как $\gamma(Q,q;\tau)$ характеристику, соединяющую точки q в момент $\tau=0$ и $Q=\pi^t(q)$ в момент $\tau=t$ (при наших предположениях, что поток π_t - диффеоморфизм и отображение $q\mapsto Q$ взаимно однозначно). Дифференцируя уравнение

$$\frac{\partial S_0}{\partial Q}(Q,t) = m\frac{\partial \gamma}{\partial t}(Q,q;t)$$

по q, получаем

$$\frac{\partial^2 S_0}{\partial Q^2}(Q,t)\frac{\partial Q}{\partial q} = m\frac{\partial^2 \gamma}{\partial q \partial t}(Q,q;t) = m\frac{d}{dt}\left(\frac{\partial Q}{\partial q}\right)$$

так что (6.9) можно переписать как

$$\frac{d}{dt}S_1(Q,t) = -\frac{1}{2}\frac{d}{dt}\log\frac{\partial Q}{\partial q}$$

и, используя (6.10), получаем

$$S_1(Q,t) = \varphi(q)\left|\frac{\partial Q}{\partial q}(q)\right|^{-\frac{1}{2}}$$

Поэтому

$$\psi_\hbar(Q,t) = \varphi(q)\left|\frac{\partial Q}{\partial q}(q)\right|^{-\frac{1}{2}} e^{\frac{i}{\hbar}(S(Q,q;t)+s(q))}(1+O(\hbar)),$$

где $S(Q,q;t)$ - классическое действие на характеристике, начинающейся в точке q в момент $\tau = 0$ и кончающейся в точке Q в момент $\tau = t$.

Строгое доказательство того, что (6.13) - асимптотическое разложение при $\hbar \to 0$, использует предположения, сделанные в разделе 1.2.3 главы 1, и оставляется заинтересованному читателю. Здесь мы только заметим, что асимптотика (6.13) согласуется с сохранением вероятности: для любого борелевского подмножества $E \subset \mathbb{R}$

$$\int\limits_{E_t} |\psi_\hbar(Q,t)|^2\, dQ = \int\limits_{E} |\varphi(q)|^2 dq + O(\hbar)$$

при $\hbar \to 0$, где $E_t = \pi_t(E)$.

[11] Не путать с оператором квантовой координаты Q. ЗАМЕчАНИЕ. Когда предположения раздела 1.2.3 главы 1 не выполняются, ситуация становится более сложной. А именно: в этом случае может быть несколько характеристик $\gamma_j(\tau)$, которые заканчиваются в точке Q при $\tau = t$, имея q_j своими соответствующими начальными точками. Тогда

$$\psi_\hbar(Q,t) = \sum_j \varphi(q_j)\left|\frac{\partial Q}{\partial q}(q_j)\right|^{-\frac{1}{2}} e^{\frac{i}{\hbar}(S(Q,q_j;t)+s(q_j))-\frac{\pi i}{2}\mu_j}(1+O(\hbar))$$

где $\mu_j \in \mathbb{Z}$ - индекс Морса характеристики γ_j. Он определяется как число фокальных точек на фазовой кривой $(q(\tau),p(\tau))$ с начальными данными q_j и $p_j = \frac{\partial s}{\partial q}(q_j)$ по отношению к конфигурационному пространству $\mathbb{R}$. Это частный случай более общего индекса Маслова.

Случай n степеней свободы рассматривается похоже. При предположениях раздела 1.2.3 главы 1 решение $\psi_\hbar(\boldsymbol{q},t)$ уравнения Шрёдингера (6.1) с начальным условием

$$\psi_\hbar(\boldsymbol{q},t)|_{t=0} = \varphi(\boldsymbol{q})e^{\frac{i}{\hbar}s(\boldsymbol{q})}$$

где вещественнозначные функции $s(\boldsymbol{q})$ и $\varphi(\boldsymbol{q})$ - гладкие, а $\varphi(\boldsymbol{q})$ - еще и с компактным носителем, имеет следующую асимптотику при $\hbar \to 0$:

$$\psi_\hbar(\boldsymbol{Q},t)=\varphi(\boldsymbol{q})\left|\det\left(\frac{\partial \boldsymbol{Q}}{\partial \boldsymbol{q}}(\boldsymbol{q})\right)\right|^{-\frac{1}{2}} e^{\frac{i}{\hbar}(S(\boldsymbol{Q},\boldsymbol{q};t)+s(\boldsymbol{q}))}(1+O(\hbar))$$

6.9.6 Time-Independent Asymptotics

Здесь мы рассмотрим квазиклассическую асимптотику для одномерного уравнения Шрёдингера

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2}+V(x)\psi=E\psi$$

Этот асимптотический метод известен также как метод BKD (в честь Дж. Венцеля, Х. Крамерса и Л. Бриллюэна). Подстановка (6.4) - это $\psi_\hbar(x)=e^{\frac{i}{\hbar}\sigma(x;\hbar)}$, и уравнение (6.5) принимает вид

$$\frac{1}{2m}\left(\frac{d\sigma}{dx}\right)^2+V(x)=E+\frac{i\hbar}{2m}\frac{d^2\sigma}{dx^2}$$

Как и в предыдущем разделе, воспользуемся разложением

$$\sigma(x,\hbar)=\sum_{n=0}^{\infty}(-i\hbar)^n\sigma_n(x)$$

и для первых двух членов получим

$$\frac{1}{2m}\sigma_0'^2=E-V(x)\quad\text{ и }\quad\sigma_0'\sigma_1'=-\frac{1}{2}\sigma_0''$$

Пусть $p(x)=\sqrt{2m(E-V(x))}$ - классический импульс частицы, движущейся в потенциале $V(x)$ с энергией E. Решение первого уравнения в (6.16) дается формулой

$$\sigma_0=\pm\int p(x)dx$$

а из второго уравнения в (6.16) мы получаем

$$\sigma_1=-\frac{1}{2}\log p$$

Волновая функция в приближении ВКБ имеет вид

$$\psi_\hbar(x)=\frac{1}{\sqrt{|p(x)|}}\left(C_1e^{\frac{i}{\hbar}\int p(x)dx}+C_2e^{-\frac{i}{\hbar}\int p(x)dx}\right)(1+O(\hbar))$$

где $p(x)$ вещественно в классической области $V(x)<E$ и чисто мнимо в классически недоступной области $V(x)>E$ (см. раздел 1.1.5 главы 1).

Заметим, что асимптотика (6.17) верна, только если $\hbar|\sigma''|\ll(\sigma')^2$, что в первом приближении дает

$$\left|\frac{d}{dx}\left(\frac{\hbar}{p(x)}\right)\right|\ll 1$$

Введя классическую силу $F=-\frac{dV}{dx}$, это условие можно переписать как

$$\frac{m\hbar F}{p^3}\ll 1$$

Таким образом, приближение ВКБ не работает, когда классический импульс $p(x)$ мал. В частности, оно неприменимо вблизи точек поворота, где $E = V(x)$, и поэтому $p(x) = 0$. Пусть $x = a$ - точка поворота. Если $F_0 = F(a) \neq 0$, то, используя приближение $E - V(x) \simeq F_0(x - a)$ вблизи $x = a$, можно заменить (6.15) уравнением

$$\frac{\hbar^2}{2m}\psi'' = F_0(x - a)\psi.$$

Это дифференциальное уравнение в явном виде решается методом Лапласа. Его ограниченное решение - это

$$\psi(x) = \Phi(\xi), \quad \xi = \left(\frac{2mF_0}{\hbar^2}\right)^{\frac{1}{3}}(a - x)$$

где $\Phi(\xi)$ - функция Эйри - Фока, определенная несобственным интегралом

$$\Phi(\xi) = \frac{1}{\sqrt{\pi}}\int\limits_0^\infty \cos\left(\frac{1}{3}t^3 + \xi t\right)dt$$

Асимптотика функции Эйри-Фока при больших ξ, полученная методом перевала, следующая:

$$\Phi(\xi) = \frac{1}{2\sqrt[4]{\xi}}e^{-\frac{2}{3}\xi^{\frac{3}{2}}}\left(1 + O\left(\xi^{-\frac{3}{2}}\right)\right) \quad \text{при} \quad \xi \to \infty$$
$$\Phi(\xi) = \frac{1}{\sqrt[4]{|\xi|}}\sin\left(\frac{2}{3}|\xi|^{\frac{3}{2}} + \frac{\pi}{4}\right)\left(1 + O\left(|\xi|^{-\frac{3}{2}}\right)\right) \quad \text{при} \quad \xi \to -\infty$$

Используя асимптотику (6.19) - (6.20), можно получить формулы, связывающие приближения ВКБ для классической и недоступной областей. Строгое обоснование этого подхода технически достаточно трудоемко, и мы не будем приводить его здесь. Вместо этого мы обсудим простейший случай, когда имеется только одна точка поворота $x = a$ с $F_0 > 0$, так что $x < a$ - классически недоступная область. Из (6.17) получаем, что волновая функция ВКБ в недоступной области $x < a$ экспоненциально затухает:

$$\psi_{\text{wKB}}(x) = \frac{A}{\sqrt{|p(x)|}}e^{\frac{1}{\hbar}\int\limits_a^x |p(s)|ds}$$

тогда как в классической области $x < a$ - осциллирует:

$$\psi_{\text{wKB}}(x) = \frac{1}{\sqrt{p(x)}}\left(C_1 e^{\frac{i}{\hbar}\int\limits_a^x p(s)ds} + C_2 e^{-\frac{i}{\hbar}\int\limits_a^x p(s)ds}\right) = \frac{B}{\sqrt{p(x)}}\sin\left(\frac{1}{\hbar}\int\limits_a^x p(s)ds + \alpha\right)$$

Как следует из (6.18), приближение ВКБ вблизи точки поворота $x = a$ остается уместным при $|x - a| \gg \frac{1}{2}\left(\frac{\hbar^2}{mF_0}\right)^{\frac{1}{3}}$, что эквивалентно условию $|\xi| \gg 1$. С другой стороны, когда $|x - a| \ll 1$, волновая функция имеет асимптотику

$$\psi_\hbar(x) = C\Phi(\xi)(1 + O(\hbar))$$

Чтобы определить неизвестную фазу α и найти соотношения между коэффициентами A, B и C, рассмотрим область $\frac{1}{2}\left(\frac{\hbar^2}{mF_0}\right)^{\frac{1}{3}} \ll |x - a| \ll 1$ и сравним приближение ВКБ для

волновой функции с асимптотикой функции Эйри-Фока при больших ξ. А именно: при $x < a$ имеем $\xi \gg 1$ и

$$\frac{2}{3}\xi^{\frac{3}{2}} = \frac{2}{3\hbar}\sqrt{2mF_0}(a-x)^{\frac{3}{2}} \simeq \frac{1}{\hbar}\int\limits_x^a |p(s)|ds, \quad \sqrt[4]{\xi} = \frac{\sqrt{|p(x)|}}{\sqrt[6]{2m\hbar F_0}}$$

Сравнивая (6.19) с волновой функцией ВКБ при $x < a$, получаем, что $2A = \sqrt[6]{2m\hbar F_0}C$. При $x > a$ имеем $\xi \ll -1$ и

$$\frac{2}{3}|\xi|^{\frac{3}{2}} = \frac{2}{3\hbar}\sqrt{2mF_0}(x-a)^{\frac{3}{2}} \simeq \frac{1}{\hbar}\int\limits_a^x p(s)ds, \quad \sqrt[4]{|\xi|} = \frac{\sqrt{p(x)}}{\sqrt[6]{2m\hbar F_0}}$$

Сравнивая (6.20) с волновой функцией ВКБ при $x < a$, получаем, что $\alpha = \frac{\pi}{4}$ и $B = \sqrt[6]{2m\hbar F_0}C$, так что $B = 2A$. Таким образом, в этом примере волновая функция ВКБ - это

$$\psi_{\text{wKB}}(x) = \begin{cases} \frac{A}{\sqrt{|p(x)|}} e^{\frac{1}{\hbar}\int\limits_a^x |p(s)|ds}, & \text{когда } x < a, \\ \frac{2A}{\sqrt{p(x)}} \sin\left(\frac{1}{\hbar}\int\limits_a^x p(s)ds + \frac{\pi}{4}\right), & \text{когда } x > a. \end{cases}$$

Случай, когда имеется только одна точка поворота $x = b$ с $F_0 < 0$, так что $x > b$ - классически недоступная область, сводится к предыдущему примеру с помощью изменения ориентации $x \mapsto -x$. Как результат, получаем

$$\psi_{\text{wB}}(x) = \begin{cases} \frac{2B}{\sqrt{p(x)}} \sin\left(\frac{1}{\hbar}\int\limits_x^b p(s)ds + \frac{\pi}{4}\right), & \text{когда } x < b, \\ \frac{B}{\sqrt{|p(x)|}} e^{-\frac{1}{\hbar}\int\limits_b^x |p(s)|ds}, & \text{когда } x > b. \end{cases}$$

ЗАДАЧА 6.1 (ПРОХОЖДЕНИЕ ЧЕРЕЗ ПОТЕНЦИАЛЬНЫЙ БАРЬЕР). Рассмотрим потенциальный барьер для заданной энергии E - потенциал $V(x)$, такой, что $\{x \in \mathbb{R} : V(x) > E\} = (a, b)$. Покажите, что

$$T_{\text{WKB}} = e^{-\frac{2}{\hbar}\int\limits_a^b |p(x)|dx}$$

Проверьте непосредственно, что коэффициент прохождения для потенциала из задачи 2.9 в квазиклассическом приближении дается этой формулой.

ЗАДАЧА 6.2 (ОТРАЖЕНИЕ НАД БАРЬЕРОМ). ПредПоЛОЖИМ, что Потенциал $V(x)$ допускает аналитическое продолжение в верхнюю полуплоскость, и пусть E - энергия, такая, что $E > V(x)$ для всех вещественных x. Предположим, что существует лишь одно комплексное x_0, такое, что $V(x_0) = E$. Покажите, что в квазиклассическом приближении

$$R_{\text{WKB}} = e^{-\frac{4}{\hbar}\operatorname{Im}\int\limits_a^{x_0} p(x)dx}$$

где $p(x) = \sqrt{2m(E - V(x))}$, а $a \in \mathbb{R}$ (выбор a не влияет на мнимую часть интеграла в экспоненте). Проверьте непосредственно, что коэффициент отражения для потенциала в задаче 2.9 в квазиклассическом приближении дается этой формулой.

ЗАДАЧА 6.3. Найдите коэффициенты прохождения и отражения для параболического барьера - потенциала $V(x) = -\frac{1}{2}kx^2$, где $k > 0$, - и проверьте непосредственно, что в квазиклассическом приближении они удовлетворяют при $E < 0$ и $E > 0$ соответственно формулам из задач 6.1 и 6.2.

6.9.7 Bohr-Wilson-Sommerfeld Quantization Rules

(combine with some sections before and move partially it to a section before!!)

Метод ВКБ позволяет определить уровни энергии в квазиклассическом приближении. Рассмотрим для простоты финитное движение одномерной частицы в потенциальной яме: в потенциале $V(x)$ с энергией E, такое, что имеются две точки поворота a и b. Классическая область - это $a \leqslant x \leqslant b$, и движение периодично с периодом

$$T = 2\int\limits_a^b \frac{dx}{\dot{x}} = 2m\int\limits_a^b \frac{dx}{p} = \sqrt{2m}\int\limits_a^b \frac{dx}{\sqrt{E - V(x)}}$$

Области $x < a$ и $x > b$ недоступны (см. раздел 1.1.5 главы 1). Из (6.21) - (6.22) следует, что волновая функция ВКБ экспоненциально затухает в недоступных областях $x < a$ и $x > b$. Воспользовавшись (6.21), мы видим, что в классической области волновая функция ВКБ имеет вид

$$\psi_{\text{wKB}}(x) = \frac{2A}{\sqrt{p(x)}} \sin\left(\frac{1}{\hbar}\int\limits_a^x p(s)ds + \frac{\pi}{4}\right)$$

тогда как, используя (6.22), получаем

$$\begin{aligned}\psi_{\text{WKB}}(x) &= \frac{2B}{\sqrt{p(x)}} \sin\left(\frac{1}{\hbar}\int\limits_x^b p(s)ds + \frac{\pi}{4}\right) = \\ &= \frac{2B}{\sqrt{p(x)}} \sin\left(\frac{1}{\hbar}\int\limits_a^b p(s)ds + \frac{\pi}{2} - \left(\frac{1}{\hbar}\int\limits_a^x p(s)ds + \frac{\pi}{4}\right)\right).\end{aligned}$$

Эти два выражения определяют одну и ту же функцию на $a \leqslant x \leqslant b$, если и только если существует положительное целое число n, такое, что

$$\frac{1}{\hbar}\int\limits_a^b p(x)dx + \frac{\pi}{2} = (n+1)\pi$$

тогда $A = (-1)^{n+1}B$. Уравнение (6.23), записанное в виде

$$1.\quad \int\limits_a^b \sqrt{2m(E - V(x))}dx = \pi\hbar\left(n + \frac{1}{2}\right),$$

определяет квазиклассические уровни энергии. Из (6.21) - (6.22) следует, что число n равно количеству нулей волновой функции ВКБ. В соответствии с теоремой об осцилляции случай $n = 0$ отвечает основному состоянию, случай $n = 1$ - состоянию со следующим уровнем энергии, и т. д. Обозначив, как и в главах 1 и 2, координату x как q, можно переписать (6.23) как

$$\oint p dq = 2\pi\hbar\left(n + \frac{1}{2}\right)$$

где интегрирование идет по замкнутой классической орбите в фазовой плоскости $\mathbb{R}^2$ с каноническими координатами p, q. Условие (6.24) - это известное правило квантования Бора - Вильсона - Зоммерфельда для случая одной степени свободы (см. раздел 2.2.5

главы 2). Подчеркнем, что, вообще говоря, правило квантования БВЗ применимо только для больших n и дает квазиклассическую асимптотику уровней энергии E_n. Однако, как было показано в разделе 2.2.6 главы 2, уровни энергии гармонического осциллятора, полученные по правилу БВЗ, точны. Правила БВЗ также точны для уровней энергии атома водорода (см. раздел 3.5.1).

Этот квазиклассический анализ можно обобщить на системы с n степенями свободы, соответствующие вполне интегрируемым классическим гамильтоновым системам (см. раздел 1.2.6 главы 1). Правила квантования Бора- Вильсона - Зоммерфельда принимают вид

$$\oint_\gamma \boldsymbol{p} d\boldsymbol{q} = 2\pi\hbar \left(\boldsymbol{n}_\gamma + \frac{1}{4} \operatorname{ind} \gamma \right).$$

Здесь интегрирование ведется по всем 1-циклам γ в лагранжевом подмногообразии $\Lambda = \{(\boldsymbol{p}, \boldsymbol{q}) \in \mathbb{R}^{2n} : H_c(\boldsymbol{p}, \boldsymbol{q}) = E, F_2(\boldsymbol{p}, \boldsymbol{q}) = E_2, ..., F_n(\boldsymbol{p}, \boldsymbol{q}) = \ = E_n\}$, a ind γ - индекс Маслова цикла γ в Λ. Для переменных действие-угол (I, φ) интегрирование в (6.25) ведется по базисным 1циклам n-тора T^n, и получаются условия квантования $I_i = \left(n_i + \frac{1}{2}\right)\hbar$, $i = 1, ..., n$.

6.9.8 Other About Semiclassics

(тут интересные дополнительные вопросы)

связь квантовой механики и оптики

(оставленный вопрос, потом подумаю.)

Метод transfer-matrix по Киселеву

(перенес сюда, потому что вряд ли это нужно)

Суть по Киселеву (???)

При наличии нескольких потенциальных ям и потенциальных барьеров применяют технику transfer-matrix. Эта техника описывает линейные преобразования для коэффициентов в суперпозиции квазиклассических решений стационарного уравнения Шрёдингера. Пусть строка

$$\left(C_-^\uparrow, C_-^\downarrow\right)$$

отвечает суперпозиции решений

$$\frac{C_-^\uparrow}{\sqrt{|p(x)|}} \mathrm{e}^{\frac{1}{\hbar}\int\limits_a^x |p(x)|\mathrm{d}x} + \frac{C_-^\downarrow}{\sqrt{|p(x)|}} \mathrm{e}^{-\frac{1}{\hbar}\int\limits_a^x |p(x)|\mathrm{d}x}$$

в области $-\infty < x < a$, где a - координата точки поворота, значение которой меньше значений всех координат других точек поворота. Ясно, что коэффициент $C_-^\uparrow$ отвечает решению, которое растет при увеличении x, а $C_-^\downarrow$ решению, которое убывает с увеличением x. Выше мы рассмотрели случай сшивки решения возле точки поворота при $C_-^\downarrow = 0$ и при $x > a$ пришли к решению

$$\frac{C_-^\dagger}{\sqrt{|p(x)|}} \left(\mathrm{e}^{\frac{i}{\hbar}\int\limits_a^x |p(x)|\mathrm{d}x - \mathrm{i}\frac{\pi}{4}} + \mathrm{e}^{-\frac{i}{\hbar}\int\limits_\alpha^x |p(x)|\mathrm{d}x + \mathrm{i}\frac{\pi}{4}} \right)$$

которое можно представить как строку, составленную из коэффициентов для волн, которые распространяются по оси x и против оси x, соответственно

$$\left(C_-^{\uparrow}\mathrm{e}^{-\mathrm{i}\frac{\pi}{4}}\mathrm{e}^{\frac{i}{\hbar}S(x,a)}, C_-^{\uparrow}\mathrm{e}^{\mathrm{i}\frac{\pi}{4}}\mathrm{e}^{-\frac{1}{\hbar}S(x,a)}\right),$$

где действие

$$S(x,a)=\int\limits_a^x |p(x)|\mathrm{d}x.$$

Если бы при $x<a$ мы точно также рассмотрели решение, которое убывает с ростом x, т.е. решение с $C_-^{\uparrow}=0$, что отвечает только смене знака аргумента в экспоненте, как видно из (12.48), то получили бы решение

$$\frac{C_-^{\downarrow}}{\sqrt{|p(x)|}}\left(\mathrm{e}^{-\frac{i}{\hbar}\int\limits_a^x |p(x)|\mathrm{d}x-\mathrm{i}\frac{\pi}{4}}+\mathrm{e}^{\frac{i}{\hbar}\int\limits_a^x |p(x)|\mathrm{d}x+\mathrm{i}\frac{\pi}{4}}\right),$$

которое можно представить как строку, составленную из коэффициентов для волн, которые распространяются по оси x и против оси x, соответственно

$$\left(C_-^{\downarrow}\mathrm{e}^{\mathrm{i}\frac{\pi}{4}}\mathrm{e}^{\frac{1}{\hbar}S(x,a)}, C_-^{\downarrow}\mathrm{e}^{-\mathrm{i}\frac{\pi}{4}}\mathrm{e}^{-\frac{i}{\hbar}S(x,a)}\right).$$

В методе transfer-matrix эти линейные преобразования со строками из коэффициентов решений из области $x<a$ слева от точки поворота в область $x>a$ справа от точки поворота представляют сначала как произведение строки на матрицу фазовых сдвигов в точке поворота,

$$T(a)=\begin{pmatrix} \mathrm{e}^{-\mathrm{i}\frac{\pi}{4}} & \mathrm{e}^{\mathrm{i}\frac{\pi}{4}} \\ \mathrm{e}^{\mathrm{i}\frac{\pi}{4}} & \mathrm{e}^{-\mathrm{i}\frac{\pi}{4}} \end{pmatrix}$$

в которой первая строка отвечает фазовым сдвигам для решения (12.50), а вторая - (12.53). Затем происходит распространение от точки поворота a до точки $x>a$, что отвечает умножению на диагональную матрицу

$$T(x,a)=\begin{pmatrix} \mathrm{e}^{\frac{1}{\hbar}S(x,a)} & 0 \\ 0 & \mathrm{e}^{-\frac{i}{\hbar}S(x,a)} \end{pmatrix}$$

так что матричное умножение

$$\left(C_-^{\uparrow}, C_-^{\downarrow}\right)\circ T(a)\circ T(x,a)$$

выдает строку, которая в точности воспроизводит оба результата (12.50) и (12.53) одновременно 1.

Универсальность метода transfer-matrix заключается в том, что матрица фазовых сдвигов $T(a)$ не зависит от того, с какой стороны от точки поворота расположена область, доступная для классической частицы! В самом деле, если мы теперь рассмотрим точку поворота b, для которой область, не доступная для классической частицы, расположена при $x>b$, то в этой области суперпозиция растущего при увеличении x решения и убывающего решения

$$\frac{C_+^{\uparrow}}{\sqrt{|p(x)|}}\mathrm{e}^{\frac{1}{\hbar}\int\limits_b^x |p(x)|\mathrm{d}x}+\frac{C_+^{\downarrow}}{\sqrt{|p(x)|}}\mathrm{e}^{-\frac{1}{\pi}\int\limits_b^x |p(x)|\mathrm{d}x}$$

можно представить в виде столбца

$$\begin{pmatrix} C_+^{\uparrow} \\ C_+^{\downarrow} \end{pmatrix}$$

так что после умножения слева на ту же матрицу фазовых сдвигов мы получим

$$T(b) \circ \begin{pmatrix} C_+^{\uparrow} \\ C_+^{\downarrow} \end{pmatrix} = \begin{pmatrix} \mathrm{e}^{-\mathrm{i}\frac{\pi}{4}} C_+^{\uparrow} + \mathrm{e}^{\mathrm{i}\frac{\pi}{4}} C_+^{\downarrow} \\ \mathrm{e}^{\mathrm{i}\frac{\pi}{4}} C_+^{\uparrow} + \mathrm{e}^{-\mathrm{i}\frac{\pi}{4}} C_+^{\downarrow} \end{pmatrix}$$

При $C_+^{\uparrow} = 0$, когда при $x > b$ есть только убывающее на бесконечности решение, это соответствует тому, что падающая на потенциальный барьер волна (верхняя позиция в столбце) опережает отраженную волну (нижняя позиция в столбце) на $\pi/2$, как это и должно быть. Затем решение в точке $x < b$ получается умножением на диагоналную матрицу распространения от точки поворота b до точки $x : T(x, b)$.

Если между потенциальными ямами встречается потенциальный барьер и $p^2 < 0$, то в матрице распространения необходимо провести подстановку: вместо вещественного действия для распространяющейся по оси x волны нужно получить растущую с увеличением x экспоненту, а значит, обобпение (12.51) имеет вид $S(x,a) = \int\limits_a^x |p(x)|\mathrm{d}x, \quad p^2(x) > 0, \; S(x,a) = -\mathrm{i}\int\limits_a^x |p(x)|\mathrm{d}x, \quad p^2(x) < 0.$ Итак, метод линейных преобразований с матрицами фазовых сдвигов и матрицами распространения позволят чисто алгебраически получать квазиклассическое решение в любой области, как доступной, так и не доступной для классической частицы, если при заданной энергии у потенциала есть несколько точек поворота и несколько потенциальных барьеров.

О применениях (???)

(пока хз)

Einstein–Brillouin–Keller method (??)

(вики. пока не актуально, но не знал, что такое есть.)

The Einstein-Brillouin-Keller method (EBK) is a semiclassical method (named after Albert Einstein, Léon Brillouin, and Joseph B. Keller) used to compute eigenvalues in quantum-mechanical systems. EBK quantization is an improvement from Bohr-Sommerfeld quantization which did not consider the caustic phase jumps at classical turning points. [1] This procedure is able to reproduce exactly the spectrum of the 3D harmonic oscillator, particle in a box, and even the relativistic fine structure of the hydrogen atom. [2]

In 1976-1977, Michael Berry and M. Tabor derived an extension to Gutzwiller trace formula for the density of states of an integrable system starting from EBK quantization. [3][4] There have been a number of recent results on computational issues related to this topic, for example, the work of Eric J. Heller and Emmanuel David Tannenbaum using a partial differential equation gradient descent approach. [5]

Given a separable classical system defined by coordinates $(q_i, p_i)\,; i \in \{1, 2, \cdots, d\}$, in which every pair (q_i, p_i) describes a closed function or a periodic function in q_i, the EBK procedure involves quantizing the line integrals of p_i over the closed orbit of q_i:

$$I_i = \frac{1}{2\pi} \oint p_i dq_i = \hbar \left(n_i + \frac{\mu_i}{4} + \frac{b_i}{2} \right)$$

where I_i is the action-angle coordinate, n_i is a positive integer, and μ_i and b_i are Maslov indexes. μ_i corresponds to the number of classical turning points in the trajectory of q_i (Dirichlet boundary condition), and b_i corresponds to the number of reflections with a hard wall (Neumann boundary condition). [6]

7 Methods for Scatterings

7.1 Green's Function Methods (??)

(разедл оставлен, потому что пока что не дошел до него,. потом мб большим сделаю)

7.1.1 Idea of GF Method

Суть (?)

Функция Грина в квантовой механике

Основным объектом диаграммной техники является функция Грина. Она определяется через ψ -операторы, взятые в представлении взаимодействия:

$$\tilde{\psi}_\alpha(x) = e^{i\widehat{\mathcal{H}}_0 t}\widehat{\psi}_\alpha(\mathbf{r})e^{-i\widehat{\mathcal{H}}_0 t},$$
$$\tilde{\psi}^+_\alpha(x) = e^{i\widehat{\mathcal{H}}_0 t}\widehat{\psi}^+_\alpha(\mathbf{r})e^{-i\widehat{\mathcal{H}}_0 t}$$

где под x понимается совокупность четырех переменных - координат $\mathbf{r}$ и времени t; α -спиновый индекс (для фермионов).

Так называемая причинная функция Грина есть среднее от хронологического произведения ψ -операторов, взятых в представлении взаимодействия:

$$G^c_{\alpha\beta}(x,x') = -i\left\langle \mathrm{T}\tilde{\psi}_\alpha(x)\tilde{\psi}^+_\beta(x')\right\rangle$$

где скобки $\langle ... \ \rangle$ означают матричный элемент $\left\langle \widehat{S}_0\right\rangle^{-1}\langle 0|...|0\rangle$, взятый по основному состоянию системы с гамильтонианом $\widehat{\mathcal{H}}_0$. (Фазовый множитель $\left\langle \widehat{S}_0\right\rangle = \left\langle 0\left|e^{-i\widehat{\mathcal{H}}_0 t}\right|0\right\rangle_{t\to\infty}$ принято вводить для нормировки.)

Таким образом, функции Грина бозонов и фермионов определяются одинаково, но операция Т-упорядочения имеет разный смысл.

В выражении (2.7) и всюду далее там, где это не приводит к недоразумениям, мы используем систему единиц, в которой $\hbar = 1, [t] = [E]^{-1}$. Кроме того, мы также часто будем писать ψ вместо $\tilde{\psi}$, ибо основную роль в диаграммной технике играет именно операторы $\tilde{\psi}$ в представлении взаимодействия, а операторы ψ в шредингеровском представлении практически не встречаются. В однородной системе (скажем, в газе или в жидкости) функция Грина (2.8), очевидно, зависит только от разности координат $\mathbf{r}-\mathbf{r}'$ и времен $t-t'$. В этом случае удобно сделать преобразование Фурье и перейти в импульсно-частотное представление

$$G_{\alpha\beta}(x-x') = \iint G_{\alpha\beta}(\varepsilon,\mathbf{p})e^{-i\varepsilon(t-t')+i\mathbf{p}(\mathbf{r}-\mathbf{r}')}\frac{d\varepsilon d^3p}{(2\pi)^4}$$

В этом представлении обычно и строится диаграммная техника.

О способах поиска (???)

$G_{\alpha\beta}(\varepsilon,\mathbf{p})$ для идеального газа находится, пользуясь определением $G^c_{\alpha\beta}(x,x') = -i\left\langle \mathrm{T}\tilde{\psi}_\alpha(x)\tilde{\psi}^+_\beta(x')\right\rangle$.

Примеры функций Грина

Например, для идеального ферми-газа она имеет вид

$$G_{\alpha\beta}(\varepsilon, \mathbf{p}) = \frac{\delta_{\alpha\beta}}{\varepsilon - \xi(\mathbf{p}) + i0\,\mathrm{sign}\,(|\mathbf{p}| - p_0)}$$

где $\xi(\mathbf{p}) = \mathbf{p}^2/2m - E_F$ -закон дисперсии, а $p_0 = \sqrt{2mE_F}$ -импульс Ферми, являющийся границей распределения ферми-частиц по импульсам.

Величины по функции Грина (!?!?!)

(добавлю сюда то, что еще не написано!!!)
Приведем вид различных физических величин через функцию Грина.

одночастичная матрица плотности

$$\rho_{\alpha\beta}\,(\mathbf{r}, \mathbf{r}', t) = \pm i \lim_{t' \to t+0} G_{\alpha\beta}\,(x, x')$$

где знак соответствует статистике: «+»для бозонов, «-» для фермионов.
(?? почему)

плотность частиц

Зная $\rho_{\alpha\beta}\,(\mathbf{r}, \mathbf{r}', t)$, нетрудно найти среднее любой величины. Например, плотность частиц выражается через функцию Грина как

$$n(x) = \pm i \lim_{t' \to t+0} \mathrm{Tr}\, G_{\alpha\beta}\,(x, x')$$

плотность тока

Плотность тока есть

$$\mathbf{j}(x) = \pm \frac{\hbar}{2m} \lim_{\substack{t' \to t+0 \\ \mathbf{r}' \to \mathbf{r}}} (\nabla_{\mathbf{r}} - \nabla_{\mathbf{r}'})\, \mathrm{Tr}\, G_{\alpha\beta}\,(x, x')$$

где Tr обозначает взятие следа по спиновым индексам α, β. Брать предел по $t' > t$ в соотношениях (2.11) – (2.13) необходимо из-за неоднозначности определения функции Грина при $t = t'$.

Пример, когда без T-упорядочения происходят неверные расчеты

(вопрос остался, потом подумаю, пока влом.)

Типичные примеры (?)

Как догадаться про это?

Equvalence of the definitions of GFs

First, the term "propagator" is usually defined as the Green's function of the first type, not the second type, i.e. as a solution to the diffential equation $\hat{L}G = \delta$.

At any rate, those definitions are ultimately equivalent – when the details are correctly written down – because the Green's function defined as the correlator in the second definition obeys the first differential equation.

The differential operator $\hat{L}$ is what appears in the linearized equations of motion for the field, in this case $\psi(x_1, t_1)$, and it only acts on $\psi(x_1, t_1)$, not $\psi^\dagger(x_2, t_2)$.

The time-ordering operator T may be written in terms of the step function

$$T(\psi\psi^\dagger) = \psi\psi^\dagger \cdot \theta(t_1 - t_2) - \psi^\dagger\psi \cdot \theta(-t_1 + t_2)$$

where ψ is always at x_1, t_1 and $\psi^\dagger$ is at x_2, t_2. Now, ask what happens when you act with $\hat{L}$ on the right hand side of the displayed equation above.

By the Leibniz rule, there are the terms with $\hat{L}\psi = 0$. It vanishes by the equations of motion. But there are extra terms where $\hat{L}$ acts on the step functions.

