а затем разобьем интервал от $\tilde{t} = t_N$ до $t'' = t_{M+N}$ с помощью M точек t_k, начиная нумерацию точек k с $N+1$ и кончая на $N+M$, и запишем матричный элемент оператора эволюции $= \lim_{M\to\infty} \int \frac{\mathrm{d}p_{N+M}}{2\pi\hbar} \prod_{k=N+1}^{N+M-1} \frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}S\left(\tilde{t},t''\right)} = \int \mathcal{D}q\mathcal{D}p \mathrm{e}^{\frac{i}{\hbar}S\left(\tilde{t},t''\right)} \cdot$ (13.25) Но тогда можно взять матричный элемент операторного соотношения (13.23)

$$\left\langle q'' \left| \hat{U}\left(t'', \tilde{t}\right) \hat{U}\left(\tilde{t}, t'\right) \right| q' \right\rangle = \left\langle q'' \left| \hat{U}\left(t'', t'\right) \right| q' \right\rangle,$$

вставив в него единичный оператор в координатном пространстве

$$1 = \int |q_N\rangle\, \mathrm{d}q_N\, \langle q_N|,$$

Так что

$$\left\langle q'' \left| \hat{U}\left(t'', \tilde{t}\right) \hat{U}\left(\tilde{t}, t'\right) \right| q' \right\rangle = \int \left\langle q'' \left| \hat{U}\left(t'', \tilde{t}\right) \right| q_N \right\rangle \mathrm{d}q_N \left\langle q_N \left| \hat{U}\left(\tilde{t}, t'\right) \right| q' \right\rangle =$$

$$= \lim_{M\to\infty} \lim_{N\to\infty} \int \mathrm{e}^{\frac{i}{\hbar}\sum\limits_{k=1}^{N+M}[p_k\dot{q}_k\ \mathrm{d}t - \mathcal{H}(p_k,\bar{q}_k,t_k)\mathrm{d}t]} \frac{\mathrm{d}p_{N+M}}{2\pi\hbar} \prod_{k=1}^{N+M-1} \frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar} =$$

$$= \lim_{M\to\infty} \lim_{N\to\infty} \int \frac{\mathrm{d}p_{N+M}}{2\pi\hbar} \prod_{k=1}^{N+M-1} \frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}S(t',t'')} =$$

$$= \int \mathcal{D}q\mathscr{D}p \mathrm{e}^{\frac{i}{\hbar}S(t',t'')} = \left\langle q'' \left| \hat{U}\left(t'', t'\right) \right| q' \right\rangle.$$

Таким образом, мы убедились, что операторная запись (13.23) согласуется с представлением для матричных элементов в формализме интегралов по траекториям (13.27).

Оператор эволюции можно представить как

$$\hat{U}\left(t'',t'\right)=\int \mathrm{d}q''\left|q''\right\rangle \left\langle q''\left|\hat{U}\left(t'',t'\right)\right|q'\right\rangle \mathrm{d}q'\left\langle q'\right|,$$

откуда

$$\hat{U}\left(t'',t'\right)=\int \mathrm{d}q''\mathrm{d}q'\left|q''\right\rangle \left\langle q'\right|\int \mathcal{D}q\mathcal{D}p\mathrm{e}^{\frac{i}{\hbar}S(t',t'')}.$$

Функция Грина через оператор эволюции по Киселеву (??)

Обычно вводят запаздывающую функцию Грина уравнения Шрёдингера

$$\mathrm{i}\hbar\mathcal{G}\left(q'',t'';q',t'\right)\overset{\text{def}}{=}\vartheta\left(t''-t'\right)\left\langle q''\left|U\left(t'',t'\right)\right|q'\right\rangle,$$

где $\vartheta(\cdot)$ - ступенчатая тэта-функция Хевисайда. Если вычислить производную по времени конечной точки эволюции

$$\mathrm{i}\hbar\frac{\partial}{\partial t''}\left\{\vartheta\left(t''-t'\right)\left\langle q''\left|U\left(t'',t'\right)\right|q'\right\rangle\right\}$$

и использовать уравнение Шрёдингера для оператора эволюции в координатном представлении $\left|q''\right\rangle$

$$\mathrm{i}\hbar\frac{\partial}{\partial t''}\left\langle q''\left|U\left(t'',t'\right)\right|q'\right\rangle=\hat{H}\left(q'',\hat{p}'',t''\right)\left\langle q''\left|U\left(t'',t'\right)\right|q'\right\rangle$$

с начальными данными $\left\langle q''\left|U\left(t',t'\right)\right|q'\right\rangle=\left\langle q''\right|\mathbb{1}\left|q'\right\rangle=\delta\left(q''-q'\right)$, а также равенством

$$\mathrm{i}\hbar\frac{\partial}{\partial t''}\vartheta\left(t''-t'\right)=\mathrm{i}\hbar\delta\left(t''-t'\right),$$

То

$$\begin{aligned}&\mathrm{i}\hbar\frac{\partial}{\partial t''}\left\{\mathrm{i}\hbar\mathcal{G}\left(q'',t'';q',t'\right)\right\}=\mathrm{i}\hbar\frac{\partial}{\partial t''}\left\{\vartheta\left(t''-t'\right)\left\langle q''\left|U\left(t'',t'\right)\right|q'\right\rangle\right\}=\\&=\mathrm{i}\hbar\delta\left(t''-t'\right)\left\langle q''\left|U\left(t'',t'\right)\right|q'\right\rangle+\vartheta\left(t''-t'\right)\hat{H}\left(q'',\hat{p}'',t''\right)\left\langle q''\left|U\left(t'',t'\right)\right|q'\right\rangle=\\&=\mathrm{i}\hbar\delta\left(t''-t'\right)\left\langle q''\left|U\left(t',t'\right)\right|q'\right\rangle+\hat{H}\left(q'',\hat{p}'',t''\right)\left\{\vartheta\left(t''-t'\right)\left\langle q''\left|U\left(t'',t'\right)\right|q'\right\rangle\right\}=\\&=\mathrm{i}\hbar\delta\left(t''-t'\right)\delta\left(q''-q'\right)+\hat{H}\left(q'',\hat{p}'',t''\right)\mathrm{i}\hbar\mathcal{G}\left(q'',t'';q',t'\right).\end{aligned}$$

Таким образом, функция Грина (13.29) удовлетворяет уравнению

$$\left\{\mathrm{i}\hbar\frac{\partial}{\partial t''}-\hat{H}\left(q'',p'',t''\right)\right\}\mathcal{G}\left(q'',t'';q',t'\right)=\delta\left(t''-t'\right)\delta\left(q''-q'\right),$$

которое представляет собой уравнение Шрёдингера с дельтаобразньм источником. Решение этого уравнения - отклик на воздействие источника как раз и называют функцией Грина. В терминах функции Грина эволюция состояния вперед во времени дается соотношением

$$\Psi\left(q'',t''\right)=-\frac{\mathrm{i}}{\hbar}\int\mathcal{G}\left(q'',t'';q',t'\right)\Psi\left(q',t'\right)\mathrm{d}q',\quad t''>t'.$$

В простейших случаях, например, для свободной частицы, можно решить это уравнение в явном виде. Однако в этом разделе мы исследуем метод континуального интеграла,

оставляя изложение аппарата запаздывающей функции Грина до рассмотрения теории рассеяния. К действию замкнутой системы $S\left(t',t''\right)$ можно добавить вклад, обусловленный воздействием на систему зависящих от времени внешних сил, которые также называют внешними источниками $j(t)$. Например,

$$S\left(t',t''\right)\mapsto S\left(t',t''\right)+S_{\text{ext}}\left[j\right],\quad S_{\text{ext}}\left[j\right]=\int\limits_{t'}^{t''}\mathrm{d}tq(t)j(t)\equiv q_{(t)}j_{(t)},$$

где в последнем равенстве мы для краткости записи интегралов, в особенности, кратных, ввели правило интегрирования по непрерывным немым индексам [1], которые, чтобы не путать их с тензорными индексами, мы указываем в скобках (в данном случае, по переменной t), в полной аналогии с суммированием по дискретным немым индексам.

Включение внешних сил позволяет более глубоко исследовать свойства физической системы, меняя величину воздействия внешних сил.

Если внешних сил нет, то говорят, что внешние источники j равны нулю, и обычно вводят обозначение для матричного элемента оператора эволюции

$$Z[0]=\left\langle q''\left|U\left(t'',t'\right)\right|q'\right\rangle\big|_{j=0}=\left.\int\mathcal{D}q\mathcal{D}p\mathrm{e}^{\frac{i}{\hbar}S(t',t'')}\right|_{j=0}$$

Классический предел.

При $\hbar\to 0$ под интегралом стоит функция с быстро осциллирующей фазой $S/\hbar$, за исключением случая, когда у действия имеется стационарная точка:

$$\delta S=0,\quad \delta q\left(t'\right)=\delta q\left(t''\right)=0,$$

т.е. вариация действия на траектории с фиксированными концами обращается в нуль. Но это есть не что иное, как принцип наименьшего действия в классической механике. Значит,

$$Z[0]=\int\mathcal{D}q\mathcal{D}p\mathrm{e}^{\frac{1}{\hbar}S(t',t'')}\approx A\mathrm{e}^{\frac{1}{\hbar}S_0(t',t'')}+\text{ квантовые поправки},$$

где S_0 - действие на «прямой классической траектории. Фактически такое доминирование имеет место только тогда, когда точность измерений наблюдаемых в системе существенно уступает точности, с которой можно зарегистрировать вклады от квантовых флуктуаций, и тогда говорят, что квантовые флуктуации очень малы. Ясно, что предел $h\to 0$ подразумевает сравнение величины измеряемого действия S_0 и точности его определения наблюдении квантовых эффектов не имеет смысла.

Интегрирование по импульсу

В случае, когда импульс входит в гамильтониан только квадратично, и в частности, только в кинетическую энергию, интегралы по импульсам в выражении для матричного элемента оператора эволюции в (13.20) можно взять, так как

$$\mathcal{I}_k=\int\limits_{-\infty}^{+\infty}\frac{\mathrm{d}p_k}{2\pi\hbar}\exp\left\{\frac{\mathrm{i}}{\hbar}\left[p_k\dot{q}_k-\frac{p_k^2}{2m}\right]\mathrm{d}t\right\}=\int\limits_{-\infty}^{+\infty}\frac{\mathrm{d}p_k}{2\pi\hbar}\exp\left\{\frac{\mathrm{i}}{\hbar}\left[-\frac{\left(p_k-m\dot{q}_k\right)^2}{2m}+\frac{m\dot{q}_k^2}{2}\right]\mathrm{d}t\right\},$$

откуда

$$\mathcal{I}_k=\mathcal{N}_k\exp\left\{\frac{\mathrm{i}}{\hbar}\frac{m\dot{q}_k^2}{2}\,\mathrm{d}t\right\}$$

где нормировочная константа $\mathcal{N}_p$ не зависит от траектории. Это значит, что в интеграле по траекториям (13.20) после интегррования по импульсам остается только интеграл по координатам, но при этом действие уже зависит не от координат и импульсов, как и должно быть в гамильтоновой механике, а от координат и скоростей, как это имеет место в лагранжевой механике. Тогда

$$Z[0] = \mathcal{N} \int \mathcal{D}q \mathrm{e}^{\frac{1}{\hbar} S(t',t'')},$$

где уже действие зависит только от траектории в координатном пространстве:

$$S\left(t', t''\right) = \int\limits_{t'}^{t''} \mathrm{d}t \left\{ \frac{m\dot{q}^2(t)}{2} - V[q(t), t] \right\},$$

а

$$\mathcal{N} = \lim_{N\to\infty} \prod_{k=1}^{N} \mathcal{N}_k$$

Поворот Вика

При интегрировании для оценки константы $\mathcal{N}_p$ часто используют поворот Вика контура интегрирования по времени. Формально полагают, что

$$\mathrm{d}t = -\mathrm{i}\mathrm{d}t_E,$$

где t_E - вевклидово время (см. рис. 20). Для правомерности такого поворота Рис. 20. Поворот Вика (слева: жирная прямая со стрелками указывает движение в положительном направлении $\mathrm{d}t > 0$ по переменной t вдоль вещественной оси, спрана: жирная прямая со стрелками указывает движение в положительном направлении $\mathrm{d}t_E > 0$ по переменной t_E, что отвечает чисто мнимым значениям $\mathrm{d}t = -\mathrm{i}\mathrm{d}t_E$ и означает поворот жирной прямой со стрелками - вещественной оси в плоскости комплексной переменной t - на угол $-\frac{\pi}{2}$, а образом этой прямой становится ось чисто мнимых значений с обратным следованием точек на оси). необходимо, чтобы на пути смещения контура не было особых точек. Обычно полагают, что это условие выполнено. Тогда при $\mathrm{d}t_E > 0$ стандартный гауссов

интеграл легко берется,

$$\mathcal{N}_k = \int\limits_{-\infty}^{+\infty} \frac{\mathrm{d}p_k}{2\pi\hbar} \exp\left\{ -\frac{1}{\hbar} \frac{\left(p_k - m\dot{q}_k\right)^2}{2m} \, \mathrm{d}t_E \right\} = \sqrt{\frac{m}{2\pi\hbar t_E}}.$$

Отсюда видно, что, во-первых, нормировочный фактор действительно не зависит от параметров траектории и его можно вынести из-под знака континуального интеграла. Во-вторых, в пределе бесконечно малого шага эволюции $\mathrm{d}t_E \to 0$. Поэтому возникает вопрос: как такое сингулярное поведение номировочных констант по времени скажется на значении континуального интеграла в целом? Для корректного определение континуального интеграла необходимо считать $\mathrm{d}t_E$ конечным на всех промежуточных стадиях расчетов и переходить к пределу $\mathrm{d}t_E \to 0$ только в самом конце, когда рассматривают наблюдаемые величины: такая процедура называется «регуляризацией». В качестве примера расчетов с регуляризацией мы предлагаем читателям самостоятельно провести расчет континуального интеграла для свободной нерелятивистской частицы.

Задача 7.1. В формализме интеграла по траекториям, используя определение (13.21), вычислить матричный элемент оператора эволюции для свободной частицы $\langle q''\left|U\left(t'',t'\right)\right|q'\rangle = \int \mathcal{D}q\mathcal{D}p\mathrm{e}^{\frac{\mathrm{i}}{\hbar}S\left(t',q',t'',q''\right)} = \sqrt{\frac{-\mathrm{i}m}{2\pi\hbar(t''-t')}}\exp\left\{\frac{\mathrm{i}}{\hbar}\frac{m}{2}\frac{(q''-q')^2}{t''-t'}\right\}$, проводя интегрирование сначала по координатам, а затем по импульсам с использованием поворота Вика. Обратите внимание, что фазой экспоненты является действие для свободной частицы между заданными граничными точками!

Убедитесь, что при $t = t'' \neq t'$ амплитуда квантового перехода свободной частицы из точки q' в точку $q = q''$, те. $A(t,q) = \langle q\left|U\left(t,t'\right)\right|q'\rangle$ удовлетворяет уравнению Шрёдингера

$$\mathrm{i}\,\hbar\frac{\partial A(t,q)}{\partial t} = -\frac{\hbar^2}{2m}\frac{\partial^2 A(t,q)}{\partial q^2}.$$

13.2. Т-пРоизведение. Прямая задача исследования отклика квантовой системы на внешнее воздействие - это вычисление матричных элементов для операторов, которые описывают такое воздействие. Для начала рассмотрим матричный элемент упорядоченных по ходу эволюции операторов в картине Шрёдингера,

$$\langle F(\tilde{t})\rangle = \left\langle q''\left|\hat{U}\left(t'',\tilde{t}\right)\hat{F}(\hat{p},\hat{q},\tilde{t})\hat{U}\left(\tilde{t},t'\right)\right|q'\right\rangle, \quad \text{при } t''>\tilde{t}>t'.$$

Физический смысл этого матричного элемента следующий: состояние, которое задается собственным значением координаты q', эволюционирует от момента t' до времени $\tilde{t}$, где на квантовое состояние воздействует оператор $\hat{F}$, и затем система эволюционирует от $\tilde{t}$ до момента времени t'', а насс интересует амплитуда вероятности того, что при $t = t''$ состемä окажется в квантовом состоянии с собственным значением координаты q''. Вставляя операторные единицы в координатном представлении

$$\mathbb{1} = \int |q_N\rangle\,\mathrm{d}q_N\left\langle q_N\right|, \quad \mathbb{1} = \int\left|q_{N+1}\right\rangle\mathrm{d}q_{N+1}\left\langle q_{N+1}\right|,$$

перепипем (13.36) в виде

$$\langle F(\tilde{t})\rangle = \int\left\langle q''\left|\hat{U}\left(t'',\tilde{t}\right)\right|q_{N+1}\right\rangle\mathrm{d}q_{N+1}\left\langle q_{N+1}|\hat{F}(\hat{p},\hat{q},\tilde{t})|q_N\right\rangle\mathrm{d}q_N\left\langle q_N\left|\hat{U}\left(\tilde{t},t'\right)\right|q'\right\rangle.$$

В этом выражении, как мы показали ранее на стр. 234 при выводе матричного элемента гамильтониана (13.8), матричный элемент оператора при квантовании по Вейлю

$$\left\langle q_{N+1}|\hat{F}(\hat{p},\hat{q},\hat{t})|q_N\right\rangle = \int\frac{\mathrm{d}p_{N+1}}{2\pi\hbar}\mathrm{e}^{\frac{\mathrm{i}}{\hbar}p_{N+1}(q_{N+1}-q_N)}\mathcal{F}\left(p_{N+1},\bar{q}_{N+1},\tilde{t}\right),$$

где $\bar{q}_{N+1} = \left(q_{N+1}+q_N\right)/2$ - срединная точка, а $\mathcal{F}\left(p_{N+1},\bar{q}_{N+1},\tilde{t}\right)$ - классическое выражение для величины $\mathcal{F}$ в терминах переменных фазового пространства. Разбивая интервалы эволюции на бесконечно малые шаги так же, как мы это уже делали при выводе произведения операторов эволюции на последовательных промежутках времени (см. стр. 241), найдем

$$\left\langle q_N\left|U\left(\tilde{t},t'\right)\right|q'\right\rangle = \lim_{N\to\infty}\int\mathrm{e}^{\frac{\mathrm{i}}{\hbar}\sum\limits_{k=1}^{N}\left[p_k\dot{q}_k\ \mathrm{d}t-\mathcal{H}(p_k,\bar{q}_k,t_k)\mathrm{d}t\right]}\frac{\mathrm{d}p_N}{2\pi\hbar}\prod_{k=1}^{N-1}\frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar} =$$

$$= \lim_{N\to\infty}\int\frac{\mathrm{d}p_N}{2\pi\hbar}\prod_{k=1}^{N-1}\frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar}\mathrm{e}^{\frac{\mathrm{i}}{\hbar}S(t',\bar{t})} = \int\mathcal{D}q\mathcal{D}p\mathrm{e}^{\frac{\mathrm{i}}{\hbar}S(t',t)},$$

где $\tilde{t} = t_N, t' = t_0$, и

$$\left\langle q_{N+M} \left| U\left(t'', \tilde{t}\right) \right| q_{N+1} \right\rangle = \lim_{M\to\infty} \int \mathrm{e}^{\frac{i}{k}\sum\limits_{k=N+2}^{N+M}[p_k\dot{q}_k\ \mathrm{d}t - \mathcal{H}(p_k,\bar{q}_k,t_k)\mathrm{d}t]} \frac{\mathrm{d}p_{N+M}}{2\pi\hbar} \times \prod_{k=N+2}^{N+M-1} \frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar} =$$

$$= \lim_{M\to\infty} \int \frac{\mathrm{d}p_{N+M}}{2\pi\hbar} \prod_{k=N+2}^{N+M-1} \frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar} \mathrm{e}^{\frac{i}{\hbar}S(\bar{t},t'')} =$$

$$= \int \mathcal{D}q\mathcal{D}p \mathrm{e}^{\dot{\hbar}S(E_t,t'')},$$

где $\tilde{t} + \mathrm{d}t = t_{N+1}, t'' = t_{N+M}$. Собирая выражения для матричных элементов, найдем

$$\left\langle q'' \left| \hat{U}\left(t'', \tilde{t}\right) \hat{F}(\hat{p},\hat{q},\tilde{t}) \hat{U}\left(\tilde{t}, t'\right) \right| q' \right\rangle = \times \lim_{M\to\infty} \lim_{N\to\infty} \int \mathrm{e}^{\frac{i}{\hbar}\sum\limits_{k=N+2}^{N+M}[p_k\tilde{q}_k\ \mathrm{d}t - \mathcal{H}(p_k,\bar{q}_k,t_k)\mathrm{d}t]} \frac{\mathrm{d}p_{N+M}}{2\pi\hbar} \prod_{k=N+2}^{N+M-1} \frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar} \times$$

$$\times \frac{\mathrm{d}q_{N+1}\ \mathrm{d}p_{N+1}}{2\pi\hbar} \mathrm{e}^{\hbar p_{N+1}(q_{N+1}-q_N)} \mathcal{F}\left(p_{N+1}, \bar{q}N+1, t_N\right) \times$$

$$\times e^{\frac{1}{\hbar}} \sum_{k=1}^{N} \left[p_k\dot{q}_k\ \mathrm{d}t - \mathcal{H}\left(p_k,\bar{q}_k,t_k\right)\mathrm{d}t\right] \frac{\mathrm{d}q_N\ \mathrm{d}p_N}{2\pi\hbar} \prod_{k=1}^{N-1} \frac{\mathrm{d}q_k\ \mathrm{d}p_k}{2\pi\hbar}.$$

Если теперь обратить внимание на вклад

$$\mathrm{e}^{\frac{i}{\pi}p_{N+1}(q_{N+1}-q_N)} \mathcal{F}\left(p_{N+1}, \bar{q}_{N+1}, t_N\right)$$

и переписать его с помощью производной по времени

$$q_{N+1} - q_N = \dot{q}_{N+1}\ \mathrm{d}t,$$

То

$$\mathrm{e}^{\frac{1}{\hbar}p_{N+1}\dot{q}N+1\ \mathrm{d}t} \mathcal{F}\left(p_{N+1}, \bar{q}_{N+1}, t_N\right) = \mathrm{e}^{\frac{i}{\hbar}p_{N+1}\dot{q}_{N+1}\ \mathrm{d}t - \frac{1}{\hbar}\mathcal{H}(p_{N+1},\bar{q}_{N+1},t_{N+1})\mathrm{d}t} \tilde{\mathcal{F}}\left(p_{N+1}, \bar{q}_{N+1}, t_{N+1}\right),$$

где величина в пределе бесконечно малого шага эволюции стремиться к классической величине, заданной в момент времени $\tilde{t}$,

$$\lim_{\mathrm{d}t\to 0} \tilde{\mathcal{F}}\left(p_{N+1}, \bar{q}_{N+1}, t_{N+1}\right) = \mathcal{F}(p(\tilde{t}), q(\tilde{t}), \tilde{t}),$$

поскольку

$$p_{N+1} = p\left(t_{N+1}\right) = p(\tilde{t}),$$

$$\bar{q}_{N+1} = q\left(t_{N+1}\right) - \frac{1}{2}\dot{q}\left(t_{N+1}\right)\mathrm{d}t = q\left(t_{N+1}\right) + \mathcal{O}(\mathrm{d}t) = q(\tilde{t}) + \mathcal{O}(\mathrm{d}t),$$

а

$$\mathrm{e}^{-\frac{\hbar}{\hbar}\mathcal{H}(p_{N+1},\bar{q}_{N+1},t_{N+1})dt} = \mathrm{e}^{-\hbar\mathcal{H}(p(\bar{t}),q(\bar{t}),\bar{t})dt} + \mathcal{O}\left(\mathrm{d}t^2\right).$$

Это значит, что предел в (13.37) приводит к стандартному выражению для интеграла по траекториям (обратите внимание на континуальную меру интегрирования и интегральные суммы в показателях экспонент) при $t'' > \tilde{t} > t'$

$$\langle F(\tilde{t})\rangle = \left\langle q'' \left| \hat{U}\left(t'', \tilde{t}\right) \hat{F}(\hat{p},\hat{q},\tilde{t}) \hat{U}\left(\tilde{t}, t'\right) \right| q' \right\rangle =$$

$$= \int \mathcal{D}q\mathcal{D}p \mathrm{e}^{\frac{1}{\hbar}S(t',t'')} \mathcal{F}(p(\tilde{t}), q(\tilde{t}), \tilde{t})$$

Если теперь заметить, что функционал с внешним источником $j_F(t)$ для величины $\mathcal{F}$

$$\mathrm{e}^{\frac{i}{\hbar}S_{\mathrm{ext}}\,[jF]} = \exp\left\{\frac{\mathrm{i}}{\hbar}\int \mathrm{d}t j_F(t)\mathcal{F}(p(t),q(t),t)\right\}$$

при вычислении вариационной производной дает

$$-\,\mathrm{i}\hbar\frac{\delta}{\delta j_F(\bar{t})}\mathrm{e}^{\frac{j}{\hbar}S_{\mathrm{uxt}}[j_F]}\Big|_{jF=0} = \mathcal{F}(p(\tilde{t}),q(\tilde{t}),\tilde{t}),$$

то приходим к формуле

$$\begin{aligned}\langle F(\tilde{t})\rangle &= \int \mathcal{D}q\mathcal{D}p\mathrm{e}^{\frac{i}{\hbar}S(t',t'')}\mathcal{F}(p(\tilde{t}),q(\tilde{t}),\tilde{t}) = \\ &= -\,\mathrm{i}\hbar\frac{\delta}{\delta j_F(\bar{t})}\int \mathcal{D}q\mathcal{D}p\mathrm{e}^{\hbar S(t',t'')+\hbar S_{\mathrm{ext}}[j_F]}\Big|_{jF=0}.\end{aligned}$$

Итак, мы установили, что матричный элемент оператора величины $\hat{F}$ в обкладках оператора эволюции сводится к вычислению интеграла по траекториям со вставкой значения этой величины на траектории в определенный момент времени (13.38), и этот интеграл по траекториям можно найти как вариационную производную от интеграла по траекториям с учетом вклада в действие члена с источником (13.39).

Связь с представлением Гейзенберга (???)

Покажем теперь, как матричный элемент величины $\hat{F}$ в обкладках оператора эволюции связан с матричным элементом этого оператора в представлении Гейзенберга,

$$\hat{F}_H = \hat{U}^{\dagger}\left(t'',t'\right)\hat{F}\hat{U}\left(t'',t'\right).$$

При $t''>\tilde{t}>t'$ $\hat{U}\left(t'',\tilde{t}\right)\hat{F}(\hat{p},\hat{q},\tilde{t})\hat{U}\left(\tilde{t},t'\right) = \hat{U}\left(t'',\tilde{t}\right)\hat{U}\left(\tilde{t},t'\right)\hat{U}^{\dagger}\left(\tilde{t},t'\right)\hat{F}(\hat{p},\hat{q},\tilde{t})\hat{U}\left(\tilde{t},t'\right) =$

$$= \hat{U}\left(t'',\tilde{t}\right)\hat{U}\left(\tilde{t},t'\right)\hat{F}_H(\hat{p},\hat{q},\hat{t}) = \hat{U}\left(t'',t'\right)\hat{F}_H(\hat{p},\hat{q},\tilde{t}),$$

где мы воспользовались определением оператора эволюции, согласно которому $\hat{U}\left(t'',\tilde{t}\right)\hat{U}\left(\tilde{t},t'\right) = \hat{U}\left(t'',t'\right)$. Поэтому матричный элемент

$$\langle F(\tilde{t})\rangle = \left\langle q''\left|\hat{U}\left(t'',\tilde{t}\right)\hat{F}(\hat{p},\hat{q},\tilde{t})\hat{U}\left(\tilde{t},t'\right)\right|q'\right\rangle = \left\langle q''\left|\hat{U}\left(t'',t'\right)\hat{F}_H(\hat{p},\hat{q},\tilde{t})\right|q'\right\rangle$$

можно переписать, если ввести обозначение для начального состояния в момент времени t'

$$|q'\rangle = |\mathrm{in}'\rangle,$$

а для конечного в момент времени t''

$$|q''\rangle = |\text{ out }''\rangle,$$

так что обратная эволюция дает

$$\ddot{U}^{\dagger}\left(t'',t'\right)|q''\rangle = |\mathrm{in}''\rangle.$$

Отсюда

$$\langle F(\tilde{t})\rangle = \left\langle q''\left|\hat{U}\left(t'',t'\right)\hat{F}_H(\hat{p},\hat{q},\tilde{t})\right|q'\right\rangle = \left\langle \mathrm{in}''\left|\hat{F}_H(\hat{p},\hat{q},\tilde{t})\right|\mathrm{in}'\right\rangle,$$

а стало быть, имеет место следующая связь континуального интеграла и матричного элемента оператора в представлении Гейзенберга по in-состояниям

$$\langle F(\tilde{t})\rangle = \left\langle \mathrm{in}'' \left| \hat{F}_H(\hat{p},\hat{q},\bar{t}) \right| \mathrm{in}' \right\rangle = \int \mathcal{D}q\mathcal{D}p \mathrm{e}^{\frac{i}{\hbar}S(t',t'')} \mathcal{F}(p(\hat{t}),q(\tilde{t}),\bar{t})$$
$$= -\mathrm{i}\hbar \frac{\delta}{\delta j_F(\bar{t})} \int \mathcal{D}q\mathcal{D}p \mathrm{e}^{\hbar} S\left(t',t''\right) + \hbar S_{\mathrm{ext}}\ [j_F]\big|_{jF=0}$$

что в конце формулы мы также записали одноточечный коррелятор $\langle F(\tilde{t})\rangle$ через вариационную производную интеграла по траекториям при наличии внешнего источника j_F для оператора $\hat{F}$ согласно (13.39).

Рассмотрим теперь связь интеграла по траекториям от двух физических наблюдаемых с операторным представлением этих величин. Если задан континуальный интеграл от двух величин F и G в моменты времени $t'' > t_1 > t_2 > t'$ $\langle F\left(t_1\right) G\left(t_2\right)\rangle = \int \mathcal{D}q\mathcal{D}p \mathrm{e}^{\frac{i}{\hbar}S(t',t'')} \mathcal{F}\left(p\left(t_1\right),q\left(t_1\right),t_1\right) \mathcal{G}\left(p\left(t_2\right),q\left(t_2\right),t_2\right)$, (13.42) который называют двухточечным коррелятором, то, как мы показали выше три рассмотрении одного оператора в обкладках оператора эволюции на стр. 247, его можно представить как

$$\langle F\left(t_1\right) G\left(t_2\right)\rangle = \left\langle q'' \left| \hat{U}\left(t'',t_1\right) \hat{F} \hat{U}\left(t_1,t_2\right) \hat{G} \hat{U}\left(t_2,t'\right) \right| q' \right\rangle .$$

В этом выражении порядок операторов строго задан условием $t_1 > t_2$! Введем операторы в представлении Гейзенберга, так что

$$\hat{G}_H\left(t_2\right) = \hat{U}^{\dagger}\left(t_2,t'\right) \hat{G} \hat{U}\left(t_2,t'\right)$$

и воспользуемся, во-первых, унитарностью оператора эволюции и, во-вторых, его основным свойством сдвига квантового состояния по времени, например,

$$\hat{U}\left(t_1,t_2\right) \hat{U}\left(t_2,t'\right) = \hat{U}\left(t_1,t'\right).$$

Тогда

$$\hat{U}\left(t'',t_1\right) \hat{F} \hat{U}\left(t_1,t_2\right) \hat{G} \hat{U}\left(t_2,t'\right) = \hat{U}\left(t'',t_1\right) \hat{F} \left\{ \hat{U}\left(t_1,t_2\right) U\left(t_2,t'\right) \right\} \times$$
$$\times \left\{ \hat{U}^{\dagger}\left(t_2,t'\right) \hat{G} \hat{U}\left(t_2,t'\right) \right\} = \hat{U}\left(t'',t_1\right) \hat{F} \hat{U}\left(t_1,t'\right) \hat{G}_H\left(t_2\right) =$$
$$= \left\{ \hat{U}\left(t'',t_1\right) \hat{U}\left(t_1,t'\right) \right\} \hat{F}_H\left(t_1\right) \hat{G}_H\left(t_2\right) = \hat{U}\left(t'',t'\right) \hat{F}_H\left(t_1\right) \hat{G}_H\left(t_2\right).$$

В итоге при $t_1 > t_2$

$$\int \mathcal{D}q\mathcal{D}p \mathrm{e}^{\frac{i}{\hbar}S(t',t'')} \mathcal{F}\left(p\left(t_1\right),q\left(t_1\right),t_1\right) \mathcal{G}\left(p\left(t_2\right),q\left(t_2\right),t_2\right) =$$
$$= \left\langle q'' \left| \hat{U}\left(t'',t'\right) \hat{F}_H\left(t_1\right) \hat{G}_H\left(t_2\right) \right| q' \right\rangle$$

Поэтому после перехода к in-состояниям получаем матричный элемент операторов в представлении Гейзенберга по базису в начальный момент времени при строгом упорядочении операторов по времени $\langle F\left(t_1\right) G\left(t_2\right)\rangle = \int \mathcal{D}q\mathcal{D}p \mathrm{e}^{\frac{i}{\hbar}S(t',t'')} \mathcal{F}\left(p\left(t_1\right),q\left(t_1\right),t_1\right) \mathcal{G}\left(p\left(t_2\right),q\left(t_2\right),t_2\right) = = \langle \mathrm{in} \left| \hat{F}_H\left(t_1\right) \hat{G}_H\left(t_2\right) \right| \mathrm{in}\ '\rangle$. (13.44) Как мы уже знаем, такой оператор хронологического упорядочивания обозначается символом $\hat{\mathrm{T}}$, так что при произвольных значениях моментов времени континуальный интеграл $\langle F\left(t_1\right) G\left(t_2\right)\rangle$ равен матричному элементу T-произведения операторов

$$\left\langle \mathrm{in}'' \left| \hat{\mathrm{T}} \left\{ \hat{F}_H\left(t_1\right) \hat{G}_H\left(t_2\right) \right\} \right| \mathrm{in}' \right\rangle = \begin{cases} \left\langle \mathrm{in}'' \left| \hat{F}_H\left(t_1\right) \hat{G}_H\left(t_2\right) \right| \mathrm{in}\ ' \right\rangle, & t_1 > t_2, \\ \left\langle \mathrm{in}'' \left| \hat{G}_H\left(t_2\right) \hat{F}_H\left(t_1\right) \right| \mathrm{in}\ ' \right\rangle, & t_2 > t_1 \end{cases}$$

Введение внешних источников для операторов за счет добавки к действию вкладов

$$\mathrm{e}^{\frac{i}{\hbar}S_{\mathrm{ext}}\,[j_F]}=\mathrm{e}^{\frac{j}{\hbar}\int dtj_F(t)\mathcal{F}(p(t),q(t),t)},\quad \mathrm{e}^{\frac{\dot{b}}{\hbar}S'_{\mathrm{axt}}\,[j_G]}=\mathrm{e}^{\frac{1}{\hbar}\int \mathrm{d}tj_G(t)\mathcal{G}(p(t),q(t),t)},$$

позволяет получить связь операторного выражения для матричного элемента с интегралом по траекториям, для которого вычисляются вариационные производные, так что двухточечный коррелятор $\langle F\left(t_1\right)G\left(t_2\right)\rangle$ равен

$$\left\langle \mathrm{in}''\left|\hat{\mathrm{T}}\left\{\hat{F}_H\left(t_1\right)\hat{G}_H\left(t_2\right)\right\}\right|\mathrm{in}'\right\rangle=(-\mathrm{i}\hbar)^2\frac{\delta^2}{\delta j_F\left(t_1\right)\delta j_G\left(t_2\right)}Z\left[j_F,j_G\right]\Big|_{jF=jG=0},$$

$$Z\left[j_F,j_G\right]=\int\mathcal{D}q\mathcal{D}p\mathrm{e}^{\frac{i}{\hbar}S(t',t'')+\frac{i}{\hbar}(S_{\mathrm{ext}}\,[jF]+S'_{\mathrm{ext}}\,[jG])}.$$

Обобщение на случай нескольких операторов очевидно. Нас же в квантовой теории будут интересовать, как говорят, T-упорядоченные корреляторы в случае, когда в качестве начального и конечного состояний выступает вакуум, $|\ \mathrm{in}\ '\rangle=|\ \mathrm{in}\ ''\rangle=|\ \mathrm{vac}\ \rangle$. При этом вакуум $|\mathrm{vac}\rangle$ мы трактуем как фоковское состояние $|0\rangle$ для асимптотически свободных элементарных осцилляторов. Тогда, например, для осциллятора вычисляется двухточечный коррелятор обобщенной координаты

$$\begin{aligned}\langle q\left(t_1\right)q\left(t_2\right)\rangle=\mathcal{D}_{(12)}=\mathcal{D}\left(t_1,t_2\right)=\left\langle 0\left|\hat{\mathrm{T}}\left\{\hat{q}\left(t_1\right)\hat{q}\left(t_2\right)\right\}\right|0\right\rangle=\\=(-\mathrm{i}\hbar)^2\frac{\delta^2}{\delta j\left(t_1\right)\delta j\left(t_2\right)}\int\mathcal{D}q\mathcal{D}p\mathrm{e}^{\hbar}S\left(t',t''\right)+\hbar S_{\mathrm{ext}}[j]\big|_{j=0}=\\=\int\mathcal{D}q\mathcal{D}p\mathrm{e}^{\frac{i}{\hbar}S(t',t'')}q\left(t_1\right)q\left(t_2\right),\end{aligned}$$

где мы опустили знак, который указывает на то, что операторы берутся в представлении Гейзенберга, а для действия с внешним источником $j(t)$ ввели стандартное выражение

$$S_{\mathrm{ext}}\,[j]=j_{(t)}q_{(t)}$$

и использовали соглашение об интегрировании по немой переменной t, записанной в виде индекса в скобках.

Поэтому в следующем разделе мы рассмотрим формулировку для оператора эволюции гармонического осциллятора для вакуум-вакуумных переходов, стартуя с более общего построения для когерентных состояний, частнъм случаем которых является вакуум.

Итак, нас интересует следующая постановка задачи: квантовая система находится в начальном вакуумном состоянии, когда на неё начинают действовать внешние силы (источники). Это приводит к тому, что в квантовой системе под воздействием внешних источников происходят виртуальные процессы. В конечном состоянии нас интересует ситуация, когда квантовая система возвращается в состояние вакуума, но виртуальные квантовые процессы приводят к тому, что возникает обратный отклик квантовой системы на конфигурацию внешних источников, т.е. сама квантовая система воздействует на внешние источники. По тому, какой это отклик при разных воздействиях, мы сможем получить полное описание всей квантовой системы по характеристикам внешних источников в начальном и конечном состоянии. Именно, необходимо вычислить амплитуды вероятности перехода от состояния с одними характеристиками внешних источников в начале эволюции к состоянию с те ми же или со всеми другими характеристикам внешних источников в конце эволюции. Такая постановка квантовой задачи - это швингеровский подход к квантовой механике. Если все амплитуды вероятности перехода «вакуумвакуум» вычислены при любых

конфигурациях внешних источников, то задача решена точно. При этом ясно, что вычисление матричных элементов, в которых, например, в начальном состоянии есть кванты, а не вакуум, типа

$$\left\langle 0 \left| \hat{F}\left(t_1\right) \right| 1 \right\rangle$$

сводится к расчету амплитуды перехода «вакуум-вакуум», если воспользоваться операторами рождения квантов в момент начала эволюции $t = t'$,

$$|1\rangle = \hat{a}^{\dagger}\left(t'\right)|0\rangle.$$

Значит,

$$\left\langle 0 \left| \hat{F}\left(t_1\right) \right| 1 \right\rangle = \left\langle 0 \left| \hat{\mathrm{T}}\left\{ \hat{F}\left(t_1\right) \hat{a}^{\dagger}\left(t'\right) \right\} \right| 0 \right\rangle,$$

и задача опять сводится к вычислению вариационных производных амплитуды вероятности перехода «вакуум-вакуум» при наличии соответствующих источников. Более того, поскольку оператор уничтожения квантов при действии на вакуум дает нуль, $\hat{a}\left(t'\right)|0\rangle = 0$, можно записать, что

$$\left\langle 0 \left| \hat{F}\left(t_1\right) \right| 1 \right\rangle = \left\langle 0 \left| \hat{\mathrm{T}}\left\{ \hat{F}\left(t_1\right) \left(\hat{a}^{\dagger}\left(t'\right) + \hat{a}\left(t'\right) \right) \right\} \right| 0 \right\rangle.$$

а так как координата выражается через операторы рождения и уничтожения, как

$$\hat{q}\left(t'\right) = \sqrt{\frac{\hbar}{2m\omega_0}} \left(\hat{a}^{\dagger}\left(t'\right) + \hat{a}\left(t'\right) \right),$$

ТО

$$\left\langle 0 \left| \hat{F}\left(t_1\right) \right| 1 \right\rangle = \sqrt{\frac{2m\omega_0}{\hbar}} \cdot \left\langle 0 \left| \hat{\mathrm{T}}\left\{ \hat{F}\left(t_1\right) \hat{q}\left(t'\right) \right\} \right| 0 \right\rangle.$$

Следовательно, амплитуда вероятности перехода «вакуум-вакуум при наличии внешних источников содержит в себе исчерпывающую информацию о всевозможных многоточечных матричных элементах операторов по различным начальным и конечным состояниям!

Как мы увидим, вычисление амплитуды вероятности перехода «вакуумвакуум означает, что уравнения для амплитуды вероятности - уравнения Швингера-Дайсона в вариационных производных решены. Как можно предположить, число точно решаемых таким способом задач невелико, а природа преподносит нам варианты реальности - квантовые системы, найти точные решения для которых нелегко. В таком случае приходится более детально рассматривать те виртуальные процессы, которые происходят в вакууме при воздействии внешних источников, выделяя среди этих процессов наиболее физически значимые. Для этой ситуации важнейшую роль играет техника диаграмм Фейнмана.

Диаграммы возникают согласно следующему рассмотрению. Вычислим в операторном подходе двухточечный коррелятор в переходах «вакуум-вакуум для осциллятора с частотой ω_0

$$\left\langle q\left(t_1\right) q\left(t_2\right) \right\rangle = \mathcal{D}_{(12)} = \left\langle 0 \left| \hat{\mathrm{T}}\left\{ \hat{q}\left(t_1\right) \hat{q}\left(t_2\right) \right\} \right| 0 \right\rangle.$$

Если гейзенберговские операторы координат записать в терминах операторов рождения и уничтожения

$$\hat{q}(t) = \sqrt{\frac{\hbar}{2m\omega_0}} \left(\hat{a}^{\dagger} \mathrm{e}^{\mathrm{i}\omega_0 t} + \hat{a} \mathrm{e}^{-\mathrm{i}\omega_0 t} \right),$$

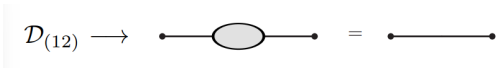
то при $t_1 > t_2$

$$\left\langle 0 \left| \hat{\mathrm{T}} \left\{ \hat{q}\left(t_1\right) \hat{q}\left(t_2\right) \right\} \right| 0 \right\rangle = \frac{\hbar}{2m\omega_0} \left\langle 0 \left| \left(\hat{a}^\dagger \mathrm{e}^{\mathrm{i}\omega_0 t_1} + \hat{a}\mathrm{e}^{-\mathrm{i}\omega_0 t_1} \right) \left(\hat{a}^\dagger \mathrm{e}^{\mathrm{i}\omega_0 t_2} + \hat{a}\mathrm{e}^{-\mathrm{i}\omega_0 t_2} \right) \right| 0 \right\rangle =$$
$$= \frac{\hbar}{2m\omega_0} \left\langle 0 \left| \left(\hat{a}^\dagger \mathrm{e}^{\mathrm{i}\omega_0 t_1} + \hat{a}\mathrm{e}^{-\mathrm{i}\omega_0 t_1} \right) \mathrm{e}^{\mathrm{i}\omega_0 t_2} \right| 1 \right\rangle = \frac{\hbar}{2m\omega_0} \mathrm{e}^{-\mathrm{i}\omega_0 (t_1 - t_2)} \langle 0|\hat{a}|1\rangle =$$
$$= \frac{\hbar}{2m\omega_0} \mathrm{e}^{-\mathrm{i}\omega_0 (t_1 - t_2)}.$$

Эти преобразования состояний имеют вполне ясный физический смысл: сначала при $t_2 < t_1$ из вакуума произопло рождения кванта энергии (частицы с квантом энергии $\hbar\omega_0$, а затем этот квант был уничтожен в момент времени $t_1 > t_2$ и система осталась в вакуумном состоянии. В случае $t_1 < t_2$ операторы координат при раскрытии Т-произведения меняются местами, и вычисления повторяются, но, как легко заметить, оба случая сводятся друг к другу, если в конечном выражении в экспоненте просто поставить положительную разность времен, т.е.

$$\left\langle q\left(t_1\right) q\left(t_2\right) \right\rangle = \mathcal{D}_{(12)} = \left\langle 0 \left| \hat{\mathrm{T}} \left\{ \hat{q}\left(t_1\right) \hat{q}\left(t_2\right) \right\} \right| 0 \right\rangle = \frac{\hbar}{2m\omega_0} \mathrm{e}^{-\mathrm{i}\omega_0 |t_1 - t_2|}.$$

Итак, пропагатор $\mathcal{D}_{(12)}$ описывает рождение кванта из вакуума в момент времени до того, как он исчез в последующий момент времени, так что двухточечному коррелятору, т.е. функции $\mathcal{D}_{(12)}$, имеет смысл сопоставить диаграмму распространения кванта из точки 1 в точку 2



где точки отвечают моментам времени, где рождается и уничтожается квант, а линия - распространение кванта между точками. При этом левая диаграмма обозначает общий случай, когда у осциллятора есть ангармонические взаимодействия, правая - свободный осциллятор. Равенство говорит о том, что для свободного осциллятора пропагатор сводится к простому распространению. Что произойдет при появлении дополнительных взаимодействий, мы рассмотрим позже. Важно, что диаграммы Фейнмана взаимнооднозначно соответствуют многоточечным корреляторам.

релятивистская частица через интеграл по траекториям

осциллятор через интеграл по траекториям

(это же в разделе про осциллятор)

8.2.2 Source and Generating Functional

(тут мы пишем большие формулы, лучше отложить чтение этого раздела, не так это актуально понимать)

Теория

Рассмотрим теперь частицу, на которую действует внешняя сила $j(t)$, зависящая от времени, так что

$$\mathcal{H} = \frac{p^2}{2m} + V(q) - j(t)q$$

В этом случае говорят о гамильтониане с источником j, и ставится задача вычисления амплитуды квантовых переходов при произвольном источнике. В присутствии источника интеграл по траекториям функционально зависит ОТ j

$$Z[j] = \mathcal{N} \int \mathcal{D}q \exp\left\{ \frac{\mathrm{i}}{\hbar} \int\limits_{t'}^{t''} \mathrm{d}t \left[\frac{m\dot{q}^2(t)}{2} - V(q(t)) + j(t)q(t) \right] \right\},$$

Или

$$Z[j] = \mathcal{N} \int \mathcal{D}q \exp\left\{ \frac{i}{\hbar} S\left(t', t'', j\right) \right\}$$

Функциональная замена переменных

$$q(t) \to \tilde{q}(t) = q(t) + \delta q(t), \quad \delta q\left(t'\right) = \delta q\left(t''\right) = 0$$

представляет собой сдвиг, который не изменяет ни меры интегрирования

$$\mathcal{D}q = \mathcal{D}\tilde{q}$$

ни значения функционального интеграла

$$Z[j] = \mathcal{N} \int \mathcal{D}\tilde{q} \exp\left\{ \frac{\mathrm{i}}{\hbar} \tilde{S}\left(t', t'', j\right) \right\}$$

Вычитая из функционала 14.5 самого себя в записи 14.3, находим при $\delta q(t) \to 0$

$$\frac{\delta Z[j]}{\delta q(t)} = 0 \quad \Leftrightarrow \quad \int \mathcal{D}q \frac{\mathrm{i}}{\hbar} \frac{\delta S}{\delta q(t)} \mathrm{e}^{\frac{\mathrm{i}}{\hbar} S(t', t'', j)} = 0.$$

Сюда нужно подставить вариацию Эйлера

$$\frac{\delta S}{\delta q(t)} = -m\ddot{q}(t) - V'(q(t)) + j(t)$$

где V' - производная потенциала по координате, так что

$$\int \mathcal{D}q \left\{ m\ddot{q}(t) + V'(q(t)) - j(t) \right\} \mathrm{e}^{\frac{\mathrm{i}}{\hbar} S(t', t'', j)} = 0.$$

Значит, мы установили квантовый аналог уравнения Лагранжа-Эйлера: уравнения движения остаются справедливыми в смысле интеграла по траекториям.

Наличие источника позволяет преобразовать квантовые уравнения Эйлера-Лагранжа. Действительно,

$$-\mathrm{i}\hbar \frac{\delta Z[j]}{\delta j(t)} = \mathcal{N} \int \mathcal{D}q \cdot q(t) \mathrm{e}^{\frac{\mathrm{i}}{\hbar} S(t', t'', j)}$$

поэтому (14.7) представимо в виде

$$m \frac{\mathrm{d}^2}{\mathrm{d}t^2} \left\{ -\mathrm{i}\hbar \frac{\delta Z[j]}{\delta j(t)} \right\} = -V' \left(-\mathrm{i}\hbar \frac{\delta}{\delta j(t)} \right) Z[j] + j(t) Z[j]$$

Принято делать подстановку

$$Z[j] = \mathcal{N} \mathrm{e}^{\frac{\mathrm{i}}{\hbar} G[j]}$$

тогда

$$m\frac{\mathrm{d}^2}{\mathrm{d}t^2}\left\{\frac{\delta G[j]}{\delta j(t)}\right\} = -\mathrm{e}^{-\frac{\mathrm{i}}{\hbar}G[j]}V'\left(-\mathrm{i}\hbar\frac{\delta}{\delta j(t)}\right)\mathrm{e}^{\frac{\mathrm{i}}{\hbar}G[j]} + j(t)$$

Уравнения в функциональных производных 14.9 и 14.11 суть уравнения Швингера-Дайсона.

Для иллюстрации приведем пример гармонического осциллятора:

$$V(q) \mapsto V_0(q) = \frac{m\omega_0^2}{2}q^2 \Rightarrow V_0'(q) = m\omega_0^2 q$$

откуда уравнение на $G[j]$ для осциллятора принимает вид

$$m\frac{\mathrm{d}^2}{\mathrm{d}t^2}\left\{\frac{\delta G[j]}{\delta j(t)}\right\} = -m\omega_0^2\frac{\delta G[j]}{\delta j(t)} + j(t).$$

Это - функциональное уравнение с источником. В нем можно брать многократные вариационные производные по току в разные моменты времени и потом полагать затем значение тока равным нулю: таким образом возникает бесконечная цепочка уравнений для n-кратных производных функционала $G[j]$ при нулевых значениях внешнего источника! Например, если положить $j = 0$ непосредственно в уравнении 14.12, то получится

$$m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t^2} + \omega_0^2\right\}\mathcal{G}^{(1)}(t) = 0, \quad \mathcal{G}^{(1)}(t) \stackrel{\text{def}}{=} \left.\frac{\delta G[j]}{\delta j(t)}\right|_{j=0}$$

а это значит, что функция $\mathcal{G}^{(1)}(t)$ - это решение уравнения для осциллятора с заданными граничными условиями: $\mathcal{G}^{(1)}(t') = q'$ и $\mathcal{G}^{(1)}(t'') = q''$.

Функционал $G[j]$ можно разложить в функциональный ряд Тейлора

$$G[j] = \mathcal{G}_0 + \int \mathcal{G}^{(1)}(t)j(t)\mathrm{d}t + \\ + \frac{1}{2!}\int \mathcal{G}_{(12)}(t_1,t_2)\,j(t_1)\,j(t_2)\,\mathrm{d}t_1\,\mathrm{d}t_2 + \ldots = \sum_{n=0}^{\infty}\mathcal{G}_{(1\ldots n)}\frac{1}{n!}j_{(1)}\cdots j_{(n)}.$$

Очевидно

$$\mathcal{G}_0 = -\mathrm{i}\hbar\ln\frac{Z[0]}{\mathcal{N}}$$

так что обычно переходят к амплитуде, которая имеет

$$Z[0] = 1$$

чтобы не загромождать формулы, и обозначают её тем же символом, и тогда $\mathcal{G}_0 = 0$

Вариационная производная основного уравнения дает

$$m\frac{\mathrm{d}^2}{\mathrm{d}t_1^2}\left\{\frac{\delta^2 G[j]}{\delta j(t_1)\,\delta j(t_2)}\right\} + m\omega_0^2\frac{\delta^2 G[j]}{\delta j(t_1)\,\delta j(t_2)} = \delta(t_1 - t_2)$$

так что, полагая $j = 0$, находим

$$m\frac{\mathrm{d}^2}{\mathrm{d}t_1^2}\mathcal{G}_{(12)}(t_1,t_2) + m\omega_0^2\mathcal{G}_{(12)}(t_1,t_2) = \delta(t_1 - t_2)$$

т. е. уравнение для двухточечной функции Грина. Домножая это уравнение на $j(t_2)$ и интегрируя по t_2, очевидно, находим уравнение движения для осциллятора с внешней силой (источником)

$$m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t_1^2}+\omega_0^2\right\}\int \mathcal{G}_{(12)}\left(t_1,t_2\right)j\left(t_2\right)\mathrm{d}t_2=j\left(t_1\right)$$

и решение этого уравнения записано в виде вынужденных колебаний

$$q(j;t)=\int \mathcal{G}^{(2)}\left(t,t_2\right)j\left(t_2\right)\mathrm{d}t_2,\quad \mathcal{G}^{(2)}\left(t,t_2\right)=\mathcal{G}_{(t2)},$$

причем общее решение получается суммированием свободных колебаний $q_0(t)=\mathcal{G}^{(1)}(t)$ и вынужденных $q(j;t)$. При этом нужно иметь ввиду, конечно, что движение не должно зависеть от источника в ненаступившем будущем, т. е. при $t>t''$, а также от того, что было до того, когда было задано исходное положение частицы, т. е. при $t<t'$, а значит, интеграл для вынужденных колебаний берется как определенный, т. е. в интервале $t'\leqslant t\leqslant t''$. Поскольку исходное уравнение для двухточечной функции 14.14 содержит оператор, симметричный по аргументам t_1 и t_2, и зависит от источника с аргументом t_1-t_2, его общее решение можно представить в виде частного решения неоднородного уравнения, зависящего, как и источник, от разности времени t_1-t_2, и общего решения однородного, которое симметрично относительно перестановки $t_1\leftrightarrow t_2$,

$$\mathcal{G}_{(12)}\left(t_1,t_2\right)=\tilde{\mathcal{G}}_{(12)}\left(t_1-t_2\right)+C\cdot\mathcal{G}_{(1)}\left(t_1\right)\mathcal{G}_{(1)}\left(t_2\right)$$

т. е. с точностью до вклада свободной волны с некоторой нормировкой C. Определить постоянную C можно, исходя из граничных условий: для свободных колебаний уже фиксированы условия $q_0\left(t'\right)=q'$ и $q_0\left(t''\right)=q''$, так что добавка к свободным вынужденных колебаний $q(j;t)$ должна подчиняться условиям

$$q\left(j;t'\right)=q\left(j;t''\right)\equiv 0$$

и следовательно, из явного вида вынужденных колебаний через двухточечную функцию 14.15 при произволъном источнике заключаем, что

$$\mathcal{G}_{(12)}\left(t',t\right)=\mathcal{G}_{(12)}\left(t'',t\right)=0,\quad t'\leqslant t\leqslant t'',$$

где мы учли, что $\mathcal{G}_{(12)}\left(t_1,t_2\right)$, как мы уже отмечали, должна быть симметрична по перестановке своих аргументов.

Задача 7.2.

Рассматривая решение уравнения 14.14 для двухточечной функции $\mathcal{G}_{(12)}\left(t_1,t_2\right)$ с заданными граничными условиями, докажите, что

$$\begin{aligned}\mathcal{G}_{(12)}\left(t_1,t_2\right)=\frac{1}{2m\omega_0\sin\omega_0\left(t''-t'\right)}\{&\sin\omega_0\left(t''-t'\right)\sin\omega_0\left|t_1-t_2\right|-\\&-\sin\omega_0\left(t_1-t'\right)\sin\omega_0\left(t''-t_2\right)-\\&-\sin\omega_0\left(t_2-t'\right)\sin\omega_0\left(t''-t_1\right)\},\end{aligned}$$

с учетом допустимого интервала значений $t'\leqslant t_{1,2}\leqslant t''$.

Точно так же при $n\geqslant 3$ уравнение Швингера-Дайсона означает, что

$$m\frac{\mathrm{d}^2}{\mathrm{d}t_1^2}\mathcal{G}_{(1\ldots n)}\left(t_1,\ldots,t_n\right)+m\omega_0^2\mathcal{G}_{(1\ldots n)}\left(t_1,\ldots,t_n\right)=0$$

и, следовательно, многоточечные функции Грина для осциллятора удовлетворяют свободному уравнению и могут быть построены в виде композиций $\mathcal{G}^{(1)}\left(t_k\right)$, что с учетом граничных условий (свободное движение уже включено в линейный вклад $\mathcal{G}_{(1)}\big)$ в виде

$\mathcal{G}_{(1...n)}(t_1,...,t_n)\big|_{t_k=t'} = \mathcal{G}_{(1...n)}(t_1,...,t_n)\big|_{t_k=t''} = 0, \quad t' \leqslant t_k \leqslant t'', \quad k = \{\overline{1,n}\}$,
приводит к результату

$$\mathcal{G}_{(1...n)}(t_1,...,t_n) = 0, \quad n \geqslant 3$$

Для осциллятора

$$G[j] = \mathcal{G}_0 + \int \mathcal{G}^{(1)}(t) j(t) \mathrm{d}t + \frac{1}{2!}\int \mathcal{G}_{(12)}(t_1,t_2)\, j(t_1)\, j(t_2)\, \mathrm{d}t_1\ \mathrm{d}t_2$$

Это есть исключительное свойство гармонического осциллятора - системы, гамильтониан которой квадратичен как по импульсу, так и по координате. Исключительное внимание к осциллятору обусловлено не столько тем, что задача решается точно, а в большей степени той ролью, которую осциллятор приобретает при рассмотрении полей: свободные поля представимы как сумма элементарных осцилляторов с волновым вектором $\boldsymbol{k}$ и частотой $\omega = \omega(\boldsymbol{k})$.

Амплитуду вероятности - матричный элемент оператора эволюции при наличии источников $-Z[j]$ также можно разложить в вариационный ряд Тейлора

$$Z[j] = 1 + \int \frac{\delta Z}{\delta j(t)}\bigg|_{j=0} j(t)\mathrm{d}t + \frac{1}{2!}\int \frac{\delta^2 Z}{\delta j(t_1)\,\delta j(t_2)}\bigg|_{j=0} j(t_1)\, j(t_2)\, \mathrm{d}t_1\ \mathrm{d}t_2 + \\ + \frac{1}{3!}\frac{\delta^3 Z}{\delta j_{(1)}\delta j_{(2)}\delta j_{(3)}}\bigg|_{j=0} j_{(1)} j_{(2)} j_{(3)} + ...$$

где мы отнормировали амплитуду на единицу, как это уже было описано выше. Это разложение записывают через кореляторы. Так,

$$-\,\mathrm{i}\hbar\frac{\delta Z}{\delta j(t)}\bigg|_{j=0} = \langle \hat{q}(t)\rangle = \mathcal{G}^{(1)}(t)$$

где усреднение берется то начальному и конечному состоянию, заданным в задаче, так что одноточечный коррелятор - это матричный элемент координаты, а в случае переходов «вакуум-вакуум» - это среднее значение координаты по вакууму. Далее, во втором порядке по внешним источникам возникает величина

$$(-\mathrm{i}\hbar)^2\frac{\delta^2 Z}{\delta j(t_1)\,\delta j(t_2)}\bigg|_{j=0} = \left\langle \hat{T}\left\{\hat{q}(t_1)\,\hat{q}(t_2)\right\}\right\rangle$$

которая есть двухточечный коррелятор, который еще называют пропагатором, а в высших порядках вводят

$$\mathcal{D}_{(1...n)} = (-\mathrm{i}\hbar)^n\frac{\delta^n Z}{\delta j_{(1)}...\delta j_{(n)}}\bigg|_{j=0} = \left\langle \hat{\mathrm{T}}\left\{\hat{q}(t_1)...\hat{q}(t_n)\right\}\right\rangle$$

который называют n-точечным коррелятором (на жаргоне «n-точка»). Значит,

$$Z[j] = \sum_{n=1}^{\infty}\left(\frac{\mathrm{i}}{\hbar}\right)^n \frac{1}{n!}\mathcal{D}_{(1...n)} j_{(1)}...j_{(n)}.$$

Для двухточечной функции $\mathcal{D}_{(12)}$ в самом общем случае имеем

$$\mathcal{D}_{(12)}(t_1,t_2) = -\mathrm{i}\hbar\mathcal{G}_{(12)}(t_1,t_2) + \mathcal{G}^{(1)}(t_1)\,\mathcal{G}^{(1)}(t_2)$$

В случае переходов «вакуум-вакуум» для осциллятора $\mathcal{G}^{(1)}(t) \equiv 0$, так что можно однозначно вычислить двухточечные функции $\mathcal{D}_{(12)}$ и $\mathcal{G}_{(12)}$. В самом деле, уравнение Швингера-Дайсона 14.9 в случае осциллятора имеет вид

$$m\frac{\mathrm{d}^2}{\mathrm{d}t^2}\left\{-\mathrm{i}\hbar\frac{\delta Z[j]}{\delta j(t)}\right\} = -m\omega_0^2(-\mathrm{i}\hbar)\frac{\delta}{\delta j(t)}Z[j] + j(t)Z[j]$$

так что, если взять вариационную производную по источникам $j\,(t_2)$ и положить $j = 0$, то получится

$$m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t_1^2} + \omega_0^2\right\}(-\mathrm{i}\hbar)^2\frac{\delta^2 Z}{\delta j_{(1)}\delta j_{(2)}}\bigg|_{j=0} = -\mathrm{i}\hbar\delta\,(t_1 - t_2)\,.$$

Поскольку

$$(-\mathrm{i}\hbar)^2\frac{\delta^2 Z}{\delta j_{(1)}\delta j_{(2)}}\bigg|_{j=0} = \mathcal{D}_{(12)} = \left\langle 0\,\middle|\hat{\mathrm{T}}\left\{\hat{q}\,(t_1)\,\hat{q}\,(t_2)\right\}\middle|\,0\right\rangle$$

находим уравнение на функцию Грина $\mathcal{D}_{(12)}$

$$m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t_1^2} + \omega_0^2\right\}\mathcal{D}_{(12)} = -\mathrm{i}\hbar\delta\,(t_1 - t_2)\,.$$

Записывая преобразование Фурье

$$\mathcal{D}_{(12)}(t) = \int\frac{\mathrm{d}\omega}{2\pi}\mathrm{e}^{-\mathrm{i}\omega t}\mathcal{D}^{(2)}(\omega)$$

найдем, что

$$\mathcal{D}^{(2)}(\omega) = \frac{\mathrm{i}\hbar}{m\,(\omega^2 - \omega_0^2)}$$

имеет полюса при $\omega = \pm\omega_0$, обход которых должен быть согласован с граничными условиями в асимптотическом прошлом и будущем. Решение в виде контура интегрирования в плоскости комплексной ω показано на рис. 21.

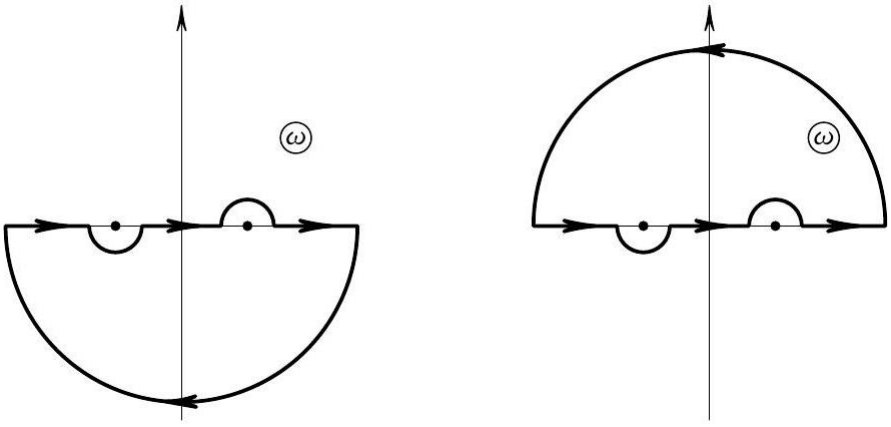


Рис. 21. Контуры интегрирования в плоскости комплексной переменной ω при $t \to +\infty$ (слева) и $t \to -\infty$ (справа)

В самом деле, при $t \to +\infty$ контур можно замкнуть в нижней полуплоскости, так как отрицательная мнимая добавка к частоте в экспоненте приводит к нулевому вкладу по полуокружности, и полюс при $\omega = \omega_0 - \mathrm{i}0$ в экспоненте дает положительно частотную моду. Аналогично, при $t \to -\infty$ вклад по полуокружности в верхней полуплоскости обращается в нуль, и полюс при $\omega = -\omega_0 + \mathrm{i}0$ дает отрицательно частотную моду.

В итоге получаем так называемую причинную двухточечную фейнмановскую функиию Грина, которую такюе называют пропагатором:

$$\mathcal{D}^{(2)}(\omega) = \frac{\mathrm{i}\hbar}{m}\frac{1}{\omega^2 - \omega_0^2 + \mathrm{i}0}.$$

Описанные граничные условия, очевидно, можно получить, заметив, что они выводятся посредством замены $\omega_0 \to \omega_0(1 - \mathrm{i}\varepsilon)$, где $\varepsilon \to +0$, т. е. добавкой бесконечно малого затухания. Мы видели, что это затухание связано с шириной резонанса. Поэтому ясно, что физически малое значение ε приводит к вымиранию возбуждений вакуума, т. е. следует из условия стабильности вакуума. Этот же аргумент приводит к математическому обоснованию поворота Вика в плоскости частот (соответствующие интегралы по контуру при вращении от вещественной оси к мнимой на угол $\pi/2$ не встречают полюсов).

После преобразования Фурье

$$\mathcal{D}_{(12)}(t) = \int\limits_{-\infty}^{+\infty} \frac{\mathrm{d}\omega}{2\pi} \cdot \mathrm{e}^{-\mathrm{i}\omega t} \mathcal{D}^{(2)}(\omega)$$

которое можно найти, взяв при $t > 0$ интеграл Коши по контуру, изображенному слева на рис. 21.

$$\mathcal{D}_{(12)}(t) = \frac{\hbar}{2\omega_0 m} \mathrm{e}^{-\mathrm{i}\omega_0 t}, \quad t > 0$$

и при $t < 0$ по контуру справа на рис. 21

$$\mathcal{D}_{(12)}(t) = \frac{\hbar}{2\omega_0 m} \mathrm{e}^{\mathrm{i}\omega_0 t}, \quad t < 0$$

получаем

$$\mathcal{D}_{(12)}(t) = \frac{\hbar}{2\omega_0 m} \mathrm{e}^{-i\omega_0 |t|}$$

Этот же результат был получен нами операторным методом (см. стр. 257 раздел 13.2.

Задача 7.3. Методом выделения гауссовых вкладов и замены переменной интегрирования в фейнмановском интеграле по траекториям показать, что квадратичное по траектории действие вида

$$S\left(t', q', t'', q''\right) = \frac{1}{2} \int\limits_{t', q'}^{t'', q''} \mathrm{d}t q(t) \hat{\Gamma} q(t) + \int\limits_{t', q'}^{t'', q''} \mathrm{d}t j(t) q(t),$$

где оператор эволюции является эрмитово самосопряженным, $\hat{\Gamma} = \hat{\Gamma}^{\dagger}$, например, для осциллятора $\hat{\Gamma} q(t) = -m \left\{ \mathrm{d}^2 q(t)/\mathrm{d}t^2 + \omega_0^2 q(t) \right\}$, приводит к производящему функционалу связных функций Грина

$$G[j] = \mathcal{G}_0 + \int \mathcal{G}^{(1)}(t) j(t) \mathrm{d}t + \frac{1}{2!} \int \mathcal{G}^{(2)}\left(t_1, t_2\right) j\left(t_1\right) j\left(t_2\right) \mathrm{d}t_1 \, \mathrm{d}t_2$$

в котором $\mathcal{G}^{(1)}(t)$ - решение однородного уравнения

$$\hat{\Gamma} \mathcal{G}^{(1)}(t) = 0$$

с граничными условиями $\mathcal{G}^{(1)}\left(t'\right) = q', \mathcal{G}^{(1)}\left(t''\right) = q''$, а

$$\hat{\Gamma}^{-1} j\left(t_1\right) = -\int \mathcal{G}^{(2)}\left(t_1, t_2\right) j\left(t_2\right) \mathrm{d}t_2.$$

Задача 7.4. Докажите, что для симметричной вещественной матрицы M с положительными собственными значениями кратный гауссов интеграл

$$\int \exp\left\{-q_\alpha M^\alpha_\beta q^\beta\right\} \prod_{\alpha=1}^{n} \mathrm{d}q^\alpha = \frac{\pi^{n/2}}{\sqrt{\det M}}$$

Решение. У равнение на собственные значения матрицы

$$M \cdot e_k = \lambda_k e_k$$

задает базис собственных векторов матрицы, так что обратимое преобразование от координат q координатам $\tilde{q}$ в базисе e_k

$$q^\alpha = \mathcal{R}^\alpha_\beta \tilde{q}^\beta$$

приводит матрицу M к диагональному виду

$$\mathcal{R}^{\mathrm{T}} \cdot M \cdot \mathcal{R} = \mathrm{diag}\,(\lambda_1, ..., \lambda_n)$$

причем

$$\det M = \frac{1}{(\det \mathcal{R})^2} \prod_{k=1}^{n} \lambda_k$$

Тогда замена переменных интегрирования дает

$$\int \det \mathcal{R} \prod_{k=1}^{n} \mathrm{d}\tilde{q}_k \exp\left\{-\tilde{q}_k^2 \lambda_k\right\} = \det \mathcal{R} \prod_{k=1}^{n} \sqrt{\frac{\pi}{\lambda_k}} = \frac{\pi^{n/2}}{\sqrt{\det M}}$$

Заметим, что для вещественной симметричной матрицы M приведение к базису собственных векторов производится ортогональной матрицей, так что $\det \mathcal{R} = 1$, и детерминант сводится к произведению собственных значений матрицы M.

Задача 7.5. Для гармонического осциллятора вычислить интеграл по траекториям с граничными условиями $q\,(t') = q\,(t'') = 0$. Использовать известное выражение для интеграла по траекториям для свободной частицы и представление детерминанта в виде произведения собственных значений.

Решение. Интеграл

$$Z = \mathcal{N} \int \mathcal{D}q \exp\left\{-\frac{\mathrm{i}}{\hbar}\frac{m}{2}\int_{t'}^{t''} \mathrm{d}t q(t) \left(\frac{\mathrm{d}^2}{\mathrm{d}t^2} + \omega_0^2\right) q(t)\right\}\Bigg|_{q'=q''=0}$$

относится к гауссову типу с операторной матрицей

$$\hat{M} = \frac{m}{2}\left(\frac{\mathrm{d}^2}{\mathrm{d}t^2} + \omega_0^2\right)$$

которая при решении уравнения на собственные значения

$$\hat{M} q(t) = \lambda q(t), \qquad \text{при } q\,(t') = q\,(t'') = 0$$

имеет собственные функции

$$q(t) = \tilde{q} \sin \frac{\pi n\,(t - t')}{t'' - t'}, \quad n \geqslant 1$$

Так чТО

$$\lambda_n = -\frac{m}{2}\left\{\left(\frac{\pi n}{t''-t'}\right)^2 - \omega_0^2\right\}$$

После поворота Вика $t''-t' = -\mathrm{i}\Delta t_E$ собственные значения становятся положительНЫМи

$$\lambda_{E,n} = \frac{m}{2}\left(\frac{\pi n}{\Delta t_E}\right)^2\left\{1+\left(\frac{\omega_0\Delta t_E}{\pi n}\right)^2\right\}$$

а значит, функциональный детерминант операторной матрицы

$$\mathrm{Det}\,\hat{M} = \prod_{n=1}^{\infty}\lambda_{E.n} = \mathrm{Det}\,\hat{M}_0\prod_{n=1}^{\infty}\left\{1+\left(\frac{\omega_0\Delta t_E}{\pi n}\right)^2\right\}$$

где $\hat{M}_0 = \lim_{\omega_0\to 0}\hat{M}$ - это операторная матрица свободной частицы. Тогда, используя связь гауссова интеграла с детерминантом матрицы, в случае с интегралом по траекториям находим, что искомый интеграл

$$Z = \mathcal{N}\int \mathcal{D}q\exp\left\{-\frac{\mathrm{i}}{\hbar}\frac{m}{2}\int_{t'}^{t''}\mathrm{d}t q(t)\frac{\mathrm{d}^2}{\mathrm{d}t^2}q(t)\right\}\Bigg|_{q'=q''=0}\cdot\frac{1}{\sqrt{\prod_{n=1}^{\infty}\left\{1+\left(\frac{\omega_0\Delta t_E}{\pi n}\right)^2\right\}}}.$$

Мы уже вычислили интеграл по траекториям для свободной частицы, который в случае нулевых значений $q'=q''=0$ равен

$$Z_0 = \mathcal{N}\int \mathcal{D}q\exp\left\{-\frac{\mathrm{i}}{\hbar}\frac{m}{2}\int_{t'}^{t''}\mathrm{d}t q(t)\frac{\mathrm{d}^2}{\mathrm{d}t^2}q(t)\right\}\Bigg|_{q'=q''=0} = \sqrt{\frac{m}{2\pi\hbar\Delta t_E}}.$$

С учетом формуль [1]

$$\prod_{n=1}^{\infty}\left\{1+\left(\frac{z}{\pi n}\right)^2\right\} = \frac{\mathrm{sh}\,z}{z}$$

находим

$$Z = \sqrt{\frac{m}{2\pi\hbar\Delta t_E}}\sqrt{\frac{\omega_0\Delta t_E}{\mathrm{sh}\,\omega_0\Delta t_E}} = \sqrt{\frac{-\mathrm{i}m\omega_0}{2\pi\hbar\sin\omega_0\left(t''-t'\right)}}$$

Задача 7.6. Для осциллятора с источником покажите, что интеграл по траекториям имеет вид

$$Z = \sqrt{\frac{-\mathrm{i}m\omega_0}{2\pi\hbar\sin\omega_0\left(t''-t'\right)}}\exp\left\{\frac{\mathrm{i}}{\hbar}S_{\mathrm{cl}}\left(t'',t',j\right)\right\}$$

где S_{cl} - действие на траектории $q_{\mathrm{cl}}(t)$ с источником,

$$m\left\{\ddot{q}_{\mathrm{cl}}(t)+\omega_0^2 q_{\mathrm{cl}}(t)\right\} = j(t),\quad q_{\mathrm{cl}}\left(t'\right)=q',\quad q_{\mathrm{cl}}\left(t''\right)=q''.$$

Используйте замену переменной интегрирования $q(t)\mapsto y(t)$,

$$q(t) = q_{\mathrm{cl}}(t)+y(t),\quad y\left(t'\right)=y\left(t''\right)=0.$$

Теорема Вика. В случае рассмотрения вакуум-вакуумных переходов для затравочного действия (bare action), квадратичного по координатам, в формализме интеграла по траекториям легко получить выражение для функции Грина функционала $Z[j]$

$$\mathcal{D}^{(n)}\left(t_1,...,t_n\right)=\left\langle \mathrm{in}\left|\hat{\mathrm{T}}\left\{\hat{q}\left(t_1\right)...\hat{q}\left(t_n\right)\right\}\right|\mathrm{in}\right\rangle$$

[1] В теории функций комплексной переменной доказывается, что целая функция $f(z)$ может быть построена как произведение полиномов первого порядка с узлами, которые расположены точно в узлах $z_n\neq 0$ функции $f(z)$:

$$f(z)=f(0)\prod_{n=-\infty}^{\infty}\left\{1-\frac{z}{z_n}\right\}$$

В случае $f(z)=\mathrm{sh}\,z/z$ разложение в ряд Тейлора гиперсинуса по нечетным степеням z показывает, что мы имеем дело с целой функцией, узлы которой $z_n=\mathrm{i}\pi n$. Тогда умножение сомножителей с противоположными значениями n

$$\left\{1-\frac{z}{\mathrm{i}\pi n}\right\}\left\{1+\frac{z}{\mathrm{i}\pi n}\right\}=\left\{1+\left(\frac{z}{\pi n}\right)^2\right\}$$

дает суммирование по $n\geqslant 1$, а $f(0)=1$ сразу воспроизводит формулу 14.23. где мы опустили индекс, обозначающий представление Гейзенберга для операторов, зависящих от времени. Напомним краткие обозначения «интегрирования по паре немых индексов», так что, например,

$$j_{(1)}q_{(1)}\cong\int \mathrm{d}t_1 j\left(t_1\right)q\left(t_1\right),\quad j_{(1)}\mathcal{G}_{(12)}j_{(2)}\cong\int \mathrm{d}t_1\ \mathrm{d}t_2 j\left(t_1\right)\mathcal{G}_{(12)}\left(t_1,t_2\right)j\left(t_2\right).$$

Тогда для квадратичного действия, как мы видели,

$$Z[j]=\exp\left\{\frac{\mathrm{i}}{\hbar}\frac{1}{2}j_{(t)}\mathcal{G}_{(tt')}j_{(t')}\right\}=\exp\left\{-\frac{1}{\hbar^2}\frac{1}{2}j_{(t)}\mathcal{D}_{(tt')}j_{(t')}\right\}$$

Заметим, что для функционала $F[j]$, который разлагается в сходящийся вариационный ряд Тейлора, имеет место соотношение,

$$j(t)=-\mathrm{i}\hbar\frac{\delta}{\delta\phi(t)}\,\mathrm{e}^{\frac{\mathrm{i}}{\hbar}j_{(\tilde{t})}\tilde{\phi}_{(\tilde{t})}}\Big|_{\tilde{\phi}=0}\quad\Rightarrow\quad F[j]=F\left[-\mathrm{i}\hbar\frac{\delta}{\delta\phi}\right]\mathrm{e}^{\frac{\mathrm{i}}{\hbar}j_{(\tilde{t})}\tilde{\phi}_{(\tilde{t})}}\Big|_{\phi=0}.$$

Используя этот трюк, сразу найдем

$$Z[j]=\exp\left\{\frac{1}{2}\mathcal{D}_{(tt')}\frac{\delta^2}{\delta\phi_{(t)}\delta\phi_{(t')}}\right\}\mathrm{e}^{\frac{\mathrm{i}}{\hbar}j_{(\tilde{t})}\phi_{(\tilde{t})}}\Big|_{\phi=0}$$

Для n-точечного коррелятора находим

$$\mathcal{D}_{(1...n)}=(-\mathrm{i}\hbar)^n\frac{\delta^n Z[j]}{\delta j_{(1)}...\delta j_{(n)}}\Big|_{j=0}=\exp\left\{\frac{1}{2}\mathcal{D}_{(tt')}\frac{\delta^2}{\delta\phi_{(t)}\delta\phi_{(t')}}\right\}\phi_{(1)}...\phi_{(n)}\Big|_{\phi=0},$$

и при нечетном $n=2p+1$, очевидно, $\mathcal{D}_{(1...n)}=0$. Введем понятие «спаривания полей»

$$\underbrace{\phi_{(k)}\phi_{(k')}}\cong\mathcal{D}_{(kk')}=-\mathrm{i}\hbar\mathcal{G}_{(kk')}.$$

Тогда при четном $n=2p$ функция Грина $\mathcal{D}_{(1...n)}$ сводится к сумме всевозможных спариваний полей [1]

$$\mathcal{D}_{(1\ldots n)} = \sum_{\substack{\text{все варианты}\\ \text{спаривания}}} \underbrace{\phi_{(k)}\phi_{(k')}} \cdots \underbrace{\phi_{(l)}\phi_{(l')}}, \quad k \neq k', l \neq l' \in \overline{\{1,n\}},$$

что и составляет суть теоремы Вика.

Пример двухточечного корреляторы мы уже рассмотрели. А для четырехточечного коррелятора мы получим 3 варианта спаривания, каждое из которых отвечает распространению кванта между точками в аргументе коррелятора,

$$\mathcal{D}_{(1234)} = \underbrace{\phi_{(1)}\phi_{(2)}}\underbrace{\phi_{(3)}\phi_{(4)}} + \underbrace{\phi_{(1)}\phi_{(3)}}\underbrace{\phi_{(2)}\phi_{(4)}} + \underbrace{\phi_{(1)}\phi_{(4)}}\underbrace{\phi_{(2)}\phi_{(3)}},$$

[1] Множитель $1/2$ в аргументе экспоненты с вариационными производными второго порядка всегда компенсируется двумя способами выбора первого и второго поля в спаривании. так что графически

В этом случае диаграммы не являются связными.

2. Теория возмущений. При введении в действие полиномиального взаимодействия по полям степени выше 2

$$S_{\text{int}}\left[q\right] = -\int \mathrm{d}t V_{\text{int}}\left(q(t)\right)$$

можно использовать ту же методику спаривания полей. Для этого сначала заметим, что экспоненту с $S_{\text{int}}\left[q\right]$ можно вынести из-под интеграла по траекториям, сделав подстановку

$$q \mapsto -\mathrm{i}\hbar\frac{\delta}{\delta j}, \quad \Rightarrow \quad S_{\text{int}}[q] \mapsto S_{\text{int}}\left[-\mathrm{i}\hbar\frac{\delta}{\delta j}\right]$$

так что действие под интегралом S включает в себя только действие для свободного осциллятора

$$S_0[q] = -\int \mathrm{d}t q(t)\left\{m\frac{\mathrm{d}^2}{\mathrm{d}t^2} + \omega_0^2\right\}q(t)$$

и вклад от внешнего источника

$$S_{\text{ext}}[j] = \int \mathrm{d}t j(t)q(t)$$

$S = S_0 + S_{\text{ext}}$, а значит, можно провести интегрирование и получить амплитуду вероятности квантовых переходов при наличии источников

$$Z[j] = \exp\left\{\frac{\mathrm{i}}{\hbar}S_{\text{int}}\left[-\mathrm{i}\hbar\frac{\delta}{\delta j}\right]\right\}\exp\left\{-\frac{1}{\hbar^2}\frac{1}{2}j_{(t)}\mathcal{D}_{(tt')}j_{(t')}\right\}.$$

Тогда трюк с ведением вариационных производных экспоненты

$$\mathrm{e}^{\frac{\mathrm{i}}{\hbar}j_{(\tilde{t})}\phi_{(\tilde{t})}}$$

по вспомогательному полю ϕ позволяет провести дальнейшие преобразования с помощью подстановок

$$-\mathrm{i}\hbar\frac{\delta}{\delta j}\mapsto\phi,\quad j\mapsto-\mathrm{i}\hbar\frac{\delta}{\delta\phi}$$

и получить

$$Z[j]=\exp\left\{\frac{1}{2}\mathcal{D}_{(tt')}\frac{\delta^2}{\delta\phi_{(t)}\delta\phi_{(t')}}\right\}\mathrm{e}^{\frac{\mathrm{i}}{\hbar}\left\{S_{\mathrm{int}}[\phi]+j_{(\tilde{t})}\phi_{(\tilde{t})}\right\}}\Bigg|_{\phi=0}.$$

Значит, для многоточечной амплитуды находим

$$\mathcal{D}_{(1\ldots n)}=\exp\left\{\frac{1}{2}\mathcal{D}_{(tt')}\frac{\delta^2}{\delta\phi_{(t)}\delta\phi_{(t')}}\right\}\mathrm{e}^{\frac{\mathrm{i}}{\hbar}S_{\mathrm{int}}[\phi]}\phi_{(1)}\ldots\phi_{(n)}\Bigg|_{\phi=0}.$$

В этом выражении нужно учитывать все спаривания полей, включая поля в S_{int} . Формула 14.29 представляет собой основу для построения теории возмущений, поскольку все многоточечные функции выражаются через спаривания «свободных» полей, часть из которых возникает при разложении экспоненты с действием взаимодействия. В свою очередь, действие взаимодействия обычно включает в себя полиномы по полям с коэффициентами - константами взаимодействия.

Пример взаимодействия - потенциал

$$V_{\mathrm{int}}\ =\frac{1}{3!}\Lambda q^3$$

где Λ постоянная, которая имеет размерность массы, деленной на длину и квадрат времени. Тогда в первом порядке по Λ трехточечный коррелятор

$$\mathcal{D}_{(123)}=\exp\left\{\frac{1}{2}\mathcal{D}_{(tt')}\frac{\delta^2}{\delta\phi_{(t)}\delta\phi_{(t')}}\right\}\left\{-\frac{\mathrm{i}}{\hbar}\frac{1}{3!}\Lambda\int\mathrm{d}\tilde{t}\phi^3(\tilde{t})\right\}\phi_{(1)}\phi_{(2)}\phi_{(3)}\Bigg|_{\phi=0}.$$

В этой формуле есть вклад, когда спаривание происходит между «полями» с внешними временами $\phi_{(1)},\phi_{(2)},\phi_{(3)}$ и «полем» $\phi(\tilde{t})$, и такое спаривание имеет 3 ! вариантов. Есть вклад, когда два поля с внешними временами спариваются между собой, а третье - с одним из трех полей $\phi(\tilde{t})$(3 варианта). В итоге,

$$\begin{aligned}\mathcal{D}_{(123)}=&-\frac{\mathrm{i}}{\hbar}\Lambda\mathcal{D}_{(1\tilde{t})}\mathcal{D}_{(2\tilde{t})}\mathcal{D}_{(3\tilde{t})}-\\&-\frac{\mathrm{i}}{\hbar}\frac{\Lambda}{2}\left\{\mathcal{D}_{(12)}\mathcal{D}_{(3\tilde{t})}\mathcal{D}_{(\tilde{t}\tilde{t})}+\mathcal{D}_{(13)}\mathcal{D}_{(3\tilde{t})}\mathcal{D}_{(\tilde{t}\tilde{t})}+\mathcal{D}_{(23)}\mathcal{D}_{(1\tilde{t})}\mathcal{D}_{(\tilde{t}\tilde{t})}\right\}\end{aligned}$$

В этой формуле по повторяющемуся немому индексу $\tilde{t}$ в скобках согласно введенному нами правилу ведется интегрирование. Следуя теперь уже обоснованному и введенному выше правилу изображения двухточечного коррелятора в виде прямой, соединяющей 2 точки в аргументе коррелятора, получим диаграмму Фейнмана, которая изображена на рис. 22 и отвечает выражению 14.31. Подчеркнем, что взаимодействие, которое записывается

Рис. 22. Диаграммы для трехточечной функции Грина в модели с потенциалом 14.30, которую называют «лямбда-фи-в-кубе». (Для краткости записи множителей на рисунке мы положили $\hbar=1$.

как интеграл, приводит к тому, что в теории возмущений пропагаторы квантов сходятся в одной точке, указанной в аргументе интеграла в действии взаимодействия. Говорят, что взаимодействие соответствует вершинам взаимодействия квантов, поскольку без него пропагаторы соединяли бы только внешние точки в аргументе корреляторов (функций Грина). Ясно, что это позволяет ввести понятие внешних и внутренних линий: у внешних есть точка из аргумента коррелятора, а у внутренних нет таких точек. Кроме того, естественно ввести и понятие числа компонент связности диаграммы Фейнмана как число непрерывных цепочек из внутренних и внешних линий на диаграмме. На рис. 22 все диаграммы содержат по одной вершине, в первой одна компонента свзности, во второй -2 компоненты.

Подчеркнем, что в рассмотренном нами простом случае, когда нет вакуумных полей, т. е. $\mathcal{G}^{(1)} \equiv 0$, вклад вакуумных амплитуд

$$\mathcal{D}_0 = \exp\left\{\frac{1}{2}\mathcal{D}_{(tt')}\frac{\delta^2}{\delta\phi_{(t)}\delta\phi_{(t')}}\right\} \mathrm{e}^{\frac{\mathrm{i}}{\hbar}S_{\mathrm{int}}\,[\phi]}\Big|_{\phi=0},$$

очевидно, факторизуется для всех многоточечных функций в виде суммы всех диаграмм без внешних концов.

8.2.3 Diagrams in the Kiselev Formalism

(это не такой распространенный формализм, следует относиться к нему как просто к иллюстрации, что так можно делать. и этот раздел нужно переписать, у Киселева очень непонятно все написано!!!)

Теория

После рассмотрения примеров в теории возмущений, когда диаграммы имеют вполне определенный смысл в виде формул имеет смысл ввести графические обозначения и для вкладов в вариационный ряд Тейлора. Например, подынтегральные выражения в разложении функционала $G[j]$

$$\begin{aligned} G[j] =& \mathcal{G}_0 + \int \mathcal{G}^{(1)}(t) j(t) \mathrm{d}t + \\ &+ \frac{1}{2!}\int \mathcal{G}^{(2)}\left(t_1, t_2\right) j\left(t_1\right) j\left(t_2\right) \mathrm{d}t_1\ \mathrm{d}t_2 + \ldots = \sum_{n=0}^{\infty} \mathcal{G}_{(1\ldots n)} \frac{1}{n!} j_{(1)} \cdots j_{(n)}. \end{aligned}$$

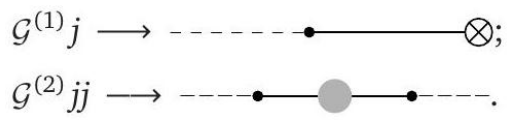
принято изображать в виде рисунков, строго соответствующих определенным выражениям, или, как говорят, в виде диаграмм Фейнмана согласно правилам:

1. источнику $j\left(t_k\right)$ сопоставляется луч, показанный штриховой линией с началом в точке t_k;

2. одноточечной функции Грина $\mathcal{G}^{(1)}\left(t_k\right)$ сопоставляется знак окружности вокруг креста в центре, т. е. $\otimes$, из которого исходит отрезок, показанный сплошной линией, с концом в точке t_k, причем метка крестом символизирует зависимость от граничных условий;

3. многоточечная функция Грина $\mathcal{G}_{(1\ldots n)}\left(t_1, \ldots, t_n\right)$ изображается окружностью с исходящими из нее n отрезками, показанными сплошной линией, причем каждому отрезку соответствует конец в одной из точек $t_1, \ldots, t_n$.

Например, в разложении функционала $G[j]$ для свободного осциллятора есть только два вклада 1



[1] Для краткости на диаграмме мы используем символ $\mathcal{G}^{2)} \equiv \mathcal{G}_{(12)}$ для двухточечной функции. В общем случае $G[j]$ называют прочзводящим функиионалом для связных функций Грина $\mathcal{G}_{(1\ldots n)}$, так как по построению в нем не содержатся вклады, которые можно представить в виде произведения интегральных множителей, которым соответствуют диаграммы Фейнмана, не соединенные никакими линиями 1. Если же рассмотреть разложение функционала $Z[j]$

$$Z[j] = \mathcal{D}_0 + \mathrm{i}/\hbar \int \mathcal{D}^{(1)}(t) j(t) \mathrm{d}t + \frac{(\mathrm{i}/\hbar)^2}{2!} \int \mathcal{D}^{(2)}\left(t_1, t_2\right) j\left(t_1\right) j\left(t_2\right) \mathrm{d}t_1 \, \mathrm{d}t_2 + \ldots$$

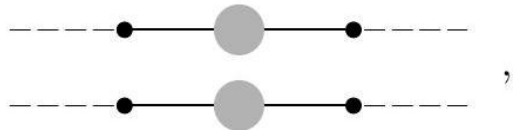
то в нем, несомненно, есть факторизуемые вклады, так как $Z[j] = \exp\left[\frac{\mathrm{i}G[j]}{\hbar}\right]$. Действительно, для двухточечной функции $\mathcal{D}$ имеем

$$\mathcal{D}_{(12)}\left(t_1, t_2\right) = -\mathrm{i}\hbar \mathcal{G}^{(2)}\left(t_1, t_2\right) + \mathcal{G}^{(1)}\left(t_1\right) \mathcal{G}^{(1)}\left(t_2\right)$$

чему соответствует диаграмма

Очевидно, что вторая диаграмма не является связной (у нее есть разрыв).

Точно так же четырехточечная функция $\mathcal{D}$ может быть представлена, в частности, вкладами произведений $\mathcal{G}^{(2)}\mathcal{G}^{(2)}$ с различными комбинациями аргументов, что дает члены типа



т. е. опять же несвязные диаграммы.

Более подробно вопрос о связных вкладах в производящем функционале функций Грина можно сформулировать следующим образом:

прежде всего для того, чтобы факторизовать величину $Z[j]$ при нулевых источниках, а заодно и нормировочный множитель $\mathcal{N}$, который не зависит от источников, вводят $\tilde{Z}[j] = Z[j]/Z[0]$. Тогда разложение в ряд по источникам начинается с единицы:

$$\tilde{Z}[j] = 1 + \sum_{k=1}^{\infty} \left(\frac{\mathrm{i}}{\hbar}\right)^k \int \mathcal{D}_{(1\ldots k)}\left(t_1, \ldots, t_k\right) \frac{1}{k!} \prod_{k'=1}^{k} j\left(t_{k'}\right) \mathrm{d}t_{k'}.$$

В функциях Грина $\mathcal{D}$, как мы видели, есть несвязные вклады, что соответствует произведениям связных функций $\mathcal{D}^c[c = \text{connected}]$, которые уже не распадаются на произведения других связных функций. Для краткости обозначений запишем k-точечные связные вклады в виде

$$a_k = \left(\frac{\mathrm{i}}{\hbar}\right)^k \int \mathcal{D}^c_{(1\ldots k)}\left(t_1, \ldots, t_k\right) \frac{1}{k!} \prod_{k'=1}^{k} j\left(t_{k'}\right) \mathrm{d}t_{k'}.$$

Тогда связные компоненты в выражении для амплитуды $\tilde{Z}[j]$ можно сгруппировать не по числу внешних токов, а так, чтобы выразить через них

[1] Доказательство мы приведем ниже. все несвязные диаграммы следующим образом: каждый k-точечный связный вклад a_k может повториться в несвязной диаграмме n_k раз, но сумма n_k фиксирует число компонент связности в диаграмме, а значит, суммирование диаграмм по числу компонент связности N примет вид

$$\tilde{Z}[j] = 1 + \sum_{N=1}^{\infty} \sum_{n_k} \left(\prod_{k=1}^{\infty} \frac{1}{(n_k)!} a_k^{n_k} \right) \Bigg|_{\sum n_k = N},$$

где N - число произведений связных вкладов, т. е. число компонент связности в диаграмме, а n_k - количество вкладов с k-точечными связными функциями Грина, которые входят симметрично и, стало быть, допускают (n_k) ! перестановок, дающих одинаковые вклады, причем $\sum n_k = N$.

Заметим теперь, что разложение экспоненты в ряд

$$\exp a_1 = 1 + \sum_{N=1}^{\infty} \sum_{n_1} \left(\prod_{k=1}^{1} \frac{1}{(n_1)!} a_1^{n_1} \right) \Bigg|_{n_1 = N}$$

для двух слагаемых принимает вид

$$\exp\{a_1 + a_2\} = 1 + \sum_{N=1}^{\infty} \sum_{n_1, n_2} \left(\prod_{k=1}^{2} \frac{1}{(n_k)!} a_k^{n_k} \right) \Bigg|_{n_1 + n_2 = N}$$

и, как нетрудно сообразить,

$$\exp\left\{ \sum_{k=1}^{\infty} a_k \right\} = 1 + \sum_{N=1}^{\infty} \sum_{n_k} \left(\prod_{k=1}^{\infty} \frac{1}{(n_k)!} a_k^{n_k} \right) \Bigg|_{\sum n_k = N}$$

Таким образом, мы показали, что факторизация несвязных амплитуд в произведение связных действительно приводит к экспоненциированию связных амплитуд, и подстановка $Z[j] = \exp\{\mathrm{i}G[j]/\hbar\}$ - это переход к производящему функционалу связных функций Грина $G[j]$. Этот вывод справедлив и при наличии ненулевых вакуумных значений $\langle q \rangle$, поскольку вклад вакуума факторизован в $Z[0]$.

Ситуация с разложением производящего функционала и, следовательно, со множеством допустимых диаграмм существенно изменяется, если ввести ангармоничность осциллятора. Для определенности, пусть

$$V(q) = V_0(q) + V_{\text{int}}(q) = \frac{m\omega_0^2}{2} q^2 + \frac{\lambda}{4!} q^4$$

где λ - постоянная, задающая степень ангармоничности. Тогда в уравнении Швингера-Дайсона вклад потенциала задается величиной

$$
\begin{aligned}
&\mathrm{e}^{-\frac{\mathrm{i}}{\hbar}G[j]}V'_{\mathrm{int}}\left(-\mathrm{i}\hbar\frac{\delta}{\delta j(t)}\right)\mathrm{e}^{\frac{\mathrm{i}}{\hbar}G[j]} = \frac{\lambda}{3!}\mathrm{e}^{-\frac{\mathrm{i}}{\hbar}G[j]}(-\mathrm{i}\hbar)^3\frac{\delta^3}{\delta j(t)^3}\left\{\mathrm{e}^{\frac{\mathrm{i}}{\hbar}G[j]}\right\} = \\
&= \mathrm{i}\hbar^3\frac{\lambda}{3!}\mathrm{e}^{-\frac{\mathrm{i}}{\hbar}G[j]}\frac{\delta^2}{\delta j(t)^2}\left\{\frac{\mathrm{i}}{\hbar}\frac{\delta G}{\delta j}\mathrm{e}^{\frac{\mathrm{i}}{\hbar}G[j]}\right\} = \\
&= \mathrm{i}\hbar^3\frac{\lambda}{3!}\mathrm{e}^{-\frac{\mathrm{i}}{\hbar}G[j]}\frac{\delta}{\delta j(t)}\left\{\left[\frac{\mathrm{i}}{\hbar}\frac{\delta^2 G}{\delta j^2} - \frac{1}{\hbar^2}\left(\frac{\delta G}{\delta j}\right)^2\right]\mathrm{e}^{\frac{\mathrm{i}}{\hbar}G[j]}\right\} = \\
&= \mathrm{i}\hbar^3\frac{\lambda}{3!}\left\{\frac{\mathrm{i}}{\hbar}\frac{\delta^3 G}{\delta j^3} - \frac{3}{\hbar^2}\frac{\delta G}{\delta j}\frac{\delta^2 G}{\delta j^2} - \frac{\mathrm{i}}{\hbar^3}\left(\frac{\delta G}{\delta j}\right)^3\right\} = \\
&= \frac{\lambda}{6}\left(\frac{\delta G}{\delta j}\right)^3 - \frac{\lambda}{2}\mathrm{i}\hbar\frac{\delta G}{\delta j}\frac{\delta^2 G}{\delta j^2} - \frac{\lambda}{6}\hbar^2\frac{\delta^3 G}{\delta j^3}
\end{aligned}
$$

Отсюда

$$
m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t^2} + \omega_0^2\right\}\frac{\delta G}{\delta j} + \frac{\lambda}{6}\left(\frac{\delta G}{\delta j}\right)^3 - \frac{\lambda}{2}\mathrm{i}\hbar\frac{\delta G}{\delta j}\frac{\delta^2 G}{\delta j^2} - \frac{\lambda}{6}\hbar^2\frac{\delta^3 G}{\delta j^3} = j
$$

В этом случае уже не приходится говорить, что многоточечные функции Грина равны нулю, так как получающиеся уравнения существенно нелинейны и содержат вклады, зависящие от источника. Однако по-прежнему можно утверждать, что многоточечные функции не содержат вкладов, построенных в виде произведения одноточечных функций.

Вид уравнения Швингера-Дайсона для производящего функционала $G[j]$ на примере осциллятора показывает, что естественно определить квантовый аналог классической траектории как

$$
q_{\mathrm{cl}}(t) = \frac{\delta G[j]}{\delta j(t)}
$$

так что

$$
q_{\mathrm{cl}}(t)\big|_{j=0} = \left.\frac{\delta G[j]}{\delta j(t)}\right|_{j=0} = q_0(t)
$$

т. е. без источников в случае осциллятора получаем свободное движение, как это и должно быть, а при наличии, скажем, ангармоничности из 14.32 следует, что величина $q_{\mathrm{cl}}(t)$ удовлетворяет уравнению

$$
m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t^2} + \omega_0^2\right\}q_{\mathrm{cl}}(t) + \frac{\lambda}{6}q_{\mathrm{cl}}^3(t) - \frac{\lambda}{2}\mathrm{i}\hbar q_{\mathrm{cl}}(t)\frac{\delta q_{\mathrm{cl}}(t)}{\delta j} - \frac{\lambda}{6}\hbar^2\frac{\delta^2 q_{\mathrm{cl}}(t)}{\delta j^2} = j
$$

а значит, в пределе $\hbar \to 0$ получаем решение классического уравнения для $q(t)$ при наличии источников. Вклады с $\hbar$ приводят к квантовым поправкам. Преобразование Лежандра от j к q_{cl} приводит к функционалу

$$
\Gamma\left[q_{\mathrm{cl}}\right] = -\int q_{\mathrm{cl}}(t)j(t)\mathrm{d}t + G[j]
$$

который называют квантовым эффективным действием. Оно раскладывается в функциональный ряд по траекториям $\bar{q}_{\mathrm{cl}}(t) = q_{\mathrm{cl}}(t) - q_0(t)$ наподобие ряда для $G[j]$, причем по построению

$$
\frac{\delta\Gamma}{\delta q_{\mathrm{cl}}(t)} = -j(t)
$$

В разложении

$$\Gamma\left[q_{\mathrm{cl}}\right]=\Gamma^{(0)}+\int\Gamma^{(1)}(t)\bar{q}_{\mathrm{cl}}(t)\mathrm{d}t+\frac{1}{2!}\int\Gamma^{(2)}\left(t_1,t_2\right)\bar{q}_{\mathrm{cl}}\left(t_1\right)\bar{q}_{\mathrm{cl}}\left(t_2\right)\mathrm{d}t_1\ \mathrm{d}t_2+\ldots$$

коэффициентные функции называются многоточечными вершинами:

$$\Gamma^{(n)}=\Gamma_{(1\ldots n)}=\left.\frac{\delta^n\Gamma}{\delta q_{\mathrm{cl}}\left(t_1\right)\delta q_{\mathrm{cl}}\left(t_2\right)\ldots\delta q_{\mathrm{cl}}\left(t_n\right)}\right|_{q_{\mathrm{cl}}=q_0},$$

где мы ввели сокращенное обозначение для аргументов многоточечных функций. Поскольку при $j=0$ имеем $q_{\mathrm{cl}}(t)=q_0(t)$ или $\bar{q}_{\mathrm{cl}}=0$, замечаем, что разложение функционала Γ происходит также при нулевом значении источника j. Поэтому

$$\Gamma^{(1)}(t)=\left.\frac{\delta\Gamma}{\delta\bar{q}_{\mathrm{cl}}(t)}\right|_{\bar{q}_{\mathrm{cl}}=0}=\left.\frac{\delta\Gamma}{\delta\bar{q}_{\mathrm{cl}}(t)}\right|_{j=0}=-\left.j(t)\right|_{j=0}=0.$$

С учетом этих обозначений дифференцирование уравнения 14.34 при $t=t_1$ по $q_{\mathrm{cl}}\left(t_2\right)$ и условие $j=0$ дают

$$m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t_1^2}+\omega_0^2\right\}\delta_{12}+\frac{\lambda}{2}q_0^2\left(t_1\right)\delta_{12}-\frac{\lambda}{2}\mathrm{i}\hbar\delta_{12}\mathcal{G}^{(2)}_{(11)}+$$
$$+\frac{\lambda}{2}\mathrm{i}\hbar q_0\left(t_1\right)\mathcal{G}^{(3)}_{(113)}\Gamma^{(2)}_{(32)}+\frac{\lambda}{6}\hbar^2\mathcal{G}^{(4)}_{(1113)}\Gamma^{(2)}_{(32)}=-\Gamma^{(2)}_{12},$$

где мы использовали равенство

$$\frac{\delta}{\delta q_{(2)}}=\frac{\delta j_{(3)}}{\delta q_{(2)}}\frac{\delta}{\delta j_{(3)}}=-\Gamma^{(2)}_{(32)}\frac{\delta}{\delta j_{(3)}}$$

и определения функций Грина. При этом, конечно,

$$\delta_{12}=\delta\left(t_1-t_2\right),\quad q_0\left(t_1\right)=\mathcal{G}^{(1)}\left(t_1\right)=\mathcal{G}^{(1)}_1$$

и мы использовали сокращенное обозначение для «свертки» индекса 3, например,

$$\mathcal{G}^{(3)}_{(113)}\Gamma^{(2)}_{(32)}=\int\mathcal{G}^{(3)}\left(t_1,t_1,t_3\right)\Gamma^{(2)}\left(t_3,t_2\right)\mathrm{d}t_3$$

Вариация второго порядка при нулевых источниках, очевидно, связана с обратной двухточечной функцией Грина:

$$\Gamma^{(2)}_{(12)}=\frac{\delta^2\Gamma}{\delta q_{\mathrm{cl}}\left(t_1\right)\delta q_{\mathrm{cl}}\left(t_2\right)}=-\frac{\delta j\left(t_1\right)}{\delta q_{\mathrm{cl}}\left(t_2\right)}=-\left[\frac{\delta q_{\mathrm{cl}}\left(t_2\right)}{\delta j\left(t_1\right)}\right]^{-1}=$$
$$=-\left[\frac{\delta^2 G}{\delta j\left(t_1\right)\delta j\left(t_2\right)}\right]^{-1}=-\left[\mathcal{G}^{(2)}_{(12)}\right]^{-1}$$

в смысле интегрального выражения

$$\Gamma^{(2)}_{(12)}\mathcal{G}^{(2)}_{(23)}=-\delta_{13}$$

Уравнение 14.37 справедливо не только при нулевом источнике, так что дифференцируя

$$\frac{\delta^2\Gamma}{\delta q_{(1)}\delta q_{(2)}}\frac{\delta^2 G}{\delta j_{(2)}\delta j_{(3)}}=-\delta_{13}$$

еще раз по $q_{\mathrm{cl}}\left(t_5\right)$, находим

$$\Gamma^{(3)}_{(12'5)}\mathcal{G}^{(2)}_{(2'3)} - \Gamma^{(2)}_{(12)}\mathcal{G}^{(3)}_{(234)}\Gamma^{(2)}_{(45)} = 0$$

или с учетом обратного двухточечного оператора

$$\Gamma^{(3)}_{(12'5)} = -\mathcal{G}^{(3)}_{(234)}\Gamma^{(2)}_{(12)}\Gamma^{(2)}_{(32')}\Gamma^{(2)}_{(45)} = \mathcal{G}^{(3)}_{(234)}\left[\mathcal{G}^{(2)}_{(12)}\right]^{-1}\left[\mathcal{G}^{(2)}_{(32')}\right]^{-1}\left[\mathcal{G}^{(2)}_{(45)}\right]^{-1}$$

и т. п. Поэтому говорят, что вершинные функции - усеченные функции Грина, т. е. функции внешние, исходящие из кружка, линии которых отсечены обратными двухточечными функциями Грина. При этом не все усеченные функции Грина дают вклад в вершинные функции, а только, как говорят, сильно связные (proper) или одночастично неприводимые (one-particle irreducible). Одночастично приводимые функции Грина соответствуют таким диаграммам, что на них найдётся хотя бы одна линия, при разрезании которой диаграмма становится несвязной. Этот факт мы докажем чуть ниже, а пока для примера, если пренебречь квантовыми поправками ($\hbar \to 0$) и взять третью производную уравнения (14.36 по q_{cl}, то получим вершину четвертой степени в эффективном действии Γ

$$\Gamma^{(4)}_{(1234)} \approx -\lambda\delta_{12}\delta_{13}\delta_{14}$$

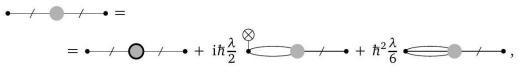
а соответствующая функция Грина

$$\mathcal{G}^{(4)}_{(1234)} \approx -\lambda\mathcal{G}^{(2)}_{(15)}\mathcal{G}^{(2)}_{(25)}\mathcal{G}^{(2)}_{(35)}\mathcal{G}^{(2)}_{(45)} + \ldots$$

С учетом сказанного уравнение для двухточечной вершиной функции 14.36 принимает вид

$$\Gamma^{(2)}_{(12)} = \left(-m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t_1^2} + \omega_0^2\right\} - \frac{\lambda}{2}\left[\mathcal{G}^{(1)}_1\right]^2 + \frac{\lambda}{2}\mathrm{i}\hbar\mathcal{G}^{(2)}_{(11)}\right)\delta_{12} + \\ + \frac{\lambda}{2}\mathrm{i}\hbar\mathcal{G}^{1}_{(1)}\mathcal{G}^{(3)}_{(113)}\left[\mathcal{G}^{(2)}_{(32)}\right]^{-1} + \frac{\lambda}{6}\hbar^2\mathcal{G}^{(4)}_{(1113)}\left[\mathcal{G}^{(2)}_{(32)}\right]^{-1}$$

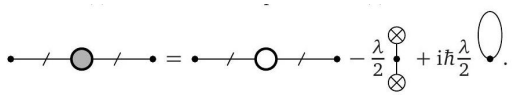
Это уравнение можно изобразить графически, если условиться обозначать вершинные функции так же, как и функции Грина, но с перечеркнутыми линиями. Итак,



где мы ввели обозначение

$$\left(-m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t_1^2} + \omega_0^2\right\} - \frac{\lambda}{2}\left[\mathcal{G}^{(1)}_1\right]^2 + \frac{\lambda}{2}\mathrm{i}\hbar\mathcal{G}^{(2)}_{11}\right)\delta_{12} \longrightarrow \bullet, \bigcirc$$

Этот вклад можно также выразить в виде



Здесь же введена двухточечная вершинная функция для свободного осциллятора или, как говорят, собственная энергия осциллятора

$$-m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t_1^2} + \omega_0^2\right\}\delta_{12} \longrightarrow \bullet, \bigcirc,$$

Напомним, что этот вклад-квадратичный член в квантовом эффективном действии, т. е. просто

$$\frac{1}{2}\Gamma_{(12)}q_{\rm cl}^{(1)}q_{\rm cl}^{(2)} = -\frac{m}{2}\int \mathrm{d}t\bar{q}_{\rm cl}(t)\left\{\frac{\mathrm{d}^2\bar{q}_{\rm cl}(t)}{\mathrm{d}t_1^2} + \omega_0^2\bar{q}_{\rm cl}(t)\right\} = \\ = \int \mathrm{d}t\left\{\frac{m}{2}\dot{\bar{q}}_{\rm cl}^2(t) - \frac{m\omega_0^2}{2}\bar{q}_{\rm cl}^2(t)\right\}$$

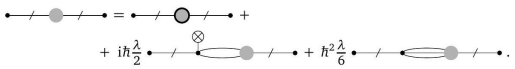
Подчеркнем, что каждая замкнутая петля приводит фактору ?.

Графическое представление уравнения Швингера-Дайсона

Графическое представление уравнения Швингера-Дайсона 14.38 для двухточечной вершинной функции становится еще более наглядным, если использовать тривиальное тождество

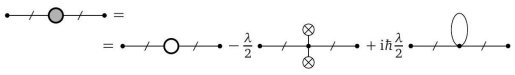
$$\left[\mathcal{G}^{(2)}_{1'4}\right]^{-1}\mathcal{G}^{(2)}_{41} = \delta_{11'}$$

Умножая уравнение на это тождество и интегрируя по $t_{1'}$, видим, что вклад с дельта-функцией не изменяется, а квантовые поправки теперь можно представить с использованием дополнительной усеченной двухточечной функции Грина («ампутированная нога»), так что



Эта запись «читается» так: двухточечная вершинная функция равна сумме вкладов собственной энергии с учетом квантовых эффектов самодействия и квантовых поправок за счет петель, причем однопетлевой вклад определяется трехточечной функцией Грина (кружок с тремя линиями) и «голой вершиной» q^4-взаимодействия λ (точка с четырьмя линиями), а двухпетлевой - «голой» четверной вершиной (точка с 4 линиями) и полной 4-точечной функцией Грина (кружок с 4 линиями).

Совершенно аналогично собственная энергия с квантовыми поправками представляется как



Значит, наряду с собственной энергией свободного осциллятора есть вклад от «голой» вершины λ с учетом граничных условий и однопетлевой вклад (так называемый «головастик»).

