$$kT = 4 \cdot 10^{-5\text{В}}$$

То есть это слабое поле, при этом все атомы сидят в нижнем положении по энергии, а сама задача стоит о поглощении а не испускании. А дальше смотрим на известную нам из теории структуру линий для этого эффекта из теории и просто записываем разницы энергий:

$$E_B = \mu B\left(g_1 m_{j1} - g_2 1 m_{j2}\right)$$
$$E_B = \mu B \begin{cases} 4/3 \cdot 1/2 - 2 \cdot (-1/2) = 5/3 \\ 4/3 \cdot (-1/2) - 2 \cdot (-1/2) = 1/3 \\ 4/3 \cdot (-3/2) - 2 \cdot (-1/2) = -1 \end{cases}$$

(!!!! с температурой еще разберусь, в 1ю часть занесу!!!!)

О3.1-6.22

В отсутствии магнитного поля газ поглощает электромагнитное излучение с длиной волны $\lambda = 500$ нм, соответствующее переходу из основного состояния $^2P_{1/2}$ в возбужденное $^2D_{3/2}$. Как изменится спектр поглощения этого газа в окрестности этой длины волны при наложении магнитного поля $B = 2$ кГс при температуре, близкой к комнатной? В спектре испускания этого газа в окрестности $\lambda = 500$ нм наблюдается дублет с $\Delta\lambda = 0,5$, соответствующий переходам $^2D_{3/2} \to {}^2P_{1/2}, {}^2D_{3/2} \to {}^2P_{3/2}$.

18.1.19 Basic problems about atoms in fields 2

О3.1-6.23 Расщепление

На сколько компонент расщепится в слабом магнитном поле мультиплет с заданным полным моментом J?

О3.1-6.24 Расщепление

Найти энергетическое расщепление термов атомов группы щелочных металлов, помещенных в слабое магнитное поле.

О3.1-6.25 Расщепление

На сколько компонент расщепится в слабом магнитном поле линия Na, отвечающая переходу $^2F_{7/2} \to {}^2D_{5/2}$?

О3.1-6.26 Расщепление

Найти число компонент сложного эффекта Зеемана линии Na, указанной в предыдущей задаче, которые поляризованы по магнитному полю.

О3.1-6.27 Расщепление

Определить расщепление спектральной линии $^2P_{3/2} \to \to {}^2S_{1/2}$ в слабом магнитном поле. Для натрия эта линия является коротковолновой компонентой ($\lambda = 589,0$ нм) двойной линии D с $\Delta\lambda = 0,6$ нм. Какие магнитные поля в этом случае являются слабыми?

О3.1-6.28 Расщепление

На сколько уровней расщепится в сильном магнитном поле терм с $L = 3$ и $S = 0$? Какова разность энергий соседних уровней?

О3.1-6.29 Расщепление

На сколько компонент расщепится в магнитном поле спектральная линия, связанная с оптическим переходом $L = 3 \to L = 2$ (излучается $E1$-фотон), при простом эффекте Зеемана?

О3.1-6.30 Направления поля

В сильном магнитном поле B при наблюдении в направлении, перпендикулярном полю (поперечный эффект Зеемана), в спектре излучения имеется три линейно поляризованных линии: несмещенная спектральная линия с длиной волны λ и электрическим вектором, направленным вдоль магнитного поля, и две смещенные - с Электрическим вектором $\mathbf{E} \perp \mathbf{B}$. Это излучение пропускается через два скрещенных поляризатора, между которыми находится анизотропная кристаллическая пластинка с заданными Δn и d. Оптическая ось пластины составляет углы 45° с направлениями поляроидов. При какой величине магнитного поля в спектре излучения будут видны лишь две крайние линии?

О3.1-6.31 Дополнительная энергия от поля

Атомарный водород помещен в магнитное поле 2 Тл, много большее характерного поля атома, т. е. магнитного поля атома, действующего на электрон. Определить максимальную дополнительную энергию (в эВ), которую приобретает атом в состоянии с $n = 3$ и нарисовать картину расщепления этого уровня.

О3.1-6.32 Разрешение простого эф. Зеемана

Наблюдается простой поперечный эффект Зеемана в магнитном поле $B = 5000$ Гс. Какова должна быть минимальная длина L дифракционной решетки, чтобы разрешить все линии зеемановского триплета?

О3.1-6.33

При какой минимальной ширине L дифракционной решетки, имеющей $n = 600$ линий/мм, можно разрешить в первом порядке дублет простого эффекта Зеемана для спектральной линии $\lambda = 0,612$ мкм? Напряженность магнитного поля $B = 10$ кГс.

О3.1-6.34

С помощью эшелона Майкельсона наблюдается зеемановское расщепление D-линии натрия в магнитном поле $B = 5000$Гс (сложный эффект). Какова должна быть максимальная толщина 51 d пластины, чтобы эшелон был пригоден для исследования расщепления? Показатель преломления материала пластины $n = 1,5$. Под D-линиями Na понимают две линии нерасщепленного полем дублета $3^2P_{3/2} \to 3^2S_{1/2}$ и $3^2P_{1/2} \to 3^2S_{1/2}$

О3.1-6.35

Определить верхний предел расстояния $L_{\max}$ между зеркалами интерферометра Фабри-Перо, чтобы с его помощью можно было исследовать (без перекрытия спектров разных порядков) простой эффект Зеемана в магнитном поле $B = 1$ Тл.

6.

35. $L_{\max} = \frac{2\pi m_e c^2}{eB} \approx 1,1$ cm.

О3.1-6.36

Какой эффект Зеемана - простой или сложный - наблюдается при расщеплении спектральной линии ${}^1D_2 \to {}^1F_3$ в магнитном поле $B = 10^4$ Гс? В каких пределах должно лежать расстояние L между зеркалами интерферометра Фабри-Перо, чтобы обнаружить и исследовать зеемановское расщепление рассматриваемой линии? Зеркала посеребрены так, что эффективное число отражений между ними $N_{\text{eff}} = 20$.

6.

36. Нормальный (простой), так как рассматриваемая линия - синглет. Разрешающая способность интерферометра $N_{\text{эфф}}$ m должна быть не меньше $\frac{\omega}{\delta\omega}$, где $\delta\omega = \Omega = \frac{eB}{2m_e c}$. Величина $\delta\lambda = \frac{2\pi c}{\omega^2}\delta\omega$ должна быть меньше дисперсионной области λ/m, где $m = L/\lambda$ - порядок спектра. Из этих условий получаем

$$\frac{2\pi m_e c^2}{eBN_{\text{эфф}}} < L < \frac{2\pi m_e c^2}{eB}$$

или в рассматриваемом случае 0,54 мм $< L < 10,7$ мм.

О3.1-6.37

Найти зеемановское расщепление $\Delta\omega$ спектральной линии

6.

37: $\Delta\omega = \frac{eB}{2m_e c}\left(\pm\frac{13}{15}; \pm\frac{11}{15}; \pm\frac{1}{15}\right)$; (6 компонент).

Решение. Определим g-факторы состояний ${}^2D_{3/2}$ и ${}^2P_{1/2}$. Квантовые числа состояния ${}^2D_{3/2}$ соответственно равны $J_1 = 3/2; L_1 = 2; S_1 = 1/2$. Квантовые числа состояния ${}^2P_{1/2}$ соответственно равны $J_2 = 1/2, L_2 = 1, S_2 = 1/2$.

$$g_1 = \frac{3}{2} + \frac{S_1(S_1+1) - L_1(L_1+1)}{2J_1(J_1+1)} = \frac{4}{5}$$

Аналогично, $g_2 = 2/3$. Таким образом, состояние $^2D_{3/2}$ расщепляется в магнитном поле на 4 подуровня (рис. 166) по m_J. Состояние $^2P_{1/2}$ расщепляется по m_J на два подуровня. Поскольку $g_1 \neq g_2$, то спектральная линия расщепляется в магнитном поле B в соответствии с правилами отбора ($\Delta m_J = 0, \pm 1$) на шесть компонент. Это сложный эффект Зеемана. Общая формула для расчета расщепления

$$\omega = \omega_0 + \frac{\mu_{\mathrm{E}} B}{\hbar}\left(g_1 m_{J1} - g_2 m_{J2}\right)$$

или

$$\Delta\omega = \omega - \omega_0 = \frac{eB}{2m_{\mathrm{e}}c}\left(g_1 m_{J1} - g_2 m_{J2}\right) = \Omega\left(\pm\frac{13}{15}; \pm\frac{11}{15}; \pm\frac{1}{15}\right)$$

где Ω - ларморовская частота.

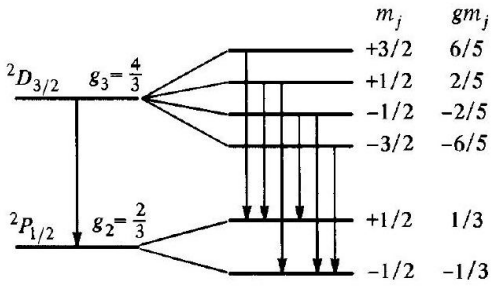

Рис. 166

О3.1-6.38

Цезий принадлежит к числу щелочных металлов. При $P \to S$ - переходе в атомарном цезии испускается дублет, состоящий из двух линий: $\lambda_{\mathrm{I}} = 0,4555$ мкм и $\lambda_2 = 0,4593$ мкм. Найти расщепление термов этого дублета в магнитном поле. Какими формулами описывается в этом случае расщепление линий в магнитном поле с индукцией $B = 3$ Тл: формулами для нормального или аномального эффектов Зеемана?

6.

38. Зеемановское расщепление в магнитном поле $\Delta\lambda_B = \frac{\Delta\S\lambda^2}{2\pi\hbar c} \sim \sim \frac{\mu_5 B\lambda^2}{2\pi\hbar c} \sim 0,1\text{Å} \ll \Delta\lambda = 38\text{Å}$ (расщепление в результате спин-орбитального

взаимодействия). Поэтому поле слабое, эффект аномальный (сложный). Од на линия дублета расщепится на шесть линий, другая - на четыре (см. задачу 6.34).

О3.1-6.39

В спектре лития две первые линии главной серии принадлежат переходам $2^2P_{1/2} \to 2^2S_{1/2}$ и $2^2P_{3/2} \to 2^2S_{1/2}$. Длины волн этих линий равны $\lambda_1 = 0,670780$ мкм и $\lambda_2 = 0,670795$ мкм. Оценить индукцию B магнитного поля, которое создает орбитальное движение электрона в атоме лития в состоянии $2P$.

О3.1-6.40

Так как атом мюония $(\mu^+ e^-)$состоит из двух точечных» частиц, то для него не нужно вводить при расчете уровней энергии никаких поправок на конечный размер ядра. В результате очень точных измерений частоты перехода $1^2S_{1/2} \to 2^2S_{1/2}$, проведенных в 1992 году, было получено значение $v = 2455529$ Гц. Найти из этих данных отношение массы мюона к массе электрона.

О3.1-6.41

Оценить расщепление уровня $n = 2, l = 1$ водорода из-за магнитного взаимодействия спина с его орбитальным движением. Ук а з а и е. Энергия взаимодействия спина с орбитой пропорциональна cos $\hat{\mathrm{l}}\mathrm{s}$, где 1 - орбитальный и $\mathbf{s}$ - спиновый моменты.

18.1.20 Basic problems about atoms in fields 3

О3.1-6.42

Оценить дублетное расщепление первой линии серии Лаймана в спектре излучения водорода, предполагая, что состояние $n = 1$ не расщепляется, а состояние $n = 2$ расщеплено на величину, вычисленную в задаче 6.41.

(дальше не выгружал пока что, хватает над чем подумать.)

6. SOLUTIONS Спин. Атом в магнитном поле. Эффект Зеемана. Магнитный резонанс.

6.

13. $d_{\min} = \mu_{\text{К}} \frac{dB}{dx} \frac{lL}{T} \left(1 + \frac{l}{2L}\right) = 1,79$ см.

6.

14. Пучок разобьется на четыре компоненты. Угол между ними $\Delta\varphi = g\mu_\sigma \frac{dB}{dx} \frac{l}{Am_{\text{p}}v^2} \approx 2 \cdot 10^{-2}$ рад $\approx 1,2°$.

В области магнита на атом действует постоянная сила $F_x = \mu_B \frac{dB}{dx}$, где μ_B - проекция магнитного момента атома на направление поля $B\mu_B = m_J g \mu_{\text{Б}}$, где $g = \frac{3}{2} + \frac{S(S+1)-L(L+1)}{2J(J+1)}$ - фактор Ланде. Из определения спектроскопического символа ${}^{2S+1}F_J$ имеем $S = 3/2; J = 3/2$ и $L = 3$, поэтому g-фактор (фактор Ланде) $g = 2/5$.

6.

15. $\frac{dB}{dx} = \frac{4\pi\hbar}{\mu_{\text{n}} Ld} \sqrt{\frac{T}{2m_{\text{n}}}} \approx 150$Гс/cm.

6.

16* $\theta = \frac{1{,}91\mu_{\text{яд}} B\lambda^2}{2\pi^2\hbar^2} m_{\text{n}} \operatorname{tg}\varphi = 86$ мкрад $\approx 3'$.

Решение. Выберем координатные оси таким образом: поле $\mathbf{B}$ направлено по оси Z, а нормаль к области поля есть ось X (рис. 160). Потенциальная энергия нейтрона в магнитном поле

$$U = -\boldsymbol{\mu}\mathbf{B} = -\mu_{\text{яд}}\, B_z g_{\text{sn}} m_s$$

где $\mu_{\text{яд}}$ - ядерный магнетон Бора, $g_{sn} = -3,82$ - спиновый g-фактор нейтрона (аналог фактора Ланде для свободного электрона),$m_s = \pm\frac{1}{2}$.

Поскольку потенциальная энергия однородна и различна в областях $x < 0$ и $x > 0$, то это приводит к силам, действую- щим на нейтрон в направленнии по нормали к поверхности, а вдоль поверхности силы не действуют. Поэтому касательная компонента импульса нейтрона будет сохраняться ($m \equiv m_{\text{n}}$ масса нейтрона):

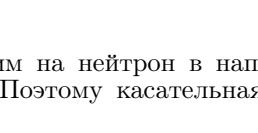

Рис. 160

$$mv_{\text{I}} \sin\varphi = mv_{\text{II}} \sin\psi, \quad \text{т. е.} \quad \frac{\sin\varphi}{\sin\psi} = \frac{v_{\text{II}}}{v_{\text{I}}} = n$$

Получили аналог оптического закона преломления. Из закона сохранения энергии

$$\frac{mv_{\text{I}}^2}{2} = \frac{mv_{\text{II}}^2}{2} \pm U_0 \quad \text{получаем} \quad n = \sqrt{1 \mp \frac{2U_0}{mv_{\text{I}}^2}}$$

Возможен другой способ получения выражения для показателя преломления нейтронов. На рис. 161 приведен график зависимости потенциальной энергии нейтрона $U(x)$ от координаты x. Из рисунка видно, что данную задачу можно рассматривать как задачу о надбарьерном отражении нейтронной волны де Бройля. Волновая функция нейтрона $\psi = Ae^{i\mathbf{kr}} = Ae^{ik_x x}$ ($k_y = \text{const}$ и $k_z = \text{const}$). Используя известный

результат задачи (3.25), за-

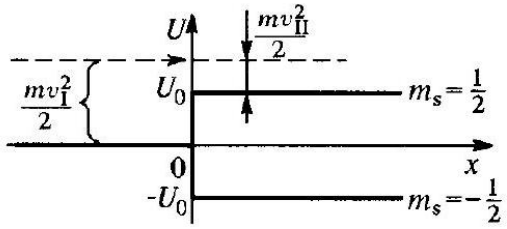

Рис. 161 пишем коэффициент отражения

$$R=\left(\frac{k_{xI}-k_{xII}}{k_{xI}+k_{xII}}\right)^2=\left(\frac{k_I\cos\varphi-k_{II}\cos\psi}{k_I\cos\varphi+k_{II}\cos\psi}\right)^2=\left[\frac{\cos\varphi-(k_{II}/k_I)\cos\psi}{\cos\psi+(k_{II}/k_I)\cos\psi}\right]^2$$

Если сравнить это выражение с соответствующей формулой Френеля, то получим, что

$$n=\frac{k_{II}}{k_I}=\sqrt{1\mp\frac{2mU_0}{\hbar^2k_1^2}}$$

При этом условие непрерывности ψ на границе соответствует условию непрерывности E_t, а условие непрерывности ψ'_x - условию непрерывности H_t. Плотность потока частиц соответствует плотности потока электромагнитной энергии (вектору Пойнтинга).

Оценим отличие n от 1:

$$\frac{2mU_0}{\hbar^2k_I^2}\approx\frac{2m\mu_g\,B}{4\pi^2\hbar^2}\lambda^2=\frac{e^2}{\hbar c}\frac{B}{e}\frac{\lambda^2}{4\pi^2}\approx2\cdot10^{-13}\ll1$$

Здесь было подставлено значение $\mu_{яд}=\frac{e\hbar}{2mc}$. Таким образом,

$$n\approx1\mp\frac{mU_0}{4\pi^2\hbar^2}\lambda^2$$

Это значение, очевидно, разное для разных значений проекции спина нейтрона на направление магнитного поля.

$$\begin{array}{lll}\text{Для} & m_s=\frac{1}{2} & n_+=1-\frac{1{,}91\mu_{яд}\,B\lambda^2}{4\pi^2\hbar^2}m.\\ \text{Для} & m_s=-\frac{1}{2} & n_-=1+\frac{1{,}91\mu_{я}\,B\lambda^2}{4\pi^2\hbar^2}m.\end{array}$$

Из закона преломления получим
или

$$\sin\psi_+=\frac{\sin\varphi}{n_+};\quad\sin\psi_-=\frac{\sin\varphi}{n_-}$$

$$\sin\psi_+-\sin\psi_-=\sin\varphi\frac{n_--n_+}{n_-n_+}$$

При разложении разности синусов двух близких углов появляются очевидные соотношения

$$|\psi_+-\psi_-|\ll\varphi;\quad\psi_++\psi_-\approx2\varphi;\quad n_+n_-\approx1$$

Окончательно

$$\theta=\Delta\psi=\psi_+-\psi_-=(n_--n_+)\,\mathrm{tg}\,\varphi=\frac{1,91\mu_s\,B\lambda^2}{2\pi^2\hbar^2}m\,\mathrm{tg}\,\varphi$$

Подстановка чисел дает $\theta\approx86\cdot10^{-6}$ рад $\approx3'$.

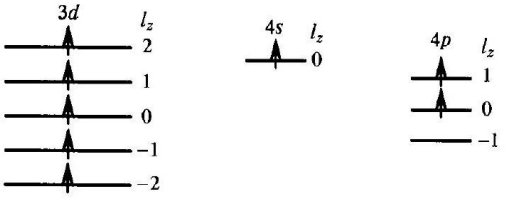

Рис. 162

6.

17: $\mathrm{H}-2; \mathrm{Li}-2; \mathrm{Fe}-1,3,5,7,9; \mathrm{Cl}-2,4,6,8; \mathrm{He}-1,3; \mathrm{Mg}$ - 1,3; $\mathrm{Hg}-1,3; \mathrm{U}-1,3,5,7$.

Решение. Рассмотрим в качестве примера атомы Fe и Cl . Электронная конфигурация атома железа представляет собой заполненные оболочки, как у Ar , сверх которых имеются 8 электронов $-3d^6 4s^2$. Максимально возможный спин атома $S = 1/2 \cdot 8 = 4$. Для этого один электрон из $3d$-оболочки и

один из $4s$-оболочки должны перейти в $4p$-оболочку (рис. 162). При этом мультиплетность $2S+1 = 2 \cdot 4 + 1 = 9$. Если из $4p$-оболочки один электрон вернется в $4s$ или $3d$-оболочку, то он обязан «перевернуть» спин, и общий спин уменьшится на 1 , и получим $2S + 1 = 2 \cdot 3 + 1 = 7$. Возврат второго электрона даст уменьшение еще на 1 , и получим $2S + 1 = 5$.

Шесть электронов в d-оболочке могут дать суммарный спин 2 , 1 и 0 . Получаются мультиплетности 5,3 и 1 (см. ответ).

У атома Cl электронная конфигурация $1s^2 2s^2 2p^5$. Максимальный спин $S = 7 \cdot 1/2 = 7/2$; мультиплетность $2S + 1 = 8$. Это достигается переходом одного электрона в $3s$-оболочку и двух - в $3p$-оболочку и т. д.

6.

18. $\mathrm{Sr}^{+} - 2; \mathrm{Li}^{+} - 1,3; \mathrm{Ca}^{+} - 2; \mathrm{C}^{2+} - 1,3; \mathrm{O}^{++} - 1,3$.

6.

19. 4.

6.

20. $\Delta\mathscr{E} = 2\pi\hbar c\left(\frac{1}{\lambda_1} - \frac{1}{\lambda_2}\right) \approx 2,1 \cdot 10^{-3} \ni$ В; $B = \frac{\Delta\mathscr{E}}{2\mu_{\mathrm{B}}} \approx 1,8 \cdot 10^5$Гс.

6.

21: $\Delta\mathscr{E}_B = \mu_{\mathrm{B}} B\left\{\frac{5}{3}; \frac{1}{3}; -1\right\}$ (три линии).

Решение. Для определения типа эффекта Зеемана (простой или сложный) необходимо сначала оценить величину спин-орбитального расщепления, пользуясь данными задачи,

$$\Delta U_{ls} = 2\pi\hbar c\left(\frac{1}{\lambda_{\mathrm{I}}} - \frac{1}{\lambda_2}\right) \approx \frac{2\pi\hbar c}{\lambda^2}\Delta\lambda \approx 2 \cdot 10^{-2} \ni \text{ В}$$

Далее оценим произведение $\mu_{\mathrm{b}} B \approx 2,9 \cdot 10^{-4}$ эВ. Сравнивая две полученные величины, мы видим, что $\mu_{\mathbf{5}} B \ll \Delta U_{ls}$, т. е. поле является слабым.

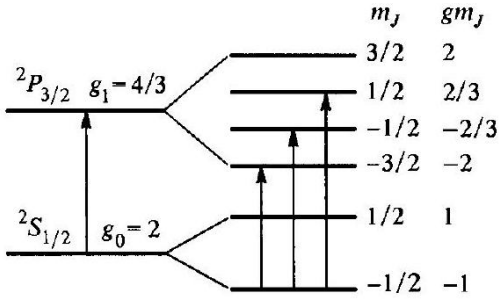

Рис. 163

Вычислим g-факторы состояний $^2P_{3/2}$ и $^2S_{1/2}$:

$$g_1 = \frac{3}{2} + \frac{S(S+1) - L(L+1)}{2J(J+1)} = \frac{3}{2} + \frac{\frac{1}{2}\cdot\frac{3}{2} - 1 \cdot 2}{2 \cdot \frac{3}{2} \cdot \frac{5}{2}} = \frac{4}{3}; \quad g_2 = 2 \quad (\text{ т. к. } L = 0)$$

Определим возможные переходы по формуле

$$\Delta\mathscr{E}_B = \mu_{\mathbf{E}} B\left(g_{\text{Кон}} m_J^{\text{кон}} - g_{\text{нач}}\, m_J^{\text{нач}}\right).$$

Однако в силу очень низкой температуры ($T = 0,5$ K) $kT \approx \approx 4 \cdot 10^{-5}$ В $\ll 2\mu_{\text{Е}}B$ (расщепление терма $^2S_{1/2}$). Таким образом, при этой

температуре заселен только нижний подуровень уровня $^2S_{1/2}\,(m_J = -1/2)$. Поэтому в спектре поглощения возможны только три линии (рис. 163):

$$\Delta\mathscr{E}_B = \mu_{\mathbf{G}}B \left\{ \begin{array}{l} \frac{2}{3} - (-1) = \frac{5}{3} \\ -\frac{2}{3} - (-1) = \frac{1}{3} \\ -2 - (-1) = -1 \end{array} \right.$$

6.

22. В спектре поглощения газа в магнитном поле будут наблюдаться шесть компонент расщепленной линии $^2P_{1/2} \to^2 D_{3/2}$. Это сложный эффект Зеемана ($\mu_{\mathbf{5}}B \ll U_{LS}; \mu_{\mathbf{6}}B \ll kT \approx 0,026$ эВ).

$$\frac{\Delta\mathscr{E}_B}{\mu_E B} = g_1 m_J^1 - g_2 m_J^2 = \left(\pm\frac{13}{15}; \pm\frac{11}{15}; \pm\frac{1}{15}\right).$$

6.

23. $2J + 1$.

6.

24. $\mathscr{E} = \mathscr{E}_0 + \mu_{\mathbf{5}}\text{Bgm}_J$, где $\mathscr{E}$ - энергия атома в магнитном поле, $\mathscr{E}_0$ без поля, $g = \frac{2J+1}{2L+1}$; а $J = \left\{ \begin{array}{l} L + 1/2 \\ L - 1/2 \end{array} \right.$, L-орбитальный момент валентного электрона, $m_J = -J, -J+1, ..., +J$.

6.

25. $\Delta\mathscr{E}_B = \mu_{\text{Е}}B\left(g_1 m_J^{(1)} - g_2 m_J^{(2)}\right) = \left\{\pm 1; \pm\frac{2}{7}; \pm\frac{39}{35}; \pm\frac{11}{7}; \pm\frac{6}{35}; \pm\frac{43}{45};\ \pm\frac{51}{35}; \pm\frac{2}{35}; \pm\frac{47}{35}\right\}\mu_{\text{Б}}\,B$ (18 линий).

6.

26. Это линии с $\Delta m_J = 0$ (колебания вдоль поля В не испытывают действие силы Лоренца). $\Delta\mathscr{S}_B = \left\{\pm\frac{2}{7}; \pm\frac{6}{35}; \pm\frac{2}{35}\right\} - 6$ линий. Такие линии называются л-линиями. Они видны при наблюдении поперек поля и не видны при наблюдении вдоль поля.

6.

27: Решение. Множитель Ланде

$$g = \frac{3}{2} + \frac{S(S+1) - L(L+1)}{2J(J+1)}$$

Для состояния $^2P_{3/2}(J = 3/2, L = 1, S = 1/2)$ этот множитель равен $g_1 = 4/3$; для состояния $^2S_{1/2}(J = 1/2, L = 0, S = 1/2), g_2 = 2$. Смещения расщепленных компонент мультиплета приведены в таблице:

$P_{3/2}$	m_J	$-3/2$	$-1/2$	$+1/2$	$+3/2$
	gm_J	-2	$-2/3$	$+2/3$	$+2$
$^2S_{1/2}$	m_J		$-1/2$	$+1/2$	
	gm_J		-1	$+1$	

Разрешенные переходы между компонентами мультиплетов (компонентами тонкой структуры) $^2P_{3/2}$ и $^2S_{1/2}$ удовлетворяют правилу отбора $\Delta m_J = m_J^{(1)} - m_J^{(2)} = 0, \pm 1$. Остальные переходы сильно подавлены. Разрешенные переходы и соответствующие им номера испускаемых спектральных линий с указанием поляризации (л или σ) приведены в таблице:

Переходы $m_j^{(1)} \to m_J^{(2)}$	Поляризация	$(gm_J)^{(1)} - (gm_J)^{(2)}$	№ линии
$-3/2 \to +1/2$	подавлен		
$-3/2 \to -1/2$	σ	$-2-(-1) = -1$	2
$-1/2 \to +1/2$	σ	$-2/3 - 1 = -5/3$	1
$-1/2 \to -1/2$	π	$-2/3 + 1 = 1/3$	4
$+1/2 \to +1/2$	π	$2/3 - 1 = -1/3$	3
$+1/2 \to -1/2$	σ	$2/3 + 1 = 5/3$	6
$3/2 \to +1/2$	σ	$2 - 1 = 1$	5
$3/2 \to -1/2$	подавлен		

Смещенные линии расположены симметрично относительно несмещенной: три линии смещены влево $(1, 2, 3)$, остальные три - вправо $(4, 5, 6)$. Всего получается шесть смещенных компонент.

Магнитное поле считается слабым, если ларморовская частота $\Omega = \mathrm{e}B/(2m_\mathrm{e}c)$ мала по сравнению с частотой $2\pi c\Delta\lambda/\lambda^2$. Это дает $B \ll \ll \left(4\pi m_\mathrm{e}c^2\Delta\lambda\right)/\left(e\lambda^2\right)$. В этом случае получается сложный эффект Зеемана. Для D-линии натрия должно быть $B \ll 3,7 \cdot 10^5$ Гс. В противоположном случае эффект Зеемана будет простым.

6.

28. $\Delta\mathscr{E}_B = \mu_\sigma B = \hbar\Omega = \hbar\frac{eB}{2mc}$; число уровней равно числу проекций $\mathbf{L}$ на B и равно $2L + \mathbf{1} = 7$.

6.

29. $\Delta\mathscr{E}_B = \mu_\mathbf{G} B\left(\Delta m_L + 2\Delta m_S\right) = \pm\mu_\mathbf{G} B, 0$, т. е. как и должно быть в сильном поле на три компоненты, поскольку для электродипольных переходов $\Delta m_S = 0, \Delta m_L = \pm 1, 0$ (правила отбора).

6.

30: $B = \frac{2\pi m_e c^2}{ed\Delta n}$.

Решение. Из трех линий спектра центральная несмещенная линия не пройдет, если пластинка для нее имеет толщину $m\lambda$.

Боковые линии пройдут, если для их длин волн λ' и λ'' толщина пластинки будет $m\lambda' + \lambda'/2$ и, соответственно, $m\lambda'' - \lambda''/2$. Таким образом, кристаллическая пластинка с заданным d и Δn (рис. 164) должна удовлетворять условию

$$d\Delta n = m\lambda = \left(m + \frac{1}{2}\right)\lambda' = \left(m - \frac{1}{2}\right)\lambda'',$$

где $\lambda' = \frac{2\pi c}{\omega+\Omega}$, а $\lambda'' = \frac{2\pi c}{\omega-\Omega}$ и ларморовская частота $\Omega = \frac{eB}{2m_e c}$. Отсюда

$$m + \frac{1}{2} = \frac{d\Delta n}{2\pi c}(\omega + \Omega); \quad m - \frac{1}{2} = \frac{d\Delta n}{2\pi c}(\omega - \Omega).$$

Вычитая эти равенства, получим

$$1 = \frac{d\Delta n}{2\pi c}2\Omega = \frac{d\Delta n}{2\pi c}\frac{eB}{2m_\mathrm{e}c},$$

откуда найдем искомое магнитное поле

$$B = \frac{2\pi m_e e^2}{\mathrm{e}d\Delta n}.$$

Ответ не зависит ни от длины волны исходной линии, ни от ориентации пластинки относительно поля (рис. 164).

6.

31. В сильном магнитном поле $\mathscr{E} = \mathscr{E}_0 + \mu_5 B\,(m_L + 2m_S)$. Уровень расщепится на 7 подуровней (рис. 165). Максимальная дополнительная энергия $\Delta U = 3\mu_5 B = 3,5 \cdot 10^{-4\text{эВ}}$.

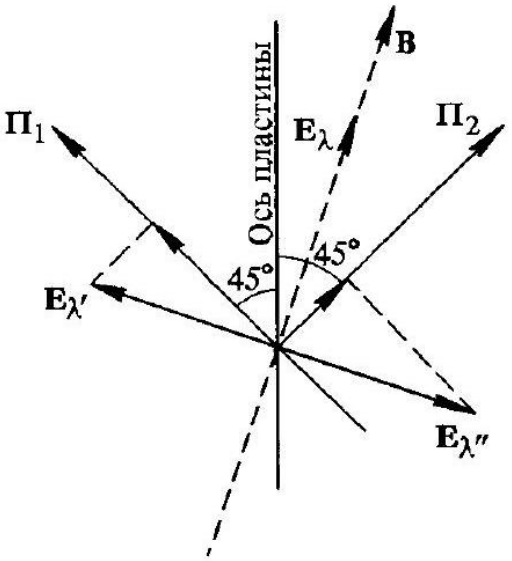

Рис. 164

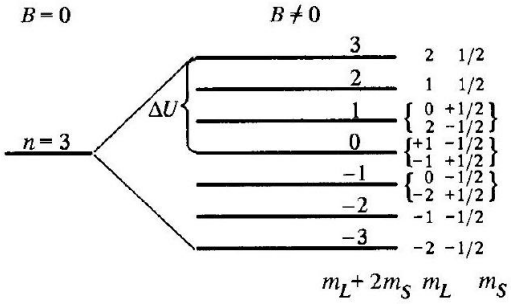

Рис. 165

6.

32. $L = \frac{4\pi m_e c^2}{eB} = 4,3$ cm.

6.

33. $L = \frac{hc}{2n\lambda\mu_5 B} = 2,8$ cm.

6.

34. Одна из линий дублета (переход ${}^2P_{3/2} \to {}^2S_{1/2}$) расщепляется в магнитном поле на 6 компонент $\left(\pm 1; \pm\frac{1}{3}; \pm\frac{5}{3}\right)\Omega$ с расстоянием между крайними компонентами

$$\Delta\omega = \frac{5}{3}\Omega - \left(-\frac{5}{3}\Omega\right) = \frac{10}{3}\Omega,$$

где $\Omega = eB/(2m_e c)$ - ларморовская частота. (Аналогично, но на 4 компоненты $\left(\pm\frac{2}{3}; \pm\frac{4}{3}\right)\Omega$, расщепляется вторая линия дублета - переход ${}^2P_{1/2} \to {}^2S_{1/2}$). Спектральный прибор для исследования расщепления должен не только разрешать расщепленные линии, но и не должен давать перекрытия порядков. Значит, область дисперсии $\Delta\lambda$ должна быть не меньше

$$\lambda\frac{\Delta\omega}{\omega} = \frac{\lambda^2}{2\pi c}\frac{10}{3}\frac{eB}{2m_e c} = \frac{5}{6}\frac{\lambda^2 eB}{\pi m_e c^2}.$$

Подставляя сюда $\Delta\lambda = \lambda/m$, где $m = d(n-1)/\lambda$ - порядок спектра, получим

$$d \leqslant \frac{6\pi m_c c^2}{5eB(n-1)} \approx 2,6 \text{ см}.$$

6.

39. $B \approx \frac{\pi\hbar c\Delta\lambda}{\mu_{\text{Б}}\lambda^2} \approx 3\kappa\text{Гс}$.

6.

40. $\frac{m_\mu}{m_e} = \left(\frac{3R_\infty}{4\cdot 2\pi\hbar\nu} - 1\right)^{-1} = 204,585$.

6.

41. $\Delta_{sl} \approx \frac{e^2\hbar^2}{2m_e^2c^2n^6r_1^3} ls\cos\hat{\mathbf{s}} \approx 0,91\cdot 10^{-17}$ эрг $\approx 0,57\cdot 10^{-5}{}_{\ni\text{В}}$.
$\Delta\mathscr{E}_{sl}$ можно найти приближенно. Для этого надо перейти в систему координат, связанную с электроном. В этой системе вращающийся протон создает магнитное поле $\mathbf{B}$, с которым и взаимодействует спиновой магнитный момент μ_s. Для оценки достаточно считать, что векторы $\mathbf{B}$ и $\boldsymbol{\mu}_{\text{s}}$ коллинеарны (точный расчет должен был бы учесть, что $\cos\hat{\mathbf{s}} \neq 1$). Укажем, что

$$\frac{(\mathbf{sl})}{r^3} = |\mathbf{s}|\cdot|1|\frac{\cos\mathbf{sl}}{n^6r_1^3}, \quad \text{где} \quad |\mathbf{s}| = s; \quad |\mathbf{1}| = l; \quad \cos\widehat{\mathbf{sl}} = \pm\mathbf{1}$$

Тогда

$$\Delta\S_{sl} \approx \frac{e^2\hbar^2}{2m_{\text{e}}^2c^2n^6r_1^3} ls\cos\hat{\mathbf{S}} \approx 0,91\cdot 10^{-17}\rho\Gamma \approx 0,57\cdot 10^{-5} \ni \text{ В}$$

При точном расчете

$$\Delta\mathscr{E}_{sl} = \frac{e^2\hbar^2}{4m_{\text{e}}^2c^2}\frac{1}{r_1^3}\frac{j_{\text{I}}(j_1+1) - j_2(j_2+1)}{n^3l\left(l+\frac{1}{2}\right)(l+1)} = \frac{\mu_{\text{B}}^2}{8r_1^3} = 4,53\cdot 10^{-5} \ni \text{ В}$$

где $n=2; l=1; j_1=3/2; j_2=1/2; s=1/2$, где r_1 - радиус первой боровской орбиты.
Отличие в 8 раз!

6.

42. $\Delta\lambda = 2\pi\hbar c\left(\frac{1}{10,2-\Delta_2} - \frac{1}{10,2+\Delta_1}\right) \approx \frac{hc}{(10,2)^2}(\Delta_1+\Delta_2) \approx 0,0004$, где 10,2 эВ - значение энергии кванта нерасщепленной первой линии серии Лаймана (переход $n=3\to n=1$); $\Delta_1 = \frac{1}{32}\frac{\mu_{\text{Б}}^2}{r_1^3}; \Delta_2 = \frac{2}{32}\frac{\mu_{\text{Б}}^2}{r_1^3}$.

6.

43. $\frac{\Delta\varrho_{Sl}|_{J+1,J}}{\Delta_{sl}|_{J,J-1}} = \frac{J+1}{J}$.

6.

44: Решение. Зеемановское расщепление должно быть больше доплеровского уширения за счет теплового движения атомов (в основном, водорода) и вращения звезды, т.е.

$$\frac{\Delta\omega}{\omega_0} = \frac{2\mu_\Sigma B}{\hbar\omega_0} \geqslant \left(\frac{\Delta\omega}{\omega_0}\right)_{\text{тепл}} + \left(\frac{\Delta\omega}{\omega_0}\right)_{\text{вращ}} = \frac{v_{\text{тепл}}}{c} + \frac{v_{\text{вращ}}}{c} \approx \frac{v_{\text{тепл}}}{c}.$$

Окончательно получим

$$B \geqslant \frac{\hbar\omega_0}{2\mu_{\mathrm{F}}c}\sqrt{\frac{2kT}{m_{\mathrm{p}}}} \approx 1,8\kappa\Gamma\mathrm{c}$$

6.

45. $B = \frac{Ry}{\mu_{\mathrm{G}}}\left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right)\frac{1}{n_1+n_2-2} \approx \frac{Ry}{\mu_{\mathrm{G}}}\frac{1}{n^4} \approx 2,3\cdot 10^5\Gamma\mathrm{c}$, где $n \approx n_2 \approx n_1 = 10$.

6.

46. $\Delta\mathscr{E} \approx \frac{m_e c^2}{1024}\alpha^4 \approx 1,4\cdot 10^{-6}{}_{\text{эВ}}$.

6.

47. $(J+I) : (J+I-1) : (J+I-2) : \ldots$ - правило интервалов Ланде.

6.

48. $\lambda = \frac{2\pi\hbar c}{|\Delta\mathscr{E}_{\text{ст}}|} = 28,1$ см, где $\Delta\mathscr{E}_{\text{ст}} = 2g_{sp}g_s\frac{\mu_{\text{ядм}}\mu_{\text{Б}}}{r_{\text{Б}}^3}, g_s = 2$ - спиновый g-фактор электрона. Экспериментальное значение $\lambda = 21$ см. Этот результат получается и при теоретическом рассмотрении с учетом реального (неоднородного) распределения плотности спинового магнитного момента электрона.

Заметим однако, что для оценки величины сверхтонкого расщепления атомных состояний обычно считается, что это диполь-дипольное взаимодействие магнитных моментов электронов и ядра. В данной задаче это маг нитное взаимодействие электрона и протона, что приводит к оценке $\Delta\& = 2\frac{g_{\text{sp}}\,\mu_{\text{gд}}\,\mu_5}{r_6^3}$, и это соответствует длине волны перехода $\lambda \simeq 1$ м. Эта оценка достаточно сильно отличается от экспериментального значения $\lambda = 21$ cm. Ясно, что это обусловлено грубостью приближения, поскольку электронная орбита здесь считается классической. На самом деле электронная плотность «размазана» в объеме порядка $\frac{4}{3}\pi r_{\text{Б}}^3$. Если считать, как указано в условии, что электронная плотность однородна по объему шара радиусом $r_{\text{Б}}$, то модельная оценка и эксперимент отличаются намного меньше.

6.

49. $\Delta\mathscr{E}_{\text{сТ}} = \mathscr{E}_{\text{сТ}}(F=2) - \mathscr{E}_{\text{сТ}}(F=1) = 4g_j g_{s\text{p}}\frac{\mu_{\text{g}}\mu_{\text{E}}}{n^6 r_{\text{G}}^3} = 0,9\cdot 10^{-7}$ эВ, где $n = 2, g_j = \frac{4}{3}$ - фактор Ланде для электрона.

$\mathbf{F} = \mathbf{j} + \mathbf{s}_{\text{p}}, F = \left\{\begin{array}{l} 3/2+1/2=2 \\ 3/2-1/2=1 \end{array}\right.$ – это полный угловой момент атома.

6.

50. $\Delta\varrho_{\mathbf{H}} \approx 0,59\cdot 10^{-5}$ эВ. Радиус позитрония в $2p$-состоянии $r = 8r_1$, где r_1 - радиус боровской орбиты. Отношения частоты излучения позитрония к частоте излучения атомарного водорода

$$\frac{\nu_{\text{поз}}}{\nu_{\text{H}}} = \frac{m_{\text{p}}}{8^3\cdot 2,79 m_{\text{e}}} \approx 1,285, \quad \text{откуда} \quad \Delta\mathscr{E}_{\text{поз}} \approx 0,76\cdot 10^{-5}\ \text{В}$$

6.

51* Такое состояние невозможно. Если бы оно было возможно, то радиус электронной орбиты в таком «атоме» был бы много меньше компотоновской длины волны нейтрона.

Решение. При нерелятивистском рассмотрении полная энергия системы должна быть отрицательной:

$$\mathscr{E} = \frac{p^2}{2m_{\text{e}}} - \frac{\mu_{\text{e}}\mu_{\text{n}}}{r^3} < 0$$

Из соотношения неопределенностей $pr \sim \hbar$ выразим импульс электрона через r и подставим в предыдущее неравенство:

$$\mathscr{E} \approx \frac{\hbar^2}{2m_{\mathrm{e}}r^2} - \frac{\mu_{\mathrm{e}}\mu_{\mathrm{n}}}{r^3}$$

Радиус стационарной орбиты электрона оценим из минимума энергии $\frac{d\mathscr{E}}{dr} = 0$, откуда $r = \frac{3\mu_{\mathrm{e}}\mu_{\mathrm{n}}}{\hbar^2}m_{\mathrm{e}} \approx 8 \cdot 10^{-16}$ см $\ll \frac{\hbar}{m_{\mathrm{n}}c} \simeq 2 \cdot 10^{-14}$ см - комптоновской длины волны нейтрона. Последнее очевидное неравенство показывает неправомерность рассмотрения нейтрона в этой задаче как точечной частицы.

6.

52. $B = \frac{3\pi^2\hbar^2}{4\mu m d^2}$.

6.

53. $B \geqq \frac{m^2ce^3}{\hbar^3} \approx 10^9$Гс.

6.

54. $\mathcal{E} \approx \pm\frac{\mu^2}{r^3} \approx 3,2 \cdot 10^{-24}$ эрг $= 2 \cdot 10^{-12}$ эВ.

6.

55. $p_{\mathrm{ат}} = \frac{2\pi\hbar c}{\lambda E} \approx 4,3 \cdot 10^{-18}$ ед. СГСЭ; $l = \frac{p_{\mathrm{ат}}}{e} \approx 1$Å.

6.

56. Решение. Поскольку в сильных полях LS-связь разрывается, можно считать, что векторы **L** и **S** прецессируют вокруг вектора **B** независимо. Таким образом, сохраняющимися величинами являются L^2, S^2, L_z, S_z и

$$\langle U_{SL}\rangle = A\langle \mathbf{SL}\rangle = A\left\langle (L_xS_x + L_yS_y + L_zS_z)\right\rangle = A\left\langle (L_zS_z)\right\rangle = Am_Lm_S$$

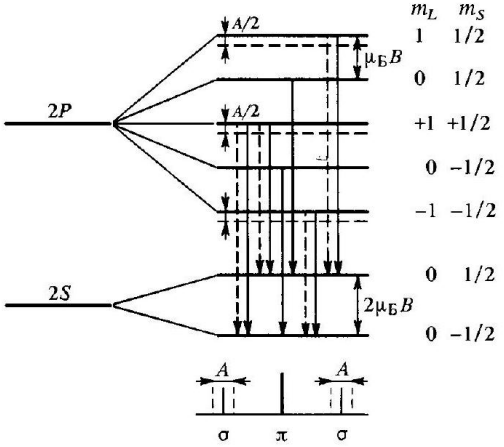

Рис. 167

Расщепление линий показано штрихами на рис. 167. В спектре излучения л-линия не расщепляется (у нее $m_L = 0$), а б-линии становятся дублетами, раздвинутыми на величину $A/\hbar\left[\mathrm{c}^{-1}\right]$. Экспериментально эффект наблюдался на Li .

6.

57. $g = 0,34; \mu = g\mu_{\text{яд}}\, I = 0,85\mu_{\text{яд}}$.

6.

58. Сигнал в магнитном поле пропорционален разности заселенности подуровней $\Delta n \approx N\frac{\mu B}{kT}$. Увеличение сигнала $a = \frac{A_0}{A_1} = \frac{\Delta n_0}{\Delta n_1} \approx \frac{B_0}{B} = 100$.

6.

59. Сигнал в резонансе $\propto (h\nu)^2_{\text{рез}}\, \frac{N_0}{kT} \propto \nu^2$, т. е. увеличится в четыре раза.

6.

60. $T_{\min} \approx \frac{h^2\nu^2 I^2}{B^2 k d^3} \approx 0,6 \cdot 10^{-7}$ K.

Решение. В методе адиабатического размагничивания поле B переводит решетку в парамагнитное состояние, в котором магнитные моменты ядер ориентируются по полю B. При этом $kT_{\text{нач}} \ll \mu_{\text{яд}}\, B$. При снятии внешнего поля происходит разупорядочение системы и понижение ее температуры. Выделившееся тепло отводится, и процесс можно повторить. При полном разупорядочении можно получить $T \approx 0$ K. Однако этого не происходит, поскольку есть взаимодействие, приводящее систему к установлению антиферромагнитного упорядочения. В принципе наличие энергии взаимодействия любой природы устанавливает предел на минимально достижимую темнературу $T_{\min}$, определяемую условием

$$kT_{\min} \approx \mathscr{E}_{\text{В3}}$$

Установление антиферромагнитного упорядочения в цепочке ядер ^{63}Cu (рис. 168) происходит за

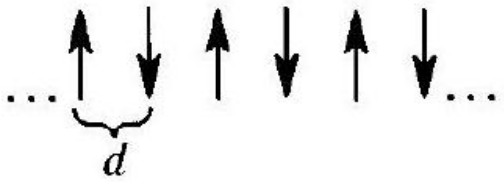

Рис. 168 счет магнитного (диполь-дипольного) взаимодействия атомов. В приближении ближайших соседей энергия взаимодействия $\mathscr{E}_{\text{вз}} = \mu^2/d^3$. Из условия на ядерный магнитный резонанс следует, что магнитный момент ядра $^{63}\text{Cu}\mu = g_I\mu_{\text{яд}}\, I$, где $g_I = \frac{h\nu}{\mu_{\text{яд}}\, B}$, откуда энергия взаимодействия атомов

$$\mathscr{E}_{\text{В3}} = \frac{g_I^2\mu_{\text{g}\mu}^2 I}{d^3} = \left(\frac{h\nu I}{B}\right)^2 \frac{1}{d^3}$$

а также

$$T_{\min} = \left(\frac{h\nu I}{B}\right)^2 \frac{1}{kd^3} \approx 0,6 \cdot 10^{-7} \text{ K}$$

6.

61* $v_{\text{рез}} = 1,6\text{ГГ}$.

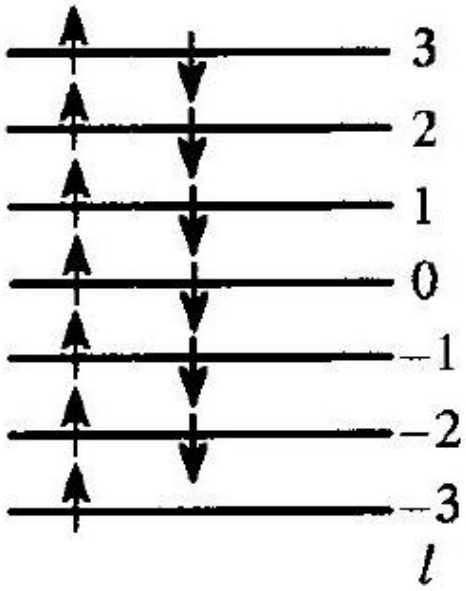

Рис. 169

Решение. Поскольку электронные оболочки $5s$ и $5p$ полностью заполнены, то парамагнитные свойства иона определяются 13 электронами незаполненной $4f$-оболочки. В соответствии с первым правилом Хунда эти электроны располагаются так, чтобы образовать максимальный спин $S_{\max}$, и при данном $S_{\max}$ - максимальный орбитальный момент $L_{\max}$ (рис. 169). На f-оболочке ($l = 3$) имеется $2(2l + 1) = 14$ мест, тринадцать из которых заняты. Поскольку в квантовой физике за велечину момента принимают значение его максимальной проекции на заданную ось (в един ницах $\hbar$), то

$$(S_z)_{\max} = \frac{1}{2}; \quad (L_z)_{\max} = 3 + 2 + 1 + 0 - 1 - 2 = 3$$

В соответствии со вторым правилом Хунда

$$J = L + S = 3 + \frac{1}{2} = \frac{7}{2}.$$

Вычислим g-фактор

$$g = \frac{3}{2} + \frac{S(S+1) - L(L+1)}{2J(J+1)} = \frac{8}{7}.$$

Резонансную частоту ЭПР найдем по формуле

$$v_{\text{рез}} = \frac{g\mu_{\text{E}}B}{h} = 1,6\text{ГГ}_{\text{L}}.$$

6.

62. $v = 1,12\text{ГГ}(S = 1; L = 5; J = 4; g = 4/5)$.

6.

63. $M_0 = \frac{N_{\text{A}}\rho h\nu}{B_{\text{рез}}\,A} = 2980$ Гс, где A - атомная масса Dy .

6.

64. $M_0 = \frac{N_{\text{A}}\rho}{A} g\mu_{\mathbf{6}} J = 2723$ Гс, где A - атомная масса эрбия Er , $v = \frac{g\mu B}{h} \approx 1,68$ ГГц, где $g = 6/5$.

6.

65. Для полученной конфигурации атома $S_{\max} = 3/2, \quad L_Z^{\max} = 2$, $J = 1/2$, т. е. состояние $^4D_{1/2}$. При этом $g = 0$, что означает, что $\boldsymbol{\mu}_{\text{сумм}} \perp \mathbf{J}$. Таким образом $\mu_{\text{J}} = 0$, а значит, пучок не расщепится.

6.

66.

$$\mu = \frac{LkT}{B\hbar N_{\text{A}}} = 2,62\mu_{\text{яД}} = 13,25 \cdot 10^{-24} \text{ эрг /Гс.}$$

Решение. Молярная масса тефлона $n \cdot 50$ г/моль, поэтому образец тефлона массой 50 г содержит $1/n$ молей тефлона. В этом образце в соответствии с химической формулой содержится $N_0 = 2N_{\text{A}} n\frac{1}{n} = 2N_{\text{A}}$ атомов фтора. На

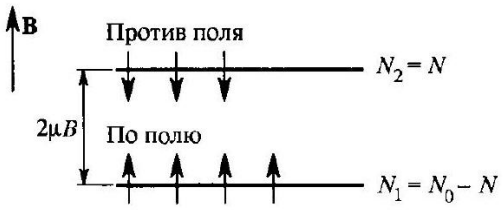

Рис. 170 рис. 170 изображена схема расщепления уровней ядра фтора в магнитом поле. Так как спин ядра равен 1/2, то получается двухуровневая система. Из полного числа N_0 ядер на верхнем уровне находятся N_2 ядер фтора. Пусть $N_2 = N$. На нижнем уровне остается $N_1 = N_0 - N$ ядер. Разность $\Delta N = N_1 - N_2 = N_0 - 2N$. В соответствии с распределением Больцмана

$$\frac{N_2}{N_1} = \frac{N}{N_0 - N} = \exp\left(-\frac{\Delta\mathscr{E}}{kT}\right),$$

где $\Delta\mathscr{E} = 2\mu B, \mu$ - магнитный момент ядер фтора.
Из этого следует

$$N = \frac{N_0 \exp(-\Delta\mathscr{E}/kT)}{1 + \exp(-\Delta\delta/kT)}$$

$$\Delta N = N_0 - 2N = N_0 \frac{1 - \exp\left(-\frac{\Delta\delta}{kT}\right)}{1 + \exp\left(-\frac{\Delta\varepsilon}{kT}\right)} \approx N_0 \frac{\frac{\mu B}{kT}}{1 - \frac{\mu B}{kT}} \approx \frac{\mu B}{kT} N_0.$$

Здесь мы учли, что $\frac{\mu_{\text{яд}} B}{kT} = 1,4 \cdot 10^{-6} \ll 1$ и поэтому разложим экспоненты в ряд. При снятии поля половина ядер из ΔN разориентируется, т. е. образец получит момент импульса

$$L = \frac{\Delta N}{2}\hbar = \frac{1}{2}\frac{\mu B\hbar}{kT} N_0 = \frac{\mu B\hbar N_{\text{A}}}{kT}$$

откуда и определим магнитный момент ядра фтора

$$\mu = \frac{LkT}{B\hbar N_{\text{A}}} = 13,25 \cdot 10^{-24} \ni \text{ г/Гс} = 2,62\mu_{\text{яд}}$$

где $\mu_{\text{яд}} = 5,05 \cdot 10^{-24}$ эрг/Гс - ядерный магнетон Бора. При написании этой формулы мы учли, что магнитный момент ядра $^{19}_{9}$ F определяется неспаренным протоном, находящемся в состоянии $2s_{1/2}$ (это один протон сверх заполненной оболочки из 8 протонов). Поскольку в этом состоянии орбитальный момент $l = 0$, то у этого протона угловой момент является чисто спиновым и равен $\hbar/2$. При перевороте спина угловой момент изменяется на $\hbar$.

6.

67. $B > \frac{\Delta\varepsilon}{2\mu} = 1,7 \cdot 10^9$Гс.

6.

68* $\alpha \approx 3 \cdot 10^{-6}$.

Решение. В магнитном поле атомы водорода поляризуются из-за того, что проекция их магнитного момента на направление поля принимает два значения

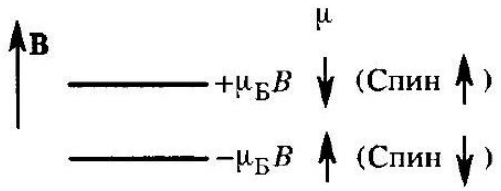

Рис. 171 $\pm\mu_{\text{Б}}$. Как в любой двухуровневой системе, полное число атомов $N_0 = N_\uparrow + N_\downarrow$. Отношение числа атомов H со спином по полю $N\uparrow$ к числу атомов со спином против поля $N\downarrow$ (рис. 171).

отсюда

$$\frac{N_\downarrow}{N_\uparrow} = \exp\left(-\frac{2\mu B}{kT}\right)$$

$$N_\uparrow = \frac{N_0}{1+\exp\left(-\frac{2\mu_{\text{E}}B}{kT}\right)}; \quad N_\downarrow = \frac{N_0 \exp\left(-\frac{2\mu_{\text{E}}B}{kT}\right)}{1+\exp\left(-\frac{2\mu_{\text{E}}B}{kT}\right)}$$

Поскольку $N_\downarrow < N_\uparrow$, то число атомов с антипараллельными спинами равно $2N_\downarrow$, а их относительное число

$$\alpha = \frac{2N_\downarrow}{N_0} = \frac{2\exp\left[-2\mu_{\text{E}}B/(kT)\right]}{1+\exp\left[-2\mu_{\text{E}}B/(kT)\right]} \approx 2\exp\left(-\frac{2\mu_\Sigma B}{kT}\right) \approx 3\cdot 10^{-6}.$$

6.

69: $T_{\max} \approx \frac{\mu_{\text{E}}^2}{ka^3} \approx 2\cdot 10^{-2}$ K.

Решение. См. также задачу 6.60. Нагревание всегда разупорядочивает структуру. Поэтому $kT_{\max} \approx \mathscr{E}_{\text{вз}}$. Энергия магнитного взаимодействия атомов $\mathscr{E}_{\text{вз}} \approx \mu^2/a^3$. Для оценки магнитного момента атома разумно взять магнетон Бора, поскольку электронный магнитный момент $\mu \lesssim \mu_{\text{б}}$. Отсюда $T_{\max} \approx \mu_{\text{B}}^2/\left(ka^3\right) \approx 2\cdot 10^{-2}$ K.

Эта оценка ясно показывает, что чисто магнитно-дипольное взаимодействие не может объяснить наблюдаемую величину температуры Кюри ферромагнетиков $T_{\text{K}} \sim 10 \div 1000$ K. Магнитное упорядочение у ферромагнетиков имеет другую природу - обменное взаимодействие, которое по своей сути является электростатическим (см. задачу 6.78). Величина электростатического взаимодействия двух электронов, находящихся на расстоянии a порядка e^2/a, что соответствует температуре упорядочения $T \sim e^2/(ka) \simeq 5\cdot 10^4$ K. Т.к. обменное взаимодействие составляет обычно $(0,01 \div 0,1)$ долю электростатического, то видно что это обеспечивает наблюдаемые T_{K} практически всех материалов.

6.

70: $\mathscr{E}_n = \hbar\omega_c\left(n+\frac{1}{2}\right)$, где $n = 0,1,2,...; \omega_c = \frac{eB}{m_e c}$ - циклотронная частота; $\mathscr{E}_0 = 5,8\cdot 10^{-6}$ эВ.

Решение. В магнитном поле электрон движется по окружности с циклотронной частатой $\omega_c = \frac{eB}{mc}$. Такое движение можно описать изменением только одной координаты - угла поворота. Тем самым задача сводится к задаче об одномерном осцилляторе с законом квантования $\mathscr{E}_n = \hbar\omega_c(n+1/2)$.

Покажем как это можно получить используя уравнения Гамильтона. В магнитном поле соотношение между импульсом $\mathbf{p}$ и скоростью $\mathbf{v}$ частицы не имеет привычной формы $\mathbf{p} = m\mathbf{v}$. Соотношение между $\mathbf{p}$ и $\mathbf{v}$ в присутствии магнитного поля можно получить двумя способами. Первый из них состоит в том, что когда частица из области $B = 0$ попадает в область $B \neq 0$ (либо B как-либо меняется от нуля до B_0), то возникает вихревое электрическое поле E. Согласно уравнению Максвелла

$$\operatorname{rot}\mathbf{E} = -\frac{1}{c}\frac{\partial\mathbf{B}}{\partial t} = -\frac{1}{c}\frac{\partial}{\partial t}\operatorname{rot}\mathbf{A}$$

откуда следует, что $\mathbf{E} = -\frac{1}{c}\frac{\partial\mathbf{A}}{\partial t}$. За время возникновения поля оно меняет скорость частицы

$$m\frac{d\mathbf{v}}{dt} = q\mathbf{E} = -\frac{q}{c}\frac{\partial\mathbf{A}}{\partial t}$$

откуда инегрированием получаем

$$m\mathbf{v} = \mathbf{p}_0 - \frac{q}{c}\int \frac{\partial \mathbf{A}}{\partial t}dt = \mathbf{p}_0 - \frac{q}{c}\mathbf{A}$$

Отсюда следует, что $m\mathbf{v} + \frac{q}{c}\mathbf{A} = \text{const}$, и эта константа не зависит от на личия поля. Эту константу можно рассматривать как эффективный импульс $\mathbf{p} = m\mathbf{v} + \frac{q}{c}\mathbf{A}$. Для электрона ($q = -e$) $\mathbf{p} = m\mathbf{v} - \frac{e}{c}\mathbf{A}$.

Второй способ состоит в том, что полный импульс заряженной частицы складывается из двух частей $\mathbf{p} = \mathbf{p}_{\text{кин}} + \mathbf{p}_{\text{пол}}$, где $\mathbf{p}_{\text{кин}} = m\mathbf{v}$, а $\mathbf{p}_{\text{пол}}$ - им пульс электромагнитного поля, образованного электрическим (кулоновским) полем частицы и постоянным магнитным полем внешних источников.

$$\mathbf{p}_{\text{пол}} = \frac{1}{4\pi c}\int [\mathbf{EB}]dV, \quad \text{где} \quad \operatorname{div}\mathbf{E}(\mathbf{r}) = 4\pi\rho = 4\pi q\delta(\mathbf{r} - \mathbf{r}')$$

$\mathbf{r}$ - положение частицы (при $v \ll$ ее можно считать покоящейся и не учитывать магнитного поля, создаваемого ею самой). Поскольку $\mathbf{B} = \operatorname{rot}\mathbf{A}$, то можно показать, что в этих предположениях $\mathbf{p}_{\text{пол}} = \frac{q}{c}\mathbf{A}$, т. е. $\mathbf{p} = m\mathbf{v} + \frac{q}{c}\mathbf{A}$.

Энергия частицы в постоянном магнитном поле есть чисто кинетическая (без учета спина), поэтому гамильтониан

$$\mathcal{H} = \frac{mv^2}{2} = \frac{1}{2m}\left(\mathbf{p} - \frac{q}{c}\mathbf{A}\right)^2 = \frac{1}{2m}\left[p_x^2 + (p_y - m\omega_c x)^2 + p_z^2\right]$$

где $\omega_c = \frac{qB}{mc}$ - циклотронная частота. Мы рассматриваем общий случай $p_z \neq 0$. Классические уравнения движения Гамильтона

дают

$$\dot{\mathbf{r}} = \frac{\partial \mathcal{H}}{\partial \mathbf{p}}; \quad \dot{\mathbf{p}} = -\frac{\partial \mathcal{H}}{\partial \mathbf{r}}$$

$$\begin{cases} \dot{x} = \frac{p_x}{m} \\ \dot{y} = \frac{p_y - m\omega_c x}{m}, \\ \dot{z} = \frac{p_z}{m}, \end{cases} \qquad \text{а также} \qquad \begin{cases} \dot{p}_x = -(p_y - m\omega_c x)\,\omega_c \\ \dot{p}_y = 0 \\ \dot{p}_z = 0 \end{cases}$$

Видно, что p_y и p_z являются интегралами движения, а $\dot{y}$ - не является интегралом движения. Это есть проявление того факта, что в магнитном поле $B_0 \| OZx$ - и y-компоненты скорости частицы не могут иметь одновременно определенных соотношений. Обозначим $p_y = p_{y0} = \text{const}; p_z = p_{z0} = \text{const}$. Поскольку по условию задачи $\mathbf{v} \perp \mathbf{B}$, то $p_{z0} = 0$.

Тогда $\mathcal{H} = \frac{1}{2m}\left[p_x^2 + (p_{y0} - m\omega_c x)^2\right]$.

Сделаем замену переменных $x' = x + \frac{p_{y0}}{m\omega_c}$. Тогда $p_x = p'_x$ и

$$\mathscr{H} = \frac{1}{2m}p_x^{2\prime} + \frac{m\omega_c^2}{2}x'^2$$

Мы свели таким образом гамильтониан частицы к гамильтониану одномерного гармонического осциллятора. Воспользовавшись результатами квантово-механической задачи о квантовом осцилляторе, запишем по аналогии энергию уровней, называемых уровнями Ландау:

$$\mathscr{E}_n = \hbar\omega_c\left(n + \frac{1}{2}\right)$$

Это - система эквидистантных уровней. Каждый уровень имеет бесконечную кратность вырождения, т. к. энергия не зависит от $p_y, -\infty < p_y < +\infty$. При этом координата положения равновесия осциллятора $x' = 0$, т. е. $x = -\frac{p_{y0}}{m\omega_c}$ - не определена.

Минимальная энергия электрона $\hbar\omega_c/2 = 5,8 \cdot 10^{-6}$ эВ. Учет спина электрона приводит к добавке $(\boldsymbol{\mu}\mathbf{B})$ в энергию и спиновому расщеплению уров-

ней $2m_s\mu_{\mathbf{5}}B, (m_s = \pm 1/2)$. Для свободного электрона $\mu_{\mathbf{D}}B = \hbar\omega_c/2$. На рис. 172 изображено расщепление уровней. Стрелками изображено направление магнитных моментов электрона. Низшее состояние определяется тем, что $\boldsymbol{\mu}\|\mathbf{B}$. При этом спин $\mathbf{S}$ антипараллелен полю $\mathbf{B}$.

6.

71: $S^{\text{p}}_{\min} = \frac{\pi\hbar eB}{c} \approx 1,66 \cdot 10^{-43}$ эрг $\cdot\Gamma$; $S^{\mathbf{R}}_{\min} = \frac{\pi\hbar c}{eB} = 6,56 \cdot 10^{-11}$ см^2.

Решение. Условие вращения электрона в магнитном поле по окружности

$$\frac{mv_\perp^2}{R} = \frac{e}{c}v_\perp B$$

дает в координатном пространстве (R-пространстве) радиус ларморовского кружка

$$R = \frac{mc}{eB} v_\perp$$

Преобразуем это выражение:

$$R^2 = \left(\frac{mc}{eB}\right)^2 v_\perp^2 = \frac{2mc^2}{e^2B^2}\frac{mv_\perp^2}{2} = \frac{2mc^2}{e^2B^2}\mathscr{E}_\perp$$

где $\mathscr{E}_\perp$ - кинетическая энергия поперечного движения частицы. Так как $\mathscr{E}_\perp$ квантуется, т. е. $\mathscr{E}_\perp = \hbar\omega_c\left(n+\frac{1}{2}\right)$, то квантуется и квадрат радиуса орбиты, т. е. площадь

$$S_n = \pi R_n^2 = 2\pi\frac{mc^2}{e^2B^2}\hbar\omega_c\left(n+\frac{1}{2}\right)$$

Запишем далее уравнение движения (**R** - это проекция **r** на плоскость, перпендикулярную B)

$$m\frac{d\mathbf{v}}{dt} = \frac{e}{c}[\mathbf{vB}], \quad \mathbf{v} = \frac{d\mathbf{r}}{dt}, \quad \text{т. е.} \quad \frac{d\mathbf{v}}{dt} = \frac{e}{mc}\left[\frac{d\mathbf{r}}{dt}, \mathbf{B}\right].$$

Интегрируя и отбрасывая постоянную интегрирования, получаем

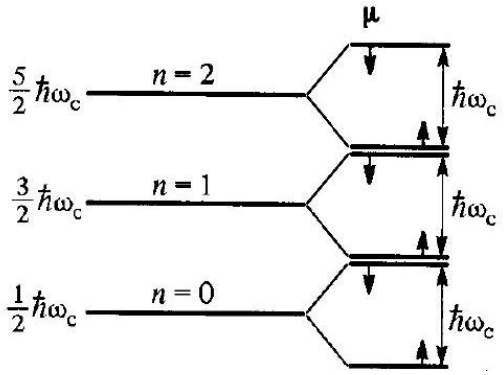

Рис. 172

$\mathbf{v} = \frac{e}{mc}[\mathbf{rB}]$. Поскольку $\mathbf{v} \perp \mathbf{B}$ и $\mathbf{r} \perp \mathbf{B}$, то $\mathbf{v}_\perp = \frac{eB}{mc}[\mathbf{R}, \mathbf{z}]$.

Отсюда видно, что в импульсном пространстве (или пространстве скоростей) траектория получается умножением на $eB/(mc)$ и ее поворотом на 90° вправо (по часовой стрелке), если смотреть с конца вектора B.

Таким образом, траектория электрона в пространстве скоростей - тоже окружность и

$$S_n^v = \pi v_\perp^2 = \pi R_n^2\left(\frac{eB}{mc}\right)^2 = 2\pi\frac{\hbar\omega_c}{m}\left(n+\frac{1}{2}\right)$$

Минимальная площадь $S_0^v = \frac{\pi\hbar\omega_c}{m}$, или, в импульсном пространстве,

$$S_{\min}^{\text{p}} = S_0^p = m^2v_\perp^2\pi = \pi m\hbar\omega_{\text{c}} = \frac{\pi\hbar eB}{c} = 1,66\cdot10^{-43} \ni \text{р}\Gamma\cdot\Gamma.$$

Минимальная площадь в **R**-пространстве

$$S_{\min}^{\mathbf{R}} = \pi\frac{mc^2}{e^2B^2}\hbar\omega_c = \frac{\pi\hbar c}{eB} = 6,56\cdot10^{-11}\ \text{см}^2$$

Заметим, что из квантования площади в **R**-пространстве следует квантование магнитного потока, пронизывающего орбиту электрона,

$$\Phi_n = \pi R_n^2 B = \Phi_0\left(n+\frac{1}{2}\right)$$

где $\Phi_0 = \frac{2\pi\hbar c}{e} = \frac{2\pi e}{\alpha}$, где α - постоянная тонкой структуры, а Φ_0 - минимальный магнитный поток (квант магнитного потока).

6.

72: $R = \frac{\gamma M}{c^2 \ln(m_e c^2/\mathscr{E}_2)} \approx 7$ км; $B = \frac{\mathscr{E}_1 m_e c^2}{2\mu_\text{b} \varepsilon_2} = 4,77 \cdot 10^{12}$Гс.

Решение. Вблизи нейтронной звезды находится другая звезда (красный гигант), образующая с нейтронной звездой двойную систему. За счет сильного гравитационного поля происходит аккреция, т. е. захват протонноэлектронной плазмы красного гиганта и ее падение на нейтронную звезду. При этом непрерывное (тормозное) рентгеновское излучение уносит выделившуюся кинетическую энергию.

Магнитное поле у нейтронной звезды возникает в силу сохранения магнитного потока из первоначального поля звезды и ее «раскрутки». Предполагается, что исходной была звезда типа Солнца. На поверхности звезды «аннигиляционный» γ-квант имеет энергию, равную $m_\text{e}c^2 = 511$ кэВ. После «преодоления» гравитационного поля он «краснеет» (см. задачу 1.4) и на поверхности Земли имеет энергию $\mathscr{E}_2 = 460$ кэВ. Таким образом,

$$\ln \frac{m_e c^2}{\mathscr{E}_2} = \frac{\gamma M}{c^2 R},$$

откуда следует ответ

$$R = \frac{\gamma M}{c^2 \ln\left(m_\text{e} c^2/\mathscr{E}_2\right)} \approx 7 \text{ км} .$$

В магнитном поле уровни энергии свободного электрона (уровни Ландау) $_n = \hbar\omega_\text{c} n = 2\mu_\mathbf{5} B n$. Как и в первом случае, это излучение преодолевает гравитационное поле нейтронной звезды и на поверхности Земли имеет энергию $\mathscr{E}_1 = 50$ кэВ. Таким образом,

$$\ln \frac{2\mu_\sigma B}{\mathscr{E}_1} = \frac{\gamma M}{c^2 R}, \text{ откуда искомое поле } B = \frac{\mathscr{E}_1 m_\text{e} c^2}{2\mu_\Sigma \mathscr{E}_2} = 4,77 \cdot 10^{12}\text{Гс}.$$

6.

73* $P = 0,3$.

Решение. В силу несохранения четности при β-распаде число электронов, вылетевших по и против спина ядра, будет различным. Но если число ядер со спином вверх и вниз будет одинаковым, то результирующая асимметрия вылета исчезнет, и эффект несохранения четности не проявится. Поэтому необходимо иметь преимущественную поляризацию ядер, что достигается в магнитном поле при низких температурах.

В магнитном поле уровень ядра с $I = 1$ расщепляется на три подуровня, соответствующие значениям магнитного квантового числа $m_I = 1, 0, -1$ и расстояние между ними $\Delta\mathscr{E} = g\mu_\text{яд} H$. Отношение заселенностей подуровней равно:

$$\frac{N(m_1)}{N(m_2)} = \exp\left[\frac{(m_1 - m_2)\, g\mu_\text{gp}\, B}{kT}\right] = e^\alpha, \text{ где } m_1 = +1, m_2 = -1$$

Искомая поляризация ядер

$$P = \frac{e^a - 1}{e^a + 1} = 0,3$$

Это означает, что только 30% распадов дадут асимметричный эффект, который наблюдается на симметричном фоне распадов остальных ядер.

6.

74* $n = 2, l = 1$, число поду ровней 5 .

Решение. Главное квантовое число $n = \sqrt{\frac{\text{Ry}}{\varrho}} = 2$. При этом $n = n_r + l + 1$, где радиальное квантовое число n_r определяет число нулей радиальной части волновой функции на $(0, \infty)$, т. е. $n_r = 0$. Отсюда следует, что $l = 1$, и мы имеем $2p$-состояние. Число подуровней равно 5 $(m_l + 2m_s = \pm 2; \pm 1; 0)$.

6.

75. $2s$-состояние $(l = 0)$; $2s + 1 = 2$ - число подуровней. Оно не зависит от величины поля $\mathbf{B}$, т. к. данный уровень - синглет.

6.

76. $\lambda = \frac{2\lambda_1\lambda_2}{\lambda_1-\lambda_2} = 1034571,4\text{Å} \approx 0,01$ cm.

Решение. В схеме Рассела-Саундерса снятие вырождения и расщегт ления терма ^3P по величине полного момента $\mathbf{J}$ с образованием подуровней тонкой структуры $^3P_2, ^3P_1, ^3P_0$ есть результат спин-орбитального взаимодействия. Энергия подуровней отличается от энергии терма на величину энергии спин-орбитального взаимодействия

$$\mathfrak{E}_{LS} = A((\mathbf{LS})\rangle = \frac{1}{2}\left\langle \mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2\right\rangle = \frac{A}{2}[J(J+1) - L(L+1) - S(S+1)]$$

При этом

$$\mathscr{E}\left(^3P_2\right) - \mathscr{E}\left(^3P_1\right) = \left[\mathscr{E}\left(^3P\right) + \mathscr{E}_{LS}(J=2)\right] - \left[\mathscr{E}\left(^3P\right) + \mathscr{E}_{LS}(J=1)\right] = 2A > 0$$

Знак константы спин-орбитального взаимодействия однозначно связан с правилом Хунда: если занято меньше половины свободных мест, то ниже по энергии лежит состояние с меньшим J и получается т. н. нормальный мультиплет. Действительно, электронная конфигурация $O^{2+} : 1s^2 2s^2 2p^2$ и в незаполненной L-оболочке, содержащей $2(2l+1) = 6$ мест, занято всего 2 места. Аналогично

$$\mathscr{E}\left(^3P_1\right) - \mathscr{E}\left(^3P_0\right) = \left[\mathscr{E}\left(^3P\right) + \mathscr{E}_{LS}(J=1)\right] - \left[\mathscr{E}\left(^3P\right) + \mathscr{E}_{LS}(J=0)\right] = A$$

Согласно правилам Бора

$$\mathscr{E}\left(^3P_2\right) - \mathscr{E}\left(^3P_1\right) = \left[\mathscr{E}\left(^1D_2\right) - \frac{hc}{\lambda_1}\right] - \left[\mathscr{E}\left(^1D_2\right) - \frac{hc}{\lambda_2}\right] = hc\left(\frac{1}{\lambda_2} - \frac{1}{\lambda_1}\right)$$

Аналогично

$$\mathscr{E}\left(^3P_1\right) - \mathscr{E}\left(^3P_0\right) = \frac{hc}{\lambda} = \frac{1}{2}\left(\mathscr{E}\left(^3P_2\right) - \mathscr{E}\left(^3P_1\right)\right) = \frac{hc}{2}\left(\frac{1}{\lambda_2} - \frac{1}{\lambda_1}\right).$$

Откуда получаем ответ:

$$\lambda = \frac{2\lambda_1\lambda_2}{\lambda_1 - \lambda_2} = 1034571,4\text{Å} \approx 0,01 \text{ cm}.$$

6.

77. $\lambda = \frac{2\lambda_1\lambda_2}{\lambda_2-\lambda_1} = 15784$Å (см. решение задачи 6.76. Однако здесь получается обращенный мультиплет (т. к. число электронов в незаполненной L-оболочке равно 4), когда большей энергии соответствует меньшее J: состояние $^3P_1$ лежит выше по энергии состояния $^3P_2$).

6.

78. $A = 0,4$ В; $\mathscr{E}_\text{k} = +9,2$ эВ.

Заметим, что энергия возбужденного состояния атома гелия $\mathscr{E}_\text{пара} = -W_\text{пара} = \mathscr{E} + \mathscr{E}_\mathbf{K} + A$, а $\mathscr{E}_\text{орто} = -W_\text{орто} = \mathscr{E} + \mathscr{E}_\mathbf{K} - A$, т. к. энергия обменного взаимодействия $V = -A(S(S+1)-1) = \begin{cases} -A \text{ для ортогелия,} \\ +A \text{ для парагелия,} \end{cases}$ а энергия электронной конфигурации $1s^1 2s^1$ равна $\mathscr{E} = -68$ эВ .

6.

79. $v_{\text{ре з}} = \frac{2\mu_\Sigma B}{h} = 18,7\Gamma\Gamma_\text{L}$.

6.

80. $L = 6$.

18.2 Nuclear and Particle Physics

18.2.1 General questions about nuclei and radioactivity

ФР.МФТИ-кр. Радиус Чармония по двум уровням (!?!?!??)

Известно, что есть частица Чармоний из - и $\bar{c}$-кварка. Известно, что у него энергия основного состояния $E_0 = 3$ГэВ, а энергия первого возбужденного состояния $E_1 = 3.7$ГэВ. Оценить характерный радиус чармония.

Указание: считать, что при сильном взаимодействии энергию можно оценить как $E = mc^2 - \frac{q^2}{2m}$, где q - цветовой заряд (по модулю) обоих частиц.

Solution

(в 2 строчки решается задача, лень писать даже)

Об адекватности и содержательности задачи.

Как вообще узнать, какой первый возбужденный уровень частицы, которая скорее всего за доли секунды распадается?

Применима ли вообще квантовая механика???

Короче, тут предполагается тупо использовать детскую аппроксимацию и скорее всего авторы вообще ничего про сильные взаимодействия не знают, и из вуза их нужно уволить.

18.2.2 Problems about radioactivity 1

О3.1-7.1

Определить среднюю плотность ядерного вещества, полагая, что радиус ядра равен $R = 1,3A^{1/3}$, где A - массовое число (число нук.1онов). Энергия связи на один нуклон $B = 8,5$МВ/ нуклон. Средняя масса нуклона $m_{\text{N}} \approx 940\text{МВ}/c^2$.1)

7.

1. $\rho = \frac{m_{\text{N}}A - BA/c^2}{4\pi R^3/3} = 1,8 \cdot 10^{14}\Gamma/\text{см}^3$.

О3.1-7.2

Определить Энергию $\mathscr{E}_{\text{k}}$ кулоновского расталкивания протонов в ядре в предположении, что протоны распределены по ядру равномерно. Установить зависимость $\mathscr{E}_{\text{k}}$ от числа нуклонов и заряда ядра Z. Радиус ядра $R = 1,3A^{1/3}$ фм.

7.

2. $\mathscr{E}_{\mathbf{K}} \approx \frac{3}{5}\frac{Z^2e^2}{R} \approx 0,66Z^2A^{-1/3}$ [МэВ].

О3.1-7.3

Поверхностная энергия атомного ядра равняется примерно $-17,8A^{1/3}$ МэВ. Радиус атомного ядра $R = 1,3A^{1/3}$ фм. Найти поверхностное натяжение о ядерного вещества. Сравнить найденное значение с поверхностным натяжением ртути ($\sigma_{\text{Hg}} = 470$ эрг/см ^{2}).

7.

3* $\alpha \approx 1,4 \cdot 10^{20}{}_{\text{эрг}}\ /\text{см}^2 \approx 3 \cdot 10^{17}\sigma_{\text{Hg}}$.
Решение. В капельной модели ядра можно по аналогии с жидкой каплей также ввести поверхностное натяжение

$$\sigma = -\frac{E_{\text{пов}}}{S} = -\frac{E_{\text{пов}}}{4\pi R^2} = \frac{17 \cdot 1,6 \cdot 10^{-6} A^{2/3}\ \ni}{4\pi \cdot 1,3^2 \cdot 10^{-26} \cdot A^{2/3}\ \text{см}^2} = 1,4 \cdot 10^{20}\ \ni\ \text{р/см}^2$$

что превышает поверхностное натяжение ртути примерно в $3 \cdot 10^{17}$ раз.

О3.1-7.4

Энергия связи атомных ядер при заданном числе A нуклонов в ядре уменьшается с увеличением числа протонов Z из-за возрастания кулоновской энергии $|\sigma_{\text{к}}| = 0,71\frac{Z^2}{A^{1/3}}$ МэВ. С другой стороны, при отличии числа нейтронов от числа протонов энергия связи уменьшается на величину $\mathscr{E} = \frac{47,4(N-Z)^2}{2A}$ МэВ. Определить при заданном A оптимальное значение Z, при котором энергия связи ядра минимальна. Определить Z/A при $A = 10; 50; 100; 150$ и 200. Найти из справочных данных подходящие изотопы.

7.

4. Решение. Энергия связи ядра
Кроме того,

$$\mathscr{E}_{\text{СВ}} = [Zm_{\text{р}} + (A-Z)m_{\text{n}} - M_{\text{g}}(A,Z)]\,c^2$$

$$\mathscr{E}_{\text{СВ}} = f(A) - \mathscr{E}_{\mathbf{K}} - \mathscr{E}$$

где через $f(A)$ обозначены вклады в энергию связи, не зависящие от Z. Отсюда масса ядра

$$M_{\text{g}}(A,Z) = Zm_{\text{р}} + (A-Z)m_{\text{n}} + [\mathscr{E}_{\mathbf{K}} + \mathscr{E} - f(A)]\,/c^2$$

Приближенно минимум $M_9(A,Z)$ можно найти, считая Z непрерывной переменной и полагая $(\partial M_g/\partial Z)_A = 0$. В результате получим

$$Z = \frac{A}{1,97 + 0,015A^{2/3}}.$$

При пользовании этой формулой нужно брать ближайшее целое значение Z:

A	Z	Ядро	A	Z	Ядро
10	5	${}^{10}_{5}$ B	150	60	${}^{150}_{62}$Sm
50	23	${}^{50}_{20}$ V	200	80	${}^{200}_{80}$Hg
100	44	^{100}Ru			

О3.1-7.5 Устойчивые ядра-изобары при нечетном A

С помощью формулы Вайцзеккера найти заряд Z_0 наиболее устойчивого ядра-изобары при заданном нечетном значении A.
Выяснить, каков характер активности у ядер ^{27}Mg, ^{29}P, ^{37} K, ^{67}Cu.

7.

5. $Z_0 = \frac{A/2}{1+7,5\cdot 10^{-3}A^{2/3}}$. ^{27}Mg – β^--активен; ^{29}P – β^+-активен; ^{37} K - β^+-активен; ^{67}Cu – β^--активен.

В формуле Вайцзеккера находим экстремум, с помощью производной, приравниваем к нулю, получаем уравнение на заряд. Выражаем его, получаем формулу, которая дает ответ.
Округляем.
получаем реакции.
(порешаю потом для других ядер.)

О3.1-7.6*

Разница в энергиях связи ядер трития $^3_1$H и гелия $^3_2$He обусловлена энергией электростатического взаимодействия протонов. Оценить размеры ядра $^3_2$He. Энергии связи ядер $^3_1$H и $^3_2$He равны соответственно $\mathcal{G}_{\text{H}} = 8,482\text{МВ}, \mathscr{O}_{\text{He}} = 7,718\text{МэВ}$.

7.

6. $R_{\text{g}} = \frac{e^2}{\Delta_{\text{cB}}} = 1,9 \cdot 10^{13}$ cm.

Решение. Прежде всего предполагаем, что расстояние между протонами не может быть больше размеров ядра в приближении точечных протонов, т. е. $R_{\text{яд}} \approx \langle r \rangle$. Кроме того, считаем, что разница в энергиях связи обоих ядер $\Delta\mathscr{E}_{\text{СВ}} = \mathscr{E}_{\text{H}} - \mathscr{E}_{\text{He}}$ целиком кулоновского происхождения, т.е. $\Delta\mathscr{E}_{\text{СВ}} = \mathscr{E}_{\text{кул}}$.

Энергия кулоновского взаимодействия протонов в ядре ^{3}He есть

$$\mathscr{E}_{\text{Куа}} = \int \psi^* \frac{e^2}{r} \psi dV$$

Здесь ψ - волновая функция системы нуклонов в ядре, r - расстояние между протонами. Интегрирование идет по объему ядра, т. е. считается, что ядро имеет жесткую форму и вне ядра $\psi \approx 0$. Конкретный вид ψ-функции в данном случае не нужен.

$$\mathscr{E}_{\text{Ку}} = e^2 \int |\psi|^2 \frac{1}{r} dV = e^2 \left\langle \frac{1}{r} \right\rangle .$$

Будем считать, что $\left\langle \frac{1}{r} \right\rangle \simeq \frac{1}{\langle r \rangle}$, и величину $\langle r \rangle$ примем за размер ядра. Таким образом,

$$R_{\text{g}\boldsymbol{A}} = \frac{e^2}{\Delta\varepsilon_{\text{cB}}} = 1,9 \cdot 10^{-13} \text{ cm}.$$

О3.1-7.7

Ядро $^{27}_{14}$Si переходит в «зеркальное» ядро $^{27}_{13}$Al, испытывая β^+ - распад. Максимальная кинетическая энергия вылетевшего позитрона $\sigma_{\max} = 3,48$ МэВ. Оценить по этим данным величину r_0 в формуле для радиуса ядра $R = r_0 A^{1/3}$.

7.

7* $r_0 = 1,4 \cdot 10^{-13}$ cm.

Ре шение. По отношению к ядерным силам протон и нейтрон ведут себя совершенно одинаково. Эта эквивалентность ядерных взаимодействий для протонов и нейтронов проявляется в так называемых зеркальных ядрах, получающихся друг из друга заменой протонов на нейтроны и наоборот. Имен но такими парами и являются ядра $^{27}_{14}\text{Si}\,(14\ \text{р}\ +13\ \text{п})$ и $^{27}_{13}\text{Al}(13\text{р} + 14\ \text{п})$. Одинаковость ядерных взаимодействий для протона и нейтрона носит название зарядовой независимости ядерных сил и является проявлением более общего свойства - изотопической инвариантности сильного взаимодействия.

Если бы изотопическая инвариантность ядерных сил была точным законом природы, то все параметры зеркальных ядер были бы одинаковыми и β раснад был бы запрещен законом сохранения энергии. Кулоновское взаимодействие нарушает зарядовую независимость и делает распад возможным.

$$^{27}_{14}\text{Si} \to {}^{27}_{13}\text{Al} + \text{e}^+ + \upsilon_{\text{e}}.$$

Электрон не может «унести» больше энергии, чем выделяется при распаде. Таким образом,

$$\begin{aligned} m_{\text{e}}c^2 + \mathscr{E}_{\max} &= [M(\text{Si}) - M(\text{Al})]c^2 = \\ &= (m_{\text{p}} - m_{\text{n}})\, c^2 + \frac{3}{5}\frac{e^2}{R}[\, Z_{\text{Si}}\,(Z_{\text{Si}} - 1) - Z_{\text{A1}}\,(Z_{\text{Al}} - 1)] = \\ &= -\,(m_{\text{n}} - m_{\text{p}})\, c^2 + \frac{3}{5}\frac{e^2}{R}(14 \cdot 13 - 13 \cdot 12), \end{aligned}$$

откуда

$$\frac{e^2}{r_0 A^{1/3}} = \frac{5}{78}\left[(m_{\text{n}} - m_{\text{p}} + m_{\text{e}})\, c^2 + \mathscr{E}_{\max}\right].$$

И окончательно, $r_0 = 1,4 \cdot 10^{-13}$ cm.

О3.1-7.8

Найти разность энергий связи для пар зеркальных ядер $\left({}^{11}\text{B},\ {}^{11}\text{c}\right)$ и $\left({}^{13}\text{N}, {}^{13}\text{c}\right)$. Показать, что эта разность в значительной степени обусловлена кулоновским взаимодействием протонов в ядре. Энергию связи ядер взять из таблицы в конце сборника.

7.

8. ${}^{11}\text{C}, {}^{11}\text{B} : \Delta_{\text{СВ}} = 2,8\text{М} \ni \text{В}; \Delta_{\text{К}} \approx 3,19\text{М} \ni \text{В};$
${}^{13}\text{C}, {}^{13}\text{N} : \Delta\mathscr{E}_{\text{СВ}} = 3,0\text{М} \ni \text{В}; \Delta\mathscr{E}_{\text{К}} \approx 3,62\text{М} \supset \text{В}.$
Подсчет $\mathscr{E}_{\text{к}}$ выполняется по формуле $0,71Z^2A^{-1/3}$.

О3.1-7.9

Ядро ${}^{7}_{4}\text{Be}$ «перегружено" протонами и испытывает превращние${}^{7}_{4}\text{Be} \to {}^{7}_{3}\text{Li}$. Массы Этих атомов равны, соответственно, 7,0169 и 1) Радиус ядра определяется по формуле $R_{\text{g}} = r_0A^{1/3}$. При этом коэффициент r_0 при различных аппроксимациях может принимать значения от 1.2 до $1,4 \cdot 10^{-13}$см. В данном задачнике r_0 нринимается равным $1,3 \cdot 10^{-13}$см. 59 7,0160 а. е. м. Определить тип бета-распада, обусловливающего это превращение.

7.

9. K-захват; β^+-распад энергетически невозможен.

О3.1-7.10

В 1942 г. американский физик Аллен измерил максимальную энергию $\mathscr{E}_0$ атомов ${}^{7}\text{Li}$, образующихся в результате K-захвата в ядре ${}^{7}\text{Be}$, и она оказалась равной 50 эВ. Оценить на основе этих данных разность масс атомов ${}^{7}\text{Be}$ и ${}^{7}\text{Li}$.

7.

10. $\Delta Mc^2 \approx \sqrt{2M_{\text{Li}}c^2\mathscr{E}_0} \approx 0,81\text{М В}$.

О3.1-7.11

Определить энергию отдачи ядра атома лития, которое образуется в основном состоянии при поглощении электрона с K-оболочки ядром атома бериллия.

7.

11. $\mathscr{E} \approx 57\ \rho\text{В}$.

О3.1-7.12

Потенциальную энергию взаимодействия нуклонов в дейтроне можно аппроксимировать сферически симметричной прямоугольной ямой (см. задачи 3.16 – 3.18). При этом в системе центра

масс волновая функция основного состояния имеет вне области ямы следующий вид $\psi = Ae^{-xr}/r$, где $A = \text{const}$, $x = 2,3 \cdot 10^{12}\text{см}^{-1}$. Найти красную границу реакции фоторасщепления дейтрона γ-квантами.

7.

12: $\mathscr{E}_{\text{гр}} \approx 2,2\text{М М}$.

Решение. Красная граница фоторасщепления дейтрона определяется энергией связи протона и нейтрона. На рис. 173 изображены потенциальная яма и волновая функция дейтрона. Вне ямы, где $U(r) = 0$, уравнение Шредингера для частицы с приведенной массой $\mu = m_{\text{N}}/2$ имеет вид

$$-\frac{\hbar^2}{2\mu}\Delta_r\psi = \mathscr{E}\psi$$

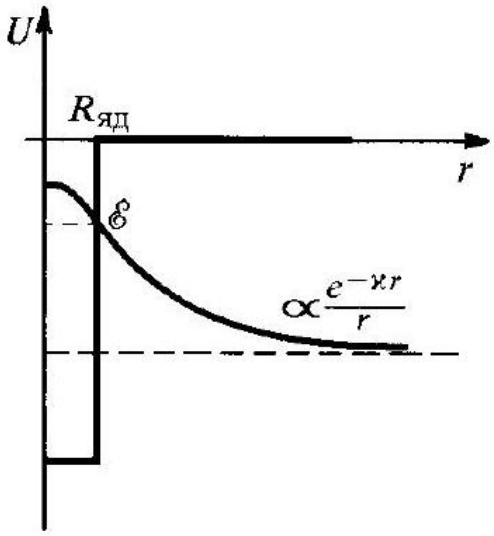

Рис. 173

где $\Delta_r = \frac{d^2}{dr^2} + \frac{2}{r}\frac{d}{dr}$ - радиальная часть оператора Лапласа.
Подставляя в уравнение $\psi = A\exp(-xr)/r$, получим $x^2\hbar^2 + 2\mu\mathscr{E} = 0$, откуда

$$\mathscr{E} = -\frac{\hbar^2 x^2}{2\mu}.$$

Таким образом, минимальное значение энергии, достаточной для расщепления дейтрона,

$$\mathfrak{E}_{\Gamma p} = \frac{\hbar^2 x^2}{2\mu} = \frac{\hbar^2 x^2}{m_{\mathrm{N}}} \approx 2,23\text{МВВ}$$

О3.1-7.13

* Согласно гидродинамической модели ядра ШтайнведеляЕнсена протоны и нейтроны образуют сжимаемые и свободно проникающие друг в друга жидкости, двигающиеся внутри жесткой оболоч ки исходного ядра. Гигантский резонанс в ядрах соответствует возбуждению противофазных колебаний этих жидкостей, при которых протоны и нейтроны в ядре то пространственно разделяются, то равномерно перемешиваются. Используя формулу Вайцзеккера, оценить рическом ядре с $A = 64(Z = N)$, который возникает при возбуждении волны с $kR = 2,08$, где $k = 2\pi/\lambda$ - волновое число, λ - длина волны, R - радиус ядра. Закон дисперсии этих волн считать линейным ($\omega = ku$, где u - скорость распространения колебаний, равная, как в любой жидкости, $u = \sqrt{K/M}$, где в данном случае K - жесткость ядра относительно смещений нуклонов, M - масса ядра).

7.

13. $\mathscr{E}_{\mathrm{GR}} = \hbar\frac{2,08}{R}\sqrt{\frac{2a_{\mathrm{s}}}{m_{\mathrm{N}}}} \approx 17,7\text{М} \supset \text{В}$, где $a_{\mathrm{s}} = 23,7\text{М В}$ - коэффициент в симметрийном члене в формуле Вайцзеккера, $R = 5,2$ фм.

Решение. Если жесткость системы равна K, то упругая энергия $\mathscr{E} = K\varepsilon^2/2$, где ε - относительное смещение. Возвращающая сила, обусловленная симметрийным членом в формуле Вайцзеккера, стремится восстановить равномерную плотность протонов и нейтронов. Симметрийный член в энергии меняется в расчете на 1 нуклон следующим образом:

$$\mathscr{E}_{\mathrm{s}} = \frac{1}{A}a_{\mathrm{s}}\frac{(A-2Z)^2}{A} = \frac{1}{2}2a_{\mathrm{s}}\left(\frac{N-Z}{A}\right)^2,$$

где $a_{\mathrm{s}} = 23,7\text{М В}$ - коэффициент в формуле Вайцзеккера, N - число нейтронов.

Изменением кулоновской энергии при сжатии протонов вдвое можно пренебречь в силу относительной малости кулоновского члена в формуле Вайцзеккера. Сравнивая $\mathscr{E}_{\mathrm{s}}$ с упругой энергией $\mathscr{E}$ и полагая, что $(N-Z)/A$ - относительное смещение протонов относительно нейтронов, можно сделать вывод, что в расчете на один нуклон жесткость системы $K = 2a_{\mathrm{S}}$. По формуле, данной в условии задачи, скорость распространения колебаний (скорость звука) $u^2 = K/m_{\mathrm{N}} = 2a_{\mathrm{s}}/m_{\mathrm{N}}$, где m_{N} - масса нуклона.

Таким образом, энергия гигантского дипольного резонанса $\mathscr{E}_{\mathrm{GR}}$ в сферическом ядре с $A = 64$ (при $Z = N$)

$$\mathscr{E}_{\mathrm{GR}} = \hbar k u = \hbar \frac{2,08}{R} u = \hbar \frac{2,08}{R} \sqrt{\frac{2a_{\mathrm{s}}}{m_{\mathrm{N}}}} \approx 17,7\mathrm{M} \ni \mathrm{B}$$

Приведем другое решение данной задачи. Подсчитаем изменение энергии, непосредственно возникающее при смещении L нейтронов вправо, а L протонов влево. Тогда в левой половине будет $N/2 - L$ нейтронов и $Z/2 + L$ протонов, а в правой половине ядра $N/2 - L$ нейтронов и $Z/2 + L$ протонов (рис. 174).

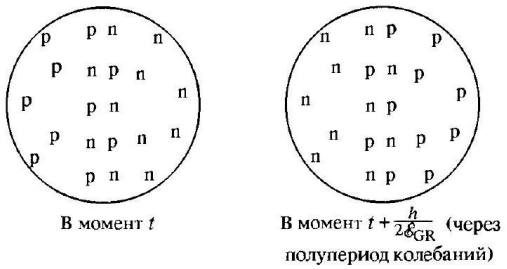

Рис. 174

Полная энергия, связанная с нарушением симметрии, есть

$$\mathscr{E}_{\mathrm{s}} = \frac{(N/2 + L - Z/2 + L)^2}{A/2} a_{\mathrm{s}} + \frac{(N/2 - L - Z/2 - L)^2}{A/2} a_{\mathrm{s}} = \frac{16L^2}{A} a_{\mathrm{S}}$$

Приведем эту формулу к тому же виду $\mathscr{E} = K\varepsilon^2/2$ (см. первое решение). При этом становится очевидно, что максимальное число смещенных протонов или нейтронов равно $A/4$. Таким образом,

откуда $K = 2a_{\mathrm{s}}A$.

$$\mathscr{E}_{\mathrm{S}} = \frac{1}{2} 2a_{\mathrm{s}} A \left(\frac{L}{A/4} \right)^2,$$

Далее легко видеть, что мы приходим к тому же выражению для $\mathscr{E}_{\mathrm{GR}}$, что и в первом решении, поскольку полученное K следует либо привести к одному нуклону, т. е. поделить на A, либо воспользоваться формулой для расчета скорости u, приведенной в условии задачи,

$$u = \sqrt{\frac{K}{M}} = \sqrt{\frac{2a_{\mathrm{s}A}}{Am_N}} = \sqrt{\frac{2a_{\mathrm{s}}}{m_N}}.$$

Заметим, что эта модель достаточно хороно описывает положение гигантского резонанса. Например, в ядре меди, у которого как раз $A = 64$, он наблюдается при энергии возбуждения 16 М МВ.

О3.1-7.14 Три первых ядерных оболочек в оболочечной модели ядра

Согласно оболочечной модели ядра нейтроны и протоны независимо заполняют потенциальную яму. Определить число нуклонов A, которые могут располагаться на трех первых ядерных оболочках, считая потенциальную яму трехмерной параболической.

7.

14. Нейтроны и протоны заполняют свои уровни независимо друг от друга, т. к. они не являются тождественными частицами. Первая оболочка $Z = N = 2; A = 4$ (He). Вторая оболочка $Z = N = 8; A = 16$ (O). Третья оболочка $Z = N = 20; A = 40$ (Ca).

(??? про модель в теории лучше напишу потом.)

О3.1-7.15

*.

Простейшей оболочечной моделью ядра является трехмерный гармонический осциллятор. Считая, что потенциальная яма ядра имеет глубину $U_0 = -70\mathrm{M} \ni \mathrm{B}$, а $U(R_0) = 0$, где R_0 - радиус ядра, оценить энергию связи нуклона для ядра кислорода 168.

7.

15: $\mathscr{E}_{\text{св}} = |U_0| - \frac{5}{2}\hbar\sqrt{-\frac{2U_0}{m_{\text{N}}R_0^2}} \approx 12\text{М}\ni\text{В}$, где m_{N} - масса нуклона.

Решение. Радиус ядра кислорода $^{16}_{8}\text{O}$ $R_0 = 1,3\cdot10^{-13}\sqrt[3]{16} \approx \approx 3,3\cdot10^{-13}$ cm. Потенциальная энергия в однонуклонном приближении описывается выражением

$$U(r) = U_0 + \frac{m\omega^2 r^2}{2}$$

При $r \geqslant R_0$ потенциал $U(r) = 0$, и следовательно

$$\omega = \sqrt{-\frac{2U_0}{mR_0^2}},$$

а уровни энергии имеют вид

$$\mathscr{E}_N = U_0 + \hbar\omega\left(N + \frac{3}{2}\right).$$

Картина уровней изображена на рис. 175. В пренебрежении конечным размером ямы уровни энергии эквидистантны. В силу зарядовой независимости ядерных сил (задача 7.7) уровни протонов и нейтронов в

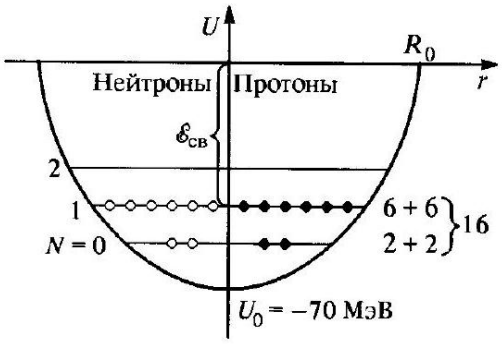

Рис. 175 ядрах с $N = Z$ должны совпадать. В легких ядрах это действительно имеет место, поскольку в них вклад кулоновского взаимодействия в энергию связи незначителен. В случае ядра $^{16}_{8}$ O полностью оказываются заполненными протонные и нейтронные уровни с $N = 0$ и $N = 1$ (дважды магическое число 8 - по протонам и по нейтронам).

На рис. 156 показано также, как отсчитывается искомая энергия связи $\mathscr{E}_{\text{св}}$ (от верхнего заполненного уровня до «потолка» ямы). Таким образом,

$$\mathfrak{E}_{\text{СВ}} \approx |U_0| - \left(N + \frac{3}{2}\right)\hbar\omega$$

где $N = 1$ (внешний нуклон). После преобразований получим

$$\mathscr{E}_{\text{СВ}} = |U_0| - \frac{5\hbar}{2}\sqrt{-\frac{2U_0}{mR_0^2}} \approx 12\text{М}\ni\ \text{В}.$$

О3.1-7.16

Аппроксимируя ядерный потенциал трехмерной параболической ямой глубиной $U_0 = -60$МВ, оценить энергию однонуклонного возбуждения в ядре $^{40}_{20}$ Ca. Считать, что $U(R_0) = 0$, где R_0 - радиус ядра.

7.

16. $\Delta\mathfrak{E} = \hbar\omega = \frac{\hbar}{R_0}\sqrt{-\frac{2U_0}{m}} = 15,8\text{М ЭВ}.$

О3.1-7.17

У ядра дейтерия - дейтрона d - нет стационарных возбужденных состояний, а энергия связи нуклонов составляет $\check{\Xi}_{\text{сВ}} = 2,23$МВ. Аппроксимируя эффективный потенциал нуклоннуклонного взаимодействия трехмерной сферически симметричной прямоугольной потенциальной ямой глубиной $U_0 = -30$М В оценить радиус эффективного потенциала (см. также задачу 3.18).

7.17.

$a^2 = \frac{\pi^2\hbar^2}{8\mu|U_0|}$; $a \approx 1,8 \cdot 10^{-13}$ см, где $\mu = \frac{m_\text{P}}{2}$ - приведенная масса дейтрона. Приведем также результат точного решения, полученного из условия сшивки волновых функций на границе (см. также задачи 3.18 и 3.12):

$$a = \frac{\hbar}{\sqrt{2\mu\left(|U_0| - \mathscr{E}_\text{CB}\right)}} \arccos\frac{\mathscr{E}_\text{CB}}{|U_0|} = 1,82 \cdot 10^{-13} \text{ cm}.$$

7.18.

7.

18. $R_\text{d} = \sqrt{\langle r^2\rangle} = \frac{\hbar}{\sqrt{2m_\text{N}}} \approx 3 \cdot 10^{-13}$ cm, где m_N - масса нуклона. Здесь для оценки можно воспользоваться волновой функцией основного состояния дейтрона (см. задачу 7.12) $\psi \approx Ae^{-xr}/r$, где $\chi = \frac{1}{\hbar}\sqrt{m_\text{N}\mathscr{E}}$.

О3.1-7.19

На рис. 43 изображен спектр низколежащих возбужденных уровней ядра ^{234}U, где $\mathscr{E}$ - энергия уровня, L - квантовое число момента импульса. Показать, что эти уровни сответствуют возбуждению вращения ядра как целого относительно оси, перпендикулярной к оси симметрии ядра. Оценить из этих данных момент инерции J ядра.

7.

19. $J \simeq 1,4 \cdot 10^{-47}\Gamma \cdot \text{ cm}^2$.

О3.1-7.20

Ядро ^{234}U является продуктом распада основного изотопа урана ^{238}U. Определить период полураспада ^{234}U, если его содержание в естественном уране в настоящее время составляет $0,0055\%$. Период полураспада ^{238}U равен $T_8 = 4,51 \cdot 10^9$ лет. Считать, что вначале «наработанного» ^{234}U не было.

7.

20. В силу радиоактивного равновесия между ^{238}U и ^{234}U $\lambda_4 N_4 = \lambda_8 N_8$ (вековое уравнение), откуда

$$\frac{T_4}{T_8} = \frac{\lambda_8}{\lambda_4} = \frac{N_4}{N_8} = 5,5 \cdot 10^{-5}; \quad T_4 = 2,48 \cdot 10^5 \text{ лет}.$$

Период полураспада ^{234}U много меньше возраста Земли ($\approx 10^9$ лет); таким образом, наше предположение о наличии радиоактивного равновесия между ^{238}U и ^{234}U оправдано.

О3.1-7.21

В настоящее время в природном уране содержится $k_8 = 99,28\%^{238}$U и $k_5 = 0,72\%$ ^{235}U. Какое соотношение между ^{238}U и ^{235}U было в момент образования Земли, если возраст Земли равен $4 \cdot 10^9$ лет? Периоды полураспада $T_5 = 0,713 \cdot 10^9$ лет; $T_8 = 4,51 \cdot 10^9$ лет. Вычислить возраст Земли в предположении, что в момент образования Земли содержание ^{235}U и ^{238}U было одинаковым.

О3.1-7.22

Период полураспада ^{234}U равняется $T_4 = 2,48 \cdot 10^5$ лет. Остался ли хотя бы один атом ^{234}U, который существовал в момент образования Земли $-4 \cdot 10^9$ лет тому назад? Как объяснить, что в природном уране содержится примесь ^{234}U в количестве $0,055\%$?

О3.1-7.23

Периоды полураспада ^{238}U и ^{235}U равны соответственно $T_8 = 4,51 \cdot 10^9$ лет и $T_5 = 0,713 \cdot 10^9$ лет. Определить средние времена жизни этих изотопов.

О3.1-7.24

Полагая, что перед α-распадом в ядре образуется самостоятельная α-частица, оценить отношение интенсивностей $_1/_2$ двух групп α-частиц с кинетическими энергиями 6,3 и 5, 7МВ, испускаемых ядрами с $Z = 86$ и $A = 220$. В обоих случаях частоту ударов о «стенку» потенциального барьера считать одинаковой.

О3.1-7.25

Оценить период полураспада $T_{1/2}$ радиоактивного ядра, испускающего α-частицы в энергией 1МВ, если ядро $^{232}_{90}$Th имеет период полураспада $T_{1/2} = 1,4 \cdot 10^{10}$ лет и испускает α-частицы с энергией 4МВ, а для ядра $^{212}_{84}$Po период полураспада равен $T_{1/2} = 3 \cdot 10^{-7}$с и $\mathscr{E}_\alpha = 8,8$МВ.

О3.1-7.26

Энергия α-частиц, испускаемых тяжелыми ядрами ($Z \sim 90$), примерно равна $\mathscr{E}_\alpha \sim 4,5$ МэВ, а период их полураспада $T_\alpha \sim 7 \cdot 10^8$ лет. Оценить период полураспада такого же ядра по отношению к вылету протона той же энергии $\oint_p = 4,5$МВ. Считать задачу одномерной, кулоновский потенциал $U \gg \hat{G}$, а предэкспоненциальный множитель в выражении для проницаемости барьера константой.

О3.1-7.27*

Исследование свойств α-радиоактивных ядер показало, что ядра в области $Z_1 \sim 90$ испускают α-частицы с энергией $\oint_1 \sim 4$ МэВ (например, ядро $^{232}_{90}$Th), а в области редкоземельных элементов, где $Z_2 \sim 65$, - с энергией $\mathscr{E}_2 \sim 2$ МэВ. Оценить период полураспада редкоземельных ядер T_2, если известно, что у тяжелых ядер он лежит в районе $T_1 \sim 10^{10}$, лет. Считать, что α-частицы при распаде преодолевают высокий одномерный потенциальный барьер, т. е. $U \gg \sigma$, а предэкспоненциальный множитель в выражении для проницаемости барьера - константа.

О3.1-7.28

Оценить высоту кулоновского барьера для α-частиц, испускаемых ядрами $^{222}_{86}$r. Какова у этих ядер ширина барьера (туннельное расстояние) для α-частиц с энергией $\mathcal{E} = 5,5$МВ?

О3.1-7.29

При радиоактивном распаде ^{60} Co испускается электрон, спин которого параллелен импульсу. Считая, что электроны вылетают из образца изотропно, оценить, на какой угол повернется диск, подвешенный на нити, если образец кобальта нанесен на одну из поверхностей диска. Толщина диска достаточна для полного поглощения в нем электронов, вылетающих в сторону диска. Активность препарата* $)\frac{dN}{dt} = 0,37$ ТБк $= 0,37 \cdot 10^{12}$ расп/с, модуль кручения нити равен $f = 10^{-6}$ дин см/рад.

О3.1-7.32 Время жизни по регистрируемом времени распада

Удельное содержание изотопа ^{14}C, усвоенного деревом при его жизни, уменьшается затем благодаря β-распаду с $T_{1/2} = 5700$ лет. Какой минимальный возраст дерева можно определить по активности ^{14}C, если регистрируется $N = 10^4$ актов распада? Считать, что скорость образования ^{14}C за счет бомбардировки атмосферы космическими лучами от времени не зависит.

(овч решал, что-то просто в край лень, формулу распада считаем и все... вроде ничего нет сложного.)

О3.1-7.34

Ядро, пролетая через кристалл, подвергается воздействию периодического поля решетки кристалла, в результате чего возможно резонансное возбуждение ядерных уровней (эффект Окорокова смотрите также задачу 4.47). Обусловлен этот эффект тем, что в системе покоя ядра возникает переменное электрическое поле. До какой полной энергии надо разогнать ядро ^{19} F фтора, чтобы при пролете через кристалл вольфрама в нем возбуждался уровень с энергией $\mathscr{E} = 110$ кэВ? Период решетки в направлении движения я,ра $a = 3,2$Å.

О3.1-7.35

Угловой и магнитный момент ядра $^{13}_{6}$C полностью определяется неспаренным нейтроном, находящимся в состоянии $1p_{1/2}$ над полностью заполненной подоболочкой $1p_{3/2}$. Определить магнитный момент μ ядра $^{13}_{6}$C (в ядерных магнетонах Бора). Магнитный момент свободного нейтрона $\mu_{\mathrm{n}} = g_{\mathrm{sn}}\mu_{\mathrm{g}}\ s_{\mathrm{n}} = -1,91\mu_{\mathrm{s}\lambda}$, где $g_{\mathrm{sn}} = -3,82$ - спиновой g-фактор нейтрона, $s_{\mathrm{n}} = 1/2$ - спин нейтрона.

Ук а за н и е. Магнитным моментом ядра принято называть величину максимальной проекции магнитного момента на заданную ось.

О3.1-7.36

Согласно оболочечной модели ядра в ядре $^{15}_{75}$ N неспаренный протон, определяющий его угловой и магнитный моменты, находится в состоянии $1p_{1/2}$ сверх полностью заполненной подоболочки $1p_{3/2}$. Определить величину магнитного момента μ этого ядра (вядерных магнетонах Бора). Магнитный момент свободного протона $\mu_{\mathrm{p}} = g_{\mathrm{sp}}\mu_{\mathrm{gM}}s_{\mathrm{p}} = 2,79\mu_{\mathrm{g}_{\prime}}$, где $g_{\mathrm{sp}} = 5,58$ - спиновой g-фактор протона, $s_{\mathrm{p}} = 1/2$ - спин протона. Смотрите указание к задаче 7.35.

О3.1-7.37*

При учете сверхтонкого взаимодействия интегралом движения является полный угловой момент атома $\mathbf{F} = \mathbf{I} + \mathbf{J}$, где I, J - полные моменты ядра и электронной оболочки соответственно. Энергия сверхтонкого взаимодействия может быть записана в виде $U_{\mathrm{cr}} = A\langle\boldsymbol{\mu}_{\mathrm{e}}\boldsymbol{\mu}_{\mathrm{g}}\rangle$, где $A = \mathrm{const}$, а $\boldsymbol{\mu}_{\mathrm{e}}, \boldsymbol{\mu}_{\mathrm{r}}$ - магнитные моменты электрона и ядра соответственно. Найти отношение сверхтонких расщеплений основного состояния атомов водорода и дейтерия, т. е. расстояний между уровнями с разными значениями F. Спиновые g-факторы протона и нейтрона равны $g_{\mathrm{sp}} = 5,58$ и $g_{\mathrm{sn}} = -3,82$, спины нуклонов в дейтроне параллельны.

7.

37: $\frac{\Delta\varrho^{\mathrm{H}}_{\mathrm{cT}}}{\Delta\varrho^{\mathrm{d}}_{\mathrm{cT}}} = \frac{4}{3}\frac{g_{\mathrm{sp}}}{g_{\mathrm{sp}}+g_{\mathrm{sn}}} = 4,23.$

Решение. В основном состоянии $L = 0$, и магнитный момент имеет чисто спиновую природу. Спин водородного ядра $S_{\mathrm{H}} = 1/2$, а дейтрона $S_{\mathrm{d}} = 1$. Магнитный момент электрона $\mu_{\mathrm{e}} = g_{\mathrm{g}}\mu_{\mathrm{b}}\mathbf{S}_{\mathrm{e}} = 2\mu_{\mathrm{b}}\mathbf{S}_{\mathrm{e}}$, а ядра $\mu_{\mathrm{g}} = g\mu_{\text{яд}}\,\mathbf{S}_{\mathrm{g.}}$. По определению для дейтерия

$$\mu_{\mathrm{g}} = \left(g_{\mathrm{sp}}\mathbf{s}_{\mathrm{p}} + g_{\mathrm{sn}}\mathbf{s}_{\mathrm{n}}\right)\mu_{\text{яд}} = g\mu_{\text{я}}\,\mathbf{s}_{\mathrm{D}}$$

откуда

$$g = \frac{g_{\mathrm{sp}} + g_{\mathrm{sn}}}{2}$$

Для водорода, естественно, $\boldsymbol{\mu_q} = g_{\mathrm{sp}}\,\mu_{\text{яд}}\,\mathbf{S_p}$. Полный момент атома $\mathbf{F} = \mathbf{S}_{\mathrm{e}} + \mathbf{S_g}$, а величина сверхтонкого расщепления

$$\vec{U}_{\mathrm{cr}} = A\cdot 2g\left(\mathbf{S}_{\mathrm{e}}\mathbf{S_g}\right)\mu_{\mathrm{G}}\mu_{\mathrm{gД}} = Ag\left\langle F^2 - S_{\mathrm{e}}^2 - S_{\mathrm{g}}^2\right\rangle\mu_{\mathbf{b}}\mu_{\mathrm{gд}} =$$
$$= Ag\left[F(F+1) - S_{\mathrm{e}}\left(S_{\mathrm{e}}+1\right) - S_{\mathrm{g}}\left(S_{\mathrm{g}}+1\right)\right]\mu_{\mathrm{Б}}\ \mu_{\mathrm{gп}}\ .$$

Для атома водорода $S_{\mathrm{g}} = 1/2, S_{\mathrm{e}} = 1/2$, поэтому возможные значения $F = 1$ или 0 . Для дейтерия, соответственно, $S_{\mathrm{g}} = 1, S_{\mathrm{e}} = 1/2$, а $F = 3/2$ или $1/2$. Поэтому величина сверхтонкого расщепления для водорода

$$\Delta\delta^{\mathrm{H}}_{\mathrm{cr}} = Ag_{\mathrm{sp}}(1\cdot 2 - 0)\mu_{\mathrm{gR}}\mu_{\mathrm{E}} = 2Ag_{\mathrm{sp}}\mu_{\mathrm{gI}}\mu_{\mathbf{\Sigma}},$$

а для дейтерия

$$\Delta\mathscr{E}^{\mathrm{d}}_{\mathrm{CT}} = Ag\left(\frac{3}{2}\cdot\frac{5}{2} - \frac{1}{2}\cdot\frac{3}{2}\right)\mu_{\mathrm{gI}}\mu_{\mathrm{E}} = 3Ag\mu_{g\Omega}\mu_{\mathrm{b}}$$

Таким образом, $\frac{\Delta\mathscr{C}^{\mathrm{H}}_{\mathrm{cr}}}{\Delta\mathcal{E}^{\mathrm{d}}_{\mathrm{cr}}} = \frac{2g_{\mathrm{sp}}}{3g} = \frac{4}{3}\frac{g_{\mathrm{sp}}}{g_{\mathrm{sp}}+g_{\mathrm{sn}}} = 4,23.$

7. Ядерные модели. Радиоактивность. Эффект Мессбауэра SOLUTIONS

7.

21. $k_8(t) = \frac{k_8}{1+k_5\left[e^{(\lambda_5-\lambda_8)t}-1\right]\cdot 10^{-2}}, \quad k_5(t) = 100 - k_8(t).$

Если подставить числовые значения, то получается, что $4 \cdot 10^9$ лет тому назад содержание ^{235}U составляло $16,08\%$. Примерно $6 \cdot 10^9$ лет тому назад содержания ^{235}U и ^{238}U могли быть равными. Конечно, в момент образования Земли в ее составе имелись и другие изотопы урана (см. задачу 7. 22).

7.

22. С момента образования Земли за время $t = 4 \cdot 10^9$ лет содержание ^{234} U на Земле должно уменьниться в $e^{(t\ln 2)/\tau_4} \approx e^{11180} \approx 10^{4855}$ раз. Если даже предположить, что в момент образования Земли на ней существовали только изотопы ^{234}U, то и тогда на Земле уже давно не осталось бы ни одного атома ^{234}U. Изотоп ^{234}U существует в природе благодаря α-распаду ^{238}U и β^--распадам ^{234}Th и ^{234} Pa

$$^{238}_{92}\mathrm{U} \underset{4{,}5\cdot 10^9 \text{ лет}}{\alpha} {}^{234}_{90}\mathrm{Th} \xrightarrow[24 \text{ дня}]{\beta^-} {}^{234}_{91}\mathrm{Pa} \underset{6{,}7 \text{ час}}{\beta^-_{92}} {}^{234}_{9}\mathrm{U}.$$

Содержание ^{234}U находится из условия радиоактивного равновесия (см. задачу 7.20).

7.

23. $\frac{T_8}{\ln 2} = 6,45 \cdot 10^9$ лет; $\frac{T_5}{\ln 2} = 1,016 \cdot 10^9$ лет.

7.

24. В связи с тем, что проницаемость кулоновского барьера экспоненциально зависит от ширины барьера, то ответ задачи оказывается чрезвьн чайно чувствителен к выбору приближения. Приведем три возможных формы ответа:

1. $\frac{1}{2} = \exp\left\{-\frac{4(Z-2)e^2\sqrt{2m_a}}{\hbar}\left[\frac{1}{\sqrt{\mathscr{E}_1}}\arccos\sqrt{\frac{\mathscr{E}_1}{U_0}} - \right.\right.$

$$\left.\left. -\frac{1}{\sqrt{\epsilon_2}}\arccos\sqrt{\frac{\varrho_2}{U_0}} + \sqrt{\frac{\mathscr{E}_2}{U_0}\left(1-\frac{\mathscr{C}_2}{U_0}\right)} - \sqrt{\frac{\mathscr{E}_1}{U_0}\left(1-\frac{\mathscr{E}_1}{U_0}\right)}\right]\right\} = 744$$

2. $\frac{\mathscr{I}_1}{2} = \exp\left[\frac{2\pi(Z-2)e^2\sqrt{2m_a}}{\hbar}\left(\frac{1}{\sqrt{2}} - \frac{1}{\sqrt{1}}\right)\right] = 942;$

3. $\frac{\mathscr{I}_1}{\mathscr{I}_2} = \exp\left[\frac{8(Z-2)e^2}{\hbar}\sqrt{2m_\alpha}\left(\frac{1}{\sqrt{\mathscr{E}_2}} - \frac{1}{\sqrt{1}}\right)\right] = 6130,$

где $U_0 = \frac{2(Z-2)e^2}{R}$, R - радиус ядра с массовым числом $A-4$.
Формулы 1)-3) получены для случая, когда вне ядра α-частица описывается плоской волной (обрыв барьера при $r = R$), что приближенно справедливо, если энергия α-частицы мала по сравнению с высотой кулоновского барьера. Полученные формулы справедливы также при вылете α-частицы «из центра» ядра, когда можно не учитывать центробежный барьер. При этом формула 1) представляет собой результат точного интегрирования; формула 2) является предельным случаем при $U_0 \to \infty$, а формула 3) есть результат интегрирования при $U(r) \gg$.

7.

25. Зависимость периода полураспада от энергии (в МэВ) хорошо описывается законом Гейгера - Неттола

$$\lg T_{1/2} \approx A + \frac{B}{\sqrt{\varepsilon_a}}$$

Из условий задачи константы $A \approx -56,5; B \approx 148,3$. Искомый период полураспада равен $T_{1/2} \simeq 3{\cdot}10^{84}$ лет.

7.

26.

$$\frac{T_{\text{p}}}{T_a}=\frac{\lambda_a}{\lambda_{\text{p}}}=\exp\left[\frac{4\sqrt{2}Ze^2}{\hbar\sqrt{\epsilon}}\left(Z_\alpha\sqrt{m_\alpha}-Z_\rho\sqrt{m_{\text{p}}}\right)\right]=e^{-169},T_{\text{p}}\approx 9\cdot 10^{-57}\text{с}.$$

В силу столь малых времен естественная протонная радиоактивность не наблюдается. Она обнаруживается экспериментально лишь в том случае, когда ей предшествует более медленный β-распад.

7.

27: $T_2\sim 10^{12}$ лет.
Решение. При выполнении условия $U\gg\mathscr{E}$ и $Z\gg 2$ проницаемость барьера равна (см. задачу 3.36)

$$D\approx\exp\left(-\frac{4\sqrt{2m}Z_uZe^2}{\hbar\sqrt{\varepsilon}}\right),$$

тогда $\frac{T_1}{T_2}=\exp\left[\frac{4\sqrt{2m}Z_\alpha e^2}{\hbar}\left(\frac{Z_1}{\sqrt{\zeta_1}}-\frac{Z_2}{\sqrt{\zeta_2}}\right)\right]\approx e^{-4,9}=7\cdot 10^{-3}$ (здесь $Z_\alpha=2$). Откуда $T_2\sim 10^{12}$ лет.
Заметим, что реальное ядро $^{152}_{65}$Tb имеет период полураспада $1,1\cdot 10^{14}$ лет при энергии α-частицы 2, 14М ЭВ.

7.

28. $U_0=\frac{2(Z-2)e^2}{R}=30,7\text{МВ};\quad d=\frac{2(Z-2)e^2}{\mathscr{E}}-R=36$ фм, где $R=r_0A^{1/3}\approx 7,9$ фм - радиус ядра.

7.

29: $\varphi=\frac{\dot{N}\hbar}{8f}\approx 5\cdot 10^{-11}$ рад $=50$ прад.
Решение. Электроны, вылетающие с поверхности диска, делятся на две равные части. Одна из них поглощается диском, а вторая, вылетающая в телесный угол 2π, покидает диск, унося момент

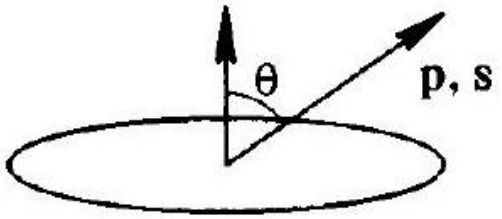

Рис. 176 импульса. Электрон, вылетающий с поверхности диска под углом θ (рис. 176), уносит момент импульса $\hbar/2$. Проекция этого момента на ось вращения равна $(\hbar/2)\cos\theta$. Поскольку все направления вылета равновероятны, то изменение момента импульса в единицу времени $\frac{dL}{dt}=\frac{\dot{N}}{2}\frac{\hbar}{2}\overline{\cos\theta}$, где черта означает усреднение по телесному углу 2π.

$$\overline{\cos\theta}=\frac{1}{2\pi}\int_\Omega\cos\theta d\Omega=\frac{1}{2\pi}\int_0^{\pi/2}2\pi\sin\theta\cos\theta d\theta=\frac{1}{2}$$

Таким образом $dL/dt=\dot{N}\hbar/8$. С другой стороны

$$\frac{dL}{dt}=f\varphi$$

откуда и следует ответ

$$\varphi=\frac{\dot{N}\hbar}{8f}\approx 5\cdot 10^{-11}\text{ рад}.$$

7.

30. $t = 1,57 \cdot 10^{17}$с $\approx 5 \cdot 10^9$ лет (практически равно времени жизни Вселенной). Т. е. таких условий на Земле, по-видимому, не существовало.

7.

31: $\tau_{\text{дип}} \simeq 2 \cdot 10^{-16}$с; $\tau_{\text{квад}} \simeq 5 \cdot 10^{-13}$с.
Решение. Число γ-квантов, излучаемых в единицу времени,

$$\frac{W}{\hbar\omega} = \frac{1}{\tau}$$

где τ - время жизни возбужденного уровня относительно излучения.
Дипольный момент $d = eR\sin\omega t$, где R - радиус ядра. Поэтому $\ddot{d} \approx eR\omega^2$ с точностью до коэффициента порядка единицы. Классическое выражение (данное в условии) для энергии дипольного излучения в единицу времени можно привести к виду:

$$W \approx \frac{2}{3c^3} e^2 R^2 \omega^4.$$

Таким образом, для дипольного излучения время жизни возбужденного уровия

$$\tau_{\text{дип}} = \frac{\hbar\omega}{W} \simeq \frac{3\hbar c^3}{2e^2 R^2 \omega^3}.$$

Если ввести $\neq \frac{c}{\omega} \simeq \frac{200}{\mathscr{E}[\text{ МэВ }]}[]$ - приведенную длину волны γ-кванта с энергией $\mathscr{E}$ в МэВ, то искомое время жизни

$$\tau_{\text{дип}} \simeq \frac{\hbar c}{e^2\omega}\left(\frac{\lambda}{R}\right)^2 \simeq \frac{8 \cdot 10^{-20}}{\mathscr{E}}\left(\frac{200}{\mathscr{E}R}\right)^2 [\text{с}].$$

При $\mathscr{E} = 1$ МэВ и $R = 4$ фм (условие задачи) формула дает Т $= 2 \cdot 10^{-16}$с.
Для мультипольных (в частности - квадрупольных) переходов оценочная формула будет примерно такой же. Изменится только степень размера ядра (размера системы). Из электродинамики известно, что при разложении электрического поля в ряд по мультиполям параметром разложения является отношение размеров системы к расстоянию до точки наблюдения (безразмерная величина). Если в дипольный момент входит R в первой степени, т. е. $d \sim eR$, то в квадрупольный момент входит R^2, а в момент порядка m - R^m. Таким образом, время излучения с моментом m равняется

$$\tau_m \approx \frac{8 \cdot 10^{-20}}{\mathscr{E}}\left(\frac{200}{\mathscr{E}R}\right)^{2m}$$

Так, для $m = 2$ (квадруполь) $R = 4$ фм, $\mathscr{E} = 1$М ВВ, $\text{Т}_{\text{квад}} \approx 5 \cdot 10^{-13}$с.

7.

32. $t = -\frac{T_{1/2}\ln 0,1}{\ln 2} \approx 1,9 \cdot 10^4$ лет.

7.

33. $t_{\min} = \frac{0,01T_{1/2}}{\ln 2} \approx 80$ лет.
Указание. Минимальный возраст, который можно определить, ограничивается статистикой отсчетов.

7.

34. $\beta^2 = \left(\frac{v}{c}\right)^2 = \frac{[\Delta\mathscr{E}a/(ch)]^2}{1+[\Delta\mathscr{E}a/(ch)]^2}$, где $\Delta\mathscr{E} = 110$ кэВ; $\gamma = \left(1-\beta^2\right)^{-1/2} = \frac{\Delta\mathscr{E}a}{ch} \approx 28,5; \mathscr{E} = \gamma M_0 c^2 \approx 510$ ГэВ.
Указание. Для возбуждения уровня в системе покоя ядра нужна ча стота, определяемая из условия $h\nu = \Delta$. Частота возбуждения есть $\nu' = \frac{v}{a'} = \frac{v}{a\sqrt{1-v^2/c^2}}$, поскольку эффективный размер решетки сокращается в направлении движения ядра.

7.

35: $\mu = -1,9\,(-\mu_{\text{яд}}\,/3) \approx 0,64\mu_{\text{gд}}$.

Решение. Векторная модель сложения угловых моментов ядра ($\mathbf{J} = \mathbf{L} + \mathbf{S}$) и магнитных моментов ($\mu_{\text{сум}} = \mu_{\mathbf{L}} + \mu_{\mathbf{S}}$) в самом общем виде изображена на рис. 177, на котором векторы моментов импульса должны быть отложены в единицах $\hbar$, а векторы магнитных моментов - в ядерных магнетонах Бора. Но в силу того, что для протона $g_{l\text{p}} = 1$, для нейтрона
$g_{l\text{n}} = 0$ (в силу его электрической нейтральности), а спиновые g-факторы, соответственно, $g_{sp} = 5,58$ и $g_{sn} = -3,82$, рис. 177 не отражает (в смысле масштабов) условие задачи, а лишь помогает по-

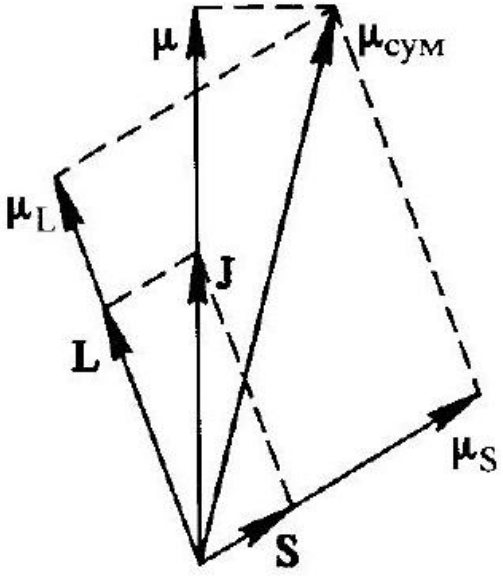

Рис. 177 нять правило сложения моментов. Средний магнитный момент ядра может быть направлен только вдоль J, единственного сохраняющегося вектора в системе, $\langle \mu_{\text{сум}} \rangle = \mu = g_{\mathbf{J}}\mu_{\text{яд}}\,\mathbf{J}$. Умножим это равенство скалярно на и усредним по состоянию с заданными J, L, S. Тогда в силу того, что J - сохраняющийся вектор, его можно внести под знак усреднения, и мы получаем:

$$\langle \mu_{cy}\mathbf{J} \rangle = g_{\mathbf{J}}\mu_{\boldsymbol{g}} \left\langle \mathbf{J}^2 \right\rangle$$

Поскольку $\mu_{\text{L}} = g_{\text{L}}\mu_{\text{яд}}\,\mathbf{L}$ и $\mu_{\text{S}} = g_{\text{S}}\mu_{\text{яд}}\,\mathbf{S}$, то

$$g_{\mathbf{S}}\langle \mathbf{SJ} \rangle + g_{\mathbf{L}}\langle \mathbf{LJ} \rangle = g_{\mathbf{J}} \left\langle \mathbf{J}^2 \right\rangle$$

Используя теорему косинусов, получим

$$\frac{g_{\text{S}} \left\langle \mathbf{J}^2 + \mathbf{S}^2 - \mathbf{L}^2 \right\rangle}{2} + \frac{g_{\text{L}} \left\langle \mathbf{J}^2 + \mathbf{L}^2 - \mathbf{S}^2 \right\rangle}{2} = g_{\text{J}} \left\langle \mathbf{J}^2 \right\rangle$$

В квантовой физике справедливы соотнонения

$$\left\langle \mathbf{J}^2 \right\rangle = J(J+1); \left\langle \mathbf{S}^2 \right\rangle = S(S+1); \left\langle \mathbf{L}^2 \right\rangle = L(L+1)$$

Используя их, получим

$$g_{\mathbf{J}} = \frac{g_{\mathbf{S}} + g_{\mathbf{L}}}{2} + \frac{g_{\mathbf{S}} - g_{\mathbf{L}}}{2} \cdot \frac{S(S+1) - L(L+1)}{J(J+1)}$$

В нашем случае магнитный момент ядра определяется состоянием нейтрона, находящегося на уровне $1p_{1/2}$, т.е. для нейтрона $g_{\mathbf{L}} = g_{l\text{n}} = 0$, $g_{\mathbf{S}} = g_{\text{sn}} = -3,82, S = 1/2; L = 1; J = 1/2$. Подставляя эти данные, получим $g_{\mathbf{J}} = 1,91 \cdot \frac{2}{3} \approx 1,273; \mu = g_{\mathbf{J}}\mu_{\text{я}}\,J \approx 0,64\mu_{\text{яд}}$.

7.

36. $\mu \approx -0,26\mu_{\text{яд}}$.

18.2.3 Problems about radioactivity 2

O3.1-7.38

Спин ядра атома лития (его полный угловой момент) $I = 3/2$. При учете сверхтонкого взаимодействия интегралом движения является полный момент атома $\mathbf{F} = \mathbf{I} + \mathbf{J}$($\mathbf{J}$ - угловой момент электронной оболочки). Найти два возможных значения магнитного момента атома лития, находящегося в состоянии $2^2P_{1/2}$. Собственным магнитным моментом ядра пренебречь.

O3.1-7.39

Свободное покоящееся атомное ядро массой M переходит из возбужденного состояния в основное, испуская γ-квант. Найти энергию γ-кванта и энергию отдачи R, если энергия возбуждения равнялась $\mathscr{E}$. Получить числовой ответ для $^{191}_{77}$Ir если $\mathscr{E} = 129$ кэВ.

O3.1-7.40

Свободное покоящееся атомное ядро массой M переходит в возбужденное состояние с энергией возбуждения $\mathscr{E}$, поглощая γ-квант. Определить энергию γ-кванта и энергию отдачи ядра R.

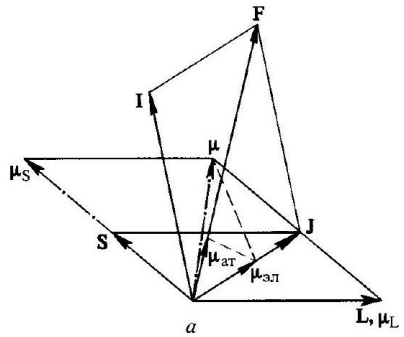
Многие другие еще не выгружены

(другие не выгружал пока что, итак есть над чем подумать.)

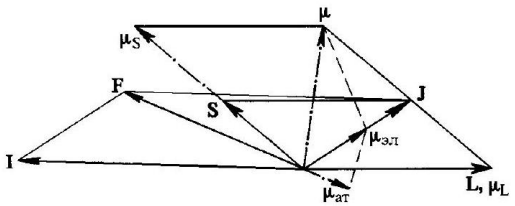
7. Ядерные модели. Радиоактивность. Эффект Мессбауэра SOLUTIONS

7.

38*: $\langle \mu_{\text{ar}} \rangle (F = 1) = -\frac{\mu_{\text{E}}}{6}; \langle \mu_{\text{at}}(F = 2) \rangle = \frac{\mu_{\text{E}}}{3}$.



a



σ

Рис. 178

Решен ие. Магнитный момент атома $\mu_{\text{ат}}$ складывается из магнитных моментов электронной оболочки и ядра $\mu_{\text{ат}} = \mu_{\text{e}} + \mu_{\text{g}} \simeq \mu_{\text{e}}$, т. к. $|\mu_{\text{e}}| \gg |\mu_{\text{g}}|$. В состоянии с заданным J средний магнитный момент электрона

$$\bar{\mu}_{\text{e}} = g_{\mathbf{j}} \mu_{\text{E}} \mathbf{J}, \quad \text{где} \quad g_{\mathbf{J}} = \frac{3}{2} + \frac{S(S+1) - L(L+1)}{2J(J+1)}.$$

В нашем случае $g_{\mathbf{J}} = 2/3$. При наличии взаимодействия ядра с электронами сохраняющимся вектором является $\mathbf{F} = \mathbf{J}+\mathbf{I}$, и средний магнитный момент атома $\langle \overline{\boldsymbol{\mu}}_{\text{a}} \rangle$ должен быть направлен по $\mathbf{F}$, т. е. $\langle \boldsymbol{\mu}_{\text{at}} \rangle = \mu \mathbf{F}$. Умножая обе части скалярно на $\mathbf{F}$ и внося вектор $\mathbf{F}$ под знак усреднения, получим $\mu \langle \mathbf{FF} \rangle = g_J \langle \mathbf{JF} \rangle \mu_{\mathbf{6}}$, или

$$\mu \left\langle \mathbf{F}^2 \right\rangle = \mu_{\mathbf{E}} g_J \frac{1}{2} \left\langle \mathbf{F}^2 + \mathbf{J}^2 - \mathbf{I}^2 \right\rangle. \quad \text{Отсюда} \quad \mu = g_J g_F \mu_{\mathbf{E}}$$

где $g_F = \frac{1}{2} + \frac{J(J+1)-I(I+1)}{2F(F+1)}$.
Поскольку $I = 3/2, J = 1/2$, то или $F = 2$ и $g_F = +1/4$ или $F = 1$ и $g_F = -1/4$. Следовательно,

$$\langle \mu_{\text{aT}}(F=2) \rangle = \frac{2}{3}\left(\frac{1}{4}\right)\mu_{\text{G}} \cdot 2 = \frac{\mu_{\text{E}}}{3}.$$

$$\langle \mu_{\text{aT}}(F=1) \rangle = \frac{2}{3}\left(-\frac{1}{4}\right)\mu_{\text{E}} \cdot 1 = -\frac{\mu_{\text{E}}}{6};$$

Примечание. Возможность такого подхода для вычисления $\mu_{\text{ат}}$ связана с малостью энергии сверхтонкого взаимодействия по сравнению с энергией спин-орбитального взаимодействия. Строго говоря, в векторной модели атома нужно сложить μ_S и μ_L и спроецировать сумму на направление **F**. Мы же проецируем сначала на **J**, а потом на **F**. Частота прецессии **J** вокруг F много меньше частоты прецессии L и S вокруг J (см. рис. 178*а* и б).

7.

39*. Решение. При испускании γ-кванта должны выполняться законы сохранения энергии и импульса

$$\mathscr{E} = \hbar\omega + R$$

$$\frac{\hbar\omega}{c} = p_R = \frac{1}{c}\sqrt{R\left(2Mc^2 + R\right)}$$

где p_R - импульс ядра после испускания γ-кванта. Решая эти уравнения, получим

$$R = \frac{\mathfrak{E}^2}{2\left(Mc^2 + \mathscr{E}\right)} \approx \frac{\mathfrak{E}^2}{2Mc^2} = 0,0468 \text{ эВ}$$

$$\hbar\omega = \mathscr{E} - \frac{\mathscr{E}^2}{2Mc^2} \approx \mathscr{E} = 129\text{k}$$

7.

40. $R \approx \frac{\mathscr{E}^2}{2Mc^2}; \hbar\omega = \mathscr{E} + R.$

7.

41. Изменение энергии γ-кванта из-за эффекта Доплера $\Delta\mathscr{E} = \mathscr{E}\frac{v}{c}$. Полагая $\Delta\mathscr{E} = \Gamma/6$, получаем $v/c = 6 \cdot 10^{-12}, v = 0,18$ см/с.

7.

42. Условие резонансного поглощения принимает вид $T_{\text{эфф}} \geq \frac{R}{4k_{\text{L}}}$. Поскольку $R = \frac{\mathscr{G}_\gamma^2}{2Mc^2} = \frac{\mathscr{C}_\gamma^2 N_{\text{A}}}{2Ac^2}$, то $T \gtrsim \frac{\mathfrak{G}_\gamma^2 N_{\text{A}}}{8k_{\text{D}}Ac^2} \approx 135$ K.

7.

43. При излучении γ-кванта энергия отдачи R воспринимается всем кристаллом и поэтому $\Delta\mathscr{E} = R = \frac{\varrho_\gamma^2}{2Mc^2} = 1,5 \cdot 10^{-25\text{эВ}}$.

7.

44. Смещение частот $\frac{\Delta\omega}{\omega} = \frac{R^2\Omega^2}{2c^2}$. Если $\frac{\Delta\omega}{\omega} = \frac{1}{3} \cdot 10^{-13}$, то $\Omega = 74$ рад/с.

7.

45. $v = \frac{\mathscr{E}}{2mc} \approx 10^4$ cm/c.

7.

46. $h = \frac{\Gamma c^2}{100 \S_\gamma g} \approx 28$ м, где g - ускорение свободного падения.

7.

47* Решение. Из-за различия эффективных температур излучателя и поглотителя частоты излученного и поглощенного γ-квантов будут смещены на величину порядка $\delta v \simeq v\frac{k_\text{B}\delta T_\text{эфф}}{Mc^2} = v\frac{R\delta T_\text{эфф}}{Ac^2}$, где R - универсальная газовая постоянная, A - атомная масса железа. Именно это смещение должно быть меньше гравитационного $\Delta v = v\frac{gh}{c^2}$ (см. задачу 1.4). Разность температур эквивалентна высоте $\delta h = \frac{R\delta T_\text{эфф}}{Ag} \simeq 15$ м, что сравнимо с высотой башни в эксперименте Паунда и Ребки. Таким образом, для того, чтобы при помощи эффекта Мессбауэра можно было наблюдать гравитационное смещение частоты γ-квантов, температуры излучателя и поглотителя должны быть одинаковыми с очень высокой степенью точности.

7.

48. $H = \frac{10hc^2}{g\tau\varrho} \approx 400$ m.

7.

49. $m = \frac{^2\tau}{\hbar c^2} \approx 5,3 \cdot 10^{-13}\Gamma; b = \left(\frac{3m}{4\pi\rho}\right)^{1/3} \approx 0,25$ мКМ.

7.

50. $\mathscr{E}_\nu = \frac{\Delta\mathscr{E}^m c^2}{2\mathscr{E}_\gamma} \approx 960\kappa$.

Решение. Естественная ширина возбужденного состояния очень мала и равна $\delta\varnothing = \hbar/\tau = 1,5 \cdot 10^{-2}$ эВ. Уширение возникает из-за доплеровского сдвига, связанного с отдачей ядра при испускании нейтрино. Согласно закону сохранения импульса $p_\text{яд} = \mathscr{E}_\gamma/c$, а доплеровский сдвиг равен

$$\Delta(h\nu) = h\nu\frac{v}{c} = \frac{\mathscr{E}_\gamma\mathscr{E}_v}{mc^2} = \frac{\Delta\mathscr{E}}{2}$$

откуда следует

$$\mathscr{E}_v = \frac{\Delta\mathscr{E}^m c^2}{2\mathscr{E}_\gamma} \approx 960 \text{ кэВ}.$$

7.

51. $\tau \approx \frac{\hbar}{(\Delta - 2\delta_\text{доп})} \approx 10^{-17}$с, где $\delta_\text{доп} \approx 160$ В.

Указание. При испускании γ-кванта с энергией 5 МэВ ядро испытывает отдачу, и поэтому линия излучения с энергией $1,5$М МВ оказывается уширенной на $2\delta\mathscr{E}_\text{доп}$.

7.

52. При переходах излучаются магнитно-дипольные (M1) γ-кванты с моментом и четностью 1^+(см. также задачу 7.57). Рассматривая крайние
компоненты расщепления ($\Delta v = 10,5\text{m/c}$), соответствующие изменению спина ядра ($-3/2 \to -1/2$ и $+3/2 \to +1/2$), получим

$$B = \frac{\mathscr{E}_0 \Delta v}{c\mu_{\text{яд}}\left(g_{1/2} + 3g_{3/2}\right)} \simeq 330\kappa\text{Гс}$$

7.

53: $\mathscr{E}_0 = -8,4\text{M эВ}$.
Решение. Предположим, что ядро - равномерно заряженный шар радиусом R (см. задачу 4.41 и рис. 135 к ней). Мюон является лептоном, поэтому он может взаимодействовать с ядром только за счет электромагнитных сил. Тогда потенциальная энергия мюона внутри ядра

$$U(r < R) = -\frac{3}{2}\frac{Ze^2}{R}\left(1 - \frac{r^2}{3R^2}\right) = -U_0 + \frac{Ze^2}{2R^3}r^2, \text{ где } U_0 = \frac{3Ze^2}{2R}$$

Видно, что это потенциал трехмерного изотропного гармонического осциллятора

$$U(r) = -U_0 + \frac{m_\mu \omega^2 r^2}{2}$$

где $\frac{m_\mu \omega^2}{2} = \frac{Ze^2}{2R}$, откуда следует, что $\omega^2 = \frac{Ze^2}{m_\mu R^3}$.
Подсчет дает $U_0 = \frac{3Ze^2}{2R} \approx 23\text{M}$; ; энергия основного состояния $\mathscr{E}_0 = -U_0 + \frac{3}{2}\hbar\omega; \hbar\omega = \sqrt{\frac{\hbar^2 Ze^2}{m_\mu R^3}} = 9,73$ МэВ. Окончательно, $\mathscr{E}_0 = -8,4\text{M МВ}$

7.

54. Для оценки областй локализации можно принять, что она совпадает с амплитудой колебаний трехмерного гармонического осциллятора в основном состоянии

$$\sqrt{\overline{r^2}} = \sqrt{\frac{3\hbar}{m_\mu}\sqrt{\frac{m_\mu R^3}{Ze^2}}} = 1,06 \cdot 10^{-12} \text{ cm}$$

и больше радиуса ядра свинца $R_{\text{Pb}} = 7,7 \cdot 10^{-13}$ cm.

7.

55. $M = 5N(t)m_\alpha \approx 3,2 \cdot 10^{-6}$ г, где число расщепившихся ядер $N(t) \approx \approx N_0 \frac{t \ln 2}{T_{1/2}} = 0,975 \cdot 10^{17}$.

7.

56. $M \approx 300$ т (точно по Маяковскому).

7.

57: $I_{\text{кон}} = \frac{1}{2}$; $2s_{1/2}$-состояние.
Решение. Уравнение Шредингера для осциллятора допускает разделение переменных как в прямоугольной, так и в сферической системе координат. С этим же связано и случайное вырождение уровней энергии в данном потенциале. В декартовой системе уровни осциллятора характеризуются квантовым числом $N = n_x + n_y + n_z$. В сферической системе можно характеризовать их по моменту l и радиальному квантовому числу n_r. При этом $N = 2n_r + l$, а уровни записываются как $(n_r + 1)\,l$. Таким образом, $N = 0$ соответствует $n_r = l = 0$, т. е. это $1s$-состояние. $N = 1$ соответствует $n_r = 0$, $l = 1$, и это $1p$-состояние. $N = 2$ соответствует $n_r = 1, l = 0$ и $n_r = 0, l = 2$,

т. е. это $2s$ и $1d$-состояния, которые в данном приближении вырождены. Учет спин-орбитального взаимодействия приводит к расщеплению $1p$-состояния на $1p_{3/2}$ и $1p_{1/2}$; $1d$-состояния на $1d_{5/2}$ и $1d_{3/2}$. Как показывает эксперимент, в ядре уровень с болыним j лежит ниже по энергии.

При поглощении фотона $E1$ ($j = 1$ - момент импульса фотона) должны выполняться правила отбора

$$|I_{\text{кон}} - I_{\text{нач}}| \leqslant j \leqslant I_{\text{кон}} + I_{\text{нач}}$$

где $I_{\text{кон}}$ и $I_{\text{нач}}$ - конечное и начальное значения спина ядра. Ядро $^{13}_{6}$ С имеет $2 \cdot 2 = 4$ нуклона на оболочке с $N = 0$ и $2 \cdot 6 = 12$ нуклонов на оболочке с $N = 1$. Остается один нейтрон из незаполненной подоболочки в состоянии $1p_{1/2}$ (см. указание к задаче). Для одного нуклона с моментом l четность состояния равна $P = (-1)^l$ ($l = 1$ для состояния $1p_{1/2}$). Таким образом,

$$\left| I_{\text{КОН}} - \frac{1}{2} \right| \leqslant 1 \leqslant I_{\text{КОН}} + \frac{1}{2}$$

Кроме того, должен выполняться закон сохранения четности состояний

$$P_{\text{кон}} \cdot P_{\text{На}} = \begin{cases} (-1)^J & \text{для } EJ - \text{ фотонов;} \\ (-1)^{J+1} & \text{для } MJ - \text{ фотонов ,} \end{cases}$$

где $P_{\text{кон}}$ и $P_{\text{нач}}$ - четности конечного и начального состояний ядра, откуда следует, что конечная четность должна быть равна $P_{\text{кон}} = +1$. С другой стороны, $p_{\text{кон}} = (-1)^{l_{\text{кон}},}$ где $l_{\text{кон}}$ - орбитальный момент конечного состояния. Таким образом, получается, что оно четное. А значит, подходят два нуклонных состояния из $N = 2$: состояние $2s_{1/2}$ ($l_{\text{кон}} = 0$)

$$\left| \frac{1}{2} - \frac{1}{2} \right| \leqslant 1 \leqslant \frac{1}{2} + \frac{1}{2}, \quad \text{т. е.} \quad (0 \leqslant 1 \leqslant 1)$$

а также состояние $1d_{3/2}$ ($l_{\text{кон}} = 2$)

$$\left| \frac{3}{2} - \frac{1}{2} \right| \leqslant 1 \leqslant \frac{3}{2} + \frac{1}{2}, \quad \text{т. е.} \quad (1 \leqslant 1 \leqslant 2)$$

Условию задачи удовлетворяет состояние с наименьшей энергией $2s_{1/2}$, спин ядра $I_{\text{кон}} = \frac{1}{2}$.

7.

58. $I_{\text{кон}} = \frac{3}{2}$; $1d_{3/2}$-состояние.

7.

59. $k = \frac{M_{\text{Т}}}{M_{\text{П}\pi}} = \left(\frac{\cdot\sqrt{2m_\alpha (??)_\alpha} N_{\text{А}} \ln 2}{4 g T_{1/2} A} - 1 \right)^{-1} \approx 0,52.$

7.

60. $\mu_{\text{d}}^{(1)} = \frac{\mu_{\text{яд}}}{2} \left[\frac{3}{2} - \frac{5,58-3,82}{2} \right] = 0,31 \mu_{\text{яд}}$ - для случая ls-связи;
$\mu_{\text{d}}^{(2)} = \frac{\mu_{\text{g}}}{2} \left[\frac{4}{3} - \frac{5,58-3,82}{2} \right] = 0,373 \mu_{\text{яд}}$ - для случая jj-связи.
Решени е. Нецентральность ядерных сил ведет к несохранению момента импульса, поэтому основное состояние не есть чистое s-состояние ($L = 0$), а содержит также примесь состояния с $L = 2$ (D-состояние). На-

личие только четных моментов - следствие закона сохранения четности. Что же касается полного момента J, то он всегда является интегралом движения. Поэтому $J = 1$ в обоих случаях. Параллельность спинов (при этом $S = 1, 2S + 1 = 3$) - экспериментальный факт, и с $S = 0$ связанного состояния нет.

Заметим, что при реализации ls-связи полный момент $\mathbf{J} = \mathbf{L} + \mathbf{S}$, где $\mathbf{L} = \sum_i \mathbf{1}_i; \mathbf{S} = \sum_i \mathbf{s}_i$. При реализации jj-связи $\mathbf{J} = \sum_i \mathbf{j}_i$, где $\mathbf{j}_i = \mathbf{1}_i + \mathbf{s}_i$.

Для дейтрона в состоянии $^3D_1 : L = 2; S = 1$; g-факторы протона и нейтрона: $g_{l\text{p}} = 1$; $g_{l\text{n}} = 0$ (поскольку заряд равен нулю); $g_{\text{sp}} = 5,58$; $g_{\text{sn}} = -3,82$. Если $\mathbf{L}$ - орбитальный момент дейтрона, а $\mathbf{S}$ - спиновый, то в силу зарядовой независимости p и n для ядерных сил $\mathbf{1}_{\text{p}} = \mathbf{1}_{\text{n}} = \mathbf{L}/2$; $s_p = s_n = \mathbf{S}/2$. Таким образом, можно записать:

$$\mu_{\text{d}} = \left(g_{l\text{pp}} \mathbf{1}_{\text{p}} + g_{sp} \mathbf{s}_{\text{p}} + g_{\text{sn}} \mathbf{s}_{\text{n}} \right) \mu_{\text{gд}} = \left[\frac{\mathbf{L}}{2} + \left(g_{sp} + g_{sn} \right) \frac{\mathbf{s}}{2} \right] \mu_{\text{яд}}$$

Далее надо вычислить проекцию вектора μ_d на направление , которая и называется магнитным моментом дейтрона в ls-связи

$$\mu_{\mathrm{d}} = \frac{\mu_{\mathrm{gn}}}{2}\left[\langle \mathbf{L}\cos(\mathbf{LJ})\rangle + (g_{sp}+g_{sn})\,\langle \mathbf{S}\cos(\mathbf{SJ})\rangle\right]$$

Здесь $\langle \mathbf{LJ}\rangle = \langle LJ\cos(\mathbf{LJ})\rangle$, откуда $\langle L\cos(\mathbf{LJ})\rangle = \frac{\langle \mathbf{LJ}\rangle}{J}\frac{J}{J} = \frac{\langle J(\mathbf{LJ})\rangle}{J^2}$. К роме того, $\langle \boldsymbol{S}\cos(\mathbf{SJ})\rangle = \frac{\langle J(\mathbf{SJ})\rangle}{J^2}$. Подсчитаем:

$$\langle L\cos(\mathbf{L})\rangle = J\frac{J(J+1)+L(L+1)-S(S+1)}{2J(J+1)} = \frac{1}{4}[2+6-2] = \frac{3}{2}$$

$$\langle S\cos(\mathbf{SJ})\rangle = \frac{J}{2J(J+1)}[J(J+1)+S(S+1)-L(L+1)] = -\frac{1}{2}$$

Отсюда и следует первый ответ: $\mu_d^{(1)} = 0,31\mu_{\text{яд}}$.
Что же касается магнитного момента дейтрона при реализации jj-связи, то в этом случае подсчет следует осуществлять так:

$$\langle \boldsymbol{\mu}\rangle = \langle g_{\mathbf{n}}\mu_{\boldsymbol{g}}\mathbf{j_n} + g_{\mathrm{p}}\mu_{\boldsymbol{gj}}\mathbf{j}_{\mathrm{p}}\rangle = g\mu_{\text{яд}}\,\mathbf{J}$$

При этом

$$g = g_{\mathrm{n}}\frac{\langle \mathbf{j}_{\mathrm{n}}\mathbf{J}\rangle}{2J^2} + g_{\mathrm{p}}\frac{\langle \mathbf{j}_{\mathrm{p}}\mathbf{J}\rangle}{2J^2} = \frac{g_{\mathrm{n}}+g_{\mathrm{p}}}{2}$$

Определим g-факторы протона и нейтрона g_{p} и g_{n}. Имеем

$$\langle \mu_{\mathbf{n}}\rangle = g_{\mathbf{n}}\mu_{\text{я}}\,\mathbf{j_n},\ \text{где}\ \mu_{\mathbf{n}} = g_{\boldsymbol{sn}}\mu_{\text{я}}\,\mathbf{s_n}$$

Умножая оба выражения на $\mathrm{j_n}$ и усредняя при этом скалярное произведение, получим

$$\langle \mu_{\mathrm{n}}\mathrm{j_n}\rangle = g_{\mathrm{n}}\mu_{\mathrm{g}}\left\langle \mathrm{j}_{\mathrm{n}}^2\right\rangle = g_{sn}\mu_{\text{gд}}\ \langle \mathbf{s}_n\mathrm{j}_n\rangle\,,\ \text{откуда следует, что}$$

$$g_{\mathrm{n}} = \frac{\langle \mathbf{s}_{\mathrm{n}}\mathrm{j_n}\rangle}{\langle \mathrm{j}_n^2\rangle}g_{sn} = g_{\mathrm{sn}}\frac{s_{\mathrm{n}}\left(s_{\mathrm{n}}+1\right)+j_{\mathrm{n}}\left(j_{\mathrm{n}}+1\right)-l_{\mathrm{n}}\left(l_{\mathrm{n}}+1\right)}{2j_{\mathrm{n}}\left(j_{\mathrm{n}}+1\right)} = -\frac{g_{sn}}{3} = \frac{3,82}{3}.$$

Совершенно аналогично опеределяется и протонный g-фактор:

$$g_{\mathrm{p}} = \frac{\langle \mathrm{I_p j_p}\rangle}{\left\langle \mathrm{j}_{\mathrm{p}}^2\right\rangle} + g_{sp}\frac{\langle\ \mathrm{s_p j_p}\rangle}{\left\langle \mathrm{j}_{\mathrm{p}}^2\right\rangle} = \frac{4}{3} - \frac{5,58}{3}$$

Подставив результаты для g_{n} и g_{p}, получим ответ

$$g = \frac{g_{\mathrm{n}}+g_{\mathrm{p}}}{2} = 0,373,\ \text{т. е.}\ \mu_{\mathrm{d}}^{(2)} = 0,373\mu_{\text{мд}}$$

Поскольку обе модели дают близкие результаты, то отдать предпочтение какой-то из них на основе экспериментальных данных невозможно (см. задачу 7.61).

7.

61. $w = 0,035(3,5\%)$ (см, также замечание в начале решения задачи 7.60). Если обозначить искомую вероятность как w, то тогда средний магнитный момент дейтрона, измеряемый в опыте, есть

$$\langle \mu\rangle = (1-w)\mu\left({}^3S_{\mathrm{I}}\right) + w\mu\left({}^3D_{\mathrm{I}}\right)$$

откуда и следует приведенный ответ.

7.

62. $\delta\varrho_{\text{допл}} = \frac{Q\mathscr{E}_\gamma}{Mc^2} = 5,7$ В; $\quad \delta\varrho_{\text{отд}} = \frac{\mathscr{E}_y^2}{2Mc^2} = 2,5$ В; $\quad \delta\mathscr{E}_0 \approx \frac{\hbar}{\tau_1} + \frac{\hbar}{\tau_2} \approx \approx \frac{\hbar}{\mathrm{T}_1} = 2\cdot 10^{-2}$ В.

7.

63. Амплитуда сигнала ЯМР пропорциональна количеству соответствующих ядер. Поэтому первый пик соответствует ЯМР на ядрах трития. $\mu(\mathrm{t}) = \frac{h\nu I}{B_1} = 2,97\mu_{\text{яд}} = 1,5 \cdot 10^{-23}$ эрг/с, где $I = \frac{1}{2}.\mu(t) - \mu_{\text{теор}}\,(\mathrm{t}) = (2,97 - 2,79)\mu_{\text{яД}} = 0,18\mu_{\text{яд}}$.

7.

64. $\Delta\mu_{\text{He}} = |\mu_{\text{эксп}} - \mu_{\text{теор}}| = 0,22\mu_{\text{яд}} = 0,11 \cdot 10^{-23}$ эрг /, где $\mu_{\text{эксп}} = -2,13\mu_{\text{яд}}$; $\mu_{\text{теор}} = -1,91\mu_{\text{яд}}$.

7.

65. $R_m = \frac{hc}{\varrho \sin\theta_m}, m = 1,2,3; R_{\text{ср}} = 3,5 \cdot 10^{-13}$ cm. $(r_0)_{\text{ср}} = \frac{R_{\text{ср}}}{AV^3} \approx 1,2.$

18.2.4 Problems about neutrons 1

O3.1-8.1

Нейтрон упруго рассеивается на ядре. Какое минимальное отличное от нуля прицельное расстояние b может реализоваться для нейтрона с энергией $\mathscr{E} = 100$ кэВ (рис. 46)?

8.

1. По закону сохранения момента импульса $bp = L = \hbar\sqrt{l(l+1)}$. Минимальное значение $l = 1$, откуда $b_{\min} = \frac{\hbar\sqrt{2}}{p} = \frac{\hbar\sqrt{2}}{\sqrt{2\ \mathrm{m}\ \S}} = \frac{\hbar}{\sqrt{\mathrm{m}}} = 2 \cdot 10^{-12}$с.

O3.1-8.2

Оценить отношение сечений образования компаунд-состояния (составного ядра) при бомбардировке ядер $^{40}_{20}$Ca нейтронами и протонами с одной и той же начальной энергией $\mathscr{E}_0 = 10$МВ.

8.

2* $\frac{\sigma_c(p)}{\sigma_c(n)} \approx 0,5.$

Решение. Рассмотрим сначала случай рассеяния нейтрона на ядре (рис. 179). Возможные значения прицельных расстояний b_l определяются из правила квантования момента импульса

$$pb_l = \hbar\sqrt{l(l+1)}$$

Импульс нейтрона $p = \hbar/\lambda$. В квазиклассическом приближении ($l \gg 1$) $b_l \approx l$. Разобьем пространство, занимаемое падаюuим пучком нейтронов, на кольцевые зопы, ширина которых равна λ. В каждой из этих зон будут двигаться частицы с определенным значением момента импульса. Число ча стиц в такой зоне (при условии их равномерного распределения в простран стве) пропорционально площади кольца со средним радиусом b_l

$$S_l = \frac{1}{2}\pi\left(b_{l+1}^2 - b_{l-1}^2\right) = \pi\hbar^2(2l+1).$$

Полученная величина S_l - это геометрическое сечение, пропорциональное доле всех частиц, имеющих квантовое число l, из всего потока падающих на ядро нейтронов. Умножая S_l на вероятность

w_l поглощения ча-

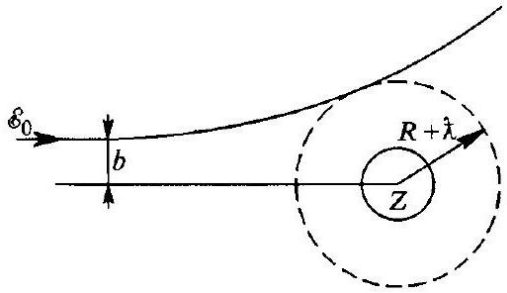


Рис. 179 стицы ядром, получим парциальное сечение образования составного ядра для частицы с моментом l.

Вероятность поглощения зависит от внутренних свойств ядра и от характеристики сил, действующих на частицу вне ядра. В общем случае она пропорциональна вероятности проникновения через кулоновский и центробежный барьеры. Конечно, существует отражение и при $l = 0$.
Представим w_l в виде

$$w_l = P_l \zeta_l,$$

где P_l - вероятность проникновения через внешний барьер, ζ_l - вероятность «прилипания» частицы к ядру. Тогда полное сечение поглощения (образования составного ядра), включая случай с $l = 0$, есть

$$\sigma_{\mathrm{c}}(\mathrm{n}) = \sum_{l=0}^{\infty} (2l+1)\pi \hat{\lambda}^2 P_l \zeta_l.$$

Чтобы ядро поглотило частицу, она должна попасть в область действия ядерных сил, т.е. $(b_l)_{\max} \leqslant R$, откуда $l_{\max} \approx R/\lambda$. Что касается величины ζ_l, то будем считать, что ядро поглощает все падающие на него частицы (модель черного ядра). Тогда $\zeta_l = 1$ при $l \leqslant R/\lambda$ и

$$\sigma_{\mathrm{c}}(\mathrm{n}) = \sum_{l=0}^{R/\lambda} (2l+1)\pi \hbar^2 P_l$$

В области энергий нейтронов порядка нескольких МэВ и выше, когда $\lambda \ll R$, можно считать, что $P_l \simeq 1$, и тогда

$$\sigma_{\mathrm{c}}(\mathrm{n}) = \sum_{l=0}^{R/\lambda} (2l+1)\pi \lambda^2 = \pi (R+\lambda)^2$$

В случае рассеяния протонов составное ядро образуется лишь тогда, когда энергия протона будет больше кулоновского барьера (туннельным эффектом при данной энергии можно пренебречь). Для вычисления воспользуемся полученным выше результатом (*). Как видно из этой формулы, эффективный размер ядра стал равным $R+\lambda$. Пусть на бесконечности энергия и прицельное расстояние протона равны $\mathscr{E}_0$ и b. Тогда закон сохранения энергии дает уравнение (в системе центра инерции)

$$\mathscr{E} = \mathscr{E}_0 - \frac{Ze^2}{R+\hbar}$$

Соответствующий закон сохранения момента импульса -

$$b\sqrt{2m\wp_0} = (R+\lambda)\sqrt{2m\complement^\circ}$$

откуда сразу следует предельное значение b:

$$b = (R+\lambda)\sqrt{\frac{\varrho}{\varrho_0}}$$

Тогда искомое сечение образования составного ядра под действием протонов

$$\sigma_{\mathrm{c}}(\mathrm{p}) = \pi b^2 = \pi (R+\hat{\lambda})^2 \frac{\mathscr{E}}{\mathscr{E}_0} = \pi (R+\lambda)^2 \left[1 - \frac{Ze^2}{\varrho_0 (R+\hbar)}\right].$$

Отношение сечений

$$\frac{\sigma_c(\mathrm{p})}{\sigma_{\mathrm{c}}(\mathrm{n})} = 1 - \frac{Ze^2}{\varrho_0 (R+\hbar)} \approx \frac{1}{2}$$

где $\hat{\lambda} = \frac{\hbar}{\sqrt{2}\ _0} = 1,5 \cdot 10^{-13}$ cm; $R_{\mathrm{Ca}} = 1,3 \cdot 10^{-13} A^{1/3} = 4,45 \cdot 10^{-13}$ cm (величины соизмеримые).

О3.1-8.3

Оценить полное сечение σ взаимодействия ультрарелятивистского нейтрона с ядром урана. Приняв для сечения нуклон-нуклонного взаимодействия величину $\sigma_{\mathrm{NN}} \approx 40$ мбн, оценить длину свободного пробега такого нейтрона в ядре.

8.

3. $\sigma_{\text{полн}} = 2\pi R_{\mathrm{U}}^2 \approx 4,1$ бн. В релятивистском случае дебройлевская длина волны $t = \hbar/p \leq \hbar/(m_{\mathrm{n}}c) = 2 \cdot 10^{-14}$ см, что много меньше $R_{\mathrm{U}} \approx \approx 8 \cdot 10^{-13}$ cm. Таким образом, сечение поглощения неупругого рассеяния $\sigma_{\text{погл}} = \pi (R_{\mathrm{U}} + \lambda)^2 \approx \pi R_{\mathrm{U}}^2$, т. е. все частицы с прицельным расстоянием, меньшим R_{U}, выбывают из пучка и поглощаются. Ядро ведет себя как поглощающий шар (модель «абсолютно черного ядра»). Действительно, длина пробега нуклона $l = \frac{1}{\sigma_{\mathrm{NN}} n} = \frac{4\pi r_0^3}{3\sigma_{\mathrm{NN}}} \approx 2 \cdot 10^{-13}$ см $\ll R_{\mathrm{U}}$. Однако из-за дифракции на краю ядра происходит отклонение частиц от первоначального направления - упругое рассеяние. Согласно принципу Бабине для дифракции Фраунгофера количество света, рассеянного на черном теле, равно количеству света, падающего на него и поглощаемого им, $\sigma_{\text{погл}} = \sigma_{\text{диф}}$. Следовательно, $\sigma_{\text{полн}} = \sigma_{\text{погл}} + \sigma_{\text{диф}} = 2\sigma_{\text{погл}}$ (дифракционное удвоение), поэтому $\sigma_{\text{полн}} = 2\pi R_{\mathrm{U}}^2 \approx 4,16$Н.

О3.1-8.4

Медленный нейтрон упруго рассеивается на свободном ядре со спином $I = 3/2$ в состоянии с орбитальным моментом $L = 0$. Определить вероятность рассеяния в состояниях с параллельной и антипараллельной взаимной ориентацией спинов нейтрона и ядра.

У к з з н и е.

Учесть, что ядерные силы между нуклонами зависят от взаимной ориентации их спинов и поэтому сечение рассеяния зависит от полного углового момента сталкивающихся частиц, являЮщегося интегралом движения. Спином ядра называют его полный момент. В данном случае (при $L = 0$) спин ядра является «чистым» спином в традиционном его понимании.

8.

4: Вероятность рассеяния с параллельной ориентацией спинов $\frac{I+1}{2I+1} = \frac{5}{8}$, а с антипараллельной $\frac{I}{2I+1} = \frac{3}{8}$.

Решение. Для медленных частиц минимальное прицельное расстояние (см. задачу 8.1) много больше размеров ядра, и поэтому реакция возможна только при $l = 0$. Таким образом, полный момент является чисто спиновым, и число спиновых состояний системы из двух частиц есть $(2S + 1)(2I + 1) = 2(2I + 1)$. При этом полный момент (спин) может принимать два значения: $I + 1/2$ и $I - 1/2$. Первому моменту соответствует $2(I + 1/2) + 1 = 2(I + 1)$ значений проекции момента, второму $2(I - 1/2) + 1 = 2I$.

Вероятность рассеяния пропорциональна относительной доле состояний с заданной проекцией полного момента, т. к. энергия взаимодействия не зависит от значения проекции.

О3.1-8.5

Вплоть до энергий $T = 20$ МэВ угловое распределение рассеянных нейтронов в реакции пр $\to$ пр в лабораторной системе отсчета хорошо описывается формулой $d\sigma(\theta) = A \cos\theta d\Omega$. Как выглядит это распределение в системе центра инерции? Какая оценка для радиуса действия ядерных сил отсюда следует?

8.

5. $\frac{d\sigma_{\text{наб}}}{d\Omega} = \frac{d\sigma_\mu(\theta')}{d\Omega'}$; $\theta' = 2\theta; d\sigma_\mu = \frac{A}{4} d\Omega'$, т. е. нейтроны в системе центра масс (СЦМ) рассеиваются изотропно. $R \approx \hbar \approx 10^{-13}$ см. Полученные формулы следуют из векторных диаграмм рассеяния в ЛСО и СЦМ.

Приведем для сведения формулу для пересчета дифференциального сечения из «Л» - лабораторной системы в «ЦМ» - систему центра масс в общем виде

$$\left(\frac{d\sigma(\theta)}{d\Omega}\right)_{\mathrm{J}} = \left(\frac{d\sigma(\theta')}{d\Omega}\right)_{\mathbf{LM}} \frac{\left(m_1^2 + 2m_1 m_2 \cos\theta' + m_2^2\right)^{3/2}}{m_2^2 (m_2 + m_1 \cos\theta')}$$

где штрихом обозначены углы в СЦМ, m_2 - покоящаяся масса, m_1 - движушаяся.

О3.1-8.6

Тепловой нейтрон из реактора попадает по нормали в биологическую защиту (рис. 47), состоящую в основном из водорода (например, парафин), толщиной $l = 1$ m и плотностью ядер $n = 10^{22}\text{см}^{-3}$. Сечение упругого рассеяния составляет $\sigma_{\text{расс}} = \sigma_0 = 20$ бн, сечение поглощения $-\sigma_{\text{погл}} = \sigma_1 = 0,3$ бн и не зависит от энергии. Угловое распределение упруго рассеянных нейтронов в системе центра масс изотропно. Считая, что после рассеяния нейтрон пролетает в защите путь в $1/\cos\theta$ раз больший, чем при прямом пролете, где θ - угол рассеяния, оценить вероятность того, что нейтрон пройдет через защиту, испытав лишь только одно упругое столкновение [l].

8.

6.* $w \approx 4 \cdot 10^{-9}$. Решение. Уменьшение потока нейтронов связано с актами захвата и рассеяния. Так, в слое защиты толщиной dx, находящемся на расстоянии x от места входа нейтронов, их поток уменьшится на величину

$$dj = -j(x)\frac{dx}{\lambda}$$

где $\lambda \approx \frac{1}{n\sigma_{\text{полн}}}$ - длина свободного пробега нейтрона. Полное сечение реакции (как захват, так и упругое рассеяние) $\sigma_{\text{полн}} = \sigma_{\text{погл}} + \sigma_{\text{расс}} \approx \sigma_{\text{расс}} = \sigma_0$. Таким образом,

$$j(x) = j_0 e^{-n_{\sigma_0} x}$$

где j_0 - поток нейтронов на входе. Перепишем это выражение в дифференциальной форме

$$dj = -j_0 n\sigma_0 e^{-n_{\sigma_0} x} dx$$

Таким образом вероятность упругого рассеяния нейтрона в слое толщиной dx на расстоянии x от входа в защиту

$$dw = \left|\frac{dj}{j_0}\right| = n\sigma_0 e^{-n_0 x} dx$$

После столкновения нейтроны проходят путь $\frac{l-x}{\langle\cos\theta\rangle}$. Определим среднее значение косинуса угла рассеяния, имея в виду замечание в условии задачи, что в системе центра масс угловое распределение упруго рассеянных нейт-
ронов изотропно. Как показано в предыдущей задаче 8.5, в этом случае в лабораторной системе отсчета $d\sigma(\theta) = A\cos\theta d\Omega$. Таким образом,

$$\langle\cos\theta\rangle = \frac{\int_0^{\pi/2}\cos\theta\cos\theta d\Omega}{\int_0^{\pi/2}\cos\theta d\Omega} = \frac{\int_0^{\pi/2}\cos^2\theta d(\cos\theta)}{\int_0^{\pi/2}\cos\theta d(\cos\theta)} = \frac{2}{3}.$$

Вероятность выйти из защиты без какого-либо взаимодействия после рассеяния в точке, находящейся на расстоянии x от места входа,

$$dw(x) = n\sigma_0 e^{-n\sigma_0 x} dx \exp\left(-n\sigma\frac{l-x}{\langle\cos\theta\rangle}\right)$$

Искомая вероятность пройти защиту, испытав лишь одно упругое столкновение,

$$w = \int_0^l n\sigma_0 e^{-n_{\sigma_0}x} e^{-n_{\sigma_0}\frac{3}{2}(l-x)} dx = n\sigma_0 e^{-\frac{3}{2}n_{\sigma_0}l}\int_0^l e^{\frac{1}{2}n_{\sigma_0}x} dx \approx 2e^{-20} = 4\cdot 10^{-9}.$$

О3.1-8.7

Плотность потока нейтронов, выходящих из реактора, равна $j_0 = 10^{14}\text{с}^{-1}\cdot\text{см}^{-2}$. Определить выход реакции в единицу времени (отношение числа актов реакции к числу частиц, упавших на единицу площади мишени в единицу времени) в мишени толщиной 1см. Сечение реакции $\sigma = 10^{-27}\text{см}^2$, плотность ядер мишени $n = 10^{22}\text{см}^{-3}$.

О3.1-8.8

Узкий пучок тепловых нейтронов проходит через слой воды толщиной 1 см. Определить доли первоначального потока нейтронов, выбывающих из пучка в результате поглощения и рассеяния. Сечение поглощения для воды $\sigma_{\text{погл}} = 0,66$ бн, а сечение рассеяния $\sigma_{\text{расс}} = 696$Н.

8.

7. $\frac{j_0-j_d}{j_0} \approx n\sigma d = 10^{-5}$.

8.

8. $\alpha_{\text{расс}} = 0,9; \alpha_{\text{погл}} = 0,022$.

О3.1-8.9

Определить, во сколько раз уменьшается интенсивность узкого пучка тепловых нейтронов после прохождения пластинки Al толщиной $d = 3$ см. На выходе из пластинки регистрируется пучок первоначальной ширины. Сечение рассеяния для алюминия $\sigma_{\text{расс}} = 1,41$ бн, а сечение поглощения $\sigma_{\text{погл}} = 0,23$ бн.

8.

9. $\frac{j_0}{j} = \exp\left(\frac{d\rho N_{\text{A}}\sigma}{A}\right) \approx 1,35$, где $\sigma = \sigma_{\text{расс}} + \sigma_{\text{погл}} = 1,64$ бн.

О3.1-8.10

Быстрые нейтроны, попав в воду, быстро замедляются до тепловых скоростей $v = 2,2$ km/c и диффундируют в ней, пока не захватятся ядрами водорода (захватом кислородом можно пренебречь). Оценить время жизни т нейтронов в воде. Сечение захвата (поглощения) теплового нейтрона протоном $\sigma_{\text{погл}} = \sigma = 0,3$ бн.

8.

10. $\tau = \frac{\mu}{2\rho N_{\text{A}}\sigma\nu} = 2,3 \cdot 10^{-4}$ с. Отметим, что в области справедливости закона Бете $\alpha = \sigma_{\text{погл}} \propto 1/v$, время жизни нейтрона в среде не зависит от его энергии.

О3.1-8.11

Исследование структуры жидкого или твердого ^{3} He с помощью пропускания нейтронов через слой вещества затруднено из-за большой величины сечения экзотермической реакции $^3\text{He}(\text{n},\text{p})^3\text{H}$, и для нейтронов с энергией 300 K оно равно $\sigma_0 = 5400$ бн. Определить энергию нейтронов, с помощью которых можно изучать слои ^{3} He толщиной $d = 1$ мм, чтобы проходило не менее 10% от потока падающих нейтронов. Концентрация ядер ^{3} He $n = 10^{22}$см$^{-3}$.

Ук а з а н и е. Сечение указанной реакции для нейтронов с энергией до 1 МэВ имеет нерезонансный характер.

8.

11. $\mathscr{E} = \mathscr{E}_0\left(\frac{\sigma_0 nd}{\ln(j_0/j)}\right)^2 \approx 0,14$ эВ, где $\mathscr{E}_0 = 0,025$ эВ.

О3.1-8.12

Для регистрации медленных нейтронов широко используются счетчики, наполненные газообразным изотопом ^{3} He. Рассчитать долю ε регистрируемых частиц - эффективность счетчика,

представляющего собой цилиндр диаметром $d = 25$ мм, наполненный газом при давлении $P = 10$ атм. Нейтроны при температуре $T = 300$ K летят вдоль диаметра цилиндра. В счетчике происходит реакция $^3\text{He}(\text{n},\text{p})^3\text{H}$, сечение которой для регистрируемых нейтронов $\sigma = 5400$ бн.

О3.1-8.13

Для детектирования медленных нейтронов широко используются ионизационные счетчики, наполненные ^{3}He. Регистрация нейтронов производится по реакции $\left(\mathrm{n}, {}^3\mathrm{He}\right) \rightarrow \left({}^3\mathrm{H}, \mathrm{p}\right)$. Показать на основе законов сохранения, что взаимодействие нейтронов с гелием-3 не может приводить к образованию ^{4} He по реакции $\mathrm{n} + {}^3\mathrm{He} \rightarrow {}^4\mathrm{He}$.Cm. также задачу 1.16.

О3.1-8.14

В сечении рассеяния нейтронов на ядрах может проявляться «волновой резонанс», когда интерференция нейтронных волн де Бройля приводит к «прозрачности» чдер (ядерный аналог эффекта Рамзауэра). Оценить, при какой минимальной энергии нейтронов должны быть видны Эти «резонансы проницаемости» на ядре ^{208} Pb. Ядерный потенциал считать одномерной ямой, ширина которой равна диаметру ядра, глубина ямы $U = 40\mathrm{M} \ni \mathrm{B}$ (см. задачу 3.33).

О3.1-8.15

Источник тепловых нейтронов установлен в центре большого графитового куба, и со временем нейтроны, многократно рассеиваясь на ядрах углерода и иногда поглощаясь, распространяются по всему объему. Оценить эффективный размер области, занимаемой в результате нейтронами, если эффективное сечение рассеяния нейтронов $\sigma_{\text{расс}} = 4,8 \cdot 10^{-24}\text{см}^2$, а поглощения $-\sigma_{\text{погл}} = 3 \cdot 10^{-27}\text{см}^2$. Плотность графита $\rho = 2,2$ г/ cm^3.

О3.1-8.16

Поликристаллический бериллий слабо поглощает, но интенсивно рассеивает нейтроны (брэгговское отражение на кристалликах). На этом основано действие поликристаллического фильтра, пропускающего нейтроны с энергией $\mathcal{E} < \mathscr{E}_{\text{гр.}}$. Найти $\sigma_{\text{гр}}$ для бериллия, у которого межплоскостное расстояние $d = 2\text{Å}$.

О3.1-8.17

Поток нейтронов из реактора, имеющих максвелловское распределение по скоростям с температурой $T = 370$ K, пропускается через толстый поликристаллический фильтр из спрессованного порошка графита. Найти. какая поля нейтпонов ппохолит чепез такой фильтр. Максимальное межплоскостное расстояние для решетки графита $a = 3,35\text{Å}$.

О3.1-8.18

Два цилиндрических стержня с одинаковыми диаметрами, один из графита, другой из висмута, совмещены основаниями. Графитовый стержень через открытый торец облучается параллельно его оси потоком нейтронов, выходящих из замедлителя с комнатной температурой 300 K (рис. 48). Полагая рассеяние нейтронов в графите и висмуте брэгговским, оценить, во сколько раз средняя кинетическая энергия нейтронов $\mathcal{E}_k$, выходящих из висмутового цилиндра через его боковую поверхность, меньше энергии падающих нейтронов $\mathcal{E}_0$. Максимальное 71 расстояние между кристаллическими плоскостями для графита $d_{\text{c}} = 3,35\text{Å}$ и для висмута $d_{\text{Bi}} = 4,05\text{Å}$. Длина стержней много боль ше их диаметров, которые сравнимы со средним пробегом нейтронов.

8. SOLUTIONS Нейтроны. Ядерные реакции

8.

12. $\varepsilon = 1 - \exp\left(-\frac{P \circ d}{kT}\right) \approx 96\%$.

8.

13* Решение. Энергия связи ^{3} Не равна 7,7 МэВ, а ^{4}He – 28,3 МэВ, т. е. реакция в принципе экзотермическая. Однако трехчастичная реакция невозможна, как это имеет место при фотоэффекте на свободном электроне, в силу законов сохранения энергии и импульса

$$\begin{cases} \frac{mv^2}{2} + Q = \frac{MV^2}{2}; \\ mv = MV \end{cases}$$

Поскольку $M \approx 4m$, то $v = 4V$. Тогда

$$16V^2 + \frac{2Q}{m} = 4V^2, \quad 5V^2 + \frac{Q}{m} = 0.$$

Из последнего равенства видно, что реакция невозможна при $Q > 0$.

8.

14. Условие резонанса $2R_{\text{Я}} = n\frac{\lambda}{2} = \frac{n\pi\hbar}{\sqrt{2m_N(\mathscr{G}_n+U)}}, \mathscr{E}_n > 0$ (энергия отсчитывается от потолка ямы), откуда $n^2 \cdot 0,864$ МэВ $> U$. Минимальное целое n, которое удовлетворяет этому условию, есть $n = 7$, при этом $\mathfrak{E}_n = 2,34$М эВ.

8.

15: $L_{\text{эфф}} = \frac{A}{\rho N_{\text{A}}\sqrt{3\sigma_{\text{расс}}\,\sigma_{\text{погл}}}} \approx 44$ cm.

Решение. Длина свободного пробега частицы $\lambda = \frac{1}{n\sigma}$. В данном случае существуют два механизма взаимодействия нейтронов с ядрами углерода рассеяние и поглощение (захват). Следовательно, имеются две длины свободного пробега. Время пробега до захвата $t_{\text{погл}} = \frac{\lambda_{\text{погл}}}{v}$. Искомый эффективный размер области, занимаемой нейтронами, определяется временем $t_{\text{погл}}$

$$L_{\text{эфф}} = \sqrt{6Dt_{\text{пог}}}$$

где коэффициент диффузии D в свою очередь определяется рассеянием нейтронов, т. е. $D = (1/3)\lambda_{\text{расс}}\, v$. Подстановкой получим

$$L = \sqrt{2\lambda_{\text{расс}}\, v \cdot \frac{\lambda_{\text{погл}}}{v}} = \sqrt{2\lambda_{\text{погл}}\,\lambda_{\text{расс}}} = \left(\frac{n^2\sigma_{\text{погл}}\,\sigma_{\text{расс}\,2}\right)^{-1/2} \ldots .}{2}.$$

Плотность атомов углерода $n = \rho N_{\text{A}}/A$. Таким образом,

$$L_{\text{эфф}} = \frac{A\sqrt{2}}{\rho N_{\text{A}}\,(\sigma_{\text{расс}}\,\sigma_{\text{погII}}\,)^{1/2}} \approx 107 \text{ cm}.$$

8.

16. Условие пропускания: $\lambda > 2d$, где λ - длина волны де Бройля для бериллия. Отсюда $\mathscr{E}_{\mathbf{r}\rho} = \frac{\pi^2\hbar^2}{2md^2} \approx 5 \cdot 10^{-3}$ эВ .

8.

17. $\alpha = \frac{1}{2}\left(\frac{\pi^2\hbar^2}{2m_{\text{n}}kTa^2}\right)^2 = 0,16\%$.

8.18. $\frac{\mathscr{E}_{\text{C}}}{\mathscr{E}_{\text{к}}} = \frac{2kT}{(\mathscr{E}_{\text{C}}+\mathscr{E}_{\text{Bi}})/2} \approx 34$, где $\mathscr{E}_{\text{C}} = \frac{\hbar^2}{2m\lambda_{\text{C}}^2}$; $\mathscr{E}_{\text{Bi}} = \frac{\hbar^2}{2m\lambda_{\text{Bi}}^2}$, а $\lambda_{\text{C}} \geqslant 2d_{\text{C}}$ и $\lambda_{\text{Bi}} \geqslant 2d_{\text{Bi}}$ (нейтроны с длинами волн от λ_{C} до λ_{Bi} рассеиваются в висмуте и выходят через его поверхность).

8.

19. $v_{\text{r}\rho} = \frac{2\hbar\sqrt{-\pi Nf}}{m_{\text{r}}}$ при условии, что $f < 0$.

8.

20. $\varphi_0 \approx \sqrt{1-n^2} = \lambda\sqrt{-\frac{Nf}{\pi}}$.

8.

21. $1-n^2=-\frac{2\pi\hbar^2\rho N_{\text{A}}f}{m_{\text{n}}{}'A}=1,23\cdot10^{-5},\theta\approx\sqrt{1-n^2}\approx12'$ (угол скольжения).

8.

22. $f=-\frac{\pi}{N\lambda^2}=-\frac{m_n^2v^2A}{4\pi\hbar^2\rho N_{\text{A}}}\approx-0,78\cdot10^{-12}$ cm.

8.

23. Сечение упругого рассеяния нейтронов $\sigma=-\frac{\ln0,7}{n_{\text{m}}d}=5,45$ бн, где $n_{\text{m}}=\rho N_{\text{A}}/A_{\text{Pb}}$ - концентрация ядер мишени. При упругом s-рассеянии $\sigma=4\pi|f|^2$, откуда $R_{\text{я}}=\sqrt{\frac{\sigma}{4\pi}}=6,6\cdot10^{-13}$ см. Доказательство того, что происходит s-рассеяние, т. е. рассеяние с нулевым моментом импульса, основано на подсчете квантового числа l в условии $pR_{\text{я}}=\sqrt{2m_n\S}R_{\text{я}}=\hbar\sqrt{l(l+1)}$, откуда $l\simeq0,4$, т. е. в самом деле преобладает s-рассеяние.

8.

24. $H=\left(\frac{3nh}{4m\sqrt{2g}}\right)^{2/3}\approx0,034$ mm.

8.

25. $f=-\frac{gHAm_{\text{n}}^2}{2\pi\hbar^2\rho N_{\text{A}}}\approx-8,4\cdot10^{-13}$с.

8.

26*. Решение. Скорость счета, т. е. число нейтронов, попавших в детектор в единицу времени, есть произведение плотности потока нейтронов j на площадь детектора. Поскольку распределение нейтронов в реакторе максвелловское, то

$$dj(v)=vdn(v)=Av\cdot v^2\exp\left(-\frac{mv^2}{2kT}\right)dv$$

где A - нормировочная постоянная.
Для ультрахолодных нейтронов $\frac{mv^2}{2k}=T^*=6\cdot10^{-3}$ K $\ll T$, поэтому с хорошей точностью экспоненту можно считать равной 1. Тогда $dj(v)=Av^3dv=A'\mathscr{E}d\mathscr{E}$, где $\mathscr{E}=mv^2/2$. При «падении» нейтронов вниз их скорость увеличивается и может превысить граничное значение $v_{\text{гр}}$, вследствие чего такой нейтрон покинет трубу и не попадет в счетчик. Предельная энергия $\mathscr{E}'=\mathfrak{E}-mgH=\frac{mv_{\text{гр}}^2}{2}-mgH$. Суммарная плотность потока нейтронов

$$j=A'\int_0^{\mathfrak{E}'}\mathscr{E}d\mathscr{E}=\frac{A'}{2}\mathfrak{E}'^2=\frac{A'}{2}\left(\frac{mv_{\text{гр}}^2}{2}-mgH\right)$$

Счет прекратится при $\mathscr{E}'=0$, откуда предельное значение

$$H=\frac{v_{\text{гр}}^2}{2g}=5\text{ m}$$

8.

27. $j\propto\left(\frac{mv_{\text{гр}}^2}{2}-mgH\right);H_{\text{гр}}=\frac{v_{\text{гр}}^2}{2g}=5$ m.

8.

28. $S = \frac{4V}{v\tau} = 0,8 \text{ mm}^2$.

8.

29. $\alpha = \sqrt{\frac{6}{\pi}}(\sin i)^3 = 3,4 \cdot 10^{-8}$.

8.

30*. $j \approx 18900$ нейтронов/с.

Решение. Чтобы понять, как ведут себя нейтроны с заданной энергией $\mathscr{E} = 10^{-7}$ эВ в меди и алюминии, вычислим длину волны таких нейтронов:

$$v = \sqrt{\frac{2\mathscr{E}}{m}} = 4,38 \text{ m/c}; \quad \lambda = \frac{h}{mv} = 9,05 \cdot 10^{-6} \text{ cm}.$$

Предельные длины волн для нейтронов в меди и алюминии

$$\lambda_{\mathbf{r}\rho} = \sqrt{\frac{\pi}{N|f|}} = \sqrt{\frac{\pi A}{\rho N_{\text{A}}|f|}} = \begin{cases} 6,9 \cdot 10^{-6} \text{ cm(Cu)}, \\ 12,2 \cdot 10^{-6} \text{ cm(Al)}. \end{cases}$$

Таким образом, длина волны нейтронов данной энергии удовлетворяет неравенству

$$\lambda_{\Gamma p}^{\text{Cu}} < \lambda < \lambda_{\Gamma p}^{\text{Al}}$$

Это означает:
а) стенки медной сферы для этих нейтронов непроницаемы;
б) по алюминиевому нейтроноводу пойдут лишь те, что падают на стенку под углом больше критического

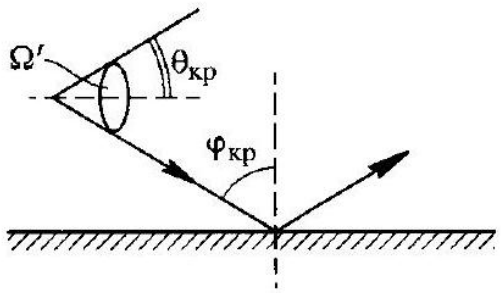

Рис. 180

$$\varphi_{\text{кр}} = \arcsin n = \arcsin \sqrt{1 - \frac{\lambda^2}{\left(\lambda_{\text{гр}}^{\text{A}}\right)^2}} = 42,1^\circ.$$

Поток нейтронов, падакщих на мишень, $\Phi = \langle j_\parallel \rangle S$, где $S = \pi r^2$ - площадь детектора, а $\langle i_\parallel \rangle$-тангенциальная по отношению к оси нейтроновода компонента плотности потока нейтронов, усредненная по телесному углу Ω (рис. 180), предельное значение которого

$$\Omega' = 2\pi\left(1 - \cos\theta_{\text{Кр}}\right) = 2\pi\left[1 - \cos\left(\frac{\pi}{2} - \varphi_{\text{Кр}}\right)\right].$$

Итак,

$$\langle j_\parallel \rangle = n_0 v \int \cos\theta \frac{d\Omega}{4\pi} = \frac{n_0 v}{4\pi} \int_0^{2\pi} d\varphi \int_0^{\pi/2-\varphi_{\text{кр}}} \cos\theta \sin\theta d\theta =$$
$$= \frac{n_0 v}{4} \sin^2\left(\frac{\pi}{2} - \varphi_{\text{Кр}}\right) = \frac{n_0 v}{4} \cos^2\varphi_{\text{Кр}}$$

Таким образом, искомый поток нейтронов на мишени

$$\Phi = S\frac{n_0 v}{4}\cos^2\varphi_{\text{К}p} = \frac{\pi r^2}{4} n_0 \sqrt{\frac{2\mathscr{E}}{m}} \cos^2\varphi_{\text{Кр}} \approx 18900 \text{ нейтронов /}.$$

8.

31. $\alpha = \frac{\lambda^2 |f| \rho N_{\text{A}} R}{2\pi A b} \approx 0,076$. Как видно из рис. 181 , по нейтроноводу пройдут лишь те нейтроны, которые падают на его поверхность под углом $\theta \leqslant \theta_{\text{кр}}$. Относительное их число α, очевидно, равно отношению h/b. Кроме того, приведем очевидные соотношения (i - угол падения):

$$\sin^2 i = \cos^2 \theta_{\text{Kp}} = n^2; 1 - \sin^2 \theta_{\text{K}p} = 1 - \frac{\lambda^2 N |f|}{\pi}.$$

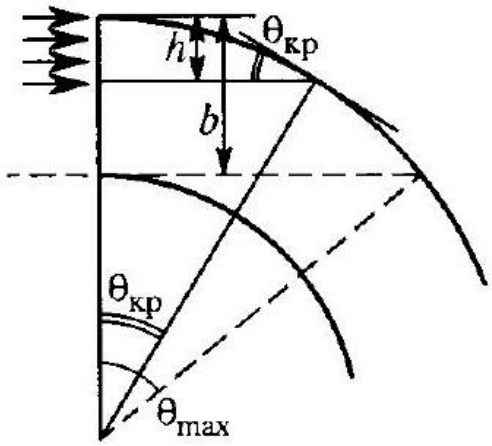

Рис. 181

8.

32. $R \approx \frac{4dm\&\lambda_0^2}{h^2 \theta_{\text{kp}}^2} \approx 75$ m.

8.

33. Отличие показателя преломления от 1 есть $1 - n = \frac{N_{\text{A}} \rho a \lambda^2}{2\pi A} = 4,74 \cdot 10^{-6}$. Тогда фокусное расстояние одного отверстия $F_1 = \frac{R}{2(1-n)} \approx \approx 10,5$ m, фокусное расстояние системы из 10 отверстий $F \approx 1$ м.

8.

40. $N_{\text{p}} = j_{\text{n}} \left[1 - \exp\left(-\frac{a}{\tau_{\text{n}} v}\right)\right] \approx 1,1 \cdot 10^6 \text{ см}^{-2} \cdot \text{с}^{-1}$, где $\tau_{\mathbf{n}} \approx 940$с - время жизни нейтрона.

8.

41: $\sigma = \frac{\eta A_{\text{Al}}}{\rho_{\text{B}} l_{\text{B}} N_{\text{A}}} \approx 0,04 \sigma$Н.
Решение. По определению сечения ядерной реакции

$$\sigma = \frac{dN/dt}{jN_{\text{M}}}$$

где dN/dt - число актов ядерного взаимодействия в единицу времени, [1/с]; j - плотность потока частиц, облучающих мишень $\left[1/\text{см}^2 \cdot \text{с}\right]$; $N_{\text{м}}$ - число ядер мишени.
Выход протонов определяется как

$$\eta = \frac{dN/dt}{jS}$$

где S - площадь поперечного сечения пучка. Тогда

$$\eta = \sigma \frac{N_{\text{M}}}{S} = \sigma n_{\text{M}} \qquad (*)$$

где $n_{\text{м}}$ $\left[1/\text{cm}^2\right]$ - поверхностная плотность ядер мешени.
Иногда эту же формулу записывают в несколько ином виде:

$$\frac{N}{S} = \sigma n_{\text{n}} n_{\text{M}},$$

где $n_{\text{п}}$ - число частиц пучка, приходящееся на 1 cm^2 сечения пучка, N число прореагировавших ядер мишени (число происшедших реакций).

Пробег α-частицы ограничен из-за потери энергии на ионизацию атомов. Очевидно, что потери пропорциональны плотности вещества, т. к. имеется приближенная пропорциональность между плотностью и порядковым номером Z элемента, а произведение пробега частицы l на эту плотность есть величина постоянная, практически не зависящая от рода вещества, а только от начальной энергии частицы. Таким образом,

$$l_{\text{B}} \rho_{\text{B}} = l_{\text{Al}} \rho_{\text{Al}}. \qquad (**)$$

Использую помеченные соотношения (*) и (**), получим

$$\sigma = \frac{\eta}{n_{\text{M}}} = \frac{\eta}{\frac{n_{\text{M}}}{l_{\text{Al}}} l_{\text{Al}}} = \frac{\eta}{n_{\text{Al}} l_{\text{Al}}},$$

где n_{Al} - концентрация ядер в алюминиевой мишени в $\left[\text{cm}^{-3}\right]$, l_{Al} - пробег α-частиц в ней. Однако в условии задан пробег $l_{\text{в}}$ - в воздухе. Подставляя $^{(**)}$ в выражение для σ, получим

$$\sigma = \frac{\eta \rho_{\text{Al}}}{n_{\text{Al}} \rho_{\text{B}} l_{\text{B}}} = \frac{\eta A_{\text{Al}}}{\rho_{\text{B}} l_{\text{B}} N_{\text{A}}} = 4 \cdot 10^{-26} \text{ cm}^2 = 0,04\sigma\text{H}.$$

Здесь использовано, что $\rho_{\text{Al}} = m_{\text{Al}} n_{\text{Al}}$, где m_{Al} - масса атома алюминия. Плотность воздуха при нормальных условиях подсчитывается по известной формуле для идеального газа

$$\rho_{\text{ВОЗ}} = \frac{P\mu}{RT} \approx 1,29 \cdot 10^{-3} \Gamma/\text{cm}^3.$$

8.

42. $\sigma(\mathcal{E}) = \frac{AC\mathscr{E}^2}{n_0}$.

8.

43. $\mathscr{J} = e\sqrt{\frac{KSc}{2l\varepsilon\sigma}} = 1,96$ А.

8.

44. $\frac{\Phi_2}{\Phi_1} = e^{-(\mu_2 - \mu_1)x}$. При $x = 5$ см $\frac{\Phi_2}{\Phi_1} \approx 1,5$.

8.

45. $\lambda' = 3\lambda = 3$Å.

18.2.5 Problems about neutrons 2

SOLUTIONS ABOUT NEUTRONS

8.

46. $\frac{N}{N_0} = \exp\left(-\frac{2P_0 N_\text{A}}{\mu g}\sigma\right) \approx 1,2 \cdot 10^{-6}$, где $\sigma = \pi r_N^2 = \pi r_0^2 A_N^{2/3}$ (это геометрическое сечение неупругого процесса поглощения, и поэтому дифракционную упругую добавку учитывать не нужно), P_0 - нормальное атмосферное давление, μ - молярная масса азота.

8.

47. $l_\text{p} = \frac{A_\text{H}}{8\pi\rho N_\text{A} r_\text{p}^2} \approx 148$ cm, $l_\text{N} = \frac{A_\text{H}}{2\pi\rho N_\text{A}(r_\text{N}+r_\text{p})^2} \approx 24$c. (См. также комментарий к ответу задачи 8.3 о дифракционном удвоении.)

8.48.

$\sigma_\text{погл} \simeq \frac{\pi}{2}\left(2R_\text{Pb} - R_\text{d}\right) R_\text{d} = 0,385$ бн.

8.

49. $T_\text{n} \approx \frac{\mathscr{E}_\gamma + \Delta\mathfrak{C}_\text{CB}}{1+M_\text{n}/M_\text{Li}} = 6,7$M В ; $T_\text{Li} = \mathscr{E}_\gamma + \Delta\mathscr{E}_\text{CB} - T_\text{n} = 1,1$M В, где $\Delta\mathscr{E}_\text{CB} = \mathscr{E}_2 - \mathscr{E}_1, M_\text{Li}$ - масса ядра ^{6}Li.

8.

50. $T_\text{p} = \frac{(4m_\text{p}-m_\pi)m_\pi}{2(m_\text{p}-m_\pi)}c^2 = 0,31$ ГэВ.

8.

51: $\varphi = \frac{\hbar_c}{\mathscr{E}_\gamma R_\text{d}} \approx 0,4$ рад.

Решение. Энергия связи нуклонов мала по сравнению с энергией падающих на мишень фотонов. Поэтому продольный импульс нуклонов можно оценить как $p_\parallel \approx \mathscr{E}_\gamma/$. Поперечный импульс нуклонов обусловлен движением нуклонов в ядре. Импульс нуклона в ядре оценим из соотношения неогг ределенностей

$$p_\perp \approx \Delta p \sim \frac{\hbar}{R_\text{d}} \approx 100\frac{\text{M В}}{c}, \quad c - \text{ скорость света.}$$

Таким образом, угол рассеяния нуклонов в пучке по порядку величины равен

$$\varphi \approx \frac{p_\perp}{p_\parallel} \approx 0,4 \text{ рад.}$$

8.

52. $p_{\text{O}^*} = m_{\text{O}^*}c\frac{\Delta\mathscr{E}}{2\mathscr{E}} = 1,49\frac{\text{Гэ В}}{c}, \alpha \approx \frac{p_{\text{O}^*}}{p} \approx 0,15$ рад.

8.

53. а) При реакции поглощается энергия (см. табл. 7 в конце книги)

$$Q = -931{,}5(7{,}016004 + 1{,}007825 - 7{,}016930 - 1{,}008665)\ \text{МэВ} = 1{,}645\ \text{МэВ}$$

б) Из закона сохранения энергии и импульса для неупругого процесса найдем, полагая $m_\text{n} = m_\text{p} = m_\text{Be}/7 = m_\text{Li}/7$:

1) в системе центра масс

$$\mathscr{E}_n^c = \mathscr{E}_\text{p}^\text{c} - \frac{7}{8}Q$$

2) в лабораторной системе

$$\mathscr{E}_\text{n} = \frac{49}{64}\left[\left(\mathscr{E}_\text{p} - \frac{8}{7}Q\right) + \frac{2}{7}\sqrt{\mathscr{E}_\text{p}\left(\mathscr{E}_\text{p} - \frac{8}{7}Q\right)}\cos\alpha_\text{c} + \frac{\mathscr{E}_\text{p}}{49}\right] =$$

$$= \frac{1}{64}\left[\sqrt{\mathscr{E}_\text{p}}\cos\alpha + \sqrt{49\left(\mathscr{E}_\text{p} - \frac{8}{7}Q\right) - \mathscr{E}_\text{p}\sin^2\alpha}\right]^2$$

где $\mathscr{E}_\text{n}^\text{c}$ и $\mathscr{E}_\text{n}$ - энергии нейтрона в системе центра масс и лабораторной системе, $\mathscr{E}_\text{p}^\text{c}, \mathscr{E}_\text{p}$ - то же для протона; α_c и α - углы между направлениями скорости протона и нейтрона в системе центра масс и лабораторной системе.

Из формул ясно, что минимальная энергия протона (порог реакции) в системе центра масс равна $\mathscr{E}_\text{p}^\text{c} = (7/8)Q = 1,44\text{М}$, а в лабораторной системе $\mathscr{E}_\text{p} = (8/7)Q = 1,88\text{М}$ эВ.

8.

54. $w \approx \frac{R\sigma\rho}{m_\text{N}} \approx 7 \cdot 10^{-6}$, где m_N - масса нуклона. Нейтрино взаимодействует только с нейтронами ядер.

8.

55. $\mathscr{E} \geqslant \frac{2m_\text{p}}{\rho R A} \approx 95 \cdot 10^3$ ГэВ.

8.

56. Ослабление потока нейтрино $\frac{\Delta\Phi}{\Phi} = \frac{\sigma N_\text{A}\rho 2R_3}{2A} = 4,2 \cdot 10^{-4}$.

8.

57*: Решение. Сечение взаимодействия нуклонов убывает с ростом скорости и стремится к «геометрическому» сечению $\sigma \sim 10^{-25}$ см^2 (радиус нуклона $r_\text{p} \approx 0,8 \cdot 10^{-13}$ см). Длина пробега при $n = 1$ см$^{-3}$

$$\lambda = \frac{1}{n\sigma} \approx 10^{25}\text{с} \approx 10^7 \text{ св. лет}$$

(1с. год $\approx 10^{18}$ см). Для массивных частиц в рамках геометрической модели рассеяния $\sigma \sim 10^{-24}$ см^2, а длина их свободного пробега $\lambda \sim 10^6$ св. лет. Т. о. прилет массивного «гостя» с такого расстояния крайне маловероятен. Заметим также, что полет комет по сильно выраженным гиперболическим траекториям не зафиксирован в истории астрономии.

8.

58. $M = \frac{\pi L^2 n\mu}{N_\text{A} N_\nu u\sigma t\eta} \approx 546$ т, где L - расстояние от Солнца до Земли, μ - молярная масса CCl_4.

8.

59: $\sigma \simeq 3 \cdot 10^{-46}$ cm^2.
Решение. Длина свободного пробега λ электрона в ядре, сечение взаимодействия σ и концентрация протонов n_p в ядре связаны известным соотношением $\lambda\sigma n_p = 1$. При этом $\lambda = 2v\tau$, где τ - время, проведенное K-электронами в ядре за $\tau_0 = 32$ дня, коэффициент «2» учитывает, что на K-оболочке находятся два электрона. Таким образом, искомое эффективное сечение

$$\sigma = \frac{1}{2nv\tau}$$

Концентрация протонов в ядре

$$n_{\text{p}} = \frac{Z}{\frac{4}{3}\pi r_0^3 A} = 5,3 \cdot 10^{37} \text{ cm}^{-3}$$

а время оценим как

$$\tau = \tau_0 \left(\frac{R_{\text{g}}}{r_1}\right)^3$$

где $R_{\text{я}} = 1,3 \cdot 10^{-13}$ A$^{1/3} = 4,3 \cdot 10^{-13}$ cm, а радиус орбиты K-электрона $r_1 = \frac{r_{\text{Б}}}{z-1} = 3,1 \cdot 10^{-10}$ cm. Таким образом, $\tau \approx 0,0074$c.
Оценку скорости K-электрона проведем, исходя из соотношения

$$\frac{mv^2}{2} = \text{Ry}(Z-1)^2$$

откуда

$$v = \sqrt{\frac{2\text{Ry}}{m}}(Z-1) = 3,7 \cdot 10^9 \frac{\text{cm}}{\text{c}}$$

Таким образом, искомое сечение

$$\sigma = \frac{1}{2nv\tau} \simeq 3 \cdot 10^{-46} \text{ cm}^2$$

8.

60. $R_{\mathbf{Pb}} = r_0 A^{1/3} \approx 7,7 \cdot 10^{-13}$ см. Для K-оболочки мюона в атоме Pb $r = r_{\text{E}} \frac{m_{\text{e}}}{m_\mu Z} \approx 3 \cdot 10^{-13}\text{c} < R_{\text{Pb}}$. Мюон взаимодействует с протоном по схеме $\mu^- + \text{p} \to \text{n} + \nu_\mu; \alpha \approx \frac{4\pi r_0^3 A}{3Z^2 \cdot c\tau\alpha} \approx 1,9 \cdot 10^{-41}$ cm^2, где $\alpha = \frac{e^2}{\hbar c} = \frac{1}{137}$.

8.

61*: Ослабление потока γ-квантов $j(L) = j(0)e^{-n_\sigma L}$ будет малым при условии $n\sigma L \ll 1$, где n - концентрация «поглотителей» - ядер ^{119}Sn, σ - сечение поглощения. Самопоглощение мессбауэровских квантов носит резонансный характер. Из формулы Брейта-Вигнера для сечения упругого процесса при $\mathscr{E}_\gamma = \mathscr{E}_{\text{рез}}$ получаем $\sigma = g\frac{4\pi}{k^2} = \frac{4\pi\hbar^2 c^2}{\mathscr{G}_\gamma^2}$. Здесь $g = \frac{1}{2} \cdot \frac{2J^*+1}{2J+1}$ - статистический фактор, учитывающий число начальных (возбужденное ядро с моментом J^*) и конечных (ядро в нормальном состоянии с моментом J плюс γ-квант) состояний. Здесь $2 = 2J + 1$ - число возможных проекций момента γ-кванта. Для ядра ^{119}Sn$J^* = 3/2, J = 1/2$ и $g = 1$. Кроме того, $n = \rho\frac{N_{\text{A}}}{\mu}\varepsilon f$. Отсюда $L \ll \frac{1}{n\sigma} = \frac{\mathscr{E}_\gamma^2 \mu}{4\pi\hbar^2 c^2 \rho N_{\text{A}} \varepsilon f} = 1,24 \cdot 10^{-3}$ см, где μ - молярная масса $BaSnO_3$.

8.