The operator $\hat{L}$ contains the term that differentiates with respect to t_1 multiplied by a coefficient C. This turns $\theta(t_1 - t_2)$ to $\delta(t_1 - t_2)$. The same occurs in the next term, but with the opposite sign which cancels the sign that was already there. So the extra terms are

$$\hat{L}T(\psi\psi^\dagger) = C\delta(t_1 - t_2)(\psi\psi^\dagger + \psi^\dagger\psi)$$

I got two terms because there were two terms. However, these two terms exactly combine to the anticommutator of ψ and $\psi^\dagger$ which only needs to be evaluated for $t_1 = t_2$, the equal-time anticommutator, and the result is $D \cdot \delta(x_1 - x_2)$.

That's why the action of $\hat{L}$ on the correlator ends up being $CD\delta(t_1 - t_2)\delta(x_1 - x_2)$ where the constants C, D are mostly just factors of i etc.

For bosonic fields, $\hat{L}$ has the second derivative with respect to time. One of the derivatives has the fate as above, the other one turns the other ϕ, which plays the role of $\psi^\dagger$, into $\partial_t\phi$ which is the canonical momentum, and it's the right variable that has the δ-function-like commutator. Also, the intermediate sign is the opposite one but the result is the same, some $CD \cdot \delta \cdot \delta$.

Что такое сечение рассеяния?

(см. Тонга, общий бэкграунд, потом напишу, пока в механике об этом писал)

Особенности сечений рассеяния

Примеры сечений

(соберу графики, чтобы представлять, что в итоге моделей)

Что если сечение расходится?

(это не редкая ситуация, ибо даже сечение рассяния на потенциале $1/r^2$ в 3д расходится. допишу потом, как это понимать???)

Пока ответ в том, что считаем просто дифференциальное и всё.

7.2.2 Spherical Waves of a Free Particle

Сферические волны по Киселеву

Уравнение для стационарного состояния с энергией $E(k) = \frac{\hbar^2 k^2}{2m}$ и заданным значением орбитального момента l и его проекции m

$$\psi(\boldsymbol{r}) = R_{kl}(r)Y_{l,m}(\theta, \phi)$$

в области, где потенциал мал, есть

$$R''_{kl}(r) + \frac{2}{r}R'_{kl}(r) + \left(k^2 - \frac{l(l+1)}{r^2}\right)R_{kl}(r) = 0$$

т.е. является уравнением для свободной частицы, которое мы и исследуем более детально В этом параграфе.

Согласно общему свойству радиального уравнения при $r \to 0$

$$R_{kl}(r) \sim r^l$$

так что проведем замену функции

$$R_{kl}(r) = r^l \chi_{kl}(r)$$

При ней $R'_{kl}(r) = r^l\chi'_{kl} + lr^{l-1}\chi_{kl}$, $R''_{kl}(r) = r^l\chi''_{kl} + 2lr^{l-1}\chi'_{kl} + l(l-1)r^{l-2}\chi_{kl}$. Подставим, придем к

$$\chi''_{kl} + \frac{2}{r}(l+1)\chi'_{kl} + k^2\chi_{kl} = 0$$

Введем

$$\chi_{kl}(r) = v_{kl}(z), \quad z = r^2$$

При ней $\chi'_{kl} = 2rv'_{kl}$, $\chi''_{kl} = 4zv''_{kl} + 2v'_{kl}$. Получим

$$4zv''_{kl} + 2(2l+3)v'_{kl} + k^2 v_{kl} = 0$$

Продифференцируем:

$$4zv'''_{kl} + 2(2(l+1)+3)v''_{kl} + k^2 v'_{kl} = 0$$

Это уравнение тождественно удовлетворяется, если v'_{kl} является решением уравнения Для $v_{k(l+1)}$, т. е.

$$v_{k(l+1)}(z) = Bv'_{kl}(z) \to \chi_{k(l+1)}(r) = \frac{B}{2r}\chi'_{kl}(r)$$

Положим $B = 2$ и запишем выведенные нами рекуррентные соотношения для радиальных волновых функций с различными значениями орбитального момента в виде

$$R_{kl}(r) = c_l \frac{r^l}{k^l} \left(\frac{1}{r} \frac{d}{dr} \right)^l R_{k0}(r)$$

Здесь $R_{k0}(r)$ -решение радиального уравнения для $l = 0$, фактор k^{-l} введен для удобства, аc_l -нормировочные постоянные.

Для $R_{k0}(r) = u(r)/r$ стандартно имеем

$$u'' + k^2 u = 0$$

откуда ясно, что функция $u(r)$ представима в виде суперпозиции двух независимых решений

$$u = \tilde{c}_0 \left\{ -e^{-\mathrm{i}kr} + S_0 e^{\mathrm{i}kr} \right\}$$

или

$$R_{k0}(r) = \frac{\tilde{c}_0}{r} \left\{ -e^{-\mathrm{i}kr} + S_0 e^{\mathrm{i}kr} \right\}$$

где S_0 -константа относительной нормировки расходящейся части волны.

Полагая $\tilde{c}_0 =$ потенциал обращается в нуль, и в частности, в асимптотической области $r \to \infty$

$$R_{kl}(r) = c_l \frac{r^l}{k^l} \left(\frac{1}{r} \frac{d}{dr} \right)^l \frac{1}{r} \left\{ -e^{-\mathrm{i}kr} + S_l e^{\mathrm{i}kr} \right\}$$

При $r \to \infty$ ведущий вклад получается дифференцированием экспонент, так что

$$\begin{aligned} R_{kl}(r) &\simeq c_l \frac{\mathrm{i}^l}{r} \left\{ (-1)^{l+1} e^{-\mathrm{i}kr} + S_l e^{\mathrm{i}kr} \right\} \\ &= c_l \frac{(-1)^l}{r} \left\{ -e^{-\mathrm{i}\left(kr - \frac{\pi}{2} l\right)} + S_l e^{\mathrm{i}\left(kr - \frac{\pi}{2} l\right)} \right\} \end{aligned}$$

Если потенциал тождественно равен нулю, то уравнение справедливо во всем пространстве, и приведенное общее выражение необходимо ограничить на случай свободной частицы: волновая функция должна вести себя как r^l при $r \to 0$. Экспоненты в радиальной функции общего вида (13.9) можно разложить в сумму синуса и косинуса от kr, из разложения которых в ряд Тейлора сразу следует, что вклад косинуса необходимо занулить, так как он приводит к члену $1/r$, дифференцирование которого дает сингулярность при $r = 0$ Напротив, для вклада синуса получим

$$\left(\frac{1}{r} \frac{d}{dr} \right)^l \frac{\sin kr}{r} \bigg|_{r \to 0} = (-1)^l \left(\frac{1}{r} \frac{d}{dr} \right)^l \frac{(kr)^{2l+1}}{r(2l+1)!} \bigg|_{r \to 0} = (-1)^l k^{2l+1} \frac{(2l)!!}{(2l+1)!}$$

так что радиальная волновая функция имеет правильное поведение в нуле.

Итак, для этого необходимо, чтобы для свободной частицы

$$S_l^{(0)} \equiv 1$$

и тогда

$$R_{kl}^{(0)}(r) = c_l^{(0)} (-1)^l \frac{r^l}{k^l} \left(\frac{1}{r} \frac{d}{dr} \right)^l \frac{1}{r} \left\{ -e^{-\mathrm{i}kr} + e^{\mathrm{i}kr} \right\}$$

что в асимптотической области $r \to \infty$ дает

$$\begin{aligned} R_{kl}^{(0)}(r) &\simeq c_l^{(0)} \frac{1}{r} \left\{ -e^{-\mathrm{i}\left(kr - \frac{\pi}{2} l\right)} + e^{\mathrm{i}\left(kr - \frac{\pi}{2} l\right)} \right\} \\ &= c_l^{(0)} \frac{2\mathrm{i}}{r} \sin\left(kr - \frac{\pi}{2} l \right) \end{aligned}$$

Для центрального потенциала, достаточно быстро обращающегося в нуль на бесконечности, радиальная волновая функция общего вида (13.9) в задаче рассеяния описывает в асимптотической области суперпозицию падающей на мишень и рассеянной волн со сферическим фронтом (27.10). В силу унитарности падающий и рассеянный потоки равны друг другу для упругого рассеяния, т. е.

$$|S_l| \equiv 1, \quad S_l = \mathrm{e}^{2\mathrm{i}\delta_l}, \quad \delta_l \in \mathbb{R},$$

где δ_l - фазовые сдвиги, зависящие от потенциала, энергии и орбитального момента. По построению

$$\delta_l \in [0, \pi]$$

Значит, при $r \to \infty$ волновая функция в разложении по парциальным волнам имеет вид

$$\begin{aligned} R_{kl}(r) &\simeq c_l^{(0)} \frac{1}{r} \left\{ -e^{-\mathrm{i}\left(kr - \frac{\pi}{2}l\right)} + S_l e^{\mathrm{i}\left(kr - \frac{\pi}{2}l\right)} \right\} \\ &= c_l^{(0)} \frac{2\mathrm{i}}{r} e^{\mathrm{i}\delta_l} \sin\left(kr - \frac{\pi}{2}l + \delta_l\right) \end{aligned}$$

Подчеркнем, что в этой формуле коэффициенты $C_l^{(0)}$ те же, что и в разложении по парциальным волнам волновой функции свободной частицы, так как в задаче рассеяния падающая волна В стационарном out-состоянии должна тождественно совпадать в падающей волной свободного in-состояния.

Итак, мы установили, что в случае исключительно упругих столкновений процесс рассеяния описывается парциальными фазовым и сдвигами, и определили асимптотический вид волновой функции в задаче рассеяния.

Теперь для расчета сечения необходимо отнормировать парциальные потоки так, Чтобы они отвечали потокам падающей волны де Бройля, потому что в эксперименте осуществляется только такая возможность, когда состояниями асимптоти ческого in-пространства являются именно свободные монохроматические волны, а для out-состояний возможен парциально-волновой анализ: наблюдается разложение по орбиталям.

7.2.3 Expansion of the de Broglie Wave into Partial Waves

Разложение волны де Бройля по парциальным волнам по Киселеву

Разложим состояние $|\boldsymbol{k}\rangle$ с заданным волновым вектором $\boldsymbol{k}$ по базису свободных сферических волн $|k; l, m\rangle$ с энергией $E = \hbar^2 k^2/2m$ и орбитальным моментом l с проекцией m в координатном пространстве:

$$\langle \boldsymbol{r}|\boldsymbol{k}\rangle = \sum_{l,m} \langle \boldsymbol{r}|k; l, m\rangle \langle k; l, m|\boldsymbol{k}\rangle$$

Обычно вводят единичные векторы

$$\boldsymbol{n} = \frac{\boldsymbol{r}}{r}, \quad \boldsymbol{n}^{(k)} = \frac{\boldsymbol{k}}{k}$$

Тогда, очевидно, волна де Бройля

$$\langle \boldsymbol{r}|\boldsymbol{k}\rangle = e^{\mathrm{i}kr\boldsymbol{n}\cdot\boldsymbol{n}^{(k)}}$$

Состояние $\langle \boldsymbol{r}|k; l, m\rangle$ есть ничто иное, как решение стационарного уравнения Шредингера для свободной частицы в координатном представлении

$$\langle \boldsymbol{r}|k; l, m\rangle = R_{kl}(r) Y_{l,m}(\boldsymbol{n})$$

где $Y_{l,m}(\boldsymbol{n})$ - сферическая гармоника, которая зависит от угловых координат единичного радиус-вектора $\boldsymbol{n}$, а $\langle k; l, m|\boldsymbol{k}\rangle$ - эрмитово сопряженное решение стационарного уравнения Шредингера в импульсном представлении (представлении волнового вектора):

$$\langle k; l, m|\boldsymbol{k}\rangle = \tilde{R}^*_{kl}(k) Y^*_{l,m}\left(\boldsymbol{n}^{(k)}\right)$$

Переопредели м радиальную волновую функцию, поглощая фактор $\widetilde{R}_{kl}(k)$, так что в согласии с общим рассмотрением свободных сферических волн разложение примет вид

$$e^{\mathrm{i}kr\boldsymbol{n}\cdot\boldsymbol{n}^{(k)}} = 4\pi \sum_{l,m} R^{(0)}_{kl}(r) Y_{l,m}(\boldsymbol{n}) Y^*_{l,m}\left(\boldsymbol{n}^{(k)}\right)$$

где

$$R^{(0)}_{kl}(r) = c^{(0)}_l (-1)^l \frac{r^l}{k^l} \left(\frac{1}{r}\frac{d}{dr}\right)^l \frac{1}{r}\left\{-e^{-\mathrm{i}kr} + e^{\mathrm{i}kr}\right\}$$

с неизвестными коэффициентами $c^{(0)}_l$, задачу определения которых мы сейчас решаем.

В волне скалярное произведение векторов $\boldsymbol{n}\cdot\boldsymbol{n}^{(k)}$ симметрично по перестановке единичных векторов, в разложении же стоит произведение сферических гармоник $Y_{l,m}(\boldsymbol{n})Y^*_{l,m}\left(\boldsymbol{n}^{(k)}\right)$, которое можно преобразовать, пользуясь свойством комплексного сопряжения сферических функций

$$Y_{l,m}(\boldsymbol{n}) = (-1)^m Y^*_{l,-m}(\boldsymbol{n})$$

откуда

$$Y_{l,m}(\boldsymbol{n}) Y^*_{l,m}\left(\boldsymbol{n}^{(k)}\right) = Y^*_{l,-m}(\boldsymbol{n}) Y_{l,-m}\left(\boldsymbol{n}^{(k)}\right)$$

и значит, суммирование по m в правой части разложения (13.19) дает результат, симметричный по перестановке единичных векторов, как это и должно быть.

Вычислим коэффициенты разложения $C^{(0)}_l$ в случае, когда волновой вектор направлен вдоль оси z, откуда $\boldsymbol{n}\cdot\boldsymbol{n}^{(k)} = \cos\theta$, т.е. $\theta^{(k)} = \phi^{(k)} = 0$, и в разложении участвуют только вклады с $m = 0$

$$Y^*_{l,m}\left(\boldsymbol{n}^{(k)}\right) \mapsto Y^*_{l,0}(0,0) = \sqrt{\frac{2l+1}{4\pi}} P_l(1) = \sqrt{\frac{2l+1}{4\pi}}$$

$$Y_{l,m}(\boldsymbol{n}) \mapsto Y_{l,0}(\theta,\phi) = \sqrt{\frac{2l+1}{4\pi}} P_l(\cos\theta)$$

Тогда разложение принимает вид

$$e^{\mathrm{i}kr\cos\theta} = \sum_l (2l+1) P_l(\cos\theta) R^{(0)}_{kl}(r)$$

Из ортогональности полиномов Лежандра

$$\int_{-1}^{1} d\cos\theta \cdot P_{l'}(\cos\theta) P_l(\cos\theta) = \frac{2}{2l+1}\delta_{ll'}$$

и принятого разложения следует, что

$$\int_{-1}^{1} d\cos\theta \cdot P_l(\cos\theta) e^{\mathrm{i}kr\cos\theta} = 2R^{(0)}_{kl}(r).$$

Рассмотрим обе части этого равенства при $r \to \infty$. Слева интегрирование по частям дает

$$\int\limits_{-1}^{1} d\cos\theta \cdot P_l(\cos\theta) e^{\mathrm{i}kr\cos\theta} = \frac{1}{\mathrm{i}kr} P_l(\cos\theta) e^{\mathrm{i}kr\cos\theta|^{+1}_{-1}} - \frac{1}{\mathrm{i}kr} \int\limits_{-1}^{1} d\cos\theta \cdot P_l'(\cos\theta) e^{\mathrm{i}kr\cos\theta}$$

Интегрирование по частям следует повторить еще $l-1$ раз, так как полином Лежандра P_l является полиномом степени l. Однако в пределе $r \to \infty$ каждый дополнительный шаг интегрирования по частям приводит к вкладам $\mathcal{O}\left(1/r^2\right)$. Таким образом,

$$\int\limits_{-1}^{1} d\cos\theta \cdot P_l(\cos\theta) e^{\mathrm{i}kr\cos\theta} = \frac{1}{\mathrm{i}kr} P_l(\cos\theta) e^{\mathrm{i}kr\cos\theta}\Big|_{-1}^{+1} + \mathcal{O}\left(\frac{1}{r^2}\right)$$

По построению $P_l(1) = 1$ и $P_l(-1) = (-1)^l$, так что окончательно асимптотически получаем

$$\int\limits_{-1}^{1} d\cos\theta \cdot P_l(\cos\theta) e^{\mathrm{i}kr\cos\theta} \simeq \frac{1}{\mathrm{i}kr} \left\{ e^{\mathrm{i}kr} - (-1)^l e^{-\mathrm{i}kr} \right\}$$

С другой стороны, асимптотическое поведение радиальной волновой функции сферической волны было нами установлено в предыдущем параграфе

$$R_{kl}^{(0)}(r) \simeq c_l^{(0)} (-\mathrm{i})^l \frac{1}{r} \left\{ e^{\mathrm{i}kr} - (-1)^l e^{-\mathrm{i}kr} \right\}$$

Значит, из (13.21) находим

$$c_l^{(0)} = \mathrm{i}^l \frac{1}{2\mathrm{i}k}$$

Таким образом, разложение окончательно принимает вид

$$e^{\mathrm{i}kr\cos\theta} = \sum_l (2l+1) P_l(\cos\theta) (-\mathrm{i})^l \frac{r^l}{2\mathrm{i}k^{l+1}} \left(\frac{1}{r}\frac{d}{dr} \right)^l \frac{1}{r} \left\{ -e^{-\mathrm{i}kr} + e^{\mathrm{i}kr} \right\}$$

с асимптотикой при $r \to \infty$

$$\begin{aligned} e^{\mathrm{i}kr\cos\theta} &\simeq \sum_l (2l+1) P_l(\cos\theta) \frac{1}{2\mathrm{i}kr} \left\{ e^{\mathrm{i}kr} - (-1)^l e^{-\mathrm{i}kr} \right\} \\ &= \sum_l (2l+1) P_l(\cos\theta) \mathrm{i}^l \cdot \frac{\sin\left(kr - \frac{\pi}{2}l\right)}{kr} \end{aligned}$$

7.2.4 Born Approximation

Теория

В ведущем приближении итераций в уравнении для $\mathcal{T}_E$-матрицы или, что то же, в интегральном уравнении для волновой функции рассеяния

$$\mathcal{T}_E \approx V, \quad \langle \boldsymbol{k}_\mathrm{f} | \mathcal{T}_E | \boldsymbol{k}_\mathrm{i} \rangle \approx \langle \boldsymbol{k}_\mathrm{f} | V | \boldsymbol{k}_\mathrm{i} \rangle ,$$

так что

$$\langle \boldsymbol{k}_\mathrm{f} | V | \boldsymbol{k}_\mathrm{i} \rangle = \int \mathrm{d}^3 r V(\boldsymbol{r}) \mathrm{e}^{-\mathrm{i}(\boldsymbol{k}_\mathrm{f} - \boldsymbol{k}_\mathrm{i})\cdot \boldsymbol{r}} = \tilde{V}\left(\boldsymbol{k}_\mathrm{f} - \boldsymbol{k}_\mathrm{i}\right),$$

где $\tilde{V}$ есть не что иное, как фурье-образ потенциала, зависящий от переданного импульса $\boldsymbol{q} = \hbar\left(\boldsymbol{k}_\mathrm{f} - \boldsymbol{k}_\mathrm{i}\right)$. В итоге амплитуда рассеяния

$$f(\theta) \approx -\frac{m}{2\pi\hbar^2}\tilde{V}\left(\boldsymbol{k}_\mathrm{f} - \boldsymbol{k}_\mathrm{i}\right).$$

Это приближение называется борновским.

Критерий применимости борновского приближения

Критерий применимости борновского приближения включает в себя два аспекта. Поскольку итерации в исследуемых интегральных уравнениях представляют собой разложение решения в ряд по теории возмущений, где в качестве такого возмущения выступает потенциал, степень сходимости ряда можно оценить, во-первых, по малости самой борновской поправки к волновой функции свободной частицы, а во-вторых, по относительной величине поправок высших порядков по возмущению к волновой функции или к сечению рассеяния. На практике обычно ограничиваются первым условием:

$$\left|\psi_\mathrm{i}^{(+)}(\boldsymbol{x}) - \psi_\mathrm{i}^{(0)}(\boldsymbol{x})\right| \ll \left|\psi_\mathrm{i}^{(0)}(\boldsymbol{x})\right|,$$

а значит, согласно $\left|\psi_\mathrm{i}^{(+)}(\boldsymbol{x}) - \psi_\mathrm{i}^{(0)}(\boldsymbol{x})\right| = \left|\int \mathcal{G}_E^{(0)}\left(\boldsymbol{x} - \boldsymbol{x}_1\right) V\left(\boldsymbol{x}_1\right) \psi_\mathrm{i}^{(+)}\left(\boldsymbol{x}_1\right) \mathrm{d}^3 x_1\right|$,

$$\left|\psi_\mathrm{i}^{(+)}(\boldsymbol{x}) - \psi_\mathrm{i}^{(0)}(\boldsymbol{x})\right| \approx \left|\int \mathcal{G}_E^{(0)}\left(\boldsymbol{x} - \boldsymbol{x}_1\right) V\left(\boldsymbol{x}_1\right) \psi_\mathrm{i}^{(0)}\left(\boldsymbol{x}_1\right) \mathrm{d}^3 x_1\right| \ll 1.$$

В качестве грубой оценки интеграла сверху можно взять интеграл от модулей сомножителей:

$$\left|\int \mathcal{G}_E^{(0)}\left(\boldsymbol{x} - \boldsymbol{x}_1\right) V\left(\boldsymbol{x}_1\right) \psi_\mathrm{i}^{(0)}\left(\boldsymbol{x}_1\right) \mathrm{d}^3 x_1\right| \leqslant \int \left|\mathcal{G}_E^{(0)}\left(\boldsymbol{x} - \boldsymbol{x}_1\right)\right| \left|V\left(\boldsymbol{x}_1\right)\right| \left|\psi_\mathrm{i}^{(0)}\left(\boldsymbol{x}_1\right)\right| \mathrm{d}^3 x_1$$

Тогда для потенциала, отличного от нуля в ограниченной области $r < a$, с характерным масштабом энергии $|V(r)| \sim V_0$, из

$$\left|\mathcal{G}_E^{(0)}\left(\boldsymbol{x} - \boldsymbol{x}_1\right)\right| \approx \frac{m}{2\pi\hbar^2}\frac{1}{a}, \quad \left|\psi_\mathrm{i}^{(0)}\left(x_1\right)\right| = 1$$

находим

$$\frac{mV_0}{\hbar^2}a^2 \ll 1.$$

Если ввести обозначение λ_0 для характерной длины волны частицы с энергией V_0:

$$V_0 = \frac{\hbar^2}{m\lambda_0^2}$$

Удобно обозначить характерную длину волны частицы с энергией V_0 как λ_0, тогда:

$$V_0 = \frac{\hbar^2}{m\lambda_0^2},$$

то условие применимости борновского приближения принимает вид

$$\frac{a^2}{\lambda_0^2} \ll 1.$$

Это означает, например, что в случае притягивающего потенциала частица с длиной волны λ_0 не помещается в яме размером a, т. е. в яме нет связанных состояний. В этом же приближении амплитуда рассеяния

$$f \sim \frac{m}{2\pi\hbar^2} V_0 \frac{4\pi}{3} a^3 \approx a \frac{a^2}{\lambda_0^2},$$

и полное сечение

$$\sigma \sim 4\pi |f|^2 \approx 4\pi a^2 \frac{a^4}{\lambda_0^4}.$$

Величину

$$\sigma_{\text{geom}} = 4\pi a^2$$

обычно называют геометрическим сечением. Поэтому условие применимости борновского приближения еще записывают в виде

$$\sigma \ll \sigma_{\text{geom}} ,$$

т. е. рассчитанное в борновском приближении полное сечение должно быть существенно меньше геометрического сечения.

Полученные ограничения на применимость приближения Борна можно ослабить, если рассмотреть различные кинематические условия рассеяния.

Медленные частицы ($kr \sim ka \ll 1$) в борновском приближении

В этом случае экспоненциальные множители в функции Грина и в падающей волне можно заменить единицами

$$\mathrm{e}^{\mathrm{i}kr} \approx \mathrm{e}^{\mathrm{i}ka} \approx 1.$$

Но это, по сути, повторяет общие рассуждения, приведенные выше, где был взят модуль этих экспоненциальных факторов, также равный единице, так что ограничение на величину потенциала остается прежним.

(пропишу это потом!)

Быстрые частицы ($kr \sim ka \gg 1$) в борновском приближении

Функция Грина при $|\boldsymbol{r} - \boldsymbol{r}'| \approx a$

$$\mathcal{G}_E^{(0)}(\boldsymbol{r} - \boldsymbol{r}') \sim \frac{m}{2\pi\hbar^2} \frac{1}{a} \mathrm{e}^{\mathrm{i}ka},$$

а волна де Бройля

$$\psi_i^{(0)}(\boldsymbol{r}') = \mathrm{e}^{\mathrm{i}kr' \cos\theta'} \sim \mathrm{e}^{\mathrm{i}ka\cos\theta'}$$

быстро осциллирует как функция от $r' \sim a$ и зануляет интеграл везде, кроме узкой области по углам:

$$\mathrm{e}^{\mathrm{i}ka\cos\theta'} \sim 1, \quad |\cos\theta'| \lesssim \frac{1}{ka} \ll 1.$$

Ограничивая область интегрирования по телесному углу этим конусом, легко находим критерий применимости борновского приближения для быстрых частиц

$$\frac{mV_0}{\hbar^2} a^2 \frac{1}{ka} \ll 1 \Leftrightarrow \frac{a^2}{\lambda_0^2} \ll ka,$$

что, конечно, значительно слабее условия для медленных частиц.

Пример применений

Как догадаться про это?

7.2.5 Lippmann–Schwinger Integral Scattering Theory (??)

(потренирую, потом пропишу её, мб больше раздел сделаю, пока есть что есть. в 1ю часть тоже добавлю!)

Суть и основные формулы

В отличие от выражения в виде «T-экспоненты» для оператора эволюции, в случае потенциала, зависящего от времени, метод функций Грина приводит к обычным интегральным выражениям. Однако здесь тоже есть сложности с упорядочиванием по времени при расчетах петлевых квантовых поправок: возникающие интегралы могут содержать расходимости, методам устранения которых посвящена теория перенормировок, выходящая за рамки данного курса.

Обзор уравнения Липпмана-Швингера

(тут его обсудим)

$$\psi_{\mathrm{i}}^{(+)}(\boldsymbol{x}) = \psi_{\mathrm{i}}^{(0)}(\boldsymbol{x}) + \int \mathcal{G}_E^{(0)}\left(\boldsymbol{x}-\boldsymbol{x}_1\right) V\left(\boldsymbol{x}_1\right) \psi_{\mathrm{i}}^{(+)}\left(\boldsymbol{x}_1\right) \mathrm{d}^3 x_1$$

Теория

Установим тождество для функции Грина, используя

$$\mathbb{1} = G_E^{(0)}\left(E - H^{(0)}\right) = G_E^{(0)}(E - \hat{H} + V).$$

Преобразуем её как:

$$\begin{aligned} G_E =& \mathbb{1} \cdot G_E = \\ =& G_E^{(0)}(E - \hat{H} + V) G_E = \\ =& G_E^{(0)}\left(\mathbb{1} + V G_E\right) = \\ =& G_E^{(0)} + G_E^{(0)} V G_E. \end{aligned}$$

В координатном представлении оно является интегральным:

$$\mathcal{G}_E\left(\boldsymbol{r}, \boldsymbol{r}'\right) = \mathcal{G}_E^{(0)}\left(\boldsymbol{r}-\boldsymbol{r}'\right) + \int \mathcal{G}_E^{(0)}\left(\boldsymbol{r}-\boldsymbol{r}_1\right) V\left(\boldsymbol{r}_1\right) \mathcal{G}_E\left(\boldsymbol{r}_1, \boldsymbol{r}'\right) \mathrm{d}^3 r_1$$

Это уравнение можно решать методом итераций, т. е. находить решение с любой точностью по степени потенциала. Такой подход эффективен, если ряд последовательных приближений быстро сходится, и этот метод лежит в основе теории возмущений.

Аналогично и для запаздывающей функции Грина, если ввести состояния $|x\rangle$, нормированные согласно

$$\langle x | x' \rangle = \delta^{(4)}\left(x - x'\right).$$

(?? к чему это??)

Тогда получим уравнение

$$G = G^{(0)} + G^{(0)} V G$$

или в интегральном виде

$$\mathcal{G}\left(x,x'\right)=\mathcal{G}^{(0)}\left(x-x'\right)+\int\mathcal{G}^{(0)}\left(x-x_1\right)V\left(x_1\right)\mathcal{G}\left(x_1,x'\right)\mathrm{d}^4x_1$$

Запаздывающая функция Грина переводит начальное состояние $\psi_{\mathrm{i}}^{(0)}(x')$ в состояние в момент времени $t>t'$, $\psi_{\mathrm{i}}^{(+)}(x)$ так что

$$\psi_{\mathrm{i}}^{(0)}(x)=\mathrm{i}\hbar\int\mathcal{G}^{(0)}\left(x-x'\right)\psi_{\mathrm{i}}^{(0)}\left(x'\right)\mathrm{d}^3x'$$

а также

$$\psi_{\mathrm{i}}^{(+)}(x)=\mathrm{i}\hbar\int\mathcal{G}\left(x,x'\right)\psi_{\mathrm{i}}^{(0)}\left(x'\right)\mathrm{d}^3x',$$

(??? выпишу выше эти формулы, с ними должно быть уже знакомство. не уверен в обозначениях Киселева, мб изменю их.)

Подставим $\mathcal{G}\left(x,x'\right)$, получим:

$$\psi_{\mathrm{i}}^{(+)}(x)=\psi_{\mathrm{i}}^{(0)}(x)+\int\mathcal{G}^{(0)}\left(x-x_1\right)V\left(x_1\right)\psi_{\mathrm{i}}^{(+)}\left(x_1\right)\mathrm{d}^4x_1.$$

(?? дальше можно подумать. мб начну параграф про стац случай)

В стационарном случае потенциал не зависит от времени $V(x)=V(\boldsymbol{x})$, и начальное асимптотическое состояние с энергией E_{i} дает стационарное решение уравнения Шрёдингера с той же энергией:

$$\psi_{\mathrm{i}}^{(+)}(x)=\mathrm{e}^{-\frac{i}{\hbar}E_{\mathrm{i}}t}\psi_{\mathrm{i}}^{(+)}(\boldsymbol{x}).$$

Поэтому, добавив также под интеграл экспоненту и обратную, интегральное уравнение сводится к виду

$$\mathrm{e}^{-\frac{\mathrm{i}}{\hbar}E_{\mathrm{i}}t}\psi_{\mathrm{i}}^{(+)}(\boldsymbol{x})=\mathrm{e}^{-\frac{\mathrm{i}}{\hbar}E_{\mathrm{i}}t}\psi_{\mathrm{i}}^{(0)}(\boldsymbol{x})+\int\frac{\mathrm{d}E\ \mathrm{d}t_1}{2\pi\hbar}\mathrm{e}^{-\frac{\mathrm{i}}{\hbar}(E_{\mathrm{i}}-E)t_1}\mathrm{e}^{-\frac{\mathrm{i}}{\hbar}Et}\int\mathcal{G}_E^{(0)}\left(\boldsymbol{x}-\boldsymbol{x}_1\right)V\left(\boldsymbol{x}_1\right)\psi_{\mathrm{i}}^{(+)}\left(\boldsymbol{x}_1\right)\mathrm{d}^3x_1$$

(??? и откуда там интегрирование по энергии??? максимально плохо написано у Киселева.)

или после сокращения временных факторов, запишем так называемое уравнение Липпмана-Швингера

$$\psi_{\mathrm{i}}^{(+)}(\boldsymbol{x})=\psi_{\mathrm{i}}^{(0)}(\boldsymbol{x})+\int\mathcal{G}_E^{(0)}\left(\boldsymbol{x}-\boldsymbol{x}_1\right)V\left(\boldsymbol{x}_1\right)\psi_{\mathrm{i}}^{(+)}\left(\boldsymbol{x}_1\right)\mathrm{d}^3x_1$$

Это интегральное уравнение для стационарной волновой функции в задаче рассеяния.

Физический смысл этого уравнения становится ясным, если записать стационарное уравнение Шрёдингера для $\psi_{\mathrm{i}}^{(+)}(\boldsymbol{x})$:

$$\left(E-H^{(0)}\right)\psi_{\mathrm{i}}^{(+)}(\boldsymbol{x})=V(\boldsymbol{x})\psi_{\mathrm{i}}^{(+)}(\boldsymbol{x}),$$

которое, естественно, следует из интегрального уравнения. Поэтому правую часть можно рассматривать в качестве источника в уравнении Шрёдингера

$$\left(E-H^{(0)}\right)\psi(\boldsymbol{x})=j(\boldsymbol{x}),$$

общее решение которого представляется в виде суммы решения для однородного уравнения без источников, т. е. $\psi_{\mathrm{i}}^{(0)}(\boldsymbol{x})$, и частного решения

$$\int\mathcal{G}_E^{(0)}\left(\boldsymbol{x}-\boldsymbol{x}_1\right)j\left(\boldsymbol{x}_1\right)\mathrm{d}^3x_1$$

Тогда подстановка в это соотношение источника $j(\boldsymbol{x})=V(\boldsymbol{x})\psi_{\mathrm{i}}^{(+)}(\boldsymbol{x})$ приводит к интегральному уравнению для стационарной волновой функции.

(очень плохо написано, на примерах или в другом месте разберу потом.)

О том, почему мы делаем именно так (??)

(оставшийся вопрос, зачем вообще такое мы рассматриваем?? с опытом придет понимание.)

Асимптотическое поведение на больших расстояниях и формула для сечения

Интегральное уравнение Липпмана-Швингера

$$\psi_{\mathrm{i}}^{(+)}(\boldsymbol{r}) = \psi_{\mathrm{i}}^{(0)}(\boldsymbol{r}) + \int \mathcal{G}_E^{(0)}\left(\boldsymbol{r}-\boldsymbol{r}'\right) V\left(\boldsymbol{r}'\right) \psi_{\mathrm{i}}^{(+)}\left(\boldsymbol{r}'\right) \mathrm{d}^3 r'$$

позволяет установить асимптотическое поведение волновой функции в задаче рассеяния при $r \to \infty$.

Исследуем интегральный член, оставляя вклад падающей волны $\psi_{\mathrm{i}}^{(0)}(\boldsymbol{r})$.

При $r \to \infty$ и ограниченном $r' < a$ функция Грина свободной частицы есть

$$\mathcal{G}_E^{(0)}\left(\boldsymbol{r}, \boldsymbol{r}'\right) = -\frac{m}{2\pi\hbar^2} \frac{\mathrm{e}^{\mathrm{i}k_E|\boldsymbol{r}-\boldsymbol{r}'|}}{|\boldsymbol{r}-\boldsymbol{r}'|} \simeq -\frac{m}{2\pi\hbar^2} \frac{\mathrm{e}^{\mathrm{i}k_E(r-\boldsymbol{n}\cdot\boldsymbol{r}')}}{r}, \quad \boldsymbol{n} = \frac{\boldsymbol{r}}{r}.$$

Подставив, имеем:

$$\psi_{\mathrm{i}}^{(+)}(\boldsymbol{r}) \simeq \psi_{\mathrm{i}}^{(0)}(\boldsymbol{r}) + \frac{\mathrm{e}^{\mathrm{i}k_{\mathrm{i}}r}}{r} f(\theta), \quad r \to \infty$$

где

$$f(\theta) = -\frac{m}{2\pi\hbar^2} \int \mathrm{d}^3 r' \mathrm{e}^{-\mathrm{i}\boldsymbol{k}_E\cdot\boldsymbol{r}'} V\left(r'\right) \psi_{\mathrm{i}}^{(+)}\left(\boldsymbol{r}'\right)$$

Учтено, что оно работает при потенциалах, для которых этот интеграл сходится.