8.2.4 Strongly Connected Diagrams by Kiselev

(мб в КТП унесу, посмотрим, пока тут)

Теория

Докажем, что производящий функционал вершинных функций Γ содержит только сильно связные диаграммы. Для этого воспользуемся методом Сиднея Коулмена и Стивена Вайнберга: построим производящий функционал функций Грина не с исходным действием на траектории S, а с эффективным действием Γ,

$$Z_\Gamma[j] = \exp\left\{\frac{\mathrm{i}}{\hbar_\Gamma} G_\Gamma[j]\right\} = \mathcal{N}\int \mathcal{D}q \exp\left\{\frac{\mathrm{i}}{\hbar_\Gamma}\left(\Gamma + \int \mathrm{d}t q(t) j(t)\right)\right\}$$

где мы также провели формальную замену $\hbar \to \hbar_\Gamma$. Тогда $G_\Gamma[j]$ - это производящий функционал связных функций Грина с действием Γ. При этом, как мы установили, в пределе при $\hbar_\Gamma \to 0$ величина $G_\Gamma[j] \to G_\Gamma^{(0)}[j]$ не будет содержать петель, т. е. будет представлять собой, как говорят, лишь набор связных древесных диаграмм. Но в этом же пределе функциональный интеграл сводится к своему значению в стационарной точке:

$$\exp\left\{\frac{\mathrm{i}}{\hbar_\Gamma} G_\Gamma^{(0)}[j]\right\} = \lim_{\hbar_\Gamma \to 0} \int \mathcal{D}q \exp\left\{\frac{\mathrm{i}}{\hbar_\Gamma}\left(\Gamma + \int \mathrm{d}t q(t) j(t)\right)\right\} =$$
$$= \exp\left\{\frac{\mathrm{i}}{\hbar_\Gamma}\left(\Gamma + \int \mathrm{d}t q(t) j(t)\right)\right\}\Bigg|_{\delta\left[\Gamma + \int \mathrm{d}t q(t) j(t)\right]/\delta q(t) = 0}.$$

Условие стационарности означает, что

$$\frac{\delta\Gamma}{\delta q(t)} = -j(t), \quad G_\Gamma^{(0)} = \Gamma + \int q(t) j(t) \mathrm{d}t$$

т. е. предел производящего функционала в точности совпадает с производящим функционалом связных функций Грина в исходной теории:

$$G_\Gamma^{(0)} = G[j]$$

Таким образом, производящий функционал связных функций Грина соответствует связным древесным диаграммам с пропагаторами и вершинами, которые задаются эффективным действием Γ (см. рис. 23).

Важно, что остается справедливым соотношение

$$\Gamma^{(2)}_{(13)} \mathcal{G}^{(2)}_{(32)} = -\delta_{12}$$

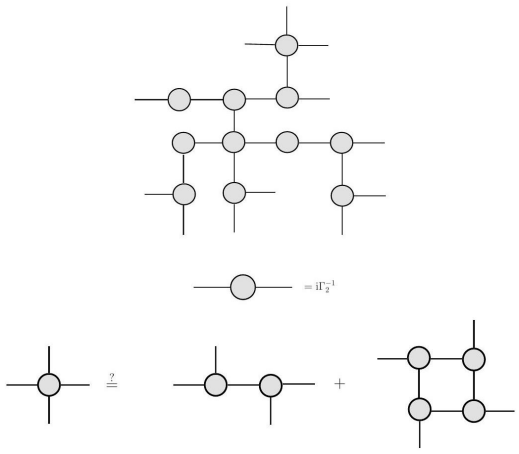


Рис. 23. Древесный предел $\hbar_\Gamma \to 0$ при построении G_Γ: пример дерева с многими ветвями, двухточечная функция Грина и 4 -точка Γ_4, представленная гипотетическим одночастично приводимым вкладом и петлей за счет 3-точечных вершин. Ясно, что одночастично приводимый вклад следует исключить по построению, поскольку он уже учтен при построении древесных диаграмм именно в качестве трехточечного сильно связного трехчастичного вклада.

так что связная двухточечная функция Грина $\mathcal{G}^{(2)}$ представляет собой двухточечную вершину $\Gamma^{(2)}$ с внешними линиями:

$$\mathrm{i}\mathcal{G}^{(2)}_{(12)} = \mathrm{i}\mathcal{G}^{(2)}_{(13)}\mathrm{i}\Gamma^{(2)}_{(33')}\mathrm{i}\mathcal{G}^{(2)}_{(3'2)}.$$

Более того, многократное повторение (вставка) блоков $\mathrm{i}\Gamma^{(2)}_{(33')}\mathrm{i}\mathcal{G}^{(2)}_{(3'2)}$ в эту диаграмму сводится к единичному оператору, т. е. все цепочки с многократной вставкой двухточечной вершины идентичны древесной диаграмме с одной двухточечной вершинной функцией!

Итак, связные функции Грина в $G[j]$ для исходной теории с затравочным действием S являются в то же время диаграммами, построенными в древесном приближении в теории, где затравочным является уже эффективное действие Г. Это значит, во-первых, что все такие древесные диаграммы, построенные по вершинам с эффективным действием, являются одночастично приводимыми: удаление любой внутренней линии делает диаграмму несвязной.

Во-вторых, никакая из вершин $\Gamma_{(1\ldots n)}$ в таких древесных диаграммах не может сама быть представлена как древесная, поскольку разложение такой вершины на сумму одночастично приводимых вкладов и одночастично неприводимый вклад означал бы, что вклад суммы одночастично приводимых диаграмм уже учтен прежде в виде такого же древесного вклада (см. илллюстрацию этого утверждения на примере 4-точки на рис. 23. Таким образом, по построению, если учтены все древесные вклады с одночастично неприводимыми вершинами низшего порядка, то вершины более высокого порядка уже не содержат одночастично приводимых вкладов.

Это можно доказать методом математической индукции. Сначала заметим, что все древесные вклады в $\mathcal{G}$, где есть вершина с одной внешней точкой $\Gamma^{(1)}$ равны нулю, так как $\delta\Gamma/\delta q_{\mathrm{cl}} = -j$ при $j = 0$ - это нуль. Потом рассмотрим все древесные диаграммы, где учтены все двухточечные вершины. Допустим, что двухточечная связная функция все же является одночастично приводимой. Тогда удаление в диаграмме внутренней линии делает диаграмму двусвязной, и у оставшихся двух компонент связности остаются два варианта по числу внешних линий: либо $2 + 0$ внешних линий, либо $1 + 1$ внешних линий. В первом варианте вторая компонента связности соединялась с диаграммой одной линией, т. е. она состояла из одноточечной функции, которую мы считаем равной нулю. Во втором варианте, обе компоненты связности до удаления внутренней линии были сформированы двухточечными функциями, а мы показали, что это сводится к одной двухточечной функции, и стало быть, такая диаграмма эквивалентна единственной двухточечной функции. Другими словами, в древесных диаграммах для построения связных функций Грина $\mathcal{G}$ из вершинных функций уже были учтены все двухточечные функции, и разбиение двухточечной вершины на древесную диаграмму из двух и более двухточечных вершин представляет собой тождественную операцию, которая ничего не меняет, и по этому двухточечную вершину можно считать сильно связной. Первый шаг индукции доказан.

Допустим теперь, что все вершинные функции с числом внешних точек меньше, чем n, являются сильно связными, а n-точечная вершинная функция имеет одночастично приводимый вклад. Это значит, что после разрезания внутренней линии в этом вкладе есть только два варианта для оставшихся компонент связности: в первом варианте у одной из компонент связности остается 0 внешних линий, и значит, эта компонента получилась из одночастичной вершины, которая равна нулю, и этот вариант невозможен. Во втором варианте, вклад в n-точечную вершинную функцию распадается на две вершинные функции, у каждой из которых число внешних точек до разрезания внутренней линии было меньше чем n, а значит, эти функции одночастично неприводимы согласно предположению о втором шаге индукции. Следовательно, одночастично приводимый вклад в n-точечную вершинную функцию построен как древесная диаграмма соединяющая две одночастично неприводимых функции. Но это

недопустимо, так как для связных функций Грина $\mathcal{G}$, построенных из вершинных функций Γ, уже учтены все древесные диаграммы с сильно связными вершинами с числом внешних точек меньше, чем n. Следовательно, и n-точечная вершинная функция может быть только одночастично неприводимой. Все шаги математической индукции выполнены.

Таким образом, доказано, что все вершинные функции должны быть одночастично неприводимыми (древесные вклады в вершины исключены, т.е. вершины либо голые, либо петли в терминах связных функций Грина для теории с исходным действием, причем, в особом случае двухточечной вершины надо иметь ввиду, что, как мы покажем, в качестве голой вершины выступает дважды усеченный, по числу внешних точек, древесный вклад.).

Покажем теперь, что вершинные функции - это усеченные сильносвязные функции Грина (одночастично неприводимые функции Грина с «ампутированными ногами»). В самом деле, рассмотрим

$$G[j] = \Gamma\left[q_{\mathrm{cl}}\right] - \int \mathrm{d}t q_{\mathrm{cl}}(t) \frac{\delta \Gamma}{\delta q_{\mathrm{cl}}(t)} = \Gamma\left[q_{\mathrm{cl}}\right] + \int \mathrm{d}t q_{\mathrm{cl}}(t) j(t)$$

Эффективное действие раскладывается в вариационный ряд

$$\Gamma\left[q_{\mathrm{cl}}\right] = \sum_{n'=0}^{\infty} \frac{1}{n'!} \Gamma_{(1' \ldots n')} q_{\mathrm{cl}}^{(1')} \ldots q_{\mathrm{cl}}^{(n')}$$

а само поле в вариационный ряд по внешнему току

$$\begin{aligned} q_{\mathrm{cl}}^{(k')} = \frac{\delta G}{\delta j_{(k')}} = \left.\frac{\delta G}{\delta j_{(k')}}\right|_{j=0} + \left.\frac{\delta^2 G}{\delta j_{(k')} \delta j_{(1)}}\right|_{j=0} j_{(1)} + \\ + \sum_{n=2}^{\infty} \frac{1}{n!} \left.\frac{\delta^{n+1} G}{\delta j_{(k')} \delta j_{(1)} \ldots j_{(n)}}\right|_{j=0} j_{(1)} \ldots j_{(n)} = \mathcal{G}^{(1)}\left(t_{k'}\right) + \mathcal{G}_{(k'1)} j_{(1)} + \\ + \sum_{n=2}^{\infty} \frac{1}{n!} \mathcal{G}_{(k'1 \ldots n)} j_{(1)} \ldots j_{(n)}, \end{aligned}$$

где для краткости изложения мы положим $\mathcal{G}^{(1)} = 0$, что легко сделать с помощью переопределения траектории координаты $\bar{q}_{\mathrm{cl}} \mapsto q_{\mathrm{cl}}$. Тогда переход в разложении эффективного потенциала от q_{cl} к источникам j в линейном приближении по токам дает вклад

$$\frac{1}{n!} \mathcal{G}'^{p}_{(1 \ldots n)} \prod_{k=1}^{n} j_{(k)} = \frac{1}{n!} \Gamma_{(1' \ldots n')} \prod_{k=1}^{n} \mathcal{G}_{(k'k)} j_{(k)}.$$

В этой формуле справа сильносвязные вершины $\Gamma_{(1' \ldots n')}$ домножаются по каждой своей внешней точке на двухточечную функцию Грина, а следовательно, в итоге и слева мы получаем сильносвязные диаграммы, которые мы пометили верхним индексом p (proper)! Это соотношение можно обратить и записать

$$\Gamma_{(1 \ldots n)} = \mathcal{G}'^{p}_{(1' \ldots n')} \prod_{k=1}^{n} \left(\mathcal{G}^{(2)}_{(kk')}\right)^{-1}$$

Это и означает, что вершины представляют собой связные одночастично неприводимые диаграммы для функций Грина $\mathcal{G}'^{p}_{(1 \ldots n)}$, в которых внешние линии ампутированы, т. е. пропагаторы этих линий удалены за счет домножения на обратный двухточечный связный пропагатор [1]

При рассмотрении нелинейного вклада в разложении $q_{\rm cl}$ по внешним токам 14.39) внешняя точка вершинной функции k' соединяется одной линией со связной функцией Грина $\mathcal{G}_{(k'1\ldots n)}, n \geqslant 2$, из которой исходят как минимум две линии во внешние точки функции Грина $\mathcal{G}$, но это значит, что нелинейные вклады отвечают одночастично приводимым диаграммам: именно разрезание этой единственной линии от точки k' вершины до связной диаграммы $\mathcal{G}_{(k'1\ldots n)}$ при $n \geqslant 2$ приводит к возникновению диаграммы с двумя компонентами связности.

Второе слагаемое в преобразовании Лежандра от вершин к связным функциям Грина

$$-\int \mathrm{d}t q_{\rm cl}(t)\frac{\delta\Gamma}{\delta q_{\rm cl}(t)}$$

устроено ровно также: квантовый аналог классической траектории $q_{\rm cl}$ также разлагается в вариационный ряд по внешнему току, а первая вариационная производная эффективного действия также может быть представлена как произведение сильносвязных вершин на полиномы по $q_{\rm cl}$, так что все рассуждения о связных функциях Грина и одночастично приводимых вкладах повторяются практически дословно. Различие возникает, если вариационную производную эффективного действия взять в линейном приближении по внешнему источнику, а «поле» $q_{\rm cl}$ разложить до членов порядка $n-1$. Тогда необходимо привести подобные члены.

Итак, единственное, что следует установить - это, как говорят, симметрийные факторы, которые задают коэффициент между одночастично неприводимыми функциями Грина $\mathcal{G}^p_{(1\ldots n)}$ и вершинами $\Gamma_{(1\ldots n)}$. Например, во втором порядке по внешним токам эффективное действие дает

$$\frac{1}{2}\Gamma_{(1'2')}\mathcal{G}_{(1'1)}\mathcal{G}_{(2'2)}j_{(1)}j_{(2)},$$

а второе слагаемое в преобразовании Лежандра, очевидно, как произведение двух линейных вкладов сводится к виду

$$-\Gamma_{(1'2')}\mathcal{G}_{(1'1)}\mathcal{G}_{(2'2)}j_{(1)}j_{(2)}$$

так что в сумме связная двухточечная функция Грина [2]

$$\mathcal{G}_{(12)} = -\Gamma_{(1'2')}\mathcal{G}_{(1'1)}\mathcal{G}_{(2'2)} = \delta_{12'}\mathcal{G}_{(2'2)} = \mathcal{G}_{(12)}$$

что и следовало ожидать. Симметрийный фактор здесь равен -1 (см. 14.42 в первом равестве).

[1] Штрих у символа $\mathcal{G}'^p_{(1\ldots n)}$ указывает на то, что мы рассмотрели не все вклады в одночастично неприводимые диаграммы.

[2] Напомним, что двухточечная вершина - обратная функция Грина со знаком минус! При $n > 2$ вклад эффективного действия

$$\frac{1}{n!}\Gamma_{(1'\ldots n')}\prod_{k=1}^{n}\mathcal{G}_{(k'k)}j_{(k)}$$

линейный член разложения поля по источнику при умножении на разложение первой вариационной производной Γ по источнику до членов порядка $n-1$ дает

$$-\mathcal{G}_{(1'1)}j_{(1)}\frac{1}{(n-1)!}\Gamma_{(1'\ldots n')}\prod_{k=2}^{n}\mathcal{G}_{(k'k)}j_{(k)}$$

а разложение поля по источнику до членов порядка $n-1$ при умножении на линейный член разложения первой вариационной производной Γ по источнику дает

$$-\frac{1}{(n-1)!}\mathcal{G}_{(1'2\ldots3)}\left(\prod_{k=2}^{n}j_{(k)}\right)\Gamma_{(1'1'')}\mathcal{G}_{(1''1)}j_{(1)}$$

Но, во-первых,

$$\Gamma_{(1'1'')}\mathcal{G}_{(1''1)}=-\delta_{1'1}$$

откуда

$$-\frac{1}{(n-1)!}\mathcal{G}_{(1'2\ldots3)}\left(\prod_{k=2}^{n}j_{(k)}\right)\Gamma_{(1'1'')}\mathcal{G}_{(1''1)}j_{(1)}=\frac{1}{(n-1)!}\mathcal{G}_{(12\ldots3)}\prod_{k=1}^{n}j_{(k)}.$$

Во-вторых, в этом слагаемом нас интересует только влад сильносвязных диаграмм, который задается формулой

$$\mathcal{G}^{p}_{(1\ldots n)}=\mathcal{C}\Gamma_{(1'\ldots n')}\prod_{k=1}^{n}\mathcal{G}^{(2)}_{(k'k)}$$

где $\mathcal{C}$ - искомый симметрийный фактор, для которого после учета всех слагаемых устанавливаем

$$\mathcal{C}=(1-n)+n\mathcal{C}\Rightarrow\mathcal{C}=1$$

Таким образом

$$\Gamma_{(1\ldots n)}=\mathcal{G}^{p}_{(1'\ldots n')}\prod_{k=1}^{n}\left(\mathcal{G}^{(2)}_{(kk')}\right)^{-1},\quad n>2$$

Если вариационные производные $Z[j]$ мы условились изображать в виде линий, исходящих из овала, а овал можно затем представить в виде сумм диаграмм в теории возмущений с распространением частиц вдоль тех же линий, то в той же логике можно условиться изображать вариационные производные $G[j]$ в виде линий, исходящих из круга, где круг можно затем представить в виде сумм связных диаграмм с вершинами в теории возмущений и с распространением частиц вдоль линий, пересекающихся в вершинах. Тогда принято изображать вариационные производные эффективного действия Γ

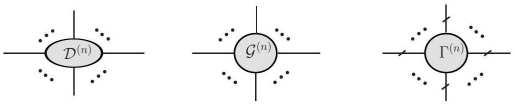

Рис. 24. Вариационные производные для амплитуды $Z[j]$, производящего функционала связных функций $G[j]$ и вершины $\Gamma\left(q_{\mathrm{cl}}\right)$, соответственно.

в виде круга с исходящими из него перечеркнутыми линиями, которые символизируют усеченные внешние пропагаторы («ампутированные ноги»), как это показано на рис. 24

Наконец, укажем альтернативный способ построения теории возмущений в терминах континуального интеграла и, следовательно, диаграмм Фейнмана в теории возмущений. Пусть гамильтониан представлен в виде

$$\mathcal{H}=\frac{p^2}{2m}+\frac{m\omega_0^2}{2}q^2+V_{\mathrm{int}}\left(q\right)-j(t)q$$

где V_{int} - малое возмущение. Тогда производящий функционал

$$Z[j] = \mathcal{N} \int \mathcal{D}q \exp\left\{ \frac{\mathrm{i}}{\hbar} \int\limits_{t'}^{t''} \mathrm{d}t \left[\frac{m\dot{q}^2(t)}{2} - \frac{m\omega_0^2}{2} q^2(t) - V_{\mathrm{int}}(q(t)) + j(t)q(t) \right] \right\}$$

можно переписать в виде

$$Z[j] = \mathcal{N} \exp\left\{ -\frac{\mathrm{i}}{\hbar} \int\limits_{t'}^{t''} \mathrm{d}t V_{\mathrm{int}} \left(-\mathrm{i}\hbar \frac{\delta}{\delta j(t)} \right) \right\} \times$$

$$\times \int \mathcal{D}q \exp\left\{ \frac{\mathrm{i}}{\hbar} \int\limits_{t'}^{t''} \mathrm{d}t \left[\frac{m\dot{q}^2(t)}{2} - \frac{m\omega_0^2}{2} q^2(t) + j(t)q(t) \right] \right\},$$

где мы воспользовались тем, что значение координаты на траектории под знаком интегрирования получается при вариации континуального интеграла. Значит, производящий функционал при наличии возмущения выражается через действие дифференциального оператора на производящий функционал для свободного осциллятора:

$$Z[j] = \exp\left\{ -\frac{\mathrm{i}}{\hbar} \int\limits_{t'}^{t''} \mathrm{d}t V_{\mathrm{int}} \left(-\mathrm{i}\hbar \frac{\delta}{\delta j(t)} \right) \right\} Z_{\mathrm{osc}}[j]$$

где, как мы выяснили,

$$Z_{\mathrm{osc}}[j] = \mathrm{e}^{\frac{\mathrm{i}}{\hbar} G[j]}$$

$$G[j] = \mathcal{G}_0 + \int \mathcal{G}^{(1)}(t) j(t) \mathrm{d}t + \frac{1}{2!} \int \mathcal{G}^{(2)}\left(t_1, t_2\right) j\left(t_1\right) j\left(t_2\right) \mathrm{d}t_1 \, \mathrm{d}t_2.$$

Дальнейшая процедура построения правил Фейнмана для многоточечных функций Грина задается вариационным дифференцированием в последовательном порядке малости по возмущению. Мы не будем рассматривать здесь далее этот вариант построения теорий возмущений в рамках интеграла по траекториям, поскольку это обычно относят к курсу квантовой теории поля.

Укажем однако, что формула 14.44 позволяет найти общее соотношение для числа петель, степени возмущения и числа внутренних линий в связной диаграмме. Действительно, если N_V - степень вклада возмущения в функцию Грина, то это значит, что N_V - это число внутренних вершин в диаграмме N_V (vertex, number of vertecies). Если в диаграмме есть внутренняя линия, то она соединяет 2 точки между вершинами, так что при последовательном счете, если рассматривать связную цепочку из N_I внутренних линий (internal lines), в этой цепочке имеется $N_I + 1$ вершин как сумма вершин на конце внутренней линии плюс одна вершина в начале цепочки внутренних линий. Однако на связной диаграмме некоторые конечные точки в цепочке внутренних линий могут совпасть с начальными точками внутренних линий. Каждое такое совпадение означает наличие замкнутой петли. Число петель N_L (loop, number of loops) определяет число точек посчитанных дважды, так что общее число вершин на связной диаграмме (напомним, у связной диаграммы только одна компонента связности, т. е. одна непрерывная цепочка внутренних линий, на которой возможны ветвления и пересечения) в действительности равно

$$N_V = N_I + 1 - N_L, \quad N_L = N_I + 1 - N_V.$$

В справедливости данной формулы читатель может наглядно убедиться на примере четырех- и двухточечной функции Грина в теории «фи-в-четвертой», как это показано на рис. 25.

Рис. 25. Диаграммы с одной и двумя вершинами в модели $V[\phi] \sim \lambda\phi^4$ с разным числом внутренних линий (слева направо): 0, 1, 3, - и петель:0, 1, 2.

Заметим теперь, что связные функции Грина $\mathrm{i}G[j]/\hbar$ с фиксированным числом петель получаются суммированием диаграмм с N_V степенями возмущения и N_I внутренними линиями, причем каждое возмущение дает фактор $1/\hbar$, а каждая внутренняя линия отвечает обратному оператору на квадратичном по траектории свободном действии, т. е. вносит фактор $\hbar$ (см. связь связной двухточечной функции Грина со связной частью двухточечной функции Грина для амплитуды вероятности $Z[j]$). В итоге связные функции Грина с петлями имеют следующий масштаб по $\hbar$:

$$\text{scale } \frac{1}{\hbar}G^{(L)} \sim \text{ scale } \sum_{N_V,N_I} \left(\frac{1}{\hbar}\right)^{N_V} \hbar^{N_I}\Bigg|_{N_L \text{ fixed}} \sim \text{ scale } \hbar^{N_L-1}.$$

Таким образом, разложение связных функций Грина по петлям совпадает с разложением по степеням $\hbar$! Это означает, что в классическом пределе $\hbar \to 0$ среди связных диаграмм остаются только диаграммы без петель или, как говорят, древесные диаграммы.

Подчеркнем также, что полученные выше закономерности, связанные с числом петель, никак не зависят от того, как устроено возмущение (кубическое по полям или высшей степени по полям) и сколько внешних линий имеют связные функции Грина.

Итак, наряду с решением задачи вычисления амплитуд квантовых переходов при наличии произвольного внешнего источника, фейнмановский интеграл по траекториям позволяет, во-первых, эффективно строить теорию возмущений при введении малой добавки к потенциалу. Во-вторых, по своему определению он дает метод численного интегрирования квантовых задач, не поддающихся анализу в рамках теории возмущений. В-третьих, континуальный интеграл в квантовой теории поля позволяет наиболее наглядно и просто получать соотношения между функциями Грина при наличии симметрий исходного классического действия и выявлять квантовые аномалии, т. е. случаи принципиально непреодолимого нарушения симметрии классического действия при квантовании, и т. п.

8.2.5 $\mathcal{S}-$Matrix Functional

(мб в КТП унесу, посмотрим, пока тут)

Теория

Для граничных условий в голоморфном представлении введем решение классического уравнения движения для свободного осциллятора [1]

$$q_0(t) = x_0\left(\alpha_{\text{in}}\,\mathrm{e}^{-\mathrm{i}\omega_0 t} + \bar{\alpha}_{\text{out}}\,\mathrm{e}^{\mathrm{i}\omega_0 t}\right), \quad x_0 = \sqrt{\frac{\hbar}{2m\omega_0}}$$

и рассмотрим голоморфное ядро $\mathcal{S}$-матрицы как функционал от этого решения, т. е. запишем его в виде

$$\mathcal{S}\left(\bar{\alpha}_{\text{out}}\,,\alpha_{\text{in}}\right)\cong\mathcal{S}\left[q_0(t)\right]=\exp\left\{-\frac{\mathrm{i}}{\hbar}\int\limits_{t'}^{t''}\mathrm{d}tV_{\text{int}}\,\left(-\mathrm{i}\hbar\frac{\delta}{\delta j(t)}\right)\right\}Z_{\text{osc}}\left[j\right]\Bigg|_{j=0}$$

где

$$Z_{\text{osc}}\left[j\right]=\exp\left\{\int\mathcal{G}^{(1)}(t)j(t)\mathrm{d}t+\frac{1}{2!}\int\mathcal{G}^{(2)}\left(t_1-t_2\right)j\left(t_1\right)j\left(t_2\right)\mathrm{d}t_1\,\mathrm{d}t_2\right\}$$

[1] Выражение $\sqrt{14.45}$, конечно, является решением однородного линейного уравнения для свободных колебаний, но оно, вообще говоря, комплекснозначное, так что трактовать его следует как матричный элемент координаты по когерентным состояниям в начале и в конце эволюции, который домножен на такой нормировочный фактор, который приводит к формуле 14.45.

$$\mathcal{G}^{(1)}(t)=q_0(t)$$

Разложение этого функционала в ряд

$$\mathcal{S}\left[q_0(t)\right]=\sum_{n=1}^{\infty}\frac{(-\mathrm{i}\hbar)^n}{n!}\mathcal{S}^{(n)}\left(t_1,...,t_n\right)\prod_{k=1}^{n}q_0\left(t_k\right)\mathrm{d}t_k$$

имеет наглядный физический смысл: коэффициентные функции $\mathcal{S}^{(n)}$ задают амплитуды перехода одного асимптотического состояния в другое с общей суммой квантов в исходном и конечном состояниях, равной n. В самом деле, дифференцирование по параметру начального состояния α_{in} и конечного $\bar{\alpha}_{\text{out}}$ можно представить как вариационную производную

$$\frac{\partial^{m+n}\mathcal{S}[q_0]}{\partial\alpha_{\text{in}}^m\partial\bar{\alpha}_{\text{out}}^n}\Bigg|_{\alpha_{\text{in}}=\bar{\alpha}_{\text{out}}=0}=\int\frac{\delta^{m+n}\mathcal{S}[q_0]}{\delta q_0(t_1)...\delta q_0(t_{m+n})}\Bigg|_{q_0=0}\times\\ \times\prod_{k=1}^{m}\frac{\partial q_0(t_k)}{\partial\alpha_{\text{in}}}\mathrm{d}t_k\prod_{l=1}^{n}\frac{\partial q_0(t_l)}{\partial\bar{\alpha}_{\text{out}}}\mathrm{d}t_l,$$

где

$$\frac{\partial q_0(t)}{\partial\bar{\alpha}_{\text{out}}}=x_0\mathrm{e}^{\mathrm{i}\omega_0 t},\quad\frac{\partial q_0(t)}{\partial\alpha_{\text{in}}}=x_0\mathrm{e}^{-\mathrm{i}\omega_0 t}$$

так что в правой части 14.49 стоит фурье-образ коэффициентной функции

$$\int\mathcal{S}^{(m+n)}\left(t_1,...,t_{m+n}\right)\prod_{k=1}^{m}\mathrm{e}^{-\mathrm{i}\omega_0 t_k}\,\mathrm{d}t_k\prod_{l=1}^{n}\mathrm{e}^{\mathrm{i}\omega_0 t_l}\,\mathrm{d}t_l=\\ =\tilde{\mathcal{S}}^{(m+n)}(\underbrace{\omega_0,...,\omega_0}_{m},\underbrace{-\omega_0,...,-\omega_0}_{n}).$$

С левой же стороны 14.49 согласно 13.65 стоит производная от голоморфного ядра оператора эволюции при нулевых источниках, т. е.

$$\frac{\partial^{m+n}\mathcal{S}\left[q_0\right]}{\partial\alpha_{\text{in}}^m\partial\bar{\alpha}_{\text{out}}^n}\Bigg|_{\alpha_{\text{in}}=\bar{\alpha}_{\text{out}}=0}=\sqrt{n!m!\mathcal{S}_{nm}}.$$

При этом матричный элемент

$$\mathcal{S}_{nm}=\left\langle n\left|\hat{U}\left(t'',t'\right)\right|m\right\rangle,\quad t''\to+\infty,\quad t'\to-\infty$$

и есть амплитуда перехода в ходе эволюции из начального состояния с m квантами в конечное состояние с n квантами 1

Редукиионные формуль. Найдем теперь связь между амплитудами переходов $\mathcal{S}^{(n)}$ и функциями Грина $\mathcal{D}^{(n)}$. Для этого заметим, что

$$\int \mathcal{G}^{(1)}(t)j(t)\mathrm{d}t + \frac{1}{2!}\int \mathcal{G}^{(2)}\left(t_1,t_2\right)j\left(t_1\right)j\left(t_2\right)\mathrm{d}t_1\ \mathrm{d}t_2 = \\ = \frac{1}{2!}\int \mathcal{G}^{(2)}\left(t_1,t_2\right)\tilde{j}\left(t_1\right)\tilde{j}\left(t_2\right)\mathrm{d}t_1\ \mathrm{d}t_2$$

1 В действительности многие подобные амплитуды могут оказаться равными нулю в силу законов сохранения энергии и т. п. где

$$\tilde{j}(t) = j(t) + \int \left[\mathcal{G}^{(2)}(t,\tilde{t})\right]^{-1}\mathcal{G}^{(1)}(\tilde{t})\mathrm{d}\tilde{t}$$

причем возникающий дополнительно вклад

$$\int \left[\mathcal{G}^{(2)}(t,\tilde{t})\right]^{-1}\mathcal{G}^{(1)}(\tilde{t})\mathcal{G}^{(1)}(t)\mathrm{d}\tilde{t}\ \mathrm{d}t = 0$$

так как $\mathcal{G}^{(1)}(t) = q_0(t)$ - решение уравнения свободного движения осциллятор[1]

Поэтому вариация функционала $\mathcal{S}$-матрицы согласно 14.46 сводится к вариации производящего функционала функций Грина $Z[\tilde{j}]$

$$-\mathrm{i}\hbar\frac{\delta\mathcal{S}\left[q_0\right]}{\delta q_0(t)}\bigg|_{j=0} = -\mathrm{i}\hbar\int\frac{\delta Z[\tilde{j}]}{\delta\tilde{j}(\tilde{t})}\frac{\delta\tilde{j}(\tilde{t})}{\delta q_0(t)}\mathrm{d}\tilde{t}\bigg|_{\tilde{j}=0}.$$

Но так как

$$\frac{\delta\tilde{j}(\tilde{t})}{\delta q_0(t)} = \left[\mathcal{G}^{(2)}(t,\tilde{t})\right]^{-1} = m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t^2}+\omega_0^2\right\}\delta(t-\tilde{t})$$

интегрирование «снимается», и

$$\frac{\delta\mathcal{S}\left[q_0\right]}{\delta q_0(t)}\bigg|_{j=0} = m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t^2}+\omega_0^2\right\}\frac{\delta Z[\tilde{j}]}{\delta\tilde{j}(t)}\bigg|_{\tilde{j}=0}$$

а значит,

$$\mathcal{S}^{(n)}\left(t_1,...,t_n\right) = \left(\prod_{k=1}^{n} m\left\{\frac{\mathrm{d}^2}{\mathrm{d}t_k^2}+\omega_0^2\right\}\right)\mathcal{D}^{(n)}\left(t_1,...,t_n\right)$$

Это и есть редукционные формулы: матричные элементы $\mathcal{S}$-матрицы получаются из функций Грина для производящего функционала оператора эволюции $\mathcal{D}$ усечением каждой линии фактором обратной связной двухточечной функции Грина для свободного осциллятора Если графически представить функции $\mathcal{D}$ аналогично функциям Грина $\mathcal{G}$, заменив кружок на овал для двухточечной функции

$$\mathcal{D}^{(2)} = \longrightarrow$$

а усечение внешних линий свободным пропагатором осциллятора двойным перечеркиванием, то, к примеру,

$$\mathcal{S}^{(2)} = \leftrightarrow \mathbb{H} \longrightarrow$$

При этом, конечно, нужно помнить о том, что многоточечные функции $\mathcal{D}$ построены из связных функций $\mathcal{G}$ и поэтому включают в себя несвязные диаграммы.

Нормалъный символ. Наряду с голоморфным ядром оператора $\hat{A}$ часто рассматривают и его нормальный символ, определенный разложением

[1] В других вкладах необходимо аккуратно обращаться с произведением двухточечной функции Грина на обратную к ней. оператора в ряд по нормально упорядоченным произведениям операторов рождения и уничтожения:

$$\hat{A} = \sum_{n,m} \mathcal{A}^N_{nm} \frac{\left(\hat{a}^\dagger\right)^n}{\sqrt{n!}} \frac{\hat{a}^m}{\sqrt{m!}}$$

где коэффициенты разложения $\mathcal{A}^N_{nm}$, конечно, не совпадают с матричными элементами оператора. Матричный элемент по когерентным состояниям -

$$\left\langle \alpha_{\rm out} \left| \hat{A} \right| \alpha_{\rm in} \right\rangle = \sum_{n,m} \mathcal{A}^N_{nm} \frac{\bar{\alpha}^n_{\rm out}}{\sqrt{n!}} \frac{\alpha^m_{\rm in}}{\sqrt{m!}} \left\langle \alpha_{\rm out} \left| \alpha_{\rm in} \right. \right\rangle .$$

Величину

$$\mathcal{A}^N \left(\bar{\alpha}_{\rm out} , \alpha_{\rm in} \right) = \sum_{n,m} \mathcal{A}^N_{nm} \frac{\bar{\alpha}^n_{\rm out}}{\sqrt{n!}} \frac{\alpha^m_{\rm in}}{\sqrt{m!}}$$

называют голоморфным ядром нормального символа оператора 1. Тогда из

$$\left\langle \alpha_{\rm out} \left| \alpha_{\rm in} \right. \right\rangle = \exp\left\{ -\frac{\bar{\alpha}_{\rm out}\, \alpha_{\rm out}}{2} - \frac{\bar{\alpha}_{\rm in}\, \alpha_{\rm in}}{2} + \bar{\alpha}_{\rm out}\, \alpha_{\rm in} \right\}$$

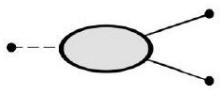
и определения ядра оператора следует связь

$$\mathcal{A}\left(\bar{\alpha}_{\rm out} , \alpha_{\rm in} \right) = \mathrm{e}^{\bar{\alpha}_{\rm out}\, \alpha_{\rm in}}\, \mathcal{A}^N \left(\bar{\alpha}_{\rm out} , \alpha_{\rm in} \right)$$

которая устанавливает соотношение между голоморфным ядром оператора и ядром его нормального символа. В литературе, использующей голоморфные представления, часто цитируется эта формула (развитие формализма континуального интеграла в квантовой механике и теории поля см. в учебном пособии 23).

Фермионный осциляятор. Построенное нами ранее голоморфное представление для фермионного осциллятора позволяет повторить для него процедуру введения интеграла по траекториям с той лишь разницей, что интегрирование ведется по грассмановым переменным.

Взаимодействие осциляяторов. Рассмотрим пример. Допустим, что физическая система включает в себя два различных осциллятора: обобщенные координаты - q_1 и q_2, частоты свободных колебаний $-\omega_1$ и ω_2. Если мы знаем, что $\omega_1 = 2\omega_2$ и при этом условии квант первого осциллятора может переходить в пару квантов второго осциллятора (сохранение энергии) с амплитудой λ, то как выглядит потенциал взаимодействия этих осцилляторов? Очевидно, что описанный процесс распада кванта первого осциллятора (штриховая линия) на пару квантов второго (сплошные линии) соответствует диаграмме



,

которая показывает уничтожение кванта типа 1 и рождение двух квантов типа 2. Эту амплитуду можно записать как

$$\left\langle 2'' \left| \hat{U} \right| 1' \right\rangle = \mathrm{i}\lambda$$

[1] Голоморфность является явной по построению. или в рамках теории возмущений

$$\mathrm{i}\lambda \longrightarrow \langle 0|\hat{a}_2\left(t''\right)\hat{a}_2\left(t''\right)\hat{U}\left(t'',t'\right)\hat{a}_1^\dagger\left(t'\right)|0\rangle =$$
$$= \left\langle 0\left|\hat{a}_2\left(t''\right)\hat{a}_2\left(t''\right)\mathrm{e}^{-\frac{\mathrm{i}}{\hbar}\int \mathrm{d}t\hat{H}_{\mathrm{int}}}\hat{a}_1^\dagger\left(t'\right)\right|0\right\rangle \approx$$
$$\approx \left\langle 0\left|\hat{a}_2\left(t''\right)\hat{a}_2\left(t''\right)\left\{1-\frac{\mathrm{i}}{\hbar}\int\limits_{t'}^{t''}\mathrm{d}t(-1)\hbar\lambda\hat{a}_2^\dagger(t)\hat{a}_2^\dagger(t)\hat{a}_1(t)\right\}\hat{a}_1^\dagger\left(t'\right)\right|0\right\rangle.$$

Но это есть не что иное, как амплитуда перехода, которая возникает при введении взаимодействия

$$V_{\mathrm{int}} = -\hbar\lambda\hat{a}_2^\dagger\hat{a}_2^\dagger\hat{a}_1 + \text{ h.c.},$$

где мы добавили эрмитово сопряженный вклад для вещественности потенциала и не приводим зависимость операторов от времени. Постоянная взаимодействия λ, очевидно, должна иметь размерность частоты. Значит,

$$V_{\mathrm{int}} \sim -\lambda\sqrt{\frac{8m_1m_2^2\omega_1\omega_2^2}{\hbar}}q_1q_2^2 \sim V_0\frac{q_1q_2^2}{\ell^3}$$

где мы учли связь операторов рождения и уничтожения с динамической переменной, а также ввели параметр энергии $V_0 = -\lambda\hbar$ и длину $\ell = \left(\hbar^3/8m_1m_2^2\omega_1\omega_2^2\right)^{1/6}$.

Таким образом, эмпирические наблюдения, т. е. измерения эффективного квантового действия, позволяют в рамках теории возмущений вводить члены с взаимодействием квантовых систем.

8.3 Scattering Theory: Features, Specific Models

8.3.1 1D delta-potential

(here will be basic theory)

8.3.2 Regularization methods for delta-function potential in two-dimensional quantum mechanics by Su-Long Nyeo

(see his article in Google for now)

8.3.3 2D scattering theory

2D Green's function

(??? приведу ее вывод. пока не додумал еще)

Developing 2D scattering theory based on a partial-wave analysis for an axially-symmetric potential $U(\rho)$ by GKKG.13.23

A theory of scattering for an axially-symmetric potential in two dimensions can be developed along the same lines as that for a spherically-symmetric potential in three dimensional quantum mechanics.

The Hamiltonian in an axially-symmetric field has the form:

$$\hat{H} = -\frac{\hbar^2}{2\mu}\left(\frac{1}{\rho}\frac{\partial}{\partial\rho}\rho\frac{\partial}{\partial\rho} + \frac{1}{\rho^2}\frac{\partial^2}{\partial\varphi^2}\right) + U(\rho) \tag{1}$$

while the solution of the Schrdinger equation has the following asymptotic behavior

$$\psi_{\mathbf{k}}^{+}(\boldsymbol{\rho}) \approx e^{ik\rho\cos\varphi} + \sqrt{i}\frac{f(k,\varphi)}{\sqrt{\rho}}e^{ik\rho}, \quad \rho \to \infty \tag{2}$$

Incident particles move in the direction of the positive x axis; here, $x = \rho\cos\varphi$. Note that now the scattered wave is cylindrical (not spherical), and so instead of $1/r$ we have $1/\sqrt{\rho}$. In this two-dimensional case, the scattering amplitude, $f(k,\varphi)$, has the physical dimension of the square root of length, and the physical dimension of the differential scattering cross-section $d\sigma/d\varphi = |f|^2$ is length. Finally, a phase factor $\sqrt{i}$ is used for convenience.

Since the operator $\hat{l}_z = -i\partial/\partial\varphi$ commutes with both the Hamiltonian of free motion and Hamiltonian (1), then the two-dimensional plane wave and the exact wavefunction $\psi_{\mathbf{k}}^{+}(\boldsymbol{\rho})$ can be expanded in the eigenfunctions, $\psi_m = e^{im\varphi}$, of this operator (analogous to the expansion over spherical functions in the case of a central potential):

$$e^{ik\rho\cos\varphi} = \sum_{m=-\infty}^{\infty} A_m J_{|m|}(k\rho)e^{im\varphi}, \quad \psi_{\mathbf{k}}^{+} = \sum_{m=-\infty}^{\infty} B_m R_{km}(\rho)e^{im\varphi} \tag{3}$$

Here, we have taken into account that the radial function of free motion with an "angular momentum" m is expressed in terms of the Bessel functions $J_{|m|}(k\rho)$, with the coefficients $A_m = i^{|m|}$. The values of the coefficients B_m are determined from the condition that the difference, $\psi_{\mathbf{k}}^{+} - e^{ikx}$, at large distances contains the outgoing waves, $\propto e^{ik\rho}$, for each term of the sum over m. Writing the asymptote of the radial function in the form [329]

$$R_{km}(\rho) = \sqrt{\frac{2}{\pi k\rho}}\sin\left(k\rho - \frac{\pi|m|}{2} + \frac{\pi}{4} + \delta_m\right) \tag{4}$$

we find $B_m = e^{i\delta_m}A_m$. As a result, we obtain a partial-wave decomposition of the scattering amplitude:

[329] The normalization factor in this function and the phase δ_m are chosen so that for $\delta_m = 0$, asymptote (4) coincides with the asymptote of a Bessel function, which describes the radial function of free motion.

$$f(k,\varphi) = \frac{1}{i\sqrt{2\pi k}}\sum_{m=-\infty}^{\infty}\left(e^{2i\delta_m} - 1\right)e^{im\varphi} \tag{5}$$

Note that the phase shift δ_m does not depend on the sign of m.
According to Eq. (5), the total scattering cross-section is

$$\sigma = \int_0^{2\pi}|f|^2 d\varphi = \frac{4}{k}\sum_{m=-\infty}^{\infty}\sin^2\delta_m \tag{6}$$

and the optical theorem in this two-dimensional case reads

$$\mathrm{Im}\, f(k,\varphi=0) = \sqrt{\frac{k}{8\pi}}\sigma(E) \tag{7}$$

Notice that extracting the factor $\sqrt{i}$ in Eq. (2) in the Born approximation is indeed convenient, as this convention ensures that for $|\delta_m| \ll 1$, the scattering amplitude given becomes real, according to Eq. (5).

Как в формулах для 3D рассеяния учесть ограниченность пространства и получить формулы 2D?

(??? вопрос на более глубокое понимание, пока не знаю и вряд ли скоро буду про это думать.)

Examples of 2D scatterings

2D scattering on δ-potential

Используем импульсное представление,

$$\frac{p^2}{2m}\psi(\boldsymbol{p}) + U_p \int (d\boldsymbol{p}')\,\psi(\boldsymbol{p}') = E\psi(\boldsymbol{p})$$

$$\psi(\boldsymbol{p}) = -\frac{U_{\boldsymbol{p}}}{-E + \frac{p^2}{2m}} \int (d\boldsymbol{p}')\,\psi(\boldsymbol{p}')$$

В размерности $d = 2$ интеграл расходится логарифмически на малых и на больших импульсах.

На больших импульсах очевидным образом интеграл нужно обрезать на масштабах $\sim 1/a$, поскольку это уравнение было выведено именно в таком предположении (это позволило нам заменить U_p на $U_{p=0}$; и поскольку интеграл логарифмический, то он нечувствителен к этой обрезке - она меняет лишь константу под логарифмом), а на маленьких - масштабом $\sqrt{2mE}$; сингулярность на малых энергиях оказывается слабой, логарифмической.

Поэтому чтобы сделать левую часть порядка единицы, уровень энергии иу очежо малежъким.

Приступим теперь к непосредственному вычислению:

$$\int \frac{d^2\boldsymbol{p}}{(2\pi)^2}\frac{1}{|E| + \frac{p^2}{2m}} = \int \frac{2\pi p dp}{4\pi^2}\frac{1}{|E| + \frac{p^2}{2m}} \approx \frac{m}{\pi}\int\limits_{\sim\sqrt{mE}}^{\sim 1/a} \frac{dp}{p} = \frac{m}{2\pi}\ln\frac{\#}{ma^2|E|}$$

Точность этого выражения следующая: число перед логарифмом определено точно, а в силу неточности при обрезании, число под логарифмом неизвестно.

Для его нахождения нужно решать уравнение Шрёдингера точно; это число уже определяется явным видом потенциала.

Тем самым, решая уравнение самосогласования, мы получаем (восстанавливая опять $\hbar$ по размерности) :

$$|E| = \#\frac{\hbar^2}{ma^2}\exp\left(-\frac{2\pi\hbar^2}{m}\left|\int U(\boldsymbol{r})d^2\boldsymbol{r}\right|^{-1}\right)$$

Таким образом, мы определили уровень энергии в мелкой двумерной яме с экспоненциальной точностью; и этот уро-оказывается действительно экспоненциально мелким.

Ведущая асимптотика даётся этой самой экспонентой, которая может быть оценена как $\exp\left(-\frac{\hbar^2/ma^2}{II_C}\right) \lll 1$. Число же в предэкспоненте таким способом определить нельзя.

Заметим, что в Левитове Шитове какой-то полнейший бред написан про эту задачу! Хотя, может, есть и другой способ обрезать интеграл тут...

2D delta-potential

8.3.4 Formalism of 3D Scattering Theory by Takhtajan

Здесь мы обрисуем теорию рассеяния для оператора Шрёдингера $H = -\Delta + V(\boldsymbol{x})$ (где мы положим $\hbar = 1$ и $\mu = \frac{1}{2}$) с быстро убывающим потенциалом. Конкретно, предположим, что ограниченная вещественнозначная функция $V(\boldsymbol{x})$ на $\mathbb{R}^3$ удовлетворяет условию

$$V(x) = O\left(|x|^{-3-\varepsilon}\right) \quad \text{при} \quad |x| \to \infty$$

для некоторого $\varepsilon > 0$. Тогда для любого $k \in \mathbb{R}^3$ уравнение Шрёдингера

$$-\Delta\psi(\boldsymbol{x}) + V(\boldsymbol{x})\psi(\boldsymbol{x}) = k^2\psi(\boldsymbol{x}), \quad k = |\boldsymbol{k}|,$$

имеет два решения $u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})$, удовлетворяющих следующим асимптотическим условиям при $|\boldsymbol{x}| \to \infty$:

$$u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k}) = e^{i\boldsymbol{k}\boldsymbol{x}} + f^{(\pm)}(k, \boldsymbol{\omega}, \boldsymbol{n})\frac{e^{\pm ikr}}{r} + o\left(\frac{1}{r}\right),$$

где $\boldsymbol{k} = k\boldsymbol{\omega}, \boldsymbol{x} = r\boldsymbol{n}$. Асимптотики (4.7) называются условиями излучения Зоммерфельда. Для доказательства существования решений $u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})$ надо рассмотреть следующие интегральные уравнения:

$$u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k}) = e^{i\boldsymbol{k}\boldsymbol{x}} + \int\limits_{\mathbb{R}^3} G^{(\pm)}(\boldsymbol{x} - \boldsymbol{y}, k)V(\boldsymbol{y})u^{(\pm)}(\boldsymbol{y}, \boldsymbol{k})d^3\boldsymbol{y}$$

где

$$G^{(\pm)}(\boldsymbol{x}, k) = -\frac{1}{4\pi}\frac{e^{\pm ikr}}{r}$$

Интегральные уравнения (4.8) эквивалентны уравнению Шрёдингера (4.6) с условиями излучения Зоммерфельда (4.7) и называются уравнениями Липпмана-Швингера. При их анализе используется теория Фредгольма и теорема Като 1.8.

Решения $u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})$ называются стачионарными рассеянными волнами. Они аналогичны решениям $u_j^{(\pm)}(x, k)$ для одномерного случая, где индекс $j = 1, 2$ заменяется вектором $\boldsymbol{\omega} \in S^2$. Абсолютно непрерывный спектр H заполняет $[0, \infty)$ и имеет равномерную бесконечную кратность, параметризованную точками двумерной сферы S^2. Решения $u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})$ - это нормированные собственные функции непрерывного спектра. В общем случае у оператора H есть конечное число отрицательных собственных значений $\lambda_l < 0$ конечной кратности $m_l, l = 1, ..., n$. В терминах операторов $\mathscr{U}_\pm : \mathscr{H} \to \mathscr{H}$, данных формулами

$$\mathscr{U}_\pm(\psi)(\boldsymbol{k}) = (2\pi)^{-\frac{3}{2}} \int\limits_{\mathbb{R}^3} \psi(\boldsymbol{x})u^{(\pm)}(\boldsymbol{x}, \boldsymbol{k})d^3\boldsymbol{x},$$

соотношения полноты и ортогональности принимают вид

$$\mathscr{U}_\pm^*\mathscr{U}_\pm = I - P, \quad \mathscr{U}_\pm\mathscr{U}_\pm^* = I,$$

где P - ортогональная проекция на инвариантное подпространство для оператора H, ассоциированное с чисто точечным спектром. Теперь пусть

$$W_\pm = \mathscr{U}_\pm^*\mathscr{U}_0$$

где $\mathscr{U}_0 = \mathscr{F}^{-1}$ - обратное преобразование Фурье. Как и в разделе 3.2.3, можно доказать следующий результат.

Теорема 4.1. Операторы $W_\pm$−волновые операторы для оператора Шрёдингера H. Соответствующий оператор рассеяния $S = W_+^* W_-$ имеет вид

$$S = \mathscr{F}\hat{S}\mathscr{F}^{-1},$$

где $\hat{S}$ - интегральный оператор,

$$(\hat{S}\psi)(k,\boldsymbol{\omega}) = \psi(k,\boldsymbol{\omega}) + \frac{ik}{2\pi}\int\limits_{S^2} f\left(k,\boldsymbol{\omega},\boldsymbol{\omega}'\right)\psi\left(k,\boldsymbol{\omega}'\right)d\boldsymbol{\omega}',$$

$uf\left(k,\boldsymbol{\omega},\boldsymbol{\omega}'\right) = f^{(+)}\left(k,\boldsymbol{\omega},\boldsymbol{\omega}'\right)$
Функция $f\left(k,\omega,\omega'\right)$ называется амплитудой рассеяния.

8.3.5 Properties of the S-Matrix for Scattering in Continuous Media (!?!??)

(пока об этом в отдельной записи, потому что тема очень большая, см. Бязь и др. про рассеяния и распады и сотни статей. Не готов сказать, что из этого на самом деле важно для этой записи.)

8.3.6 Phase Shift Formalism and Partial Cross-Sections

Связь фазовых сдвигов и парциальных сечений по Киселеву

Стационарная волновая функция в задаче рассеяния имеет асимптотический вид

$$\psi_i^{(+)}(r) \simeq e^{ik_i\cdot r} + \frac{e^{\mathrm{i}kr}}{r}f(\theta), \quad k = |\boldsymbol{k}_\mathrm{i}|$$

Разложим амплитуду рассеяния по базису полиномов Лежандра $f(\theta) = \sum\limits_l f_l P_l(\cos\theta)$

Асимптотическое разложение волновой функции по сферическим волнам

$$\psi_i^{(+)}(\boldsymbol{r}) \simeq \sum_l (2l+1)P_l(\cos\theta)\frac{1}{2\mathrm{i}kr}\left\{S_l e^{\mathrm{i}kr} - (-1)^l e^{-\mathrm{i}kr}\right\}$$

С другой стороны, разложение плоской волны свободной частицы и амплитуды рассеяния по полиномам Лежандра дает

$$e^{\mathrm{i}\boldsymbol{k}_\mathrm{i}\cdot\boldsymbol{r}} + \frac{e^{\mathrm{i}kr}}{r}f(\theta) \simeq \sum_l (2l+1)P_l(\cos\theta)\frac{1}{2\mathrm{i}kr}\left\{\left(1+\frac{2\mathrm{i}kf_l}{2l+1}\right)e^{\mathrm{i}kr} - (-1)^l e^{-\mathrm{i}kr}\right\}.$$

Значит,

$$S_l = 1 + \frac{2\mathrm{i}kf_l}{2l+1}$$

и

$$f_l = \frac{(2l+1)}{2\mathrm{i}k}\left(S_l - 1\right)$$

Выражая S_l через фазовые сдвиги

$$S_l = e^{2\mathrm{i}\delta_l},$$

легко находим

$$f_l = \frac{2l+1}{k} e^{\mathrm{i}\delta_l} \sin\delta_l$$

Дифференциальное сечение рассеяния по общей формуле

$$\frac{d\sigma}{d\Omega} = \sum_{l,l'} f_l P_l(\cos\theta) f_{l'}^* P_{l'}(\cos\theta)$$

имеет характерную зависимость от углов, которая и подвергается парциально-волновому анализу при исследовании экспериментальных данных.

В силу ортогональности полиномов Лежандра полное сечение рассеяния

$$\sigma = 4\pi \sum_l \frac{|f_l|^2}{2l+1} = \frac{4\pi}{k^2} \sum_l (2l+1)\sin^2\delta_l$$

Обычно вводят понятие парциального сечения

$$\sigma_l := \frac{4\pi}{k^2}(2l+1)\sin^2\delta_l.$$

Оно принимает максимальное значение при $\delta_l = \pi/2$. Отметим, что для рассеяния вперед $P_l(\cos\theta = 1) = 1$ и

$$\mathrm{Imm} f_l = \frac{2l+1}{k}\sin^2\delta_l$$

так что

$$\sigma_l = \frac{4\pi}{k}\mathrm{Imm} f_l$$

т.е. оптическая теорема справедлива для каждого парциального сечения упругого рассеяния в отдельности.

Свойства фазовых сдвигов по Киселеву

Согласно интегральному уравнению Для амплитуды рассеяния

$$f(\theta) = -\frac{m}{2\pi\hbar^2}\int d^3\boldsymbol{r}' e^{-\mathrm{i}\boldsymbol{k}_E\cdot\boldsymbol{r}'} V(r')\,\psi_{\mathrm{i}}^{(+)}(\boldsymbol{r}')$$

несложно получить выражение и для фазы рассеяния, если воспользоваться разложением по парциальным волнам для волны де Бройля и точного решения стационарного уравнения $\psi_i^{(+)}(\boldsymbol{r})$ с подходящими граничными условиями. В самом деле,

$$e^{-\mathrm{i}\boldsymbol{k}\cdot\boldsymbol{r}'} = \left(\ \mathrm{i}\boldsymbol{k}\cdot\boldsymbol{r}'\ \right) = 4\pi\sum_{l,m} R_{kl}^{*(0)}(r) Y_{l,m}^*(\boldsymbol{n}')\, Y_{l,m}\left(\boldsymbol{n}^{(k)}\right)$$

где $Y_{l,m}^*(\boldsymbol{n}') = Y_{l,m}^*(\theta',\phi')$, $Y_{l,m}\left(\boldsymbol{n}^{(k)}\right) = Y_{l,m}(\theta,\phi)$, и

$$\psi_i^{(+)}(\boldsymbol{r}') = \sum_{l'}(2l'+1)\,P_{l'}(\cos\theta')\,R_{kl'}(r')$$

так что интегрирование по телесному углу в выражении для амплитуды рассеяния (12.28) элементарно дает

$$\int d\Omega'\cdot Y_{l,m}^*(\theta',\phi')\sqrt{\frac{2l'+1}{4\pi}}P_{l'}(\cos\theta') = \langle l,m|l',0\rangle = \delta_{ll'}\delta_{m0}$$

Поэтому амплитуда выражается в виде ряда

$$f(\theta) = -\frac{2m}{\hbar^2}\sum_l (2l+1)P_l(\cos\theta)\int dr\cdot r^2 R^{*(0)}_{kl}(r)V(r)R_{kl}(r).$$

По определению, парциальные амплитуды имеют вид

$$f_l = -\frac{2m}{\hbar^2}(2l+1)\int dr\cdot r^2 R^{*(0)}_{kl}(r)V(r)R_{kl}(r).$$

Функция $R^{(0)}_{kl}(r)$ - решение одномерного радиального уравнения Шредингера, комплексная фаза которого фиксирована асимптотическим условием

$$R^{(0)}_{kl}(r) \simeq \mathrm{i}^l\cdot\frac{\sin\left(kr-\frac{\pi}{2}l\right)}{kr}$$

так же, как и фаза точного решения стационарного уравнения Шредингера с потенциалом

$$R_{kl}(r) \simeq e^{\mathrm{i}\delta_l}\mathrm{i}^l\cdot\frac{\sin\left(kr-\frac{\pi}{2}l+\delta_l\right)}{kr}$$

Поэтому можно перейти к вещественным волновым функциям $\Phi(r)$ в радиальных уравнения с заданными асимптотикам и на бесконечности, так что

$$R^{(0)}_{kl}(r) = \mathrm{i}^l\cdot\Phi^{(0)}_{kl}(r),\quad R_{kl}(r) = e^{\mathrm{i}\delta_l}\mathrm{i}^l\cdot\Phi_{kl}(r)$$

Тогда

$$f_l = -\frac{2m}{\hbar^2}(2l+1)e^{\mathrm{i}\delta_l}\int dr\cdot r^2\Phi^{(0)}_{kl}(r)V(r)\Phi_{kl}(r)$$

Сравнивая последнее выражение с формулой для парциальной амплитуды в терминах сдвига фазы (13.31), получаем интегральное представление для фазы

$$\sin\delta_l = -\frac{2mk}{\hbar^2}\int dr\cdot r^2\Phi^{(0)}_{kl}(r)V(r)\Phi_{kl}(r)$$

В борновском приближении, очевидно,

$$\sin\delta_l \approx -\frac{2mk}{\hbar^2}\int dr\cdot\left\{r\Phi^{(0)}_{kl}(r)\right\}^2 V(r)$$

Интегральное представление позволяет установить некоторые свойства сдвигов фаз, причем, поскольку основные свойства радиальных волновых функций для свободных волн и вблизи нуля и периоду осцилляций практически совпадают, Выводы о парциальных амплитудах, сделанные на основе борновского приближения и точного интегрального представления, мало отличаются друг от друга, за исключением важного случая резонансов.

Пусть потенциал имеет характерную величину $|V| \simeq V_0$, и он существенно отличен от нуля только в области $r < a$. Как мы выяснили, вблизи нуля поведение радиальной волновой функции

$$R_{kl} \sim (rk)^l\frac{(2l)!!}{(2l+1)!} \sim (rk)^l\frac{2^l l^l e^{-l}\sqrt{2\pi l}}{(2l+1)^{2l+1}e^{-2l-1}\sqrt{2\pi(2l+1)}} \sim \left(\frac{erk}{2l}\right)^l \sim \left(\frac{rk}{l}\right)^l$$

где мы воспользовались формулой Стирлинга для оценки факториалов и опустили несущественные числовые множители.

При этом удобно считать для общности рассмотрения, что эти выражения остаются справедливыми и при $l \to 0$, если формально положить $l^l \to \text{const}$.

В Оправданности чего можно убедиться, непосредственно подставив $R_{k0} \sim \text{const}$.

Значит, интеграл, определяющий фазу, можно оценить как

$$\int dr \cdot \left\{ r\Phi_{kl}^{(0)}(r) \right\}^2 V(r) \sim \frac{a^2 V_0}{k} \left(\frac{ak}{l} \right)^{2l+1}$$

откуда

$$\sin \delta_l \sim \frac{2mV_0}{\hbar^2} a^2 \left(\frac{ak}{l} \right)^{2l+1} \qquad \text{и} \qquad \sin \delta_0 \sim \frac{2mV_0}{\hbar^2} a^3 k$$

Из этих оценок заключаем, что рассеяние частиц с $l \gg ka$ подавлено. Этот ϕ акт согласуется с классически м рассмотрением, поскольку орбитальный момент падающей на мишень частицы можно оценить как произведение волнового вектора (импульса) на прицельное расстояние b, так что при

$$l \sim kb \gg ka \to b \gg a$$

т.е. прицельное расстояние много больше радиуса действия потенциала, и рассеяния не происходит.

С другой стороны, малый вклад в сечение парциальных волн с $l \gg ka$ можно понять, исходя из относительного вклада центробежного потенциала в энергию частицы при больших $l \gg 1$

$$\frac{\Delta V_l(r)}{E} = \frac{\hbar^2 l^2}{2mEr^2} \approx \left(\frac{l}{kr} \right)^2$$

Значит, вклад орбитального момента в энергию радиального движения создает при $r = a$ потенциальный барьер относительной высоты

$$\frac{l^2}{(ka)^2}$$

При $l \ll ka$ происходит надбарьерное рассеяние, и частица достигает потенциала, отличного от нуля при $r < a$. При $l \gg ka$ проницаем ость Высокого и шпрокого барьера сильно подавлена, вероятность проникновения на расстояния $r < a$ крайне мала, так что частица практически рассеивается также, как и в случае свободного движения: вклад области, где существенно наличие потенциала, пренебрежимо мал, т.е. фазы рассеяния близки к нулю.

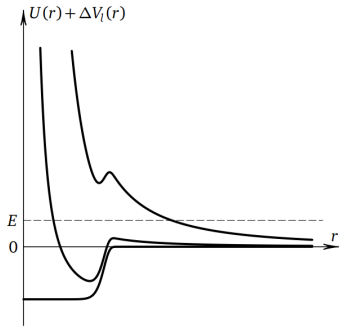


Figure 8.1: Потенциал радиального движения для $l = 0$ (нижняя кривая), $l = 0,7ka$ (средняя кривая) и $l = 2ka$ (верхняя кривая)

Отличие квантового описания рассеяния от классического

(четко опишу, какое оно?)

8.3.7 Scattering of Identical Particles

(см пока лекцию Киселева, там пара страниц нетривиальных мыслей)

8.3.8 Scattering on Coulomb Potential

(типично это решается отдельно, ибо особенностей много. скоро выпишу из Тонга!)

Main theory

Другие свойства кулоновского рассеяния

Two-dimensional coulomb scattering of a quantum particle: wave functions and green's functions by v. V. Pupyshev (2016)

(есть статья на 18 страниц, где получено много сложных формул. Не уверен, что они нужны, но если нужны будут - допишу сюда. Впечатление от статьи: там возня со спецфункциями, нужно пару дней про это думать, чтобы понять, как вообще их применять. Ну и вряд ли приложения этой теории есть. Пока сам это не могу сделать - пусть заготовка побудет)

Annotation:

We solve the problem of the propagation of a charged quantum particle in a two-dimensional plane embedded in the three-dimensional coordinate space. We consider scattering of this particle by a stable Coulomb center situated in the same plane. We study the wave function of this particle, its Green's function, and all radial components of these functions. We derive uniform majorant bounds on absolute values of these functions and find the wave function representation in terms of regular radial Coulomb functions and the scattering amplitude representation via partial phases. We obtain integral representations of the Greens's function and all its radial components.

8.3.9 Illustrative Examples of Typical Scattering Models

(для больших примеров - см. задачи, а для особых ситуаций - см. дальнейшие части и разделы)

8.3.10 Comparison of Quantum and Classical Scattering Theories

(проведу анализ. уже это многим делалось. конкретные примеры и графики добавлю!)

8.4 Analytical Properties of Physical Quantities

(это перенесу скорее всего в другие записи, потому что квантмех тут вообще не везде.)

Все физические величины при реальных значениях параметров не должны обращаться в бесконечность. Иными словами, на вещественной оси в реально достижимых областях физические функции конечны. Единственные допустимые особые точки - это точки ветвления. В каждом случае для их появления должны быть физические причинь.

В комплексной плоскости параметров физические функции могут иметь различные особые точки. Однако всегда можно выделить области, в которых функции аналитичны.

Из свойств аналитичности можно делать важные заключения о связях между различными физическими величинами. Рассмотрим несколько примеров.

8.4.1 Dependence of the Nuclear Moment of Inertia on Deformation

Для квантовомеханической сферической системы момент инерции равен нулю, так как ее вращение не имеет физического смысла. Рассиотрим момент инерции J при малых деформацнлх (??). С какого члена начинается разложение J по степеням δ? Легко убедиться в том, что выражение $J = A\delta$ неправильно. Предположим, что $J = A\delta$ для положительных δ («огурец»). Так как J всегда положительная величина, то для отрицательных δ («блин») по принципу аналитического продолжения $J = A|\delta| = A\sqrt{\delta^2}$. Следовательно, момент инерции как функция δ^2 имел бы в нуле точку ветвления. Между тем, можно убедиться, что нет никаких причин для появления особой точки. Действительно, перейдем от слабо деформированного ядра к сферическому с помощью соответствующего преобразования координат. В гамильтониане появится малая добавка H', пропорииональная величине деформации δ. Для конечной системы применение теории возмущений дает сходящийся ряд. Следовательно, момент инерции не имеет особой точки при $\delta = 0$. Поэтому разложение J по степеням δ начинается с квадратичного члена

$$J = B\delta^2 + ...$$

(??? потом про это еще подумаю.)

8.4.2 Dependence of Sound Frequency on the Wave Vector

Как известно, при малых волновых числах k (т. е. больших длинах волн $\lambda\!\!\!^{-} = 1/k$) в некоторых системах могут распространяться звуковые возбуждения с частотой $\omega = ck$. Здесь c - скорость звука. Так как ω - скаляр, а $\boldsymbol{k}$ - вектор, то это соотношение означает $\omega = c\sqrt{\boldsymbol{k}^2}$. Итак, при $k = 0$ частота ω как функция k^2 имеет точку ветвления. Объясним, почему здесь возникает особая точка.

Уравнения, описывающие состояние системы, инвариантны при замене $t \longrightarrow -t$, если нет диссипации. Поэтому уравнение для определения частоты всегда содержит ω^2, а не ω. Например, в классической механике уравнение Ньютона для каждой колеблющейся частицы при малых колебаниях имеет вид

$$m\ddot{u}_n = -\sum_m F_{mn}u_m.$$

Здесь m - масса n-й частицы, u_n - ее смещение, а F_{mn} сила, действующая на n-ю частицу со стороны m-й. Полагая $u_n = u_{0n}e^{i\omega t}$, получим дисперсионное уравнение для квадрата частоты звука ω^2 в виде

$$m\omega^2 u_{0n} = \sum_m F_{mn}u_{0m}.$$

Следовательно, квадрат частоты ω^2, а не сама частота ω, должен быть аналитической функцией параметров задачи. Поэтому

$$\omega^2 = a + c^2k^2 + bk^4 + ...$$

Для звуковых волн $a = 0$, следовательно, для малых k частота $\omega = c|\boldsymbol{k}|$.

8.4.3 Analytical Properties of the Wave Function

(??? maybe move it to the part of basics)

Движение частицы в поле с потенциалом $V(r)$ определяется волновой функцией Ψ, которая подчиняется уравнению Шредингера:

$$-\frac{1}{2}\Delta\Psi + V\Psi = E\Psi$$

Для сферически-симметрического потенциала $V(r)$ радиальная и угловые переменные разделяются, т. е.

$$\Psi = R_{nl}(r)Y_{lm}(\theta,\varphi),$$

причем $R_{nl}(r)$ удовлетворяет уравнению

$$R'' + \frac{2}{r}R' + 2\left[E - V - \frac{l(l+1)}{2r^2}\right]R = 0.$$

Обозначим $V_l = V + \frac{l(l+1)}{2r^2}$ и заменим $R = \frac{u}{r}$. Тогда для u получается следующее уравнение:

$$u'' + 2\left(E - V_l\right)u = 0.$$

Так как волновая функция R во всех точках пространства конечна, то $u(0) = 0$.

Известно, что особые точки решения линейного дифференциального уравнения всегда совпадают с особыми точками коэффициентов уравнения (кроме бесконечно удаленной особой точки). Однако особые точки коэффициентов могут и не быть особыми точками решения. Например, в уравнении (1.14) точка $r = 0$-особая точка коэффициента уравнения, так как $V_l \to \infty$. Если $l \neq 0$, то при малых r можно пренебречь $V(r)$ по сравнению $l(l+1)/r^2$. Следовательно, уравнение (1.14) приобретает вид $r^2u'' - l(l+1)u = 0$, откуда $u_1 \sim r^{l+1}$ или $u_2 \sim r^{-l}$. Итак, существует решение $u_1 \sim r^{l+1}$, которое не обращается в бесконечность при $r \longrightarrow 0$. $\underset{r\to 0, l\neq 0}{}$

Итак, особые точки решения уравнения Шредингера (1.14) могут быть только там, где потенциал имеет особенность.

Например, осцилляторный потенциал $V = \frac{1}{2} \propto x^2$ имеет особую точку на бесконечности. Поэтому и решение имеет особую точку только на бесконечности.

Кулоновский потенциал, рассматриваемый как функция r^2, имеет особенность при $r^2 = 0$. По этой причине радиальные функции имеют особенность при $r^2 = 0$, а именно, $R_{nl}\left(r^2\right)$ имеет в нуле точку ветвления (например, функция основного состояния $R \sim e^{-Vr^2}\Big)$. Ниже (стр. 53) мы увидим, что эта особенность кулоновских функций приводит к важным следствиям. (!??!?!?)

8.4.4 Scattering Amplitude at Low Energies

Ψ-функция при больших r в задаче рассеяния имеет асимптотический вид

$$\Psi \underset{r\to\infty}{\to} e^{ikz} + \frac{f}{r}e^{ikr},$$

где f - амплитуда рассеяния.

Предположим для простоты, что рассеяние сферически-симметрично, т. е. f не зависит от углов. Рассмотрим сферически-симметричную часть Ψ:

$$\int \Psi\frac{d\Omega}{4\pi} \equiv \frac{u}{r} = \frac{1}{2}\int_0^\pi e^{ikr\cos\vartheta}\sin\vartheta d\vartheta + \frac{f}{r}e^{ikr} = \left(\frac{\sin kr}{k} + fe^{ikr}\right)\frac{1}{r}.$$

Функцию u можно представить в виде

$$u = -\frac{1}{2ik}e^{-ikr} + \frac{1+2ikf}{2ik}e^{ikr}.$$

Если рассеивающий центр не поглощает и не испускает частиц, то радиальный ток частиц равен нулю. Перекрестные члены сокращаются, и оказывается, что ток равен разности токов, составленных из двух слагаемых и. Условие равенства этик двух токов дает

$$|1+2ikf|^2 = 1,$$

или, иначе,

$$f - f^* = 2ikff^*, \quad \operatorname{Im} f = k|f|^2$$

откуда получаем

$$\operatorname{Im}\frac{1}{f} = -k, \quad f^{-1} = \varkappa - ik,$$

где $\varkappa$ - вещественное число.

Величину $\varkappa$ можно выразить через энергию связанного состояния частицы в рассеивающей яме (если такое состояние существует). Действительно, функция ι может быть аналитически продолжена из области положительных энергий в область отрицательных, что соответствует мнимым значениям $\boldsymbol{k}$. Пусть энергия связанного состояния равна $(-E_0)$. Обозначим $x_0 = \sqrt{2E_0}$. Тогда при $k = \pm ix_0\Psi$-функция для положительных энергий должна переходить в Ψ-функцию связанного состояния. Поэтому в выражении для u при $k = \pm i\varkappa_0$ не должно оставаться слагаемого с растущей экспонентой.

Подставляя (1.17) в выражение (1.15), получим

$$u = -\frac{1}{2ik}\left(e^{-ikr} + \frac{x+ik}{x-ik}e^{ikr}\right).$$

При $\Leftrightarrow= ix_0$ получаем

$$u = \frac{1}{2x_0}\left(e^{x_0 r} + \frac{x-x_0}{x+x_0}e^{-x_0 r}\right).$$

Для того чтобы можно было пренебречь растущей экспонентой, необходимо $x = -\varkappa_0$. При $k = -ix_0$ получается это же условие. Таким образом, амплитуда рассеяния имеет полюс

$$f = -\frac{1}{x_0 + ik},$$

положение которого определяется энергией связанного состояния.

8.4.5 Analytical Properties of a Dielectric Constant

Аналитичность некоторых физических величин, как мы увидим, есть следствие причинности.

Рассмотрим, например, аналитические свойства диэлектрической постоянной. Индукция $D(t)$, возникающая в системе при наложении электрического поля, определяется амплитудой поля E во все предыдущие моменты времени $t - \tau(\tau > 0)$. Итак,

$$D(t) = \int_0^\infty K(\tau)E(t-\tau)d\tau$$

$K(\tau)$ - вещественная функция, так как она связывает физические величины. Это соотношение вытекает лишь из того, что следствие наступает позже причины. Разложим E и D в ряды Фурье:

$$E = \int E_\omega e^{-i\omega t} d\omega, \quad D = \int D_\omega e^{-i\omega t} d\omega.$$

Тогда из (1.19) находим

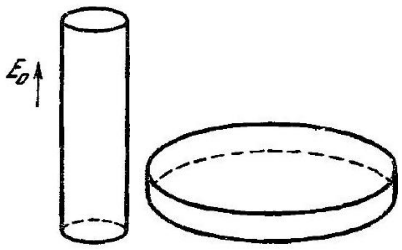
$$D_\omega = E_\omega \int_0^\infty K(\tau) e^{i\omega\tau} d\tau,$$

откуда диэлектрическая постоянная

$$\varepsilon_\omega = \frac{D_\omega}{E_\omega} = \int_0^\infty K(\tau) e^{i\omega\tau} d\tau.$$

Величина ε_u аналитична в верхпей полуплоскости комплексной переменіой ω. Действительно, если обозначить $\omega = \omega_0 + i\omega_1$, где $\omega_1 > 0$, то подынтегральное выражение в (1.20) содержит затухающую эксионенту $e^{-\omega_1\tau}$, и ноэтому интеграл (1.20) сходится, а следовательно, представляет аналитическую функцию.

Нетрудно видеть, что аналитические свойства $\boldsymbol{\varepsilon}$ и $1/\varepsilon$ совнадают. Рассмотрим длинный и короткий цнлиндры вещества, на которые наложено внешнее поле E_0 (рнс. 8).

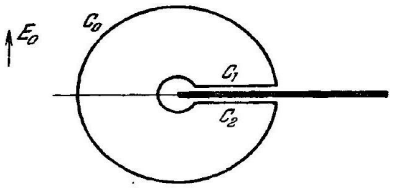


В случае длинного цилиндра поле внутри E равняется внешнему полю E_0, а индукция $D = \varepsilon E_0$. В случае короткого цилиндра индукция D равняется внешнему полю E_0, а поле внутри $E = E_0/\varepsilon$. В первом случае $D = \int_0^\infty K_1(\tau) E_0(t-\tau) d\tau$ и $\varepsilon = \int_0^\infty K_1(\tau) e^{i\omega t} d\tau$. Во втором случае поле E определяется значеннями $E_0 = D$ в предыдущие моменты времени, $E = \int_0^\infty K_2(\tau) D(t-\tau) d\tau$, откуда $1/\varepsilon = \int_0^\infty K_2 e^{i\omega\tau} d\tau$. Таким образом, аналитические свойства е и $1/\varepsilon$ совпадагот. Следовательно, диэлектрическая постоянная не имеет ни полдосов, ни нулей в верхней полуглоскости.

Так как $\varepsilon(i\omega_1) \underset{\omega_1>0}{\Rightarrow} \int_0^\infty K(\tau) e^{-\omega_1\tau} d\tau$, то ввиду веществеппостн поднптегрального выражения и $\varepsilon(i\omega_1)\,|\omega_1 > 0$ вещественна, т. е. $\operatorname{Im}\varepsilon(i\omega_1) = 0$

$\omega_1 > 0$

Используя аналигичпость, можно выразить вещественную часть диэлектрической постояпной через ее мнимую часть. Рассмотрим комплексную плоскость ω^2. В этом случае область аналитичности ε представляет собой первый лист римановони илоскости - все особые точки лежат на втором листе. Первый лист переходит во второй через разрез, идущий вдоль положительных ω^2 от точки $\omega^2 = 0$ (рис. 9).



Согласно теореме Коши

$$f(z) = \frac{1}{2\pi i} \int\limits_C \frac{f(z')\,dz'}{z - z'}$$

где C-замкнутый контур, не содержащий внутри себя особых точек $f(z)$. Применим эту теорему к $\varepsilon(\omega)^2)$, взяв в качестве C контур, изображенный на рис. 9. При больших ω^2, как мы увидим, $\varepsilon\left(\omega^2\right)$ имеет вид $\varepsilon \to 1 - \frac{c_1}{\omega^2}$. Поэтому для того, чтобы интеграл по контуру C_0 обращался в нуль, нужно в качестве f взять функцию $f = \varepsilon - 1$. Итак,

$$\varepsilon\left(\omega^2\right) - 1 = \frac{1}{2\pi i} \int \frac{\varepsilon\left(\omega_1^2\right) - 1}{\omega_1^2 - \omega^2} d\omega_1^2.$$

Кз рис, 9 видно, что этот интеграл сводится к обходу разреза. Обозначим через $\varepsilon_1\left(\omega^2\right)$ значение ε на верхнем берегу разреза, а через $\varepsilon_2\left(\omega^2\right)$ значение ε на нижнем берегу. Покажем, что $\varepsilon_2\left(\omega^2\right) = \left[\varepsilon_i\left(\omega^2\right)\right]^*$. Мы видели, что & вещественно на мнимой верхней полуосія плоскости. п. Следовательно, в плоскости ω^2 величина ε вещественна на полуосн $\omega^2 < 0$. Продолжая аналитически это соотношение на верхний и нижний берега разреза, получаем

$$\varepsilon_1\left(\omega^2\right) = \left[\varepsilon_2\left(\omega^2\right)\right]^* |\omega^2 > 0.$$

Учитывая (1.22), из (1.21) находим

$$\varepsilon\left(\omega^2\right) - 1 = \frac{1}{2\pi i} \int\limits_{C_1} \frac{\varepsilon_1\left(\omega_1^2\right) - \varepsilon_3\left(\omega_1^2\right)}{\omega_1^2 - \omega^2} d\omega_1^2 = \frac{1}{2\pi} \int\limits_{C_1} \frac{2\,\mathrm{Im}\,\varepsilon\left(\omega_1^2\right) d\omega_1^2}{\omega_1^2 - \omega^2}.$$

Итак,

$$\varepsilon\left(\omega^2\right) = 1 + \frac{1}{\pi} \int\limits_0^\infty \frac{\mathrm{Im}\,\varepsilon\left(\omega_1^2\right) d\omega_1^2}{\omega_1^2 - \omega^2},$$

т. е., зная мнимую часть диэлектрнческой постоянной ε, можно восстановить всю величину ε.

Мнимая часть диэлектрической постояиной, определяюиая поглощение электромагнитных волн системо, отлична от нуля только, когда частота волн совпадаст с собствннымн частотамн системы ω_n. Иными словами,

$$\mathrm{Im}\,\varepsilon\left(\omega^2\right) = \sum_n \pi f_n \delta\left(\omega^2 - \omega_n^2\right).$$

Подставляя (1.24) в (1.23), получаем

$$\varepsilon\left(\omega^2\right) = 1 + \sum_n \frac{f_n}{\omega_n^2 - \omega^2}$$

При $\omega^2 \gg \omega_n^2$ величина ε должна перейти в диэлектрическую постоянную идеального газа электронов, т. е. $\varepsilon \underset{\omega^2 \to \infty}{\longrightarrow} 1 - \frac{4\pi n e^2}{m\omega^2}$, где n - число электронов в единице объема, а m - масса электрона. Таким образом, из (1.23) и (1.25) получаем

$$\frac{1}{\pi}\int \operatorname{lm}\varepsilon\left(\omega_1^2\right)d\omega_1^2 = \frac{4\pi n e^2}{m} = \sum_n f_n.$$

Это соотношение называется правилом сумм.

(по идее это должен я уже хорошо знать, но пока еще не отработал, потом потренируюсь. типичная такая тема.)

8.4.6 Analytical Properties of a Scattering Amplitude

Аналогичным способом доказываются аналитические свойства амплитуды рассеяния. Рассмотрим, например, рассеяние света заряженной системой. Пусть амплитуда рассеянной волны характеризуется величиной B, а падающей - A. Эти величины связаны друг с другом соотношением

$$B(t) = SA(t),$$

где S - некоторый интегральный оператор. Сделаем предположение, что до момента времени $t = 0$ амплитуда падающей волны на некоторой контрольной плоскости, расположенной до рассеивающей системи, равна нуло. Относительно B можно утверждать, что $B(t) = 0$ для $t < t_1$, где $t_1 > 0$.

Перейдем к фурье-компоненте $A_\omega = \int\limits_0^\infty A(t)e^{i\omega t}dt$. Так как $A(t) = 0$ при $t < 0$, то A_ω не имеет особенностей в верхней полуплоскости. Аналогично имеем $B_\omega = \int\limits_{t_x>0}^\infty B(t)e^{i\omega t}dt$, т. е. B_ω также не имеет особенностей в верхней полуплоскости. Из (1.26) следует, что $B_\omega = SA_\omega$.

Отсюда видно, что величина S может иметь особенности лишь в нулях A. Но S не может зависеть от частного вида A, следовательно, S вообще не может иметь особенностей в верхней полуплоскости. Оператор S линейно связан с амплитудой рассеяния f света. Поэтому дисперсионное соотношение для f аналогично дисперсионному соотношению для диэлектрической постоянной ε (напомним, что $\varepsilon\left(\omega^2\right) = 1 + \frac{1}{\pi}\int\limits_0^\infty \frac{\operatorname{Im}\varepsilon\left(\omega_1^2\right)d\omega_1^2}{\omega_1^2-\omega^2}$):

$$f\left(\omega^2\right) = \frac{1}{\pi}\int \frac{\operatorname{Im} f\left(\omega_1^2\right)d\omega_1^2}{\omega_1^2-\omega^2}$$

В случае рассеяния света заряженной системой такое выражение для амплитуды неверно, так как амплитуда при больших частотах стремится не к нулю, а к сумме амплитуд рассеяния на свободных частицах. Поэтому дисперсионное соотношение нужно применять не к величине f, а к величине $f\left(\omega^2\right) - f(\infty)$ аналогично тому, как это делалось в случае диэлектрической постоянной. (!?!?!!??!?!)

8.5 Scattering theory: Other features and methods

8.5.1 Eikonal Approximation (??)

(нужно додумывать, не типичная теория)

Конструкция эйконального приближения по Зинн-Жюстену

Решение, удовлетворяющее граничным условиям представления (9.11) и соответствующее свободному гамильтониану

$$H_0 = \mathrm{p}^2/2m, \text{ где } \mathrm{p} \in \mathbb{R}^d$$
$$\mathrm{q}(t) = \mathrm{q}' + (\mathrm{q}'' - \mathrm{q}')\,\tfrac{t-t'}{t''-t'}$$

После сдвига переменных интегрирования $\mathrm{q}(t)$ на классическое решение (9.36) вычисление сводится к нормировочному интегралу, который может быть определен сравнением с точным результатом ($\hbar = 1$)

$$\langle \mathrm{q}''|U\left(t'',t'\right)|q'\rangle = \left(\frac{m}{2i\pi\left(t''-t'\right)}\right)^{d/2} \exp\left[i\frac{m}{2}\frac{\left(q''-q'\right)^2}{\left(t''-t'\right)}\right].$$

Эйкональное приближение соответствует кинематическому режиму

$$p' = p - k/2, \quad p'' = p + k/2, \quad p^2 \to \infty, \quad p^2 \gg k^2$$

В этом случае в действии кинетический член преобладает над потенциальным.

Поэтому будем вычислять континуальный интеграл тах же, как и в свободном случае, разлагая траектории вблизи классической траекторий свободного движения (9.36).

Вычисление оператора эволюции в ведущем порядке достаточно просто.

Полагая $q'' - q' = s(q'' + q')/2 = x$, получим:

(упущена формула) 9.38

классическое действие теперь имеет вид:

$$A(s,x) = \frac{im}{2}\frac{s^2}{t''-t'} - i\int\limits_{t'}^{t''} dtV\left(x - \frac{s}{2} + \frac{t-t'}{t''-t'}s\right)$$

а нормировка в равенстве (9.38) определяется сравнением с результатом (9.37), отвечающим свободному движению.

В пределе большого временного интервала, если пренебречь вкладом потенциального слагаемого, основной вклад в интеграл по s дает седловая точка

$$\mathrm{s} = \left(t''-t'\right)\mathrm{p}/m$$

После подстановки s и замены переменных $t - \left(t'+t''\right)/2 \mapsto t$, такой, что $|t| \leqslant \left(t''-t'\right)/2$, аргумент потенциала принимает вид $\mathrm{x} + \mathrm{tp/m}$.

Будем считать, что потенциал достаточно быстро убывает, чтобы существовал предел интеграла в (9.39) при больших временах, т.е. при $t''-t' \to \infty$. Вклад потенциала в действие в этом случае имеет вид

$$-i\int\limits_{-\infty}^{+\infty} dtV(\mathrm{x} + t\mathrm{p/m})$$

Как только мы перешли к пределу, можно сдвинуть переменную интегрирования t, не меняя область интегрирования.

Это сводится к сдвигу вектора x в аргументе потенциала V на вектор, пропорциональный .

Выберем этот вектор так, чтобы V зависел только от

$$b = x - p\left(x \cdot p/p^2\right)$$

- компоненты x, ортогональной p.

Тогда интеграл по компоненте x вдоль p может быть вычислен, и из него следует условне $\mathrm{p} \cdot \mathrm{k} = 0$. В области применимости эйконального приближения это равенство выражает закон сохранения энергии:

$$0 = \mathrm{p}''^2 - \mathrm{p}'^2 = (\mathrm{p} + \mathrm{k}/2)^2 - (\mathrm{p} - \mathrm{k}/2)^2 \sim 2\mathrm{p} \cdot \mathrm{k}$$

Получим:

$$\langle \mathrm{p} + \mathrm{k}/2 \left| U\left(t'', t'\right) \right| \mathrm{p} - \mathrm{k}/2) \simeq \delta(\mathrm{p} \cdot \mathrm{k}) \mathcal{N}(\mathrm{p}) \int d^{d-1} b e^{-ik \cdot b} \exp\left[-i \int\limits_{-\infty}^{+\infty} dt V\left(\frac{\mathrm{p}t}{m} + \mathrm{b}\right)\right],$$

$$\mathcal{N}(\mathrm{p}) \sim \exp\left[i\left(t'' - t'\right) \frac{\mathrm{p}^2}{2m}\right]$$

Равенство (9.42) дает после преобразования Фурье матричные элементы оператора рассеяния T в импульсном базисе (определенные равенством (9.9)) :

$$\langle \mathrm{p} + \mathrm{k}/2 | T | \mathrm{p} - \mathrm{k}/2 \rangle \simeq \frac{i|\mathrm{p}|}{m} \int \frac{d^{d-1} b}{(2\pi)^d} e^{-i\mathrm{k} \cdot \mathrm{b}} \left\{ \exp\left[-i \int\limits_{-\infty}^{+\infty} dt V\left(\frac{\mathrm{p}t}{m} + \mathrm{b}\right)\right] - 1 \right\}$$

Через Фурье-представление

$$V(\mathbf{q}) = \int d^d s e^{iq \cdot s} \tilde{V}(\mathrm{~s})$$

Интеграл от потенциала может быть записан в виде:

$$\int\limits_{-\infty}^{+\infty} dt V\left(\frac{\mathrm{p}t}{m} + \mathrm{b}\right) = \int d^d s \widetilde{V}(\mathrm{~s}) \int\limits_{-\infty}^{+\infty} dt e^{\mathrm{i}(\mathrm{p}t/m + \mathrm{b}) \cdot \mathrm{s}}$$

Интеграл по времени теперь можно взять и свести интеграл по интегралу по компонентам s, ортогональным p:

$$\int\limits_{-\infty}^{+\infty} dt V\left(\frac{\mathbf{p}t}{m} + \mathbf{b}\right) = 2\pi \frac{m}{|\mathbf{p}|} \int d^d s \delta(\mathbf{s} \cdot \widehat{\mathbf{p}}) e^{i\mathbf{b} \cdot \mathbf{s}} \tilde{V}(\mathrm{~s})$$

В это выражение входит Фурье-образ $\widetilde{V}$, но в $(d-1)$ -мерном подпро странстве, ортогональном p Наконец, отметим, что в ведущем порядке по V эйкональное при ближение сводится к

$$\langle \mathbf{p} + \mathbf{k}/2 | T | \mathbf{p} - \mathbf{k}/2 \rangle = \tilde{V}(\mathbf{k})$$

т.е. к точному борновскому приближению (см. Раздел 9.2).

Применение эйконального приближения к кулоновскому потенциалу

Применим теперь эйкональное приближение к нахождению амплитуды рассеяния в случае потенциала вида $1/q$ - кулоновского типа.

В этом случае интеграл от потенциала не имеет предела для бесконечного временного интервала, потому что потенциал слишком медленно убывает на больших расстояниях.

Поэтому необходимо сначала интегрировать по конечному временному интервалу.

Параметризуем потенциал следующим образом:

$$V(\mathbf{q}) = \frac{\alpha}{|\mathbf{q}|}$$

Тогда

$$\int\limits_{(t'-t'')/2}^{(t''-t')/2} \mathrm{d}t V\left(\frac{\mathbf{p}t}{m} + \mathbf{x}\right) \simeq \frac{2\alpha m}{p} \ln\left(\left(t''-t'\right) p/mb\right)$$

Эта бесконечная фаза имеет следующее происхождение: так как кулоновский потенциал слишком медленно убывает на больших рас стояниях, классическая траектория слишком медленно приближает к траектории свободного движения, которая при нашем определенi, S -матрицы принята в качестве эталонной.

В кулоновском потенциале амплитуды не определены - определены только сечения.

Факторизуя бесконечную фазу, можно завершить вычисление зм: плитуды рассеяния.

Интегрируя по вектору b, получим:

$$T(\mathbf{p}+\mathbf{k}/2, \mathbf{p}-\mathbf{k}/2) \simeq \frac{i\pi^{(d-1)/2}}{(2\pi)^d} \frac{p}{m} \exp\left[-i\frac{2\alpha m}{p} \ln\left(\left(t''-t'\right) p/m^b\right)\right] \frac{\Gamma\left[\frac{1}{2}(d-1)-\theta\right]}{\Gamma(\theta)} \left(\frac{k^2}{4}\right)^{[\theta+(1-d)/2)}$$

rде $\theta = -iam/p$. В физической размерности з выраженне (9.47) совпадает с точным результатом.

При $\alpha < 0$ (случай притяжения) оно дает энергин E_n связанных состояний в кулоновском потенциале, которые проявляются в виде полюсов амплитуды рассеяния:

$$\theta = \frac{1}{2}(d-1) + n \to E_n = \frac{\mathrm{p}^2}{2m} = -\frac{2\alpha^2 m}{(d-1+2n)^2}$$

Узнается хорошо известный кулоновский спектр.

Наконец, эйкональное приближение обладает релятивистским обоб- щением, которое дает очень интересные приближения для спектра энергий в квантовой электродинамике.

В последнем случае оно состоит в приближенном суммировании лестничных и перекрестных лестничных диаграмм Фейнмана.

Теория возмущений и операторы

Чтобы проиллюстрировать соответствие между формулировкой квантовой механики с помощью континуального интеграла и операторной формулировкой, напомним основы теории возмущений в операторном формализме для случая не зависящих от времени гамильтонианов.

Разложение S -матрицы может быть получено, например, из разложения оператора (см. (9.6))

$$\Omega(t) = e^{iH_0 t} e^{-iHt}$$

где H_0 - невозмущенный гамильтониан, и

$$V = H - H_0$$

возмущение.

Вводя оператор возмущения в представлении взаимодействия

$$V_1(t) = e^{iH_0 t} V e^{-iH_0 t}$$

можно убедиться, что оператор $\Omega(t)$ удовлетворяет уравнению

$$\dot{\Omega}(t) = -iV_1(t)\Omega(t)$$

граничным условием

$$\Omega(0) = 1$$

(допишу потом)

Применения эйконального приближения

(потом разберу, это важно)

8.5.2 Resonances

Резонансы по Киселеву

(добавлю напоминание, что происходит вообще?)

Парциальное сечение достигает своего макси мума $\sigma_l = 4\pi(2l+1)/k^2$ при Энергии, когда $\delta_l = \pi/2$. В этом случае говорят о наличии резонанса в l -канале.

Запишем Парциальную амплитуду

$$\frac{k}{2l+1} f_l = \frac{\sin\delta_l}{e^{-\mathrm{i}\delta_l}} = \frac{\sin\delta_l}{\cos\delta_l - \mathrm{i}\sin\delta_l} = \frac{1}{\operatorname{ctg}\delta_l - \mathrm{i}}$$

Котангенс парциального сдвига δ_l обращается в нуль, если энергия близка к резонансной $E \approx E_*$, Т.е.

$$\operatorname{ctg}\delta_l \approx 2\frac{E_* - E}{\Gamma}$$

где мы ввели величину размерности энергии Γ и положили, что в ведущем приближении Зануление происходит линейно по энергии.

Значит,

$$\delta_l \approx \arctan\frac{\Gamma}{2\,(E_* - E)}$$

при вариации энергии вблизи резонанса в малой области размером в несколько Γ пробегает Значения от нуля до π. Для парциальной фазы можно записать

$$\frac{k}{2l+1} f_l = \frac{e^{2\mathrm{i}\delta_l} - 1}{2\mathrm{i}} = \frac{\mathrm{i}}{2} - \frac{\mathrm{i}}{2} e^{2\mathrm{i}\delta_l}$$

Это показывает, что в Комплексной плоскости парциальная амплитуда с ростом энергии пробегает против часовой стрелки по окружности, центр которой смещен из нуля на чисто мнимую ось, как это показано на рис.

9.5.

Подобный график называют "Арганд-плот".

Окружность на таком графике практически замкнутая, если вдали от резонанса сдвиг фазы относительно мал.

Парциальное сечение рассеяния вблизи резонанса как функция энергии приобретает Зависи мость брейт-вигнеровского типа

$$\sigma_l = \frac{\pi(2l+1)}{k^2(E)} \frac{\Gamma^2}{(E_* - E)^2 + \Gamma^2/4}$$

т.е. имеет вид пика с ширин ой на полувысоте Г.

Однако пикообразная форма зависи мости сечения от энергии сама по себе может возникать по различным динамическим причинам, поэтому для идентификации резонансов при парциально-волновом анализе экспериМентальных данных по рассеянию поточечно строят Арганд-плот, что в случае характерной

Зависи мости и служит достоверным доказательством наличия резонанса в том или ином канале.

Выше мы молчаливо полагали, что ширина Г положительна.

Это отвечает том у, что аамплитуда рассеяния

$$\frac{k}{2l+1} f_l \approx \frac{\frac{\Gamma}{2}}{E_* - E - \mathrm{i}\frac{\Gamma}{2}}$$

и меет полюс в комплексной плоскости энергии при $E = E_* - \mathrm{i}\Gamma/2$, т.е. полюс смещен в нижнюю полуплоскость.

Этот вопрос тесно связан с исследовани ем аналитических свойств как амплитуд рассеяния, так и функции Грина стационарн ого уравнения Шредингера, что Выходит за рамки нашего изложения.

Вкратце же отметим, что, в частности, на примере функции Грина свободной частицы мы видели, что по энергии она и меет разрез в комплексн ой плоскости вдоль вещественной оси от нуля до бесконечности, т.е.

при значениях энергии в непрерывн Ом спектре.

При наличии связанных состояний функция Грина, как следует из разложения по базису стационарных состояний, приобретает полюса на вещественной оси в точках дискретного спектра.

Резонансы имеют место в непрерывн Ом спектре, так что отмеченный полюс расположен "за" разрезом, т.е.

на нефизическом листе двулистной функции Г рина, зависяшей от $k = \sqrt{2mE/\hbar^2}$

Арганд-плот и его применения

Наконец, отметим, что резонанс при наличии неупругих каналов рассеяния на "Арганд-плоте" проявляется в Виде витка неправильной спирали.

(тут укажу, где он нужен!!!)

8.5.3 Fundamentals of Inelastic Collisions

(тут большая теория, в том числе в ЛЛ3, потом напишу)

Неупругие столкновения

При изложении фазовой теории рассеяния мы полагали, что поток вероятности сохраняется: число падающих на мишень частиц равно числу рассеянных, так что имеет место тождество

$$|S_l| \equiv 1$$

и рассеяние происходит упругим образом.

Однако, если в процессе столкновения образуются частицы, отличные от исходных, то говорят, что открываются неупругие каналы рассеяния: пространство асимптотических состояний двух частиц становится неполным, часть падающего потока инициирует неупругие процессы, и

$$|S_l| < 1$$

Тогда сечение упругих (elastic) столкновений с $f_l = (2l+1)(S_l - 1)/(2\mathrm{i}k)$

$$\sigma_{\mathrm{el}} = \frac{\pi}{k^2}\sum_l (2l+1)\,|S_l - 1|^2$$

а недостающий поток вероятности в рассеянной волне, пропорциональный $1 - |S_l|^2$, естественно отнести к сечению неупругих (inelastic) столкновений, так что его полное сечение

$$\sigma_{\mathrm{inel.}} = \frac{\pi}{k^2}\sum_l (2l+1)\left(1 - |S_l|^2\right)$$

Полное (total) сечение

$$\sigma_{\mathrm{tot.}} = \sigma_{\mathrm{el.}} + \sigma_{\mathrm{inel.}} = \frac{\pi}{k^2}\sum_l (2l+1)\left\{|S_l - 1|^2 + 1 - |S_l|^2\right\}$$

Преобразуем

$$|S_l - 1|^2 + 1 - |S_l|^2 = (S_l - 1)(S_l^* - 1) + 1 - |S_l|^2 = 2 - (S_l + S_l^*) = 2\,(1 - \mathrm{Re}_\ell S_l)$$

В итоге

$$\sigma_{\mathrm{tot.}} = \frac{2\pi}{k^2}\sum_l (2l+1)\,(1 - \mathrm{Re}eS_l)$$

Заметим, что

$$\mathrm{Im}\mathfrak{m} f_l = \frac{2l+1}{2k}\mathrm{Im}\mathfrak{m}\frac{1}{i}\left(\mathrm{Re}_{\mathfrak{e}} S_l - 1 + \mathrm{i}\mathrm{Im}\mathfrak{m} S_l\right) = \frac{2l+1}{2k}\left(1 - \mathrm{Re}_e S_l\right)$$

тогда по прежнему справедлива оптическая теорема

$$\sigma_{\mathrm{tot.}} = \frac{4\pi}{k}\sum_l \mathrm{Im}m f_l$$

Что отражает факт сохранения вероятности с учетом вклада неупругих столкновений.

8.5.4 Second order Born approximation (??)

(see articles for now!)

Formalism of second order Born approximation

Examples of second order Born approximation

Details of second order Born approximation

8.5.5 Reconstruction of the potential from scattering

(??? currently have no idea how to do it)

8.5.6 Time Delay in Scattering

(тоже инетерсно, как ее посчитать?)

8.5.7 Quantum mechanics of the $1/x^2$ potential by Essin, Griffiths (2005) 1

Abstract

In quantum mechanics a localized attractive potential typically supports a (possibly infinite) set of bound states, characterized by a discrete spectrum of allowed energies, together with a continuum of scattering states, characterized (in one dimension) by an energy-dependent phase shift. The $1/x^2$ potential on $0 < x < \infty$ confounds all of our intuitions and expectations. Resolving its paradoxes requires sophisticated theoretical machinery: regularization, renormalization, anomalous symmetry-breaking, and self-adjoint extensions. Our goal is to introduce the essential ideas at a level accessible to advanced undergraduates. © 2006 American Association of Physics Teachers.

I. INTRODUCTION

Ordinarily, an attractive potential admits discrete bound states, together (perhaps) with a continuum of scattering states. In a first course on quantum mechanics, students encounter the infinite square well, the harmonic oscillator, the Dirac delta function, the finite square well, and (in three dimensions) the spherical well and the Coulomb potential, all of which fit this paradigm (though the first two lack scattering states). We do not study the $1/x^2$ potential, and for good reason: It violates every rule in the book, and discredits all the intuition we are trying to instill in our students. In spite of this (or rather, precisely because of it) the $1/x^2$ potential is a fascinating system, and analyzing its paradoxes provides an illuminating introduction to some of the more subtle techniques in contemporary theoretical physics: regularization and renormalization, anomalous symmetry-breaking, and self-adjoint extensions. In this paper we tell the story from a pedagogical perspective, starting out innocent and naive, and letting the unfolding saga force us to become wiser and more sophisticated.

In Sec. II we introduce the problem in its simplest (onedimensional) form, and approach it as we would any other quantum system. We quickly encounter a series of puzzles and surprises. In Sec. III we identify the source of the difficulties and modify the potential so as to avoid the trouble. This leads naturally to renormalization and anomalies. In Sec. IV we notice that the Hamiltonian is not Hermitian, and modify the space of permissible functions to make it so; this introduces the method of self-adjoint extensions. In Sec. V we draw lessons from our experience and point to some realworld applications.

II. PECULIARITIES OF THE $1/x^2$ POTENTIAL

Consider a particle of mass m in the one-dimensional potential [1]

$$V(x) = \begin{cases} \infty & (x \leqslant 0) \\ -a/x^2 & (x > 0) \end{cases} \tag{1}$$

shown in Fig. 1. Here a is a constant with the (MKS) units Jm^2. In truth, the alarm should already be sounding, for there is no way to construct a quantity with the dimensions of energy from the parameters at hand ($\hbar, m$, and a), and hence no possible formula for the eigenvalues of the

Hamiltonian. [2] But let's pretend for a moment that we did not notice this problem. We look for bound states-normalizable negative-energy solutions of the Schrödinger equation:

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2} - \frac{a}{x^2}\psi = E\psi \quad (x > 0) \tag{2}$$

or, multiplying through by $-2m/\hbar^2$,

$$\frac{d^2\psi}{dx^2} + \frac{\alpha}{x^2}\psi = \kappa^2\psi, \tag{3}$$

where $\alpha \equiv 2ma/\hbar^2$ and $\kappa \equiv \sqrt{-2mE}/\hbar$, subject to the boundary conditions

$$\psi \to 0 \text{ as } x \to 0 \text{ and } x \to \infty. \tag{4}$$

The first boundary condition is necessary to make ψ continuous at the origin ($\psi = 0$, of course, for $x < 0$); the second is required for normalization:

$$\int_0^\infty |\psi(x)|^2 dx = 1 \tag{5}$$

Suppose we could find just one bound state $\psi(x)$, with energy E. Scaling x by a factor β, we can immediately construct a new solution, $\psi_\beta(x) \equiv \psi(\beta x)$, with energy $\beta^2 E$:

$$\begin{aligned}\frac{d^2\psi_\beta}{dx^2} + \frac{\alpha}{x^2}\psi_\beta =& \frac{d^2}{dx^2}\psi(\beta x) + \frac{\alpha}{x^2}\psi(\beta x) = \beta^2\frac{d^2}{du^2}\psi(u) \\ &+ \beta^2\frac{\alpha}{u^2}\psi(u) = \beta^2\kappa^2\psi(u) = (\beta\kappa)^2\psi_\beta(x)\end{aligned} \tag{6}$$

where $u \equiv \beta x$. But β can be any real number. [3] So if there exist any bound states, then there is a bound state for every negative energy! In particular, the $1/x^2$ potential has no ground state. This is disturbing, for a system without a lower limit on its allowed energies would be wildly unstable, cascading down with the release of an unlimited amount of energy. A reasonable inference would be that there are no negative energy states, which is indeed the case for $\alpha < 1/4$ (trivially so, for $\alpha < 0$, because the potential is then repulsive).

Fig. 1. The $1/x^2$ potential.

One particularly nice way to show that there are no bound states for $0 < \alpha < 1/4$ is to factor the Hamiltonian. [4] Let $\alpha = \nu(1-\nu)$ define the new constant ν,

$$H = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} - \frac{a}{x^2} = -\frac{\hbar^2}{2m}\left(\frac{d}{dx} + \frac{\nu}{x}\right)\left(\frac{d}{dx} - \frac{\nu}{x}\right). \tag{7}$$

For an arbitrary test function $f(x)$ we have

$$\left(\frac{d}{dx} + \frac{\nu}{x}\right)\left(\frac{d}{dx} - \frac{\nu}{x}\right)f(x) = \left(\frac{d}{dx} + \frac{\nu}{x}\right)\left(\frac{df}{dx} - \frac{\nu}{x}f\right) \tag{8a}$$

$$= \frac{d^2f}{dx^2} + \frac{\nu}{x^2}f - \frac{\nu}{x}\frac{df}{dx} + \frac{\nu}{x}\frac{df}{dx} - \frac{\nu^2}{x^2}f \tag{8b}$$

$$= \frac{d^2f}{dx^2} + \frac{\nu(1-\nu)}{x^2}f = \left(\frac{d^2}{dx^2} + \frac{\alpha}{x^2}\right)f \tag{8c}$$

Now, the Hermitian conjugate of $(d/dx + \nu/x)$ is $(-d/dx\ + \nu^*/x)$:

$$\left\langle f \left| \left(\frac{d}{dx} + \frac{\nu}{x}\right) g \right\rangle = \int_0^\infty f^* \left(\frac{dg}{dx} + \frac{\nu}{x} g\right) dx \tag{9a}$$

$$= f^* g|_0^\infty - \int_0^\infty \left(\frac{df}{dx}\right)^* g dx + \int_0^\infty \left(\frac{\nu^*}{x} f\right)^* g dx \tag{9b}$$

$$= \left\langle \left(-\frac{d}{dx} + \frac{\nu^*}{x}\right) f \right| g \right\rangle, \tag{9c}$$

provided that $f(x)$ and $g(x)$ go to zero at 0 and ∞. Thus

$$E = \langle H \rangle = \langle \psi | H | \psi \rangle = -\frac{\hbar^2}{2m} \left\langle \psi \left| \left(\frac{d}{dx} + \frac{\nu}{x}\right) \left(\frac{d}{dx} - \frac{\nu}{x}\right) \psi \right\rangle \right. \tag{10a}$$

$$= \frac{\hbar^2}{2m} \left\langle \left(\frac{d}{dx} - \frac{\nu^*}{x}\right) \psi \right| \left(\frac{d}{dx} - \frac{\nu}{x}\right) \psi \right\rangle. \tag{10b}$$

If ν is real, then,

$$E = \frac{\hbar^2}{2m} \int_0^\infty \left| \left(\frac{d\psi}{dx} - \frac{\nu}{x}\psi\right) \right|^2 dx > 0 \tag{11}$$

so negative energy states cannot occur if ν is real. But $\nu(1 - \nu) = \alpha$, so

$$\nu = \frac{1}{2} \pm \sqrt{\frac{1}{4} - \alpha}, \tag{12}$$

and hence if $\alpha < 1/4$, then ν is real, and there can be no bound states.

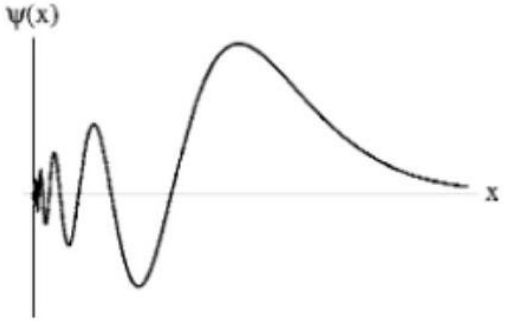


Fig. 2. The bound state wave function, $\psi_\kappa(x)$.

But when $\alpha > 1/4$ there certainly do exist negative energy solutions. The Schrödinger equation can be solved by the method of Frobenius: We write $\psi(x)$ as a power series,

$$\psi(x) = x^s \sum_{j=0}^\infty a_j x^j \quad (a_0 \neq 0) \tag{13}$$

and substitute this into Eq. (3):

$$\sum_{j=0}^\infty a_j [(j+s)(j+s-1) + \alpha] x^{j-2} = \kappa^2 \sum_{j=0}^\infty a_j x^j \tag{14}$$

We equate like powers and find that the x^{-2} term yields $s(s\ -1) + \alpha = 0$, so

$$s = \nu = (1/2) \pm \sqrt{(1/4) - \alpha} \tag{15}$$

the x^{-1} term forces $a_1 = 0$, and the remaining coefficients are determined by the recursion relation

$$a_j = \frac{\kappa^2}{j(j+2s-1)} a_{j-2} \quad (j = 2, 3, 4, ...) \tag{16}$$

There are two solutions-one for each sign in Eq. (15). Near the origin they go like $a_0 x^s$; for $\alpha > 1/4$ this means

$$\sqrt{x} e^{\pm ig \ln x} \tag{17}$$

where $g \equiv \sqrt{\alpha - 1/4}$.
The general solution is a linear combination, but it turns out that only one combination is normalizable:

$$\psi_\kappa(x) = A\sqrt{x} K_{ig}(\kappa x) \tag{18}$$

where K_{ig} is the modified Bessel function of order ig;[5] ψ_κ is real, as long as g is real (which is to say, for $\alpha > 1/4$), and finite at the origin (so $\psi_\kappa \to 0$ as $x \to 0$); ψ_κ itself is square-integrable: [(1)]

$$\int_0^\infty \left|\sqrt{x} K_{ig}(\kappa x)\right|^2 dx = \frac{\pi g}{2\kappa^2 \sinh(\pi g)} \tag{19}$$

so the normalization constant is

$$A = \kappa \sqrt{\frac{2\sinh(\pi g)}{\pi g}} \tag{20}$$

A plot of the wave function is shown in Fig. 2. Notice the oscillations as $x \to 0$, which result from the sinusoidal dependence on $g \ln x$ in Eq. (17). We are accustomed to the idea that the ground state has no zero crossings, the first excited state has one, the second two, and so on. But the $1/x^2$ potential has no ground state, and every (negative energy) solution has an infinite number of zero crossings. If the number of nodes counts the number of lower energy states, then no matter what the energy, there are always infinitely many states even lower.

What about positive energy (scattering) states? For $E > 0$ the general solution to Schrödinger's equation [Eq. (2)] is

$$\psi_k(x) = \sqrt{x}\left[A H_{ig}^{(2)}(kx) + B H_{ig}^{(1)}(kx)\right], \tag{21}$$

where $k \equiv \sqrt{2mE}/\hbar$, and $H^{(1)}$ and $H^{(2)}$ are Hankel functions. For large x, [8]

$$H_{ig}^{(1)}(kx) \sim \sqrt{\frac{2}{\pi kx}} e^{i(kx - \pi/4)} e^{\pi g/2} \tag{22a}$$

$$H_{ig}^{(2)}(kx) \sim \sqrt{\frac{2}{\pi kx}} e^{-i(kx - \pi/4)} e^{-\pi g/2} \tag{22b}$$

so

$$\psi_k(x) \sim A\sqrt{\frac{2}{\pi k}} e^{-\pi g/2} e^{i\pi/4}\left[e^{-ikx} - i\frac{B}{A} e^{\pi g} e^{ikx}\right] \tag{23}$$

The first term (e^{-ikx}) represents a wave incident from the right; the second $\left(e^{ikx}\right)$ is the reflected wave. Ordinarily, setting $\psi_k(0) = 0$ in Eq. (21) would determine B/A, and the asymptotic expression Eq. (23) would reduce to [9]

$$\psi_k(x) \sim \left[e^{-ikx} - e^{i(2\delta+kx)}\right] \tag{24}$$

indicating that the reflected wave is equal in amplitude to the incident wave (as required by conservation of probability) and shifted in phase by an amount $\delta(k)$. But in this case $\psi_k(0)$ is automatically zero (according to Eq. (17), $|\psi| \sim \sqrt{x}$). There is no constraint on B, no formula for $\delta(k)$, and (most alarming) no enforcement of conservation of probability; the outgoing wave can have any amplitude!

Conclusion: The $1/x^2$ potential has no ground state, and the allowed energies are not quantized. As long as $\alpha > 1/4$, the Schrödinger equation can be solved (and the boundary conditions satisfied) for every negative energy; the solutions are real and normalizable, and each of them has an infinite number of zero crossings. Scattering states occur for every positive energy, but the boundary condition at $x = 0$ imposes no constraint on the reflection coefficient, and does not determine the phase shift. It would be difficult to imagine a situation more at odds with our expectations.