62. $N_{\text{Ar}} = \frac{jN_{\text{Cl}}\sigma}{\lambda}\left(1 - e^{-\lambda t}\right) \simeq 30$ ядер, где $N_{\text{Cl}} \approx 2,2 \cdot 10^{30}, \lambda = \frac{\ln 2}{T_{1/2}} \approx \approx 2,3 \cdot 10^{-7}\text{c}^{-1}$.

8.

63. $N_{\text{Ge}} \approx 5$ ядер.

8.

64. $\frac{\sigma_{\text{рез}}}{\sigma_0} \sim 10^6$. Здесь сечение поглощения в центре резонансной линии определяется формулой Брейта - Вигнера для неупругого поглощения $\sigma_{\text{рез}} = \pi\lambda^2 = \lambda^2/4\pi$.

8.

65. $\alpha_{\text{погл}} = \frac{j_0 - j_{\text{погл}}}{j_0} = 1 - e^{-n_{\text{м}}\,\sigma_{\text{погл}}\,d} \approx 0,1; \alpha_{\text{расс}} = \frac{j_0 - j_{\text{расс}}}{j_0} = 1 - e^{-n_{\text{м}}\sigma_{\text{расс}}d} \approx 0,37.$

8.

66. $\sigma_1 = \sigma_2 \frac{N_2^2 (kT)^2}{(2P_0)^2} \approx 11\sigma\text{Н}.$

8.

67. $a_{\text{эл}} = \frac{\pi\theta_{\text{кр}}^2 / \lambda^2 - N_2 a_2 + N_1 a_1}{z_2 N_2 - z_1 N_1} = -2,6 \cdot 10^{-16}$с. При учете рассеяния нейтронов на электронах, показатель преломления $n^2 = 1 - \frac{Na\lambda^2}{\pi} - \frac{ZNa_{\text{эл}}\,\lambda^2}{\pi}$. Кроме того, в данной задаче $\theta_{\text{кр}}^2 \approx n_1^2 - n_2^2$.

Возможны два различных механизма взаимодействия, приводящих к рассеянию нейтронов на электронах. Еще в 1947 г. Ферми указал на воз можность существования специфического взаимодействия между нейтроном и электроном, не сводящегося к взаимодействию между магнитными моментами этих частиц. Появление этого взаимодействия следует ожидать, исходя из представления о том, что ядерное взаимодействие есть результат обмена виртуальными пионами между нуклонами, так что часть времени нейтрон проводит в диссоциированном состоянии $n \rightleftarrows p + \pi^-$. Тем самым должны возникать силы притяжения, обусловленные электростатическим притяжением между электроном и протоном. Как следует из эксперимента, длина рассеяния очень мала и поэтому эти силы должны быть весьма короткодействующими. Нейтрон состоит из трех заряженных кварков, и это взаимодействие фактически есть взаимодействие между составляющими нейтрон кварками и электроном.

Второй механизм - это так называемое фолдиевское взаимодействие был получен и рассчитан Л. Фолди. Не вдаваясь в подробности, отметим, что взаимодействие медленного нейтрона с электростатическим полем возникает в результате учета квантовых эффектов и связано с «дрожанием» нейтрона в области размером в комптоновскую длину волны виртуальных пионов. На та ких расстояниях нейтрон уже нельзя считать точечной частицей.

8.

68. $\text{t} \approx \frac{m_{\text{n}} \mathring{\text{A}}_{\text{n}} \sigma_{\text{полн}}}{2h\Gamma_{\text{n}}} = 4,1 \cdot 10^{-15}$с.

8.

69: $\frac{\sigma_n(\mathscr{E}_1)}{\sigma_n(\mathscr{E}_2)} \approx 1$, т. е. сечения примерно равны.

Решение. Парциальное сечение нейтронного распада составного ядра

$$\sigma_{\text{n}} = \sigma_{\text{c}} \frac{\Gamma_{\text{n}}}{\Gamma_{\text{полн}}} = \sigma_{\text{c}} \frac{\Gamma_{\text{n}}}{\Gamma_{\text{n}} + \Gamma_{\text{y}}} \approx \sigma_{\text{c}} \frac{\Gamma_{\text{n}}}{\Gamma_{\text{y}}}$$

где сечение образования составного ядра $\sigma_{\text{c}} = \pi\hat{\hbar}^2 D$, а $D = 4\frac{kk'}{(k+k')^2} \approx \approx 4\frac{k}{k'} \propto \sqrt{\delta}$ - вероятность проникновения нейтрона в тяжелое ядро. Здесь $k = \frac{1}{\hbar}\sqrt{2m\mathscr{E}}; k' = \frac{1}{\hbar}\sqrt{2m\,(U_0 + \mathscr{E})} > k; \quad \hat{\lambda} = \frac{\hbar}{\sqrt{2m_{\mathscr{E}}}}$. Вероятность нейтрону покинуть составное ядро также пропорциональна D. Таким образом, $\sigma_n \propto \pi\lambda^2 D^2 \propto \frac{1}{\mathscr{E}}\mathscr{E} = \text{const}$, откуда и следует, что сечение распада составного ядра по нейтронному каналу от $\mathfrak{E}$ не зависит.

О3.1-8.19

Чему равна критическая скорость нейтронов, испытывающих полное отражение на границе вещества при произвольном угле падения? Число рассеивающих ядер в единице объема N и амплитуду рассеяния нейтронов f считать заданными.

О3.1-8.20

Найти критический угол скольжения чо для тепловых нейтронов с заданной длиной волны λ при отражении от материала с известными значениями N и f. При $\varphi < \varphi_0$ нейтроны полностью отражаются.

О3.1-8.21 Коэффициент преломления нейтронов

Вычислить коэффициент преломления нейтронов с энергией $\mathcal{E} = 2 \cdot 10^{-2}$ эВ в металлическом Be $\left(\rho \approx 1,85 \mathrm{g/cm^3}\right)$, если амплитуда рассеяния $f = -0,77 \cdot 10^{-12}$см. Чему равен угол полного отражения нейтронов?

О3.1-8.22

Максимальная скорость нейтронов, накапливаемых в ловушке в силу полного отражения от медных стенок, равна $v = 5,7$ m/c. Определить амплитуду рассеяния нейтронов на ядрах меди.

О3.1-8.23

После прохождения свинцовой пластинки толщиной $d = 2$ см интенсивность потока нейтронов с энергией $\mathcal{E} = 0,25$МВ уменьшилась и составила 70% от интенсивности падающего пучка. Показать, что это ослабление потока обусловлено преимущественно упругим изотропным s-рассеянием нейтронов ядрами свинца. Считая, что величина амплитуды рассеяния равна радиусу ядра, оценить размер ядра ^{208} Pb. Плотность свинца $\rho = 11,3 \mathrm{g/cm^3}$.

О3.1-8.24

Ультрахолодные нейтроны выходят широким пучком из горизонтального нейтроновода и затем движутся свободно над горизон тально расположенной пластинкой, упруго от нее отражаясь и тем самым совершая периодическое движение, как показано на рис. 49. Это движение в гравитационном поле квантуется, и поэтому пройдут над пластинкой только те нейтроны, у которых высота движения H соответствует разрешенной энергии. Оценить на основе правила квантования Бора-Зоммерфельда, какова третья разрешенная высота. См. задачу 3.6.

О3.1-8.25

Гравитационный рефрактометр (рис. 50) дает возможность оп ределить амплитуду рассеяния медленных нейтронов атомными ядрами, используя падение нейтронов в гравитационном поле Земли. Найти амплитуду рассеяния для ^{209}Bi, если известно, что для него на высоте $H = 60$ см резко изменяется скорость счета. Плотность висмута $\rho = 9,8 \mathrm{g/cm^3}$

О3.1-8.26

На рис. 51 показаны: реактор P, работающий на тепловых нейтронах, полая изогнутая труба (нейтроновод) и детектор нейтронов Д. Распределение нейтронов в реакторе по скоростям максвелловское при температуре $T \simeq 400$ K. Нейтроны, скорость v которых меньше граничной скорости ($v_p \sim 10$ m/c), называют ультрахолодными. Особенностью таких нейтронов является то, что они испытывают полное упругое отражение от стенок при любом угле падения. Найти зависимость скорости счета детектора от высоты колена H, полагая, что детектор одинаково эффективно регистрирует все ультрахолодные нейтроны. При каком значении H детектор не регистрирует ультрахолодные нейтроны?

О3.1-8.27

В реакторах, работающих на тепловых нейтронах, имеются очень медленные ультрахолодные нейтроны (УХН). Особенностью УХН является то, что при скоростях $v < v_{\text{гр}}$ (обычно граничная скорость $v \sim 10$ m/c) нейтроны упруго отражаются от стенок при любых углах падения. Для вывода УХН из реактора используют полые трубы - нейтроноводы. На рис. 52 изображен реактор P, нейтроновод специальной формы и на его конце - детектор нейтронов Д. Полагая, что распределение нейтронов по скоростям в реакторе максвелловское (при температуре $T \simeq 400$ K), найти, как зависит поток нейтронов, доходящих до детектора, от высоты его поднятия H. Оценить высоту $H_{\text{гр},}$, на которой поток нейтронов исчезает.

О3.1-8.28

В эвакуированном сосуде объемом $V = 1$ л находятся ультрахолодные нейтроны, отражающиеся от стенок с коэффициентом отражения, практически равным единице. В сосуде имеется отверстие площадью S, заклеенное фольгой, полностью прозрачной для ультрахолодных нейтронов. Какова должна быть площадь окошка 73 S, если наблюдаемое время хранения нейтронов в ловушке в 2 раза меньше среднего времени жизни свободных нейтронов $\tau \sim 10^3$ с. Считать, что скорость всех ультрахолодных нейтронов одинакова и равна $v = 5$ m/c.

О3.1-8.29

Вхождение нейтронов из вакуума в большинство веществ связано с преодолением энергетического барьера. Поэтому в замкнутой полости достаточно медленные нейтроны оказываются запертыми и могут накапливаться. Определить, какая доля из потока тепловых нейтронов, распределение по скоростям которых максвелловское, окажется запертой в медной камере. Предельный угол скольжения при полном «внешнем» отражении для нейтронов, движущихся со среднеквадратичной скоростью, составляет $i = 10$ угл. мин. Соударения нейтронов со стенками камеры могут рассматриваться как упругие.

О3.1-8.30

Монохроматические нейтроны с энергией $\mathscr{E} = 10^{-7}$ эВ транспортируются к мишени из источника (медной сферы радиусом R) по длинному круглому алюминиевому нейтроноводу радиусом $r = 10\text{см}R$. Концентрация нейтронов в источнике $n_0 = 1\text{с}^{-3}$ все время поддерживается постоянной, плотности алюминия и меди равны соответственно 2,7 и 8,9 г/см ^{3}, а их амплитуды когерентного рассеяния $-3,5 \cdot 10^{-13}$см и $-7,8 \cdot 10^{-13}$с. Вычислить поток нейтронов на мишени (распадом нейтронов пренебречь).
(пару пропустил)

18.2.6 Problems about neutrons 3

О3.1-8.34

Образец иода ^{127} I облучается нейтронным потоком такой интенсивности, что в 1 с образуется 10^7 атомов радиоактивного иода ^{128}I, период полураспада $T_{1/2}$ которого 25 мин. Найти число атомов ^{128} I и активность препарата через $1, 10, 25, 50$ мин после начала облучения. Каковы максимальные числа атомов ^{128} I и активность препарата при долгом облучении (т. е. при облучении до насыщения)?

8.

34: При облучении до насыщения число распадающихся в 1 с атомов йода (т. е. активность препарата) равно числу атомов, образующихся ежесекундно, т. е. $dn/dt = A = 10^7$ расп/с. Число атомов йода при активации до насыщения равно

$$N_{\text{нас}} = \frac{A}{\lambda} = 10^7 \frac{T}{\ln 2} = 2,16 \cdot 10^{10} \text{ атомов}$$

Число атомов йода через время t после облучения

$$N = N_{\text{нас}} \left(1 - e^{-\lambda t}\right)$$

или при малых $t (t \ll T)$

$$N = N_{\text{нас}}\, \lambda t = \dot{n} t$$

При $t = 1$ мин

$$N = At = 10^7 \cdot 60 = 6 \cdot 10^8 \text{ атомов.}$$

При $t = 25$ мин

$$N = N_{\text{нас}} \left(1 - e^{-\lambda t}\right) = 1,08 \cdot 10^{10} \text{ атомов}$$

О3.1-8.35

При облучении образца золота в потоке тепловых нейтронов плотностью $j = 10^{14}\text{см}^{-2} \cdot \text{с}^{-1}$ в реакторе в результате реакции $^{197}\text{Au}(\text{n}, \gamma)^{198}\text{Au}$ (сечение $\sigma_1 = 96$ бн) образуется β^--активный нуклид ^{198}Au, переходящий в ^{198}Hg с периодом полураспада $T_{1/2} = 2,7$ суток. В то же время, сечение реакции $^{198}\text{Au}(\text{n}, \gamma)^{199}\text{Au}$ очень велико и равно $\sigma_2 = 26000$ бн, так что изотоп ^{198} Au активно поглощает нейтроны (вторичная активация). На сколько уменьшается при учете вторичной реакции число образующихся ядер ^{198}Hg при времени облучения $t = 10T_{1/2}$?

8.

35: $\frac{N^*\left(10T_{1/2}\right)}{N\left(10T_{1/2}\right)} \approx \frac{\lambda}{\lambda+j\sigma_2} = 0,53.$

Решение. Пусть N_0 - исходное число ядер ^{197}Au, N^* - число ядер ^{198}Au. На изотопах золота идут следующие реакции:

$$\begin{array}{rcl} \mathrm{n} + {}^{197}\mathrm{Au} & \longrightarrow & {}^{198}\mathrm{Au} + \gamma \\ {}^{198}\mathrm{Au} & \xrightarrow{\beta^-} & {}^{198}\mathrm{Hg} \\ \mathrm{n} + {}^{198}\mathrm{Au} & \longrightarrow & {}^{199}\mathrm{Au} + \gamma. \end{array}$$

Уравнение баланса для ядер ^{198}Au имеет вид:

$$\frac{dN^*}{dt} \approx \sigma_1 j N_0 - \lambda N^* - \sigma_2 j N^* \qquad (*)$$

Обратим внимание на то, что в правой части в первом члене $\sigma_1 j N_0$ вместо текущего числа ядер ^{197}Au поставлено их исходное число N_0 (этим и обусловлен значок приближенного равенства). Простая оценка показывает, что за $t = 27$ суток ($t = 10T_{1/2}$) исчезнет всего

$$j\sigma_1 10T_{1/2} \approx 2 \cdot 10^{-3} = 0.2\% \quad \text{ядер} \quad {}^{197}\mathrm{Au}$$

что и обусловливает справедливость сделанного приближения.
Вычислим постоянную β^--распада ядер ^{198}Au

$$\lambda = \frac{\ln 2}{T_{1/2}} = 2,97 \cdot 10^{-6}\mathrm{c}^{-1}$$

а также второй коэффициент при N^* в уравнении (*)

$$\sigma_2 j = 2,6 \cdot 10^{-6}\mathrm{c}^{-1}$$

Решение дифференциального уравнения (*) имеет вид

$$N^*(t) = \frac{j\sigma_1 N_0}{\lambda + \sigma_2}\left\{1 - \exp\left[-\left(\lambda + j\sigma_2\right)t\right]\right\}$$

Вычислим показатель экспоненты

$$\left(\lambda + j\sigma_2\right) 10T_{1/2} \approx 13$$

Таким образом, $1 - e^{-13} \approx 1$. Отсюда следует, что

$$N^*(t) \approx \frac{j\sigma_{\mathrm{I}} N_0}{\lambda + j\sigma_2}.$$

Если бы за счет радиационного захвата нейтронов не «выгорали» ядра ^{198}Au, то

$$N(t) = \frac{j\sigma_1 N_0}{\lambda}\left(1 - e^{-\lambda t}\right) \approx \frac{j\sigma_1 N_0}{\lambda}.$$

Искомое уменьшение числа образующихся ядер ^{198}Hg равно

$$\frac{N^*\left(10T_{1/2}\right)}{N\left(10T_{1/2}\right)} \approx \frac{\lambda}{\lambda + j\sigma_2} = 0,53$$

О3.1-8.36

Образец золота ^{197}Au массой $m = 10$ мг облучали в потоке тепловых нейтронов плотностью $j = 10^{12}\mathrm{см}^{-2} \cdot \mathrm{с}^{-1}$ дважды: в течение первого дня с 9 до 17 час и в то же время на следующий день. Найти число образовавшихся радиоактивных ядер ^{198}Au $\left(T_{1/2} = 2,7\mathrm{су}\right.$, сечение активации, т. е. радиационного захвата нейтронов ядрами ^{197}Au, $\sigma = 96$ бн) к концу облучения во второй день. За какое время это же количество ядер ^{198}Au может быть получено при непрерывном облучении?

8.

36. $N = N_0\left(1 - e^{-\lambda t}\right)\left(1 + e^{-\lambda T}\right) = 1,4 \cdot 10^{14}$ ядер, где $T = 24$ ч; $t = 8$ ч (рис. 182). При непрерывном облучении $N = N_0\left(1 - e^{-\lambda t^*}\right)$, откуда $t^* = \frac{1}{\lambda}\ln\frac{N_0}{N_0 - N} = 14,5$.

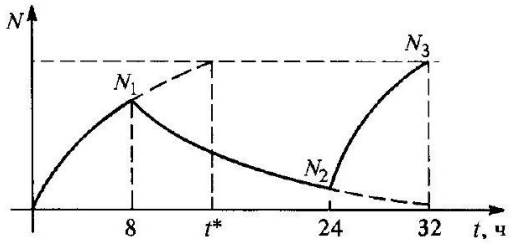

Рис. 182

О3.1-8.37

Образец алюминия облучается дейтронами с энергией 7МэВ, в результате чего происходит реакция $^{27}\mathrm{Al(d,p)}^{28}\mathrm{Al}$. Период полураспада ^{28}Al равен $T_{1/2} = 2,24$ мин. Облучение длится в течение $t_1 = 3,5$ мин, какое-то время t_2 уходит на перенос образца к детектору, а затем в течение времени $t_3 = 6$ мин производится измерение активности образца. Какую часть распадов регистрирует детектор от максимально возможного при том же времени переноса образца?

8.

37. $\frac{N_1}{N_1^{\max}} = \left(1 - e^{-\lambda t_1}\right)\left(1 - e^{-\lambda t_3}\right) = 0,55$, где $N_1^{\max} = n_0 e^{-\lambda t_2}$.

О3.1-8.38

Распространенность группы легких элементов Li, Be, B в Земле, Солнце, метеоритах намного меньше, чем более тяжелых C, N, O, однако в космических лучах содержание группы легких элементов Li, Be, B относительно группы c, N, O равно $\alpha = 0,34$. Это объясняется фрагментацией (развалом) C, N, O при прохождении через межзвездную среду, состоящую в основном из водорода. Оценить в г/см^2 количество водорода, которое должны при этом пройти высокоэнергетичные ядра C, N, O. Сечение деления (фрагментации) тяжелых элементов с образованием легких $\sigma_\phi = 90$ мбн, полное сечение их взаимодействия с водородом $\sigma_0 = 200$ мбн, фрагментацией легких элементов пренебречь.

8.

38. $l\rho = \frac{\ln(1+\alpha\sigma_0/\sigma_\phi)}{\sigma_0 N_\mathrm{A}} = 4,7\Gamma/\mathrm{cm}^2$.

О3.1-8.39

Сосуд объемом $V = 1$ л помещен в активную зону реактора на тепловых нейтронах с плотностью потока $j = 10^{12}\mathrm{см}^{-2} \cdot \mathrm{с}^{-1}$. Считая, что сосуд не возмущает пространственное максвелловское распределение нейтронов с $T = 300$ К, найти количество протонов, накопившееся в сосуде за счет распада нейтронов в течение $t = 6$ месяцев.

8.

39. За 6 месяцев накопится $1,08 \cdot 10^{14}$ протонов ($1,8 \cdot 10^{-10}$ г).

О3.1-8.44

При распаде ядра ^{60} Co одновременно (в каскаде) образуются два γ-кванта с энергиями $\mathscr{E}_1 = 1,17\mathrm{M} \ni \mathrm{B}$ и $\sigma_2 = 1,33$ МэВ соответственно. Определить, как изменится отношение потоков этих γ-квантов после их прохождения через свинец толщиной d и вычислить это отношение при $d = 5$ см. Коэффициенты ослабления потока γ-квантов в свинце равны соответственно $\mu_1 = 0,7\mathrm{см}^{-1}, \mu_2 = 0,62\mathrm{см}^{-1}$.

О3.1-8.45

При просвечивании детали монохроматическими тепловыми нейтронами с длиной волны $\lambda = 1$Å на изображении было обнаружено слабое темное пятно, свидетельствующее о наличии внутри детали инородного включения. Контраст изображения (отношение интенсивностей прошедших нейтронов в области включения к соседним однородным областям) был равен 1,26. Какова должна быть длина волны нейтрона, чтобы контраст возрос до 2? Считать, что сечение взаимодействия нейтронов с веществом носит нерезонансный характер.

МФТИ-ГКЭ.2020.5А Антинейтрино при бета-распаде

При β^--распаде ядра ^{137}Cs разность энергий покоя материнского и дочернего ядер ΔE составила две энергии покоя электрона. Электрон и антинейтрино разлетелись под углом $\alpha = 120°$. Дочернее ядро начало двигаться под углом $\varphi = 150°$ к направлению вылета электрона. Найти энергию вылетевшего антинейтрино в единицах энергии покоя электрона. Считать антинейтрино безмассовой частицей.

Первое Решение

Задача решается геометрией и релятивистской механикой (???)

Дочернее ядро движется в направлении, противоположном суммарному импульсу электрона и антинейтрино. Из равенства модулей составляющих их импульсов, перпендикулярных этому направлению, получаем $cp_e = ckp_v$, где $k^2 = \frac{\sin^2(\alpha+\varphi)}{\sin^2(\varphi)} = 4$. (?????)

Из закона сохранения энергии находим, вводя обозначения $x = \frac{\varepsilon_v}{m_e c^2}$, $\quad a = \frac{\Delta E}{m_e c^2} = 2$

$$a = x + \sqrt{1 + k^2 x^2}, \quad \text{откуда} \quad x = \frac{a - \sqrt{k^2\left(a^2-1\right)+1}}{1-k^2} = 0,54$$

Второе решение

(???)

Проектируя импульсы всех частиц на направление импульса электрона и перпендикулярное ему, получим

$$p_e = p_v \cos\left(180° - \alpha\right) + p_{\text{яд}} \cos\left(180° - \varphi\right)$$
$$p_v \sin\left(180° - \alpha\right) = p_{\text{яд}} \sin\left(180° - \varphi\right).$$

Из второго уравнения получаем $p_{\text{яд}} = \sqrt{3} p_v$, а из первого – $p_e = 2p_v$. Поскольку $\Delta E = 2m_e c^2 \ll M_{\text{яд}}\, c^2 (1\text{МВ} < 137$ ГэВ), то кинетической энергией ядра по сравнению с энергиями легких частиц можно пренебречь и закон сохранения энергии примет вид

$$\Delta E = p_v c + \sqrt{\left(p_e c\right)^2 + \left(m_e c^2\right)^2}$$

Подставляя сюда выражение для импульса электрона, получаем уравнение относительно $x = p_v c / \left(m_e c^2\right)$

$$\frac{\Delta E}{m_e c^2} = x + \sqrt{4x^2+1} \quad \text{или} \quad 2 - x = \sqrt{4x^2+1}$$

откуда

$$3x^2 + 4x - 3 = 0 \text{ и } x = \frac{\sqrt{13}-2}{3} \cong 0.54$$

P.S. Интересно, что при указанных в задаче углах, импульсы нейтрино и ядра оказываются взаимно перпендикулярными.

МФТИ-ГКЭ.2020.5А Электрон при бета-распаде

При β^--распаде ядра ^{137} Cs разность энергий покоя материнского и дочернего ядра ΔE составила две энергии покоя электрона. Дочернее ядро начало двигаться вдоль линии, являющейся биссектрисой угла разлёта электрона и антинейтрино. Найти кинетическую энергию вылетевшего электрона в единицах его энергии покоя. Массу антинейтрино считать равной нулю.

Первое решение.

Дочернее ядро движется в направлении, противоположном суммарному импульсу электрона и антинейтрино. Из равенства модулей составляющих их импульсов, перпендикулярных этому направлению, получаем $cp_e = ckp_v$, где $k^2 = 1$. Из закона сохранения энергии находим, вводя обозначения $x = \frac{\varepsilon_v}{m_e c^2}, a = \frac{\Delta E}{m_e c^2} = 2$: $a = x + \sqrt{1 + k^2 x^2}$, Откуда

$$x = \frac{a^2 - 1}{2a} = \frac{3}{4}; \frac{T_e}{m_e c^2} = a - x - 1 = 0,25.$$

Второе решение.

Проектируя импульсы всех частиц на направление импульса ядра и перпендикулярное ему, получим

$$p_{\text{яд}} = p_v \cos\alpha + p_e \cos\alpha$$
$$p_v \sin\alpha = p_{\text{яд}} \sin\alpha.$$

Из второго уравнения получаем $p_e = p_v$, а из первого $-- p_{\text{яд}} = 2p_v \cos\alpha$. Поскольку $\Delta E = 2m_e c^2 \ll M_{\text{яд}}\, c^2$(1МэВ $<<$ 137 ГэВ), то кинетической энергией ядра по сравнению с энергиями легких частиц можно пренебречь и закон сохранения энергии примет вид

$$\Delta E = p_v c + \sqrt{(p_e c)^2 + (m_e c^2)^2}$$

Подставляя сюда выражение для импульса электрона, получаем уравнение относительно $x = p_e c / \left(m_e c^2\right)$

$$\frac{\Delta E}{m_e c^2} = x + \sqrt{x^2 + 1} \text{ или } 2 - x = \sqrt{x^2 + 1}$$

откуда $x = 3/4$. Относительная кинетическая энергия электрона

$$\frac{T}{m_e c^2} = \sqrt{\left(\frac{p_e c}{m_e c^2}\right)^2 + 1} - 1 = \sqrt{x^2 + 1} - 1 = \frac{1}{4}$$

МФТИ-ГКЭ.2020.5В Антинейтрино при бета-распаде

При β^--распаде ядра ^{137}Cs разность энергий покоя материнского и дочернего ядра ΔE составила две энергии покоя электрона. Электрон и антинейтрино разлетелись под углом $\alpha = 90°$. Дочернее ядро начало двигаться под углом $\varphi = 150°$ к направлению вылета антинейтрино. Найти энергию вылетевшего антинейтрино в единицах энергии покоя электрона. Считать антинейтрино безмассовой частицей.

Решения

Решения просто дословно повторяю то же, что в предыдущих задачах, поэтому потом сам просто решу.

Дочернее ядро движется в направлении, противоположном суммарному импульсу электрона и антинейтрино. Из равенства модулей составляющих их импульсов, перпендикулярных этому направлению, получаем $cp_e = ckp_v$, где $k^2 = \frac{\sin^2(\varphi)}{\sin^2(\alpha+\varphi)} = \frac{1}{3}$. Из закона сохранения энергии находим, вводя обозначения
$x = \frac{\varepsilon_v}{m_e c^2}$, $a = \frac{\Delta E}{m_e c^2} = 2$

$$a = x + \sqrt{1 + k^2 x^2}, \quad \text{откуда } x = \frac{a - \sqrt{k^2\left(a^2 - 1\right) + 1}}{1 - k^2} = 0,88$$

О3.1-8.46

Оценить, какая доля ультрарелятивистких протонов космического излучения дойдет до поверхности Земли, не испытав ядерного взаимодействия.

О3.1-8.47

Оценить длины свободного пробега l_{p} и l_{N} ультрарелятивистских протонов и ядер азота в жидководородной камере. Радиус протона $r_p = 0,8 \cdot 10^{-13}$см, плотность жидкого водорода $\rho_{\text{H}} = 0,07\text{g/cm}^3$.

О3.1-8.48

Для создания пучков быстрых нейтронов часто используют взаимодействие релятивистских дейтронов с тяжелыми ядрами, когда в результате периферийного взаимодействия протон поглощается ядром - т.н. реакция срыва. Оценить сечение $\sigma_{\text{погл}}^{\text{такого процесса,}}$ когда мишенью служит абсолютно поглощающее нуклоны ядро свинца ^{208} Pb. Среднее расстояние между нуклонами в дейтроне равно $2R_{\text{d}} = 3,6$ фм.

О3.1-8.44

При распаде ядра ^{60} Co одновременно (в каскаде) образуются два γ-кванта с энергиями $\mathscr{E}_1 = 1,17\text{М} \ni \text{В}$ и $\sigma_2 = 1,33$ МэВ соответственно. Определить, как изменится отношение потоков этих γ-квантов после их прохождения через свинец толщиной d и вычислить это отношение при $d = 5$ см. Коэффициенты ослабления потока γ-квантов в свинце равны соответственно $\mu_1 = 0,7\text{см}^{-1}, \mu_2 = 0,62\text{см}^{-1}$.

О3.1-8.45

При просвечивании детали монохроматическими тепловыми нейтронами с длиной волны $\lambda = 1$Å на изображении было обнаружено слабое темное пятно, свидетельствующее о наличии внутри детали инородного включения. Контраст изображения (отношение интенсивностей прошедших нейтронов в области включения к соседним однородным областям) был равен 1,26. Какова должна быть длина волны нейтрона, чтобы контраст возрос до 2? Считать, что сечение взаимодействия нейтронов с веществом носит нерезонансный характер.

(и там еще их много, не до других, итак кучу выгрузил.)

18.2.7 Problems about nuclear fission and reactors 1

О3.1-9.1

Кулоновские силы способствуют делению атомного ядра, а силы поверхностного натяжения препятствуют. Определить отношение кулоновской $\mathscr{E}_{\text{K}}$ и поверхностной $\mathscr{E}_{\text{п}}$ энергий атомного ядра, при котором деление на два равных осколка энергетически выгодно. Выразить то же условие через параметр деления Z^2/A, пользуясь формулой Вайцзеккера для энергий $\mathcal{O}_{\text{K}}$ и $\mathscr{E}_{\pi}$. Четности A и Z не учитывать.

9.

1*: Решение. При делении ядер на два равных осколка

$$\Delta\mathscr{E}_{\text{II}} = \mathscr{E}_{\text{I}}\left(2^{1/3} - 1\right), \Delta\mathscr{E}_{\text{кул}} = \mathscr{E}_{\text{кул}}\left(2^{-2/3} - 1\right)$$

где $\mathscr{E}_{\text{п}} = -17,8A^{2/3}$ [МэВ], $\mathscr{E}_{\text{кул}} = -0,71\frac{Z^2}{A^{1/3}}$ [МэВ].

Деление энергетически выгодно, когда $\Delta\mathscr{G}_{\text{п}} + \Delta\mathscr{E}_{\text{кул}} > 0$, т. е.

$$-|\mathscr{E}_{\text{II}}|\left(2^{1/3}-1\right)+|\mathscr{E}_{\text{ку}\Omega}|\left(1-2^{-2/3}\right)>0$$

Отсюда находим

$$\frac{\left|\text{Å}_{\text{кул}}\right|}{\left|\text{Å}_{\pi}\right|}>\frac{2^{1/3}-1}{1-2^{-2/3}}=0,70,\ \text{или}\ \frac{Z^2}{A}\geqslant 17,6.$$

О3.1-9.2

С помощью полуэмпирической формулы Вайцзеккера найти минимальное значение параметра Z^2/A, при котором становится энергетически возможным деление ядра с четным A и четным Z на две одинаковые части. Рассмотреть три случая: 1) $A/2$ - нечетное, $Z/2$ - произвольное; 2) $A/2$ - четное, $Z/2$ - нечетное; 3) $A/2$ четное, $Z/2$ - четное.

9.

2. 1) $\frac{Z^2}{A}\geqslant 17,62+129,4A^{-1,42}$; 2) $\frac{Z^2}{A}\geqslant 17,62+564,8A^{-1,42}$; 3) $\frac{Z^2}{A}\geqslant$
$\geqslant 17,62+305,9A^{-1,42}$.
Наметим путь решения задачи. Энергия связи четно-четного ядра

$$\mathscr{E}_{\text{СВ}}(A,Z)=\mathscr{E}_1A-\mathscr{E}_2A^{2/3}-\mathscr{E}_3\frac{Z^2}{A^{1/3}}-\mathscr{E}_4\frac{(A-2Z)^2}{A/2}-\mathscr{E}_5A^{-3/4}$$

где $\mathscr{E}_1=15,75;\mathscr{E}_2=17,8;\mathscr{E}_3=0,71;\mathscr{E}_4=23,7;\mathscr{E}_5=34$[М В]. Энергия связи половинок ядра

$$\mathscr{E}'_{\text{СВ}}\left(\frac{A}{2};\frac{Z}{2}\right)=\mathscr{E}_1\frac{A}{2}-\mathscr{E}_2\left(\frac{A}{2}\right)^{2/3}-\mathscr{E}_3\frac{(Z/2)}{(A/2)^{1/3}}-\mathscr{E}_4\frac{(A/2-Z)^2}{A/2}-\mathscr{E}_5\left(\frac{A}{2}\right)^{-3/4}\cdot\delta,$$

$$\text{где }\delta=\begin{cases}-1, & \text{если} \quad \frac{A}{2}=2p;\frac{Z}{2}=2k\\ 0, & \text{если} \quad \frac{A}{2}=2p+1,\\ +1, & \text{если} \quad \frac{A}{2}=2p;\frac{Z}{2}=2k+1.\end{cases}$$

Условие распада

$$2\mathscr{E}'_{\text{СВ}}\left(\frac{A}{2};\frac{Z}{2}\right)-\mathscr{E}_{\text{СВ}}\geqslant 0.$$

Далее легко получить приведенные выше ответы.

О3.1-9.3

Предполагая, что форма ядра является сферической, получить критерий устойчивости ядер по отношению к малым статическим деформациям формы. Ядерную материю считать несжимаемой. Проверить по полученному критерию устойчивость тяжелых естественных ядер. Как можно объяснить явления спонтанного деления?

У к а з а н и е. Площадь поверхности вытянутого эллипсоида вращения с полуосями a и b

$$S=2\pi ab\left(\frac{b}{a}+\frac{a}{\sqrt{a^2-b^2}}\arcsin\frac{\sqrt{a^2-b^2}}{a}\right)$$

Энергия равномерно заряженного по объему эллипсоида с зарядом Q равна

$$\mathcal{E}=\frac{3}{10}\frac{Q^2}{\sqrt{a^2-b^2}}\ln\frac{a+\sqrt{a^2-b^2}}{a-\sqrt{a^2-b^2}}.$$

9.

3* Решение. При деформации формы ядра изменяются энергия поверхностного натяжения и энергия кулоновского взаимодействия. Если $\Delta\mathfrak{E}_{\text{кул}}+\Delta\mathfrak{E}_{\text{пов}}\geqslant 0$, то энергия в конечном состоянии больше, и исходное сферическое ядро устойчиво:

$$\Delta\mathscr{E}_{\text{кул}}=\mathscr{E}^{\text{эллл}}_{\text{кул}}-\mathscr{E}^{\text{шар}}_{\text{Куал}};\quad \Delta\mathscr{E}_{\text{пов}}=\sigma\left(S^{\text{эллл}}-S^{\text{шар}}\right),$$

где σ - коэффициент поверхностного натяжения ядра. Будем статически "вытягивать» сферическое ядро радиусом r, превращая его в эллипсоид вращения с полуосями a и b. Введем эксцентриситет меридионального сечения

$$\varepsilon = \frac{\sqrt{a^2 - b^2}}{a}$$

Тогда $a = r\left(1-\varepsilon^2\right)^{-1/6}; ab = r^2\left(1-\varepsilon^2\right)^{1/6};$

$$\mathscr{E} = \frac{3}{5}\frac{Q^2}{r}\frac{\left(1-\varepsilon^2\right)^{1/3}}{2\varepsilon}\ln\frac{1+\varepsilon}{1-\varepsilon}$$

$$S = 4\pi r^2\frac{\left(1-\varepsilon^2\right)^{-1/6}}{2\varepsilon}\left(\sqrt{1-\varepsilon^2} + \frac{1}{\varepsilon}\arcsin\varepsilon\right)$$

При малых деформациях $\varepsilon \ll 0$. Эти выражения можно разложить в ряды и мы получаем:
Отсюда следует условие устойчивости ядра

$$\mathscr{E}_{\text{кул}}^{\text{шар}} / \mathscr{E}_{\text{П}} \leq 2.$$

Использовав формулу Вайцзеккера

$$\mathscr{E}_{\text{пов}} = 17,8A^{2/3}[\text{М В}] \text{ и } \mathscr{E}_{\text{кул}} = 0,71\frac{Z^2}{A^{1/3}}[\text{М В}]$$

легко получить искомый критерий устойчивости ядер к статическим деформациям формы

$$\frac{Z^2}{A} \leqslant 50$$

Рассмотренная задача - модельная, потому что большинство тяжелых ядер имеют несферическую форму.

Реально, конечно, процесс деления ядра - динамический. При взаимодействии нейтрона с ядром возникают колебания формы капли практически несжимаемой ядерной жидкости. Частота этих колебаний определяется соотношением $\mathscr{E}_{\text{кул}}$ и $\mathscr{E}_{\text{пов}}$. При $\mathscr{E}_{\text{кул}} / \mathscr{E}_{\text{пов}} \leqslant 2$ частота становится мнимой (колебания апериодическими), и амплитуда колебаний нарастает со временем. Это приводит к возникновению перетяжки, и ядро делится на два осколка.

О3.1-9.4

*: Оценить эффективное сечение деления ядра 235U нейтронами с энергиями 0,025 эВ (тепловые нейтроны) и 10 кэВ. Считать, что сечение деления равно сечению образования составного ядра. Ядерный потенциал аппроксимировать прямоугольной потенциальной ямой глубиной 40МВ.

9.

4: $\sigma = \frac{4\pi}{kk'} \approx \begin{cases} 2600 & \text{бн (тепловые нейтроны)}, \\ 4,16\text{Н}(\mathscr{E} = 10 \text{ кэВ}), \end{cases}$

где $k = \frac{1}{\hbar}\sqrt{2m\mathscr{E}}, k' = \frac{1}{\hbar}\sqrt{2m\left(\mathcal{E}+U_0\right)}$.

Решение. При энергиях тепловых нейтронов дебройлевская длина волны нейтрона $\lambda = \hbar/\sqrt{2m\mathscr{E}} = 3\cdot 10^{-9}$ cm $> R_{\text{U}} = 8\cdot 10^{-13}$ cm и сечение образования составного ядра $\sigma \approx \pi\hbar^2 D$, где D - коэффициент прохождения нейтронной волной границы ядра. Коэффициент прохождения D определяется соотношением (см. задачу 3.25)

$$D = \frac{4kk'}{\left(k+k'\right)^2} \approx \frac{4k}{k'}$$

где волновые числа k и k' определяются как коэффициенты в уравнениях Шредингера для областей вне ядра и внутри ядра (рис. 183)

$$k = \frac{1}{\hbar}\sqrt{2m\mathscr{E}}, k' = \frac{1}{\hbar}\sqrt{2m\left(\mathscr{E}+U_0\right)}.$$

Искомое сечение взаимодействия

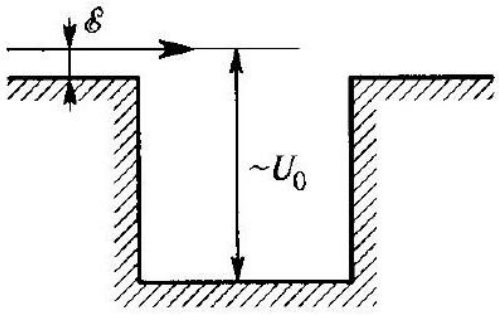

Рис. 183

$$\alpha \approx \frac{4\pi}{kk} \approx \frac{2\pi\hbar^2}{m\sqrt{\varrho}U_0} \approx 2600\sigma\text{Н}$$

Для нейтрона с энсргией 10 кэВ $\hat{t} \approx 3 \cdot 10^{-9}$ см, и искомое сечение $\sigma \approx 4,16$Н. Как видно из формулы, при данных энергиях $\sigma \propto 1/\sqrt{\S} \propto 1/v$. Такая зависимость сечения деления от скорости нейтронов называстся законом Бете. Здесь он имеет место, поскольку рассматриваемые энергии лежат далеко от области резонансного поглощения нейтронов ядрами ^{235}U$(1 \div 100$ э В).

О3.1-9.5

Сечение деления ^{238}U быстрыми нейтронами с энергией $= 5$МВ равно $\sigma(n,f) = 0,5$ бн. Какова относительная вероятность этого нерезонансного процесса по отношению ко всем процессам, идущим через компаунд-состояние? Глубину потенциальной ямы ядра урана принять равной $U = 50$ МэВ.

9.

5. $\sigma_\text{с} = \pi(R+\lambda)^2 D = 2,3\sigma$Н, где $D = \frac{4k_1k_2}{(k_1+k_2)^2} \approx 0,7$. Относительная вероятность деления к полной вероятности реакций, идущих через составное ядро, $\frac{\Gamma_\text{дел}}{\Gamma_\text{сост}} = \frac{\sigma_\text{дел}}{\sigma_\text{с}} \simeq 0,2$.

О3.1-9.6

Размножение нейтронов в делящейся среде можно условно представить как смену поколений. Существовавшие в некоторое время нейтроны будут все рано или поздно поглощены ядрами. На смену «умершему» поколению нейтронов появится новое поколение нейтронов, которое опять через некоторое время «умрет», чтобы дать «жизнь» следующему поколению. Конечно, время жизни нейтронов неодинаково, но можно ввести среднее время жизни одного поколения, точно так же, как это делается для человеческих поколений. Отношение числа нейтронов второго поколения к числу нейтронов первого поколения в делящейся среде называется коэффициентом размножения k_∞. Если $k_\infty < 1$, то говорят, что система находится в подкритическом состоянии. Число нейтронов в такой системе будет уменьшаться во времени. Пусть в подкрити ческой бесконечной системе в некоторый момент времени появилось N_0 нейтронов. Определить общее число нейтронов, образующихся в системе, если исходное их число равнялось N_0.

9.

6. $N = \frac{N_0}{1-k_\infty}$.

О3.1-9.7

Показать, что в системе из чистого ^{238}U нельзя достигнуть $k_\infty > 1$ (см. задачу 9.6). Для энергии нейтронов больше 1,1 МэВ се- чение поглощения не превышает величины 10^{-24}см^2 : $\sigma_\text{погл} = \sigma_\text{дел} + \sigma_\text{захв} < 10^{-24}$см^2, где $\sigma_\text{дел}$ - сечение деления, а $\sigma_\text{захв}$ - сечение радиационного захвата. В то же время сечение упругого рассеяния, при котором нейтрон теряет относительно большую часть своей энергии, $\sigma_\text{расс} \simeq 3 \cdot 10^{-24}$см^2.

9.

7. $k_\infty = \frac{\sigma_{\text{расс}}}{\sigma_{\text{погл}}} \frac{\sigma_{\text{дел}}}{\sigma_{\text{погл}} + \sigma_{\text{расс}}}$. В данном случае $k_\infty = 0,75 < 1$, что и требовалось показать.

О3.1-9.8 характерное время T реактора (??)

Реактивностью реактора называют величину $\rho = \frac{k-1}{k}$, где k - коэффициент размножения нейтронов; если $|k-1| \ll 1$, то $\rho \approx k-1$. Найти в этом приближении изменение мощности $W(t)$ реактора в надкритическом режиме, когда $k > 1$. Определить характерное время T реактора, т.е. время возрастания мощности W в e раз. Среднее время жизни одного поколения нейтронов равно т.

9.

8. $P(t) = P(0)k^{t/\tau} \approx P(0)e^{t \ln k/\tau} \approx P(0)e^{\rho t/\tau}; T = \frac{\tau}{\rho}$.

О3.1-9.9

При каких значениях реактивности реактора ρ, определенного в предыдущей задаче, запаздывающие нейтроны определяют зависимость мощности от времени? Доля запаздывающих нейтронов $\beta = 0,0064$.

9.9.

При $\rho < \beta$. В отсутствие запаздывающих нейтронов $k - \beta < 1$ реакция только на мгновенных делительных нейтронах затухла бы. При $\rho > \beta$ реакция может развиваться и без запаздывающих нейтронов.

О3.1-9.10

Активная зона ядерного реактора заполнена смесью урана и графита, имеющей при бесконечных размерах коэффициент размножения нейтронов $k_\infty = 1,05$. Среднее расстояние, проходимое нейтроном от места рождения до поглощения, $L = 50$ см. Оценить критический радиус реактора R, при котором полное число нейтронов остается постоянным, считая, что плотность нейтронов изменяется линейно по радиусу и равна нулю на границе.

О3.1-9.11

В работающем ядерном реакторе в числе многих элементов из урана все время образуются изотопы иода ^{135} I, претерпевающие следующую последовательность бета-распадов (периоды полураспада указаны)

$^{135}\text{I} \overset{6.744\text{ac}}{\rightarrow} {}^{135}\text{Xe} \overset{9.24\text{qac}}{\longrightarrow} {}^{135}\text{Cs} \rightarrow \ldots$

Так как ядра ^{135} Xe обладают очень большим сечением поглощения нейтронов, в работающем реакторе накопления этого изотопа не происходит. Однако при остановке реактора ксенон начинает накапливаться, тем самым уменьшается коэффициент размножения нейтронов и сразу же повторный запуск реактора затрудняется (образуется так называемая иодная яма). Через какое время после остановки реактора количество ядер ^{135} Xe будет максимальным? Считать, что в момент остановки реактора ядер ксенона в нем нет.

О3.1-9.12

Один из способов утилизации оружейного плутония (почти чистый ^{239}Pu) состоит в его облучении в реакторе, где за счет захвата (поглощения) нейтронов ^{239}Pu либо делится, либо переводится в ^{240}Pu, который в свою очередь переходит в ^{241}Pu. Сечения этих реакций равны $\sigma_{f1} = 741, \sigma_{n1} = 267, \sigma_{n2} = 290$ бн. Плутоний считается непригодным для создания ядерного оружия, если содержание в нем ^{240}Pu составляет 40% от ^{239}Pu. Определить время, необходимое аля достижения этой концентрации ^{240}Pu в образце оружейного плутония в реакторе с массой $M = 2,75$ т ^{235}U и мощностью $W = 3500$МВ. Сечение деления ^{235}U равно $\sigma_{f3} = 579$ бн, в одном акте деления выделяется энергия $\varepsilon = 180\text{M} \ni \text{В}$.

МФТИ-ГКЭ.2021.5 Полураспад (!!!!!!)

Сечение деления урана- 238γ-квантами с энергией $E_0 = 3$ МэВ составляет $\sigma = 0,1$ нбн. Если плотность потока энергии в пучке γ-квантов превышает $S = 740$ мкВт / см^2, то в куске урана массой $m = 10$ г за время $t_0 = 10$ ч можно заметить вклад вынужденного деления на фоне спонтанного. Оценить по этим данным период полураспада $T_{1/2}$ урана-238.

Solution

(???)

Радиоактивный распад в результате спонтанного деления описывается уравнением $\frac{dN_{\text{сп}}}{dt} = \lambda N$, где $\lambda = \frac{\ln 2}{T_{1/2}}, N = N_{\text{A}}\frac{m}{A} = 2,53 \cdot 10^{22}$. Поскольку $t_0 \ll T_{1/2}$, то среднее число распавшихся атомов равно $N_{\text{сп}} = \lambda N t_0$. Так как радиоактивный распад является случайным процессом, то возможны отклонения от среднего числа порядка $\delta N_{\text{сп}} = \sqrt{\lambda N t_0}$. Распад в результате вынужденного деления описывается уравнением $\frac{dN_{\text{вын}}}{dt} = \sigma \Phi N$, где Φ - плотность потока квантов. Процесс вынужденного деления можно заметить, если число таких распадов за время наблюдения превысит отклонение от среднего в спонтанном процессе распада: $N_{\text{вын}}\ (t_0) = \sigma \Phi N t_0 \geq \delta N_{\text{сп}} = \sqrt{\lambda N t_0}$, откуда $\Phi \geq \frac{1}{\sigma}\sqrt{\frac{\lambda}{N t_0}}$. Считая поток γ-квантов монохроматическим, находим $\Phi = S/E_0$. Из этих двух соотношений, получаем $T_{1/2} \geq \left(\frac{E_0}{S\sigma}\right)^2 \frac{\ln 2}{N t_0} \cong 3,19 \cdot 10^{22}\text{с} \approx 10^{15}$ лет.

О3.1-9.13

Под действием нейтронной компоненты космического излучения на поверхности Земли из ^{238}U образуется ^{239}Pu. Считая, что плотность потока космических нейтронов равна $j_{\text{n}} = 1\ \text{м}^{-2} \cdot \text{с}^{-2}$ и эффективное сечение захвата (поглощения) нейтронов ядром урана равно $\sigma = 3$ бн, определить отношение концентрации ^{239}Pu и ^{238}U при временах $t \gg T_{1/2}$ от начала облучения $\left(T_{1/2} = 2,4 \cdot 10^4\right.$ лет - период полураспада плутония).

О3.1-9.14

Много лет тому назад в урановом месторождении в Окло (Габон, Африка) «работал» природный ядерный реактор на ^{235}U. Из $_3$ массы $M = 200$ т имевшегося там урана выделилась энергия $\mathscr{E} = 10^{11}\text{В}^-$. Оценить, какая часть массы $^{235}\text{U}\Delta M/M$ была при этом израсходована, если его начальная концентрация составляла $n_0 = 3,5\%$ Время «работы» реактора много меньше периода полураспада урана. Энергию $\mathscr{E}_0$, выделяющуюся при делении ядра ^{235}U, принять равной 200МВ

О3.1-9.15

Естественный уран состоит из $99,3\%$ изотопа ^{238}U и $0,7\%$ 235U. При обогащении смеси изотопов ^{235}U до 3% возможна цепная реакция деления. Какое время t тому назад такой природный реактор мог «загореться»?

О3.1-9.16

В урановом реакторе мощностью $W = 1$ МВт образуется в среднем $N = 6$ антинейтрино на один акт деления ядра урана. Энергия антинейтрино & $= 1,5$ МэВ. Реактор окружен биологической защитой (бетон). Оценить плотность потока антинейтрино j за биологической защитой на расстоянии $L = 5$ м и долю энергии э, уносимой антинейтрино из реактора. Считать, что реактор имеет сферическую форму.

О3.1-9.17

При спонтанном делении тяжелых элементов (тория, урана) внутри Земли выделяется мощность $W \simeq$ 15 ТВт. Делящиеся элементы являются источниками антинейтрино (≈ 6 антинейтрино на акт распада). Предполагая распределение элементов в Земле равномерным, оценить плотность потока антинейтрино на ее поверхности. Сечение поглощения антинейтрино принять равным $\sigma = 10^{-43}\text{см}^2/$ нуклон.

О3.1-9.18

Во всем мире в 1978 г. была выработана тепловая энергия, эквивалентная сжиганию около 10^{10} т условного топлива. Условное топливо имеет тепловыделение 7000 кал на 1 г. Какое количество естественного урана потребовалось бы взамен сжигания 10^{10} т условного топлива для получения такого же

количества тепловой энергии? Считать, что в реакторах коэффициент воспроизводства «ядерного горюго» к числу атомов затраченного). За один акт деления выделяется 200 МэВ энергии. В естественном уране содержится $0,714\%235\mathrm{U}$.

О3.1-9.19

Один из перспективных методов получения новых изотопов - синтез сверхтяжелых ядер с их последующим распадом. Найти пороговую скорость v ядер урана, бомбардирующих урановую мишень, для реакции

$$^{238}_{92}\mathrm{U} + ^{238}_{92}\mathrm{U} \to ^{476}_{184}\mathrm{X} \to \sum \mathrm{X}_i$$

18.2.8 Problems about nuclear fission and reactors 2

О3.1-9.20

В термоядерном реакторе концентрация дейтерия $n_\mathrm{d} = 2,5 \cdot 10^{15}$ ядер/см cm^3 поддерживается на постоянном уровне с помощью внешнего источника дейтронов, который обеспечивает поступление q ядер/(с cm^3). Принимая во внимание только реакции (d,d) и (d,t), найти: 1) установившуюся концентрацию n_t трития $\mathrm{t}; 2)$ вели- 84 чину $q; 3)$ мощность W, выделяемую в 1 см ^{3} плазмы. При температуре плазмы $T = 60$ кэВ усредненные по максвелловскому распределению произведения сечений реакций на относительную скорость частиц равны $\overline{\sigma v_\mathrm{dd}} = 1,6 \cdot 10^{-17}\mathrm{см}^3 \cdot \mathrm{c}^{-1}; \overline{\sigma v_\mathrm{dt}} = 10^{-15}\mathrm{см}^3 \cdot \mathrm{c}^{-1}$.

О3.1-9.21

Каково количество термоядерных реакций, происходящих в $1\mathrm{см}^3$ в 1с, если известно сечение реакции $\sigma(v)$, где v-относительная скорость реагирующих дейтронов, а n - число дейтронов в $1\mathrm{см}^3$?

О3.1-9.22

Какая плотность тепловой мощности $W\left[/c \cdot \mathrm{cm}^3\right]$ со- ется термоядерными реакциями в чисто дейтериевой плазме с концетрацией ядер $n_\mathrm{d} = 10^{15}\mathrm{см}^{-3}, \overline{\sigma v_\mathrm{dd}} = 10^{-17}\mathrm{см}^3/\mathrm{c}$, что соответствует температуре плазмы $4,6 \cdot 10^8$ К или 40 кэВ в энергетических единиах? При вычислениях vчитывать лишь энергию реакиий $\mathrm{d} + \mathrm{d}$.

9. Деление ядер. Реакторы. Термоядерный синтез

9.

10: $R = \sqrt{\frac{3}{k_\infty - 1}} L = 4$ m.

Решение. Полное число нейтронов

$$N = \int_0^R n_0 \left(1 - \frac{r}{R}\right) 4\pi r^2 dr = \frac{\pi n_0 R^3}{3}$$

где n_0 - концентрация нейтронов при $r = 0$. Полагая $L \ll R$, подставляя числовые данные получим, что из тонкого наружного слоя реактора, содержащего $4\pi R^2 L \frac{n_0 L}{2R}$ нейтронов (где $\frac{n_0 L}{2R}$ - средняя плотность нейтронов внутри этого слоя), примерно половина этих нейтронов уйдет из реактора, а половина останется. За это же время внутри реактора появится $(k_\infty - 1) N$ новых нейтронов. Таким образом,

$$\pi R n_0 L^2 = \frac{1}{3} \pi n_0 R^3 (k_\infty - 1)$$

откуда и следует ответ $R = \sqrt{\frac{3}{k_\infty - 1}} L = 400$ см.

9.

11*** $t^* = \frac{T_1 T_2 \ln(T_2/T_1)}{(T_2 - T_1)\ln 2} \approx 11$ час.

Решение. Пусть при $t = 0$ имсется N_0 ядер йода I, а ядер ксенона Xe $N_2(0) = 0$. Процесс β-распада / описывается уравнением

$$dN_1 = -N_1 \lambda_1 dt$$

откуда $N_1(t) = N_0 e^{-\lambda_1 t}$, где λ_1 - постоянная распада ядер йода. Ядра ксенона не только постоянно образуются из йода, но и одновременно распадаются с постоянной распада λ_2. Запишем уравнение этого процесса и его решение:

$$dN_2 = -N_2\lambda_2 dt + N_1\lambda_1 dt$$
$$N_2(t) = ae^{-\lambda_1 t} + be^{-\lambda_2 t}$$

Поскольку $N_2(0) = 0$, то $a = -b, N_2(t) = b\left(e^{-\lambda_2 t} - e^{-\lambda_1 t}\right)$. Подстановка $N_1(t)$ в дифференциальное уравнение для N_2 дает

$$b(\lambda_1 - \lambda_2) = N_0\lambda_1, \text{ откуда } b = \frac{N_0\lambda_1}{\lambda_1 - \lambda_2}$$

Таким образом,

$$N_2(t) = \frac{\lambda_1 N_0}{\lambda_1 - \lambda_2}\left(e^{-\lambda_1 t} - e^{-\lambda_2 t}\right)$$

Условие максимума числа ядер ксенона $\frac{dN_2}{dt} = 0$, откуда $\ln\frac{\lambda_1}{\lambda_2} = (\lambda_1 - \lambda_2)\,t^*$. Таким образом, искомое время

$$t^* = \frac{T_1 T_2 \ln(T_2/T_1)}{(T_2 - T_1)\ln 2} \approx 11 \text{ час.}$$

9.

12* $t = 3,4 \cdot 10^7$с ≈ 390 дней.

Решение. Полное нейтронное сечение σ_t ^{239}Pu складывается из сечеиия деления σ_{f1} и сечения радиационного захвата нейтрона σ_{n1} (переход в ^{240}Pu), т. е. $\sigma_t = \sigma_{f1} + \sigma_{\text{nl}} = 1008\sigma$Н.

Пусть плотность потока нейтронов, облучающих ^{239}Pu, равна $j\left[\text{ см}^{-2}\cdot\text{с}^{-1}\right]$. Тогда число ядер N_1 ^{239}Pu убывает по закону

$$\frac{dN_1}{dt} = -j\sigma_t N_1$$

У равнение, описывающие накопление ядер N_2 ^{240}Pu с учетом их распада имеет вид:

$$\frac{dN_2}{dt} = j\sigma_{n1}N_1 - j\sigma_{\text{n2}}N_2.$$

Решение этой системы уравнений (см. задачу 9.11) есть

$$N_1 = N_{10}\exp(-j\sigma_t t)\,; N_2 = \frac{\sigma_{\text{n1}}N_{10}}{\sigma_{\text{n2}} - \sigma_t}\left[\exp(-j\sigma_t t) - \exp(-j\sigma_{\text{n2}}t)\right]$$

Требуемое отношение концентраций

$$\frac{N_{240}}{N_{239}} = 0,4 = \frac{N_2}{N_1} = \frac{\sigma_{\text{n1}}}{\sigma_{\mathbf{n2}} - \sigma_t}\left\{1 - \exp\left[-j\left(\sigma_{\text{n2}} - \sigma_t\right)t\right]\right\}$$

откуда

$$-j\left(\sigma_{\text{n2}} - \sigma_t\right)t = \ln\left(1 - 0,4\frac{\sigma_{\text{n2}} - \sigma_t}{\sigma_{\text{n1}}}\right).$$

Плотность потока j находится из энергетических соображений. Мощность реактора W равна (N_3 - число ядер горючего)

$$W = \varepsilon j\sigma_{j3}N_3 = \varepsilon j\sigma_{f3}MN_{\text{A}}/235$$

откуда искомый поток нейтронов

$$j = \frac{235W}{\varepsilon\sigma_{f3}MN_{\text{A}}} \approx 3\cdot 10^{13}\text{ см}^{-2}\cdot\text{с}^{-1}$$

Время наработки необходимой концентрации ^{240}Pu равно

$$t = \frac{\ln\left[1 + 0,4\left(\sigma_t - \sigma_{\text{n2}}\right)/\sigma_{\text{n1}}\right]}{j\left(\sigma_t - \sigma_{\text{n2}}\right)} = 3,4\cdot 10^7\text{с} \approx 390 \text{ дней.}$$

9.

13. $\frac{n_{\mathrm{Pu}}}{n_{\mathrm{U}}} = \frac{\sigma j_{\mathrm{n}} T_{1/2}}{\ln 2} \approx 3,3 \cdot 10^{-16}$.

9.

14. $\frac{\Delta M}{M} = \frac{\mathscr{E}_{\mathrm{U}} m_{\mathrm{n}}}{\mathscr{C}_0 M n_0} \approx 0,63$, где $A_{\mathrm{U}} = 235$.

9.

15. $t = \frac{T_1 T_2}{(T_1 - T_2)\ln 2} \ln\left(\frac{N_{10}}{N_{20}} \frac{N_2}{N_1}\right) \approx 1,7 \cdot 10^9$ лет, где $T_1 = 4,5 \cdot 10^9$ лет, $T_2 = 0,7 \cdot 10^9$ лет - периоды полураспада ^{238}U и ^{235}U.

9.

16. $j = \frac{WN}{4\pi L^2 Q} \approx 6 \cdot 10^{10}$ см$^{-2} \cdot$ с$^{-1}$; $\eta = \frac{N}{Q} = 0,045$, где $Q = 200$М В энергия, выделяемая при делении ядра урана.

9.

17* Земля практически не поглощает антинейтрино, поэтому $j = \frac{6W}{Q 4\pi R_3^2} \approx 6 \cdot 10^5$ см$^{-2} \cdot$ с$^{-1}$.

Решение. В соответствии с законами сохранения электрического и лептонного зарядов антинейтрино взаимодействуют только с протонами:

$$\tilde{\nu}_{\mathrm{e}} + \mathrm{p} \to \mathrm{n} + \mathrm{e}^+$$

Реакция взаимодействия $\tilde{\nu}_{\mathrm{e}}$ с нейтронами невозможна в силу закона сохранения лептонного заряда. Наибольшее поглощение толщей Земли будут испытывать антинейтрино, проходящие внутри Земли максимальный путь, равный диаметру Земли. Концентрация нуклонов $n = \rho/m_{\mathbf{H}} = \rho N_{\mathrm{A}}/\mu_{\mathrm{H}}$, где m_{H} - масса нуклона; $\mu_{\mathrm{H}} = 1$ г/моль. Поскольку Земля состоит в основном из элементов с $A \leq 60$, то числа протонов и нейтронов примерно равны, т. е. $n_p = n/2$. Тогда число протонов в «столбике» длиной $2R_3$ с поперечным сечением 1 см^2

$$N_{\mathrm{p}} = n_{\mathrm{p}} 2R_3 = \frac{1}{2}\frac{\rho N_{\mathrm{A}}}{\mu_{\mathrm{H}}} 2R_3 = \frac{\rho N_{\mathrm{A}} R_3}{\mu_{\mathrm{H}}}$$

Уравнение, описывающее убыль антинейтрино из потока,

$$dN_v = -\sigma N_v dN_{\mathrm{p}}$$

Интегрируя это уравнение, получим

$$N_v = N_0 e^{-\sigma N_{\mathrm{p}}} = N_0 \exp\left\{-\sigma \frac{\rho N_{\mathrm{A}} R_3}{\mu_{\mathrm{H}}}\right\},$$

где N_0 - начальный поток антинейтрино. Поскольку показатель экспоненты

$$\frac{\sigma \rho N_{\mathrm{A}} R_3}{\mu_{\mathrm{H}}} \approx 1,4 \cdot 10^{-10} \ll 1,$$

то $N_v \approx N_0$, т. е. Земля практически не ослабляет поток антинейтрино, т. е. поглощением антинейтрино Землей можно пренебречь.

Полный поток антинейтрино на поверхности Земли от распада распре деленных по объему ядер тяжелых элементов равен потоку от всех распадающихся ядер, помещенных в центре Земли. По существу это аналог электростатической теоремы Гаусса. Поэтому

$$j = \frac{6W/Q}{4\pi R_3^2} = 6 \cdot 10^5 \frac{\text{нейтрино}}{\text{см}^2 \cdot \text{с}},$$

где $\boldsymbol{W} = 15$ ТВ - мощность, выделяемая подземными источниками деления, $Q = 200$М Э - энергия, выделяющаяся при одном акте деления.

9.

18. $m = 282,6 \cdot 10^3$ т естественного урана.

9.19.

$v = \frac{\sqrt{2}Ze}{\sqrt{MR_{\text{g}}}} \approx 3,5 \cdot 10^9$ см /с, где Z, M, R_{g} - порядковый номер, масса и радиус ядра урана.

9.

20: 1) $n_{\text{t}} = 10^{13}$ см$^{-3}$; 2) $q = 1,25 \cdot 10^{14}$с$^{-1} \cdot$ см$^{-3}$; 3) $W = 99,6$ВТ/см^3.
Решение. Отметим энерговыделение при указанных реакциях синтеза ядер

$$\text{d} + \text{d} \to \begin{cases} \text{t} + \text{p}, & Q_1 = 3,94\text{M В}; \\ {}^3\text{He} + \text{n}, & Q_2 = 3,26\text{M В}; \end{cases}$$
$$\text{d} + \text{t} \to {}^4\text{He} + \text{n}, \quad Q_3 = 17,6\text{M} \ni \text{В}.$$

Первые две реакции (d, d) идут с равной вероятностью в силу зеркаль ности ядер t и ^{3}He. Изменение со временем концентрации частиц в резуль тате взаимодействия определяется скоростями реакций (d, d) и (d, t) и скоростью поступления ядер извне.

Скорость реакции - это число столкновений частиц сорта 1 и 2 в единицу времени, приводящее к реакции. Пусть $f_1(\mathbf{v}_1)$ и $f_2(\mathbf{v}_2)$ - функции распределения частиц сортов 1 и 2 по скоростям. Будем считать, что эти функции нормированы, т. е. $\int f(\mathbf{v}) d\mathbf{v} = 1$. Тогда каждую секунду в каждом см ^{3} объема плазмы число актов взаимодействия частиц, имеющих скорости от v_1 до $v_1 + dv_1$, и от v_2 до $v_2 + dv_2$ равно

$$dN_{12} = n_1 f_1(\mathbf{v}_1)\, n_2 f_2(\mathbf{v}_2)\, |\mathbf{v}_1 - \mathbf{v}_2|\, \sigma(|\mathbf{v}_1 - \mathbf{v}_2|)\, d\mathbf{v}_1 d\mathbf{v}_2,$$

где n_1 и n_2 - плотности частиц, $\sigma(v)$ - сечение реакции, зависящее от относительной скорости частиц, $\mathbf{v} = \mathbf{v}_1 - \mathbf{v}_2$ (рис. 184). Следовательно,

$$N_{12} = \iint d\mathbf{v}_1 d\mathbf{v}_2 n_1 f_1(\mathbf{v}_1)\, n_2 f_2(\mathbf{v}_2)\, v\sigma(v) \quad \left[\text{см}^{-3} \cdot \text{с}^{-1}\right]$$

Считая, что пнотность частиц n_1 и n_2 неизменны, получаем

$$N_{12} = n_1 n_2 \overline{\sigma v}, \quad \text{где} \quad \overline{\sigma v} = \iint d\mathbf{v}_1 d\mathbf{v}_2 f_1(\mathbf{v}_1)\, f_2(\mathbf{v}_2)\, v\sigma(v').$$

Запишем уравнение для изменения концентрации ядер дейтерия n_{d} со временем

$$\frac{\partial n_{\text{d}}}{\partial t} = -2\frac{(n_{\text{d}} - 1)\, n_{\text{d}}}{2}\overline{\sigma v_{\text{dd}}} - n_{\text{d}} n_{\text{t}} \overline{\sigma v_{\text{dt}}} + q.$$

Здесь первое слагаемое описывает убыль ядер дейтерия из-за столкновений друг с другом. Одно ядро d имеет $(n_{\text{d}} - 1)$ столкновений (в расчете на единицу объема); n_{d} ядер имеют $n_{\text{d}}(n_{\text{d}} - 1) \approx n_{\text{d}}^2$

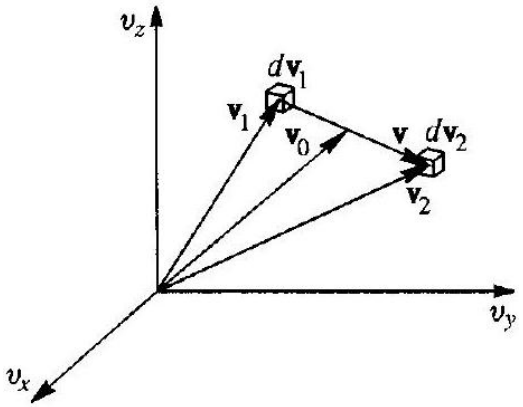

Рис. 184 столкновений. Для реакции (d, d) безразличен порядок дейтронов в паре, поэтому число взаимодействующих пар равно $n_{\text{d}}^2/2$, и в каждом акте реакции исчезают два дейтрона. Таким образом,

$$\frac{\partial n_{\text{d}}}{\partial t} = -n_{\text{d}}^2 \overline{\sigma v_{\text{dd}}} - n_{\text{d}} n_{\text{t}} \overline{\sigma v_{\text{dt}}} + q.$$

Аналогично, для ядер трития можно записать:
$\frac{\partial n_\mathrm{t}}{\partial t} = -n_\mathrm{t} n_\mathrm{d} \overline{\sigma v_\mathrm{dt}} + \frac{1}{2}\frac{n_\mathrm{d}(n_\mathrm{d}-1)}{2}\overline{\sigma v_\mathrm{dd}}$.
Во втором слагаемом первый коэффициент 1/2 учитывает вероятность получения трития в результате столкновения пары дейтронов. Таким образом,

$$\frac{\partial n_\mathrm{t}}{\partial t} = -n_\mathrm{t} n_\mathrm{d} \overline{\sigma v_\mathrm{dt}} + \frac{1}{4} n_\mathrm{d}^{2\overline{\sigma v}}\mathrm{dd}.$$

В стационарном состоянии производные $\dot{n}_\mathrm{d}$ и $\dot{n}_\mathrm{t}$ равны нулю, и мы получаем уравнения баланса

$$\begin{cases} q = n_\mathrm{d}^2 \overline{\sigma v_\mathrm{dd}} + n_\mathrm{d} n_\mathrm{t} \overline{\sigma v_\mathrm{dt}}, \\ \frac{1}{4} n_\mathrm{d}^2 \overline{\sigma v_\mathrm{dd}} = n_\mathrm{d} n_\mathrm{t} \overline{\sigma v_\mathrm{dt}}, \end{cases}$$

откуда вычисляем стационарную концентрацию ядер трития

$$n_\mathrm{t} = \frac{1}{4} n_\mathrm{d} \frac{\langle \sigma v_\mathrm{dd} \rangle}{\langle \sigma v_\mathrm{dt} \rangle} = 10^{13}\ \mathrm{cm}^{-3},$$

а также интенсивность поступления в зону реакции дейтронов от внешнего источника

$$q = \frac{5}{4} n_\mathrm{d}^2 \overline{v v_\mathrm{dd}} = 1,25 \cdot 10^{14} \frac{\text{ядер}}{\mathrm{c} \cdot\ \mathrm{cm}^3}.$$

Выделяющаяся в термоядерных реакциях мощность W может быть выражена через скорости изменения концентраций ядер дейтерия по каналам (d, d) и (d, t)

$$W = Q_\mathrm{dd} \frac{1}{2} \left(\frac{\partial n_\mathrm{d}}{\partial t} \right)_\mathrm{dd} + Q_\mathrm{dt} \left(\frac{\partial n_\mathrm{d}}{\partial t} \right)_\mathrm{dt},$$

где Q_dd и Q_dt - энерговыделения в реакциях (d, d) и (d, t). Коэффициент 1/2 учитывает, что для реакции (d, d) нужно два дейтрона. Поскольку эта реакция идет с равной вероятностью по двум каналам, то $Q_{dd} = \frac{Q_1+Q_2}{2}, Q_\mathrm{dt} = Q_3$. Окончательно,

$$\boldsymbol{w} = n_\mathrm{d}^2 \overline{\sigma v_\mathrm{dd}} \frac{Q_1 + Q_2 + Q_3}{4} = 9,96 \cdot 10^8 \frac{9\mathrm{pr}}{\mathrm{ccm}^3} = 99,6 \frac{\mathrm{Br}}{\mathrm{cm}^3}.$$

9.

21. Число реакций, происходящих в 1 с в 1 cm^3, равно $n^2 \overline{\sigma(v)v}/2$, где черта означает усреднение по всем значениям относительных скоростей атомов дейтерия (см. задачу 9.20).

9.

22. $W = \frac{n_\mathrm{d}^2}{2} \overline{\alpha v_\mathrm{dd}} \left(\frac{3,94+3,26}{2} \right) = 2,88 \cdot 10^7 \frac{\text{Дж}}{\mathrm{c} \cdot \mathrm{cm}^3} = 2,88 \frac{\mathrm{Вт}}{\mathrm{cm}^3}$ (см. также задачу 9.20).

9.

27. $R > \frac{12 \sigma_\mathrm{c} T^4}{Q \eta_\mathrm{d}^2 \sigma v_\mathrm{dd}} = 3,45 \cdot 10^{10}\ \mathrm{cm} = 3,45 \cdot 10^5 \mathrm{KM}$,
$Q = Q_1 + Q_2 + Q_3 = 24,8\mathrm{MB}$ - выделение энергии, соответствующие суммарному уравнению синтеза $5\ \mathrm{d} \to {}^3\mathrm{He} + {}^4\mathrm{He} + \mathrm{p} + 2\mathrm{n}, \sigma_\mathrm{c}$ - константа Сте-фана-Больцмана.

9.

28: $\frac{N_\mathrm{dd}^{\mathrm{KB}}}{N_\mathrm{dd}^{\mathrm{KJ}}} \approx 1,6 \cdot 10^{21}$.
Решение. Как следует из решения задачи 9.20, скорость реакции (d, d) можно представить в виде

$$N_\mathrm{dd} = \frac{n_\mathrm{d}^2}{2} \overline{\sigma v_\mathrm{dd}}, \quad \text{где } \overline{\sigma v_\mathrm{dd}} = A(m,T) \int_0^\infty v^3 \exp\left(-\frac{\mu v^2}{2kT} \right) \sigma(v) dv,$$

где $\mu = m/2$ - приведенная масса, v - относительная скорость.
При классическом рассмотрении реакция произойдет только тогда, когда кинетическая энергия относительного движения будет больше высоты кулоновского барьера $\mu v^2/2 \geqslant U_{\text{кул}} = e^2/(2R_\mathrm{d})$, где R_d

- классический радиус дейтрона ($R_{\text{d}} = 1,7 \cdot 10^{-13}$ cm). В этом случае сечение взаимодействия $\sigma_{\text{KI}}(v) = 4\pi R_{\text{d}}^2$ и

$$\overline{\sigma v}_{\text{dd}}^{\text{KJ}} = A\int_0^\infty v^3\sigma_{\text{K}\Omega}(v)\exp\left(-\frac{\mu v^2}{2kT_0}\right)dv = \tilde{A}\pi\left(\frac{e^2}{U_{\text{ky}}}\right)^2\int_{U_{\text{ky}}}^\infty \mathscr{E}\exp\left(-\frac{\mathscr{E}}{kT_0}\right)d\mathscr{E} \approx$$
$$\approx \tilde{A}\pi\left(\frac{e^2}{U_{\text{y}\boldsymbol{J}}}\right)^2(kT_0)^2\left(\frac{U_{\text{Ky}}}{kT_0}+1\right)\exp\left(-\frac{U_{\text{Ky}}}{kT_0}\right) \approx$$
$$\approx \tilde{A}\pi\left(\frac{e^2}{U_{\text{ky}}}\right)^2 kT_0U_{\text{ky}}\exp\left(-\frac{U_{\text{Ky}}}{kT_0}\right)$$

поскольку $\frac{U_{\text{кул}}}{kT_0} \approx 58 \gg 1$.

При вычислениях были введены обозначения $\mathscr{E} = \mu v^2/2, \tilde{A} = A(2/\mu)^2$.

В квантовом случае определяющую роль играет проницаемость кулоновского барьера. При $\mathscr{E} \ll U_{\text{кул}}$ (это условие выполняется в задаче, поскольку $\mathscr{E} \sim (3/2)kT \approx 1,4 \cdot 10^4$ эВ $\ll 0,5$М Э)

$$D(\mathscr{E}) \simeq \exp\left(-\frac{4e^2}{\hbar}\sqrt{\frac{2\mu}{\mathscr{E}}}\right)$$

В этом случае сечение взаимодействия $\sigma_{\text{кв}}(\mathscr{E}) = \sigma(\mathscr{E})D(\mathscr{E})$, где $\sigma(\mathscr{E})$ геометрическое сечение образования составного ядра, и

$$\overline{\sigma v}_{\text{dd}}^{\text{KB}} = A\int_0^\infty v^3\sigma_{\text{KB}}(v)\exp\left(-\frac{\mu v^2}{2kT_0}\right)dv = \tilde{A}\int_0^\infty \mathscr{E}\sigma_{\text{KB}}(\mathscr{E})\exp\left(-\frac{\mathscr{E}}{kT_0}\right)d\mathscr{E};$$
$$\sigma_{\text{KB}}(\mathscr{E}) = \sigma(\mathscr{E})D(\mathscr{E}) \approx \sigma(\mathscr{E})\exp\left(-\frac{4e^2}{\hbar}\sqrt{\frac{2\mu}{\mathscr{E}}}\right)$$

Выражение для $\overline{\sigma v}_{dd}^{\text{KB}}$ содержит интеграл с произведением двух экспонент (падающей и медленно растущей). Главную роль здесь играет область значений энергий вблизи максимума показателя экспоненциальной функции

$$\frac{d}{d\mathscr{E}}\left(\frac{\mathscr{E}}{kT_0}+\frac{4e^2\sqrt{2\mu}}{\hbar\sqrt{\mathscr{E}}}\right)\Big|_{\mathscr{E}=\mathscr{E}_{\max}} = 0$$

откуда

$$\S_{\max} = 2kT_0\sqrt[3]{\frac{\mu e^4}{\hbar^2 kT_0}} = 3,1 \cdot 10^4 \ni \text{ В}$$

Соответствующая длина волны де Бройля $\hat{\lambda} = \frac{\hbar}{\sqrt{2\mu\varphi_{\max}}} = 3,66 \cdot 10^{-11}\text{c} \gg R_{\text{d}}$. Таким образом, в наиболее существенной области значений энергий справедлива аппроксимация $\sigma(\mathscr{E}) = \pi\hbar^2 = \pi\hbar^2/(2\mu)$ и

$$\bar{\sigma}_{\text{d d}}^{\text{KB}} = \tilde{A}\frac{\pi\hbar^2}{2\mu}\int_0^\infty \exp\left(-\frac{\mathscr{E}}{kT_0}-\frac{4e^2}{\hbar}\sqrt{\frac{2\mu}{\mathscr{G}}}\right)d\mathscr{E}$$

Подынтегральное выражение представляет собой функцию с острым максимумом и шириной порядка kT_0. Т.к. $kT_0 > \mathscr{E}_{\max}$, то спадание функции вблизи экстремума определяется экспонентой $\exp(-\mathscr{E}/kT_0)$. Таким образом,

$$\overline{\sigma v}_{\text{dd}}^{\text{KB}} = \tilde{A}\frac{\pi\hbar^2}{2\mu}kT_0\exp\left(-\frac{\mathscr{E}_{\max}}{kT_0}-\frac{4e^2\sqrt{2\mu}}{\hbar\sqrt{\mathscr{E}_{\max}}}\right) = \tilde{A}\frac{\pi\hbar^2}{2\mu}kT_0\exp\left(-6\sqrt[3]{\frac{\mu e^4}{\hbar^2 kT_0}}\right)$$

Окончательно,

$$\frac{N_{\text{dd}}^{\text{KB}}}{N_{\text{dd}}^{\text{KJ}}} = \frac{\hbar^2}{2\mu e^4}U_{\kappa\text{y}}\exp\left(\frac{U_{\text{Ky}}}{kT_0}-6\sqrt[3]{\frac{\mu e^4}{\hbar^2 kT_0}}\right) \approx 1,6 \cdot 10^{21}$$

9.

29: В магнитном поле все столкновения идут с моментом импульса $J = 3/2$ и среднее сечение увеличивается в 1,5 раза.

Решение. При низких энергиях, т. е. при малых импульсах, дебройлевская длина волны очень велика по сравнению с размерами частиц. По правилу квантования момента импульса взаимодействие возможно только в состоянии с $\mathbf{L} = 0$, и полный момент импульса ядра как целого - чисто спиновый. Полный момент импульса системы $d + t : I = \mathbf{S}_d + \mathbf{S}_\mathrm{t}$ может принимать два значения $I = 3/2$ и $I = 1/2$. Так как ядерные силы зависят от спинов сталкивающихся частиц и полный спин есть интеграл движения, то

$$\langle\sigma\rangle = w_{3/2}\sigma_{3/2} + w_{1/2}\sigma_{1/2}$$

Здесь $\langle\sigma\rangle$ - среднее сечение реакции; $\sigma_{3/2}$ и $\sigma_{1/2}$ - сечения реакции, соответствующие $I = 3/2$ и $I = 1/2; w_{3/2}$ и $w_{1/2}$ - доли состояний, соответствующие значениям полного момента импульса I из общего числа состояний, равного $(2S_\mathrm{d} + 1)(2S_\mathrm{t} + 1)$. По условию $\sigma_{1/2} \approx 0$, тогда $\langle\sigma\rangle = w_{3/2}\sigma_{1/2} = \frac{2\cdot(3/2)+1}{(2\cdot1+1)(2\cdot1/2+1)}\sigma_{3/2} = \frac{2}{3}\sigma_{3/2}$. В магнитном поле, полностью поляризующем спины взаимодействующих ядер, возможно только одно состояние $S_{\mathrm{d}z} = 1$ и $S_{\mathrm{t}z} = 1/2; J_z = 3/2$ (ось z совпадает с направлением магнитного поля B). Тогда $\langle\sigma(B)\rangle = \sigma_{3/2}$ и, следовательно, среднее сечение возрастает в 1,5 раза.

9.

30: Если учесть четыре реакции

$$\mathrm{d} + \mathrm{d} \to \mathrm{t} + \mathrm{p} + 3{,}94\ \text{М эВ};$$
$$\mathrm{d} + \mathrm{d} \to {}^3\mathrm{He} + \mathrm{n} + 3{,}26\text{М} \ni \ \text{В};$$
$$d + {}^3\mathrm{He} \to \alpha + \mathrm{p} + 18{,}3\text{М эВ};$$
$$\mathrm{d} + \mathrm{t} \to \alpha + \mathrm{n} + 17{,}6\text{М} \to \ \text{В},$$

то на один "сгоревший» дейтрон выделяется энергия 7,18 МэВ. Пользуясь этим, легко найти, что при полном сгорании дейтерия, содержащегося в 1 л воды, выделится энергия $3{,}6 \cdot 10^3\text{КВ} \cdot$, что равно энергии, получающейся ири сгорании 277 кг бензина.

9.

31. $\mathscr{E} = 3 \cdot 10^7$ кДж.

9.

32. $\frac{\mathscr{E}_{\text{кин}}}{\text{конечн}} = \frac{36kT}{3Q_1+2Q_2+2Q_3} \approx 0{,}06,$

где Q_1, Q_2, Q_3 - энергии, выделяющиеся при реакциях синтеза, равные соответственно 3,3; 4; 17, 6М ЭВ.

9.

33. $n_\mathrm{d}\tau = \frac{3kT}{\frac{\eta}{\eta-1}\overline{\sigma v_\mathrm{dd}}\frac{2Q_\mathrm{dd}+Q_\mathrm{dt}}{4} - 1{,}5\cdot10^{-34}\sqrt{T}} \approx 7 \cdot 10^{15}\mathrm{c/cm}^3.$

Решение. Реакция будет самоподдерживающейся, если выделяемая в реакторе плотность мощности превысит плотность мощности совокупных

потерь: $W \geqslant W_\text{пот}$. Последняя состоит из тепловых потерь, связанных с уходом частиц из зоны реакции, и потерь на тормозное излучение:

$$\boldsymbol{W} = \boldsymbol{W}_\mathrm{T} + \boldsymbol{W}_\text{изЗл}$$

Выделяемая в реакторе мощность W берется из мощности термоядерного синтеза W_0 и частичного полезного преобразования мощности потерь в корпусе реактора, так и в окружающей защите

$$\boldsymbol{W} = \eta\boldsymbol{W}_0 + \beta\left(\boldsymbol{W}_\mathrm{T} + \boldsymbol{W}_\text{из3.}\ \right)$$

Таким образом, условие стационарной работы на уровне нулевой мощности при $\eta = \beta$

$$\eta \cdot (W_0 + W_{\text{Т}} + W_{\text{изл}}) = W_{\text{Т}} + W_{\text{изл}}$$

Используя выражения для $\boldsymbol{W}_0$ и $W_{\text{Т}}$, полученные в задачах 9.20 и 9.24 ,

$$W_0 = n_{\text{d}}^2 \overline{\sigma v}_{\text{dd}} \frac{1}{4} (2Q_{\text{dd}} + Q_{\text{dt}}), W_{\text{Т}} = \frac{3 n_{\text{d}} kT}{\tau}$$

получим

$$n_{\text{d}}\tau = \frac{3kT}{\frac{\eta}{\eta-1}\overline{\sigma v}_{\text{dd}}\frac{2Q_{\text{dd}}+Q_{\text{dt}}}{4} - 1,5 \cdot 10^{-34}\sqrt{T}} \approx 7 \cdot 10^{15} \text{c/см}^3$$

9.

34. $\eta = \frac{Q}{Q_{\text{П}}} = \frac{4{,}964}{24{,}68} = 0,2.$

9.

35. $\mathscr{E}_{\text{K}}^{\max} = 19,8\text{М ВВ}.$

9.

36. $= \frac{e m_{\text{p}}}{\sigma l t} \approx 9300$ А.

9.

37: $t_{1/2} = 1,2 \cdot 10^{10}$ лет - время, за которое концентрация протонов убывает в два раза.

Решение. Согласно решению задачи 9.20 уравнение, описывающее изменение концентрации протонов, имеет вид

$$\frac{dn_{\text{p}}(t)}{dt} = -\frac{n_{\text{p}}^2(t)}{2}\overline{\sigma v_{\text{p}}} \approx -\frac{n_{\text{p}}^2(t)}{2}\sigma\bar{v}$$

где $n_{\text{p}}(0) = \rho N_{\text{A}} = 9,25 \cdot 10^{25}$ см$^{-3}$ начальная плотность ядер водорода, $\bar{v} = \sqrt{\frac{8kT}{\pi m_{\text{p}}}} = 5,6 \cdot 10^7$ см/с - средняя тепловая скорость протонов. Интегрируя это уравнение, получаем

$$\frac{1}{n_{\text{p}}(t)} - \frac{1}{n_{\text{p}}(0)} = \frac{\sigma\bar{v}t}{2}.$$

Откуда следует, что концентрация протонов уменьшается вдвое за время $t_{1/2} = \frac{2}{n_{\text{p}}(0)\sigma\bar{v}} = 1,2 \cdot 10^{10}$ лет.

9.

38. Эффект можно заметить, если число ядер, подверженных вынужденному делению, $N_{\text{вын}}$ превысит дисперсию фона, т. е. дисперсию числа спонтанно делящихся ядер $N_{\text{сп}}$. Дисперсия фона $\sqrt{\overline{\Delta N_{\text{c}}^2}} \approx \sqrt{N_{\text{c}}'} = \sqrt{\lambda N t_0}$.

За время t_0 $\overline{N_{\text{вын}}} \approx \sigma N j t_0$, где N - число ядер урана в момент времени t. Таким образом, $j \geqslant \frac{1}{\sigma}\sqrt{\frac{A \ln 2}{T_{1/2} N_{\text{A}} m t_0}} \approx 5 \cdot 10^{10}$ см$^{-2} \cdot$ с$^{-1}$.

9.39.

Грубая оценка: $R \sim \lambda \approx \frac{1}{n\sigma} = \frac{A}{\rho N_{\text{A}} \sigma} \approx 4,2$ см, откуда масса «шарика» $M \approx 5,7$ кг. Более точный рассчет дает $R \approx \frac{3A}{\sigma\rho N_{\text{A}}(\upsilon-1)} \approx 8,3$ см и $M \approx 45$ кг.

9.

40. $t = \frac{n}{n_0\sigma\sqrt{2\S/M}} \simeq 2\cdot 10^{-4}$с, где n_0 - концентрация ядер ^{235}U, M - масса нейтрона, n - число поколений нейтронов, сменившихся к моменту заданного выделения энергии деления: n находится из уравнения $\frac{k_\infty^n-1}{k_\infty-1} = \frac{W}{\mathscr{E}_{\text{дел}}}$, где $\mathscr{E}_{\text{дел}} \simeq 200$М В/акт деления, $n \approx 3,27\cdot 10^4$.

9.

41* $\beta = \left(\frac{\hbar c}{E_\gamma r_0 A^{1/3}}\right)^2 \approx 17$.

Решение. Фотоделение через состояние I^-происходит при поглощении $E1$ (электрических дипольных) квантов, а через состояние 2^+- при поглощении $E2$ (квадрупольных) квантов. Так как энергия гамма-квантов болыше высоты барьеров, то отношение вероятностей деления определяется только отношением сечений поглощения квантов ядром, равным $\beta = (\lambda/R_{\text{я}})^2$. Здесь $\hat{\lambda} = \lambda/2\pi$ - приведенная длина волны γ-кванта, а $R_{\text{я}}$ радиус ядра. Таким образом, отношение равно

$$\beta = \left(\frac{\hbar c}{E_\gamma r_0 A^{1/3}}\right)^2 \simeq 17$$

Это значит, что происходит преимущественное деление под действием El-фотонов. При двухфотонном поглощении световой квант, практически не меняя энергии ядра, фактически меняет спин и четность основного состояния, и деление уже будет происходить под действием $E1$-квантов через состояние 2^+. Вероятность деления через канал 2^+увеличится в 17 раз и будет равна сечению деления через канал 1^-под действием $E1$-квантов.

9.

42. $\frac{w_{\text{дел}}\,(1^-}{w_{\text{дел}}\,(2^+)} = \frac{\sigma_{\text{дел}}\,(1^-)}{\sigma_{\text{дел}}\,(2^+)} D\,(\delta_\gamma) = \left(\frac{\hbar}{R_{\text{яд}}}\right)^2 \exp\left\{-\frac{2\pi(U_0-\mathscr{E}_\gamma)}{\hbar\omega}\right\} = 4,8,$ где $D\,(\mathscr{C}_\gamma)$ - проницаемость параболического барьера (см. задачу 3.41). См. также решение задачи 9.41 .

9.

43. $L_{\max} = \sqrt{\frac{(1-\alpha)W}{8\pi\Phi_0}} \leqslant 110$ км.

О3.1-9.23

В первом поколении термоядерных реакторов предполагается использовать реакцию дейтерия с тритием:

$$\mathrm{d} + \mathrm{t} \to {}^4\mathrm{He} + \mathrm{n}.$$

Теплота реакции $Q = 17,6$ МэВ. Предполагая, что квазинейтральная плазма содержит равное количество ядер дейтерия и трития при плотности электронов $n = 10^{14}$см$^{-3}$, рассчитать плотность тепловой мощности W, а также полную мощность N термоядерной установки. Объем плазмы $V = 500$ м ^{3}. Для данной реакции

$$\overline{\sigma v}_{\mathrm{dt}} = \begin{cases} 6,2\cdot 10^{-21}\text{см}^3/\text{с} & \text{при} \quad kT = 1, \\ 6\cdot 10^{-17}\text{см}^3/\text{с} & \text{при} \quad kT = 10 \text{ кэВ}. \end{cases}$$

9.

23. $W = n_{\mathrm{d}} n_{\mathrm{t}} \overline{\sigma v_{\mathrm{dt}}} Q_{\mathrm{dt}} = \frac{n^2}{4}\overline{\sigma n_{\mathrm{dt}}} Q_{\mathrm{dt}}$, где $n_{\mathrm{d}} = n_{\mathrm{t}} = n/2$. (См. задачу 9.20). $N = WV$.
При $kT = 1$ кэВ $\quad \boldsymbol{W} = 4,36\cdot 10^{-5}\text{В/см}^3, N = 21,8$ кВт.
При $kT = 10$ кэВ $W = 0,422\text{В/см}^3, N = 211$МВт.

О3.1-9.24

Термоядерная реакция называется самоподдерживающейся, если выделяемая энергия полностью уходит на разогрев плазмы (ядер дейтерия, трития и электронов) до необходимой темературы T. Исходя из этого, найти минимально необходимое время с удержания квазинейтральной дейтериево-тритиевой плазмы с полной концетрацией частиц $n_{\mathrm{d}} + n_{\mathrm{t}} = n$. Для данной реакции при данной температуре величины Q_{dt} и $\overline{\sigma v}_{\mathrm{dt}}$ считать заданными.

Пр и меч а н и е. Время удержания плазмы определяется в первую очередь различными неустойчивостями, а также процессами диффузии и излучения.

9.

24. $\tau \geqslant \frac{12kT}{\overline{\sigma v}_{\mathrm{dt}} n Q_{\mathrm{dt}}}$.

О3.1-9.25

Согласно критерию Лоусона в равнокомпонентной смеси дейтерия и трития при $kT = 10$ кэВ термоядерная реакция будет самоподдерживающейся, если $n\tau = 10^{14}\mathrm{c/cm}^{-3}$, где n - плотность элекетонов, т - время удержания плазмы (см. задачу 9.24). Какова для Этого случая должна быть плотность тепловой мощности, выделяемой в реакторе, если $n = 10^{14}\mathrm{см}^{-3}$.

П р и м е ч а н и е. Такой режим работы называют режимом нулевой мощности.

9.

25. $W_{\mathrm{выд}} = W_{\mathrm{нагр}} = \frac{3kTn^2}{n\tau} = 0,48\frac{\mathrm{Br}}{\mathrm{cm}^3}$.

9.26. $n\tau > \dfrac{36kT}{\overline{\sigma v_{\mathrm{dt}}} Q_{\mathrm{dt}}} \approx 3 \cdot 10^{14}\ \mathrm{с/см}^3$.

О3.1-9.26

Экономически выгодным считается такой термоядерный реактор, в котором выделяемая энергия втрое превышает затраты на ра- зогрев плазмы. Это связано с тем, что часть выделямой мощности должна идти на поддержание работы различных вспомогательных 85 устройств. Показать, что для квазинейтральной равнокомпонентной дейтериево-тритиевой плазмы при $kT = 10$ кэВ критерий Лоусона имеет вид $n\tau > 3 \cdot 10^{14}\mathrm{c/cm}^{-3}$. Здесь n - плотность электронов, т время удержания плазмы (см. задачу 9.24). Для данной реакции при заданной температуре $\overline{\sigma v_{\mathrm{dt}}} = 6 \cdot 10^{-17}\mathrm{см}^3/\mathrm{c}$, а $Q_{\mathrm{dt}} = 17,6\mathrm{МВ}$.

О3.1-9.27

Оценить радиус плазменного дейтериевого шара, для которого термоядерная реакция станет самоподдерживающейся при $kT = 10$ кэВ. Плазму можно рассматривать, как абсолютно черное тело, непрозрачное для излучения, и считать, что основные потери энергии связаны с излучением через поверхность шара. Концетрация дейтерия равна $n_{\mathrm{d}} = 3,0 \cdot 10^{20}\mathrm{см}^{-3}$; при данной температуре величина $\overline{\sigma v_{\mathrm{dd}}} = 10^{-18}\mathrm{см}^3/\mathrm{c}$. Учитывать только реакции (d,d) и (d,t) (см. задачу 9.20). Концентрации дейтерия и трития считать стационарными.

О3.1-9.28

При классическом рассмотрении реакция термоядерного синтеза (d,d) может произойти только тогда, когда кинетическая энергия сталкивающихся дейтронов достаточна для преодоления кулоновского барьера $U_{\mathrm{кул}} = 0,5$ МэВ. Однако, благодаря туннельному эффекту эта реакция возможна и при меньших энергиях. Оценить, во сколько раз увеличивается скорость реакции при квантовом рассмотрении по сравнению с классическим. Температура дейтериевой плазмы $T_0 = 10^8$ К.

О3.1-9.29

Реакция термоядерного синтеза $\mathrm{d}+\mathrm{t} \to \mathrm{n}+\alpha$ при низких энергиях идет преимущественно в состоянии с полным моментом импульса сталкивающихся ядер $I = 3/2$. Во сколько раз изменится среднее сечение этой реакции, если дейтериево-тритиевая плазма помещена в магнитное поле, полностью поляризующее спины взаимодей-

ствующих ядер? Спины ядер дейтерия и трития равны соответственно $S_{\mathrm{d}} = 1$ и $S_{\mathrm{t}} = 1/2$ (см. указание к задаче 8.4).

О3.1-9.30

В морской воде примерно на каждые 6000 молекул обычной воды приходится одна молекула тяжелой воды D_2O. Учитывая четыре основные реакции синтеза, возможные в дейтериевой плазме, определить, какая энергия выделится в термоядерном реакторе при сжигании всего дейтерия, содержащегося в 1 л морской воды. Какому количеству бензина эквивалентен по энергии 1 л воды, если при сжигании 1 кг бензина выделяется 13 кВт.ч энергии?

О3.1-9.31

Оценить запас термоядерной энергии $\mathcal{E}$ в 1 м ^{3} морской воды, если использовать 10% дейтерия, содержащегося в воде, для осуществления реакции $\mathrm{d}+\mathrm{d}$. Число атомов дейтерия в природной смеси изотопов равно $0,015\%$.

О3.1-9.32

Определить отношение начальной кинетической энергии частиц дейтериевой плазмы, нагретой до $T = 10^9$ К, к энергии, выделившейся после «выгорания» всего дейтерия в результате реакции термоядерного синтеза. Учитывать только реакции (d,d) и (d,t).

О3.1-9.33

На рис. 60 изображена предполагаемая схема термоядерной электростанции. В реактор вводится подогретое до необходимой температуры топливо - дейтериевая плазма. Часть частиц покидает зону реакции, не испытав ядерного взаимодействия. Часть энергии заряженных частиц, которая бесполезно излучается из зоны реакции за счет тормозного излучения, с помощью системы отражателей возвращается обратно в реактор. Коэффициент преобразования выделенной энергии в электрическую (КПД станции) $\eta = 30\%$ Температура дейтериевой плазмы $T = 10^9$ К. Найти $n_\mathrm{d}\tau$ - произведение концентрации ядер дейтерия на время удержания дейтериевой плазмы в зоне реакции, необходимое для протекания самоподдерживающейся реакции. Принять во внимание только реакции (d,d) и (d,t). При заданной температуре $\overline{\sigma v_{\mathrm{dd}}} = 2,5\cdot 10^{17}\text{см}^3\cdot\text{с}^{-1}$. Считать, что за единицу времени из единицы объема плазмы уходит в среднем n_d/τ частиц. Интенсивность тормозного излучения единицы объема $W_{\text{изл}} = 1,5\cdot 10^{-34} n_\mathrm{d}^2\sqrt{T}$ Вт/см. Для упрощения расчета принять, что доля β мощности потерь из-за тормозного излучения, возвращенная обратно в реактор отражателями, равна КПД станции, т.е. $\beta = \eta$.

О3.1-9.34

. Согласно современным представлениям на Солнце осуществляется звездный углеродный цикл, в результате которого из четырех протонов образуется $\alpha-$частица Конечной реакцией этого цикла является реакция $\mathrm{p} + {}^{15}\mathrm{N} \to {}^{12}\mathrm{c} + {}^4\mathrm{He}$. Оценить, какая доля энергии η от полной энергии цикла выделяется в указанной реакции.

О3.1-9.35

. Под действием медленных нейтронов из литиевой мишени, состоящей из изотопа 6 Li, вылетают тритоны. Они в свою очередь попадают в дейтериевую мишень и могут приводить к реакции $\mathrm{t}+\mathrm{d} \to \mathrm{n}+\boldsymbol{\alpha}$. Какова при этом максимальная кинетическая энергия вторичных нейтронов?

О3.1-9.36

Основная реакция в водородной среде в центрах звезд $\mathrm{p}+\mathrm{p} \to \mathrm{d}+\mathrm{e}^+ + v_\mathrm{e}$ обусловлена слабым взаимодействием. Этот процесс можно промоделировать в лабораторных условиях. Рассчитать, какой ток ϑ протонов с энергией 1 МэВ должен падать на водородную мишень, чтобы за $t = 1$ ч произошла одна такая реакция. Пробег протонов данной энергии в мишени до взаимодействия $l = 8\cdot 10^{-4}\text{г/см}^2$, сечение взаимодействия при данной энергии $\sigma = 10^{-47}\text{см}^2$.

О3.1-9.37

В центре Солнца плотность ядер водорода $\rho \approx 160$ г/см ^{3}, температура $T = 1,5\cdot 10^7$ К($kT \simeq 1$В). Рассчитать время выгорания 50% ядер водорода в центре Солнца за счет реакции $\mathrm{p}+\mathrm{p} \to \mathrm{d}+\mathrm{e}^+ + v_\mathrm{e}$. Считать, что все протоны в центре Солнца имеют скорость, равную скорости при данной температуре, а сечение их взаимодействия $\sigma = 10^{-51}\text{см}^2$.

О3.1-9.38

Сечение деления ядер ^{238}U составляет $\sigma = 0,1$ нбн $\left(10^{-34}\text{см}^2\right)$. Какова должна быть плотность потока $j\left[\text{см}^{-2}\cdot\text{с}^{-1}\right]$ падающих на мишень γ-квантов, чтобы можно было заметить вынужденное деление в $m = 1$ мг урана на фоне спонтанного деления $\left(T_{1/2} = 10^{15}\right.$ лет) при продолжительности эксперимента $t_0 = 100$ час?

О3.1-9.39

Оценить критический радиус и массу шара из металлического урана-235 плотностью $\rho = 18,7\text{g/cm}^3$ (заряда ядерной бомбы), если известно, что среднее сечение деления ядер рождающимися нейтронами $\sigma = 1,5$ бн, среднее число рождающихся в одном акте деления нейтронов $\upsilon = 2,5$. Всеми аругими каналами реакции, кроме делительного, пренебречь. Плотность потока нейтронов считать однородной.

18.2.9 Problems about nuclear fission and reactors 3

О3.1-9.40

В бесконечной среде, состоящей из металлического урана-235, самопроизвольно разделилось одно ядро. Коэффициент размножения нейтронов $k_\infty = 1,001$, средняя энергия делительных нейтронов $\mathscr{E} = 1,6\text{МВ}$, сечение деления этими нейтронами $\sigma = 1,5$ бн. Оценить. за какое впемя в среле выделится энергия $W = 5$ МДж. Плотность урана $\rho = 18,7\text{g/cm}^3$, неупругими процессами пренебречь.

О3.1-9.41

Высота и форма барьера деления зависят от спина (полного момента) и четности делящегося ядра (рис. 61). Так, например, в уране-238, у которого спин и четность основного состояния 0^+, высоты барьеров деления для возбужденных состояний ядра 2^+и 1^-равны 5,2 и 5,7 МэВ соответственно. Найти отношение β вероятностей деления ядра через эти состояния под действием γ - квантов с энергией $\mathcal{E}_\gamma = 6,0$ МэВ. Как изменится вероятность деления через состояние 2^+, если поместить ядра в поле интенсивного лазерного излучения (т. е. в случае, когда ядро практически одновременно поглощает γ-квант и фотон)?

О3.1-9.42

Высота и форма барьера деления зависят от спина (полного момента) и четности делящегося ядра (рис. 61). Так, например, у ядра ^{240}Pu, основное состояние есть 0^+, высоты барьеров деления для возбужденных состояний ядра
2^+и 1^-равны соответственно 5,2 и 5,7 МэВ. Оценить отношение вероятностей деления ядра через эти состояния под действием γ квантов с энергией $\mathcal{E}_\gamma = 5,4$ МэВ. Форму барьера деления для состояния 1^-можно аппроксимировать «перевернутой параболой» с характерным квантом $\hbar\omega = 1,3$ МэВ. См. также задачу 3.41.

О3.1-9.43

Источником питания находящегося на околоземной орбите спутника является ядерный реактор мощностью $W = 3$ кВт. Оценить, на каком максимальном расстоянии от спутника можно обнаружить наличие реактора с помощью γ-телескопа. Считать, что сигнал надежно регистрируется, если он вдвое превышает γ - фон неба $\Phi_0 = 10^{-2}\text{см}^{-2}\cdot\text{с}^{-1}$. В каждом акте деления в среднем испускается $k = 7$ γ-квантов, защита реактора поглощает $\alpha = 95\%$ образующегося излучения. Считать, что угловое разрешение телескопа равно угловому размеру спутника.

18.2.10 Basic Problems about Elementary Particles 1

О3.1-10.1

При рождении и распаде частиц выполняется (помимо законов сохранения энергии, импульса и момента импульса) ряд точных законов сохранения (тильда сверху в обозначении частицы является знаком античастицы): 1) Закон сохранения электрического заряда; 2) закон сохранения барионного заряда (барионный заряд равен 1 д.я барионов, т. е., например, для нуклонов (n, p) и гиперонов (Λ, Σ, Ξ); -1 для антибарионов, т. е., например, для антинукло (частиц); 3) законы сохранения электронного лептонного заряда L_e, мюонного лептонного заряда L_μ и таонного лептонного заряда L_τ. Для электрона (e^-)и электронного нейтрино (υ_e) принято, что $L_\text{e} = 1$, а для позитрона и электронного антинейтрино $L_\text{c} = -1$. Для всех остальных частиц $L_\text{e} = 0$. Аналогично, L_μ отлично от нуля только для четырех частиц: $\mu^-, \upsilon_\mu, \mu^+, \tilde{\upsilon}_\mu$ (мюонов и мюонных нейтрино), причем для первых двух частиц $L_\mu = 1$, а для последних

двух $L_\mu = -1$. Аналогично вводятся лептонные заряды и для сверхтяжелого лептона τ^-. Y какие из приведенных ниже реакций запрещены перечисленными законами сохранения: 1. $\to \mathrm{p} + \mathrm{e}^- + \tilde{v}_\mathrm{e}$ 5. $\pi^- + \mathrm{p} \to \Lambda^0 + \mathrm{K}^0$ 2. $\mathrm{p} \to n + \mathrm{e}^+$. 6. $\mathrm{K}^- + \pi \to \Lambda^0 + \pi^-$. 3. $\mu^- \to \mathrm{e}^- + v_\mu + \tilde{v}_\mathrm{e}$. 7. $\pi^+ + \Pi \to \Lambda^0 + K^+$. 4. $\mathrm{K}^+ \to \pi^- + 2\mathrm{e}^+$. 8. $\pi^+ + \mathrm{n} \to \mathrm{K}^+ + \mathrm{K}^0$.

O3.1-10.2

Рассмотреть приведенные ниже распады и реакции и указать, какие из них запрещены: 1. $\pi^- \to \mu^- + \tilde{v}_{\mu^*}$ 6. $\tilde{v}_\mu + \mathrm{p} \to \mathrm{n} + \mathrm{e}^+$. 2. $\pi^- \to \mu^- + \tilde{v}_{\mathrm{e}^*}$ 7. $\tilde{v}_\mathrm{e} + \mathrm{p} \to \mathrm{n} + \mu^+$. 3. $\mu^- \to \mathrm{e}^- + v_\mathrm{e} + \tilde{v}_\mathrm{e}$. 8. $\tilde{v}_\mathrm{e} + \mathrm{p} \to \mathrm{n} + \mathrm{e}^+$. 4. $\mu^- \to \mathrm{e}^- + \tilde{v}_\mathrm{e} + v_u$. 9. $\mu^- \to \mathrm{e}^- + \gamma$.

O3.1-10.3

Взаимодействие и распад частиц происходят в результате сильного, электромагнитного или слабого взаимодействий. Вероятность процессов при слабом взаимодействии на много порядков меньше, чем при сильном. Сильное взаимодействие может происходить только между адронами. При сильном и электромагнитном взаимодействиях сохраняется квантовое число S (странность). При слабом взаимодействии странность не сохраняется. Принято приписывать странность S частицам следующим образом: $S = 0$ аля нуклонов, антинуклонов, л-мезонов; 89 $S = -1$ для $\Lambda, \Sigma^+, \Sigma^-, \mathrm{K}^-, \Sigma^0, \tilde{K}^0$(K-мезонов, Σ-гиперонов, Λ - частицы);

$S = -2$ для Ξ^-, Ξ^0 (каскадных гиперонов);

$S = -3$ для $\Omega^-_\sim$(гиперона)

$S = +1$ для $\tilde{\Lambda}, \tilde{\Sigma}^+, \tilde{\Sigma}^-, \tilde{\Sigma}^0,\ \mathrm{K}^+, \mathrm{K}^0$

$S = +2$ для $\tilde{\Xi}^-, \tilde{\Xi}^0$;

$S = +3$ для Ω^+.

В этих формулах тильда сверху - знак античастицы. При изменении странности на 1 вероятность процесса уменьшается в $10^{10} \div 10^{12}$ раз по сравнению со случаем сильного взаимодействия, а при изменении S на 2 реакция фактически не наблюдается, если возможна реакция с изменением S только на 1. При существующей интенсивности частиц, генерируемых в ускорителях, реакции меж- ду ними с нарушением странности практически ненаблюдаемы. Олду ними с нарушением странности практически ненаблюдаемы. Однако распады частиц с нарушением закона сохранения странности наблюдаются всегда.

Выяснить, какие из перечисленных реакций и распадов разрешены по закону сохранения S, какие не наблюдаются:

1. $\pi^- + \mathrm{p} \to \Lambda + \mathrm{K}^0$. 8. $\pi^+ + \mathrm{n} \to \Lambda + \mathrm{K}^+$. 2. $\pi^- + p \to \Lambda + \pi^0$. 9. $\mathrm{K} + \mathrm{p} \to \Sigma^+ + \pi^+$. 3. $\Lambda \to \mathrm{p} + \pi^-$.

10. $\mathrm{p} + \tilde{\Sigma}^+ \to \mathrm{K}^+ + \pi^+$. 4. $\Xi^- \to \Lambda + \pi^-$. 11. $\mathrm{p} + \tilde{\Sigma}^+ \to \pi^+ + \pi^+$. 5. $\Xi^- \to 2\pi^- + \mathrm{p}$. 12. $\pi^- + \mathrm{p} \to \Xi^- + \Xi^+ + \mathrm{n}$. 6. $\pi^+ + \tilde{p} \to \underset{\tilde{\Sigma}^+}{} + \mathrm{K}^-$. 13. $\pi^- + \mathrm{p} \to \Sigma^+ + \mathrm{K}^-$. 7. $\pi^+ + \tilde{p} \to \tilde{\Sigma}^+ + \pi^-$. 14. $\pi^- + \mathrm{p} \to \Xi^- + \mathrm{K}^+ + \mathrm{K}^0$.

O3.1-10.4

При распадах странных адронов (барионов и мезонов), приводящих к рождению лептонов, существует эмпирическое правило, управляющее вероятностью распада. Если изменение странности адрона при реакции ΔS не равняется изменению заряда адронов ΔZ, то такой распад не наблюдается. Например, наблюдается распад

$$\Sigma^- \to \mathrm{n} + \mathrm{e}^- + \tilde{v}_\mathrm{e} (\Delta Z = \Delta S = +1),$$

но не наблюдается распад

$$\Sigma^+ \to \mathrm{n} + \mathrm{e}^+ + v_\mathrm{e} (\Delta Z = -1; \Delta S = +1).$$

Существование первого и отсутствие второго из этих распадов можно рассматривать как потверждение кварковой структуры адронов. Определить, какие из перечисленных ниже распадов разрешены по правилу $\Delta Z = \Delta S$, а какие запрещены:

1. $\mathrm{K}^+ \to \pi^+ + \pi^+ + \mathrm{e}^- + \tilde{v}_\mathrm{e}$.
6. $\Xi^0 \to \Sigma^+ + \mathrm{e}^- + \tilde{v}_\mathrm{e}$.
2. $\mathrm{K}^+ \to \pi^+ + \pi^- + \mathrm{e}^+ + v_\mathrm{e}$.
7. $\Xi^0 \to \Sigma^- + \mathrm{e}^+ + v_\mathrm{e}$.
3. $\Xi^- \to \Lambda + \mathrm{e}^- + \tilde{v}_{\mathrm{e}^-}$.
8. $\mathrm{K}^+ \to \mathrm{e}^+ + v_\mathrm{e} + \pi^0$.
4. $\Sigma^0 \to \Lambda + \mathrm{e}^- + \mathrm{e}^+$.
9. $\mathrm{K}^+ \to \pi^+ + \mu^+ + \mu^-$.
5. $\Lambda \to \mathrm{p} + \mathrm{e}^- + \tilde{v}_\mathrm{e}$.
10. $\mathrm{K}^- \to \pi^- + \pi^- + \mathrm{e}^+ + v_\mathrm{e}$.

О3.1-10.5

Все частицы естественным образом разбиваются на группы с близкими значениями масс (отличие масс в группе порядка 1%). Группу частиц с близкими массами называют изотопическим муль типлетом (синглетом, дублетом, триплетом, квартетом). Частицы мультиплета можно трактовать как различные состояния одной фиктивной частицы, отличающиеся значениями проекции нового квантового числа - изотопического спина T. Как и обычный спин (момент импульса), изотопический спин имеет $2T + 1$ проекций на ось квантования в фиктивном изотопическом пространстве. Число проекций изотопического спина совпадает с числом частиц в мультиплете, т. е. $N = 2T + 1$. При этом проекция изотопического спина на ось квантования T_3 связывается с электрическим зарядом члена мультиплета $T_3 = Z - Y/2$, где Y-квантовое число, одинаковое для всех членов мультиплета, называемое гиперзарядом (или унитарным спином). Поскольку $\Sigma T_3 = 0$, то $Y = 2\frac{Z}{N+1} = 2Z_{\text{ср}}$ - удвоенный средний заряд мультиплета. Оказалось, что странность S (см. задачу 10.3) связана с гиперзарядом Y и барионным зарядом B простым соотношением: $S = Y - B$. Пользуясь приведенными равенствами, определить S, T, T_3 и Y для $\Lambda, \Sigma^-, \Xi-, \Omega^-, \pi^-, \mathrm{K}^-$, η-частиц.

Пр и меч а ни е. Для античастиц все заряды (электрический, барионный, лептонный, гиперзаряд) противоположны зарядам частиц. Противоположны также странность S и проекция изотопического спина T_3. Массы, времена жизни, спины и изотопические спины T у частиц и античастиц совпадают. Частицы, у которых все заряды равны нулю, называются истинно нейтральными.

О3.1-10.6

Строгие законы сохранения (см. задачу 10.1) ограничивают число типов реакций и распадов. Нестрогие законы сохранения ограничивают типы взаимодействий. Какие из приведенных ниже реакций и распадов разрешены законами сохранения, какие строго запрещены, какие практически ненаблюдаемы? (См. задачу 10.3.)

1. $\mathrm{p} \to \mathrm{n} + \mathrm{e}^+ + v_{\mathrm{e}}$. 4. $\mu^- \to \mathrm{e}^- + \mathrm{e}^+ + \mathrm{e}^-$. 2. $\mu^- \to \mathrm{e}^- + \tilde{v}_{\mathrm{e}} + \gamma$. 5. $\mathrm{K}^+ + \Pi \to \Sigma^+ + \pi^0$. 3. $\pi^0 \to \mathrm{e}^- + \mathrm{e}^+ + \gamma$. 6. $\to \mathrm{p} + \mathrm{e}^- + \tilde{v}_{\mathrm{e}}$

О3.1-10.7

Указать, какие из перечисленных ниже реакций и распадов невозможны или практически ненаблюдаемы из-за нарушения законов сохранения: 1. $\Sigma^+ \to \pi^+ + \pi$. 5. $\pi^- + \mathrm{p} \to \Sigma^- + \mathrm{K}^+$. 2. $\Sigma^- + \mathrm{p} \to \pi^0 + \tilde{K}^0$. 6. $\Sigma^0 \to \Lambda + \gamma$ 3. $\pi^- + \mathrm{p} \to \Lambda + \tilde{K}^0$ 7. $\Sigma^- \to \Lambda + \mathrm{e}^- + \tilde{v}_{\mathrm{e}}$. 4. $\pi^- + \mathrm{p} \to \Sigma^+ + \mathrm{K}^-$. 8. $\Sigma^0 \to \pi^0 + \pi^0$. По какому типу взаимодействия происходят процессы $1, 5, 6, 7$?

О3.1-10.8

Рассмотреть приводимые ниже реакции и распады и определить тип взаимодействия:
1. $\mathrm{K}^- + \mathrm{p} \to \Lambda + \pi^0$. 4. $\Xi^0 \to \Lambda + \pi^0$ 2. $\pi^+ + \mathrm{p} \to \Sigma^+ + \mathrm{K}^+$ 5. $\pi^0 \to \gamma + \gamma$. 3. $\Sigma^0 \to \Lambda + \gamma$ 6. $\Omega^- \to \Xi^- + \pi^0$.

О3.1-10.9

Как отличаются друг от друга значения квантовых чисел K^0-мезона и $\tilde{K}^0$-мезона и как это сказывается на поглощении K^0 и $\tilde{\mathrm{K}}^0-$ мезонов веществом? Возможны ли переходы этих частиц друг в друга?

О3.1-10.10

Определить типы взаимодействий при следующих реакциях и распадах: 1. $\mathrm{K}^- + {}^4_2\mathrm{He} \to {}^3_2\mathrm{He} + \Lambda + \pi^-$. 5. ${}^4_2\mathrm{He} + {}^4_2\mathrm{He} \to {}^6_3\mathrm{Li} + {}^2_1\mathrm{H} + \pi^0$. 2. ${}^2_1\mathrm{H} + {}^2_1\mathrm{H} \to {}^4_2\mathrm{He} + \pi^0$. 6. $\Omega^- \to \mathrm{K}^- + \Lambda$. 3. $\mathrm{p} + {}^4_2\mathrm{He} \to {}^3_2\mathrm{He} + {}^2_1\mathrm{H}$. 7. $\pi^- \to \mu^- + \tilde{v}_\mu$. 4. ${}^3_2\mathrm{He} + {}^3_1\mathrm{H} \to {}^4_2\mathrm{He} + {}^2_1\mathrm{H}$. 8. $\mathrm{n} \to \mathrm{p} + \mathrm{e}^- + \tilde{v}_{\mathrm{e}}$.

О3.1-10.11

Возможны ли следующие схемы распада частиц, и если нет, то по какой причине? 1. $\Omega^- \to \Lambda^0 + \pi^-$. 4. $\mathrm{n} \to \mathrm{p} + \mathrm{e}^- + \tilde{v}_{\mu^*}$ 2. $\Xi^- \to \mathrm{n} + \pi^-$. 5. $\mathrm{p} \to \mu^+ + \tilde{v}_\mu$. 3. $\mathrm{n} \to \mathrm{p} + \mu^- + \tilde{v}_\mu$. 6. $\Omega^- \to \Xi^0 + \mu^-$.

О3.1-10.12

Какая частица обязана образоваться одновременно с K^0 - мезоном при соударении π^--мезона с протоном? Реакция идет по сильному взаимодействию.

О3.1-10.13

«Эспериментом века» были названы опыты по определению времени жизни протона. Теория великого объединения предсказывает, что протон распадается на пион и лептоны со временем жизни $\tau \sim 10^{31}$ лет. Оценить, какую массу вещества необходимо использовать, чтобы за время эксперимента $t = 1$ год произошло $N = 10$ таких распадов.

О3.1-10.14

Определить время жизни мюона, образовавшегося при распаде положительно заряженного каона. До распада каон покоился.

О3.1-10.15

Определить время жизни ипсилон-частицы Υ по ширине ее резонанса $\Delta\mathscr{E}$, взятой на половине высоты и равной 25 кэВ.

О3.1-10.16*

Найти, какие из самых тяжелых ядер и антиядер могут образоваться в реакции $\mathrm{p} + \mathrm{p}$ при соударении протона с энергией протонов, ускоренных до такой же энергии.

О3.1-10.17

В 1976 г. Нобелевская премия по физике была присуждена за открытие новой элементарной частицы - джи-мезона (ныне: J/ψ-мезон). Открытие было сделано практически одновременно и независимо в двух разных лабораториях. В одной из них опыт был поставлен на встречных пучках электронов и позитронов, ускоренных до одинаковой энергии $_{\text{сцм}}$ ($\mathscr{E}_{\text{сцм}}$ - энергия сталкивающихся частиц в системе центра масс). Полученные в этом эксперименте результаты показаны на рис. 62. Определить энергию покоя и оценить нижнюю границу времени жизни джи-частицы.

О3.1-10.18

В 1984 г. появилось сообщение, впоследствии не подтвердившееся, об открытии реакции $\Upsilon \to \xi + \gamma$. Определить энергию покоя и скорость гипотетической ξ-частицы в системе покоя Υ-частицы, если энергия γ-кванта в этой системе оказалась $\mathscr{Q}_\gamma = 1072$ МэВ. Энергия покоя Υ-частицы равна $m_\Upsilon c^2 = 9460$ МэВ.

О3.1-10.19

В 1974 г. была открыта элементарная частица J/ψ, названная впоследствии чармонием. В одном из опытов были зарегистрированы продукты ее распада «на лету»: $\mathrm{J}/\psi \to \mathrm{e}^+ + \mathrm{e}^-$. Найти
массу и скорость чармония, если энергии и электрона, и позитрона были равны $\mathcal{E} = 3,1$ ГэВ, а угол между направлениями разлета электрона и позитрона составил $\theta = 60°$.

О3.1-10.20

В 1976 г. были получены первые указания о существовании заряженной «очарованной» $\tilde{\Lambda}_c^-$ частицы, распадающейся по схеме

$$\tilde{\Lambda}_\mathrm{c}^- \to \tilde{\Lambda} + \pi^- + \pi^+ + \pi^-.$$

Найти кинетическую энергию, уносимую продуктами распада $\tilde{\Lambda}_c^-$-частицы в ее системе покоя.

О3.1-10.21

Определить, выше какой минимальной энергии $_{\min}$ встречных электрон-позитронных пучков, имеющих одинаковую энергию, могут рождаться частицы из семейства «красивых» (B-мезоны). Энергия покоя B-мезона $m_\mathrm{B}c^2 \approx 5279$М.

О3.1-10.22

Определить пороговую энергию $\mathscr{E}_{\text{пор}}$ рождения пары Σ-гиперонов при облучении протонами жидководородной мишени.

О3.1-10.23

Найти, чему равно наибольшее количество заряженных или нейтральных пионов, которое может быть образовано при столкновении протона с энергией $\mathscr{E}_p = 5$ ГэВ с покоящимся протоном. 93

О3.1-10.24

Определить минимальную (пороговую) кинетическую энергию нейтрона, при столкновении которого с ядром водорода в Жидководородной мишени образуется лямбда-частица.

О3.1-10.25

Найти минимальную (пороговую) кинетическую энергию налетающего протона, необходимую для рождения пары барионов $\left(\Xi^0\widetilde{\Xi}^0\right)$, имеющих энергию покоя по 1315 МэВ дарениях в жидководородной камере.

О3.1-10.26

Определить максимальную энергию $\mathscr{E}_{\max}$ электрона, образующегося при распаде покоящегося мюона.

О3.1-10.27

Определить в лабораторной системе отсчета минимальную и максимальную энергии электрона, образованного при распаде мюона с энергией 10.5 ГэВ.

О3.1-10.28

Нейтральный пион распался на два γ-кванта с энергиями $\mho_1 = 3,1$ и $\sigma_2 = 2,0$ ГэВ. Найти угол разлета θ между γ-квантами.

О3.1-10.29

Оценить, при какой энергии $\mathfrak{o}$ ультрарелятивистского заряженного пиона его пробег до распада равен пробегу в воздухе при плотности $\rho = 10^{-5}\mathrm{g/cm}^3$. Собственное время жизни и энергия покоя пиона равны $\tau_0 = 2,6 \cdot 10^{-8}$ с и $m_\pi c^2 = 140\mathrm{M}$.

О3.1-10.30

Нейтральный пион π^0с энергией покоя $m_\pi c^2 = 135\mathrm{MB}$ распадается на лету на два одинаковых γ-кванта, разлетающихся под углом $\alpha = 2 \cdot 10^{-2}$ рад по отношению к направлению движения пиона. Какова кинетическая энергия пиона π^0? Чему равна неопределенность энергии покоя пиона π^0 и каково его время жизни в лабораторной системе координат, если в собственной системе он живет $\tau_0 = 0,84 \cdot 10^{-16}$с?

О3.1-10.31

D^0-мезон распадается на лету на K^-−и $^+$−мезоны. Расстояние от точки его рождения до точки распада равно $L = 350$ мкм. Импульсы каона и пиона равны $p_K = 3,6\Gamma$ В/c и $p_\pi = 1,9\Gamma$ В/c и направлены под углами $\theta_\mathrm{K} = 13°30'$ и $\theta_\pi = 27°50'$ к направлению импульса D^0-мезона. Определить энергию покоя, скорость и время жизни D^0 −

О3.1-10.32

* При распаде «на лету» Ω^--гиперона $(\Omega^- \to \Lambda + \mathrm{K}^-)$измерены импульсы частиц распада $p_\Lambda = 5,7\Gamma\Xi/c$ и $p_\mathrm{K} = 2,0\Gamma$ В/с и угол разлета между ними $\theta = 28,5°$. Определить энергию покоя Ω^--гиперона.

О3.1-10.33

За распадом остановившегося в ядерной фотоэмульсии K^+ мезона по схеме $\mathrm{K}^+ \to \pi^+ + \pi^0$ последовал распад нейтрального пиона π^0 по схеме $\pi^0 \to \gamma + \mathrm{e}^+ + \mathrm{e}^-$, причем точка рождения пары $\mathrm{e}^+\mathrm{e}^-$находилась на расстоянии $L = 0,04$ мкм от места остановки К-мезона. Оценить собственное время жизни нейтрального пиона π^0.

О3.1-10.34

Какова средняя длина пути L до распада Λ-гиперона в воздухе, если его энергия $E_A = 7$ ГэВ?
(их еще просто дохрена, лень выгружать.)

Рассеяние электрона на неподвижном литии++

дана энергия лития.
у лития один свободный электрон, знать типа нужно и что у лития $Z = 3$
минимальная возможная энергия электрона после взаимодействия?
рассматривать нужно неупругое рассеяние, ибо так она теряется больше.
масса лития на много порядков больше массы электрона
нужно разобраться, какую максимальную энергию может отдать электрон литию.
посмотрим, куда может перейти электрон?
а очень просто, мы смотрим на разницу уровней, один первый уровень - при $n = 1$, тогда для второго уровня подбираем n_2 такое, чтобы хватило энергии электрона, то есть разница энергий должна быть менее энергии электрона. так и находим, сколько он может отдать.
(интересно, а через теорию рассеяния кавнтмеха если сделать, что будет?)

10. Элементарные частицы. Резонансы. Лептоны и кварки. Реакции при высоких энергиях

10.

1. Запрещены распады 2 и 4 , так как не сохраняется лептонный заряд, и распад 8, так как не сохраняется барионный заряд; в распаде 2 нарушается еще закон сохранения энергии.

10.

2. Распады $2, 3, 9, 10$ и реакции 6,7 запрещены, так как в них не сохраняется лептонный заряд. При изучении взаимодействия нейтрино, полученных в распаде 1 , с протонами было показано, что идет реакция 5 , а не 6, хотя последняя энергетически более выгодна. Тем самым было доказано существование двух типов нейтрино.

10.

3. В реакциях $1, 6, 8, 10, 12, 14|\Delta S| = 0$, и они идут по сильному взаимодействию с характерными временами $10^{-22} \div 10^{-24}$ с (ядерные времена). В реакциях $2, 7, 9, 11|\Delta S| = 1$, и они практически ненаблюдаемы. В распадах 3 и $4|\Delta S| = 1$, и они идут по слабому взаимодействию с характерными временами $\sim 10^{-10}$ с. В процессах 5 и $13|\Delta S| = 2$, и поэтому такие процессы не наблюдаются.

10.

4. По указанному правилу разрешены распады $2, 3, 4, 5, 6, 8$; запрещены распады $1, 7, 9, 10$.

10.

5. 1. Барион Λ - синглет с зарядом $Z = 0$. Следовательно, $N = 1$, $T = 0, Z_{\text{ср}} = 0, S = -1, Y = 0, T_3 = 0$.
2. Барион Σ - триплет с зарядом ± 1 и 0 . Следовательно, $Z_{\text{ср}} = 0$, $N = 3, T = 1, Y = 0, S = -1, T_3 = Z$.
3. Барион Ξ - дублет с зарядами 0 и -1. Следовательно, $N = 2$, $T = 1/2$, $Z_{\text{ср}} = -1/2$, $S = -2$, $Y = -1$, $T_3 = -1/2$ для $Z = -1$ и $T_3 = \pm 1/2$ для $Z = 0$.
4. Отрицательно заряженный барион Ω^-- синглет. Следовательно, $N = 0, Z_{\text{ср}} = -1, S = -3, Y = -2, T = 0, T_3 = 0$.
5. Мезон л с зарядами $\pm 1, 0$. Следовательно, $N = 3, T = 1, T_3 = Z$, $S = 0, Y = 0$. Заметим, что если в составе мультиплета имеется истинно нейтральная частица, то при вычислении числа частиц в мультиплете N нужно вместе считать частицы и античастицы. Во всех других случаях под N подразумевается число частиц.
6. Мезон K - дублет с зарядами 0 и +1 . Следовательно, $N = 2$, $Z_{\text{ср}} = 1/2, S = 1, T = 1/2, T_3 = 1/2$ для K^+и $T_3 = -1/2$ для K^0.
7. Мезон η - нейтральный синглет. Следовательно, $N = 1, T = S = Z_{cp} = T_3 = 0$.

10.

6. Распады 2 и 4 запрещены законом сохранения лептонного заряда. Реакция 5 практически ненаблюдаема из-за несохранения странности. Распад 3 и 6 разрешены. Распад 1 запрещен законом сохранения энергии.

10.

7. Реакция 2 и распад 8 невозможны, так как не сохраняется барнионный заряд. Реакции 3 и 4 практически ненаблюдаемы из-за несохранения странности. Распады 1 и 7 происходят по слабому взаимодействию, распад 6 - по электромагнитному. Реакция 5 происходит по сильному взаимодействию.

10.

8. Реакции 1 и 2 происходят по сильному взаимодействию; распады 3 и 5 - по электромагнитному; 4 и 6 - по слабому взаимодействию.

10.

9* Странность K^0-мезона равна +1 , а странность $\tilde{K}^0$-мезона равна -1. Поскольку странность нуклонов равна 0, а странность других барионов либо равна нулю, либо отрицательна, то поглощение $\tilde{K}^0$-мезона может происходить с сохранением странности, т. е. по сильному взаимодействию. Погло-

щение K^0-мезона может происходить лишь с несохранением странности, т. е. по слабому взаимодействию. Следовательно, K^0-мезон в отличие от $\tilde{K}^0$ будет слабо поглощаться веществом. Поскольку при переходах $K^0 \rightleftarrows K^0 |\Delta S| = 2$, то такие переходы крайне маловероятны (см. задачу 10.3).

10.10.

Реакции $1, 3, 4$ происходят по сильному взаимодействию; распады $6, 7, 8$ - по слабому; реакции 2 и 5 - по электромагнитному взаимодействию.

10.

11. 1. Так как $\Delta S = 2$, то возможна, но маловероятна.
2. Так как $\Delta S = 2$, то возможна, но маловероятна.
3. Нет, так как $(m_\text{n} - m_\text{p}) < m_\mu$.
4. Нет, не сохраняется лептонный заряд.
5. Нет, не сохраняется барионный заряд.
6. Нет, не сохраняется лептонный заряд.

10.

12. Λ-гиперон или Σ^0-гиперон.

10.

13. $M = m_\text{n} N \frac{\text{t}}{t} \approx 170$ т, где $m_\text{n} \approx 1,7 \cdot 10^{-24}$ г - масса нуклона.

10.

14. $\tau = \frac{\mathscr{E}_\mu \tau_0}{m_\mu c^2} = 5,4$ мкс, где τ_0 - собственное время жизни мюона, $\mathscr{E}_\mu = \frac{m_{\mathrm{K}}^2 c^4 + m_\mu^2 c^4}{2 m_{\mathrm{K}} c^2}$.

10.

15. $\tau \sim \frac{\hbar}{\Delta \S} \approx 2,6 \cdot 10^{-20}$с.

10.

16* 1. $A = 38$ (на неподвижной мишени). 2. $A \approx 3000$ (на встречных пучках), т. е. все известные ядра.

Решение. Найдем сначала скорость центра масс системы. Пусть энергия налетающей частицы $\mathscr{E}_1$, а покоящейся $m_2 c^2$. Суммарная энергия системы $\mathscr{E} = \mathscr{E}_1 + m_2 c^2$. Полный импульс системы $\mathbf{p}_1$. Рассматривая эту систему как сложную частицу, находим скорость центра масс

$$\frac{\mathbf{v}_{\mathrm{LL,M.}}}{\boldsymbol{c}} = \frac{\mathbf{p_I c}}{\mathfrak{E}_1 + m_2 c^2}.$$

Энергии частиц в системе центра масс (СЦМ) равны

$$\mathscr{E}_1^* = \frac{\mathscr{E}_1 - \mathbf{p}_1 \mathbf{v}_{\text{ц. м.}}}{\sqrt{1 - (v_{\text{ц. м}}/c)^2}}; \quad \mathscr{E}_2^* = \frac{m_2 c^2 - 0}{\sqrt{1 - (v_{\mathrm{L.}}/c)^2}}.$$

Таким образом, суммарная энергия в СЦМ

$$\mathscr{E}_{\mathrm{L,M.}}^* = \mathscr{E}_1^* + \mathscr{E}_2^* = \sqrt{m_1^2 c^4 + m_2^2 c^4 + 2 m_2 c^2 \mathscr{E}_1},$$

где было использовано релятивистское выражение для полной энергии частицы

$$\mathscr{E}_1^2 = (p_1 c)^2 + \left(m_1 c^2\right)^2.$$

Эту формулу можно было бы получить и без преобразований Лоренца, считая, что две частицы в СЦМ рождают одну с массой $Mc^2 = \mathfrak{E}_{\text{ц. м.}}^*$. Исполь-

зуя инвариант, получим $\left(Mc^2\right)^2 = \mathscr{E}_{\text{ц. м.}}^2 - 0^2 = \left(\mathscr{E}_1 + m_2 c^2\right)^2 - p_1^2 c^2 = \left(\mathscr{E}_1 + m_2 c^2\right)^2 - \left[\mathscr{E}_1^2 - \left(m_1 c^2\right)^2\right]$, откуда следует то же выражение

$$\mathscr{E}_{\mathrm{L,M.}}^* = \sqrt{m_1^2 c^4 + m_2^2 c^4 + 2 m_2 c^2 \mathscr{E}_1}$$

Для двух одинаковых частиц $m_1 = m_2 = m_{\mathrm{p}}$ получаем

$$\mathrm{p} + \mathrm{p} \to \mathrm{M} + \tilde{\mathrm{M}} + \mathrm{p} + \mathrm{p}$$

и $\mathscr{E}_{\mathrm{L,M.}}^* = \sqrt{2 m_{\mathrm{p}} c^2 \left(\mathscr{E}_1 + m_{\mathrm{p}} c^2\right)}$.

Очевидно, что $\mathscr{E}_{\text{н. м.}}^* \geqslant \left[2 A m_{\mathrm{p}} + 2 m_{\mathrm{p}}\right] c^2$, откуда $2 m_{\mathrm{p}} c^2 \mathscr{E}_1 + 2\left(m_{\mathrm{p}} c^2\right)^2 \geqslant \geqslant 4\left(m_{\mathrm{p}} c^2\right)^2 (A+1)^2$. Если учесть, что $\mathscr{E}_1 \gg m_{\mathrm{p}} c^2$, то получим ответ в первом случае (столкновения с неподвижным протоном)

$$A \lesssim \sqrt{\frac{1}{2 m_{\mathrm{p}} c^2}} - 1 \lesssim 39, \text{ т. е. } A = 38 \text{ (включительно).}$$

На встречных пучках

$$2\mathscr{E}'' = 2 A m_{\mathrm{p}} c^2 + 2 m_{\mathrm{p}} c^2 \approx 2 A m_{\mathrm{p}} c^2$$

откуда $A \approx 3000$, т.е. практически все известные ядра.

10.

17* $\tau \approx 3 \cdot 10^{-22}$с; $mc^2 \approx 3,1$ ГэВ.

Решение. Масса частицы в данном случае равна $\mathscr{E}_{\text{сцм}}$, соответствующей положению максимума на графике. Полуширина резонансной кривой на уровне $1/2$ высоты $\Delta\mathscr{E} \approx 2$М В. Время жизни находим из соотношения неопределенностей $\tau \approx \hbar/\Delta\mathscr{E} \approx 3 \cdot 10^{-22}$ с.

10.

18. $m_\xi c^2 = \sqrt{m_Y c^2 \left(m_Y c^2 - 2\mathscr{E}_\gamma\right)} = 8,32$ ГЭВ, $\beta = \frac{\mathscr{E}_\gamma}{m_\gamma c^2 - \mathscr{E}_\gamma} \approx 0,13$.

10.

19. $m_{J/\Psi} c^2 = \mathscr{E}\sqrt{2(1-\cos\theta)} = 3,1$ ГЭВ; $\beta = \sqrt{\frac{1+\cos\theta}{2}} = \frac{\sqrt{3}}{2} \approx 0,87$.

10.

20. $T \approx 751$М В .

10.

21. $\mathscr{E}_{\min} \geqslant 2m_{\mathrm{B}}c^2 \approx 10,56$ ГэВ.

10.

22. $_{\text{пор}} = 4m_\Sigma c^2 + m_{\mathrm{p}}c^2 + 2\frac{m_\Sigma^2}{m_{\mathrm{p}}}c^2 = 8,8$ ГэВ.

10.

23. $N_{\max} = \frac{\sqrt{2m_{\mathrm{p}}c^2(\varrho_{\mathrm{p}}+m_{\mathrm{p}}c^2)}-2m_{\mathrm{p}}c^2}{2m_{\mathrm{r}}c^2} = 5,2$ (пар пионов), всего может родиться не более 10 пионов.

10.

24. $T_{\text{пор}} = \frac{(m+M)^2-(2m)^2}{2m}c^2 = 1,6$ ГэВ, где $m_{\mathrm{p}} \approx m_{\mathrm{n}} = m$; $M = m_\Lambda + m_{\mathrm{K}}$, где m_{K} - масса либо K^0-, либо K^+-мезона.

10.

25. $T_{\text{пор}} = 8,94$ ГэВ.

10.

26. $\mathscr{E}_{\max} = \frac{m_\mu c^2}{2}\left(1 + \frac{m_{\mathrm{e}}^2}{m_\mu^2}\right) \approx \frac{m_\mu c^2}{2} \approx 52,8$М э В.

10.

27. $\mathscr{E}_{\min} = m_{\mathrm{e}}c^2 \simeq 0,5$М ВВ $\mathscr{E}_{\max} \simeq \mathscr{E}_\mu - \frac{m_\mu^2 c^4}{2\mathscr{E}_\mu} \approx 10,5$ ГэВ.

10.

28. $\sin\frac{\theta}{2}=\frac{m_\pi c^2}{2\sqrt{\varepsilon_1\varepsilon_2}}=0,027.$

10.

29. $\mathscr{E}=m_\pi c^2\frac{2A_{\mathrm{N}}}{c\tau\rho N_{\mathrm{A}}\sigma}\approx 1,4$ Т ТВ, где A_{N} - атомная масса азота, $\sigma=2\pi R_{\mathrm{N}}^2$ - сечение рассеяния быстрых пионов, равное удвоенному геометрическому сечению ядра, $R_{\mathrm{N}}=1,3\cdot 10^{-13}A_{\mathrm{N}}^{1/3}$.

10.

30. $T=6,615$ ГэВ; $\delta\&\approx 7,8\ni$ В; $\tau=4,2\cdot 10^{-15}$с.

10.

31. $m_{\mathrm{D}}\mathrm{c}^2\approx 1,85\Gamma\ni$ В; $\beta=0,94;\tau\approx 4,2\cdot 10^{-13}$с.

10.

32: $m_\Omega c^2\approx 1,7$ ГэВ.

Решение. Для нахождения массы Ω^--гиперона воспользуемся инвариантностью квадрата четырехимпульса

$$m_\Omega^2c^4=\left(\mathscr{E}_1+\mathscr{E}_2\right)^2-\left(\mathbf{p}_1+\mathbf{p}_2\right)^2c^2$$

Нетрудно видеть, что Λ^0-гиперон и K^0-мезон можно считать ультрарелятивистскими, поскольку массы этих частиц малы по сравнению с произ ведениями pc : $m_\Lambda c^2\approx 1,1$ ГэВ; $m_\kappa c^2\approx 0,49$ ГэВ (табличные данные). Поэтому $\mathscr{E}_1\approx p_1c;\mathscr{E}_2\approx p_2c$. Раскрывая скобки, получим $m_\Omega^2c^4\approx 2\mathscr{E}_1\mathscr{E}_2$ - $-2p_1p_2c^2\cos\theta\approx 2p_1p_2c^2(1-\cos\theta)$, откуда

$$m_\Omega c^2\approx 2\sqrt{p_\Lambda p_{\mathrm{K}}}c\sin\frac{\theta}{2}=1,68\ \text{ В}\approx 1,7\text{ ГэВ}.$$

10.

33. $\mathrm{T}_0\approx 0,88\cdot 10^{-16}$с, $\beta=0,835$.

10.

34. $L=\frac{c\tau_{0\Lambda}}{m_\Lambda c^2}\approx 50$ см, где $\tau_0\approx 2,66\cdot 10^{-10}$с; $m_\Lambda c^2=1116$ МэВ.

18.2.11 Basic Problems about Elementary Particles 2

other solutions, I'll add problems later

10.

35: $L=(2\ln 2)\frac{c\tau_0\lambda\!\!\!^{-}_\pi}{m_\pi c^2}=770$ m, где $\mathbf{t}_0=2,6\cdot 10^{-8}$с; $m_\pi c^2\approx 140$М МВ .

Решение. За период полураспада $T_{1/2}$ пиона (по схеме $\pi^+\to\mu_++\upsilon_\mu$) половина пионов переходит в мюоны. Еще через $T_{1/2}$ число мюонов в потоке превышает число пионов в три раза. Таким образом, искомая длина $L=\upsilon_\pi 2T_{1/2}\gamma$, где $\gamma=\frac{1}{\sqrt{1-\beta^2}}=\frac{\lambda\!\!\!^{-}_\pi}{m_\pi c^2}$.

Скорость пионов v_π близка к скорости света, поскольку $\mathscr{E}_\pi \gg m_\pi c^2$. Период полураспада $T_{1/2} = \tau_0 \ln 2$, где τ_0 - собственное время жизни π^+ ($\boldsymbol{\tau}_0 = 2,6 \cdot 10^{-8}$с). Окончательно

$$L \approx (2 \ln 2) \frac{c_0 \mathscr{E}_\pi}{m_\pi c^2} \approx 770\text{М}.$$

Можно решить задачу иначе. Поскольку $\mathscr{E}_\pi = 10$ ГэВ $\gg m_\pi c^2$, то пионы можно считать ультрарелятивистскими. Мюоны, вылетающие в направлении движения пионов, также имеют скорость $v \approx c$. Собственное время жизни мюона примерно в 100 раз больше времени жизни пиона. Поэтому распадом мюонов в данной задаче пренебрегаем. Тогда $N_\pi(x) + N_\mu(x) = N_\pi(0)$. По закону радиоактивного распада

$$dN_\pi(x) = -\lambda N_\pi(x) dt = -\frac{N_\pi(x)}{\tau} dt.$$

Здесь $\tau = \gamma\tau_0 = \tau_0 \frac{\varrho_\pi}{m_\pi c^2}$, а $vdt = cdt = dx$, откуда $\frac{dN_\pi(x)}{dx} = -N_\pi \frac{m_\pi c^2}{\varrho_\pi \tau_0 c}$ или $N_\pi(x) = N_\pi(0) \exp\left(-\frac{m_\text{п} c^2}{\mathscr{E}_\pi c_0} x\right)$. По условию $3N_\pi(L) = N_\mu(L)$, поэтому $4 \exp\left(-\frac{m_\pi c^2}{\pi c_0} L\right) = 1$, откуда и следует приведенный выше ответ задачи.

10.

36. $\frac{N_\mu(L)}{N_\text{К}(0)} = 1 - \exp\left(-\frac{m_\text{К} c^2}{\mathscr{E}_\text{К}} \frac{L}{v\tau_0}\right) = 0,364$, где $\tau_0 = 1,24 \cdot 10^{-8}$с - время жизни $K^\pm$.

10.

37. $\frac{N_\mu(L)}{N_\text{К}(L)} \simeq 1800$.

10.

38. $\mathscr{E}_\mu = \frac{m_\pi^2 c^4 + m_\mu^2 c^4}{2 m_\pi c^2} \cdot \frac{\mathscr{E}_\pi}{m_\pi c^2} \approx 330\text{М} \ni \text{В}$.

10.

39: $N_\pi \approx 3,6 \cdot 10^7$ частиц/с.

Решение. Число пионов, достигших детектора, $-n = \frac{N_\pi}{4\pi} \Omega e^{-t/\tau}$, где N_π - число всех генерированных пионов, $\Omega = S/L^2$ - телесный угол, под которым виден детектор из точки генерации пионов, t - время пролета пионом пути L, т - время жизни пиона в лабораторной системе отсчета:

$$\tau = \frac{\tau_0}{\sqrt{1-\beta^2}} = \tau_0 \frac{\mathscr{E}}{m_\text{а} c^2} = \tau_0 \left(1 + \frac{T}{m_\pi c^2}\right).$$

Окончательно получаем

$$N_\pi = n \frac{4\pi L^2}{S} \exp\left(\frac{L}{c\tau_0} \frac{m_\pi c^2}{\sqrt{T^2 + 2 m_\pi c^2 T}}\right) \approx 3,6 \cdot 10^7 \frac{\text{частиц}}{c}.$$

10.

40. $\mathscr{E}_\text{пор} = (m_\text{п} - m_\text{р} + m_\text{е}) c^2 \approx 1,8\text{М} \ni \text{В}$.

10.

41. $\mathscr{E}_{\mathrm{e}}^{\max} \approx \mathscr{E}_{\mu}^{\max} \approx \frac{\left(m_{\mathrm{e}}c^2\right)^2+\left(m_{\mu}c^2\right)^2}{2m_{\tau}c^2} \approx 0,9$ ГэВ. Точнее: $\mathscr{E}_{\mu}^{\max} \approx \frac{m_{\tau}c^2}{2} \times \times \left[1+\left(m_{\mu}/m_{\imath}\right)^2\right] = 0,894$ ГЭВ , $\mathscr{E}_{\mathrm{e}}^{\max} \approx \mathscr{E}_{\mu}^{\max}\left[1-\left(\frac{m_{\mu}c^2}{2\mathscr{E}_{\mu}^{\max}}\right)^2\right] = 0,891$ ГЭВ.

10.

42. $T = m_{\pi}c^2 \frac{2(m_{\mathrm{p}}+m_{\mathrm{n}})+m_{\pi}}{2(m_{\mathrm{p}}-m_{\pi})} \approx 330$М3 В.

10.

43. $\mathscr{E}_{\mathrm{p}} = m_{\mathrm{p}}c^2 \simeq 1$ ГЭВ.

10.

44. $\mathscr{E}_{\mathrm{p}} = m_{\mathrm{p}}\mathrm{c}^2 \frac{T}{2\varepsilon} = 6,57 \cdot 10^{19}$ДВ; $\tau \approx \frac{1}{n\sigma c} \approx 10^{15}\mathrm{c} \sim 3 \cdot 10^7$ лет.

10.

45. $T \approx 2,6 \cdot 10^{14} \ni$ В; $\tau \approx 8 \cdot 10^{10}$с.

10.

46. $\mathscr{E}_{\mu} = m_{\mu}c^2 \frac{H}{\tau_0 c} \approx 6,4$ ГЭВ.

10.

47. $\mathscr{E}_{\min} = \Delta\mathscr{E} \approx \rho\alpha H \simeq 9$ ГэВ, где $\Delta\mathscr{E}$ - потери энергии на ионизацию.

10.

48. $\frac{\delta T_{\mu}}{T_{\mu}} = \left(\frac{m_v}{m_{\pi}-m_v}\right)^2 \approx \begin{cases} 0,15 \cdot 10^{-4} \text{ при } m_v c^2 = 0,17\text{М МВ} , \\ 0,86 \cdot 10^{-5} \text{ при } m_v c^2 = 0,1 \text{ МэВ}. \end{cases}$

10.

49. Выход мюонных антинейтрино (нейтрино) составляет $2,0002\%$ от числа пионов. Выход электронных антинейтрино (нейтрино) составляет $0,0002\%$ от числа пионов.

10.

50. Процесс рассеяния нейтрино на электронах - это тот же Комп-тон-эффект (рассеяние фотонов на электронах):

$$\mathscr{E} = \frac{T_{\mathrm{e}}+pc}{2} = \frac{\left[T_{\mathrm{e}}+\sqrt{T_{\mathrm{e}}\left(T_{\mathrm{e}}+2m_{\mathrm{e}}c^2\right)}\right]}{2} = 5,24\text{М} \ni \text{ В}.$$

10.

51. $\cos\beta = \frac{T_e\left(\mathscr{E}+m_e c^2\right)}{\mathscr{E}\sqrt{T_e(T_e+2m_e c^2)}} = 0.927; \beta \approx 22^\circ$ (для $\mathscr{E} = 15$М В).

10.

52. $\frac{\Phi(v_\mu)}{\Phi(v_e)} = 2$. Наблюдение потоков атмосферных нейтрино на установке Super-Kamiokande не подтверждает этот результат. Таким образом, следует признать факт несохранения лептонного заряда и нейтринных осциляций, что является следствием наличия у нейтрино массы.

10.

53. $\left(m_{\mathrm{W}}c^2\right)_{\min} = (1+\sqrt{2}/2)\mathscr{E} \simeq 100$ ГэВ. (Современное значение $m_{\mathrm{W}}c^2 = 80,22 \pm 0,26$ ГэВ.)

10.

54. Электрон - продукт распада $\tau^- \to \mathrm{e}^- + \tilde{v}_\mathrm{e} + v_\mathrm{t}$. Искомая проекция электрона максимальна, когда $\mathbf{p}_{v_\mathrm{e}} = \mathbf{p}_{v_\mathrm{t}}$ и когда она перпендикулярна $\mathbf{p}_\mathrm{r}$. Тогда $p_\mathrm{e} \perp c = m_\tau c^2/2 = 0,896$ ГэВ.

10.

55. $m_{\boldsymbol{Z}}c^2 \approx 2p_\mu c\sin(\theta/2) = 97,5$ ГэВ; $\beta = \cos(\theta/2) = 0,82$ (Современное значение $m_Z c^2 = 91,173 \pm 0,020$).

10.

56. Минимальная длина волны γ-кванта соответствует максимальной энергии. Как видно из графика, максимальная зарегистрированная энергия (γ-квант $+\psi$) составляет 3,14 ГэВ.
$\lambda_\gamma = \frac{2\pi\hbar c}{\mathscr{E}_\gamma}$; $\mathscr{E}_\gamma = \mathscr{E}_{\max} - m_\psi c^2 = 40\mathrm{M} \ll 3,1$ ГэВ; $\lambda_\gamma \approx 3,1 \cdot 10^{-12}$ cm (пренебрегаем отдачей ψ-мезона).

10.

57* Спин мюона направлен против его импульса; $l \approx 1470$ м.

Решение. Определение спина как собственного момента импульса, т. е. момента импульса в системе покоя частицы, оказывается неприменимым к безмассовым частицам, обладающим нулевой энергией покоя, т. е. $m = 0$. Для них принято вводить спиральность, т. е. проекцию собственного момента импульса на направление движения частицы - единственное выделенное направление для частиц с $m = 0$. При этом частицы с $\mathbf{S} \uparrow\uparrow \mathbf{p}$ называются

правоспиральныцми (правополяризованными), а частицы с $\mathbf{S} \uparrow\downarrow \mathbf{p}$ называются левоспиральными (левополяризованными). При этом фотон как истинно нейтральная частица может менять свою спиральность (с номощью пластинки $\lambda/2$), а нейтрино - нет. Нейтрино но определению - левоспиральная частица, а антинейтрино - правоспиральная.

Так как каон K^+имеет спин $S = 0$, то $\mathbf{S}_\mu + \mathbf{S}_v = 0$. Кроме того, $\mathbf{p}_\mu + \mathbf{p}_\nu = 0$. Отсюда следует, что $\mathbf{S}_\mu$ антипараллелен $\mathbf{p}_\mu$ ($\mathbf{S}_\mu \uparrow\downarrow \mathbf{p}_\mu$). Для ответа на второй вопрос задачи. Запишем закон сохранения энергии при распаде

$$m_{\mathrm{K}}c^2 = \mathscr{E}_\nu + \mathscr{E}_\mu = pc + \sqrt{\left(m_\mu c^2\right)^2 + p^2c^2}, \text{ где } p_\mu = p_\nu = p.$$

Возведя это равенство в квадрат, получим

$$pc = \frac{(m_{\mathrm{K}}c^2)^2 - (m_u c^2)^2}{2m_{\mathrm{K}}c^2} = 235,6 \text{ МэВ}.$$

Полная энергия мюона

Рис. 185

$$\mathscr{E}_\mu = \sqrt{p^2c^2 + m_\mu^2 c^4} \approx 258\text{М} \ni \text{ В}.$$

Из релятивистской формулы $\mathscr{E}_\mu = m_\mu c^2/\sqrt{1-\beta^2} = \gamma m_\mu c^2$ определим: $\gamma \approx 2,444$ и $\beta = 0,912$ (относительная скорость мюона). Пробег мюона в лабораторной системе отсчета

$$l = \beta c \mathrm{r}_0 \gamma = 1,47 \cdot 10^5 \text{ cm} = 1,47\text{Km}.$$

При этом использовались табличные данные $m_\text{K}\mathrm{c}^2 = 493,6\text{М Э}$; $m_\mu c^2 = 105,7\text{М}$; $\mathbf{I}_\mu = \boldsymbol{\tau}_0 = 2,2$ мкс. Схема распада приведена на рис. 185.

10.

58. $\frac{q^2}{\hbar c} \sim \frac{\hbar}{2m_\text{n} c R_\text{d}} \sim 0,1.$

10.

59: $r_{\text{J}/\psi} = \frac{\sqrt{3}}{2} \frac{\hbar c}{\sqrt{(4\mathscr{Q}_2 - \mathscr{E}_1)(\mathscr{C}_2 - 1)}} = 1,5 \cdot 10^{-14}$ cm.

Решение. Связанная система кварк-антикварк (в данном случае (cc)) с потенциалом взаимодействия $U = -q^2/r$ аналогична позитронию и спектр ее возбуждений подобен энергетическому спектру атома водорода. Поэтому можно записать, что массы мезонов складываются из энергий покоя кварков за вычетом их энергии связи

$$\mathscr{E}_1 = 2m_c c^2 - \frac{\mu q^4}{2\hbar^2}\frac{1}{1^2}$$
$$\mathscr{E}_2 = 2m_c c^2 - \frac{\mu q^4}{2\hbar^2}\frac{1}{2^2},$$

где $\mu = m_\text{c}/2$ - приведенная масса. Здесь m_c обозначает массу с-кварка. Отличие в энергиях покоя двух состояний чармония (т. е. J/-мезона и ψ'-мезона) $\Delta\mathscr{E} = \mathscr{E}_2 - \mathscr{E}_1 = \frac{3}{16}\frac{m_c q^4}{\hbar^2}$. Из двух уравнений находим

$$m_c c^2 = \frac{4\mathscr{E}_2 - \varepsilon_\text{I}}{6} = 1,95\Gamma_\jmath\mathbf{B}$$

и характерный радиус чармония

$$r_{\text{J}/\psi} = \frac{\hbar^2}{\mu q^2} = \frac{3}{\sqrt{2}} \frac{\hbar c}{\sqrt{(4\mathscr{E}_2 - \mathscr{E}_1)(\mathscr{E}_2 - \mathscr{E}_1)}} = 1,5 \cdot 10^{-14} \text{ cm}$$

Поскольку кварки отсутствуют в свободном состоянии, то определение их энергии невозможно. Это связано с тем, что в адронах кварки окружены глюонами и виртуальными парами кварк-антикварк, и масса кварка дложна зависеть от расстояния, на котором она определяется. На расстояниях $x \lesssim 10^{-14}$ см, где начинается асимптотическая свобода и «облака» глюонов и виртуальных кварковых пар «редеют», принято говорить о токовых (свободных) кварках. На больших расстояниях мы имеем дело с «одетыми» кварками, которые называются блоковыми или конституентными. (см. Приложение III, табл. 5).

В рамках данного приближения по результатам эксперимента можно определить, как энергию покоя кварков, так и энергию их взаимодействия.

10.

60. $m_\text{B}c^2 = \frac{1}{6}(4\mathscr{E}_2 - \mathscr{E}_1) \approx 5,1\Gamma \ni \text{ В}; g^4 = \left(\frac{q^2}{\hbar c}\right)^2 = 32\frac{(\mathscr{E}_2 - \mathscr{E}_1)}{(4\mathscr{E}_2 - \mathscr{E}_1)} \approx 0,585,\ g^2 \approx 0,765 \sim 1.$

10.

61. $R \approx \frac{\hbar c}{m_\text{W} c^2} \approx 2,5 \cdot 10^{-16}$ cm.

10.

62. $m_\Delta c^2 = \sqrt{2m_\text{p}c^2T_\pi + (m_\text{p}+m_\pi)^2c^4} = 1232,5\text{МЭ}$;
$\tau \approx \frac{\hbar}{\Gamma} = 5,5\cdot 10^{-24}\text{с}$.

10.

63*. Решение. Резонансный характер поглощения пионов свидетельствует об образовании составного ядра, которое можно уподобить короткоживущей частице. Сечение образования составного ядра в резонансной области (рис. 186) определяется для бесспиновых частиц формулой Брейта-Вигнера

$$\sigma_\text{полн} = \pi\lambda^2\frac{\Gamma_\text{упр}\,\Gamma_\text{полн}}{(\mathscr{E}-\mathscr{E}_0)^2+\frac{\Gamma^2_\text{полн}}{4}},$$

где $\lambda = \frac{\lambda}{2\pi}, \lambda$ - длина волны падающей частицы в системе центра масс, $\mathscr{E}$ - суммарная энергия частиц в этой системе, $\mathscr{E}_0$ - энергия составного ядра (резонанса), $\Gamma_{\text{упр и}}$

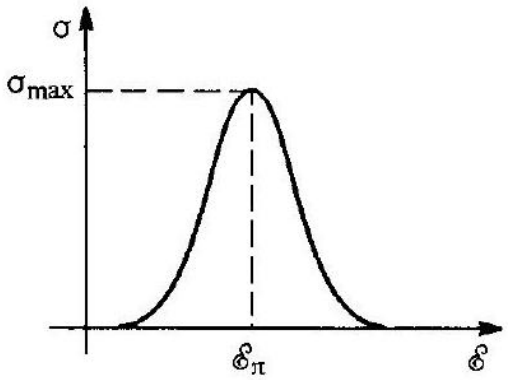

Рис. 186 $\Gamma_\text{неупр} = \Gamma_\text{полн} - \Gamma_\text{упр}$ - ширины резонанса, связанные с распадом по упругому и неупругим каналам.

Согласно закону сохранения электрического заряда распад резонанса возможен только по каналу $\Delta \to \pi^+ p$, то есть происходит только упругое рассеяние и в резонансе сечение

$$\sigma_\text{полн} = \sigma_\text{упр} = 4\pi t^2 = \frac{4\pi\hbar^2}{p^2}$$

Импульс сталкивающихся частиц в системе центра масс $p = p_\pi = p_\text{p}$ находитея из условия

$$M_\Delta c^2 = \sqrt{(pc)^2 + (m_\text{p}c^2)^2} + \sqrt{(pc^2) + (m_\pi c^2)^2}$$

откуда

$$p = \sqrt{\frac{\left(M_\Delta^2 + m_\text{p}^2 - m_\pi^2\right)^2}{4M_\Delta^2}c^2 - m_\text{p}^2c^2} = 227\text{МэВ}/c;$$

$$\sigma_\text{полн} = \frac{4\pi\hbar^2c^2}{p^2c^2} = 95\cdot 10^{-27}\ \text{см}^2 = 95\ \text{м б}\ .$$

Экспериментальное значение для данной реакции $\sigma_\text{полн} \simeq 200$ мбн. Различие связано с тем, что в простейшем варианте формулы Брейта-Вигнера не учитываются спиновые состояния начального и конечного состоя ния системы. Имеются $(2S_\text{p}+1)(2S_\pi+1)$ начальных состояний системы и $2J+1$ конечных состояний Δ-резонанса, приводящих к одинаковому сечению.

В результате в формуле Брейта-Вигнера появляется множитель $g = \frac{2J+1}{(2S_\text{p}+1)(2S_\pi+1)}$, учитывающий стастистический вес входного и выходного состояний системы. Сравнение теоретического и экспериментальных значений позволяет определить, что $g \simeq 2$, откуда находится полный момент резонанса $J = 3/2$.

Полученный результат требует пояснения. Так как $S_\text{p} = 1/2; S_\pi = 0$, то в сумме они не могут дать $J = 3/2$. Поэтому необходимо учитывать и орбитальное движение, т. е. закон сохранения момента нужно записывать в виде $\mathbf{J} = \mathbf{S}_\text{p} + \mathbf{S}_\pi + \mathbf{L}_\pi$, где $\mathbf{L}_{\pi\text{p}}$ - орбитальный момент относительного движения. Считая, что радиус протона $r_\text{p} \simeq 0,8\cdot 10^{-13}$ см (фактически это комптоновская длина волны протона), получаем $pr_\text{p} = \hbar\sqrt{L(L+1)}$, или $\sqrt{L(L+1)} = \frac{r_\text{p}}{\hbar}$. Так как $\lambda = 0,87\cdot 10^{-13}$с, то $L \simeq 0,83$. Следовательно, возможные значения $L = 0,1$. Соображения, основанные на законе сохранения четности, показывают, что $L = 1$ и $J = 1/2 + 1 = 3/2$. Образно говоря, пролетающий пион захватывается за счет сильного взаимодействия протоном на орбиту с $L = 1$, делает несколько оборотов и затем улетает.

Во второй реакции (в отличие от предыдущей) возможен распад резонанса

$$\pi^- + p \to \Delta^0 \to \left\{ \begin{array}{l} \pi^- + p \\ \pi^0 + n \end{array} \right.$$

и таким образом появляется «неупругий» канал.

$$\sigma_{\text{полн}} = \sigma_{\text{упр}} + \sigma_{\text{неупр}} ,$$

где в резонансе

$$\sigma_{\text{полн}} = 8\pi\pi^2 \frac{\Gamma_{\text{упр}}}{\Gamma_{\text{полн}}} \quad \text{или} \quad 68 \approx 190 \frac{\Gamma_{\text{упр}}}{\Gamma_{\text{полн}}},$$

откуда
$\frac{\Gamma_{\text{упр}}}{\Gamma_{\text{полн}}} = \frac{\sigma_{\text{упр}}}{\sigma_{\text{упр}} + \sigma_{\text{неупр}}} \approx 0,358; \quad \sigma_{\text{неупр}} \approx 1,8\sigma_{\text{упр}} \approx 0,64\sigma_{\text{полн}} \approx 44$ мбн.
Отметим, что другие неупругие процессы типа $\pi^0\pi^0 n$ или $\pi^-\pi^0$p запрещены законами сохранения энергии.

Рассмотренные резонансные состояния Δ^{++}и Δ^0 различаются проекциями изотопического спина. Изотопический спин пионов 1 , а нуклонов 1/2. Полный изоспин резонанса поэтому может быть 3/2 и 1/2. При этом (π^+p) система обладает проекцией изоспина $T_3 = 3/2$, а ($\pi^- p$) - проекцией $T_3 = 1/2$, т. е. является суперпозицией состояний с $T = 3/2$ и $T = 1/2$.

10.

64. p = (uud); n = (udd) ; Ω^- = (sss).

10.

65. $\pi^+ = (ud); K^+ = (u\tilde{s})$.

10.

66. $\mathrm{K}^0 = (\mathrm{d}\tilde{\mathrm{s}}), \tilde{\mathrm{K}}^0 = (\tilde{\mathrm{d}})$.

10.

67. Ξ^0 = (uss) ; Λ = (uds).

10.

68. $\pi^-; K^-$.

10.

69* $\sigma_3 = 2\sigma_2 - \sigma_1$.
Решение. Кварковый состав частиц из задачи:

$$\mathrm{K}^+ = (\mathrm{us}), \quad \Sigma^+ = (\mathrm{uus}\ ), \quad \Xi^0 = (\ \mathrm{uss}\ ), \quad \Omega^- = (\mathrm{sss})$$

Обозначим сечения взаимодействия кварков, имея в виду, что в задаче могут взаимодействовать кварки двух поколений: и - из первого поколения, s - из второго. Кроме того, заметим, что при $\mathscr{E} \gg c^2$ сечения рассеяния частицы и античастицы одинаковы (теорема Померанчука). Таким образом,

$$\begin{array}{l} \sigma_a = \sigma(\mathrm{uu}) \approx \sigma(\mathrm{ud}) = \sigma(\mathrm{u}\ \tilde{\mathrm{d}}) = \sigma(\tilde{\mathrm{u}}\ \tilde{\mathrm{d}}) \\ \sigma_b = \sigma(\mathrm{us}) = \sigma(\mathrm{us}) \approx \sigma(\mathrm{d}\ \tilde{\mathrm{s}}) = \sigma(\tilde{\mathrm{u}}s) \text{ и т. д.;} \\ \sigma_c = \sigma(\mathrm{ss}) = \sigma(\mathrm{s}\ \tilde{\mathrm{s}}) = \sigma(\tilde{\mathrm{s}}s) \end{array}$$

Рассмотрим в качестве примера первую реакцию (рис. 187). Стрелками обозначены взаимодействия кварков: сплошная стрелка - с сечением σ_a; штриховая стрелка - с сечением σ_b; волнистая стрелка - с сечением σ_c. При указанных в задаче энергиях дебройлевская длина волны кварков оказывается много меньше размера частиц. Поэтому можно считать, что происходят

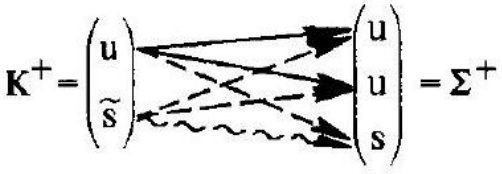

Рис. 187 только одночастичные взаимодействия кварков и в каждой из указанных реакций сечения надо просуммировать по всем возможным каналам. Таким образом, сечение взаимодействия

$$\sigma_1 = 2\sigma_a + 3\sigma_b + \sigma_c$$

Вторая реакция $\mathrm{K}^+ + \Xi^0$ дает сечение

$$\sigma_2 = \sigma_a + 3\sigma_b + 2\sigma_c$$

Аналогичное рассмотрение взаимодействия $\mathrm{K}^+ + \Omega^-$приводит к следующему выражению

$$\sigma_3 = 3\sigma_b + 3\sigma_c.$$

Решая полученную систему уравнений, выражаем неизвестное сечение σ_3 через заданные сечения σ_1 и σ_2:

$$\alpha_3 = 2\alpha_2 - \sigma_1.$$

10.

70. $\sigma(\pi\mathrm{p}) = 26$ мбн, $\sigma(\Lambda N) = 32$ мбн; $\sigma(\Xi N) = 25$ мбн.

10.

71. $\alpha(\Lambda N) = 32$ мбн; $\sigma(EN) = 25$ мбн, $\sigma(\Omega N) = 18$ мбн.

10.

72. $m_\Xi \approx m_\mathrm{u} + 2m_\mathrm{s} \approx m_\mathrm{u} + 2\,(\Delta + m_\mathrm{u}) \approx 1290\mathrm{M} \ni \mathrm{B}$.
Замечание. Речь идет о блоковых (тяжелых) кварках, и $m_\mathrm{d} \approx m_\mathrm{u}$. Поэтому $m_\Lambda - m_\mathrm{p} = m_\mathrm{s} - m_\mathrm{u}$.

10.

73. а) $v_\mu + p \to \mu^- + \Delta^{++}$. Здесь возможны две схемы реакции (рис. 188):
б) $\nu_\mu + \mathrm{n} \to \mu^- + \mathrm{p}$ или $\mu^- + \Delta^+$;
в) $\tilde{v}_\mu + \mathrm{p} \to \mu^+ + \mathrm{n}$ или $\mu^+ + \Delta^0$;
г) $\tilde{\nu}_\mu + n \to \mu^+ + \Delta^-$.

Рис. 188
Отношение эффективных сечений этих реакций $\sigma_a : \sigma_\sigma : \sigma_6 : \sigma_2 = 1 : 2 : 2 : 1$.

10.

74. Решение. Схема распада протона $\mathrm{p} \to \pi^0 + \mathrm{e}^+$изображена на рис. 189. Масса X -бозона определяется из соотношения неопределенностей

$$Mc^2 \approx \frac{\hbar}{\tau} \approx 0,6 \cdot 10^{23} \ni \text{ B} = 0,6 \cdot 10^{14}\Gamma \ni \text{ B}.$$

Заряд X-бозона равен сумме зарядов двух и-кварков

$$Q_X = +\frac{4}{3}e$$

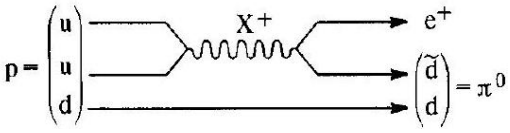

Рис. 189

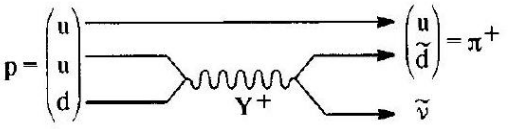

Рис. 190

10.

75. $R \approx 2 \cdot 10^{-29}$ cm; $Q_Y = +e/3$. Схема распада изображена на рис. 190.

10.

76: Решение. На рис. 191 и 192 показаны все $24(2 \times 12)$ перехода между кварками и лептонами, идущих через нейтральный Z^0 и заряженные

промежуточные бозоны $\mathrm{W}^{\pm}$, допустимые по теории электрослабого взаимодействия. При этом не наблюдавшиеся экспериментально переходы $t \leftrightarrow s$ и $t \leftrightarrow d$ изображены штриховыми линиями. Приведем примеры наблюдаемых переходов:

$$\mathrm{e}^+ + \mathrm{e}^- \to \mathrm{Z}^0 \to v_l + \tilde{v}_l, \text{ где } l \equiv \mathrm{e}, v, \tau - \text{ лептоны},$$

- это рождение нейтринных пар в результате ее-столкновений;

$$\mathrm{e}^+ + \mathrm{e}^- \leftrightarrow \mathrm{Z}^0 \leftrightarrow \mathrm{u} + \tilde{\mathrm{u}}$$

- рождение в ее-столкновениях и распад в адроны, либо рождение в р рстолкновениях и распад на пару лептон-антилептон;

$$\mathrm{d} \to \mathrm{u} + \mathrm{w}^- \to \mathrm{u} + \mathrm{e}^- + \tilde{v}_{\mathrm{e}}$$

- распад нейтрона;

$$\mathrm{u} + \tilde{\mathrm{d}} \to \ \mathrm{W}^+ \to \tilde{l} + v_l, \text{ где } l \equiv \mathrm{e}, \mu, \mathrm{r} \text{ - лептоны}$$

- рождение в р $\tilde{p}$-столкновениях и распад на пару лептон-антилептон.

Как следует из рис. 191 в процессах с участием Z^0-бозона аромат кварков не меняется. На рис. 193 приведены доминирующие при слабых распадах адронов переходы между кварками, идущие через обмен $W^{\pm}$-бозонами. В то же время допустимые законом сохранения заряда переходы $c \to d$, $b \to u$ и другие, изображенные на рис. 192, так же возможны. Например, экспериментально наблюдается как распад $D^0 \to K^- + \pi^+$, соответствующий переходу $c \to \tilde{s}$ (рис. 194), так и распад $D^0 \to \pi^- + \pi^+$, соответствующий переходу $c \to d$. Отношение вероятностей этих переходов составляет $5 \cdot 10^{-2}$. Переходы же через поколение подавлены еще сильнее.

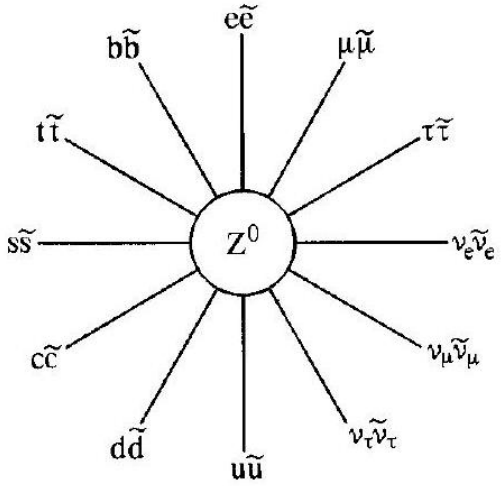

Рис. 191

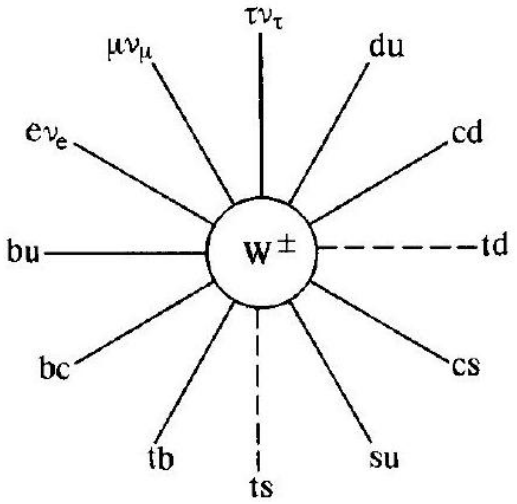

Рис. 192

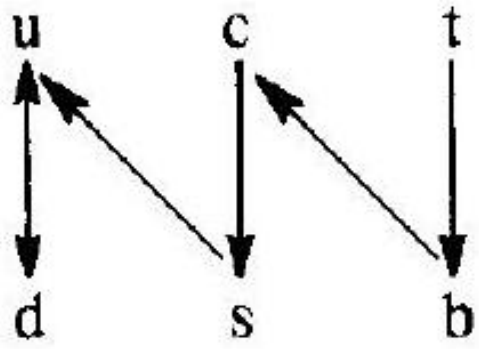

Рис. 193

В условии задачи B^--мезон, имеющий кварковый состав (b), в вершине 2 (рис. 64 из условия) распадается. Наиболее вероятный процесс - это распад b кварка по схеме $b \to c + W^-$(преобразование в ближайший более легкий кварк второго поколения).

Таким образом, в вершине 2 рождается тяжелая частица с кварковым составом (си). Это D^0-мезон, т. е. $X \equiv D^0$. Кроме того, в эмульсии оставил

след возможно мюон, поскольку образовавпийся при распаде b -кварка W^-бозон мог распасться по схеме

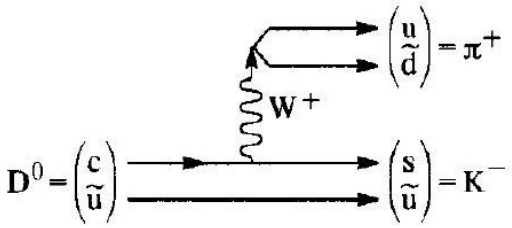

Рис. 194

$$W^- \to \left\{ \begin{array}{l} \mu^- + \tilde{\upsilon_\mu} \\ \mathrm{e}^- + \tilde{\upsilon_\mathrm{e}} \\ \tau^- + \tilde{\upsilon_\tau} \end{array} \right.$$

Далее в вершине $3\mathrm{D}^0$-мезон распадается. Схема его распада изображена на рис. 194. Наиболее вероятен распад скварка в рамках второго поколения по схеме

$$\mathrm{c} \to \ \mathrm{s} + \mathrm{W}^+$$

В свою очередь W^+-бозон распадается, как сказано в условии задачи, по нелептонному каналу. Наиболее вероятен такой распад:

$$\mathrm{W}^+ \to \mathrm{u} + \tilde{\mathrm{d}} \equiv \pi^+.$$

Таким образом, в вершине $3\mathrm{D}^0$-мезон распадается по схеме:

$$\mathrm{D}^0 \to \ \mathrm{K}^- + \pi^+, \quad \text{где} \quad \mathrm{K}^- = (\mathrm{s}\tilde{\mathbf{u}})$$

Возможны и другие каналы распада D^0-мезона через K^--мезон с образованием любого числа пионов: $\mathrm{D}^0 \to \ \mathrm{K}^- + \pi^+\pi^0$ или, например, $\mathrm{D}^0 \to \ \mathrm{K}^- + \pi^+ + \pi^+ + \pi^-$.

10.

77. Неизвестная частица X - это Ω^--гиперон. При соударении K^-и p кроме Ω^-образовались еще две частицы. Это пара каонов K^0 и K^+.

10.

78: Странность частицы $S = 1$. Это могут быть K^0, а также D^0, или B^0.

Решение. По условию задачи электрический и барионный заряды частицы равны $Q = 0, B = 0$, а проекция изотопического спина $T_3 = -1/2$. Ответ надо искать, очевидно, среди мезонов, т.е. частиц, имеющих состав (кварк, антикварк).

По условию это может быть странный мезон, хотя не исключен очарованный или красивый мезон. Воспользуемся формулой Гелл-Мана-Нишиджимы

$$Q = T_3 + \frac{1}{2}(B + S + C + b + t) = T_3 + \frac{1}{2}Y$$

где B - барионный заряд, S - странность, C - очарование, b - красота, t - правдивость, Y - гиперзаряд. Подстановка в эту формулу данных задачи дает уравнение (для случая поиска странного мезона)

$$0 = -\frac{1}{2} + \frac{1}{2}(0 + S)$$

откуда $S = 1$. Таким образом, это $\mathrm{K}^0 = (\mathrm{d}\tilde{\mathrm{s}})$. В принципе, это может быть и очарованный мезон $\mathrm{D}^0 = (\tilde{\mathbf{u}})$. В этом случае по формуле Гелл-Мана - Нишиджимы должно быть $C = 1$. Также не исключен случай совсем редкой частицы с кварками третьего поколения B^0-мезон.

10.

79. Антинейтрон n.

10.

80. $Y = -2, S = -3.\Omega^-$-гиперон.

10.

81. $Y = -1; S = -2.\Xi^0 \equiv$ (uss)-гиперон.

10.

82. $\mu_{\Delta^{++}} = 2\mu_{\text{p}} = 5,6\mu_{\text{гд}}$.

10.

83. $\mu_{\Omega^-} = 1,7\mu_{\text{яд}}$. Масса странного кварка принята равной $m_{\text{s}} \approx \approx M_\Omega/3 \approx 557\text{M} \ni \text{B}$.

10.

84* $k \approx 8 \cdot 10^{27}$ монополей.

Решение. Монополь, летящий со скоростью $v = \sqrt{2\text{Å}/M}$, в 1 с инициирует $N =$ опи распадов протонов (σ - сечение реакции, n - концентрация протонов). При этом освобождается энергия

$$Nm_{\text{p}}c^2 = \sigma nvm_{\text{p}}c^2$$

переходящая в тепло при поглощении позитрона и γ-квантов. По условию $k\sigma nvm_{\text{p}}c^2 = L_{\text{C}}$, где k - число монополей в Солнце. Сечение реакции распада протона находится из условия распада одного протона на длине 1c : $n_{\text{p}}\alpha = 1$; $\sigma = 1/n_{\text{p}} = 3 \cdot 10^{-24}$ cm^2, где n_{p} - концентрация протонов в 1 cm^3 воды, $n_{\text{p}} = 10N_{\text{A}}(\text{m}/\mu) \approx 3,3 \cdot 10^{23}$ cm^{-3}, (в молекуле воды 10 протонов).

Число протонов в 1 cm^3 Солнца

Отсюда

$$n = \frac{\rho}{m_{\text{p}}} = \frac{M_{\text{C}}}{(4/3)\pi R_{\text{C}}^3}\frac{1}{m_{\text{p}}}$$

$$k = \frac{L_{\text{C}}}{\sigma nvm_{\text{p}}c^2} = \frac{4L_{\text{C}}n_{\text{p}}\pi R_{\text{C}}^3}{3M_{\text{C}}c^2\sqrt{2\mathscr{E}/M}} \approx 8 \cdot 10^{27}$$

10.

85* $\mathscr{E}_{\text{пор}} \approx 270$ ГэВ.

Решение. На встречных пучках протонов (uud) и антипротонов () может родиться реальный W^+_- $\text{u} + \tilde{\text{d}} = \text{W}^+$, если $\mathscr{E}_{\text{W}} > m_{\text{W}}c^2$. В ультрарелятивистском случае энергия распределяется между кварками точно так же, как и импульс. По закону сохранения энергии

Откуда

$$\mathscr{E}_{\text{пор}} = \frac{m_{\text{W}}c^2}{0,3} \approx 270 \text{ ГэВ}$$

Совершенно аналогично при столкновении кварков d и и может родиться W^--бозон. Порог реакции будет таким же.

10.

86. $_{\text{пор}} \approx 300$ ГэВ.

10.

87. См. рис. 195.

89. См. рис. 197.

10.

90. См. рис. 198.

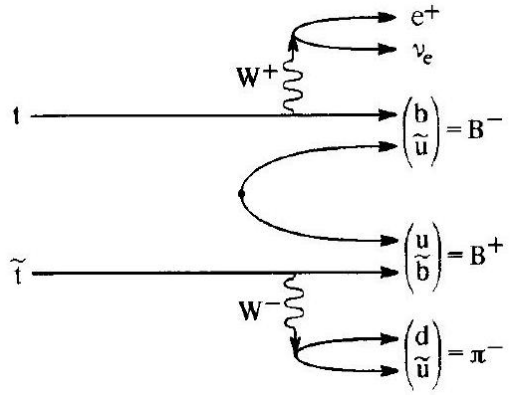

Рис. 196

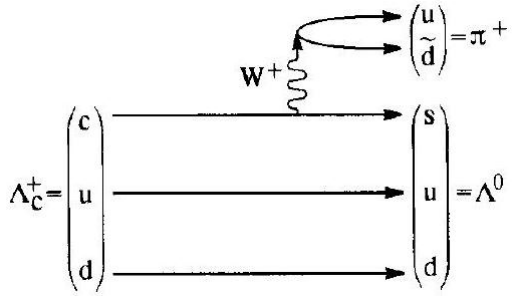

Рис. 197

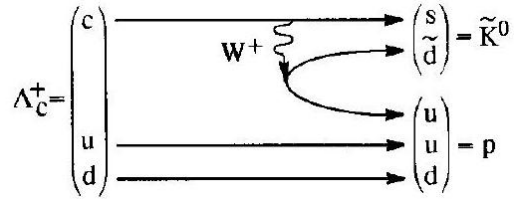

Рис. 198

10.

91. Заметим, что реакция $v_{\mathrm{e}} + \mathrm{p} \rightarrow \mathrm{n} + \mathrm{e}^{+}$не идет, поскольку запрещена законом сохранения лептонного заряда. Поэтому реакция может идти только на нейтронах. Причем, так как энергия нейтрино меньше 15 М МВ, то возможно детектирование только электронных нейтрино v_{e} на нейтронах дейтерия в реакции $v_{\mathrm{e}} + {}^{2}_{1}\,\mathrm{d} \rightarrow \mathrm{p} + \mathrm{p} + \mathrm{e}^{-}$, откуда $\mathscr{E}_{\text{пор}} = 1,37\text{М эВ}$.

10.

92. $\mathscr{E}^{\Pi\circ\rho}_{\nu_e} = 15,5\text{М }\ni;\ ;\mathscr{E}^{\Pi\circ}_{\gamma_\mu} = 121,5\text{М ВВ}$.

10.

93*: $\frac{\mu_{\mathrm{n}}}{\mu_{\mathrm{p}}} = -\frac{2}{3} = -0,667$ (эк сперимент дает $\frac{\mu_{\mathrm{n}}}{\mu_{\mathrm{p}}} = -0,685$).

Решение. Для протона вероятность спинового состояния ($\uparrow \mathbf{u}, \uparrow u, \downarrow\ \mathrm{d}$) равняется 2/3, а спинового состояния ($\uparrow \mathrm{u}, \downarrow \mathrm{u}, \uparrow \mathrm{d}$) равняется 1/3 (согласно условию). Следовательно, предполагая, что магнитный момент кварка пропорционален его заряду, получим, что $\mu_u = \frac{2}{3}\mu_1$; $\mu_{\mathrm{d}} = -\frac{1}{3}\mu_1$, где μ_1 - «элементарный» магнитный момент. Таким образом, магнитный момент протона равен

$$\mu_p = \frac{1}{3}\left(\frac{2}{3}\mu_1 - \frac{2}{3}\mu_1 - \frac{1}{3}\mu_1\right) + \frac{2}{3}\left[\frac{2}{3}\mu_1 + \frac{2}{3}\mu_1 - \left(-\frac{1}{3}\mu_1\right)\right] = 3\mu_1$$

Аналогично для нейтрона состояние ($\uparrow \mathrm{d}, \uparrow \mathrm{d}, \downarrow \mathrm{u}$) имеет вероятность 2/3, а состояние ($\uparrow \mathbf{d}, \downarrow \mathbf{d}, \uparrow \mathbf{u}$) - вероятность 1/3. Поэтому

$$\mu_{\Pi} = \frac{2}{3}\left(-\frac{1}{3}\mu_I - \frac{1}{3}\mu_1 - \frac{2}{3}\mu_1\right) + \frac{1}{3}\left[-\frac{1}{3}\mu_1 - \left(-\frac{1}{3}\mu_1\right) + \frac{2}{3}\mu_1\right] = -2\mu_1$$

Откуда искомое отношение $\frac{\mu_{\mathrm{n}}}{\mu_{\mathrm{p}}} = -\frac{2}{3} = -0,667$, тогда как экспериментальное значение $\left(\frac{\mu_n}{\mu_p}\right)_{\text{эксп}} = -0,685$.

Покажем, почему появляются вероятности 1/3 и 2/3 при разных спиновых состояниях протона. Каждый кварк имеет спин 1/2, поэтому максимальный спин системы из трех кварков равен 3/2 - это состояние ($\uparrow \mathrm{u}, \uparrow \mathrm{u}, \uparrow \mathrm{d}$), соответствующее Δ^{+}-изобаре.

Если перевернуть спин одного из кварков в Δ^{+}-изобаре, то получим систему со спином 1/2. Таких состояний возможно три: ($\uparrow \mathbf{u}, \uparrow u, \downarrow d$), ($\uparrow \mathrm{u}, \downarrow \mathrm{u}, \uparrow \mathrm{d}$) и ($\downarrow \mathrm{u}, \uparrow \mathrm{u}, \uparrow \mathrm{d}$). При этом последние два совершенно неразличимы физически - это одно состояние. Таким образом, вероятность состояния ($\uparrow u, \uparrow u, \downarrow d$) вдвое выше состояния ($\uparrow u, \downarrow u, \uparrow d$) и составляет 2/3 против 1/3 в последнем случае.

Аналогично можно поступить и в системе кварков, ($\uparrow\ u, \uparrow\ d, \uparrow\ d$), соответствующей Δ^{0}-изобаре, имеющей спин 3/2. Если перевернув спин одного из кварков, получить систему со спином 1/2, то таких вариантов также три: ($\downarrow \mathrm{u}, \uparrow \mathrm{d}, \uparrow \mathrm{d}$), ($\uparrow \mathrm{u}, \downarrow \mathrm{d}, \uparrow \mathrm{d}$) и ($\uparrow \mathrm{u}, \uparrow \mathrm{d}, \downarrow \mathrm{d}$). Последние два варианта физически неотличимы. Поэтому вероятность состояния ($\downarrow \mathrm{u}, \uparrow \mathrm{d}, \uparrow \mathrm{d}$) вдвое больше состояния ($\uparrow \mathrm{u}, \downarrow \mathrm{d}, \uparrow \mathrm{d}$) и составляет 2/3 против 1/3.

Заметим, что разность масс Δ-изобар и нуклонов связана только с переворотом спина, а не с возникновением орбитального момента кварка. И нуклон и Δ-изобары - это S-состояния с различными $J: 1/2$ и $3/2$.

Сейчас к проблеме магнитных моментов нуклонов развит более наглядный подход, основанный на обобщенном принципе Паули. Согласно этому принципу волновая функция нуклона (произведение орбитальной, спиновой, изоспиновой и цветовой функций кварков) должна быть антисимметрична относительно перестановки любой пары тождественных кварков. Отсюда следует, что спины одинаковых кварков в нуклонах параллельны (цветовая функция всегда антисимметрична, орбитальная функция при $l = 0$ симметрична, следовательно изоспиновая и спиновая функции - симметричны). Тем самым задача вычисления магнитных моментов нуклонов сводится к вычислению суммарного магнитного момента двух частиц со спином 1 (пара одинаковых кварков с параллельными спинами) и одной со спином 1/2 (оставшийся кварк).

10.

94. $\mathscr{E} = (m_\Delta - m_n)\,c^2 = 1231 - 939 = 292\text{М ЭВ}$. (См. решение задачи

10.

93.)

10.

95. $\tau \simeq \frac{\hbar}{\alpha^2 m_e c^2} \frac{8 r_{\text{Б}}^3}{\text{Å}_e^3} = \frac{8 r_{\text{кл}}}{\alpha^6 c} = 5 \cdot 10^{-10} c$, где $r_{\text{Б}}$ - боровский радиус электрона в атоме водорода, $r_{\text{кл}} = \frac{e^2}{mc^2}$ - классический радиус электрона.

10.

96. $t_{\text{р}} \simeq t_{\text{яд}} \frac{r_{1\text{p}}^3}{\text{Å}_\pi^3} = 0,32 \cdot 10^{-18}$с, где $\text{А} = \frac{\hbar}{m_\pi c} = 1,4 \cdot 10^{-13}$с - комптоновская длина волны пиона (радиус сильного взаимодействия), $t_{\text{яд}} \simeq 0,5 \cdot 10^{-23}$ с - характерное «ядерное время», r_{1p} - радиус основного состояния протониума.

10.

97* $\mathscr{E}_{\Gamma\pi} = \frac{m_{\text{n}} c^2}{4}; R_{\text{П}} = \frac{4\pi\hbar}{m_{\text{n}} c} = 2,64$ фм.

Решение. Волновая функция основного сферически симметричного состояния (орбитальный момент равен нулю) частицы в трехмерной сферической яме с непроницаемыми стенками $\psi = A\frac{\sin kr}{r}$. Условие на границе $\psi(R) = 0$ дает разрешенные значения волновых чисел $k = \frac{\pi}{R} n$. Таким образом, минимальная энергия трех безмассовых кварков в непроницаемой сфере $\mathscr{E}_{\text{Кв}} = 3\hbar kc = \frac{3\pi\hbar c}{R}$, т. к. из-за различия в цвете они могут втроем находится на нижнем уровне. Обозначим плотность энергии глюонного поля через ε. Тогда энергия кварков и глюонов

$$\mathscr{E} = \mathscr{E}_{\text{КВ}} + \mathscr{E}_{\text{ГЛ}} = \frac{3\pi\hbar c}{R} + \varepsilon \frac{4}{3}\pi R^3$$

Минимизируя это выражение, получаем

$$R_{\min} = \left(\frac{3\hbar c}{4\varepsilon}\right)^{1/4}, \text{ а } \mathcal{E}_{\min} = 4\pi\hbar c \left(\frac{4\varepsilon}{3\hbar c}\right)^{1/4} = \frac{4\pi\hbar c}{R_{\min}}$$

Поскольку $\mathscr{E}_{\min} = m_{\text{n}} c^2$, то

$$R_{\text{n}} = R_{\min} = 4\pi \frac{\hbar}{m_{\text{n}}} = 4\pi t_{\text{n}} = 2\lambda_{\text{n}} = 2 \cdot 1,32 \cdot 10^{-13} \phi\text{М}$$

Энергия глюонного поля составляет:

$$\mathscr{E}_{\text{г}J} = \varepsilon \cdot \frac{4}{3}\pi R_{\min}^3 = \frac{\pi\hbar c}{R_{\min}} = \frac{m_{\text{n}} c^2}{4}$$

т. е. четверть энергии покоя нуклона.

10.

98. Поскольку $\sigma(\mathscr{E}) \propto \mathscr{E}^2$, то $\frac{\sigma(\mathscr{E}=1\text{М. })}{\sigma(\mathscr{E}=10\text{М В })} = 10^{-2}$.

19 Problems about Formalism of QM

19.1 Problems about Operators

19.1.1 Problems about Basic Quantum Operators

(начало белоусова и любого типичного курса. в запись про простые задачи перенесу то, что простое и скучное.)

ПТФ-1.y1. Унитарные матрицы

Покажите, что унитарные матрицы, как и эрмитовы, диагонализуемы. *Указание*: покажите, что эрмитова и анти-эрмитова часть унитарного оператора диагонализуемы совместно.

Solution.

Разложим унитарный оператор на эрмитову и анти-эрмитову части:

$$\hat{U} = \frac{\hat{U} + \hat{U}^\dagger}{2} + i\frac{\hat{U} - \hat{U}^\dagger}{2i}$$

Вычислим их коммутатор, учитывая унитарность оператора $\hat{U}$ ($\hat{U}^\dagger\hat{U} = \hat{U}\hat{U}^\dagger = \mathbb{I}$):

$$[\hat{U} + \hat{U}^\dagger, \hat{U} - \hat{U}^\dagger] = \hat{U}\hat{U} + \hat{U}^\dagger\hat{U} - \hat{U}\hat{U}^\dagger - \hat{U}^\dagger\hat{U}^\dagger - \hat{U}\hat{U} + \hat{U}^\dagger\hat{U} - \hat{U}\hat{U}^\dagger + \hat{U}^\dagger\hat{U}^\dagger = 2(\hat{U}^\dagger\hat{U} - \hat{U}\hat{U}^\dagger) = 0$$

Часть $\frac{\hat{U}+\hat{U}^\dagger}{2}$ эрмитова, $i\frac{\hat{U}-\hat{U}^\dagger}{2i}$ антиэрмитова. Докажем следующее предложение:
Если операторы коммутируют, то их можно одновременно диагонализировать.

Proof. Пусть $\vec{a}$ – собственный вектор оператора $\hat{A}$, соответствующий некратному собственному значению λ ($\hat{A}\vec{a} = \lambda\vec{a}$). Вектор $\hat{B}\vec{a}$ тоже будет принадлежать собственному значению λ матрицы A:

$$\hat{A}\hat{B}\vec{a} = \hat{B}\hat{A}\vec{a} = \lambda\hat{B}\vec{a}$$

Следовательно, вектор $B\vec{a}$ пропорционален $\vec{a}$, т.е. $\vec{a}$ является собственным вектором матрицы $\hat{B}$.
В случае кратного собственного значения λ имеем несколько собственных векторов x_i, принадлежащим этому собственному значению. Пусть $Bx_i = b_{ij}x^j$, где b_{ij} – некоторые числа. Матрицу b_{ij} можно диагонализовать, выбрав в качестве принадлежащих λ собственных векторов матрицы $\hat{A}$ другие векторы $y_i = c_{ij}x^j : Ay_i = \lambda y_i$ и $By_i = \Lambda_i y_i$ (в последнем равенстве суммы по i нет).
Т.е. у операторов общая система собственных векторов. Можно перейти к базису, состоящему из собственных векторов, и в этом базисе обе матрицы будут диагональны. □

Таким образом, эрмитова и анти-эрмитовы части диагонализуемы совместно. Следовательно, и их сумма – унитарный оператор $\hat{U}$ диагонализуем.

ПТФ-1.y2. Замена базиса

В квантовой механике замена базиса реализуется унитарными преобразованиями $|\psi'\rangle = \hat{U}|\psi\rangle$.
• Покажите, что гамильтониан при этом заменяется на $\hat{H}' = \hat{U}\hat{H}\hat{U}^\dagger$.
• Последнее утверждение необходимо модифицировать, если унитарное преобразование зависит явно от времени $\hat{U} = \hat{U}(t)$. Покажите, что в таком случае гамильтониан необходимо заменить на $\hat{H}' = \hat{U}\hat{H}\hat{U}^\dagger - i\hbar\hat{U}\partial_t\hat{U}^\dagger$.

Solution.

Запишем нестационарное уравнение Шрёдингера:

$$i\hbar\frac{\partial|\psi\rangle}{\partial t} = \hat{H}|\psi\rangle$$

Поскольку преобразование $\hat{U}$ унитарное, то

$$\hat{U}\hat{U}^\dagger = \hat{\mathbb{I}} \to \hat{U}^{-1} = \hat{U}^\dagger \to |\psi\rangle = \hat{U}^\dagger|\psi'\rangle$$

- $$i\hbar\frac{\partial(\hat{U}^\dagger|\psi'\rangle)}{\partial t} = \hat{H}\hat{U}^\dagger|\psi'\rangle \to i\hbar\frac{\partial|\psi'\rangle}{\partial t} = \hat{U}\hat{H}\hat{U}^\dagger|\psi'\rangle$$

Таким образом,

$$\hat{H}' = \hat{U}\hat{H}\hat{U}^\dagger$$

- $$i\hbar\frac{\partial(\hat{U}^\dagger(t)|\psi'\rangle)}{\partial t} = \hat{H}\hat{U}^\dagger|\psi'\rangle \to i\hbar\hat{U}^\dagger\frac{\partial|\psi'\rangle}{\partial t} + i\hbar|\psi'\rangle\partial_t\hat{U}^\dagger = \hat{U}\hat{H}\hat{U}^\dagger|\psi'\rangle$$

$$i\hbar\frac{\partial|\psi'\rangle}{\partial t} = (\hat{U}\hat{H}\hat{U}^\dagger - i\hbar\hat{U}\partial_t\hat{U}^\dagger)|\psi'\rangle$$

$$H' = \hat{U}\hat{H}\hat{U}^\dagger - i\hbar\hat{U}\partial_t\hat{U}^\dagger$$

ПТФ-1.у3. Матрицы Паули

Покажите следующие свойства матриц Паули (по повторяющимся индексам подразумевается суммирование):

• Они, совместно с единичной матрицей $\sigma^0 = \hat{\mathbb{I}}_{2\times2}$, представляют собой базис в пространстве эрмитовых матриц 2×2.

• Они удовлетворяют следующими правилам перемножения: $\hat{\sigma}^\alpha\hat{\sigma}^\beta = \delta_{\alpha\beta}\hat{\mathbb{I}} + i\epsilon_{\alpha\beta\gamma}\hat{\sigma}^\gamma$ ($\alpha, \beta, \gamma \in \{x, y, z\}$, а $\epsilon_{\alpha\beta\gamma}$ – символ Леви-Чивиты).

• Они удобно экспоненциируются: $\exp(ian_\alpha\hat{\sigma}^\alpha) = \cos a + in_\alpha\hat{\sigma}^\alpha \sin a$ (тут $\vec{n}$ – произвольный единичный вектор). *Указание*: разложите экспоненту в ряд; из-за простого правила произведения матриц Паули, произвольные степени отих линейных комбинаций вычисляются достаточно просто.

Solution.

Матрицы Паули:

$$\hat{\sigma}^x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \hat{\sigma}^y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \hat{\sigma}^z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

• Проверим, что матрицы Паули являются линейно независимой системой от противного: предположим, что существуют a_0, a_1, a_2, $a_3 \in \mathbb{R}$:

$$a_0\hat{\sigma}^0 + a_1\hat{\sigma}^1 + a_2\hat{\sigma}^2 + a_3\hat{\sigma}^3 = 0$$

$$\begin{pmatrix} a_0 + a_3 & a_1 - ia_2 \\ a_1 + ia_2 & a_0 - a_3 \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$$

Единственное решение: $a_0 = a_1 = a_2 = a_3 = 0$, значит матрицы Паули действительно линейно независимы. Покажем, что любая эрмитова матрица 2×2 $B = (b_i)$ лежит в их линейной оболочке:

$$\begin{pmatrix} a_0 + a_3 & a_1 - ia_2 \\ a_1 + ia_2 & a_0 - a_3 \end{pmatrix} = \begin{pmatrix} b_1 & b_2 \\ b_3 & b_4 \end{pmatrix}$$

Заметим, что матрица слева (а значит и справа) является эрмитовой (на главной диагонали величины вещественные, на побочной – комплексно-сопряжённые). Единственное решение: $a_0 = \frac{b_1+b_4}{2}$, $a_1 = \frac{b_2+b_3}{2}$, $a_2 = \frac{i(b_2-b_3)}{2}$, $a_3 = \frac{b_1-b_4}{2}$. Таким образом, матрицы Паули совместно с единичной матрицей образуют базис в пространстве эрмитовых матриц 2×2.

• Проверим соотношения на матрицы Паули:

$$\sigma^1\sigma^1 = \sigma^2\sigma^2 = \sigma^3\sigma^3 = \mathbb{I}$$

$$\sigma^1\sigma^2 = -\sigma^2\sigma^1 = -i\sigma^3, \quad \sigma^1\sigma^3 = -\sigma^3\sigma^1 = -i\sigma^2, \quad \sigma^2\sigma^3 = -\sigma^3\sigma^2 = -i\sigma^1$$

Таким образом,

$$\hat{\sigma}^\alpha\hat{\sigma}^\beta = \delta_{\alpha\beta}\hat{\mathbb{I}} + i\epsilon_{\alpha\beta\gamma}\hat{\sigma}^\gamma$$

- $$\exp(ian_\alpha\hat{\sigma}^\alpha) = \sum_{k=0}^{\infty}\frac{(ian_\alpha\hat{\sigma}^\alpha)^k}{k!}$$

Найдём $(n_\alpha\hat\sigma^\alpha)^2$. Для этого воспользуемся правилом перемножения матриц Паули из п. 2:

$$n_\alpha\hat\sigma^\alpha n_\beta\hat\sigma^\beta = \hat{\mathbb{I}} + i\epsilon^{\alpha\beta\gamma}n_\alpha n_\beta\hat\sigma_\gamma = \hat{\mathbb{I}}$$

Из этого следует:

$$(n_\alpha\hat\sigma^\alpha)^{2k} = \hat{\mathbb{I}}, \quad (n_\alpha\hat\sigma^\alpha)^{2k+1} = n_\alpha\hat\sigma^\alpha, \quad k \in \{0\}\cup\mathbb{N}$$

$$\exp(ian_\alpha\hat\sigma^\alpha) = \sum_{k=0}^{\infty}\frac{(-1)^k a^{2k}(n_\alpha\hat\sigma^\alpha)^{2k}}{(2k)!} + i\sum_{k=0}^{\infty}\frac{(-1)^k a^{2k+1}(n_\alpha\hat\sigma^\alpha)^{2k+1}}{(2k+1)!}$$

$$\exp(ian_\alpha\hat\sigma^\alpha) = \mathbb{I}\sum_{k=0}^{\infty}\frac{(-1)^k a^{2k}}{(2k)!} + in_\alpha\hat\sigma^\alpha\sum_{k=0}^{\infty}\frac{(-1)^k a^{2k+1}}{(2k+1)!}$$

$$\exp(ian_\alpha\hat\sigma^\alpha) = \mathbb{I}\cos a + in_\alpha\hat\sigma^\alpha\sin a$$

ПТФ-3.з1. Каноническое квантование

Один из способов построения квантовой механики заключается в постулировании коммутационных соотношений, связанных с классической скобкой Пуассона: $[\hat A, \hat B] \to i\hbar\{\hat A, \hat B\}$; для канонически сопряжённых операторов координаты импульса это даёт $[\hat x, \hat p] = i\hbar$.

Пусть известно, что у оператора $\hat x$ имеется непрерывный спектр собственных значений $\mathbb{R}$, а также известны коммутационные соотношения $[\hat x, \hat p] = i\hbar$. Продемонстрируйте, что только этих знаний достаточно, чтобы вывести явный вид оператора импульса в координатном представлении $\hat p = -i\hbar\frac{\partial}{\partial x}$.

Дополнительно: покажите, что не существует конечномерных представлений этой алгебры: операторы $\hat x$ и $\hat p$, определённые таким образом, не могут действовать в гильбертовом пространстве конечной размерности.

Указания:

• Вычислите по индукции $[\hat x, \hat p^n]$.

• Оператор трансляции определим стандартным образом как $\hat T_a = e^{i\hat p a/\hbar}$. Используя предыдущий пункт, вычислите коммутатор $[\hat x, \hat T_a]$.

• Пусть $|x\rangle$ – базис собственных состояний оператора $\hat x$, так что $\hat x|x\rangle = x|x\rangle$. Покажите, что построенный оператор $\hat T_a$ действительно является оператором трансляции: $\hat T_a|x\rangle = |x-a\rangle$.

• Используя матричный элемент $\langle x|\hat T_a|\psi\rangle$ для инфинитезимальной трансляции $a \to 0$, найдите матричный элемент $\langle x|\hat p|\psi\rangle \equiv \hat p\psi(x)$.

Solution.

(допишу в пару строк основную идею)
Воспользуемся указаниями:
• Вычислим $[\hat x, \hat p^n]$ по индукции:

$$[\hat x, \hat p] = i\hbar$$

$$[\hat x, \hat p^n]\psi(x) \equiv \hat x\hat p^n\psi(x) - \hat p^n\hat x\psi(x) = \hat x\hat p^{n-1}\hat p\psi(x) - \hat p^{n-1}\hat p\hat x\psi(x) = \hat x\hat p^{n-1}\hat p\psi(x) - \\ - \hat p^{n-1}(\hat x\hat p - i\hbar)\psi(x) = [\hat x, \hat p^{n-1}]\hat p\psi(x) + i\hbar\hat p^{n-1}\psi(x)$$

$$[\hat x, \hat p^n] = i\hbar n\hat p^{n-1}$$

• Распишем оператор трансляции в ряд Тейлора:

$$\hat T_a = e^{i\hat p a/\hbar} = \sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{i\hat p a}{\hbar}\right)^n$$

$$[\hat x, \hat T_a] = \left[\hat x, \sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{i\hat p a}{\hbar}\right)^n\right] = \sum_{n=1}^{\infty}\frac{1}{n!}\left(\frac{ia}{\hbar}\right)^n[\hat x, \hat p^n]$$

Воспользуемся предыдущим пунктом:

$$[\hat x, \hat T_a] = \sum_{n=1}^{\infty}\frac{1}{n!}\left(\frac{ia}{\hbar}\right)^n i\hbar n\hat p^{n-1} = -a\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{ia\hat p}{\hbar}\right)^n$$

$$[\hat x, \hat T_a] = -a\hat T_a$$

• Воспользуемся предыдущим пунктом:

$$[\hat{x}, \hat{T}_a]|x\rangle = -a\hat{T}_a|x\rangle$$

$$\hat{x}\hat{T}_a|x\rangle - \hat{T}_a\hat{x}|x\rangle = -a\hat{T}_a|x\rangle$$

$$\hat{x}\hat{T}_a|x\rangle = \hat{T}_a x|x\rangle - a\hat{T}_a|x\rangle = (x-a)\hat{T}_a|x\rangle$$

Как видно, действие оператора $\hat{x}$ на $|x-a\rangle$

$$\hat{x}|x-a\rangle = (x-a)|x-a\rangle$$

совпадает с действием на $\hat{T}_a|x\rangle$, следовательно

$$\hat{T}_a|x\rangle = |x-a\rangle$$

• Для инфинитезимальной трансляции $a \to 0$:

$$\langle x|\hat{T}_a|\psi\rangle = \langle x|\mathbb{I} + i\hat{p}a/\hbar|\psi\rangle = \psi(x) + \frac{ia}{\hbar}\hat{p}\psi(x)$$

$$\langle x|\hat{T}_a|\psi\rangle = \langle \hat{T}_a^\dagger x|\psi\rangle = \langle x+a|\psi\rangle = \psi(x+a) = \psi(x) + a\frac{\partial\psi(x)}{\partial x}$$

Сравнивая предущие равенства, получаем

$$\hat{p} = -i\hbar\frac{\partial}{\partial x}$$

Покажем, что не существует конечномерных представлений этой алгебры. От противного, предположим существуют представления $\hat{x}$ и $\hat{p}$ в виде матриц конечного размера $n \times n$.

$$\mathrm{tr}([\hat{x}, \hat{p}]_{n\times n}) = \mathrm{tr}(i\hbar\mathbb{I}_{n\times n}) = i\hbar n$$

$$\mathrm{tr}([\hat{x}, \hat{p}]_{n\times n}) = \mathrm{tr}(\hat{x}\hat{p} - \hat{p}\hat{x}) = 0$$

$i\hbar n \neq 0$, противоречие.

(??? вопрос в духе, что если взять поле чисел характеритики n, где $n \equiv 0$ - сложный вопрос и я даже не знаю, кто на него сможет ответить. Поэтому пока считаем, что такой вот ответ и все. см. мои последние главы, там когда-то обсужу этот вопрос)

ПТФ-3.з2. Преобразование Галлилея

Пусть частица находится в потенциале, который движется со скоростью v:

$$\hat{H}(t) = \frac{\hat{p}^2}{2m} + V(\hat{x} - vt)$$

Придумайте унитарное преобразование $\hat{U}(t)$ ("преобразование Галлилея"), которое приведёт Гамильтониан к аналогичному, но независящему от времени виду:

$$\hat{H}' \equiv \hat{U}(t)\hat{H}(t)\hat{U}^\dagger(t) - i\hbar\hat{U}(t)\partial_t\hat{U}^\dagger(t) = \frac{\hat{p}^2}{2m} + V(\hat{x})$$

Запишите явно его действие на произвольную волновую функцию $\langle x|\hat{U}(t)|\psi(t)\rangle$.

Solution.