Здесь в силу сохранения энергии $k_E = k_{\mathrm{i}}$, и $\boldsymbol{k}_E = \boldsymbol{n}k_E$. Поскольку скалярная величина f зависит от двух векторов $\boldsymbol{k}_{\mathrm{i}}$ и $\boldsymbol{k}_E$ в случае центрально симметричного поля, она может определяться только скалярными величинами: квадратами векторов и их скалярным произведением $\boldsymbol{k}_{\mathrm{i}} \cdot \boldsymbol{k}_E = k_{\mathrm{i}}^2 \cos\theta$, а значит, f является функцией угла между этими векторами, как мы и записали выше.

Если фиксировать нормировку падающей волны, то

$$\psi_{\mathrm{i}}^{(+)}(\boldsymbol{r}) \simeq \mathrm{e}^{\mathrm{i}\boldsymbol{k}_{\mathrm{i}}\cdot\boldsymbol{r}} + \frac{\mathrm{e}^{\mathrm{i}k_{\mathrm{i}}r}}{r} f(\theta), \quad r \to \infty$$

(?? про нормировку пока не доехал)

Величину $f(\theta)$ называют амплитудой рассеяния.

Поток вероятности после рассеяния и сечение

Поток начальной волны $\psi_i^{(0)}(\boldsymbol{r})$

$$\boldsymbol{j}_{\mathrm{i}} = \frac{\hbar}{m}\boldsymbol{k}_{\mathrm{i}}$$

Для расчета потока вероятности

$$j = -\frac{\mathrm{i}\hbar}{2m}\left\{\psi^*\boldsymbol{\nabla}\psi - \psi\boldsymbol{\nabla}\psi^*\right\}$$

вычислим в асимптотической области $r \to \infty$ градиент вклада рассеяния.

В полярных координатах в $\boldsymbol{\nabla} = \boldsymbol{e}_r \frac{\partial}{\partial r} + \boldsymbol{e}_\theta \frac{\partial}{r\partial\theta} + \boldsymbol{e}_\phi \frac{\partial}{r\sin\theta\partial\phi}$ при $r \to \infty$ угловые компоненты убывают как $\mathcal{O}\left(1/r^2\right)$, так что вклад дает только компонента вдоль радиус-вектора $\boldsymbol{e}_r = \boldsymbol{n}$:

$$\boldsymbol{\nabla}\frac{\mathrm{e}^{\mathrm{i}k_{\mathrm{i}}r}}{r} f(\theta) \approx \mathrm{i}k_{\mathrm{i}} \frac{\mathrm{e}^{\mathrm{i}k_{\mathrm{i}}r}}{r} f(\theta)\boldsymbol{n} = \mathrm{i}\boldsymbol{k}_E \frac{\mathrm{e}^{\mathrm{i}k_{\mathrm{i}}r}}{r} f(\theta).$$

Подставив, получаем поток вероятности рассеяния

$$\boldsymbol{j}_{\text{out}} = \frac{\hbar}{m}\boldsymbol{k}_E \frac{1}{r^2}|f(\theta)|^2.$$

Он зависит от угла рассеяния θ и является симметричным по полярному углу ϕ (в случае сферически симметричного потенциала).

В асимптотической области в малом телесном угле этот поток можно аппроксимировать плоской волной с волновым вектором $\boldsymbol{k}_\text{f} = \boldsymbol{n}k_\text{i}$ и нормировкой, которая определяет вероятность рассеяния. В самом деле, за счет потока вероятности через площадь на сфере радиуса r в телесном угле $\mathrm{d}\Omega$

$$\mathrm{d}\boldsymbol{s} = \boldsymbol{n} \cdot r^2 \, \mathrm{d}\Omega$$

вероятность рассеяния в единицу времени составляет

$$\mathrm{d}w = \boldsymbol{j}_{\text{out}} \cdot \mathrm{d}s = \frac{\hbar}{m}k_\text{i}|f(\theta)|^2 \, \mathrm{d}\Omega.$$

Следовательно, дифференциальное сечение рассеяния как функция амплитуды есть:

$$\mathrm{d}\sigma = |f(\theta)|^2 \, \mathrm{d}\Omega.$$

(в 1ю добавлю эти формулы, вроде полезные!)

Обзор применений (?!!!!!)

(пока хз, где конкретно она нужна)

Как догадаться до уравнения Липпмана-Швингера (??)

(?? суть не понял, так что на это тоже не отвечу еще.)

7.2.6 Expansion of the S-Matrix and T-Matrix

(!! снова с обозначениями проблемы, нужно указать их четче, тут много самых разных волновых функций.)

Теория (??)

Выражение $\mathcal{S}_\text{fi} = \lim_{t\to+\infty}\left\langle \psi_\text{f}^{(0)}(t)|\psi_\text{i}^{(+)}(t)\right\rangle$ можно вычислить, подставив уравнение Липпмана-Швингера для $\left|\psi_\text{f}^{(0)}(t)\right\rangle$, получим:

$$\mathcal{S}_{fi} = \left\langle \psi_\text{f}^{(0)}|\psi_i^{(0)}\right\rangle + \int \psi_\text{f}^{*(0)}(x)\mathcal{G}^{(0)}\left(x-x_1\right)V\left(x_1\right)\psi_i^{(+)}\left(x_1\right)d^4x_1 d^3\boldsymbol{x}$$

Здесь

$$\left\langle \psi_\text{f}^{(0)}|\psi_\text{i}^{(0)}\right\rangle = e^{-\frac{\mathrm{i}}{\hbar}(E_\text{i}-E_\text{f})t}\left\langle \boldsymbol{k}_\text{f}|\boldsymbol{k}_\text{i}\right\rangle = (2\pi)^3\delta\left(\boldsymbol{k}_\text{f}-\boldsymbol{k}_\text{i}\right)$$

И при $t > t_1$

$$\mathrm{i}\hbar\int \psi_\text{f}^{*(0)}(x)\mathcal{G}^{(0)}\left(x-x_1\right)d^3\boldsymbol{x} = \int \left\langle \boldsymbol{k}_\text{f}|\boldsymbol{k}\right\rangle \frac{d^3\boldsymbol{k}}{(2\pi)^3}\left\langle \boldsymbol{k}|\boldsymbol{x}_1\right\rangle e^{\frac{\mathrm{i}}{\hbar}(E_\text{i}-E)t+\frac{\mathrm{i}}{\hbar}Et_1} = \psi_\text{f}^{*(0)}\left(x_1\right)$$

(??? окей, что выше - не так уж понимаю, нужно основы про волновую функцию прописать лучше.)

Это есть функциональное выражение тождества Для унитарного оператора эволюции

$$U\left(t,t'\right)U\left(t',t\right)=\mathbb{1}\quad\rightarrow\quad U\left(t,t'\right)=U^{\dagger}\left(t',t\right)$$

которое означает, что этот оператор описывает также и эволюцию назад по времени.

(??? пока это совсем не понимаю, какая связь??)

(ну там мысль в том, что пара произведений так вот переходит в финальное состояние)

Поэтому интегральный член в матричном элементе $\mathcal{S}_{\mathfrak{fi}}$ записывается в виде

$$\int\psi_{\mathrm{f}}^{*(0)}\left(x_1\right)V\left(x_1\right)\psi_{\mathrm{i}}^{(+)}\left(x_1\right)d^4x_1$$

Однако в стационарном случае потенциал пс зависит от времени, а волновая функция $\psi_i^{(+)}(x)$ является решением стационарного уравнения Шредингера с энергией начального асимптотического состояния E_{i}, так что интегрирование по t_1 легко выполняется

$$\int dt_1 e^{\frac{\mathrm{i}}{\hbar}\left(E_{\mathrm{f}}-E_{\mathrm{i}}\right)t}=2\pi\hbar\delta\left(E_{\mathrm{f}}-E_{\mathrm{i}}\right)$$

В итоге, матричный элемент

$$\mathcal{S}_{\mathfrak{f}i}=(2\pi)^3\delta\left(\boldsymbol{k}_{\mathfrak{f}}-\boldsymbol{k}_{\mathfrak{i}}\right)-\mathrm{i}2\pi\delta\left(E_{\mathfrak{f}}-E_{\mathfrak{i}}\right)\int\psi_{\mathfrak{f}}^{*(0)}(\boldsymbol{r})V(r)\psi_{\mathfrak{i}}^{(+)}(\boldsymbol{r})d^3\boldsymbol{r}$$

В этом выражении первый член отвечает вкладу за счет падающей на мишень волны в задаче рассеяния

$$(2\pi)^3\delta\left(\boldsymbol{k}_{\mathfrak{f}}-\boldsymbol{k}_{\mathfrak{i}}\right)=\langle\boldsymbol{k}_{\mathfrak{f}}|\boldsymbol{k}_{\mathfrak{i}}\rangle$$

а второй можно записать через амплитуду рассеяния $f(\theta)$ согласно ее определению:

$$\int\psi_{\mathrm{f}}^{*(0)}(\boldsymbol{r})V(r)\psi_{\mathrm{i}}^{(+)}(\boldsymbol{r})d^3\boldsymbol{r}=\int d^3\boldsymbol{r}e^{-\mathrm{i}\boldsymbol{k}_{\mathrm{f}}\cdot\boldsymbol{r}}V(r)\psi_{\mathrm{i}}^{(+)}(\boldsymbol{r})=-\frac{2\pi\hbar^2}{m}f(\theta)$$

Важно подчеркнуть, что интегральное представление для волновой функции и матричного элемента позволило нам доказать сделанное при постановке задачи рассеяния утверждение, что амплитуда перехода пропорциональна дельта-функции от разности энергий начального и конечного асимптотического состояний, так что ее квадрат определяет вероятность перехода в единицу времени.

T-матрица

Поскольку S-матрица есть предельное значение оператора эволюции при бесконечном Времени эволюции, она, как частный случай оператора эволюции, унитарного в любой момент времени, также является унитарной

$$\mathcal{S}\mathcal{S}^{\dagger}=\mathbb{1}$$

Обычно вводят понятие T-матрицы рассеяния, чтобы исключить тривиальный вклад падающих на мишень волн из $\mathcal{S}$-матрицы

$$\mathcal{S}=1-\frac{i}{\hbar}\mathcal{T}.$$

Унитарность $\mathcal{S}$-матрицы дает

$$\left(\mathbb{1} - \frac{\mathrm{i}}{\hbar}\mathcal{T}\right)\left(\mathbb{1} + \frac{\mathrm{i}}{\hbar}\mathcal{T}^\dagger\right) = \mathbb{1},$$

откуда следует соотношение унитарности для $\mathcal{T}$ - матрицы

$$\mathcal{T}\mathcal{T}^\dagger = -2\hbar\,\mathrm{Im}\,\mathcal{T}$$

В стационарном случае

$$\mathrm{S_{fi}} = \langle \boldsymbol{k}_\mathrm{f}|\boldsymbol{k}_\mathrm{i}\rangle - \frac{\mathrm{i}}{\hbar}\langle \boldsymbol{k}_\mathrm{f}|\mathcal{T}|\boldsymbol{k}_\mathrm{i}\rangle = \langle \boldsymbol{k}_\mathrm{f}|\boldsymbol{k}_\mathrm{i}\rangle - \frac{\mathrm{i}}{\hbar}2\pi\hbar\delta\left(E_\mathrm{f} - E_\mathrm{i}\right)\left\langle \boldsymbol{k}_\mathrm{f}|V|\psi_\mathrm{i}^{(+)}\right\rangle,$$

то есть

$$\mathcal{T}_\mathrm{fi} = \langle \boldsymbol{k}_\mathrm{f}|\mathcal{T}|\boldsymbol{k}_\mathrm{i}\rangle = -2\pi\hbar\delta\left(E_\mathrm{f} - E_\mathrm{i}\right)\frac{2\pi\hbar^2}{m}f(\theta).$$

(?? пропишу там потом еще раз эти формулы, потому что не усвоено, что именно такие свойства S матрицы.)

Если взять диагональный матричный элемент соотношения унитарности для $\mathcal{T}$-матрицы

$$\left\langle \boldsymbol{k}_\mathrm{i}\left|\mathcal{T}\mathcal{T}^\dagger\right|\boldsymbol{k}_\mathrm{i}\right\rangle = -2\hbar\,\mathrm{Im}\,\langle \boldsymbol{k}_\mathrm{i}|\mathcal{T}|\boldsymbol{k}_\mathrm{i}\rangle,$$

то в правой части будет стоять величина

$$-2\hbar\,\mathrm{Im}\,\langle \boldsymbol{k}_\mathrm{i}|\mathcal{T}|\boldsymbol{k}_\mathrm{i}\rangle = 2\pi\hbar\delta(E)|_{E\to 0}\,\frac{4\pi\hbar^3}{m}\,\mathrm{Im}\,f(0),$$

где $f(0)$ - амплитуда упругого рассеяния вперед, и, как обычно, формально $2\pi\hbar\delta(E)|_{E\to 0} = T \to \infty$ - время наблюдения за частицей при рассеянии.

Для левой части тождества унитарности T-матрицы запишем

$$\left\langle \boldsymbol{k}_\mathrm{i}\left|\mathcal{T}\mathcal{J}^\dagger\right|\boldsymbol{k}_\mathrm{i}\right\rangle = \int \langle \boldsymbol{k}_\mathrm{i}|\mathcal{T}|\boldsymbol{k}_\mathrm{f}\rangle\,\frac{\mathrm{d}^3k_\mathrm{f}}{(2\pi)^3}\left\langle \boldsymbol{k}_\mathrm{f}\left|\mathcal{T}^\dagger\right|\boldsymbol{k}_\mathrm{i}\right\rangle = \int \frac{\mathrm{d}^3k_\mathrm{f}}{(2\pi)^3}\left|\mathcal{T}_\mathrm{fi}\right|^2.$$

Вероятность рассеяния в единицу времени через T-матрицу есть

$$\mathrm{d}w_\mathrm{fi} = \frac{\left|\mathcal{S}_\mathrm{fi}\right|^2}{T}\frac{\mathrm{d}^3k_\mathrm{f}}{(2\pi)^3} = \frac{\left|\mathcal{T}_\mathrm{fi}\right|^2}{\hbar^2 T}\frac{\mathrm{d}^3k_\mathrm{f}}{(2\pi)^3},$$

а полное сечение рассеяния

$$\sigma = \frac{1}{j_\mathrm{i}}\int \mathrm{d}w_\mathrm{fi} = \frac{1}{T\hbar^2 j_\mathrm{i}}\int \frac{\mathrm{d}^3k_\mathrm{f}}{(2\pi)^3}\left|\mathcal{T}_\mathrm{fi}\right|^2.$$

В итоге время наблюдения T в равенстве сокращается, и унитарность приводит к тождеству

$$\hbar^2 j_\mathrm{i}\sigma = \frac{4\pi\hbar^3}{m}\,\mathrm{Im}\,f(0),$$

так что с учетом $j_\mathrm{i} = \hbar k_\mathrm{i}/m$ окончательно находим

$$\sigma = \frac{4\pi}{k_\mathrm{i}}\,\mathrm{Im}\,f(0).$$

Это тождество составляет содержание оптической теоремы, или соотношения Бора-Пайерлса-Плачека, связывающего полное сечение рассеяния с мнимой частью амплитуды упругого рассеяния вперед.

(чуть улучшу верстку, также строчкой опишу идею вывода. вроде понял.)

Стационарная $\mathcal{T}_E$

Наконец, введем стационарную $\mathcal{T}$-матрицу

$$\mathcal{T} = 2\pi\hbar\delta\left(E_{\mathrm{f}} - E_{\mathrm{i}}\right)\mathcal{T}_E.$$

Тогда интегральное уравнение для состояния

$$\left|\psi_{\mathrm{i}}^{(+)}\right\rangle = \left|\psi_{\mathrm{i}}^{(0)}\right\rangle + G_E^{(0)} V \left|\psi_{\mathrm{i}}^{(+)}\right\rangle$$

позволяет установить для матричного элемента $\mathcal{T}_E$

$$\langle \boldsymbol{k_f} \left|\mathcal{T}_E\right| \boldsymbol{k}_{\mathrm{i}}\rangle = \left\langle \boldsymbol{k_f} | V | \psi_{\mathrm{i}}^{(+)} \right\rangle$$

следующее равенство

$$\begin{aligned}
\langle \boldsymbol{k}_{\mathrm{f}} \left|\mathcal{T}_E\right| \boldsymbol{k}_{\mathrm{i}}\rangle &= \langle \boldsymbol{k}_{\mathrm{f}} | V | \boldsymbol{k}_{\mathrm{i}}\rangle + \left\langle \boldsymbol{k}_{\mathrm{f}} \left| V G_E^{(0)} V \right| \psi_{\mathrm{i}}^{(+)} \right\rangle = \\
&= \langle \boldsymbol{k}_{\mathrm{f}} | V | \boldsymbol{k}_{\mathrm{i}}\rangle + \int \left\langle \boldsymbol{k}_{\mathrm{f}} \left| V G_E^{(0)} \right| \boldsymbol{k} \right\rangle \frac{\mathrm{d}^3 k}{(2\pi)^3} \left\langle \boldsymbol{k} | V | \psi_{\mathrm{i}}^{(+)} \right\rangle = \\
&= \langle \boldsymbol{k}_{\mathrm{f}} | V | \boldsymbol{k}_{\mathrm{i}}\rangle + \int \left\langle \boldsymbol{k}_{\mathrm{f}} \left| V G_E^{(0)} \right| \boldsymbol{k} \right\rangle \frac{\mathrm{d}^3 k}{(2\pi)^3} \langle \boldsymbol{k} \left|\mathcal{T}_E\right| \boldsymbol{k}_{\mathrm{i}}\rangle .
\end{aligned}$$

Или в операторной форме

$$\mathcal{T}_E = V + V G_E^{(0)} \mathcal{T}_E,$$

что позволяет строить итерационный ряд, сходящийся в теории возмущений по малому потенциалу.

Представление взаимодействия and S-matrix по Левитову Шитову

(??? про это еще остаются вопросы, так и не понял, почему это важно. потом подумаю.)

В теории возмущений гамильтониан записывают в виде $\widehat{\mathcal{H}} = \widehat{\mathcal{H}}_0 + \widehat{\mathcal{H}}_{\mathrm{int}}$, где $\widehat{\mathcal{H}}_0$ - невозмущенная часть, а $\widehat{\mathcal{H}}_{\mathrm{int}}$ -возмущенная.

Наиболее удобно работать в представлении взаимодействия, т. е. в представлении Гейзенберга невозмущенной задачи.

В качестве базиса этого представления используются зависящие от времени собственные состояния невозмущенного гамильтониана $\widehat{\mathcal{H}_0}$:

$$|\alpha\rangle(t) = e^{-(i/\hbar)E_\alpha t}|\alpha\rangle,$$

где E_α -спектр $\widehat{\mathcal{H}}_0$. Уравнение Шредингера, записанное в этом базисе, принимает вид

$$i\hbar\frac{\partial\tilde{\psi}}{\partial t} = \widehat{\mathcal{H}}_{\mathrm{int}}(t)\tilde{\psi}$$

где $\widehat{\mathcal{H}}_{\mathrm{int}}(t) = e^{(i/\hbar)\widehat{\mathcal{H}}_0 t}\widehat{\mathcal{H}}_{\mathrm{int}}\, e^{-(i/\hbar)\widehat{\mathcal{H}}_0 t}$, а обозначение $\tilde{\psi}$ указывает, что ψ берется в представлении взаимодействия.

Формальное решение записывается через S-матрицу, $\tilde{\psi}(t) = \widehat{S}(t)\tilde{\psi}(0)$, которая дается так называемой хронологической экспонентой:

$$\widehat{S}(t) = \mathrm{T}\exp\left[-\frac{i}{\hbar}\int\limits_0^t \widehat{\mathcal{H}}_{\mathrm{int}}(t')\,dt'\right] = \sum_{n=0}^{\infty}\left(-\frac{i}{\hbar}\right)^n \int\limits_0^t\int\limits_0^{t_1}\ldots\int\limits_0^{t_{n-1}} \widehat{\mathcal{H}}_{\mathrm{int}}(t_1)\ldots\widehat{\mathcal{H}}_{\mathrm{int}}(t_n)\,dt_n\ldots dt_1$$

где $0 < t_n < ... < t_1 < t$. Преобразования $(2.1) - (2.3)$ имеют общий квантово механический характер: они применимы и к одночастичной и к многочастичной задачам.

В многочастичном случае, представляющем основной интерес, необходимо перейти к ψ -операторам, после чего члены ряд разложения S-матрицы становятся полиномами по операторам рождения и уничтожения.

Анализ операторной структуры этих выражений приводит к простым правилам вычисления средних (теорема Вика) и к диаграммной технике, дающей удобное графическое представление для разложения S -матрицы в ряд по взаимодействию.

Введем хронологическое произведение операторов, которое часто называют также T-упорядоченным произведением операторов, или просто T-произведением. Для бозе-операторов

$$\mathrm{T}\widehat{A}(x)\widehat{B}(x') = \begin{cases} \widehat{A}(x)\widehat{B}(x') & \text{если } t > t' \\ \widehat{B}(x')\,\hat{A}(x) & \text{если } t < t' \end{cases}$$

а для ферми-операторов

$$\mathrm{T}\widehat{A}(x)\widehat{B}(x') = \begin{cases} \widehat{A}(x)\hat{B}(x') & \text{при } t > t' \\ -\widehat{B}(x')\,\widehat{A}(x) & \text{при } t < t' \end{cases}$$

(??? и почему это так???)

Иначе говоря, при T-упорядочении операторов их переставляют так, чтобы моменты времени, в которые взяты операторы, возрастали справа налево. При этом знак перестановки соответствует их коммутационным соотношениям: « + » для бозонов, " - » для фермионов.

С помощью T-произведения операторов можно записать выражение для хронологической экспоненты в более привычном виде:

$$\widehat{S}(t) = \sum_{n=0}^{\infty} \left(-\frac{i}{\hbar}\right)^n \frac{1}{n!} \mathrm{T}\left(\int_0^t \widehat{\mathcal{H}}_{\text{int}}(t')\,dt'\right)^n$$

7.2.7 Unitarity and the Optical Theorem

Теория оптической теоремы

она не применима в Борновском приближении. Тут об этом.

Optical theorem is applicable even if there are inelastic processes

The optical theorem follows from very basic conservation laws and as such has a very general nature. It is valid even for scattering of composite particles, where inelastic processes are possible. In the latter case, we should use in Eq. (XIII.11), the total collision cross-section for $\sigma(E)$, while $f(E, 0)$ should be understood as the forward-scattering amplitude of elastic scattering of the composite particle.

(???? why?? this is what Galitski wrote)

7.3 Scattering Theory: Phase Decomposition Approach

(I'll write formulas about it later)

8 Specific Methods and Templates

8.1 Path Integral Formulation of QM: Basics

8.1.1 1. Feynman Path Integral

Here we present Feynman's path integral approach to quantum mechanics, which expresses the propagator of a quantum system with the Hamiltonian H - the kernel of the evolution operator $U(t) = e^{-\frac{i}{\hbar}tH}$ - as a "sum over trajectories" of the corresponding classical system.

1.1. The fundamental solution of the Schrdinger equation.

Recall (see Section 1.3 of Chapter 2) that in terms of the evolution operator $U(t) = e^{-\frac{i}{\hbar}tH}$, the solution $\psi(t)$ of the initial value problem for the time-dependent Schrdinger equation

$$i\hbar\frac{d\psi}{dt}(t) = H\psi(t), \tag{1.1}$$

$$\psi(t)|_{t=0} = \psi \tag{1.2}$$

is given by $\psi(t) = U(t)\psi$. For the Hamiltonian operator

$$H = \frac{\boldsymbol{P}^2}{2m} + V(\boldsymbol{Q})$$

of a quantum particle in $\mathbb{R}^n$ moving in the potential field $V(\boldsymbol{q})$, the initial value problem (1.1)-(1.2) in coordinate representation becomes the following

Cauchy problem:

$$i\hbar\frac{\partial\psi}{\partial t} = -\frac{\hbar^2}{2m}\Delta\psi + V(\boldsymbol{q})\psi \tag{1.3}$$

$$\psi(\boldsymbol{q},t)|_{t=0} = \psi(\boldsymbol{q}) \tag{1.4}$$

where Δ is the Laplace operator on $\mathbb{R}^n$. Under rather general conditions on the potential $V(\boldsymbol{q})$ (i.e., when $V \in L^\infty_{\text{loc}}(\mathbb{R}^n)$ is bounded from below) the Cauchy problem (1.3)-(1.4) has a fundamental solution: a function $K(\boldsymbol{q},\boldsymbol{q}',t)$ which satisfies partial differential equation (1.3) with respect to the variable $\boldsymbol{q}$ in the distributional sense (i.e., $K(\boldsymbol{q},\boldsymbol{q}',t)$ is a weak solution of the Schrdinger equation), and the initial condition

$$K(\boldsymbol{q},\boldsymbol{q}',t)|_{t=0} = \delta(\boldsymbol{q}-\boldsymbol{q}') \tag{1.5}$$

The solution of the Cauchy problem (1.3)-(1.4) can be formally written as

$$\psi(\boldsymbol{q}',t) = \int_{\mathbb{R}^n} K(\boldsymbol{q}',\boldsymbol{q},t)\,\psi(\boldsymbol{q})d^n\boldsymbol{q} \tag{1.6}$$

where the integral is understood in the distributional sense.
For $\psi \in L^2(\mathbb{R}^n)$ formula (1.6) should be understood as

$$\psi(\boldsymbol{q}',t) = \operatorname*{li.m.}_{R\to\infty}\int_{|\boldsymbol{q}|\le R} K(\boldsymbol{q}',\boldsymbol{q},t)\,\psi(\boldsymbol{q})d^n\boldsymbol{q} = \text{l.i.m.}\int_{\mathbb{R}^n} K(\boldsymbol{q}',\boldsymbol{q},t)\,\psi(\boldsymbol{q})d^n\boldsymbol{q},$$

where l.i.m. stands for the limit in the L^2-norm. In general, $\psi(\boldsymbol{q},t)$ is only a weak solution of the Schrdinger equation (1.3), and it is a regular solution when ψ belongs to the Grding domain

D_0 (see Problem 1.7 in Section 1.3 of Chapter 2). The fundamental solution $K(\boldsymbol{q}, \boldsymbol{q}', t)$ is the distributional kernel (in the sense of the Schwartz kernel theorem) of the evolution operator $U(t)$.

Using the group property $U(t+t') = U(t)U(t')$, we can rewrite (1.6) in the form

$$\psi(\boldsymbol{q}', t') = \int_{\mathbb{R}^n} K(\boldsymbol{q}', t'; \boldsymbol{q}, t)\, \psi(\boldsymbol{q}, t) d^n\boldsymbol{q} \tag{1.7}$$

where $K(\boldsymbol{q}', t'; \boldsymbol{q}, t) = K(\boldsymbol{q}', \boldsymbol{q}, t'-t)$. The function $|K(\boldsymbol{q}', t'; \boldsymbol{q}, t)|^2$ has a physical meaning of conditional probability distribution of finding a quantum particle at a point $\boldsymbol{q}' \in \mathbb{R}^n$ at time t' provided that it was at the point $\boldsymbol{q} \in \mathbb{R}^n$ at time t.

Remark. In physics terminology, the distributional kernel $K(\boldsymbol{q}', t'; \boldsymbol{q}, t)$ of the evolution operator $U(t'-t)$ is called the complex probability amplitude, or simply the amplitude or propagator. In Dirac's notation, $K(\boldsymbol{q}', t'; \boldsymbol{q}, t) = \langle \boldsymbol{q}', t' | \boldsymbol{q}, t \rangle$.

Finding the propagator of a given quantum system is a fundamental problem of quantum mechanics. When the spectral decomposition of the Hamiltonian operator H is known, the propagator can be obtained in

a closed form. Namely, suppose for simplicity that H has a pure point spectrum, i.e., there is an orthonormal basis of the Hilbert space $\mathscr{H} = L^2(\mathbb{R}^n, d^n\boldsymbol{q})$ consisting of the eigenfunctions $\{\psi_n(\boldsymbol{q})\}_{n=0}^{\infty}$ of H with the eigenvalues E_n. We have

$$\psi(\boldsymbol{q}) = \sum_{n=0}^{\infty} c_n \psi_n(\boldsymbol{q}), \quad c_n = \int_{\mathbb{R}^n} \psi(\boldsymbol{q}) \overline{\psi_n(\boldsymbol{q})} d^n\boldsymbol{q}$$

so that

$$(U(t)\psi)(\boldsymbol{q}) = \sum_{n=0}^{\infty} e^{-\frac{i}{\hbar}E_n t} c_n \psi_n(\boldsymbol{q})$$

and

$$\psi(\boldsymbol{q}', t') = \sum_{n=0}^{\infty} e^{-\frac{i}{\hbar}E_n t'} \psi_n(\boldsymbol{q}') \int_{\mathbb{R}^n} \overline{\psi_n(\boldsymbol{q})} \psi(\boldsymbol{q}) d^n\boldsymbol{q},$$

where the series and integrals converge in the L^2-sense. If the change of orders of summation and integration was justified, we could write

$$K(\boldsymbol{q}', t; \boldsymbol{q}, t) = \sum_{n=0}^{\infty} e^{-\frac{i}{\hbar}E_n T} \psi_n(\boldsymbol{q}') \overline{\psi_n(\boldsymbol{q})}, \quad T = t' - t \tag{1.8}$$

The series (1.8) converges in the distributional sense, and gives a representation of the propogator in terms of the spectral decomposition of H.

A similar representation of the propagator exists when the Hamiltonian H has absolutely continuous spectrum. Consider the simplest case of a free quantum particle with the Hamiltonian operator

$$H_0 = \frac{\boldsymbol{P}^2}{2m}.$$

The corresponding Schrdinger equation can be solved by the Fourier method (see Section 2.3 in Chapter 2), and we obtain

$$\psi(\boldsymbol{q}',t') = \text{ l.i.m. } (2\pi\hbar)^{-\frac{n}{2}} \int_{\mathbb{R}^n} e^{\frac{i}{\hbar}\left(\boldsymbol{q}'\boldsymbol{p}-\frac{p^2}{2m}T\right)} \hat{\psi}(\boldsymbol{p},t) d^n\boldsymbol{p}$$
$$= \text{ l.i.m. } \int_{\mathbb{R}^n} K(\boldsymbol{q}',t';\boldsymbol{q},t)\,\psi(\boldsymbol{q},t) d^n\boldsymbol{q}$$

where

$$K(\boldsymbol{q}',t';\boldsymbol{q},t) = \frac{1}{(2\pi\hbar)^n} \int_{\mathbb{R}^n} e^{\frac{i}{\hbar}\left(\boldsymbol{p}(\boldsymbol{q}'-\boldsymbol{q})-\frac{p^2}{2m}T\right)} d^n\boldsymbol{p}, \quad T = t'-t. \tag{1.9}$$

Using the classical Fresnel integral formula

$$\int_{-\infty}^{\infty} e^{iax^2} dx = e^{\frac{\pi i \operatorname{sgn}(a)}{4}} \sqrt{\frac{\pi}{|a|}} \tag{1.10}$$

and completing the square in (1.9), we obtain the following expression for the propagator of a free quantum particle:

$$K(\boldsymbol{q}',t';\boldsymbol{q},t) = \left(\frac{m}{2\pi i\hbar T}\right)^{\frac{n}{2}} e^{\frac{im}{2\hbar T}(\boldsymbol{q}-\boldsymbol{q}')^2} \tag{1.11}$$

where $i^{\frac{n}{2}} = e^{-\frac{\pi i n}{4}}$ and $T > 0$.

Remark. Formally replacing the actual "physical" time t in the Schrdinger equation

$$i\hbar\frac{\partial\psi}{\partial t} = -\frac{\hbar^2}{2m}\Delta\psi$$

for a free quantum particle of mass m by the Euclidean time (or pure imaginary time) $-it$, we obtain the heat (diffusion) equation

$$\frac{1}{D}\frac{\partial u}{\partial t} = \Delta u$$

on $\mathbb{R}^n$ with the diffusion coefficient $D = \frac{\hbar}{2m}$. It is quite remarkable that in agreement with this formal procedure the propagator (1.11) for a free quantum particle is obtained from the heat kernel on $\mathbb{R}^n$ by the analytic continuation $T \mapsto -iT$.

Problem 1.1. Show that

$$\lim_{R\to\infty}\int_0^R \sin x^2 dx = \lim_{R\to\infty}\int_0^R \cos x^2 dx = \frac{1}{2}\sqrt{\frac{\pi}{2}}$$

by integrating the function e^{-z^2} over an appropriate "pizza-sliced" contour.

Problem 1.2. Show directly that

$$\psi(\boldsymbol{q}',t) = \left(e^{-\frac{i}{\hbar}tH_0}\psi\right)(\boldsymbol{q}') = \text{ l.i.m. } \left(\frac{m}{2\pi i\hbar t}\right)^{\frac{n}{2}} \int_{\mathbb{R}^n} e^{\frac{im}{2\hbar t}(\boldsymbol{q}-\boldsymbol{q}')^2}\psi(\boldsymbol{q}) d^n\boldsymbol{q}.$$

Problem 1.3. Give an expression for the propagator when H is a Schrdinger operator with rapidly decreasing potential, considered in Section 2 in Chapter 3.

1.2. Feynman path integral in the phase space. For a general Hamiltonian operator $H = H_0 + V$, where $V = V(\boldsymbol{Q})$, there is no simple formula for the propagator $K(\boldsymbol{q}',t';\boldsymbol{q},t)$ like (1.11). This is because operators H_0 and V do not commute, so that $e^{-\frac{i}{\hbar}tH} \neq e^{-\frac{i}{\hbar}tH_0}e^{-\frac{i}{\hbar}tV}$.

It was Feynman's fundamental discovery that there is another representation of the propagator for a quantum system in terms of the corresponding classical system. We start by describing Feynman's approach for the case of a quantum particle with one degree of freedom. It is based on the so-called Lie-Kato-Trotter product formula, which allows us to express the exponential

$e^{i(A+B)}$ of two non-commuting self-adjoint operators in terms of the individual exponentials e^{iA} and e^{iB}.