III. REGULARIZATION, RENORMALIZATION, AND ANOMALIES

Physically, the $1/x^2$ potential is just too strong at the origin- $1/x$ is acceptable, [10] but $1/x^2$ is not. One way to avoid the problem is to move the "wall" over to the right a distance ϵ:

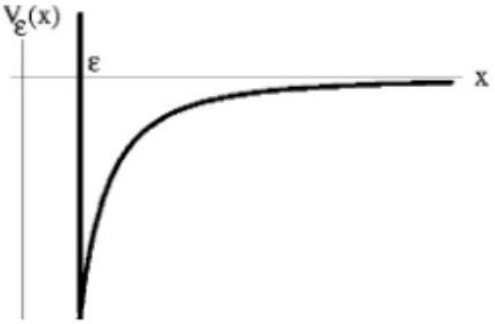

Fig. 3. The regularized potential.

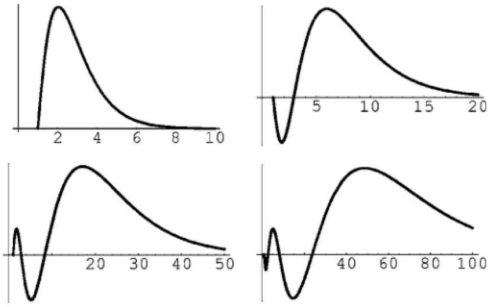

Fig. 4. Ground state and first three excited states, as functions of κx, for V_ϵ, with $\epsilon = 1$ and $g = 3$ (not normalized).

$$V_\epsilon(x) = \begin{cases} \infty & (x \leqslant \epsilon) \\ -a/x^2 & (x > \epsilon), \end{cases} \tag{25}$$

as shown in Fig. 3. This "regularized" potential suffers none of the ills that afflict $V(x)$; we propose to work with $V_\epsilon(x)$, and take the limit $\epsilon \to 0$ only at the very end. Of course, the pathologies can be expected to reappear in this limit, but as we shall see, some predictions survive, and these we take to be the "true" physical content of the $1/x^2$ system. This is the strategy of "renormalization."

Having introduced a parameter (ϵ) with the units of length, we are now able to construct an expression with the dimensions of energy:

$$\frac{a}{\epsilon^2} f(\alpha) \tag{26}$$

where f is a function of the dimensionless quantity $\alpha = 2ma/\hbar^2$. The system is no longer scale invariant; it possesses both a ground state [11] and a discrete spectrum of bound states. These have the same functional form as in Eq. (18), but the boundary condition is now $\psi_\kappa(\epsilon) = 0$, which implies that

$$K_{ig}(\kappa\epsilon) = 0 \tag{27}$$

which is not automatically satisfied, and serves to quantize the energy. Figure 4 shows the ground state and the first three excited states for the case $\alpha = 9.25 (g = 3)$.[12] Figure 5 shows the ground state energy (or rather, $\kappa_1\epsilon$) for g ranging up to 7 .

If $\kappa\epsilon \ll 1$, [13] we can provide a relatively simple formula for the allowed energies: [14]

$$K_{ig}(z) \approx -\sqrt{\frac{\pi}{g\sinh(\pi g)}} \times \sin\left[g\ln\left(\frac{z}{2}\right) - \arg\Gamma(1+ig)\right] \quad (z \ll 1) \tag{28}$$

so $K_{ig}(\kappa\epsilon) = 0$ implies

$$g\ln\left(\frac{\kappa\epsilon}{2}\right) - \arg\Gamma(1+ig) + n\pi = 0 \tag{29}$$

where n is an integer. The ground state is $n = 1$, [15] and the excited states are $n = 2, 3, ...$, with

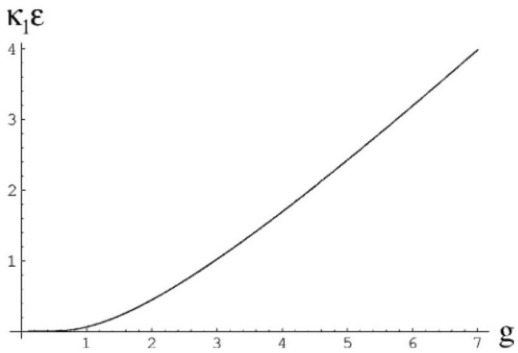

Fig. 5. The ground state $\kappa_1\epsilon$ as a function of g.

$$\kappa_n = \frac{2}{\epsilon} e^{[\arg\Gamma(1+ig) - n\pi]/g}, \tag{30}$$

or

$$E_n = -\frac{2\hbar^2}{m\epsilon^2} e^{2[\arg\Gamma(1+ig) - n\pi]/g} \tag{31}$$

There are infinitely many discrete bound states, as one might expect. [16]

For positive energies (scattering) the wave function is still given by Eq. (21), but now

$$\psi_k(\epsilon) = 0, \tag{32}$$

and hence $AH_{ig}^{(2)}(k\epsilon) + BH_{ig}^{(1)}(k\epsilon) = 0$, so

$$\frac{B}{A} = -\frac{H_{ig}^{(2)}(k\epsilon)}{H_{ig}^{(1)}(k\epsilon)}. \tag{33}$$

Referring to Eqs. (23) and (24), we find that the phase shift satisfies [P]

$$e^{2i\delta} = i\frac{B}{A}e^{\pi g} = -i\frac{H_{ig}^{(2)}(k\epsilon)}{H_{ig}^{(1)}(k\epsilon)}e^{\pi g} = -i\frac{\left[H_{ig}^{(1)}(k\epsilon)\right]^*}{H_{ig}^{(1)}(k\epsilon)}. \tag{34}$$

Notice that conservation of probability has been enforced by Eq. (32). Thus

$$\delta = -\arg\left[H_{ig}^{(1)}(k\epsilon)\right] - \frac{\pi}{4}. \tag{35}$$

This function is plotted in Fig. 6.
As the graphs suggest, $\arg\left[H_{ig}^{(1)}(x)\right]$ is extremely steep near the origin. Indeed, for $|z| \ll 1$, [18]

$$H_{ig}^{(1)}(z) \approx e^{ig\ln(z/2)}\frac{1+\coth\pi g}{\Gamma(1+ig)} - e^{-ig\ln(z/2)}\frac{\Gamma(1+ig)}{\pi g}, \tag{36}$$

so [19]

$$\tan\left[\arg H_{ig}^{(1)}(z)\right] \approx \coth\left(\frac{\pi g}{2}\right) \times \tan[g\ln(z/2) - \arg\Gamma(1+ig)] \tag{37}$$

and hence

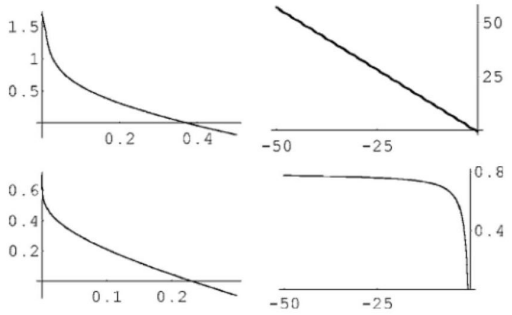

Fig. 6. Graphs of δ as a function of $k\epsilon$, for $g = 0.5$ (top) and $g = 0$ (bottom). The graphs on the right show the behavior near the origin (the horizontal scale is in powers of 10); they suggest that there is no limit when $g = 0.5$, whereas $\delta \to \pi/4$ when $g = 0$ (though that limit is only approached when $k \in \ll 10^{-10}$).

$$\tan\delta \approx \frac{\tan\xi + \tanh(\pi g/2)}{\tan\xi - \tanh(\pi g/2)}, \tag{38}$$

where

$$\xi \equiv g\ln(k\epsilon/2) - \arg\Gamma(1+ig). \tag{39}$$

As $k\epsilon \to 0, \xi \to -\infty$, and $\tan\xi$ fluctuates wildly: Whenever ξ hits an integer multiple of π, $\tan\xi = 0$, so (unless $g = 0$) $\tan\delta = -1$; whenever ξ is a half-integer multiple of $\pi, \tan\xi \to \pm\infty$, so $\tan\delta = 1$. Clearly, δ does not approach a limit. The case $g = 0$ is special, and it is best to treat it separately: For $|z| \ll 1$,

$$H_0^{(1)}(z) \approx 1 + \frac{2i}{\pi}[\ln(z/2) + C] = 1 + \frac{2i}{\pi}\ln(\gamma z/2), \tag{40}$$

where $C = 0.577215$ is Euler's constant and $\gamma \equiv e^C = 1.781072$.[20] Thus $\tan\left[\arg H_0^{(1)}(z)\right] \approx 2\ln(\gamma z/2)/\pi$, and hence

$$\tan\delta \approx \frac{\ln(\gamma k\epsilon/2)+\pi/2}{\ln(\gamma k\epsilon/2)-\pi/2} \tag{41}$$

At this point we would like to send $\epsilon \to 0$, to recover the pure $1/x^2$ potential. Naively, Eq. (31) suggests that E_1 will go to $-\infty$-precisely the trap we were hoping to avoid. But closer inspection reveals that the boundary condition, Eq. (27), only determines the product $\kappa_1\epsilon$. Suppose we stipulate that E_1 (and hence κ_1) remain constant as $\epsilon \to 0$. From Fig. 5 we see that this assumption forces $g \to 0$, leaving [16]

$$\kappa_1 = \frac{2}{\gamma\epsilon}e^{-\pi/g} \quad (\epsilon \to 0, g \to 0). \tag{42}$$

The excited states, Eq. (30), are squeezed out

$$\kappa_n = \frac{2}{\gamma\epsilon}e^{-n\pi/g} = \kappa_1 e^{-(n-1)\pi/g} \to 0 \quad (n = 2, 3, 4, ...), \tag{43}$$

but there remains a single bound state at finite (though indeterminate) energy.

We can use Eq. (42) to eliminate the cutoff ϵ in favor of κ_1, in the scattering problem:

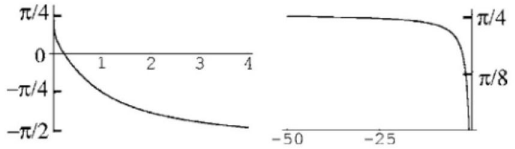

Fig. 7. The scattering phase shift $\delta(k/\kappa_1)$, Eq. (47), for $g \ll 1$. The graph on the right shows the behavior near the origin (the horizontal scale is in powers of 10).

$$k\epsilon = \frac{k}{\kappa_1}\frac{2}{\gamma}e^{-\pi/g}. \tag{44}$$

So for low energy scattering, Eq. (39) becomes

$$\xi \approx g\ln(k/\kappa_1) - \pi \tag{45}$$

$$\tan\xi \approx \tan[g\ln(k/\kappa_1)] \approx g\ln(k/\kappa_1) \tag{46}$$

and Eq. (38) reads

$$\tan\delta \approx \frac{\ln(k/\kappa_1)+\pi/2}{\ln(k/\kappa_1)-\pi/2} \tag{47}$$

Curiously, the phase shift is independent of g (although we have stipulated that $g \ll 1$). [21] For extremely low-energy scattering, $k \ll \kappa_1$, the phase shift is evidently $\pi/4$ (see Fig. 7).

Conclusion: The regularized potential, Eq. (25), has a nonproblematic spectrum of discrete bound states, and a continuum of scattering states with well-defined phase shifts. Naively, the limit $\epsilon \to 0$ (which restores the pure $1/x^2$ potential) reintroduces all of the pathological features of the original. But closer examination reveals a loophole: If as we send $\epsilon \to 0$ we simultaneously let $g \to 0$, in such a way as to hold κ_1 constant (Fig. 8), then a single bound state with energy

$$E_1 = -\frac{\hbar^2\kappa_1^2}{2m} \tag{48}$$

survives, and the scattering phase shift is given by

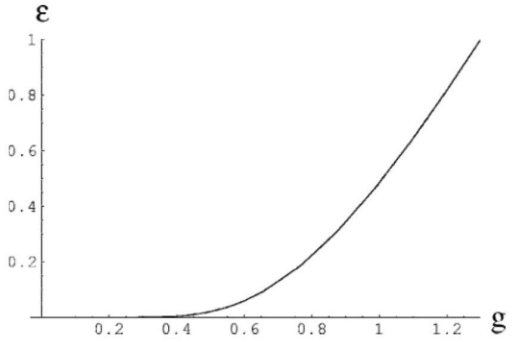

Fig. 8. Graph of ϵ as a function of g, Eq. (42), with $\kappa_1 = 0.1$.

$$\delta(k) = \tan^{-1}\left[\frac{\ln(k/\kappa_1) + \pi/2}{\ln(k/\kappa_1) - \pi/2}\right] \tag{49}$$

This scheme does not determine κ_1, and it forces $\alpha \to 1/4$, but the physical implications of the theory are perfectly sensible.

The renormalization procedure we have just described may sound artificial, but it is not altogether unreasonable. [22] After all, in practice we would have no way of knowing whether the potential is really $1/x^2$ all the way down to $x = 0$; what we actually measure is the ground state energy and the scattering phase shift. The former provides us with a relation between ϵ and g, Eq. (42), but it does not determine either one separately, and the latter, Eq. (49), stands as a testable prediction irrespective of the actual (but unmeasurable) value of the cutoff. [23]

What about the symmetry argument based on scale invariance (or, if you prefer, dimensional analysis) that seemed to prove conclusively that the $1/x^2$ potential can have no ground state (if it has one negative allowed energy, then every negative energy is an eigenvalue)? Well, we broke that symmetry when we introduced the cutoff, and the break persists even as we eliminate ϵ from the theory in favor of κ_1, and (implicitly) send $\epsilon \to 0$. This is an example of "anomalous" symmetry breaking. There are three standard mechanisms for breaking a symmetry in physics:

1. External (or dynamical): An imposed force spoils the symmetry (for example, at the surface of the earth gravity breaks the three-dimensional isotropy of space).

2. Spontaneous: The ground state of a system is degenerate, and historical accident selects a particular one (for example, the magnetization of a small piece of iron, which could have pointed in any direction, but in fact has to point in some specific direction).

3. Anomalies: The process of renormalization breaks the symmetry. [24]

8.5.8 Quantum mechanics of the $1/x^2$ potential by Essin, Griffiths (2005) 2

IV. SELF-ADJOINT EXTENSIONS

In Sec. II we examined the patient and diagnosed the illness. In Sec. III we provided a partial cure. Now it is time to identify the root cause of the disease and propose a more comprehensive treatment. The fundamental problem with the $1/x^2$ potential is that the Hamiltonian

$$H = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} - \frac{a}{x^2} = -\frac{\hbar^2}{2m}\left(\frac{d^2}{dx^2} + \frac{\alpha}{x^2}\right) \tag{50}$$

is not Hermitian (more precisely, it is not self-adjoint). In quantum mechanics self-adjoint operators occupy a privileged position, because they alone represent observable quantities.

Most of our experience and intuition is predicated on the self-adjointness of the Hamiltonian, and when this fails, the intelligibility of the theory goes with it.

An operator is defined not only by its action, A, but also by its domain, $\mathcal{D}_A$, the space of functions $\{\psi\}$ on which it acts. Physicists tend to forget the second part, because in most cases the domain is not problematic. Of course, ψ and $A\psi$ must lie in the Hilbert space of square-integrable functions, L_2 (in our case, on the interval $0 < x < \infty$), to ensure that inner products are well-defined. In fact, to guarantee the existence of the Hermitian conjugate (or "adjoint") $A^\dagger$,

$$\langle \phi | A\psi \rangle = \left\langle A^\dagger \phi | \psi \right\rangle, \tag{51}$$

the allowed functions must be dense in L_2.[25] Typically there will be other conditions on $\mathcal{D}_A$ as well.

If there exists a domain such that for all ψ and ϕ in $\mathcal{D}_A$

$$\langle \phi | A\psi \rangle = \langle A\phi | \psi \rangle \tag{52}$$

(that is, the actions of A and $A^\dagger$ are identical), then the operator is Hermitian (mathematicians would say "symmetric") over that domain. However, it may happen that as long as ψ is in $\mathcal{D}_A$ (the domain of the operator), ϕ can be in a larger domain, $\mathcal{D}_{A^\dagger}$ (the domain of the adjoint), [26] and yet Eq. (52) still holds. In that case ($\mathcal{D}_{A^*} \supset \mathcal{D}_A$) we may be able to extend the domain of the operator (which will automatically restrict the domain of the adjoint) until the two domains coincide. In this circumstance, with $A = A^\dagger$ and $\mathcal{D}_{A^\dagger} = \mathcal{D}_A$, the operator is said to be self-adjoint. For self-adjoint operators, in other words, both the action and the domain of the adjoint are the same as for the operator itself.

The process we have sketched is called "self-adjoint extension." You start with a Hermitian operator on a specified domain, and extend $\mathcal{D}_A$ (thereby contracting $\mathcal{D}_{A^\dagger}$) until the domains are identical. This process raises several questions, which were first addressed by Weyl and later generalized by von Neumann and Stone: [27] How can you tell whether a given operator admits a self-adjoint extension? Is the extension (if it exists) unique? How do you construct the self-adjoint domain? The answers are buried in abstruse mathematical literature that is largely inaccessible to physicists, [28] but two recent articles provide a relatively straightforward guide for the uninitiated. [29,30]

We begin by asking whether H in Eq. (50) is Hermitian. Suppose $\phi(x)$ and $\psi(x)$ are two functions in $L_2(0,\infty)$ such that $H\phi$ and $H\psi$ are also in $L_2(0,\infty)$. Using integration by parts (twice), we have

$$\langle \phi | H\psi \rangle = \frac{-\hbar^2}{2m} \int_0^\infty \phi^* \left(\frac{d^2\psi}{dx^2} + \frac{\alpha}{x^2}\psi \right) dx \tag{53a}$$

$$= -\frac{\hbar^2}{2m} \left[\phi^* \frac{d\psi}{dx}\bigg|_0^\infty - \psi \frac{d\phi^*}{dx}\bigg|_0^\infty + \int_0^\infty \left(\frac{d^2\phi^*}{dx^2} + \frac{\alpha}{x^2}\phi^* \right) \psi dx \right] \tag{53b}$$

$$= \langle H\phi | \psi \rangle - \frac{\hbar^2}{2m} \left(\phi^* \frac{d\psi}{dx} - \psi \frac{d\phi^*}{dx} \right) \bigg|_0^\infty \tag{53c}$$

Evidently H is Hermitian,

$$\langle \phi | H\psi \rangle = \langle H\phi | \psi \rangle, \tag{54}$$

if the boundary term in Eq. (53c) is zero (for all ψ and ϕ). There is no problem at infinity, where the functions and their derivatives can safely be taken to vanish; [31] the trouble arises at the lower limit. If we want H to be Hermitian, we shall have to restrict its domain. Earlier, we

stipulated (for reasons of continuity) that wave functions go to zero at the origin, but in spite of appearances this condition does not suffice to kill the boundary term, because the derivatives can (and in the critical cases do) diverge. For example, we found in Eq. (15) that solutions to the Schrödinger equation behave near the origin like

$$u_\pm(x) = x^{S_\pm} \tag{55a}$$

with

$$s_\pm = \frac{1}{2} \pm \sqrt{\frac{1}{4} - \alpha} \tag{55b}$$

So, using $\psi = u_+$and $\phi = u_-$, we have [32]

$$\begin{aligned}\left(u_-^* \frac{du_+}{dx} - u_+ \frac{du_-^*}{dx}\right)\Big|_0 &= x^{(s_-)^*} s_+ x^{(s_+-1)} - x^{s_+} s_-^* x^{\left(s_-^*-1\right)} \\ &= \left(s_+ - s_-^*\right) x^{\left(s_++s_-^*-1\right)} = \sqrt{1-4\alpha}\end{aligned} \tag{56}$$

Unless $\alpha = 1/4$ (a special case that keeps recurring and to which we shall return) some other condition must be imposed.

What if we insist that allowed functions vanish in a finite (but arbitrarily small) neighborhood [33] of the origin? Then the boundary term vanishes trivially, and H is Hermitian (on this domain). But if ψ is in this very restricted domain, ϕ could be any square-integrable function, and the boundary term will still vanish. So the domain of the adjoint is very much larger than the domain of the operator, and hence H is not self-adjoint. Question: Does H admit a self-adjoint extension, and if so, what is the self-adjoint domain? [34] In von Neumann's procedure the first step is to look for eigenfunctions of H with imaginary eigenvalues: [35]

$$H\phi_\pm = \pm i\eta\phi_\pm, \tag{57}$$

where η is real and positive. [36] Thus

$$\left(\frac{d^2}{dx^2} + \frac{\alpha}{x^2}\right)\phi_\pm = \kappa_\pm^2 \phi_\pm \tag{58}$$

where

$$\kappa_\pm \equiv \frac{\sqrt{\mp i 2m\eta}}{\hbar} = e^{\mp i\pi/4}\beta \tag{59}$$

with $\beta \equiv \sqrt{2m\eta}/\hbar$. The general solution is

$$\phi_\pm(x) = \sqrt{x}\left[A_\pm H_{ig}^{(1)}\left(i\kappa_\pm x\right) + B_\pm H_{ig}^{(2)}\left(i\kappa_\pm x\right)\right] \tag{60}$$

where (as always) $g = \sqrt{\alpha - 1/4}$, and $A_\pm$and $B_\pm$are arbitrary constants. But $H_{ig}^{(2)}\left(i\kappa_\pm x\right)$ is not in L_2 (and hence not in $\mathcal{D}_{H^\dagger}$), because at large x [Eq. (22b)][37]

$$\begin{aligned}H_{ig}^{(2)}\left(i\kappa_\pm x\right) &\approx \sqrt{\frac{2}{\pi i\kappa_\pm x}} e^{-i(i\kappa_\pm x - \pi/4)} e^{-\pi g/2} \\ &= \sqrt{\frac{2}{\pi\kappa_\pm x}} e^{-\pi g/2} e^{\kappa_\pm x}\end{aligned} \tag{61}$$

and because $\kappa = \beta(1 \mp i)/\sqrt{2}, H_{ig}^{(2)}$ diverges exponentially. Thus

$$\phi_{\pm}(x) = A_{\pm}\sqrt{x}H_{ig}^{(1)}\left(i\kappa_{\pm}x\right) \tag{62}$$

Let n_+be the number of linearly independent solutions for ϕ_+, and $n_-$the corresponding number for ϕ_-; n_1 and n_2 are called "deficiency indices," and they play a major role in the theory. Weyl and von Neumann showed that if $n_+ = n_- = n$, there exists an n^2-parameter family of self-adjoint extensions. (If $n = 0$, the operator is already self-adjoint, and if $n_+ \neq n_-$, there is no self-adjoint extension.) In our case, n_+
$= n_- = 1$, and it remains only to characterize the oneparameter family of self-adjoint domains. The prescription is as follows: ψ is in the self-adjoint domain if

$$\langle\Phi|H\psi\rangle = \langle H\Phi|\psi\rangle, \tag{63}$$

where $\Phi \equiv \phi_+ + \lambda\phi_-$for some λ, which is to say [Eq. (53c)] if

$$\lim_{x\to 0}\left[\Phi^*\frac{d\psi}{dx} - \psi\frac{d\Phi^*}{dx}\right] = 0 \tag{64}$$

Evidently we need to know the behavior of $\phi_{\pm}$for small x. From Eq. (36),

$$\begin{aligned} H_{ig}^{(1)}\left(i\kappa_{\pm}x\right) \approx & e^{ig\ln(i\kappa_{\pm}x/2)}\frac{1+\coth\pi g}{\Gamma(1+ig)} \\ & - e^{-ig\ln(i\kappa_{\pm}x/2)}\frac{\Gamma(1+ig)}{\pi g} \end{aligned} \tag{65}$$

provided that $g \neq 0$. But $\kappa_{\pm} = \exp(\mp i\pi/4)\beta$, so

$$\ln\left(i\kappa_{\pm}x/2\right) = \ln(\beta x) - \ln 2 + i\ell_{\pm}\pi/4, \tag{66}$$

where $\ell_+ \equiv 1$ and $\ell_- \equiv 3$. Thus

$$e^{ig\ln(i\kappa_{\pm}x/2)} = e^{ig\ln\beta x}e^{-ig\ln 2}e^{-\ell_{\pm}g\pi/4} \tag{67}$$

and hence

$$\phi_+ \approx A_+\sqrt{x}\left[De^{ig\ln\beta x} - Fe^{-ig\ln\beta x}\right], \tag{68a}$$

$$\phi_- \approx A_-\sqrt{x}\left[De^{-\pi g/2}e^{ig\ln\beta x} - Fe^{\pi g/2}e^{-ig\ln\beta x}\right], \tag{68b}$$

where

$$D \equiv e^{-ig\ln 2}e^{-\pi g/4}\left[\frac{1+\coth\pi g}{\Gamma(1+ig)}\right], \tag{69a}$$

$$F \equiv e^{ig\ln 2}e^{\pi g/4}\left[\frac{\Gamma(1+ig)}{\pi g}\right]. \tag{69b}$$

It follows that

$$\Phi \approx \sqrt{x}\left[Ge^{ig\ln\beta x} - Je^{-ig\ln\beta x}\right] \quad (x \ll 1), \tag{70}$$

where

$$G \equiv D\left(A_+ + \lambda A_- e^{-\pi g/2}\right) \tag{71a}$$

$$J \equiv F\left(A_+ + \lambda A_- e^{\pi g/2}\right) \tag{71b}$$

Therefore

$$\frac{d\Phi}{dx} \approx \frac{1}{\sqrt{x}}\left[\left(\frac{1}{2}+ig\right)Ge^{ig\ln\beta x} - \left(\frac{1}{2}-ig\right)Je^{-ig\ln\beta x}\right]. \tag{72}$$

Using Eqs. (70) and (72), the boundary condition [Eq. (64), or more simply its complex conjugate] becomes

$$\sqrt{x}\left[e^{2ig\ln(x/x_0)}-1\right]\frac{d\psi^*}{dx} - \frac{1}{\sqrt{x}}\left[\left(\frac{1}{2}+ig\right)e^{2ig\ln(x/x_0)} - \left(\frac{1}{2}-ig\right)\right]\psi^* \to 0 \tag{73}$$

(as $x \to 0$), where

$$x_0 \equiv \frac{1}{\beta}\left(\frac{G}{J}\right)^{i/2g} \tag{74}$$

is a free constant [38]-the anticipated parameter that characterizes the particular self-adjoint extension. For example, if $\alpha = 0$ (so $g = i/2$), Eq. (73) reduces to

$$\frac{1}{\sqrt{x}}\left[x_0\frac{d\psi}{dx} + \psi\right] \to 0 \tag{75}$$

which is the self-adjoint extension for the free particle on $0 \leqslant x < \infty$. [39]
In the critical case $g = 0(\alpha = 1/4)$ Eq. (65) is replaced by

$$H_0^{(1)}(i\kappa_\pm x) \approx 1 - \frac{\ell_\pm}{2} + \frac{2i}{\pi}\ln(\gamma\beta x/2) \tag{76}$$

[see Eq. (40)], and

$$\phi_\pm \approx A_\pm\sqrt{x}\left[\pm\frac{1}{2} + \frac{2i}{\pi}\ln(\gamma\beta x/2)\right], \tag{77}$$

so

$$\Phi \approx \sqrt{x}[G + J\ln(\gamma\beta x/2)] \tag{78}$$

with

$$G \equiv \frac{1}{2}(A_+ - \lambda A_-) \tag{79a}$$

$$J \equiv \frac{2i}{\pi}(A_+ + \lambda A_-) \tag{79b}$$

and

$$\frac{d\Phi}{dx} \approx \frac{1}{2\sqrt{x}}[G + 2J + J\ln(\gamma\beta x/2)] \tag{80}$$

According to Eq. (64), then, a function ψ is in the selfadjoint domain if

$$\sqrt{x}\ln(x/x_0)\frac{d\psi}{dx} - \frac{1}{\sqrt{x}}\left[1+\frac{1}{2}\ln(x/x_0)\right]\psi \to 0 \tag{81}$$

where in this case $x_0 \equiv (2/\gamma\beta)e^{-G/J}$ is the free parameter characterizing the particular self-adjoint extension. [40]

Where does all this leave us? If we want the $1/x^2$ Hamiltonian, Eq. (50), to be self-adjoint, we must tighten up the naive boundary condition $\psi(0) = 0$, Eq. (4), in favor of a selfadjoint extension [Eq. (73) if $\alpha \neq 1/4$ and Eq. (81) for the critical case $\alpha = 1/4$]. [41] The choice of a particular extension (which is to say, a particular value of x_0) is arbitrary, and in this sense there exists an entire one-parameter family of distinct physical theories described by the $1/x^2$ potential. Question: Do they admit reasonable bound state spectra? We know that the normalized eigenstates of H are given by Eq. (18):

$$\psi_\kappa(x) = A\sqrt{x}K_{ig}(\kappa x) = \frac{i\pi}{2}A\sqrt{x}H_{ig}^{(1)}(i\kappa x) \tag{82}$$

where $\kappa \equiv \sqrt{-2mE}/\hbar$. Which (if any) of these reside in the self-adjoint domain of H?

In the critical case $g = 0$, Eq. (40) yields (for small x)

$$\psi_\kappa(x) \approx -A\sqrt{x}\ln(\gamma\kappa x/2) \tag{83}$$

and

$$\frac{d\psi_\kappa}{dx} \approx -A\frac{1}{\sqrt{x}}\left[1+\frac{1}{2}\ln(\gamma\kappa x/2)\right] \tag{84}$$

Inserting these expressions into Eq. (81) yields the condition $A\ln(\gamma\kappa x_0/2) \to 0$. This holds only if $\gamma\kappa x_0/2 = 1$, which is to say, if $\kappa = 2/\gamma x_0$. Evidently there is exactly one bound state for $\alpha = 1/4$, just as we found (by a completely different route) in Sec. III [Eq. (48)]. But we cannot calculate the allowed energy, because it depends on the arbitrary parameter x_0 (just as, in the renormalization method, it depended on the arbitrary cutoff ϵ).

The case $g \neq 0$ is a little more complicated. Equation (28) gives (for small x)

$$\psi_\kappa(x) \approx B\sqrt{x}\sin\theta \tag{85}$$

where $B \equiv -A\sqrt{\pi/g\sinh(\pi g)}$ and

$$\theta(x) \equiv g\ln(\kappa x/2) - \arg\Gamma(1+ig) \tag{86}$$

It follows that

$$\frac{d\psi_\kappa}{dx} \approx B\frac{1}{\sqrt{x}}\left[\frac{1}{2}\sin\theta + g\cos\theta\right] \tag{87}$$

According to Eq. (73), then, ψ_κ is in the self-adjoint domain if

$$g\ln\left(\frac{2}{\kappa x_0}\right) + \arg\Gamma(1+ig) = n\pi \quad (n = 0, \pm1, \pm2, ...) \tag{88}$$

for g real ($\alpha > 1/4$), or $2/\kappa x_0 = 1$ for g imaginary ($\alpha < 1/4$). In the former case we obtain an infinite set of eigenvalues; in the latter case just one.

Conclusion: To make the $1/x^2$ Hamiltonian self-adjoint we are obliged to impose more stringent boundary conditions [Eq. (73) or (81)] than we naively supposed. This imposition necessarily introduces a free parameter x_0 with the dimensions of length, thereby breaking the

scale invariance of the theory. The result is a reasonable spectrum of allowed states, whose energies, however, we are unable to predict, because they depend on the value of the arbitrary parameter. [42]

V. CONCLUSION

The $1/x^2$ potential is clearly problematic. We can fix it (sort of) by renormalization or by self-adjoint extension, but a reasonable person would likely conclude that the problem itself is artificial and unphysical-maybe there is no such thing as a $1/x^2$ potential in nature. Perhaps some potentials are just plain illegal in quantum mechanics. It seems odd, though, that we never encounter such difficulties in classical mechanics.

Well, in the first place there are classical precursors. [43] Moreover, there do exist systems represented (at least, to good approximation) by a $1/x^2$ potential (at any rate by its three-dimensional analog). The best example is the motion of a charged particle in the field of a stationary electric dipole, for instance, an electron in the vicinity of a polar molecule. Here the potential is $-ep\cos\theta/r^2$, and (surprisingly) the radial Schrödinger equation is mathematically identical to Eq. (2). [44] The critical parameter $\alpha = 1/4$ was noted in early studies of this system, [45] which has attracted renewed attention recently. [46] Like it or not, we have to take this problem seriously.

Comments

[1] Of course, $V(x)$ is unbounded as $x \to 0$, but this by itself is not problematic-the same is true of the Coulomb potential and the delta function well. Our study of the $1/x^2$ potential was inspired by (and in the early parts modeled on) S. A. Coon and B. R. Holstein, "Anomalies in quantum mechanics: The $1/r^2$ potential" Am. J. Phys. 70, 513-519 (2002).
[2] Is there any other potential with this defect? In other words, is there another function of position that contains no dimensional constants and has the same units as $1/x^2$? There is-the two-dimensional delta function, $\delta^2(\mathbf{r}) = \delta(x)\delta(y)$. Our story can be told using the two-dimensional delta function, but because the extra dimension makes the details a little more cumbersome and because the $1/x^2$ potential is arguably more realistic, we prefer to consider it as the model. In fact, for states with circular symmetry the two-dimensional delta function is mathematically equivalent to the $1/x^2$ potential with $\alpha = 1/4$ [Eq. (3)]-see Exercise 1 in Ref. 30. For discussion of the two-dimensional delta function see L. R. Mead, and J. Godines, "An analytical example of renormalization in two-dimensional quantum mechanics," Am. J. Phys. 59, 935-937 (1991); R. Jackiw,
"Delta-function potentials in two- and three-dimensional quantum mechanics," in M. A. B. Bég Memorial Volume, edited by A. Ali and P. Hoodbhoy (World Scientific, Singapore, 1991), pp. 25-42.

[3] Notice that if $\psi(x)$ is normalizable, so too is $\psi_\beta(x)$.

[21] Note that this is a correlated limit in which ϵ and g both go to zero in such a way as to hold κ_1 in Eq. (42) fixed. This is not the same as going straight to $g = 0$ and then letting $\epsilon \to 0$ [Eq. (41)], which only reproduces the limiting value $\pi/4$.
[22] This is not the only way to tame the $1/x^2$ potential. Other regularizations have been proposed. See, for example, C. Schwartz, "Almost singular potentials," J. Math. Phys. 17, 863-867 (1976); H. E. Camblong, L. N. Epele, H. Fanchiotti, and C. A. Garca Canal, "Dimensional transmutation and dimensional regularization in quantum mechanics, I. General theory," and "II. Rotational invariance," Ann. Phys. 287, 14-100 (2001). Our approach follows Ref. 4. It is important in principle to demonstrate that all regularizations lead to the

same physical predictions. If they do not, the theory is non-renormalizable and there is very little that can be done with it.

[23] Of course, if we could detect several bound states, or measure the phase shifts at sufficiently high energy, then we could map out any departures from the $1/x^2$ potential. The question is whether we can make any sense out of the pure $1/x^2$ potential; renormalization offers a means for doing so. By the way, something very similar happens in quantum electrodynamics, where the theory, naively construed, yields an infinite mass for the electron. The introduction of a cutoff renders the mass finite but indeterminate. We take the observed mass of the electron as input and use it to eliminate any explicit reference to the cutoff. The resulting renormalized theory has been spectacularly successful, yielding by far the most precise (and precisely confirmed) predictions in all of physics.
[24] The classic example of an anomaly is the decay of the neutral pion, $\pi^0{}_{25} \to \gamma + \gamma$, which could not occur without the breaking of chiral symmetry.
[25] See, for instance, E. Zeidler, Applied Functional Analysis: Applications to Mathematical Physics (Springer, New York, 1997), pp. 116-117.
[26] Note the logical structure here: We choose $\mathcal{D}_A$, but $\mathcal{D}_{A^\dagger}$ is then determined-it is the space of functions ϕ (in L_2) such that if ψ is in $\mathcal{D}_A$ then Eq. (52) holds.

[32] We assume here that $\alpha < 1/4$; for $\alpha > 1/4$ we could run the same argument using $\psi = \phi = u_+$to obtain the same result.

[33] More explicitly, functions in $\mathcal{D}_H$ vanish if $0 \leqslant x \leqslant \epsilon$ or $x \geqslant \tau$ for arbitrarily small ϵ and arbitrarily large τ.

[34] We follow the treatment in Ref. 30, where the special case $\alpha = 1/4$ is posed as an exercise.

[35] Of course, the eigenvalues of a Hermitian operator are real, so $\phi_+$and ϕ_- cannot be in $\mathcal{D}_H$; rather, the eigenfunctions we seek lie in $\mathcal{D}_{H^+}$.

[36] Mathematicians usually take $\eta = 1$, but this choice offends the physicist's concern for dimensional consistency. In any case, it combines with other arbitrary constants at the end.

[37] This approximation assumes $\mathrm{Re}(ig) > -1/2$, which is fine as long as $\alpha > 0$ (the potential is attractive). It is of some interest to explore selfadjoint extensions of the repulsive $1/x^2$ potential, but we shall not do so here.

[38] Here x_0 is simply a convenient packaging of the arbitrary constants $m, A_\pm$, λ, and η. It is clear from Eq. (73) [if not from Eq. (74)] that x_0 carries the dimensions of length, and hence the choice of a particular self-adjoint extension entails breaking the scale invariance that led to all the difficulties in Sec. II.

[39] This case violates our assumption in Ref. 37, so it should be taken with a grain of salt. See Ref. 30, Example 1, for a more rigorous analysis.

[40] This result agrees with Eq. (80) of Ref. 30, with $r \to x$ and $\varphi \to \psi/x$.

[41] The term "self-adjoint extension" is potentially misleading, because at first sight it appears to involve a contraction, not an expansion, of the domain. The point is that you must

start out with a Hermitian operator, and H is not Hermitian with respect to the set of functions that satisfy the boundary condition $\psi(0) = 0$. That is why we first had to restrict the domain (see Ref. 33), and the "extension" is with respect to that much more limited domain.

[42] By changing the boundary conditions it could be argued that we are radically altering the physical system, albeit at a single point. The process is analogous (in some cases identical) to adding a delta function to the potential, and it is hardly surprising that this changes the spectrum of allowed states. But the question was whether there is anything we could do to salvage the $1/x^2$ potential, and if the remedy is necessarily radical, so be it.

9 Typical Addition of Angular Momenta

Обсудим подробно сложение моментов.

9.0.1 Addition of Two Momenta

Суть

Коэффициенты Клебша-Гордана для простейших моментов находятся в таблице от PDG

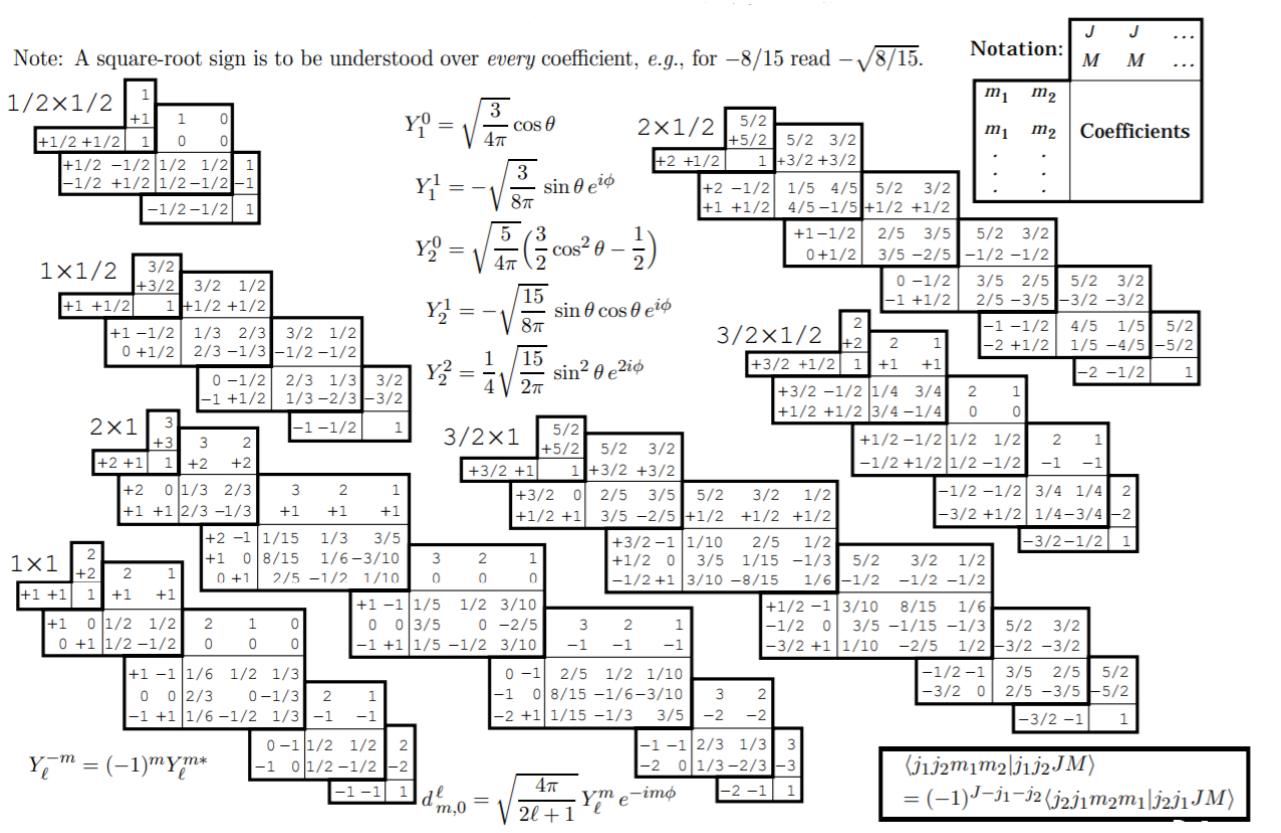

Figure 9.1: PDG таблица коэффициентов Клебша-Гордана

Структура спектра операторов квадрата суммарного момента и проекции момента на выделенную ось

Пусть у нас есть система двух невзаимодействующих моментов l_1 и l_2. Будем считать, что $l_1 \geq l_2$. Найдем суммарный момент такой системы. Каждый из моментов описывается операторами квадрата момента $\hat{L}^2$ и проекции момента на выделенную ось $\hat{L}_z$. Поскольку моменты для каждой системы фиксированы, мы можем работать с этими операторами, суженными на собственные подпространства $\mathbb{C}^{2l_1+1}$ и $\mathbb{C}^{2l_2+1}$ соответственно. Таким образом, мы будем работать с ограниченными операторами. Обозначим эти операторы как $\hat{L}_1^2, \hat{L}_{1,z}, \hat{L}_2^2$ и $\hat{L}_{2,z}$. Напомним, что в базисе из общих собственных векторов операторов $\hat{L}^2$ и $\hat{L}_z$ операторы $\hat{L}_i^2$ и $\hat{L}_{i,z}, i = 1, 2$, - это матрицы с соответствующими собственными числами на главной диагонали. Базисные векторы этих пространств будем обозначать $\psi_m, m = -l_1 ... l_1$, и $\varphi_n, n = -l_2 ... l_2$, то есть нумеровать соответствующим значением проекции момента на выделенную ось.

Подчеркнем здесь, что мы не "ищем" суммарный момент. Наша задача состоит в том, чтобы построить четыре оператора суммарного момента $\hat{L}_\Sigma^2, \hat{L}_{\Sigma,z}, \hat{L}_{\Sigma,x}$ и $\hat{L}_{\Sigma,y}$, обладающих свойствами операторов момента: должны выполняться коммутационные соотношения, и структура спектра должна быть такой же, как у оператора одного момента.

Мы будем строить полный набор наблюдаемых для нашей задачи - операторы квадрата суммарного момента $\hat{L}_\Sigma^2$ и проекции момента на выделенную ось $\hat{L}_{z,\Sigma}$. Поскольку суммарный момент должен обладать всеми свойствами момента, то естественно строить эти операторы как сужение операторов $\hat{L}^2$ и $\hat{L}_z$ на некое подпространство E. Так как моменты не взаимодействуют, то подпространство E совпадает с тензорным произведением $\mathbb{C}^{2l_1+1} \otimes \mathbb{C}^{2l_2+1}$. Размерность пространства E равна $(2l_1 + 1)(2l_2 + 1)$. Базисом в E будет являться множество вида $\{\psi_m \otimes \varphi_n\}$

В пространстве E нам надо выбрать базисные векторы, которые будут общими собственными векторами операторов $\hat{L}_\Sigma^2$ и 14 $\hat{L}_{\Sigma,z}$ (и линейными комбинациями векторов $\{\psi_m \otimes \varphi_n\}$), и присвоить им (из физических соображений) значения собственных чисел этих операторов. Зададим оператор $\hat{L}_{\Sigma,z}$. Мы можем определить

$$\hat{l}_{\Sigma,z} = \hat{L}_{1,z} \otimes \hat{E} + \hat{E} \otimes \hat{L}_{2,z}$$

По аналогии со случаем одного момента введем в пространстве E операторы повышения и понижения проекции суммарного момента на единицу:

$$\hat{L}_- = \hat{L}_{1,-} \otimes \hat{E} + \hat{E} \otimes \hat{L}_{2,-}, \quad \hat{L}_+ = \hat{L}_{1,+} \otimes \hat{E} + \hat{E} \otimes \hat{L}_{2,+},$$

где оператор $\hat{L}_{1,-}$ является оператором понижения проекции первого момента (остальные - соответственно), а оператор $\hat{E}$ - единичный. Отметим, что векторы вида $\psi_{m_1} \otimes \varphi_{m_2}$ являются собственными для оператора $\hat{l}_{\Sigma,z}$ с собственными числами $m_1 + m_2$ соответственно. Каждое их этих собственных чисел, за исключением $\pm(l_1 + l_2)$, вырождено. Назовем максимальной проекцией суммарного момента на ось (то есть первым собственным числом оператора $\hat{L}_{\Sigma,z}$) число $l_1 + l_2$. Соответствующим ему собственным вектором выберем $\psi_{l_1} \otimes \varphi_{l_2}$, который будем обозначать α_1. Легко проверить, что $\hat{L}_+\alpha_1 = 0$. Тогда собственное число оператора $\hat{L}_\Sigma^2$, соответствующее этому собственному вектору, выберем равным $(l_1 + l_2)(l_1 + l_2 + 1)$ Подействовав оператором $\hat{L}_-$на вектор α_1, получим

$$\begin{aligned}\hat{L}_-\alpha_1 = \sqrt{l_1(l_1+1) - l_1(l_1-1)}\psi_{l_1-1} \otimes \varphi_{l_2} + \\ + \sqrt{l_2(l_2+1) - l_2(l_2-1)}\psi_{l_1} \otimes \varphi_{l_2-1}.\end{aligned}$$

Этот вектор после нормировки назовем α_2. Назовем его общим собственным вектором операторов $\hat{L}_\Sigma^2$ и $\hat{L}_{\Sigma,z}$ с собственными значениями $(l_1 + l_2)(l_1 + l_2 + 1)$ и $l_1 + l_2 - 1$ соответственно. Линейная оболочка векторов $\psi_{l_1-1} \otimes \varphi_{l_2}$ и $\psi_{l_1} \otimes \varphi_{l_2-1}$ является двумерным пространством, в котором лежит α_2. Поэтому в нем можно выбрать вектор β_1, ортогональный α_2. Так как сумма магнитных квантовых чисел у базисных векторов β_1 также равна $l_1 + l_2 - 1$, то естественно присвоить этому вектору то же самое значение проекции суммарного момента: $l_1 + l_2 - 1$. Так как на каждом 15 собственном для $\hat{L}^2$ подпространстве оператор $\hat{L}_z$ имеет невырожденный спектр, то суммарное орбитальное квантовое число выберем равным $l_1 + l_2 - 1$, то есть собственное значение оператора $\hat{L}_\Sigma^2$ на этом векторе равно $(l_1 + l_2 - 1)(l_1 + l_2)$. Рассмотрим k-ю степень оператора $\hat{L}_-$:

$$\left(\hat{L}_-\right)^k = \sum_{n=0}^{k} C_k^n \left(\hat{L}_{-,1} \otimes \hat{E}\right)^{k-n} \left(\hat{E} \otimes \hat{L}_{-,2}\right)^n$$

В зависимости от значения k возникают два случая. 1. При $k \leq 2l_2$, действуя оператором понижения 12 на вектор α_1, мы получим линейную комбинацию $k + 1$ попарно ортогональных векторов $\psi_i \otimes \varphi_j, i + j = l_1 + l_2 - k$. Вектору $\left(\hat{L}_-\right)^k \alpha_1$ после нормировки мы присваиваем собственные числа для проекции и квадрата суммарного момента $l_1 + l_2 - k$ и $(l_1 + l_2)(l_1 + l_2 + 1)$ соответственно. Остальным k векторам в этом $k + 1$-мерном подпространстве, ортогональным $\left(\hat{L}_-\right)^k \alpha_1$, присвоим то же значение для проекции момента, а для квадрата момента выберем значения $(l_1 + l_2 - n)(l_1 + l_2 - n + 1), n = \overline{1,k}$. 2. При $2l_2 < k \leq l_1 + l_2$ размерность подпространства, которому принадлежит вектор $\left(\hat{L}_-\right)^k \alpha_1$, остается равной $2l_2 + 1$. Это связано с тем, что вектор

$$\left(\hat{L}_-\right)^{2l_2} \alpha_1$$

имеет в качестве слагаемого элемент $\psi_{l_1} \otimes \varphi_{-l_2}$. Последующее действие на 13 оператора $\hat{L}_-$имеет нулевое слагаемое, так как $\hat{L}_{-,2}\varphi_{-l_2} = 0$. Следовательно, начиная с $k = 2l_2$, оператор 12, действуя на α_1, дает вектор, лежащий в подпространстве одной и той же размерности. Наглядно размерность соответствующего подпространства представлена, например, в [2]. Вектору $\left(\hat{L}_-\right)^k \alpha_1$ мы приписываем собственные числа $l_1 + l_2 - k$ и $(l_1 + l_2)(l_1 + l_2 + 1)$, а $2l_2$ ортогональным им векторам присвоим то же значение для проекции момента, а для квадрата момента выберем значения $(l_1 + l_2 - n)(l_1 + l_2 - n + 1), n = \overline{1, 2l_2}$. Мы видим, что, начиная с $k = 2l_2$, при уменьшении проекции суммарного момента не нужно вводить новых (меньших $l_1 - l_2$) значений для орбитального квантового числа l. Таким образом, мы получили, что минимальное $l = l_1 - l_2$, а минимальное собственное значение оператора $\hat{L}^2_\Sigma$ равно $(l_1 - l_2)(l_1 - l_2 + 1)$ соответственно. Всю эту процедуру можно провести и для оператора повышения проекции момента, стартуя с вектора $\psi_{-l_1} \otimes \varphi_{-l_2}$ с минимальной суммарной проекцией $-(l_1 + l_2)$.

Итак, мы определили спектр операторов квадрата $\hat{L}^2_\Sigma$ и проекции $\hat{L}_{z,\Sigma}$ суммы моментов. Для двух моментов, характеризуемых орбитальными квантовыми числами l_1 и l_2, получено, что суммарный момент характеризуется орбитальными квантовыми числами l, принимающими значения от $l_1 - l_2$ до $l_1 + l_2$. Для каждого такого числа l собственные значения оператора $\hat{L}^2_\Sigma$ равны $l(l+1)$ и $2l+1$ раз вырождены. Собственные числа оператора $\hat{L}_{z,\Sigma}$ при этом принимают значения от $-l$ до l. Суммарная кратность вырождения

$$K = \sum_{n=l_1-l_2}^{l_1+l_2} (2n+1) = (2l_1+1)(2l_2+1)$$

совпадает с размерностью пространства E.

2.2. Построение общего базиса для операторов квадрата суммарного момента и его проекции на выделенную ось

Пока построенный нами базис определен неоднозначно: в каждом подпространстве, соответствующем определенному значению проекции суммарного момента, векторы ортогональны, но иначе никак не фиксированы. Эти векторы определяются однозначно, если потребовать выполнения всех коммутационных соотношений, выполняющихся для одного момента, а именно:

$$\left[\hat{L}^2_\Sigma, \hat{L}_{\Sigma,z}\right] = 0,$$
$$\left[\hat{L}_{\Sigma,x}, \hat{L}_{\Sigma,x}\right] = -i\hat{L}_{\Sigma,y},$$
$$\left[\hat{L}_{\Sigma,y}, \hat{L}_{\Sigma,z}\right] = i\hat{L}_{\Sigma,x},$$
$$\left[\hat{L}^2_\Sigma, \hat{L}_{\Sigma,j}\right] = 0 \quad j = x, y.$$

Причем должно выполняться $\hat{L}_\pm = \hat{L}_{\Sigma,x} \pm i\hat{L}_{\Sigma,y}$. Коммутационное соотношение (14) выполнено автоматически, а вместо соотношений (15) - 17 удобнее рассматривать эквивалентные им

$$\left[\hat{L}^2_\Sigma, \hat{L}_\pm\right] = 0,$$
$$\left[\hat{L}_+, \hat{L}_-\right] = 2\hat{L}_{\Sigma,z},$$
$$\left[\hat{L}_{\Sigma,z}, \hat{L}_\pm\right] = \pm\hat{L}_\pm.$$

Упражнение. Зная, как записываются операторы $\hat{L}_{\pm}$через тензорные произведения операторов $\hat{L}_{\pm,j}, j = 1,2$, а также пользуясь коммутационными соотношениями для последних, доказать соотношения (19) и (20).

Для выполнения (18) необходимо, чтобы действие операторов повышения и понижения не выводили вектор из собственного для конструируемого оператора $\hat{L}^2_\Sigma$ подпространства с фиксированным значением орбитального квантового числа суммарного момента l. Чтобы это гарантировать, будем строить базис из собственных векторов следующим образом. Для собственного подпространства с $l = l_1 + l_2$ собственный вектор с проекцией момента $l_1 + l_2 - n$ равен $\alpha_{n+1} = \left(\hat{L}_-\right)^n \alpha_1, \quad n \leq 2l_1 + 2l_2$, а C выбирается из условия нормировки. Вектор β_1 с $l = l_1 + l_2 - 1$ и максимальной проекцией момента получаем как ортогональный к α_2, а векторы β_n с проекциями $l_1 + l_2 - 1 - n$ для этого l получаем снова как $\beta_{n+1} = \left(\hat{L}_-\right)^n \beta_1, \quad n \leq 2\left(l_1 + l_2 - 1\right)$. И так далее. Если полученные таким образом векторы будут попарно ортогональны друг другу (т.е. образовывать базис), то коммутационное соотношение (18), очевидно, будет выполнено. Докажем ортогональность векторов, соответствующих одной и той же суммарной проекции момента m, но различным орбитальным числам l (ортогональность остальных пар очевидна). То есть докажем, что если $(\alpha_k, \beta_{k-1}) = 0$, то $\left(\hat{L}_-\alpha_k, \hat{L}_-\beta_{k-1}\right) = 0 \quad \forall k = \overline{2, 2l-1}$:

$$\left(\hat{L}_-\alpha_k, \hat{L}_-\beta_{k-1}\right) = \left(\alpha_k, \hat{L}_+\hat{L}_-\beta_{k-1}\right) = \left(\alpha_k, \hat{L}_+\beta_k\right) = \\ = (\alpha_k, \text{ const } \cdot \beta_{k-1}) = 0.$$

Мы показали, что векторы, соответствующие одной и той же проекции момента, ортогональны. Тем самым доказана верность коммутационного соотношения 18, что и завершает построение оператора суммарного момента. Построенные векторы образуют ортонормированный базис, каждый вектор которого мы можем индексировать соответствующими значениями орбитального и магнитного квантовых чисел суммарного момента $\Psi_{l_\Sigma, m_\Sigma}$. Определенные на этом базисе операторы $\hat{L}_{\Sigma,i}, i = 1,2,3$, и $\hat{L}^2_\Sigma$ имеют структуру спектра операторв момента и удовлетворяют коммутационным соотношениям 17.

Если обозначить как $\mathbb{J}_k$ собственное подпространство операторов $\hat{L}^2$ и $\hat{L}_z$ со значением орбитального квантового числа $l = k$, то удобно работать не с пространством $\mathbb{C}^{2l_1+1} \otimes \mathbb{C}^{2l_2+1}$, а с изометрически изоморфным ему

Определив для каждого значения $k \in [(l_1 - l_2), ..., (l_1 + l_2)]$ диагональные матрицы размера $(2k+1) \times (2k+1)$:

$$B_k = \begin{pmatrix} k & & \\ & \ddots & \\ & & -k \end{pmatrix}, \quad D_k = \begin{pmatrix} k(k+1) & & \\ & \ddots & \\ & & k(k+1) \end{pmatrix}$$

получим в пространстве (21) блочно-диагональные матрицы опе- 19 ратора проекции суммарного момента

$$\begin{pmatrix} B_{l_1+l_2} & & \\ & \ddots & \\ & & B_{l_1-l_2} \end{pmatrix}$$

и оператора квадрата суммарного момента

$$\begin{pmatrix} D_{l_1+l_2} & & \\ & \ddots & \\ & & D_{l_1-l_2} \end{pmatrix}.$$

Пример 11. Суммарный момент электрона со спином $1/2$ и орбитальным моментом $l = 1$.

Нужно просуммировать моменты $l = 1$ и $s = 1/2$. Пространство $E = \mathbb{C}^{2\cdot 1+1} \otimes \mathbb{C}^{2\cdot 1/2+1}$, размерность равна 6. Базис в пространстве состоит из векторов

$$\psi_1 \otimes \varphi_{1/2} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \psi_1 \otimes \varphi_{-1/2} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

$$\psi_0 \otimes \varphi_{1/2} = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \psi_0 \otimes \varphi_{-1/2} = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

$$\psi_{-1} \otimes \varphi_{1/2} = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \psi_{-1} \otimes \varphi_{-1/2} = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \otimes \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

Структура спектра ясна из приведенных выше общих рассуждений: орбитальное число l_Σ суммарного момента должно принимать значения $1/2$ (что соответствует $l - s$) и $3/2$ (что соответствует $l + s$). Других значений нет, так как $l - s + 1$ совпадает с максимальным значением суммарного момента. Соответствующие собственные числа оператора $\hat{L}^2_\Sigma$ равны $(l + s)(l + s + 1) = 15/4$ с кратностью вырождения $2(l + s) + 1 = 4$ и $(l - s)(l - s + 1) = 3/4$ с кратностью вырождения $2(l - s) + 1 = 2$. Таким образом, собственные числа оператора $\hat{L}^2_\Sigma$ равны

$$\left\{\frac{15}{4}, \frac{15}{4}, \frac{15}{4}, \frac{15}{4}, \frac{3}{4}, \frac{3}{4}\right\},$$

20 а собственные числа $\hat{L}_{\Sigma,z}$ равны

$$\left\{\frac{3}{2}, \frac{1}{2}, -\frac{1}{2}, -\frac{3}{2}, \frac{1}{2}, -\frac{1}{2}\right\}.$$

Построим собственные векторы:

$$\alpha_1 = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \otimes \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \Psi_{3/2,3/2}$$

Действуем оператором понижения $\hat{L}_- = \hat{L}_{-,1} \otimes \hat{E} + \hat{E} \otimes \hat{s}_-$на вектор α_1:

$$\hat{L}_-\alpha_1 = \sqrt{2}\psi_0 \otimes \varphi_{1/2} + \psi_1 \otimes \varphi_{-1/2}$$

Нормируем этот вектор:

$$\begin{aligned}
&\left\|\sqrt{2}\psi_0 \otimes \varphi_{1/2} + \psi_1 \otimes \varphi_{-1/2}\right\|^2 = \\
&= \left(\sqrt{2}\psi_0 \otimes \varphi_{1/2} + \psi_1 \otimes \varphi_{-1/2}, \sqrt{2}\psi_0 \otimes \varphi_{1/2} + \psi_1 \otimes \varphi_{-1/2}\right) = \\
&= \left(\sqrt{2}\psi_0 \otimes \varphi_{1/2}, \sqrt{2}\psi_0 \otimes \varphi_{1/2}\right) + \left(\sqrt{2}\psi_0 \otimes \varphi_{1/2}, \psi_1 \otimes \varphi_{-1/2}\right) + \\
&\quad + \left(\psi_1 \otimes \varphi_{-1/2}, \sqrt{2}\psi_0 \otimes \varphi_{1/2}\right) + \left(\psi_1 \otimes \varphi_{-1/2}, \psi_1 \otimes \varphi_{-1/2}\right) = \\
&= 2\left(\psi_0, \psi_0\right)\left(\varphi_{1/2}, \varphi_{1/2}\right) + \left(\psi_1, \psi_1\right)\left(\varphi_{-1/2}, \varphi_{-1/2}\right) = 3
\end{aligned}$$

Тогда

$$\alpha_2 = \sqrt{\frac{2}{3}}\psi_0 \otimes \varphi_{1/2} + \sqrt{\frac{1}{3}}\psi_1 \otimes \varphi_{-1/2}.$$

Этот вектор соответствует собственным числам 15/4 и 1/2 (орбитальное квантовое число 3/2), и его можно обозначить $\Psi_{3/2,1/2}$. Ортогональный ему вектор в подпространстве $\mathrm{Lin}\left\{\psi_0 \otimes \varphi_{1/2}, \psi_1 \otimes \varphi_{-1/2}\right\}$ также будет иметь проекцию 1/2, но орбитальное квантовое число 1/2, поэтому сразу назовем его $\alpha_5 = c_1 \cdot \psi_0 \otimes \varphi_{1/2} + c_2 \cdot \psi_1 \otimes \varphi_{-1/2}$. Постоянные определяются условиями $(\alpha_2, \alpha_5) = 0$ и $\|\alpha_5\| = 1 : c_1 = \frac{1}{\sqrt{3}}, c_2 = -\sqrt{\frac{2}{3}}$. Нормированный α_5 обозначим $\Psi_{1/2,1/2}$. Орбитальному квантовому числу 3/2 и минимальной проекции момента $-3/2$ соответствует только один вектор: $\alpha_4 = \psi_{-1} \otimes \varphi_{-1/2} = \Psi_{3/2,-3/2}$. Действуя на него оператором повышения, получим

$$\hat{L}_+\alpha_4 = \sqrt{2}\psi_0 \otimes \varphi_{-1/2} + \psi_{-1} \otimes \varphi_{1/2}$$

и тогда

$$\alpha_3 = \sqrt{\frac{2}{3}}\psi_0 \otimes \varphi_{-1/2} + \sqrt{\frac{1}{3}}\psi_{-1} \otimes \varphi_{1/2} = \Psi_{3/2,-1/2}.$$

Последний нормированный вектор α_6 из соображений ортогональности α_3 в подпространстве $\mathrm{Lin}\left\{\psi_0 \otimes \varphi_{-1/2}, \psi_{-1} \otimes \varphi_{1/2}\right\}$ paBeH

$$\alpha_6 = \frac{1}{\sqrt{3}}\psi_0 \otimes \varphi_{-1/2} - \sqrt{\frac{2}{3}}\psi_{-1} \otimes \varphi_{1/2} = \Psi_{1/2,-1/2}$$

Базисные векторы $\{\Psi_{l_\Sigma,m_\Sigma}\}$ вместе с собственными значениями (22) и 23 задают операторы $\hat{L}^2_\Sigma$ и $\hat{L}_{\Sigma,z}$ на пространстве $\mathbb{C}^3 \otimes \mathbb{C}^2$. Матрицы $\hat{L}_{\Sigma,x}$ и $\hat{L}_{\Sigma,y}$ можно записать с помощью операторов $\hat{L}_\pm$, записанных в построенном базисе. Как было доказано в пункте 2.1, построенные таким образом операторы будут удовлетворять коммутационным соотношениям для операторов одного момента. Построим естественный изоморфизм $U : \mathbb{C}^3 \otimes \mathbb{C}^2 \to \mathbb{J}_{3/2} \oplus \mathbb{J}_{1/2}$:

$$U\left(\psi_1 \otimes \varphi_{1/2}\right) = \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

$$U\left(\sqrt{\frac{2}{3}}\psi_0 \otimes \varphi_{1/2} + \sqrt{\frac{1}{3}}\psi_1 \otimes \varphi_{-1/2}\right) = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

и так далее. Тогда операторы суммарного момента в этом базисе запишутся как

$$\hat{L}_{\Sigma,z} = \begin{pmatrix} 3/2 & & & & & \\ & 1/2 & & & & \\ & & -1/2 & & & \\ & & & -3/2 & & \\ & & & & 1/2 & \\ & & & & & -1/2 \end{pmatrix}.$$

У пражнение. Постройте операторы суммарного спина для двух частиц со спином 1/2. Докажите, что $\hat{S}_\Sigma$ не коммутирует с $\hat{S}_{1,z}$. Покажите, что эти операторы коммутируют на каждом собственном для $\hat{S}_\Sigma$ подпространстве. 2.3. Восстановление волновых функций в координатном представлении

В результате процедуры сложения двух моментов мы получили векторы $\Psi_{L,M}$. Интересно восстановить этот вектор в координатном представлении, так как именно в нем мы получим плотности распределения того или иного состояния по координате.

Пример 12. Суммарный момент двух невзаимодействующих частиц, каждая их которых находится в состоянии с моментом, имеющим орбитальное квантовое число 1. Базис состояний для каждой частицы - это векторы $\psi_{1,m}$ и $\varphi_{1,m}$, где $m = \{-1, 0, 1\}$. В координатном представлении базис состояний записывается как $\{Y_1^{m_1}(\theta_1, \varphi_1)\}$ и $\{Y_1^{m_2}(\theta_2, \varphi_2)\}$, где $m = \{-1, 0, 1\}$, а $Y_l^m(\theta, \varphi)$ - сферические функции.

Общий вектор суммарного момента, соответствующий, например, пример, квантовым числам $L = 2$ и $M = 1$, равен

$$\Psi_{2,1} = \frac{\psi_{1,0} \otimes \varphi_{1,1} + \psi_{1,1} \otimes \varphi_{1,0}}{\sqrt{2}}$$

В координатном представлении этот вектор запишется как

$$\Psi_{2,1}(\theta_1, \varphi_1, \theta_2, \varphi_2) =$$
$$= \frac{1}{\sqrt{2}} \left(Y_1^0(\theta_1, \varphi_1) Y_1^1(\theta_2, \varphi_2) + Y_1^1(\theta_1, \varphi_1) Y_1^0(\theta_2, \varphi_2) \right).$$

Пример 13. Суммарный момент частицы с моментом 1 и спином 1/2.

Воспользуемся результатами Примера 11. Запишем, например, вектор $\Psi_{3/2,1/2}$ в координатном представлении. Векторы, описывающие состояние проекции спина, не могут быть записаны в координатном представлении, так как они конструируются сразу в собственном представлении (отражение чисто квантовой природы спина), то интересующий нас вектор записывается в виде разложения волновой функции по собственным векторам проекции спина на ось OZ:

$$\Psi_{3/2,1/2}(\theta, \varphi) = \begin{pmatrix} \sqrt{\frac{2}{3}} Y_1^0(\theta, \varphi) \\ \sqrt{\frac{1}{3}} Y_1^1(\theta, \varphi) \end{pmatrix}.$$

§3. Соотношения ортогональности для коэффициентов Клебша-Гордана

Определение 14. Коэффициенты $K^{l_\Sigma, m_\Sigma}_{l_1, m_1, l_2, m_2}$ разложения базиса $\Psi_{l_\Sigma, m_\Sigma}$ по базису $\{\psi_{m_1} \otimes \varphi_{m_2}\}$ называются коэффициентами Клебша-Гордана.

Нередко индексы l_1 и l_2 опускаются для каждой определенной задачи, в которой они фиксированы.

Пример 15. Коэффициенты Клебша-Гордана для Примера 11 обозначим $K^{l_\Sigma, m_\Sigma}_{m, s_m}$, где число m - проекция на выделенную ось момента l, s_m - проекция на ту же ось спина электрона, l_Σ - орбитальное квантовое число суммарного момента, m_Σ - проекция су|ммарного момента. Первая пара аргументов характеризует старый базис $\psi_i \otimes \varphi_j$, а вторая пара аргументов - новый базис α_k. Выше мы нашли, что

$$K^{3/2,3/2}_{1,1/2} = 1, \quad K^{3/2,1/2}_{0,1/2} = \sqrt{\frac{2}{3}}, \quad K^{3/2,1/2}_{1,-1/2} = \frac{1}{\sqrt{3}}, \quad \text{etc.}$$

Утверждение 16. Коэффициенты Клебша-Гордана удовлетворяют "условию ортогональности":

$$\sum_{m_1,m_2} K^{L,M}_{m_1,m_2} K^{L',M'}_{m_1,m_2} = \delta_{LL'}\delta_{MM'}$$

Доказательство. Векторы Ψ_{LM} и $\Psi_{L'M'}$ ортогональны, если не совпадает хотя бы одна пара индексов:

$$\delta_{LL'}\delta_{MM'} = (\Psi_{LM}, \Psi_{L'M'}) =$$

$$= \left(\sum_{m_1,m_2} K^{LM}_{m_1,m_2} \psi_{m_1} \otimes \varphi_{m_2}, \sum_{m'_1,m'_2} K^{L'M'}_{m'_1,m'_2} \psi_{m'_1} \otimes \varphi_{m'_2} \right) =$$

$$= \sum_{m_1,m_2} \sum_{m'_1,m'_2} K^{LM}_{m_1,m_2}, K^{L'M'}_{m'_1,m'_2} \left(\psi_{m_1} \otimes \varphi_{m_2}, \psi_{m'_1} \otimes \varphi_{m'_2} \right) =$$

$$= \sum_{m_1,m_2} K^{LM}_{m_1,m_2} K^{L'M'}_{m_1,m_2}$$

что и доказывает утверждение.

Утверждение 17. Коэффициенты Клебша-Гордана удовлетворяют "условию ортогональности":

$$\sum_{L,M} K^{L,M}_{m_1,m_2} K^{L,M}_{m'_1,m'_2} = \delta_{m_1 m'_1}\delta_{m_2 m'_2}$$

Доказательство. Матрица, составленная из коэффициентов Клебша-Гордана $K^{LM}_{m_1 m_2}$, осуществляет изометрический изоморфизм пространства $\mathbb{C}^{2l_1+1} \otimes \mathbb{C}^{2l_2+1}$ на пространство $\bigoplus_{k=l_1-l_2}^{l_1+l_2} \mathbb{J}_k$. Компоненты матрицы обратного преобразования обозначим $\tilde{K}^{m_1 m_2}_{LM}$. Заметим, что

$$\tilde{K}^{m_1 m_2}_{LM} = (\Psi_{LM}, \psi_{m_1} \otimes \varphi_{m_2}) = K^{LM}_{m_1 m_2}$$

Доказательство утверждения следует из равенства

$$\delta_{m_1 m'_1}\delta_{m_2 m'_2} = \left(\psi_{m_1} \otimes \varphi_{m_2}, \psi_{m'_1} \otimes \varphi_{m'_2} \right) =$$
$$= \sum_{LM} K^{LM}_{m_1 m_2} K^{LM}_{m'_1 m'_2}$$

9.0.2 Wigner–Eckart Theorem

Теория

Теорема Вигнера-Эккарта является важным техническим инструментом в задачах квантовой механики. Для ее правильного применения необходимо понимать утверждение теоремы. Учебники квантовой механики, такие как [1, 3], предполагают при формулировании теоремы дополнительную подготовку студентов в этом вопросе. В частности, доказательство и применение теоремы Вигнера-Эккарта предполагает как минимум знакомство с теорией групп. Для нужд второго семестра квантовой механики, изучаемой в МФТИ, эта теорема может быть сформулирована и доказана без аппеляции к этому разделу математики. Ниже приводится доказательство этой теоремы по книге |2| и ее применение к вычислению фактора Ланде и получению правил отбора для дипольного излучения. Приведенное доказательство предполагает хорошее знакомство читателя с процедурой построения оператора суммарного момента.

Здесь и далее в основном используются обозначения Дирака. Будем обозначать общий собственный для некоторого полного набора наблюдаемых П вектор какого-либо

гильбертова пространства $\mathcal{H}$ его индексами - квантовыми числами соответствующего полного набора наблюдаемых $-|a_1, a_2, ..., a_n\rangle$. Такое обозначение не конкретизирует пространство $\mathcal{H}$, то есть какое-то определенное представление. В этом случае говорят, что вектор $|a_1, a_2, ..., a_n\rangle$ лежит в "абстрактном гильбертовом пространстве". Мы также будем работать с определенным представлением. В этом случае будем обозначать как $\Psi_{a_1,...,a_n}$ волновую функ- цию в этом представлении. Например, вектор $|1, 0\rangle$, собственный для операторов орбитального момента $\hat{L}^2$ и проекции момента на ось $OZ\hat{L}_z$, заданный орбитальным квантовым числом $l = 1$ и магнитным квантовым числом $m = 0$, в координатном представлении записывается как

$$\Psi_{1,0}(\theta, |\varphi) = \langle\theta, \varphi|1, 0\rangle = \sqrt{\frac{3}{4\pi}}\cos\theta.$$

Этот же вектор $|1, 0\rangle$ в собственном представлении для $l = 1$, $m = \{1, 0, -1\}$, может быь записан в виде

$$\Psi_{1,0} = \langle 1, m|1, 0\rangle = \{0, 1, 0\} = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}.$$

При этом запись, например, $\left\langle JM'|\hat{A}|JM\right\rangle \in \mathbb{C}$ и означает скалярное произведение $\left(\Psi_{J,M'}, \hat{A}\Psi_{J,M}\right)$.

Ниже мы используем стандартно определенные [1, 3] операторы орбитального момента $\hat{L}^2, \hat{L}_i, i = 1, 2, 3, \hat{L}_\pm$, операторы спина $\hat{S}^2, \hat{S}_i, i = 1, 2, 3, \hat{S}_\pm$, и оперторы суммарного момента $\hat{J}^2, \hat{J}_i,\ i = 1, 2, 3, \hat{J}_\pm$.

Сферические тензоры

Определение 1 сферического тензора. Пусть операторы $\hat{T}^{(k)}_q, q \in [-k, k]$, определены на собственном для $\hat{J}^2$ подпространстве $\mathbb{J}_K$ или на конечной прямой сумме таких подпространств [4]:

$$\bigoplus_{J=K}^{J=N} \mathbb{J}_K$$

Набор операторов $\hat{T}^{(k)}_q, q \in [-k, k]$, будем называть сферическим тензором, если выполнены следующие коммутационные соотношения: 1. $\left[\hat{J}_\pm, \hat{T}^{(k)}_q\right] = C_\pm(k, q)\hat{T}^{(k)}_{q\pm1}$ 2. $\left[\hat{J}_z, \hat{T}^{(k)}_q\right] = q\hat{T}^{(k)}_q$. Замечание 2. Обратите внманиние, что так как мы определили операторы $\hat{T}^{(k)}_q$ на конечномерном подпространстве гильбертова пространства $\mathcal{H}$, то мы работаем с ограниченными операторами, при определении коммутации которых не возникает тех проблем, которые свойственны определению коммутатора неограниченных операторов в бесконечномерном пространстве.

В рассматриваемом нами случае коммутация операторов, определенных на конечномерных подпространствах гильбертова пространства, совпадает с перестановочностью матриц.

Определение 3. Постоянные $C_\pm(k, q) = \sqrt{(k \mp q)(k \pm q + 1)}$ - стандартные коэффициенты при действии операторов повышения/понижения момента $\hat{J}_\pm$на общие для операторов квадрата $\hat{J}^2$ и проекции момента $\hat{J}_z$ собственные векторы $|j, m\rangle$.

Приведем примеры сферических тензоров, которые мы будем использовать в дальнейшем.

Пример 4. Для вычисления фактора Ланде нам понадобятся матричные элементы $\left\langle JM' \left| \hat{1} \otimes \hat{S}_z \right| JM \right\rangle$. Поэтому сделаем предположение, что мы можем ввести сферический тензор $\hat{A}_q^{(k)}$ с $k = 1$ и $\hat{A}_0^{(1)} = \hat{1} \otimes \hat{S}_z$. Найдем остальные компоненты $\hat{A}_{\pm 1}^{(1)}$. По Определению 1] сферического тензора для набора операторов $\hat{A}_q^{(1)}$, $q = -1, 0, 1$, должно быть выполнено

$$\left[\hat{J}_\pm, \hat{A}_0^{(1)}\right] = C_\pm(1,0)\hat{A}_{\pm 1}^{(1)} = \sqrt{2}\hat{A}_{\pm 1}^{(1)}$$

Вычислим, чему равен на самом деле коммутатор в левой части этого равенства:

$$\left[\hat{J}_\pm, \hat{1} \otimes \hat{S}_z\right] = \left[\hat{L}_\pm \otimes \hat{1} + \hat{1} \otimes \hat{S}_\pm, \hat{1} \otimes \hat{S}_z\right] = \mp \hat{1} \otimes \hat{S}_\pm$$

Таким образом,

$$\hat{A}_{\pm 1}^{(1)} = \mp \frac{1}{\sqrt{2}} \hat{1} \otimes \hat{S}_\pm.$$

Упражнение. Пользуясь Определением 3 и выражениями (1), проверьте самостоятельно выполнение остальных 7 коммутационных соотношений в Определении 1:

$$\begin{gathered}
\left[\hat{J}_+, \hat{A}_{+1}^{(1)}\right] = 0, \\
\left[\hat{J}_+, \hat{A}_{-1}^{(1)}\right] = \sqrt{2}\hat{A}_0^{(1)}, \\
\left[\hat{J}_-, \hat{A}_{+1}^{(1)}\right] = \sqrt{2}\hat{A}_0^{(1)}, \\
\left[\hat{J}_-, \hat{A}_{-1}^{(1)}\right] = 0,
\end{gathered}$$

$$\begin{gathered}
\left[\hat{J}_z, \hat{A}_0^{(1)}\right] = 0, \\
\left[\hat{J}_z, \hat{A}_{+1}^{(1)}\right] = \hat{A}_{+1}^{(1)}, \\
\left[\hat{J}_z, \hat{A}_{-1}^{(1)}\right] = \hat{A}_{-1}^{(1)}.
\end{gathered}$$

Пример 5. Для правил отбора для дипольного излучения нам понадобятся матричные элементы компонент дипольного момента $\left\langle JM' \left| \hat{d}_i \right| JM \right\rangle$. Выберем в качестве нулевой компоненты сферического тензора $\hat{B}_0^{(1)} = \hat{d}_z$. Тогда из коммутационных соотношений [2] получим

$$\hat{B}_{\pm 1}^{(1)} = \mp \frac{1}{\sqrt{2}} \left(\hat{d}_x \pm i\hat{d}_y \right) = \mp \frac{1}{\sqrt{2}} \hat{d}_\pm.$$

У пражнение. Проверьте все коммутационные соотношения из Определения 1. Для этого покажите, что все собственные функции операторов проекции момента лежат в области опеределения операторов $\hat{x}_i$. Покажите, что для суженных на собственные для $\hat{L}^2$ подпространства операторов $\hat{x}_i$ выполнены нужные коммутационные соотношения. Покажите, что соотношения из Определения 1 выполнены и для операторов $\hat{J}_i$.

Пример 6. В частности, и сами компоненты оператора момента образуют сферический тензор:

$$\begin{aligned}
\hat{C}_0^{(1)} &= \hat{J}_z, \\
\hat{C}_{\pm 1}^{(1)} &= | \mp \frac{1}{\sqrt{2}} \hat{J}_\pm.
\end{aligned}$$

Теорема Вигнера-Эккарта

Теорема 7 Вигнера-Эккарта.

Пусть $\hat{T}_q^{(k)}, q \in [-k,k]$ для фиксированного k, - сферический тензор. Тогда матричный элемент каждой компоненты сферического тензора $\left\langle j', m' \left| \hat{T}_q^{(k)} \right| j, m \right\rangle$ пропорционален соответствующему коэффициенту Клебша-Гордана $K_{j,m;k,q}^{j',m'}$[1, 3, 4], а коэффициент пропорциональности Λ не зависит от квантовых чисел m, m', q и может зависеть лишь только от j, j', k:

$$\left\langle j', m' \left| \hat{T}_q^{(k)} \right| j, m \right\rangle = \Lambda\left(j, j', k\right) K_{j,m;k,q}^{j',m'}$$

Здесь $K_{j,m;k,q}^{j',m'} = \langle j', m' | j, m; k, q \rangle$ - коэффициенты Клебша-Гордана сложения моментов j и k|4|. Так как эти квантовые числа фиксированы, то в дальнейшем будем их опускать в записи коэффициентов:

$$K_{j,m;k,q}^{j',m'} \equiv K_{mq}^{j'm'}$$

Доказательство. А. Докажем реккурентные соотношения для коэффициентов Клебша-Гордана. При сложении моментов j и k получаем значения квантового числа j', характеризующего суммарный момент: $j' = |j-k|...(j+k)$. Подействуем операторами повышения/понижения суммарного момента $\hat{J}_\pm$на собственный вектор суммарного момента $|j', m'\rangle$:

$$\hat{J}_\pm \left|j', m'\right\rangle = C_\pm\left(j', m'\right) \left|j', (m' \pm 1)\right\rangle$$

С другой стороны, мы, во-первых, можем записать вектор суммарного момента через коэффициенты Клебша-Гордана и собственные векторы складываемых моментов:

$$|j', m'\rangle = \sum_{m_1, m_2} K_{m_1 m_2}^{j'm'} |j, m_1\rangle \otimes |k, m_2\rangle$$

а во-вторых, сам оператор повышения/понижения переписать в виде суммы соответствующих операторов для первого и второго моментов:

$$\hat{J}_\pm = \hat{j}_{1,\pm} \otimes \hat{1} + \hat{1} \otimes \hat{j}_{2,\pm}$$

Тогда получаем равенство

$$\begin{aligned} C_\pm\left(j', m'\right) \left|j', (m' \pm 1)\right\rangle = \\ = \sum_{m_1, m_2} K_{m_1 m_2}^{j'm_2'} \left[C_\pm\left(j, m_1\right) \left|j, (m_1 \pm 1)\right\rangle \otimes |k, m_2\rangle + \right. \\ \left. + C_\pm\left(k, m_2\right) |j, m_1\rangle \otimes \left|k, (m_2 \pm 1)\right\rangle\right]. \end{aligned}$$

Умножим полученное равенство слева на вектор $\langle j, m| \otimes \langle k, q|$:

$$C_\pm\left(j', m'\right) K_{mq}^{j'(m'\pm1)} = C_\pm(j, m \mp 1) K_{(m\mp1)q}^{j'm'} + C_\pm(k, q \mp 1) K_{m(q\mp1)}^{j'm'}.$$

Заметим, что

$$\begin{aligned} C_\pm(j, m \mp 1) = \sqrt{[j \mp (m \mp 1)][j \pm (m \mp 1) + 1]} = \\ = \sqrt{(j \mp m + 1)(j \pm m)} = C_\mp(j, m). \end{aligned}$$

Окончательно получаем реккурентные соотношения для коэффициентов Клебша-Гордана в виде

$$C_\pm\left(j', m'\right) K_{mq}^{j'(m'\pm1)} = C_\mp(j, m) K_{(m\mp1)q}^{j'm'} + C_\mp(k, q) K_{m(q\mp1)}^{j'm'}.$$

B. Получим подобные соотношения для матричных элементов компонент сферического тензора. Для этого рассмотрим матричный элемент коммутатора

$$\left\langle j', m' \left| \left[\hat{J}_{\pm}, \hat{T}_q^{(k)} \right] \right| j, m \right\rangle .$$

С одной стороны, запишем этот матричный элемент, воспользовавшись коммутационным соотношением из определения сферического тензора:

$$\left\langle j', m' \left| \left[\hat{J}_{\pm}, \hat{T}_q^{(k)} \right] \right| j, m \right\rangle = C_{\pm}(k, q) \left\langle j', m' \left| \hat{T}_{q\pm1}^{(k)} \right| j, m \right\rangle .$$

С другой стороны, мы можем воспользоваться непосредственно определением коммутатора и определением операторов, сопря- 10 женных к операторам $\hat{J}_{\pm}$:

$$\begin{gathered} \left\langle j', m' \left| \left[\hat{J}_{\pm}, \hat{T}_q^{(k)} \right] \right| j, m \right\rangle = \\ = C_{\mp}(j', m') \left\langle j', m' \mp 1 \left| \hat{T}_q^{(k)} \right| j, m \right\rangle - \\ - C_{\pm}(j, m) \left\langle j', m' \left| \hat{T}_q^{(k)} \right| j, m \pm 1 \right\rangle . \end{gathered}$$

Заметив, что

$$C_{\mp}(j, m) = C_{\pm}(j, -m),$$

получаем

$$\begin{gathered} C_{\pm}(j', -m') \left\langle j', m' \mp 1 \left| \hat{T}_q^{(k)} \right| j, m \right\rangle = \\ = C_{\mp}(j, -m) \left\langle j', m' \left| \hat{T}_q^{(k)} \right| j, m \pm 1 \right\rangle + \\ + C_{\mp}(k, -q) \left\langle j', m' \left| \hat{T}_{q\pm1}^{(k)} \right| j, m \right\rangle . \end{gathered}$$

Делая в этом выражении замену $m \to -m, m' \to -m'$ и $q \to -q$, приходим к равенству

$$\begin{gathered} C_{\pm}(j', m') \left\langle j', -(m' \pm 1) \left| \hat{T}_{-q}^{(k)} \right| j, -m \right\rangle = \\ = C_{\mp}(j, m) \left\langle j', -m' \left| \hat{T}_{-q}^{(k)} \right| j, -(m \mp 1) \right\rangle + \\ + C_{\mp}(k, q) \left\langle j', -m' \left| \hat{T}_{-(q\mp1)}^{(k)} \right| j, -m \right\rangle . \end{gathered}$$

C. Система (2) - система линейных уравнений на коэффициенты Клебша-Гордана $K_m^{j'm'}$. Эта система была получена действием операторов повышения/понижения на собственные векторы суммарного момента. Так как эти операторы действуют только на собственных для $\hat{J}^2$ подпространствах (переход между подпространствами осуществляется поиском ортогонального вектора, [4]), то эти реккурентные соотношения верны для фиксированных j, j' и k. 11 Система (2) является линейной однородной системой с известными коэффициентами $C_{\pm}(j, m)$ для поиска коэффициентов Клебша-Гордана $K_{mq}^{j'm'}$, которые можно нумеровать сквозным параметром $i = \{m, m', q\} : K_{mq}^{j''} = K_i(j, j', k)$. Найденные коэффициенты Клебша-Гордана будем называть вектором решения, понимая под термином "вектор" не объект с определёнными трансформационными свойствами при замене координат, а просто набор чисел, нумеруемых индексом i.

Из процедуры сложения моментов для каждого фиксированного j' точно известны коэффициенты Клебша-Гордана, если мы нормируем хотя бы один собственный вектор суммарного момента. При решении системы (2) нормировки вектора не происходит, и, значит, коэффициенты Клебша-Гордана находятся с точностью до одного для всех

постоянного множителя. Значит, решение системы (2) образует одномерное пространство.

Система (3) - та же самая линейная система с теми же коэффициентами, но на поиск матричных элементов сферического тензора. Только что было показано, что решение этой системы является одномерным. Значит, матричные элементы должны быть пропорциональны соответствующим коэффициентам Клебша-Гордана. Коэффициент пропорциональности Λ не может зависеть от индекса i, нумерующего компоненту вектора решения, то есть Λ не зависит от m, m' и q, и может зависеть только от внешних параметров системы $-j, j'$ и k. Значит, мы можем записать:

$$\left\langle j', -m' \left| \hat{T}^{(k)}_{-(q\mp1)} \right| j, -m \right\rangle = \Lambda\left(j, j', k\right) K^{j',m'}_{j,m;k,(q\mp1)}.$$

Окончательно, меняя знак у проекции моментов в левой части равенства и обозначая $q' = (q \mp 1)$, получаем стандартную форму утверждения теоремы Вигнера-Эккарта:

$$\left\langle j', m' \left| \hat{T}^{(k)}_{q'} \right| j, m \right\rangle = \Lambda\left(j, j', k\right) K^{j',m'}_{j,m;k,q'}$$

Тем самым теорема доказана.

Матричный элемент неприводимого тензорного оператора $T^{(j)}_m$

что это???

пока что так и не въехал.

теорема Вигнера-Эккарта

теорема Вигнера-Эккарта утверждает, что матричный элемент неприводимого тензорного оператора $T^{(j)}_m$ порядка j с проекцией m по состояниям с заданными значениям и момента выражается через коэффициенты Клебша-Гордона в виде

$$\left\langle J, M \left| T^{(j)}_m \right| J', M' \right\rangle = \frac{\left\langle J \left\| T^{(j)} \right\| J' \right\rangle}{\sqrt{2J+1}} \left\langle J, M | J', M'; j, m \right\rangle$$

где $\left\langle J \left\| T^{(j)} \right\| J' \right\rangle$ -приведенный матричный элемент оператора, который зависит только ОТ J и J', но не зависит от проекций моментов.

Здесь фактор $1/\sqrt{2J+1}$ введен согласно общепринятому соглашению для удобства при вычислениях.

Мы по существу доказали эту теорему явным построением неприводимых тензорных Операторов общего вида [5], затем определив их трансформационные свойства.

Обычно поступают наоборот, постулируют закон преобразования величин при вращениях и отсюда получают общий вид оператора, т.е.

его матричный элемент, отвечаю щий теореме.

удобство множителя $1/\sqrt{2J+1}$

по сути никогда не понимал, в чем это удобство состоит???

пример применения теоремы Вигнера-Эккарта

а хз, я не знаю.

О применениях (???)

(мб тут и укажу про правила отбора)

Сложение по Ландау

Полученное в §31 правило сложения моментов определяет возможные значения полного момента системы, состоящей из двух частиц (или более сложных частей), обладающих моментами j_1 и j_2[1]). Это правило в действительности тесно связано со свойствами волновых функций по отношению к пространственным вращениям и непосредственно следует из свойств спиноров. Волновые функции частиц с моментами j_1 и j_2 представляют собой симметричные спиноры рангов $2j_1$ и $2j_2$, а волновая функция системы дается их произведением

$$\psi^{(1)}\overbrace{\lambda\mu\cdots}^{2j_1}\psi^{(2)}\overbrace{\rho\sigma\cdots}^{2j_2}$$

Симметризуя это произведение по всем индексам, получим симметричный спинор ранга $2(j_1+j_2)$, отвечающий состоянию с полным моментом j_1+j_2. Далее, упростим произведение (106.1) по одной паре индексов, из которых один должен принадлежать $\psi^{(1)}$, а другой - $\psi^{(2)}$ (в противном случае получится нуль); при этом, в силу симметрии каждого из спиноров $\psi^{(1)}$ и $\psi^{(2)}$, безразлично, какие именно индексы берутся из $\lambda,\mu,...$, и $\rho,\sigma,...$ После симметризации получим симметричный спинор ранга $2(j_1+j_2-1)$, отвечающий состоянию с моментом j_1+j_2-1[2]).

Продолжая этот процесс, мы найдем в соответствии с известным уже нам правилом, что j пробегает значения от j_1+j_2 до $|j_1-j_2|$, причем каждое по одному разу. С математической точки зрения, речь идет здесь о разложении прямого произведения $D^{(j_1)}\times D^{(j_2)}$ двух неприводимых представлений группы вращений (с размерностями $2j_1+1$ и $2j_2+1$) на неприводимые части. В этих терминах правило сложения моментов записывается в виде разбиения

$$D^{(j_1)}\times D^{(j_2)}=D^{(j_1+j_2)}+D^{(j_1+j_2-1)}+...+D^{(|j_1-j_2|)}.$$

Для полного решения задачи о сложении моментов мы должны еще рассмотреть вопрос о составлении волновой функции системы с заданным значением полного момента по волновым функциям составляющих ее двух частиц.

Начнем с наиболее простого случая сложения двух моментов в равный нулю суммарный момент. При этом, очевидно, должно быть $j_1=j_2$, а проекции моментов $m_1=-m_2$. Пусть ψ_{jm} - нормированные волновые функции состояний одной частицы с моментом j и его проекцией m (в неспинорном представлении). Искомая волновая функция системы ψ_0 представляет собой сумму произведений волновых функций обеих частиц с противоположными значениями m:

$$\psi_0=\frac{1}{\sqrt{2j+1}}\sum_{m=-j}^{j}(-1)^{j-m}\psi^{(1)}_{jm}\psi^{(2)}_{j,-m}$$

(j- общее значение j_1 и j_2). Множитель перед суммой есть результат нормировки. Что касается коэффициентов в сумме, то все они должны быть одинаковы по своей абсолютной величине - уже в силу того, что все значения проекций m моментов частиц равновероятны. Порядок же чередования знаков в (106.2) легко найти с помощью спинорного представления волновых функций. В спинорных обозначениях сумма в (106.2) представляет собой скаляр (полный момент системы равен нулю!)

$$\psi^{(1)\lambda\mu...}\psi^{(2)}_{\lambda\mu...}$$

составленный из двух спиноров ранга $2j$. Заметив это, мы найдем знаки в (106.2) непосредственно из формулы (57.3).

Следует, однако, иметь в виду, что однозначными являются, вообще говоря, лишь относительные знаки членов суммы (106.2), общий же знак может оказаться зависящим от

«порядка сложения» моментов. Действительно, если опустить все спинорные индексы (среди которых $j+m$ единиц и $j-m$ двоек) у $\psi^{(1)}$ и поднять у $\psi^{(2)}$, то скаляр (106.3) умножится на $(-1)^{2j}$, т. е. при полуцелом j изменит знак.

Далее, рассмотрим систему с равным нулю полным моментом, составленную из трех частиц с моментами j_1, j_2, j_3 и их проекциями m_1, m_2, m_3. Условие равенства полного момента нулю подразумевает, что $m_1+m_2+m_3=0$, а j_1, j_2, j_3 имеют такие значения, что каждое из них может получиться в результате векторного сложения двух других, т.е. геометрически j_1, j_2, j_3 должны быть сторонами замкнутого треугольника; другими словами, каждое из них не меньше разности и не больше суммы двух других:

$$|j_1-j_2| \leqslant j_3 \leqslant j_1+j_2 \quad \text{и т. д.}$$

Очевидно, что алгебраическая сумма $j_1+j_2+j_3$ является при этом целым числом.

Волновая функция рассматриваемой системы имеет вид суммы

$$\psi_0 = \sum_{m_1 m_2 m_3} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \psi^{(1)}_{j_1 m_1} \psi^{(2)}_{j_2 m_2} \psi^{(3)}_{j_3 m_3},$$

взятой по значениям каждого из m_j в пределах от $-j_1$ до j_1. Коэффициенты в этой формуле называют $3j$-символами Вагнера. По определению, они отличны от нуля только при условии

$$m_1+m_2+m_3=0$$

При перестановке индексов $1,2,3$ волновая функция (106.4) может измениться лишь на несущественный фазовый множитель. Фактически $3j$-символы могут быть определены как чисто вещественные (см. ниже) и тогда неоднозначность ψ_0 может заключаться лишь в неопределенности ее общего знака (как это имеет место и для функции (106.2)). Это значит, что перестановка колонок $3j$-символа может либо оставлять его неизменным, либо менять его знак.

Наиболее симметричный способ определения коэффициентов в сумме (106.4), которым и принято определять $3j$-символы, заключается в следующем. В спинорных обозначениях ψ_0 представляет собой скаляр, составленный как произведение трех спиноров $\psi^{(1)\lambda\mu\cdots}, \psi^{(2)\lambda\mu\cdots}, \psi^{(3)\lambda\mu\cdots}$, упрощенное по всем парам индексов, каждая из которых относится к двум различным спинорам. Условимся, что в каждой паре, относящейся к частицам 1 и 2, спинорный индекс будет писаться сверху у $\psi^{(1)}$ и снизу у $\psi^{(2)}$; в паре, относящейся к частицам 2 и 3, - сверху у $\psi^{(2)}$ и снизу у $\psi^{(3)}$; в паре, относящейся к частицам 3 и 1, - сверху у $\psi^{(3)}$ и снизу у $\psi^{(1)}$ (легко подсчитать, что всего имеется соответственно $j_1+j_2-j_3, j_2+j_3-j_1$ и $j_1+j_3-j_2$ пар каждого из этих «сортов»). Этим правилом знак ψ_0 устанавливается однозначно. Очевидно, что при таком определении циклическая перестановка индексов $1,2,3$ оставляет ψ_0 неизменной. Это значит, что $3j$-символ не меняется при циклической перестановке его столбцов. Перестановка же двух (любых) индексов приведет, как легко сообразить, к необходимости поднять нижние и опустить верхние индексы во всех $j_1+j_2+j_3$ парах. Это значит, что ψ_0 умножится на $(-1)^{j_1+j_2+j_3}$; другими словами, $3j$-символы обладают свойством

$$\begin{pmatrix} j_2 & j_1 & j_3 \\ m_2 & m_1 & m_3 \end{pmatrix} = (-1)^{j_1+j_2+j_3} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \quad \text{и т. д.},$$

т. е. меняют знак при перестановке двух колонок, если $j_1 + j_2 + +j_3$ - нечетное число. Наконец, легко видеть, что

$$\begin{pmatrix} j_1 & j_2 & j_3 \\ -m_1 & -m_2 & -m_3 \end{pmatrix} = (-1)^{j_1+j_2+j_3} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}$$

Действительно, изменение знака z-компонент всех моментов может рассматриваться как результат поворота на угол π вокруг оси y. Но такое преобразование эквивалентно поднятию всех нижних и опусканию всех верхних спинорных индексов (cm. (58.5)).

От выражения (106.4) можно перейти к важной формуле, определяющей волновую функцию ψ_{jm} системы, состоящей из двух частиц и обладающей заданными значениями j и m. Для этого будем рассматривать совокупность частиц 1 и 2 как одну систему. Поскольку момент $\mathbf{j}$ этой системы вместе с моментом $\mathbf{j}_3$ частицы 3 складывается в равный нулю суммарный момент, должно быть $j = j_3, m = -m_3$. Согласно (106.2) можно тогда написать

$$\psi_0 = \frac{1}{\sqrt{2j+1}} \sum_m (-1)^{j-m} \psi_{jm} \psi^{(3)}_{j,-m}$$

Эту формулу надо сравнить с выражением (106.4) (в котором пишем $j, -m$ вместо j_3, m_3). При этом, однако, надо предварительно учесть, что правило составления суммы в (106.7) согласно (106.3) не соответствует правилу составления суммы (106.4): для приведения (106.7) к (106.4) надо, как легко сообразить, переставить верхние и нижние индексы в парах, соответствующих частицам 1 и 3; это приводит к появлению дополнительного множителя $(-1)^{j_1-j_2+j_3}$. В результате получим [1])

$$\psi_{jm} = (-1)^{j_1-j_2+m} \sqrt{2j+1} \sum_{m_1,m_2} \begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix} \psi^{(1)}_{j_1 m_1} \psi^{(2)}_{j_2 m_2}$$

где суммирование по m_1 и m_2 производится с учетом условия $m_1 + m_2 = m$

Формула (106.8) дает искомое разложение волновой функции системы по волновым функциям обеих частиц, обладающих определенными моментами j_1 и j_2. Ее можно записать в виде

$$\psi_{jm} = \sum_{m_1 m_2} \langle m_1 m_2 | jm \rangle \, \psi^{(1)}_{j_1 m_1} \psi^{(2)}_{j_2 m_2}, \quad m_2 = m - m_1.$$

Коэффициенты

$$\langle m_1 m_2 | jm \rangle = (-1)^{j_1-j_2+m} \sqrt{2j+1} \begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix}$$

составляют матрицу преобразования от полной ортонормированной системы $(2j_1+1)(2j_2+1)$ волновых функций состояний $|m_1 m_2\rangle$ к такой же системе волновых функций состояний $|jm\rangle$ (при заданных значениях j_1, j_2). Их называют коэффициентами векторного сложения или коэффициентами Клебша-Гордана. Обозначение символом $\langle m_1 m_2 | jm \rangle$ соответствует общему способу обозначений коэффициентов разложения одной системы функций по другой согласно (11.18). Для упрощения записи мы опустили в этом символе совпадающие в обеих системах функций квантовые числа j_1, j_2; при необходимости эти числа включаются в обозначение: $\langle j_1 m_1 j_2 m_2 | j_1 j_2 jm \rangle^2$).

Матрица преобразования (106.9) унитарна (см. §12). Поэтому коэффициенты обратного преобразования

$$\psi^{(1)}_{j_1 m_1} \psi^{(2)}_{j_2 m_2} = \sum_{j=|j_2-j_1|}^{j_1+j_2} \langle j, m_1+m_2 | m_1 m_2 \rangle \, \psi_{j,m_1+m_2}$$

комплексно сопряжены с коэффициентами преобразования A06.9). Мы увидим ниже, что эти коэффициенты вещественны; поэтому просто

$$\langle m_1 m_2 | jm \rangle = \langle jm | m_1 m_2 \rangle \,.$$

Согласно общим правилам квантовой механики квадраты коэффициентов разложения (106.11) определяют вероятности системе иметь те или иные значения j, m (при заданных j_1, m_1 и j_2, m_2). Унитарность преобразования (106.9) означает, что его коэффициенты удовлетворяют определенным условиям ортогональности. Согласно формулам (12.5), (12.6) имеем

$$\begin{aligned}
&\sum_{m_1 m_2} \langle m_1 m_2 | jm \rangle \langle m_1 m_2 | j'm' \rangle = \\
=&(2j+1) \sum_{m_1, m_2} \begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix} \begin{pmatrix} j_1 & j_2 & j' \\ m_1 & m_2 & -m' \end{pmatrix} = \delta_{jj'} \delta_{mm'}, \\
&\sum_{j} \langle m_1 m_2 | jm \rangle \langle m_1' m_2' | jm \rangle = \\
&= \sum_{j} (2j+1) \begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix} \begin{pmatrix} j_1 & j_2 & j \\ m_1' & m_2' & -m \end{pmatrix} = \delta_{m_1 m_1'} \delta_{m_2 m_2'}.
\end{aligned}$$

Явное общее выражение $3j$-символов довольно громоздко. Оно может быть представлено в виде [1])

$$\begin{aligned}
\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} = &\left[\frac{(j_1+j_2-j_3)!\,(j_1-j_2+j_3)!\,(-j_1+j_2+j_3)!}{(j_1+j_2+j_3+1)!} \right]^{1/2} \times \\
\times &\left[(j_1+m_1)!\,(j_1-m_1)!\,(j_2+m_2)!\,(j_2-m_2)!\,(j_3+m_3)!\,(j_3-m_3)! \right]^{1/2} \times \\
&\times \sum_z \Big\{ [) - 1)^{z+j_1-j_2-m_3}] \left[z!\,(j_1+j_2-j_3-z)!\,(j_1-m_1-z)! \times \right. \\
&\left. \times (j_2+m_2-z)!\,(j_3-j_2+m_1+z)!\,(j_3-j_1-m_2+z)! \right]^{-1} \Big\} \,.
\end{aligned}$$

Суммирование производится по всем целым числам z; однако, поскольку факториал отрицательного числа равен ∞, число членов в сумме фактически конечно. Коэффициент перед суммой явно симметричен по индексам $1, 2, 3$; симметрия же суммы выявляется после соответствующего переобозначения переменной суммирования z.

Помимо свойств симметрии (106.5), (106.6), следующих простым образом из определения $3j$-символов, последние обладают еще и другими свойствами симметрии, вывод которых, однако, более сложен, и мы его здесь не приводим. Эти свойства удобно формулировать, если ввести квадратную (3×3) таблицу чисел, связанных с параметрами $3j$-символа следующим образом:

$$\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} = \begin{bmatrix} j_2+j_3-j_1 & j_3+j_1-j_2 & j_1+j_2-j_3 \\ j_1-m_1 & j_2-m_2 & j_3-m_3 \\ j_1+m_1 & j_2+m_2 & j_3+m_3 \end{bmatrix}$$

(сумма чисел в каждой строке и каждом столбце этой таблицы равна $j_1+j_2+j_3$). Тогда: 1) перестановка любых двух столбцов таблицы умножает $3j$-символ на $(-1)^{j_1+j_2+j_3}$ (это свойство совпадает с (106.5)); 2) то же справедливо для перестановки любых двух строк (в отношении двух нижних строк это свойство совпадает с (106.6)); 3) 3j-символ не меняется при замене строк таблицы ее столбцами [1]).

Выпишем ряд более простых формул для некоторых частных случаев. Значение

$$\begin{pmatrix} j & j & 0 \\ m & -m & 0 \end{pmatrix} = (-1)^{j-m}\frac{1}{\sqrt{2j+1}}$$

соответствует формуле (106.2). Формулы

$$\begin{pmatrix} j_1 & j_2 & j_1+j_2 \\ m_1 & m_2 & -m_1-m_2 \end{pmatrix} = (-1)^{j_1-j_2+m_1+m_2}\times$$
$$\times\left[\frac{(2j_1)!\,(2j_2)!\,(j_1+j_2+m_1+m_2)!\,(j_1+j_2-m_1-m_2)!}{(2j_1+2j_2+1)!\,(j_1+m_1)!\,(j_1-m_1)!\,(j_2+m_2)!\,(j_2-m_2)!}\right]^{1/2},$$
$$\begin{pmatrix} j_1 & j_2 & j_3 \\ j_1 & -j_1-m_3 & m_3 \end{pmatrix} = (-1)^{-j_1+j_2+m_2}\times$$
$$\times\left[\frac{(2j_1)!\,(-j_1+j_2+j_3)!\,(j_1+j_2+m_3)!\,(j_3-m_3)!}{(j_1+j_2+j_3+1)!\,(j_1-j_2+j_3)!\,(j_1+j_2-j_3)!\,(-j_1+j_2-m_3)!\,(j_3+m_3)!}\right]^{1/2}$$

получаются непосредственно из (106.14). Вывод же формулы

$$\begin{pmatrix} j_1 & j_2 & j_3 \\ 0 & 0 & 0 \end{pmatrix} = (-1)^p\left[\frac{(j_1+j_2-j_3)!(j_1-j_2+j_3)!(-j_1+j_2+j_3)!}{(2p+1)!}\right]^{1/2}\frac{p!}{(p-j_1)!(p-j_2)!(p-j_3)!},$$

где

$$2p = j_1+j_2+j_3$$

есть четное число, требует ряда дополнительных вычислений [1]) (при нечетном $2p$ этот $3j$-символ равен нулю в силу свойства симметрии (106.6)).

В табл. 9 приведены, для справок, значения $3j$-символов для $j_3 = 1/2, 1, 3/2, 2$. Для каждого j_3 указано минимальное число $3j$-символов, из которых с помощью соотношений (106.5), (106.6) можно получить остальные.

(тут большая таблица, ну и фиг с ней, не до нее, все равно чуть что сборник свойств углового момента буду открывать, если будет это нужно.)

ЛЛ-108.1

Определить угловую зависимость волновых функций частицы со спином $1/2$ в состояниях с заданными значениями орбитального момента l, полного момента j и его проекции m.

Р е ш е н и е.

Задача решается общей формулой (106.8), в которой надо под $\psi^{(1)}$ понимать собственные функции орбитального момента (т. е. сферические функции Y_{lm_l}), а под $\psi^{(2)}$ - спиновую волновую функцию $\chi(\sigma)$ (где $\sigma = \pm 1/2$):

$$\psi_{jm} = (-1)^{l+m-1/2}\sqrt{2j+1}\sum_\sigma \begin{pmatrix} l & 1/2 & j \\ m-\sigma & \sigma & -m \end{pmatrix} Y_{l,m-\sigma}\chi(\sigma).$$

Подставив значения $3j$-символов, получим

$$\psi_{l+1/2,m} = \sqrt{\frac{j+m}{2j}}\chi\left(\frac{1}{2}\right)Y_{l,m-1/2} + \sqrt{\frac{j-m}{2j}}\chi\left(-\frac{1}{2}\right)Y_{l,m+1/2},$$
$$\psi_{l-1/2,m} = -\sqrt{\frac{j-m+1}{2j+2}}\chi\left(\frac{1}{2}\right)Y_{l,m-1/2} + \sqrt{\frac{j+m+1}{2j+2}}\chi\left(-\frac{1}{2}\right)Y_{l,m+1/2}.$$

9.0.3 Matrix Elements of Tensors by Landau (?????)

Теория

В § 29 были получены формулы, определяющие зависимость матричных элементов векторной физической величины от значения проекции момента. Эти формулы являются в действительности частным случаем общих формул, решающих такую же задачу для неприводимого (см. с. 268) тензора любого ран Гa^1)

Совокупность $2k+1$ компонент неприводимого тензора ранга k(k - целое число) по своим трансформационным свойствам эквивалентна совокупности $2k+1$ сферических функций $Y_{kq}(q=-k,...,k)$ (см. примеч. на с. 268). Это значит, что путем составления соответствующих линейных комбинаций компонент тензора можно получить набор величин, преобразующихся при вращениях как функции Y_{kq}. Совокупность таких величин, которые мы будем обозначать здесь через f_{kq}, назовем сферическим тензором ранга k.

Так, вектору соответствует значение $k=1$, а величины f_{1q} связаны с компонентами вектора следующими формулами:

$$f_{10}=ia_z,\quad f_{1,\pm1}=\mp(i/\sqrt{2})\,(a_x\pm ia_y)$$

(ср. (57.7)). Аналогичные формулы для тензора второго ранга имеют вид

$$f_{20}=-\sqrt{3/2}a_{zz},\quad f_{2,\pm1}=\pm\,(a_{xz}\pm ia_{yz})\,,$$
$$f_{2,\pm2}=-(1/2)\,(a_{xx}-a_{yy}\pm 2ia_{xy})\,.$$

причем $a_{xx}+a_{yy}+a_{zz}=0$[1]). Составление тензорных произведений из двух (или большего числа) сферических тензоров $f_{k_1q_1}, f_{k_2q_2}$ происходит в соответствии с правилами сложения моментов, причем k_1, k_2 играют формально роль «моментов», соответствующих этим тензорам. Таким образом, из двух сферических тензоров рангов k_1 и k_2 можно образовать сферические тензоры рангов $K=k_1++k_2,...,|k_1-k_2|$ по формулам

$$(f_{k_1}g_{k_2})_{KQ}=\sum_{q_1q_2}\langle q_1q_2|KQ\rangle\, f_{k_1q_1}g_{k_2q_2}=$$
$$=(-1)^{k_1-k_2+Q}\sqrt{2K+1}\sum_{q_1q_2}\begin{pmatrix}k_1 & k_2 & K\\ q_1 & q_2 & -Q\end{pmatrix} f_{k_1q_1}g_{k_2q_2}$$

(ср. (106.9)). Скалярное произведение двух сферических тензоров одинакового ранга k принято, однако, определять как

$$(f_kg_k)_{00}=\sum_q(-1)^{k-q}f_{kq}g_{k,-q}$$

что отличается от определения по формуле (107.3) с $K=Q=0$ множителем $\sqrt{2k+1}$(ср. (106.2))[2]). Это определение можно представить также в виде

$$(f_kg_k)_{00}=\sum_q f_{kq}g^*_{kq},$$

если заметить, что комплексное сопряжение сферического тензора производится по правилу

$$f^*_{kq}=(-1)^{k-q}f_{k,-q}$$

ср. (28.9)[3]).

Представление физических величин в виде сферических тензоров в особенности удобно при вычислении их матричных элементов, так как позволяет воспользоваться для этой цели результатами теории сложения моментов. По определению матричных элементов, имеем

$$\widehat{f}_{kq}\psi_{njm} = \sum_{n'j'm'} \langle n'j'm' \,|f_{kq}|\, njm\rangle \, \psi_{n'j'm'},$$

где ψ_{njm} - волновые функции стационарных состояний системы, характеризуемых величиной ее момента j, его проекцией m и набором остальных квантовых чисел n. По своим трансформационным свойствам функции в правой и левой частях равенства (107.5)) соответствуют функциям в правой и левой частях равенства (106.11). Отсюда сразу следуют правила отбора.

Матричные элементы компонент f_{kq} неприводимого тензора ранга k отличны от нуля лишь для переходов $jm \to j'm'$, удовлетворяющих «правилу сложения моментов» $\mathbf{j}' = \mathbf{j} + \mathbf{k}$; при этом числа j', j, k должны удовлетворять «правилу треугольника» (т.е. могут измерять стороны замкнутого треугольника), а $m' = m + q$. В частности, диагональные матричные элементы могут быть отличны от нуля только при условии $2j \geqslant k$.

Далее, из той же трансформационной аналогии следует, что коэффициенты в сумме (107.5) должны быть пропорциональны коэффициентам в (106.11) (теорема Вагнера-Эккарта). Этим определяется зависимость коэффициентов от чисел m, m', в соответствии с чем представим матричные элементы в виде

$$\langle n'j'm' \,|f_{kq}|\, njm\rangle = i^k(-1)^{j_{\max}-m'} \begin{pmatrix} j' & k & j \\ -m' & q & m \end{pmatrix} \langle n'j' \,\|f_k\|\, nj\rangle$$

($j_{\max}$ - большее из чисел j и j'), где $\langle n'j' \,\|f_k\|\, nj\rangle$ - величины, не зависящие от m, m', q'; их называют приведенными матричными элементами. Эта формула решает поставленный вопрос об определении зависимости матричных элементов от проекций моментов. Эта зависимость оказывается полностью связанной со свойствами симметрии по отношению к группе вращений, между тем как зависимость от остальных квантовых чисел определяется уже физической природой самих величин f_{kq}[1]).