Избавимся от зависимости от времени в качестве преобразования при помощи оператора трансляции $\hat{T}_{vt}$:

$$\hat{T}_{vt} = \exp\left(vt\frac{\partial}{\partial x}\right) = \exp\left(\frac{ivt}{\hbar}\hat{p}\right), \quad \hat{T}_{vt}^\dagger = \hat{T}_{vt}^{-1} = \exp\left(-\frac{ivt}{\hbar}\hat{p}\right)$$

$$\hat{T}_{vt}(t)\hat{H}(t)\hat{T}_{vt}^\dagger(t) = \hat{T}_{vt}(t)\left(\frac{\hat{p}^2}{2m} + V(\hat{x} - vt)\right)\hat{T}_{vt}^\dagger(t) - i\hbar\hat{T}_{vt}(t)\partial_t\hat{T}_{vt}^\dagger(t)$$

Поскольку $\left[\hat{T}_{vt}(t), \frac{\hat{p}^2}{2m}\right] = 0$, то

$$\hat{T}_{vt}(t)\hat{H}(t)\hat{T}^{\dagger}_{vt}(t) = \frac{\hat{p}^2}{2m} + V(\hat{x}) - i\hbar \exp\left(\frac{ivt}{\hbar}\hat{p}\right)\left(-\frac{iv\hat{p}}{\hbar}\right)\exp\left(-\frac{ivt}{\hbar}\hat{p}\right) = \frac{\hat{p}^2}{2m} + V(\hat{x}) - v\hat{p}$$

Избавимся от слагаемого $-v\hat{p}$ при помощи оператора трансляции по импульсу:

$$\exp\left(a\frac{\partial}{\partial p}\right) = \exp\left(-\frac{ia\hat{x}}{\hbar}\right)$$

Поскольку $\left[\exp\left(-\frac{ia\hat{x}}{\hbar}\right), V(x)\right] = 0$, то

$$\exp\left(-\frac{ia\hat{x}}{\hbar}\right)\left(\frac{\hat{p}^2}{2m} + V(\hat{x}) - v\hat{p}\right)\exp\left(\frac{ia\hat{x}}{\hbar}\right) = \frac{(\hat{p}+a)^2}{2m} - v(\hat{p}+a) + V(\hat{x}) =$$
$$= \frac{\hat{p}^2}{2m} + \frac{a\hat{p}}{m} + \frac{a^2}{2m} - v\hat{p} - va + V(\hat{x})$$

Выберем $a = mv$:

$$\exp\left(-\frac{ia\hat{x}}{\hbar}\right)\left(\frac{\hat{p}^2}{2m} + V(\hat{x}) - v\hat{p}\right)\exp\left(\frac{ia\hat{x}}{\hbar}\right) = \frac{\hat{p}^2}{2m} - \frac{mv^2}{2} + V(\hat{x})$$

Избавимся от слагаемого $-\frac{mv^2}{2}$ при помощи оператора e^{ibt}, который коммутирует и с $\hat{x}$, и с $\hat{p}$:

$$\exp(ibt)\left(\frac{\hat{p}^2}{2m} - \frac{mv^2}{2} + V(\hat{x})\right)\exp(-ibt) - i\hbar\exp(ibt)(-ib)\exp(-ibt) = \frac{\hat{p}^2}{2m} - \frac{mv^2}{2} +$$
$$+ V(\hat{x}) - \hbar b$$

Выберем $b = -\frac{mv^2}{2\hbar}$. Таким образом, искомое унитарное преобразование:

$$U(t) = \exp\left(-\frac{imv^2t}{2\hbar}\right)\exp\left(-\frac{imv\hat{x}}{\hbar}\right)\exp\left(\frac{ivt\hat{p}}{\hbar}\right)$$

Подействуем оператором $\hat{U}(t)$ на функцию ψ:

$$\langle x|\hat{U}(t)|\psi(t)\rangle = \langle \hat{U}^{\dagger}(t)x|\psi(t)\rangle = \langle x+vt|\psi(t)\rangle \exp\left(-\frac{imv(x+vt)}{\hbar}\right)\exp\left(-\frac{imv^2t}{2\hbar}\right)$$

$$\langle x|\hat{U}(t)|\psi(t)\rangle = \psi(t, x+vt)\exp\left(-\frac{imv(x+vt)}{\hbar}\right)\exp\left(-\frac{imv^2t}{2\hbar}\right)$$

ФР. Оператор силы

Найти выражение для оператора силы

Solution..

(решение утеряно, напишу 1ю часть, потом пропишу это!)

Обсуждение (???)

(???? мы вообще можем использовать это выражение? проверю! укажу в теории его тоже!!!)

ФР. Момент силы

Найти выражение для оператора момента силы

Solution..

Воспользуемся $\hat{\dot{f}} = \frac{\partial \hat{f}}{\partial t} + \frac{i}{\hbar}\{\hat{H}, \hat{f}\}$, в нашем случае

$$\hat{\boldsymbol{M}}_\alpha = \epsilon_{\alpha\beta\gamma}\hat{\boldsymbol{r}}_\beta \hat{\boldsymbol{F}}_\gamma = \epsilon_{\alpha\beta\gamma}\hat{\boldsymbol{r}}_\beta \left(\frac{\partial \hat{p}}{\partial t} + \frac{i}{\hbar}\{\hat{H}, \hat{p}\}\right)$$

Ответ:

$$\hat{\boldsymbol{M}}_\alpha = \epsilon_{\beta\alpha\gamma}\hat{\boldsymbol{r}}_\beta \vec{\nabla}_\gamma U.$$

(решение не годящееся, потому что требуется из основ выводить. да? но ответ верный, да?)

ФР. Оператор дипольного момента

Найти выражение для оператора дипольного момента

Solution..

(решение утеряно, напишу 1ю часть, потом пропишу это!)

ФР. Найти выражение для оператора времени

Solution..

(??? ну тут проблема, конечно, в теории отдельный раздел про это напишу. пока оставил задачу.)

ФР. Найти выражение для оператора производной от дипольного момента

Solution..

(решение утеряно, напишу 1ю часть, потом пропишу это!)

Б-2.1.23 Расплывание волнового пакета

Используя оператор координаты свободной частицы в представлении Гейзенберга, найти закон движения и "расплывания" волнового пакета.

Solution..

(просто посмотрю ответы, слишком мало еще работал над этим, чтобы самому думать было легко.)

ПТФ-2.y1. (10 б). Среднее спина

Вычислите среднее значение спина $\langle \vec{S} \rangle$ и его дисперсию $\langle (\vec{S} - \langle \vec{S} \rangle)^2 \rangle$ для чистого $|\chi\rangle = \frac{|\uparrow\rangle + |\downarrow\rangle}{\sqrt{2}}$ и смешанного $\hat{\rho} = \frac{\hat{\mathbb{P}}_\uparrow + \hat{\mathbb{P}}_\downarrow}{2}$ состояний спина $1/2$.

Комментарий: первая величина – это вектор, а вторая – это скаляр, длина вектора. *Указание*: Для частицы со спином $1/2$ (например, электрон) *оператор спина* (собственного момента) равен $\hat{\vec{S}} = \frac{\hbar}{2}\hat{\vec{\sigma}}$ (то есть $\hat{S}_x = (\hbar/2)\hat{\sigma}_x$ и т. д.).

Solution.

Решим упражнение для чистого состояния:

$$|\chi\rangle\langle\chi| = \frac{1}{2}(|\uparrow\rangle\langle\uparrow| + |\uparrow\rangle\langle\downarrow| + |\downarrow\rangle\langle\uparrow| + |\downarrow\rangle\langle\downarrow|) = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}$$

$$\langle \hat{S}_x \rangle = \mathrm{Tr}(|\chi\rangle\langle\chi|\hat{S}_x) = \frac{\hbar}{4}\mathrm{Tr}\left(\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\right) = \frac{\hbar}{2}$$

$$\langle \hat{S}_y \rangle = \mathrm{Tr}(|\chi\rangle\langle\chi|\hat{S}_y) = \frac{\hbar}{4}\mathrm{Tr}\left(\begin{pmatrix}1 & 1\\ 1 & 1\end{pmatrix}\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix}\right) = 0$$

$$\langle \hat{S}_z \rangle = \mathrm{Tr}(|\chi\rangle\langle\chi|\hat{S}_z) = \frac{\hbar}{4}\mathrm{Tr}\left(\begin{pmatrix}1 & 1\\ 1 & 1\end{pmatrix}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\right) = 0$$

Среднее значение спина:

$$\langle \vec{S} \rangle = \frac{\hbar}{2}\begin{pmatrix}1\\0\\0\end{pmatrix}$$

$$\vec{S}^2 = \frac{\hbar^2}{4}(\sigma_x^2 + \sigma_y^2 + \sigma_z^2) = \frac{3\hbar^2}{4}$$

$$\langle \vec{S} \rangle^2 = \frac{3\hbar^2}{4}$$

Дисперсия:

$$\langle \vec{S}^2 \rangle - \langle \vec{S} \rangle^2 = \frac{\hbar^2}{2}$$

Решим упражнение для смешанного состояния:

$$\hat{\rho} = \frac{\hat{\mathbb{P}}_\uparrow + \hat{\mathbb{P}}_\downarrow}{2} = \frac{1}{2}(|\uparrow\rangle]\langle\uparrow| + |\downarrow\rangle]\langle\downarrow|) = \frac{1}{2}\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}$$

$$\langle \hat{S}_x \rangle = \mathrm{Tr}(|\chi\rangle\langle\chi|\hat{S}_x) = \frac{\hbar}{4}\mathrm{Tr}\left(\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}\right) = 0$$

$$\langle \hat{S}_y \rangle = \mathrm{Tr}(|\chi\rangle\langle\chi|\hat{S}_y) = \frac{\hbar}{4}\mathrm{Tr}\left(\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}\begin{pmatrix}0 & -i\\ i & 0\end{pmatrix}\right) = 0$$

$$\langle \hat{S}_z \rangle = \mathrm{Tr}(|\chi\rangle\langle\chi|\hat{S}_z) = \frac{\hbar}{4}\mathrm{Tr}\left(\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\right) = 0$$

Среднее значение спина:

$$\langle \vec{S} \rangle = 0$$

$$\vec{S}^2 = \frac{\hbar^2}{4}(\sigma_x^2 + \sigma_y^2 + \sigma_z^2) = \frac{3\hbar^2}{4}$$

$$\langle \vec{S} \rangle^2 = 0$$

Дисперсия:

$$\langle \vec{S}^2 \rangle - \langle \vec{S} \rangle^2 = \frac{3\hbar^2}{4}$$

19.1.2 Problems about formalism of second quantization

(похожее в конд средах. about how to construct, unsertand and extract basic physics from such models?)

19.1.3 Problems about Angular Momentum and Spin

ЛЛ3-54 Наклонная проекция спина

Частица со спином 1/2 находится в состоянии с определенным значением $s_z = 1/2$. Определить вероятности возможных значений проекции спина на ось z', наклоненную под углом θ к оси z.

Solution..

Средний вектор спина $\bar{\mathbf{s}}$ направлен, очевидно, по оси z и равен по величине 1/2. Проецируя его на ось z', найдем, что среднее значение спина в направлении z' есть $\bar{s}_{z'} = \frac{1}{2}\cos\theta$. С другой стороны, имеем $\bar{s}_{z'} = \frac{1}{2}w_+ - \frac{1}{2}w_-$, где $w_\pm$ - вероятности значений $s_{z'} = \pm 1/2$. Учитывая также, что $w_+ + w_- = 1$, получаем

$$w_+ = \cos^2(\theta/2), \quad w_- = \sin^2(\theta/2).$$

ЛЛ-28.1 Усреднение по l (?????)

Усреднить тензор $n_i n_k - \frac{1}{3}\delta_{ik}$ (где $\mathbf{n}$ - единичный вектор в направлении радиуса-вектора частицы) по состоянию с заданной абсолютной величиной вектора l, но не его направлением (т. е. неопределенным l_z).

Solution.

(???? видимо, я l не так глубоко еще понимаю??)

Искомое среднее значение есть оператор, который может выражаться лишь через оператор $\widehat{1}$. Ищем его в виде

$$\overline{n_i n_k} - \frac{1}{3}\delta_{ik} = a\left[\widehat{l}_i\widehat{l}_k + \widehat{l}_k\widehat{l}_i - \frac{2}{3}\delta_{ik}l(l+1)\right];$$

это есть наиболее общий вид составленного из компонент $\hat{\mathbf{l}}$ симметричного тензора второго ранга с равным нулю следом.

Для определения постоянной a умножаем написанное равенство слева на $\widehat{l}_i$, и справа на $\widehat{l}_k$ (с суммированием по i и k) (??? почему так??). Поскольку вектор $\mathbf{n}$ перпендикулярен к вектору $\hbar\widehat{\mathbf{l}} = [\widehat{\mathbf{r}}\widehat{\mathbf{p}}]$, то $n_i\widehat{l}_i = 0$. Произведение $\widehat{l}_i\widehat{l}_i\widehat{l}_k\widehat{l}_k = \left(\widehat{\mathbf{l}}^2\right)^2$ заменяем его собственным значением $l^2(l+1)^2$, а произведение $\widehat{l}_i\widehat{l}_k\widehat{l}_i\widehat{l}_k$ преобразуем с помощью соотношений коммутации (26.7) следующим образом:

$$\widehat{l}_i\widehat{l}_k\widehat{l}_i\widehat{l}_k = \widehat{l}_i\widehat{l}_i\widehat{l}_k\widehat{l}_k - ie_{ikl}\widehat{l}_i\widehat{l}_l\widehat{l}_k = \left(\widehat{\mathbf{l}}^2\right)^2 - \frac{i}{2}e_{ikl}\widehat{l}_i\left(\widehat{l}_l\widehat{l}_k - \widehat{l}_k\widehat{l}_l\right) =$$
$$= \left(\widehat{\mathbf{l}}^2\right)^2 + \frac{1}{2}e_{ikl}e_{lkm}\widehat{l}_i\widehat{l}_m = \left(\widehat{\mathbf{l}}^2\right)^2 - \widehat{\mathbf{l}}^2 = l^2(l+1)^2 - l(l+1)$$

(мы воспользовались $e_{ikl}e_{mkl} = 2\delta_{im}$). После простого приведения получим в результате

$$a = -\frac{1}{(2l-1)(2l+3)}$$

Б-2.4.1 Раскрытие коммутаторов

Раскрыть коммутаторы

а) $\left[\hat{l}_i, \hat{\mathbf{r}}^2\right]$; б) $\left[\hat{l}_i, \hat{\mathbf{p}}^2\right]$; в) $\left[\hat{l}_i, (\hat{\mathbf{r}}\mathbf{p})\right]$; г) $\left[\hat{l}_i, (\hat{\mathbf{p}}\hat{\mathbf{r}})\hat{\mathrm{p}}_k\right]$;

д) $\left[\hat{l}_i, \hat{\mathrm{p}}_k\hat{\mathrm{p}}_l\right]$; е) $\left[\hat{l}_z, \hat{l}_\pm\right]$; ж) $\left[\hat{I}_+, \hat{I}_-\right]$; з) $\left[\hat{l}_i, \hat{p}_k\right]$; и) $\left[\hat{l}_i, \hat{\mathrm{x}}_k\right]$; к) $\left[\hat{l}_i, f(r)\right]$.

Solution.

(потом подумаю еще раз)

2.4.1. а) 0 ; б) 0 ; в) 0 ; г) $i(\hat{\mathrm{p}}\hat{\mathrm{r}})e_{ikj}\hat{\mathrm{p}}_j$; д) $i\left(e_{ikj}\hat{\mathrm{p}}_j\hat{\mathrm{p}}_l + e_{ilj}\hat{\mathrm{p}}_k\hat{\mathrm{p}}_j\right)$; е) $\pm\hat{I}_{\pm}$;ж) $2\hat{I}_z$; 3) $ie_{ikj}\hat{\mathrm{p}}_j$; и) $ie_{ikj}\hat{x}_j$; к) 0.

Равенство нулю результатов в п.п. а), б), в), и к) связано с тем, что они отвечают коммутаторам $\hat{1}_i$ со скалярными операторами. Такие операторы не преобразуются при поворотах системы координат, а оператор $\hat{I}_i$ описывает преобразование векторов состояний именно при таких поворотах.

Одинаковая структура результатов в п.п. з) и и) есть следствие того, что $\hat{x}_k$ и $\hat{p}_k$ являются компонентами векторных операторов, т. е. преобразуются при поворотах, как компоненты векторов (см. также задачу 2.4.9).

Б-2.4.2 Следы (??)

Найти $\mathrm{Tr}\,\hat{l}_i$, используя коммутационные соотношения и свойство следа $\mathrm{Tr}(\hat{\mathrm{A}}\hat{\mathrm{B}}) = \mathrm{Tr}(\hat{\mathrm{B}}\hat{\mathrm{A}})$.

Solution.

(потом подумаю еще раз)

У нас оператор орбитального момента это как раз коммутатор, а след коммутатора равен нулю: $\mathrm{Tr}\,\hat{l}_i = 0$.

Б-2.4.3 Квадрат орбитального момента

Доказать, что собственные значения оператора $\hat{l}^2$ равны $l(l+1)$, исходя из того, что все координатные оси равноправны и возможные значения проекции m на данную ось равновероятны.

Solution.

Поскольку все оси координат равноправны, то

$$\langle \hat{\mathbf{I}}^2 \rangle = \langle \hat{I}_x^2 \rangle + \langle \hat{I}_y^2 \rangle + \langle \hat{I}_z^2 \rangle = 3\langle \hat{I}_z^2 \rangle.$$

Далее, исходя из равновероятности различных значений $\hat{l}_z$ имеем

$$\langle \hat{I}_z^2 \rangle = \frac{1}{2l+1} \sum_{m=-l}^{l} m^2 = \frac{2}{2l+1} \sum_{m=0}^{l} m^2 = \frac{l(l+1)}{3}.$$

Окончательно получаем, что $\mathbf{1}^2 = \langle \hat{I}^2 \rangle = l(l+1)$.

Б-2.4.4 Минимизация соотношением неопределённостей

Используя соотношение неопределённостей для $\hat{M}_x$ и $\hat{M}_y$, определить минимальное значение выражения

$$\langle l, l | \hat{M}_x^2 + \hat{M}_y^2 | l, l \rangle.$$

Solution.

Исходя из $\left[\hat{M}_x, \hat{M}_y\right] = i\hbar \hat{M}_z$ получаем (в соответствии с Б-2.1.9)

$$\langle \Delta \hat{M}_x^2 \rangle_{\min} \langle \Delta \hat{M}_y^2 \rangle_{\min} = \frac{\hbar^2}{4} \langle \hat{M}_z \rangle^2 = \frac{\hbar^2}{4} \hbar^2 l^2,$$

ибо усреднение проводится по состоянию $|l, l\rangle$. В силу симметрии задачи относительно осей x и y можно считать $\langle \Delta \hat{M}_x^2 \rangle_{\min} = \langle \Delta \hat{M}_y^2 \rangle_{\min}$, откуда

$$\langle \Delta \hat{M}_x^2 \rangle_{\min} = \frac{\hbar^2}{2} l,$$

Учитывая также, что $\langle \hat{M}_x \rangle = \langle \hat{M}_y \rangle = 0$ (см. Б-2.4.6), имеем $\langle \hat{M}_x \rangle$ и окончательно получаем

$$\langle l, l | \hat{M}_x^2 + \hat{M}_y^2 | l, l \rangle_{\min} = \hbar^2 \left(\frac{l}{2} + \frac{l}{2} \right) = \hbar^2 l$$

Б-2.4.5 Экспоненты и $\hat{l}$ (?)

Преобразовать оператор $e^{i\alpha L \hat{l}_z} \hat{l}_\pm e^{-i\alpha \hat{l}_z}$.

Solution.

(проделаю потом)
Использовать результаты задач 2.1.17 и 2.4.1.
Ответ: $e^{\pm i\alpha} \hat{I}_\pm$.

Б-2.4.6 Свойства проекций орбитального момента

Показать, что в состоянии $|l, m\rangle$ (определена проекция на ось z) выполняются соотношения:
а) $\langle \hat{I}_x \rangle = \langle \hat{I}_y \rangle = 0$;
б) $\langle \hat{I}_x \hat{I}_y \rangle = -\langle \hat{I}_y \hat{I}_x \rangle = \frac{im}{2}$
в) $\langle \hat{I}_x^2 \rangle = \langle \hat{I}_y^2 \rangle = \langle \Delta \hat{I}_x^2 \rangle = \frac{1}{2} \left[l(l+1) - m^2 \right]$.

Solution.

Поскольку

$$\hat{I}_{\pm}|l,m\rangle = \sqrt{l(l+1)-m(m\pm 1)}|l,m\pm 1\rangle$$

то $\langle \hat{I}_{\pm}\rangle \sim \langle l,m|l,m\pm 1\rangle = 0$. Отсюда получаем $\langle \hat{I}_x\rangle \pm i\langle \hat{I}_y\rangle = 0$, поэтому $\langle \hat{I}_x\rangle = \langle \hat{I}_y\rangle = 0$. Далее, из соотношения (1) имеем $\langle \hat{I}_{\pm}^2\rangle = 0$, откуда

$$\langle \hat{I}_x^2 - \hat{I}_y^2\rangle \pm i\langle \hat{I}_x\hat{I}_y + \hat{I}_y\hat{I}_x\rangle = 0,$$

и поэтому $\langle \hat{I}_x^2\rangle = \langle \hat{i}_y^2\rangle, \langle \hat{I}_x\hat{I}_y + \hat{I}_y\hat{I}_x\rangle = 0$. Исходя из этого и учитывая также, что $\langle \hat{I}_x\hat{I}_y - \hat{I}_y\hat{I}_x\rangle = i\langle \mathbb{1}_z\rangle$, получаем $\langle \hat{I}_x\hat{I}_y\rangle = -\langle \hat{I}_y\hat{I}_x\rangle = im/2$.

Из $\langle \hat{I}_x^2 + \hat{I}_y^2\rangle = \langle \hat{I}^2 - \hat{I}_z^2\rangle$, нетрудно получить утверждение в) данной задачи.

Б-2.4.7 Матрицы для $l = 1$

Для системы с $l = 1$ найти матрицы операторов $\hat{l}^2, \hat{l}_z, \hat{l}_+, \hat{l}_-, \hat{l}_x, \hat{l}_y$.

Solution.

Известно, что

$$\langle l,m'|\hat{1}_{\pm}|l,m\rangle = \sqrt{l(l+1)-m(m\pm 1)}\delta_{m',m\pm 1}.$$

Подставляя сюда разные для $l = 1$ разные m, получаем матрицы $\hat{l}_+, \hat{l}_-$, из них $\hat{l}_x, \hat{l}_y$. Также формулы $\langle l,m'|\hat{l}_z|l,m\rangle = m\delta_{m',m}$, и $\langle l,m'|\hat{\mathbb{1}}^2|l,m\rangle = l(l+1)\delta_{m',m}$ дают $\hat{l}^2$ и $\hat{l}_z$, которые диагональны. В итоге:

$$\hat{l}_+ = \sqrt{2}\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \quad \hat{l}_- = \sqrt{2}\begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix},$$

$$\hat{l}_x = \frac{1}{\sqrt{2}}\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad \hat{l}_y = \frac{i}{\sqrt{2}}\begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, \qquad \hat{l}_z = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \quad \hat{1}^2 = 2\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Б-2.4.8

Найти собственные значения и собственные векторы оператора $\hat{\mathrm{j}}_n = (\hat{\mathrm{j}n})$ для квантовой системы с угловым моментом $j = 1$, где $\mathbf{n}$ - единичный вектор с составляющими $\mathbf{n} = \{\sin\theta\cos\varphi, \sin\theta\sin\varphi, \cos\theta\}$.

Solution.

Б-2.4.9

Исходя из свойств оператора момента $\hat{\mathbf{j}}$ и векторного оператора $\hat{\mathbf{A}}$ при преобразованиях поворота, получить коммутационные соотношения

$$\left[\hat{\mathrm{j}}_i, \hat{\mathrm{A}}_k\right] = ie_{ikl}\hat{\mathrm{A}}_l.$$

Solution.

Б-2.4.10 Коммутаторы с $\hat{j}^2$

Доказать тождества

$$\left[\hat{\mathbf{j}}^2, \hat{\mathbf{A}}\right] = i\left(|\hat{\mathbf{A}}\times\hat{\mathbf{j}}] - [\hat{\mathbf{j}}\times\hat{\mathbf{A}}]\right);$$

$$\left[\hat{\mathbf{j}}^2, \left[\hat{\mathbf{j}}^2, \hat{\mathbf{A}}\right]\right] = 2\left(\hat{\mathbf{j}}^2\hat{\mathbf{A}} + \hat{\mathbf{A}}\hat{\mathbf{j}}^2\right) - 4\hat{\mathbf{j}}(\hat{\mathbf{j}}\hat{\mathbf{A}}),$$

где $\hat{\mathbf{j}}$ - оператор момента, а $\hat{\mathbf{A}}$ - произвольный векторный оператор, т. е. $\left[\hat{\mathrm{j}}_i, \hat{\mathrm{A}}_k\right] = ie_{ikl}\hat{\mathrm{A}}_l$.

Solution.

(как-то скучно это решать, когда-то порешаю, есть задачи интереснее и актуальнее)

Б-2.4.11 Найти собственные функции и собственные значения матриц Паули.

Solution.

(?? разве из определения это не очевидно?)

Б-2.4.12 Вектор поляризации

Вектор поляризации спина $\mathbf{P}$ определяется как вектор с компонентами $\mathrm{P}_i = \langle\hat{\sigma}_i\rangle = \langle\chi|\hat{\sigma}_i|\chi\rangle = \chi^+\hat{\sigma}_i\chi$, где χ - спиновая функция данного состояния. В состояниях а) $\chi = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$ и б) $\chi = \begin{pmatrix} \cos\theta/2 \\ e^{i\delta}\sin\theta/2 \end{pmatrix}$ найти P_i и $|\mathbf{P}|$.

Solution.

Б-2.4.13

Получить соотношение $\hat{\sigma}_i\hat{\sigma}_k = \hat{1}\delta_{ik} + ie_{ikl}\hat{\sigma}_l$.

Б-2.4.14

Доказать, что $(\hat{\sigma}\mathbf{A})(\hat{\sigma}\mathbf{B}) = (\mathbf{AB}) + i(\hat{\sigma}[\mathbf{A}\times\mathbf{B}])$, где $\mathbf{A}$ и $\mathbf{B}$ - обычные (не спиновые) векторные операторы.

Б-2.4.15

Вычислить $\hat{\sigma}_\pm^2$ и антикоммутаторы $\{\hat{\sigma}_\pm, \hat{\sigma}_x\}, \{\hat{\sigma}_\pm, \hat{\sigma}_y\}, \{\hat{\sigma}_\pm, \hat{\sigma}_z\}$.

Б-2.4.16

Вычислить $\mathrm{Tr}\,\hat{\sigma}_i\hat{\sigma}_k, \mathrm{Tr}\,\hat{\sigma}_i\hat{\sigma}_k\hat{\sigma}_l$.

Б-2.4.17

Вычислить $(\hat{\sigma}\mathbf{a})^k$, где $\mathbf{a}$ - обычный вектор.

Б-2.4.18

Найти явный вид оператора $\exp[i\alpha(\hat{\sigma}\mathbf{n})]$.

Б-2.4.19

Найти собственные значения и собственные функции спинового оператора $\hat{\sigma}_n = (\hat{\sigma}\mathbf{n}_0)$, где $\mathbf{n}_0$ - единичный вектор с составляющими $\mathbf{n}_0 = \{\sin\theta_0\cos\varphi_0, \sin\theta_0\sin\varphi_0, \cos\theta_0\}$.

Б-2.4.20 Поворот спинора

Записать оператор, преобразующий спинор (спиновую волновую функцию ψ) при повороте системы координат на угол α вокруг оси с направлением, заданным единичным вектором $\mathbf{n}$. Найти явный вид оператора преобразования спинора при повороте системы координат, при котором ось z совмещается с направлением $\mathbf{n}_0 = \{\sin\theta_0\cos\varphi_0, \sin\theta_0\sin\varphi_0, \cos\theta_0\}$.

Solution.

(!??!?!!! добавлю в 1ю часть это!!!)

Искомый оператор преобразования спинора имеет вид $\hat{R}(\alpha\mathbf{n}) = \exp\left[i\frac{\alpha}{2}(\hat{\sigma}\mathbf{n})\right]$ (см. (II.23)).

Для того, чтобы ось z оказалась совмещенной с направлением вектора $\mathbf{n}_0$, необходимо осуществить поворот системы координат на угол θ_0 вокруг оси с направлением, заданным единичным вектором n, лежащим в плоскости xOy, а также перпендикулярным оси z и вектору $\mathbf{n}_0$. Несложный расчет показывает, что $\mathbf{n} = \{-\sin\varphi_0, \cos\varphi_0, 0\}$. Поэтому матрица оператора преобразования спинора будет иметь вид

$$\hat{\mathrm{R}}\,(\theta_0\mathbf{n}) = \exp\left[i\frac{\theta_0}{2}(\hat{\sigma}\mathbf{n})\right] = \cos\frac{\theta_0}{2} - i\sin\frac{\theta_0}{2}\,(\sin\varphi_0\hat{\sigma}_x - \cos\varphi_0\hat{\sigma}_y) = \begin{pmatrix} \cos\frac{\theta_0}{2} & \sin\frac{\theta_0}{2}e^{-i\varphi_0} \\ -\sin\frac{\theta_0}{2}e^{i\varphi_0} & \cos\frac{\theta_0}{2} \end{pmatrix}.$$

Действуя оператором $\hat{\mathrm{R}}$ на функции $\Psi_{\pm1}$ предыдущей задачи, получим с точностью до общего фазового множителя $\chi_{\pm1/2}$ (см. (II.26)).

Б-2.4.21

Используя результат предыдущей задачи, найти волновые функции частицы со спином $1/2$ в случае, когда проекция ее спина на направление $\mathbf{n}_0 = \{\sin\theta_0\cos\varphi_0, \sin\theta_0\sin\varphi_0, \cos\theta_0\}$ равна соответственно $\pm1/2$. Сравнить с результатом задачи 2.4.19.

Solution.

Б-2.4.23 Два поворота

Используя результат задачи 2.4.20, решить следующую геометрическую задачу: система координат поворачивается на угол φ_1 вокруг оси $\mathbf{n}_1$ и затем на угол φ_2 вокруг оси $\mathbf{n}_2$. Найти угол и направление оси вращения для результирующего поворота.

Solution.

Б-2.4.24 Матрицы со спином 1

Записать спиновые матрицы $\hat{\mathrm{S}}_x, \hat{\mathrm{S}}_y, \hat{\mathrm{S}}_z$ для частицы со спином 1 (взяв в качестве базиса состояния с определенной проекцией спина на ось z).

Solution.

(это в 1й уже написано, но все-таки еще раз решу! как ничего не помня это найти? додумаю потом. мб так же, как и с орбитальным моментам, одинаковые ведь матрицы?)

Б-2.4.25 Проекции 3D спина (!??!?!??)

Используя матрицы $\hat{\mathrm{S}}_x, \hat{\mathrm{S}}_y, \hat{\mathrm{S}}_z$, найти для частицы со спином 1 спиновую функцию состояния, отвечающего проекции спина $+1$ на направление $\mathrm{n}_0 = \{\sin\theta_0\cos\varphi_0, \cdots\}$. Найти вероятности различных проекций на ось z в этом состоянии. Исследовать специально случай θ_0, близких к нулю и к π, а также к $\pi/2$. Чем отличаются при $\theta_0 = \pi/2$ состояния со спином вдоль оси $x\,(\varphi_0 = 0)$ и со спином по оси $y\,(\varphi_0 = \pi/2)$?

Solution.

(!! додумаю скоро!)

2.4.25. Спиновая функция состояния, отвечающая проекции спина $+1$ на ось $\mathbf{n_0}$, совпадает с функцией ψ_1, найденной в решении задачи 2.4.8 для орбитального момента $l = 1$. Вероятности различных проекций спина на ось z в этом состоянии:

$$w(\pm1) = \frac{1}{4}\,(1 \pm \cos\theta_0)^2\,, \quad w(0) = \frac{1}{2}\sin^2\theta_0.$$

При $\theta_0 \to 0$ и $\theta_0 \to \pi$ функция переходит в $\begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$ и $\begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$ - функции, описывающие состояния с проекцией спина на ось z, равной ± 1. При $\theta_0 \to \pi/2, \varphi_0 \to 0$ и $\varphi_0 \to \pi/2$ решение переходит в $\frac{1}{2}\begin{pmatrix} 1 \\ \sqrt{2} \\ 1 \end{pmatrix}$ и $\frac{1}{2}\begin{pmatrix} -i \\ \sqrt{2} \\ i \end{pmatrix}$ - функции, описывающие состояния, в которых проекция спина на оси x и у равна $+1$.

19.1.4 Problems about Mathematical Properties of Quantum Mechanical Operators

(начало белоусова и любого типичного курса)

Киселев-л2.1.2. Тождество с коммутаторами

Докажите операторное тождество $\mathrm{e}^{A} B \mathrm{e}^{-A} = B + \sum\limits_{n=1}^{\infty} \underbrace{[A,[A,...[A,B]...]]}_{n}$.

Solution..

Нам полезно рассмотреть операторную функцию $F(\lambda) := \mathrm{e}^{\lambda A} B \mathrm{e}^{-\lambda A}$, возьмем его производную по λ в нуле:

$$\left.\frac{\mathrm{d}^n F(\lambda)}{\mathrm{d}\lambda^n}\right|_{\lambda=0} = \left.\sum_{k=0}^{n} C_n^k A^k \mathrm{e}^{\lambda A} B \mathrm{e}^{-\lambda A} A^{n-k} (-1)^{n-k}\right|_{\lambda=0} = \sum_{k=0}^{n} C_n^k A^k B A^{n-k} (-1)^{n-k},$$

где $C_n^k = n!/k!(n-k)!$ - комбинаторное число вариантов дифференцирования, т. е. коэффициент бинома Ньютона.

Поэтому искомый оператор имеет вид:

$$\mathrm{e}^{A} B \mathrm{e}^{-A} = F(1) = \sum_{n=0}^{\infty} \frac{1}{n!} \sum_{k=0}^{n} C_n^k A^k B A^{n-k} (-1)^{n-k}.$$

При $n = 0$ коэффициент C_0^0 равен 1 и

$$\sum_{k=0}^{0} A^k B A^{n-k} (-1)^{n-k} = B.$$

Докажем методом индукции равенство

$$\sum_{k=0}^{n} C_n^k A^k B A^{n-k} (-1)^{n-k} = \underbrace{[A,[A,...[A,B]...]}_{n}.$$

Действительно, при $n = 1$ находим тождество

$$\sum_{k=0}^{1} C_1^k A^k B A^{n-k} (-1)^{n-k} = -BA + AB \equiv [A,B].$$

Пусть при $n = m \geqslant 1$ верно равенство

$$\sum_{k=0}^{m} C_m^k A^k B A^{m-k} (-1)^{m-k} = \underbrace{[A,[A,...[A,B]...]}_{m},$$

тогда при $n = m+1$ заметим прежде всего, что $C_{m+1}^k = \frac{m!}{k!(m-k)!} \frac{(m+1-k)+k}{m+1-k} = C_m^k + C_m^{k-1}$, причем это тождество справедливо при $k = m+1$, когда следует положить $C_m^{m+1} = 0$, и при $k = 0$, когда мы полагаем

$C_m^{-1}=0$. (???? подумаю про это потом!!) Тогда

$$\sum_{k=0}^{m+1} C_{m+1}^k A^k B A^{m+1-k}(-1)^{m+1-k} = \sum_{k=0}^{m} C_m^k A^k B A^{m+1-k}(-1)^{m+1-k} + \sum_{k=1}^{m+1} C_m^{k-1} A^k B A^{m-(k-1)}(-1)^{m-(k-1)} =$$
$$= -\left(\sum_{k=0}^{m} C_m^k A^k B A^{m-k}(-1)^{m-k}\right) A + A\left(\sum_{k=0}^{m} C_m^k A^k B A^{m-k}(-1)^{m-k}\right) =$$
$$= [A, \underbrace{[A,[A,...[A,B]...]}_{m}] = \underbrace{[A,[A,...[A,B]...]}_{(m+1)},$$

т. е. мы получаем верное равенство. Таким образом, утверждение доказано.

Киселев-л2.1.3. Экспоненты и операторы

Докажите операторное тождество для любой операторной функции $F(B)$:

$$\mathrm{e}^{A} F(B) \mathrm{e}^{-A} = F\left(\mathrm{e}^{A} B \mathrm{e}^{-A}\right).$$

Solution..

Согласно общему определению функция от оператора записывается в виде ряда Тейлора

$$F(B) = \sum_{n=0}^{\infty} \frac{1}{n!} F^{(n)}(0) B^n,$$

так что рассмотрим выражение

$$\mathrm{e}^{A} B^n \mathrm{e}^{-A} = \underbrace{\mathrm{e}^{A} B \mathrm{e}^{-A} ... \mathrm{e}^{A} B \mathrm{e}^{-A}}_{n} = \left(\mathrm{e}^{A} B \mathrm{e}^{-A}\right)^n,$$

где мы учли, что $\mathrm{e}^{A}\mathrm{e}^{-A} = \mathbb{1}$. Значит, действительно,

$$\mathrm{e}^{A} F(B) \mathrm{e}^{-A} = \sum_{n=0}^{\infty} \frac{1}{n!} F^{(n)}(0) \left(\mathrm{e}^{A} B \mathrm{e}^{-A}\right)^n = F\left(\mathrm{e}^{A} B \mathrm{e}^{-A}\right)$$

(??? еще чуть подумаю об этом.)

Киселев-л2.1.4. Коммутаторы и перестановки

Докажите, что для операторов A и B, перестановочных со своим коммутатором $[A,B]$, имеют место равенства

$$\mathrm{e}^{A}\mathrm{e}^{B} = \mathrm{e}^{[A,B]}\mathrm{e}^{B}\mathrm{e}^{A}$$

и

$$\left(\mathrm{e}^{A}\mathrm{e}^{B}\right)^n = \mathrm{e}^{\frac{1}{2}n(n+1)[A,B]}\mathrm{e}^{nB}\mathrm{e}^{nA}.$$

Solution..

Известно, что для любой операторной функции $\mathrm{e}^{A} F(B) \mathrm{e}^{-A} = F\left(\mathrm{e}^{A} B \mathrm{e}^{-A}\right)$, поэтому

$$\mathrm{e}^{A}\mathrm{e}^{B} = \mathrm{e}^{A}\mathrm{e}^{B}\mathrm{e}^{-A}\mathrm{e}^{A} = \exp\left(\mathrm{e}^{A} B \mathrm{e}^{-A}\right)\mathrm{e}^{A}.$$

А также известно, что $\mathrm{e}^{A} B \mathrm{e}^{-A} = B + \sum_{n=1}^{\infty} \frac{1}{n!} \underbrace{[A,[A,...[A,B]...]}_{n}$, и тут по условию задачи обрывается на первом слагаемом:

$$\mathrm{e}^{A} B \mathrm{e}^{-A} = B + [A,B]$$

Поэтому,

$$\mathrm{e}^{A}\mathrm{e}^{B} = \mathrm{e}^{B+[A,B]}\mathrm{e}^{A} = \mathrm{e}^{[A,B]}\mathrm{e}^{B}\mathrm{e}^{A},$$

поскольку $[B,[A,B]] = [A,[A,B]] = 0$, и первая часть утверждения доказана.

(??? дальше я уже не соображаю, потом заново подумаю.)
Далее,

$$\left(\mathrm{e}^{A}\mathrm{e}^{B}\right)^{n}=\left(\mathrm{e}^{A}\mathrm{e}^{B}\right)^{n-1}\mathrm{e}^{A}\mathrm{e}^{B}=\left(\mathrm{e}^{A}\mathrm{e}^{B}\right)^{n-1}\mathrm{e}^{[A,B]}\mathrm{e}^{B}\mathrm{e}^{A}=\mathrm{e}^{[A,B]}\left(\mathrm{e}^{A}\mathrm{e}^{B}\right)^{n-1}\mathrm{e}^{B}\mathrm{e}^{A}.$$

Эту цепочку можно продолжить, поскольку аналогичным образом

$$\left(\mathrm{e}^{A}\mathrm{e}^{B}\right)^{n-1}\mathrm{e}^{B}\mathrm{e}^{A}=\mathrm{e}^{[A,B]}\left(\mathrm{e}^{A}\mathrm{e}^{B}\right)^{n-2}\mathrm{e}^{B}\left(\mathrm{e}^{A}\mathrm{e}^{B}\right)\mathrm{e}^{A}=\mathrm{e}^{2[A,B]}\left(\mathrm{e}^{A}\mathrm{e}^{B}\right)^{n-2}\mathrm{e}^{2B}\mathrm{e}^{2A}.$$

Уже доказано, что

$$\mathrm{e}^{A}\mathrm{e}^{kB}=\mathrm{e}^{k[A,B]}\mathrm{e}^{kB}\mathrm{e}^{A},$$

где k - число. Значит, продолжая понижать степень так, как это было сделано выше, находим

$$\left(\mathrm{e}^{A}\mathrm{e}^{B}\right)^{n}=\mathrm{e}^{\sum\limits_{k=1}^{m}k[A,B]}\left(\mathrm{e}^{A}\mathrm{e}^{B}\right)^{n-m}\mathrm{e}^{mB}\mathrm{e}^{mA}=\mathrm{e}^{\frac{1}{2}n(n+1)[A,B]}\mathrm{e}^{nB}\mathrm{e}^{nA},$$

где мы использовали известное выражение для суммы арифметической прогрессии.

Киселев-л2.1.5. Тождество Бейкера-Хаусдорфа

Докажите, что для операторов A и B, перестановочных со своим коммутатором $[A,B]$, имеет место тождество Бейкера-Хаусдорфа

$$\mathrm{e}^{A+B}=\mathrm{e}^{\frac{1}{2}[A,B]}\mathrm{e}^{B}\mathrm{e}^{A}.$$

Solution..

Вычислим $\exp(A+B)$ как предел

$$\mathrm{e}^{A+B}=\lim_{n\to\infty}\left(1+\frac{1}{n}(A+B)\right)^{n}=\lim_{n\to\infty}\left(\mathrm{e}^{A/n}\mathrm{e}^{B/n}\right)^{n},$$

где порядок сомножителей под знаком степени, конечно, можно было выбрать и обратным, что не умаляет общности дальнейшего рассмотрения. В предыдущей задаче мы показали, что

$$\left(\mathrm{e}^{A/n}\mathrm{e}^{B/n}\right)^{n}=\mathrm{e}^{\frac{1}{2}n(n+1)\frac{1}{n^2}[A,B]}\mathrm{e}^{B}\mathrm{e}^{A},$$

так что

$$\mathrm{e}^{A+B}=\lim_{n\to\infty}\mathrm{e}^{\frac{1}{2}n(n+1)\frac{1}{n^2}[A,B]}\mathrm{e}^{B}\mathrm{e}^{A}=\mathrm{e}^{\frac{1}{2}[A,B]}\mathrm{e}^{B}\mathrm{e}^{A}$$

Б-2.1.14

Раскрыть коммутаторы $\left[\hat{\mathrm{p}}_x,f(r)\right]$, $\left[\hat{\mathrm{p}}_x^2,f(r)\right]$, $\left[\hat{x},\exp\left(\frac{i}{\hbar}a\hat{\mathrm{p}}_x\right)\right]$, где $r=\sqrt{x^2+y^2+z^2}$.

Solution.

Б-2.1.15 оператор скорости

Получить выражение для оператора скорости частицы массы m.

Solution.

Б-2.1.16 Оператор эволюции и разная координата

Показать, что $\langle\mathbf{r}|U(\hat{\mathbf{r}})|\mathbf{r}'\rangle=U(\mathbf{r})\delta\left(\mathbf{r}-\mathbf{r}'\right)$.

Solution.

Б-2.1.17

Доказать справедливость соотношения ($[\hat{\mathrm{A}},\hat{\mathrm{B}}]\neq 0$)

$$e^{\xi\hat{\mathrm{A}}}\hat{\mathrm{B}}e^{-\xi\hat{\mathrm{A}}}=\hat{\mathrm{B}}+\xi[\hat{\mathrm{A}},\hat{\mathrm{B}}]+\frac{1}{2!}\xi^2[\hat{\mathrm{A}},[\hat{\mathrm{A}},\hat{\mathrm{B}}]]+...$$

Solution.

Б-2.1.18

Чему равен оператор

$$\exp\left(\frac{i}{\hbar}\mathbf{a}\hat{\mathbf{p}}\right)\hat{U}(\mathbf{r})\exp\left(-\frac{i}{\hbar}\mathbf{a}\hat{\mathbf{p}}\right),$$

где a - постоянный вектор?

Solution.

Б-2.1.19.

Оператор трансляции $\hat{T}_{\mathbf{a}}$ действует на векторы состояний с определенной координатой $|\mathbf{r}\rangle$ следующим образом: $\hat{T}_{\mathbf{a}}|\mathbf{r}\rangle = |\mathbf{r}-\mathbf{a}\rangle$. Как действует этот оператор на произвольный вектор состояния $|\psi\rangle$?

Solution.

19.1.5 Problems about Models of Many-Body Systems (!?!?!!)

Leuven-s7.ex3: Two fermions in a 1D well

Consider two spin- 1/2 particles in a one-dimensional infinite square well of size l ($V_{\text{pot}} = 0$ if $0 < x < L, \infty$ otherwise). The eigenfunctions and energies for the one particle problem are ($n > 0$)

$$u_n(x) = \sqrt{\frac{2}{L}}\sin\left(\frac{n\pi x}{L}\right), \quad E_n = n^2 E_1, \quad E_1 = \frac{\pi^2\hbar^2}{2mL^2}$$

(a) We neglect the interactions between the particles. Determine the three lowest energy levels.
(b) We suppose that the particles interact via the contact potential $V(x_1 - x_2) = g\delta(x_1 - x_2)$, where g does not depend on spin. Determine to first order in g the three lowest energy levels of this two-particles system.

Solutions:

(a) If we neglect the interaction, the energy is given by the sum of the 1 particle energies. The three lowest energy levels are

$$\begin{cases} 2E_1 & n_1 = 1, n_2 = 1 \\ 5E_1 & n_1 = 1, n_2 = 2 \text{ or } n_1 = 2, n_2 = 1 \\ 8E_1 & n_1 = 2, n_2 = 2 \end{cases}$$

The ground state being symmetric, the only allowed spin state is a singlet. Using the notation $|n, k; s, m_s\rangle$ for a general state (n and k can equivalently refer to n_1 or n_2), the ground state is given by $|1, 1; 0, 0\rangle$. The same is found for the second excited state. The first excited state, however, is neither symmetric or antisymmetric. We must thus construct the states coupled to a singlet and triplet states

$$|1, 2; 0, 0\rangle = \frac{1}{\sqrt{2}}\left(|n_1 = 1, n_2 = 2\rangle + |n_1 = 2, n_2 = 1\rangle\right)|s = 0, m_s = 0\rangle$$
$$|1, 2; 1, m_s\rangle = \frac{1}{\sqrt{2}}\left(|n_1 = 1, n_2 = 2\rangle + |n_1 = 2, n_2 = 1\rangle\right)|s = 1, m_s\rangle$$

(b) Since the perturbation does not depend on spin, we have for the ground state

$$\begin{aligned}\langle 1, 1; 0, 0|\hat{V}|1, 1; 0, 0\rangle &= \frac{4}{L^2}\iint \sin^2\left(\frac{\pi}{L}x_1\right)\sin^2\left(\frac{\pi}{L}x_2\right) g\delta(x_1 - x_2)\, dx_1 dx_2 \\ &= \frac{4}{L^2}g\int_0^L \sin^4\left(\frac{\pi}{L}x_1\right) dx_1\end{aligned}$$

We then find $\Delta_0^{(1)} = \frac{3g}{2L}$. We get exactly the same for the second excited state $\Delta_2^{(1)} = \frac{3g}{2L}$. For the first excited states, there is a degeneracy, because $|1, 2; 0, 0\rangle$ and $|1, 2; 1, m_s\rangle$ all have the same energy. However,

the perturbation does not affect the spin, so we can anticipate that it is already diagonal in the spin basis $\left(\langle 1,2;s,m_s|\hat{V}|1,2;s',m_s'\rangle = \langle 1,2|\hat{V}|1,2\rangle\langle s,m_s|s',m_s'\rangle \text{ with } \langle s,m_s|s',m_s'\rangle = \delta_{ss'}\delta_{m_s,m_s'}\right)$. The diagonal elements will then give the first-order energy shifts. For a triplet state, we have the diagonal elements

$$\begin{aligned}&\langle 1,2;1,m_s|\hat{V}|1,2;1,m_s\rangle \\ &= \frac{4}{L^2}\iint \frac{1}{2}\left[\sin\left(\frac{\pi}{L}x_1\right)\sin\left(\frac{2\pi}{L}x_2\right) - \sin\left(\frac{2\pi}{L}x_1\right)\sin\left(\frac{\pi}{L}x_2\right)\right]^2 g\delta\left(x_1-x_2\right)dx_1dx_2 = 0\end{aligned}$$

It makes sense since the triplet state does not allow for particles to be at the same position, so they will never feel the potential. For the singlet state, we have

$$|1,2;0,0|\hat{V}|1,2;0,0\rangle = \frac{4}{L^2}\frac{g}{2}\int_0^L 4\sin^2\left(\frac{\pi}{L}x_1\right)\sin^2\left(\frac{2\pi}{L}x_1\right)dx_1 = \frac{2g}{L}$$

So $\Delta_{1,\text{ triplet}} = 0$ and $\Delta_{1,\text{ singlet}} = 2g/L$.

19.2 Problems about Derivations of Properties

19.2.1 Problems about derivation of special constructions

Б-2.8.13 Вывод фазы Берри (??)

Квантовая система описывается гамильтонианом $\hat{\mathrm{H}}(\xi(t))$, зависящим от некоторого параметра $\xi(t)$, медленно (адиабатически) меняющегося во времени, так что в каждый момент времени имеем $\hat{H}(\xi(t))|\psi_n(\xi(t))\rangle = E_n(\xi(t))|\psi_n(\xi(t))\rangle$.

Показать, что для невырожденного уровня энергии $E_n(\xi(t))$ эволюция состояния во времени может быть представлена в виде

$$|\Psi_n(\xi(t))\rangle = e^{i\gamma(t)}e^{-\frac{i}{\hbar}\int_0^t E_n\left(\xi\left(t'\right)\right)dt'}|\psi_n(\xi(t))\rangle.$$

Получить уравнения для определения фазы γ и найти эту фазу (фаза Берри).

Solution.

Задача на воспроизведение известного теоретического результата.
(Maybe I'll just put it to the theory later, or focus more on technical side of it.)

Вначале рассмотрим динамическую часть фазы, приобретаемой вектором $|\psi_n(\xi(t))\rangle$ (см. условие задачи). Заметим, что временная эволюция состояния неконсервативной системы может быть представлена в виде

$$|\Psi(t)\rangle = \hat{\mathrm{U}}\left(t,t_0\right)|\Psi_0\rangle,$$

$$\hat{\mathrm{U}}\left(t,t_0\right) = \hat{\mathrm{T}}\exp\left(-\frac{i}{\hbar}\int_{t_0}^t \hat{\mathrm{H}}\left(\xi\left(t'\right)\right)dt'\right).$$

Пусть начальное состояние является одним из собственных векторов мгновенного гамильтониана в момент времени $t^{(n)}$, совпадающим с моментом времени оператора $\hat{\mathrm{H}}\left(t^{(n)}\right)$ в соответствующем n-м члене разложения правой части соотношения (1) (см. также (II.45)). Тогда оператор $\hat{\mathrm{H}}\left(t^{(n)}\right)$ может быть заменен соответствующим собственным значением энергии, а в силу невырожденности уровня энергии мгновенное состояние останется тем же самым. Поскольку параметр ξ изменяется во времени медленно, на интервале времени $\Delta t = t - t_0 \ll \tau$, где τ - характерное время изменения параметра, можно считать, что состояние будет близко к собственному состоянию для всех сомножителей членов ряда T exp. В этом случае действие оператора эволюции сводится к умножению исходного вектора состояния на фазовый множитель $\exp\left(-\frac{i}{\hbar}\int_0^t E_n\left(\xi\left(t'\right)\right)dt'\right)$. При этом в силу невырожденности уровня энергии состояние по-прежнему будет мгновенным собственным вектором гамильтониана в текущий момент времени.

Для интервала времени $\Delta t \geqslant \tau$ представим решение в виде, записанном в условии задачи, которое теперь должно удовлетворять уравнению Шредингера

$$i\hbar\frac{\partial}{\partial t}|\Psi(t,\xi(t))\rangle = \hat{\mathrm{H}}(\xi(t))|\psi(t,\xi(t))\rangle.$$

В силу того, что гамильтониан зависит от времени только через параметр $\xi(t)$,

$$i\hbar\frac{\partial}{\partial t}|\Psi(t,\xi(t))\rangle = \left[-\hbar j(t) + E_n(\xi(t))\right]|\Psi(t,\xi(t))\rangle + i\hbar\dot{\xi}(t)\left(\frac{\partial}{\partial\xi}|\psi_n(\xi(t))\rangle\right)e^{i\gamma(t)}e^{-\frac{i}{\hbar}\int E_0 E_n\left(\xi(t')\right)dt'}.$$

$$\frac{\partial}{\partial\xi}|\psi_n(\xi(t))\rangle = \sum_k |\psi_k(\xi(t))\rangle\langle\psi_k(\xi(t))|\frac{\partial}{\partial\xi}|\psi_n(\xi(t))\rangle \approx \langle\psi_n(\xi(t))|\frac{\partial}{\partial\xi}|\psi_n(\xi(t))\rangle|\psi_n(\xi(t))\rangle.$$

Здесь мы воспользовались адиабатическим приближением и опустили в сумме все слагаемые с $k \neq n$, имея в виду, что вероятности переходов в эти состояния экспоненциально малы. Таким образом, с учетом мгновенного стационарного уравнения Шредингера получаем

$$i\hbar\frac{\partial}{\partial t}|\Psi(t,\xi(t))\rangle = \left[-\hbar\dot{\gamma}(t) + i\hbar\dot{\xi}(t)\langle\psi_n(\xi(t))|\frac{\partial}{\partial\xi}|\psi_n(\xi(t))\rangle + E_n(\xi(t))\right]|\Psi(t,\xi(t))\rangle.$$

Поскольку уровень энергии $E_n(\xi(t))$ невырожден, состояние $|\Psi(t,\xi(t))\rangle$ также должно соответствовать этому же уровню энергии. Поэтому в правой части полученного уравнения можно заменить значение $E_n(\xi)$ действием гамильтониана $\hat{\mathrm{H}}(\xi)$. Таким образом, видим, что в правой части уравнения Шредингера появляются дополнительные члены, которые обязаны обратиться в нуль, что возможно при выполнении условия

$$\dot{\gamma}(t) = i\dot{\xi}(t)\langle\psi_n(\xi(t))|\frac{\partial}{\partial\xi}|\psi_n(\xi(t))\rangle.$$

Нетрудно показать, что функция $\dot{\gamma}(t)$ является действительной: продифференцируем условие нормировки $1 = \langle\psi_n(\xi)|\psi_n(\xi)\rangle$ и найдем соотношение

$$0 = \langle\psi_n(\xi)|\frac{\partial}{\partial\xi}|\psi_n(\xi)\rangle^* + \langle\psi_n(\xi)|\frac{\partial}{\partial\xi}|\psi_n(\xi)\rangle = 2\,\mathrm{Re}\left\{\langle\psi_n(\xi)|\frac{\partial}{\partial\xi}|\psi_n(\xi)\rangle\right\},$$

которое, по существу, и доказывает данное утверждение.

Если параметр ξ изменяется периодически с периодом T, описывая замкнутую траекторию в параметрическом пространстве, изменение фазы за период можно выразить через интеграл по замкнутому контуру Γ в параметрическом пространстве:

$$\gamma = \int_0^T dt\dot{\gamma}(t) = i\oint_\Gamma d\xi\langle\psi_n(\xi(t))|\frac{\partial}{\partial\xi}|\psi_n(\xi(t))\rangle.$$

19.3 Problems about Mathematical Quantum Mechanics

19.3.1 Problems about Mathematical Scattering

(add Takhtajayan in English here!!)

ЗАДАЧА 4.1. Докажите, что если

$$\sup_{\boldsymbol{x}\in\mathbb{R}^3}\int_{\mathbb{R}^3}|V(\boldsymbol{y})|\frac{1}{|\boldsymbol{x}-\boldsymbol{y}|}d^3\boldsymbol{y} < 4\pi$$

то интегральные уравнения Липпмана - Швингера можно решить с помощью ряда Неймана, а для фиксированных $\boldsymbol{x}$ и $\boldsymbol{\omega}$ решения $u^{(\pm)}(\boldsymbol{x},\boldsymbol{k})$, $\boldsymbol{k} = k\boldsymbol{\omega}$, допускают аналитическое продолжение в верхнюю полуплоскость $\mathrm{Im}\,k > 0$. Покажите также, что в этом случае у оператора Шрёдингера H нет собственных значений.

ЗАДАЧА 4.2 (БОРНОВСКОЕ ПРИБЛИЖЕНИЕ). Покажите, что $u^{(+)}(\boldsymbol{x},\boldsymbol{k}) = e^{i\boldsymbol{k}\boldsymbol{x}} + o(1)$ при $k\to\infty$, и выведите из этого, что

$$f(k,\boldsymbol{n},\boldsymbol{\omega}) + \frac{1}{4\pi}\int_{\mathbb{R}^3} e^{ik(\boldsymbol{n}-\boldsymbol{\omega})\boldsymbol{x}}V(\boldsymbol{x})d^3\boldsymbol{x} = o(1) \quad \text{при} \quad k\to\infty$$

равномерно на $\boldsymbol{n}, \omega \in S^2$.

ЗАдАЧА 4.3. Докажите унитарность оператора $\hat{S}$, используя уравнение Шрёдингера (4.6), условия излучения (4.7) и формулу Грина.

ЗАДАЧА 4.4 (ОПТИЧЕСКАЯ ТЕОРЕМА). ПокажИте, что

$$\int\limits_{S^2} |f(k, \boldsymbol{n}, \boldsymbol{\omega})|^2 d\boldsymbol{n} = \frac{4\pi}{k} \operatorname{Im} f(k, \boldsymbol{\omega}, \boldsymbol{\omega})$$

(Здесь левая часть - это полное сечение в направлении ω при энергии $E = k^2$)

ЗАДАЧА 4.5. Пусть $\lambda_l = -\varkappa_l^2 < 0$ - собственные значения H с кратностями $m_l, l = 1, ..., n$. Докажите, что для фиксированных $\boldsymbol{x}$ и $\boldsymbol{\omega}$ решения $u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})$ допускают мероморфное продолжение в верхнюю полуплоскость $\operatorname{Im} k > 0$ с полюсами порядка m_l в точках $i\varkappa_l, l = 1, ..., n$.

ЗАДАЧА 4.6. Докажите, что волновые операторы $W_{\pm}$существуют, используя нестационарный подход. (Указание: покажите, что когда $V(\boldsymbol{x})$ удовлетворяет (4.5), применим критерий Кука, сформулированный в задаче 2.7.)

20 Other, Special Parts and Special Methods

20.1 Deep Understanding of Quantum Mechanics

20.1.1 Questions about the True Understanding of Quantum Mechanics

Приведем вопросы, которые покажут, понимает ли человек, что вообще происходит в квантмехе? Конечно же, это такие вопросы, ответы на которые приходят после лет размышлений, так что бессмысленно докапываться с ними до студентов, учащих квантовую механику первый год.

Я. Чем на самом деле квантовая физика отличается от классической

постановкой задачи, в квантовой - пучок траекторий,
в классической - одна
подробно про это.
(тут еще дисскуссия небольшая про неверные ответы)

Я. Откуда на самом деле появилось соотношение неопределённостей?

все его знают, однако четко указать, откуда - дело большое.
(тут еще дисскуссия небольшая про неверные ответы)

Я. Что необходимо для построения интеграла по траекториям?

тоже часто возникает вопрос.
(тут еще дисскуссия небольшая про неверные ответы)

Я. Почему некоторые квантовые системы не достигают равновесия?

(вообще не знаю, в интернете что-то про это было написано)
(тут еще дисскуссия небольшая про неверные ответы)

Я. Почему бы весь мир не описывался одним электроном в суперпозиции?

(?? мб можно что-то интересное сформулировать в рамках этой гипотезы? почитаю про это, если интересный вопрос, то оставлю тут, если нет - в конце записи вставлю.)

Я. Записывается ли информация о прошлом, или навсегда теряется? (???)

Если мы не можем отличить электроны, то казалось бы, информация теряется и прошлое полностью забывается? Или нет, в каких-то свойствах информацию о прошлом всегда можно найти?
(пока не знаю.)

Я. откуда появилась волновая функция

хз

Я. является ли оператор импульса самосопряженным?

Я. We measure some observable $\hat{A}$, what is the state of the system just after the measurement?

Казалось бы, в том же состоянии, где мы и измерили систему?
(??? надо бы это было еще продумать!)

Я. Why does non-degenerate perturbation theory break down if some states are degenerate?

(очень хороший типичный вопрос!)

20.1.2 Problems about Strict Mathematical Properties of Quantum Mechanics

(пока см. Тахтаджаян, добавлю их из других разделов)

20.1.3 Problems about Understanding the Details of the Mathematical Foundations of Quantum Mechanics

Приведем вопросы, которые покажут, понимает ли человек, как мы математически реализуем наше понимание квантовой механики?

Я. Матрицы канонических операторов, но с особой алгеброй

Могут ли существовать конечного размера матрицы, соответствующие координате и импульсу? Можно привести доказательство, что если взять след их коммутатора, то он равен нулю, а если взять след правой части, то получится всегда не ноль.

$$
\begin{aligned}
&[p;q] = i\hbar \\
&pq - qp = i\hbar \\
&t_2(pq - 4p) = i\hbar t_2 E \to \\
&t_2 py - t_7 qp = 0 = t_{11} E \cdot i\hbar \to 0
\end{aligned}
$$

Допустим можно взять поле чисел характиристики равной размерности пространства, тогда след единичной матрицы будет тоже ноль, и такое доказательство не работает. Спасает ли это эту ситуацию? Получается, что переходя к другому полю чисел можно сделать "квантовость" системы?

Solution

(Задачу очень на долго оставил, не актуально про это думать, да и не готов я к такому еще)

20.2 Special Theoretical Models

20.2.1 Problems about Open Systems

ПТФ-з1. Флуктуационно-диссипационная теорема (15 б).

Вне зависимости от происхождения индуцированного окружающей средой шума $\hat{\Phi}(t)$, на его корреляционные функции можно вывести соотношения самого общего вида, использующие лишь следующие общие предположения: гамильтониан $\hat{H}_e$ не зависит от времени; и матрица плотности окружающей среды имеет вид $\hat{\rho}_e = \frac{1}{Z} e^{-\beta \hat{H}_e}$.

• Используя формальное сходство между матрицей плотности и оператором эволюции в мнимом времени, покажите, что имеется связь на корреляционные функции $S_<(t) = S_>(t - i\beta)$. Что это означает для их фурье-образов, $S_<(\omega)$ и $S_>(\omega)$?

• Определим спектральную плотность как $J(\omega) = \frac{1}{2}(S_>(\omega) - S_<(\omega))$, и Келдышевский коррелятор как $S_K(t_1 - t_2) = \left\langle \left\{ \hat{\Phi}(t_1), \hat{\Phi}(t_2) \right\} \right\rangle$. Как связаны $S_K(\omega)$ и $J(\omega)$?

Solution

•

$$n_B(\omega) = \frac{1}{e^{\beta\omega} - 1}, \quad n_B(\omega) + 1 = -n_B(-\omega)$$

Корреляционные функции:

$$S_>(t) = \int\limits_0^\infty \frac{d\omega}{\pi} J(\omega)((n_B(\omega)+1)e^{-i\omega t} + n_B(\omega)e^{i\omega t}), \quad S_>(\omega) = 2\tilde{J}(\omega)(n_B(\omega)+1)$$

$$S_<(t) = \int\limits_0^\infty \frac{d\omega}{\pi} J(\omega)(n_B(\omega)e^{-i\omega t} + (n_B(\omega)+1)e^{i\omega t}), \quad S_<(\omega) = 2\tilde{J}(\omega)n_B(\omega)$$

где $\tilde{J}(\omega) = J(\omega) - J(-\omega)$.

$$S_>(t - i\beta) = \int\limits_0^\infty \frac{d\omega}{\pi} J(\omega)((n_B(\omega)+1)\exp(-i\omega t - \beta\omega) + n_B(\omega)\exp(i\omega t + \beta\omega)) =$$

$$= \int\limits_0^\infty \frac{d\omega}{\pi} J(\omega)\left(\frac{e^{\beta\omega}}{e^{\beta\omega}-1}e^{-i\omega t-\beta\omega} + \frac{1}{e^{\beta\omega}-1}e^{-i\omega t+\beta\omega}\right) = \int\limits_0^\infty \frac{d\omega}{\pi} J(\omega)\left(\frac{1}{e^{\beta\omega}-1}e^{-i\omega t} + \frac{e^{\beta\omega}}{e^{\beta\omega}-1}e^{-i\omega t}\right) =$$

$$= \int\limits_0^\infty \frac{d\omega}{\pi} J(\omega)(n_B(\omega)e^{-i\omega t} + (n_B(\omega)+1)e^{i\omega t}) = S_<(t)$$

$$S_>(t - i\beta) = S_<(t)$$

Покажем, что это означает для фурье-образов:

$$S_<(\omega) = \int\limits_{-\infty}^\infty dt S_<(t)e^{i\omega t} = \int\limits_{-\infty}^\infty dt S_>(t - i\beta)e^{i\omega(t-i\beta+i\beta)} = S_>(\omega)e^{-\omega\beta}$$

$$\frac{S_<(\omega)}{S_>(\omega)} = e^{-\omega\beta}$$

Это же равенство можно получить и из (**??**) и (**??**).

$$J(\omega) = \frac{1}{2}(S_>(\omega) - S_<(\omega))$$

$$S_K(t) = S_>(t) + S_<(t)$$

$$\frac{S_<(\omega)}{S_>(\omega)} = e^{-\omega\beta}$$

$$S_K(\omega) = 2J(\omega)\coth\left(\frac{\omega\beta}{2}\right)$$

ПТФ-з2. Релаксация (20 б).

Полученное на семинаре время релаксации T_1 для спин-бозонной модели, описываемой гамильтонианом

$$\hat{H} = -\frac{\Delta}{2}\hat{\sigma}_z + \sum_n \omega_n \hat{a}_n^\dagger \hat{a}_n + \hat{\sigma}_x\hat{\Phi}, \quad \hat{\Phi} = \sum_n \lambda_n(\hat{a}_n + \hat{a}_n^\dagger)$$

можно просто интерпретировать на языке золотого правила Ферми.

Solution

• Считая, что все осцилляторы находятся в квантовом состоянии с фиксированными числами заполнения n_n, вычислите частоту переходов $w_{i\to f} = w_{\uparrow\to\downarrow}$ и $w_{\downarrow\to\uparrow}$.

• Проведите усреднение полученных величин по Гиббсовскому ансамблю для осцилляторов $\hat{\rho}_e = \frac{1}{Z}e^{-\beta\hat{H}_e}$.

• Релаксационная динамика, описываемая золотым правилом Ферми, может быть сведена к классическому кинетическому уравнению:

$$\begin{cases} \frac{dP_\uparrow(t)}{dt} = -w_{\uparrow\to\downarrow}P_\uparrow(t) + w_{\downarrow\to\uparrow}P_\downarrow(t) \\ \frac{dP_\downarrow(t)}{dt} = -w_{\downarrow\to\uparrow}P_\downarrow(t) + w_{\uparrow\to\downarrow}P_\uparrow(t) \end{cases}$$

Исходя из такого уравнения, выразите время релаксации системы через величины $w_{\uparrow\to\downarrow}$ и $w_{\downarrow\to\uparrow}$ и сравните со временем релаксации, найденным на семинаре.

ПТФ-з3. Чистая дефазирока (50 б).

Исследуйте эволюцию матрицы плотности двухуровневой системы, взаимодействующую с резервуаром (набором осцилляторов). Система описывается следующим гамильтонианом:

$$\hat{H} = -\frac{\Delta}{2}\hat{\sigma}_z + \sum_n \omega_n \hat{a}_n^\dagger \hat{a}_n + \hat{\sigma}_z\hat{\Phi}, \quad \hat{\Phi} = \sum_n \lambda_n(\hat{a}_n + \hat{a}_n^\dagger)$$

• Перейдите к представлению взаимодействия. Оператор эволюции в представлении взаимодействия записывается при помощи $\mathcal{T}$-упорядоченной экспоненты:

$$\hat{S}(t,t_0) = \hat{\mathcal{T}}\left\{\exp\left(-i\int\limits_{t_0}^{t}\hat{V}(\tau)d\tau\right)\right\}$$

Гамильтониан в различные моменты времени не коммутирует сам с собой, поэтому $\mathcal{T}$-упорядочение убрать нельзя. Однако задачу можно значительно упростить, используя тот факт, что гамильтониан в различные моменты времени коммутирует на число:

$$[\hat{V}(t_1), \hat{V}(t_2)] = i\phi(t_1,t_2)$$

Используя этот факт, покажите, что знак $\mathcal{T}$-упорядочения можно снять ценой дополнительной добавки:

$$\hat{S}(t,t_0) = e^{i\Phi(t,t_0)}\exp\left(-i\int\limits_{t_0}^{t}\hat{V}(\tau)d\tau\right)$$

Указание: это соотношение можно вывести по индукции, рассмотрев $\hat{S}(t+\delta t,t_0) = \hat{S}(t+\delta t,t)\hat{S}(t,t_0)$ для $\delta t \to 0$, и объединив экспоненты при помощи формулы **Бейкера-Кэмбелла-Хаусдорфа**:

$$e^{\hat{A}}e^{\hat{B}} = \exp\left(\hat{A}+\hat{B}+\frac{1}{2}[\hat{A},\hat{B}]\right), \quad [\hat{A},\hat{B}] = \text{const}$$

• Пусть в начальный момент времени $t_0 = 0$ матрица плотности системы имела вид $\hat{\rho}_{tot}(t_0) = \hat{\rho}_s(t_0)\otimes\hat{\rho}_e(t_0)$, и резервуар находится в равновесии при температуре T: $\hat{\rho}_e(t_0) = \frac{1}{Z}e^{-\beta\hat{H}_0^{(e)}}$. Вычислите редуцированную матрицу плотности в произвольный момент времени:

$$\hat{\rho}_s(t) = \mathrm{Tr}_e(\hat{S}(t,t_0)\hat{\rho}_s(t_0)\hat{\rho}_e\hat{S}(t_0,t))$$

Указание: для усреднения по степеням бани вам может пригодиться тождество из задачи 6.1.

• Поскольку величина $\hat{\sigma}_z$ в данной задаче коммутирует с гамильтонианом, никакой релаксации наблюдаться не будет. Поэтому вся динамика сведётся к следующей временной зависимости матрицы плотности:

$$\hat{\rho}_s(t) = \begin{pmatrix} \rho_{11} & \rho_{12}\exp(-\Gamma(t)) \\ \rho_{21}\exp(-\Gamma(t)) & \rho_{22} \end{pmatrix}$$

Найдите выражение для **функции декогеренции** $\Gamma(t)$.

Solution

- Докажем соотношение $\hat{S}(t,t_0) = e^{i\Phi(t,t_0)} \exp\left(-i \int\limits_{t_0}^{t} \hat{V}(\tau) d\tau\right)$ по индукции.
- База индукции. Пусть соотношение верно для $t = t_0 + \delta t, \delta t \to 0$.

$$\hat{S}(t_0+\delta t, t_0) = e^{i\Phi(t_0+\delta t, t_0)} \exp\left(-i \int\limits_{t_0}^{t_0+\delta t} \hat{V}(\tau) d\tau\right) = \exp\left(-i \int\limits_{t_0}^{t_0+\delta t} \hat{V}(\tau) d\tau\right)$$

$$\Phi(t_0, t_0) = 0$$

- Пусть верно для момента t:

$$\hat{S}(t,t_0) = e^{i\Phi(t,t_0)} \exp\left(-i \int\limits_{t_0}^{t} \hat{V}(\tau) d\tau\right)$$

- Проверим, что выполняется для момента $t + \delta t$:

$$\hat{S}(t+\delta t, t_0) = e^{i\Phi(t,t_0)} \exp\left(-i \int\limits_{t_0}^{t+\delta t} \hat{V}(\tau) d\tau\right) =$$

$$= e^{i\Phi(t,t_0)} \exp\left(-i\hat{V}(t)\delta t\right) \exp\left(-i \int\limits_{t_0}^{t} \hat{V}(\tau) d\tau\right) =$$

$$= e^{i\Phi(t,t_0)} \exp\left(-i \int\limits_{t_0}^{t+\delta t} \hat{V}(\tau) d\tau - \frac{i}{2}\left[V(t)\delta t, \int\limits_{t_0}^{t} V(\tau) d\tau\right]\right) =$$

$$= e^{i\Phi(t,t_0) - \frac{i\delta t}{2}\int\limits_{t_0}^{t}\phi(t,\tau)d\tau} \exp\left(-i \int\limits_{t_0}^{t+\delta t} \hat{V}(\tau) d\tau\right) = e^{i\Phi(t+\delta t, t_0)} \exp\left(-i \int\limits_{t_0}^{t+\delta t} \hat{V}(\tau) d\tau\right)$$

$$\Phi(t+\delta t, t_0) = \Phi(t,t_0) - \frac{\delta t}{2} \int\limits_{t_0}^{t} \phi(t,\tau) d\tau \to \frac{d\Phi(t,t_0)}{dt} = -\frac{1}{2} \int\limits_{t_0}^{t} \phi(t,\tau) d\tau$$

$$\hat{S}(t,t_0) = e^{i\Phi(t,t_0)} \exp\left(-i \int\limits_{t_0}^{t} \hat{V}(\tau) d\tau\right), \quad \Phi(t,t_0) = -\frac{1}{2} \int\limits_{t_0}^{t} \int\limits_{t_0}^{\eta} \phi(\eta,\tau) d\tau d\eta$$

- Из определения коммутатора:

$$\phi(t_1,t_2) = -\phi(t_2,t_1) \to \Phi(t,0) = \Phi(-t,0)$$

$$\hat{\rho}_s(t) = \mathrm{Tr}_e(\hat{S}(t,t_0)\hat{\rho}_s(t_0)\hat{\rho}_e\hat{S}(t_0,t)) = e^{2i\Phi(t,t_0)}\mathrm{Tr}_e(e^{-i\int\limits_{t_0}^{t}\hat{V}(\tau)d\tau}\hat{\rho}_s(t_0)\hat{\rho}_e e^{i\int\limits_{t_0}^{t}\hat{V}(\tau)d\tau})$$

$$\hat{V} = \hat{\sigma}_z \sum_n \lambda_n (a_n e^{-i\omega_n t} + a_n^\dagger e^{i\omega_n t})$$

$$S = -i \int\limits_{t_0}^{t} \hat{V}(\tau) d\tau = \hat{\sigma}_z \sum_n \frac{\lambda_n}{\omega_n} (a_n(e^{-i\omega_n t_0} - e^{-i\omega_n t}) + a_n^\dagger (e^{i\omega_n t} - e^{i\omega_n t_0}))$$

$$\hat{\rho}_s(t) = e^{2i\Phi(t,t_0)}\mathrm{Tr}_e(e^S \hat{\rho}_s(t_0)\hat{\rho}_e e^{-S})$$

$$\hat{\rho}_s(t_0) = \begin{pmatrix}\rho_{11} & \rho_{12}\\ \rho_{21} & \rho_{22}\end{pmatrix} = \hat{\rho}_d + \rho_0, \quad \hat{\rho}_d = \begin{pmatrix}\rho_{11} & 0\\ 0 & \rho_{22}\end{pmatrix}, \quad \hat{\rho}_0 = \begin{pmatrix}0 & \rho_{12}\\ \rho_{21} & 0\end{pmatrix}$$

$$[\rho_d, \sigma_z] = 0 \to [\rho_d, e^S] = 0$$

$$e^{2i\Phi(t,t_0)}\mathrm{Tr}_e(e^S\hat\rho_d\hat\rho_e e^{-S}) = e^{2i\Phi(t,t_0)}\mathrm{Tr}_e(\hat\rho_d e^S\hat\rho_e e^{-S}) = \mathrm{Tr}_e(\hat\rho_d\hat S(t,t_0)\hat\rho_e\hat S(t_0,t)) =$$
$$= \mathrm{Tr}_e(\hat\rho_d\hat\rho_e(t)) = \hat\rho_d$$

$$\hat S = A\hat\sigma_z \to e^{\hat S} = \sum_n \frac{A^n}{n!}\hat\sigma_z^n = \sum_k \frac{A^{2k}}{(2k)!} + \sum_k \frac{A^{2k+1}}{(2k+1)!}\hat\sigma_z = \begin{pmatrix} e^A & 0 \\ 0 & e^{-A}\end{pmatrix}$$

$$e^{2i\Phi(t,t_0)}\mathrm{Tr}_e(e^S\hat\rho_0(t_0)e^{-S}e^S\hat\rho_e(t_0)e^{-S}) = \mathrm{Tr}_e(e^S\hat\rho_0(t_0)e^{-S}\hat\rho_e(t)) = \left\langle\begin{pmatrix} 0 & \rho_{12}e^{2A} \\ \rho_{21}e^{-2A} & 0\end{pmatrix}\right\rangle$$

$$\langle e^{2A}\rangle = e^{2\langle A^2\rangle}, \quad \langle a_n^\dagger a_n\rangle = n_B(\omega_n) = \frac{1}{e^{\beta\omega_n}-1}$$

$$\langle e^{2A}\rangle = \langle e^{-2A}\rangle = \exp\left(4\sum_n \frac{\lambda_n^2}{\omega_n^2}2\sin^2\frac{\omega_n(t-t_0)}{2}\coth\frac{\beta\omega_n}{2}\right)$$

$$\hat\rho_s(t) = \begin{pmatrix} \rho_{11} & \rho_{12}\exp\left(4\sum_n \frac{\lambda_n^2}{\omega_n^2}2\sin^2\frac{\omega(t-t_0)}{2}\coth\frac{\beta\omega_n}{2}\right) \\ \rho_{21}\exp\left(4\sum_n \frac{\lambda_n^2}{\omega_n^2}2\sin^2\frac{\omega(t-t_0)}{2}\coth\frac{\beta\omega_n}{2}\right) & \rho_{22}\end{pmatrix}$$

$$\hat\rho_s(t) = \begin{pmatrix} \rho_{11} & \rho_{12}\exp(-\Gamma(t)) \\ \rho_{21}\exp(-\Gamma(t)) & \rho_{22}\end{pmatrix}$$

Сравнивая с ответом из предыдущего пункта, получим

$$\Gamma(t) = -4\sum_n \frac{\lambda_n^2}{\omega_n^2}2\sin^2\frac{\omega_n(t-t_0)}{2}\coth\frac{\beta\omega_n}{2} = 4\sum_n \frac{\lambda_n^2}{\omega_n^2}(\cos\omega_n(t-t_0)-1)\coth\frac{\beta\omega_n}{2}$$

Спектральная плотность среды:

$$J(\omega) = \pi\sum_n \lambda_n^2\delta(\omega-\omega_n)$$

$t_0 = 0$.

$$\Gamma(t) = \frac{4}{\pi}\int_0^\infty d\omega J(\omega)\frac{\cos\omega t - 1}{\omega^2}\coth\frac{\omega}{2T}$$

ПТФ-з4 (15 б).

Используя функцию декогеренции из предыдущей задачи:

$$\Gamma(t) = \frac{4}{\pi}\int_0^\infty d\omega J(\omega)\coth\frac{\omega}{2T}\frac{1-\cos\omega t}{\omega^2},$$

исследуйте декогеренцию для омической бани, с модельной функцией $J(\omega) = \pi\alpha\omega e^{-\omega/\omega_c}$. Тут ω_c выступает в роли экспоненциальной ультрафиолетовой обрезки, и можно считать $\omega_c \gg T$. *Указание:* для вычисления удобно отделить вклад чисто квантовых флуктуаций (при $T = 0$), который зависит от обрезки ω_c; а затем найти температурный вклад, для которого обрезку уже можно выбросить.

Solution

Рассмотрим вклад чисто квантовых флуктуаций ($T = 0$):

$$\Gamma(t)\Big|_{T=0} = \frac{4}{\pi}\int_0^\infty d\omega\pi\alpha\omega e^{-\omega/\omega_c}\frac{1-\cos\omega t}{\omega^2} = 2\alpha\log(1+\omega_c^2t^2)$$

Температурный вклад ($T \neq 0$). Рассмотрим 2 случая:

- $Tt \gg 1$.

$$\Gamma(t) = 4\alpha\int_0^\infty d\omega\coth\left(\frac{\omega}{2T}\right)e^{-\frac{\omega}{\omega_c}}\frac{1-\cos\omega t}{\omega} \approx 4\alpha\int_0^\infty d\omega\frac{2T}{\omega}\frac{1-\cos\omega t}{\omega} = 4\pi\alpha tT$$

$$\Gamma(t) = 4\pi\alpha t T$$

- $Tt \ll 1$.

$$\frac{1-\cos\omega t}{\omega^2} \approx \frac{t^2}{2}$$

$$\Gamma(t) - \Gamma(t)\Big|_{T=0} = 4\alpha \int\limits_0^\infty d\omega \left(\coth\left(\frac{\omega}{2T}\right) - 1\right) e^{-\frac{\omega}{\omega_c}} \frac{1-\cos\omega t}{\omega} \approx$$

$$\approx 4\alpha \int\limits_0^\infty d\omega \left(\coth\left(\frac{\omega}{2T}\right) - 1\right) e^{-\frac{\omega}{\omega_c}} \frac{\omega t^2}{2} = 4\alpha t^2 \left(T^2\psi'\left(\frac{T}{\omega_c}\right) - \omega_c^2\right)$$

$$\Gamma(t) - \Gamma(t)\Big|_{T=0} \approx \frac{2\pi^2\alpha t^2 T^2}{3}$$

$$\Gamma(t) = 2\alpha\log(1+\omega_c^2 t^2) + \frac{2\pi^2\alpha t^2 T^2}{3}$$

ПТФ-15.з1. Модель Рубина (25 б).

Рассмотрите тяжёлую частицу массы M, которая соединена с баней, моделируемой одномерным полубесконечным кристаллом. В гармоническом приближении, система описывается следующим гамильтонианом:

$$\hat{H} = \frac{\hat{P}^2}{2M} + V(\hat{X}) + \sum_{n=1}^{\infty}\left(\frac{\hat{p}_n^2}{2m} + \frac{m\omega_0^2}{2}(\hat{u}_{n+1} - \hat{u}_n)^2\right) + \frac{m\omega_0^2}{2}(\hat{X} - \hat{u}_1)^2$$

Вычислите явный вид спектральной плотности $J(\omega)$, а также вид диссипативного ядра $\gamma(t)$.

Solution

$$\hat{H}_{\text{bath}} = \sum_{n=1}^{\infty}\left(\frac{\hat{p}_n^2}{2m} + \frac{m\omega_0^2}{2}(\hat{u}_{n+1} - \hat{u}_n)^2\right)$$

Пусть $\hat{u}_0 = 0$, $\hat{u}_{-i} = -\hat{u}_i$, тогда

$$\hat{u}_k = \sum_{l=-\infty}^{\infty} \hat{u}_n \sin kn, \quad \hat{p}_k = \sum_{l=-\infty}^{\infty} \hat{p}_n \sin kn$$

$$\hat{u}_n = \int\limits_0^\pi \frac{dk}{\pi}\hat{u}_k \sin kn, \quad \hat{p}_n = \int\limits_0^\pi \frac{dk}{\pi}\hat{p}_k \sin kn$$

$$\hat{H}_{\text{bath}} = \sum_{n=1}^{\infty}\int\limits_0^\pi\int\limits_0^\pi \frac{dkdk'}{\pi^2}\left(\frac{\hat{p}_k\hat{p}_{k'}\sin kn\sin k'n}{2m} + \frac{m\omega_0^2}{2}(\hat{u}_k\hat{u}_{k'}\sin kn\sin k'n + \right.$$

$$\left. + \hat{u}_k\hat{u}_{k'}\sin k(n+1)\sin k'(n+1) - 2\hat{u}_k\hat{u}_{k'}\sin k'n\sin k(n+1))\right)$$

$$\sin kn\sin k'n = \frac{1}{2}(\cos(k-k')n - \cos(k+k')n)$$

$$\sin k'n\sin k(n+1) = \frac{1}{2}(\cos((k'-k)n - k) - \cos((k'+k)n + k)) =$$

$$= \frac{1}{2}(\cos(k'-k)n\cos k - \sin(k'-k)n\cos k - \cos((k'+k)n+k))$$

$$\frac{1}{2\pi}\sum_{n=-\infty}^{\infty}\cos kn = \delta(k)$$

$$\hat{H}_{\text{bath}} = \int\limits_0^\pi \int\limits_0^\pi \frac{dkdk'}{\pi} \left(\frac{\hat{p}_k \hat{p}_{k'} \delta(k-k')}{2m} + \frac{m\omega_0^2}{2} 2\hat{u}_k \hat{u}_{k'} (1-\cos k) \right) =$$

$$= \int\limits_0^\pi \frac{dk}{\pi} \left(\frac{\hat{p}_k^2}{2m} + m\omega_0^2 \hat{u}_k^2 (1-\cos k) \right)$$

$$\hat{H}_{\text{int}} = \frac{m\omega_0^2}{2}(\hat{X}-\hat{u}_1)^2 - \frac{m\omega_0^2 \hat{u}_1^2}{2} = \frac{m\omega_0^2 \hat{X}}{2}(\hat{X}-2\hat{u}_1) = \int\limits_0^\pi \frac{dk}{\pi} \frac{m\omega_0^2 \hat{X}}{2}(\hat{X}-2\hat{u}_k \sin k)$$

$$\hat{H} = \frac{\hat{P}^2}{2M} + V(\hat{X}) + \int\limits_0^\pi \frac{dk}{\pi} \left(\frac{\hat{p}_k^2}{2m} + m\omega_0^2 \hat{u}_k^2 (1-\cos k) + \frac{m\omega_0^2 \hat{X}}{2}(\hat{X}-2\hat{u}_k \sin k) \right)$$

$$\hat{H} = \frac{\hat{P}^2}{2M} + V(\hat{X}) + \frac{m\omega_0^2 \hat{X}^2}{2} + \int\limits_0^\pi \frac{dk}{\pi} \left(\frac{\hat{p}_k^2}{2m} + m\omega_0^2 \hat{u}_k^2 (1-\cos k) - m\omega_0^2 \hat{X}\hat{u}_k \sin k) \right)$$

$$\hat{H} = \frac{\hat{P}^2}{2M} + V(\hat{X}) + \frac{m\omega_0^2 \hat{X}^2}{2} + \int\limits_0^\pi \frac{dk}{\pi} \left(\frac{\hat{p}_k^2}{2m} + \frac{m\omega^2(k)\hat{u}_k^2}{2} - c(k)\hat{X}\hat{u}_k) \right)$$

$$\omega(k) = 2\omega_0 \sin\frac{k}{2}, \quad c(k) = m\omega_0^2 \sin k$$

Спектральная плотность:

$$J(\omega) = \int\limits_0^\pi dk \frac{c^2(k)}{2m\omega(k)} \delta(\omega - \omega(k)) = \frac{m\omega_0^3}{4} \int\limits_0^\pi \frac{\sin^2 k}{\sin\frac{k}{2}} \delta\left(\omega - 2\omega_0 \sin\frac{k}{2}\right) dk =$$

$$= \frac{m\omega_0^3}{2} \int\limits_0^\pi dk \sin\frac{k}{2} \cos^2\frac{k}{2} \frac{\delta(k - 2\arcsin\frac{\omega}{2\omega_0})}{|\omega_0 \cos\frac{k}{2}|}$$

$$J(\omega) = \frac{m\omega_0\omega}{4} \sqrt{1 - \frac{\omega^2}{4\omega_0^2}} \theta\left(1 - \frac{\omega}{2\omega_0}\right)$$

Диссипативное ядро:

$$\gamma(t) = \frac{2}{\pi} \int\limits_0^\infty \frac{d\omega}{\omega} J(\omega) \cos\omega t = \frac{2}{\pi} \int\limits_0^{2\omega_0} d\omega \frac{m\omega_0}{4} \sqrt{1 - \frac{\omega^2}{4\omega_0^2}} \cos\omega t$$

$$\gamma(t) = \frac{m\omega_0}{4t} J_1(2\omega_0 t)$$

ПТФ-15.з2. Кинетическое уравнение (35 б).

Используя приближение Борна-Маркова для омической бани со спектральным весом $J(\omega) = \eta\omega$, выведите уравнение на преобразование Вигнера матрицы плотности $\rho_W(\mathbf{x}, \mathbf{p}, t)$.

ПТФ-15.з3. Расплывание волнового пакета (что, опять?) (40 б).

Упражнение. Преамбула (5 б).

Как известно из квантовой механики, волновые пакеты имеют обыкновение расплываться. С другой стороны, как известно, электрон имеет массу $m = 9.1 \cdot 10^{-28} g$, и его классический радиус $x_0 \simeq 10^{-13}$cm (определяемый как его комптоновская длина волны). Пусть в начальный момент времени электрон представлял собой ровно такой волновой пакет:

$$\psi(x) = \frac{1}{(2\pi x_0^2)^{1/4}} e^{-x^2/4x_0^2}$$

Найдите его ширину через время $t = 1\mu s$.

Solution

Перейдём в импульсное представление:

$$\Psi(p) = \int dx e^{-\frac{ipx}{\hbar}} \psi(x) = (8\pi x_0^2)^{\frac{1}{4}} e^{-\frac{p^2 x_0^2}{\hbar^2}}$$

Нестационарное уравнение Шрёдингера в импульсном представлении:

$$i\hbar \frac{\partial \Psi(p,t)}{\partial t} = \langle p|\hat{H}(t)|\psi(t)\rangle = \frac{p^2}{2m}\Psi(p,t), \quad \Psi(p,0) = \Psi(p)$$

$$\Psi(p,t) = \Psi(p) \exp\left(-\frac{ip^2}{2m\hbar}t\right)$$

$$\psi(x,t) = \int dx e^{\frac{ipx}{\hbar}} \Psi(p,t) = \left(\frac{2}{\pi}\right)^{\frac{1}{4}} \frac{\exp\left(-\frac{x^2}{4(x_0^2 + \frac{i\hbar}{2m}t)}\right)}{\sqrt{2x_0 + \frac{i\hbar t}{m x_0}}}$$

$$\mathrm{Re}\left(\frac{1}{x_0^2 + \frac{i\hbar t}{2m}}\right) = \mathrm{Re}\left(\frac{x_0^2 - \frac{i\hbar t}{2m}}{x_0^4 + \frac{\hbar^2 t^2}{4m^2}}\right) = \frac{1}{x_0^2 + \frac{\hbar^2 t^2}{4m^2 x_0^2}}$$

$$\Delta x^2(t) = x_0^2 + \frac{\hbar^2 t^2}{4m^2 x_0^2} \approx \frac{\hbar^2 t^2}{4m^2 x_0^2}$$

$$\Delta x(t) = \frac{\hbar t}{2m x_0} = 5.8 \cdot 10^6 \mathrm{cm}$$

ПТФ-15.з(35 б).

В предыдущем упражнении вы должны были получить ответ, который должен был вас удивить и насторожить. Рассмотрите теперь движение свободного электрона, взаимодействующего с окружающей средой в рамках модели Калдейры-Леггетта с омической баней. Получите асимптотические выражения для $\langle \hat{x}^2(t)\rangle$ в следующих режимах:
• Классическая диффузия: $Tt \gg 1$
• Квантовая диффузия: $Tt \ll 1$
Чтобы не рассматривать баллистические эффекты, оценённые в преамбуле, можете также считать $\omega_c \gg \gamma \gg t^{-1}$.

Solution

$$m\ddot{x} + \eta\dot{x} = \zeta(t) \to m\dot{v} + \eta v = \zeta(t)$$

$$v(t) = e^{-\frac{\eta t}{m}} \left(v_0 + \int_0^t d\tau \frac{\zeta(\tau)}{m} e^{\frac{\eta\tau}{m}}\right), \quad v(0) = 0$$

$$\dot{x}^2(t) = e^{-\frac{2\eta t}{m}} \int_0^t d\tau_1 \int_0^t d\tau_2 \frac{e^{\frac{\eta(\tau_1+\tau_2)}{m}}}{m^2} \zeta(\tau_1)\zeta(\tau_2)$$

20.2.2 Problems about the Functional Integral

ПТФ-16.у(10 б).

Восстановите координатную зависимость пропагатора квантового гармонического осциллятора $G(x,y,T)$. Исходя из полученного выражения, найдите его спектр.

Solution

Лагранжиан гармонического осциллятора:

$$L = \frac{m}{2}(\dot{x}^2 - \omega^2 x^2)$$

$$G^R(x,y,T) = \int\limits_{x(0)=x}^{x(T)=y} \mathcal{D}[x(t)] e^{\frac{iS[x(t)]}{\hbar}}, \quad \mathcal{D}[x(t)] = \left(\frac{m}{2\pi i\epsilon}\right)^{\frac{N}{2}} \prod_{k=1}^{N-1} \int dx_k$$

Сделаем подстановку в функциональный интеграл $x(t) = x_{\text{cl}}(t) + z(t)$, где $x_{\text{cl}}(t)$ – классическая траектория, удовлетворяющая граничным условиям $x_{\text{cl}}(0) = x$, $x_{\text{cl}}(T) = y$, $z(t)$ – произвольная функция (квантовая поправка) с граничными условиями $z(0) = 0$, $z(T) = 0$. Для систем, у которых действие зависит от x квадратично, выполняется

$$S[x(t)] = S[x_{\text{cl}}(t)] + S[z(t)]$$

$$S[x(t)] = \int\limits_0^T dt \frac{m}{2}(\dot{x}(t)^2 - \omega^2 x(t)^2) = \frac{m}{2}\left(x(t)\dot{x}(t)|_0^T - \int\limits_0^T dt x(t)(\ddot{x}(t) + \omega^2 x(t))\right)$$

Пусть $\hat{L} = -\partial_t^2 - \omega^2$, тогда

$$S[x(t)] = \frac{m}{2}\left(x(t)\dot{x}(t)|_0^T + \int\limits_0^T dt x\hat{L}x\right)$$

Поскольку на классической траектории $\hat{L}x_{\text{cl}}(t) = 0$, то в случае $x = y = 0$ выполняется $S[x_{\text{cl}}(t)] = 0$ и

$$G^R(0,0,T) = \int\limits_{x(0)=0}^{x(T)=0} \mathcal{D}[z(t)] e^{\frac{iS[z(t)]}{\hbar}} \to G^R(x,y,T) = G^R(0,0,T) e^{\frac{iS[x_{\text{cl}}(t)]}{\hbar}}$$

Определим действие на классической траектории:

$$\hat{L}x_{\text{cl}}(t) = 0 \to x_{\text{cl}}(t) = a\sin\omega t + b\cos\omega t$$

$$x_{\text{cl}}(0) = b = x, \quad x_{\text{cl}}(T) = a\sin\omega T + b\cos\omega T = y$$

$$x_{\text{cl}}(t) = \frac{y - x\cos\omega T}{\sin\omega T}\sin\omega t + x\cos\omega t, \quad \dot{x}_{\text{cl}}(t) = \frac{y - x\cos\omega T}{\sin\omega T}\omega\cos\omega t - x\omega\sin\omega t$$

$$S[x_{\text{cl}}(t)] = \frac{m}{2}(x_{\text{cl}}(T)\dot{x}_{\text{cl}}(T) - x_{\text{cl}}(0)\dot{x}_{\text{cl}}(0)) = \frac{m}{2}\left(\frac{y - x\cos\omega T}{\sin\omega T} y\omega\cos\omega T - xy\omega\sin\omega T - \right.$$
$$\left. - \frac{y - x\cos\omega T}{\sin\omega T} x\omega\right) = \frac{m\omega}{2}\frac{y^2\cos\omega T - xy\cos^2\omega T - xy\sin^2\omega T - yx + x^2\cos\omega T}{\sin\omega T} =$$
$$= \frac{m\omega}{2}\frac{(x^2+y^2)\cos\omega T - 2xy}{\sin\omega T}$$

Разложим произвольную функцию $z(t)$ по базису собственных функций оператора $\hat{L}$:

$$z(t) = \sum_n c_n z_n(t), \quad \hat{L}z_n(t) = \lambda_n z_n(t)$$

$$z_n(t) = \sqrt{\frac{2}{T}}\sin\frac{\pi n t}{T}, \quad \lambda_n = \frac{\pi^2 n^2}{T^2} - \omega^2$$

$$\mathcal{D}[z(t)] = \mathcal{N}\prod_{n=1}^{\infty}\int\limits_{-\infty}^{\infty} dc_n$$

$$S[z(t)] = S\left[\sum_n c_n z_n(t)\right] = \frac{m}{2}\int\limits_0^T dt\left(\sum_n c_n z_n(t)\right)\hat{L}\left(\sum_n c_n z_n(t)\right)$$

В силу ортонормированности набора $z_n(t)$ действие факторизуется:

$$S[z(t)] = \frac{m}{2}\int\limits_0^T dt\left(\sum_n c_n^2\lambda_n z_n^2(t)\right) = \frac{m}{2}\sum_{n=1}^{\infty}\lambda_n c_n^2$$

$$G_\omega^R(0,0,T) = \mathcal{N}\int\limits_{-\infty}^{\infty}\prod_{n=1}^{\infty}dc_n\exp\left(\frac{im}{2\hbar}\lambda_n c_n^2\right) = \mathcal{N}\prod_{n=1}^{\infty}\sqrt{\frac{2\pi i\hbar}{m\left(\frac{\pi^2n^2}{T^2}-\omega^2\right)}}$$

$$G_0^R(0,0,T) = \mathcal{N}\prod_{n=1}^{\infty}\sqrt{\frac{2\pi i\hbar T^2}{m\pi^2n^2}}$$

$$\frac{G_\omega^R(0,0,T)}{G_0^R(0,0,T)} = \prod_{n=1}^{\infty}\left(1-\frac{\omega^2T^2}{\pi^2n^2}\right)^{-\frac{1}{2}} = \sqrt{\frac{\omega T}{\sin\omega T}},\quad G_0^R(0,0,T) = \sqrt{\frac{m}{2\pi i\hbar T}}$$

$$G_\omega^R(0,0,T) = \sqrt{\frac{m}{2\pi i\hbar T}}\sqrt{\frac{\omega T}{\sin\omega T}} = \sqrt{\frac{m\omega}{2\pi i\hbar\sin\omega T}}$$

$$G_\omega^R(x,y,T) = \sqrt{\frac{m\omega}{2\pi i\hbar\sin\omega T}}\exp\left(\frac{im\omega((x^2+y^2)\cos\omega T-2xy)}{2\hbar\sin\omega T}\right)$$

Из знания запаздывающего пропагатора можно извлечь спектр гамильтониана.

$$G_\omega^R(x,y,T) = \langle y|e^{-\frac{i\hat{H}T}{\hbar}}|x\rangle = \sum_n\langle y|n\rangle e^{-\frac{iE_nT}{\hbar}}\langle n|x\rangle = \sum_n\psi_n^*(x)\psi_n(y)e^{-\frac{iE_nT}{\hbar}}$$

Воспользуемся разложениями:

$$\frac{1}{\sqrt{2i\sin\omega T}} = e^{-\frac{i\omega T}{2}}\sum_{n=0}^{\infty}C_{-\frac{1}{2}}^n e^{-2ni\omega T},\quad -\frac{i}{2\sin\omega T} = e^{-i\omega T}\sum_{n=0}^{\infty}e^{-2ni\omega T}$$

$$i\cot\omega T = -\frac{1+e^{-2i\omega T}}{1-e^{-2i\omega T}} = -\left(1+e^{-2i\omega T}\right)\sum_{n=0}^{\infty}e^{-2ni\omega T} = -2\sum_{n=0}^{\infty}e^{-2in\omega T}$$

$$G_\omega^R(x,y,T) = \sqrt{\frac{m\omega}{2\pi\hbar}}e^{-\frac{i\omega T}{2}}\left(\sum_{n=0}^{\infty}C_{-\frac{1}{2}}^n e^{-2i\omega nT}\right)\sum_{q=0}^{\infty}\frac{1}{q!}\left(\frac{m\omega}{\hbar}\right)^q\left(-(x^2+y^2)\left(\sum_{j=0}^{\infty}e^{-2i\omega jT}\right)+\right.$$
$$\left.+2xye^{-i\omega T}\sum_{j=0}^{\infty}e^{-2i\omega jT}\right)^q$$

$$E_n = \hbar\omega\left(n+\frac{1}{2}\right)$$

Также получим спектр, рассмотрев следующую величину

$$\mathrm{Tr}\,G_\omega^R(x,y,T) = \int\limits_{-\infty}^{\infty}dxG_\omega^R(x,x,T) = \sqrt{\frac{m\omega}{2\pi i\hbar\sin\omega T}}\int\limits_{-\infty}^{\infty}\exp\left(\frac{im\omega x^2}{\hbar\sin\omega T}\left(\cos\omega T-1\right)\right)dx =$$
$$= \sqrt{\frac{m\omega}{2\pi i\hbar\sin\omega T}}\sqrt{\frac{\hbar\sin\omega T}{m\omega(1-\cos\omega T)}}\sqrt{\pi}e^{-i\pi/4} = \frac{1}{2i}\frac{1}{\sin\frac{\omega T}{2}} = e^{-\frac{i\omega T}{2}}\sum_{n=0}^{\infty}e^{-i\omega nT} = \sum_{n=0}^{\infty}e^{-\frac{iE_nT}{\hbar}}$$

ПТФ-16.з1. Пропагатор свободной частицы (15 б).

Вычислите интеграл для запаздывающего пропагатора свободной частицы явно, используя дискретизацию по времени:

$$G(x,y,t>0) = \left(\frac{m}{2\pi i\hbar\epsilon}\right)^{\frac{N}{2}}\int\prod_{k=1}^{N-1}dx_k\exp\left(i\epsilon\sum_{k=1}^{N}\frac{m}{2\hbar}\left(\frac{x_k-x_{k-1}}{\epsilon}\right)^2\right),\quad x_0\equiv x,\quad x_N\equiv y$$

Solution

Вычислим интеграл по индукции.

$$\sqrt{\frac{m}{2\pi\hbar i\epsilon}}\int\limits_{-\infty}^{\infty}\exp\left(\frac{mi}{2\hbar\epsilon}((x_2-x_1)^2+(x_1-x_0)^2)\right)dx_1=$$

$$=\sqrt{\frac{m}{2\pi\hbar i\epsilon}}\int\limits_{-\infty}^{\infty}\exp\left(\frac{mi}{2\pi\hbar\epsilon}\left(2\left(x_1-\frac{x_0+x_2}{2}\right)^2+\frac{(x_2-x_0)^2}{2}\right)\right)dx_1=\frac{\exp(\frac{mi}{2\cdot2\hbar\epsilon}(x_2-x_0)^2)}{\sqrt{2}}$$

$$\sqrt{\frac{m}{2\cdot2\pi\hbar i\epsilon}}\int\limits_{-\infty}^{\infty}\exp\left(\frac{mi}{2\hbar\epsilon}\left((x_3-x_2)^2+\frac{(x_2-x_0)^2}{2}\right)\right)dx_2=$$

$$=\sqrt{\frac{m}{2\cdot2\pi\hbar i\epsilon}}\int\limits_{-\infty}^{\infty}\exp\left(\frac{mi}{2\hbar\epsilon}\left(\frac{3}{2}\left(x_2-\frac{x_0+2x_3}{9}\right)^2+\frac{(x_3-x_0)^2}{3}\right)\right)dx_2=$$

$$=\frac{\exp(\frac{mi}{2\cdot3\hbar\epsilon}(x_3-x_0)^2)}{\sqrt{3}}$$

Для k-го интеграла получим

$$\sqrt{\frac{m}{2k\pi\hbar i\epsilon}}\int\limits_{-\infty}^{\infty}\exp\left(\frac{mi}{2\hbar\epsilon}\left((x_{k+1}-x_k)^2+\frac{(x_k-x_0)^2}{k}\right)\right)dx_k=$$

$$=\sqrt{\frac{m}{2k\pi\hbar i\epsilon}}\int\limits_{-\infty}^{\infty}\exp\left(\frac{mi}{2\hbar\epsilon}\left(\frac{k+1}{k}\left(x_k-\frac{kx_{k+1}+x_0}{k+1}\right)^2+\frac{(x_{k+1}-x_0)^2}{k+1}\right)\right)dx_k=$$

$$=\frac{\exp(\frac{mi}{2(k+1)\hbar\epsilon}(x_{k+1}-x_0)^2)}{\sqrt{k+1}}$$

$$G(x,y,t>0)=\sqrt{\frac{m}{2\pi i\hbar\epsilon N}}\exp\left(\frac{mi}{2N\hbar\epsilon}(x_N-x_0)^2\right)$$

$$x_0=x,\quad x_N=y,\quad N\epsilon=T$$

$$G(x,y,t>0)=\sqrt{\frac{m}{2\pi i\hbar T}}\exp\left(\frac{im(y-x)^2}{2\hbar T}\right)$$

ПТФ-16.з2. Частица в магнитном поле (50 б).

Вычислите пропагатор квантовой частицы, движущийся в плоскости в постоянном магнитном поле B, перпендикулярном этой плоскости ($\mathbf{r}(t)=(x(t),y(t))$):

$$G(\mathbf{R}_1,\mathbf{R}_2,T)=\int\limits_{\mathbf{r}(0)=\mathbf{R}_1}^{\mathbf{r}(T)=\mathbf{R}_2}\mathcal{D}[\mathbf{r}(t)]\exp\left(\frac{i}{2\hbar}\int\limits_0^T\left(m(\dot{x}^2+\dot{y}^2)+\frac{e}{c}B(x\dot{y}-y\dot{x})\right)dt\right)$$

(сперва убедившись, что данное действие действительно описывает именно эту систему). Используя функцию Грина, найдите спектр соответствующей квантовой задачи (решение которой, напомним, даётся макроскопически вырожденными *уровнями Ландау*).
Подсказка: хотя этот интеграл можно вычислить и непосредственно, может оказаться удобным переход во вращающуюся систему отсчёта – провести следующую замену в функциональном интеграле:

$$\begin{cases}x'(t)=x(t)\cos\Omega t+y(t)\sin\Omega t,\\ y'(t)=-x(t)\sin\Omega t+y(t)\cos\Omega t\end{cases}$$

и при правильном выборе частоты Ω задача значительно упрощается. Не забудьте о модификации граничных условий из-за такой замены!

Solution

Сделаем замену:

$$\begin{cases} x'(t) = x(t)\cos\Omega t + y(t)\sin\Omega t, \\ y'(t) = -x(t)\sin\Omega t + y(t)\cos\Omega t \end{cases}$$

Обратная замена:

$$\begin{cases} x(t) = x'(t)\cos\Omega t - y'(t)\sin\Omega t, \\ y(t) = x'(t)\sin\Omega t + y'(t)\cos\Omega t \end{cases}$$

$$\begin{cases} \dot{x}(t) = (\dot{x}'(t) - \Omega y'[t])\cos\Omega t - (\dot{y}'(t) + \Omega x'(t))\sin\Omega t, \\ \dot{y}(t) = (\dot{x}'(t) - \Omega y'[t])\sin\Omega t + (\dot{y}'(t) + \Omega x'(t))\cos\Omega t \end{cases}$$

$$\dot{x}^2(t) + \dot{y}^2(t) = \dot{x}'^2(t) + \dot{y}'^2(t) + \Omega^2(x'^2(t) + y'^2(t)) + 2\Omega(x'(t)\dot{y}'(t) - y'(t)\dot{x}'(t))$$

$$x(t)\dot{y}(t) - y(t)\dot{x}(t) = \Omega(x'^2(t) + y'^2(t)) + x'(t)\dot{y}'(t) - \dot{x}'(t)y'(t)$$

$$m(\dot{x}^2 + \dot{y}^2) + \frac{e}{c}B(x\dot{y} - y\dot{x}) = m(\dot{x}'^2(t) + \dot{y}'^2(t)) + \left(m\Omega^2 + \frac{eB\Omega}{c}\right)(x'^2(t) + y'^2(t)) + \\ + \left(2m\Omega + \frac{eB}{c}\right)(x'(t)\dot{y}'(t) - \dot{x}'(t)y'(t))$$

Пусть $\Omega = -\frac{eB}{2mc}$, тогда

$$m(\dot{x}^2 + \dot{y}^2) + \frac{e}{c}B(x\dot{y} - y\dot{x}) = m(\dot{x}'^2(t) + \dot{y}'^2(t)) + \Omega\frac{eB}{2c}(x'^2(t) + y'^2(t)) = m(\dot{x}'^2(t) + \dot{y}'^2(t)) - \\ - \frac{e^2B^2}{4mc^2}(x'^2(t) + y'^2(t))$$

$$G(\mathbf{R}_1, \mathbf{R}_2, T) = \int\limits_{\mathbf{r}'(0)=\mathbf{R}_1}^{\mathbf{r}'(T)=\mathbf{R}_2} \mathcal{D}[\mathbf{r}'(t)] \exp\left(\frac{i}{2\hbar}\int\limits_0^T \left(m(\dot{x}'^2 + \dot{y}'^2) - \frac{e^2B^2}{4mc^2}(x'^2 + y'^2)\right)dt\right)$$

Получился пропагатор с лагранжианом:

$$L = \frac{m(\dot{x}'^2 + \dot{y}'^2)}{2} - \frac{e^2B^2}{8mc^2}(x'^2 + y'^2)$$

Получившийся потенциал $V(\mathbf{r}\,') = \frac{e^2B^2}{8mc^2}(x'^2 + y'^2)$ – гармонический осциллятор в 2D с частотой $\omega = \frac{eB}{2mc} = \Omega$.

$$G(\mathbf{R}_1, \mathbf{R}_2, T) = \int\limits_{\mathbf{r}\,'(0)=\mathbf{R}_1'}^{\mathbf{r}\,'(T)=\mathbf{R}_2'} \mathcal{D}[\mathbf{r}\,'(t)] e^{\frac{iS[\mathbf{r}_{\text{cl}}'(t)]}{\hbar}}$$

$$\int\limits_{\mathbf{r}'(0)=\mathbf{R}_1'}^{\mathbf{r}'(T)=\mathbf{R}_2'} \mathcal{D}[\mathbf{r}'(t)] = \left(\sqrt{\frac{m\omega}{2\pi i\hbar\sin\omega T}}\right)^2 = \frac{m\omega}{2\pi i\hbar\sin\omega T}$$

$$S[\mathbf{r}_{\text{cl}}'(t)] = \frac{m\omega}{2}\frac{(r'^2(0) + r'^2(T))\cos\omega T - 2\mathbf{r}'(0)\cdot\mathbf{r}'(T)}{\sin\omega T}$$

$$r'^2(0) = x^2(0) + y^2(0) = r^2(0) = R_1^2, \quad r'^2(T) = x^2(T) + y^2(T) = r^2(T) = R_2^2$$

$$\mathbf{r}'(0)\cdot\mathbf{r}'(T) = (x(0)x(T) + y(0)y(T))\cos\Omega T + (x(0)y(T) - x(T)y(0))\sin\Omega T = \\ = (R_{1x}R_{2x} + R_{1y}R_{2y})\cos\Omega T + (R_{1x}R_{2y} - R_{2x}R_{1y})\sin\Omega T$$

$$S[\mathbf{r}_{\text{cl}}'(t)] = \frac{m\Omega}{2}((R_1^2 + R_2^2)\operatorname{ctg}\Omega T - 2((R_{1x}R_{2x} + R_{1y}R_{2y})\operatorname{ctg}\Omega T + (R_{1x}R_{2y} - R_{2x}R_{1y})))$$

$$S[\mathbf{r}_{\text{cl}}'(t)] = \frac{m\Omega}{2}(((R_{1x} - R_{2x})^2 + (R_{1y} - R_{2y})^2)\operatorname{ctg}\Omega T - 2(R_{1x}R_{2y} - R_{2x}R_{1y}))$$

$$G(\mathbf{R}_1, \mathbf{R}_2, T) = \frac{m\Omega}{2\pi i\hbar\sin\Omega T}\exp\left(\frac{im\Omega}{2\hbar}(((R_{1x} - R_{2x})^2 + (R_{1y} - R_{2y})^2)\operatorname{ctg}\Omega T - 2(R_{1x}R_{2y} - R_{2x}R_{1y}))\right)$$

$$\frac{1}{2i\sin\omega T} = e^{-i\omega T}\sum_{l=0}^{\infty} e^{-2i\omega lT}, \quad i\cot\omega T = -\frac{1 + e^{-2i\omega T}}{1 - e^{-2i\omega T}} = -\left(1 + e^{-2i\omega T}\right)\sum_{l=0}^{\infty} e^{-2i\omega lT} = -2\sum_{l=0}^{\infty} e^{-2i\omega lT}$$

Уровни энергии:

$$E_{n_x,n_y} = \frac{eB\hbar}{mc}(n_x + n_y + 1), \quad n_x, n_y \in \mathbb{N}_0$$

ПТФ-16.з3. «Мацубаровский» функциональный интеграл (25 б).

Рассмотрите квантовую частицу, описываемую гамильтонианом $\hat{H} = \frac{\hat{p}^2}{2m} + V(\hat{x})$. Если такая частица находится в равновесии при температуре $T = \beta^{-1}$, её матрица плотности имеет вид $\hat{\rho} = \frac{1}{Z} e^{-\beta \hat{H}}$, и её статсумма

$$Z = \mathrm{Tr}(e^{-\beta \hat{H}})$$

Используя аналогию между равновесной матрицей плотности и оператором эволюции в мнимом времени $t = -i\tau \Rightarrow \hat{U}(t) = e^{-\hat{H}\tau}$, постройте представление функционального интеграла для статсуммы Z. Покажите, что интегрирование должно проводиться по всем траекториям в мнимом времени $x(\tau)$, которые периодичны в мнимом времени: $x(\tau + \beta) \equiv x(\tau)$. Полученное выражение при этом должно получаться формальной заменой $t = -i\tau$ в исходном выражении (такая формальная замена носит название *Виковского поворота*).

Solution

Запаздывающая функция Грина – аплитуда распространения квантовомеханической частицы из точки $\mathbf{x}$ в точку $\mathbf{y}$ за время β:

$$G^R(\mathbf{x}, \mathbf{y}, \beta) = \langle \mathbf{y} | \hat{U}(\beta) | \mathbf{x} \rangle$$

В гамильтониане импульс и координата разделяются. Разобъём отрезок времени длины β на $N \to \infty$ одинаковых кусочков размера $\epsilon = \frac{\beta}{N} \to 0$ и представим оператор эволюции в виде $\hat{U}(\beta) = \prod\limits_{i=1}^{N} \hat{U}(\epsilon)$. Эволюцию на бесконечно малое время ϵ можно записать в виде $\hat{U}(\epsilon \to 0) = e^{-\hat{H}\epsilon} \approx e^{-\hat{V}\epsilon} e^{-\hat{K}\epsilon}$. Получаем выражение для оператора эволюции в виде произведения $2N$ множителей (удобно каждому приписать своё время $\tau_k = k\epsilon$):

$$\hat{U}(\tau) = e^{-\hat{V}\epsilon} e^{-\hat{K}\epsilon} ... e^{-\hat{V}\epsilon} e^{-\hat{K}\epsilon}$$

Вставим после каждого члена $e^{-\hat{K}\epsilon}$ (при $\tau = \tau_k$) единицу в виде разложения по координатному базису $\mathbb{I} = \int d\mathbf{x}_k |\mathbf{x}_k\rangle\langle\mathbf{x}_k|$, а после членов $e^{-\hat{V}\epsilon}$ – по импульсному $\hat{I} = \int (d\mathbf{p}_k) |\mathbf{p}_k\rangle\langle\mathbf{p}_k|$

$$G^R(\mathbf{x}, \mathbf{y}, \beta) = \int \prod_{k=1}^{N-1} d\mathbf{x}_k \int \prod_{k=1}^{N} (d\mathbf{p}_k) \langle \mathbf{y} | e^{-\hat{V}\epsilon} | \mathbf{p}_N \rangle \langle \mathbf{p}_N | e^{-i\hat{K}\epsilon} | \mathbf{x}_{N-1} \rangle ... \langle \mathbf{x}_1 | e^{-\hat{V}\epsilon} | \mathbf{p}_1 \rangle \langle \mathbf{p}_1 | e^{-i\hat{K}\epsilon} | \mathbf{x} \rangle$$

Поскольку операторы $e^{-\hat{V}\epsilon}$ – собственные для координаты, а $e^{-\hat{K}\epsilon}$ – для импульса, то блоки вычисляются:

$$\langle \mathbf{x}_k | e^{-\hat{V}\epsilon} | \mathbf{p}_k \rangle \langle \mathbf{p}_k | e^{-\hat{K}\epsilon} | \mathbf{x}_{k-1} \rangle = e^{-V(\mathbf{x}_k)\epsilon} e^{i\mathbf{p}_k \mathbf{x}_k} e^{-K(\mathbf{p}_k)\epsilon} e^{-i\mathbf{p}_k \mathbf{x}_{k-1}}$$

$$G^R(\mathbf{x}, \mathbf{y}, \beta) = \int \prod_{k=1}^{N-1} d\mathbf{x}_k \int \prod_{k=1}^{N} (d\mathbf{p}_k) \exp\left(\epsilon \sum_{k=1}^{N} \left(i\mathbf{p}_k \frac{\mathbf{x}_k - \mathbf{x}_{k-1}}{\epsilon} - \hat{H}(\mathbf{x}_k, \mathbf{p}_k) \right) \right)$$

Возьмём интеграл по импульсам. Кинетическая энергия $K(p) = \frac{p^2}{2m}$, поэтому

$$\int (d\mathbf{p}_k) \exp\left(\epsilon \sum_{k=1}^{N} \left(i\mathbf{p}_k \frac{\mathbf{x}_k - \mathbf{x}_{k-1}}{\epsilon} - \frac{\mathbf{p}_k^2}{2m} \right) \right) = \left(\frac{m}{2\pi\epsilon} \right)^{\frac{d}{2}} \exp\left(-\epsilon \frac{m}{2} \left(\frac{\mathbf{x}_k - \mathbf{x}_{k-1}}{\epsilon} \right)^2 \right)$$

$$G^R(\mathbf{x}, \mathbf{y}, \beta) = \left(\frac{m}{2\pi\epsilon} \right)^{\frac{Nd}{2}} \int \prod_{k=1}^{N-1} d\mathbf{x}_k \exp\left(-\epsilon \sum_{k=1}^{N} \left(\frac{m}{2} \left(\frac{\mathbf{x}_k - \mathbf{x}_{k-1}}{\epsilon} \right)^2 + V(\mathbf{x}_k) \right) \right)$$

В экспоненте стоит конечная аппроксимация интеграла:

$$\sum_{k=1}^{N} \epsilon \left(\frac{m}{2} \left(\frac{\mathbf{x}_k - \mathbf{x}_{k-1}}{\epsilon} \right)^2 + V(\mathbf{x}_k) \right) \approx \int_0^\beta d\tau \left(\frac{m}{2} \dot{\mathbf{x}}(\tau)^2 + V(\mathbf{x}(\tau)) \right)$$

Выберем меру интегрирования:

$$\mathcal{D}[\mathbf{x}(t)] = \left(\frac{m}{2\pi\epsilon} \right)^{\frac{Nd}{2}} \prod_{k=1}^{N-1} d\mathbf{x}_k$$

$$G^R(\mathbf{x},\mathbf{y},\beta)=\int\limits_{\mathbf{x}(0)=\mathbf{x}}^{\mathbf{x}(\beta)=\mathbf{y}}\mathcal{D}[\mathbf{x}(t)]\exp\left(-\int\limits_0^\beta d\tau\left(\frac{m}{2}\dot{\mathbf{x}}(\tau)^2+V(\mathbf{x}(\tau)\right)\right)$$

Матрица плотности в координатном представлении:

$$\rho(\mathbf{x},\mathbf{y},\beta)=\langle\mathbf{y}|\hat{\rho}|\mathbf{x}\rangle=\int\limits_{\mathbf{x}(0)=\mathbf{x}}^{\mathbf{x}(\beta)=\mathbf{y}}\mathcal{D}[\mathbf{x}(t)]\exp\left(-\int\limits_0^\beta d\tau\left(\frac{m}{2}\dot{\mathbf{x}}(\tau)^2+V(\mathbf{x}(\tau)\right)\right)$$

Статистическая сумма:

$$Z=\mathrm{Tr}\rho(\mathbf{x},\mathbf{y},\beta)=\int d\mathbf{x}\rho(\mathbf{x},\mathbf{x},\beta)=\int d\mathbf{x}\int\limits_{\mathbf{x}(0)=\mathbf{x}}^{\mathbf{x}(\beta)=\mathbf{x}}\mathcal{D}[\mathbf{x}(t)]\exp\left(-\int\limits_0^\beta d\tau\left(\frac{m}{2}\dot{\mathbf{x}}(\tau)^2+V(\mathbf{x}(\tau)\right)\right)$$

Как видно, интегрирование идёт по периодическим траекториям $x(\tau)=x(\tau+\beta)$. Заметим, что полученное выражение получается из исходного при помощи Виковского поворота $t=-i\tau$.

20.2.3 Problems about Instantons and Tunneling

ПТФ-17.y1 Квазиклассика и инстантоны (30 б).

Для двухъямного потенциала, что разбирался на семинаре (???), вычислите расщепление уровней в квазиклассическом приближении. Насколько квазиклассическое приближение отличается от правильного ответа, даваемого инстантонным вычислением?

Указание: стандартная формула в квазиклассическом приближении гарантирует правильный численный фактор в предэкспоненте; поэтому именно с такой точностью необходимо вычислить и квазиклассическое действие. Обратите внимание, что действие необходимо считать на энергии, отличной от минимума в соответствующей яме; поправка от этого отличия существенна, поскольку она стоит в экспоненте, и имеется серия неравенств $S(0)\gg|S(E)-S(0)|\gg1$. Несложно убедиться, что эта поправка логарифмическая; причём **вычисление необходимо проводить с точностью до числа под логарифмом** (поскольку это число в конечном итоге модифицирует численный префактор в конечном ответе!).

Сделать это можно следующим образом. Во-первых, технически чуть проще вычислять не само действие $S(E)$, а его производную $\partial S/\partial E$, которая логарифмически расходится при $E\to0$. Для вычисления численного фактора под логарифмом, предлагается ввести произвольный промежуточный пространственный масштаб Λ, удовлетворяющий серии неравенств $|x_1+\eta|\ll\Lambda\ll\eta$ (где x_1 – положение левой точки остановки, которая близка к минимуму $-\eta$), и разбить интеграл на два интервала $\int\limits_{x_1}^{\Lambda}+\int\limits_{\Lambda}^{0}$. В первом интеграле первое же неравенство позволяет использовать осцилляторное приближение для потенциала; а во втором интеграле второе неравенство позволяет использовать разложение в ряд Тейлора по энергии. После соответствующих вычислений (с необходимой точностью!), промежуточный масштаб Λ, в силу своей произвольности, из ответа должен сократиться.

Solution

Гамильтониан:

$$\hat{H}=-\frac{1}{2}\partial_x^2+\lambda(x^2-\eta^2)^2$$

Действие в квазиклассическим приближении:

$$S=2\sqrt{2}\int\limits_{-\eta+\delta\eta}^{0}\sqrt{\lambda(x^2-\eta^2)^2-E}dx,\quad E=4\lambda\eta^2\delta\eta^2$$

Разобьём пределы интегрирования на 2:

$$S=2\sqrt{2}\int\limits_{-\eta+\delta\eta}^{-\eta+\Lambda}\sqrt{\lambda(x^2-\eta^2)^2-E}dx+2\sqrt{2}\int\limits_{-\eta+\Lambda}^{0}\sqrt{\lambda(x^2-\eta^2)^2-E}dx=$$

$$=2\sqrt{2}\int\limits_{\delta\eta}^{\Lambda}\sqrt{4\lambda\eta^2y^2-E}dy+2\sqrt{2}\int\limits_{-\eta+\Lambda}^{0}\sqrt{\lambda(x^2-\eta^2)^2-E}dx$$

В 1 интеграле (S_1) работает осцилляторное приближение, поскольку $\Lambda \ll \eta$. Вычислим его, воспользовавшись уазанием:

$$\frac{\partial S_1}{\partial E} = -2\sqrt{2}\int\limits_{\delta\eta}^{\Lambda} \frac{dy}{2\sqrt{4\lambda\eta^2 y^2 - E}} = -\frac{\sqrt{2}}{2\sqrt{\lambda}\eta}\int\limits_{1}^{\frac{\Lambda}{\delta\eta}} \frac{dz}{\sqrt{z^2-1}} = -\frac{\sqrt{2}}{2\sqrt{\lambda}\eta}\log\left(\frac{\Lambda}{\delta\eta} + \sqrt{\left(\frac{\Lambda}{\delta\eta}\right)^2 - 1}\right)$$

$$S_1 = -\frac{\sqrt{2}}{2\sqrt{\lambda}\eta}\int \log\left(\frac{\Lambda}{\delta\eta} + \sqrt{\left(\frac{\Lambda}{\delta\eta}\right)^2 - 1}\right) dE, \quad dE = 8\lambda\eta^2\delta\eta d(\delta\eta)$$

$$S_1 = -4\sqrt{2\lambda}\eta\int\limits_0^{\delta\eta} \delta\eta \log\left(\frac{\Lambda}{\delta\eta} + \sqrt{\left(\frac{\Lambda}{\delta\eta}\right)^2 - 1}\right) d(\delta\eta) = -2\sqrt{2\lambda}\eta\left(\Lambda(\Lambda - \sqrt{\Lambda^2 - (d\eta)^2}) + \right.$$
$$\left. + (\delta\eta)^2 \log\left(\frac{\Lambda}{\delta\eta} + \sqrt{\left(\frac{\Lambda}{\delta\eta}\right)^2 - 1}\right)\right) \approx 2\sqrt{2\lambda}\eta^2 - \sqrt{2\lambda}\eta(\delta\eta)^2\left(1 + 2\log\left(\frac{2\Lambda}{\delta\eta}\right)\right)$$

Во 2 интеграле (S_2) будет раскладывать в ряд по степеням $\frac{E}{\lambda(\eta^2 - x^2)^2}$.

$$S_2 = 2\sqrt{2}\int\limits_{-\eta+\Lambda}^{0} \sqrt{\lambda(x^2-\eta^2)^2 - E}dx \approx 2\sqrt{2\lambda}\int\limits_{-\eta+\Lambda}^{0} |x^2-\eta^2|\left(1 - \frac{E}{4(\eta^2-x^2)^2}\right)dx =$$
$$= 2\sqrt{2\lambda}\left(\eta^2(\Lambda-\eta) - \frac{(\Lambda-\eta)^3}{3} - \frac{E\sqrt{\lambda}}{2}\int\limits_{-\eta+\Lambda}^{0}\frac{dx}{\lambda(\eta^2-x^2)}\right) =$$
$$= 2\sqrt{2\lambda}\left(\frac{2}{3}\eta^3 - \eta\Lambda^2 + \frac{\Lambda^3}{3} - \frac{E\log\left(-1+\frac{2\eta}{\Lambda}\right)}{4\eta\lambda}\right) = 2\sqrt{2\lambda}\left(\frac{2}{3}\eta^3 - \eta\Lambda^2 + \frac{\Lambda^3}{3}\right) -$$
$$- \frac{E\sqrt{2}\left(\log\left(\frac{2\eta}{\Lambda}\right) - \frac{\Lambda}{2\eta}\right)}{2\eta\sqrt{\lambda}} = 2\sqrt{2\lambda}\left(\frac{2\eta^3}{3} - \eta\Lambda^2 + \frac{\Lambda^3}{3} - \eta(\delta\eta)^2\left(\log\left(\frac{2\eta}{\Lambda}\right) - \frac{\Lambda}{2\eta}\right)\right)$$

$$S = S_1 + S_2 = \frac{2}{3}\omega\eta^2 - \log\left(\frac{4\eta}{\delta\eta}\right) - \frac{1}{2}, \quad \omega = 8\lambda\eta^2(\delta\eta)^2$$

Расщепление уровней:

$$E = \frac{\omega}{2} \pm \frac{\omega}{2\pi}e^{-S} = \frac{\omega}{2} \pm \frac{\omega}{2\pi}e^{-S} = \frac{\omega}{2} \pm \frac{\omega}{2\pi}\exp\left(-\frac{2\omega\eta^2}{3}\right)\frac{4\eta}{\delta\eta}e^{\frac{1}{2}}$$

$$\Delta = \frac{2\sqrt{e}}{\pi}\omega^{\frac{3}{2}}\eta e^{-\frac{2\omega\eta^2}{3}}$$

Ответ отличается от инстантонного в $\sqrt{\frac{e}{\pi}}$ раз.

ПТФ-17.з1. Инстантоны и “математический маятник” (70 б).

Рассмотрите движение частицы массы $m = 1$ в периодическом потенциале $U(x) = \lambda(1 - \cos\frac{x}{\eta})$. Вычислите одноинстантонный вклад в амплитуду перехода между двумя минимумами $0 \to 2\pi\eta$ за большое мнимое время β – Евклидову функцию Грина $G_E(2\pi\eta, 0, \beta)$.

• **(5 б)** Найдите инстантонную траекторию, соответствующую такому переходу, вычислите действие на ней. Вычислите явно оператор, определяющий квадратичные флуктуации в окрестности инстантона.

• **(10 б)** Исследуйте спектр полученного оператора. Вычислите фазовые сдвиги непрерывного спектра и уровни энергии связанных состояний.

• **(10 б)** Рассмотрите отнормированный на осциллятор пропагатор. Идентифицируйте нулевую моду, выполните интегрирование по ней.

• **(35 б)** Вычислите вклад в отношение определителей от дискретного и непрерывного спектра.

• **(10 б)** Просуммируйте инстантонный газ для искомой амплитуды перехода. Сравнив полученный ответ с ответом для соответствующей модели сильной связи, извлеките из полученного ответа ширину зоны непрерывного спектра соответствующей квантомеханической задачи.

Solution

• Потенциал имеет минимумы в точках $x = 2\pi\eta n, n \in \mathbb{Z}$, вблизи которых он имеет осцилляторное разложение $U(x) = \frac{1}{2}\omega^2 x^2$ с частотами $\omega^2 = \frac{\lambda}{\eta^2}$. Евклидово действие:

$$S_E[x(\tau)] = \int \left(\frac{1}{2}(\partial_\tau x)^2 + U(x(\tau))\right) d\tau$$

Нужно найти экстремум действия с граничными условиями $x(\tau \to -\infty) = 0$, $x(\tau \to \infty) = 2\pi\eta$.

$$\frac{\delta S_E}{\delta x(\tau)} = 0 \to \partial_\tau^2 x = U'(x(\tau))$$

Закон сохранения энергии:

$$E = \frac{1}{2}(\partial_\tau x)^2 - U(x(\tau)) = \text{const}$$

На нашей траектории $E = 0$, поэтому

$$\frac{1}{2}(\partial_\tau x)^2 = U(x(\tau)) \to \frac{dx}{\sqrt{1 - \cos\frac{x}{\eta}}} = \sqrt{2\lambda} d\tau$$

$$\sqrt{2}\eta \ln\left(\tan\frac{x}{4\eta}\right) = \sqrt{2\lambda}\tau \to x_{\text{cl}}(\tau) = 4\eta \arctan\left(e^{\omega\tau}\right)$$

Действие на инстантоне:

$$S_0 = S_E[x_{\text{cl}}(\tau)] = \int\limits_{-\infty}^{\infty} (\partial_\tau x_{\text{cl}})^2 d\tau = \int\limits_{-\infty}^{\infty} \frac{4\lambda}{\cosh^2\left(\frac{\sqrt{\lambda}\tau}{\eta}\right)} d\tau$$

$$S_0 = 8\eta\sqrt{\lambda} = 8\eta^2\omega$$

Квадратичное разложение вблизи потенциала:

$$S_E[x_{\text{cl}}(\tau) + z(\tau)] \approx S_0 + \frac{1}{2}\int\limits_0^\beta d\tau((\partial_\tau z)^2 + U''(x_{\text{cl}}(\tau))z^2(\tau))$$

$$U''(x_{\text{cl}}(\tau)) = \frac{\lambda}{\eta^2}\cos\frac{x_{\text{cl}}}{\eta} = \omega^2\cos\left(4\arctan\left(e^{\omega\tau}\right)\right)$$

В квадратичном разложении действия стоит линейный оператор:

$$\hat{L} = -\partial_\tau^2 + U''(x_{\text{cl}}(\tau)) = -\partial_\tau^2 + \omega^2\cos\left(4\arctan\left(e^{\omega\tau}\right)\right)$$

$$\hat{L} = -\partial_\tau^2 + \omega^2\left(1 - \frac{2}{\cosh^2\omega\tau}\right)$$

• Уравнение на спектр оператора $\hat{L}$:

$$\left(-\partial_\tau^2 - \frac{2\omega^2}{\cosh^2\omega\tau}\right)\psi_n(\tau) = (\epsilon_n - \omega^2)\psi_n(\tau)$$

Данное уравнение – уравнение Шрёдингера в потенциале $\frac{1}{\cosh^2 x}$, которое было разобрано в семинаре 4. Воспользуемся ответами из того семинара, в которые нужно подставить следующие значения параметров:

$$m = \frac{1}{2}, \quad a = \frac{1}{\omega}, \quad U_0 = 2\omega^2$$

$$u = \frac{U_0}{1/2ma^2} = 2, \quad s = \frac{1}{2}(\sqrt{1+4u} - 1) = 1$$

Энергии связанных состояний:

$$E_n = -\frac{(s-n)^2}{2ma^2} = -\omega^2(s-n)^2 \to E_0 = -\omega^2$$

$$\epsilon_0 = E_0 + \omega^2 = 0$$

Волноваяя функция нулевой моды:

$$\psi_0(\tau) = \frac{C_0}{\cosh \omega\tau}$$

При целом $s = 1$ рассеяние оказывается безотражательным. Непрерывный спектр характеризуется волновым вектором k, так что энергия $E_k = \frac{k^2}{2m} = k^2 \to \epsilon_k = \omega^2 + k^2$. Волновые функции:

$$\psi_k(x) \approx \begin{cases} \frac{\Gamma(1-ika)\Gamma(-ika)}{\Gamma(-ika-1)\Gamma(-ika+2)} e^{ikx} \equiv e^{ikx+i\delta(k)}, & x \to -\infty \\ e^{ikx}, & x \to +\infty \end{cases}$$

$$e^{-i\delta(k)} = \frac{\Gamma(-ika-1)\Gamma(-ika+2)}{\Gamma(1-ika)\Gamma(-ika)} = \frac{1-ika}{-1-ika} = -\frac{1-ika}{1+ika} = e^{-i\pi - 2i\arctan ka}$$

$$\delta(k) = 2\arctan ka - \pi = \begin{cases} \pi, & k = 0 \\ 0, & k \to \infty \end{cases}$$

Дискретизация непрерывного спектра. Волновая функция имеет вид $\psi_n(x) = A\psi_k(x) + B\psi_k^*(x)$, тогда граничные условия:

$$\begin{cases} A\psi_k(0) + B\psi_k^*(0) = 0, \\ A\psi_k(\beta) + B\psi_k^*(\beta) = 0 \end{cases}$$

Условие совместности системы:

$$\det \begin{pmatrix} \psi_k(0) & \psi_k^*(0) \\ \psi_k(\beta) & \psi_k^*(\beta) \end{pmatrix} = 0$$

Подставляем асимптотики:

$$\det \begin{pmatrix} 1 & 1 \\ e^{ik\beta - i\delta(k)} & e^{-ik\beta + i\delta(k)} \end{pmatrix} = 0 \to k_n\beta - \delta(k_n) = \pi n$$

Решим трансцендентное уравнение по теории возмущений:

$$k_n^{(0)} \approx p_n = \frac{\pi n}{\beta} \to k_n^{(1)} \approx p_n + \frac{\delta(p_n)}{\beta}$$

- Функция Грина гармонического осциллятора:

$$G_0(\beta) = \int\limits_{z(0)=0}^{z(\beta)=0} \mathcal{D}[z(\tau)] \exp\left(-\frac{1}{2}\int\limits_0^\beta ((\partial_\tau z)^2 + \omega^2 z^2)\right)$$

Отношение функций Грина:

$$\frac{G(2\pi\eta, 0, \beta)}{G_0(\beta)} = e^{-S_0} \frac{\int\limits_{z(0)=0}^{z(\beta)=0} \mathcal{D}[z(\tau)] \exp\left(-\frac{1}{2}\int\limits_0^\beta d\tau((\partial_\tau z)^2 + U''(x_{\text{cl}}(\tau))z^2(\tau))\right)}{\int\limits_{z(0)=0}^{z(\beta)=0} \mathcal{D}[z(\tau)] \exp\left(-\frac{1}{2}\int\limits_0^\beta d\tau((\partial_\tau z)^2 + \omega^2 z^2(\tau))\right)}$$

Спектр гармонического осциллятора:

$$\epsilon_p^{(0)} = \omega^2 + p^2, \quad p = p_n = \frac{\pi n}{\beta}$$

Разложене в числителе $z(\tau) = \sum\limits_n c_n\psi_n(\tau)$ и в знаменателе $z(\tau) = \sum\limits_n c_n\psi_n^{(0)}(\tau)$. Интеграл по нулевой моде:

$$\int dc_0 = \int d\tau_c \frac{dc_0}{d\tau_c} = \sqrt{S_0}\beta$$

$$\int dc_1 e^{-\frac{1}{2}\epsilon_1^{(0)} c_1^2} = \sqrt{\frac{2\pi}{\epsilon_1^{(0)}}} = \sqrt{\frac{2\pi}{\omega^2 + \frac{\pi^2}{\beta^2}}} \approx \frac{\sqrt{2\pi}}{\omega}$$

$$\frac{G(2\pi\eta, 0, \beta)}{G_0(\beta)} = e^{-S_0}\omega\beta\sqrt{\frac{S_0}{2\pi}} \left(\frac{\det'(-\partial_\tau^2 + U''(x_{\rm cl}(\tau)))}{\det'(-\partial_\tau^2 + \omega^2)}\right)^{-\frac{1}{2}}$$

$$\frac{\det'}{\det'} = \prod_{n=1}^{\infty} \frac{\omega^2 + k_n^2}{\omega^2 + p_{n+1}^2} = \exp\left(\sum_{n=1}^{\infty} \log \frac{\omega^2 + k_n^2}{\omega^2 + p_{n+1}^2}\right) = \exp\left(\sum_{n=1}^{\infty} \log\left(1 + \frac{k_n^2 - p_{n+1}^2}{\omega^2 + p_{n+1}^2}\right)\right) \approx$$
$$\approx \exp\left(\sum_{n=1}^{\infty} \frac{2p_{n+1}(k_n - p_{n+1})}{\omega^2 + p_{n+1}^2}\right) = \exp\left(\frac{1}{\beta}\sum_{n=1}^{\infty} \frac{2p_{n+1}(\delta(p_n) - \pi)}{\omega^2 + p_{n+1}^2}\right)$$

Для суммирования плавной функции заменим сумму на интеграл $\sum\limits_n = \int\limits_0^\infty \frac{\beta dp}{\pi}$:

$$\frac{\det'}{\det'} = \exp\left(\int_0^\infty \frac{dp 2p(\delta(p) - \pi)}{\pi(\omega^2 + p^2)}\right) = \exp\left(-\frac{1}{\pi}\int_0^\infty dp \frac{d\delta}{dp} \log\frac{\omega^2 + p^2}{\omega^2}\right)$$

$$\frac{\det'}{\det'} = \frac{1}{4}$$

Одноинстантонный ответ:

$$\frac{G(2\pi\eta, 0, \beta)}{G_0(\beta)} = e^{-S_0}\omega\beta\sqrt{\frac{S_0}{2\pi}}\sqrt{4} = \sqrt{\frac{S_0}{\pi}}\omega\beta e^{-S_0} = \sqrt{\frac{8\eta^2\omega}{\pi}}\omega\beta e^{-8\eta^2\omega}$$

• В случае n инстантонов вклад $S_n = nS_0$, полная фаза рассеяния $\delta^{(n)}(p) = n\delta(p)$. С каждым из инстантонов связана нулевая мода

$$\int\limits_{0<\tau_1<\ldots<\tau_n<\beta} d\tau_1 \ldots d\tau_n = \frac{\beta^n}{n!}$$

Для перехода $0 \to 2\pi\eta$ только конфигурации с нечётным количеством интсантонов дают вклад.

$$\frac{G(2\pi\eta, 0, \beta)}{G_0(\beta)} = \sum_{n=0}^{\infty} \frac{^n_{2n+1}}{(2n+1)!} \left(\sqrt{\frac{8\eta^2\omega}{\pi}}\omega\beta e^{-8\eta^2\omega}\right)^{2n+1}$$

ПТФ-18.у1 «Математический маятник», продолжение (10 б).

Вычислите функциональный детерминант, возникающий при исследовании задачи из предыдущего семинара, и сравните его с полученным непосредственным вычислением.

Solution

ПТФ-18.з1. Модификации Гельфанда-Яглома (50 б)

Покажите, как нужно модифицировать теорему Гельфанда-Яглома для вычисления следующих определителей типа уравнения Шрёдингера:

(30 б) Одномерный оператор $\hat{H} = -\partial_x^2 + U(x)$, но для случая периодических граничных условий $\psi(x) \equiv \psi(x + L)$. Вычислите отношение определителей $\frac{\det(-\partial_x^2 + k_1^2)}{\det(-\partial_x^2 + k_2^2)}$.

(10 б) Двумерный оператор $\hat{H} = -\nabla^2 + U(r)$ для сферически-симметричного потенциала.

(10 б) Аналогично, трёхмерный случай.

Solution

•
• Двумерный оператор:

$$\hat{H} = -\nabla^2 + U(r) = -\partial_r^2 - \frac{1}{r}\partial_r - \frac{1}{r^2}\partial_\varphi^2 + U(r)$$

Уравнение на собственные значения:

$$\hat{H}\psi = \lambda\psi$$

Сведём уравнение к одномерному. Разложим волновую функцию по базису $\psi(r,\varphi) = \sum\limits_{m=-\infty}^{\infty} f_m(r)e^{im\varphi}$ и получим

$$-\partial_r^2 f_m(r) - \frac{1}{r}\partial_r f_m(r) + \left(\frac{m^2}{r^2} + U(r) - \lambda\right) f_m(r) = 0$$

Модификация Гельфанда-Яглома для двумерного сферически-симметричного потенциала:

$$\frac{\det(\hat{H}_1 - \lambda)}{\det(\hat{H}_2 - \lambda)} = \prod_{m=-\infty}^{\infty} \frac{f_m^1(R|\lambda)}{f_m^2(R|\lambda)} = \frac{f_0^1(R|\lambda)}{f_0^2(R|\lambda)} \prod_{m=1}^{\infty} \left(\frac{f_m^1(R|\lambda)}{f_m^2(R|\lambda)}\right)^2$$

где $f_m^{1,2}(r|\lambda)$ – решения задачи

$$-\partial_r^2 f_m^{1,2}(r|\lambda) - \frac{1}{r}\partial_r f_m^{1,2}(r|\lambda) + \left(\frac{m^2}{r^2} + U_{1,2}(r) - \lambda\right) f_m^{1,2}(r|\lambda) = 0$$

с граничными условиями $f_m^{1,2}(0|\lambda) = 0$, $\partial_r f_m^{1,2}(0|\lambda) = 1$.

• Трёхмерный оператор:

$$\hat{H} = -\nabla^2 + U(r)$$

Уравнение на собственные значения:

$$\hat{H}\psi = \lambda\psi$$

Сведём уравнение к одномерному. Разложим волновую функцию по базису $\psi(r,\theta,\varphi) = \sum\limits_{l=0}^{\infty}\sum\limits_{m=-l}^{l} R_l(r)Y_{l,m}(\theta,\varphi)$ и получим

$$-\partial_r^2 R_l(r) - \frac{2}{r}\partial_r R_l + \left(\frac{l(l+1)}{r^2} + U(r) - \lambda\right) R_l(r) = 0$$

Модификация Гельфанда-Яглома для трёхмерного сферически-симметричного потенциала:

$$\frac{\det(\hat{H}_1 - \lambda)}{\det(\hat{H}_2 - \lambda)} = \prod_{l=0}^{\infty}\prod_{m=-l}^{l} \frac{R_l^1(R|\lambda)}{R_l^2(R|\lambda)} = \prod_{l=0}^{\infty} \left(\frac{R_l^1(R|\lambda)}{R_l^2(R|\lambda)}\right)^{2l+1}$$

где $R_l^{1,2}(r|\lambda)$ – решения задачи

$$-\partial_r^2 R_l^{1,2}(r) - \frac{2}{r}\partial_r R_l^{1,2} + \left(\frac{l(l+1)}{r^2} + U_{1,2}(r) - \lambda\right) R_l^{1,2}(r) = 0$$

с граничными условиями $R_l^{1,2}(0|\lambda) = 0$, $\partial_r R_l^{1,2}(0|\lambda) = 1$.

ПТФ-18.з2. Дзета-функция Бесселя? (40 б)

• Вычислите следующее бесконечное произведение, в котором $\mu_n^{(m)}$ – n-тый нуль m-той функции Бесселя $J_m(z)$ (очевидным образом $J_{m>0}(0) = 0$; и этот тривиальный нуль в произведении не участвует):

$$P_m(R) = \prod_{n=1}^{\infty} \frac{1 + (\mu_n^{(m)}/R)^2}{(\mu_n^{(m)}/R)^2}$$

Для этого найдите операторы, которые дают соответствующие собственные числа, а затем вычислите их отношения, используя теорему Гельфанда-Яглома.

• Пусть λ_n – все собственные числа эрмитового оператора $\hat{H}$. Покажите, что дзета-функцию оператора $\hat{H}$, которую мы определим следующим образом:

$$\zeta_H(s) = \sum_{n=0} \frac{1}{\lambda_n^s}$$

для натурального аргумента $s \in \mathbb{N}$ можно сосчитать следующим образом:

$$\zeta_H(s) = \frac{(-1)^{s-1}}{(s-1)!} \frac{\partial^s}{\partial \lambda^s} \left(\log \frac{\det(\hat{H} + \lambda)}{\det \hat{H}} \right) \Big|_{\lambda=0}$$

• Докажите следующие равенства:

$$\sum_{n=1}^{\infty} \frac{1}{(\mu_n^{(0)})^2} = \frac{1}{4}, \quad \sum_{n=1}^{\infty} \frac{1}{(\mu_n^{(0)})^4} = \frac{1}{32}, \quad \sum_{n=1}^{\infty} \frac{1}{(\mu_n^{(1)})^2} = \frac{1}{8}$$

Solution

• Рассмотрим гамильтониан:

$$\hat{H}_m = -\partial_r^2 - \frac{1}{r}\partial_r + \frac{m^2}{r^2}$$

Уравнение на собственные значения:

$$\hat{H}_m \psi_m = \lambda \psi_m, \quad \psi_m(0) = \psi_m(R) = 0$$

$$-\partial_r^2 \psi_m - \frac{1}{r}\partial_r \psi_m + \frac{m^2}{r^2}\psi_m = \lambda \psi_m$$

Пусть $z = \sqrt{\lambda} r$ и $f(z) = \psi(z(r))$, тогда

$$z^2 \partial_z^2 f_m + z \partial_z f_m + (z^2 - m^2) f_m = 0$$

Получилась функция Бесселя (функция Неймана сингулярна в 0):

$$f_m(r|\lambda_m) = C_1 J_m(z) \to \psi_m(r|\lambda_m) = C_1 J_m(\sqrt{\lambda_m} r)$$

$$\psi_m(0|\lambda) = 0, \quad \psi_m(R|\lambda) = 0 \to \sqrt{\lambda_n} R = \mu_n^{(m)}$$

$$\lambda_n = \frac{(\mu_n^{(m)})^2}{R^2}$$

$$P_m(R) = \prod_{n=1}^{\infty} \frac{1 + (\mu_n^{(m)}/R)^2}{(\mu_n^{(m)}/R)^2} = \frac{\det(\hat{H}_m + 1)}{\det(\hat{H}_m)}$$

По теореме Гельфанда-Яглома:

$$P_m(R) = \frac{\det(\hat{H}_m + 1)}{\det(\hat{H}_m)} = \frac{\psi_m^{(1)}(R|\lambda_0)}{\psi_m(R|\lambda_0)}, \quad \lambda_0 \to 0$$

где $\psi_m(r|\lambda_0) = C J_m(\sqrt{\lambda_0} r)$, а $\psi_m^{(1)}(r|\lambda_0)$ – решение задачи

$$-\partial_r^2 \psi_m^{(1)} - \frac{1}{r}\partial_r \psi_m^{(1)} + \frac{m^2}{r^2}\psi_m^{(1)} + \psi_m^{(1)} = \lambda_0 \psi_m^{(1)}$$

Пусть $z = \sqrt{1 - \lambda_0} r$ и $f^{(1)}(z) = \psi^{(1)}(z(r))$, тогда

$$z^2 \partial_z^2 f_m^{(1)} + z \partial_z f_m^{(1)} - (z^2 + m^2) f_m^{(1)} = 0$$

Получилась функция Инфильда (функция Макдональда сингулярна в 0):

$$\psi_m^{(1)}(r|\lambda_0) = C_2 I_m(\sqrt{1 - \lambda_0} r)$$

Асимптотики функций Бесселя и Инфильда:

$$\begin{cases} J_m(\sqrt{\lambda_0}r) \approx \frac{1}{m!}\left(\frac{\sqrt{\lambda_0}r}{2}\right)^m \\ I_m(\sqrt{1-\lambda_0}r) \approx \frac{1}{m!}\left(\frac{\sqrt{1-\lambda_0}r}{2}\right)^m \end{cases}, \quad r \to 0$$

Для того, чтобы $\psi_m^{(1)}(r) \sim \psi_m(r)$, выберем $\frac{C_2}{C_1} = \left(\frac{\lambda_0}{1-\lambda_0}\right)^{\frac{m}{2}}$.

$$P_m(R) = \lim_{\lambda_0 \to 0}\left(\frac{\lambda_0}{1-\lambda_0}\right)^{\frac{m}{2}} \frac{I_m(\sqrt{1-\lambda_0}R)}{J_m(\sqrt{\lambda_0}R)} = \frac{I_m(R)2^m m!}{R^m}$$

$$P_m(R) = \frac{2^m m!}{R^m} I_m(R)$$

$$\frac{\det(\hat{H}+\lambda)}{\det \hat{H}} = \prod_{n=0}^{\infty}\frac{\lambda_n+\lambda}{\lambda_n} = \prod_{n=0}^{\infty}\left(1+\frac{\lambda}{\lambda_n}\right)$$

$$\log\left(\frac{\det(\hat{H}+\lambda)}{\det \hat{H}}\right) = \sum_{n=0}^{\infty}\log\left(1+\frac{\lambda}{\lambda_n}\right) = \sum_{n=0}^{\infty}\sum_{k=1}^{\infty}\frac{(-1)^{k-1}}{k}\left(\frac{\lambda}{\lambda_n}\right)^k$$

$$\frac{\partial^s}{\partial\lambda^s}\left(\log\left(\frac{\det(\hat{H}+\lambda)}{\det \hat{H}}\right)\right)\Big|_{\lambda=0} = \sum_{n=0}^{\infty}\sum_{k=s}^{\infty}\frac{(-1)^{k-1}}{k}\frac{\lambda^{k-s}}{\lambda_n^k}\prod_{m=0}^{s-1}(k-m)\Big|_{\lambda=0} =$$

$$= \sum_{n=0}^{\infty}\frac{(-1)^{s-1}}{s}\frac{1}{\lambda_n^s}s! = \sum_{n=0}^{\infty}\frac{(-1)^{s-1}}{\lambda_n^s}(s-1)!$$

$$\zeta_H(s) = \sum_{n=0}\frac{1}{\lambda_n^s} = \frac{(-1)^{s-1}}{(s-1)!}\frac{\partial^s}{\partial\lambda^s}\left(\log\left(\frac{\det(\hat{H}+\lambda)}{\det \hat{H}}\right)\right)\Big|_{\lambda=0}$$

- $$\frac{\det(\hat{H}_m+\lambda)}{\det(\hat{H}_m)} = \prod_{n=0}^{\infty}\left(1+\frac{\lambda}{\lambda_n}\right), \quad \lambda_n = \frac{(\mu_n^{(m)})^2}{R^2}$$

Положим $R=1$, тогда из 2 пункта:

$$\sum_{n=0}\frac{1}{(\mu_n^{(m)})^{2s}} = \frac{(-1)^{s-1}}{(s-1)!}\frac{\partial^s}{\partial\lambda^s}\left(\log\left(\frac{\det(\hat{H}_m+\lambda)}{\det \hat{H}_m}\right)\right)\Big|_{\lambda=0}$$

Повторяя рассуждения пункта 1, получим выражение (R=1):

$$\frac{\det(\hat{H}_m+\lambda)}{\det(\hat{H}_m)} = \frac{2^m m!}{\lambda^{\frac{m}{2}}}I_m(\sqrt{\lambda})$$

$$\sum_{n=0}\frac{1}{(\mu_n^{(m)})^{2s}} = \frac{(-1)^{s-1}}{(s-1)!}\frac{\partial^s}{\partial\lambda^s}\left(\log\left(\frac{2^m m!}{\lambda^{\frac{m}{2}}}I_m(\sqrt{\lambda})\right)\right)\Big|_{\lambda=0}$$

$$\sum_{n=0}^{\infty}\frac{1}{\left(\mu_n^{(0)}\right)^2} = \frac{\partial}{\partial\lambda}\left(\log\left(I_0(\sqrt{\lambda})\right)\right)\Big|_{\lambda=0} = \frac{\partial}{\partial\lambda}\left(\log\left(1+\frac{\lambda}{4}+...\right)\right)\Big|_{\lambda=0}$$

$$\sum_{n=0}^{\infty}\frac{1}{\left(\mu_n^{(0)}\right)^2} = \frac{1}{4}$$

$$\sum_{n=0}^{\infty}\frac{1}{\left(\mu_n^{(0)}\right)^4} = \frac{\partial^2}{\partial\lambda^2}\left(\log\left(I_0(\sqrt{\lambda})\right)\right)\Big|_{\lambda=0} = \frac{\partial^2}{\partial\lambda^2}\left(\log\left(1+\frac{\lambda}{4}+\frac{\lambda^2}{2^6}...\right)\right)\Big|_{\lambda=0}$$

$$\sum_{n=0}^{\infty}\frac{1}{\left(\mu_n^{(0)}\right)^4} = \frac{1}{32}$$

$$\sum_{n=0}^{\infty}\frac{1}{\left(\mu_n^{(1)}\right)^2}=\frac{\partial}{\partial\lambda}\left(\frac{2}{\sqrt{\lambda}}\log\left(I_1(\sqrt{\lambda})\right)\right)\Big|_{\lambda=0}=\frac{\partial}{\partial\lambda}\left(\log\left(\frac{2}{\sqrt{\lambda}}\left(\frac{\sqrt{\lambda}}{2}+\frac{\lambda^{\frac{3}{2}}}{2^4}+...\right)\right)\right)\Big|_{\lambda=0}$$

$$\sum_{n=0}^{\infty}\frac{1}{\left(\mu_n^{(1)}\right)^2}=\frac{1}{8}$$

20.2.4 Decay of a Metastable State (??)

(очень малонужная специфика)

ПТФ-19.у1 (30 б).

В этом упражнении мы будем работать с потенциалом, рассматриваемом на семинаре (????)
• **(10 б)** Вычислите соответствующее отношение функциональных определителей.
• **(20 б)** Найдите ширину уровней энергии для рассматриваемого на семинаре потенциале в квазиклассическом приближении. Сравните квазиклассическое приближение для основного состояния с найденным на семинаре ответом (см. комментарий к упражнению из семинара про двухъямный потенциал).

ПТФ-19.у2 (20 б).

Рассмотрите следующий интеграл, сходящийся при $\mathrm{Re}g>0$:

$$I(g)=\int\limits_{-\infty}^{\infty}dx\cdot\exp\left(-\frac{1}{2}x^2-gx^4\right)$$

• Постройте аналитическое продолжение этого интеграла на всю комплексную плоскость (включая область $\mathrm{Re}g<0$, где этот интеграл буквально расходится).
• Считая $g\ll 1$, найдите линии Стокса для построенного аналитического продолжения. Найдите асимптотическое поведение интеграла в различных секторах комплексной плоскости. Что можно сказать про вклады на самой линии Стокса?

ПТФ-19.з(50 б)

Рассмотрите распад метастабильного состояния частицы массы $m=1$ в потенциале $U(x)=\lambda x^2(\eta^2-x^2)$. Рассматривая Евклидову функцию Грина $G_E(0,0,\beta)$, найдите ширину уровня основного метастабильного состояния.
• **(20 б)** Найдите одноинстантонные траектории, соответствующую такому переходу, вычислите действия на них. Вычислите явно оператор, определяющий квадратичные флуктуации в окрестности инстантона.
• **(20 б)** Вычислите интегралы по нулевым модам, найдите соответствующий флуктуационный детерминант (используя метод Гельфанда-Яглома).
• **(10 б)** Просуммируйте разреженный инстантонный газ, найдите ответ.

20.3 Special Phenomena for Experiments

20.3.1 Problems about Blackbody Radiation and Photons

(Тут мощные задачи, которые нужно дня 4 продумывать. Это же в оптике будет. потом)

О3.2-1.1 Свойства черного тела

Рассматривая равновесное тепловое излучение как идеальный газ фотонов, содержащихся в вакуумированной полости с неподвижными непрозрачными стенками, имеющими постоянную температуру, получить формулу $P=\rho/3$, связывающую плотность энергии теплового излучения ρс давлением излучения P. Найти связь между энергетической светимостью R (интегральной излучательной способностью) абсолютно черного тела и плотностью энергии теплового излучения $\rho(T)$.

Solution

(в статфизе уже это выведено ведь? еще раз сделаю!)

О3.2-1.2 Свойства черного тела

Используя тот факт, что плотность энергии теплового излучения ρ не зависит от объема системы, а также формулу $P = \rho/3$, найти с помощью законов термодинамики зависимость ρ и энтропии s единицы объема от температуры T.

Solution

(???)

1.2* $\rho(T) = aT^4; s(T) = \frac{4a}{3}T^3$, где $a = \frac{4\sigma}{c}$.
Решение. Пусть равновесное тепловое излучение содержится в объеме V. Тогда его внутренняя энергия U и энтропия S соответственно равны

$$U(V,T) = \rho(T)V; S(V,T) = s(T)V$$

Воспользуемся термодинамическими тождествами

$$\left(\frac{\partial S}{\partial V}\right)_T = \left(\frac{\partial P}{\partial T}\right)_V; T\left(\frac{\partial S}{\partial T}\right)_V = C_V = \left(\frac{\partial U}{\partial T}\right)_V$$

Подставляя в первое из них уравнение состояния излучения $P = \rho(T)/3$ и соотношение (*), находим, что

$$s(T) = \frac{1}{3}\frac{d\rho}{dT}$$

Подставляя полученный результат и первое из соотношений (*) во второе тождество, находим уравнение для $\rho(T)$

$$\frac{d^2\rho}{dT^2} = \frac{3}{T}\frac{d\rho}{dT}$$

откуда $\rho(T) = aT^4$, а также

$$s(T) = \frac{1}{3}\frac{d\rho}{dT} = \frac{4}{3}aT^3$$

Полученная постоянная a в этих выражениях может быть выражена через постоянную Стефана - Больцмана $\sigma = 5,67 \cdot 10^{-5}$ эрг / $\left(\text{с} \cdot \text{см}^2 \cdot \text{К}^4\right)$. Интегральная плотность потока теплового излучения j [эрг/(см $^2 \cdot$ с)] зависит от температуры по закону Стефана-Больцмана $j = \sigma T^4$. Кроме того, $j = c\rho/4$ (см. задачу 1.1), откуда постоянная $a = 4\sigma/c = 7,56 \cdot 10^{-15}$ эрг/(см $^3 \cdot$ К^4).

Заметим, что соотношение $j = c\rho/4$ легко получить, если рассматривать излучение как идеальный газ фотонов, движущихся со скоростью c. Как известно из молекулярно-кинетической теории газов, плотность потока частиц, т. е. число частиц z, движущихся со средней тепловой скоростью $\bar{v}$ и пересекающих за 1 с единицу площади поверхности стенки сосуда, равно $z = n\bar{v}/4$. В этой формуле n - концентрация молекул газа, в нашем случае - это число фотонов в единице объема.

О3.2-1.3 Энтропия при расширении

Найти изменение энтропии равновесного теплового излучения абсолютно черного тела при расширении объема, занятого излучением, от V_1 до V_2 при постоянной температуре T.

Solution

(???)

1.3. $S_2 - S_1 = \frac{16\sigma}{3c}T^3(V_2 - V_1)$.

О3.2-1.4 Свойства черного тела

Используя формулы для энергии и энтропии равновесного теплового излучения, показать, что свободная энергия излучения может быть представлена в виде $\Psi = -AVT^4$, где V - объем, T - температура. Воспользовавшись законом Стефана-Больцмана, выразить A через постоянную Стефана-Больцмана σ. Пользуясь термодинамическими формулами, определить по найденному ч теплоемкость c_V фотонного газа в расчете на единицу объема и давление излучения P. Сравнить ее с теплоемкостью с $'$ единицы объема идеального одноатомного газа при одинаковых значениях P и T. Вычислить значение термодинамического потенциала Гиббса $\Phi = \Psi + PV$

Solution

(???)

1.4. $A = \frac{4\sigma}{3c}; c_V = \frac{16\sigma}{3c}T^3; P = \frac{4\sigma}{3c}T^4; c_V = 8c_V^{\text{ид.}}; \Phi = 0.$

О3.2-1.5 Цикл Карно фотонами (?????)

Найти работу, которую совершает в цикле Карно равновесное тепловое излучение абсолютно черного тела, полагая известными температуры «горячей» и «холодной изотерм T_1 и T_2, а также максимальный и минимальный объемы V_2 и V_1 системы на изотерме T_1.

Solution

(??по идее какая-то типичная термодинамика даст ответ, просто у нас другое ур. состояния?)

1.5. $A = \frac{16\sigma}{3c}T_1^3\,(T_1 - T_2)\,(V_2 - V_1).$

О3.2-1.6 Неон и фотоны

Газообразный неон находится в замкнутом сосуде постоянного объема в равновесии с тепловым излучением. При каком давлении P неона его теплоемкость равна теплоемкости теплового излучения в том же объеме при $T = 500$ К?

Solution

(???)

1.6. $P = \frac{32\sigma}{3c}T^4 = 1,26 \cdot 10^{-3}$ дин $/\text{см}^2 = 1,26 \cdot 10^{-4}\text{П} \approx 10^{-6}$ мм рт. ст.

О3.2-1.7 Теплоемкость и адиабата фотонов

Найти теплоемкость C_P и уравнение адиабаты фотонного газа, заключенного в сосуд с переменным объемом.

Solution

(???)

1.7. $C_P = \infty; VT^3 = \text{const}$ или $PV^{4/3} = \text{const}.$

О3.2-1.8 Температура фотонов

При какой температуре T давление равновесного теплового излучения равно $P = 1$ атм?

Solution

(? по идее где-то есть формула P(T).... такое нужно бы уметь делать??)

1.8. $T = \left(\frac{3c}{4\sigma}P\right)^{1/4} \approx 1,4 \cdot 10^5$ К.

О3.2-1.9 Концентрация газа для свойств фотона

При какой концентрации n молекул газа газокинетическое давление равно давлению равновесного теплового излучения при той же температуре $T = 300$ К?

Solution

(???)

1.9. $n = \frac{4\sigma}{3ck_\text{B}}T^3 \approx 1,8 \cdot 10^7\ \text{см}^{-3}.$

O3.2-1.10

При расчете теплоемкости C_V идеального газа, находящегося в равновесии с тепловым излучением в замкнутом сосуде постоянного объема, обычно пренебрегают вкладом равновесного излучения в теплоемкость системы. Найти отношение теплоемкостей C_y одноатомного газа и равновесного излучения, когда их давления одинаковы.

Solution

(???)

1.10. $\frac{C_V^{\text{ид}}}{C_V^{\text{идг}}} = \frac{1}{8}$.

O3.2-1.11 Сосуд, фотоны и поршень

Цилиндрический сосуд разделен на две части теплонепроницаемым поршнем, который может свободно перемещаться вдоль цилиндра герметично и без трения. В одной части сосуда находится идеальный газ, а в другой - равновесное тепловое излучение при температуре $T = 10^3$ K. Найти концентрацию атомов газа, если при малых изменениях температуры в обеих частях сосуда на одну и ту же величину направление смещения поршня не зависит or знака этой величины. Чему была равна начальная температура газа $T_{\text{г}}$?

Solution

(???)

Температуры в обеих частях сосуда разные. Запишем условие механического равновесия поршня

$$P_1 = nk_{\text{Б}}T_1 = \frac{4\sigma}{3c}T_2^4 = P_2$$

где индекс 1 относится к газу, а 2 - к излучению. Естественно предположить, что $T_1 \ll T_2$, так что давлением излучения при T_1 можно пренебречь. По условию задачи при малых изменениях температуры в обеих частях сосуда на одну и ту же величину направление смещения поршня не зависит от знака этой величины. Это означает, что в зависимости объема одной из частей сосуда от температуры имеется экстремум (минимум, если система устойчива), в окрестности которого $\partial V/\partial T = 0$. Так как $N = nV = \text{const}$, то в линейном приближении по отклонениям от равновесия $n\frac{\partial V}{\partial T} + V\frac{\partial n}{\partial T} = 0$, и, следовательно, $n/\partial T = 0$. Тогда из соотношения (*) следует

$$nk_{\text{Б}}\, dT_1 = \frac{16}{3c}\sigma T_2^3 dT_2$$

По условию задачи $dT_1 = dT_2$, откуда

$$n = \frac{16\sigma T_2^3}{3ck_{\text{Б}}} = 7,3 \cdot 10^{10}\ \text{см}^{-3}$$

Начальная температура газа $T_1 = T_2/4 = 250$ K. Поэтому отношение давлений излучения $\frac{P_1^{\text{изл}}}{P_2^{\text{изл}}} = \left(\frac{T_1}{T_2}\right)^4 = \frac{1}{256} \ll 1$, что оправдывает сделанное предположение о малости температуры газа в сравнении с температурой излучения.

ответ: 1.11* $n = \frac{16\sigma}{3ck_{\text{b}}}T^3 = 7,3 \cdot 10^{10}\ \text{см}^{-3}, T_{\text{г}} = \frac{T}{4} = 250$ K.

O3.2-1.12 Плоскость, шар и фотоны

Над плоскостью, зачерненной с обеих сторон, на высоте h расположен центр шара радиусом $a \propto h$, являющийся источником равновесного теплового излучения с температурой T_0. Найти стационарное распределение температуры на плоскости. Считать, что система находится в вакууме, фон теплового излучения отсутствует и теплопроводностью вдоль плоскости можно пренебречь.

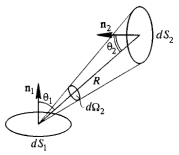
Solution

(???впишу в 1ю часть, не очевидный метод!! также в оптике это укажу!)

Поток энергии, излученный элементом поверхности dS_1, и падающий на элемент другой поверхности dS_2, определяется соотношением

$$d^2\Phi = \frac{B dS_1 ds_2 \cos\theta_1 \cos\theta_2}{R^2}$$

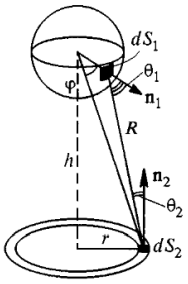
где в соответствии с рис. $200\mathbf{n}_1$ и $\mathbf{n}_2$ - единичные векторы нормалей к соответствующим площадкам, R - расстояние между площадками, B - коэффициент пропорциональности, называемый поверхностной яркостью (см. задачу 1.1), вообще говоря, зависящий от угла θ_1 (а также азимутального угла φ_1, не изображенного на рисунке).



угла φ_1, не изображенного на рисунке). Для абсолютно черного тела $B = \text{const}$ (закон Ламберта) и $B = \frac{\sigma T^4}{\pi}$. Если ввести телесный угол $d\Omega_2 = \frac{dS_2 \cos\theta_2}{R^2}$, под которым видна площадка dS_2 из центра первой плоIщадки, то

$$d^2\Phi = \frac{\sigma T^4}{\pi} dS_1 \cos\theta_1 d\Omega_2$$

На рис. 201 изображен шар - источник равновесного излучения, а под ним - зачерненная с обеих сторон поверхность, где и надо найти распределение температур.



Из соображений симметрии ясно, что $T = T(r)$. При условии $h \gg a$ телесный угол, под которым из центра шара видно кольцо радиусом r на плоскости

$$d\Omega_2 \simeq \frac{2\pi r dr \cos\theta_2}{R^2} = \frac{2\pi r dr}{h^2 r^2} \frac{h}{\sqrt{h^2 + r^2}}$$

Кроме того, условие $h \gg a$ позволяет считать, что $\theta_1 \approx \varphi$, где φ - угол между нормалью к dS_1 (т. е. радиусом) и вертикалью. Поэтому $dS_1 \cos\theta_1 \approx\approx dS_1 \cos\varphi = dS_1'$, где dS_1' - проекция dS_1 на экваториальную плоскость шара. Суммирование (интегрирование) по всем элементам полусферы дает πa^2. Поэтому поток излученной шаром энергии и поглощенный кольцом

$$d\Phi = \pi a^2 \frac{\sigma T_0^4}{\pi} \frac{2\pi r dr h}{\left(h^2 + r^2\right)^{3/2}}$$

В равновесии этот поток переизлучается кольцом по обе стороны плоскости:

$$d\Phi = 2\pi r dr \cdot 2\sigma T^4(r)$$

Из равенства этих потоков и следует ответ

$$T^4(r) = T_0^4 \frac{a^2 h}{2\left(h^2 + r^2\right)^{3/2}}$$

Ответ: 1.12* $T^4(r) = T_0^4 \frac{R^2 h}{2(h^2+r^2)^{3/2}}$.

О3.2-1.13

Решить предыдущую задачу, считая источником теплового излучения бесконечный круглый цилиндр радиусом a. Ось цилиндра параллельна плоскости и находится на расстоянии h от нее.

Solution

(???по идее для решения достаточно понять 1.12 задачу!)

O3.2-1.14

Над плоскостью, зачерненной с обеих сторон, на высоте h расположен круглый диск радиусом a, являющийся источником равновесного теплового излучения с температурой T_0. Радиус диска $a \propto h$, диск расположен параллельно плоскости. Найти стационарное распределение температуры $T = T(r)$ на плоскости, где r - расстояние от проекции центра диска. Считать, что система находится в вакууме, фон теплового излучения отсутствует и теплопроводностью вдоль плоскости можно пренебречь.

Solution

(???по идее для решения достаточно понять 1.12 задачу!)

O3.2-1.15

Имеются два полых тела, абсолютно отражающих снаружи и черных внутри. Оба тела имеют отверстия радиусом r и расположены на расстоянии $R (R \gg r)$. Первое тело имеет температуру T_1 и является единственным источником тепла для второго тела. Найти температуру второго тела T_2 при различных наклонах плоскостей отверстий по отношению k соединяющей их прямой. Насколько изменится T_2 при изменении угла наклона второго тела от 0 до 45*?

Solution

(???по идее для решения достаточно понять 1.12 задачу!)

O3.2-1.16

Два одинаковых абсолютно черных шарика расположены в вакууме на расстоянии $2l = 8$ см друг от друга. Посередине между двумя шариками помещена линза диаметром $D = 6$ cm, собирающая излучение одного шарика на поверхность другого. Один из шариков раскален до температуры $T_1 = 2000$ K. Определить температуру другого шарика, пренебрегая фоном теплового излучения и потерями в линзе.

Solution

(???по идее для решения достаточно понять 1.12 задачу!)

O3.2-1.17

В сферической оболочке диаметром D имеется отверстие диаметром $d \propto D$. Внутренняя поверхность оболочки рассеивает излучение диффузно по закону Ламберта с коэффициентом рассеяния $\rho < 1$. Определить коэффициент поглощения A, характеризующий отверстие для внешнего наблюдателя. При каком отношении диаметров d/D коэффициент поглощения A будет отличаться от I меньше, чем на $0,1\%$, если $\rho \approx 1$?

Solution

(???по идее для решения достаточно понять 1.12 задачу!)

O3.2-1.18 Нагревание линзой (!?!?!??!)

Линза со светосилой 1:16 (это отношение D^2/F^2) собирает солнечный свет на поверхность черного шарика, помещенного в вакуум. До какой температуры T может нагреться шарик, диаметр которого равен диаметру изображения Солнца? Считать Солнце абсолютно черным телом с температурой $T_\mathrm{C} = 6000$ K.

Solution

(???)

Вычислим величину телесного угла Ω, под которым была бы видна линза из центра Солнца. Пусть L - расстояние от Солнца до Земли, а D - диаметр линзы. Угол α, под которым из центра Солнца виден радиус линзы, равен $\alpha = D/2L$, отсюда

$$\Omega = 2\pi(1 - \cos\alpha) = 4\pi \sin^2 \frac{\alpha}{2} \approx \pi\alpha^2 = \pi \left(\frac{D}{2I}\right)^2$$

Плотность потока энергии, излучаемой с поверхности Солнца, $j = \sigma T_{\text{C}}^4$. Поток энергии, излучаемой с поверхности Солнца в единицу телесного угла, равен $\frac{\sigma T_{\text{C}}^4 4\pi R_{\text{C}}^2}{4\pi}$. Мощность солнечного излучения, падающего на линзу,

$$N_{\text{C}} = \sigma T_{\text{C}}^4 R_{\text{C}}^2 \pi \left(\frac{D}{2L}\right)^2$$

Нагреваясь, шарик, излучает. Когда поток энергии, полученной от Солнца, сравняется с потоком излученной энергии, установится равновесная температура шарика. Поток энергии с поверхности шарика диаметром d

$$N_{\text{Ш}} = \sigma T^4 4\pi \frac{d^2}{4}$$

По условию размер изображения Солнца $\alpha_C F$ равен диаметру d шарика, где $\alpha_C = \frac{2R_C^2}{L}$ - угловой размер Солнца, а F - фокусное расстояние линзы. Таким образом,

$$N_{\text{m}} = \sigma T^4 \pi d^2 = \sigma T^4 \pi \alpha_{\text{C}}^2 F^2 = \sigma T^4 \pi F^2 \frac{4R_{\text{C}}^2}{L^2}$$

Приравнивая потоки энергии N_{C} и $N_{\text{ш}}$, получаем

$$\sigma T_{\text{C}}^4 R_{\text{C}}^2 \pi \frac{D^2}{4L^2} = \sigma T^4 F^2 \pi \frac{4R_{\text{C}}^2}{L^2}$$

откуда и находим искомую температуру шарика

$$T = \frac{T_{\text{C}}}{2}\sqrt{\frac{D}{F}} = 1500 \text{ K}$$

Ответ: 1.18* $T = \frac{T_{\text{C}}}{2}\sqrt{\frac{D}{F}} = 1500$ K.

О3.2-1.19 Нагревание воздушного шара

Объектив диаметром $D = 5$см и фокусным расстоянием $F = 5$ см фокусирует солнечный свет на абсолютно черный шар диаметром $d = 1$ мм, обладающий высокой теплопроводностью и находящийся в высоком вакууме вне Земли, на ее орбите. Определить температуру T шара. Принять, что плотность потока солнечной энергии равна $J_{\text{C}} = 0,14\text{Вт/см}^2$, температура стенок сосуда $T_0 = 300$ K. Потерями энергии в объективе пренебречь. Угловой размер Солнца $a_{\text{C}} = 0,01$ рад.

Solution

(???)

1.19. $T = T_0 \left(1 + \frac{j_{\text{C}} D^2}{4\sigma T_0^4 d^2}\right)^{1/4} \approx 1980$ K.

О3.2-1.20

Найти отношение плотностей потоков энергии корпускулярного и электромагнитного излучения Солнца в околоземном пространстве. Считать, что корпускулярный поток представляет собой нейтральную плазму из протонов и электронов с концентрацией $n = 5\ \text{см}^{-3}$ частиц каждого сорта и скоростью потока $v = 300$ км/с, а Солнце - источник равновесного теплового излучения с температурой $T = 6000$ K. Выразить результат через угловой размер α_{C} Солнца, т. е. угол, под которым с Земли виден диаметр Солнца ($\alpha_{\text{C}} = 0,01$ рад).

О3.2-1.21

Солнечная постоянная $J_{\text{С}}$ означает мощность излучения, падающего на единицу площади, помещенной перпендикулярно солнечным лучам за пределами земной атмосферы на расстоянии от Солнца, равном среднему расстоянию межау Землей и Солнцем $L = 1,5 \cdot 10^8$ км. Принимая $J_{\text{С}} = 0,14\text{ВТ}/\text{ см }^2$ и радиус Солнца $R_{\text{С}} = 7 \cdot 10^5$, определить радиационную температуру $T_{\text{раа}}$ излучающей поверхности Солнца.

О3.2-1.22

Спектр излучения космического рентгеновского источника соответствует спектру излучения абсолютно черного тела. Максимум плотности излучения $\rho(\lambda)$ наблюдается на длине волны $\lambda_{\max} = 2$ А, а суммарная по спектру (интегральная) плотность потока на Земле $j = 10^{-11}\text{В}/\text{см}^2$. Расстояние от Земли до источника $L = 1,3 \cdot 10^4$ световых лет. Оценить диаметр источника.

О3.2-1.23

Абсолютно черное тело подвешено в вакуумной установке так, что через оптическое окно на него падает солнечный свет. Если стенки установки охладить до температуры $T_{\text{ст}} = 77$ К, то тело будет иметь $T_1 = 275$ К. Найти температуру тела T_2 при $T_{\text{ст}2} = 295$ К. Теплопроводностью остаточных газов и подвески пренебречь.

О3.2-1.24

На графитовый шарик радиусом $r = 1$ см, подвешенный точно в центре сферы с зеркальными стенками, находящейся в околоземном пространстве, с помощью линзы фокусируется изображение Солнца (рис. 66). Радиус сферы $R = 0,25$М, диаметр линзы $D = 2,5$ cm, фокусное расстояние линзы $F = 0,25$, угловой размер Солнца $\alpha_{\text{С}} = 10^{-2}$, температура поверхности Солнца $T_{\text{С}} = 6 \cdot 10^3$ К. Считая графит абсолютно чер- ным телом, найти установившуюся темпера- туру шарика T

О3.2-1.25

. Хорошо теплопроводящий шар с за- черненной поверхностью находится в косми- ческом пространстве на некотором расстоянии r от центра Солнца. Найти температуру шара, если он находится or Солнца на расстояниях, равных радиусам орбит Венеры, Земли, Марса и Юпитера, равных (в млн км) $R_{\text{В}} = 108, R_3 = 150, R_{\text{М}} = 228$, $R_l = 780$. Солнце считать источником равновесного теплового излучить полученные величины с радиоастрономическими данными: средЗемли, Марса и Юпитера оцениваются, соответственно, как $T_{\text{В}} = 735$ К, $T_3 = 275$ К, $T_{\text{М}} = 235$ К и $T = 135$ К. Чем можно объяснить большое расхождение рассчитанной таким образом и полученной в измерениях температуры поверхности Венеры?

О3.2-1.26

Оценить температуру Солнца, исходя из его видимого углового размера $a_{\text{С}} = 0,01$ рад и температуры земной поверхности ($T_3 \simeq 300$ К)

О3.2-1.27

Космонавт оказался в свободном пространстве в тени Земли. Считая что его организм в процессе нормальной жизнедеятельности выделяет мощность $W = 100$ВТ, оценить скорость изменения температуры космонавта. Коэффициент отражения скафандра $\varepsilon = 0,95$.

О3.2-1.28

Межпланетная станция имеет оболочку в форме шара диаметром $2r = 1$ м. На борту станции находится радиопередатчик моцностью $N = 200$Вт с КПД $\eta = 50\%$. Станция заполнена теплообменным газом. Аппаратура станции может работать в интервале температур $t = -50 \div 100°$С. Определить, при каких удалениях L от Солнца станция может работать: 1) при кратковременных включениях; 2) в непрерывном режиме. Какова должна быть отражательная способность а поверхности станции, чтобы станция могла работать при сколь угодно большом удалении от Солнца? Радиус Солнца $R_{\text{С}} = 7 \cdot 10^5$; считать, что оно излучает как абсолютно черное тело с температурой $T_{\text{С}} = 6000$ К.

О3.2-1.29

В свободном пространстве находится железная пластина, одна поверхность которой абсолютно «чернаяэ, а другая - идеально

О3.2-1.42

Слой вещества поглощает практически все фотоны солнечного спектра с энергией $\mathscr{E} \geqslant 0,2$ эВ и полностью прозрачен для фотонов с меньшей энергией. Оценить, какую долю x солнечной энергии пропускает вещество. Считать спектр Солнца планковским с температурой $T = 6000$ К.

О3.2-1.43

Слой вещества поглощает практически все фотоны солнечного спектра с энергией § $\geqslant$ 12 эВ и полностью прозрачен для фотонов с меньшей энергией. Оценить, какую долю x солнечной энергии пропускает вещество. Считать спектр Солнца планковским с температурой $T = 6000$ К.

О3.2-1.44

Поверхность некоторого тела приготовлена таким образом, что коэффициент поглощения электромагнитного излучения $A = 1$ для частот $\omega \leqslant \omega_0$ и $A = 0$ при $\omega > \omega_0$. Это тело помещено в вакуум и в отсутствии аругих источников излучения нагревается за счет внутреннего источника энергии до температуры T. Определить эту температуру, если известно, что для такого же тела с абсолютно черной поверхностью в тех же условиях равновесная температура $T^* = 300$ К. Граничная частота соответствует температуре $\theta = \hbar\omega_0/k_5 = 300$ К.

О3.2-1.45

Частотная зависимость коэффициента поглощения A некоторого тела, имеющего внутренний источник энергии, изображена на рис. 70. Это тело помещено в космическом пространстве вдали от источников излучения. Такое же тело, но с абсолютно черной поверхностью, нагревается там до температуры $T^* = 100$ К. Определить температуру тела, если величины ω_1 и ω_2 соответствуют энергиям квантов 0,015 эВ и 0,6 эВ. дется в направлении, перпендикулльрном илоскости слоя. Піри какой толщине d слоя Рис. 70 ся равной 90% интенсивности равновесного излучения? Линейный коэффициент поглощения данной длины волны $x = 0,1$ cm^{-1}. Показатели преломления плазмы и окружающей среды считать при этом одинаковыми.

О3.2-1.47

Излучение Солнца регистрируется селективным приемником на длине волны $\lambda = 300$ нм с относительной шириной области чувствительности $\Delta\lambda/\lambda = 10^{-3}$ за промежутки времени $\tau = 10^{-3}$с. Найти относительную среднеквадратичную флуктуацию принимаемого сигнала. Солнце считать абсолютно черным телом с температурой $T = 6000$ К и видимым угловым размером $\alpha_C = 0,01$. Площадь, приемной площадки равна $S = 1$ мм^2. [2].

Указание. Так как энергия кванта $\hbar\omega \gg k_5 T$, то среднее планковское число заполнения (среднее число фотонов) $\bar{n}_\infty$ &1, и поэтому к фотонам можно применять классическую, а не квантовую статистику.

О3.2-1.48

Радиоизлучение из межзвездного пространства (реликтовое излучение) регистрируется приемником с фиксированной относительной полосой пропускания $\Delta v/v = \text{const}$. Оказалось, что при переходе от приема на длине волны $\lambda_1 = 3$ cm приему на длине волны $\lambda_2 = 0,3$ см величина сигнала возросла в 400 раз, причем при дальнейшем небольшом уменьшении λ увеличилась незначительно. Исходя из этих данных, определить температуру реликтового излучения, считая его равновесным тепловым излучением. Во сколько раз изменится сигнал при переходе от $\lambda = 3$см$\lambda = 30$ cm?

Указание. Корнем уравнения $e^x - 2,5x = 1$, которое возникает при решении задачи, является $x \approx 1,62$.

О3.2-1.49

Лазер на рубине излучает в импульсе длительностью $\tau = 0,5$ мс энергию $= 10$ Дж в виде почти параллельного светового пучка сечением $S = 1$ cm^2. Рабочая длина волны лазера $\lambda = 6943$Å, ширина линии $\Delta\lambda = 0,01$ Å. Определить по спектральной плотности пучке а) до фокусировки, б) при максимально возможном сужении пучка (в фокусе).

О3.2-1.50

Определить температуру абсолютно черного тела, спектральная яркость излучения которого равна яркости лазерного излучения с энергией в импульсе $\mathscr{E} = 1$ Дж. Считать, что расходимость лазерного пучка определяется только дифракцией на выходном отверстии, а немонохроматичность - длительностью импульса.

O3.2-1.51

При какой температуре интенсивность излучения поверхности абсолютно черного тела в соответствующем спектральном интервале (энергия, уносимая с единицы поверхности в единицу времени в единицу телесного угла) сравнится с интенсивностью лазера с плотностью потока энергии $j = 1$ мВт/см ^{2} и относительной стабильностью частоты $\Delta v/v = 10^{-12}$, работающего на длине волны $\lambda = 6900$ А? Диаметр пучка принять равным $d = 1$ cm.

O3.2-1.52

Оценить эффективную температуру гелий-неонового лазера, генерирующего в непрерывном режиме свет с шириной спектраль ной линии $\partial v = 10^4$ Гц. Мощность излучения лазера $W = 1$ мВт.

O3.2-1.53

Измерение интенсивности реликтового излучения Вселенной производится радиоскопом вблизи $\lambda = 3$ см. Его антенный тракт находится при температуре $T = 300$ K и поглощает $a = 1\%$ поступающей мощности. Какой аффективной температуре абсолютно черного тела T_{eff} соответствует тепловой шум антенного тракта в области данной длины волны?

Solution

(???)

O3.2-1.54

Атом Na находится в пучке лазерного света с плотностью потока энергии j и длиной волны $\lambda = 0,59$ мкм, совпадающей с одной из спектральных линий Na. Время спонтанного испускания Na для этой линии $\tau = 16$ нс. При больших плотностях потока $j > j_0$ ускорение a, приобретаемое атомом за счет давления света, перестает зависеть от j. Оценить значение плотности потока насыщения j_0. Определить также предельную величину a. Доплеровским сдвигом частоты при излучении движущегося атома пренебречь.

Solution

(???)

O3.2-1.55

. Возбужденный атом с энергией возбуждения & = 1 эВ находится в поле равновесного излучения с температурой $T = 300$ K. Найти отношение вероятностей индуцированного и спонтанного излучений атома. Найти аналогичное отношение для электронного спина в магнитном поле с индукцией $B = 10^3$Гс.

O3.2-1.56 Когда спонтанное вероятнее индуцированного

Определить диапазон частот излучения, при котором вероятность спонтанного перехода более чем в 100 раз превосходит вероятность индуцированного перехода под влиянием равновесного излучения температуры $T = 293$ K.

Solution

(???)

O3.2-1.57

Система, состоящая из атомов, имеющих два невырожденных уровня энергии $\oint_1$ и $\oint_2 > \oint_1$, находится в тепловом равновесии. Выразить коэффициент поглощения света $\varkappa(T, \omega)$ этой системой на частоте $\omega = (_2 - _1)/h$ через его значение x_0 при $T = 0$. Рассмотреть два предельных случая: 1) $k_{\text{b}}T \gg h\omega$ и 2) $k_{\text{b}}T \& h\omega$.

Solution

(???)

O3.2-1.58

Оценить вероятность $W_{\text{сп}}$ спонтанного излучения молекулы при переходе с возбужденного уровня $\oint_n$ на уровень $\oint_m$ в случае, когда молекула помещена внутрь объемного резонатора, настроенного на частоту $\omega = (\delta_n - \delta_m)/h$. Соответствующая вероятность спонтанного излучения в свободном пространстве равна $W^0_{\text{сп}}$ Объем резонатора равен V, его добротность - Q. Считать, что ширина Γ молекулярных уровней все время остается меньше ширины ω/Q линии резонатора: $\Gamma < \omega/Q$. Сделать численную оценку для случаев: 1) $V = 1$ см$^3, \lambda = 1$ см, $Q = 10^4$ и 2) $V = 1$ см$^3, \lambda = 1$ мкм, $Q = 10^6$.

Solution

(???)

O3.2-1.59

Резонатор лазера с кристаллом рубина имеет одно зеркало со 100%-ным отражением, а другое - с коэффициентом пропускания $\tau = 0,1$ на длине волны, отвечающей генерации лазера. Длина кристалла $l = 12$ см. Известно, что коэффициент поглощения света в невозбужденном кристалле рубина в максимуме рабочей линии равен $k_n = 0,4$ см$^{-1}$. Найти, какую часть атомов хрома нужно перевести в возбужденное состояние, чтобы лазер начал работать. Рассеянием света в кристалле пренебречь.

Solution

(???)

O3.2-1.60 Перестройка частоты

В спектре энергетических уровней молекулы воды есть два уровня A и B с разностью энергий δ_{0+} между которыми разрешены оптические переходы. Создавая в разреженном водяном паре при температуре $T = 300$ К тлеющий разряд, не нагревающий пар, можно получить инверсную заселенность этих уровней. На этом основана работа лазера, в котором электромагнитная волна с частотой $v_0 = \delta_0/h = 8,48 \cdot 10^{11}\Gamma$ усиливается по мощности на длине резонатора в $\beta_0 = 1,04$ раз. Расстояние между зеркалами резонатора можно слегка менять, регулируя тем самым собственную частоту резонатора. Коэффициент отражения каждого из зеркал $R = 0,99$. Определить возможную перестройку частоты излучения лазера, принимая во внимание эффект Доплера, обусловленный тепловым движением молекул.

Solution

(???)

O3.2-1.70

. Зеркальный металлический прямоугольный волновод с поперечным сечением 34×72 мм и длиной $L =$ 10 м замкнут накоротко с обоих концов и через малое отверстие соединен с абсолютно черной полостью, нагретой до температуры $T = 600$ К. Оценить плотность электромагнитной Энергии в волноводе (в эрг/Гц) в диа пазоне длин волн 10 см.

O3.2-1.71. Время жизни черной дыры (??)

Как показал в 1974 г. С. Хокинг, черная дыра массой M за счет квантовых эффектов и конечных размеров излучает как абсолютно черное тело с температурой $T(M) = hc^3/(8\pi k_{\text{ь}}\psi M)$. Оценить время жизни черной дыры с массой $M = 10^{15}$г до ее полного испарения.

Solution (????)

O3.2-1.72

Яркая желто-зеленая линия полярного сияния (aurora borealis) возникает при возбуждении атомов кислорода в верхних слоях атмосферы под действием солнечного ветра (потока быстрых электронов и протонов). Время жизни возбужаенного состояния атома кислорода относительно спонтанного перехода составляет т $\simeq 0,74$с. Однако столкновения атомов кислорода с молекулами атмосферы могут снять это возбуждение безызлучательным способом. Эффективное сечение этого процесса $\sigma \simeq 7 \cdot 10^{-15}$ см^2. Оценить, на какой высоте над Землей «загорается эта линия. Атмосферу считать изотермической с $T = 240$ К

O3.2-1.73

Рекомбинация ионов и злектронов в межзвездной среде приводит к образованию атомов в высоковозбужденных состояниях с главным Квантовым числом $n > 1$ (ридберговских атомов). При переходах с $\Delta n = 1$ очень высоковозбужденные атомы излучают радиоволны, что было обнаружено в 1964 г радиотелескопом РТ-22 в г. Пущино.

В межзвездной среде есть и изотропное магнитотормозное излучение со спектральной интенсивностью в коротковолновом радиодиапазоне $I(\omega) \simeq 2{\cdot}10^{-15} \frac{\text{эрт}}{\text{с}^2\ \text{см}^2\text{с}^{-1}}$. Оценить максимально возможное n для атома водорода в этих условиях. Спонтанное время жизни высоковозбужденных состояний атома водорода в вакууме (с $n \sim 10^3$) равно $\tau_{cu}(n) \simeq 6 \cdot 10^{-12} n^5$с.

O3.2-1.74

Взаимодействие электрона в атоме водорода с нулевыми колебаниями электромагнитного поля в вакууме, приводящее в частности к расщеплению по энергии состояний $2s_{1/2}$ и $2p_{1/2}$ (лэмбовский сдвиг) можно в интервале частот $\left(Ry/\hbar, 2mc^2/\hbar\right)$ рассматривать, кақ взаимодействие свободного электрона с однородным переменным электромагнитным полем, которое приводит к случайным смещениям электрона на орбите. Оценить величину среднеквадратичного смещения электрона.

20.3.2 Problems about line widths and their detection 1

O3.1-5.1 Естественная ширина

Среднее время жизни атома в возбужденном состоянии составляет около $\tau \sim 10^{-8}$ с. При переходе атома в основное состояние испускается фотон, средняя длина волны которого равна $\lambda = 500$ нм. Оценить ширину $\Delta\lambda$ и относительную ширину $\Delta\lambda/\lambda$ излучаемой спектральной линии, если не происходит ее уширения за счет других процессов.

5.

1. $\Delta\lambda \sim \frac{\lambda^2}{c\Delta t} \sim 10^{-4}$НМ, $\quad \frac{\Delta\lambda}{\lambda} \sim \frac{\lambda}{c\Delta t} \sim 10^{-7}$.

O3.1-5.2 Излучение π-мезоатома

В π-мезоатоме водорода роль электрона играет отрицательный пион π^-, энергия покоя которого составляет 140 МэВ. Оценить связанную с распадом пиона относительную ширину спектральной линии, соответствующей переходу пиона с L на K-оболочку. Время жизни пиона равно $2,6 \cdot 10^{-8}$с.

5.

2. $\frac{\Delta\lambda}{\lambda} \approx \frac{\hbar}{\tau E_{21}} \approx 1,4 \cdot 10^{-11}$, где $E_{21} = \frac{3}{8}\mu c^2\alpha^2; \mu = \frac{m_\pi m_\text{p}}{m_\pi + m_\text{p}}; \alpha$ - постоянная тонкой структуры.

O3.1-5.3 Размер решетки для естественную ширины

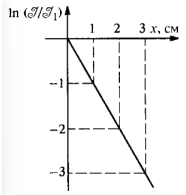
Оценить минимальную ширину L_min, которую должна иметь дифракционная решетка, чтобы с ее помощью можно было обнаружить естественную ширину линии, испускаемой атомами с временем жизни возбужденного состояния $\tau = 0,1$ нс. (Все условия постановки опыта предполагаются идеальными.)

5.

3. $L_{\min} = c\tau = 3$ cm.

О3.1-5.4

Моноэнергетический параллельный пучок возбужденных атомов движется вдоль оси вакуумной трубки со скоростью $v = 10^8$см/с. В стенках трубки сделаны окошки для регистрации излучения атомов пучка в зависимости от пути, пройденного атомами. Результаты этих измерений изображены на рис. ниже



По оси абсцисс отложено расстояние x, пройденное атомами вдоль трубки, отсчитанное от 1-го окошка, а по оси ординат - натуральный логарифм отношения интенсивности света $\mathcal{J}$ интенсивности $\mathcal{J}_1$, измеренной детектором, стоящим в 1-м окошке. Определить естественную ширину линии Δv, излучаемой атомами пучка.

5.

4. $\Delta v \approx \tau^{-1} = 10$ МГц, где $\tau = -\frac{\Delta x}{v\Delta(\ln \mathscr{G}/\mathscr{O})}$.

О3.1-5.5 Температура водородного облака

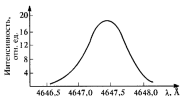
Температуру газовых облаков в межзвездном пространстве можно оценить по доплеровскому уширению спектральных линий, испускаемых атомами, входящими в состав газа. Для этой цели обычно используют водородную линию с длиной волны $\lambda = 21$ см (см. также тексты задач 6.48 и 6.50, объясняющие природу этой линии). Оценить температуру T газового водородного облака, если испускаемая им водородная линия имеет полуширину $\Delta v = 5$ кГц.

5.

5. $T \approx \frac{m_{\text{p}}\lambda^2(\Delta v)^2}{4k} \approx 33$ К.

О3.1-5.6.

На рис. 37 изображено распределение энергии в спектральной линии дважды ионизованного углерода ^{12}с (эту спектральную линию можно наблюдать в дуговом разряде в сильном магнитном поле). Уширение спектральной линии обусловлено движением излучающих атомов (эффект Доплера). Оценить температуру T излучающих атомов.



5.

6. $T = \left(\frac{\Delta\lambda}{\lambda}\right)^2 \frac{\mu c^2}{4R} = 8 \cdot 10^5$ К, где R - универсальная газовая постоянная, $\Delta\lambda$ - ширина на половине высоты резонансной кривой.

О3.1-5.7

Изучается спектр излучения газа в разрядной трубке. Считая, что при столкновениях возбужденные атомы мгновенно переходят в нижележащие состояния, оценить соотношение между доплеровской шириной спектральных линий в диапазоне видимого света и их уширением за счет столкновений, если длина свободного пробега $l \approx 10^{-4}$см.

5.

7. $\frac{\Delta\lambda_\mu}{\Delta\lambda_{\text{ст}}} = \frac{2l}{\lambda} \approx 3,6.$

О3.1-5.8

Возбужденные атомы с временем жизни $\tau \sim 10^{-10}$с и энергией ионизации $\mathscr{E}_{\text{и}} \sim 10$ эВ ионизуются излучением с длиной волны $\lambda \sim 100$Å. Оценить относительный разброс фотоэлектронов по энергиям.

5.

8. $\frac{\delta\mathscr{E}}{\hbar\omega - \mathscr{E}_{\text{ион}}} \approx \frac{\hbar/\tau}{2\pi\hbar c/\lambda - \mathscr{E}_{\text{ион}}} \approx 6 \cdot 10^{-8}.$

О3.1-5.9 Уширение от столкновений

Одна из причин уширения спектральных линий атомов в газе связана со столкновениями, которые ограничивают время жизни возбужденного состояния. Оценить вклад этого механизма в относительную ширину линии перехода в неоне на длине волны $\lambda = 0,63$ мкм, используемой в гелий-неоновом газовом лазере, в условиях, когда коэффициент диффузии атомов неона $D = 100\text{см}^2/\text{с}$. Температуру газа принять равной $T = 400$ К.

5.

9. $\frac{\Delta\nu}{\nu} = \frac{kT\lambda}{m_{\text{Ne}}Dc} \approx 3,5 \cdot 10^{-8}.$

О3.1-5.10

Молекула CO_2 имеет множество дискретных переходов, пригодных для генерации лазерного излучения вблизи 1000см^{-1} с расстоянием между линиями $\Delta q \approx 2\text{см}^{-1}$. Для осуществления плавной перестройки частоты лазера пользуются повышенным давлением, когда ударное уширение приводит к слиянию этих линий в одну полосу. Оценить необходимое для этого давление P при температуре $T = 400$ К Сечение столкновения молекул $\sigma \approx 10^{-15}\text{см}^2$.

5.

10* $P \approx \frac{2\pi c\Delta q}{\sigma}\sqrt{\frac{MkT}{3}} \approx 440$ атм.

Решение. Ударное уширение спектральных линий связано с тем, что при определенных давлениях газа время жизни атомов в возбужденном состоянии определяется временем между столкновениями молекул

$$\tau \sim \frac{l}{v_{\text{T}}} \approx \frac{1}{n\sigma v_{\text{T}}}$$

где l - длина свободного пробега молекул, $v_{\boldsymbol{\tau}}$ - среднеквадратичная скорость молекул, соответствующая температуре T, т. е. $v_\tau = \sqrt{3kT/M}, n$ - концентрация, σ - сечение столкновений. Таким образом, необходимое давление

$$P = nkT \approx \frac{kT}{\sigma v_{\text{T}}\tau} = \frac{1}{\sigma\tau}\sqrt{\frac{MkT}{3}}$$

С другой стороны, время жизни атомов в возбужденном состоянии, определяемое столкновениями атомов, и уширение спектральных линий связаны соотношением неопределенностей: $\Delta\boldsymbol{v}_{\text{ст}}\,\tau \approx 1$ (или $\Delta\omega_{\text{ст}}\,\tau \approx 2\pi$).

Если расстояние между спектральными линиями (в обратных сантиметрах) Δq станет равным ударному уширению, то произойдет слияние этих линий, т. е.

$$\Delta v_{\text{ст}} \gtrsim \Delta v = \Delta\left(\frac{c}{\lambda}\right) = 2\pi c \Delta q, \quad \text{где} \quad q = \frac{2\pi}{\lambda} \gg \Delta q.$$

Отсюда искомое время жизни $\tau^{-1} \approx 2\pi c \Delta q$. Окончательно необходимое для слияния линий давление

$$P = \frac{1}{\sigma\tau}\sqrt{\frac{MkT}{3}} \approx \frac{2\pi c \Delta q}{\sigma}\sqrt{\frac{MkT}{3}} \approx 440 \cdot 10^6 \text{ дин } /\text{см}^2 \approx 440\text{а}.$$

О3.1-5.11

В опытах с разными молекулами измерялись энергии перехода между тремя последовательными уровнями энергии вращательной полосы двухатомной молекулы (рис. 38a и б). Найти квантовые числа I этих уровней и момент инерции I молекулы в случаях а и б.

5.

11. а) $l = 0, 1, 2; I = 6,9 \cdot 10^{-39}\Gamma \cdot \text{ см}^2$.
б) $l = 1, 2, 3; I = 13,8 \cdot 10^{-39}\Gamma \cdot \text{ см}^2$.

О3.1-5.12

Из опыта известно отношение длин волн электромагнитного излучения, соответствующего переходам в молекулах HCl и HI из основного в первое вращательное востояние: $\alpha = \lambda_{\text{HCl}}/\lambda_{\text{HI}}$ Определить отношение междуядерных расстояний в этих молекуsax $x = r_{\text{HCl}}/r_{\text{HI}}$.

5.

12. $x = \sqrt{\alpha \frac{\mu_{\text{HJ}}}{\mu_{\text{HCl}}}} \approx 1,01\sqrt{\alpha}$, где μ - приведенная масса молекулы.

О3.1-5.13

Какова максимальная длина волны СВЧ-излучения, с помощью которой можно вызвать переход между ротационными уровнями молекул хлора? Расстояние между ядрами атомов в молекуле Cl_2 равно $a = 2 \cdot 10^{-8}$см. Относительная атомная масса изотопа хлора $A = 35$.

О3.1-5.14

Найти отношение частот линий поглощения наиболее длинноволновых вращательных переходов молекулы HCl для двух изотопов хлора ^{35}Cl и ^{37}Cl. Считать, что межатомные расстояния не зависят от изотопического состава молекулы. Вычисления произвести с точностью $10^{-2\%}$

О3.1-5.15

Найти отношение наименьших энергий переходов между вращательными уровнями газа, состоящего из смеси водорода и дейтерия, в котором присутствуют молекулы H_2, HD и D_2. Считать, что межатомное расстояние не зависит от изотопического состава.

О3.1-5.16 Переходы между вращательными

Дальний инфракрасный спектр молекулы HBr, обусловленный переходами между соседними вращательными уровнями молекул, состоит из ряда линий, отстоящих друг от друга на расстояние $\Delta\left(\frac{1}{\lambda}\right) = 17\text{см}^{-1}$. Найти расстояние между ядрами в моле куле HBr.

О3.1-5.17

Оценить в видимой области спектра ($\lambda = 6000$Å) разрешающую способность R спектрального прибора, пригодного для исследования спектра молекулярного водорода (т. е. спектра, обусловленного переходами между электронновращательными уровнями молекулы). Момент инерции молекулы H_2 в основном электронном состоянии $I = 0,46 \cdot 10^{-40}\text{г} \cdot \text{см}^2$.

О3.1-5.18

При каких величинах периода вращения T песчинки с характерным размером $a = 0,1$ мкм начинает проявляться квантовый характер вращения, т. е. дискретность вращательного спектра? Плотность песчинки ρ принять равной $5/\text{cm}^3$.

О3.1-5.19

При температурах ниже приблизительно $T = 100$ K молярная теплоемкость C_V молекулярного водорода составляет $3R/2$, тогда как при комнатных температурах она равна $5R/2$(R - универсальная газовая постоянная). Пользуясь этими данными, оценить момент инерции I молекулы водорода относительно оси, проходящей через ее центр перпендикулярно к оси, проходящей через атомы, из которых построена молекула. Оценить также частоты v и длины волн λ спектральных линий, возникающих при переходах между вращательнымн уровнями молекулы.

О3.1-5.20

Оценить количество вращательных уровней молекулы HCl, возбуждаемых при комнатной температуре. Межъядерное расстояние у этой молекулы равно $d = 1,27$Å.

О3.1-5.21

Показать, что в основном состоянии гармонического осциллятора $\overline{\Delta p^2} \cdot \overline{\Delta x^2} = \hbar^2/4$, где $\overline{\Delta p^2}$ и $\overline{\Delta x^2}$ - среднеквадратичные отклонения импульса и координаты от их средних значений. Волновая функция основного состояния гармонического осциллятора $\psi_0(x) = \left(\frac{\alpha}{\pi}\right)^{1/4} \exp\left(-\frac{\alpha x^2}{2}\right)$, где $\alpha = \frac{m\omega}{\hbar}$ Смотрите также задачу 2.43.

О3.1-5.22

Показать, что уравнение Шредингера, описывающее одномерный гармонический осциллятор, помещенный в однородное электрическое поле $\mathbf{E}$, может быть сведено к задаче о гармоническом осцилляторе, т. е. движению в потенциале вида $U = m\omega^2 x^2/2$. Каковы уровни энергии частицы в этом случае?

О3.1-5.23

В спектре испускания молекулярного азота имеются линии с длинами волн 3371 Å, 3577 Å и 3805Å. Можно ли интерпретировать Эти линии как переходы с изменением колебательного квантового числа на 0,1 и 2, если измерения сделаны с точностью $0,2\%$? Определить энергетическое расстояние между соответствующими уровнями молекулы азота. С помощью полученных результатов по формулам классической физики оценить жесткость k упругой связи атомов в молекуле азота.

О3.1-5.24

Оценить отношение кванта колебаний молекул H_2 и O_2 к характерной энергии возбуждения валентных электронов $\mathscr{E}_e$, считая, что эффективный коэффициент упругости молекулярной связи $k = \mathscr{E}_\text{e}/a^2$, где a - межатомное расстояние. Выразить ответ через отношение массы электрона m к массе ядра M. Оценить амплитуду нулевых колебаний молекул и выразить ее через отношение m/M и a.

О3.1-5.25 Параметры газа CO по пику поглощения на данной длине волны

В угарном газе CO из-за возбуждения колебаний молекул наблюдается пик поглощения инфракрасного излучения на длине волны $\lambda = 4,61$ мкм. Определить амплитуду A_0 нулевых колебаний молекулы CO. Оценить температуру, при которой амплитуда тепловых колебаний превзойдет A_0.

Теорема вириала тут используется.

О3.1-5.26

Какова амплитуда колебаний молекулы кислорода O_2 при комнатной температуре, если известно, что расстояние между ее колебательными уровнями равно $\Delta\mathscr{E} = 0,25$ эВ?

О3.1-5.27

На рис. 39 изображена часть графика зависимости энергии взаимодействия U атомов азота друг с другом от межатомного расстояния r. Считая яму параболической, найти отношение колебательного кванта к энергии возбуждения первого вращательного состояния в молекуле азота.

О3.1-5.28

Пылинка с плотностью $\rho = 2$ г/см ^{3} и радиусом r прикреплена к неподвижной стенке невесомым стержнем длиной $l = 4r$ и диаметром $d = 2r = 1$ мкм (рис. 40). Модуль Юнга стержня $E = 10^{11}$ Па. Определить энергию кванта колебаний пылинки вдоль нормали к стенке, а также длину электромагнитной волны, способной возбудить такие колебания, и амплитуду нулевых колебаний.

О3.1-5.29

Разность энергий диссоциации молекул D_2 и H_2 равна $\Delta\mathscr{E} = 0,08$ эВ, а потенциал взаимодействия атомов в этих молекулах одинаков. Каковы энергии нулевых колебаний этих молекул (в эВ)?

О3.1-5.30

Оценить энергию нулевых колебаний атомов жидкого гелия (плотность $\rho = 0,145$ г/см ^{3}).

О3.1-5.31

Определить отношение энергий возбуждения первого вращательного уровня молекулы азота в основном и первом возбужденном колебательном состояниях. Расстояние между атомами азота в основном состоянии молекулы $r_0 = 1,1$Å, квант вибрационных возбуждений $\hbar\omega = 0,3$ эВ.

О3.1-5.32

Поле, в котором движется атом жидкого гелия, хорошо описывается потенциалом Леннард-Джонса $U(r) = \varphi\left[(r_0/r)^{12} - -2\,(r_0/r)^6\right.$, где $\varphi = 232$ К, а $r_0 = 3 \cdot 10^{-8}$ см. Оценить энергию нулевых колебаний.

О3.1-5.33 Колебания атоме, описываемым потенциалом Морса (??)