Theorem 1.1 (Lie-Kato-Trotter product formula). Let A and B be selfadjoint operators on $\mathscr{H}$ such that $A+B$ is essentially self-adjoint on $D(A)\cap D(B)$. Then for $\psi\in\mathscr{H}$,

$$e^{i(A+B)}\psi=\lim_{n\to\infty}\left(e^{\frac{i}{n}A}e^{\frac{i}{n}B}\right)^n\psi$$

Proof. We consider only the special case when A and B are bounded operators, which was already proved by Sophus Lie. Set $C_n=e^{i(A+B)/n}$ and $D_n=e^{iA/n}e^{iB/n}$. We have the telescopic sum

$$\begin{aligned}C_n^n-D_n^n&=C_n^n-C_n^{n-1}D_n+C_n^{n-1}D_n-C_n^{n-2}D_n^2+\cdots+C_nD_n^{n-1}-D_n^n\\&=\sum_{k=0}^{n-1}C_n^{n-k-1}\left(C_n-D_n\right)D_n^k\end{aligned}$$

and since by the Taylor formula $\|C_n-D_n\|\leq\frac{c}{n^2}$ for some constant $c>0$, we obtain

$$\|C_n^n-D_n^n\|\leq\frac{c}{n}$$

This proves the result with convergence in the uniform topology.
We will always assume that the Hamiltonian $H=H_0+V$ is essentially self-adjoint on $D\left(H_0\right)\cap D(V)$, so that the Lie-Kato-Trotter formula is applicable. (According to Theorem 1.2 in Section 1.1 of Chapter 3, for the case $n=3$ we can assume that $V=V_1+V_2$, where $V_1\in L^2\left(\mathbb{R}^3\right)$ and $V_2\in L^\infty\left(\mathbb{R}^3\right)$.) Applying the Lie-Kato-Trotter formula to $A=-\frac{T}{\hbar}H_0$ and $B=-\frac{T}{\hbar}V$, we obtain that in the strong operator topology

$$e^{-\frac{i}{\hbar}TH}=\lim_{n\to\infty}\left(e^{-\frac{i\Delta t}{\hbar}H_0}e^{-\frac{i\Delta t}{\hbar}V}\right)^n,\quad\Delta t=\frac{T}{n}\tag{1.12}$$

where $T=t'-t$. In the coordinate representation the operator $e^{-\frac{i\Delta t}{\hbar}V}$ is a multiplication by $e^{-\frac{i}{\hbar}V(q)\Delta t}$ operator, and the distributional kernel of the operator $e^{-\frac{i\Delta t}{\hbar}H_0}$ is given by (1.9), where T is replaced by Δt. Thus the distributional kernel $K\left(q',q;\Delta t\right)$ of the operator $e^{-\frac{i\Delta t}{\hbar}H_0}e^{-\frac{i\Delta t}{\hbar}V}$ is given by

$$K\left(q',q;\Delta t\right)=\frac{1}{2\pi\hbar}\int_{-\infty}^{\infty}e^{\frac{i}{\hbar}\left(p(q'-q)-\left(\frac{p^2}{2m}+V(q)\right)\Delta t\right)}dp\tag{1.13}$$

Since the kernel of a product of two operators is a composition of corresponding individual kernels, for the distributional kernel $K_n\left(q',t';q,t\right)$ of the operator $\left(e^{-\frac{i\Delta t}{\hbar}H_0}e^{-\frac{i\Delta t}{\hbar}V}\right)^n$ we obtain the following integral representation:

$$K_n\left(q',t';q,t\right)=\int\ldots\int\prod_{k=0}^{n-1}K\left(q_{k+1},q_k;\Delta t\right)\prod_{k=1}^{n-1}dq_k\tag{1.14}$$

where $q_0=q,q_n=q'$. Now replace each factor $K\left(q_{k+1},q_k;\Delta t\right)$ in (1.14) by its integral representation (1.13), where the corresponding variable of integration is denoted by $p_k,k=0,\ldots,n-1$. Changing the order of integrations in the resulting $(2n-1)$-fold integral and using (1.12), we obtain the following remarkable representation of the propagator of a quantum particle as a limit of multiple integrals when the number of integrations goes to infinity:

$$K\left(q',t';q,t\right)=\lim_{n\to\infty}K_n\left(q',t';q,t\right)\tag{1.15}$$

$= \lim_{n\to\infty} \int_{\mathbb{R}^{2n-1}} ... \int \exp\left\{ \frac{i}{\hbar} \sum_{k=0}^{n-1} \left(p_k \left(q_{k+1} - q_k \right) - H_c \left(p_k, q_k \right) \Delta t \right) \right\} \frac{dp_0}{2\pi\hbar} \prod_{k=1}^{n-1} \frac{dp_k dq_k}{2\pi\hbar}$.
Here $H_c(p,q) = \frac{p^2}{2m} + V(q)$ is the classical Hamiltonian function, and $q_0 = q, q_n = q'$.

Heuristically, formula (1.15) admits the following interpretation. To every point $(p_0, p_1, ..., p_{n-1}, q_1, ..., q_{n-1}) \in \mathbb{R}^{2n-1}$ assign a piece-wise linear path σ in the extended phase space $\mathbb{R}^2 \times \mathbb{R}$ of the classical particle, defined by the following time slicing procedure. Let $t_k = t + k\Delta t$ and $\sigma(\tau) = (p(\tau), q(\tau), \tau)$, where

$$p(\tau) = p_k, \quad q(\tau) = q_k + (\tau - t_k) \frac{q_{k+1} - q_k}{t_{k+1} - t_k}$$

and $\tau \in [t_k, t_{k+1}], k = 0, ..., n-1$. Then for the Riemann integrable potentials $V(q)$ we have

$$\sum_{k=0}^{n-1} \left(p_k \left(q_{k+1} - q_k \right) - H_c \left(p_k, q_k \right) \Delta t \right) = S(\sigma) + o(1), \quad \text{as} \quad n \to \infty \tag{1.16}$$

where

$$S(\sigma) = \int_\sigma \left(pdq - H_c d\tau \right) = \int_t^{t'} \left(p(\tau)\dot{q}(\tau) - H_c(p(\tau), q(\tau)) \right) d\tau$$

is the action functional of a classical system with the Hamiltonian function $H_c(p,q)$ (see Section 2.2 in Chapter 1). This suggests to interpret (1.15) as a kind of "integral" over the space $\tilde{P}\left(\mathbb{R}^2\right)_{q,t}^{q,t'}$ of all paths $\sigma(\tau) = (p(\tau), q(\tau), \tau)$ in the extended phase space $\mathbb{R}^2 \times \mathbb{R}$ such that ${}^1q(t) = q$ and $q\left(t'\right) = q'$, which was used in the formulation of the principle of the least action in the phase space (see Section 2.2 in Chapter 1). Thus we put

$$K\left(q', t'; q, t\right) = \int_{\tilde{P}(\mathbb{R}^2)_{q,t}^{q',t'}} e^{\frac{i}{\hbar} S(\sigma)} \mathscr{D}p\mathscr{D}q \tag{1.17}$$

where the "measure" $\mathscr{D}p\mathscr{D}q$ on $\tilde{P}\left(\mathbb{R}^2\right)_{q,t}^{q',t'}$ is given by

$$\mathscr{D}p\mathscr{D}q = \lim_{n\to\infty} \frac{dp_0}{2\pi\hbar} \prod_{k=1}^{n-1} \frac{dp_k dq_k}{2\pi\hbar}. \tag{1.18}$$

Representation (1.17)-(1.18) is the famous Feynman path integral in the phase space for the propagator of a quantum particle. It expresses the propagator $K\left(q', t'; q, t\right)$ as the "weighted sum" over all possible "histories" of the classical particle, the paths $\sigma \in \tilde{P}\left(\mathbb{R}^2\right)_{q,t}^{q',t'}$, where each path σ has a complex weight $\exp\left\{ \frac{i}{\hbar} S(\sigma) \right\}$. On one hand, this representation clearly shows the fundamental difference between classical mechanics and quantum mechanics. Thus in classical mechanics, the particle moves along classical trajectories, which are the critical points (extremals) of the action functional $S(\sigma)$, whereas in quantum mechanics all possible paths contribute to the complex probability amplitude $K\left(q', t'; q, t\right)$. On the other hand, representation (1.17)-(1.18) clearly points at the relation between quantum mechanics and classical mechanics in the semi-classical limit $\hbar \to 0$. Namely, as $\hbar \to 0$ the weights $\exp\left\{ \frac{i}{\hbar} S(\sigma) \right\}$ become rapidly oscillating and their contributions to (1.17) will mutually cancel, unless the action is almost constant. The latter happens near the critical points, which give the major contribution to (1.17). This is how classical trajectories of a particle emerge from its quantum description, which will be discussed in detail in Section 6.1.

Remark. The Feynman path integral in the phase space in not an integral in the sense of abstract integration theory, since the formal expression $\mathscr{D}p\mathscr{D}q$ does not define a measure [2] on

[01] Note that there is no condition on the values of $p(\tau)$ at the endpoints.

the path space $\tilde{P}\left(\mathbb{R}^2\right)_{q,t}^{q',t'}$. Besides, the functional $\exp\left\{\frac{i}{\hbar}S(\sigma)\right\}$ has absolute value 1 and cannot be integrable with respect to any measure $d\mu$ with the property $\mu\left(\tilde{P}\left(\mathbb{R}^2\right)_{q,t}^{q',t'}\right)=\infty$. The rigorous mathematical meaning of (1.17)-(1.18) is the original formula (1.15), which expresses the propagator as a limit of multiple integrals as the number of integrations goes to infinity. This explains the apparent "paradox" that quantum mechanics is defined entirely in classical terms by (1.17). It is not so, since there is no "intrinsic" definition of (1.17) in classical terms, besides the time slicing procedure (1.15), which also requires the special choice of the approximation (1.16) of $S(\sigma)$ by the Riemann sums.

1.3. Feynman path integral in the configuration space. Using the Fresnel integral (1.10) for the integration over p in (1.13), we obtain the following formula for the distributional kernel of the operator $e^{-\frac{i\Delta t}{\hbar}H_0}e^{-\frac{i\Delta t}{\hbar}V}$:

$$\sqrt{\frac{m}{2\pi i\hbar\Delta t}}e^{\frac{i}{\hbar}\left\{\frac{m}{2}\frac{(q-q')^2}{\Delta t}-V(q)\Delta t\right\}}$$

Repeating the time slicing procedure from the previous section, instead of (1.15) we now get

$$K\left(q',t';q,t\right)=\lim_{n\to\infty}\left(\frac{m}{2\pi\hbar i\Delta t}\right)^{\frac{n}{2}} \tag{1.19}$$
$$\times\int_{\mathbb{R}^{n-1}}...\int\exp\left\{\frac{i}{\hbar}\sum_{k=0}^{n-1}\left(\frac{m}{2}\left(\frac{q_{k+1}-q_k}{\Delta t}\right)^2-V\left(q_k\right)\right)\Delta t\right\}\prod_{k=1}^{n-1}dq_k$$

Assuming that $q_k=q\left(t_k\right),k=0,...,n$, for some smooth path $\gamma(\tau)=q(\tau)$ in $\mathbb{R}$, where $q_0=q$ and $q_n=q'$, we obtain as $n\to\infty$,

$$\sum_{k=0}^{n-1}\left(\frac{m}{2}\left(\frac{q_{k+1}-q_k}{\Delta t}\right)^2-V\left(q_k\right)\right)\Delta t=S(\gamma)+o(1)$$

where

$$S(\gamma)=\int_t^{t'}L\left(\gamma'(\tau)\right)d\tau=\int_t^{t'}L(q(\tau),\dot{q}(\tau))d\tau,\quad L(q,\dot{q})=\frac{1}{2}m\dot{q}^2-V(q)$$

is the action functional of a classical particle of mass m moving in the potential field $V(q)$ (see Section 1.3 in Chapter 1). This suggests to interpret the limit of multiple integrals (1.19) as the Feynman path integral in the configuration space

$$K\left(q',t';q,t\right)=\int_{P(\mathbb{R})_{q,t}^{q,tt'}}e^{\frac{i}{\hbar}S(\gamma)}\mathscr{D}q \tag{1.20}$$

Here $P(\mathbb{R})_{q,t}^{q',t'}$ is the space of smooth parametrized paths γ in the configuration space $\mathbb{R}$ connecting points q and q', and the "measure" $\mathscr{D}q$ on $P(\mathbb{R})_{q,t}^{q',t'}$ is given by

$$\mathscr{D}q=\lim_{n\to\infty}\left(\frac{m}{2\pi\hbar i\Delta t}\right)^{\frac{n}{2}}\prod_{k=1}^{n-1}dq_k \tag{1.21}$$

As the Feynman path integral in the phase space, the Feynman path integral in the configuration space is not actually an integral in the sense of integration theory, and the correct

[02] In abstract measure theory the measure is non-negative and countably additive.

mathematical meaning of (1.20)-(1.21) is given by (1.19). Formula (1.20) expresses the propagator $K(q',t';q,t)$ as the sum over all histories in the configuration space of classical particle - paths $\gamma \in P(\mathbb{R})_{q,t}^{q',t'}$, by assigning to each path γ a complex weight $\exp\left\{\frac{i}{\hbar}S(\gamma)\right\}$.

Remark. Convergence in (1.19), as well as in (1.15), is understood in the distributional sense. In particular, for every $\psi \in L^2(\mathbb{R})$,

$$\left(e^{-\frac{i}{\hbar}TH}\psi\right)(q) = \lim_{n\to\infty}\left(\frac{m}{2\pi\hbar i\Delta t}\right)^{\frac{n}{2}}$$
$$\times\int\cdots\int\exp\left\{\frac{i}{\hbar}\sum_{k=0}^{n-1}\left(\frac{m}{2}\left(\frac{q_{k+1}-q_k}{\Delta t}\right)^2 - V(q_k)\right)\Delta t\right\}\psi(q_n)\prod_{k=1}^{n}dq_k,$$

where all integrals are understood as $\int_{-\infty}^{\infty} = \lim_{R\to\infty}\int_{|q|\le R}$, and all limits — in the L^2-sense.

Remark. It is said in physics textbooks that the Feynman path integral in the configuration space is obtained from the Feynman path integral in the phase space by evaluating the Fresnel integral over $\mathscr{D}p$,

$$\int_{P(\mathbb{R})_{q,t}^{q',t'}} e^{\frac{i}{\hbar}\int_t^{t'}\left(\frac{m}{2}\dot{q}^2 - V(q)\right)d\tau}\mathscr{D}q = \int_{\tilde{P}(\mathbb{R}^2)_{q,t}^{q',t'}} e^{\frac{i}{\hbar}\int_t^{t'}(p\dot{q}-H_{\mathrm{c}}(p,q))d\tau}\mathscr{D}p\mathscr{D}q. \tag{1.22}$$

Note that the symbol $\mathscr{D}q$ has two different meanings: in the left-hand side of (1.22) it is defined by (1.21), whereas in the right-hand side it is defined as a part of (1.18).

1.4. Several degrees of freedom.

Let

$$H = \frac{\boldsymbol{P}^2}{2m} + V(\boldsymbol{Q})$$

be the Hamiltonian operator of a quantum particle in $\mathbb{R}^n$ moving in the potential field $V(\boldsymbol{q})$. As in the case of one degree of freedom, by using the Lie-Kato-Trotter product formula, the propagator $K(\boldsymbol{q}',t';\boldsymbol{q},t)$ is expressed as a limit of multiple integrals when the number of integrations goes to infinity,

$$K(\boldsymbol{q}',t';\boldsymbol{q},t) = \lim_{N\to\infty}\int_{\mathbb{R}^{(2N-1)n}}\cdots\int \tag{1.23}$$
$$\exp\left\{\frac{i}{\hbar}\sum_{k=0}^{N-1}\left(\boldsymbol{p}_k(\boldsymbol{q}_{k+1}-\boldsymbol{q}_k) - H_{\mathrm{c}}(\boldsymbol{p}_k,\boldsymbol{q}_k)\Delta t\right)\right\}\frac{d^n\boldsymbol{p}_0}{(2\pi\hbar)^n}\prod_{k=1}^{N-1}\frac{d^n\boldsymbol{p}_k d^n\boldsymbol{q}_k}{(2\pi\hbar)^n}.$$

Here $H_{\mathrm{c}}(\boldsymbol{p},\boldsymbol{q}) = \frac{\boldsymbol{p}^2}{2m} + V(\boldsymbol{q})$ is the classical Hamiltonian function, and $\boldsymbol{q}_0 = \boldsymbol{q}, \boldsymbol{q}_N = \boldsymbol{q}'$. This representation is symbolized by the Feynman path integral in the phase space $\mathscr{M} = T^*\mathbb{R}^n$,

$$K(\boldsymbol{q}',t';\boldsymbol{q},t) = \int_{\tilde{P}(\mathscr{M})_{\boldsymbol{q},t}^{\boldsymbol{q},t'}} e^{\frac{i}{\hbar}\int_\sigma(\boldsymbol{p}\dot{\boldsymbol{q}}-H_{\mathrm{c}}(\boldsymbol{p},\boldsymbol{q}))d\tau}\mathscr{D}\boldsymbol{p}\mathscr{D}\boldsymbol{q}, \tag{1.24}$$

where

$$\mathscr{D}\boldsymbol{p}\mathscr{D}\boldsymbol{q} = \lim_{N\to\infty}\frac{d^n\boldsymbol{p}_0}{(2\pi\hbar)^n}\prod_{k=1}^{N-1}\frac{d^n\boldsymbol{p}_k d^n\boldsymbol{q}_k}{(2\pi\hbar)^n}$$

and $\tilde{P}(\mathscr{M})_{q,t}^{\boldsymbol{q}',t'}$ is the space of all admissible paths σ in the extended phase space $\mathscr{M}\times\mathbb{R}$ connecting points $(\boldsymbol{q},t)$ and $(\boldsymbol{q}',t')$ (see Section 2.2 in Chapter 1).

Equivalently, the propagator $K(\boldsymbol{q}',t';\boldsymbol{q},t)$ can be written as

$$K(\boldsymbol{q}',t';\boldsymbol{q},t)=\lim_{N\to\infty}\left(\frac{m}{2\pi\hbar i\Delta t}\right)^{\frac{nN}{2}} \tag{1.25}$$
$$\times\int_{\mathbb{R}^{(n-1)}N}\cdots\int_{N}\exp\left\{\frac{i}{\hbar}\sum_{k=0}^{N-1}\left(\frac{m}{2}\left(\frac{\boldsymbol{q}_{k+1}-\boldsymbol{q}_k}{\Delta t}\right)^2-V(\boldsymbol{q}_k)\right)\Delta t\right\}\prod_{k=1}^{N-1}d^n\boldsymbol{q}_k$$

This formula is symbolized by the Feynman path integral in the configuration space,

$$K(\boldsymbol{q}',t';\boldsymbol{q},t)=\int_{P(M)_{q,t}^{q',t'}}e^{\frac{i}{\hbar}\int_t^{t'}L(\boldsymbol{q},\dot{\boldsymbol{q}})d\tau}\mathscr{D}\boldsymbol{q}, \tag{1.26}$$

where $L(\boldsymbol{q},\dot{\boldsymbol{q}})=\frac{1}{2}m\dot{\boldsymbol{q}}^2-V(\boldsymbol{q})$ is the corresponding Lagrangian,

$$\mathscr{D}\boldsymbol{q}=\lim_{N\to\infty}\left(\frac{m}{2\pi i\hbar\Delta t}\right)^{\frac{nN}{2}}\prod_{k=1}^{N-1}d^n\boldsymbol{q}_k,$$

and $P(M)_{\boldsymbol{q},t}^{\boldsymbol{q}'_t,t'}$ is the space of smooth parametrized paths in the configuration space M connecting points $\boldsymbol{q}$ and $\boldsymbol{q}'$. The precise mathematical meaning of formula (1.26) is the same as of (1.20).

Remark. Formally, definition (1.24) of the Feynman path integral in the phase space can be extended to the case $(\mathscr{M},\omega,H_c)$, where $\mathscr{M}=T^*M$ and $\omega=d\theta$, the canonical Liouville 1 -form on $\mathscr{M}$. Namely, one can obtain a distributional kernel $K(\boldsymbol{q}',t';\boldsymbol{q},t)$ by using the same time slicing as in (1.24) and replacing the 1 -form $\boldsymbol{p}d\boldsymbol{q}$ by θ, and the volume form $d^n\boldsymbol{p}_kd^n\boldsymbol{q}_k$ by an appropriate multiple of the Liouville volume form on $\mathscr{M}$. Similarly, representation (1.26) can be formally extended to the case of general Lagrangian system (M,L), where the configuration space M is a Riemannian manifold, by using the same time slicing and replacing $d^n\boldsymbol{q}_k$ by the Riemannian volume form on M. However, in general it is not clear for which unitary operators these Feynman integrals are actual distributional kernels. Moreover, even in the case $M=\mathbb{R}^n$ with the standard Euclidean metric, representations (1.26) and (1.24), where H_c is a Legendre transform of L, do not necessarily agree if L is not of the form "kinetic energy minus potential energy". However,
when $L=\frac{1}{2}g_{\mu\nu}(\boldsymbol{x})\dot{x}^\mu\dot{x}^\nu-V(\boldsymbol{x})$ (cf. Example 1.7 in Section 1.3 of Chapter 1), then with appropriately defined time slicing, Feynman path integrals (1.26) and (1.24) agree, and are equal to the propagator for the Hamiltonian operator

$$H=\frac{\hbar^2}{2}\Delta_g+V$$

Here Δ_g is the Laplace operator of the Riemannian metric on M, introduced in Example 2.4 in Section 2.4 of Chapter 2.

Remark. Formula (1.24) could serve as a heuristic tool which enables us, in some cases, to quantize the classical Hamiltonian system $(\mathscr{M},\omega,H_c)$. In general this is a rather non-trivial problem, especially when the phase space $\mathscr{M}$ is a compact manifold.

8.1.2 2. Symbols of the evolution operator and path integrals

In Sections 2.7 and 3.3 of Chapter 2 we introduced Wick, $\boldsymbol{pq-qqp}$-, and Weyl symbols of operators. For the evolution operator $U(T)=e^{-\frac{i}{\hbar}TH}$ these symbols can also be represented by Feynman path integrals. Here we consider only the case of one degree of freedom, since generalization to several degrees of freedom is straightforward.

2.1. The pq-symbol. Let $F_1(p,q,T)$ be the pq-symbol of the evolution operator $U(T)$. Using

(1.15) and formula (3.18) in Section 3.3 of Chapter 2 - the relation between the pq-symbol of an operator and its distributional kernel - we get

$$F_1(p,q,T)=\int_{-\infty}^{\infty}K(q-v,T;q,0)e^{\frac{i}{\hbar}pv}dv \tag{2.1}$$

$$=\lim_{n\to\infty}\int_{\mathbb{R}^{2n-2}}...\int\exp\left\{\frac{i}{\hbar}\sum_{k=0}^{n-1}\left(p_k\left(q_{k+1}-q_k\right)-H_{\mathrm{c}}\left(p_k,q_k\right)\Delta t\right)\right\}\prod_{k=1}^{n-1}\frac{dp_{k-1}dq_k}{2\pi\hbar}$$

where $p_{n-1}=p$ and $q_0=q_n=q$. Formula (2.1) can also be obtained from the composition formula for pq-symbols (see Problem 3.9 in Section 3.4 of Chapter 2). Indeed, it is sufficient to observe that the pq-symbol of the operator $e^{-\frac{i\Delta t}{\hbar}H_0}e^{-\frac{i\Delta t}{\hbar}V}$ is $f(p,q)=e^{-\frac{i\Delta t}{\hbar}H_c(p,q)}$, and to represent the pq-symbol of the operator $\left(e^{-\frac{i\Delta t}{\hbar}H_0}e^{-\frac{i\Delta t}{\hbar}V}\right)^n$ as the multiple integral

$$\int_{\mathbb{R}^{2n-2}}\cdots\int f\left(p,q_{n-1}\right)f\left(p_{n-2},q_{n-2}\right)\cdots f\left(p_2,q_2\right)f\left(p_0,q\right)$$
$$\times\exp\left\{\frac{i}{\hbar}\sum_{k=0}^{n-2}\left(p-p_k\right)\left(q_k-q_{k+1}\right)\right\}\prod_{k=1}^{n-1}\frac{dp_{k-1}dq_k}{2\pi\hbar}$$

where $q_0=q$. In the same spirit as (1.15), formula (2.1) can be written as the following Feynman path integral for the pq-symbol:

$$F_1(p,q,T)=\int_{\Omega_{(p,q)}(\mathbb{R}^2)}e^{\frac{i}{\hbar}S(\sigma)}\mathscr{D}p\mathscr{D}q,\quad S(\sigma)=\int_{\sigma}(pdq-H_{\mathrm{c}}dt) \tag{2.2}$$

where $\Omega_{(p,q)}\left(\mathbb{R}^2\right)=\left\{\sigma:[0,T]\to\mathbb{R}^2:\sigma(0)=\sigma(T)=(p,q)\in\mathbb{R}^2\right\}$ is the space of parametrized loops in the phase space $\mathbb{R}^2$ which start and end at the point (p,q).

Remark. The mathematical meaning of (2.2) is the original formula (2.1) with a special choice of the approximation of $S(\sigma)$ by Riemann sums.

2.2. The qp-symbol. Let $F_2(p,q,T)$ be the qp-symbol of the evolution operator $U(T)$. In this case instead of formula (1.12), convenient for pq symbols, one should consider the equivalent representation

$$e^{-\frac{i}{\hbar}TH}=\lim_{n\to\infty}\left(e^{-\frac{i\Delta t}{\hbar}V}e^{-\frac{i\Delta t}{\hbar}H_0}\right)^n. \tag{2.3}$$

The distributional kernel $\tilde{K}\left(q',q;\Delta t\right)$ of the operator $e^{-\frac{i\Delta t}{\hbar}V}e^{-\frac{i\Delta t}{\hbar}H_0}$ is given by

$$\tilde{K}\left(q',q;\Delta t\right)=\frac{1}{2\pi\hbar}\int_{-\infty}^{\infty}e^{\frac{i}{\hbar}\left(p(q'-q)-\left(\frac{p^2}{2m}+V(q')\right)\Delta t\right)}dp \tag{2.4}$$

and as in Section 1.2 we obtain

$$K\left(q',t';q,t\right)=\lim_{n\to\infty}\int_{\mathbb{R}^{n-1}}...\prod_{k=0}^{n-1}\tilde{K}\left(q_{k+1},q_k;\Delta t\right)\prod_{k=1}^{n-1}dq_k \tag{2.5}$$

$=\lim_{n\to\infty}\int_{\mathbb{R}^{2n-1}}...\int\exp\left\{\frac{i}{\hbar}\sum_{k=0}^{n-1}\left(p_k\left(q_{k+1}-q_k\right)-H_{\mathrm{c}}\left(p_k,q_{k+1}\right)\Delta t\right)\right\}\frac{dp_0}{2\pi\hbar}\prod_{k=1}^{n-1}\frac{dp_kdq_k}{2\pi\hbar}$.
Using formula (3.19) in Section 3.3 of Chapter 2, we get from (2.5),

$$F_2(p,q,T)=\int_{-\infty}^{\infty}K(q,T;q+v,0)e^{\frac{i}{\hbar}pv}dv \tag{2.6}$$

$=\lim_{n\to\infty}\int_{\mathbb{R}^{2n-2}}\cdots\int\exp\left\{\frac{i}{\hbar}\sum_{k=0}^{n-1}\left(p_k\left(q_{k+1}-q_k\right)-H_{\mathrm{c}}\left(p_k,q_{k+1}\right)\Delta t\right)\right\}\prod_{k=1}^{n-1}\frac{dp_{k-1}dq_k}{2\pi\hbar}$,
where $p_0=p$ and $q_0=q_n=q$. Formula (2.6) can also be obtained from the composition formula

for qp-symbols (see Problem 3.10 in Section 3.4 of Chapter 2) by observing that the qp-symbol of the operator $e^{-\frac{i\Delta t}{\hbar}V}e^{-\frac{i\Delta t}{\hbar}H_0}$ is again $e^{-\frac{i\Delta t}{\hbar}H_c(p,q)}$. In the same spirit as (1.15), formula (2.6) can be written
as the following Feynman path integral for the qp-symbol:

$$F_2(p,q,T)=\int_{\Omega_{(p,q)}(\mathbb{R}^2)}e^{\frac{i}{\hbar}S(\sigma)}\mathscr{D}p\mathscr{D}q \tag{2.7}$$

This expression looks exactly like (2.2), so that the formal path integral representation does not distinguish between pq - and qp-symbols! Of course, the mathematical meaning of (2.7) is the original formula (2.6), which requires a special choice of the approximation of $S(\sigma)$ by Riemann sums, which is different from the one used for the pq-symbol.

Problem 2.1. Deduce formula (2.6) from the composition formula for qp-symbols.

2.3. The Weyl symbol. Let $F(p,q;T)$ be the Weyl symbol of the evolution operator $U(T)$. It follows from the Weyl inversion formula - formula (3.12) in Section 3.3 of Chapter 2 - that

$$F(p,q,T)=\int_{-\infty}^{\infty}K\left(q-\frac{1}{2}v,T;q+\frac{1}{2}v,0\right)e^{\frac{i}{\hbar}pv}dv$$

However, for general potentials $V(q)$ one cannot perform integration over v by using either (1.15) or (2.5), and we choose another approach. Namely, denote by $\tilde{U}(\Delta t)$ an operator [3] with the Weyl symbol $e^{-\frac{i}{\hbar}H_c(p,q)\Delta t}$, and suppose that

$$U(T)=\lim_{n\to\infty}\tilde{U}(\Delta t)^n \tag{2.8}$$

Using the composition formula for the Weyl symbols, formula (3.24) in Section 3.3 of Chapter 2, we can express the Weyl symbol as

$$F(p,q,T)=\lim_{n\to\infty}\int_{\mathbb{R}^{4(n-1)}}...\int_k\exp\left\{\frac{i}{\hbar}\left(2\sum_{k=0}^{n-2}\left(\left(p_k-\xi_k\right)\left(\eta_{k+1}-\eta_k\right)\right.\right.\right. \tag{2.9}$$
$$\left.\left.\left.-\left(q_k-\eta_k\right)\left(\xi_{k+1}-\xi_k\right)\right)-\sum_{k=0}^{n-1}H_c\left(p_k,q_k\right)\Delta t\right)\right\}\prod_{k=1}^{n-1}\frac{dp_kdq_kd\xi_{k-1}d\eta_{k-1}}{\pi\hbar}$$

where $\xi_0=p,\eta_0=q$ and $\xi_{n-1}=p_{n-1},\eta_{n-1}=q_{n-1}$. As for formula (1.15), formula (2.9) can be written as the following Feynman path integral for the Weyl symbol:

$$F(p,q,T) \tag{2.10}$$
$$=\int e^{\frac{i}{\hbar}\int_0^T\left\{2(p(t)-\xi(t))\dot{\eta}(t)-2(q(t)-\eta(t))\dot{\xi}(t)-H_c(p(t),q(t))\right\}dt}\mathscr{D}p\mathscr{D}q\mathscr{D}\xi\mathscr{D}\eta,$$

where

$$\mathscr{D}p\mathscr{D}q\mathscr{D}\xi\mathscr{D}\eta=\lim_{n\to\infty}\prod_{k=1}^{n-1}\frac{dp_kdq_kd\xi_{k-1}d\eta_{k-1}}{\pi\hbar}$$

and "integration" goes over the space of real-valued functions $p(t),q(t),\xi(t)$, and $\eta(t)$ on $[0,T]$ satisfying $\xi(0)=p,\eta(0)=q$ and $\xi(T)=p(T),\eta(T)=q(T)$.

Remark. Expression (2.10) looks very different from (2.2) and (2.7). However, the variables $\xi(t)$ and $\eta(t)$ appear only linearly in the exponential in (2.10), and the integration over them

[03] There is no easy way to express it in terms of $e^{-\frac{i\Delta t}{\hbar}H_0}$ and $e^{-\frac{i\Delta t}{\hbar}V}$.

can be performed explicitly. Indeed, using integration by parts (and ignoring subtleties with the boundary terms) we can transform the integral over $\mathscr{D}\xi$ to

$$\int e^{\frac{2i}{\hbar}\int_0^T \xi(t)(\dot{q}(t)-2\dot{\eta}(t))dt}\mathscr{D}\xi$$

which equals the product of delta-functions $\delta(2\dot{\eta}(t)-\dot{q}(t))$ over $[0,T]$ and allows us to replace $2\dot{\eta}(t)$ by $\dot{q}(t)$ in (2.10). Thus we obtain the formula

$$F(p,q,T)=\int e^{\frac{i}{\hbar}\int_0^T (p\dot{q}-H_c(p,q))dt}\mathscr{D}p\mathscr{D}q$$

which looks exactly like (2.2) and (2.7)! This heuristic argument shows that the Feynman path integral, understood naively, "erases" the difference between various symbols of the evolution operator. Of course, one should always specify particular finite-dimensional approximation of $S(\sigma)$ in order to get correct results.

Problem 2.2. Find the integral kernel of the operator $\tilde{U}(\Delta t)$.

Problem 2.3. Derive formula (2.9).

2.4. The Wick symbol. Instead of the variables $\bar{z}$ and z, used in Section 2.7 of Chapter 2 , it is convenient to use variables $\bar{a}=\sqrt{\hbar}\bar{z}$ and $a=\sqrt{\hbar}z$, which introduce explicit $\hbar$-dependence in the calculus of Wick symbols. Let $H(\bar{a},a)$ be the Wick symbol of a Hamiltonian operator H. Here we derive a formula for the Wick symbol $U(\bar{a},a;T)$ of the evolution operator $U(T)=e^{-\frac{i}{\hbar}TH}$. Denote by $\tilde{U}(\Delta t)$ an operator with the Wick symbol $e^{-\frac{i}{\hbar}H(\bar{a},a)\Delta t}$, and as in the previous section, suppose that

$$U(T)=\lim_{n\to\infty}\tilde{U}(\Delta t)^n \tag{2.11}$$

Using the formula for the composition of Wick symbols (see Theorem 2.2 and Problem 2.18 in Section 2.7 of Chapter 2), we get the following expression
for the Wick symbol $U_n(\bar{a},a;T)$ of the operator $\tilde{U}(\Delta t)^n$:

$$U_n(\bar{a},a;T)=\int\cdots\int\exp\left\{\frac{1}{\hbar}\left(\bar{a}\left(a_{n-1}-a\right)-iH\left(\bar{a},a_{n-1}\right)\Delta t\right.\right. \tag{2.12}$$
$$\left.\left.+\sum_{k=1}^{n-1}\left(\bar{a}_k\left(a_{k-1}-a_k\right)-iH\left(\bar{a}_k,a_{k-1}\right)\Delta t\right)\right)\right\}\prod_{k=1}^{n-1}\frac{d^2a_k}{\pi\hbar},$$

where $a_0=a$. Setting $\bar{a}_n=\bar{a}$, we can rewrite the sum in (2.12) as

$$\sum_{k=1}^{n}\left(\bar{a}_k\left(a_{k-1}-a_k\right)+\bar{a}\left(a_n-a\right)-iH\left(\bar{a}_k,a_{k-1}\right)\Delta t\right),$$

and obtain

$$U(\bar{a},a;T)=\lim_{n\to\infty}U_n(\bar{a},a;T)=\lim_{n\to\infty}\int\cdots\int \tag{2.13}$$
$$\exp\left\{\frac{1}{\hbar}\left(\sum_{k=1}^{n}\left(\bar{a}_k\left(a_{k-1}-a_k\right)+\bar{a}\left(a_n-a\right)-iH\left(\bar{a}_k,a_{k-1}\right)\Delta t\right)\right)\right\}\prod_{k=1}^{n-1}\frac{d^2a_k}{\pi\hbar}.$$

As in the previous examples, we can represent formula (2.13) by the following Feynman path integral for the Wick symbol:

$$U(\bar{a},a;T)=\int\limits_{\left\{\begin{array}{l}\bar{a}(T)=\bar{a}\\ a(0)=a\end{array}\right\}} e^{\frac{i}{\hbar}\int_0^T(i\bar{a}\dot{a}-H(\bar{a},a))dt+\frac{1}{\hbar}\bar{a}(a(T)-a)}\mathscr{D}\bar{a}\mathscr{D}a, \tag{2.14}$$

where

$$\mathscr{D}\bar{a}\mathscr{D}a=\lim_{n\to\infty}\prod_{k=1}^{n-1}\frac{d^2a_k}{\pi\hbar}.$$

Here integration goes over all complex-valued functions $a(t)$ and $\bar{a}(t)$ satisfying boundary conditions $a(0)=a$ and $\bar{a}(T)=\bar{a}$, and such that $\bar{a}(t)$ is complex-conjugated to $a(t)$ for $0<t<T$.