Операторы $\widehat{f}_{kq}$ связаны друг с другом соотношениями

$$\widehat{f}^{+}_{kq} = (-1)^{k-q}\widehat{f}_{k,-q}.$$

Поэтому для их матричных элементов имеет место равенство

$$\langle n'j'm' \,|f_{kq}|\, njm\rangle^* = (-1)^{k-q} \langle njm \,|f_{k,-q}|\, n'j'm'\rangle \,.$$

Подставив сюда (107.6) и воспользовавшись свойствами $3j$-символов (106.5), (106.6), получим для приведенных матричных элементов соотношение «эрмитовости» [1])

$$\langle n'j' \,\|f_k\|\, nj\rangle = \langle nj \,\|f_k\|\, n'j'\rangle^*$$

Матричные элементы скаляра (107.4) диагональны по j и m. Согласно правилу умножения матриц имеем

$$\langle n'jm \,|(f_k g_k)_{00}|\, njm\rangle = \\ = \sum_q (-1)^{k-q} \sum_{n''j''m''} \langle n'jm \,|f_{kq}|\, n''j''m''\rangle \, \langle n''j''m'' \,|g_{k,-q}|\, njm\rangle \,.$$

Подставив сюда выражения (107.6) и произведя суммирование по q и m'' с помощью соотношения ортогональности $3j$-символов (106.12), получим следующую формулу:

$$\langle n'jm \,|(f_k g_k)_{00}|\, njm\rangle = \frac{1}{2j+1} \sum_{n''j''} \langle n'j \,\|f_k\|\, n''j''\rangle \, \langle n''j'' \,\|g_k\|\, nj\rangle \,.$$

Аналогичным образом легко получить следующие формулы суммирования квадратов матричных элементов:

$$\sum_{qm'} |\langle n'j'm' | f_{kq} | njm\rangle|^2 = \frac{1}{2j+1} |\langle n'j' \| f_k \| nj\rangle|^2,$$
$$\sum_{mm'} |\langle n'j'm' | f_{kq} | njm\rangle|^2 = \frac{1}{2k+1} |\langle n'j' \| f_k \| nj\rangle|^2.$$

В первой из них суммирование производится по q и m' при заданном m, а во второй - по m и m' при заданном q (причем всегда $m' = m + q$)

Рассмотрим, со справочными целями, случай, когда величинами f_{kq} являются сами шаровые функции Y_{kq}, и дадим выражения их матричных элементов для переходов между состояниями одной частицы с целочисленными орбитальными моментами l_1 и l_2, т. е. интегралов

$$\langle l_1 m_1 | Y_{lm} | l_2 m_2\rangle = \int Y^*_{l_1 m_1} Y_{lm} Y_{l_2 m_2} do.$$

Помимо правила отбора, соответствующего правилу сложения моментов ($\mathbf{l} + \mathbf{l}_2 = \mathbf{l}_1$), для этих матричных элементов имеет место также правило, согласно которому сумма $l + l_1 + l_2$ должна быть четным числом. Оно связано с сохранением четности, в силу которого произведение четностей $(-1)^{l_1+l_2}$ обоих состояний должно совпадать с четностью $(-1)^l$ рассматриваемой физической величины (см. § 30).

Матричные элементы (107.13) являются частным случаем более общего интеграла, который будет вычислен в §110 (см. примеч. на с. 547). Они даются формулой

$$\langle l_1 m_1 | Y_{lm} | l_2 m_2\rangle = (-1)^{m_1} i^{-l_1+l_2+l} \begin{pmatrix} l_1 & l & l_2 \\ -m_1 & m & m_2 \end{pmatrix} \begin{pmatrix} l_1 & l & l_2 \\ 0 & 0 & 0 \end{pmatrix} \left[\frac{(2l+1)(2l_1+1)(2l_2+1)}{4\pi}\right]^{1/2}.$$

В частности, при $m_1 = m_2 = m = 0$ находим значение интеграла от произведения трех полиномов Лежандра

$$\int_{-1}^{1} P_l(\mu) P_{l_1}(\mu) P_{l_2}(\mu) d\mu = 2 \begin{pmatrix} l_1 & l & l_2 \\ 0 & 0 & 0 \end{pmatrix}^2$$

9.0.4 6j-Symbols by Landau

Теория

Мы определили в §106 $3j$-символы как коэффициенты в сумме (106.4), представляющей собой волновую функцию системы трех частиц с равным нулю полным моментом. С точки зрения трансформационных свойств по отношению к вращениям эта сумма является скаляром. Отсюда следует, что набор $3j$-символов с заданными значениями j_1, j_2, j_3 (и всеми возможными m_1, m_2, m_3) можно рассматривать как совокупность величин, преобразующихся при вращениях по закону, контраградиентному закону преобразования произведений $\psi_{j_1 m_1} \psi_{j_2 m_2} \psi_{j_3 m_3}$ - так, чтобы обеспечить инвариантность всей суммы.

В связи с такой точкой зрения можно поставить вопрос о построении скаляра, составленного из одних только $3j$-символов. Такой скаляр должен зависеть только от чисел j, но не от чисел m, меняющихся при вращениях. Другими словами, он должен выражаться в виде сумм по всем числам m. Каждое такое суммирование состоит в

«упрощении» произведения двух $3j$-символов по правилу

$$\sum_m (-1)^{j-m} \begin{pmatrix} j.. \\ m.. \end{pmatrix} \begin{pmatrix} j.. \\ -m.. \end{pmatrix}$$

(ср. способ составления скаляра (106.2)).

Поскольку в каждом «упрощении» фигурирует пара чисел m, для составления полного скаляра надо рассматривать произведения четного числа $3j$-символов. Упрощение произведения двух $3j$-символов приводит, в силу свойства их ортогональности, к тривиальному результату:

$$\sum_{m_1 m_2 m_3} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \begin{pmatrix} j_1 & j_2 & j_3 \\ -m_1 & -m_2 & -m_3 \end{pmatrix} \times$$

$$\times (-1)^{j_1+j_2+j_3-m_1-m_2-m_3} = \sum_{m_1 m_2 m_3} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}^2 = 1$$

(здесь использовано равенство $m_1 + m_2 + m_3 = 0$ и формулы (106.6) и (106.12)). Поэтому наименьшее число сомножителей, необходимое для получения нетривиального скаляра, равно четырем. В каждом $3j$-символе три числа j составляют геометрически замкнутый треугольник. Поскольку каждое число j должно фигурировать, при «упрощении», в двух $3j$-символах, то ясно, что при составлении скаляра из произведений четырех $3j$-символов имеется 6 чисел j, которые геометрически должны изображаться длинами ребер неправильного тетраэдра (рис. 45); каждому из $3j$-символов соответствует одна из его граней. В определении искомого скаляра принято определенное условие в отношении произведения процесса упрощения, выражаемое следующей формулой:

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ j_4 & j_5 & j_6 \end{Bmatrix} = \sum_{\text{все } m} (-1)^{\sum_i^{i(j_i - m_i)}} \begin{pmatrix} j_1 & j_2 & j_3 \\ -m_1 & -m_2 & -m_3 \end{pmatrix} \times$$

$$\times \begin{pmatrix} j_1 & j_5 & j_6 \\ m_1 & -m_5 & m_6 \end{pmatrix} \begin{pmatrix} j_4 & j_2 & j_6 \\ m_4 & m_2 & -m_6 \end{pmatrix} \begin{pmatrix} j_4 & j_5 & j_3 \\ -m_4 & m_5 & m_3 \end{pmatrix}$$

Суммирование производится здесь по всем возможным значениям всех чисел m; поскольку, однако, сумма трех m в каждом $3j$-символе должна быть равна нулю, фактически лишь три из шести m независимы. Величины, определенные формулой (108.2), называют $6j$-символами или коэффициентами *Рака*[1]).

Из определения (108.2), с учетом свойств симметрии $3j$-символов, легко убедиться в том, что $6j$-символ не меняется при Рис. 45 любой перестановке трех его столбцов, а в каждой паре столбцов можно переставить верхнее и нижнее числа. В силу этих свойств симметрии последовательность чисел $j_1 \ldots j_6$ в $6j$-символе можно представить в 24 эквивалентных видах [2]). Кроме того, $6j$-символы обладают еще одним, менее очевидным, свойством симметрии, устанавливающим равенство между символами с различными наборами чисел j:

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ j_4 & j_5 & j_6 \end{Bmatrix} = \begin{Bmatrix} j_1 & \frac{1}{2}(j_2 + j_5 + j_3 - j_6) & \frac{1}{2}(j_3 + j_6 + j_2 - j_5) \\ j_4 & \frac{1}{2}(j_2 + j_5 + j_6 - j_3) & \frac{1}{2}(j_3 + j_6 + j_5 - j_2) \end{Bmatrix}$$

(T. Regge, 1959) Укажем полезное соотношение между $6j$ - и $3j$-символами, которое можно получить с помощью определения (108.2):

$$\sum_{m_4 m_5 m_6} (-1)^{j_4+j_5+j_6-m_4-m_5-m_6} \begin{pmatrix} j_1 & j_5 & j_6 \\ m_1 & -m_5 & m_6 \end{pmatrix} \begin{pmatrix} j_4 & j_2 & j_6 \\ m_4 & m_2 & -m_6 \end{pmatrix} \times$$

$$\times \begin{pmatrix} j_4 & j_5 & j_3 \\ -m_4 & m_5 & m_3 \end{pmatrix} = \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \begin{Bmatrix} j_1 & j_2 & j_3 \\ j_4 & j_5 & j_6 \end{Bmatrix}. \quad (108.4)$$

Выражение, суммируемое в левой части равенства, отличается от суммы в (108.2), отсутствием одного множителя (3j-символа). Можно сказать поэтому, что сумма в (108.4) изображается тетраэдром (рис. 45) без одной из его граней; этим определяется отличие суммы от скаляра. Другими словами, по своим трансформационным свойствам она соответствует одному $3j$-символу - стоящему в правой части равенства (108.4), которому она должна быть пропорциональна. Коэффициент же пропорциональности ($6j$-символ в правой части равенства) легко получить, умножив обе части равенства на

$$\begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}$$

и просуммировав по оставшимся числам m_1, m_2, m_3. $6j$-символы появляются естественным образом при рассмотрении следующего вопроса, связанного со сложением трех моментов.

Пусть три момента j_1, j_2, j_3 складываются в результирующий момент J. Заданием момента J (и его проекции M) состояние системы, однако, еще не определяется однозначным образом; оно зависит и от способа сложения моментов (или, как говорят, от схемы их связи).

Рассмотрим, например, такие две схемы связи: 1) сначала моменты j_1 и j_2 складываются в суммарный момент j_{12}, а затем j_{12} и j_3 складываются в окончательный момент J; 2) моменты j_2 и j_3 складываются в j_{23}, а затем j_{23} и j_1 - в J. Первой схеме соответствуют состояния, в которых (наряду с $j_1, j_2 j_3,\ J, M$) имеет определенное значение величина j_{12}; их волновые функции обозначим через $\psi_{j_{12}JM}$ (опуская, для краткости, повторяющиеся индексы $j_1 j_2 j_3$). Аналогично, волновые функции второй схемы связи обозначим через $\psi_{j_{23}JM}$ В обоих случаях значения «промежуточного» момента (j_{12} или j_{23}), вообще говоря, неоднозначны, так что мы имеем (при заданных J, M) два различных набора состояний, различающихся значениями j_{12} или j_{13}. Согласно общим правилам функции этих двух наборов связаны друг с другом определенным унитарным преобразованием

$$\psi_{j_{23}JM} = \sum_{j_{12}} \langle j_{12}|j_{23}\rangle\, \psi_{j_{12}JM}$$

Из физических соображений очевидно, что коэффициенты этого преобразования не зависят от числа M - они не могут зависеть от ориентации всей системы в пространстве. Таким образом, они зависят лишь от значений шести моментов лярными (в указанном выше смысле) величинами. Фактическое вычисление этих коэффициентов легко произвести следующим образом. Путем двукратного применения формулы (106.9) находим

$$\begin{aligned}\psi_{j_{23}JM} &= \sum_{(m)} \langle m_1 m_{23}|JM\rangle\, \psi_{j_1 m_1}\psi_{j_{23}m_{23}} = \\ &= \sum_{(m)} \langle m_1 m_{23}|JM\rangle\, \langle m_2 m_3|j_{23}m_{23}\rangle\, \psi_{j_1 m_1}\psi_{j_2}m_2\psi_{j_3 m_3}, \\ \psi_{j_{12}JM} &= \sum_{(m)} \langle m_3 m_{12}|JM\rangle\, \langle m_1 m_2|j_{12}m_{12}\rangle\, \psi_{j_1 m_1}\psi_{j_2 m_2}\psi_{j_3 m_3}\end{aligned}$$

(знак (m) под знаком суммы означает, что суммирование производится по всем входящим в выражение числам $m_1, m_2, \ldots$). Используя ортонормированность функций ψ_{jm}, найдем теперь

$$\begin{aligned}&\langle j_{12}|j_{23}\rangle \equiv \int \psi^*_{j_{12}JM}\psi_{j_{23}JM}dq = \\ &= \sum_{(m)} \langle m_3 m_{12}|JM\rangle\, \langle m_1 m_{23}|JM\rangle\, \langle m_1 m_2|j_{12}m_{12}\rangle\, \langle m_2 m_3|j_{23}m_{23}\rangle\,.\end{aligned}$$

Сумма в правой части равенства берется при заданном значении M, но результат суммирования в действительности (по указанной выше причине) от M не зависит. Поэтому суммирование можно распространить и по значениям M, введя при этом перед суммой множитель $1/(2J+1)$. Выражая затем коэффициенты $\langle m_1 m_2|jm\rangle$ через $3j$-символы согласно (106.10), получим:

$$\langle j_{12}|j_{23}\rangle = (-1)^{j_1+j_2+j_3+J}\sqrt{(2j_{12}+1)\,(2j_{23+1})}\left\{\begin{array}{ccc} j_1 & j_2 & j_{12} \\ j_3 & J & j_{23}\end{array}\right\}.$$

Связь $6j$-символов с коэффициентами преобразования (108.5) позволяет легко получить некоторые полезные формулы для суммирования произведений $6j$-символов.

Прежде всего, в силу унитарности преобразования (108.5) (и вещественности его коэффициентов), имеет место соотношение

$$\sum_j (2j+1)\,(2j''+1)\left\{\begin{array}{ccc} j_1 & j_2 & j' \\ j_3 & j_4 & j\end{array}\right\}\left\{\begin{array}{ccc} j_3 & j_2 & j \\ j_1 & j_4 & j''\end{array}\right\} = \delta_{j'j''}$$

Далее рассмотрим три схемы связи трех моментов-с промежуточными суммами соответственно j_{12}, j_{23} и j_{31}. Коэффициенты соответствующих преобразований (108.6) связаны между собой, согласно правилу умножения матриц, соотношением

$$\sum_{j_{23}} \langle j_{12}|j_{23}\rangle\,\langle j_{23}|j_{31}\rangle = \langle j_{12}|j_{31}\rangle$$

Подставив сюда (108.6) и изменив обозначение индексов, получим

$$\sum_j (-1)^{j+j_3+j_6}(2j+1)\left\{\begin{array}{ccc} j_2 & j_4 & j_6 \\ j_1 & j_5 & j\end{array}\right\}\left\{\begin{array}{ccc} j_4 & j_1 & j_6 \\ j_2 & j_5 & j_3\end{array}\right\} = \left\{\begin{array}{ccc} j_1 & j_2 & j_3 \\ j_4 & j_5 & j_6\end{array}\right\}.$$

Наконец, путем рассмотрения различных схем связи четырех моментов можно получить [1]) следующую формулу сложения для произведений трех $6j$-символов:

$$\sum_j (-1)^{j+\sum_1^9 j_i}(2j+1)\left\{\begin{array}{ccc} j_4 & j_2 & j_6 \\ j_9 & j_8 & j\end{array}\right\}\left\{\begin{array}{ccc} j_2 & j_1 & j_3 \\ j_7 & j & j_9\end{array}\right\}\left\{\begin{array}{ccc} j_4 & j_3 & j_5 \\ j_7 & j_8 & j\end{array}\right\} =$$
$$= \left\{\begin{array}{ccc} j_1 & j_2 & j_3 \\ j_4 & j_5 & j_6\end{array}\right\}\left\{\begin{array}{ccc} j_6 & j_1 & j_5 \\ j_7 & j_8 & j_9\end{array}\right\} \quad (108.9)$$

(L. C. Biedenharn, J. P. Elliott, 1953). Приведем, для справок, некоторые явные выражения для $6j$-символов. $6j$-символ может быть представлен в общем случае в виде следующей суммы:

$$\left\{\begin{array}{ccc} j_1 & j_2 & j_3 \\ j_4 & j_5 & j_6\end{array}\right\} = \Delta\,(j_1 j_2 j_3)\,\Delta\,(j_1 j_5 j_6)\,\Delta\,(j_4 j_2 j_6)\,\Delta\,(j_4 j_5 j_3)\times$$
$$\times \sum_z \frac{(-1)^z (z+1)!}{(z-j_1-j_2-j_3)!\,(z-j_1-j_5-j_6)!\,(z-j_4-j_2-j_6)!\,(z-j_4-j_5-j_3)!}\times$$
$$\times\,(j_1+j_2+j_4+j_5-z)!\,(j_2+j_3+j_5+j_6-z)!\,(j_3+j_1+j_6+j_4-z)!$$

где

$$\Delta(abc) = \left[\frac{(a+b-c)!(a-b+c)!(-a+b+c)!}{(a+b+c+1)!}\right],$$

а сумма берется по всем положительным целым значениям z, при которых ни один из факториалов в знаменателе не имеет отрицательного аргумента. В табл. 10 даны

формулы $6j$-символов для случаев, когда один из параметров равен $0, 1/2$ или 1. В заключение сделаем несколько замечаний о составляемых из $3j$-символов скалярах более высокого порядка.

Следующим по сложности после $3j$-символа является скаляр, составляемый путем упрощения произведений шести $3j$-символов. Эти $3j$-символы содержат 18 попарно совпадающих чисел j, так что возникающий в результате скаляр зависит от 9 параметров j. Его принято называть $9j$-символом и определять следующим образом (E. Wigner, 1951):

$$\left\{ \begin{array}{ccc} j_{11} & j_{12} & j_{13} \\ j_{21} & j_{22} & j_{23} \\ j_{31} & j_{32} & j_{33} \end{array} \right\} = \sum_{\text{все } m} \left(\begin{array}{ccc} j_{11} & j_{12} & j_{13} \\ m_{11} & m_{12} & m_{13} \end{array} \right) \left(\begin{array}{ccc} j_{21} & j_{22} & j_{23} \\ m_{21} & m_{22} & m_{23} \end{array} \right) \times$$
$$\times \left(\begin{array}{ccc} j_{31} & j_{32} & j_{33} \\ m_{31} & m_{32} & m_{33} \end{array} \right) \left(\begin{array}{ccc} j_{11} & j_{21} & j_{31} \\ m_{11} & m_{21} & m_{31} \end{array} \right) \times$$
$$\times \left(\begin{array}{ccc} j_{12} & j_{22} & j_{32} \\ m_{12} & m_{22} & m_{32} \end{array} \right) \left(\begin{array}{ccc} j_{13} & j_{23} & j_{33} \\ m_{13} & m_{23} & m_{33} \end{array} \right) \cdot \quad (108.11)$$

(тут таблица еще, ее тоже не пишу, потому что не нужна она вообще)

Эта величина может быть также представлена в виде суммы произведений трех $6j$-символов:

$$\left\{ \begin{array}{ccc} j_{11} & j_{12} & j_{13} \\ j_{21} & j_{22} & j_{23} \\ j_{31} & j_{32} & j_{33} \end{array} \right\} = \sum_j (-1)^{2j} (2j+1) \left\{ \begin{array}{ccc} j_{11} & j_{21} & j_{31} \\ j_{32} & j_{33} & j \end{array} \right\} \times$$
$$\times \left\{ \begin{array}{ccc} j_{12} & j_{22} & j_{32} \\ j_{21} & j & j_{23} \end{array} \right\} \left\{ \begin{array}{ccc} j_{13} & j_{23} & j_{33} \\ j & j_{11} & j_{12} \end{array} \right\}.$$

В эквивалентности (108.11) и (108.12) можно убедиться, подставив в (108.12) определение (108.2) и воспользовавшись свойствами ортогональности $3j$-символов. $9j$-символ обладает высокой симметрией, следующей непосредственно из определения (108.11) и свойств симметрии $3j$-символов. Легко убедиться, что при перестановке любых его двух строк или двух столбцов $9j$-символ умножается на $(-1)^{\Sigma j}$. Кроме того, $9j$-символ не меняется при транспонировании, т.е. при взаимной замене строк и столбцов.

Скаляры еще более высоких порядков зависят от еще большего числа параметров j. Очевидно, что это число должно быть всегда кратно трем ($3nj$-символы). Мы не будем останавливаться здесь на свойствах этих величин. Упомянем лишь, что при каждом $n > 3$ имеется более чем по одному различному не сводящемуся друг к другу типу $3nj$-символов. Так, имеется два различных типа $12j$-символов [1]).

9.0.5 Matrix Elements in the Addition of Momenta by Landau (!!!)

(!!! а вот это очень важно проработать, выше уже были про это темы)

Теория

Рассмотрим снова систему, состоящую из двух частей (о которых будем говорить как о подсистемах 1 и 2), и пусть $f^{(1)}_{kq}$ сферический тензор, характеризующий первую из них. Его матричные элементы по отношению к волновым функциям этой же подсистемы определяются, согласно (107.6), формулой

$$\left\langle n'_1 j'_1 m'_1 \left| f^{(1)}_{kq} \right| n_1 j_1 m_1 \right\rangle = i^k (-1)^{j_1 \max - m'_1} \left(\begin{array}{ccc} j'_1 & k & j_1 \\ -m'_1 & q & m_1 \end{array} \right) \left\langle n'_1 j'_1 \left\| f^{(1)}_k \right\| n_1 j_1 \right\rangle$$

Возникает вопрос о вычислении матричных элементов этих же величин по отношению к волновым функциям системы в целом; покажем, как они могут быть выражены через те же приведенные матричные элементы, которые фигурируют в выражениях (109.1).

Состояния системы в целом определяются квантовыми числами $j_1 j_2 JM n_1 n_2 (J, M$ - величина и проекция момента всей системы). Поскольку $f^{(1)}_{kq}$ относится к подсистеме 1, ее оператор коммутирует с оператором момента подсистемы 2. Поэтому ее матрица диагональна по j_2; она диагональна также и по остальным квантовым числам n_2 этой подсистемы. Эти индексы (j_2, n_2) мы будем для краткости опускать и будем писать искомые матричные элементы в виде

$$\left\langle n'_1 j'_1 J' M' \left| f^{(1)}_{kq} \right| n_1 j_1 J M \right\rangle$$

Согласно (107.6) их зависимость от числа M определяется формулой

$$\left\langle n'_1 j'_1 J' M' \left| f^{(1)}_{kq} \right| n_1 j_1 J M \right\rangle = i^k (-1)^{J_{\max} - M'} \begin{pmatrix} J' & k & J \\ -M' & q & M \end{pmatrix} \left\langle n'_1 j'_1 J' \left\| f^{(1)}_{k} \right\| n_1 j_1 J \right\rangle .$$

Для установления связи между приведенными матричными элементами в правых частях (109.1) и (109.2) пишем, по определению матричных элементов:

$$\begin{aligned} &\left\langle n'_1 j'_1 J' M' \left| f^{(1)}_{kq} \right| n_1 j_1 J M \right\rangle = \int \psi^*_{J'M'} \widehat{f}^{(1)}_{kq} \psi_{JM} dq = \\ &= \sum_{m_1 m'_1} (-1)^{j'_1 - j_2 + M' - M} \sqrt{(2J'+1)(2J+1)} \begin{pmatrix} j'_1 & j_2 & J' \\ m'_1 & m_2 & -M' \end{pmatrix} \times \\ &\times \begin{pmatrix} j_1 & j_2 & J \\ m_1 & m_2 & -M \end{pmatrix} \left\langle n'_1 j'_1 m'_1 \left| f^{(1)}_{kq} \right| n_1 j_1 m_1 \right\rangle . \end{aligned}$$

Подставив сюда (109.1), (109.2) и сравнив полученное соотношение с формулой (108.4), мы увидим, что отношение приведенных матричных элементов (в (109.1), (109.2)) должно быть пропорционально определенному $6j$-символу. Тщательное сравнение обоих указанных соотношений приводит к следующей окончательной формуле:

$$\begin{aligned} \left\langle n'_1 j'_1 J' \left\| f^{(1)}_{k} \right\| n_1 j_1 J \right\rangle =& (-1)^{j_{1\max} + j_2 + J_{\min} + k} \sqrt{(2J+1)(2J'+1)} \times \\ &\times \begin{Bmatrix} j'_1 & J' & j_2 \\ J & j_1 & k \end{Bmatrix} \left\langle n'_1 j'_1 \left\| f^{(1)}_{k} \right\| n_1 j_1 \right\rangle \end{aligned} \quad (109.3)$$

(здесь $j_{1\max}$ - большее из j_1, j'_1; $J_{\min}$ - меньшее из J, J'). Аналогичная формула для приведенных матричных элементов сферического тензора, относящегося к второй подсистеме:

$$\begin{aligned} \left\langle n'_2 j'_2 J' \left\| f^{(2)}_{k} \right\| n_2 j_2 J \right\rangle =& (-1)^{j_1 + j_{2\min} + J_{\max} + k} \sqrt{(2J+1)(2J'+1)} \times \\ &\times \begin{Bmatrix} j'_2 & J' & j_1 \\ J & j_2 & k \end{Bmatrix} \left\langle n'_2 j'_2 \left\| f^{(2)}_{k} \right\| n_2 j_2 \right\rangle . \end{aligned} \quad (109.4)$$

Отсутствие полной симметрии между выражениями (109.3) и (109.4) (в показателе степени у -1) связано с зависимостью фазы волновых функций от порядка сложения моментов. Эту разницу надо иметь в виду, если приходится вычислять матричные элементы одновременно для обеих подсистем.

Далее, найдем полезную формулу для матричных элементов по отношению к волновым функциям всей системы от скалярного произведения (см. определение (107.4))

двух сферических тензоров одинакового ранга k, относящихся к различным подсистемам (и потому коммутирующих друг с другом). Согласно (107.10) эти матричные элементы выражаются через приведенные матричные элементы каждого из тензоров (по отношению к волновым функциям системы в целом) следующим обраЗом:

$$\left\langle n_1' n_2' j_1' j_2' JM \left| \left(f_k^{(1)} f_k^{(2)} \right)_{00} \right| n_1 n_2 j_1 j_2 JM \right\rangle =$$

$$= \frac{1}{2J+1} \sum_{J''} \left\langle n_1' j_1' J \left\| f_k^{(1)} \right\| n_1 j_1 J'' \right\rangle \left\langle n_2' j_2' J'' \left\| f_k^{(2)} \right\| n_2 j_2 J \right\rangle$$

(здесь использовано, что матрица величины, относящейся к одной из подсистем, диагональна по квантовым числам другой подсистемы). Подставив сюда (109.3), (109.4) и воспользовавшись формулой суммирования (108.8), получим искомую формулу, выражающую матричные элементы скалярного произведения через приведенные матричные элементы каждого из тензоров по отношению к волновым функциям соответствующих подсистем:

$$\left\langle n_1' n_2' j_1' j_2' JM \left| \left(f_k^{(1)} f_k^{(2)} \right)_{00} \right| n_1 n_2 j_1 j_2 JM \right\rangle =$$

$$= (-1)^{j_1 \min + j_2 \max + J} \left\{ \begin{array}{ccc} J & j_2' & j_1' \\ k & j_1 & j_2 \end{array} \right\} \left\langle n_1' j_1' \left\| f_k^{(1)} \right\| n_1 j_1 \right\rangle \left\langle n_2' j_2' \left\| f_k^{(2)} \right\| n_2 j_2 \right\rangle .$$

9.0.6 Matrix Elements for Axially Symmetric Systems by Landau

Теория

Основой для вычисления матричных элементов величин, характеризующих системы типа симметричного волчка, служит выражение интеграла от произведения трех D-функций.

Для вывода этой формулы вернемся к разложению (106.11)

$$\psi_{j_1 m_1} \psi_{j_2 m_2} = \sum_j \langle jm | m_1 m_2 \rangle \, \psi_{jm}, \quad m = m_1 + m_2$$

и преобразуем обе части равенства конечным поворотом системы координат. Каждая из ψ-функций преобразуется согласно (58.7), так что получим

$$\sum_{m_1' m_2'} D^{(j_1)}_{m_1' m_1} D^{(j_2)}_{m_2' m_2} \psi_{j_1 m_1'} \psi_{j_2 m_2'} = \sum_j \sum_m \langle jm | m_1 m_2 \rangle \, D^{(j)}_{m' m} \psi_{jm'}$$

Выразив теперь функции $\psi_{jm'}$ в правой части равенства в виде разложения (106.9) и сравнив коэффициенты при одинаковых произведениях $\psi_{j_1 m_1}, \psi_{j_2 m_2}$, получим соотношения

$$D^{(j_1)}_{m_1' m_1}(\omega) D^{(j_2)}_{m_2' m_2}(\omega) = \sum_j \langle m_1' m_2' | jm' \rangle \, D^{(j)}_{m' m}(\omega) \, \langle m_1 m_2 | jm \rangle$$

(причем $m = m_1 + m_2, m' = m_1' + m_2'$, а ω обозначает совокупность трех эйлеровых углов α, β, γ. Выраженная через $3j$-символы, эта формула принимает вид

$$D^{(j_1)}_{m_1' m_1}(\omega) D^{(j_2)}_{m_2' m_2}(\omega) = \sum_j (2j+1) \begin{pmatrix} j_1 & j_2 & j \\ m_1' & m_2' & -m' \end{pmatrix} \begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix} D^{(j)*}_{-m', -m}(\omega)$$

(здесь использовано также свойство D-функций (58.19)).

Умножив равенство (110.2) с обеих сторон на $D^{(j)}_{-m',-m}(\omega)$ и проинтегрировав его по $d\omega$ с помощью соотношения ортогональности (58.20), получим

$$\int D^{(j_1)}_{m'_1 m_1}(\omega) D^{(j_2)}_{m'_2 m_2}(\omega) D^{(j_3)}_{m'_3 m_3}(\omega) \frac{d\omega}{8\pi^2} = \begin{pmatrix} j_1 & j_2 & j_3 \\ m'_1 & m'_2 & m'_3 \end{pmatrix} \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix}$$

(для большей симметрии здесь произведено очевидное изменение обозначений индексов). Это и есть искомая формула [1]).

Пусть $f_{kq'}$ - сферический тензор ранга k, характеризующий волчок в связанных с ним координатных осях $x'y'z' \equiv \xi\eta\zeta$ (ось ζ - по оси волчка); это может быть, например, тензор мультипольного электрического или магнитного момента. Пусть f_{kq} - компоненты того же тензора относительно неподвижных осей координат xyz. Связь между теми и другими определяется матрицей конечных вращений согласно

$$f_{kq} = \sum_{q'} D^{(k)}_{q'q}(\omega) f_{kq'}$$

Волновые функции, описывающие вращение системы как целого, отличаются от D-функций лишь нормировкой:

$$\psi_{jm\mu} = i^j \sqrt{\frac{2j+1}{8\pi^2}} D^{(j)}_{\mu m}(\omega)$$

где j - полный момент системы; m - его проекция на неподвижную ось z; μ-проекция на ось системы; фазовый множитель выбран так, чтобы при целочисленном j и $\mu = 0$ функция (110.5) переходила в собственную функцию свободного момента (ср. (103.8)). Вычисляя по этим функциям матричный элемент величины (110.4) с помощью (110.3) (причем комплексно сопряженная D-функция выражается согласно (58.19)), получим

$$\langle j'\mu'm' \,|f_{kq}|\, j\mu m\rangle = i^{j-j'}(-1)^{\mu'-m'} \sqrt{(2j+1)(2j'+1)} \begin{pmatrix} j' & k & j \\ -\mu' & q' & \mu \end{pmatrix} \begin{pmatrix} j' & k & j \\ -m' & q & m \end{pmatrix} \langle \mu' \,|f_{kq'}|\, \mu\rangle$$
$$(\text{причем } \; q' = \mu' - \mu, q = m' - m)\,.$$

Эта формула решает поставленную задачу. Она определяет зависимость матричных элементов от моментов j, j' и их проекций m, m'. Что касается зависимости от квантовых чисел μ, μ', то она остается, разумеется, неопределенной: значения этих чисел зависят от «внутренних» состояний системы, между которыми берется «внутренний» матричный элемент $\langle \mu' \,|f_{kq'}|\, \mu\rangle$. Зависимость матричных элементов (110.6) от чисел m, m', такая же, как для всякой системы с заданным полным моментом. Отделив эту зависимость введением приведенных матричных элементов согласно (107.6), получим для последних выражение

$$\langle j'\mu' \,\|f_k\|\, j\mu\rangle = i^{j-j'-k}(-1)^{j_{\max}-\mu'} \sqrt{(2j+1)(2j'+1)} \begin{pmatrix} j' & k & j \\ -\mu' & q' & \mu \end{pmatrix} \langle \mu' \,|f_{kq'}|\, \mu\rangle\,.$$

Квадрат модуля матричного элемента (110.6), просуммированный по всем значениям конечного числа m' (и по $q = m' - m$) при заданном m, не зависит от значения m и равен, по общему правилу (107.11):

$$\sum_{qm'} |\langle j'\mu'm' \,|f_{kq}|\, j\mu m\rangle|^2 = \frac{1}{2j+1} |\langle j'\mu' \,\|f_k\|\, j\mu\rangle|^2 = (2j'+1) \begin{pmatrix} j' & k & j \\ -\mu' & q' & \mu \end{pmatrix}^2 |\langle \mu' \,|f_{kq'}|\, \mu\rangle|^2$$

Соотношения эрмитовости (107.9) для приведенных матричных элементов в координатах xyz(110.7), как и следовало, находятся в согласии с соотношениями (107.8)

$$\langle \mu \,|f_{kq'}|\, \mu\rangle = (-1)^{k-q} \langle \mu \,|f_{k,-q'}|\, \mu'\rangle^*$$

для матричных элементов в координатах $\xi\eta\zeta$. Вращение таких аксиально-симметричных систем, как двухатомная молекула (или аксиальное ядро), описывается всего двумя углами ($\alpha \equiv \varphi, \beta \equiv \theta$), определяющими направление оси системы. Вращательная волновая функция отличается в этом случае от (110.5) отсутствием множителя $e^{i\mu\gamma}/\sqrt{2\pi}$ (ср. примеч. на с. 389). Это изменение, однако, не отражается на матричных элементах: поскольку зависимость $D^{(j)}_{m'm}(\alpha,\beta,\gamma)$ от γ сводится к множителю $e^{im'\gamma}$, то (110.3) можно переписать в виде

$$\delta_{m'0} \int D^{(j_1)}_{m'_1 m_1}(\alpha,\beta,0) D^{(j_2)}_{m'_2 m_2}(\alpha,\beta,0) D^{(j_3)}_{m'_3 m_3}(\alpha,\beta,0) \frac{\sin\alpha d\alpha d\beta}{4\pi} = \begin{pmatrix} j_1 & j_2 & j_3 \\ m_1 & m_2 & m_3 \end{pmatrix} \begin{pmatrix} j_1 & j_2 & j_3 \\ m'_1 & m'_2 & m'_3 \end{pmatrix}$$

(где $m' = m'_1 + m'_2 + m'_3$) и результат вычисления интеграла не меняется. При этом правило отбора по проекции момента на ось системы соблюдается в прежнем виде ($\mu' - \mu = q'$), возникая (как следствие симметрии молекулы относительно оси ζ) в результате ортогональности электронных волновых функций. В формулах (110.6), (110.7) под $\langle \mu' \,|f_{kq'}|\, \mu\rangle$ надо понимать теперь матричные элементы по отношению к электронным состояниям при неподвижных ядрах.

9.0.7 Other About Addition of Momenta

(тут много можно дополнений найти, некоторые укажу.)

Электрон находится в двух состояниях одновременно

(тут с формулами это и покажу, это мы и видим.)

В задаче про сложение моментов проявляется принцип суперпозиции

(тут и укажу это)

О возможных классических аналогиях (??)

10.1.4 2.1. Pauli Hamiltonian by Tahtajan

The classical particle of charge e moving in the electromagnetic field with the vector potential $\boldsymbol{A}(\boldsymbol{x})$ and the scalar potential $\varphi(\boldsymbol{x})$ is described by the Hamiltonian function

$$H_{\mathrm{c}}(\boldsymbol{p},\boldsymbol{x})=\frac{1}{2m}\left(\boldsymbol{p}-\frac{e}{c}\boldsymbol{A}\right)^2+e\varphi(\boldsymbol{x}),\quad \boldsymbol{x}=(x,y,z)\in\mathbb{R}^3$$

(see Problem 1.27 in Section 1.7 of Chapter 1). As we have seen in Example 2.3 in Section 2.4 of Chapter 2, the corresponding Hamiltonian operator of the spinless particle is given by

$$H^0=\frac{1}{2m}\left(\boldsymbol{P}-\frac{e}{c}\boldsymbol{A}\right)^2+e\varphi(\boldsymbol{x}). \tag{2.1}$$

However, quantum particles with spin interact with the magnetic field, so that the Hamiltonian H^0, which is an operator in the Hilbert space $\mathscr{H}=$
$L^2\left(\mathbb{R}^3,d^3\boldsymbol{x}\right)$, is not adequate when $s\neq 0$. The correct prescription is to include the spin degrees of freedom and consider the Hamiltonian operator in the Hilbert space $\mathscr{H}_S=\mathscr{H}\otimes V_s$. For the case of an electron – particle with spin $\frac{1}{2}$ - the corresponding Hamiltonian is given by

$$H=\frac{1}{2m}\left(\boldsymbol{P}_A\cdot\boldsymbol{\sigma}\right)^2+e\varphi(\boldsymbol{x}),\quad \boldsymbol{P}_A=\boldsymbol{P}-\frac{e}{c}\boldsymbol{A}. \tag{2.2}$$

Using the basic facts that Pauli matrices anti-commute and satisfy $\sigma_1^2=\sigma_2^2=\sigma_3^2=I_2$ and

$$\sigma_1\sigma_2=i\sigma_3,\quad \sigma_2\sigma_3=i\sigma_1,\quad \sigma_3\sigma_1=i\sigma_2$$

we readily obtain

$$\begin{aligned}\left(\boldsymbol{P}_A\cdot\boldsymbol{\sigma}\right)^2&=\left(P_1-\frac{e}{c}A_1\right)^2+\left(P_2-\frac{e}{c}A_2\right)^2+\left(P_3-\frac{e}{c}A_3\right)^2\\&+i\left[P_1-\frac{e}{c}A_1,P_2-\frac{e}{c}A_2\right]\sigma_3+i\left[P_2-\frac{e}{c}A_2,P_3-\frac{e}{c}A_3\right]\sigma_1\\&+\quad+i\left[P_3-\frac{e}{c}A_3,P_1-\frac{e}{c}A_1\right]\sigma_2\\&=\left(\boldsymbol{P}-\frac{e}{c}\boldsymbol{A}\right)^2-\frac{\hbar e}{c}\left(B_1\sigma_1+B_2\sigma_2+B_3\sigma_3\right).\end{aligned}$$

Here $\boldsymbol{B}=(B_1,B_2,B_3)$ is the magnetic field, $\boldsymbol{B}=\operatorname{curl}\boldsymbol{A}$, and in the last line we have used Heisenberg commutation relations (cf. a similar computation in Example 2.3 in Section 2.4 of Chapter 2). The Hamiltonian (2.2) takes the form

$$H=H^0-\mu\boldsymbol{B}\cdot\boldsymbol{\sigma},\quad \mu=\frac{\hbar e}{2mc}, \tag{2.3}$$

and is known as the Pauli Hamiltonian; the quantity μ is the total magnetic moment of an electron. It is customary to put $\mu=-\mu_{\mathrm{B}}$, where

$$\mu_{\mathrm{B}}=\frac{\hbar|e|}{2mc}=0.927\times10^{-20}\frac{\mathrm{erg}}{\mathrm{gauss}}$$

is the so-called Bohr magneton. The corresponding time-dependent Schrdinger equation

$$i\hbar\frac{\partial\psi}{\partial t} = H\psi$$

in this context is called the Pauli wave equation.

Remark. The Pauli wave equation is obtained from the relativistic Dirac equation for the electron in the limit $c \to \infty$ by neglecting the terms of order c^{-2}.

The corresponding Hamiltonian for a quantum particle of spin s and charge e has a similar form

$$H = H^0 - \boldsymbol{B}\cdot\boldsymbol{\mu}, \quad \boldsymbol{\mu} = \frac{\mu}{\hbar s}\boldsymbol{S},$$

where $S = (S_1, S_2, S_3)$ are spin operators of spin s, quantity μ is the total magnetic moment of a particle, and the operator $\boldsymbol{\mu}$ is its "intrinsic" magnetic moment.

10.1.5 2.2. Particle in a uniform magnetic field by Tahtajan

Here we consider the problem of finding the energy levels of a charged spin $\frac{1}{2}$ particle moving in a constant uniform magnetic field. Choosing the z-axis along the direction of the field, $\boldsymbol{B} = (0, 0, B)$, we get $A_1(\boldsymbol{x}) = -By, A_2(\boldsymbol{x}) = A_3(\boldsymbol{x}) = 0$, and $\varphi(\boldsymbol{x}) = 0$. The Pauli Hamiltonian takes the form

$$H = \frac{1}{2m}\left[\left(P_1 + \frac{e}{c}By\right)^2 + P_2^2 + P_3^2\right] - \mu B\sigma_3 \tag{2.4}$$

The eigenvalue equation

$$H\psi(\boldsymbol{x},\sigma) = E\psi(\boldsymbol{x},\sigma)$$

in $\mathscr{H}_S$ reduces to two (for each value of $\sigma = \pm\frac{1}{2}$) eigenvalue equations

$$\frac{1}{2m}\left[\left(P_1 + \frac{e}{c}By\right)^2 + P_2^2 + P_3^2\right]\psi - \mu B\sigma\psi = E\psi$$

in $\mathscr{H}$. Separating the variables

$$\psi(\boldsymbol{x}) = e^{\frac{i}{\hbar}(k_1x + k_3z)}\chi(y)$$

we obtain

$$-\frac{\hbar^2}{2m}\chi'' + \frac{m\omega_{\mathrm{B}}^2}{2}(y - y_0)^2\chi = \left(E + \mu B\sigma - \frac{k_3^2}{2m}\right)\chi \tag{2.5}$$

where

$$y_0 = -\frac{ck_1}{eB} \quad \text{and} \quad \omega_{\mathrm{B}} = \frac{|e|B}{mc}$$

Equation (2.5) coincides with the eigenvalue problem for the one-dimensional harmonic oscillator with the frequency ω_{B}, solved in Section 2.6 of Chapter 2. Thus we obtain

$$E = \left(n + \frac{1}{2}\right)\hbar\omega_{\mathrm{B}} + \frac{k_3^2}{2m} - \mu B\sigma, \quad n = 0, 1, ...; \quad \sigma = \pm\frac{1}{2} \tag{2.6}$$

The first term in this formula gives discrete energy levels, called Landau levels, for the motion in the plane perpendicular to the magnetic field.

The spectrum of Pauli Hamiltonian (2.4) is absolutely continuous and fills $\left[\frac{1}{2}\left(\hbar\omega_{\mathrm{B}}-\mu B\right),\infty\right)$ with variable infinite multiplicity. It can be visualized as a countable union of branches $\left[\left(n+\frac{1}{2}\right)\hbar\omega_{\mathrm{B}}-\mu B\sigma,\infty\right)$, each with a multiplicity parametrized by $\mathbb{R}\times\{\pm 1\}$ (all $k_1\in\mathbb{R}$ and $\pm k_3$ for fixed k_3
correspond to the same E). Corresponding normalized eigenfunctions of the continuous spectrum are
$\psi_n\left(\boldsymbol{x};k_1,k_3\right)=\frac{1}{2\pi\hbar}\sqrt[4]{\frac{m\omega_{\mathrm{B}}}{\pi\hbar}}\frac{1}{\sqrt{2^n n!}}e^{\frac{i}{\hbar}(k_1x+k_3z)-\frac{m\omega_{\mathrm{B}}}{2\hbar}(y-y_0)^2}H_n\left(\sqrt{\frac{m\omega_{\mathrm{B}}}{\hbar}}y\right)$,
where $-\infty<k_1,k_3<\infty$.
For the electron, $\hbar\omega_{\mathrm{B}}=\frac{1}{2}\mu_{\mathrm{B}}$, and formula (2.6) takes the form

$$E=\left(n+\frac{1}{2}+\sigma\right)\mu_{\mathrm{B}}B+\frac{k_3^2}{2m}.$$

In this case there is an extra degeneration of the spectrum: energy levels with n and $\sigma=\frac{1}{2}$ and those with $n+1$ and $\sigma=-\frac{1}{2}$ coincide.
Problem 2.1. Derive the eigenfunction expansion theorem for the Hamiltonian (2.4).

Problem 2.2. Show that the operators

$$X_0=Q_1+\frac{c}{eB}P_2\quad\text{ and }\quad Y_0=-\frac{c}{eB}P_1,$$

which correspond to the coordinates of a center of a circle (see Problem 1.5 in Section 1.3 of Chapter 1), are quantum integrals of motion, i.e., commute with the Hamiltonian H, but

$$\{X_0,Y_0\}_\hbar=\frac{c}{eB}I.$$

10.1.6 Motion in magnetic field in Dirac notation

(тут другое решение этой задачи)

Model of Dirac particle in a monolayer of graphene in magnetic field

(тут неплохо бы вставить теоирю про графен, что так-то можно разделить его на две подрешетки K, K', найти дисперс. соотношение. Про это отдельно нужно думать и это не тема этого раздела. потом коротко напишу то, что нужно для задачи ниже из этого.)

The low-energy properties, corresponding to the electronic states near the Fermi energy, can be described by expanding the energy dispersion around the K and K′ points. Let us write the graphene wave vector for valley K as $\mathbf{q}=\mathbf{K}+\mathbf{k}$. What we get for $|\mathbf{k}|\ll 1$ is

$$\epsilon(\mathbf{K}+\mathbf{k})\approx\pm\hbar v_F|\mathbf{k}|$$

where $v_F=\frac{3a|t|}{2\hbar}\approx 10^6$ m/s is Fermi velocity (which is comparable to that in metals). The expression for the expansion around K' is the same. The expression (3) corresponds to the two cones meeting at the K point with linear dependence on the wave vector. Because we know, that energy dispersion which is linear in wave vector belongs to massless particles, we say that electrons and holes with wave vectors close to K and K' points behave as massless. Those massless Dirac fermions made study of monolayer graphene so enticing.

As we know from particle physics, (almost) massless neutrinos are not described by Schrödinger equation, but by Dirac equation. Therefore, we would like to see whether Hamiltonian ascribed to our system (1) also have the form of Hamiltonian in the Dirac

equation. Since particles behave as massless only around the K and K', we expand the Hamiltonian

$$H(\mathbf{q}) = \begin{pmatrix} \epsilon_0 & tg(\mathbf{q}) \\ tg(\mathbf{q})^* & \epsilon_0 \end{pmatrix}$$

around these points as well. The Hamiltonian in the vicinity of the K point is for $\mathbf{q} = \mathbf{K}+\mathbf{k}$

$$H_K^0(\mathbf{k}) = \hbar v_F \begin{pmatrix} 0 & i\left(k_x - ik_y\right) \\ -i\left(k_x + ik_y\right) & 0 \end{pmatrix}$$

which does not yet fully resemble the form of Dirac equation. To get rid of the imaginary factors, which spoil the equivalence, we redefine wavefunctions containing coefficients $c_{\alpha,\beta}$ as

$$\Psi_0^K = \begin{pmatrix} c_{A,K} \\ c_{B,K} \end{pmatrix} \rightarrow \Psi^K = \begin{pmatrix} -ic_{A,K} \\ c_{B,K} \end{pmatrix}, \quad \Psi_0^{K'} = \begin{pmatrix} c_{A,K'} \\ c_{B,K'} \end{pmatrix} \rightarrow \Psi^{K'} = \begin{pmatrix} c_{A,K'} \\ -ic_{B,K'} \end{pmatrix}$$

and consequently change the Hamiltonian, so that equations, coming from each line of the matrix representation of $H_K\Psi_K = \epsilon\Psi_K$, do not change. The new Hamiltonian is then

$$H_K(\mathbf{k}) = \hbar v_F \vec{\sigma} \cdot \mathbf{k}$$

where the $\vec{\sigma} = (\sigma_x, \sigma_y)$ is a vector of Pauli matrices. For the Hamiltonian in the vicinity of the K' holds $H_{K'}(\mathbf{k}) = -H_K^T(\mathbf{k})$. In relation with Dirac equation, we call the wavefunction Ψ^β spinor. In its upper and lower term it has the quantum mechanical amplitudes of finding the particle in one of the two sublattices A and B, respectively. And for each valley K and K' we have one such spinor. If we put them together in one bispinor $\Psi = \left(\Psi^{K'}, \Psi^K\right)^T$ and both Hamiltonian in a common one, we get

$$H\Psi = v_F \begin{pmatrix} -\vec{\sigma}^* \cdot \mathbf{p} & 0 \\ 0 & \vec{\sigma} \cdot \mathbf{p} \end{pmatrix} \Psi$$

Although we speak of Dirac particles, equation (6) is not completely the same as true Dirac equation which would be in chiral representation equal to

$$H\Psi = c \begin{pmatrix} -\vec{\sigma} \cdot \mathbf{p} & 0 \\ 0 & \vec{\sigma} \cdot \mathbf{p} \end{pmatrix} \Psi$$

The motion of relativistic charges in graphene in a strong magnetic field is also quantized. In a conventional electron gas (non-relativistic) Landau quantization produces equidistant energy levels, which is due to the parabolic dispersion law of free electrons. In graphene the electrons have relativistic dispersion law, which strongly modifies the Landau quantization of the energy and the position of the levels.

As for free electrons, we make the substitution $p_i \rightarrow p_{0i} = p_i - \frac{e}{c}A_i$. The Hamiltonian (6) will therefore change to

$$H = v_F \begin{pmatrix} 0 & -\left(p_{0x} + ip_{0y}\right) & 0 & 0 \\ -\left(p_{0x} - ip_{0y}\right) & 0 & 0 & 0 \\ 0 & 0 & 0 & p_{0x} - ip_{0y} \\ 0 & 0 & p_{0x} + ip_{0y} & 0 \end{pmatrix}$$

where the four-component wave function

$$\Psi = \begin{pmatrix} \Phi_A^{K'} \\ \Phi_B^{K'} \\ \Phi_A^K \\ \Phi_B^K \end{pmatrix}$$

corresponding to the Hamiltonian (9) now takes on broader meaning, such that Φ_A^K and Φ_B^K are envelope wavefunctions of A and B sites for the valley K, and $\Phi_A^{K'}, \Phi_B^{K'}$ for the valley K '.

For the magnetic field orthogonal to the graphene layer, the vector potential can be chosen in Landau gauge as $A = (-By, 0)$. For such gauge, $[H, \hat{p}_x] = 0, p_x$ is good quantum number. Because equations for K and K′ valley are decoupled, let us first look for the solutions of the K valley. We are solving the system

$$\begin{aligned}\epsilon\Phi_A^K &= v_F\left(\hat{p}_{0x} - i\hat{p}_{0y}\right)\Phi_B^K \\ \epsilon\Phi_B^K &= v_F\left(\hat{p}_{0x} + i\hat{p}_{0y}\right)\Phi_A^K\end{aligned}$$

which can be by inserting one equation into another further decoupled into

$$\begin{aligned}\epsilon^2\Phi_A^K &= v_F^2\left(p_{0x} - ip_{0y}\right)\left(p_{0x} + ip_{0y}\right)\Phi_A^K \\ \epsilon^2\Phi_B^K &= v_F^2\left(p_{0x} + ip_{0y}\right)\left(p_{0x} - ip_{0y}\right)\Phi_B^K\end{aligned}$$

Let us find the energy levels ϵ for the Φ_B^K, using $[H, \hat{p}_x] = 0$ and that for electron $e = -e_0$

$$\begin{aligned}\frac{\epsilon^2}{v_F^2}\Phi_B^K &= \left(\left(\hat{p}_x + \frac{e}{c}B\hat{y}\right) + i\hat{p}_y\right)\left(\left(\hat{p}_x + \frac{e}{c}B\hat{y}\right) - i\hat{p}_y\right)\Phi_B^K \\ &= \left(\left(\hat{p}_x + \frac{eB}{c}\hat{y}\right)^2 - i\left[\hat{p}_x + \frac{eB}{c}\hat{y}, \hat{p}_y\right] + \hat{p}_y^2\right)\Phi_B^K \\ &= \left(\left(p_x + \frac{eB}{c}\hat{y}\right)^2 + \frac{\hbar eB}{c} + \hat{p}_y^2\right)\Phi_B^K \\ \frac{1}{2m}\left(\frac{\epsilon^2}{v_F^2} + \frac{\hbar e_0 B}{c}\right)\Phi_B^K &= \left(\frac{\tilde{k}}{2}\left(\hat{y} - y_0\right)^2 + \frac{\hat{p}_y^2}{2m}\right)\Phi_B^K\end{aligned}$$

Where $\tilde{k} = \frac{e_0 B}{c\sqrt{m}}, y_0 = \frac{p_x c}{e_0 B}$. Again the right side of the equation has the form of Hamiltonian for the harmonic oscillator, oscillating around y_0. If Φ_B^K is eigenfunction of such Hamiltonian, its eigenvalues will be $\hbar\omega_c\left(n + \frac{1}{2}\right)$ where as for the standard Landau quantization $\omega_c = \sqrt{\frac{k}{m}} = \frac{c_0 B}{mc}$. Consequently, the energy values for Landau levels in graphene monolayer must satisfy

$$\frac{\epsilon^2}{v_F^2} = \frac{\hbar e_0 B}{c}(2n + 1 - 1)$$

where $n = 0, 1, 2...$ goes through the same values as for harmonic oscillator. Since ϵ has positive and negative roots, we can extend the domain of n to integer values and write energy levels as

$$\epsilon = \mathrm{sgn}(n)\sqrt{\frac{2\hbar e_0 B}{c}}v_F\sqrt{|n|} = \hbar\omega^{\mathrm{Dirac}}\ \mathrm{sgn}(n)\sqrt{|n|}, \quad \omega^{\mathrm{Dirac}} = v_F\sqrt{\frac{2e_0 B}{\hbar c}}$$

The Landau level index, n, can be positive or negative. The positive values correspond to electrons (conduction band), while the negative values correspond to holes (valence band). Furthermore, they are not equidistant as in conventional case and the largest energy separation is between the zero and the first Landau level. This large gap allows one to observe the quantum Hall effect in graphene, even at room temperature (Physical Review B, 65(24):245420, 2002.).

In the above derivation we disregarded the spin of the electron, which brings additional twofold degeneracy of the Landau levels due to the spin. Because we are working with electrons in magnetic field, this degeneracy is actually splitted by the Zeeman interaction. Having derived the energy difference between successive Landau levels, we can compare it to the strength of

Zeeman interaction. For $B = 10T$, ratio between the latter and the difference between n = 1, 0 Landau level is

$$\frac{\hbar\omega_c/2}{v_F\sqrt{e\hbar B/c}} \approx 0.01$$

which in a way justifies our assumption for spin degeneration. If we repeat the whole procedure also for equation (10) with Φ_A^K, we get

$$\frac{\epsilon^2}{v_F^2} = \frac{\hbar e_0 B}{c} 2(n+1), \quad n = 0, 1, ...$$

which, comparing to the previous result for Φ_B^K, lacks the level with $\epsilon = 0$. In terms of the occupation of the sublattices A and B, we can therefore expect interesting properties. Specifically, the wave function at the Landau level $n \neq 0$ should always have non-zero amplitudes on both sublattices A and B, while the wavefunctions at the Landau level $n = 0$ should have non-zero amplitude only on one sublattice: B sublattice for valley K or A sublattice for valley K '. The asymmetry between A and B sublattice originates from asymmetry in positions of the nearest neighbors for atoms at A and B sublattice. This property of the wavefunctions for the Landau levels in graphene makes the $n = 0$ level very special for different magnetic applications of graphene.

The wave functions corresponding to the Landau levels (13) are labeled by three indices (nLandau level index, k -wave vector along the x -axis, K, K '-valley of wave vectors) and are given by the following expressions (Physical Review B, 65(24):245420, 2002.)

$$\Psi_{n,k}^K = \frac{C_n}{\sqrt{L}} e^{-ikx} \begin{pmatrix} 0 \\ 0 \\ \mathrm{sgn}(n)(-i)\phi_{|n|-1,k} \\ \phi_{|n|,k} \end{pmatrix}$$

for valley K and

$$\Psi_{n,k}^{K'} = \frac{C_n}{\sqrt{L}} e^{-ikx} \begin{pmatrix} \phi_{|n|,k} \\ \mathrm{sgn}(n)(-i)\phi_{|n|-1,k} \\ 0 \\ 0 \end{pmatrix}$$

for valley K . Here L^2 is the area of the system,

$$C_n(x) = \begin{cases} 1 & \text{for n} = 0, \\ \frac{1}{\sqrt{2}} & \text{for } n \neq 0 \end{cases}, \quad \mathrm{sgn}(n) = \begin{cases} 0 & \text{for n} = 0, \\ \frac{n}{|n|} & \text{for } n \neq 0 \end{cases}$$

$$\phi_{n,k} \propto \exp\left(-\frac{1}{2}\frac{(y - kl_B^2)^2}{l_B^2}\right) H_n\left[\frac{(y - kl_B^2)}{l_B}\right]$$

where $l_B = \sqrt{\hbar/eB}$ is the magnetic length and $H_n(x)$ are Hermite polynomials. $\phi_{n,k}$ is the wavefunction for a non-relativistic electron at the nth Landau level. All in all, their structure is reasonable: they are obviously eigenfunction of $\hat{p_x}$, in the $n = 0$ level only one sublattice is occupied and $(-i)$ factor comes from the redefinition of coefficients c_α. Another consequence of different dependence of energy levels on index n $\left(\epsilon_A \propto \sqrt{|n|-1}, \epsilon_B \propto \sqrt{|n|}\right)$ for sublattices A and B results also in different wavefunctions $\phi_{n,k}$ at both sites, which must differ in their index n for 1 to yield the same energy eigenvalue for both. Figure 3 shows the the profile of wavefunctions in the K valley along the y -axis for the sublattices A and B in magnetic field B = 10 T for the index n = 3.

Model of Dirac particle in a mbilayer of graphene in magnetic field

When two graphene layers stack to form a bilayer, the interlayer coupling leads to the appearance of band mass but it does not open a gap at the Dirac points. Here the Landau level spectrum takes the form

$$E_n = \mathrm{sgn}(n)\hbar\omega_c\sqrt{|n|(|n|-1)}, \quad n \in Z, \quad \omega_c = \frac{eB}{m^*c}$$

This sequence is linear in field, similar to the standard case, but it contains an additional zero-energy level, which is independent of the field.

(я удивлен, что такое решение только в одной методичке находится. в статьях что-то сложнее и эксперименты, но конкретно этого вывода я не находил.)

Details of model of Dirac particle in graphene in magnetic field

Почему все-таки формулы отличны от тех, которые для обычной частицы и как из одних перейти в другие?

(ведь эти модели связаны. приведу переход от одной модели к другой. пока не думал про это еще.)

Experimental differences of these models

(это упомянуто в начале статьи Magnetic oscillations in planar systems with the Dirac-like spectrum of quasiparticle excitations II: transport properties by V.P. Gusynin and S.G. Sharapov, пока не до этого)

Experimental confirmation of LL levels in graphene

(тонна статей про это, какую вставить - пока не знаю, потом прочитаю пару, вставлю самые полезные и разные графики типичные, разбираться в них еще нужно.)

On Landau Level Splitting in Graphene in High Magnetic Fields by Y. Zhang et. al.

(известаная статья что эксп. подтвердили, потом почитаю)
In summary, they report the observation of splittings of LLs in high quality graphene samples under high magnetic field up to 45 T. They discover the $n = 0$LL splits into four sublevels, lifting spin and sublattice degeneracy, potentially indicating a many-body correlation in this LL. In the $n = \pm 1$LL, only the spin degeneracy seems to be lifted within experimentally accessible high magnetic field. The effective g-factors were found close to the bare electron g-factor.

Link of LL levels and Quantum Hall effect

(тоже куча статей про это есть, уже в записи по КЭХ это написано, додумаю - и напишу сюда тоже)

Explanation from Two-Dimensional Gas of Massless Dirac Fermions in Graphene by K.S. Novoselov, A.K. Geim, S.V. Morozov, D. Jiang, M.I. Katsnelson, I.V. Grigorieva, S.V. Dubonos, A.A. Firsov

To explain the half-integer QHE qualitatively, we invoke the formal expression [9-12] for the energy of massless relativistic fermions in quantized fields, $E_N = [2e\hbar {c_*}^2 B(N + 1/2 \pm 1/2)]^{1/2}$. In QED, sign $\pm$ describes two spins whereas in the case of graphene it refers to "pseudospins". The latter have nothing to do with the real spin but are "built in" the Dirac-like spectrum of graphene, and their origin can be traced to the presence of two carbon sublattices. The above formula shows that the lowest LL($N = 0$) appears at $E = 0$ (in agreement with the index theorem) and accommodates fermions with only one (minus) projection of the pseudospin. All other levels $N \geq 1$ are occupied by fermions with both ($\pm$) pseudospins. This implies that for $N = 0$ the degeneracy is half of that for any other N. Alternatively, one can say that all LL have the same "compound" degeneracy but zeroenergy LL is shared equally by electrons and holes. As a result the first Hall plateau occurs at half the normal filling and, oddly, both $v = -1/2$ and $+1/2$ correspond to the same LL ($N = 0$). All other levels have normal degeneracy $4B/\phi_0$ and, therefore, remain shifted by the same $1/2$ from the standard sequence. This explains the QHE at $v = N + 1/2$ and, at the same time, the "odd" phase of SdHO (minima in ρ_{xx} correspond to plateaux in ρ_{xy} and, hence, occur at half-integer v; see Figs. 2&3), in agreement with theory [9-12]. Note however that from another perspective the phase shift can be viewed as the direct manifestation of Berry's phase acquired by Dirac fermions moving in magnetic field [15, 16].

10.2 Selection Rules

Правила отбора по Нохриной

Рассмотрим в качестве примера применения теоремы Вигнера-Эккарта правила отбора для дипольного излучения в атомах. Плотность вероятности перехода из начального состояние в конечное с дипольным излучением пропорциональна следующему матричному элементу оператора проекции дипольного момента $\hat{d}_i$ (см., например, |1|) : $dw_{fi} \propto \left\langle J'M' \left| \hat{d}_i \right| JM \right\rangle$. Соответственно, "Запрещены" те переходы, для которых эти матричные элементы равны нулю. Анализ того, какие матричные элементы могут иметь нетривиальное значение, и приводит к правилам отбора для дипольного излучения.

Пример 8. Правила отбора по J. В качестве сферического тензора $\hat{T}_q^{(k)}$ рассмотрим набор операторов из примера 5. В этом случае $k = 1, q = -1, 0, 1$:

$$\hat{B}_0^{(1)} = \hat{d}_z, \quad \hat{B}_{\pm 1}^{(1)} = \mp \frac{1}{\sqrt{2}} \hat{d}_{\pm}.$$

Матричные элементы для компонент сферического тензора $\hat{B}_q^{(1)}$ в соответствии с утверждением теоремы Вигнера-Эккарта записываются в виде

$$\left\langle J'M' \left| \hat{d}_z \right| JM \right\rangle = \Lambda_0 (J, J') K_{J,M,1,0}^{J',M'},$$
$$\frac{\mp 1}{\sqrt{2}} \left\langle J'M' \left| \hat{d}_{\pm} \right| JM \right\rangle = \Lambda_{\pm} (J, J') K_{J,M,1,\pm 1}^{J',M'},$$

где коэффициенты пропорциональности Λ_0 и $\Lambda_{\pm}$зависят только от чисел J и J', и мы восстановили все индексы в записи коэффициентов Клебша-Гордана. Коэффициенты Клебша-Гордана в правых частях равенств могут быть не равны нулю, только если квантовые числа суммарного момента принимают допустимый диапазон значений. В нашем случае J' - это допустимые квантовые числа, характеризующие квадрат

суммарного момента, при сложении моментов J и 1. Из техники сложения моментов сле-13 дует, что

$$J' = \begin{cases} J+1 \\ J \\ J-1 \end{cases}$$

Значит, ненулевыми матричными элементами для операторов $\hat{d}_i$ могут быть только матричные элементы с квантовыми числами J и J', удовлетворяющими первому правилу отбора:

$$|J' - J| \leq 1$$

Пример 9. При сложении моментов, характеризуемых орбитальными квантовыми числами J и 1, имеем: при $J = 0$ суммарный момент $J' = 1$, при $J = 1$ суммарный момент $J' = \{0, 1, 2\}$ и так далее. То есть при $k = 1$ равенство $J = J' = 0$ не может быть выполнено. Значит, соответствующий коэффициент Клебша-Гордана, а вместе с ним и матричный элемент для операторов $\hat{d}_i$ равны нулю. Отсюда второе правило отбора:

$$\text{переход } J = 0 \to J' = 0 \text{ запрещен.}$$

Пример 10. Правило отбора для проекции момента следует из сложения моментов:

$$M' = M + 0 \quad \text{или} \quad M' = M \pm 1.$$

Все коэффициенты Клебша-Гордана для других M и M' равны нулю, отсюда следует третье правило отбора по проекции суммарного момента:

$$|M' - M| \leq 1$$

У пражнение. Получите правила отбора для состояний, описываемых квантовыми числами $S, M_{\mathrm{S}}, L, M_{\mathrm{L}}$.

правила отбора по Киселеву

Коэффициенты Клебша-Гордана принимают ненулевые значения, только если моменты и их проекции при сложении пробегают допустимую область своего изменения.

Поэтому и матричные элементы неприводимых тензорных операторов, пропорциональные, как мы убедились согласно теореме Вигнера-Эккарта, коэффициентам Клебша-Гордана, отличны от нуля, если, Во-первых,

$$M' = M + m, \quad m \in \{-j, -j+1, ..., j-1, j\}$$

Значит для оператора ранга j с произвольной допустимой проекцией имеет место, как говорят, правило отбора по проекции момента

$$|\Delta M| \leqslant j$$

В противном случае, матричные элементы этого оператора заведомо равны нулю.

Во-вторых, так как

$$|J - j| \leqslant J' \leqslant J + j$$

правило отбора по модулю момента принимает вид

$$|\Delta J| \leqslant j, \quad j \leqslant J + J'$$

Как следствие, получаем правило запрета: если $j \neq 0$, то матричные элементы с $J = J' = 0$ тож дественно равны нулю, или, как говорят, переход $0 \to 0'$ запрещен.

Примеры применения правил отбора в квантовой теории излучения (!!!)

(очень важно указать, иначе невозможно будет ими пользоваться.)

как происходит поглощение атомом фотона?

(напишу потом)

Если фотон берется из флуктуации вакуума, то можно ли черпать из флуктуации вакуума бесконечно энергию (??)

(? остался вопрос, не знаю, почему нет?)

Фактор Ланде

(?? тут что ли его подробно и обсудим???)

При решении задачи об эффекте Зеемана в слабом поле возникает необходимость вычислять матричные элементы вида

$$\left\langle JM' \left| \hat{S}_z + \hat{J}_z \right| JM \right\rangle .$$

14 Решение этой задачи базируется на введении фактора Ланде. Для вычисления этого фактора докажем несколько вспомогательных утверждений.

Утверждение 11. Матричные элементы операторов $\hat{S}_i$ и $\hat{J}_i$ пропорциональны друг другу, а коэффициент пропорциональности зависит только от квантового числа J.

Доказательство. Операторы $\hat{S}_z$ и $\mp\hat{S}_\pm/\sqrt{2}$ являются компонентами сферического тензора $\hat{A}^{(1)}_q$ (см. Пример 1). Применим к ним теорему Вигнера-Эккарта:

$$\left\langle JM' \left| \hat{S}_z \right| JM \right\rangle = \Lambda_0(J) K^{J,M'}_{M,0} ,$$
$$\frac{\mp 1}{\sqrt{2}} \left\langle JM' \left| \hat{S}_\pm \right| JM \right\rangle = \Lambda_\pm(J) K^{J,M'}_{M,\pm 1}.$$

Применяя теорему к сферическому тензору, компонентами которого являются $\hat{J}_z$ и $\mp\frac{1}{\sqrt{2}}\hat{J}_\pm$, получим

$$\left\langle JM' \left| \hat{J}_z \right| JM \right\rangle = \widetilde{\Lambda}_0(J) K^{J,M'}_{M,0} ,$$
$$\frac{\mp 1}{\sqrt{2}} \left\langle JM' \left| \hat{J}_\pm \right| JM \right\rangle = \widetilde{\Lambda}_\pm(J) K^{J,M'}_{M,\pm 1}.$$

Сравнивая равенства (9) и (10), получаем, что матричные элементы операторов $\hat{S}_i$ и $\hat{J}_i$ пропорциональны друг другу:

$$\left\langle JM' \left| \hat{S}_z \right| JM \right\rangle = \frac{\widetilde{\Lambda}_0(J)}{\Lambda_0(J)} \left\langle JM' \left| \hat{J}_z \right| JM \right\rangle ,$$
$$\left\langle JM' \left| \hat{S}_x \right| JM \right\rangle = \frac{\widetilde{\Lambda}_+(J) + \widetilde{\Lambda}_-(J)}{\Lambda_+(J) + \Lambda_-(J)} \left\langle JM' \left| \hat{J}_x \right| JM \right\rangle ,$$
$$\left\langle JM' \left| \hat{S}_y \right| JM \right\rangle = \frac{\widetilde{\Lambda}_+(J) - \widetilde{\Lambda}_-(J)}{\Lambda_+(J) - \Lambda_-(J)} \left\langle JM' \left| \hat{J}_y \right| JM \right\rangle .$$

Утверждение 12. Коэффициенты пропорциональности в равенствах (11) - (13) равны, и, значит, выполнено

$$\left\langle JM' \left| \hat{S}_i \right| JM \right\rangle = \Lambda(J) \left\langle JM' \left| \hat{J}_i \right| JM \right\rangle ,$$

где коэффициент $\Lambda(J)$ не зависит от i.

Доказательство. Вспомним, что векторы $\varphi_{LM_L}, \psi_{SM_S}$ и операторы $\hat{L}_i, \hat{S}_i$ могут быть записаны в представлении, собств енном для операторов $\hat{L}^2, \hat{L}_z$ и $\hat{S}^2, \hat{S}_z$ соответственно, где подразумевается, что в координатном пространстве $\mathbb{R}^3$ выбрана система координат K с осями OX, OY и OZ. То есть выбрано представление, собственное для проекции момента и спина на ось OZ. То же самое в ерно для в екторов Ψ_{JM} и операторов $\hat{J}_i$.

Поворотом преобразуем систему координат K в систему K' так, чтобы ось OX совпадала с осью OZ'.С одной стороны, в системе K' векторы, записанные в представлении, собств енном для проекции спина и момента на ось OZ', будут иметь те же компоненты, что и векторы, записанные в представлении, собственном для проекции спина или момента на ось OZ в системе K. Например, вектор проекции спина на ось OZ', равной $+\hbar/2$, в собственном представлении записывается в виде

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}.$$

Будем обозначать в се векторы и операторы, записанные в представлении, собств енн ом для проекции момента на ось OZ', штрихом. Тогда выполнено равенство

$$\left(\Psi'_{JM'}, \hat{S}'_z \Psi'_{JM}\right) = \left(\Psi_{JM'}, \hat{S}_z \Psi_{JM}\right)$$

Таким образом,

$$\left(\Psi'_{JM'}, \hat{S}'_z \Psi'_{JM}\right) = \frac{\tilde{\Lambda}_0(J)}{\Lambda_0(J)} \left(\Psi_{JM'}, \hat{J}_z \Psi_{JM}\right)$$

С другой стороны, переход из OZ - представдения в OZ' - представление может быть осуществлен повором осей. Такое преобразование реализуется унитарными матрицами [1]:

$$\varphi'_{SM_S} = U_S \varphi_{SM_S},$$
$$\psi'_{LM_L} = U_L \psi_{LM_L}$$

16 Соответственно,

$$\Psi'_{JM} = \sum K^{J,M}_{S,M_S,L,M_L} \varphi'_{SM_S} \otimes \psi'_{LM_L} =$$
$$= \sum K^{J,M}_{S,M_S,L,M_L} \left(U_S \otimes U_L\right) \varphi_{SM_S} \otimes \psi_{LM_L} =$$
$$= \left(U_S \otimes U_L\right) \Psi_{JM} = U \Psi_{JM},$$

где $U = U_S \otimes U_L$ унитарна. Рассмотрим цепочку равенств

$$\left(\Psi_{JM'}, \hat{S}_x \Psi_{JM}\right) = \left(\Psi_{JM'}, U^{-1} U \hat{S}_x U^{-1} U \Psi_{JM}\right) =$$
$$= \left(U \Psi_{JM'}, \left(U \hat{S}_x U^{-1}\right) U \Psi_{JM}\right) = \left(\Psi'_{JM'}, \hat{S}'_z \Psi'_{JM}\right).$$

Таким образом, мы получили, что

$$\left(\Psi_{JM'}, \hat{S}_x \Psi_{JM}\right) = \left(\Psi'_{JM'}, \hat{S}'_z \Psi'_{JM}\right) =$$
$$= \frac{\tilde{\Lambda}_+(J) + \tilde{\Lambda}_-(J)}{\Lambda_+(J) + \Lambda_-(J)} \left(\Psi_{JM'}, \hat{J}_z \Psi_{JM}\right).$$

Из равенств (14) - (15) следует, что

$$\frac{\tilde{\Lambda}_0(J)}{\Lambda_0(J)} = \frac{\tilde{\Lambda}_+(J) + \tilde{\Lambda}_-(J)}{\Lambda_+(J) + \Lambda_-(J)}.$$

Будем обозначать каждое из отношений в этом равенстве $\Lambda(J)$. Аналогично доказываются и остальные равенства.

Вспомним задачу о сложении моментов и освежим в памяти обознач ения [4]. Пусть складываются моменты L и S. Это значит, что мы работаем в пространстве $\mathcal{M} = \mathbb{C}^{(2S+1)} \otimes \mathbb{C}^{(2L+1)}$. В процессе сложения моментов мы строим изометрический изоморфизм

$$\mathcal{M} \cong \bigoplus_{K=|L-S|}^{L+S} \mathbb{J}_K$$

где $\mathbb{J}_K$ - собственные для оператора $\hat{J}^2$ подпространства. Мы строим операторы суммарного момента так, чтобы матричные элементы вне $\mathbb{J}_K$ были равны нулю:

$$\left\langle JM \left| \hat{J}_i \right| J'M' \right\rangle \propto \delta_{JJ'} \quad \text{и} \quad \left\langle JM \left| \hat{J}^2 \right| J'M' \right\rangle \propto \delta_{JJ'}$$

Ниже нам понадобится работать с операторами, суженными на некоторое подпростр анство (причём на подпространство, необязательно собственное для рассматриваемого оператора, - и в этом вся тонкость). Будем обозначать оператор $\hat{A}$, суженный на подпростр анство $\mathcal{N}$, так: $(\hat{A}|\mathcal{N})$. твержение 13. Операторы $\hat{1} \otimes \hat{S}_i$ и $\hat{L}_j \otimes \hat{1}$ в собственном для $\hat{J}^2$ и $\hat{J}_z$ представлении обязательно имеют ненулевые матричные элементы вне $\mathbb{J}_K$. Доказательство. А. Докажем, что $\hat{1} \otimes \hat{S}_z$ имеет ненулевые недиагональные элементы. Доказательства для остальных компонент и для всех компонент $\hat{\mathbf{L}} \otimes \hat{1}$ легко проводятся в собственном для соответствующей компоненты представлении и здесь не приведены, чтобы избежать загромождения. Итак, рассмотрим старший вектор $|J, J\rangle \cong |L, L\rangle \otimes |S, S\rangle$. Дейст уя на него оператором понижения и нор мируя, получи м в ектор

$$|J, J-1\rangle \cong \sqrt{\frac{L}{L+S}}|L, L-1\rangle \otimes |S, S\rangle + \sqrt{\frac{S}{L+S}}|L, L\rangle \otimes |S, S-1\rangle.$$

Этот вектор не является собственным для операторов $\hat{1} \otimes \hat{S}_z$ и $\hat{L}_z \otimes \hat{1}$. Значит, он может быть разложен на сумму в екторов $\Psi_{J,J-1}$ и ортогонального ему вектора $\beta \in \mathcal{M}$:

$$\hat{S}_z|J, J-1\rangle = \text{ const } \cdot |J, J-1\rangle + |\beta\rangle, \quad \text{где} \quad \langle J, J-1|\beta\rangle = 0.$$

Так как $(2L+1)(2S+1)$ векторов $|J, M\rangle$ образуют базис в $\mathcal{M}$, то существ ует вектор $|J', M'\rangle$, на который проекция $|\beta\rangle$ ненулевая. Это и доказывает наличие ненулевых недиагональных элементов оператора $\hat{1} \otimes \hat{S}_z$. Докажем теперь, что ненулевой недиагональный элемент может лежать лишь вне $\mathbb{J}_K$.

В. По определению $\hat{S}_z$ и $\hat{J}_z = \hat{L}_z \otimes \hat{1} + \hat{1} \otimes \hat{S}_z$ коммутируют на $\mathcal{M}$:

$$\left[\hat{S}_z, \hat{J}_z\right] = 0$$

Из этого следует, что

$$\left\langle J', M' \left| \left[\hat{S}_z, \hat{J}_z\right] \right| J, M \right\rangle = 0$$

$$M \cdot \left\langle J', M' \left| \hat{S}_z \right| J, M \right\rangle - M' \cdot \left\langle J', M' \left| \hat{S}_z \right| J, M \right\rangle = 0$$

Значит, матричный элемент $\left\langle J', M' \left| \hat{S}_z \right| J, M \right\rangle$ может быть не равен нулю только для $M = M'$. Так как матрица оператора $\hat{S}_z$ в выбранном представлении и меет ненулевые недиаг ональные элементы, а одинаковые кв антовые числа M и $M' = M$ могут принадлежать

только различным $\mathbb{J}_K$, то ненулевой недиагональный матричный элемент для $\hat{S}_z$ может лежать лишь вне собственных для $\hat{J}^2$ подпространств $\mathbb{J}_K$.

Пример 14. Рассмотрим сумму моментов $S = 1/2$ и $L = 1/2$ (формально L может принимать только целые значения, но наши рассуждения верны для суммы моментов любой природы, а обозначение L мы сохраним только для единообразия обозначений). J может принимать значения 1 и 0. Рутинные вычисления дают:

$$\hat{1} \otimes \hat{S}^2 = \frac{3}{4} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

$$\hat{1} \otimes \hat{S}_z = \frac{1}{2} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix},$$

$$\hat{1} \otimes \hat{S}_x = \frac{1}{2\sqrt{2}} \begin{pmatrix} 0 & 1 & 0 & -1 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ -1 & 0 & 1 & 0 \end{pmatrix}$$

$$\hat{1} \otimes \hat{S}_y = \frac{1}{2\sqrt{2}} \begin{pmatrix} 0 & i & 0 & -i \\ -i & 0 & i & 0 \\ 0 & -i & 0 & -i \\ i & 0 & i & 0 \end{pmatrix}$$

$$\hat{J}^2 = \begin{pmatrix} 2 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 2 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \hat{J}_z = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix},$$

$$\hat{J}_x = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \hat{J}_y = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & -i & 0 & 0 \\ i & 0 & -i & 0 \\ 0 & i & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

Легко видеть, что операторы $\hat{1} \otimes \hat{S}_i$ имеют нетривиальные матричные элементы вне $\mathbb{J}_0$ и $\mathbb{J}_1$.

У твердждение 15. Если оператор $\hat{A}_i$ имеет только нулевые матричные элементы вне $\mathbb{J}_K$, то

$$\left(\hat{S}_i \hat{A}_i | \mathbb{J}_K\right) = \left(\hat{S}_i | \mathbb{J}_K\right) \left(\hat{A}_i | \mathbb{J}_K\right) = \left(\hat{S}_i | \mathbb{J}_K\right) \hat{A}_i$$

Здесь левая часть равенства означает, что сначала мы перемножаем матрицы операторов в выбранном представлении на $\mathcal{M}$, а потом сужаем результат на нужное подпространство, например, на $\mathbb{J}_K$. Средняя часть равенства означает, что сначала мы сужаем перемножаемые операторы на $\mathbb{J}_K$, а потом перемножаем матрицы меньшей размерности. Здесь также предполагается суммирование по повторяющемуся индексу.

Доказательство. Матричные элементы $\left(\hat{S}_i \hat{A}_i | \mathbb{J}_K\right)$ по опр еделению сужения равны

$$\left\langle J, M \left| \left(\hat{S}_i \hat{A}_i | \mathbb{J}_K\right) \right| J', M' \right\rangle = \left\langle K, M \left| \hat{S}_i \hat{A}_i \right| K, M' \right\rangle$$

Рассмотрим теперь матричные элементы произведения операторов на $\mathcal{M}\left(\hat{S}_i|\mathbb{J}_K\right)\hat{A}_i$:

$$\left\langle J,M\left|\left(\hat{S}_i|\mathbb{J}_K\right)\hat{A}_i\right|J',M'\right\rangle =$$
$$=\sum_{J'',M''}\left\langle J,M\left|\left(\hat{S}_i|\mathbb{J}_K\right)\right|J'',M''\right\rangle\left\langle J'',M''\left|\hat{A}_i\right|J',M'\right\rangle =$$
$$=\sum_{J'',M''}\left\langle K,M\left|\hat{S}_i\right|K,M''\right\rangle\delta_{J,K'}\delta_{K,J''}\left\langle J'',M''\left|\hat{A}_i\right|J',M'\right\rangle =$$
$$=\sum_{M''}\left\langle K,M\left|\hat{S}_i\right|K,M''\right\rangle\left\langle K,M''\left|\hat{A}_i\right|J',M'\right\rangle .$$

20 Так как матричные элементы $\hat{A}_i$ равны нулю вне $\mathbb{J}_K$, то

$$=\sum_{M''}\left\langle K,M\left|\hat{S}_i\right|K,M''\right\rangle\left\langle K,M''\left|\hat{A}_i\right|J',M'\right\rangle=\sum_{M''}\left\langle K,M\left|\hat{S}_i\right|K,M''\right\rangle\left\langle K,M''\left|\hat{A}_i\right|K,M'\right\rangle .$$

Так как на $\mathbb{J}_K$ множеств о $|K,M\rangle_{M=-K}^{M=K}$ является базисом, то последнее выражение равно

$$\sum_{M''}\left\langle K,M\left|\hat{S}_i\right|K,M''\right\rangle\left\langle K,M''\left|\hat{A}_i\right|K,M'\right\rangle =$$
$$=\left\langle K,M\left|\hat{S}_i\hat{A}_i\right|K,M'\right\rangle .$$

Отсюда получаем требуемое равенство:

$$\left\langle J,M\left|\left(\hat{S}_i|\mathbb{J}_K\right)\hat{A}_i\right|J',M'\right\rangle=\left\langle J,M\left|\left(\hat{S}_i\hat{A}_i|\mathbb{J}_K\right)\right|J',M'\right\rangle .$$

Замечание 16. В частности, для $\hat{A}_i=\hat{J}_i$ выполнено:

$$\left\langle J,M\left|\left(\hat{S}_i|\mathbb{J}_K\right)\hat{J}_i\right|J',M'\right\rangle=\left\langle J,M\left|\left(\hat{S}_i\hat{J}_i|\mathbb{J}_K\right)\right|J',M'\right\rangle .$$

Утверждение 17. Если оператор $\hat{A}_i$ имеет ненулевые элементы вне $\mathbb{J}_K$, то может быть

$$\left(\hat{S}_i\hat{A}_i|\mathbb{J}_K\right)\neq\left(\hat{S}_i|\mathbb{J}_K\right)\left(\hat{A}_i|\mathbb{J}_K\right)$$

Доказательство. В качестве доказательства приведем пример. Возьмем в качестве $\hat{A}_i$ операторы $\hat{S}_i$. Выберем $K=1$. Пользуясь матрицами из примера (14), пря мым вычислением получи м

$$\left\langle J,M\left|\left(\hat{S}_i\hat{S}_i|\mathbb{J}_1\right)\right|J',M'\right\rangle=\left\langle 1,M\left|\hat{S}_i\hat{S}_i\right|1,M'\right\rangle=\frac{3}{4}\delta_{M,M'}$$
$$\left\langle J,M\left|\left(\hat{S}_i|\mathbb{J}_1\right)\left(\hat{S}_i|\mathbb{J}_1\right)\right|J',M'\right\rangle =$$
$$=\sum_{J'',M''}\left\langle J,M\left|\left(\hat{S}_i|\mathbb{J}_1\right)\right|J'',M''\right\rangle\left\langle J'',M''\left|\left(\hat{S}_i|\mathbb{J}_1\right)\right|J',M'\right\rangle =$$
$$=\sum_{M''}\left\langle 1,M\left|\hat{S}_i\right|1,M''\right\rangle\left\langle 1,M''\left|\hat{S}_i\right|1,M'\right\rangle=\frac{1}{2}\delta_{M,M'}$$

21 Утверждение 18 (вычисление фактора Ланде). На каждом собственном для оператора $\hat{J}^2$ подпространстве выполнено

$$\left\langle JM'\left|\hat{S}_z+\hat{J}_z\right|JM\right\rangle=g_{LSJ}\left\langle JM'\left|\hat{J}_z\right|JM\right\rangle ,$$

где множитель

$$g_{LSJ} = 1 + \frac{J(J+1) - L(L+1) + S(S+1)}{2J(J+1)}$$

называется фактором Ланде. Доказательство. В соответствии с Утверждением 12 матричный элемент

$$\left\langle JM' \left| \hat{S}_z \right| JM \right\rangle = \Lambda(J) \left\langle JM' \left| \hat{J}_z \right| JM \right\rangle.$$

Для вычисления $\Lambda(J)$ запишем матричный элемент оператора

$$\left\langle JM' \left| \hat{S}_i \hat{J}_i \right| JM \right\rangle.$$

По определению на всем $\mathcal{M}$

$$\hat{\mathbf{S}} \cdot \hat{\mathbf{J}} = \hat{S}^2 - \frac{\hat{J}^2 - \hat{L}^2 - \hat{S}^2}{2}$$

Значит, матричный элемент (17) равен

$$\begin{aligned} &\left\langle JM' \left| \hat{S}^2 + \frac{1}{2}\left(\hat{J}^2 - \hat{L}^2 - \hat{S}^2\right) \right| JM \right\rangle = \\ =&\frac{J(J+1) - L(L+1) + S(S+1)}{2} \delta_{MM'} \end{aligned}$$

С другой стороны, в силу У тверждения 15 выполнено равенство

$$\begin{aligned} &\left\langle JM' \left| \hat{S}_i \hat{J}_i \right| JM \right\rangle = \\ &= \left\langle J'M' \left| \left(\hat{S}_i \hat{J}_i | \mathbb{J}_J \right) \right| \tilde{J}M \right\rangle = \\ = \sum_{J'',M''} &\left\langle J'M' \left| \left(\hat{S}_i | \mathbb{J}_J \right) \right| J''M'' \right\rangle \left\langle J''M'' \left| \left(\hat{J}_i | \mathbb{J}_J \right) \right| \tilde{J}M \right\rangle = \\ &= \sum_{M''} \left\langle JM' \left| \hat{S}_i \right| JM'' \right\rangle \left\langle JM'' \left| \hat{J}_i \right| JM \right\rangle. \end{aligned}$$

Матричные элементы $\left\langle JM' \left| \hat{S}_i \right| JM'' \right\rangle$ в силу Утверждения 12 могут быть записаны в виде

$$\left\langle JM' \left| \hat{S}_i \right| JM'' \right\rangle = \Lambda(J) \left\langle JM' \left| \hat{J}_i \right| JM'' \right\rangle.$$

Значит,

$$\begin{aligned} &\left\langle JM' \left| \hat{S}_i \hat{J}_i \right| JM \right\rangle = \\ = \Lambda(J) \sum_{M''} &\left\langle JM' \left| \hat{J}_i \right| JM'' \right\rangle \left\langle JM'' \left| \hat{J}_i \right| JM \right\rangle = \\ &= \Lambda(J) J(J+1) \delta_{MM'} \end{aligned}$$

Равенства (18) и (19) позволяют вычислять значение множителя $\Lambda(J)$ для каждого J:

$$\Lambda(J) = \frac{J(J+1) - L(L+1) + S(S+1)}{2J(J+1)}.$$

Отсюда после простых вычислений следует искомое выражение (16) для фактора Ланде g_{LSJ}.

Обсуждение вывода фактора Ланде. Вычисление фактора Ланде опирается на вычисление матричных элементов оператора $\hat{1} \otimes \hat{S}_z$. Для этого в качестве технического приема рассматрив аются матричные элементы оператора $\hat{S}_i \hat{J}_i$. Исследование такого оператора позволяет вычислить фактор $\Lambda(J)$, пользуясь теоремой Вигнера-Эккарта. При этом именно Утверждения 15 и 17 позволяют провести вычисления, так как теорема Вигнера-Эккарта устанавливает пропорциональность матричных элементов сферических тензоров коэффициентам КлебшаГордана лишь на собственных для $\hat{J}^2$ подпространствах.

Для демонстрации важности аккуратного подхода к вычислению фактора Ланде хочется обратить внимание на следующий пример неверного вычисления g_{LSJ}. Из частного обсуждения с Алексеем Леонидовичем Барабановым: кажется, что можно вы-числять фактор Ланде следующим образом. Рассмотрим матричные элементы $\left\langle JM' | \hat{\mathbf{S}} \cdot \hat{\mathbf{S}} | JM \right\rangle$. С одной стороны, они равны

$$\left\langle JM' | \hat{\mathbf{S}} \cdot \hat{\mathbf{S}} | JM \right\rangle =$$
$$= \left\langle J'M' \left| \left(\hat{S}_i \hat{S}_i | \mathbb{J}_K \right) \right| JM \right\rangle = S(S+1)\delta_{MM'}$$

23 С другой стороны,

$$\left\langle JM' \left| \hat{S}_i \hat{S}_i \right| JM \right\rangle = \left\langle JM' \left| \Lambda^2(J) \hat{J}_i \hat{J}_i \right| JM \right\rangle =$$
$$= \Lambda^2(J) J(J+1) \delta_{MM'}.$$

Отсюда получаем другой результат: кажется, что фактор Ланде равен

$$g_{JLS}^{\text{wrong}} = 1 + \sqrt{\frac{S(S+1)}{J(J+1)}}.$$

Равенства (22) и, следовательно, (23) неверны. В самом деле, теорема Вигнера-Эккарта утверждает не пропорциональность операторов $\hat{S}_i$ и $\hat{J}_i$, а пропорциональность их матричных элементов на каждом $\mathbb{J}_K$:

$$\left\langle JM' \left| \hat{S}_i \hat{S}_i \right| JM \right\rangle =$$
$$= \sum_{J'', M''} \left\langle JM' \left| \hat{S}_i \right| J'', M'' \right\rangle \left\langle J'', M'' \left| \hat{S}_i \right| JM \right\rangle$$

Для применения теоремы Вигнера-Эккарта к матричным элементам в последнем равенстве нужно, чтобы операторы $\hat{S}_i$ рассматривались лишь на подпространствах $\mathbb{J}_K$. То есть чтобы матричные элементы сужения произведения операторов, записанного в левой части равенства (24), были равны матричным элементам произведения сужений операторов на $\mathbb{J}_K$ - правой части равенства (24). В Утверждении 17 показано, что это неверно. Соответственно, фактор Ланде не может быть вычислен с помощью рассмотрения матричных элементов $\hat{S}_i \hat{S}_i$.

10.3 Two- and Three-Body Problems

(??????????????????????????)

10.3.1 Separation of the Center of Mass

(из Киселева) $\frac{1}{2m_1}\boldsymbol{\nabla}_1^2+\frac{1}{2m_2}\boldsymbol{\nabla}_2^2=(\boldsymbol{\nabla}_1,\boldsymbol{\nabla}_2)\begin{pmatrix}\frac{1}{2m_1} & 0\\ 0 & \frac{1}{2m_2}\end{pmatrix}\cdot\begin{pmatrix}\boldsymbol{\nabla}_1\\ \boldsymbol{\nabla}_2\end{pmatrix}$

Рассмотрим оператор Шрёдингера для задачи двух тел (см. пример 2.2 в разделе 2.2.4 главы 2):

$$H=-\frac{\hbar^2}{2m_1}\Delta_1-\frac{\hbar^2}{2m_2}\Delta_2+V\left(x_1-x_2\right)$$

Вводя

$$\boldsymbol{X}=\frac{m_1\boldsymbol{x}_1+m_2\boldsymbol{x}_2}{m_1+m_2}\quad\text{и}\quad\boldsymbol{x}=\boldsymbol{x}_1-\boldsymbol{x}_2$$

координаты центра масс и относительную координату, получаем

$$H=-\frac{\hbar^2}{2M}\Delta_{\boldsymbol{X}}-\frac{\hbar^2}{2\mu}\Delta_{\boldsymbol{x}}+V(\boldsymbol{x})$$

где $M=m_1+m_2$ - полная масса, а $\mu=\frac{m_1m_2}{m_1+m_2}$ - приведенная масса.

Оператор Гамильтона H диагонализуется методом разделения переменных. Конкретно, рассмотрим следующее разложение двухчастичного гильбертова пространства $\mathscr{H}=L^2\left(\mathbb{R}^6\right)$ в тензорное произведение гильбертовых пространств:

$$\mathscr{H}=L^2\left(\mathbb{R}^3,d^3\boldsymbol{X}\right)\otimes L^2\left(\mathbb{R}^3,d^3\boldsymbol{x}\right)$$

Оператор

$$H_X=-\frac{\hbar^2}{2M}\Delta_{\boldsymbol{X}}$$

действует как тождественный на втором сомножителе в (4.1), а оператор

$$H_{\boldsymbol{x}}=-\frac{\hbar^2}{2\mu}\Delta_{\boldsymbol{x}}+V(\boldsymbol{x})$$

как тождественный оператор на первом сомножителе в (4.1). У функцийрешений задачи на собственные значения

$$H\psi=E\psi$$

имеющих вид произведения

$$\psi(\boldsymbol{X},\boldsymbol{x})=\Psi(\boldsymbol{X})\psi(\boldsymbol{x})$$

переменные разделяются:

$$H_{\boldsymbol{X}}\Psi(\boldsymbol{X})=E_1\Psi(\boldsymbol{X})\quad\text{и}\quad H_{\boldsymbol{x}}\psi(\boldsymbol{x})=E_2\psi(\boldsymbol{x})$$

где $E=E_1+E_2$. Поскольку

$$\Psi(\boldsymbol{X})=\left(\frac{1}{2\pi\hbar}\right)^{\frac{3}{2}}e^{\frac{i}{\hbar}\boldsymbol{k}\boldsymbol{X}},\quad\boldsymbol{k}^2=2ME_1,$$

квантовая задача двух тел сводится к задаче о квантовой частице, движущейся в потенциальном поле, и описывается оператором Гамильтона (4.3) в гильбертовом пространстве $L^2\left(\mathbb{R}^3,d^3x\right)$.

Parts of Quantum Mechanics

(сюда многое перенесу из разделов выше, что не является типичным методом)

13 Estimations and Well-known Effects

13.1 Estimates in Atomic Mechanics

В этом разделе будут получены основные результаты атомной механики. Для получения соотношений мы будем использовать, кроме размерных, также модельные оценки. Идея модельных оценок состоит в рассмотрении предельных случаев и упрощенных вариантов задачи.

(!!!! это в 1ю часть во многом перенесу!!!)

13.1.1 Estimates of Velocities and Sizes of Inner Electron Orbits in the Atom

Для оценки скорости электрона на внутренней орбите атома нужно составить величину с размерностью скорости из величин, определяющих структуру атома, т. е. из массы электрона m, постоянной Планка $\hbar$ и произведения заряда ядра и заряда электрона $Ze \cdot e$. Действительно, в уравнение движения заряд электрона входит только в виде произведения на заряд ядра, поскольку при рассмотрении внутренних электронов влиянием других электронов можно пренебречь. Задача нерелятивистская, поэтому скорость света не войдет. Единственная величина размерности скорости, которую можно составить из $m, \hbar$ и $Ze^2 - 9v \subset \Omega e^2/\hbar$.

Для оценки порядка величины радиуса внутренних орбит электрона a воспользуемся тем, что потенциальная энергия электрона Ze^2/a порядка его кинетической энергии mv^2, т. е. $Ze^2/a \sim mv^2$ или $a \sim \hbar^2/Zme^2$. Из оценок α и v видно, что при рассмотрении атомных явлений удобны единицы $e = \hbar = m = 1$ (так называемые атомные единицы). В этих единицах скорость света $c = 137,2$, а масса протона $M = 1840$.

13.1.2 Stationary States

Яма

Рассмотрим движение частицы в потенциальной яме (рис. 10).

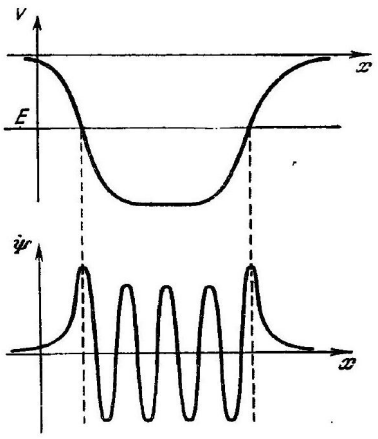

Рис. 10.

Уравнение Шредингера для этого случая имеет вид

$$\Psi'' + k^2\Psi = 0,$$

причем $k^2 = 2(E - V)$. В классически доступной области потенциальная энергия V меньше полной энергии E. Следовательно, волновая функция Ψ осциллирует в этой области (см. 1.1). В области, где $E < V$, Ψ-функция экспоненциально затухает. Энергию стационарных состояний можно оценить из условия, что характерный размер l области, в которой может двигаться частица, содержит целое число n полуволн де-Бройля.

Стационарные уровни энергин нельзя получить, исходя из одних лишь размерных соображений, так как величина n безразмерна. Мы будем делать модельные оценки, заменяя реальную потенциальную яму ящиком (рис. 11) с длиной, зависящей от энергии частицы.

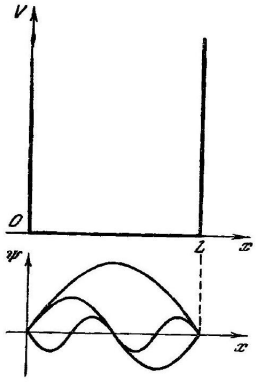

Рис. 11.

Длина де-Бройлевской волны

$$\lambda\!\!\!^{-} = 1/p = 1/\sqrt{2(E - V)},$$

где p - импульс частицы. Для произвольной потенциальной ямы λ зависит от координаты x. Для оценки всегда можно считать $\hbar \sim 1/\sqrt{2E}$, если E отсчитано от дна ямы.

Итак, оценка стационарных уровней системы E_n получается из соотношения

$$L\,(E_n) \approx \frac{n}{2}\lambda \sim \frac{2\pi n}{2\sqrt{2E_n}},$$

где $L\,(E_n)$ - характерная длина области, в которой может двигаться частица.

Для прямоугольной ямы величина $L\,(E_n) = L$ - длине ямы.

Следовательно, $L = \frac{\pi n}{\sqrt{2E_n}}$, откуда $E_n = \frac{\pi^2 n^2}{2L^2}$. Это выражение удовлетворяет принципу соответствия Бора: при больших квантовых числах расстояние между соседними энергетическими уровнями должно равняться классической частоте движения Действительно,

$$\frac{dE_n}{dn} = 2\frac{\pi^2 n}{2L^2} = \frac{\pi n}{L}\frac{2\pi}{2L} = \frac{2\pi}{2L/\frac{\pi n}{L}} = \frac{2\pi}{2L/v} = \frac{2\pi}{T_{\text{K}J}},$$

где $T_{\text{кл}}$ - классический период движення, равный $2L/v$.

Одномерный осциллятор

Следующий пример - одномерный осциллятор, потенциальная энергия которого $V = \frac{1}{2}\omega^2 x^2$. Здесь ω - частота классического осциллятора. Заметим, что частота осцилляций Ψ-функции около начала координат (рис. 12) больше, чем у краев ямы.

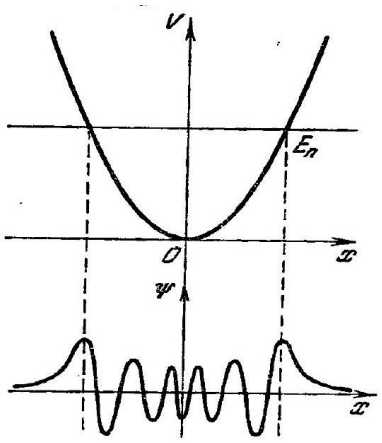

Рис. 12.

Действительно, при $x = 0$ кинетическая энергия движения максимальна, следовательно, длина волны k минимальна. При заданной энергии E_n характерная длина области L, в которой может двигаться частица, находится из условия $V(L) = E_n$. Итак, $\frac{1}{2}\omega^2 L_n^2 \sim E_n$, откуда $L_n \sim \sqrt{E_n}/\omega$. Условие квантования (1.27) имеет вид $\sqrt{E_n}/\omega \sim n/\sqrt{E_n}$, откуда $E_n = C_1 n\omega$. Из принципа соответствня следует, что $C_1 = 1$

Как известно, точное решение задачи приводит к спектру осциллятора $E_n = \left(n + \frac{1}{2}\right)\omega$, т. е. при $n = 0$ энергия колебаний отлична от нуля. Это связано с соотношением неопределенностей: частица, движущаяся в малой области d, не может иметь импульс, меньше $\sim 1/d$. Энергия E имеет оценку $E \sim \frac{1}{d^2} + \omega^2 d^2$. Возьмем минимум этого выражения. Эта минимизация соответствует вариационному принципу квантовой механики: $E = \min(\psi|H|\psi)$. В данном случае ψ-функция зависит от одного лишь параметра d. Выражение для E минимально при $d \sim 1/\sqrt{\omega}$. При этом $E_{\min} = C_2\omega\,(C_2 = 1/2)$. Величина $d^2_{\min} \sim 1/\omega$ дает оценку квадрата амплитуды нулевых колебаний.

Движение в кулоновском поле(!!??!?!)

Рассмотрим движение в кулоновском поле (рис. 13). Ограничимся случаем $l = 0$ (случай $l \neq 0$ будет рассмотрен квазиклассически на стр. 138).

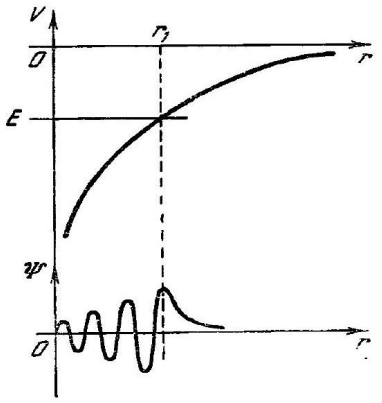

Рис. 13.

Существенная длина движения L находится из условия $E \sim Z/L$, т. е. $L \sim Z/E$. Из условия квантования (1.27) находим $Z/E_n \sim n/\sqrt{E_n}$, т. е. $E_n = C_1 \frac{Z^2}{n^2}$. Число C_1 найдем из принципа соответствия:

$$\frac{dE_n}{dn} = -C_1 \frac{2Z^2}{n^3} = \omega_{\text{К}\pi} = \frac{2\pi}{T_{\text{К}\pi}}.$$

Период классического движения

$$T_{\text{кл}} = 2\int_0^{r_1} \frac{dr}{v} = 2\int_0^{-Z/E} \frac{dr}{\sqrt{2\left(E_n + Z/r\right)}} = \frac{2\pi Z}{\left(2E_n\right)^{3/2}}.$$

Итак, $-C_1 \frac{2Z^2}{n^3} = \frac{2\pi}{2\pi Z}\left(-2C_1 \frac{Z^2}{n^2}\right)^{3/2}$, откуда $C_1 = -\frac{1}{2}$. Окончательно $E_n = -\frac{1}{2}\frac{Z^2}{n^2}$, что, как известно, совпадает с точным решением.

13.1.3 Distribution of Electric Charge in an Atom

Распределение заряда в тяжелых атомах можно вычислять с помощью приближенного метода, называемого методом Томаса-Ферми. При этом используется тот факт, что в тяжелом атоме большинство электронов имеет большие квантовые числа. Длины волн электронов при этом малы по сравнению с областью изменения потенциала. Тогда плотность электронов в каждой точке атома можно рассчитывать так же, как и плотность свободных электронов в потенциальном ящике с плоским дном.

Пусть наибольший импульс электронов в данной точке равен p_0. Тогда число состояний в интервале $(p, p+dp)$ равно $d\boldsymbol{p}/(2\pi)^3$. Поскольку в основном состоянии атома Электроны должны заполнять все состояния с импульсом, меньшим p_0, то число электронов в единице объема равно

$$n = 2\int \frac{dp}{(2\pi)^3} = 2\frac{4}{3}\pi p_0^3 \frac{1}{(2\pi)^8}$$

(множитель 2 возникает из-за двух возможных проекций спина электрона).

Обозначим через $\varphi(r)$ электростатический потенциал атомного поля. Согласно уравнению Пуассона

$$\Delta\varphi = 4\pi n,$$

Т. е.

$$\Delta\varphi \sim p_{0^3}.$$

Свяжем $p_0 c\varphi$. Полная энергия электрона равна $\frac{p^2}{2} - \varphi(r)$. Пусть $\varepsilon_0 \to$ максимальное значение полной энергии в каждой точке атома, т. е.

$$\varepsilon_0 = \frac{p_0^2}{2} - \varphi(r)$$

Величина ε_0 должна быть постоянной, иначе электроны будут переходить из точек с большей энергией в точки с меньшей энергией. Uз двух последних формул находим

$$\Delta\varphi \sim \left(\varphi + \varepsilon_0\right)^{3/2}$$

или

$$\Delta\varphi \sim \varphi^{3/2},$$

если отсчитывать ϕ от $-\varepsilon_0$.

Определим радиус l области, в которой находится большинство атомных электронов. Из последней формулы имеем по порядку величины

$$\frac{\varphi}{l^2} \sim \varphi^{3/2}, \text{ откуда } l \sim \varphi^{-1/4}.$$

С другой стороны, величину l можно связать с числом всех электронов атома Z:

$$Z \sim nl^3$$

или, учитывая соотношение $\Delta\varphi \sim p_0^8$,

$$Z \sim \Delta\varphi l^3 \sim \frac{\varphi}{l^2} l^3 \sim \varphi l.$$

Сравнивая два последних выражения, находим $Z \sim l^{-4} \cdot l$ или

$$l \sim \frac{1}{Z^{1/3}}.$$

(?????? почему????) Средняя энергия ε атомного электрона по порядку величины равна электростатическому потенциалу $\varphi(l)$. Так как $l \sim \varphi^{-1/4}$, то получаем

$$\varepsilon \sim l^{-4} \sim Z^{4/3}.$$

Полная энергия всех электронов E имеет порядок величины

$$E \sim \varepsilon Z \sim Z^{7/3}.$$

Число узлов волновой функции есть $l\sqrt{\varepsilon} \sim Z^{1/3}$.

Итак, радиус K, L-оболочки атома $r_K \sim 1/Z$, расстояние l (томас-фермиевский радиус) $\sim 1/Z1/3$ и радиус наружных оболочек ~ 1, поскольку эффективный зарлд для электронов наружных оболочек ~ 1.

Распределение электрического заряда в атоме рассматривается в разделе 3.2 подробнее. (?????)

13.1.4 Rutherford Formula

(???? это повторение механики??? в 1й части по механике скорее всего это же будет, мб чуть короче. пока тренироваться нужно!)

Рассмотрим рассеяние легкой частицы с массой m и зарядом e на тяжелой частице с зарядом Ze в нерелятивистском классическом случае.

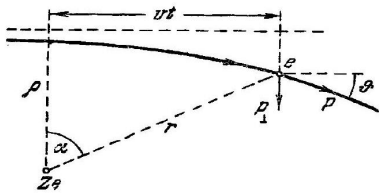

Рис. 14.

Сечение рассеяния не зависит от массы тяжелой частицы; оно определяется скоростью налетающсй частицы v, ее массой и зарядами e и Ze. Из закона Кулона следует бнлннейность сечения по зарядам, т. е. сечение σ будет зависеть лишь от комбинации Ze^2. Из этих параметров можно составить только одну величину с размерностьюдлины, а именно Ze^2/mv^2; следовательно, сечение рассеяния

$$\sigma(\theta) = \left(\frac{Ze^2}{mv^2}\right)^2 f(\theta)$$

Найдем зависимость сечения от угла рассеяния в предельном случае малых углов. Угол отклонения θ приближенно равен (рис. 14) $\theta \approx p_\perp/p$, где p-импульс частицы, а $p_\perp$ - импульс, возникающий в направлении, перпендикулярном к исходному. Вычислим $p_\perp$:

$$p_\perp = \int\limits_{-\infty}^{\infty} F_\perp dt = \int\limits_{-\infty}^{\infty} \frac{Ze^2}{r^2}\cos\alpha dt = \int\limits_{-\infty}^{\infty} \frac{Ze^2\rho dt}{(\rho^2+v^2t^2)^{3/2}} = \frac{2Ze^2}{\rho v}\int\limits_0^{\infty}\frac{dx}{(1+x^2)^{3/2}} = \frac{2Ze^2}{\rho v}$$

(интеграл берется сразу заменой $x = \operatorname{tg} y$); здесь ρ-прицельное расстояние (см. рис. 14). Следовательно,

$$\theta(\rho) = \frac{2Ze^2}{mv^2\rho}.$$

Го определению дифференциального сечения рассеяния:

$$d\sigma = \rho d\rho d\varphi = \rho\left|\frac{d\rho}{d\theta}\right| d\theta d\varphi = \rho\left|\frac{d\rho}{d\theta}\right|\frac{\sin\theta d\theta d\varphi}{\sin\theta},$$

или

$$\frac{d\sigma}{d\Omega} = \rho\left|\frac{d\rho}{d\theta}\right|\frac{1}{\sin\theta}$$

Используя (1.28) и (1.29), получаем формулу Резерфорда для малых углов рассеяния:

$$\frac{d\sigma}{d\Omega} = \left(\frac{2Ze^2}{mv^2}\right)^2\frac{1}{\theta^4}$$

13.1.5 Inapplicability of Classical Mechanics at Large Impact Parameters (!!!!!!!)

(!?!?!!? важный раздел, потом подумаю больше про него!!! в 1х частях укажу точно!)

В классической механике полное сечение рассеяния

$$\sigma = \int\limits_0^{\infty} 2\pi\rho d\rho$$

обращается в бесконечность для любых потенциалов (кроме обрывающихся, как, например, потенциал твердого иарика). В квантовой механике полное сечение конечно для потенциалов, убывающих с расстоянием быстрее, чем $1/r^2$ (см. задачу). Покажем, что классическая механика становится неприменимой при достаточно малых углах рассеяния, т. е. при достаточно больших прицельных параметрах о. Мы увидим, что с увеличением прицельного параметра угол квантовомеханической дифракции θ_d уменьшается медленнее, чем угол классинеского рассеяния θ. Поэтому, начиная с некоторого прицельного па- раметра ρ_1 угол θ_d становится больше $\theta_{\text{кл}}$.

Следовательно, дифференциальное сечение рассеяция для прицельных параметров рассеяиня, ббльших ρ_1, нужно рассчитывать по квантовомеханическим формулам. Итак, хотя длина волны λ здесь много меньше характерного размера, т. е. ρ_1, условия классичности рассеяния не выполняются, т. е. условие $\lambda \ll \rho_1$ - необходимое, но вовсе не догтаточное условие применимости классической механики. Получим критерий применимости классической меха ники. Согласно оценке $\theta \approx p_\perp/p$ заключаем, что

$\theta_{\text{КІ}} \sim F_\perp \Delta t/p \sim \frac{\partial V}{\partial \rho}\frac{\Delta t}{p} \sim \frac{V(\rho)}{p}\frac{\Delta t}{\rho} \sim \frac{V(\rho)}{pv}$, т. е. $\theta_{\kappa\Omega} \sim \frac{V(\rho)}{E}$. Здесь мы предположили, что $\frac{\partial V}{\partial \rho} \sim \frac{V}{\rho}$ (см. стр. 8) (E- энергия частицы, V - потенциал взаимодействия).