Потенциал взаимодействия атомов в двухатомной молекуле можно с достаточной точностью аппроксимировать потенциалом Морса $U(r) = D\left[\exp\left(-2\alpha\left(r - r_0\right)\right) - 2\exp\left(-\alpha\left(r - r_0\right)\right)\right]$. У молекулы азота постоянная $\alpha = 4 \cdot 10^8 \text{см}^{-1}$, энергия диссоциации равна $D = 7,4$ эВ. Оценить расстояние между колебательными уровнями молекулы азота.

О3.1-5.34

Смесь атомов двух видов A и B имеет уровни возбужденных с частотой v, такой что $hv = \mathscr{E}_A$, кроме последующего обратного излучения той же частоты в результате соударений атомов A и B появ- 45 ляется также излучение с частотой $v' = \mathscr{E}_B/h$ и происходит увеличение кинетической энергии атомов. Найти скорости атомов после соударений, если известны массы атомов m_A и m_B. Считать, что энергия теплового движения мала по сравнению с $\Delta\wp$.

О3.1-5.35

При лазерном разделении изотопов в газообразной фазе один из разделяемых изотопов ионизуется лазерным лучом и затем удаляется из смеси электростатическим полем. Такому разделению изотопов препятствует тепловое движение атомов. Определить, возможно ли подобное разделение изотопов ^{6}Li и ^{7}Lic помощью ультрафиолетового лазера, если известно, что энергия ионизации лития 5,4 эВ; газообразный литий может существовать при температуре $t^\circ \geqslant 800°$c. Принять, что Z_{eff} для электрона незаполненной оболочки не зависит от массы изотопа.

О3.1-5.36

В атоме тантала ($Z = 73$) совершается переход с M-слоя на L-слой. Определить длину волны λ испущенного фотона, если постоянная экранирования $\sigma = 5,5$.

О3.1-5.37

Вычислить приближенно частоту и длину волны K_α-линии Mo, а также энергию кванта, соответствующую этой линии.

О3.1-5.38

Найти приближенно минимальное напряжение V на рентгеновской трубке, при котором начинают появляться K_α-линии Mo, Cu, Fe.

O3.1-5.39

Найти границу K-полосы излучения Mo, Cu и Fe.

O3.1-5.40

Какие линии Ni возбуждаются K-излучением Co?

O3.1-5.41

Известно, что длина K_α-линии одного элемента равна 0,0788 нм, а другого 0,0713 нм. Выяснить, стоят ли эти элементы рядом в таблице Менделеева. Какие Это элементы?

O3.1-5.42

Начиная с какого элемента появляется L-серия?

O3.1-5.43

Определить напряжение V на рентгеновской трубке с никелевым антикатодом, если разность длин волн между K_α-линией и коротковолновой границей сплошного рентгеновского спектра равна $\Delta\lambda =$ 84НМ.

20.3.3 Problems about line widths and their detection 2

O3.1-5.44

Какой минимальной кинетической энергией должна обладать α-частица, чтобы при бомбардировке такими частицами атомов лития ^{7}Li эти атомы начали излучать полный спектр своего характеристического рентгеновского излучения?

5.

44. $T_{\min} = \frac{m_e c^2 \alpha^2 (Z-1)^2}{2[1-m_\alpha/(m_{\mathrm{Li}}+m_\alpha)]} = 85,5$ эВ, где α - постоянная тонкой структуры.

O3.1-5.45

Какова максимальная скорость v электронов, вырываемых из свинца характеристическим излучением железа?

5.

45. $v \approx 5 \cdot 10^9$ cm/c.

O3.1-5.46

У каких элементов характеристическое рентгеновское излучение длинноволновой границы K-серии может испытывать брэгговское отражение от кристалла LiF, постоянная решетки которого $d = 0,23$ нм?

5.

46. Минимальное значение Z находится из условия Брэгга-Вульфа $\lambda \leqslant 2d \quad (m = 1)$. Тогда $Z_{\min} = 18$.

O3.1-5.47

Какой потенциал V следует приложить к рентгеновской трубке, чтобы тормозное рентгеновское излучение могло испытывать брэгговское отражение от кристалла LiF, межплоскостное расстояние в котором составляет $d = 2,3$Å?

5.

47. $V \geqslant \frac{hc}{2ed}; V_{\min} = 2,7\text{кВ}$.

О3.1-5.48

Длина волны, соответствующая переходу между двумя соседними состояниями вращательного спектра молекулы HBr, равна $\lambda = 202$ мкм. Определить, между состояниями с какими квантовыми вращательными числами происходит переход. Межъядерное рассто- яние $d = 1,41$Å.

5.

48. Переход из $l = 3$ в $l = 2$.

О3.1-5.49

Оценить, при какой температуре отношение числа молекул NO, находящихся в чисто вращательных состояниях с квантовыми числами $l = 1$ и $l = 0$, равно $\alpha = 0,1$. Межъядерное расстояние в молекуле равно $d = 1,15$Å.

О3.1-5.50

С какой относительной точностью $\Delta\lambda/\lambda$ надо измерить длинноволновую часть вращательного спектра CO, чтобы увидеть изотопическое расщепление спектра, появляющееся при наличии примеси ^{12}c^{17}O в обычном ^{12}c^{16}O? Чему равна наибольшая длина волны вращательного кванта у молекул CO? Расстояние между ядрами с и O равно $d = 1,13$Å

О3.1-5.51

Природный хлор представляет собой смесь двух изотопов ^{35}Cl и ^{37}Cl. С какой относительной точностью $\Delta\lambda/\lambda$ надо измерять длину волны колебательного кванта у молекулы HCl, чтобы увидеть изотопическое расщепление колебательного спектра?

О3.1-5.52

Одномерный осциллятор находится в состоянии с главным квантовым числом $n = 10$. Оценить, какова вероятность обнаружить частицу вблизи положения равновесия в области размером порядка плюс-минус амплитуда его нулевых колебаний.

Ука з а и ие. При больших квантовых числах движение частицы можно рассматривать как классическое.

О3.1-5.53

Одномерный осциллятор находится в основном состоянии. Оценить вероятность нахождения частицы в классически разрешенной области. Волновая функция основного состояния $\psi = A\exp\left(-x^2/2a_0^2\right)$, где $a_0 = \sqrt{\hbar/m\omega}$.

Ука за н и е. Для оценки получающегося интеграла использовать разложение подынтегральной функции в ряд.

О3.1-5.54

Для молекулы азота N_2 оценить число вращательных уровней, приходящихся на интервал между соседними колебатель ными уровнями.

О3.1-5.55

Потенциальная энергия взаимодействия атомов в двухатомной молекуле не является чисто квадратичной (гармонической). При слабой ангармоничности уровни осциллятора можно представить в виде $_n = \hbar\omega(n + 1/2) - \alpha\hbar\omega(n + 1/2)^2$, где α - коэффициент ангармоничности, ω - частота осциллятора. Найти в Этой модели максимальное число колебательных уровней молекулы N_2, у которой $\alpha = 0,006145$.

Указан и е. Для реальных состояний функция $\mathscr{E}_n(n)$ должна быть монотонно возрастающей.

О3.1-5.56

Из-за конечного размера ядра энергетический уровень K электрона претерпевает небольшое смещение $\delta\mathscr{E} \propto R^2$, где R - рааиус ядра, который находится по формуле $R = 1,3 \cdot 10^{-13} A^{1/3}$см, A - относительная атомная масса. Оценить величину изотопического сдвига $\delta(hv)_{205}$ границы характеристического рентгеновского K-из.уучения для ядра $^{205}_{805}$Tl, если известно, что для $^{203}_{81}$Tl этот сдвиг 47 $\delta(hv)_{203} = -8,25$ эВ, т. к. энергия ионизации K-электрона уменьшается по сравнению со случаем точечного ядра.

О3.1-5.57

Считая, что взаимодействие атомов в молекуле HCl описывается потенциалом Кратцера $U(r) = 2\varepsilon\left[\frac{1}{2}\left(\frac{\sigma}{r}\right)^2 - \frac{\sigma}{r}\right]$, определить относительное изменение частоты $\frac{\Delta\omega}{\omega_0}$ колебаний молекулы при возбуждении ее с вращательного уровня c$l = 0$ на уровень $l = 10$. В молекуле HCl$\varepsilon = 4,62$ эВ $, \sigma = 1,27$Å.

О3.1-? Разрешающая способность прибора для различения колебательного спектра

Природный бром представляет собой смесь двух изотопов ^{79}Br(50.56%) и ^{81}Br(49.44%).

Оценить разрешающую способность спектрального прибора, с помощью которого можно различить изотопическое расщепление колебательного спектра поглощения паров брома.

Бром это двухатомная молекула, каждая из которой может быть своим изотопом.

колебательная энергия есть

$$E_{\text{кол}} = \hbar\omega(n + 1/2)$$

При этом частота зависит от приведенной массы как $\omega = \sqrt{\frac{k}{\mu}}$, так что нулевой уровень колебательной энергии разный для разных молекул. Также и частота перехода зависит от молекулы, соответственно её спектр тоже.

k одинаковая, потому что оно определяется электромагнитным взаимодействием и электронами, так что оно одинаково для разных изотопов.

разрешающая способность есть (вообще говоря модуль от)

$$R = \frac{\lambda}{\Delta\lambda} = \frac{\omega}{\omega_2 - \omega_1}$$

находим

$$\Delta\omega = \sqrt{k}\left(\frac{1}{\sqrt{\mu_1}} - \frac{1}{\sqrt{\mu_2}}\right)$$

$$R = \frac{1}{\frac{\omega_2}{\omega_1} - 1} = \frac{1}{\sqrt{\frac{\mu_1}{\mu_2}} - 1}$$

и считаем разные приведенные массы.

в итоге $R = 160$.

(потом в оптике качну про разрешающие способности)

SOLUTIONS 5. Ширина линий. Спектры молекул. Рентгеновское излучение

5.

13. $\lambda_{\max} = \frac{\pi c A m_{\text{p}} a^2}{\hbar} \approx 2,1$ cm.

5.

14. $\frac{\omega_{35}}{\omega_{37}} = \frac{I_{37}}{I_{35}} = 1,0015$, где индексы 35 и 37 относятся к изотопам хлора ^{35}Cl и ^{37}Cl, I - моменты инерции молекул относительно центра масс.

5.

15. $\mathscr{E}_{\text{H}_2} : \mathscr{E}_{\text{HD}} : \mathscr{E}_{\text{D}_2} = 2 : \frac{3}{2} : 1$.

5.

16. $r = \left(\frac{\hbar}{2\pi\mu_{\mathrm{HBr}}c\Delta}\right)^{1/2} = 1,4 \cdot 10^{-8}$c, где $\mu_{\mathbf{HBr}} \approx m_{\mathrm{p}}$ - приведенная масса молекулы HBr .

5.

17. $R = \frac{\lambda}{\Delta\lambda} = \frac{\omega}{\Delta\omega} = \frac{2\pi cI}{\hbar\lambda} \approx 140$, т. е. требуемая разрешающая способность $R > 140$. Такое разрешение может быть получено в спектрометре, использующем призму.

5.

18. $T \geqq \frac{\rho a^5}{\hbar} \approx 500$c.

5.

19. Решение. Теплоемкость молекулярного водорода $\mathbf{C} = C_{\text{пост}} + C_{\text{вр}} + C_{\text{кол}}$. Поскольку расстояния между колебательными уровнями велики ($\Delta\mathscr{E}_{\text{кол}} \sim \sqrt{\frac{M}{m}}\Delta\varrho_{\text{вр}} \approx 40\Delta\mathscr{E}_{\text{вр}}$), то при комнатных температурах колебательные уровни не возбуждены, а вращательные уровни возбуждены все, поскольку по условию $C_V = (5/2)R$. При $T = 100$ K вращательные уровни не возбуждены вовсе. Таким образом,

$$kT \lesssim \Delta\mathscr{E}_{\text{Вр}} = \frac{\hbar^2}{I}, \quad \text{откуда} \quad I \leqq \frac{\hbar^2}{kT} \sim 10^{-40}\Gamma \cdot \text{ cm}^2$$

где k - постоянная Больцмана. Следовательно,

$$h\nu = \frac{\hbar^2}{2l}2(l+1) \approx kT(l+1); \quad \nu = \frac{kT}{h}(l+1), \quad \text{где} \quad l = 0, 1, 2, ...;$$

$$\nu_{\min} \approx \frac{kT}{h} \approx 2,1 \cdot 10^{12}\Gamma, \quad \lambda_{\max} \approx 1,5 \cdot 10^{-2} \text{ cm} = 0,15\text{m}$$

Соответствующая линия лежит в далекой инфракрасной области спектра.

5.

20. Количество вращательных уровней $l_{\max} \simeq 4$.

5.

22: $\mathscr{E}_n = \hbar\omega\left(n + \frac{1}{2}\right) - \frac{e^2E^2}{2m\omega^2}$, где $n = 0, 1, 2, ...$

Решение. Запишем уравнение Шредингера для одномерного гармонического осциллятора в электрическом поле $\mathbf{E}$

$$\hat{H}\psi = -\frac{\hbar^2}{2m}\frac{\partial^2\psi}{\partial x^2} + \left(\frac{m\omega^2x^2}{2} - eEx\right)\psi.$$

Перепишем его в таком виде:

$$\widehat{H}\psi = -\frac{\hbar^2}{2m}\psi'' + \frac{m\omega^2}{2}\left(x^2 - \frac{2eE}{m\omega^2}x\right)\psi.$$

Полученное уравнение можно свести к уравнению колебаний осциллятора со смещенным положением равновесия, если выделить полный квадрат в выражении в скобках в правой части уравнения

$$x^2 - \frac{2eE}{m\omega^2}x = \left(x - \frac{eE}{m\omega^2}\right)^2 - \frac{E^2e^2}{m^2\omega^4} = (x^*)^2 - \frac{e^2E^2}{m^2\omega^4}.$$

Тогда уравнение Шредингера примет вид

$$-\frac{\hbar^2}{2m}\psi'' + \frac{m\omega^2}{2}\left(x - \frac{eE}{m\omega^2}\right)^2 \psi = \left(\hat{H} + \frac{e^2E^2}{2m\omega^2}\right)\psi$$

или

$$-\frac{\hbar^2}{2m}\psi'' + \frac{m\omega^2}{2}x^{*^2}\psi = \mathfrak{E}^*\Psi.$$

Уровни энергии в этом случае, очевидно, следующие:

$$\mathscr{E}_n^* = \hbar\omega\left(n + \frac{1}{2}\right), \quad \text{или} \quad \mathscr{E}_n = \hbar\omega\left(n + \frac{1}{2}\right) - \frac{e^2E^2}{2m\omega^2}, \quad \text{где} \quad n = 0, 1, 2, ...$$

5.

23: $\omega_1 - \omega_2 = \omega_2 - \omega_3 = \Omega = 0,32 \cdot 10^{15}\mathrm{c}^{-1} = \sqrt{k/\mu}$, откуда вычисляем $k \approx 1,2 \cdot 10^6$ дин/см.
Решение. Найдем частоты, соответствующие заданным переходам (рис. 156),

$$\omega_1 = \frac{2\pi c}{\lambda_1} = 5,59 \cdot 10^{15}\mathrm{c}^{-1}$$
$$\omega_2 = \frac{2\pi c}{\lambda_2} = 5,27 \cdot 10^{15}\mathrm{c}^{-1}$$
$$\omega_3 = \frac{2\pi c}{\lambda_3} = 4,95 \cdot 10^{15}\mathrm{c}^{-1}$$

При вычислении мы сделаем округление в третьем знаке. Это дает точ ность $(0,01/5) \cdot 100\% = 0,2\%$, что укладывается в интервал измерений ($0,2\%$ - по условию). Вычислим разности частот

$$\omega_1 - \omega_2 = 0,32 \cdot 10^{15}c^{-1}; \quad \omega_2 - \omega_3 = 0,32 \cdot 10^{15}c^{-1}$$

Такое совпадение указывает на эквидистантность уровней $1, 2, 3$. Следовательно, они могут быть связаны с колебательными уровнями молекулы

$$\omega_1 - \omega_2 = \omega_2 - \omega_3 = \Omega = \sqrt{\frac{k}{\mu}}$$

где k - жесткость упругой связи, μ - приведенная масса молекулы N_2. Таким образом, искомая жесткость

$$k = \mu\Omega^2 = 1,2 \cdot 10^6 \text{ дин } /, \text{ где } \mu = 11,69 \cdot 10^{-24}.$$

Заметим, что найденный колебательный квант молекулы азота Вращат $\Delta\mathscr{E} = \hbar\Omega = 0,21$ эВ. Табличное значение 0,29 эВ.

5.

24: $\frac{\hbar\omega_0}{\mathrm{e}} \approx 2\sqrt{\frac{2m_\mathrm{e}}{M}}$; $A \approx a\sqrt[4]{\frac{m_\mathrm{e}}{M}}$, где M - масса атома.
Решение. Двухатомную молекулу можно рассматривать как квантовый гармонический осциллятор. На рис. 157 изображен потенциал взаимодействия атомов в такой молекуле. Вблизи положения равновесия форма ямы приближенно параболическая. Однако из-за соотношения неопределенностей квантово-механическая система не может находиться в этом положении - на дне потенциальной ямы. В результате возникают нулевые колебания с полной энергией $\mathscr{E}_0 = \hbar\omega_0/2$. Далее идут эквидистантные

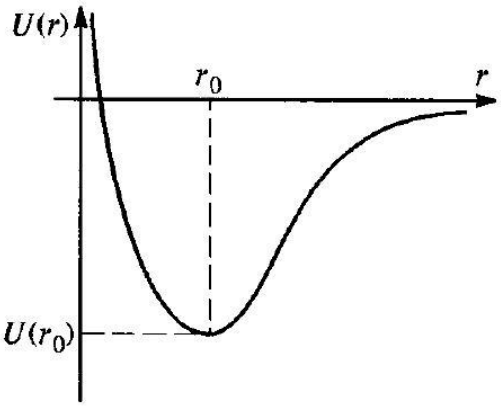


Рис. 157 уровни возбужденных состояний двухатомной молекулы с $\Delta\mathscr{E} = \hbar\omega_0$, где ω_0 частота колебаний двухатомной молекулы $\omega_0 = \sqrt{k/\mu} = \sqrt{2k/M}$, где k - коэффициент упругой молекулярной связи, μ приведенная масса молекулы, M - масса атома в молекуле типа H_2 или O_2.

Согласно соотношению неопределенностей и теореме вириала для осцилятора можно записать $\mathscr{E}_e \sim 2\frac{p^2}{2m_e} \sim \frac{\hbar^2}{m_e a^2}$ (считаем, что область локализации электрона порядка межатомного расстояния). Отсюда искомое отношение

$$\frac{\hbar\omega}{\mathscr{E}_e} = \frac{\hbar\sqrt{2k/M}}{\mathscr{E}_e} = \sqrt{2\frac{\hbar^2}{a^2 m_e M \mathscr{E}_e}\frac{m_e}{M}} \sim \sqrt{\frac{2m_e}{M}} \approx \begin{cases} 0,035 \text{ для } H_2 \\ 0,01 \text{ для } O_2 \end{cases}$$

Для оценки амплитуды нулевых колебаний воспользуемся приведенной в условии соотношением $k = \mathscr{E}_e/a^2$. Как указывалось выше, энергия нулевых колебаний

$$\mathscr{E}_0 = \frac{\hbar\omega_0}{2} = \frac{kA^2}{2}, \quad \text{откуда} \quad A^2 = \frac{\hbar\omega_0 a^2}{\mathscr{E}_e}$$

Подстановкой найдем

$$A \approx a\sqrt[4]{\frac{m_e}{M}} \approx \begin{cases} 0,15a \text{ для } H_2 \\ 0,08a \text{ для } O_2 \end{cases}$$

Величина $K = \sqrt[4]{\frac{m_e}{M}}$ носит название параметра неадиабатичности (см. задачу 5.29).

5.

25. $A_0 = \sqrt{\frac{\hbar\lambda}{2\pi c\mu}} \approx 4,74 \cdot 10^{-10}$c; $T \geqq 3100$ K.

5.

26. Молекула O_2 находится в основном состоянии, так как $kT = 0,025$ В $\ll \Delta\mathscr{E}$. Поэтому $A_0 = \frac{\hbar}{\sqrt{\mu\Delta\mathscr{E}}} = 0,058$Å, где μ - приведенная масса O_2.

5.

27. $\frac{\Delta\mathscr{E}_{\text{кол}}}{\Delta\mathscr{E}_{\text{вр}}} = \frac{\mu r_0^2\omega}{\hbar} \approx 180$, где μ - приведенная масса молекулы азота, r_0 - положение минимума кривой, берется из графика.

5.

28. $\lambda = 2\pi c\sqrt{\frac{4lr\rho}{3\varrho}} \approx 31$ cm; $\hbar\omega = 4 \cdot 10^{-6} \ni$ В; $A_0 = \sqrt{\frac{\hbar}{m\omega}} = \sqrt{\frac{\hbar}{\pi r^2}\sqrt{\frac{3}{\mathscr{G}\rho}}} \approx \approx 4 \cdot 10^{-13}$ cm.

5.

29: $\mathscr{E}_{\text{OH}} = \frac{\hbar\omega_{\text{H}}}{2} = \frac{\sqrt{2}\Delta\mathscr{E}}{\sqrt{2}-1} = 0,27_{\text{эВ}}; \mathscr{E}_{\text{OD}} = \frac{\hbar\omega_{\text{D}}}{2} = \frac{\Delta\mathscr{E}}{\sqrt{2}-1} = 0,19$ эВ.

Решение. Поскольку масса электрона много меньше массы ядер, то скорости движения последних малы по сравнению со скоростями электронов. Тогда в первом приближении можно найти энергию электронов при неподвижных ядрах, а затем учесть движение ядер. Такой подход носит название адиабатического приближения.

Энергия молекулы с учетом движения ядер может быть записана как $\mathscr{E} = \mathscr{E}_{\text{эл}}(R) + \mathscr{E}_{\text{яд}}^{\text{кии}} + \mathscr{E}$. При этом энергия электронов зависит от межъядерного расстояния как от параметра. В энергию $\mathscr{E}(R)$ включена также энергия электростатического отталкивания ядер, поэтому $\mathscr{E}_{\text{эл}}(R)$ фактически является полной энергией молекулы при фиксированном положении ядер. Полагая далее, что $R = R_0 + \delta R$, где R_0 - равновесное расстояние между ядрами, а δR - отклонение от него вследствие движения ядер, запишем $\mathscr{E}_{\text{эл}}(R) \approx \approx \mathscr{E}(R_0) + \frac{1}{2}\frac{\partial^2\mathscr{E}(R)}{\partial R^2}\Big|_{R=R_0}(\delta R)^2$. Второй член представляет собой потенциальную энергию ядер $U_{\text{яд}}^{\text{пот}}$, т. е. усредненный потенциал, создаваемый электронами. Вместе с кинетической энергией они образуют энергию колебаний $\mathscr{E}_{\text{яд}}^{\text{кин}} + U_{\text{яд}}^{\text{пот}} = \mathscr{E}_{\text{кол}}$. Если сюда добавить энергию вращения молекулы как целого $\mathscr{E}$, то получим энергию молекулы в адиабатическом приближении $\mathscr{E} = \mathscr{E}(R_0) + \mathscr{E}_{\text{кол}} + \mathscr{E}_{\text{вр}}$. Заменяя по принципу соответствия классические выражения двух последних членов их квантовыми аналогами, получим

$$\mathscr{E}_0 = \mathscr{E}_{9\Omega}(R_0) + \hbar\omega_{\text{кол}}\left(n + \frac{1}{2}\right) + Bl(l+1)$$

где $B = \frac{\hbar^2}{2\mu R_0^2}$ - постоянная вращения, μ - приведенная масса ядер, $\omega_{\text{кол}}^2 = \frac{1}{\mu}\frac{\partial^2\mathscr{E}(R)}{\partial R^2}\Big|_{R=R_0}$ - квадрат частоты колебаний ядер. Можно показать, что $\mathscr{E}_{\text{эл}}(R_0) : \hbar\omega_{\text{кол}} : B = 1 : K^2 : K^4$ (см. задачу 5.24).

Энергия диссоциации - это разница между энергиями основного состояния молекулы и энергии двух удаленных атомов водорода (дейтерия), принимаемую равной нулю. Т.о. $I = \mathscr{E}_0$. Энергия основного состояния молекулы $\mathscr{E}_0 = \mathscr{E}(R_0) + \frac{1}{2}\hbar\omega_{\text{кол}}$. Разность энергий диссоциаций молекул D_2 и H_2

$$\Delta\mathscr{E} = I_{\text{D}_2} - I_{\text{H}_2} = 2\mathscr{E}_{\text{D}} - 2\mathscr{E}_{\text{эл. D}}(R_0) - \frac{\hbar\omega_{\text{D}}}{2} - 2\mathscr{E}_{\text{H}} + 2\mathscr{E}_{\text{эл. H}}(R_0) + \frac{\hbar\omega_{\text{H}}}{2}.$$

Поскольку

$$\mathscr{E}_{\text{D}} - \mathscr{E}_{\text{H}} = \frac{e^4}{2\hbar^2}(\mu_{\text{D}} - \mu_{\text{H}})$$

где $\mu = \frac{m_{\text{e}}M}{m_{\text{e}}+M} \approx m_{\text{e}}\left(1 - \frac{m_{\text{e}}}{M}\right)$ - приведенная масса электрона, то с учетом одинаковости потенциалов взаимодействия, получим

$$\Delta\mathscr{E} \approx \hbar\frac{\omega_{\text{H}} - \omega_{\text{D}}}{2} = \frac{\hbar\omega_{\text{D}}}{2}\left(\frac{\omega_{\text{H}}}{\omega_{\text{D}}} - 1\right).$$

Отношение $\frac{\omega_{\text{H}}}{\omega_{\text{D}}} = \sqrt{\frac{\mu_{\text{D}}}{\mu_{\text{H}}}} = \sqrt{2}$, откуда следует $\frac{\hbar\omega_{\text{D}}}{2} = \frac{\Delta\mathscr{E}}{\sqrt{2}-1} \approx 0,19$ эВ и $\frac{\hbar\omega_{\text{H}}}{2} = \sqrt{2}\frac{\Delta\mathscr{E}}{\sqrt{2}-1} = 0,27^{\text{g}}$В.

5.

30. $_0 \approx \frac{3\hbar^2}{8mr^2} \approx 1,2\cdot10^{-16}$ эрг $= 0,75\cdot10^{-4}{}_{\text{эВ, где } 2r} \approx 4,5\cdot10^{-8}$ см характерный размер области, занимаемый одним атомом в жидком гелии, $2r \approx \left(\frac{6\mu}{\pi\rho N_{\text{A}}}\right)^{1/3}$.

5.

31*: $\frac{\Delta\mathscr{E}_{\text{вр}}}{\Delta\mathscr{E}_{\text{кол}}} = \frac{\hbar}{\omega\mu r_0^2} = 1,63\cdot10^{-3}$.

Решение. С ростом номера колебательного возбуждения меняется средний квадрат расстояния между атомами в молекуле и, следовательно, момент инерции молекулы (рис. 158) зависит от n.

$\mathscr{E}_{\text{кол}} = \hbar\left(n + \frac{1}{2}\right) = \langle K\rangle + \langle U\rangle = 2\langle U\rangle$ - теорема вириала. Далее, $\langle U\rangle = 2\frac{\mu\omega^2}{2}\langle x_n^2\rangle \to \langle x_n^2\rangle = \frac{\hbar}{\mu\omega}\left(n + \frac{1}{2}\right)$, где

μ - приве-

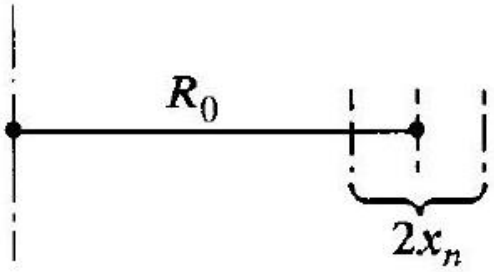

Рис. 158 денная масса ядер. При этом $\left\langle x_0^2 \right\rangle = \frac{1}{2}\frac{\hbar}{\mu\omega} = \frac{A_0^2}{2}$ (см. задачу 5.25). Тогда

$$\sqrt{\langle x_0^2 \rangle} = \sqrt{\frac{1}{2}\frac{\hbar^2}{\mu\hbar\omega}} = 10^{-9}\ \text{cm} = 0,1\text{Å} \ll 1,1\text{Å} = r_0.$$

Среднее значение вращательной энергии

$$\left\langle \frac{1}{2I} \right\rangle \hbar^2 l(l+1) = \frac{\hbar^2}{2\mu} l(l+1) \left\langle \frac{1}{r_n^2} \right\rangle \approx \frac{\hbar^2}{2\mu} \frac{l(l+1)}{\langle r_n^2 \rangle}.$$

Надо отметить, что усреднение ведетсяя по заданному колебательному состоянию. В силу адиабатичности, $\mathscr{E}_{\text{вр}}$ - поправка к $\mathscr{E}_{\text{кол}}$.

Последнее равенство $\left(\left\langle \frac{1}{r_n^2} \right\rangle \approx \frac{1}{\langle r_n^2 \rangle}\right)$ справедливо, поскольку для небольших $n < 100$ справедливо соотношение $\left\langle x_n^2 \right\rangle \ll r_0$.

$$\Delta\mathscr{E}_{\text{Вр}}(l=1, \to l=0) = \frac{\hbar^2}{\mu \left\langle r_n^2 \right\rangle}$$

$$\frac{\Delta\varrho_{\text{Вр}}(n=0)}{\Delta\mathscr{G}_{\text{Вр}}(n=1)} = \frac{\left\langle (r_0 + x_1)^2 \right\rangle}{\left\langle (r_0 + x_0)^2 \right\rangle} = \frac{\left\langle r_0^2 + 2x_1 r_0 + x_1^2 \right\rangle}{\left\langle r_0^2 + 2x_0 r_0 + x_0^2 \right\rangle} = \frac{r_0^2 + \left\langle x_1^2 \right\rangle}{r_0^2 + \left\langle x_0^2 \right\rangle} =$$

$$= \frac{r_0^2 + 3\hbar/(2\mu\omega)}{r_0^2 + \hbar/(2\mu\omega)} \approx \left(1 + \frac{3}{2}\frac{\hbar}{\mu\omega r_0^2} - 1 - \frac{1}{2}\frac{\hbar}{\mu\omega r_0^2}\right) = \frac{\hbar}{\mu\omega r_0^2} = 1,63 \cdot 10^{-3}$$

Как видно из решения, существует взаимодействие между вращением и колебаниями ядер, что соответствует выходу за пределы адиабатического приближения (см. задачи 5.29 и 5.57).

5.

32. $\mathscr{E}_0 = \frac{3\hbar\omega}{2} = 3\hbar\sqrt{\frac{18\varphi}{mr_0^2}} = 1,944 \cdot 10^{-2} \ni$ В ≈ 226 К.

5.

33. $\Delta\mathscr{E}_{\text{кол}} = \hbar\alpha\sqrt{\frac{4D}{m}} \approx 0,3$ эВ.

5.

34. $v_{\text{A}} = \sqrt{\frac{2\Delta\varrho m_{\text{B}}}{m_{\text{A}}(m_{\text{A}}+m_{\text{B}})}}$; $\quad v_{\text{B}} = \sqrt{\frac{2\Delta\varrho m_{\text{A}}}{m_{\text{B}}(m_{\text{A}}+m_{\text{B}})}}$, где $\Delta\mathscr{E} = h\,(v - v')$.

5.

35. Разность энергий ионизации атомов $^6_3$Li и $^7_3$Li$\Delta\mathscr{E} = 7 \cdot 10^{-5}$ эВ; ширина линии поглощения из-за эффекта Доплера $2\hbar\Delta\omega \approx \hbar\omega\frac{v}{c} \approx \approx 4,4 \cdot 10^{-5}$, точнее (с учетом коэффициента $2\sqrt{\ln 2}$, см. Д. В. Сивухин «Общий курс физики. Оптика», формула 89.11) 5,1710-5 эВ. Поскольку $\Delta\mathscr{E} > \hbar\Delta\omega$ (при $t \approx 800°$C), разделение изотопов возможно.

5.

36. $\lambda = \frac{hc}{\mathrm{Ry}(Z-\sigma)^2(1/n^2-1/m^2)} = 1,44 \cdot 10^{-8}$ см, где $n = 2; m = 3$.

5.

37. $\mathscr{E} = h\nu = \mathrm{Ry}(Z-1)\left(\frac{1}{1^2} - \frac{1}{2^2}\right) \approx 17,15$ кэВ; $\nu \approx 4,14 \cdot 10^{18}\Gamma, \lambda_\alpha \approx \approx 0,072$ нм. Из экспериментальных данных известно, что для $20 < Z < 30$ постоянная экранирования $\sigma_{\text{экр}} = 1,13$.

5.

38. Чтобы появилась линия K_α нужно выбить электрон из K-оболочки. В грубом приближении для этого требуется ионизовать атом. При этом $eV = \mathrm{Ry}(Z-1)^2$. Таким образом, $V_{\text{Mo}} \approx 23$kB; $V_{\text{Cu}} \approx 10,6\kappa$B; $V_{\text{Fe}} \approx 8,5\kappa$B.

Эти результаты можно уточнить. Так, в атоме Mo структура незаполненных электронных оболочек $-4d^55s^1$, т. е. есть свободные места в $4d$-оболочке, откуда $eV_{\text{Mo}'} = \mathrm{Ry}(Z-1)^2\left(\frac{1}{1^2} - \frac{1}{4^2}\right) \approx 21,4$ кэВ. В атоме Cu структура

внешних электронных оболочек $-3d^{10}4s^1$, при этом в $3d$-оболочке мест нет и, следовательно, требуемый переход - в $4s$. Поэтому $V_{\text{Cu}} \approx 10$ кВ. Структура внешних электронных оболочек Fe $- 3d^64s^2$, откуда $V_{\text{Fe}} \approx 7,55$ кВ .

5.

39. Решение. K-полоса образуется при переходах K-электронов на свободные места. При таких переходах наиболее вероятно излучение электродипольных или El-фотонов. Самое коротковолновое излучение было бы при переходе внешнего электрона, т. е. $5s \to 1s$. Но такой переход с излучением $E1$-фотона является $(0-0)$-переходом и поэтому запрещен правилами отбора по L. Кроме того, для $E1$-фотона этот переход запрещен еще и по закону сохранения четности. Таким образом, границы K-серии соответствуют переходу $4p$-электрона (d-электроны не дают электродипольного излучения, потому что $\Delta L = 2$). Возможные и запрещен-

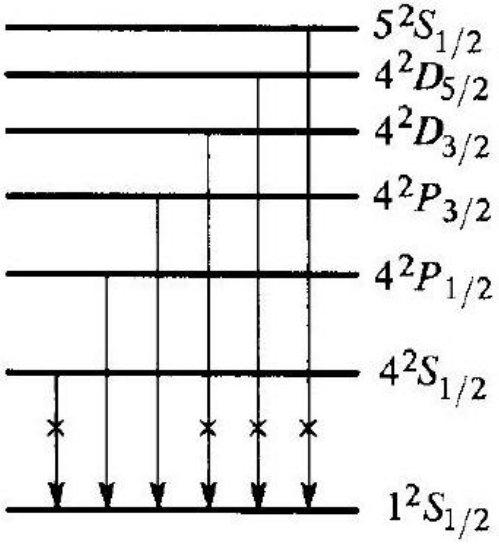

Рис. 159 ные переходы изображены на рис. 159. Пренебрегая расщеплением уровней из-за спин-орбитального расщепления, получаем

$$\frac{hc}{\lambda_{\text{гр}}} = \text{Ry}(Z-1)^2\left(\frac{1}{1^2}-\frac{1}{4^2}\right)$$

откуда $\lambda_{\text{гр}} = 5,79\cdot 10^{-9}$ см $\approx 0,058$ нм.
Для атома меди (Cu) с конфигурацией электронных оболочек $1s^22s^22p^63s^23p^63d^{10}4s^1$ границы соответствуют переходу $3p$-электрона

$$\lambda_{гр} \approx 0,013$$

Для атома железа (Fe) конфигурация электронной оболочки имеет вид $1s^22s^22p^63s^23p^63d^64s^2$ - все аналогично меди

$$\lambda_{\text{гр}} = 1,64\cdot 10^{-9}\text{с} \approx 0,016\text{Н}$$

5.

40. Электронная конфигурация атома Co $1s^22s^22p^63s^23p^63d^74s^2$. Учитывая, что для этого атома переход $4s-1s$ с излучением $E1$-фотона запрещен, $\mathscr{E}^{\text{Co}}_{K_{\text{гр}}} \approx 8,172$ кэВ. Минимальная энергия для возбуждения K-излучения Ni(линия K_α) есть $\mathscr{E}^{\text{Ni}}_{K_\alpha} \approx 8,813$ кэВ. Поскольку $\mathscr{E}^{\text{Ni}}_{K_\alpha} > \mathscr{E}^{\text{Co}}_{K_{\text{гр}}}$, то K-серия атома Ni не возбуждается. Остальные линии - возбуждаются.

5.

41. Zr и Mo; между ними находится элемент Nb .

5.

42. Na ($3S \to 2P$-переходы).

5.

43. $V = 15\kappa B$.

5.

49. $T = -\frac{\hbar^2}{k\mu d^2\ln(\alpha/3)} = 1,4$ K. Здесь отношение заселенностей состояний записано с учетом их статистических весов (кратностей вырождения): $\alpha = \frac{N(l_1=1)}{N(l_2=0)} = \frac{2l_1+1}{2l_2+1}\exp\left(-\frac{\mathscr{E}(l_1)-\mathscr{E}(l_2)}{kT}\right) = 3\exp\left(-\frac{\hbar^2}{kTI}\right)$.

5.

50. $\frac{\Delta\lambda}{\lambda} = \frac{\Delta\mu}{\mu} = 2,5\cdot 10^{-2}$, где μ - приведенная масса молекулы. Наибольшей длине волны соответствует переход из $l=1$ в $l=0$, откуда $\lambda = 2,65$ мм .

5.

51. $\frac{\Delta\lambda}{\lambda} = \frac{\Delta\mu}{2\mu} = 7,7\cdot 10^{-4}$, где μ - приведенная масса молекулы.

5.

52. $w(0) = \frac{2}{\pi\sqrt{2n}} = 0,14.$

$$\int^{x_0} e^{-x^2/x_0^2} dx$$

5.

53. $w = \frac{-x_0}{\infty} \approx 0,865.$

$$\int_{-\infty}^{\infty} e^{-x^2/x_0^2} dx$$

5.

54. $l_{\max} \approx \left[\sqrt[4]{\frac{4M_{\text{а3}}}{m_{\text{e}}}}\right] + 1 = 18$, где $M_{\text{а3}}$ - масса атома азота, m_{e} масса электрона. Квадратные скобки здесь и в следующей задаче означают операцию взятия целой части числа.

5.

55. $N_{\max} = [n_{\max}] + 1 = 81$, где $n_{\max} = \frac{1-\alpha}{2\alpha} \approx 80,9.$

5.

56. $\delta\mathscr{E}_{205} - \delta\mathscr{E}_{203} = \delta\mathscr{E}_{203}\frac{2}{3}\frac{\Delta A}{A} \approx 0,05$ эВ. Тогда $\delta\mathscr{E}_{205} = \delta\mathscr{E}_{203} + 0,05 = -8,2$ эВ (энергия ионизации в атоме с ядром ^{205}Tl меньше, чем в атоме с ядром ^{203} T1).

5.

57: $\frac{\Delta\omega}{\omega_0} = -0,046.$
Решение. Гамильтониан относительного движения атомов в молекуле имеет вид

$$\widehat{H} = -\frac{\hbar^2}{2\mu}\Delta_r + \frac{\hbar^2 l(l+1)}{2\mu r^2} + \frac{\varepsilon\sigma^2}{r^2} - 2\frac{\varepsilon\sigma}{r}$$

где $\Delta_r = \frac{d^2}{dr^2} + \frac{2}{r}\frac{d}{dr}$ - радиальная часть лаплассиана, $\mu = \frac{m_{\text{H}} m_{\text{Cl}}}{m_{\text{H}} + m_{\text{Cl}}} \approx m_{\text{H}}$ - приведенная масса. Следовательно, эффективный потенциал

$$U(r) = U_{\text{цбеж}}(r) + U(r) = \frac{A_l}{r^2} - \frac{B}{r}$$

где $A_l = \frac{\hbar^2 l(l+1)}{2\mu} + \varepsilon\sigma^2 = \varepsilon\sigma^2\left[1 + \frac{\hbar^2 l(l+1)}{2\mu\varepsilon\sigma^2}\right] = \varepsilon\sigma^2(1+\delta_l), B = 2\varepsilon\sigma$. Минимум эффективного потенциала находится при $r_0 = \frac{2A_l}{B}$. Раскладывая потенциал вблизи минимума

$$U_{\text{Эфф}}(r) \simeq U_\phi(r_0) + \frac{1}{2}\frac{d^2 U_{\text{эфф}}}{dr^2}\bigg|_{r=r_0}(r-r_0)^2,$$

получаем выражение для коэффициента жесткости

$$k = \frac{1}{2}\frac{d^2 U_{\text{эфф}}}{dr^2}\bigg|_{r=r_0} = \frac{B^4}{8A_l^3}.$$

Частота колебаний $\omega_l = \sqrt{\frac{k}{\mu}} = \left(\frac{B}{A_l}\right)^2\sqrt{\frac{A_l}{8\mu}}$.
Поскольку $\delta_l = \frac{\hbar^2 l(l+1)}{2\mu\varepsilon\sigma^2} = 0,024 \ll 1$, то

$$\omega_l \approx \frac{4}{\sigma^2}(1-2\delta_l)\sqrt{\frac{\varepsilon\sigma^2}{8\mu}}\left(1+\frac{\delta_l}{2}\right) \approx \sqrt{\frac{2\varepsilon}{\mu\sigma^2}}\left(1-\frac{3}{2}\delta_l\right).$$

Введем обозначение $\omega_0 = \sqrt{\frac{2\varepsilon}{\mu\sigma^2}}$ - частота колебаний в основном состоянии.
Тогда

$$\omega_l = \omega_0\left(1-\frac{3}{2}\delta_l\right) \text{ и } \frac{\Delta\omega}{\omega} = -\frac{3}{2}\delta_l = -0,046.$$

См. также решение задачи 5.31.
Заметим, что квант колебаний $\hbar\omega_0 = \sqrt{2\varepsilon\frac{\hbar^2}{\mu\sigma^2}} = 0,146$ эВ. Равновесное расстояние между атомами $r_0 \approx \alpha$.

Если ввести обозначения $\frac{\hbar^2 l(l+1)}{2\mu r^2} + \frac{\varepsilon\sigma^2}{r^2} = \frac{\hbar^2 l^*(l^*+1)}{2\mu r^2}$ и $2\varepsilon\sigma = (l^*)^2$, то получим гамильтониан атома водорода. Используя известный результат, получаем полную энергию молекулы $\mathscr{E} = -\frac{\mu(e^*)^4}{2\hbar^2}\frac{1}{(n_r+l^*+1)^2}$. Если $n_r,\, l \ll \frac{2\mu\varepsilon\sigma^2}{\hbar^2}$, то полученную формулу можно разложить в ряд и получить

$$\mathscr{E} = -\varepsilon + \hbar\sqrt{\frac{2\varepsilon}{\mu\sigma^2}}\left(n_r+\frac{1}{2}\right) + \frac{\hbar^2}{2\mu\sigma^2}\left(l+\frac{1}{2}\right)^2 - \\ - \frac{3\hbar^2}{2\mu\sigma^2}\left(n_r+\frac{1}{2}\right)^2 - \frac{3\hbar^3}{2\mu^2\sigma^4}\sqrt{\frac{\mu\sigma^2}{2\varepsilon}}\left(n_r+\frac{1}{2}\right)\left(l+\frac{1}{2}\right).$$

Первые три члена этой формулы соответствуют электронной, колебательной и вращательной энергиям молекулы (задача 5.29). Четвертый член соответствует ангармонизму колебаний (задача 5.55), а пятый - взаимодействию колебаний и вращений ядер (задачи 5.31 и 5.57). Не смотря на свою простоту, которая позволяет получить аналитическое решение, потенциал Кратцера плохо описывает реальную форму потенциала взаимодействия: на малых расстояниях отталкивание атомов в молекулах сильнее, а на больших расстояниях - притяжение слабее. Поэтому в теории молекул обычно используют потенциал Морса (задача 5.33), а в конденсированных средах потенциал Леннарда-Джонса.

20.4 Many-Body Quantum Mechanics Problems

20.4.1 Problems about Addition of Momenta and Particle Identity

(потом быстро мб потренируюсь, пропишу теорию про это! сложение моментов и операторы дискретных симметрий. тут еще подумать нужно про это!)

Б-2.10.1 Суммарный спин системы с двумя электронами

Найти собственные значения и собственные функции операторов $\hat{\mathbf{S}}^2$ и $\hat{\mathrm{S}}_z$ системы двух электронов $\left(\hat{\mathbf{S}} = \hat{\mathbf{s}}_1 + \hat{\mathbf{s}}_2\right)$, $s_i = 1/2$. Установить связь перестановочной симметрии спиновой функции с суммарным спином S.

Обозначим одночастичные спиновые функции $\chi_{1/2}(1,2)$, $\chi_{1/2}(2)$ и $\chi_{-1/2}(1)$, $\chi_{-1/2}(2)$ где цифры 1,2 нумеруют частицы. Должны выполняться условия

$$\hat{s}_{1z}\chi_{1/2}(1) = +\frac{1}{2}\chi_{1/2}(1),$$

$$\hat{s}_{2z}\chi_{1/2}(2) = +\frac{1}{2}\chi_{1/2}(2),$$

$$\hat{s}_{1,2z}\chi_{-1/2}(1) = -\frac{1}{2}\chi_{-1/2}(1),$$

$$\hat{s}_{1,2z}\chi_{-1/2}(2) = -\frac{1}{2}\chi_{-1/2}(2).$$

где $\hat{s}_{1z}, \hat{s}_{2z}$ - одночастичные спиновые операторы, действующие только на спиновые функции 1-й или 2-й частицы. Для волновой функции с суммарным спином ψ_{SM} выполняется

$$\hat{\mathbf{S}}^2\psi_{SM} = S(S+1)\psi_{SM},$$
$$\hat{S}_z\psi_{SM} = M\psi_{SM},$$

где $\hat{\mathbf{S}} = \hat{\mathbf{s}}_1 + \hat{\mathbf{s}}_2$ - оператор суммарного спина.

Находим старший и младший вектор - собственные функции операторов $\hat{\mathbf{S}}^2$ и $\hat{\mathrm{S}}_z$, отвечающие собственным значениям $S = 1, M = \pm 1$. Эти вектора реализуются, если обе частицы имеют спин или только в одну или только в противоположную сторону:

$$\psi_{1,1} = \chi_{1/2}(1)\chi_{1/2}(2),$$
$$\psi_{1,-1} = \chi_{-1/2}(1)\chi_{-1/2}(2).$$

Действуем на старший вектор $\psi_{1,1}$ понижающим оператором S_-, которым воспользуемся, представив его как $\hat{\mathrm{S}}_- = \hat{\mathrm{s}}_{1-} + \hat{\mathrm{s}}_{2-}$. После действия его получатся функция с $M = 0$:

$$\psi_{1,0} = \frac{1}{\sqrt{2}}\left(\chi_{1/2}(1)\chi_{-1/2}(2) + \chi_{-1/2}(1)\chi_{1/2}(2)\right).$$

и также она же получается, если подействовать по формуле $J_-|J, M\rangle = \sqrt{J(J+1) - M(M-1)}|J, M-1\rangle$. То есть мы вывели, что $|j^A + j^B, j^A + j^B - 1\rangle = \sqrt{\frac{j^A}{j^A+j^B}}|j^A, j^A - 1\rangle|j^B, j^B\rangle + \sqrt{\frac{j^B}{j^A+j^B}}|j^A, j^A\rangle|j^B, j^B - 1\rangle$.

Из вида вектора $\psi_{1,0}$ заключаем, что он имеет один ортогональный. Выберем его как

$$\psi_{1,0\perp} = \frac{1}{\sqrt{2}}\left(\chi_{1/2}(1)\chi_{-1/2}(2) - \chi_{-1/2}(1)\chi_{1/2}(2)\right).$$

Ортогональность очевидна, а коэффициент вначале находится из нормировки. Подействовав на него повышающим оператором $S_+ = s_{1+} + s_{2+}$, где каждый действует как $j_\pm|j, m\rangle = \sqrt{j(j+1) - m(m \pm 1)}|j, m \pm 1\rangle$, видим, что он обращается в ноль, таким образом, для $M = 0$ мы имеем старший вектор, то есть

$$\psi_{0,0} = \frac{1}{\sqrt{2}}\left(\chi_{1/2}(1)\chi_{-1/2}(2) - \chi_{-1/2}(1)\chi_{1/2}(2)\right).$$

Спиновые функции ψ_{SM} обладают определенной симметрией по отношению к перестановкам спиновых переменных $1 \leftrightarrow 2$: они симметричны при $S = 1$ и антисимметричны при $S = 0$.

Об операторе спинового обмена (??)

(не понял, как им пользоваться пока что.)

Заметим в этой связи, что для нахождения функций ψ мм можно было бы воспользоваться оператором спинового обмена $\hat{\mathrm{P}}_{12}$. Он действует на спиновые функции следующим образом: $\hat{\mathrm{P}}_{12}\psi_{SM}(1, 2) = \psi_{SM}(2, 1)$, т. е. как раз переставляет спиновые переменные. Оператор $\hat{\mathrm{P}}_{12}$ коммутирует с $\hat{\mathbf{S}}^2$ и $\hat{\mathrm{S}}_2$, а поэтому искомые функции должны быть и его собственными функциями: $\hat{\mathrm{P}}_{12}\psi_{SM}(1, 2) = \lambda\psi_{SM}(1, 2)$. Легко видеть, что $\lambda = \pm 1$, а собственные функции должны быть симметричными ($\lambda = 1$) или антисимметричными ($\lambda = -1$). Поэтому можно сразу составить из одночастичных функций симметричные и антисимметричные комбинации, и тогда останется только определить значения квантовых чисел S и M.

Б-2.10.2 Элементарное сложение моментов

Найти собственные значения и собственные функции операторов $\hat{\mathbf{l}}^2$ и $\hat{\mathrm{l}}_z$ системы двух частиц с орбитальными моментами $l_1 = l_2 = 1$ $\left(\hat{\mathbf{l}} = \hat{\mathbf{l}}_1 + \hat{\mathbf{l}}_2\right)$. Воспользоваться соотношениями ортогональности для коэффициентов Клебша-Гордана. Определить связь между квантовым числом суммарного момента L и перестановочной симметрией координатной волновой функции.

Б-2.10.3 Элементарное сложение моментов

Найти собственные значения и собственные функции операторов $\hat{j}^2$ и $\hat{j}_z$ частицы со спином 1/2 в случае, когда орбитальное квантовое число равно $l(\hat{\mathbf{j}} = \hat{I} + \hat{\mathbf{s}})$.

(У киселева решена, соберу потом сюда решение тоже!)

Б-2.10.4 Средние значения операторов частицы в атоме водорода (??)

Вычислить средние значения операторов $(\hat{I}\hat{\mathrm{s}})$, $(\hat{\mathrm{j}})$ и $(\hat{\mathrm{j}}\hat{\mathrm{s}})$ в состоянии $|l, s, j, m_j\rangle$.

(?? что за операторы???)

Б-2.10.5 Оператор обмена спинами (!?!??)

Показать, что оператор $\hat{\mathrm{P}}_{12} = \frac{1}{2}(1 + \hat{\boldsymbol{\sigma}}_1\hat{\sigma}_2)$ является оператором обмена спинами, т. е. $\hat{\mathrm{P}}_{12}\hat{\boldsymbol{\sigma}}_1\hat{\mathrm{P}}_{12}^{-1} = \hat{\boldsymbol{\sigma}}_2$.

Б-2.10.6 Ферми- и бозе- частицы в ящике

Найти уровни энергии и волновые функции стационарных состояний двух невзаимодействующих тождественных частиц в потенциальном ящике

$$V(x) = \begin{cases} 0, & 0 < x < a \\ \infty, & x < 0, x > a \end{cases}$$

если этими частицами являются:
а) ферми-частицы со спинами $s = 1/2$;
б) бозе-частицы со спинами $s = 0$;
в) бозе-частицы со спинами $s = 1$.
Чему равна в каждом из этих случаев энергия основного состояния N частиц?
(??? тупая задача, неужели суть её в том, что не важно, ферми и бозе ли частицы у нас?)
Одночастичные координатные функции и уровни энергии имеют вид

$$\psi_n(x) = \begin{cases} \sqrt{\frac{2}{a}} \sin \frac{\pi n}{a} x, & 0 < x < a, \\ 0, & x \leqslant 0, x \geqslant a, \end{cases} \qquad E_n = \frac{\hbar^2 k^2}{2m} = \frac{\pi^2 \hbar^2}{2ma^2} n^2.$$

а) Ферми-частицы со спином $1/2$. Полная волновая функция Ψ (произведение координатной и спиновой функций) должна быть антисимметричной, поэтому в случае $n_1 \neq n_2$ возможны два варнанта:

$$\Psi_{n_1 n_2} = \psi_A(x_1, x_2)\, \chi_S(S, M) \quad \text{и} \quad \Psi_{n_1 n_2} = \psi_S(x_1, x_2)\, \chi_A(S, M),$$

где ψ_A и ψ_S - антисимметричная и симметричная комбинации одночаные в задаче 2.10.1. Таким образом, х отвечает значению суммарного спина $S = 0$ (одна функция), а \ s отвечает состояниям с $S = 1$ (три функции). Энергия состояния двух частиц $E_{n_1 n_2} = \frac{\pi^2 \hbar^2}{2ma^2} \left(n_1^2 + n_2^2\right)$.

В случае $n_1 = n_2 = n$ может реализоваться только симметричная координатная функция ψ_S, поэтому спиновая функция должна быть антисимметричной: χ A, т. е. такому состоянию отвечает значение $S = 0$. Энергия состояня двух частиц равна $E_{nn} = \frac{\pi^2 \hbar^2}{ma^2} n^2$. Энергия основного состояния N частиц:

$$E = \begin{cases} \frac{\pi^2 \hbar^2}{24ma^2} N(N+1)(N+2), & \text{если } N = 2n \\ \frac{\pi^2 \hbar^2}{24ma^2} (N+1)\left(N^2 + 2N + 3\right), & \text{если } N = 2n+1 \end{cases}$$

б) Бозе-частицы со спином 0. Полная волновая функция (она же - координатная) может быть только симметричной:

$$\Psi_{n_1 n_2} = \psi_S(x_1, x_2) = \frac{1}{\sqrt{2}} \left[\psi_{n_1}(x_1)\, \psi_{n_2}(x_2) + \psi_{n_1}(x_2)\, \psi_{n_2}(x_1)\right]$$

Энергия двух частиц: $E_{n_1 n_2} = \frac{\pi^2 \hbar^2}{2ma^2} \left(n_1^2 + n_2^2\right)$.

в) Бозе-частицы со спином 1. Полная волновая функция Ψ (произведение координатной и спиновой функций) должна быть симметричной, поэтому возможны два варианта ($n_1 \neq n_2$):

$$\Psi_{n_1 n_2} = \psi_S(x_1, x_2)\, \chi_S(S, M) \text{ и } \Psi_{n_1 n_2} = \psi_A(x_1, x_2)\, \chi_A(S, M),$$

где спиновые функции имеют точно такой же вид, как и общие собственные функции операторов $\hat{\mathbf{L}}^2$ и $\hat{l}_z$ из решения задачи 2.10.2. Следоа χ_S отвечает состояниям с $S = 0, 2$ (шесть функций). Энергия двух частиц: $E_{n_1 n_2} = \frac{\pi^2 \hbar^2}{2ma^2} \left(n_1^2 + n_2^2\right)$.

В случае $n_1 = n_2 = n$ может реализоваться только симметричная координатная функция ψ_s, поэтому спиновая функция должна быть также симметричной: χS, т. е. такому состоянию отвечают значения $S = 0, 2$.

Энергия основного состояния N частиц для случаев б) и в) одинакова и равна

$$E = \frac{\pi^2 \hbar^2}{2ma^2} N$$

Б-2.10.7 Распад на две альфа-частицы ядра с $J = 1$

Может ли распасться на две альфа-частицы нестабильное ядро $^8\mathrm{Be}^*$, находящееся в состоянии с $J = 1$?

Спин α-частиц равен нулю, и их общая волновая функция должна быть симметрична по отношению к перестановкам пространственных переменных. В системе центра масс такая перестановка приводит к преобразованию $\mathbf{r} \to -\mathbf{r}$, где $\mathbf{r}$ - относительная координата.

Для определения вида волновой функции нам может понимание P-четности. При зеркальном отражении всех осей евклидова пространства $\boldsymbol{r} \xrightarrow{\hat{P}} -\boldsymbol{r}$ углы преобразуются как

$$\phi \xrightarrow{\hat{P}} \phi + \pi, \quad \theta \xrightarrow{\hat{P}} \pi - \theta,$$

или

$$e^{im\phi} \xrightarrow{\hat{P}} e^{im(\phi+\pi)} = (-1)^m e^{im\phi}, \quad \cos\theta \xrightarrow{\hat{P}} -\cos\theta.$$

Присоединенные полиномы Лежандра суть производные функции четности $(-1)^l$, так что их четность определяется просто числом производных, и

$$P_{l,m}(\cos\theta) \xrightarrow{\hat{P}} (-1)^{l-m} P_{l,m}(\cos\theta).$$

Собирая факторы, находим

$$y_{l,m}(\theta,\phi) \xrightarrow{\hat{P}} (-1)^l y_{l,m}(\theta,\phi).$$

Другими словами, P-четность сферических гармоник равна

$$\lambda_P = (-1)^l.$$

То есть при данной замене угловая часть волновой функции α-частиц должна умножаться на $(-1)^L$ - четность состояния (L - полный орбитальный момент). Число L должно быть четным, потому что волновая функция симметрична. Поэтому и полный момент ядра Be также должен быть четным. Следовательно, при $J = 1$ распад невозможен.

20.4.2 Simple Problems of Solid State Physics

(если это не простейшее - в физику твердого тела занесу)

простейшие одномерные модели

Модели типа Кронига-Пенни

мотивация

если Пироженко ей занималась, значит, все-таки что-то есть в этом.
наверное, там много моделей.

типичная модель

(задача из Белоусова)

ЛШ-1 Классическая цепочка осцилляторов

итоговые свойства

описание модели

Рассмотрим цепочку атомов массы m_i, соединенньх одинаковыми пружинками жесткости K:

$$\mathcal{H} = \sum_{i=-\infty}^{\infty} \left[p_i^2/(2m_i) + (K/2)(x_i - x_{i+1})^2 \right]$$

где $m_i = m$, если i четно, и $m_i = M$, если i нечетно.

1. Определите нормальные моды для этой системы. Покажите, что их две: акустическая и оптическая.

2. Чему равна скорость звука c? Получится ли такой же ответ, если вычислять c по формуле Лапласа $c = \sqrt{\partial P/\partial\rho}$, где P -давление, а ρ -плотность?

3. Чему равна ширина щели между оптической и акустической ветвями? Покажите, что при $M \gg m$ дисперсия оптической моды практически отсутствует. Как можно объяснить это качественно?

решение модели

$$m\ddot{x}_i = K\left(y_i + y_{i-1} - 2x_i\right), \quad M\ddot{y}_i = K\left(x_i + x_{i+1} - 2y_i\right)$$

(x_i - смещение атома массы m в i -й элементарной ячейке, y_i -смещение атома массы M).

Будем искать решение в виде плоских волн:

$$x_n = e^{i(qn-\omega t)}x_q, \quad y_n = e^{i[q(n+1/2)-\omega t]}y_q$$

Отсюда

$$m\omega^2 x_q = 2Kx_q - 2K\cos(q/2)y_q, \quad M\omega^2 y_q = 2Ky_q - 2K\cos(q/2)x_q$$

(Здесь q -волновой вектор в первой зоне Бриллюэна: $-\pi < q < \pi$.) Нормальные моды имеют закон дисперсии, определяемый из условия

$$\det\begin{pmatrix} 2K - m\omega^2 & -2K\cos(q/2) \\ -2K\cos(q/2) & 2K - M\omega^2 \end{pmatrix} = 0$$

что дает $\omega^4 - (2K/\mu)\omega^2 + \left(4K^2/mM\right)\sin^2(q/2) = 0$, где $\mu = Mm/(M+m)$.

Получаем

$$\omega_{\pm}^2(q) = \frac{K}{\mu}\left(1 \pm \sqrt{1 - \frac{4\mu^2}{mM}\sin^2(q/2)}\right)$$

Здесь «+» соответствует оптической, а «-» - акустической моде.

Дисперсия нормальных мод (1.27) показана на рис. 1.1.

(вставлю, типичный рисунок)

При малых q разлагаем закон дисперсии акустической моды:

$$\omega_-^2(q) = \frac{2K\mu}{mM}(q/2)^2$$

и получаем скорость звука:

$$c = \left(\omega_-/q\right)|_{q\to 0} = \frac{1}{2}(2K/(M+m))^{1/2}$$

При выводе предполагалось, что период решетки $2a$ равен единице.

Чтобы получить выражение, имеющее размерность скорости, надо умножить результат на $2a$, где a -расстояние между атомами M и m.

При этом получается скорость $c = a\sqrt{2K/(M+m)}$ Проверим, что найденная скорость звука согласуется с формулой Лапласа $c^2 = \partial P/\partial\rho$, связываюшей скорость звука и сжимаемость системы.

Для цепочки длины x, содержашей N атомов каждого типа, сила пропорциональна удлинению, $dP = -(K/2N)dx($ в одном измерении сила и давление - это одно и то же), а изменение плотности есть

$$d\rho = \frac{d}{dx}\left(\frac{(M+m)N}{x}\right)dx = -\frac{(M+m)N}{x_0^2}dx$$

где $x_0 = 2$ Na.

Отсюда получаем $c^2 = 2\mathrm{Ka}^2/(M+m)$, как и следовало.

Верхний край акустической ветви спектра:

$$\max\left[\omega_-^2(q)\right] = \omega_-^2(\pi) = \frac{K}{\mu}\left(1 - \sqrt{1 - \frac{4\mu^2}{mM}}\right) = \frac{K}{\mu}\left(1 - \frac{M-m}{M+m}\right) = \frac{2K}{M}$$

Аналогично, нижний край оптической ветви есть

$$\min\left[\omega_+^2(q)\right] = \omega_+^2(\pi) = \frac{2K}{m}$$

и поэтому ширина щели $\Delta\omega = \sqrt{2K/m} - \sqrt{2K/M}$.

При $M \gg m$ частота оптической ветви

$$\omega_+(q) = \sqrt{\frac{2K}{m}}\left(1 + \frac{m}{2M}\cos^2(q/2) + O\left(\frac{m^2}{M^2}\right)\right)$$

практически не зависит от q, что соответствует колебаниям легких атомов между почти неподвижными тяжелыми.

Физическая причина отсутствия дисперсии - взаимная независимость колебаний соседних атомов массы m.

При $M \gg m$ неважно, колеблются ли соседние легкие атомы в фазе или же в противофазе, поскольку через тяжелые стенки (т.е.

атомы массы M) влияние не передается.

ЛШ-2 Фермионная цепочка

итоговые свойства

обзор и применения

хз зачем нужна.

описание модели

Найдите преобразование Боголюбова, диагонализующее фермионный гамильтониан

$$\hat{\mathcal{H}} = \sum_{i=-\infty}^{\infty} \left(J_1 a_i^+ a_{i+1} + J_1 a_{i+1}^+ a_i + J_2 a_i a_{i+1} + J_2 a_{i+1}^+ a_i^+ - 2B a_i^+ a_i \right)$$

Такой гамильтониан возникает при рассмотрении одномерной модели квантового магнетика, так называемой «XY-модели»
(см. раздел 1.4).
Определите спектр квазичастиц $\varepsilon(k)$ этого гамильтониана.
Обратите внимание, что при $B = 0$ и $J_1 = J_2$ дисперсия пропадает.
Можно ли понять это без вычислений?

решение 1

Сделаем преобразование Фурье $a_m = \int\limits_{-\pi}^{\pi} e^{ikm} a_k \frac{dk}{2\pi}$.

При этом члены гамильтониана преобразуются к такому виду:

$$\sum_m a_m^+ a_{m+1} = \sum_k a_k^+ a_k e^{ik}, \sum_m a_m a_{m+1} = \sum_k a_k a_{-k} e^{-ik}$$
$$\sum_m a_m^+ a_{m+1} + a_{m+1}^+ a_m = \sum_k 2\cos k a_k^+ a_k$$

где сумма по k есть сокращенное обозначение для $\int\limits_{-}^{\pi} \ldots \frac{dk}{2\pi}$.

Пользуясь антикоммутативностью a_k и a_{-k}, перепишем вторую сумму так:

$$\sum_m a_m a_{m+1} = -i \sum_k \sin k a_k a_{-k}$$

после чего гамильтониан принимает вид

$$\hat{\mathcal{H}} = \sum_k \left(2\left(J_1 \cos k - B\right) a_k^+ a_k - i J_2 \sin k a_k a_{-k} + i J_2 \sin k a_{-k}^+ a_k^+ \right)$$

После «поворота» $a_k = e^{i\pi/4} b_k, a_k^+ = e^{-i\pi/4} b_k^+$ гамильтониан становится вещественным:

$$\hat{\mathcal{H}} = \sum_k \left(\left(J_1 \cos k - B\right) b_k^+ b_k + J_2 \sin k b_k b_{-k} + \text{ h.c} \right)$$

Будем искать фермионное преобразование Боголюбова в виде

$$b_k = u_k c_k + v_k c_{-k}^+, \qquad b_k^+ = u_k c_k^+ + v_k c_{-k}$$
$$b_{-k}^+ = -v_k c_k + u_k c_{-k}^+, \quad b_{-k} = -v_k c_k^+ + u_k c_{-k}$$

с вещественными u_k и v_k, причем $u_k^2 + v_k^2 = 1$.
Получаем

$$\hat{\mathcal{H}} = \sum_k \left(J_1 \cos k - B\right) \left(u_k^2 c_k^+ c_k + u_k v_k \left(c_k^+ c_{-k}^+ + c_{-k} c_k \right) + v_k^2 c_{-k} c_{-k}^+ \right) +$$
$$+ J_2 \sin k \left(u_k^2 c_k c_{-k} + u_k v_k \left(c_{-k}^+ c_{-k} - c_k c_k^+ \right) - v_k^2 c_{-k}^+ c_k^+ \right) + \text{h.c}$$

Приравняем коэффициент при $c_{-k}c_k$ нулю, потребовав чтобы

$$2u_kv_k\left(J_1\cos k - B\right) + \left(-u_k^2 + v_k^2\right)J_2\sin k = 0$$

Тогда будем иметь слкдующее

$$\frac{v_k}{u_k} = \frac{B - J_1\cos k \pm \sqrt{\left(J_1\cos k - B\right)^2 + J_2^2\sin^2 k}}{J_2\sin k}$$

Решив это уравнение при условии $u_k^2 + v_k^2 = 1$, найдем значения u_k, v_k и подставим их в гамильтониан:

$$\hat{\mathcal{H}} = \text{const} + \sum_k \left[2\left(J_1\cos k - B\right)\left(u_k^2 - v_k^2\right) + 4J_2\sin k u_k v_k\right] c_k^+ c_k =$$

$$= \text{const} + \sum_k \varepsilon_k c_k^+ c_k$$

Спектр возбуждений, таким образом, есть

$$\varepsilon_k = 2\sqrt{\left(J_1\cos k - B\right)^2 + J_2^2\sin^2 k}$$

Отсутствие дисперсии при $J_1 = J_2$ и $B = 0$ означает, что возбуждения локализованы на одном или нескольких соседних узлах.

Это можно понять с точки зрения преобразования Йордана-Вигнера (см.
раздел 1.4), которое в данном случае приводит к изинговской спиновой цепочке:

$$\hat{\mathcal{H}} = \sum_{i=-\infty}^{\infty} J_y\sigma_i^y\sigma_{i+1}^y$$

В такой цепочке каждый спин характеризуется определенной проекцией на ось y.

Поэтому элементарное возбуждение в этой системе - просто переворот спина на любом из узлов, никак не затрагивающий остальные узлы.

Таким образом, полная локализация возбуждения на одном узле эквивалентна отсутствию дисперсии.

Обратим внимание на аналогию с задачей 1 в случае $M \gg m$ когда оптическая мода колебаний становится почти бездисперсионной из-за того, что колебания соседних легких атомов почти полностью развязаны.

второе решение

не актуально к сожалению.

ЛШ-3 Нелинейные канонические преобразования

итоговые свойства

описание модели

Рассмотрим фермиевские операторы a и a^+, действующие в пространстве состояний фермиона, который может заполнять или не заполнять ровно одно состояние.

В этом случае пространство многочастичных состояний двумерно и каноническим базисом в нем служат состояния $|0\rangle$ и $|1\rangle$.

Найдите все канонические преобразования операторов a и a^+, сохраняющие соотношения $a^2 = \left(a^+\right)^2 = 0$ и $a^+a + aa^+ = 1$.

Убедитесь в том, что канонические преобразования наиболее общего вида не описываются линейными соотношениями вида (1.11).

Рассмотрите представление фермиевских операторов спиновыми матрицами Паули:

$$\sigma_x = a + a^+, \quad \sigma_y = i\left(a - a^+\right), \quad \sigma_z = 2a^+a - 1$$

Покажите, что канонические преобразования a и a^+ соответствуют вращениям в спиновом пространстве.

Связь между фермиевскими операторами и операторами спина 1/2 более подробно рассмотрена в разделе 1.4.

решение

Решение 3.
Будем искать каноническое преобразование в таком виде:

$$a' = ua + va^+ + wa^+a + q$$
$$a'^+ = u^*a^+ + v^*a + w^*a^+a + q^*$$

Это наиболее общая форма, к которой может быть приведено любое полиномиальное по a и a^+ выражение.
Убедиться в этом можно следующим образом.
Во-первьх, помощью коммутационньх соотношений любое выражение может быть приведено к нормальной форме, в которой в каждом слагаемом оператор a^+(если он есть) стоит слева от a.

Во-вторых, поскольку $a^2 = (a^+)^2 = 0$, выражение (1.56) представляет собой нормальную форму наиболее общего вида.
Рассмотрим выражение a'^2.
Приведем квадрат правой части выражения (1.56) для a' к нормальной форме и потребуем, чтобы все коэффициенты обратились в нуль.
Это дает два условия:

$$w + 2q = 0, \quad uv + q^2 = 0$$

Аналогично, условие $a'a'^+ + a'^+a' = 1$ приводит к соотношению

$$|u|^2 + |v|^2 + 2|q|^2 = 1$$

Из полученных соотношений следует, что

$$|u| + |v| = 1$$

Таким образом, наиболее общее каноническое преобразование задается двумя комплексными параметрами u и v, удовлетворяющими условию (1.60).
Коэффициенты q и w определяются таким образом: $q = \pm i\sqrt{uv}, w = -2q$.
Нетрудно видеть, что в обшем случае каноническое преобразование нелинейное, поскольку коэффициент w не обращается в нуль.
Более того, линейными оказываются лишь тривиальные преобразования (с u или v равным нулю).
Решим теперь задачу другим способом, воспользовавшись представлением (1.21) фермиевских операторов через матрицы Паули.
Обратим соотношения (1.21):

$$a = (\sigma_x - i\sigma_y)/2, \quad a^+ = (\sigma_x + i\sigma_y)/2$$

Нетрудно проверить, что условия $a^2 = (a^+)^2 = 0, a^+a + aa^+ = 1$ эквивалентны соотношениям антикоммутативности для σ_i:

$$[\sigma_i, \sigma_j]_+ = 2\delta_{ij}$$

Преобразования, сохраняющие соотношения (1.62), можно записать в виде

$$\sigma_i' = R_{ij}\sigma_j$$

где R_{ij} -вещественная ортогональная матрица 3×3.
Поэтому канонические преобразования в данном случае образуют группу SO(3).

ЛШ-4 Квантовая цепочка осцилляторов

итоговые свойства

описание модели

(??? условие утеряно??)
Пусть теперь гамильтониан (1.19) определяет квантовую задачу, т.е.
$p_i = -i\hbar\partial/\partial x_i$.
Перейдите к бозонным операторам рождения и уничтожения:

$$\hat{x}_i = \sqrt{\frac{\hbar}{m_i\omega_i}}\frac{a_i + a_i^+}{\sqrt{2}}, \quad \hat{p}_i = \sqrt{\hbar m_i\omega_i}\frac{a_i - a_i^+}{i\sqrt{2}}$$

Первое решение

(ниже все понятно, нужно бы когда-то проделать, чтобы потренироваться, пока забил, потому что суть понятна.)

Выразим $\hat{\mathcal{H}}$ через a_i и a_i^+ по формулам (1.22), не определяя пока частоту ω_0:

$$\hat{\mathcal{H}} = \sum \left(\frac{p_i^2}{2m} + \frac{K}{2} (x_i - x_{i+1})^2 \right) = -\sum \left[\frac{\hbar\omega_0}{4} \left(a_i - a_i^+\right)^2 + \frac{K\hbar}{4m\omega_0} \left(a_i + a_i^+ - a_{i+1} - a_{i+1}^+\right)^2 \right] =$$
$$= \sum \left[\frac{\hbar\omega_0}{4} \left(a_i^+ a_i - a_i^2\right) + \frac{\hbar K}{4m\omega_0} \left((a_i - a_{i+1}) \left(a_i^+ - a_{i+1}^+\right) + (a_i - a_{i+1})^2 \right) + \text{h.c} \right]$$

(с точностью до константы, возникающей из-за коммутационных соотношений бозеоператоров).

(потом мб проверю, пока не проверял)

Выполним преобразование Фурье:

$$a_m = \int_{-\pi}^{\pi} a_k e^{ikm} \frac{dk}{2\pi} = \sum_k a_k e^{ikm}, \quad a_k = \sum_m a_m e^{-ikm}$$

При этом

$$a_i - a_{i+1} \to \left(1 - e^{ik}\right) a_k,$$
$$a_i^+ - a_{i+1}^+ \to \left(1 - e^{-ik}\right) a_k^+$$

Подставляя эти выражения в (1.64), получаем

$$\hat{\mathcal{H}} = \sum_k \left(p(k) a_k^+ a_k + q(k) a_k a_{-k} + \text{ h.c} \right)$$

где $p(k) = \frac{\hbar\omega_0}{4} + \frac{\hbar K}{2m\omega_0}(1 - \cos k)$, $q(k) = \frac{\hbar K}{2m\omega_0}(1 - \cos k) - \frac{\hbar\omega_0}{4}$.

Рассмотрим каноническое преобразование:

$$a_k = u_k b_k + v_k b_{-k}^+, \quad a_{-k}^+ = v_k b_k + u_k b_{-k}^+$$

где $u_k = \operatorname{ch} \lambda_k, v_k = \operatorname{sh} \lambda_k$.

Нетрудно проверить, что при преобразовании (1.69) гамильтониан сохраняет свой вид, причем $p(k)$ и $q(k)$ меняются так:

$$p'(k) = \operatorname{ch} 2\lambda_k p(k) + \operatorname{sh} 2\lambda_k q(k)$$
$$q'(k) = \operatorname{sh} 2\lambda_k p(k) + \operatorname{ch} 2\lambda_k q(k)$$

(???? пока не вижу, почему они так меняются???)

Подберем λ_k так, чтобы $q'(k)$ обратилось в нуль:

$$\operatorname{th} 2\lambda_k = -q(k)/p(k)$$

При этом $p'(k) = \sqrt{p^2(k) - q^2(k)} = \hbar\sqrt{K/m} \sin|k/2|$.

Обратим внимание на то, что частота ω_0, значение которой может быть произвольным, выпадает из выражения для $p'(k)$ (но не из выражения для λ_k!).

Диагонализованный гамильтониан имеет вид

$$\hat{\mathcal{H}} = \sum_k \left(p'(k) b_k^+ b_k + \text{h.c} \right) = \sum_k \omega(k) \left(b_k^+ b_k + \frac{1}{2} \right)$$

второе решение

не актуально

20.4.3 Simple Problems of Quantum Mechanics of Gases

(пока тут, потом перенесу мб в статфиз)

ЛШ-7. Элементарные свойства ферми газа через обход полюса

Выразите плотность n ферми-газа через функцию Грина $G(\varepsilon, p)$, воспользовавшись соотношением (2.12).

Вычислите интеграл и получите формулу $p_0^3 = 3\pi^2 n$ для импульса Ферми p_0.

Solution

Используем причинную функцию Грина

$$G_{\alpha\beta} = -i\langle \mathrm{T}\psi_\alpha(\mathbf{r}, t)\psi_\beta^+(\mathbf{r}', t')\rangle = \delta_{\alpha\beta}G,$$

введенную в (2.8). Плотность частиц с проекцией спина α есть

$$n_\alpha(\mathbf{r}, t) = \lim_{t'\to t+0}\langle\psi_\alpha^+(\mathbf{r}, t')\,\psi_\alpha(\mathbf{r}, t)\rangle = -iG_{\alpha\alpha}(\mathbf{r}' = \mathbf{r}, t' = t + 0)$$

(при $t' = t - 0$ из-за перестановки ψ и ψ^+получилось бы $n_\alpha - 1$, по определению функции Грина). В нашем случае система однородна, и G зависит только от разности $\mathbf{r} - \mathbf{r}'$ и $t - t'$. Поэтому переходим в фурье-представление:

$$n_\alpha = -i\lim_{\tau\to-0}\int G(\varepsilon, \mathbf{p})e^{-i\varepsilon\tau}\frac{d^3\mathbf{p}d\varepsilon}{(2\pi)^4} =$$

$$= -i\lim_{\tau\to-0}\int_0^\infty \frac{4\pi p^2 dp}{(2\pi)^3}\int_{-\infty}^{+\infty}\frac{d\varepsilon}{2\pi}\frac{e^{-i\varepsilon\tau}}{\varepsilon - \xi(p) + i\delta\,\mathrm{sign}\,(p - p_0)},$$

где $\tau = t - t', \xi(p) = \mathbf{p}^2/2m - E_F$. Контур интегрирования по ε замыкаем в верхней полуплоскости, поскольку $\tau < 0$. При этом при $p > p_0$ полюс не захвачен:

$$\int\frac{d\varepsilon}{2\pi}\frac{e^{-i\varepsilon\tau}}{\varepsilon - \xi(p) + i\delta} = 0$$

а при $p < p_0$ захвачен:

$$\int\frac{d\varepsilon}{2\pi}\frac{e^{-i\varepsilon\tau}}{\varepsilon - \xi(p) - i\delta} = ie^{-i\xi(p)\tau}.$$

Знак мнимой части $i\delta$ определяет, заполнено ли состояние с данным p. С учетом спиновой двойки

$$n = 2\int_0^{p_0}\frac{4\pi p^2 dp}{(2\pi)^3} = p_0^3/\left(3\pi^2\right),$$

откуда находим $p_0^3 = 3\pi^2 n$.

ЛШ-8. Ферми частицы на прямой и полупрямой

а) Для невзаимодействующих ферми-частиц на прямой найдите функцию Грина $G_{\alpha\beta}(\varepsilon, x, x')$

б) То же для ферми-частиц на полупрямой $x > 0$ с граничным условием $\psi|_{x=0} = 0$

в) (Осцилляции Фриделя.) В случае полупрямой покажите, что плотность ферми-газа, как функция расстояния до стенки, осциллирует. Чему равен период осцилляций?

Solution 8 a.

Найдем

$$G_{\alpha\beta}(\varepsilon, x, x') = -i\int e^{i\varepsilon\tau}\langle\mathrm{T}\psi_\alpha(x)\psi_\beta^+(x')\rangle d\tau,$$

где $\tau = t - t'$. В импульсном представлении

$$G_{\alpha\beta}(\varepsilon, p) = \frac{\delta_{\alpha\beta}}{\varepsilon - \xi(p) + i\delta\,\mathrm{sign}\,\varepsilon}, \quad \xi(p) = \frac{p^2}{2m} - E_F.$$

Поэтому

$$G_{\alpha\beta}(\varepsilon, x, x') = \int e^{ip(x-x')}G_{\alpha\beta}(\varepsilon, p)\frac{dp}{2\pi} = -2m\delta_{\alpha\beta}\int\frac{e^{ip(x-x')}}{(p - p_1)(p - p_2)}\frac{dp}{2\pi}.$$

Полюсы подинтегрального выражения

$$p_{1,2} = \pm\varkappa,$$

где $\varkappa = \sqrt{2m(\varepsilon + E_F + i\delta\,\mathrm{sign}\,\varepsilon)}$. Если $\varepsilon > 0$, то p_1 лежит в верхней полуплоскости, а p_2 - в нижней, а если $\varepsilon < 0$, то наоборот.

Solution 8 б.

В присутствии стенки функцию Грина $G^{(1)}$ находим с помощью метода изображений:

$$G^{(1)}_{\alpha\beta}(\varepsilon, x, x') = G_{\alpha\beta}(\varepsilon, x, x') - G_{\alpha\beta}(\varepsilon, x, -x'),$$

где G дается (2.75). Обосновать такой ответ можно так же, как и при использовании метода изображений в электростатике. В самом деле, $G^{(1)}_{\alpha\beta}$ удовлетворяет уравнению

$$(\varepsilon - \hat{\mathcal{H}})G^{(1)}_{\alpha\beta}(\varepsilon, x, x') = \delta(x - x')\,\delta_{\alpha\beta}$$

и граничному условию $G^{(1)}_{\alpha\beta}(\varepsilon, 0, x') = 0$, а переход к изображениям обычным образом заменяет граничное условие условием антисимметрии.

Solution 8 в.

Выразим плотность через функцию Грина, найденную в части):

$$n(x) = -i \lim_{\tau \to -0} \mathrm{Tr} \int G^{(1)}_{\alpha\beta}(\varepsilon, x, x) e^{-i\varepsilon\tau} \frac{d\varepsilon}{2\pi},$$

где Tr означает взятие следа. Суммируя по спинам, получаем

$$n(x) = -2i \lim_{\tau \to -0} \int \frac{e^{-i\varepsilon\tau}\left(1 - e^{-2ipx}\right)}{\varepsilon - \xi(p) + i\delta\,\mathrm{sign}\,\xi(p)} \frac{dpd\varepsilon}{(2\pi)^2}.$$

При интегрировании по ε, поскольку $\tau < 0$, замыкаем контур в верхней полуплоскости. Полюс захватывается при $\xi(p) < 0$, т. е. при $p^2/2m < E_F$. Находим

$$n(x) = -2i \int\limits_{p^2 < 2mE_F} \left(1 - e^{-2ipx}\right) \frac{2\pi i}{(2\pi)} dp.$$

Интегрируем по p:

$$n(x) = 2 \int\limits_{-p_0}^{p_0} \left(1 - e^{-2ipx}\right) \frac{dp}{2\pi} = \frac{1}{\pi}\left(2p_0 - \int\limits_{-p_0}^{p_0} e^{-2ipx} dp\right) =$$
$$= \frac{1}{\pi}\left(2p_0 - \frac{\sin 2p_0 x}{x}\right) = n_0\left(1 - \frac{\sin 2p_0 x}{2p_0 x}\right)$$

где n_0 - плотность вдали от стенки. (Коэффициент в (2.81) можно проверить, подсчитав плотность частиц квазиклассически: $n_0 L = 2\,(2p_0 L)\,/2\pi\hbar$.)

Плотность $n(x)$ обращается в нуль на стенке, а вдали осциллирует с периодом $\lambda_0 = \pi\hbar/p_0$

Рис. 2.1

Сравним среднее расстояние между электронами $d = n_0^{-1} = \pi\hbar/2p_0$ с периодом осцилляций λ_0 - они отличаются в два раза. Это отличие связано со спином электронов. Фермиевские коррелящии, приводящие к осцилляциям, имеются только для электронов с одинаковой проекцией спина. Плотность таких электронов есть $n_0/2 = \lambda_0^{-1}$, что как раз соответствует периоду осцилляций.

20.5 Problems of Other Parts

20.5.1 Typical Problems of Relativistic Quantum Mechanics

Б-2.9.1 Коммутирование в релятивистском случае

Выяснить, какие из указанных ниже операторов коммутируют с гамильтонианом свободной релятивистской частицы со спином $s = 1/2$ (и являются интегралами движения):

а) $\hat{\mathrm{p}} = -i\hbar\nabla$

д) $\hat{\mathbf{s}}^2$

б) $\hat{\mathbf{l}} = \frac{1}{\hbar}[\hat{\mathbf{r}} \times \hat{\mathbf{p}}] = -i[\mathbf{r} \times \nabla]$

е) $\hat{\mathrm{j}} = \hat{\mathrm{i}} + \hat{\mathbf{s}}$

в) $\hat{1}^2$;

ж) $\hat{j}^2$;

г) $\hat{\mathbf{s}} = \frac{1}{\hbar}\hat{\mathbf{S}} = \frac{1}{2}\hat{\mathbf{\Sigma}}$

3) $(\hat{\mathbf{\Sigma}}\hat{\mathbf{p}})/p$

и) $\gamma^5 = -i\gamma^0\gamma^1\gamma^2\gamma^3$.

Б-2.9.2 Инвариантность уравнения Дирака

Показать, что уравнение Дирака инвариантно относительно калибровочного преобразования. Как при этом преобразуется волновая функция?

Solution

Б-2.9.3 Простейшее решение уравнения Дирака

Найти решения уравнения Дирака, описывающие свободную частицу, имеющую определенный импульс и энергию. Для конкретизации спинового состояния частицы использовать оператор $(\hat{\mathbf{\Sigma}}\mathbf{p})/p$ (продольной поляризации).

Solution

(!?!?? удивительно, все еще не отработал это!)
2.9.3. Уравнение Дирака для свободной частицы в гамильтоновой форме имеет вид

$$i\hbar\frac{\partial}{\partial t}\Psi = \hat{\mathrm{H}}_D\Psi = \left\{c(\hat{\boldsymbol{\alpha}}\hat{\mathbf{p}}) + \hat{\beta}mc^2\right\}\Psi$$

Для стационарных состояний можно записать $\Psi(\mathbf{r},t) = e^{-\frac{i}{\hbar}Et}\psi(\mathbf{r})$, причем $\psi(r)$ удовлетворяет стационарному уравнению - уравнению на собственные значения гамильтониана Дирака. Кроме того, $\psi(\mathbf{r})$ должна быть собственной функцией оператора импульса, потому что операторы трех компонент импульса $\hat{\mathbf{p}}$ коммутируют с гамильтонианом:

$$\begin{cases}\hat{\mathrm{H}}_D\psi(\mathbf{r}) = E\psi(\mathbf{r}),\\ \hat{\mathbf{p}}\psi(\mathbf{r}) = \mathbf{p}\psi(\mathbf{r}).\end{cases}$$

Условия (2) указывают на то, что решения уравнения (1) следует искать в виде плоских волн

$$\psi(\mathbf{r}) = u(\mathbf{p},E)e^{\frac{i}{\hbar}(\mathbf{pr})},$$

где $u(\mathbf{p},E)$ - не зависящий от координат и времени биспинор. Учитывая (3), перейдем к так называемой «расщепленной» форме записи стационарного уравнения Дирака:

$$\begin{cases}c(\hat{\sigma}\mathbf{p})\chi = \left(E - mc^2\right)\varphi,\\ c(\hat{\sigma}\mathbf{p})\varphi = \left(E + mc^2\right)\chi.\end{cases}$$

Здесь мы использовали формулы, выражающие дираковские матрицы в блочном виде через $\hat{\sigma}$-матрицы Паули (II.52):

$$\hat{\alpha}_i = \begin{pmatrix}0 & \hat{\sigma}_i\\ \hat{\sigma}_i & 0\end{pmatrix},\quad \hat{\beta} = \begin{pmatrix}\mathbb{1} & 0\\ 0 & -\mathbb{1}\end{pmatrix},\quad \hat{\Sigma}_i = \begin{pmatrix}\hat{\sigma}_i & 0\\ 0 & \hat{\sigma}_i\end{pmatrix},$$

а также ввели обозначения

$$u(\mathbf{p},E) = \begin{pmatrix}\varphi(\mathbf{p},E)\\ \chi(\mathbf{p},E)\end{pmatrix};\quad \varphi = \begin{pmatrix}u_1\\ u_2\end{pmatrix},\quad \chi = \begin{pmatrix}u_3\\ u_4\end{pmatrix}$$

- двухкомпонентные функции. Условие совместности системы уравнений (4) имеет вид

$$c^2(\hat{\sigma}\mathbf{p})(\hat{\sigma}\mathbf{p}) = E^2 - m^2c^4.$$

С учетом тождества $\hat{\sigma}_n\hat{\sigma}_m = \delta_{nm}\hat{1} + ie_{nmk}\hat{\sigma}_k$ (задача 2.4.13) из этого соотношения получаем

$$E = \xi E_p \equiv \xi\sqrt{c^2\mathbf{p}^2 + m^2c^4},$$

где $\xi = \pm 1 - 3$ зак энергии. Двум знакам энергии отвечают два типа решений уравнения Дирака, соответствующие различным знакам энергии в экспоненте, т. е. различным типам зависимости функций от времени. Рассмотрим далее так называемый знаковый оператор

$$\hat{\Lambda} = \frac{\hat{\mathrm{H}}_D}{\left(\hat{\mathrm{H}}_D^2\right)^{1/2}} = \frac{c(\hat{\alpha}\mathbf{p}) + \hat{\beta}mc^2}{E_\rho},$$

записанный в общем виде и в импульсном представлении. Очевидно он коммутирует с гамильтонианом $\hat{\mathrm{H}}_D$, и поэтому его собственные значения могут быть использованы для классификации состояний, собственных для $\hat{\mathrm{H}}_D$. Собственные значения оператора $\hat{\Lambda}$ есть $\xi = \pm 1$, причем $\xi = +1$ соответствует положительному ($E > 0$), а $\xi = -1$ - отрицательному знаку энергии ($E < 0$). Для свободного движения энергия E_p, импульс $\mathbf{p}$ и ξ (знак энергии) являются интегралами движения и могут одновременно принимать определенные значения. Далее, из (4) следует, что биспинор $u(\mathbf{p}, E)$ можно представить в виде

$$u(\mathbf{p}, E) = N \begin{pmatrix} \varphi \\ \frac{c(\hat{\sigma}\mathrm{p})}{\xi E_\rho + mc^2}\varphi \end{pmatrix},$$

где N - нормировочный коэффициент, а φ - остающийся пока неопределенным двухкомпонентный спинор, нормируемый условием $\varphi^+\varphi = 1$. Нормировочный коэффициент в (8) легко находится:

$$N = \frac{1}{\sqrt{2}}\sqrt{1 + \xi\frac{mc^2}{E_p}}.$$

Осталось найти функцию φ. Неоднозначность в выборе φ связана с наличием спиновой степени свободы у дираковской частицы, Рассмотрим оператор $(\hat{\Sigma}\mathbf{p})/p$, где $p = |\mathbf{p}|$. Собственные значения этого оператора характеризуют проекцию спина на направление движения, т. е. это оператор продольной поляризации. Оператор продольной поляризации коммутирует с гамильтонианом, следовательно, физическая величина, соответствующая ему, является интегралом движения. Поэтому к уравнениям (2) можно добавить уравнение

$$\frac{(\hat{\mathbf{\Sigma}}\mathbf{p})}{p}\psi(\mathbf{r}) = s\psi(\mathbf{r})$$

где собственное значение $s = \pm 1$ называется спиральностью частицы. Используя (8), а также явный вид матриц $\hat{\Sigma}_i$(5), сводим это уравнение к двухкомпонентному:

$$(\hat{\sigma}\mathrm{p})\varphi = sp\varphi,$$

т. е. к уравнению для паулиевских спиноров с определенным значением проекции спина на направление импульса. Ясно, что уравнение (9) определяет двухкомпонентный спинор, собственный для оператора $(\hat{\sigma}\mathbf{n})$, где $\mathbf{n} = \mathbf{p}/p$. Такие функции были найдены нами в задаче 2.4.19. На этом можно было бы и завершить решение данной задачи, но представ- ляется полезным получить также другой вид решения уравнения (9) с явной зависимостью от спиральности s. Такое решение может быть представлено в виде

$$\varphi_s = \frac{1}{\sqrt{2}}\begin{pmatrix} (1 + sp_z/p)^{1/2} \\ s\,(1 - sp_z/p)^{1/2}\,e^{i\delta} \end{pmatrix}.$$

где $\mathrm{tg}\,\delta = p_y/p_x$. Если ввести сферические координаты вектора $\mathbf{n} = \mathbf{p}/p$, то эти функции перейдут в функции $\Psi_{\pm!}$задачи 2.4.19. Объединяя наши результаты (10) и (8), мы получаем нормированные собственные функции операторов $\hat{\mathrm{H}}_D, \hat{\mathbf{p}}, \hat{\Lambda}$ и $(\hat{\mathbf{\Sigma}}\mathbf{p})/p$:

$$\Psi_{\mathrm{p},\xi,s}(\mathbf{r}, t) = \frac{e^{-\frac{i}{\hbar}(\xi E_p - pr)}}{2\sqrt{V}}\begin{pmatrix} \left(1 + \xi\frac{mc^2}{E_p}\right)^{1/2}\left(1 + s\frac{p_z}{p}\right)^{1/2} \\ s\left(1 + \xi\frac{mc^2}{E_p}\right)^{1/2}\left(1 - s\frac{p_z}{p}\right)^{1/2}e^{i\delta} \\ s\xi\left(1 - \xi\frac{mc^2}{E_p}\right)^{1/2}\left(1 + s\frac{p_z}{p}\right)^{1/2} \\ \xi\left(1 - \xi\frac{mc^2}{E_p}\right)^{1/2}\left(1 - s\frac{p_z}{p}\right)^{1/2}e^{i\delta} \end{pmatrix}.$$

Б-2.9.4 Скорость дираковской частицы (!?!??!?)

а) Найти оператор скорости $\hat{\mathrm{v}}_x$ в теории Дирака в случае свободного движения.
б) Показать, что четная часть этого оператора $[\hat{\mathrm{v}}_x]$ допускает простую классическую интерпретацию.
в) Показать, что его нечетная часть $\{\hat{\mathrm{v}}_x\}$ осциллирует с частотой $\omega = 2E/\hbar$ (Zitterbewegung).

Указание: оператор, описывающий физическую величину $\hat{\mathrm{F}}$, можно записать в виде $\hat{F} = [\hat{F}] + \{\hat{F}\}$, где

$$[\hat{\mathrm{F}}] = \frac{1}{2}(\hat{\mathrm{F}} + \hat{\Lambda}\hat{\mathrm{F}}\hat{\Lambda}), \quad \{\hat{\mathrm{F}}\} = \frac{1}{2}(\hat{\mathrm{F}} - \hat{\Lambda}\hat{\mathrm{F}}\hat{\Lambda}); \quad \hat{\Lambda} = \frac{\hat{\mathrm{H}}}{E}.$$

Solution

2.9.4. Перейдем в гейзенберговское представление и вычислим оператор $d\hat{x}/dt$, представляющий собой, очевидно, x-компоненту оператора скорости:

$$\frac{d\hat{x}}{dt} = \hat{\mathrm{v}}_x = \frac{i}{\hbar}\left[\hat{\mathrm{H}}_D, \hat{x}\right] = \frac{i}{\hbar} c\hat{\alpha}_1 \left[\hat{\mathrm{p}}_x, \hat{x}\right] = c\hat{\alpha}_1.$$

Данный результат не поддается интерпретации в духе принципа соответствия. Во-первых, поскольку собственные значения оператора $\hat{\alpha}_1$ равны ± 1, то оказывается, что собственные значения операторов компонент скорости равны $\pm c$, хотя в действительности скорость может принимать любые значения в промежутке от $-c$ до $+c$. Во-вторых, матрицы $\hat{\alpha}_i$ не коммутируют между собой, что должно приводить к принципиальной невозможности одновременно измерить хотя бы две компоненты скорости.

И, наконец, в теории Дирака происходит так называемое «расщепление» понятий скорости и импульса, т. е. отсутствуют обычные, аналогичные существующим в релятивистской классической механике связи между операторами скорости и импульса. Эти сложности в физической интерпретации оператора скорости, связаны с интерференцией состояний с различными знаками энергии.

В последовательной одночастичной теории физические величины должны описываться операторами, не смешивающими между собой состояния с различными знаками энергии. Такие операторы называются четными (или «одночастичными»). Четный оператор переводит волновую функцию с определенным знаком энергии в функцию с тем же знаком энергии, а нечетный оператор - в функцию с другим знаком энергии:

$$[\hat{\mathrm{F}}]\Psi(\pm) = \widetilde{\Psi}(\pm), \quad \{\hat{\mathrm{F}}\}\Psi(\pm) = \widetilde{\Psi}(\mp).$$

Найдем четную часть оператора скорости:

$$[\hat{\mathrm{v}}_x] = c\,[\hat{\alpha}_1] = \frac{1}{2}\left(\hat{\mathrm{v}}_x + \hat{\Lambda}_x\hat{\mathrm{v}}_x\right) = \frac{c}{2E_\rho}\left\{\hat{\alpha}_1, \hat{\mathrm{H}}_D\right\}\hat{\Lambda} = \frac{c^2 p_x}{E_\rho}\hat{\Lambda}.$$

Отсюда следует, что четная часть оператора скорости для решений с положительной энергией ($\xi = +1$) связана с оператором импульса соотношением, соответствующим связи между скоростью и импульсом в классической релятивистской теории - четная часть оператора скорости допускает простую классическую интерпретацию.

Нечетная часть оператора скорости $\{\hat{\mathrm{v}}_x\} = \frac{1}{2}\left(\hat{\mathrm{v}}_x - \hat{\Lambda}\hat{\mathrm{v}}_x\hat{\Lambda}\right)$ антикоммутирует с гамильтонианом, потому что

$$\frac{\hat{\mathrm{H}}_D}{E_\rho}\{\hat{\mathrm{v}}_x\} = \frac{1}{2}\left(\hat{\Lambda}\hat{\mathrm{v}}_x - \hat{\mathrm{v}}_x\hat{\Lambda}\right) = -\{\hat{\mathrm{v}}_x\}\frac{\hat{\mathrm{H}}_D}{E_\rho}.$$

Отсюда следует, что

$$\frac{d}{dt}\{\hat{\mathrm{v}}_x\} = \frac{i}{\hbar}\left[\hat{\mathrm{H}}_D, \{\hat{\mathrm{v}}_x\}\right] = -\frac{2i}{\hbar}\{\hat{\mathrm{v}}_x\}\hat{\mathrm{H}}_D.$$

Интегрирование этого уравнения с учетом $\partial\hat{\mathrm{H}}_D/\partial t = 0$ дает

$$\{\hat{\mathrm{v}}_x\} = c\{\hat{\alpha}_1\} = c\{\hat{\alpha}_1(0)\}\, e^{-\frac{2i\hat{\mathrm{H}}_D t}{\hbar}}.$$

Таким образом, нечетная часть оператора скорости не имеет классического аналога и характеризуется быстрыми осцилляциями с частотой $\sim 2|E|/\hbar$, вызывая явление Zitterbewegung («дрожащее движение»), которое, по существу, и затрудняет физическую интерпретацию операторов в теории Дирака.

Б-2.9.5 Парадокс Клейна: рождение пары частиц в поле

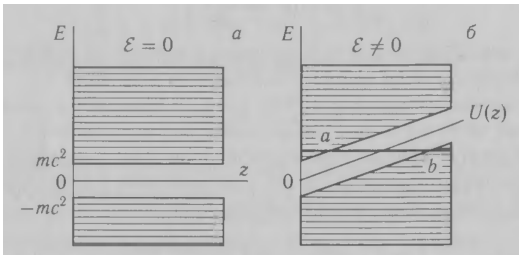
Оценить вероятность рождения пары e^+e^--пары в однородном постоянном электрическом поле в квазиклассическом приближении (парадокс Клейна).

Solution

2.9.5. Система уровней энергии свободного электрона Дирака

$$E = \xi\sqrt{c^2\mathbf{p}^2 + m^2c^4}, \quad \xi = \pm 1$$

представляет собой два континуума состояний для положительных и отрицательных значений энергии, которые разделены энергетической щелью $\Delta E = 2mc^2$ (рис. 2.11, a).



Предположим, что электрон находится в постоянном и однородном электрическом поле, направленном вдоль оси z. Пусть движ ение происходит вдоль поля $\mathcal{E}=\{0,0,\mathcal{E}\}$.

При этом существенно изменяется конфигурация уровней энергии электрона: изменяются границы верхнего $\left(E=mc^2\right)$ и нижнего $\left(E=-mc^2\right)$ континуумов энергии (рис. 2.11, 6).

Новыми границами верхнего и нижнего континуумов состояний станут линии

$$E=\pm mc^2+e\mathcal{E}z,$$

где $U(z)=e\varepsilon z$ - потенциальная энергия электрона в электрическом поле (подразумевается $-e<0$ - заряд электрона). В результате поворота запрещенной энергетической зоны, разделяющей верхний и нижний континуумы, состояния с отрицательной и положительной энергией будут разделены лишь пространственно.

Таким образом, электрон, имеющий определенную энергию E, будет находиться в есостоянии с положительной энергией ($\xi=+1$) при $z\leqslant a$ и в есостоянии с отрицательной энергией ($\xi=-1$) при $z\geqslant b$. Но на самом деле (рис. 2.11) энергия электрона при этом остается одной и той же. Значит, при наличии внешнего электрического поля (или любого другого потенциала) не может быть строгого разделения состояний на состояния с положительной и отрицательной энергией. Более того, возможен туннельный переход через запрещенную зону из верхнего континуума в нижний (или наоборот). Этот эффект и представляет собой парадокс Клейна.

Оценим вероятность туннельного перехода из верхнего континуума в нижний, используя квазиклассическое приближение (II.38):

$$D\simeq\exp\left\{-\frac{2}{\hbar}\int\limits_a^b|p(z)|dz\right\}.$$

где $|p(z)|=\frac{1}{c}\sqrt{m^2c^4-(E-e\mathcal{E}z)^2}$. Вычисляем интеграл и получаем, что

$$D\simeq\exp\left\{-\pi\frac{m^2c^3}{e\hbar\mathcal{E}}\right\}.$$

Очевидно, что такой же вид должна иметь и вероятность обратного туннельного перехода - из нижнего континуума в верхний.

Итак, наложение электрического поля не приводит к локализации дираковской частицы - она может оказаться в состоянии с противоположным знаком энергии в результате туннельного перехода, причем вероятность такого перехода растет с ростом поля и стремится к единице в том случае, если напряженность поля равна

$$\mathcal{E}=\mathcal{E}_{\text{кр}}=\frac{m^2c^3}{e\hbar}=1,3\cdot10^{16}\text{ В/см}$$

- так называемому швингеровскому значению. В соответствии с дырочной интерпретацией Дирака при переходе электрона из нижнего континуума состояний в верхний появляется пара частиц: электрон в верхнем континууме с энергией $E>0$ и едырка в нижнем континууме (среди состояний с $E<0$). Эта едырка» интерпретируется, как античастица по отношению к электрону, т.е. позитрон. Следовательно, мы описали процесс рождения электрон-позитронной пары.

Б-2.9.6 нерелятивистский предел уравнения Дирака

Показать, что в нерелятивистском пределе уравнение Дирака переходит в уравнение Паули.
(мб удалю и просто в теории будет это, чисто типичная теория)

Solution

2.9.6. Уравнение Дирака, описывающее движение заряженной частицы во внешнем электромагнитном поле, имеет вид

$$i\hbar\frac{\partial}{\partial t}\Psi(\mathbf{r},t)=\left(c(\hat{\alpha}\hat{\mathcal{P}})+\hat{\beta}mc^2-e\phi\right)\Psi(\mathbf{r},t).$$

где $\hat{\mathcal{P}} = \hat{\mathbf{p}} + \frac{e}{c}\mathbf{A}$, $-e < 0$ - заряд электрона. Считаем состояние $\Psi(\mathbf{r}, t)$ стационарным: $\Psi(\mathbf{r}, t) = e^{-\frac{i}{\hbar}Et}\psi(\mathbf{r})$. В дальнейшем будем полагать $E > 0$, т. е. мы фиксируем знак энергии (считаем энергию положительной, ибо в нерелятивистской квантовой механике имеются только состояния с положительной энергией). Представим далее, как и обычно, волновую функцию в виде $\psi(\mathbf{r}) = \begin{pmatrix} \varphi(\mathbf{r}) \\ \chi(\mathbf{r}) \end{pmatrix}$ и запишем (1) в «расщепленномь виде:

$$\begin{cases} \left(E - mc^2 + e\phi\right)\varphi = c(\hat{\sigma}\hat{\mathcal{P}})\chi. \\ \left(E + mc^2 + e\phi\right)\chi = c(\hat{\sigma}\hat{\mathcal{P}})\varphi. \end{cases}$$

Исследуем эту систему в нерелятивистском пределе и в слабых полях, т. е.

$$E \simeq mc^2 + \varepsilon, \quad |\varepsilon + e\phi| \ll mc^2.$$

В этом случае (2) перейдет в

$$\begin{cases} (\varepsilon + e\phi)\varphi(\mathbf{r}) = c(\hat{\boldsymbol{\sigma}}\hat{\mathcal{P}})\chi(\mathbf{r}) \\ \left(\varepsilon + e\phi + 2mc^2\right)\chi(\mathbf{r}) = c(\hat{\boldsymbol{\sigma}}\hat{\mathcal{P}})\varphi(\mathbf{r}) \end{cases}$$

Из второго уравнения с учетом (3) находим

$$\gamma(\mathbf{r}) \simeq \frac{(\hat{\sigma}\hat{\mathcal{P}})}{2mc}\varphi(\mathbf{r}),$$

откуда видно, что в нерелятивистском приближении двухкомпонентный спинор $\chi(\mathbf{r})$ имеет по отношению к $\varphi(\mathbf{r})$ порядок малости $(v/c) \ll 1$. Это и позволяет (в случае положительной энергии $E > 0$) говорить о двух нижних компонентах дираковского спинора как о малых.

Подставим (4) в первое уравнение системы и получим с линейной точностью по (v/c) уравнение для двухкомпонентного спинора $\varphi(\mathbf{r})$:

$$(\varepsilon + e\phi)\varphi(\mathbf{r}) = \frac{1}{2m}(\hat{\sigma}\hat{\mathcal{P}})(\hat{\boldsymbol{\sigma}}\hat{\mathcal{P}})\varphi(\mathbf{r}).$$

Преобразуя правую часть данного уравнения, находим

$$\begin{aligned}(\hat{\sigma}\hat{\mathcal{P}})(\hat{\sigma}\hat{\mathcal{P}}) = \hat{\mathcal{P}}_i\hat{\mathcal{P}}_i\left(\delta_{ij} + ie_{ijk}\hat{\sigma}_k\right) =& \hat{\mathcal{P}}^2 + i\frac{e}{c}\hat{\sigma}_k e_{ijk}\left(\hat{p}_i\ \mathrm{A}_i + \mathrm{A}_i\hat{\mathrm{p}}_j\right) = \\ &= \hat{\mathcal{P}}^2 + i\frac{e}{c}\hat{\sigma}_k e_{i/k}\left[\hat{p}_i,\ \mathrm{A}_j\right] = \hat{\mathcal{P}}^2 + \frac{e\hbar}{c}(\hat{\sigma}\mathcal{H}),\end{aligned}$$

где $\mathcal{H} = \operatorname{rot}\mathbf{A}$. В результате получаем нерелятивистское уравнение, описывающее движение частицы со спином $1/2$ в электромагнитном поле:

$$\left(\frac{\hat{\mathcal{P}}^2}{2m} + \frac{eh}{2mc}(\hat{\sigma}\mathcal{H}) - e\phi\right)\varphi(\mathbf{r}) = \varepsilon\varphi(\mathbf{r}).$$

Это и есть уравнение Паули, а $\varphi(\mathbf{r})$ - паулиевский двухкомпонентный спинор.

Б-2.9.7

Найти релятивистские поправки порядка $(v/c)^2$ к нерелятивистскому гамильтониану атома водорода с помощью разложения гамильтониана Дирака, описывающего состояния в кулоновском поле ядра, по степеням v/c. Провести классификацию полученных поправок.

Solution

2.9.7. В уравнении Дирака для электрона во внешнем электромагнитном поле

$$ih\frac{\partial}{\partial t}\Psi(\mathbf{r}, t) = \left(c(\hat{\alpha}\hat{\mathcal{P}}) + \hat{\beta}mc^2 - e\phi\right)\Psi(\mathbf{r}, t)$$

положим

$$U(r) = -e\phi(r) = -\frac{Ze^2}{r}, \quad \mathbf{A} = 0,$$

т. е. будем считать, что внешнее поле - чисто кулоновское, при этом, очевидно, $\hat{\mathcal{P}} = \hat{\mathbf{p}} + \frac{e}{c}\mathbf{A} \to \hat{\mathbf{p}}$, и, как и ранее, $-e < 0$ - заряд электрона.

Полагаем, что задача - стационарная: $\Psi(\mathbf{r}, t) = e^{-\frac{i}{\hbar}Et}\psi(\mathbf{r})$, фиксируем знак энергии $E > 0$. Переходим к «расщепленной форме записи уравнения Дирака:

$$\psi(\mathbf{r}) = \begin{pmatrix} \varphi(\mathbf{r}) \\ \chi(\mathbf{r}) \end{pmatrix}; \begin{cases} \left(E - mc^2 + e\phi\right)\varphi = c(\hat{\sigma}\hat{\mathbf{p}})\chi, \\ \left(E + mc^2 + e\phi\right)\chi = c(\hat{\boldsymbol{\sigma}}\hat{\mathbf{p}})\varphi. \end{cases}$$

Из второго уравнения системы (1) выражаем $\chi(\mathbf{r})$:

$$\chi(\mathbf{r}) = \frac{1}{E + mc^2 + e\phi} c(\hat{\sigma}\hat{\mathbf{p}})\varphi(\mathbf{r})\Big|_{\frac{e}{c}\to 0} \simeq \frac{(\hat{\sigma}\hat{\mathbf{p}})}{2mc^2}\varphi(\mathbf{r}).$$

т. е. в нерелятивистском приближении функция $\chi(\mathbf{r})$ имеет по отношению к $\varphi(\mathbf{r})$ порядок малости $(v/c) \ll 1$. Подставляем результат (2) в первое уравнение (1) и получим (пока еще точное) уравнение для $\varphi(\mathbf{r})$:

$$\left(E - mc^2 + e\phi\right)\varphi(\mathbf{r}) = c^2(\hat{\sigma}\hat{\mathbf{p}})\frac{1}{E + mc^2 + e\phi}(\hat{\sigma}\hat{\mathbf{p}})\varphi(\mathbf{r}).$$

Переходим к нерелятивистскому приближению:

$$E \simeq mc^2 + \varepsilon, \quad |\varepsilon + e\phi| \ll mc^2.$$

и в дальнейшем при разложениях будем ограничиваться членами порядка $(v/c)^2$. Поэтому

$$\left(E + mc^2 + e\phi\right)^{-1} = \left(2mc^2 + \varepsilon + e\phi\right)^{-1} \simeq \frac{1}{2mc^2}\left(1 - \frac{\varepsilon + e\phi}{2mc^2}\right).$$

При этом уравнение (3) принимает вид

$$\left(\varepsilon + e\phi - \frac{\hat{\mathbf{p}}^2}{2m}\right)\varphi(\mathbf{r}) = -(\hat{\sigma}\hat{\mathbf{p}})\frac{\varepsilon + e\phi}{4m^2c^2}(\hat{\sigma}\hat{\mathbf{p}})\varphi(\mathbf{r}).$$

В правой части уравнения (4) преобразуем слагаемое

$$\begin{aligned} -(\hat{\sigma}\hat{\mathbf{p}})e\phi(\hat{\sigma}\hat{\mathbf{p}}) = (\hat{\sigma}\hat{\mathbf{p}})U(r)(\hat{\sigma}\hat{\mathbf{p}}) = U(r)\hat{\mathbf{p}}^2 + [(\hat{\sigma}\hat{\mathbf{p}}), U(r)](\hat{\sigma}\hat{\mathbf{p}}) = \\ = U(r)\hat{\mathbf{p}}^2 + \left(\delta_{ij} + ie_{ijk}\hat{\sigma}_k\right)\left(-i\hbar\nabla_i U(r)\right)\hat{\mathrm{p}}_i = \\ = U(r)\hat{\mathbf{p}}^2 - ih((\nabla U(r))\hat{\mathbf{p}}) + \hbar^2\frac{dU(r)}{dr}\frac{1}{r}(\hat{\boldsymbol{q}}\hat{l}). \end{aligned}$$

Здесь $\hat{\mathbf{l}} = \frac{1}{\hbar}[\hat{\mathbf{r}} \times \hat{\mathbf{p}}]$ - орбитальный момент. Уравнение (4) при этом перейдет в

$$\begin{aligned} \left(\varepsilon + e\phi - \frac{\hat{\mathbf{p}}^2}{2m}\right)\varphi(\mathbf{r}) = \\ = \left\{-\frac{\varepsilon + e\phi}{4m^2c^2}\hat{\mathbf{p}}^2 + \frac{\hbar}{4m^2c^2}\left[-i((\nabla U(r))\hat{\mathbf{p}}) + \hbar\frac{dU(r)}{dr}\frac{(\sigma\mathrm{i})}{r}\right]\right\}\varphi(\mathbf{r}). \end{aligned}$$

Далее, в правой части (6) преобразуем первое слагаемое:

$$\begin{aligned} (\varepsilon + e\phi)\hat{\mathbf{p}}^2 = \hat{\mathbf{p}}^2(\varepsilon + e\phi) + \left[(\varepsilon + e\phi), \hat{\mathbf{p}}^2\right] \simeq \frac{\hat{\mathbf{p}}^4}{2m} - \hat{\mathbf{p}}|U(r), \hat{\mathbf{p}}| - |U(r), \hat{\mathbf{p}}|\hat{\mathbf{p}} = \\ = \frac{\hat{\mathbf{p}}^4}{2m} - \hbar^2\left(\nabla^2 U(r)\right) - 2i\hbar((\nabla U(r))\hat{\mathbf{p}}). \end{aligned}$$

Здесь мы учли, что на решениях уравнения в рассматриваемом приближении $(\varepsilon + e\phi)\varphi(\mathbf{r}) \simeq \frac{\hat{\mathbf{p}}^2}{2m}\varphi(\mathbf{r})$, а также использовали правило дифференцирования произведения функций.

Теперь вспомним общий вид нашей (четырехкомпонентной) волновой функции (1) с учетом (2). Запишем условие нормировки функции $\psi(\mathbf{r})$ с точностью до $(v/c)^2$:

$$\mathrm{I} = \int \psi^+(\mathbf{r})\psi(\mathbf{r})d^3x \simeq \int d^3x\left\{\varphi^+(\mathbf{r})\varphi(\mathbf{r}) + \frac{\hbar^2}{4m^2c^2}((\hat{\boldsymbol{\sigma}}\nabla)\varphi(\mathbf{r}))^+((\hat{\boldsymbol{\sigma}}\nabla)\varphi(\mathbf{r}))\right\}.$$

Здесь мы использовали вид оператора импульса: $\hat{\mathbf{p}} = -i\hbar\boldsymbol{\nabla}$. Заметим, что мы хотим получить приближенное уравнение для двухкомпонентной паулиевской (нерелятивистской) функции, которую в дальнейшем будем обозначать $\psi^{\Pi}(\mathbf{r})$. Две компоненты такой функции должны, как всегда, описывать две возможные ориентации спина, и условие нормировки для $\psi^{\Pi}(\mathbf{r})$ должно иметь традиционный вид:

$$1 = \int \psi^{\Pi+}(\mathbf{r})\psi^{\Pi}(\mathbf{r})d^3x.$$

Наше приближенное уравнение (6) пока записано для двухкомпонентной функцин $\varphi(\mathbf{r})$ (верхние компоненты биспинора $\psi(\mathbf{r})$), но функция $\varphi(\mathbf{r})$ имеет существенно иное условие нормировки, следующее из (8).

В связи с этим в условии нормировки (8) проинтегрируем по частям второе слагаемое:

$$\int d^3x((\hat{\sigma}\nabla)\varphi)^+((\hat{\sigma}\nabla)\varphi) = -\int d^3x\varphi^+(\Delta\varphi) = -\int d^3x\left(\Delta\varphi^+\right)\varphi.$$

Симметризуя эти два варианта, из условия (8) мы получим

$$1 = \int d^3x\left\{\varphi^+\varphi - \frac{\hbar^2}{8m^2c^2}\left[\left(\Delta\varphi^+\right)\varphi + \varphi^+(\Delta\varphi)\right]\right\}.$$

Для согласования нормировочных условий (9) и (10) с точностью до $(v/c)^2$ положим

$$\psi^{\Pi}(\mathbf{r}) = \left(1 + \frac{\hat{\mathbf{p}}^2}{8m^2c^2}\right)\varphi(\mathbf{r}), \quad \text{или } \varphi(\mathbf{r}) = \left(1 - \frac{\hat{\mathbf{p}}^2}{8m^2c^2}\right)\psi^{\Pi}(\mathbf{r}),$$

где мы учли, что $\hat{\mathbf{p}}^2 = -\hbar^2\Delta$. Это есть не что иное, как каноническое преобразование волновой функции, ибо оно сохраняет значение нормировочного интеграла, т. е. вероятность.

Теперь подставим в уравнение (6) соотношение (7), а также функцию $\varphi(\mathbf{r})$, выраженную через $\psi^{\Pi}(\mathbf{r})$. В итоге получим окончательный вид приближенного уравнения:

$$\left(\varepsilon + e\phi - \frac{\hat{\mathbf{p}}^2}{2m}\right)\psi^{\Pi}(\mathbf{r}) = \hat{\mathrm{V}}\psi^{\Pi}(\mathbf{r})$$

$$\hat{\mathrm{V}} = -\frac{\hat{\mathbf{p}}^4}{8m^3c^2} + \frac{\hbar^2}{2m^2c^2}\frac{dU}{dr}\frac{(\hat{\mathbf{s}}\hat{i})}{r} + \frac{1}{8}\left(\frac{\hbar}{mc}\right)^2\left(\nabla^2 U\right).$$

В правой части полученного уравнения сгруппированы поправки к движению электрона в кулоновском поле. В порядке следования это: релятивистская поправка, спин-орбитальное взаимодействие и контактное взаимодействие.

Б-2.9.8

Найти энергетический спектр заряженной дираковской частицы в однородном магнитном поле.

Solution

2.9.8. Пусть магнитное поле направлено по оси $z : \mathcal{H} = \{0, 0, \mathcal{H}\}$. Выберем вектор-потенциал так же, как в нерелятивистском случае в задаче 2.5.1, т. е. $\mathbf{A} = \{0, \mathcal{H}x, 0\}$. Тогда стационарное уравнение Дирака будет иметь вид $\hat{\mathrm{H}}_D\psi(\mathbf{r}) = E\psi(\mathbf{r})$, причем

$$\hat{\mathrm{H}}_D = c(\hat{\boldsymbol{\alpha}}\hat{\mathcal{P}}) + \hat{\beta}mc^2, \quad \hat{\mathcal{P}} = \hat{\mathbf{p}} + \frac{e}{c}\mathbf{A}, \quad -e < 0$$

- заряд электрона. Перейдем к «расщепленной» форме записи уравнения Дирака:

$$\psi(\mathbf{r}) = \begin{pmatrix} \varphi(\mathbf{r}) \\ \chi(\mathbf{r}) \end{pmatrix}; \begin{cases} c(\hat{\boldsymbol{\sigma}}\hat{\mathcal{P}})\chi = \left(E - mc^2\right)\varphi, \\ c(\hat{\boldsymbol{\sigma}}\hat{\mathcal{P}})\varphi = \left(E + mc^2\right)\chi. \end{cases}$$

Выразим из второго уравнения системы (1) $\chi(\mathbf{r})$ через $\varphi(\mathbf{r})$ и подставим результат в первое уравнение:

$$\left(E^2 - m^2c^4\right)\varphi(\mathbf{r}) = c^2(\hat{\boldsymbol{\sigma}}\hat{\mathcal{P}})(\hat{\boldsymbol{\sigma}}\hat{\mathcal{P}})\varphi(\mathbf{r}).$$

Используем тождество (задача 2.9.6) $(\hat{\sigma}\hat{\mathcal{P}})(\hat{\sigma}\hat{\mathcal{P}}) = \hat{\mathcal{P}}^2 + \frac{e\hbar}{c}(\hat{\sigma}\mathcal{H})$, и тогда уравнение (2) примет вид

$$\left\{\hat{\mathrm{p}}_x^2 + \left(\hat{\mathrm{p}}_y + \frac{e}{c}\mathcal{H}x\right)^2 + \hat{\mathrm{p}}_z^2 + \frac{e\hbar}{c}\mathcal{H}\hat{\sigma}_z\right\}\varphi(\mathbf{r}) = \frac{E^2 - m^2c^4}{c^2}\varphi(\mathbf{r}).$$

Полученное уравнение формально имеет вид уравнения Шредингера $\hat{\mathrm{H}}_{\text{eff}}\varphi(\mathbf{r}) = E_{\text{eff}}\,\varphi(\mathbf{r})$, причем легко заметить, что $\hat{\mathrm{H}}_{\text{eff}}$ коммутирует с операторами $\hat{\mathrm{p}}_y$ и $\hat{\mathrm{p}}_z$. Это значит, что можно искать решение уравнения (3) в виде

$$\varphi(\mathbf{r}) = Ce^{\frac{i}{\hbar}(p_y y + p_z z)}f(x).$$

Далее положим $f(x) = \begin{pmatrix} f_1(x) \\ f_2(x) \end{pmatrix}$ и приведем уравнение (3) к следующему виду:

$$\left\{\frac{\hat{p}_x^2}{2m} + \frac{m}{2}\left(\frac{e\mathcal{H}}{mc}\right)^2\left(x + \frac{cp_y}{e\mathcal{H}}\right)^2\right\}f_{1,2}(x) = \frac{1}{2mc^2}\left[E^2 - m^2c^4 \mp e\hbar c\mathcal{H} - c^2p_z^2\right]f_{1,2}(x).$$

Уравнение (5) есть не что иное, как нерелятивистское уравнение для осциллятора $\hat{\mathrm{H}}'_{\text{eff}}f_{1,2}(x) = E'_{\text{eff}}\,f_{1,2}(x)$, причем

$$\hat{\mathrm{H}}'_{\text{eff}} = \frac{\hat{\mathrm{p}}_x^2}{2m} + \frac{m}{2}\Omega^2x'^2, \quad x' = x + \frac{cp_y}{e\mathcal{H}}, \quad \Omega = \frac{e\mathscr{H}}{mc}, \quad \frac{d^2}{dx^2} = \frac{d^2}{dx'^2}.$$

Ясно, что должно выполняться $E'_{\text{eff}} = \hbar\Omega\,(n' + 1/2)$ и на основании этого получаем

$$E^2 - m^2c^4 - c^2p_z^2 = e\hbar c\mathcal{H}\,(2n' + 1 \pm 1)\,.$$

Очевидно, что $2n' + 1 \pm 1$ - всегда четное число. Обозначим его $2n$ и получим окончательный результат:

$$E_{np_z} = \sqrt{m^2c^4 + c^2p_z^2 + 2e\hbar c\mathcal{H}n}.$$

Поскольку в соотношении $2n' + 1 \pm 1 = 2n$ знак $\pm$ относится к компонентам $f_{1,2}(x)$ функции $f(x)$, то ясно, что общий вид функции $\varphi(\mathbf{r})$ (формула (4)) должен быть таким:

$$\varphi_{\pi p_y p_z}(\mathbf{r}) = \exp\left[\frac{i}{\hbar}\,(p_y y + p_z z)\right]\begin{pmatrix} C_1 u_{n-1}^{\text{oclu}}\,(x') \\ C_2 u_n^{\text{ocll}}\,(x') \end{pmatrix}.$$

где $u_n^{\text{ocu}}\,(x)$ есть обычное решение уравнения Шредингера для гармонического осциллятора (II.18). Коэффициенты $C_{1,2}$ можно определить, если конкретизировать спиновое состояние частицы, для этого нужен еще один оператор - спиновый интеграл движения.

Найденные нами уровни энергии (6) не являются эквидистантными в отличие от уровней Ландау (задача 2.5.1). Уровни энергии вырождены по спину с кратностью 2 (кроме основного состояния $n = 0$) и по p_y - с бесконечной кратностью.

Б-2.9.9

Найти в нерелятивистском пределе выражение для плотности заряда и тока заряженной дираковской частицы, находящейся во внешнем электромагнитном поле.

Solution

Б-2.9.10

Показать, что преобразование зарядового сопряжения позволяет интерпретировать решения уравнения Дирака с отрицательными значениями энергии как волновые функции античастиц.

Solution

2.9.11. Мы полагаем, что нейтрино - нейтральные массивные дираковские частицы. Кроме того, мы считаем, что нейтрино определенного типа (например, электронное или мюонное), или, как принято говорить, определенного аромата, не являются состояниями с определенной массой, а представляют собой суперпозицию таких состояний:

$$\begin{cases} |\nu_e\rangle = |\nu_1\rangle\cos\theta + |\nu_2\rangle\sin\theta, \\ |\nu_\mu\rangle = -|\nu_1\rangle\sin\theta + |\nu_2\rangle\cos\theta. \end{cases}$$

Состояния $|\nu_{1,2}\rangle$ в (1) удовлетворяют уравнениям Дирака соответственно с массами m_1 и m_2, а θ - угол смешивания нейтрино. Эволюция во времени состояний $|\nu_1\rangle$ и $|\nu_2\rangle$ дается выражением

$$|\nu_1(t)\rangle = e^{-\frac{i}{\hbar}E_1 t}|\nu_1(0)\rangle; \quad |\nu_2(t)\rangle = e^{-\frac{i}{\hbar}E_2 t}|\nu_2(0)\rangle.$$

где $E_{1,2} = \sqrt{\mathbf{p}^2c^2 + m_{1,2}^2c^4}$. Если в момент $t = 0$ рождается электронное нейтрино, то его состояние эволюционирует во времени следующим образом:

$$\begin{aligned}|\nu_e(t)\rangle &= \cos\theta e^{-\frac{i}{\hbar}E_1 t}|\nu_1(0)\rangle + \sin\theta e^{-\frac{i}{\hbar}E_2 t}|\nu_2(0)\rangle = \\ &= \left(e^{-\frac{i}{\hbar}E_1 t}\cos^2\theta + e^{-\frac{i}{\hbar}E_2 t}\sin^2\theta\right)|\nu_e(0)\rangle + \\ &+ \cos\theta\sin\theta\left(e^{-\frac{i}{\hbar}E_2 t} - e^{-\frac{i}{\hbar}E_1 t}\right)|\nu_\mu(0)\rangle.\end{aligned}$$

Вероятность того, что нейтрино, родившись в момент $t = 0$, как электронное, перейдет в момент t в состояние $|\nu_\mu\rangle$, имеет вид

$$P(\nu_e \to \nu_\mu) = |\langle\nu_\mu|\nu_e(t)\rangle|^2 = \frac{1}{2}\sin^2 2\theta\left[1 - \cos\frac{\left(m_2^2 - m_1^2\right)c^3}{2p\hbar}t\right].$$

Здесь мы предположили, что $p \gg m_{1,2}c$. Вероятность появления нейтрино нового сорта периодически зависит от времени, поэтому яанное явление и носит название осцилляций.

Описание столкновения двух электронов с помощью уравнения Дирака (??)

(??? завис вопрос, хз, что сделать, как решат такое? пока супер слабая теория для этого.)

Б-2.9.11 осцилляции нейтрино (??)

Предполагая, что состояния электронного и мюонного нейтрино представляют собой суперпозиции состояний нейтрино $|\nu_1\rangle$ и $|\nu_2\rangle$ с определенными массами m_1 и m_2:

$$\begin{cases} |\nu_e\rangle = |\nu_1\rangle\cos\theta + |\nu_2\rangle\sin\theta, \\ |\nu_\mu\rangle = -|\nu_1\rangle\sin\theta + |\nu_2\rangle\cos\theta, \end{cases}$$

найти вероятность перехода нейтрино в состояние $|\nu_\mu\rangle$ к моменту времени t, если при $t = 0$ оно было электронным (осцилляции нейтрино).

(в 1ю часть продублирую мб)

20.5.2 Problems about the Heisenberg Formalism (??)

(пока не знаю отдельные такие, пусть повесит раздел, мб удалю.)

20.6 Problems on the Foundations of Quantum Information Theory

(тут прорешаю еще раз Филиппова, если что на сайте кафедры многие его задачи, так что в них разберусь. подробнее - в записи по квантовой теории информации. не такое тривиальное тут!)

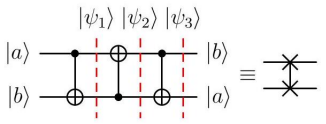
(see note on quantum information about it for now)

20.6.1 Problems on basic quantum gates

KUL-2023-10.1.1 Quantum circuits

Consider the CNOT gate 
where $\oplus$ is the addition modulo 2. Show that the SWAP gate 
is indeed swapping the state of the two qubits, i.e. $|a, b\rangle \to |b, a\rangle$.

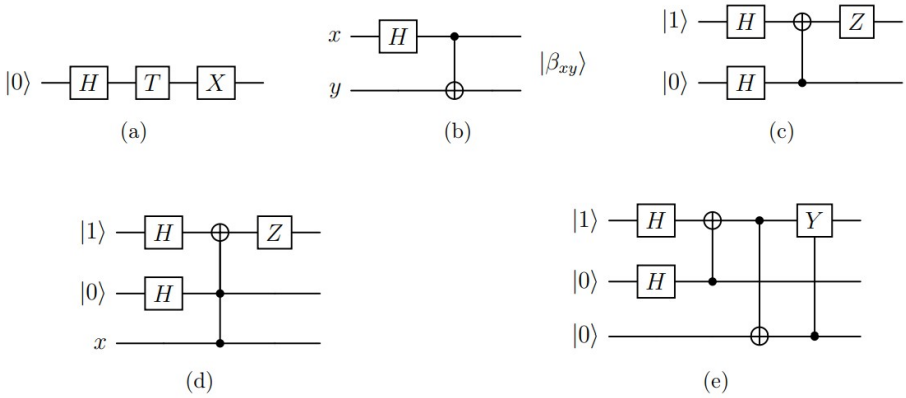
Solution



$$|\psi_1\rangle = |a, a \oplus b\rangle$$
$$|\psi_2\rangle = |a \oplus (a \oplus b), a \oplus b\rangle = |b, a \oplus b\rangle$$
$$|\psi_3\rangle = |b, b \oplus (a \oplus b)\rangle = |b, a\rangle$$

KUL-2023-10.1.2

What are the output states of the following circuits?



Solutions

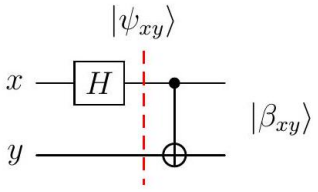
The solutions is generally more easily obtained using the ket representation than the matrix representation (especially for more than 1 qubit). We can then use, for example, that $\hat{H}|0\rangle = \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle)$ and $\hat{H}|1\rangle = \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle)$.

Let's denote the output state as $|\alpha\rangle$.

Solutions to (a)

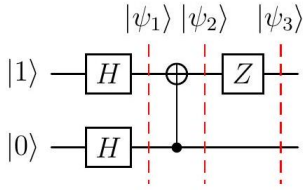
$|\alpha\rangle = \hat{X}\hat{T}\hat{H}|0\rangle = \frac{1}{\sqrt{2}}\left(e^{i\pi/4}|0\rangle + |1\rangle\right)$.

Solutions to (b)



x	y	$\lvert\psi_{xy}\rangle$	$\lvert\beta_{xy}\rangle$
0	0	$\frac{1}{\sqrt{2}}(\lvert00\rangle + \lvert10\rangle)$	$\frac{1}{\sqrt{2}}(\lvert00\rangle + \lvert11\rangle)$
0	1	$\frac{1}{\sqrt{2}}(\lvert01\rangle + \lvert11\rangle)$	$\frac{1}{\sqrt{2}}(\lvert01\rangle + \lvert10\rangle)$
1	0	$\frac{1}{\sqrt{2}}(\lvert00\rangle - \lvert10\rangle)$	$\frac{1}{\sqrt{2}}(\lvert00\rangle - \lvert11\rangle)$
1	1	$\frac{1}{\sqrt{2}}(\lvert01\rangle - \lvert11\rangle)$	$\frac{1}{\sqrt{2}}(\lvert01\rangle - \lvert10\rangle)$

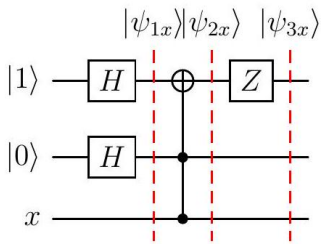
Solutions to (c)



$$|\psi_1\rangle = \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle) \otimes \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle) =$$
$$= \frac{1}{2}(|00\rangle + |01\rangle - |10\rangle - |11\rangle)$$
$$|\psi_2\rangle = \frac{1}{2}(|00\rangle + |11\rangle - |10\rangle - |01\rangle)$$
$$|\psi_3\rangle = \frac{1}{2}(|00\rangle + |11\rangle - |10\rangle - |01\rangle)$$

Solutions to (d)

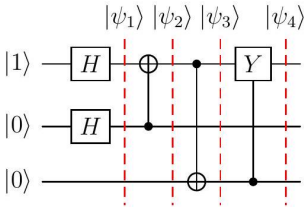
The controlled-NOT with two control qubits (Toffoli gate) applies the NOT if the two control qubits are 1.



$$|\psi_{1x}\rangle = \frac{1}{2}(|00\rangle + |01\rangle - |10\rangle - |11\rangle) \otimes |x\rangle =$$
$$= \frac{1}{2}(|00x\rangle + |01x\rangle - |10x\rangle - |11x\rangle)$$
$$|\psi_{2,x=0}\rangle = \frac{1}{2}(|000\rangle + |010\rangle - |100\rangle - |110\rangle) = |\psi_{1,x=0}\rangle$$
$$|\psi_{2,x=1}\rangle = \frac{1}{2}(|001\rangle + |111\rangle - |101\rangle - |011\rangle)$$
$$|\psi_{3,x=0}\rangle = \frac{1}{2}(|000\rangle + |010\rangle + |100\rangle + |110\rangle)$$
$$|\psi_{3,x=1}\rangle = \frac{1}{2}(|001\rangle - |111\rangle + |101\rangle - |011\rangle)$$

Solutions to (e)

The last gate of the circuit is a controlled- Y gate, i.e. the Y gate is applied only if the control qubit is 1.



$$|\psi_1\rangle = \frac{1}{2}(|000\rangle + |010\rangle - |100\rangle - |110\rangle)$$
$$|\psi_2\rangle = \frac{1}{2}(|000\rangle + |110\rangle - |100\rangle - |010\rangle)$$
$$|\psi_3\rangle = \frac{1}{2}(|000\rangle + |111\rangle - |101\rangle - |010\rangle)$$
$$|\psi_4\rangle = \frac{1}{2}(|000\rangle - i|011\rangle + i|001\rangle - |010\rangle)$$

KUL-2023-10.1.3

Show that if $A^2 = I$ then $\exp(iAx) = \cos(x)I + i\sin(x)A$. Use this result to express the rotation matrix $R_J(\theta) = \exp(-iJ\theta/2)$ with $J = X, Y, Z$ and check that $T = R_z(\pi/4)$ up to a global phase.

Solution

If $A^2 = I$, then we can transform separately contributions from even and odd exponents in the Taylor expansion, since $A^{2n} = I$ and $A^{2n+1} = A$:

$$e^{iAx} = \sum_n \frac{(iAx)^n}{n!} = \sum_n \frac{(ix)^{2n}}{(2n)!} I + \sum_n \frac{(ix)^{2n+1}}{(2n+1)!} A = I \sum_n \frac{(-1)^n (x)^{2n}}{(2n)!} + iA \sum_n \frac{(-1)^n (x)^{2n+1}}{(2n+1)!} = I\cos(x) + iA\sin(x)$$

We can then easily see that $X^2 = I, Y^2 = I$ and $Z^2 = I$, so we have

$$R_z(\theta) = e^{-iZ\theta/2} = \cos\left(\frac{\theta}{2}\right) I - i \sin\left(\frac{\theta}{2}\right) Z = \begin{bmatrix} \cos\left(\frac{\theta}{2}\right) - i\sin\left(\frac{\theta}{2}\right) & 0 \\ 0 & \cos\left(\frac{\theta}{2}\right) + i\sin\left(\frac{\theta}{2}\right) \end{bmatrix} = \begin{bmatrix} e^{-i\theta/2} & 0 \\ 0 & e^{i\theta/2} \end{bmatrix}$$

We can then apply a rotation of $\pi/4$ to obtain

$$R_z(\pi/4) = \begin{bmatrix} e^{-i\pi/8} & 0 \\ 0 & e^{i\pi/8} \end{bmatrix} = e^{-i\pi/8} \begin{bmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{bmatrix} = e^{-i\pi/8} T$$

KUL-2023-10.2 Quantum Fourier Transform (???)

For a given vector of N complex numbers x_i, the discrete Fourier transform outputs a new vector of N complex numbers $y_k \equiv \frac{1}{\sqrt{N}} \sum_{j=0}^{N-1} x_j e^{i2\pi jk/N}$.

The quantum Fourier transform is defined in a similar way. The quantum Fourier transform in an orthonormal basis $|0\rangle, |1\rangle, ..., |N-1\rangle$ is the linear operator such that, for a basis vector,

$$|j\rangle \longrightarrow \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} e^{i2\pi jk/N} |k\rangle$$

and for an arbitrary state, we can write

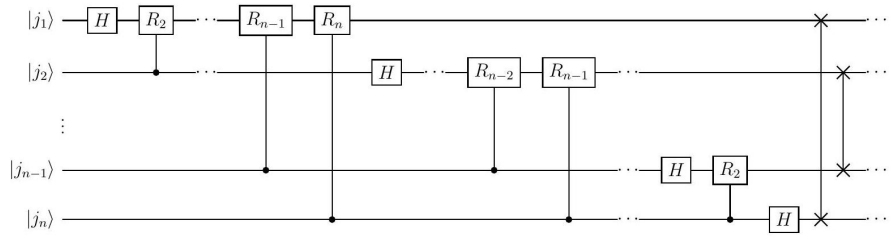
$$\sum_{j=0}^{N-1} x_j|j\rangle \longrightarrow \sum_{k=0}^{N-1} y_k|k\rangle$$

where the y_k are the discrete Fourier transform of the x_j. Moreover, it can be shown to be unitary.

The trick to design a quantum circuit able to perform this unitary transformation is to notice that it can be rewritten using products of states. We consider $N = 2^n$ so that the basis $|0\rangle, |1\rangle, ..., |2^n - 1\rangle$ forms a basis for n qubits. Each state $|j\rangle$ is then represented by $|j_1, ..., j_n\rangle$ where the binary numbers j_k form the representation of the number j in the binary basis, i.e. $j = j_1 2^{n-1} + j_2 2^{n-2} + \cdots + j_{n-1}2^1 + j_n 2^0$. Each state $|j_k\rangle$ is thus the state of a qubit. We also use the notation $0.j_l j_{l+1} ... j_m$ for a binary fraction $j_l 2^{-1} + j_{l+1}2^{-2} + \cdots + j_m 2^{l-m-1}$. It can then be shown that the product representation of the quantum Fourier transform of a basis state is

$$|j_1, ..., j_n\rangle \longrightarrow \frac{\left(|0\rangle + e^{2\pi i 0 \cdot j_n}|1\rangle\right)\left(|0\rangle + e^{2\pi i 0 \cdot j_{n-1} j_n}|1\rangle\right) \cdots \left(|0\rangle + e^{2\pi i 0 . j_1 j_2 \cdots j_n}|1\rangle\right)}{2^{n/2}}$$

From this representation, we can design a quantum circuit that will perform the quantum Fourier transformation:



$$R_k \equiv \begin{bmatrix} 1 & 0 \\ 0 & e^{2\pi i/2^k} \end{bmatrix}$$

We will break it down to check that it indeed does what it is supposed to do.

(a) Check that the Hadamard gate applied on a qubit $|j_k\rangle$ can be written

$$|j_k\rangle \longrightarrow \frac{1}{\sqrt{2}}\left(|0\rangle + e^{i\pi j_k}|1\rangle\right) = \frac{1}{\sqrt{2}}\left(|0\rangle + e^{2\pi i 0 \cdot j_k}|1\rangle\right)$$

(b) Check that the controlled-R_3 gate changes a target qubit $|0\rangle$ into $|0\rangle$ and $|1\rangle$ into $e^{2\pi i 0.00 j_l}|1\rangle$ if the control qubit is $|j_l\rangle$.

(c) What is then the state $|j_k\rangle$ after a Hadamard gate and the controlled- R_2 gate with control qubit $|j_{k+1}\rangle$?

d) Write the state of a qubit $|j_k\rangle$ before the swaps.

As a result, after the swap, we retrieve as output exactly the formula of the quantum Fourier transform, i.e.

$$\frac{\left(|0\rangle + e^{2\pi i 0 \cdot j_n}|1\rangle\right)\left(|0\rangle + e^{2\pi i 0 \cdot j_{n-1} j_n}|1\rangle\right) \cdots \left(|0\rangle + e^{2\pi i 0 . j_1 j_2 \cdots j_n}|1\rangle\right)}{2^{n/2}}$$

Solutions to (a)

We need to check that $\hat{H}|j_k\rangle = \frac{1}{\sqrt{2}}\left(|0\rangle + e^{i\pi j_k}|1\rangle\right)$. By definition of H, we have

$$\hat{H}|0\rangle = \frac{1}{\sqrt{2}}(|0\rangle + |1\rangle)$$
$$\hat{H}|1\rangle = \frac{1}{\sqrt{2}}(|0\rangle - |1\rangle)$$

In our case, if $j_k = 0$, we get $e^{i\pi j_k} = e^0 = 1$ and get the expected results, and if $j_k = 1$, we have $e^{i\pi j_k} = e^{i\pi} = -1$, and we also get the expected result. In the binary basis and with our notation, we can write j_k as $2 \cdot 0.j_k$ (since $j_k = j_k \cdot 2^0$ and $0.j_k = j_k \cdot 2^{-1}$), so we can indeed write

$$\hat{H}|j_k\rangle = \frac{1}{\sqrt{2}}\left(|0\rangle + e^{i\pi j_k}|1\rangle\right) = \frac{1}{\sqrt{2}}\left(|0\rangle + e^{2\pi i 0 . j_k}|1\rangle\right)$$

Solutions to (b)

With a controlled- R_3 (CR_3), the target qubit remains unchanged if the control qubit is 0. As a result, writing first the target qubit, then the control qubit, we have $C\hat{R}_3|x,0\rangle = |x,0\rangle$. If the control qubit is 1, then we have

$$C\hat{R}_3|0,1\rangle = |0,1\rangle$$
$$C\hat{R}_3|1,1\rangle = e^{2\pi i/8}|1,1\rangle$$

We must now check that $|0\rangle$ is always transformed into $|0\rangle$, which is straightforward from the relations above, and that $|1\rangle$ is transformed into $e^{2\pi i 0.00 j_l}|1\rangle$. If $j_l = 0$, then we get $|1\rangle \to e^0|1\rangle = |1\rangle$, as expected. If $j_l = 1$, we get

$$|1\rangle \to e^{2\pi i \cdot 0.001}|1\rangle = e^{2\pi i \cdot 2^{-3}}|1\rangle = e^{2\pi i/8}|1\rangle$$

again as expected. We can then notice that for a controlled- R_2 gate, we would get a factor $e^{2\pi i j_l \cdot 2^{-2}} = e^{2\pi i \cdot 0.0 j_l}$, and for a controlled- $R_2 e^{2\pi i j_l \cdot 2^{-n}} = e^{2\pi i \cdot 0.0000 \ldots j_l}$

Solutions to (c)

We consider the state (target qubit, control qubit) $|j_k, j_{k+1}\rangle$. Using 1., the Hadamard gate will transform it into

$$\hat{H}|j_k, j_{k+1}\rangle = \frac{|0, j_{k+1}\rangle + e^{2\pi i 0.j_k}|1, j_{k+1}\rangle}{\sqrt{2}}$$

Then, from 2., we have that $|0\rangle$ will remain unchanged after the CR_2 gate, and $|1\rangle$ will be multiplied by a certain factor. We have

$$\begin{aligned} C\hat{R}_2\left(\left(\hat{H}|j_k\rangle\right)\otimes|j_{k+1}\rangle\right) &= \frac{CR_2|0, j_{k+1}\rangle + e^{2\hat{\pi} i 0.j_k}\hat{}\,|1, j_{k+1}\rangle}{\sqrt{2}} \\ &= \frac{|0, j_{k+1}\rangle + e^{2\pi i 0.j_k} e^{2\pi i 0.0 j_{k+1}}|1, j_{k+1}\rangle}{\sqrt{2}} \\ &= \frac{|0, j_{k+1}\rangle + e^{2\pi i 0.j_k j_{k+1}}|1, j_{k+1}\rangle}{\sqrt{2}} \\ &= \frac{|0\rangle + e^{2\pi i 0.j_k j_{k+1}}|1\rangle}{\sqrt{2}}|j_{k+1}\rangle \end{aligned}$$

since $0.j_k + 0.0j_{k+1} = j_k \cdot 2^{-1} + j_{k+1} \cdot 2^{-2} = 0.j_k j_{k+1}$. Note that the control qubit does not change after the whole process.

Solutions to (d)

According to Fig. 2, a qubit $|j_k\rangle (1 \leq k < n)$ will undergo the transformation H followed by CR_2 (control qubit j_{k+1}), then CR_3 (control qubit j_{k+2}), and so on up to
CR_{n-k+1} (control qubit j_n). Let us consider the full state $|j_1, ..., j_n\rangle$. We thus have that the circuit before the swaps acts on a qubit $|j_k\rangle$ as

$$|j_1, ..., j_{k-1}\rangle \otimes \left(C\hat{R_{n-k+1}} ... C\hat{R}_3 C\hat{R}_2\left(\left(\hat{H}|j_k\rangle\right)\otimes|j_{k+1}, ..., j_n\rangle\right)\right)$$

Let us take it step by step. We already know that $C\hat{R}_2\left(\left(\hat{H}|j_k\rangle\right)\otimes|j_{k+1}\rangle\right) = \frac{|0\rangle + e^{2\pi i 0.j_k j_{k+1}}|1\rangle}{\sqrt{2}}|j_{k+1}\rangle$. With the same reasoning as for 3., we can deduce that

$$C\hat{R}_3 C\hat{R}_2\left(\left(\hat{H}|j_k\rangle\right)\otimes|j_{k+1}, j_{k+2}\rangle\right) = \frac{|0\rangle + e^{2\pi i 0.j_k j_{k+1} j_{k+2}}|1\rangle}{\sqrt{2}}|j_{k+1}, j_{k+2}\rangle$$

Applying again the same reasoning for all the remaining gates, we get

$$C\hat{R_{n-k+1}} ... C\hat{R}_3 C\hat{R}_2\left(\left(\hat{H}|j_k\rangle\right)\otimes|j_{k+1}, ..., j_n\rangle\right) = \frac{|0\rangle + e^{2\pi i 0.j_k j_{k+1} ... j_n}|1\rangle}{\sqrt{2}}|j_{k+1}, ..., j_n\rangle$$

or discarding all the control qubits

$$|j_k\rangle \rightarrow \frac{|0\rangle + e^{2\pi i 0 \cdot j_k j_{k+1} \cdots j_n}|1\rangle}{\sqrt{2}}$$

Note that to get the final output, we perform the above transformation for all k and we get

$$|j_1, ..., j_n\rangle \rightarrow \frac{|0\rangle + e^{2\pi i 0.j_1 j_2 ... j_n}|1\rangle}{\sqrt{2}} \frac{|0\rangle + e^{2\pi i 0.j_2 j_3 ... j_n}|1\rangle}{\sqrt{2}} \cdots \frac{|0\rangle + e^{2\pi i 0.j_n}|1\rangle}{\sqrt{2}}$$

The swap operations in the end will reverse the order to get the Quantum Fourier Transform.

Formulas for 2D scattering

$$\hat{H} = -\frac{\hbar^2}{2\mu}\left(\frac{1}{\rho}\frac{\partial}{\partial\rho}\rho\frac{\partial}{\partial\rho} + \frac{1}{\rho^2}\frac{\partial^2}{\partial\varphi^2}\right) + U(\rho)$$
$$\psi^+_{\mathbf{k}}(\boldsymbol{\rho}) \approx e^{ik\rho\cos\varphi} + \sqrt{i}\frac{f(k,\varphi)}{\sqrt{\rho}}e^{ik\rho}, \quad \rho\to\infty$$

(!!! тут про функцию Грина и функцию Генкеля, ее свойства!!!)

$$H_0^{(1)}(x) \approx -(2i/\pi)\log(2i/\gamma x), \quad |x| \ll 1$$

where $\gamma = e^C$ and C is Euler's constant (see Landau)

Примем, что: (?? это пока не могу вывести, в теории напишу про это)

$$G^{(0,R)}_{E\ 2D}(\mathbf{r},\mathbf{r}') = \frac{m}{\sqrt{2\pi k_E r}}e^{ik_E|\mathbf{r}-\mathbf{r}'|+i\frac{\pi}{4}}$$

$$\begin{aligned}\chi_{\mathbf{k}2D}(\mathbf{r}) &= \int d\mathbf{r}'\frac{d\mathbf{k}'}{(2\pi)^2}G^{(0,R)}_{E\ 2D}(\mathbf{r},\mathbf{r}')\ e^{i\mathbf{k}'\mathbf{r}'}\ \langle\mathbf{k}'|\hat{V}|\mathbf{k}\rangle = \\ &= \frac{m}{\sqrt{2\pi kr}}\int d\mathbf{r}'\delta(\mathbf{r}')e^{ik|\mathbf{r}-\mathbf{r}'|+i\frac{\pi}{4}}e^{i\mathbf{k}'\mathbf{r}'}\tilde{V}_{\mathbf{k}-\mathbf{k}'} = \\ &= \frac{m}{\sqrt{2\pi kr}}e^{ikr+i\frac{\pi}{4}}\tilde{V}_{\mathbf{k}-\mathbf{k}'}\end{aligned}$$

$$f_{2D}(\mathbf{n},\mathbf{n}') = \frac{m}{\sqrt{2\pi k}}\tilde{V}_{\mathbf{k}-\mathbf{k}'}$$

$$d\sigma_{2D} = |f(\mathbf{n}, \mathbf{n}')|^2 d\theta$$

(тут про то, что если медленные частицы?)

(тут про то, что если быстрые частицы?)

$$e^{ik\rho\cos\varphi} = \sum_{m=-\infty}^{\infty} A_m J_{|m|}(k\rho) e^{im\varphi}, \quad \psi^+_{\mathbf{k}} = \sum_{m=-\infty}^{\infty} B_m R_{km}(\rho) e^{im\varphi}$$

$$R_{km2D}(\rho) = \sqrt{\frac{2}{\pi k\rho}} \sin\left(k\rho - \frac{\pi|m|}{2} + \frac{\pi}{4} + \delta_m\right)$$

$$f_{2D}(k,\varphi) = \frac{1}{i\sqrt{2\pi k}} \sum_{m=-\infty}^{\infty} \left(e^{2i\delta_m} - 1\right) e^{im\varphi}$$

$$\sigma_{\text{tot}2D} = \int_0^{2\pi} |f|^2 d\varphi = \frac{4}{k} \sum_{m=-\infty}^{\infty} \sin^2\delta_m$$

$$\operatorname{Im} f(k, \varphi = 0) = \sqrt{\frac{k}{8\pi}}\sigma(E). \qquad \text{opt th 2D}$$

Features of 2d scattering

(emphasis main statements, what works here, what is wrong here)
Особенности 2D случая:

$$\psi_{2D}(\mathbf{r}) = e^{i\mathbf{kr}} + f(\mathbf{n}, \mathbf{n}') e^{\frac{i\pi}{4}} \frac{e^{ikr}}{\sqrt{r}}$$

(??? почему???)

3D Scatterings: Features and examples

Scattering on a 3d hard sphere (elastic bounce back):

$$R_l(r) = A_l \left[\cos\alpha_l j_l(\rho) - \sin\alpha_l n_l(\rho)\right]$$

$$R_l(r) \sim \frac{1}{\rho}\left[\cos\alpha_l \sin\left(\rho - \frac{1}{2}l\pi\right) + \sin\alpha_l \cos\left(\rho - \frac{1}{2}l\pi\right)\right] = \frac{1}{\rho}\sin\left(\rho - \frac{1}{2}l\pi + \alpha_l\right) \equiv$$

$$\equiv \sim \left[(-1)^{l+1}\frac{e^{-i\rho}}{\rho} + e^{2i\delta_l}\frac{e^{i\rho}}{\rho}\right] = \frac{e^{i\delta_l}e^{i\pi l/2}}{\rho}\left[-e^{-i(\rho+\delta_l-\pi l/2)} + e^{i(\rho+\delta_l-\pi l/2)}\right]$$

$$\alpha_l = \delta_l$$

$$R_l(a) = 0 \qquad \Rightarrow \qquad \cos\delta_l j_l(ka) = \sin\delta_l n_l(ka) \qquad \Rightarrow \qquad \tan\delta_l = \frac{j_l(ka)}{n_l(ka)}$$

$$\delta_0 = -ka$$

$$\delta_l^{ka\ll 1} \approx -\frac{(ka)^{2l+1}}{(2l+1)!!(2l-1)!!} \qquad j_l(\rho) \overset{\rho\to 0}{\to} \frac{\rho^l}{(2l+1)!!};$$
$$n_l(\rho) \overset{\rho\to 0}{\to} -(2l-1)!!\rho^{-(l+1)}$$

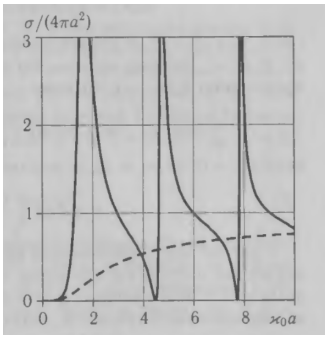
$$\sigma_l^{ka\ll 1} \approx 4\pi a^2\left(1+\mathcal{O}\left((ka)^4\right)\right) \qquad \sigma = \frac{4\pi}{k^2}\sum_l (2l+1)\sin^2\delta_l$$

This is a factor of 4 bigger than the classical, geometric result.

Scattering on a 3d black sphere (absorption, elastic and inelastic):
(??? what are boundary conditions for this model???)

Эффект Рамзауэра

Медленные частицы рассеиваются на сферически-симметричной прямоугольной потенциальной яме с пиками и нулями в сечении при некоторых соотношениях между глубиной V_0 и радиусом ямы a:



(коротко, почему? см. задачу, это еще продумать нужно)

(строчка про эксп подтверждения)

Поляризуемость связанного состояния диаграммным методом

Пусть заряженная частица находится в мелкой 2D яме в основном состоянии во слабом внешнем поле.

$G = G_0 + G_0 F G_0$,

$$G(\varepsilon, \mathbf{p}, \mathbf{p}') = (2\pi)^2 \frac{\delta^{(2)}(\mathbf{p}-\mathbf{p}')}{\varepsilon - p^2/(2m) + i\delta} + \frac{F(\varepsilon)}{[\varepsilon - p^2/(2m) + i\delta]\,[\varepsilon - p'^2/(2m) + i\delta]}.$$

Положительный знак мнимой части $i\delta$ означает, что состояния непрерывного спектра пусты. При интегрировании по ε эти полюсы надо обходить сверху. Осталось выбрать обход полюса в $F(\varepsilon)$ при $\varepsilon = \varepsilon_0$. Это состояние заполнено, поэтому сдвигаем полюс вверх: $\varepsilon_0 \to \varepsilon_0 + i\delta$. Получаем $F(\varepsilon) = 2\pi\hbar^2/\left(m\ln\left(\varepsilon/\varepsilon_0\right)\right)$, причем обход полюса $\varepsilon = \varepsilon_0$ и точки ветвления $\varepsilon = 0$ такой:

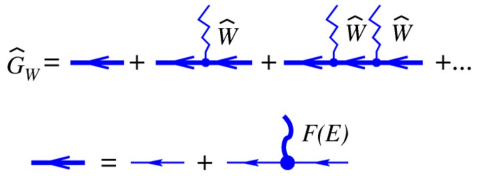
$$\mathcal{P} := e\int \mathbf{r}n(\mathbf{r})d^2r = -ie\int \lim_{t\to-0}\mathbf{r}G(t,\mathbf{r},\mathbf{r})d^2r =$$
$$= e\iint\left(\int \mathbf{r}e^{i(\mathbf{p}_1-\mathbf{p}_2)\mathbf{r}}d^2r\right)\cdot\left(\lim_{t\to-0}\int e^{-i\omega t}G\left(\omega,\mathbf{p}_1,\mathbf{p}_2\right)\frac{d\omega}{2\pi i}\right)\frac{d^2p_1d^2p_2}{(2\pi)^4} =$$
$$= -ie\iint\nabla_1\delta\left(\mathbf{p}_1-\mathbf{p}_2\right)\sum \mathrm{Res}_\omega\, G\left(\omega,\mathbf{p}_1,\mathbf{p}_2\right)\frac{d^2p_1d^2p_2}{(2\pi)^2},$$

(??????????) тут вычеты в полюсах ω функции G в верхней полуплоскости ε, что соответствует заполненным уровням.

$$\mathcal{P} \overset{\text{int b p}}{=} ie\int\left[\nabla_{\mathbf{p}}\sum \mathrm{Res}_\omega\, G\left(\omega,\mathbf{p},\mathbf{p}'\right)\right]\Big|_{\mathbf{p}'=\mathbf{p}}\frac{d^2p}{(2\pi)^2}.$$

Пусть есть поле $W=-eEx$, тогда

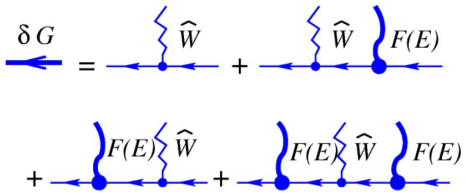
$$\hat{G}_W = \hat{G}+\hat{G}\hat{W}\hat{G}+\hat{G}\hat{W}\hat{W}\hat{G}+\ldots$$



$$W(\mathbf{p}) = -\int eExe^{-i\mathbf{pr}}d^2r = -ie(2\pi)^2E\frac{\partial}{\partial p_x}\delta^{(2)}(\mathbf{p}).$$

Линейный по полю и требуемый для поляризуемости ряд имеет 4 члена:

$$G = G_0+G_0FG_0,$$



1) $G_0WG_0=0$. (нет особенностей над контуром интегрирования по E.)

2) $$\hat{G}_0W\hat{G}_0\hat{F}\hat{G}_0\left(p,p'\right) = \int\frac{-ieE\partial/\partial p_x\delta^{(2)}\left(\mathbf{p}-\mathbf{p}_1\right)}{\left(\varepsilon-p^2/2m+i\delta\right)}\frac{F(\varepsilon)}{\left(\varepsilon-p_1^2/2m+i\delta\right)\left(\varepsilon-p^2/2m+i\delta\right)}d^2\mathbf{p}_1 =$$
$$= \int\delta\left(\mathbf{p}_1-\mathbf{p}\right)\frac{\partial}{\partial p_{1x}}\frac{-ieEF(\varepsilon)}{\left(\varepsilon-p^2/2m+i\delta\right)}\frac{1}{\left(\varepsilon-p_1^2/2m+i\delta\right)\left(\varepsilon-p^2/2m+i\delta\right)}d^2\mathbf{p}_1 =$$
$$= -\frac{ieE}{m}F(\varepsilon)\frac{p_x}{\left(\varepsilon-p^2/2m+i\delta\right)^3\left(\varepsilon-p^2/2m+i\delta\right)}.$$

3) $$\hat{G}_0\hat{F}\hat{G}_0\hat{W}\hat{G}_0\left(\mathbf{p},\mathbf{p}'\right) = \frac{ieEp'_xF(\varepsilon)/m}{\left(\varepsilon-p^2/2m+i\delta\right)\left(\varepsilon-p'^2/2m+i\delta\right)^3}.$$

c.c., $p\leftrightarrow p'$

4) $$\hat{G}_0\hat{F}\hat{G}_0\hat{W}\hat{G}_0\hat{F}\hat{G}_0\left(p,p'\right) =$$
$$= ieEF^2(\varepsilon)\iint\frac{d^2p_1d^2p_2}{(2\pi)^2}G_0(\varepsilon,\mathbf{p})G_0\left(\varepsilon,\mathbf{p}_2\right)G_0\left(\varepsilon,\mathbf{p}_1\right)G_0\left(\varepsilon,\mathbf{p}'\right)\nabla_{1x}\delta\left(\mathbf{p}_2-\mathbf{p}_1\right) =$$
$$= -ieEF^2(\varepsilon)G_0(\varepsilon,p)G_0\left(\varepsilon,\mathbf{p}'\right)\int\frac{d^2p_1}{(2\pi)^2}\frac{p_{1,x}/m}{\left(\varepsilon-p_1^2/2m+i\delta\right)^3} = 0, \quad \text{(odd f)}$$

Итог:

$$\sum_{\omega} \operatorname{Res} G(\omega, \mathbf{p}, \mathbf{p}') = \operatorname{Res}_{\varepsilon_0} F(\varepsilon) \frac{ie}{m} E \left[p'_x G_0(\varepsilon_0, \mathbf{p}) G_0^3(\varepsilon_0, \mathbf{p}') - p_x G_0^3(\varepsilon_0, \mathbf{p}) G_0(\varepsilon_0, \mathbf{p}') \right]$$

$$\mathcal{P}_x = -2 \frac{e^2}{m^2} E \int \frac{p_x^2}{\left(\varepsilon_0 - p^2/2m + i\delta\right)^5} \operatorname{Res}_{\varepsilon_0} F(\varepsilon) \frac{d^2p}{(2\pi)^2}.$$

Итак, поляризуемость:

$$\chi_{\alpha\beta} = \frac{2e^2}{m^2} \int \frac{p_\alpha p_\beta (2m)^5}{\left(p^2 + \varkappa^2\right)^5} \operatorname{Res}_{\varepsilon_0} F(\varepsilon) \frac{d^2p}{(2\pi)^2}, \qquad \varkappa^2 := 2m\,|\varepsilon_0|$$

$$\varepsilon = \varepsilon_0 + z \qquad F(\varepsilon) = \frac{2\pi}{m \ln(1 + z/\varepsilon_0)} \approx \frac{2\pi\varepsilon_0}{mz}, \quad \Rightarrow \quad \operatorname{Res} = \frac{2\pi\varepsilon_0}{m}.$$

$$\chi_{\alpha\beta} = e^2 m^2 \varepsilon_0 \int_0^{+\infty} \frac{2^6 \pi \delta_{\alpha\beta}}{\left(p^2 + \varkappa^2\right)^5} \frac{p^3 dp}{2\pi} = \delta_{\alpha\beta} \frac{16 e^2 m^2 \varepsilon_0}{(2m\varepsilon_0)^3} \int_0^{+\infty} \frac{x dx}{(x+1)^5} = \frac{e^2 \delta_{\alpha\beta}}{6 m \varepsilon_0^2} \cdot \hbar^2.$$

General features of scattering formalisms

Properties of scattering amplitudes

$$f(\mathbf{k}, \mathbf{k}_0) - f^*(\mathbf{k}_0, \mathbf{k}) = \frac{ik}{2\pi} \int f(\mathbf{k}', \mathbf{k}_0) f^*(\mathbf{k}', \mathbf{k}) \, d\Omega' \tag{XIII.26}$$

(For $\mathbf{k} = \mathbf{k}_0$, the optical theorem is reproduced.)

$$f(E, 0) = f^B(0) + \sum_n \frac{d_n}{E - E_n} + \frac{1}{\pi} \int_0^{\infty} \frac{\operatorname{Im} f(E', 0)}{E' - E} dE' \tag{XIII.27}$$

The energy has the following singular points: branch points $E = 0$ and $E = \infty$ and poles E_n on real half-axis $E < 0$, which coincide with the positions of discrete levels.

Here, $f^B(0)$ is the amplitude of the first Born approximation; see Eq. (XIII.6). The summation is performed over all the discrete states in the potential (each of which corresponds to a pole in the scattering amplitude); d_n is the residue at the pole corresponding to E_n, and is given by

$$d_n = -(-1)^{l_n} (2l_n + 1) \frac{\hbar^2 A_n^2}{2m} \tag{XIII.28}$$

where A_n is a normalization coefficient for the large-distance asymptote of the radial wave-function corresponding to a bound state with the angular momentum l_n; that is, $rR_n \approx A_n \exp\{-\kappa_n r\}$ (compare to Eq. (XI.5)).

Extra properties of S-matrix

$$\begin{pmatrix} \psi_R \\ \psi_L \end{pmatrix} = \begin{pmatrix} I_R \\ I_L \end{pmatrix} + S \begin{pmatrix} O_R \\ O_L \end{pmatrix}, \quad S = \begin{pmatrix} t & r \\ r' & t' \end{pmatrix}$$

(????? I don't get the idea of parity basis and all things here by Tong)

For a general parity-symmetric potential $V(x) = V(-x)$. we switch to a parity basis,

$$I_+(x) = e^{-ik|x|}, \quad I_-(x) = \text{sign}(x)e^{-ik|x|}, \quad O_+(x) = e^{ik|x|}, \quad O_-(x) = -\,\text{sign}(x)e^{ik|x|}$$

$$\begin{pmatrix} I_+ \\ I_- \end{pmatrix} = M\begin{pmatrix} I_R \\ I_L \end{pmatrix}, \quad \begin{pmatrix} O_+ \\ O_- \end{pmatrix} = M\begin{pmatrix} O_R \\ O_L \end{pmatrix}, \quad M = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}$$

$$S^P = MSM^{-1}.$$

- For a parity-symmetric potential, $r = r'$ because $\psi_R(x) = \psi_L(-x)$. Then S^P simplifies to

$$S^P = \begin{pmatrix} S_{++} & \\ & S_{--} \end{pmatrix}, \quad S_{++} = t + r, \quad S_{--} = t - r$$

The off-diagonal elements are zero because parity is conserved. - Combining our identities shows that $S_{++}$and $S_{--}$are phases,

$$S_{++} = e^{2i\delta_+(k)}, \quad S_{--} = e^{2i\delta_-(k)}$$

This is analogous to how we distilled three-dimensional central force scattering into a set of phases in the partial wave decomposition. - The S-matrix can also detect bound states. Since the algebra used to derive $r(k)$ and $t(k)$ never assumed that k was real, the same expressions hold for general complex k. Consider a pure imaginary wavenumber $k = i\lambda$ with even parity,

$$\lim_{|x|\to\infty} \psi_+(x) = I_+(x) + S_{++}O_+(x), \quad I_+(x) = e^{\lambda|x|}, \quad O_+(x) = e^{-\lambda|x|}$$

It looks like there can't be a bound state solution here, since the I_+component diverges at infinity. The trick is to rewrite this as

$$\lim_{|x|\to\infty} \psi_+(x) = S_{++}^{-1}I_+(x) + O_+(x)$$

which gives a valid bound state as long as $S_{++}^{-1} = 0$, which corresponds to a pole in S_{++}. That is, we can identify bound states from poles in S-matrix elements! (The same reasoning works in the original left/right basis, though there are more terms.)

$$S_{++}(k) = -e^{-ika}\frac{q\tan(qa/2) - ik}{q\tan(qa/2) + ik}$$

which shows that bound states of even parity occur when $\lambda = q\tan(qa/2)$, a familiar result. We can recover the bound state energy from $E = -\hbar^2\lambda^2/2m$.

Типичные модели рассеяния в приложениях

Рассеяние Мотта

Рассеяние Мотта - рассеяние, обусловленное взаимодействием спина заряженной частицы с её орбитальным моментом, возникающим при движении в электрическом поле рассеивающего центра. Характерной особенностью рассеяния Мотта является его асимметрия относительно плоскости, содержащей спин и импульс электрона. Такая асимметрия используется для измерения поляризации электронов.

Дифференциальное сечение упругого рассеяния частицы со спином 1/2 и зарядом e на неподвижном кулоновском центре (атомном ядре) с зарядом Ze выражается:

$$\left(\frac{d\sigma}{d\Omega}\right)_{\text{Mott}} = 4\left(Ze^2\right)^2\frac{E^2}{(qc)^4}\left(1 - \beta^2\sin^2\frac{\theta}{2}\right) \qquad \text{(ф Мотта)}$$

где σ - сечение рассеяния, Ω - телесный угол, Z - зарядовое число атомного ядра, e - элементарный электрический заряд, $E = \gamma c^2$ - энергия частицы, $q = 2\gamma v \sin(\theta/2)$ - переданный импульс (тут $\gamma = 1/\sqrt{1-\beta^2}$ - лоренц-фактор частицы, m - масса частицы, v - скорость частицы, c - скорость света), $\beta = v/c, \theta$ - угол рассеяния. Для нерелятивистских частиц $v \ll c$ и формула Мотта переходит в формулу Резерфорда:

$$\left(\frac{d\sigma}{d\Omega}\right)_{\text{Rutherford}} = \left(\frac{Ze^2}{2mv^2}\right)^2 \frac{1}{\sin^4(\theta/2)}$$

21.1.2 Special Scatterings

Spin-dependent scattering

(see Galitski!)
The operator describing interaction of a spin-1/2 particle with an external field has the form:

$$\hat{U} = U_0(r) + U_1(r)\hat{\sigma} \cdot \hat{\mathbf{l}}$$

In case of a spin-dependent interaction, the scattering amplitude becomes a matrix, $\hat{f}$, in the spin-basis, whose elements $\chi_f^* \hat{f} \chi_i$ describe the scattering from an initial spin state χ_i into

a final state χ_f. For the scattering of spin- 1/2 particles off of spinless ones and in the case of a parity-conserving interaction,

$$\hat{f} = A(k,\theta) + iB(k,\theta)\boldsymbol{\nu}\cdot\hat{\boldsymbol{\sigma}}, \quad \boldsymbol{\nu} = \frac{[\mathbf{k}_0\times\mathbf{k}]}{|[\mathbf{k}_0\times\mathbf{k}]|} \tag{XIII.22}$$

The factorization of i - convention, it can be different in other conventions.

The differential scattering cross-section summed over the spin states of the scattered particles is given by

$$\frac{d\sigma}{d\Omega} = |A|^2 + |B|^2 + 2\,\mathrm{Im}\,(AB^*)\,\boldsymbol{\nu}\cdot\mathbf{P}_0 \tag{XIII.23}$$

where $\mathbf{P}_0 = 2\chi_i^*\hat{\boldsymbol{\sigma}}\chi_i$ is the polarization vector of the particles before collision. The polarization state of the scattered particles depends on both the interaction and the initial polarization, $\mathbf{P}_0$. If the particles were not polarized before collision, $\mathbf{P}_0 = \mathbf{0}$, then the polarization vector after scattering is

$$\mathbf{P} = \frac{2\,\mathrm{Im}\,(AB^*)}{|A|^2+|B|^2}\boldsymbol{\nu} \tag{XIII.24}$$

As before, Eq. (XIII.22) for the amplitude can be expanded in terms of the partial waves:

$$\begin{aligned} A &= \frac{1}{2ik}\sum_{l=0}^{\infty}\left[(l+1)\left(\exp\left\{2i\delta_l^+\right\}-1\right)+l\left(\exp\left\{2i\delta_l^-\right\}-1\right)\right]P_l(\cos\theta)\\ B &= \frac{1}{2ik}\sum_{l=1}^{\infty}\left(\exp\left\{2i\delta_l^+\right\}-\exp\left\{2i\delta_l^-\right\}\right)\sin\theta P_l'(\cos\theta), \end{aligned} \tag{XIII.25}$$

$\delta_l^{\pm}$ are the phase shifts for states with the orbital angular momentum l and the total angular momentum $j = l \pm 1/2$.

Scattering Off a Lattice

(это же в конд среды добавлю)

Typical formalism

$$\psi(\mathbf{r}) \sim e^{i\mathbf{k}\cdot(\mathbf{r}-\mathbf{R})} + f\left(\mathbf{k},\mathbf{k}'\right)\frac{e^{ik|\mathbf{r}-\mathbf{R}|}}{|\mathbf{r}-\mathbf{R}|}$$

$$|\mathbf{r}-\mathbf{R}| = \sqrt{r^2+R^2-2\mathbf{r}\cdot\mathbf{R}} \approx r\sqrt{1-2\mathbf{r}\cdot\mathbf{R}/r^2} \approx r - \hat{\mathbf{r}}\cdot\mathbf{R}$$

$$\psi(\mathbf{r}) \sim e^{-i\mathbf{k}\cdot\mathbf{R}}\left[e^{i\mathbf{k}\cdot\mathbf{r}} + f\left(\mathbf{k},\mathbf{k}'\right)e^{-i(\mathbf{k}'-\mathbf{k})\cdot\mathbf{R}}\frac{e^{ikr}}{r}\right]$$

$$f_{\mathbf{R}}(\mathbf{k};\hat{\mathbf{r}}) = f\left(\mathbf{k},\mathbf{k}'\right)e^{i\mathbf{q}\cdot\mathbf{R}}$$

$$\mathrm{q} = \mathrm{k} - \mathrm{k}'$$

$$f_{\Lambda}\left(\mathbf{k},\mathbf{k}'\right) = f\left(\mathbf{k},\mathbf{k}'\right)\sum_{\mathbf{R}\in\Lambda}e^{i\mathbf{q}\cdot\mathbf{R}}$$

$$\Delta(\mathbf{q}) \equiv \sum_{\mathbf{R}\in\Lambda} e^{i\mathbf{q}\cdot\mathbf{R}} = \sum_{\mathbf{R}\in\Lambda} e^{i\mathbf{q}\cdot(\mathbf{R}-\mathbf{R}_0)} = e^{-i\mathbf{q}\cdot\mathbf{R}_0}\Delta(\mathbf{q})$$

either $e^{-i\mathbf{q}\cdot\mathbf{R}_0} = 1$ or $\Delta(\mathbf{q}) = 0$.
$\mathrm{q} \in \Lambda^\star$.

$$\sum_{\mathbf{R}\in\Lambda} e^{i\mathbf{q}\cdot\mathbf{R}} \equiv \Delta(\mathbf{q}) = V^\star \sum_{\mathbf{Q}\in\Lambda^*} \delta(\mathbf{q}-\mathbf{Q})$$

$\mathbf{k}-\mathbf{k}' \in \Lambda^\star$ laue condition

(добавлю картинки и пояснения)

The Bragg Condition

$$d = \frac{2\pi}{Q}$$

$$\lambda = 2d\sin(\theta/2)$$

$$n\lambda = 2d\sin(\theta/2)$$

(добавлю картинки и пояснения)

The Structure Factor

$$f_{\text{lattice}}\ (\mathbf{k},\mathbf{k}') = \Delta(\mathbf{q})S(\mathbf{q})$$
$$S(\mathbf{q}) = \sum_i f_i\,(\mathbf{k},\mathbf{k}')\,e^{i\mathbf{q}\cdot\mathbf{d}_i} \quad \text{structure factor.}$$

An Example: BCC Lattice
(??)

Another Example: Diamond
(???)

The Debye-Waller Factor

(абзац с сутью и постановкой задачи!)

$$f_\Lambda\,(\mathbf{k},\mathbf{k}') = f\,(\mathbf{k},\mathbf{k}')\sum_n e^{i\mathbf{q}\cdot\mathbf{R}_n}$$

$$R_n \to R_n + \mathbf{u}_n(t)$$

$$\tilde{\Delta}(\mathbf{q}) = \sum_n e^{i\mathbf{q}\cdot\mathbf{R}_n} e^{i\mathbf{q}\cdot\mathbf{u}_n}$$

$$\tilde{\Delta}(\mathbf{q}) = \sum_n e^{i\mathbf{q}\cdot\mathbf{R}_n}\langle 0|e^{i\mathbf{q}\cdot\mathbf{u}_n(t)}|0\rangle$$

$$u_n(t) = X_0(t) + \sqrt{\frac{\hbar}{2m\omega_l N}} \sum_{l\neq 0} \left[a_l e^{-i(\omega_l t - k_l na)} + a_l^\dagger e^{i(\omega_l t - k_l na)} \right]$$

$$u_0 = \sum_{k\neq 0} \sqrt{\frac{\hbar}{2mN\omega(k)}} \left(a(k) + a^\dagger(k) \right) \equiv A + A^\dagger$$

$$\left[A, A^\dagger \right] = \sum_{k\neq 0} \frac{\hbar}{2mN\omega(k)}$$

$\langle 0 | e^{iq\left(A+A^\dagger\right)} | 0 \rangle$=?

$$e^{iq\left(A+A^\dagger\right)} = e^{iqA^\dagger} e^{iqA} e^{\frac{1}{2}q^2\left[A^\dagger, A\right]}$$

$\langle 0 | e^{i\mathbf{q}\cdot\mathbf{u}_0} | 0 \rangle = e^{-W(\mathbf{q})}$ where $W(\mathbf{q}) = \sum_{\mathbf{k}} \frac{\hbar \mathbf{q}^2}{4mN\omega(\mathbf{k})}$ Debye-Waller factor

$$f_\Lambda\left(\mathbf{k}, \mathbf{k}'\right) = e^{-W(\mathbf{q})} f\left(\mathbf{k}, \mathbf{k}'\right) \Delta(\mathbf{q})$$

21.1.3 Details of typical adiabatics

Адиабатические возмущения по Мигдалу Крайнову

Захват электрона протоном (перезарядка) (89).

О быстрой и медленной подсистемах по Мигдалу Крайнову и приближении Борна-Опенгеймера

(лучше только у МК спишу сперва, по идее у ПТФ это же, потом уже у них буду выписывать это все)

Формализм деления на быстрые и медленные переменные (!!!)

(!! впишу очень скоро!!!)

адиабатический квантовый транспорт

Оценки в адиабатике по МК

Колебательные уровни молекулы

Возбуждение ядерных дипольных уровней быстрой частицей (98).

Рассеяние протона на атоме водорода (перезарядка) (101).

Рождение мягких квантов при рассеянии («инфракрасная катастрофа») (103).

21.1.4 Scattering: Other Details of Basic Methods

Scattering as a time-dependent perturbation by Sakurai

$$U_I(t,t_0) = 1 - \frac{i}{\hbar}\int\limits_{t_0}^{t} V_I(t')\,U_I(t',t_0)\,dt'.$$

$$\langle n\,|U_I(t,t_0)|\,i\rangle = \delta_{ni} - \frac{i}{\hbar}\sum_m \langle n|V|m\rangle \int\limits_{t_0}^{t} e^{i\omega_{nm}t'}\,\langle m\,|U_I(t',t_0)|\,i\rangle\,dt',$$

$\langle n|i\rangle = \delta_{ni}, \quad \hbar\omega_{nm} = E_n - E_m.$

$$\begin{aligned}\langle n\,|U_I(t,t_0)|\,i\rangle &= \delta_{ni} - \frac{i}{\hbar}\langle n|V|i\rangle \int\limits_{t_0}^{t} e^{i\omega_{ni}t'}dt' \\ &= \delta_{ni} - \frac{i}{\hbar}T_{ni}\int\limits_{t_0}^{t} e^{i\omega_{ni}t'+\varepsilon t'}dt'\end{aligned}$$

$$\begin{aligned}S_{ni} := \lim_{t\to\infty}\left[\lim_{\varepsilon\to 0}\langle n\,|U_I(t,-\infty)|\,i\rangle\right] &= \delta_{ni} - \frac{i}{\hbar}T_{ni}\int\limits_{-\infty}^{\infty} e^{i\omega_{nit}t'}dt' \\ &= \delta_{ni} - 2\pi i\delta(E_n - E_i)\,T_{ni}.\end{aligned}$$

$$w(i\to n) = \frac{d}{dt}\left|\langle n\,|U_I(t,-\infty)|\,i\rangle\right|^2,$$

$$\langle n\,|U_I(t,-\infty)|\,i\neq n\rangle = -\frac{i}{\hbar}T_{ni}\int\limits_{-\infty}^{t} e^{i\omega_{ni}t'+\varepsilon t'}dt' = -\frac{i}{\hbar}T_{ni}\frac{e^{i\omega_{ni}t+\varepsilon t}}{i\omega_{ni}+\varepsilon}$$

$$w(i\to n) = \frac{d}{dt}\left[\frac{1}{\hbar^2}|T_{ni}|^2\frac{e^{2\varepsilon t}}{\omega_{ni}^2+\varepsilon^2}\right] = \frac{1}{\hbar^2}|T_{ni}|^2\frac{2\varepsilon e^{2\varepsilon t}}{\omega_{ni}^2+\varepsilon^2}.$$

We need to take $\varepsilon\to 0$ for finite values of t, and then $t\to\infty$. Clearly this will send $w\to 0$ if $\omega_{ni}\neq 0$, so we see something like $\delta(\omega_{ni})$ emerging, which is not unexpected given (6.1.11). In fact, because

$$\int\limits_{-\infty}^{\infty}\frac{1}{\omega^2+\varepsilon^2}d\omega = \frac{\pi}{\varepsilon}$$

$$\lim_{\varepsilon\to 0}\frac{\varepsilon e^{2\varepsilon t}}{\omega_{ni}^2+\varepsilon^2}=\pi\delta\left(\omega_{ni}\right)=\pi\hbar\delta\left(E_n-E_i\right).$$

$$w(i\to n)=\frac{2\pi}{\hbar}\left|T_{ni}\right|^2\delta\left(E_n-E_i\right)$$

$$\Delta n=4\pi|\mathbf{n}|^2\Delta|\mathbf{n}|\times\frac{d\Omega}{4\pi},$$

$$\rho\left(E_n\right)=\frac{\Delta n}{\Delta E_n}=\frac{m}{\hbar^2}\left(\frac{L}{2\pi}\right)^2|\mathbf{n}|d\Omega=\frac{mk}{\hbar^2}\left(\frac{L}{2\pi}\right)^3 d\Omega,$$

$$w(i\to n)=\frac{mkL^3}{(2\pi)^2\hbar^3}\left|T_{ni}\right|^2 d\Omega.$$

$$\mathbf{j}(\mathbf{x},t)=\left(\frac{\hbar}{m}\right)\frac{\mathbf{k}}{L^3}=\frac{v}{L^3}$$

Solving for the T Matrix:

$$\left\langle n\left|U_I(t,-\infty)\right|i\right\rangle=\delta_{ni}+\frac{1}{\hbar}T_{ni}\frac{e^{i\omega_{ni}t+\varepsilon t}}{-\omega_{ni}+i\varepsilon}.$$

$V_{nm}=\langle n|V|m\rangle$,

$$\left\langle n\left|U_I(t,-\infty)\right|i\right\rangle=\delta_{ni}-\frac{i}{\hbar}\sum_m V_{nm}\int_{-\infty}^{t}e^{i\omega_{nm}t'}\left\langle m\left|U_I\left(t',-\infty\right)\right|i\right\rangle dt'.$$

$$-\frac{i}{\hbar}\frac{1}{\hbar}\sum_m V_{nm}\frac{T_{mi}}{-\omega_{mi}+i\varepsilon}\int_{-\infty}^{t}e^{i\omega_{nm}t'+i\omega_{mi}t'+\varepsilon t'}dt'.$$

$$T_{ni}=V_{ni}+\frac{1}{\hbar}\sum_m V_{nm}\frac{T_{mi}}{-\omega_{mi}+i\varepsilon}=V_{ni}+\sum_m V_{nm}\frac{T_{mi}}{E_i-E_m+i\hbar\varepsilon}.$$

$$T_{ni}=\sum_j\langle n|V|j\rangle\left\langle j|\psi^{(+)}\right\rangle=\left\langle n|V|\psi^{(+)}\right\rangle.$$

$$\left\langle n|V|\psi^{(+)}\right\rangle=\langle n|V|i\rangle+\sum_m\langle n|V|m\rangle\frac{\left\langle m|V|\psi^{(+)}\right\rangle}{E_i-E_m+i\hbar\varepsilon}.$$

$$\left|\psi^{(+)}\right\rangle=|i\rangle+\frac{1}{E_i-H_0+i\hbar\varepsilon}V\left|\psi^{(+)}\right\rangle.\qquad\text{Lippmann-Schwinger eq}$$

$$T=V+V\frac{1}{E_i-H_0+i\hbar\varepsilon}T$$

$$T=V+V\frac{1}{E_i-H_0+i\hbar\varepsilon}V+V\frac{1}{E_i-H_0+i\hbar\varepsilon}V\frac{1}{E_i-H_0+i\hbar\varepsilon}V+\cdots.$$

$$G_\pm\left(\mathbf{x},\mathbf{x}'\right)\equiv\frac{\hbar^2}{2m}\left\langle\mathbf{x}\left|\frac{1}{E-H_0\pm i\varepsilon}\right|\mathbf{x}'\right\rangle$$

$$G_\pm\left(\mathbf{x},\mathbf{x}'\right)=\frac{\hbar^2}{2m}\sum_{\mathbf{k}'}\sum_{\mathbf{k}''}\langle\mathbf{x}|\mathbf{k}'\rangle\left\langle\mathbf{k}'\left|\frac{1}{E-H_0\pm i\varepsilon}\right|\mathbf{k}''\right\rangle\langle\mathbf{k}''|\mathbf{x}'\rangle.$$

$$\left\langle \mathbf{k}' \left| \frac{1}{E-(\hbar^2\mathbf{k}'^2/2m)\pm i\varepsilon} \right| \mathbf{k}'' \right\rangle = \frac{\delta_{\mathbf{k}'\mathbf{k}''}}{E-(\hbar^2\mathbf{k}'^2/2m)\pm i\varepsilon}$$

$$\langle \mathbf{x}|\mathbf{k}'\rangle = \frac{e^{i\mathbf{k}'\cdot\mathbf{x}}}{L^{3/2}}$$

$$\text{and} \qquad \langle \mathbf{k}''|\mathbf{x}'\rangle = \frac{e^{-i\mathbf{k}''\cdot\mathbf{x}'}}{L^{3/2}},$$

$E=\hbar^2k^2/2m$.

$$G_\pm(\mathbf{x},\mathbf{x}') = \frac{1}{L^3}\sum_{\mathbf{k}'} \frac{e^{i\mathbf{k}'\cdot(\mathbf{x}-\mathbf{x}')}}{k^2-k'^2\pm i\varepsilon}$$

$$\begin{aligned} G_\pm(\mathbf{x},\mathbf{x}') &= \frac{1}{(2\pi)^3}\int d^3k' \frac{e^{i\mathbf{k}'\cdot(\mathbf{x}-\mathbf{x}')}}{k^2-k^2\pm i\varepsilon} \\ &= \frac{1}{(2\pi)^2}\int\limits_0^\infty k'^2dk' \int\limits_{+1}^{-1} d\mu \frac{e^{ik'|\mathbf{x}-\mathbf{x}'|\mu}}{k^2-k^2\pm i\varepsilon} \\ &= \frac{1}{8\pi^2}\frac{1}{i\,|\mathbf{x}-\mathbf{x}'|}\int\limits_{-\infty}^{\infty} k'dk' \left[\frac{e^{-ik'|\mathbf{x}-\mathbf{x}'|}-e^{ik'|\mathbf{x}-\mathbf{x}'|}}{k^2-k'^2\pm i\varepsilon}\right] \end{aligned}$$

(??? is the formula below useful?)

$$c_n^{(2)} = \frac{i}{\hbar}\sum_m \frac{V_{nm}V_{mi}}{E_m-E_i}\int\limits_0^t dt' \left(e^{i\omega_{nit}t'} - e^{i\omega_{nm}t'}\right)$$

Амплитуда рассеяния в энергетической нормировке и диаграммный ряд для нее

$$\hat{G}^{-1}\psi_{\mathbf{k}}(\mathbf{r}) = 0 \quad \Leftrightarrow \quad \left(\hat{G}_0^{-1}-\hat{V}\right)\psi_{\mathbf{k}}(\mathbf{r}) = 0.$$

$$\psi_{\mathbf{k}}(\mathbf{r}) = e^{i\mathbf{k}\mathbf{r}} + \chi_{\mathbf{k}}(\mathbf{r})$$

$$\varepsilon = k^2/2m \qquad \Rightarrow \qquad \left(\hat{G}_0^{-1}-\hat{V}\right)\chi_{\mathbf{k}}(\mathbf{r}) = V|\mathbf{k}\rangle$$

$$\chi_{\mathbf{k}}(\mathbf{r}) = \langle \mathbf{r}|\hat{G}\hat{V}|\mathbf{k}\rangle = \left\langle \mathbf{r}\left|\hat{G}_0\hat{V}+\hat{G}_0\hat{V}\hat{G}_0\hat{V}+...\right|\mathbf{k}\right\rangle.$$

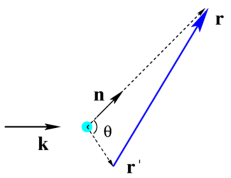
$$\hat{F} := \hat{V}+\hat{V}\hat{G}_0\hat{V}+\hat{V}\hat{G}_0\hat{V}\hat{G}_0\hat{V}+...$$

$\hat{F}$ - т.н. амплитуда рассеяния в энергетической нормировке.

$$\chi_{\mathbf{k}}(\mathbf{r}) = \left\langle \mathbf{r}\left|\hat{G}_0\hat{F}\right|\mathbf{k}\right\rangle.$$

$\hat{F}$ описывает многократное рассеяние падающей волны на потенциале $V(\mathbf{r})$, а $\hat{G}_0$ - свободное движение после последнего рассеяния.

$$G_0(\varepsilon,\mathbf{r},\mathbf{r}') = \int \frac{e^{i\mathbf{p}(\mathbf{r}-\mathbf{r}')}}{\varepsilon-\mathbf{p}^2/2m+i\delta}\frac{d^3p}{(2\pi)^3} = -\frac{m}{2\pi\hbar^2}\frac{e^{i\varkappa|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|}, \qquad \hbar\varkappa = \sqrt{2m\varepsilon}$$

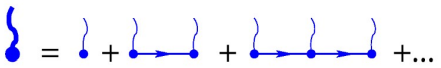


$\mathbf{r} \equiv R\mathbf{n}$, $|\mathbf{r}-\mathbf{r}'| = R - |\mathbf{r}'|\cos\theta + O(1/R)$,

$$\chi_{\mathbf{k}}(\mathbf{r}) = \left\langle \mathbf{r}\left|\hat{G}_0\hat{F}\right|\mathbf{k}\right\rangle = -\frac{m}{2\pi\hbar^2}\frac{e^{i\varkappa R}}{R}\int e^{-i\varkappa|\mathbf{r}'|\cos\theta}\,\langle\mathbf{r}'|F|\mathbf{k}\rangle\,d^3r'$$

$$f(\mathbf{k}_1,\mathbf{k}_2) := -\frac{m}{2\pi\hbar^2}\left\langle \mathbf{k}_2|\hat{F}|\mathbf{k}_1\right\rangle \qquad \text{def}, \quad \mathbf{k}_2 := |k_1|\,\mathbf{n}$$

Рассеяние частицы в статическом $V(\mathbf{r})$ описывается так:



$$\widehat{F} = \widehat{V} + \widehat{V}\widehat{G}_0\widehat{V} + \widehat{V}\widehat{G}_0\widehat{V}\widehat{G}_0\widehat{V} + \ldots = \widehat{V} + \widehat{V}\widehat{G}_0\left(\widehat{V} + \widehat{V}\widehat{G}_0\widehat{V} + \ldots\right) = \widehat{V} + \widehat{V}\widehat{G}_0\widehat{F}$$

$$F(\mathbf{k}_1,\mathbf{k}_2) = F^{(1)}(\mathbf{k}_1,\mathbf{k}_2) + F^{(2)}(\mathbf{k}_1,\mathbf{k}_2) + \ldots,$$

$F^{(1)}(\mathbf{k}_1,\mathbf{k}_2) = V(\mathbf{k}_2-\mathbf{k}_1)$,

$F^{(2)}(\mathbf{k}_1,\mathbf{k}_2) = \int \dfrac{V(\mathbf{k}_2-\mathbf{q})\,V(\mathbf{q}-\mathbf{k}_1)\,(d^3q)}{\varepsilon - \mathbf{q}^2/(2m) + i\delta}$,

$F^{(n)}(\mathbf{k}_1,\mathbf{k}_2) = \int\ldots\int \dfrac{V(\mathbf{k}_2-\mathbf{q}_{n-1})\ldots V(\mathbf{q}_1-\mathbf{k}_1)\,(d^3q_{n-1})\ldots(d^3q_1)}{\left(\varepsilon-\mathbf{q}_{n-1}^2/(2m)+i\delta\right)\ldots\left(\varepsilon-\mathbf{q}_1^2/(2m)+i\delta\right)} \qquad (d^3q_i) := d^3q_i/(2\pi)^3,\ \varepsilon := \hbar^2\mathbf{k}_1^2/(2m)$

$$F(\mathbf{k}_1,\mathbf{k}_2) = V(\mathbf{k}_2-\mathbf{k}_1) + \frac{2m}{\hbar^2}\int \frac{V(\mathbf{k}_2-\mathbf{q})\,F(\mathbf{k}_1,\mathbf{q})}{k_1^2-q^2+i\delta}\frac{d^3q}{(2\pi)^3}.$$

Полюсы $G(\varepsilon)$ дают спектр системы, и так как $\widehat{G} = \widehat{G}_0 + \widehat{G}_0\widehat{F}\widehat{G}_0$, каждому связанному состоянию отвечает полюс $\widehat{F}(\varepsilon)$.

Coulomb scattering

Main formulas for Coulomb scattering

(берем просто предел для Юкавы и всё)
(из ЛЛ3 самые важные выпишу!)

Coulomb scattering by Tong

$$\left(-\frac{\hbar^2}{2m}\nabla^2 + \frac{A}{r}\right)\psi(\mathbf{r}) = E\psi(\mathbf{r})$$

$$\left(\nabla^2 + k^2 - \frac{2\gamma k}{r}\right)\psi(\mathbf{r}) = 0$$

$$\left(\frac{d^2}{dr^2}+\frac{2}{r}\frac{d}{dr}+k^2-\frac{l(l+1)}{r^2}-\frac{2\gamma k}{r}\right)R_l(r)=0$$

$$R_l(r)\sim\frac{e^{\pm ikr+g(r)}}{r}$$

$$\frac{d^2g}{dr^2}+\left(\frac{dg}{dr}\right)^2\pm 2ik\frac{dg}{dr}=\frac{2\gamma k}{r}$$

$$\pm i\frac{dg}{dr}=\frac{\gamma}{r}\quad\text{as}\quad r\to\infty$$

$$\psi(\mathbf{r})=e^{i\mathbf{k}\cdot\mathbf{r}}e^{-\pi\gamma/2}\Gamma(1+i\gamma)_1F_1(-i\gamma;1;i(kr-\mathbf{k}\cdot\mathbf{r}))$$

$${}_1F_1(a;b;w)=1+\tfrac{a}{b}w+\tfrac{a(a+1)}{b(b+1)}\tfrac{w^2}{2!}+\tfrac{a(a+1)(a+2)}{b(b+1)(b+2)}\tfrac{w^3}{3!}+\ldots$$

$$\psi(\mathbf{r})\sim e^{ikz+i\gamma\log(k(r-z))}-\underbrace{\frac{\gamma}{k(r-z)}\frac{\Gamma(1+i\gamma)}{\Gamma(1-i\gamma)}}_{f(\theta)/r}e^{ikr-i\gamma\log(k(r-z))}+\ldots$$

$$f(\theta)=-\frac{\gamma}{k}\frac{\Gamma(1+i\gamma)}{\Gamma(1-i\gamma)}\frac{r}{r-z}=-\frac{\gamma}{2k}\frac{\Gamma(1+i\gamma)}{\Gamma(1-i\gamma)}\frac{1}{\sin^2(\theta/2)}$$

$$\frac{d\sigma}{d\Omega}=|f(\theta)|^2=\left(\frac{mA}{2\hbar^2k^2}\right)^2\frac{1}{\sin^4(\theta/2)}$$

Recovering the Hydrogen Atom:
$\Gamma(z)$ has poles at $z=0,-1,-2,\ldots$, the scattering amplitude therefore has poles when

$$1+i\gamma=-(n-1)\quad\Rightarrow\quad k=-i\frac{mA}{\hbar^2}\frac{1}{n},\qquad n=1,2,3,\ldots$$

(???)

$$E_n=\frac{\hbar^2k^2}{2m}=-\frac{mA^2}{2\hbar^2}\frac{1}{n^2}$$

Coulomb scattering by LL3.136

(тут большие формулы, в теории лучше сперва напишу их!)

$$\psi=\left[1+\frac{1}{ik^3r(1-\cos\theta)}\right]\exp\left\{ikz+\frac{i}{k}\ln[kr(1-\cos\theta)]\right\}+$$
$$+\frac{f(\theta)}{r}\exp\left\{ikr-\frac{i}{k}\ln(2kr)\right\}$$

$f(\theta)=-\frac{1}{2k^2\sin^2(\theta/2)}\frac{\Gamma(1+i/k)}{\Gamma(1-i/k)}\exp\left(-\frac{2i}{k}\ln\sin\frac{\theta}{2}\right)$

$$\exp\left(2i\delta_l^{\text{Кул}}\right)\frac{\Gamma(l+1+i/k)}{\Gamma(l+1-i/k)}$$

$$f(\theta)=\frac{1}{2ik}\sum_l(2l+1)\frac{\Gamma(l+1+i/k)}{\Gamma(l+1-i/k)}P_l(\cos\theta)$$

$$\psi_{\mathbf{k}}^{(+)} = \frac{1}{2k}\sum_{l=0}^{\infty} i^l(2l+1)e^{i\delta_l}R_{kl}(r)P_l\left(\frac{\mathbf{rk}}{kr}\right)$$

$$\psi_{\mathbf{k}}^{(-)} = \psi_{-\mathbf{k}}^{(+)}$$

Для кулонова поля отталкивания:

$$\psi_{\mathbf{k}}^{(+)} = e^{-\pi/2k}\Gamma\left(1+\frac{i}{k}\right)e^{i\mathbf{kr}}F\left(-\frac{i}{k},1,i(kr-\mathbf{kr})\right)$$
$$\psi_{\mathbf{k}}^{(-)} = e^{-\pi/2k}\Gamma\left(1-\frac{i}{k}\right)e^{i\mathbf{kr}}F\left(\frac{i}{k},1,-i(kr+\mathbf{kr})\right)$$

Для поля притяжения получаются: замена знака у k и r:

$$\psi_{\mathbf{k}}^{(+)} = e^{\pi/2k}\Gamma\left(1-\frac{i}{k}\right)e^{i\mathbf{kr}}F\left(\frac{i}{k},i(kr-\mathbf{kr})\right)$$
$$\psi_{\mathbf{k}}^{(-)} = e^{\pi/2k}\Gamma\left(1+\frac{i}{k}\right)e^{i\mathbf{kr}}F\left(-\frac{i}{k},1,-i(kr+\mathbf{kr})\right)$$

Special useful methods for scattering

Слабо связанное состояние в мелкой яме через диаграммы для амплитуды рассеяния заменой на дельта-потенциал

Мелкая яма - яма у которой $U_0 \ll \hbar^2/2ma^2$, a - радиус ямы. Размер связанного состояния в такой яме много больше ее радиуса, а энергия связи - много меньше глубины ямы U_0.

В $D = 1$ заменим потенциал на δ-функцию $V(x) = -U_0a\delta(x)$, получаем фурье-компоненту $V(q) = -U_0a = \text{const}$, считаем:

$$F(k,k') = -U_0a + U_0a\int \frac{F(k,q)}{\varepsilon - q^2/2m + i\delta}\frac{dq}{2\pi}.$$

(?? поч?)

$$F(k) = -U_0a - \frac{U_0a}{2\pi}F(k)\int\limits_{-\infty}^{+\infty}\frac{2mdq}{q^2-k^2-i\delta},$$

$$\text{res} \Rightarrow \qquad F^{-1} + (U_0a)^{-1} = -im/k \equiv -i\sqrt{m/2\varepsilon}, \qquad \varepsilon := k^2/(2m)$$

$$F(\varepsilon) = -\frac{U_0a\sqrt{2(\varepsilon+i\delta)/m}}{\sqrt{2(\varepsilon+i\delta)/m}+iU_0a}.$$

Имеем полюс при $\varepsilon_0 = -mU_0^2a^2/(2\hbar^2)$, это известный уровень 1D δ-ямы.

For 2D well we compute by a cut-off: $V(k) = -U_0a^2$,

$$F(\varepsilon) = -U_0a^2 + U_0a^2\frac{2m}{\hbar^2}\int F(\varepsilon)\frac{2\pi q}{q^2-k^2-i\delta}\frac{dq}{(2\pi)^2},$$

Интеграл $\int\limits_0^\infty \frac{dq^2}{q^2-k^2-i\delta}$ логарифмически расходится на ∞, но при $q \geqslant a^{-1}$ фурье-компонента $V(k)$ начинает быстро осциллировать (??? какая она??), и интеграл с $V(k)$ сходится. Обрежем "вручную" при $q \approx a^{-1}$:

$$\int\limits_0^{a^{-2}} \frac{dq^2}{q^2-k^2-i\delta} = \pi i + \ln \frac{1}{a^2\left(k^2+i\delta\right)}$$

$$F(\varepsilon) \approx -\frac{U_0 a^2}{1+\left(2ma^2U_0/4\pi\hbar^2\right)\ln\left(-k^2a^2\right)} = -\frac{U_0 a^2}{1+\left(mU_0a^2/2\pi\hbar^2\right)\ln\left(-\varepsilon ma^2/\hbar^2\right)}$$

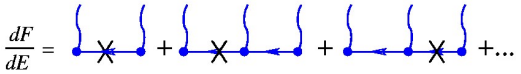
$$\varepsilon_0 \approx -\frac{\hbar^2}{ma^2}\exp\left(-\frac{2\pi\hbar^2}{ma^2U_0}\right)$$

Из-за неизвестного множителя порядка единицы, появившегося при обрезании перед логарифмом, ε_0 найден только по порядку величины.

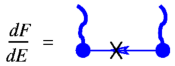
В $D > 2$ интеграл $\int\limits_0^{a^{-1}} \frac{q^{D-1}dq}{q^2-k^2-i\delta}$ остается конечным при $k \to 0$, поэтому для слабого потенциала $F(\varepsilon)$ не имеет полюсов при $|k| \ll a^{-1}$, т.е. нет связанного состояния.

Двумерное рассеяние методом логарифма и ренормгруппы

Дифференцируем  , (???)



$:= \frac{\partial}{\partial\varepsilon}G_0 = -\frac{1}{(\varepsilon-p^2/2m+i\delta)^2} = -G_0^2.$



$$\frac{\partial}{\partial\varepsilon}F_\varepsilon\left(k_1,k_2\right) = -\int \frac{F_\varepsilon\left(k_1,q\right)F_\varepsilon\left(q,k_2\right)}{\left(\varepsilon-q^2/2m+i\delta\right)^2}\frac{d^2q}{(2\pi)^2}$$

$F_\varepsilon\left(k_1,k_2\right)$ от k_1 и k_2 имеет характерный масштаб $k_{1,2} \approx a^{-1}$, поэтому при малых $|\varepsilon| \ll \varepsilon_a = \hbar^2/\left(ma^2\right)$ интеграл по q сходится в области, где зависимость F от q несущественна. Вычисляя интеграл (???), получаем

$$\frac{\partial}{\partial\varepsilon}F = -\frac{m}{2\pi\hbar^2\varepsilon}F^2.$$

$$F(\varepsilon) = \frac{2\pi\hbar^2}{m\ln\left((\varepsilon+i\delta)/\varepsilon_0\right)},$$

ε_0 - неизвестная константа. Точка ветвления логарифма при $\varepsilon = 0$ смещена в нижнюю полуплоскость. Константа ε_0 вещественна и отрицательна, поскольку при $\varepsilon < 0$ амплитуда F вещественна.

В итоге длня ε_0 в низкоэнергетической области, $|\varepsilon_0| \leqslant \varepsilon_a$, и полюс при $\varepsilon = \varepsilon_0$ имеет реальный смысл, ему соответствует дискретный уровень. В случае больших энергий полюс находится вне области энергий, где применимо сделанное приближение, и поэтому смысла не имеет.

On rigorous scattering theory

(пока не актуально, потом, может, изучу и создам пару разделов про это, очень много теории про неё.)

Об S матрице (!!!!!!!)

(главные ее свойства! супер важный параграф)

Математические свойства

В предыдущем разделе было показано, что для потенциалов $V(x)$, удовлетворяющих условию (2.2), операторы $H = H_0 + V$ и H_0 имеют один и тот же абсолютно непрерывный спектр. Среди множества операторов частичной изометрии в $\mathscr{H}$, устанавливающих унитарную эквивалентность между $H|_{\mathscr{H}_{\text{ac}}}$ и H_0, имеются два оператора $W_{\pm}$фундаментальной физической значимости. Они определяются как

$$W_{\pm} = \lim_{t \to \pm\infty} e^{iHt} e^{-itH_0}$$

где предел понимается в сильной операторной топологии, и называются волновыми операторами (или операторами Меллера). В общем случае волновые операторы существуют для оператора Шрёдингера $H = H_0 + V$ на $\mathbb{R}^n$ с потенциалом $V(\boldsymbol{q})$, достаточно быстро затухающим при $|\boldsymbol{q}| \to \infty$.

Для потенциалов $V(x)$, удовлетворяющих условию (2.2), пределы (2.31) существуют.

Волновые операторы используются для описания рассеяния квантовой частицы на потенциальном центре. А именно: для заданного $\varphi_- \in \mathscr{H}$, существует $\psi = W_-\varphi_- \in \mathscr{H}$, такое, что решение $\psi(t) = U(t)\psi$ нестационарного уравнения Шрёдингера с гамильтонианом H и начальным условием $\psi(0) = \psi$ при $t \to -\infty$ приближается к решению $\varphi_-(t) = U_0(t)\varphi_-$ нестационарного уравнения Шрёдингера со свободным гамильтонианом H_0 и начальным условием $\varphi_-(0) = \varphi_-$. Поскольку $\operatorname{Im} W_- = \operatorname{In} W_+$, существует $\varphi_+ \in \mathscr{H}$, такое, что $\psi = W_+\varphi_+$и решение $\psi(t)$ нестационарного уравнения Шрёдингера с гамильтонианом H и начальным условием $\psi(0) = \psi$ при $t \to \infty$ приближается к решению $\varphi_+(t) = U_0(t)\varphi_+$нестационарного уравнения Шрёдингера со свободным гамильтонианом H_0 и начальным условием $\varphi_+(0) = \varphi_+$. Переход от решения $\varphi_-(t)$ свободного уравнения Шрёдингера, описывающего движение квантовой частицы при $t = -\infty$, к решению $\varphi_+(t)$, описывающему ее движение при $t = \infty$, - результат рассеяния квантовой частицы потенциальным центром. Вся информация о рассеянии содержится в операторе рассеяния S (в физике также называемом S-матрицей), связывающем начальное и конечное условия φ_-и φ_+:

$$\varphi_+ = S\varphi_-.$$

Из (2.32) и $\psi = W_-\varphi_- = W_+\varphi_+$мгновенно получается, что

$$S = W_+^* W_-,$$

а из (2.32) - (2.34) получается, что оператор рассеяния S унитарен в $\mathscr{H}$ и коммутирует со свободным гамильтонианом H_0:

$$S^*S = SS^* = I \quad \text{и} \quad SH_0 = H_0S.$$

Это - набросок нестационарного подхода к теории рассеяния. В стационарном подходе к теории рассеяния волновые операторы $W_{\pm}$ и оператор рассеяния S строятся как

интегральные операторы в координатном представлении с интегральными ядрами, выраженными через особые решения стационарного уравнения Шрёдингера. Здесь мы представим эту конструкцию для одномерного оператора Шрёдингера, рассмотренного в предыдущем разделе.

$$S(k) = \begin{pmatrix} s_{11}(k) & s_{12}(k) \\ s_{21}(k) & s_{22}(k) \end{pmatrix}$$

называется матрицей рассеяния. Из (2.14) следует, что матрица рассеяния унитарна, $S^*(k)S(k) = I$, где I - единичная матрица 2×2, и удовлетворяет условию $\overline{S(k)} = S(-k)$. В частности, из унитарности матрицы рассеяния следует, что $T + R = 1$, что называется сохранением вероятности.

(???? хз????)