Remark. It should be emphasized that in (2.14) the values $\bar{a}(0)$ and $a(T)$ are not complex-conjugated to the fixed boundary values $a(0)=a$ and $\bar{a}(T)=\bar{a}$, but rather are "variables of integration". This should be compared with formula (1.17), where the boundary values for the function $q(\tau)$ are fixed, and the boundary values for the function $p(\tau)$ are free. The difference is that at $t=0$ we fix the boundary value of the function $a(t)$, while at $t=T$ we fix the boundary value of another function $\bar{a}(t)$.

Remark. The Wick symbol $U(\bar{a},a;-iT)$ of the operator $e^{-\frac{1}{\hbar}TH}=U(-iT)$ can also be represented by

$$\begin{array}{c}U(\bar{a},a;-iT)=\lim\limits_{n\to\infty}U_n(\bar{a},a;-iT)=\lim\limits_{n\to\infty}\int_{\mathbb{C}^{n-1}}\cdots\int\\ \exp\left\{\frac{1}{\hbar}\left(\sum\limits_{k=1}^{n}\left(\bar{a}_k\left(a_{k-1}-a_k\right)-H\left(\bar{a}_k,a_{k-1}\right)\Delta t\right)+\bar{a}\left(a_n-a\right)\right)\right\}\prod\limits_{k=1}^{n-1}\frac{d^2a_k}{\pi\hbar}\\ =\int\limits_{\substack{\bar{a}(T)=\bar{a}\\ a(0)=a}}e^{-\frac{1}{\hbar}\int_0^T(\bar{a}\dot{a}+H(\bar{a},a))dt+\frac{1}{\hbar}\bar{a}(a(T)-a)}\mathscr{D}\bar{a}\mathscr{D}a,\end{array} \tag{2.15}$$

which is the so-called Euclidean path integral - the Feynman path integral with respect to the Euclidean time, which will be discussed in Section 2.3 of Chapter 6. In particular, if the Hamiltonian H has a pure point spectrum and $e^{-\frac{1}{\hbar}TH}$ is of trace class, then using the relation between the trace and Wick symbols (see Problem 2.17 in Section 2.7 of Chapter 2), we obtain from (2.15)

$$\operatorname{Tr}e^{-\frac{1}{\hbar}TH}=\int\limits_{\substack{\bar{a}(0)=\bar{a}(T)\\ a(0)=a(T)}}e^{-\frac{1}{\hbar}\int_0^T(\bar{a}\dot{a}+H(\bar{a},a))dt}\mathscr{D}\bar{a}\mathscr{D}a, \tag{2.16}$$

where now integration goes over all complex-conjugate functions $a(t)$ and $\bar{a}(t)$ satisfying periodic boundary conditions $a(0)=a(T)$ and $\bar{a}(0)=\bar{a}(T)$, and

$$\mathscr{D}\bar{a}\mathscr{D}a=\lim_{n\to\infty}e^{-\frac{1}{\hbar}\bar{a}_na_n}\prod_{k=1}^{n}\frac{d^2a_k}{\pi\hbar}.$$

Indeed, it follows from the identity

$$\begin{array}{c}\sum\limits_{k=1}^{n-1}\bar{a}_k\left(a_{k-1}-a_k\right)+\bar{a}\left(a_{n-1}-a\right)\\ -\ a_k)+\left(\bar{a}_{k+1}-\bar{a}_k\right)a_k\}+\frac{1}{2}\left\{\bar{a}\left(a_{n-1}-a\right)+\left(\bar{a}_1-\bar{a}\right)a\right\}\end{array} \tag{2.17}$$

that when $\bar{a}$ and a are variables of integration, one can put $a_n = a$ and $\bar{a}_0 = \bar{a}$, which together with $\bar{a}_n = \bar{a}$ and $a_0 = a$ imply periodic boundary conditions. Thus

$$\sum_{k=1}^{n-1} \bar{a}_k \left(a_{k-1} - a_k\right) + \bar{a}\left(a_{n-1} - a\right) = \frac{1}{2}\sum_{k=1}^{n} \left\{\bar{a}_k \left(a_{k-1} - a_k\right) + \left(\bar{a}_{k+1} - \bar{a}_k\right) a_k\right\},$$

which in the limit $n \to \infty$ becomes

$$\frac{1}{2}\int_0^T (-\bar{a}\dot{a} + \dot{\bar{a}}a)dt = -\int_0^T \bar{a}\dot{a}dt$$

due to the periodic boundary conditions.
In the holomorphic representation, the matrix symbol $K(\bar{a}, a; T)$ of the evolution operator plays the role of a propagator $K\left(q', T; q, 0\right)$ in the coordinate representation. Using the relation between matrix and Wick symbols (see Lemma 2.4 in Section 2.7 of Chapter 2), we obtain

$$K(\bar{a}, a; T) = \int_{\left\{\begin{array}{l} \bar{a}(T) = \bar{a} \\ a(0) = a \end{array}\right\}} e^{\frac{i}{\hbar}\int_0^T (i\bar{a}\dot{a} - H(\bar{a},a))dt + \frac{1}{\hbar}\bar{a}a(T)} \mathscr{D}\bar{a}\mathscr{D}a. \tag{2.18}$$

Problem 2.4. Find the relation between the Wick symbol of the evolution operator and the propagator. (Hint: Use the analog of formula (2.45) in Section 2.7 of Chapter 2.)

8.1.3 3. Feynman path integral for the harmonic oscillator

As a first impression, one may think that Feynman path integrals are not very practical. Indeed, they are defined as limits of multiple integrals when the number of integrations goes to infinity, and it seems difficult to evaluate them. In fact, this is not so: Feynman path integrals turned out to be very useful for various computations, and for several important cases they can be evaluated exactly. Here we consider the basic example [4], the Feynman path integral for the harmonic oscillator.
3.1. Gaussian integration. Evaluation of Feynman path integrals simplifies when corresponding finite-dimensional integrals can be computed exactly for every n (or for large enough n). This is the case for the important class of Gaussian integrals.

Lemma 3.1 (Gaussian integration). Let A be a positive-definite, real symmetric $n \times n$ matrix. We have

$$\int_{\mathbb{R}^n} e^{-\frac{1}{2}(A\boldsymbol{q},\boldsymbol{q}) + (\boldsymbol{p},\boldsymbol{q})} d^n\boldsymbol{q} = \frac{\sqrt{(2\pi)^n}}{\sqrt{\det A}} e^{\frac{1}{2}\left(A^{-1}\boldsymbol{p},\boldsymbol{p}\right)} \tag{3.1}$$

where $(,)$ stands for the standard Euclidian inner product in $\mathbb{R}^n$.

Proof. Completing the square we obtain

$$-\frac{1}{2}(A\boldsymbol{q},\boldsymbol{q}) + (\boldsymbol{p},\boldsymbol{q}) = -\frac{1}{2}\left(A\left(\boldsymbol{q} - A^{-1}\boldsymbol{p}\right), \left(\boldsymbol{q} - A^{-1}\boldsymbol{p}\right)\right) + \frac{1}{2}\left(A^{-1}\boldsymbol{p}, \boldsymbol{p}\right)$$

so by the change of variables $\boldsymbol{q} = \boldsymbol{x} + A^{-1}\boldsymbol{p}$ the integral reduces to the standard Gaussian integral $\int_{\mathbb{R}^n} e^{-\frac{1}{2}(A\boldsymbol{x},\boldsymbol{x})} d^n\boldsymbol{x}$, which is evaluated by diagonalizing the matrix A and using the one-dimensional Gaussian integral

$$\int_{-\infty}^{\infty} e^{-\frac{1}{2}ax^2} dx = \sqrt{\frac{2\pi}{a}}, \quad a > 0$$

[04] The simplest case of a free particle provides a trivial example, since the Lie-Kato-Trotter product formula reduces to $e^{iA} = \left(e^{\frac{i}{n}A}\right)^n$, and formula (1.14) gives the same answer as (1.11) for every n.

Formula (3.1) is one of the fundamental mathematical facts which is used in many disciplines, from probability theory to number theory. For applications to quantum mechanics, one needs a version of Lemma 3.1 when the decaying exponential factor is replaced by the oscillating exponential factor, as in (1.10).

Corollary 3.1. Let A be a real, non-degenerate symmetric $n \times n$ matrix. Then

$$\int_{\mathbb{R}^n} e^{\frac{i}{2}(A\boldsymbol{q},\boldsymbol{q})+i(\boldsymbol{p},\boldsymbol{q})} d^n\boldsymbol{q} = e^{\frac{\pi i n}{4}-\frac{\pi i \nu}{2}} \frac{\sqrt{(2\pi)^n}}{\sqrt{|\det A|}} e^{-\frac{i}{2}\left(A^{-1}\boldsymbol{p},\boldsymbol{p}\right)} \tag{3.2}$$

where the integral is understood in the distributional sense as $\lim_{R\to\infty}\int_{|q|\le R}$ and ν is the number of negative eigenvalues of A.

Proof. Formula (3.2) follows from (3.1) by analytic continuation. It also can be proved directly by completing the square, diagonalizing the matrix A, and using the Fresnel integral formula (1.10).

There is also a complex version of Gaussian integration, given by the following analog of Lemma 3.1.

Lemma 3.2 (Gaussian integration in complex domain). Let C be a complex $n \times n$ matrix such that its Hermitian part $\frac{1}{2}(C + C^*)$ is positive-definite. We have

$$\int_{\mathbb{C}^n} e^{-(C\boldsymbol{z},\boldsymbol{z})+(\boldsymbol{a},\boldsymbol{z})+(\boldsymbol{z},\boldsymbol{b})} d^{2n}\boldsymbol{z} = \frac{\pi^n}{\det C} e^{\left(C^{-1}\boldsymbol{a},\boldsymbol{b}\right)} \tag{3.3}$$

where $(,)$ stands for the standard Hermitian inner product in $\mathbb{C}^n$, $\boldsymbol{a},\boldsymbol{b} \in \mathbb{C}^n$, and $d^{2n}\boldsymbol{z} = d^2z_1...d^2z_n$.

Problem 3.1. Prove Lemma 3.2.

3.2. Propagator of the harmonic oscillator. The classical harmonic oscillator with one degree of freedom is described by the Lagrangian function $L(q,\dot{q}) = \frac{1}{2}m\left(\dot{q}^2 - \omega^2 q^2\right)$. The corresponding Hamiltonian operator for a quantum harmonic oscillator is given by

$$H = \frac{P^2}{2m} + \frac{m\omega^2 Q^2}{2}$$

The following result is an exact computation of the propagator $K\left(q',t';q,t\right)$ for the harmonic oscillator, using the Feynman path integral in configuration space.

Proposition 3.1. The Feynman path integral for the harmonic oscillator is explicitly evaluated as follows:

$$\int_{P(\mathbb{R})_{q,t}^{q',t'}} e^{\frac{im}{2\hbar}\int_t^{t'}\left(\dot{q}^2-\omega^2q^2\right)d\tau}\mathscr{D}q = \sqrt{\frac{m\omega}{2\pi i\hbar\sin\omega T}}\, e^{\frac{im\omega}{2\hbar\sin\omega T}\left\{\left(q^2+q'^2\right)\cos\omega T-2qq'\right\}}$$

where for $\frac{\pi\nu}{\omega} = T_\nu < T < T_{\nu+1} = \frac{\pi(\nu+1)}{\omega}$, $\nu \in \mathbb{N}$, we have

$$\sqrt{\frac{m\omega}{2\pi i\hbar\sin\omega T}} = e^{-\frac{\pi i}{4}-\frac{\pi i\nu}{2}}\sqrt{\frac{m\omega}{2\pi\hbar|\sin\omega T|}}$$

When $T \to T_\nu$, the right-hand side converges in the distributional sense to $e^{-\frac{\pi i\nu}{2}}\delta\left(q-q'\right)$ for even ν, and to $e^{-\frac{\pi i\nu}{2}}\delta\left(q+q'\right)$ for odd ν.

Proof. In this case the $(n-1)$-fold integral in (1.19) is Gaussian and can be computed exactly using (3.2). Namely, we have

$$\sum_{k=0}^{n-1}\left(\left(q_{k+1}-q_k\right)^2 - \varepsilon^2 q_k^2\right) = \left(A_{n-1}\boldsymbol{q},\boldsymbol{q}\right) - 2(\boldsymbol{p},\boldsymbol{q}) + q^2 + q'^2$$

where $\varepsilon = \omega\Delta t, \boldsymbol{q} = (q_1, ..., q_{n-1}), \boldsymbol{p} = (q, 0, ..., 0, q')$ are vectors in $\mathbb{R}^{n-1}$, and A_{n-1} is the following three-diagonal $(n-1) \times (n-1)$ matrix:

$$A_{n-1} = \begin{pmatrix} 2-\varepsilon^2 & -1 & 0 & \cdots & 0 & 0 \\ -1 & 2-\varepsilon^2 & -1 & \cdots & 0 & 0 \\ 0 & -1 & 2-\varepsilon^2 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 2-\varepsilon^2 & -1 \\ 0 & 0 & 0 & \cdots & -1 & 2-\varepsilon^2 \end{pmatrix}$$

It follows from (3.2) that

$$\begin{aligned} &\left(\frac{m}{2\pi i\hbar\Delta t}\right)^{\frac{n}{2}} \int_{\mathbb{R}^{n-1}} e^{\frac{im}{2\hbar\Delta t}\sum_{k=0}^{n-1}\left((q_{k+1}-q_k)^2 - \varepsilon^2 q_k^2\right)} \\ &\prod_{k=1}^{n-1} dq_k \\ &= e^{-\frac{\pi i\nu}{2}} \sqrt{\frac{m}{2\pi i\hbar\Delta t\,|\det A_{n-1}|}}\, e^{\frac{im}{2\hbar\Delta t}\left\{q^2+q'^2-\left(A_{n-1}^{-1}p,p\right)\right\}}, \end{aligned} \tag{3.4}$$

where $\nu = \nu_{n-1}$ is the number of negative eigenvalues of the matrix A_{n-1}. It is easy to find $\det A_{n-1}$ and $(A_{n-1}\boldsymbol{p}, \boldsymbol{p})$. Namely, put $a_n = \det A_n$. Expanding $\det A_n$ with respect to the last row, we obtain the three-term recurrence relation

$$a_{n+1} = \left(2-\varepsilon^2\right) a_n - a_{n-1}, \quad n = 0, 1, 2, ..., \tag{3.5}$$

with the initial conditions $a_{-1} = 0$ and $a_0 = 1$. Recurrence relation (3.5) has two linearly independent solutions z^n and z^{-n}, where $2-\varepsilon^2 = z + z^{-1}$, and a solution a_n satisfying these initial conditions is given by

$$a_n = \frac{z^{n+1} - z^{-n-1}}{z - z^{-1}}.$$

From here it is easy to obtain that the eigenvalues of the matrix A_n are given by

$$\lambda_k = z + z^{-1} - 2\cos\frac{\pi k}{n+1}, \quad k = 1, ..., n$$

Since $\varepsilon = \frac{\omega T}{n}$ we have $z = e^{i\theta}$ where $\theta = \varepsilon + O\left(n^{-2}\right)$ and

$$\det A_{n-1} = \frac{\sin n\theta}{\sin\theta} = \frac{\sin\omega T}{\omega\Delta t}\left(1 + O\left(n^{-1}\right)\right) \quad \text{as} \quad n \to \infty,$$

and for n large enough the matrix A_{n-1} has exactly ν negative eigenvalues whenever $T_\nu < T < T_{\nu+1}$. In order to evaluate the inner product $(A_{n-1}\boldsymbol{p}, \boldsymbol{p})$ we only need to know the corner elements of the inverse matrix $B = A_{n-1}^{-1}$, which are given by

$$B_{11} = B_{n-1n-1} = \frac{a_{n-2}}{a_{n-1}} = \frac{\sin(n-1)\theta}{\sin n\theta}, \quad B_{1n-1} = B_{n-11} = \frac{1}{a_n} = \frac{\sin n\theta}{\sin\theta}.$$

Thus we get
$q^2 + q'^2 - \left(A_{n-1}^{-1}\boldsymbol{p}, \boldsymbol{p}\right) = \frac{1}{\sin n\theta}\left(2\sin\frac{\theta}{2}\cos\frac{(2n-1)\theta}{2}\left(q^2+q^2\right) - 2\sin\theta qq'\right)$.
Using these formulas and passing to the limit $n \to \infty$ in (3.4), we obtain the expression for the

propagator for the case $T \neq T_\nu$. The limit $T \to T_\nu$ is evaluated by using the following standard formula in the theory of distributions:

$$\lim_{t\to 0} \frac{1}{\sqrt{2\pi t}} e^{\frac{i(x-y)^2}{2t}} = e^{\frac{\pi i}{4}} \delta(x-y)$$

Remark. It follows from Proposition 3.1 that in the limit $\omega \to 0$ the propagator of the harmonic oscillator turns into the propagator (1.11) of a free particle.

Remark. For even ν, special values T_ν are integer multiples of the period $\frac{2\pi}{\omega}$ of the harmonic oscillator (see Section 1.5 in Chapter 1), so when $t' - t = \widetilde{T}_\nu$, the extremal connecting q at time t and q' at time t' exists if and only if $q' = q$. Correspondingly, when $t' - t = T_\nu$ for odd ν, the extremal connecting q and q' exists if and only if $q' = -q$. For the general case $t' - t \neq T_\nu$, the extremal connecting q at time t and q' at time t' exists for all q and q'. The integer ν is the Morse index of the trajectory $q(\tau)$ - the number of negative eigenvalues of the corresponding Jacobi operator $\mathcal{J}$,

$$\mathcal{J} = -m\frac{d^2}{d\tau^2} - m\omega^2, \quad t \leq \tau \leq t'$$

with Dirichlet boundary conditions (see Problem 1.7 in Section 1.3 in Chapter 1).

Problem 3.2. Compute Weyl, pq, and qp-symbols of the evolution operator for the harmonic oscillator by using: (a) formula (3.2) and path integral representations from Section 2; (b) formula (3.6) and formulas (3.12), (3.18) and (3.19) in Section 3.3 of Chapter 2.

Problem 3.3. Show that the matrix symbol of the evolution operator for the harmonic oscillator is $K(\bar{a}, a; T) = \exp\left\{\bar{a}ae^{-i\omega T} - \frac{i}{2}\omega T\right\}$ by using: (a) series (1.8) in holomorphic representation; (b) Lemma 3.2 and path integral representation from Section 2; (c) formula (3.6) and result of Problem 2.4.

3.3. Mehler identity. It is instructive to compare the closed expression

$$K\left(q', t'; q, t\right) = \sqrt{\frac{m\omega}{2\pi i\hbar \sin \omega T}} e^{\frac{im\omega}{2\hbar \sin \omega T}\left\{\left(q^2+q'^2\right)\cos \omega T - 2qq'\right\}} \tag{3.6}$$

for the propagator of the harmonic oscillator with the series (1.8). Putting $x = \sqrt{\frac{m\omega}{\hbar}}q, y = \sqrt{\frac{m\omega}{\hbar}}q'$ and using the explicit formula for the normalized eigenfunctions

$$\psi_n(q) = \sqrt[4]{\frac{m\omega}{\pi\hbar}} \frac{1}{\sqrt{2^n n!}} e^{-\frac{m\omega}{2\hbar}q^2} H_n(x)$$

corresponding to the eigenvalues $E_n = \hbar\omega\left(n + \frac{1}{2}\right)$, where $H_n(q)$ are classical Hermite-Tchebyscheff polynomials (see Section 2.6 in Chapter 2), we obtain the series

$$K\left(q', t'; q, t\right) = \sqrt{\frac{m\omega}{\pi\hbar}} \sum_{n=0}^{\infty} \frac{e^{-\frac{m\omega}{2\hbar}\left(q^2+q'^2\right) - i\omega T\left(n+\frac{1}{2}\right)}}{2^n n!} H_n(x) H_n(y)$$

which converges in the distributional sense. Setting $z = e^{-i\omega T}$ and comparing with (3.6), we get the formula

$$\sum_{n=0}^{\infty} \frac{z^n}{2^n n!} H_n(x) H_n(y) = \frac{1}{\sqrt{1-z^2}} \exp\left\{\frac{2xyz - \left(x^2+y^2\right)z^2}{1-z^2}\right\} \tag{3.7}$$

where $z \neq \pm 1$, and the square root in the right-hand side is understood as in Proposition 3.1. When $|z| < 1$, formula (3.7) is the classical Mehler identity from the theory of Hermite-Tchebyscheff polynomials. Thus we obtained a distributional form of the Mehler identity for $|z| = 1$ by computing the propagator of the harmonic oscillator in two different ways.

Formula (3.6) shows that the propagator $K(q',t';q,t)$ is a smooth function of q,q' and $T=t'-t$ whenever $T\neq T_\nu$, and it is singular at $T=T_\nu$. Corresponding eigenvalues of the evolution operator $U(T_\nu)$ are $e^{-\pi i\nu\left(n+\frac{1}{2}\right)}$, so that when ν is even we have $U(T_\nu)=e^{-\frac{\pi i\nu}{2}}I$, and therefore

$$K(q',t+T_\nu;q,t)=e^{-\frac{\pi i\nu}{2}}\delta(q-q')$$

in perfect agreement with Proposition 3.1. For odd ν using the series (1.8) we obtain

$$e^{-\frac{i}{\hbar}HT_\nu}=e^{-\frac{\pi i\nu}{2}}\sum_{n=0}^{\infty}(-1)^nP_n$$

where P_n are projection operators on the eigenspaces $\mathbb{C}\psi_n$ of H. Since $H_n(-q)=(-1)^nH_n(q)$, in this case we have

$$K(q',t+T_\nu;q,t)=e^{-\frac{\pi i\nu}{2}}\delta(q+q')$$

which again agrees with Proposition 3.1.

8.1.4 4. Gaussian path integrals

It was already mentioned in Section 1 that in the semi-classical limit $\hbar\to 0$ the leading contribution to the propagator $K(q,t';q,t)$ is given by the classical trajectory $q_{\rm cl}(\tau)$. This suggests to represent the paths $\gamma=q(\tau)\in P(\mathbb{R})_{q,t}^{q',t'}$ as $q(\tau)=q_{\rm cl}(\tau)+y(\tau)$, where $y(\tau)$ - the quantum fluctuation part - satisfies Dirichlet boundary conditions $y(t)=y(t')=0$. It follows from the principle of the least action (see Section 1.2 in Chapter 1) that

$$S(q_{\rm cl}+y)=S_{\rm cl}+\frac{1}{2}\int_t^{t'}\left(m\dot{y}^2-V''(q_{\rm cl}(\tau))\,y^2\right)d\tau+\text{ higher order terms in }y \tag{4.1}$$

where $S_{\rm cl}=S(q_{\rm cl})$ is the classical action. Similarly, for the case of several degrees of freedom,

$$S(\boldsymbol{q}_{\rm cl}+\boldsymbol{y})=S_{\rm cl}+\frac{1}{2}\int_t^{t'}\mathcal{J}(\boldsymbol{y})\boldsymbol{y}d\tau+\text{ higher order terms in }\boldsymbol{y} \tag{4.2}$$

where $\mathcal{J}$ is the corresponding Jacobi operator (see Problem 1.7 in Section 1.3 of Chapter 1). It is remarkable that the Gaussian path integral

$$\int_{\left\{\begin{array}{l}y(t')=0\\ y(t)=0\end{array}\right\}}e^{\frac{im}{2\hbar}\int_t^{t'}\mathcal{J}(\boldsymbol{y})\boldsymbol{y}d\tau}\mathscr{D}\boldsymbol{y} \tag{4.3}$$

over the fluctuating part can be evaluated explicitly in terms of the regularized determinant of the second order differential operator $\mathcal{J}$. Here we do this calculation for the case of the free particle and harmonic oscillator, and give another interpretation of formulas (1.11) and (3.6) for the propagators. The Gaussian path integral (4.3) also plays a fundamental role in the semi-classical asymptotics which we discuss in Section 6.1. In general, formula (4.2), with higher order terms in $\boldsymbol{y}$, and Gaussian integration over $\mathscr{D}\boldsymbol{y}$, constitute a basis for the perturbative expansion of the propagator.

4.1. Gaussian path integral for a free particle. The propagator of a free quantum particle is and the corresponding classical trajectory is

$$q_{\rm cl}(\tau)=q+(\tau-t)\frac{q'-q}{T},\quad T=t'-t$$

Using the decomposition $q(\tau) = q_{\rm cl}(\tau) + y(\tau)$, where $y(t) = y(t') = 0$, we obtain

$$S(q) = \frac{1}{2}\int_t^{t'} m\dot{q}^2 d\tau = S_{\rm cl} + S(y)$$

where

$$S_{\rm cl} = \frac{1}{2}\int_t^{t'} m\dot{q}_{\rm cl}^2 d\tau = \frac{m\,(q-q')^2}{2T}$$

Assuming that $\mathscr{D}q = \mathscr{D}y$ under the "change of variable" $q = q_{\rm cl} + y$, we can rewrite the Feynman path integral for a free particle as

$$K\,(q',t';q,t) = e^{\frac{i}{\hbar}S_{\rm cl}} \int_{\substack{y(t')=0\\ y(t)=0}} e^{\frac{im}{2\hbar}\int_t^{t'}\dot{y}^2 d\tau}\mathscr{D}y.$$

Remarkably, the classical contribution $e^{\frac{i}{\hbar}S_{\rm cl}} = e^{\frac{im(q-q')^2}{2\hbar T}}$ exactly reproduces the exponential factor in the propagator for a free particle. The integral over the fluctuating part - the Gaussian path integral for a free particle - does not depend on q and q' and, as we know, coincides with the prefactor in (4.4).

A more conceptual way to interpret this result is the following. Let

$$A = -D^2, \quad D = \frac{d}{d\tau},$$

be the second order differential operator on the interval $[t,t']$ with Dirichlet boundary conditions $y(t) = y\,(t') = 0$. The operator A is self-adjoint on $L^2\,(t,t')$. For any real-valued, absolutely continuous function $y(\tau)$ satisfying Dirichlet boundary conditions and $y, \dot{y} \in L^2\,(t,t')$, we have by using integration by parts

$$(Ay,y) = -\int_t^{t'} \ddot{y}y d\tau = \int_t^{t'} \dot{y}^2 d\tau$$

The "integrand" in the fluctuation factor

$$\int_{\left\{\begin{array}{l} y\,(t') = 0 \\ y(t) = 0 \end{array}\right\}} e^{\frac{im}{2\hbar}\int_t^{t'}\dot{y}^2 d\tau}\mathscr{D}y$$

is the exponent of the quadratic form of the operator A, and in accordance with the finite-dimensional formula (3.1) it is natural to expect that this Gaussian path integral is proportional to $(\det A)^{-\frac{1}{2}}$. Of course, the problem here is to understand what we mean by a determinant of a differential operator. Clearly, it should be defined by some regularization of the divergent infinite product $\prod_{n=1}^{\infty}\lambda_n$, where λ_n are non-zero eigenvalues of A.

The most natural and useful regularization is given by the so-called operator zeta-function. Namely, let A be a non-negative self-adjoint operator in the Hilbert space $\mathscr{H}$ with pure point spectrum $0 \le \lambda_1 \le \lambda_2 \le \ldots$, such that for some $\alpha > 0$ the operator $(A+I)^{-\alpha}$ is of trace class. Then the zetafunction $\zeta_A(s)$ of the operator A is defined for $\mathrm{Re}\,s > \alpha$ by the following absolutely convergent series:

$$\zeta_A(s) = \sum_{\lambda_n > 0} \frac{1}{\lambda_n^s}.$$

If $\zeta_A(s)$ admits a meromorphic continuation to a larger domain containing the point $s = 0$ and is regular at $s = 0$, then we define a regularized determinant of A by

$$\det' A = \exp\left\{-\frac{d\zeta_A}{ds}(0)\right\} \tag{4.5}$$

Here the prime on the symbol det indicates that zero eigenvalues are excluded from the definition of an operator zeta-function. In the special case when 0 is not the eigenvalue of A, it is customary to denote the regularized
determinant of A by $\det A$. We will also write

$$\det' A = \prod_{\lambda_n>0}{}' \lambda_n$$

where the prime indicates that the infinite product is regularized by the operator zeta-function. We have $\zeta_{cA}(s) = c^{-s}\zeta_A(s)$ for $c > 0$, so that

$$\det' cA = c^{\zeta_A(0)} \det' A$$

which shows that $\zeta_A(0)$ plays the role of "regularized scaling dimension" of the Hilbert space $\mathscr{H}$ (with respect to the operator A). When $\dim_{\mathbb{C}} \mathscr{H} = n < \infty$ and $A > 0$, then $\zeta_A(0) = n$ and $\zeta'_A(0) = \log\lambda_1 + \cdots + \log\lambda_n$, and we recover the usual definition of $\det A$.

This basic outline works for the general case of elliptic operators on a compact manifold M. In quantum mechanics, only determinants of differential operators on one-dimensional [5] manifolds $M = [t, t']$ or $M = S^1$ appear. Their systematic study will be presented in Section 5 , while here we consider the simplest case of the second derivative operator $A = -D^2$ associated with a free particle. The corresponding eigenvalues of A are $\lambda_n = \left(\frac{\pi n}{T}\right)^2$, $n = 1, 2, ...$, and we have for the operator zeta-function

$$\zeta_A(s) = \left(\frac{T}{\pi}\right)^{2s} \zeta(2s)$$

where $\zeta(s)$ is the Riemann zeta-function. Using classical formulas $\zeta(0) = -\frac{1}{2}$ and $\zeta'(0) = -\frac{1}{2}\log 2\pi$, we obtain

$$\zeta_A(0) = -\frac{1}{2} \quad \text{and} \quad \zeta'_A(0) = -\log\frac{T}{\pi} - \log 2\pi = -\log 2T \tag{4.6}$$

Thus for the operator $A = -D^2$ on the interval $[t, t']$ with Dirichlet boundary conditions we have

$$\det A = 2T \tag{4.7}$$

The formula

$$\int_{\left\{\begin{array}{c} y(t') = 0 \\ y(t) = 0 \end{array}\right\}} e^{\frac{im}{2\hbar}\int_t^{t'} \dot{y}^2 d\tau} \mathscr{D}y = \sqrt{\frac{m}{2\pi i\hbar T}}$$

agrees with our interpretation that the Gaussian path integral is proportional to $(\det A)^{-\frac{1}{2}}$. The coefficient of proportionality $c_{m,\hbar} = \sqrt{\frac{m}{\pi i\hbar}}$ is determined by comparison with the actual propagator for a free particle.

Remark. In Section 3.1 of Chapter 6 we will prove that for Gaussian Wiener integrals the corresponding constant is $\sqrt{\frac{m}{\pi\hbar}}$.

Problem 4.1. Show that the propagator of a particle in a constant uniform field f is given by the following formula:

[05] Higher-dimensional manifolds are used in quantum field theory.

$$K(q',t';q,t)=\sqrt{\frac{m}{2\pi i\hbar T}}e^{\frac{i}{2\hbar}\left\{\frac{m(q-q')^2}{T}+fT(q+q')-\frac{f^2T^3}{12m}\right\}}.$$

(Hint: Use Lagrangian function $L=\frac{1}{2}m\dot{q}^2+fq$.)

4.2. Gaussian path integral for the harmonic oscillator. It is remarkable that the same interpretation (with the same constant $c_{m,\hbar}$) holds for the harmonic oscillator. Namely, according to Proposition 3.1 we have

$$\begin{aligned}K(q',t';q,t)&=\int_{P(\mathbb{R})^{q,t}_{q,t}}e^{\frac{im}{2\hbar}\int_t^{t'}\left(\dot{q}^2-\omega^2q^2\right)d\tau}\mathscr{D}q\\&=\sqrt{\frac{m\omega}{2\pi i\hbar\sin\omega T}}\exp\left\{\frac{im\omega}{2\hbar\sin\omega T}\left(\left(q^2+q^2\right)\cos\omega T-2qq'\right)\right\}.\end{aligned}$$

Now solving classical equations of motion with the boundary conditions $q(t)=q$ and $q(t')=q'$, we readily compute that for $T\neq T_\nu$,

$$S_{\mathrm{cl}}=\frac{m}{2}\int_t^{t'}\left(\dot{q}_{\mathrm{cl}}^2-\omega^2q_{\mathrm{cl}}^2\right)d\tau=\frac{m\omega}{2\sin\omega T}\left(\left(q^2+q'^2\right)\cos\omega T-2qq'\right)$$

so that $e^{\frac{i}{\hbar}S_{\mathrm{cl}}}$ is exactly the exponential factor in the propagator. For the fluctuating factor - the Gaussian path integral for the harmonic oscillator - we have

$$\int_{\left\{\begin{array}{c}y(t')=0\\y(t)=0\end{array}\right\}}e^{\frac{im}{2\hbar}\int_t^{t'}\left(\dot{y}^2-\omega^2y^2\right)d\tau}\mathscr{D}y=\sqrt{\frac{m}{\pi i\hbar\det A_\omega}},$$

where $A_\omega=-D^2-\omega^2$ is the second order differential operator on the interval $[t,t']$ with Dirichlet boundary conditions. Thus to justify, in this case, the interpretation of the fluctuating factor in terms of the regularized determinant, we need to show that $\det A_\omega=\frac{2\sin\omega T}{\omega}$ when $T\neq T_\nu$.

At a heuristic level, this can be done by the following beautiful computation, which goes back to Euler. Namely, the eigenvalues of A_ω are $\lambda_n(\omega)=\left(\frac{\pi n}{T}\right)^2-\omega^2$ (0 is not an eigenvalue for A_ω since $T\neq T_\nu$), and we have

$$\frac{\det A_\omega}{\det A_0}=\prod_{n=1}^{\infty}\frac{\lambda_n(\omega)}{\lambda_n(0)}=\prod_{n=1}^{\infty}\left(1-\frac{\omega^2T^2}{\pi^2n^2}\right)=\frac{\sin\omega T}{\omega T}$$

Since $\det A_0=2T$, we get the result! For the rigorous derivation, it is more convenient to consider the positive-definite operator $A_{i\omega}$, where $\omega>0$, instead of the operator A_ω.