Для нахождения угла дифракции рассмотрим следующий опыт. Экран с отверстием диаметра a ограничивает прицельные параметры рассеяния значениями $\rho \pm a$ (рис. 15). Для применимости классической механики необходимо, чтобы ши-

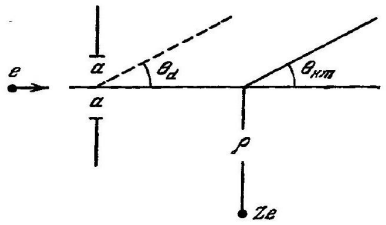

Рис. 15.

рина цели a была много меньше прицельного параметра ρ, иначе само понятие прицельного параметра теряет смысл. При сужении отверстия возникает дифракционное рассеяние. Чтобы можно было наблюдать отклонение, необходимо, чтобы дифракционный угол был много меньше угла рассеяния.

Из соотношения неопределенностей видно, что неопределенность в координате a соответствует неопределенности в поперечном импульсе $\Delta p \sim \hbar/a$. Следовательно, угол дифракции

$$\theta_d \sim \frac{\Delta p}{p} \sim \frac{1}{pa},$$

где p - импульс налетающей частицы. Для применимости классической механики необходимо, чтобы $\theta_{\text{cl}} \geqslant \theta_d$, или $\theta_{\text{cl}} \geqslant 1/pa$. Тем более,

$$\theta_{\text{cl}} = \frac{V(\rho)}{E} \geqslant \frac{1}{p\rho}.$$

Это-общий критерий применимости классической механики для задачи рассеяния. Для потенциалов, спадающих с расстоянием быстрее, чем кулоновский, классический угол рассеяния убывает с ростом прицельного параметра сильнее, чем $1/\rho$. Поэтому всегда найдется прицельный параметр ρ_1, для которого $\theta_{\text{кл}} \sim \theta_d$. В случае резерфордовского рассеяния $\theta = \frac{2Ze^2}{p\rho v}$ и рассеяние будет для всех углов классическим, если $Ze^2/\hbar v \gg 1$.

13.1.6 Estimate of Cross Sections for Potentials Decaying Faster than Coulomb (?????)

Мы получили, что классическая механика неприменима при прицельных параметрах, больших ρ_1, которое определяется из условия равенства классического угла рассеяния дифракционному:

$$\frac{\hbar}{\rho_1 p} = \theta_{\text{КІ}}(\rho_1),$$

т. е. величина ρ_1 находится из соотношения

$$\frac{\hbar}{\rho_1 p} \sim \frac{V(\rho_1)}{E}$$

)E - энергия налетающей частицы). Из (1.32) можно найти ρ_1 для любого конкретного вида потенциала $V(\rho)$, спадающего с расстоянием быстрее кулоновского (для последнего обе части соотношения (1.32) пропорциональны $1/\rho$, т. е. ρ_1 найти

нельзя). Следовательно, при $\rho < \rho_1$ дифференциальное сечение рассеяния можно вычислять по формулам классической механики.

Полное сечение рассеяния

$$\sigma = \pi\rho_1^2 + \sigma_{\text{диФ}} ,$$

где $\sigma_{\text{диф}}$ - дифракционное сечение рассеяния.

Если потенциал достаточно быстро убывает ($V(r) \underset{r\to\infty}{<} 1/r^2$, см. задачу), то сечение рассеяние может быть оценено как дифракционное сечение рассеяния на экране радиуса ρ_1, т. е. $\sigma_{\text{диф}}$ имеет порядок $\pi\rho_1^2$, так что

$$\sigma \sim 2\pi\rho_1^2.$$

Оценим полное сечение рассеяния для степенного потенциала $V = \alpha/r^n$. Из формулы (1.32) находим $\frac{1}{\rho_1 p} \sim \frac{\alpha}{\rho_1^n E}$, откуда $\rho_1 \sim (\alpha/v)^{\frac{1}{n-1}}$. Следовательно,

$$\sigma \sim 2\pi\rho_1^2 \sim 2\pi \left(\frac{\alpha}{i}\right)^{\frac{2}{n-1}} .$$

При n, близком к 2, эта оценка не годится (см. задачу).

З а дача. Определить, при какой степени убывания потенциала полное сечение рассеяния конечно.

13.1.7 Resonance Effects in Scattering (!!!!!)

Рассмотрим сначала рассеяние на потенциале, имеющем сильно отталкивающую сердцевину (рис. 16).

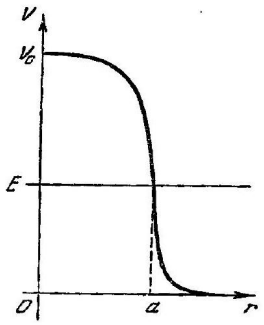

Рис. 16.

Обозначим через V_0 и a соответственно высоту и ширину потенциального барьера. Предположим, что $V_0 \gg E$-энергии налетающей частицы. Тогда на границе барьера волновая функция обращается в нуль: $\Psi(a) = 0$. Рассмотрим для простоты сферически - симметричное рассеяние и предположим, что при $r > a$ частица движется свободно, т. е. ее волновая функция есть сумма падающей плоской волны e^{ik2} и расходящейся сферической волны $\frac{f}{r}e^{ikr}$, где f-амплитуда рассеяния. Плоская волна e^{ikz} имеет сферически-симметричную часть, равную $\frac{\sin kr}{kr}$. Действительно, если разложить e^{ikz} в ряд по полиномам Лежандра: $e^{ikz} = e^{ikr\cos\theta} = \sum\limits_{l=0}^{\infty} f_l P_l(\cos\theta)$, то $f_0 = \frac{1}{2}\int\limits_0^{\pi} e^{ikr\cos\theta}\sin\theta d\theta = \frac{\sin kr}{kr}$. Итак,

$$\int \Psi \frac{d\Omega}{4\pi}\bigg|_{r>a} = \frac{\sin kr}{kr} + \frac{f_i}{r}e^{ikr}.$$

Используя граничное условие $\Psi(a) = 0$, находим $\frac{\sin ka}{k} + + fe^{ika} = 0$, или

$$f = -\frac{\sin ka}{k} e^{-ika}.$$

Если энергия частицы такова, что $ka = n\pi$, где n-пелое число, то $f = 0$, т. е. сечение s-рассеяния обращается в нуль. Этот резонансні:й эффект для отталкивательного потенциала ослаблен тем, что при $ka \geqslant 1$ в рассеянии существенны и волны с $l \neq 0$. Поэтому полное сечение рассеяния не обращается в нуль.

Как видно из выражения для амплитуды рассеяния, нанбольшее сечение получается при $ka = (2n+1)\frac{\pi}{2}$: $\sigma = 4\pi\star^2$. При малых $k(ka$

Резонансные эффекты при рассеянии используются в так называемой просветленной оптике: на поверхность линзы наносится слой вещества такой толщнны, чтобы разность фаз от слоя и линзы составила целое число . В результате на поверхности линзы не происходит отражения света и все потери обусловлены лишь поглощением.

Аналогичное явление происходит при рассеянии частиц на потенциальной яме ($V < 0$). Как и в случае $V > 0$, сечение рассеяния принимает различные значения в зависимости от фазы волновой функции у края ямы. При определенных значениях фазы сечение обрацаается в нуль. Этот эффект наблюдался впервые Рамзауэром при рассеянии электронов на атомах. Классическая теория рассеяния не может объяснить это явление. Другой пример, где классическая механика решительно противоречит эксперименту,- это захват медленных нейтронов ядрами. Сечение этого процесса ($\sim 4\pi\lambda^2$) превышает классическое сечение ($\sigma_{\text{кл}} = \pi R^2$, где R - радиус ядра) в десятки тысяч раз.

13.1.8 Interaction Between Atoms

Оценим величину взаимодействия нейтрального атома с ионом и с нейтральным атомом на больших расстояниях. Ион создает электрическое поле $E = Z_1/r^2$, где Z_1-заряд иона. Нейтральный атом, находящийся в электрическом поле E, приобретает дипольный момент $d = \alpha E$, где α-поляризуемость атома. Следовательно, взаимодействие иона с нейтральным атомом $V = -Ed = -Z_1^2\alpha/r^4$. В атомных единицах $\alpha \sim 1$, так как главную роль в поляризации атома играют наружные оболочки, для которых все величины ~ 1 в атомных единицах. Таким образом, $V \sim -Z_1^2/r^4$.

Рассмотрим теперь случай, когда оба атома нейтральны. Они индуцируют друг у друга дипольные моменты $\overline{d_1}$ и $\bar{d}_2$. Диполь-дипольное взаимодействие между атомами равно $V \sim -\vec{d}_1\vec{d}_2/r^3$

Среднее значение $\bar{d}_1$ и $\bar{d}_2$ по основному состоянию равно нулю, так как атомы не имеют постоянных дипольных моментов. Однако среднее значение $\bar{d}_1^2, \bar{d}_2^2$ отлично от нуля, так как дипольный момент колеблется со всеми возможными атомными частотами:

$$\bar{d} = \sum_\omega d_\omega e^{i\omega t}$$

Дипольный момент $d_{1\omega}$ создает поле $E_\omega \sim \frac{d_{1\omega}}{r^3}$. Момент $d_{2\omega}$ в этом поле равен $d_{2\omega} = \alpha_2 E_\omega$. Подставляя $d_{2\omega}$ в энергию взаимодействия, получим после усреднения по времени:

$$V \sim \sum_\omega d_{2\omega}E_\omega = -\frac{1}{r^6}\sum_\omega d_{1\omega}^2\alpha_2(\omega) \sim -\frac{1}{r^6}$$

13.1.9 Ionization of Atoms

Оценим потери энергии при движении быстрого электрона в газе. Налетающий электрон, сталкиваясь с электронами атомных оболочек, выбрасывает их из атома. При

большой энергии налетающего электрона его угол отклонения $\boldsymbol{v}$ мал. Поэтому сечение рассеяния на одном электроне оболочки определяется формулой $\frac{d\sigma}{d\Omega} \sim \frac{1}{p^4\vartheta^4}$; здесь p - импульс электрона.

Обозначим через q изменение импульса налетающего электрона; величина q связана с углом рассеяния $\forall$ соотношением $q \sim p\theta$. Энергия ΔE, передаваемая при столкновении, равна $q^2/2$. Потеря энергии электрона на единице длины пути равна:

$$\frac{dE}{dx} = -nZ \int \Delta E d\sigma,$$

где nZ - полное число электронов в единице объема, $d\sigma$ - дифференциальное сечение. Имеем:

$-\frac{dE}{dx} \sim Zn \int q^2 \frac{1}{p^4} \frac{1}{\vartheta^4} \vartheta d\vartheta =$

$$= Zn \int q^2 \frac{1}{p^4} \frac{p^2 dq}{q^3} = Zn \frac{1}{p^2} \int \frac{dq}{q} = \frac{Zn}{p^2} \ln \frac{q_{\max}}{q_{\min}}.$$

Максимальный классический угол отклонения $\vartheta^{\text{кл}}_{\max} \sim 1$, но он соответствует прицельным параметрам, много меньшим длины волны налетающей частицы. Такие прицельные параметры квантовомеханически бессмысленны. Минимальный прицельный параметр, о котором можно говорить в квантовой механике, имеет порядок длины волны λ. Отсюда $\vartheta_{\max} \sim \frac{1}{\rho_{\min} E} \sim \frac{1}{p}$ и $q_{\max} \sim p\vartheta_{\max} \sim 1$.

Минимальный передаваемый импульс соответствует случаю, когда время пролета электрона τ сравнивается с собственными временами (обратными частотами) атома $1/\omega_0$. При больших временах пролета поле налетающего электрона не содержит фурье-компонент с атомными частотами и вероятность ионизации резко убывает. Величина $\tau \sim \rho/\tau$, где v-скорость налетающего электрона. Итак, $q_{\min}$ находится из условия $\frac{\rho}{v} \sim \frac{1}{\omega_0}$. Так как $\boldsymbol{\vartheta} \sim 1/\rho E$, то $\vartheta_{\min} \sim \omega_0/vE$, а $q_{\min} \sim p\vartheta_{\min} \sim p\omega_0/vE \sim \omega_0/p^2$. Следовательно,

$$-\frac{dE}{dx} \sim \frac{Zn}{p^2} \ln \frac{p^2}{\omega_0}.$$

Как мы видели (см. стр. 36), основная масса электронов атома расположена в области радиуса $a_0/Z^{1/s}$ и энергия каждого из них $\sim Z^{4/3}$. Величина ω_0 имеет порядок $v/a \sim Z^2 !_3 / Z^{-1/3} \sim Z$. Поэтому

$$-\frac{dE}{dx} \sim \frac{Zn}{p^2} \ln \frac{p^2}{Z}.$$

13.1.10 Multiple Scattering

Узкий пучок электронов при прохождении через среду размывается по углам из-за многократного рассеяния. Действительно, хотя отклонение электрона, скажем, направо и налево, равновероятно, средний квадрат угла отклонения отличен от нуля.

С аналогичным явлением встречаются люди, имеющие телефон с трубкой телефона на шнуре, в обыденной жизни, наблюдая, как закручивается со временем этот шнур. При каждом телефонном разговоре шнур закручивается в ту или иную сторону равновероятно. Однако после больного числа разговоров шнур оказывается закрученным на угол, пропорциональный квадратному корню из числа разговоров. (????? что?? подумаю про это когда-то не скоро.)

Поскольку разброс электронов пучка по углам представляет собой совокупность большого числа независимых случайных процессов, то распределение по углам имеет

вид $\Phi(\vartheta) = Ae^{-\vartheta^2/\bar{\vartheta}^2}$ (гауссово распределение). Средний квадрат угла отклонения $\overline{\vartheta^2}$ пропорционален числу столкновений N, равному отношению толщины образца L к длине свободного пробега h. Если $\overline{\$_1^2}$ - средний квадрат угла отклонения при одном столкновении, то

$$\overline{\vartheta^2} = \overline{\vartheta_1^2}N = \overline{\vartheta_1^2}\frac{L}{l} = n\sigma L\overline{\vartheta_1^2} = \overline{0^2}L,$$

где σ-сечение рассеяния, n-число ядер в единице объема, а $\overline{\theta^2}$ - средний квадрат угла отклонения на единице длины пути, т. е. $\overline{\theta^2} = n\sigma\overline{\vartheta_1^2}$. Так как, по определению, $\overline{\vartheta_1^2} = \frac{1}{\sigma}\int \sigma(\vartheta)\vartheta^2 a\Omega$, то $\overline{\theta^2} = n\int \sigma(\vartheta)\vartheta^2 d\Omega$.

Для резерфордовского рассеяния получаем

$$\overline{\theta^2} \sim 2\pi n\frac{Z^2}{E^2}\ln\frac{\vartheta_{\max}}{\vartheta_{\min}}.$$

Эта формула годится как в релятивистском, так и в нерелятивнстском случае.

Рассмотрим два предельных случая: $Ze^2/\hbar v \gg 1$ и $2e^2/\hbar v \ll 1$. В первом случае рассеяние для всех углов можно считать классическим (см. стр. 40). Максимальный угол рассеяния определяется из условня, что прицельный параметр равен радиусу ядра R, т. е. $\vartheta_{\max} \sim V(R)/E = Z/RE$. Однако в случае рассеяния электронов значение $E \geqslant Z/R$ противоречит условию классичности; в обратном случае, который соответствует условию $Z/RE > 1, \dot{\vartheta}_{\max} \sim 1$. Минимальный угол отклонения определяется атомными размерами $a : \dot{\vartheta}_{\min} \sim Z/aE$. Оцценная а по модели Томаса-Ферми, находим $\vartheta_{\min} \sim Z/Z^{-1_{i3}}E \sim Z^4/E$. Следовательно, для электронов с $E < Z/R$

$$\overline{\vartheta^2} \sim 2\pi n\frac{Z^2}{E^2}\ln\frac{E}{Z^{4/3}}.$$

В случае, когда $Ze^2/\hbar v \ll 1$, классический угол отклонения меньше угла квантовомеханической дифракции ϑ_d. Поэтому углы $\vartheta_{\max}$ и $\vartheta_{\min}$ должны определяться следующим образом: $\vartheta_{\min}$ - угол дифракции на радиусе атома:

$$\vartheta_{\min} \sim \frac{\hbar}{a} \sim \frac{Z^{1/3}}{p}.$$

Тут $\vartheta_{\max}$ - угол дифракции на ядре:

$$\vartheta_{\max} \sim \frac{\hbar}{R} \sim \frac{1}{pR} \text{ при } \frac{\lambda}{R} < 1,$$
$$\vartheta_{\max} \sim 1 \quad \text{при } \frac{\lambda}{R} > 1.$$

Таким образом, в случае $Ze^2/\hbar v$

$$\overline{\theta^2} = 2\pi n\frac{Z^2}{E^2} \times \begin{cases} \ln\frac{a}{R}, & \lambda/R < 1, \\ \ln\frac{a}{\hbar}, & \star/R > 1. \end{cases}$$

13.2 Estimations and Effects in Quantum Electrodynamics

13.2.1 Zero Fluctuations of the Electromagnetic Field

Как известно, энергия электромагнитного поля равна $\int\left(\frac{\mathcal{E}^2}{8\pi} + \frac{g^2}{8\pi}\right)dr$, где $\mathscr{O}$ и $\mathscr{H}$ - напряженности электрического и магнитного полей. Если в пространстве нет зарядов, то

электростатический потенциал φ можно считать равным нулю. Тогда $\mathscr{E} = -\frac{1}{c}\frac{\partial A}{\partial t}, \mathscr{H} = \operatorname{rot} A$, где A - векторный потенциал.

Разложим векторный потенциал по плоским волнам:

$$A = \sum_{\boldsymbol{k}} A_k e^{ikr} + \text{ компл. сопряж.}$$

Тогда для энергии электромагнитного поля E получаем следующее выражение:

$$E = \sum_k \left\{ \frac{1}{8\pi c^2} \left|\dot{A}_k\right|^2 + \frac{k^2}{8\pi} \left|\dot{A}_k\right|^2 \right\}.$$

Здесь нормировочнын объем пространства, в котором находится поле, считается равным 1.

Легко видеть отсюда, что энергия электромагнитного поля равна сумме энергий невзаимодействующих гармонических осцилляторов. Действительно, величина $A_{\boldsymbol{k}}$ играет здесь роль координаты, $\dot{A}_k$ - скорости, $1/4\pi c^2$ - массы гармонического осциллятора. Частота осциллятора $\omega_k = \sqrt{\frac{\alpha}{m}}$, где α - жесткость, а m - масса. данном случае $\alpha = k^2/4\pi, m = 1/4\pi c^2$, следовательно, $\omega_k = ck$. Первое слагаемое в выражении (1.33) представляет собой кинетическуюо энергию электромагнитного поля, а второе-потенциальную.

Итак, электромагнитное поле в пространстве без зарядов можно рассматривать как совокупность независимых гармонических осцилляторов со всеми возможными значениями волнового вектора k.

ГПриеним к совокупности гармонических осцилляторов законы квантовой механики. Тогда энергия электромагнитного поля равна

$$E = \sum_k \left(n_k + \frac{1}{2}\right) \omega_k,$$

где n_k - номер возбужденного состояния осциллятора с волновым вектором k (число квантов с волновым вектором k). Для простоты здесь опускается значок λ поляризации кванта. Он определяет направление ориентации вектора A_k, лежаиего в плоскости, перпендикулярной к k. 8 основном состоянит все $n_k = 0$ (нет квантов) и $E = \frac{1}{2}\sum_k \omega_k$. При этом ни кинетическая, ни потенциальная. энергии колебаний не имеет определенного значения.

Следовательно, ни напряженность электрического поля, ни напряженность магнитного поля не имеют определенного значения. Средние значения электрического и магнитного полей при этом равны нулю, но средние значения от квадратов этих величин отличны от нуля. Это означает, что электромагнитное поле в пустоте колеблется. Эти колебания называются нулевыми колебаниями электромагнитного поля.

Теперь можно ответить на следующий вопрос: почему атомы не находятся неограниченно долго в возбужденных состояниях? Ведь возбужденные состояння есть точные стационарные состояния уравнения Шредингера. Причина заключается в том, цто в пустоте всегда есть электромагнитное поле, с которым взанмодействует атом. В результате состояния атома перестают быть стационарными.

Рассмотрим взаимодействие частицы с электромагнитным полем. Для того чтобы найти изменение гамильтониана при наложении поля, нужно импульс частицы p заменить на $p - \frac{e}{c}A$, где A - векторный потенциал поля. Следовательно, оператор кннетической энергии $\frac{p^2}{2m}$ преобразуется в $\frac{p^2}{2m} - \frac{e}{mc}pA + \frac{e^2}{2mc^2}A^2$. Последнее слагаемое в

этом выражении мало. Его нужно учитывать в задачах, где первый порядок теории возмущений дает нулевой вклад, например, в задаче рассеяния кванта на электроне. Операторы A_k играют роль координаты соответствующего осциллятора поля и поэтому имеют матричные элементы, соответствующие изменению числа квантов на 1.

Вычислим матричный элемент $(A_k)_{01}$ перехода из вакуумного состояния в состояние с одним квантом. Для этого найдем величину $(A_k^2)_{00} = \sum_n (0\,|A_k|\,nj)\,(n\,|A_k|\,0)$. Так как оператор A_k рождает один квант (с частотой ω_k), то в сумме отличен от нуля только член с $n = 1$. Итак, $|(A_k)_{01}| = \sqrt{\left(|A_k|^2\right)_{00}}$ Для гармонического осциллятора средние значения кинетической и потенциальной энергий совпалают и равны половине полной энергии. Следовательно, для основного состояния $\bar{T}_k = \bar{U}_k = \frac{1}{2}E_k = \frac{1}{4}ck$. Так как $\bar{U}_k = \frac{k^2}{8\pi}\left(|A_k|^2\right)_{00}$, то $\frac{1}{4}ck = \frac{k^2}{8\pi}\left(|A_k|^2\right)_{00}$, откуда $(A_k^2)_{00} = \frac{2\pi c}{k}$. Следовательно,

$$|(A_k)_{01}| = \sqrt{\frac{2\pi c}{k}} = \sqrt{\frac{2\pi c^2}{\omega_k}}.$$

Аналогично находится матричный элемент от A_k для перехода из состояния с n квантами в состояние с $n+1$ квантами.

Таким образом, матричный элемент перехода частицы из состояния φ_{λ_1} в состояние φ_{λ_2} с испусканием кванта равен

$$V_{\lambda_1\lambda_2} = \left(-\frac{ep}{mc}A_k\right)_{\lambda_1\lambda_2} = -\frac{e}{mc}\left(\varphi_{\lambda_1}\left|p\eta_{k\lambda}e^{ikr}\right|\varphi_{\lambda_2}\right)\sqrt{\frac{2\pi c^2}{\omega_k}}.$$

Чтобы перейти к релятивистскому случаю, достаточно для оценки заменить $\boldsymbol{p}/m$ на $\boldsymbol{v}$. Здесь $\boldsymbol{p}\eta_{k\lambda}$ - проекция импульса на направление $\boldsymbol{A_k}$ ($\eta_{k\lambda}$ - единичный вектор поляризации кванта).

13.2.2 Photoelectric Effect

Рассмотрим фотоэффект: квант света поглощается атомом, в результате чего из атома вылетает электрон. Число переходов за единицу времени равно $\frac{2\pi}{\hbar}\left|V_{\lambda_1\lambda_3}\right|^2 \times \delta\left(E_i - E_f\right)$, где E_i - энергия начального состояния, равная сумме энергий кванта ω_k и энергии электрона в начальном состоянии ε_{λ_1}, а $E_f = \varepsilon_p$ - энергия вылетевшего электрона. Число переходов электрона за единицу времени в состояния с импульсами $\boldsymbol{p}$ в интервале $[\boldsymbol{p}, \boldsymbol{p} + d\boldsymbol{p}]$ равно

$$\begin{aligned} dW &= 2\pi \int |V_{12}|^2\,\delta\left(\varepsilon_{\lambda_1} + \omega_k - \varepsilon_{\lambda_2}\right)\frac{dp}{(2\pi)^3} = \\ &= 2\pi \int |V_{12}|^2\,\frac{p^2\frac{dp}{dE}dE}{(2\pi)^3}\delta\left(\varepsilon_{\lambda_1} + \omega_k - \varepsilon_{\lambda_2}\right)d\Omega = \\ &= \frac{1}{(2\pi)^2}\int |V_{12}|^2\,\frac{p^2}{v}d\Omega. \end{aligned}$$

Сечение фотоэффекта равно отношению числа переходов за единицу времени к интенсивности потока квантов. Последняя равна скорости кванта c, так как в нормировочном объеме ($= 1$) находится один квант. Следовательно, по порядку величины имеем

$$\sigma \sim \frac{4\pi p}{(2\pi)^2 c}\left|V_{12}\right|^2.$$

Покажем, что в выражении (1.34) экспоненту e^{ikr} можно заменить единицей. Действительно, волновое число $k = \omega/c \sim I/c$, где I - потенциал ионизации атома; $I \sim Z^2$ для внутренних электронных оболочек. Радиус этих оболочек $\sim 1/Z$, следовательно, $kr \sim \frac{Z^2}{c}\frac{1}{Z} \sim \frac{Z}{c} \ll 1$ и $e^{ikr} \approx 1$. Экспоненту e^{ikr} тем более можно заменить единицей для наружных оболочек, где $kr \sim 1/c = 1/137$.

Так как $(\varphi_{\lambda_2} p \varphi_{\lambda_2}) = (\varphi\lambda_1 r \varphi\lambda_2) = i\left(\varepsilon_{\lambda_1} - \varepsilon_{\lambda_2}\right)(\varphi_{\lambda_1} r \varphi\lambda_2) = i\omega\left(\varphi_{\lambda_1} r \varphi_{\lambda_2}\right)$, то сечение фотоэффекта имеет порядок величины

$$\sigma \sim \frac{p}{c}\omega^2 \left|(\varphi_0 r \varphi_p)\right|^2 \frac{1}{\omega} \sim \frac{p\omega}{c}\left|(\varphi_0 r \varphi_p)\right|^2 .$$

Рассмотрим фотоионизацию K-оболочки в двух предельных случаях, когда энергия вылетающего электрона много меньше потенциала ионизации и когда она много больше потенциала ионизации. В первом случае энергия кванта близка к энергии ионизации $I \sim Z^2$, т. е.

$$\sigma \sim \frac{pZ^2}{c}\left|(\varphi_0 r \varphi_p)\right|^2 .$$

Возле порога реакции это сечение содержит множитель $p \sim \sqrt{E}$. Если бы матричный элемент r_{0p} не зависел от энергии, то $\sigma \sim \sqrt{E}$. Это-обычный результат для сечения реакций вблизи порога. Зависимость сечения $\sim \sqrt{E}$ возиикла из-за статистического веса конечных состояний:

$$\int \delta(E-\omega)\frac{dp}{(2\pi)^3} \sim \int \delta(E-\omega)p^2 dp \sim \int \delta(E-\omega)pdE \sim p.$$

В случае водородоподобного атома дело обстоит иначе: сечение фотоэффекта при малых энергиях вылетающего электрона не зависит от энергии. Это связано с тем, что дипольный матричный элемент из-за корневой особенности кулоновских волновых функций при $r^2 = 0$ (см. стр. 26) ведет себя как $1/\sqrt{p}$ вблизи порога реакции. Оценим r_{op} вблизи порога.

Волновая функция K-электрона $\varphi_0 \sim e^{-zr}$, и, следовательно, в дипольном матричном элементе существенны малые расстояння $r \sim 1/Z$. Для вылетевшего электрона волновая функция на большом расстоянии от ядра имеет вид плоской волны

$$\varphi_p = e^{ipr}.$$

Таким образом, чтобы оценить r_{0p}, нужно иайти φ_p при $r \sim 1/Z$. Для этого напишем уравнение Шредингера для радиальной части волновой функции $u_p/r : u_p'' + k^2 u_p = 0$, где $k^2 = 2(E + Z/r)$. В 1.1 мы получили следующее приближенное решение этого уравнения (так называемое квазиклассическое решение):

$$u_p = \frac{A}{\sqrt{k}}\cos\left(\int_{r_1}^{r} k dr - \frac{\pi}{4}\right), k = \sqrt{2(E+Z/r)}.$$

Здесь E-энергия вылетающего электрона на бесконечности, т. е. очень маленькая величина. Условия применимости (1.36) : $\frac{d\lambda}{dr} \ll 1$ (см. 1.1 и 3.1); отсюда получаем: $\frac{d\lambda}{dr} \sim 1/\sqrt{Zr}$, и условие квазиклассичности движения имеет вид $Zr > 1$, т. е. $r > 1/Z$. Итак, условие квазиклассичности движения выполняется вплоть до K-оболочки атома. Оценим нормировочный множитель A. Для этого рассмотрим u_p на больших расстояниях r:

$$u_p \approx \frac{A}{\sqrt[4]{2E}} \cos(pr + \alpha).$$

С другой стороны, при $r \to \infty$ волновая функция u_p/r должна совпадать с радиальной частью первой гармоники (оператор $\boldsymbol{r}$ меняет момент на 1) разложения плоской волны e^{ipr} по полиномам Лежандра: $e^{ipr\cos\theta} = \sum\limits_l f_l P_l(\cos\theta)$, амплитуда которой $\sim 1/pr$. Следовательно, из (1.36) находим: $A/\sqrt{p} \sim 1/p$, откуда $A \sim 1/\sqrt{p}$. Итак, волновая функция вылетевшего электрона φp при $r \sim 1/Z$ имеет оценку $\frac{1/\sqrt{p}}{r\sqrt[4]{Z/r}} \sim \frac{\sqrt{Z}}{\sqrt{p}}$.

Дипольныӈ матричный элемент $(\varphi_0 r \varphi_p)$ имеет порядок $(\varphi_0 \Gamma \varphi_p) \sim Z^3/2 \int\limits_0^\infty e^{-Zr} r \frac{\sqrt{Z}}{\sqrt{p}} r^2 dr \sim \frac{Z^2}{Z^4\sqrt{p}} \sim \frac{1}{Z^2\sqrt{p}}$.

Так как квадрат дипольного матричного элемента обратно пропорционален корню из энергии вылетающего электрона E, то сечение фотоэффекта σ не зависит от энергии E. Итак, при $E - I \ll I$ полное сечение фотоэффекта

$$\sigma \sim \frac{pZ^2}{c} \left(\frac{1}{Z^2}\right)^2 \frac{1}{p},$$

или

$$\sigma = \frac{C_1}{cZ^2}.$$

Рассмотрим другой предельный случай, когда энергия вылетающего электрона много больше потенциала ионизации. Оценим дипольный матричный элемент и сечение фотоэффекта. Волновая функция непрерывного спектра имеет вид $\varphi_p \underset{r\to\infty}{=} Fe^{ipr}$, где F - функция, стремящаяся к единице при $pr \gg 1$. В матричном элементе $(\varphi_0 p_0)$, как мы увидим, существенны расстояния $r \sim 1/p$. Отклонение F от единицы определяется величиной $V(r)/E$. При $r \sim 1/p$ можно полагать $F \approx 1$. Тогда в интеграле $(\varphi_0 p \varphi_p)$ оператор $\boldsymbol{p}$ можно вынести из-нод знака интеграла, заменив его числом p. Учет поляризации квантов внесет лишь множитель порядка 1. Следовательно,

$$\sigma \sim \frac{p}{c} |(\varphi_0 p \varphi_p)|^2 \sim \frac{p^2}{c} \left|\left(\varphi_0 e^{ipr}\right)\right|^2.$$

Интегрируя по углам, получаем

$$\left(\varphi_0 e^{ipr}\right) \sim Z^{3/2} \int_0^\infty e^{-Zr} \frac{\sin pr}{pr} r^2 dr = \frac{Z^{3/2}}{2p} \int_{-\infty}^\infty r e^{-Z|r|} \sin pr dr.$$

Оценим это выражение. Легко видеть, что вторая производная от функции $f(r) = re^{-Z|r|}$ имеет скачок при $r = 0$. Поэтому далекие фурье-компоненты этой функции имеют оценку (см. 1.1) $\sim Z/p^3$.

Если бы потенциал V как функция r^2 не имел особых точек на вещественной оси, то волновая функция как скаляр была бы аналитической функцией r^2. В этом случае далекая фурье-комнонента волновой функции как функция энергии была бы экспоненциально мала (см. 1.1). Мы видим, что степенная зависимость матричного элемента от энергии в нашем случае возникает из-за того, что Ψ в кулоновском потенциале как функция r^2 имеет точку ветвления при $r^2 = 0$. Эго связано с тем, что кулоновский потенциал $1/r$ имеет особенность при $r = 0$. Полюсная особенность кулоновского потенциала привела к корневой особенности в ренении уравнения Шредингера.

Iгак, матричный элемент $(\varphi_0 e^{ipr})$ при $p \to \infty$ имеет оленку $Z^{5/2}/p^4$, а сечение фотозффекта.

$$\sigma \sim \frac{Z^5 p}{cp^8}, \text{ т. е. } \sigma = \frac{C_2 Z^5}{cE^{7/2}}, \quad \text{или} \quad \sigma = \frac{2^{7/2} C_2}{cZ^2}\left(\frac{I}{E}\right)^{7/2}.$$

Здесь I-потенциал ионизации K-электрона, равный $Z^2/2$. Численный расчет показывает, что $C_2 \sim 10$.

Если положить в (1.39) энергию кванта E равной потенциалу ионизации I, то мы должны получить по порядку величины формулу (1.38). Однако, как показывают численные расчеты, формула (1.39) дает при $E = I$ сечение, на порядок большее, чем (1.38). Это означает, что переход от области $E - I \ll I$ к области $E \gg I$ оказывается сильно растянутым.

13.2.3 Lifetimes of Excited Atomic States

а) Оценим время жизни состояния $2p$ водородоподобного атома.

Электрон из состояния $2p$ переходит в состояние $1s$, испуская дипольный γ-квант. Число переходов в единицу времени (обратное время жизни) равно

$$W_{01} = 2\pi \int |V_{01}|^2 \frac{dk}{(2\pi)^3} \delta\left(E_0 - E_1 - \omega\right)$$

где $V = -\frac{1}{c} pA$ - потенциал взаимодействия электрона с электромагнитным полем. Индекс 0 соответствует состоянию $1s$, индекс 1 -состоянию $2p, \omega$ энергия γ-кванта. Так как

$$dk = k^2 dk d\Omega = k^2 \frac{dk}{d\omega} d\Omega d\omega$$

то

$$W_{01} = 2\pi \int |V_{01}|^2 \frac{k^2 \frac{dk}{d\omega} d\Omega}{(2\pi)^3}$$

Оценим матричиый элемент перехода V_{01}; учитывая нормировку потенциала A электромагнитного поля (см. стр. 49), находим

$$V_{01} = -\frac{1}{c}(p.A)_{01} \sim \sqrt{\frac{2\pi}{\omega}} p_{01}$$

Здесь мы не интересуемся поляризацией γ-кванта, которая внесет лишь численные множители. Оценим матричный элемент импульса p:

$$p_{01} = i\omega r_{01} \sim \frac{\omega}{Z}$$

$$W_{01} \sim \frac{\omega^2}{Z^2} \frac{1}{\omega} k^2 \frac{dk}{d\omega} \sim \frac{\omega^3}{Z^2 c^3}.$$

Следовательно,

Так как частота перехода имеет иорядок Z^2, то окончательно находим

$$W_{01} \sim \frac{Z^q}{c^3}$$

Оценим численно время жизни состояния относительно дипольного перехода. Атомное время жизни имеет порядок

$$\tau_{\text{at}} \sim \frac{\hbar}{E_{\text{at}}} \sim \frac{10^{-27} spz \cdot ce\kappa}{27s8 \cdot 1,6 \cdot 10^{-12} \text{ erg/eV}} = 0,3 \cdot 10^{-16}\text{s}.$$

Следовательно, $\tau_{\text{дип}} \sim \frac{c^9}{Z^4}\tau_{\text{ат}}$. Для атома водорода $\tau_{\text{дип}} \sim 10^7 \cdot 10^{-17} = 10^{-10}$ сек. Точный расчет дает несколько большие значения $\tau_{\text{дип}}$.

б) Оценим время жизни квадрупольных переходов, например, $3d \to 1s$**.**

Ранее в операторе A электромагнитного поля мы заменяли множитель e^{ikr} ($\boldsymbol{k}$-волновой вектор кванта) единицей $\left(kr = \frac{\omega}{c}r \sim \frac{Z}{c} \ll 1\right)$. При рассмотрении квадрупольных переходов нужно разложить e^{ikr} в ряд, Причем главный вклад внесет член разложения $i\boldsymbol{kr}$. Получаем

$$V_{01} = i\sqrt{\frac{2\pi}{\omega}}((\eta p)(kr))_{01},$$

где $\boldsymbol{\eta}$-поляризация кванта.

Направим ось z по вектору η, а ось x - по k (вектор поляризации кванта $\geqslant$ перпендикулярен к волиовому вектору k). Тогда

$$\begin{aligned} V_{01} = ik \quad & \sqrt{\frac{2\pi}{\omega}}\,(p_z x)_{01} = \\ & = ik\sqrt{\frac{2\pi}{\omega}}\left[\frac{1}{2}\,(p_z x - p_x z) + \frac{1}{2}\,(p_z x + p_x z)\right]_{01} = \\ & = ik\sqrt{\frac{2\pi}{\omega}}\left[-\frac{1}{2}[rp]_y + \frac{1}{2}\frac{d}{dt}(zx)\right]_{01}. \end{aligned}$$

Гервое слагаемое в этом выражении представляет собой матричный элемент от y-проекции момента количества дывижения, т. е. соответствует дипольному магнитному переходу. Произведение zx - это компонента квадрупольного момента, т. е. второе слагаемое определяет вероятность квадрупольного электрического перехода. Оба слагаемых имеют одинаковый порядок величины.

Оценим численно время жизни состояния относительно квадрупольного перехода. В отличие от дипольных переходов, в матричный элемепт добавляется множитель kr. Следовательно,

$$\tau_{\text{квад}} \sim \tau_{\text{дип}}\,\frac{1}{(kr)^2} \sim \tau_{\text{дип}}\,\frac{c^2}{Z^2}.$$

Для атома водорода $\tau_{\text{квад}} \sim 10^{-10} \cdot 10^4 \sim 10^{-6}$се.

З а д ач а.

Оценить время жизни водородоподобного атома по отношению к испусканию двух квантов. (!!??!?!?!?)

О т в е т. $\tau \sim c^6/Z^6$.

(хорошая задача, подумаю потом там!)

13.2.4 Braking radiation (!?!?)

(this is a big fundamental topic, I'll definetely create later several sections for it)

Оценим эффективное сечение излучения γ-квантов при рассеянии электронов иа ядре. Предположим, что частота φ-квантов много меньше энергии электрона. Тогда излучение слабо влияет на движение электрона и эффективное сечение приближенно равно произведению сечения рассеяния электрона на вероятность испускания γ-кванта.

Оценим вероятность испускания фотона при заданном дывижнии электрона. Уравнение Шрредингера для фотона в энергетическом представлении имеет вид

$$i\dot{C}_n = \sum_{n'} V_{nn'} C_{n'} e^{i(\omega_n - \omega_{n'})t},$$

где V описывает взаимодействие электрона с электромагнитным полем, а C_n - амплитуда состояния с n квантами с заданными волновым вектором и поляризацией.

В основном состоянии $C_0 = 1$, а все $C_n = 0$. В первом порядке теории возмущений отлична от нуля амплитуда перехода в состояние c одним квантом, C_1. Из (1.40) получаем

$$i\dot{C}_1 = V_{10} e^{i\omega t},$$

откуда

$$C_1 = -i \int\limits_{-\infty}^{\infty} V_{10} e^{i\omega t} dt = +i \int\limits_{-\infty}^{\infty} \left(\frac{1}{c} v A\right)_{10} e^{i\omega t} dt.$$

Мы написали взаимодействие с излучением для бесспиновых частиц. Для частиц со спином взаимодействие усложняется, но по порядку величины может быть оценено по этой же формуле.

Поскольку излучение не влияет на рассеяние электрона, то скорость v можно считать заданной функцией времени. Следовательно, так как $A \sim \eta e^{-ikr} \approx \eta e^{-i\omega \cdot \frac{\partial n}{c} t}$, то

$$C_1 = i\sqrt{\frac{2\pi}{\omega}} \int\limits_{-\infty}^{\infty} (\boldsymbol{\eta}) e^{i\omega t - i\omega \frac{\boldsymbol{n}}{c} t} dt$$

где η-единичный вектор поляризации кванта, $\boldsymbol{n}$-единичный вектор $\frac{k}{k}$.

Так как время соударения электрона много меньше, чем интервал t, существенный в этом интеграле, $t \sim \frac{1}{\omega\left(1 - \frac{vn}{c}\right)}$,

то можно считать, что скорость частицы в момент времени $t = 0$ скачкообразно изменилась с $v = v_1$ на $v = v_2$. Тогда из (1.41) находим

$$C_1 = i\sqrt{\frac{2\pi}{\omega}} \left\{ (v\eta) \left. \frac{e^{i\omega\left(t - \frac{vn}{c} t\right)}}{i\omega\left(1 - \frac{vn}{c}\right)} \right|_{-\infty}^{0} + (v\eta) \left. \frac{e^{i\omega\left(t - \frac{vn}{c} t\right)}}{i\omega\left(1 - \frac{vn}{c}\right)} \right|_{0}^{\infty} \right\} =$$

$$= \sqrt{\frac{2\pi}{\omega^3}} \eta \left(\frac{v_1}{1 - \frac{v_1 n}{c} - \frac{v_2}{1 - \frac{v_2 n}{c}}} \right).$$

Для малых углов отклонения электрона и кванта из (1.42) получаем

$$C_1^2 \sim \frac{1}{\omega^3} \frac{(\Delta v)^2}{(1 - v/c)^2}$$

здесь Δv - изменение скорости электрона. Так как знаменатели выражения (1.42) при малых углах отклонения кванта ϑ_κ и электрона ϑ_e имеют вид

$$1 - \frac{v}{c} + \frac{(\vartheta_\mathrm{k} + \vartheta_\mathrm{e})^2}{2}, \quad 1 - \frac{v}{c} + \frac{\vartheta_\mathrm{K}^2}{2},$$

то существенные углы отклонения ограничены условием

$$\boldsymbol{\vartheta}_\mathrm{k}, \boldsymbol{\vartheta}_\mathrm{e} \leqslant \sqrt{1 - \frac{v}{c}}.$$

Оценим вероятность испускания кванта в интервал частот $[\omega, \omega + d\omega]$ при заданном изменении скорости электрона Δv. Для этого умножим (1.43) на статистический вес конечных состояний кванта $dk/(2\pi)^3$:

$$dW \sim \frac{1}{\omega^3} \frac{(\Delta v)^2}{\left(1 - \frac{v}{c}\right)^2} k^2 dk d\Omega_{\mathrm{K}} \sim \frac{(\Delta v)^2}{c^3 \left(1 - \frac{v}{c}\right)^2} \frac{d\omega}{\omega} \vartheta_{\mathrm{K}} d\vartheta_{\mathrm{K}}.$$

Сечение тормозного излучения равно произведению вероятности испускания кванта dW на сечение кулоновского рассеяния для релятивистских электронов:

$$d\sigma_{\mathrm{T,h}} \sim \frac{(\Delta v)^2 \vartheta_{\mathrm{K}}^2}{c^3 \left(1 - \frac{v}{c}\right)^2} \frac{d\omega}{\omega} \cdot \frac{Z^2}{E^2} \frac{d\Omega_{\mathrm{e}}}{\sin^4 \frac{\theta_{\mathrm{e}}}{2}}$$

или при малых углах рассеяния ($\sin \theta_{\mathrm{e}} \approx \theta_{\mathrm{e}} \approx q/p$)

$$d\sigma_{T,u} \sim \frac{q^2 \left(1 - \frac{v}{c}\right)}{c^3 \left(1 - \frac{v}{c}\right)} \frac{d\omega}{\omega} \cdot \frac{Z^2}{p^2 c^2} \frac{\theta_{\mathrm{e}} d\theta_{\mathrm{e}}}{\theta_{\mathrm{e}}^4} \sim \frac{Z^2}{c^5} \frac{d\omega}{\omega} \frac{dq}{q}.$$

Найдем вероятность иснускания кванта для произвольного изменения импульса электрона. Для этого проинтегрируем (1.46) по q. Будем считать электрон ультрарелятивистским, т. е. $1 - v/c \ll 1$. Так как $Ze^2; \hbar c \ll 1$, то минимальный угол отклонения будет определяться дифракцией электрона на радиусе атома $a \sim Z^{-1/3}$, а максимальный условием (1.44).

Мнтегрируя (1.46) по q, получаем

$$\int \frac{d\sigma_{\text{Т. и}}}{dq} dq \sim \frac{Z^2}{c^5} \frac{d\omega}{\omega} \ln \frac{q_{\max}}{q_{\min}} \sim \frac{Z^2}{c^5} \frac{d\omega}{\omega} \ln \frac{c}{Z^{1/3}}.$$

Оценим сечение тормозного излучения квантов с произвольными частотами. Интегрируя (1.47) по ω, находим

$$\sigma_{\text{т.и}} \sim \frac{Z^2}{c^5} \ln \frac{c}{Z^{1/3}} \cdot \ln \frac{\omega_{\max}}{\omega_{\min}}.$$

Максимальная частота кванта - порядка энергии электрона:

$$\omega_{\max} \sim \frac{mc^2}{\sqrt{1 - v^2/c^2}}.$$

При $\omega_{\min} \to 0$ выражение (1.48) расходится (см. стр. 109). Однако потери энергии электрона на тормозное излучение будут конечными: $-\frac{dE}{dx} = \int N \omega d\sigma$ и, где N число ядер в единице объема. Окончательно,

$$-\frac{dE}{dx} \sim \frac{Z^2 N}{c^5} E \ln \frac{c}{Z^{1/3}}$$

13.2.5 Pair Production (!!!)

Напомним читателю, что релятивистски инвариантное уравнение диижения электрона - уравнение Дирака - при заданном импульсе p электрона имеет собственные функции, отвечающие не только положительным, но и отрицательным значениям энергии: $E = \pm\sqrt{m^2c^4 + p^2c^2}$. Для того чтобы объяснить, почему электрон не переходит в отрицательные состояния с испусканием кванта, Дирак предположил, что все отрицательные состояния в вакууме заполнены электронами. Тогда переход в эти

состояния запрещен принципом Паули. Незаполненное отрицательное состояние означает, что в вакууме есть позитрон.

С этой точки зрения механизм образования пар аналогичен механизму фотоэффекта: квант переводит электрон из состояния с отрицательной энергией в состояние с положительной энергией. В пустоте такой процесс невозможен, как это сразу видно из законов сохранения энергии и импульса. В поле ядра процесс делается возможным, так как электрон передает излишек импульса ядру.

Можно оценить сечение образования пар на ядре аналогично тому, как это делалось для тормозного излучения: найти вероятность образования пар при заданной величине передаваемого ядру импульса, а затем умножить эту вероятность на сечение рассеяния электрона на ядре и проинтегрировать по всем значениям передаваемого импульса.

Можно получить сечение образования пар, рассматривая этот процесс как обратный тормозному излучению. Строго говоря, процесс, обратный тормозному излучениіо, соответствует поглощеиию кванта и переходу электрона из одного состояния с положительной энергией в другое. Однако в ультрарелятивистском случае, которым мы для простоты ограничимся, собственные функции, соответствующие отрицательной энергии (т. е. соответствующис позитрону), мало отличаются от функций для положительной энергии (кулоновское поле ялра вносит малую поправку). Следовательно, сечение образования пар можно приближенно рассматривать как процесс, обратный тормозному излучению.

Сечения прямого и обратного процессов относятся как статистические веса конечных состояний. В случае тормозного излучения в конечном состоянии есть электрон и квант, тогда как в случае образования пар-позитрон и электрон. Но при больиих энергиях статистический вес кванта не отличается от статистического веса электрона той же энергии, и поэтому сечение образования пар совпадает по порядку величины с сечением тормозного излучения, проинтегрированным по энергиям квантов порядка энергии электрона. Таким образом,

$$\sigma_{\text{пар}} \sim \frac{Z^2}{c^5} \ln \frac{c}{Z^{1/3}}.$$

Потери энергии квантов на единице пути вследствие образования пар имеют порядок

$$-\frac{dE}{dx} \sim \frac{NZ^2}{c^5} E \ln \frac{c}{Z^{1/3}},$$

т. е. совпадают по порядку величины с потерями энергин ультрарелятивистского электрона на тормозное излучение.

13.2.6 Lamb Shift

Электрон атома, взаимодействуя с нулевыми колебаниями электромагнитного поля, дрожит на своси орбите. Вследствие этого его заряд размазывается в пространстве и взаимодействие с кулоновским полем ядра ослабевает. Такнм образом, уровни энергии из-за взаимодействия с нулевыми колебаниями повышаются. Это явление называется лэмбовским смещением. Оценим величину смещения.

Пусть δ-отклонение электрона от равновесного положения из-за взаимодействия с нулевыми колебаниями. Тогда изменение потенциала взаимодействия равно

$$H' = V(r+\delta) - V(r) = \frac{\partial V}{\partial r}\delta + \frac{1}{2}\frac{\partial^2 V}{\partial x_i \partial x_j}\delta_i \delta_j (i,j = x,y,z),$$

Здесь $\boldsymbol{r}$-координата электрона относительно ядра. Усредним это выражение по дрожанию электрона. Тогда $\overline{\delta} = 0$, а $\overline{\delta_x^2} = \overline{\delta_y^2} = \overline{\delta_z^2} = \frac{1}{3}\overline{\delta^2}$. Следовательно,

$$H' = \frac{1}{6}\overline{\delta^2}\Delta V.$$

Итак, для определения величины лэмбовского смещения необходимо знать средний квадрат амплитуды дрожания электрона $\overline{\delta^2}$.

Уравиение движения электрона в поле нулевых колебаний E для оценок можно записать в виде

$$-\ddot{\boldsymbol{\delta}} = +E + \omega_{\text{ar}}^2\delta,$$

где ω_{ax} - частота обращения электрона. Предположим, что частота дрожания электрона много больше $\omega_{\text{ат}}$. Тогда членом $\omega_{a\tau}^2\delta$ в этом выражении можно пренебречь.

Разложим в ряд Фурье отклонение электрона δ и поле нулевых колебаний E:

$$\delta = \sum_{k\lambda}\delta_{k\lambda}e^{-i\omega_{k\lambda}^t}, \quad E = \sum_{k\lambda}E_{k\lambda}e^{-i\omega_{\text{mot}}^*}$$

При этом мы предположили, что $k\delta \ll 1$. Ниже мы в этом убедимся.

Уравнение движения электрона в фурье-представлении приобретает вид

$$\omega_{k\lambda}^2\delta_{k\lambda} = E_{k\lambda}.$$

Средний квадрат амплитуды дрожания $\overline{\delta^2}$ равен

$$\overline{\delta^2} = \sum_{k\lambda}\bar{\delta}_{k\lambda}^2 = \sum_{k\lambda}\frac{E_{k\lambda}^2}{\omega_{k\lambda}^4}.$$

Найдем $E_{k\lambda}^2$. Энергия нулевых колебаний типа $k\lambda$ равна

$$\delta_{k\lambda} = \int\frac{E_{k\lambda}^2}{4\pi}dV = \frac{E_{k\lambda}^2}{4\pi} = \frac{1}{2}\omega_{k\lambda}$$

(нормировочный объем равен 1). Отсюда $E_{k\lambda}^2 = 2\pi\omega_{k\lambda}$; следовательно,

$$\overline{\delta^2} = 2\pi\sum_{k\lambda}\frac{1}{\omega_{k\lambda}^3}.$$

Заменим суммирование по k интегрированием:

$$\sum_{k\lambda} = 2\int\frac{4\pi k^2dk}{(2\pi)^3} = \frac{1}{\pi^2}\int\frac{\omega^2d\omega}{c^3}$$

(множитель 2 возникает из суммы по двум поляризациям кванта). Тогда получаем

$$\overline{\delta^2} = \frac{2}{\pi c^3}\int\frac{d\omega}{\omega} = \frac{2}{\pi c^3}\ln\frac{\omega_{\max}}{\omega_{\min}}.$$

Каковы пределы интегрирования в этом выражении? $\omega_{\max}$ определяется условием нерелятивистского движения электрона в поле нулевых колебаний. Действительно, если электрон при дрожании приобретает релятивистский импульс, то в уравнение движения войдет релятивистская масса и $\delta_{k\lambda}$ будет уменьшена. Поэтому интеграл обрезается условием $k \ll c, \omega \ll c^2$. При этом величина $k\delta$, которой мы пренебрегли, $k\delta \sim c^{-112} \ll 1$.

$\omega_{\mathbf{mn}}$ определяется из того условия, что, как мы предположили, частота поля должна быть не меньше, чем частота обращения электрона на атомной орбите ω_{ar}. Как легко видеть из уравнения для δ, область $\omega < \omega_a^{\text{вносит}}$ малый вклад. Итак, $\overline{\delta^2} = \frac{2}{\pi c^3}\ln\frac{\omega_{\max}}{\omega_{a\tau}}$.

Так как $\overline{\delta^2}$ логарифми- чески зависит от ω_{mln} и $\omega_{\max}$, то нетичноств в их определении несущественна.

Смещение электронного терма в первом поорядке теории возмущений дается днагональным матричным элементом возмущения H' по состоянию электрона Ψ_n, т. е.

$$\delta E = \frac{1}{6}\overline{\delta^2}\int \Psi_n \Delta V \Psi_n dr = \frac{1}{6}\overline{\delta^2}\int \Psi_n 4\pi\rho\Psi_n dr,$$

где ρ - плотность заряда. Так как заряд ядра сосредоточен в области, малой по сравнению с радиусом электронной орбиты, то электронную волновую функцию можно взять в начале координат. Интеграл $\int \rho dr$ равен заряду ядра Z.Итак,

$$\delta E = \frac{2\pi Z}{3}\overline{\delta^2}\left|\Psi_n(0)\right|^2 = \frac{4Z}{3c^3}\left|\Psi_n(0)\right|^2 \ln\frac{\omega_{\max}}{\omega_{\min}},$$

т. е. лэмбовское смещенне определяется значением волновой функции электрона в начале координат.

Таким образом, смещение имеет заметнуго величину лишь для s-электронов, так как только для них отсутствует центробежный барьер и электрон может находиться в начале координат. Смещение электронных термов, обладающих угловым моментом, будет значительно меньшим.

Лэмбовское смещение приводит к расщеилению термов $2s_{1/2}$ и $2p_{1,2}$ водородонодобного атома. Согласно сказанному выше уровень $2p_{1/2}$ смешается значительно слабее, чем $2s_{1/2}$. Так как $\left|\Psi_{2s}(0)\right|^2 = Z^3/8\pi$, то $\delta E = \frac{4Z}{3c^3}\frac{Z^3}{8\pi}\ln\frac{c^2}{Z^2} = \frac{Z^4}{6\pi c^3}\ln\frac{c^2}{Z^2}$

13.2.7 Divergence of Series in Quantum Electrodynamics

В квантовой электродинамике используют теорию возмучений по электромагнитному взаимодействию. Действительно, ряды теории возмущений содержат безразмерный малый параметр $e^2/\hbar c \approx 1/137$.

Покажем, что эти ряды асимптотические, т. е. расходятся при увеличении числа членов. Существует оптимальное число членов ряда, которое лучше всего изображает изучаемый процесс. Нже это число будет оценено. Для этого прежде всего убедимся, что физические величнны как функции e^2 имеют особую точку при $e^2 = 0$ и, следовательно, не могут быть разложены в ряд по степеням e^2.

В качестве примера рассмотрим энергию вакуума (Дайсон, 1952). Если бы не было особой точки при $e^2 = 0$, то энергня вакуума не зависела бы от способа стремления e^2 к нулю. Пусть энергия вакуума, найденная по теории возмушений, стремится к E_0. какой величине стремится энергия вакуума, когда $e^2 \longrightarrow 0$ со стороны отрицательных значений? Рассмотрим при $e^2 < 0$ рождение в вакууме N электронно-позитронных пар. ГПри $e^2 < 0$ электроны (так же как и позитроны) притягнваются друг к другу. Определим, при каком N процесс образования пар энергетически выгоден. Пусть электронное и позитронное облака разошлись на достаточно большое расстояние друг от друга, так что отталкиванием между ними можно пренебречь. Энергиь каждого из этих облаков можно оценить по методу Томаса Ферми. Находим, что выигрыш в энергии $-E \sim N^{\gamma/3}$. Проигрыш в энергии составляет $2mc^2$ на каждую электроннопозитронную пару, а для всех частиц $2mc^2N$. Следовательно, если $N^{7/3} > c^2N$, т. е. если $N > c^{3/2}$, то рождение электронно-позитронных пар оказывается выгодньм.

При $N \sim c^{3/2}$ величина $\varphi \sim c^2$, поэтому нужно рассмотреть, какой результат получится в релятивистском случае. Рассмотрим для простоты ультрарелятивистский предел. В этом случае $p_0 \sim \varphi/c$, следовательно (стр. 36), $\frac{\varphi}{l^2} \sim \left(\frac{\varphi}{c}\right)^3$, откуда $\varphi l \sim c^{3/2}$. Так как $N \sim \frac{\varphi}{l^2}l^3$, то получаем $N \sim \varphi l \sim c^{3/2}$, т. е. ту же оценку, что и в нерелятивистском случае.

Энергия системы при этом - $E \sim N\varphi \sim c^3/l$, т. е. может быть неограниченно понижена уменьцением L. Мы получили, что электромагнитный вакуум при $e^2 < 0$ оказывается неустойчивым. Так как при $e^2 > 0$ он устойчнв, то это означает, что имеется особая точка при $e^2 = 0$.

Рождение N электронно-позитронных пар соответствует N-му порядку теории возмущений. Найденное число $N \sim c^{z/2}$ указывает порядок числа членов теории возмущений, начиная с которого будет сказываться особая точка при $e^2 = 0$. Учет более высоких порядков теории возмущений не улуч шит, а ухудиит результат.

13.3 Light-Matter Interactions

(it is a big topic and there are many research about it. see cond matter for now about it, but I'll write here some important concepts)

14 Atomic and Nuclear Physics

14.1 Radiation, Transitions in Atoms

(!! write it later, this is a very important part of QM)

14.1.1 Typical radiation

(all what one needs to solve problems)

14.1.2 Taking into account special features in radiation

How lattice symmetries determine rules of radiation?

(answer to this question. Currently, I don't know)

14.2 Hydrogen atom with extra physics

14.2.1 Relativistic hydrogen atom

(потом допишу его)

14.2.2 Fine Splitting and Spin–Orbit Interaction

Классическое выражение энергии спин-орбитального взаимодействия

Пусть электрон движется равномерно и прямолинейно со скоростью v в поле ядра, помещённого в начале системы координат 1 и которое создаёт кулоновское поле $e\mathbf{E} = -\frac{\mathbf{r}}{r}\frac{\partial V}{\partial r}$. В системе координат 2, связанной с движущимся электроном, наблюдатель будет видеть движущееся ядро, которое создает как электрическое, так и магнитное поле, с напряженностью $'$ и $'$, соответственно. Как следует из теории относительности $\mathbf{E}'$ и $\mathbf{H}'$ связаны с $\mathbf{E}$ следующими соотношениями:

$$\mathbf{E}' = \mathbf{E}, \quad \mathbf{H}' \approx -\frac{1}{c}\mathbf{v} \times \mathbf{E} = -\frac{1}{mc}\mathbf{p} \times \mathbf{E}$$

Где отброшены члены порядка v^2/c^2. Тогда уравнение изменения спинового момента количества движения $\mathbf{S} = \frac{\hbar}{2}\boldsymbol{\sigma}$ (связанного гиромагнитным отношением как $\frac{|\boldsymbol{\mu}|}{|\mathbf{S}|} = \frac{|e|}{mc}$) в системе координат 2 будет иметь вид:

$$\frac{d\mathbf{S}}{dt} = \mu \times \mathbf{H}' = -\frac{e\hbar}{2m^2c^2}\boldsymbol{\sigma} \times [\mathbf{p} \times \mathbf{E}].$$

Это уравнение соответствует взаимодействию спина электрона с электромагнитным полем, которое описывается гамильтонианом следующего вида:

$$\mathcal{H}'_{so} = \frac{e\hbar}{2m^2c^2}\boldsymbol{\sigma} \cdot \mathbf{p} \times \mathbf{E}.$$

Совпадение с другой формулой (!?!??!)

Заметим, что вид гамильтониана с точностью до множителя 1/2 совпадает с видом спин-орбитальной части гамильтониана полученного из уравнения Дирака с помощью преобразования Фолди и Ваутхайзена.

Отсутствие этого множителя связано с тем, что уравнение изменения магнитного момента электрона будет верно только в том случае, если система 2 не будет вращающейся, в противном случае это уравнение, из-за прецессии Томаса, должно иметь вид

$$\frac{d\mathbf{S}}{dt} = \frac{e\hbar}{2mc}\boldsymbol{\sigma} \times \mathbf{H}' - \omega_T \times \mathbf{S}$$

где ω_T - томосовская угловая скорость вращения. Электрон в атоме ускоряется экранированным кулоновским полем поэтому томосовская угловая скорость описывается соотношением

$$\omega_T \approx \frac{1}{2m^2c^2}\frac{1}{r}\frac{\partial V}{\partial r}[\mathbf{r} \times \mathbf{p}]$$

Таким образом гамильтониан спин-орбитального взаимодействия будет иметь вид:

$$\mathcal{H}_{so} = \frac{\hbar}{2m^2c^2}\frac{1}{r}\frac{dV}{dr}\boldsymbol{\sigma} \cdot \mathbf{r} \times \mathbf{p} - \frac{\hbar}{4m^2c^2}\frac{1}{r}\frac{\partial V}{\partial r}\boldsymbol{\sigma} \cdot \mathbf{r} \times \mathbf{p} = \frac{\hbar}{4m^2c^2}\frac{1}{r}\frac{\partial V}{\partial r}\boldsymbol{\sigma} \cdot \mathbf{r} \times \mathbf{p}$$

Что в точности совпадает с ранее полученным результатом.

Связь спин орбитального взаимодействия с прецессией Томаса (??)

Об аналогии, что в системе электрона имеется поле от тока атома (??)

14.2.3 Stark Effect

теория эффекта Штарка

Гамильтониан атома водорода, помещённого в однородное электрическое поле, имеет вид

$$H = \frac{\mathbf{p}^2}{2m} - \frac{e^2}{r} + e\mathcal{E}r\cos\vartheta \equiv H_0 + V$$

Волновая функция основного состояния атома водорода с гамильтонианом H_0 в координатном представлении

$$\psi_{(0)}(\mathbf{r}) = \langle \mathbf{r}|\psi_{(0)}\rangle = \frac{1}{\sqrt{\pi a^3}}e^{-\frac{r}{a}}$$

Поправка первого порядка ϵ_1 к энергии по теории возмущений равна нулю в силу сферической симметрии волновой функции основного состояния.

Действительно,

$$\epsilon_1 = \left\langle \psi_{(0)} | V | \psi_{(0)} \right\rangle = 2\pi e\mathcal{E} \int\limits_0^\infty dr \frac{r^3}{\pi a^3} e^{-\frac{2r}{a}} \int\limits_0^\pi \cos\vartheta \sin\vartheta d\vartheta = 0$$

Поправку к энергии второго порядка по теории возмущений можно вычислить через поправку первого порядка к волновой функции $\psi_{(1)}(\mathbf{r})$

$$\epsilon_2 = \left\langle \psi_{(0)} | V | \psi_{(1)} \right\rangle = e\mathcal{E} \int d_3x \psi_{(0)}(\mathbf{r}) \cdot r\cos\vartheta \cdot \psi_{(1)}(\mathbf{r})$$

Поправка первого порядка к волновой функции $\psi_{(1)}(\mathbf{r})$ с учётом (5.3) удовлетворяет уравнению

$$\left(-\frac{\hbar^2}{2m}\Delta - \frac{e^2}{r} + \frac{me^4}{2\hbar^2} \right) \psi_{(1)}(r,\vartheta) = -V\psi_{(0)}(\mathbf{r}) = -\frac{e\mathcal{E}r}{\sqrt{\pi a^3}} \cos\vartheta \cdot e^{-\frac{r}{a}}$$

Вспоминая, что лапласиан в сферических кооридинатах имеет вид

$$\triangle = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2 \frac{\partial}{\partial r} \right) + \frac{1}{r^2}\Delta_{\vartheta,\varphi}, \quad \Delta_{\vartheta,\varphi} = \frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\left(\sin\vartheta \frac{\partial}{\partial\vartheta} \right) + \frac{1}{\sin^2\vartheta}\frac{\partial^2}{\partial\varphi^2}$$

будем искать решение уравнения (5.5) в виде

$$\psi_{(1)}(r,\vartheta) = f(r) \cdot e^{-\frac{r}{a}} \cos\vartheta, \quad f(r) = a_0 + a_1 r + a_2 r^2.$$

Подставляя (5.6) в (5.5), получаем

$$\begin{gathered} -\tfrac{\hbar^2}{2m}\left[f''(r) + \tfrac{2}{r}f'(r) - \tfrac{2}{a}f'(r) - \tfrac{2}{ra}f(r) + \tfrac{1}{a^2}f(r) \right] e^{-\frac{r}{a}} \cos\vartheta + \tfrac{\hbar^2}{mr^2} f(r) \cdot e^{-\frac{r}{a}} \cos\vartheta - \\ -\tfrac{e^2}{r} f(r) \cdot e^{-\frac{r}{a}} \cos\vartheta + \tfrac{me^4}{2\hbar^2} f(r) \cdot e^{-\frac{r}{a}} \cos\vartheta = -\tfrac{e\mathcal{E}r}{\sqrt{\pi a^3}} \cos\vartheta \cdot e^{-\frac{r}{a}} \end{gathered}$$

Расписывая функцию $f(r)$ и её производные, имеем

$$-\frac{\hbar^2}{m}\left[3a_2 + \frac{a_1}{r} - \frac{2a_1}{a} - \frac{3a_2}{a}r - \frac{a_0}{ar} \right] + \frac{\hbar^2}{mr^2} f(r) - \frac{e^2}{r} f(r) + \left[\frac{me^4}{2\hbar^2} - \frac{\hbar^2}{2ma^2} \right] f(r) = -\frac{e\mathcal{E}r}{\sqrt{\pi a^3}}$$

что после тождественных преобразований даёт

$$\frac{\hbar^2}{m}\left[\frac{a_0}{r^2} - 2a_2 + \frac{2a_1}{a} + \frac{3a_2}{a}r \right] - e^2\left(a_1 + a_2 r \right) = -\frac{e\mathcal{E}r}{\sqrt{\pi a^3}}$$

Из последнего выражения находим, что

$$a_0 = 0, \quad a_1 = -a\frac{\mathcal{E}}{e\sqrt{\pi a^3}}, \quad a_2 = -\frac{\mathcal{E}}{2e\sqrt{\pi a^3}}$$

Подставляя полученные коэффициенты в функцию $f(r)$, находим

$$\psi_{(1)}(r,\vartheta) = f(r) \cdot e^{-\frac{r}{a}} \cos\vartheta = -a\frac{\mathcal{E}r}{e\sqrt{\pi a^3}}\left(1 + \frac{r}{2a} \right) \cdot e^{-\frac{r}{a}} \cos\vartheta.$$

С учётом (5.9) уравнение (5.4) для поправки к энергии во втором порядке теории возмущений принимает вид

$$\epsilon_2 = e\mathcal{E} \int d_3x \psi_{(0)}(\mathbf{r}) \cdot r\cos\vartheta \cdot \psi_{(1)}(\mathbf{r}) = -2\pi\frac{\mathcal{E}^2}{\pi a^2} \int\limits_0^\infty dr r^4 \left(1 + \frac{r}{2a} \right) \cdot e^{-\frac{2r}{a}} \int\limits_0^\pi \cos^2\vartheta d\vartheta$$

Или

$$\epsilon_2 = -\frac{4}{3}\frac{\mathcal{E}^2}{a^2}\int\limits_0^\infty drr^4\left(1+\frac{r}{2a}\right)\cdot e^{-\frac{2r}{a}} = -\frac{4}{3}\mathcal{E}^2a^3\int\limits_0^\infty dxx^4\left(1+\frac{x}{2}\right)\cdot e^{-2x}$$

Интеграл

$$I = \int\limits_0^\infty dxx^4\left(1+\frac{x}{2}\right)\cdot e^{-2x} = \frac{27}{16}$$

и поэтому

$$\epsilon_2 = -\frac{9}{4}\mathcal{E}^2a^3 = -\frac{9}{4}\frac{\hbar^6\mathcal{E}^2}{m^3e^6}$$

Из выражения (5.11) находим поляризуемость κ атома по формуле

$$\kappa = -\frac{\partial^2\epsilon_2}{\partial\mathcal{E}^2} = \frac{9}{2}a^3 = \frac{9}{2}\frac{\hbar^6}{m^3e^6}$$

Применения эффекта Штарка

(?? почитаю книги для экспериментаторов)

14.2.4 Zeeman effects: basics

Эффект Зеемана по общей физике

Эффект Зеемана в слабых магнитных полях??

Основные формулы (??)

общефизическое представление

Прежде всего обратимся к влиянию внутренних полей.

Со спиновым механическим моментом электрона s связан магнитный момент

$$\mu_{\rm s} = -\frac{e}{m}\,{\rm s}$$

Это означает, что при наличии магнитного поля произойдет взаимодействие спина с последним, и появится дополнительная «магнитная» энергия.

На примере атома водорода мы видели,

что существование магнитного момента электрона приводит к появлению спин-орбитального взаимодействия, в результате которого уровни с $l \neq 0$ расщепляются по энергии на два подуровня с $j = l \pm 1/2$ -как говорят, возникает тонкая структура уровней.

Такое расщепление мало по сравнению с расстоянием между уровнями с разными n (см. формулу (6.54)).

Сразу отметим, что энергия спин-орбитального взаимодействия, а значит и величина расщепления, зависят от l; это хорошо видно из той же формулы (6.54)

На рис. 8.2 приведен пример тонкой структуры водородоподобного атома с $n = 2$: уровень с $l = 1$ расщеплен на два с$j = l \pm s = l \pm 1/2$, спектроскопические обозначения которых $P_{3/2}$ и $P_{1/2}$.

Спин-орбитальное взаимодействие снимает вырождение уровней по l (вспомним, что в чисто кулоновском поле энергия зависит только от $n, 0 \leqslant l \leqslant n-1$, с каждым l связано $(2l+$

1) -кратное вырождение по m_l, итого с учетом спина получается $2n^2$ -кратное вырождение или $2n^2$ -мультиплетность уров ня).

Мы уже упоминали хорошо известный пример снятия такого вырождения у натрия, в спектре которого наблюдается желтый дублет с длинами волн 5890 и 5896 Å.

Аналогично, взаимодействие магнитного момента ядра со спиновыми и орбитальными магнитными моментами электронов приводит к появлению сверхтонкой структуры атомных спектров.

Интервалы этого расщепления чрезвычайно малы: их масштаб на два-три порядка меньше масштаба расщепления, обусловленного тонкой структурой.

Поэтому сверхтонкая структура может рассматриваться для каждой из компонент тонкой структуры в отдельности.

Если спин ядра обозначить через I, а электронной оболочки - через J, то полный момент атома будет равен $\mathbf{F} = \mathbf{J} + \mathbf{I}$, и F пробегает значения

$$F = J + I, J + I - 1, ..., |J - I|$$

Соответственно, число компонент сверхтонкой структуры уровня с данным J равно $2I+1$(если $J > I$) или $2J + 1$(если $J < I$). Перейдем теперь к рассмотрению поведения атома во внешнем магнитном поле - эффекту Зеемана.

Это явление - расщепление спектральных линий в магнитном поле - было открыто голландским физиком П. Зееманом в 1896 г.

С внешним магнитным полем взаимодействуют как орбитальный, так и спиновый магнитные моменты электронов.

Кроме того, нужно иметь в виду, что эти магнитные моменты взаимодействуют между собой (знакомое нам спин-орбитальное взаимодействие).

В зависимости от относительной величины указанных взаимодействий различают два случая: слабого магнитного поля и сильного магнитного поля.

В первом случае взаимодействие внешнего магнитного поля с орбитальным и спиновым магнитными моментами электронов существенно меньше спин-орбитального взаимодействия, и в результате расщепление уровней за счет внешнего магнитного поля оказывается меньшим, чем расщепление, обусловленное внутренним полем самого атома (тонкая структура).

Этот случай носит название сложного эффекта Зеемана, поскольку в сильных полях структура спектра оказывается намного проще (как мы увидим чуть позже).

Дополнительная энергия в магнитном поле в данном случае равна

$$E_B = -(\mu \mathrm{B}) = g\mu(\mathrm{JB}) = g\mu m_J B$$

Здесь m_J определяет проекции вектора $\mathbf{J}$ на направление внешнего поля B и принимает $2J + 1$ значений, т. е. все зависит от взаимной ориентации векторов J и B.

Расщепление уровней оказывается эквидистантным, а сама величина расщепления линейно растет с полем.

О таком случае говорят, что магнитное поле снимает вырождение уровней по m_J. Поскольку внешнее расщепление меньше внутреннего (тонкой структуры), то картина слегка расщепленных спектральных уровней остается практически такой же, как и без поля.

Хотя расщепление одного уровня является эквидистантным, значения фактора Ланде g, вообще говоря, различны у разных уровней, что приводит к возникновению сложного расщепления линий перехода.

При этом существенное значение имеют правила отбора для излучения.

Общефизное описание расщепление линий натрия (??)

Классический пример эффекта Зеемана - поведение желтого дублета натрия в магнитном поле (сам дублет есть проявление тонкой структуры уровней).

Основное состояние натрия $3^2S_{1/2}$, а выше расположены два возбужденных состояния $3^2P_{1/2}$ и $3^2P_{3/2}$.

На рис. 8.3 стрелками показаны переходы, разрешенные правилами отбора, запрещенные переходы показаны штриховыми линиями. В чисто кулоновском поле энергия зависит только от квантового числа n и поэтому, казалось бы, не должно быть разницы в энергии уровней с разными l. Однако реально это справедливо лишь для водорода и водородоподобных атомов, а в натрии внутренние электроны экранируют поле ядра, таким образом, для p-электронов заряд ядра как бы меньше, чем для s -электронов, и они располагаются несколько выше.

Из-за спин-орбитального взаимодействия p -уровень расщепляется на два (тонкая структура), и в спектре излучения появляется желтый дублет.

Величина спин-орбитального расщепления у натрия равна $U_{L_S} = 2 \times \times 10^{-3}$ эВ, а во внешнем поле $B = 10^2$ Тл оно, согласно формуле (8.11), порядка

$$\Delta U_B = \mu_0 \mu_{\text{B}} B = 4\pi \cdot 10^{-7} \cdot 9,3 \cdot 10^{-24} \cdot \left(10^6/4\pi\right) = \\ = 10^{-24}\text{Дж} \ = 6 \cdot 10^{-6} \ni \text{В} \ll U_{LS},$$

т. е. поля такого порядка являются слабыми.

Во внешнем поле уровень $3^2P_{1/2}$ расщепляется, как и уровень $3^2S_{1/2}$, на два подуровня с проекциями $m_J = \pm 1/2$, а уровень $3^2P_{3/2}$ - на 4 подуровня с $m_J = 3/2, 1/2, -1/2, -3/2$ (при этом уровень с $m_J = 3/2$ расположен выше всех, а с $m_J = -3/2$ - самый низкий, что непосредственно следует из формулы (8.11)).

Всего в слабом магнитном поле наблюдается 10 переходов.

В силу правил отбора ($\Delta m_S = 0,\ \Delta m_L = 0, \pm 1,\ \Delta m_J = 0, \pm 1$) подавлены переходы с $m_J = 3/2$ на уровень $m_J = -1/2$ и с$m_J = -3/2$ на $m_J = 1/2$. Еще раз подчеркнем: так много линий наблюдается из-за того, что у разных уровней разная величина расщепления.

Поэтому, в частности, переходы с уровня $3^2P_{1/2}$ на $3^2S_{1/2}$ между подуровнями с $(1/2 \to 1/2)$ и $(-1/2 \to -1/2)$ по энергии неравны.

Действительно, у всех рассмотренных нами уровней натрия значения фактора Ланде разные:

$$g_{\text{л}}\ \left(P_{3/2}\right) = 1 + \frac{3/2 \cdot 5/2 + 1/2 \cdot 3/2 - 1 \cdot 2}{2 \cdot 3/2 \cdot 5/2} = \frac{4}{3}$$

$$g_{\text{л}}\ \left(P_{1/2}\right) = 1 + \frac{1/2 \cdot 3/2 + 1/2 \cdot 3/2 - 1 \cdot 2}{2 \cdot 1/2 \cdot 3/2} = \frac{2}{3}$$

$$g_{\text{л}}\ \left(S_{1/2}\right) = 1 + \frac{1/2 \cdot 3/2 + 1/2 \cdot 3/2 - 0}{2 \cdot 3/2 \cdot 5/2} = 2$$

Простой эффект Зеемана в сильном поле

Теперь рассмотрим простой эффект Зеемана, наблюдаемый в сильном магнитном поле.

Здесь термин «сильное поле» означает, что энергия спин-орбитального взаимодействия U_{SL} намного меньше, чем энергия взаимодействия как спинового, так и орбитального магнитных моментов с внешним полем, т. е. $U_{SL} \ll U_{SB}, U_{LB}$. В случае слабого поля мы классифицировали состояния точно так же, как и без поля, а в данном случае этого делать уже нельзя.

Теперь мы считаем величину U_{SL} практически равной нулю, т. е. пренебрегаем данным взаимодействием.

Последнее означает, что оператор энергии не зависит от ориентации спинового и орбитального моментов, а следовательно, он не зависит и от суммарного вектора $\mathbf{J} = \mathbf{L} + \mathbf{S}$. Остается зависимость энергии лишь от проекций векторов $\mathbf{L}$ и $\mathbf{S}$ на вектор B, т. е. только от квантовых чисел m_L и m_S. Для этого случая существует жаргонное выражение: говорят, что в сильном поле «разрывается LS-связь».

Итак, учитывая, что $g_L = 1, g_S = 2$, магнитная часть энергии в сильном поле равна

$$U_B = g_L \mu m_L B + g_S \mu_e m_S B = \mu B$$

Теперь уже «нет» спин-орбитального расщепления, уровень 3^2P расщепляется на 5 компонент с $m_L + 2m_S = 2, 1, 0, -1, -2$, уровень 3^2S - на 2, как это показано на рис. 8.4.

В сильном поле 3 линии

Покажем, что в сильном поле всегда будут наблюдаться лишь 3 линии.

Пусть имеется два уровня с энергиями E_{01} и E_{02}, характеризующихся квантовыми числами $L1, L2, S1, S2$. Разность энергий этих уровней в сильном поле равна

$$\Delta U_B = [E_{02} + \mu B\,(m_{L2} + 2m_{S2})] - [E_{01} + \mu B\,(m_{L1} + 2m_{S1})]$$

Так как по правилам отбора возможны переходы только между уровнями с $m_{S1} = m_{S2}$, то

$$\Delta U_B = (E_{02} - E_{01}) + \mu B\,(m_{L2} - m_{L1})$$

Но $\Delta m_L = 0, \pm 1$, а значит, в спектрах излучения в сильном поле всегда будут наблюдаться лишь три линии - одна несмещенная и две смещенные на $\pm\mu B$. Вот почему эффект Зеемана в сильном магнитном поле называется простым.

В заключение рассмотрим, как будет поляризован свет при простом эффекте Зеемана.

Когда наблюдение ведется вдоль приложенного магнитного поля, эффект Зеемана называют продольным.

При этом, поскольку $\Delta m_S = 0$, а $\Delta m_L = 0, \pm 1$, уносимый фотоном момент равен 1 (дипольное излучение), и оказывается, что смещенные компоненты имеют круговую поляризацию (у них $\Delta m_L = \pm 1$).

Несмещенная компонента вообще видна не будет, так как для нее $\Delta m_L = 0$, а фотона с $m_z = 0$ не существует.

В поперечном эффекте Зеемана (наблюдение поперек магнитного поля) несмещенная линия - это просто линейно-поляризованный свет, а циркулярно поляризованные смещенные линии также будут выглядить как линейно-поляризованные волны

В результате при наблюдении в перпендикулярном направлении мы увидим три линейно-поляризованных волны.

Таким образом, энергетические уровни частиц (любых - это могут быть и ядра, и молекулы), обладающих ненулевыми магнитными моментами, во внешнем магнитном поле испытывают зеемановское расщепление.

Если облучать такие частицы внешним электромагнитным излучением с частотой, равной энергии переходов между подуровнями:

$$\omega = \frac{g \mu_\text{Ь} B}{\hbar}$$

то будет происходить резонансное поглощение излучения.

В зависимости от сорта частиц это может быть ЭПР - электронный парамагнитный резонанс, либо ЯМР - ядерный магнитный резонанс.

В последнем случае масштаб измерения магнитных моментов определяется не магнетоном Бора, а так называемым ядерным магнетоном $\mu_я = e\hbar/2m_p$, где m_p - масса протона, т.е. ядерный магнетон примерно в 1800 раз меньше магнетона Бора: он равен $5,05 \cdot 10^{-27}$ Дж/Тл $= 5,05 \cdot 10^{-24}$ эрг/Гс.

Обычно опыты проводят так, что частота генератора, создающего переменное электромагнитное поле, держится постоянной, а меняется внешнее магнитное поле B.

В образце энергия атомов с $\mu \neq 0$ зависит от ориентации магнитных моментов.

Если приложено внешнее поле, то после установления теплового равновесия в соответствии с больцмановским распределением заселенности уровней число частиц с моментами, ориентированными вдоль поля, оказывается больше числа частиц с противоположной ориентацией магнитных моментов.

Таким образом, результирующий магнитный момент образца становится отличным от нуля, т.е. образец намагничивается.

Этот эффект получил название парамагнитный резонанс, его впервые наблюдал советский физик Е.К. Завойский в 1944 г.

нормальное описание

как релятивистские поправки потом пропишу

Эффекты в магнитном поле

Основные формулы (??)

Описание атома водорода в магнитном поле

Гамильтониан взаимодействия электронов атома с постоянным внешним магнитным полем $\mathcal{H}$ есть:

$$H = \sum_f \left\{ \frac{1}{2m} \left(\boldsymbol{p}_f - \frac{e}{c} \boldsymbol{A}\left(\boldsymbol{r}_f\right) \right)^2 + \left(\boldsymbol{\mu}_f \cdot \boldsymbol{\mathcal{H}}\right) \right\} + V$$

здесь вклад вектор-потенциала происходит за счет ковариантной производной, V -потенциал, включающий в себя как нерелятивистские вклады кулоновского взаимодействия электронов с ядром и попарно друг с другом, так и релятивистские поправки, зависящие от спина.

Магнитный момент электрона, обусловленный спином, согласно уравнению Дирака с $g = 2$

$$\boldsymbol{\mu} = g \frac{e\hbar}{2mc} \boldsymbol{s}$$

Калибровка обычно фиксируется так, чтобы

$$\mathcal{A}(r) = \frac{1}{2}(\mathcal{H} \times r)$$

откуда заключаем, что

$$\operatorname{div} \boldsymbol{A}(\boldsymbol{r}) = \frac{1}{2} \epsilon_{\alpha\beta\gamma} \partial_\alpha \mathcal{H}_\beta x_\gamma = \frac{1}{2} \epsilon_{\alpha\beta\gamma} \mathcal{H}_\beta \delta_{\alpha\gamma} = 0$$

Поэтому при возведении в квадрат обобщенного импульса

$$\left(p - \frac{e}{c} \mathcal{A}(r) \right)^2 = p^2 - \frac{e}{c} \{ (p \cdot \mathcal{A}) + (\mathcal{A} \cdot p) \} + \frac{e^2}{c^2} \mathcal{A}^2$$

вклад ниже равен

$$(\boldsymbol{p}\cdot\boldsymbol{\mathcal{A}})+(\boldsymbol{\mathcal{A}}\cdot\boldsymbol{p})=2(\boldsymbol{\mathcal{A}}\cdot\boldsymbol{p})-\mathrm{i}\hbar\,\mathrm{div}\,\boldsymbol{\mathcal{A}}=\epsilon_{\alpha\beta\gamma}H_\alpha x_\beta p_\gamma=\mathcal{H}\cdot(\boldsymbol{r}\times\boldsymbol{p})=\hbar\boldsymbol{\mathcal{H}}\cdot\boldsymbol{l}$$

т.е. возникает член взаимодействия с магнитным моментом вращения:

$$\frac{1}{2m}\left(\boldsymbol{p}-\frac{e}{c}\boldsymbol{A}(\boldsymbol{r})\right)^2=\frac{\boldsymbol{p}^2}{2m}-\frac{e\hbar}{2mc}(\boldsymbol{\mathcal{H}}\cdot\boldsymbol{l})+\frac{e^2}{8mc^2}(\mathcal{H}\times\boldsymbol{r})^2$$

Значит, гамильтониан атома в постоянном внешнем магнитном поле принимает вид

$$H=H_0^{\mathrm{at}}+\sum_f\left\{\mu_0\mathcal{H}\cdot(l_f+2s_f)+\frac{e^2}{8mc^2}\left(\mathcal{H}\times r_f\right)^2\right\}$$

где H_0^{at} - гамильтониан атома в отсутствие внешних источников, а магнетон Бора $\mu_0=e\hbar/2mc$. Суммирование орбитального момента и спина очевидно приводит к возмущению в Виде вза имодействия магнитного поля с магнитным моментом электронов атома:

$$V_{\text{mag.}}=\mu_0\mathcal{H}\cdot(\boldsymbol{L}+2\boldsymbol{S})$$

а квадратичный по полно член равен

$$V_d=\frac{e^2}{8mc^2}\sum_f\left(\mathcal{H}\times r_f\right)^2=\frac{e^2\mathcal{H}^2}{8mc^2}\sum_f r_f^2\sin^2\theta_f.$$

Он обусловливает диамагнитные свойства электронов, потому что коэффициент при квадрате поля имеет положительный знак: наведенный магнитный момент пропорционален внешнему полю $\boldsymbol{\mu}_{\text{ext.}}=B\mathcal{H}$, и он дает вклад в потенциальную энергию $U_{\text{ext.}}=-(\boldsymbol{\mu}_{\text{ext.}}\cdot\mathcal{H})$ так что, если $B<0$, то наведенный магнитный момент направлен против внешнего поля и положительна.

Количественная оценка

Оценим по порядку величины вклад во взаимодействие магнитного момента электронов и диамагнитный член.

Для этого прежде введем напряженность поля, характерную для атома:

$$\mathcal{H}_{\mathrm{at}}=\frac{e}{a^2}\sim 2\cdot 10^7\ \text{Гаусс.}$$

тогда

$$\mu_0\mathcal{H}\sim\frac{e^2\hbar}{mca^2}\frac{\mathcal{H}}{\mathcal{H}_{\mathrm{at}}}=\frac{e^2}{\hbar c}\frac{\hbar^2}{ma^2}\frac{\mathcal{H}}{\mathcal{H}_{\mathrm{at}}}=mc^2\alpha_{\mathrm{em}}^3\frac{\mathcal{H}}{\mathcal{H}_{\mathrm{at}}}$$

и, если $L\neq 0$ или $S\neq 0$, энергия взаимодействия магнитного момента с постоянным магнитным полем при $\mathcal{H}\ll\alpha_{\mathrm{em}}\mathcal{H}_{\mathrm{at}}\sim 10^5$ Гс оказывается существенно меньше энергии спин-орбитального взаимодействия за счет релятивистских поправок.

Диамагнитный вклад:

$$V_d\sim\frac{e^2}{mc^2}a^2\frac{e^2}{a^4}\frac{\mathcal{H}^2}{\mathcal{H}_{\mathrm{at}}^2}=\frac{e^4}{\hbar^2c^2}\frac{\hbar^2}{ma^2}\frac{\mathcal{H}^2}{\mathcal{H}_{\mathrm{at}}^2}=mc^2\alpha_{\mathrm{em}}^4\frac{\mathcal{H}^2}{\mathcal{H}_{\mathrm{at}}^2}$$

Отсюда немедленно следует, что если магнитный момент электронов не равен тождественно нулю, то диамагнитным вкладом заведомо можно пренебречь, поскольку он сравнивается с членом магнитного момента только при гигантских полях порядка

$$\mathcal{H}\sim\frac{\mathcal{H}_{\mathrm{at}}}{\alpha_{\mathrm{em}}}\sim 10^9\ \text{Гс}$$

При которых и поправки за счет магнитного момента становятся сравнимыми с энергией связи в атоме, т.е. поля становятся настолько велики, что приводят к ионизации атома,

Аномальный эффект Зеемана (??)

Основные формулы (??)

Если поместить излучающее тело в магнитное поле, за счет *эффекта Зеемана* спектр линий расщепится и появятся еще (?) две компоненты.
(???)

модель аномального эффекта Зеемана

(что это? где связь с эл?) магнитный диполь имеет энергию $U = -\vec{\mu}\vec{H}$.
черт, нужно в магнитном моменте разбираться!!! (потом доучу это все)
итак, магнитный момент (?????) $\vec{\mu} = \frac{e}{2c}[h, \vec{v}] = \frac{e}{2mc}[h, \vec{p}] = \frac{e}{2mc}\vec{L}$
в итоге энергия $U = -\frac{e}{2mc}\vec{L}\vec{H}$.
Если магнитный момент терма не равен нулю, То взаимодействие атома со слабым внешним Магнитным полем $\mathcal{H} \ll \alpha_{\rm em}\mathcal{H}_{\rm at} \sim 10^5$Гс является малым возмущением по сравнению с релятивистски ми спин-орбитальным и поправками.

Это означает, что в качестве волновых функций ведущего приближения следует рассматривать термы $^{2S+1}L_J$ В возмущении (10.5) магнитное поле задает выделенное направление, которое примем За направление оси z. Коммутатор

$$[J_\alpha, (\mathcal{H} \cdot \{\boldsymbol{J} + \boldsymbol{S}\})] = \mathrm{i}\epsilon_{\alpha\beta\gamma}\mathcal{H}_\beta\{J + S\}_\gamma$$

обращается в нуль для J_z. Далее, используя алгебру коммутаторов для произведения, легко Найти, ЧТО

$$\left[\boldsymbol{J}^2, (\mathcal{H} \cdot \{\boldsymbol{J} + \boldsymbol{S}\})\right] = 0$$

дение по M_J, которое имело место в отсутствие магнитного поля вследствие того, что сохранялись и компоненты $J_\pm : [J_\pm, H_0^{\rm at}] = 0$, некоммутирующе с$J_z : [J_\pm, J_z] \neq 0$, теперь ОКазывается "снятым": энергия зависит от M_J.

Для Вычисления матричного элемента возмущения заметим, что операторы полного момента и спина являются неприводимыми тензорными операторами первого порядка, Т.е. момента 1, так как при вращениях они преобразуются соответствующим образом - как векторы.

Отсюда следует, во-первых, элементарно

$$\langle J, M_J \,|J_z|\, J, M'_J\rangle = M_J\delta_{M_JM'_J}$$

Для вычисления матричного элемента возмущения заметим, что операторы полного момента и спина являются неприводимыми тензорными операторами первого порядка, Т.е. момента 1, так как при вращениях они преобразуются соответствующим образом - как векторы.

Отсюда следует, во-первых, элементарно

$$\langle J, M_J \,|J_z|\, J, M'_J\rangle = M_J\delta_{M_JM'_J}$$

а во-вторых,

$$[J_z, S_z] = 0$$

и значит, S_z -это нулевая компонента векторного оператора в стандартном представлении, и согласно теореме Вигнера-Эккарта

$$\langle J, M_J \,|S_m|\, J, M'_J\rangle = \frac{\langle J\|S\|J\rangle}{\sqrt{2J+1}}\langle J, M_J|J, M'_J; 1, m\rangle\,, \quad m = \{z, \pm\}$$

где коэффициент Клебша-Гордона отличен от нуля при $J \neq 0$ (правило запрета переходов $0 \to 0'$ за счет тензоров, не являющихся скалярами).

В этом параграфе мы будем иметь ввиду это условие.

Совершенно аналогично для полного момента

$$\langle J, M_J \left| J_m \right| J, M'_J \rangle = \frac{\langle J \| J \| J \rangle}{\sqrt{2J+1}} \langle J, M_J | J, M'_J; 1, m \rangle \,, \quad m = \{z, \pm\}$$

откуда заключаем, что для одного и того жсе терма оператор полного спина S пропорциОН а.Лен оператору полного момента $\boldsymbol{J}$:

$$\boldsymbol{S} = \lambda \boldsymbol{J}$$

где параметр λ определяется значениями приведенных матричных элементов для заданного терма

$$\lambda = \frac{\langle J \| S \| J \rangle}{\langle J \| J \| J \rangle}$$

и не зависит от вели чины проекции M_J. Определим λ, рассчитав матри чные элементы

$$\langle (\boldsymbol{S} \cdot \boldsymbol{J}) \rangle = \lambda \left\langle \boldsymbol{J}^2 \right\rangle \quad \to \quad \left\langle (\boldsymbol{L} \cdot \boldsymbol{S}) + \boldsymbol{S}^2 \right\rangle = \lambda J(J+1)$$

откуда

$$\lambda = \frac{J(J+1) - L(L+1) + S(S+1)}{2J(J+1)}$$

В итоге, матричный элемент возмущения

$$\langle V_{\text{mag.}} \rangle = \mu_0 \mathcal{H} M_J g_{\text{LSJ}}$$

где фактор Ланде

$$g_{\text{LSJ}} = 1 + \frac{J(J+1) - L(L+1) + S(S+1)}{2J(J+1)}$$

В терминах ларморовской частоты $\Omega = e\mathcal{H}/(2mc)$ расщепление уровней В терме

$$\epsilon_1 \left(M_J \right) = \hbar \Omega g_{\text{LSJ}} M_J$$

Итак, атомный терм в слабом магнитном поле расщепляется на $2J+1$ уровней, т.е. вырождение терма сним ается полностью.

14.2.5 Zeeman effects: other topics

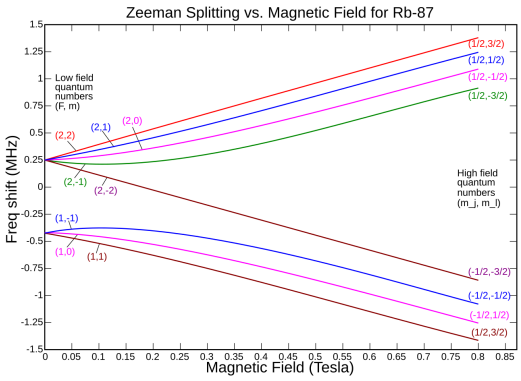
Intermediate Zeeman effect or why one level ran away?

(for now it is a question, later I'll think more about it!)

What happens in intermediate fields?

why one level ran away?

(see wiki for it)



(???)

14.2.6 Hyperfine interactions: basics

Основные формулы (??)

мотивация

где встречается?
что дает?

модель сверхтонкого расщепления

(задача из Белоусова по сути)
(мб уже это было раньше обсуждено????)
Гамильтониан

$$H = \frac{\mathbf{p}^2}{2m} - \frac{e^2}{r} - (\boldsymbol{\mu} \cdot \mathbf{H}) \equiv H_0 + V, \quad V = -(\boldsymbol{\mu} \cdot \mathbf{H})$$

где

$$\mu = -\mu_0 \sigma_e, \quad \mathbf{H} = \operatorname{rot} A$$

Как известно из теории поля,

$$A = \frac{(\mu_p \times \mathbf{r})}{r^3} = -(\mu_p \times \nabla)\frac{1}{r}, \quad \mu_p = \mu_p \sigma_p$$

Подставляя (17.3) в (17.2), получаем

$$\mathbf{H} = -(\nabla \times (\mu_p \times \nabla))\frac{1}{r}$$

откуда

$$V = -\mu_0 \mu_p \sigma_e (\nabla \times (\sigma_p \times \nabla))\frac{1}{r}$$

Преобразуем немного $(\nabla \times (\sigma_p \times \nabla))_\alpha$:
$(\nabla \times (\sigma_p \times \nabla))_\alpha = \epsilon_{\alpha\beta\gamma}\nabla_\beta \epsilon_{\gamma\mu\nu}\sigma_p^\mu \nabla_\nu = (\delta_{\alpha\mu}\delta_{\beta\nu} - \delta_{\alpha\nu}\delta_{\beta\mu})\nabla_\beta \sigma_p^\mu \nabla_\nu = (\sigma_p \Delta - (\sigma_p \cdot \nabla)\nabla)_\alpha$

Тогда возмущение примет вид

$$V = -\mu_0 \mu_p \sigma_e (\sigma_p \Delta - (\sigma_p \cdot \nabla)\nabla)\frac{1}{r}$$

Поправка к энергии основного состояния атома водорода с возмущением (17.5) вычисляется по формуле

$$\epsilon_1 = \int d_3 x \psi^\dagger \left(\mathbf{r}, s_e, s_p\right) V \psi \left(\mathbf{r}, s_e, s_p\right)$$

Волновая функция нулевого приближения факторизуется в произведение пространственной и спиновой волновых функций

$$\psi \left(\mathbf{r}, s_e, s_p\right) = \psi_{100}(\mathbf{r}) \cdot \chi \left(s_e, s_p\right), \quad \psi_{100}(\mathbf{r}) = \frac{1}{\sqrt{\pi a^3}} e^{-r/a}$$

Интегрирование выражения (17.6) по углам в сферических координатах даёт нам выражение, в котором необходимо $\nabla_\alpha \nabla_\beta$ заменить на $\frac{1}{3}\delta_{\alpha\beta}\triangle$, то есть

$$\epsilon_1 = -\frac{2}{3}\mu_0\mu_p \int dr |\psi_{100}(\mathbf{r})|^2 \chi^\dagger \sigma_e \cdot \sigma_p \chi \Delta \frac{1}{r}$$

Учитывая, что $\triangle \frac{1}{r} = -4\pi\delta(\mathbf{r})$, получаем

$$\epsilon_1 = \frac{8\pi}{3}\mu_0\mu_p \left|\psi_{100}(0)\right|^2 \chi^\dagger \sigma_e \cdot \sigma_p \chi = \frac{8\pi}{3}\mu_0\mu_p \frac{1}{\pi a^3} \chi^\dagger \sigma_e \cdot \sigma_p \chi$$

Проведём теперь усреднение по спиновым волным функциям.

Суммарный спин

$$s = s_e + s_p$$

то есть

$$s^2 = s_e^2 + s_p^2 + 2\left(s_e \cdot s_p\right) = \tfrac{1}{2}\left(\tfrac{1}{2}+1\right) + \tfrac{1}{2}\left(\tfrac{1}{2}+1\right) + \tfrac{1}{2}\left(\sigma_e \cdot \sigma_p\right) = \tfrac{3}{2} + \tfrac{1}{2}\left(\sigma_e \cdot \sigma_p\right)$$
$$\left(\sigma_e \cdot \sigma_p\right) = 2s^2 - 3$$

Подставляя (17.9) в (17.8), находим

$$\epsilon_1 = \epsilon_1(s) = \frac{8}{3a^3}\mu_0\mu_p[2s(s+1) - 3]$$

где $s = 0; 1$.

Значит,

$$\epsilon_1(0) = -\frac{8}{a^3}\mu_0\mu_p, \quad \epsilon_1(1) = \frac{8}{3a^3}\mu_0\mu_p$$

Таким образм, исходный уровень расщепляется на два в соответствии со значением суммарного спина (см. (17.10) и (17.11)), причём один из этих уровней трёхкратно вырожден ($s = 1, m = 0, \pm 1$), а другой - невырожденный ($s = 0$). Частота перехода

$$\nu = \frac{\epsilon_1(1) - \epsilon_1(0)}{h} = 1417 \text{ Hz}$$

14.4 Other on Quantum Scattering Theory

(тут многие другие темы, нпр из ЛЛ3. супер редко они нужны, так что раздел и вдали.)

14.4.1 Gell-Mann and Low theorem

(пока по вики)

Statement of the theorem

Let $|\Psi_0\rangle$ be an eigenstate of H_0 with energy E_0 and let the 'interacting' Hamiltonian be $H = H_0 + gV$, where g is a coupling constant and V the interaction term. We define a Hamiltonian $H_\epsilon = H_0 + e^{-\epsilon|t|}gV$ which effectively interpolates between H and H_0 in the limit $\epsilon \to 0^+$and $|t| \to \infty$. Let $U_{\epsilon I}$ denote the evolution operator in the interaction picture. The Gell-Mann and Low theorem asserts that if the limit as $\epsilon \to 0^+$of

$$\left|\Psi_\epsilon^{(\pm)}\right\rangle = \frac{U_{\epsilon I}(0, \pm\infty)\,|\Psi_0\rangle}{\langle\Psi_0\,|U_{\epsilon I}(0, \pm\infty)|\,\Psi_0\rangle}$$

exists, then $\left|\Psi_\epsilon^{(\pm)}\right\rangle$are eigenstates of H Note that when applied to, say, the ground-state, the theorem does not guarantee that the evolved state will be a ground state. In other words, level crossing is not excluded.

Proof

As in the original paper, the theorem is typically proved making use of Dyson's expansion of the evolution operator. Its validity however extends beyond the scope of perturbation theory as has been demonstrated by Molinari. We follow Molinari's method here. Focus on H_ϵ and let $g = e^{\epsilon\theta}$. From Schrdinger's equation for the time-evolution operator

$$i\hbar\partial_{t_1} U_\epsilon(t_1, t_2) = H_\epsilon(t_1)\, U_\epsilon(t_1, t_2)$$

and the boundary condition $U_\epsilon(t_2, t_2) = 1$ we can formally write

$$U_\epsilon(t_1, t_2) = 1 + \frac{1}{i\hbar}\int_{t_2}^{t_1} dt' \left(H_0 + e^{\epsilon(\theta - |t'|)}V\right) U_\epsilon(t', t_2)$$

Focus for the moment on the case $0 \geq t_1 \geq t_2$. Through a change of variables $\tau = t' + \theta$ we can write

$$U_\epsilon(t_1, t_2) = 1 + \frac{1}{i\hbar}\int_{\theta+t_2}^{\theta+t_1} d\tau \left(H_0 + e^{\epsilon\tau}V\right) U_\epsilon(\tau - \theta, t_2)$$

We therefore have that

$$\partial_\theta U_\epsilon(t_1,t_2) = \epsilon g \partial_g U_\epsilon(t_1,t_2) = \partial_{t_1} U_\epsilon(t_1,t_2) + \partial_{t_2} U_\epsilon(t_1,t_2)$$

This result can be combined with the Schrdinger equation and its adjoint

$$-i\hbar\partial_{t_1} U_\epsilon(t_2,t_1) = U_\epsilon(t_2,t_1) H_\epsilon(t_1)$$

to obtain

$$i\hbar\epsilon g\partial_g U_\epsilon(t_1,t_2) = H_\epsilon(t_1) U_\epsilon(t_1,t_2) - U_\epsilon(t_1,t_2) H_\epsilon(t_2)$$

The corresponding equation between $H_{\epsilon I}, U_{\epsilon I}$ is the same. It can be obtained by pre-multiplying both sides with $e^{iH_0 t_1/\hbar}$, post-multiplying with $e^{iH_0 t_2/\hbar}$ and making use of

$$U_{\epsilon I}(t_1,t_2) = e^{iH_0 t_1/\hbar} U_\epsilon(t_1,t_2) e^{-iH_0 t_2/\hbar}$$

The other case we are interested in, namely $t_2 \geq t_1 \geq 0$ can be treated in an analogous fashion and yields an additional minus sign in front of the commutator (we are not concerned here with the case where $t_{1,2}$ have mixed signs). In summary, we obtain

$$(H_{\epsilon,t=0} - E_0 \pm i\hbar\epsilon g\partial_g) U_{\epsilon I}(0,\pm\infty)|\Psi_0\rangle = 0$$

We proceed for the negative-times case. Abbreviating the various operators for clarity

$$i\hbar\epsilon g\partial_g (U|\Psi_0\rangle) = (H_\epsilon - E_0) U|\Psi_0\rangle$$

Now using the definition of Ψ_ϵ we differentiate and eliminate derivatives $\partial_g(U|\Psi_0\rangle)$ using the above expression, finding

$$\begin{aligned} i\hbar\epsilon g\partial_g|\Psi_\epsilon\rangle &= \frac{1}{\langle\Psi_0|U|\Psi_0\rangle}(H_\epsilon - E_0) U|\Psi_0\rangle - \frac{U|\Psi_0\rangle}{\langle\Psi_0|U|\Psi_0\rangle}\langle\Psi_0|(H_\epsilon - E_0)U|\Psi_0\rangle \\ &= (H_\epsilon - E_0)|\Psi_\epsilon\rangle - |\Psi_\epsilon\rangle\langle\Psi_0|H_\epsilon - E_0|\Psi_\epsilon\rangle \\ &= [H_\epsilon - E]|\Psi_\epsilon\rangle . \end{aligned}$$

where $E = E_0 + \langle\Psi_0|H_\epsilon - H_0|\Psi_\epsilon\rangle$. We can now let $\epsilon \to 0^+$as by assumption the $g\partial_g|\Psi_\epsilon\rangle$ in left hand side is finite. We then clearly see that $|\Psi_\epsilon\rangle$ is an eigenstate of H and the proof is complete.

Примеры применений (???)

(я не знаю, где эта теорема применяется, потому что почти не понял ее. напишу, если узнаю.)

14.4.2 Ramsauer Effect

(по идее тут должна быть достаточная теория, пока так)

Общефизическая теория

Эффект Рамзауэра это явление аномально слабого рассеяния медленных электронов атомами нейтральных газов

К. Рамзауэр в 1921 году изучал рассеяние электронов в газообразном аргоне, и находил зависимость сечения упругого рассеяния электрона в зависимости от его энергии. Оказалось, что при уменьшении энергии меньших 16 эВ наблюдалось

уменьшение сечения практически до нуля с минимумом, достигаемым при энергии порядка 1 эВ, хотя в соответствии с классической механикой сечение должно возрастать.

Позднее аналогичные наблюдения были сделаны и для некоторых других тяжёлых газов.

Эффект также был косвенно подтверждён в опытах по измерению подвижности электронов в нейтральных газах.

(далее посмотрим на классическое и квантовое описание этого)

15 Open Quantum Systems, Many Particle Systems

Обсудим подробно открытые квантовые системы.

15.1 Typical Models of Open Quantum Systems (?)

15.1.1 Spin-Boson Model

Изучем на микроскопическом уровне динамику открытой системы, взаимодействующей с окружением. Изучать её мы будем на примере простейшей модели, которую можно придумать - так называемой спинбозонной модели (spin-boson model). Система (s, system) будет представлять собой двухуровневую систему (это может быть спин-1/2 в магнитном поле, это может быть частица в двухъямном потенциале - детали совершенно не важны), которую мы будем описывать на языке спина-1/2 и матриц Паули. В качестве модели окружающей среды (e, environment; также часто её называют баней - bath) мы возьмём набор гармонических осцилляторов. Гамильтониан всей системы имеет вид:

$$\hat{H} = \underbrace{-\frac{\Delta}{2}\hat{\sigma}_z}_{\hat{H}_s} + \underbrace{\sum_n \omega_n \hat{a}_n^\dagger \hat{a}_n}_{\hat{H}_e} + \underbrace{\hat{\sigma}_x \sum_n \lambda_n \hat{X}_n}_{\hat{V}}, \quad \hat{X}_n = \hat{a}_n + \hat{a}_n^\dagger$$

Такой вид взаимодействия обусловлен следующими простыми соображениями. Во-первых, ничего сложнее чем какаято линейная комбинация матриц Паули для двухуровневой системы предложить нельзя; поэтому взаимодействие линейно по $\hat{\boldsymbol{\sigma}}$; без ограничения общности [1] можно устроить взаимодействие именно посредством $\hat{\sigma}_z$. Во-вторых, мы будем предполагать, что отклонения осцилляторов от положения равновесия будут в каком-то смысле малы, и поэтому «сила» раскладывается линейно по отклонениям $\hat{X}$. Величины λ_n играют роль констант связи, которые будут предполагаться в каком-то смысле маленькими; по ним мы будем устраивать теорию возмущений.

В принципе, вся система s+e является замкнутой и допускает описание на языке волновых функций. Однако интересоваться мы будем именно динамикой двухуровневой системы, для описания которой необходимо ввести редуцированную матрицу плотности $\hat{\rho}_s(t) = \mathrm{Tr}_e\, \hat{\rho}(t)$, где $\hat{\rho}(t)$ - матрица плотности всей системы, а операция Tr_e подразумевает взятие частичного следа по степеням свободы окружающей среды. Полученный в результате такой операции объект - это матрица 2×2.

15.1.2 Interaction Representation of Open Systems

Работать мы будем в операторном формализме, используя представление взаимодействия по отношению к невозмущённому гамильтониану $\hat{H}_e + \hat{H}_s$ и с возмущением $\hat{V}$. Среда Динамика повышающих и понижающих операторов записывается просто:

$$\frac{d\hat{a}_n}{dt} = i\left[\hat{H}_e, \hat{a}_n\right] = i\left[\omega_n \hat{a}_n^\dagger \hat{a}_n, \hat{a}_n\right] = -i\omega_n \hat{a}_n \Rightarrow \hat{a}_n(t) = \hat{a}_n e^{-i\omega_n t}, \quad \hat{a}_n^\dagger(t) = \hat{a}_n^\dagger e^{i\omega_n t}$$

Система Для матриц Паули мы получаем:

$$\frac{d\hat{\sigma}_x}{dt} = i\left[\hat{H}_s, \hat{\sigma}_x\right] = \Delta\hat{\sigma}_y, \quad \frac{d\hat{\sigma}_y}{dt} = -\Delta\hat{\sigma}_x, \quad \frac{d\hat{\sigma}_z}{dt} = 0$$

и решение записывается как:

$$\begin{cases} \hat{\sigma}_x(t) = \hat{\sigma}_x \cos\Delta t + \hat{\sigma}_y \sin\Delta t \\ \hat{\sigma}_y(t) = -\hat{\sigma}_x \sin\Delta t + \hat{\sigma}_y \cos\Delta t \\ \hat{\sigma}_z(t) = \hat{\sigma}_z \end{cases}$$

Такая «тривиальная» невозмущённая эволюция тем самым описывает просто прецессию спина с угловой скоростью Δ вокруг направления «магнитного поля» z. Если же мы говорим, к примеру, о частице в двухъямном потенциале то такая когерентная прецессия соответствует осцилляциям Раби. В контексте спинов или кубитов, такое представление также часто называют приближением вращающейся волны (rotating wave approximation); это связано с тем, что в каком-то смысле оно эквивалентно переходу во вращающуюся систему отсчёта. Возмущение Соответственно, от гамильтониана с представлении взаимодействия остаётся только лишь возмущение. Последнее мы можем записать через один-единственный оператор «случайной силы» $\hat{\Phi}(t)$, с которой баня действует на нашу двухуровневую систему:

$$\hat{V}(t) = \hat{\sigma}_x(t)\hat{\Phi}(t), \quad \hat{\Phi}(t) = \sum_n \lambda_n \hat{X}_n(t)$$

В дальнейшем мы увидим, что явный вид «силы», который тут предложен, в действительности не сильно важен - а важны лишь определённые корреляционные функции этой силы.

15.1.3 Born–Markov Approximation

Полная матрица плотности в представлении взаимодействия удовлетворяет следующему уравнению:

$$\frac{d\hat{\rho}(t)}{dt} = i[\hat{\rho}(t), \hat{V}(t)]$$

Мы интересуемся следующей постановкой задачи. В начальный момент времени $t = 0$ баня находилась в равновесии с температурой T, и поэтому описывалась своей матрицей

плотности $\hat{\rho}_e(0) = \frac{1}{Z} e^{-\beta \hat{H}_e}$; а система была приготовлена со своей матрицей плотности $\hat{\rho}_s(0)$ (которая может соответствовать чистому состоянию $|\psi_0\rangle \langle\psi_0|$, или описывать смешанное состояние - сейчас это не очень важно); и изначально мы предполагаем, что баня и система никак не взаимодействовали, $\hat{\rho}(0) = \hat{\rho}_e(0) \otimes \hat{\rho}_s(0)$. В результате временной эволюции, происходит запутывание и матрица плотности больше не представляет собой простое тензорное произведение; поэтому, вообще говоря, не очень понятно, как брать частичный след в правой части уравнения (9.6).