Имеется эквивалентность стационарного и нестационарного подходов к теории рассеяния:

Теорема 2.5. Для одномерного оператора Шрёдингера $H = H_0 + V$ с потенциалом $V(x)$, удовлетворяючии условию (2.2), волновые операторы существуют и могут быть заданы явными формулами

$$W_\pm = \mathscr{U}_\pm^* \mathscr{U}_0,$$

где $\mathscr{U}_\pm : \mathscr{H} \to \mathfrak{H}_0$ - интегральные операторы, задаваемые формулами

$$\mathscr{U}_\pm(\psi) = \frac{1}{\sqrt{2\pi}} \int\limits_{-\infty}^{\infty} \psi(x) \overline{U_\pm(x, \sqrt{\lambda})} dx$$

а оператором $\mathscr{U}_0 : \mathscr{H} \to \mathfrak{H}_0$ устанавливается унитарная эквивалентность между оператором H_0 в $\mathscr{H}$ и оператором умножения на λ в $\mathfrak{H}_0$,

$$\mathscr{U}_0(\psi) = \frac{1}{\sqrt{2\pi}} \int\limits_{-\infty}^{\infty} \psi(x) \begin{pmatrix} e^{-i\sqrt{\lambda}x} \\ e^{i\sqrt{\lambda}x} \end{pmatrix} dx.$$

Оператор рассеяния S в $\mathscr{H}$ и оператор умножения на матрицу рассеяния $S(\sqrt{\lambda})$ на $\mathfrak{H}_0$ унитарно эквивалентны:

$$S = \mathscr{U}_0^* S(\sqrt{\lambda}) \mathscr{U}_0.$$

Следствие 2.6. Волновые операторы удовлетворяют соотношениям ортогональности и полноты $W_\pm^* W_\pm = I$ и $W_\pm W_\pm^* = I - P$.

Уравннеие Липпмана-Швингера и операторы по Тахтаджаяну (???)

В терминах операторов $\mathscr{U}_\pm : \mathscr{H} \to \mathscr{H}$, $\mathscr{U}_\pm(\psi)(\boldsymbol{k}) := (2\pi)^{-\frac{3}{2}} \int\limits_{\mathbb{R}^3} \psi(\boldsymbol{x}) u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k}) d^3\boldsymbol{x}$, соотношения полноты и ортогональности принимают вид

$$\mathscr{U}_\pm^* \mathscr{U}_\pm = I - P, \quad \mathscr{U}_\pm \mathscr{U}_\pm^* = I,$$

где P - ортогональная проекция на инвариантное подпространство для оператора H, ассоциированное с чисто точечным спектром. Теперь пусть

$$W_\pm = \mathscr{U}_\pm^* \mathscr{U}_0$$

где $\mathscr{U}_0 = \mathscr{F}^{-1}$ - обратное преобразование Фурье.

(???? дочитаю!)

О других граничных условиях (????)

Предположим, что потенциал $V(x)$ удовлетворяет условию

$$\int\limits_{-\infty}^{0}(1+|x|)\left|V(x)-c^2\right|dx<\infty \quad \text{и} \quad \int\limits_{0}^{\infty}(1+|x|)|V(x)|dx<\infty$$

Абсолютно непрерывный спектр оператора Шрёдингера H заполняет $[0,\infty)$. При $0<\lambda=k^2<c^2$ спектр прост, а

$$u(x,\lambda)=\frac{1}{a(k)}f_2(x,k), \quad 0<k<c,$$

- это аналоги нормированных собственных функций непрерывного спектра. При $\lambda=k^2>c^2$ спектр имеет кратность два, и

$$u_1(x,\lambda)=\frac{1}{a(k)}f_2(x,k), \quad u_2(x,k)=\frac{k_1}{ka(k)}f_1(x,k), \quad k>c,$$

- это аналоги нормированных собственных функций непрерывного спектра.

Допустим, что потенциал $V(x)$ растет при $x\to-\infty$ и затухает при $x\to\infty$:

$$\int\limits_{a}^{\infty}(1+|x|)|V(x)|dx<\infty \qquad \forall a,$$

и что существует $x_0\in\mathbb{R}$, такое, что спектр задачи Штурма - Лиувилля

$$-y''+V(x)y=\lambda y, \quad -\infty<x\leqslant x_0, \quad \text{и} \quad y'(x_0)=0$$

ограничен снизу и дискретен. Последнее условие - это конкретная формулировка свойства $\lim_{x\to-\infty}V(x)=\infty$.

Тогда для любого вещественного k существует решение $f(x,k)$ дифференциального уравнения (2.43) с асимптотикой

$$f(x,k)=e^{ikx}+o(1) \quad \text{при} \quad x\to\infty$$

и существует функция $s(k)$, такая, что

$$u(x,k)=f(x,-k)+s(k)f(x,k)$$

интегрируемо с квадратом на промежутке $(-\infty,a)$ для любого вещественного a. Оператор Шрёдингера H имеет простой абсолютно непрерывный спектр $[0,\infty)$ и дискретный спектр, состоящий из конечного числа отрицательных собственных значений.

21.1.5 Details of typical QM methods for simple atoms

(там ЛЛ3, много всякого есть, что хочется сказать, но точно не нужно знать в рамках минимального понимания атомов)

Другие общие свойства атома водорода

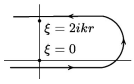
Вывод непрерывного спектра в центральном поле в сферических координатах

(!?!?!?? это сесть и продумать заново нужно!!!)

$$n = -\frac{i}{\sqrt{2E}} = -\frac{i}{k}, \quad \rho = 2ikr$$

$$R_{kl} = \frac{C_{kl}}{(2l+1)!}(2kr)^l e^{-ikr} F\left(\frac{i}{k} + l + 1, 2l+2, 2ikr\right),$$

$$R_{kl} = C_{kl}(2kr)^l e^{-ikr} \cdot \frac{1}{2\pi i} \oint e^{\xi} \left(1 - \frac{2ikr}{\xi}\right)^{-\frac{i}{k}-l-1} \xi^{-2l-2} d\xi$$



$$\xi \equiv 2ikr(t + 1/2)$$

$$R_{kl} = C_{kl}\frac{(-2kr)^{-l-1}}{2\pi} \oint e^{2ikrt} \left(t + \frac{1}{2}\right)^{\frac{i}{k}-l-1} \left(t - \frac{1}{2}\right)^{-\frac{i}{k}-l-1} dt$$

$$\approx \frac{2}{r} \sin\left(kr + \frac{1}{k}\ln 2kr - \frac{\pi}{2}l + \delta_l\right),$$

$$\delta_l = \arg\Gamma\left(l + 1 - \frac{i}{k}\right)$$

$$C_{kl} = \left[\frac{8\pi k}{1 - e^{-2\pi/k}}\right]^{1/2} \prod_{s=1}^{l} \sqrt{s^2 + \frac{1}{k^2}}$$

(словами напишу, что за математика тут)

Водород в параболических координатах по ЛЛ3.37

(тут суть и преимущества)

Каждое стационарное состояние дискретного спектра определяется в параболических координатах «тремя целыми параболическими квантовыми числами» n_1 и n_2 и m. Для числа n («главное квантовое число») имеем из (37.9) и (37.12)

$$n = n_1 + n_2 + |m| + 1.$$

Для уровней энергии получается, разумеется, прежний результат (36.9).

При заданном n число $|m|$ пробегает n значений от 0 до $n-1$. При фиксированных n и $|m|$ число n_1 пробегает $n - |m|$ значений от 0 до $n - |m| - 1$; также при заданном $|m|$ можно еще выбрать функции с $m = \pm|m|$, поэтому всего для данного n имеется уровней (???)

$$2\sum_{m=1}^{n-1}(n-m) + (n-0) = n^2$$

$$x = \sqrt{\xi\eta}\cos\varphi, \quad y = \sqrt{\xi\eta}\sin\varphi, \quad z = \frac{1}{2}(\xi - \eta),$$

$$r = \sqrt{x^2 + y^2 + z^2} = \frac{1}{2}(\xi + \eta)$$

$$\xi = r + z, \quad \eta = r - z, \quad \varphi = \operatorname{arctg}\frac{y}{x};$$

$$dl^2 = \frac{\xi+\eta}{4\xi}d\xi^2 + \frac{\xi+\eta}{4\eta}d\eta^2 + \xi\eta d\varphi^2, \qquad dV = \frac{1}{4}(\xi+\eta)d\xi d\eta d\varphi.$$

$$\Delta = \frac{4}{\xi+\eta}\left[\frac{\partial}{\partial\xi}\left(\xi\frac{\partial}{\partial\xi}\right) + \frac{\partial}{\partial\eta}\left(\eta\frac{\partial}{\partial\eta}\right)\right] + \frac{1}{\xi\eta}\frac{\partial^2}{\partial\varphi^2}.$$

$$\int |\psi_{n_1n_2m}|^2\, dV = \tfrac{1}{4}\int_0^\infty\int_0^\infty\int_0^{2\pi} |\psi_{n_1n_2m}|^2\,(\xi+\eta)d\varphi d\xi d\eta \equiv 1,$$

$$\psi_{n_1n_2m} = \frac{\sqrt{2}}{n^2} f_{n_1m}\left(\frac{\xi}{n}\right) f_{n_2m}\left(\frac{\eta}{n}\right)\frac{e^{im\varphi}}{\sqrt{2\pi}}$$

$$f_{pm}(\rho) := \frac{1}{|m|!}\sqrt{\frac{(p+|m|)!}{p!}}F(-p,|m|+1,\rho)e^{-\rho/2}\rho^{|m|/2}.$$

Волновые функции в параболических координатах, в противоположность волновым функциям в сферических координатах, не симметричны относительно плоскости $z=0$. При $n_1 > n_2$ вероятность нахождения частицы на стороне $z>0$ больше, чем на стороне $z<0$, а при $n_1 < n_2$ - наоборот (??? додумаю??).

(где используется это вообще???)

Поляризуемость атома водорода в основном состоянии

(см. ЛЛ3 стр 354, задача есть на это, укажу на 1/4 страницы идею и основные формулы, а то не очевидно)

О других применениях модели водорода

(буду узнавать - буду дописывать)

О падении на центр по ЛЛ3 пар 35 (??)

$$R'' + \frac{2}{r}R' + \frac{\gamma}{r^2}R = 0 \qquad \gamma := \frac{2m\beta}{\hbar^2} - l(l+1)$$

(тут словами переходы укажу)

$$R = \text{ const } \cdot \frac{1}{\sqrt{r}}\cos\left(\sqrt{\gamma - \frac{1}{4}}\ln\frac{r}{r_0} + \text{ const }\right).$$

«Критическое» поле $U_{\text{кр}}$, при котором становится возможным падение частицы на центр, соответствует значению $\gamma = 1/4$. Наименьшее значение коэффициента при $-1/r^2$ получается, когда $l=0$, т. е.

$$U_{\text{кр}} = -\frac{\hbar^2}{8mr^2}$$

(тут еще качественный анализ, додумаю его!)

Дискретный спектр в центральном поле в сферических координатах

(суть ЛЛ3 пар 36. не понял пока, что тут особенного???)

$$\frac{d^2R}{dr^2} + \frac{2}{r}\frac{dR}{dr} - \frac{l(l+1)}{r^2}R + \frac{2m}{\hbar^2}\left(E + \frac{\alpha}{r}\right)R = 0$$

$$\frac{d^2R}{dr^2}+\frac{2}{r}\frac{dR}{dr}-\frac{l(l+1)}{r^2}R+2\left(E+\frac{1}{r}\right)R=0$$

$$n:=\frac{1}{\sqrt{-2E}},\quad \rho:=\frac{2r}{n}$$

$$E=-\frac{m\alpha^2}{2\hbar^2n^2}$$

Волновые функции стационарных состояний определяются формулами (36.5), (36.7).

Вырожденная гипергеометрическая функция с целыми значениями обоих параметров совпадает с обобщенными полиномами Лагерра (с точностью до множителя):

$$R_{nl}=\ \text{const}\ \cdot\rho^l e^{-\rho/2}L_{n+1}^{2l+1}(\rho).$$

$\int\limits_0^\infty R_{nl}^2r^2dr=1.$

$$R_{nl}=-\frac{2}{n^2}\sqrt{\frac{(n-l-1)!}{[(n+l)!]^3}}e^{-r/n}\left(\frac{2r}{n}\right)^l L_{n+l}^{2l+1}\left(\frac{2r}{n}\right)=$$

$$=\frac{2}{n^{l+2}(2l+1)!}\sqrt{\frac{(n+l)!}{(n-l-1)!}}(2r)^l e^{-r/n}F\left(-n+l+1,2l+2,\frac{2r}{n}\right)$$

21.2 Typical numerical methods

21.2.1 On density functional theory

(нужно будет - изучу, готов уже)

Basic theory of DFT

Hohenberg-Kohn theorem

Kohn-Sham equations

The transformation of the Hohenberg-Kohn theorem from a curiosity into a useful tool takes place via the Kohn-Sham (KS) approach and via a simple approximation known as Local-Density Approximation, LDA (1965). Since the Hohenberg-Kohn theorem holds irrespective of the electron-electron repulsion U, we may introduce an auxiliary system of non-interacting electrons having the same density as the true system:

$$\rho(\mathbf{r})=\sum_i|\psi_i(\mathbf{r})|^2$$

where the ψ_i (Kohn-Sham orbitals) are single-electron wavefunctions, to be determined by the condition that $E[\rho]$ is minimized, under orthonormality constraints $\langle\psi_i|\psi_j\rangle=\delta_{ij}$. We still do not know the functional to be minimized, but let us write it as a sum of known terms, large and easy to compute, and the rest:

$$E=T_s[\rho]+E_H[\rho]+\int\rho(\mathbf{r})v(\mathbf{r})d^3r+E_{xc}[\rho]$$

where T_s is the kinetic energy of the non-interacting electrons:

$$T_s = -\frac{\hbar^2}{2m}\sum_i \int \psi_i^*(\mathbf{r})\nabla^2\psi_i(\mathbf{r})d^3r$$

(note that in general $T_s \neq \langle\Psi|T|\Psi\rangle$), E_H is the electrostatic (Hartree) energy:

$$E_H[\rho] = \frac{q_e^2}{2}\int \frac{\rho(\mathbf{r})\rho\left(\mathbf{r}'\right)}{|\mathbf{r}-\mathbf{r}'|}d^3r d^3r'$$

$$\left(-\frac{\hbar^2\nabla^2}{2m} + V_{KS}(\mathbf{r})\right)\psi_i(\mathbf{r}) = \epsilon_i\psi_i(\mathbf{r})$$

where the effective, or Kohn-Sham potential, $V_{KS} = v(\mathbf{r}) + V_H(\mathbf{r}) + V_{xc}(\mathbf{r})$, is a functional of the charge density:

$$V_H(\mathbf{r}) = q_e^2\int \frac{\rho\left(\mathbf{r}'\right)}{|\mathbf{r}-\mathbf{r}'|}d^3r', \quad V_{xc}(\mathbf{r}) = \frac{\delta E_{xc}[\rho]}{\delta\rho(\mathbf{r})}$$

KS equations are reminiscent of Hartree-Fock equations, Eq.(6.19), with the exchange potential replaced by the exchange-correlation potential. Note that the latter is a local potential, while the exchange potential is non-local. The energy can be rewritten using the sum over KS eigenvalues ϵ_i. It is straightforward to prove that the energy functional can be written as

$$E = \sum_i \epsilon_i - E_H[\rho] + E_{xc} - \int \rho(\mathbf{r})V_{xc}(\mathbf{r})d^3r$$

Approximated functionals

Not much progress seems to be done yet: E_{xc} is still an unknown functional, and so is V_{xc}. There is however a long tradition, pre-dating DFT, of using homogeneous electron gas results to approximate similar functions. The most famous historical method is Slater's local approximation to the exchange potential:

$$V_x(\mathbf{r}) \simeq -\frac{3q_e^2}{2\pi}\left(3\pi^2\rho(\mathbf{r})\right)^{(1/3)}$$

Kohn and Sham extend and improve upon such ideas by introducing the local density approximation (LDA): they re-write the the energy functional as

$$E_{xc} = \int \rho(\mathbf{r})e_{xc}(\mathbf{r})d^3r$$

Structure of a DFT code

The basic [3] algorithm for the solution of the DFT problem consists of a self-consistent loop in which, at iteration n:

1. the KS potential $V_{KS}^{(n)}$ is computed from $\rho^{(n)}$.
2. KS equations are solved, yielding KS orbitals $\psi_i^{(n)}$;
3. the output charge density $\rho_{\text{out}}^{(n)}$ is calculated by summing the square of all occupied KS orbitals: $\rho_{\text{out}}^{(n)} = \sum_i \left|\psi_i^{(n)}\right|^2$;
4. the new charge density $\rho^{(n+1)}$ is computed from a linear combination of previous input $\rho^{(n)}$ and output $\rho_{\text{out}}^{(n)}$ charge densities.

(see a special note about it for now)

О матрице плотности (!?!??!??!)

(пересмотрю Филиппова потом, дополню им этот раздел! важный раздел для приложений!!!)

Суть

$$\langle \hat{O} \rangle = \sum_{\alpha} p_\alpha \langle \alpha | \hat{O} | \alpha \rangle = \mathrm{Tr}\left(|\alpha\rangle p_\alpha \langle \alpha | \hat{O} \right) \equiv \mathrm{Tr}(\hat{\rho}\hat{O}),$$

$$\hat{\rho} = \sum_{\alpha} p_\alpha |\alpha\rangle\langle\alpha|$$

$$\bar{f} = \int \left[\hat{f} \rho\left(x, x'\right) \right]_{x'=x} dx$$

(????)

$$\rho\left(x, x'\right) = \int \Psi(q, x) \Psi^*\left(q, x'\right) dq$$

Матрица плотности имеет свойства:
$\rho^*\left(x, x'\right) = \rho\left(x', x\right)$.

$$\mathrm{Tr}\,\hat{\rho} = \sum_{\alpha\beta} \psi_{\alpha\beta} \psi^*_{\alpha\beta} = 1$$

положительно определенность

$$\frac{\partial \hat{\rho}}{\partial t} = \frac{i}{\hbar} [\hat{\rho}(t), \hat{H}]$$

Введя этот объект мы видим, что из него можно с помощью *частичного следа* получать объект, описывающий подсистемы:

$$\hat{\rho}_A = \mathrm{Tr}_B\, \hat{\rho}_{AB} \leftrightarrow \left(\hat{\rho}_A\right)_{\alpha\alpha'} = \sum_{\beta} \left(\hat{\rho}_{AB}\right)_{\alpha\beta,\alpha'\beta}$$

как кстати обратно к волновой функции прийти?
на практике мы используем

$$\hat{\rho} = \sum_n p_n |n\rangle\langle n|, \quad 0 \le p_n \le 1, \quad \sum_n p_n = 1$$

Для любых двухуровневых систем она имеет такой вид: $\hat{\rho} = \frac{1}{2}(\hat{\mathbb{I}} + \hat{\boldsymbol{\sigma}} \cdot \boldsymbol{n})$

Пусть $\mathcal{H} = \mathcal{H}_A \otimes \mathcal{H}_B$, занумеруем базисные элементы $\{|\alpha\rangle\} \in \mathcal{H}_A$ и $\{|\beta\rangle\} \in \mathcal{H}_B$, преобразуем наблюдаемую величину для системы A оператор дает δ-функцию и в итоге мы приходим к этим переходам.

(потом еще подумаю про это):

$$\langle\psi_{AB}|\hat{O}_A|\psi_{AB}\rangle = \sum_{\alpha\beta,\alpha'\beta'} \langle\psi_{AB}|\alpha'_A,\beta'_B\rangle \left\langle \alpha'_A,\beta'_B \left| \hat{O}_A \right| \alpha_A,\beta_B \right\rangle \langle\alpha_A,\beta_B|\psi_{AB}\rangle =$$
$$= \sum_{\alpha\alpha'} \underbrace{\sum_{\beta} \psi_{\alpha\beta}\psi_{\alpha^*\beta}}_{\equiv(\hat{\rho}_A)_{\alpha\alpha'}} \left(\hat{O}_A\right)_{\alpha'\alpha} \equiv \mathrm{Tr}(\hat{\rho}_A\hat{O}_A)$$

Тут $(\hat{\rho}_A)_{\alpha\alpha'} = \sum_\beta \psi_{\alpha\beta}\psi^*_{\alpha'\beta}$

появление матрицы плотности

как конкретно она появляется?

Другое важное о матрице плотности

(там много очень всего, так что точно что-то еще полезно будет указать.)

Typical parameters

$$\phi(\mathbf{r}) = \frac{q}{r} + \frac{\mathbf{d}\cdot\mathbf{r}}{r^3} + \frac{1}{6}\sum_{ij}\frac{Q_{ij}T_{ij}}{r^5} + ..., \quad T_{ij} = 3x_ix_j - r^2\delta_{ij}$$

$$q = \int d\mathbf{r}\rho(\mathbf{r}), \quad \mathbf{d} = \int d\mathbf{r}\rho(\mathbf{r})\mathbf{r}, \quad Q_{ij} = \int d\mathbf{r}\rho(\mathbf{r})T_{ij}$$

$$\mathbf{A}(\mathbf{r}) = \frac{\boldsymbol{\mu}\times\mathbf{r}}{r^3}, \quad \boldsymbol{\mu} = \frac{1}{2}\int d\mathbf{r}\mathbf{r}\times\mathbf{J}(\mathbf{r})$$

(потом напишу, там много особенностей ее)

(потом напишу, там много особенностей его, в КТП еще подробнее про него, тут лишь результаты напишу)

(тут только +- общефиз, а также типичный квантмех про это)

21.3.3 The Meaning and Main Interpretations of Quantum Mechanics (???)

(пока этим не занимаюсь, это очень большие вопросы, при этом многое можно сделать, абсолютно плохо это понимая.)

В чем же суть квантовой механики?

(потом пропишу свой ответ)

Что такое квантовые флуктуации?

(они мб важные, но пока так я и мало въехал в них)

О казуальной неопределенности (??)

и все про неопределенность и ее влияние на все

казуальная - просто умное слово, по факту типичная неубираемая неопределенность, которая нам уже известна.

Откуда могут быть вообще потенциалы и стенки (???)

Если частица описывается волновой функцией, то как может быть так, что есть какой-то центр, который создает центральный потенциал? как может быть стенка? ведь там же тоже частицы, которые тоже описываются волновой функцией.

Как по волновой функции восстановить потенциал?

Как на квантовом уровне устроен мир?

(потом пропишу свой ответ)

О переходе от частицам к волнам (!??!??!?!?!?!)

(потом пропишу свой ответ. Пока отвечаю на это в рамках типичной квантовой теории поля, и такой ответ мне совершенно не нравится.)

наглядный переход от частицы к волне

снова этим же вопросом задамся и найду ответ.
???

О квантовых полях и квантовой механике (???)

О связи квантовой механики и классической

О функционале достоверности Киселева (??)

(?? пока только тут про него, скоро допишу!!!)

О переходе в классику усреднением, теореме вириала, теореме Эренфеста

(???? подумаю про это позже еще??? пока для меня это просто общие свойства, ничего применяющегося. так что потом это додумаю.)

По теореме Эренфеста динамика средней величины имеет вид:

$$\frac{d}{dt}\langle A\rangle = \frac{1}{i\hbar}\langle [A,H]\rangle + \left\langle \frac{\partial A}{\partial t}\right\rangle$$

В частности:

$$\frac{d}{dt}\langle q\rangle = \frac{1}{m}\langle p\rangle$$
$$\frac{d}{dt}\langle p\rangle = -\left\langle \frac{\partial U}{\partial q}\right\rangle$$

Квантовая *теорема вириала*:

$$-2\langle \hat{T}\rangle + \left\langle \boldsymbol{r}\frac{\partial V}{\partial \boldsymbol{r}}\right\rangle = 0$$

(??? строчка обоснований!)

$$V(x)\sim x^{\nu} \qquad \Rightarrow \qquad 2\bar{T} = \nu\bar{V}.$$

Proof by Tong:
$V(\mathbf{x}) = Ar^n$
$V(\lambda\mathbf{x}) = \lambda^n V(\mathbf{x})$

$$E_0 = \int d^d\mathbf{x}\frac{\hbar^2}{2m}\left|\nabla\psi_0(\mathbf{x})\right|^2 + V(\mathbf{x})\left|\psi_0(\mathbf{x})\right|^2 \equiv \langle T\rangle_0 + \langle V\rangle_0$$

$\psi(\mathbf{x}) = \alpha^{d/2}\psi_0(\alpha\mathbf{x})$,

$$E(\alpha) = \alpha^2\langle T\rangle_0 + \alpha^{-n}\langle V\rangle_0$$

$$\frac{dE}{d\alpha} = 2\alpha\langle T\rangle_0 - n\alpha^{-n+1}\langle V\rangle_0 = 0$$

$\alpha = 1$

$$2\langle T\rangle_0 = n\langle V\rangle_0$$

О связи квантовой механики и КТП (????)

(пока тут, мб подподглаву создам потом)

21.3.4 Constants of quantum mechanics

fine structure constant $\frac{e^2}{\hbar c} = \alpha_{\text{em}}$

(?? experiments?)

Plank's constant

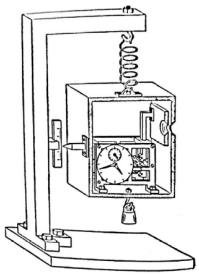
(?? experiments?)

21.3.5 Other important real and thought experiments

(I'll add them later, there are a lot of articles)

Einstein's light box

(см. нпр эксперименты Эйнштейна https://en.wikipedia.org/wiki/Einstein%27s_thought_experiments. потом разберу разные, напишу самые многое иллюстрирующие!)



On Einstain-Podolski-Roren thought experiment

(EPR, later I'll write)

21.3.6 Uncertainty Relation (????)

(в конце, потому что да, оно основное в квантмехе, но так прямо знать его не приходилось нужным.)

О соотношении неопределенностей

Основные формулы

Если наблюдаемая $A, B, C : [A, B] = i\hbar C$, то

$$\Delta A \Delta B \geq \frac{\hbar}{2}|\langle C \rangle|$$

В частности

$$\Delta E \Delta t \geq \frac{\hbar}{2}$$

(??? смысл выше формулы нужно пояснить!!!)
(!!! больше частных случаев???)
Доказывается соотношение неопределенностей из

$$(\Delta F)^2 := \langle \Psi | (\hat{F} - \overline{F})^2 | \Psi \rangle$$

$\overline{A} = \langle \psi | \hat{A} | \psi \rangle, \overline{B} = \langle \psi | \hat{B} | \psi \rangle$.

$$\hat{a} = \hat{A} - \overline{A}, \quad \hat{b} = \hat{B} - \overline{B}$$

Коммутатор операторов $[\hat{A}, \hat{B}] = i\hbar\hat{C}$ после сдвига не изменится:

$$[\hat{a}, \hat{b}] = i\hbar\hat{C}$$

Средние малых операторов по построению равны нулю: $\langle i|\hat{a}|i\rangle = 0, \langle i|\hat{b}|i\rangle = 0$, а дисперсия такая же, как и у больших.

$$|\Phi\rangle = (\hat{a} - i\xi\hat{b})|\Psi\rangle$$

Из $\langle \Psi | (\hat{a} - i\xi\hat{b})^\dagger (\hat{a} - i\xi\hat{b}) | \Psi \rangle \geq 0$ получаем:

$$\Delta A \Delta B \geq \frac{\hbar}{2}|\langle C \rangle|$$

Если у нас

$$[\hat{q}, \hat{p}] = i\hbar,$$

то имеем $\hat{C} = 1$, так что:

$$\Delta q \Delta p \geq \frac{\hbar}{2}$$

Обобщенное соотношение неопределенности Гейзенберга (Г. Вейль). Пусть $A, B \in \mathscr{A}$ и пусть $M = P_\psi$ - чистое состояние, такое, что $\psi \in D(A) \cap D(B) \boldsymbol{u} A\psi, B\psi \in D(A) \cap D(B)$. Тогда

$$\sigma_M^2(A)\sigma_M^2(B) \geqslant \frac{1}{4}\langle i[A, B]|M\rangle^2.$$

Такое же неравенство выполняется для любого $M \in \mathscr{S}$, где по определению $\langle i[A, B]||M\rangle = \lim_{n\to\infty} \langle i\left[A_n, B_n\right]|M\rangle$.

(строчка, как соотн неопр связано с УШ?)

(строчка, относится ли оно к измерениям или без измерений тоже оно как-то проявляется???)

(с ним столько проблем, что отдельный раздел сделал про него. вообще не понимаю его)

О применениях соотношения неопределенностей (!!!)

(очень часто оно применяется, тут укажу!!! под рукой всегда будет!!)

21.3.7 Other features of basics of QM

О функциях Йоста

(?? все то же самое, только называется сложно?)
Пусть

$$\sigma(x) = \int\limits_x^\infty |V(s)|ds \quad \text{и} \quad \sigma_1(x) = \int\limits_x^\infty \sigma(s)ds.$$

Поскольку $V \in L^1(\mathbb{R})$, имеем $\lim_{x\to\infty} \sigma(x) = 0$ и, используя условие (2.2) и теорему Фубини, получаем

$$\sigma_1(x) = \int\limits_x^\infty \int\limits_s^\infty |V(t)|dtds = \int\limits_x^\infty \int\limits_x^t |V(t)|dsdt = \int\limits_x^\infty (t-x)|V(t)|dt < \infty,$$

так что $\sigma \in L^1(x,\infty)$ для любого $x \in \mathbb{R}$ и $\lim_{x\to\infty} \sigma_1(x) = 0$. Аналогично функции

$$\tilde\sigma(x) = \int\limits_{-\infty}^x |V(s)|ds \quad \text{и} \quad \bar\sigma_1(x) = \int\limits_{-\infty}^x \bar\sigma(s)ds$$

удовлетворяют условию $\lim_{x\to-\infty} \tilde\sigma(x) = \lim_{x\to-\infty} \bar\sigma_1(x) = 0$. Условие (2.2) гарантирует, что для вещественных k дифференциальное уравнение (2.1) имеет решения $f_1(x,k)$ и $f_2(x,k)$, однозначно определяемые следующими асимптотиками:

$$\begin{aligned} f_1(x,k) &= e^{ikx} + o(1) \quad &&\text{при} \quad x \to \infty, \\ f_2(x,k) &= e^{-ikx} + o(1) \quad &&\text{при} \quad x \to -\infty. \end{aligned}$$

Они называются решенияии Йоста и играют фундаментальную роль в теории одномерного уравнения Шрёдингера.

Теорема 2.1. Для вечественных k дифференциальное уравнение (2.1) имеет решения $f_1(x,k)$ и $f_2(x,k)$, удовлетворяючие следующим свойствам.

(i) Оценки для $k \in \mathbb{R}$:

$$\begin{aligned} \left|e^{-ikx} f_1(x,k) - 1\right| &\leqslant \left(\sigma_1(x) - \sigma_1\left(x + \tfrac{1}{|k|}\right)\right) e^{\sigma_1(x)}, \\ \left|e^{ikx} f_2(x,k) - 1\right| &\leqslant \left(\tilde\sigma_1(x) - \tilde\sigma_1\left(x - \tfrac{1}{|k|}\right)\right) e^{\bar\sigma_1(x)}. \end{aligned}$$

(ii) Асимптотики при $|x| \to \infty$:

$$\begin{aligned} \lim_{x\to\infty} e^{-ikx} f_1(x,k) = 1, \quad \lim_{x\to\infty} e^{-ikx} f_1'(x,k) = ik, \\ \lim_{x\to-\infty} e^{ikx} f_2(x,k) = 1, \quad \lim_{x\to-\infty} e^{ikx} f_2'(x,k) = -ik. \end{aligned}$$

(iii) Аналитичность: функции $f_1(x,k)$ и $f_2(x,k)$ допускают аналитическое продолжение в верхнюю полуплоскость $\operatorname{Im} k > 0$ и являются непрерывными в области $\operatorname{Im} k \geqslant 0$ равномерно по x на компактных подмножествах $\mathbb{R}$.

(iv) Свойство сопряжения:

$$\overline{f_1(x,k)} = f_1(x,-\bar k), \quad \overline{f_2(x,k)} = f_2(x,-\bar k), \quad \operatorname{Im} k \geqslant 0.$$

(v) Оценки в части (i) выполняются для $\operatorname{Im} k \geqslant 0$. Для $k \neq 0$

$$\left|f_1(x,k) - e^{ikx}\right| \leqslant \frac{e^{-\operatorname{Im} kx}}{|k|}\sigma(x)e^{\frac{1}{|k|}\sigma(x)},$$
$$\left|f_2(x,k) - e^{-ikx}\right| \leqslant \frac{e^{\operatorname{Im} kx}}{|k|}\tilde{\sigma}(x)e^{\frac{1}{|k|}\tilde{\sigma}(x)}.$$

(vi) Асимптотика при $|k| \to \infty, \operatorname{Im} k \geqslant 0$:

$$e^{-ikx}f_1(x,k) = 1 + O\left(|k|^{-1}\right), \quad e^{ikx}f_2(x,k) = 1 + O\left(|k|^{-1}\right).$$

Следствие 2.2. Для $\operatorname{Im} k \geqslant 0 u k \neq 0$.

$$\lim_{x\to\infty} e^{-ikx}\left(\dot{f}_1(x,k) - ixf_1(x,k)\right) = 0, \quad \lim_{x\to-\infty} e^{ikx}\left(\dot{f}_2(x,k) + ixf_2(x,k)\right) = 0,$$

где точка обозначает частную производную по k.

Предложение 2.1. функчии $a(k)$ в верхней полуплоскости $\operatorname{Im} k > 0$ лишь конечное число чисто мнимых простых нулей $k_l = i\varkappa_l, \boldsymbol{u}$

$$\dot{a}\left(i\varkappa_l\right) = -ic_l \left\|f_2\left(\cdot, i\varkappa_l\right)\right\|^2, \quad l = 1, ..., n$$

где точка обозначает производную, $f_1\left(x, i\varkappa_l\right) = c_l f_2\left(x, i\varkappa_l\right)$. Функчия $1/a(k)$ ограничена в некоторой окрестности точки $k = 0$ в обласmu $\operatorname{Im} k \geqslant 0$.

Собственные значения оператора Шрёдингера H просты. Действительно, функция $f_1(x, i\varkappa)$ - решение дифференциального уравнения (2.1) для $\lambda = -\varkappa^2 < 0$, экспоненциально затухающее при $x \to \infty$. Поскольку вронскиан любых двух решений (2.1) постоянен, другое решение (2.1), линейно независимое с $f_1(x, i\varkappa)$, экспоненциально возрастает при $x \to \infty$. Таким образом, любое экспоненциально затухающее при $x \to \infty$ решение (2.1) для $\lambda = -\varkappa^2$ отличается от $f_1(x, i\varkappa)$ на постоянный множитель. В частности, это доказывает, что точечный спектр H прост. Этот результат следует также из простоты нулей функции $a(k)$ и теоремы о разложении по собственным функциям, которую мы докажем в следующем разделе.

О разложении по собственным функциям (????)

Построим ядро резольвенты для одномерного оператора Шрёдингера H и покажем, что оно самосопряжено и имеет область определения, состоящую из функций $\psi \in L^2(\mathbb{R})$, дважды дифференцируемых на $\mathbb{R}$ и таких, что $-\psi'' + V(x)\psi \in L^2(\mathbb{R})$. С помощью комплексного интегрирования мы выведем теорему о разложении собственных функций для оператора H, обобщающую соответсвующий результат для оператора H_0 свободной квантовой частицы, рассмотренный в разделе 2.2.3 главы 2.

Для $\lambda \in \mathbb{C}\backslash[0,\infty)$ пусть

$$R_\lambda(x,y) = \begin{cases} -\frac{f_1(x,k)f_2(y,k)}{2ika(k)}, & \text{если } x \geqslant y, \\ -\frac{f_1(y,k)f_2(x,k)}{2ika(k)}, & \text{если } x \leqslant y, \end{cases}$$

где ветвь функции $k = \sqrt{\lambda}$ на $\mathbb{C}\backslash[0,\infty)$ определяется условием, что $\operatorname{Im} k > 0$. При фиксированных x и y функция $R_\lambda(x,y)$ мероморфна на $\mathbb{C}\backslash[0,\infty)$ и имеет простые полюса в точках $\lambda_l = -\varkappa_l^2, l = 1, ..., n$.

Лемма 2.1. Оператор H самосопряжен и $R_\lambda = (H - \lambda I)^{-1}$ при $\lambda \in$ $\in \mathbb{C}\backslash\left\{[0,\infty) \cup \{\lambda_1, ..., \lambda_n\}\right\}$, где I-тождественный оператор в $L^2(\mathbb{R})$.

Теорема 2.3. Оператор $\mathscr{U}$ продолжается до оператора частичной изометрии $\mathscr{U} : \mathscr{H} \to \mathfrak{H}_0$

$$\mathscr{U}^*\mathscr{U} = I - P \quad \text{и} \quad \mathscr{U}\mathscr{U}^* = I_0,$$

и устанавливает изоморфизм $(I-P)\mathscr{H} \simeq \mathfrak{H}_0$. Здесь I и I_0 - соответственно тождественные операторы в $\mathscr{H}$ и $\mathfrak{H}_0$. Для спектра соответствующего оператора Шрёдингера H имеем $\sigma(H) = \{-\varkappa_1^2, ..., -\varkappa_n^2\} \cup \cup[0, \infty)u$

$$\mathscr{H} = \mathscr{H}_{\text{pp}} \oplus \mathscr{H}_{\text{ac}}$$

где $\mathscr{H}_{\text{pp}} = P\mathscr{H}$ и $\mathscr{H}_{\text{ac}} = (I - P)\mathscr{H}$ - соответственно инвариантные подпространства, связанные с чисто точечным и абсолютно непрерывным спектрами H. Оператор $\mathscr{U}H\mathscr{U}^*$ - это оператор умножения на λ в $\mathfrak{H}_0$, так что абсолютно непрерывный спектр $[0, \infty)$ оператора H имеет кратность два, а оператор $\mathscr{U}$ «диагонализует» ограничение H на подпространство $\mathscr{H}_{\text{ac}}$.

Следствие 2.4. Ограничение H на абсолютно непрерывное подпространство $\mathscr{H}_{\text{ac}}$ унитарно эквивалентно H_0:

$$H|_{\mathscr{H}_{\mathbf{ac}}} = UH_0U^{-1}.$$

О свободной квантовой частице в искривленном пространстве

На римановом многообразии (M, g): фазовое пространство классической частицы массы $m = 1$ - это кокасательное расслоение T^*M, и $H_{\text{c}}(\boldsymbol{p}, \boldsymbol{x}) = \frac{1}{2}g^{\mu\nu}(\boldsymbol{x})p_\mu p_\nu$, где $g^{\mu\nu}(\boldsymbol{x})$ - тензор, обратный к $g_{\mu\nu}(\boldsymbol{x})$, а $(\boldsymbol{p}, \boldsymbol{x}) = (p_1, ..., p_n, x^1, ..., x^n)$ - координаты на T^*M.

Гильбертово пространство квантовой системы - это $\mathscr{H} = L^2(M, d\mu)$, где $d\mu = \sqrt{g(\boldsymbol{x})}d^n\boldsymbol{x}, g(\boldsymbol{x}) = \det\left(g_{\mu\nu}(\boldsymbol{x})\right)$, - мера, ассоциированная с плотностью римановой метрики (римановой формы объема, если M ориентировано). Когда канонические координаты $(\boldsymbol{p}, \boldsymbol{x})$ определены на T^*M лишь локально, построить соответствующие операторы $\boldsymbol{P}$ и $\boldsymbol{Q}$ невозможно. Тем не менее всегда можно определить оператор Гамильтона

$$H = \frac{\hbar^2}{2}\Delta_g, \quad \text{где} \quad \Delta_g = -\frac{1}{\sqrt{g(\boldsymbol{x})}}\frac{\partial}{\partial x^\mu}\left(\sqrt{g(\boldsymbol{x})}g^{\mu\nu}\frac{\partial}{\partial x^\nu}\right)$$

- оператор Лапласа - Бельтрами римановой метрики g на M. Заметим, что в этом случае имеется нетривиальная задача упорядочивания некоммутирующих оператор в квантовании $H_{\text{c}}(\boldsymbol{p}, \boldsymbol{x})$, возникающая, если в координатной окрестности на M заменить канонические координаты $\boldsymbol{p}$ и $\boldsymbol{x}$ операторами $\boldsymbol{P}$ и $\boldsymbol{Q}$.

Формула $\Delta_g = -g^{\mu\nu}(\boldsymbol{x})\frac{\partial^2}{\partial x^\mu \partial x^\nu} + g^{\mu\sigma}(\boldsymbol{x})\Gamma^\nu_{\mu\sigma}(\boldsymbol{x})\frac{\partial}{\partial x^\nu}$ показывает, что самосопряженный оператор $H = \frac{\hbar^2}{2}\Delta_g$ склеивается из локальных выражений

$$H_{\text{c}}(\boldsymbol{P}, \boldsymbol{Q}) = \frac{1}{2}\left(g^{\mu\nu}(\boldsymbol{Q})P_\mu P_\nu + i\hbar g^{\mu\sigma}(\boldsymbol{Q})\Gamma^\nu_{\mu\sigma}(\boldsymbol{Q})P_\nu\right)$$

(?????????????????????? место подумать про это. мб это и так, но про это лучше еще подумать.)

Связи формализмов квантовой механики (!?!)

(очень хотелось бы иметь под рукой как раз переходы между формулизмами! тут же формализмы КТП, между ними и в квантмех тоже переходы. додумаю - напишу)

Changing from high scale to low scale models

(там такие какие-то переходы были, потом про это буду думать)

Планетарная модель атома, атом Бора-Зоммерфельда

Основные идеи планетарной модели

We can view electron as a current on contour around a nuclei and the orbit is round:

$$\mu = \frac{i}{c}S, \qquad \text{(magn mom)}$$

$$\mu = \frac{e}{c}\frac{S}{T} = \frac{e}{cT}\pi r^2 = \frac{e}{2mc}m\omega r^2 = \frac{e}{2mc}p,$$

$$\frac{\mu}{p} = \frac{e}{2mc}.$$

$$p = m\omega r^2 = n\frac{h}{2\pi}, \qquad n \in \mathbb{Z}.$$

$$\varepsilon_n = -\frac{2\pi^2 m e^4}{n^2 h^2 (1 + m/M)},$$

$$p_\varphi \to p_l = \sqrt{l(l+1)}\frac{h}{2\pi}; \quad \mu_l = \sqrt{l(l+1)}\mu_{\text{B}}$$

(?????)

Экспериментальные факты, вне рамок планетарной моделью

Тонкая структура спектральных линий вне рамок планетарной модели. При достаточно точном анализе линейчатых спектров выясняется, что почти все линии имеют тонкую структуру - состоят из ряда близких линий. При этом у щелочных металлов (Li, Na, K и т. д.) все линии двойные (дублеты), у щёлочноземельных (Be, Mg, Ca, Zn и т.д.) - простые и тройные (синглеты и триплеты), у элементов третьей группы (B, Al, Ga и т. д.) - дублеты и квартеты, у элементов четвёртой (C, Si и т. д.) синглеты, триплеты и квинтеты и т.д.

Эффект Зеемана вне рамок планетарной модели. Эффектом Зеемана называется расщепление линий при помещении излучающего вещества в магнитное поле. Оно возникает из-за изменения энергетического состояния атома вследствие взаимодействия его магнитного момента с внешним полем.

Действительно, энергия атома, помещённого в магнитное поле, равна

$$W = W_0 - \mu_H H,$$

W_0 - энергия атома при отсутствии поля. Как было указано выше (см. (1.9)), $\mu_H = -m_l\mu_{\text{B}}$; следовательно,

$$W = W_0 + \mu_{\text{B}} m_l H.$$

Таким образом, в присутствии магнитного поля состояния с различными m_l имеют различную энергию, а единый уровень энергии, отвечающий данному значению l и различным m_l, расщепляется на несколько подуровней.

Иначе говоря, вместо первоначальной линии с частотой ν_0 получаются три: одна с прежней частотой и две сдвинутые по частоте на равные расстояния по обе стороны от неё:

$$\Delta\nu = \pm\frac{\mu_{\text{B}} H}{h} = \pm\frac{eH}{4\pi mc}$$

Опыт Штерна и Герлаха вне рамок планетарной модели. (???? тут у Боровика мб ложь написана, потому что в первой группе нет некоторых металлов, которые он пишет, и вообще не нашел я за пару минут инфо про эти проверки для разных металлов, потом еще посмотрю. Пока не считаю, что этот опыт опровергает план. модель атома.) Для атомов первой группы (Li, Na, K, Cu, Ag, Au) в рамках планетарной модели полный момент равен нулю (??? почему???), но их пучок разбился на два симметрично смещённых пучка, причём из величины смещения было определено

$$\mu_H = \pm\mu_\text{B}.$$

Спин. Собственный магнитный момент электрона

(???????)

$$p_s = \sqrt{s(s+1)}\frac{h}{2\pi} = \sqrt{\frac{1}{2}\left(\frac{1}{2}+1\right)}\frac{h}{2\pi},$$

$$\mu_{sH} = 2m_s\mu_\text{B}.$$

$$\frac{\mu_s}{p_s} = \frac{2\sqrt{s(s+1)}\mu_\text{B}}{\sqrt{s(s+1)}h/(2\pi)} = \frac{e}{mc} \equiv 2\frac{\mu}{p}$$

(????)

(!! задачи общефиза еще нарешаю ей!)

Магнитный момент атома. Фактор Ланде

$$\boldsymbol{\mu}_j = \mu_L \cos\left(\widehat{\mathbf{P}_L\mathbf{P}_J}\right) + \mu_S \cos\left(\widehat{\mathbf{P}_S\mathbf{P}_J}\right);$$

$$\mu_L = \sqrt{L(L+1)}\mu_\text{B}$$

$$\mu_S = 2\sqrt{S(S+1)}\mu_\text{B}$$

$$\begin{cases} \cos\left(\widehat{\mathbf{P}_L\mathbf{P}_J}\right) = \frac{L(L+1)+J(J+1)-S(S+1)}{2\sqrt{L(L+1)}\sqrt{J(J+1)}}, \\ \cos\left(\widehat{\mathbf{P}_S\mathbf{P}_J}\right) = \frac{S(S+1)+J(J+1)-L(L+1)}{2\sqrt{S(S+1)}\sqrt{J(J+1)}}. \end{cases}$$

$$g = 1 + \frac{J(J+1)+S(S+1)-L(L+1)}{2J(J+1)}$$

21.3.8 Quantum Fields and the Poincaré Group (!?!??!)

(напишу суть этого, очень важные темы, подробнее в теорполе или отдельной записи)

21.3.9 What can be and what cannot be in QM? (???)

(можно ли нарушать ЗСЭ? все такое. большие вопросы.)

21.3.10 Special Quantization Methods

О операторах рождения и уничтожения (??)

(??? пройду потом, пока мало с ними работал, но это важно. задачи порешаю, запишу в раздел про операторы их, про них есть задачи!)

О квантовании через правило Бора-Зоммерфельда

(!!! потренируюсь на задачах еще!!!)

$$\oint pdq = 2\pi\hbar\left(n + \frac{1}{2}\right)$$

где $n \geq 0, \in Z$, и интегрирование ведется по замкну той орбите в фазовом пространстве $\mathbb{R}^2$. (??? для каких систем это так???)

Для вполне интегрируемым гамильтоновым системам (??)с несколькими степенями свободы (см. раздел 1.2.6 главы 1). А именно: пусть $F_1 = H_c, ..., F_N - N$ независимых интегралов движения в инволюции. Правила квантования БВЗ - это

$$\oint_\gamma \boldsymbol{p}d\boldsymbol{q} = 2\pi\hbar\left(n_\gamma + \frac{1}{4}\,\mathrm{ind}\,\gamma\right),$$

где интегрирование ведется по всем 1-циклам γ в лагранжевом подмногообразии $\Lambda = \left\{(\boldsymbol{p},\boldsymbol{q}) \in \mathbb{R}^{2\boldsymbol{N}} : H_c(\boldsymbol{p},\boldsymbol{q}) = E, F_2(\boldsymbol{p},\boldsymbol{q}) = E_2, ..., F_N(\boldsymbol{p},\boldsymbol{q}) = E_N\right\}$, $\mathrm{ind}\,\gamma \in \mathbb{Z}$ - индекс Маслова цикла γ в Λ. В одно-

Правила БЗ дают только асимптотику уровней энергии при $\hbar \to 0$, однако для интегрируемых систем с дополнительной симметрией, таких как гармонический осциллятор или задача Кеплера, они определяют уровни энергии точно.

О квантовании через функцию Грина

(сомнительный метод)
(когда нужно? все такое?)
Пусть у нас есть частица, которая описывается уравнением Гамильтона:
...
Запишем для такой частицы уравнение Шредингера
...
Далее для него напишем уравнение на функцию Грина:

$$(i\hbar\partial_t - \hat{H})G(t_0, x_0, t, x) = \delta(t - t_0)\delta(x - x_0)$$

Решим это уравнение, перейдя к фурье-образу: $G(..) =$
(короче, спишу у Володи позже)

Примеры

О квантовании Вейля

(тут жестко, пока не разобрался, даже не знаю, как написать это в пару строк. начну пока в теории писать это.)

Пусть $\mathcal{A}_0 = \mathscr{S}(\mathbb{R}^{2n}, \mathbb{R}) \subset \mathcal{A}$ - подалгебра быстро убывающих классических наблюдаемых на $\mathbb{R}^{2n}$, а $\mathscr{A}_0 = \mathscr{A} \cap \mathscr{L}(\mathscr{H})$ - пространство ограниченных квантовых наблюдаемых.

Предложение 3.2. Отображение $\mathcal{A}_0 \ni f \mapsto \Phi(f) \in \mathscr{A}_0$ является квантованием, т.е. оно удовлетворяет условию

$$\lim_{\hbar\to 0} \frac{1}{2}\Phi^{-1}\left(\Phi\left(f_1\right)\Phi\left(f_2\right)+\Phi\left(f_2\right)\Phi\left(f_1\right)\right)=f_1 f_2$$

и принципу соответствия

$$\lim_{\hbar\to 0} \Phi^{-1}\left(\left\{\Phi\left(f_1\right),\Phi\left(f_2\right)\right\}_\hbar\right)=\left\{f_1,f_2\right\}, \quad f_1,f_2\in\mathcal{A}_0,$$

где

$$\left\{\Phi\left(f_1\right),\Phi\left(f_2\right)\right\}_\hbar := \frac{i}{\hbar}\left[\Phi\left(f_1\right),\Phi\left(f_2\right)\right] \qquad u \qquad \left\{f_1,f_2\right\} := \frac{\partial f_1}{\partial \boldsymbol{p}}\frac{\partial f_2}{\partial \boldsymbol{q}}-\frac{\partial f_1}{\partial \boldsymbol{q}}\frac{\partial f_2}{\partial \boldsymbol{p}}$$

- квантовая скобка и скобка Пуассона соответственно.

Квантование, связанное с отображением $\Phi = W\circ\mathscr{F}-1$, называется квантованием Вейля.

Соответствие $f\mapsto\Phi(f)$ можно легко продолжить на векторное пространство $\widehat{L^1\left(\mathbb{R}^{2n}\right)}$ - образ $L^1\left(\mathbb{R}^{2n}\right)$ при преобразовании Фурье, лежащий в пространстве $C\left(\mathbb{R}^{2n}\right)$. В более общем виде для $f\in\in\mathscr{S}\left(\mathbb{R}^{2n}\right)'$ - пространству обобщенных функций медленного роста на $\mathbb{R}^{2n}$ - соответствующее ядро

$$K\left(\boldsymbol{q},\boldsymbol{q}'\right)=\frac{1}{(2\pi\hbar)^n}\int\limits_{\mathbb{R}^n} f\left(\boldsymbol{p},\frac{\boldsymbol{q}+\boldsymbol{q}'}{2}\right)e^{\frac{i}{\hbar}\boldsymbol{p}(\boldsymbol{q}-\boldsymbol{q}')}d^n\boldsymbol{p},$$

рассматриваемое как обобщенная функция медленного роста на $\mathbb{R}^n\times\mathbb{R}^n$, является ядром Шварца линейного оператора

$$\Phi(f):\mathscr{S}\left(\mathbb{R}^n\right)\to\mathscr{S}\left(\mathbb{R}^n\right)'.$$

В частности, постоянная функция $f=1$ соответствует тождественному оператору I с ядром $K\left(\boldsymbol{q},\boldsymbol{q}'\right)=\delta\left(\boldsymbol{q}-\boldsymbol{q}'\right)$. В терминах ядра $K\left(\boldsymbol{q},\boldsymbol{q}'\right)$ формула обращения Вейля принимает вид

$$f(\boldsymbol{p},\boldsymbol{q})=\int\limits_{\mathbb{R}^n} K\left(\boldsymbol{q}-\frac{1}{2}\boldsymbol{v},\boldsymbol{q}+\frac{1}{2}\boldsymbol{v}\right)e^{\frac{i}{\hbar}\boldsymbol{p}\boldsymbol{v}}d^n\boldsymbol{v}.$$

Обобщенная функция $f(\boldsymbol{p},\boldsymbol{q})$, определенная равенством (3.12), называется вейлевским символом оператора в $L^2\left(\mathbb{R}^n,d^n\boldsymbol{q}\right)$ с ядром Шварца $K\left(\boldsymbol{q},\boldsymbol{q}'\right)$.

Предложение 3.1. Подпространство $\operatorname{Im}\Phi\subset\mathscr{L}(\mathscr{H})$ состоит из операторов $B\in\mathscr{S}_1$, таких, что соответствующие функиии $g(\boldsymbol{u},\boldsymbol{v})=\hbar^n\operatorname{Tr}\left(BS(\boldsymbol{u},\boldsymbol{v})^{-1}\right)$ принадлежат классу Шварца $\mathscr{S}\left(\mathbb{R}^{2n}\right)$; в этом случае $W(g)=B$. Обратное отображение $\Phi^{-1}=\mathscr{F}\circ W^{-1}$ дается формулой обращения Вейля

$$\check{f}(\boldsymbol{u},\boldsymbol{v})=\hbar^n\operatorname{Tr}\left(\Phi(f)S(\boldsymbol{u},\boldsymbol{v})^{-1}\right), \quad f\in\mathscr{S}\left(\mathbb{R}^{2n}\right).$$

(?????)

Следствие 3.3.

$$\operatorname{Tr}\Phi(f)=\frac{1}{(2\pi\hbar)^n}\int\limits_{\mathbb{R}^{2n}} f(\boldsymbol{p},\boldsymbol{q})d^n\boldsymbol{p}d^n\boldsymbol{q}$$

О других квантованиях

(тут лишь укажу их, только по потребности буду разбираться нормально)

(???? где каждое нужно??? допишу потом в конце раздела. пока не знаю.)

О $qp-$квантовании (????)

Вдобавок к квантованию Вейля Φ рассмотрим также отображения $\Phi_1 : \mathscr{S}(\mathbb{R}^{2n}) \to \mathscr{L}(\mathscr{H})$ и $\Phi_2 : \mathscr{S}(\mathbb{R}^{2n}) \to \mathscr{L}(\mathscr{H})$, определяемые формулами

$$\Phi_1(f) = \frac{1}{(2\pi)^n} \int\limits_{\mathbb{R}^{2n}} \check{f}(\boldsymbol{u},\boldsymbol{v}) e^{\frac{i\hbar}{2}\boldsymbol{u}v} S(\boldsymbol{u},\boldsymbol{v}) d^n\boldsymbol{u} d^n\boldsymbol{v}$$

и

$$\Phi_2(f) = \frac{1}{(2\pi)^n} \int\limits_{\mathbb{R}^{2n}} \check{f}(\boldsymbol{u},\boldsymbol{v}) e^{-\frac{i\hbar}{2}\boldsymbol{u}\boldsymbol{v}} S(\boldsymbol{u},\boldsymbol{v}) d^n\boldsymbol{u} d^n\boldsymbol{v},$$

где $\check{f} = \mathscr{F}^{-1}(f)$ - обратное преобразование Фурье. Хотя Φ_1 и Φ_2 уже не отображают $\mathcal{A}_0$ в вещественное векторное пространство $\mathscr{A}_0$ ограниченных квантовых наблюдаемых, они удовлетворяют всем свойствам из предложения 3.2. Из (3.5) следует, что для $f \in \mathscr{S}(\mathbb{R}^{2n})$ операторы $\Phi_1(f)$ и $\Phi_2(f)$ являются интегральными операторами с интегральными ядрами:

$$K_1(\boldsymbol{q},\boldsymbol{q}') = \frac{1}{(2\pi\hbar)^n} \int\limits_{\mathbb{R}^n} f(\boldsymbol{p},\boldsymbol{q}')\, e^{\frac{i}{\hbar}\boldsymbol{p}(\boldsymbol{q}-\boldsymbol{q}')} d^n\boldsymbol{p}$$

И

$$K_2(\boldsymbol{q},\boldsymbol{q}') = \frac{1}{(2\pi\hbar)^n} \int\limits_{\mathbb{R}^n} f(\boldsymbol{p},\boldsymbol{q}) e^{\frac{i}{\hbar}\boldsymbol{p}(\boldsymbol{q}-\boldsymbol{q}')} d^n\boldsymbol{p}$$

соответственно. Как и в случае квантования Вейля, эти формулы продолжают отображения $f \mapsto \Phi_1(f)$ и $f \mapsto \Phi_2(f)$ пространства $\mathscr{S}(\mathbb{R}^{2n})'$ обобщенных функций умеренного роста на $\mathbb{R}^{2n}$. В частности, если $f(\boldsymbol{p},\boldsymbol{q})$ - полиномиальная функция (3.13), то

$$\Phi_1(f) = \sum_{|\alpha|,|\beta|\leqslant N} c_{\alpha\beta} \boldsymbol{P}^\alpha \boldsymbol{Q}^\beta$$

и

$$\Phi_2(f) = \sum_{|\alpha|,|\beta|\leqslant N} c_{\alpha\beta} \boldsymbol{Q}^\beta \boldsymbol{P}^\alpha.$$

Поэтому отображение $f \mapsto \Phi_1(f)$ называется $\boldsymbol{pq}$-квантованием, а отображение $f \mapsto \Phi_2(f) - \boldsymbol{qp}$-квантованием. Соответствующие формулы обращения -

$$f(\boldsymbol{p},\boldsymbol{q}) = \int\limits_{\mathbb{R}^n} K_1(\boldsymbol{q}-\boldsymbol{v},\boldsymbol{q}) e^{\frac{i}{\hbar}\boldsymbol{p}\boldsymbol{v}} d^n\boldsymbol{v}$$

и

$$f(\boldsymbol{p},\boldsymbol{q}) = \int\limits_{\mathbb{R}^n} K_2(\boldsymbol{q},\boldsymbol{q}+\boldsymbol{v}) e^{\frac{i}{\hbar}\boldsymbol{p}\boldsymbol{v}} d^n\boldsymbol{v}.$$

Обобщенная функция $f(\boldsymbol{p},\boldsymbol{q})$, определенная в (3.18), называется $\boldsymbol{pq}$ символом оператора с ядром Шварца $K_1(\boldsymbol{q},\boldsymbol{q}')$, а обобщенная функция $f(\boldsymbol{p},\boldsymbol{q})$, определенная в (3.19), $-\boldsymbol{qp}$-символом оператора с ядром Шварца $K_2(\boldsymbol{q},\boldsymbol{q}')$. Эти символы повсеместно используются в теории псевдодифференциальных операторов. Из (3.18) и (3.19) следует, что если $f(\boldsymbol{p},\boldsymbol{q}) - \boldsymbol{pq}$-символ оператора $\Phi_1(f)$, то $\overline{f(\boldsymbol{p},\boldsymbol{q})} - \boldsymbol{qp}$-символ сопряженного оператора $\Phi_1(f)^*$.

О деформационном квантовании (???)

Пусть $\mathcal{A}$ - $\mathbb{C}$-алгебра (или ассоциативная алгебра с единицей над полем k характеристики ноль) с билинейным отображением умножения $m_0 : \mathcal{A} \otimes_{\mathbb{C}} \mathcal{A} \to \mathcal{A}$, которое мы будем кратко записывать как $a \cdot b = m_0(a, b)$. Обозначим как $\mathbb{C}[[t]]$ кольцо формальных степенных рядов от t с коэффициентами из $\mathbb{C}$,

$$\mathbb{C}[[t]] = \left\{ \sum_{n=0}^{\infty} a_n t^n : a_n \in \mathbb{C} \right\},$$

и пусть $\mathcal{A}_t = \mathcal{A}[[t]]$ - это $\mathbb{C}[[t]]$-алгебра формальных степенных рядов от t с коэффициентами из $\mathcal{A}$. мы будем также обозначать m_0. Алгебра $\mathcal{A}_t\mathbb{Z}$-градуирована,

$$\mathcal{A}_t = \bigoplus_{n=0}^{\infty} A_n$$

где $A_n = t^n\mathcal{A}$, так что $A_m \cdot A_m \subset A_{m+n}$.

Определение. Формальная деформачия $\mathbb{C}$-алгебры $\mathcal{A}$ с умножением m_0 это ассоциативная алгебра $\mathcal{A}_t$ над кольцом $\mathbb{C}[[t]]$ с $\mathbb{C}[[t]]$-билинейным отображением умножения $m_t : \mathcal{A}_t \otimes_{\mathbb{C}[[t]]} \mathcal{A}_t \to \mathcal{A}_t$, таким, что

$$m_t(a, b) = a \cdot b + \sum_{n=1}^{\infty} t^n m_n(a, b)$$

для всех $a, b \in \mathcal{A}$, где $m_n : \mathcal{A} \otimes_{\mathbb{C}} \mathcal{A} \to \mathcal{A}$ - билинейные отображения.

Определение. Две формальные деформации m_t и $\tilde{m}_t\mathbb{C}$-алгебры $\mathcal{A}$ эквивалентны, если существует $\mathbb{C}[[t]]$-линейное отображение $F_t : \mathcal{A}_t \to \mathcal{A}_t$, такое, что (i) для любого $a \in \mathcal{A}$

$$F_t(a) = a + \sum_{n=1}^{\infty} t^n f_n(a)$$

где $f_n : \mathcal{A} \to \mathcal{A}$ - линейные отображения; (ii) для любых $a, b \in \mathcal{A}$

$$F_t\left(\tilde{m}_t(a, b)\right) = m_t\left(F_t(a), F_t(b)\right).$$

Определение. Коцепной комплекс Хохшильда $\mathrm{C}^\bullet(\mathcal{A}, M)\mathbb{C}$-алгебры $\mathcal{A}$ с коэффициентами в $\mathcal{A}$-бимодуле M определяется коцепями

$$\mathrm{C}^n(\mathcal{A}, M) = \mathrm{Hom}_{\mathbb{C}}\left(\mathcal{A}^{\otimes n}, M\right)$$

т. е. n-линейными отображениями $f\left(a_1, ..., a_n\right)$, определенными на $\mathcal{A}$ со значениями в M, и дифференциалом $d_n : \mathrm{C}^n(\mathcal{A}, M) \to \mathrm{C}^{n+1}(\mathcal{A}, M)$,

$$\begin{aligned}
&\left(d_n f\right)\left(a_1, a_2, ..., a_{n+1}\right) = a_1 \cdot f\left(a_2, ..., a_{n+1}\right) + \\
&+ \sum_{j=1}^{n} (-1)^j f\left(a_1, ..., a_{j-1}, a_j \cdot a_{j+1}, a_{j+2}..., a_{n+1}\right) + \\
&+ (-1)^{n+1} f\left(a_1, ..., a_n\right) \cdot a_{n+1}.
\end{aligned}$$

Имеем $d^2 = 0$, т. е. $d_{n+1} \circ d_n = 0$, и когомологии $H^\bullet(\mathcal{A}, M)$ комплекса $(\mathrm{C}^\bullet(\mathcal{A}, M), d)$,

$$H^n(\mathcal{A}, M) = \ker d_n / \operatorname{Im} d_{n-1},$$

называются когомологиями Хохшильда алгебры $\mathcal{A}$ с коэффициентами в $\mathcal{A}$ бимодуле M.

Лемма 3.3. Формальная деформачия $\mathcal{A}_t$ коммутативной $\mathbb{C}$-алгебры $\mathcal{A}$ оснащает $\mathcal{A}$ структурой алгебры Пуассона со скобкой $\{,\}$.

Определение. Деформационное квантование алгебры Пуассона $(\mathcal{A}, \{\},)$ с коммутативным произведением $m_0 : \mathcal{A} \otimes_{\mathbb{C}} \mathcal{A} \to \mathcal{A}$ - это формальная деформация $\mathcal{A}_t$ алгебры $\mathcal{A}$, такая, что отображение умножения m_t удовлетворяет (3.28).

По лемме 3.3 любая формальная деформация $\mathcal{A}_t$ коммутативной алгебры $\mathcal{A}$ является деформационным квантованием алгебры Пуассона $(\mathcal{A}, \{\}$, со скобкой Пуассона, заданной формулой (3.27).

Согласно лемме 3.2, деформационное квантование алгебры Пуассона $(\mathscr{S}(\mathbb{R}^{2n}), \{\},)$, в которой скобка Пуассона ассоциирована с канонической симплектической формой $\omega = d\boldsymbol{p} \wedge d\boldsymbol{q}$, есть алгебра $\mathscr{S}(\mathbb{R}^{2n})[[t]]$, где $t = -i\hbar$, а $\hbar$ рассматривается как формальный параметр, и отображение умножения дается $\star$-произведением. Следующее утверждение - формальный алгебраический аналог представления (3.22) для $\star$-произведения. Теорема 3.4 (Универсальная деформация). Пусть $\mathcal{A}$ - коммутативная $\mathbb{C}$-алгебра с отображением умножения m_0 и пусть $\varphi_1 \boldsymbol{u} \varphi_2$ - два коммутируючих дифференцирования алгебры $\mathcal{A}$, т.е. линейных отображения $\varphi_1, \varphi_2 : \mathcal{A} \to \mathcal{A}$, удовлетворяющих правилу Лейбница и условию

$$\varphi_1 \circ \varphi_2 = \varphi_2 \circ \varphi_1.$$

Тогда выражение

$$\{a, b\} = \varphi_1(a) \cdot \varphi_2(b) - \varphi_2(a) \cdot \varphi_1(b), \quad a, b \in \mathcal{A},$$

определяет на $\mathcal{A}$ скобку Пуассона, и формулой

$$m_t = m_0 \circ e^{t\Phi}, \quad \Phi = \varphi_1 \otimes \varphi_2,$$

называемой формулой универсальной деформачии, дается деформачионное квантование алгебры Пуассона $(\mathcal{A}, \{\})$.

21.4 Methods for special applications 1

21.4.1 Rotations, C-, P-, T-Symmetry

О Т-четности и обращении времени

Main methods

(нужно отдельно про это почитать!!!)

$$\Theta \mathbf{x} \Theta^\dagger = \mathbf{x}, \quad \Theta \mathbf{p} \Theta^\dagger = -\mathbf{p}$$
$$\Theta H \Theta^\dagger = H \quad \text{or} \quad [\Theta, H] = 0$$

Because if $\tau = -t$, so $|\psi_r(t)\rangle = \Theta|\psi(\tau)\rangle$, then

$$i\hbar \frac{\partial}{\partial t} |\psi_r(t)\rangle = \Theta \left[i\hbar \frac{\partial}{\partial \tau} |\psi(\tau)\rangle \right] = \Theta H |\psi(\tau)\rangle = \left(\Theta H \Theta^\dagger\right) \Theta |\psi(\tau)\rangle = \left(\Theta H \Theta^\dagger\right) |\psi_r(t)\rangle$$

The time-reversal operator unitary or antiunitary:

$$T(iH)T^{-1} = -iH$$

Because if we take the canonical commutation relations, $[x_i, p_j] = i\hbar\delta_{ij}$, and conjugate with Θ, we find $\Theta [x_i, p_j] \Theta^\dagger = -[x_i, p_j] = -i\hbar\delta_{ij} = \Theta (i\hbar\delta_{ij}) \Theta^\dagger$ The quantity $i\hbar\delta_{ij}$ is just a number, so if Θ is unitary it can be brought through to cancel $\Theta^\dagger$, and we obtain a contradiction.

Time reversibility by Zhou

$$|\psi_r(t)\rangle = \Theta|\psi(-t)\rangle$$

$$\Theta^\dagger\Theta = 1$$

$$\Theta\mathbf{x}\Theta^\dagger = \mathbf{x}, \quad \Theta\mathbf{p}\Theta^\dagger = -\mathbf{p}$$

$$\Theta[x,p]\Theta^\dagger = i\hbar\Theta\Theta^\dagger = i\hbar = [x,p]$$

Applications of time reversibility (????)

(очень много про это написано, потом продумаю)

О P-четности и инверсии пространства

Parity by Zhou

$$\pi^\dagger\pi = 1, \quad \pi^2 = 1, \quad \pi U(R)\pi^\dagger = U(R)$$

$$\pi\mathbf{x}\pi^\dagger = -\mathbf{x}, \quad \pi\mathbf{p}\pi^\dagger = -\mathbf{p}, \quad \pi\mathbf{L}\pi^\dagger = \mathbf{L}$$

$\mathbf{L} = \mathbf{r} \times \mathbf{p}$.
the parity of the state $|lm\rangle$ is $(-1)^l$.

Vector $\pi\mathbf{V}\pi^\dagger = \pm\mathbf{V}$ true/pseudo- v

Scalar $\pi K\pi^\dagger = \pm K$ true/pseudo- s

О соотношении и преобразовании Вейля

$$W(f) = \frac{1}{(2\pi)^n} \int\limits_{\mathbb{R}^{2n}} f(\boldsymbol{u}, \boldsymbol{v}) e^{-i(\boldsymbol{u}\boldsymbol{P}+\boldsymbol{v}\boldsymbol{Q})} d^n\boldsymbol{u} d^n\boldsymbol{v}$$

Пусть R - неприводимое унитарное представление группы Гейзенберга $\mathbf{H}_n$ в гильбертовом пространстве $\mathscr{H}$. Из леммы Шура следует, что $R(e^{\alpha c}) = e^{i\hbar\alpha} I$ для некоторого $\hbar \in \mathbb{R}$, где I - тождественный оператор в $\mathscr{H}$. Если $\hbar = 0, n$-параметрические абелевы группы унитарных операторов $U(\boldsymbol{u}) = R\left(e^{\boldsymbol{u}X}\right)$ и $V(\boldsymbol{v}) = R\left(e^{\boldsymbol{v}Y}\right)$ коммутируют, так что, еще раз воспользовавшись леммой Шура, заключаем, что существуют $\boldsymbol{p}, \boldsymbol{q} \in \mathbb{R}^n$, такие, что $U(\boldsymbol{u}) = e^{-i\boldsymbol{u}\boldsymbol{p}} I$ и $V(\boldsymbol{v}) = e^{-i\boldsymbol{v}\boldsymbol{q}} I$. Потому в этом случае неприводимое представление R одномерно и параметризуется вектором $(\boldsymbol{p}, \boldsymbol{q}) \in \mathbb{R}^{2n}$. Когда $\hbar \neq 0$, унитарные операторы $U(\boldsymbol{u})$ и $V(\boldsymbol{v})$ удовлетворяют соотношениям Вейля

$$U(\boldsymbol{u})V(\boldsymbol{v}) = e^{i\hbar uv} V(\boldsymbol{v})U(\boldsymbol{u}),$$

допускающим представление Шрёдингера, введенное в разделе 2.2.2. Оказывается, что любое неприводимое представление группы Гейзенберга $\mathbf{H}_n$ унитарно эквивалентно либо одномерному представлению с параметрами $(\boldsymbol{p}, \boldsymbol{q}) \in \mathbb{R}^{2n}$, либо представлению Шрёдингера для какого-то $\hbar \neq 0$. Физически осмысленный случай соответствует значению $\hbar > 0$, и представление с $-\hbar$ дается операторами $U^{-1}(\boldsymbol{u}) = U(-\boldsymbol{u})$ и $V(\boldsymbol{v})$.

Теорема Стоуна-фон Неймана: Любое неприводимое унитарное представление соотношений Вейля для n степеней свободы, $U(\boldsymbol{u})V(\boldsymbol{v}) = e^{i\hbar\boldsymbol{u}v} V(\boldsymbol{v})U(\boldsymbol{u})$ унитарно эквивалентно представлению Шрёдингера.

Определим линейное отображение $W : L^1(\mathbb{R}^2) \to \mathscr{L}(\mathscr{H})$, называемое преобразованием Вейля, по формуле

$$W(f) = \frac{1}{2\pi} \int\limits_{\mathbb{R}^2} f(u, v) S(u, v) du dv.$$

Здесь интеграл понимается в слабом смысле: для любого $\psi_1, \psi_2 \in \mathscr{H}$

$$(W(f)\psi_1, \psi_2) = \frac{1}{2\pi} \int\limits_{\mathbb{R}^2} f(u,v)\,(S(u,v)\psi_1, \psi_2)\,dudv$$

Преобразование Вейля обладает следующими свойствами.

WT1. Для $f \in L^1(\mathbb{R}^2)$

$$W(f)^* = W(f^*)$$

где $f^*(u,v) = \overline{f(-u,-v)}$.

WT2. Для $f \in L^1(\mathbb{R}^2)$

$$S(u_1,v_1)\,W(f)S(u_2,v_2) = W(\tilde{f}),$$

где $\tilde{f}(u,v) = e^{\frac{i\hbar}{2}\{(u_1-u_2)v-(v_1-v_2)u+u_1v_2-u_2v_1\}} f(u-u_1-u_2, v-v_1-v_2)$.

WT3. $\operatorname{Ker} W = \{0\}$.

WT4. Для $f_1, f_2 \in L^1(\mathbb{R}^2)$

$$W(f_1)\,W(f_2) = W(f_1 *_\hbar f_2),$$

где $(f_1 *_\hbar f_2)(u,v) = \frac{1}{2\pi} \int\limits_{\mathbb{R}^2} e^{\frac{i\hbar}{2}(uv'-u'v)} f_1(u-u', v-v')\,f_2(u',v')\,du'dv'$.

Таким образом, преобразование Вейля

$$W(f) = \frac{1}{(2\pi)^n} \int\limits_{\mathbb{R}^{2n}} f(\boldsymbol{u},\boldsymbol{v}) e^{-i(\boldsymbol{uP}+\boldsymbol{vQ})} d^n\boldsymbol{u}\,d^n\boldsymbol{v}$$

можно рассматривать как некоммутативное преобразование Фурье - операторнозначное обобщение «обычного» преобразования Фурье

$$\hat{f}(\boldsymbol{p},\boldsymbol{q}) = \frac{1}{(2\pi)^n} \int\limits_{\mathbb{R}^{2n}} f(\boldsymbol{u},\boldsymbol{v}) e^{-i(\boldsymbol{up}+\boldsymbol{vq})} d^n\boldsymbol{u}\,d^n\boldsymbol{v}$$

(???? подумаю про это!!!!)

Лемма 3.1. Преобразование Вейля W определяет изоморфизм $L^2(\mathbb{R}^{2n}) \simeq \mathscr{S}_2$

Бескоординатное представление Шредингера по Тахтаджаяну (?????)

(!!! в 1/3 страницы сверну это, не больше, это прикольно, но бесполезно!!!)

Пусть (V,ω) - конечномерное симплектическое векторное пространство, $\dim V = 2n$. Напомним, что (см. раздел 2.2.1) алгебра Гейзенберга $\mathfrak{g} = \mathfrak{g}(V)$ - это одномерное центральное расширение абелевой алгебры Ли V с помощью кососимметрической билинейной формы ω. Как векторное пространство алгебра Ли $\mathfrak{g}$ совпадает с алгеброй $V \oplus \mathbb{R}$, в которой скобка Ли определена равенством

$$[u+\alpha c, v+\beta c] = \omega(u,v)c, \quad u,v \in V, \alpha,\beta \in \mathbb{R}.$$

Любое лагранжево подпространство ℓ пространства V определяет абелеву подалгебру $\ell \oplus \mathbb{R}c$ в $\mathfrak{g}$. Лагранжево подпространство ℓ' дополнительно к ℓ в V, если $\ell \oplus \ell' = V$. Выбором дополнительного к ℓ лагранжева подпространства ℓ' устанавливается изоморфизм

$$\mathfrak{g}/(\ell \oplus \mathbb{R}c) \simeq \ell'$$

Группа Гейзенберга $G = G(V)$ - связная и односвязная группа Ли с алгеброй Ли g. Экспоненциальным отображением осуществляется изоморфизм G и многообразия $V \oplus \mathbb{R}c$, в котором групповой закон задан равенством

$$\exp(v_1 + \alpha_1 c)\exp(v_2 + \alpha_2 c) = \exp\left(v_1 + v_2 + \left(\alpha_1 + \alpha_2 + \frac{1}{2}\omega(v_1, v_2)\right)c\right),$$

где $v_1, v_2 \in V, \alpha_1, \alpha_2 \in \mathbb{R}$. Выбором симплектического базиса для V устанавливается изоморфизм $G(V) \simeq \mathbf{H}_n$ с матричной группой Гейзенберга, определенной в разделе 2.2.1. Форма объема $d^{2n}\boldsymbol{v} \wedge dc$, где $d^{2n}\boldsymbol{v} \in \Lambda^{2n}V^*$ - форма объема на V, а V^* - двойственное к V векторное пространство, определяет биинвариантную меру Хаара на G. Любое лагранжево подпространство ℓ определяет абелеву подгруппу $L = \exp(\ell \oplus \mathbb{R}c)$ в G, а выбором дополнительного лагранжева подмножества ℓ' устанавливается изоморфизм

$$G/L \simeq \ell'.$$

Изоморфизм $\Lambda^{2n}V^* \simeq \Lambda^n\ell^* \wedge \Lambda^n\ell'^*$ приводит к форме объема d^nv' на ℓ' и определяет меру dg на однородном пространстве G/L. Мера dg инвариантна при левом действии G и не зависит от выбора ℓ'. Для заданного $\hbar \in \mathbb{R}$ функция $\chi : L \to \mathbb{C}$,

$$\chi(\exp(v + \alpha c)) = e^{i\hbar\alpha}, \quad v \in V, \alpha \in \mathbb{R},$$

определяет одномерный унитарный характер на L,

$$\chi(l_1 l_2) = \chi(l_1)\chi(l_2), \quad l_1, l_2 \in L.$$

Определение. Бескоординатное представление Шрёдингера S_ℓ группы Гейзенберга $G(V)$, ассоциированное с лагранжевым подпространством ℓ пространства V, - это представление группы G, индуцированное одномерным представлением χ соответствующей абелевой группы Ли L,

$$S_\ell = \mathrm{Ind}_L^G \chi.$$

По определению индуцированного представления гильбертово пространство $\mathscr{H}_\ell$ представления S_ℓ состоит из измеримых функций $f : G \to \mathbb{C}$, удовлетворяющих свойству $f(gl) = \chi(l)^{-1}f(g), \quad g \in G, l \in L$, и таких, что $\|f\|^2 = \int\limits_{G/L} |f(g)|^2 dg < \infty$.

О виковском символе (???)

Представим A в виковской нормальной форме следующим образом:

$$A = \sum_{l,m} A_{lm} (a^*)^l a^m.$$

По определению виковский символ $A(\bar{z}, z)$ оператора A - это

$$A(\bar{z}, z) = \sum_{l,m} A_{lm} \bar{z}^l z^m$$

Теорема 2.2. Виковские символы ограниченных операторов в $\overline{\mathscr{D}}$ обладают следующими свойствами.

(i) Если $A(\bar{z}, z)$ - виковский символ оператора A, то для виковского символа оператора A^* имеем $A^*(\bar{z}, z) = \overline{A(\bar{z}, z)}u$

$$A^*(v, z) = \overline{A(\bar{z}, \bar{v})}$$

(ii) Для $f \in \overline{\mathscr{D}}$

$$(Af)(\bar{z}) = \frac{1}{\pi} \int\limits_{\mathbb{C}} A(\bar{z}, v) f(\bar{v}) e^{-v(\bar{v}-\bar{z})} d^2 v.$$

(iii) Вещественно-аналитическая функиия $A(\bar{z}, z)$ является виковским символом ограниченного оператора A в $\overline{\mathscr{D}}$, если и только если она есть ограничение на подпространство $v = \bar{z}$ челой функции $A(v, z)$ в переменных v и z со свойством, что для любого $f \in \mathscr{D}$ интеграл в части (ii) абсолютно сходится и определяет функиию в $\bar{D}$.

(iv) Если $A_1(\bar{z}, z)$ и $A_2(\bar{z}, z)$ - виковские символь операторов A_1 и A_2, то виковский символ оператора $A = A_1 A_2$ задается формулой

$$A(\bar{z}, z) = \frac{1}{\pi} \int\limits_{\mathbb{C}} A_1(\bar{z}, v) A_2(\bar{v}, z) e^{-(v-z)(\bar{v}-\bar{z})} d^2 v$$

Матричный символ $\tilde{A}(\bar{z}, z)$ ограниченного оператора A в гильбертовом пространстве $\mathscr{D}$ - это ограничение на подпространство $v = \bar{z}$ целой функции $A(v, z)$ в переменных v и z, определенной следующим абсолютно сходящимся рядом:

$$\tilde{A}(v, z) = \sum_{m,n=0}^{\infty} \left(A\bar{f}_m, \bar{f}_n\right) f_n(v) f_m(z).$$

Матричный и виковский символы связаны следующим образом.

Следствие 2.3. Если $\tilde{A}_1(\bar{z}, z)$ и $\tilde{A}_2(\bar{z}, z)$-матричные символы операторов A_1 и A_2, то матричный символ оператора $A = A_1 A_2$ дается формулой

$$\tilde{A}(\bar{z}, z) = \frac{1}{\pi} \int\limits_{\mathbb{C}} \tilde{A}_1(\bar{z}, v) \tilde{A}_2(\bar{v}, z) e^{-|v|^2} d^2 v$$

Лемма 2.4. Для ограниченного оператора A в гильбертовом пространстве $\bar{D}$

$$\tilde{A}(v, z) = e^{vz} A(v, z)$$

21.4.4 Symmetries in Quantum Mechanics and Their Consequences

(см. ЛЛ3, там большой раздел про это, я не много пока этим занимался. пока я очень плохо понимаю, что там происходит и как этим пользоваться?)

О правилах отбора из симметрий (!?!?)

(ЛЛ3, по идее разберусь, пару абзацев на это, пока мало думал про это.)

21.4.5 Absence of Hidden Variables, Bell's Theorem, EPR

(это большие темы, только когда основное сделано будет, будут проведены исследования и написаны статьи, буду смотреть это.)

Парадокс Эйнштейна—Подольского—Розена

(Киселев, дополнения)

О неравенстве Белла (???)

(Киселев, дополнения)

21.4.6 Response, Polarization, Susceptibility

(пока об этом в конд средах или статфизе)

О параметрах электродинамики через квантовую механику

О поляризации (!?!??)

$$\mathbf{P}(t) = \langle \chi(t) | \hat{\sigma} | \chi(t) \rangle,$$

Просто среднее значение спина (??)

О восприимчивости (??)

(там в статфизе уже про это писал, формула Кубо, отклик, все такое, потом сюда тоже добавлю, или удалю этот раздел просто, посмотрим)

21.4.7 Generalized Functions in Quantum Mechanics

(all about it here, maybe I'll merge it with some subsubsectinos of mathematics for QM)

21.4.8 Other Useful Methods for the Schrödinger Equation

Строгие математикческие методы в двух словах

(тут половина страницы на методы Константинова!!! запросто впишу, если только нужно будет!)

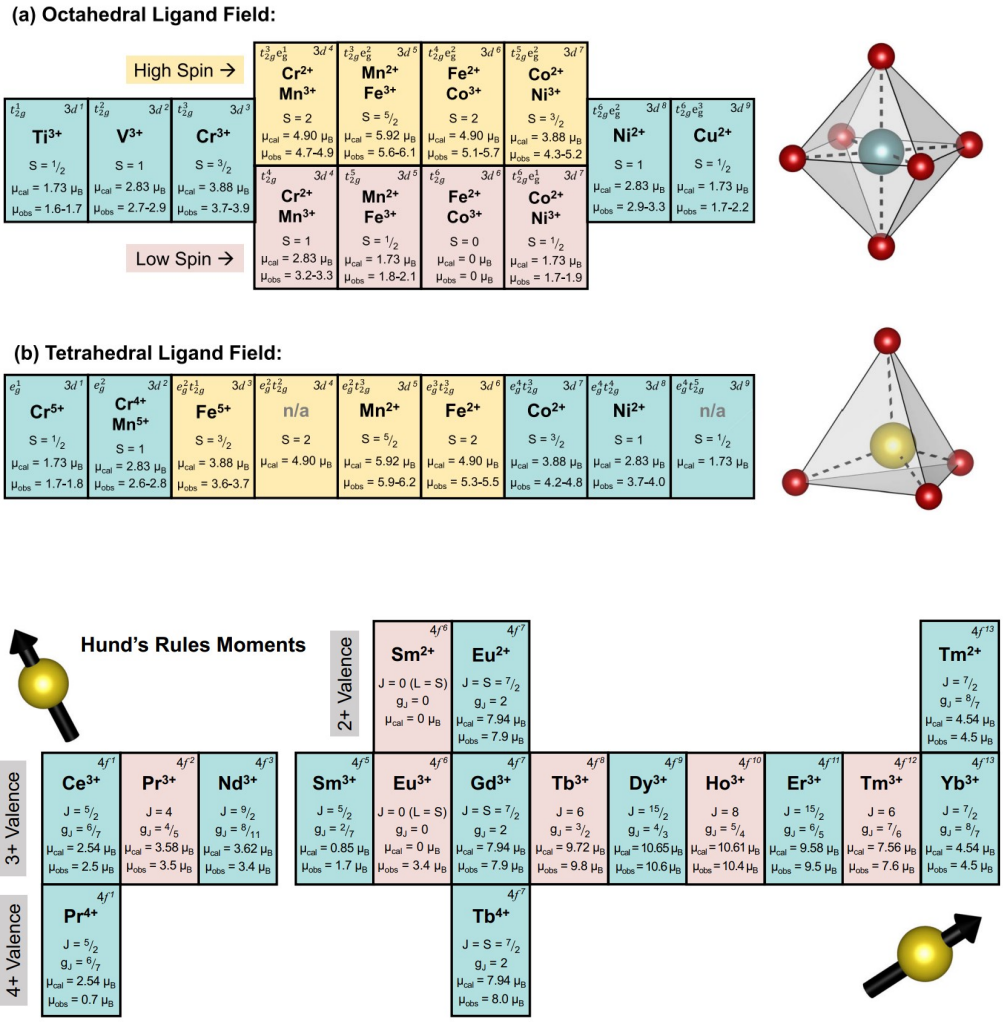
21.4.9 Other Estimates (!!!!)

(У МК много крутого еще есть, так что вот, для них раздел. мб даже пару разделов создам потом)

21.4.10 Other methods of atomic properties

Hund's rules details (????)

(в планах продумать глубже эти правила и связь с экспериментами, пока не актуально это просто)



(images from "Guide to Interpreting Magnetic Susceptibility Data with the Curie-Weiss Law" article, I'll think about them later, they are illustrating Hund's rule)

21.4.11 Perturbation theory in QM: other methods

On rigorous perturbation theory

(см. Саймонс Рид, Тахтаджаяна и многих дргуих. Это большая тема, тут просто пунктами идеи и выводы укажу, во 2й 1й части будет обзор формул. Все равно крайне маловеротяно, что они будут использоваться.)

21.5 Methods for special applications 2

21.5.1 Path integral in QM: special methods

(потом сделаю пару разделов скорее всего, пока все тут об этом.)

Основные формулы интеграла по траекториям

Суть и важность интеграла по траекториям

Об основной идее

(суть по Зи скорее всего напишу)

Основные формулы интеграла по траекториям

отличие интеграла по траекториям в квантой механики от интеграла в КТП

Примеры

(самые типичные иллюстративные добавлю)

О другом про траекториям (?)

(их очень много, но сперва пишу про них в отдельной записи)

о неверных подходах к интегралу по траекториям

про них можно говорить долго, так что лишь вкратце упомянем суть.

О Формализме Гельфанда–Яглома

(см. ПТФ, уже в этой записи написано, позже продумаю)

Об интеграле Швингера–Келдыша

(доп от Киселева, напишу потом)

21.5.2 Diagrammatic Techniques (???)

(думаю, важно указать это, все-таки много чего тут есть. но мб нет, мб в КТП это будет написано, посмотрим.)

21.5.3 Quantum information theory: Basic models

О разложениях состояний

О состояниях

- Bell States:

$$|\beta_{00}\rangle = \frac{|00\rangle+|11\rangle}{\sqrt{2}} \quad |\beta_{01}\rangle = \frac{|10\rangle+|01\rangle}{\sqrt{2}}$$
$$|\beta_{10}\rangle = \frac{|00\rangle-|11\rangle}{\sqrt{2}} \quad |\beta_{11}\rangle = \frac{|10\rangle-|01\rangle}{\sqrt{2}}$$

Параметры Стокса (????)

Разложение Шмидта (?????)

(???? укажу, что вообще происходит??? не понимаю пока)

$$\left|\psi^{AB}\right\rangle \in \mathcal{H}^A \otimes \mathcal{H}^B \quad \dim \mathcal{H}^A = d \leqslant D = \dim \mathcal{H}^B$$
$$\left|\psi^{AB}\right\rangle = \sum_{i=1}^{d}\sum_{j=1}^{D}\sum_{k=1}^{d} U_{ik}\lambda_k V_{kj}|i\rangle \otimes |j\rangle$$
$$\left|\psi^{AB}\right\rangle = \sum_{k=1}^{d} \lambda_k \left(\sum_{i=1}^{d} U_{ik}|i\rangle\right) \otimes \left(\sum_{j=1}^{D} V_{kj}|j\rangle\right)$$

Об информационной энтропии (!!!???)

О квантовых вентилях

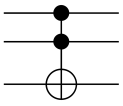
$$X_{(\text{Not})} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix} \qquad Y = \begin{bmatrix} 0 & -i \\ i & 0 \end{bmatrix} \qquad Z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

$$H_{(\text{Hdmrd})} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \qquad S_{(\text{phase})} = \begin{bmatrix} 1 & 0 \\ 0 & i \end{bmatrix} \qquad T = \begin{bmatrix} 1 & 0 \\ 0 & e^{i\pi/4} \end{bmatrix}$$

$$\begin{pmatrix} |0\rangle \\ |1\rangle \end{pmatrix}$$

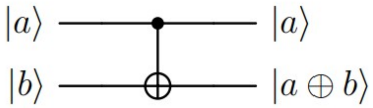
Sometimes it is more useful to work with bra-ket notation, not in matrix form.

Toffoli gate (CCNOT):

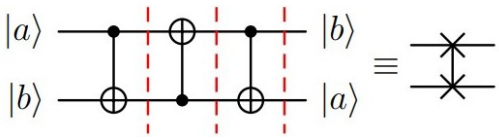


It applies the NOT if the two control qubits are 1.

cnot:



swap:



(!!! I'll add some basic methods for gates and proofs!!!!)

On some gate methods and constructions

On Quantum Fourier transform

(напишу потом на половину страницы, что да, такое есть, там соображения такие отдельные)

21.5.4 Quantum information theory: Basic theorems

(см. отдельную мою запись, а также лекции Тонга пока что, потом допишу, если будет нужно.)

21.5.5 Methods for open systems

(теория про это в 1й части, тут типичные модели, страниц мб 6-8 будет в итоге)

Спин-бозонная модель

Система (s, system) будет представлять собой двухуровневую систему (это может быть спин-1/2 в магнитном поле, это может быть частица в двухъямном потенциале - детали совершенно не важны), которую мы будем описывать на языке спина-1/2 и матриц Паули. В качестве модели окружающей среды (e, environment; также часто её называют баней - bath) мы возьмём набор гармонических осцилляторов. Гамильтониан всей системы имеет вид:

$$\hat{H} = \underbrace{-\frac{\Delta}{2}\hat{\sigma}_z}_{\hat{H}_s} + \underbrace{\sum_n \omega_n \hat{a}_n^\dagger \hat{a}_n}_{\hat{H}_e} + \underbrace{\hat{\sigma}_x \sum_n \lambda_n \hat{X}_n}_{\hat{V}}, \quad \hat{X}_n = \hat{a}_n + \hat{a}_n^\dagger$$

Система Для матриц Паули мы получаем:

$$\frac{d\hat{\sigma}_x}{dt} = i\left[\hat{H}_s, \hat{\sigma}_x\right] = \Delta\hat{\sigma}_y, \quad \frac{d\hat{\sigma}_y}{dt} = -\Delta\hat{\sigma}_x, \quad \frac{d\hat{\sigma}_z}{dt} = 0$$

и решение записывается как:

$$\begin{cases} \hat{\sigma}_x(t) = \hat{\sigma}_x \cos\Delta t + \hat{\sigma}_y \sin\Delta t \\ \hat{\sigma}_y(t) = -\hat{\sigma}_x \sin\Delta t + \hat{\sigma}_y \cos\Delta t \\ \hat{\sigma}_z(t) = \hat{\sigma}_z \end{cases}$$

Представление взаимодействия

. 102

Приближение Борна – Маркова

. 103
(тут еще формулы)
Если предположить, что этот масштаб времени много меньше масштаба времени, на котором меняется сама матрица плотности, то можно заменить $\hat{\rho}_s(t-\tau) \mapsto \hat{\rho}_s(t)$, а также в силу сходимости интеграла, заменить его верхний предел до бесконечности. В результате мы получаем следующее квантовое кинетическое уравнение (master equation):

$$\frac{d\hat{\rho}_s}{dt} = -\int_0^\infty d\tau \, \mathrm{Tr}_e\left(\left[\left[\hat{\rho}_s(t)\hat{\rho}_e, \hat{V}(t-\tau)\right], \hat{V}(t)\right]\right)$$

В таком виде это - система линейных дифференциальных уравнений с постоянными коэффициентами на компоненты матрицы плотности $\hat{\rho}_s$. Если окружающая среда не обладает памятью, то самый общий вид квантового кинетического уравнения имеет вид уравнения Линблада [4]:

$$\frac{d\hat{\rho}_s(t)}{dt} = i\left[\hat{\rho}_s(t), \hat{H}_s\right] + \mathcal{L}\hat{\rho}_s(t)$$

9.1.3

Корреляционные функции среды

105
9.1.4

Уравнения Блоха

. 105

О спектральной плотности

107

О применениях

(полстраницы словами пишу, что на самом деле это нужные темы и многое тут можно исследовать и многие этим занимаются. как конкретно?)
9.2

Подавление туннелирования в двухуровневой системе

108

Пертурбативное рассмотрение

.. 108

Адиабатическое рассмотрение

(чисто атомная физика разная)

Regge poles (!?)

(основная идея)

(осн. формулы, см. пока ЛЛ3.141)

(1 раз посижу над этим - и впишу! интересно, просто пока не нужно было, а так бы выучил!)

138. Резонансное рассеяние заряженных частиц

(см. ЛЛ3.138, на самом деле это специфика, отдельно сидеть нужно над ней)

$$\chi'' + \left(k^2 - \frac{2}{r}\right)\chi = 0$$

$$F_0{}^{ikr} krF\left(\frac{i}{k} + 1, 2, -2ikr\right), \quad A^2 = \frac{2\pi/k}{e^{2\pi/k} - 1}$$

$$F_0 \approx \sin\left[kr - \frac{1}{k}\ln(2kr) + \delta_0^{\text{кул}}\right], \quad \delta_0^{\text{кУл}} = \arg\Gamma\left(1 + \frac{i}{k}\right)$$

$r(kr \ll 1, r \ll 1)$

$$F_0 = Akr(1 + r + ...)$$

139. Упругие столкновения быстрых электронов с атомами

(см. ЛЛ3.139, на самом деле это специфика, отдельно сидеть нужно над ней)

140. Рассеяние при спин-орбитальном взаимодействии

(см. ЛЛ3.140, на самом деле это специфика, отдельно сидеть нужно над ней)

Разные конкретные известные решенные задачи

Сечение рассеяния протона на атоме водорода (151).

(порешаю по МК, впишу на 1/4 страницы суть)

22.2.5 Inelastic Collisions

(пока см. отдельную запись и книгу Ландау, не такие типичные задачи.)

Упругое рассеяние при наличии неупругих процессов

Неупругое рассеяние медленных частиц

Матрица рассеяния при наличии реакций

Формулы Брейта и Вигнера

Взаимодействие в конечном состоянии при реакциях

Поведение сечений вблизи порога реакции

Неупругие столкновения быстрых электронов с атомами

Эффективное торможение

Неупругие столкновения

22.2.6 The Essence of Typical Models of Elementary Particles

(должны задачи решаться с помощью этой главы!!!!)

Основные свойства

Все лептоны - фермионы. Нейтрино имеют только отрицательную спиральность (левоспиральные частицы), а антинейтрино - только положительную (правоспиральные).

Поколение	Частица	Символ		Масса, МэВ	Время жизни τ	Лептонный заряд			Преобладающая схема распада
		Частица	Античастица			L_e	L_μ	L_τ	
I	электрон	e^-	e^+	0,511	$> 4{,}3 \cdot 10^{23}$ лет	+1	0	0	—
	электронное нейтрино	ν_e	$\tilde{\nu}_e$	$< (2 \div 2{,}5)$ эВ	$\frac{\tau}{m_{\nu_e}} > 300 \frac{c}{\text{эВ}}$	+1	0	0	—
II	мюон	μ^-	μ^+	$\frac{105{,}658}{207{,}767} m_e$	$2{,}197 \cdot 10^{-6}$ с	0	+1	0	$e^- \tilde{\nu}_e \nu_\mu$
	мюонное нейтрино	ν_μ	$\tilde{\nu}_\mu$	< 0,17	$\frac{\tau}{m_{\nu_e}} > 15{,}4 \frac{c}{\text{эВ}}$	0	+1	0	—
III	таон	τ^-	τ^+	1777,0	$0{,}290 \cdot 10^{-12}$ с	0	0	+1	$\mu^- \tilde{\nu}_\mu \nu_\tau$; $e^- \tilde{\nu}_e \nu_\tau$
	таонное нейтрино	ν_τ	$\tilde{\nu}_\tau$	< 18,2	?	0	0	+1	—

Все кварки - фермионы (спин 1/2), с барионным зарядом 1/3. Антикварки имеют квантовые числа с противоположными знаками.

Поколение	Название	Символ	Электр. заряд, ед. e	«Токовая» масса	Проекция изоспина, I_3	Заряд				Блоковая масса (в составе адрона), ГэВ
						c	s	t	b	
I	верхний (up)	u	+ 2/3	1,5—4 МэВ	+ 1/2	0	0	0	0	0,33
	нижний (down)	d	−1/3	4—8 МэВ	−1/2	0	0	0	0	0,33
II	очарованный (charm)	c	+ 2/3	1,1—1,4 ГэВ	0	+ 1	0	0	0	1,8
	странный (strange)	s	−1/3	80—130 МэВ	0	0	−1	0	0	0,51
III	t-кварк (top)	t	+ 2/3	$174{,}3 \pm 5{,}1$ ГэВ	0	0	0	+ 1	0	*)
	b-кварк (bottom)	b	−1/3	4,1—4,4 ГэВ	0	0	0	0	−1	5,0

*) t - кварк имеет такое малое время жизни, что он распадается до образования t - адронов, поэтому блоковой массы не имеет. Токовая масса t - кварка $174{,}3 \pm 5{,}1$ ГэВ.

22.2.7 Estimates in Nuclear Physics

(МК собираю сюда, в 1й части нечего этому делать!)

Оценки ядерных матричных элементов

В сферическом ядре существует вырождение по проекции углового момента с кратностью порядка величины углового момента $l \sim p_{\vec{F}} R$, где R - радиус ядра, а p_F - импульс нуклона на границе ферми. Так как $R = r_0 A^{1/3}$, где r_0-величина порядка среднего расстояния между нуклонами, то $p_F R = p_F r_0 A^{1/3} \sim A^{1/3}$. Следовательно, среднее расстояние между ближайшими уровнями сферического ядра имеет порядок величины $\varepsilon_F / A^{2/3}$.

Оценим сначала расстояние между уровнями, отличающимися лишь радиальными квантовыми числами n, причем $\delta n \sim 1$. Для этого продифференцируем по n условие квантования Бора $\int p_r dr = n$, где p_r - радиальный импульс:

$$1 = \int \frac{\partial p_r}{\partial n} dr = \int \frac{\partial p_r}{\partial \varepsilon_{nl}} \frac{\partial \varepsilon_{nl}}{\partial n} dr \sim \frac{\partial \varepsilon_{nl}}{\partial n} \int \frac{dr}{v} \sim \frac{\partial \varepsilon_{nl}}{\partial n} \frac{R}{v},$$

где ε_{nl}-уровень энергии, а $v = \frac{\partial \varepsilon_{nl}}{\partial p_r}$ - скорость нуклона. В итоге

$$\frac{\partial \varepsilon_{nl}}{\partial n} \sim \frac{v}{R} = \frac{v}{r_0 A^{1/3}} \sim \frac{p_F v}{A^{1/s}} \sim \frac{\varepsilon_F}{A^{1/3}}.$$

22.2.8 Ionizing radiation

(взял из лабника, не будет нужно - уменьшу раздел)

Main methods

Some laboratory examples

(see labnik)

Определение энергии α-частиц по величине их пробега в воздухе

Исследование энергетического спектра β-частиц и определение их максимальной энергии при помощи магнитного спектрометра.

0

Измерение абсолютной активности препарата ^{60}Co методом $\gamma - \gamma$ совпадений

22.2.9 Mass spectrometry

Some laboratory examples

(see labnik)

Измерение коэффициента ослабления потока γ-лучей в веществе и определение их энергии.

Спектрометрия α-излучения с помощь ю полупроводникового детектора.

Определение энергии γ-квантов с помощью сцинтилляционного спектрометра

Исследование процессов взаимодействия γ-излучения со сцинтилляционными детекторами

22.2.10 Structure of Atomic Nuclei

(см. пока ЛЛ3, вообще это отдельное направление, тут основы просто укажу.)

Изотопическая инвариантность

(см. Ландау 3)

Ядерные силы

Оператор взаимодействия двух нуклонов может быть представлен в виде суммы трех (???) независимых членов (?? why??)

$$\widehat{U}_{\text{обыч}} = U_1(r) + U_2(r)\left(\widehat{\mathbf{s}}_1\widehat{\mathbf{s}}_2\right) + U_3(r)\left[3\left(\widehat{\mathbf{s}}_1\mathbf{n}\right)\left(\mathbf{s}_2\mathbf{n}\right) - \widehat{\mathbf{s}}_1\widehat{\mathbf{s}}_2\right]$$

$$\widehat{U}_{\text{обм}} = \left\{U_4(r) + U_5(r)\left(\widehat{\mathbf{s}}_1\widehat{\mathbf{s}}_2\right) + U_6(r)\left[3\left(\widehat{\mathbf{s}}_1\mathbf{n}\right)\left(\widehat{\mathbf{s}}_2\mathbf{n}\right) - \widehat{\mathbf{s}}_1\widehat{\mathbf{s}}_2\right]\right\}\widehat{P}$$

Полный оператор взаимодействия дается суммой

$$\widehat{U} = \widehat{U}_{\text{обыч}} + \widehat{U}_{\text{обм}}\,.$$

при $T = 1 : {}^3P_0^-, {}^3P_1^-, \left({}^3P_2 + {}^3F_2\right)^-, {}^3F_3^-, ...; {}^1S_0^+, {}^1D_2^+, {}^1G_4^+, ...,$
при $T = 0 : \left({}^3S_1 + {}^3D_1\right)^+, {}^3D_2^+ \left({}^3D_3 + {}^3G_3\right)^+, ...; {}^1P_1^-, {}^1F_3^-, ...$

$$R = r_0 A^{1/3},$$

Предельный импульс нуклонов в ядерном веществе.

Объем фазового пространства, соответствующий частицам, находящимся в единице объема физического пространства и обладающим импульсами $p \leqslant p_0$, равен $4\pi p_0^3/3$. Разделив его на $(2\pi\hbar)^3$, получим число «клеток», в каждой из которых может находиться по два протона и два нейтрона. Положив число протонов равным числу нейтронов, получим

$$4\frac{4\pi}{3}\left(\frac{p_0}{2\pi\hbar}\right)^3 = \frac{A}{V}$$

где V - объем ядра. Подставив сюда (117.5), получим

$$p_0 = \left(\frac{3\pi^2 A}{2V}\right)^{1/3}\hbar = \frac{(9\pi)^{1/3}\hbar}{2r_0} = 1,4\cdot 10^{-14}\text{g}\cdot\text{cm}\cdot\text{c}^{-1}.$$

Соответствующая энергия $p_0^2/2m_p$ (m_p - масса нуклона) составляет $\sim$ 30МэВ, а скорость $p_0/m_p \approx c/4$.

Модель оболочек

Для правильного описания, нужно сделать замены: (???)

$$\mathbf{r}_i \to \mathbf{r}_i - \mathbf{R}, \qquad \mathbf{p}_i \to \mathbf{p}_i - \frac{\mathbf{P}}{A}$$

где $\mathbf{R}$ - радиус-вектор центра инерции ядра; A - число частиц в нем; $\mathbf{P}$ - импульс его движения как целого; $\mathbf{p}_i \to \mathbf{p}_i - \frac{\mathbf{P}}{A}$ соответствует вычитанию $\mathbf{v}_i \to \mathbf{v}_i - \mathbf{V}$ из скоростей нуклонов скорости центра инерции $\mathbf{V}$, с которой импульс $\mathbf{P}$ связан соотношением $\mathbf{P} = Am_p\mathbf{V}$ (S. Gartenhaus, C. Schwartz, 1957).

Так, оператор дипольного момента ядра есть $\mathbf{d} = e\sum \mathbf{r}_p$, суммирование производится по всем протонам в ядре. Для вычисления же матричных элементов в методе самосогласованного поля этот оператор надо заменить оператором $e\sum(\mathbf{r}_p - \mathbf{R})$. Координаты центра ядра

$$\mathbf{R} = \frac{1}{A}\left(\sum_p \mathbf{r}_p + \sum_n \mathbf{r}_n\right)$$

Поскольку число протонов в ядре есть Z, то окончательно оператор дипольного момента должен быть заменен согласно

$$e\sum_p \mathbf{r}_p \to e\left(1 - \frac{Z}{A}\right)\sum_p \mathbf{r}_p - e\frac{Z}{A}\sum_n \mathbf{r}_n$$

Из трех векторов $\mathbf{s}, \mathbf{n}$ и $\mathbf{v}$ можно составить истинный скаляр: $[\mathbf{nv}]\mathbf{s}$. Поэтому оператор спин-орбитальной связи нуклона в ядре имеет вид

$$\widehat{V}_{sl} = -\varphi(r)[\mathbf{n}\widehat{\mathbf{v}}]\widehat{\mathbf{s}},$$

где $\varphi(r)$ - некоторая функция от r. Поскольку $m_p[\mathbf{rv}] = \hbar\widehat{\mathbf{l}}$, то

$$\widehat{V}_{sl} = -f(r)\widehat{\mathbf{l}}\widehat{\mathbf{s}},$$

где $f = \hbar\varphi/rm_p$. Подчеркнем, что это взаимодействие-первого порядка по v/c, между тем как спин-орбитальная связь электрона в атоме - эффект второго порядка (§72);

Поскольку

$$\begin{aligned} \mathbf{ls} &= l/2 && \text{при} \quad j = l + 1/2, \\ \mathbf{ls} &= -(l+1)/2 && \text{при} \quad j = l - 1/2 \end{aligned}$$

(по формуле (31.3)), то величина этого расщепления

$$\Delta E = E_{l-1/2} - E_{l+1/2} = \overline{f(r)}(l + 1/2).$$

Следующее правило относится к изотопическому спину ядер. Напомним, что проекция T_ζ изоспина определяется уже весом и номером ядра (см. (116.1)). При заданном значении T_ζ абсолютная величина изоспина может иметь любые значения, удовлетворяющие неравенству $T \gg |T_\zeta|$. Обычно основное состояние ядра имеет наименьшее из этих допустимых значений изоспина, т. е.

$$T_{\text{осн}} = |T_\zeta| = (1/2)(N - Z).$$

Это правило связано с характером взаимодействия нейтрона с протоном, - с тем, что в системе np состояние с изоспином $T = 0$ (состояние нейтрона) имеет бóльшую энергию связи, чем состояние с $T = 1$ (см. примечание на с. 580).

$1s_{1/2}$	2 нуклона,
$1p_{3/2}, 1p_{1/2}$	6 нуклонов,
$1d_{5/2}, 1d_{3/2}, 2s_{1/2}$	12 нуклонов,
$1f_{7/2}, 2p_{3/2}, 1f_{5/2}, 2p_{1/2}, 1g_{9/2}$	30 нуклонов,
$2d_{5/2}, 1g_{7/2}, 1h_{11/2}, 2d_{3/4}, 3s_{1/2}$	32 нуклона,
$2f_{7/2}, 1h_{9/2}, 1i_{13/2}, 2f_{5/2}, 3p_{3/2}, 3p_{1/2}$	44 нуклона.

Для каждой группы указано полное число протонных или нейтронных вакансий. Соответственно этим числам заполнение какой-либо из групп заканчивается, когда полное число протонов Z или нейтронов N в ядре равно одному из следующих чисел:

$$2, 8, 20, 50, 82, 126.$$

Эти числа принято называть магическими.

$$\widehat{\overline{\boldsymbol{\mu}}} = \mu_0 g \widehat{\mathbf{J}}$$

где μ_0 - ядерный магнетон, а g-гиромагнитный множитель. Собственное значение проекции этого момента $\bar{\mu}_z = \mu_0 g M_J$. Обычно (ср. (111.1)) под магнитным моментом μ, ядра понимают просто максимальное значение его проекции, т. е. $\mu = \mu_0 g J$; с таким обозначением

$$\widehat{\overline{\boldsymbol{\mu}}} = \mu(\widehat{\mathbf{J}}/J).$$

С указанными выше значениями гиромагнитных множителей это дает для магнитного момента протона $\mu_p = g_j j$:

$$\begin{aligned} \mu_p &= \left(1 - \tfrac{2{,}29}{j+1}\right) j \quad \text{при} \quad j = l - 1/2, \\ \mu_p &= j + 2{,}29 \quad \text{при} \quad j = l + 1/2 \end{aligned}$$

и для магнитного момента нейтрона

$$\begin{aligned} \mu_n &= \tfrac{1{,}91}{j+1} j \quad \text{при} \quad j = l - 1/2. \\ \mu_n &= -1{,}91 \quad \text{при} \quad j = l + 1/2 \end{aligned}$$

$$\varphi(r)\frac{e}{cm_p}[\mathbf{nA}]\widehat{\mathbf{s}} = f(r)\frac{e}{2c\hbar}[\mathbf{r}[\mathbf{Hr}]]\widehat{\mathbf{s}} = f(r)\frac{e}{2c\hbar}[\mathbf{r}[\widehat{\mathbf{s}}\mathbf{r}]\mathbf{H}$$

Такой член эквивалентен возникновению дополнительного магнитного момента с оператором

$$\widehat{\mu}_{\text{доп}} = -\frac{e}{2c\hbar} f(r)[\mathbf{r}[\widehat{\mathbf{s}}\mathbf{r}]] = -\frac{e}{2c\hbar} r^2 f(r)\{\widehat{\mathbf{s}} - (\widehat{\mathbf{s}}\mathbf{n})\mathbf{n}\}.$$

Несферические ядра

Полный момент вращающегося ядра $\mathbf{J}$, разумеется, сохраняется. При заданном Ω его величина J пробегает значения, начинающиеся от Ω:

$$J = \Omega, \quad \Omega + 1, \quad \Omega + 2, \ldots$$

(см. (83.2)). Дополнительное ограничение возможных значений J имеет место для ядер с $\Omega = 0$: в состояниях 0_g^+ и 0_u^- число J пробегает лишь четные значения, а в состояниях 0_g^- и 0_u^+- нечетные (см. §86). В частности, во вращательных уровнях основного терма четно-четных ядер $\left(0_g^+\right)$ число J пробегает значения $0, 2, 4, \ldots$ Вращательная энергия ядра определяется формулой

$$E_{\text{Вр}} = \frac{\hbar^2}{2I} J(J+1)$$

Как известно из механики (см. I, §39), энергия частицы во вращающейся системе координат содержит дополнительный член, равный произведению угловой скорости вращения на момент импульса частицы. Соответствующий член в гамильтониане ядра можно представить в виде $2b\widehat{\mathbf{K}}\widehat{\boldsymbol{\sigma}}$, где b-некоторая постоянная; $\widehat{\mathbf{K}}$ - вращательный момент остова ядра (ядро без последнего нуклона), а $\widehat{\boldsymbol{\sigma}}$ - момент нуклона; последний надо понимать здесь в чисто формальном смысле (в действительности вектор момента нуклона в аксиальном поле ядра не существует), как оператор, аналогичный оператору спина $1/2$, дающий переходы между состояниями со значениями проекции момента $\pm 1/2$ - в соответствии со значением $\Omega = 1/2$[1]). Поскольку $\mathbf{K} = \mathbf{J} - \boldsymbol{\sigma}$, то собственные значения этого оператора

$$2b\mathbf{K}\boldsymbol{\sigma} = b\left[J(J+1) - K(K+1) - \frac{3}{4}\right].$$

Добавив сюда для удобства не зависящую от J постоянную $b/2$, найдем, что эта величина равна $\pm b(J+1/2)$ при $J = K \pm 1/2$. Это выражение можно записать в виде $(-1)^{J-1/2}b(J+1/2)$, если учесть, что момент K остова (представляющего собой четно-четное ядро) является четным числом. Таким образом,

окончательно получаем следующее выражение для вращательной энергии ядра с $\Omega = 1/2$:

$$E_{\text{Вр}} = \frac{\hbar^2}{2I}J(J+1) + (-1)^{J-1/2}b\left(J + \frac{1}{2}\right)$$

(A. Bohr, B. Mottelson, 1953). Отметим, что если постоянная b положительна и достаточно велика, то уровень с $J = 3/2$ может оказаться лежащим ниже уровня с $J = 1/2$, т.е. может нарушиться нормальный порядок вращательных уровней, при котором низший уровень соответствует наименьшему возможному значению J.

$$\boldsymbol{\mu} = \mu'\mathbf{n} + g_r(\mathbf{J} - \Omega\mathbf{n}).$$

Здесь g_r есть гиромагнитный множитель вращения ядра. Поскольку вклад в магнитный момент при вращении дают только протоны, то

$$g_r = \frac{I_p}{I_p + I_n}$$

где I_n и I_p - нейтронная и протонная части момента инерции ядра (для системы из одних только протонов должно было бы быть просто $g_r = 1$). Отношение (119.5), вообще говоря, не совпадает с отношением Z/A числа протонов к полной массе ядра.

После усреднения по вращению ядра магнитный момент направлен по сохраняющемуся вектору $\mathbf{J}$:

$$\overline{\widehat{\boldsymbol{\mu}}} = \frac{\mu}{J}\widehat{\mathbf{J}} = (\mu' - \Omega g_r)\,\overline{\mathbf{n}} + g_r\widehat{\mathbf{J}}.$$

Как обычно, умножаем обе части этого равенства на $\widehat{\mathbf{J}}$ и переходим к собственным значениям. В основном состоянии ядра $\Omega = J$ в результате находим

$$\mu = (\mu' + g_r)\,\frac{J}{J+1}.$$

Изотопическое смещение

У двух изотопов (одинаковых элементов, но с разным числом протонов и нейтронов в ядре) разная энергия, она равна разности энергий

$$E = \frac{2\pi}{3}\psi^2(0)Ze^2\overline{r^2}$$

Тут $\overline{r^2} = \frac{1}{Ze}\int \rho r^2 dV$ - протонный средний квадратичный радиус ядра (при однородном распределении протонов $\overline{r^2} = 3R^2/5$, где R - геометрический радиус ядра).

Обоснование следующее. В легких атомах основным источником изотопического смещения является эффект конечности массы ядра. $\frac{1}{2M}\left(\sum_i \widehat{\mathbf{p}}_i\right)^2$, где M - масса ядра, а $\mathbf{p}_i$ - импульсы электронов. Поэтому связанное с данным эффектом изотопическое смещение находится как среднее значение $\frac{1}{2}\left(\frac{1}{M_1}-\frac{1}{M_2}\right)\overline{\left(\sum_i \mathbf{p}_i\right)^2}$, вычисленное по волновой функции данного состояния атома (M_1, M_2 - массы ядер изотопов).

$$\Delta E = -e\int\left(\varphi - \frac{Ze}{r}\right)\psi^2(r)dV = \overset{\Delta r^2=6}{=} -\frac{1}{6}e\psi^2(0)\int\left(\varphi-\frac{Ze}{r}\right)\Delta r^2 dV = -\frac{1}{6}e\psi^2(0)\int r^2\Delta\left(\varphi-\frac{Ze}{r}\right)dV$$

(??? подумаю еще про это!) Тут $\Delta\frac{1}{r} = -4\pi\delta(\mathbf{r})$, а $r^2\delta(\mathbf{r}) = 0$ при всех r. Также по уравнению Пуассона $\Delta\varphi = -4\pi\rho$, где ρ - плотность распределения электрического заряда в ядре. Отсюда и заявленная формула.

В §71ЛЛ3 была произведена оценка величины $\psi(0)$ и выяснено, что она зависит от (предполагаемого большим) атомного номера как $\sqrt{Z}$. Поэтому величина расщепления (120.3) оказывается пропорциональной R^2Z^2.

Об учете движения ядра (???)

(??? как это учесть??? тоже от этого поправка есть какая-то???)

22.2.11 Hyperfine Structure (!?)

(пока только тут про это планирую писать, чуть что - отдельная запись.)

Основные свойства

(напишу когда-то суть, типа такие-то вклады, квадрупольное, магнитодипольное, да???)

Hyperfine structure comes from the multipole moments of the atomic nucleus, in particular the magnetic dipole and electric quadrupole fields.

- Hyperfine effects couple the nucleus and electrons together, thereby enlarging the Hilbert space. They have many useful applications. For example, the hyperfine splitting of the ground state of hydrogen produces the 21 cm line, which is useful in radio astronomy. Most atomic clocks use the frequency of a hyperfine transition in a heavy alkali atom, such as rubidium or cesium, the latter of which defines the second.

- We will denote the spin of the nucleus by $\mathbf{I}$, and as usual assume the nucleus is described by a single irrep, of I^2 eigenvalue $i(i+1)\hbar^2$. The nucleus Hilbert space is spanned by $|im_i\rangle$.

- For stable nuclei, i ranges from 0 to 15/2. For example, the proton has $i = 1/2$, the deuteron has $i = 1$, and ^{133}Cs, used in atomic clocks, has $i = 7/2$.

- We restrict to nuclei with $i = 1/2$, in which case the only possible multipole moment, besides the electric monopole, is the magnetic dipole.

Expansion of the Hamiltonian and terms for hyperfine structure

$$\mathbf{A}(\mathbf{r}) = (\boldsymbol{\mu} \times \mathbf{r}) \left(\frac{4\pi}{3} \delta(\mathbf{r}) + \frac{1}{r^3} \right), \qquad \mathbf{B}(\mathbf{r}) = \boldsymbol{\mu} \cdot \left(\frac{8\pi}{3} \delta(\mathbf{r}) I + \frac{T}{r^5} \right). \text{ (dipole)}$$

Here we're mixing vector and tensor notation; I is the identity tensor, T is the quadrupole tensor, and dotting with $\boldsymbol{\mu}$ on the left indicates contraction with the first index. The delta function terms, present for all physical dipoles, will be important for the final result.

- The Hamiltonian is similar to that of the Zeeman effect,

$$H = \frac{1}{2} \left(\mathbf{p} + \frac{\mathbf{A}}{c} \right)^2 + V(r) + H_{\text{FS}} + H_{\text{Lamb}} + \frac{1}{c} \mathbf{S} \cdot \mathbf{B}.$$

The magnetic moment of the nucleus is

$$\boldsymbol{\mu} = g_N \mu_N \mathbf{I}$$

where μ_N is the nuclear magneton. The states in the Hilbert space can be written as $|n\ell j m_j m_i\rangle$, which we refer to as the "uncoupled" basis since $\mathbf{J}$ and $\mathbf{I}$ are uncoupled.

- As in our analysis of the Zeeman effect, the vector potential is in Coulomb gauge and the A^2 term is negligible, so by the same logic we have

$$H_1 = \frac{1}{c} (\mathbf{p} \cdot \mathbf{A} + \mathbf{S} \cdot \mathbf{B}).$$

However, it will be more difficult to evaluate these orbital and spin terms.

- The orbital term is proportional to

$$\mathbf{P} \cdot (\mathbf{I} \times \mathbf{r}) = \mathbf{I} \cdot (\mathbf{r} \times \mathbf{p}) = \mathbf{I} \cdot \mathbf{L}$$

where one can check there are no ordering issues. Similarly, there are no ordering issues in the spin term, since $\mathbf{S}$ and $\mathbf{I}$ act on separate spaces. Hence we arrive at

$$H_{1,\text{orb}} = k(\mathbf{I} \cdot \mathbf{L}) \left(\frac{4\pi}{3} \delta(\mathbf{r}) + \frac{1}{r^3} \right), \quad H_{1,\text{spin}} = k \left(\frac{8\pi}{3} \delta(\mathbf{r}) (\mathbf{I} \cdot \mathbf{S}) + \frac{\mathbf{I} \cdot T \cdot \mathbf{S}}{r^5} \right).$$

The delta function terms are called Fermi contact terms, and we have defined

$$k = 2 g_N \mu_B \mu_N = g_e g_N \mu_B \mu_N.$$

The term $H_{1,\text{ spin}}$ is a spin-spin interaction, while $H_{1,\text{ orb}}$ can be thought of as the interaction of the moving electron with the proton's magnetic field.

- It's tempting to add in additional terms, representing the interaction of the proton's magnetic moment with the magnetic field produced by the electron, due to its spin and orbital motion. These give additional copies of $H_{1,\text{ spin}}$ and $H_{1,\text{ orb}}$ respectively, but they shouldn't be added since they would double count the interaction.

- The terms I - L and I - S don't commute with $\mathbf{L}, \mathbf{S}$, or $\mathbf{I}$. So just as for fine structure, we are motivated to go to the coupled basis. We define $\mathbf{F} = \mathbf{J} + \mathbf{I}$ and diagonalize L^2, J^2, F^2, and F_z. The coupled basis is related to the uncoupled one as

$$|n\ell j f m_f\rangle = \sum_{m_j, m_i} |n\ell j m_j m_i\rangle \langle j i m_j m_i | f m_f\rangle .$$

To relate this coupled basis to the original uncoupled basis $|n\ell m_\ell m_s m_f\rangle$, we need to apply Clebsch-Gordan coefficients twice. Alternatively, we can use tools such as the Wigner 6j symbols or the Racah coefficients to do the addition in one step.

Calculation of the energy shifts for hyperfine structure

- In the coupled basis, the perturbation is diagonal, so we again can avoid diagonalizing matrices. It suffices to compute diagonal matrix elements,

$$\Delta E = \langle n\ell jfm_f \left|H_1\right| n\ell jfm_f\rangle$$

- First we consider the case $\ell \neq 0$, where the contact terms do not contribute. We can write the energy shift as

$$\Delta E = k \langle n\ell jfm_f|\mathbf{I}\cdot\mathbf{G}|n\ell jfm_f\rangle\,, \quad \mathbf{G} = \frac{\mathbf{L}}{r^3} + \frac{T\cdot\mathbf{S}}{r^5} = \frac{\mathbf{L}}{r^3} + \frac{3\mathbf{r}(\mathbf{r}\cdot\mathbf{S}) - r^2\mathbf{S}}{r^5}.$$

- The quantity $\mathbf{G}$ is a purely electronic vector operator, and we are taking matrix elements within a single irrep of electronic rotations (generated by $\mathbf{J}$), so we may apply the projection theorem,

$$\Delta E = \frac{k}{j(j+1)} \langle n\ell jfm_f|(\mathbf{I}\cdot\mathbf{J})(\mathbf{J}\cdot\mathbf{G})|n\ell jfm_f\rangle\,.$$

- The first term may be simplified by noting that

$$\mathbf{I}\cdot\mathbf{J} = \frac{1}{2}\left(F^2 - J^2 - I^2\right).$$

This gives a factor similar to the Lande g-factor.

- For the second term, direct substitution gives

$$\mathbf{J}\cdot\mathbf{G} = \frac{L^2 - S^2}{r^3} + \frac{3(\mathbf{r}\cdot\mathbf{S})^2}{r^5}$$

where we used $\mathbf{r}\cdot\mathbf{L} = 0$. Now, we have

$$(\mathbf{r}\cdot\mathbf{S})^2 = \frac{1}{4}r_i r_j \sigma_i \sigma_j = \frac{1}{4}r_i r_j \left(\delta_{ij} + i\epsilon_{ijk}\sigma_k\right) = \frac{r^2}{4}.$$

Plugging this in cancels the $-S^2/r^3$ term, leaving

$$\mathbf{J}\cdot\mathbf{G} = \frac{L^2}{r^3}.$$

- Therefore, the energy shift becomes

$$\Delta E = k\frac{f(f+1) - j(j+1) - i(i+1)}{2j(j+1)}\ell(\ell+1)\left\langle\frac{1}{r^3}\right\rangle.$$

Specializing to hydrogen and evaluating $\langle 1/r^3\rangle$ as earlier, we get the final result

$$\Delta E = \frac{g_e g_N \mu_B \mu_N}{a_0^3}\frac{1}{n^3}\frac{f(f+1) - j(j+1) - i(i+1)}{j(j+1)(2\ell+1)}$$

where we restored the Bohr radius.

- Now consider the case $\ell = 0$. As we just saw, the non-contact terms get a factor of $\mathbf{J}\cdot\mathbf{G} = L^2/r^3$, so they vanish in this case. Only the contact term in $H_{1,\,\text{spin}}$ contributes, giving

$$\Delta E = \frac{8\pi}{3}k\langle\delta(\mathbf{r})(\mathbf{I}\cdot\mathbf{S})\rangle.$$

Since $\mathbf{F} = \mathbf{I} + \mathbf{S}$ when $\mathbf{L} = 0$, we have

$$\mathbf{I} \cdot \mathbf{S} = \frac{1}{2}\left(F^2 - I^2 - S^2\right) = \frac{1}{2}\left(f(f+1) - \frac{3}{2}\right).$$

The delta function is evaluated as for the Darwin term. The end result is that the energy shift we found above for $\ell \neq 0$ also holds for $\ell = 0$.

- When the hyperfine splitting is included, the energy levels become $E_{n\ell jf}$. The states $|n\ell jfm_f\rangle$ are $(2f+1)$-fold degenerate.

- For example, the ground state $1s_{1/2}$ of hydrogen splits into two levels, where $f = 0$ is the true ground state and $f = 1$ is three-fold degenerate; these correspond to antiparallel and parallel nuclear and electronic spins. The frequency difference is about 1.42GHz, which corresponds to a 21 cm wavelength.

- The $2s_{1/2}$ and $2p_{1/2}$ states each split similarly; the hyperfine splitting within these levels is smaller than, but comparable to, the Lamb shift between them. The fine structure level $2p_{3/2}$ also splits, into $f = 1$ and $f = 2$.

- Electric dipole transitions are governed by the matrix element

$$\left\langle n\ell jfm_f \left| x_q \right| n'\ell' j' f' m_f' \right\rangle.$$

The Wigner-Eckart theorem can be applied to rotations in $\mathbf{J}, \mathbf{F}$, and I separately, under each of which x_q is a $k = 1$ irreducible tensor operator, giving the constraints

$$m_f = m_f' + q, \quad |\Delta f| \leq 1, \quad |\Delta j| \leq 1, \quad |\Delta \ell| \leq 1.$$

As usual, parity gives the additional constraint $\Delta\ell \neq 0$.

- Finally, there is a special case for $f' = 0$, because this is the only representation that, upon multiplication by the spin 1 representation, does not contain itself: $0 \notin 0 \otimes 1$. This means we cannot have a transition from $f' = 0$ to $f = 0$. The same goes for ℓ, but this case is already excluded by parity.

- Note that the 21 cm line of hydrogen is forbidden by the rules above; it actually proceeds as a magnetic dipole transition. The splitting is small enough for it to be excited by even the cosmic microwave background radiation. The 21 cm line is especially useful because its wavelength is too large to be scattered effectively by dust. Measuring its intensity gives a map of the atomic hydrogen gas distribution, measuring its Doppler shift gives information about the gas velocity, and measuring its line width determines the temperature. Doppler shift measurements were used to map out the arms of the Milky Way. (These statements hold for atomic hydrogen; molecular hydrogen (H_2) has a rather different hyperfine structure.)

- It is occasionally useful to consider both the weak-field Zeeman effect and hyperfine structure. Consider a fine structure energy level with $j = 1/2$. For each value of m_f there are two states, with $f = i \pm 1/2$. The two perturbations don't change m_f, so they only mix pairs of states. Thus the energy level splits into pairs of levels, which are relatively easy to calculate; the result is the Breit-Rabi formula. The situation is just like how the Zeeman effect interacts with fine structure, but with (ℓ, s) replaced with (j, i). At lower fields the coupled basis is preferred, while at higher fields the uncoupled basis is preferred.

Сверхтонкая структура атомных уровней

(?????? вот тут у Ландау мб фигня, потом про это нужно еще думать много)

та. По общим правилам сложения моментов квантовое число F принимает значения

$$F = J + i, \quad J + i - 1, ..., |J - i|,$$

так что каждый уровень с заданным J расщепляется на $2i+1$ (если $i<J$) или $2J+1$(если $i>J$) компонент.

Поскольку средние расстояния r электронов в атоме велики по сравнению с радиусом R ядра, основную роль в сверхтонком расщеплении играет взаимодействие электронов с мультипольными моментами ядра наиболее низких порядков. Таковыми являются магнитный дипольный и электрический квадрупольный моменты (средний дипольный момент равен нулю-см. 75). Магнитный момент ядра имеет порядок величины $\mu_{\text{яд}} \sim \sim eRv_{\text{яд}}/c$, где $v_{\text{яд}}$ - скорости нуклонов в ядре. Энергия его взаимодействия с магнитным моментом электрона ($\mu_{\text{эл}} \sim e\hbar/mc$)

порядка

$$\frac{\mu_{\text{Яд}}\,\mu_{\text{эл}}}{r^3} \sim \frac{e^2\hbar}{mc^2}\frac{Rv_{\text{яд}}}{r^3}.$$

Квадрупольный момент ядра $Q \sim eR^2$; энергия взаимодействия создаваемого им поля с зарядом электрона порядка

$$\frac{eQ}{r^3} \sim \frac{e^2R^2}{r^3}.$$

Сравнивая (121.2) и (121.3), мы видим, что магнитное взаимодействие (а потому и вызываемое им расщепление уровней) в $(v_{\text{яд}}/c)\,(\hbar/mcR) \sim 15$ раз больше квадрупольного взаимодействия; хотя отношение $v_{\text{яд}}/c$ сравнительно мало, зато отношение $\hbar/mcR$ велико.

Оператор магнитного взаимодействия электронов с ядром имеет вид

$$\widehat{V}_{iJ} = a\widehat{\mathbf{i}}\widehat{\mathbf{J}}$$

(аналогично спин-орбитальному взаимодействию электронов (72.4)). Зависимость вызываемого им расщепления уровней от F дается, следовательно, выражением

$$\frac{a}{2}F(F+1)$$

Согласно известной формуле электродинамики это поле

$$\widehat{\mathbf{H}} = \frac{1}{c}\int \frac{[\widehat{\mathbf{n}}]}{r^2}dV,$$

где $\hat{\mathbf{j}}$ - оператор плотности тока, создаваемого движущимся электронным спином, а $\mathbf{r}=\mathbf{n}r$-радиус-вектор из центра К элементу dV[2]). Согласно (115.4) имеем

$$\widehat{\mathbf{j}} = -2\mu_B c\,\mathrm{rot}\left(\psi^2\widehat{\mathbf{s}}\right) = -2\mu_B c\frac{d\psi^2(r)}{dr}[\mathbf{n}\widehat{\mathbf{s}}]$$

)μ_B - магнетон Бора). Написав $dV=r^2drdo$ и произведя интегрирование, находим

$$\widehat{\mathbf{H}} = -2\mu_B\int_0^\infty \frac{d\psi^2}{dr}dr\int[\mathbf{n}[\mathbf{n}\widehat{\mathbf{s}}]]do = -2\mu_B\psi^2(0)\frac{8\pi}{3}\widehat{\mathbf{s}}.$$

Окончательно для оператора взаимодействия имеем

$$\widehat{V}_{is} = -\widehat{\boldsymbol{\mu}}\widehat{\mathbf{H}} = \frac{16\pi}{3i}\mu\mu_B\psi^2(0)\widehat{\mathbf{i}}\widehat{\mathbf{s}}.$$

$$E_{i+1/2} - E_{i-1/2} = \frac{8\pi}{3i}\mu\mu_B(2i+1)\psi^2(0)$$

Сверхтонкая структура молекулярных уровней (????)

(???? это заново читать нужно, пока не усвоено и не актуально)

Для $\widehat{Q}_{ii}=0$: (??? о чем речь???)

$$\widehat{b}\widehat{i}_i\widehat{i}_k\left(n_in_k-\frac{1}{3}\delta_{ik}\right)$$

при заданной величине проекции i_ζ спина ядра на ось молекулы эта величина равна $b\left[i_\zeta^2-\frac{1}{3}i(i+1)\right]$.

В результате же усреднения оператора (122.1) по вращению молекулы он оказывается выраженным через оператор $\widehat{\mathbf{K}}$ сохраняющегося вращательного момента. Усреднение произведения n_in_k производится по формуле, полученной в задаче к §29 (с вектором $\mathbf{K}$ вместо 1), и дает в результате

$$-\frac{b}{(2K-1)(2K+3)}\widehat{i}_i\widehat{i}_k\left[\widehat{K}_i\widehat{K}_k+\widehat{K}_k\widehat{K}_i-\frac{2}{3}\delta_{ik}K(K+1)\right].$$

Собственные значения этого оператора находятся так же, как это было указано для оператора (121.6).

В случае многоатомной молекулы вместо (122.1) получается, вообще говоря, оператор вида

$$b_{ik}\widehat{i}_i\widehat{i}_k$$

$$\overline{J_\zeta^2}=k^2,\overline{J_\xi^2}=\overline{J_\eta^2}=\frac{1}{2}\left[J(J+1)-k^2\right].$$

Если спины ядер равны $1/2$, квадрупольное взаимодействие отсутствует.

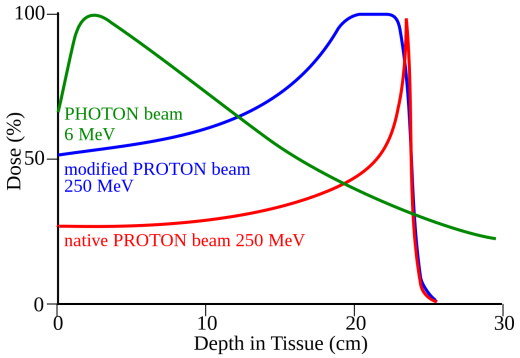
Одним из основных источников сверхтонкого расщепления в этом случае является прямое магнитное взаимодействие ядерных магнитных моментов друг с другом. Оператор взаимодействия двух магнитных моментов $\boldsymbol{\mu}_1=\mu_1\mathbf{i}_1/i_1,\boldsymbol{\mu}_2=\mu_2\mathbf{i}_2/i_2$ дается формулой

$$\frac{\mu_1\mu_2}{i_1i_2r^3}\left[\widehat{\mathbf{i}}_1\widehat{\mathbf{i}}_2-3\left(\mathbf{i}_1\mathbf{n}\right)\left(\mathbf{i}_2\mathbf{n}\right)\right]$$

22.3 Other Quantum Phenomena

22.3.1 Penetration of particles through medium in a nutshell

Bragg peaks and etc



(??? a paragraph about treating cancer with protons. Why exactly this way it is possible to do it? also I'll add some important formulas)

(пока у меня в ЭД сплошных сред это, потому что Ландау про это там написал. Все равно, специфическая тема, можно и не знать ее и жить счастливо)

22.3.2 Cosmic rays

Cosmic rays experiments

22.3.3 Magnetic resonances and nuclei

(see labnik 5 semestr)

Общая теория магнитного резонанса

Магнитный резонанс - это избирательное поглощение веществом электромагнитных волн определенной частоты, обусловленное изменением ориентации магнитных моментов частиц вещества. Если поглощение энергии осуществляется ядрами, то магнитный резонанс называется ядерным магнитным резонансом (ЯМР). Магнитный резонанс, обусловленный магнитными моментами неспаренных электронов в парамагнетиках, называется электронным парамагнитным резонансом (ЭПР). В магнитоупорядоченных веществах электронный магнитный резонанс называют антиферромагнитным или ферромагнитным в зависимости от симметрии упорядочения.

(см первые страницы раздела X лабника про это)

Электронный парамагнитный резонанс (ЭПР)

Классическая интерпретация этих резонансный явлений следующая. У нас есть спин (в случае электронного парамагнитного резонанса у электрона, в случае ядерного - у ядра), у нас есть внешнее постоянное магнитное поле. Спин может быть направлен по или против этого поля, в зависимости от этого энергия у такого спина будет разной. Но под действием внешнего переменного поля мы можем заставить спин поворачиваться. Это соответствует обычному переходу в двухуровневой системе. В качестве альтернативы, можно сказать, что это переход соответствует $M1$ фотонам.

Основная формула этого эффекта:

$$\hbar\omega_0 = g\mu B$$

(?? видимо, лабник нужно читать еще много!)

Сверхтонкая структура электронного парамагнитного резонанса

Изучение ядерного магнитного резонанса (ЯМР)

(!! тут важный абзац с сутью явления!)

$$E = -(\boldsymbol{\mu}, \mathrm{B})$$

$$\mu = \gamma \mathrm{M}$$

$$\mu_\mathrm{s} = \frac{e\hbar}{2m_p} = 0,5 \cdot 10^{-23} \cdot \text{ c}^{-1}$$

$$g = \frac{\mu/\mu_\mathrm{g}}{M/\hbar} = \frac{\mu}{\mu_\mathrm{g}}\frac{\hbar}{M} = \frac{\hbar}{\mu_\mathrm{g}}\gamma.$$

$$\boldsymbol{\mu} = \frac{\mu_\mathrm{g}}{\hbar} g \mathrm{M}$$

$$\mathrm{M}^2 = \hbar^2 I(I+1)$$

$$M_z = m\hbar$$

$$-I \leqslant m \leqslant +I$$

$$\mu_B = \frac{\mu_\mathrm{g}}{\hbar} g M_B = \frac{\mu_\mathrm{g}}{\hbar} g m \hbar = \mu_\mathrm{g} g m.$$

$$\Delta E = B \Delta \mu_B = B \mu_\mathrm{q} g \Delta m = B \mu_\mathrm{q} g.$$

(вставлю картинку из лабника!)

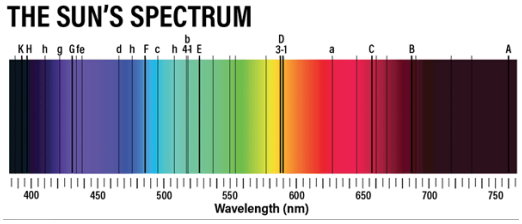
О солнце

Hydrogen and helium are by far the most abundant elements found in the Sun, making up about 98 percent of its mass, but other, heavier elements play an important role in the physical processes that occur in the Sun. The process of nuclear fusion combines hydrogen atoms to produce helium and the energy that keeps the Sun shining.

he next three elements heavier than helium — lithium, beryllium, and boron — are sometimes formed as intermediate products during the fusion process. Elements even heavier than these are present throughout the Sun. They come not from nuclear fusion in our own Sun, but from previous generations of massive stars in the solar neighborhood, the remains of which have been scattered by supernova explosions. The same cloud of enriched material that formed the Sun also formed Earth and the other planets. Thus, the same naturally occurring elements that

can be found on Earth, up to and including elements as heavy as uranium, are also present in the Sun.

Although elements heavier than helium are much less common than hydrogen and helium in the Sun, elements like iron, nickel, calcium, sodium, and magnesium are prominent in the solar spectrum and are important tools for astronomers studying the Sun.



(это не полностью еще понимаю, додумаю потом когда-то, тут больше объема про Солнце не планирую.)

Part VII
Introduction to Other Parts of QM

23 Experiments in Quantum Mechanics

Обсудим различные эксперименты в квантовой механике.

(??? уже где-то должен был быть этот раздел, если его не было, то тут будет. странно, что так не находится сразу он. такой вот подглавы должно хватить, итак много места указать многое.)

23.1 Review of Basic Devices for Experiments in QM

Обсудим различные квантовые приборы.

!!! по сути мы уже все это прошли, особенно когда делали лабы - все это изучали. особенно в оптике кстати.

просто потом придет отдельное время - я внимательно посмотрю на приборы, что они показывают и как работают.

это важный, но второстепенный раздел.

актуальные квантовые приборы

Обсудим сперва самые полезные квантовые приборы.

камера Вильсона

самый интересный прибор будто бы.

лабораторные приборы

монохроматоры

полезные вещи, на лабах они везде, потом разберу, что можно с ними интересного сказать про физику.

опыты!!!

осциллограф

я знаю, что это в электричестве, но пока буду писать сюда.

приборы для физики элементарных частиц

газовые детекторы

полупроводниковые детекторы

калориметры

23.2 How Exactly Basic Experiments of Quantum Mechanics Were Made?

(мб в другое место это напишу, пока тут. скорее не задачи, а просто каталог моделей)

23.2.1 Photoelectric Effect

(тут вмеру подробно обсуждаю, подробнее - только КТП.)

Суть фотоэффекта

Суть в том, что при облучении металлов светом определенной волны, из этих металлов могут выбиваться электроны.

Соотношение между энергией падающего фотона, работой выхода и кинетической энергией электронов есть

$$E_{h\nu} = A + T_e$$

Идейные вопросы о фотоэффекте

(тут полно их будет...)

Нормальная модель и описание фотоэффекта

тут КТП

Упрощенная модель фотоэффекта

(общефиз)

фотоэффект

Фотоэффект - испускание электронов фотокатодом, облучаемым светом (любым что ли, который выбьет частицы?)

Рассматривается катод (про другие материалы - хз), на который падает фотон $\hbar\omega$.

Энергетический баланс описывается *уравнением Эйнштейна*:

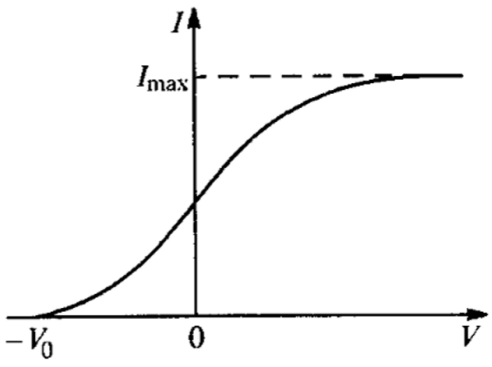
$$\hbar\omega = E_{\max} + A_{\text{вых}}$$

(возможно, наше внимание тут обращают на то, что энергия почти всегда меньше максимальной, а это уравнение справедливо только для максимальной?)

мы хотим измерять энергию вылетевших электронов вблизи катода.

для этого поместим анод рядом с ним и на него будем подавать разные потенциалы, а также измерять ток через него.

ток на аноде имеет такую зависимость для данной частоты фотонов:



В таком случае если мы приложим положительный потенциал V, то все выбитые фотоэлектроны достигнут анода, а если подадим задерживающее напряжение - то какие-то, которые с меньшей энергией вылетели, не смогут достичь анода, а при уменьшении

напряжения настанет случай, когда только с максимальной энергией электроны смогут достигать анод, этот потенциал называется *потенциал запирания* V_0. (в реальности есть какая-то оговорка про это, что сложно его поменять)

поэтому при потенциале запирания $E_{max} = eV_0$.

таким образом, зная работу выхода, зависимость запирающего потенциала от частоты имеет вид $eV_0 = \hbar\omega - W$.

окей, теперь в реальности оказывается, что выбиваются электроны не только с самых поверхностей материала, а еще и из внутренних частей, поэтому (я хз, ка это связано на самом деле, но так говорят) поэтому наблюдается плавное уменьшение фототока.

Чтобы определить зависимость тока от задерживающего потенциала, построим модель вылетающих электронов, распределенных по гауссу:

$$n(\vartheta) = n_0 e^{-\delta^2/\hat{v}_0^2}$$

,

где v_0 - ширина углового распредееления.

Тогда

$$dn(\vartheta) = n(\vartheta)d\vartheta = 2\pi n_0 \sin\vartheta e^{-j^2/D_0^2} d\vartheta$$

(я хз, откуда 2π, все заметаем под ковер словами "так расписывается телесный угол)

а так как фототок при малых углах будет, то нужно рассмотреть

$$dn(\vartheta) \simeq 2\pi n_0 \vartheta \left(1 - \vartheta^2/\overline{\vartheta}_0^2\right) d\vartheta$$

Ток I, или число электронов за единицу веремени, под углами меньшими θ определяется

$$N(\vartheta) = 2\pi n_0 \int_0^{\mathfrak{d}} \vartheta \left(1 - \mathfrak{v}^2/\overline{\vartheta}_0^2\right) d\vartheta = 2\pi n_0 \left(\vartheta^2/2 - \vartheta^4/4\overline{\vartheta_0^2}\right)$$

критический угол определяется из энергий, при угле большем скорости тупо не хватит: θ: $V = mv_z^2/2 = mv_0^2 \cos^2\vartheta/2$, расписывая cos для малого угла и вводя V_0, видим зависимость максимального угла отклонения от напряжения:$\vartheta^2/2 = 1 - V/V_0$.

супер, осталось подставить.

в итоге:

$$\boxed{I \propto N(V) = 2\pi n_0 \left[\frac{\vartheta_0^2}{4} - \left(\frac{1 - V/V_0}{\vartheta_0} - \frac{\partial_0}{2}\right)^2\right]} \tag{23.1}$$

В итоге видим, что корень квадратный фототока линейно зависит от запирающего напряжения.

Сделаем пару ключевых выводов:

мы можем с помощью 23.1 можем определить величину запирающего потенциала V_0, если измерим зависимость $\sqrt{I}(V)$

при изменении ω, зависимость V должна быть такой: $V_0(\omega) = (\hbar\omega - W)/e$.

Поэтому, строя график $V(\omega)$, мы ожидаем видеть прямую, по коэффициенту наклона которой можно определить постоянную Планка: $\frac{dV_0}{d\omega} = \frac{\hbar}{e}$.

Интересно, что такая зависимость будет одинаковой для любого вещества.

С помощью 23.1 мы можем можем определить величину запирающего потенциала, если измерим зависимость $\sqrt{I}(V)$

Виды фотоэффектов

из лабника спишу потом, пока не актуально.

О влиянии структуры твердых тел на фотоэффект (?????)

общефиз и опытные факты

(??? вообще мы его смотрим ведь только в твердых телах, а не в атомах в пространстве, чего тогде это будто бы не учитываем???)

Облучение проводящего шара и вылет конечного числа электронов

тупая задача для маги

Дано шар, столько-то электронов улетело, еще что-то..

На шаре образовывается положительный заряд, за счет которого однажды электронам не хватит энергии улететь на бесконечность.

Потенциальная энергия это

$$W_0 = q\varphi = q\frac{Q}{r}$$

где Q - заряд шара.

(кстати, она отрицательна, потому что q отрицательный, подумаю про это потом)

Величина барьера равна энергии выхода.

$$W_0 = T_e$$

В итоге формула фотоэффекта дает ответ

Формула Эйнштейна для фотоэффекта

Фотоэффект Нерелятивистский случай по Ландау 4

(подробнее в другой записи будет, тут суть напишу. сперва скорее всего просто выгрузки будут.)

Упрощенные формулы и суть (?)

Теория

В 49-52 мы рассматривали радиационные переходы (испускание или поглощение фотона) между атомными уровнями дискретного спектра. Фотоэффект отличается от такого процесса поглощения фотона лишь тем, что конечнсе состояние относится к непрерывному спектру.

Сечение фотоэффекта может быть вычислено до конца в аналитическом виде для атома водорода или для водородоподобного иона (с зарядом ядра $Z \ll 137$).

В начальном состоянии имеем электрон на дискретном уровне $\varepsilon_i \equiv -I$ (I- потенциал ионизации атома) и фотон с определенным нмпульсом k. В конечном состоянии электрон имеет импульс p (и энергию $\varepsilon_f \equiv \varepsilon$). Поскольку p пробегает непрерывный ряд значений, сечение фотоэффекта дается формулой

$$d\sigma = 2\pi \left|V_{fl}\right|^2 \delta(-I + \omega - \varepsilon)\frac{d^3p}{(2\pi)^3}$$

(ср. $(44, 3)$), причем волновая функция конечного состояния электрона предполагается нормированной на одну частицу в объеме $V = 1$. Таким же образом по-прежнему

нормирована волновая функция фотона; для. перехода к сечению do вероятность dw должна быть при этом разделена на плотность потока фотонов (равную $c/V = c$), но в релятивистских единицах это не отражается на виде формулы $(56, 1)$.

Выберем, как и в $(45, 2)$, трехмерно поперечную калибровку фотона. Тогда

$$V_{fi} = -e\mathbf{A}\mathbf{j}_{fi} = -e\sqrt{4\pi}\frac{1}{\sqrt{2\omega}}M_{fl}$$

где обозначено

$$M_{fi} = \int \psi'^{*}(\alpha \mathrm{e})e^{i\mathrm{kr}}\psi d^3x$$

($\psi \equiv \psi_i$ и $\psi' \equiv \psi_f$ - начальная и конечная волновые функции электрона). Заменив в $(56, 1) d^3p \to \mathbf{p}^2 d|\mathbf{p}|do = \varepsilon|\mathbf{p}|d\varepsilon do$ и проинтегрировав δ-функцию по $d\varepsilon$, перепишем эту формулу в-виде

$$d\sigma = e^2\frac{\varepsilon|\mathrm{p}|}{2\pi\omega}\left|M_{fi}\right|^2 do$$

Мы произведем вычисления в двух случаях, различающихся значением энергии фотона: для $\omega \gg I$ и для $\omega \ll m$. Поскольку $I \sim me^4Z^2 \ll m$, эти две области частично перекрываются (при $I \ll \omega \ll m$), так что исследование этих случаев дает по существу полное описание фотоэффекта. Начнем со случая

$$\omega \ll m$$

При этом скорость электрона мала как в начальном, так и в конечном состоянии, так что по отношению к электрону задача - целиком нерелятивистская. Соответственно этому заменим в $(56, 2)\boldsymbol{\alpha}$ нерелятивистским оператором скорости $\hat{\mathbf{v}} = -i\nabla/m$ (ср. 45). Кроме того, можно перейти к дипольному приближению - положить $e^{i\mathrm{kr}} \approx 1$, т. е. пренебречь импульсом фотона по сравнению с импульсом электрона. Тогда

$$d\sigma = e^2\frac{m|\mathbf{p}|}{2\pi\omega}\left|\mathbf{e}\mathbf{v}_{fl}\right|^2 do, \quad \mathbf{v}_{fi} = -\frac{i}{m}\int \psi'^{*}\nabla\psi \cdot d^3x. \qquad (56{,}5)$$

Будем рассматривать фотоэффект с основного уровня атома водорода (или водородоподобного иона). Тогда

$$\psi = \frac{(Ze^2m)^{3/2}}{\sqrt{\pi}}e^{-Ze^2mr}$$

(в обычных единицах $me^2 \to 1/a_0$, где $a_0 = \hbar^2/me^2$ - боровский радиус).

В качестве же ψ' надо взять волновую функцию, асимптос ней сходящуюся сферическую (см. III, 136, где такая функция обозначалась $\psi_{\mathrm{p}}^{(-)}$). В силу правила отбора по l переход из s-состояния возможен лишь в p-состояние (дипольный случай). Поэтому в разложении [1])

$$\psi_{\mathrm{p}}^{(-)} = \frac{1}{2p}\sum_{l=0}^{\infty} i^l(2l+1)e^{-i\delta_l}R_{pl}(r)P_l\left(\mathrm{nn}_1\right)$$

($\mathrm{n} = \mathrm{p}/p, \mathrm{n}_1 = \mathrm{r}/r$) достаточно оставить лишь член с$l = 1$, Опустив несущественные фазовые множители, получим

$$\psi' = \frac{3}{2p}\left(\mathrm{nn}_1\right)R_{p1}(r)$$

С функциями ψ и ψ' из (56, 6), (56, 8) имеем

$$\mathrm{ev}_{fi} = \frac{3\left(Ze^2m\right)^{5/2}}{2\sqrt{\pi}mp} \iint (\mathbf{nn}_1)\,(\mathrm{n}_1\mathrm{e})\, e^{-Ze^2mr} R_{p1}(r) do_1 \cdot r^2 dr =$$
$$= \frac{\sqrt{2\pi}\left(Ze^2m\right)^{5/2}}{pm}(\mathrm{ne}) \int\limits_0^\infty r^2 e^{-Ze^2mr} R_{p1}(r) dr.$$

Согласно III (36, 18) и III (36, 24) радиальная функция (в прннятых здесь единицах)

$$R_{p1} = \frac{\sqrt{8\pi}Ze^2m}{3}\sqrt{\frac{1+v^2}{v\left(1-e^{-2\pi v}\right)}}\ \mathrm{pre}\ e^{-ipr}F(2+iv, 4, 2ipr),$$

где обозначено:

$$v = \frac{Ze^2m}{p}\left(= \frac{Ze^2}{\hbar v}\right).$$

Нужный нам интеграл вычисляется с помощью формулы

$$\int\limits_0^\infty e^{-\lambda z} z^{\gamma-1} F(\alpha, \gamma, kz) dz = \Gamma(\gamma)\lambda^{\alpha-\gamma}(\lambda - k)^{-\alpha}$$

(см. III (f, 3)). Заметив также, что

$$\left(\frac{v+i}{v-i}\right)^{iv} = e^{-2v\,\mathrm{arcctg}\,v}$$

получим

$$\mathrm{ev}_{fi} = \frac{2^{7/2}\pi v^3(\mathrm{ne})}{\sqrt{p}m\left(1+v^2\right)^{3/2}} \frac{e^{-2v\,\mathrm{arcctg}\,v}}{\sqrt{1-e^{-2\pi v}}}$$

нергия ионизации с основного уровня атома водорода (или водородоподобного иона) $I = Z^2e^4m/2$. Поэтому

$$\omega = \frac{p^2}{2m} + I = \frac{p^2}{2m}\left(1+v^2\right)$$

Учитывая это соотношение, пишем окончательное выражение для сечения фотоэффекта с испусканием электрона в элемент телесного угла do:

$$d\sigma = 2^7\pi\alpha a^2 \left(\frac{I}{\hbar\omega}\right)^4 \frac{e^{-4v\,\mathrm{arcctg}\,v}}{1-e^{-2\pi v}}(\ \mathrm{ne}\ )^2 do,$$

где $a = \hbar^2/mZe^2 = a_0/Z$ (здесь и ниже - обычные единицы). Отметим, что угловое распределение фотоэлектронов определяется множителем $(\mathrm{ne}\ )^2$. Он максимален в направлениях, параллельных направлению поляризации падающих фотонов, и обращается в нуль в перпендикулярных вектору e направлениях, в том числе в направлении падения. Для неполяризованных фотонов формула (56, 11) должна быть усреднена по направлениям e, что сводится к замене

$$(\mathrm{ne})^2 \to \frac{1}{2}\left[\mathrm{n}_0\mathrm{n}\right]^2$$

где $\mathrm{n}_0 = \mathbf{k}/k$ (см. (45, 46)). Интегрирование же формулы (56,11) по углам дает полное сечение фотоэффекта:

$$\sigma = \frac{2^9\pi^2}{3}\alpha a^2 \left(\frac{1}{\hbar\omega}\right)^4 \frac{e^{-4v\,\mathrm{arcctg}\,v}}{1-e^{-2\pi\nu}}$$

(M. Stobbe, 1930). Предельное значение σ при $\hbar\omega \to I$ (т. е. $v \to \infty$):

$$\sigma = \frac{2^9\pi^2}{3e^4}\alpha a^2 = \frac{2^9\pi^2}{3e^4}\frac{\alpha a_0^2}{Z^2} = 0,23\frac{a_0^2}{Z^2}$$

(в знаменателе $e = 2,71...$).. Как и должно быть для реакции с образованием заряженных частиц (см. III, \$147), сечение фотоэффекта вблизи его порога стремится к постоянному пределі.

Случай же $\hbar\omega \gg I$ (причем по-прежнему $\hbar\omega \ll mc^2$) отвечает борновскому приближению ($v = Ze^2/\hbar v \ll 1$). Формула (56, 12), принимает вид

$$\sigma = \frac{2^8\pi}{3}\alpha a_0^2 Z^5 \left(\frac{I_0}{\hbar\omega}\right)^{7/2}$$

($I_0 = e^4m/2\hbar^2-$ энергия ионизации атома водорода). Процессом, обратным фотоэффекту, является радиационная рекомбинация электрона с неподвижным ионом. Сечение этого процесса ($\sigma_{\text{рек}}$) можно найти по сечению фотоэффекта (σ_ϕ) с помощью принципа детального равновесия (III, 144). Согласно этому принципу сечения процессов $i \to f$ и $f \to i$ (с двумя частицами в каждом из состояний i и f) связаны соотношением

$$g_l p_i^2 \sigma_{l\to f} = g_f p_f^2 \sigma_{f\to i}$$

где p_i, p_f - импульсы относительного движения частиц, а g_i, g_f - спиновые статистические веса состояний i и f. Учитывая также, что для фотона $g = 2$ (два направления поляризации), а статистический вес свободного электрона и иона равен статистическому весу основного состояния атома водорода, получаем для этого состояния

$$\sigma_{\text{рек}} = \sigma_\phi \frac{2\text{k}^2}{\text{p}^2}$$

)$\mathbf{p} = m\mathbf{v}$ - импульс падающего электрона, $\mathbf{k}$ - импульс испускаемого фотона). 3 а дачи 1. Получить формулу (56, 14) путем прямого использования борновского приближения в нерелятивистском случае.

Р е ше н и е. В борновском приближенни в качестве ψ' в формуле (56, 5) надо писать просто плоскую волну $\psi' = e^{i\text{pr}}$, а ψ - по-прежнему функция (56, 6). Тогда

$$\mathbf{v}_{ft} = \mathbf{v}_{if} = \frac{1}{m}\int \psi\hat{\mathbf{p}}\psi' d^3x = \frac{\mathbf{p}}{m}\frac{(Ze^2m)^{3/2}}{\sqrt{\pi}}\left(e^{-Ze^2mr}\right)_{\mathbf{p}'}$$

Фурье-компонента дается формулой (57, 66), так что

$$\mathbf{v}_{ft} \approx 8\sqrt{\pi}p^{-3}m^{3/2}\left(Ze^2\right)^{5/2}\mathbf{n}.$$

Подставив в (56, 5) и проинтегрировав по do, получим (56,14) (при этом, с достаточной точностью, $p^2/2m \approx \omega$). 2. Определить полное сечение радиационной рекомбннацни быстрого нерелятивистского электрона ($I \ll mv^2 \ll mc^2$) с ядром (заряд $Z \ll 137$).

р е ше н ие. Сечение захвата на K-оболочку (главное квантовое число $n = 1$) получается подстановкой (56, 14) в (56, 15) :

$$\sigma_1^{\text{рек}} = \frac{2^7\pi}{3}Z^5\alpha^3 a_0^2\left(\frac{I_0}{\varepsilon}\right)^{5/2}$$

)$\varepsilon = mv^2/2$ - энергия падающего электрона; $\omega \approx \varepsilon$). Из других состояний образующегося атома существенны лншь s-состояния: прн вычнсления матричного элемента в борновском

приближенни существенны значения волновой функции связанного состояния при малых r (как это будет видно из вычислений в 57), а при $l > 0$ эти значения малы по сравнению со значениями функций с $l = 0$; при этом достаточно учитывать два первых члена разложения ψ по степеням r. Для состояний с $l = 0$ и пронзвольным n эти члены

$$\psi = \frac{1}{\sqrt{\pi} a^{3/2} n^{3/2}} \left(1 - \frac{r}{a}\right)$$

т. е. содержат n лишь в виде общего множителя $n^{-3/2}$ (написанное выражение получается разложением функции III $(36, 13)$). Поэтому полное сечение рекомбинадни

$$\sigma^{\text{рек}} = \sum_{n=1}^{\infty} \sigma_n^{\text{рек}} = \sigma_1^{\text{рек}} \sum_{n=1}^{\infty} \frac{1}{n^3} = \zeta(3) \sigma_1^{\text{рек}}$$

(значение ζ-функщии: $\zeta(3) = 1,202$).

Фотоэффект Релятивистский случай по Ландау 4

(подробнее в другой записи будет, тут суть напишу. сперва скорее всего просто выгрузки будут.)

Упрощенные формулы и суть (?)

Теория

Обратимся к случаю $\omega \gg I$. $(57, 1)$ При этом также $\varepsilon = \omega - I \gg I$, и потому влияние кулонова поля ядра на волновую функцию фотоэлектрона (ψ') может быть учтено с помощью теории возмущении. Пишем ψ' в виде

$$\psi' = \frac{1}{\sqrt{2\varepsilon}} \left(u' e^{i\text{pr}} + \psi^{(1)}\right)$$

Фотоэлектрон может быть релятивистским; поэтожу невозмущенная функция в $(57, 2)$ напнсана в виде релятивистской плоской волны $(23, 1)$.

Хотя в начальном состоянии электрон нерелятивистский, в его волновой функции ф тем не менее должна быть (по выясняю; щимся ниже причинам) учтена релятивистская поправка ($\sim Ze^2$). Такая функция дается формулой (см. задачу к 39).

$$\psi = \left(1 - \frac{i}{2m} \gamma^0 \gamma \nabla\right) \frac{u}{\sqrt{2m}} \psi_{\text{нр}}$$

где ψ - нерелятивистская функция связанного состояния $(56, 6)$, а и-бнспинорная амплитуда покоящегося электрона, нормнрованная принятым нами условием $\bar{u}u = 2m$.

Подставим функцин $(57, 2 - 3)$ в матричный элемент $(56, 2)$[1]):

$$M_{fi} = \frac{1}{2\sqrt{m\varepsilon}} \int \left\{ \bar{u}'(\text{ve}) \left[\left(1 - \frac{i}{2m} \gamma^0 \boldsymbol{\gamma} \nabla\right) u \psi_{\text{up}}\right] e^{-i(\mathbf{p}-\mathbf{k})\mathbf{r}} + \right.$$
$$\left. + \bar{\psi}^{(1)}(\text{ve}) e^{i\text{kr}} u \Psi \right\} d^3x. \quad (57, 4)$$

Имея в виду получить первый член разложения этой величины по Ze^2, мы можем во втором члене в фигурных скобках замезультате такой замены обратился бы (при $\mathbf{p} - \text{k} \neq 0$) в нуль (именно поэтому в ф необходимо учитывать также и первую релятивистскую

поправку, пропорциональную Ze^2; при $v \sim 1$ эта поправка дает вклад в сечение того же порядка, что и следующий член разложения $\Psi_{\rm n}$ по Ze^2).

В первом члене в $(57,4)$ производим интегрирование по частям, переводя действие оператора ∇ с фир на экспоненциальный множитель. В результате получим

$$M_{fi} = \frac{(Ze^2m)^{3/2}}{2(\pi m\varepsilon)^{1/2}} \left\{ \bar{u}'(\mathrm{ve}) \left[1 + \frac{1}{2m} v^0 v(\mathbf{p} - \mathrm{k}) \right] u \left(e^{-Ze^2mr} \right)_{\mathrm{p-k}} + \right.$$
$$\left. + \bar{\psi} - \overset{(1)}{}_{-k}(\mathrm{ve}) u \right\}, \quad (57,5)$$

где векторный индекс означает пространственную компоненту Фурье. С точностью до члена $\sim Ze^{22})$

$$\left(e^{-Ze^2mr} \right)_{\mathrm{p-k}} = \frac{8\pi Ze^2m}{(\mathbf{p} - \mathbf{k})^4}.$$

1) Функция $(57,3)$ была получена дла расстояний $r \sim 1/mZe^2$, на которых поправочный член в ней относительного порядка величнны Ze. Но для основного состояния (а также и для всех вообще s-состояний) формула $(57,3)$ пригодна для любых r, поскольку пронзводная от чисто экспоненциальной функиии $(56,6)$ (а с нею и поправочнй член в $(57,3)$) всегда пропорциональна Ze^2. Это обстоятельство позволяет воспользоваться формулой $(57,3)$ в рассматриваемой задаче, в которой существенны малые r. (При $v \sim 1$ существенны $r \sim 1/\ \mathrm{m}$.) 2) Взяв компоненту Фурье от обеих сторон равенства

$$\left(\Delta - \lambda^2 \right) \frac{e^{-\lambda r}}{r} = -4\pi\delta(r),$$

получим

$$\left(\frac{e^{-\lambda r}}{r} \right)_{\mathbf{q}} = \frac{4\pi}{\mathbf{q}^2 + \lambda^2}.$$

Дифференцирование этого выражения по параметру λ дает

$$\left(e^{-\lambda r} \right)_{\mathrm{q}} = \frac{8\pi\lambda}{\left(q^2 + \lambda^2 \right)^2}$$

Для вычисления же компоненты Фурье $\psi^{(1)}_{\mathrm{k}}$ пишем уравнение, которому удовлетворяет функция $\psi^{(1)}$:

$$\left(\gamma^0\varepsilon + i\gamma\nabla - m \right) \psi^{(1)} = e \left(\gamma^\mu A_\mu \right) u' e^{i\mathrm{pr}} = -\frac{Ze^2}{r} \gamma^0 u' e^{i\mathrm{pr}}$$

(оно получается подстановкой $(57,2)$ в $(32,1)$). Применив к обеим сторонам этого уравнения оператор $(\gamma^0\varepsilon + i\gamma\nabla + m)$, получим

$$\left(\Delta + \mathbf{p}^2 \right) \psi^{(1)} = -Ze^2 \left(\gamma^0\varepsilon + i\gamma\nabla + m \right) \left(\gamma^0 u' \right) \frac{1}{r} e^{i\mathrm{pr}}.$$

причем в членах с Δ и $\boldsymbol{\nabla}$ производим обычным образом интегрирование по частям:

$$\left(\mathbf{p}^2 - \mathbf{k}^2 \right) \psi^{(1)}_{\mathbf{k}} = -Ze^2 \left(\gamma^0\varepsilon - \gamma\mathbf{k} + m \right) \left(\gamma^0 u' \right) \left(\frac{1}{r} \right)_{\mathbf{k-p}} =$$
$$= -\ Ze^2 \left(2\varepsilon\gamma^0 - v(\mathbf{k} - \mathbf{p}) \right) \left(\gamma^0 u' \right) \frac{4\pi}{(\mathbf{k} - \mathbf{p})^2}.$$

В последней строке учтено, что амплитуда u' удовлетворяет уравнению

$$\left(\varepsilon\gamma^0 - \mathbf{p} - m \right) u' = 0, \text{ или } \quad \left(\varepsilon\gamma^0 + \mathbf{p}\gamma - m \right) \gamma^0 u' = 0.$$

Отсюда находим

$$\bar{\psi}^{(1)}_{-\mathrm{k}} = \psi^{(\mathrm{I})}_{\mathrm{k}}\gamma^0 = 4\pi Ze^2\bar{u}'\frac{2\varepsilon\gamma^0 + \gamma(\mathrm{k}-\mathrm{p})}{(\mathrm{k}^2-\mathrm{p}^2)\,(\mathrm{k}-\mathrm{p})^2}\gamma^0.$$

Подставив $(57,6-7)$ в матричный элемент $(57,5)$, представим его в виде

$$M_{fi} = \frac{4\pi^{1/2}\,(Ze^2m)^{5/2}}{(\ell m)^{1/2}(\mathbf{k}-\mathbf{p})^2}\bar{u}'Au$$

где

$$A = a(\mathrm{ve}) + (\mathrm{ve})\gamma^0(\boldsymbol{\gamma}\mathbf{b}) + (\gamma\mathbf{c})\gamma^0(\gamma\mathrm{e}),$$

$$a = \frac{1}{(\mathbf{k}-\mathbf{p})^2} + \frac{\varepsilon}{m}\frac{1}{\mathbf{k}^2-\mathbf{p}^2}, \quad \mathbf{b} = -\frac{\mathbf{k}-\mathrm{p}}{2m(\mathrm{k}-\mathbf{p})^2}, \quad \mathbf{c} = \frac{\mathbf{k}-\mathbf{p}}{2m\,(\mathbf{k}^2-\mathrm{p}^2)}.$$

Сечение

$$d\sigma = \frac{8e^2\,(Ze^2m)^5\,|\mathbf{p}|}{\omega(\mathbf{k}-\mathbf{p})^4m}\,(\bar{u}'Au)\left(\bar{u}\bar{A}u'\right)do,$$

где $\bar{A} = \gamma^0A^+\gamma^0$ (см. §65). Это выражение надо еще просуммировать по конечным и усреднить по начальным направлениям спина электрона. Эти действия производятся по описанным ниже, в 65, правилам с помощью поляризационных матриц плотности начального и конечного состояний:

$$\rho = \frac{m}{2}\left(\gamma^0+1\right), \quad \rho' = \frac{1}{2}\left(\gamma^0\varepsilon - v\mathbf{p} + m\right)$$

(в начальном состоянии $\mathrm{p}=0, \varepsilon = m$). Они приводят к выражению

$$d\sigma = \frac{16e^2\,(Ze^2m)^5\,\lfloor\mathbf{p}\,|}{m\omega(\mathbf{k}-\mathbf{p})^4}\mathrm{Sp}\left(\rho'A\rho\bar{A}\right)do$$

Вычисление следа (с использованием формул (22,22)) представляет собой чисто алгебраическую операцию и приводит к следующему результату:

$$\mathrm{Sp}\left(\rho'A\rho\bar{A}\right) = \frac{m}{\varepsilon+m}[a\mathbf{p} - (\mathbf{b}-\mathbf{c})(\varepsilon+m)]^2 + \\ + 4m(\mathbf{be})[(\varepsilon+m)(\mathbf{ce}) + a(\mathrm{pe})]$$

(вектор e предполагается вещественным - линейная поляризация фотона).

Придадим формуле сечения фотоэффета окончательный вид, введя полярный угол θ и азимут φ направления p относительно направления $\mathbf{k}$ в качестве оси z и плоскости $\mathbf{k}$, e в качестве плоскости $xz($ так что $\mathrm{pe} = |p|\cos\varphi\sin\theta)$. При $\omega \gg I$ сохранение энергии можно записать в виде $\varepsilon - m = \omega$ (вместо $\varepsilon - m = \omega - I$). Легко проверить, что тогда

$$\mathbf{k}^2 - \mathbf{p}^2 = -2m(\varepsilon - m), \quad (\mathbf{k}-\mathbf{p})^2 = 2\varepsilon(\varepsilon-m)(1-v\cos\theta),$$

где $\mathbf{v} = \mathrm{p}/\varepsilon$ - скорость фотоэлектрона. После простых преобразований получим окончательно

$$d\sigma = Z^0\alpha^4r_e^2\frac{v^3\,(1-v^2)^3\sin^2\theta}{\left(1-\sqrt{1-v^2}\right)^5(1-v\cos\theta)^4}\times \\ \times\left\{\frac{\left(1-\sqrt{1-v^2}\right)^2}{2\,(1-v^2)^{3/y}}(1-v\cos\theta) + \right. \\ \left. + \left[2 - \frac{\left(1-\sqrt{1-v^2}\right)(1-v\cos\theta)}{1-v^2}\right]\cos^2\varphi\right\}do, \quad (57,8)$$

где $r_e = e^2/m$.

В ультрарелятивистском случае ($\varepsilon \gg m$) сечение фотоэффекта имеет резкий максимум при малых углах $\left(\theta \sim \sqrt{1-v^2}\right)$, т. е. электроны испускаются преимущественно в направлении падения фотона. Вблизи максимума пишем

$$1 - v\cos\theta \approx \frac{1}{2}\left[\left(1-v^2\right) + \theta^2\right]$$

и главные члены в $(57,8)$ дают

$$d\sigma \approx 4Z^5\alpha^4 r^2 \frac{\left(1-v^2\right)^{1/2}\theta^3}{\left(1-v^2+\theta^2\right)^3} d\theta d\varphi.$$

лементарное, хотя и довольно длинное интегрирование выражения $(57,8)$ по углам приводит.к следующей формуле для полного сечения (F. Sauter, 1931):

$$\sigma = 2\pi Z^5\alpha^4 r_e^2 \frac{\left(\gamma^2-1\right)^{2/}}{(\gamma-1)^5}\left\{\frac{4}{3}+\right.$$
$$\left.+\frac{\gamma(\gamma-2)}{\gamma+1}\left(1-\frac{1}{2\gamma\sqrt{\gamma^2-1}}\ln\frac{\gamma+\sqrt{\gamma^2-1}}{\gamma-\sqrt{\gamma^2-1}}\right)\right\}.$$

где для краткости введен «лоренцев множитель»

$$\gamma = \frac{1}{\sqrt{1-v^2}} = \frac{\varepsilon}{m} \approx \frac{m+\omega}{m}.$$

В ультрарелятивистском случае эта формула сводится к простому вьражению

$$\sigma = 2\pi Z^5\alpha^4 r_e^2/\gamma$$

В случае же $I \ll \omega \ll m$ переход в $(57,10)$ пределу малых $\boldsymbol{\gamma} - 1$ приводит к известному уже нам результату $(56,14)$.

Theory of photoeffect for XPS method

Об истории открытия фотоэффекта (?)

(тоже потом укажу.)

23.2.2 Young's Double-Slit Experiment

Обсудим подробно опыт Юнга.

Об опыте Юнга

(конкретно, в каких параметрах установки он будет?)

Один из самых важнейших опытов квантовой механики, дающий пояснение, что такое суперпозиция состояний - это опыт Юнга

оценки параметров для опыта Юнга (?)

тоже важно, но сперва это пропишу в оптике.

Важно понимать, какие параметры системы и почему они такие, чтобы была возможность воспроизводить опыт Юнга.

???

Связь с невозможностью этого опыта с отсутствией дырки в барьере до барьера с двумя щелями (!?!??!?)

(??? где мы учитываем, что он на самом деле обязателен??? вообще хз, казалось бы...)

Опыт Юнга и переход в классику по Фельдбругге (!!??!??!?!?!)

(про это остаются вопросы, тем не менее, теория крутая и полезная.)

Обсудим описание эксперимента Юнга как пример применения теории Пикара-Лефшеца.

мотивация

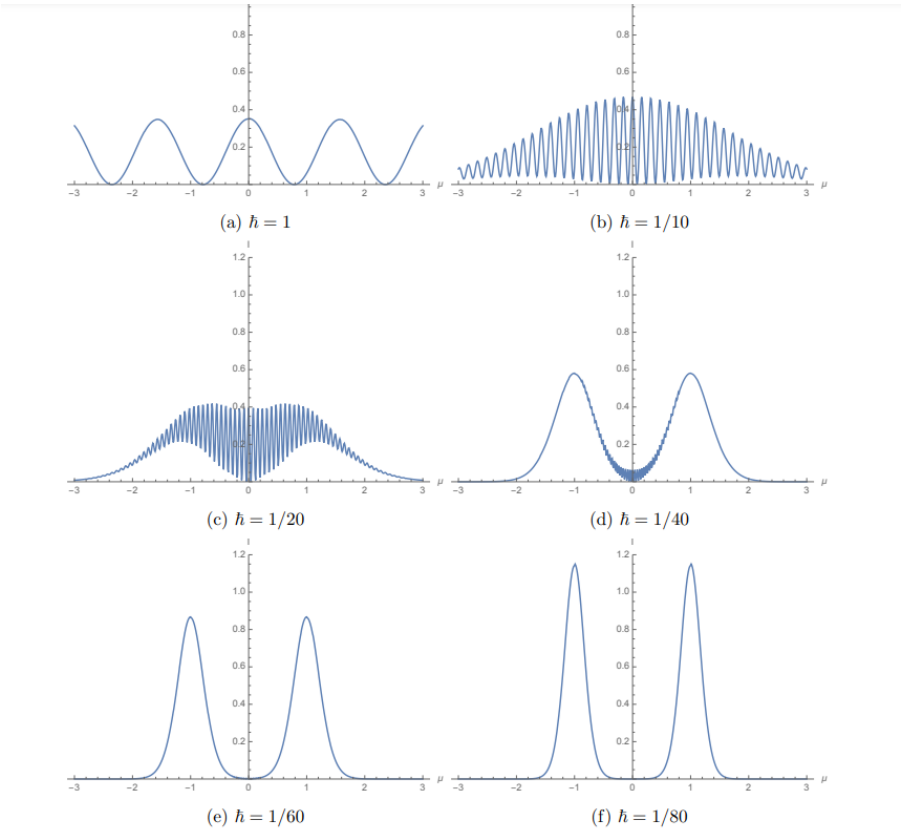
Опыт Юнга интересно изучить, потому что с одной стороны это один из самых популярных квантовых экспериментов, с другой - прекрасный способ применить методы, разработанные при изучении гравитационного линзирования.

Также вокруг него существует много домыслов и неверных трактовок, с которыми можно в корне неверно начать понимать квантовую механику, поэтому иметь четкое представление о нем крайне полезно.

Несмотря на чрезвычайную простоту этого примера и его центральную роль в идейном понимании квантовой физики и оптики, детальные интерференционные картины на удивление трудно вычислить.

модель опыта Юнга в двух словах

??? а там кстати не классическая это дифракция ведь, нет??
именно квантовые эффекты???
что там квантового?



(a) $\hbar = 1$ (b) $\hbar = 1/10$ (c) $\hbar = 1/20$ (d) $\hbar = 1/40$ (e) $\hbar = 1/60$ (f) $\hbar = 1/80$

Дифракционная картина опыта Юнга сполна находится возведением в квадрат $I(\mu) = |\Psi(\mu)|^2$ амплитуды $\Psi(\mu)$, которая имеет вид

$$\Psi(\mu) = \mathcal{N} \int e^{\frac{i}{\hbar}(x-\mu)^2} T(x) dx,$$

где $\mathcal{N}$ - нормировочный множитель, а $T(x)$ - функция пропускания:

$$T(x) \propto \exp\left[\frac{\epsilon}{\epsilon^2 + (x-s_1)^2} + \frac{\epsilon}{\epsilon^2 + (x-s_2)^2} - \frac{1}{\epsilon}\right]$$

описание опыта Юнга

(темы статьи Турока)

Изучим дифракционную картину от пары гладких щелей конечного размера.

Посмотрим, как меняется дифракционная картина в классическом пределе, то есть когда $\hbar$ приравнивается к нулю.

Требуется обобщение, чтобы сделать интерференционную "фазу" комплексной, чтобы заглушить амплитуду вдали от двух узких щелей.

Моделируя эту сложную фазу с помощью простой рациональной функции, легко находятся наперстки Лефшеца и вычисляется интерференционная картина при всех значениях параметров.

функция пропускания

Рассмотрим удаленный точечный источник, излучающий частицы в направлении экрана, с тонким барьером, отделяющим экран от источника.

Барьер за исключением двух щелей, непрозрачен для частиц.

??? я не знаю, как другие делают люди решение этой задачи, но тут я так понял, суть метода в том, что такой вид функции пропускания с одной стороны физически абсолютно верный, с другой - аналитически хорошо продолжается, именно поэтому мы такой выбрали.

В безразмерных координатах, которые будут определены ниже, ???????амплитуда проходящего света имеет вид

$$T(x) \propto \exp\left[\frac{\epsilon}{\epsilon^2 + (x-s_1)^2} + \frac{\epsilon}{\epsilon^2 + (x-s_2)^2} - \frac{1}{\epsilon}\right]$$

состоящий из двух пиков, каждый интенсивностью равным единицей с центром в $x = s_1$ и $x = s_2$ соответственно.

Здесь, $\epsilon > 0$ это небольшое число, отражающее небольшую ширину щелей в непрозрачном барьере.

(место вставить рисунок-иллюстрацию)

Вдали от щелей имеем зависимость $T \sim \exp(-1/\epsilon)$.

амплитуда прохождения

!!! тут используется в точности теория из оптики, которую нужно сперва прописать, потом будут понятны формулы.

Предполагая, что амплитуда падающих частиц когерентна и постоянна через щели, мы можем затем вычислить интегральную амплитуду пути как и делали ранее.

Однако здесь мы имеем дело с частицей фиксированной массы m, энергии E и импульса $p = \sqrt{2mE}$.

Последняя формула в $S_r[\boldsymbol{x}] = \int_{x_i}^{x_f} |d\boldsymbol{x}||\boldsymbol{p}|$, в тех же малых приближениях смещения, сделанных в уравнении $\Psi\left(\boldsymbol{x}_{\text{obs}}, \boldsymbol{x}_s; \nu\right) \propto \int d\boldsymbol{x} \exp\left[i\frac{\omega}{2c}\left(\frac{(\boldsymbol{x}-\boldsymbol{\mu})^2}{d} - \frac{\Sigma_e(\boldsymbol{x})e^2}{m_e\epsilon_0\omega^2}\right)\right]$, выше, ??????? дает пифагорейский вклад в фазу, $p(x-\mu)^2/(2d\hbar)$, где d-расстояние от щелей до экрана.

Установив $x \to xa$, где a - характерный размер щелей, а x - безразмерный, мы примем величину $\hbar 2d/\left(pa^2\right)$ за нашу новую, безразмерную $\hbar$.

В терминах этих безразмерных величин амплитуда для частицы, чтобы прибыть в положение μ на экране, следовательно, задается осциллирующим интегралом

$$\Psi(\mu) = \mathcal{N} \int e^{\frac{i}{\hbar}(x-\mu)^2} T(x) dx$$

с константой нормализации $\mathcal{N}$, обеспечивающей унитарность $\int |\Psi(\mu)|^2 \, d\mu = 1$.

Вероятность того, что частица достигнет μ на экране, задается абсолютным квадратом волновой функции

$$I(\mu) = |\Psi(\mu)|^2$$

Заметим, что безразмерная версия постоянной Планка $\hbar$ появляется в этой нерелятивистской задаче, тогда как она отменяется из наших более ранних формул для безмассовой частицы в результате масштабной ковариации последней. (????)

Вычислим волновую функцию за счет аналитического продолжения экспоненты

$$\phi(x;\mu) = \frac{i}{\hbar}(x-\mu)^2 + \frac{\epsilon}{\epsilon^2 + (x-s_1)^2} + \frac{\epsilon}{\epsilon^2 + (x-s_2)^2} - \frac{1}{\epsilon},$$

и вычисления наперстка Лефшеца.

(???) Экспонента имеет 4 полюса и 9 седловых точек.

Полюсы в точке $x = s_i \pm i\epsilon$ соответствуют щели с центром в точке s_i. Седловые точки являются корнями многочлена девятого порядка.

Мы можем связать четыре седловые точки с каждой щелью.

Оставшаяся седловая точка является общей и перемещается между полюсами, соответствующими двум щелям, в зависимости от положения на экране μ.

тут на рис. показаны соответствующие диаграммы Пикара-Лефшеца для различных положений μ для $\hbar = 1$.

В описании мы для простоты предположим, что левая щель находится в точке s_1, а правая-в точке s_1.

щель должна быть на уровне s_2, то есть $s_1 < s_2$:

анализ диаграмм Пикара-Лефшеца для эксперимента Юнга

- Для позиций на экране далеко слева от щелей, $\mu \ll_1$, наперсток состоит из пяти самых крутых контуров спуска.

Наперсток проходит от нижнего левого угла к верхнему правому через сложную седловую точку.

Затем наперсток обвивается вокруг верхнего левого и верхнего правого полюсов.

Для позиций $\mu \leq \frac{s_1+s_2}{2}$ в волновой функции доминирует левая щель.

Поэтому неудивительно, что наперсток, соответствующий правой щели, является репрезентативным в этом режиме.

- Когда μ приближается к s_1, мы наблюдаем преобразования Стокса, после которого релевантны только четыре седловые точки.

Наперсток перемещается из нижнего левого угла через седловую точку в верхний левый полюс, после чего он проходит через седловую точку между двумя левыми полюсами.

Правая часть наперстка практически не изменилась.

- Когда μ приближается к средней точке $\frac{\mu_1+\mu_2}{2}$, мы наблюдаем, что комплексная седловая точка становится актуальной (?) после явления Стокса.

Наперсток теперь состоит из четырех контуров наискорейшего спуска.

- Для μ вблизи средней точки $\mu = \frac{\mu_1+\mu_2}{2}$ мы наблюдаем, что после еще одного стоксова перехода мы получаем наперсток, состоящий из пяти самых крутых контуров спуска.

Обратите внимание, что средняя седловая точка переместилась в начало координат $x = 0$.

Когда положение μ будет еще больше увеличено, эта седловая точка переместится к полюсам, соответствующим правой щели. Соответствующие диаграммы Пикара-Лефшеца являются зеркальными отражениями рассмотренных выше.

(тут снова можно вставлять крышесносные диаграммы Пикара-Лефшеца)

В квазиклассическом пределе $\hbar \to 0$ геометрия наперстка Лефшеца во все большей степени определяется пифагорейским членом в уравнении (B4).

Как следствие, после нескольких преобразований Стокса восемь седловых точек, которые могут быть связаны с полюсами, соответствующим двум щелям, становятся более тесно связанными с полюсами, представляющими геометрию правой части наперстка на рис.37.

Оставшаяся седловая точка все еще движется между полюсами, соответствующими двум щелям.

Однако заметим, что в интеграле все больше доминируют две седловые точки между четырьмя полюсами.

Эти две седловые точки приближаются к реальной линии при $x = s_1$ и $x = s_2$ в этом пределе.

Учитывая наперсток, мы можем эффективно оценить осциллирующий интеграл для различных $\hbar$

(см. рис. 38).

Для относительно больших $\hbar$ интенсивность на экране доминирует из-за интерференционных эффектов.

Как для $\hbar = 1$, так и для $\hbar = 1/2$ мы не наблюдаем классических пиков интенсивности, соответствующих двум щелям.

В квазиклассическом пределе, $\hbar \to 0$, интерференционная картина медленно заменяется классическими пиками.

(вот это явно покажу!!!)

Заметим, что этот переход от квантового к классическому режиму не может быть исследован в традиционном тонкощелевом приближении.

Заметим, что в то время как в поведении сильных линз преобладают каустики, где седловые точки вырождаются, качественное поведение двухщелевого эксперимента полностью определяется стоксовыми преобразованиями.

Седловые точки всюду невырождены, и h - функция является функцией Морса.

В обоих случаях аппроксимация седловой точки не работает, и интеграл должен оцениваться вдоль всего наперстка Лефшеца.

Мы ожидаем, что это будет общей чертой квантовомеханических интерференционных явлений.

вид диаграмм

Приведем интерференционные диаграммы.
(когда дойду - почитаю эи интегралы, приведу картинки. вряд ли скоро дойду)

Типичное квантовое описание

для сравнения приведем также типичное описание этого эксперимента, которое многим известно.
(я не помню пока, из оптики допишу)

программный расчет

Приведем строчки кода, которые можно вставить в итоговый файл и посчитать диаграммы.
Функция, введенная в Wolfram, соответствующая опыту Юнга, имеет вид:

```
[Alpha] = 1;
f[x_, μ_]:= I ((x - μ)^2 + [Alpha]/([Alpha]^2 + (x + 0.5)^2) + [Alpha]/([Alpha]^2 + (x -
    0.7)^2) + 1/[Alpha]);
```

Где учтено, что если свет падает сразу на 2 щели, без вначале 1-й, то эффекта не будет? (??)

(??? не понимаю это пока что. мб оптика поможет понять.)

О заблуждениях про опыт Юнга

23.2.3 Experiment on the Compton Effect

Обсудим вмеру подробно эффект Комптона.
(maybe I'll move theory about it to some parts before)

Суть эффекта Комптона

(a paragraph with main ideas from theory about it)
Суть в том, что если фотон рассеивается на электроне, то длина волны фотона изменяется и она зависит от угла, на который он рассеивается. Соотношение следующее

$$\lambda - \lambda_0 = \frac{h}{mc}(1 - \cos\theta)$$

Для работы с ней, часто нужно подставлять длину волны через энергию $\lambda = hc/E$
(тут мб вывод в пару строк соберу, вроде обычные законы нужно использовать)

Определение 23.1. *Эффект Комптона - увеличение длины волны рассеянного излучения в сравнении в падающим.*

$$\begin{gathered} mc^2 + \hbar\omega_0 = \gamma mc^2 + \hbar\omega_1 \\ \frac{\hbar\omega_0}{c} = \gamma mv\cos\varphi + \frac{\hbar\omega_1}{c}\cos\theta \\ \gamma mv\sin\varphi = \frac{\hbar\omega_1}{c}\sin\theta \end{gathered}$$

Solution:

$$\Delta\lambda = \lambda_1 - \lambda_0 = \frac{h}{mc}(1 - \cos\theta) = \lambda_K(1 - \cos\theta)$$

λ_1 is the wavelength after scattering, $\lambda_K = \frac{h}{mc} = 2,42 \cdot 10^{-10}$cm - Compton wavelength.

In practice it is more conventional to measure the energies, not the wavelengths, of the scattered photons.

For a given incident energy, the outgoing final-state photon energy $E_\gamma = hc/\lambda$, $E_{\gamma'}$, is given by

$$E_{\gamma'} = \frac{E_\gamma}{1 + (E_\gamma/m_e c^2)\,(1 - \cos\theta)}$$

the same:

$$\nu' = \nu \frac{1}{1 + \frac{h\nu}{m_e c^2}(1 - \cos\theta)}$$

KleinNishina formula cross sections

The *KleinNishina* formula:

$$\sigma_k = 2\pi r_0^2 \left(\frac{1+\epsilon}{\epsilon^2} \left(\frac{2+2\epsilon}{1+2\epsilon} - \frac{\ln(1+2\epsilon)}{\epsilon} \right) + \frac{\ln(1+2\epsilon)}{2\epsilon} - \frac{1+3\epsilon}{(1+2\epsilon)^2} \right)$$

in another words,

$$\frac{d\sigma}{d\Omega} = \frac{1}{2} r_e^2 \left(\frac{\lambda}{\lambda'} \right)^2 \left[\frac{\lambda}{\lambda'} + \frac{\lambda'}{\lambda} - \sin^2(\theta) \right]$$

where $r_c = \hbar/m_e c$, α is the fine structure constant.
$r_e = \alpha r_c$
if $\hbar\omega \gg m_0 c^2$

$$\sigma_k = \frac{\pi r_0^2}{\epsilon} \left(\frac{1}{2} + \ln(2\epsilon) \right) = \pi r_0^2 \frac{m_0 c^2}{\hbar\omega} \left(\ln \frac{2\hbar\omega}{m_0 c^2} + \frac{1}{2} \right)$$

Intensity:

$$I' = \frac{I}{R^2} \frac{\omega'}{\omega} \frac{d\sigma}{d\Omega}$$

Thompson's scattering

If we speak about connected electrons, for them incoming wave make electrons hesitate on the same frequency, and it is called *Thompson's scattering.*

There two different properties of scattering cross section in this two effects.

комптоновская длина волны

она наверное слишком важная, поэтому оставлю себе напоминание, что нужно порешать задачи на ее применение.

Границы применимости эффекта Комптона для разных материалов

если у этого материала валентные электроны имеют энергию намного менее чем энергия гамма кванта.

и это же говорит о том, что можно считать электрон покоящимся

(потом лучше проработаю)

Экспериментальные свойства

общефиз и опытные факты

Обзор применений эффекта Комптона

Минимальная энергия гамма кванта от аннигиляции э-поз пары после рассеяния на графитовой мишени

Определить минимальную энергию гама-кванта образовавшегося в результате аннигиляции электрон-позитронной пары при его рассеянии на валентных электронах графитовой мишени. Дать численный ответ в электрон-вольтах. Энергия покоя для электрона $E_0 = 0,51$ МэВ.

Просто знаем, что родятся 2 гамма кванта, и просто у каждого будет такая же энергия, как и у электрона. А минимальная энергия - при максимальной длине волны, а по формуле Комптона это происходит при $\cos = -1$, то есть при рассеянии назад. Подставляя длину волны $\lambda = hc/E$

(короче тут тривиально всё считается)

тупо в итоге энергия в 3 раза меньше.

23.2.4 Davisson–Germer Experiment (?)

Опыт Дэвиссона-Джермера - физический эксперимент по дифракции электронов, проведённый в 1927 г.

американскими учёными Клинтоном Дэвиссоном и Лестером Джермером.

В нем наблюдалась дифракция электронов на кристаллической решётке монокристалла.

говорят, что это с УШ связано, а также с волнами де бройля, да я хз.

23.2.5 Franck–Hertz Experiment (??)

(?? важно суть его описать!!)

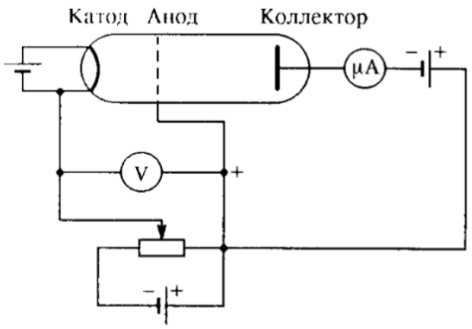
Это классический эксперимент, доказывающий, что у атомов дискретный уровень энергии.

Между катодом и анодом помещается гелий, далее увеличивая напряжение будем мерить проходящий ток.

В итоге зависимость показана на рисунке **??**

Об экспериментальной установке

Сперва остановимся на экспериментальной установке



23.2.6 Thomson Experiment

(редко его упоминают)

мотивация

Обсудим, для чего и насколько важно понимать опыт Юнга.
??? Опыт Юнга важен как мысленный эксперимент для понимания суперпозиции.
Для всего остального он бесполезен, так что копать тут нечего.

описание эксперимента

подробно, при каких условиях что получается?

объяснение

самое важное.
пока хз.
????

электрон не проходит через две щели одновременно

Согласно копенгагенской интерпретации, у нас электрон всегда локализован как частица.

заморочки про электрон и дырки (???)

зависимость от величины $\hbar$

тоже такая есть, я не шарю.

обзор неверных пониманий

Опыт Юнга интересен тем, что можно про него совершенно неправильно думать, так уйти в тупик по физике и на этом закончится всё обучение.
так что очень важно не затупить в нем.

23.2.7 Lasers

Обсудим минимальное, что хорошо бы знать о лазерах.
(пока в других разделах про это не предполагается теория.)

Принцип работы лазера

23.2.8 Microscopes

(currently, the idea is to write its main concepts)

On Scanning tunneling microscope

(см вики, страница где-то будет про него у меня тут для полноты, подробнее - в отдельной записи, мб в записи про наночастицы.)

24.1 More About the Path Integral

Об источнике и производящем функционале по Киселеву

(только коротко укажу, что там есть. пишу под конец записи, потому что это максимально не приоритетная тема!!!)

Об интеграле по траекториям для инстантонов (!???)

(пока такой мелкий раздел, потому что где-то в другом месте по идее должна быть эта теория.)

Постановка задачи

На данном семинаре мы будем искать туннельное расщепление в двухъямном потенциале, следуя классической обзорной работе [Вай +82. Для удобства мы положим массу частицы $m = 1$, а потенциал зададим в виде $U(x) = \lambda\left(x^2 - \eta^2\right)^2$, и тем самым Гамильтониан задачи имеет следующий вид:

$$\hat{H} = -\frac{1}{2}\partial_x^2 + \lambda\left(x^2 - \eta^2\right)^2$$

Потенциал имеет пару минимумов в точках $x = \pm\eta$, вблизи которых он имеет осцилляторное разложение $V(x) = \frac{1}{2}\omega^2 x^2$, с частотами $\omega^2 = 8\lambda\eta^2$. Высота барьера, разделяющего эти две ямы, равна $U(0) = \lambda\eta^4$; поэтому квазиклассическому приближению соответствует $\lambda\eta^6 \gg 1 \Leftrightarrow \omega\eta^2 \gg 1$. Именно в таком приближении мы и будем решать эту задачу. На самом деле, её мы уже обсуждали в семинаре, посвящённому квазиклассическому приближению; в частности, мы вычисляли расщепление n-того осцилляторного уровня (на симметричные и антисимметричные комбинации). Квазиклассическое приближение, впрочем, работает только при $n \gg 1$; а сейчас мы сфокусируемся на расщеплении основного состояния $n = 0$. Для вычисления, мы воспользуемся слегка модифицированным аппаратом функций Грина, и функциональным интегралом.

Виковский поворот и Евклидово действие

Удобнее всего исследовать свойства основного состояния в мнимом времени $t = -i\tau$[4]. Функцию Грина во мнимом времени мы будем обозначать следующим образом [5]:

$$G_E(x,y,\tau) \equiv G(x,y,-i\tau) = \left\langle x \left| e^{-\hat{H}\tau} \right| y \right\rangle = \sum_n \psi_n(x)\psi_n^*(y)e^{-E_n\tau}$$

Обратим внимание, что чем выше возбуждение, тем меньший вклад оно даёт в эту сумму. Поэтому, в принципе, если рассмотреть $\tau = \beta \to +\infty$, то главный вклад останется только от основного (и, в нашем случае - первого возбуждённого) состояния. Именно этот случай мы и будем исследовать.

Для Евклидовой функции Грина можно вывести представление через функциональный интеграл, полностью эквивалентно тому, что мы делали на предыдущем семинаре. Ответ, в действительности, будет таким же, как если бы мы попросту в действие сделали формальную подстановку $t = -i\tau$. При этом:

$$iS[x(t)] = i\int \left[\frac{1}{2}\left(\partial_t x\right)^2 - U(x(t))\right] dt = -\int \left[\frac{1}{2}\left(\partial_\tau x\right)^2 + U(x(\tau))\right] d\tau \equiv -S_E[x(\tau)]$$

$$G_E(x,y,\beta) = \int\limits_{x(-\beta/2)=y}^{x(\beta/2)=x} \mathcal{D}x(\tau) \exp\left(-\int\limits_{-\beta/2}^{\beta/2} d\tau \left[\frac{1}{2}\left(\partial_\tau x\right)^2 + U(x(\tau))\right]\right)$$

Последнее называют «Евклидовым действием», и, как мы видим, оно отличается от обычного только изменением знака у потенциала $U(x)$ - тем самым, с классической точки зрения оно описывает движение в перевёрнутом потенциале. В дальнейшем нижний индекс «E» мы будем опускать, помня, что мы отныне работаем в мнимом времени.

Метод перевала

Поскольку $U(x)$ представляет собой полином четвёртой степени, мы имеем дело с нелинейным действием и с негауссовым функциональным интегралом. Брать этот интеграл мы будем методом перевала, который соответствует нахождению классических траекторий, минимизирующих действие - и квадратичному разложению вблизи них. Две тривиальных классических траектории очевидны - они соответствуют покоящимся частицам в точках $x(t) = \pm\eta$. Действие на них равно нулю, а квадратичное разложение устроено так же, как и для квантового гармонического осциллятора; и они дадут соответствующий вклад в следующие функции Грина в совпадающих точках, связанной с посчитанной на предыдущем семинаре функцией Грина квантового гармонического осциллятора $G_0(\beta)$ (с массой $m = 1$):

$$G^{(0)}(\eta,\eta,\beta) = G^{(0)}(-\eta,-\eta,\beta) \simeq G_0(\beta) = \sqrt{\frac{\omega}{2\pi\sinh(\beta\omega)}} \approx \sqrt{\frac{\omega}{\pi}}e^{-\beta\omega/2}$$

Из этого мы действительно видим, что в ведущем приближении имеется (двукратно вырожденный) осцилляторный уровень энергии $E = \omega/2$; но это не то, что нас интересует - нас интересует туннельное расщепление! Туннелированию соответствует переход из левой ямы в правую, поэтому именно такую функцию Грина мы будем считать: $G_E(\eta,-\eta,\beta)$.

Логика

Давайте вспомним, как мы берём многомерные интегралы методом перевала $I = \int \exp(-f(\boldsymbol{x}))d^d\boldsymbol{x}$. Рецепт прост: мы сперва мы ищем максимум, решая седловое уравнение (или систему уравнений) $\frac{\partial f(\boldsymbol{x}_0)}{\partial x_i} = 0$ - и находя решение, точку $\boldsymbol{x}_0$. В ведущем приближении, значение интеграла даётся значением функции в этой точке: $I \approx \exp\left(-f\left(\boldsymbol{x}_0\right)\right)$. Затем мы рассматриваем квадратичное разложение вблизи седловой точки: $f\left(\boldsymbol{x}_0+\boldsymbol{z}\right) \approx f\left(\boldsymbol{x}_0\right) + \frac{1}{2}\frac{\partial^2 f}{\partial x_i \partial x_j} z_i z_j$; и, наконец, берём гауссов интеграл:

$$I \approx e^{-f(\boldsymbol{x}_0)} \int d^d\boldsymbol{z} \exp\left(-\frac{1}{2}L_{ij}z_i z_j\right) = \frac{1}{\sqrt{\det \frac{\hat{L}}{2\pi}}} e^{-f(\boldsymbol{x}_0)}$$

Функциональный интеграл в этом смысле ничем не отличается - и мы применим этот рецепт и тут.

Седло

11.4.5 Седло Итак, нам нужно найти классическую траекторию $x_{cl}(\tau)$, удовлетворяющую экстремуму действия с граничными условиями $x(-\beta/2) = -\eta$ и $x(\beta/2) = \eta$:

$$\frac{\delta S_E}{\delta x(\tau)} = 0 \Rightarrow \partial_\tau^2 x = U'(x(\tau))$$

Данное уравнение можно решить в квадратурах, но проще всего решение устроено, если тут сразу взять предел $\beta \to \infty$. В таком случае, траектории соответствует перекатывающаяся за бесконечное время частица из левого «горба» перевёрнутого потенциала на правый. Чтобы найти эту траекторию, можно воспользоваться законом сохранения «энергии» $E = \frac{1}{2}\left(\partial_\tau x\right)^2 - U(x(\tau)) = \text{const}$ (на нашей траектории $E = 0$), благодаря чему понизить степень уравнения до первой:

$$\frac{1}{2}\left(\partial_\tau x\right)^2 = U(x(\tau)) \Rightarrow \frac{dx}{\eta^2 - x^2} = \sqrt{2\lambda}d\tau \Rightarrow x_{cl}(\tau) = \eta \tanh\frac{\omega\tau}{2}$$

Такую траекторию - нетривиальный экстремум нелинейного действия в функциональном интеграле - называют инстантоном.

Тут мы сталкиваемся с важной особенностью задачи. Вместо одной седловой траектории, мы, в действительности, имеем дело с целым седловым многообразием $x_{cl}\left(\tau - \tau_c\right)$, параметризуемым вещественным числом τ_c - положением инстантона. Наличие этой свободны, конечно, связано с трансляционной инвариантностью по времени - мы ведь взяли предел $\beta \to \infty$! Инстантон имеет характерную ширину $\sim \omega^{-1}$, которая мала (в частности, $\omega^{-1} \ll \beta$), и поэтому краевые эффекты, связанные с удержанием конечного β, будут экспоненциально малы на фоне основного результата, и в ведущем порядке они действительно не важны. Величина же τ_c с этой же точностью может пробегать все значения $\tau_c \in (-\beta/2, \beta/2)$. К этой свободе выбора центра инстантона мы ещё вернёмся, а пока давайте рассмотрим одно седло на этом многообразии, скажем, $\tau_c = 0$.

Итак, в главном порядке значение интеграла определяется действием на этом инстантоне. Давайте его вычислим (для этого удобно воспользоваться «законом сохранения энергии» и выразить член с потенциальной энергией через кинетическую):

$$S_0 = \int\limits_{-\infty}^{\infty} d\tau \left(\partial_\tau x_{cl}\right)^2 = \frac{2}{3}\omega\eta^2 \gg 1$$

Несложно убедиться, что это действие тождественно совпадает с «квазиклассическим действием» $\int\limits_{-\eta}^{\eta} p(x)dx$, которое определяло бы расщепление в квазиклассическом приближении.

Квадратичное разложение

Следуя логике метода перевала, нам нужно провести квадратичное разложение вблизи инстантона:

$$S_E\left[x_{cl}(\tau)+z(\tau)\right] \approx S_0 + \frac{1}{2}\int\limits_{-\beta/2}^{\beta/2} d\tau \left[(\partial_\tau z)^2 + U''\left(x_{cl}(\tau)\right) z^2(\tau)\right] \equiv S_0 + S_2[z(\tau)]$$

В квадратичном разложении действия стоит линейный оператор $\hat{L} = -\partial_\tau^2 + U''\left(x_{cl}(\tau)\right)$, спектр которого нам предстоит исследовать при взятии гауссового интеграла по квадратичным флуктуациям. Ответ тем самым с точки зрения метода перевала устроен следующим образом:

$$G(\eta,-\eta,\beta) \approx e^{-S_0} \int\limits_{z(-\beta/2)=0}^{z(\beta/2)=0} \mathcal{D}[z(\tau)] e^{-S_2[z(\tau)]}$$

Явный вид оператора следующий:

$$U''\left(x_{cl}(\tau)\right) = \frac{\omega^2}{2}\left(3\tanh^2\frac{\omega\tau}{2} - 1\right) = \omega^2\left(1 - \frac{3/2}{\cosh^2\frac{\omega\tau}{2}}\right)$$

Спектр оператора

11.4.7 Спектр оператора Итак, для взятия гауссового интеграла по $z(\tau)$ нам необходимо исследовать свойства (спектр) оператора $-\partial_\tau^2 + U''\left(x_{cl}(\tau)\right)$. Задача на его собственные значения ϵ_n и собственные функции $\psi_n(\tau)$ выглядит следующим образом:

$$\left(-\partial_\tau^2 - \frac{3\omega^2/2}{\cosh^2\frac{\omega\tau}{2}}\right)\psi_n(\tau) = \left(\epsilon_n - \omega^2\right)\psi_n(\tau)$$

Данное уравнение выглядит в точности как уравнение Шрёдингера в потенциале $\frac{1}{\cosh^2 x}$, решение которого нам известно - оно выражается через гипергеометрическую функцию ${}_2F_1$, и мы его обсуждали на четвёртом семинаре прошлого семестра. Воспользуемся ответами из того семинара, в которые нужно подставить следующие значения параметров:

$$m = \frac{1}{2}, \quad a = \frac{2}{\omega}, \quad U_0 = \frac{3\omega^2}{2}$$

Важным для исследования потенциала оказываются следующие два безразмерных параметра:

$$u = \frac{U_0}{1/2ma^2} = 6, \quad s = \frac{1}{2}(\sqrt{1+4u}-1) = 2$$

Дискретный спектр Как мы помним, число s характеризует количество связанных состояний. Для энергий $E_n \equiv \epsilon_n - \omega^2$ работает следующая формула: (число $n = 0, 1, ...$ и

$n < s$). Кроме того, целые числа s соответствуют случаю возникновению в яме связанного состояния (что означает, что есть состояния со строго нулевой энергией $E = 0$, которое, тем не менее, уже относится к непрерывному спектру).

Нулевая мода Обратим внимание - в задаче имеется нулевая мода $\epsilon_0 = 0$, соответствующая основному состоянию на языке квантовой механики. Его «волновая функция» тоже выписывалась на семинаре, и она выглядит как (константа C_0 обеспечит нормировку на единицу; $s = 2$):

$$\psi_0(\tau) = \frac{C_0}{\cosh^s \frac{\omega\tau}{2}}$$

В действительности же, наличие нулевой моды, как мы сказали выше, связано с свободой выбора центра инстантона. Это утверждение можно формализовать: $S\left[x_{cl}(\tau)\right] \equiv S\left[x_{cl}(\tau + \delta\tau)\right]$, поэтому инфинитезимальная $\delta\tau$ соответствует «приращению» $z(\tau) = \delta\tau \frac{\partial x_{cl}(\tau)}{\partial \tau}$. С другой стороны,

$$S\left[x_{cl}(\tau) + z(\tau)\right] \approx S\left[x_{cl}(\tau)\right] + S_2[z(\tau)] = S\left[x_{cl}(\tau)\right] + \delta\tau^2 \cdot S_2\left[\frac{\partial x_{cl}}{\partial \tau}\right]$$

и тем самым мы понимаем, что $\frac{\partial x_{cl}}{\partial \tau}$ (с точностью до нормировки) даёт нулевую моду действия S_2. Несложно убедиться, что она (с точностью до константы) совпадает с выписанной тут $\psi_0(\tau)$. В дальнейшем нам приходится нормированное выражение для $\psi_0(\tau)$; это можно сделать в общем виде, используя выражения для действия на инстантоне (11.42). Тем самым, мы получаем:

$$\psi_0(\tau) = \frac{1}{\sqrt{S_0}} \frac{\partial x_{cl}}{\partial \tau}$$

Непрерывный спектр В том-же 4 семинаре исследовался также и непрерывный спектр оператора. В частности, имелось выражение для волновых функций задачи рассеяния (волна падает слева направо - для полного набора к ним, конечно же, нужно добавить также решения, соответствующие падению волны справа налево). Особенностью данного потенциала является то, что при целом s рассеяния оказывается безотражательным, и волновая функция задачи рассеяния содержит только прошедший «кусок».