Lemma 4.1. Let $A_{i\omega}=-D^2+\omega^2$ be the second order differential operator on the interval $[t,t']$ with Dirichlet boundary conditions. Then

$$\det A_{i\omega}=\frac{2\sinh\omega T}{\omega}$$

Proof. Denoting $\zeta_{i\omega}(s)=\zeta_{A_{i\omega}}(s)$, we have for $\operatorname{Re}s>\frac{1}{2}$,

$$\begin{aligned}\zeta_{i\omega}(s)&=\frac{1}{\Gamma(s)}\int_0^{\infty}e^{-\omega^2x}\sum_{n=1}^{\infty}e^{-\frac{\pi^2n^2}{T^2}x}x^s\frac{dx}{x}\\&=\frac{1}{2\Gamma(s)}\int_0^{\infty}e^{-\omega^2x}\vartheta\left(\frac{\pi x}{T^2}\right)x^s\frac{dx}{x}-\frac{1}{2\omega^{2s}}\end{aligned}$$

where $\vartheta(x)=\sum_{n\in\mathbb{Z}}e^{-\pi n^2x}$ is the Jacobi theta series. Using the Jacobi inversion formula

$$\vartheta\left(\frac{1}{x}\right)=\sqrt{x}\vartheta(x),\quad x>0$$

we get the following representation:

$$\begin{aligned}\zeta_{i\omega}(s)&=-\frac{1}{2\omega^{2s}}+\frac{T}{2\sqrt{\pi}\Gamma(s)}\int_0^\infty e^{-\omega^2x}\vartheta\left(\frac{T^2}{\pi x}\right)x^{s-\frac{1}{2}}\frac{dx}{x}\\&=-\frac{1}{2\omega^{2s}}+\frac{T\Gamma\left(s-\frac{1}{2}\right)}{2\sqrt{\pi}\omega^{2s-1}\Gamma(s)}+\frac{T}{\sqrt{\pi}\Gamma(s)}\int_0^\infty e^{-\omega^2x}\sum_{n=1}^\infty e^{-\frac{n^2T^2}{x}}x^{s-\frac{1}{2}}\frac{dx}{x}\\(4.8)&=-\frac{1}{2\omega^{2s}}+\frac{T\Gamma\left(s-\frac{1}{2}\right)}{2\sqrt{\pi}\omega^{2s-1}\Gamma(s)}+\frac{2T}{\sqrt{\pi}\Gamma(s)}\sum_{n=1}^\infty\left(\frac{nT}{\omega}\right)^{s-\frac{1}{2}}K_{s-\frac{1}{2}}(2\omega nT),\end{aligned}\tag{4.8}$$

where

$$K_s(x)=\frac{1}{2}\int_0^\infty e^{-\frac{x}{2}\left(u+u^{-1}\right)}u^s\frac{du}{u},x>0$$

is Macdonald's K-function (modified Bessel function of the second kind). Since $K_s(x)=O\left(e^{-x}\right)$ as $x\to\infty$, uniformly in $s\in\mathbb{C}$ on compact subsets, it follows from representation (4.8) and the Weierstrass M-test that $\zeta_{i\omega}(s)$ admits meromorphic continuation to the entire s-plane with simple poles at $s\in-\frac{1}{2}+\mathbb{Z}_{\geq0}$. Since $\lim_{s\to0}s\Gamma(s)=1$, we obtain $\zeta_{i\omega}(0)=-\frac{1}{2}$. Using classical formulas

$$K_{\frac{1}{2}}(x)=K_{-\frac{1}{2}}(x)=\sqrt{\frac{\pi}{2x}}e^{-x}\tag{4.9}$$

and $\Gamma\left(\frac{1}{2}\right)=\sqrt{\pi}$, we obtain from (4.8),

$$\begin{aligned}\frac{d\zeta_{i\omega}}{ds}(0)&=\log\omega-\omega T+\sum_{n=1}^\infty\frac{1}{n}e^{-2n\omega T}\\&=\log\omega-\omega T-\log\left(1-e^{-2\omega T}\right)\end{aligned}$$

so that

$$\det A_{i\omega}=\exp\left\{-\frac{d\zeta_{i\omega}}{ds}(0)\right\}=\frac{2\sinh\omega T}{\omega}$$

Corollary 4.1. Let $B_\omega=-D^2+i\omega D$ be the second order differential operator on the interval $[t,t']$ with Dirichlet boundary conditions. Then $\det B_{2\omega}=\det A_\omega$.

Proof. The substitution $y(\tau)=e^{i\omega\tau}f(\tau)$ transforms the eigenvalue problem $B_{2\omega}y=\lambda y$ to the eigenvalue problem $A_\omega f=\lambda f$.

Let I be the identity operator in $L^2(t,t')$. In addition to the regularized determinant $\det' A$ of the differential operator $A=-D^2$, it is possible to define the so-called characteristic determinant of A - an entire function $\det(A-\lambda I)$ on the complex λ-plane, whose only simple zeros are the eigenvalues $\lambda_n=\left(\frac{\pi n}{T}\right)^2$.

Indeed, for $\operatorname{Re}(\lambda_1-\lambda)>0$ consider the zeta-function

$$\zeta_{A-\lambda I}(s)=\sum_{n=1}^\infty\frac{1}{(\lambda_n-\lambda)^s}=\sum_{n=1}^\infty e^{-s\log(\lambda_n-\lambda)}\tag{4.10}$$

where we are using the principal branch of the logarithm. As before, $\zeta_{A-\lambda I}(s)$ is absolutely convergent for $\operatorname{Re} s > \frac{1}{2}$, admits a meromorphic continuation to the complex s-plane, and is regular at $s = 0$. Thus for $\operatorname{Re}(\lambda_1 - \lambda) > 0$ we define

$$\det(A - \lambda I) = \prod_{n=1}^{\infty} (\lambda_n - \lambda) = \exp\left\{ -\frac{\partial \zeta_{A-\lambda I}}{\partial s}(0) \right\}$$

which is a holomorphic function of λ. Now suppose that $\det(A - \lambda I)$ is already defined for $\operatorname{Re}(\lambda_N - \lambda) > 0$ and is holomorphic. To extend it to the domain $\operatorname{Re}(\lambda_{N+1} - \lambda) > 0$, we set

$$\det(A - \lambda I) = \prod_{k=1}^{N} (\lambda_k - \lambda) \prod_{n=N+1}^{\infty} (\lambda_n - \lambda)$$

where the regularized product is defined by the "truncated" zeta-function

$$\zeta_{A-\lambda I}^{(N+1)}(s) = \sum_{n=N+1}^{\infty} \frac{1}{(\lambda_n - \lambda)^s}$$

as

$$\prod_{n=N+1}^{\infty} (\lambda_n - \lambda) = \exp\left\{ -\frac{\partial \zeta_{A-\lambda I}^{(N+1)}}{\partial s}(0) \right\} \tag{4.11}$$

It requires to prove that $\zeta_{A-\lambda I}^{(N+1)}(s)$ admits a meromorphic continuation to the complex s-plane and is regular at $s = 0$. This is done by using the representation

$$\zeta_{A-\lambda I}^{(N+1)}(s) = \frac{1}{2\Gamma(s)} \int_1^{\infty} e^{-\lambda x} \vartheta_{N+1}(x) x^s \frac{dx}{x} + \frac{1}{2\Gamma(s)} \int_0^1 e^{-\lambda x} \vartheta_{N+1}(x) x^s \frac{dx}{x}$$

where

$$\vartheta_{N+1}(x) = \vartheta(x) - 2 \sum_{n=1}^{N} e^{-\lambda_n x} - 1$$

Since $\operatorname{Re}(\lambda_n - \lambda) > 0$ for all $n > N$, the first integral in this formula is absolutely convergent for all $s \in \mathbb{C}$ and represents a holomorphic function. Using the Jacobi inversion formula and expanding $e^{-\lambda x}, e^{-\lambda_1 x}, \ldots, e^{-\lambda_N x}$ into power series in x, we conclude, just as before, that the second integral admits a meromorphic continuation to the s-plane with simple poles at $s \in -\frac{1}{2} + \mathbb{Z}_{\geq 0}$. Since for $M > N$

$$\prod_{n=N+1}^{\infty} (\lambda_n - \lambda) = \prod_{k=N+1}^{M} (\lambda_k - \lambda) \prod_{n=M+1}^{\infty} (\lambda_n - \lambda)$$

$\det(A - \lambda I)$ is well defined, and is an entire function of λ with simple zeros at $\lambda = \lambda_n$.

To obtain a closed (and simple) formula for $\det(A - \lambda I)$, observe that for $\operatorname{Re}(\lambda_1 - \lambda) > 0$ it follows from (4.10) that

$$\frac{\partial \zeta_{A-\lambda I}}{\partial \lambda}(s) = s \sum_{n=1}^{\infty} \frac{1}{(\lambda_n - \lambda)^{s+1}}$$

This series is absolutely convergent for $\operatorname{Re} s > -\frac{1}{2}$, so that for $\operatorname{Re}(\lambda_1 - \lambda) > 0$ we have

$$\frac{d}{d\lambda} \log \det(A - \lambda I) = -\frac{\partial^2}{\partial s \partial \lambda} \zeta_{A-\lambda I}(0) = \sum_{n=1}^{\infty} \frac{1}{\lambda - \lambda_n} \tag{4.12}$$

By analytic continuation, formula (4.12) is valid for all $\lambda \neq \lambda_n$. Since $\lambda_n = \left(\frac{\pi n}{T}\right)^2$, we have

$$\sum_{n=1}^{\infty} \frac{1}{\lambda - \lambda_n} = \frac{T}{2\sqrt{\lambda}} \cot \sqrt{\lambda} T - \frac{1}{2\lambda}$$

so that

$$\det(A - \lambda I) = c \frac{\sin \sqrt{\lambda} T}{\sqrt{\lambda}}$$

and comparison between formula $\det(A + \omega^2 I) = \det A_{i\omega}$ and Lemma 4.1 gives $c = 2$. Thus we have proved the following result.

Lemma 4.2. The characteristic determinant $\det(A - \lambda I)$ of the operator $A = -D^2$ on the interval $[t, t']$ with Dirichlet boundary conditions is well defined, and is an entire function of λ. It is given explicitly by

$$\det(A - \lambda I) = \det A \prod_{n=1}^{\infty} \left(1 - \frac{\lambda}{\lambda_n}\right) = \frac{2 \sin \sqrt{\lambda} T}{\sqrt{\lambda}}$$

Problem 4.2. Prove the Jacobi inversion formula. (Hint: Use the Poisson summation formula

$$\sum_{n=-\infty}^{\infty} f(n) = \sqrt{2\pi} \sum_{n=-\infty}^{\infty} \hat{f}(2\pi n)$$

where $f \in \mathscr{S}(\mathbb{R})$ and $\hat{f}$ is the Fourier transform of f.)

Problem 4.3. Prove formula (4.9).

Problem 4.4. Let

$$L = \frac{m}{2}\left(\dot{x}^2 + \dot{y}^2 + \dot{z}^2\right) + \frac{eB}{2c}(x\dot{y} - y\dot{x})$$

be the Lagrangian of a classical particle moving in the constant uniform magnetic field $\boldsymbol{B} = (0, 0, B)$. Show that the propagator of the corresponding quantum particle (see Example 2.3 in Section 2.4 of Chapter 2) is given by

$$K(\boldsymbol{r}', t'; \boldsymbol{r}, t) = \left(\frac{m}{2\pi i \hbar T}\right)^{\frac{3}{2}} \frac{\omega T}{\sin \omega T} \exp \frac{im}{2\hbar} \left\{ \frac{(z - z')^2}{T} + \omega \cot \omega T \left[(x - x')^2 + (y - y')^2\right] + 2\omega (xy' - yx') \right\}.$$

(Hint: Use Corollary 4.1.)

8.1.5 5. Regularized determinants of differential operators

Here we study the characteristic determinant $\det(A - \lambda I)$ of the SturmLiouville operator

$$A = -D^2 + u(x), \quad D = \frac{d}{dx}$$

on the interval $[0, T]$ with Dirichlet or periodic boundary conditions, and its generalizations to the matrix case.

5.1. Dirichlet boundary conditions. Suppose that $u(x) \in C^1([0, T], \mathbb{R})$. The operator A is self-adjoint on $L^2(0, T)$ with domain

$$D(A) = \left\{y(x) \in W^{2,2}(0, T) : y(0) = y(T) = 0\right\}$$

where $W^{2,2}(0,T)$ is the Sobolev space. It has a pure point spectrum with simple eigenvalues $\lambda_1 < \lambda_2 < \cdots < \lambda_n < \cdots$, accumulating to ∞. Moreover, as $n \to \infty$,

$$\lambda_n = \frac{\pi^2 n^2}{T^2} + c + O\left(n^{-2}\right), \quad \text{where} \quad c = \frac{1}{T}\int_0^T u(x)dx \tag{5.1}$$

Consider first the case $A > 0$. Putting

$$\vartheta_A(t) = \sum_{n=1}^{\infty} e^{-\lambda_n t}$$

we have for $\operatorname{Re} s > \frac{1}{2}$,

$$\zeta_A(s) = \frac{1}{\Gamma(s)}\int_0^\infty \vartheta_A(t)t^s\frac{dt}{t} \tag{5.2}$$

$$= \frac{1}{\Gamma(s)}\int_1^\infty \vartheta_A(t)t^s\frac{dt}{t} + \frac{1}{\Gamma(s)}\int_0^1 \vartheta_A(t)t^s\frac{dt}{t} \tag{5.3}$$

Since $\vartheta_A(t) = O\left(e^{-\lambda_1 t}\right)$ as $t \to \infty$, the first integral in (5.3) converges absolutely for all $s \in \mathbb{C}$ and represents an entire function. Using asymptotics (5.1) and the Jacobi inversion formula we get as $t \to 0$,

$$\vartheta_A(t) = \frac{1}{2}e^{-ct}\left(\vartheta\left(\frac{\pi t}{T^2}\right) - 1\right)(1 + O(t)) = \frac{a_{-\frac{1}{2}}}{\sqrt{t}} + a_0 + \tilde{\vartheta}_A(t),$$

where

$$a_{-\frac{1}{2}} = \frac{T}{2\sqrt{\pi}}, \quad a_0 = -\frac{1}{2} \tag{5.4}$$

and $\widetilde{\vartheta}_A(t) = O(\sqrt{t})$. Thus for the second integral in (5.3) we have

$$\frac{1}{\Gamma(s)}\int_0^1 \vartheta_A(t)t^s\frac{dt}{t} = \frac{a_{-\frac{1}{2}}}{\left(s-\frac{1}{2}\right)\Gamma(s)} + \frac{a_0}{s\Gamma(s)} + \frac{1}{\Gamma(s)}\int_0^1 \widetilde{\vartheta}_A(t)t^s\frac{dt}{t},$$

so that it admits a meromorphic continuation to the half-plane $\operatorname{Re} s > -\frac{1}{2}$ and is regular at $s = 0$. Therefore we can define

$$\det{}' A = \prod_{n=1}^{\infty}\lambda_n = \exp\left\{-\frac{d\zeta_A}{ds}(0)\right\}$$

Now repeating verbatim the arguments in the proof of Lemma 4.2, we see that for $\operatorname{Re}(\lambda_N - \lambda) > 0$ the truncated zeta-function $\zeta_{A-\lambda I}^{(N+1)}(s)$ admits a meromorphic continuation to $\operatorname{Re} s > -\frac{1}{2}$, and is regular at $s = 0$. Defining the regularized product $\prod_{n=N+1}^{\infty}(\lambda_n - \lambda)$ by the same formula (4.11), we see that

$$\det(A - \lambda I) = \prod_{k=1}^{N}(\lambda_k - \lambda)\prod_{n=N+1}^{\infty}(\lambda_n - \lambda)$$

is an entire function of λ with simple zeros at λ_n. To remove the assumption $A > 0$, replace A by $\tilde{A} = A + (a - \lambda_1)I > 0$, where $a > 0$. Then [6]

$$\det(A - \lambda I) = \det\left(\tilde{A} - (\lambda + \lambda_1 - a)I\right)$$

and

$$\det{}' A = \begin{cases} \det A & \text{if 0 is not an eigenvalue of } A \\ \lim_{\lambda\to 0} \lambda^{-1} \det(A+\lambda I) & \text{if 0 is an eigenvalue of } A \end{cases}$$

Let $y_1(x,\lambda)$ be the solution of the second order differential equation

$$-y'' + u(x)y = \lambda y \tag{5.5}$$

on $[0,T]$, satisfying initial conditions

$$y_1(0,\lambda) = 0, \quad y_1'(0,\lambda) = 1 \tag{5.6}$$

It is known that for every $0 \le x \le T$, the solution $y_1(x,\lambda)$ is an entire function of λ of order $\frac{1}{2}$ and as $\lambda \to \infty$,

$$y_1(x,\lambda) = \frac{\sin\sqrt{\lambda}x}{\sqrt{\lambda}} + O\left(|\lambda|^{-1} e^{|\operatorname{Re}\sqrt{\lambda}|x}\right) \tag{5.7}$$

The entire function $d(\lambda) = y_1(T,\lambda)$ has simple zeros at the eigenvalues λ_n of the operator A, and has the following Hadamard product representation:

$$d(\lambda) = c\lambda^\delta \prod_{\lambda_n \neq 0} \left(1 - \frac{\lambda}{\lambda_n}\right). \tag{5.8}$$

Here c is a constant, $\delta = 1$ if 0 is an eigenvalue of A, and $\delta = 0$ otherwise.

Theorem 5.1. The characteristic determinant $\det(A-\lambda I)$ is given by the simple formula

$$\det(A-\lambda I) = 2d(\lambda)$$

Moreover,

$$\frac{\det(A-\lambda I)}{\det' A} = (-\lambda)^\delta \prod_{\lambda_n \neq 0} \left(1 - \frac{\lambda}{\lambda_n}\right)$$

which fixes the constant in (5.8) as $c = \frac{1}{2}(-1)^\delta \det' A$.

Proof. Since both functions are entire, it is sufficient to prove the equality $\det(A-\lambda I) = 2d(\lambda)$ for $\operatorname{Re}(\lambda_1 - \lambda) > 0$. In this case, using

$$\zeta_{A-\lambda I}(s) = \frac{1}{\Gamma(s)} \int_0^\infty \operatorname{Tr} e^{-(A-\lambda I)t} t^s \frac{dt}{t}$$

for $\operatorname{Re} s > \frac{1}{2}$, and differentiating under the integral sign we get

$$\frac{\partial}{\partial\lambda}\zeta_{\Lambda-\lambda I}(s) = \frac{1}{\Gamma(s)} \int_0^\infty \operatorname{Tr} e^{-(A-\lambda I)t} t^s dt$$

which is now absolutely convergent for $\operatorname{Re} s > -\frac{1}{2}$. Differentiating with respect to s at $s = 0$, we obtain

$$\frac{\partial^2}{\partial s \partial\lambda}\zeta_{A-\lambda I}(0) = \int_0^\infty \operatorname{Tr} e^{-(A-\lambda I)t} dt = \operatorname{Tr}(A-\lambda I)^{-1}$$

It follows from (5.1) that the operator $R_\lambda = (A-\lambda I)^{-1}$ - the resolvent of A - is of trace class. Thus all our manipulations are justified and we arrive at the following very useful formula:

[06] The definition of $\det' A$ does not depend on the choice of $a > 0$.

$$\frac{d}{d\lambda}\log\det(A-\lambda I) = -\operatorname{Tr} R_\lambda \tag{5.9}$$

which generalizes the familiar property of finite-dimensional determinants.
To compute the trace in (5.9), we use the representation of R_λ for $\lambda \neq \lambda_n$ as an integral operator with the continuous kernel $R_\lambda(x,\xi)$ (cf. formula (2.21) in Section 2.2 of Chapter 3). Namely, let $y_2(x,\lambda)$ be another solution of (5.5) with boundary conditions $y_2(T,\lambda)=0$ and $y_2'(T,\lambda)=1$, so that

$$W(y_1,y_2)(\lambda) = y_1'(x,\lambda)y_2(x,\lambda) - y_1(x,\lambda)y_2'(x,\lambda) = -d(\lambda).$$

Using the method of variation of parameters, for the solution of the inhomogeneous equation

$$-y'' + u(x)y = \lambda y + f(x), \quad \lambda \neq \lambda_n,$$

satisfying Dirichlet boundary conditions we get

$$y(x) = \int_0^T R_\lambda(x,\xi)f(\xi)d\xi$$

where

$$R_\lambda(x,\xi) = \begin{cases} -\frac{y_1(x,\lambda)y_2(\xi,\lambda)}{d(\lambda)} & \text{if } x \le \xi \\ -\frac{y_1(\xi,\lambda)y_2(x,\lambda)}{d(\lambda)} & \text{if } x \ge \xi \end{cases} \tag{5.10}$$

Since R_λ is a trace class operator on $L^2(0,T)$ with the integral kernel $R_\lambda(x,\xi)$, which is a continuous function on $[0,T]\times[0,T]$, its operator trace equals the "matrix trace",

$$\operatorname{Tr} R_\lambda = \int_0^T R_\lambda(x,x)dx = -\frac{1}{d(\lambda)}\int_0^T y_1(x,\lambda)y_2(x,\lambda)dx$$

We evaluate the last integral by the same computation used in the proof of Proposition 2.1 in Section 2.1 of Chapter 3. Namely, put $\dot y(x,\lambda) = \frac{\partial y}{\partial\lambda}(x,\lambda)$, and consider the following pair of equations:

$$\begin{aligned} -\dot y_1'' + u(x)\dot y_1 &= \lambda\dot y_1 + y_1, \\ -y_2'' + u(x)y_2 &= \lambda y_2. \end{aligned}$$

Multiplying the first equation by $y_2(x,\lambda)$, the second equation by $\dot y_1(x,\lambda)$ and subtracting, we obtain

$$y_1y_2 = \dot y_1y_2'' - \dot y_1''y_2 = -W(\dot y_1,y_2)'$$

so that

$$\int_0^T y_1(x,\lambda)y_2(x,\lambda)dx = -W(\dot y_1,y_2)\big|_0^T \tag{5.11}$$

This formula is valid for any two solutions of the differential equation (5.5). Using boundary conditions for the solutions y_1 and y_2, we finally get

$$\int_0^T y_1(x,\lambda)y_2(x,\lambda)dx = \dot y_1(T,\lambda) \tag{5.12}$$

Thus we have proved that for $\operatorname{Re}(\lambda_1-\lambda)>0$,

$$\operatorname{Tr} R_\lambda = -\frac{d}{d\lambda}\log d(\lambda) \tag{5.13}$$

which implies that

$$\det(A-\lambda I) = Cd(\lambda) \tag{5.14}$$

for all $\lambda \in \mathbb{C}$ and some constant C.
It follows from (5.7) that

$$d(-\mu) = \frac{e^{\sqrt{\mu}T}}{2\sqrt{\mu}}\left(1+O\left(\mu^{-\frac{1}{2}}\right)\right) \quad \text{as} \quad \mu \to +\infty. \tag{5.15}$$

Thus in order to determine the constant C in (5.14), it is sufficient to compute the asymptotics of $\det(A+\mu I)$ as $\mu \to +\infty$. We have

$$\zeta_{A+\mu I}(s) = \frac{1}{\Gamma(s)}\int_1^\infty \vartheta_A(t)e^{-\mu t}t^s\frac{dt}{t} + \frac{1}{\Gamma(s)}\int_0^1 \vartheta_A(t)e^{-\mu t}t^s\frac{dt}{t}$$

The first integral is an entire function of s whose derivative at $s=0$ exponentially decays as $\mu \to +\infty$. For the second integral we have

$$\begin{aligned}\frac{1}{\Gamma(s)}\int_0^1 \vartheta_A(t)e^{-\mu t}t^s\frac{dt}{t} &= \frac{1}{\Gamma(s)}\int_0^1 \tilde{\vartheta}_A(t)e^{-\mu t}t^s\frac{dt}{t}\\ &\quad + \frac{1}{\Gamma(s)}\int_0^1 \left(\frac{a_{-\frac{1}{2}}}{\sqrt{t}}+a_0\right)e^{-\mu t}t^s\frac{dt}{t}\end{aligned}$$

Since $\widetilde{\vartheta}_A(t) = O(\sqrt{t})$ as $t \to 0$, the first integral is absolutely convergent for $\operatorname{Re} s > -\frac{1}{2}$ and its derivative at $s=0$ is $O\left(\mu^{-\frac{1}{2}}\right)$ as $\mu \to +\infty$. For the
remaining integral we have

$$\begin{aligned}\frac{1}{\Gamma(s)}\int_0^1 \left(\frac{a_{-\frac{1}{2}}}{\sqrt{t}}+a_0\right)e^{-\mu t}t^s\frac{dt}{t} &= \frac{a_{-\frac{1}{2}}\mu^{\frac{1}{2}-s}}{\Gamma(s)}\left(\Gamma\left(s-\frac{1}{2}\right)-\int_\mu^\infty e^{-t}t^{s-\frac{1}{2}}\frac{dt}{t}\right)\\ &\quad + \frac{a_0\mu^{-s}}{\Gamma(s)}\left(\Gamma(s)-\int_\mu^\infty e^{-t}t^s\frac{dt}{t}\right)\end{aligned}$$

It is elementary to show that the s-derivative of this integral at $s=0$ has asymptotics $-2\sqrt{\pi}a_{-\frac{1}{2}}\sqrt{\mu} - a_0\log\mu + O\left(e^{-\mu/2}\right)$ as $\mu \to +\infty$. Using (5.4) we finally obtain

$$\det(A+\mu I) = \frac{e^{\sqrt{\mu}T}}{\sqrt{\mu}}\left(1+O\left(\mu^{-\frac{1}{2}}\right)\right)$$

as $\mu \to +\infty$, and comparison with (5.15) gives $C=2$.
Remark. When zero is not an eigenvalue of A, its inverse A^{-1} is a trace class operator and

$$\frac{\det(A-\lambda I)}{\det A} = \det{}_F\left(I-\lambda A^{-1}\right)$$

where $\det_F$ is the Fredholm determinant.
Remark. In Section 6.1 we will use Theorem 5.1 for evaluating the fluctuating factor in the semi-classical asymptotics of the propagator, and in Section 3.1 of Chapter 6 - for evaluating Gaussian Wiener integrals.

A similar result holds for the matrix-valued Sturm-Liouville operator with Dirichlet boundary conditions. Namely, let $U(x) = \{u_{ij}(x)\}_{i,j=1}^n$ be a C^1-function on $[0,T]$ which takes values in real, symmetric $n \times n$ matrices, and consider

$$\boldsymbol{A} = -D^2 I_n + U(x)$$

where I_n is the $n \times n$ identity matrix. The differential operator $\boldsymbol{A}$ with Dirichlet boundary conditions is self-adjoint on the Hilbert space $L^2([0,T],\mathbb{C}^n)$ of $\mathbb{C}^n$-valued functions, and has a pure point spectrum accumulating to ∞. Its regularized determinant $\det'\boldsymbol{A}$ and characteristic determinant $\det(\boldsymbol{A}-\lambda\boldsymbol{I})$, where I is the identity operator in $L^2([0,T],\mathbb{C}^n)$, are defined as in the $n=1$ case. Let $\boldsymbol{Y}(x,\lambda)$ be the solution of the differential equation

$$-\boldsymbol{Y}'' + U(x)\boldsymbol{Y} = \lambda \boldsymbol{Y}$$

satisfying initial conditions

$$\boldsymbol{Y}(0,\lambda) = 0, \quad \boldsymbol{Y}'(0,\lambda) = I_n$$

and put $\boldsymbol{D}(\lambda) = \det \boldsymbol{Y}(T,\lambda)$. The entire function $\boldsymbol{D}(\lambda)$ has properties similar to that of $d(\lambda)$, and the following analog of Theorem 5.1 holds.

Proposition 5.1. The characteristic determinant $\det(\boldsymbol{A}-\lambda\boldsymbol{I})$ is given by the formula

$$\det(\boldsymbol{A}-\lambda\boldsymbol{I}) = 2^n \boldsymbol{D}(\lambda)$$

Moreover,

$$\frac{\det(\boldsymbol{A}-\lambda\boldsymbol{I})}{\det'\boldsymbol{A}} = (-\lambda)^\delta \prod_{\lambda_n \neq 0} \left(1 - \frac{\lambda}{\lambda_n}\right)$$

where δ is the multiplicity of the eigenvalue $\lambda = 0$.

Problem 5.1 (Gelfand-Levitan trace identity). Prove that

$$\sum_{n=1}^{\infty} \left(\lambda_n - \lambda_n^{(0)} - c\right) = \frac{1}{2T}\int_0^T u(x)dx - \frac{u(0)+u(T)}{4}$$

where $\lambda_n^{(0)} = \left(\frac{\pi n}{T}\right)^2$ and $c = \frac{1}{T}\int_0^T u(x)dx$.

5.2. Periodic boundary conditions. As in the previous section, we assume that $u(x) \in C^1([0,T],\mathbb{R})$. The Sturm-Liouville operator $A = -D^2 + u(x)$ with periodic boundary conditions is self-adjoint on $L^2(0,T)$ with the domain

$$D(A) = \left\{y(x) \in W^{2,2}(0,T) : y(0) = y(T) \text{ and } y'(0) = y'(T)\right\}$$

It has a pure point spectrum with the eigenvalues

$$\lambda_0 < \lambda_1 \leq \lambda_2 < \cdots < \lambda_{2n-1} \leq \lambda_{2n} < \cdots$$

accumulating to ∞. Moreover, as $n \to \infty$,

$$\lambda_{2n-1} = \frac{4\pi^2 n^2}{T^2} + c + O\left(n^{-2}\right), \quad \lambda_{2n} = \frac{4\pi^2 n^2}{T^2} + c + O\left(n^{-2}\right) \tag{5.16}$$

where c is the same as in (5.1). Replacing, if necessary, A by $A - (\lambda_0 + a)\,I$ with $a > 0$, we can always assume that $\lambda_0 > 0$, and define

$$\vartheta_A(t) = \sum_{n=0}^{\infty} e^{-\lambda_n t}, t > 0$$

Using asymptotics (5.16), we get that as $t \to 0$,

$$\vartheta_A(t) = e^{-ct}\vartheta\left(\frac{4\pi t}{T^2}\right)(1+O(t)) = \frac{a_{-\frac{1}{2}}}{\sqrt{t}} + O(\sqrt{t})$$

where $a_{-\frac{1}{2}} = \frac{T}{2\sqrt{\pi}}$ as in (5.4), but $a_0 = 0$. This allows us to define the regularized determinant $\det' A$ and the characteristic determinant $\det(A - \lambda I)$ exactly as in the previous section. Since $a_0 = 0$, we now get as $\mu \to +\infty$

$$\det(A+\mu I) = e^{\sqrt{\mu}T}\left(1 + O\left(\mu^{-\frac{1}{2}}\right)\right) \tag{5.17}$$

(see the end of the proof of Theorem 5.1).

Here we denote [7] by $y_1(x,\lambda)$ and $y_2(x,\lambda)$ solutions of the Sturm-Liouville equation (5.5) satisfying initial conditions $y_1(0,\lambda) = 1, y_1'(0,\lambda) = 0$ and $y_2(0,\lambda) = 0, y_2'(0,\lambda) = 1$. Solutions y_1 and y_2 are linearly independent for all λ and the matrix

$$Y(x,\lambda) = \begin{pmatrix} y_1(x,\lambda) & y_2(x,\lambda) \\ y_1'(x,\lambda) & y_2'(x,\lambda) \end{pmatrix}$$

satisfies the initial condition $Y(0,\lambda) = I_2$, where I_2 is the 2×2 identity matrix, and has the property $\det Y(x,\lambda) = 1$. For fixed x the matrix $Y(x,\lambda)$ is an entire matrix-valued function of λ having the following asymptotics as $\lambda \to \infty$:

$$Y(x,\lambda) = \begin{pmatrix} \cos\sqrt{\lambda}x & \frac{1}{\sqrt{\lambda}}\sin\sqrt{\lambda}x \\ \sqrt{\lambda}\sin\sqrt{\lambda}x & \cos\sqrt{\lambda}x \end{pmatrix}\left(I_2 + O\left(|\lambda|^{-1}e^{|\operatorname{Re}\sqrt{\lambda}|x}\right)\right) \tag{5.18}$$

By definition, the monodromy matrix of the periodic Sturm-Liouville problem is the matrix

$$T(\lambda) = Y(T,\lambda)$$

The monodromy matrix satisfies $\det T(\lambda) = 1$ and is an entire matrix-valued function. The following result is the analog of Theorem 5.1 for the periodic boundary conditions.

Theorem 5.2. One has

$$\det(A-\lambda I) = -\det{}_2\left(T(\lambda) - I_2\right) = y_1(T,\lambda) + y_2'(T,\lambda) - 2$$

where $\det_2$ is the determinant of a 2×2 matrix. Moreover,

$$\frac{\det(A-\lambda I)}{\det' A} = (-\lambda)^\delta \prod_{\lambda_n \neq 0}\left(1 - \frac{\lambda}{\lambda_n}\right)$$

where $\{\lambda_n\}_{n=0}^\infty$ are the eigenvalues of A, and $0 \le \delta \le 2$ is a multiplicity of the eigenvalue $\lambda = 0$.

Proof. The proof follows closely the proof of Theorem 5.1, and we will assume that $A > 0$. First, in exact analogy with (5.9) we obtain that for $\lambda \neq \lambda_n$,

$$\frac{d}{d\lambda}\log\det(A-\lambda I) = -\operatorname{Tr} R_\lambda$$

where $R_\lambda = (A-\lambda I)^{-1}$. To get a closed expression for the integral kernel $R(x,\xi)$ of the operator R_λ, we use the same variation of parameters method as in the previous section, but now for periodic boundary conditions. As a

result, we obtain that the symmetric, continuous kernel $R_\lambda(x,\xi)$ is given for $x \le \xi$ by the formula

[07] There should be no confusion with the notation in the previous section.

$$R_\lambda(x,\xi) = -\left(y_1(x,\lambda), y_2(x,\lambda)\right)\left(T(\lambda)-I_2\right)^{-1}T(\lambda)\begin{pmatrix} y_2(\xi,\lambda) \\ -y_1(\xi,\lambda)\end{pmatrix}$$
$$= -\operatorname{Tr}_2\left\{\left(T(\lambda)-I_2\right)^{-1}T(\lambda)Z(x,\xi;\lambda)\right\},$$

where Tr_2 in the last formula is the matrix trace and

$$Z(x,\xi;\lambda) = \begin{pmatrix} y_1(x,\lambda)y_2(\xi,\lambda) & y_2(x,\lambda)y_2(\xi,\lambda) \\ -y_1(x,\lambda)y_1(\xi,\lambda) & -y_2(x,\lambda)y_1(\xi,\lambda)\end{pmatrix}.$$

As in the proof of Theorem 5.1, we need to compute $\int_0^T Z(x,x;\lambda)dx$. It readily follows from formula (5.11) and the definition of the monodromy matrix that

$$\int_0^T Z(x,x;\lambda)dx = T^{-1}(\lambda)\frac{d}{d\lambda}T(\lambda).$$

Therefore
$\frac{d}{d\lambda}\log\det(A-\lambda I) = \operatorname{Tr}_2\left(\left(T(\lambda)-I_2\right)^{-1}\frac{d}{d\lambda}T(\lambda)\right) = \frac{d}{d\lambda}\log\det_2\left(T(\lambda)-I_2\right)$, and $\det(A-\lambda I) = C\det\left(T(\lambda)-I_2\right)$. To determine the constant C we set $\lambda=-\mu\to+\infty$ and compare asymptotics (5.17) with the asymptotics

$$\det_2\left(T(-\mu)-I_2\right) = 2-\operatorname{Tr}T(-\mu) = 2-2\cosh\sqrt{\mu}T\left(1+O\left(\mu^{-\frac{1}{2}}\right)\right)$$
$$= -e^{\sqrt{\mu}T}\left(1+O\left(\mu^{-\frac{1}{2}}\right)\right)$$

which follows from (5.18). Thus $C=-1$.
Remark. In Section 3.2 of Chapter 6 we will use Theorem 5.2 for calculating Gaussian Wiener integrals over the loop spaces.