Предлагается сделать несколько приближений. Первое приближение заключается в том, что если система достаточно маленькая, а среда - достаточно большая [2], то разумно считать, что матрица плотности среды практически не меняется с течением времени. Если мы, однако, предположим, что матрица плотности в произвольный момент времени выглядит как $\hat{\rho}(t) = \hat{\rho}_e \otimes \hat{\rho}_s(t)$, и возьмём в уравнении (9.6) частичный след, мы немедленно получим ноль в правой части; и связанно это с тем, что в равновесии средняя сила равна нулю:

$$\mathrm{Tr}_e \left(\hat{\rho}_e \hat{\Phi}(t) \right) \equiv \langle \hat{\Phi}(t) \rangle = \sum_n \lambda_n \left\langle \hat{X}_n(t) \right\rangle = 0$$

поэтому делать такое такое приближение наивно нельзя. Можно, однако, обойти эту трудность, сделав серию тождественных преобразований в уравнении (9.6): сперва мы его проинтегрируем от какого-то произвольного момента времени t_0 до t, а затем полученное выражение подставим опять в правую часть уравнения [3]:

$$\hat{\rho}(t) = \hat{\rho}\left(t_0\right) + i \int\limits_{t_0}^{t} dt' \left[\hat{\rho}\left(t'\right), \hat{V}\left(t'\right) \right] \Rightarrow \frac{d\hat{\rho}(t)}{dt} = i \left[\hat{\rho}\left(t_0\right), \hat{V}(t) \right] - \int\limits_{t_0}^{t} dt' \left[\left[\hat{\rho}\left(t'\right), \hat{V}\left(t'\right) \right], \hat{V}(t) \right]$$

В этом уравнении уже можно взять частичный след, предположив матрицу плотности в таком виде. Идеологически то что было сейчас проделано - это второй порядок теории возмущений по $\hat{V}$, и сделанное приближение носит название Борновского приближения. Беря частичный след слева и справа, и переходя к $\tau = t - t'$, мы получаем:

$$\frac{d\hat{\rho}_s}{dt} = - \int\limits_{0}^{t-t_0} d\tau \, \mathrm{Tr}_e \left(\left[\left[\hat{\rho}_s(t-\tau) \hat{\rho}_e, \hat{V}(t-\tau) \right], \hat{V}(t) \right] \right)$$

Как мы продемонстрируем далее явно, в результате взятия частичного следа возникнут корреляционные функции вида $S\left(t - t'\right) \equiv \left\langle \hat{\Phi}(t) \hat{\Phi}\left(t'\right) \right\rangle$ (несложно видеть, они зависят только от разности времён). Такие автокорреляционные функции определяются динамикой среды, и как правило, они быстро спадают до нуля на очень малых масштабах времени - если окружающая среда содержит огромное количество степеней свободы, то о корреляциях на сколь либо продолжительных временах говорить не приходится. Это приближение носит название Марковского приближения, и сводится оно к следующему физическому свойству окружающей среды - как правило, среда не обладает памятью.

Если предположить, что этот масштаб времени много меньше масштаба времени, на котором меняется сама матрица плотности, то можно заменить $\hat{\rho}_s(t-\tau) \mapsto \hat{\rho}_s(t)$, а также в силу сходимости интеграла, заменить его верхний предел до бесконечности. В результате мы получаем следующее квантовое кинетическое уравнение (master equation):

$$\frac{d\hat{\rho}_s}{dt} = - \int\limits_{0}^{\infty} d\tau \, \mathrm{Tr}_e \left(\left[\left[\hat{\rho}_s(t) \hat{\rho}_e, \hat{V}(t-\tau) \right], \hat{V}(t) \right] \right)$$

В таком виде это - система линейных дифференциальных уравнений с постоянными коэффициентами на компоненты матрицы плотности $\hat{\rho}_s$. Если окружающая среда не обладает памятью, то самый общий вид квантового кинетического уравнения имеет вид уравнения Линблад **a**[4]:

$$\frac{d\hat{\rho}_s(t)}{dt} = i\left[\hat{\rho}_s(t), \hat{H}_s\right] + \mathcal{L}\hat{\rho}_s(t)$$

В правой части стоит супероператор - линейный оператор, действующий на пространстве линейных операторов носящий название оператора Линблада; он имеет смысл аналога интеграла столкновений в обычном кинетическом уравнении. Оператор этот не может быть произвольным - даже при взаимодействии с окружающей средой, такое уравнение должно сохранять нормировку $\operatorname{Tr}\hat{\rho}_s(t) = 1$ и положительную определённость матрицы $\hat{\rho}_s$. То что мы сейчас получили - это явный вид оператора Линблада в приближении Борна-Маркова.

Явный вид

Чтобы продвинуться дальше, давайте подставим явный вид возмущения и раскроем коммутаторы:

$$\frac{d\hat{\rho}_s}{dt} = -\int_0^\infty d\tau \operatorname{Tr}_e\Big(\hat{\rho}_s(t)\underline{\hat{\rho}_e}\hat{\sigma}_x(t-\tau)\underline{\hat{\Phi}(t-\tau)}\hat{\sigma}_x(t)\underline{\hat{\Phi}(t)} - \hat{\sigma}_x(t-\tau)\underline{\hat{\Phi}(t-\tau)}\hat{\rho}_s(t)\underline{\hat{\rho}_e}\hat{\sigma}_x(t)\underline{\hat{\Phi}(t)}$$
$$-\hat{\sigma}_x(t)\underline{\hat{\Phi}(t)}\hat{\rho}_s(t)\underline{\hat{\rho}_e}\hat{\sigma}_x(t-\tau)\underline{\hat{\Phi}(t-\tau)} + \hat{\sigma}_x(t)\underline{\hat{\Phi}(t)}\hat{\sigma}_x(t-\tau)\underline{\hat{\Phi}(t-\tau)}\hat{\rho}_s(t)\underline{\hat{\rho}_e}\Big)$$

Подчёркнуты операторы, которые действуют на степени свободы окружающей среды (и которые, собственно, участвуют в операции взятии следа). При взятии следа мы: - можем как угодно менять местами подчёркнутые и не подчёркнутые операторы - ведь они действуют на разные степени свободы, и потому коммутируют. - не можем менять относительный порядок подчёркнутых операторов (аналогично и с не подчёркнутыми) - их коммутатор в общем случае отличен от нуля. - можем циклически переставлять подчёркнутые операторы как хотим - из-за операции взятии следа

Наконец, введя следующие корреляционные функции:

$$S_>(\tau) = \operatorname{Tr}_e\left(\hat{\rho}_e\hat{\Phi}(t)\hat{\Phi}(t-\tau)\right), \quad S_<(\tau) \equiv \operatorname{Tr}_e\left(\hat{\rho}_e\hat{\Phi}(t-\tau)\hat{\Phi}(t)\right) = S_>(-\tau)$$

мы можем избавиться от частичного следа и получить:

$$\frac{d\hat{\rho}_s}{dt} = -\int_0^\infty d\tau \left(S_<(\tau)\left[\hat{\rho}_s(t)\hat{\sigma}_x(t-\tau)\hat{\sigma}_x(t) - \hat{\sigma}_x(t)\hat{\rho}_s(t)\hat{\sigma}_x(t-\tau)\right] + S_>(\tau)\left[\hat{\sigma}_x(t)\hat{\sigma}_x(t-\tau)\hat{\rho}_s(t) - \hat{\sigma}_x(t-\tau)\hat{\rho}_s\right.\right.$$

15.1.4 Correlation Functions of the Environment

Дальше нам необходимо научиться вычислять корреляционные функции среды:

$$S_>(t) = \langle\hat{\Phi}(t)\hat{\Phi}(0)\rangle = \sum_{nm}\lambda_n\lambda_m\left\langle\hat{X}_n(t)\hat{X}_m(0)\right\rangle = \sum_n\lambda_n^2\left\langle\left(\hat{a}_n e^{-i\omega_n t} + \hat{a}_n^\dagger e^{i\omega_n t}\right)\left(\hat{a}_n + \hat{a}_n^\dagger\right)\right\rangle = \sum_n\lambda_n^2\left(\left\langle\hat{a}_n\hat{a}_n^\dagger\right\rangle\right.$$

Тут мы воспользовались тем, что осцилляторы независимы - поэтому остаются только члены $n = m$; и что средние значения $\langle\hat{a}_n\hat{a}_n\rangle = \left\langle\hat{a}_n^\dagger\hat{a}_n^\dagger\right\rangle = 0$, поскольку матрица плотности

диагональна в представлении чисел заполнения:

$$\hat{\rho}_e^{(n)} = \frac{1}{Z_n} e^{-\beta\omega_n \hat{a}_n^\dagger \hat{a}_n} \equiv \frac{1}{Z_n} \sum_{k=0}^{\infty} |k\rangle\langle k| \cdot e^{-\beta\omega_n k}$$

Отличные от нуля средние - следующие:

$$\left\langle \hat{a}_n^\dagger \hat{a}_n \right\rangle = \frac{\sum\limits_{k=0}^{\infty} \left\langle k \left| \hat{a}_n^\dagger \hat{a}_n \right| k \right\rangle e^{-\beta\omega_n k}}{\sum\limits_{k=0}^{\infty} e^{-\beta\omega_n k}} \equiv \frac{\sum\limits_{k=0}^{\infty} k e^{-\beta\omega_n k}}{\sum\limits_{k=0}^{\infty} e^{-\beta\omega_n k}} = n_B(\omega_n) \equiv \frac{1}{e^{\beta\omega_n} - 1}, \quad \left\langle \hat{a}_n \hat{a}_n^\dagger \right\rangle = \left\langle \hat{a}_n^\dagger \hat{a}_n \right\rangle + 1$$

Поскольку числа заполнения являются функциями энергии, то можно заметить, что вся информация о среде содержится в следующей функции - так называемой спектральной плотности среды:

$$J(\omega) \equiv \pi \sum_n \lambda_n^2 \delta(\omega - \omega_n)$$

Континуальный предел для среды как раз будет представлять собой замену $J(\omega)$ на некоторую непрерывную функцию частоты; её явный вид мы обсудим позже, а пока перепишем корреляционную функцию среды в следующем виде:

$$S_>(t) = \int_0^\infty \frac{d\omega}{\pi} J(\omega) \left((n_B(\omega) + 1) e^{-i\omega t} + n_B(\omega) e^{i\omega t} \right) \Rightarrow S_>(\omega) = 2\widetilde{J}(\omega) (n_B(\omega) + 1)$$

$$S_<(t) = \int_0^\infty \frac{d\omega}{\pi} J(\omega) \left(n_B(\omega) e^{-i\omega t} + (n_B(\omega) + 1) e^{i\omega t} \right) \Rightarrow S_<(\omega) = 2\widetilde{J}(\omega) n_B(\omega)$$

где обозначено $\widetilde{J}(\omega) \equiv J(\omega) - J(-\omega)$ и использовано $n_B(\omega) + 1 = -n_B(-\omega)$.

15.1.5 Bloch Equations

В принципе, дальше можно было бы подставить явный вид матриц Паули в представлении взаимодействия, и получить систему из 4 уравнений на 4 компоненты матрицы плотности. Однако, более наглядным является представление Блоха, которое параметризует матрицу плотности произвольной двухуровневой системы при помощи вектора $\boldsymbol{n}$ согласно:

$$\hat{\rho}_s(t) = \frac{1}{2}(\hat{\mathbb{I}} + \boldsymbol{n}(t) \cdot \hat{\boldsymbol{\sigma}}(t)) = \frac{1}{2} \begin{pmatrix} 1 + n_z & n_- e^{-i\Delta t} \\ n_+ e^{i\Delta t} & 1 - n_z \end{pmatrix}, \quad \boldsymbol{n}(t) \equiv \mathrm{Tr}\left(\hat{\rho}_s(t) \hat{\boldsymbol{\sigma}}(t)\right) = \langle \hat{\boldsymbol{\sigma}}(t) \rangle_s$$

(у вектора наглядный физический смысл - он представляет собой вектор поляризации спина). Напишем уравнения на компоненты вектора $\boldsymbol{n}$:

$$\frac{d\boldsymbol{n}(t)}{dt} = \mathrm{Tr}\left(\frac{d\hat{\boldsymbol{\sigma}}(t)}{dt} \hat{\rho}_s(t) \right) + \mathrm{Tr}\left(\hat{\boldsymbol{\sigma}}(t) \frac{d\hat{\rho}_s(t)}{dt} \right) = i \left\langle \left[\hat{H}_s, \hat{\boldsymbol{\sigma}}(t) \right] \right\rangle_s + \mathrm{Tr}\left(\hat{\boldsymbol{\sigma}}(t) \frac{d\hat{\rho}_s(t)}{dt} \right)$$

Первый член тривиален, он описывает когерентную прецессию в отсутствии взаимодействия, см. (9.3); поэтому мы сфокусируемся на втором члене, подставив в него (9.14), а также все операторы в представлении взаимодействия; исследуем что получилось покомпонентно. Сразу отметим, что уравнение на x-компоненту тривиально $-\frac{dn_x^{(2)}}{dt} = 0$. Связано это с тем, что $\left[\hat{\sigma}_x, \hat{V} \right] = 0$ - и поэтому точное уравнение имеет вид:

$$\frac{dn_x(t)}{dt} = -\Delta n_y(t)$$

Z-компонента

Подставляя и упрощая, получаем:

$$\frac{dn_z^{(2)}(t)}{dt} = -2\int\limits_0^\infty d\tau \left[n_z(t)S_K(\tau)\cos\Delta\tau - iS_R(\tau)\sin\Delta\tau\right]$$

где обозначены так называемые Келдышевские (K) и запаздывающие (R, retarded) корреляционные функции:

$$S_K(\tau) \equiv S_>(\tau)+S_<(\tau) \equiv \langle\{\hat\Phi(\tau),\hat\Phi(0)\}\rangle, \quad S_R(\tau) \equiv \theta(\tau)\left(S_>(\tau)-S_<(\tau)\right) \equiv \theta(\tau)\langle[\hat\Phi(\tau),\hat\Phi(0)]\rangle$$

Вычислим стоящие тут преобразования Фурье (используя тот факт, что $S_K(\tau)\equiv S_K(-\tau)$ и $2n_B(\omega)+1=\coth\frac{\beta\Delta}{2}$):

$$2\int\limits_0^\infty d\tau S_K(\tau)\cos\Delta\tau = S_K(\omega=\Delta) = 2J(\Delta)\coth\frac{\beta\Delta}{2}$$

$$2i\int\limits_0^\infty d\tau S_R(\tau)\sin\Delta\tau = S_>(\omega=\Delta)-S_<(\omega=\Delta) = 2J(\Delta)$$

Поэтому мы перепишем уравнение на z-компоненту в следующем виде:

$$\frac{dn_z(t)}{dt} = -\frac{n_z(t)-n_z^{(\mathrm{eq})}}{T_1}, \quad \frac{1}{T_1} = 2J(\Delta)\coth\frac{\beta\Delta}{2}, \quad n_z^{(\mathrm{eq})} = \tanh\frac{\beta\Delta}{2}$$

Это уравнение описывает процессы релаксации. Произвольное начальное значение намагниченности будет релаксировать за время T_1 (которое носит название времени релаксации) к своему равновесному значению $n_z^{(eq)}$ по закону $n_z(t) = n_z^{(eq)} + \left(n_z(0)-n_z^{(eq)}\right)e^{-t/T_1}$. Отметим, что величина $n_z^{(eq)}$ совпадает со средней «намагниченностью», если система, описываемая гамильтонианом $\hat H_s$, будет находится в термодинамическом равновесии с температурой, которая совпадает с температурой бани T. Тем самым, за время T_1 происходит термализация - устанавливается равновесие.

Для термализации необходимо, чтобы происходили реальные процессы переворота спина - при этом система должна забирать из бани (или отдавать туда) энергию Δ. Поэтому тот факт, что скорость релаксации оказалась пропорциональна $J(\Delta)$ - не удивительно; ведь если в окружающей среде, скажем, осцилляторы с частотой Δ отсутствовали бы, то было бы невозможно диссипировать в неё квант энергии Δ (во всяком случае, в первом порядке теории возмущений). Y-компонента Аналогично, путём прямых вычислений мы получаем:

$$\frac{dn_y^{(2)}(t)}{dt} = -2\int\limits_0^\infty d\tau S_K(\tau)\left(n_y(t)\cos\Delta\tau + n_x(t)\sin\Delta\tau\right)$$

Первый член уже был сосчитан ранее, а вот второй отличается - он не сводится к преобразованию Фурье и для его вычисления требуется регуляризация $e^{-\epsilon\tau}$ - которая, после использования формулы Сохоцкого, говорит нам, что оставшийся интеграл по частоте нужно брать в смысле главного значения:

$$2\int\limits_0^\infty d\tau S_K(\tau)\sin\Delta\tau = 2\int(d\omega)\widetilde J(\omega)\coth\frac{\beta\omega}{2}\int\limits_0^\infty d\tau e^{-i\omega\tau}\sin\Delta\tau = -\text{ v.p. }\int\limits_0^\infty\frac{d\omega}{\pi}J(\omega)\coth\frac{\beta\omega}{2}\frac{2\Delta}{\omega^2-\Delta^2}$$

Окончательно, собирая всё вместе, уравнение на y-компоненту выглядит следующим образом:

$$\frac{dn_y}{dt} = (\Delta - 2\delta)n_x(t) - \frac{n_y(t)}{T_2/2}, \quad \frac{1}{T_2} = J(\Delta)\coth\frac{\beta\Delta}{2}, \quad \delta = \text{ v.p.} \int\limits_0^\infty \frac{d\omega}{\pi} J(\omega)\coth\frac{\beta\omega}{2}\frac{2\Delta}{\omega^2-\Delta^2}$$

Выбор двоек в этом уравнении мотивирован следующим соображением. Полученная система линейных дифференциальных уравнений описывается следующей матрицей:

$$\frac{d}{dt}\begin{pmatrix} n_x \\ n_y \end{pmatrix} = \begin{pmatrix} 0 & -\Delta \\ \Delta - 2\delta & 2/T_2 \end{pmatrix}\begin{pmatrix} n_x \\ n_y \end{pmatrix}$$

которая имеет собственные частоты $\omega_{1,2} \approx \pm(\Delta - \delta) - \frac{i}{T_2}$. Поэтому величина δ - это поправка к частоте Δ, а затухание всех решений происходит как e^{-t/T_2}.

Вклад δ носит название Лэмбовского сдвига [5], он отвечает за перенормировку частоты «прецессии» Δ, связанную со взаимодействием с окружающей средой. В контексте двухъямного потенциала, Δ имеет смысл туннельного матричного элемента; тот факт, что δ уменьшает эффективную величину [6]Δ, является демонстрацией того, как взаимодействие с окружающей средой подавляет туннелирование. Хотя уравнения были написаны в рамках теории возмущений, можно показать, что в данной модели имеется квантовый фазовый переход - при достаточно сильном взаимодействии со средой, туннелирование подавляется до нуля.

Наконец, член T_2 носит название дефазировки, он подавляет поперечную компоненту $n_{x,y}(t)$ так, что они начинают затухать как e^{-t/T_2}. На этом характерном времени затухают когерентные осцилляции Раби. Имеется наглядный способ представить себе дефазировку. Давайте рассмотрим ансамбль спинов, вращающихся когерентно (синфазно) вокруг оси z с одинаковой частотой Δ. Однако, из-за взаимодействия с «шумом», индуцированным окружающей средой, частота каждого из этих спинов чуть «дрожит», из-за чего каждый из них начинает вращаться с чуть изменённой частотой. Хотя на малых временах эта поправка будет незаметна, и динамика будет оставаться когерентной - однако спустя какое-то время спины окажутся совершенно случайным образом разбросаны в плоскости, и среднее значение проекции спина на плоскость xy выйдет на нулевое значение.

Подчеркнём, что физически члены T_1 и T_2 имеют совершенно разную природу, и отвечают за различные физические процессы (хотя в рамках тривиальной теории возмущений и получилось, что они отличаются в два раза - в реальной жизни они могут быть совершенно различными; в частности, в домашней задаче будет предложена модель с отсутствующей релаксацией, но с наличием дефазировки). Грубо говоря, время T_2 - это время, в течение которого в нашей квантомеханической системе ещё могут наблюдаться какие-либо когерентные квантовые эффекты, и после которого система ведёт себя в большой мере классически. Время T_1 же говорит нам, когда измеряемые значения наблюдаемых перестанут зависеть от времени (разумеется, усреднив по быстрым квантовым осцилляциям).

15.1.6 On the Spectral Density

Всю информацию о структуре окружающей среды мы «спрятали» в спектральную функцию $J(\omega)$. С другой стороны, мы пока ничего не говорили о том, как $J(\omega)$ устроена. Она зависит от констант связи и от плотности состояний в бане; как правило, последняя растёт как какая-то степень частоты; как следствие, типичное поведение - это $J(\omega) \propto \omega^s$. С другой стороны, как правило в окружающей среде нельзя найти моды со сколь угодно большими частотами - у функции $J(\omega)$ может иметься обрезка на какой-то достаточно

большой частоте [7]ω_c, выше которой $J(\omega)$ быстро спадает до нуля. Наличие такой обрезки может быть существенно для некоторых эффектов, которые происходят от ультрафиолетовых степеней свободы бани (к примеру, при исследовании Лэмбовского сдвига). По поведению скорости релаксации при $\Delta \to 0$, выделяют несколько случаев:

- Омическая баня: $s = 1, J(\omega) = \pi\alpha\omega\theta(\omega_c - \omega)$. При этом $\frac{1}{T_{1,2}} \to \text{const}$ при $\Delta \to 0$. Наиболее часто встречаемый и простой тип «бани».
- Суб-омическая баня: $s < 1, \frac{1}{T_{1,2}} \to \infty$ при $\Delta \to 0$.
- Супер-омическая баня: $s > 1, \frac{1}{T_{1,2}} \to 0$ при $\Delta \to 0$.

15.2 Suppression of Tunneling in a Two-Level System

15.2.1 Perturbative Consideration

Исследуем чуть более подробно роль Лэмбовского сдвига δ, полученного для спин-бозонной модели ранее. Напомним, его роль заключается в подавлении матричного элемента $\Delta_{\text{eff}} = \Delta - \delta$, отвечающего туннельной амплитуде или частоте когерентных осцилляций Раби для двухъямного потенциала. Для простоты, мы будем исследовать случай нуля температур $T = 0$, и омическую баню $J(\omega) = \pi\alpha\omega\theta(\omega_c - \omega)$, считая $\omega_c \gg \Delta$. Прямое вычисление (9.30) даёт:

$$\delta = \text{ v.p.} \int_0^{\omega_c} \frac{d\omega}{\pi} \cdot \pi\alpha\omega \cdot \frac{2\Delta}{\omega^2 - \Delta^2} \approx 2\alpha\Delta \ln \frac{\omega_c}{\Delta}$$

Мы получили логарифмический интеграл, который набирается на всех масштабах, начиная от Δ и заканчивая ультрафиолетовой обрезкой на больших частотах ω_c (в отличие от всех предыдущих членов, которые определялись резонансным поведением - осцилляторами с частотами $\omega \approx \Delta$). Это значит, что несмотря на малость величины α, сам ответ δ вполне может оказаться сравним с Δ !

В старших порядках теории возмущений, вообще говоря, могут возникать такие же большие члены $\left(\alpha \ln \frac{\omega_c}{\Delta}\right)^n$; и если логарифм достаточно большой, то, по-хорошему, такие члены нужно учитывать все. Систематический способ учёта логарифмических расходимостей в рамках теории возмущений вплоть до бесконечных порядков возможен, и составляет суть метода ренормгруппы. С ним вы ознакомитесь позже, а здесь мы ограничимся более простым и физически наглядным способом, который приводит к такому же результату.

15.2.2 Adiabatic Consideration

Итак, мы получили логарифмическую поправку, которая приходит из широкого диапазона частот. Подавляющий вклад дают «быстрые» степени свободы бани с частотами $\omega_c \gg \omega \gg \Delta$.К счастью, когда имеется разделение быстрых и медленных степеней свободы, на помощь приходит адиабатическое приближение, которым можно воспользоваться и в этой задаче.

С точки зрения быстрых осцилляторов, удобно работать в базисе собственных состояний оператора $\hat{\sigma}_x$, соответствующих «частице в левой яме» $|\leftarrow\rangle = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 \\ -1 \end{pmatrix}, \sigma_x = -1$ и «частице в правой яме» $|\rightarrow\rangle = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \sigma_x = +1($ в терминах двухъямного потенциала). Для анализа поведения системы, перепишем гамильтониан осцилляторов обратно в терминах операторов координаты $\hat{X} = \hat{a} + \hat{a}^\dagger$ и импульса $\hat{P} = \frac{\hat{a} - \hat{a}^\dagger}{2i}$, так что $[\hat{X}, \hat{P}] = i$: Итак, мы получили логарифмическую поправку,

которая приходит из широкого диапазона частот. Подавляющий вклад дают «быстрые» степени свободы бани с частотами $\omega_c \gg \omega \gg \Delta$. К счастью, когда имеется разделение быстрых и медленных степеней свободы, на помощь приходит адиабатическое приближение, которым можно воспользоваться и в этой задаче.

С точки зрения быстрых осцилляторов, удобно работать в базисе собственных состояний оператора $\hat{\sigma}_x$, соответствующих «частице в левой яме» $|\leftarrow\rangle = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 \\ -1 \end{pmatrix}, \sigma_x = -1$ и «частице в правой яме» $|\rightarrow\rangle = \frac{1}{\sqrt{2}}\begin{pmatrix} 1 \\ 1 \end{pmatrix}, \sigma_x = +1($ в терминах двухъямного потенциала). Для анализа поведения системы, перепишем гамильтониан осцилляторов обратно в терминах операторов координаты $\hat{X} = \hat{a} + \hat{a}^\dagger$ и импульса $\hat{P} = \frac{\hat{a}-\hat{a}^\dagger}{2i}$, так что $[\hat{X}, \hat{P}] = i$:

$$\hat{a}_n^\dagger \hat{a}_n = \left(\frac{\hat{X}_n}{2} - i\hat{P}_n\right)\left(\frac{\hat{X}_n}{2} + i\hat{P}_n\right) = \hat{P}_n^2 + \frac{1}{4}\hat{X}_n^2 + \text{ const}$$

В таком случае, с точки зрения «быстрых» осцилляторов, нахождение частицы в левой или правой яме соответствует попросту сдвижке центра осциллятора:

$$\hat{H}_n \simeq \omega_n\left(\hat{P}_n^2 + \frac{1}{4}\hat{X}_n^2 \mp \frac{\lambda_n}{\omega_n}\hat{X}_n\right) = \omega_n\left(\hat{P}_n^2 + \frac{1}{4}\left[\hat{X}_n \mp 2\frac{\lambda_n}{\omega_n}\right]^2\right) + \text{ const}$$

и основное состояние такого «сдвинутого» осциллятора устроено как $e^{\pm i\hat{P}_n \cdot 2\frac{\lambda_n}{\omega_n}}|0_n\rangle$ (применили оператор трансляции). Поскольку быстрые осцилляторы «подстраиваются» под движение медленной двухуровневой подсистемы, с точки зрения «быстрых» осцилляторов полная волновая функция системы при этом соответствует следующей:

$$|\leftarrow\rangle_{\text{tot}} = |\leftarrow\rangle \otimes \prod_{\omega_n \gg \Delta} e^{2i\frac{\lambda_n}{\omega_n}\hat{P}_n}|0_n\rangle\,, \quad |\rightarrow\rangle_{\text{tot}} = |\rightarrow\rangle \otimes \prod_{\omega_n \gg \Delta} e^{-2i\frac{\lambda_n}{\omega_n}\hat{P}_n}|0_n\rangle\,,$$

где тензорное произведение берётся по всем осцилляторам бани. Из-за смещения осцилляторов из «бани», меняется также и эффективный матричный элемент, определяющий динамику двухуровневой системы: $\Delta_{\text{eff}} \equiv 2\left\langle \leftarrow \left| \hat{H}_{\text{spin}} \right| \rightarrow \right\rangle = \Delta \cdot \prod_{\omega_n \gg \Delta}\left\langle e^{-4i\frac{\lambda_n}{\omega_n}\hat{P}_n}\right\rangle_n$. Последнее произведение несложно вычислить (включая усреднение по основному состоянию осциллятора [8]), и получить:

$$\Delta_{\text{eff}} = \Delta \cdot \exp\left(-2\sum_{\omega_n \gg \Delta}\frac{\lambda_n^2}{\omega_n^2}\right) = \Delta \cdot \exp\left(-\frac{2}{\pi}\int\limits_{\omega \gg \Delta} d\omega \frac{J(\omega)}{\omega^2}\right) \simeq \Delta \cdot \exp\left(-2\alpha \ln\frac{\omega_c}{\Delta}\right)$$

В первом приближении это выражение совпадает с пертурбативным результатом (в пределе малых α), однако в этом выводе мы не накладывали никаких ограничений на α. Кроме того, заметим, что в действительности нижняя обрезка полученного логарифмического интеграла выбиралась из условия адиабатичности; поскольку реальная динамика двухуровневой подсистемы определяется именно Δ_{eff} , а не Δ, то это выражение нужно исправить и взять в качестве нижней обрезки именно $\Delta_{\text{eff.}}$ Это позволяет записать следующее уравнение самосогласования:

$$\Delta_{\text{eff}} = \Delta\left(\frac{\Delta_{\text{eff}}}{\omega_c}\right)^{2\alpha} \Rightarrow \Delta_{\text{eff}} = \Delta \cdot \left(\frac{\Delta}{\omega_c}\right)^{\frac{2\alpha}{1-2\alpha}}$$

Мы получили замечательный непертурбативный результат: в данной системе имеется квантовый фазовый переход при $\alpha = \frac{1}{2}$. При $\alpha < \frac{1}{2}$, система ведёт себя как квантовая

двухуровневая система, в ней наблюдается туннелирование и осцилляции Раби (с перенормированной частотой Δ_{eff}). Однако при достаточно сильной связи с окружающей средой, а именно, при $\alpha > \frac{1}{2}$, единственное решение уравнений самосогласования - это $\Delta_{\text{eff}} = 0$. Это означает полное подавление квантового туннелирования; с точки зрения двухъямного потенциала, частица, «посаженная» в одну из ям, там и остаётся.

15.2.3 Caldeira–Leggett Model

На этом семинаре мы обсудим микроскопическую модель диссипативной квантовой механики одной частицы, предложенную Калдейрой и Леггеттом. Заметим, что каким-нибудь тривиальным образом включить трение в квантовую механику не получится - гамильтонов формализм требует сохранения энергии и фазового объема. Но оказывается, что диссипативная механика получается естественным образом в системе частица-баня, как эффективная теория для частицы, полученная исключением степеней свободы бани [9]. При этом неизбежно возникает и второй компонент эффективного описания - случайная сила, действующая на частицу, характеристики которой, как мы увидим ниже, жёстко связаны с диссипативной частью. Гамильтониан мы запишем в следующем виде:

$$\hat{H} = \underbrace{\frac{\hat{P}^2}{2M} + V(\hat{X})}_{\hat{H}_s} + \underbrace{\sum_n \left(\frac{\hat{p}_n^2}{2m_n} + \frac{m_n \omega_n^2 \hat{x}_n^2}{2} \right)}_{\hat{H}_e} + \underbrace{\sum_n \left(-c_n \hat{x}_n \hat{X} + \frac{c_n^2}{2m\omega_n^2} \hat{X}^2 \right)}_{\hat{V}}$$

Величины c_n играют роль констант связи с баней. Член $\propto \hat{X}^2$ был написан для того, чтобы взаимодействие с осцилляторами «собиралось» в виде полного квадрата:

$$\frac{m_n \omega_n^2 \hat{x}_n^2}{2} - c_n \hat{x}_n \hat{X} + \frac{c_n^2}{2m\omega_n^2} \hat{X}^2 \equiv \frac{1}{2} m_n \omega_n^2 \left(\hat{x}_n - \frac{c_n}{m\omega_n^2} \hat{X} \right)^2$$

Такой гамильтониан «уважает» трансляционную инвариантность в случае отсутствия потенциала $V(X) = 0$ (сдвижка $X \mapsto X + a$, сопровождаемая сдвижкой $\hat{x}_n \mapsto \hat{x}_n + \frac{c_n}{m\omega_n^2} a$, оставляет гамильтониан инвариантным) - и поэтому, когда осцилляторы находятся в равновесии, средняя сила, действующая со стороны бани, равна нулю. Отклонение же любого из осцилляторов из положения равновесия вызывает дополнительную силу, действующую на исходную частицу.

Приближение Борна Маркова

Сперва обсудим, как можно было бы, по аналогии со спин-бозонной моделью, попробовать вывести кинетическое уравнение на матрицу плотности частицы, в приближении слабой связи. В предыдущей задаче мы могли выписать явно выписать невозмущённую динамику как системы, так и бани, что позволило нам обсудить поведение системы, когда характерные частоты бани и внутренней динамики системы одного порядка. Полностью аналогичное вычисление можно проделать для простых случаев, допускающих точное решение — к примеру, свободной частицы, осциллятора, линейного потенциала. Без указания явного вида потенциала, его проделать невозможно — мы попросту не сможем выписать представление взаимодействия для невозмущённой системы. Тем не менее,

Операторный формализм

мы можем это сделать в квазиклассическом пределе, когда динамика бани гораздо быстрее динамики системы - в таком случае достаточпо использовать прсдставлспис

взаимодсйствис только для бапи. УравIспии па матрицу плотпости в таком случае запишется в следующем виде:

$$\frac{d\hat{\rho}}{dt} = i\left[\hat{\rho}(t), \hat{H}_s\right] + i[\hat{\rho}(t), \hat{V}(t)], \quad \hat{V}(t) = \hat{\Phi}(t)\hat{X}, \quad \hat{\Phi}(t) = \sum_n c_n \hat{x}_n(t)$$

Дальнейший вывод производится так же - мы интегрируем это уравнение по отрезку $[t_0, t]$; дополнительное различие заключается в том, что мы подставляем полученное выражение для $\hat{\rho}(t)$ только во второе слагаемое. Наконец, беря след по степеням свободы бани, и используя тот факт, что корреляционные функции $\hat{\Phi}(t)$ локальны во времени, мы получаем кинетическое уравнение в несколько ином виде:

$$\frac{d\hat{\rho}_s}{dt} = i\left[\hat{\rho}_s(t), \hat{H}_s\right] - \int_0^\infty d\tau \,\mathrm{Tr}_e\left(\left[\left[\hat{\rho}_s(t)\hat{\rho}_e, \hat{V}(t-\tau)\right], \hat{V}(t)\right]\right)$$

Подчеркнём различие с предыдущим случаем - и сделанное дополнительное приближение. Тут имеется член, отвечающий динамике с $\hat{H}_s$, поскольку мы не производили переход в представление взаимодействия с $\hat{H}_s$; и в связи с этим, выражение для $\hat{V}(t)$ не содержит временную зависимость оператора координаты $\hat{X}$. Физически это отвечает квазиклассическому пределу - предположению о медленной динамике системы по сравнению с баней. Дальнейшее рассмотрение этого уравнение предлагается проделать в качестве домашнего упражнения.

Вместо этого мы будем исследовать операторные уравнения движения для частицы и осцилляторов - уравнения Гейзенберга. В действительности удобно писать уравнения на смещения $\hat{y}_n \equiv \hat{x}_n - \frac{c_n}{m\omega_n^2}\hat{X}$. Они имеют следующий вид:

$$\begin{cases} d\hat{X}/dt = \hat{P}/M \\ d\hat{P}/dt = -\partial V/\partial X + \sum_n c_n \hat{y}_n \end{cases}, \quad \begin{cases} d\hat{y}_n/dt = \hat{p}_n/m_n - \frac{c_n}{m\omega_n^2}\frac{d\hat{X}}{dt} \\ d\hat{p}_n/dt = -m_n\omega_n^2 \hat{y}_n \end{cases}$$

или, исключая импульсы:

$$M\frac{d^2\hat{X}}{dt^2} + \frac{\partial V}{\partial X} - \sum_n c_n \hat{y}_n = 0, \quad \frac{d^2\hat{y}_n}{dt^2} + \omega_n^2 \hat{y}_n = -\frac{c_n}{m\omega_n^2}\frac{d^2\hat{X}}{dt^2}$$

Наша задача - исключить степени свободы бани (осцилляторы) - и получить уравнения, описывающие движение только частицы. Это делается более или менее прямолинейно - уравнения движения среды линейны, и их можно решить с использованием классической функции Грина простого гармонического осциллятора $G_n(t) = \sin\omega_n t/\omega_n$, и используя интегрирование по частям:

$$\hat{y}_n(t) = \hat{y}_n(0)\dot{G}_n(t) + \left(\frac{\hat{p}_n(0)}{m_n} - \frac{c_n}{m\omega_n^2}\frac{d\hat{X}(0)}{dt}\right)G_n(t) - \frac{c_n}{m\omega_n^2}\int_0^t G_n(t-\tau)\frac{d^2\hat{X}(\tau)}{d\tau^2}d\tau$$

$$= \hat{y}_n(0)\dot{G}_n(t) + \frac{\hat{p}_n(0)}{m_n}G_n(t) - \frac{c_n}{m\omega_n^2}\int_0^t \dot{G}_n(t-\tau)\frac{d\hat{X}(\tau)}{d\tau}d\tau$$

Подставляя и группируя члены, мы можем записать уравнение на координату частицы в следующем виде:

$$M\frac{d^2\hat{X}}{dt^2} + \int_0^t \gamma(t-\tau)\frac{d\hat{X}(\tau)}{d\tau}d\tau + \frac{\partial V}{\partial X} = \hat{\zeta}(t), \quad \gamma(t) = \sum_n \frac{c_n^2}{m\omega_n^2}\dot{G}_n(t), \quad \hat{\zeta}(t) = \sum_n c_n\left(\hat{y}_n(0)\dot{G}_n(t) + \frac{\hat{p}_n(0)}{m_n}G_n\right.$$

Величина $\hat{\zeta}(t)$ выглядит как эффективная дополнительная сила, действующая на частицу и определяемая степенями свободы бани - в классической механике такого рода силы называют Ланжевеновскими. Член, зависящий от первой производной, несёт чисто диссипативный характер - он устроен как вязкое трение и приводит к несохранению энергии. Его нелокальность во времени отвечает «памяти» среды.

15.2.4 Spectral Weight and Ohmic Bath (???)

Как и ранее, всю информацию о степенях свободы бани, и о константах связи бани с частицей, можно «закодировать» в спектральной функции:

$$J(\omega) = \pi \sum_n \frac{c_n^2}{2m\omega_n} \delta(\omega - \omega_n) \Rightarrow \gamma(t) = \frac{2}{\pi} \int_0^\infty \frac{d\omega}{\omega} J(\omega) \cos \omega t$$

Другой важной характеристикой является корреляционная функция ланжевеновских сил [10], вычислить которую мы можем используя равновесные значения для осцилляторов

$$\left\langle \hat{y}_n^2 \right\rangle = \frac{1}{2m_n\omega_n} \coth \frac{\beta\omega_n}{2}, \quad \left\langle \hat{p}_n^2 \right\rangle = \frac{m_n\omega_n}{2} \coth \frac{\beta\omega_n}{2},$$

$$\left\langle \hat{\zeta}(t)\hat{\zeta}(t') \right\rangle = \sum_n \frac{c_n^2}{m\omega_n} \frac{1}{2} \coth \frac{\beta\omega}{2} \cos \omega (t - t') = \frac{1}{\pi} \int_0^\infty d\omega J(\omega) \coth \frac{\beta\omega}{2} \cos \omega (t - t')$$

Рассмотрим теперь случай омической бани $J(\omega) = \eta\omega$. Тогда:

$$\gamma(t) = \frac{2\eta}{\pi} \int_0^\infty d\omega \cos \omega t = 2\eta\delta(t)$$

Стоит быть аккуратным, поскольку в интеральном члене дельта-функция попадает ровно на границу области интегрирования, поэтому интеграл требует дополнительной регуляризации. В данном случае мы понимаем, что при внесении любой ультрафиолетовой обрезки для $J(\omega)$, функция $\gamma(t)$ останется чётной функцией времени. Поскольку она будет также являться узким пиком как функции времени, ровно половина этого пика войдёт в интеграл; это соответствует регуляризации типа $\int_0^t \delta(t-\tau)d\tau = \frac{1}{2}$:

$$M\frac{d^2\hat{X}}{dt^2} + \eta\frac{d\hat{X}}{dt} + \frac{\partial V}{\partial X} = \hat{\zeta}(t)$$

Кроме того, в высокотемпературном пределе $\coth \frac{\beta\omega}{2} \approx \frac{2T}{\omega}$, и это выражение прямо пропорционально «диссипативному ядру» и температуре: $\left\langle \hat{\zeta}(t)\hat{\zeta}(t') \right\rangle \approx T\gamma(t - t')$. В общем случае несложно видеть, что их Фурье-гармоники связаны друг с другом, что выражает собой флуктуационно-диссипационную теорему (ФДТ).

Данное уравнение является главным результатом семинара. Мы рассмотрели микроскопическую модель квантовомеханической диссипативной системы, и получили операторное уравнение, описывающее динамику частицы. От «бани» пришли две важных части - диссипация, или трение, и флуктуирующая возмущающая коротко коррелированная сила $\hat{\zeta}(t)$, коррелятор которой специальным образом связан с трением.

О случаях применения (!??!?)

(оставшийся вопрос)

Именно эти модели дают подготовку к кинетике

(проверю, чтобы там именно этот раздел и использовался. пока что связка слабая, потому что не писал этот раздел.)

ПТФ-7.з1. Поляризуемость частицы на кольце

Частица с массой M и зарядом e движется на кольце радиуса R. К системе прикладывается слабое электрическое поле $\mathcal{E}$ параллельно плоскости кольца. Определите поляризуемости $\alpha_n = -\frac{\partial^2 E_n}{\partial \mathcal{E}^2}$ всех уровней энергии.
Проведите вычисления, используя два различных базиса:
- Базис состояний с фиксированным угловым моментом m («волны де-Бройля»)
- Базис состояний с фиксированной чётностью

Указание: обратите внимание, что поскольку в задаче с приложенным электрическим полем чётность по-прежнему сохраняется, то для вычисления второго пункта применять вырожденную теорию возмущений нет необходимости.

Solution. в базисе состояний с фиксированным угловым моментом

$$\hat{p}^2 = -\hbar^2\Delta = -\frac{\hbar^2}{r^2}\frac{\partial^2}{\partial\varphi^2}$$

$$\hat{H}_0\psi = E_m^{(0)}\psi$$

$$-\frac{\hbar^2}{2M}\Delta\psi = E_m^{(0)}\psi \qquad \Rightarrow \qquad \psi_m(\varphi) = \frac{e^{im\varphi}}{\sqrt{2\pi}}; \qquad m \in \mathbb{Z}.$$

$\int_0^{2\pi} \psi_m^*\psi_{m'}d\varphi = \delta(m-m')$

$$E_m^{(0)} = \frac{m^2}{2MR^2}$$

Как видно, кратность вырождения энергии равна 2 (состояниям m и $-m$ соответствует энергия E_m).

$$\hat{H} = \hat{H}_0 + \hat{V} = -\frac{\hbar^2}{2MR^2}\frac{\partial^2}{\partial\varphi^2} - e\mathcal{E}R\cos\varphi$$

$$V_{\alpha\beta} \equiv \langle n_\alpha^{(0)}|\hat{V}|n_\beta^{(0)}\rangle = -e\mathcal{E}R\int_0^{2\pi}\cos\varphi e^{i(\beta-\alpha)\varphi}d\varphi = -\frac{1}{2}e\mathcal{E}R(\delta_{\beta-\alpha,1}+\delta_{\beta-\alpha,-1})$$

(since only $\int\cos^2(x) \neq 0$). $V_{\alpha\alpha} = 0$, и вырождение не снято, поэтому нужно рассматривать 2 порядок.
$\hat{H}^{(\text{eff})}_{\alpha\beta} = \sum\limits_{m\neq n}\frac{V_{\alpha m}V_{m\beta}}{\omega_{mn}}$, $\omega_{mn} = E_m^{(0)} - E_n^{(0)} = \frac{m^2-n^2}{2MR^2}$.

$$\hat{H}^{(\text{eff},n)}_{\alpha\beta} = e^2\mathcal{E}^2MR^4\begin{pmatrix} \frac{1}{4n^2-1} & \frac{\delta_{n,1}}{2} \\ \frac{\delta_{n,1}}{2} & \frac{1}{4n^2-1}\end{pmatrix}$$

$\det(\hat{H}^{(\text{eff})}_{\alpha\beta} - E_n^{(2)}) = 0 \qquad \Rightarrow$

$$E_1^{(2)} = -\frac{e^2\mathcal{E}^2MR^4}{6}, \qquad E_1^{(2)} = \frac{5e^2\mathcal{E}^2MR^4}{6}, \qquad E_n^{(2)} = \frac{e^2\mathcal{E}^2MR^4}{4n^2-1}$$

$$\alpha_{1(1)} = +\frac{e^2MR^4}{3}, \qquad \alpha_{1(2)} = -\frac{5e^2MR^4}{3}, \qquad \alpha_n = -\frac{2e^2MR^4}{4n^2-1}.$$

For $n = 0$ there is no degeneracy, so

$$V_{00} = 0$$
$$E_0^{(2)} = \sum_{m\neq 0} \frac{|V_{0n}|^2}{\omega_{0m}}$$
$$E_0^{(2)} = -e^2\mathcal{E}^2 MR^4$$
$$\alpha_0 = 2e^2 MR^4$$

Solution. в базисе состояний с фиксированной чётностью.

$$\psi_m^{(+)} = \frac{1}{\sqrt{\pi}}\cos(m\varphi), \qquad \psi_m^{(-)} = \frac{1}{\sqrt{\pi}}\sin(m\varphi)$$

$$V_{\alpha+,\beta+} = \frac{e\mathcal{E}R}{\varphi}\int_0^{2\pi}\cos(\varphi\alpha)\cos(\varphi\beta)\cos\varphi d\varphi = \frac{e\mathcal{E}R}{2}\left(\delta_{\alpha-\beta,1} + \delta_{\beta-\alpha,1} + \delta_{n+m,1}\right)$$

$$V_{\alpha-,\beta-} = \frac{e\mathcal{E}R}{\pi}\int_0^{2\pi}\sin(\varphi\alpha)\sin(\varphi\cdot\beta)\cos\varphi d\phi = \frac{e\mathcal{E}R}{2}\left(\delta_{\alpha-\beta,1} + \delta_{\alpha-\beta,1} - \delta_{\alpha+\beta,1}\right)$$

$$V_{\alpha-,\beta+} = \frac{e\mathcal{E}R}{\pi}\int_0^{2\pi}\sin(\varphi\alpha)\cos(\varphi\beta)\cos\varphi d\phi = 0 = V_{\alpha+,\beta-}$$

$$\hat{H}^{(\text{eff})}_{\alpha\beta} = \frac{e^2\mathcal{E}^2 MR^4}{\hbar^2}\begin{pmatrix} \frac{\delta_{n,1}}{2} + \frac{1}{4n^2-1} & 0 \\ 0 & -\frac{\delta_{n,1}}{2} + \frac{1}{4n^2-1}\end{pmatrix}$$

$\det(\hat{H}^{(\text{eff})}_{\alpha\beta} - E_n^{(2)}) = 0 \qquad \Rightarrow \qquad$ same answer.

В случае $n = 0$:

$$V_{0\beta,+} = \frac{e\mathcal{E}R}{\sqrt{2}}\delta_{n,1}, V_{0\beta,-} \equiv 0$$

Поправка к энергии получается такой же.

ПТФ-7.з2. Двуслойный графен

В силу решёточной структуры графена, волновая функция электронов представляет собой двухкомпонентный псевдоспинор $\psi(x) = (\psi_A(x), \psi_B(x))^T$, где различные компоненты отвечают различным подрешёткам. Возбуждения вблизи так называемой K-долины зоны Бриллюэна описываются эффективным гамильтонианом размера 2×2, который записывается следующим образом:

$$\hat{H} = v_F\hat{\vec{\sigma}}\cdot\hat{\vec{p}} = v_F(\hat{\sigma}_x\hat{p}_x + \hat{\sigma}_y\hat{p}_y) = v_F\begin{pmatrix} 0 & \hat{p}_x - i\hat{p}_y \\ \hat{p}_x + i\hat{p}_y & 0\end{pmatrix}$$

Для двуслойного графена, соответственно, волновая функция уже образует четырёхкомпонентный спинор

$$\psi(x) = (\psi_A^{(1)}(x), \psi_B^{(1)}(x), \psi_A^{(2)}(x), \psi_B^{(2)}(x))$$

Если бы между не было никакого взаимодействия, то гамильтониан системы имеет просто блочно-диагональный вид $\hat{H} = v_F\begin{pmatrix}\hat{\vec{\sigma}}\cdot\hat{\vec{p}} & 0 \\ 0 & \hat{\vec{\sigma}}\cdot\hat{\vec{p}}\end{pmatrix}$; однако, если два листа графена положить друг на друга определённым образом, то возникает возможность туннелирования электронов между слоями. Гамильтониан такой системы имеет вид:

$$\hat{H} = \begin{pmatrix} 0 & v_F(\hat{p}_x - i\hat{p}_y) & 0 & 0 \\ v_F(\hat{p}_x + i\hat{p}_y) & 0 & \Delta & 0 \\ 0 & \Delta & 0 & v_F(\hat{p}_x - i\hat{p}_y) \\ 0 & 0 & v_F(\hat{p}_x + i\hat{p}_y) & 0\end{pmatrix}$$

При нулевом импульсе p, матрица имеет двукратно вырожденное собственное число 0 и однократно вырожденные числа $\pm\Delta$. Если мы исследуем свойства возбуждений при маленькой энергии $|E| \ll \Delta$ и, соответственно, малом импульсе $p \ll \frac{\Delta}{v_F}$, то высокоэнергетические состояния $\pm\Delta$ несущественны.

Используя теорию возмущений, выведите эффективный гамильтониан, описывающий низкоэнергетические возбуждения, и определите спектр соответствующих двух зон.

Solution.

Пусть $a = v_F(\hat{p}_x - i\hat{p}_y)$.

$$w_{11} = w_{14} = 0, \quad w_{12} = \Delta, \quad w_{13} = -\Delta$$

1 порядок не убирает вырождение по энергии.
(???)

$$\hat{V} = v_F \begin{pmatrix} \hat{\vec{\sigma}} \cdot \hat{\vec{p}} & 0 \\ 0 & \hat{\vec{\sigma}} \cdot \hat{\vec{p}} \end{pmatrix}$$

$$H_{11}^{(1)} = \frac{V_{12}V_{21}}{\omega_{12}} + \frac{V_{13}V_{31}}{\omega_{13}} = -\frac{aa^\dagger}{\Delta}, \quad H_{14}^{(1)} = \frac{V_{12}V_{24}}{\omega_{12}} + \frac{V_{13}V_{34}}{\omega_{13}} = 0$$

$$H_{41}^{(1)} = \frac{V_{42}V_{21}}{\omega_{12}} + \frac{V_{13}V_{31}}{\omega_{13}} = 0, \quad H_{44}^{(1)} = \frac{V_{42}V_{24}}{\omega_{12}} + \frac{V_{43}V_{34}}{\omega_{13}} = \frac{aa^\dagger}{\Delta}$$

$$\hat{H}^{\text{eff}} = \frac{v_F^2 p^2}{\Delta} \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}$$

$$\det(\hat{H}^{\text{eff}} - E_0^{(2)}) = 0 \to E_0^{(2)} = \pm \frac{p^2}{\Delta} v_F^2$$

Feigelman.EntrExam.th-2/8 2D particle in magnetic field

Charged particle those free Hamiltonian is $H = v\,(\sigma_x p_x + \sigma_y p_y)$ (where $\sigma_{x,y}$ are Pauli matrices) is moving in a magnetic field $\mathbf{B} = (0, 0, B)$. Find all eigenvalues and their degeneracies.

Solution

(???)

ПТФ-7.з3. Поляризуемость атома водорода

Атом водорода находится в основном состоянии, $\psi_{100}(r) = \frac{e^{-r/a}}{\sqrt{\pi a^3}}$, $a := \frac{\hbar^2}{me^2}$. Он помещается в постоянное электрическое поле, описываемое гамильтонианом $\hat{V} = -e\mathcal{E}\hat{z}$; требуется определить сдвиг уровня энергии и поляризуемость основного состояния.

Для расчёта сдвига энергии во втором порядке теории возмущений, вообще говоря, необходимо вычислять все матричные элементы $\langle 1,0,0|\hat{z}|n,l,m\rangle$, а кроме них ещё и матричные элементы $\langle 1,0,0|\hat{z}|k,l,m\rangle$ (k определяет энергию $\frac{\hbar^2 k^2}{2m} = E$) для состояний непрерывного спектра, а затем вычислять соответствующую сумму и интеграл. Это сложная задача; но, к счастью, тут можно поступить иначе. Для этого первую поправку по теории возмущений к волновой функции предлагается найти *точно*, а не искать её в виде разложения.

• Напишите точное уравнение для поправки первого порядка $\psi^{(1)}(r)$ по теории возмущений. Покажите, что в нём можно разделить переменные, сделав анзац $\psi^{(1)}(r,\theta) = f(r)e^{-r/a}\cos\theta$; напишите уравнение на функцию $f(r)$.
Hint: обезразмерьте это уравнение!

• Покажите, что это уравнение имеет простое полиномиальное решение $f(r) = A + Br + Cr^2$; найдите A, B, C.

• Найдя волновую функцию, вычислите поправку $E_{100}^{(2)}$ и поляризуемость α.

Замечание: альтернативный способ решения задачи об атоме водорода в постоянном электрическом поле — это использование параболических координат. Эти координаты замечательны в частности тем, что в них разделяются переменные и в электрическом поле; а кроме этого, лишь небольшое количество матричных элементов оператора $\hat{z}$ отлично от нуля. Именно благодаря этому обстоятельству поправка первого порядка и имеет такой простой вид.

Solution.

$$\hat{H}_0 = \frac{\hat{p}^2}{2m} - \frac{e^2}{r}; \qquad \psi^{(0)}(r) = \frac{e^{-r/a}}{\sqrt{\pi a^3}}, \quad E^{(0)} = -\frac{e^2}{2a}; \qquad \hat{V} = -e\mathcal{E}\hat{z}$$

$$\psi = \psi^{(0)}(r) + \psi^{(1)}(r,\theta)$$

$$(\hat{H}_0 + \hat{V})(\psi^{(0)}(r) + \psi^{(1)}(r,\theta)) = (E^{(0)} + E^{(1)})(\psi^{(0)}(r) + \psi^{(1)}(r,\theta))$$

$$z = r\cos\theta$$

$$\hat{H}_0\psi^{(1)} + \hat{V}\psi^{(0)} = E^{(0)}\psi^{(1)}$$

$$-\frac{ae^2}{2}\left(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r} + \frac{1}{r^2}\frac{\partial^2}{\partial\theta^2} + \frac{1}{r^2}\operatorname{ctg}\theta\frac{\partial}{\partial\theta}\right)\psi^{(1)}(r,\theta) - \frac{e^2}{r}\psi^{(1)}(r,\theta) - \frac{e\mathcal{E}e^{-\frac{r}{a}}}{\sqrt{\pi a^3}}r\cos\theta = -\frac{e^2}{2a}\psi^{(1)}(r,\theta)$$

$$\psi^{(1)}(r,\theta) = f(r)e^{-r/a}\cos\theta$$

$$\frac{af''(r)}{2} + \frac{(a-r)f'(r)}{r} + \frac{r^2 - 2ar - 2a^2}{2ar^2}f(r) + \frac{f(r)}{r} + \frac{\mathcal{E}r}{e\sqrt{\pi a^3}} = \frac{f(r)}{2a}$$

$$\frac{af''(r)}{2} + \frac{(a-r)f'(r)}{r} - \frac{af(r)}{r^2} + \frac{\mathcal{E}r}{e\sqrt{\pi a^3}} = 0$$

$x := \frac{r}{a}$,

$$f''(x) + \frac{2(1-x)f'(x)}{x} - \frac{2f(x)}{x^2} + 2\sqrt{\frac{a}{\pi}}\frac{\mathcal{E}x}{e} = 0$$

$$f(x) \equiv A + Bx + Cx^2$$

$$C + \frac{(1-x)(B+2Cx)}{x} - \frac{A + Bx + Cx^2}{x^2} + \sqrt{\frac{a}{\pi}}\frac{\mathcal{E}x}{e} = 0$$

$$2C - B - 2Cx - \frac{A}{x^2} + \sqrt{\frac{a}{\pi}}\frac{\mathcal{E}x}{e} = 0$$

$$\begin{cases} A = 0, \\ 2C - B = 0. \\ C = \sqrt{\frac{a}{\pi}}\frac{\mathcal{E}}{2e} \end{cases}$$

$$A = 0, \quad B = \sqrt{\frac{a}{\pi}}\frac{\mathcal{E}}{e}, \quad C = \sqrt{\frac{a}{\pi}}\frac{\mathcal{E}}{2e}$$

$$f(x) = A + Bx + Cx^2 = \sqrt{\frac{a}{\pi}}\frac{\mathcal{E}x}{e}\left(1 + \frac{x}{2}\right)$$

$$\psi^{(1)}(r,\theta) = f(r)e^{-r/a}\cos\theta = \frac{\mathcal{E}r}{e\sqrt{\pi a}}\left(1 + \frac{r}{2a}\right)e^{-r/a}\cos\theta$$

2 порядок теории возмущений:

$$(\hat{H}_0 + \hat{V})(\psi^{(0)}(r) + \psi^{(1)}(r,\theta) + \psi^{(2)}(r,\theta)) = (E^{(0)} + E^{(2)})(\psi^{(0)}(r) + \psi^{(1)}(r,\theta) + \psi^{(2)}(r,\theta))$$

$$\hat{H}_0\psi^{(2)}(r,\theta) + \hat{V}\psi^{(1)}(r,\theta) = E^{(0)}\psi^{(2)}(r) + E^{(2)}\psi^{(0)}(r)$$

$$E^{(2)} = \langle\psi^{(0)}(r)|\hat{V}|\psi^{(1)}(r,\theta)\rangle = \int\limits_{-\pi}^{\pi} d\varphi \int\limits_{1}^{-1} d\cos\theta \int\limits_{0}^{\infty} dr r^2 \frac{e^{-r/a}}{\sqrt{\pi a^3}}(-e\mathcal{E}r\cos\theta)\frac{\mathcal{E}r}{e\sqrt{\pi a}}\left(1 + \frac{r}{2a}\right)e^{-r/a}\cos\theta = -\frac{9}{4}a^3\mathcal{E}^2$$

$$E^{(2)} = -\frac{9}{4}a^3\mathcal{E}^2$$

$$\chi = -\frac{\partial^2 E^{(2)}}{\partial\mathcal{E}^2} = \frac{9a^3}{2}$$

Solution. еще одно, давнее

как энергии -поскольку $\frac{\partial E_0}{\partial \varepsilon} = \langle \frac{\partial \hat{V}}{\partial \mathcal{E}} \rangle = -\langle \hat{d}(\mathcal{E}) \rangle = -\chi \mathcal{E} \to \delta E_0 = -\frac{1}{2}\chi \mathcal{E}^2$. Именно второй поправкой к уровню энергии мы и займёмся.

Для конкретности, мы будем исследовать поляризуемость основного состояния в одномерной мелкой яме $\hat{H}_0 = \hat{p}^2/(2m) - (\kappa/m)\cdot\delta(x)$, в которой параметр κ связан с энергией связанного состояния в этой яме как $E_0 = \kappa^2/(2m)$ и в таком случае, оператор дипольного момента - это просто $\hat{d} = -e\hat{x}$.

Волновая функция связанного состояния мелкой ямы $\langle x|\psi_0\rangle = \sqrt{\kappa}e^{-\kappa|x|}$ является чётной; возмущение же -нечётное.

Поэтому первый порядок теории возмущений $E_0^{(1)} = \langle\psi_0|\hat{V}|\psi_0\rangle \equiv 0$ - что неудивительно (если сдвиг энергии линеен но полю, то это означает, что исходно система обладает дипольным моментом $\frac{\partial E_0}{\partial \varepsilon} = d = \text{const}$).

Волновые функции непрерывного спектра также удобно классифицировать по чётности - имеются чётные функции $\psi_k^{(+)}$ и нечётные функции $\psi_k^{(-)}$

$$\langle x|\psi_k^{(-)}\rangle = \sin kx, \quad \langle x|\psi_k^{(+)}\rangle = \cos\left(k|x| + \varphi_k\right), \quad E_k = \frac{k^2}{2m}$$

Такой вид волновых функций обусловлен следующим соображением.

Нечётная функция в нуле обращается в ноль, из-за чего она эффективно не чувствуется дельта-яму - поэтому волновая функция нечётного состояния совпадает с волновой функцией свободного движения.

Чётная же функция обязана испытывать излом шри $x = 0$, что обуславливает наличие фазового сдвига φ_k, как-то зависящего от параметров задачи.

Явный вид фазового сдвига, тем не менее, нам не нужен - ведь, опять-таки, из соображений чётности, виртуальные переходы будут только в нечётные состояния непрерывного спектра (только для них матричный элемент возмущения V_{0k} отличен от нуля).

Поправка второго порядка тогда имеет виу:

$$E_0^{(2)} = \int d\nu_k \frac{|V_{k0}|^2}{E_0^{(0)} - E_k^{(0)}}$$

Плотность состояний непрерывного спектра $d\nu_k$ находится из нормировки волновых функций - несложно убедиться, что $\langle\psi_{k'}^{(+)}|\psi_k^{(+)}\rangle = \pi\delta\left(k - k'\right)$, поэтому $d\nu_k = \frac{dk}{\pi}$.

Величины V_{k0} вычисляются по определению:

$$V_{k0} = \int\limits_{-\infty}^{\infty} dx \sin kx \cdot e\mathcal{E}x \cdot \sqrt{\kappa}e^{-\kappa|x|} = -2e\mathcal{E}\sqrt{\kappa}\partial_k \operatorname{Re}\int\limits_0^{\infty} dx e^{ikx-\kappa x} = 4e\mathcal{E}\frac{k\kappa^{3/2}}{\left(\kappa^2+k^2\right)^2}$$

Теперь посчитаем $E_0^{(2)}$, Подставим $k = \kappa x$, получаем:

$$E_0^{(2)} = -\frac{8me^2\mathcal{E}^2}{\pi\kappa^4}\int\limits_0^{\infty}\frac{x^2dx}{\left(1+x^2\right)^5} = -\frac{5}{32}\frac{e^2\mathcal{E}^2}{mE_0^2}$$

и в итоге:

$$\chi = -\frac{\partial^2 E_0}{\partial\mathcal{E}^2} = \frac{5}{16}\frac{e^2}{mE_0^2}$$

ПТФ-7.з4. Суперсимметричная квантовая механика

Рассмотрите гармонический осциллятор для частицы массы $m = 1$ с частотой $\omega = 1$, гамильтониан которого имеет вид $\hat{H} = \frac{1}{2}(\hat{p}^2 + \hat{x}^2 - 1)$, и основное состояние имеет нулевую энергию $E_0 = 0$. Помимо этого, имеется ангармонизм *очень* специального вида $V(x) = gx(1-x^2) + \frac{1}{2}g^2x^4$; безразмерный параметр $g \ll 1$. Требуется исследовать сдвиг энергии основного состояния с точки зрения теории возмущений.

• Найдите поправку $O(g^2)$ к энергии основного состояния осциллятора.

• Полученный ответ должен вас натолкнуть на мысль, что нужно считать старшие порядки ТВ (если нет, то перепроверьте). Удобнее всего это делать в координатном базисе, выписывая явно дифференциальные уравнения на поправки к волновым функциям. Выпишите такое уравнение на поправки $O(g)$ и $O(g^2)$, и решите их явно.

• Проделайте это в *произвольном* порядке теории возмущений, выпишите явно поправку произвольного порядка к волновой функции $\psi_0^{(n)}(x)$ и $E_0^{(n)}$. Просуммируйте весь ряд теории возмущений, и убедитесь, что вы, в действительности, нашли *точное решение* соответствующего

уравнения Шрёдингера. Расстройтесь, потому что это решение никак не позволяет ответить на вопрос, каков же в действительности сдвиг энергии основного состояния δE_0.

• Очевидно, что поправка к энергии основного состояния всё-таки имеется – но она *непертурбативна*, для неё невозможно построить асимптотический ряд по степеням малого параметра g. Не смотря на это, теорией возмущений всё-таки можно пользоваться для приближения основного состояния, просто использовать для этого *полный ряд* теории возмущений незаконно. Используя критерии применимости теории возмущений, определите максимальный порядок n^*, до которого результату ещё можно верить.

• Погрешность асимптотического ряда для волновой функции – то есть отличие истинной волновой функции от вычисленной при помощи ряда теории возмущений – может быть оценена как член ряда теории возмущений с порядковым номером n^*. Оцените с экспоненциальной точностью квадрат нормы $\langle\delta\psi|\delta\psi\rangle$ этой погрешности; это даст также и оценку отличия энергии основного состояния от нуля.

Указание: хотя возмущение и содержит линейный член по x, с точки зрения вычислений оказывается удобно не сдвигать центр осциллятора.

Solution.

• Обозначим возмущения $V_1 = gx(1-x^2)$, $V_2(x) = \frac{g^2x^4}{2}$. Основное состояние осциллятора: $\psi^{(0)}(x) = \frac{e^{-\frac{x^2}{2}}}{\sqrt[4]{\pi}}$.

Рассмотрим 1 порядок теории возмущений:

$$(\hat{H}+\hat{V}_1)(|\psi^{(0)}\rangle + |\psi^{(1)}\rangle) = (E^{(0)}+E^{(1)})(|\psi^{(0)}\rangle + |\psi^{(1)}\rangle)$$

Поскольку $E^{(0)} = E_0 = 0$, то $\hat{H}|\psi^{(0)}\rangle = 0$ и

$$\hat{V}_1|\psi^{(0)}\rangle + \hat{H}|\psi^{(1)}\rangle = E^{(1)}|\psi^{(0)}\rangle$$

Домножив скалярно на $\langle\psi^{(0)}|$, получим

$$\langle\psi^{(0)}|\hat{V}_1|\psi^{(0)}\rangle + \langle\psi^{(0)}|\hat{H}|\psi^{(1)}\rangle = \langle\psi^{(0)}|E^{(1)}|\psi^{(0)}\rangle$$

$$E^{(1)} = \langle\psi^{(0)}|\hat{V}_1|\psi^{(0)}\rangle$$

Из нечётности $\hat{V}_1$ получим

$$E^{(1)} = 0$$

Полученный ответ наталкивает на мысль перейти ко 2 пункту.

• 1 порядок теории возмущений:

$$\hat{H}\psi^{(1)} + \hat{V}^{(1)}\psi^{(0)} = 0$$

$$\frac{1}{2}\left(-\frac{\partial^2}{\partial x^2} + x^2 - 1\right)\psi^{(1)}(x) + gx(1-x^2)\frac{e^{-\frac{x^2}{2}}}{\sqrt[4]{\pi}} = 0$$

$$\psi^{(1)}(x) = e^{-\frac{x^2}{2}}f(x)$$

$$\left(fe^{-\frac{x^2}{2}}\right)'' = \left(-xfe^{-\frac{x^2}{2}} + f'e^{-\frac{x^2}{2}}\right)' = e^{-\frac{x^2}{2}}((x^2-1)f(x) - 2xf'(x) + f''(x))$$

$$2xf'(x) - f''(x) + \frac{2gx(1-x^2)}{\sqrt[4]{\pi}} = 0$$

Ищем $f(x)$ в виде:

$$f(x) = Bx + Cx^2 + Dx^3$$

$$2x(B + 2Cx + 3Dx^2) - 2C - 6Dx + \frac{2gx(1-x^2)}{\sqrt[4]{\pi}} = 0$$

$$\begin{cases} C = 0, \\ 2B - 6D + \frac{2g}{\sqrt[4]{\pi}} = 0, \\ 6D - \frac{2g}{\sqrt[4]{\pi}} = 0. \end{cases}$$

$$B = C = 0, \quad D = \frac{g}{3\sqrt[4]{\pi}}$$

$$f(x) = \frac{gx^3}{3\sqrt[4]{\pi}}$$

$$\psi^{(1)}(x) = \frac{gx^3 e^{-\frac{x^2}{2}}}{3\sqrt[4]{\pi}}$$

Рассмотрим 2 порядок теории возмущений:

$$(\hat{H} + \hat{V}_1 + \hat{V}_2)(|\psi^{(0)}\rangle + |\psi^{(1)}\rangle + |\psi^{(2)}\rangle) = (E^{(0)} + E^{(1)} + E^{(2)})(|\psi^{(0)}\rangle + |\psi^{(1)}\rangle + |\psi^{(2)}\rangle)$$

$$\hat{H}|\psi^{(2)}\rangle + \hat{V}_1|\psi^{(1)}\rangle + \hat{V}_2|\psi^{(0)}\rangle = E^{(0)}|\psi^{(2)}\rangle + E^{(1)}|\psi^{(1)}\rangle + E^{(2)}|\psi^{(0)}\rangle$$

Домножим скалярно на $\langle\psi^{(0)}|$ и воспользуемся тем, что $E^{(0)} = 0$:

$$\langle\psi^{(0)}|\hat{V}_1|\psi^{(1)}\rangle + \langle\psi^{(0)}|\hat{V}_2|\psi^{(0)}\rangle = E^{(2)}$$

$$E^{(2)} = \int\limits_{-\infty}^{\infty} \frac{e^{-\frac{x^2}{2}}}{\sqrt[4]{\pi}} \frac{gx^3 e^{-\frac{x^2}{2}}}{3\sqrt[4]{\pi}} gx(1-x^2)dx + \int\limits_{-\infty}^{\infty} \frac{e^{-x^2}}{\sqrt{\pi}} \frac{g^2x^4}{2} dx = -\frac{3g^2}{8} + \frac{3g^2}{8} = 0$$

$$E^{(2)} = 0$$

$$\hat{H}^{(0)}\psi^{(2)} + \hat{V}^{(1)}\psi^{(1)} + \hat{V}^{(2)}\psi^{(0)} = 0$$

$$\frac{1}{2}\left(-\frac{\partial^2}{\partial x^2} + x^2\right)\psi^{(2)} + gx(1-x^2)\frac{gx^3}{3\sqrt[4]{\pi}} e^{-\frac{x^2}{2}} + \frac{g^2x^4 e^{-\frac{x^2}{2}}}{2\sqrt[4]{\pi}} = 0$$

Решая ДУ аналогично предыдущему, получим

$$\psi^{(2)} = \frac{g^2x^6}{18\sqrt[4]{\pi}} e^{-\frac{x^2}{2}}$$

- Рассмотрим произвольный n-й порядок теории возмущений:

$$\hat{H}|\psi^{(n)}\rangle + \hat{V}_1|\psi^{(n-1)}\rangle + \hat{V}_2|\psi^{(n-2)}\rangle = E^{(0)}|\psi^{(n)}\rangle + E^{(1)}|\psi^{(n-1)}\rangle + ... + E^{(n)}|\psi^{(0)}\rangle$$

Домножим скалярно на $\langle\psi^{(0)}|$ и воспользуемся тем, что $E^{(0)} = 0$:

$$E^{(n)} = \langle\psi^{(0)}|\hat{V}_1|\psi^{(n-1)}\rangle + \langle\psi^{(0)}|\hat{V}_2|\psi^{(n-2)}\rangle$$

Докажем по индукции одновременно 2 утверждения: $E^{(n)} = 0$ и $\psi^{(n)} = \frac{g^n x^{3n}}{\sqrt[4]{\pi} 3^n n!} e^{-\frac{x^2}{2}}$. Пусть это верно $\forall k \leq n-1$. Тогда

$$E^{(n)} = \int\limits_{-\infty}^{\infty} \frac{e^{-\frac{x^2}{2}}}{\sqrt[4]{\pi}} \frac{g^n x^{3(n-1)}}{\sqrt[4]{\pi} 3^{n-1}(n-1)!} e^{-\frac{x^2}{2}} gx(1-x^2)dx + \int\limits_{-\infty}^{\infty} \frac{e^{-\frac{x^2}{2}}}{\sqrt[4]{\pi}} \frac{g^{n-2} x^{3(n-2)}}{\sqrt[4]{\pi} 3^{n-2}(n-2)!} e^{-\frac{x^2}{2}} \frac{g^2x^4}{2} dx =$$

$$= -\frac{3^{2-n}(1+(-1)^{3n}) g^n \Gamma(\frac{3n}{2} - \frac{1}{2})}{4\sqrt{\pi}(n-2)!} + \frac{3^{2-n}(1+(-1)^{3n}) g^n \Gamma(\frac{3n}{2} - \frac{1}{2})}{4\sqrt{\pi}(n-2)!} = 0$$

$$E^{(n)} = 0$$

Теперь проверим, что будет выполняться:

$$\hat{H}\psi^{(n)} + \hat{V}^{(1)}\psi^{(n-1)} + \hat{V}^{(2)}\psi^{(n-2)} = 0$$

$$\frac{1}{2}\left(-\frac{\partial^2}{\partial x^2} + x^2\right)\frac{g^n x^{3n}}{\sqrt[4]{\pi} 3^n n!} e^{-\frac{x^2}{2}} + gx(1 - x^2)\frac{g^{n-1} x^{3(n-1)}}{\sqrt[4]{\pi} 3^{n-1}(n-1)!} e^{-\frac{x^2}{2}} + \frac{g^2x^4}{2}\frac{g^{n-2} x^{3(n-2)}}{\sqrt[4]{\pi} 3^{n-2}(n-2)!} e^{-\frac{x^2}{2}} = 0$$

Таким образом, поправка произвольного порядка к волновой функции:

$$\psi^{(n)} = \frac{g^n x^{3n}}{\sqrt[4]{\pi} 3^n n!} e^{-\frac{x^2}{2}}$$

Просуммируем ряд возмущений:

$$\psi(x) = \sum_{n=0}^{\infty} \frac{g^n x^{3n}}{\sqrt[4]{\pi} 3^n n!} e^{-\frac{x^2}{2}} = \frac{e^{-\frac{x^2}{2}}}{\sqrt[4]{\pi}} \sum_{n=0}^{\infty} \frac{1}{n!}\left(\frac{gx^3}{3}\right)^n = \frac{\exp\left(g\frac{x^3}{3} - \frac{x^2}{2}\right)}{\sqrt[4]{\pi}}$$

Проверим, что это точное решение уравнения Шрёдингера:

$$\left(\frac{1}{2}\left(-\frac{\partial^2}{\partial x^2}+x^2-1\right)+gx(1-x^2)+\frac{g^2x^4}{2}\right)\psi(x)=E\psi(x)$$

$$\frac{1}{2}\left(-\frac{\partial^2}{\partial x^2}+x^2-1\right)\psi(x)=-\frac{gx(2-2x^2+gx^3)}{2\sqrt[4]{\pi}}\exp\left(g\frac{x^3}{3}-\frac{x^2}{2}\right)$$

$$\left(\frac{1}{2}\left(-\frac{\partial^2}{\partial x^2}+x^2-1\right)+gx(1-x^2)+\frac{g^2x^4}{2}\right)\psi(x)=0$$

Таким образом, точное решение уравнения Шрёдингера:

$$\psi(x)=\frac{\exp\left(g\frac{x^3}{3}-\frac{x^2}{2}\right)}{\sqrt[4]{\pi}}$$

Расстраиваемся, поскольку это решение никак не позволяет ответить на вопрос, какой сдвиг энергии $\delta E_0=\sum\limits_{n=0}^{\infty}E^{(n)}=0$.

- Критерий применимости теории возмущений:

$$\langle\psi^{(n)}|\psi^{(n)}\rangle\gg\langle\psi^{(n+1)}|\psi^{(n+1)}\rangle$$

$$\langle\psi^{(n)}|\psi^{(n)}\rangle=\int\limits_{-\infty}^{\infty}\frac{g^{2n}x^{6n}}{\sqrt{\pi}3^{2n}(n!)^2}e^{-x^2}dx=\frac{g^{2n}\Gamma(3n+\frac{1}{2})}{\sqrt{\pi}3^{2n}\Gamma(n+1)^2}=\frac{g^{2n}(6n)!}{2^{6n}3^{2n}(n!)^2(3n)!}$$

При больших n воспользуемся формулой Стирлинга:

$$n!\approx\sqrt{2\pi n}\left(\frac{n}{e}\right)^n$$

$$\langle\psi^{(n)}|\psi^{(n)}\rangle\sim\frac{g^{2n}\sqrt{12\pi n}(6n)^{6n}}{2^{6n}3^{2n}2\pi n^{2n+1}\sqrt{6\pi n}(3n)^{3n}}=\frac{3^ng^{2n}n^{n-1}}{\sqrt{2}\pi}$$

$$\frac{\langle\psi^{(n+1)}|\psi^{(n+1)}\rangle}{\langle\psi^{(n)}|\psi^{(n)}\rangle}=\frac{3g^2(n+1)^n}{n^{n-1}}\approx3g^2n\ll1$$

$$n^*\gg\frac{1}{3g^2}$$

Например, можно взять другую степень g:

$$n^*=\frac{1}{3g}$$

- Подставим n^*:

$$\langle\delta\psi|\delta\psi\rangle=\langle\psi^{(n^*)}|\psi^{(n^*)}\rangle=\frac{3^{n^*}g^{2n^*}(n^*)^{n^*-1}}{\sqrt{2}\pi}$$

Смещение энергии в колодце при $\mathrm{V(x)}=\frac{\mathrm{V_0}}{a^2}(a-\mathrm{x})\mathrm{x}$ (???)

Solution.

Для частицы, находящейся в бесконечно глубокой потенциальной яме шириной, $a(0<x<a)$ найти в первом приближении теории возмущений смещение энергетических уровней под воздействием возмущения вида

$$\mathrm{V(x)}=\frac{\mathrm{V_0}}{a^2}(a-\mathrm{x})\mathrm{x}.$$

Волновые функции для координаты в яме: $\varphi_n(x)=\sqrt{\frac{2}{a}}\sin\left(\frac{\pi n}{a}x\right)$, в других координатах 0.

По первому порядку нестационарной теории возмущений $\Delta E=V_{nn}=\frac{V_0}{a^3}\int\limits_0^a(ax-x^2)\left(a-\cos\left(\frac{2\pi nx}{a}\right)\right)dx$.

Разбиваем интеграл на 4, один равен нулю, остальные дают:

$$\Delta E=\frac{V_0}{a^3}\left(\frac{a^3}{2}-\frac{a^3}{3}-\frac{a^3}{2(\pi n)^2}\right)=V_0\left(\frac{1}{6}-\frac{1}{2(\pi n)^2}\right).$$

Б-2.8.1 Поправки к осциллятору при $\hat{\mathrm{V}} = \alpha x$ и $\hat{\mathrm{V}} = Ax^3 + Bx^4$

Найти с помощью теории возмущений поправки к уровням энергии линейного гармонического осциллятора, возмущенного полем вида:

а) однородное поле $\hat{\mathrm{V}} = \alpha x$;

б) $\hat{\mathrm{V}} = Ax^3 + Bx^4$.

Поправка к энергии осциллятора при $V = \alpha x$.

Операторы координаты в представлении операторов рождения и уничтожения равен $x = \frac{x_0}{\sqrt{2}}\left(a^\dagger + a\right)$, где $x_0 = \sqrt{\frac{\hbar}{m\omega}}$.

Поправка первого порядка ϵ_1 по теории возмущений для $V = \alpha x$ равна нулю:

$$\epsilon_1 = V_{nn} = \frac{\alpha x_0}{\sqrt{2}}\langle n|a^\dagger + a|n\rangle = 0,$$

ведь $\langle n|a^\dagger|n\rangle \sim \langle n|n+1\rangle = 0$, $\langle n|a|n\rangle \sim \langle n|n-1\rangle = 0$.

Вычислим поправку второго порядка по $\epsilon_2 = \sum\limits_{k\neq n} \frac{|V_{kn}|^2}{E_n - E_k}$, в ней

$$V_{kn} \equiv \langle k|V|n\rangle = \frac{\alpha x_0}{\sqrt{2}}\langle k|a^\dagger + a|n\rangle = \frac{\alpha x_0}{\sqrt{2}}\left[\sqrt{n+1}\delta_{k,n+1} + \sqrt{n}\delta_{k,n-1}\right].$$

То есть у нас $k = \{n+1, n-1\}$. Из того, что $E_n = \hbar\omega\left(n + \frac{1}{2}\right)$, знаменатели двух членов суммы равны $\hbar\omega$ и -$\hbar\omega$. В итоге

$$\epsilon_2 = \sum_{k\neq n}\frac{|V_{kn}|^2}{E_n - E_k} = \frac{\alpha^2 x_0^2}{2}\left[-\frac{n+1}{\hbar\omega} + \frac{n}{\hbar\omega}\right] = -\frac{\alpha^2 x_0^2}{2\hbar\omega} = -\frac{\alpha^2}{2m\omega^2}$$

(???? что за классическая интерпретация этой поправки????)

Как видим, поправка оказалась не зависящей от постоянной Планка, поэтому она имеет классическую интерпретацию. Действительно, если бы мы записали полный гамильтониан с учетом возмущения (1) и выделили бы полный квадрат, мы бы получили, что все уровни энергии сдвинулись на одинаковую величину, совпадающую с полученной по теории возмущений, но при этом и изменилось бы равновесное значение координаты осциллятора. Для нахождения смещения положения равновесия осциллятора по теории возмущений необходимо знать «поправленные векторы состояния.

Поправка к энергии осциллятора при $V = \alpha x^3$.

Для поправки первого порядка $\epsilon_1 = V_{nn} = \frac{\alpha x_0^3}{2\sqrt{2}}\langle n|\left(a^\dagger + a\right)^3|n\rangle$ преобразуем $\left(a^\dagger + a\right)^3$:

$$\left(a^\dagger + a\right)^2 = \left(a^\dagger + a\right)\left(a^\dagger + a\right) = a^\dagger a^\dagger + aa + aa^\dagger + a^\dagger a = a^\dagger a^\dagger + aa + 2N + 1.$$

Тут учтено, что $\left[a, a^\dagger\right] = 1$, $N = a^\dagger a$ - оператор числа квантов: $N|n\rangle = n|n\rangle$, $Na \neq aN$. Получаем оператор

$$\left(a^\dagger + a\right)^3 = a^\dagger a^\dagger a^\dagger + aaa + (N+1)a^\dagger + a^\dagger(2N+1) + Na + a(2N+1),$$

тогда поправка:

$$\epsilon_1 = V_{nn} = \frac{\alpha x_0^3}{2\sqrt{2}}\langle n|\left(a^\dagger + a\right)^3|n\rangle \sim 0 + 0 + 0 + 0 + 0 + 0 = 0.$$

Для поправки второго порядка $\epsilon_2 = \sum\limits_{k\neq n}\frac{|V_{kn}|^2}{E_n - E_k}$, где $V_{kn} = \frac{\alpha x_0^3}{2\sqrt{2}}\langle k|\left(a^\dagger + a\right)^3|n\rangle$ посчитаем

$$\begin{aligned}
\langle k|a^\dagger a^\dagger a^\dagger|n\rangle &= ((n+1)(n+2)(n+3))^{1/2}\delta_{k,n+3}\\
\langle k|aaa|n\rangle &= (n(n-1)(n-2))^{1/2}\delta_{k,n-3}\\
\langle k|(N+1)a^\dagger + a^\dagger(2N+1)|n\rangle &= \sqrt{n+1}(n+2+2n+1)\langle k|n+1\rangle = 3(n+1)^{3/2}\delta_{k,n+1}\\
\langle k|Na + a(2N+1)|n\rangle &= \sqrt{n}(n-1+2n+1)\langle k|n-1\rangle = 3n^{3/2}\delta_{k,n-1}
\end{aligned}$$

Получим:

$$\begin{aligned}
\epsilon_2 &= \frac{\alpha^2 x_0^6}{8\hbar\omega}\left[\frac{9n^3}{n-(n-1)} + \frac{9(n+1)^3}{n-(n+1)} + \frac{(n+1)(n+2)(n+3)}{n-(n+3)} + \frac{n(n-1)(n-2)}{n-(n-3)}\right] =\\
&= \frac{\alpha^2 x_0^6}{8\hbar\omega}\left[-27n^2 - 27n - 9 - 3n^2 - 3n - 2\right] =\\
&= -\alpha^2\left(\frac{\hbar}{m\omega}\right)^3\frac{15}{4\hbar\omega}\left[n^2 + n + \frac{11}{30}\right]
\end{aligned}$$

Поправка к энергии осциллятора при $V = \beta x^4$.

Для поправки первого порядка $\epsilon_1' = \langle n|V|n\rangle = \frac{\beta x_0^4}{4}\langle n|\left(a^\dagger + a\right)^4|n\rangle$ найдем:

$$\begin{aligned}\left(a^\dagger + a\right)^4 &= \left(a^\dagger a^\dagger + aa + 2N + 1\right)\left(a^\dagger a^\dagger + aa + 2N + 1\right) = \\ &= a^\dagger a^\dagger a^\dagger a^\dagger + aaaa + a^\dagger N a + a^\dagger a^\dagger (2N+1) + \\ &\quad + a(N+1)a^\dagger + aa(2N+1) + (2N+1)a^\dagger a^\dagger + (2N+1)aa + (2N+1)^2.\end{aligned}$$

Ненулевые останутся для первого порядка теории возмущений только члены, в которых одинаковое количество a и $a^\dagger$, подставим их:

$$\epsilon_1' = \frac{\beta x_0^4}{4}\langle n|\left(a^\dagger + a\right)^4|n\rangle = \frac{\beta x_0^4}{4}\left[n(n-1) + (n+1)(n+2) + (2n+1)^2\right] = \frac{3\beta x_0^4}{2}\left(n^2 + n + \frac{1}{2}\right)$$

Для поправки при $\hat{\mathrm{V}} = Ax^3 + Bx^4$ имеем сумму:

$$\Delta\epsilon = \frac{3}{2}\beta\left(\frac{\hbar}{m\omega}\right)^2\left[n^2 + n + \frac{1}{2}\right] - \alpha^2\left(\frac{\hbar}{m\omega}\right)^3\frac{15}{4\hbar\omega}\left[n^2 + n + \frac{11}{30}\right]$$

(??? почему так можно складывать - зависший вопрос в теории, пока забил.)

(тут мб когда-то посчитаю поправку 2го порядка. Так типично мало кто делает, потому что куча возни с операторами, так что пока что я забил. когда-то мб вернусь к этому, пока тут нерешенная часть задачи.)

Поправка к энергии осциллятора при $V = \alpha x$, если работать через функции Эрмита (!??!??!?)

(??? что если не переходить к оператором рождения и уничтожения, задача так вообще решается??)

Б-2.8.2 Поправки к векторам состояния осциллятора в $\hat{\mathrm{V}} = \alpha\hat{x}$

Найти поправки к уровням энергии и векторам состояния одномерного гармонического осциллятора, помещенного в однородное поле $\hat{\mathrm{V}} = \alpha\hat{x} = \frac{\alpha x_0}{\sqrt{2}}(\hat{a}^+ + \hat{a})$, где α - некоторая константа взаимодействия.

Solution.

Поправки первого порядка к векторам состояний находим по типичной формуле $|\psi_n^{(1)}\rangle = \sum\limits_{k\neq n}\frac{\langle k|\hat{\mathrm{V}}|n\rangle}{E_n^{(0)} - E_k^{(0)}}|\psi_k^{(0)}\rangle$. Уже найдено $V_{kn} = \frac{\alpha x_0}{\sqrt{2}}\langle k|a^\dagger + a|n\rangle = \frac{\alpha x_0}{\sqrt{2}}\left[\sqrt{n+1}\delta_{k,n+1} + \sqrt{n}\delta_{k,n-1}\right]$, поэтому

$$|\psi_n\rangle = |n\rangle + |\psi_n^{(1)}\rangle = |n\rangle + \frac{\alpha x_0}{\sqrt{2}\hbar\omega}(\sqrt{n}|n-1\rangle - \sqrt{(n+1)}|n+1\rangle).$$

Кстати, среднее значение оператора координаты $\hat{x}$ для состояния $|\psi_n\rangle$ с учетом поправок первого приближения:

$$\begin{aligned}\langle\psi_n|\hat{x}|\psi_n\rangle &= \frac{x_0}{\sqrt{2}}\left(\langle n|\left(\hat{a} + \hat{a}^+\right)|\psi_n^{(1)}\rangle + \langle\psi_n^{(1)}|\left(\hat{a} + \hat{a}^+\right)|n\rangle\right) = \\ &= \frac{\alpha x_0^2}{\hbar\omega}\left(\sqrt{n}\langle n|\hat{a}^+|n-1\rangle - \sqrt{(n+1)}\langle n|\hat{a}|n+1\rangle\right) = -\frac{\alpha}{m\omega^2}.\end{aligned}$$

Полученный результат в точности совпадает с тем, который получается в результате выделения в гамильтониане полного квадрата (????? пока верю, потом проделаю, проверю!!!!).

(?? а с учетом поправок второго приближения что можно сказать???)

Б-2.8.3 Расщепление 1го уровня энергии и правильные волновые функции функции 3D осциллятора при $\hat{\mathrm{V}} = \alpha xy$

Определить расщепление первого возбужденного уровня энергии трехмерного изотропного гармонического осциллятора и найти правильные векторы нулевого приближения при воздействии на него возмущения вида $\hat{\mathrm{V}} = \alpha xy$.

Solution.

Состояния 3D изотропного осциллятора определяются 3-мя квантовыми числами $|n_1, n_2, n_3\rangle$. Первый возбужденный уровень энергии трехкратно вырожден.

Обозначим состояния следующим образом:

$$|1\rangle = |1,0,0\rangle, \quad |2\rangle = |0,1,0\rangle, \quad |3\rangle = |0,0,1\rangle.$$

Оператор возмущения выразим через повышающие и понижающие операторы

$$\hat{\mathrm{V}} = \frac{1}{2}\alpha x_0^2 \left(\hat{a}_x^+ + \hat{a}_x\right)\left(\hat{a}_y^+ + \hat{a}_y\right),$$

где ω - частота осциллятора, $x_0 = \sqrt{\hbar/(m\omega)}$.

Легко видеть, что все диагональные матричные элементы оператора возмущения равны нулю, а отличны от нуля только два недиагональных:

$$V_{11} = V_{22} = V_{33} = V_{13} = V_{23} = 0, \quad V_{12} = V_{21} = \frac{1}{2}\alpha x_0^2.$$

Таким образом, получаем, что состояние $|3\rangle = |0,0,1\rangle$ - правильное и имеет энергию, совпадающую с энергией первого возбужденного уровня невозмущенного осциллятора. Два других правильных состояния определяются линейными комбинациями

$$|\pm\Delta\rangle = \frac{1}{\sqrt{2}}(|1,0,0\rangle \pm |0,1,0\rangle)$$

и поправки к невозмущенному уровню энергии $\Delta E \pm \alpha x_0^2/2$.

Расщепление 1го уровня энергии 2d осциллятора при $V = \alpha x^3 y^3$

Найти расщепление первого возбужденного уровня энергии плоского гармонического осциллятора под действием возмущения вида $V = \alpha x^3 y^3$ (плоскость x, y-плоскость колебаний) в первом порядке теории возмущений.

Solution.

(!! укажу потом, что важно нормально занумеровать, в каком состоянии частица сколько энергии дает. в этом самая основная путаница, дальше уже их операторами рождения и уничтожения переводим одно в другое. собственно, все тут однообразно решается.)

Первый уровень двумерного осциллятора двукратно вырожден, его энергия $E = \hbar\omega(0+1/2) + \hbar\omega(1+1/2) = 2\hbar\omega$.

Для секулярного уравнения расписываем оператор возмущения выразим через повышающие и понижающие операторы

$$\hat{\mathrm{V}} = \frac{1}{8}\alpha x_0^6 \left(\hat{a}_x^+ + \hat{a}_x\right)^3 \left(\hat{a}_y^+ + \hat{a}_y\right)^3,$$

дальше их в полиномы раскладываем по типичным формулам, действуем на состояния, диагональные элементы дают ноль, кросдиагональные равны $\frac{9\alpha x_0^6}{8}$, из секулярного уравнения получаем, что поправка $\Delta E = +\frac{9\alpha x_0^6}{8}$ и $\Delta E = -\frac{9\alpha x_0^6}{8}$. В итоге $E_1' = 2\hbar\omega \pm \frac{9\alpha\hbar^3}{8m^3\omega^3}$.

Б-2.8.4 Уравнение на эффективный оператор возмущения (???)

Предположим, что в случае вырожденного энергетического спектра все матричные элементы оператора возмущения для состояний, относящихся к данному уровню энергии $E_n^{(0)}$, равны нулю.

Показать, что при этом поправки к уровню энергии и правильные векторы нулевого приближения можно найти из уравнения (??) для эффективного оператора возмущения

$$\hat{\mathrm{V}}^{\mathrm{eff}} = \hat{\mathrm{V}} \sum_{k,\nu} \frac{|\psi_{k\nu}^{(0)}\rangle\langle\psi_{k\nu}^{(0)}|}{E_n^{(0)} - E_k^{(0)}} \hat{\mathrm{V}},$$

которым можно пользоваться только при действии на состояния, относящиеся к уровню энергии $E_n^{(0)}$.

Solution.

(?? вообще не знаю такое ещё. какая-то тупая теория.)

2.8.4. Поскольку в рассматриваемом случае все матричные элементы оператора возмущения для состояний, относящихся к вырожденному уровню энергии $E_n^{(0)}$, равны нулю, то общий вид вектора состояния с учетом первого приближения теории возмущений определяется стандартным образом в соответствии с (II.40):

$$|\psi_{n\mu}\rangle \simeq |\psi_{n\mu}^{(0)}\rangle + \sum_{k,\nu}{}' \frac{\langle k\nu|\hat{\mathrm{V}}|n\mu\rangle}{E_n^{(0)} - E_k^{(0)}} |\psi_{k\nu}^{(0)}\rangle,$$

где штрих означает отсутствие в сумме слагаемых с $n = k, \mu = \nu$. Составим теперь из состояний (1), относящихся к одному и тому же уровню энергии $E_n^{(0)}$, линейные комбинации

$$|\Phi_{n\alpha}\rangle = \sum_{\mu} C_\mu^\alpha |\psi_{n\mu}\rangle$$

и подставим их в уравнение Шредингера:

$$\left(\hat{\mathrm{H}}^{(0)} + \hat{\mathrm{V}}\right) |\Phi_{n\alpha}\rangle = E_{n\alpha} |\Phi_{n\alpha}\rangle.$$

Теперь мы можем получить систему алгебраических уравнений, аналогичную системе (II.41), из которой определяются поправки второго порядка к уровню энергии и, соответственно, коэффициенты линейных комбинаций (2), дающих правильные векторы первого приближения:

$$\sum_{\beta} \left(\sum_{k,\nu}{}' \langle n\alpha|\hat{\mathrm{V}}|k\nu\rangle \frac{\langle k\nu|\hat{\mathrm{V}}|n\beta\rangle}{E_n^{(0)} - E_k^{(0)}} - \varepsilon\delta_{\alpha\beta} \right) C_\beta = 0.$$

Уравнение формально сводится к стандартному (см. (II.41)), если ввести оператор возмущения $\hat{\mathrm{V}}^{\mathrm{elf}}$.

17.1.2 Problems about Time-Independent PT 2

Б-2.8.5 Поправка ко 2му уровню 3d осциллятора при $\hat{\mathrm{V}} = \beta xz$

Определить поправки ко второму возбужденному уровню энергии трехмерного изотропного гармонического осциллятора и правильные векторы нулевого приближения при воздействии на него возмущения вида $\hat{\mathrm{V}} = \beta xz$.

Solution.

2.8.5. Второй возбужденный уровень трехмерного изотропного гармонического осциллятора шестикратно вырожден. Обозначим состояния так же, как и в задаче 2.8.3:

$$\begin{array}{lll} |1\rangle = |2,0,0\rangle, & |2\rangle = |0,2,0\rangle, & |3\rangle = |0,0,2\rangle, \\ |4\rangle = |1,1,0\rangle, & |5\rangle = |1,0,1\rangle, & |6\rangle = |0,1,1\rangle. \end{array}$$

Для состояний $|4\rangle - |6\rangle$ отличны от нуля только диагональные матричные элементы эффективного оператора возмущения $\hat{\mathrm{V}}^{\mathrm{eff}}$ задачи 2.8.4. Таким образом, получаем трехкратно вырожденный уровень, смещенный на величину $-\Delta$, где

$$\Delta = \frac{\beta^2\hbar}{4m^2\omega_0^3},$$

которому соответствуют три произвольные линейно независимые комбинации состояний $|4\rangle - |6\rangle$. При действии оператора возмущения $\hat{\mathrm{V}}^{\mathrm{eff}}$ состояния $|1\rangle - |3\rangle$ «смешиваются», поскольку отличны от нуля как диагональные, так и недиагональные матричные элементы:

$$V_{11} = V_{22} = V_{33} = -\frac{1}{2}\Delta, \quad V_{12} = V_{23} = V_{13} = -\Delta.$$

Таким образом, получаем секулярное уравнение третьей степени, корни которого, однако, легко находятся и равны

$$\varepsilon_{1,2} = \Delta, \quad \varepsilon_3 = -\frac{5}{8}\Delta.$$

Правильный вектор состояния для поправки ε_3 равен

$$|\varepsilon_3\rangle = \frac{1}{\sqrt{3}}(|2,0,0\rangle + |0,2,0\rangle + |0,0,2\rangle).$$

Для двукратно вырожденного уровня $\varepsilon_{1.2}$ правильными будут линейные комбинации, ортогональные вектору состояния $|\varepsilon_3\rangle$ и имеющие вид

$$|I\rangle = \sqrt{\frac{2}{3}}\left(\frac{1}{2}(|2,0,0\rangle + |0,2,0\rangle) - |0,0,2\rangle\right).$$
$$|II\rangle = \sqrt{\frac{2}{3}}\left(\frac{1}{2}(|2,0,0\rangle + |0,0,2\rangle) - |0,2,0\rangle\right).$$

Как видим, шестикратно вырожденный уровень энергии расщепился на три: невырожденный, один двукратно и один трехкратно вырожденный уровни энергии. Учет более высоких порядков теории возмущений уже не сможет качественно изменить картину.

Б-2.8.6 Скрещивание уровней

Уровни энергии невозмущенной системы зависят от параметра λ, и при некотором значении λ_0 два уровня энергии совпадают: $E_1^{(0)}(\lambda_0) = E_2^{(0)}(\lambda_0)$. В начальный момент времени система находится на первом уровне в состоянии $\psi_1^{(0)}$. Найти вероятность того, что система будет находиться в момент времени t в состоянии $\psi_2^{(0)}$, если на нее накладывается малое постоянное возмущение $\hat{\mathrm{V}}$. Считать, что матричные элементы $V_{11} = V_{22} = 0$, но $V_{12} = V_{21}^* \neq 0$.

Solution.

2.8.6. В невозмущенной задаче уровни энергии очень близки или совпадают, поэтому применим теорию возмущений для близких уровней энергии. Сформируем линейные комбинации волновых функций нулевого приближения $\tilde{\psi} = C_1\psi_1^{(0)} + C_2\psi_2^{(0)}$ и подставим их в уравнение $\left(\hat{\mathrm{H}}^{(0)} + \hat{\mathrm{V}}\right)\tilde{\psi} = E\tilde{\psi}$. В результате для нахождения коэффициентов C_1, C_2 мы получим систему

$$\begin{pmatrix} H_{11} - E & H_{12} \\ H_{21} & H_{22} - E \end{pmatrix}\begin{pmatrix} C_1 \\ C_2 \end{pmatrix} = 0,$$

где введены обозначения

$$H_{mn} = \langle\psi_m^{(0)}|\hat{\mathrm{H}}|\psi_n^{(0)}\rangle = \begin{cases} V_{nn} + E_n^{(0)}, & m = n, \\ V_{mn}, & m \neq n. \end{cases} \quad m, n = 1, 2.$$

Вообще говоря, здесь не предлолагается, что уровни энергии в невозмущенной задаче совпадают, т. е. $E_1^{(0)} \neq E_2^{(0)}$. Из условия разрешимости системы (1) находим значения уровней энергии для линейных комбинаций $\widetilde{\psi}_{1,2}$:

$$E_{1,2} = \frac{1}{2}\left\{(H_{11} + H_{22}) \pm \hbar\omega\right\}, \quad \hbar\omega = \sqrt{(H_{11} - H_{22})^2 + 4|H_{12}|^2}.$$

Из системы (1) находим коэффициенты C_1, C_2, позволяющие построить функции $\widetilde{\psi}_{1,2} = C_1^{1.2}\psi_1^{(0)} + C_2^{1.2}\psi_2^{(0)}$, нормированные на единицу, т. е. Далее выразим $\psi_{1,2}^{(0)}$ через $\widetilde{\psi}_{1,2}$: $\psi_{1,2}^{(0)} = \mp\left(C_{2,1}^2\widetilde{\psi}_1 - C_{2,1}^1\widetilde{\psi}_2\right)$. Здесь мы учли, что $\det C = -1$. Функции $\widetilde{\psi}_{1,2}$ описывают состояния с определенной энергией, поэтому, восстанавливая зависимость от времени, получим

$$\Psi_1^{(0)}(x,t) = C_2^1\tilde{\psi}_2 e^{-\frac{i}{\hbar}E_2 t} - C_2^2\tilde{\psi}_1 e^{-\frac{i}{\hbar}E_1 t}.$$

Полученная нами волновая функция описывает состояние, в котором $\Psi_1^{(0)}(x,0) = \psi_1^{(0)}$, как и требуется по условию задачи. Подставим в соотношение (3) функции $\widetilde{\psi}_1$ и $\widetilde{\psi}_2$, выраженные через $\psi_{1,2}^{(0)}$. В результате получим функцию $\Psi_1^{(0)}(x,t)$ в виде разложения по состояниям $\psi_{1,2}^{(0)}$, причем коэффициенты разложения теперь будут зависеть от времени. В соответствии с вероятностной интерпретацией квадрат модуля коэффициента перед $\psi_2^{(0)}$ должен быть равен вероятности обнаружить систему в момент t в состоянии $\psi_2^{(0)}$:

$$W = |C_2^1 C_2^2\left[e^{-\frac{i}{\hbar}E_2 t} - e^{-\frac{i}{\hbar}E_1 t}\right]|^2 = \frac{2|H_{12}|^2}{(\hbar\omega)^2}[1 - \cos\omega t] = \frac{4\left[H_{12}\right|^2}{(\hbar\omega)^2}\sin^2\left(\frac{\omega t}{2}\right).$$

Здесь мы использовали соотношения (2).

Б-2.8.7 Переходы при β-распаде трития

Найти вероятность того, что при β-распаде трития ион $^3\mathrm{He}^+$ окажется: **а)** в 1s-состоянии; **б)** в 2s-состоянии; **в)** в 2p-состоянии, если атом трития находился в 1s-состоянии.

Solution.

(??? суть???)
β-Распад трития

$$^3_1\mathrm{H} \to {}^3_2\mathrm{He} + \mathrm{e}^- + \widetilde{\nu}_\mathrm{e}$$

представляет собой быстрый процесс, в течение которого изменяется потенциальная энергия электрона в атоме:

$$U_\mathrm{H}(r) = -\frac{e^2}{r} \quad \to \quad U_\mathrm{He}(r) = -\frac{2e^2}{r},$$

поскольку ядро трития превращается в ядро изотопа ^{3}He. Время распада можно оценить, как время пролета β-электрона через область, занимаемую атомом $t_\beta \sim a/v_\beta$, где a - радиус боровской орбиты, v_β – скорость β-электрона. Поскольку энергия β-электрона имеет порядок нескольких кэВ, то $v_\beta/c \sim 10^{-1} \gg v_\mathrm{at}/c \sim \alpha \simeq 1/137$, где $v_\mathrm{at} \sim e^2/\hbar$ - скорость атомных электронов. В итоге получаем, что t_β гораздо меньше характерных атомных времен:

$$t_\beta \sim \frac{a}{v_\beta} \sim \frac{\hbar^2}{me^2}\frac{1}{v_\beta} \ll \frac{\hbar^2}{me^2}\frac{1}{v_\mathrm{at}} \sim \frac{\hbar^3}{me^4} \sim \tau_\mathrm{aT}.$$

Это означает, что волновая функция электрона не успевает измениться за время t_β, в течение которого меняется потенциальная гамильтониана этой системы. Вместе с гамильтонианом меняется и система его собственных функций, поэтому мы можем разложить исходную волновую функцию электрона ψ^H в поле $U_\mathrm{H}(r)$ по собственным функциям в поле $U_\mathrm{He}(r)$:

$$\psi^\mathrm{H} = \sum_n C_n \psi_n^\mathrm{He} + \int C_\mathbf{k} \psi_\mathbf{k}^\mathrm{He} d\mathbf{k},$$

где коэффициенты разложения $C_n = \langle \psi_n^\mathrm{He} | \psi^\mathrm{H} \rangle = \int \psi_n^{\mathrm{He}*}\, \psi^\mathrm{H} d^3x$ определяют вероятности перехода электрона $w_n = |C_n|^2$ в одно из связанных состояний иона He.

Имея в виду явный вид радиальных функций электрона

$$R_{10} = 2\left(\frac{Z}{a_0}\right)^{\frac{3}{2}} e^{-Zr/a_0}, \qquad R_{21} = \frac{1}{\sqrt{3}}\left(\frac{Z}{2a_0}\right)^{\frac{3}{2}}\left(\frac{Zr}{a_0}\right) e^{-Zr/2a_0}$$

$$R_{20} = 2\left(\frac{Z}{2a_0}\right)^{\frac{3}{2}}\left(1 - \frac{Zr}{2a_0}\right) e^{-Zr/2a_0}, \qquad R_{32} = \frac{2\sqrt{2}}{27\sqrt{5}}\left(\frac{Z}{3a_0}\right)^{\frac{3}{2}}\left(\frac{Zr}{a_0}\right)^2 e^{-Zr/3a_0}$$

в тритии и в гелии имеем

$$R_{10}^\mathrm{H}(r) = \frac{2}{a^{3/2}} e^{-\frac{r}{a}}, \qquad R_{10}^\mathrm{He}(r) = \frac{4\sqrt{2}}{a^{3/2}} e^{-\frac{2r}{a}},$$

$$R_{20}^\mathrm{He}(r) = \frac{2}{a^{3/2}}\left(1 - \frac{r}{a}\right) e^{-\frac{r}{a}}, \quad R_{21}^\mathrm{He}(r) = \frac{2}{a^{3/2}}\frac{r}{a\sqrt{3}} e^{-\frac{r}{a}},$$

получим окончательно

$$w_{1s} = \left(\frac{16\sqrt{2}}{27}\right)^2 \simeq 0,70; \quad w_{2s} = \frac{1}{4}; \quad w_{2p} = 0.$$

Б-2.8.8 Эффект Мессбауэра через теорию возмущений (??)

Определить вероятность процесса, при котором ядро, связанное гармоническим потенциалом, останется в основном состоянии после испускания γ-кванта (эффект Мессбауэра).

Solution.

(??? суть???)
(!!! в теории укажу про этот эффект и про его применения!!! пока что про него почти ничего не написано там, это плохо.)
(??? решал кстати, давно не повторял это.)
При резонансном испускания γ-кванта ядром, переходящим из возбужденного состояния в основное, энергия испущенного γ-кванта ε_γ должна быть в точности равна энергии возбуждения ядра: $\varepsilon_\gamma = \varepsilon$. Известно, что для свободно движущегося ядра такой процесс не идет, потому что этому мешает отдача ядра, возникающая вследствие действия закона сохранения импульса (см. задачу 1.3.36). Оказалось, что в твердом теле связанные ядра-излучатели могут излучать γ-кванты «без отдачи». Причем процесс возможен именно потому, что ядро связано, а не свободно.
В дальнейшем рассмотрим простую одномерную модель, предполагающую, что ядро-излучатель связано гармоническим потенциалом:

$$\hat{\mathrm{H}} = \frac{\hat{\mathrm{p}}^2}{2M} + \frac{M\omega^2\hat{x}^2}{2}; \quad \hat{\mathrm{H}}|n\rangle = E_n|n\rangle, \quad E_n = \hbar\omega\left(n + \frac{1}{2}\right).$$

где M - масса ядра. Вектор $|n\rangle$ теперь характеризует состояние ядра в пространстве в целом.
В отличие от этого, если бы ядро было свободным, то его пространственное состояние следовало бы характеризовать собственным вектором оператора импульса $|k'\rangle$, где $\hat{p}|k'\rangle = \hbar k'|k'\rangle$. При испускании γ-кванта свободным ядром это состояние переходит в $|k' - k\rangle$, где $\hbar k$ - импульс испущенного γ-кванта.
При движении в гармоническом потенциале импульс уже не будет интегралом движения, и начальное состояние ядра $|n\rangle$ не является собственным вектором оператора импульса. Поэтому теперь невозможно применить закон сохранения импульса по схеме $|k'\rangle \to |k' - k\rangle$, как для свободного случая. Однако состояние ядра $|n\rangle$ можно разложить по собственным векторам оператора импульса:

$$|n\rangle = \int |k'\rangle\langle k'|n\rangle dk'.$$

Дальнейшие рассуждения будут существенным образом использовать тот факт, что рассматриваемый нами процесс является быстрым по сравнению с характерным временем движения в гармоническом потенциале. Приведем оценку времени взаимодействия. Длина волны γ-кванта намного больше размеров ядра, ибо $\hbar\omega_\gamma \sim \hbar c/\lambda_\gamma \ll \hbar c/R_{\text{ядра}} \simeq 40$ МэВ. Поэтому время взаимодействия можно оценить, как $\tau_\gamma \sim \lambda_\gamma/c \sim \omega_\gamma^{-1}$. Поскольку энергия γ-кванта гораздо больше характерной энергии колебаний ядра $\hbar\omega$ (см. (1)), то время взаимодействия τ_γ оказывается много меньше $\tau_{\text{ядра}} \sim \omega^{-1}$ - характерного времени эволюции состояния ядра в гармоническом потенциале.
На основании этого делаем вывод о том, что процесс испускания γ-кванта действительно является быстрым. Одновременно и так же быстро срабатывает и закон сохранения импульса. Поэтому можно считать, что в выражении (2) каждое состояние с определенным значением импульса $|k'\rangle$ получает сдвиг: $|k'\rangle \to |k' - k\rangle$. Коэффициенты в разложении не изменяются. Следовательно, вектор конечного состояния ядра можно записать в виде

$$|f\rangle = \int |k' - k\rangle\langle k'|n\rangle dk' = \int e^{-ik\hat{x}}|k'\rangle\langle k'|n\rangle dk' = e^{-ik\hat{x}}|n\rangle.$$

Очевидно, что состояние $|f\rangle$ не является собственным вектором гамильтониана (1), но его можно разложить по полной системе собственных векторов $\{|n\rangle\}$:

$$|f\rangle = e^{-ik\hat{x}}|n\rangle = \sum_{n'} |n'\rangle\langle n'|e^{-ik\hat{x}}|n\rangle.$$

Отсюда видно, что вероятность того, что ядро при испускании перейдет в одно из состояний гармонического осциллятора, равна

$$W_{n\to n'} = |\langle n'|e^{-ik\hat{x}}|n\rangle|^2.$$

Энергия испущенного γ-кванта при этом $\varepsilon_\gamma = \varepsilon - \hbar\omega\,(n' - n)$, где последнее слагаемое - это энергия, забираемая ядром. Случай $n' = n$ отвечает условию $\varepsilon_\gamma = \varepsilon$, следовательно, это и есть условие резонансного испускания. Вычислим вероятность резонансного испускания из основного состояния осциллятора:

$$W_{0\to 0} = |\langle 0|e^{-ik\hat{x}}|0\rangle|^2 = \left|\frac{1}{x_0\sqrt{\pi}}\int\limits_{-\infty}^{+\infty} e^{-ikx}e^{-\left(\frac{x}{x_0}\right)^2}dx\right|^2 = e^{-\frac{x_0^2k^2}{2}}.$$

Мы получили так называемый фактор Дебая-Уоллера.

Куда девается энергия при эффекте Мессбауэра (??)

(!!! в теорию отнесу потом этот вопрос, тут тупо задача на метод.)

ПТФ-5.пр.1.2 Сжатие сферы с бесконечными стенками (?)

(!!! укажу и во введении и в других местах, почему именно так такую задачу решают!! потом напишу ее!!)