Непрерывный спектр параметризуется волновым вектором k, так что энергия $E_k = \frac{k^2}{2m} = k^2 \Rightarrow \epsilon_k = \omega^2 + k^2$; а сами волновые функции имеют следующий вид:

$$\psi_k(x) \approx \begin{cases} \frac{\Gamma(1-ika)\Gamma(-ika)}{\Gamma(-ika-s)\Gamma(-ika+s+1)} e^{ikx} \equiv e^{ikx+i\delta(k)} & x \to -\infty \\ e^{ikx}, & x \to +\infty \end{cases}$$

(безотражательность рассеяния означает, что амплитуда прохождения сводится к чистой фазе: $t = e^{-\imath\delta_k}$). Аналитическое выражение для фазы тоже можно выписать (подставляя $a = \frac{2}{\omega}$ и $s = 2$)[6]:

$$e^{-i\delta(k)} = \frac{\Gamma(-ika-2)\Gamma(-ika+3)}{\Gamma(1-ika)\Gamma(-ika)} = \frac{(2-ika)(1-ika)}{(2+ika)(1+ika)} = \frac{1-\frac{ik}{\omega}}{1+\frac{ik}{\omega}} \cdot \frac{1-\frac{2ik}{\omega}}{1+\frac{2ik}{\omega}} = \exp\left(-2i\left[\arctan\frac{k}{\omega} + \arctan\frac{2k}{\omega}\right]\right)$$

$$\delta(k) = 2\left[\arctan\frac{k}{\omega} + \arctan\frac{2k}{\omega}\right] = \begin{cases} 0, & k = 0 \\ 2\pi, & k \to \infty \end{cases}$$

Помимо таких состояний, имеются также и комплексно-сопряжённые решения $\psi^*(x)$, которые описывают волны, падающие справа налево; и вместе они образуют полный набор.

Дискретизация непрерывного спектра В действительности же тут пора вспомнить о том, что на языке функционального интеграла мы рассматриваем траектории на

конечном, хоть и большом, интервале β с нулевыми граничными условиями. Поэтому непрерывный спектр в действительности является дискретным - нам необходимо лишь составить линейную комбинацию ψ_k и ψ_k^*, которая занулялась бы на обоих стенках. Те k, при которых это возможно, и будут давать уровни энергии $\epsilon_n = \omega^2 + k_n^2$. Итак, пусть волновая функция имеет вид $\psi_n(x) = A\psi_k(x) + B\psi_k^*(x)$. Тогда имеется пара условий:

$$\begin{cases} A\psi_k(-\beta/2) + B\psi_k^*(-\beta/2) & = 0 \\ A\psi_k(\beta/2) + B\psi_k^*(\beta/2) & = 0 \end{cases}$$

Такая система уравнений на A и B совместна и имеет ненулевое решение только если её определитель равен нулю:

$$\det \begin{vmatrix} \psi_k(-\beta/2) & \psi_k^*(-\beta/2) \\ \psi_k(\beta/2) & \psi_k^*(\beta/2) \end{vmatrix} = 0$$

Используя асимптотики волновой функции на $\pm\infty$ (известные из задачи рассеяния) мы тем самым получаем:

$$\det \begin{vmatrix} e^{-ik\beta/2+i\delta(k)} & e^{ik\beta/2-i\delta(k)} \\ e^{ik\beta/2} & e^{-ik\beta/2} \end{vmatrix} = 0 \Leftrightarrow \sin(k\beta + \delta(k)) = 0$$

Тем самым, имеется набор k_n, которые являются решением следующего трансцендентного уравнения:

$$k_n\beta - \delta(k_n) = \pi n$$

Обратим внимание, что случаю $n = 0$ соответствует тривиальное решение этого, вообще говоря, трансцендентного уравнения: $k = 0$. Такая волновая функция - тождественный ноль, и нас не интересует. Поэтому нумерация n начинается с 1.

Давайте исследуем, как устроены решения этого уравнения. Вообще говоря, поскольку $\beta \gg 1$ - очень большое число, то при $n \ll \beta$ решения этого уравнения очень близки к $k_n \approx p_n \equiv \frac{\pi n}{\beta}$; поправки можно найти по теории возмущений. С другой стороны, при $n \gtrsim \beta$, фазы рассеяния уже выходят на константу $\delta(k_n) \approx \delta(k_n \to \infty) = 2\pi$. Поэтому решение уравнения устроены следующим образом:

$$k_n \approx p_n + \delta(p_n)/\beta, \quad p_n = \pi n/\beta$$

Нормировка функционального интеграла

11.4.8 Нормировка функционального интеграла Конечно, как мы уже обсуждали ранее, мера функционального интеграла $\mathcal{D}$ содержит бесконечную константу $\mathcal{N}$, связанную с дискретизацией - и поэтому буквально выписанным выражением воспользоваться не удастся. Для того, чтобы придать этому выражению смысл, необходимо рассмотреть отношение двух функциональных интегралов, в котором эта бесконечная нормировка сократится. В качестве такого выражения удобно использовать уже сосчитанную ранее функцию Грина квантового гармонического осциллятора; удобно выбрать его с такой же частотой ω, чтобы квадратичные операторы, стоящие в действии были похожи:

Спектр оператора (знаменатель)

$$G_0(\beta) = \int\limits_{z(-\beta/2)=0}^{z(\beta/2)=0} \mathcal{D}[z(\tau)] \exp\left(-\frac{1}{2}\int\limits_{-\beta/2}^{\beta/2} \left[(\partial_\tau z)^2 + \omega^2 z^2\right]\right) = \sqrt{\frac{\omega}{2\pi \sinh \omega\beta}}$$

И тем самым мы, в действительности, будем работать со следующим выражением:

$$\frac{G(\eta,-\eta,\beta)}{G_0(\beta)} = e^{-S_0}\frac{\int\limits_{z(-\beta/2)=0}^{z(\beta/2)=0}\mathcal{D}[z(\tau)]\exp\left(-\frac{1}{2}\int\limits_{-\beta/2}^{\beta/2}d\tau\left[(\partial_\tau z)^2+U''\left(x_{cl}(\tau)\right)z^2(\tau)\right]\right)}{\int\limits_{z(-\beta/2)=0}^{z(\beta/2)=0}\mathcal{D}[z(\tau)]\exp\left(-\frac{1}{2}\int\limits_{-\beta/2}^{\beta/2}d\tau\left[(\partial_\tau z)^2+\omega^2 z^2\right]\right)}$$

11.4.9 Спектр оператора (знаменатель) Собственно, с функциональным интегралом, что стоит в знаменателе, мы уже работали - поэтому кратко озвучим результаты. В принципе, оператор $(-\partial_\tau^2+\omega^2)$, который там стоит, тоже похож на уравнение Шрёдингера в константном потенциале $U(\tau)=\omega^2=\text{const}$, и тоже обладает лишь непрерывным спектром. Однако нулевые граничные условия, как и в прошлый раз, спектр дискретизуют, волновые функции $\psi_k^{(0)}(\tau)$ представляют собой стоячие волны, а спектр получается следующий:

$$\epsilon_p^{(0)}=\omega^2+p^2,\quad p=p_n=\pi n/\beta$$

Вычисление гауссового интеграла

11.4.10 Вычисление гауссового интеграла Итак, мы вплотную приблизились к тому, чтобы, наконец, посчитать гауссов функциональный интеграл. Мы делаем разложение в числителе вида $z(\tau)=\sum\limits_n c_n\psi_n(\tau)$ (учитывая дискретный спектр!) и в знаменателе $z(\tau)=\sum\limits_n c_n\psi_n^{(0)}(\tau)$. Учитывая гауссовость обоих интегралов, мы получаем:

$$\frac{G(\eta,-\eta,\beta)}{G_0(\beta)} = e^{-S_0}\prod_n\left(\frac{\int dc_n\exp\left(-\frac{1}{2}\epsilon_n c_n^2\right)}{\int dc_n\exp\left(-\frac{1}{2}\epsilon_n^{(0)}c_n^2\right)}\right)$$

Нулевая мода Итак, интеграл по dc_0, соответствующий нулевой моде $\psi_n(\tau)$, происходит в бесконечных пределах, выглядит как $\int dc_0$ и в гауссовом приближении расходится - в таком случае, как правило, интеграл нужно брать точно. Наличие нулевых мод, как правило, связаны с какой-то симметрией - в данном случае, трансляционной; и в таком случае интегрирование обычно сводится к объёму соответствующей группы симметрии.

В нашем случае, нулевая мода напрямую связана с произвольностью выбора константы τ_c в инстантоне, который имеет вид $x_c(\tau-\tau_c)$. Заметим, что смещение вдоль нулевой моды dc_0 в точности соответствует смещению центра инстантона:

$$d\left(x_{cl}(\tau-\tau_c)\right)\equiv\psi_0(\tau)dc_0,\quad d\left(x_{cl}(\tau-\tau_c)\right)\equiv\frac{\partial x_{cl}}{\partial\tau}d\tau_c$$

Приравнивая эти два выражения, и замечая, что $\psi_0(\tau)=\frac{1}{\sqrt{S_0}}\frac{\partial x_{cl}}{\partial\tau}$, мы получаем следующий вид интеграла по нулевой моде в числителе: $\int dc_0\equiv\sqrt{S_0}\int d\tau_c=\beta\sqrt{S_0}$. В соответствующем выражении в знаменателе стоит следующий интеграл (там нумерация n начинается с 1, что, впрочем, не очень важно - ведь мы имеем дело с непрерывным спектром, и все собственные числа с маленькими номерами малы):

$$\int dc_1 e^{-\frac{1}{2}\epsilon_1^{(0)}c_1^2}=\sqrt{\frac{2\pi}{\epsilon_1^{(0)}}}=\sqrt{\frac{2\pi}{\omega^2+\pi^2/\beta^2}}\underset{\beta\to\infty}{\approx}\frac{\sqrt{2\pi}}{\omega}$$

Тем самым, если ввести условное обозначение $\det' \hat{L}$ - интеграл с исключённым наименьшим собственным числом то бишь отщепив нулевую моду - мы получаем:

$$\frac{G(\eta,-\eta,\beta)}{G_0(\beta)} = e^{-S_0} \cdot \left(\omega\beta\sqrt{\frac{S_0}{2\pi}}\right) \cdot \left(\frac{\det'\left(-\partial_\tau^2 + U''\left(x_{cl}(\tau)\right)\right)}{\det'\left(-\partial_\tau^2+\omega^2\right)}\right)^{-1/2}$$

Возникновение множителя $\sqrt{S_0}$, связанного с нулевой модой - утверждение в действительности совершенно общего характера.

Дискретный спектр Помимо нулевой моды, имеется также ещё одно состояние дискретного спектра, $\epsilon_1 = \frac{3}{4}\omega^2$. Оно даст следующий вклад (отнормированный на соответствующий вклад $\epsilon_2^{(0)} = \omega^2 + (2\pi/\beta)^2 \approx \omega^2$ от осциллятора:

$$\frac{\epsilon_1}{\epsilon_2^{(0)}} \underset{\beta\to\infty}{\approx} \frac{\frac{3}{4}\omega^2}{\omega^2} = \frac{3}{4}$$

Непрерывный спектр Итак, самое сложное - вычисление состояния непрерывного спектра, бесконечного произведения (обратите внимание, нумерация в числителе начинается с $n=1$, а в знаменателе - с $n=3$, поскольку первых два состояния мы уже «отщепили» при работе с дискретным спектром). Для вычисления, это бесконечное произведение удобно прологарифмировать, а также воспользоваться приближенным решением трансцедентного уравнения $k_n \approx p_n - \delta\left(p_n\right)/\beta$:

$$\begin{aligned}
\frac{\det''}{\det''} &= \prod_{n=1}^{\infty} \frac{\omega^2+k_n^2}{\omega^2+p_{n+2}^2} = \\
&= \exp\left(\sum_{n=1}^{\infty} \ln\frac{\omega^2+k_n^2}{\omega^2+p_{n+2}^2}\right) = \\
&= \exp\left(\sum_{n=1}^{\infty} \ln\left(1+\frac{k_n^2-p_{n+2}^2}{\omega^2+p_{n+2}^2}\right)\right) \approx \exp\left(\sum_{n=1}^{\infty}\frac{k_n^2-p_{n+2}^2}{\omega^2+p_{n+2}^2}\right) \approx \\
&\approx \exp\left(\sum_{n=1}^{\infty}\frac{2p_{n+2}\left(k_n-p_{n+2}\right)}{\omega^2+p_{n+2}^2}\right) = \qquad\qquad = \exp\left(\frac{1}{\beta}\sum_{n=1}^{\infty}\frac{\left(\delta\left(p_n\right)-2\pi\right)2p_{n+2}}{\omega^2+p_{n+2}^2}\right)
\end{aligned}$$

Вообще говоря, тот факт, что k_n и p_n очень близки (по $\frac{1}{\beta}$) на всём промежутке произведения означает, что все члены произведения очень близки к 1, и только за счёт их большого количества ($\sim\beta$) это произведение оказывается отличным от единицы (а сумма - от нуля). Для суммирования плавной функции, удобно заменить сумму на интеграл, согласно $\sum\limits_n = \int\limits_0^\infty \frac{\beta dp}{\pi}$ и увидеть, что β из ответа полностью выпадает, а ответ - конечный:

$$\frac{\det''}{\det''} = \exp\left(\int_0^\infty \frac{dp}{\pi}\frac{2p(\delta(p)-2\pi)}{\omega^2+p^2}\right)$$

Обратим внимание, что полученный тут член 2π обеспечивает сходимость интеграла на бесконечности (ведь $\delta(p\to\infty)\to 2\pi$); в противном случае интеграл бы логарифмически расходится. Само число 2π явно связано с количеством связанных состояний; но ровно с этим же и связана фаза $\delta(p\to\infty)$! - поэтому теорема Левинсона, о которой сказано в примечании, в действительности гарантирует сходимость этого интеграла на бесконечности. Следующий шаг - интегрирование по частям:

$$\frac{\det''}{\det''} = \exp\left(-\frac{1}{\pi}\int_0^\infty dp\frac{d\delta}{dp}\ln\frac{\omega^2+p^2}{\omega^2}\right)$$

Прелесть этого выражения ещё и в том, что этот неприятный 2π-член, который «помнит» о количестве связанных состояний, в него не входит; а кроме того, фаза - вообще говоря, многозначная функция, и плохо определена (с точностью до $2\pi n$), а вот производная фазы определена уже хорошо. Поэтому, например, в инстантонной азбуке не сильно «заморачиваются» с явным выражением для фазы и отделением этого 2π-члена, а приходят к этому выражению, с которым уже и работают. Итак, оставшийся интеграл обезразмеривается подстановкой $p = \omega y$, считается явно и даёт:

$$\int\limits_0^\infty dp \frac{d\delta}{dp} \ln\left(1+\frac{p^2}{\omega^2}\right) = 2\int\limits_0^\infty dy \ln\left(1+y^2\right)\left[\frac{1}{y^2+1}+\frac{2}{4y^2+1}\right] = 2\pi\ln 3$$

а вклад от непрерывного спектра равен:

$$\frac{\det''}{\det''} = \frac{1}{9}$$

Одноинстантонный ответ

Во-первых, тем самым мы получили ответ для отношения детерминантов (с исключённой нулевой модой):

$$\frac{\det'\left(-\partial_\tau^2+\omega^2-\frac{3\omega^2/2}{\cosh^2(\omega\tau/2)}\right)}{\det'\left(-\partial_\tau^2+\omega^2\right)} = \frac{3}{4}\cdot\frac{1}{9} = \frac{1}{12}$$

и мы получили следуюгцй ответ (в одноинстантонном приближении):

$$\frac{G(\eta,-\eta,\beta)}{G_0(\beta)} = e^{-S_0}\cdot\underbrace{\left(\omega\beta\sqrt{\frac{S_0}{2\pi}}\right)}_{\text{zero mode}}\cdot\underbrace{\sqrt{\frac{4}{3}}}_{\text{bound state}}\cdot\underbrace{\sqrt{9}}_{\text{continuous spectrum}} = \sqrt{\frac{6}{\pi}S_0}\omega\beta e^{-S_0}$$

Наличие тут явной зависимости от бесконечной величины β должно смущать - ведь мы рассматриваем предел $\beta\to\infty$. В действительности же этот ответ, как инстантонная поправка, получен в пределе, покуда он мал $-\sqrt{S_0}\omega\beta e^{-S_0} \ll 1$ - и поэтому буквально бесконечной β сделать не удастся. С другой стороны, от β он явно зависит не экспоненциальным образом, поэтому пока непонятно, как извлечь из него непосредственно туннельное расщепление.

В действительности же найденный ответ - это первый порядок разложения по e^{-S_0}. Настоящий же ответ устроен попросту как

$$\frac{G(\eta,-\eta,\beta)}{G_0(\beta)} = \sinh(\Delta\beta), \quad \Delta = \omega\cdot\sqrt{\frac{6S_0}{\pi}}e^{-S_0} = \frac{2}{\sqrt{\pi}}\omega\cdot\sqrt{\omega\eta^2}e^{-2\omega\eta^2/3}.$$

То, что ответ должен быть таким, само по себе достаточно очевидно - мы знаем, что в реальном времени если посадить частицу в одну из ям, то она будет испытывать осцилляции Раби $\sin(\Delta t)$, и Δ даётся как раз туннельным расщеплением симметричного и антисимметричного состояния. В мнимом же времени, экспоненциальная зависимость восстанавливается; рассматривая разложения по собственным модам вида $G(x,y,\beta) = \sum\limits_n \psi_n(x)\psi_n^*(y)e^{-\beta E_n}$, мы немедленно понимаем, что в задаче имеется пара уровней энергии $E = \frac{\omega}{2}\pm\Delta$. Тем не менее, чтобы получить этот ответ систематически, необходимо уйти за рамки одноинстантонного приближения, и рассмотреть многоинстантонные вклады.

Разреженный инстантонный газ

Помимо найденной единственной траектории $x_{cl}(\tau)$, при которой частица перекатывается из одного «горба» перевёрнутого потенциала на другой, имеются также и траектории, в которых она многократно катается «туда-сюда» (см. рис.).

Давайте выясним, как устроен вклад от таких траекторий в приближении, что инстантоны расположены достаточно далеко друг от друга (это приближение носит название приближения разреженного инстантонного газа; ниже мы выясним, какому параметру оно соответствует). Во-первых, действие на такой траектории из n инстантонов, очевидным образом, будет равно $S_n = nS_0$, а эффективный потенциал с экспоненциальной точностью устроен как набор аналогичных ям от каждого инстантона. Интуитивно понятно, что и квадратичные флуктуации вблизи каждого инстантона факторизуются,'

поскольку инстантоны достаточно хорошо разнесены в пространстве [7]; это можно показать и явно. В каждой из ям будет свой набор состояний дискретного спектра, поэтому вклад от последнего факторизуется. Непрерывный же спектр устроен безотражательно для каждого из инстантонов - поэтому полная фаза рассеяния на всех инстантонах будет попросту суммой фаз от каждого из инстантонов, $\delta^{(n)}(p) = n\delta(p)$ - из-за чего факторизуется также и вклад от непрерывного спектра. Наконец, с каждым из инстантонов будет связана своя нулевая мода - интегрирование по положению его центра; и вклад от нулевых мод будет устроен следующим образом:

$$\int\limits_{-\beta/2<\tau_1<\tau_2<\cdots<\tau_n<\beta/2} d\tau_1 ... d\tau_n = \frac{\beta^n}{n!}$$

Для перехода $-\eta \to \eta$, только конфигурации с нечётным количеством инстантонов дают вклад. Поэтому, суммирование разреженного инстантонного газа приводит к следующему ответу:

$$\frac{G(\eta, -\eta, \beta)}{G_0(\beta)} = \sum_{n=0}^{\infty} \frac{1}{(2n+1)!} \left(\sqrt{\frac{6}{\pi} S_0} \omega \beta e^{-S_0} \right)^{2n+1} = \sinh \left(\sqrt{\frac{6}{\pi} S_0} \omega \beta e^{-S_0} \right)$$

Точно такое же суммирование можно было бы провести и для, например, $\eta \to \eta$. В таком случае очевидным образом вклад давали бы только конфигурации с чётным количеством инстантонов, и в ответе ожидаемым образом получился бы cosh.

Давайте выясним, по какому параметру работает наше приближение. Мы имеем дело с суммой $\sum\limits_{n=0}^{\infty} \frac{(\Delta\beta)^{2n+1}}{(2n+1)!}$. Члены этого ряда с n сначала возрастают (из-за, вообще говоря, большого множителя $\Delta\beta$), а затем убывают (из-за факториала в знаменателе - ряд-то сходится!). Можно убедиться, что пик приходится на $n^* \approx \Delta\beta$, и именно такие инстантонные конфигурации дают наибольший вклад в сумму, и условие разреженности должно выполняться именно для них. С другой стороны, типичная ширина каждого инстантона равна, как мы помним, ω^{-1}; требование сводится к тому, что ширина n^* инстантонов должна быть по-прежнему маленькой по сравнению со всей длиной отрезка β. Этот критерий соответствует $\Delta \ll \omega$; тем самым, наше приближение работает только покуда инстантонная поправка является маленькой (что совершенно ожидаемо) - это, в свою очередь, соответствует туннельному пределу $S_0 \gg 1$.

Формализм Гельфанда - Яглома

На прошлом семинаре мы столкнулись с необходимостью вычисления функциональных детерминантов операторов типа Шрёдингера. Для его вычисления нам

потребовалось найти собственные значения дискретного, и волновые функции непрерывного спектра, а затем вычислять бесконечные произведения. В задаче прошлого семинара мы смогли с этим справиться из-за наличия точного решения потенциала в терминах гипергеометрической функции. С другой стороны, в более сложных приложениях такого решения может не существовать, и возможно, детерминант придётся находить численно - и достаточно очевидно, что изложенный выше способ непригоден для численного анализа. В данном семинаре будет изложен альтернативный и достаточно красивый способ, который позволяет найти ответ значительно проще.

Дискретная формулировка и доказательство

Допустим, мы хотим найти «характеристический многочлен» $f(\lambda) = \det(\hat{H} - \lambda)$, где $\hat{H} = -\partial_x^2 + U(\hat{x})$ - какой-то квантомеханический гамильтониан (забудем пока на время о бесконечных нормировочных константа и что сам детерминант, вообще говоря, определён плохо). Чтобы определить задачу полностью, помимо оператора, нам также необходимо задать класс функций, на которых он действует - например, функции, заданные на отрезке с бесконечными стенками $\psi(0) = \psi(L) = 0$. Дискретизуем пространство с шагом ϵ; матрицу $\hat{H}$ в таком случае можно задать совершенно явно $(x_k = k \cdot \epsilon, \epsilon = L/(N+1), \psi_0 = 0)$

$$\left(\hat{H}_N \psi\right)_n = -\frac{\psi_{n+1} - 2\psi_n + \psi_{n-1}}{\epsilon^2} + U(x_n)\,\psi_n,$$

$$\hat{H}_N = \frac{1}{\epsilon^2}\begin{pmatrix} 2+\epsilon^2 U(x_1) & -1 & 0 & ... & 0 & \\ -1 & 2+\epsilon^2 U(x_2) & -1 & \cdots & 0 & \\ 0 & -1 & 2+\epsilon^2 U(x_3) & \ddots & \vdots & \\ \vdots & \vdots & \ddots & \ddots & -1 & \\ 0 & 0 & & ... & -1 & 2+\epsilon^2 U(x_N) \end{pmatrix}$$

(и задача становится хорошо определённой). Обозначим $f_N(\lambda) = \det\left(\hat{H}_N - \lambda\right)$; чуть удобнее будет вынести ϵ^{-2}, как на формуле выше, вычислить определитель оставшейся матрицы $g_N(\lambda) = \epsilon^{2N} f_N(\lambda)$. Не мудрствуя лукаво, давайте распишем оставшийся определитель по последней строчке; тем самым он свяжется с определителями подматрицы на один и два размера меньше рекуррентным соотношением [8]:

$$g_{N+1} = \left(2 + \epsilon^2\left(U(x_{N+1}) - \lambda\right)\right) g_N - (-1)(-1) g_{N-1} \Rightarrow -\frac{g_{N+1} - 2g_N + g_{N-1}}{\epsilon^2} + \left(U(x_{N+1}) - \lambda\right) g_N = 0$$

Возвращаясь к непрерывному пределу $g_N(\lambda) = g(x = N\epsilon|\lambda)$, мы немедленно видим нетривиальный факт - сам определитель удовлетворлет такому уравнению Шрёдингера! В этом - суть теоремы Гельфанда-Яглома, и это уже хороший рецепт нахождения определителя - осталось лишь добавить начальные условия. В дискретном представлении они следующие:

$$g_1(\lambda) = 2 + \epsilon^2 U(x_1) \approx 2, \quad g_2(\lambda) = \left(2 + \epsilon^2 U(x_1)\right)\left(2 + \epsilon^2 U(x_2)\right) - 1 \approx 3,$$

что означает, что в непрерывном пределе функция $\psi(x|\lambda) = \epsilon g(x|\lambda)$ имеет хорошо определённые граниченые условия. Тем самым, в пределе $\epsilon \to 0$ задача решается следующим образом:

$$\det\left(\hat{H}_N - \lambda\right) = \frac{1}{\epsilon^{2N-1}}\psi(L = N\epsilon|\lambda), \quad \hat{H}\psi(x|\lambda) = \lambda\psi(x|\lambda), \quad \psi(0|\lambda) = 0, \quad \partial_x\psi(0|\lambda) = 1$$

Вместо нахождения всех решений краевой задачи $\psi(0) = \psi(L) = 0$, нам необходимо решить одну единственную эволюционную задачу (как в «методе стрельбы») - это существенное упрощение. Как обычно, чтобы кроме того избавиться от всевозможных бесконечных нормировочных констант, связанных с дискретизацией, мы можем рассмотреть отношение двух детерминантов - которое уже определено хорошо:

$$\frac{\det\left(\hat{H}_1 - \lambda\right)}{\det\left(\hat{H}_2 - \lambda\right)} = \frac{\psi_1(L|\lambda)}{\psi_2(L|\lambda)}$$

Теперь давайте обсудим полученный результат. Во-первых, выбрать граничное условие $\partial_x\psi$ можно любым - лишь бы для обоих волновых функций $\psi_{1,2}$ оно было выбрано одинаковым. Во-вторых, полученный результат непосредственно обобщается и на более сложные операторы, например, на уравнение Шрёдингера в двух или трёх измерениях (где оператор, задающий уравнение волновую функцию устроено не буквально как $-\partial_x^2 + U(x)$). Предложенные тут правдоподобные рассуждения как вариант доказательства теоремы Гельфанда-Яглома не единственные - вообще говоря, к тому же результату можно было бы прийти иначе. А именно, можно заметить, что если $\psi(0|\lambda) = 0$, то $\psi(L|\lambda) = 0$ тогда и только тогда, когда λ является собственным числом оператора $\hat{H}$ - а это, в свою очередь, означает, что нули функций $\det(\hat{H} - \lambda)$ и $\psi(L|\lambda)$ как функции переменной λ совпадают. Из ТФКП известно, что эти функции в таком случае могут отличаться лишь на какую-то целую функцию - и эта целая функция для числителя и знаменателя оказывается одинаковой, если выбраны одинаковые граничные условия задачи «стрельбы» $\partial_x\psi(0|\lambda)$. Поэтому полученная тут связь совершенно неудивительна, и её стоило бы ожидать.

Пример: осциллятор

Давайте рассмотрим в качестве примера простой гармонический осциллятор в мнимом времени, $\hat{H}_1 = -\partial_\tau^2 + \omega^2$; а в качестве знаменателя возьмём свободную частицу, $\hat{H}_2 = -\partial_\tau^2$; положим $\lambda = 0$ (такую задачу в реальном времени мы решали два семинара назад, когда только учились брать гауссовы интегралы). Решения соответствующих эволюционных задач записываются устно:

$$\left(-\partial_\tau^2 + \omega^2\right)\psi_1(x) = 0 \Rightarrow \psi_1(\tau) = \frac{\sinh\omega\tau}{\omega}$$
$$-\partial_\tau^2\psi_2(x) = 0 \Rightarrow \psi_2(\tau) = \tau$$

и значит, для функций, заданных на отрезке длины β, отношение определителей равно:

$$\frac{\det\hat{H}_1}{\det\hat{H}_2} = \frac{\sinh\omega\beta}{\omega\beta}$$

Тот же результат получался и ранее с нахождением спектра, что было несколько сложнее.

Пример: флуктуации вблизи инстантона

Теперь давайте перейдём к примеру сложнее - а именно, рассмотрим оператор $\hat{H}_s = -\partial_x^2 - \frac{s(s+1)}{\cosh^2 x}$. Именно с таким оператором ($s = 2$) мы имели дело на прошлом семинаре. Обозначим также $\lambda = -\kappa^2$. Нам нужно решать задачу стрельбы; сразу заметим, что поскольку $\lambda < 0$, то уравнение Шрёдингера решается на отрицательных

энергиях, поэтому решения непременно будут экспоненциально растущими. Нормировать мы будем на осциллятор - такой же оператор, но с $s = 0$. Наконец, поскольку мы рассматриваем задачу на отрезке $(-L, L)$, то удобно воспользоваться симметрией задачи относительно инверсии. Как мы знаем, эта симметрия означает, что все собственные волновые функции можно выбрать либо чётными, либо нечётными - а значит, и в определитель будет вклад как от чётных, так и от нечётных мод, и эти вклады разделяются. Поэтому и мы тоже можем искать отдельно отношение определителей, вычисленных по чётным и по нечётным состояниям - для этого можно «стрелять» не из $x = -\beta/2$, а из нуля $x = 0$, и решать следующие две задачи («+» и «-» соответствуют чётным и нечётным решениям):

Давайте теперь решать уравнение Шрёдингера. Конечно, без гипергеометрической функции не обойтись - УШ ведь получается таким же. Для поиска чётных и нечётных решений удобно воспользоваться заменой переменных $y = \cosh^2 x$, которая приводит УШ к следующему виду:

$$y(1-y)\psi''(y) + \left(\frac{1}{2} - y\right)\psi'(y) - \left(\frac{s(s+1)}{4y} - \frac{\kappa^2}{4}\right)\psi(y) = 0$$

Подстановка $\psi(y) = y^{(s+1)/2}\chi(y)$ приводит его к гипергеометрическому виду:

$$y(1-y)\chi''(y) + \left[\left(s + \frac{3}{2}\right) - y(s+2)\right]\chi'(y) - \left(\frac{(s+1)^2 - \kappa^2}{4}\right)\chi(y) = 0,$$

однако чуть проще оно записывается для переменной $z = 1 - y = -\sinh^2 x$:

$$z(1-z)\chi''(z) + \left[\frac{1}{2} - z(s+2)\right]\chi'(z) - \left(\frac{(s+1)^2 - \kappa^2}{4}\right)\chi(z) = 0.$$

Сравнивая полученное уравнение с уравнением для гипергеометрической функции, мы немедленно получаем следующие значения параметров:

$$a = \frac{s+1+\kappa}{2}, \quad b = \frac{s+1-\kappa}{2}, \quad c = \frac{1}{2},$$

а также общий вид решения в виде линейной комбинации ${}_2F_1(a, b; c; z)$ и $z^{1-c}{}_2F_1(b-c+1, a-c+1; 2-c; z)$; для исходных функций решения имеют следующий вид:

$$\begin{cases} \psi^{(+)}(x) = \cosh^{s+1} x \cdot {}_2F_1\left(\frac{s+1+\kappa}{2}, \frac{s+1-\kappa}{2}; \frac{1}{2}; -\sinh^2 x\right) \\ \psi^{(-)}(x) = \sinh x \cdot \cosh^{s+1} x \cdot {}_2F_1\left(\frac{s-\kappa+2}{2}, \frac{s+\kappa+2}{2}; \frac{3}{2}; -\sinh^2 x\right) \end{cases}$$

Выбранные таким образом, они удовлетворяют необходимым граничным условиям: $\psi^{(+)}(x \ll 1) \approx 1$ и $\psi^{(-)}(x \ll 1) \approx x$. Асимптотики (бесконечность) Мы хотим найти определитель для системы со стенками, расположенными достаточно далеко $\kappa L \gg 1$, поэтому нам необходимо найти далёкие асимптотики функций $\psi^{(\pm)}(x \to \infty)$ (которые, напомним, должны быть экспоненциально возрастающими, поскольку мы имеем дело с движением на отрицательной энергии). Для того, чтобы найти асимптотику гипергеометрической функции, нам необходимо воспользоваться одной из многих формул преобразования аргумента в данном случае, $z \mapsto \frac{1}{z}$ (который переводит ∞ в 0, а асимптотика в нуле уже хорошо известна). Преобразование имеет следующий вид:

$${}_2F_1(a, b; c; z) = \frac{\Gamma(c)\Gamma(b-a)}{\Gamma(b)\Gamma(c-a)}\frac{1}{(-z)^a}\cdot{}_2F_1\left(a, 1-c+a; 1-b+a; \frac{1}{z}\right) + \frac{\Gamma(c)\Gamma(a-b)}{\Gamma(a)\Gamma(c-b)}\frac{1}{(-z)^b}\cdot{}_2F_1\left(b, 1-c+b;\right.$$

Сами гипергеометрические функции дают асимптотику ${}_2F_1(...,0) \approx 1$; для функции $\psi^{(+)}$значение $a > b$, из-за чего важнее оказывается второе слагаемое; а для $\psi^{(-)}$—наоборот, первое. Асимптотики получаются следующими:

$$\begin{cases} \psi^{(+)}(x) \approx \frac{\Gamma(1/2)\Gamma(\kappa)}{\Gamma((s+1+\kappa)/2)\Gamma((\kappa-s)/2)} \coth^{s+1} x \cdot \sinh^{\kappa} x \approx \frac{\Gamma(1/2)\Gamma(\kappa)}{2^{\kappa}\Gamma((1+s+\kappa)/2)\Gamma((\kappa-s)/2)} e^{\kappa x} \\ \psi^{(-)}(x) \approx \frac{\Gamma(3/2)\Gamma(\kappa)}{\Gamma((s+\kappa+2)/2)\Gamma((1-s+\kappa)/2)} \coth^{s+1} x \sinh^{\kappa} x = \frac{\Gamma(3/2)\Gamma(\kappa)}{2^{\kappa}\Gamma((s+\kappa+2)/2)\Gamma((1-s+\kappa)/2)} e^{\kappa x} \end{cases}$$

В знаменателе же стоит решение задачи в отсутствии потенциала («квантовый гармонический осциллятор» в терминах исходной задачи, или свободная частица в терминах соответствующего УШ), который мы уже выписывали ранее:

$$\begin{cases} \psi_0^{(+)}(x) = \cosh \kappa x \approx e^{\kappa x}/2 \\ \psi_0^{(-)}(x) = \sinh \kappa x/\kappa \approx e^{\kappa x}/2\kappa \end{cases}$$

Тем самым, отношение определителей принимает следующий вид:

$$\frac{\det\left(\hat{H}_s + \kappa^2\right)}{\det\left(\hat{H}_0 + \kappa^2\right)} = \frac{2\Gamma(1/2)\Gamma(\kappa)}{2^{\kappa}\Gamma((1+s+\kappa)/2)\Gamma((\kappa-s)/2)} \cdot \frac{2\kappa\Gamma(3/2)\Gamma(\kappa)}{2^{\kappa}\Gamma((s+\kappa+2)/2)\Gamma((1-s+\kappa)/2)}$$

$$= \frac{\pi\kappa\Gamma^2(\kappa)}{2^{2\kappa-1}\Gamma((1+s+\kappa)/2)\Gamma((\kappa-s)/2)\Gamma((s+\kappa+2)/2)\Gamma((1-s+\kappa)/2)}$$

'Полученный ответ можно ещё упростить, используя соотношение $\Gamma(x)\Gamma(x+1/2) = \sqrt{\pi}\Gamma(2x)/2^{2x-1}$. Окончательно, имеем:

$$\frac{\det\left(\hat{H}_s + \kappa^2\right)}{\det\left(\hat{H}_0 + \kappa^2\right)} = \frac{\kappa\Gamma^2(\kappa)}{\Gamma(1+s+\kappa)\Gamma(\kappa-s)}$$

Применение к инстантону

На прошлом семинаре мы считали следующее отношение определителей:

$$\frac{\det'\left(-\partial_\tau^2 + \omega^2 - 3\omega^2/2\cosh^2(\omega\tau/2)\right)}{\det'\left(-\partial_\tau^2 + \omega^2\right)}.$$

Напомним, штрих в числителе означал, что нужно «убрать» нулевую моду, а в знаменателе - что нужно убрать наинизшую моду. Давайте вычислим его, используя нашу общую формулу.Во-первых, чтобы привести его к нужному виду, необходимо сделать замену $x = \frac{\omega\tau}{2}$:

$$\frac{\det'\left(\frac{\omega^2}{4}\left[-\partial_x^2 + 4 - 6/\cosh^2 x\right]\right)}{\det'\left(\frac{\omega^2}{4}\left[-\partial_x^2 + 4\right]\right)} = \frac{\det'\left(\hat{H}_2 + 4\right)}{\det'\left(\hat{H}_0 + 4\right)}$$

Во-вторых, поскольку оба определителя «штрихованные», то константы можно сократить (собственные числа делятся друг на друга попарно и эти константы попарно же сокращаются - в противном случае, скажем, для отношения вида $\det'/\det$, такая константа могла бы «выскочить» в ответ); значит, мы немедленно получаем $s = 2$ и $\kappa = 2$. Если подставить эти параметры буквально в полученную выше формулу, мы получим ноль (поскольку $(\kappa - s)$ в знаменателе обращается в бесконечность), что

ожидаемо - в формуле штрихи стоят неспроста. В формализме Гельфанда-Яглома выбросить нулевую моду можно достаточно просто: давайте чуть-чуть сместим λ и рассмотрим отношение определителей $\det\left(\hat{H}_2+\ 4+\epsilon\right)/\det\left(\hat{H}_0+4+\epsilon\right)$. В таком случае, нулевая мода станет малой и равной ϵ; остальные же моды изменятся слабо. Добавив также «выброшенную» наименьшую моду в знаменателе, чтобы убрать штрих и оттуда, мы получаем:

$$\frac{\det'\left(\hat{H}_2+4\right)}{\det'\left(\hat{H}_0+4\right)}=\lim_{\epsilon\to 0}\frac{\frac{1}{\epsilon}\det\left(\hat{H}_2+4+\epsilon\right)}{\frac{1}{4}\det\left(\hat{H}_0+4+\epsilon\right)}$$

Теперь мы готовы считать. Подставляем $\kappa^2=4+\epsilon\Rightarrow\kappa=2+\epsilon/4$ и получаем:

$$\frac{\det\left(\hat{H}_2+4+\epsilon\right)}{\det\left(\hat{H}_0+4+\epsilon\right)}\underset{\epsilon\ll 1}{\approx}\frac{2\Gamma^2(2)}{\Gamma(5)\Gamma\left(\frac{\epsilon}{4}\right)}=\frac{\epsilon}{48},$$

и тем самым мы воспроизводим ответ, полученный ранее: $\frac{\det'\left(\hat{H}_2+4\right)}{\det'\left(\hat{H}_0+4\right)}=1/12$.

Инстантоны: распад метастабильного состояния

На этом семинаре мы разберём ещё одну задачу квантовой механики, которая тоже решается при помощи инстантонов и которая тоже имеет туннельную природу. Речь идёт о задаче распада метастабильного состояния (см. семинар 8 прошлого семестра). Хотя технически эта задача очень похожа на задачу о туннельном расщеплении в двухъямном потенциале, в ней есть несколько крайне важных мест, которые стоит обсудить отдельно. Сама задача формулируется следующим образом. Частица массы $m=1$ описывается следующим гамильтонианом:

$$\hat{H}=-\frac{1}{2}\partial_x^2+\lambda x^2(\eta-x)$$

В окрестности $x=0$ имеется локальный минимум, а сам потенциал имеет вид осциллятора с частотой $\omega=\sqrt{2\lambda\eta}$. Если бы этот минимум был бы глобальным, то для низколежащих уровней имелась бы серия стационарных связанных состояний $E_n=\omega\left(n+\frac{1}{2}\right)$. Однако в нашей задаче никаких стационарных состояний нет, имеется только непрерывный спектр - поэтому если частицу поместить на один из этих осцилляторных уровней энергии, то рано или поздно частица протуннелирует через барьер (который мы считаем достаточно высоким, чтобы квазистационарное состояние было хорошо определённым). Как мы обсуждали ранее, такой процесс формально эквивалентен мнимой добавке к уровням энергии $E_n-i\frac{\Gamma_n}{2}$, так что обычная унитарная эволюция для таких состояний будет приводить к экспоненциальному затуханию вероятности со временем $\psi_n\propto e^{-i(E_n-i\Gamma_n/2)t}\Rightarrow|\psi_n|^2\propto e^{-\Gamma_n t}$.

Давайте сперва формально повторим инстантонное вычисление, пропуская важные моменты - а в самом конце обсудим их. 11.6.1

Функциональный интеграл

Итак, мы хотим исследовать функцию Грина, дающую вероятность остаться в яме, $G(0,0,t)=\left\langle 0\left|e^{-i\hat{H}t}\right|0\right\rangle$. В мнимом времени $t=-i\beta$, в эту величину будет давать основной вклад основное состояние [10], и мы получим:

$$G_E(0,0,\beta)\approx\sum_n|\langle 0|n\rangle|^2e^{-\beta E_n+i\beta\Gamma_n/2}\approx|\langle 0|n=0\rangle|^2e^{-\beta E_0+i\beta\Gamma_0/2}$$

С другой стороны, для Евклидовой функции Грина можно записать следующий функциональный интеграл:

$$G_E(0,0,\beta) = \int\limits_{x(-\beta/2)=0}^{x(\beta/2)=0} \mathcal{D}x(\tau) e^{-S_E}, \quad S_E = \int\limits_{-\beta/2}^{\beta/2} d\tau \left(\frac{1}{2} \left(\partial_\tau x\right)^2 + U(x) \right)$$

Как обычно, Евклидово действие представляет собой обычное действиие, но в перевёрнутом потенциале [11], имеющим вид, изображённый на рисунке.

Инстантон

Следуя пройденному ранее пути, нам необходимо найти инстантон (в пределе $\beta \to \infty$) - седловую траекторию, дающую экстремум действия S_E. Как обычно, мы будем это делать, используя первый интеграл:

$$\partial_\tau^2 x = U'(x) = \lambda x(2\eta - 3x), \quad E = \frac{1}{2}\left(\partial_\tau x\right)^2 - U(x) = 0 \Rightarrow \partial_\tau x = \sqrt{2U(x)}$$

Имеются тривиальные траектории $x = 0$ (которая даст нам осцилляторные уровни энергии) и $x = \frac{2}{3}\eta$ (которая вообще является локальным максимумом и не интересна), а также нетривиальная траектория - инстантон:

$$\frac{dx}{\sqrt{2U(x)}} = d\tau \Rightarrow x_{cl}(\tau) = \frac{\eta}{\cosh^2 \frac{\omega\tau}{2}}$$

Эта траектория - «отскок» («bounce trajectory»), на ней частица «скатывается» с локального максимума $x = 0$ вправо, закатывается на точку остановки $x = \eta$, а затем скатывается обратно и опять закатывается на $x = 0$. Сама траектория изображена на рисунке: Как обычно, центр инстантона может быть выбран произвольным: $x_{cl}\left(\tau - \tau_c\right), \tau_c \in (-\beta/2, \beta/2)$ – с чем, как обычно, будет связано наличие нулевой моды в этом функциональном интеграле. Действие на этом инстантоне считается тривиально, используя закон сохранения энергии:

$$S_0 = \int\limits_{-\infty}^{\infty} \left(\partial_\tau x_{cl}\right)^2 d\tau = 2\omega\eta^2 \int\limits_{-\infty}^{\infty} \frac{\sinh^2 z}{\cosh^6 z} dz = \frac{8}{15}\omega\eta^2 \gg 1$$

Квадратичные флуктуации Мы делаем разложение вблизи инстантона, и получаем $S_E\left[x_{cl}(\tau) + z(\tau)\right] \approx S_0 + S_2[z(\tau)]$ и

$$S_2[z(\tau)] \approx \frac{1}{2}\int z(\tau)\left(-\partial_\tau^2 + U''\left(x_{cl}(\tau)\right)\right) z(\tau) d\tau$$

Как обычно, мы имеем дело с оператором типа «уравнения Шрёдингера» $\hat{L} = -\partial_\tau^2 + U''\left(x_{cl}(\tau)\right)$. «отенциальная энергия» этого уравнения следующая:

$$U''\left(x_{cl}(\tau)\right) = \omega^2\left(1 - \frac{3}{\cosh^2 \frac{\omega\tau}{2}}\right)$$

Потенциал опять имеет вид Пешля-Теллеря $\left(\sim \frac{1}{\cosh^2 x}\right)$, поэтому для этой задачи опять можно найти аналитическое решение. Нам опять необходимо решать задачу поиска спектра оператора:

$$\hat{L}\psi_n(\tau) = \epsilon_n \psi_n(\tau)$$

У оператора имеется нулевая мода, связанная с произвольностью выбора центра инстантона, и она устроена аналогично:

$$\psi_1(\tau) = \frac{1}{\sqrt{S_0}} \frac{\partial x_{cl}}{\partial \tau}$$

Тут возникает третий важный момент, который отличается от рассматриваемого ранее двухъямного потенциала. Траектория $x_{cl}(\tau)$ имеет максимум, поэтому нулевая мода имеет узел. Она не может давать волновую функцию основного состояния - а только первого возбуждённого. Это означает, что основное состояние даёт отрицательную моду $\epsilon_0 = -|\epsilon_0| < 0$, и Гауссов интеграл по ней, устроенный как $\int dc_0 e^{\frac{1}{2}c_0^2|\epsilon_0|}$ - расходится! Тем не менее, давайте закроем глаза и на это, и воспользуемся стандартной формулой, говорящей, что этот интеграл равен $\sqrt{\frac{2\pi}{\epsilon_0}} = \pm i\sqrt{\frac{2\pi}{|\epsilon_0|}}$. Действительно, поскольку мы ожидаем наличие именно метастабильного состояния с комплексной энергией, мнимый вклад - это как раз то, что нам следует ожидать! (вещественный вклад означал бы лишь, что уровень энергии как-то изменился - и это не то, что нам интересно). Мистическим образом, поступая так, мы теряем двойку - и это четвёртый важный момент, который мы обсудим ниже.

Отщепляя интегрирование по нулевой моде, которое устроено точно так же и даёт $\sqrt{\frac{S_0}{2\pi}}\omega\beta$, и учитывая эту «потерянную» двойку, мы приходим к следующему ответу:

$$\frac{G_E(0,0,\beta)}{G_0(0,0,\beta)} = \pm ie^{-S_0}\frac{1}{2}\sqrt{\frac{S_0}{2\pi}}\omega\beta \cdot \left(-\frac{\det'\left(-\partial_\tau^2 + U''\left(x_{cl}(\tau)\right)\right)}{\det'\left(-\partial_\tau^2+\omega^2\right)}\right)^{-1/2}$$

Отношение определителей проще сосчитать, используя метод Гельфанда-Яглома; оно оказывается равным

$$\frac{\det'\left(-\partial_\tau^2 + U''\left(x_{cl}(\tau)\right)\right)}{\det'\left(-\partial_\tau^2+\omega^2\right)} = -\frac{1}{60}$$

(как и следовало ожидать, из-за отрицательной моды определитель тоже отрицателен). Наконец, суммирование разреженного инстантонного газа также тривиально - количество траекторий-отскоков может быть произвольным $n = 0, 1, ...$, и инстантонный газ даст попросту превратит найденное нами число (вклад с $n = 1$) в экспоненту от него же $\sum\limits_{n=0}^{\infty} \frac{1}{n!}\left(\pm i\Gamma_0\beta/2\right)^n = \exp\left(\pm i\Gamma_0\beta/2\right)$. Собирая всё вместе, мы получаем следующий ответ:

$$\frac{G_E(0,0,\beta)}{G_0(0,0,\beta)} = \exp\left(\pm ie^{-S_0}\frac{1}{2}\sqrt{\frac{30S_0}{\pi}}\omega\beta\right)$$

Сравнивая с ожидаемым ответом $\exp\left(i\Gamma_0\beta/2\right)$, мы понимаем, что необходимо выбрать знак «+» и ответ даётся:

$$\Gamma_0 = \omega\sqrt{\frac{30S_0}{\pi}}e^{-S_0} = \frac{4}{\sqrt{\pi}}\omega \cdot \sqrt{\omega\eta^2}e^{-8\omega\eta^2/15}$$

11.6.2

Обсуждение вопросов

Итак, к этому моменту у внимательного читателя могло накопиться порядочное количество вопросов, которые мы старались отмечать по ходу текста. Основной вопрос, конечно, можно сформулировать следующим образом: как мы берём расходящийся (sic!) вещественный интеграл, и получаем конечный и мнимый (sic!) ответ?!

Ответ кроется в процедуре аналитического продолжения. Исходный функциональный интеграл хорошо определён и является аналитической функцией на вещественной оси времени $t \in \mathbb{R}$. Мы строим его аналитическое продолжение в комплексную плоскость, и рассматриваем его на мнимой оси $t = -i\beta$. К сожалению, если буквально подставить мнимое время в функциональный интеграл, мы действительно получаем расходящийся интеграл - и это означает, что процедура такого аналитического продолжения устроена чуть сложнее; ниже мы обсудим, как именно.

С другой стороны, в мнимом времени инстантонная траектория - вещественная, что очень хорошо! Для взятия соответствующего интеграла мы можем пользоваться обычным вещественным методом перевала, для которого у нас имеется хорошо развитая интуиция. В терминах исходного интеграла - у него тоже, конечно, имеется седло, но оно комплексное - и значит, нам требуется комплексный метод перевала (для многомерного комплексного интеграла!). Более того, комплексных сёдел в действительности очень много, и задача определения тех, которые всё-таки дают вклад в интеграл нетривиальная задача [12]. Именно поэтому мы делаем Виковский поворот - он значительно упрощает нам жизнь. Цена, которую приходится заплатить за это упрощение — необходимость аналитического продолжения — в действительности невелика. Процедура аналитического продолжения (формально) Формально такую процедуру можно устроить следующим образом. Рассмотрим функциональный интеграл как аналитическую функцию трёх параметров λ, η, t. При этом (λ, η, t) соответствует исходному функциональному интегралу, а $(\lambda, \eta, -i\beta)$ - Евклидовому, который мы считаем. Проследим, как меняется действие при вращении $t = |t|e^{-i\varphi}$:

$$iS\left[x(\tau), \lambda, \eta, |t|e^{-i\varphi}\right] = \int\limits_{-\tau/2}^{\tau/2} d\tau \left(\frac{1}{2}e^{i\frac{\pi}{2}+i\varphi}\left(\partial_\tau x\right)^2 - e^{i\frac{\pi}{2}-i\varphi}\lambda x^2(\eta - x)\right)$$

При сопровождающем вращении $\lambda = |\lambda|e^{i\varphi}$ интеграл будет оставаться сходящимся (т.к траектории с большими $x(\tau)$ дают осциллирующий вклад), поэтому аналитическое продолжение $(\lambda, \eta, t) \to (|\lambda|e^{i\varphi}, \eta, |t|e^{-i\varphi})$ происходит тривиально, используя исходное выражение. При таком аналитическом продолжении при $\varphi = \frac{\pi}{2}$ мы получаем Евклидово действие (в мнимом времени), но с параматром $i\lambda : G_E(i\lambda, \eta, \beta)$. Нетривиальной остаётся процедура аналитического продолжения $\lambda \to -i\lambda$, потому что при буквально такой подстановке в интеграл он теряет свою сходимость. То, как устроено такое аналитическое продолжение, мы продемонстрируем на модельном (обычном) интеграле. Модельный интеграл Конечно, для функционального интеграла процедуру аналитического продолжения в явном виде предоставить достаточно тяжело - но ключевые её моменты (включая «мистическую двойку») можно ухватить на простом модельном одномерном интеграле. Рассмотрим следующий интеграл:

$$I(g) = \int\limits_{-\infty}^{\infty} dx \cdot \exp\left(-\frac{x^2}{2} + igx^3\right)$$

Полученная функция аналитична при $g \in \mathbb{R}$ (аналог «вещественного времени»). С другой стороны, если мы попытаемся «наивно» её продолжить в $g \to \mp ig$ (аналог нашего «мнимого времени»), мы немедленно получим расходящийся интеграл, который даже внешне похож на наш: $I(\pm ig) \simeq \int\limits_{-\infty}^{\infty} dx \exp\left(-\frac{x^2}{2} \pm gx^3\right)$. Тем не менее, процедуру аналитического продолжения можно построить достаточно просто. Заметим, что при комплексном $g = |g|e^{-i\varphi}$, интеграл сходится в комплексной плоскости в следующих

секторах комплексной плоскости:

$$\mathrm{Im}\left(gx^3\right) \geq 0 \leftrightarrow \begin{cases} \frac{\varphi}{3} & \leq \arg x \leq \frac{\pi}{3} + \frac{\varphi}{3} \\ \frac{2\pi}{3} + \frac{\varphi}{3} & \leq \arg x \leq \pi + \frac{\varphi}{3} \\ \frac{4\pi}{3} + \frac{\varphi}{3} & \leq \arg x \leq \frac{5\pi}{3} + \frac{\varphi}{3} \end{cases}$$

При $\varphi = 0$ наші интеграл $I(g)$ проходит по контуру, который лежит в первом секторе (вещественная ось). Поэтому если при уходе g в комплексную плоскость мы будем вращать соответствующим образом контур интеграла (чтобы он оставался в первой области), то полученный интеграл будет сходится, а также будет являться аналитической функцией g. Тем самым, аналитическое продолжения интеграла $I(g)$ строится следующим образом:

$$I(g) = \int\limits_C dx \exp\left(-\frac{x^2}{2} + igx^3\right), \quad C = \left\{\arg x \in \left[\frac{\varphi}{3}; \frac{\pi}{3} + \frac{\varphi}{3}\right]\right\}, \quad \varphi = -\arg g \in (-\pi, \pi)$$

(например, мы можем попросту вращать контур так, чтобы $\arg x = \frac{1}{3}\varphi$ - и интеграл всегда оставался осциллирующим). Теперь можно приступить к исследованию асимптотик полученной аналитической функции при $g \ll 1$, для чего можно применить метод перевала. У интеграла имеются две седловых точки:

$$\varphi(x) = -\frac{x^2}{2} + igx^3, \quad \varphi'(x) = -x + 3igx^2 \Rightarrow \begin{cases} x_1 = 0 \\ x_2 = \frac{-i}{3g} \end{cases}, \quad \varphi(x) = \begin{cases} 0, & x = x_1 \\ \frac{1}{54g^2}, & x = x_2 \end{cases}$$

$$\varphi''(x) = -1 + 6 \text{ igx } = \begin{cases} -1, & x = x_1 \\ 1, & x = x_2 \end{cases}$$

1. Первая седловая точка $x = x_1$ - тривиальная, она является аналогом нашего тривиального «осцилляторного» седла - траектории $x_{cl} = 0$. Она всегда вещественная, и вклад от неё не зависит от g. Направление наискорейшего спуска на ней соответствует действительной оси, и это седло всегда даёт вклад в интеграл. Сам вклад устроен следующим образом:

$$I_1(g) \approx \int\limits_{-\infty}^{\infty} e^{-x^2/2} dx = \sqrt{2\pi}$$

2. Вторая седловая точка - наш «инстантон». Для интеграла в «реальном времени» ($g \in \mathbb{R}$) она комплексна, и если бы мы не знали ничего о комплексных числах - мы бы её попросту упустили. Вторая производная в ней положительна - поэтому с точки зрения обычного Гауссового интегрирования, интеграл по ней расходился бы $\left(\sim \int\limits_{-\infty}^{\infty} dx e^{x^2}\right)$ - впрочем, мы знаем,что в действительности это означает, что направление наискорейшего спуска на ней идёт параллельно мнимой оси. С учётом этого, вклад от второго седла оказывается следующщй:

$$I_2(g) \approx \pm i\sqrt{2\pi} e^{1/54g^2}$$

В «мнимом времени» $g = \pm i|g|$ седло становится вещественным $x_2 = \mp\frac{1}{3|g|}$, а вклад от него - экспоненциально мал $\propto \exp\left(-1/54|g|^2\right)$, а также он чисто мнимый (хотя, напомним, подынтегральное выражение выглядит чисто вещественным $\int\limits_C e^{-x^2/2+gx^3} dx\Big)$. Так или иначе, аналогия тут практически полная. Для того, чтобы понять, как устроен вклад этой седловой точки, можно проследить устройство топологии комплексной плоскости

при вращении $g \to ge^{-i\pi/2}$(смотри рисунки). Какой вывод стоит сделать из рисунка? При $\varphi < \frac{\pi}{2}$, вклад приходит только от тривиального седла и интеграл оценивается как

$$I\left(|g|e^{-i\varphi}\right) \approx I_1(g) \approx \sqrt{2\pi}, \quad 0 \le \varphi < \frac{\pi}{2},$$

в то время как при $\varphi > \frac{\pi}{2}$, вклад даёт также и второе седло (причём направление наискорейшего спуска $+\frac{\pi}{2}$, поэтому знак $\operatorname{Im} I(g) > 0$) и оценка получается следующей:

$$I\left(|g|e^{-i\varphi}\right) \approx I_1(g) + I_2(g) \approx \sqrt{2\pi}\left(1 + ie^{1/54g^2}\right), \quad \pi > \varphi > \frac{\pi}{2}.$$

В действительности мы тут имеем дело с явлением Стокса. У функции $I(g)$ мнимая ось (а именно она нас интересует!) - это линия Стокса, на которой появляется экспоненциально малый вклад $e^{-1/54|g|^2}$ на фоне «большого» вклада от основного седла. Обычно это означает, что на самой линии Стокса экспоненциально малый вклад плохо определён - ведь с «большим» вкладом $I_1(g)$ связан асимптотический ряд, погрешность которого больше экспоненциально малого вклада $I_2(g)$. Однако в данном случае (как и в функциональном интеграле) экспоненциально малый вклад выделить всё-таки возможно, потому что только он - мнимый (в этом смысле в $\operatorname{Im} I(g)$ мы сравниваем не $|I_2(g)|$ с $|I_1(g)|$, а с нулём - такое сравнение вполне законно).

Что же происходит на самой линии Стокса? Глядя на рисунок мы видим, что мы должны деформировать контур таким образом, что мы проходим по вещественной оси через первое седло, доходим до второго (но вдоль линии наискорейшего возрастания!); а затем на втором седле начинаем двигаться вдоль линии наискорейшего спуска, которая параллельна мнимой оси - тем самым, второе седло строго на линии Стокса даёт половинный вклад $\frac{1}{2}I_2(g)$:

$$\operatorname{Im} I(-i|g|) \approx \frac{1}{2}I_2(g)$$

Выводы Наш модельный интеграл оказался крайне полезным. На нём мы поняли смысл отрицательной моды, и законность нашего способа работы с ней, ровно как и происхождение множителя $\frac{1}{2}$. В функциональном интеграле мы также имеем дело с явлением Стокса (как аналитической функции амплитуды потенциала, или, что эквивалентно, туннельного действия) - асимптотический ряд, связанный с ангармонизмом осциллятора ($\frac{\omega}{2}$ - это лишь нулевой порядок!) имеет экспоненциально малую погрешность, которая сравнима с шириной уровня Г. Последняя, тем не менее, хорошо определа, поскольку является чисто мнимой [13] (на самом деле, точно такое же явление Стокса происходит и в задаче о туннельном расщеплении). Дальнейшее аналитическое продолжение $(\lambda, \eta, -i\beta) \to (\lambda, \eta, t)$ в конечном итоге сохранит эту $\frac{1}{2}$, поскольку мы всё время остаёмся на линии Стокса по переменной λ; поэтому конечный ответ именно такой.

Метастабильные состояния Д Другой вопрос был связан с тем, как мы интерпретировали метастабильные состояния в частности, раскладывались по ним, как будто они образуют базис. Разложение, конечно, правильно проводить по всем состояниям непрерывного спектра. Тем не менее, квазистационарные состояния проявляют себя как полюса амплитуды рассеяния - S-матрицы - расположенные вблизи вещественной оси. При вычислении различных интегралов по непрерывному спектру (ну, например - функции Грина) именно эти состояния будут давать наибольший (полюсной) вклад. Поэтому, хоть разложение буквально не запишется в нужном виде, но в действительности с хорошей точностью [14] эта формула всё-таки работает:

$$G(0,0,t) \simeq \sum_n |\langle 0|n\rangle|^2 e^{-iE_n t - \Gamma_n t/2},$$

классическая теория вращения пространства

О применениях методов вращения пространства (??????!!!)

(нахрена я вообще учил бы их!!!???? пока главный вопрос. вроде итак умеем из линала это делать)

постановка задачи

(Кузьмин)
“Были" в фиксированной системе координат (СК).
Теперь пусть две декартовы СК:
$-S$ -исходная, координаты x, y, z $-\tilde{S}$ -"другая", координаты $\tilde{x}, \tilde{y}, \tilde{z}$
Начала отсчёта совпадают; обе правые, т.е.
правый винт, расположенный вдоль оси Z, движется в положительном направлении оси Z при вращении в плоскости XY в направлении от X к Y.
Положение одной СК относительно другой: 3 орта $\times 3$ координаты $= 9$ чисел; но: $9-3($ условия ортогональнности ортов $)-3($ длина орта равна единице $)=3$
Популярные способы выбора 3-х чисел. а) теорема Эйлера: Произвольное перемещение твёрдого тела, имеющего неподвижную точку, можно осуществить посредством вращения вокруг некоторой оси. [цитата из Г.
Голдстейн, Классическая механика] $\vec{n} = (\sin\theta\cos\phi, \sin\theta\sin\phi, \cos\theta)$ и угол поворота ω Вопрос: справедлива ли теорема Эйлера в 4-х мерном евклидовом про-ве? б) углы Эйлера (α, β, γ): β -угол между осями Z и $\tilde{Z}$ α -угол между линией пересечения плоскостей XY и $\tilde{X}\tilde{Y}$ и осью Y; γ - угол между линией пересечения плоскостей XY и $\tilde{X}\tilde{Y}$ и осью $\tilde{Y}$. Укажите область значений углов Эйлера α, β, γ.
Операции для перехода от S к $\tilde{S}$:

$R_Z(\alpha) -$ поворот вокруг оси Z на угол α
$R_{Y'}(\beta) -$ поворот вокруг оси Y' на угол β
$R_{Z'}(\gamma)$ - поворот вокруг оси Z' на угол γ

Пусть $|jm\rangle$ -вектор состояния "тела" с заданными значениями j и проекции на ось Z, $|\widehat{jm}\rangle$ - вектор состояния "тела" с заданными значениями j и проекции на ось $\tilde{Z}$. Перевод "тела" из одного состояния в другое

$$|\widehat{jm}\rangle = R(\omega)|jm\rangle$$

ω - параметры преобразования "тела".

оператор конечных вращений

Действие оператора поворота "тела" вокруг оси Z на угол α

$$R_Z(\alpha)f(r,\theta,\phi) = f(r,\theta,\phi-\alpha)$$

$R_Z(\alpha) = \exp\left(-\alpha\frac{d}{d\phi}\right), \ell_Z = \frac{\hbar}{i}\frac{d}{d\phi}, R_Z(\alpha) = \exp\left(-i\alpha\ell_Z\right)$, здесь и далее $\hbar = 1$

$$R(\omega) = \exp\left(-i\gamma\ell_{Z'}\right)\exp\left(-i\beta\ell_{Y'}\right)\exp\left(-i\alpha\ell_Z\right)$$

Повороты вокруг "подвижных" осей.

Как вычислять действие такого оператора на функции, заданные в "неподвижных" осях?

Перевод "тела" из одного состояния в другое

$$|\widehat{jm}\rangle = R(\alpha,\beta,\gamma)|jm\rangle$$

α,β,γ - параметры преобразования "тела"; сокращённое обозначение, ω.

Показали:

$$R(\omega) = \exp\left(-i\gamma\ell_{Z'}\right)\exp\left(-i\beta\ell_{Y'}\right)\exp\left(-i\alpha\ell_Z\right)$$

Повороты вокруг "подвижных" осей!

переход от подвижных осей к неподвижным

Связь поворота вокруг оси $\vec{a}$ на угол Φ с поворотом вокруг оси $\vec{b}$:

$$R_{\vec{a}}(\Phi) = R(\vec{b}\to\vec{a})R_{\vec{b}}(\Phi)R^{-1}(\vec{b}\to\vec{a})$$
$$R(\omega) = R_{Z'}(\gamma)R_{Y'}(\beta)R_Z(\alpha)$$
$$R_{Z'}(\gamma) = R_{Y'}(\beta)R_Z(\gamma)R^{-1}_{Y'}(\beta)$$
$$R_{Y'}(\beta) = R_Z(\alpha)R_Y(\beta)R^{-1}_Z(\alpha)$$
$$R(\omega) = R_Z(\alpha)R_Y(\beta)R^{-1}_Z(\alpha)\cdot R_Z(\gamma)\cdot R^{-1}_{Y'}(\beta)\times R_{Y'}(\beta)R_Z(\alpha) =$$
$$= R_Z(\alpha)R_Y(\beta)R^{-1}_Z(\alpha)\cdot R_Z(\gamma)\times R_Z(\alpha) =$$
$$= R_Z(\alpha)R_Y(\beta)R_Z(\gamma)$$
$$R(\alpha,\beta,\gamma) = \exp\left(-i\alpha\ell_Z\right)\exp\left(-i\beta\ell_Y\right)\exp\left(-i\gamma\ell_Z\right)$$

Все операторы относятся к исходному положению "тела".

матрицы конечных вращений

Поскольку $\ell^2 = \ell^2_X + \ell^2_Y + \ell^2_X,$ то $\left[\ell^2, R(\omega)\right]_- = 0,$ и $\ell^2|\widetilde{lm}\rangle = \ell^2 R(\omega)|lm\rangle = l(l+1)|\widetilde{lm}\rangle$

$$R(\omega)\psi_{lm} = \sum_{m_\prime} \psi_{lm'} \left(\psi_{lm'}, R_Z(\alpha)R_Y(\beta)R_Z(\gamma)\psi_{lm}\right) = \sum_{m_\prime} \mathcal{D}^l_{m'm}(\alpha,\beta,\gamma)\psi_{lm'}$$

Определим:

$$\mathcal{D}^l_{m'm}(\alpha,\beta,\gamma) \equiv \left(\psi_{lm'}, R_Z(\alpha)R_Y(\beta)R_Z(\gamma)\psi_{lm}\right)$$

тогда:

$$R_Z(\alpha) = \exp\left(-i\alpha\ell_Z\right),$$

$$\left(\psi_{lm'}R_Z(\alpha)\psi_{ln}\right) = \exp\left(-i\alpha m'\right)\delta\left(n-m'\right)$$

Поэтому запишем:

$$\begin{aligned}\mathcal{D}^l_{m'm}(\alpha,\beta,\gamma) &= \exp\left(-i\alpha m'\right)\exp(-i\gamma m)\left(\psi_{lm'}, R_Y(\beta)\psi_{lm}\right) = \\ &= \exp\left(-i\alpha m'\right)\exp(-i\gamma m)d^l_{m'm}(\beta)\end{aligned}$$

и определим

$$d^l_{m'm}(\beta) \equiv \left(\psi_{lm'}, \exp\left(-i\beta\ell_Y\right)\psi_{lm}\right)$$

пример: вращения со спином 1/2

$$s_{x,y,z} = \tfrac{\sigma_{x,y,z}}{2},\ \text{где}\ \sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \sigma_y = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}; \sigma^2_{x,y,z} = I$$

$$s_z\begin{pmatrix} 1 \\ 0 \end{pmatrix} = \tfrac{1}{2}\begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad s_z\begin{pmatrix} 0 \\ 1 \end{pmatrix} = -\tfrac{1}{2}\begin{pmatrix} 0 \\ 1 \end{pmatrix}, R_Z(\alpha)\psi_{1/2,\pm1/2} = \exp(\mp i\alpha/2)\psi_{1/2,\pm1/2}$$

$$\begin{aligned}R_Y(\beta) &= \exp\left(-i\beta\sigma_y/2\right) = \exp\left(-i\frac{\beta}{2}\sigma_y\right) = \cos\frac{\beta}{2}I - i\sin\frac{\beta}{2}\sigma_y = \\ &= \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}\cos\frac{\beta}{2} + \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\sin\frac{\beta}{2} = \begin{pmatrix} \cos\beta/2 & -\sin\beta/2 \\ \sin\beta/2 & \cos\beta/2 \end{pmatrix}\end{aligned}$$

(кривая таблица, потом переклею ее:)

$d^{1/2}_{m'm}(\beta):$	$-1/2$	$1/2$
$-1/2$	$\cos\beta/2$	$\sin\beta/2$
$1/2$	$-\sin\beta/2$	$\cos\beta/2$

$$R(\alpha,\beta,\gamma) = \exp\left(-i\alpha J_Z\right)\exp\left(-i\beta J_Y\right)\exp\left(-i\gamma J_Z\right)$$

(типичный вопрос, на который нужно ответить)

Методы вращения пространства в двух словах

(?? какие тут формулы?)
полный набор наблюдаемых составляют $\{s^2, s_z\}$.
(в строчку поясню, почему)
(далее методы вращения от рел квант мех)

Типичные примеры вращения пространства

(думаю, тут без ключевых примеров никуда не уйти.)

О применениях методов вращения пространства

(??? так где это нужно по итогу???)
(мб тут укажу, что в квантовых компьютерах, там вроде есть повороты кубитов??)

операторы поворота

(выпишу суть потом. пока не владею этой теорией)
(???? начало упущено)
ного умножения

$$\hat{R}(\alpha, \beta, \gamma) = \hat{R}_{z'}(\gamma) \cdot \hat{R}_{y'}(\beta) \cdot \hat{R}_z(\alpha)$$

где мы указали в качестве аргументов углы поворотов, а соответствующие оси вращений как нижние индексы.

Точный вид первого операторного фактора нам уже известен:

$$\hat{R}_z(\alpha) = e^{\mathrm{i}\hat{s}_z\alpha}, \quad \hat{s}_z = \frac{1}{2}\boldsymbol{\sigma}_3$$

Для определения второго фактора необходимо знать выражение для генератора $\hat{s}_{y'}$, запишем его в виде

$$\hat{s}_{y'} = \frac{1}{2}\left(\hat{\boldsymbol{\sigma}}' \cdot \boldsymbol{e}_{y'}\right)$$

где $e_{y'}$ -единичный вектор вдоль оси y', а $\hat{\sigma}'$ -матрицы Паули в базисе $\{x', y', z\}$.

Таким образом, это - оператор, который получается при вращении вокруг оси z на угол α и сходного оператора

$$\hat{s}_y = \frac{1}{2}\left(\hat{\boldsymbol{\sigma}} \cdot \boldsymbol{e}_y\right)$$

согласно закону преобразования операторов

$$\left(\hat{\boldsymbol{\sigma}}' \cdot \boldsymbol{e}_{y'}\right) = \hat{R}_z(\alpha) \cdot \left(\hat{\boldsymbol{\sigma}} \cdot \boldsymbol{e}_y\right) \cdot \hat{R}_z^\dagger(\alpha),$$

откуда сразу получаем

$$\hat{R}_{y'}(\beta) = \hat{R}_z(\alpha) \cdot \hat{R}_y(\beta) \cdot \hat{R}_z^\dagger(\alpha)$$

так что

$$\hat{R}_{z'}(\gamma) = \hat{R}_{y'}(\beta) \cdot \hat{R}_z(\gamma) \cdot \hat{R}_{y'}^\dagger(\beta)$$

значит

$$\hat{R}(\alpha, \beta, \gamma) = \hat{R}_{z'}(\gamma) \cdot \hat{R}_{y'}(\beta) \cdot \hat{R}_z(\alpha) = \hat{R}_{y'}(\beta) \cdot \hat{R}_z(\gamma) \cdot \hat{R}_{y'}^\dagger(\beta) \cdot \hat{R}_{y'}(\beta) \cdot \hat{R}_z(\alpha)$$

Унитарность оператора вращений дает

$$\hat{R}^{\dagger}_{y'}(\beta)\cdot\hat{R}_{y'}(\beta)=\mathbb{1}$$

так что

$$\hat{R}(\alpha,\beta,\gamma)=\hat{R}_{y'}(\beta)\cdot\hat{R}_z(\gamma)\cdot\hat{R}_z(\alpha)=\hat{R}_z(\alpha)\cdot\hat{R}_y(\beta)\cdot\hat{R}^{\dagger}_z(\alpha)\cdot\hat{R}_z(\gamma)\cdot\hat{R}_z(\alpha)$$

$$\hat{R}^{\dagger}_z(\alpha)\cdot\hat{R}_z(\gamma)\cdot\hat{R}_z(\alpha)=\hat{R}_z(\gamma)$$

так как вращение на угол α компенсируется обратным вращением.

Окончательно находим

$$\hat{R}(\alpha,\beta,\gamma)=\hat{R}_z(\alpha)\cdot\hat{R}_y(\beta)\cdot\hat{R}_z(\gamma)$$

откуда сразу полу чаем

$$\hat{R}_{y'}(\beta)=\hat{R}_z(\alpha)\cdot\hat{R}_y(\beta)\cdot\hat{R}^{\dagger}_z(\alpha)$$

так что

$$\hat{R}_{z'}(\gamma)=\hat{R}_{y'}(\beta)\cdot\hat{R}_z(\gamma)\cdot\hat{R}^{\dagger}_{y'}(\beta)$$

значит

$$\hat{R}(\alpha,\beta,\gamma)=\hat{R}_{z'}(\gamma)\cdot\hat{R}_{y'}(\beta)\cdot\hat{R}_z(\alpha)=\hat{R}_{y'}(\beta)\cdot\hat{R}_z(\gamma)\cdot\hat{R}^{\dagger}_{y'}(\beta)\cdot\hat{R}_{y'}(\beta)\cdot\hat{R}_z(\alpha)$$

Унитарность оператора вращений дает

$$\hat{R}^{\dagger}_{y'}(\beta)\cdot\hat{R}_{y'}(\beta)=\mathbb{1}$$

так что

$$\hat{R}(\alpha,\beta,\gamma)=\hat{R}_{y'}(\beta)\cdot\hat{R}_z(\gamma)\cdot\hat{R}_z(\alpha)=\hat{R}_z(\alpha)\cdot\hat{R}_y(\beta)\cdot\hat{R}^{\dagger}_z(\alpha)\cdot\hat{R}_z(\gamma)\cdot\hat{R}_z(\alpha)$$

$$\hat{R}^{\dagger}_z(\alpha)\cdot\hat{R}_z(\gamma)\cdot\hat{R}_z(\alpha)=\hat{R}_z(\gamma)$$

так как вращение на угол α компенсируется обратным вращением.

Окончательно находим

$$\hat{R}(\alpha,\beta,\gamma)=\hat{R}_z(\alpha)\cdot\hat{R}_y(\beta)\cdot\hat{R}_z(\gamma)$$

Очевидно, что вывод этого выражения нигде не опирался на свойства операторов спина $\frac{1}{2}$ так что полученная формула справедлива для частиц произвольного спина.

В этом выражении все факторы строго определены.

Например, спинорный оператор конечных вращений получается последовательным перемножением матриц

$$\hat{R}_z(\alpha)=\cos\frac{\alpha}{2}+\mathrm{i}\boldsymbol{\sigma}_3\sin\frac{\alpha}{2}=\begin{pmatrix}\cos\frac{\alpha}{2}+\mathrm{i}\sin\frac{\alpha}{2} & 0\\ 0 & \cos\frac{\alpha}{2}-\mathrm{i}\sin\frac{\alpha}{2}\end{pmatrix}=\begin{pmatrix}e^{\mathrm{i}\alpha/2} & 0\\ 0 & e^{-\mathrm{i}\alpha/2}\end{pmatrix}$$

$$\hat{R}_y(\alpha)=\cos\frac{\beta}{2}+\mathrm{i}\boldsymbol{\sigma}_2\sin\frac{\beta}{2}=\begin{pmatrix}\cos\frac{\beta}{2} & \sin\frac{\beta}{2}\\ -\sin\frac{\beta}{2} & \cos\frac{\beta}{2}\end{pmatrix}$$

$$\hat{R}_z(\gamma)=\begin{pmatrix}e^{\mathrm{i}\gamma/2} & 0\\ 0 & e^{-\mathrm{i}\gamma/2}\end{pmatrix}$$

В явном виде умножение матриц дает

$$\hat{R}_S(\alpha,\beta,\gamma)=\begin{pmatrix}\cos\frac{\beta}{2}\cdot e^{\mathrm{i}(\gamma+\alpha)/2} & \sin\frac{\beta}{2}\cdot e^{\mathrm{i}(\alpha-\gamma)/2}\\ -\sin\frac{\beta}{2}\cdot e^{\mathrm{i}(\gamma-\alpha)/2} & \cos\frac{\beta}{2}\cdot e^{-\mathrm{i}(\gamma+\alpha)/2}\end{pmatrix}$$

Поэтому преобразование спинора запишется в виде

$$\psi_a^R(\boldsymbol{r}) = \left\{\hat{R}_S(\alpha,\beta,\gamma)\right\}_a^b \psi_b\left(\mathcal{R}^{\mathrm{T}}\boldsymbol{r}\right),$$

где мы записали спинорный оператор вращений в матричной форме и использовали латинские спинорные индексы, чтобы не возникло путаницы с греческими обозначениями углов Эйлера.

Здесь матрица вращений в координатном пространстве

$$\mathcal{R}^{\mathrm{T}} = \mathcal{R}^{\mathrm{T}}(\alpha,\beta,\gamma) = \mathcal{R}_z^{\mathrm{T}}(\alpha)\mathcal{R}_{y'}^{\mathrm{T}}(\beta)\mathcal{R}_{z'}^{\mathrm{T}}(\gamma)$$

определяется теми же углами Эйлера.

При этом пространственная часть оператора вращения дает

$$\hat{R}_r(\alpha,\beta,\gamma)\psi_b(\boldsymbol{r}) = \psi_b(\mathcal{R}\boldsymbol{r})$$

где

$$\hat{R}_r(\alpha,\beta,\gamma) = \hat{R}_z^r(\alpha)\cdot\hat{R}_y^r(\beta)\cdot\hat{R}_z^r(\gamma)$$

Определяются операторами орбитального момента.

В итоге, преобразование спинора предСтавляется в факторизованной форме как произведение зав исяших от углов Эйлера спинорного и орбитального операторов

$$\psi^R(\boldsymbol{r}) = \hat{R}_S\cdot\hat{R}^r\psi(\boldsymbol{r}), \quad \hat{R} = \hat{R}(\alpha,\beta,\gamma) = \hat{R}_S\cdot\hat{R}^r$$

Действ ие пространственных и спинорных операторов можно продемонстрировать слеДующим образом: рассм отрим оператор

$$\boldsymbol{\sigma}\cdot\boldsymbol{n}$$

где $\boldsymbol{\sigma}$ -матрицы Паули, а вектор $\boldsymbol{n}$ - единичный вектор вдоль радиус-вектора $\boldsymbol{r}$. Вектор определяющий ось z:

$$\boldsymbol{n} = \hat{R}^r\boldsymbol{e}_z\left(\hat{R}^r\right)^\dagger$$

где вращение производится, как мы видели, на углы Эйлера в обратном порядке: сначала вокруг оси z на угол γ, потом на угол β и затем лишь вокруг оси самого вектора $\boldsymbol{n}$ на угол α, так что координаты вектора $\boldsymbol{n}$ в исходной системе -

$$\boldsymbol{n} = \{\cos\gamma\cos\beta, \sin\gamma\cos\beta, \sin\beta\}$$

при этом, конечно, значение угла α никак ни сказывается на координатах вектора $\boldsymbol{n}$, так как он задает вращен ие вектора $\boldsymbol{n}$ вокруг его собственной оси.

Найдем собственные векторы

$$(\boldsymbol{\sigma}\cdot\boldsymbol{n})\chi_{(k)} = \lambda_k\chi_{(k)}$$

где нет суммирован ия по k, который задает номер собствен ного значения спинора χ^a с индексом $a = \{1,2\}$. Подействуем на предыдущее уравнен ие спинорным оператором вращений R_S и учтем его унитарность,

$$\hat{R}_S(\boldsymbol{\sigma}\cdot\boldsymbol{n})\hat{R}_S^\dagger\hat{R}_S\chi_{(k)} = \lambda_k\hat{R}_S\chi_{(k)}$$

$$\hat{R}_S(\boldsymbol{\sigma}\cdot\boldsymbol{n})\hat{R}_S^\dagger = \hat{R}_S\hat{R}^r\left(\boldsymbol{\sigma}\cdot\boldsymbol{e}_z\right)\hat{R}_S^\dagger\left(\hat{R}^r\right)^\dagger = \boldsymbol{\sigma}_{z'}\cdot\boldsymbol{e}_{z'}$$

$$\boldsymbol{\sigma}_{z'} \cdot \boldsymbol{e}_{z'} \psi_{(k)} = \lambda_k \psi_{(k)}$$

Значит, спиноры $\psi_{(k)} = \hat{R}_S \chi(k)$ удовлетворяют уравнению на собственные значения

$$\boldsymbol{\sigma}_{z'} \cdot \boldsymbol{e}_{z'} \psi_{(k)} = \lambda_k \psi_{(k)}$$

екции спина на заданную ось.

Поэтому в базисе собственных векторов

$$\boldsymbol{\sigma}_{z'} \cdot \boldsymbol{e}_{z'} = \boldsymbol{\sigma}_3$$

n

$$\boldsymbol{\sigma}_3 \psi_{1,2} = \pm \psi_{1,2}$$

'T.e.

$$\psi_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \psi_2 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

$$\chi_{1,2} = \hat{R}_S^\dagger \psi_{1,2}$$

Tak ч'TO

$$\chi_1 = \begin{pmatrix} \cos\frac{\beta}{2} \cdot e^{-\mathrm{i}(\alpha+\gamma)/2} \\ \sin\frac{\beta}{2} \cdot e^{-\mathrm{i}(\alpha-\gamma)/2} \end{pmatrix}, \quad \chi_2 = \begin{pmatrix} -\sin\frac{\beta}{2} \cdot e^{\mathrm{i}(\alpha-\gamma)/2} \\ \cos\frac{\beta}{2} \cdot e^{\mathrm{i}(\gamma+\alpha)/2} \end{pmatrix}$$

на угол α приводит к введен ию общей фазы у этих собственн ых векторов.

О вращениях по Вигнеру (???)

(там его Д-функция и все такое, никак не усвоил, но по идее сюда могу суть этого подхода записать. начну с другого раздела вдали.)

Квантование нерелятивистского спина в двух словах

(??? зачем мы делаем то, что ниже??? вроде тут крутая теория, ее только потренировать нужно, и можно будет пользоваться. хотя, перенесу только в следующую часть потом)

Пусть s - эрмитовы матрицы, которые удовлетворяют коммутационным соотношениям генераторов группы вращений:

$$[s_\alpha, s_\beta] = \mathrm{i}\epsilon_{\alpha\beta\gamma} s_\gamma$$

Поэтому в полный набор наблюдаемых можно включить лишь один из генераторов, например, s_z, ведь два других генератора не коммутируют с ним и не могут иметь совместного с ним базиса собственных векторов.

Нулевой коммутатор у генератора вращений может быть только с самим собой или со скалярной величиной, которая не преобразуется при вращениях, поскольку собственное значение скалярной величины до вращения и после вращения не изменяется.

Из генераторов группы вращений можно построить лишь один независимый скаляр s^2.

Вычислим коммутатор

$$\left[s^2, s_\alpha\right] = [s_\beta s_\beta, s_\alpha]$$

с помощью тождества $[AB, C] = A[B, C] + [A, C]B$ откуда

$$[s_\beta s_\beta, s_\alpha] = s_\beta \left[s_\beta, s_\alpha\right] + \left[s_\beta, s_\alpha\right] s_\beta = i\epsilon_{\beta\alpha\gamma} \left(s_\beta s_\gamma + s_\gamma s_\beta\right)$$

Здесь в круглых скобках - симметричный относительно перестановок индексов β и γ тензор второго ранга - сворачивается с тензором $\epsilon_{\beta\alpha\gamma}$, антисимметричным по перестановкам тех же индексов β и γ, поэтому

$$\left[s^2, s_\alpha\right] = 0$$

и полный набор наблюдаемых составляют $\{s^2, s_z\}$.

Базис тензорных полей удовлетворяет уравнениям на собственные значения полного набора наблюдаемых для группы вращений:

$$\begin{aligned} s^2 \left|\lambda_s, m_s\right\rangle =& \lambda_s \left|\lambda_s, m_s\right\rangle, \\ s_z \left|\lambda_s, m_s\right\rangle =& m_s \left|\lambda_s, m_s\right\rangle \end{aligned}$$

Будем считать этот базис ортонормированным.

В силу (??) повышающий и понижающий генераторы $s_\pm = s_x \pm \mathrm{i} s_y$ коммутируют с квадратом спина:

$$\left[s^2, s_\pm\right] = 0$$

и это означает, что значение λ_s не меняется при действии бесконечно малых преобразований с генераторами $s_{x,y}$, но при действии тех же преобразований меняется значение m_s, так как в противном случае, эти генераторы коммутировали бы с s_z, что неверно.

Такое положение указывает, что одному и тому же значению λ_s отвечают несколько значений m_s, т.е. имеет место вырождение спектра собственных значений λ_s по значениям m_s. Между прочим, мы установили общее условие вырожденности спектра эрмитовой матрицы A : если эрмитова матрица A коммутирует с эрмитовыми матрицами B и C, но сами матрицы B и C не коммутируют между собой, то спектр собственных значений матрицы A вырожден, например, по собственным значениям в совместном базисе с матрицей B

Найдем действие повышающего и понижающего генератора на совместный базис $\left|\lambda_s, m_s\right\rangle$. Для этого сначала вычислим коммутаторы

$$\left[s_\pm, s_z\right] = \left[s_x, s_z\right] \pm \mathrm{i}\left[s_y, s_z\right] = -\mathrm{i} s_y \pm \mathrm{i} i s_x = \mp s_\pm$$

Тогда

$$s_z s_\pm \left|\lambda_s, m_s\right\rangle = \left(s_\pm s_z \pm s_\pm\right) \left|\lambda_s, m_s\right\rangle = \left(m_s \pm 1\right) s_\pm \left|\lambda_s, m_s\right\rangle$$

Значит, вектор $s_\pm \left|\lambda_s, m_s\right\rangle$ имеет собственные значения s_z, равные $m_s \pm 1$:

$$s_\pm \left|\lambda_s, m_s\right\rangle = N_\pm\left(\lambda_s, m_s\right) \left|\lambda_s, m_s \pm 1\right\rangle \quad \rightarrow \quad \left(s_\pm \left|\lambda_s, m_s\right\rangle\right)^\dagger = \left\langle\lambda_s, m_s\right| s_\mp = N_\pm\left(\lambda_s, m_s\right) \left\langle\lambda_s, m_s\right|$$

где мы задали комплексную фазу собственного вектора $\left|\lambda_s, m_s\right\rangle$ так, чтобы нормировочный коэффициент был бы вещественным.

Найдем нормировочный коэффициент $N_\pm\left(\lambda_s, m_s\right)$. Для этого заметим, что

$$s^2 = s_x^2 + s_y^2 + s_z^2 = s_+ s_- + \mathrm{i}\left[s_x, s_y\right] + s_z^2 = s_+ s_- - s_z + s_z^2$$

и аналогично

$$s^2 = s_x^2 + s_y^2 + s_z^2 = s_- s_+ - \mathrm{i}\left[s_x, s_y\right] + s_z^2 = s_- s_+ + s_z + s_z^2$$

Тогда

$$\left\langle\lambda_s, m_s\right| s_\mp s_\pm \left|\lambda_s, m_s\right\rangle = \left(s_\pm \left|\lambda_s, m_s\right\rangle\right)^\dagger s_\pm \left|\lambda_s, m_s\right\rangle = N_\pm^2\left(\lambda_s, m_s\right)$$

Т.е.

$$N_\pm^2\left(\lambda_s, m_s\right) = \left\langle\lambda_s, m_s\right| s_\mp s_\pm \left|\lambda_s, m_s\right\rangle = \left\langle\lambda_s, m_s\right| \left(s^2 - s_z^2 \mp s_z\right) \left|\lambda_s, m_s\right\rangle = \lambda_s - m_s\left(m_s \pm 1\right)$$

Поскольку нормировка вектора не может быть отрицательной, $N_{\pm}^{2}\left(\lambda_{s}, m_{s}\right) \geqslant 0$. Это условие может быть выполнено, только если в цепочках многократного действия повышающего и понижающего операторов, во-первых, значения m_s не произвольны, а принимают такие значения, чтобы

$$m_{s}\left(m_{s} \pm 1\right) \leqslant \lambda_{s}$$

и во-вторых, должны существовать максимальное $m_{s}^{\max}$ и минимальное $m_{s}^{\min}$ значения, которые дают в точности нулевые Значения нормы вектора после повышения и понижения, соответственно, так как в противном случае повышение и понижение приводило бы к возникновению векторов с отрицательной нормой, что недопустимо, т.е.

$$m_{s}^{\max}\left(m_{s}^{\max}+1\right)=\lambda_{s}, \quad m_{s}^{\min}\left(m_{s}^{\min}-1\right)=\lambda_{s}$$

Вместе с тем, действуя многократно на вектор $\left|\lambda_{s}, m_{s}^{\max}\right\rangle$ понижаюпим оператором n раз, мы получим $m_{s}=m_{s}^{\max}-n$ и в конце концов вектор, в Точности равный $\left|\lambda_{s}, m_{s}^{\min}\right\rangle$, в силу существования минимально допустимого значения m_s, т.е. для некоторого неотрицательного целого значения n верно $m_{s}^{\min}=m_{s}^{\max}-n$. Тогда связь минимального и максимального значений проекции спина на ось zс собственным значением квадрата спина λ_s приводит к единственному решению в виде

$$\begin{gathered}
m_{s}^{\max}\left(m_{s}^{\max}+1\right)-m_{s}^{\min}\left(m_{s}^{\min}-1\right)=0, \\
m_{s}^{\max}\left(m_{s}^{\max}+1\right)-\left(m_{s}^{\max}-n\right)\left(m_{s}^{\max}-n-1\right)=0, \\
m_{s}^{\max}=\tfrac{n}{2}, \quad m_{s}^{\min}=-\tfrac{n}{2}
\end{gathered}$$

Максимальное значение проекции спина на ось z обозначают символом s, так что

$$s=\frac{n}{2}$$

т.е. допустимые значения проекции спина - это положительные полуцелые и целые значения.

Целые значения отвечают полям, которые называют тензорными, а полуцелые - спинорным полям.

Базис полей, таким образом, образуют совместные собственные векторы квадрата спина и его проекции на выбранную ось, так что изменяя обозначения путем подстановки $\lambda_{s}=s(s+1) \mapsto s$ запишем его в виде

$$\left|s, m_{s}\right\rangle, \quad m_{s} \in\{-s,-s+1, ..., s-1, s\}$$

Действие повышающей и понижающей матрицы спина на базисные вектора строго определено,

$$s_{\pm}\left|s, m_{s}\right\rangle=\sqrt{s(s+1)-m_{s}\left(m_{s} \pm 1\right)}\left|s, m_{s} \pm 1\right\rangle$$

В частном случае $s = 1$, Мы убедились, что соотношения (3.36) являются тождествами согласно проведенной нами процедуре прямого построения матриц спина и собственных векторов для матрицы s_z. Размерность пространства собственных векторов квадрата спина и его проекции на выбранную ось равна один старший вектор с максимальным значением проекции и n шагов от старшего вектора до младшего, т.е. вектора с минимальным значением проекции, а значит,

$$k=1+n=1+2 s$$

Это число компонент называют мультиплетностью неприводимого представления группы вращений для поля.

Неприводимым это представление называют потому, что при вращениях, а значит, при многократном действии генераторов спина, век'тор с заданной проекцией спина на ось z перемешивается со всеми другими векторами базиса с тем же значением квадрата спина, т.е. пространство собственных векторов с заданным квадратом спина не содержит в себе подпространств, вектора которых не смешивались бы друг с другом при действии группы вращений.

Для скаляра $s = 0$, и поле имеет одну единственную компоненту, поэтому скаляр называют синглетом и обозначают символом 1.

У вектора $s = 1$, и поле имеет три компоненты, это - триплет 3, у спинора $s = \frac{1}{2}$, и поле имеет две компоненты, это -дублет 2

Напомним, что построенный нами базис называют стандартным, он решает задачу классификации полей по базису собственных векторов генераторов спина.

О связи спина со статистикой (????)

(?? тут Киселев о чем угодно рассуждает, нужно переписать нормально. да и вообще, переставить в следующую часть, а суть выписать в новый параграф)

Рассмотрим два тождественных фермиона.

Их волновая функция -

$$\left\langle \boldsymbol{r}_1, \theta^{\alpha}_{(1)}, n_1; \boldsymbol{r}_2, \theta^{\beta}_{(2)}, n_2 | \Psi \right\rangle = \psi^{(n_1,n_2)}_{\alpha\beta} \left(\boldsymbol{r}_1, \boldsymbol{r}_2 \right)$$

где мы указали возможные многомерные квантовые числа (n_1, n_2), не связанные со спинорными характеристиками.

После поворота на угол 2π координаты первой частицы r_1 и ее

$$\psi^{(n_1,n_2)}_{\alpha\beta} \left(\boldsymbol{r}_1, \boldsymbol{r}_2 \right) \overset{\mathcal{R}_1(2\pi)}{\longrightarrow} \psi^{\mathcal{R}_1(n_1,n_2)}_{\alpha\beta} \left(\boldsymbol{r}_1, \boldsymbol{r}_2 \right) = -\psi_{\alpha\beta} \left(\boldsymbol{r}_1, \boldsymbol{r}_2 \right)$$

Подобное отличие в фазе волновой функции фермионов после вращения на угол 2π моделируют ситуацию, когда квантовые числа двух ферм ионов тождествен но совпадают:

$$\boldsymbol{r}_1 = \boldsymbol{r}_2 = \boldsymbol{r}, \quad \theta^{\alpha}_{(1)} = \theta^{\beta}_{(2)} = \theta^1, \quad n_1 = n_2 = n$$

т.е., другим и словами, поместим тождественные частицы с одним и тем же набором значений наблюдаемых величин в одну точку пространства.

В полной аналогии с выводом допустимых значений квантованного орбитального момента потребуем выполнение следующего принци па: если состояния каждой из двух тождественных частиц не отличи мы, то вращение одной из них на угол 2π не наблюдаемо, т.е. должно приводить к тождественному преобразованию состояния.

По сути, речь идет о вращении одной частицы относительно одной точке, то такое вращение не имеет физического смысла, т.е. не наблюдаемо.

Следовательно, исходная волновая функция

$$\psi^{(n,n)}_{11}(\boldsymbol{r}, \boldsymbol{r})$$

должна тождественно совпадать с волновой функцией после вращения координат одной из частиц на угол 2π :

$$\psi^{(n,n)}_{11} \left(\mathbf{r}, \mathbf{r}' \right) = -\psi^{(n,n)}_{11}(\mathbf{r}, \boldsymbol{r}) \equiv 0$$

что достигается только в случае равенства нулю волновой функции тождественных фер-

.

(??)

Этот принцип автоматически удовлетворяется, если волновую функцию тождественных

(????)

$$\psi_{\alpha\beta}^{A(n_1,n_2)}(\boldsymbol{r}_1,\boldsymbol{r}_2)=\frac{1}{\sqrt{2}}\left\{\psi_{\alpha\beta}^{(n_1,n_2)}(\boldsymbol{r}_1,\boldsymbol{r}_2)-\psi_{\beta\alpha}^{(n_2,n_1)}(\boldsymbol{r}_2,\boldsymbol{r}_1)\right\}$$

так как она обращается в нуль, если квантовые состояния фермионов тождественны

А атисимметризованная волновая функция двух фермионов являет собой пример общего принципа, возникающего в Квантовой механике с тождествен ными частицами.

В самом деле, физическая система из тождествен ных частиц не изменится, если поменять местами пару этих частиц.

В квантовой механике это утвержден ие означает, что состояние системы

$$|\Psi:\{Q_1,Q_2,...\}\rangle=\lambda\,|\Psi:\{Q_2,Q_1,...\}\rangle\,,\quad |\lambda|=1$$

где $\{Q_1,Q_2,...\}$ -полный набор наблюдаемых для частиц $\{1,2,...\}$.В этом уравнении мы требуем, чтобы при перестановке квантовых чисел первой и второй частиц вектор состояния остался прежним с точностью до фазового множителя (нормировка остается без изменения).

Если ввести оператор перестановок

$$\hat{\delta}_{1\leftrightarrow 2}\,|\Psi:\{Q_1,Q_2,...\}\rangle=|\Psi:\{Q_2,Q_1,...\}\rangle$$

то (9.28) есть ни что и ное, как уравнение на собствен ные значения для.

Двукратное применение перестановки возвращает систему к исходному состоянию:

$$\hat{\mathcal{S}}\hat{\mathcal{S}}=1$$

откуда немедлен но следует, что спектр собственных значений оператора перестановок тождественных частиц

$$\lambda^2=1\leftrightarrow\quad \lambda=\pm 1$$

Поскольку перестановки не изменяют никаких наблюдаемых характеристик системы тождественных частиц, оператор перестановок коммутирует со всеми наблюдаемыми

$$[\hat{\mathrm{S}},\hat{H}]=[\hat{\mathrm{S}},\hat{\boldsymbol{p}}]=[\hat{\mathrm{s}},\hat{\boldsymbol{j}}]=...=0$$

Числа двух тождественных частиц совпадают.

Как мы видели, это имеет место Для фермионов - частиц с полуцелым сп ином.

В этом случае

$$\lambda=e^{2\pi\mathrm{i}s},$$

где s -значение сп ина каждой из тождественных частиц.

Эта формула, полученная для полуцелых значений спина частиц, остается справедлива и для целых значений спина, Т.е. для бозонов, которые, таким образом, имеют симметризованные по перестановкам волновые функции.

Именно, в природе не наблюдаются псевдо-бозоны целого спина с антисимметричным и по перестановкам волновыми функциями.

Тем не менее, поля так их частиц используются Для вспомогательных целей в квантовой теории поля для наиболее наглядной форм ули ровк и некоторых прин ципов сим метрии.

Поля псевдо-бозонов называют "гостам и" (от ан глийского ghost, Что значит "дух") или просто "духами".

При этом, ОДн ако, полагаЮт, что число духов в начальном и конечном состоянии равно нулю, т.е.

В полный набор наблюдаемых включают число ДУхов, тождественно равн ое нулю.

Подчеркнем, что рассмотренная связь спина со стати стикой возникла благодаря пространственной вращательной симметрии для спиноров, т.е.

благодаря группе $SU(2)$. ОДнако это не знач ит, что присутствие какой-либо Другой си мметри и со спинорами в группе $SU(2)$ так же неми нуемо при ведет к антисимметризации волновых функций.

Например, в стандартную модель взаимодействий элементарн ых части ц включено скалярное, а следовательно, бозонное, поле со спином 0, которое является спинором по калибровочной группе $SU(2)$. Как мы показали, нали чие калибровочной группы симметрии отвечает сохранению заряда, который в данном случае - заряд частицы в слабом взаимодействии.

Эта калибровочная группа никак не связана с пространственными вращениям и, и поэтом у она не означает введения каких-либо дополнительных ограни чений на волновую функцию, связанных с сим метрией по перестановкам.

Такие группы, не связанные с вращениям и пространства, называются группами внутрен ней симметрии.

Генераторы таких групп, следовательно, Коммутируют с генераторами вращений и трансляций

Квантование релятивистского спина в двух словах

О спине 1/2

Обсудим самое основное о спине $1/2$.

(?? не в теории поля ли это??)

Типичный вывод матриц Паули

(?? а какой еще мог бы быть вывод??)

(?? этот раздел точно тут должен быть?)

Рассмотрим поле с полуцелым спином, $s = \frac{1}{2}$. В этом случае соответствующая спиновая матрица представляется в виде

$$s = \frac{1}{2}\sigma$$

где σ - матрицы Паули.

Найдем явный вид матриц Паули, используя общие выражения для действия матриц спина на базисные поля.

Базис спиновых состояний для краткости обозначений записывают как

$$\left|\frac{1}{2}, +\frac{1}{2}\right\rangle = |+\rangle, \quad \left|\frac{1}{2}, -\frac{1}{2}\right\rangle = |-\rangle$$

причем это - собственные векторы проекции спина

$$s_z|+\rangle = \frac{1}{2}|+\rangle, \quad s_z|-\rangle = -\frac{1}{2}|-\rangle$$

Следовательно, эта матрица в рассматриваемом базисе имеет диагональный вид

$$s_z = \frac{1}{2}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

Согласно (3.36) ненулевые матричные элементы повышающего и понижающего операторов

$$\langle + |s_+| - \rangle = \sqrt{\frac{1}{2}\left(\frac{1}{2}+1\right) - (-1)\frac{1}{2}\left(-\frac{1}{2}+1\right)} = 1$$
$$\langle - |s_-| + \rangle = (\langle + |s_+| - \rangle)^\dagger = 1$$

откуда

$$s_+ = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad s_- = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$$

Тогда обратное преобразование $s_\pm \leftrightarrow s_{x,y}$ дает

$$s_x = \frac{1}{2}(s_+ + s_-) = \frac{1}{2}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$
$$s_y = \frac{1}{2\mathrm{i}}(s_+ - s_-) = \frac{1}{2}\begin{pmatrix} 0 & -\mathrm{i} \\ \mathrm{i} & 0 \end{pmatrix}$$

Поэтому сигма-матрицы Паули - это

$$\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_y = \begin{pmatrix} 0 & -\mathrm{i} \\ \mathrm{i} & 0 \end{pmatrix}, \quad \sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

О спинах

О популярных аналогиях спина

(тут примеры, как про него думать можно и насколько корректно это? пока такое не готовил. например, там если я повращаюсь и изменю внутреннюю стрелку на противоположную. насколько так можно думать?)

Примеры спинов и спиноров

(самые частые тут укажу, чтобы конкретику тоже иметь)

О моделях из спинов

(их полным полно, укажу лишь самые типичные)

О том, как взаимодействуют разные спины, если они разные предствления (??)

(такой вопрос все еще есть, разве что мб это больше в теорию поля. пока связь ее с квантмехом не отработана.)

24.2.2 Wigner D-Function

Wigner D-Function

основные свойства D-функций Вигнера

1.

Унитарность $\overline{D}$ - комплексно-сопряжённая функция

$$\sum_{m=-j}^{j} \overline{\mathcal{D}}^{j}_{m,n}(\alpha,\beta,\gamma)\mathcal{D}^{j}_{m,n'}(\alpha,\beta,\gamma) = \delta\left(n'-n\right)$$

2.

Ортогональность

$$\int_0^{2\pi}\int_0^{2\pi}\int_0^{\pi} \overline{\mathcal{D}}^{j}_{m,n}(\alpha,\beta,\gamma)\mathcal{D}^{j'}_{m',n'}(\alpha,\beta,\gamma)\sin\beta d\beta d\gamma d\alpha = \\ = \frac{8\pi^2}{2j+1}\delta\left(j'-j\right)\delta\left(m'-m\right)\delta\left(n'-n\right)$$

Свойства $\mathcal{D}$ -функций

1.

Унитарность ($\overline{D--}\mathcal{D}$ -функция)

$$\sum_{m=-j}^{j} \overline{\mathcal{D}}^{j}_{m,n}(\alpha,\beta,\gamma)\mathcal{D}^{j}_{m,n'}(\alpha,\beta,\gamma) = \delta\left(n'-n\right)$$

2.

Ортогональность

$$\int_0^{2\pi}\int_0^{2\pi}\int_0^{\pi} \overline{\mathcal{D}}^{j}_{m,n}(\alpha,\beta,\gamma)\mathcal{D}^{j'}_{m',n'}(\alpha,\beta,\gamma)\sin\beta d\beta d\gamma d\alpha = \\ = \frac{8\pi^2}{2j+1}\delta\left(j'-j\right)\delta\left(m'-m\right)\delta\left(n'-n\right)$$

3.

Произведение двух D-функций одинаковых аргументов (см. домашнее задание лекции 5, слайд 5).

4.

Используя пункты 1 и 3, вычислите

$$\iiint \overline{\mathcal{D}}^{j}_{m,n}(\alpha,\beta,\gamma)\mathcal{D}^{j_1}_{m_1,n_1}(\alpha,\beta,\gamma)\mathcal{D}^{j_2}_{m_2,n_2}(\alpha,\beta,\gamma)\sin\beta d\beta d\gamma d\alpha$$

вычисление $D-$функции Вигнера

Вариант 1:

$$\mathcal{D}^{J}_{M'M}(\omega) = (\psi_{LM'}, R(\omega)\psi_{LM})$$

Вариант 2:

$$\mathcal{D}^{J}_{M'M}(\omega) = \sum_{m_1,m_2}\sum_{n_1,n_2}\langle j_1 m_1 j_2 m_2|JM\rangle\langle j_1 n_1 j_2 n_2|JM'\rangle\,\mathcal{D}^{j_1}_{n_1 m_1}(\omega)\mathcal{D}^{j_2}_{n_2 m_2}(\omega)$$

Вариант 3: Унитарное преобразование двух комплексных переменных z_1, z_2

$$z_1' = a_{11}z_1 + a_{12}z_2$$
$$z_2' = a_{11}z_1 + a_{12}z_2$$
$$\sum_k a_{ik}a^*_{jk} = \sum_k a_{ki}a^*_{kj} = \delta(j-i)$$

матрицы и векторы

$$Z=\begin{pmatrix} z_1 \\ z_2 \end{pmatrix}, Z'=WZ, W=\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}, W^{\dagger}=\begin{pmatrix} a_{11}^{*} & a_{21}^{*} \\ a_{12}^{*} & a_{22}^{*} \end{pmatrix}$$

8 вещественных чисел.

Условие

$$W^{\dagger}W=\begin{pmatrix} a_{11}^{*}a_{11}+a_{21}^{*}a_{21} & a_{11}^{*}a_{12}+a_{21}^{*}a_{22} \\ a_{12}^{*}a_{11}+a_{22}^{*}a_{21} & a_{12}^{*}a_{12}+a_{22}^{*}a_{22} \end{pmatrix}=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}=I; \quad \text{4 уравнения}$$

Потребуем $\det W=1$. Унитарность даёт, $|\det W|=1$. 3 независимых вещественных параметра

$$W=\begin{pmatrix} a & b \\ -b^{*} & a^{*} \end{pmatrix}, \det W=|a|^2+|b|^2; \begin{array}{l} a=\exp(i\xi)\cos\omega \\ b=\exp(i\eta)\sin\omega \end{array}$$

Рассмотрим радиус-вектор с координатами (x,y,z) и построим эрмитову матрицу

$$\alpha=\begin{pmatrix} \alpha_{11} & \alpha_{12} \\ \alpha_{21} & \alpha_{22} \end{pmatrix}=\gamma I+x\sigma_x+y\sigma_y+z\sigma_z=\begin{pmatrix} \gamma+z & x-iy \\ x+iy & \gamma-z \end{pmatrix}$$

Матрица α эрмитова: $\alpha_{11}^{*}=\alpha_{11}, \alpha_{22}^{*}=\alpha_{22}, \alpha_{12}^{*}=\alpha_{21}, \alpha_{21}^{*}=\alpha_{12}$.

$$\gamma=\frac{1}{2}\left(\alpha_{11}+\alpha_{22}\right), x=\frac{1}{2}\left(\alpha_{12}+\alpha_{21}\right), y=\frac{1}{2i}\left(\alpha_{21}-\alpha_{12}\right), z=\frac{1}{2}\left(\alpha_{11}-\alpha_{21}\right)$$

преобразование матрицы α

$$\begin{gathered} \alpha\to\alpha'=W\alpha W^{\dagger}=\gamma' I+x'\sigma_x+y'\sigma_y+z'\sigma_z \\ \operatorname{Sp}(\alpha')=\operatorname{Sp}\left(W\alpha W^{\dagger}\right)=\operatorname{Sp}\left(W^{\dagger}W\alpha\right)=\operatorname{Sp}(\alpha)\to\gamma'=\gamma \\ \det\alpha'=\det\left(W\alpha W^{\dagger}\right)=\det\alpha\to\gamma'^2-\left(x'^2+y'^2+z'^2\right)=\gamma^2-\left(x^2+y^2+z^2\right) \\ x'^2+y'^2+z'^2=x^2+y^2+z^2 \end{gathered}$$

Если взять $W: W^{\dagger}W\neq I, \det W=1$, и $\gamma=ct$

$$\begin{gathered} (ct')^2-\left(x'^2+y'^2+z'^2\right)=(ct)^2-\left(x^2+y^2+z^2\right) \\ \alpha'=\begin{pmatrix} \gamma+\left(a^{*}b+ab^{*}\right)x+i\left(a^{*}b-ab^{*}\right)y+\left(|a|^2-|b|^2\right)z \\ \left(a^{*2}-b^{*2}\right)x+i\left(a^{*2}+b^{*2}\right)y-2a^{*}b^{*}z \\ \left(a^2-b^2\right)x-i\left(a^2+b^2\right)y-2abz \\ \gamma-\left(a^{*}b+ab^{*}\right)x-i\left(a^{*}b-ab^{*}\right)y-\left(|a|^2-|b|^2\right)z \end{pmatrix} \end{gathered}$$

Преобразование радиус-вектора

$$\begin{pmatrix} x' \\ y' \\ z' \end{pmatrix}=\begin{pmatrix} \frac{1}{2}\left(a^2+a^{*2}-b^2-b^{*2}\right) & \frac{i}{2}\left(a^{*2}-a^2+b^{*2}-b^2\right) & -ab-a^{*}b^{*} \\ \frac{i}{2}\left(a^{*2}-a^2+b^{*2}-b^2\right) & \frac{1}{2}\left(a^2+a^{*2}+b^2+b^{*2}\right) & i\left(a^{*}b^{*}-ab\right) \\ \left(a^{*}b+ab^{*}\right) & i\left(a^{*}b-ab^{*}\right) & \left(|a|^2-|b|^2\right) \end{pmatrix}\begin{pmatrix} x \\ y \\ z \end{pmatrix}$$

Проверьте и подставьте выражения a и b через ξ,η и ω.

Выразите переменные ξ,η и ω через углы Эйлера.

$$\begin{gathered} \vec{x}'=M\vec{x}, \quad x'^2+y'^2+z'^2=x^2+y^2+z^2 \\ \gamma I+x'\sigma_x+y'\sigma_y+z'\sigma_z=\gamma I+W\left(x\sigma_x+y\sigma_y+z\sigma_z\right)W^{\dagger} \end{gathered}$$

Умножим обе части равенства слева на σ_l и возьмём шпур

$$x'_l = \frac{1}{2}\,\mathrm{Sp}\left(\sigma_l W\left(x\sigma_x + y\sigma_y + z\sigma_z\right)W^\dagger\right)$$

$$M_{lk} = \frac{1}{2}\,\mathrm{Sp}\left(\sigma_l W \sigma_k W^\dagger\right)$$

наблюдения от Кузьмина

(пока что я хз, к чему он вообще это дал)
Наблюдения
1.
Каждой унитарной матрице W соответствует ортогональная матрица M, причём единичной W соответствует единичная M.
2.
Пусть $W_1 \to M_1$ и $W_2 \to M_2$.

$$\alpha = \gamma I + \vec{x}\cdot\vec{\sigma};\quad \alpha \to \alpha' = W_1\alpha W_1^\dagger = \gamma I + \vec{x}_1\cdot\vec{\sigma};\quad \vec{x}_1 = M_1\vec{x}$$
$$\alpha' \to \alpha'' = W_2\alpha' W_2^\dagger = W_2W_1\alpha W_1^\dagger W_2^\dagger = (W_2W_1)\,\alpha\,(W_2W_1)^\dagger$$
$$\alpha'' = W_2\left(\gamma I + \vec{x}_1\cdot\vec{\sigma}\right)W_2^\dagger = \gamma I + \vec{x}_2\cdot\vec{\sigma},\quad \vec{x}_2 = M_2\vec{x}_1 = (M_2M_1)\,\vec{x}$$

Произведению матриц W_2W_1 соответствует произведение M_2M_1. 3.
При одновременной смене знаков у матричных элементов a и b матрица $W \to -W$, но $M \to M$. В частности, $W = \pm I$ отвечает единичная матрица $M = I$.

вкратце итог

Основная задача

$$R(\alpha,\beta,\gamma) = \exp\left(-i\alpha J_Z\right)\exp\left(-i\beta J_Y\right)\exp\left(-i\gamma J_Z\right)$$
$$R(\alpha,\beta,\gamma)\psi_{jm} = \sum_{n=-j}^{j}\psi_{jn}\left(\psi_{jn}, R_Z(\alpha)R_Y(\beta)R_Z(\gamma)\psi_{jm}\right) = \sum_{n=-j}^{j}\mathcal{D}^j_{n,m}(\alpha,\beta,\gamma)\psi_{jn}$$

Вспомогательная задача

$$\vec{x} = (x_1,x_2,x_3) \longleftrightarrow \alpha = \gamma I + \vec{x}\cdot\vec{\sigma},\quad \alpha^\dagger = \alpha;$$

$$W^\dagger = W, \det W = 1,\quad W = \begin{pmatrix} \exp(i\xi)\cos\omega & \exp(i\eta)\sin\omega \\ -\exp(-i\eta)\sin\omega & \exp(-i\xi)\cos\omega \end{pmatrix}$$
$$\alpha \to \alpha' = W\alpha W^\dagger \to \vec{x}'$$
$$x_1'^2 + x_2'^2 + x_3'^2 = x_1^2 + x_2^2 + x_3^2, x'_k = M_{kl}x_l,\quad M_{kl} = \mathrm{Sp}\left(\sigma_k W \sigma_l W^\dagger\right)$$
$$\text{Если } W_1 \to M_1, W_2 \to M_2, \text{ то } W_2W_1 \to M_2M_1$$
$$\text{Если } W \to M, \text{ то } (-W) \to M$$
$$\text{Если } W = \pm I, \text{ то } M[W] = I$$

Из домашнего задания

$$W(\omega = 0) \to M = \begin{pmatrix} \cos 2\xi & \sin 2\xi & 0 \\ -\sin 2\xi & \cos 2\xi & 0 \\ 0 & 0 & 1 \end{pmatrix}$$
$$W(\xi = \eta = 0) \to M = \begin{pmatrix} \cos 2\omega & 0 & -\sin 2\omega \\ 0 & 1 & 0 \\ \sin 2\omega & 0 & \cos 2\omega \end{pmatrix}$$

Идея: найти совокупность из $2j+1(j=0,1/2,1,...)$ линейно-независимых функций $B_{jm}(z_1,z_2),(m=-j,-j+1,...,j-1,j)$, таких, что

$$B_{jm}(z_1',z_2')=\sum_{m'=-j}^{j}A^j_{m',m}B_{jm'}(z_1,z_2),\text{ если }\begin{pmatrix}z_1'\\z_2'\end{pmatrix}=W\begin{pmatrix}z_1\\z_2\end{pmatrix}$$
$$A^j=A^j(W),\text{ и }A^{j\dagger}A^j=I$$
$$\text{Для } j=0, A^0=I, B_{00}=\text{const}$$
$$\text{для } j=1/2, A^{1/2}=W, B_{1/2,-1/2}=z_2, B_{1/2,1/2}=z_1$$

конечные вращения 2

внутренние квантовые числа

“Внутренние" квантовые числа

$$W=\begin{pmatrix}1+i\xi_3 & i\xi_1+\xi_2\\ i\xi_1-\xi_2 & 1-i\xi_3\end{pmatrix}=I+\delta W$$
$$\delta W=i\left[\begin{pmatrix}0&1\\1&0\end{pmatrix}\xi_1+\begin{pmatrix}0&-i\\i&0\end{pmatrix}\xi_2+\begin{pmatrix}1&0\\0&-1\end{pmatrix}\xi_3\right]=i\sum_{k=1}^{3}\tau_k\xi_k$$
$$t_k\equiv\tfrac{1}{2}\tau_k:[t_1,t_2]_-=it_3;\quad t_1^2+t_2^2+t_3^2=\tfrac{3}{4}=t(t+1)\to t=\tfrac{1}{2}$$

Пусть имеется s нуклонов.

Состояние будет задано числами $A_1,A_2,...A_s,A_j=1,2$ Временно забудем про статистику Ферми-Дирака, $\psi=\psi(A_1)\psi(A_2)...\psi(A_s)$.

$$\psi\to\phi=(W)_1(W)_2...(W)_s\psi_{A_1,A_2,...,A_s}$$

Для бесконечно-малых преобразований

$$\delta\psi=\sum_{j=1}^{s}(\delta W)_j\psi=\sum_{j=1}^{s}i\sum_{k=1}^{3}(\tau_k)_j\xi_k\psi=i\sum_{k=1}^{3}\xi_k\left[\sum_{j=1}^{s}(\tau_k)_j\right]\psi=i2\sum_{k=1}^{3}\xi_k\left[\sum_{j=1}^{s}(t_k)_j\right]\psi$$
$$T_k\equiv\sum_{j=1}^{s}(t_k)_j,[T_1,T_2]_-=iT_3;\quad\delta\psi=2i\sum_{k=1}^{3}\xi_kT_k\psi$$

Неприводимое представление для группы $SU(2)$: базис

$$B_{jm}=N_{jm}z_1^{j+m}z_2^{j-m},m=-j,-j+1,...,j-1,j$$
$$B'_{jm}=N_{jm}z_1'^{j+m}z_2'^{j-m}=N_{jm}(az_1+bz_2)^{j+m}(-b^*z_1+a^*z_2)^{j-m}$$

Преобразование будет унитарным, если $\sum_{n=-j}^{j}\left|B'_{jn}\right|^2=\sum_{m=-j}^{j}|B_{jm}|^2$. Инвариант преобразования $Z'=WZ:\quad|z_1'|^2+|z_2'|^2=|z_1|^2+|z_2|^2$.

$$\sum_{m=-j}^{j}|B_{jm}|^2=\sum_{m=-j}^{j}N_{jm}^2(z_1^*z_1)^{j+m}(z_2^*z_2)^{j-m}\sim\left(|z_1|^2+|z_2|^2\right)^{2j}$$
$$(a+b)^n=\sum_{k=0}^{n}C_k^na^kb^{n-k}=\sum_{k=0}^{n}\tfrac{n!}{k!(n-k)!}a^kb^{n-k}$$
$$n=2j,k=j+m,n-k=j-m;k=0\to m=-j,k=2j\to m=j$$
$$(a+b)^{2j}=\sum_{m=-j}^{2j}C_{j+m}^{2j}a^{j+m}b^{j-m}=\sum_{m=-j}^{2j}\tfrac{2j!}{(j+m)!(j-m)!}a^{j+m}b^{j-m}.$$

Неприводимое представление для группы $SU(2)$: матрица

$$N_{jm}=\frac{1}{\sqrt{(j+m)!(j-m)!}},B_{jm}=\frac{1}{\sqrt{(j+m)!(j-m)!}}z_1^{j+m}z_2^{j-m}$$

$$\sum_{n=-j}^{j}\left|B'_{jn}\right|^2=\frac{1}{2j!}\left|z'_1\right|^2+\left|z'_2\right|^2=\frac{1}{2j!}\left|z_1\right|^2+\left|z_2\right|^2=\sum_{m=-j}^{j}\left|B_{jm}\right|^2$$

$$B'_{jm}=\sum_n A^j_{nm}B_{jn}=\frac{1}{\sqrt{(j+m)!(j-m)!}}\left(az_1+bz_2\right)^{j+m}\left(-\bar{b}z_1+\bar{a}z_2\right)^{j-m}=$$

$$=\frac{1}{\sqrt{(j+m)!(j-m)!}}\sum_{s_1,s_2}\frac{(j+m)!}{s_1!(j+m-s_1)!}\left(az_1\right)^{j+m-s_1}\left(bz_2\right)^{s_1}\times$$

$$\times\frac{(j-m)!}{s_2!(j-m-s_2)!}\left(-\bar{b}z_1\right)^{j-m-s_2}\left(\bar{a}z_2\right)^{s_2}=$$

$$=\sum_{s_1,s_2}\frac{\sqrt{(j+m)!(j-m)!}(-)^{j-m-s_2}}{s_1!s_2!\left(j+m-s_1\right)!\left(j-m-s_2\right)!}a^{j+m-s_1}\bar{a}^{s_2}b^{s_1}\bar{b}^{j-m-s_2}z_1^{j+m-s_1+j-m-s_2}z_2^{s_1+s_2}$$

$$=\sum_{s_1,s_2}\frac{\sqrt{(j+m)!(j-m)!}(-)^{j-m-s_2}}{s_1!s_2!\left(j+m-s_1\right)!\left(j-m-s_2\right)!}a^{j+m-s_1}\bar{a}^{s_2}b^{s_1}\bar{b}^{j-m-s_2}z_1^{2j-s_1-s_2}z_2^{s_1+s_2}$$

Обозначим $n\equiv j-s_1-s_2;s_1+s_2=j-n,s_2=j-n-s_1,j-m-s_2=n-m+s_1$

$$B'_{jm}=\sum_n\sum_s\frac{\sqrt{(j+m)!(j-m)!}(-)^{n-m+s}}{s!(j+m-s)!(j-n-s)!(n-m+s)!}a^{j+m-s}\bar{a}^{j-n-s}b^s\bar{b}^{n-m+s}z_1^{j+n}z_2^{j-n}$$

$$=\sum_n\sum_s\frac{\sqrt{(j+m)!(j-m)!(j+n)!(j-n)!}}{s!(j+m-s)!(j-n-s)!(n-m+s)!}(-)^{n-m+s}a^{j+m-s}\bar{a}^{j-n-s}b^s\bar{b}^{n-m+s}B_{jn}$$

Покажите, что n меняется от $-j$ до j.

$$A^j_{n,m}=(-)^{n-m}\sum_s(-)^s\frac{\sqrt{(j+m)!(j-m)!(j+n)!(j-n)!}}{s!(j+m-s)!(j-n-s)!(n-m+s)!}\times$$

$$\times a^{j+m-s}\bar{a}^{j-n-s}b^s\bar{b}^{n-m+s}$$

1.
$W=I:a=1,b=0$. Чтобы ушли степени $b:s=0,n=m$, и $A^j_{nm}=\delta(n-m)$.
2.
Каждому W -своя матрица A^j. Если $W_1\to A^j_1$ и $W_2\to A^j_2$, то $W_2W_1\to A^j_2A^j_1$.
3.
Если $a\to -a,b\to -b$, то $(-)^{j+m-s+j-n-s+s+n-m+s}=(-)^{2j}$, и $A^j\to(-)^{2j}A^j$.

24.2.3 Transformations of Minkowski Space

Бусты пространства Минковского

24.3 Quantum Chaos: Some Concepts

(когда-то подумаю про это)

24.3.1 Concept of Quantum Chaos

(когда-то подумаю про это, но подробнее - отдельная запись)

24.3.2 Main Models of Quantum Chaos

(когда-то подумаю про это, но подробнее - отдельная запись)

24.3.3 Chaos and the semiclassical limit of quantum mechanics (is the moon there when somebody looks?) by Berry 1

Summary

According to the correspondence principle, the classical world should emerge from the quantum world whenever Planck's constant h is negligible. But the limit $h \to 0$ is mathematically singular. This fact (shared by many physical theories that are limits of other theories) complicates the reduction to classical mechanics. Particular interest attaches to the situation where the classical orbits are chaotic, that is, unpredictable. Then if the system is isolated the corresponding quantum motion (e.g. of a wave-packet) cannot be chaotic; this is the 'quantum suppression of chaos'. Chaos occurs in the world because quantum systems are not isolated: the limit $h \to 0$ is unstable, and the associated quantum interference effects are easily destroyed by tiny uncontrolled influences from the environment, and chaos returns; that is, 'decoherence' suppresses the quantum suppression of chaos. This is illustrated by the chaotic tumbling of Saturn's satellite Hyperion. For isolated systems, there are nevertheless quantal reflections of classical chaos, in the form of borderland phenomena, allowed because the semiclassical limit is singular. These are nonclassical, but emerge as $h \to 0$. Examples are interference associated with focusing (e.g. supernumerary rainbows), and the energy-level statistics of highly excited states, with tantalizing connections to prime numbers and the Riemann hypothesis.

1. Introduction

The question of how chaos in classical mechanics gets reflected in the quantum mechanics of the microworld is slippery and subtle [1-3]. On the one hand, it is known from observations, computations, and mathematical theorems that newtonian mechanics often predicts unpredictability: some systems of forces are so unstable that nearby trajectories separate exponentially fast [4]. This is chaos - the celebrated 'sensitivity to initial conditions'. Chaos is, strictly speaking, a phenomenon defined in the limit of long times, for systems that are confined to a restricted region of space (for example, a particle bouncing in a billiard table in the shape of a stadium). One of the hallmarks of chaos is the lack of periodicity or quasi-periodicity in the time-development of any dynamical variable (for example, the x component of position or the y component of velocity); the mathematical statement of this is that these variables have a continuous spectrum.

On the other hand, the corresponding quantum systems always have discrete (that is, quantized) energy levels, and since the energy spectrum governs the time-development of any dynamical quantity such evolution cannot be chaotic. This is the origin of the often-repeated, and strictly true, assertion that there is no chaos in quantum mechanics. Two awkward questions immediately arise. The first stems from the fact that classical mechanics is supposed to be the limit of quantum mechanics in situations where Planck's constant h can be neglected. This looks like a contradiction, and we ask: what kind of limit is it where a system is not chaotic for any finite value of h, yet is chaotic when $h = 0$? The second question is connected with the recognition that strictly speaking all systems - even our orbiting moon - obey the laws of

quantum mechanics, and yet they are often observed to evolve chaotically (even the moon is slightly chaotic, and other astronomical bodies much more so). We ask: what is the origin of the observed chaos in our macroscopic but strictly quantum world?

My purpose here is to try to answer these questions in the simplest way, that is without formalism. First, though, I draw attention to the fact that the relation between chaos and quantum physics, important enough as it is in its own right, can also be regarded as a microcosm of much larger questions. Our scientific understanding of the world is a patchwork of vast scope; it covers the intricate chemistry of life, the sociology of animal communities, the gigantic wheeling galaxies, and the dances of elusive elementary particles. But it is a patchwork nevertheless, and the different areas do not fit well together. This is the notorious problem of reduction: we might believe that a living organism is described completely by the quantum mechanics of all its molecular (atomic, electronic, nucleonic, quarkish...) parts, but where in its byzantine wavefunction, governed by the Schrödinger equation, is the spark of life? Even if we knew, how could that quantum description extend beyond living cells and individual creatures, to the displays of peacocks and the flocking of birds?

Even within physical science, reduction between different levels of explanation is problematic - indeed, it is almost always so. Chemistry is supposed to have been reduced to quantum mechanics, yet people still argue over the basic question of how quantum mechanics can describe the shape of a molecule. The statistical mechanics of a fluid reduces to its thermodynamics in the limit of infinitely many particles, yet that limit breaks down near the critical point, where liquid and vapour merge, and where we never see a continuum no matter how distantly we observe the particles; the critical state is a fractal, and much theoretical physics of the last forty years has gone into getting a clear understanding of it. The geometrical (newtonian) optics of rays should be the limit of wave optics as the wavelength becomes negligibly small, yet we shall see that the reduction (mathematically similar to that of classical to quantum mechanics) is obstructed by singularities, even when there is no chaos. (A singularity is a place where the smoothness of a mathematical quantity or geometrical pattern is disrupted, for example by the quantity becoming infinite; I will give examples later.)

What follows should not be misconstrued as antireductionist. On the contrary, I am firmly of the view, beautifully expressed recently [5], that all the sciences are compatible and that detailed links can be, and are being, forged between them. But of course the links are subtle, and my emphasis will be on a mathematical aspect of theory reduction that I regard as central, but which cannot be captured by the purely verbal arguments commonly employed in philosophical discussions of reduction.

My contention here will be that many difficulties associated with reduction arise because they involve singular limits [6]. These singularities have both negative and positive aspects: they obstruct the smooth reduction of more general theories to less general ones, but they also point to a great richness of borderland physics between the theories. So, indeed, the problem to be considered here, of chaos in the quantum world, is an example of something grander. But examples are important. To paraphrase the numerical analyst Beresford Parlett: "Only wimps study only the general case. Real scientists study examples".

Before getting started, I must make four points. The first is that although we will be dealing with the limit $h \to 0$, at first encounter this seems meaningless. Planck's constant cannot be set equal to zero, because it is a constant of nature, with a fixed value. And on the other hand, h has dimensions, so its 'fixed' value can be anything, depending on the system of units used. In fact, by 'the semiclassical limit $h \to 0$ ' I will mean 'situations where the dimensionless variable obtained by dividing h by any classical quantity with the same dimensions (action) is negligibly small'.

The second point is that discussions of chaos have been confused by conflating two different questions. The first is: How does classical behaviour (e.g. chaos) emerge in the semiclassical

limit? If the limit $h \to 0$ were not singular, this emergence would be trivial: simply solve the quantum problem, which involves h, then set $h = 0$. But we shall see that the true answer is much more subtle. This first question is important for the intellectual coherence of our description of the physical world, yet in a sense it is backward-looking, since we know the answer: the classical
world has to emerge somehow. The second question, more productive of new physics, is: What nonclassical phenomena emerge as $h \to 0$? This sounds like nonsense, and indeed if the limit were not singular the answer would be: no such phenomena.

The third point is that in discussions of chaos and quantum physics there always lurks a second limit, in addition to $h \to 0$. This is the limit of long times, $t \to \infty$. As mentioned above, it is only in the long-time limit that classical chaos emerges: it takes infinitely long time to verify that a trajectory explores all the possibilities compatible with conservation of energy (and similar quantities), or to determine that two initially infinitesimally close trajectories separate exponentially fast. But the semiclassical and long-time limits do not commute, and thereby hangs much of the difficulty and subtlety associated with our subject.

The fourth point is that there are two questions that were the legitimate focus of attention by most of the other participants at the meeting, but that I will not discuss. One is the relation, if any, that these considerations of quantum chaology bear to theological matters; I am unqualified (and also, as a nonbeliever, unmotivated) to do that. The other is the relation, if any, between quantum chaology and the interpretation of quantum mechanics (measurement, wavepacket reduction, etc); I have some sympathy with the opinion mischievously expressed recently [7] that such interpretation is unnecessary.

24.3.4 Chaos and the semiclassical limit of quantum mechanics (is the moon there when somebody looks?) by Berry 2

2. Singular limits: when one plus one does not make two

To see that singularities in the semiclassical limit are unavoidable, consider the simplest possible situation [8] (where there is no chaos) of two beams of quantum particles, or waves of light, + and - , travelling in opposite directions, and coherent (e.g. created from a common source). The associated waves - complex functions of position and time - are

$$\psi_{\pm}(x,t) = \exp\left\{2\pi \mathrm{i}\left(\pm\frac{x}{\lambda} - vt\right)\right\} \tag{1}$$

where the wavelength λ and frequency v are related to the momentum p
and and energy E of the quantum particles by the de Broglie and Planck laws:

$$\lambda = h/p, \quad v = E/h. \tag{2}$$

Each wave has intensity $|\psi|^2 = 1$.
By linearity (one of the principles of quantum mechanics), the resultant wave is the sum (superposition) of the two, so the (observable) intensity is

$$I(x) = |\psi_+ + \psi_-|^2 = 4\cos^2\left(\frac{2\pi x}{\lambda}\right) \tag{3}$$

This is the simplest representation of interferometry, where x would be distance measured on an observation screen. The oscillatory function (3) describes the interference fringes familiar since their explanation in terms of superposition by Young two centuries ago, and its mathematization by Fresnel (they were studying light, but nowadays the same interference is routinely observed for all quantum particles). Its values oscillate (figure 1a) between zero and 4 , with a spatial period of $\lambda/2$.

Now we ask: what is the classical, or geometrical-optics, limit of this wave? By (2), $h \to 0$ corresponds to fixing the momentum and letting $\lambda \to 0$. Classically (or in geometrical optics) there is no interference, so the intensity resulting from adding two waves, each with unit intensity, should be $I = 2$. But it is not! As $h \to 0$, the intensity (3) oscillates faster and faster (figure 1b), and in the limit it attains all values between zero and 4 in arbitrarily small ranges of x. In fact, (3) has a powerful singularity at $\lambda = 0$ (or $h = 0$), obstructing the smooth passage to the limit. We used to tell ourselves, and our students, that this singular function, and others like it, are mathematical curiosities, of no interest in physics. Now we see that the singularity arises unavoidably when we try to bridge the gap between two of our major theories, in the simplest possible case. For wave intensities, $1 + 1 = 2$ is false, all the way to the classical limit.

And yet we know that, in words attributed to Lord Rayleigh, two candles are twice as bright as one, that is, when waves are irrelevant, one plus one is indeed two. The only way to extract this result from (3) is by averaging. Any external influence that compromises the purity of (3) will have the effect of blurring (3), and in the classical limit this function is infinitely sensitive to blurring. Two possible influences are finite x sensitivity (window size) of the detector, and non-monochromaticity of the beams (finite spreads in wavelength or momentum). Now the average of the function $\cos^2$ is $1/2$, so

$$\langle I(x) \rangle = 4 \left\langle \cos^2 \left(\frac{2\pi x}{\lambda} \right) \right\rangle = 4 \times \frac{1}{2} = 2 \tag{4}$$

which is of course the classical result.

We need a slightly expanded version of (4). The average is over the phase difference χ between the two waves. Imagine the external influences result in a gauss-distributed χ with spread Δ; then

$$\left\langle \cos^2 \chi \right\rangle = \frac{1}{\Delta\sqrt{2\pi}} \int_{-\infty}^{\infty} \mathrm{d}\chi \cos^2 \chi \exp\left\{ -\frac{\chi^2}{2\Delta^2} \right\} = \frac{1}{2} \left(1 + \exp\left\{ -2\Delta^2 \right\} \right) \tag{5}$$

Phase randomness is very efficient: for phase spread $\Delta = \pi/2$, $\langle \cos^2 \chi \rangle = 0.5003$; for $\Delta = \pi$, $\langle \cos^2 \chi \rangle = 0.500000001$.

So, the correspondence principle does hold, but there has been a price to pay: because of the singularity, classical mechanics emerges not directly, but only after averaging over phase-scrambling effects that can be ascribed to the environment - that is, influences external to the pure quantum wave initially calculated - in modern parlance, decoherence effects. All this to get $1 + 1 = 2$! I cannot resist recalling that in a classic work [9] constructing mathematics from its basis in logic (before Gödel proved that enterprise is doomed), $1 + 1 = 2$ is derived as a theorem, somewhere in the middle of volume 2 .

3. Decoherence and the emergence of chaos

Now, what about chaos? To fix our ideas, consider Hyperion, the sixteenth satellite of the planet Saturn. This body is a potato-shaped rock about as big as New York City ($R \sim 142$ km). To the best of our knowledge, Hyperion is unique in that its rotation is chaotic [10,11]. Under resonant forcing from the big moon Titan, in combination with Saturn's gravity and its own nonsphericity, Hyperion tumbles erratically. The instability has a time-constant (for exponential forgetting of its initial state) of about 100 days, long compared with both its orbital period (21.3 days) and its instantaneous rotation period (about 5 days).

Now consider the rotation of Hyperion, regarded as a quantum object. Its quantized angular momentum J consists of $2\pi J/h \approx 2 \times 10^{58}$ Planck units (see Appendix A for the basis of the estimates given in this section). From this enormous number, together with the correspondence

principle - and with the same modelling as we use for the classical dynamics, where the only forces come from Saturn and Titan - the quantum predictions for the motion ought to coincide with the classical to very high accuracy. Let us see.

It helps to think of the classical motion on the phase space represented by the angular momentum vector $\mathbf{J}$ (whose magnitude is $J = |\mathbf{J}|$); this is the surface of a sphere with polar coordinates θ, ϕ. The motion of the vector $\mathbf{J}$ can be regarded as that of a mechanical system with a single freedom, whose 'coordinate' is the azimuth angle ϕ and whose 'momentum' is $p = J\cos\theta$; therefore phase-space area is area on the sphere, divided by J. For Hyperion, the total available phase-space area is $4\pi J^2/J \approx 10^{58}h$.

If we knew the motion precisely, Hyperion's rotation would be a single point moving on the sphere. But even classically our measurements are not perfectly precise, so the state of Hyperion is a little blurry patch, tiny on the sphere but with an area many times h; call its boundary $B(0)$, evolving into $B(t)$. Chaotic evolution means that the different points on B separate exponentially, so that $B(t)$ develops into a convoluted curve, with tendrils exploring the whole phase sphere. The area enclosed by $B(t)$ remains constant (this is Liouville's theorem); however B 's perimeter length grows exponentially, as $L(t) \approx L(0)\exp(t/T_{\rm c})$, where for Hyperion the chaos time is $T_{\rm c} \approx 100$ days.

Classically, the convolutions get ever more intricate. For a while, the quantum state representing Hyperion follows these convolutions; this is the spreading of the wavepacket, chaos-style. But quantum physics prevents the intricacy - that is, the chaos - from developing forever, because phase-space fine structure is limited by Planck's constant h. Any smaller structure must be blurred. After some time $T_{\rm q}$, the areas of typical tendrils get finer than h; thereafter, classical and quantum evolutions are different. This is the quantum suppression of classical chaos [12-14]. At first thought, $T_{\rm q}$ for astronomical objects must be enormously long, probably irrelevant to any observations on time scales relevant to astronomers - remember that gigantic 10^{58}. Not so. A simple estimate (Appendix A) gives

$$T_{\rm q} \sim T_{\rm c}\log(J/h) \tag{6}$$

For Hyperion, this is

$$T_{\rm q} \sim 100 \text{ days } \times \log\left(10^{58}\right) = 37 \text{ years} \tag{7}$$

- an astonishingly short time, first calculated in a similar way by Ronald Fox (private communication).

Now, the chaotic rotation of Hyperion was discovered less than 37 years ago, but nobody thinks that after the year 2020 astronomers will begin to see quantum effects - specifically the calming of Hyperion's instability and its replacement by some more moderate multiply periodic motion. And indeed, the predicted quantum suppression of chaos is itself suppressed, and classicality restored, by another quantum effect. This is decoherence. It arises from the fact that Hyperion is not isolated.

At the very least, seeing Hyperion involves photons from the sun, arriving unpredictably. We would never think to include these photons in
the calculation of Hyperion's dynamics, because their energy is so minuscule: 4×10^{-19} J for a visible photon, as compared with $2 \times 10^{+19}$ J for Hyperion's rotational energy. On the other hand, their energy is vast in comparison with the energy spacing 10^{-39} J of Hyperion's quantum rotational levels, so a quantum effect from these photons is conceivable.

The proper way to calculate this effect would be to enlarge the physical system to include not just Hyperion in the field of Saturn and Titan but also the sun's radiation field, and formally eliminate the radiation variables (by tracing over them), to get a modified quantum mechanics

involving only Hyperion's dynamics. In recent years powerful formalisms have been developed for doing this [15, 16], and have been applied to the situation where there is classical chaos [17-19]. Rather than repeat these arguments here, I will first estimate the effects of decoherence in a bare-handed way, by treating the environment as a random time-dependent modification of Hyperion's hamiltonian - a kick from each impact of a photon from the sun. In Appendix B I give a slightly more formal treatment, but still incorporating what John Polkinghorne calls 'the patter of photons' as an external influence, rather than a constituent of a composite system.

We begin by noting that the quantum suppression of chaos involves the interference of waves and therefore their phases (in some situations this is analogous to Anderson localization in solids [20]). Therefore the suppression can be easily - and quickly - destroyed by decoherence from external influences. The change in Hyperion's angular momentum resulting from the random impact (impulsive torque) of a single visible photon (wavelength λ) is $\Delta J \sim (h/\lambda)R$. This impact will change the total phase of Hyperion's wavefunction. And, with even slight convolutions of B, so there is more than one classical contribution to the wavefunction for some azimuth values ϕ, it will also (by about the same amount) change the phase difference between these contributions. The change (associated with the component of $\mathbf{\Delta J}$ parallel to $\mathbf{J}$, which spins up Hyperion and swells the sphere and therefore also the convolutions of B on it) is

$$\Delta J/h \sim (h/\lambda)R/h = R/\lambda \sim 10^{11} \tag{8}$$

This uncontrollable phase shift between the waves associated with any two classical contributions, acting according to (5), is overwhelmingly sufficient to induce decoherence, and so suppress the suppression of chaos - and just from a single photon. In the stream of sunlight (flux˜10 Wm $^{-2}$), photons arrive at a rate of one every 10^{-30} s, so decoherence occurs extremely fast. Stretching this argument, we can estimate the decoherence time $T_{\rm d}$ for the stream of photons from the sun to disturb the phase by about 2π radians:

$$T_{\rm d} \sim 10^{-53} \text{ s} \tag{9}$$

Do not take the precise value of this number seriously. The foregoing is very far from a proper calculation of the decoherence effect for Hyperion. But the extreme smallness of $T_{\rm d}$ should be taken very seriously. It shows that an external disturbance so small that its effect on a system's dynamics is negligible (one photon, or a tiny fraction of a photon) can nevertheless dramatically and effectively instantaneously influence the kinematics of its quantum state - and more strongly as the classical limit is approached. Decoherence - the generalization of the $1 + 1 = 2$ calculation of the previous section - emerges as a dominant physical effect, allowing classical chaos to persist [17-19].

I chose Hyperion's chaos to dramatize the way in which uncontrolled environmental influences can induce quantal decoherence. In fact, when applied in such extreme situations the decoherence argument has nothing to do with chaos per se, but to classicalization: since $T_{\rm d} \ll T_{\rm c}$, the destruction of quantum interference occurs long before chaos develops. So the claim sometimes made, that chaos amplifies quantum indeterminacy, is misleading. The situation is more subtle: chaos magnifies any uncertainty, but in the quantum case h has a smoothing effect, which would suppress chaos if this suppression were not itself suppressed by externally-induced decoherence, that restores classicality (including chaos if the classical orbits are unstable).

The calculation in Appendix B shows this decoherence-induced classicalization more clearly for the illustrative example of Hyperion; very recently, a more general and formal argument for the universality of the phenomenon has been given [21]. At the opposite extreme from Hyperion are the humble 2-state systems, where decoherence, and the related inhibition of quantum transitions through the quantum Zeno effect, can be explored in detail [22-29].

24.3.5 Chaos and the semiclassical limit of quantum mechanics (is the moon there when somebody looks?) by Berry 3

4. Emergent semiclassical phenomena

The example of Hyperion addressed the first of the two commonlyconflated questions mentioned near the end of the Introduction, namely the emergence of classical effects - specifically, chaos - as $h \to 0$. Now, with two examples, we consider the more interesting question of what nonclassical effects emerge and persist in the limit $h \to 0$. The first does not involve chaos; the second does. Both of these emergent phenomena are delicate, in the sense that their detection requires magnification that increases as h gets smaller; this contrasts with more familiar examples of macroscopic quantum phenomena (superfluidity, superconductivity, the impenetrability of matter in bulk...).

Corresponding to a quantum scattering wavefunction (for example of a beam of atoms striking a target of other atoms, or electrons in an electron microscope) or to a field of diffracted light waves (for example sunlight encountering a raindrop), is a family of trajectories. These are the orbits of massive particles, or light rays. (Even a localized wavepacket corresponds to a family, rather than a single trajectory, because its localization cannot be perfect.)

Now, a family of trajectories possesses a holistic property not inherent in any individual trajectory, namely focusing. In three dimensions, focusing usually occurs on surfaces, and in two dimensions, on lines. These are the envelopes of the family of trajectories. They are called caustics. Caustics are the singularities of ray (geometrical, classical) theory [30, 31]. On them, the ray intensity rises to infinity.

They are the brightest places in the field. Examples are rainbows (angular focusing of sunlight refracted and reflected by raindrops, and their analogues in atomic and molecular scattering) and the patterns of light dancing on the bottom of a swimming-pool. In our eyes, microscopes and cameras, the images of each point are also formed by focusing, but of a very special kind, namely the non-generic points fashioned by evolution or lensmakers' art, rather than the surfaces and lines occurring when there is no symmetry. Caustics are important.

But they are nonexistent! Close examination, on the scale of the wavelength, dissolves the singularities, and reveals that they are decorated by intricate and beautiful interference patterns. These can be understood by an application of the same mathematics, developed in the 1960s and 1970s, that enables the different caustic singularities to be classified. This is the celebrated and (in other contexts) notorious catastrophe theory [32, 33]. The diffraction catastrophes [31, 34, 35] are emergent semiclassical (more generally, short-wave) phenomena, with many applications throughout mathematics as well as physics (they describe the supernumerary arcs sometimes seen just inside the main rainbow, that were impossible to explain using ray theory). Although they are contained in wave equations (Schrödinger's, Maxwell's), they were not derived by the reductionist approach of starting with solutions of wave equations, but by top-down methods, starting with the caustic singularities of ray physics; only later were the full connections with wave equations elucidated, and consilience [5] established.

Before getting to the second example, I digress to point out that the caustics story extends deep into wave physics, and in a way that nicely illustrates the role of singularities. Wave physics dissolves the caustic singularities of geometrical optics. But wave physics has singularities of its own, complementary to caustics; these are the singularities of phase the new quantity introduced in the generalization from rays to waves. The singularities are the dislocation lines [31, 36-38] (so called because of their close analogy with dislocations in crystals), where the phase is singular and the intensity is zero. Dislocations are fine-scale features of waves; they are now beginning to be investigated in detail in optical
experiments with interfering laser beams [39,40]. They are optical singularities in the approximation where light is regarded as a scalar wave. But light is not a scalar wave; its vector nature

allows for polarization. And in the passage from scalar to vector, the dislocations are dissolved, and replaced by yet other singularities, of the pattern of field vectors: lines again, but where the polarization is purely circular or purely linear [41-43]. At each stage, generalization to a deeper theory dissolves the singularities of the old theory, and replaces them by new ones.

Now we return to chaos, with our second example, and consider the conventional quantum mechanics of isolated systems, mindful of the fact that as the classical limit is approached the criteria for effective isolation become more stringent. An isolated bounded system possesses discrete energy levels. For fixed energy, the semiclassical limit corresponds to highly excited states, so we expect these to reflect the nature of the corresponding classical trajectories, in particular their chaology. And so it turns out, in a remarkable example of an asymptotically emergent phenomenon associated with a singular limit.

First, there is an obvious way in which the classical limit is singular. Between the classical energy continuum and the quantum discontinuum is a logically unbridgeable gap. In philosophers' parlance, the two theories are incommensurable. In practice, the incommensurability is inconsequential, because any spectroscope has finite resolution, and under sufficiently semiclassical conditions the discrete levels (spacing h^D for systems with D freedoms) cannot be discriminated. Beyond this, we can imagine studying the details of the semiclassical spectrum by performing a mental magnification to keep the average level spacing unity.

Now it is possible to ask whether the thus-magnified spectrum is qualitatively different for a classically integrable (regular, non-chaotic) system and for a chaotic one. For example, the much-investigated quantum dots can be caricatured as quantum billiards, that is electrons moving freely in planar regions with specular reflection at the boundary walls; square or circular boundaries generate classically regular motion, a
stadium-shaped wall generates chaos. (Other chaotic systems that have been studied experimentally include hydrogen atoms in very strong magnetic fields, and the vibrations of molecules whose atoms are anharmonically coupled.)

These spectra display universality. There is a sense in which the spectra of all quantum systems whose classical mechanics is chaotic are the same, and similarly for integrable systems [2, 44-46]. The universality does not extend to the positions of the individual levels: of course these are different for different systems in each class. It is to the statistics of the levels that universality applies. Statistics are natural in the semiclassical limit, since there are many levels in a classically small energy interval. Spectral statistics has become a richly elaborated subject [47], of which the merest sketch must suffice here.

Consider one of the simplest statistics of the magnified spectrum (where the mean spacing is unity), namely the probability $P(S)$ that neighbouring levels have spacing S. For almost all integrable systems with more than one freedom,

$$P(S) = \exp(-S) \text{ (integrable)}; \tag{10}$$

this is the negative exponential characteristic of Poisson-distributed 'events' (levels); in particular, the most probable spacing is $S = 0$, indicating clustering of the levels [44]. It is a little strange at first encounter that regular classical motion coresponds to a random quantum spectrum, but it is so.

For chaotic classical motion, the level spacings distribution is very different, and closely approximated by the Wigner distribution [1,48]

$$P(S) = \frac{1}{2}\pi S \exp\left(-\frac{1}{4}\pi S^2\right) \text{ (chaotic)}. \tag{11}$$

This is the statistic characteristic of the eigenvalues of random matrices [49, 50]. Note that $P(0) = 0$, indicating repulsion of levels, in contrast to the clustering of (10).

I have simplified matters. There are actually three universality classes for classically chaotic quantum spectra. Equation (10) applies when there is time-reversal symmetry, when the particles have integer spin (bosons) or where spin plays no part (as in electrons in quantum billiards). The other universalities apply when there is time-reversal symmetry for fermions [51], and when there is no time-reversal symmetry [52-54].

It is one thing to identify universality classes, by computer experiments inspired by intuition, or (now) by laboratory experiment, but quite another to provide a theoretical explanation of the universality. However, this has now been achieved, both in broad outline and in many details [55-57]. It turns out that the quantum spectral universality is begotten by a universality of the classical mechanics, connected with the distribution of very long periodic orbits [58, 59]. And in one of those unexpected connections that make theoretical physics so delightful, the quantum chaology of spectra turns out to be deeply connected to the arithmetic of prime numbers, through the celebrated zeros of the Riemann zeta function: the zeros mimic quantum energy levels of a classically chaotic system. The connection is not only deep but also tantalizing, since its basis is still obscure - though it has been fruitful both for mathematics and physics [60-66].

It is important to emphasize why spectral universality is an emergent nonclassical semiclassical phenomenon. It is nonclassical because it is a property of discrete energy levels, which have no classical counterpart. It is semiclassically emergent because only as $h \to 0$ are there many levels in a classically small interval - it is impossible to calculate statistics using only the ground state. And only the singular nature of the semiclassical limit allows such nonclassical phenomena to emerge without paradox.

Appendix A

Caricaturing Hyperion as a homogeneous sphere with radius $R(= 142\,\mathrm{km})$ and mass $M\,(= 1.77 \times 10^{19}\ \mathrm{kg})$, its moment of inertia is $I = 2MR^2/5$, and from its rotational angular speed $\Omega_\mathrm{H} \sim 2\pi/(5\ \mathrm{days}\ )$ follows the angular momentum

$$J = I\Omega_\mathrm{H} = \frac{2}{5}MR^2\Omega_\mathrm{H} \tag{A1}$$

and thence the number $N = 2\pi J/h = 2\times 10^{58}$ given in the text, of Planck units in Hyperion's angular momentum.

For the estimate of T_q (equations 6 and 7), we imagine the boundary of the patch representing Hyperion's classical state evolving into tendrils each of area h. Since the total area of the angular-momentum sphere (phase space) is $4\pi J$, the number of such tendrils is about N, and their total perimeter is $L\,(T_\mathrm{q}) \sim N\mathrm{x}$ (radius of J sphere) $\sim N\sqrt{J} = N^{3/2}\sqrt{h}$; the initial perimeter is $L(0) \sim \sqrt{J} = \sqrt{(Nh)}$. Solving the chaos equation

$$L\,(T_\mathrm{q}) = L(0)\exp\,(T_\mathrm{q}/T_\mathrm{c}) \tag{A2}$$

for T_q now gives (6) and (7).

To estimate the spacing of Hyperion's rotational eigenenergies E_N, we use

$$E_N = \frac{J^2}{2I} = \frac{N^2h^2}{8\pi^2 I} \tag{A3}$$

whence

$$\Delta E_N \equiv E_{N+1} - E_N = \frac{Nh^2}{4\pi^2 I} = \frac{Jh}{2\pi I} = \frac{h\Omega_\mathrm{H}}{2\pi} \tag{A4}$$

This gives $\Delta E_N \sim 10^{-39}$ J as stated in the text.

Finally, to estimate the decoherence time T_d we start with the energy of sunlight reaching unit area of Hyperion each second. This is about $P = 10\mathrm{Wm}^{-2}$, since $1000\mathrm{Wm}^{-2}$ reaches the

earth and Saturn is about 10 times further from the Sun. The total power reaching Hyperion is thus $\pi R^2 P$; thence the number of photons (frequency v) reaching hyperion in $T_{\rm d}$ is $N_{\rm p} \sim \pi R^2 P T_{\rm d}/hv$. These give random impacts, so the total phase change is $\sqrt{N_{\rm p}}$ times the value in (8), and this must be of order unity, leading to

$$T_{\rm d} \sim \frac{hc\lambda}{\pi R^4 P} \tag{A8}$$

and thence to (9).

Appendix B

My aim here is to use a simple model to get an expression for the 'decoherence factor' that describes explicitly how impacts from photons 'classicalize' Hyperion's rotation, by causing the density matrix, in the representation corresponding to Hyperion's angular position, to become diagonal very rapidly.

On the very small time scales associated with the onset of decoherence, Hyperion's chaotic tumbling is irrelevant, so it suffices to treat the rotation by a single angle θ, with associated angular momentum component J. Let a photon with momentum p strike Hyperion with impact parameter $b(-R \le b \le R)$, and the the reflectivity be r. This will change J by

$$\Delta J = pb(1-r) \tag{B1}$$

A classical hamiltonian incorporating these impacts (denoted by subscripts i) is

$$H = \frac{J^2}{2I} + \theta \sum_i \Delta J_i \delta\left(t - t_i\right) \tag{B2}$$

(H is not periodic in θ, but in the present context θ can be considered as living on the covering space consisting of the whole real line.)

Quantally, the variables θ and J become operators $\hat{\theta}$ and $\hat{J}$, and the evolution of a state $|\psi(t)\rangle$ over the interval $\tau_i = t_{i+1} - t_i \, (\sim 10^{-30}$ s) between the successive impacts is determined (from the Schrödinger equation corresponding to (B2)) by the unitary evolution operator

$$U_i = \exp\left\{-\mathrm{i}\hat{\theta}\Delta J_i/\hbar\right\} \exp\left\{-\mathrm{i}\hat{J}^2\tau_i/(2I\hbar)\right\}. \tag{B3}$$

We apply this in the position representation, for wavepackets $\psi(\theta,t) \equiv \langle\theta \mid \psi(t)\rangle$ that are classically narrow (corresponding to an accurate specification of Hyperion's rotation) and correspond to rotation with average angular momentum J, yet wide enough to neglect the spreading of the wavepacket during the tiny interval τ_i between photon impacts. These conditions are very easy to justify for a planetary wavepacket, as can be confirmed by exact calculations on a gaussian model. Then the evolution is, approximately,

$$\begin{aligned}\psi\left(\theta, t_{i+1}\right) &= \exp\left\{-\mathrm{i}\theta\Delta J_i/\hbar\right\} \langle\theta| \exp\left\{-\mathrm{i}\hat{J}^2\tau_i/(2I\hbar)\right\} |\psi\left(t_i\right)\rangle \\ &\approx \exp\left\{-\mathrm{i}\theta\Delta J_i/\hbar\right\} \exp\left\{-\mathrm{i}J^2\tau_i/(2I\hbar)\right\} \psi\left(\theta, t_i\right)\end{aligned} \tag{B4}$$

Expressing this in terms of the density matrix $\hat{\rho}_i = |\psi\left(t_i\right)\rangle \langle\psi\left(t_i\right)|$ gives, for the evolution after N impacts,

$$\langle\theta|\hat{\rho}_{i+N}\,|\theta'\rangle \approx \exp\left\{-\mathrm{i}\left(\theta-\theta'\right)\sum_{m=i}^{i+N}\Delta J_m/\hbar\right\} \langle\theta|\hat{\rho}_i\,|\theta'\rangle \tag{B5}$$

Now comes the central step: averaging the exponential factor over the random impacts. In a time T during which there are many impacts (which can still be macroscopically extremely short), the exponent is a gaussian random variable. With this observation, and introducing the average photon frequency ω, the decoherence factor can be written

$$F(\theta,\theta',T) = \left[\exp\left[-\mathrm{i}(\theta-\theta')\sum_{i=1}^{N} p_i b_i (1-r_i)/\hbar\right]\right]_{\mathrm{av}} \tag{B6}$$
$$= \exp\left\{-A\omega T(\theta-\theta')^2\right\}$$

where the dimensionless decoherence amplification constant A, expressed in terms of the power P striking unit area of Hyperion, is

$$A \sim \frac{PR^4}{hc^2} \sim 10^{38} \tag{B7}$$

The enormous value of A, together with (B6), ensures that in even the shortest macroscopically significant time T the off-diagonal elements of the density matrix are negligible for any difference $\theta-\theta'$ in Hyperion's angular position that is large enough to conceivably be measured. For a more general version of (B6), see equation (3) of reference [21].

Examples of real applications of Dirac's quantization

(??? never heard that it was used)

24.5.2 Dirac's Lecture 1: The Hamilton Method

I'm very happy to be here at Yeshiva and to have this chance to talk to you about some mathematical methods that I have been working on for a number of years. I would like first to describe in a few words the general object of these methods.

In atomic theory we have to deal with various fields. There are some fields which are very familiar, like the electromagnetic and the gravitational fields; but in recent times we have a number of other fields also to concern ourselves with, because according to the general ideas of De Broglie and Schrödinger every particle is associated with waves and these waves may be considered as a field. So we have in atomic physics the general problem of setting up a theory of various fields in interaction with each other. We need a theory conforming to the principles of quantum mechanics, but it is quite a difficult matter to get such a theory.

One can get a much simpler theory if one goes over to the corresponding classical mechanics, which is the form which quantum mechanics takes when one makes Planck's constant $\hbar$ tend to zero. It is very much easier to visualize what one is doing in terms of classical

mechanics. It will be mainly about classical mechanics that I shall be talking in these lectures.

Now you may think that that is really not good enough, because classical mechanics is not good enough to describe Nature. Nature is described by quantum mechanics. Why should one, therefore, bother so much about classical mechanics? Well, the quantum field theories are, as I said, quite difficult and so far, people have been able to build up quantum field theories only for fairly simple kinds of fields with simple interactions between them. It is quite possible that these simple fields with the simple interactions between them are not adequate for a description of Nature. The successes which we get with quantum field theories are rather limited. One is continually running into difficulties and one would like to broaden one's basis and have some possibility of bringing more general fields into account. For example, one would like to take into account the possibility that Maxwell's equations are not accurately valid. When one goes to distances very close to the charges that are producing the fields, one may have to modify Maxwell's field theory so as to make it into a nonlinear electrodynamics. This is only one example of the kind of generalization which it is profitable to consider in our present state of ignorance of the basic ideas, the basic forces and the basic character of the fields of atomic theory.

In order to be able to start on this problem of dealing with more general fields, we must go over the classical theory. Now, if we can put the classical theory into the Hamiltonian form, then we can always apply certain standard rules so as to get a first approximation to a quantum theory. My talks will be mainly concerned with this problem of putting a general classical theory into the Hamiltonian form. When one has done that, one is well launched onto the path of getting an accurate quantum theory. One has, in any case, a first approximation.

Of course, this work is to be considered as a preliminary piece of work. The final conclusion of this piece of work must be to set up an accurate quantum theory, and that involves quite serious difficulties, difficulties of a fundamental character which people have been worrying over for quite a number of years. Some people are so much impressed by the difficulties of passing over from Hamiltonian classical mechanics to quantum mechanics that they think that maybe the whole method of working from Hamiltonian classical theory is a bad method. Particularly in the last few years people have been trying to set up alternative methods for getting quantum field theories. They have made quite considerable progress on these lines. They have obtained a number of conditions which have to be satisfied. Still I feel that these alternative methods, although they go quite a long way towards accounting for experimental results, will not lead to a final solution to the problem. I feel that there will always be something missing from them which we can only get by working from a Hamiltonian, or maybe from some generalization of the concept of a Hamiltonian. So I take the point of view that the Hamiltonian is really very important for quantum theory.

In fact, without using Hamiltonian methods one cannot solve some of the simplest problems in quantum theory, for example the problem of getting the Balmer formula for hydrogen, which was the very beginning of quantum mechanics. A Hamiltonian comes in therefore in very elementary ways and it seems to me that it is really quite

curritial to work from a Hamiltonian; so I want to talk 10. you about how far one can develop Hamiltonian methods.

I would like to begin in an elementary way and I take as my starting point an action principle. That is to say, I assume that there is an action integral which depends on the motion, such that, when one varies the motion, and puts down the conditions for the action integral to be stationary, one gets the equations of motion. The method of starting from an action principle

has the one great dvantage, that one can easily make the theory conform to the principle of relativity. We need our atomic theory to conform to relativity because in general we are dealing with particles moving with high velocities.

If we want to bring in the gravitational field, then we have to make our theory conform to the general principle of relativity, which means working with a space-time which is not flat. Now the gravitational field is not very important in atomic physics, because gravitational forces are extremely weak compared with the other kinds of forces which are present in atomic processes, and for practical purposes one can neglect the gravitational field. People have in recent years worked to some extent on bringing the gravitational field into the quantum theory, but I think that the main object of this work was the hope that bringing in the gravitational field might help to solve some of the difficulties. As far as one can see at present, that hope is not realized, and bringing in the gravitational field seems to add to the difficulties rather than remove them. So that there is not very much point at present in bringing gravitational fields into atomic theory. However, the methods which I am going to describe are powerful mathematical methods which

would be available whether one brings in the gravitational field or not.

We start off with an action integral which I denote by

$$I = \int L dt \tag{1-1}$$

It is expressed as a time integral, the integrand L being the Lagrangian. So with an action principle we have a Lagrangian. We have to consider how to pass from that Lagrangian to a Hamiltonian. When we have got the Hamiltonian, we have made the first step toward getting a quantum theory.

You might wonder whether one could not take the Hamiltonian as the starting point and short-circuit this work of beginning with an action integral, getting a Lagrangian from it and passing from the Lagrangian to the Hamiltonian. The objection to trying to make this short-circuit is that it is not at all easy to formulate the conditions for a theory to be relativistic in terms of the Hamiltonian. In terms of the action integral, it is very easy to formulate the conditions for the theory to be relativistic: one simply has to require that the action integral shall be invariant. One can easily construct innumerable examples of action integrals which are invariant. They will automatically lead to equations of motion agreeing with relativity, and any developments from this action integral will therefore also be in agreement with relativity.

When we have the Hamiltonian, we can apply a standard method which gives us a first approximation to a quantum theory, and if we are lucky we might be able to go on and get an accurate quantum theory. You might

again wonder whether one could not short-circuit that work to some extent. Could one not perhaps pass directly from the Lagrangian to the quantum theory, and shortcircuit altogether the Hamiltonian? Well, for some simple examples one can do that. For some of the simple fields which are used in physics the Lagrangian is quadratic in the velocities, and is like the Lagrangian which one has in the non-relativistic dynamics of particles. For these examples for which the Lagrangian is quadratic in the velocities, people have devised some methods for passing directly from the Lagrangian to the quantum theory. Still, this limitation of the Lagrangian's being quadratic in the velocities is quite a severe one. I want to avoid this limitation and to work with a Lagrangian which can be quite a general function of the velocities. To get a general formalism which will be applicable, for example, to the non-linear electrodynamics which I mentioned previously, I don't think one can in any way shortcircuit the route of starting with an action integral, getting a Lagrangian, passing from the Langrangian to the Hamiltonian, and then passing from the Hamiltonian to the quantum theory. That is the route which I want to discuss in this course of lectures.

In order to express things in a simple way to begin with, I would like to start with a dynamical theory involving only a finite number of degrees of freedom, such as you are familiar with in particle dynamics. It is then merely a formal matter to pass from this finite number of degrees of freedom to the infinite number of degrees of freedom which we need for a field theory.

Starting with a finite number of degrees of freedom, we have dynamical coordinates which I denote by q.

The general one is $q_n, n = 1, \cdots, N, N$ being the number of degrees of freedom. Then we have the velocities $dq_n/dt = \dot{q}_n$. The Lagrangian is a function $L = L(q, \dot{q})$ of the coordinates and the velocities.

You may be a little disturbed at this stage by the importance that the time variable plays in the formalism. We have a time variable t occurring already as soon as we introduce the Lagrangian. It occurs again in the velocities, and all the work of passing from Lagrangian to Hamiltonian involves one particular time variable. From the relativistic point of view we are thus singling out one particular observer and making our whole formalism refer to the time for this observer. That, of course, is not really very pleasant to a relativist, who would like to treat all observers on the same footing. However, it is a feature of the present formalism which I do not see how one can avoid if one wants to keep to the generality of allowing the Lagrangian to be any function of the coordinates and velocities. We can be sure that the contents of the theory are relativistic, even though the form of the equations is not manifestly relativistic on account of the appearance of one particular time in a dominant place in the theory.

Let us now develop this Lagrangian dynamics and pass over to Hamiltonian dynamics, following as closely as we can the ideas which one learns about as soon as one deals with dynamics from the point of view of working with general coordinates. We have the Lagrangian equations of motion which follow from the variation of the action integral:

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}_n}\right) = \frac{\partial L}{\partial q_n} \tag{1-2}$$

To go over to the Hamiltonian formalism, we introduce the momentum variables p_n, which are defined by

$$p_n = \frac{\partial L}{\partial \dot{q}_n} \tag{1-3}$$

Now in the usual dynamical theory, one makes the assumption that the momenta are independent functions of the velocities, but that assumption is too restrictive for the applications which we are going to make. We want to allow for the possibility of these momenta not being independent functions of the velocities. In that case, there exist certain relations connecting the momentum variables, of the type $\phi(q, p) = 0$.

There may be several independent relations of this type, and if there are, we distinguish them one from another by a suffix $m = 1, \cdots, M$, so we have

$$\phi_m(q, p) = 0. \tag{1-4}$$

The q 's and the p 's are the dynamical variables of the Hamiltonian theory. They are connected by the relations (1-4), which are called the primary constraints of the Hamiltonian formalism. This terminology is due to Bergmann, and I think it is a good one.

Let us now consider the quantity $p_n\dot{q}_n - L$. (Whenever there is a repeated suffix I assume a summation over all values of that suffix.) Let us make variations in the variables q and $\dot{q}$, in the coordinates and the velocities. These variations will cause variations to occur in the momentum variables p. As a result of these variations, $\delta\left(p_n\dot{q}_n - L\right)$

$$= \delta p_n \dot{q}_n + p_n \delta \dot{q}_n - \left(\frac{\partial L}{\partial q_n}\right) \delta q_n - \left(\frac{\partial L}{\partial \dot{q}_n}\right) \delta \dot{q}_n$$
$$= \delta p_n \dot{q}_n - \left(\frac{\partial L}{\partial q_n}\right) \delta q_n \tag{1-5}$$

by (1-3). Now you see that the variation of this quantity $p_n \dot{q}_n - L$ involves only the variation of the q 's and that of the p 's. It does not involve the variation of the velocities. That means that $p_n \dot{q}_n L -$ can be expressed in terms of the q 's and the p 's, independent of the velocities. Expressed in this way, it is called the Hamiltonian H.

However, the Hamiltonian defined in this way is not uniquely determined, because we may add to it any linear combination of the ϕ 's, which are zero. Thus, we could go over to another Hamiltonian

$$H^* = H + c_m \phi_m, \tag{1-6}$$

where the quantities c_m are coefficients which can be any function of the q 's and the p 's. H^* is then just as good as H; our theory cannot distinguish between H and H^*. The Hamiltonian is not uniquely determined.

We have seen in (1-5) that

$$\delta H = \dot{q}_n \delta p_n - \left(\frac{\partial L}{\partial q_n}\right) \delta q_n$$

This equation holds for any variation of the q 's and the p 's subject to the condition that the constraints (1-4) are preserved. The q 's and the p 's cannot be varied independently because they are restricted by (1-4), but for any variation of the q 's and the p 's which preserves these conditions, we have this equation holding. From the general method of the calculus of variations applied to a variational equation with constraints of this kind, we deduce
and

$$\dot{q}_n = \frac{\partial H}{\partial p_n} + u_m \frac{\partial \phi_m}{\partial p_n} \tag{1-7}$$
$$-\frac{\partial L}{\partial q_n} = \frac{\partial H}{\partial q_n} + u_m \frac{\partial \phi_m}{\partial q_n} \tag{9}$$

$$\text{or} \quad p_n = -\frac{\partial H}{\partial q_n} - u_m \frac{\partial \phi_m}{\partial q_n}, \tag{1-8}$$

with the help of (1-2) and (1-3), where the u_m are unknown coefficients. We have here the Hamiltonian equations of motion, describing how the variables q and p vary in time, but these equations involve unknown coefficients u_m.

It is convenient to introduce a certain formalism which enables one to write these equations briefly, namely the Poisson bracket formalism. It consists of the following: If we have two functions of the q 's and the p 's, say $f(q,p)$ and $g(q,p)$, they have a Poisson bracket $[f,g]$ which is defined by

$$[f,g] = \frac{\partial f}{\partial q_n}\frac{\partial g}{\partial p_n} - \frac{\partial f}{\partial p_n}\frac{\partial g}{\partial q_n} \tag{1-9}$$

The Poisson brackets have certain properties which follow from their definition, namely $[f,g]$ is antisymmetric in f and g :

$$[f, g] = -[g, f] \tag{1-10}$$

it is linear in either member:

$$[f_1 + f_2, g] = [f_1, g] + [f_2, g]\,, \text{ etc.} \tag{1-11}$$

and we have the product law,

$$[f_1 f_2, g] = f_1\,[f_2, g] + [f_1, g]\,f_2 \tag{1-12}$$

Finally, there is the relationship, known as the 7 acobi Identity, connecting three quantities:

$$[f, [g, h]] + [g, [h, f]] + [h, [f, g]] = 0. \tag{1-13}$$

With the help of the Poisson bracket, one can rewrite

[10]

the equations of motion. For any function g of the q 's and the p 's, we have

$$\dot{g} = \frac{\partial g}{\partial q_n}\dot{q}_n + \frac{\partial g}{\partial p_n}\dot{p}_n \tag{1-14}$$

If we substitute for q_n and p_n their values given by (1-7) and (1-8), we find that (1-14) is just

$$\dot{g} = [g, H] + u_m\,[g, \phi_m] \tag{1-15}$$

The equations of motion are thus all written concisely in the Poisson bracket formalism.

We can write them in a still more concise formalism if we extend the notion of Poisson bracket somewhat. As I have defined Poisson brackets, they have a meaning only for quantities f and g which can be expressed in terms of the q 's and the p 's. Something more general, such as a general velocity variable which is not expressible in terms of the q 's and p 's, does not have a Poisson bracket with another quantity. Let us extend the meaning of Poisson brackets and suppose that they exist for any two quantities and that they satisfy the laws (1-10), $(1-11), (1-12)$, and (1-13), but are otherwise undetermined when the quantities are not functions of the q 's and p 's.

Then we may write (1-15) as

$$\dot{g} = [g, H + u_m\phi_m]\,. \tag{1-16}$$

Here you see the coefficients u occurring in one of the members of a Poisson bracket. The coefficients u_m are not functions of the q 's and the p 's, so that we cannot use the definition (1-9) for determining the Poisson bracket in (1-16). However, we can proceed to work out

this Poisson bracket using the laws (1-10), (1-11), (1-12), and (1-13). Using the summation law (1-11) we have:

$$[g, H + u_m\phi_m] = [g, H] + [g, u_m\phi_m] \tag{1-17}$$

and using the product law (1-12),

$$[g, u_m\phi_m] = [g, u_m]\,\phi_m + u_m\,[g, \phi_m] \tag{1-18}$$

The last bracket in (1-18) is well-defined, for g and ϕ_m are both functions of the q 's and the p 's. The Poisson bracket $[\ g, u_m\ ]$ is not defined, but it is multiplied by something that vanishes, ϕ_m. So the first term on the right of (1-18) vanishes. The result is that

$$[g, H + u_m\phi_m] = [g, H] + u_m [g, \phi_m] \tag{1-19}$$

making (1-16) agree with (1-15).

There is something that we have to be careful about in working with the Poisson bracket formalism: We have the constraints (1-4), but must not use one of these constraints before working out a Poisson bracket. If we did, we would get a wrong result. So we take it as a rule that Poisson brackets must all be worked out before we make use of the constraint equations. To remind us of this rule in the formalism, I write the constraints (1-4) as equations with a different equality sign $\approx$ from the usual. Thus they are written

$$\phi_m \approx 0. \tag{1-20}$$

I call such equations weak equations, to distinguish them from the usual or strong equations.

One can make use of (1-20) only after one has worked out all the Poisson brackets which one is interested in. Subject to this rule, the Poisson bracket (1-19) is quite

definite, and we have the possibility of writing our cquations of motion (1-16) in a very concise form:

$$\dot{g} \approx [g, H_T] \tag{1-21}$$

with a Hamiltonian I call the total Hamiltonian,

$$H_T = H + u_m\phi_m. \tag{1-22}$$

Now let us examine the consequences of these cquations of motion. In the first place, there will be some consistency conditions. We have the quantities ϕ which have to be zero throughout all time. We can apply the equation of motion (1-21) or (1-15) taking g to be one of the ϕ 's. We know that $\dot{g}$ must be zero for consistency, and so we get some consistency conditions. Let us see what they are like. Putting $g = \phi_m$ and $\dot{g} = 0$ in (1-15), we have:

$$[\phi_m, H] + u_{m'} [\phi_m, \phi_{m'}] \approx 0 \tag{1-23}$$

We have here a number of consistency conditions, one for each value of m. We must examine these conditions to see what they lead to. It is possible for them to lead directly to an inconsistency. They might lead to the inconsistency $1 = 0$. If that happens, it would mean that our original Lagrangian is such that the Lagrangian equations of motion are inconsistent. One can easily construct an example with just one degree of freedom. If we take $L = q$ then the Lagrangian equation of motion (1-2) gives immediately $1 = 0$. So you see, we cannot take the Lagrangian to be completely arbitrary. We must impose on it the condition that the Lagrangian equations of motion do not involve an inconsistency. With this restriction the equations (1-23) can be divided into three kinds.

One kind of equation reduces to $0 = 0$, i.e. it is identically satisfied, with the help of the primary constraints.

Another kind of equation reduces to an equation independent of the u 's, thus involving only the q 's and the p 's. Such an equation must be independent of the primary constraints, otherwise it is of the first kind. Thus it is of the form

$$\chi(q, p) = 0. \tag{1-24}$$

Finally, an equation in (1-23) may not reduce in either of these ways; it then imposes a condition on the u 's.

The first kind we do not have to bother about any more. Each equation of the second kind means that we have another constraint on the Hamiltonian variables. Constraints which turn up in this way are called secondary constraints. They differ from the primary constraints in that the primary constraints are consequences merely of the equations (1-3) that define the momentum variables, while for the secondary constraints, one has to make use of the Lagrangian equations of motion as well.

If we have a secondary constraint turning up in our theory, then we get yet another consistency condition, because we can work out $\dot{\chi}$ according to the equation of motion (1-15) and we require that $\dot{\chi} \approx 0$. So we get another equation

$$[\chi, H] + u_m [\chi, \phi_m] \approx 0. \tag{1-25}$$

This equation has to be treated on the same footing as (1-23). One must again see which of the three kinds it is. If it is of the second kind, then we have to push the process one stage further because we have a further

[14]

wondary constraint. We carry on like that until we have whausted all the consistency conditions, and the final wsult will be that we are left with a number of secondary constraints of the type (1-24) together with a number of conditions on the coefficients u of the type (1-23).

The secondary constraints will for many purposes be licated on the same footing as the primary constraints. It is convenient to use the notation for them:

$$\phi_k \approx 0, \quad k = M + 1, ..., M + K \tag{1-26}$$

where K is the total number of secondary constraints. They ought to be written as weak equations in the same way as primary constraints, as they are also equations which one must not make use of before one works out Poisson brackets. So all the constraints together may be written as

$$\phi_j \approx 0, \quad j = 1, ..., M + K \equiv \mathscr{F}. \tag{1-27}$$

Let us now go over to the remaining equations of the third kind. We have to see what conditions they impose on the coefficients u. These equations are

$$[\phi_j, H] + u_m [\phi_j, \phi_m] \approx 0 \tag{1-28}$$

where m is summed from 1 to M and j takes on any of the values from 1 to 7 . We have these equations involving conditions on the coefficients u, insofar as they do not reduce merely to the constraint equations.

Let us look at these equations from the following point of view. Let us suppose that the u 's are unknowns and that we have in (1-28) a number of non-homogeneous linear equations in these unknowns u, with coefficients which are functions of the q 's and the p 's. Let us look

[15]

for a solution of these equations, which gives us the u 's as functions of the q 's and the p 's, say

$$u_m = U_m(q, p) \tag{1-29}$$

There must exist a solution of this type, because if there were none it would mean that the Lagrangian equations of motion are inconsistent, and we are excluding that case.

The solution is not unique. If we have one solution, we may add to it any solution $V_m(q,p)$ of the homogeneous equations associated with (1-28):

$$V_m\left[\phi_j, \phi_m\right] = 0 \tag{1-30}$$

and that will give us another solution of the inhomogeneous equations (1-28). We want the most general solution of (1-28) and that means that we must consider all the independent solutions of (1-30), which we may denote by $V_{am}(q,p), a = 1, ..., A$. The general solution of (1-28) is then

$$u_m = U_m + v_a V_{am}, \tag{1-31}$$

in terms of coefficients v_a which can be arbitrary.
Let us substitute these expressions for u into the total Hamiltonian of the theory (1-22). That will give us the total Hamiltonian

$$H_T = H + U_m\phi_m + v_a V_{am}\phi_m \tag{1-32}$$

We can write this as

$$H_T = H' + v_a\phi_a, \tag{1-33}$$

where

$$H' = H + U_m\phi_m \tag{1-33}$$

and

$$\phi_a = V_{am}\phi_m. \tag{1-34}$$

In terms of this total Hamiltonian (1-33) we still have the equations of motion (1-21).

As a result of carrying out this analysis, we have ratisfied all the consistency requirements of the theory and we still have arbitrary coefficients v. The number of the coefficients v will usually be less than the number of coefficients u. The u 's are not arbitrary but have to atisfy consistency conditions, while the v's are arbitrary coefficients. We may take the v's to be arbitrary functions of the time and we have still satisfied all the requirements of our dynamical theory.

This provides a difference of the generalized Hamilonnian formalism from what one is familiar with in clementary dynamics. We have arbitrary functions of the time occurring in the general solution of the equations of motion with given initial conditions. These arbitrary lunctions of the time must mean that we are using a mathematical framework containing arbitrary features, for example, a coordinate system which we can choose in some arbitrary way, or the gauge in electrodynamics. As a result of this arbitrariness in the mathematical framework, the dynamical variables at future times are not completely determined by the initial dynamical variables, and this shows itself up through arbitrary functions appearing in the general solution.

We require some terminology which will enable one to appreciate the relationships between the quantities which occur in the formalism. I find the following terminology useful. I define any dynamical variable, R, a function of the q 's and the p 's, to be first-class if it has zero Poisson brackets with all the ϕ 's:

$$[R, \phi_j] \approx 0, \quad j = 1, ..., \mathscr{F} \tag{1-35}$$

[17]

It is sufficient if these conditions hold weakly. Otherwise R is second-class. If R is first-class, then $[R, \phi_j]$ has to be strongly equal to some linear function of the ϕ 's, as anything that is weakly zero in the present theory is strongly equal to some linear function of the ϕ 's. The ϕ 's are, by definition, the only independent quantities which are weakly zero. So we have the strong equations

$$[R, \phi_j] = r_{jj'}\phi_{j'}. \tag{1-36}$$

Before going on, I would like to prove a
Theorem: the Poisson bracket of two first-class quantities is also first-class. Proof. Let R, S be first-class: then in addition to (1-36), we have

$$[S, \phi_j] = s_{jj'}\phi_{j'} \tag{1-36}$$

Let us form $[[R, S], \phi_j]$. We can work out this Poisson bracket using Jacobi's identity (1-13)

$$\begin{aligned}
[[R, S], \phi_j] &= [[R, \phi_j], S] - [[S, \phi_j], R] \\
&= [r_{jj'}\phi_{j'}, S] - [s_{jj'}\phi_{j'}, R] \\
&= r_{jj'}[\phi_{j'}, S] + [r_{jj'}, S]\phi_{j'} - s_{jj'}[\phi_{j'}, R] \\
&- [s_{jj'}, R]\phi_{j'} \\
&\approx 0
\end{aligned}$$

by (1-36), (1-36)', the product law (1-12), and (1-20). The whole thing vanishes weakly. We have proved therefore that $[R, S]$ is first-class.

We have altogether four different kinds of constraints. We can divide constraints into first-class and secondclass, which is quite independent of the division into primary and secondary.

I would like you to notice that H' given by $(1-33)'$ and

thr ϕ_a given by (1-34) are first-class. Forming the Prisson bracket of ϕ_a with ϕ_j we get, by (1-34), $_{1\ldots}||_m, \phi_j]$ plus terms that vanish weakly. Since the I_{4m} are defined to satisfy ($1-30$), ϕ_a is first-class. immilarly (1-28) with U_m for u_m shows that H' is first– lass. Thus (1-33) gives the total Hamiltonian in terms . 11 a first-class Hamiltonian H' together with some first– hass ϕ 's.

Any linear combination of the ϕ 's is of course another constraint, and if we take a linear combination of the primary constraints we get another primary constraint. io each ϕ_a is a primary constraint; and it is first-class. So the final situation is that we have the total Hamiltomian expressed as the sum of a first-class Hamiltonian plus a linear combination of the primary, first-class constraints.

The number of independent arbitrary functions of the tume occurring in the general solution of the equations of motion is equal to the number of values which the suffix a takes on. That is equal to the number of independent primary first-class constraints, because all the independcut primary first-class constraints are included in the sum (1-33).

That gives you then the general situation. We have deduced it by just starting from the Lagrangian equations of motion, passing to the Hamiltonian and working out consistency conditions.

From the practical point of view one can tell from the general transformation properties of the action integral what arbitrary functions of the time will occur in the general solution of the equations of motion. To each of these functions of the time there must correspond some primary first-class constraint. So we can tell which

primary first-class constraints we are going to have without going through all the detailed calculation of working out Poisson brackets; in practical applications of this theory we can obviously save a lot of work by using that method.

I would like to go on a bit more and develop one further point of the theory. Let us try to get a physical understanding of the situation where we start with given initial variables and get a solution of the equations of motion containing arbitrary functions. The initial variables which we need are the q 's and the p 's. We don't need to be given initial values for the coefficients v. These initial conditions describe what physicists would call the initial physical state of the system. The physical state is determined only by the q 's and the p 's and not by the coefficients τ.

Now the initial state must determine the state at later times. But the q 's and the p 's at later times are not uniquely determined by the initial state because we have the arbitrary functions v coming in. That means that the state does not uniquely determine a set of q 's and p 's, even though a set of q 's and p 's uniquely determines a state. There must be several choices of q 's and p 's which correspond to the same state. So we have the problem of looking for all the sets of q 's and p 's that correspond to one particular physical state.

All those values for the q 's and p 's at a certain time which can evolve from one initial state must correspond to the same physical state at that time. Let us take particular initial values for the q 's and the p 's at time $t = 0$, and consider what the q 's and the p 's are after a short time interval δt. For a general dynamical variable g, with initial value g_0, its value at time δt is

$$\begin{aligned} g(\delta t) &= g_0 + \dot{g}\delta t \\ &= g_0 + [g, H_T]\,\delta t \\ &= g_0 + \delta t\,\{[g, H'] + v_a\,[g, \phi_a]\}\,. \end{aligned} \tag{1-37}$$

The coefficients v are completely arbitrary and at our disposal. Suppose we take different values, v', for these coefficients. That would give a different $g(\delta t)$, the difference being

$$\Delta g(\delta t) = \delta t\,(v_a - v'_a)\,[g, \phi_a] \tag{1-38}$$

We may write this as

$$\begin{aligned} &\Delta g(\delta t) = \varepsilon_a\,[g, \phi_a]\,, \\ \text{where}\quad &\varepsilon_a = \delta t\,(v_a - v'_a) \end{aligned}$$

is a small arbitrary number, small because of the coefficient δt and arbitrary because the v 's and the v 's are arbitrary. We can change all our Hamiltonian variables in accordance with the rule (1-39) and the new Hamiltonian variables will describe the same state. This change in the Hamiltonian variables consists in applying an infinitesimal contact transformation with a generating function $\varepsilon_a\phi_a$. We come to the conclusion that the ϕ_a 's, which appeared in the theory in the first place as the primary first-class constraints, have this meaning: as generating functions of infinitesimal contact transformations, they lead to changes in the q's and the p's that do not affect the physical state.

However, that is not the end of the story. We can go on further in the same direction. Suppose we apply two of these contact transformations in succession. Apply first a contact transformation with generating function

$\varepsilon_a\phi_a$ and then apply a second contact transformation with generating function $\gamma_{a'}\phi_{a'}$, where the gamma's are some new small coefficients. We get finally

$$g' = g_0 + \varepsilon_a [g, \phi_a] + \gamma_{a'} [g + \varepsilon_a [g, \phi_a], \phi_{a'}] . (1 - 41)$$

(I retain the second order terms involving products $\varepsilon\gamma$, but I neglect the second order terms involving ε^2 or involving γ^2. This is legitimate and sufficient. I do that because I do not want to write down more than I really need for getting the desired result.) If we apply the two transformations in succession in the reverse order, w get finally

$$g'' = g_0 + \gamma_{a'} [g, \phi_{a'}] + \varepsilon_a [g + \gamma_{a'} [g, \phi_{a'}], \phi_a] . \quad (1\text{-}42)$$

Now let us subtract these two. The difference is

$$\Delta g = \varepsilon_a \gamma_{a'} \{[[g, \phi_a], \phi_{a'}] - [[g, \phi_{a'}], \phi_a]\} . \quad (1\text{-}43)$$

By Jacobi's identity (1-13) this reduces to

$$\Delta g = \varepsilon_a \gamma_{a'} [g, [\phi_a, \phi_{a'}]] . \quad (1\text{-}44)$$

This Δg must also correspond to a change in the q 's and the p 's which does not involve any change in the physical state, because it is made up by processes which individually don't involve any change in the physical state. Thus we see that we can use

$$[\phi_a, \phi_{a'}] \quad (1\text{-}45)$$

as a generating function of an infinitesimal contact transformation and it will still cause no change in the physical state.

Now the ϕ_a are first-class: their Poisson brackets are walkly zero, and therefore strongly equal to some linear function of the ϕ 's. This linear function of the ϕ 's must low lirst-class because of the theorem I proved a little while back, that the Poisson bracket of two first-class quantities is first-class. So we see that the transformations which we get this way, corresponding to no change in the physical state, are transformations for which the generalong function is a first-class constraint. The only way these transformations are more general than the ones we had before is that the generating functions which we had before are restricted to be first-class primary constraints. Those that we get now could be first-class secondary constraints. The result of this calculation is to show that we might have a first-class secondary constraint as a penerating function of an infinitesimal contact translormation which leads to a change in the q 's and the p 's without changing the state.

For the sake of completeness, there is a little bit of lurther work one ought to do which shows that a Poisson bracket [H', ϕ_a] of the first-class Hamiltonian H' with a first-class ϕ is again a linear function of first-class constraints. This can also be shown to be a possible generator for infinitesimal contact transformations which do not change the state.

The final result is that those transformations of the dynamical variables which do not change physical states are infinitesimal contact transformations in which the generating function is a primary first-class constraint or possibly a secondary first-class constraint. A good many of the secondary first-class constraints do turn up by the process (1-45) or as [H', ϕ_a]. I think it may be that all the first-class secondary constraints should be included

among the transformations which don't change the physical state, but I haven't been able to prove it. Also, I haven't found any example for which there exist first-class secondary constraints which do generate a change in the physical state.

24.5.3 Dirac's Lecture 2: The Problem of Quantization

We were led to the idea that there are certain changes in the p 's and q 's that do not correspond to a change of tate, and which have as generators first-class secondary constraints. That suggests that one should generalize the rquations of motion in order to allow as variation of a dynamical variable g with the time not only any variation piven by (1-21), but also any variation which does not correspond to a change of state. So we should consider a more general equation of motion

$$\dot{g} = [g, H_E] \tag{2-1}$$

with an extended Hamiltonian H_E, consisting of the previous Hamiltonian, H_T, plus all those generators which do not change the state, with arbitrary coefficients:

$$H_E = H_T + v'_{a'}\phi_{a'} \tag{2-2}$$

'l'hose generators $\phi_{a'}$, which are not included already in H_T will be the first-class secondary constraints. The presence of these further terms in the Hamiltonian will give further changes in g, but these further changes in g do not correspond to any change of state and so they should certainly be included, even though we did not

arrive at these further changes of g by direct work from the Lagrangian.

That, then, is the general Hamiltonian theory. The theory as I have developed it applies to a finite number of degrees of freedom but we can easily extend it to the case of an infinite number of degrees of freedom. Our suffix denoting the degree of freedom is $n = 1, ..., N$; we may easily make N infinite. We may further generalize it by allowing the number of degrees of freedom to be continuously infinite. That is to say, we may have as our q 's and p 's variables q_x, p_x where x is a suffix which can take on all values in a continuous range. If we work with this continuous x, then we have to change all our sums over n in the previous work into integrals. The previous work can all be taken over directly with this change.

There is just one equation which we will have to think of a bit differently, the equation which defines the momentum variables,

$$p_n = \frac{dL}{d\dot{q}_n}. \tag{1-3}$$

If n takes on a continuous range of values, we have to understand by this partial differentiation a process of partial functional differentiation that can be made precise in this way: We vary the velocities by $\delta\dot{q}_x$ in the Lagrangian and then put

$$\delta L = \int p_x \delta\dot{q}_x \tag{2-3}$$

The coefficient of $\delta\dot{q}_x$ occurring in the integrand in δL is defined to be p_x.

After giving this general abstract theory, I think it would be a help if I gave a simple example as illustration.

I will take as an example just the electromagnetic field of Maxwell, which is defined in terms of potentials A_μ. The dynamical coordinates now consist of the potentials tor all points of space at a certain time. That is to say, the dynamical coordinates consist of $A_{\mu x}$, where the suffix x a ands for the three coordinates x^1, x^2, x^3 of a point in three-dimensional space at a certain time x^0 (not the lour x 's which one is used to in relativity). We shall have then as the dynamical velocities the time derivatives of the dynamical coordinates, and I shall denote these by a nuffix 0 preceded by a comma.

Any suffix with a comma before it denotes differentiaton according to the general scheme

$$\xi_{,\mu} = \frac{d\xi}{dx^\mu} \tag{2-4}$$

We are dealing with special relativity so that we can raise and lower these suffixes according to the rules of upecial relativity: we have a change in sign if we raise or lower a suffix 1,2 , or 3 but no change of sign when we taise or lower the suffix 0 .

We have as our Lagrangian for the Maxwell electrodynamics, if we work in Heaviside units,

$$L = -\frac{1}{4}\int F_{\mu v}F^{\mu y}d^3x \tag{2-5}$$

Here d^3x means $dx^1dx^2dx^3$, the integration is over three-dimensional space, and $F_{\mu\nu}$ means the field quantities defined in terms of the potentials by

$$F_{\mu v} = A_{v,\mu} - A_{\mu,v}. \tag{2-6}$$

This L is the Lagrangian because its time integral is the action integral of the Maxwell field.

Let us now take this Lagrangian and apply the rules of our formalism for passing to the Hamiltonian. We first of all have to introduce the momenta. We do that by varying the velocities in the Lagrangian. If we vary the velocities, we have

$$\begin{aligned}\delta L &= -\frac{1}{2}\int F^{\mu v}\delta F_{\mu v}d^3x \\ &= \int F^{\mu 0}\delta A_{\mu,0}d^3x\end{aligned} \tag{2-7}$$

Now the momenta B^μ are defined by

$$\delta L = \int B^\mu \delta A_{\mu 0}d^3x \tag{2-8}$$

and these momenta will satisfy the basic Poisson bracket relations

$$[A_{ux}, B^v_{x'}] = g^v_\mu \delta^3(x - x')\,; \quad \mu, \nu = 0, 1, 2, 3. \tag{2-9}$$

In this formula A is taken at a point x in three-dimensional space and B is taken at a point x' in the threedimensional space. g^ν_μ is just the Kronecker delta function. $\delta^3(x - x')$ is the three-dimensional delta function of $x - x'$.

We compare the two expressions (2-7) and (2-8) for δL and that gives us

$$B^\mu = F^{\mu 0} \tag{2-10}$$

Now $F^{\mu v}$ is anti-symmetrical

$$F^{\mu v} = -F^{\nu\mu} \tag{2-11}$$

So if we put $\mu = 0$, in (2-10) we get zero. Thus B^0_x is
equal to zero. This is a primary constraint. I write it as a weak equation:

$$B^0_x \approx 0 \tag{2-12}$$

The other three momenta $B^r (r = 1, 2, 3)$ are just equal to the components of the electric field.

I should remind you that (2-12) is not just one primary constraint: there is a whole threefold infinity of primary constraints because there is the suffix x which stands for some point in three-dimensional space; and each value for x will give us a different primary constraint.

Let us now introduce the Hamiltonian. We define that in the usual way by

$$\begin{aligned} H &= \int B^{\mu} A_{\mu,0} d^3x - L \\ &= \int \left(F^{r0} A_{r,0} + \frac{1}{4} F^{rs} F_{rs} + \frac{1}{2} F^{r0} F_{r0} \right) d^3x \\ &= \int \left(\frac{1}{4} F^{rs} F_{rs} - \frac{1}{2} F^{r0} F_{r0} + F^{r0} A_{0,r} \right) d^3x \\ &= \int \left(\frac{1}{4} F^{rs} F_{rs} + \frac{1}{2} B^r B^r - A_0 B^r_{\ r} \right) d^3x \end{aligned} \tag{2-13}$$

I've done a partial integration of the last term in (2-13) to get it in this form. Now here we have an expression for the Hamiltonian which does not involve any velocities. It involves only dynamical coordinates and momenta. It is true that F_{rs} involves partial differentiations of the potentials, but it involves partial differentiations only with respect to x^1, x^2, x^3. That does not bring in any velocities. These partial derivatives are functions of the dynamical coordinates.

We can now work out the consistency conditions by

using the primary constraints (2-12). Since they have to remain satisfied at all times, $[B^0, H]$ has to be zero. This leads to the equation

$$B^r_{\ ,r} \approx 0 \tag{2-14}$$

This is again a constraint because there are no velocities occurring in it. This is a secondary constraint, which appears in the Maxwell theory in this way. If we proceed further to examine the consistency relations, we must work out

$$\left[B^r_{\ ,r}, H \right] = 0 \tag{2-15}$$

We find that this reduces to $0 = 0$. It does not give us anything new, but is automatically satisfied. We have therefore obtained all the constraints in our problem. (2-12) gives the primary constraints. (2-14) gives the secondary constraints.

We now have to look to see whether they are first-class or second-class, and we easily see that they are all firstclass. The B_0 are momenta variables. They all have zero Poisson brackets with each other. $B^r_{\ ,r}$ and B_0 also have zero Poisson brackets with each other. And B^r_{rx} and $B^r_{r,x'}$ also have zero Poisson brackets with cach other. All these quantities are therefore first-class constraints. There are no second-class constraints occurring in the Maxwell electrodynamics.

The expression (2-13) for H is first-class, so this H can be taken as the H' of (1-33). Let us now see what the total Hamiltonian is:

$$\begin{aligned} H_T = \int \left(\frac{1}{4} F^{rs} F_{rs} + \frac{1}{2} B_r B_r \right) d^3x - \int A_0 B^r_{\ ,r} d^3x \\ + \int v_x B^0 d^3x \end{aligned} \tag{2-16}$$

[30]

This v_x is an arbitrary coefficient for each point in threedimensional space. We have just added on the primary first-class constraints with arbitrary coefficients, which is what we must do according to the rules to get the total Hamiltonian.

In terms of the total Hamiltonian we have the equation of motion in the standard form

$$\dot{g} \approx [g, H_T] \tag{1-21}$$

The g which we have here may be any field quantity at some point x in three-dimensional space, or may also be a function of field quantities at different points in threedimensional space. It could, for example, be an integral over three-dimensional space. This g can be perfectly generally any function of the q 's and the p 's throughout three-dimensional space.

It is permissible to take $g = A_0$ and then we get

$$A_{0,0} = v \tag{2-17}$$

because A_0 has zero Poisson brackets with everything except the B_0 occurring in the last term of (2-16). This gives us a meaning for the arbitrary coefficient v_x occurring in the total Hamiltonian. It is the time derivative of A_0.

Now to get the most general motion which is physically permissible, we ought to pass over to the extended llamiltonian. To do this we add on the first-class mecondary constraints with arbitrary coefficients u_x. This gives the extended Hamiltonian:

$$H_E = H_T + \int u_x B^r_{,r} d^3x \tag{2-18}$$

Bringing in this extra term into the Hamiltonian allows

a more general motion. It gives more variation of the q 's and the p 's, of the nature of a gauge transformation. When this additional variation of the q 's and the p 's is brought in, it leads to a further set of q 's and p 's which must correspond to the same state.

That is the result of working out, according to our rules, the Hamiltonian form of the Maxwell theory. When we've got to this stage, we see that there is a certain simplification which is possible. This simplification comes about because the variables A_0, B_0 are not of any physical significance. Let us see what the equations of motion tell us about A_0 and B_0.$B_0 = 0$ all the time. That is not of interest. A_0 is something whose time derivative is quite arbitrary. That again is something which is not of interest. The variables A_0 and B_0 are therefore not of interest at all. We can drop them out from the theory and that will lead to a simplified Hamiltonian formalism where we have fewer degrees of freedom, but still retain all the degrees of freedom which are physically of interest.

In order to carry out this discard of the variables A_0 and B_0, we drop out the term $v_x B^0$ from the Hamiltonian. This term merely has the effect of allowing A_0 to vary arbitrarily. The term - $A_0 B^r_{,r}$ in H_T can be combined with the $u_x B^r_{,r}$ in the extended Hamiltonian. The coefficient u_x is an arbitrary coefficient in any case. When we combine these two terms, we just have this u_x replaced by $u'_x = u_x - A_0$ which is equally arbitrary. So that we get a new Hamiltonian

$$H = \int \left(\frac{1}{4} F^{rs} F_{rs} + \frac{1}{2} B_r B_r \right) d^3x + \int u'_x B^r_{,r} d^3x \tag{2-19}$$

This Hamiltonian is sufficient to give the equations of motion for all the variables which are of physical interest. The variables A_0, B_0 no longer appear in it. This is the Hamiltonian for the Maxwell theory in its simplest form.

Now the usual Hamiltonian which people work with in quantum electrodynamics is not quite the same as that. The usual one is based on a theory which was originally set up by Fermi. Fermi's theory involves putting this restriction on the potentials:

$$A^\mu_{,\mu} = 0. \tag{2-20}$$

It is quite permissible to bring in this restriction on the gauge. The Hamiltonian theory which I have given here does not involve this restriction, so that it allows a completely general gauge. It's thus a somewhat different formalism from the Fermi formalism. It's a formalism which displays the full transforming power of the Maxwell theory, which we get when we have

completely general changes of gauge. This Maxwell theory gives us an illustration of the general ideas of primary and "condary constraints.

I would like now to go back to general theory and to consider the problem of quantizing the Hamiltonian theory. To discuss this question of quantization, let us lirst take the case when there are no second-class constraints, when all the constraints are first-class. We make our dynamical coordinates and momenta, the q 's ...nd p 's, into operators satisfying commutation relations which correspond to the Poisson bracket relations of the classical theory. That is quite straightforward. Then we ut up a Schrödinger equation

$$i\hbar\frac{d\psi}{dt} = H'\psi. \tag{2-21}$$

ψ is the wave function on which the q 's and the p 's operate. H' is the first-class Hamiltonian of our theory.

We further impose certain supplementary conditions on the wave function, namely:

$$\phi_j\psi = 0 \tag{2-22}$$

Each of our constraints thus leads to a supplementary condition on the wave function. (The constraints, remember, are now all first-class.)

The first thing we have to do now is to see whether these equations for ψ are consistent with one another. Let us take two of the supplementary conditions and see whether they are consistent. Let us take (2-22) and

$$\phi_{j'}\psi = 0 \tag{2-22}$$

If we multiply (2-22) by $\phi_{j'}$, we get

$$\phi_{j'}\phi_j\psi = 0 \tag{2-23}$$

If we multiply $(2-22)'$ by ϕ_j, we get

$$\phi_j\phi_{j'}\psi = 0. \tag{2-23}$$

If we now subtract these two equations, we get:

$$[\phi_j, \phi_{j'}]\,\psi = 0 \tag{2-24}$$

This further condition on ψ is necessary for consistency. Now we don't want to have any fresh conditions on ψ. We want all the conditions on ψ to be included among (2-22). That means to say, we want to have (2-24) a consequence of (2-22) which means we require

$$[\phi_j, \phi_{j'}] = c_{jj'j''}\phi_{j''}. \tag{2-25}$$

[34]

If (2-25) does hold, then (2-24) is a consequence of (2-22) and is not a new condition on the wave function.

Now we know that the ϕ 's are all first-class in the classical theory, and that means that the Poisson bracket of any two of the ϕ 's is a linear combination of the ϕ 's in the classical theory. When we go over to the quantum theory, we must have a similar equation holding for the commutator, but it does not necessarily follow that the coefficients c are all on the left. We need to have these coefficients all on the left, because the c 's will in general be functions of the coordinates and momenta and will not commute with the ϕ 's in the quantum theory, and (2-24) will be a consequence of (2-22) only provided the c's are all on the left.

When we set up the quantities ϕ in the quantum theory, there may be some arbitrariness coming in. The corresponding classical expressions may involve quantities which don't commute in the quantum theory and then we have to decide on the order in which to put the lactors in the quantum theory. We have to try to arrange the order of these factors so that we have (2-25) holding with all the coefficients on the left. If we can do that, then we have the supplementary conditions all consistent with each other. If we cannot do it, then we are out of luck and we cannot make an accurate quantum theory. In any case we have a first approximation to the quantum theory, because our equations would be all right if we look at them only to the order of accuracy of Planck's constant $\hbar$ and neglect quantities of order $\hbar^2$.

I have just discussed the requirements for the supplementary conditions to be consistent with one another. There is a similar discussion needed in order to check that the supplementary conditions shall be consistent

with the Schrödinger equation. If we start with a ψ satisfying the supplementary conditions (2-24) and let that ψ vary with the time in accordance with the Schrödinger equation, then after a lapse of a short interval of time will our ψ still satisfy the supplementary conditions? We can work out the requirement for that to be the case and we get

$$[\phi_j, H]\,\psi = 0 \tag{2-26}$$

which means that $[\phi_j, H]$ must be some linear function of the ϕ 's :

$$[\phi_j, H] = b_{jj'}\phi_{j'} \tag{2-27}$$

if we are not to get a new supplementary condition. Again we have an equation which we know is all right in the classical theory. ϕ_j and H are both first-class, so their Poisson bracket vanishes weakly. The Poisson bracket is thus strongly equal to some linear function of the ϕ 's in the classical theory. Again we have to try to arrange things so that in the corresponding quantum equation we have all our coefficients on the left. That is necessary to get an accurate quantum theory, and we need a bit of luck, in general, in order to be able to bring it about.

Let us now consider how to quantize a Hamiltonian theory in which there are second-class constraints. Let us think of this question first in terms of a simple example. We might take as the simplest example of two second-class constraints

$$q_1 \approx 0 \text{ and } p_1 \approx 0 \tag{2-28}$$

If we have these two constraints appearing in the theory, then their Poisson bracket is not zero, so they

are second-class. What can we do with them when we go over to the quantum theory? We cannot impose (2-28) as supplementary conditions on the wave function as we did with the first-class constraints. If we try to put $q_1\psi = 0, p_1\psi = 0$, then we should immediately get a contradiction because we should have $(q_1p_1 - p_1q_1)\,\psi = i\hbar\psi = 0$. So that won't do. We must adopt some different plan.

Now in this simple case it's pretty obvious what the plan must be. The variables q_1 and p_1 are not of interest if they are both restricted to be zero. So the degree of freedom 1 is not of any importance. We can just discard the degree of freedom 1 and work with the other degrees of freedom. That means a different definition for a Poisson bracket. We should have to work with a definition of a Poisson bracket in the classical theory

$$[\xi, \eta] = \frac{\partial\xi}{\partial q_n}\frac{\partial\eta}{\partial p_n} - \frac{\partial\xi}{\partial p_n}\frac{\partial\eta}{\partial q_n} \quad \text{summed over } n = 2, \ldots N. \tag{2-29}$$

This would be sufficient because it would deal with all the variables which are of physical interest. Then we could just take q_1 and p_1 as identically zero. There's no contradiction involved

there, and we can pass over to the quantum theory, setting it up in terms only of the degrees of freedom $n = 2, ..., N$.

In this simple case it is fairly obvious what we have to do to build up a quantum theory. Let us try now to generalize it. Suppose we have $p_1 \approx 0, q_1 \approx f(q_r, p_r)$, $r = 2, ..., N$, so f is any function of all the other q 's and p 's. We could drop out the number 1 degree of freedom if we substitute $f(q_r, p_r)$ for q_1 in the Hamiltonian and in all the other constraints. Again we can forget

about the number 1 degree of freedom and simply work with the other degrees of freedom and pass over to a quantum theory in these other degrees of freedom. Again we should have to work with the (2-29) kind of Poisson bracket, referring only to the other degrees of freedom.

That is the idea which one uses for quantizing a theory which involves second-class constraints. The existence of second-class constraints means that there are some degrees of freedom which are not physically important. We have to pick out these degrees of freedom and set up new Poisson brackets referring only to the other degrees of freedom which are of physical importance. Then in terms of those new Poisson brackets we can pass over to the quantum theory. I would like to discuss a general procedure for carrying that out.

For the present, we are going back to the classical theory. We have a number of constraints $\phi_j \approx 0$, some of them first-class, some second-class. We can replace these constraints by independent linear combinations of them, which will do just as well as the original constraints. We try to arrange to take the linear combinations in such a way as to have as many constraints as possible brought into the first class. There may then be some left in the second class which we just cannot bring into the first class by taking linear combinations of them. Those which are left in the second class I will call χ_s, $s = 1, ..., S$ is the number of second-class constraints which are such that no linear combination of them is first-class.

We take these surviving second-class constraints and we form all their Poisson brackets with each other and arrange these Poisson brackets as a determinant Δ :

THE PROBLEM OF QUANTIZATION

$$\Delta = \begin{vmatrix} 0 & [\chi_1, \chi_2] & [\chi_1, \chi_3] & \cdots & [\chi_1, \chi_S] \\ [\chi_2, \chi_1] & 0 & [\chi_2, \chi_3] & \cdots & [\chi_2, \chi_S] \\ \vdots & \vdots & \vdots & & \vdots \\ [\chi_S, \chi_1] & [\chi_S, \chi_2] & [\chi_S, \chi_3] & \cdots & \vdots \end{vmatrix}$$

I would like now to prove a

Theorem: The determinant Δ does not vanish, not even weakly. Proof: Assume that the determinant does vanish. I'm going to show that we get a contradiction. If the determinant vanishes, then it is of some rank $T < S$. Now let us set up the determinant A :

$$A = \begin{vmatrix} \chi_1 & 0 & [\chi_1, \chi_2] & \cdots & [\chi_1, \chi_T] \\ \chi_2 & [\chi_2, \chi_1] & 0 & & [\chi_2, \chi_T] \\ \vdots & \vdots & \vdots & & \vdots \\ \chi_{T+1} & [\chi_{T+1}, \chi_1] & [\chi_{T+1}, \chi_2] & \cdots & [\chi_{T+1}, \chi_T] \end{vmatrix}$$

1 has $T + 1$ rows and columns. $T + 1$ might equal S or might be less than S. If we expand A in terms of the clements of its first column, we will get each of these dements multiplied into one of the sub-determinants of 1. Now I don't want all of these sub-determinants to vanish. It might so happen that they do all vanish. And in that case, I would choose the χ 's which are referred to mong the rows and columns of A in a different way. There must always be some way of choosing the χ 's which occur in A so that the sub-determinants don't all valuish, because Δ is of rank T. So we choose the χ 's in auch a way that the coefficients of the elements in the first column are not all zero.

Now I will show that A has zero Poisson brackets with ....y of the ϕ 's. If we form the Poisson bracket of ϕ with 'determinant, we get the result by forming the Poisson bracket of ϕ with the first column of the determinant, adding on the result of forming the Poisson bracket of ϕ with the second column of the determinant, and so on. Thus

$$
\begin{aligned}
[\phi, A] = &\begin{vmatrix} [\phi,\chi_1] & 0 & \cdots \\ [\phi,\chi_2] & [\chi_2,\chi_1] & \cdots \\ \vdots & \vdots & \\ [\phi,\chi_{T+1}] & [\chi_{T+1},\chi_1] & \cdots \end{vmatrix} \\
&+ \begin{vmatrix} \chi_1 & 0 & \cdots \\ \chi_2 & [\phi,[\chi_2,\chi_1]] & \cdots \\ \vdots & \vdots & \\ \chi_{T+1} & [\phi,[\chi_{T+1},\chi_1]] & \cdots \end{vmatrix} \\
&+ \begin{vmatrix} \chi_1 & 0 & [\phi,[\chi_1,\chi_2]] & \cdots \\ \chi_2 & [\chi_2,\chi_1] & 0 & \cdots \\ \vdots & \vdots & \vdots & \\ \chi_{T+1} & [\chi_{T+1},\chi_1] & [\phi,[\chi_{T+1},\chi_2]] & \cdots \end{vmatrix} + \cdots
\end{aligned}
$$

This looks rather complicated, but one can easily see that every one of these determinants vanishes. In the first place, the first determinant on the right vanishes: if ϕ is first class, then the first column vanishes; if ϕ is second class, then ϕ is one of the χ 's and we have a determinant which is a part of the determinant Δ with $T+1$ rows and columns. But Δ is assumed to be of rank T, so that any part of it with $T+1$ rows and columns vanishes. Now, the second determinant on the right vanishes weakly because the first column vanishes weakly. Similarly all the other determinants vanish weakly. The result is that the whole right-hand side vanishes weakly.