In the special case $u(x)=0$, we have

$$y_1(x,\lambda) = \cos\sqrt{\lambda}x \quad \text{and} \quad y_2(x,\lambda) = \frac{\sin\sqrt{\lambda}x}{\sqrt{\lambda}}$$

so that

$$\det\left(-D^2-\lambda I\right) = 2(\cos\sqrt{\lambda}T-1) = -4\sin^2\frac{\sqrt{\lambda}T}{2} \tag{5.19}$$

Setting $\lambda=-\omega^2<0$, for the operator $A_{i\omega}=-D^2+\omega^2$ we get

$$\det A_{i\omega} = 4\sinh^2\frac{\omega T}{2}, \tag{5.20}$$

and also

$$\det' A_0 = -\lim_{\lambda\to 0^-}\frac{\det(A-\lambda I)}{\lambda} = \lim_{\omega\to 0}\frac{\det' A_{i\omega}}{\omega^2} = T^2. \tag{5.21}$$

Remark. Using that the spectrum of $A_{i\omega}$ consists of double eigenvalues $\lambda_n(\omega) = \left(\frac{2\pi n}{T}\right)^2, n=1,2,...$, and of the simple eigenvalue ω^2, we can derive formulas (5.20)-(5.21) directly, as was done in Section 4.2 for Dirichlet boundary conditions. There is also an analog of the heuristic computation in Section 4.2:

$$\frac{\det A_{i\omega}}{\det' A_0} = \omega^2\prod_{n=1}^{\infty}\frac{\lambda_n(\omega)^2}{\lambda_n(0)^2} = \omega^2\prod_{n=1}^{\infty}\left(1+\frac{\omega^2T^2}{4\pi^2n^2}\right)^2 = \frac{4}{T^2}\sinh^2\frac{\omega T}{2}.$$

A similar result holds for the general second order differential operator $A = -D^2 + v(x)D + u(x)$ on the interval $[0, T]$ with periodic boundary conditions. Namely, repeating the proof of Theorem 5.2, we have the following

Theorem 5.3. For the differential operator $A = -D^2 + v(x)D + u(x)$ one has

$$\begin{aligned}\det(A - \lambda I) &= -e^{-\frac{1}{2}\int_0^T v(x)dx} \det{}_2 \left(T(\lambda) - I_2\right) \\ &= e^{-\frac{1}{2}\int_0^T v(x)dx} \left(y_1(T,\lambda) + y_2'(T,\lambda) - 1 - e^{\int_0^T v(x)dx}\right)\end{aligned}$$

where solutions $y_{1,2}(x, \lambda)$ and the monodromy matrix $T(\lambda)$ are defined by the same formulas as for the case $v(x) = 0$.

In particular, the following result will be used in Section 2.2 of Chapter 8.

Corollary 5.4.

$$\det{}' \left(-D^2 + \omega D\right) = \frac{2T}{\omega} \sinh \frac{\omega T}{2}$$

Proof. The proof is an elementary computation, using Theorem 5.3, an explicit form of the solutions $y_{1,2}(x, \lambda)$, and the formula

$$\det{}' \left(-D^2 + \omega D\right) = -\lim_{\lambda \to 0} \frac{\det\left(-D^2 + \omega D - \lambda I\right)}{\lambda}$$

Remark. Since the operator $-D^2 + \omega D$ on $[0, T]$ with periodic boundary conditions has simple eigenvalues $\lambda_n(a) = \left(\frac{2\pi n}{T}\right)^2 + i\omega \left(\frac{2\pi n}{T}\right), n = -\infty, ..., \infty$, we can also repeat the heuristic computation in Section 4.2:

$$\frac{\det'\left(-D^2 + \omega D\right)}{\det'\left(-D^2\right)} = \prod_{n=1}^{\infty} \left(1 + \frac{\omega^2 T^2}{4\pi^2 n^2}\right) = \frac{2}{\omega T} \sinh \frac{\omega T}{2}$$

A similar result holds for the matrix-valued Sturm-Liouville operator with periodic boundary conditions. Namely, let $U(x) = \{u_{ij}(x)\}_{i,j=1}^n$ be a C^1-function on $[0, T]$ which takes values in real, symmetric $n \times n$ matrices, and consider

$$\boldsymbol{A} = -D^2 I_n + U(x)$$

The differential operator $\boldsymbol{A}$ with periodic boundary conditions is self-adjoint on the Hilbert space $L^2\left([0, T], \mathbb{C}^n\right)$ of $\mathbb{C}^n$-valued functions, and has a pure point spectrum accumulating to ∞. Its regularized determinant $\det'\boldsymbol{A}$ and characteristic determinant $\det(\boldsymbol{A} - \lambda \boldsymbol{I})$, where $\boldsymbol{I}$ is the identity operator in $L^2\left([0, T], \mathbb{C}^n\right)$, are defined as in the $n = 1$ case. Let $\boldsymbol{Y}_1(x, \lambda)$ and $\boldsymbol{Y}_2(x, \lambda)$ be the solutions of the differential equation

$$-\boldsymbol{Y}'' + U(x)\boldsymbol{Y} = \lambda \boldsymbol{Y}$$

satisfying, respectively, the initial conditions

$$\boldsymbol{Y}_1(0, \lambda) = I_n, \quad \boldsymbol{Y}_1'(0, \lambda) = 0 \quad \text{and} \quad \boldsymbol{Y}_2(0, \lambda) = 0, \quad \boldsymbol{Y}_2'(0, \lambda) = I_n.$$

The monodromy matrix $\boldsymbol{T}(\lambda)$ is defined as the following $2n \times 2n$ block matrix:

$$\boldsymbol{T}(\lambda) = \begin{pmatrix} \boldsymbol{Y}_1(T, \lambda) & \boldsymbol{Y}_2(T, \lambda) \\ \boldsymbol{Y}_1'(T, \lambda) & \boldsymbol{Y}_2'(T, \lambda) \end{pmatrix}$$

and is a matrix-valued entire function. The analog of Theorem 5.2 is the following statement.

Proposition 5.2. The characteristic determinant is given by the formula

$$\det(\boldsymbol{A}-\lambda\boldsymbol{I})=(-1)^n\det{}_{2n}\left(\boldsymbol{T}(\lambda)-I_{2n}\right)$$

where $\det_{2n}$ is the determinant of a $2n\times 2n$ matrix, and

$$\frac{\det(\boldsymbol{A}-\lambda\boldsymbol{I})}{\det'\boldsymbol{A}}=(-\lambda)^\delta\prod_{\lambda_n\neq 0}\left(1-\frac{\lambda}{\lambda_n}\right)$$

where δ is the multiplicity of the eigenvalue $\lambda=0$.

Problem 5.2. Prove Theorem 5.3.

Problem 5.3. Derive Corollary 5.4.

5.3. First order differential operators. Here we continue to assume that $u(x)\in C^1([0,T],\mathbb{R})$, and consider the first order differential operator

$$A=D+u(x)$$

on the interval $[0,T]$ with periodic boundary conditions $y(0)=y(T)$. The equation

$$y'+u(x)y=\lambda y$$

has an explicit solution $y(x)=Ce^{\lambda x-\int_0^x u(\tau)d\tau}$, which is periodic if and only if $\lambda=\lambda_n$, where

$$\lambda_n=u_0+\frac{2\pi in}{T},\quad n\in\mathbb{Z},\qquad\text{and}\qquad u_0=\frac{1}{T}\int_0^T u(x)dx$$

Thus the spectrum of the operator A coincides with the spectrum of the operator $A_0=D+u_0$.

Proposition 5.3. For $u_0>0$,

$$\det(D+u(x))=1-e^{-u_0T}$$

and $\det' D=T$ for $u_0=0$.

Proof. The zeta-function of the operator A with $u_0>0$ is given by the series

$$\zeta_A(s)=\sum_{n=-\infty}^{\infty}\frac{1}{\lambda_n^s}$$

where $\lambda_n^{-s}=e^{-s\log\lambda_n}$ with the principal branch of the logarithm. This series is absolutely convergent for $\operatorname{Re}s>1$. Introducing the Hurwitz zeta-function

$$\zeta(s,a)=\sum_{n=0}^{\infty}\frac{1}{(n+a)^s}$$

where $\operatorname{Re}a>0$ and $\operatorname{Re}s>1$, we can rewrite $\zeta_A(s)$ as

$$\zeta_A(s)=\left(\frac{2\pi}{T}\right)^{-s}\left(e^{-\frac{\pi is}{2}}\zeta(s,a)+e^{\frac{\pi is}{2}}\zeta(s,\bar a)\right)+\frac{1}{u_0^s},\quad a=1-\frac{u_0T}{2\pi}i$$

It is well known that the Hurwitz zeta-function admits a meromorphic continuation to the whole s-plane with single simple pole at $s=1$ with residue 1 , and

$$\zeta(0,a)=\frac{1}{2}-a,\quad \frac{\partial\zeta}{\partial s}(0,a)=\log\Gamma(a)-\frac{1}{2}\log 2\pi$$

Using the classical formula

$$\Gamma(1+z)\Gamma(1-z)=\frac{\pi z}{\sin\pi z}$$

we obtain

$$\frac{d\zeta_A}{ds}(0) = \log|\Gamma(a)|^2 - \log u_0 T + \frac{u_0 T}{2}$$
$$= -\log\left(e^{\frac{u_0 T}{2}} - e^{-\frac{u_0 T}{2}}\right) + \frac{u_0 T}{2}$$

so that $\det(D + u(x)) = 1 - e^{-u_0 T}$. Finally, $\zeta_D(s) = \lim_{u_0 \to 0}\left(\zeta_A(s) - u_0^{-s}\right)$, and we get

$$\det' D = \lim_{u_0 \to 0} \frac{\det'(D + u_0)}{u_0} = T$$

Remark. For $u_0 < 0$ one should use the branch of the logarithm with the cut along the positive semi-axis, and the above arguments give

$$\det(D + u(x)) = 1 - e^{u_0 T}$$

Remark. One can also consider the operator $A = D + u(x)$ on the interval $[0, T]$ with anti-periodic boundary conditions $y(0) = -y(T)$. The corresponding eigenvalues are

$$\lambda_n = u_0 + \frac{\pi i(2n+1)}{T}, n \in \mathbb{Z}$$

and the passage from periodic to anti-periodic boundary conditions amounts to replacing u_0 by $u_0 + \frac{\pi i}{T}$. It follows from Proposition 5.3 that for $u_0 > 0$,

$$\det(D + u(x)) = 1 + e^{-u_0 T}.$$

Remark. Proposition 5.3 is very useful for calculating Gaussian path integrals in the holomorphic representation, discussed in Section 2.4. As an example, consider the harmonic oscillator with the Wick symbol $H(\bar{a}, a) = \omega\left(\bar{a}a + \frac{1}{2}\hbar\right)$. Formula (2.16) expresses the trace $\operatorname{Tr} e^{-\frac{1}{\hbar}TH}$ as a path integral in the holomorphic representation. On the other hand, using the explicit form of the eigenvalues $E_n = \omega\hbar\left(n + \frac{1}{2}\right)$, we immediately get

$$\operatorname{Tr} e^{-\frac{1}{\hbar}TH} = \sum_{n=0}^{\infty} e^{-\frac{1}{\hbar}E_n T} = \frac{e^{-\frac{1}{2}\omega T}}{1 - e^{-\omega T}} = \frac{1}{2\sinh\frac{\omega T}{2}}$$

Comparing with (2.16), we obtain that

$$\int\!\!\int_{\left\{\begin{array}{l}\bar{a}(0) = \bar{a}(T)\\ a(0) = a(T)\end{array}\right\}} e^{-\frac{1}{\hbar}\int_0^T(\bar{a}\dot{a} + \omega\bar{a}a)dt}\mathscr{D}\bar{a}\mathscr{D}a = \frac{1}{\det(D + \omega)}, \tag{5.22}$$

which should be considered as a special analog of the finite-dimensional Gaussian integration in the complex domain - formula (3.3).

Problem 5.4. Give a direct proof of formula (5.22).

8.1.6 6. Semi-classical asymptotics - II

Here we consider the semi-classical asymptotics - the asymptotics of the propagator [8] $K_\hbar(\boldsymbol{q}', t'; \boldsymbol{q}, t)$ as $\hbar \to 0$. We compare the heuristic method, based on the Feynman path integral representation (1.26), with the rigorous analysis, based on the short-wave asymptotics, derived in Section 6.1 of Chapter 3.

6.1. Using the Feynman path integral. Start with the Lagrangian $L(q, \dot{q}) = \frac{1}{2}m\dot{q}^2 - V(q)$ for a classical particle with one degree of freedom. The propagator $K_\hbar(q', t'; q, t)$ is given by

[08] Here the dependence on the Planck constant $\hbar$ is introduced explicitly.

the Feynman path integral (1.20), and we will formally apply the stationary phase method to investigate its behavior as $\hbar \to 0$. As in Section 4, we assume that there is a unique classical trajectory $q_{\rm cl}(\tau)$ connecting points q and q' at times t and t', set $q(\tau) = q_{\rm cl}(\tau) + y(\tau)$, and consider the expansion (4.1), i.e.,

$$S(q) = S_{\rm cl} + \frac{1}{2}m \int_t^{t'} \left(\dot{y}^2 - u(\tau)y^2\right) d\tau + O\left(y^3\right)$$

where $u(\tau) = \frac{1}{m}V''\left(q_{\rm cl}(\tau)\right)$ and

$$S_{\rm cl} = \int_t^{t'} \left(\frac{1}{2}m\dot{q}_{\rm cl}^2 - V\left(q_{\rm cl}\right)\right) d\tau = S\left(q', t'; q, t\right).$$

According to the stationary phase method (see Section 2.3 in Chapter 2), the leading contribution to the Feynman integral (1.20) as $\hbar \to 0$ comes from a critical point of the action functional - the classical trajectory $q_{\rm cl}(\tau)$. Thus we obtain as $\hbar \to 0$,

$$\begin{aligned} K_\hbar\left(q', t'; q, t\right) &\simeq e^{\frac{i}{\hbar}S_{\rm cl}} \int_{\substack{y(t')=0 \\ y(t)=0}} e^{\frac{im}{2\hbar}\int_t^{t'}\left(\dot{y}^2 - u(\tau)y^2\right)d\tau} \mathscr{D}y \\ &= \sqrt{\frac{m}{\pi i \hbar \det A}} \exp\left\{\frac{i}{\hbar}S\left(q', t'; q, t\right)\right\}. \end{aligned} \tag{6.1}$$

Here A is the corresponding Jacobi operator - a second order differential operator $-D^2 - u(\tau)$ on the interval $[t, t']$ with Dirichlet boundary conditions. (We are assuming that the potential $V(q)$ is sufficiently smooth so that $u(\tau) \in C^1\left([t, t']\right)$.) Formula (6.1) is a remarkably simple expression which shows a deep relation between semi-classical asymptotics of a quantum mechanical propagator and classical motion.

Remark. When $u(\tau) = \frac{1}{m}V''\left(q_{\rm cl}(\tau)\right)$, the regularized determinant of the differential operator $A = -D^2 - u(\tau)$ on the interval $[t, t']$ with Dirichlet boundary conditions can be expressed entirely in terms of the classical trajectory $q_{\rm cl}(\tau)$. Namely, differentiating Newton's equation

$$m\ddot{q} = -V'(q), \tag{6.2}$$

with respect to τ, we find that the function $y(\tau) = \dot{q}_{\rm cl}(\tau)$ satisfies the differential equation $Ay = 0$. When $y(t) = \dot{q}_{\rm cl}(t) = 0$, the function [9]

$$y_1(\tau) = \frac{y(\tau)}{\dot{y}(t)}$$

satisfies initial condition (5.6) (where the interval $[0, T]$ is replaced by the interval $[t, t']$). According to Theorem 5.1, we have in this case,

$$\det A = 2y_1\left(t'\right) = -2m\frac{\dot{q}_{\rm cl}\left(t'\right)}{V'(q)}. \tag{6.3}$$

In order to find the solution $y_1(\tau)$ of the differential equation $Ay = 0$ for the case $y(t) \neq 0$, observe that the Wronskian $\dot{y}_1 y - \dot{y} y_1$ of its two solutions is constant on $[t, t']$. Using (5.6) we get

$$\dot{y}_1 y - \dot{y} y_1 = y(t),$$

[09] Here we assume that $\dot{y}(t) \neq 0$, so that $V'(q) \neq 0$.

and solving this differential equation we obtain

$$y_1(\tau) = y(\tau)y(t)\int_t^\tau \frac{ds}{y^2(s)}.$$

Thus we get the formula

$$\det A = 2y(t)y\left(t'\right)\int_t^{t'} \frac{d\tau}{y^2(\tau)}, \quad y(\tau) = \dot{q}_{\mathrm{cl}}(\tau) \tag{6.4}$$

which expresses the fluctuating factor in the semi-classical asymptotics of the propagator in terms of the classical motion.

Similarly, for the case of n degrees of freedom, when

$$L = \frac{1}{2}m\dot{\boldsymbol{q}}^2 - V(\boldsymbol{q}),$$

and $V(\boldsymbol{q}) \in C^3\left(\mathbb{R}^n, \mathbb{R}\right)$, we obtain

$$K_\hbar\left(\boldsymbol{q}', t'; \boldsymbol{q}, t\right) \simeq \left(\frac{m}{\pi i\hbar}\right)^{\frac{n}{2}} \frac{1}{\sqrt{\det \boldsymbol{A}}} e^{\frac{i}{\hbar}S(\boldsymbol{q}', t'; \boldsymbol{q}, t)} \tag{6.5}$$

as $\hbar \to 0$, where $\boldsymbol{A} = -D^2 - U(\tau)$ and

$$U(\tau) = \frac{\partial^2 V}{\partial \boldsymbol{q}^2}\left(\boldsymbol{q}_{\mathrm{cl}}(\tau)\right) = \left\{\frac{\partial^2 V}{\partial q_i \partial q_j}\left(\boldsymbol{q}_{\mathrm{cl}}(\tau)\right)\right\}_{i,j=1}^n.$$

6.2. Rigorous derivation. Let $K_\hbar\left(q, q', t\right)$ be the fundamental solution of the Schrdinger equation - the solution of the Cauchy problem (1.3) and (1.5). Since $K_\hbar\left(q', t'; q, t\right) = K_\hbar\left(q', q, T\right)$, where $T = t' - t$, we need to find the asymptotics of a fundamental solution $K_\hbar\left(q, q', T\right)$ as $\hbar \to 0$. The solution of this problem can be divided into two parts.

1. Find the short-wave asymptotics - asymptotics as $\hbar \to 0$ of the solution $\psi_\hbar(q, T)$ of the Cauchy problem for the Schrdinger equation

$$i\hbar\frac{\partial \psi}{\partial t} = -\frac{\hbar^2}{2m}\frac{\partial^2 \psi}{\partial q^2} + V(q)\psi$$

with the initial condition

$$\psi_\hbar(q, t)|_{t=0} = \varphi(q)e^{\frac{i}{\hbar}s(q)},$$

where $s(q), \varphi(q) \in C^\infty(\mathbb{R}, \mathbb{R})$, and the amplitude $\varphi(q)$ has compact support.

2. Using the representation

$$\delta\left(q - q_0\right) = \frac{\varphi(q)}{2\pi\hbar}\int_{-\infty}^{\infty} e^{\frac{i}{\hbar}\xi(q - q_0)}d\xi$$

where φ has compact support and satisfies $\varphi\left(q_0\right) = 1$, express $K_\hbar\left(Q, q_0, T\right)$ as an integral over $d\xi$ of solutions of the Schrdinger equation with initial amplitude $\varphi(q)$ and initial phase $s(q, \xi) = \xi\left(q - q_0\right)$. Use asymptotics from part 1 to evaluate the resulting integral by the stationary phase method as $\hbar \to 0$.

The problem in the first part was solved in Section 6.1 in Chapter 3, so we proceed to the second part. For fixed ξ, let $\psi_\hbar(q, t; \xi)$ be the solution of the Schrdinger equation with the initial amplitude $\varphi(q)$ and the initial phase $s(q) = \xi\left(q - q_0\right)$. By the superposition principle,

$$K_\hbar(Q,q_0,T)=\frac{1}{2\pi\hbar}\int_{-\infty}^{\infty}\psi_\hbar(Q,T;\xi)d\xi \tag{6.6}$$

Let $\gamma(t;q,\xi)$ be the classical trajectory - the solution of Newton's equation (6.2) with the initial conditions

$$\gamma(0;q,\xi)=q \quad \text{and} \quad \dot\gamma(0;q,\xi)=\frac{\xi}{m} \tag{6.7}$$

As in Section 2.3 of Chapter 1, here we assume that the mapping $q\mapsto Q=\gamma(T;q,\xi)$ is a diffeomorphism, and denote by $q=q(\xi,Q)$ the corresponding inverse function,

$$\gamma(T;q(\xi,Q),\xi)=Q \tag{6.8}$$

The asymptotics of $\psi_\hbar(Q,T;\xi)$ as $\hbar\to 0$ is given by formula (6.13) in Section 6.1 of Chapter 3 , where $p(q)=\frac{\partial s}{\partial q}=\xi$, so that the characteristic ending at Q has the initial momentum ξ and the initial coordinate $q=q(\xi,Q)$. Substituting this expression into (6.6), we obtain

$$K_\hbar(Q,q_0;T)\simeq\frac{1}{2\pi\hbar}\int_{-\infty}^{\infty}\varphi(q(\xi,Q))\left|\frac{\partial\gamma}{\partial q}(T;q(\xi,Q),\xi)\right|^{-\frac12}$$
$$\times\exp\left\{\frac{i}{\hbar}\left(S(Q,q(\xi,Q);T)+\xi\left(q(\xi,Q)-q_0\right)\right)\right\}d\xi$$

To apply the stationary phase method to this integral, we need to find the critical points of the function $S(Q,q(\xi,Q);T)+\xi\left(q(\xi,Q)-q_0\right)$. Using the formula

$$\frac{\partial S}{\partial q}(Q,q;T)=-p=-\xi$$

which follows from Proposition 2.2 in Section 2.3 of Chapter 1, we obtain

$$\frac{\partial}{\partial\xi}\left(S(Q,q(\xi,Q);T)+\xi\left(q(\xi,Q)-q_0\right)\right)$$
$$=-\xi\frac{\partial q}{\partial\xi}(\xi,Q)+q(\xi,Q)-q_0+\xi\frac{\partial q}{\partial\xi}(\xi,Q)=q(\xi,Q)-q_0$$

so that a single critical point ξ_0 is determined from the equation $q\left(\xi_0,Q\right)=q_0$. The prefactor in the stationary phase method is given by

$$\varphi\left(q_0\right)\left|\frac{\partial\gamma}{\partial q}\left(T;q_0,\xi_0\right)\frac{\partial q}{\partial\xi}\left(\xi_0,Q\right)\right|^{-\frac12}$$

which can be simplified using $\varphi\left(q_0\right)=1$ and the equation

$$\frac{\partial\gamma}{\partial\xi}+\frac{\partial\gamma}{\partial q}\frac{\partial q}{\partial\xi}=0$$

which follows from (6.8). Thus the final expression for the semi-classical asymptotics is

$$K_\hbar(Q,q_0;T)\simeq\frac{1}{\sqrt{2\pi i\hbar}}\left|\frac{\partial\gamma}{\partial\xi}\left(T;q_0,\xi_0\right)\right|^{-\frac12}e^{\frac{i}{\hbar}S(Q,q_0;T)} \tag{6.9}$$

It is remarkable that formula (6.9), after the identification $Q=q'$ and $q_0=q$, coincides with formula (6.1)! Indeed, they have exactly the same exponential factors, and equality of the corresponding prefactors follows from the following result.

Lemma 6.1. Let $\gamma(t;q,\xi)$ be the classical trajectory with the initial conditions (6.7). Then

$$\frac{\partial\gamma}{\partial\xi}(T;q,\xi)=\frac{1}{2m}\det A, \tag{6.10}$$

where A is the differential operator $-D^2-u(t)$ on the interval $[0,T]$ with Dirichlet boundary conditions, and $u(t)=\frac{V''(\gamma(t,q,\xi))}{m}$.

Proof. Differentiating equation (6.2) with respect to ξ, we obtain that $y(t)=\frac{\partial\gamma}{\partial\xi}(t;q,\xi)$ satisfies the differential equation

$$m\ddot{y}=-V''(\gamma(t,q,\xi))y,$$

so that $Ay=0$. Differentiating initial conditions (6.7) with respect to ξ, we get

$$y(0)=0 \quad \text{and} \quad \dot{y}=\frac{1}{m},$$

so that by Theorem 5.1, $\det A=2my(T)$.

Remark. One can get another remarkable formula for the prefactor in representation (6.9). Namely, differentiating $\frac{\partial S}{\partial q}(Q,q;T)=-\xi$ with respect to Q we get

$$\frac{\partial^2 S}{\partial q\partial Q}=-\frac{\partial\xi}{\partial Q}$$

where $Q=\gamma(T;q,\xi)$. Thus (6.9) can be rewritten entirely in terms of the classical action

$$K_\hbar\left(Q,q_0;T\right)\simeq\frac{1}{\sqrt{2\pi i\hbar}}\left|\frac{\partial^2 S}{\partial q\partial Q}\left(Q,q_0;T\right)\right|^{\frac{1}{2}}e^{\frac{i}{\hbar}S(Q,q_0;T)} \tag{6.11}$$

Remark. When assumptions in Section 2.3 of Chapter 1 are not satisfied, there are several characteristics connecting points q_0 and Q, and the situation becomes more complicated. In this case we have

$$K_\hbar\left(Q,q_0,T\right)\simeq\sum_j\frac{1}{\sqrt{2\pi i\hbar}}\left|\frac{\partial\gamma}{\partial\xi}\left(T;q_0,\xi_j\right)\right|^{-\frac{1}{2}}e^{\frac{i}{\hbar}S(Q,q_0,\xi_j;T)-\frac{\pi i}{2}\mu_j}$$

where ξ_j is the initial momentum, and μ_j is the Morse index of the characteristic $\gamma\left(t;q_0,\xi_j\right)$ (see Section 6.1 in Chapter 3).

The case of n degrees of freedom is considered similarly. Using shortwave asymptotics (6.14) in Section 6.1 of Chapter 3 , we obtain as $\hbar\to 0$,

$$K_\hbar\left(\boldsymbol{Q},\boldsymbol{q}_0,T\right)\simeq(2\pi i\hbar)^{-\frac{n}{2}}\left|\det\left(\frac{\partial\boldsymbol{Q}}{\partial\boldsymbol{\xi}}\left(\boldsymbol{q}_0,\boldsymbol{\xi}_0\right)\right)\right|^{-\frac{1}{2}}e^{\frac{i}{\hbar}S(\boldsymbol{Q},\boldsymbol{q}_0;T)} \tag{6.12}$$

where $\boldsymbol{Q}=\gamma\left(t,\boldsymbol{q}_0,\boldsymbol{\xi}_0\right)$. Using the equation

$$\frac{\partial\boldsymbol{\xi}}{\partial\boldsymbol{Q}}=-\frac{\partial^2 S}{\partial\boldsymbol{q}\partial\boldsymbol{Q}}=-\left\{\frac{\partial^2 S}{\partial q_i\partial Q_j}\right\}_{i,j=1}^{n}$$

(6.12) can be rewritten as

$$K_\hbar\left(\boldsymbol{Q},\boldsymbol{q}_0;T\right)\simeq(2\pi i\hbar)^{-\frac{n}{2}}\left|\det\left(\frac{\partial^2 S}{\partial\boldsymbol{q}\partial\boldsymbol{Q}}\left(\boldsymbol{Q},\boldsymbol{q}_0;T\right)\right)\right|^{\frac{1}{2}}e^{\frac{i}{\hbar}S(\boldsymbol{Q},\boldsymbol{q}_0;T)}$$

Here $\det\frac{\partial^2 S}{\partial\boldsymbol{q}\partial\boldsymbol{Q}}$ is known as the van Vleck determinant.

Problem 6.1. Justify all computations in this section.

8.1.7 7. Notes and references

The path integral approach to quantum mechanics was developed by Feynman in his 1942 Princeton thesis, and was published in [Fey48]. In addition to the classic text [FH65] - the best introduction to Feynman path integrals in configuration space, written from a physics perspective - we also refer the reader to a modern
textbook [DR01]. The Feynman path integral in the phase space was introduced by Feynman [Fey51] in 1951 and by Tobocman [Tob56] in 1956. Nowadays it is a very useful method in quantum field theory (see, e.g., Faddeev's Les Houches lectures [Fad76] and the monograph [FS91]). Our derivation of the Feynman path integral in Section 1 is standard and follows monograph [RS75], which also contains a complete proof of the Kato-Lie-Trotter formula. As we mentioned in Section 1, this approach establishes only the L^2-convergence of finite-dimensional approximations like (1.15) and (1.23) to the propagator. We refer the reader to the paper [Fuj80] for the proof of the convergence in other topologies on functional spaces, and to the monograph [AHK76] for the rigorous definition of Feynman path integrals as infinite-dimensional Fresnel integrals.

In Section 2 we follow the outline in [Ber71a] and [Fad76, FS91], and rigorously derive formulas (2.1) and (2.6) for the *pq* and *qp*-symbols of the evolution operator by using explicit relations between the symbols and the propagator. However, corresponding formulas (2.9) and (2.13) for the Weyl and Wick symbols of the evolution operator were derived only heuristically. As was already emphasized in [Ber71a], in this case one needs to justify formulas (2.8) and (2.11). This nontrivial problem was only recently solved in [Dyn98] for a large class of symbols, and we refer to this paper for further details and references. However, following [Fad76, FS91], we carefully treat boundary conditions for the Wick symbol, deriving the correct expression (2.14) (as opposed to the formula in [Ber71a]). Material in Section 3 is standard, and in our exposition we made a special emphasis on the details of computation related to the Morse index. The formula for the propagator of the harmonic oscillator in Proposition 3.1 is called the Feynman-Souriau formula in [DR01]. The relation between formula (3.6) for the propagator of the harmonic oscillator and the Mehler identity for Hermite-Tchebyscheff polynomials, was stated in [FH65]. For the answer to Problem 3.2 we refer the reader to [Ber71a] (after correcting the typos), and for the elegant heuristic solution of Problem 3.3 - to [FS91].

Besides having a conceptual meaning, the path integral formalism is a very convenient computational tool, since it allows us to use, albeit at a heuristic level, such methods of finite-dimensional integration as change of variables, integration by parts, and stationary phase approximation. There is a vast literature devoted to the applications of Feynman path integration in quantum physics. We only mention a perturbative expansion of the propagator using Feynman diagrams [FH65], which is nowadays the main computational method in quantum mechanics and quantum field theory (see also lectures [Kaz99] for the rigorous treatment of a finitedimensional example). For more applications see [DR01], and references therein.

The idea of computing Gaussian path integrals by evaluating separately the classical contribution and the fluctuation factor goes back to [FH65], and Problems 4.1 and 4.4 are taken from this source. In Section 4 we emphasized the role of the
zeta-function regularized determinants of differential operators, by considering the simplest example of the operator $A = -D^2$. We refer the reader to the textbook [Apo76] for the basic properties of the Riemann zeta-function. Our proof of Lemma 4.1 can be considered as a simplified one-dimensional analog of the derivation of the first Kronecker limit formula given in [Lan87]. For the case of Laplace operators on compact Riemannian manifolds, the definition (4.5) of a regularized determinant $\det' A$ (under the name analytic torsion) was given in [**RS71**], and the operator zeta-function $\zeta_A(s)$ was introduced in [MP49]. A similar notion of a perturbation determinant goes back to M.G. Krein [Kre62]; according to Problem 2.6 in Section 2.2 of Chapter 3, the transition coefficient $a(\sqrt{\lambda})$ is the perturbation determinant of $H - \lambda I$,

where H is a one-dimensional Schrdinger operator. We also note that regularized determinants of differential operators have been extensively used in quantum field theory. The corresponding definition was given by V.A. Fock in 1937 and J. Schwinger in 1951, and is similar to (4.5). It is currently known [IZ80] as the Fock-Schwinger proper time method.

In general, the proof of meromorphic continuation of the zeta-function $\zeta_A(s)$ of an elliptic operator A, and its regularity at $s = 0$, uses the theory of complex powers A^{-s}, developed in [See67] (or the short-time asymptotics $t \to 0$ of $\operatorname{Tr} e^{-At}$ - the trace of a heat kernel of A - when A is non-negative [Gil95]). In Section 5 we are using an elementary approach to the short-time asymptotics of the heat kernel, which is based on the large n asymptotics of the eigenvalues of the corresponding boundary value Sturm-Liouville problems. The monograph [LS91] contains all the facts used in Sections 5.1 and 5.2. The coefficients $a_{-\frac{1}{2}}$ and a_0 in formula (5.4), and in their analogs for the periodic case, are called Seeley coefficients. Our proof of the key relation (5.13) and its analog for the periodic case uses Wronskian identities (5.11), and goes back to the papers [Fad57, BF60] on the trace identities for onedimensional Schrdinger operators (see also Problem 2.6 in Section 2.2 of Chapter 3). The theorem that "the operator trace is equal to the matrix trace", used in Sections 5.1 and 5.2, as well as the properties of the Fredholm determinant, can be found in the classic monograph [GK69]. Problem 5.1– the Gelfand-Levitan trace identity – is taken from the paper [GL53] (see also [Dik58] for its generalization). Properties of the Hurwitz zeta-function, used in Section 5.3, are proved in [Apo76]. For the general approach to characteristic determinants of the n-th order differential operators on the interval with matrix coefficients and Dirichlet or periodic boundary conditions, we refer to [BFK91, BFK95].

Our exposition in Section 6 follows [GS77], with simplifications arising from considering the case of one degree of freedom. Lemma 6.1 establishes the equivalence between the heuristic approach in Section 6.1 using path integrals, and the rigorous approach in Section 6.2 using short-wave asymptotics. We refer to [GS77] and [MF81] for the details. Also, see [Foc78] for the relation between the van Vleck determinant and canonical transformation in classical mechanics, and [DR01] for the examples.

8.1.8 Path Integral Formalism

вывод интеграла по траекториям

метод происходит в измерениях на каждой поверхности.?????
это эквивалентно вставке полного набора наблюдаемых.
итак, разобьем на N интервалов наш интервал времени

$$\left\langle q_F \left| e^{-iHT} \right| q_I \right\rangle = \left\langle q_F \left| e^{-iH\delta t} e^{-iH\delta t} ... e^{-iH\delta t} \right| q_I \right\rangle$$

Теперь воспользуемся тем фактом, что $|q\rangle$ образует полный набор состояний, то есть $\int dq|q\rangle\langle q| = 1$.