(первый порядок теории возмущений)

Пусть $U(\boldsymbol{r}) = \begin{cases} 0, & |\boldsymbol{r}| < R \\ \infty, & |\boldsymbol{r}| > R \end{cases}$

Гамильтониан можно записать через недеформированный как:

$$\hat{H} = \frac{\hat{p}^2}{2m} = \frac{\hat{p}^2}{2m} + \frac{\hat{p}_z^2}{2m}\left(\left(\frac{r}{R'}\right)^2 - 1\right) \approx \underbrace{\frac{\hat{p}^2}{m}}_{\hat{H}_0} + \underbrace{\frac{\hat{p}_z^2 \epsilon}{m}}_{\hat{V}}$$

Уравнение Шредингера:

$$-\frac{1}{2m}\left(\frac{\partial^2\psi}{\partial r^2} + \frac{2}{r}\frac{\partial\psi}{\partial r}\right) = E\psi(r), \quad \psi(r=R) = 0$$

(?? дальше не улавливаю суть)

$$-\frac{1}{2m}\chi''(r) = E\chi(r) \to \chi(r) = A\sin(kr) + B\cos(kr), \quad \frac{k^2}{2m} = E$$

$$\int_0^r 4\pi r^2 dr \cdot \frac{\sin^2 kr}{r^2} = 2\pi R \to \psi(r) = \frac{1}{\sqrt{2\pi r}}\frac{\sin kr}{r}$$

$$E_0^{(1)} = \frac{\pi^2}{3mR^3}\epsilon$$

Указания на общий метод решения задач с сжатием размеров (???)

(по идее это в теории напишу)

Г-8.15. Стационарные состояния в Кулоне с а) $U_0/\left(e^{r/a}-1\right)$, б) $-U_0 a e^{-r/a}/r$

Частица находится в центральном потенциале вида а) $U = -U_0/\left(e^{r/a}-1\right)$ б) $U = -U_0 a e^{-r/a}/r$, причем $U_0 \gg \hbar^2/ma^2$. В первом порядке теории возмущений найти отличие энергетических уровней нижней части спектра от уровней в кулоновском поле $U = -U_0 a/r$. Обратить внимание на снятие случайного кулоновского вырождения уровней.

Solution.

8.15. При $r \ll a$ рассматриваемые потенциалы имеют вид $U \approx -U_0 a/r$. В таком кулоновском поле в. ф. нижних энергетических уровней локализованы на расстоянии порядка $r_n \sim a_0 n^2$ от центра поля; здесь $a_0 = \hbar^2/m^2 U_0, n$ - главное квантовое число. Если $r_n \ll a$ (т. е. $\xi \equiv ma^2U_0/\hbar^2 \gg n^2$), то, очевидно, в нулевом приближении искомые уровни нижней части спектра и соответствующие им с.ф. будут такие же, как и в кулоновском поле:

$$E_{n_r l}^{(0)} = -\frac{ma^2U_0^2}{2\hbar^2 n^2}, \quad \Psi_{n_r lm}^{(0)} = \Psi_{n_r lm}^{\text{Ky}J},$$

см. (IV.3). При этом отличие рассматриваемых потенциалов от кулоновского играет роль возмущения $V(r) = U(r) + U_0 a/r$. Ввиду того что орбитальный момент частицы является интегралом движения и при действии возмущения, с.ф. (1) являются правильными функциями нулевого прибінжения и поправка первого порядка определяется выражением

$$E_{n_r l}^{(1)} = \int V(r)|\Psi_{n_r lm}^{(0)}|^2 d^3r.$$

а) Разлагая потенциал возмущения в ряд по степеням r/a, что дает и учитывая значение интеграла (см. [1, §36]) согласно (2) - (4) находим

$$E_{n_r l}^{(1)} = U_0\left\{\frac{1}{2} - \frac{3n^2 - l(l+1)}{24\xi}\right\}, \quad n = n_r + l + 1$$

6) Теперь $V \approx U_0\left(1 - r/2a + r^2/6a^2\right)$ и

$$E^{(1)}_{n_r l} = U_0\left\{1 - \frac{3n^2 - l(l+1)}{4\xi} + \frac{n^2}{12\xi^2}\left[5n^2 + 1 - 3l(l+1)\right]\right\}.$$

Как видно из (5) и (6), случайное кулоновское вырождение уровней по l снимается.

Заметим, что для потенциала Хюльтена у. Ш. для s-состояний допускает точное решение, см. 4.8. При этом (для $l = 0$) $E^{(0)}_{n_r 0}$ совместно с (5) описывают точный результат.

ADD PROBLEMS FROM GALITSKI!!!

17.1.3 Problems about Time-Independent PT 3

Г-8.16.

Для частицы в центральном потенциале $U = -\alpha/r^v$, причем $0 < v < 2$, найти энергетические уровни $E_{n_r l}$ с большим значением момента $l \gg 1$ и с не слишком большим радиальным квантовым числом n_r. В случае кулоновского потенциала, $v = 1$, сравнить полученный результат с точным.

Solution.

Г-8.17.

То же, что и в предыдущей задаче, но для потенциала $U = \alpha r^v$ с $\alpha, v > 0$ (теперь $E_{n_r l} > 0$). В случае сферического осциллятора, $v = 2$, сравнить полученный результат с точным.

Solution.

Г-8.18.

Частица находится внутри непроницаемого эллипсоида вращения, так что потенциал имеет вид

$$U(x,y,z) = \begin{cases} 0, & \left(x^2+y^2\right)/a^2 + z^2/b^2 < 1, \\ \infty, & \left(x^2+y^2\right)/a^2 + z^2/b^2 \geqslant 1, \end{cases}$$

причем $|a - b| \ll a$. Найти в первом порядке теории возмущений сдвиг основного энергетического уровня по отношению к уровню в сферической яме такого же объема.

Solution.

Г-8.19.

Обобщить результат предыдущей задачи на случай возбужденных состояний частицы. Обсудить вопрос о характере снятия вырождения по проекциям момента в первом и более высоких порядках теории возмущений.

Solution.

Киселев-?(m) Два уровня, один из которых вырожден

Рассмотрим систему, гамильтонан которой представляет собой матрицу 3×3, которая описывает двукратно вырожденный уровень энергии E_1 и отделённый от него энергетической щелью уровень энергии E_2. Недиагональные элементы гамильтониана - возмущение, дающее туннелирование между этими уровнями энергии, и оно не снимает вырождение в первом порядке теории возмущений:

$$\hat{H} = \begin{pmatrix} E_1 & 0 & t_1 \\ 0 & E_1 & t_2 \\ t_1 & t_2 & E_2 \end{pmatrix}, \quad |\Delta| = |E_2 - E_1| \gg t^2_{1,2}$$

Определить уровни энергии.

Solution.

Разумеется, задачу эту можно решить точно. Точные собственные значения записываются следующим образом:

$$E = \left\{ E_1, \quad \frac{1}{2}\left(E_1 + E_2\right) \pm \sqrt{(\Delta/2)^2 + |t_1|^2 + |t_2|^2} \right\} \approx \left\{ E_1 - \frac{t_1^2 + t_2^2}{\Delta}, \quad E_1, \quad E_2 + \frac{t_1^2 + t_2^2}{\Delta} \right\}$$

Поскольку возмущение не связывает состояния с вырожденного подпространства, то можно было бы попробовать наивно применить второй порядок невырожденной теории возмущений (5.8):

$$E_{1,1}^{(2)} = \frac{|V_{13}|^2}{E_1 - E_2} = -\frac{t_1^2}{\Delta}, \quad E_{1,2}^{(2)} = \frac{|V_{23}|^2}{E_1 - E_2} = -\frac{t_2^2}{\Delta}, \quad E_2^{(2)} = \frac{|V_{31}|^2}{E_2 - E_1} + \frac{|V_{32}|^2}{E_2 - E_1} = \frac{t_1^2 + t_2^2}{\Delta}$$

что для уровня энергии E_2 даёт правильный ответ, а для вырожденного уровня E_1 - нет. Чтобы получить правильные ответы, необходимо пользоваться вторым порядком вырожденной теории возмущений. Рецепт говорит, что необходимо составить эффективный гамильтониан для первых двух уровней:

$$H_{11}^{(\text{eff})} = \frac{V_{13}V_{31}}{E_2 - E_1} = -\frac{t_1^2}{\Delta}, \quad H_{12}^{(\text{eff})} = H_{21}^{(\text{eff})} = \frac{V_{13}V_{32}}{E_2 - E_1} = -\frac{t_1 t_2}{\Delta}, \quad H_{22}^{(\text{eff})} = \frac{V_{23}V_{32}}{E_2 - E_1} = -\frac{t_2^2}{\Delta} =$$

поэтому

$$\hat{H}^{(\text{eff})} = -\frac{1}{\Delta}\begin{pmatrix} t_1^2 & t_1 t_2 \\ t_1 t_2 & t_2^2 \end{pmatrix}$$

Диагонализуя матрицу, мы получаем поправки второго порядка к вырожденному уровню:

$$E_{1,1}^{(2)} = 0, \quad E_{1,2}^{(2)} = -\frac{t_1^2 + t_2^2}{\Delta}$$

которые на сей раз воспроизводят правильный ответ (5.27), полученный из точного решения. Наивный же подход не учитывает недигональные элементы матрицы эффективного гамильтониана, которые дают вклад того же порядка, что и диагональные.

Landau-Inst-summer-2025.8/8. Repulsive ball in a sphere

A particle of mass m is in the ground state in a spherical cavity of radius R with infinite walls:

$$U(\boldsymbol{r}) = \begin{cases} 0, & r < R, \\ \infty, & r \geqslant R. \end{cases}$$

To an arbitrary point $\boldsymbol{r}_0$ inside the sphere, located at a distance of $r_0 < (R - a)$ from the center, an impurity is placed, which is an impenetrable ball of radius $a \ll R$:

$$\delta U(\boldsymbol{r}) = \begin{cases} 0, & |\boldsymbol{r} - \boldsymbol{r}_0| > a, \\ \infty, & |\boldsymbol{r} - \boldsymbol{r}_0| \leqslant a. \end{cases}$$

Determine the energy shift of the ground state in the first non-vanishing order by a.

Solution.

(??? a really good problem, I'll think when I work out theory and other problems)
I guess one needs to use first order perturbation theory and evaluate accurately the integral, by approximating it by delta-function with strength that is depended a.
(???)

17.1.4 Problems about Time-Dependent PT 1

ADD PROBLEMS FROM GALITSKI!!!

Leuven-s6.ex1 The two-state system

Consider a two-state system with the Hamiltonian $H_0 = \begin{pmatrix} E_1^0 & 0 \\ 0 & E_2^0 \end{pmatrix}$ with a time-dependent perturbation $V = \begin{pmatrix} 0 & \lambda\cos(\omega t) \\ \lambda\cos(\omega t) & 0 \end{pmatrix}$, with $\lambda \in \mathbb{R}$ and little.

At $t = 0$ the system is known to be in the first state $|1\rangle$ represented by $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$.

Assume that $E_1^0 - E_2^0$ is not close to $\pm\hbar\omega$, derive an approximate expression for the probability that the system is found in the state $|2\rangle$ as a function of time ($t > 0$).

Why is this procedure not valid when $E_1^0 - E_2^0$ is close to $\pm\hbar\omega$?

Solution

We use the framework of time-dependent perturbation theory, and we already have formulas for the change of the wavefunction, thus we just plug there our perturbation and get the answer.

1. We need $|c_2^{(1)}(t)|^2$, where

$$c_2^{(1)}(t) = -\frac{i}{\hbar}\int_0^t e^{i\omega_{21}t'}\langle 2|\hat{V}|1\rangle dt' = -\frac{i}{\hbar}\int_0^t e^{i\omega_{21}t'}\lambda\cos(\omega t')\,dt' = \frac{i\lambda}{2\hbar}\int_0^t e^{i(\omega_{21}-\omega)t'} + e^{i(\omega_{21}+\omega)t'}\,dt'$$

We introduce $\omega_\pm = \omega_{21} \pm \omega$, so the coefficient is given by

$$c_2^{(1)} = -\frac{\lambda}{2\hbar}\left[\frac{e^{i\omega_- t} - 1}{\omega_-} + \frac{e^{i\omega_+ t} - 1}{\omega+}\right]$$

After some algebra (write it!!), we have

$$|c_2^{(1)}|^2 = \frac{\lambda^2}{\hbar^2}\left[\frac{\sin^2(\omega_- t/2)}{\omega_-^2} + \frac{\sin^2(\omega_+ t/2)}{\omega_+^2} + \frac{\cos(\omega t)\left(\cos(\omega t) - \cos(\omega_{21} t)\right)}{\omega_{21}^2 - \omega^2}\right]$$

2. If $E_1^0 - E_2^0$ is close to $\pm\hbar\omega$, then $\omega_{21}^2 - \omega^2 \approx 0$, so the perturbative framework is no longer valid.
(???? what it the limit of littleness of λ???)

Г-8.33.

Заряженный линейный осциллятор подвергается воздействию однородного электрического поля, изменяющегося во времени по закону: а) $\mathscr{E}(t) = \mathscr{E}_0\exp\left(-t^2/\tau^2\right)$, б) $\mathscr{E}(t) = \mathscr{E}_0\left(1 + t^2/\tau^2\right)^{-1}$, в) $\mathscr{E}(t) = \mathscr{E}_0\exp\left(-t^2/\tau^2\right)\cos\omega_0 t$. Считая, что до включения поля (при $t \to -\infty$) осциллятор находился в n-м квантовом состоянии, найти в первом порядке теории возмущений вероятности возбуждения различных его состояний при $t \to +\infty$. Для случая $n = 0$ сравнить полученный результат с точным, см. 6.25.

Solution.

(add the original solution and problem in English!)

Г-8.34.

На плоский ротатор, имеющий дипольный момент d, накладывается однородное, переменное во времени электрическое поле $\mathscr{E}(t) = \mathscr{E}(t)\mathbf{n}_0$. До включения поля ротатор имел определенное значение энергии и проекции момента m. Вычислить в первом порядке теории возмущений вероятности различных значений проекции момента и энергии ротатора при $t \to +\infty$. Рассмотреть конкретные виды $\mathscr{E}(t)$, указанные в предыдущей задаче.

Solution.

(add the original solution and problem in English!)

Г-8.35.

То же, что и в предыдущей задаче, но для сферического ротатора. До включения электрического поля ротатор находился в состоянии с квантовыми числами $l, l_z = m$; поле направлено вдоль оси z.

Solution.

(add the original solution and problem in English!)

Г-8.36.

В условиях задачи 8.34 рассмотреть переходы ротатора в случае, когда вектор электрического поля вращается в плоскости вращения ротатора с угловой скоростью ω_0, так что $\mathscr{E}_x = \mathscr{E}(t)\cos\omega_0 t, \mathscr{E}_y = \mathscr{E}(t)\sin\omega_0 t$. Обратить внимание на возможность существенного возрастания вероятности перехода даже в случае «Плавной» зависимости $\mathscr{E}(t)$ вида) и б) из 8.33.

Solution.

(add the original solution and problem in English!)

Получить выражения для волновой функции и амплитуды перехода системы из начального. (при $t \to -\infty$) n-го состояния дискретного спектра в ко-

Solution.

(add the original solution and problem in English!)

Б-2.8.9 δ-potential with $\hat{\mathrm{V}}(t) = Fx\cos\omega t$

Find the probability of transition of a particle in a bound state in the field of a δ well into a continuous spectrum under the influence of an external field of the form $\hat{\mathrm{V}}(t) = Fx\cos\omega t$ in the case when $\hbar\omega > \hbar^2\varkappa_0^2/(2m)$.

Solution.

We use Fermi golden rule (since we have a periodic potential), for which we just compute the matrix element and known properties of delta-potential.

$$\hat{\mathrm{H}} = \frac{\hat{\mathrm{p}}^2}{2m} - \frac{\hbar^2}{m}\varkappa_0\delta(x) + \frac{Fx}{2}\left(e^{i\omega t} + e^{-i\omega t}\right).$$

$$\psi_0^{(0)}(x) = \sqrt{\varkappa_0}e^{-\varkappa_0|x|}, \qquad E_0^{(0)} = E_0 = -\frac{\hbar^2\varkappa_0^2}{2m}$$

$$w = \frac{2\pi}{\hbar}\int |F_{\nu 0}|^2\delta\left(E_\nu - E_0 - \hbar\omega\right)d\nu,$$

где ν - квантовое число, нумерующие состояния непрерывного спектра. Прежде всего рассмотрим случай $\hbar\omega \gg |E_0|$, т. е. приближение, когда δ-потенциал не действует на частицу в конечном состоянии. Тогда в качестве волновой функции конечного состояния можно просто выбрать функцию свободной частицы:

$$\psi_k(x) = \frac{1}{\sqrt{2\pi}}e^{ikx}, \qquad \nu = k \in (-\infty, \infty), \qquad E_k = \frac{\hbar^2k^2}{2m}.$$

$$F_{k0} := \langle\psi_0^{(0)}|\frac{Fx}{2}|\psi_k(x)\rangle = \frac{F\sqrt{\varkappa_0}}{2\sqrt{2\pi}}\int\limits_{-\infty}^{\infty} xe^{-\varkappa_0|x|+ikx}dx = i\frac{2F\varkappa_0^{3/2}k}{\sqrt{2\pi}\left(k^2+\varkappa_0^2\right)^2},$$

(we take away the time-dependent part of the perturbation (?? why??))

After using $\delta(f(x)) = \sum_{i=1}^{n} \frac{\delta(x-x_i)}{|f'(x_i)|}$, one gets (??? do it!!)

$$w = \frac{2\pi}{\hbar}\left[|F_{k_10}|^2 + |F_{k_20}|^2\right]\left|\frac{dE_k}{dk}\right|^{-1}, \qquad k_{1,2} = \pm\frac{1}{\hbar}\sqrt{2m\left(\hbar\omega + E_0\right)}.$$

(do computations here!)

$$w = \frac{2\hbar F^2}{m(\hbar\omega)^4}|E_0|^{3/2}\sqrt{\hbar\omega - |E_0|}.$$

Solution for the case $\hbar\omega \gtrsim |E_0|$

In this case, it is necessary to choose the exact eigenfunctions of the undisturbed Hamiltonian (for a continuous spectrum) as the zero approximation functions. Since the undisturbed Hamiltonian commutes with the inversion operator, even and odd functions can be considered separately. Obviously, even functions will give zero contribution to the matrix element. Odd solutions have the form $\psi_k(x) = (1/\sqrt{\pi})\sin kx$. Calculating the probability with these functions leads us back to the formula

$$w = \frac{2\hbar F^2}{m(\hbar\omega)^4}|E_0|^{3/2}\sqrt{\hbar\omega - |E_0|}.$$

(??? do the computations)

And if there $\hbar\omega < |E_0|$, there will be never a transfer to continuum state.

Б-2.8.10 Transition in $V(t) = \frac{V_0}{2}\left(1 + \frac{2}{\pi}\operatorname{arctg}\frac{t}{\tau}\right)$

Find the formula for a probability of transition between states of a discrete spectrum of an abstract quantum system under $V(t) = \frac{V_0}{2}\left(1 + \frac{2}{\pi}\operatorname{arctg}\frac{t}{\tau}\right)$.

Solution.

We use the basic time-dependent perturbation theory.

$$W_{fi}(t) = \frac{1}{\hbar^2}\left|\int\limits_{-\infty}^{t} V_{fi}\left(t'\right)e^{i\omega_h t'}dt'\right|^2 \equiv \frac{|V_{0ji}|^2}{4\hbar^2}|I(t)|^2,$$

(??? what is I?)

Here, the upper limit of the integral t must be further limited to infinity. In order not to get a divergence, we integrate by parts

$$I(t) = \frac{e^{i\omega_{fi}t'}}{i\omega_{fi}}\left[1 + \frac{2}{\pi}\operatorname{arctg}\frac{t'}{\tau}\right]\Bigg|_{-\infty}^{t} - \frac{2\tau}{i\pi\omega_{fi}}\int\limits_{-\infty}^{t}\frac{e^{i\omega_{fi}t'}dt'}{t'^2+\tau^2}.$$

Here, the first term describes the correction of the first approximation to the initial wave function at $t > 0$ and does not contribute to the transitions. (??? why?? this is how we get rid of infinities!)

Quantum transitions are described by the second term, and after striving $t \to \infty$, the integral is taken by (???? I forgot, how to take it???? write here! by residues https://www.youtube.com/watch?v=jpT0maiGZAY&ab_channel=CrystalMath...) Anyway, we use $\int_{-\infty}^{\infty}\frac{e^{itx}}{1+x^2}dx = \begin{cases}\pi e^{-t}, & \text{for } t > 0\\ \pi, & \text{for } t = 0\end{cases}$ and we get

$$W'_{fi} = \frac{|V_{0fi}|^2}{\hbar^2\omega_{fi}^2}e^{-2\omega_{fi}\tau}.$$

Б-2.8.11 Oscillator and increasing field

For a charged linear harmonic oscillator that is initially in the ground state, determine the probabilities of transitions to various excited states under the influence of a homogeneous electric field of the form

$$\mathcal{E} = \begin{cases}0, & t < 0,\\ \mathcal{E}_0\frac{t}{\tau}, & 0 \leqslant t \leqslant \tau,\\ \mathcal{E}_0, & t > \tau\end{cases}$$

Consider the limits of instantaneous and slow field activation.

Solution.

This problem is typical for time-dependent perturbation theory, one needs to apply basic formulas and also get rid of some typical divergence of an integral.

$$\hat{\mathrm{H}} = \frac{\hat{\mathrm{p}}^2}{2m} + \frac{m\omega^2 x^2}{2} - e\mathcal{E}x,$$

$$a_{0n}^{(1)} = \frac{1}{i\hbar}\int\limits_{-\infty}^{t} V_{n0}\left(t'\right) e^{i\omega_{n0}t'}dt' \overset{\text{i b p}}{=} i\int\limits_{-\infty}^{t} \frac{\partial V_{n0}\left(t'\right)}{\partial t'}\frac{e^{i\omega_{n0}t'}}{\hbar\omega_{n0}}dt' + \text{const.}$$

Here we said that the first term after i.b.p. is zero (??? think more, why exactly it is so???)

The only nonzero matrix element is

$$V_{10} = -e\mathcal{E}\langle 1|\hat{x}|0\rangle = -\frac{e\mathcal{E}x_0}{\sqrt{2}}, \qquad x_0 := \sqrt{\frac{\hbar}{m\omega}}.$$

$$W_{0\to 1} = W_0\frac{\sin^2\left(\frac{\omega\tau}{2}\right)}{\left(\frac{\omega\tau}{2}\right)^2}, \qquad W_0 := \frac{e^2\varepsilon^2}{2\hbar m\omega^3}.$$

В случае мгновенного включения поля ($\omega\tau \ll 1$) имеем $W_{0\to 1} \simeq W_0$.

При адиабатически медленном включении поля ($\omega\tau \gg 1$) получим $W_{0\to 1} \simeq 0$, т. е. переходы в возбужденные состояния практически не происходят.

Б-2.8.12 Muon in a rotating field

Muon, which is at rest in a strong homogeneous magnetic field $\mathcal{H}_0 \| z$, is affected by a weak circularly polarized radio frequency field $\mathbf{h}(t) \perp \mathcal{H}_0$. Find the time dependence of the spin function $\chi(t)$ and the muon polarization $\mathbf{P}(t) = \langle\chi(t)|\hat{\sigma}|\chi(t)\rangle$, if at the initial moment $\chi(0) = \chi_{1/2}$.

Hint: here the muon is just a particle with spin 1/2, and only spin component of it is affected by a magnetic field. It has interaction with magnetic field by a magnetic dipole term.

Solution by perturbation theory

The model is as follows:

$$ih\frac{\partial}{\partial t}\chi(t) = \hat{\mathrm{H}}\chi(t),$$

and the interaction with the field is

$$\hat{\mathrm{H}} = -\mu_0(\hat{\boldsymbol{\sigma}}\boldsymbol{\mathcal{H}})\chi(t) = -\mu_0\left(\hat{\sigma}\mathcal{H}_0\right) - \mu_0(\hat{\boldsymbol{\sigma}}\mathbf{h}) = \underbrace{-\mu_0\left(\hat{\boldsymbol{\sigma}}\boldsymbol{\mathcal{H}}\right)}_{\hat{\mathrm{H}}_0}\underbrace{-\mu_0 h\left(\hat{\sigma}_x\cos\omega t + \hat{\sigma}_y\sin\omega t\right)}_{\hat{\mathrm{V}}(t)}. \quad \omega_0 := \gamma\mathcal{H}_0, \quad \gamma := e/(mc)$$

Here

$$\hat{\mathrm{H}}_0 = -\mu_0\mathcal{H}_0\hat{\sigma}_z = -\left(\hbar\omega_0/2\right)\hat{\sigma}_z,$$

and we used the gyromagnetic ratio $\mu_0 = \gamma\hbar/2$.

At the zero order one has

$$\hat{\mathrm{H}}_0\chi^{(0)} = E^{(0)}\chi^{(0)}; \quad E_{1,2}^{(0)} = \mp\mu_0\mathcal{H}_0 = \mp\frac{\hbar\omega_0}{2}, \quad \chi_{1,2}^{(0)} = \chi \pm 1/2.$$

(??? calculate the matrix element here!!!! just multiply matrices by raw and column, it should be very easy)
(check that $V_{11} = 0$, thus $a_{11} = 0$)

$$a_{12}^{(1)} = \frac{1}{i\hbar}\int\limits_0^t V_{21}\left(t'\right)e^{i\omega_0 t'}dt' \overset{\omega_1 := \gamma h}{=} -\frac{\omega_1}{2i}\int\limits_0^t e^{i(\omega+\omega_0)t'}dt' = \frac{\omega_1}{2\left(\omega+\omega_0\right)}\left(e^{i(\omega+\omega_0)t} - 1\right),$$

Thus

$$\chi(t) \approx \begin{pmatrix} e^{i\frac{\omega_0 t}{2}} \\ \frac{\omega_1}{2(\omega+\omega_0)}\left(e^{i(\omega+\omega_0)t} - 1\right)e^{-i\frac{\omega_0 t}{2}} \end{pmatrix}.$$

The conditions of applicability of perturbation theory is $|a_{12}^{(1)}|$ $ll1$. This can be implemented either with $\omega_1 \ll |\omega+\omega_0|$, i.e. the system must be far from resonance: $\omega \not\approx -\omega_0$, or with a short duration of the disturbance. Both options do not allow us to consider resonant phenomena in detail, thus one needs to have a better solution then perturbation theory.

Exact solution

The model is as follows:

$$ih\frac{\partial}{\partial t}\chi(t) = \hat{\mathrm{H}}\chi(t),$$

and the interaction with the field is

$$\hat{\mathrm{H}} = -\mu_0(\hat{\boldsymbol{\sigma}}\boldsymbol{\mathcal{H}})\chi(t) = -\mu_0\left(\hat{\sigma}\mathcal{H}_0\right) - \mu_0(\hat{\boldsymbol{\sigma}}\mathbf{h}) = \underbrace{-\mu_0\left(\hat{\boldsymbol{\sigma}}\boldsymbol{\mathcal{H}}\right)}_{\hat{\mathrm{H}}_0}\underbrace{-\mu_0 h\left(\hat{\sigma}_x\cos\omega t + \hat{\sigma}_y\sin\omega t\right)}_{\hat{\mathrm{V}}(t)}. \quad \omega_0 := \gamma\mathcal{H}_0, \quad \gamma := e/(mc)$$

Here

$$\hat{\mathrm{H}}_0 = -\mu_0\mathcal{H}_0\hat{\sigma}_z = -\left(\hbar\omega_0/2\right)\hat{\sigma}_z,$$

We solve as

$$\chi(t) := \begin{pmatrix} C_1 \\ C_2 \end{pmatrix} \qquad \begin{cases} i\dot{C}_1 = -\dfrac{\omega_0}{2}C_1 - \dfrac{\omega_1}{2}e^{-i\omega t}C_2, \\ i\dot{C}_2 = -\dfrac{\omega_1}{2}e^{i\omega t}C_1 + \dfrac{\omega_0}{2}C_2, \end{cases} \qquad \begin{cases} C_1(0) = 1, \\ C_2(0) = 0, \end{cases}.$$

We substitute

$$C_1 = e^{-\frac{1}{2}\omega t}a, \qquad C_2 = e^{\frac{1}{2}\omega t}b$$

to get rid of time-dependence and get

$$\frac{d}{dt}\begin{pmatrix} a \\ b \end{pmatrix} = -i\begin{pmatrix} \varepsilon & \omega_1 \\ \omega_1 & -\varepsilon \end{pmatrix}\begin{pmatrix} a \\ b \end{pmatrix}, \qquad \begin{pmatrix} a(0) \\ b(0) \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \qquad \varepsilon := \omega + \omega_0.$$

$$\begin{pmatrix} a \\ b \end{pmatrix} \equiv e^{i\Lambda t}\begin{pmatrix} 1 \\ 0 \end{pmatrix}; \qquad \Lambda := \begin{pmatrix} \varepsilon & \omega_1 \\ \omega_1 & -\varepsilon \end{pmatrix} \equiv \Omega\begin{pmatrix} \varepsilon/\Omega & \omega_1/\Omega \\ \omega_1/\Omega & -\varepsilon/\Omega \end{pmatrix}, \qquad \Omega := \sqrt{\varepsilon^2 + \omega_1^2}.$$

Because $\Lambda^2 = \Omega^2 \cdot \mathbf{1}$, all even powers of the matrix Λ will be proportional to the identity matrix, and we arrive at the relation (??? check!!)

$$e^{i\Lambda t} = \cos\Omega t\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + i\frac{\sin\Omega t}{\Omega}\begin{pmatrix} \varepsilon & \omega_1 \\ \omega_1 & -\varepsilon \end{pmatrix} = \cos\Omega t + i\frac{\Lambda}{\Omega}\sin\Omega t.$$

So, we have:

$$\begin{pmatrix} a \\ b \end{pmatrix} = \cos\Omega t\begin{pmatrix} 1 \\ 0 \end{pmatrix} + i\frac{\sin\Omega t}{\Omega}\begin{pmatrix} \varepsilon \\ \omega_1 \end{pmatrix}.$$

Thus, the answer is

$$\chi(t) = \begin{pmatrix} \left[\cos\left(\frac{\Omega}{2}t\right) + i\frac{\varepsilon}{\Omega}\sin\left(\frac{\Omega}{2}t\right)\right]e^{-i\frac{\omega}{2}t} \\ i\frac{\omega_i}{\Omega}\sin\left(\frac{\Omega}{2}t\right)e^{i\frac{\omega}{2}t} \end{pmatrix}.$$

Вероятность переворота спина, вычисленная при помощи данной функции, в точности совпадает с найденной в задаче 2.5.6. Реализация условия $\omega_1 \ll |\varepsilon|$ позволяет получить результат теории возмущений (3). Точный и приближенный результаты согласуются также и при малом времени действия возмущения $\Omega 2t \ll 1$.

Приведем также значения проекций вектора поляризации мюона:

$$\begin{aligned} \mathrm{P}_x &= \sin\theta[\cos\theta(1-\cos\Omega t)\cos\omega t - \sin\Omega t\sin\omega t], \\ \mathrm{P}_y &= \sin\theta[\cos\theta(1-\cos\Omega t)\sin\omega t + \sin\Omega t\cos\omega t], \\ P_z &= \cos^2\theta + \sin^2\theta\cos\Omega t \end{aligned}$$

где $\sin\theta = \omega_{\mathrm{I}}/\Omega, \cos\theta = \varepsilon/\Omega$, что совпадает с обозначениями задачи 2.5.6.

(?? it should be easy to derive it, do it!!)

Заметим, что фактически мы нашли оператор эволюции для данной задачи, который, как нетрудно сообразить, будет иметь вид $\hat{\mathrm{U}}(t) = e^{-\frac{t}{2}\omega\hat{\sigma}_z t}e^{i\Lambda t}$, где первая экспонента отвечает начальной замене переменных (переходу $C_1, C_2 \to a, b$). Подумайте, совпадает ли этот оператор с оператором эволюции, полученным другим методом в задаче 2.5.6.

Solution with circular motion

(??? the particle is also moving, right? Why one does not consider this??? or maybe it does not affect spin component anyway?)

ПТФ-8.з1. Осцилляция Раби

An alternating electric field is applied to the hydrogen atom in the ground state. $\hat{V} = -e\mathcal{E}\hat{z}\cos(\omega t)$, with the frequency near $\frac{3}{4}$Ry, which we write by introduction of a little frequency ε as $\omega = \frac{3}{4}\text{Ry} + \varepsilon$. The field satisfies $e\mathcal{E}a$, $\varepsilon \ll$ Ry. The ratio of the $\mathcal{E}$ field and the ε frequency tuning is, generally speaking, arbitrary. Determine the probability of detecting a particle in the ground and first excited states $n = 1$ and $n = 2$ after a long time T.

Reminder: Ry $= \frac{me^4}{2\hbar^2}$ – постоянная Ридберга, а $a = \frac{1}{me^2}$ – Боровский радиус.

Solution.

This problem is a typical for time-dependent PT.

$$i\hbar\frac{\partial}{\partial t}|\psi(t)\rangle = (\hat{H}_0 + \hat{V}(t))|\psi(t)\rangle$$

$$\hat{H}_0 = \frac{\hat{p}^2}{2m} - \frac{e^2}{r}, \quad \hat{V}(t) = -e\mathcal{E}\hat{z}\cos(\omega t), \quad \hat{z} = r\cos\theta$$

Эволюция основного и возбуждённого состояний, если бы не было возмущения: (??? check that indeed energies are indeed so)

$$|\psi_1(t)\rangle = e^{-\frac{\text{iRyt}}{\hbar}}|\psi_1\rangle, \quad |\psi_2(t)\rangle = e^{-\frac{\text{iRyt}}{4\hbar}}|\psi_2\rangle$$

Нестационарная теория возмущений:

$$i\hbar\frac{\partial\psi_2}{\partial t} = V_{21}\psi_1(t), \quad V_{21} = \langle\psi_2(t)|\hat{V}(t)|\psi_1(t)\rangle$$

$$i\hbar\frac{\partial\psi_2}{\partial t} = -e\mathcal{E}\cos(\omega t)e^{\frac{3i\text{Ryt}}{4\hbar}}\langle\psi_2|r\cos\theta|\psi_1\rangle\psi_1(t)$$

$$\langle\psi_2|r\cos\theta|\psi_1\rangle = \iint d\Omega r^3\cos\theta R_{2,1}Y_{1,0}R_{1,0}Y_{0,0} = \frac{2^6\sqrt{2}a}{3^4}$$

(?? check!!)

Остальные усреднения с ψ_2 при $n = 2$: $l = 0, m = 0$, $l = 1, m = -1$, $l = 1, m = 1$ дают 0 ввиду нечётности по углу θ. (??check!)

$$i\hbar\frac{\partial\psi_2}{\partial t} = -e\mathcal{E}(e^{i\omega t} + e^{-i\omega t})e^{\frac{3i\text{Ryt}}{4\hbar}}\frac{2^5\sqrt{2}a}{3^4}\psi_1(t) \approx 0 - e\mathcal{E}e^{-\frac{i\epsilon t}{\hbar}}\frac{2^5\sqrt{2}a}{3^4}\psi_1(t),$$

here we пренебрегли быстроосциллирующим слагаемым.

The same way one gets (check!!)

$$i\hbar\frac{\partial\psi_1}{\partial t} = -e\mathcal{E}e^{\frac{i\epsilon t}{\hbar}}\frac{2^5\sqrt{2}a}{3^4}\psi_2(t)$$

Totally, one has:

$$\frac{\partial\psi_1}{\partial t} = i\frac{e\mathcal{E}a}{\hbar}e^{\frac{i\epsilon t}{\hbar}}\frac{2^5\sqrt{2}}{3^4}\psi_2(t),$$
$$\frac{\partial\psi_2}{\partial t} = i\frac{e\mathcal{E}a}{\hbar}e^{-\frac{i\epsilon t}{\hbar}}\frac{2^5\sqrt{2}}{3^4}\psi_1(t).$$

Решая полученную систему, получим

$$\psi_2(t) = -ie^{-i\frac{\epsilon}{2}t}\frac{C}{\sqrt{\epsilon^2 + C^2}}\sin\left(\frac{\sqrt{\epsilon^2 + C^2}}{2\hbar}t\right); \qquad C := \frac{2^6\sqrt{2}}{3^4}e\mathcal{E}a.$$

And we have the answer. The probability of being in an excited state:

$$P_{n=2}(T) = \frac{C^2}{\epsilon^2 + C^2}\sin^2\left(\frac{\sqrt{\epsilon^2 + C^2}}{2\hbar}T\right)$$

The probability of remaining in the ground state:

$$P_{n=1}(T) = 1 - \frac{C^2}{\epsilon^2 + C^2}\sin^2\left(\frac{\sqrt{\epsilon^2 + C^2}}{2\hbar}T\right)$$

ПТФ-8.з2. Landau-Zener problem by PT

Рассмотрим произвольную двухуровневую систему, описываемую волновой функцией $|\psi(t)\rangle = \begin{pmatrix}\psi_1(t)\\ \psi_2(t)\end{pmatrix}$ и следующим гамильтонианом, зависящим от времени: $\hat{H}(t) = \begin{pmatrix}\alpha t & \gamma\\ \gamma & -\alpha t\end{pmatrix}$. В начальный момент времени $t \to -\infty$, система находилась в первом состоянии (так что $|\psi_1(t \to -\infty)|^2 = 1$). Определите вероятность перехода системы во второе состояние после такой эволюции $|\psi_2(t \to \infty)|^2$, считая «скорость движения уровней» большой $\alpha \gg \gamma^2$.

Solution.

Выделим в гамильтониане невозмущённую и возмущённую части:

$$\hat{H}(t) = \hat{H}_0(t) + \hat{V}(t), \qquad \hat{H}_0(t) = \begin{pmatrix}\alpha t & 0\\ 0 & -\alpha t\end{pmatrix}, \qquad \hat{V} = \begin{pmatrix}0 & \gamma\\ \gamma & 0\end{pmatrix}$$

Эволюция состояний, если бы не было возмущения ($\gamma = 0$):

$$i\hbar\frac{\partial|\psi_1(t)\rangle}{\partial t} = \alpha t|\psi_1\rangle, \quad i\hbar\frac{\partial|\psi_2(t)\rangle}{\partial t} = -\alpha t|\psi_2\rangle$$

$$|\psi_1(t)\rangle = \exp\left(-i\frac{\alpha t^2}{2\hbar}\right)|\psi_1\rangle \qquad |\psi_2(t)\rangle = \exp\left(i\frac{\alpha t^2}{2\hbar}\right)|\psi_2\rangle,$$

Нестационарная теория возмущений:

$$i\hbar\frac{\partial\psi_2(t)}{\partial t} = V_{21}\psi_1(t), \quad V_{21} = \langle\psi_2(t)|\hat{V}|\psi_1(t)\rangle$$

$$V_{21} = \gamma\exp\left(-i\alpha t^2/\hbar\right)$$

It is really important that here we take matrix element with time-dependent wavefunctions.

$$i\hbar\frac{\partial\psi_2(t)}{\partial t} = \gamma\exp\left(-i\alpha t^2/\hbar\right)\psi_1(t) \approx \gamma\exp\left(-i\alpha t^2/\hbar\right)$$

This approximation is taken because anyway we know that the probability is little.

$$\psi_2(t \to \infty) = -\frac{i\gamma}{\hbar}\int\limits_{-\infty}^{\infty}\exp\left(-i\alpha t^2/\hbar\right)dt = \frac{\sqrt{\pi i}\gamma}{\sqrt{\alpha}\hbar}$$

(??? check $\hbar$ by dimensions????)
Вероятность перехода системы во второе состояние:

$$P = \frac{\pi\gamma^2}{\alpha\hbar^2}$$

ПТФ-8.з3. Осциллятор

Consider an electron moving in a harmonic oscillator and in an electric field that changes with time.:

$$\hat{H}(t) = \frac{\hat{p}^2}{2m} + \frac{m\omega^2\hat{x}^2}{2} + e\mathcal{E}(t)\hat{x}, \quad \mathcal{E}(t) = \mathcal{E}_0 e^{-\frac{t^2}{\tau^2}}$$

At $t \to -\infty$, the electron is in the ground state of the system. Determine the probability of detecting it in an arbitrary n-th excited state at $t \to +\infty$ in the leading order of perturbation theory (considering the field weak $e^2\mathcal{E}^2 \ll m\omega^3$).

Solution.

this needs to be think again!!!

Эволюция состояний, если бы не было возмущения:

$$|n(t)\rangle = e^{-i\omega(n+\frac{1}{2})t}|n(0)\rangle$$

$$V_{nm}(t) = -e\mathcal{E}_0 e^{-\frac{t^2}{\tau^2}}\langle n(t)|x|m(t)\rangle = -\frac{e\mathcal{E}_0 e^{-\frac{t^2}{\tau^2}}}{\sqrt{2m\omega}}\begin{cases} e^{i\omega t}\sqrt{n}, & m = n-1 \\ e^{-i\omega t}\sqrt{n+1}, & m = n+1 \end{cases}$$

n-ый порядок теории возмущений:

$$i\hbar\frac{\partial\psi_n(t)}{\partial t} = V_{nn-1}\psi_{n-1}(t) = -\frac{e\mathcal{E}_0 e^{-\frac{t^2}{\tau^2}}e^{i\omega t}}{\sqrt{2m\omega}}\sqrt{n}\psi_{n-1}(t)$$

$$\psi_n(t\to\infty) = \left(\frac{ie\mathcal{E}_0}{\hbar\sqrt{2m\omega}}\right)^n\sqrt{n!}\int\limits_{-\infty}^{\infty}d\tau_1 e^{-\frac{\tau_1^2}{\tau^2}+i\omega\tau_1}\int\limits_{-\infty}^{\tau_1}d\tau_2 e^{-\frac{\tau_2^2}{\tau^2}+i\omega\tau_2}...\int\limits_{-\infty}^{\tau_{n-1}}d\tau_n e^{-\frac{\tau_n^2}{\tau^2}+i\omega\tau_n}$$

Эти интегралы можно превратить в интеграл по всему $\mathbb{R}^n$, разделив на 2^{n-1}:

$$\psi_n(t\to\infty) = 2^{1-n}\left(\frac{ie\mathcal{E}_0}{\hbar\sqrt{2m\omega}}\right)^n\sqrt{n!}\int\limits_{\mathbb{R}^n}dt^n e^{-\frac{t^2}{\tau^2}}e^{i\omega\sum\limits_{i=1}^{n}t_i} = \frac{2}{\sqrt{n!}}\left(\frac{ie\mathcal{E}_0\sqrt{\pi}\tau e^{-\frac{\omega^2\tau^2}{4}}}{2\hbar\sqrt{2m\omega}}\right)^n$$

Вероятность оказаться в n-том состоянии:

$$P_n = \frac{4}{n!}\left(\frac{e^2\mathcal{E}_0^2\pi\tau^2 e^{-\frac{\omega^2\tau^2}{2}}}{8m\hbar^2\omega}\right)^n$$

(?? не очень понимаю, там Планк в знаменателе, от этого не будет ли большая вероятность? не должна быть, но из формулы это не очень видно)

ПТФ-8.з.4. Two-photon ionization (??????)

Fermi's golden rule is typically used to calculate the ionization intensity of a bound state in a one-dimensional delta well $U(x) = -\frac{\kappa}{m}\delta(x)$. Did the problem have an ionization threshold ? - in particular, when $\omega < E_0 = \frac{\kappa^2}{2m}$, the answer was zero. Of course, the reason for this is the use of first-order perturbation theory ('single-photon approximation"); the real answer is nonzero at all frequencies. In this task, it is proposed to investigate, how is the generalization of Fermi's golden rule based on the example of the same problem at frequencies $\frac{E_0}{2} < \omega < E_0$, where two-photon processes provide the leading contribution.

a) Derive a second-order correction of perturbation theory for a harmonic perturbation of the general form $\hat{V}(t) = \hat{F}e^{-i\omega t} + \hat{F}^\dagger e^{i\omega t}$ to an arbitrary coefficient $a_f(t)$, assuming that the particle was originally located in some state of the $|\psi_i\rangle$ discrete spectrum. The structure of the response allows for the following interpretation: the transition occurs first in a virtual way to a certain intermediate level of $i \to \nu$, and then ? - to the final state of $\nu \to f$. Note that the intermediate state of ν, generally speaking, refers to a continuous spectrum.

b) The resulting expression contains quite a lot of terms, having different interpretations, the time-dependent parts in the limit of $t \to \infty$ will turn into a delta function of a certain type. Given the absence of single-photon processes ($\omega < E_0$), demonstrate, that the contribution in the limit of $t \to \infty$ will be from only one member. Based on this, write out an analogue of Fermi's golden rule for this task.

c) Calculate the necessary matrix elements of transitions from the initial state to the intermediate state $F_{i\nu}$ and from the intermediate to the final state $F_{\nu f}$. Because as an intermediate, Similarly, the final states belong to a continuous spectrum., then the corresponding integral, formally speaking, diverges. To determine it, use, for example, the exponential regularization of $e^{-\alpha|x|}$, considering the limit of $\alpha \to 0$.

d) Calculate the necessary integral over the intermediate states of $d\nu$. If we use the matrix element from the previous paragraph at $\alpha \equiv 0$, The corresponding integral, generally speaking, will diverge, since it will contain a pole on the real axis. However, an arbitrarily small $\alpha \to 0$ will shift this pole into a complex plane, making it possible to calculate the integral using the deduction theorem. Finally, using the generalization of Fermi's golden rule derived in the second paragraph, write, how the probability of ionization works as a function of frequency. Express the answer in terms of the frequency ω, the energy of the bound state in the well E_0, and the mass m, the charge e and the amplitude of the electric field $\mathcal{E}$. Construct the answer numerically.

17.1.5 Problems about Time-Dependent PT 2

ФР. Переход в колодце под $\hat{V} = F_0 x^3 \frac{1}{1+t^2/\tau^2}$

На заряженную частицу, находящейся в бесконечно глубокой потенциальной яме шириной $a(0 < x < a)$, действует внешнее возмущение $\hat{V} = \mathrm{F_0 x^3} \frac{1}{1+\mathrm{t}^2/\tau^2}$. Считая, что до включения возмущения $(t \to -\infty)$ частица находилась в n-м возбужденном состоянии, найти в первом порядке теории возмущений вероятность его спонтанного перехода в основное состояние $(t \to \infty)$.

Solution.

(??? тут фигня какая-то, все нужно переписать!!!)

$$I = \int_a^a \sin\left(\frac{nx}{a}\right) \sin\left(\frac{\pi n x}{a}\right) x^3 dx = \int_0^{a_0^0} \frac{1}{2} \cos\left(\frac{\pi x}{a} - \frac{\pi n x}{a}\right) x^3 dx - \int_0^a \frac{1}{2} \cos\left(\frac{\pi n x}{a} + \frac{\pi x}{a}\right) x^3 dx$$

$$\int_0^a \cos\left(\frac{\Delta \pi x}{a}\right) x^3 dx = \frac{a^4}{A^4 \pi^4} \left\{6 + 3\left(-2 + \Delta^2 \pi^2\right) \cos(A\pi) + A\pi \left(A^2 \pi^2 - 6\right) \sin(A\pi)\right\}, n_0 \neq 0$$

Вычисление интегралов на wolfram (???)

(??? вроде какие-то у вольфрама проблемы с этим???)

Г-8.47. Внезапно

Система, описываемая гамильтонианом $\hat{H}_\mathbf{0}$, находится в n-м стационарном состоянии дискретного спектра. При $t = 0$ гамильтониан системы внезапно изменяется и становится равным (при $t > 0$) $\hat{H}_f = \hat{H}_0 + \hat{V}_0$, где $\hat{V}_0$, как и $\hat{H}_0$, от времени не зависят. Найти вероятности различных стационарных состояний системы при $t > 0$. Каково среднее значение энергии, приобретаемой системой? Показать, что в случае малого возмущения $\hat{V}_0$ установленные результаты могут быть получены также в рамках нестационарной теории возмущений.

Г-8.48. Переходы при внезапном воздействии дельта импульсом

Система подвергается импульсному воздействию $\hat{V} = \hat{W}_0 \delta(t)$, так что ее гамильтониан имеет вид $\hat{H} = \hat{H}_0 + \hat{W}_0 \delta(t)$. При $t < 0$ система находилась в n-м состоянии дискретного спектра. Найти вероятности различных квантовых состояний при $t > 0$. В случае $\hat{W}_0 = -xP_0$ дать наглядную интерпретацию полученного результата. Сравнить его для малого возмущения $\hat{V}$ с результатом нестационарной теории возмущений.

8.48. Для определения измеления волновой функции под влиянием импульсного воздействия его удобно рассматривать как предельный переход при $\tau \to 0$ взаимодействия вида $\nabla(t, \tau) = \tilde{W}_0 f(t)$, где функция $f(t)$ отлична от нуля лишь при $|t| < \tau$, Шрёдингера при $|t| < \tau$ принимает вид $i\hbar\dot{\Psi} = \hat{W}_0 f(t)\Psi$ (слагаемое $\hat{H}_0$ в гамильтониане опущено, так как оно не дает изменения в. ф. за бесконечно малый промежуток времени τ; в учтенном же слагаемом при этом $f(t) \sim 1/\tau \to \infty$). Решение этого уравнения

$$\Psi(t) = \exp\left(-\frac{i}{\hbar} \int_{-\tau}^{t} f\left(t'\right) dt' \hat{W}_0\right) \Psi(-\tau).$$

Положив здесь $t = \tau$ и устремляя $\tau \to 0$, находим искомое изменение волновой функции

$$\Psi(t = 0+) = \exp\left(-i\hat{W}_0/\hbar\right)\Psi(t = 0-).$$

Учитывая, что по условию задачи $\Psi(0-) = \Psi_n^{(0)}$, находим искомые вероятности

$$w(n \to k) = |\int \Psi_k^{(0)*} \exp\left(-\frac{i}{\hbar}\hat{W}_0\right)\Psi_n^{(0)} d\tau_q|^2.$$

Разложение экспоненты в ряд в случае малого возмущения, когда $|\,(\mathscr{W}_0)_{kn}\,| \ll \hbar$, дает

$$w^{(1)}(n \to k) = \frac{1}{\hbar^2}|\left(\hat{W}_0\right)_{kn}|^2, \quad k \neq n$$

что совпадает с результатом нестационарной теории возмущений, получающимся непосредственным (благодаря δ-функции) интегрированием в формуле (VIII.8).

Воздействие вида $V(x,t) = -xP_0\delta(t)$ на классическую частицу состоит в мгновенной передаче ей импульса $P_0 = \int F(t)dt$. Это утверждение остается справедливым и в квантовой механике, что следует из формулы (2). Действительно, в. ф. состояний частицы в импульсном представлении непосредственно до: $a_i(p) = \langle p|t = 0-\rangle$, и сразу после: $a_f(p) = \langle p|t = 0+\rangle$, воздействия связаны соотношением $a_f(p) = a_i\,(p - P_0)$, что и отражает отмеченное выше обстоятельство об изменении импульса частицы.

Г-8.49. Внезапно

Частица находится в основном состоянии в бесконечно глубокой потенциальной яме шириной a ($0 < x < a$). В некоторый момент времени правая стенка ямы за короткий интервал времени τ смещается в точку $b > a$. Найти вероятности возбуждения различных квантовых состояний частицы после остановки стенки.

Г-8.50. Внезапно

Частица находится в основном состоянии в δ-яме, так что $U = -\alpha\delta(x)$. Внезапно параметр α, характеризующий «глубину» ямы, изменяется и становится равным $\tilde{\alpha}$ (сравнить с изменением заряда ядра атома, например, при β-распаде). Найти

Г-8.52. Переходы при внезапном наложение поля на осциллятор

На заряженный осциллятор, находящийся в основном состоянии, внезапно накладывается однородное электрическое поле, направленное вдоль оси колебаний. Найти вероятности возбуждения различных состояний осциллятора после включения поля. Сравнить с результатом задачи 6.25.

Solution.

Для решения задачи важно понимать решение задачи о резком изменении гамильтониана $\hat{H}_0$ с дискретным спектром, который внезапно становится равным $\hat{H}_f = \hat{H}_0 + \hat{V}_0$, где $\hat{V}_0$, как и $\hat{H}_0$ от времени не зависят. В этой задаче важно видеть, что коэффициенты в разложении в. ф. $\Psi_{n,i}$ по с. ф. $\Psi_{k,f}$ конечного гамильтониана $\left(H_f = H_0 + \hat{V}_0\right)$,

$$\Psi_{n,i} = \sum_k c_{kn}\Psi_{k,f},$$

определяют искомые вероятности перехода:

$$w(n \to k) = |c_{kn}|^2 = |\langle k, f|n, i\rangle|^2.$$

В этих же обозначениях и будем решать эту задачу.

Воспользуемся формализмом операторов рождения и уничтожения $\hat{a}^+, \hat{a}$. Для невозмущенного осциллятора $\hat{a}_i = (2\hbar)^{-1/2}(\lambda x + i\lambda^{-1}\hat{p})$, где $\lambda = \sqrt{m\omega}$; при этом его основное состояние определяется соотношением $\hat{a}_i|0, i\rangle = 0$. Наложение электрического поля эквивалентно смещению точки равновесия осциллятора на расстояние $x_0 = e\mathscr{E}/m\omega^2$, так что теперь $\hat{a}_f = \hat{a}_i - \lambda(2\hbar)^{-1/2}x_0$, а конечные (при $t > 0$, после наложения поля) стационарные состояния определяются соотношениями

$$|n, f\rangle = \frac{1}{\sqrt{n!}}\left(\hat{a}_f^+\right)^n|0, f\rangle, \quad \hat{a}_f|0, f\rangle = 0.$$

Найдем коэффициенты c_n. Подействовав на обе части $|0,i\rangle = \sum\limits_n c_n|n,f\rangle$ оператором $\hat{a}_{in}$ и учтя, что $\hat{a}(t) = e^{-i\omega t}\hat{a}_i$ при $t \to -\infty$, а также соотношение

$$\hat{a}_f|n,f\rangle = \sqrt{n}|n-1,f\rangle,$$

приходим к рекуррентному соотношению $c_n = (\alpha/\sqrt{n})c_{n-1}$. Из него следует, что $c_n = \left(\alpha^n/\sqrt{n!}\right)c_0$. При этом условие нормировки

$$\langle 0,\ \mathrm{i}\ |0,\ \mathrm{i}\ \rangle = \sum_n |c_n|^2 = 1$$

дает

$$|c_0|^2 = \exp\left(-|\alpha|^2\right).$$

Вероятности переходов:

$$w(0 \to n) = |c_n|^2 = \frac{1}{n!}\alpha^{2n}e^{-\alpha^2}, \quad a = -\frac{\lambda x_0}{\sqrt{2\hbar}}.$$

Видно, что зависимость вероятностей от номера n квантового состояния осциллятора описывается распределением Пуассона.

ФР-кр-3-курс.1.(???)

Частица массы m движется в одномерной потенциальной яме вида рис.1.

$$U(x) = \begin{cases} \infty, & x < 0, \\ 0, & (0 < x < a), \\ v_0, & x > a. \end{cases}$$

При каких соотношениях между a и v_0 в этой яме имеются 4 дискретные уровни.

(??? тут типичные задачи контрольной, которые нужно научиться решать, я все еще не научился, потому что забил. плохо, нужно тренироваться!!!!! уже мб похожее и вписано, если так, то удалю их тут потом)

ФР-кр-3-курс.2.(???)

Частица находится в основном состоянии линейного гармонического осциллятора. Найти вероятность пребывания этой частицы в области, запрещенной для классического движения.

ФР-кр-3-курс.3.(???)

Состояние частицы, находящейся в бесконечно глубокой потенциальной яме шириной $a(0 < \mathrm{x} < a)$ описывается волновой функцией вида:

$$\Psi(\mathrm{x}) = c\sin^3(\pi \mathrm{x}/a).$$

Найти распределение вероятностей различных значений энергий.

ФР-кр-3-курс.4.(???)

Угловая часть ВФ частицы в центральном поле имеет вид $\Phi(\theta,\varphi) = C\cos^2\theta$. Найти вероятности различных значений момента частицы и среднее значение квадрата момента.

ФР-кр-3-курс.5.(???)

Состояние плоского ротатора описывается волновой функцией вида $\Psi = A\sin(2\varphi)$. Найти функции распределения ротатора по энергиям и проекциям момента, а также средние значения этих величин в указанном состоянии.

ФР-кр-3-курс.6.(???)

Для основного состояния частицы в бесконечно глубокой сферической потенциальной яме:

$$\mathrm{U(r)} = \begin{cases} 0, & r \le a \\ \infty, & r > a \end{cases}$$

найти $\langle \mathrm{r} \rangle$.

ФР-кр-3-курс.7.(???)

Покажите, что среднее значение $\langle \mathrm{r}^{-3} \rangle$ для 3 d волновой функции водородоподобного атома равно $27z^3/15a^3$.

17.1.6 Problems about adiabatics 1: Fun Models

ПТФ-9.у1. Ионизация

Имеется двухъямный потенциал $U(x) = -\frac{\kappa}{m}\left[\delta(x+\frac{L(t)}{2}) + \delta(x-\frac{L(t)}{2})\right]$. В начальный момент времени ямы разнесены друг от друга бесконечно далеко, $L \to \infty$, и электрон находится в одной из ям. Расстояние между ямами затем меленно уменьшается до нуля, так что в какой-то момент времени две ямы сливаются в одну: $U(x) = -\frac{2\kappa}{m}\delta(x)$. Определите, с какой вероятностью электрон останется в яме в результате такого процесса.

Solution.

Воспользуемся решением 3 задачи 3 недели. При $L \to \infty$ реализуется туннельный режим. Волновая функция электрона в начальный момент времени:

$$|\psi\rangle = \frac{1}{\sqrt{2}}(\psi_{\text{чёт}} + \psi_{\text{нечет}})$$

где $\psi_{\text{чёт}}$ – чётная волновая функция, $\psi_{\text{нечет}}$ – нечётная. Нечётное состояние существует только при $\kappa L \geq 1$. Поэтому при $L \to 0$ выживет только чётное связанное состояние, нужно узнать вероятность нахождения электрона в нём. По адиабатической теореме в процессе, состояние частицы в произвольный момент времени электрон будет оставаться в состоянии той чётности, в котором он оказался в начальный момент.

$$\psi_{\text{чёт}}(t) \propto \frac{1}{\sqrt{2}}\psi_{\text{чёт}}(0)$$

Вероятность остаться в яме:

$$P = \frac{1}{2}$$

ПТФ-9.у2. Адиабатика для колебаний ямы

Частица массы m движется в бесконечно глубокой потенциальной яме ширины $a(t)$, которая меняется во времени согласно следующему закону:

$$a(t) = a(1 - \alpha \sin^2 \omega t), \quad \alpha < 1$$

При каких условиях в такой задаче следует ожидать применимость адиабатического приближения?

Solution.

Уровни энергии в бесконечно глубокой яме:

$$E_n = \frac{\pi^2\hbar^2 n^2}{2ma^2}$$

$$\Delta E = E_{n+1} - E_n = \frac{\pi^2\hbar^2(2n+1)}{2ma^2} \geq \frac{\pi^2\hbar^2}{2ma^2}$$

Критерий адиабатичности:

$$\omega \ll \Delta E$$

Таким образом, условия применимости адиабатичности:

$$\frac{\pi^2\hbar^2}{2ma^2} \gg \omega$$

ПТФ-9.з1. Переворот спина

Спин-1/2 находится в магнитном поле $\vec{B}$, которое медленно вращается в плоскости yz:

$$\hat{H} = -\mu\vec{B}\cdot\hat{\vec{\sigma}}, \quad \vec{B}(t) = B\left(0, \frac{1}{\cosh\omega t}, -\tanh\omega t\right)$$

и $\omega \ll \mu B$. В начальный момент времени $t \to -\infty$ спин и магнитное поле направлены по оси z. Найдите в первом неисчезающем порядке вероятность того, что спин останется направленным по оси z после завершения вращения при $t \to \infty$.

Solution.

$$\hat{H} = -\mu\vec{B}\cdot\hat{\vec{\sigma}} = -\mu\begin{pmatrix} B_z & B_x - iB_y \\ B_x + iB_y & -B_z \end{pmatrix} = \mu B\begin{pmatrix} \tanh\omega t & \frac{i}{\cosh\omega t} \\ -\frac{i}{\cosh\omega t} & -\tanh\omega t \end{pmatrix}$$

Собственные значения и векторы этой матрицы:

$$E_- = -\mu B, \quad E_+ = \mu B$$

$$|\psi_-\rangle = \frac{1}{\sqrt{1+e^{-2\omega t}}}\begin{pmatrix} -ie^{-\omega t} \\ 1 \end{pmatrix}, \quad |\psi_+\rangle = \frac{1}{\sqrt{1+e^{2\omega t}}}\begin{pmatrix} ie^{\omega t} \\ 1 \end{pmatrix}$$

В начальный момент $c_- = 1$, $c_+ = 0$. Нестационарная адиабатика:

$$c_+(T\to\infty) = \int\limits_{-\infty}^{\infty} \exp\left(i\int\limits_0^t \omega_{+-}(\tau)d\tau\right)\frac{\langle\psi_+|\partial_t\hat{H}|\psi_-\rangle}{\omega_{+-}(t)}dt, \quad \omega_{+-} = E_+ - E_- = 2\mu B$$

$$\partial_t\hat{H} = \frac{\mu B\omega}{\cosh^2\omega t}\begin{pmatrix} 1 & -i\sinh\omega t \\ i\sinh\omega t & -1 \end{pmatrix}$$

$$\langle\psi_+|\partial_t\hat{H}|\psi_-\rangle = -\frac{\mu B\omega}{\cosh\omega t}$$

(!!! add the derivation of it here!!!)

$$c_-(T\to\infty) = -\int\limits_{-\infty}^{\infty}\frac{\exp\left(i2\mu Bt\right)}{2\cosh\omega t}\omega dt = -\int\limits_{-\infty}^{\infty}\frac{\exp\left(i\frac{2\mu Bx}{\omega}\right)}{2\cosh x}dx - \frac{\pi}{2\cosh\frac{\pi\mu B}{\omega}}$$

Вычислим интеграл при помощи вычетов. Нули знаменателя: $z_k = \pi i\left(\frac{1}{2}+k\right), k\in\mathbb{Z}$. Берём только полюс $z_0 = \frac{i\pi}{2}$.

$$c_-(T\to\infty) = -2\pi i\operatorname*{res}_{z=\frac{i\pi}{2}}\frac{\exp\left(i\frac{2\mu Bz}{\omega}\right)}{2\cosh z} = -\pi\exp\left(-\frac{\pi\mu B}{\omega}\right)$$

Вероятность того, что спин будет направлен по оси z:

$$P = \pi^2\exp\left(-\frac{2\pi\mu B}{\omega}\right)$$

ПТФ-9.з2. Эффект Ааронова-Бома

The electron can move along the ring of radius R, and is in the bound state of the potential well $U(\varphi) = -U_0\delta(\varphi-\varphi_0)$. A magnetic flux Φ is passed through the ring, so that the Hamiltonian of the system has the form:

$$\hat{H} = \frac{(\hat{p}_\varphi - \frac{e}{c}A_\varphi)^2}{2m} - U_0\delta(\varphi-\varphi_0), \qquad \hat{p}_\varphi = -\frac{i}{R}\frac{\partial}{\partial\varphi}, \qquad A_\varphi = \frac{\Phi}{2\pi R}$$

Then, one slowly moves the delta-potential around the ring clockwise (the value of φ_0 varies from $\varphi_0(0) = 0$ to $\varphi_0(T) = 2\pi$). Determine the dependence of the phase that the electron wave function will receive as a result of such evolution on the energy. Assume, that size of the bound state is much smaller than the radius of the ring.

Solution.

Стационарное уравнение Шрёдингера:

$$\hat{H}\psi(\varphi) = E\psi(\varphi)$$

$$\hat{H} = \frac{(\frac{i}{R}\frac{\partial}{\partial\varphi} + \frac{e\Phi}{2\pi Rc})^2}{2m} - U_0\delta(\varphi-\varphi_0) = -\frac{1}{2mR^2}\partial_\varphi^2 + \frac{ie\Phi}{2\pi R^2 mc}\partial_\varphi + \frac{e^2\Phi^2}{8\pi^2R^2mc^2} - U_0\delta(\varphi-\varphi_0)$$

При $\varphi \neq \varphi_0$:

$$\left(\frac{i}{R}\frac{\partial}{\partial\varphi} + \frac{e\Phi}{2\pi Rc}\right)^2\psi(\varphi) = 2mE\psi(\varphi)$$

Ищем решение $\psi(\varphi)$ в виде экспоненты:

$$\left(\frac{i}{R}\lambda + \frac{e\Phi}{2\pi Rc}\right)^2 = 2mE$$

$$\lambda_{1,2} = i\left(\frac{e\Phi}{2\pi c} \pm \sqrt{2mE}R\right)$$

Поскольку состояние связанное $E<0$, то

$$\lambda_{1,2} = \left(\frac{ie\Phi}{2\pi c} \mp \sqrt{2m|E|}R\right)$$

We introduce

$$A = \frac{e\Phi}{2\pi c}, \qquad B = \sqrt{2m|E|}R.$$

$$\psi(\varphi) = C_1e^{(iA-B)\varphi} + C_2e^{(iA+B)\varphi}$$

Положим $\varphi_0 = 0$, а после сшивки сдивнем φ обратно. Условия сшивки:

$$\begin{cases}\psi(0+0) = \psi(2\pi-0),\\ \psi'(0) - \psi'(2\pi-0) = -2mU_0R^2;\end{cases}$$

(!!!! write math here!!!!)

$$\begin{cases}C_1 + C_2 = C_1e^{(iA-B)2\pi} + C_2e^{(iA+B)2\pi},\\ (iA-B)C_1 + (iA+B)C_2 - (iA-B)C_1e^{(iA-B)2\pi} - (iA+B)C_2e^{(iA+B)2\pi} = -2mU_0R^2(C_1+C_2);\end{cases}$$

Выразим C_2 через C_1:
(!!!! write math here!!!! I think, there is a big problem with math here!!!)

$$C_2 = -C_1e^{-2\pi B}\frac{\sin(\pi(A+iB))}{\sin(\pi(A-iB))}$$

Характерный размер волновой функции $\ll R$, поэтому $e^{-B\varphi} \ll 1$ и $B \gg 1$. Условие нормировки:

$$\int\limits_0^{2\pi}|\psi(\varphi)|^2d\varphi = 1$$

(??? here are problems, I don't know, how to extract these coefficients)
Пользуясь тем, что $B \gg 1$, получим

$$C_2 = \sqrt{B}e^{-2\pi B}, \quad C_1 = \sqrt{B}e^{2\pi iA}$$

$$\psi(\varphi) = \sqrt{B}e^{2\pi iA}e^{(iA-B)\varphi} + \sqrt{B}e^{-2\pi B}e^{(iA+B)\varphi}$$

Сдвигая на угол φ_0, получим

$$\psi(\varphi) = \sqrt{B}e^{2\pi iA}e^{(iA-B)(\varphi-\varphi_0)} + \sqrt{B}e^{-2\pi B}e^{(iA+B)(\varphi-\varphi_0)}$$

Now, we need only to plug this wavefunction in the definition of Barry's phase:

$$\gamma = \int_0^{2\pi} d\varphi_0 \langle \psi(\varphi_0) | i\partial_{\varphi_0} | \psi(\varphi_0) \rangle$$

$$\partial_{\varphi_0}\psi(\varphi_0) = -\sqrt{B}e^{2\pi i A}(iA-B)e^{(iA-B)(\varphi-\varphi_0)} - \sqrt{B}(iA+B)e^{-2\pi B}e^{(iA+B)(\varphi-\varphi_0)}$$

$$\langle \psi(\varphi_0) | i\partial_{\varphi_0} | \psi(\varphi_0) \rangle = -\int_0^{2\pi} d\varphi (\sqrt{B}e^{-2\pi i A}e^{(-iA-B)(\varphi-\varphi_0)} + \sqrt{B}e^{-2\pi B}e^{(-iA+B)(\varphi-\varphi_0)})i$$
$$(\sqrt{B}e^{2\pi i A}(iA-B)e^{(iA-B)(\varphi-\varphi_0)} + \sqrt{B}(iA+B)e^{-2\pi B}e^{(iA+B)(\varphi-\varphi_0)}) = A$$

(!! I'll check math later)

$$\gamma = \int_0^{2\pi} d\varphi_0 A = 2\pi A$$

$$\gamma = \frac{e\Phi}{c}$$

ПТФ-9.з3. Adiabatic rotation of a box

Consider a square two-dimensional box of size $L \times L$ with infinite walls. An arbitrary stationary state can be characterized by two quantum numbers $|n_x, n_y\rangle$, which number the number of nodes x and y components of the wave function; in particular, the states $|1,0\rangle$ and $|0,1\rangle$ have the same energy. Let's assume that at the initial moment of time the wave function was an arbitrary linear combination of the ground states:

$$|\psi(0)\rangle = \psi_1|1,0\rangle + \psi_2|0,1\rangle$$

Here ψ_1, ψ_2 are some complex numbers. Then the box slowly rotates in the plane at an angle of 2π clockwise, so that after rotation its new position coincides with the original one. Determine the wave function $|\psi(T)\rangle$ after such a rotation.

Introduction to solution

Slow rotation is described by a nonstationary adiabatics, where

$$\psi_n(t) \equiv c_n(t) \cdot \exp\left(-i\int_{t_0}^{t} E_n(\tau)d\tau\right),$$

$$c_m(T) \approx \int_{t_0}^{T} \exp\left(i\int_{t_0}^{t}\omega_{mn}(\tau)d\tau\right)\frac{\left\langle m(t)\left|\partial_t\hat{H}\right|n(t)\right\rangle}{\omega_{mn}(t)}dt.$$

$\omega_{nm} = E_n - E_m$.

$$i\partial_\theta c_n(\theta) = -i\sum_m \exp\left(i\int\omega_{nm}(\tau)d\tau\right)\langle n(\theta)|\partial_\theta|m(\theta)\rangle c_m(\theta),$$

Here n is the number of a state in which there is a particle
(???? write a good intro to solutions!!!)

Solution.

This problem is solved by a non-stationary adiabatics. One just need to be careful, use proper equation for the coefficients, do a good approximation and use Wolfram to compute the integrals. The most important part is to consider change of the state only to the ground states and to integrate in formula for adiabatics for the coordinates that correspond to the current position of a box, not the initial one.

Let us assume that the center of coordinates of the box coincides with the center of coordinates of XY system. The wavefunction of a particle in a box is:

$$\psi_{n,m} = \frac{2}{L}\sin\left(k_n\left(x+\frac{L}{2}\right)\right)\sin\left(k_m\left(\frac{L}{2}+y\right)\right)$$

$$|1,0\rangle = \frac{2}{L}\sin\left(\frac{2\pi}{L}\left(x+\frac{L}{2}\right)\right)\sin\left(\frac{\pi}{L}\left(\frac{L}{2}+y\right)\right) = \frac{2}{L}\sin\left(\frac{2\pi}{L}x\right)\cos\left(\frac{\pi}{L}y\right),$$
$$|0,1\rangle = \frac{2}{L}\sin\left(\frac{\pi}{L}\left(x+\frac{L}{2}\right)\right)\sin\left(\frac{2\pi}{L}\left(\frac{L}{2}+y\right)\right) = \frac{2}{L}\sin\left(\frac{2\pi}{L}y\right)\cos\left(\frac{\pi}{L}x\right)$$

Here we neglected minus from $\sin(x+\pi) = -\sin(x)$, because anyway the result will be the same.

By rotation we mean that coordinates are changed as:

$$\begin{cases} x_\theta = x\cos\theta - y\sin\theta, \\ y_\theta = x\sin\theta + y\cos\theta. \end{cases}$$

Thus, the bases vectors will change as

$$|1,0\rangle = \frac{2}{L}\sin\left(\frac{2\pi}{L}x_\theta\right)\cos\left(\frac{\pi}{L}y_\theta\right),$$

$$|0,1\rangle = \frac{2}{L}\sin\left(\frac{2\pi}{L}y_\theta\right)\cos\left(\frac{\pi}{L}x_\theta\right).$$

It is important to work with for instance x_θ, and not with the full its expression, because otherwise the expressions will be incomprehensible big. Now we use the framework of the non-stationary adiabatics, in which

$$\partial_\theta c_n(\theta) = -\sum_{m=|0,1\rangle,|1,0\rangle} \langle n(\theta)|\partial_\theta|m(\theta)\rangle c_m(\theta)$$

This is the consequence of the general formula $i\partial_\theta c_n(\theta) = -i\sum\limits_m \exp\left(i\int\omega_{nm}(\tau)d\tau\right)\cdot\cdot\langle n(\theta)|\partial_\theta|m(\theta)\rangle c_m(\theta)$, were $\omega_{nm} = E_n - E_m = 0$ because we have here only the ground states, which have the same energy (they give the biggest contribution).

Or, explicitly, we have:

$$\partial_\theta c_1(\theta) = -\langle 1,0|\partial_\theta|1,0\rangle c_1(\theta) - \langle 1,0|\partial_\theta|0,1\rangle c_2(\theta)$$
$$\partial_\theta c_2(\theta) = -\langle 0,1|\partial_\theta|1,0\rangle c_1(\theta) - \langle 0,1|\partial_\theta|0,1\rangle c_2(\theta)$$

Now, we compute from expressions of the basis vectors. First, we note that $dx_\theta/d\theta = -y_\theta$ and $dy_\theta/d\theta = +x_\theta$. Then, we compute

$$\begin{aligned}\partial_\theta|0,1\rangle &= \partial_\theta\left[\frac{2}{L}\sin\left(\frac{2\pi}{L}y_\theta\right)\cos\left(\frac{\pi}{L}x_\theta\right)\right] = \\ &= \frac{2}{L}\left[\cos\left(\frac{2\pi}{L}y_\theta\right)(+\frac{2\pi}{L}x_\theta)\cos\left(\frac{\pi}{L}x_\theta\right) - \sin\left(\frac{2\pi}{L}y_\theta\right)\sin\left(\frac{\pi}{L}x_\theta\right)(-\frac{\pi}{L}y_\theta)\right] = \\ &= \frac{2\pi}{L^2}\left[2\cos\left(\frac{2\pi}{L}y_\theta\right)x_\theta\cos\left(\frac{\pi}{L}x_\theta\right) + \sin\left(\frac{2\pi}{L}y_\theta\right)\sin\left(\frac{\pi}{L}x_\theta\right)y_\theta\right].\end{aligned}$$

Then

$$\langle 0,1|\partial_\theta|0,1\rangle = \int dx_\theta dy_\theta \frac{2}{L}\frac{4\pi}{L^2}\sin\left(\frac{2\pi}{L}y_\theta\right)\cos\left(\frac{\pi}{L}x_\theta\right)\left[2\cos\left(\frac{2\pi}{L}y_\theta\right)x_\theta\cos\left(\frac{\pi}{L}x_\theta\right) + \sin\left(\frac{2\pi}{L}y_\theta\right)\sin\left(\frac{\pi}{L}x_\theta\right)y_\theta\right] = 0.$$

The integration over dx_θ is the manifestation of our main philosophy of adiabatic method, that at each time we consider box as stationary.

(???? think more about this! why is it so? write better theory, that states that this is the meaning of the terms of th r.h.s. of the equation for coefficients.)

(??? do the integral analytically)

Currently the proof is by Wolfram:

```
Integrate[
Sin[2 Pi/L y] Cos[Pi/L x] (2Cos[(2 Pi)/L y] x Cos[Pi/L x] + Sin[(2 Pi)/L y] y Sin[Pi/L x]),
    {x, -L/2, L/2}, {y, -L/2, L/2}]
```

Now, it is clear, what is going on with other factors:

$$\partial_\theta|1,0\rangle = \partial_\theta\left[\frac{2}{L}\sin\left(\frac{2\pi}{L}x_\theta\right)\cos\left(\frac{\pi}{L}y_\theta\right)\right] =$$
$$= \frac{2}{L}\left[\cos\left(\frac{2\pi}{L}x_\theta\right)(-\frac{2\pi}{L}y_\theta)\cos\left(\frac{\pi}{L}y_\theta\right) - \sin\left(\frac{2\pi}{L}x_\theta\right)\sin\left(\frac{\pi}{L}y_\theta\right)(+\frac{\pi}{L}x_\theta)\right] =$$
$$= -\frac{2\pi}{L^2}\left[2\cos\left(\frac{2\pi}{L}x_\theta\right)y_\theta\cos\left(\frac{\pi}{L}y_\theta\right) + \sin\left(\frac{2\pi}{L}x_\theta\right)\sin\left(\frac{\pi}{L}y_\theta\right)x_\theta\right].$$

Thus

$$\langle 1,0|\partial_\theta|1,0\rangle = \int dx_\theta dy_\theta \frac{2}{L}\frac{2\pi}{L^2}\sin\left(\frac{2\pi}{L}x_\theta\right)\cos\left(\frac{\pi}{L}y_\theta\right)\left[-2\cos\left(\frac{2\pi}{L}x_\theta\right)y_\theta\cos\left(\frac{\pi}{L}x_\theta\right) - \sin\left(\frac{2\pi}{L}x_\theta\right)\sin\left(\frac{\pi}{L}y_\theta\right)x_\theta\right] = 0.$$

```
Integrate[
Sin[2 Pi/L x] Cos[ Pi/L y] (-2Cos[(2 Pi)/L x] y Cos[Pi/L y] - Sin[(2 Pi)/L x] x Sin[Pi/L
    y]), {x, -L/2, L/2}, {y, -L/2, L/2}]
```

The fact that it is also zero is obvious because this integral is just exactly the same as the one before, but with different labels of x and y.

Now, two more complicated ones:

$$\langle 1,0|\partial_\theta|0,1\rangle = \int dx_\theta dy_\theta \frac{2}{L}\frac{2\pi}{L^2}\sin\left(\frac{2\pi}{L}x_\theta\right)\cos\left(\frac{\pi}{L}y_\theta\right)\left[2\cos\left(\frac{2\pi}{L}y_\theta\right)x_\theta\cos\left(\frac{\pi}{L}x_\theta\right) + \sin\left(\frac{2\pi}{L}y_\theta\right)\sin\left(\frac{\pi}{L}x_\theta\right)y_\theta\right] =$$
$$= \frac{4\pi}{L^3}\frac{64L^3}{27\pi^3} = \frac{256}{27\pi^3}.$$

(??? analytical calculation of the integral?? I think, it will be just boring and long since all integrals will come to the form $\iint dxdyx\cos(x)$, which is trivially taken by parts)

```
Integrate[
Sin[2 Pi/L x] Cos[ Pi/L y] (2Cos[(2 Pi)/L y] x Cos[Pi/L x] + Sin[(2 Pi)/L y] y Sin[Pi/L x]),
    {x, -L/2, L/2}, {y, -L/2, L/2}]
```

$$\langle 0,1|\partial_\theta|1,0\rangle = \int dx_\theta dy_\theta \frac{2}{L}\frac{2\pi}{L^2}\sin\left(\frac{2\pi}{L}y_\theta\right)\cos\left(\frac{\pi}{L}x_\theta\right)\left[-2\cos\left(\frac{2\pi}{L}x_\theta\right)y_\theta\cos\left(\frac{\pi}{L}y_\theta\right) - \sin\left(\frac{2\pi}{L}x_\theta\right)\sin\left(\frac{\pi}{L}y_\theta\right)x_\theta\right] =$$
$$= -\frac{4\pi}{L^3}\frac{64L^3}{27\pi^3} = -\frac{256}{27\pi^3}.$$

(??? analytical calculation of the integral?? I think, it will be just boring and long since all integrals will come to the form $\iint dxdyx\cos(x)$, which is trivially taken by parts)

```
Integrate[
Sin[2 Pi/L x] Cos[ Pi/L y] (-2 Cos[(2 Pi)/L y] x Cos[Pi/L x] - Sin[(2 Pi)/L y] y Sin[Pi/L
    x]), {x, -L/2, L/2}, {y, -L/2, L/2}]
```

Totally, we have:

$$\langle 1,0|\partial_\theta|1,0\rangle = \langle 0,1|\partial_\theta|0,1\rangle = 0, \quad \langle 1,0|\partial_\theta|0,1\rangle = -\langle 0,1|\partial_\theta|1,0\rangle = \frac{256}{27\pi^2}$$

And equations for the dynamical phase will give us

$$\partial_\theta c_1(\theta) = -\frac{256}{27\pi^2}c_2(\theta), \quad c_1(0) = \psi_1$$
$$\partial_\theta c_2(\theta) = \frac{256}{27\pi^2}c_1(\theta), \quad c_2(0) = \psi_2,$$

We combine these two equations into the second order linear differential equation and the solution of it is

$$c_1(\theta) = \psi_1 \cos\left(\frac{256\theta}{27\pi^2}\right) - \psi_2 \sin\left(\frac{256\theta}{27\pi^2}\right)$$
$$c_2(\theta) = \psi_1 \sin\left(\frac{256\theta}{27\pi^2}\right) + \psi_2 \cos\left(\frac{256\theta}{27\pi^2}\right)$$

The coefficients here are obtained by usual matching boundary conditions $c_1(0) = \psi_1, c_2(0) = \psi_2$.

Thus, for the whole rotation, one just need to plug 2π:

$$\begin{aligned}|\psi(T)\rangle &= c_1(2\pi)|1,0\rangle + c_2(2\pi)|0,1\rangle \\ &= \left(\psi_1 \cos\left(\frac{512\theta}{27\pi}\right) - \psi_2 \sin\left(\frac{512\theta}{27\pi}\right)\right)|1,0\rangle + \left(\psi_1 \sin\left(\frac{512\theta}{27\pi}\right) + \psi_2 \cos\left(\frac{512\theta}{27\pi}\right)\right)|0,1\rangle\end{aligned}$$

This is how our wavefunction will change.

Solution in different coordinates

(??? one can introduce zero of coordinates not in the center of the box, but in the edge. Maybe I'll comment about it, currently, I didn't try this yet)

Solution by Hamiltonian

(???? I don't know, is it possible to write the Hamiltonian of the system and use another formula for the adiabatics? maybe it is possible, since the formulas are equivalent. I'll try later)

What happens with the energy of the system?

(???? a good question, currently, I have no idea. Does the system observe the energy?)

Limits of applicability of the solution

(???? a good question, I first need to write this in the theory)
(?? how many rotations can be done for the system to change the state to the excited state? I think, the adiabatic approximation which is written here should be just rewritten with also other states for m index. So, maybe it is not a trivial problem, I don't know....)

Connection to Berry's phase

(??? can one solve it by Berry's phase??? maybe this is the exactly it, what we are calculating???)

Why does the particle at all will feel the rotation?

If there is no inertia force, then particle will not feel rotation at all.
(???? this is why I think this problem is just broken. the solution above is maybe even generally wrong.)

17.1.7 Problems about adiabatics 2: Template Models

ПТФ-6.пр.1 Landau-Zener problem by adiabatics

Suppose we have a two-level system, where level spacing is changed in time and models by a Hamiltonian

$$\hat{H}(t) = \begin{pmatrix} \alpha t & \gamma \\ \gamma & -\alpha t \end{pmatrix}.$$

Here α and γ are constants.

Find a probability of transfer to the lower state at $t \to \infty$ from the upper one, on which a particle was initially (in time $t \to -\infty$).

Solution

This is the basic example for non-stationary adiabatic methods.

First of all, we compute the energy levels exactly as:

$$E_+(t) = \sqrt{\gamma^2 + (\alpha t)^2}, \quad |\psi_+(t)\rangle = \frac{1}{\sqrt{2\left(\gamma^2 + (\alpha t)^2 + \alpha t\sqrt{\gamma^2 + (\alpha t)^2}\right)}} \begin{pmatrix} \alpha t + \sqrt{\gamma^2 + (\alpha t)^2} \\ \gamma \end{pmatrix}$$

$$E_-(t) = -\sqrt{\gamma^2 + (\alpha t)^2}, \quad |\psi_-(t)\rangle = \frac{1}{\sqrt{2\left(\gamma^2 + (\alpha t)^2 - \alpha t\sqrt{\gamma^2 + (\alpha t)^2}\right)}} \begin{pmatrix} \alpha t - \sqrt{\gamma^2 + (\alpha t)^2} \\ \gamma \end{pmatrix}$$

It is convenient to perametrise them by $\alpha t = \gamma \sinh\theta$

$$E_+(\theta) = \gamma \operatorname{ch}\theta, \quad |\psi_+(\theta)\rangle = \tfrac{1}{\sqrt{2\operatorname{ch}\theta}} \begin{pmatrix} e^{\theta/2} \\ e^{-\theta/2} \end{pmatrix}$$
$$E_-(\theta) = -\gamma \operatorname{ch}\theta, \quad |\psi_-(\theta)\rangle = \tfrac{1}{\sqrt{2\operatorname{ch}\theta}} \begin{pmatrix} e^{-\theta/2} \\ -e^{\theta/2} \end{pmatrix}$$

Initially, at $t \to -\infty$ there was $|\psi_+(-\infty)| = 1$ and $|\psi_-(-\infty)| = 0$; The probability of the transition is

$$P = |\psi_-(+\infty)|^2.$$

(??? why?????)

Сразу выделим параметр адиабатичности.

Если уровни находятся достаточно далеко по энергии, то переходов не будет - поэтому масштаб времени T, который входит в критерий адиабатичности, определяется из условия достаточной близости уровней: $\alpha T \sim \gamma \to T \sim \frac{\gamma}{\alpha}$. С другой стороны, масштаб расстояния между уровнями при этом равен γ. Поэтому адиабатическое приближение соответствует случаю, когда $\gamma^2 \gg \alpha$.

Now, again we use that very non-trivial non-stationary adiabatics. Решая уравнение (6.4) методом последовательных приближений, и в качестве нулевого приближения беря $c_+^{(0)}(t) = 1 = \text{const}$ и $c_-^{(0)}(t) = 0$, в первом приближении мы получаем следующее уравнение на $c_-^{(1)}(t)$, которое, в свою очередь, тривиально интегрируется; наконец, в интеграле удобно перейти опять вместо интегрирования по времени к интегрированию по вспомогательному параметру θ:

$$i\frac{dc_-(t)}{dt} = -ie^{-i\int_0^t \omega_{+-}(\tau)d\tau} \frac{\langle\psi_-(\theta)|\frac{\partial\hat{H}}{\partial\theta}|\psi_+(\theta)\rangle}{\omega_{-+}(\theta)} \cdot \frac{d\theta}{dt}$$

Интегрируем:

$$c_-^{(1)}(\infty) = \int\limits_{-\infty}^{\infty} d\theta \cdot e^{-i\int_0^t \omega_{+-}(\tau)d\tau} \frac{\langle\psi_-(\theta)|\frac{\partial\hat{H}}{\partial\theta}|\psi_+(\theta)\rangle}{2\gamma\operatorname{ch}\theta},$$

where

$$\langle\psi_-(\theta)|\frac{\partial\hat{H}}{\partial\theta}|\psi_+(\theta)\rangle = \frac{1}{2\operatorname{ch}\theta}\begin{pmatrix} e^{-\theta/2} & -e^{\theta/2} \end{pmatrix}\begin{pmatrix} \gamma\operatorname{ch}\theta & 0 \\ 0 & -\gamma\operatorname{ch}\theta \end{pmatrix}\begin{pmatrix} e^{\theta/2} \\ e^{-\theta/2} \end{pmatrix} = \gamma,$$

$$\int\limits_0^t \omega_{+-}(\tau)d\tau = 2\frac{\gamma^2}{\alpha}\int\limits_0^\theta \operatorname{ch}^2\theta d\theta = \frac{\gamma^2}{\alpha}\left[\theta + \frac{1}{2}\operatorname{sh}2\theta\right].$$

And we get the final formula:

$$c_-^{(1)}(\infty) = \int\limits_{-\infty}^{\infty} \frac{\exp\left(-i\frac{\gamma^2}{\alpha}\left(\theta + \frac{1}{2}\operatorname{sh}2\theta\right)\right)}{2\operatorname{ch}\theta}d\theta$$

Now, it is relatively easy to proceed. We have a an integral of the form "fast-oscillating function + slow envelope". Integrals of this type are taken by the stationary phase method, or more generally by the pass method. Here, the phase $f(\theta) = \theta + \frac{1}{2}\operatorname{sh}2\theta$, which has $f'(\theta) = 1 + \operatorname{ch}2\theta \geq 2$, поэтому точек стационарной фазы на вещественной оси нет. (?????????????) Для этого мы можем сделать так, чтобы в экспоненте стояла линейная функция, перейдя к интегралу по $z = \theta + \frac{1}{2}\operatorname{sh}2\theta \to dz = d\theta(1 + \cos 2\theta) = 2\operatorname{ch}^2\theta d\theta$, и переписав интеграл в виде:

$$c_-^{(1)}(\infty) = \int\limits_{-\infty}^{\infty} \frac{\exp\left(-i\frac{\gamma^2}{\alpha}z\right)}{4\operatorname{ch}^3\theta}dz$$

Теперь мы можем применить лемму Жордана, замкнув контур интегрирования в нижней полуплоскости (где экспонента затухает), и сведя его к вычетам в полюсах, которые определяются из $\operatorname{ch}\theta = 0$, то есть $\theta_k = -i\frac{\pi}{2}(1+2k) = z_k$. Беря только полюс с $k = 0$, и оставляя только экспоненту, получаем:

$$c_-^{(1)}(\infty) \sim e^{-\pi\gamma^2/2\alpha}$$

В итоге

$$P \sim e^{-\pi\gamma^2/\alpha}$$

ПТФ-6.пр.1 Landau-Zener problem by adiabatics

Suppose we have a two-level system, where level spacing is changed in time and models by a Hamiltonian

$$\hat{H}(t) = \begin{pmatrix} \alpha t & \gamma \\ \gamma & -\alpha t \end{pmatrix}.$$

Here α and γ are constants.

Find a probability of transfer to the upper state at $t \to \infty$ from the lower one, on which a particle was initially (in time $t \to -\infty$).

Solution

(the solution is exactly the same, as it was for the transfer vice versa. The answer is the same. But it is a good practice, to do carefully all transformations again, assuming that initial state is purely different.)

(??? by the way, why do we expect that always the probability of transfer to one direction is the same for transfer to another? Which exactly part of the theory assures us about it?)

ПТФ-6.пр.2.4 Adiabatic quantum transport

Представим себе длинную двумерную полосу, ширина которой a(x) как-то медленно зависит от координаты x.

Такая задача имеет важные применения — буквально такие системы умеют создавать экспериментаторы, занимающиеся наноинженерией (см. схему).

Solution

This is the basic example for stationary adiabatics methods.

Если бы ширина не изменялась, то то иеременшые разделялись бы, и точное решение гамильтониаша иредставлялось бы в виде $\psi_{p,n}(x,y) = e^{ipx}\sqrt{\frac{2}{a}}\sin\left(\frac{\pi n y}{a} - \frac{\pi n}{2}\right)$ (если стешка соответствует $y \in \left(-\frac{a}{2}; \frac{a}{2}\right)$; эиергия такого состояния равнялась бы $E_{p,n} = \frac{p^2}{2m} + \frac{\pi^2 n^2}{2ma^2}$. Когда ширина как-то неявно зависит от координаты x, то мы можем иримснить адиабати-

мы в первую очередь должны зафиксировать координату x и решить задачу для быстрой подсистемы.

Решение записывается тривиально: $\psi_n^{(f)}(y,x) = \sqrt{\frac{2}{a(x)}}\sin\left[\frac{\pi n y}{a(x)} - \frac{\pi n}{2}\right], E_n^{(f)}(x) = \frac{\pi^2 n^2}{2ma^2(x)}$. В результате для оставшегося эффективного одномерного движения мы можем записать эффективный гамильтониан:

$$\hat{H}_{eff} = \frac{\hat{p}_x^2}{2m} + \frac{\pi^2 n^2}{2ma^2(x)}$$

Дальше можно уже работать с этим гамильтонианом - к примеру, интересна задача рассеяния, когда электрон запускают с фиксированной энергией E с $x \to -\infty$, и интересуются, с какой вероятностью он пройдёт через такое сужение.

Однако решение оставшейся одномерной задачи (скажем, когда $a(x)$ задано явно) уже производится другими методами, которые обсуждаются в других семинарах, поэтому на этом мы остановимся.

В данной задаче адиабатическое приближение, как всегда, будет работать, покуда не будут возбуждаться другие поперечные моды.

Это будет верно, если потенциал плавный и не может передать частице импульс порядка $\delta p \sim \frac{1}{a}$ – а значит, масштаб типичного изменения величины $a(x)$ должен быть меньше самой величины $a(x)$: $\frac{da}{dx} \ll 1$.

ПТФ-6.пр.2.5 Particle in ellipse

Let the free particle be placed in a strongly elongated ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1, a \gg b$. Find low-lying energy levels.

Note that there is a well-known solution for a circle (when $a = b$), and there is also a solution for the slightly deformed circle (when $\frac{|a-b|}{a} \ll 1$) by perturbation theory.

Solution

This is the basic example for stationary adiabatic methods.

Типичный энергетический масштаб поперечного движения (вдоль y) - это $\omega^{(f)} \sim \frac{1}{mb^2}$, большая величина; из этого мы заключаем, что нонеречное движение - быстрое, а продольное - медленное.

We write the effective Hamiltonian for the motion along x axes (отличие в том, что теперь $y \in (-y(x), y(x))$) from

$$\psi_n^{(f)}(y,x) = \frac{1}{\sqrt{y(x)}} \sin\left[\frac{\pi n y}{2y(x)} - \frac{\pi n}{2}\right] \qquad E_n^{(f)} = \frac{\pi^2 n^2}{8my^2(x)}$$

as

$$\hat{H}_{\text{eff}} = \frac{\hat{p}_x^2}{2m} + \frac{\pi^2 n^2}{8my^2(x)} = \frac{\hat{p}_x^2}{2m} + \frac{\pi^2 n^2}{8mb^2}\left(1 - \frac{x^2}{a^2}\right)^{-1} \overset{x \ll a}{\approx} \frac{\hat{p}_x^2}{2m} + \frac{\pi^2 n^2}{8mb^2}\left(1 + \frac{x^2}{a^2}\right)$$

This potential corresponds to the oscillator with $\omega_N = \frac{\pi N}{2mab}$. Из этого мы заключаем, что уровни энергии можно приближённо записать как:

$$E_{N,n} = \frac{\pi^2 N^2}{8mb^2} + \frac{\pi N}{2mab}\left(n + \frac{1}{2}\right)$$

(????? I should learn better theory, why it is so???)

Отметим, что типичное расстояние между «быстрыми» подуровнями оценивается как $\Delta E^{(f)} \sim \frac{1}{mb^2}$, а между «медленными» - как $\Delta E^{(s)} = \omega \sim \frac{1}{mab}$, и несложно видеть, что $\Delta E^{(f)} \gg \Delta E^{(s)}$, поэтому адиабатическое приближение оправдано. В этом смысле, для буквально низколежащих уровней энергии необходимо положить $N = 1$.

Второе, что необходимо проверить - что разложение по x/a тоже было законным. Движение вдоль оси x в нашем решении соответствует осциллятору, у которого масштаб волновой функции - это $x_0 \sim \frac{1}{\sqrt{m\omega}} = \sqrt{ab} \ll a$ - поэтому это приближение тоже работает.

Relation to chaos (???)

Наконец, отметим, что такую же задачу можно было бы поставить и в классической механике, в которой частицу с фиксированным импульсом запускают в такой эллиптический бильярд. В таком случае уже с классической точки зрения, поперечное движение было бы быстрым (это означает, что прежде чем x-компонента импульса поменяет знак, произойдёт огромное количество столкновений вдоль оси y), а вдоль оси x частица бы испытывала практически гармонические колебания.

(??? I don't know relation to chaos, here there is no chaos, there there is chaos....)

ПТФ-6.пр.2.6 Частица в конусе

(выпишу потом эту задачу из их конспектов)

Б-2.8.14 Фаза берри мюона в магнитном поле (??)

Рассмотреть задачу о покоящемся положительном мюоне, находящемся в однородном магнитном поле. Напряженность поля $\mathcal{H}$ составляет постоянный угол θ с осью z и медленно вращается вокруг нее. Предполагая, что вектор $\mathcal{H}$ совершает полный оборот вокруг оси z, определить фазу Берри.

Reminder: the Berry's phase is $\gamma := \int\limits_0^T dt\dot{\gamma}(t) = i \oint_\Gamma d\xi \langle\psi_n(\xi(t))|\frac{\partial}{\partial\xi}|\psi_n(\xi(t))\rangle$ and muon is just spin 1/2 particle.

Solution.

Состояния с определенными значениями проекции спина $S_{\mathcal{H}} = \pm 1/2$ на направление магнитного поля определяются векторами (см. задачу 2.4.19)

$$|+\rangle_{\mathcal{K}} = \cos\frac{\theta}{2}|+\rangle + \sin\frac{\theta}{2}e^{i\varphi}|-\rangle,$$
$$|-\rangle_{\mathcal{K}} = -\sin\frac{\theta}{2}|+\rangle + \cos\frac{\theta}{2}e^{i\varphi}|-\rangle,$$

где векторы $|+\rangle$ и $|-\rangle$ описывают состояния с положительной и отрицательной проекциями спина на ось z (см. (II.26)).

Два состояния $|\pm\rangle_{\mathcal{K}}$ (1) отвечают значениям энергии $\mp\mu_0\mathcal{H}/2$. Таким образом, энергетический спектр невырожден. Пусть теперь магнитное поле адиабатически медленно вращается вокруг оси z при постоянном угле θ (рис. 2.10). В этом случае применимо адиабатическое приближение, из которого следует, что частица, находившаяся первоначально в основном состоянии, в нем и останется, а вектор состояния будет отличаться от исходного вектора (1) фазовым множителем (найденным в формуле (2) задачи 2.8.13).

Периоду T изменения параметров соответствует изменение азимутального угла φ от 0 до 2π, поэтому для фазы Берри имеем

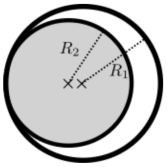
$$\gamma = i\int\limits_0^{2\pi} d\varphi\mathcal{H}\langle\chi|\frac{\partial}{\partial\varphi}|\chi\rangle_{\mathcal{H}} = -\frac{1}{2}\int\limits_0^{2\pi} d\varphi(1-\cos\theta) = -s\mathcal{H}\int\limits_0^{2\pi} d\varphi\int\limits_0^{\theta}\sin\theta' d\theta' = -\,\mathrm{sH}\,\Omega,$$

где Ω - телесный угол, под которым из начала координат видна траектория, описываемая средним значением спина (рис. 2.10), $s_H = 1/2$ - проекция спина на направление магнитного поля.

17.1.8 Problems about adiabatics 3: Specific Models

ПТФ-10.з1. Particle inside two cylinders

A particle of mass m is located between two infinite cylinders $|R_1 - R_2| \ll R_{1,2}$, which touch each other internally.



Find the low-lying energy levels of such a system.

Solution.

Адиабатическое разделение переменных:

$$\hat{H}(r,\varphi) = \hat{H}_s(\varphi) + \hat{H}_f(r,\varphi)$$

$$\hat{H}_s(\varphi) = -\frac{\hbar^2}{2mR_2^2}\left(\frac{\partial}{\partial\varphi}\right)^2, \quad \hat{H}_f(r,\varphi) = -\frac{\hbar^2}{2m}\left(\frac{\partial}{\partial r}\right)^2$$

Зафиксируем положение медленной подсистемы и решим задачу для быстрой. В первом приближении пренебрегаем производной по φ:

$$\frac{\hbar^2}{2m}\left(\frac{\partial}{\partial r}\right)^2\psi(r,\varphi) = \varepsilon^{(f)}(\varphi)\psi(r,\varphi)$$

Обозначим $k(\varphi) = \frac{2m\varepsilon^{(f)}(\varphi)}{\hbar^2}$. Тогда решение с учетом граничного условия при $r = R_2$:

$$\psi(r,\varphi) = A(\varphi)\sin(k(\varphi)(r-R_2))$$

Пусть $h(\varphi)$ – длина отрезка луча в полости между цилиндрами, идушего под углом φ (φ отсчитываем от плоскости симметрии системы), а $\Delta = R_1 - R_2$. Используя $|R_1 - R_2| \ll R_{1,2}$ и теорему косинусов, получим: (write it better and add picture!!!)

$$h(\varphi) = (R_1 - R_2)(1+\cos\varphi)$$

Граничное условия на внешнем цилиндре:

$$\psi(R_2 + h(\varphi),\varphi) = 0 \to k_N(\varphi) = \frac{\pi N}{(1+\cos\varphi)\Delta}$$

Соответствующие нормированные волновые функции:

$$\psi_N^{(f)} = \sqrt{\frac{2}{\Delta(1+\cos\varphi)}}\sin\left(\frac{\pi N(r-R_2)}{(1+\cos\varphi)\Delta}\right)$$

Уровни энергии быстрой подсистемы:

$$\varepsilon_N(\varphi) = \frac{\hbar^2\pi^2N^2}{2m\Delta^2(1+\cos\varphi)^2}$$

$$-\frac{\hbar^2}{2mR_2^2}\frac{d^2\psi_N(\varphi)}{d\varphi^2} + \frac{\hbar^2\pi^2N^2}{2m\Delta^2(1+\cos\varphi)^2}\psi_N(\varphi) = E_N^{(s)}\psi_N(\varphi)$$

Сведём задачу к гармоническому осциллятору. Разложим по малому углу φ:

$$-\frac{\hbar^2}{2mR_2^2}\frac{d^2\psi_N(\varphi)}{d\varphi^2} + \frac{\hbar^2\pi^2N^2}{2m\Delta^2(1+\cos\varphi)^2}\psi_N(\varphi) = E_N^{(s)}\psi_N(\varphi)$$

Уровни энергии:

$$E_{N,n} = \frac{\hbar^2\pi^2N^2}{8m(R_1-R_2)^2} + \frac{\hbar^2\pi N}{2\sqrt{2}mR_1(R_1-R_2)}\left(n+\frac{1}{2}\right)$$

ПТФ-10.з.2. Поправки к энергии в эллипсе (???)

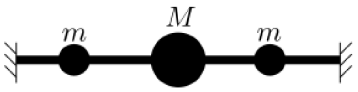
Определите ведущую поправку к энергии основного состояния свободной частицы в эллиптической полости с полуосями $a \gg b$.

Solution.

(на семинаре по идее она разобрана, пропишу потом.)

ПТФ-10.з3. Three big particles in a box

В одномерный ящик ширины L помещены три частицы, две из которых имеют массу m, а третья находится между ними и имеет массу $M \gg m$. Частицы взаимодействуют точечным образом так, что они оказываются непроницаемы друг для друга. Определите низколежащие уровни энергии такой системы.



Solution.

Гамильтониан системы:

$$\hat{H} = -\frac{1}{2m}\left(\frac{\partial}{\partial x_1}\right)^2 - \frac{1}{2m}\left(\frac{\partial}{\partial x_2}\right)^2 - \frac{1}{2M}\left(\frac{\partial}{\partial X}\right)^2 + U(x_1,x_2,X)$$

где $x_{1,2}$ – координаты частиц m, X – координата частицы M. $U(x_1,x_2,X) = U_1(x_1,X) + U_2(x_2,X)$ – потенциальная энергия взаимодействия частиц, обеспечивающая непроницаемость. Частица M – медленная подсистема, а частицы m в совокупности – быстрая.
Адиабатическое приближение:

$$\hat{H}_f = -\frac{1}{2m}\left(\frac{\partial}{\partial x_1}\right)^2 - \frac{1}{2m}\left(\frac{\partial}{\partial x_2}\right)^2 + U_1(x_1,X) + U_2(x_2,X), \quad \hat{H}_s = -\frac{1}{2M}\left(\frac{\partial}{\partial X}\right)^2$$

Волновые функции шариков m, соответствующие $\hat{H}_f$:

$$\psi_{1,N_1}(x_1,X) = \sqrt{\frac{2}{X}}\sin\left(\frac{\pi N_1}{X}x_1\right), \quad \psi_{2,N_2}(x_2,X) = \sqrt{\frac{2}{L-X}}\sin\left(\frac{\pi N_2}{L-X}(L-x_2)\right)$$

$$\psi_{N_1,N_2}(x_1,x_2,y)=\frac{2}{\sqrt{y(L-y)}}\sin\left(\frac{\pi N_1}{y}x_1\right)\cdot\sin\left(\frac{\pi N_2}{L-y}(L-x_2)\right)$$

Энергия – сумма энергий каждого движения:

$$\varepsilon^{(f)}_{N_1,N_2}=\frac{\pi^2}{2m}\left(\frac{N_1^2}{X^2}+\frac{N_2^2}{(L-X)^2}\right)$$

Эффективная потенциальная энергия для медленной подсистемы:

$$\hat{H}^{(\text{eff})}_s(X)=\frac{\hat{p}_X^2}{2M}+\frac{\pi^2}{2m}\left(\frac{N_1^2}{X^2}+\frac{N_2^2}{(L-X)^2}\right)$$

Минимум энергии находится в точке: $X_0=\frac{L}{1+(N_2/N_1)^{2/3}}$.

$$U''_{\text{eff}}(X_0)=\frac{3\pi^2}{mL^4}\left(N_1^2\left(1+\left(\frac{N_2}{N_1}\right)^{2/3}\right)^4+N_2^2\left(1+\left(\frac{N_1}{N_2}\right)^{2/3}\right)^4\right)$$

$$E_{N_1,N_2,n}=\frac{\pi^2}{2mL^2}\left(N_1^2\left(1+\left(\frac{N_2}{N_1}\right)^{2/3}\right)^2+N_2^2\left(1+\left(\frac{N_1}{N_2}\right)^{2/3}\right)^2\right)+$$
$$+\sqrt{\frac{3\pi^2}{MmL^4}\left(N_1^2\left(1+\left(\frac{N_2}{N_1}\right)^{2/3}\right)^4+N_2^2\left(1+\left(\frac{N_1}{N_2}\right)^{2/3}\right)^4\right)}\left(n+\frac{1}{2}\right)$$

Я. Частица в треугольнике (!?!?)

(?? а тут то что делать??)

ПТФ-10.з4. Particle in a ring with strong magnetic field

A particle with spin $1/2$ of mass m moves along a ring of radius R. A magnetic monopole is placed in the center of the ring, which creates a large magnetic field B on the ring. The Hamiltonian of such a system has the form:

$$\hat{H}=-\frac{1}{2mR^2}\partial_\varphi^2-\mu_B B(\cos\varphi\hat{\sigma}_x+\sin\varphi\hat{\sigma}_y)$$

Determine the energy levels of such a system in the limit $\mu_B B\gg\frac{1}{mR^2}$.

Solution.

$$\hat{H}=-\frac{1}{2mR^2}\left(\frac{d}{d\varphi}\right)^2-\mu_0 B\begin{pmatrix}0 & e^{-i\varphi}\\ e^{i\varphi} & 0\end{pmatrix}$$

Медленная подсистема – движение по углу, быстрая – вращение спина:

$$\hat{H}=\hat{H}_s+\hat{H}_f,\quad \hat{H}_s=-\frac{1}{2mR^2}\left(\frac{d}{d\varphi}\right)^2,\quad \hat{H}_f=-\mu_0 B\begin{pmatrix}0 & e^{-i\varphi}\\ e^{i\varphi} & 0\end{pmatrix}$$

Зафиксируем положение медленной подсистемы и решим стационарное уравнение Шрёдингера для быстрой:

$$\hat{H}_f|\psi^{(f)}\rangle=\varepsilon^{(f)}|\psi^{(f)}\rangle$$
$$\varepsilon^{(f)}_-=-\mu_0 B_0,\quad \varepsilon^{(f)}_+=+\mu_0 B_0$$
$$|\psi^{(f)}_-\rangle=\frac{1}{\sqrt{2}}\begin{pmatrix}-e^{-i\varphi}\\ 1\end{pmatrix},\quad |\psi^{(f)}_+\rangle=\frac{1}{\sqrt{2}}\begin{pmatrix}e^{-i\varphi}\\ 1\end{pmatrix}$$

Представим полную волновую функцию в виде:

$$|\psi(\varphi)\rangle\equiv f_+(\varphi)|\psi^{(f)}_+\rangle+f_-(\varphi)|\psi^{(f)}_-\rangle$$

$$\frac{d^2|\psi(\varphi)\rangle}{d\varphi^2} = f_+''(\varphi)|\psi_+^{(f)}(\varphi)\rangle + 2f_+'(\varphi)|\psi_+^{(f)}(\varphi)\rangle' + f_+(\varphi)|\psi_+^{(f)}(\varphi)\rangle''+$$
$$+ f_-''(\varphi)|\psi_-^{(f)}(\varphi)\rangle + 2f_-'(\varphi)|\psi_-^{(f)}(\varphi)\rangle' + f_-(\varphi)|\psi_-^{(f)}(\varphi)\rangle''$$

Подставим в гамильтониан и получим систему уравнений на $f_\pm(\varphi)$:

(??? это непонятно, как оно получается?? I remember that I thought about it, but still, currently I should think again about it)

$$\begin{cases} f_+''(\varphi) + if_+'(\varphi) - \frac{1}{2}f_+(\varphi) - if_-'(\varphi)e^{-2i\varphi} - \frac{f_-(\varphi)}{2}e^{-2i\varphi} + 2mR^2\mu_0 B f_+(\varphi) = -2mR^2 E f_+(\varphi) \\ f_-''(\varphi) - if_-'(\varphi) - \frac{1}{2}f_-(\varphi) + if_-'(\varphi)e^{2i\varphi} - \frac{f_+(\varphi)}{2}e^{2i\varphi} - 2mR^2\mu_0 B f_-(\varphi) = -2mR^2 E f_-(\varphi) \end{cases}$$

Ищем решение в виде:

$$f_\pm(\varphi) = \alpha_\pm e^{i\omega_\pm \varphi}$$

Граничные условия:

$$\begin{cases} |\psi(0)\rangle = |\psi(2\pi)\rangle \\ |\psi(0)\rangle' = |\psi(2\pi)\rangle' \end{cases}$$

$$\begin{cases} f_\pm(0) = f_\pm(2\pi) \\ f_\pm'(0) = f_\pm'(2\pi) \end{cases} \quad \to \omega_\pm = n_\pm \in \mathbb{Z}$$

$$\begin{cases} \alpha_+\left(n_+^2 - n_+ - \frac{1}{2} + 2mR^2\mu_0 B + 2mR^2 E\right) + \alpha_-\left(n_- - \frac{1}{2}\right) = 0 \\ \alpha_-\left(n_-^2 + n_- - \frac{1}{2} - 2mR^2\mu_0 B + 2mR^2 E\right) - \alpha_+\left(n_+ + \frac{1}{2}\right) = 0 \end{cases}$$

$$\left((n+2)^2 - n - \frac{5}{2} + 2mR^2\mu_0 B + 2mR^2 E\right)\left(n^2 + n - \frac{1}{2} - 2mR^2\mu_0 B + 2mR^2 E\right) = -\left(n - \frac{1}{2}\right)\left(n + \frac{5}{2}\right)$$

Для $2mR^2\mu_0 B \gg 1$, $n \ll \sqrt{2mR^2\mu_0 B}$:

$$\left(2mR^2\mu_0 B + 2mR^2 E\right)\left(-2mR^2\mu_0 B + 2mR^2 E\right) \approx -\left(n - \frac{1}{2}\right)\left(n + \frac{5}{2}\right)$$

$$E^2 \approx \mu_0^2 B^2 - \frac{\left(n - \frac{1}{2}\right)\left(n + \frac{5}{2}\right)}{4m^2R^4}$$

$$E_n \approx \pm\mu_0 B \mp \frac{\left(n - \frac{1}{2}\right)\left(n + \frac{5}{2}\right)}{8m^2R^4\mu_0 B}$$

(add from English)Г-8.59.

Гамильтониан системы имеет вид

$$\hat{H} = \frac{1}{2m}\hat{p}_x^2 + \frac{1}{2M}\hat{p}_y^2 + \frac{k\left(x^2 + y^2\right)}{2} + \alpha xy, \quad |\alpha| < k,$$

причем $M \gg m$ (два связанных осциллятора с сильно различающимися массами). Найти уровни энергии системы и соответствующие им волновые функции на основе адиабатического приближения. Сравнить полученный результат с точным решением, см. 2.50.

(add from English)Г-8.60.

Две частицы с сильно различающимися массами $M \gg m$ находятся в бесконечно глубокой потенциальной яме ширины и взаимодействуют друг с другом как взаимно непроницаемые точки. Найти энергетические уровни нижней части спектра и соответствующие им волновые функции.

(add from English)Г-8.61.

Используя адиабатическое приближение, обсудить вопрос об энергетическом спектре и виде соответствующих волновых функций связанных состояний частицы в центральном потенциале притяжения $U(r)$ в присутствии достаточно сильного однородного магнитного поля.

Найти сдвиги уровней Ландау под влиянием короткодействующего потенциала, а также основной уровень атома водорода в сильном магнитном поле.

TM. Ionization with moving δ-potential

A 1D particle is located in the δ-potential. It starts moving slowly by a hyperbolic tangents law. Find a probability of ionization.
(add a plot of a hyperbolic tangent)

Solution

(use that formula from adiabatics, but I need to practice more in it)

Feigelman.EntrExam.th-4/8

Particle with strongly anisotropic spectrum $E = \frac{p_x^2}{2m_1} + \frac{p_x^2+p_y^2}{m_2}$, $m_1 \gg m_2$, is moving in the attractive potential $U(r) = -\alpha/r$. Find few low-lying energy levels.

Solution by Oleg Baburin.

(??? write here why we do so!!!)