Thus A is a quantity whose Poisson bracket with every one of the ϕ 's vanishes weakly.

Also, we can expand the determinant A in terms of the elements of the first column, and get A as a linear combination of the χ 's. So we have the result that a certain linear combination of the χ 's has zero Poisson brackets with all the ϕ 's. That means that this linear combination of the χ 's is first class. That contradicts our assumption that we have put as many χ 's as possible into the first class. That proves the theorem.

Incidentally, we see that the number of surviving χ 's, which cannot be brought into the first class, must be even, because the determinant Δ is antisymmetrical. Any antisymmetrical determinant with an odd number of rows and columns vanishes. This one doesn't vanish and therefore must have an even number of rows and columns.

Because this determinant, Δ, doesn't vanish, we can bring in the reciprocal $c_{ss'}$ of the matrix whose determinant is Δ. We define the matrix $c_{ss'}$ by

$$c_{ss'}\,[\chi_{s'},\chi_{s'}] = \delta_{ss''} \tag{2-30}$$

We now define new Poisson brackets in accordance with this formalism: any two quantities ξ, η have a new Poisson bracket defined by

$$[\xi,\eta]^* = [\xi,\eta] - [\xi,\chi_s]\,c_{ss'}\,[\chi_{s'},\eta]\,. \tag{2-31}$$

It is easy to check that new Poisson brackets defined in this way satisfy the laws which Poisson brackets usually satisfy: $[\xi,\eta]^*$ is antisymmetrical between ξ and η, is linear in ξ, is linear in η, satisfies the product law $[\xi_1\xi_2,\eta]^* = \xi_1\,[\xi_2\eta]^* + [\xi_1,\eta]^*\,\xi_2$, and obeys the Jacobi identity $[[\xi,\eta]^*,\zeta]^* + [[\eta,\zeta]^*\xi]^* + [[\zeta,\xi]^*,\eta]^* = 0$.

I don't know of any neat way of proving the Jacobi identity for the new Poisson brackets. If one just substitutes according to the definition and works it out in a complicated way, one does find that all the terms cancel out and that the left-hand side equals zero. I think there ought to be some neat way of proving it, but I haven't been able to find it. The straightforward method I have given in the Canadian Journal of Mathematics, 2, 147 (1950). The problem has been dealt with by Bergmann, Physical Review, 98, 531 (1955).

Now let us see what we can do with these new Poisson brackets. First of all, I would like you to notice that the equations of motion are as valid for the new Poisson brackets as for the original ones.

$$\begin{aligned}[g, H_T]^* &= [g, H_T] - [g, \chi_s]\, c_{ss'}\, [\chi_{s'}, H_T] \\ &\approx [g, H_T]\end{aligned}$$

because the terms $[\chi_{s'}, H_T]$ all vanish weakly on account of H_T being first-class. Thus we can write

$$\dot{g} \approx [g, H_T]^* .$$

Now if we take any function ξ whatever of the q 's and p 's, and form its new Poisson bracket with one of the χ 's, say $\chi_{s''}$, we have

$$\begin{aligned}[\xi, \chi_{s''}]^* &= [\xi, \chi_{s''}] - [\xi, \chi_s]\, c_{ss'}\, [\chi_{s'}, \chi_{s''}] \\ &= [\xi, \chi_{s''}] - [\xi, \chi_s]\, \delta_{ss''} \quad \text{by } (2-30) \\ &= 0\end{aligned}$$

Thus we can put the χ 's equal to 0 before working out new Poisson brackets. This means that the equation

$$\chi_s = 0 \tag{2-32}$$

may be considered as a strong equation.

[42]

We modify our classical theory in this way, bringing in these new Poisson brackets, and this prepares the ground for passing to the quantum theory. We pass over to the quantum theory by taking the commutation relations to correspond to the new Poisson bracket relations and taking the strong equations (2-32) to be cquations between operators in the quantum theory. The remaining weak equations, which are all first class, become again supplementary conditions on the wave functions. The situation is then reduced to the previous case where there were only first-class ϕ 's. We have again, therefore, a method of quantizing our general classical Hamiltonian theory. Of course, we again need a bit of luck in order to arrange that the coefficients are all on the left in the consistency conditions.

That gives the general method of quantization. You notice that when we have passed over to the quantum theory, the distinction between primary constraints and secondary constraints ceases to be of any importance. The distinction between primary and secondary constraints is not a very fundamental one. It depends very much on the original Lagrangian which we start off with. Once we have gone over to the Hamiltonian formalism, we can really forget about the distinction between primary and secondary constraints. The distinction between first-class and second-class constraints is very important. We must put as many as possible into the first class and bring in new Poisson brackets which cnable us to treat the surviving second-class constraints as strong.

24.5.4 Dirac's Lecture 3: Quantization on Curved Surfaces

We started off with a classical action principle. We took our action integral to be Lorentz-invariant. This action gives us a Lagrangian. We then passed from the Lagrangian to the Hamiltonian, and then to the quantum theory by following through certain rules. The result is that, starting with a classical field theory, described by an action principle, we end up with a quantum field theory. Now you might think that that finishes our work, but there is one important problem still to be considered: whether our quantum field theory obtained in this way is a relativistic theory. For the purposes of discussion, we may confine ourselves to special relativity. We have then to consider whether our quantum theory is in agreement with special relativity.

We started from an action principle and we required that our action should be Lorentz-invariant. That is sufficient to ensure that our classical theory shall be relativistic. The equations of motion that follow from a Lorentz invariant action principle must be relativistic equations. It is true that when we put these equations of motion into the Hamiltonian form, we are disturbing
the four-dimensional symmetry. We are expressing our equations in the form

$$\dot{g} \approx [g, H_T]\,. \tag{1-21}$$

The dot here means dg/dt and refers to one absolute time, so that the classical equations of motion in the Hamiltonian form are not manifestly relativistic, but we know that they must be relativistic in content because they follow from relativistic assumptions.

However, when we pass over to the quantum theory we are making new assumptions. The expression for H_T which we have in the classical theory does not uniquely determine the quantum Hamiltonian. We have to decide questions about the order in which to put non-commuting factors in the quantum theory. We have something at our disposal in choosing this order, and so we are making new assumptions. These new assumptions may disturb the relativistic invariance of the theory, so that the quantum field theory obtained by this method is not necessarily in agreement with relativity. We now have to face the problem of seeing how we can ensure that our quantum theory shall be a relativistic theory.

For that purpose we have to go back to first principles. It is no longer sufficient to consider just one time variable referring to one particular observer; we have to consider different observers moving relatively to one another. We must set up a quantum theory which applies equally to any of these observers, that is, to any time axis. To get a theory involving all the different time axes, we should first get the corresponding classical theory and then pass from this classical theory to the quantum theory by the standard rules.

I would like to go back to the beginning of our

Hamiltonian development and consider a special case. We started our development by taking a Lagrangian L, which is a function of dynamical coordinates and velocities $q, \dot{q}$, introducing the momenta, then introducing the Hamiltonian. Let us take the special case when L is homogeneous of the first degree in the q 's. Then Euler's Theorem tells us that

$$\dot{q}_n \frac{\partial L}{\partial \dot{q}_n} = L \tag{3-1}$$

That just tells us that $p_n \dot{q}_n - L = 0$. Thus we get in this special case a Hamiltonian that is zero.

We necessarily get primary constraints in this case. There must certainly be one primary constraint, because the p 's are homogeneous functions of degree zero in the velocities. The p 's are thus functions only of the ratios of the velocities. The number of p 's is equal to N, the number of degrees of freedom, and the number of ratios of the velocities is $N - 1$. N functions

of $N-1$ ratios of the velocities cannot be independent. There must be at least one function of the p 's and q 's which is equal to zero; there must be at least one primary constraint. There may very well be more than one. One can also see that, if we are to have any motion at all with a zero Hamiltonian, we must have at least one primary first-class constraint.

We have the expression (1-33) for the total Hamiltonian

$$H_T = H' + v_a\phi_a.$$

H' must be a first-class Hamiltonian, and as 0 is certainly a first-class quantity we may take $H' = 0$. Our total

Ilamiltonian is now built up entirely from the primary first-class constraints with arbitrary coefficients:

$$H_T = v_a\phi_a \tag{3-2}$$

showing that there must be at least one primary firstclass constraint if we are to have any motion at all.

Our equations of motion now read like this:

$$\dot{g} \approx v_a\,[g, \phi_a]$$

We can see that the $\dot{g}$'s may all be multiplied by a factor because, since the coefficients v are arbitrary, we may multiply them all by a factor. If we multiply all the dg/dt 's by a factor, it means that we have a different time scale. So we have now Hamiltonian equations of motion in which the time scale is arbitrary. We could introduce another time variable τ instead of t and use τ to give us equations of motion

$$\frac{dg}{d\tau} \approx v'_a\,[g, \phi_a] \tag{3-3}$$

So we have now a Hamiltonian scheme of equations of motion in which there is no absolute time variable. Any variable increasing monotonically with t could be used as time and the equations of motion would be of the same form. Thus the characteristic of a Hamiltonian theory where the Hamiltonian H' is zero and where every Hamiltonian is weakly equal to zero, is that there is no absolute time.

We may look at the question also from the point of view of the action principle. If I is the action integral, then

$$I = \int L(q, \dot{q})dt = \int L\left(q, \frac{dq}{d\tau}\right)d\tau \tag{3-4}$$

bed use L is homogeneous of the first degree in ti. dq/l^t. So we can express the action integral with respe. to [in] the same form as with respect to t. That show that the equations of motion which follow from the action pris [ciple] must be invariant under the passage from t to τ. The equations of motion do not refer to any absolute tim.

ve have thus a special form of Hamiltonian theory but [in] fact this form is not really so special because, star ing with any Hamiltonian, it is always permissible to ake the time variable as an extra coordinate and brif the theory into a form in which the Hamiltonian is weady equal to zero. The general rule for doing this is the following: we take t and put it equal to another dyn [mical] coordinate q_0. We set up a new Lagrangian

$$L^* = \frac{dq_0}{d\tau} L\left(q, \frac{dq/d\tau}{dq_0/d\tau}\right)$$
$$= L^*\left(q_k, \frac{dq_k}{d\tau}\right), \quad k = 0, 1, 2, ..., N(\tag{3-5}$$

L^* avolves one more degree of freedom than the original L.1* is not equal to L but

$$\int L^* d\tau = \int L dt$$

Thi the action is the same whether it refers to L^* and τ of to L and t. So for any dynamical system we can trea $^{\text{the time as an extra coordinate}}$ q_0 and then pass to a $\mathrm{n}^{\mathbb{N}}$ Lagrangian L^*, involving one extra degree of free $^{\text{om}}$ and homogeneous of the first degree in the veloties. L^* gives us a Hamiltonian which is weakly equ to zero.
T^{is} special case of the Hamiltonian formalism where

Ur llamiltonian is weakly equal to zero is what we need In a relativistic theory, because in a relativistic theory wr don't want to have one particular time playing a elucial role; we want to have the possibility of various turnes τ which are all on the same footing. Let us see in detail how we can apply this idea.

We want to consider states at specified times with (w) pect to different observers. Now if we set up a spacetome picture as in Fig. 1, the state at a certain time refers (1) the physical conditions on a three-dimensional flat arace-like surface S_1 which is orthogonal to the time axis. The state at different times will refer to physical conditions on different surfaces $S_2, S_3, ...$ Now we want to bring in other time axes referring to different observers and the state, with respect to the other time .xes, will involve physical conditions on other flat upace-like surfaces like S_1'. We want to have a Hamiltonban theory which will enable us to pass from the state, S_1 say, to the state S_1'. Starting off with given initial conditions on the surface S_1 and applying the equations of motion, we must be able to pass over to the physical conditions on the surface S_1^f. There must thus be four freedoms in the motion of a state, one freedom corresponding to the movement of the surface parallel to itself, then three more freedoms corresponding to a general change of direction of this flat surface. That means that there will be four arbitrary functions occurring in the solution of the equations of motion which we are trying to get. So we need a Hamiltonian theory with (at least) four primary first-class constraints.

There may be other primary first-class constraints if there are other kinds of freedom in the motion, for example, if we have the possibility of the gauge

LECTURES ON QUANTUM MECHANICS

transformations of electrodynamics. To simplify the discussion, I will ignore this possibility of other firstclass primary constraints, and consider only the ones which arise from the requirements of relativity.

We could proceed to set up our theory referring to these flat space-like surfaces which can move with the four freedoms, but I would like first to consider a more

Figure 2

general theory in which we consider a state to be defined on an arbitrary curved space-like surface, such as S of Fig. 2. This represents a three-dimensional surface in space-time which has the property of being everywhere space-like, that is to say, the normal to the surface must lie within the light-cone. We may set up a Hamiltonian theory which tells us how the physical conditions

vary when we go from one of the curved space-like surfaces to a neighboring one.

Now, bringing in the curved surfaces means bringing in something which is not necessary from the point of view of special relativity. If we wanted to bring in general relativity and

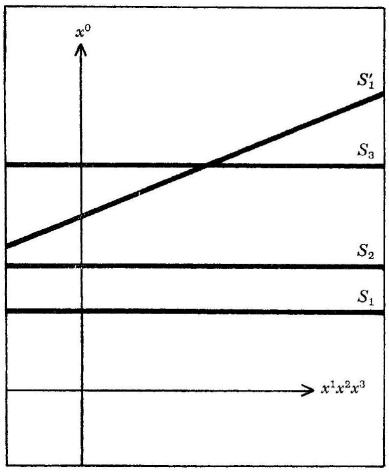

Figure 1

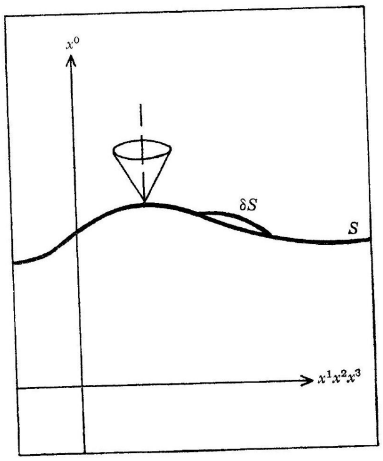


gravitational fields, then it would be essential to work with these curved surfaces, but for special relativity, the curved surfaces are not essential. However, I like to bring them in at this stage, even for the discussion of a theory in special relativity, because I find it easier to explain the basic ideas with reference to these curved surfaces than with reference to the flat surfaces. The reason is that with these curved surfaces we can make local deformations of the surface like δS in Fig. 2, and discuss the equations of motion with respect to these local deformations of the surface.

One way of proceeding now would be to refer our action integral to a set of curved surfaces, like S, take the amount of action between two neighboring curved surfaces, divide it by some parameter $\delta\tau$ expressing the distance between these two surfaces, take this amount of action as our Lagrangian, then apply our standard method of passing from the Lagrangian to the Hamiltonian. Our Lagrangian would necessarily be homogeneous of the first degree in the velocities with respect to the time parameter τ which specifies the passage from one of these space-like surfaces to a neighboring one, and it would lead to a Hamiltonian theory for which the Hamiltonian is weakly equal to zero.

However, I don't want to go through all the work of following through in detail what we get from an action principle. I want to short-circuit that work and discuss the form of the final Hamiltonian theory which results.

We can get quite a lot of information about the form of this Hamiltonian theory just from our knowledge that there must be freedom for the space-like surface to move arbitrarily so

long as it remains always space-like. This freedom of motion of the space-like surface must correspond to first-class primary constraints in the Hamiltonian, there being one primary first-class constraint for each type of elementary motion of the surface which can be set up. I shall develop the theory from that point of view.

First of all we have to introduce suitable dynamical variables. Let us describe a point on the space-like surface S by three curvilinear coordinates $(x^1, x^2, x^3) = (x^r)$. In order to fix the position of this space-like surface in space-time, we introduce another set of coordinates $y_A (\Lambda = 0, 1, 2, 3)$, which we may take to be rectilinear, orthogonal coordinates in special relativity. (I use a capital suffix for referring to the y coordinate system and a small suffix such as r for referring to the x coordinate system.) The four functions y_A, of x^r, will specify the surface S in space time and will also specify its parameterization, i.e. the system of coordinates x^1, x^2, x^3.

We can use these y_A as dynamical coordinates, q 's. If we form

$$y_{\Lambda,r} = \frac{\partial y_\Lambda}{\partial x^r}, \quad (r = 1, 2, 3) \tag{3-6}$$

this is a function of the q 's, the dynamical coordinates.

$$\dot{y}_\Lambda = \frac{\partial y_\Lambda}{\partial \tau} \tag{3-7}$$

τ being the parameter changing from one surface to the neighboring surface, will be a velocity, a $\dot{q}$. Thus y_A are the dynamical coordinates needed for describing the surface and $\dot{y}_A$ are the velocities.

We shall need to introduce momentum variables w_A conjugate to these dynamical coordinates. The momentum variables will be connected with the coordinates by the Poisson bracket relations

$$[y_{Ax}, w_{\Gamma x'}] = g_{A\Gamma} \delta^3 (x - x') . \tag{3-8}$$

We shall need other variables for describing any physical fields which occur in the problem. If we are dealing with a scalar field V, then $V(x)$ for all values of x^1, x^2, x^3 will provide us with further dynamical coordinates, q 's. $V_{,r}$ will be functions of the q 's. $\partial V/\partial \tau$ will be a velocity. The derivative of V in any direction is expressible of terms of $\hat{\varepsilon} V/\hat{c}\tau$ and $V_{,r}$ and so is expressible in terms of the dynamical coordinates and velocities. The Lagrangian will involve these V 's differentiated in general directions and is thus a function of the dynamical coordinates and velocities. For each V, we shall need a conjugate momentum U, satisfying the Poisson bracket conditions

$$[V(x), U(x')] = \delta^3 (x - x') . \tag{3-9}$$

That is how one would treat a scalar field. There is a similar method for vector, tensor, or spinor fields, just bringing in the necessary additional suffixes. I need not go into that.

Now let us see what the Hamiltonian will be like. The Hamiltonian has to be a linear function of primary first-class constraints of the type (3-2). First of all I shall put down what the primary first-class constraints are like. There must be primary first-class constraints which allow for arbitrary deformations of the surface. They must involve the variables w which are conjugate to the y 's, in order to make the y 's vary, and they will involve other field quantities. We can express them in the form

$$w_A + K_A \approx 0, \tag{3-10}$$

where K_Λ is some function of the Hamiltonian variables, the q 's and p 's, not involving the w 's.

Now we can assert that the Hamiltonian is just an arbitrary linear function of all the quantities (3-10):

$$H_T = \int c^\Lambda \left(w_\Lambda + K_\Lambda\right) d^3x \tag{3-11}$$

This is integrated over the three x 's which specify a point on the surface. The c 's are arbitrary functions of the three x 's and the time.

The general equation of motion is of course $\dot{g} \approx [g, H_T]$. We can get a meaning for the coefficient c^A by taking this cquation of motion and applying it for g equal to one of the y variables. For $g = y_A$ at some particular point x^1, x^2, x^3 we get

$$\begin{aligned} \dot{y}_\Lambda &= \left[y_\Lambda, \int c'^T \left(w'_\Gamma + K'_\Gamma\right) d^3x'\right] \\ &= \int c'^T \left[y_\Lambda, w'_\Gamma + K'_\Gamma\right] d^3x \end{aligned} \tag{3-12}$$

Here the ' attached to a field quantity c^Γ, w_Γ or K_Γ denotes the value of that quantity at the point $X^{1'}, X^{2'}, X^{3'}$. y_A has zero Poisson brackets with K'_T because K'_T is independent of the w 's, so we just have to take into

account the Poisson bracket of y_A with $w'_\Gamma = w_\Gamma\left(x'\right)$ This gives us the delta function and so

$$\dot{y}_A = c_A. \tag{3-13}$$

Thus the coefficients c_A turn out to be the velocity variables which tell us how our surface varies with the parameter τ. We can get an arbitrary variation of the surface with τ by choosing these c_A in an arbitrary way.

This tells us what the Hamiltonian is like for a field theory expressed with respect to states on curvilinear surfaces.

We can make a deeper analysis of this Hamiltonian by resolving the vectors which occur in it into components which are normal and tangential to the surface. If we have any vector whatever, ξ_A, we can obtain from ξ_A a normal component

$$\xi_\perp = \xi_A l^\Lambda$$

where l^4 is the unit normal vector, and tangential components (referred to the x coordinate system)

$$\xi_r = \xi_A y^A_{,r}$$

The l are determined by the $y^A_{,r}$ and are thus functions of the dynamical coordinates. Any vector can be resolved in this way into a part normal to the surface and a part tangential to the surface. We have the scalar product law

$$\xi_\Lambda \eta^\Lambda = \xi_\perp \eta_\perp + \gamma^{rs} \xi_r \eta_s \tag{3-14}$$

where $\gamma_{rs} dx^r dx^s$ is the metric in the surface referred to the x-coordinate system. γ^{rs} is the reciprocal matrix of the γ_{rs}.$(r, s = 1, 2, 3)$.

We can use this scalar product law (3-14) to express

our total Hamiltonian in terms of the tangential and normal components of w and K :

$$H_T = \int \dot{y}^\Lambda \left(w_A + K_\Lambda\right) d^3x$$
$$= \int \left(\dot{y}_\perp \left(w_\perp + K_\perp\right) + \gamma^{rs}\dot{y}_r \left(w_s + K_s\right)\right) d^3x \tag{3-15}$$

Here $\dot{y} = \dot{y}^A l_A$ and $\dot{y}_r = \dot{y}^A y_{A,r}$.
We shall need the Poisson bracket relationships between the normal and tangential terms in (3-15). I will first write down the Poisson bracket relations for the different components of w. We have of course

$$[w_A, w'_\Gamma] = 0 \tag{3-16}$$

referred to the external coordinates y; but when we resolve our w 's into normal and tangential components, they will no longer have zero Poisson brackets with each other. The Poisson brackets can easily be worked out by straightforward arguments. I don't want to go through the details of that work. I will just mention that the details can be found in a paper of mine (Canadian Fournal of Mathematics, 3, 1 (1951)). The results are

$$[w_r, w'_s] = w_s \delta_r \left(x - x'\right) + w'_r \delta_s \left(x - x'\right) \tag{3-17}$$
$$[w_\perp, w'_r] = w'_\perp \delta_r \left(x - x'\right) \tag{3-18}$$
$$[w_\perp, w'_\perp] = -2w^r \delta_r \left(x - x'\right) - w^r_r \delta \left(x - x'\right) \tag{3-19}$$

Now we know that

$$[w_\mu + K_\mu, w'_\nu + K'_\nu] \approx 0 \quad \text{for } \mu, \nu = r, s \text{ or } \perp . \tag{3-20}$$

We can infer that

$$[w_r + K_r, w'_s + K'_s]$$
$$= \left(w_s + K_s\right) \delta_{,r} \left(x - x'\right) + \left(w'_r + K'_r\right) \delta_{,s} \left(x - x'\right)$$
$$[w_\perp + K_\perp, w'_r + K'_r] \qquad ((3-21;)$$
$$= \left(w'_\perp + K'_\perp\right) \delta_{,r} \left(x - x'\right), \tag{3-22}$$
$$[w_\perp + K_\perp, w'_\perp + K'_\perp]$$
$$= -2\left(w^r + K^r\right) \delta_{,r} \left(x - x'\right) - \left(w^r + K^r\right)_{,r} \delta \left(x - x'\right). \tag{3-23}$$

These results could be worked out directly from the definitions of the normal and tangential components of the w 's, but they can be inferred more simply by the following argument. Since $w_r + K_r, w_\perp + K_\perp$ are all first class, their Poisson brackets are zero weakly. Thus $[w_r + K_r, w'_s + K'_s], [W_\perp + K_\perp, w'_r + K'_r]$ and $[w. \ + K_\perp, \mathfrak{w}'_\perp + K'_\perp]$ must all be weakly equal to zero. We can now infer what they are equal to strongly. We have to put on the right-hand side in each of (3-21,) (3-22,) and (3-23) a quantity which is weakly equal to zero and which is therefore built up from $w_r + K_r$ and $w_\perp + K_\perp$ with certain coefficients. Further, we can see what these coefficients are by working out what terms containing w there are on the right-hand sides. Terms containing w's can arise only from taking the Poisson bracket of a w with a w, according to (3-17), (3-18), and (3-19). Taking a Poisson bracket $[\ w, K'\ ]$ will not lead to anything involving w, because it means taking the Poisson bracket of a w momentum with some functions of dynamical coordinates and momenta other than w 's, and that won't involve the w momentum variables. Similarly the Poisson bracket of a K with a K won't involve any

w variables. Thus the only w variables which occur on the right side of (3-21) will be the ones which occur on the right side of (3-17). We have to put certain further terms in the ught side of (3-21) in order that the total expression whall be weakly equal to zero. It is then quite clear what we should put here, namely, $(w_s + K_s)\,\delta_r\,(x - x') + (ww'_r + K'_r)\,\delta_{,s}\,(x - x')$. We do the same with the right :ides of (3-22), (3-23).

The next thing to notice is that the terms $w_s + K_s$ in the Hamiltonian (3-15) correspond to a motion in which we change the system of coordinates in the curved wurface but do not have the surface moving. It correponds to each point in the surface moving tangentially to the surface.

Let us put $\dot{y}_\perp = 0$, which means that we are taking no motion of the surface perpendicular to itself but are merely making a change of the coordinates of the surface, and then we have equations of motion of the type

$$\dot{g} = \int \gamma^{rs}\dot{y}_r\,[g, w_s + K_s]\,d^3x \tag{3-24}$$

This must be the equation of motion which tells us how g varies when we change the system of coordinates in the surface without moving the surface itself. Now this change in g must be a trivial one, which can be inferred merely from the geometrical nature of the dynamical variable g. If g is a scalar, then we know how that changes when we change the system of coordinates x^1, x^2, x^3. If it is a component of a vector or a tensor there will be a rather more complicated change for g, but still we can work it out; similarly if g is a spinor. In every case, this change of g is a trivial one. That means that K_s can be determined from geometrical arguments only.

I will give one or two examples of that. For a scal field V with a conjugate momentum U, there is a ter,

$$V_{,r}U \tag{5}$$

in K_r. For a vector field, say a three-vector A_s, wit conjugate B^s, there is a term

$$A_{s,r}B^s - (A_rB^s)_{,s} \tag{3-26}$$

in K_r; and so on for tensors, with something rather mort complicated for spinors. The first term in (3-26) is th: change in A_s coming from the translation associated with the change in the system of coordinates, and the second is the change in the A_s arising from the rotation associated with the change in the system of coordinates. There is no such rotation term coming in in the case (3-25) of the scalar.

We can obtain the total K_r by adding the contribution needed for all the different kinds of fields which are present in the problem. The result is that we can work out this tangential component of K just from geometrical arguments. One can see in this way that the tangential component of K is something which is not of real physical importance, it is just concerned with the mathematical technique. The quantity which is of real physical importance is the normal component of K in (3-15). This normal component of K added on to the normal component of w gives us the first-class constraint which is associated with a motion of the surface normal to itself. That is something which is of dynamical importance.

The problem of getting a Hamiltonian field theory on these curved surfaces involves finding the expressions K to satisfy the required Poisson bracket relations

[60]

(1-21), (3-22), and (3-23). The tangential part of K can lic worked out from geometrical arguments as I discussed, and when we have worked it out we should find of course that it satisfies the first Poisson bracket relation (3-21). The second Poisson bracket relation (3-22)

involves $K_\perp$ lumearly and this Poisson bracket relation would be mutisfied by any quantity $K_\perp$ which satisfies the condition if being a scalar density. This Poisson bracket relation wally tells us that if the quantity $K_\perp$ varies suitably under . change of coordinate system X^1, X^2, X^3, this Poisson bracket relation will be fulfilled. The difficult relation to tulfill is the third one, which is quadratic in K_1. So the problem of setting up a Hamiltonian field theory on curved space-like surfaces is reduced to the problem of finding a normal component of K which is a scalar density and which satisfies the Poisson bracket relationship (3-23).

One way of finding such a normal component of K is to work from a Lorentzinvariant action principle. We might obtain all the components of K by working from the action principle. If we did that, the tangential part of K which we get would not necessarily be the same as that built up from terms like (3-25) and (3-26), because it might differ by a contact transformation. But one could eliminate such a contact transformation by rewriting the action principle, adding to it a perfect differential term. This doesn't affect the equations of motion. By such a change of the action principle, one can arrange that the tangential part of K given by the action principle agrees precisely with the value which is obtained by the simple application of geometrical arguments. We are then able to find the normal component of K by working with our general method of passing from the action principle to

the Hamiltonian. If the action principle is relativistic, then the normal component of K obtained in this way would have to satisfy the condition (3-23).

We can now discuss the passage to the quantum theory. Quantization involves making the quantities w and the variables which enter in K into operators. We have to be careful now how we define the tangential and the normal components of w, and I choose this way to define them:

$$w_r = y_{\Lambda,r} w^\Lambda \tag{3-27}$$

putting the momentum variable w on the right. (In the quantum theory, you see, the result is different, depending on whether we put the w on the right or the left.) Similarly,

$$w_\perp = l_\Lambda w^\Lambda \tag{3-28}$$

Then these quantities are well defined.
Now in the quantum theory we have the weak equations $w_r + K_r \approx 0$ and $w_\perp + K_\perp \approx 0$, which provide us with supplementary conditions on the wave function:

$$(w_r + K_r)\,\psi = 0 \tag{3-29}$$

$$(w_\perp + K_\perp)\,\psi = 0 \tag{3-30}$$

corresponding to (2-22). We require that these supplementary conditions be consistent. According to (2-25), we must arrange that in the commutation relations (3-21), (3-22), and (3-23) the coefficients on the righthand sides stand before (on the left of) the constraints.

In the case of (3-21), the tangential components, the conditions fit if we choose the order of the factors in K_r so that the momentum variables are always on the right. We have now in (3-21) a number of quantities,

linear in the momentum variables with the momentum variables on the right, and the commutator of any two such quantities will again be linear in the momentum variables with the momentum variables on the right. Thus we shall always have the momentum variables on the right and we shall always have our factors occurring in the order in which we want them to.

Now we have the problem of bringing in $K_\perp$, which cannot be disposed of so simply. $K_\perp$ will usually involve the product of non-commuting factors and we have to arrange the order of

those factors so that (3-22) and (3-23) shall be satisfied with the coefficients occurring on the left in every term on the right-hand side. The equation (3-22) is again a fairly simple one to dispose of. If we simply take $K_\perp$ to be a scalar density, that is all that is needed, because we have $w_\perp + K_\perp$ occurring on the right-hand side without any coefficients which don't commute with it; the only coefficient is the delta function, which is a number.

But the relationship (3-23) is the troublesome one. For the purposes of the quantum theory, I ought to write out the right-hand side here rather more explicitly:

$$[w_\perp + K_\perp, w'_\perp + K'_\perp] = -2\gamma^{rs}\,(w_s + K_s)\,\delta_{,r}\,(x - x') \\ -\left(\gamma^{rs}\,(w_s + K_s)\right)_{,r}\,\delta\,(x - x') \tag{3-31}$$

I've written this out with the coefficients γ^{rs} occurring on the left, and that is how we need to have these coefficients in the quantum theory.

The problem of setting up a quantum field theory on general curved surfaces involves finding $K_\perp$ so that this Poisson bracket relationship (3-31) holds with the coefficients $\gamma^{\tau s}$ occurring on the left. If we do satisfy (3-31),

then the supplementary conditions (3-30) are consistent with each other, and we already have (3-29) consistent with each other and (3-30) consistent with (3-29).

There we have formulated the conditions for our quantum theory to be relativistic. We need a bit of luck to be able to satisfy the conditions. We cannot always satisfy them. There is one general rule which is of importance, which tells us that when we've got a $K_\perp$ satisfying these conditions and certain other conditions, we can easily construct other $K_\perp$'s to satisfy the conditions. Let us suppose that we have a solution in which $K_\perp$ involves only undifferentiated momentum variables together with dynamical coordinates which may be differentiated. There are a number of simple fields for which $K_\perp$ does satisfy the Poisson bracket relations (3-22) and (3-23) and does have this simple character. Then we may add to $K_\perp$ any function of the undifferentiated q 's. That is to say, we take a new K_1,

$$K^*_\perp = K_\perp + \phi(q).$$

Then we see that adding on this ϕ to $K_\perp$ can affect the right-hand side of (3-31) only by bringing in a multiple of the delta function. We cannot get any differentiations of the delta function coming in, because the extra terms come from Poisson brackets of $\phi(q)$ with undifferentiated momentum variables. So that the only effect on the right-hand side of adding the term ϕ to $K_\perp$ can be adding on a multiple of the delta function. But the right-hand side has to be antisymmetrical between x and x', because the left-hand side is obviously antisymmetrical between x and x'. That prevents us from just adding a multiple of the delta function to the right-hand side of (3-31), so that it is not altered at all. Thus if the

original $K_\perp$ satisfies the Poisson bracket relation (3-31), then the new one will also satisfy it.

There is a further factor which has to be taken into account to complete the proof. ϕ may also involve $\Gamma = \sqrt{-\det g_{rs}}$. One finds that $[w_1, \Gamma']$ involves $\delta\,(x - x')$ undifferentiated (one just has to work this out) and thus we can bring Γ into ϕ without disturbing the argument. In fact, we have to bring in Γ in order to preserve the validity of (3-22), which requires that $K^*_\perp$ and $K_\perp$ shall be scalar densities. We must thus bring in a suitable power of Γ to make ϕ a scalar density.

This is the method which is usually used in practice for bringing in interaction between fields without disturbing the relativistic character of the theory. For various simple fields the conditions turn out to be satisfied. We have the necessary bit of luck, and we can bring in interaction between fields of the simple character described and the conditions for the quantum theory to be relativistic are preserved.

There are some examples for which we don't have the necessary luck and we just cannot arrange the factors in $K_\perp$ to get (3-31) holding with the coefficients on the left, and then we do not know how to quantize the theory with states on curved surfaces. But actually, we are trying to do rather more than is necessary when we try to set up our quantum theory with states on curved surfaces. For the purposes of getting a theory in agreement with special relativity, it would be quite sufficient to have our states defined only on flat surfaces. That will involve some conditions on $K_\perp$ which are less stringent than those which I have formulated here. And it may be that we can satisfy these less stringent conditions without being able to satisfy those which I have formulated here.

An example for that is provided by the Born-Infeld electrodynamics, which is a modification of the Maxwell electrodynamics based on a different action integral, an action integral which is in agreement with the Maxwell one for weak fields, but differs from it for strong fields. This Born-Infeld electrodynamics leads to a classical $K_\perp$ which involves square roots. It is of such a nature that it doesn't seem possible to fulfill the conditions which are necessary for building up a relativistic quantum theory on curved surfaces. However, it does seem to be possible to build up a relativistic quantum theory on flat surfaces, for which the conditions are less stringent.

24.5.5 Dirac's Lecture 4: Quantization on Flat Surfaces

We have been working with states on general space-like curved surfaces in space-time. I will just summarize the results that we obtained concerning the conditions for a quantum field theory, formulated in terms of these states, to be relativistic. We introduce variables to describe the surface, consisting of the four coordinates y^Λ of each point $x^r = (x^1, x^2, x^3)$ on the surface. The x 's form a curvilinear system of coordinates on the surface. Then the y 's are treated as dynamical coordinates and there are momenta conjugate to them, $w_A(x)$, again functions of the x 's. And then we get a number of primary first-class constraints appearing in the Hamiltonian formalism, of the nature

$$w_\Lambda + K_\Lambda \approx 0 \tag{3-10}$$

The K 's are independent of the w 's, but may be functions of any of the other Hamiltonian variables. The K 's will involve the physical fields which are present. We analyze these constraints by resolving them into components tangential to the surface and normal to the surface. The tangential components are

$$w_r + K_r \approx 0 \tag{4-1}$$

and the normal component is

$$w_\perp + K_\perp \approx 0 \tag{4-2}$$

With this analysis, we find that the K_r can be worked out just from geometrical considerations. The K_r should be looked upon as something rather trivial, associated with transformations in which the coordinates of the surface are varied, but the surface itself doesn't move. The first-class constraints (4-2) are associated with the motion of the surface normal to itself and are the important ones physically.

Certain Poisson bracket relations (3-21), (3-22), and (3-23) have to be fulfilled for consistency. Some of the Poisson bracket relations involve merely the K_r, and they are automatically satisfied when the K_r are chosen in accordance with the geometrical requirements. Some of the consistency conditions are linear in $K_\perp$ and they are automatically satisfied provided we choose $K_\perp$ to be a scalar density. Then finally we have the consistency conditions which are

quadratic in the $K_\perp$ and those are the important ones, the ones which cannot be satisfied by trivial arguments.

These important consistency conditions can be satisfied in the classical theory if we work from a Lorentzinvariant action principle and calculate the $K_\perp$ by following the standard rules of passing from the action principle to the Hamiltonian. The problem of getting a relativistic quantum theory then reduces to the problem of suitably choosing the non-commuting factors which occur in the quantum $K_\perp$ in such a way that the quantum consistency conditions are fulfilled, which means that the commutator of two of the quantities (4-2) at two points in space x^1, x^2, x^3 has to be a linear combination of the

constraints with coefficients occurring on the left. These quantum consistency conditions will usually be quite difficult to satisfy. It turns out that one can satisfy them with certain simple examples, but with more complicated examples it doesn't seem to be possible to satisfy them. That leads to the conclusion that one cannot set up a quantum theory for these more general fields with the states defined on general curved surfaces.

I might mention that the quantities K have a simple physical meaning. K_r can be interpreted as the momentum density, $K_\perp$ as the energy density; so the momentum density, expressed in terms of Hamiltonian variables, is something which is always easy to work out just from the geometrical nature of the problem and the energy density is the important quantity which one has to choose correctly (satisfying certain commutation relations) in order to satisfy the requirements of relativity.

If we cannot set up a quantum theory with states on general curved surfaces, it might still be possible to set it up with states defined only on flat surfaces.

We can get the corresponding classical theory simply by imposing conditions which make our previous curved surface into a flat surface. The conditions will be the following: The surface is specified by $y_\Lambda(x)$; in order to make the surface flat, we require that these functions shall be in the form

$$y_A(x) = a_A + b_{\Lambda r} x^r \tag{4-3}$$

where the a 's and b 's are independent of the x 's. This will result in the surface being flat, and in the system of coordinates x^r being rectilinear. At present we are not imposing the conditions that the x^r coordinate system shall be orthogonal: I shall bring that in a little later. [69]

We are thus working with general, oblique, rectilinear axes x^r.

We now have our surface fixed by quantities a_A, b_{Ar} and these quantities will appear as the dynamical variables needed to fix the surface. We have far fewer of them than previously. In fact, we have only $4 + 12 = 16$ variables here. We have these 16 dynamical coordinates to fix the surface instead of the previous $y_A(x)$, which meant $4 \cdot \infty^3$ dynamical coordinates.

When we restrict the surface in this way, we may look upon the restriction as bringing a number of constraints into our Hamiltonian formalism, constraints which express the $4 \cdot \infty^3 y$ coordinates in terms of 16 coordinates. These constraints will be second-class. Their presence means a reduction in the number of effective degrees of freedom for the surface from $4 \cdot \infty^3$ to 16 , a very big reduction!

In a previous lecture I gave the general technique for dealing with second-class constraints. The reduction in the number of effective degrees of freedom leads to a new definition of Poisson brackets. This general technique is not needed in our present case, where conditions are sufficiently simple for one to be able to use a more direct method. In fact, we can work out directly what effective momentum variables remain in the theory when we have reduced the number of effective degrees of freedom for the surface.

With our dynamical coordinates restricted in this way, we have of course the velocities restricted by the equation

$$\dot{y}_A = \dot{a}_A + b_{\Lambda r} x^r. \tag{4-4}$$

The dot refers to differentiation with respect to some parameter τ. As τ varies, this flat surface varies, moving

parallel to itself and also changing its direction. The surface thus moves with a four-fold freedom, and this motion is expressed by our taking a_A, b_{Ar} to be functions of the parameter τ.

The total Hamiltonian is now

$$\begin{aligned} H_T &= \int \dot{y}^A \left(w_\Lambda + K_\Lambda\right) d^3x \\ &= \dot{a}^A \int \left(w_\Lambda + K_\Lambda\right) d^3x + b_r^A \int x^r \left(w_\Lambda + K_\Lambda\right) d^3x \end{aligned} \tag{4-5}$$

(I have taken the quantities $\dot{a}^A, b^\Lambda$. outside the integral signs, because they are independent of the x variables.) (4-5) involves the w variables only through the combinations $\int w_\Lambda d^3x$ and $\int x^r w_\Lambda d^3x$. We have here 16 combinations of the w 's, which will be the new momentum variables conjugate to the 16 variables a, b which are now needed to describe the surface.

We can again express H_T in terms of the normal and tangential components of these quantities:

$$\begin{aligned} H_T = \dot{a}^\Lambda l_\Lambda \int \left(w_\perp + K_\perp\right) d^3x + \dot{a}^\Lambda b_{\Lambda r} \int \left(w^r + K^r\right) d^3x \\ + b_r^\Lambda l_\Lambda \int x^r \left(w_\perp + K_\perp\right) d^3x + b_{\Lambda r} b_{\mathrm{s}}^\Lambda \int x^r \left(w^s + K^8\right) d^3x \end{aligned} \tag{4-6}$$

Let us now bring in the condition that the x^r coordinate system is orthogonal. That means

$$b_{\Lambda r} b_s^\Lambda = g_{rs} = -\delta_{rs}. \tag{4-7}$$

Differentiating (4-7) with respect to τ, we get

$$b_{\Lambda r} b_s^\Lambda + b_{\Lambda s} b_r^\Lambda = 0$$
$$\left[7^1\right]$$

(I have been raising the Λ suffixes quite freely because the Λ coordinate system is just the coordinate system of special relativity.) This equation tells us that $b_{Ar} b_s^\Lambda$ is antisymmetric between r and s. So the last term in (4-6) is equal to

$$\frac{1}{2} b_{\Lambda r} b_s^A \int \left\{x^r \left(w^s + K^s\right) - x^s \left(w^r + K^r\right)\right\} d^3x$$

Now you see that we don't have so many linear combinations of the w's occurring in the H_T as before. The only linear combinations of the w's which survive are the following ones:

$$P_\perp \equiv \int w_\perp d^3x, \tag{4-9}$$

$$P_r \equiv \int w_r d^3x, \tag{4-10}$$

$$\text{and also} \quad M_{r\perp} \equiv \int x^r w_\perp d^3x, \tag{4-11}$$

$$\text{and} \quad M_{rs} \equiv \int \left(x_r w_s - x_s w_r\right) d^3x. \tag{4-12}$$

(We can raise and lower the suffixes r quite freely now because they refer to rectilinear orthogonal axes.) These are the momentum variables which are conjugate to the variables needed to fix the surface when the surface is restricted to be a flat one referred to rectilinear orthogonal coordinates.

The whole set of momentum variables included in (4-9), (4-10), (4-11), and (4-12) can be written as P_μ and $M_{\mu\nu} = -M_{\nu\mu}$, where the suffixes μ and ν take on 4 values, a value 0 associated with the normal component, and $1, 2, 3$ associated with the three x 's. μ, ν are small

[72]

suffixes referring to the x coordinate system, to distinguish them from the capital suffixes Λ referring to the fixed y coordinate system.

So now our momentum variables are reduced to just 10 in number, and associated with these 10 momentum variables we have 10 primary first-class constraints, which we may write

$$P_\mu + p_\mu \approx 0 \tag{4-13}$$

$$M_{\mu\nu} + m_{\mu\nu} \approx 0 \tag{4-14}$$

$$\text{where } p_\perp \equiv \int K_\perp d^3x$$

$$p_r \equiv \int K_r d^3x \tag{4-15}$$

$$m_{r\perp} \equiv \int x_r K_\perp d^3x \tag{4-16}$$

$$\text{and} \tag{4-17}$$

$$m_{rs} \equiv \int (x_r K_s - x_s K_r)\, d^3x \tag{4-18}$$

We have now 10 primary first-class constraints associated with a motion of the flat surface. In Lecture (3) I said that we would need 4 primary first-class constraints ($3 - 10$) to allow for the general motion of a flat surface. We see now that 4 is not really adequate. The 4 has to be increased to 10 , because 4 elementary motions of the surface normal to itself and changing its direction would not form a group; in order to have these elementary motions forming a group, we have to extend the 4 to 10 , the extra 6 members of the group including the translations and rotations of the surface, which motions affect merely the system of coordinates in the surface without affecting the surface as a whole. In this

way we are brought to a Hamiltonian theory involving 10 primary firstclass constraints

We have now to discuss the consistency conditions, the conditions in terms of Poisson bracket relations which are necessary for all the constraints to be first classLet us first discuss the Poisson bracket relations between the momentum variables $P_\mu, M_{\mu v}$ We are given these momentum variables in terms of the w variables 4 nd we know the Poisson bracket relations (317) , (318) ,and (319) between the w variables,so we can calculate the Poisson bracket relations between the P and M variablesIt is not really necessary to go through all this work to determine the Poisson bracket relations between the P and M variables It is sufficient to realize that these variables just corre spond to the operators of translation and rotation in four dimensional flat spacetime,and thus their Poisson bracket relations must just correspond to the commuta tion relations between the operators of translation and rotationIn either way we get the following Poisson bracket relations

$$[P_u, P_v] = 0 \tag{4-19}$$

which expresses that the various translations commute

$$[P_\mu, M_{\rho\sigma}] = g_{\mu\rho}P_\sigma - g_{\mu\sigma}P_\rho; \tag{4-20}$$
$$\text{and} \quad [M_{\mu\nu}, M_{\rho\sigma}] = -g_{\mu\rho}M_{v\sigma} + g_{v\rho}M_{\mu\sigma} + g_{\mu\sigma}M_{v\rho} - g_{v\sigma}M_{\mu\rho}.$$

Let us now consider the requirements for the equations (413) and (414) to be firstclassThe Poisson bracket of any two of them must be something which vanishes weakly and must therefore be a linear combination of

[74]

themSo we are led to these Poisson bracket relations

$$[P_\mu + p_\mu, P_v + p_v] = 0,(4-22) \tag{4-22}$$
$$[P_\mu + p_\mu, M_{\mu\sigma} + m_{\mu\sigma}] = g_{\mu\rho}\left(P_\sigma + p_\sigma\right) - g_{\mu\sigma}\left(P_\rho + p_\rho\right), \tag{4-23}$$
$$\text{and } [M_{\mu\nu} + m_{\mu\nu}, M_{\rho\sigma} + m_{\rho\sigma}] = -g_{\mu\rho}\left(M_{\nu\sigma} + m_{\nu\sigma}\right) + g_{\nu\rho}\left(M_{\mu\sigma} + m_{\mu\sigma}\right) + g_{\mu\sigma}\left(M_{\nu\rho} + m_{\nu\rho}\right) - g_{\nu\sigma}\left(M_{\mu\rho} + m_{\mu\rho}\right).(4-24) \tag{4-24}$$

The argument for getting these relations is that,on the righthand sides we had to put something which is weakly equal to zero in each case,and we know the terms on the righthand sides which involve the momentum variables P, M because these terms come only from the Poisson brackets of momenta with momenta and so are given by (419) , (420) ,and (421) (I have already used the same argument in the curvilinear case for (321) , (322) ,and (323) ,so there is no need to go into detail hereFor example,see how (423) comes aboutThe terms involving P are just the same as in (420) They come from the Poisson bracket of P and M The remain ing terms are filled in in order to make the total expres sion weakly equal to zero) (422) , (423) ,and (424) are the requirements for consistency

We can make a further simplification,which we could not do in the case of curvilinear coordinates,in this way Let us suppose that our basic field quantities are chosen to refer only to the x coordinate systemThey are field quantities at specific points x in the surface,and we can choose them so as to be quite independent of the y coordinate systemThen the quantities $K_\perp, K_r$ will be quite independent of the y coordinate system,and that means that they will have zero Poisson brackets with the

variables P, M. We then have a zero Poisson bracket between each of the variables p, m and each of the P, M.

This condition follows with the natural choice of dynamical variables to describe the physical fields which are present. We cannot do the corresponding simplification when we are working with the curved surfaces, because the g_{rs} variables that fix the metric will enter into the quantities $K_\perp, K_r$. The result is that we cannot set them up in a form which does not refer at all to the y coordinate system, because the y coordinates enter into the g_{rs} variables. However, with the flat surfaces, we can make this simplification, and that results in equations (4-22), (4-23), and (4-24) simplifying to

$$[p_\mu, p_\nu] = 0; \tag{4-25}$$
$$[p_\mu, m_{\rho\sigma}] = g_{\mu\rho}p_\sigma - g_{\mu\sigma}p_\rho; \tag{4-26}$$

and

$$[m_{\mu\nu}, m_{\rho\sigma}] = -g_{\mu\rho}m_{\nu\sigma} + g_{\nu\rho}m_{\mu\sigma} + g_{\mu\sigma}m_{\nu\rho} - g_{\nu\sigma}m_{\mu\rho}. \tag{4-27}$$

P and M have disappeared from these equations, so the consistency conditions now involve only the field variables, and not the variables, which are introduced for describing the surface. In fact, these conditions merely say that the p, m shall satisfy Poisson bracket relations corresponding to the operators of translation and rotation in flat space-time. The problem of setting up a relativistic field theory now reduces to finding the quantities p, m to satisfy the Poisson bracket relations (4-25), (4-26), and (4-27).

These quantities, remember, are defined in terms of $K_\perp$ and K_r, the energy density and the momentum

density. The expression for the momentum density is just the same as in curvilinear coordinates. It is determined by geometrical arguments only. Our problem reduces to finding the energy density $K_\perp$ leading to p 's and m 's such that the Poisson bracket relations (4-25), 4-26), and (4-27) are fulfilled.

If we work from a Lorentz-invariant action integral and deduce $K_\perp$ from it by standard Hamiltonian methods, $K_\perp$ will automatically satisfy these requirements in the classical theory. The problem of getting a relativistic quantum theory then reduces the problem of suitably choosing the order of factors which occur in $K_\perp$ so as to satisfy the equations (4-25), (4-26), and (4-27) also in the quantum theory, where the Poisson bracket becomes a commutator and the p, m involve non-commuting quantities.

Let us look at (4-25), (4-26), and (4-27) and substitute for p and m their values in terms of K 's. Then you see that some of these conditions will be independent of $K_\perp$. These are automatically satisfied when we choose K_r properly, in accordance with the geometrical requirements. Some of the conditions are linear in $K_\perp$. These will be satisfied by taking $K_\perp$ to be any three-dimensional scalar density in the space of the x 's. So that there is no problem in satisfying the conditions which are linear in $K_\perp$. The awkward ones to satisfy are the ones which are quadratic in $K_\perp$. They are the following:

$$\left[\int x_r K_\perp d^3x, \int K'_\perp d^3x'\right] = \int K_r d^3x \tag{4-28}$$

(This equation comes from (4-26) where we put $\mu = \perp$, $\rho = r$, and $\sigma = \perp$.)

$$\left[\int x_r K_\perp d^3x, \int x'_s K'_\perp d^3x'\right] = -\int (x_r K_s - x_r K_r)\, d^3x \tag{4-29}$$

(from (427) where we take $\nu = \perp$ and $\sigma = \perp$) So the problem of getting a relativistic quantum field theory now reduces to the problem of finding an energy density $K_\perp$ which satisfies the conditions (428) and (429) when we take into account noncommutation of the factors

We can analyze these conditions a little more when we take into account that the Poisson bracket connecting $K_\perp$ at one point and $K'_\perp$ at another point will be a sum of terms involving delta functions and derivatives of delta functions

$$[K_\perp, K'_\perp] = a\delta + 2b_r\delta_{,r} + c_{rs}\delta_{,rs} + \ldots \tag{4-30}$$

(This delta is the threedimensional delta function in volving the three coordinates x and the three coordinates x' of the first and second points) Here $a = a(x)$, $b = b(x), c = c(x), \ldots$ One could have the coefficients involving also x' ,but then one could replace them by coefficients involving x only at the expense of making some changes in the earlier coefficients in the series There is no fundamental dissymmetry between x and x' , only a dissymmetry in regard to the way the equation is written

(430) is the general relationship connecting the energy density at two pointsNow for many examples, including all the more usual fields,derivatives of the delta function higher than the second do not occurLet us examine this case further

Assume derivatives higher that the second do not occurThat means that the series (430) stops at the

[78]

third termIn this special case we can get quite a bit of information about the coefficients a, b, c by making use of the condition that the Poisson bracket (430) is anti symmetrical between the two points x and x' Inter changing x and x' in (430) ,we get

$$\begin{aligned}[K'_\perp, K_\perp] &= a'\delta - 2b'_r\delta_{,r} + c'_{rs}\delta_{,rs} \\ &= a'\delta - 2\left(b'_r\delta\right)_{,r} + \left(c'_{rs}\delta\right)_{,rs}\end{aligned}$$

(since $\partial b_r\left(x'\right)/\partial x^r = 0$,etc)

$$\begin{aligned}&= a\delta - 2\left(b_r\delta\right)_{,r} + \left(c_{rs}\delta\right)_{,rs} \\ &= \left(a - 2b_{r,r} + c_{rs,rs}\right)\delta + \left(-2b_r + 2c_{rs,r}\right)\delta_{,r} + c_{rs}\delta_{,rs}. \quad (4-31)\end{aligned}$$

The expression (431) must equal minus the expression (430) identicallyIn order that the coefficients of $\delta_{,rs}$ shall agree we must have

$$c_{rs} = 0. \tag{4-32}$$

This then makes the coefficients of $\delta_{,r}$ agreeFinally,in order that the coefficients of δ shall agree,we must have

$$a = b_{r,r} \tag{4-33}$$

This gives us the equation

$$[K_\perp, K'_\perp] = 2b_r\delta_r + b_{r,\gamma}\delta. \tag{4-34}$$

Let us now substitute in (428) and (429) They become

$$\begin{aligned}\int K_r d^3x &= \iint x_r\left(2b_s\delta_{,s} + b_{s,s}\delta\right)d^3x d^3x' \\ &= \int x_r b_{s,s} d^3x \\ &= \int b_r d^3x\end{aligned} \tag{4-35}$$

(Note that $x_{r,s} = \partial x_r/\partial x^s = -\delta_{rs}$)

[79]

$$\begin{aligned}-\int\left(x_r K_s - x_s K_r\right)d^3x &= \iint x_r x'_s\left(2b_t\delta_t + b_{t,t}\delta\right)d^3x d^3x' \\ &= \int\left(-2x_r b_s + x_r x_s b_{t,t}\right)d^3x \\ &= \int\left(-x_r b_s + x_s b_r\right)d^3x\end{aligned} \tag{4-36}$$

This is what our consistency conditions reduce to, and we see that they are satisfied by taking $b_r = K_r$. This is not quite the most general solution; more generally we could have

$$b_r = K_r + \theta_{rs,s} \tag{4-37}$$

for any quantity θ_{rs} satisfying the condition that

$$\int (\theta_{rs} - \theta_{sr})\, d^3x = 0 \tag{4-38}$$

Thus θ can have any symmetrical part and its antisymmetrical part must be a divergence.

That gives the general requirement for a field theory to be relativistic. We have to find the energy density $K_\perp$ satisfying the Poisson bracket relation (4-34) where b_r is connected with the momentum density by (4-37). If we work out the energy density from a Lorentz-invariant action then this condition will certainly be satisfied in the classical theory. It might not be satisfied in the quantum theory because the order of the factors might be wrong. It is only when one can choose the order of the factors in the energy density so as to make (4-34), (4-37) hold accurately that we have a relativistic quantum theory. The conditions which we have here for a quantum theory to be relativistic are less stringent than the ones

which we obtained when we had states defined on general curved surfaces.

I would like to illustrate that by taking the example of Born-Infeld electrodynamics. This is an electrodynamics which is in agreement with Maxwell electrodynamics for weak fields but differs from it for strong fields. (We now refer the electromagnetic field quantities to some absolute unit defined in terms of the charge of the electron and classical radius of the electron, so that we can talk of strong fields and weak fields.) The general equations of the Born-Infeld electrodynamics follow from the action principle:

$$I = \int \sqrt{-\det\left(g_{\mu\nu} + F_{\mu\nu}\right) d^4x} \tag{4-39}$$

We may use curvilinear coordinates at this stage. $g_{\mu\nu}$ gives the metric referred to these curvilinear coordinates and $F_{\mu\nu}$ gives the electromagnetic field referred to the absolute unit.

We can pass from this action integral to a Hamiltonian by using the general procedure. The result is to give us a Hamiltonian in which we have, in addition to the variables needed to describe the surface, the dynamical coordinates $A_r, r = 1, 2, 3$. A_0 turns out to be an unimportant variable just like in the Maxwell field. The conjugate momenta D^r to the A_r are the components of the electric induction, and satisfy the Poisson bracket relations

$$[A_r, D'^s] = g_r^s \delta\left(x - x'\right). \tag{4-40}$$

It turns out that in the Hamiltonian we only have A occurring through its curl, namely through the field quantities:

LECTURES ON QUANTUM MECHANICS

$$B^r = \frac{1}{2}\varepsilon^{rst} F_{st} = \varepsilon^{rst} A_{t,s} \tag{4-41}$$

$\varepsilon^{rst} = 1$ when $(rst) = (1, 2, 3)$ and is anti-symmetrical between the suffixes. The commutation relation between B and D is

$$[B^r, D'^s] = \varepsilon^{rst} \delta_{,t}\left(x - x'\right) \tag{4-42}$$

The momentum density now has the value

$$K_r = F_{rs} D^s \tag{4-43}$$

This is just the same as in the Maxwell theory. It is in agreement with the general principle that the momentum density depends only on geometrical arguments, i.e. on the geometrical character of the fields we are using, and the action principle doesn't matter.

The energy density now has the value

$$K_\perp = \left\{\Gamma^2 - \gamma_{rs}\left(D^r D^s + B^r B^s\right) - \gamma^{rs} F_{rt} F_{su} D^t D^u\right\}^{1/2} \tag{4-44}$$

Here γ_{rs} is the metric in the three-dimensional surface and

$$-\Gamma^2 = \det \gamma_{rs} \tag{4-45}$$

If we work with curved surfaces we require $K_\perp$ to satisfy the Poisson bracket relation (3-31). In the classical theory it must do so because it is deduced from a Lorentz-invariant action integral. But we cannot get it to satisfy the required commutation relationship in the quantum theory. The expression for $K_\perp$ has a square root occurring in it, which makes it very awkward to work with. It seems to be quite hopeless to try to get the commutation relations correctly fulfilled with the coefficients γ^{rs} occurring on the left. So it does not seem to be possible to get a Born-Infeld quantum electro-

dynamics with the state defined on general curved surfaces.

Let us, however, go over to flat surfaces. For that purpose, we need to work out the Poisson bracket relationship (4-34). Now we know that conditions are all right in the classical theory. Classically we must therefore have the Poisson bracket relationship:

$$[K_\perp, K'_\perp] = 2K_r \delta_{,r} + K_{r,r}\delta \tag{4-46}$$

We can see without going into detailed calculations that this must hold also in the quantum theory, because K_r is built up entirely from the quantities D^s and B^t. When we work things out in the quantum theory, we shall have the D 's and the B 's occurring in a certain order, but the D 's and B 's all commute with each other when we take them at the same point. We see that from (4-42). If we put the $x' = x$ we get

$$[B^r, D^s] = \varepsilon^{rst}\delta_{.t}(0) = 0 \tag{4-47}$$

(the derivative of the delta function with the argument 0 is to be taken as zero). Thus we are not bothered by the non-commutation of the D 's and the B 's that occur in K_r. We must therefore get the classical expression, so that the consistency conditions are fulfilled.

So for the Born-Infeld electrodynamics, the consistency conditions for the quantum theory on flat surfaces are fulfilled, while they are not fulfilled on curved surfaces. Physically that means that we can set up the basic equations for a quantum theory of the Born-Infeld electrodynamics agreeing with special relativity, but we should have difficulties if we wanted to have this quantum theory agreeing with general relativity.

That completes the discussion of the consistency

requirements for the quantum theory to be relativistic. However, even if we have satisfied these consistency requirements, we have not yet disposed of all the difficulties. There are some quite formidable difficulties still lying ahead of us. If we were dealing with a system involving only a finite number of degrees of freedom, then we should have disposed of all of the difficulties, and it would be a straightforward matter to solve the differential equations on ψ. But with field theory, we have an infinite number of degrees of freedom, and this infinity may lead to trouble. It usually does lead to trouble.

We have to solve equations in which the unknown, the wave function ψ, involves an infinite number of variables. The usual method that people have for solving this kind of equation is to use perturbation methods in which the wave function is expanded in powers of some small

parameter, and one tries to get a solution step by step. But one usually runs into the difficulty that after a certain stage the equations lead to divergent integrals.

People have done a great deal of work on this problem. They have found methods for handling these divergent integrals which seem to be tolerable to physicists even though they cannot be justified mathematically, and they have built up the renormalization technique, which allows one to disregard the infinities in the case of certain kinds of field theory.

So, even when we have formally satisfied the consistency requirements, we still have the difficulty that we may not know how to get solutions of the wave equation satisfying the required supplementary conditions. If we can get such solutions, there remains the further problem of introducing scalar products for these

[84]

solutions, which means considering these solutions as the vectors in a Hilbert space. It is necessary to introduce these scalar products before we can get a physical interpretation for our wave function in terms of the standard rules for the physical interpretation of quantum mechanics. It is necessary that we should have scalar products for the wave functions which satisfy the supplementary conditions, but we do not need to worry about scalar products for general wave functions which do not satisfy the supplementary conditions. There may be no way of defining scalar products for these general wave functions, but that would not matter at all. The physical interpretation for quantum mechanics requires that scalar products exist only for wave functions satisfying all the supplementary conditions.

You see that there are quite formidable difficulties in getting the Hamiltonian theory to work, in connection with quantum mechanics. So far as concerns classical mechanics, the method seems to be fairly complete and we know exactly what the situation is; but for quantum mechanics we have only really started on the problem. There are the difficulties of finding solutions even when the supplementary conditions are formally consistent, and possibly also the difficulty of introducing scalar products of the solutions.

The difficulties are quite serious, and they have led some physicists to challenge the whole Hamiltonian method. A good many physicists are now working on the problem of trying to set up a quantum field theory independently of any Hamiltonian. Their general method is to introduce quantities which are of physical importance, then to bring in accepted general principles in order to impose conditions on these quantities; and

their hope is that ultimately they will get enough conditions imposed on these quantities of physical importance to be able to calculate them. They are still very far from achieving that end, and my own belief is that it will not be possible to dispense entirely with the Hamiltonian method. The Hamiltonian method dominates mechanics from the classical point of view. It may be that our method of passing from classical mechanics to quantum mechanics is not yet correct. I still think that in any future quantum theory there will have to be something corresponding to Hamiltonian theory, even if it is not in the same form as at present.

I have given the treatment of the Hamiltonian method as far as it has yet been developed. It is quite a general and powerful method which can be adapted to a variety of problems. It can be adapted to problems where singularities (point or surface) occur in the field. The general idea governing this development of the Hamiltonian theory is to find an action I which involves certain parameters q, such that when we vary the q 's, δI is linear in the δq 's. It is indispensable that we should have δI linear in the δq 's in order that we may apply the treatment described in these lectures.

The way to bring about linearity when we have singularities is to work in terms of curvilinear coordinates, and not to vary any equations which determine the position of a singular point or a singular surface. For example, if we are dealing with a singular surface specified by an equation $f(x) = 0$, then we must have a variation principle in which $f(x)$ is not varied. If we

allow $f(x)$ to vary, if we treat f itself as providing some of the q 's, then we do not have δI linear in the δq 's. But we can keep $f(x)$ fixed with respect to some curvilinear

coordinate system x and we can vary the surface by varying the curvilinear coordinate system without varying the function f. Then the general method which I have discussed here works very well in the classical theory. When we go over to quantization we have the difficulties arising which I have discussed.

24.5.6 Introduction to Supersymmetric Quantum Mechanics

(у киселева почитаю, мб выгружу потом, пока не до этого)

24.5.7 Quantum scars

(там крутые картинки есть, похоже на грав волновое линзирование, подумаю потом. все равно много времени нужно, чтобы разобраться.)

Quantum scarring refers to a phenomenon where the eigenstates of a classically chaotic quantum system have enhanced probability density around the paths of unstable classical periodic orbits.[2][3] The instability of the periodic orbit is a decisive point that differentiates quantum scars from the more trivial observation that the probability density is enhanced in the neighborhood of stable periodic orbits. The latter can be understood as a purely classical phenomenon, a manifestation of the Bohr correspondence principle, whereas in the former, quantum interference is essential. As such, scarring is both a visual example of quantum-classical correspondence, and simultaneously an example of a (local) quantum suppression of chaos.

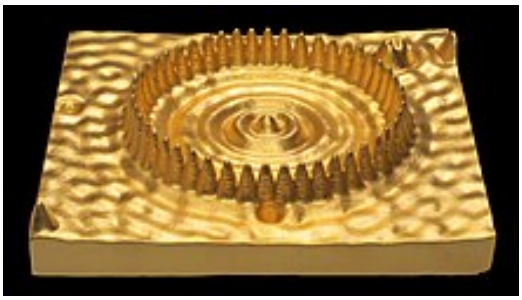
A classically chaotic system is also ergodic, and therefore (almost) all of its trajectories eventually explore evenly the entire accessible phase space. Thus, it would be natural to expect that the eigenstates of the quantum counterpart would fill the quantum phase space in the uniform manner up to random fluctuations in the semiclassical limit. However, scars are a significant correction to this assumption. Scars can therefore be considered as an eigenstate counterpart of how short periodic orbits provide corrections to the universal spectral statistics of the random matrix theory. There are rigorous mathematical theorems on quantum nature of ergodicity,[4][5][6] proving that the expectation value of an operator converges in the semiclassical limit to the corresponding microcanonical classical average. Nonetheless, the quantum ergodicity theorems do not exclude scarring if the quantum phase space volume of the scars gradually vanishes in the semiclassical limit.

24.5.8 Quantum mirage

(там крутые картинки есть, подумаю потом. все равно много времени нужно, чтобы разобраться.)

In physics, a quantum mirage is a peculiar result in quantum chaos. Every system of quantum dynamical billiards will exhibit an effect called scarring, where the quantum probability density shows traces of the paths a classical billiard ball would take. For an elliptical arena, the scarring is particularly pronounced at the foci, as this is the region where many classical trajectories converge. The scars at the foci are colloquially referred to as the "quantum mirage".

The quantum mirage was first experimentally observed by Hari Manoharan, Christopher Lutz and Donald Eigler at the IBM Almaden Research Center in San Jose, California in 2000. The effect is quite remarkable but in general agreement with prior work on the quantum mechanics of dynamical billiards in elliptical arenas.



25 Very Special Methods, Phenomena, Applications

25.1 More on Quantum Scattering Theory

(тут многие другие темы, нпр из ЛЛ3. супер редко они нужны, так что раздел и вдали.)

25.1.1 Gell-Mann and Low theorem

(пока по вики)

Statement of the theorem

Let $|\Psi_0\rangle$ be an eigenstate of H_0 with energy E_0 and let the 'interacting' Hamiltonian be $H = H_0 + gV$, where g is a coupling constant and V the interaction term. We define a Hamiltonian $H_\epsilon = H_0 + e^{-\epsilon|t|}gV$ which effectively interpolates between H and H_0 in the limit $\epsilon \to 0^+$and $|t| \to \infty$. Let $U_{\epsilon I}$ denote the evolution operator in the interaction picture. The Gell-Mann and Low theorem asserts that if the limit as $\epsilon \to 0^+$of

$$\left|\Psi_\epsilon^{(\pm)}\right\rangle = \frac{U_{\epsilon I}(0, \pm\infty)\,|\Psi_0\rangle}{\langle\Psi_0\,|U_{\epsilon I}(0, \pm\infty)|\,\Psi_0\rangle}$$

exists, then $\left|\Psi_\epsilon^{(\pm)}\right\rangle$are eigenstates of H Note that when applied to, say, the ground-state, the theorem does not guarantee that the evolved state will be a ground state. In other words, level crossing is not excluded.

Proof

As in the original paper, the theorem is typically proved making use of Dyson's expansion of the evolution operator. Its validity however extends beyond the scope of perturbation theory as has been demonstrated by Molinari. We follow Molinari's method here. Focus on H_ϵ and let $g = e^{\epsilon\theta}$. From Schrdinger's equation for the time-evolution operator

$$i\hbar\partial_{t_1}U_\epsilon(t_1, t_2) = H_\epsilon(t_1)\,U_\epsilon(t_1, t_2)$$

and the boundary condition $U_\epsilon(t_2, t_2) = 1$ we can formally write

$$U_\epsilon(t_1, t_2) = 1 + \frac{1}{i\hbar}\int_{t_2}^{t_1} dt'\left(H_0 + e^{\epsilon(\theta-|t'|)}V\right)U_\epsilon(t', t_2)$$

Focus for the moment on the case $0 \geq t_1 \geq t_2$. Through a change of variables $\tau = t' + \theta$ we can write

$$U_\epsilon(t_1, t_2) = 1 + \frac{1}{i\hbar}\int_{\theta+t_2}^{\theta+t_1} d\tau\,(H_0 + e^{\epsilon\tau}V)\,U_\epsilon(\tau - \theta, t_2)$$

We therefore have that

$$\partial_\theta U_\epsilon(t_1,t_2) = \epsilon g \partial_g U_\epsilon(t_1,t_2) = \partial_{t_1} U_\epsilon(t_1,t_2) + \partial_{t_2} U_\epsilon(t_1,t_2)$$

This result can be combined with the Schrdinger equation and its adjoint

$$-i\hbar\partial_{t_1} U_\epsilon(t_2,t_1) = U_\epsilon(t_2,t_1) H_\epsilon(t_1)$$

to obtain

$$i\hbar\epsilon g\partial_g U_\epsilon(t_1,t_2) = H_\epsilon(t_1) U_\epsilon(t_1,t_2) - U_\epsilon(t_1,t_2) H_\epsilon(t_2)$$

The corresponding equation between $H_{\epsilon I}, U_{\epsilon I}$ is the same. It can be obtained by pre-multiplying both sides with $e^{iH_0 t_1/\hbar}$, post-multiplying with $e^{iH_0 t_2/\hbar}$ and making use of

$$U_{\epsilon I}(t_1,t_2) = e^{iH_0 t_1/\hbar} U_\epsilon(t_1,t_2) e^{-iH_0 t_2/\hbar}$$

The other case we are interested in, namely $t_2 \geq t_1 \geq 0$ can be treated in an analogous fashion and yields an additional minus sign in front of the commutator (we are not concerned here with the case where $t_{1,2}$ have mixed signs). In summary, we obtain

$$(H_{\epsilon,t=0} - E_0 \pm i\hbar\epsilon g\partial_g) U_{\epsilon I}(0,\pm\infty)|\Psi_0\rangle = 0$$

We proceed for the negative-times case. Abbreviating the various operators for clarity

$$i\hbar\epsilon g\partial_g (U|\Psi_0\rangle) = (H_\epsilon - E_0) U|\Psi_0\rangle$$

Now using the definition of Ψ_ϵ we differentiate and eliminate derivatives $\partial_g(U|\Psi_0\rangle)$ using the above expression, finding

$$\begin{aligned} i\hbar\epsilon g\partial_g|\Psi_\epsilon\rangle &= \frac{1}{\langle\Psi_0|U|\Psi_0\rangle}(H_\epsilon - E_0) U|\Psi_0\rangle - \frac{U|\Psi_0\rangle}{\langle\Psi_0|U|\Psi_0\rangle}\langle\Psi_0|(H_\epsilon - E_0) U|\Psi_0\rangle \\ &= (H_\epsilon - E_0)|\Psi_\epsilon\rangle - |\Psi_\epsilon\rangle\langle\Psi_0|H_\epsilon - E_0|\Psi_\epsilon\rangle \\ &= [H_\epsilon - E]|\Psi_\epsilon\rangle . \end{aligned}$$

where $E = E_0 + \langle\Psi_0|H_\epsilon - H_0|\Psi_\epsilon\rangle$. We can now let $\epsilon \to 0^+$as by assumption the $g\partial_g|\Psi_\epsilon\rangle$ in left hand side is finite. We then clearly see that $|\Psi_\epsilon\rangle$ is an eigenstate of H and the proof is complete.

фермионы

Для фермионов запишем операторы в матричном представлении:

$$(b)_{m,n} = \delta(m)\delta(n-1), \quad \left(b^\dagger\right)_{m,n} = (b)_{n,m} = \delta(m-1)\delta(n) \quad m,n = 0,1$$

$$b = \begin{bmatrix} 0 & 0.1 \\ 0 & 0 \end{bmatrix}, \quad b^\dagger = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}, \quad (c)_{m,n} = (-1)^m\delta(n-m), \quad c = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$$

$$bc + cb = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}\begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} 0 & -1 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} = 0$$

$$bc + cb = 0, \quad b^\dagger c + cb^\dagger = 0, \quad c^2 = 1$$

$$[bw](n) = \delta(n)w(1), \quad \left[b^\dagger w\right](n) = \delta(n-1)w(0)$$

$$\text{Для вакуумной} w_0 = \delta(n): \quad [bw_0](n) = 0, \quad \left[b^\dagger w_0\right](n) = \delta(n-1)\underset{0.}{w_0}(0) = \delta(n-1)$$

$$\text{Для получается, что } w_1 = \delta(n-1): \quad [bw_1](n) = \delta(n), \quad \left[b^\dagger w_1\right](n) = 0$$

то есть b уменьшает на единицу, $b^\dagger$ - увеличивает.

коммутационные соотношения

$$\begin{gathered} \left[b^\dagger bw\right](n) = [\delta(n-1)\delta(p)\delta(p)\delta(m-1)w(m)](n) = \\ = [\delta(n-1)\delta(m-1)w(m)](n) = nw(n) \\ \left[bb_0^\dagger w\right](n) = [\delta(n)\delta(p-1)\delta(p-1)\delta(m)w(m)](n) = \\ = [\delta(n)\delta(m)w(m)](n) = (1-n)w(n) \\ \left[\left(bb^\dagger + b^\dagger b\right)w\right](n) = w(n), \quad \text{или} \quad bb^\dagger + b^\dagger b = 1 \end{gathered}$$

в матричном виде тоже все видано:

$$b^\dagger b + bb^\dagger = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}\begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

осталось проверить, что со степенями операторов
для квадрата:

$$\begin{gathered} [bw](n) = \delta(n)w(1) \to \left[b^2 w\right](n) = 0, b^2 = 0 \\ \left[b^\dagger w\right](n) = \delta(n-1)w(0) \to \left[\left(b^\dagger\right)^2 w\right](n) = 0, \left(b^\dagger\right)^2 = 0 \end{gathered}$$

фермионы продолжение

$$w_1(n) = \delta(n-1): [bw_1](n) = \delta(n), \quad \left[b^\dagger w_1\right](n) = 0$$
$$\left[\left(bb^\dagger + b^\dagger b\right)w\right](n) = w(n), \quad bb^\dagger + b^\dagger b = 1$$
$$\forall w(n): \quad [b^2 w](n) = 0, b^2 = 0; \quad \left[\left(b^\dagger\right)^2 w\right](n) = 0, \left(b^\dagger\right)^2 = 0.$$

$$\mathcal{C}(...n_f...), \quad n_f = 0, 1$$

$$\forall f: \left(b_f, b_f^\dagger, c_f\right); \quad b_f^2 = 0 = \left(b_f^\dagger\right)^2, \hat{n}_f = b_f^\dagger b_f, b_f b_f^\dagger + b_f^\dagger b_f = 1, b_f c_f + c_f b_f = 0, c_f^2 = 1$$

$\left(b_f, b_f^\dagger, c_f\right)$ действуют на n_f, $\quad \left(b_g, b_g^\dagger, c_g\right)$ действуют на n_g.

При $f \neq g$: операторы действуют независимо.

$b_f b_g - b_g b_f = 0, \quad b_f b_g^\dagger - b_g^\dagger b_f = 0, \quad c_f b_g - b_g c_f = 0, \quad$ (и это называется операторами Паули)

$$\mathcal{C}_{\text{vac}} = \prod_g \delta(n_g), (\mathcal{C}_{\text{vac}}, \mathcal{C}_{\text{vac}}) = 1, b_f \mathcal{C}_{\text{vac}} = 0, b_f^\dagger \mathcal{C}_{\text{vac}} = \delta(n_f - 1) \prod_{g \neq f} \delta(n_f)$$

Операторы Паули и операторы Ферми

Получим операторы B_λ из операторов b, то есть перейдем к другому базису.
делается это с помощью унитарного преобразования.

$$B_\lambda = \sum_f u_{\lambda,f} b_f; \quad \sum_f u_{\lambda,f} u_{\mu,f}^* = \delta(\lambda - \mu), \quad \sum_\lambda u_{\lambda,f} u_{\lambda,g}^* = \delta(g - f)$$

$$B_\lambda B_\lambda^\dagger + B_\lambda^\dagger B_\lambda = \sum_{f,g} u_{\lambda,f} u_{\lambda,g}^* \left(b_f b_g^\dagger + b_g^\dagger b_f\right) =$$
$$= \sum_f u_{\lambda,f} u_{\lambda,f}^* \left(b_f b_f^\dagger + b_f^\dagger b_f\right) + \sum_{f \neq g} u_{\lambda,f} u_{\lambda,g}^* \left(b_f b_g^\dagger + b_g^\dagger b_f\right) =$$
$$= \sum_f u_{\lambda,f} u_{\lambda,f}^* + \sum_{f \neq g} u_{\lambda,f} u_{\lambda,g}^* \left(b_f b_g^\dagger + b_g^\dagger b_f\right) = 1 + \sum_{f \neq g} u_{\lambda,f} u_{\lambda,g}^* \left(b_f b_g^\dagger + b_g^\dagger b_f\right)$$

И у нас чтобы был ноль, то есть преобразование было унитарным, нужно, чтобы в правой части занулялось кое-что.

Перестановочные соотношения для операторов Паули не сохраняются при унитарных преобразованиях!

Вводим операторы с помощью домножения на операторы c

$$a_f \equiv \left(\prod_{g<f} c_g\right) b_f = b_f \left(\prod_{g<f} c_g\right) \quad (c_g b_f = b_f c_g, g \neq f);$$

и можем спокойно создать эрмитово сопряженный

$$a_f^\dagger = \left(\prod_{g<f} c_g\right) b_f^\dagger$$

при этому конструкция такова, что основные соотношения не поменялись, действительно:

$$a_f^\dagger a_f = \left(\prod_{g<f} c_g\right) b_f^\dagger \left(\prod_{h<f} c_h\right) b_f = \left(\prod_{g<f} c_g\right)\left(\prod_{h<f} c_h\right) b_f^\dagger b_f = b_f^\dagger b_f = \hat{n}_f$$

и также:

$$a_f^2 = \left(a_f^\dagger\right)^2 = 0, \quad a_f a_f^\dagger + a_f^\dagger a_f = b_f b_f^\dagger + b_f^\dagger b_f = 1$$

теперь посмотрим что мы получили:

$$f < g: \quad a_f a_g + a_g a_f = \left(\prod_{h<f} c_h\right) b_f \left(\prod_{i<g} c_i\right) b_g + \left(\prod_{i<g} c_i\right) b_g \left(\prod_{h<f} c_h\right) b_f \neq \Bigg)$$

$$= b_f \left(\prod_{h<f} c_h\right)\left(\prod_{i<g} c_i\right) b_g + b_g \left(\prod_{i<g} c_i\right)\left(\prod_{h<f} c_h\right) b_f = b_f \left(\prod_{f\le i<g} c_i\right) b_g + b_g \left(\prod_{f\le h<g} c_h\right) b_f =$$

но тепер ь операторов i больше, чем операторов h

но один из операторов c будет антикоммутировать с b, так что вынесется все так:

$$= b_f b_g \left(\prod_{f\le i<g} c_i\right) - b_g b_f \left(\prod_{f\le h<g} c_h\right) = [b_f b_g - b_g b_f]\left(\prod_{f\le h<g} c_h\right) = 0$$

в последнем равенстве у нас появились операторы паули, коммутатор который равен нулю.

и имеем:

$$c_g^\dagger = c_g, \quad f < g: \quad a_f a_g^\dagger + a_g^\dagger a_f = 0$$

а поскольку все симметрично, то можно сказать, что так для любого:

$$\forall f, g: \quad a_f a_g + a_g a_f = 0, \quad a_f a_g^\dagger + a_g^\dagger a_f = \delta(g - f)$$

и именно из-за этой конструкции это называется операторами ферми.

таким образом, они выживают при унитарном преобразовании

и строго говоря они не являются одночастичными операторами, потому что есть в них часть, которая действует на все частицы.

в квантовой механике операторы, которые действуют на разные координаты коммутрируют, поэтому операторы Паули коммутируют, но они не обладают унитарностью, поэтому вводятся операторы, которые похожие на одночастичные, но по факту они многочастинчые. и они антикоммутируют, а не коммутируют.

и казалось бы, что операторы действуют на разные части системы и антикоммутируют.

секрет в том, что есть члены, которые действуют на другие части системы

получили операторы Ферми

$$B_\lambda = \sum_f u_{\lambda,f} a_f, \sum_f u_{\lambda,f} u_{\mu,f}^* = \delta(\lambda - \mu), \quad B_\lambda B_\mu^\dagger + B_\mu^\dagger B_\lambda = \delta(\mu - \lambda)$$

$$[cw](n) = (-1)^n w_n \to c_f \mathcal{C}_{\text{vac}} = \mathcal{C}_{\text{vac}};$$

поэтому когда действуем на вакуум, делается это так:

$$a_f \mathcal{C}_{\text{vac}} = b_f \prod_{h<f} c_h \mathcal{C}_{\text{vac}} = b_f \mathcal{C}_{\text{vac}} = 0$$

$$a_f^\dagger \mathcal{C}_{\text{vac}} = b_f \prod_{h<f} c_h \mathcal{C}_{\text{vac}} = b_f^\dagger \mathcal{C}_{\text{vac}} = \delta(n_f - 1) \prod_{g \neq f} \delta(n_g)$$

$$g < f: \quad a_g^\dagger a_f^\dagger \mathcal{C}_{\text{vac}} = b_g^\dagger \left(\prod_{h<g} c_h \right) \delta(n_f - 1) \prod_{k \neq f} \delta(n_k) = \delta(n_f - 1)\, \delta(n_g - 1) \prod_{k \neq g,f} \delta(n_k)$$

теперь давайте посмотрим, чему равен оператор:

$$a_{g_1}^\dagger a_{g_2}^\dagger ... a_{g_N}^\dagger \mathcal{C}_{\text{vac}} = \delta(n_{g_1} - 1)\, \delta(n_{g_2} - 1) ... \delta(n_{g_n} - 1) \prod_{f \neq g_1 ... g_N} \delta(n_f)$$

где

$$g_1 < g_2 < ... < g_N :$$

рассмотрим

$$\frac{1}{\sqrt{N!}} \sum_{f_1,...,f_N} F(f_1, ... f_N)\, a_{f_1}^\dagger ... a_{f_N}^\dagger \mathcal{C}_{\text{vac}} =$$

$$= \frac{1}{\sqrt{N!}} \sum_{\substack{(...m_f...) \\ \sum_f m_f = N}} \sum_{\substack{f_1,...,f_f \\ (...m_f \cdots)}} F(f_1, ..., f_N)\, a_{f_1}^\dagger ... a_{f_N}^\dagger \mathcal{C}_{\text{vac}}$$

$$\sum_{\substack{f_1,...,f_N \propto \\ (...m_f \cdots)}} F(f_1, ..., f_N)\, a_{f_1}^\dagger ... a_{f_N}^\dagger \mathcal{C}_{\text{vac}} =$$

$$= N! F(g_1, ..., g_N)\, a_{g_1}^\dagger ... a_{g_N}^\dagger \mathcal{C}_{\text{vac}}, \quad (g_1 < g_2 < ... < g_N);$$

$$\frac{1}{\sqrt{N!}} \sum_{f_1,...,f_N} F(f_1, ... f_N)\, a_{f_1}^\dagger ... a_{f_N}^\dagger \mathcal{C}_{\text{vac}} =$$

$$= \sqrt{N!} \sum_{\substack{(...m_f...) \\ \sum_f m_f = N}} F(g_1, ..., g_N)\, a_{g_1}^\dagger ... a_{g_N}^\dagger \mathcal{C}_{\text{vac}}$$

таким образом, это сумма по всем числам заполнений.
потому что они образуют базис и можно разложить по нему
????
Волновая функция в пространстве чисел заполнения

$$a_{g_1}^\dagger a_{g_2}^\dagger ... a_{g_N}^\dagger \mathcal{C}_{\text{vac}} = \prod_g \delta(n_g - m_g)$$

где $m_g = 0$, если $g \neq g_1, g_2, ... g_N$; $m_g = 1$, если $g = g_k, k = 1, 2 ... N$
Определение: $\mathcal{C}(...n_f...) = \sqrt{N!} F(g_1, ..., g_N)$, где $(g_1 < g_2 < ... < g_N)(...n_f...)$
это амплитуда вероятности нахождения именно в этой состоянии чисел заполнения.

$$\frac{1}{\sqrt{N!}}\sum_{f_1,...,f_N} F\left(f_1,...f_N\right) a^\dagger_{f_1}...a^\dagger_{f_N}\mathcal{C}_{\text{vac}} =$$
$$\sum_{(...m_f...)} \mathcal{C}\left(...m_f...\right)\left\{\prod_g \delta\left(n_g - m_g\right)\right\} =$$
$$\sum_f m_f = N$$
$$= \mathcal{C}\left(...n_f...\right)$$

Для фермионов

$$\mathcal{C} = \frac{1}{\sqrt{N!}}\sum_{f_1,...,f_N} F\left(f_1,...f_N\right) a^\dagger_{f_1}...a^\dagger_{f_N}\mathcal{C}_{\text{vac}}$$

таким образом, мы получили функцию в пространстве чисел заполнения.

в итоге формула одна и та же, но смысл элементов в этой формуле разный для бозонов и фермионов.

Бозоны	Фермионы
$F\left(f_1,...,f_N\right)$ - симметричная	$F\left(f_1,...,f_N\right)$ - антисимметричная
$n_f = 0,1,...,N$	$n_f = 0,1$
$a_f a^\dagger_g - a^\dagger_g a_f = \delta(g-f)$	$a_f a^\dagger_g + a^\dagger_g a_f = \delta(g-f)$
$a_f a_g - a_g a_f = 0$	$a_f a_g + a_g a_f = 0$
$a^\dagger_f a^\dagger_g - a^\dagger_g a^\dagger_f = 0$	$a^\dagger_f a^\dagger_g + a^\dagger_g a^\dagger_f = 0$
Вакуумная волновая функция $a_f\mathcal{C}_{\text{vac}} = 0$	

для бозонов - операторы коммутируют, для фермионов - антикоммутируют.

и в обоих случаях вакуумное состояние опередеяется с помощью действия A_f

фоковское представление

$$\mathcal{C} = \frac{1}{\sqrt{N!}}\sum_{f_1,...,f_N} F\left(f_1,...f_N\right) a^\dagger_{f_1}...a^\dagger_{f_N}\mathcal{C}_{\text{vac}}$$

$$F\left(f_1,...f_N\right) = \int \varphi\left(x_1,...,x_N\right)\psi^*_{f_1}\left(x_1\right)...\psi^*_{f_N}\left(x_N\right)dx_1...dx_N$$

$$\mathcal{C} = \frac{1}{\sqrt{N!}}\sum_{f_1,...,f_N}\int \varphi\left(x_1,x_2,...,x_N\right)\psi^*_{f_1}\left(x_1\right)\psi^*_{f_2}\left(x_2\right)...\psi^*_{f_N}\left(x_N\right)dx_1dx_2...dx_N\times$$
$$\times a^\dagger_{f_1}a^\dagger_{f_2}...a^\dagger_{f_N}\mathcal{C}_{\text{vac}}$$

введем функции, зависящие от координат вида

$$\Psi^\dagger(x) \equiv \sum_f \psi^*_f(x)a^\dagger_f, \quad \Psi(x) = \sum_f \psi_f(x)a_f$$

через эти функции можно записать волновую функцию в пространстве чисел заполнения:

сумма уходит после перехода к Ψ

$$\mathcal{C} = \frac{1}{\sqrt{N!}}\int \varphi\left(x_1,x_2,...,x_N\right)\Psi^\dagger\left(x_1\right)\Psi^\dagger\left(x_2\right)...\Psi^\dagger\left(x_N\right)dx_1dx_2...dx_N\mathcal{C}_{\text{vac}}$$

эта конструкция называется представлением фока или функционалом Фока.

$$\text{Для всех } x: \Psi(x)\mathcal{C}_{\text{vac}} = 0; \quad (\mathcal{C}_{\text{vac}}, \mathcal{C}_{\text{vac}}) = 1.$$

коммутационные соотношения

$$[A, B]_{\pm} \equiv AB \pm BA$$

$$\left[a_f, a_g^{\dagger}\right]_{\pm} = a_f a_g^{\dagger} \pm a_g^{\dagger} a_f = \delta\left(f^{0\cdot} g\right), \quad [a_f, a_g]_{\pm} = a_f a_g \pm a_g a_f = 0$$

знак " + " для фермионов и знак " - " для бозонов.
Дальше посмотрим на

$$\left[\Psi(x), \Psi^{\dagger}(y)\right]_{\pm} = \Psi(x)\Psi^{\dagger}(y) \pm \Psi^{\dagger}(y)\Psi(x) =$$

и дальше выносим операторы, по соотношению полноты появляется дельта функция и по соотношению полноты приходим к дельта функции.

$$= \sum_{f,g} \left[\psi_f(x) a_f, \psi_g^*(y) a_g^{\dagger}\right]_{\pm} = \sum_{f,g} \psi_f(x)\psi_g^*(y) \left[a_f, a_g^{\dagger}\right]_{\pm} = \sum_{f,g} \psi_f(x)\psi_g^*(y)\delta(g-f) =$$

$$= \sum_{f} \psi_f(x)\psi_f^*(y) = \delta(f-g)$$

здесь знак + для фермионов, - для бозонов
Аналогично,

$$[\Psi(x), \Psi(y)]_{\pm} = 0$$

$\Psi(x)$ - будет нужна позже для...

Вторичное квантование по Кузьмину 2

кузьмин лекция 12 наверное, просто выгрузка
$\Psi(y) \int \Psi^{\dagger}(x_1) ... \Psi^{\dagger}(x_N) \mathcal{C}_{\text{vac}} \varphi(x_1, ... x_N)\, dx_1 ... dx_N = ?$

$$\times \int \Psi^{\dagger}(x_1) ... \Psi^{\dagger}(x_N) \mathcal{C}_{\text{vac}} \varphi(x_1, ..., x_N) \, dx_1 ... dx_N = \int \Psi^{\dagger}(x) A(x, y) \Psi(y) dx dy \mathcal{C}$$
$$\mathbf{A} = \int \Psi^{\dagger}(x) A(x, y) \Psi(y) dy dx = \int \Psi^{\dagger}(x) [A\Psi](x) dx$$

Плотность числа частиц: $r(\vec{q}) = \sum\limits_{j=1}^{N} \delta(\vec{q} - \vec{q}_j)$; $[r\Psi](\vec{q}_1, \nu) = \delta(\vec{q} - \vec{q}_1) \Psi(\vec{q}_1, \nu)$ $\mathbf{r}(\vec{q}) =$
$\sum\limits_{\nu} \int \Psi^{\dagger}(\vec{q}_1, \nu) \delta(\vec{q} - \vec{q}_1) \Psi(\vec{q}_1, \nu) \, d\vec{q}_1 = \sum\limits_{\nu} \Psi^{\dagger}(\vec{q}, \nu) \Psi(\vec{q}, \nu)$

Число частиц: $\mathbf{N} = \int \mathbf{r}(\vec{q}) d\vec{q} = \sum\limits_{\nu} \int \Psi^{\dagger}(\vec{q}, \nu) \Psi(\vec{q}, \nu) d\vec{q} = \int \Psi^{\dagger}(x) \Psi(x) dx = \sum\limits_{f} a_f^{\dagger} a_f$

для

$$\mathcal{C} = \frac{1}{\sqrt{N!}} \int \varphi(x_1, ..., x_N) \Psi^{\dagger}(x_1) ... \Psi^{\dagger}(x_N) \mathcal{C}_{\text{vac}} dx_1 ... dx_N$$
$$(\mathbf{N} - N)\mathcal{C} = 0; \quad \mathbf{N}\Psi(x)\mathcal{C} = (N-1)\Psi(x)\mathcal{C}; \quad \mathbf{N}\Psi^{\dagger}(x)\mathcal{C} = (N+1)\Psi^{\dagger}(x)\mathcal{C}$$

оператор для взаимодействия двух частиц

$$\mathfrak{B} \equiv \sum_{1 \le j_1 < j_2 \le N} B_{j_1, j_2} = \frac{1}{2} \sum_{1 \le j_1, j_2 \le N; j_1 \ne j_2} B_{j_1, j_2}$$
Лекция 8: $\int \Theta(X) [\mathfrak{B}\Phi](X) dX = \frac{N(N-1)}{2} \int \Theta(x_1, x_2, x_3, ..., x_N) \times$
$\times B(x_1, x_2; y_2, y_1) \Phi(y_1, y_2, x_3, ..., x_N) \, dy_1 dy_2 dx_1 dx_2 ... dx_N$

то есть перестановочная симметрия от такого оператора сводится к большому числу одинаковых интегралов.

Ну и просто действуем этим оператором и считаем функционал Фока от этой конструкции.

Выпишем по сути оперделеение функционала для данного случая:

$$\mathcal{C}\{\mathfrak{B}\varphi\} = \frac{1}{\sqrt{N!}} \int \Psi^{\dagger}(x_1) ... \Psi^{\dagger}(x_N) \mathcal{C}_{\text{vac}} [\mathfrak{B}\varphi](x_1, ..., x_N) \, dx_1 ... dx_N =$$

$$= \frac{N(N-1)}{2} \frac{1}{\sqrt{N!}} \int \Psi^{\dagger}(x_1) \Psi^{\dagger}(x_2) \Psi^{\dagger}(x_3) ... \Psi^{\dagger}(x_N) \mathcal{C}_{\text{vac}} B(x_1, x_2; y_2, y_1) \times$$
$$\times \varphi(y_1, y_2, x_3 ..., x_N) \, dy_1 dy_2 dx_1 dx_2 ... dx_N$$

такие уже интегралы у нас возникали про дейсвтии функционала фока...

только у нас число действий операторов больше, так как у нас теперь двухчастичный оператор.

а мы уже заметили, что

$$N(N-1) \int \Psi^{\dagger}(x_3) ... \Psi^{\dagger}(x_N) \mathcal{C}_{\text{vac}} \varphi(y_1, y_2, x_3, ..., x_N) \, dx_3 ... dx_N =$$
$$= \int \Psi(y_2) \Psi(y_1) \Psi^{\dagger}(x_1) \Psi^{\dagger}(x_2) ... \Psi^{\dagger}(x_N) \mathcal{C}_{\text{vac}} \varphi(x_1, x_2, ..., x_N) \, dx_1 dx_2 ... dx_N$$

то есть у нас функционал фока и два оператора умножения.

$$\mathcal{C}\{\mathfrak{B}\varphi\} = \frac{1}{2}\int \Psi^{\dagger}(x_1)\,\Psi^{\dagger}(x_2)\,B(x_1,x_2;y_2,y_1)\,\Psi(y_2)\,\Psi(y_1)\,dy_1dy_2dx_1dx_2\mathcal{C}\{\varphi\}$$

в итоге симметричный двухчастичный оператор равен

$$\begin{gathered}\mathbf{B} = \tfrac{1}{2}\int \Psi^{\dagger}(x_1)\,\Psi^{\dagger}(x_2)\,B(x_1,x_2;y_2,y_1)\,\Psi(y_2)\,\Psi(y_1)\,dy_1dy_2dx_1dx_2 = \\ = \tfrac{1}{2}\int \Psi^{\dagger}(x_1)\,\Psi^{\dagger}(x_2)\,[B_{1,2}\Psi_2\Psi_1](x_1,x_2)\,dx_1dx_2\end{gathered}$$

$$\begin{gathered}\text{Iror: } \int \Psi(y)\Psi^{\dagger}(x_1)\ldots\Psi^{\dagger}(x_N)\,\mathcal{C}_{\text{vac}}\,\varphi(x_1,\ldots x_N)\,dx_1\ldots x_N = \\ = N\int \Psi^{\dagger}(x_2)\ldots\Psi^{\dagger}(x_N)\,\mathcal{C}_{\text{vac}}\,\delta(x_1-y)\,\varphi(x_1,\ldots x_N)\,dx_1\ldots x_N \\ \int \Psi(y_2)\,\Psi(y_1)\,\Psi^{\dagger}(x_1)\ldots\mathscr{U}^{\dagger}(x_N)\,\mathcal{C}_{\text{vac}}\,\varphi(x_1,\ldots x_N)\,dx_1\ldots x_N = \\ = N\int \Psi(y_2)\,\Psi^{\dagger}(x_2)\ldots\Psi^{\dagger}(x_N)\,\mathcal{C}_{\text{vac}}\,\delta(x_1-y_1)\,\varphi(x_1,\ldots x_N)\,dx_1\ldots x_N = \\ = N!\int \mathcal{C}_{\text{vac}}\,\delta(x_1-y_1)\ldots\delta(x_N-y_N)\,\varphi(x_1,\ldots x_N)\,dx_1\ldots x_N\end{gathered}$$

гамильтониан

(13я лекция кузьмина)

$$\begin{gathered}H = \sum_{1\le J\le N} T_j + \sum_{1\le j_1<j_2\le N} U_{j_1,j_2} \\ T^*(x,y) = T(y,x), \quad U^*(x_1,x_2;y_2,y_1) = U(y_1,y_2;x_2,x_1) \\ H = -\sum_{1\le J\le N}\frac{\hbar^2}{2m}\Delta_{q_j} + \sum_{1\le j_1<j_2\le N} V(q_{j_1}-q_{j_2}), \quad V(-q) = V(q) \\ T(x,x') = -\frac{\hbar^2}{2m}\Delta_q\delta(x'-x) = -\frac{\hbar^2}{2m}\Delta_q\delta(q'-q)\,\delta(\nu'-\nu) \\ U(x_1,x_2;x_2',x_1') = V(q_2-q_1)\,\delta(q_1'-q_1)\,\delta(q_2'-q_2)\,\delta(\nu_1'-\nu_1)\,\delta(\nu_2'-\nu_2).\end{gathered}$$

гамильтониан теперь во вторично квантованном представлении не зависит от числа частиц!

и он одинаков для фермионов и бозонов

$$\begin{gathered}\mathbf{H} = -\tfrac{\hbar^2}{2m}\int \Psi^{\dagger}(x)\Delta_q\Psi(x)dx + \\ +\tfrac{1}{2}\iint V(q_1-q_2)\,\Psi^{\dagger}(x_1)\,\Psi^{\dagger}(x_2)\,\Psi(x_2)\,\Psi(x_1)\,dx_1dx_2\end{gathered}$$

$$\text{Внешнее поле} \quad \sum_{j=1}^{N} U_{\text{ext}}(q_j) \to \int U_{\text{ext}}(q)\Psi^{\dagger}(x)\Psi(x)dx$$

зависимость от времени

$$\begin{gathered}H(t) = e^{i\frac{H}{\hbar}t}He^{-i\frac{H}{\hbar}t} = H, \quad \mathbf{H} = -\tfrac{\hbar^2}{2m}\int \Psi^{\dagger}(t,x)\Delta_q\Psi(t,x)dx + \\ +\tfrac{1}{2}\iint V(q_1-q_2)\,\Psi^{\dagger}(t,x_1)\,\Psi^{\dagger}(t,x_2)\,\Psi(t,x_2)\,\Psi(t,x_1)\,dx_1dx_2 = \\ = -\tfrac{\hbar^2}{2m}\int \Psi^{\dagger}(x)\triangle_q\Psi(x)dx + \tfrac{1}{2}\iint V(q_1-q_2)\,\Psi^{\dagger}(x_1)\,\Psi^{\dagger}(x_2)\,\Psi(x_2)\,\Psi(x_1)\,dx_1dx_2\end{gathered}$$

$$\begin{gathered}\mathfrak{A} = \sum_{j=1,\ldots,N} A_j; \quad \mathbf{A} = \int \Psi^{\dagger}(x)A(x,y)\Psi(y)dydx = \\ = \int \sum_{f,g}\psi_f^*(x)a_f^{\dagger}A(x,y)\psi_g(y)a_gdydx = \sum_{f,g}\langle f|A|g\rangle a_f^{\dagger}a_g\end{gathered}$$

$$\langle f|A|g\rangle \equiv \int \psi_f^*(x)A(x,y)\psi_g(y)dydx$$

$$\mathbf{B} = \tfrac{1}{2}\iint V(q_1-q_2)\,\Psi^\dagger(x_1)\,\Psi^\dagger(x_2)\,\Psi(x_2)\,\Psi(x_1)\,dx_1dx_2 = \\ = \tfrac{1}{2}\sum_{f,g,h,i}\langle fg|V|hi\rangle a_f^\dagger a_g^\dagger a_i a_h$$

$$\langle fg|V|hi\rangle \equiv \iint \psi_f^*(x_1)\,\psi_g^*(x_2)\,V(q_1-q_2)\,\psi_h(x_1)\,\psi_i(x_2)\,dx_1dx_2$$

теперь с операторами конец

Гамильтониан и метод Хартри-Фока

$$H = \sum_{i=1}^{N} T(\mathbf{r}_i) + \tfrac{1}{2}\sum_{i\neq j=1}^{N} V(\mathbf{r}_i,\mathbf{r}_j)$$
$$H = \sum_{k,l}\langle k|T|l\rangle a_k^\dagger a_l + \tfrac{1}{2}\sum_{k,l,m,n}\langle kl|V|mn\rangle a_k^\dagger a_l^\dagger a_n a_m$$

где

$$\langle k|T|l\rangle \equiv \int \phi_k^*(\mathbf{r})T(\mathbf{r})\phi_l(\mathbf{r})d\mathbf{r}$$
$$\langle kl|V|mn\rangle \equiv \int \phi_k^*(\mathbf{r}_1)\,\phi_l^*(\mathbf{r}_2)\,V(\mathbf{r}_1,\mathbf{r}_2)\,\phi_m(\mathbf{r}_1)\,\phi_n(\mathbf{r}_2)\,d\mathbf{r}_1d\mathbf{r}_2$$
$$a_k^\dagger a_l^\dagger + a_l^\dagger a_k^\dagger = 0, \quad a_k a_l + a_l a_k = 0, \quad a_k a_l^\dagger + a_l^\dagger a_k = \delta(k-l)$$
$$|\Phi\rangle = \textstyle\prod_{h=1}^{N} a_h^\dagger|0\rangle, \quad \forall k: a_k|0\rangle = 0; \quad \langle\Phi|H|\Phi\rangle = \min, \quad \delta\langle\Phi|H|\Phi\rangle = 0$$
$$\Phi(\mathbf{r}_1,...,\mathbf{r}_N) = \tfrac{1}{\sqrt{N!}}\begin{vmatrix} \phi_1(\mathbf{r}_1) & \phi_1(\mathbf{r}_2) & ... & \phi_1(\mathbf{r}_N) \\ \phi_2(\mathbf{r}_1) & \phi_2(\mathbf{r}_2) & ... & \phi_2(\mathbf{r}_N) \\ ... & ... & ... & ... \\ \phi_N(\mathbf{r}_1) & \phi_N(\mathbf{r}_2) & ... & \phi_N(\mathbf{r}_N) \end{vmatrix}$$

Как варьировать определитель Слэтера

$$\delta\langle\Phi|H|\Phi\rangle = 0 \Longleftrightarrow \langle\delta\Phi|H|\Phi\rangle = 0, \quad \langle\Phi|H|\delta\Phi\rangle = 0$$
$$\phi_h(\mathbf{r}) \to \phi_h(\mathbf{r}) + \eta\phi_p(\mathbf{r}), \quad 1 \leqslant h \leqslant N, p > N$$
$$|\delta\Phi\rangle = \eta a_p^\dagger a_h|\Phi\rangle: \quad \left\langle\Phi\left|Ha_p^\dagger a_h\right|\Phi\right\rangle = 0, \quad \left\langle\Phi\left|a_h^\dagger a_p H\right|\Phi\right\rangle = 0$$

Средние по состоянию Х-Ф

$$\langle k|T|l\rangle: \quad \left\langle\Phi\left|a_h^\dagger a_p a_k^\dagger a_l\right|\Phi\right\rangle = \left\langle\Phi\left|a_h^\dagger\left(\delta(k-p) - a_k^\dagger a_p\right)a_l\right|\Phi\right\rangle \\ = \delta(k-p)\left\langle\Phi\left|a_h^\dagger a_l\right|\Phi\right\rangle - \left\langle\Phi\left|a_h^\dagger a_k^\dagger a_p a_l\right|\Phi\right\rangle = \delta(k-p)\delta(l-h)$$

$$\langle kl|V|mn\rangle: \quad \left\langle\Phi\left|a_h^\dagger a_p a_k^\dagger a_l^\dagger a_n a_m\right|\Phi\right\rangle = \left\langle\Phi\left|a_h^\dagger\left(\delta(k-p) - a_k^\dagger a_p\right)a_l^\dagger a_n a_m\right|\Phi\right\rangle = \\ = -\delta(k-p)\delta(n-h)\left\langle\Phi\left|a_l^\dagger a_m\right|\Phi\right\rangle + \delta(l-p)\left\langle\Phi\left|a_k^\dagger a_h^\dagger a_n a_m\right|\Phi\right\rangle + \\ +\delta(k-p)\left\langle\Phi\left|a_l^\dagger a_n a_h^\dagger a_m\right|\Phi\right\rangle =$$

Про источники энергии звезд

Теория

В 1929 г. Р. Аткинсон и Ф. Хоутерманс (1903 – 1966) высказали гипотезу о том, что внутри Солнца и других звезд существуют условия для протекания реакций ядерного синтеза, и их излучение создается за счет термоядерных реакций.

В настоящее время принято считать, что Солнце и звезды образовались (и образуются) в результате постепенной гравитационной конденсации межзвездного газа, состоящего в основном из водорода.

В первоначальной фазе сжатия, которая для звезды с массой, близкой к массе Солнца, длится около 10^7 лет, температура звезды повышается только за счет гравитационной энергиИ.

Когда температура внутренних областей достигает 10^7K, они превращаются в горячую плазму и начинаются ядерные реакции водородного цикла, при которых четыре ядра водорода в конечном счете превращаются в ядро ^{4}He с выделением около 26,2 МэВ энергии.

Эти реакции происходят через ряд последовательных ступеней:

$$
\begin{aligned}
{}^1\mathrm{H} + {}^1\mathrm{H} &\to {}^2\mathrm{H} + e^+ + \nu \\
{}^2\mathrm{H} + {}^1\mathrm{H} &\to {}^3\mathrm{He} + \gamma \\
{}^3\mathrm{He} + {}^3\mathrm{He} &\to {}^4\mathrm{He} + 2{}^1\mathrm{H} \\
{}^3\mathrm{He} + {}^4\mathrm{He} &\to {}^7\mathrm{Be} + \gamma \\
{}^7\mathrm{Be} + {}^1\mathrm{H} &\to {}^8\ \mathrm{B} \to {}^8\mathrm{Be} + e^+ + \nu \\
{}^8\mathrm{Be} &\to 2{}^4\mathrm{He} \\
{}^7\mathrm{Be} + e^- &\to {}^7\mathrm{Li} + \nu \\
{}^7\mathrm{Li} + {}^1\mathrm{H} &\to 2{}^4\mathrm{He}
\end{aligned}
$$

состоит из водорода и гелия.

Это дает основание предположить, что источником энергии Солнца действительно служит превращение водорода в гелий. Гидродинамическое и тепловое равновесие в звезде обеспечивается равенством сил тяготения и давления, действующих на каждый элемент ее массы.

Выделение ядерной энергии компенсирует потери энергии на излучение.

Длительность данной стадии зависит от массы звезды и от запасов водорода. Другой возможный процесс превращения водорода в гелий был предложен Г. Бете (19062005).

Он называется углеродным циклом.

Протекание углеродного цикла возможно в звездах, которые уже содержат достаточное количество ядер атомов углерода и кислорода, служащих катализаторами.

Он состоит из последовательности реакций:

$$
\begin{aligned}
12\mathrm{C} + {}^1\mathrm{H} &\to {}^{13}\mathrm{H} + \gamma \\
{}^{13}\ \mathrm{N} &\to {}^{13}\mathrm{C} + e^+ + \nu\,(1,2\mathrm{M}_\ni\mathrm{B})\,, \\
{}^1\mathrm{H} + {}^{13}\mathrm{C} &\to {}^{14}\ \mathrm{N} + \gamma \\
{}^1\mathrm{H} + {}^{14}\ \mathrm{N} &\to {}^{15}\mathrm{O} + \gamma \\
{}^{15}\mathrm{O} &\to {}^{15}\ \mathrm{N} + e^+ + \nu\,(1,7\mathrm{M}_\ni\mathrm{B})\,, \\
{}^1\mathrm{H} + {}^{15}\ \mathrm{N} &\to {}^{12}\mathrm{C} + {}^4\mathrm{He}
\end{aligned}
$$

в результате которых четыре ядра водорода превращаются в ядро ^{4}He с выделением около $25\mathrm{M}_\ni\mathrm{B}$, как и при водородном цикле.

Поведение ядра углерода в данном случае очень похоже на поведение катализаторов при химических реакциях, сохраняющихся после завершения цикла.

На Солнце, по-видимому, главную роль играет водородный цикл.

Каждую секунду в нем около $8 \cdot 10^8$ т водорода превращается в гелий.

Если этот процесс будет продолжаться с той же интенсивностью, то запасов водорода хватит еще на 10^{10} лет.

Интересно, что около 5% энергии Солнца и звезд, в которых энергия выделяется в результате водородного цикла, излучается в виде нейтрино.

26 Advanced Exotic Mathematical Methods of Quantum Mechanics

Here, I'll put purely mathematical theories which I have no idea how to use or which have not been used much by others.

(I'll move some theory from theoretical sections here. From Takhtajayan and others, there are a lot of such methods)

26.1 Supersymmetry

26.1.1 Why Does One Need Supersymmetry and What Does It Give?

(a very important question, I'll write it here)

26.1.2 Supermanifolds

The coordinate vector space $V = \mathbb{R}^n$ has a natural structure of a smooth manifold, which to every open subset $U \subseteq \mathbb{R}^n$ assigns a commutative $\mathbb{R}$ algebra $C^\infty(U)$ of all smooth functions on U. The assignment

$$U \mapsto C^\infty(U)$$

for all open $U \subseteq \mathbb{R}^n$ defines a sheaf of commutative $\mathbb{R}$-algebras (commutative rings) on a topological space $\mathbb{R}^n$, and turns it into a ringed space. Every smooth n-dimensional manifold M is a ringed space - a topological space with a sheaf of commutative rings, which is locally isomorphic to the ringed space $\mathbb{R}^n$. It is easy to see that this definition is equivalent to the standard one, defined by gluing coordinate charts. The notion of a supermanifold generalizes this idea by using local models associated with graded vector spaces.

Namely, let $W = \mathbb{R}^{p|q}$ be the coordinate graded vector space of dimension $p|q$ over $\mathbb{R}$. The following definition formalizes the intuitive idea that odd coordinates on W are anticommuting.

Definition. A supermanifold $\mathbb{R}^{p|q}$ is a topological space $\mathbb{R}^p$ with a sheaf of commutative $\mathbb{R}$-superalgebras (supercommutative rings) over $\mathbb{R}$, called the structure sheaf, defined by the assignment

$$U \mapsto C^\infty(U)\left[\theta^1, ..., \theta^q\right]$$

for all open $U \subseteq \mathbb{R}^p$, where $C^\infty(U)\left[\theta^1, ..., \theta^q\right]$ is a Grassmann algebra with generators $\theta^1, ..., \theta^q$ over the commutative ring $C^\infty(U)$.

Remark. Elements of $C^\infty(U)\left[\theta^1, ..., \theta^q\right]$ have the form

$$f = \sum_I f_I \theta^I, \quad \theta^I = \theta^{i_1} ... \theta^{i_k} \quad \text{and} \quad f_I \in C^\infty(U)$$

for $I = \{i_1, ..., i_k\} \subset \{1, ..., q\}$, and are called functions on a supermanifold $\mathbb{R}^{p|q}$ over U. Thus $\mathbb{R}^{p|q}$ is a coordinate space with even coordinates $\boldsymbol{x} = (x^1, ..., x^p)$ and odd coordinates $\boldsymbol{\theta} = (\theta^1, ..., \theta^q)$, and we will write $f \in C^\infty(U)\left[\theta^1, ..., \theta^q\right]$ as $f(\boldsymbol{x}, \boldsymbol{\theta})$.

Definition. A supermanifold of dimension $p|q$ is a pair $(X, \mathcal{O}_X)$ - a topological space X with a sheaf $\mathcal{O}_X$ of supercommutative rings over $\mathbb{R}$, called the structure sheaf, which is locally isomorphic to $\mathbb{R}^{p|q}$.

Supermanifolds form a category: a morphism between supermanifolds $(X, \mathcal{O}_X)$ and $(Y, \mathcal{O}_Y)$ is a continuous map $\varphi : X \to Y$, together with a sheaf map $\varphi^* : \mathcal{O}_Y \to \mathcal{O}_X$ over φ, a collection of homomorphisms of supercommutative rings over $\mathbb{R}$,

$$\varphi_V^* : \mathcal{O}_Y(V) \to \mathcal{O}_X\left(\varphi^{-1}(V)\right), \quad V \subseteq Y \quad \text{open}$$

which commute with restriction maps of the sheaves.

To every vector bundle E of rank q over an ordinary p-dimensional manifold M there is an associated supermanifold ΠE of dimension $p|q$, defined by reversing parity in the fibers of E. Namely, for every open $U \subseteq M$ let $C^\infty(U, E)$ be the space of all smooth sections of E over U. It is a free $C^\infty(U)$ module generated by q sections $\theta^1, ..., \theta^q$. Consider them as generators of the Grassmann algebra (this explains using Greek letters), and define the structure sheaf of ΠE by the assignment $U \mapsto C^\infty(U)\left[\theta^1, ..., \theta^q\right]$. It can be shown that every supermanifold is isomorphic (non-canonically) to ΠE for some vector bundle E over M.

Remark. Supermanifolds have many more morphisms than vector bundles, since one is allowed to mix even and odd variables. Thus for the supermanifold $\mathbb{R}^{1|2}$ with even coordinate x and odd coordinates θ_1, θ_2 the mapping

$$\varphi(x) = x + \theta^1\theta^2, \quad \varphi\left(\theta^i\right) = \theta^i, \quad i = 1, 2$$

is an isomorphism of $\mathbb{R}^{1/2}$, but it is not induced by an isomorphism of a trivial rank 2 vector bundle over $\mathbb{R}$.

Using these definitions, one can develop differential geometry of supermanifolds and the corresponding theory of integration, which is quite similar to that for ordinary manifolds (see Section 7 for the references). Here we will only consider the simplest example of supermanifolds ΠTM, where M is an ordinary manifold. It is quite remarkable that the basic notions of differential geometry on a manifold M can be formulated in terms of the supermanifold $\Pi\mathrm{T}\, M$.

Namely, let $\mathcal{A}^\bullet(M)$ be a commutative superalgebra of smooth differential forms on the n-dimensional manifold M, and let $C^\infty(\Pi TM)$ be a commutative superalgebra of global sections of the structure sheaf of ΠTM - the superalgebra of functions on a supermanifold ΠTM. The isomorphism

$$\mathcal{A}^\bullet(M) \simeq C^\infty(\Pi TM)$$

allows us to interpret differential forms on M as functions on ΠTM. Indeed, to every $\omega_p \in \mathcal{A}^p(M)$, given in local coordinates on $U \subset M$ by

$$\omega_p = \sum_{1 \le i_1 < \cdots < i_p \le n} a_{i_1 \ldots i_p}(\boldsymbol{x}) dx^{i_1} \wedge \cdots \wedge dx^{i_p}$$

we assign

$$\omega_p(\boldsymbol{x}, \boldsymbol{\theta}) = \sum_{1 \le i_1 < \cdots < i_p \le n} a_{i_1 \ldots i_p}(\boldsymbol{x}) \theta^{i_1} \ldots \theta^{i_p} \in C^\infty(U)\left[\theta^1, ..., \theta^n\right].$$

It trivially follows from the definition of differential form and of ΠTM that under a change of coordinates $a_{i_1 \ldots i_p}(\boldsymbol{x})$ transform like coefficients of differential forms, and $\theta^1, ..., \theta^n$ transform like components of tangent vectors, so that $\omega_p(\boldsymbol{x}, \boldsymbol{\theta})$ is a well-defined function on the supermanifold ΠTM. Correspondingly, the de Rham differential d gives rise to an odd vector field δ on ΠTM,

$$\delta = \sum_{k=1}^{n} \theta^k \frac{\partial}{\partial x^k},$$

with the property that $\delta^2 = 0$. Finally, the supermanifold ΠTM carries a canonical volume form $d\boldsymbol{x}d\boldsymbol{\theta} = dx^1...dx^n d\theta^1...d\theta^n$, which is well defined due to the opposite change of variables formulas for the ordinary and Berezin's integrals (see Section 2.3 of Chapter 7). The integration of a top differential form over M reduces to the integration of a corresponding function over ΠTM with respect to the canonical volume form,

$$\int_M \omega_n = \int_{\Pi TM} \omega_n(\boldsymbol{x}, \boldsymbol{\theta}) d\boldsymbol{x} d\boldsymbol{\theta}$$

Remark. Sometimes in the mathematics literature, in order to emphasize the opposite change of variables formulas for the ordinary and Berezin's integrals, the volume form on the supermanifold ΠTM is denoted by $d\boldsymbol{x}d\boldsymbol{\theta}^{-1}$.

Problem 1.1. Prove all statements in this section.

26.1.3 Equivariant Cohomology and Localization

2.1. Finite-dimensional case.

Let M be a compact orientable n-dimensional manifold with the circle action - an action of abelian group $U(1) = S^1$ - and let $V \in \mathrm{Vect}(M)$ be the vector field corresponding to this action,

$$V(f)(x) = \left.\frac{d}{dt}\right|_{t=0} f\left(e^{it} \cdot x\right), \quad x \in M.$$

Consider the linear operator

$$D = d - i_V : \mathcal{A}^\bullet(M) \to \mathcal{A}^\bullet(M),$$

where i_V is the inner product operator with V. Using the identification $\mathcal{A}^\bullet(M) \simeq C^\infty(\Pi TM)$, in local coordinates $\boldsymbol{x} = (x^1, ..., x^n)$ on $U \subset M$ we can represent D by

$$D = \sum_{\mu=1}^n \left(\theta^\mu \frac{\partial}{\partial x^\mu} - v^\mu \frac{\partial}{\partial \theta^\mu}\right), \quad \text{where} \quad V = \sum_{\mu=1}^n v^\mu \frac{\partial}{\partial x^\mu}. \tag{2.1}$$

It follows from the Cartan formula (see Chapter 1), or directly from (2.1), that

$$D^2 = -\mathcal{L}_V,$$

where $\mathcal{L}_V$ is a Lie derivative. Thus D is a differential on the subcomplex $\mathcal{A}^\bullet(M)^{S^1}$ of S^1-invariant differential forms on M. The cohomology of this complex is an equivariant cohomology in the Cartan formulation. Since d and i_V have, respectively, degrees 1 and -1 , equivariantly closed forms on M necessarily have several components. Namely, the equation $D\alpha = 0$ for $\alpha = \sum_{p=0}^n \alpha_p \in \mathcal{A}^\bullet(M)$ is equivalent to the following system of equations:

$$d\alpha_p = i_V \alpha_{p+2}, \quad p = 0, ..., n-2, \quad \text{and} \quad d\alpha_{n-1} = 0.$$

Let M_V be a zero locus of the vector field V - the set of fixed points of the circle action. We have the following fundamental property of equivariantly closed differential forms.

Lemma 2.1. An equivariantly closed differential form an a compact manifold M is equivariantly exact on $M \backslash M_V$.

Proof. Let $\alpha \in \mathcal{A}^\bullet(M)$ be such that $D\alpha = 0$. We want to find a differential form λ on $M \backslash M_V$ such that $\alpha = D\lambda$ on $M \backslash M_V$. Suppose there is a form ξ on $M \backslash M_V$, with components of odd degrees, satisfying $D\xi = 1$. Setting $\lambda = \xi \wedge \alpha$ we get

$$D\lambda = D\xi \wedge \alpha - \xi \wedge D\alpha = \alpha$$

To construct such a form ξ, choose an S^1-invariant Riemannian metric g on M, and denote by $\beta \in \mathcal{A}^1(M)$ the 1-form on M dual to the vector field V with respect to the Riemannian metric, $\beta = \langle V, \cdot \rangle$. Since the metric g is S^1-invariant, $\mathcal{L}_V g = 0$ and, therefore, $\mathcal{L}_V \beta = 0$. We have

$$D\beta = K + \Omega, \quad \text{where} \quad K = -\|V\|^2 \quad \text{and} \quad \Omega = d\beta.$$

Since $K \in \mathcal{A}^0(M)$ does not vanish on $M \backslash M_V$,

$$\xi = \beta(D\beta)^{-1} = \frac{\beta}{K}\left(1 + K^{-1}\Omega\right)^{-1} = \frac{\beta}{K}\sum_{i=0}^{l}(-1)^i\frac{\Omega^i}{K^i}, \quad l = \left[\frac{n}{2}\right],$$

is a well-defined form on $M \backslash M_V$ satisfying $D\xi = 1$.

Corollary 2.1. The top component of an equivariantly closed form on M is exact on $M \backslash M_V$.

Remark. In local coordinates $\boldsymbol{x} = (x^1, ..., x^n)$ on M the Riemannian metric g has the form [1] $ds^2 = g_{\mu\nu}dx^\mu dx^\nu$, and equation $\mathcal{L}_V g = 0$ - the condition that V is a Killing vector field with respect to the metric g - can be written as

$$g_{\mu\lambda}\nabla_\nu v^\lambda + g_{\nu\lambda}\nabla_\mu v^\lambda = 0. \tag{2.2}$$

Here ∇_μ is a covariant derivative with respect to the vector field $\frac{\partial}{\partial x^\mu}$. For the 1 -form $\beta = g_{\mu\nu}v^\nu dx^\mu$ we also have

$$D\beta = -g_{\mu\nu}v^\mu v^\nu + \omega_{\mu\nu}dx^\mu \wedge dx^\nu, \quad \text{where} \quad \omega_{\mu\nu} = g_{\nu\lambda}\nabla_\mu v^\lambda. \tag{2.3}$$

By (2.2), the $n \times n$ matrix $\omega(\boldsymbol{x}) = \{\omega_{\mu\nu}(\boldsymbol{x})\}_{\mu,\nu=1}^n$ is skew-symmetric. For even $n = 2l$, orientation on M allows us to define $\mathrm{Pf}(\omega(x))$ as the product $\lambda_1 ... \lambda_l$ of above-diagonal elements in the canonical form [2] of a skewsymmetric matrix $\omega(\boldsymbol{x})$ (see Section 2.3 of Chapter 7). Correspondingly, $\mathrm{Pf}(\omega)(\boldsymbol{x})(\det g(\boldsymbol{x}))^{-\frac{1}{2}}$ does not depend on a choice of local coordinates, and defines a function on M. For every $x \in M$ there is also a linear mapping $L_x : T_xM \to T_xM$, defined by $L_x W = (\nabla_W V)(x)$, where ∇_W is a covariant derivative with respect to $W \in T_xM$. Since $\det L_x \det g(x) = \mathrm{Pf}(\omega(x))^2$, we define

$$\sqrt{\det L_x} = \frac{\mathrm{Pf}(\omega(x))}{\sqrt{\det g(x)}}. \tag{2.4}$$

For $x \in M_V$ the mapping L_x does not depend on the choice of an S^1-invariant metric g, and is given by the matrix $\left\{\frac{\partial v^\mu}{\partial x^\nu}(\boldsymbol{x})\right\}_{\mu,\nu=1}^n$.

According to Lemma 2.1, the integral $\int_M \alpha$ of an equivariantly closed differential form α localizes on the zero locus M_V. A quantitative result is given by the following statement.

Proposition 2.1. Suppose that $D\alpha = 0$ on M. Then for every S^1-invariant $\beta \in \mathcal{A}^1(M)$ the integral $\int_M \alpha e^{tD\beta}$ does not depend on t.

Proof. Denote this integral by $Z(t)$. We have

$$\frac{dZ}{dt} = \int_M \alpha D\beta e^{tD\beta} = \int_M D\left(\beta\alpha e^{tD\beta}\right) + \int_M \beta D\left(\alpha e^{tD\beta}\right) = 0$$

where the first integral is zero by Stokes' theorem, and the second integral is zero by the conditions $D\alpha = 0$ and $D^2\beta = 0$.

[01] We are assuming the summation over repeated indices.

[2] Obtained by using orthogonal transformation with determinant 1 .

This result is usually used to evaluate $Z(0) = \int_M \alpha$ by computing the asymptotics of $Z(t)$ as $t \to \infty$. For a suitably chosen 1-form β the leading contribution is given by the integral over a tubular neighborhood of the zero locus of the component $K = (D\beta)_0 \in \mathcal{A}^0(M)$, which can be computed in the closed form as $t \to \infty$. The simplest case of a localization phenomenon is when the circle action on M has only isolated fixed points, i.e., when M_V is a finite set and L_x is non-degenerate for $x \in M_V$. In particular, in this case n is even.

Theorem 2.2 (Berline-Vergne localization theorem). Let M be a compact oriented $2l$-dimensional manifold with a circle action which has only isolated fixed points. Then for every equivariantly closed form $\alpha \in \mathcal{A}^\bullet(M)$,

$$\int_M \alpha = (2\pi)^l \sum_{x \in M_V} \frac{\alpha_0(x)}{\sqrt{\det L_x}}.$$

Proof. Let β be the 1-form introduced in the proof of Lemma 2.1, so that in local coordinates $\Omega = d\beta = \omega_{\mu\nu} dx^\mu \wedge dx^\nu$. Using Proposition 2.1 and the identification $\mathcal{A}^\bullet(M) \simeq C^\infty(\Pi TM)$, we get

$$\int_M \alpha = \lim_{t\to\infty} \int_{\Pi TM} \alpha(\boldsymbol{x}, \boldsymbol{\theta}) e^{-t g_{\mu\nu}(\boldsymbol{x}) v^\mu(\boldsymbol{x}) v^\nu(\boldsymbol{x}) + t\omega_{\mu\nu}(\boldsymbol{x})\theta^\mu\theta^\nu} d\boldsymbol{x} d\boldsymbol{\theta}$$

We have in the distributional sense,

$$\lim_{t\to\infty} \left(\frac{t}{\pi}\right)^l \sqrt{\det g(\boldsymbol{x})} e^{-t g_{\mu\nu}(\boldsymbol{x}) v^\mu(\boldsymbol{x}) v^\nu(\boldsymbol{x})} = \delta(V(\boldsymbol{x})) \tag{2.5}$$

- the main formula of the method of steepest descent (cf. the method of stationary phase in Section 2.3 of Chapter 2) - and

$$\lim_{t\to\infty} (2t)^{-l} \frac{1}{\mathrm{Pf}(\omega(\boldsymbol{x}))} e^{t\omega_{\mu\nu}(\boldsymbol{x})\theta^\mu\theta^\nu} = \delta(\boldsymbol{\theta}) \tag{2.6}$$

- the main formula of Gaussian integration over Grassmann variables (see Proposition 2.3 in Section 2.3 of Chapter 7). Since $\alpha_0(\boldsymbol{x}) = \alpha(\boldsymbol{x}, 0)$, we obtain the result by using formulas (2.5)-(2.6), (2.4), and

$$\delta(V(\boldsymbol{x})) = \sum_{x_i \in M_V} \frac{1}{|\det L_{x_i}|} \delta(\boldsymbol{x} - \boldsymbol{x}_i).$$

Problem 2.1. Prove formulas (2.2)-(2.4).

Problem 2.2. Prove formulas (2.5)-(2.6) and complete the proof of Theorem 2.2.

2.2. Infinite-dimensional case. An important class of infinite-dimensional manifolds is given by the loop spaces. Let M be a compact orientable n-dimensional manifold and let

$$\mathcal{L}(M) = C^\infty\left(S^1, M\right),$$

where $S^1 = \mathbb{R}/\mathbb{Z}$, be its free loop space. The loop space $\mathcal{L}(M)$ is an infinitedimensional Frchet manifold, and the tangent space $T_\gamma\mathcal{L}(M)$ to $\mathcal{L}(M)$ at a point $\gamma \in \mathcal{L}(M)$ is

$$T_\gamma\mathcal{L}(M) = \Gamma\left(S^1, \gamma^*(TM)\right)$$

- the vector space of smooth vector fields $V = \left\{v(t) \in T_{\gamma(t)}M, 0 \le t \le 1\right\}$ along the loop γ in M.

The loop space $\mathcal{L}(M)$ has a canonical circle action given by the action of S^1 on itself by rotations. The vector field corresponding to this action is $\dot\gamma$ - the velocity vector field $\dot\gamma(t)$ along the loop γ in M. The fixed points of the action are constant loops, so that $\mathcal{L}(M)_{\dot\gamma} = M$.

The vector field $\dot\gamma$ on $\mathcal{L}(M)$ - a generator of the circle action on $\mathcal{L}(M)$ is analogous to the vector field V on M, considered in the previous section. As in the finite-dimensional case, denote by $D = d - i_{\dot\gamma}$ the equivariant differential on the complex $\mathcal{A}^\bullet(\mathcal{L}(M))^{S^1}$ of equivariant differential forms on $\mathcal{L}M$. Using the identification $\mathcal{A}^\bullet(\mathcal{L}(M)) \simeq C^\infty(\Pi T\mathcal{L}(M))$, we have the following infinite-dimensional analog of representation (2.1):

$$DF = \int_0^1 \left(\theta^\mu(t) \frac{\delta F}{\delta x^\mu(t)} - \dot x^\mu(t) \frac{\delta F}{\delta \theta^\mu(t)} \right) dt, \quad F \in C^\infty(\Pi T\mathcal{L}(M)). \tag{2.7}$$

Here we are using functional derivatives (as in calculus of variations), local coordinates $\boldsymbol{x} = (x^1, ..., x^n)$ on M, and associated standard coordinates in $T_{\gamma(t)}M$ and $\Pi T_{\gamma(t)}M$, so that $\dot\gamma(t) = (\dot x^1(t), ..., \dot x^n(t)) \in T_{\gamma(t)}M$ and $\boldsymbol{\theta}(t) = (\theta^1(t), ..., \theta^n(t)) \in \Pi T_{\gamma(t)}M$. As in the finite-dimensional case,

$$D^2 = -\int_0^1 \left(\dot x^\mu(t) \frac{\delta}{\delta x^\mu(t)} + \dot\theta^\mu(t) \frac{\delta}{\delta \theta^\mu(t)} \right) dt = -\mathcal{L}_{\dot\gamma}. \tag{2.8}$$

To define the infinite-dimensional analog of a 1 -form β, we choose a Riemannian metric $g_{\mu\nu}dx^\mu dx^\nu$ on M and consider an S^1-invariant Riemannian metric on $\mathcal{L}(M)$, obtained by the integration of g along a loop [3],

$$\langle V_1, V_2 \rangle_\gamma = \int_0^1 \langle v_1(t), v_2(t) \rangle \, dt, \quad V_1, V_2 \in T_\gamma \mathcal{L}(M).$$

The 1 -form β on $\mathcal{L}(M)$ is dual to the vector field $\dot\gamma$ with respect to the Riemannian metric on $\mathcal{L}(M)$, and is given by the following function on $\Pi T\mathcal{L}(M)$:

$$\beta(\gamma, \theta) = \int_0^1 \langle \dot\gamma(t), \boldsymbol{\theta}(t) \rangle dt = \int_0^1 g_{\mu\nu}(\gamma(t)) \dot x^\mu(t) \theta^\nu(t) dt. \tag{2.9}$$

Lemma 2.2. The 1 -form β on $\mathcal{L}(M)$ is S^1 invariant, and the function $D\beta = -2S$ on $\Pi T\mathcal{L}(M)$ is given by

$$S(\gamma, \theta) = \frac{1}{2} \int_0^1 \left(\|\dot\gamma(t)\|^2 + \left\langle \boldsymbol{\theta}(t), \nabla_{\dot\gamma(t)} \boldsymbol{\theta}(t) \right\rangle \right) dt \tag{2.10}$$

where $\nabla_{\dot\gamma}$ is a covariant derivative along γ. The first term in $-2S$ is an analog of the function K in the finite-dimensional case, and the second term is an analog of the 2 -form Ω.

Proof. The 1 -form β is S^1-invariant by definition. We have

$$D\beta = d\beta - i_{\dot\gamma}\beta,$$

where the second term, a function $-i_{\dot\gamma}\beta$ on $\Pi T\mathcal{L}(M)$, clearly gives the first term in (2.10). Now using that in the distributional sense

$$\frac{\delta}{\delta x^\rho(s)} x^\mu(t) = \delta^{\rho\mu} \delta(t - s)$$

and

[03] Here and in what follows $\langle v_1(t), v_2(t) \rangle$ always stands for the inner product in $T_{\gamma(t)}M$ given by the Riemannian metric g.

$$\frac{\delta}{\delta x^\rho(s)}\dot{x}^\mu(t) = \delta^{\rho\mu}\frac{d}{dt}\delta(t-s) = -\delta^{\rho\mu}\frac{d}{ds}\delta(t-s),$$

we compute the term $d\beta$ as follows:

$$\begin{aligned} d\beta(\gamma,\theta) &= \int_0^1\int_0^1 \theta^\rho(s)\frac{\delta}{\delta x^\rho(s)}\left(g_{\mu\nu}(\boldsymbol{x}(t))\dot{x}^\mu(t)\right)\theta^\nu(t)dsdt \\ &= \int_0^1\int_0^1 \theta^\rho(s)\left(\frac{\partial g_{\mu\nu}}{\partial x^\rho}\dot{x}^\mu(t)\delta(t-s) - \delta^{\rho\mu}g_{\mu\nu}\frac{d}{ds}\delta(t-s)\right)\theta^\nu(t)dsdt \\ &= \int_0^1 \left(g_{\mu\nu}(\boldsymbol{x}(t))\dot{\theta}^\mu(t)\theta^\nu(t) + \frac{\partial g_{\mu\nu}}{\partial x^\rho}(\boldsymbol{x}(t))\dot{x}^\mu(t)\theta^\rho(t)\theta^\nu(t)\right)dt. \end{aligned}$$

It follows from the definition of Christoffel's symbols (see Example 1.7 in Section 1.3 of Chapter 1) and anticommutativity of θ^μ that

$$\frac{\partial g_{\mu\nu}}{\partial x^\rho}\dot{x}^\mu\theta^\rho\theta^\nu = g_{\mu\nu}\Gamma^\nu_{\lambda\sigma}\dot{x}^\lambda\theta^\mu\theta^\sigma, \tag{2.11}$$

and we obtain

$$\begin{aligned} d\beta(\gamma,\theta) &= \int_0^1 g_{\mu\nu}(\boldsymbol{x}(t))\left(\dot{\theta}^\mu(t) + \Gamma^\mu_{\sigma\lambda}(\boldsymbol{x}(t))\dot{x}^\sigma(t)\theta^\lambda(t)\right)\theta^\nu(t)dt \\ &= \int_0^1 \left\langle \nabla_{\dot{\gamma}(t)}\boldsymbol{\theta}(t), \boldsymbol{\theta}(t)\right\rangle dt. \end{aligned}$$

As in Chapter 6, one can develop the integration theory on $\mathcal{L}(M)$ with respect to the Wiener measure associated with a Riemannian metric on M by using the corresponding heat kernel [4]. One can also integrate differential forms over $\mathcal{L}(M)$, provided that $\mathcal{L}(M)$ is orientable. As in the finitedimensional case, the latter is defined by the condition that the structure group of an $\mathcal{L}(\mathrm{SO}(n))$-bundle $\mathcal{L}(FM) \to \mathcal{L}(M)$, where $FM \to M$ is the frame bundle, reduces to the connected component of the identity. It follows from the transgression homomorphism

$$H^2(M,\mathbb{Z}_2) \to H^1(\mathcal{L}(M),\mathbb{Z}_2)$$

that the image of the second Stiefel-Whitney class of M is the obstruction to orientability of $\mathcal{L}(M)$. In particular, if M is a spin manifold, then $\mathcal{L}(M)$ is orientable, and if M is simply connected, then this is also a necessary condition.

In what follows we will not attempt to develop the integration theory on $\mathcal{L}(M)$, and will formulate and "prove" the infinite-dimensional version of the general Berline-Vergne localization theorem at a heuristic level only. The key observation, by Lemma 2.2, is that the differential form e^{-S} on $\mathcal{L}(M)$ is equivariantly closed, therefore the functional integral $\int_{\mathcal{L}(M)} e^{-S}$ localizes reduces to the finite-dimensional integral over $\mathcal{L}(M)_{\dot{\gamma}} = M$, the zero locus of the vector field $\dot{\gamma}$.

To give the quantitative formulation of this result, recall the notion of the $\hat{A}$-genus. Namely, the $\hat{A}$-genus of a Riemannian manifold (M,g) is a differential form $\hat{A}(M)$, defined as follows. Let $R \in \mathcal{A}^2(M,\mathfrak{so}(TM))$ be the Riemannian curvature of M, and let e_μ be a local orthonormal frame of TM. Put

$$\mathrm{R}_{\mu\nu} = (Re_\mu, e_\nu) \in \mathcal{A}^2(M)$$

and let

$$j(\mathrm{R}) = \det\left(\frac{\sinh \mathrm{R}/2}{\mathrm{R}/2}\right)$$

be an even degree differential form on M. It does not depend on the choice of a local orthonormal frame of TM, and the $\hat{A}$-genus of the manifold M is defined by [5]

$$\hat{A}(M) = j(\mathrm{R})^{-\frac{1}{2}} = \det\left(\frac{\mathrm{R}/2}{\sinh \mathrm{R}/2}\right)^{\frac{1}{2}} \in \mathcal{A}^{\bullet}(M)$$

It is a closed differential form, whose cohomology class does not depend on the choice of a Riemannian metric on M.

Remark. In local coordinates on M,

$$\mathrm{R}_{\mu\nu} = \frac{1}{2} R_{\mu\nu\rho\sigma} dx^{\rho} \wedge dx^{\sigma},$$

where $R_{\mu\nu\rho\sigma}$ is the Riemann curvature tensor.

Theorem 2.3. Let M be a compact orientable manifold such that the free loop space $\mathcal{L}(M)$ is orientable. Then

$$\int_{\mathcal{L}(M)} e^{-S} = (2\pi i)^{-\frac{n}{2}} \int_{M} \hat{A}(M).$$

Proof. The proof is at a heuristic level of rigor. The integral

$$\int_{\mathcal{L}(M)} e^{-S} = \int_{\Pi T\mathcal{L}(M)} e^{-S(\gamma,\theta)} \mathscr{D}\boldsymbol{x} \mathscr{D}\boldsymbol{\theta}$$

localizes at the zero locus $\mathcal{L}(M)_{\dot{\gamma}} = M$, so it is sufficient to integrate over a small tubular neighborhood of ΠTM in $\Pi T\mathcal{L}(M)$. For this aim, consider Riemann normal coordinates of the normal bundle $\mathcal{N}(\Pi TM)$ to ΠTM at a point $(x_0, \theta_0) \in \Pi T_{x_0} M$, given by $\boldsymbol{y}(t) = (y^1(t), ..., y^n(t)) \in T_{x_0} M$ and $\boldsymbol{\eta}(t) = (\eta^1(t), ..., \eta^n(t)) \in \Pi T_{x_0} M$, satisfying

$$\int_0^1 y^{\mu}(t) dt = 0 \quad \text{and} \quad \int_0^1 \eta^{\mu}(t) dt = 0, \quad \mu = 1, ..., n$$

Coordinates $(\varepsilon \boldsymbol{y}(t), \varepsilon \boldsymbol{\eta}(t))$, where real ε is sufficiently small, correspond to a point $\left(\exp_{x_0}(\varepsilon \boldsymbol{y}(t)), P_{(\varepsilon,t)}\left(\theta_0 + \boldsymbol{\eta}(t)\right)\right)$, in the normal bundle $\mathcal{N}(\Pi TM)$, where $\exp_{x_0}$ is the exponential map, and $P_{(\varepsilon,t)}$ is a parallel transport in ΠTM from x_0 along the path $\exp_{x_0}(sy(t))$ as s changes from 0 to ε.

Since we are integrating over an arbitrarily small tubular neighborhood of ΠTM in $\Pi T\mathcal{L}(M)$, it is sufficient to expand $S(\gamma, \theta)$ up to terms of second order in local coordinates $(\boldsymbol{y}(t), \boldsymbol{\eta}(t))$. Since in Riemann normal coordinates around x_0 on M

$$g_{\mu\nu}(\boldsymbol{x}) = \delta_{\mu\nu} + O\left(\|\boldsymbol{x}\|^2\right) \quad \text{and} \quad R_{\mu\nu\rho\sigma}(x_0) = \frac{\partial \Gamma^{\rho}_{\nu\sigma}}{\partial x^{\mu}} - \frac{\partial \Gamma^{\rho}_{\mu\sigma}}{\partial x^{\nu}}$$

we readily obtain that at $(x_0, \theta_0) \in \Pi T_{x_0} M$

$$S(\gamma, \theta) = S_0(x_0, \theta_0; \boldsymbol{y}, \boldsymbol{\eta}) + \text{ higher order terms in } y^{\mu}(t), \eta^{\mu}(t)$$

where

$$S_0(x_0, \theta_0; \boldsymbol{y}, \boldsymbol{\eta})$$
$$= \frac{1}{2} \int_0^1 \left(\dot{y}^{\mu}(t) \dot{y}^{\mu}(t) - \tilde{\mathrm{R}}_{\mu\nu}(x_0)\, \dot{y}^{\mu}(t) y^{\nu}(t) - \dot{\eta}^{\mu}(t) \eta^{\mu}(t) \right) dt, \tag{2.12}$$

[04] In Chapter 6 we considered the case of $M = \mathbb{R}^n$ with the standard Euclidean metric.

[5] This is the geometer's definition of the $\hat{A}$-genus; in topology one replaces R by $(2\pi i)^{-1}$R.

and

$$\tilde{\mathrm{R}}_{\mu\nu}\left(x_0\right)=\frac{1}{2}R_{\mu\nu\rho\sigma}\left(x_0\right)\theta_0^\rho\theta_0^\sigma.$$

Now using property (2.6) in Section 2.2 of Chapter 6 (where $m=\hbar=1$ and $T=1$), formula (4.10) in Section 4.3 of Chapter 7, and performing Gaussian integration, we get

$$\begin{aligned}\int_{\mathcal{L}(M)}e^{-S}&=(2\pi)^{-\frac{n}{2}}\int_{\Pi TM}\left(\int_{\mathcal{N}(\Pi TM)}e^{-S_0(x_0,\theta_0;\boldsymbol{y},\boldsymbol{\eta})}\mathscr{D}\boldsymbol{y}\mathscr{D}\boldsymbol{\eta}\right)d\boldsymbol{x}_0d\boldsymbol{\theta}_0\\&=(2\pi)^{-\frac{n}{2}}\int_{\Pi TM}\det{}'\left(-D^2\delta_{\mu\nu}-\tilde{\mathrm{R}}_{\mu\nu}\left(x_0,\theta_0\right)D\right)^{-\frac{1}{2}}d\boldsymbol{x}_0d\boldsymbol{\theta}_0\end{aligned}$$

where we have also used formula (4.12) in Section 4.3 of Chapter 7. Since $\tilde{\mathrm{R}}=\left\{\tilde{\mathrm{R}}_{\mu\nu}\right\}_{\mu,\nu=1}^{n}$ is a skew-symmetric matrix with even matrix elements, there is an orthogonal matrix C of determinant 1 such that

$$C\tilde{\mathrm{R}}C^{-1}=\begin{pmatrix}0&r_1&\cdots&0&0\\-r_1&0&\cdots&0&0\\\vdots&\vdots&\ddots&\vdots&\vdots\\0&0&\cdots&0&r_m\\0&0&\cdots&-r_m&0\end{pmatrix},\quad m=\frac{n}{2}.$$

It is easy to see that second order matrix differential operators

$$-D^2I_2+\begin{pmatrix}0&-r\\r&0\end{pmatrix}D\quad\text{and}\quad-D^2I_2+\begin{pmatrix}-ir&0\\0&ir\end{pmatrix}D$$

where I_2 is the 2×2 identity matrix, have the same spectrum. Using formula (3.5) in Section 3.2 of Chapter 6 with $\omega=\pm ir_k$, we get

$$\begin{aligned}\det{}'\left(-D^2\delta_{\mu\nu}-\tilde{\mathrm{R}}_{\mu\nu}D\right)&=\prod_{k=1}^{m}\det{}'\left(-D^2I_2+\begin{pmatrix}0&-r_k\\r_k&0\end{pmatrix}D\right)\\&=\prod_{k=1}^{m}\det{}'\left(-D^2-ir_kD\right)\det{}'\left(-D^2+ir_kD\right)\\&=\prod_{k=1}^{m}\left(\frac{\sin r_k/2}{r_k/2}\right)^2=\det\left(\frac{\sin\tilde{\mathrm{R}}/2}{\tilde{\mathrm{R}}/2}\right)\\&=j(i\tilde{\mathrm{R}})\end{aligned}$$

Therefore, using the identification $C^\infty(\Pi TM)\simeq\mathcal{A}^\bullet(M)$ we finally obtain

$$\begin{aligned}\int_{\mathcal{L}(M)}e^{-S}&=(2\pi)^{-\frac{n}{2}}\int_{\Pi ITM}j(i\tilde{\mathrm{R}}(x,\theta))^{-\frac{1}{2}}d\boldsymbol{x}d\boldsymbol{\theta}\\&=(2\pi i)^{-\frac{n}{2}}\int_M\hat{A}(M)\end{aligned}$$

Remark. Using formulas (2.6) in Section 2.2 of Chapter 6 and (4.10) in Section 4.3 of Chapter 7, we see that the same result holds for the space $\mathcal{L}_I(M)$ of loops on M parametrized by the interval $I=[0,T]$,

$$\int_{\Pi T\mathcal{L}_I(M)}e^{-\frac{1}{2}\int_0^T\left(\|\dot\gamma(t)\|^2+\left\langle\boldsymbol{\theta}(t),\nabla_{\dot\gamma(t)}\boldsymbol{\theta}(t)\right\rangle\right)dt}\mathscr{D}\boldsymbol{x}\mathscr{D}\boldsymbol{\theta}=(2\pi i)^{-\frac{n}{2}}\int_M\hat{A}(M).$$

Problem 2.3. Derive formula (2.8).
Problem 2.4. Derive formulas (2.11) and (2.12).
Problem 2.5. Justify the arguments in the "proof" of Theorem 2.3. (Hint: See the references in Section 7.)

26.1.4 Classical mechanics on supermanifolds

As was mentioned in Chapter 4, spin is a pure quantum notion which has no classical analog, and the same applies to fermion systems, considered in Chapter 7. However, one can formally consider particles with anticommuting coordinates and formulate classical mechanics on supermanifolds. Though such systems have no physical interpretation [6], their formal quantization yields fermion systems. This allows us to interpret particles with odd degrees of freedom as semi-classical limit of fermions.

3.1. Functions with anticommuting values.

Any smooth map $f : M \to N$ of smooth manifolds M and N gives rise to a Frchet algebra homomorphism

$$f^* : C^\infty(N) \to C^\infty(M)$$

where $f^*(\varphi) = \varphi \circ f$ for $\varphi \in C^\infty(N)$. Conversely, any Frchet algebra homomorphism $F : C^\infty(N) \to C^\infty(M)$ is of this form for some smooth map $f : M \to N$.

By definition, a map (morphism) between supermanifolds X and Y is a homomorphism of superalgebras

$$F : C^\infty(Y) \to C^\infty(X)$$

where $C^\infty(X)$ and $C^\infty(Y)$ are commutative superalgebras of global sections of corresponding structure sheaves $\mathcal{O}_X$ and $\mathcal{O}_Y$ (see Section 1). We will denote by $\mathrm{Map}(X, Y)$ the space of all maps between supermanifolds X and Y. The simplest cases are the following.

1. $X = \mathbb{R}^{0|1}$ - odd one-dimensional supermanifold, and $Y = M$ - an ordinary (even) manifold.
2. $X = \mathbb{R}$ (or S^1 and $I = [t_0, t_1]$) - even one-dimensional manifold, and $Y = \mathbb{R}^{0|n}$ - odd n-dimensional coordinate vector space.

In the first case every homomorphism of superalgebras $F : C^\infty(M) \to \mathbb{R}[\theta]$ has the form

$$F(\varphi) = A(\varphi) + B(\varphi)\theta, \quad \varphi \in C^\infty(M)$$

where $A : C^\infty(M) \to \mathbb{R}$ is an $\mathbb{R}$-algebra homomorphism, and $B : C^\infty(M) \to C^\infty(M)$ is a derivation of the commutative algebra $C^\infty(M)$. By the GelfandNaimark theorem, there exists $x \in M$ such that $A(\varphi) = \varphi(x)$, and $B(\varphi) = d\varphi(v)$ where $v \in T_xM$. Thus every map $f : \mathbb{R}^{0|1} \to M$ is given by a point $(x, v) \in TM$.

However, in the second case we have a homomorphism of superalgebras

$$F : \mathbb{R}\left[\theta^1, ..., \theta^n\right] \to C^\infty(\mathbb{R})$$

and since the commutative algebra $C^\infty(\mathbb{R})$ contains no nilpotents,

$$F\left(\theta^1\right) = \cdots = F\left(\theta^n\right) = 0$$

[06] Classical mechanics, which describes physical phenomena at the macroscopic level, necessarily uses commuting coordinates.

This result is clearly unsatisfactory, since every map $\mathbb{R} \to \mathbb{R}^{0|n}$ is trivial: $\theta^k(t) = 0, k = 1, ..., n$. To remedy this situation, one should consider the analog of Grothendieck's functor of points from algebraic geometry. Namely, introduce an auxiliary Grassmann algebra $W = \mathbb{R}\left[\eta^1, ..., \eta^N\right]$ and consider the product [7] $W \times \mathbb{R}$ with the superalgebra of functions $C^\infty(\mathbb{R})\left[\eta^1, ..., \eta^N\right]$. The " W-points" of Map $\left(\mathbb{R}, \mathbb{R}^{0|n}\right)$ are defined by homomorphisms of commutative superalgebras

$$F : \mathbb{R}\left[\theta^1, ..., \theta^n\right] \to \mathbb{C}^\infty(\mathbb{R})\left[\eta^1, ..., \eta^N\right]$$

In this case it is customary to write

$$\theta^k(t) = F\left(\theta^k\right) = a_1^k(t)\eta^1 + \cdots + a_N^k(t)\eta^N, \quad k = 1, ..., n \tag{3.1}$$

where real-valued $a_1^k(t), ..., a_N^k(t) \in C^\infty(\mathbb{R})$. It is convenient to think of $\theta^k(t)$ as smooth functions of variable t with anticommuting values, and define

$$\dot{\theta}^k(t) = \dot{a}_1^k(t)\eta^1 + \cdots + \dot{a}_N^k(t)\eta^N \tag{3.2}$$

where the dot stands for the derivative. To emphasize that Grassmann variables $\theta^k(t)$ are "real-valued", we will always assume that W is a set of fixed points in a Grassmann algebra with involution over $\mathbb{C}$, so that

$$\bar{\theta}^k(t) = \theta^k(t), \quad k = 1, ..., n$$

In the same way one defines W-points of Map $\left(S^1, \mathbb{R}^{0|n}\right)$ and Map $\left(I, \mathbb{R}^{0|n}\right)$.

Remark. This definition of the space of maps Map $\left(I, \mathbb{R}^{0|n}\right)$ (and also of the spaces Map $\left(\mathbb{R}, \mathbb{R}^{0|n}\right)$ and Map $\left(S^1, \mathbb{R}^{0|n}\right)$) is motivated by the definition used by physicists, who introduce an infinite-dimensional auxiliary Grassmann algebra W, so that for every t the values $\theta^k(t)$ are "independent real Grassmann variables".

Remark. One can also define functions on the space Map $\left(I, \mathbb{R}^{0|n}\right)$ - the functionals of functions with anticommuting values $\theta^k(t)$. Thus for the simplest example of the quadratic functional

$$S(\theta) = \frac{i}{2}\int_{t_0}^{t_1} \theta(t)\dot{\theta}(t)dt, \tag{3.3}$$

where we put $n = 1$ and $\theta^1(t) = \theta(t)$, using (3.1)-(3.2) we obtain

$$S(\theta) = \frac{i}{2}\int_{t_0}^{t_1} \left(a_k(t)\dot{a}_l(t) - \dot{a}_k(t)a_l(t)\right) dt\eta^k\eta^l \in \mathbb{R}\left[\eta^1, ..., \eta^N\right].$$

Here the factor $i = \sqrt{-1}$ ensures that $i\eta^k\eta^l$ are real Grassmann elements, i.e., $\overline{i\eta^k\eta^l} = -i\eta^l\eta^k = i\eta^k\eta^l$. In general, the space of "functions" on Map $\left(I, \mathbb{R}^{0|n}\right)$ is $\Lambda^\bullet\left(\text{Map}\left(I, \mathbb{R}^n\right)^*\right) \otimes W$, where Map $\left(I, \mathbb{R}^n\right)^*$ is the (topological) dual to the vector space Map $\left(I, \mathbb{R}^n\right)$, and W is a Grassmann algebra with infinitely many generators.

Vector fields with anticommuting values are naturally associated with the path space of a smooth manifold M. Namely, let

$$P_I(M) = \{\gamma : I \to M\},$$

where $I = [t_0, t_1]$, be the space of smooth parametrized paths in M. Consider the supermanifold ΠTM (see Section 1), and for every $\gamma \in P_I(M)$ let $\gamma^*(\Pi TM)$ be the pullback bundle

[07] Geometrically this corresponds to the family of spaces parametrized by W.

over I. By definition, a vector field with anticommuting values $\theta(t)$ is a section of $\gamma^*(\Pi TM)$ over I. In local coordinates $\boldsymbol{x} = (x^1, ..., x^n)$,

$$\boldsymbol{\theta}(t) = \theta^\mu(t)\frac{\partial}{\partial x^\mu} \in \Pi T_{\gamma(t)}M.$$

Thus

$$\Pi TP_I(M) = \{(\gamma, \theta) : \gamma \in P_I(M), \theta \in \Gamma\left(I, \gamma^*(\Pi TM)\right)\}.$$

Problem 3.1. Show that $S \in \Lambda^\bullet\left(\mathrm{Map}(I, \mathbb{R})^*\right) \otimes W$, where S is the quadratic functional given by (3.3).

3.2. Classical systems. Here we consider the basic examples of classical systems on supermanifolds.

Example 3.1 (Free classical particle of spin $\frac{1}{2}$). The configuration space is the supermanifold $\Pi T\mathbb{R}^3 \simeq \mathbb{R}^{3|3}$ - the tangent bundle to $\mathbb{R}^3$ with reversed parity of the fibers, with even and odd coordinates $\boldsymbol{x} = (x^1, x^2, x^3)$ and $\boldsymbol{\theta} = (\theta^1, \theta^2, \theta^3)$. The action functional $S : \Pi TP_I\left(\mathbb{R}^3\right) \to W$, where W is
some auxiliary Grassmann algebra, is defined by

$$\begin{aligned} S(\boldsymbol{x}(t), \boldsymbol{\theta}(t)) &= \int_{t_0}^{t_1} L(\boldsymbol{x}(t), \dot{\boldsymbol{x}}(t), \boldsymbol{\theta}(t))dt \\ &= \frac{1}{2}\int_{t_0}^{t_1} \left(m\dot{\boldsymbol{x}}^2 + i\boldsymbol{\theta}\dot{\boldsymbol{\theta}}\right)dt, \quad (\boldsymbol{x}(t), \boldsymbol{\theta}(t)) \in \Pi TP_I\left(\mathbb{R}^3\right) \end{aligned} \tag{3.4}$$

Here

$$L(\boldsymbol{x}(t), \dot{\boldsymbol{x}}(t), \boldsymbol{\theta}(t)) = \frac{1}{2}\left(m\dot{\boldsymbol{x}}^2(t) + i\boldsymbol{\theta}(t)\dot{\boldsymbol{\theta}}(t)\right)$$

is the Lagrangian function, which is real-valued since

$$\overline{i\boldsymbol{\theta}(t)\dot{\boldsymbol{\theta}}(t)} = -i\dot{\boldsymbol{\theta}}(t)\boldsymbol{\theta}(t) = i\boldsymbol{\theta}(t)\dot{\boldsymbol{\theta}}(t)$$

As in Section 1.2 of Chapter 1, we readily derive classical equations of motion as the following Euler-Lagrange equations:

$$\ddot{\boldsymbol{x}}(t) = 0 \quad \text{and} \quad \dot{\boldsymbol{\theta}}(t) = 0$$

Canonically conjugated momenta [8] are defined by

$$p^k = \frac{\partial L}{\partial \dot{x}^k} = m\dot{x}^k \quad \text{and} \quad \pi^k = \frac{\partial}{\partial \dot{\theta}^k}L = -\frac{i}{2}\theta^k, \quad k = 1, 2, 3$$

and the Hamiltonian function H is given by the Legendre transformation,

$$H = \boldsymbol{p}\dot{\boldsymbol{x}} + \dot{\boldsymbol{\theta}}\boldsymbol{\pi} - L = \frac{\boldsymbol{p}^2}{2m}$$

In agreement with classical equations of motion $\dot{\boldsymbol{\theta}}(t) = 0$, the Hamiltonian H does not depend on the odd variables. The phase space is a supermanifold $\mathbb{R}^{6|3}$ with real coordinates $\boldsymbol{p}, \boldsymbol{x}, \boldsymbol{\theta}$ and the symplectic form

$$\omega = d\boldsymbol{p} \wedge d\boldsymbol{x} - \frac{i}{2}d\boldsymbol{\theta}d\boldsymbol{\theta}$$

In accordance with Section 2.2 of Chapter 7, Poisson brackets between the odd variables are given by

$$\left\{\theta^k, \theta^l\right\} = i\delta^{kl}, \quad k, l = 1, 2, 3 \tag{3.5}$$

Poisson brackets satisfy the following involution property:

$$\overline{\{f_1, f_2\}} = (-1)^{|f_1||f_2|} \left\{\bar{f}_1, \bar{f}_2\right\}, \quad f_1, f_2 \in \mathbb{C}\left[\theta^1, \theta^2, \theta^3\right]. \tag{3.6}$$

We will see in Section 5 that quantization of this system describes the free quantum particle of spin $\frac{1}{2}$.

Example 3.2 (Classical spin $\frac{1}{2}$ particle in constant magnetic field). This system is described by the configuration space $\mathbb{R}^{3|3}$ with real coordinates $\boldsymbol{x}, \boldsymbol{\theta}$ and Lagrangian function

$$L = \frac{1}{2}\left(m\dot{\boldsymbol{x}}^2(t) + i\boldsymbol{\theta}(t)\dot{\boldsymbol{\theta}}(t) - i(\boldsymbol{B} \times \boldsymbol{\theta})\boldsymbol{\theta}\right).$$

The corresponding phase space and symplectic form are the same as in the previous example, and the Hamiltonian function is

$$H = \frac{\boldsymbol{p}^2}{2m} + \frac{i}{2}(\boldsymbol{B} \times \boldsymbol{\theta})\boldsymbol{\theta} \tag{3.7}$$

We will see in Section 5 that quantization of the Hamiltonian (3.7) yields the Pauli Hamiltonian.

Example 3.3 (Free particle on $\mathbb{R}^{n|n}$). Generalizing Example 3.1, consider the configuration space $\Pi T\mathbb{R}^n \simeq \mathbb{R}^{n|n}$ - the tangent bundle to $\mathbb{R}^n$ with reversed parity of the fibers, with even and odd real coordinates $\boldsymbol{x} = (x^1, ..., x^n)$ and $\boldsymbol{\theta} = (\theta^1, ..., \theta^n)$. The Lagrangian function

$$L(\boldsymbol{x}(t), \dot{\boldsymbol{x}}(t), \boldsymbol{\theta}(t)) = \frac{1}{2}\left(m\dot{x}^\mu\dot{x}^\mu + i\theta^\mu\dot{\theta}^\mu\right) \tag{3.8}$$

yields the same Euler-Lagrange equations as in Example 3.1,

$$\ddot{\boldsymbol{x}} = 0 \quad \text{and} \quad \dot{\boldsymbol{\theta}} = 0.$$

The corresponding phase space is a supermanifold $\mathbb{R}^{2n|n}$ with real coordinates $\boldsymbol{p}, \boldsymbol{x}, \boldsymbol{\theta}$ and the symplectic form

$$\omega = d\boldsymbol{p} \wedge d\boldsymbol{x} - \frac{i}{2}d\boldsymbol{\theta}d\boldsymbol{\theta}$$

and the Hamiltonian function is

$$H = \frac{\boldsymbol{p}^2}{2m}$$

Example 3.4 (Free particle on ΠTM). Let (M, g) be a Riemannian manifold with Riemannian metric $g_{\mu\nu}dx^\mu dx^\nu$. Similar to the construction in Section 2.2, we consider the phase space ΠTM with the Lagrangian function

$$L = \frac{1}{2}\left(\|\dot{\boldsymbol{x}}\|^2 + i\left\langle\boldsymbol{\theta}, \nabla_{\dot{\boldsymbol{x}}}\boldsymbol{\theta}\right\rangle\right), \tag{3.9}$$

where $\nabla_{\dot{\boldsymbol{x}}}$ is a covariant derivative along the path $\boldsymbol{x}(t)$ (which is also customarily denoted by D/Dt), and $\boldsymbol{\theta}(t) \in \Pi T_x M$. The corresponding action functional is defined by

[08] Here the indices are raised by the standard Euclidean metric on $\mathbb{R}^3$.

$$S = \frac{1}{2}\int_{t_0}^{t_1} \left(\|\dot{\boldsymbol{x}}\|^2 + i \left\langle \theta, \nabla_{\dot{\boldsymbol{x}}} \boldsymbol{\theta} \right\rangle \right) dt$$

or in local coordinates $\boldsymbol{x} = (x^1, ..., x^n)$ on M,

$$\begin{aligned} S &= \frac{1}{2}\int_{t_0}^{t_1} g_{\mu\nu}(\boldsymbol{x}(t)) \left(\dot{x}^\mu \dot{x}^\nu + \theta^\mu \frac{D\theta^\nu}{Dt} \right) dt \\ &= \frac{1}{2}\int_{t_0}^{t_1} g_{\mu\nu}(\boldsymbol{x}(t)) \left(\dot{x}^\mu \dot{x}^\nu + \theta^\mu \dot{\theta}^\nu + \Gamma^\nu_{\lambda\rho}(\boldsymbol{x}(t)) \dot{x}^\lambda \theta^\mu \theta^\rho \right) dt \end{aligned}$$

We will see in the next section that this system describes a supersymmetric particle on a Riemannian manifold.

Problem 3.2. Develop Lagrangian and Hamiltonian formalisms for classical mechanics on supermanifolds.

Problem 3.3. Prove formula (3.6).

Problem 3.4. Show that Euler-Lagrange equations for the system with Lagrangian (3.9) are

$$g_{\lambda\mu} \frac{D\dot{x}^\mu}{Dt} = \frac{1}{2} R_{\lambda\rho\mu\nu} \dot{x}^\rho \theta^\mu \theta^\nu \quad \text{and} \quad \frac{D\theta^\mu}{Dt} = 0$$

- equations for a spinning particle in a gravitational field.

Problem 3.5. Describe the phase space and find the Hamiltonian function for Example 3.4.

26.1.5 Supersymmetry

The Lagrangian system considered in Example 3.3 in the previous section possesses remarkable symmetries.

4.1. Total angular momentum.

First of all, the Lagrangian (3.8) is obviously invariant with respect to the action of the orthogonal group $G = \mathrm{SO}(n)$

$$L(g \cdot \dot{\boldsymbol{x}}, g \cdot \boldsymbol{\theta}) = L(\dot{\boldsymbol{x}}, \boldsymbol{\theta}), \quad g \in G \tag{4.1}$$

The corresponding conserved quantity - the Noether charge $\boldsymbol{J} \in \mathfrak{g}^*$ - the dual space to the Lie algebra $\mathfrak{g} = \mathfrak{so}(n)$, can be obtained as follows (cf. the proof of Theorem 1.3 in Section 1.4 of Chapter 1).

Consider an infinitesimal change of even and odd coordinates

$$\boldsymbol{x}(t) \mapsto \tilde{\boldsymbol{x}}(t) = \boldsymbol{x}(t) + \delta\boldsymbol{x}(t), \quad \boldsymbol{\theta}(t) \mapsto \tilde{\boldsymbol{\theta}}(t) = \boldsymbol{\theta}(t) + \delta\boldsymbol{\theta}(t),$$

and using $\dot{\boldsymbol{\theta}}\delta\boldsymbol{\theta} = -\delta\boldsymbol{\theta}\dot{\boldsymbol{\theta}}$, compute $\delta L = L(\dot{\boldsymbol{x}} + \delta\dot{\boldsymbol{x}}, \boldsymbol{\theta} + \delta\boldsymbol{\theta}) - L(\dot{\boldsymbol{x}}, \boldsymbol{\theta})$ up to the second order terms in $\delta\boldsymbol{x}$ and $\delta\boldsymbol{\theta}$,

$$\begin{aligned} \delta L &= m\dot{\boldsymbol{x}}\delta\dot{\boldsymbol{x}} + \frac{i}{2}(\delta\boldsymbol{\theta}\dot{\boldsymbol{\theta}} + \boldsymbol{\theta}\delta\dot{\boldsymbol{\theta}}) \\ &= -m\ddot{\boldsymbol{x}}\delta\boldsymbol{x} + m\frac{d}{dt}(\dot{\boldsymbol{x}}\delta\boldsymbol{x}) + \frac{i}{2}(\delta\boldsymbol{\theta}\dot{\boldsymbol{\theta}} - \dot{\boldsymbol{\theta}}\delta\boldsymbol{\theta}) + \frac{i}{2}\frac{d}{dt}(\boldsymbol{\theta}\delta\boldsymbol{\theta}) \\ &= -m\ddot{\boldsymbol{x}}\delta\boldsymbol{x} + m\frac{d}{dt}(\dot{\boldsymbol{x}}\delta\boldsymbol{x}) + i\delta\boldsymbol{\theta}\dot{\boldsymbol{\theta}} + \frac{i}{2}\frac{d}{dt}(\boldsymbol{\theta}\delta\boldsymbol{\theta}). \end{aligned}$$

Thus on the solutions of Euler-Lagrange equations $\ddot{\boldsymbol{x}} = 0, \dot{\boldsymbol{\theta}} = 0$ we have

$$\delta L = \frac{d}{dt}\left(m\dot{\boldsymbol{x}}\delta\boldsymbol{x} + \frac{i}{2}\boldsymbol{\theta}\delta\boldsymbol{\theta}\right).$$

Now using (4.1) with $g = e^{\varepsilon u}$, where $\boldsymbol{u} = \{u^\mu_\nu\}^n_{\mu,\nu=1}$ is a skew-symmetric $n \times n$ matrix, we see that $\delta L = 0$ for $\delta x^\mu = \varepsilon u^\mu_\nu x^\nu$ and $\delta\theta^\mu = \varepsilon u^\mu_\nu \theta^\nu$. Choosing the standard basis in the space of skew-symmetric $n \times n$ matrices, we obtain that components

$$J^{\mu\nu} = m\left(x^\mu \dot{x}^\nu - x^\nu \dot{x}^\mu\right) - i\theta^\mu\theta^\nu \tag{4.2}$$

are integrals of motion:

$$\frac{d}{dt}J^{\mu\nu} = 0$$

on solutions of the Euler-Lagrange equations. In particular, for $n = 3$ we get

$$\begin{aligned} J^1 &:= J^{23} = M^1 - i\theta^2\theta^3, \\ J^2 &:= J^{31} = M^2 - i\theta^3\theta^1, \\ J^3 &:= J^{12} = M^3 - i\theta^1\theta^2, \end{aligned}$$

where M^1, M^2, M^3 are components of the angular momentum $\boldsymbol{M}$ of a particle in $\mathbb{R}^3$ (see Section 1.4 in Chapter 1). We will see in the next section that after quantization the vector $\boldsymbol{J} = (J^1, J^2, J^3)$ becomes the total angular momentum operator of a quantum particle of spin $\frac{1}{2}$ in $\mathbb{R}^3$.

Remark. In fact, the Lagrangian (3.8) is invariant under the action of $G \times G$ on $\mathbb{R}^{n|n}$, so that both the angular momentum $m\left(x^\mu \dot{x}^\nu - x^\nu \dot{x}^\mu\right)$ in $\mathbb{R}^n$ and the "Grassmann angular momentum" $-i\theta^\mu\theta^\nu$ in $\mathbb{R}^{0|n}$ are conserved.

4.2. Supersymmetry transformation. It is quite remarkable that in addition to the symmetries discussed in the previous section, the Lagrangian (3.8) is also invariant under special transformations on $\mathbb{R}^{n|n}$ that mix even and odd coordinates. Namely, let $(\gamma(t), \boldsymbol{\theta}(t)) \in \Pi T P_I(\mathbb{R}^n)$, where $\boldsymbol{\theta}(t) \in \Pi T_\gamma P_I(\mathbb{R}^n)$ is a section over $I = [t_0, t_1]$ of the pull-back by γ of the tangent bundle of $T\mathbb{R}^n$ with reverse parity of the fibers,

$$\boldsymbol{\theta}(t) = \theta^\mu(t)\frac{\partial}{\partial x^\mu} \in \Pi T_{\gamma(t)} M$$

Consider the following infinitesimal change of coordinates which mixes even and odd variables:

$$\boldsymbol{x}(t) \mapsto \boldsymbol{x}(t) + \delta_\varepsilon \boldsymbol{x}(t) \quad \text{and} \quad \boldsymbol{\theta}(t) \mapsto \boldsymbol{\theta}(t) + \delta_\varepsilon \boldsymbol{\theta}(t), \tag{4.3}$$

where

$$\delta_\varepsilon \boldsymbol{x}(t) = i\varepsilon\boldsymbol{\theta}(t) \in T_{\boldsymbol{x}(t)}\mathbb{R}^n \quad \text{and} \quad \delta_\varepsilon\boldsymbol{\theta}(t) = -m\varepsilon\dot{\boldsymbol{x}}(t) \in \Pi T_{\boldsymbol{x}(t)}\mathbb{R}^n \tag{4.4}$$

and ε is an odd real element. Then for

$$\delta_\varepsilon L = L\left(\boldsymbol{x} + \delta_\varepsilon\boldsymbol{x}, \boldsymbol{\theta} + \delta_\varepsilon\boldsymbol{\theta}\right) - L(\boldsymbol{x}, \boldsymbol{\theta})$$

we obtain

$$\begin{aligned}\delta_\varepsilon L &= m\dot{\boldsymbol{x}}\delta_\varepsilon\dot{\boldsymbol{x}} + \frac{i}{2}\left(\delta_\varepsilon\boldsymbol{\theta}\dot{\boldsymbol{\theta}} + \boldsymbol{\theta}\delta_\varepsilon\dot{\boldsymbol{\theta}}\right)\\ &= im\dot{\boldsymbol{x}}\varepsilon\dot{\boldsymbol{\theta}} - \frac{im}{2}(\varepsilon\dot{\boldsymbol{x}}\dot{\boldsymbol{\theta}} + \boldsymbol{\theta}\varepsilon\ddot{\boldsymbol{x}})\\ &= \frac{im}{2}(\dot{\boldsymbol{x}}\varepsilon\dot{\boldsymbol{\theta}} + \varepsilon\boldsymbol{\theta}\ddot{\boldsymbol{x}})\\ &= \frac{im\varepsilon}{2}\frac{d}{dt}(\boldsymbol{\theta}\dot{\boldsymbol{x}}).\end{aligned}$$

Thus for periodic boundary conditions the action functional

$$S(\gamma,\theta) = \int_{t_0}^{t_1} L(\gamma(t),\boldsymbol{\theta}(t))dt$$

is invariant under the change of coordinates (4.3),

$$\delta_\varepsilon S(\gamma,\theta) = 0 \quad \text{for all periodic } (\gamma,\theta)\in \Pi TP_I(\mathbb{R}^n)$$

The infinitesimal transformation (4.3) is called the supersymmetry transformation.

Remark. We emphasize that invariance of the action under the supersymmetry transformations holds for all $(\gamma(t),\boldsymbol{\theta}(t))$ with periodic boundary conditions, and not only on equations of motion!

Introducing the quantity

$$Q = im\boldsymbol{\theta}\dot{\boldsymbol{x}} = i\boldsymbol{\theta}\boldsymbol{p} = i\theta^\mu p_\mu,$$

called the generator of supersymmetry (or the supercharge), we can summarize the above computation as

$$\delta_\varepsilon L = \frac{\varepsilon}{2}\frac{dQ}{dt}. \tag{4.5}$$

Another remarkable property is that the Lagrangian L can be recovered from the supercharge Q. Namely, the simple computation

$$\delta_\varepsilon Q = m\left(\delta_\varepsilon\boldsymbol{\theta}\dot{\boldsymbol{x}} + \boldsymbol{\theta}\delta_\varepsilon\dot{\boldsymbol{x}}\right) = m\varepsilon\left(-m\dot{\boldsymbol{x}}^2 - i\boldsymbol{\theta}\dot{\boldsymbol{\theta}}\right)$$

gives

$$-2mi\varepsilon L = \delta_\varepsilon Q \tag{4.6}$$

Using (3.5) we obtain

$$\{Q,Q\} = -i\boldsymbol{p}^2 = -2miH \tag{4.7}$$

which shows that the Hamiltonian H can also be recovered from the supercharge Q.

Remark. Geometrically, supersymmetry transformation is just an equivariant differential on the space $\mathcal{L}_I(\mathbb{R}^n)$ of free loops on $\mathbb{R}^n$ parametrized by the interval $I=[t_0,t_1]$, considered in Section 2.2 (for the interval $[0,1]$). Namely, set $m=1$ and consider the Wick rotation $t\mapsto -it$ to the Euclidean time, so that the sypersymmetry transformation (4.3)-(4.4) becomes

$$\delta_\varepsilon\boldsymbol{x}(t) = i\varepsilon\boldsymbol{\theta}(t), \quad \delta_\varepsilon\boldsymbol{\theta}(t) = -i\varepsilon\dot{\boldsymbol{x}}(t). \tag{4.8}$$

Now we immediately see that formulas (4.8) can be written as

$$\delta_\varepsilon\boldsymbol{x}(t) = i\varepsilon D\boldsymbol{x}(t) \quad \text{and} \quad \delta_\varepsilon\boldsymbol{\theta}(t) = i\varepsilon D\boldsymbol{\theta}(t),$$

where D is the equivariant differential (2.7),

$$D = \int_{t_0}^{t_1} \left(\theta^\mu(t) \frac{\delta}{\delta x^\mu(t)} - \dot{x}^\mu(t) \frac{\delta}{\delta \theta^\mu(t)} \right) dt,$$

which satisfies $D^2 = -\mathcal{L}_{\dot{\gamma}}$. The corresponding Euclidean supercharge Q coincides with the function β on $\Pi T\mathcal{L}(\mathbb{R}^n)$, given by formula (2.9), so that

$$Q = \int_{t_0}^{t_1} \theta^\mu(t) \dot{x}^\mu(t) dt$$

where we are using the standard Euclidean metric on $\mathbb{R}^n$. It follows from Lemma 2.2 that

$$DQ = -\int_{t_0}^{t_1} (\dot{\boldsymbol{x}}(t)\dot{\boldsymbol{x}}(t) + \boldsymbol{\theta}(t)\dot{\boldsymbol{\theta}}(t)) dt = -2S(\boldsymbol{x}(t), \boldsymbol{\theta}(t)),$$

where now S stands for the Euclidean action. The invariance of the action S under the supersymmetry transformation is the property that S is equivariantly closed, $DS = 0$.

Problem 4.1. Verify that

$$[\delta_{\varepsilon_1}, \delta_{\varepsilon_2}] = 2i\varepsilon_1\varepsilon_2 \frac{d}{dt},$$

where $\varepsilon_1, \varepsilon_2$ are odd variables, and deduce from it formula (4.7).

4.3. Supersymmetric particle on a Riemannian manifold. The classical system with Lagrangian (3.9), considered in Example 3.4 in Section 3.2 , describes a supersymmetric particle on a Riemannian manifold (M, g). Namely, for $(\gamma, \theta) \in \Pi T P_I(M)$ define the supersymmetry transformation $\boldsymbol{x}(t) \mapsto \boldsymbol{x}(t) + \delta_\varepsilon \boldsymbol{x}(t)$ and $\boldsymbol{\theta}(t) \mapsto \boldsymbol{\theta}(t) + \delta_{\boldsymbol{\varepsilon}} \boldsymbol{\theta}(t)$, in local coordinantes $\boldsymbol{x}(t)$ and $\boldsymbol{\theta}(t)$, by the same formula (4.4),

$$\delta_\varepsilon \boldsymbol{x}(t) = i\varepsilon \boldsymbol{\theta}(t) \in \Pi T_{\gamma(t)} M, \quad \delta_\varepsilon \boldsymbol{\theta}(t) = -m\varepsilon \dot{\boldsymbol{x}}(t) \in \Pi T_{\gamma(t)} M, \tag{4.9}$$

where ε is an odd real element.

Lemma 4.1. Supersymmetry transformation (4.9) does not depend on the choice of local coordinates.

Proof. Let $\tilde{\boldsymbol{x}} = (\tilde{x}^1, ..., \tilde{x}^n)$ be another local coordinates on $M, \tilde{x}^\mu = f^\mu(\boldsymbol{x}), \mu = 1, ..., n$. Along the path $\gamma = \boldsymbol{x}(t)$,

$$\dot{\tilde{x}}^\mu(t) = \frac{\partial f^\mu}{\partial x^\nu}(\boldsymbol{x}(t)) \dot{x}^\nu(t) \quad \text{and} \quad \boldsymbol{\theta}(t) = \tilde{\theta}^\mu(t) \frac{\partial}{\partial \tilde{x}^\mu}$$

where

$$\tilde{\theta}^\mu(t) = \frac{\partial f^\mu}{\partial x^\nu}(\boldsymbol{x}(t)) \theta^\nu(t).$$

We have

$$\delta_\varepsilon \tilde{x}^\mu(t) = \frac{\partial f^\mu}{\partial x^\nu}(\boldsymbol{x}(t)) \delta_\varepsilon x^\nu(t) = i \frac{\partial f^\mu}{\partial x^\nu}(\boldsymbol{x}(t)) \varepsilon \theta^\nu(t) = i\varepsilon \tilde{\theta}^\mu(t),$$

and

$$\begin{aligned} \delta_\varepsilon \tilde{\theta}^\mu(t) &= \frac{\partial f^\mu}{\partial x^\nu}(\boldsymbol{x}(t)) \delta_\varepsilon \theta^\nu(t) + \frac{\partial^2 f^\mu}{\partial x^\nu \partial x^\sigma}(\boldsymbol{x}(t)) \delta_\varepsilon x^\sigma(t) \theta^\nu(t) \\ &= -m\varepsilon \frac{\partial f^\mu}{\partial x^\nu}(\boldsymbol{x}(t)) \dot{x}^\nu(t) + i\varepsilon \frac{\partial^2 f^\mu}{\partial x^\nu \partial x^\sigma}(\boldsymbol{x}(t)) \theta^\sigma(t) \theta^\nu(t) \\ &= -m\varepsilon \dot{\tilde{x}}^\mu(t), \end{aligned}$$

since $\theta^\mu(t)$ anticommute.
As in the previous section, we define the supercharge Q by

$$Q(t) = im\langle \dot{\boldsymbol{x}}(t), \boldsymbol{\theta}(t)\rangle$$

The main result of this section is the following statement.
Proposition 4.1. Under the supersymmetry transformation (4.9),

$$\delta_\varepsilon Q = -2mi\varepsilon L \tag{4.10}$$

where

$$L = \frac{m}{2}\|\dot{\boldsymbol{x}}\|^2 + \frac{i}{2}\langle \boldsymbol{\theta}, \nabla_{\dot\gamma}\boldsymbol{\theta}\rangle \tag{4.11}$$

is the Lagrangian of a free particle on Π TM. Also

$$\delta_\varepsilon L = \frac{\varepsilon}{2}\frac{dQ}{dt}. \tag{4.12}$$

Proof. The derivation of (4.10) is a straightforward computation using formula (2.11). Formula (4.12) is proved by another computation, similar to the one used to prove (4.5) in the previous section.

Corollary 4.1. The action functional

$$S(\gamma,\theta) = \int_{t_0}^{t_1} L(\gamma(t), \boldsymbol{\theta}(t))dt$$

is invariant under the supersymmetry transformations,

$$\delta_\varepsilon S(\gamma,\theta) = 0 \quad \text{for all periodic } (\gamma,\theta) \in \Pi TP_I(M)$$

Remark. As for the example of a free particle on $\mathbb{R}^{n|n}$, considered in Section 4.2, the Euclidean version of the sypersymmetry transformation (4.9) corresponds to the equivariant differential (2.7) on the space $\boldsymbol{\mathcal{L}}_I(M)$ of free loops on M parametrized by the interval $I = [t_0, t_1]$. The corresponding Euclidean supercharge Q (for $m = 1$) coincides with the function β on $\Pi T\boldsymbol{\mathcal{L}}_I(M)$ given by formula (2.9), and Proposition 4.1 reduces to the statements that $DQ = -2S$ and $DS = 0$, where S is the Euclidean action, proved in Lemma 2.2.

Problem 4.2. Prove all the formulas in this section.
Problem 4.3 (Superfield formalism). For $(\gamma,\theta) \in \Pi TM$ define the superfield by $X(t) = \boldsymbol{x}(t) + \eta\boldsymbol{\theta}(t)$, where η is an auxiliary Grassmann variable, and let $\mathcal{D} = \frac{\partial}{\partial\eta} - \eta\frac{\partial}{\partial t}$. Show that

$$\int g_{\mu\nu}(X(t))\dot X(t)\mathcal{D}(X)(t)dtd\eta = -\int_{t_0}^{t^1}\left(\|\dot{\boldsymbol{x}}\|^2 + \langle\boldsymbol{\theta}, \nabla_{\dot\gamma}\boldsymbol{\theta}\rangle\right)dt$$

- twice the Euclidean action of a supersymmetric particle on a Riemannian manifold M.

26.1.6 Quantum mechanics on supermanifolds

Here we describe quantum systems which correspond to classical systems in Section 3.2. According to the correspondence principle (see Section 2 of Chapter 2), for quantization of even coordinates we replace Poisson brackets $\{,\}byi[,], wherei = \sqrt{-1}$ and $[,]isthecommutator$[9]. For quantization of odd coordinates, in accordance with Section 1 of Chapter 7, we replace corresponding Poisson brackets by $i[,]_+$, where $[,]_+$is the anticommutator.

Example 5.1 (Quantum particle of spin $\frac{1}{2}$). The corresponding phase space is a supermanifold $\mathbb{R}^{6|3}$ with even coordinates $\boldsymbol{p} = (p_1, p_2, p_3)$ and $\boldsymbol{x} = (x_1, x_2, x_3)$, and odd coordinates ${}^{10}\boldsymbol{\theta} = (\theta_1, \theta_2, \theta_3)$, with canonical Poisson brackets

$$\{p_\mu, x_\nu\} = \delta_{\mu\nu} \quad \text{and} \quad \{\theta_\mu, \theta_\nu\} = i\delta_{\mu\nu}, \quad \mu, \nu = 1, 2, 3$$

Quantum operators $\boldsymbol{P} = (P_1, P_2, P_3)$ and $\boldsymbol{Q} = (Q_1, Q_2, Q_3)$, which correspond to canonical coordinates $\boldsymbol{p}$ and $\boldsymbol{x}$, satisfy Heisenberg commutation relations (see Section 2.1 of Chapter 2), while operators $\boldsymbol{\Theta} = (\Theta_1, \Theta_2, \Theta_3)$, which correspond to the anticommuting coordinates $\boldsymbol{\theta}$, satisfy the following anticommutation relations:

$$[\Theta_\mu, \Theta_\nu]_+ = \delta_{\mu\nu} I, \quad \mu, \nu = 1, 2, 3. \tag{5.1}$$

Since operators $\sqrt{2}\Theta_\mu$ define a representation of a Clifford algebra C_3, the only irreducible realization of (5.1) is given by

$$\Theta_\mu = \frac{1}{\sqrt{2}}\sigma_\mu, \quad \mu = 1, 2, 3 \tag{5.2}$$

where σ_μ are Pauli matrices (see Section 1.1 of Chapter 4). Thus the Hilbert space of the system is $\mathscr{H} = L^2(\mathbb{R}^3) \otimes \mathbb{C}^2$ - the Hilbert space of a quantum particle of spin $\frac{1}{2}$ - and the Hamiltonian operator is

$$H = \frac{\boldsymbol{P}^2}{2m}$$

Using (5.2) and the multiplication table of Pauli matrices, we obtain the following form for quantum Noether integrals of motion (4.2):

$$J = M + S$$

where $\boldsymbol{M}$ is the angular momentum operator (see Section 3.1 of Chapter 3), and $\boldsymbol{S} = \frac{1}{2}\boldsymbol{\sigma}$. Thus $\boldsymbol{J}$ is the total angular momentum operator of a quantum spin $\frac{1}{2}$ particle (see Section 1.2 of Chapter 4).

Example 5.2 (Quantum spin $\frac{1}{2}$ particle in constant magnetic field). The Hilbert space is the same as in the previous example, while the Hamiltonian operator which corresponds to (3.7) takes the form

$$H = \frac{\boldsymbol{P}^2}{2m} + \frac{i}{2}(\boldsymbol{B} \times \boldsymbol{\Theta})\boldsymbol{\Theta} = \frac{\boldsymbol{P}^2}{2m} - \frac{\mathbf{B} \cdot \boldsymbol{\sigma}}{2}.$$

Thus operator H is the Pauli Hamiltonian with total magnetic moment $\mu = \frac{1}{2}$ (see Section 2.1 of Chapter 4).

Example 5.3 (Supersymmetric quantum particle on $\mathbb{R}^n$). The phase space is a supermanifold $\mathbb{R}^{2n|n}$ with even coordinates $\boldsymbol{p} = (p_1, ..., p_n)$ and $\boldsymbol{x} = (x_1, ..., x_n)$, and odd coordinates $\boldsymbol{\theta} = (\theta_1, ..., \theta_n)$, with canonical Poisson brackets

$$\{p_\mu, x_\nu\} = \delta_{\mu\nu} \quad \text{and} \quad \{\theta_\mu, \theta_\nu\} = i\delta_{\mu\nu}, \quad \mu, \nu = 1, ..., n$$

Quantum operators $\boldsymbol{P} = (P_1, ..., P_n)$ and $\boldsymbol{Q} = (Q_1, ..., Q_n)$, which correspond to canonical coordinates $\boldsymbol{p}$ and $\boldsymbol{x}$, satisfy Heisenberg commutation relations, and operators $\Theta = (\Theta_1, ..., \Theta_n)$, which correspond to the anticommuting coordinates $\boldsymbol{\theta}$, satisfy the following anticommutation relations:

[09] Here we put $h = 1$.

[10] Here it is convenient to lower all indices by the standard Euclidean metric on $\mathbb{R}^3$.

$$[\Theta_\mu, \Theta_\nu]_+ = \delta_{\mu\nu} I, \quad \mu, \nu = 1, ..., n \tag{5.3}$$

The operators $\sqrt{2}\Theta^\mu$ define a representation of a Clifford algebra C_n. When n is even, the only irreducible realization of (5.3) is

$$\Theta_\mu = \frac{1}{\sqrt{2}}\gamma_\mu$$

where γ_μ are operators in $\mathscr{H}_F = (\mathbb{C}^2)^{\otimes d}, d = \frac{n}{2}$, given by formulas (1.12)(1.13) in Section 1.2 of Chapter 7 . For odd n, operators γ act in $(\mathbb{C}^2)^{\otimes d}$, where $d = \left[\frac{n}{2}\right]$ (see Problem 1.4 in Section 1.2 of Chapter 7). In both cases, the Hilbert space of the system is $\mathscr{H} = L^2(\mathbb{R}^n) \otimes \mathscr{H}_F = L^2(\mathbb{R}^n) \otimes \mathbb{C}^{2^d}$, the Hamiltonian operator is given by

$$H = \frac{\boldsymbol{P}^2}{2m}$$

and quantum Noether integrals of motion are

$$J_{\mu\nu} = Q_\mu P_\nu - Q_\nu P_\mu - i\Theta_\mu\Theta_\nu$$

Quantization of the supercharge gives the operator

$$Q = i\Theta_\mu P_\mu = \frac{i}{\sqrt{2}}\gamma_\mu P_\mu = \frac{1}{\sqrt{2}}\gamma_\mu\frac{\partial}{\partial x_\mu} = \frac{1}{\sqrt{2}}\ \not{\partial} \tag{5.4}$$

where

$$\not{\partial} = \gamma_\mu\frac{\partial}{\partial x_\mu}$$

is the Dirac operator on $\mathbb{R}^n$. The Dirac operator is skew-adjoint in $\mathscr{H}$,

$$\not{\partial}^* = -\ \not{\partial}.$$

When n is even, decomposition $\mathscr{H}_F = \mathscr{H}_F^+ \oplus \mathscr{H}_F^-$ into the subspaces of positive and negative chirality spinors (see Section 1.2 of Chapter 7) gives decomposition

$$\mathscr{H} = \mathscr{H}_+ \oplus \mathscr{H}_-, \qquad \text{where} \qquad \mathscr{H}_\pm = L^2(\mathbb{R}^n) \otimes \mathscr{H}_F^\pm$$

and using that $\gamma_\mu\left(\mathscr{H}_F^+\right) = \mathscr{H}_F^-$ (see Section 1.2 of Chapter 7), we can represent the Dirac operator in the following 2×2 block-matrix form:

$$\not{\partial} = \begin{pmatrix} 0 & -\ \not{\partial}_+^* \\ \not{\partial}\partial_+ & 0 \end{pmatrix}$$

Here the operator $\not{\partial}: \mathscr{H}_+ \to \mathscr{H}_-$ is called the chiral Dirac operator. We have

$$[Q, Q]_+ = 2Q^2 = \not{\partial}^2 = -2mH$$

so that $2mH$ is the Dirac Laplacian $-\ \not{\partial}^2$. In matrix form,

$$2mH = \begin{pmatrix} \ddot{\not{\partial}}_+^* \not{\partial}_+ & 0 \\ 0 & \not{\partial}_+ \ddot{\not{\partial}}_+^* \end{pmatrix}$$

Example 5.4 (Supersymmetric quantum particle on Riemannian manifold). We have seen in Example 2.4 in Section 2.4 of Chapter 2 that though for a free quantum particle on a Riemannian manifold (M, g) it is not possible to construct operators $\boldsymbol{P}$ and $\boldsymbol{Q}$ which correspond to standard

local coordinates $(\boldsymbol{p}, \boldsymbol{x})$ on T^*M, the Hamiltonian operator H is well defined as the Laplace-Beltrami operator of the Riemannian metric. It is remarkable
that consistent quantization of a supersymmetric particle requires M to be a spin manifold, and for even $n = \dim M$ the corresponding supercharge operator Q coincides with the Dirac operator!

Namely, let $\mathrm{Spin}(n)$ be the spin group: connected, simply connected Lie group which is a double cover of $\mathrm{SO}(n)$. The oriented Riemannian manifold (M, g) of dimension n is said to have a spin structure (and is called a spin manifold) if the bundle $\mathrm{SO}(M)$ of oriented orthonormal frames over M principal $\mathrm{SO}(n)$-bundle - can be extended to the principal $\mathrm{Spin}(n)$-bundle $\mathrm{Spin}(M)$. This is equivalent to the condition that for some open covering $M = \bigcup_{\alpha\in A} U_\alpha$ transition functions $t_{\alpha\beta} : U_\alpha \cap U_\beta \to \mathrm{SO}(n)$ of a tangent bundle TM can be lifted to the transition functions $\tau_{\alpha\beta} : U_\alpha \cap U_\beta \to \mathrm{Spin}(n)$; $t_{\alpha\beta} = \rho(\tau_{\alpha\beta})$, where $\rho : \mathrm{Spin}(n) \to \mathrm{SO}(n)$ is the canonical projection. The manifold M is a spin manifold if and only if its second Stieffel-Whitney class $w_2 \in H^2(M, \mathbb{Z}_2)$ vanishes; in this case different spin structures are parametrized by $H^1(M, \mathbb{Z}_2) \simeq \mathrm{Hom}(\pi_1(M), \mathbb{Z}_2)$, where $\pi_1(M)$ is the fundamental group of M. For even $n = 2d$, the irreducible representation ρ of the Clifford algebra C_n in $\mathscr{H}_F \simeq \mathbb{C}^{2^d}$ (see Section 1.2 of Chapter 7) defines unitary representation R of the spin group $\mathrm{Spin}(n)$ in $\mathscr{H}_F$, which commutes with the parity operator Γ. By definition, the spinor bundle $\mathcal{S}$ on an evendimensional spin manifold M is a Hermitian vector bundle associated with the principal $\mathrm{Spin}(n)$-bundle $\mathrm{Spin}(M)$ by the unitary representation R. In other words, $\mathcal{S}$ is a complex vector bundle with the transition functions $R(\tau_{\alpha\beta}) : U_\alpha \cap U_\beta \to \mathrm{U}\left(2^d\right)$, where $\mathrm{U}\left(2^d\right)$ is the group of unitary $2^d \times 2^d$ matrices. Decomposition of vector spaces $\mathscr{H}_F = \mathscr{H}_F^+ \oplus \mathscr{H}_F^-$ defines the decomposition

$$\mathcal{S} = \mathcal{S}_+ \oplus \mathcal{S}_-$$

of the spinor bundle $\mathcal{S}$ into the bundles $\mathcal{S}_+$and $\mathcal{S}_-$ of positive and negative chirality spinors.

The Dirac operator $\not{\partial} : C^\infty(M, \mathcal{S}) \to C^\infty(M, \mathcal{S})$ of the even-dimensional spin manifold M is defined as follows. Let $\nabla^{\mathcal{S}}$ be the connection on the spinor bundle $\mathcal{S}$ induced by the Levi-Civita connection in the tangent bundle TM. Then in the coordinate chart $U \subset M$ with local coordinates $\boldsymbol{x} = (x^1, ..., x^n)$ we have

$$\not{\partial} = \gamma^\mu(\boldsymbol{x})\nabla_\mu^{\mathcal{S}} \tag{5.5}$$

where $\nabla_\mu^{\mathcal{S}}$ is the covariant derivative with respect to the vector field $\frac{\partial}{\partial x^\mu}$ over U, and $\gamma^\mu(\boldsymbol{x})$ are endomorphisms of the spinor bundle $\mathcal{S}$ over U satisfying

$$[\gamma^\mu(\boldsymbol{x}), \gamma^\nu(\boldsymbol{x})]_+ = 2g^{\mu\nu}(\boldsymbol{x})I \tag{5.6}$$

where I is the identity endomorphism. It is easy to show that there is an open covering $M = \bigcup_{\alpha\in A} U_\alpha$ such that $\gamma^\mu(\boldsymbol{x})$ exist over each U_α, and that local
expressions (5.5) give rise to a globally defined operator $\not{\partial}$: $C^\infty(M, \mathcal{S}) \to C^\infty(M, \mathcal{S})$. Equivalently, if $\xi \in C^\infty(M, \mathcal{S})$ is given by $\xi = \{\xi_\alpha\}_{\alpha\in A}, \xi_\alpha$: $U_\alpha \to \mathscr{H}_F$, where $\xi_\alpha = R(\tau_{\alpha\beta})\,\xi_\beta$ on $U_\alpha \cap U_\beta$, then

$$\not{\partial}_\alpha \xi_\alpha = R(\tau_{\alpha\beta})\ \not{\partial}_\beta \xi_\beta, \tag{5.7}$$

where $\not{\partial}$ is given by (5.5) for $U = U_\alpha$. We also have

$$\not{\partial} : C^\infty(M, \mathcal{S}_\pm) \to C^\infty(M, \mathcal{S}_\mp).$$

The Hermitian metric $\|\|_{\mathcal{S}}$ in the spinor bundle $\mathcal{S}$ and the Riemannian metric g on M allow us to define the Hilbert space $\mathscr{H}$ of square integrable global sections of $\mathcal{S}$,

$$\mathscr{H} = \left\{ \xi \in \Gamma(M, \mathcal{S}) : \|\xi\|^2 = \int_M \|\xi(x)\|^2_{\mathcal{S}} d\mu(x) < \infty \right\}.$$

Initially defined on $C^\infty(M, \mathcal{S})$, the Dirac operator extends to the skewadjoint operator in $\mathscr{H}$, which we continue to denote by $\not{\partial}$. As in the previous example, using the Hilbert space decomposition $\mathscr{H} = \mathscr{H}_+ \oplus \mathscr{H}_-$, we can represent the Dirac operator in the following 2×2 block-matrix form:

$$\not{\partial} = \begin{pmatrix} 0 & -\not{\partial}^*_+ \\ \not{\partial}_+ & 0 \end{pmatrix},$$

where $\partial_+ : \mathscr{H}_+ \to \mathscr{H}_-$is the chiral Dirac operator on a spin manifold M.

Remark. The Dirac operator from the previous example is the Dirac operator on the spin manifold $\mathbb{R}^n$ with the standard Euclidean metric; the corresponding spinor bundle is a trivial Hermitian vector bundle $\mathbb{R}^n \times \mathscr{H}_F$.

The space of states of a quantum supersymmetric particle on a spin manifold (M, g) is the Hilbert space $\mathscr{H}$ of square-integrable sections of the spinor bundle S over M. The corresponding supercharge operator Q and Hamiltonian operator H are given by the same formulas as in the previous example,

$$Q = \frac{1}{\sqrt{2}} \not{\partial} \quad \text{and} \quad [Q, Q]_+ = 2Q^2 = \not{\partial}^2 = -2mH.$$

The operator

$$2mH = \begin{pmatrix} \not{\partial}^*_+ \not{\partial}_+ & 0 \\ 0 & \not{\partial}_+ \not{\partial}^*_+ \end{pmatrix}$$

is the Dirac Laplacian on a spin manifold M.

Problem 5.1. Identify the spin group $\mathrm{Spin}(n)$ as a subgroup in the group of invertible elements of the Clifford algebra C_n.

Problem 5.2. Prove relations (5.7).

26.1.7 Atiyah-Singer index formula

Let M be an even-dimensional, oriented, compact spin manifold with the Riemannian metric g. Operators $\not{\partial}^*_+ \not{\partial}_+$and $\not{\partial}_+ \not{\partial}^*_+$ are, respectively, selfadjoint on Hilbert spaces $\mathscr{H}_+$and $\mathscr{H}_-$, and have pure point spectra consisting of non-negative eigenvalues of finite multiplicity with the only accumulation point at ∞. In particular, complex vector spaces $\ker \not{\partial}^*_+ \not{\partial}_+ = \ker \not{\partial}_+$and $\ker \not{\partial}_+ \not{\partial}^*_+ = \ker \not{\partial}^*_+$ are finite-dimensional, and we define the index $\mathrm{ind}\ \not{\partial}_+$of the chiral Dirac operator $\not{\partial}_+$by

$$\mathrm{ind}\ \not{\partial}_+ = \dim \ker \not{\partial}_+ - \dim \ker \not{\partial}^*_+.$$

We have the following basic result.

Theorem 6.1 (McKean-Singer). For every $T > 0$,

$$\mathrm{ind}\ \not{\partial}_+ = \mathrm{Tr}_s\, e^{T\not{\partial}^2} = \mathrm{Tr}\, e^{-T\not{\partial}^*_+ \not{\partial}_+} - \mathrm{Tr}\, e^{-T\not{\partial}_+ \not{\partial}^*_+}.$$

On the other hand, we have seen in Example 5.4 in the last section that $-\not{\partial}^2 = 2H$, where H is the Hamiltonian operator of free supersymmetric particle of mass $m = 1$ on the spin manifold M. Thus for every $T > 0$,

$$\mathrm{ind}\ \not{\partial}_+ = \mathrm{Tr}_s\, e^{-2TH}$$

In Section 2.2 of Chapter 6 and in Sections 4.2 and 4.3 of Chapter 7 we developed a formalism for expressing traces and supertraces of the evolution operator in Euclidean time by path integrals. Using these results, we can, at a physical level of rigor, represent the supertrace $\mathrm{Tr}_s\, e^{-2TH}$ by the path integral

$$\mathrm{Tr}_s\, e^{-2TH} = \int_{\Pi T\mathcal{L}_I(M)} e^{-S_{\mathrm{E}}(\gamma,\theta)}\mathscr{D}\boldsymbol{x}\mathscr{D}\boldsymbol{\theta} \tag{6.1}$$

Here

$$S_{\mathrm{E}}(\gamma,\theta) = \frac{1}{2}\int_0^{2T}\left(\|\dot\gamma\|^2 + \langle\boldsymbol{\theta}(t), \nabla_{\dot\gamma}\boldsymbol{\theta}(t)\rangle\right)dt$$

is the Euclidean action of a supersymmetric particle on a Riemannian manifold M, obtained from the Lagrangian function (4.11) by replacing time t by the Euclidean time $-it$, and $\mathcal{L}_I(M)$ is the space of free loops on M parametrized by the interval $[0, 2T]$. When [11]$2T = 1$, the integral in (6.1) coincides with integral $\int_{\mathcal{L}(M)} e^{-S}$, considered in Section 2.2. Using Theorem 2.3, we obtain

$$\mathrm{ind}\ \not{\partial}_+ = \mathrm{Tr}_s\, e^{-H} = (2\pi i)^{-\frac{n}{2}}\int_M \hat{A}(M),$$

which is the celebrated Atiyah-Singer formula for the index of the Dirac operator on a spin manifold!

Remark. Integrating over Grassmann variables in (6.1), we obtain

$$\mathrm{Tr}_s\, e^{-H} = \int_{\mathcal{L}(M)} \mathrm{Pf}\,(\nabla_{\dot\gamma})\, d\mu_W \tag{6.2}$$

where $d\mu_W$ is the Wiener measure on the loop space $\mathcal{L}(M)$ associated with the Riemannian metric g on M. It can be shown that when M is a spin manifold, the Pfaffian $\mathrm{Pf}\,(\nabla_{\dot\gamma})$ of a covariant derivative operator along $\gamma \in \mathcal{L}(M)$ is a well-defined function on $\mathcal{L}(M)$. Thus formula (6.2), as opposed to the local computation in the derivation of Theorem 2.3, captures global properties of the manifold M.

Problem 6.1. Prove the McKean-Singer theorem.

Problem 6.2. "Derive" formula (6.1). (Hint: See the references in the next section.)

27 Deeper Understanding of Quantum Mechanics

(I'll merge it with the part 2 later)

27.1 Construction of Quantum Mechanics (?)

(пока так раздел называется, посмотрим, мб назову иначе)

27.1.1 Gauges in Quantum Mechanics (??)

(пока так сказать мало что могу)

[011] According to a remark in Section 2.2, the same result holds for every $T > 0$.

О калибровочной инвариантности (???)

Нам известно, что волновая функция определена с точностью до глобальной фазы, так как она не влияет ни на интерференцию всех слагаемых, ни на модуль вероятности.

(?? честно, пока хз, что сказать про это с точки зрения квантмеха, повисит пока раздел)

вывод методов про калибровочную инвариантность (????)

Поэтому можно воспользоваться теоремой Нетер, чтобы найти сохраняющиеся величины при движении.

$$\Psi_u(\boldsymbol{r},t) = e^{-\mathrm{i}u}\Psi(\boldsymbol{r},t), \quad \Psi_u^\dagger(\boldsymbol{r},t) = e^{\mathrm{i}u}\Psi^\dagger(\boldsymbol{r},t)$$

$$\frac{dS}{du} = \int dt d^3r \partial_\mu \left\{ \frac{\partial \mathcal{L}}{\partial \partial_\mu \Psi}\frac{\partial \Psi_u}{\partial u} + \frac{\partial \mathcal{L}}{\partial \partial_\mu \Psi^\dagger}\frac{\partial \Psi_u^\dagger}{\partial u} \right\} = 0$$

(???)

В итоге у нас равен нулю 4-дивергенция тока:

$$\partial_\mu \mathcal{J}^\mu = 0, \quad \mathcal{J}^\mu = \frac{\partial \mathcal{L}}{\partial \partial_\mu \Psi}\frac{\partial \Psi_u}{\partial u} + \frac{\partial \mathcal{L}}{\partial \partial_\mu \Psi^\dagger}\frac{\partial \Psi_u^\dagger}{\partial u}$$

$$\int dt d^3r \partial_0 \mathcal{J}^0 + \int dt d^3r \boldsymbol{\nabla}\cdot\mathcal{J} = \int d^3r \mathcal{J}_0 \Big|_{t_1}^{t_2} + \int dt \oint d^2s \cdot \mathcal{J} = 0$$

$$Q = \int d^3r \mathcal{J}_0$$

$$\frac{\partial \Psi_u}{\partial u} = -\mathrm{i}\Psi, \quad \frac{\partial \Psi_u^\dagger}{\partial u} = \mathrm{i}\Psi^\dagger$$

$$\mathcal{L} = \mathrm{i}\hbar\Psi^\dagger\dot{\Psi} - \tfrac{\hbar^2}{2m}\left(\nabla\Psi^\dagger\right)\cdot(\nabla\Psi)$$
$$\mathcal{J}_0 = c\hbar\Psi^\dagger\Psi, \quad \mathcal{J} = -\tfrac{\mathrm{i}\hbar^2}{2m}\left[\Psi^\dagger\nabla\Psi - \left(\nabla\Psi^\dagger\right)\Psi\right]$$

$$\mathcal{J}^\mu = \hbar(c\rho, j)$$

$$\hat{p}_\mu\Psi = \mathrm{i}\hbar\partial_\mu\Psi = \mathrm{i}\hbar\left(\frac{\partial\Psi}{c\partial t}, \boldsymbol{\nabla}\Psi\right), \quad p_\mu = (E/c, -\boldsymbol{p})$$

(пропущено много)

в итоге лагранжиан является калибровочно инвариантным относительно локальных преобразований.

$$\mathcal{L} = c\Psi^\dagger\left(\hat{p}_0 + \frac{e}{c}A_0\right)\Psi + \frac{1}{2m}\left(\hat{p}\Psi + \frac{e}{c}\boldsymbol{A}\Psi\right)^\dagger\cdot\left(\hat{p}\Psi + \frac{e}{c}\boldsymbol{A}\Psi\right)$$

как будто в итоге у нас обычная механика...

27.1.2 Ways to Combine Quantum Mechanics and Gravity

(мб этому разделу тут не место, но идея в том, что вообще-то можно было бы иначе все строить, тогда бы гравитация добавилась. в любом случае, подробно - или под конец записи или в других записях.)

27.1.3 On the Construction of Quantum Mechanics Without Imaginary Numbers (???)

(то пока не знаю, вроде нельзя, почему - пока не готов объяснить.)

27.1.4 Quantum Mechanics Methods in Solid-State Physics

(тут компактно их укажу, особо большой главы не нужно, достаточно просто указать)

Об описании взаимодействия частиц

(левитов Шитов глава 4, пока я не настолько освоился с основами, чтобы этим заниматься. потом напишу суть.)

27.2 How to Understand Quantum Mechanics?

(по идее все про это тут)

27.2.1 Copenhagen Interpretation

Многие физики по поводу смысла квантовой механики не задумываются, а чуть что - понимают то, что называется копенгагенской интерпретацией. Действительно, это простая и удобная конструкция, понимание которой необходимо для понимание квантовой механики. Обсудим ее, понимая, что есть также другие интерпретации, которые обсуждаются в другом разделе.

обзор

Копенгагенская интерпретация — интерпретация (толкование) квантовой механики, которую сформулировали Нильс Бор и Вернер Гейзенберг во время совместной работы в Копенгагене около 1927 года[1][2][3][4]. Бор и Гейзенберг усовершенствовали вероятностную интерпретацию волновой функции, данную М. Борном, и попытались ответить на ряд вопросов, возникающих вследствие свойственного квантовой механике корпускулярно-волнового дуализма, в частности на вопрос об измерении.

Основные идеи копенгагенской интерпретации

Физический мир состоит из квантовых (малых) объектов и классических измерительных приборов.

Уравнение Шрёдингера (волновой функцией) описывает изменение квантового состояния объектов.

Изменение состояния классических измерительных приборов описывается необратимым статистическим процессом измерения характеристик квантовых микрообъектов.