Вставим 1 между всеми этими множителями $e^{-iH\delta T}$ и запишем

$$\begin{gathered}\left\langle q_F \left| e^{-iHT} \right| q_I \right\rangle = \\ = \left(\prod_{j=1}^{N-1} \int dq_j\right) \left\langle q_F \left| e^{-iH\delta t} \right| q_{N-1} \right\rangle \left\langle q_{N-1} \left| e^{-iH\delta t} \right| q_{N-2} \right\rangle ... \\ \cdots \left\langle q_2 \left| e^{-iH\delta t} \right| q_I \right\rangle\end{gathered}$$

$$\begin{gathered}\left\langle q_{j+1} \left| e^{-i\delta t\left(\hat{p}^2/2m\right)} \right| q_j \right\rangle = \int \frac{dp}{2\pi} \left\langle q_{j+1} \left| e^{-i\delta t\left(\hat{p}^2/2m\right)} \right| p \right\rangle \langle p|q_j\rangle = \\ = \int \frac{dp}{2\pi} e^{-i\delta t\left(p^2/2m\right)} \langle q_{j+1}|p\rangle \langle p|q_j\rangle = \\ = \int \frac{dp}{2\pi} e^{-i\delta t\left(p^2/2m\right)} e^{ip(q_{j+1}-q_j)}\end{gathered}$$

Вычисляя интеграл по p, получаем

$$\left\langle q_{j+1}\left|e^{-i\delta t\left(\hat{p}^2/2m\right)}\right|q_j\right\rangle=\left(\tfrac{-i2\pi m}{\delta t}\right)^{1/2}e^{\left[im(q_{j+1}-q_j)^2\right]/2\delta t}=$$
$$=\left(\tfrac{-i2\pi m}{\delta t}\right)^{1/2}e^{i\delta t(m/2)\left[(q_{j+1}-q_j)^2/\delta t\right]^2}$$

Подставляя это выражение в (3), приходим к

$$\left\langle q_F\left|e^{-iHT}\right|q_I\right\rangle=\left(\frac{-i2\pi m}{\delta t}\right)^{N/2}\prod_{j=0}^{N-1}\int dq_j e^{i\delta t(m/2)}\sum_{j=1}^{N-1}\left[\left(q_{j+1}-q_j\right)/\delta t\right]^2$$

с $q_0\equiv q_I$ и $q_N\equiv q_F$

$$\int Dq(t)=\lim_{N\to\infty}\left(\frac{-i2\pi m}{\delta t}\right)^{N/2}\prod_{j=1}^{N-1}\int dq_j$$

Таким образом, мы получили представление в виде интеграла по траекториям

$$\left\langle q_F\left|e^{-iHT}\right|q_I\right\rangle=\int Dq(t)e^{i\int\limits_0^T dt\frac{1}{2}m\dot{q}^2}$$

$$\int dq_F\int dq_I\left\langle F|q_F\right\rangle\left\langle q_F\left|e^{-iHT}\right|q_I\right\rangle\left\langle q_I|I\right\rangle$$

или, если смешать обозначения Шредингера и Дирака, в виде

$$\int dq_F\int dq_I\Psi_F\left(q_F\right)^*\left\langle q_F\left|e^{-iHT}\right|q_I\right\rangle\Psi\left(q_I\right)$$

$$Z=\int Dq(t)e^{-\int\limits_0^T dt\left[\frac{1}{2}m\dot{q}^2+V(q)\right]}$$

связь интеграла по траекториям с измерениями

пока что думаю, на каждом этапе мы измеряем.

наивный подсчет траекторий

вспомним из научпопа эксперимент с двумя щелями и запишем это все количественно.
сперва давайте добавим одну щель.
потом вторую.
суммируется вот так вот

О проблемах с нестрогим подходом

(пока не въехал, в чем проблема делать как мы делали в квантмехе? там что-то говорят про это, потом узнаю еще раз)

О строгом подходе

(по идее из теории меры тут ответ может быть запишу. пока не планирую этим заниматься, потому что не хочу с математиками общаться.)

О схожести интеграла по траекториям в квантмехе и КТП (??)

(подумаю, хз)

8.2 Path Integral Formulation of QM: Advanced Ideas

8.2.1 Typical Path Integral by Kiselev

нерелятивистская частица через интеграл по траекториям

Рассмотрим эволюцию состояния $|\Psi(t')\rangle$, заданного в начальный момент времени t' в координатном представлении

$$|\Psi(t')\rangle = \int |q'\rangle \, \mathrm{d}q' \Psi(q', t'), \quad \Psi(q', t') = \langle q'|\Psi(t')\rangle,$$

где q'-обобщенная координата (для простоты-в одномерном случае). Тогда согласно общему формализму состояние в момент времени t получается в результате действия оператора эволюции $\hat{U}(t, t')$

$$|\Psi(t)\rangle = \hat{U}(t, t') |\Psi(t')\rangle,$$

где

$$\hat{U}(t, t') = \hat{\mathrm{T}} \exp\left\{ -\frac{\mathrm{i}}{\hbar} \int_{t'}^{t} \hat{H} \, \mathrm{d}t \right\}, \quad \hat{U}(t', t') = 1.$$

Здесь оператор эволюции записан в общем виде как символ "Т-экспоненты", т.е. понимается в виде предела произведения бесконечно малых сдвигов по времени, строго упорядоченных в порядке возрастания моментов времени, а нормировка записана с учетом ненулевого значения исходного момента времени.

В соответствии с таким разбиением интервала $t - t'$ на N отрезков, так что $\mathrm{d}t = (t - t')/N$, при $N \to \infty$ бесконечно малый сдвиг по времени $t' \to t_1 = t' + \mathrm{d}t$ дает

$$|\Psi(t' + \mathrm{d}t)\rangle = \int \exp\left\{ -\frac{\mathrm{i}}{\hbar} \hat{H}(\hat{p}, \hat{q}, t_1) \, \mathrm{d}t \right\} |q'\rangle \, \mathrm{d}q' \Psi(q', t') + \mathcal{O}\left(\mathrm{d}t^2\right),$$

и, подставляя единичные операторы в координатном и импульсном представлениях, находим

$$\hat{H}(\hat{p}, \hat{q}, t) = \frac{\hat{p}^2}{2m} + V(\hat{q}, t),$$

очевидно,

$$\langle p|\hat{H}(\hat{p}, \hat{q}, t)|q\rangle = \mathcal{H}(p, q, t)\langle p|q\rangle,$$

где $\mathcal{H}(p, q, t)$ - гамильтониан классической системы. Тогда

$$\begin{aligned}
\left\langle p_1 \left| \exp\left\{ -\frac{\mathrm{i}}{\hbar} \hat{H}(\hat{p}, \hat{q}, t_1) \, \mathrm{d}t \right\} \right| q' \right\rangle &= \left\langle p_1 \left| \left\{ \mathbb{1} - \frac{\mathrm{i}}{\hbar} \hat{H}(\hat{p}, \hat{q}, t_1) \, \mathrm{d}t \right\} \right| q' \right\rangle + \mathcal{O}\left(\mathrm{d}t^2\right) = \\
&= \langle p_1|q'\rangle \left\{ 1 - \frac{\mathrm{i}}{\hbar} \mathcal{H}(p_1, q', t_1) \, \mathrm{d}t \right\} + \mathcal{O}\left(\mathrm{d}t^2\right) = \\
&= \langle p_1|q'\rangle \exp\left\{ -\frac{\mathrm{i}}{\hbar} \mathcal{H}(p_1, q', t_1) \, \mathrm{d}t \right\} + \mathcal{O}\left(\mathrm{d}t^2\right).
\end{aligned}$$

Пренебрегая в этих выражениях членами второго порядка малости по инкременту времени, введем обозначение $q_0 = q'$ и в (13.3) учтем, что

$$\langle q_1|p_1\rangle = \mathrm{e}^{\mathrm{i}p_1 q_1/\hbar}, \quad \langle p_1|q_0\rangle = \mathrm{e}^{-\mathrm{i}p_1 q_0/\hbar},$$

и в простейшем случае, когда гамильтониан есть сумма кинетической и потенциальной энергии, найдем

$$|\Psi\left(t_1\right)\rangle = \int |q_1\rangle \, \frac{\mathrm{d}q_1 \, \mathrm{d}p_1}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}[p_1(q_1-q')-\mathcal{H}(p_1,q_0,t_1)\mathrm{d}t]} \mathrm{d}q' \Psi\left(q', t'\right).$$

В общем случае при переходе от классического гамильтониана к квантовому возникает проблема упорядочивания некоммутирующих между собой наблюдаемых - координаты и импульса - так, чтобы оператор гамильтониана

конечно, приводит к различным квантовым обобщениям классической теории.

анзатц Вейля (????)

Что касается самой процедуры упорядочивания, то укажем стандартную схему - анзатц Вейля. Пусть дана классическая величина как функция импульса и координаты, $F(p,q)$. Вычислим ее фурье-образ

$$\mathcal{F}(u,v) = \int \mathrm{d}p \, \mathrm{d}q \mathrm{e}^{\mathrm{i}(up+vq)} F(q,p)$$

и построим оператор, упорядоченый по Вейлю, как обратный образ с операторами в экспонентах

$$\hat{F}(\hat{p},\hat{q}) = \int \frac{\mathrm{d}u \, \mathrm{d}v}{(2\pi)^2} \mathrm{e}^{-\mathrm{i}(u\hat{p}+v\tilde{q})} \mathcal{F}(u,v).$$

Этот оператор заведомо эрмитов, если исходная величина F вещественна, а значит, $\mathcal{F}^*(u,v) = \mathcal{F}(-u,-v)$, и эрмитово сопряжение оператора $\hat{F}$ после замены переменных интегрирования $u \mapsto -u, v \mapsto -v$ приводит к искомому тождеству $\hat{F} = \hat{F}^\dagger$.

Вычислим, например, оператор, соответствующий упорядочиванию Вейля для величины $F = pq$. Преобразование Фурье для линейной функции

$$\int \mathrm{d}p p \mathrm{e}^{\mathrm{i}up} = \frac{\partial}{\mathrm{i}\partial u} \int \mathrm{d}p \mathrm{e}^{\mathrm{i}up} = 2\pi \frac{\partial}{\mathrm{i}\partial u} \delta(u),$$

дает фурье-образ

$$\mathcal{F}(u,v) = -(2\pi)^2 \delta'(u)\delta'(v).$$

Тогда обратное преобразование приводит к

$$\hat{F}(\hat{p},\hat{q}) = -\int \frac{\mathrm{d}u \, \mathrm{d}v}{(2\pi)^2} \mathrm{e}^{-\mathrm{i}(u\hat{p}+v\hat{q})} (2\pi)^2 \delta'(u)\delta'(v) = -\left. \frac{\partial^2}{\partial u \partial v} \mathrm{e}^{-\mathrm{i}(u\hat{p}+v\hat{q})} \right|_{u=v=0},$$

так что элементарное разложение экспоненты в ряд до членов квадратичных по аргументу

$$\begin{aligned} \mathrm{e}^{-\mathrm{i}(u\hat{p}+v\hat{q})} &= 1 - \mathrm{i}(u\hat{p}+v\hat{q}) - \frac{1}{2}(u\hat{p}+v\hat{q})^2 + \ldots \\ &= 1 - \mathrm{i}(u\hat{p}+v\hat{q}) - \frac{1}{2}\left(u^2\hat{p}^2 + uv\hat{p}\hat{q} + uv\hat{q}\hat{p} + v^2\hat{q}^2\right) + \ldots \end{aligned}$$

приводит к эрмитово самосопряженному оператору

$$\hat{F} = \frac{1}{2}(\hat{p}\hat{q} + \hat{q}\hat{p})$$

Ясно также, что для функций коммутирующих наблюдаемых, например, для функции, зависящей только от импульса или только от координаты, упорядочивание Вейля

сводится к стандартной подстановке в функцию соответствующего оператора (импульса или координаты). В общем случае вычислим матричный элемент

$$H_{10} = \left\langle q_1 | \hat{H}(\hat{p},\hat{q},t) | q_0 \right\rangle = \int \langle q_1|p\rangle \frac{\mathrm{d}p}{2\pi\hbar} \left\langle p | \hat{H}(\hat{p},\hat{q},t) | q_0 \right\rangle$$

в схеме с упорядочиванием по Вейлю. Для этого следует записать гамильтониан в виде

$$\hat{H}(\hat{p},\hat{q},t) = \int \frac{\mathrm{d}u\ \mathrm{d}v}{(2\pi)^2} \mathrm{e}^{-\mathrm{i}(u\hat{p}+v\hat{q})} \mathcal{H}(u,v,t),$$

где $\mathcal{H}(u,v,t)$ - фурье-образ функции Гамильтона в классической механике $\mathcal{H}(p,q,t)$. Следовательно, необходимо найти матричный элемент

$$\left\langle p \left| \mathrm{e}^{-\mathrm{i}(u\tilde{p}+v\tilde{q})} \right| q_0 \right\rangle,$$

который легко вычисляется согласно общей формуле Бейкера-Хаусдорфа для произведения экспонент операторов A и B, коммутирующих с их коммутатором $[A,B]$,

$$\mathrm{e}^{A+B} = \mathrm{e}^{-\frac{1}{2}[A,B]} \mathrm{e}^{A} \mathrm{e}^{B}$$

так что

$$\mathrm{e}^{-\mathrm{i}(u\hat{p}+v\hat{q})} = \mathrm{e}^{-\frac{1}{2}\mathrm{i}^2 uv[\hat{p},\hat{q}]} \mathrm{e}^{-\mathrm{i}u\hat{p}} \mathrm{e}^{-\mathrm{i}v\hat{q}}$$

и в силу $[\hat{p},\hat{q}] = -\mathrm{i}\hbar$ получаем

$$\left\langle p \left| \mathrm{e}^{-\mathrm{i}(u\hat{p}+v\tilde{q})} \right| q_0 \right\rangle = \mathrm{e}^{-\frac{1}{2}\mathrm{i}\hbar uv} \mathrm{e}^{-\mathrm{i}up} \mathrm{e}^{-\mathrm{i}vq_0} \langle p|q_0\rangle.$$

Значит,

$$H_{10} = \int \frac{\mathrm{d}p}{2\pi\hbar} \frac{\mathrm{d}u\ \mathrm{d}v}{(2\pi)^2} \mathrm{e}^{\frac{\mathrm{i}}{\hbar}p(q_1-q_0-\hbar u)} \mathrm{e}^{-\mathrm{i}vqq_0} \mathrm{e}^{-\frac{1}{2}\mathrm{i}\hbar uv\mathcal{H}(u,v,t).}$$

Однако интегрирование по импульсу дает дельта-функцию для переменной u:

$$\int \frac{\mathrm{d}p}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}p(q_1-q_0-\hbar u)} = \delta\left(q_1 - q_0 - \hbar u\right),$$

а значит, под интегралом в H_{10} можно произвести интегрирование по u, что приводит к следующему преообразованию аргумента в экспоненте

$$v\left(q_0 + \frac{1}{2}\hbar u\right) = v\left(q_0 + \frac{1}{2}\left(q_1 - q_0\right)\right) = \frac{1}{2}v\left(q_1 + q_0\right).$$

Тогда, если ввести срединную точку

$$\bar{q}_1 = \left(q_1 + q_0\right)/2,$$

То

$$\begin{aligned} H_{10} &= \int \mathrm{d}u \delta\left(q_1 - q_0 - \hbar u\right) \int \frac{\mathrm{d}v}{(2\pi)^2} \mathrm{e}^{-\mathrm{i}\varepsilon\bar{q}_1} \mathcal{H}(u,v,t) = \\ &= \int \mathrm{d}u \int \frac{\mathrm{d}p}{2\pi\hbar} \mathrm{e}^{\hbar p(q_1-q_0)-\mathrm{i}up} \int \frac{\mathrm{d}v}{(2\pi)^2} \mathrm{e}^{-\mathrm{i}v\bar{q}_1} \mathcal{H}(u,v,t) = \\ &= \int \frac{\mathrm{d}p}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}p(q_1-q_0)} \int \frac{\mathrm{d}u\ \mathrm{d}v}{(2\pi)^2} \mathrm{e}^{-\mathrm{i}(up+v\bar{q}_1)} \mathcal{H}(u,v,t). \end{aligned}$$

В итоге берется обратное преобразование Фурье для классических величин

$$\int \frac{\mathrm{d}u\ \mathrm{d}v}{(2\pi)^2} \mathrm{e}^{-\mathrm{i}(up+v\bar{q}_1)} \mathcal{H}(u,v,t) = \mathcal{H}\left(p,\bar{q}_1,t\right),$$

и Таким образом, упорядочивание Вейля приводит к тому, что классический гамильтониан берется в срединной точке координаты. В остальном проведенный

ранее вывод матричного элемента гамильтониана в виде суммы кинетической энергии, которая задается импульсом, и потенциала, который задается в точке начального положения частицы (в данном случае это q_0) остается в силе. Итак, бесконечно малый шаг эволюции от начального состояния $|\Psi(t')\rangle$ давал нам при $t_1 = t' + \mathrm{d}t$ в случае, когда гамильтониан - это сумма потенциальной и кинетической энергии, следующее состояние:

$$|\Psi(t_1)\rangle = \int |q_1\rangle \frac{\mathrm{d}q_1\ \mathrm{d}p_1}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}[p_1(q_1-q')-\mathcal{H}(p_1,q_0,t_1)\mathrm{d}t]} \mathrm{d}q' \Psi(q',t'),$$

которое в случае гамильтониана общего вида с упорядочиванием по Вейлю, как мы показали, переходит в

$$|\Psi(t_1)\rangle = \int |q_1\rangle \frac{\mathrm{d}q_1\ \mathrm{d}p_1}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}[p_1(q_1-q_0)-\mathcal{H}(p_1,\bar{q}_1,t_1)\mathrm{d}t]} \mathrm{d}q_0 \Psi(q_0,t'),$$

где $q_0 = q'$, а $\bar{q}_1 = (q_1+q_0)/2$ - срединная точка. Но это же выражение можно записать с помощью оператора эволюции $\hat{U}(t_1,t')$,

$$|\Psi(t_1)\rangle = \int |q_1\rangle \mathrm{d}q_1 \left\langle q_1 \left| \hat{U}(t_1,t_0) \right| q_0 \right\rangle \mathrm{d}q_0 \Psi(q_0,t'),$$

где $t_0 = t'$ - время начального состояния, так что

$$\left\langle q_1 \left| \hat{U}(t_1,t_0) \right| q_0 \right\rangle = \int \frac{\mathrm{d}p_1}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}[p_1(q_1-q_0)-\mathcal{H}(p_1,\bar{q}_1,t_1)\mathrm{d}t]}.$$

Разбиение интервала эволюции на бесконечно малые отрезки длиной $\mathrm{d}t \to 0$ точками $t_k = t_{k-1} + \mathrm{d}t$ при $k = \overline{\{1,N\}}$ и $t_N = t$ позволяет построить конечное состояние в момент времени t как результат последовательного действия операторов эволюции на каждом бесконечно малом шаге,

$$\begin{aligned} |\Psi(t)\rangle = \lim_{N\to\infty} \hat{U}(t_N,t_{N-1}) ... \hat{U}(t_{k-1}+\mathrm{d}t,t_{k-1}) ... \hat{U}(t_1,t_0) |\Psi(t_0)\rangle = \\ = \lim_{N\to\infty} \int |q_n\rangle \mathrm{d}q_N \left\langle q_N \left| \hat{U}(t_N,t_{N-1}) \right| q_{N-1} \right\rangle ... \mathrm{d}q_k \left\langle q_k \left| \hat{U}(t_k,t_{k-1}) \right| q_{k-1} \right\rangle ... \\ ... \mathrm{d}q_1 \left\langle q_1 \left| \hat{U}(t_1,t_0) \right| q_0 \right\rangle \mathrm{d}q_0 \langle q_0 | \Psi(t_0) \rangle . \end{aligned}$$

Введем срединные точки

$$\bar{q}_k = \frac{1}{2}(q_k + q_{k-1}).$$

Тогда матричный элемент $\left\langle q_k \left| \hat{U}(t_k,t_{k-1}) \right| q_{k-1} \right\rangle$ может быть вычислен точно так же, как мы получили раньше (13.11) путем интегрирования по импульсу, Т. е.

$$\left\langle q_k \left| \hat{U}(t_k,t_{k-1}) \right| q_{k-1} \right\rangle = \int \frac{\mathrm{d}p_k}{2\pi\hbar} \mathrm{e}^{\frac{\mathrm{j}}{\hbar}[p_k(q_k-q_{k-1})-\mathcal{H}(p_k,\bar{q}_k,t_k)\mathrm{d}t]}.$$

Повторим описанную процедуру расчета матричного элемента оператора эволюции $\hat{U}(t_k+\mathrm{d}t,t_k)$ на каждом бесконечно малом шаге эволюции, т.е. N раз, что согласно (13.12) и (13.13) приведет нас к выражению

$$|\Psi(t)\rangle = \lim_{N\to\infty} \int |q_N\rangle \prod_{k=1}^{N} \frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar} \mathrm{e}^{\frac{\hbar}{k}[p_k(q_k-q_{k-1})-\mathcal{H}(p_k,\bar{q}_k,t_k)\mathrm{d}t]} \mathrm{d}q_0 \Psi(q_0,t'),$$

где $q_0 = q'$. Введем скорость

$$\dot{q}\left(t_k\right) = \frac{q_k - q_{k-1}}{\mathrm{d}t}.$$

Под интегралом произведение экспонент можно записать в виде

$$\prod_{k=1}^{N} \mathrm{e}^{\frac{i}{\hbar}\left[p_k \tilde{q}_k \ \mathrm{d}t - \mathcal{H}\left(p_k, \bar{q}_k, t_k\right)\mathrm{d}t\right]} = \exp\left\{\frac{\mathrm{i}}{\hbar}\sum_{k=1}^{N}\left[p_k \dot{q}_k \ \mathrm{d}t - \mathcal{H}\left(p_k, \bar{q}_k, t_k\right)\mathrm{d}t\right]\right\},$$

и в этом выражении мы, во-первых, введем обозначения

$$p\left(t_k\right) = p_k, \quad q\left(t_k\right) = q_k, \quad \dot{q}\left(t_k\right) = \dot{q}_k,$$

во-вторых, заметим, что срединную координату можно записать в виде

$$\bar{q}_k = \frac{1}{2}\left(q_k + q_{k-1}\right) = \frac{1}{2}\left(q\left(t_k\right) + q\left(t_k\right) - \dot{q}\left(t_k\right)\mathrm{d}t\right) = q\left(t_k\right) - \frac{1}{2}\dot{q}\left(t_k\right)\mathrm{d}t = q\left(t_k\right) + \mathcal{O}(\mathrm{d}t),$$

и поэтому в пределе $N \to \infty$ и $\mathrm{d}t \to 0$ выражение (13.16) сводится к

$$\exp\left\{\frac{\mathrm{i}}{\hbar}\int_{t'}^{t}[p(t)\dot{q}(t) - \mathcal{H}(p(t), q(t), t)]\mathrm{d}t\right\} = \exp\left\{\frac{\mathrm{i}}{\hbar}S\left(t', t\right)\right\},$$

где $S\left(t', t\right)$-классическое действие на траектории с граничными условиями для координат $q\left(t'\right) = q' = q_0$ и $q(t) = q_N$. При этом действие рассматривается в фазовом пространстве $\{q(t), p(t)\}$, где точки $\{q_k, p_k\}$ задают положение частицы в момент времени t_k. Тогда множество точек $\{q_k\}$ образует ломаную траекторию, которая показана на рис. 19. Точно так же можно говорить и о траектории в импульсном пространстве $\{p_k\} \to p(t)$. Другое дело, что формально действие зависит от скорости в координатном пространстве: $\dot{q}_k$ входят в интеграл для действия в (13.16), - а для импульсов тоже можно определить скорость изменения импульса $\dot{p}_k = \left(p_k - p_{k-1}\right)/\mathrm{d}t$ при $k = \overline{\{2, N\}}$, но эта скорость не входит в интеграл для действия в явном виде. Это обусловлено, во-первых, тем, что уравнения движения включают в себя только первую производную импульса по времени, а во-вторых, чисто формально

$$\int p(t)\dot{q}(t)\mathrm{d}t = -\int \dot{p}(t)q(t)\mathrm{d}t + \int \mathrm{d}\{p(t)q(t)\}$$

так что можно рассматривать и траектории в импульсном пространстве, но тогда нужно ставить и другую квантовую задачу: вычислять матричный элемент оператора эволюции не в координатном пространстве, а в импульсном: $\left\langle p'' \left| \hat{U}\left(t, t'\right) \right| p' \right\rangle$ В итоге мы получаем выражение для состояния

$$|\Psi(t)\rangle = \lim_{N\to\infty}\int |q_N\rangle \, \mathrm{d}q' \Psi\left(q', t'\right) \prod_{k=1}^{N} \frac{\mathrm{d}q_k \ \mathrm{d}p_k}{2\pi\hbar} \mathrm{e}^{\frac{\lambda}{k}S(t', t)}$$

Рассмотрим матричный элемент $\langle q''|\Psi\left(t''\right)\rangle = \Psi\left(q'', t''\right)$ - волновую функцию состояния в момент времени $t = t''$, (обратите внимание на пределы изменения номера интервала эволюции k)

$$\langle q''|\Psi\left(t''\right)\rangle = \lim_{N\to\infty}\int \langle q''|q_N\rangle \, \mathrm{d}q' \Psi\left(q', t'\right) \frac{\mathrm{d}q_N \ \mathrm{d}p_N}{2\pi\hbar} \prod_{k=1}^{N-1} \frac{\mathrm{d}q_k \ \mathrm{d}p_k}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}S(t', t'')}$$

Но поскольку

$$\int \langle q''|q_N\rangle \, \mathrm{d}q_N = 1$$

итоговый результат -

$$\langle q''|\Psi\left(t''\right)\rangle = \int \mathrm{d}q' \Psi\left(q',t'\right) \lim_{N\to\infty} \int \frac{\mathrm{d}p_N}{2\pi\hbar} \prod_{k=1}^{N-1} \frac{\mathrm{d}q_k \; \mathrm{d}p_k}{2\pi\hbar} \mathrm{e}^{\frac{i}{k}S(t',t'')}.$$

Сравнивая эту формулу с общим выражением

$$\langle q''|\Psi\left(t''\right)\rangle = \int \mathrm{d}q' \Psi\left(q',t'\right) \langle q'' \left|U\left(t'',t'\right)\right| q'\rangle$$

заключаем, что матричный элемент оператора эволюции задается формулой

$$= \lim_{N\to\infty} \int \frac{\mathrm{d}p_N}{2\pi\hbar} \prod_{k=1}^{N-1} \frac{\mathrm{d}q_k \; \mathrm{d}p_k}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}S(t',t'')} = \int \mathcal{D}q\mathcal{D}p \mathrm{e}^{\frac{i}{\hbar}S(t',t'')},$$

где мера интегрирования получается при предельном переходе к континууму

$$\mathcal{D}q\mathcal{D}p = \lim_{N\to\infty} \frac{\mathrm{d}p_N}{2\pi\hbar} \prod_{k=1}^{N-1} \frac{\mathrm{d}q_k \; \mathrm{d}p_k}{2\pi\hbar},$$

и поэтому фейнмановский интеграл по траекториям называют также континуальным интегралом. Подчеркнем, что матричный элемент - это число или числовая функция, т.е. классический объект, и континуальный интеграл построен из чисто классических величин: траекторий и действия на них. При этом траектории движения в координатном пространстве имеют граничные условия

$$q\left(t'\right) = q', \quad q\left(t''\right) = q'',$$

а траектории в импульсном пространстве не имеют каких-либо определенных граничных условий, и это есть следствие квантового рассмотрения: в классической механике траектории в фазовом пространстве имеют определенные граничные условия - начальные и конечные точки на фазовой плоскости, а в квантовой механике в силу соотношения неопределенности координатаимпульс выбор граничной точки координаты означает, что граничная точка по импульсу имеет бесконечно больпую неопределенность, т.е. произвольна. Физический смысл такого представления матричного элемента в виде интеграла по траекториям прост: амплитуда перехода из точки $q\left(t'\right) = q'$ в точку $q\left(t''\right) = q''$ есть суперпозиция амплитуд для всех траекторий из истодной точки 6 конечнуо, так что каждая траектория 6 фазобом пространв фейнмановской формулировке прослеживается явная связь с принципом Гюйгенса в теории волн, а именно, интеграл по траекториям устанавливает квантовый аналог принципа Гюйгенса.

Классическая механика неявно предполагает, что «прямая траектория, удовлетворяющая уравнениям движения, следующим из принципа экстремальности действия с фиксированными конечными точками, с вероятностью, рабной единице, проходит через бсе промежсточные точки экстремальной траектории.

Проиллюстрируем это утверждение на простейшем примере свободной нерелятивистской частицы (потенциал равен нулю, а все экстремальные траектории - прямые линии в декартовых координатах). Согласно принципу экстремума действия в классической механике между точками начала и конца траектории, q' и q'', соответственно, за время от t' до t'' пролегает единственная прямая траектория.

Рассмотрим промежуточный момент времени $\tilde{t} : t' < \tilde{t} < t''$. Классическая траектория в этот момент времени проходит через точку $\tilde{q} = q(\tilde{t})$. Если теперь рассмотреть распространение частицы последовательно за два интервала времени от t' до $\tilde{t}$ с граничными точками q' и $\tilde{q}$ и от $\tilde{t}$ до t'' с граничньми точками $\tilde{q}$ и q'', то для экстремальной траектории действие

$$S\left(q'', t''; q', t'\right) = S\left(q'', t''; \tilde{q}, \tilde{t}\right) + S\left(\tilde{q}, \tilde{t}; q', t'\right),$$

а произведение амплитуд для отрезков траекторий в точности дает амплитуду для исходной экстремальной траектории. При этом действие удовлетворяет уравнениям Гамильтона-Якоби, в которых берутся частные производные по координатам и времени конечных точек. Итак, разбиение классической траектории промежуточной точкой эволюции на этой же траектории приводит к тождественному преобразованию для амплитуды вероятности, которая соответствует этой экстремальной траектории. Это и значит, что в классике фактически считается, что все промежуточные точки траектории безусловно проходятся частицей с вероятностью, равной единице. Однако в самой постановке задачи заложено условие, что известны только начальная и конечная точки эволюции, а промежуточная точка на траектории не регистрируется. Поэтому допустимо рассмотреть построенные нами выше два интервала эволюции, но с промежуточной точкой в момент времени $\tilde{t}$, отличной от координаты на классической экстремальной траектории в этот момент времени, $\tilde{q}' = \tilde{q} + \delta\tilde{q} \neq \tilde{q}$. Мы можем теперь поставить задачу найти две экстремальные траектории для этих граничных точек. Для свободной частицы задача элементарна: траектория - это ломаная линия из двух отрезков, проходящих по заданным конечным точкам. При этом действие для каждого их этих отрезков опять будет удовлетворять уравнениям Гамильтона-Якобби, но их сумма, конечно, будет отличаться от экстремального действия для траектории в целом, Так как действие для ломаной траектории пе совнадает уравнениям Гамильтона-Якоби по конечной точке эволюции сразу следует, что амплитуды вероятности как для классической экстремальной траектории, так и для ломаной траектории, удовлетворяют одному и тому же уравнению Шрёдингера, которое как раз и строилось по этому принципу!

Поэтому в квантовой механике поступают более аккуратно: если наблюдаются только конечные точки на траектории, необходимо рассмотреть вероятность того, что в промежуточных точках частица движется по экстремальной траектории классической механики или имеют место отклонения от этой классической траектории в промежуточных точках эволюции. Эти отклонения - квантовые флуктуации траектории. Для решения задачи - вероятности флуктуаций в квантовой механике вычисляется амплитуда вероятности прохождения частицы через произвольные промежуточные точки траектории между конечными точками в виде суперпозиции амплитуд вероятности для каждой промежуточной траектории, причем амплитуда A_k на k-той траектории определяется действием S_k на этой траектории,

$A_k = \exp\left\{\mathrm{i}S_k/\hbar\right\}$. Сами промежуточные точки возникают при малых шагах эволюции от исходной точки в промежуточные так, что действие на каждой такой квантовой флуктуации траектории удовлетворяет уравнениям Гамильтона-Якоби (уравнения в частных производных по координатам и времени промежуточной точки), и поэтому, как следствие, суперпозиция амплитуд удовлетворяет уравнению Шрёдингера на каждом шаге эволюции от исходной точки к промежуточным и от промежуточных к последующим промежуточным, и наконец, от промежуточных к конечной точке эволюции. Результат суммирования - амплитуда вероятности - может отличаться от единственного вклада, который в сумму дает классическая экстремальная траектория, и тогда говорят, что причина такого отличия - вклад квантовых флуктуаций траекторий.

Квантовая теория опирается на возможность квантовых флуктуаций траектории.

Она утверждает, что вероятность таких флуктуаций описывается количественно, и способна предсказать вероятностные характеристики квантовых флуктуаций. Это означает, что предсказуемы величины для ансамбля идентичных квантовых состояний. Если ансамбля нет, то возможно говорить только о тех характеристиках, вероятность которых в квантовой теории равна нулю, например, атом водорода с вероятностью, равной нулю, может иметь энергию связи, отличную от допустимого спектра энергий атома водорода в квантовой теории. Вообще же, рассмотрение квантовой системы вне ансамбля никак не связано с волновой функцией, и следовательно, всякое понятие о редукции волновой функции для системы вне ансамбля лишено какоголибо физического смысла и обычно вводится математиками для операций с элементами гильбертова пространства вне связи с реальностью.

Последовательная эволюция квантового состояния от t' до t, а затем от t до t'', где $t'' > t > t'$, выражается в операторном тождестве

$$\hat{U}\left(t'', \tilde{t}\right) \hat{U}\left(\tilde{t}, t'\right) = \hat{U}\left(t'', t'\right).$$

Продемонстрируем, что это может быть зашисано и в терминах интегралов по траекториям. Для этого сначала разобьем интервал от $t' = t_0$ до $\tilde{t} = t_N$ с помощью N точек t_k, как мы это уже делали раньше, и запишем матричный элемент оператора эволюции на этом интервале времени в форме (13.20),

$$\left\langle q_N \left| U\left(\tilde{t}, t'\right) \right| q' \right\rangle = \lim_{N\to\infty} \int \mathrm{e}^{\frac{i}{\hbar}\sum\limits_{k=1}^{N}[p_k\dot{q}_k\ \mathrm{d}t - \mathcal{H}(p_k,\bar{q}_k,t_k)\mathrm{d}t]} \frac{\mathrm{d}p_N}{2\pi\hbar} \prod_{k=1}^{N-1} \frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar} =$$

$$= \lim_{N\to\infty} \int \frac{\mathrm{d}p_N}{2\pi\hbar} \prod_{k=1}^{N-1} \frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}S(t',\bar{t})} = \int \mathcal{D}q\mathcal{D}p \mathrm{e}^{\frac{i}{\hbar}S(t',\bar{t})}, \quad (13.24)$$

где скорость координаты согласно (13.15)

$$\dot{q}_k = \frac{q_k - q_{k-1}}{\mathrm{d}t},$$