В процессе взаимодействия микрообъекта с атомами измерительного прибора происходит редукция волновой функции измеряемого микрообъекта, то есть сведение суперпозиции к одному состоянию. Этот результат не следует из уравнения Шрёдингера.

Согласно копенгагенской интерпретации, квантовая механика описывает не микрообъекты сами по себе, а их свойства, проявляющиеся в макроусловиях, создающихся классическими измерительными приборами в процессе акта наблюдения.

Поведение атомных объектов невозможно резко отграничить от их взаимодействия с измерительными приборами, фиксирующими условия, при которых происходят

явления[5] Квантовая механика является статистической теорией, вследствие того, что измерение начальных условий микрообъекта изменяет его состояние и приводит к вероятностному описанию исходного положения микрообъекта, которое описывается волновой функцией[6]. Центральным понятием квантовой механики является комплексная волновая функция. Можно описать изменение волновой функции до нового измерения. Его ожидаемый результат зависит вероятностным образом от волновой функции. Физически значимым является лишь квадрат модуля волновой функции, означающий вероятность нахождения изучаемого микрообъекта в некотором месте пространства.[7][8]

Закон причинности в квантовой механике выполняется по отношению к волновой функции, изменение которой во времени полностью определяется её начальными условиями, а не по отношению к координатам и скоростям частиц, как в классической механике. Вследствие того, что физический смысл имеет лишь квадрат модуля волновой функции, начальные значения волновой функции невозможно полностью найти в принципе, что приводит к неопределённости знаний о начальном состоянии квантовой системы.[9]

Философскую основу копенгагенской интерпретации составляют гносеологические принцип наблюдаемости (исключение, насколько возможно, из физической теории утверждений, которые не могут быть проверены непосредственным наблюдением)[10], принцип дополнительности (волновое и корпускулярное описание микрообъектов являются дополнительными друг к другу)[11], принцип неопределённости (координата и импульс микрообъектов не могут быть определены независимо друг от друга и с абсолютной точностью)[11], принцип статистического детерминизма (данное состояние замкнутой физической системы определяет её последующее состояние не однозначно, а лишь с определённой вероятностью, описывающей меру возможности осуществления заложенных в прошлом тенденций изменения) и принцип соответствия (законы квантовой механики переходят в законы классической, когда можно пренебречь величиной кванта действия).

в квантовой физике данные об атомных объектах, полученные при помощи разных экспериментальных установок, находятся в своеобразном дополнительном отношении друг к другу.[12] соотношения неопределённостей Гейзенбергадают связь (обратную пропорциональность) между неточностями допустимого в квантовой механике фиксирования тех кинематических и динамических переменных, которыми в классической механике определяется состояние физической системы.[12] Серьёзным преимуществом копенгагенской интерпретации является то, что она не использует детальных высказываний о непосредственно физически не наблюдаемых величинах и при минимуме используемых предпосылок выстраивает систему понятий, которые исчерпывающим образом описывают имеющиеся на сегодня экспериментальные факты[13].

Смысл волновой функции

Копенгагенская интерпретация предполагает, что на волновую функцию могут влиять два процесса:

унитарная эволюция согласно уравнению Шрёдингера процесс измерения По поводу первого процесса не возникает разногласий ни у кого, а по поводу второго имеется ряд различных интерпретаций, даже в пределах самой копенгагенской интерпретации. С одной стороны, можно полагать, что волновая функция является реальным физическим объектом и что она во время второго процесса претерпевает коллапс, с другой стороны, можно считать, что волновая функция — лишь вспомогательный математический инструмент (а не реальная сущность), единственное предназначение которой — это

давать нам возможность рассчитывать вероятности. Бор подчёркивал, что единственное, что можно предсказывать — это результаты физических опытов, поэтому дополнительные вопросы относятся не к науке, а к философии. Бор разделял философскую концепцию позитивизма, которая требует, чтобы наука говорила только о реально измеримых вещах.

В классическом двухщелевом опыте свет проходит через две щели и падает на экран, где появляются тёмные и светлые интерференционные полосы. Это можно объяснить тем, что в некоторых местах световые волны взаимно усиливаются, а в других — гасятся. С другой стороны, эксперимент показывает, что свет обладает и свойствами потока частиц, а такие объекты, как электроны могут проявлять и волновые свойства и тоже могут давать интерференционную картину.

Это ставит несколько интересных вопросов. Допустим, двухщелевой эксперимент проводится с настолько низкой интенсивностью потока фотонов (или электронов), что каждый раз через щели проходит только по одной частице. Однако, когда экспериментатор сложит точки попадания всех фотонов на экран, он получит ту же интерференционную картину от накладывающихся волн, несмотря на то, что вроде бы опыт касался отдельных частиц. Это можно интерпретировать так, что мы живём в «вероятностной» вселенной — такой, что в ней с каждым будущим событием связана определённая степень возможности, а не в такой, что в каждый следующий момент может случиться всё что угодно.

Следствия копенгагенской интерпретации

Данный опыт ставит следующие вопросы:

Законы квантовой механики говорят о том, где частицы попадут в экран статистически и дают возможность рассчитать местоположение светлых полос, куда скорее всего попадёт много частиц и местоположение тёмных полос, куда скорее всего попадёт мало частиц. Однако для отдельной частицы законы квантовой механики не способны предсказать, где она окажется фактически. Каковы в таком случае правила поведения отдельных частиц? Что происходит с частицей между моментом испускания и моментом регистрации? Создаётся впечатление, что частица претерпевает взаимодействие с обеими щелями. И это кажется противоречащим тому, как может себя вести точечная частица. Тем более что, когда частица регистрируется, она оказывается точечной. Что заставляет частицу переключаться от статистического к нестатистическому поведению и обратно? Когда частица летит сквозь щели, её поведение описывается нелокализованной волновой функцией, которая одновременно проходит через обе щели. Когда же частица регистрируется, никогда не получается размытый волновой пакет, но всегда фиксируется точечная частица. Копенгагенская интерпретация отвечает на эти вопросы так:

Вероятностный характер предсказаний квантовой механики принципиально неустраним, то есть он вовсе не говорит о том, что наши знания ограничены, что мы не знаем значений каких-то скрытых переменных. В классической физике вероятность использовалась для описания результатов типа подбрасывания игральной кости, хотя фактически этот процесс считался детерминированным. То есть вероятности использовались вместо неполного знания. Напротив, копенгагенская интерпретация утверждает, что в квантовой механике результат измерения принципиально недетерминирован. Физика — это наука о результатах измерительных процессов. Измышления на тему того, что происходит за ними, неправомерны. Копенгагенская интерпретация отбрасывает вопросы типа «где была частица до того, как я зарегистрировал её местоположение» как бессмысленные. Акт измерения вызывает мгновенное схлопывание, «коллапс волновой функции». Это означает, что процесс

измерения случайно выбирает в точности одну из возможностей, допустимых волновой функцией данного состояния, а волновая функция мгновенно изменяется, чтобы отразить этот выбор. Оригинальная формулировка копенгагенской интерпретации породила ряд вариаций; наиболее уважаемая основана на подходе непротиворечивых событий («Копенгаген прав?») и понятии квантовой декогеренции, которая позволяет рассчитывать нечёткую границу между «микро» и «макро» мирами. Другие вариации различаются степенью «реалистичности» волнового мира.

Критика и недостатки копенгагенской интерпретации

Полнота квантовой механики (тезис 1) была подвергнута сомнению в мысленном эксперименте Эйнштейна, Подольского и Розена (ЭПР-парадокс), который был предназначен для того, чтобы доказать, что скрытые параметры должны существовать, чтобы теория не приводила к нелокальному и мгновенному «дальнодействию». Однако проверка ЭПР-парадокса на опыте при помощи неравенств Белла показала, что квантовая механика верна и что различные теории локальных скрытых параметров не согласуются с экспериментом.

Из всех трёх тезисов с физической точки зрения наиболее проблематичен последний, поскольку он ставит процессы измерения в особое положение, но не определяет ясно, что они такое, и не указывает на их отличительные черты.

Многие физики и философы не соглашаются с копенгагенской интерпретацией, как потому, что она не детерминистична, так и потому, что она вводит неопределённое понятие измерения, которое превращает вероятностные функции в достоверные результаты измерений.

Эйнштейн был убежден в неполноте описания физической реальности, даваемого квантовой механикой в её копенгагенской интерпретации: «Думать так логически допустимо, но это настолько противоречит моему научному инстинкту, что я не могу отказаться от поисков более полной концепции».[14]

Иллюстрируя это, Эйнштейн писал[прим. 1] Борну: «Я убеждён, что Бог не бросает кости», — а также восклицал в беседе с Абрахамом Пайсом: «Вы и вправду думаете, что Луна существует, лишь когда вы на неё смотрите?». Н. Бор отвечал ему: «Эйнштейн, не указывайте Богу, что делать». Эрвин Шрёдингер придумал знаменитый мысленный эксперимент про кота Шрёдингера, которым он хотел показать неполноту квантовой механики при переходе от субатомных систем к макроскопическим.

Аналогично вызывает проблемы необходимый «мгновенный» коллапс волновой функции во всём пространстве. Теория относительности Эйнштейна говорит, что мгновенность, одновременность, имеет смысл только для наблюдателей, находящихся в одной системе отсчёта — не существует единого для всех времени, поэтому мгновенный коллапс тоже остаётся не определён.

27.2.2 Other Attempts to Construct Quantum Mechanics

О квантовой механики без комплексных чисел (!??!?!)

(интересно, почему без них никуда, или все-таки есть ли способ без них???? хз вообще.)

27.3 Paradoxes

(по идее тут подробно все их соберу)

27.3.1 EPR

Связь ЭПР и космологии

Он нужен в космологии хотя бы где-то???

(а я хз на самом деле, мб где-то и встретил я его, раз написал. потом подумаю.)

Теория парадокса ЭПР

Согласно соотношению неопределённостей Гейзенберга, нет возможности одновременно точно измерить координату частицы и её импульс.

Предполагая, что причиной неопределённости является то, что измерение одной величины вносит принципиально неустранимые возмущения в состояние и производит искажение значения другой величины, можно предложить гипотетический способ, которым соотношение неопределённостей можно обойти.

Допустим, две одинаковые частицы A и B образовались в результате распада третьей частицы C.

В этом случае, по закону сохранения импульса, их суммарный импульс p A + p B должен быть равен исходному импульсу третьей частицы p C p C, то есть, импульсы двух частиц должны быть связаны.

Это даёт возможность измерить импульс одной частицы)A A) и по закону сохранения импульса p A p B = p C - p A рассчитать импульс второй)B B), не внося в её движение никаких возмущений.

Теперь, измерив координату второй частицы, можно получить для этой частицы значения двух неизмеримых одновременно величин, что по законам квантовой механики невозможно.

Исходя из этого, можно было бы заключить, что соотношение неопределённостей не является абсолютным, а законы квантовой механики являются неполными и должны быть в будущем уточнены.

Если же законы квантовой механики в данном случае не нарушаются, то измерение импульса одной частицы равносильно измерению импульса второй частицы.

Однако это создаёт впечатление мгновенного воздействия первой частицы на вторую в противоречии с принципом причинности.

27.4 Deeper Understanding of Philosophy of Quantum Mechanics

Подробно обсудим философию квантовой механики.

(сперва делаю важное, потом в свободное время Иванова М.Г. мб почитаю, пропишу этот раздел подробно. мб эзотерику обсужу также.)

(I'll merge it with the part 2 later)

27.4.1 Is QM Created This Way By The Way How Humans Want or By Nature?

(this question which Kant answered: by Humans, because all what we see is that we already analyze. so, all concepts are what we want to see, all "quantums" is our ideas, because this is what we understand. the discussion of this will be here)

27.4.2 Other Philosophical Questions

(unstructured, no time for it now, I'll do it later and put some of them to the first part)

интуитивное представление квантовой физики (????)

это естественно и очевидно, что в микромире все начнет делиться на части.

как уровни.

????

и что переходы должны не зависеть ни от чего, но если и зависеть - то только от природы, а значит, как раз это и происходит, вероятностное описание, вот мы и осознали, почему так.

что такое квант материи

обсудим это, и что мы описываем квантами?

принцип дополнительности

хз к чему он, просто выгрузка пока

мы с ним уже встречались, когда рассматривали атомы, тут хотелось бы сделать какие-то общие выводы про то, как работает мир.

сперва этот принцип во всей красе:

Перейти к поиску Принцип дополнительности — один из важнейших методологических и эвристических принципов науки, а также один из важнейших принципов квантовой механики, сформулированный в 1927 году Нильсом Бором.

Согласно этому принципу, для полного описания квантовомеханических явлений необходимо применять два взаимоисключающих («дополнительных») набора классических понятий, совокупность которых даёт исчерпывающую информацию об этих явлениях как о целостных.

Например, дополнительными в квантовой механике являются пространственно-временная и энергетически-импульсная картины.

Описания любого физического объекта как частицы и как волны дополняют друг друга, одно без другого лишено смысла, корпускулярный и волновой аспекты описания обязательно должны входить в описание физической реальности[1].

При получении информации об одних физических величинах, описывающих микрообъект, неизбежно теряется информация о других физических величинах, дополнительных к первым.[2]

о существовании эффекта наблюдателя

(? пока не разобрался, существует он, или нет?)

насколько правда то, что если наблюдаем за системой, она ведет себя иначе, чем без наблюдения?

пока что думаю, что это неправда и такого не бывает

В квантовой механике, «наблюдение» является синонимом измерения, «наблюдатель» — синонимом измерительной аппаратуры, а наблюдаемое — с тем, что можно измерить.

Одним из основных понятий квантовой механики является сформулированная ещё в 1924 году в совместной работе Бора, Крамерса и Слэйтера, интерпретация волновой функции ψ как волны вероятности, а не реальной волны, как предполагал де Бройль.

До измерения квантовая система находится в суперпозиции допустимых состояний.

Считается, что после измерения, которое определяет часть параметров системы, волновая функция скачком меняется, принимая вид, соответствующий измеренным значениям параметров[6].

Примером может служить кот Шрёдингера.

Наблюдение невозможно без взаимодействия наблюдаемого объекта с окружающей средой — чтобы наблюдатель мог определить параметры объекта, он должен получить информацию от такого взаимодействия.

Квантовый объект при этом неизбежно изменяет своё состояние.

Для элементарных частиц это очевидно, поскольку наблюдать такие частицы мы можем только по их взаимодействию (либо с фотонами, либо с веществом, через которое пролетает частица)[8].

В экспериментах с крупными молекулами, наблюдать которые можно по их тепловому излучению, было определено, что «эффект наблюдателя» проявляется и в отсутствие непосредственного воздействия наблюдателя на квантовый объект, но при любом взаимодействии (обмене энергией) между квантовой системой и окружающим пространством.

Экспериментаторы улавливали тепло (инфракрасные фотоны), излучённое нагретыми молекулами фуллерена C70, и чем выше была температура молекул, тем более классически вели себя нагретые молекулы.

В этих экспериментах было продемонстрировано, что величина квантовых эффектов обратна интенсивности взаимодействия квантового объекта с окружающей его средой, наличие наблюдателя при этом не имеет значения[9][8].

Таким образом, эффект наблюдателя меняет состояние квантовой системы, отражённое в главном её описании — волновой функции.

Более поздние исследования показали, что такое влияние наблюдателя распространяется не только на изучаемую частицу, но и на взаимодействовавшую с ней, приведя к понятию «запутанных состояний».

Волновая функция связанной частицы также испытывает скачок своего состояния после наблюдения, что используется в квантовой криптографии.

Поскольку прослушивание канала передачи данных является наблюдением, этот эффект можно отследить

(????)

Доказала ли квантовая механика, что реальности не существует?

(там вроде про это рассуждения есть, посмотрю потом. чисто тема для научпоп видео или разговоров.)

27.4.3 Criticism by Fock of Bohr's Views on Quantum Mechanics (!?!??!)

Criticism by Fock of Bohr's Views on Quantum Mechanics (!?!??!)

В 1948 г. на страницах издаваемого в Швейцарии журнала «Диалектика» состоялась дискуссия по принципиальным вопросам квантовой механики. В этой дискуссии приняли участие многие выдающиеся зарубежные физики: Бор, Гейзенберг, Эйнштейн, Паули и другие, статьи которых были напечатаны в № 7; 8 упомянутого журнала за 1948 г. Руководящей является статья Бора «О понятиях причинности и дополнительности». Эту статью можно рассматривать не только как выражение взглядов собственно копенгагенской школы, но и как выражение тех взглядов на квантовую механику, которые господствуют среди зарубежных физиков. Взгляды эти вырабатывались на основе идеалистической философии— так называемого позитивизма, нзсовместимой с марксистсколенинской философией диалектического материализма. Неправильные философские установки, применённые к какой-либо конкретной области науки, почти неизбежно приводят к ошибкам в самой этой области. Поэтому особенно важно

проанализировать, нет ли во взглядах представителей копенгагенской школы на квантовую механику помимо неприемлемых общефилософских высказываний, неправильность которых для советского читателя очевидна, также и конкретных ошибок, приводящих к неправильному толкованию самой квантовой механики. Поскольку упомянутая статья Бора представляет резюме этих взглядов, формулированное признанным главой копенгагенской школы, она даёт удобный материал для такого анализа. Чтобы быть точными, нам придётся подробно изложить содержание упомянутой статьи Бора и привести из неё достаточно полные цитаты. Во вводной части своей статьи Бор говорит о причинном способе описания явлений в классической физике, и пишет: «теория относительности, которая придала классической физике небывалое единство и широту, позволила точно формулировать принцип причинности в самом общем виде». По этому поводу можно заметить следующее. Несомненно, что в области физики теория относительности значительно уточнила понятие причинности. Точная же формулировка принципа причинности в самом общем виде есть вопрос общефилософский и решение этог о вопроса принадлежит классикам марксизма. Дальше Бор пишет следующее: «Совершенно новое положение вещей в физической науке создалось, однако, благодаря открытию универсального кванта действия. Это открытие обнаружило первичную черту неделимости атомных процессов, идущей гораздо дальше старого учения об ограниченной делимости материи, которое было первоначально введено для причинного объяснения свойств вещества и служило основанием этому объяснению. Эта новая черта не только совершенно чужда классическим теориям механики и электромагнетизма, но даже несовместна с самой идеей причинности». Таким образом. Бор утверждает, что существование кванта действия несовместно с самой идеей причинности. Чем он это мотивирует? Продолжаем цитату. «В самом деле, если задано состояние физической системы, то этим, очевидно, ещё не определяется, какой именно из различных элементарных процессов перехода в другие состояния будет иметь место. При учёте квантовых эффектов приходится существенным образом оперировать с понятием вероятности различных возможных процессов перехода». , Сказанное здесь верно, но никак не может служить доводом в пользу несоблюдения принципа причинности. Прежде всего, причинность не сводится к однозначной детерминированности, а включает более общее понятие о закономерности. Кроме того, в квантовых явлениях необходимо различать между развитием во рремени состояния системы, находящейся в строго определённых физических условиях, и тем скачкообразным изменением состояния, которое приходится вводить при резком и не поддающемся точному контролю изменении физических условий. (Такое резкое изменение физических условий бывает необходимо для измерения той или иной физической величины).Совершенно естественно, что в квантовой механике волновое уравнение, описывающее с той или иной степенью точности состояние системы, находящейся в определённых физических условиях, перестаёт быть применимым, когда эти условия резко меняются и становятся не вполне определёнными. Когда физические условия заданы, изменение состояния происходит но определённому закону, в полном соответствии с принципом причинности. Когда же эти условия резко и неощщделённым образом меняются, никак нельзя требовать, чтобы изменение состояния было предопределено наперёд. Но и это изменение состояния отнюдь не является бессистемным, а подчиняется определённым вероятностным законам, что также соответствует принципу причинности. Состояние объекта в момент времени, непосредственно предшествующий внешнему вмешательству, определяет собой вероятность того или иного поведения объекта при этом вмешательстве. Можно даже сказать, что и само состояние характеризуется вероятностью того или иного поведения объекта при всевозможных потенциальных внешних воздействиях. К этому вопросу мы

вернёмся в дальнейшем. Далее Бор указывает на наличие корпускулярных и волновых свойств частиц и говорит, что «всякое определение постоянной Планка основано на сопоставлении двух аспектов явления, которым соответствуют картины, не совместимые в рамках классических теорий». Последнее замечание представляется нам довольно тривиальным, так как из опытов, в которых не проявляются квантовые эффекты, конечно, нельзя определить постоянной Планка. Бор, однако, после этого говорит: «При таком положении вещей мы встречаемся с необходимостью радикального пересмотра самых основ для описания и объяснения физических явлений», предпосылая эти слова изложению основных идей квантовой механики в его понимании. Переходя к изложению квантовой механики. Бор прежде всего подчёркивает, «что описание экспериментальной установки и регистрация наблюдений всегда должны быть выражены на обычном языке, пользующемся терминологией классической физики». Само по себе это утверждение бесспорно верно. Однако из него отнюдь нельзя делать таких выводов, какие делает Бор, а именно, что всё остальное, кроме описания экспериментальной установки и регистрации наблюдений, имеет лишь символический характер. К этой точке зрения Бора мы вернёмся ниже. Затем Бор говорит: «Тот факт, что квантовые явления не могут быть анализированы в духе классической физики, влечёт за собой невозможность разделить поведение атомных объектов от их взаимодействия с измерительными приборами, которые фиксируют условия, в каких происходят явления. В частности, неделимость типичных квантовых эффектов выражается в том,что всякая попытка подразделить явление требует изменения экспериментальной установки, каковое изменение вносит новые источники неконтролируемого взаимодействия между объектами и измерительными приборами». В первой фразе правильно указывается на то, что состояние атомных объектов и их «поведение», т. е. изменение состояния, зависят от внешних условий, и что поэтому существенно необходимо эти внешние условия фиксировать. Мысль, высказанная во второй фразе, также в общем правильна, хотя слова о неконтролируемом взаимодействии, строго говоря, лишены точного смысла. В самом деле, здесь речь идёт о взаимодействии в самом акте измерения. Но что значит «контролировать»? По существу, это значит «измерять». Таким образом, «неконтролируемость» означает, по нашему мнению, просто невозможность вставить добавочное измерение, не нарушая условия данного измерения. Повидимому, слова Бора о неконтролируемом взаимодействии представляют попытку пояснить на языке классической физики то положение вещей, которое возникает из соотношений Гейзенберга, применённых к взаимодействию между объектом и прибором. Что бы ни понимал под этими словами Бор, с нашей точки зрения они во всяком случае никакого более глубокого смысла не имеют и тем более не должны пониматься в смысле какого-либо утверждения о непознаваемости процесса взаимодействия и т. п. Утверждение Бора о невозможности разделить поведение атомных объектов от их взаимодействия с измерительными приборами также можно принять лишь с оговорками. Как видно из дальнейшего, Бор понимает эго утверждение не в смысле взаимосвязи между изучаемым объектом и окружающим его полем и внешними предметами, в частности измерительными приборами, а в том смысле, что атомный объект как бы растворяется в измерительном приборе и становится менее реальным, чем измерительный прибор. Кроме того. Бор не указывает, что именно он разумеет под измерительным прибором: считает ли он, что измерительный прибор включает ту часть, где объект находится в фиксированных внешних условиях и явление развивается без помех, или же он разумеет под прибором то устройство, которое вводится в действие лишь в последней стадии опыта и служит для регистрации результата измерения. Например, в явлении диффракции электронов мы имеем фиксированные внешние условия внутри кристаллической решётки, сквозь которую проходит электрон

(регулярное расположение атомов, упругий характер столкновении электронов с ними). Для наблюдения диффракционной картины мы можем поставить позади кристалла фотографическую пластинку, ряд счётчиков иль какой-нибудь иной прибор, способный измерять координату электрона. Детали его устройства безразличны; в случае фотопластинки или счётчика мы имеем дело с усилительным устройством, в котором развиваются процессы лавинного характера. Наличие же кристалла для явления диффракции существенно: если крлсгалла нет, то и диффракции не будет, а если он есть, то диффракция будет, независимо от того, как будет регистрироваться диффракционная картина и будет ли она вообще регистрироваться. Для краткости мы будем называть ту часть прибора, где происходит само явление, рабочей частью прибора, а ту часть, где оно регистрируется,— регистрирующей частью. В нашем примере рабочей частью является кристалл, а регистрирующей — фотопластинка или счётчик.

Кроме рабочей и регистрирующей частей можно говорить о приготовляющей части: это—та часть, которая фиксирует состояние объекта перед его попаданием в рабочую часть. В налам примере приготовляющей частью является источник монохроматического пучка электронов, а также диафрагмы и другие устройства, поставленные перед кристаллом. Необходимо отметить, что, поскольку явление может происходить и в естественных условиях, приготовляющая, а также рабочая часть могут осуществляться сами собою и лишь регистрирующая часть требует, вообще говоря, особого устройства. Упомянутая выше неточность Бора заключается в том, что он не проводит разграничения между различными частями измерительного прибора и оставляет открытым, разумеет ли он под измерительным прибором только его регистрирующую часть или же он включает в это понятие также и рабочую часть. Слова о «неконтролируемом взаимодействии» относятся, очевидно, к регистрирующей части, тогда как утверждение, что измерительные приборы фиксируют условия, в каких происходят явления, повидимому, может относиться только к рабочей части.:. ' В результате этой неточности (возможно умышленной") затушёвано существенно важное различие между поведением объекта в фиксированных внешних условиях и его поведением в условиях, не вполне определённых. Поведение объекта в фиксированных внешних условиях вполне определяется начальным состоянием и свойствами самого объекта и может быть весьма точнэ оплсано на язык квантовой механики. Результат же последнего эгапа измерения, связанного с взаимодействием объекта с регисгрируюдей частью измерительного прибора, должен уже оплсызагься Hi языке классической физики, причём вероятность того или иного результата вычисляется по формулам квантовой механики. Из сказанного им Бор делает следующий вызэд: «При таком положенлл вещей прлллсызлнлг атомным объектам обычных, условно прлнлгых, флзлческих атрибутов (conventional physical attributes) связано с неоднозначностью». Несколько туманная фраза об услозных флзлческих атрибутах требует расшифровки. Еслл здесь разумеется невозможность приписывать, например, электрону при всех услозиях определённую координату или определённое количество движения, то с этим можно согласиться, поскольку, согласно квантовой механике, какие бы то ни было классические модели атомных объектов имеют лишь ограниченную применимость*). Но фраза сосгазланд в такой общей форме, что под физическими атрибутами могут разуметься '*) Толкование соотношений неопределённости Гейзенберга как принципа ограниченной применимости кпссшескях мэдглея дало в нашей работе (Вестник Ленинградского университета, № 4, стр. 31, 191Э).

и такие свойства электрона, как заряд, масса, спин, свойства, связанные с видом оператора энергии и определяющие взаимодействие электрона с другими частицами и с внешними полями. Все эти свойства совершенно объективны и несомненны, и ни о какой их условности не может быть и речи. Поэтому, если Бор имел здесь в виду оспаривать

наличие у атомных объектов объективных свойств, подобных перечисленным, то в этом с ним никак согласиться нельзя. Дальше Бор вводит свой термин «дополнительность» (сперва в применении к наблюдениям, произведённым при различных экспериментальных установках) и переходит к характеристике квантовой механики. Чрезвычайно любопытна та роль, которую отводит Бор квантовой механике в описании и объяснении атомных явлений. Вместо того, чтобы прямо признать, что предметом и назначением квантовой механики является более глубокое изучение свойств атомных объектов. Бор с самого начала говорит: «Надлежащим средством для дополнительного способа описания является аппарат квантовой механики». Тем самым роль квантовой механики заранее сводится к составлению формальных рецептов для вычисления вероятностей различных результатов наблюдений, без всякого проникновения в сущность явления. Характеризуя аппарат квантовой механики. Бор всячески подчёркивает его будто бы исключительно символический характер. Бор говорит, что в этом аппарате «сохраняются канонические уравнения классической механики, но физические переменные заменяются символическими операторами, подчинёнными некоммутативной алгебре». Непонятно, почему математический аппарат квантовой механики более символичен, чем аппарат любой другой физической теории. Математика всегда оперирует с символами, но поскольку в физической теории эти символы допускают определённое физическое толкование, они перестают быть абстрактными символами, а отражают действительность. Так обстоит дело независимо от сложности применяемого математического аппарата. Уравнение Шредингера квантовой механики не более и не менее символично, чем уравнение Гамильтона— Якоби классической механики. Бор же подчёркивает, что классическая механика имеет дело с физическими переменными, тогда как квантовая механика — будто бы лишь с символическими операторами. Трудно удержаться от мысли, что такое противопоставление нужно Бору для того, чтобы оставить за собою право подвергнуть сомнению реальность существования и свойств атомных объектов, с которыми оперирует квантовая механика. Стремление устранить прямое физическое толкование аппарата квантовой механики, оставив за ним только символический смысл, доводит Бора до абсурда. Так, он говорит: «Самые же эти символы не допускают наглядной интерпретации, на что указывает уже употребление мнимых чисел».

Как будто бы мнимые числа заключают в себе что-то мистическое и употребление и исключает возможность наглядной интерпретации! Ведь с ним; постоянно оперирует и классическая физика, особенно электро техника. Свою мысль о том, что математический аппарат квантово механики будто бы не связан непосредственно со свойствами атом ных объектов (о реальности которых Бор вообще нигде не упоминает), а играет чисто вспомогательную роль для координаций результатов измерений. Бор выражает и прямо. Он пишет: «Весь аппарат следует рассматривать как средство для вывод, предсказаний, однозначного или статистического характера, относя щихся к результатам, которые могут быть получены при опре делённых экспериментальных условиях». Эта мысль, что не просто знание объективных свойств реаль ных атомных объектов, а нечто чисто символическое являете! основой для предсказаний, несомненно внушена Бору его идеали стической философской установкой. Бор не является вполне по следовательным идеалистом, поскольку он, повидимому, всё же признаёт реальность тех явлений, которые могут быть описань на языке классической физики, но его точка зрения на квантовук механику является бесспорно идеалистической. Переходя затем к рассмотрению соотношений Гейзенберга, Бор указывает на «взаимно исключающие условия, при которых можно без противоречий пользоваться локализацией в пространстве и времени, с одной стороны, и законами сохранения механики, с другой». «В самом деле, — говорит Бор,—всякая попытка локализации атомного объекта в

пространстве и времени требует такого экспериментального устройства, в котором происходит прин шпиально не поддающийся контролю обмен количеством движения и энергией между объектом и масштабами и часами, определяющими систему отсчёта. Обратно, никакое устройство, пригодное для контроля над балансом количества движения и энергии, не допускает точного описания явлений, как цепи событий, локализованных в пространстве и времени». Всё это совершенно верно при условии, что анализ поведения атомного объекта производится на основе классической механики (о чём сам Бор и говорит в следующей своей фразе). Но на самом целе лишь последний этап измерения (связанный обычно с действием какого-нибудь усилительного устройства) требует такого классического анализа. Предшествующее же поведение объекта, когда он находился ещё в фиксированных внешних условиях, может быть гораздо более точно проанализировано на основе квантовомеханических представлений. Поэтому нельзя согласиться с утверждением Бора, что «соотношения неопределённости явным образом указывают на ограниченость причинного расмотрения». Соотношения неопределённости налагают ограничения на применимость классических моделей, но принцип причинности не составляет монополии классической физики, и отказ от классических моделей не означает отказа от причинности. Переходя к перечислению положительных до стижений квантовой механики, Бор как бы забывает о том, что он на предыдущих страницах придавал её математическому аппарату лишь чисто символическое значение и связывал его не со свойствами атомных объектов, а с координадией результатов измерений. Бор пишет следующее: «Квантовая механика представляет обобщение классической механики, позволяющее учитывать существование кванта действия. Рамки её достаточно широки для того, чтобы включать в себя объяснение наблюдаемых на опыте закономерностей, не поддающихся описанию классическим способом. Укажем здесь на характерную устойчивость атомов, наличие которой дало первый толчок к развитию квантовой механики. Кроме того, можно указать на своеобразные закономерности, наблюдаемые в системах, составленных из одинаковых частиц, например фотонов или электронов. Эти закономерности играют решающую роль в равновесном излучении и в свойствах вещества. Как известно, они адекватно отображаются свойствами симметрии волновых функций, представляющих состояния сложных систем». В приведённой цитате Бор как бы переходит на материалистическую?иу зрения— на точку зрения учёного-естествоиспытателя. Он говорит об объективных свойствах атомов .(устойчивость), об объективно существующих закономерностях и об отображении их математическим аппаратом квантовой механики. С этими высказываниями можно вполне согласиться. В то же время нельзя не видеть их противоречия с тем, что Бор говорил несколькими страни ими выше. Но на этой магерчалисгической точке зрения Бор остаётся недолго. После разбора мысленного опыта, послужившего в своё время (1935 г.) предметом дискуссии между Бором и Эйнштейном, Бор возвращается к вопросу о предмете квантовой механики говорит, что в квантовомеханическом описании «мы имеем дело с математически непротиворечивой схемой, которая подходит в пределах своей области применимости) ко всякому измерительному процессу».

Таким образом, Бор здесь опять придаёт кванювой механике значение схемы, применяемой для координадии результатов измерительных процессов. Об отображении квантовой механикой объективных свойств реальных атомных объектов больше нет и речи. Особенно ярко идеалистическая философская установка Бора проявляется в рекомендуемом им толковании понятия «явление». Бор пишет: «Мы бы очень настаивали на том, чтобы. слово явление" употреблялось только в ограниченном смысле. Слово явление" должно относиться только к наблюдениям, произведённым в точно определённых условиях, включая указания о всём опыте в целом». Ввиду

важности этого определения для характеристики философской позиции Бора мы приведём соответствующую цитату, (на которую одобрительно ссылается Паули в своей редакционной статье) также и в подлиннике: «As a more appropriate way of expression, one may strongly advocate limitation of the use of the word phenomenon to refer exclusively to observations obtained under specified circumstances, including an account of the whole experiment» (Dialectica, 7/8, 1948, стр. 317). Проанализируем это определение. Во-первых, в нём отсутствует всякое указание на тот объект, который собственно и производит явление. Ссылка на объект заменена ссылкой на производимые наблюдения. Во-вторых, в нём не учтено, что собственно измерение составляет лишь последнюю стадию постановки опыта, а этой последней стадии должно предлзствоиать приготовление самого явления по возможности в чистом виде, т. е. в точно определённых условиях; последняя же стадия эти условии заведомо нарушает, о чём много раз в других местах говорит и сам Бэр, когда упоминает о «неконтролируемом взаимодействии». В последних словах определения Бора подчёркнуто, что опыт должен рассматриваться в целом, т. е. без подразделения на стадии; новидимому Бэр ставит это в связь с тем, что он говорил раньше о неделимости атомных процессов. Мзжду тем, если отказаться от подразделения опыта на стадии, то получится противоречие даже в самих словах Бора, который, с одной стороны, говорит о точно определённых условиях, а с другой стороны, неоднократно подчёркивает, что с измерением связано «неконтролируемое взаимодействие» между объектом и прибором. Ясно, что «точно определённые условия» и «неконтролируемое взаимодействие» могут относиться только к разным стадиям опыта. Необходимость подразделения опыта на невозмущённое явление и на самый акт измерения ясна сама по себе. Ведь невозмущённое явление может происходить и в естественных условиях, на которые мы даже не можгм повлиять (например, излучение атомов на какой-нибудь звезде). Таким образом, предлагаемое Бором определение не отвечает самым основным научным требованиям и является ошибочным как с точки зрения философии, так и с точки зрения физики. Философская ошибка Бора очевидна В угоду позитивистской идеалистической философии он стремится избежать даже упоминания об объекте, подлежащем изучению в данном опыте; это нужно ему для того, чтобы рассматривать этот объект только как вспомогательное логическое построение, необходимое для координации показаний приборов. Если Бор и не говорит этого прямо, то он расчищает путь к такому толкованию, и по этому пути идут затем другие, более открытые, приверженцы идеалистической философии. Но мы хотели бы здесь особенно подчеркнуть физическую ошибку Бора, которая, быть может, не столь очевидна, но не менее важна. Ведь именно путём неправильного толкования физических фактов зарубежные физики-идеалисты и пытаются обосновать свою философию. Основную физическую ошибку Бора, которая отражается не только на данном им определении «явления», но и на его понимании квантовой механики и которая проходит через всю егл статью, мы видим в следующем. Бор игнорирует, что в физическом эксперименте помимо начальной и конечной стадий (приготовления объекта и собственно акта измерения) существует ещё и средняя стадия, когда определённым образом приготовленный объект находится в фиксированных внешних условиях. Подразделение эксперимента на стадии не умозрительно, а зполне реально. Ему соответствует (в тех случаях, когда весь эксперимент проходит в лабораторных условиях) подразделение экспериментальной установки на приготовляющую, рабочую и регистрирующую части. Игнорируя среднюю стадию эксперимента, Зор как бы хочет отвлечь наше внимание от самой сущности тления, от той его части, которая может быть наиболее глубоко «учена методами квантовой механики. Ведь именно к этой средней стадии и применимо волновое уравнение квантовой механики, тогда как приготовление объекта и результат измерения должны

шисываться на языке классической физики. Состояние объекта з средней стадии описывается волновой функцией. Состояни е)то характеризуется, как мы уже говорили, вероятностью того или иного потенциального поведения объект а при каждом из возможны х внешни х в о з1ействий. Состояние даёт как бы настройку объекта, которая гвляется чем-то вполне реальным, несмотря на то, что для опре- (еления этой настройки нужно её нарушить. То обстоятельство, [то волновая функция характеризует поведение объекта не в слассическом смысле, не самого по себе, а лишь по отношению к конкретному внешнему воздействию, позволяет говорить о не абсолютном характере волновой функции в отличие от абсолютюго характера полей классической физики. Волнова я функция представляет новую (по сравнению с классической физикой) форму описани я состояни я объекта.

Игнорируя среднюю стадию эксперимента, Бор хочет свести его к приготовлению и измерению, которые описываются на языке классической физики с учётом лишь соотношения неопределённостей. Тем самым он принижает роль квантовой механики (оставляя за ней только некий символический смысл) и преувеличивает) значение соотношения неопределённостей. На самом дгле это соотношение ограничивает применимость классической механики(ничего не говорит о сущности квантовой механики. Существенная часть квантовой механики, позволяющая глубже проникнуть в изучение свойств атомных объектов, формулируется не при помощи соотношения неопределённостей, а при помощи математического аппарата, включающего в себя операторы в гильбертовом пространстве, волновые уравнения, волновые функции и т. и. Соотношение неопределённостей для координат и количества движения является следствие м аппарата квантовой механики, и лишь соотношение для энергии и времени, относящееся к акту измерения, вводится отдельно, причём и тут должно быть показано, что оно не противоречит уравнению Шредингера. Переоценка соотношения неопределённостей приводит Бора к далеко идущей переоценке его принципа дополнительности. Первоначально под дополнительностью разумелось то положение вещей, которое вытекало непосредственно из соотношения неопределённостей: дополнительность относилась к неопределённостям в координате и в количестве движения (в смысле их обратной пропорциональности) и термин «принцип дополнительности» понимался как синоним соотношений Гейзенберга*). Очень скоро, однако. Бор стал видеть в своем принципе дополнительности некий универсальный принцип, ограничивающий не только возможности описания в духе классической физики, но и возможности всякого научного описания, и применимый не только в физике, но и в биологии, психологии, социологии и во всех науках. Такая точка зрения проводится и в разбираемой статье Бора (на последних страницах). Ввиду явной необоснованности такой точки зрения мы её разбирать здесь не будем. Однако, поскольку термин «принцип дополнительности» потерял свой первоначальный смысл и стал употребляться как обозначение для несуществующих ограничений познания и для других неправильных понятий, лучше всего от него отказаться. В заключительных словах своей статьи Бор возвращается к своей мысли о том, что идея дополнительности призвана заменить *) В частности, в нашей статье в журнале «Под знаменем марксизма» № 1, за 1938 г., стр. 149, термин «принцип дополнительности» употребляется исключительно в смысле соотношений Гейзеноерга собою прежнюю идею причинности и что квантовая механика осуществляет эту замену в области физики. Нам кажется, однако, что квантовая механика доказывает как раз обратное. В ней найдены новые-форм ы выр а жен и я принцип а причинности, который наряду с другими принципами философии диалектического материализма останется надёжным руководителем в нашем стремлении к познанию природы.

27.4.4 Universe from the Point of View of Quantum Mechanics

о том, сколько времени помнит Вселенная то, что было в прошлом

есть одна точка зрения, что вселенная все помнит, и где-то да будут точно следы чего угодно из прошлого.

вторая точка зрения, что информация через некоторое время стирается, и все, прошлое абсолютно нигде не сохраняется.

что и насколько верно с точки зрения квантовой механики?

очень важный вопрос, а мне даже нечего сказать про него...

27.4.5 On the Applications of Quantum Mechanics Principles to Non-Quantum Objects

(????)

27.4.6 On the Limits of Applicability of Quantum Mechanics

(очень важный и большой вопрос, подробно отвечу на него)

27.4.7 On the Determinism of the World

(потом пообсуждаю, что там с ней. когда она есть, когда нет.)

об обратимости (?!!!)

27.4.8 On the Possibility of Predicting Future and Past (?)

(a really good question)

27.5 Some Hypothetical Projects

27.5.1 On Quantum Teleportation

(тут основное, что я про это знаю, подробнее - в статье напишу. морозов методичку писал, с нее начать можно)

А нельзя ли поставить процесс редукции волновой функции на службу?

Можно: был предложен защищенный от прослушивания квантовый канал связи.

Теория

Опишем принцип его работы на примере упрощенной схемы.

Пусть мы посылаем по нашему каналу последовательность нулей и единиц.

В случае посылки нуля создается пара фермионов со спином $1/2$ в состоянии

$$\Phi^{-}_{1,2} = \left(\frac{1}{\sqrt{2}}\right)(|\uparrow,\uparrow\rangle - |\downarrow,\downarrow\rangle)$$

а в случае посылки единицы в состоянии, описываемом выражением (5). Проекция спина фермиона 1 регистрируется и записывается отправителем сообщения A, а проекция спина фермиона 2 его получателем B.

Если кто-нибудь попытается перехватить сообщение на

пути к получателю, это приведет к редукции волновой функции второй частицы и будет замечено получателем.

Но по своим записям получатель не может ничего прочитать.

Ведь и в случае посылки нуля, и в случае посылки единицы получатель может зарегистрировать как проекцию спина $+1/2$, так и проекцию спина -1/2.

Одни измерения получателя не несут информации.

Чтобы понять послание он должен получить по обычному каналу связи (например, телефону) результаты измерений отправителя.

То есть информация передается не со сверхсветовой скоростью, а со скоростью обычного канала связи.

Сравнивая свои результаты измерений с результатами измерений отправителя, получатель может прочесть сообщение: если знаки проекций спинов для данного номера измерения (скажем, в десятом измерении) совпали, то это ноль, а если они противоположны то это единица.

И даже если сообщение по обычному каналу связи будет перехвачено, это не страшно.

Ведь у перехватившего разговор нет записей получателя.

Как видно из предшествующего раздела, для создания квантового канала связи достаточно источника ЭПР-пар частиц и двух измерительных проборов-приемников.

Но в этом случае человек, создающий запутанные пары, знает текст передаваемого сообщения, ведь он создает «нули» и «единицы» в соответствии с текстом послания. А можно ли использовать квантовый канал связи так, чтобы создатель ЭПР-пар частиц (назовем его С) был не в курсе передаваемого сообщения? Оказывается да.

Опишем идею такого процесса, предложенного в работе [9]. Пара, состоящая из двух ферми-частиц со спином, находится в состоянии, волновая функция которого может быть представлена, как суперпозиция следующих четырех состояний

$$\Phi^{\pm}_{1,2} = \left(\frac{1}{\sqrt{2}}\right)\left(\left|\uparrow_1\right\rangle\left|\uparrow_2\right\rangle \pm \left|\downarrow_1\right\rangle\left|\downarrow_2\right\rangle\right), \quad \Psi^{\pm}_{1,2} = \left(\frac{1}{\sqrt{2}}\right)\left(\left|\uparrow_1\right\rangle\left|\downarrow_2\right\rangle \pm \left|\downarrow_1\right\rangle\left|\uparrow_2\right\rangle\right)$$

Пусть С создает ЭПР-пары в состоянии .

Первая частица пары поступает к отправителю сообщения (обозначим его А) (рис. 3). Он добавляет к ней третью частицу, такую же, как и частицы пары, в состоянии

$$\psi_3 = \alpha\left|\uparrow_3\right\rangle + \beta\left|\downarrow_3\right\rangle, \quad |\alpha|^2 + |\beta|^2 = 1$$

.....

$$\begin{array}{l}\Psi_{1,2,3} = \frac{1}{2}\left\{\left(-\alpha\left|\uparrow_2\right\rangle - \beta\left|\downarrow_2\right\rangle\right)\Psi^{-}_{3,1} + \left(-\alpha\left|\uparrow_2\right\rangle + \beta\left|\downarrow_2\right\rangle\right)\Psi^{+}_{3,1}\right. \\ \left. + \left(\beta\left|\uparrow_2\right\rangle + \alpha\left|\downarrow_2\right\rangle\right)\Phi^{-}_{3,1} + \left(-\beta\left|\uparrow_2\right\rangle + \alpha\left|\downarrow_2\right\rangle\right)\Phi^{+}_{3,1}\right\}\end{array}$$

производит над прилетевшей частицей соответствующее преобразование (оно зависит от номера, но не зависит от и) и получает клон третьей частицы.

В случае фотона это достигается набором полуволновых пластин.

В случае электрона можно использовать импульс магнитного поля.

При этом С не имеет представления о полученной В информации. Явление возникновения в результате ЭПР-процесса клона частицы отправителя получило название «квантовая телепортация».

В этом процессе отсутствует телепортация материи, передается только информация. Вернемся теперь к квантовому каналу связи.

Можно выбрать третью частицу в состоянии с для передачи нуля, а в состоянии - для передачи единицы.

Измеряя проекцию спина полученного клона на выделенную ось, B получает бит информации. Экспериментально процесс квантовой телепортации осуществлялся неоднократно различными группами ученых.

В 2012 г. китайскими учеными была осуществлена телепортация фотонов в атмосфере на расстояние около 100 км [10]

Теория квантовой телепортации

(потом посмотрю, мб расширю раздел этот)
просто знаю, что начинать нужно с википедии
и тут много таких прямо интересных глав.

27.6 Quantum Theories that are Considered to be Bad or False

(когда буду на самом деле пользоваться записей, полезный очень будет раздел, пока - на всякий случай просто создан.)

27.6.1 Introduction to Matrix Mechanics

(нужно будет, тут поизучаю)

27.6.2 Other Theories

(всё остальное тупо сюда собираю и всё)

Квантовая механика в многомерных пространствах

(потом подумаю мб про это, пока что не до этого)

Реляционная квантовая механика

хз зачем, но такое есть

альтернативные квантовые теории

разумно и достаточно строго обсудим их.

Теория Гирарди — Римини — Вебера

(Пока из Википедии и не нужно было ни разу)

обзор

как типа неработающая теория, но такая есть, так что и я немного скажу про нее

Теория Гирарди — Римини — Вебера или теория ГРВ (англ. Ghirardi — Rimini — Weber theory, GRW) — одна из теорий объективного коллапса волновой функции в квантовой механике. Теория пытается решить проблему измерения и восполнить пробел в копенгагенской интерпретации, ответив на вопрос, как происходит коллапс волновой функции.

Теория ГРВ отличается от других теорий объективного коллапса тем, что коллапс волновой функции происходит спонтанно, без вмешательства внешнего измерения. Такой подход даёт возможность решить проблему измерения, в частности ответить на вопрос, где и когда квантовая система, находившаяся изначально в состоянии

суперпозиции, переходит к однозначным результатам, наблюдаемым на макроскопическом уровне с помощью измерительного прибора.

Теория ГРВ была предложена в 1985 году итальянскими физиками Джанкарло Гирарди, Альберто Римини и Туллио Вебером[1][2].

формулировка

пока не актуально, но потом мб займусь.

мелкие странные интерпретации

у МГ иванова спишу их.
потом.

Новые теории мироздания

(потом подумаю мб про это, пока что не до этого)

Сознание человека с точки зрения квантовой механики

(мб когда-то почитаю про это, но это скорее всего бесполезное занятие)

27.6.3 Erroneous Understandings of Quantum Mechanics

(тут то, как не нужно учить квантмеху!!! соберу, почему это так, укажу, как нужно. а то много путаниц тут тоже! со временем.)

27.6.4 On Quantum Cosmology (??)

(?? нужно писать вообще её сюда или нет?)

27.6.5 On Multiverses

27.6.6 On Hidden Variables Theory

(???)

Проверка неравенств Белла

Part VIII
Appendix

A Introduction and Overview of Quantum Mechanics

A.1 More Motivation for Quantum Mechanics

A.1.1 Other General Motivation

Квантовая механика - один из фундаментальных разделов физики

Квантовая физика - важнейший предмет физики, потому что почти каждый раздел в нее упирается, использует ее.

Формирование картины мира

Квантовая механика как прекрасно формирует картину мира, так и прекрасно разрушает различные заблуждения о том, что есть квантовый мир.

Такое видение в долгосроке может очень сильно повлиять на различные действия.

Можно строить квантовые компьютеры

это востребовано в мире

Это крутая вещь.

только этим отдельно нужно заняться, если отдельно не засиживаться в этом направлении, то толку от таких возможностей нет.

но у меня есть глава про них, ибо она очень и нужна.

(укажу, как начать в них разбираться и как выйти на исследования. ссылки на статьи или организации, которые этим занимаются)

Можно заняться квантовой оптикой

это востребовано в мире

(укажу, как начать в них разбираться и как выйти на исследования. ссылки на статьи или организации, которые этим занимаются)

Можно понять, как на самом деле атом устроен

(разве что полно принципиальных сложностей, но по идее в это тоже можно пойти)

Можно попробовать исследовать наше сознание

потому что где-то в мозгу если душа и есть, то она точно будет находиться в месте, описываемом квантовой механикой.

(пока не до этого)

Удивительные факты квантовой механики

(тут многие есть опыты, которые я почти готов описать, но о них сперва в самой записи напишу)

Удивительные совпадения

The most exact value for the ratio of proton to electron mass is $1836.12 \approx 0.05$. It may be of interest to note that this number coincides with $6\pi^5 \approx 1836.12$.

(энергия связи электрона и время жизни вселенной (??? напишу потом))

Квантовая механика контринтуитивна (????)

(раскрою тут эту мысль, почему так. пока не могу, потому что не засиживался в научпоп, потом когда-то подумаю про это)

Результаты квантовой механики

(самые принципиально необъяснимые и важные тут напишу, всякие второстепенные эффекты не буду указывать тут.)

Объяснены спектры атомов

(тут формула, почему они на самом деле есть)

Польза для развития

Обсудим пользу для общего саморазвития и для развития как физика.

(выделю потом главное, пока я хз, про что стоит писать, а про что нет. что там с мировоззренческим развитием??? его что-то мало кто получает.)

Квантовая механика может хорошо тренировать прикладную и фундаментальную математику

Это тоже очень важно, потому что часто очень нужны некоторые математические функции, методы комплексного анализа и дифференциальных уравнений, так что потренироваться в них и объединить в одну теорию очень круто с помощью квантовой механике.

Потом смотришь - в самых разных разделах и используются эти методы, что тоже круто.

Прикладная:
- методы точных решений диффуров
- методы приближенных решений диффуров
- численные методы

фундаментальная:
- Можно собрать функан параллельно, если заниматься строгой квантовой механикой

О том, как меняются взгляды на мир, когда занимаешься квантовой механикой

(укажу их, акцентируя мотивацию к квантмеху)

A.1.2 Motivation for Sections of Quantum Mechanics

Польза квантовой механики для общества

(тут подумать нужно, но такой вопрос тоже часто может возникнуть у тех, кто не в науке)

Изучив квантовую механику, будет что ответить эзотерикам

Потому что полно людей, которые верят в мистику и магию, при этом иногда приплетают физику, причем чаще всего квантовую.

Мотивация к феноменологической квантовой физике

основы квантовой механики принципиально объясняют суть природы и физики

связь с классической механикой, наблюдения...

Можно четко понимать, почему иные описания неверные

Если свой способ описания есть, то другим теориям уже верить не будешь. Что сути прочищает разум. Наверное..

Мотивация к типичным частям квантовой механики (?)

мотивация изучать модели рассеяния

вроде много где они нужны, но это не точно.

Мотивация к строгой квантовой механике

Возможность понять что-то хотя бы в какой-то степени нормально

Полностью квантовую механику мало кто может понять, разве что, возможно, специалисты. Тем же, кто решил за 3 месяца понять ее, занимаясь только этим вопросом и оставив занятия по изучению ее методов и приложений, тому только и остается, что открыть книгу с математической стороной. Темы с физической стороной и следствиями сути квантовой механики не научат. Конечно, математическая книга тоже может мало помочь понять, но точно - это то, с чего следует начинать, чтобы заложить хороший фундамент.

Исчезновение путаницы в общей картине квантовой физике

Если делать нестрого - то непонятно вообще, что и почему там есть. Строгий подход поможет всё собрать в связанную картину.
(так говорят, вроде такое может и быть.)

Развитие способности четко определять понятия, с которыми мы работаем

без строгого подхода тут не уехать.

Может быть, какие-то задачи можно решить, которые с нестрогим подходом не будут решаться (??)

(пока с этим хз)

Мотивация к квантовой теории информации

Наиболее известно приложение квантовой механики - это квантовые компьютеры. Обсудим, зачем этим заниматься, потому что скорее всего занятие квантовыми компьютерами будет самое полезное и дающее больше всего результатов.

Квантовые компьютеры востребованы в мире

то се, все говорят про это.

Изучая квантовую теорию информации, можно некоторые важные темы понять очень строго

То есть по сути нормально разобраться в предмете, что очень сложно сделать, без строгого подхода.

(конечно, речь о том, что преподаватель тоже хороший. но это большая мотивация потратить пару недель на это направление)

Многие лучшие ученые мира занимались квантовыми компьютерами

Фон Нейман, Фейнман, Тьюринг, т.п.
Так что тоже хочется этот путь пройти.

Мотивация к другим разделам квантовой механики

мотивация изучать ядерную физику

???? вроде это и круто, вот только мы простейшие модели будем понимать, а то, что в реальности происходит - другой вопрос.

так что толку от простейших моделей?

плюс они кстати сложные и требуют отдельного времения.

Глубокое понимание, что такое ядро и что внутри

и так можно лучше понимать природу. Только вот займет это уж очень много времени.

Можно понимать как работают ядерные реакторы

Разве что все равно пользы не много от этого будет, потому что к реакторам не допустят, если ты не специализируешься на ядерной физике.

A.2 How Professionals in Quantum Mechanics Think?

Обсудим подробно мышление профессионалов в квантовой механике.

A.2.1 Useless and Useful Parts of Quantum Mechanics

(discuss, which are which)

A.2.2 Approaches for Description of Quantum Phenomena

Отношение к квантовой механике

Квантовая механика как в первую очередь пара уравнений и их решений, во вторую уже - понятия и построения ее

(именно этот подход для теормина оказывается самый годный. мб он вообще почти всегда годный. потом подумаю про это. стоит ли вообще думать про нюансы ее построения и определений, если это вообще не нужно? пока думаю, что просто нужно заботать модели, потом уже задаваться идейными вопросами.)

квантовая механика как аппарат, который можно применять к другим разделам физики

То есть квантовая механика именно способ, причем совершенный.
(интересный взгляд, созрею - обсужу, насколько он верен. Слепо верить, что это так не считаю нужным.)

доказательство совершенности квантовой механики в двух словах

часто так говорят, Вайнберг доказал, я мб тоже это когда-то посмотрю.
пока так, чисто заготовка.

О том, что в квантовой механике нет ничего контринтуитивного

(часто говорят, что есть, тут обосную, почему это не так.)

Квантовая механика как загадки и разгадки

именно так к этому и нужно относиться.
а то можно утонуть в формализме.

Are big books of QM meaningful?

(currently, I think that often - no. discussion of models and methods is made just to avoid attention from the fact that we don't know how nature works. i am not sure. I'll write later, is a big discussion of methods and models are worth at all our attention? maybe yes, for applications...)

Как понимать классическую механику, чтобы догадаться до квантовой механики? (!?!??!??)

(очень важный вопрос для профессионализма, продумаю потом!!)

What is finally going on with the idea "I want to understand life around me better, so I'll start with fundamental microscopic quantum mechanics"?

Same idea is "to speak better with people, I'll learn quantum communication and will be the top world speaker".

So, currently, I think that this is just a dead end. One would not understand anything in the world better.

The moral of the story that 21st century physics still have no answers about the real life, only about some specific setups (however, there are a lot of them and it is still a big progress of humanity).

(???? or there is something, which QM really teaches us??? I'll think later)

Типичные неверные понимания квантовой механики

представление, что соотношение неопределенностей имеет отношение к происхождению волновой функции

Вспомним вывод волновой функции....

Некоторые утверждают, что мы не можем точно измерять параметры частицы, поэтому возникают волновые функции.

К сожалению, такие взгляды обречены на неудачу, в самом деле

...

Поэтому

"частица и волна одновременно"

ух, типичное дело.

"волна материи"

соотношение де бройля такое не простое, что его можно по-разному трактовать.

Думать, что каноническое квантование и вторичное это разное

(Вообще не актуально, но Володя говорил, в П Ш написано, мб посмотрю.)

О строгой квантовой механике

О необходимости математической подготовки по многим фронтам

без нее нормально не поймешь.

но стоит ли она того? пока думаю, что нет, ибо заморочек много, а обойтись без нее тоже вроде еще как можно.

Но это большая проблема, потому что нормальная подготовка к строгой квантовой механике - отдельное занятие на месяц как минимум.

(мб когда-то займусь этим, вряд ли скоро)

О том, что в ней нет физики

Пока в точности так и думаю. а где она там? какие-то свойства операторов.

Может, стану лучше разбираться - что-нибудь скажу про это другое.

Так всё-таки, можно ли понять квантмех? (???????)

Распишу ответ про это. Все это упирается в разделы что такое волновая функция или что такое матрица плотности? . Один из первых пар в мышлении профи.

Чтобы выучить квантовую механику нужно мыслить по-квантовому. Что это значит?

(конечно, это больше шутка, но в качестве шутки тоже можно придумать интересные соображения. подумаю потом когда-то.)

О строгом математическом подходе

О том, когда он нужен, а когда нет

(тут порассуждаю об этом, большой вопрос.)

О том, почему в жизни никто строгим подходом не пользуется

Нпр психология, размышления о жизни - у людей нестрогий подход и они даже не думают как-то его делать более строгим. Порассуждаю, почему в квантовой физике мы внезапно так меняем подход.

О важности математики для квантовой механики

(тут рассуждения про то, насколько вообще её нужно знать? и что нужно из неё знать. тоже много порассуждать можно. Думаю, малого раздела должно хватить, если не хватит - расширю!)

О применениях квантовой механики (??)

Укажем, какие самые полезные темы в квантовой механике, как они приеменяются в других разделах физики и других науках.
(пока фоном ищу ответы. потом очень четко укажу все применениях, которые знаю!!)

обзор того, что квантовая механика дает теории электричества

где она там нужна?
что с ней делать можем новое?

квантовая механика в космологии

мб как раз про связь с линзированием и напишу тут?

Обзор применения в финансах

хз, там континуальный интеграл используется.

обзор применений интеграла по траекториям

О важности раздела про матрицу плотности и открыте системы

(мб это и очень важный раздел, но порассуждать про это нужно.)

обзор применений квантовой физики в астрономии

Что есть знать квантовую механику? (?)

(напишу потом ответ на этот вопрос, пока не уверен. думаю, обычные 2 семестра квантмеха + 1 семестр общефиза. Если пройти без скатывания, то этого и можно считать, что основы изучены. Если катка была, то не нужно переделывать.)

О выборе тем в квантовой механике

(сперва выбрать нужно, на чем сосредоточимся?)

О важности изучения задач рассеяния

(ну окей, вот ямы, так рассеивается, зачем вообще на это тратить время? тут ответ, пока занимаюсь этим, ибо тренировка хорошая)

Необходимые предметы для квантовой механики

Хорошие основы классической механики

Она очень важна.
(потом раскрою)

Хорошие минимальные основы математики

(потом раскрою, что общие основы тут используются, а также потом в строгий квантмех переход может быть, если они будут нормальными.)

Дополнительные предметы для квантовой механики

Функциональный анализ

ибо там большая тусовка, которая на этом языке всё и описывает.

Wolfram/ Другой язык программирования

Потому что многое хочется вычислять и моделировать, так что очень уж он будет кстати.

Типичные заблуждения про изучение квантовой механики

Обсудим то, что не следует делать при изучении квантовой механики, ведь иначе можно уйти в тупик, из которого выход будет месяцами длиться.

(самую суть именно про квантмех укажу. с опытом очень важных выводов будет много, пока особо исследованиями не занимался.)

Не следует во время изучения квантовой механики общаться с мало знающими в ней о ней

Если общаться о ней с теми, кто не владеет ей без сформированной своей картины происходящего, то очень легко подцепить тупиковое мышление, с которым изучение и закончится. Поэтому если человек не признанный авторитет в квантовой механике, то

не следует свободное время с ним проводить за общением о ней. Только после сформированной своей картины мира такое общение не будет вредить.

А именно, не следует общаться со студентами, с прочитавшими популярные книги, а особенно - с уверенными в эзотерических концепциях. Особенно не следует общаться с теми, кто понял пару конструкций квантовой механики, научился их рассказывать, при этом отрицает многое также присутствующее в этом предмете. Такие могут на месяцы увести развитие не в ту сторону, так что их очень важно стороной обойти.

(в пример Володю приведу мб чтобы четко указать, что общение с ним замедлит развитие на пару месяцев на пустом месте, и хотя что-то и даст, это будет совсем не то, что на самом деле нужно. пока плохо раскрыл, почему так не следует делать.)

Не следует общаться с экспериментаторами, не овладев теоретической базой

Так следует делать тому, кто хочет стать мастером в квантовой механике. Предмет слишком большой, чтобы одновременно и теоретическую и экспериментальную части изучать. Сперва пройти минимальную теоретическую нужно, потом уже эксперименты изучать.

(проверю с опытом такую точку зрения.)

Не следует начинать математический подход изучать без теоретической и экспериментальной базы

Потому что зависнешь в математике раньше времени. Физику куда проще изучить, чем пройти все математические концепции. Да и потребность в них возникает только тогда, когда сам по себе предмет изучен и есть навыки хотя бы простейшие эксперименты описывать.

Многие считают иначе, моё мнение по поводу них: они лгут.

A.2.3 On Studying Quantum Mechanics

Об общефизическом подходе к изучению квантовой механики

Про него многие говорят, причем в негативном ключе, поэтому приведем свои небольшие соображения.

Общефизический подход хорош для кругозора

Это только про него думаю.
с опытом уточню.

Общефизическая квантовая физика имеет особенности, но берется обычным образом

общая квантовая физика большая, много деталей имеет и пока не будет четкой теории квантовой механики, будет казаться, что мало связок в них, тем не менее, работаем как обычно.

Всё по тем же давно понятным методам, спокойно всё изучается. Кто не может - тот просто не умеет учиться, ну или обстоятельства появились, что редко бывает.

Сложностей с ним нет, однако есть многие другие вопросы.

О проблеме общефизического подхода в преподавании

Просто Овчинкин, как и многие другие, объясняет супер кончено и так, что проще самому решить. Вот и очень большой фактор, почему общефизом мало кто занимается, потому что подача просто конченная, это очень раздражает. Не следует забывать этот фактор, он среди решающих.

Насколько те или иные темы важно изучать?

(порассуждаю, насколько нужно вообще мастерить 1Д рассеяние через точнорешаемые потенциалы и все такое. ПТФ вставляет в курс свой, но это очень спорно. Потом подумаю, пропишу, стоит ли это того? Думаю, что точно тому, кто не владеет общими соображениями про основы, а также не имеет отлично выученный какой-то сложный предмет, чтобы в принципе уверенным быть в своих силах изучать большие темы - нет, не стоит того фокусироваться на эти темы.)

A.2.4 Ways to Earn Money by Knowing Quantum Mechanics (!!)

(!! накидаю вскоре!)

Устроиться в компанию, занимающейся квантовыми вычислениями

(и в этом случае открывается просто новая большая сфера квантовой информатики, так что нужно быть готовым а неё погружаться. Для меня это такой себе вариант, потому что это не самый приятный раздел квантовой механики, скорее задротский и математический)

Плюсы:

Минусы:

- это вмеру скучно. Есть разделы интереснее

Делать популярные видео о квантовых явлениях

A.2.5 People, Who Are Engaged in Quantum Mechanics

(write who are they, what are known about them? not all people are doing QM and are capable for it. psychological features)

Вопросы на проверку тем, кто говорит, что знает квантовую механику (?!)

(потом соберу интересные, пока не очень понимаю их.)

Расскажите о теореме Вигнера-Эккарта

(пока прикол в том, что там все супер детальное, так что очень многое видно, если человек про нее будет рассказывать.)

A.2.6 Use of Quantum Mechanics in Everyday Life

Укажем, как квантовая механика используется в обычной жизни

A.2.7 Ways to Guess the Main Ideas of Quantum Mechanics

незаменимая часть нормального понимания предмета.

В чем были основные ошибки и непонимания ученых в прошлом, когда не было КТП и до этих методов не могли догадаться? (!?!??!??!?)

(для профессионального уровня очень важно ответить на этот вопрос подробно!!)

Способы догадаться до основных концепций и идей квантовой механики (???)

(для профессионального уровня очень важно ответить на этот вопрос подробно!!)

Способы догадаться до основных уравнений (???)

хз

способы догадаться до экспериментальных методов проверки квантовой механики

я хз и как проверять и как догадываться до нее.

A.2.8 Influence of Quantum Mechanics on Worldview

(пока я слишком плохо её понимаю, чтобы говорить об этом, потом подумаю. Много про это также написано, в том числе в научпопе.)

Обсудим вкратце, что говорит нам квантовая механика про то, из чего состоит мир.

Подробнее это описано в разделе про философию в конце записи, а еще более подробно - в отдельной записи про философию.

A.2.9 Overview of Special Applications of Quantum Mechanics (???)

(just general overview what to do and why?)

Квантовая механика для промышленности

(укажу, где она нужна, что с ней можно сделать? пока не знаю, и это проблемка)

A.2.10 On Dead Ends in the Creation and Understanding of Quantum

Квантовая механика интересна тем, что многие, кто ее изучают, могут нести лютый бред в плане различных интерпретаций. Еще больший бред можно услышать от тех, кто о ней что-то слышал. Соберем разные такие утверждения не чтобы поржать, а чтобы лучше понимать, какова на самом деле суть квантовой механики.

A.3 Acknowledgements

Currently, no one except me has worked on the sections of this note (with the exception of sections taken from books).

A.4 Literature

Обсудим литературу по квантовой механике, из которой создана эта запись.

(потом структуру улучшу, пока почти рандомно все книги записаны после самых основных)

A.4.1 Main Literature

Basic educational literature

David Tong: Lectures on Topics in Quantum Mechanics

Лекции, в которых много основ изложены, отлично для начала. Кстати, кто совсем не знает квантовую механику, может начать с "первой части" курса Tong-a "Lectures on Quantum Mechanics", просто спустя время эта запись кажется очень известной и поврехностной. А вот лекции по отдельным темам - там есть, что почитать, о чем подумать, и к чему вернуться чуть что.

Masatsugu Sei Suzuki Lecture Notes on Quantum Mechanics II https://bingweb.binghamton.edu/~suzuki/QuantumMechanics2.html

Набор очень хороших и подробных лекций про разные модели. Много тем разобрано, написаны без желания сэкономить место. Очень приятно читать и очень много полезной информации.

[1] Побойко И., Антоненко Д., Степанов Н. Семинары по квантовой механике в институте Ландау

Короткий конспект пары хороших методов, про которые очень много времени ушло бы самому вычитывать в книгах. Однако, некоторые разделы написаны абсолютно нечитаемо, видимо, один из авторов абсолютно не умел писать своё понимание темы.

Мигдал Крайнов Качественные методы в квантовой теории

Очень крутая книга на 150 страниц, которая очень многому учит, так что обязательная для понимания происходящего.

[2] Griffiths, D. J., Schroeter, D. F. Introduction to Quantum Mechanics

Wonderful and famous book that covers all basic topics. Also, see solutions to it https://stemjock.com/griffithsqm3e.htm TODO: add very good problems from it (after I finish doing problems which I already started).

[2] Griffiths, D. J. Solutions to Introduction to Quantum Mechanics 3e https://stemjock.com/griffithsqm3e.htm

Wonderful solutions, they will help a lot in understanding. Unfortunately, not all solutions are given in 2024.

[3] Киселев Квантовая механика часть 1

Книга, по которой я учился. Очень много хороших тем, однако не везде изложение понятное и не все темы в ней важные для понимания.

[4] Киселев квантовая механика часть 2

Книга, по которой я учился. Очень много хороших тем, однако не везде изложение понятное и не все темы в ней важные для понимания. Некоторые темы вообще такие, про которые лучше не думать, потому что время впустую потратите.

[5] K. Zhou Lecture Notes on Undergraduate Physics

Great short notes about some parts of physics and with many sections about quantum mechanics.

[6] Кингсеп, А.С и др. Общая физика: квантовая физика и термодинамика

Обсуждается много вводных и простых тем в квантовой механике, можно во многом разобраться и почитать в меру подробные описания. Типичный вузовский российский учебник.

Карлов Н. В., Кириченко Н. А. Начальные главы квантовой механики. - М.: ФИЗМАТЛИТ, 2004. - 360 с. - ISBN 5-9221-0538-8.

Многие темы просто объяснены, типичная книга по общей физике, можно многому научиться.

Основные задачники

[7] (GKKG) Galitski, V.M. and Karnakov, B. and Galitski, V. and Kogan, V.I. Exploring Quantum Mechanics: A Collection of 700+ Solved Problems for Students, Lecturers, and Researchers

Основной задачник. Изучать из него задачи его следует 2/3 всего времени в первом цикле изучения квантовой механики. Конечно, она слишком большая, чтобы ставить целью изучить полностью, но многие задчи разобрать - крайне полезно и в других местах вообще не написаны они.

(ГК) Гольдман Кривченков Сборник задач по квантовой механике

Очень крутые задачи, решение многих приведено, книга номер 1 по изучению квантмеха. Однако некоторые задачи очень непонятны, так что иногда хочется просто открыть другую книгу.

[8] (Б) Белоусов задачник по теоретической физике

Неплохие элементарные задачи, но их очень мало.

Основная профессиональная литература

[9] Тахтаджян Л. А. Квантовая механика для математиков

Прекрасная книга для понимания математической квантовой механики. Хотелось бы разве что больше примеров и больше связей с не математической квантовой механикой, но уже с ней очень многое можно понять.

[10] Зинн-Жюстен, Жан Континуальный интеграл в квантовой механике

самая прекрасная книга, по которой и буду создавать изначально запись. книга настолько прекрасна, что ничего другого перед ней читать не хочу! и уже многее выгрузки по ней сделаны!

[11] Michael A. Nielsen, Isaac L. Chang Quantum Computation and Quantum Information

Большая, очень известная книга про квантовую теорию информации.

[12] А. И. Базь, Я. Б. Зельдович, А. М. Переломов Рассеяние, реакции и распады в нерелятивистской квантовой механике

Хорошая полезная книга, 500 страниц только теория рассеяния, нужно будет - скорее всего основной книгой и будет.

A.4.2 Additional Literature on Basic Topics

Literature with detailed explanations

Wheeler's notes https://www.reed.edu/physics/faculty/wheeler/documents/
Notes by a pure genius, well-written and very informative. I would even pay 200 euros to have them, but I am not sure that they are really used for the research, just for general education. Later, I'll add all of this to my notes.

Suzuki's notes https://bingweb.binghamton.edu/~suzuki/index.html
Also, a lot of notes by a pure genius, well-written and very informative. I would also even pay 200 euros to have them, but I am not sure that they are really used for the research, just for general education. Later, I'll add all of this to my notes.

Литература о профессиональных методах

Зайцев Р.О., Михайлова Ю.В. Метод вторичного квантования для систем многих частиц
Подробная методичка про вторичное квантование, давно в планах продумать её.

[13] Ландау Квантовая механика
Хорошая книга, много полезного, но гораздо легче утонуть в объеме, чем получить пользу, так что ее читать лучше только после основных. В целом, ничего супер важного там нет, чего в других не рассказано, тем не менее, раз в своей жизни неделю глубоко думать о ней, будучи готовым к ней, очень полезно.

По математике и начальной физике в помощь

Нейман Математические основы квантовой механики [1964]
Хз.
Вейль
вроде вымерло, но тоже интересно почитать, теорию групп прокачать бы сперва!

Статьи, раскрывающие углубленный подход к квантовой механике

[14] Alireza Behtash, Gerald V. Dunne, Thomas Schafer, Tin Sulejmanpasic, Mithat Unsala, Toward Picard-Lefschetz Theory of Path Integrals, Complex Saddles and Resurgence
Крутая статья на 100 страниц со многими деталями. как теоретический подход профессиональный дается, так и много иллюстраций. Так что основы квантовой механики будут созданы со многими из нее идеями, по сути это известные идеи, подача просто мне нравится. вроде должно получиться.

[15] Kleinert, Hagen Path integrals in quantum mechanics, statistics, polymer physics, and financial markets
1600 страниц наверное шикарного текста, который наверное возьму в основу этой записи.

[16] Дирак П. Лекции по квантовой механике
искривленные пространства там тоже есть, так что интересная книга. 100 страниц - круто, почитаю потом.

[17] Tomonaga, S., The Story of Spin

Очень много есть информации про спины, про их открытия, про историю. Если очень интересует этот вопрос, то, возможно, одна из лучших книг для ответа на него. Узнал о ней из лекций L. Paolasini по магнетизму.

Профессиональная литература по атомной и ядерной физике

[18] Соловьев В. Г. Теория ядра. Модели ядер

говорят, крутейшая книга по ядерке. после общефиза могу попробовать, пока что скорее всего не скоро дойду до этого, ибо не актуально.

[19] Бор О., Моттельсон Б. Структура атомного ядра т. 1

Говорят, крутая очень книга по ядерке, пока что не до нее, но, возможно, очень много буду ее смотреть, потому что интересно.

[19] Бор О., Моттельсон Б. Структура атомного ядра т. 2

тут, наверное, жесткая ядерка, мне даже представить сложно, что там. по сравнению с этой книгой, такое чувство, что я знаю ядерку на нуле.

Бете Г. Элементарная теория атомного ядра

Может, потом почитаю, похоже на заморочку на минимум в пару недель, пока нет в этом потребности.

Мигдал А. Б. Теория конечных ферми-систем и свойства атомных ядер. - 2-е. изд.

мб добавлю

Ситенко А. Г. Теория ядерных реакций.

говорят, жесткая книга. так или иначе, не до нее.

Notes and references about classical mechanics by Takhtajayan

Classical references are the textbooks [Arn89] and [LL76], which are written, respectively, from mathematics and physics perspectives. The elegance of [LL76] is supplemented by the attention to detail in [Gol80], another physics classic. A brief overview of Hamiltonian formalism necessary for quantum mechanics can be found in [FY80]. The treatise [AM78] and the encyclopaedia surveys [AG90], [AKN97] provide a comprehensive exposition of classical mechanics, including the history of the subject, and the references to classical works and recent contributions. The textbook [Ste83], monographs [DFN84], [DFN85], and lecture notes [Bry95] contain all the necessary material from differential geometry and the theory of Lie groups, as well as references to other sources. In addition, the lectures [God69] also provide an introduction to differential geometry and classical mechanics. In particular, [God69] and [Bry95] discuss the role the second tangent bundle plays in Lagrangian mechanics (see also the monograph [YI73] and [Cra83]). For a brief review of integration theory, including the Riesz-Markov theorem, see [RS80]; for the proof of the Gelfand-Naimark theorem and more details on $\mathbb{C}^*$-algebras, see [Str05] and references therein.

Our exposition follows the traditional outline in [LL76] and [Arn89], which starts with the Lagrangian formalism and introduces Hamiltonian formalism through
the Legendre transform. As in [Arn89], we made special emphasis on precise mathematical formulations. Having graduate students and research mathematicians as a main audience, we have the advantage to use freely the calculus of differential forms and vector fields on smooth manifolds. This differs from the presentation in [Arn89], which is oriented at undergraduate students and needs to introduce this material in the main text. Since the goal of this chapter was to present only those basics of classical mechanics which are fundamental for the formulation

of quantum mechanics, we have omitted many important topics, including mechanicalgeometrical optics analogy, theory of oscillations, rotation of a rigid body, perturbation theory, etc. The interested reader can find this material in [LL76] and [Arn89] and in the above-mentioned monographs. Completely integrable Hamiltonian systems were also only briefly mentioned at the end of Section 2.6. We refer the reader to [AKN97] and references therein for a comprehensive exposition, and to the monograph [FT07] for the so-called Lax pair method in the theory of integrable systems, especially for the case of infinitely many degrees of freedom.

In Section 2.7, following [FY80], [DFN84], [DFN85], we discussed Poisson manifolds and Poisson algebras. These notions, usually not emphasized in standard exposition of classical mechanics, are fundamental for understanding the meaning of quantization - a passage from classical mechanics to quantum mechanics. We also have included in Sections 1.6 and 2.7 the treatment of the Laplace-Runge-Lenz vector, whose components are extra integrals of motions for the Kepler problem [24]. Though briefly mentioned in [LL76], the Laplace-Runge-Lenz vector does not actually appear in many textbooks, with the exception of [Gol80] and [DFN84]. In Section 2.7, following [FY80], we also included Theorem 2.19, which clarifies the meaning of the Jacobi identity, and presented Hamilton's and Liouville's descriptions of the dynamics.

Most of the problems in this chapter are fairly standard and are taken from various sources, mainly from [Arn89], [LL76], [Bry95], [DFN84], and [DFN85]. Other problems indicate interesting relations with representation theory and symplectic geometry. Thus Problems 2.12 and 2.20 introduce the reader to the orbit method [Kir04], and Problem 2.18 - to the method of symplectic reduction (see [Arn89], [Bry95] and references therein). Problems 2.21-2.23 introduce the reader to the theory of Lie-Poisson groups (see [Dri86], [Dri87], [STS85], and [Tak90] for an elementary exposition).

Notes and references from Takhtajayan's section about basics of quantum mechanics

Dirac's classical monograph [Dir47] is the fundamental text. Other classical references are physics textbooks [Foc78] and [LL58]. The monograph [Sak94] is a popular text for graduate courses in physics departments. Another useful physics reference is the encyclopedic treatise [Mes99], which discusses at length the origin of quantum theory and the development of its mathematical formalism. An elementary textbook [PW35] provides an introduction to the old quantum theory, including Bohr-Wilson-Sommerfeld quantization rules, and applications of quantum mechanics to chemistry. We refer the interested reader to these sources for physical formulation and the origin of quantum mechanics, including a discussion of basic experimental facts: the double-slit experiment and particle-wave duality. Quantum mechanics does not account for single measurement outcomes in a deterministic way, and the quantum process of measurement admits different interpretations. The accepted one is the so-called Copenhagen interpretation, in which a measurement causes an instantaneous "collapse" of the wave function describing the quantum system.

Monographs [Rud87, BS87, AG93], as well as [RS80, RS75], contain all the necessary material from the theory of operators in Hilbert spaces; the latter treatise also covers the theory of distributions, Fourier transform, and self-adjointness. The book [Kir76] introduces the reader to various methods in the representation theory, and the monograph [BR86], written for theoretical physicists, contains all the necessary information on the representation theory of Lie groups and Lie algebras. A succinct introduction to the method of stationary phase and other asymptotic methods is given in the classical text [Erd56] and in [Olv97]; see also Appendix B in [BW97]. Properties of Hermite-Tchebyscheff polynomials [29] can be found in the classical mono-

[024] We will see in Chapter 3 that these extra integrals are responsible for the hidden SO(4) symmetry of the hydrogen atom.

graph [**Sze75**], as well as in many other reference books on special functions and orthogonal polynomials.

Our exposition in Section 1.1 follows a traditional approach to the mathematical foundation of quantum mechanics based on Dirac-von Neumann axioms. These axioms go back to von Neumann's classical monograph [vN96], with more detailed discussion in [Mac04]; see also [BS91], notes to Chapter VIII of [RS80], and references therein. Another mathematical description of quantum mechanics is based

on $\mathbb{C}^*$-algebras and the Gelfand-Naimark-Segal reconstruction theorem, and can be found in [**Str05**] and references therein.

Our exposition in Section 2 follows the outline in [FY80]; see [Ber74] for the general mathematical formulation of the quantization problem and the recent survey [AE05]. Having in mind a more advanced audience than for [FY80], in Sections 2.1 and 2.2 we included a complete mathematical treatment of Heisenberg commutation relations and coordinate and momentum representations. In Sections 2.2 and 2.3 we use the same normalization of the eigenfunctions of continuous spectrum as in [Foc78]; it corresponds to the orthogonality relation in Section 2.2 of Chapter 3. In our exposition in Section 2.6, which is otherwise standard, we include a proof of the completeness of the eigenfunctions $\psi_n(q)$, which is usually only mentioned in the physics textbooks. Holomorphic representation in quantum mechanics was introduced by V.A. Fock in 1932 [Foc32], where the scalar product in $\mathscr{D}_n$ was given in terms of the orthonormal basis of monomials $f_m(\boldsymbol{z})$. In terms of the integral (2.52) this scalar product was defined by V. Bargmann [Bar61]; holomorphic representation is also called Fock-Bargmann representation. Discussion of Wick symbols of operators in Section 2.7 essentially follows [BS91]; more details can be found in the original paper [Ber71b]. The method of geometric quantization is only briefly mentioned in remarks in Sections 2.2 and 2.7 ; the interested reader is referred to monographs [GS77, Woo92], lecture notes [SW76, BW97] and the survey [Kir90].

Our proof of the celebrated Stone-von Neumann theorem in Section 3.1 essentially follows the original paper of von Neumann [vN31]. The main instrument of the proof - the Weyl transform - was introduced by Weyl in the classical monograph [Wey50] (see [Ros04] for the history and generalizations of the Stonevon Neumann theorem). Invariant formulation of the Stone-von Neumann theorem, discussed in Section 3.2, as well as the relation with the triple Maslov index, methaplectic group, Shale-Weil representation, and applications to number theory, can be found in [LV80]. We refer to [BS91] for the extended discussion of $\boldsymbol{pq}$ and $q\boldsymbol{p}$-quantizations as their relations with the Weyl quantization, as well as for more details on the $\star$-product, introduced in Section 3.4. The beautiful formula (3.24) for the $\star$-product - composition of the Weyl symbols - belongs to Berezin [Ber71a].

The notion of the deformation quantization was introduced in [**BFF$^+$78a**, **BFF$^+$78b**], where the solution of Problem 3.12 can be found. The fundamental theorem that every Poisson manifold admits a deformation quantization was proved by Kontsevich in [Kon03]. More on Hochschild cohomology and the deformation theory of associative algebras can be found in the survey [Vor05] and references therein. The deformation theory point of view on the evolution of physical theories, like a passage from classical mechanics to quantum mechanics emphasized in Faddeev's lectures [FY80], can be found in [Fla82] and [Fad98].

Most of the problems in this chapter are rather standard and are mainly taken from the references [RS80, BS91]. Other require more sophistication and are aimed at introducing the reader to a new topic. Thus the asymptotic expansion in Problem 2.11, which can be found in monograph [Sze75], is an example of semi-classical asymptotics, and Problem 3.1, taken from [Nel59], gives a criterion when the irreducible unitary representation of the Heisenberg algebra is integrable. Problems 3.17-3.19 introduce the reader to the theory of quantum groups (see

[029] Following V.A. Fock [Foc78], in Section 2.6 we used the more appropriate name Hermite-Tchebyscheff polynomials instcad of the customary Hermite polynomials (see [Ger50] for the relevant historic arguments).

[Jim85, Dri86, Dri87, RTF89]) and are taken from [Dri83] (see also [Tak90]). The fundamental result that every Lie-Poisson group admits a deformation quantization described in Problem 3.18 has been proved in [EK96] (see also [Enr01]).

4. Notes and references about spin, spinors

The notion of electron spin is fundamental for the agreement of quantum mechanics with experiments. See [Mes99] for a thorough discussion of the principal evidence supporting the hypothesis of electron spin (Zeeman effect, Stern-Gerlach experiment). Classic texts [LL58, Foc78] also introduce the concept of spin from a physics perspective. Representation theory of the Lie group SU(2) - the simplest compact non-abelian Lie group - is discussed in detail in [Vil68]; for the description of all irreducible representations of U(n) see [FH91]. Our discussion of the Pauli Hamiltonian in Section 2.1 follows [Foc78]; the case of a particle in a uniform magnetic field in Section 2.2 was first considered by L.D. Landau in 1930 (see [LL58]). Problem 2.2 shows that in the presence of a magnetic field the operators
X_0 and Y_0, associated with coordinates of classical trajectories of a charged particle, do not commute and cannot be measured simultaneously.

The Pauli wave equation in Section 2.1 is non-relativistic, i.e., it does not take into account the postulates of special relativity. The correct quantum description of the electron in an external electromagnetic field was proposed by Dirac and is given by the Dirac equation; the Pauli wave equation is obtained as its non-relativistic limit [Foc78]. The Dirac equation is a single particle equation which describes an electron and a particle with charge - e - a positron. In order to describe quantum processes of creation and annihilation of particles, one needs to pass from quantum mechanics to quantum field theory, which deals with systems with infinitely many degrees of freedom, and we refer to [IZ80] for an introduction.

The symmetrization postulate, formulated in Section 3.1, is another fundamental principle of quantum mechanics, and we refer to [Mes99] for its physical motivation. The N-particle Schrdinger equation describes all the properties of atoms. However, it is almost impossible to solve this equation analytically (for the potentials in atomic physics), and even numerically when $N > 2$; the case of the helium atom ($N = 3$) illustrates the difficulties of the problem. For this purpose various approximate methods like the one-electron approximation, the Hartree-Fock method and its modifications, have been developed (see [LL58, Foc78] for the details and [FY80] for a clear introduction). A correct description of the properties of atoms and an explanation of D.I. Mendeleev's periodic table of elements, based on these methods, has been a major triumph of quantum mechanics. For a detailed account we refer the interested reader to [LL58, Foc78] and [FY80]. The N-particle Schrdinger equation, in principle, also describes [5] all properties of molecules studied in chemistry. However, this "reductionism" does not work due to the complexity of the quantum N-body problem, and approximate methods like Hartree-Fock approximation play a central role in quantum chemistry.

The vector space $\mathbb{C}^2 \otimes \mathbb{C}^2$ describes the spin degrees of freedom of two electrons, and the spin states which are not represented as a tensor product $u \otimes v$ are called entangled. Entangled states are used to describe the Einstein-PodolskiRozen paradox, a quantum experiment, which apparently violates the principle of locality (see its description in [Bel87, Sak94]). The fact that quantum mechanics is correct and allows for an accurate description of the microworld is beyond any doubt, and is confirmed by numerous physical experiments. The Einstein-Podolski-Rosen paradox is only a "paradox" because classical intuition does not always correspond to the physical reality. Moreover, it follows from the Bell inequalities [Bel87] that any attempt to turn quantum mechanics into a deterministic theory by introducing the so-called hidden variables is fallacious; we refer to the web site http://en.wikipedia.org/wiki/EPR_paradox for further references. The vector space $\mathbb{C}^2 \otimes \cdots \otimes \mathbb{C}^2$, describing the spin degrees of freedom of

several

identical particles of spin $\frac{1}{2}$, also plays a fundamental role in quantum computation theory. This is a rapidly developing field, and we refer the interested reader to the monograph [KSV02] for the mathematical introduction, and to the web site http://en.wikipedia.org/wiki/Quantum_computer for updates on the specialized literature. Another rapidly developing and exciting new application of quantum mechanics is quantum cryptography, reviewed at http://en.wikipedia.org/wiki /Quantum_cryptography.

Section 3.2 is a crash course on the representation theory of the symmetric group Sym_N - a beautiful piece of classical mathematics which has many interesting applications in modern combinatorics and representation theory. Our goal here was to give a concise and clear presentation of the basic necessary facts, and we refer to the classic text [Wey50] and to [FH91] for detailed accounts of representation theory, and to [GW98] for the Schur-Weyl duality. In Section 3.3 we emphasize the role of Schur-Weyl duality in studying the symmetry properties of coordinate wave functions. Physics textbooks like [LL58], [Dav76] and [Sak94] carefully treat the basic examples, but are somewhat vague in describing the form of the total wave function of N particles. The monograph [Foc78] is very precise in this regard, but in his presentation V.A. Fock is trying to reduce the usage of group theory to a minimum. Our goal in Section 3.3 was to fill this gap and to give a clear description of the symmetry properties of coordinate and spin parts of the total wave function by using the language of representation theory. For the case of N particles of spin $\frac{1}{2}$ this problem was solved by V.A. Fock in 1940; see [Foc78], as well as in yet another classic [Wig59]. For more applications of group theory to quantum mechanics we refer to the latter text, and to [Wey50].

Notes and references about Fermionic systems by Takhtajayan

Canonical anticommutation relations, discussed in Section 1, were introduced by P. Jordan and E. Wigner in 1928 [JW28]. We refer the reader to F.A. Berezin's classical monograph [Ber66] for a comprehensive mathematical treatment of canonical commutation and anticommutation relations. Though [Ber66] is mainly devoted to quantum systems with infinitely many degrees of freedom, which are studied by quantum field theory, it also discusses the simpler case of finitely many degrees of freedom. A self-contained mathematical introduction to Clifford algebras, their representations, and other topics can be found in [Var04] and references therein. The fundamental idea that systems with Grassmann variables appear as a semi-classical limit of fermions was formulated by I.L. Martin in 1959 [Mar59b, Mar59a]. Independently, F.A. Berezin in [Ber61] introduced Grassmann variables for rigorous mathematical description of the second quantization for fermion systems by using generating functionals for vectors and operators. Material in Section 2 - differential and integral calculus on the Grassmann algebra - belongs to F.A. Berezin, and our exposition follows [Ber66] and [Ber87]. The superalgebra - graded linear algebra - which we very briefly describe in Section 3, was also discovered and developed by F.A. Berezin [Ber87]. The references [Man97], [Fre99], and [DM99] provide the reader with a more abstract mathematical treatment, while lecture notes [Var04] supplement the category theory approach of [DM99] with
motivation from physics. We refer to [Ber61, Ber66] for the general discussion of the path integral over Grassmann variables, and of the matrix and Wick symbols of operators in the fermion Hilbert space. In Section 4 we follow the elegant exposition in [FS91]; as in Section 2.4 of Chapter 5, we carefully treat boundary conditions for Grassmann path integrals for the Wick symbols (as opposed to the formulas [Ber71a]).

[05] In this sense, quantum mechanics is a "theory of everything" for chemistry.

Notes and references about Schrodinger equation from Takhtajayan

The classical text [LL58] is the source of many basic facts on the Schrodinger equation, written from the physics perspective. The textbook [Foc78], another classic, shows meticulous attention to detail. There are numerous mathematics papers and monographs devoted to the different aspects of the Schrodinger equation, and here we mention only the sources being used. For the self-adjointness criteria in Section 1.1 we refer the reader to the encyclopaedia survey [RSS94] and to the treatise
[RS75], and references therein; in particular, in [RS75] one can find the proof that the Schrodinger operator for a complex atom is essentially self-adjoint. For the proof of Sears theorem, see [BS91]. Theorems 1.6 and 1.7 (the latter in the special case $V_1 = 0$) in Section 1.2 are proved in [BS91] and [RSS94]; see [RS78] for the proof of Theorem 1.7 in the general case, and for other generalizations. The proof of the Kato theorem can be found in [RS78]; see also [RSS94]. For the proof of the Birman-Schwinger bound, see [RS78]. The monograph [HS96], besides the introduction to spectral theory, contains the proofs of many results in Sections 1.1-1.2; see also the monograph [CFKS08] for these and other results.

Section 2 is based on the fundamental paper [Fad64], classical surveys [Fad59, Fad74], and the monograph [Mar86], devoted to the inverse scattering problems. For more information and details on the material in Section 2.1 and Problems 2.2, 2.3, 2.4, see [Fad64] and [Mar86]. The complex integration of the resolvent kernel is a powerful method for proving the eigenfunction expansion theorem, especially in the presence of the absolutely continuous spectrum, and in Section 2.2 we followed the elegant approach from [Fad59]; Problem 2.6 is taken from [Fad74]. Section 2.3 is based on [Fad59, Fad64, Fad74]; see also the monograph [New02] for a comprehensive exposition of the scattering theory from the physics perspective, and the recent book [Yaf92] for its abstract mathematical formulation. We refer the reader to [**Fad**74] and references therein for more details on the material in Section 2.4.

Section 3 is fairly standard; from a physics point of view, its material can be found in almost any textbook on quantum mechanics; see [LL58, Foc78] for a clear exposition. It was H . Weyl who introduced Lie groups into quantum mechanics [Wey50], and nowadays representation theory of Lie groups is a part of the theoretical physics curriculum; see, e.g., [BR86]. There are also many mathematics textbooks and monographs on representation theory of compact Lie groups; see, e.g., [Kir76, FH91], as well as [Vil68]. Section 4 contains the standard material presented in any textbook on quantum mechanics; see [LL58, Foc78, Mes99] for the physics presentation. Our goal here was precise mathematical formulation of the basic facts; for the proofs of all results in this section (and of the problems as well), and for their generalizations, we refer the reader to the treatise [RS79].

The solution of the eigenvalue problem for the hydrogen atom, given by E . Schrodinger in 1926, was the major triumph of quantum mechanics. Before that, the energy levels of the hydrogen atom were obtained by N. Bohr in 1913 using the Bohr model (later replaced by the Bohr-Sommerfeld model and the BWS quantization rules), and in 1926 by W. Pauli by using the quantum Laplace-Runge-Lenz vector. Sections 5.1 and 5.2 are standard and our exposition follows [LL58, Foc78]. We started Section 5.3 by presenting Pauli's approach (see [BR86] for more details on representation theory). The hidden SO(4) symmetry of the hydrogen atom was discovered by V.A. Fork, and the end of Section 5.3 is based on [Foc78] (see
[BI66a, BI66b] for more details and for the treatment of the absolutely continuous spectrum).

There exists an extensive literature on semi-classical asymptotics and the WKB method, which we just barely touched on in Section 6. We refer to [LL58] and [Dav76] for a physics discussion and to [GS77, BW97] for a mathematical introduction. Detailed exposition of the one-dimensional WKB method can be found in [Olv97] - a reference book on special functions used in this chapter. We refer to the monographs [MF81] and [Ler81] for the detailed exposition of the much more complicated multi-dimensional WKB method.

4. Notes and references about Integration in Functional Spaces by Takhtajayan

There is a vast literature on Wiener integration theory and Brownian motion, and here we present, in a succinct form, only the very basic facts. Material in Section 1 is standard, and our exposition follows the exercise section in [Rab95]. For necessary facts from probability theory, including Kolmogoroff's extension theorem and an introduction to the stochastic processes, we refer to the classic treatise [Lo77, Lo78] and recent text [Kho07]. In particular, the statement $\mu(\mathscr{H}) = 0$ in Proposition 1.1 follows from the strong law of large numbers.

Th elegant construction of the Wiener measure in Section 2 belongs to E. Nelson [Nel64], and our exposition, including the proof of the Feynman-Kac formula, follows [RS75]. We refer the reader to Ito-McKean's classic monograph [IM74] for the construction of the Wiener measure from the probability theory point of view; along this way Problems 2.1 and 2.2 get solutions. The classic book [Kac59]
and lectures [Kac80] by M. Kac are another excellent source of information on Wiener integration and its applications in different areas of mathematics. The relation between Wiener and Feynman path integrals in Section 2.3 belongs to E. Nelson [Nel64]. Problem 2.6 is taken from R.H. Cameron's paper [Cam63] (see also [RS75]); this result shows that there is no complex-valued analog of Wiener measure associated with the complex diffusion coefficient with $\operatorname{Re} D > 0$ (as opposed to the statement made in [GY56]).

Theorems proved in Section 3 serve as a rigorous foundation for our discussion of the Gaussian Feynman path integrals in Section 4 of Chapter 5. Our proof of Theorem 3.1 in Section 3.1, which uses the method of finite differences, follows the outline in [GY56] which attributed it to [Mon52]. The proof of Theorem 3.2 in Section 3.2 seems to be new.

The Euclidean quantum mechanics, obtained by replacing the physical time t by the Euclidean (or imaginary) time $-it$, is ultimately related to the theory of stochastic processes. It can be formulated by a set of axioms of the one-dimensional Euclidean quantum field theory, and we refer the interested reader to [Str05] for the detailed discussion.

Notes and references about supersymmetry

The goal of Section 1, besides giving a definition of a supermanifold, was to introduce the isomorphism $\mathcal{A}^\bullet(M) \simeq C^\infty(\Pi TM)$, emphasized by E. Witten [Wit82a, Wit82b], and commonly used in the physics literature. For a systematic introduction to supermanifolds, we refer to the classic texts [Kos77, Ber87], as well as to the modern sources [Man97, DM99, Var04] and references therein. A detailed exposition of equivariant cohomology and localization in the finite-dimensional case can be found in the monograph [BGV04]; our proof of the Berline-Vergne localization theorem in Section 2.1 follows [Sza00]. Our presentation of the infinitedimensional case, based on [BT95, Sza00], is at a physical level of rigor. Theorem 2.3 was originally formulated by E . Witten in his famous path integral derivation of the Atiyah-Singer formula for the index of the Dirac operator. Witten's original approach was lucidly presented by Atiyah [Ati85]. Our exposition follows [Wit99b], with special attention to constant factors; see also [AG83, Alv95], as well as [BT95, Sza00].

For a detailed explanation of the functor of points and a discussion of classical mechanics on supermanifolds, see [Fre99]; our examples of classical systems are taken from [Alv95]. Supersymmetry introduced in Sections 4.2-4.3 is called $N = \frac{1}{2}$ supersymmetry and is obtained as a reduction of $N = 1$ supersymmetry; see lectures [Alv95, DF99b, Fre99, Wit99a, Wit99b] and [CFKS08] for more details and references. In particular, [Fre99, Wit99a] describe useful superfield formalism for producing supersymmetric Lagrangians, sketched in Problem 4.3 in Section 4.3. Material in Section 5 is based on [Alv95]; we refer the reader to the monograph [BGV04] for the invariant definition of Dirac operators on spin manifolds and related topics.

It should be emphasized that our derivation of the Atiyah-Singer formula in Section 6 is

purely heuristic. Rigorous justification of this approach using Ito-Malliavin stochastic calculus was made by J.-M. Bismut [Bis84a, Bis84b, Bis85]; it turns out that formula (6.2) in Section 6 requires an extra factor: the exponential of the integral along the path of a multiple of a scalar curvature. When $T \to 0$, this rigorous formula for the index coincides with the heuristic expression (6.2). Still, the integration of a differential form of "top degree" over the loop space in [Bis85] remains formal, and is a challenging open problem. Finally, we refer the interested reader to [ASW90] for a path integral derivation of the H . Weyl character formula, and to [Wit99b] for the treatment of the Dirac operator on the loop space.

Литература по прикладной квантовой механике

[20] Шмиедт Вольфрам для квантовой механики

Хорошо объяснены решения некоторых простейших задач. Обязательно вскоре впишу, уже многое заготовлено!!! шаг по основам - и все, займусь численным решением, прога уже тоже готова к этому! Первая прикладная книга, которая будет вписана.

[21] А.Мессиа Квантовая механика.

имею в планах почитать, потому что в отличие от Ландау много общих интересных вопросов рассмотрено там, так что интересно многое из него добавить. так что после того, как создам по основным книгам - почитаю, доделаю разные параграфы.

хотя по сути это тот же квантмех, ее хочется прочитать просто, но это после того, как важное сделаю.

[22] (????)

О квантовых полях, связанная с квантовой механикой

[23] Ландау Л Д Лифшиц Е М Кватовая электродинамика

разные отдельные концепции взял, потому что квантовая механика переходит в КТП, так что эти связи также будут проработаны.

A.4.3 Additional Literature on Other Topics

Дополнительные обучающие книги, методички

Physicspages Quantum Mechanics 2021 https://physicspages.com/TOC-Quantummechanics.html

Куча методичек (или решенных задач) по разным тем, большая вероятноть, что то, что ищется, найдется. Жаль, что всё время до 2021го года не было это доступно...

[24] Sakurai J.J. Modern quantum mechanics. Addison Wesley Publishing Company, 1994

Typical good student book, very famous, covers all typical university topics. Nothing is very special about it, Zhou wrote that there are typos, but I wasn't reading it much.

Franz Schwabl Advanced Quantum Mechanics

A good book with some good computations in some topics, might be very useful for understanding some concepts. It is not the main book, because many also important topics are not there. I'll look at it and increase the level of mu sections later.

[25] Littlejohn R. Physics 221AB: Quantum Mechanics

Many excellent and pretty famous lectures that can help a lot!

(ЕК) Елютин Пт.В., Кривченков В. Д. Квантовая механика с задачами
301 страница теории и указаний на задач, наверное, крутые задачи. Потом добавлю их и теорию, пока хватает других тем на тренировку.

[26] Игошин Ф.Ф., Самарский Ю. А., Ципенюк Ю. М. Лабораторный практикум по общей физике. Квантовая физика
Прекрасный вузовский лабораторный практикум, где также коротко приведена основная теория типичных тем.

[27] Левитов Шитов Функция Грина
Очень много короткой теории и задач добавится. Важная книга, но это не совсем квантовая механика, так что не среди основных.

Е. С. Андрианов, А. П. Виноградов, А. А. Пухов ЛЕКЦИИ ПО КВАНТОВОЙ ОПТИКЕ Учебное пособие МОСКВА МФТИ 2018
Обсуждается много полезных моделей квантовой механики, думаю, точно многое из них добавлю в эту запись.

Базь А.И., Зельдович Я.Б., Переломов А.М. Рассеяние, реакции и распады в нерелятивистской квантовой механике
Очень хорошая книга, в которой отвечены очень многие вопросы, которые возникают в квантовой механике. (!!! многое выгружу потом отсюда!)

[28] Сивухин Д.В. Атомная и ядерная физика
Большая книга с введением в многие темы и подробным обсуждением. Не все темы актуальные, и всё равно, чтобы разобраться, потом придется открыть специализированную литературу. Не рекомендую читать, если нет лишнего свободного времени.

Robert G. Littlejohn Fall 2019 Notes 21 Time Reversal https://bohr.physics.berkeley.edu/classes/221/1112/notes/timerev.pdf
Небольшая методичка по обращению времени, гуглится, вроде бы в ней хорошо раскрыта эта тема. Подумаю еще раз про это потом.

Л. П. Суханов Лекции по квантовой механике МФТИ
Типичные лекции физтеха до того, как не начали пихать в программу кучу лишнего. Полезная, если хочется увидеть основные формулы или простую теорию. (!!! кстати, выпишу в 1ю часть из нее многое!)

Banks T. Quantum Mechanics: An Introduction
Большая книга на первый взгляд обычной теории. Возможно, что-то особенное есть и там, но похожа на просто обычный хороший вузовский учебник.

Нохрина Е. Е. Сложение двух моментов в квантовой механике Учебно-методическое пособие
Возможно, хорошее объяснение темы, в планах её додумать, хотя, возможно, я уже знаю всё из неё.

Е. Е. Нохрина Теорема Вигнера–Эккарта Учебно-методическое пособие
Возможно, хорошее объяснение темы, в планах её додумать. Больше математическое.

Ишмухаметов, Б. Х., Кацнельсон, М. И., Поликарпов, А. Ф. Одноэлектронные задачи квантовой механики в квазиклассическом рассмотрении. Краткий курс ВКБ Учебный электронный текстовый ресурс
Методичка по квазиклассике, 65 страниц, вроде хорошая и полезная.

El-Batanouny M. Advanced Quantum Condensed Matter Physics
Про фазу Берри скорее всего отличная теория, которая в Левене нам давалась. Многое выгружено, разберусь позже, у меня должна быть написана подготовка к этим темам, которые в физике твердого тела используются.

Andrei Tokmakoff Time Dependent Quantum Mechanics and Spectroscopy
I was reading about density matrix from this book. I don't know, if it is a good book, but at least about density matrix it has some information. Looks like there is a lot of topics which are not present in a basic course of QM at all!

Mitchel Weissbluth Atoms and Molecules
This book looks like it is a great introduction to QM with emphasis on models of atoms and molecules. It has basic theory and, maybe, many examples of applications. Maybe it is the best book to learn atoms?

George C. Schatz Mark A. Ratner Quantum Mechanics In Chemistry
Maybe this book is an excellent bride from QM to chemistry? Still, all basic questions about it would require weeks or months of learning.

Mladen Pavicic Quantum Computation and Quantum Communication: Theory and Experiments
A great mini encyclopedia about experiments in quantum information. Looks like it is essential for real understanding this part of physics. But the author is not that famous, so I am not sure that topics from it are important.

Други задачники

(МС) Мартинсов Смирнов Квантовая Физика для Баумана
Вроде неплохая методичка по основам, которые итак понятны после продумывания обычного курса.

(Ф1, Ф2) Флюгге З. "Задачи по квантовой механике (в 2 томах)", Мир, 1974
Хорошая книга с подробно разобранными небычными задачами. Просто итак очень много современных книг, где уже много задач разобрано, так что вряд ли есть смысл открывать её. Потом, когда-то, когда решено будет штук как минимум 200 задач из основных книг, можно будет и его порешать.

K.K.Prasad Quantum Chemistry Through Problems and Solutions
1/2 of book is basic QM problems, but another 1/2 - is a collection of very unique for QM problems. Maybe it is a really great book to understand these parts of QM about applications to chemistry? Otherwise like in Landau's book, the theory is written, but what is next? Here is what is next: this book.

(ККЧ) И.В. Копытин, А.С. Корнев, Т.А. Чуракова Задачи по квантовой механике ч 1, ч 2, ч 3.

Хорошая методички, немного задач решены, полезно и не сложно написано, 3 книги.

(Г-1981) В.М.Галицкий, Б. М.Карнаков, В.И.Коган Задачи по квантовой механике, 1981

Есть задачи, которых нет в сборнике 1992-го года. Так пока сложно сказать, какая версия лучше, потому что эта более компактная и содержит тоже многие отличнейшие задачи.

(БКП) В.С. Булыгин, М.Г. Кремлев, Э.В. Прут Избранные задачи студенческих олимпиад МФТИ по курсу общей физики Долгопрудный: Издательский Дом «Интеллект», 2015. - 312 с.

Доступ через lib.mipt, дальше по http://books.mipt.ru/book/301280. Крутой сборник задач, тоже прорешаю потом его, очень интересные и простые задачи, шикарное проведение времени на них.

F. Constantinescu, E. Magyari, Translated by V. V. Grecu Edited by J. A. Spiers Problems in Quantum mechanics

Обычный неплохой задачник, если прорешать Галицкого, то потребность в нем вряд ли будет.

Популярная литература и с упрощенным изложением

Это очень важные книги, ибо популярные идеи - неотъемлемая часть квантовой механики. И в популярных книгах они прекрасно описаны, так что радуемся и используем.

(пока не смотрел тут почти ничего, только после теормина мб буду прорабатывать)

[29] Каку М. Физика невозможного

Популярная интересная книга для мотивации и кругозора, однако не думаю, что всерьез использовать темы из неё кому-то придется.

[30] Каку М. Параллельные миры: Об устройстве мироздания, высших измерениях и будущем Космоса

Наверняка много интересной теории, но выглядит как популярная литература просто поболтать о заведомо неизвестном.

[31] Иванов, М. Г. Как понимать квантовую механику

Большая, философско-обзорная книга с обсуждением многих общих вопросов. Прекрасная книга на свободное время, но для минимальной подготовки она излишня.

[32] Фейнман Р. Квантовая электродинамика

Известные лекции по квантовой механике. Я пока не читал, итак хватает материала для изучения. Не знаю, что в них особенного?

[33] Мухин К. Н. Занимательная ядерная физика

Открыл, интересно, но абсолютно не актуально. В свободное время на пенсии почитать - хорошая идея.

Справочники

(некоторые уже видел, нужно будет - допишу)

[34]
Д. А. Варшалович, А. Н. Москалев, В. К. Херсонский Квантовая Теория Углового Момента Аппарат Неприводимых Тензоров Сферические Функции 3nj-символы Издательство Наука: Ленинградское Отделение Ленинград - 1975
Библия углового момента, огромная книга с кучей формул про сложение моментов.

A.4.4 Articles on Special Models, Experiments and Special Methods

Статьи про различные эффекты квантовой механики

[35] Л. А. Халфин Квантовый эффект Зенона
статья про квантовый парадокс зенона. интересно изучить, уйдет скорее всего часа 3 на нее, пока не актуально.

[36] Purcell, E. M Spontaneous Emission Probabilities at Ratio Frequencies
Атом спонтанно в резонаторе может излучать быстрее, оказывается! Я это не понимаю, это удивительно, потом подумаю про это, теорию доработаю для него.

Ales Navrat Geometric phase in quantum theory, 2006
A good review of Berry phase by a student.

Д.Н. Клышко Геометрическая Фаза Берри В Колебательных Процессах Ноябрь 1993 Г. Том 163, № 11 Успехи Физических Наук
Вроде крутая статья про фазу Берри, может, когда-то дойду до неё?

A. Tomita, R. Y. Chiao, "Observation of Berry's topological phase by use of an optical fibre", Phys. Rev. Lett. 57 (1986) 937-940.
This was the first experiment to confirm the prediction of Berry.

R.Y. Chiao and Y.S. Wu, "Manifestations of Bery's topological phase for the photon", Phys. Rev. Lett. 57 (1986) 933-936.
Realization of the first experiment to confirm the prediction of Berry.

Статьи про теоретические методы

[37] Aharonov, Yakir and Albert, David Z. and Vaidman, Lev How the result of a measurement of a component of the spin of a spin-1/2 particle can turn out to be 100
Можно измерить спин частицы равный 100, почему - тут когда-то почитаю, очень интересно.

[38] Hubac, Ivan and Wilson, Stephen Brillouin-Wigner Methods for Many-Body Systems
Крутая книга на 190 страниц про теорию возмущений, еще по приложениям в атомной физике и диаграммам Фейнамана, сделаю основы - скорее всего почитаю. После нее по идее очень хорошо теория возмущений станет понятна.

В. М. Шабаев, Теория возмущений Рэлея–Шредингера для релятивистского атома, ТМФ, 1990, том 82, номер 1, 83–89

Рассуждения про теорию возмущений. Выглядит интересно, однако не факт, что она полезная. Когда-то посмотрю, по идее с ней может стать глубже понятны теория возмущений и атомы.

[39] Sergey Bravyi and David P. DiVincenzo and Daniel Loss Schrieffer–Wolff transformation for quantum many-body systems

Оказывается, есть такие преобразования, которые в многочастичных системах применяются. Наверное, хорошая статья, выглядит как 5 дней моей работы над ней, чтобы понять. Там в многочастичных системах еще много статей и тренировок мне нужно, чтобы научиться им.

Статьи про моделирование

[40] Feldbrugge, Job and Pen, Ue-Li and Turok, Neil, Oscillatory path integrals for radio astronomy

В конце описан эксперимент Юнга и переход в классику, неплохое дополнение, потом отработаю.

https://jfeldbrugge.github.io/Schrodinger/ Job Feldbrugge Уравнение Шредингера: The Suzuki-Trotter integrator Young's double-slit experiment

численное решение УШ в математике, интересное моделирование. как сделаю основные записи - за часа 3 пойму, как это моделирование устроено. очень будет крутое дополнение.

Статьи про атомную физику и теорию к ней

https://www.chemistry.tcd.ie/assets/pdf/ss/DAMB/DAMBSS/PERTURBATIONTHEORY.pdf Rayleigh-Schrödinger Perturbation Theory

Автор неизвестен. 17 страниц про теорию возмущений в атомной физике, по идее это все уже должно быть известно, но когда-то может еще подчитаю, там скорее всего пара интересных еще есть деталей.

A.4.5 Additional Literature on Other Topics

Обсудим самые основные профессиональные книги о науках, связанных с квантовой механикой.

(ими займусь, когда основные проработаю, не раньше)

Статьи п атомной физике

Зоммерфельд А. Строение атома и спектры. Том 1

Когда-то открывал, никогда не доходил до прочтения.

Статьи по ядерной физике

Основная и вводная по статистической физике, магнетизму

[41] Nicola A. Spaldin Magnetic Materials: Fundamentals and Applications

Известная книга про простой магнетизм и введение в сложные темы.

[42] Боголюбов Н.Н., Боголюбов Н.Н. (мл.). Введение в квантовую статистическую механику Изд. 3 URSS. 2018. 384 с. ISBN 978-5-9710-4456-7.

Известная книга про квантовую механику многочастичных систем, в планах почитать её.

Основная и вводная по физике конденсированных сред

Литература про математические модификации квантовой механики

В. С. Владимиров, И. В. Волович, p-Адическая квантовая механика, Докл. АН СССР, 1988, том 302, номер 2, 320–323

Если будет интересно - как раз и почитаю, пока не знаю, как там поля чисел вообще учитываются?

A.5 Overview of Quantum Mechanics

Выделим самое главное, что есть в квантовой физике, чтобы уверенно пользоваться ей.

A.5.1 Quantum Mechanics in 2 Hours

Обсудим в двух словах всю квантовую механику.
(потом напишу, пока вообще не актуально)

Map of quantum mechanics

(add picture and discussion about it!!!)

Введение в квантовую механику для тех, кто ничего о ней не слышал

(сформулирую потом)
(найду какую-то красивую фотку потом, тут была некрасивая, удалил ее)

наглядное представление как строится квантовая механика

О методах решений уравнений квантовой механики

(тут максимально коротко, все формулы)

Появление квантовой механики в нашей картине мира

обзор типичных моделей

Обсудим, какие модели существуют?
излучение, рассеяние, теория атомов, (?)
их не много, это типичные применения квантовой механики, которыми мы и занимаемся.

Качественное отличие квантовой механики и классической

(конкретно приведу эти отличия. нпр там рассеяние такое, тут - такое. укажу, почему. пока не готов писать это.)

О точно решаемых моделях квантовой механики

(соберу их, указав суть и идею решения)
- атом водорода
- осциллятор

многие задачи на обобщенные функции:
- задача Ландау-Зенера
- куча всего (да??)

Определения квантовой механики

выпишу из теории ниже, по итогу что есть что.

Определение кванта

Квант - это
(тут пояснение, почему это определение важно, порой на самом деле про это возникают большие дискуссии)

Определение квантования

Квантование это -.....
(тут пояснение, почему это определение важно, порой на самом деле про это возникают большие дискуссии)

О границе применимости квантовой механики

какой должна быть система, чтобы к ней применялась квантовая физика?

четко пропишу. пока хз.

О типичных мысленных экспериментах в квантовой механике (?)

(потом напишу)

основы квантового описания

Классическая механика неплохо описывает при привычный нам мир.

Зная начальные данные с помощью второго закона Ньютона можно однозначно описать поведение частицы.

В квантовой физике вводится состояние системы, и решается уравнение Шредингера.

Со временем волновая функция расплывается (?)

Таким образом в классической механике и квантовой есть одно уравнение, которое описывает все происходящее в будущем.

но после измерения мы видим конкретную точку в пространстве.

возникает вопрос, как согласовать волновую функцию и измерение с конкретным значением?

Переход из волновой функции в частицы совершенно случаен, но известно, что модуль ее в квадрате дает вероятность нахождения частицы в данной точке пространства.

Это предположение было высказано Борном.

Эйнштейну это не понравилось.

Таким образом, пока мы не смотрим, существует волновая функция, а как только мы смотрим, она коллапсирует и мгновенно появляется частица.

кот Шредингера

(!! после текста будет все с формулами!!)

Шредингеру это очень не нравилось.

поэтому он придумал эксперимент с котом Шредингера.

Мы возьмем коробку, поместим в нее кота, добавляем атом радиоактивного элемента и детектор типа счетчика гейгера, который при срабатывании выпустит радиоактивный газ.

оградим от вмешательства самого кота.

если атом распадается, то детектор улавливает радиацию, испускает радиоактивный газ и кот погибает.

если не срабатывает, кот живет дальше.

состояние кота зависит от состояния детектора и атома, назовем эту связку запутанностью

разве что атому не обязательно быть распавшемся или не распавшемся, потому что согласно квантовой механике, большую часть времени он находится в суперпозиции состояний, он одновременно распавшийся и не распавшийся, пока его не измерят его.

таким образом состояние запутанное и пока мы не произведем измерения, одновременно вся коробка находится в двух состояниях, где атом распался и кот мертв, или где атом не распался и кот жив.

Тем самым Шредингер хотел сказать, что такого быть не может.

Поэтому у нас есть глава про другие объяснения квантовой механики.

(и что еще?)

суперпозиция, запутанность, измерения (??)

(откуда я эту хрень вытянул?)

Итак, у нас есть три понятия, с которыми нужно разобраться: суперпозиция, запутанность, измерения.

суперпозиция - что объект может находиться в двух состояниях одновременно.

(?) Если например в опыте Юнга описывать электрон волновой функцией, то может показаться, что электрон проходит через две щели одновременно.

запутанность - что если после взаимодействия двух частиц мы измерим одну волновую функцию - моментально сколлапсируется вторая.

то есть это как если бы была одна волновая функция на двоих частиц.

может показаться, что так как все взаимодействует со всем, то есть одна волновая функция для всей вселенной.

но и про волновую функцию отдельной частицы говорить также можно.

запутывание происходит только в момент взаимодействия с другими объектами.

то есть запутанность - что состояние двух разных частиц можно описывать одной волновой функцией.

измерения.

измерение это взаимодействие.

Типичные квантовые соотношения

В квантовой физике имеются некоторые фундаментальные формулы, которые позволяют делать ключевые переходы, а также раскрывают суть понятий.

(тут будет обсуждение, откуда взялись эти соотношения и когда они верные, когда нет)

Энергия через параметры $E = \hbar\omega$

распространяющаяся материя при взаимодействии с веществом распадается на конечный набор корпускул, энергия каждой:

$$E = \hbar\omega.$$

Энергию можно записать через длину волны как

$$E = \hbar kc = \frac{2\pi\hbar}{\lambda},$$

то есть она обратно пропорциональная длине волны.

Соотношение де Бройля $p = \hbar k$ в двух словах

Суть соотношения де Бройля в том, что

$$p = \hbar k.$$

Его можно получить из (????)
На этом моменте видно, что зная импульс, сразу мы знаем волновое число
(как вводится кстатиати оно? на теорпол все падает).
(?? в чем смысл его)
что частица есть волна мб, но тут подумать можно.

Длина волны через параметры

Длина волны через энергию выражает, расписав формулу $E = \hbar\omega$, в итоге

$$\lambda = \frac{hc}{E}$$

соотношение де Бройля: обзор применений

Часто есть задачи про него, так что соберем теорию для него

волновые характеристики любого тела

можно посчитать волновые характеристики любого тела, пока не задумываясь, что это значит. ?????

$$\lambda = \frac{2\pi}{k} = \frac{2\pi\hbar}{p} = \frac{2\pi\hbar}{m\upsilon} = \frac{2\pi\hbar}{\sqrt{2mE}}$$

Критерием, который говорит, когда частица - корпускула, а когда волна(откуда?) введена была волновая функция частицы.

Обзор формализмов квантовой механики

обзор способов описания квантовых систем

(что есть там волновая функция, а есть матрица плотности, опишу сравнение этих методов. сперва в них разберусь нормально.)

Обзор дальнейших развитий формализма

Обзор математизированной квантовой механики

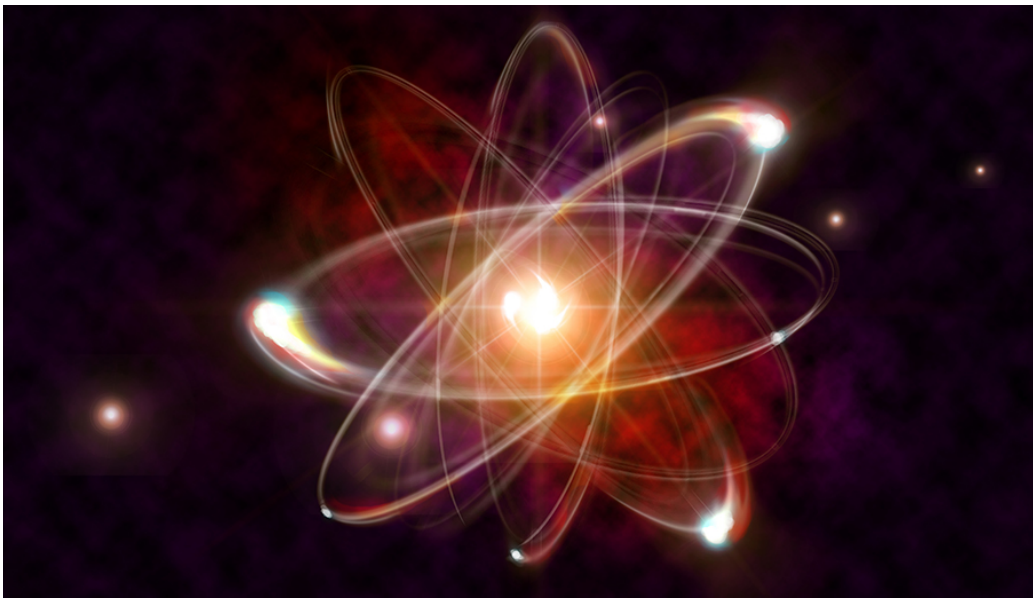
Обзор операторов в квантовой механике

(напишу, что такие-то есть, такие-то их особенности ключевые)

A.5.2 Popular About Quantum Mechanics (??)

(!!! напишу потом круто и нормально! много книг - примеры как это можно написать! мб страниц 15 потом будет, но качественной записи!)

Каков квантовый мир?



A.5.3 Overview of Sections of Quantum Mechanics

Об атомной физике

О квантовых числах

(опишу, какие есть, ориентироваться в них - базовая подготовка)

A.5.4 Seeing a Quantum World (???)

(тот самый взгляд, который я аж целой частью хотел сделать! опишу, как мы вообще видим квантовую механику, когда все изучили уже! пока все еще не готов написать)

(здесь просто обозреваем квантовый мир и смотрим на разные принципиальные его закономерности. много феноменологии и популряных тем. то, что раньше на целую часть хотел растянуть)

A.5.5 Mathematics in Quantum Mechanics

обзор применений теории групп в квантовой механике

Связь с теорией вероятностей

по сути с вероятностями работаем же?
подумаю, как связаны они?

Связь с теорией меры

Там как-то она строится через нее, вот потом и узнаю.

A.5.6 Connections with Other Parts of Physics

Для углубленного понимания подхода квантовой механики, подчеркнем её фундаментальную связь с другими разделами.

Связь с механикой

Одна из из главных связей - это связь с механикой, её обсудим первее всего. На самом деле конструкция эта широко известна и ниже она написана сполна хорошо.

Связь с оптикой

сформулирую потом ту самую связку важную.

Связь со статистической физикой

A.5.7 Overview of Typical Quantum Phenomena

Приведем группировку типичных явлений, которая позволит в них ориентироваться.
все заготовки из овчоса. прорешаю его - пропишу.

A.5.8 Quantitative Estimates

Приведем типичные масштабы квантовых величин для полной ориентации и сравнения.

(полезный очень раздел, чуть что - его и использую, пересоберу потом нормально, когда опыт появится)

например, импульс измеряется в $\frac{eV}{c}$, c - скорость света.
по порядку величины энергия электрона - несколько эВ.

Характеристики типичных объектов

Значения типичных величин

Приведем значения типичных величин.
(с опытом нормаьлно сбласнсирую)

Свойства электрона

Масса электрона
$9.1 \cdot 10^{-31}$ кг.
Типичный импульс электрона?????
радиус электрона????
Энергия электрона:

$$E_e = m_e c^2 \approx 0,51\text{МэВ}$$

10^{-13}см - размер атома.
при комнатной температуре $kT = 0,1\text{eV}$.
(?)
величина ямы потенциальлной в атоме: $4 - 5eV$
колебательная энергия на одну молекулу $\sim 0.1 \sim 10^3 K$
если $\lambda \sim 5mkm$, то $\hbar\omega \sim 0,2eV$
можно делить и умножать на $2r_b^2 m_e/\hbar$, сводим расчеты к ридбергу.
дальше $\hbar\omega$ и массы можно подставлять.

Свойства других частиц

масса протона
$m_{\text{протона}} = 1,67 \cdot 10^{-29}$ кг.

Свойства типичных атомов (!!!)

(тут подготовка по общей физике!)
радиус Бора

$$a = \frac{\hbar^2}{m_e e^2} \approx 5 \cdot 10^{-9}\text{см}$$

типичные значения волновых функций

в основном состоянии атома водорода его волновая функция - экспонента.

Константы

Часто полезно в преобразованиях приводить величины к одной из типичных констант квантовой механики. Обсудим их ниже.
(мб потом даже укажу, в каких местах какая возникать будет)

Фундаментальные константы

Постоянная Планка:
постоянная планка имеет вид:

$$\hbar = 1,054571 \times 10^{-34}\text{Дж} \cdot \text{с}. = 1,054571 \times 10^{-27}\text{эрг} \cdot \text{с}; = 6,582119 \times 10^{-16}\text{эВ}.$$

,
Также встречается

$$h = 2\pi\hbar$$

которая удобна в????
размерность совпадает с размерностью момента импульса (????)

(а смысл ее какой?)
(откуда такое значение?)
Магнетон Бора

$$\mu_{\text{B}} = \frac{e\hbar}{2mec} = 0,92740 \cdot 10^{-20}{}_{\text{e}}/\text{Гс}$$

Ядерный магнетон

$$\mu_{\text{gR}} = \frac{e\hbar}{2m_{\text{p}}c} = 0,50508 \cdot 10^{-23} \text{ эрг } /\text{Гс}$$

Постоянная тонкой структуры

$$\alpha = \frac{e^2}{\hbar c} = 7,2973 \cdot 10^{-3} = \frac{1}{137,036}$$

Постоянная Ридберга

$$R_\infty = \frac{me^4}{4\pi\hbar^3 c} = \frac{\alpha^2}{4\pi\lambda_e} = 109737,31 \text{ см}^{-1}$$

Боровский радиус

$$r_1 = \frac{\hbar^2}{me^2} = \frac{\lambda_e}{\alpha} = 0,52918 \cdot 10^{-8}\text{см}$$

Квант магнитного потока (сверхпроводящий)

$$\Phi_0^{\text{сп}} = \frac{hc}{2e} = 2,0678 \cdot 10^{-7}\text{Гс} \cdot \text{см}^2$$

Квант холловского сопротивления

$$R_0 = \frac{h}{e^2} = 25812,806377\text{Ом}$$

Постоянная Стефана-Больцмана

$$\alpha = \frac{\pi^2 k^4}{60\hbar^3 c^2} = 5,6705 \cdot 10^{-5}\frac{\text{эрг}}{\text{с} \cdot \text{см}^2 \cdot \text{К}^4} = 5,6705 \cdot 10^{-8}\frac{\text{Вт}}{\text{М}^2 \cdot \text{К}^4}$$

Постоянная в законе смещения Вина

$$b = \lambda_{\max} T = 0,2898\text{см} \cdot \text{К}$$

Элементарный заряд

$$e = 4,8032 \cdot 10^{-10} \text{ ед. СГСЭ } = 1,60218 \cdot 10^{-19} \text{ К л}$$

Электрон-вольт

$$1 \text{ В} = 1,60218 \cdot 10^{-12} \text{ эрг}$$

Температура, соответствующая 1 эВ

$$T_{\text{эВ}} = 11606 \text{ К}$$

Атомная единица массы

$$1 \text{ а. е. М. } = 1,66054 \cdot 10^{-24}\Gamma(931,494\text{М} \ni \text{В})$$

Электрон

Масса

$$m_{\text{e}} = 9,10939 \cdot 10^{-28} \text{ г}$$
$$m_{\text{e}}c^2 = 0,511 \text{ МэВ}$$

Удельный заряд:

$$\frac{e}{m_e} = -5,2728 \cdot 10^{17} \text{ ед СГСЭ } = -1,7588 \cdot 10^{11} \text{К/Г}$$

Комптоновская длина волны

$$A_{\text{e}} = \frac{\hbar}{m_{\text{e}}c} = 3,8616 \cdot 10^{-11} \text{см}; \Lambda_{\text{e}} = \frac{h}{m_{\text{e}}c} = 2,4263 \cdot 10^{-10} \text{см}$$

Классический радиус

$$r_{\text{К}\pi} = \frac{e^2}{m_{\text{e}}c^2} = 2,8179 \cdot 10^{-13} \text{см}$$

Протон

Масса

$$m_{\text{p}} = 1,6726 \cdot 10^{-24}{}_{\Gamma} = 1,007276 \text{ а. е. М.}$$
$$m_{\text{p}}c^2 = 938,272 \text{М } \ni \text{ В}$$

Отношение массы протона К массе электрона

$$\frac{m_{\text{p}}}{m_{\text{e}}} = 1836,1527$$

Удельный заряд

$$\frac{e_{\text{p}}}{m_{\text{p}}} = 2,8716 \cdot 10^{14} \text{ ед. СГСЭ } = 9,5788 \cdot 10^{7} \text{ К}\pi/$$

Комптоновская длина волны

$$\lambda\!\!\!^{-}_{\text{p}} = \frac{\hbar}{m_{\text{p}}c} = 2,103 \cdot 10^{-14} \text{см}; \quad \Lambda_{\text{p}} = \frac{h}{m_{\text{p}}c} = 1,3214 \cdot 10^{-13} \text{см}$$

Магнитный момент

$$\mu_p = 2,7928 \cdot \mu_{\text{яд}} = 1,4106 \cdot 10^{-23} \text{ эрг /Гс}$$

Нейтрон

Масса

$$m_{\text{n}} = 1,6746 \cdot 10^{-24} \Gamma = 1,00866 \text{ а. е. М.}$$
$$m_{\text{n}}c^2 = 939,565 MB \text{ В}$$

Отношение массы нейтрона к массе протона

$$\frac{m_{\text{n}}}{m_{\text{p}}} = 1,001378$$

Комптоновская длина волны

$$\lambda\!\!\!^{-}_{n} = \frac{\hbar}{m_n c} = 0,210 \cdot 10^{-13} \text{см}; \quad \Lambda_n = \frac{h}{m_n c} = 1,31959 \cdot 10^{-13} \text{см}$$

Магнитный момент

$$\mu_n = -1,9130 \cdot \mu_{\text{яд}} = -0,9662 \cdot 10^{-23} \text{ эрг /ГС}$$

Типичные составные константы

(вот именно их чаще всего мы используем в быстрых преобразованиях!)
постоянная Ридберга 109722,267 $\frac{\text{эрг}}{\text{см}^2} = 10^5 \frac{\text{дин}}{\text{см}}$

$$R_g = \frac{\hbar^2}{2m_e r_b^2} = \frac{l^2}{2r_b} = 13,6eV \tag{A.1}$$

$r_b = \frac{\hbar^2}{m_e e^2}$ - радиус бора!
постоянная тонкой структуры!!! $\frac{e^2}{\hbar c} = \alpha$
постоянная тонкой структуры:
магнетон бора:
$\mu_B = \frac{e\hbar}{2cm_e}$

комптоновская длина волны

Разберём все, что с ней связано, там полно деталей интересных.

g-фактор

тоже популярная конструкция.

единицы измерения СГС

Приведем все необходимые знания про СГС

см, г, с,...

Энергия в СГС

про энергию:
1 eV = 1,6 10^{-19} Дж.
1 eV = 11600 K
Энергия в эВ через длину волны может быстро быть численно посчитана:

$$E = \frac{2\pi\hbar}{\lambda} = \frac{12390}{\lambda[\text{A}]}\text{эВ} \tag{A.2}$$

1 эрг = 1 гсм$^2/c^2 = 10^{-7}$Дж = $6.24150965(16) \cdot 10^{11}$ эВ = 0,6 ТэВ.

Переход в эВ

Из Джоулей чтобы перейти, просто делим на 1.6 10^{-12}

Обзор применений СГС

когда она нужна?

Атомные единицы массы

другое название Дальтон.

$$1\text{aem} = \frac{1}{12}M_{_6{}^{12}C} \cong 931,5\text{МэВ} \to 1,66 \cdot 10^{-24} \text{ г.}$$

Величины ядерной физики

Беккерель - распад в секунду.

Натуральная система единиц

единицы измерения $\hbar = c = 1$

Обсудим эту систему единиц и все нюансы, потому что как в теоретических вычислениях, так и в разных приложениях именно она используется.

Обзор применений натуральной системы

когда она нужна?
вроде когда не хочется думать про константы.
хз когда

A.5.9 Description of Notation

Структура по квантовой физике - одна из самых принципиально замороченных и непростых, и мало кто её со всех сторон в принципе собирал. Поэтому опишем, что из себя представляет эта запись, ведь именно на этой структуре и держится абсолютно всё понимание.

части записи

(потом напишу, что такая-то глава содержит такие-то темы.)

О первой части про квантовую механику в двух словах

Все, что наиболее используемое.

О первой части с основами квантовой механики

Темы теормина и указания их углублений.

О третьей части с задачами

Важнейшая часть, ради которых и сделаны другие части.

приложения

какие вообще приложения я разбирал?

A.5.10 On the History of the Development of Quantum Mechanics

(потом напишу, пока не актуально, вообще тут много разного интересного рассказать можно.)

О развитии взглядов на квантовые системы (???)

Обсудим основные моменты развития квантовой механики.
(тут много вопросов и мне не до них, на них правильнее забить пока что.)

древние подходов к квантовой механике

(!! укажу потом их пользу!!!)
там куча бреда, который не так интересен

первые квантовые теории

хз

Шредингер, Дирак,...

короче, потом мб разберу.

постулаты Бора

постулаты Бора: польза в настоящее время

они вообще нужны или как?

Об открытии таблицы Менделеева (???)

(мб напишу, есть инфа про это, но не до этого. там Мендеев что-то думал, Бор что-то думал, сейчас это супер малоприоритетно, все это поудалял, потом может быть как-то напишу без воды. а может и не напишу, будет оставленный вопрос, о чем я и не сожалею ни капли. плюс тут химию нужно помнить или знать, я на нее же забил полностью.)

Об тупиках в создании и понимании квантовой механики

(с этой стороны посмотрю на историю.)

Об истории ядерной физики

(думаю, это вообще не нужно, так, на самом деле.)

краткая история ядерной физики

резерфорд создавал свои атомы, заметил, что 1/8000 частиц летит назад.
подумав над этом он пришел к модели решения задачи на кулоновском потенциале.
все было механическое описание
резерфорд поставил перед мозли задачу, что определяет длину характеристического рентгеновского излучения?
характеристического рентгеновского излучение - это когда переход между двумя дискретными состояними определяется напрямую структурой.
и это четко выделенные пики, которые с помощью фотопластинки замечаются.
мозли показал, что закон такой-то...
азотная катастрофа.
паули был учеником кронекера.
удвоение спектра можно объяснить тем, что у электрона мог бы быть собственный магнитный момент.
черзе год...
подумали.
прибежали к эренфесту со словами отдавать назад, но ее уже послали.

в письме паули написал, что избавитсяот азотной катострофы можно, если допустить, что в ядре есть кроме протона и электрона есть нейтральные частицы с полуцелым спином. и также они при бетта распаде могут вылетать.

и так паули объяснил азотную катастрофу и непрерывный спектр бетта распада.

ситуация висела до 1932г когда чадвик нашел нейтральный протон - нейтрон.

потом Гоепперт-Майер и Енсен написали про оболочечную модель со спин-орбтальным взаимодействимем

потом производили эксперименты по кулоновскому возбуждению ядер при рассеинии альфа-частиц.

гигантский дипольный резонанс связан с огромным числом колебательных возбуждений.

и там огибающая есть, которая так и называется.

и одночастичные возбуждения есть, но они не часто наблюдаются.

они относятся к коллекстивным возбужедниям.

в 1972 году открыли гигантский квадрупольный резонанс.

дипольный - значит был передан дипольный орбитальный момент, квадрупольный - значит передается орбитальный момент =2, монопольный =0.

1949 M. Goeppert-Mayer, D. Jensen: Оболочечная модель со спин-орбитальным взаимодействием

1950− Эксперименты по кулоновскому возбуждению ядер при рассеянии $\alpha-$
1953 частиц. - ротационные, $E_I \sim \frac{I(I+1)}{2\mathcal{J}}$(десятки k ∋ B)
- колебательные, $E_k \sim \hbar\omega \cdot k$ (M_3B)
- Одночастичные,)несколько M_3B) A. Bohr, B. Mottelson, J. Rainwater
1972 Открытие гигантского квадрупольного резонанса в (e, e') и адронных реакциях
1977 Открытие гигантского монопольного резонанса
1961 Открытие изобар-аналогового резонанса в (p, n)
1979 Открытие гигантского гамов-теллеровского резонанса в (p, n)

он идет благодаря взаимодействим спинов.

происходит в бетта распадах.

также открывались двойные гигантские резонансы.

A.6 Puzzles for Various Occasions

Одна из главных польз квантовой механики в том, что она дает ответы на самые идейно непонятные задачи. Поэтому сразу же после появления общего представления, перейдем к обсуждению самых типичных загадок и тупиков.

A.6.1 Interesting Questions of General QM Just for Fun

(кв теор информ, формализм, математика для квантмеха, то, что интереснее всего. чаще всего именно это используется)

A.6.2 Interesting Questions of Atomic, Nuclear Physics Just for Fun

Про атомы можно задавать много идейных и очень простых вопросов, которые здесь и приведем.

момент количества движения электрона в атоме может любым.

сколько может привнести фотон - сколько угодно.

ЛЛ-140.1 Поляризация фермиона при рассеянии

Для рассеяния частиц со спином 1/2 на частицах со спином 0 определить поляризацию после рассеяния, если до рассеяния она тоже была отлична от нуля.

(в теории об этом будет, тут укажу суть этой идеи)

почему таблица менделеева такая

говорят, бор объяснил это.

я пока не уверен в формулировке вопроса

из чего состоит ядро и почему?

почему альфа распад происходит?

A.6.3 Questions for Those Who Claim They Know QM

Что такое квантование?

(почитаю Тахтаджаяна, пойму, буду спрашивать. пока не понял, почему именно так мы определяем это.)

A.6.4 Conceptual Questions on Quantum Mechanics

зависимость вероятности от частоты измерения

Будет ли уменьшаться вероятность распада нестабильного состояния, если достаточно часто измерять — распадается ли это состояние?

Будет ли уменьшаться вероятность перехода из начального состояния под влиянием фиксированного взаимодействия, если достаточно часто измерять, произошел ли этот переход?

Квантовая теория утверждает: да, что с классической точки зрения кажется невозможным и парадоксальным.

см квантовый парадокс Зенона

связь квантовой механики и энтропии

(?? чет придумал, да не знаю особо)

случайность с точки зрения квантовой механики

интересно

Что будет, если увеличить постоянную Планка?

(подробно напишу, как изменится все важное. про опыт Юнга уже знаю, но про остальное четко сказать пока не могу. мб с формулами отвечу про это)

Записать уравнение Шредингера в искривленном пространстве или в бескоординатном виде?

(мб Тахтаджаян в помощь.)

A.6.5 Fun Technical Puzzles

Тут я укажу типичные хорошие задачи по квантовой механике на тренировку типичных уравнений.

Получить релятивистские поправки к атому водорода (????)

(тут тренироваться еще нужно денёк.)

Требуется вывести формулу

$$\hat{H} = \frac{p^2}{2m} + e\Phi - \frac{\boldsymbol{p}^4}{8m^3c^2} + \frac{e\hbar}{2m^2c^2}\frac{\Phi'(r)}{r}(\boldsymbol{s}\cdot\boldsymbol{L}) + \frac{e\hbar^2}{8m^2c^2}\triangle\Phi$$

Для этого нужно знать, как работать с уравнением Дирака $(\mathcal{P} - mc)\psi = 0$, где $\mathcal{P}_\mu = \mathrm{i}\hbar\partial_\mu - \frac{e}{c}\mathcal{A}_\mu$, подставить $\psi(t,\boldsymbol{r}) = \mathrm{e}^{-\frac{\mathrm{i}}{\hbar}mc^2t}\begin{pmatrix}\varphi(t,\boldsymbol{r})\\ \chi(t,\boldsymbol{r})\end{pmatrix}$ (???? тут пока проблемы), получить, что

$$\chi = \frac{1}{1+\frac{\hat{\epsilon}-e\Phi}{2mc^2}}\frac{(\boldsymbol{\sigma}\cdot\mathcal{P})}{2mc}\varphi \approx \frac{(\boldsymbol{\sigma}\cdot\mathcal{P})}{2mc}\varphi.$$

Дальше сперва найти только лишь нерелятивистское действие через верхнюю компоненту, для этого использовать некоторые формулы векторного анализа:

$$\begin{aligned} S_{\mathrm{NR}} &= \int \mathrm{d}^4x\bar{\psi}(x)(\not{p} - mc)\psi(x) = \int \mathrm{d}t\mathrm{d}^3r\varphi^\dagger\left\{\hat{\epsilon} - e\Phi - \frac{1}{2m}(\boldsymbol{\sigma}\cdot\boldsymbol{P})^2\right\}\varphi \\ &= \int \mathrm{d}t\int \mathrm{d}^3r\varphi^\dagger\left\{\hat{\epsilon} - e\Phi - \frac{\mathcal{P}^2}{2m} + \frac{e\hbar}{2mc}(\boldsymbol{\sigma}\cdot\boldsymbol{\mathcal{H}})\right\}\varphi. \end{aligned}$$

Если подставить в действие первую поправку и преобразовать с помощью векторного анализа и свойств σ-матриц:

$$\begin{aligned} S &\approx \int \mathrm{d}t\int \mathrm{d}^3r\varphi^\dagger\left\{\hat{\epsilon} - e\Phi - \frac{\boldsymbol{p}^2}{2m} + \frac{1}{4m^2c^2}(\boldsymbol{\sigma}\cdot\boldsymbol{p})(\hat{\epsilon}-e\Phi)(\boldsymbol{\sigma}\cdot\boldsymbol{p})\right\}\varphi \\ &\approx \int \mathrm{d}t\int \mathrm{d}^3r\varphi^\dagger\left\{\hat{\epsilon}\left(1+\frac{\boldsymbol{p}^2}{4m^2c^2}\right) - e\Phi - \frac{\boldsymbol{p}^2}{2m} - \frac{e}{4m^2c^2}\left(\Phi\boldsymbol{p}^2 - \mathrm{i}\hbar\{\boldsymbol{\nabla}\Phi\cdot\boldsymbol{p} + \mathrm{i}\boldsymbol{\sigma}\cdot(\boldsymbol{\nabla}\Phi\times\boldsymbol{p})\}\right)\right\}\varphi \\ &\approx \int \mathrm{d}t\int \mathrm{d}^3r\varphi^\dagger_{\mathrm{NR}}\left\{\hat{\epsilon} - e\Phi - \frac{\boldsymbol{p}^2}{2m} + \frac{\boldsymbol{p}^4}{8m^3c^2} - \frac{e\hbar}{4m^2c^2}\boldsymbol{\sigma}\cdot(\boldsymbol{\nabla}\Phi\times\boldsymbol{p}) - \frac{e\hbar^2}{8m^2c^2}\triangle\Phi\right\}\varphi_{\mathrm{NR}}, \end{aligned}$$

где введен φ_{NR} такой, что $\varphi = \left\{1 - \frac{\boldsymbol{p}^2}{8m^2c^2}\right\}\varphi_{\mathrm{NR}}$ и $\boldsymbol{L} = (\boldsymbol{r}\times\boldsymbol{p})$. (??? тут математика, к которой мне еще нужно тренироваться!)

Можно записать проще, явно подставив $\Phi = -\frac{e}{r}$, $\Phi'(r) = \frac{e}{r^2}$, $\triangle\Phi(r) = 4\pi e\delta(\boldsymbol{r})$, в итоге

$$V = -\frac{\boldsymbol{p}^4}{8m^3c^2} + \frac{e^2\hbar}{2m^2c^2}\frac{1}{r^3}(\boldsymbol{s}\cdot\boldsymbol{L}) + \frac{e^2\hbar^2}{2m^2c^2}\pi\delta(\boldsymbol{r}).$$

Это типичная задача на релятивистскую квантовую механику, в первую очередь для нее мы и занимались этой теорией.

Определить уровни энергии атома водорода с учетом тонкой структуры

Ответ - известная формула Зоммерфельда

$$E_{nj} = -\frac{Z^2}{2n^2}\left(\frac{e^2}{a}\right)\left\{1 + \frac{Z^2\alpha^2}{n^2}\left[\frac{n}{j+1/2} - \frac{3}{4}\right]\right\}.$$

(у белоусова порешаю еще!)

Это типичная задача по атомной физике, общефизники на нее ссылаются в книгах (? мб и в задачах). Чтобы вывести ее, нужно владеть техникой атомной физики.

вывести g-фактор электрона, а потом и поправку к нему

дано: (???)

...

Подвох задачи в том, что если к ней фигово подходить, то можно кучу раз это делать и прийти к выводу, что не способен учить квантовую физику. Такая типичная, принципиальная задача квантовой механики.

(тут будет вкратце решение, я просто всё еще тупой пока что)

B Some Mathematics and Physics for QM

Обсудим математические методы, применяемые в квантовой механике.

B.1 Some Mathematical Background

B.1.1 Elements of Functional Analysis

(какое-то введение)

про скалярное произведение скажем пару слов и методы интегрирования обсудим, дальше часто ими будем мы пользоваться.

обзор применений в квантовой физике

гильбертово пространство

свойства:

$$\langle\chi|\psi\rangle = \langle\psi|\chi\rangle^*, \quad \langle\psi|\psi\rangle \geq 0, \quad \langle\psi|\psi\rangle = 0 \leftrightarrow |\psi\rangle = 0$$

любой элемент разложим по базису.

дальше поговрим о проекторе и полноте базиса

$$|\Psi\rangle \xrightarrow{P_n} |\Psi_n\rangle$$

свойства:

$$P_n\,|\Psi_n\rangle = |\Psi_n\rangle \leftrightarrow P_n^2|\Psi\rangle = P_n|\Psi\rangle, \forall|\Psi\rangle \leftrightarrow P_n^2 = P_n$$

и у нас есть очень важный математический инструмент: разложение единицы

$$\hat{1} = \sum_n P_n = \sum_n |n\rangle\langle n|$$

дельта функция

понятно, что это такое, докажем про нее некоторые свойства.

нпр скачок производной.

а также нормировку ее.

это все нужно в задачах

Отнормируйте на дельта-функцию от энергии состояния непрерывного спектра, инфинитные в обе стороны для случая, когда потенциал растет от 0 к константе.

мы знаем свойства:

$$\int\limits_{-\infty}^{\infty} e^{-i(k-k')x}dx = 2\pi\delta\left(k-k'\right)$$

они нам понадобятся для нормировок непрерывного спектра.
она часто возникает при подсчетах интеграла и есть многие свойства интегралов с ней.
тут приведем эти свойства.

B.1.2 Useful Methods of Differential Equations for QM

Laplace Method

Обсудим метод Лапласа решения дифференциальных уравнений.

B.1.3 Special Functions for Quantum Mechanics

(see note on special functions for now, I'll collect statements from it later)

Функции Бесселя $J_m(z), Y_m(z), H_m^{(1,2)}(z), I_m(z), K_m(z)$

(тут все что нужно о них будет)
(!!! применения потом укажу, пока это не раскрыто и это очень плохо)

краткая теория функций Бесселя

Функции Бесселя являются решением диффура (какого? одного?)
И их можно понимать в аналогии с одномерным движением

$1d:$	e^x	e^{-x}	$\cos x$	$\sin x$	e^{ix}	e^{-ix}
$2d:$	$I_m(x)$	$K_m(x)$	$J_m(x)$	$Y_m(x)$	$H_m^{(1)}(x)$	$H_m^{(2)}(x)$

(?? и??? пока не так глубоко въезжаю в это)

определение и свойства Бесселей

(тут мб перепишу с методичками конста, все-таки нужна нормальная теория.
но вообще в матфизе настоящая сборка этого, тут все вкратце)

Функции Инфельда и Макдональда $I_m(z), K_m(z)$

Функции Инфельда и Макдональда являются решением уравнения

$$\psi''(z) + \frac{1}{z}\psi'(z) - \left(1 + \frac{m^2}{z^2}\right)\psi(z) = 0,$$

то есть

$$\psi(z) = A_1 I_m(z) + A_2 K_m(z)$$

Асимптотики при больших значениях аргумента:

$$I_m(z) \approx \frac{1}{\sqrt{2\pi z}}e^z, \quad K_m(z) \approx \sqrt{\frac{\pi}{2z}}e^{-z}, \quad z \gg 1$$

и при малых:

$$I_m(z) \approx \frac{1}{m!}\left(\frac{z}{2}\right)^m, \quad K_m(z) \approx \begin{cases} \frac{(m-1)!}{2}\left(\frac{2}{z}\right)^m, & m \neq 0 \\ \ln\frac{2}{z} - \gamma, & m = 0 \end{cases}, \quad z \ll 1\,,$$

где $\gamma \approx 0.577$ -постоянная Эйлера-Маскерони.

Функция $K_m(z)$ расходится в нуле. Действительно, одно из решений должно так себя вести поскольку вронскиан этого уравнения по формуле Лиувилля-Остроградского с точностью до произвольной постоянной равен 1/x.

(можно подробнее про них и их вид написать)

Функции Бесселя, Неймана Y_m, Ганкеля $H_m^{(1)}, H_m^{(2)}$

функциями Бесселя $J_m(z)$ и Неймана Y_m, либо функциями Ганкеля $H_m^{(1)}, H_m^{(2)}$ являются решением уравнения

$$\psi''(z) + \frac{1}{z}\psi'(z) + \left(1 - \frac{m^2}{z^2}\right)\psi(z) = 0$$

то есть

$$\psi(z) = B_1 J_m(z) + B_2 Y_m(z) = C_1 H_m^{(1)}(z) + C_2 H_m^{(2)}(z)$$

Функции Бесселя и Неймана имеют асимптотики при больших z:

$$J_m(z) \approx \sqrt{\frac{2}{\pi z}}\cos\left(z - \frac{m\pi}{2} - \frac{\pi}{4}\right), \quad Y_m(x) \approx \sqrt{\frac{2}{\pi z}}\sin\left(z - \frac{m\pi}{2} - \frac{\pi}{4}\right), \quad z \gg 1$$

при малых:

$$J_m(z) \approx \frac{1}{m!}\left(\frac{z}{2}\right)^m, \quad Y_m(z) \approx \begin{cases} -\frac{(m-1)!}{\pi}\left(\frac{2}{z}\right)^m, & m \neq 0 \\ -\frac{2}{\pi}\left(\ln\frac{2}{z} - \gamma\right), & m = 0 \end{cases}, \quad x \ll 1$$

И функции Ганкеля определяются как $H_m^{(1,2)}(x) = J_m(x) \pm iY_m(x)$.

Они обе, естественно, сингулярны в нуле, но представляет интерес их асимптотика на бесконечности она соответствует сходящейся и расходящейся цилиндрическим волнам:

$$H_m^{(1,2)}(z) \approx \sqrt{\frac{2}{\pi z}} e^{\pm i(z - m\pi/2 - \pi/4)}, z \gg 1$$

$$H_m^{(1,2)}(z) \approx \begin{cases} \mp i\frac{(m-1)!}{\pi}\left(\frac{2}{z}\right)^m, m \neq 0 \\ \mp\frac{2i}{\pi}\left(\ln\frac{2}{z} - \gamma\right) + 1, m = 0 \end{cases} \quad z \ll 1$$

Переход от одной функции Бесселя к другой

между функциями Бесселя имеются соотношения

$$K_m(x) = \frac{\pi}{2} i^{m+1} H_m^{(1)}(ix) = \frac{\pi}{2}(-i)^{m+1} H_m^{(2)}(-ix),$$

$$J_m(ix) = i^m I_m(x)$$

Функция Эйри

О применениях

Функция Эйри возникает буквально при решении уравнения Шрёдингера под действием постоянной силы (в постоянном электрическом поле) - потенциал $U(x) = Fx$:

$$-\frac{\hbar^2}{2m}\psi''(x) + Fx\psi(x) = E\psi(x)$$

Первым делом, как и раньше, стоит это уравнение обезразмерить.

Обратим внимание, что от энергии E можно тривиально избавиться, сделав дополнительную сдвижку начала координат:

$$z = \frac{x - E/F}{(\hbar^2/2mF)^{1/3}}$$

Такая подстановка приводит уравнение к уравнению Эйри:

$$\psi''(z) - z\psi(z) = 0$$

Его общее решение - произвольная линейная комбинация функций Эйри первого и второго рода:

$$\psi(z) = C_1\,\mathrm{Ai}(z) + C_2\,\mathrm{Bi}(z)$$

Следуя общей логике, в классически разрешённой области решения - растущие и затухающие экспоненты.

Для квантовой механики наиболее интересно решение с затухающей асимптотикой - собственно, функция Эйри - которая обладает следующей асимптотикой:

$\mathrm{Ai}(z) \approx \begin{cases} \frac{1}{2\sqrt{\pi}}\frac{1}{z^{1/4}}\exp\left(-\frac{2}{3}z^{3/2}\right), & z \to +\infty \\ \frac{1}{\sqrt{\pi}}\frac{1}{(-z)^{1/4}}\sin\left(\frac{2}{3}(-z)^{3/2} + \frac{\pi}{4}\right), & z \to -\infty \end{cases}$ Второе линейно независимое решение выбирается из условия, чтобы на $-\infty$ его асимптотика соответствовала косинусу; при этом, разумеется, на $+\infty$ решение - растущая экспонента [8]:

Функция Эйри возникает естественным образом при выводе граничных условий для квазиклассического приближения (мы обсудим это в соответствующем семинаре).

свойства и явление Стокса

(из птф)

Ремарка о комплексной плоскости Имеется несколько тонкостей, связанных с поведением функции Эйри в комплексной плоскости $z \in \mathbb{C}$. Более подробно эти тонкости будут обсуждаться в следуюпих семинарах, а пока просто наметим, в чём они заключаются.

Кажется естественным, что асимптотические выражения можно аналитически продолжать за пределы вещественной оси.

Однако, обратите внимание на то, что асимптотики не представляются однозначными функциями на комплексной плоскости - для их определения требуется проведение разрезов и выделение ветвей.

В то же время сама функция Эйри, разумеется, является однозначной.

Другой такой тонкостью является то, что, например, функция $\mathrm{Ai}(z)$ на $+\infty$ содержит одну экспоненту, а на $-\infty$ -две (в составе синуса), и одно из другого получить аналитическим продолжением невозможно.

Всё это связано с так называемым явлением Стокса.

В действительности, асимптотики работают только в определённых секторах комплексной плоскости, разделённых лучами (они называются линиями Стокса), на которых коэффициенты перед компонентами асимптотики (одна компонента содержит $\exp\left(\frac{2}{3}y^{3/2}\right)$, другая $-\exp\left(-\frac{2}{3}y^{3/2}\right)$) меняются скачком.

На этих линиях выражение в экспоненте является вещественным, так что одна из экспонент является максимально убывающей, а другая - максимально растущей.

За этими наблюдениями стоит интересная разработанная наука, с который некоторые из вас ещё столкнутся в процессе обучения.

комплексный метод перевала

гипергеометрическая функция

Определение

Гипергеометрическая функция в общем случае определяется от p и q параметров и имеет вид:

$$ {}_pF_q\left(a_1,...,a_p;b_1,...,b_q;z\right) = 1+\frac{a_1...a_p}{b_1...b_q}z+\frac{a_1\left(a_1+1\right)a_2\left(a_2+1\right)...a_p\left(a_p+1\right)}{b_1\left(b_1+1\right)b_2\left(b_2+1\right)\cdots b_q\left(b_q+1\right)}\frac{z^2}{2}+\cdots = $$
$$ =\sum_{n=0}^{\infty}\frac{\left(a_1\right)^{(n)}...\left(a_p\right)^{(n)}}{\left(b_1\right)^{(n)}...\left(b_p\right)^{(n)}}\frac{z^n}{n!} $$

Частные важные случаи это ${}_2F_1$ и ${}_1F_1$

Функция ${}_2F_1(a,b;c;z)$

Поговорим про ${}_2F_1$.

Альтернативно её можно определить как регулярное в нуле решение следующего дифференциального уравнения:

$$ z(1-z)f''(z)+(c-(a+b+1)z)f'(z)-abf(z)=0, \quad f(0)=1 $$

Общее решение этого уравнения имеет вид:

(место убедиться в эквивалентности определений)

Можно убедиться, что второе линейно-независимое решение этого уравнения тоже можно выразить через гипергеометрическую функцию.

Общее решение имеет следующий вид (при $c\neq 1$)

$$ f(z)=C_1{}_2F_1(a,b;c;z)+C_2z^{1-c}{}_2F_1(b-c+1,a-c+1;2-c;z) $$

К уравнению такого вида можно свести очень большой класс дифференциальных уравнений.

В действительности, имеется классификация линейных дифференциальных уравнений с дробно-рациональными коэффициентами по их особенностям в комплексной плоскости (особенностями уравнения, записанного в канонической форме $f^{(n)}(z)+p_1(z)f^{(n-1)}(z)+\cdots+p_n(z)f(z)=0$, называются особенности функций $p_k(z)$ -точки, где она обрапается в бесконечность) -в частности, у гипергеометрической функции их ровно три: $z=\{0,1,\infty\}$; и более или менее любое уравнение с тремя особенностями можно свести к гипергеометрическому виду.

Продолжая обсуждение свойств этой функции, отметим, что она не определена при целых отрицательных c (знаменатель зануляется).

Радиус сходимости ряда равен единице, и в действительности у гипергеометрической функции в точке $z = 1$ имеется особенность.

Единственное исключение из этого правила - это когда либо a, либо b - отрицательное целое число: в таком случае, ряд обраывается и превращается в полином конечной степени, имеющий, естественно, бесконечный радиус сходимости.

Последнее замечание будет важно при поиске связанных состояний.

Некоторые свойства гипергеометрической функции

(пишу только то, что применялось в квантовой механике!!! так-то много свойств разных.)

$$ {}_2F_1(a,b;c;z) = \frac{\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)} {}_2F_1(a,b,a+b+1-c,1-z) + \\ + \frac{\Gamma(c)\Gamma(a+b-c)}{\Gamma(a)\Gamma(b)}(1-z)^{c-a-b} {}_2F_1(c-a,c-b;c+1-a-b;1-z) $$

Функция ${}_1F_1(a;b;z)$

На прошлом семинаре обсуждался обший класс гипергеометрических функций ${}_pF_q$;

однако для приложений наиболее часто встречаются именно функции ${}_2F_1$ (обсуждённая на прошлом семинаре) и ${}_1F_1$. Она, естественно, тоже определяется через гипергеометрический ряд [5]:

$$ {}_1F_1(a;b;z) = 1 + \frac{a}{b}z + \frac{a(a+1)}{b(b+1)}\frac{z^2}{2} + \cdots = \sum_{n=0}^{\infty} \frac{a^{(n)}}{b^{(n)}}\frac{z^n}{n!} $$

Кроме того, альтернативное её определение - через решение дифференциального уравнения следуюпего вида:

$$ zf''(z) + (b-z)f'(z) - af(z) = 0, \quad f(0) = 1 $$

тоже выражается через гипергеометрическую функцию [6] : $f^{(2)}(z) = z^{1-b} {}_1F_1(a-b+1;2-b;z)$. Как и с обычной гипергеометрической функцией, несложно видеть, что при целых отрицательных $b = -n$ функция не определена, а при целых отрицательных $a = -n$ она является конечным полиномом степени n. В обшем случае, отношение соседних коэффициентов разложения в ряд ведёт себя как $1/n$, поэтому радиус сходимости этого ряда - бесконечность (в отличии ${}_2F_1$, где радиус сходимости был единичным).

Асимптотическое поведение на бесконечности следуюпее:

$$ {}_1F_1(a;b;z) \approx \frac{\Gamma(b)}{\Gamma(a)} z^{a-b} e^z, \quad z \gg 1 $$

Опять-таки, мы ранее говорили, что всякое уравнение с тремя особенностями сводится к гипергеометрическому виду так и всякое уравнение с коэффициентами, которые представляют собой линейные функции z приводится к Вырожденному гипергеометрическому виду.

B.1.4 Properties of Operators in Quantum Mechanics

одно из важнейших понятий - собственный вектор.
(место про него всей записи)
дисперсия оператора вводится.

$$(\Delta F)^2 \stackrel{\text{def}}{=} \left\langle \Psi \left| (\hat{F} - \bar{F})^2 \right| \Psi \right\rangle, \quad \bar{F} = \langle \Psi | \hat{F} | \Psi \rangle$$

вообще хз, откуда мы достали это.
среднее как-то считается.
а еще собственные числа через матрицу грамма находсятся

коммутационные соотношения

важная модель и есть много на нее задач.
из этого можно даже соотношение неопределенности высрать

$$\Delta A \Delta B \geqslant \frac{\hbar}{2} |\langle C \rangle|$$

(дальше ссылка на соотношение неопределенности, у Киселева это вообще источник его.
а я хз.
просто пока что тут будет расписана его теория)

Операторные тождества

(тут порешаю потом задачи на них)

Тождества с коммутатором

$$[AB, C] = ABC - CAB = ABC - ACB + ACB - CAB = A[B, C] + [A, C]B$$

коммутаторы

Наберем математические методы, которые далее используются часто (для чего?)
Известно соотношение на коммутаторы:

$$[\widehat{\mathrm{A}\mathrm{B}}, \widehat{\mathrm{C}}] = \widehat{\mathrm{A}}[\widehat{\mathrm{B}}, \widehat{\mathrm{C}}] + |\widehat{\mathrm{A}}, \widehat{\mathrm{C}}|\widehat{\mathrm{B}}$$
$$|\widehat{\mathrm{A}}, \widehat{\mathrm{B}\mathrm{C}}| = \widehat{\mathrm{B}}|\widehat{\mathrm{A}}, \widehat{\mathrm{C}}| + [\widehat{\mathrm{A}}, \widehat{\mathrm{B}}]\widehat{\mathrm{C}}$$

Применения тождеств с коммутаторами

(тут их укажу)

$$\left[\frac{\partial}{\partial x}, x\right]$$

делаем как-то так

$$\left(\frac{\partial}{\partial x} x - x \frac{\partial}{\partial x}\right) \Psi = \frac{\partial}{\partial x}(x\Psi) - x\frac{\partial \Psi}{\partial x} = \Psi + x\frac{\partial \Psi}{\partial x} - x\frac{\partial \Psi}{\partial x} = \Psi$$

другие еще пространства и их свойства

проектор

На языке операторов то, что мы представляем, записывается так:

$$|\Psi\rangle \xrightarrow{P_n} |\Psi_n\rangle$$

$$P_n = |n\rangle\langle n|$$

$$\mathbb{1} = \sum_n P_n = \sum_n |n\rangle\langle n|$$

преобразование операторов

подробно вся та же теория операторов.
преобразовываются они так:

$$\hat{A}' |\psi'\rangle = \hat{U}_s \hat{A} |\psi\rangle = \hat{U}_s \hat{A} \hat{U}_s^\dagger |\psi'\rangle \quad \hat{A}' = \hat{U}_s \hat{A} \hat{U}_s^\dagger$$

унитарные операторы

Посмотрим, какими свойствами обладают унитарные операторы и укажем, где это используется в физике.

Основные свойства (???)

$$\hat{A}|\lambda\rangle = \lambda|\lambda\rangle$$

$$\langle A\lambda|A\lambda\rangle = \langle \lambda|A^\dagger A\lambda\rangle = \langle\lambda|\lambda\rangle$$

$$\lambda^*\lambda\langle\lambda|\lambda\rangle = \langle\lambda|\lambda\rangle \quad \to \quad \lambda^*\lambda = 1$$

$$\lambda = \mathbf{e}^{i\phi}, \quad \phi \in \mathbb{R}(\mathrm{mod}[2\pi])$$

По сути мы доказали, что унитарный оператор представим в виде

$$\hat{A} = e^{\mathrm{i}\hat{\varphi}}, \quad \hat{\phi} = \hat{\phi}^\dagger,$$

наблюдаемые

если есть зависимость от параметра, то
можно пользоваться соотношениями *Фейнмана-Хеллмана*

$$\frac{\partial f_n}{\partial \lambda} = \left\langle n \left| \frac{\partial \hat{f}}{\partial \lambda} \right| n \right\rangle$$

Собственные функции и разложения

такое встречается и по сути это главное в анализе Гамильтониана!

вообще, по базису оператор раскладывать очень важно вроде бы, УМФ в том числе об этом, но я так и на освоил инструменты, как мы делаем все-таки это???

Другие методы с операторами

(остальное, что нужно или может быть нужно, тут.)

не разу не пригодилось, но в принципе звучит полезно:

можем раскладывать

$$f(\hat{O}) = f(0)\hat{\mathbb{I}} + \sum_{n=1}^{\infty} \frac{f^{(n)}(0)}{n!}\hat{O}^n$$

B.1.5 Matrices for Quantum Mechanics

мб про частичный след и тензорное произведение тут напишу (со ссылками на то, где это нужно).

(I'll shift it later to the theoretical sections!!!)

Матрицы Паули в квантовой механике

Основные свойства матриц Паули

Посмотрим на определение свойства матриц Паули.

Матрицы Паули по определению есть

$$\hat{\sigma}^1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \hat{\sigma}^2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \hat{\sigma}^3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

Их свойства:

$$\hat{\sigma}^\alpha \hat{\sigma}^\beta = \delta_{\alpha\beta}\hat{\mathbb{I}} + i\epsilon_{\alpha\beta\gamma}\hat{\sigma}^\gamma,$$

где $\alpha, \beta, \gamma \in \{x, y, z\}$.

доказывается легко просто вручную, но есть способ (в котором я забыл, что эти скобки значат? и который я пока не освоил, но он прямо лучший, мб.

хз.

короче, потом додумаю):

$$[\sigma_a, \sigma_b] = 2i\varepsilon_{abc}\sigma_c \qquad \{\sigma_a, \sigma_b\} = 2\delta_{ab}I,$$
$$[\sigma_a, \sigma_b] + \{\sigma_a, \sigma_b\} = (\sigma_a\sigma_b - \sigma_b\sigma_a) + (\sigma_a\sigma_b + \sigma_b\sigma_a)$$
$$2i\varepsilon_{abc}\sigma_c + 2\delta_{ab}I = 2\sigma_a\sigma_b$$

Также

$$e^{ia(\hat{n}\cdot\vec{\sigma})} = I\cos a + i(\hat{n}\cdot\vec{\sigma})\sin a$$

(тут я скипаю методы, вообще математику всю я потом думать буду)

$$\exp\left(ian_\alpha\hat{\sigma}^\alpha\right) = \cos a + in_\alpha\hat{\sigma}^\alpha \sin a$$

First let's see, that if $|\hat{n}| = 1$, we have

$$(\hat{n}\cdot\vec{\sigma})^{2p}=I.$$

If we sum three matrices $n_\alpha\sigma^\alpha$, we will have

$$M=\begin{pmatrix} n_3 & n_1-in_2 \\ n_1+in_2 & -n_3 \end{pmatrix}$$

and after multiplying $M\cdot M$, using $n_1^2+n_2^2+n_3^2=1$, we have $M^2=I$, so $(\hat{n}\cdot\vec{\sigma})^{2p}=I$. And this is the reason why

$$(\hat{n}\cdot\vec{\sigma})^{2q+1}=\hat{n}\cdot\vec{\sigma}$$

(нужно кстати научиться работать с экспонентой)

$$e^{ia(\hat{n}\cdot\vec{\sigma})}=\sum_{k=0}^{\infty}\frac{i^k[a(\hat{n}\cdot\vec{\sigma})]^k}{k!}=\sum_{p=0}^{\infty}\frac{(-1)^p(a\hat{n}\cdot\vec{\sigma})^{2p}}{(2p)!}+i\sum_{q=0}^{\infty}\frac{(-1)^q(a\hat{n}\cdot\vec{\sigma})^{2q+1}}{(2q+1)!}=$$
$$=I\sum_{p=0}^{\infty}\frac{(-1)^pa^{2p}}{(2p)!}+i(\hat{n}\cdot\vec{\sigma})\sum_{q=0}^{\infty}\frac{(-1)^qa^{2q+1}}{(2q+1)!}$$

interesting that

$$[\sigma_a,\sigma_b]+\{\sigma_a,\sigma_b\}=(\sigma_a\sigma_b-\sigma_b\sigma_a)+(\sigma_a\sigma_b+\sigma_b\sigma_a)$$

$$(\vec{a}\cdot\vec{\sigma})(\vec{b}\cdot\vec{\sigma})=(\vec{a}\cdot\vec{b})I+i(\vec{a}\times\vec{b})\cdot\vec{\sigma}$$

we need them because

$$\hat{H}=c\cdot\hat{\mathrm{I}}+b_x\sigma^x+b_y\sigma^y+b_z\sigma^z=c+(b,\hat{\sigma})$$

в общем, тема не раскрыта, написано много, а нужно от сюда хз, что, все нужно переусваивать, и мощь матриц паули я так и не понял.

Другие свойства матриц Паули

Тензорные произведения есть:

$$\hat{\sigma}_1^x\otimes\hat{\sigma}_2^x=\begin{pmatrix}0&0&0&1\\0&0&1&0\\0&1&0&0\\1&0&0&0\end{pmatrix},\quad \hat{\sigma}_1^y\otimes\hat{\sigma}_2^y=\begin{pmatrix}0&0&0&-1\\0&0&1&0\\0&1&0&0\\-1&0&0&0\end{pmatrix},\quad \hat{\sigma}_1^y\otimes\hat{\sigma}_2^y=\begin{pmatrix}1&0&0&0\\0&-1&0&0\\0&0&-1&0\\0&0&0&1\end{pmatrix},$$

что легко выводится перемножением.

(а как явно будет в этом пространстве базис выглядеть?)

Появление матриц Паули

Покажем, каким образом появились матрицы Паули?

(пока завис вопрос, забыл немного, Киселев там выводил, потом сюда напишу. мб там несколько будет выводов?)

О применениях Матриц Паули

Во-первых, матрицы Паули нужны в записи оператора спина.
(формулы)
(здесь разберем подробно их пользу)

B.1.6 Tensor Operators

(I'll shift it later to the theoretical sections!!!)
(the idea is to give an intro to just mathematical side of this, but I'll write it first in the note on algebra, it is a very big topic)

определение и свойства

Дипольные сферические функции и циклические координаты $\mathcal{D}^1_{m',m}(\alpha,0,\beta)$

m'	1	0	-1
1	$\exp(-i(\alpha+\beta))$	0	0
0	0	1	0
-1	0	0	$\exp(i(\alpha+\beta))$

и еще таблица

m	$Y_{1,m}$	$rY_{1,m}$	r_m	$\vec{e}_m$
+1	$-\sqrt{\frac{3}{8\pi}}\sin\theta e^{i\phi}$	$-\sqrt{\frac{3}{8\pi}}(x+iy)$	$-\frac{1}{\sqrt{2}}(x+iy)$	$-\frac{1}{\sqrt{2}}(\vec{e}_x+i\vec{e}_y)$
0	$\sqrt{\frac{3}{4\pi}}\cos\theta$	$\sqrt{\frac{3}{4\pi}}z$	z	$\vec{e}_z$
-1	$\sqrt{\frac{3}{8\pi}}\sin\theta e^{-i\phi}$	$\sqrt{\frac{3}{8\pi}}(x-iy)$	$\frac{1}{\sqrt{2}}(x-iy)$	$\frac{1}{\sqrt{2}}(\vec{e}_x-i\vec{e}_y)$

r_m - циклические координаты радиуса-вектора;
p_m - циклические координаты импульса; J_m - циклические координаты углового момента; $J_{+1}=-\frac{1}{\sqrt{2}}J_+, \quad J_0=J_z, \quad J_{-1}=\frac{1}{\sqrt{2}}J_-$
Пусть $\Phi=T\Psi$. $R(\omega)\Phi=R(\omega)TR^{-1}(\omega)R(\omega)\Psi$
Если $\Psi=\Psi_{jm}$, то $R(\omega)\Psi_{jm}=\sum\limits_{n=-j}^{j}\mathcal{D}^j_{n,m}(\omega)\Psi_{jn}$

Набор из $(2k+1)$ операторов $T^k_q(k$ -целое или полуцелое неотрицательное число, $q=-k,-k+1,...,k-1,k)$ называется тензорным оператором ранга k, если при повороте тела (или системы координат) операторы T^k_q преобразуются так же как собственные функции операторов J^2 и $J_0\psi_{kq}$:

$$R(\omega)T^k_qR^{-1}(\omega)=\sum_{q'=-k}^{k}\mathcal{D}^k_{q',q}(\omega)T^k_{q'}$$

Примеры: ранг $k=1$ - операторы координаты, импульса, углового момента (их циклические координаты); ранг $k=L$ -сферические функции Y_{LM}, $M=-L,-L+1,...,L-1,L$

Покажите, что линейная комбинация тензорных операторов A^k и B^k ранга k есть тензорный оператор $\left(cA^k_q+dB^k_q, c \text{ и } d \text{ -числа}\right)$.

Теорема Вигнера-Эккарта

тут тупо по математике посмотрим все.
мб даже перекину в строгую квантовую механику.

формулировка

(потом)

$$\left\langle j'm' \left| T^k_q \right| jm \right\rangle = (-1)^{2k} \frac{\langle jmkq|j'm'\rangle}{\sqrt{2j'+1}} \left\langle j' \left\| T^k \right\| j \right\rangle$$

доказательство

(?? и в чем её идея???)

$$\begin{aligned}
\left\langle j'm' \left| T^k_q \right| jm \right\rangle &= \int \psi^*_{j'm'}(x) T^k_q(x) \psi_{jm}(x) dx = \\
&= \int \left(R(\omega)\psi_{j'm'}(x)\right)^* R(\omega) T^k_q(x) R^{-1}(\omega) R(\omega) \psi_{jm}(x) dx' = \\
&= \sum_{n',q',n} \int \overline{\mathcal{D}}^{j'}_{n',m'}(\omega) \psi^*_{j'm'}(x) \mathcal{D}^k_{q',q}(\omega) T^k_{q'}(x) \mathcal{D}^j_{n,m}(\omega) \psi_{jn}(x) dx = \\
&= \sum_{n',q',n} \overline{\mathcal{D}}^{j'}_{n',m'}(\omega) \mathcal{D}^k_{q',q}(\omega) \mathcal{D}^j_{n,m}(\omega) \left\langle j'n' \left| T^k_{q'} \right| jn \right\rangle .
\end{aligned}$$

Здесь мы (???? что сделали?? повращали зачем-то пространство???)

из какого-то домашнего задания:

$$\iiint \overline{\mathcal{D}}^{j}_{m,n}(\alpha,\beta,\gamma) \mathcal{D}^{j_1}_{m_1,n_1}(\alpha,\beta,\gamma) \mathcal{D}^{j_2}_{m_2,n_2}(\alpha,\beta,\gamma) \sin\beta d\beta d\gamma d\alpha =$$

$$= \frac{8\pi^2}{2j+1} \langle j_1 m_1 j_2 m_2 | jn \rangle \langle j_1 n_1 j_2 n_2 | jm \rangle$$

$$8\pi^2 \left\langle j'm' \left| T^k_q \right| jm \right\rangle = \langle jmkq|j'm'\rangle \sum_{n',q',n} \frac{8\pi^2}{2j'+1} \langle jnkq'|j'n'\rangle \left\langle j'n' \left| T^k_{q'} \right| jn \right\rangle$$

Матричный элемент тензорного оператора, вычисленный в обкладках функций с определёнными значениями j и m, можно представить в виде произведения коэффициента Клебша-Гордана и приведённого матричного элемента, который не зависит от магнитных квантовых чисел.

(??)

О применениях теоремы Вигнера-Эккарта

(?? хз)

Покажем простейшие случаи, где используется теорема Вигнера-Эккарта.

1.

Правила отбора по угловому моменту: $\triangle(j,k,j')$ и $m+q=m'$.

2.

Коэффициенты пересвязки $\left(\psi'_{jm}, \psi_{jm}\right) = \left(\psi'_{jm}, I\psi_{jm}\right) \sim \langle jm00|jm\rangle = 1$.

3.

Вероятность перехода системы из состояния $|j_1 m_1\rangle$ в состояние $|j_2 m_2\rangle$ под действием тензорного оператора T^k_q:

$$\frac{1}{2j_1+1}\sum_{m_1,m_2}\left|\left\langle j_2m_2\left|\sum_q T^k_q\right|j_1m_1\right\rangle\right|^2=\frac{1}{2j_1+1}\sum_{m_1,m_2,q_1,q_2}\langle j_1m_1kq_1|j_2m_2\rangle\times$$
$$\times\langle j_1m_1kq_2|j_2m_2\rangle\frac{1}{2j_2+1}\left\langle j_2\left\|T^k\right\|j_1\right\rangle^*\left\langle j_2\left\|T^k\right\|j_1\right\rangle=\frac{1}{2j_1+1}\left|\left\langle j_2\left\|T^k\right\|j_1\right\rangle\right|^2$$

Докажите эту формулу и вычислите (S и T - тензорные операторы)

$$\frac{1}{2j_1+1}\sum_{m_1,m_2}\left|\left\langle j_2m_2\left|\sum_{q_1}T^{k_1}_{q_1}+\sum_{q_2}S^{k_2}_{q_2}\right|j_1m_1\right\rangle\right|^2\text{ при }k_1\neq k_2$$

Тензорное произведение тензорных операторов

теория

(какие-то выгрузки, я хз вообще, мб когда-то посмотрю)

$$\left[U^{k_1}\times V^{k_2}\right]^k_q\equiv\sum_{q_1,q_2}\langle k_1q_1k_2q_2|kq\rangle\,U^{k_1}_{q_1}V^{k_2}_{q_2}$$

$$R(\omega)\left[U^{k_1}\times V^{k_2}\right]^k_qR^{-1}(\omega)=\sum_{q_1,q_2}\langle k_1q_1k_2q_2|kq\rangle\sum_{r_1,r_2}\mathcal{D}^{k_1}_{r_1,q_1}(\omega)\mathcal{D}^{k_2}_{r_2,q_2}(\omega)U^{k_1}_{r_1}V^{k_2}_{r_2}=$$

$$=\sum_{q_1,q_2}\frac{\langle k_1q_1k_2q_2|kq\rangle}{\sum\limits_{r_1,r_2}U^{k_1}_{r_1}V^{k_2}_{r_2}\sum\limits_{l,r}}\langle k_1r_1k_2r_2|lr\rangle\,\underline{\langle k_1q_1k_2q_2|lq\rangle}\mathcal{D}^l_{r,q}(\omega)=$$

$$=\sum_{r_1,r_2,r}\langle k_1r_1k_2r_2|kr\rangle\,U^{k_1}_{r_1}V^{k_2}_{r_2}\mathcal{D}^r_{r,q}(\omega)=\sum_r\mathcal{D}^r_{r,q}(\omega)\left[U^{k_1}\times V^{k_2}\right]^k_r$$

$$\left\langle aj'm'\left|\left[U^{k_1}\times V^{k_2}\right]^k_q\right|bjm\right\rangle=(-)^{2k}\frac{\langle jmkq|j'm'\rangle}{\sqrt{2j'+1}}\left\langle aj'\left\|\left[U^{k_1}\times V^{k_2}\right]^k\right\|bj\right\rangle$$

$$(-)^{2k}\left\langle aj'\left\|\left[U^{k_1}\times V^{k_2}\right]^k\right\|bj\right\rangle=\sqrt{2j'+1}\sum_{mq}\langle jmkq|j'm'\rangle\left\langle aj'm'\left|\left[U^{k_1}\times V^{k_2}\right]^k_q\right|bjm\right\rangle=$$

$$=\sqrt{2j'+1}\sum_{mq}\langle jmkq|j'm'\rangle\sum_{q_1q_2}\langle k_1q_1k_2q_2|kq\rangle\left\langle aj'm'\left|U^{k_1}_{q_1}V^{k_2}_{q_2}\right|bjm\right\rangle=$$

$$=\sqrt{2j'+1}\sum_{mq}\sum_{q_1q_2}\sum_{cJM}\langle jmkq|j'm'\rangle\langle k_1q_1k_2q_2|kq\rangle\left\langle aj'm'\left|U^{k_1}_{q_1}\right|cJM\right\rangle\left\langle cJM\left|V^{k_2}_{q_2}\right|bjm\right\rangle=$$

$$=\sqrt{2j'+1}\sum_{mq}\sum_{q_1q_2}\sum_{cJM}\langle jmkq|j'm'\rangle\langle k_1q_1k_2q_2|kq\rangle\times$$

$$\times(-)^{2k_1}\frac{\langle JMk_1q_1|j'm'\rangle}{\sqrt{2j'+1}}\left\langle aj'\left\|U^{k_1}\right\|cJ\right\rangle(-)^{2k_2}\frac{\langle jmk_2q_2|JM\rangle}{\sqrt{2J+1}}\left\langle cJ\left\|U^{k_1}\right\|bj\right\rangle=$$

$$=(-)^{2(k_1+k_2)}\sqrt{2j'+1}(-)^{j+k+j'}\sum_{cJ}\left\{\begin{array}{ccc}k_1&k_2&k\\j&j'&J\end{array}\right\}\left\langle aj'\left\|U^{k_1}\right\|cJ\right\rangle\left\langle cJ\left\|V^{k_2}\right\|bj\right\rangle$$
$$(-)^{2k}=(-)^{2(k_1+k_2)}$$

Коммутационные соотношения $J_0, J_\pm$ с тензорными операторами

$$R(\omega)T^k_q R^{-1}(\omega) = \sum_{r=-k}^{k} T^k_r \mathcal{D}^k_{r,q}(\omega)$$
$$\mathcal{D}^k_{r,q}(\omega) = (\psi_{j=k,m=r}, \exp(i\gamma J_0)\exp(i\beta J_y)\exp(i\alpha J_0)\,\psi_{j=k,m=q})$$

Покажите, рассмотрев бесконечно-малые повороты вокруг координатных осей, что (неприводимые) тензорные операторы должны удовлетворять коммутационным соотношениям

$$\left[J_0, T^k_q\right]_- = qT^k_q$$
$$\left[J_\pm, T^k_q\right]_- = \sqrt{(k\mp q)(k\pm q+1)}T^k_{q\pm1}$$

приведенные матричные элементы

(уже была эта часть теории выше, я все равно хз про это все)

$$Y_{l_1,m_1}(\theta,\phi)Y_{l_2,m_2}(\theta,\phi) = \sum_l \sqrt{\frac{(2l_1+1)(2l_2+1)}{4\pi(2l+1)}}\langle l_1m_1l_2m_2|lm\rangle\langle l_10l_20|l0\rangle Y_{l,m}(\theta,\phi)$$

$$\iint Y^*_{l,m}(\theta,\phi)Y_{l_2,m_2}(\theta,\phi)Y_{l_1,m_1}(\theta,\phi)\sin\theta d\theta d\phi = \sqrt{\frac{(2l_1+1)(2l_2+1)}{4\pi}}\frac{\langle l_1m_1l_2m_2|lm\rangle}{\sqrt{2l+1}}\langle l_10l_20|l0\rangle$$

$$\langle l\,\|Y_{l_2}\|\,l_1\rangle = \sqrt{\frac{(2l_1+1)(2l_2+1)}{4\pi}}\langle l_10l_20|l0\rangle; \quad \langle l\|1\|l_1\rangle = \delta(l-l_1)\sqrt{2l_1+1}$$

"Конструктор" для тензорных операторов

$$\left[U^{k_1}\times V^{k2}\right]^k_q = \sum_{q_1=-k_1}^{k_1}\sum_{q_2=-k_2}^{k_2}\langle k_1q_1k_2q_2|kq\rangle U^{k_1}_{q_1}V^{k_2}_{q_2}$$

$$\left\langle aj'\|\left[U^{k_1}\times V^{k_2}\int^k\|bj\right\rangle = (-)^{j+k+j'}\sqrt{2j'+1}\sum_{cJ}\left\{\begin{array}{ccc} k_1 & k_2 & k \\ j & j' & J\end{array}\right\}\left\langle aj'\left\|U^{k_1}\right\|cJ\right\rangle\left\langle cJ\left\|V^{k_2}\right\|bj\right\rangle$$

Скалярное произведение тензорных операторов

$$\left(U^k, V^k\right) \equiv \sum_{g=-k}^{k}(-)^qU^k_{-q}V^k_q$$

$$\left\langle bj'\left\|\left(U^k,V^k\right)\right\|aj\right\rangle = \frac{\delta(j'-j)}{\sqrt{2j+1}}\sum_{c,j_1}(-)^{j'-j_1}\left\langle bj'\left\|U^k\right\|cj_1\right\rangle\left\langle cj_1\left\|V^k\right\|aj\right\rangle$$

$$\left\langle bj'\|(\vec{A},\vec{J})\|aj\right\rangle = \frac{\delta(j'-j)}{\sqrt{2j+1}}\sum_{c,j_1}(-)^{j'-j_1}\left\langle bj'\|\vec{A}\|cj_1\right\rangle\left\langle cj_1\|\vec{J}\|aj\right\rangle =$$

$$= \frac{\delta(j'-j)}{\sqrt{2j+1}}\sum_{c,j_1}(-)^{j'-j_1}\left\langle bj'\|\vec{A}\|cj_1\right\rangle\delta(c-a)\delta(j_1-j)\sqrt{j(j+1)(2j+1)} =$$

$$= \delta\left(j'-j\right)\sqrt{j(j+1)}\left\langle bj'\|\vec{A}\|aj\right\rangle$$

$$= \delta\left(j'-j\right)\sqrt{j(j+1)}\left\langle bj'\|\vec{A}\|aj\right\rangle$$

в итоге:

$$\langle bj\|\vec{A}\|aj\rangle = \frac{1}{\sqrt{j(j+1)}}\langle bj\|(\vec{A},\vec{J})\|aj\rangle, \quad j>0$$

схемы связи тензорных операторов

Тензорное взаимодействие

$$V\left(r_{1,2}\right) = \left[\frac{\left(\vec{\sigma}_1,\vec{r}_{1,2}\right)\left(\vec{\sigma}_2,\vec{r}_{1,2}\right)}{r_{1,2}^2} - \frac{1}{3}\left(\vec{\sigma}_1,\vec{\sigma}_2\right)\right], \quad \vec{r}_{1,2} = \vec{r}_1 - \vec{r}_2$$

$$\left(\vec{\sigma}_1,\vec{r}_{1,2}\right)\left(\vec{\sigma}_2,\vec{r}_{1,2}\right) = 3\left[\sigma_1^1\times r_{1,2}^1\right]_0^0\left[\sigma_2^1\times r_{1,2}^1\right]_0^0 = 3\left[\left[\sigma_1^1\times r_{1,2}^1\right]^0\times\left[\sigma_2^1\times r_{1,2}^1\right]^0\right]_0^0 =$$

$$= 3\sum_{\lambda=0}^{2}(2\lambda+1)\left\{\begin{array}{ccc}1&1&0\\1&1&0\\\lambda&\lambda&0\end{array}\right\}\left[\left[\sigma_1^1\times\sigma_2^1\right]^\lambda\times\left[r_{1,2}^1\times r_{1,2}^1\right]^\lambda\right]_0^0 =$$

$$\lambda = 1: \quad \left[r_{1,2}^1\times r_{1,2}^1\right]^1 \sim \left[\vec{r}_{1,2}\times\vec{r}_{1,2}\right] = 0$$

$$\lambda = 0: \quad 3\left[\sigma_1^1\times\sigma_2^1\right]_0^0\left[r_{1,2}^1\times r_{1,2}^1\right]_0^0\frac{1}{3} = \frac{1}{3}\left(\vec{\sigma}_1,\vec{\sigma}_2\right)\left(\vec{r}_{1,2},\vec{r}_{1,2}\right) = \frac{1}{3}\left(\vec{\sigma}_1,\vec{\sigma}_2\right)r_{1,2}^2$$

$$= 3\left[\left[\sigma_1^1\times\sigma_2^1\right]^2\times\left[r_{1,2}^1\times r_{1,2}^1\right]^2\right]_0^0 5\left\{\begin{array}{ccc}1&1&0\\1&1&0\\2&2&0\end{array}\right\}$$

$$\left[\sigma_1^1\times\sigma_2^1\right]_m^2 = \Sigma_m^2, \quad \left[r_{1,2}^1\times r_{1,2}^1\right]_m^2 \sim r_{1,2}^2 Y_{2,m}\left(\theta_{1,2},\phi_{1,2}\right)$$

симметричные операторы

Переставим частицы в функции $\varphi(X)$

$$\left[DP^{-1}\varphi\right](X) = \int D\left(X,X'\right)\varphi\left(P^{-1}X'\right)dX' =$$
$$\text{замена переменных} \quad X'\to PX', \quad d\left(PX'\right) = dX'$$
$$= \int D\left(X,PX'\right)\varphi\left(X'\right)dX'$$
$$\left[PDP^{-1}\varphi\right](X) = \int D\left(PX,PX'\right)\varphi\left(X'\right)dX'$$

Ядро $D\left(PX,PX'\right)$ соответствует оператору PDP^{-1}, и наоборот.

Чтобы D не зависел от способа нумерации частиц, надо потребовать

$$D\left(PX,PX'\right) = D\left(X,X'\right) \text{ или } PDP^{-1} = D$$
$$PD = DP$$
$$PH - HP = 0 \text{ для любых перестановок } P.$$

действие на волновую функцию

T - транспозиция (перестановка между двумя неравными элементами).
$[H,T]_- = 0$.

$$T\varphi\left(x_1,x_2,...,x_N\right)=\lambda\varphi\left(x_1,x_2,...,x_N\right)$$
$$T^2\varphi\left(x_1,x_2,...,x_N\right)=\lambda^2\varphi\left(x_1,x_2,...,x_N\right)=\varphi\left(x_1,x_2,...,x_N\right),$$
$$\lambda^2=1,\quad \lambda=\pm1$$
$$\lambda=1:\quad T\varphi=\varphi,\quad P\varphi=\varphi$$
$$\lambda=-1:\quad T\varphi=-\varphi,\quad P\varphi=(-1)^P\varphi$$

$(-1)^P$ -четность перестановки (функция перестановки).

$$P\varphi=\varphi:\begin{cases}\text{симметричные функции; статистика "Бозе-Эйнштейна";}\\ \text{спин - ноль или целый; частицы - "бозоны".}\end{cases}$$
$$P\varphi=(-1)^P\varphi:\begin{cases}\text{антисимметричные функции; статистика "Ферми-Дирака";}\\ \text{спин - полуцелый; частицы - "фермионы".}\end{cases}$$

Симметричный одночастичный оператор

$$A-\ \text{одночастичный оператор};\quad A\rightleftharpoons A\left(x,x'\right)$$

A_j действует на j -ую частицу;

$$A_j\left(X,X'\right)=A\left(x_j,x'_j\right)\prod_{k\neq j}\delta\left(x'_k-x_k\right)$$

Если оператором P поменять местами j и i в $(x_1,...,x_N)$ и в $(x'_1,...,x'_N)$, то

$$A_j\left(PX,PX'\right)=A\left(x_i,x'_i\right)\prod_{k\neq i}\delta\left(x_k-x'_k\right)=A_i\left(X,X'\right)=A_{Pj}\left(X,X'\right)$$
$$PA_jP^{-1}=A_{Pj}$$
$$P\sum_{j=1}^{N}A_jP^{-1}=\sum_{j=1}^{N}A_{Pj}=\sum_{j=1}^{N}A_j$$
$$\mathfrak{A}\equiv\sum_{j=1}^{N}A_j$$
$$P\mathfrak{A}P^{-1}=\mathfrak{A}$$

Симметричный двухчастичный оператор

пока что я хз, что он делает и зачем он.
B действует на $\varphi(x,y)$

$$B\rightleftharpoons B\left(x,y;y',x'\right),\ \text{рассматриваем только:}\quad B\left(x,y;y',x'\right)=B\left(y,x;x',y'\right)$$

$$B_{j_1,j_2}\left(X,X'\right)=B\left(x_{j_1},x_{j_2};x'_{j_2},x'_{j_1}\right)\prod_{i\neq j_1,j_2}\delta\left(x'_i-x_i\right)$$

$$B_{j_2,j_1}\left(X,X'\right)=B_{j_1,j_2}\left(X,X'\right)$$

$$B_{j_1,j_2}\left(PX,PX'\right)=B_{Pj_1,Pj_2}\left(X,X'\right)\quad\rightleftharpoons\quad PB_{j_1,j_2}P^{-1}=B_{Pj_1,Pj_2}$$

$$\mathfrak{B} \equiv \sum_{1\le j_1<j_2\le N} B_{j_1,j_2} = \frac{1}{2}\sum_{1\le j_1,j_2\le N; j_1\ne j_2} B_{j_1,j_2}$$

$$P\mathfrak{B}P^{-1} = \frac{1}{2}\sum_{1\le j_1,j_2\le N; j_1\ne j_2} B_{Pj_1,Pj_2} = \frac{1}{2}\sum_{1\le j_1,j_2\le N; j_1\ne j_2} B_{j_1,j_2}$$

$$P\mathfrak{B}P^{-1} = \mathfrak{B}$$

$$\mathfrak{S}^{(s)} = \frac{1}{s!}\sum_{1\le j_1,j_2,\dots,j_s\le N; j_\alpha\ne j_\beta} S_{j_1,j_2,\dots,j_s}$$

B.1.7 Mathematical Analysis for Quantum Physics

также неплохо в отдельном месте разобраться с тем, как решаем мы просто математические задачи.

и тут основные методы решения я запишу.

обзор применений в квантовой физике

гипергеометрическая функция

обзор ее применений

вкратце теория

гипергеометрическая функция и атом водорода

приведем эту связь.

полиномы Эрмита

обзор ее применений

в линейном осцилляторе решение как раз через них и идет.

$$H_n(z) = (-1)^n e^{z^2}\frac{d^n}{dz^n}\left(e^{-z^2}\right)$$

вкратце теория

B.1.8 Integrals

пока просто буду собирать, потом пойму, что в каком месте нужно

$$e^{-iA^2} = \frac{e^{i\pi/4}}{\sqrt{\pi}}\int\limits_{-\infty}^{\infty} dz e^{iz^2-2izA}$$

обзор применений ТФКП в квантовой физике

метод перевала

суть метода перевала

Пусть зафиксирован некоторый контур; и нам требуется найти асимптотики функции $y(x \to \pm\infty)$. Эту задачу отлично решает метод перевала, который применяется к интегралам вида:

$$y = \int\limits_C A(z)e^{\Phi(z)}dz$$

С вещественным методом перевала мы уже сталкивались; если функция $\Phi(z)$ чисто вещественна на контуре интегрирования, то достаточно найти максимумы этой функции $\Phi'(z_0) = 0$, разложиться квадратично вблизи этих максимумов (а медленную огибающую $A(z)$ можно просто взять в максимуме $A(z_0)$). Метод перевала в комплексной плоскости базируется на этой же простой идее, и он использует то хорошее свойство комплексных интегралов от аналитических функций, а именно - возможность модифицировать контур интегрирования.

Таким образом, для асимптотической оценки интеграла всегда модифицировать контур так, чтобы уходить только по линиям постоянной фазы $\mathrm{Im}\Phi\ (z) = \mathrm{const}$.

Обратим внимание, что линии постоянной фазы тождественно совпадают с линиями жаискорейшего спуска, то есть с направлением $\nabla Re\Phi$.

реализация метода перевала

??? пойму его, потом потренируюсь.

(по птф пока что алгоритм выписал)

Шаг первый Сперва требуется найти положение так называемых седловых точек $^{13}\Phi'(z_0) = 0$. В напем случае есть функция $\Phi(t) = xt - \frac{t^3}{3} \to \Phi' = x - t^2 = 0$. При $x > 0$, имеется пара седловых точек на вещественной оси $t_{1,2} = \pm\sqrt{x}$; при $x < 0$ имеется пара седловых точек на мнимой оси $t_{3,4} = \pm i\sqrt{|x|}$. Определим сразу значения функции в этих седловых точках:

$$\Phi(t) = \begin{cases} \pm\frac{2}{3}x^{3/2}, & t = t_{1,2} = \pm\sqrt{x} \\ \mp\frac{2}{3}i|x|^{3/2} & t = t_{3,4} = \pm i\sqrt{|x|} \end{cases}$$

Шаг второй Затем требуется найти направление линий наискорейпего спуска из точки z_0. Вблизи каждой точки функция в общем виде раскладывается квадратично $\Phi(z) \approx \Phi(z_0) + \frac{1}{2}\Phi''(z_0)\cdot(z - z_0)^2 + \ldots$. Рассмотрим поведение функции $\mathrm{Re}\,\Phi(z)$ в окрестности z_0; если положить $\Phi'' = |\Phi''|\, e^{i\arg\Phi''}$ и $z - z_0 = \rho e^{i\theta}$, тогда $\mathrm{Re}\,(\Phi(z) - \Phi(z_0)) = \frac{1}{2}|\Phi''|\,\rho^2 e^{i(\arg\Phi'' + 2\theta)}$

Имеются следующие взаимно-перпендикулярные направления: $\arg\Phi'' + 2\theta = 2\pi n \to \theta = -\frac{1}{2}\arg\Phi''$, $\theta = -\frac{1}{2}\arg\Phi'' + \pi$ (направления наискорейшего возрастания) $\arg\Phi'' + 2\theta = \pi + 2\pi n \to \theta = -\frac{1}{2}\arg\Phi'' \pm \frac{\pi}{2}$, (направления наискорейпего спуска) В нашем случае получается следующее:

$$\Phi''(t) = -2t = \begin{cases} -2\sqrt{x} \to \theta = 0, \pi, & t_1 = \sqrt{x}, \quad x > 0 \\ 2\sqrt{x} \to \theta = \pm\frac{\pi}{2} & t_2 = -\sqrt{x}, \quad x > 0 \\ -2i\sqrt{|x|} \to \theta = -\frac{\pi}{4}, \frac{3\pi}{4}, & t_3 = i\sqrt{|x|}, \quad x < 0 \\ 2i\sqrt{|x|} \to \theta = -\frac{3\pi}{4}, \frac{\pi}{4}, & t_4 = -i\sqrt{|x|}, \quad x < 0 \end{cases}$$

Шаг третий Таким образом, нам бы хотелось пустить контур через точку z_0 под углом, соответствующим линии постоянной фазы - линии наискорейшего спуска.

Если мы поступим так, то вклад в интеграл от окрестности z_0 оденится следующим образом [14]:

$$y = \int\limits_C dz A(z) e^{-\Phi(z)} \approx \int\limits_{-\infty}^{\infty} e^{i\theta} d\rho A(z) e^{\Phi(z_0) - \frac{1}{2}|\Phi''|\rho^2} = \sqrt{\frac{2\pi}{|\Phi''|}} A\left(z_0\right) e^{\Phi(z_0)+i\theta}$$

Обратим внимание, что ведущая зависимость от параметра, как правило, даётся просто посредством $e^{\Phi(z_0)}$. Конечно, тут предполагается выполнение стандартных критериев метода перевала (а именно, что максимум достаточно узкий, и функция $A(z)$ достаточно медленна, так что такое разложение оправдано).

выбрать контур, соответствующий функции Эйри

Шаг четвёртый Теперь нам можно наконец выбрать контур, соответствуюпий функции Эйри.

Функция Эйри определяется как вещественное решение, которое при $x > 0$ экспоненциально затухает.

Поэтому при $x > 0$ контур должен проходить только через седловую точку t_2, и никак не через t_1. Такой контур единственный - это C_1 (контур, идущий из нижнего сектора в верхний).

Для удобства его можно пустить чисто по мнимой оси; выбирая константу так, чтобы определение совпало с стандартным (она равна $\frac{1}{2\pi i}$), мы можем написать:

$$\mathrm{Ai}(x) = \frac{1}{2\pi i} \int\limits_{C_1} e^{xt - t^3/3} dt = \frac{1}{\pi} \int\limits_0^{\infty} \cos\left(xt - \frac{t^3}{3}\right) dt$$

Шаг пятый Теперь проведём непосредственно перевальную оценку интеграла по выбранному контуру для различных знаков x. При $x > 0$, контур кнасаживается на единственную седловую точку $t = t_2 = -\sqrt{x}$ и проходит через неё по направлению $\theta = \frac{\pi}{2}$; получается вклад:

$$\mathrm{Ai}(x \to \infty) \approx \frac{1}{2\sqrt{\pi} x^{1/4}} e^{-\frac{2}{3}x^{3/2}}$$

При $x < 0$ контур насаживается на обе седловые точки.

Однако стоит обратить внимания, что фазы в них различны $\mathrm{Im}\,\Phi\left(t_3\right) \neq \mathrm{Im}\,\Phi\left(t_4\right)$;

в связи с этим, вообще говоря, не существует единого контура, который проходит по линиям постоянной фазы через обе седловые точки.

В действительности же контур идёт кснизуж, проходит через седло $t = -2i\sqrt{|x|}$ под углом $\theta = \frac{\pi}{4}$; затем уходит на $t \to +\infty$ (подобно контуру $-C_3$!).

Там он перескакивает на другую линию постоянной фазы, откуда от возвращается по ней до второго седла $t = 2i\sqrt{|x|}$, проходит его под направлением $\theta = \frac{3\pi}{4}$ и уходит кнаверх (как контур $-C_2$; смотри рисунок 4.2). Перевальная оценка тем самьгм даёт:

$$\mathrm{Ai}(x \to -\infty) \approx \frac{1}{2\pi i} \sqrt{\frac{2\pi}{2\sqrt{|x|}}} \left[e^{\frac{2}{3}i|x|^{3/2} i\frac{\pi}{4}} + e^{-\frac{2}{3}i|x|^{3/2} + i\frac{3\pi}{4}} \right] = \frac{1}{\sqrt{\pi}|x|^{1/4}} \sin\left(\frac{2}{3}|x|^{3/2} + \frac{\pi}{4}\right)$$

Template integrals, which are very useful for some problems

Полезные математические заготовки для стационарной теории возмущений в невырожденном случае

Обсудим интегралы и другие нужные преобразования.

Всегда сперва проверяем по компу формулой типа:

```
Integrate[(Sin[2 Pi x/ a ])^2 x^2, {x, 0, a }]
```

(??? какая-то фигня у вольфрама с двойными интегралами, так что считаю их по отдельности.)

Далее, если считаем руками, то используем полезные заготовки неопределенного интеграла:

$$\int \sin^2(Cx)\,dx = \frac{x}{2} - \frac{\sin(2Cx)}{4C},$$
$$\int \sin^2(Cx)\,xdx = x^2/4 - \frac{\cos[2Cx]}{8C^2} - \frac{x\sin[2Cx]}{4C},$$
$$\int \sin^2(Cx)\,x^2dx = x^3/6 - \frac{x\cos[2Cx]}{4C^2} - \frac{(-1+2C^2x^2)\sin[2Cx]}{8C^3},$$
$$\int \sin^2(\pi Cx)\,x^3dx = x^4/8 - (3(-1+2C^2x^2)\cos[2Cx])/(16C^4) - (x(-3+2C^2x^2)\sin[2Cx])/(8C^3),$$

И определенного интеграла:

$$\int_0^a \sin^2\left(\pi\frac{x}{a}\right)dx = \frac{a}{2},$$
$$\int_0^a \sin^2\left(\pi\frac{x}{a}\right)xdx = \frac{a^2}{4},$$
$$\int_0^a \sin^2\left(\pi\frac{x}{a}\right)x^2dx = \frac{1}{12}a^3(2-\frac{3}{\pi^2}),$$
$$\int_0^a \sin^2\left(\pi\frac{x}{a}\right)x^3dx = (a^4(-3+\pi^2))/(8\pi^2),$$
$$\int_0^a \sin\left(2\pi\frac{x}{a}\right)\sin\left(\pi\frac{x}{a}\right)x = -\frac{8a^2}{9\pi^2},$$

(добавлю потом другие)

B.1.9 Iterative Methods

просто можно делать какие-то итерационные решения, тут про них я изучу все

$$1 = \frac{maU_0}{\sqrt{2m|E|}}2\ln\frac{1}{\sqrt{2m|E|}a} \qquad \leftrightarrow \qquad \frac{a\sqrt{2m|E|}}{ma^2U_0} = -2\ln\sqrt{2m|E|}a \tag{B.1}$$

Засунем мелкость в параметр $\beta = ma^2U_0 \ll 1$.
(я пока что хз, зачем, но еще вводим) $\alpha := a\sqrt{2m|E|}/\beta$.
в итоге начинаем эту хрень писать:

$$\alpha = -2\ln(\alpha\beta) \tag{B.2}$$
$$\alpha_0 = 1 \ \rightarrow \tag{B.3}$$
$$\alpha_1 = -2\ln(\beta) \ \rightarrow \tag{B.4}$$
$$\alpha_2 = -2\ln(-2\beta\ln(\beta)) \tag{B.5}$$
$$\tag{B.6}$$

то есть глава посвящена ответу на вопрос: какого хрена так происходит????

C Programming for Quantum Mechanics

Обсудим приложения квантовой механики в программировании.

(раздел на страниц 30, соберу все методы в вольфраме проги, которые уже написаны у Шмиеда "вольфрам в квантмехе". также про квантовое машинное обучение и всё такое, это тут)

C.1 Modeling of Typical Objects and Phenomena

Refs from Quantum mechanics of the $1/x^2$ potential by Essin, Griffiths (2005)

[4] K. S. Gupta and S. G. Rajeev, "Renormalization in quantum mechanics," Phys. Rev. D 48, 5940-5945 (1993).
[5] G. Arfken and H.-J. Weber, Mathematical Methods for Physicists (Academic, Orlando (2000), 5th ed., Chap. 11. The other solution, $\sqrt{x}I_{ig}(\kappa x)$, diverges for large x.
[6] I. S. Gradshteyn and I. M. Ryzhik, Tables of Integrals, Series, and Products (Academic, San Diego, (1980), Eqs. (6.576.4) and (8.332.3). Incidentally, states with different κ are not orthogonal.
[7] One might ask what the usual approximation schemes have to say about this potential. Not much. For the general power law $V(x) = ax^\nu$ on $0 < x < \infty$, the WKB approximation yields $E_n \approx a[(n - 1/4)\hbar\sqrt{2\pi/ma}\Gamma(1/\nu + 3/2)/\Gamma(1/\nu + 1)]^{2\nu/(\nu+2)}$ [see D. J. Griffiths, Introduction to Quantum Mechanics (Prentice Hall, Englewood Cliffs, NJ, 2004), 2nd ed., Problem 8.11], and the exponent is infinite when $\nu = -2$. The variational principle only confirms what we already knew-that the ground state is lower than every negative energy.
[8] Reference 6, p. 962, Eqs. (3) and (4).
[9] Some authors use a plus sign in Eq. (24), which adds $\pi/2$ to the phase shift. We prefer the minus sign, because it reduces to $\delta = 0$ when the potential is zero.
[10] For a list of accessible references see C. V. Siclen, "The one-dimensional hydrogen atom," Am. J. Phys. 56, 9-10 (1988).
[11] Indeed, because allowed energies must exceed $V_{\min}, E_1 > -a/\epsilon^2$.
[12] For these parameters $\kappa_1\epsilon = 1.024645, \kappa_2\epsilon = 0.350972, \kappa_3\epsilon = 0.122830$, and $\kappa_4\epsilon = 0.043089$.
[13] For the ground state this inequality would appear to require $g \ll 3$ (see Fig. 5), but in practice the approximation is good up to $g = 3$. For the excited states κ is smaller, and the approximation is valid for even higher g.
[14] Reference 5, Eqs. (11.112) and (11.118), and Ref. 6, Eqs. (8.331) and (8.332).
[15] This holds for $g < 3$, as we can easily confirm by comparing the graph of Eq. (30) with Fig. 5. For larger values of g the approximation itself is invalid for the ground state. Incidentally, Eq. (29) has solutions for negative n, but these are spurious, because they violate the assumption $\kappa\epsilon < 1$.
[16] The limiting case $g = 0$ is obviously problematic-indeed, $K_0(z)$ has no zeros for positive z. For $|z| \ll 1, \Gamma(1 + z) \approx 1 - Cz$, where $C = 0.577215$ is Euler's constant, so for small g arg $\Gamma(1 + ig) \approx -Cg$, and Eq. (30) is replaced by $\kappa_n = (2/\gamma\epsilon)\exp(-n\pi/g)$, where $\gamma \equiv \exp(C) = 1.781072$. See Ref. 6, Eq. (8.321.1), and p. xxviii.
[17] We used the identity $H_{ig}^{(2)}(x) = \left[H_{-ig}^{(1)}(x)\right]^* = e^{-\pi g}\left[H_{ig}^{(1)}(x)\right]^*$ (valid for real x and real g). See Ref. 6, p. 969.
[18] We used Ref. 6, Eq. (8.405.1), to express $H_\nu^{(1)}$ in terms of J_ν and N_ν, Eq. (8.440) to approximate J_v, Eq. (8.443) to approximate N_v, and Eq. (8.332.3) to eliminate $\Gamma(1 - ig)$.
[19] Reference 6, Eqs. (8.331) and (8.332.1).

[20] Reference 6, Eqs. (8.441.1) and (8.444.1), and p. xxviii.