1. Разделим переменные:

$$\Psi(\rho, z) = R_{00}(\rho)\chi(z)$$

2. В атомных единицах:

$$\hat{\boldsymbol{p}}_\perp = -i\boldsymbol{\nabla}_\perp \quad \Rightarrow \quad \hat{p}_\perp^2 = -\Delta_\perp$$

3. Поперечное состояние:

$$R_{00}(\rho) = 4e^{-2\rho}$$

4. Дифференцируем:

$$\frac{dR_{00}}{d\rho} = -8e^{-2\rho}, \quad \frac{d^2R_{00}}{d\rho^2} = 16e^{-2\rho}$$

Теперь подействуем оператором $\hat{p}_\perp^2$ на $R_{00}(\rho)$:

$$\frac{\hat{p}_\perp^2}{2}R_{00}(\rho) = \left(\frac{1}{\rho} - 2\right)R_{00}(\rho)$$

(!!! write here the approximation that is done. it is a cool approximation, we integrate over R00 also!!)
5. Получаем эффективный одномерный гамильтониан:

$$\left[\frac{\hat{P}_z^2}{2m_1} - \left\langle \frac{1}{\sqrt{\rho^2+\varepsilon^2 z^2}} - \frac{1}{\rho} \right\rangle\right]\chi(z) = (E+2)\chi(z)$$

6. Интеграл:

$$\left\langle \frac{1}{\rho} - \frac{1}{\sqrt{\rho^2+\varepsilon^2 z^2}} \right\rangle = 16J(a), \quad a := \varepsilon|z|$$

Где:

$$J(a) = \int_0^\infty e^{-4\rho}\left[1 - \frac{\rho}{\sqrt{\rho^2+a^2}}\right]d\rho$$

Для малых a :

$$J(a) = a + O\left(a^2\right), \quad (a \to 0)$$

Подставляем:

$$\left\langle \frac{1}{\rho} - \frac{1}{\sqrt{\rho^2 + \varepsilon^2 z^2}} \right\rangle = 16\varepsilon|z| + O\left(\varepsilon^2 z^2\right)$$

7. Сведение к уравнению Эйри Подставляем полученный эффективный потенциал в одномерное уравнение:

$$-\frac{\hbar^2}{2m_1}\chi''(z) - F|z|\chi(z) = \mathcal{E}\chi(z)$$

где $\mathcal{E} = E + 2$. Для $z > 0$:

$$\chi''(z) + \frac{2m_1 F}{\hbar^2}\left(z + \frac{\mathcal{E}}{F}\right)\chi(z) = 0$$

Вводим характеристическую длину:

$$\ell = \left(\frac{\hbar^2}{2m_1 F}\right)^{1/3}$$

и безразмерную переменную:

$$u = \frac{z}{\ell} + \frac{\mathcal{E}}{F\ell}.$$

Получаем уравнение Эйри:

$$\frac{d^2\chi}{du^2} + u\chi = 0$$

Решение для $z \to +\infty$:

$$\chi(z) = C\mathscr{A}i(u),$$

где $\mathscr{A}i(u)$ - это функция Эйри. Из чётности потенциала $-F|z|$ получаем условия на $z = 0$:

$$\text{нечётные: } \chi(0) = 0 \Rightarrow \mathscr{A}i\left(\frac{\mathcal{E}}{F\ell}\right) = 0,$$
$$\text{чётные: } \chi'(0) = 0 \Rightarrow \mathscr{A}i'\left(\frac{\mathcal{E}}{F\ell}\right) = 0.$$

8. Уровни энергии Обозначим нули функции Эйри как β_n для нечётных состояний и δ_n для чётных состояний. Тогда уровни энергии для эффективной одномерной задачи будут:

$$\mathcal{E}_n = \left(\frac{F^2\hbar^2}{2m_1}\right)^{\frac{1}{3}} \begin{cases} \beta_n, & \text{нечётные} \\ \delta_n, & \text{чётные} \end{cases}$$

9. Итоговая формула для энергии Подставляем $F = 16\alpha\varepsilon$. Итого:

$$\text{для нечетных: } \mathrm{E}_n = \alpha^2 m_1\left(-2 + 2^{\frac{7}{3}}\varepsilon^{\frac{2}{3}}\beta_n\right) \text{ для четных: } \mathrm{E}_n = \alpha^2 m_1\left(-2 + 2^{\frac{7}{3}}\varepsilon^{\frac{2}{3}}\delta_n\right)$$

17.1.9 Simple Problems about adiabatics in Condensed Matter

El-Batanouny.10.1 Dirac and Berry

Consider Dirac fermions in two dimensions described by the Hamiltonian

$$\mathcal{H}(\mathbf{k}) = \sum_{\alpha} d_{\alpha}(\mathbf{k})\sigma_{\alpha}, \quad d_1(\mathbf{k}) = k_x, d_2(\mathbf{k}) = k_y, d_3(\mathbf{k}) = m.$$

(a) Show that the Berry connection of the lower band can be written as

$$\mathcal{A}_{\mu} = i\langle\psi_{-}(\mathbf{k})|\partial_{k_\mu}\psi_{-}(\mathbf{k})\rangle = -\frac{1}{2d(\mathbf{k})\left[d(\mathbf{k}) - d_3(\mathbf{k})\right]}\left[d_2(\mathbf{k})\partial_{k_\mu}d_1(\mathbf{k}) - d_1(\mathbf{k})\partial_{k_\mu}d_2(\mathbf{k})\right]$$

where $d(\mathbf{k}) = |\mathbf{d}(\mathbf{k})|$.
(b) Show that the corresponding Berry curvature is given by

$$\mathcal{F}_{\mu\nu}(\mathbf{k}) = \frac{1}{2}\epsilon_{\alpha\beta\gamma}\hat{d}_{\alpha}\partial_{k_\mu}\hat{d}_{\beta}\partial_{k_\nu}\hat{d}_{\gamma}, \quad \hat{\mathbf{d}}(\mathbf{k}) = \frac{\mathbf{d}(\mathbf{k})}{|\mathbf{d}(\mathbf{k})|}.$$

Solution.

(??? I think it is nearly fully useless problem, so I'll think about it very later)
(!!! вспомню автора книги - переназову задачу!!!)

El-Batanouny.10.2 Parallel transport gauge

Consider a system subject to a weak adiabatic perturbation that is periodic in time. With the total Hamiltonian $\mathcal{H}(t+T) = \mathcal{H}(t)$, a general state $|\psi(t)\rangle$ obeys the Schrödinger equation

$$i\partial_t|\psi(t)\rangle = \mathcal{H}(t)|\psi(t)\rangle$$

and can be expressed as

$$|\psi(t)\rangle = \sum_{\ell'} \exp\left[-\frac{i}{\hbar}\int_0^t dt'\varepsilon_{\ell'}(t')\right] c_{\ell'}(t)|\ell'(t)\rangle,$$

where $|\ell'(t)\rangle$ is an eigenket of $\mathcal{H}(t)$, which are single-valued in $t : |\ell'(t+T)\rangle = |\ell'(t)\rangle$.
(a) Use the Schrödinger equation to derive an expression for $\dot{c}_{\ell}(t)$.
(b) Parallel transport, or horizontal lift, requires that

$$\langle\tilde{\ell}(t)|\partial_t\tilde{\ell}(t)\rangle \equiv \langle\bar{\ell}(\eta)|\mathrm{d}|\tilde{\ell}(t\eta)\rangle\frac{d\eta}{dt} = 0.$$

Show that the horizontal lift condition is satisfied by the gauge transformation

$$|\ell(t)\rangle \to |\bar{\ell}(t)\rangle = \exp\left[i\int_0^t dt'|\ell(t')\,|\partial_{t'}\ell(t')\rangle\right]|\ell(t)\rangle$$

(c) If the system starts in the eigenstate $|\tilde{\ell}(0)\rangle$, so that $c_{\ell} = 1, c_{\ell} = 0, \ell' \neq \ell$.
(i) Determine $\dot{c}_{\ell}$ and $\dot{c}_{\ell}$. Is the adiabatic theorem satisfied?
(ii) Check if the ansatz solution

$$c_{\ell'}(t) = -i\hbar\frac{\langle\bar{\ell}'(t)|\partial_t\bar{\ell}(t)\rangle}{\varepsilon_{\ell}(t) - \varepsilon_{\ell'}(t)}\exp\left[-\frac{i}{\hbar}\int_0^t dt'\left(\varepsilon_{\ell}(t') - \varepsilon_{\ell'}(t')\right)\right]$$

obeys the differential equation you obtained for $\dot{c}_{\ell}$. (Neglect terms of 2nd order).
(iii) Write down an expression for the state function that includes the first-order approximation.

Solution.

El-Batanouny.10.3 Divergence of Berry curvature

Use expression (10.24) to show that for $E_m \neq E_n$,

$$\nabla \cdot \mathcal{F} = 0.$$

Hint: Use the Hermitian operator

$$\mathbf{O} = -i \sum_n |\nabla n\rangle\langle n|$$

to express (10.24) as

$$\mathcal{F} = \mathrm{Im}\langle n|\mathbf{O} \times \mathbf{O}|n\rangle.$$

Solution.

El-Batanouny.10.4

In Section 10.3, we derived Berry's curvature for the two-level system using two methods: the direct geometric method, and the one- and two-form method. Alternatively, use the Hamiltonian derivative method outlined in Section 2.2.3 to derive Berry's curvature for that system.

Solution.

El-Batanouny.10.5

Consider a spin-J particle in a slowly rotating magnetic field. The Hamiltonian is given by

$$\mathcal{H} = -\boldsymbol{\mu} \cdot \mathbf{J}$$

where $\mathbf{J}$ is the spin angular momentum operator, and $\boldsymbol{\mu} = \mu_B \mathbf{B}(\hat{\mathbf{n}}(t))$. Use the Hamiltonian derivative method of Section 2.2.3 to determine the state Berry curvature and the corresponding Berry phase.

Solution.

El-Batanouny.10.6

We shall consider the ABE ring of Section 10.3 from a different perspective. We shall look at the system as consisting of a one-dimensional metallic ring with circumference L, threaded by a magnetic flux Φ. The Hamiltonian is again

$$\mathcal{H} = \frac{1}{2m_e}\left(\mathbf{p} - \frac{e}{c}\mathbf{A}\right)^2, \quad \nabla \times \mathcal{A} = 0.$$

We may recast the ring into a one-dimensional periodic structure of period L, by defining $x = L\varphi/2\pi$.

(a) If we write $\mathcal{A} = \nabla\chi(x)$, what will $\chi(x)$ be?

(b) Perform a gauge transformation on the one-dimensional Hamiltonian to eliminate $\mathcal{A}$. What boundary conditions have to be applied to the solutions of the corresponding Schrödinger equation?

(c) Determine the eigenfunctions and energy spectrum, by writing the solution in the Bloch form Ae^{ikx} and applying the boundary conditions you obtained in part (b).

(d) Calculate the current carried by an electron in a state $n, I_n(\phi) = ev_n/L = \frac{e}{\hbar L}\frac{\partial E_n}{\partial k_n}$.

(e) Let us fill the ring with and odd number N_{odd} of electrons, at zero temperature. What is the total current flowing through the system, $I(\phi)$? What happens when $\phi = \phi_0/2$?

(f) How does the current change when the number of electrons in the ring is even?

Solution.

El-Batanouny.10.7 Spin-orbit coupling in an ABE-like configuration

An electron is constrained to move on a 1D ring of radius a. The electron experiences a spin-orbit interaction with the electric field created by a charge Q placed at the center of the ring.

1. Write the Hamiltonian $\mathcal{H}(x, p, \mathbf{s})$.

2. Determine the electron eigenenergies and corresponding velocities.

3. Determine that the magnetic flux Φ through the ring would cancel the interaction of Q with a spin up electron.

Solution.

El-Batanouny.10.8

We consider the case of a time-reversal symmetric system with half-integer spin, represented by a Hamiltonian $\mathcal{H}(\eta)$, with $\eta = [\eta_1, ..., \eta_n]$. We label degenerate orthonormal Kramers' pair eigenkets as $|\mu, \eta\rangle, \mu = \pm 1$, that are smooth functions of the parameters η within a given patch. We need to define a new Berry connection A_ℓ, which is a 2×2 matrix, as

$$A_\ell^{\mu v}(\eta) = i\langle \mu, \eta | \partial_\ell | v, \eta \rangle,$$

where ∂_ℓ is the partial derivative with respect to η_ℓ. A gauge transformation to a basis set $|\mu, \eta\rangle'$, is obtained via a unitary transformation

$$|\mu, \eta\rangle' = \sum_\nu |v, \eta\rangle U_{v\mu}(\eta),$$

where $U(\eta)$ is a 2×2 unitary matrix that varies smoothly with η .[14] The non-Abelian Berry curvatures corresponding to the Berry connections $\mathcal{A}_\ell$ are defined as

$$\mathcal{F}_{\ell\ell'} = \partial_\ell \mathcal{A}_{\ell'} - \partial_{\ell'} \mathcal{A}_\ell - i\left[\mathcal{A}_\ell, \mathcal{A}_{\ell'}\right].$$

(a) Show that If $\boldsymbol{\Theta}|+, \boldsymbol{\eta}\rangle = |-, \boldsymbol{\eta}\rangle e^{i\phi} \rightarrow \boldsymbol{\Theta}|-, \boldsymbol{\eta}\rangle = -|+, \boldsymbol{\eta}\rangle e^{i\phi}$.

(b) Derive an expression for the Berry connection $\overline{\mathcal{A}}_\ell$, corresponding to the new states $|\mu, \eta\rangle'$, in terms of $\mathcal{A}_\ell$ and $U(\eta)$.

(c) Derive an expression for the Berry curvature $\overline{\mathcal{F}}_{\ell\ell'}$

$$\overline{\mathcal{F}}_{\ell\ell'} = \partial_\ell \overline{\mathcal{A}}_{\ell'} - \partial_{\ell'} \overline{\mathcal{A}}_\ell - i\left[\overline{\mathcal{A}}_\ell, \overline{\mathcal{A}}_{\ell'}\right]$$

in terms of $\mathcal{F}_{\ell\ell}$ and $U(\eta)$.

Solution.

El-Batanouny.10.9

In our consideration of the trimer problem, we only included coupling between the electronic orbitals and the E_g vibronic states linear in Q. Here, we will include a higher-order quadratic coupling term; it takes the form

$$gQ^2\left(-\cos(2\varphi)\sigma_z - \sin(2\varphi)\sigma_x\right), \quad g \ll 1.$$

This term becomes important when Q is large, since it depends on Q^2.

(a) Add the quadratic terms to the Hamiltonian matrix in (10.32), and determine the electronic energy eigenvalues.

(b) The modified Hamiltonian can still be mapped onto the spin-1/2 system Hamiltonian. Write down the eigenkets in terms of a new phase angle θ and define θ in terms of the Hamiltonian matrix components.

(c) Express the effective ion potential in terms of the new electronic eigenenergies and determine its degeneracy points.

Solution.

17.1.10 Problems about adiabatics in Applications

(write about which experiments do really use this method?)

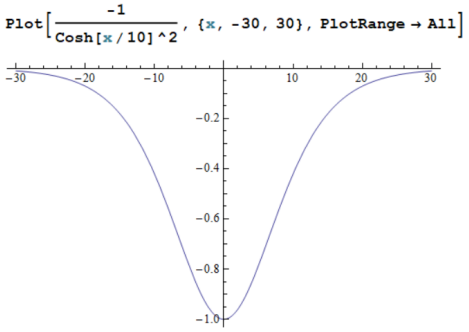
17.1.11 Problems about quasiclassical method 1: Easy Templates

ГК-1.17. Semiclassics in $V = -\frac{V_0}{\mathrm{ch}^2 \frac{x}{a}}$

For the potential $V = -\frac{V_0}{\mathrm{ch}^2 \frac{x}{a}}$, determine the energy levels and the total number of discrete levels in the quasi-classical approximation.

Solution.

This is a typical problem about WKB method. It is very easy one, except that one needs to take the integral, which can be a very big problem.



Reminder: the energy levels E_n are determined from the Bohr quantization rule

$$\int_{x_1}^{x_2} p dx = \pi \left(n + \frac{1}{2}\right) \hbar; \qquad p = \sqrt{2\mu \left(E_n + \frac{V_0}{\mathrm{ch}^2 \frac{x}{a}}\right)}$$

x_1 and x_2 are the turning points determined from the condition $p = 0$ (with $E_n < 0$ for the considered case of a discrete spectrum).

On needs to calculate the integral

$$I(E) = \int_{x_1}^{x_2} \sqrt{2\mu \left(E + \frac{V_0}{\mathrm{ch}^2 \frac{x}{a}}\right)} dx.$$

We differentiate both parts by E. In this case, the derivative of the integral along the upper and lower limits vanishes, since at points x_1 and x_2 the root expression is zero. Thus,

$$\frac{dI}{dE} = \mu \int_{x_1}^{x_2} \frac{dx}{\sqrt{2\mu \left(E + \frac{V_0}{\mathrm{ch}^2 \frac{x}{a}}\right)}}.$$

By replacing the variable $\mathrm{sh}\, \frac{x}{a} = z$, the last integral is reduced to the following form:

$$\frac{dI}{dE} = \mu a \int_{\varepsilon_1'}^{\varepsilon_3} \frac{dz}{\sqrt{2\mu \left[E\left(1 + z^2\right) + V_0\right]}} = \frac{\mu a}{\sqrt{-2\mu E}} \pi.$$

(???? I STILL HAVE NOT SOLVED THIS INTEGRAL, PLEASE HELP ME!!! I NEED TO LEARN THE MATH AGAIN)

From here we find

$$I(E) = -\sqrt{-2\mu a^2 E}\pi + C.$$

The constant C is determined from the condition that for $E = -V_0$, the integration region contracts to a point and from where

$$I\left(-V_0\right) = 0,$$

$I(E) = \sqrt{2\mu a^2}\left(\sqrt{V_0} - \sqrt{-E}\right)\pi$ Thus, in the quasi-classical approximation, energy levels are determined by the following expression:

$$E_n = -\frac{\hbar^2}{2\mu a^2}\left[\sqrt{\frac{2\mu a^2 V_0}{\hbar^2}} - \left(n + \frac{1}{2}\right)\right]^2 \quad (n = 0, 1, 2, ...).(2)$$

Number of levels $N = \frac{\sqrt{2\mu V_0}}{\hbar}a$. Note that the calculation of energy levels using the quantization rule (1) is legal if the number of levels is large, i.e.

$$\frac{2\mu a^2 V_0}{\hbar^2} \gg 1.$$

When this condition is fulfilled, the expression for energy levels (2) coincides with the exact formula for E_n obtained in problem 11, §1.

(???? додумаю ответ, пока не очень понял.)

By the way, one can compute the integral by residue theorem (?? I'll try later this).

Solution using complex analysis.

(???? I still don't know how to do it)

Numerical solution.

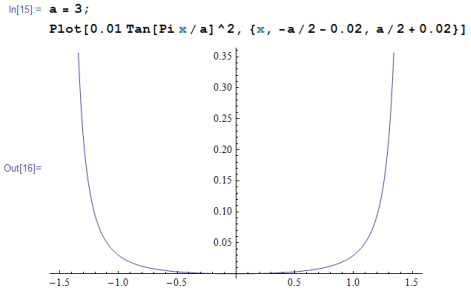
(???? I still don't know how to do it)

Typical. WKB spectrum and number of levels in $V = -U_0 \tan^2\left(\frac{\pi x}{a}\right)$

For the potential $V = -\frac{V_0}{\mathrm{ch}^2\frac{x}{a}}$, determine the energy levels and the total number of discrete levels in the quasi-classical approximation.

Solution by standard integration.

One needs just to do a careful WKB and obtain the integral by some clever method, for example, by differentiation over the parameter.



If we define

$$I(E) = \int\limits_{x_1(E)}^{x_2(E)} \sqrt{2m\left(E - U_0\tan^2\left(\frac{\pi x}{a}\right)\right)}dx,$$

where $x_1(E)$ and $x_2(E)$ are the solution to $E - U_0\tan^2\left(\frac{\pi x}{a}\right) = 0$:

$$x_{1,2} = \mp\frac{a}{\pi}\arctan\left(\sqrt{\frac{E}{U_0}}\right)$$

The minus is here at the top, because it corresponds to the left point, and the plus corresponds to the right one. Using Leibniz integral rule with, in our case $f(E,x) = \sqrt{2m\left(E - U_0\tan^2\left(\frac{\pi x}{a}\right)\right)}$ and, by definition of x_1

and x_2, we have $f\left(E, x_{1,2}(E)\right) = 0$, and we get

$$\frac{dI(E)}{dE} = f\left(E, x_2(E)\right)\frac{d}{dE}x_2(E) - f\left(E, x_1(E)\right)\frac{d}{dE}x_1(E) + \int\limits_{x_1(E)}^{x_2(E)} \frac{\partial}{\partial E} f(E,x)dx$$

$$= 0 + 0 + \sqrt{2m}\int\limits_{x_1(E)}^{x_2(E)} \frac{1}{2}\frac{1}{\sqrt{\left(E - U_0\tan^2\left(\frac{\pi x}{a}\right)\right)}}dx$$

Let us set $z := \sin\left(\frac{\pi x}{a}\right)$, so $dz = \frac{\pi}{a}\cos\left(\frac{\pi x}{a}\right)dx$ and using $\cos\alpha = \sqrt{1-\sin^2\alpha}$ we find $dx = adz/\left(\pi\sqrt{1-z^2}\right)$, also $\tan^2(\pi x/a) = z^2/\left(1-z^2\right)$. Performing the change of variable, we get

$$\frac{dI(E)}{dE} = \frac{\sqrt{2m}}{2}\int\limits_{z_1(E)}^{z_2(E)} \frac{1}{\sqrt{\left(E - U_0\frac{z^2}{1-z^2}\right)}}\frac{a}{\pi}\frac{dz}{\sqrt{1-z^2}} =$$

$$= \frac{a\sqrt{2m}}{2\pi}\int\limits_{z_1(E)}^{z_2(E)} \frac{1}{\sqrt{\left(E - (E+U_0)\,z^2\right)}}dz = \frac{a\sqrt{2m}}{2\pi\sqrt{E}}\int\limits_{z_1(E)}^{z_2(E)} \frac{1}{\sqrt{\left(1 - \frac{E+U_0}{E}z^2\right)}}dz,$$

where $z_{1,2}(E) = \sin\left(\frac{\pi x_{1,2}(E)}{a}\right)$. Then we make another change of variable: $\alpha := \sqrt{\frac{E+U_0}{E}}z$ so $d\alpha = \sqrt{\frac{E+U_0}{E}}dz$, and the integral becomes

$$\frac{dI(E)}{dE} = \frac{a\sqrt{2m}}{2\pi\sqrt{E}}\sqrt{\frac{E}{E+U_0}}\int\limits_{\alpha_1(E)}^{\alpha_2(E)} \frac{d\alpha}{\sqrt{1-\alpha^2}} = \frac{a\sqrt{2m}}{2\pi\sqrt{E+U_0}}\left(\arcsin\alpha_2 - \arcsin\alpha_1\right).$$

The bounds $\alpha_{1,2}$ are defined by

$$\alpha_{1,2} = \sqrt{\frac{E+U_0}{E}}z_{1,2} = \sqrt{\frac{E+U_0}{E}}\sin\left(\frac{\pi x_{1,2}(E)}{a}\right) = \sqrt{\frac{E+U_0}{E}}\sin\left(\frac{\mp\pi\frac{a}{\pi}\arctan\left(\sqrt{\frac{E}{U_0}}\right)}{a}\right)$$

$$= \mp\sqrt{\frac{E+U_0}{E}}\sin\left(\arctan\left(\sqrt{\frac{E}{U_0}}\right)\right).$$

Then by $\sin(\arctan(x)) = \frac{x}{\sqrt{1+x^2}}$ we find

$$\alpha_{1,2} = \mp\sqrt{\frac{E+U_0}{E}}\frac{\sqrt{\frac{E}{U_0}}}{\sqrt{1+\frac{E}{U_0}}} = \mp 1$$

The integral is thus

$$\frac{dI(E)}{dE} = \frac{a\sqrt{2m}}{2\pi\sqrt{E+U_0}}(\arcsin(1) - \arcsin(-1)) = \frac{a\sqrt{2m}}{2\sqrt{E+U_0}}$$

Remembering that $I(0) = 0$, since at $E = 0, x_1 = x_2$, we have

$$I(E) = \sqrt{2m}a\left(\sqrt{E+U_0} - \sqrt{U_0}\right).$$

The energy is then found using $I(E) = \pi\hbar(n+1/2)$:

$$E = \left(\sqrt{U_0} + \frac{\pi\hbar(n+1/2)}{\sqrt{2m}a}\right)^2 - U_0$$

This formula is a combination of the energy of a harmonic oscillator $E = \hbar\omega(n+1/2)$ and of the potential well $E = \hbar^2\pi^2n^2/(2ma^2)$. If we set $U \to 0$, the quasiclassic method does not produce the exact result, but for high n it is a good approximaiton.

Solution using complex analysis.

Рассмотреть случаи $U_0 > 0, U_0 < 0$.

ЕК.7.з.10.

Оценить ВКБ-коэффициент прохождения $D(E)$ в поле с потенциалом (рис. 25)

$$\begin{array}{ll} U(x) \approx -U_0 & (x < 0) \\ U(x) \approx -Fx & (x > 0) \end{array}$$

Такой потенциал представляет интерес для описания холодной эмиссии электронов из металла в электрическом поле напряженности F. Величина U_0 соответствует работе выхода.

Б-2.7.1 Квазиклассика в осцилляторе и обрезанном осцилляторе

Найти в квазиклассическом приближении уровни энергии и собственные функции:
а) линейного гармонического осциллятора;
б) частицы, движущейся в поле

$$U(x) = \begin{cases} \infty, & x \leqslant 0 \\ \frac{m\omega^2 x^2}{2} & x > 0 \end{cases}$$

(add picture)

а) решение в осцилляторе

Исходя из правила квантования Бора-Зоммерфельда, имеем

$$\int\limits_a^b p(x)dx = \int\limits_{-x_0}^{x_0} \sqrt{2mE - m^2\omega^2 x^2}dx = \pi\hbar\left(n + \frac{1}{2}\right),$$

где $x_0 = \sqrt{2E/(m\omega^2)}$ - классическая точка поворота. Вычисляя интеграл (1), получим $E\pi/\omega$, откуда найдем уровни энергии:

$$E_n = \hbar\omega\left(n + \frac{1}{2}\right), \quad n = 0, 1, 2, ...$$

Построим волновую функцию, исходя из правила согласования квазиклассических решений при переходе из классически запрещенной области в классически разрешенную (II.36):

$$\psi_n(x) = C \begin{cases} \frac{(-1)^n}{2\sqrt{|p(x)|}} \exp\{-z_1\}, & x < -a \\ \frac{1}{\sqrt{p(x)}} \sin\{z_2 + \pi/4\}, & -a < x < a \\ \frac{1}{2\sqrt{|p(x)|}} \exp\{-z_3\}, & x > a \end{cases}$$

$$z_1 := \frac{1}{\hbar}\int\limits_x^{-a} |p(\xi)|d\xi, \quad z_2 := \frac{1}{\hbar}\int\limits_{-a}^{a} p(\xi)d\xi, \quad z_3 := \frac{1}{\hbar}\int\limits_a^{x} |p(\xi)|d\xi.$$

При расчете нормировочного множителя, как и обычно, пренебрегаем вкладом экспонент и считаем, что $\sin^2\alpha = 1/2$ (функция быстро осциллирует), поэтому $C \simeq \sqrt{2m\omega/\pi}$.

(check!!!)

Вычисляя интегралы, окончательно получаем (check!!!)

$$z_2 = \frac{E_n}{\hbar\omega}\left[\frac{x}{x_0}\sqrt{1-\left(\frac{x}{x_0}\right)^2} + \arcsin\left(\frac{x}{x_0}\right) + \frac{\pi}{2}\right],$$

$$z_{1,3} = \frac{E_n}{\hbar\omega}\left[\mp\frac{x}{x_0}\sqrt{\left(\frac{x}{x_0}\right)^2 - 1} - \ln\left(\mp\frac{x}{x_0} + \sqrt{\left(\frac{x}{x_0}\right)^2 - 1}\right)\right].$$

The prefactor is

$$\frac{C}{2\sqrt{|p(x)|}} \simeq \frac{1}{\sqrt{2\pi\sqrt{x^2 - x_0^2}}}, \qquad \frac{C}{\sqrt{p(x)}} \simeq \sqrt{\frac{2}{\pi\sqrt{x_0^2 - x^2}}}.$$

(x_0 was introduced in the beginning, it is a turning point)

(write the final formula)

б) решение в обрезанном осцилляторе (!?!!!)

(!!! нужно еще раз про модификацию БЗ прописать и продумать!)

Прежде всего заметим, что условия применимости метода ВКБ (плавный ход потенциала взаимодействия) выполняются вплоть до $x = 0$, а в точке $x = 0$ необходимо поставить граничное условие $\psi(0) = 0$ (рис. 2.8).

Поэтому должно выполняться условие (для классически разрешенной области)

$$\sin\left\{\frac{1}{\hbar}\int\limits_0^{x_0} p(x)dx + \frac{\pi}{4}\right\} = 0$$

что приводит к модификации правила квантования Бора-Зоммерфельда:

$$\int\limits_0^{x_0} p(x)dx = \pi\hbar\left(n + \frac{3}{4}\right).$$

Из соотношения (3) получаем уровни энергии:

$$E_n = \hbar\omega\left(2n + \frac{3}{2}\right), \quad n = 0, 1, 2...$$

которые совпадают с нечетными уровнями для случая а).

Thuus, the wave functions are the $\widetilde{\psi}_n(x)$ for the oscillator, but only the odd ones, and only in the positive side (which is allowed by the potential). They were normalized, so since now we have half of them, then square of them equal to one, so the final wave function look like this:

$$\widetilde{\psi}_n(x) = \begin{cases} \sqrt{2}\psi_{2n+1}(x), & x > 0, \\ 0, & x \leqslant 0. \end{cases}$$

(write the final formulas)

17.1.13 Problems about quasiclassical method 2

Б-2.7.2 Спектр в угле

Найти в квазиклассическом приближении уровни энергии и собственные функции частицы в поле

$$U(x) = \begin{cases} \infty, & x \leqslant 0 \\ Fx, & x > 0 \end{cases}$$

Solution.

В данной задаче, как и в задаче 2.7.1 п. б) необходимо поставить специальное граничное условие при $x = 0$, т. е. $\psi(0) = 0$. Это приводит к следующему виду правила квантования:

$$\int\limits_0^{x_0} p(\xi)d\xi = \int\limits_0^{E/F} \sqrt{2m(E - F\xi)}d\xi = \pi\hbar\left(n + \frac{3}{4}\right).$$

В итоге получаем энергетические уровни:

$$E_n = \left(\frac{3\pi\hbar F}{2\sqrt{2m}}\right)^{2/3}\left(n + \frac{3}{4}\right)^{2/3}$$

и согласованные квазиклассические функции. В классически разрешенной области функция имеет вид

$$\psi_n(x)|_{0<x<\frac{E_n}{F}} = \left(\frac{F^2}{E_n - Fx}\right)^{1/4}\sin\left\{\frac{2\sqrt{2m}}{3F\hbar}\left(E_n - Fx\right)^{3/2} + \frac{\pi}{4}\right\},$$

и в классически запрещенной:

$$\psi_n(x)|_{x>\frac{E_n}{F}} = \frac{1}{2}\left(\frac{F^2}{Fx - E_n}\right)^{1/4}\exp\left\{-\frac{2\sqrt{2m}}{3F\hbar}\left(Fx - E_n\right)^{3/2}\right\}.$$

Б-2.7.3 Закон Гейгера-Неттола

Найти в квазиклассическом приближении коэффициент прохождения через потенциальный барьер

$$U(x) = \begin{cases} -U_0, & x \leqslant r_0 \\ \frac{2Ze^2}{x}, & x > r_0. \end{cases}$$

Получить приближенное выражение для коэффициента прохождения, считая, что $r_0 \ll 2Ze^2/E$. Обсудить связь этой задачи с элементарной теорией альфа-распада и получить закон Гейгера-Неттола.

Solution.

(! в 1ю часть в типичные модели про это напишу!)
Согласно формуле Гамова (II.38) коэффициент прохождения через потенциальный барьер равен

$$D \simeq \exp\left\{-\frac{2}{\hbar}\int\limits_a^b |p(x)|dx\right\},$$

где

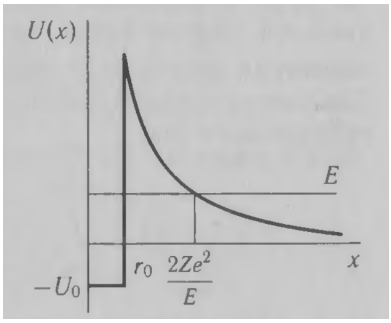
$$\int\limits_a^b |p(x)|dx = \int\limits_a^b \sqrt{2m(U(x) - E)}dx = \sqrt{2m}\int\limits_{r_0}^{2Ze^2/E}\sqrt{\frac{2Ze^2}{x} - E}dx.$$

Вычисляя интеграл, получаем

$$D \simeq \exp\left\{-\frac{4Ze^2}{\hbar}\sqrt{\frac{2m}{E}}(\arccos\sqrt{\alpha} - \sqrt{\alpha(1-\alpha)})\right\},$$

где $\alpha = \frac{r_0 E}{2Ze^2}$. В случае, если $\alpha \ll 1$, выражение (1) упрощается:

$$D \simeq \exp\left\{-\frac{2\pi Ze^2}{\hbar}\sqrt{\frac{2m}{E}}\right\}.$$



Следует заметить, что выражения (1) и (2) определяют коэффициент прохождения лишь по порядку величины, т. е. показывают его экспоненциальную малость. Поскольку условия применимости метода ВКБ нарушаются в точке $x = r_0$ (резкий скачок потенциала), то условия сшивания решений в данной точке требуют уточнения. В точном выражении в отличие от (2) появляется предэкспоненциальный множитель ~ 1.

Данная задача рассматривалась впервые в связи с теорией α-распада. С точки зрения квантовой механики α-распад представляет собой типичное явление прохождения частицы через потенциальный барьер.

Итак, α-частица вначале «заперта» в области $x \leqslant r_0$ (зона действия потенциала притяжения ядра, рис. 2.9). Для того, чтобы выйти из ядра, т. е. излучиться, α-частица должна преодолеть потенциальный барьер (при $x > r_0$ на частицу будут действовать кулоновские силы отталкивания).

Вероятность α-распада (или прохождения через барьер) в единицу времени λ пропорциональна коэффициенту прохождения D : $\lambda = nD$, где n - число столкновений со стенкой барьера в единицу времени.

Величину n можно оценить следующим образом: $n \sim v/r_0$, где v - характерная скорость частицы в потенциальной яме. Далее

$$v \sim \frac{p}{m_\alpha} \sim \frac{\hbar}{m_\alpha r_0}, \quad \text{поэтому } n \sim \frac{\hbar}{m_\alpha r_0^2}.$$

Период полураспада $T_{1/2}$ связан с вероятностью распада в единицу времени λ известным соотношением:

$$T_{1/2} = \frac{\ln 2}{\lambda} \simeq \frac{m_\alpha r_0^2 \ln 2}{\hbar D} = C_1 \exp\left[\frac{C_2}{\sqrt{E}}\right],$$

где последнее равенство является следствием (2). Логарифмируем (3) и получаем соотношение

$$\ln T_{1/2} = A + \frac{B}{\sqrt{E}},$$

которое и представляет собой закон Гейгера-Неттола. Величины A и B, разумеется, несложно выразить через исходные данные задачи.

Б-2.7.4

Найти в квазиклассическом приближении коэффициент прохождения через потенциальный барьер

$$U(x) = \begin{cases} 0, & |x| > x_0, \\ U_0 - \frac{m\omega^2 x^2}{2}, & |x| < x_0, \end{cases}$$

при условии $0 < E < U_0$.

Solution.

2.7.4. $D \simeq \exp\left\{-\frac{2\pi(U_0 - E)}{\hbar\omega}\right\}$.

Б-2.7.5

Исходя из правила квантования Бора-Зоммерфельда, получить выражение для смещения энергетических уровней частицы при изменении потенциальной энергии на малую величину $\delta U(x)$.

Solution.

2.7.5. Пусть возмущенный потенциал имеет вид $U(x) = U_0(x) + \delta U(x)$, где $U_0(x)$ - начальный потенциал, а $U(x)$ - малое изменение потенциальной энергии. Будем считать, что дискретные уровни энергии при наложении возмущения изменяются по схеме: $E_n^{(0)} \to E_n = E_n^{(0)} + \delta E_n$. Для поиска поправки δE_n представим формулу квантования Бора-30ммерфельда в виде

$$\pi\hbar\left(n+\frac{1}{2}\right) = \int\limits_{a+\delta a}^{b+\delta b} \sqrt{2m\left(E_n^{(0)} + \delta E_n - U_0(x) - \delta U(x)\right)}dx$$

где δa и δb характеризуют возможные сдвиги точек поворота. Очевидно, что должно выполняться

$$U_0(a+\delta a) + \delta U(a) = E_n^{(0)} + \delta E_n,$$

откуда легко получить, что

$$|\delta a| = |\frac{\delta E_n - \delta U(a)}{U'(a)}| \ll 1,$$

т. е. $|\delta a| \ll 1$ и $|\delta b| \ll 1$, если выполнены условия квазиклассичности. Нетрудно показать, что изменение интеграла за счет сдвига точек поворота $\sim (\delta a)^{3/2}$ (или $\sim (\delta b)^{3/2}$), и в линейном приближении соответствующие поправки должны быть отброшены. Поэтому оставляем в интеграле (1) в пределах интегрирования только a и b, и, проводя разложение подынтегрального выражения с линейной точностью по $\delta U(x)$, δE_n, получаем

$$\delta E_n \simeq \int\limits_a^b \frac{\delta U(x)dx}{\sqrt{2m\left(U_0(x) - E_n^{(0)}\right)}} / \int\limits_a^b \frac{dx}{\sqrt{2m\left(U_0(x) - E_n^{(0)}\right)}} = \frac{2}{T}\int\limits_a^b \frac{\delta U(x)dx}{v_0(x)},$$

где T - полный период классического движения частицы в потенциале $U_0(x)$, $v_0(x)$ - классическая скорость частицы.

Данный результат может быть получен и в первом приближении теории возмущений, если в качестве невозмущенной функции взять квазиклассическую функцию. В этом случае при расчете интегралов нужно пренебречь вкладом экспонент и заменить квадрат синуса на 1/2 под знаком интеграла, считая, что функция быстро осциллирует.

ПТФ-11.y1. Другие задачи сшивки

Найдите квазиклассические уровни энергии для следующих потенциалов, и сравните полученные ответы с уже известными.

• треугольная яма $U(x) = \begin{cases} +\infty, x < 0, \\ Fx, x > 0. \end{cases}$

• трёхмерный кулоновский потенциал $U(r) = -\frac{e^2}{r}$ для сферически симметричных состояний.

Указание: определите граничное условие в нуле, а в правой точке остановки используйте стандартное. Обратите внимание, что в этих задачах в одной из точек остановки линейное приближение для потенциала неприменимо, поэтому условие сшивки необходимо модифицировать. Для второй задачи вам может помочь упражнение 5.2.

Solution. Треугольный потенциал

Волновая функция в квазиклассике:

$$\psi(x) = \frac{1}{\sqrt{p(x)}}\cos\left(\int\limits_b^x p(y)dy - \frac{\pi}{4}\right)$$

где b – правая точка остановки. Условие непрерывности волновой функции в нуле

$$\psi(0) = 0$$

дает условие квантования Бора-Зоммерфельда:

$$\int\limits_a^b p(y)dy + \frac{\pi}{4} = \pi n - \frac{\pi}{2}, \quad p(x) = \sqrt{2m(E-Fx)}$$

(???? перевыведу формулу ниже, в теории она должна быть уже, где нули функции Айри.)

$$E_n = \left(\frac{3\pi F}{2\sqrt{2m}}\left(n - \frac{3}{4}\right)\right)^{2/3}$$

Solution. Кулоновский потенциал

(???? не уверен, насколько это решение верное. непонятно, откуда взялся $\nu = 1/2s$. Интегралы непонятно как взяты. Плохо решена задача, переделывать нужно!)

Поскольку рассматриваются сферически-симметричные состояния, то $l = m = 0$.

В упражнении 5.2. мы нашли решение для кулоновского потенциала для $E = 0$:

$$\psi(r,\theta,\phi) = J_{2l+1}\left(2\sqrt{\frac{2M\alpha}{\hbar^2}r}\right)\left(\sqrt{\frac{2M\alpha}{\hbar^2}r}\right)^{-1}\mathcal{Y}_{l,m}(\theta,\phi)$$

$$-\frac{\hbar^2}{2m}u''(r) - \frac{e^2}{r}u(r) = Eu(r), \quad \psi_{l,m}(r,\theta,\varphi) = R_E(r)\mathcal{Y}_{l,m}(\theta,\varphi), \quad R(r) = \frac{u(r)}{r}$$

Применим квазиклассическое приближение к этому уравнению. Волновая функция ограничена, а значит $u(r) \to 0$ при $r \to 0$. Т.е. все решения при малых r эквивалентны ассимтотически решению на нулевой энергии, поскольку совпадают стационарные уравнения Шрёдингера:

$$\frac{\hbar^2}{2m}u''(r) - \frac{e^2}{r}u(r) = 0$$

Поскольку в правой точке нужно использовать стандартное граничное условие, то

$$u(r) = \frac{1}{\sqrt{p(r)}}\cos\left(\int\limits_b^r p(r)dr - \frac{\pi}{4}\right), \quad p(r) = \sqrt{2m\left(E + \frac{e^2}{r}\right)}$$

где b - правая точка остановки. Сшиваем решение для нулевой энергии с квазиклассическим решением, где они оба применимы. Ассимптотика функции Бесселя:

$$J_\nu(z) \approx \sqrt{\frac{2}{\pi z}}\cos\left(z - \frac{\pi\nu}{2} - \frac{\pi}{4}\right), \quad z \to \infty$$

$$u(r) \sim r^{1/4}\cos\left(2\sqrt{\frac{2M\alpha}{\hbar^2}r} - \frac{\pi}{4} - \frac{\pi}{2}\right)$$

But from another side,

$$u(r) = \frac{1}{\sqrt{p(r)}}\cos\left(\int\limits_0^r p(r)dr + \phi\right)$$

$$\int\limits_0^r p(r)dr = \sqrt{2m}\int\limits_0^r \sqrt{E + \frac{e^2}{r}}dr \approx 2\sqrt{2me^2}\sqrt{r}$$

$$\phi = -\frac{3\pi}{4} \equiv \frac{\pi}{2} \qquad \text{(since under cos)}$$

Условие квантования:

$$\int\limits_0^b p(r)dr = \pi\hbar n$$

$$\int\limits_0^b p(r)dr = \sqrt{2me^2}\cdot\int\limits_0^b \sqrt{\frac{1}{r}-\frac{1}{b}}dr \overset{\text{wlf}}{=} \int\limits_0^b p(r)dr = \sqrt{2me^2}\cdot\frac{\pi}{2}\sqrt{b}$$

(?? что-то рукой не поситал его, потом поупражняюсь еще. попробовал заменить всё под корнем как новую переменную, но пока не увидел, к какому интегралу сводится он, что аж π вылазит)

$$\sqrt{2me^2 b_n}\frac{\pi}{2} = \pi\hbar n$$

$$E_n = -\frac{me^4}{2\hbar^2 n^2}$$

Получился точный ответ для уровней энергии!

ПТФ-11.y2

Рассмотрите $N(E)$ – количество состояний с энергией, меньше заданной E в поле произвольного адекватного трехмерного сферически-симметричного потенциала $U(r)$ в рамках квазиклассического приближения. Покажите, что следующие два способа вычисления приводят к одному и тому же результату а) одномерное правило квантования Бора-Зоммерфельда для радиальной переменной (отдельно для каждой сферической гармоники) с последующим суммированием по гармоникам и б) использование интеграла по трехмерному фазовому объему: $N(E) = \int d^3r \int \frac{d^3p}{(2\pi\hbar)^3}\theta(E-E_p)$, где $E_p = \frac{p^2}{2m}$.

[а)] Уравнение Шредингера для радиальной переменной

$$-\frac{\hbar^2}{2M}u''(r) + U'(r)u(r) = Eu(r), \quad u(r) = rR_E(r), \quad U'(r) = U(r) + \frac{l(l+1)}{2Mr^2}$$

Одномерное правило квантования Бора-Зоммерфельда:

$$\int\limits_{r^l_{\min}}^{r^l_{\max}} \sqrt{2M(E_{n,l,m} - U'(r))}dr = \pi\hbar\left(n+\frac{1}{2}\right)$$

Обозначим через $N_{E,l}$ – максимальное n, для которого $E_{n,l,m} \le E$.

$$\int\limits_{r^l_{\min}}^{r^l_{\max}} \sqrt{2M(E - U'(r))}dr = \pi\hbar\left(N_{E,l}+\frac{1}{2}\right)$$

$$\begin{aligned}
N(E) &= \sum_m \sum_{l=0}^{l_{\max}} N_{E,l} = \sum_{l=0}^{l_{\max}} (2l+1)N_{E,l} = \\
&= \int\limits_0^{l_{\max}} dl(2l+1)\frac{\sqrt{2M}}{\pi\hbar}\int\limits_{r^l_{\min}}^{r^l_{\max}} \sqrt{E - U(r) - \frac{l(l+1)}{2Mr^2}}dr = \\
&= -\frac{\sqrt{2M}}{\pi\hbar}\frac{4M}{3}\int\limits_{r_{\min}}^{r_{\max}} drr^2\left(E - U(r) - \frac{l(l+1)}{2Mr^2}\right)^{3/2}\Bigg|_{l=0}^{l=l_{\max}} \overset{\text{only } l=0}{=} \\
&= \frac{2(2M)^{3/2}}{3\pi\hbar}\int\limits_{r_{\min}}^{r_{\max}} r^2(E-U(r))^{3/2}dr
\end{aligned}$$

[б)] Интеграл по трёхмерному фазовому объёму:

$$N(E) = \int d^3r \int \frac{d^3p}{(2\pi\hbar)^3}\theta(E - E_p) = \int d^3r \int\limits_0^{p_{\max}} \frac{dp 4\pi p^2}{(2\pi\hbar)^3}$$

$$p_{\max} = \sqrt{2m(E - U(\vec{r}))}$$

$$N(E) = \frac{4\pi(2m)^{3/2}}{3(2\pi\hbar)^3}\int d^3r (E - U(r))^{3/2} = \frac{2(2m)^{3/2}}{3\pi\hbar}\int\limits_{r_{\min}}^{r_{\max}} dr r^2 (E - U(r))^{3/2}$$

ПТФ-11.у3 Туннелирование под $\frac{1}{\cosh^2(x/a)}$

Найдите вероятность квазиклассического туннелирования под барьером $U(x) = \frac{U_0}{\cosh^2(x/a)}$ для частиц энергии $0 < E < U_0$. Сравните ответ с точным (?допишу формулу).

Solution.

Общий вид волновой функции в квазиклассическом приближении:

$$\psi(x) = c_+\psi_+(x) + c_-\psi_-(x), \quad \psi_\pm(x) = \frac{e^{\pm i\int\limits_{x_0}^{x} p(x)dx}}{\sqrt{p(x)}}$$

Задача рассеяния:

$$\psi(x) = \begin{cases} \frac{1}{\sqrt{p(x)}}e^{i\int\limits_0^x p(z)dz} + \frac{r}{\sqrt{p(x)}}e^{-i\int\limits_0^x p(z)dz}, & x < 0 \\ \frac{t}{\sqrt{p(x)}}e^{i\int\limits_0^x p(z)dz}, & x > 0 \end{cases}$$

Это решение переписывается в следующем виде:

$$\psi(x) = \begin{cases} \psi_+(x) + r\psi_-(x), & x < 0 \\ t\psi_+(x), & x > 0 \end{cases}$$

Связь на коэффициенты:

$$\begin{pmatrix} c^+_{\text{left}} \\ c^-_{\text{left}} \end{pmatrix} = \hat{A}\hat{S}\hat{A}^\dagger \begin{pmatrix} c^+_{\text{right}} \\ c^-_{\text{right}} \end{pmatrix}, \quad \hat{A} = \begin{pmatrix} \frac{e^{-\frac{i\pi}{4}}}{2} & e^{\frac{i\pi}{4}} \\ \frac{e^{\frac{i\pi}{4}}}{2} & e^{-\frac{i\pi}{4}} \end{pmatrix}, \quad \hat{S} = \begin{pmatrix} e^{-S} & 0 \\ 0 & e^{S} \end{pmatrix}$$

$$\hat{A}\hat{S}\hat{A}^\dagger = \begin{pmatrix} \frac{1}{4}e^{-S} + \frac{1}{2}e^{S} & -\frac{i}{2}e^{-S} + ie^{S} \\ \frac{i}{4}e^{-S} - \frac{i}{2}e^{S} & \frac{1}{2}e^{-S} + e^{S} \end{pmatrix}$$

$$\begin{pmatrix} c^+_{\text{right}} \\ c^-_{\text{right}} \end{pmatrix} = \begin{pmatrix} 0 \\ t \end{pmatrix} \to \begin{pmatrix} c^+_{\text{left}} \\ c^-_{\text{left}} \end{pmatrix} = \begin{pmatrix} 1 \\ r \end{pmatrix} = t\begin{pmatrix} -\frac{i}{2}e^{-S} + ie^{S} \\ \frac{1}{2}e^{-S} + e^{S} \end{pmatrix}$$

$$t = \frac{i}{\frac{e^{-S}}{2} - e^{S}}, \quad r = i\frac{e^{-S} + 2e^{S}}{e^{-S} - 2e^{S}}$$

$$T = (\frac{e^{-S}}{2} - e^{S})^{-2}$$

Точки остановки:

$$\frac{U_0}{\cosh^2(x_{1,2}/a)} = E \to x_{1,2} = a\,\text{arccosh}\left(\pm\sqrt{\frac{U_0}{E}}\right)$$

$$S = \int\limits_{x_1}^{x_2}\sqrt{2m(U(x) - E)}dx = \sqrt{2m}\pi a(\sqrt{U_0} + \sqrt{E})$$

$$T = \left(\frac{e^{-\sqrt{2m}\pi a(\sqrt{U_0}+\sqrt{E})}}{2} - e^{\sqrt{2m}\pi a(\sqrt{U_0}+\sqrt{E})}\right)^{-2}$$

(!! тут скорее всего большая халтура, интеграл то не считается так просто! а у меня где-то в этом файле приведено решение его, впишу)

ПТФ-11.y4 Нормировка в квазиклассике

• Отнормируйте волновые функции связанного состояния, которые следуют из правила квантования Бора-Зоммерфельда, на единицу.
• Отнормируйте квазиклассические бегущие волны (в отсутствие отражения) на $2\pi\delta(E-E_0)$

Solution.

• Волновые функции для частицы в потенциальной яме:

$$\psi(x)=\frac{C}{\sqrt{p(x)}}\cos\left(\frac{1}{\hbar}\int\limits_a^x p(y)dy-\frac{\pi}{4}\right)$$

Условие нормировки:

$$\int\limits_a^b|\psi(x)|^2dx=\int\limits_a^b\frac{C^2}{p(x)}\cos^2\left(\frac{1}{\hbar}\int\limits_a^x p(y)dy-\frac{\pi}{4}\right)dx=1$$

Импульс меняется медленно, а косинус между точками остановки успевает совершить достаточно много колебаний. Поэтому, заменим $\cos^2$ на среднее значение за период.

$$\frac{C^2}{2}\int\limits_a^b\frac{dx}{p(x)}=1$$

Стоящий здесь интеграл выражается через период колебаний классической частицы в этом же потенциале:

$$T=2\int\limits_a^b\frac{dx}{v(x)}=2m\int\limits_a^b\frac{dx}{p(x)}dx\to C=\sqrt{\frac{4m}{T}}$$

$$\psi(x)=\sqrt{\frac{4m}{Tp(x)}}\cos\left(\frac{1}{\hbar}\int\limits_a^x p(y)dy-\frac{\pi}{4}\right)$$

• Квазиклассические бегущие волны:

$$\psi_\pm(x)=\frac{C}{\sqrt{p(x)}}\exp\left(\pm\frac{i}{\hbar}\int\limits_0^x p(y)dy\right)$$

$$\langle\psi_+^E|\psi_+^{E'}\rangle=C^2\int\limits_{-\infty}^{\infty}\frac{e^{\frac{i}{\hbar}\int\limits_0^x(p^{E+\delta E}(y)-p^E(y))dy}}{p^E(x)}dx$$

$$p^{E+\delta E}(y)-p^E(y)\approx\frac{\partial p^E(y)}{\partial E}\delta E=\frac{m}{p(y)}\delta E$$

Пусть $\xi=\frac{m}{\hbar}\int\limits_0^x\frac{dy}{p(y)}$, тогда

$$\langle\psi_+^E|\psi_+^{E'}\rangle=C^2\frac{m}{\hbar}\int\limits_{-\infty}^{\infty}e^{i\xi\delta E}d\xi=C^2\frac{m}{\hbar}2\pi\delta(E'-E)$$

Для перекрекстных скалярных произведений:

$$\langle\psi_+^E|\psi_-^{E'}\rangle=C^2\frac{m}{\hbar}\int\limits_{-\infty}^{\infty}e^{i\xi(E+E')}d\xi=C^2\frac{m}{\hbar}2\pi\delta(E'+E)\approx0$$

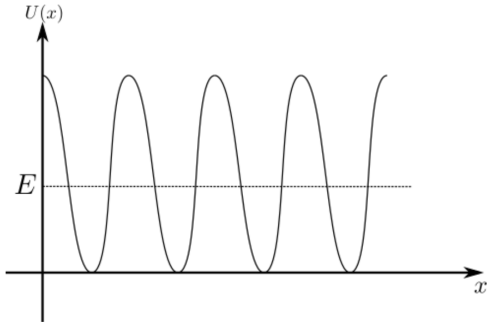
Таким образом, нормированные на дельта-функцию квазиклассические бегущие волны:

$$\psi_\pm(x)=\sqrt{\frac{\hbar}{2\pi mp(x)}}\exp\left(\pm\frac{i}{\hbar}\int\limits_0^x p(y)dy\right)$$

ПТФ-11.з2. Одномерный кристалл и модель сильной связи

Определите зоны и их законы дисперсии для периодической задачи, изображённой на рисунке, считая применимым квазиклассическое приближение. Проинтерпретируйте результат в терминах модели сильной связи и следующего гамильтониана (для каждой зоны). Определите E_n и t_n.

$$\hat{H}_n = \begin{pmatrix} \ddots & -t_n & 0 & 0 & \dots \\ -t_n & E_n & -t_n & 0 & 0 \\ 0 & -t_n & E_n & -t_n & 0 \\ 0 & 0 & -t_n & E_n & -t_n \\ \vdots & 0 & 0 & -t_n & \ddots \end{pmatrix}$$



Solution.

Рассмотрим кристалл из очень большого, но все же конечного количества атомов $N \gg 1$.

$$\hat{Q} = \hat{A}^\dagger \begin{pmatrix} e^{-iS} & 0 \\ 0 & e^{iS} \end{pmatrix} \hat{A} \begin{pmatrix} e^{-S_T} & 0 \\ 0 & e^{S_T} \end{pmatrix}, \quad \hat{A} = \begin{pmatrix} \frac{e^{-i\pi/4}}{2} & e^{i\pi/4} \\ \frac{e^{i\pi/4}}{2} & e^{-i\pi/4} \end{pmatrix}$$

На границах кристалла потенциал имеет бесконечные стенки, то есть, что частица не может вылететь из кристалла. Тогда, если в кристалле N атомов, то столбцы коэффициентов разложения по квазиклассическим функциям слева и справа имеет вид:

$$\vec{c}_{\text{left}} = \hat{Q}^{N-1} \hat{S} \hat{A} \vec{c}_{\text{right}}$$

Мы рассматриваем состояния частицы, находящейся в кристалле, поэтому выбираем

$$\vec{c}_{\text{left}} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \qquad \vec{c}_{\text{right}} = \begin{pmatrix} 0 \\ t \end{pmatrix}$$

Характеристический многочлен оператора $\hat{Q}$:

$$\chi_{\hat{Q}}(z) = z^2 - \cos S \left(2e^{S_T} + \frac{1}{2} e^{-S_T} \right) z + 1$$

Произведение собственных чисел $\hat{Q}$ равно 1. Вектор $\vec{c}_{\text{right}}$ раскладывается по обоим собственным векторам, и поэтому если $|\lambda_1| \neq |\lambda_2|$, то существует собственное значение по модулю, большее 1. Но тогда при возведении в очень большую степень норма образа вектора $\vec{c}_{\text{right}}$ будет тожет расти неограниченно. Таким образом,

$$|\lambda_1| = |\lambda_2| = 1 \to \lambda_1 = \lambda = e^{i\varphi}, \lambda_2 = e^{-i\varphi}$$

$$\hat{Q}^{N-1} = \Lambda \begin{pmatrix} e^{i\varphi(N-1)} & 0 \\ 0 & e^{-i\varphi(N-1)} \end{pmatrix} \Lambda^{-1}$$

где Λ – матрица перехода к собственным векторам $\hat{Q}$:

$$\Lambda = \begin{pmatrix} \sin S & \sin S \\ e^{S_T} e^{i\varphi} - \frac{1}{2} \cos S & e^{S_T} e^{-i\varphi} - \frac{1}{2} \cos S \end{pmatrix}$$

$$e^{2i(N-1)\varphi} = 1 \to \varphi_k = \frac{\pi k}{N-1}, \qquad k = 0, ..., 2N-3$$

По теореме Виета:

$$\cos\varphi_k = \cos S e^{S_T}\left(1 + \frac{1}{4}e^{-2S_T}\right) \to \cos S_{n,k} = e^{-S_T}\cos\varphi_k$$

При помощи метода последовательных приближений получаем:

$$E^{(1)}_{n,k} = E^{(0)}_n + (-1)^{n-1}\frac{\hbar\omega}{\pi}\cos\left(\frac{\pi k}{N-1}\right)e^{-\frac{1}{\hbar}\int|p(x)|dx}, \quad k = 0, ..., N-1$$

Рассмотрим модель сильной связи. Система функций:

$$\psi_{n,j}(x) = \begin{cases} \frac{C_{n,j}}{\sqrt{|p(x)|}}e^{-\frac{1}{\hbar}\int\limits_{x_2}^{x} p(x)dx}, & x > x_2 \\ \frac{C_{n,j}}{\sqrt{p(x)}}\cos\left(\frac{1}{\hbar}\int\limits_{x_1}^{x_2} p(x)dx - \frac{\pi}{4}\right), & x_1 < x < x_2. \\ \frac{C_{n,j}}{\sqrt{|p(x)|}}e^{\frac{1}{\hbar}\int\limits_{x_1}^{x} p(x)dx} & x > x_1 \end{cases}$$

где x_1 – левая точка остановки, x_2 – правая.
Нормировочные константы связанных состояний:

$$C_{n,j} = \sqrt{\frac{4\pi}{T_n}}$$

где T_n – классический период колебаний частицы с данной энергией в рассматриваемом потенциале. Тогда

$$t_n = \langle\psi_{n,j+1}|\psi_{n,j}\rangle = \frac{4\pi}{T_n}\int\limits_{-z_0}^{z_0}\frac{dz}{|p(z)|}e^{-\int\limits_{-z_0}^{z_0} p(z)dz}, \quad U(z_0) = E^{(0)}_n$$

ПТФ-10.з.1. Почти квазиклассический потенциал

Определите в квазиклассическом приближении коэффициент отражения частицы энергии E от потенциала, который в некоторой точке x_0 имеет особенность. Исследуйте следующие случаи:
1. Потенциал в точке x_0 испытывает скачок, то есть $U(x_0 - 0) = U_1$ и $U(x_0 + 0) = U_2$.
2. Потенциал в точке x_0 испытывает излом, то есть $U(x < x_0) \approx U_0 - F_1(x - x_0)$ и $U(x > x_0) \approx U_0 - F_2(x - x_0)$.

Solution.

17.1.14 Problems about quasiclassical method 3

ФР. Прохождении лоренцева барьера

В квазиклассическом приближении найти коэффициент прохождения барьера

$$U(x) = \frac{U_0 a^2}{x^2 + a^2}.$$

Обсудить границу применимости решения.

Solution.

$D(E) = \exp\left\{-\frac{2}{\hbar}\int\limits_a^b |p(x,E)|dx\right\}$, тут интеграл заменой $x := a\ \mathrm{sh}\ t$ приводится к виду $\left(\mathrm{sh}\, t_0 = \sqrt{U_0/E - 1} \equiv b^{-1}\right)$ (???)

$$\int\limits_{x_1}^{x_2}|p|dx = 2a\sqrt{2m(U_0 - E)}\int\limits_0^{t_0}\sqrt{1 - \frac{E}{U_0 - E}\,\mathrm{sh}^2\, t}dt.$$

Мы получили эллиптический интеграл второго рода. При $E \ll U_0$ его легко вычислить приближенно, если учесть, что при этом подкоренное выражение равно единице во всем интервале интегрирования, за исключением узкой области вблизи верхнего предела интегрирования, в которой $\operatorname{sh} t \gg 1$, и поэтому можно положить во всем интервале интегрирования $\operatorname{sh}^2 t \approx e^{2t}/4$, так что интеграл принимает вид

$$I = \int\limits_0^t \sqrt{1 - b^2 \operatorname{sh}^2 t} dt \approx \int\limits_0^t \sqrt{1 - \frac{b^2}{4} e^{2t}} dt$$

Этот же интеграл с помощью замены переменной $(b/2)e^t = \sin z$ легко вычисляется и при $(b \ll 1)$

$$I = -1 + \ln \left[4\sqrt{U_0/E} \right].$$

Таким образом,

$$D(E) \approx \left(\frac{E}{16U_0} \right)^{\frac{2}{\hbar} a\sqrt{2mU}} \exp\left(\frac{4}{\hbar} a\sqrt{2mU_0} \right).$$

О границах применимости решения

Для справедливости полученного результата требуется выполнение двух условий:
1) $|d\lambda(x)/dx| \ll 1$ во всей области переменной x, за исключением узких интервалов, непосредственно примыкающих к точкам поворота;
2) расстояния $\Delta x_{1,2} \equiv (x - x_{1,2})$ от точек поворота, на которых уже выполняются условия применимости квазиклассики $|d\lambda/dx| \ll 1$, должны быть такими, чтобы при этом можно было ограничиться линейным разложением потенциальной энергии

$$U(x) \approx U(x_{1,2}) + U'(x_{1,2}) \Delta x_{1,2}$$

(при дальнейшем увеличении $|\Delta x_{1,2}|$ выполнения условия линейного разложения, конечно, не требуется).
В рассматриваемой задаче при $|x| > a$ имеем $|d\lambda/dx| \equiv \equiv 0 \ll 1$. При $|x| < a$

$$\left|\frac{d\lambda}{dx}\right| = \frac{\hbar U_0 |x|}{\sqrt{2m} a^2 |E - U(x)|^{3/2}} = \frac{\hbar |x| a}{\sqrt{2m U_0} |x^2 - x_0^2|^{3/2}},$$

и в случае

$$\sqrt{mU_0 a^2/\hbar^2} \gg 1$$

выражение $|\frac{d\lambda}{dx}|$ много меньше единицы при всех значениях x, за исключением узких областей в окрестности точек поворота, причем ширина области неквазиклассичности по порядку величины равна

$$\Delta x = |x - x_{1,2}| \sim \frac{\hbar^{2/3} a^{1/3}}{m^{1/3}} \frac{1}{U_0^{1/6} (U_0 - E)^{1/6}}$$

(для получения этой оценки Δx в выражении $|\frac{d\lambda}{dx}|$ следует положить $|x| \approx x_0$ и $|x^2 - x_0^2| \equiv |x^2 - x_{1,2}^2| = |(x - x_{1,2})(x + x_{1,2})| \approx \approx 2\Delta x x_0$). Применимость квазиклассики требует выполнения оче видного неравенства

$$\Delta x \ll x_0, \quad \text{или } \frac{(U_0 - E) a\sqrt{m}}{\hbar\sqrt{U_0}} \gg 1$$

(в противном случае в интервале между точками поворота $|x| < x_0$ условия применимости квазиклассики не выполнены ни при каких значениях x). Условие $\frac{(U_0 - E) a\sqrt{m}}{\hbar\sqrt{U_0}} \gg 1$ дает, согласно формуле для D, $D \ll 1$, что, как известно, является необходимым (но не доста точным!) условием применимости квазиклассического рассмотрения.
Т.о. для данной задачи условиями применимости полученного результата являются

$$\frac{a}{\hbar}\sqrt{2mU_0} \gg 1, \quad E \ll \frac{\hbar}{a}\sqrt{\frac{U_0}{m}},$$

первое из которых обеспечивает применимость квазиклассики. Второе же заменяет условие $E \ll U_0$, использованное при вычислении интеграла в самом начале. Причина этой замены состоит в том, что при приближенном расчете величины f вида $f = e^A$, когда приближенно вычисляется значение A, для того чтобы было выполнено условне $f_{\text{точн}}/f_{\text{прибл}} \approx 1$, требуется $|A_{\text{точн}} - A_{\text{прибл}}| \ll 1$ (а не просто $A_{\text{точн}}/A_{\text{прибл}} \approx 1$, и это обстоятельство следует учитывать в случае $|A| \gg 1$). И именно второе из этих условий (а не условие $E \ll U_0$) обеспечивает справедливость полученного значения коэффициента прохождения.

Киселев-6.1. Осциллятор с $\delta V = \epsilon m^2\omega^3 x^4/\hbar$ квазиклассикой

Вычислить поправку к энергии осциллятора за счет возмущения $\delta V = \epsilon m^2\omega^3 x^4/\hbar$, где $\epsilon \to 0$, и определить условие применимости метода теории возмущений для конечных значений ϵ.

Solution.

(?? казалось бы, причем тут квазиклассика?? видно, не усвоил еще. укажу в теории, чтобы очевидно это было!!!)

Согласно общему правилу квантования Бора-Зоммерфельда, спектр невозмущенного осциллятора задается условием

$$\oint p_0(x)\mathrm{d}x = 2\pi\hbar\left(n+\frac{1}{2}\right), \quad p_0(x) = \sqrt{2m\left(E_n^{(0)} - \frac{m\omega^2 x^2}{2}\right)},$$

так что с помощью замены $x = \sqrt{\frac{2E_n^{(0)}}{m\omega^2}}\sin\phi$ находим

$$\oint p_0(x)\mathrm{d}x = \frac{2E_n^{(0)}}{\omega}\int\limits_0^{2\pi}\cos^2\phi\mathrm{d}\phi = \frac{2\pi}{\omega}E_n^{(0)}.$$

В итоге спектр осциллятора в квазиклассике

$$E_n^{(0)} = \hbar\omega\left(n+\frac{1}{2}\right)$$

совпадает с точным выражением.

Поправку к энергии

$$\delta E_n = \frac{\oint \frac{\mathrm{d}x}{p_0}\delta V(x)}{\oint \frac{\mathrm{d}x}{p_0}}$$

определяют

$$\oint \frac{\mathrm{d}x}{p_0} = \frac{1}{m\omega}\int\limits_0^{2\pi}\mathrm{d}\phi = \frac{2\pi}{m\omega}$$

$$\oint \frac{\mathrm{d}x}{p_0}\delta V(x) = \epsilon\frac{4\left(E_n^{(0)}\right)^2}{m\omega^2\hbar}\int\limits_0^{2\pi}\sin^4\phi\mathrm{d}\phi = \frac{3}{2}\epsilon\frac{2\pi h}{m}\left(n+\frac{1}{2}\right)^2.$$

В итоге

$$\delta E_n = \frac{3}{2}\epsilon\hbar\omega\left(n+\frac{1}{2}\right)^2.$$

Критерий применимости теории возмущений в квазиклассике, $\delta E \ll \hbar\omega$, дает

$$\epsilon\cdot n^2 \ll 1 \text{ при условии } n \gg 1.$$

Отсюда, между прочим, следует, что требование точности вычислений по теории возмущений в квазиклассике на уровне, скажем, порядка нескольких процентов при конечном значении параметра малости $\epsilon \sim 0,1$ может оказаться совершенно недостижимым, поскольку для этого квантовое число n должно принимать слишком малые значения, что недопустимо в квазиклассическом приближении.

Комбинированный критерий применимости квазиклассического приближения и теории возмущений приводит к двустороннему ограничению на квантовое число

$$1 \ll n \ll \frac{1}{\sqrt{\epsilon}},$$

что, впрочем, совершенно ясно, поскольку четвертая степень координаты в конце концов начинает доминировать над квадратом при больших значениях x, где, следовательно, возмущение велико.

Киселев-6.2. Квантование в $V = U_0\left(\frac{x^4}{a^4} + \epsilon\frac{x^6}{a^6}\right)$ (????)

Провести квазиклассическое квантование спектра частицы, движущейся в потенциале

$$V = U_0\left(\frac{x^4}{a^4} + \epsilon\frac{x^6}{a^6}\right), \quad U_0 > 0,$$

считая ϵ малым параметром. Провести сравнение с точным спектром при параметре $\zeta := \frac{mU_0}{h^2}a^2 = \frac{1}{6}, \quad \epsilon = 0, 1.$

Solution.

(???? нужно обзор решения дописать!)

Введем безразмерную координату $u = x/a$, в терминах которой стационарное уравнение Шрёдингера для $\psi(u)$ запишется в виде

$$-\frac{h^2}{2ma^2}\psi'' + U_0\left(u^4 + \epsilon u^6\right)\psi = E\psi,$$

или после использования безразмерных параметров глубины потенциальной ямы ζ и энергии $\nu = E/U_0$

$$-\frac{1}{2}\psi'' + \zeta\left(u^4 + \epsilon u^6\right)\psi = \zeta\nu\psi.$$

В задаче без возмущения ($\epsilon \to 0$) правило квантования Бора-Зоммерфельда $\oint p_0(u)\mathrm{d}u = 2\pi\left(n + \frac{1}{2}\right)$ дает

$$\oint p_0(u)\mathrm{d}u = \oint \sqrt{2\left(\zeta\nu - \zeta u^4\right)}\mathrm{d}u = 4\sqrt{2\zeta}\int\limits_0^{\sqrt[4]{\nu}} \mathrm{d}u\sqrt{\nu - u^4},$$

что введением переменной $v = u^4/\nu$ сводится к бета-функции

$$\oint p_0(u)\mathrm{d}u = \sqrt{2\zeta\nu}\sqrt[4]{\nu}\int\limits_0^1 \mathrm{d}v \cdot v^{-\frac{3}{4}}(1-v)^{\frac{1}{2}} = \sqrt{2\zeta}\sqrt[4]{\nu^3}\mathcal{B}\left(\frac{1}{4}, \frac{3}{2}\right) = \sqrt{2\zeta}\sqrt[4]{\nu^3}\frac{\Gamma\left(\frac{1}{4}\right)\Gamma\left(\frac{3}{2}\right)}{\Gamma\left(\frac{7}{4}\right)}.$$

Свойства гамма-функции $z\Gamma(z) = \Gamma(z+1), \Gamma(z)\Gamma(1-z) = \pi/\sin(\pi z)$ позволяют записать

$$\Gamma\left(\frac{1}{2}\right) = \sqrt{\pi}, \quad \Gamma\left(\frac{7}{4}\right) = \frac{3}{4}\Gamma\left(\frac{3}{4}\right), \quad \Gamma\left(\frac{3}{2}\right) = \frac{1}{2}\Gamma\left(\frac{1}{2}\right), \quad \Gamma\left(\frac{1}{4}\right)\Gamma\left(\frac{3}{4}\right) = \pi\sqrt{2},$$

так что в итоге

$$\oint p_0(u)\mathrm{d}u = \frac{4\pi^2}{3\Gamma^2\left(\frac{3}{4}\right)}\sqrt{\frac{\zeta}{\pi}}v^{\frac{3}{4}}.$$

Введем число

$$g = \frac{3}{2\pi}\Gamma^2\left(\frac{3}{4}\right) \approx 0,717$$

и запишем спектр невозмущенной задачи

$$\nu^{(0)} = \frac{E_n^{(0)}}{U_0} = \left(g\sqrt{\frac{\pi}{\zeta}}\left(n + \frac{1}{2}\right)\right)^{4/3}.$$

Эта формула достаточно точно описывает систему уровней в задаче без возмущения уже при $n > 1$, что видно из рис. 15, где в случае $\zeta = 1/6, \epsilon = 0$ представлена величина $\delta n^{(0)}$, которая определена как приращение к номеру уровня, необходимое пія получения спектра, рассчитанного численно, и задана согласно формуле

$$\nu|_{e=0} = \nu^{(0)} + \frac{\mathrm{d}\nu^{(0)}}{\mathrm{d}n}\delta n^{(0)}$$

Для расчета поправки используем ту же замену переменных в интегралах:

$$\oint \frac{\mathrm{d}u}{p_0(u)} = \frac{\nu^{-\frac{1}{4}}}{\sqrt{2\zeta}}\int\limits_0^1 \mathrm{d}v \cdot v^{-\frac{3}{4}}(1-v)^{-\frac{1}{2}} = \frac{\nu^{-\frac{1}{4}}}{\sqrt{2\zeta}}\frac{\Gamma\left(\frac{1}{4}\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{3}{4}\right)}$$

и

$$\oint \frac{\mathrm{d}u}{p_0(u)}u^6 = \frac{\nu^{\frac{5}{4}}}{\sqrt{2\zeta}}\int\limits_0^1 \mathrm{d}v\cdot v^{\frac{3}{4}}(1-v)^{-\frac{1}{2}} = \frac{\nu^{\frac{\pi}{4}}}{\sqrt{2\zeta}}\frac{\Gamma\left(\frac{7}{4}\right)\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{9}{4}\right)}$$

откуда по общей формуле

$$\zeta\delta\nu^{(1)} = \zeta\epsilon\left(\oint \frac{\mathrm{d}u}{p_0(u)}u^6\right)/\left(\oint \frac{\mathrm{d}u}{p_0(u)}\right)$$

так что

$$\delta\nu^{(1)} = \epsilon\nu^{\frac{3}{2}}\frac{\Gamma\left(\frac{7}{4}\right)\Gamma\left(\frac{3}{4}\right)}{\Gamma\left(\frac{9}{4}\right)\Gamma\left(\frac{1}{4}\right)} = \epsilon\nu^{\frac{3}{2}}\frac{\frac{3}{4}\Gamma^2\left(\frac{3}{4}\right)}{\frac{5}{4}\frac{1}{4}\Gamma^2\left(\frac{1}{4}\right)} = \frac{8}{15}\epsilon\nu^{\frac{3}{2}}\frac{9\Gamma^4\left(\frac{3}{4}\right)}{4\pi^2}.$$

В итоге

$$\delta\nu^{(1)} = \frac{8}{15}\epsilon g^4\frac{\pi}{\zeta}\left(n+\frac{1}{2}\right)^2.$$

Вычислим эффективный сдвиг номера уровня

$$\delta n = \frac{\delta\nu^{(1)}}{\mathrm{d}\nu^{(0)}/\mathrm{d}n} = \frac{2}{5}\epsilon g^{\frac{8}{3}}\left(\frac{\pi}{\zeta}\right)^{\frac{1}{3}}\left(n+\frac{1}{2}\right)^{\frac{5}{3}} \ll 1.$$

Значит, теория возмущений применима при

$$n \ll \left(\frac{125\zeta}{8g^8\pi\epsilon^3}\right)^{\frac{1}{3}} \approx \frac{7}{3}\left(\frac{\zeta}{\epsilon^3}\right)^{\frac{1}{5}}.$$

Подчеркнем, что прямое сравнение поправки к энергии уровня со значением энергии в невозмущенной задаче привело бы к ошибочной оценке верхней границы области применимости теории возмущений по квантовому числу n, так как необходимо сравнивать поправку с расстоянием между соседними уровнями.

При заданных значениях параметров задачи $\zeta = 1/6, \epsilon = 0,1$ для сравнения приближенных оценок в квазиклассической теории возмущений с точным расположением уровней следует провести численный расчет спектральной задачи. Стандартный прием состоит в том, чтобы построить схему итераций, реализуемую в виде алгоритма. Мы использовали следующий метод: при заданном начальном значении энергии вычислялись точки поворота $a < b$, после чего в качестве начальных

значений задачи Копи бралось квазиклассическое выражение достаточно глубоко в области затухания волновой функции, скажем, правее b; тем самым определялась необходимая для решения уравнения второго порядка первая производная волновой функции в исходной точке $x_0 > b$ с произвольной нормировкой $\psi(x_0)$. Затем вычислялось значение волновой функции в зеркальной точке $\psi(-x_0)$ и определялось значение асимметричности $d = |\psi(x_0)| - |\psi(-x_0)|$. Рис. 15.

Оценка точности квазиклассического приближения по приращению к номеру уровня $\delta n^{(0)}$, которое нужно добавить для согласия с точным численным расчетом энергии связанных состояний, в зависимости от квантового числа n в невозмущенной задаче $\epsilon = 0, \zeta = 1/6$ В изучаемой задаче потенциал - четная функция координаты, так что при верном выборе энергии в спектре уровней асимметричность d должна обращаться в нуль; при этом затухание волновой функции при отрицательных x также гарантировано выбором квазиклассического условия затухания при положительных x. Выбирая пару значений энергии E_1, E_2, легко провести линейную итерацию в точку, где асимметричность должна обратиться в нуль:

$$E_{k+2} = \frac{d_k E_{k+1} - d_{k+1}E_k}{d_k - d_{k+1}}.$$

Этот метод оказывается достаточно точным и быстро сходящимся при малом числе итераций, причем номер уровня контролируется прямым подсчетом числа узлов волновой функции, что легко реализуется в пакете аналитических и численных расчетов и графических построений Mathematica.

Описанная процедура использовалась при численном расчете спектра как невозмущенной задачи, так и при наличии возмущения. Результат сравнения квазиклассических вычислений с точными представлен на рис. 16 в терминах поправки к номеру уровня. Согласно нашему исследованию квазиклассика в совокупности с теорией возмущений может быть применима в ограниченной области значений квантового числа n:

$$1 < n < 7,$$

что и подтверждается данными рис. 16: при малых n, в данном случае для основного состояния, квазиклассика дает плохую оценку и без возмущения, и при его наличии, а при больших n неприменима теория возмущений, так как, во-первых, поправки по сути начинают «перемешивать» соседние уровни, а во-вторых, ведущее приближение оказывается слишком неточным и становится необходимым суммирование поправок высшего порядка, т.е. выход за рамки теории возмущений. Фактически теория возмущений в рамках квазиклассического приближения в этой задаче применима в весьма узкой области квантовых чисел, а именно при $1 < n < 4$.

Киселев-6.3. $e - e^+$ пары в постоянном электрическом поле

В рамках квазиклассического приближения для туннельного эффекта оценить вероятность образования электрон-позитронных пар в постоянном электрическом поле за счет флуктуаций вакуума во внешнем поле.

Solution.

Квантовые флуктуации вакуума, которые приводят к рождению пар частица-античастица, возможны, если энергия флуктуации порядка массы частицы

$$\Delta E \simeq mc^2,$$

а значит, время такой флуктуации согласно соотношению неопределённостей

$$\Delta t \simeq \frac{\hbar}{mc^2}.$$

Если на электрон-позитронную пару в вакуумной флуктуации действует внешнее электрическое поле $\mathcal{E}$, то возникающие силы разводят электрон и позитрон в разные стороны, так что эти виртуальные частицы могут перейти в состолние реальных, наблюдаемых частиц, т.е. может произойти туннельный переход-пробой вакуума. времени равна силе электрического поля;

$$\frac{\Delta p}{\Delta t} = e\mathcal{E} \to \Delta p \simeq \frac{e\hbar\mathcal{E}}{mc^2}.$$

Но флуктуация импульса связана с флуктуацией координаты соотношением неопределённостей

$$\Delta p \cdot \Delta x \simeq \hbar, \quad \Delta x \simeq \frac{mc^2}{e\mathcal{E}}$$

Вероятность туннельного перехода задается квазиклассической формулой

$$w \sim \mathrm{e}^{-2\frac{S}{\hbar}}$$

$$S \simeq \Delta \cdot \Delta x \simeq \hbar \frac{\Delta x}{\lambda_e}$$

где S - действие виртуальной частицы а характерная комптоновская длина волны массивной частицы, согласно критерию применимости квазиклассики, должна быть много меньше ширины потенциального барьера

$$\lambda_e = \frac{\hbar}{mc} \ll \Delta x$$

В итоге, действие

$$S \simeq \frac{m^2c^3}{e\mathcal{E}},$$

а вероятность рождения электрон-позитронной пары в постоянном электрическом поле

$$w \sim \mathrm{e}^{-\mathrm{const}\ \frac{m^2c^3}{k\ell\varepsilon}}.$$

В квантовой теории поля вычисляется и постоянная const $= \pi$, и предэкспоненциальный множитель. Здесь же отметим лишь то, что введение комптоновской длины волны электрона

$$\lambda_e = \frac{\hbar}{mc}$$

позволяет записать аргумент экспоненты в виде фактора

$$\frac{mc^2}{e\mathcal{E}\lambda_e}$$

т.е. он задается отношением массы покоя электрона к работе сил постоянного электрического поля на комптоновской длине волны электрона λ_e Рождение пар из вакуума становится статистически значимым, если значение этого фактора сравнимо с единицей, а значит, когда поле настолько велико, что его напряженность разрывает вакуум на комптоновской длине электрона. Численно это поле чудовищно велико: $\mathcal{E} \sim 10^{14}$ В/.

При осмыслении полученного результата следует обратить внимание на то, что рождение пар частиц в течение бесконечного времени существования поля неминуемо приведет к необходимости учета обратного влияния рождающихся частиц на источники поля (согласно закону сохранения энергии), поэтому в действительности процесс рождения частиц носит существенно нестационарный характер, и при строгом подходе надо рассматривать поля с конечным временем существования.

Киселев-6.4. Рождение фотонов в черной дыре

В рамках квазиклассического приближения для туннельного эффекта определить энергетическую зависимость вероятности рождения пар фотонов в гравитационном поле черной дыры вблизи поверхности Шварцшильда за счет флуктуаций вакуума, если гравитационное ускорение возле сферы Шварцшильда равно $\varkappa c^2$ (для $\varkappa$ вводят термин «поверхностная гравитация»).

Solution.

Предположим, что в вакууме в течение времени Δt имеет место флуктуация: образуется пара фотонов с энергией $E > 0$ и $-E < 0$. На фотон с энергией E и гравитационной массой $m = E/c^2$ действует сила гравитационного поля

$$F = \varkappa c^2 \cdot m = \varkappa E,$$

где, как видим, вместо массы покоя в релятивистском случае стоит энергия частицы. Эта сила направлена к центру черной дыры. На фотон с энергией $-E$ действует такая же по модулю сила, направленная в другую сторону, от центра, так как энергия отрицательна. Таким образом, гравитационные силы растаскивают фотоны из вакуумной флуктуации в разные стороны, так что может иметь место «пробой вакуума», что, естественно, невозможно в отсутствие внешних сил. Поэтому говорят, что под действием гравитационного поля имеет место туннельный переход флуктуации в состояние с реальными фотонами. Сила определяет изменение импульса, так что в конечных приращениях

$$\frac{\Delta p}{\Delta t} \simeq F = \varkappa E,$$

а изменение импульса для фотона связано с энергией флуктуации

$$\Delta p \simeq \frac{E}{c}.$$

Отсюда время флуктуации, в течение которого фотон приобретает энергию E,

$$\Delta t \simeq \frac{1}{\varkappa c}.$$

За это время фотон проходит расстояние

$$\Delta x \simeq c\Delta t \simeq \frac{1}{\varkappa}.$$

Поэтому характерное значение действия S для такой флуктуации

$$S \simeq p \cdot \Delta x \simeq \frac{E}{c} \cdot \frac{1}{x},$$

а вероятность туннельного перехода в квазиклассике

$$w \sim \mathrm{e}^{-2\frac{S}{\hbar}}$$

дает

$$w \sim \mathrm{e}^{-\,\mathrm{const}\,\frac{E}{\hbar\epsilon x}} = \mathrm{e}^{-\beta E}$$

где точное значение постоянной $\mathrm{const} = 2\pi$ было рассчитано Хокингом (Hawking), так что

$$\beta = \frac{2\pi}{\hbar c \varkappa}.$$

В итоге энергетическая зависимость вероятности наблюдения флуктуации повторяет распределение Гиббса для излучения абсолютно черного тела с температурой $kT = 1/\beta$

$$T = \frac{\hbar c}{k} \cdot \frac{\varkappa}{2\pi},$$

где k - постоянная Больцмана и мы выделили фактор из фундаментальных постоянных, который обычно полагают равным единице за счет выбора единиц измерения температуры, длины, времени и энергии.

Значит, гравитационные силы способны приводить к детектированию удаленным наблюдателем фотонов со спектром излучения абсолютно черного тела. При этом, конечно, необходимо, чтобы фотон с отрицательной энергией никогда не попадал в область действия измерительных приборов вне черной дыры. Это действительно возможно при наличии сферы Шварцшильда: тогда при квантовой

флуктуации вблизи этой сферы фотон с положительной энергией достигает удаленного наблюдателя, а фотон с отрицательной энергией падает в черную дыру. В результате энергия черной дыры уменьшается ровно на столько, сколько ее унес с собой фотон к стороннему наблюдателю в измеряемом им спектре излучения. Качественно описанный процесс есть квантовый эффект испарения черных дыр, который носит имя Хокинга.

Отметим, что, подобно предыдущему примеру с рождением пар частица-античастица в электрическом поле, в наших оценочных рассуждениях мы не учитывали нестационарность задачи о возникновении и существовании черной дыры, что в действительности весьма существенно в последовательной теории эффекта Хокинга. Наконец, определим значение поверхностной гравитации из качественных соображений. Фотон не может покинуть черную дыру, так как работа сил гравитации на расстоянии порядка размера черной дыры r_g равна его энергии

$$\varkappa E \cdot r_g \simeq E \to \varkappa \simeq \frac{1}{r_g},$$

так что температура черной дыры обратно пропорциональна размеру черной дыры. Для примера, гравитационный радиус Солнца $\left(M_\odot \approx 2 \cdot 10^{30}\right)$

$$r\odot = \frac{2GM_\odot}{c^2} \approx 3\text{KM},$$

а температура черной дыры с массой Солнца была бы лишь

$$T_\odot \simeq 5 \cdot 10^{-8} K,$$

но масса Солнца недостаточно велика, чтобы гравитационные силы необратимо сжали бы его в черную дыру после исчерпания запасов термоядерного топлива (коллапс Солнца по современным представлениям невозможен).

17.1.15 Problems about variational method (!?)

(потом подумаю про него, пока см. лекции Тонга, если интересно)

17.1.16 Problems about solutions by special functions 1

ПТФ-5.y1

Исследуйте прямоугольную двумерную яму $U(r) = -U_0\theta(a - |r|)$ в обратном пределе глубокой ямы $U_0 \gg \frac{\hbar^2}{Ma^2}$. Оцените N_m – количество связанных состояний в яме для фиксированного орбитального квантового числа $m \in \mathbb{Z}$, а также полное число связанных состояний $N = \sum\limits_m N_m$.

Определите промежуточную асимптотику уровней энергии $E_{n,m}$ (интересны высоколежащие уровни, но не близкие к верху ямы).

Solution.

$$\hat{H}\psi = E\psi$$

$$\hat{H} = \frac{\hat{\vec{p}}^2}{2m} + U(\vec{r}) = -\frac{\hbar^2}{2m}\Delta - U_0\theta(a - |r|)$$

$$\Delta = \frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right) + \frac{1}{r^2}\frac{\partial^2}{\partial\varphi^2} = \frac{\partial^2}{\partial r^2} + \frac{1}{r}\frac{\partial}{\partial r} + \frac{1}{r^2}\frac{\partial^2}{\partial\varphi^2}$$

$$\psi(r,\varphi) = \psi(r)e^{im\varphi}$$

$$-\frac{\hbar^2}{2M}\left(\psi''(r) + \frac{1}{r}\psi'(r) - \frac{m^2}{r^2}\psi(r)\right) - U_0\theta(a - |r|)\psi(r) = E\psi(r)$$

- Вне ямы $r > a$:

$$-\frac{\hbar^2}{2M}\left(\psi''(r) + \frac{1}{r}\psi'(r) - \frac{m^2}{r^2}\psi(r)\right) = E\psi(r)$$

Пусть $\chi^2 = -\frac{2ME}{\hbar^2}$ и $z = \chi r$, тогда

$$\psi'(r) = \frac{d\psi}{dz}\frac{dz}{dr} = \chi\psi'(z), \quad \psi''(r) = \frac{d\psi'}{dz}\frac{dz}{dr} = \chi^2\psi''(z)$$

$$\psi''(z) + \frac{1}{z}\psi'(z) - \left(1 + \frac{m^2}{z^2}\right)\psi(z) = 0$$

Решение уравнения:

$$\psi(z) = A_1 I_m(z) + A_2 K_m(z)$$

Асимптотика при больших $z \gg 1$:

$$I_m(z) \approx \frac{e^z}{\sqrt{2\pi z}}, \quad K_m(z) \approx \sqrt{\frac{\pi}{2z}}e^{-z}$$

Поскольку волновая функция должна затухать на бесконечности, $A_1 = 0$, $A_2 = A$:

$$\psi(z) = AK_m(z)$$

- Внутри ямы $r < a$:

$$-\frac{\hbar^2}{2M}\left(\psi''(r) + \frac{1}{r}\psi'(r) - \frac{m^2}{r^2}\psi(r)\right) - U_0\psi(r) = E\psi(r)$$

Пусть $k^2 = \frac{2M(U_0+E)}{\hbar^2}$ и $z = kr$, тогда

$$\psi'(r) = \frac{d\psi}{dz}\frac{dz}{dr} = k\psi'(z), \quad \psi''(r) = \frac{d\psi'}{dz}\frac{dz}{dr} = k^2\psi''(z)$$

$$\psi''(z) + \frac{1}{z}\psi'(z) + \left(1 - \frac{m^2}{z^2}\right)\psi(z) = 0$$

Решение уравнения:

$$\psi(z) = B_1 J_m(z) + B_2 Y_m(z)$$

Асимптотика при малых $z \ll 1$:

$$J_m(z) \approx \frac{1}{m!}\left(\frac{z}{2}\right)^m, \quad Y_m(z) \approx \begin{cases} -\frac{(m-1)!}{\pi}\left(\frac{2}{z}\right)^m, & m \neq 0 \\ -\frac{2}{\pi}(\ln\frac{2}{z} - \gamma), & m = 0 \end{cases}$$

Поскольку волновая функция должна быть регулярной в 0, $B_1 = B$, $B_2 = 0$:

$$\psi(z) = BJ_m(z)$$

Сшивка логарифмической производной:

$$\frac{d\ln\psi(a-0)}{dz} = \frac{d\ln\psi(a+0)}{dz} \to \frac{kaJ'_m(ka)}{J_m(ka)} = \frac{\chi aK'_m(\chi a)}{K_m(\chi a)}$$

Рассматривается задача о глубокой яме $U_0 \gg \frac{\hbar^2}{Ma^2}$. поэтому $z \gg 1$. Соответствующие асимптотики при $z \gg 1$:

$$J_m(z) \approx \sqrt{\frac{2}{\pi z}}\cos\left(z - \frac{m\pi}{2} - \frac{\pi}{4}\right), \quad K_m(z) \approx \sqrt{\frac{\pi}{2z}}e^{-z}$$

$$J'_m(z) = -\sqrt{\frac{\pi}{2z^3}}\left(z\sin\left(z - \frac{\pi m}{2} - \frac{\pi}{4}\right) + \frac{1}{2}\cos\left(z - \frac{\pi m}{2} - \frac{\pi}{4}\right)\right), \quad K'_m(z) = -\sqrt{\frac{\pi}{2z^3}}e^{-z}\left(\frac{1}{2} + z\right)$$

Рассмотрим случай $\chi a \gg ka \gg 1$.

$$-ka\frac{1}{ka}\left(ka\tan\left(ka - \frac{\pi m}{2} - \frac{\pi}{4}\right) + \frac{1}{2}\right) = -\chi a\frac{1}{\chi a}\left(\frac{1}{2} + \chi a\right)$$

$$\tan\left(ka - \frac{\pi m}{2} - \frac{\pi}{4}\right) = \frac{\chi}{k} \gg 1$$

$$ka - \frac{\pi m}{2} - \frac{\pi}{4} = \frac{\pi}{2} + \pi n \to ka = \frac{3\pi}{4} + \frac{\pi m}{2} + \pi n$$

$$k^2a^2 = \pi^2\left(\frac{3}{4}+\frac{m}{2}+n\right)^2 = \frac{2Ma^2(U_0-|E_{n.m}|)}{\hbar^2}$$

$$E_{n,m} = U_0 - \frac{\pi^2\hbar^2}{2Ma^2}\left(\frac{3}{4}+\frac{m}{2}+n\right)^2$$

Число решений:

$$N_m = \frac{\sqrt{2Ma^2U_0}}{\pi\hbar} - \frac{m}{2} - \frac{3}{4}$$

$$N_{m_{\max}} = 0 \to m_{\max} = 2\frac{\sqrt{2Ma^2U_0}}{\pi\hbar} - \frac{3}{2}$$

$$N = \sum_{m=0}^{m_{\max}} N_m = \sum_{m=0}^{m_{\max}}\left(\frac{\sqrt{2Ma^2U_0}}{\pi\hbar} - \frac{m}{2} - \frac{3}{4}\right) \approx \frac{m_{\max}(m_{\max}+1)}{2} - \frac{m_{\max}(m_{\max}-1)}{2} = \frac{m_{\max}^2}{4}$$

$$N = \frac{2Ma^2U_0}{\pi^2\hbar^2}$$

ПТФ-5.y2

Определите волновую функцию для движения в трёхмерном Кулоновском потенциале $U(\vec{r}) = -\alpha/r$ частицы с орбитальным квантовым числом L на строго нулевой энергии $E = 0$.
Указание: соответствующее уравнение сводится к уравнению Бесселя.

Solution.

Стационарное уравнение Шрёдингера:

$$\hat{H}\Psi = E\Psi = 0$$

$$\hat{H} = \frac{\hat{\vec{p}}^2}{2M} + U(\vec{r}) = -\frac{\hbar^2}{2M}\Delta - \frac{\alpha}{r}$$

Лапласиан в сферических координатах:

$$\Delta = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) + \frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right) + \frac{1}{r^2\sin\theta}\frac{\partial}{\partial\varphi^2}$$

Разделим переменные на радиальную и угловую части:

$$\Psi(r,\theta,\varphi) = \psi(r)Y(\theta,\varphi)$$

Уравнение на радиальную часть:

$$-\frac{\hbar^2}{2mr^2}(r^2\psi'(r))' + \left(\frac{\hbar^2L(L+1)}{2mr^2} - \frac{\alpha}{r}\right)\psi(r) = 0$$

$$\psi''(r) + \frac{2}{r}\psi'(r) - \left(\frac{L(L+1)}{r^2} - \frac{2m\alpha}{\hbar r}\right)\psi(r) = 0$$

Сделаем замену $z = 2\sqrt{\frac{2m\alpha r}{\hbar}} \to r = \frac{z^2\hbar}{8m\alpha}$, $u(z) = \psi(r)$:

$$\psi'(r) = \frac{d\psi}{dr} = \frac{dz}{dr}\frac{du}{dz} = \sqrt{\frac{2m\alpha}{\hbar r}}u'(z) = \frac{4m\alpha}{\hbar z}u'(z)$$

$$\psi''(r) = \frac{d^2\psi}{dr^2} = \frac{4m\alpha}{\hbar z}\frac{d}{dz}\left(\frac{4m\alpha}{\hbar z}u'(z)\right) = \frac{16m^2\alpha^2}{\hbar^2z^3}u'(z) + \frac{16m^2\alpha^2}{\hbar^2z^2}u''(z)$$

$$\frac{16m^2\alpha^2}{\hbar^2z^2}u''(z) + \frac{48m^2\alpha^2}{\hbar^2z^3}u'(z) + \frac{16m^2\alpha^2}{\hbar^2z^2}\left(1 - \frac{4L(L+1)}{z^2}\right)u(z) = 0$$

$$z^2u''(z) + 3zu'(z) + (z^2 - 4L(L+1))u(z) = 0$$

Сделаем замену $v(z) = zu(z) \to u(z) = \frac{v(z)}{z}$:

$$u'(z) = \frac{v'(z)}{z} - \frac{v(z)}{z^2}, \quad u''(z) = \frac{v''(z)}{z} - \frac{2v'(z)}{z^2} + \frac{2v(z)}{z^3}$$

$$zv''(z) - 2v'(z) + \frac{2v(z)}{z} + 3v'(z) - \frac{3v(z)}{z} + zv(z) - \frac{4L(L+1)}{z}v(z) = 0$$

$$v''(z) + \frac{1}{z}v'(z) + \left(1 - \frac{(2L+1)^2}{z^2}\right)v(z) = 0$$

Получилось уравнение Бесселя с $m = 2L + 1$. Его решение:

$$v(z) = A_1 J_{2L+1}(z) + A_2 Y_{2L+1}(z)$$

Вернёмся к замене:

$$\psi(r) = \frac{1}{2}\sqrt{\frac{\hbar}{2m\alpha r}}\left(A_1 J_{2L+1}\left(2\sqrt{\frac{2m\alpha r}{\hbar}}\right) + A_2 Y_{2L+1}\left(2\sqrt{\frac{2m\alpha r}{\hbar}}\right)\right)$$

ПТФ-5.з1

Рассмотрите трёхмерную частицу массы m, движущуюся в трёхмерной шаровой полости радиуса a с бесконечными стенками:

$$U(\vec{r}) = \begin{cases} 0, & |\vec{r}| < a \\ \infty, & |\vec{r}| > a \end{cases}$$

Каким уравнением определяются уровни энергии с фиксированным орбитальным моментом L? Решите уравнение точно для $L = 0$, а также приближённо для высоколежащих уровней энергии при $L \geq 1$.

Указание: свободное движение в трёхмерном пространстве также сводится к функциям Бесселя, но с полуцелым индексом $J_{n+1/2}(z)$ (которые, в действительности, специальными функциями не являются, а имеют явное представление через обычные тригонометрические функции).

Solution.

При $r > a$:

$$\psi(r) = 0$$

Стационарное уравнение Шрёдингера при $r < a$ для радиальной части:

$$\psi''(r) + \frac{2}{r}\psi'(r) + \left(\frac{2mE}{\hbar^2} - \frac{L(L+1)}{r^2}\right)\psi(r) = 0$$

Введём замену $\psi(r) = \frac{u(r)}{\sqrt{r}}$.

$$\psi'(r) = \frac{u'(r)}{\sqrt{r}} - \frac{u(r)}{2r^{\frac{3}{2}}}, \quad \psi''(r) = \frac{u''(r)}{\sqrt{r}} - \frac{u'(r)}{r^{\frac{3}{2}}} + \frac{3u(r)}{4r^{\frac{5}{2}}}$$

$$\frac{u''(r)}{\sqrt{r}} - \frac{u'(r)}{r^{\frac{3}{2}}} + \frac{3u(r)}{4r^{\frac{5}{2}}} + \frac{2u'(r)}{r^{\frac{3}{2}}} - \frac{u(r)}{r^{\frac{5}{2}}} + \left(\frac{2mE}{\hbar^2} - \frac{L(L+1)}{r^2}\right)\frac{u(r)}{\sqrt{r}} = 0$$

$$u''(r) + \frac{u'(r)}{r} + \left(\frac{2mE}{\hbar^2} - \frac{L(L+1)}{r^2} - \frac{1}{4}\right)u(r) = 0$$

$$u''(r) + \frac{u'(r)}{r} + \left(\frac{2mE}{\hbar^2} - \frac{(L+\frac{1}{2})^2}{r^2}\right)u(r) = 0$$

$$u(r) = B_1 J_{L+\frac{1}{2}}\left(\frac{\sqrt{2mE}}{\hbar}r\right) + B_2 Y_{L+\frac{1}{2}}\left(\frac{\sqrt{2mE}}{\hbar}\right)$$

Вернёмся к замене:

$$\psi(r) = \frac{B_1}{\sqrt{r}} J_{L+\frac{1}{2}}\left(\frac{\sqrt{2mE}}{\hbar}r\right) + \frac{B_2}{\sqrt{r}} Y_{L+\frac{1}{2}}\left(\frac{\sqrt{2mE}}{\hbar}r\right)$$

Поскольку функция Неймана сингулярна в 0, то $B_2 = 0$. Сшивка при $r = a$:

$$J_{L+\frac{1}{2}}\left(\frac{\sqrt{2mE}a}{\hbar}\right) = 0$$

- Случай $L = 0$.

$$\sqrt{\frac{2\hbar}{\pi a\sqrt{2mE}}}\sin\left(\frac{\sqrt{2mE}a}{\hbar}\right) = 0 \to \frac{\sqrt{2mE}a}{\hbar} = \pi n$$

$$E_n = \frac{\pi^2\hbar^2 n^2}{2ma^2}$$

- Случай $L \geq 1$. Для высоколежащих уровней $\frac{\sqrt{2mE}a}{\hbar} \gg 1$. Асимптотика функции Бесселя при $z \gg 1$:

$$J_m(z) \approx \sqrt{\frac{2}{\pi z}}\cos\left(z - \frac{m\pi}{2} - \frac{\pi}{4}\right)$$

$$\frac{\sqrt{2\hbar}}{\sqrt{\pi a\sqrt{2mE}}}\cos\left(\frac{\sqrt{2mE}a}{\hbar} - \frac{(L+\frac{1}{2})\pi}{2} - \frac{\pi}{4}\right) = 0$$

$$\sin\left(\frac{\sqrt{2mE}a}{\hbar} - \frac{\pi L}{2}\right) = 0$$

$$\frac{\sqrt{2mE}a}{\hbar} - \frac{\pi L}{2} = \pi n$$

$$E_n = \frac{\pi^2\hbar^2(2n+L)^2}{8ma^2}$$

ПТФ-5.з2. Ступенька (40 б).

Определите коэффициенты прохождения и отражения от потенциала $U(x) = \frac{1}{2}U_0\tanh\frac{x}{a}$. Указание: при помощи замены $\xi = -e^{-2x/a}$ задача приводится к гипергеометрической функции ${}_2F_1$.

Solution.

Стационарное уравнение Шрёдингера:

$$-\frac{\hbar^2}{2m}\psi''(x) + \left(\frac{1}{2}U_0\tanh\frac{x}{a} - E\right)\psi(x) = 0$$

Пусть $\xi = -e^{-\frac{2x}{a}}$, тогда $x = -\frac{a}{2}\ln(-\xi)$.

$$\text{th}\,\frac{x}{a} = \frac{1+\xi}{1-\xi}$$

$$\psi'(x) = -\frac{2}{a}\xi\psi'(\xi), \quad \psi''(x) = \frac{4\xi}{a^2}\psi'(\xi) + \frac{4\xi^2}{a^2}\psi''(\xi)$$

Пусть $k^2 = \frac{ma^2}{4\hbar^2}U_0$, $\kappa^2 = \frac{ma^2}{2\hbar^2}E$.

$$\xi\frac{\partial\psi}{\partial\xi} + \xi^2\frac{\partial^2\psi}{\partial\xi^2} + k^2\frac{\xi+1}{\xi-1}\psi + \kappa^2\psi = 0$$

$$\psi(\xi) = \Psi(\xi)\xi^{\sqrt{k^2-\chi^2}}$$

$$\xi(1-\xi)\Psi''(\xi) - (2\sqrt{k^2-\kappa^2}+1)(\xi-1)\Psi'(\xi) - 2k^2\Psi(\xi) = 0$$

$$\Psi(\xi) = C_1\xi^{\sqrt{k^2-\kappa^2}}{}_2F_1(\sqrt{-k^2-\kappa^2}+\sqrt{k^2-\kappa^2}, -\sqrt{-k^2-\kappa^2}+\sqrt{k^2-\kappa^2}, 1+2\sqrt{k^2-\chi^2}, \xi) +$$
$$+ C_2\xi^{-\sqrt{k^2-\kappa^2}}{}_2F_1(-\sqrt{k^2-\kappa^2}-\sqrt{-k^2-\kappa^2}, -\sqrt{k^2-\kappa^2}+\sqrt{-k^2-\kappa^2}, 1-2\sqrt{k^2-\chi^2}, \xi)$$

Рассмотрим 2 базисное решение:

$$\psi(\xi) = \xi^{-i\sqrt{\kappa^2-k^2}}{}_2F_1(-\sqrt{k^2-\kappa^2}-\sqrt{-k^2-\kappa^2}, -\sqrt{k^2-\kappa^2}+\sqrt{-k^2-\kappa^2}, 1-2\sqrt{k^2-\chi^2}, \xi)$$

При $x \to \infty$

$$ {}_2F_1(..., e^{-\frac{2x}{a}}) \sim 1$$

$$\psi(x) = (-1)^{i\sqrt{k^2+\kappa^2}} e^{-i\frac{2x}{a}\sqrt{k^2+\kappa^2}} = e^{\pi\sqrt{\kappa^2-k^2}} e^{i\frac{2x}{a}\sqrt{\kappa^2-k^2}}$$

При $x \to -\infty$

$$\frac{\sin(\pi(b-a))}{\pi}{}_2F_1(a,b,c,\xi) = \frac{(-\xi)^a}{\Gamma(b)\Gamma(c-a)}{}_2F_1(a, a-c+1, a-b+1, \frac{1}{\xi}) - \\ - \frac{(-\xi)^{-b}}{\Gamma(a)\Gamma(c-b)}{}_2F_1(b, b-c+1, b-a+1, \frac{1}{\xi})$$

$$ {}_2F_1(a,b,c,\frac{1}{\xi}) \sim 1$$

$$\Psi(\xi) = -\frac{\pi}{i\sinh(\pi\sqrt{k^2+\kappa^2})} e^{\pi\sqrt{\kappa^2-k^2}} \left(\frac{e^{-i\frac{2x}{a}\sqrt{k^2+\kappa^2}}}{(i\sqrt{\kappa^2-k^2}-i\sqrt{\kappa^2+k^2})\Gamma^2(i\sqrt{\kappa^2-k^2}-i\sqrt{\kappa^2+k^2})} - \right. \\ \left. - \frac{e^{i\frac{2x}{a}\sqrt{k^2+\kappa^2}}}{(i\sqrt{\kappa^2-k^2}+i\sqrt{\kappa^2+k^2})\Gamma^2(i\sqrt{\kappa^2-k^2}+i\sqrt{\kappa^2+k^2})} \right)$$

$$r = \frac{\pi i}{\sinh \pi\sqrt{\kappa^2+k^2}} (i\sqrt{\kappa^2-k^2}+i\sqrt{\kappa^2+k^2})\Gamma^2(i\sqrt{\kappa^2-k^2}+i\sqrt{\kappa^2+k^2})$$

$$t = \frac{\pi i}{\sinh \pi\sqrt{\kappa^2+k^2}} (i\sqrt{\kappa^2-k^2}-i\sqrt{\kappa^2+k^2})\Gamma^2(i\sqrt{\kappa^2-k^2}-i\sqrt{\kappa^2+k^2})$$

Определим коэффициенты отражения и прохождения. Упростим r и t и получим:

$$R = |r|^2 = \frac{\sinh^2(\pi(\sqrt{\kappa^2-k^2}-\sqrt{\kappa^2+k^2}))}{\sinh^2(\pi(\sqrt{\kappa^2-k^2}+\sqrt{\kappa^2+k^2}))}$$

$$T = \frac{\sqrt{\kappa^2+k^2}}{\sqrt{\kappa^2-k^2}}|t|^2 = \frac{\sinh(2\pi(\sqrt{\kappa^2-k^2}))\sinh(2\pi\sqrt{\kappa^2+k^2}))}{\sinh^2(\pi(\sqrt{\kappa^2-k^2}+\sqrt{\kappa^2+k^2}))}$$

ПТФ-6.у1. Функция Эйри

Используя асимптотики функций Эйри для инфинитного движения (без бесконечной стенки), отнормируйте их на дельта-функцию от энергии, а также убедитесь в соотношении полноты. А именно, выпишите волновые функции, удовлетворяющие следующему условию:

$$\int dx \psi^*_E(x)\psi_{E'}(x) = \delta(E-E')$$

и убедитесь, что для них выполняется соотношение

$$\int dE \psi^*_E(x')\psi_E(x) = \delta(x-x')$$

Solution.

$$-\frac{\hbar^2}{2m}\psi''(x) + Fx\psi(x) = E\psi(x)$$

$$z = \frac{x - E/F}{(\hbar^2/2mF)^{\frac{1}{3}}}$$

$$\psi''(z) - z\psi(z) = 0$$

Общее решение – произвольная линейная комбинация функций Эйри первого и второго рода:

$$\psi(z) = C_1 \mathrm{Ai}(z) + C_2 \mathrm{Bi}(z)$$

Асимптотики функции Эйри:

$$\mathrm{Ai}(z) \approx \begin{cases} \frac{1}{2\sqrt{\pi} z^{\frac{1}{4}}} \exp\left(-\frac{2}{3} z^{\frac{3}{2}}\right), & z \to \infty \\ \frac{1}{\sqrt{\pi}(-z)^{\frac{1}{4}}} \sin\left(\frac{2}{3}(-z)^{\frac{3}{2}} + \frac{\pi}{4}\right), & z \to -\infty \end{cases}$$

$$\frac{1}{\sqrt{\pi}(-z)^{\frac{1}{4}}} \sin\left(\frac{2}{3}(-z)^{\frac{3}{2}} + \frac{\pi}{4}\right) = \frac{1}{2\sqrt{\pi}(-z)^{\frac{1}{4}}} \left(e^{i\left(\frac{2}{3}(-z)^{\frac{3}{2}} - \frac{\pi}{4}\right)} + e^{-i\left(\frac{2}{3}(-z)^{\frac{3}{2}} + \frac{3\pi}{4}\right)}\right)$$

$$\psi_E(x) = C\mathrm{Ai}(z)$$

$$\int dx \psi_E^*(x)\psi_{E'}(x) =$$

$$= \frac{C^2}{4\pi(zz')^{\frac{1}{4}}} \int\limits_{-\infty}^{0} dx \left(e^{-i\left(\frac{2}{3}(-z)^{\frac{3}{2}} - \frac{\pi}{4}\right)} + e^{i\left(\frac{2}{3}(-z)^{\frac{3}{2}} + \frac{3\pi}{4}\right)}\right)\left(e^{i\left(\frac{2}{3}(-z')^{\frac{3}{2}} - \frac{\pi}{4}\right)} + e^{-i\left(\frac{2}{3}(-z')^{\frac{3}{2}} + \frac{3\pi}{4}\right)}\right) +$$

$$+ \frac{C^2}{4\pi(zz')^{\frac{1}{4}}} \int\limits_{0}^{\infty} dx \left(e^{-i\left(\frac{2}{3}(-z)^{\frac{3}{2}} - \frac{\pi}{4}\right)} + e^{i\left(\frac{2}{3}(-z)^{\frac{3}{2}} + \frac{3\pi}{4}\right)}\right)\left(e^{i\left(\frac{2}{3}(-z')^{\frac{3}{2}} - \frac{\pi}{4}\right)} + e^{-i\left(\frac{2}{3}(-z')^{\frac{3}{2}} + \frac{3\pi}{4}\right)}\right) + \mathrm{reg.} =$$

$$= \frac{C^2}{4\pi(zz')^{\frac{1}{4}}} \int\limits_{-\infty}^{0} dx \left(e^{\frac{2i}{3}\left((-z')^{\frac{3}{2}} - (-z)^{\frac{3}{2}}\right)} + e^{-\frac{2i}{3}\left((-z')^{\frac{3}{2}} - (-z)^{\frac{3}{2}}\right)}\right) + \mathrm{reg.}$$

$$\Delta z = z - z' = \frac{\Delta E}{F}\left(\frac{2mF}{\hbar^2}\right)^{\frac{1}{3}}$$

$$\int dx \psi_E^*(x)\psi_{E'}(x) = \frac{C^2}{4\pi z^{\frac{1}{2}}}\left(\frac{\hbar^2}{2mF}\right)^{\frac{1}{3}} \int\limits_{-\infty}^{0} dz (e^{-\frac{2}{3}i(-z)^{\frac{3}{2}}\frac{3\Delta z}{2z}} + e^{\frac{2}{3}i(-z)^{\frac{3}{2}}\frac{3\Delta z}{2z}}) =$$

$$= \left(\frac{\hbar^2}{2mF}\right)^{\frac{1}{3}} \frac{C^2}{2\pi} \int\limits_{-\infty}^{\infty} d(\sqrt{z}) e^{-i\Delta z\sqrt{z}} = C^2 \left(\frac{\hbar^2\sqrt{F}}{2m}\right)^{\frac{2}{3}} \delta(E' - E) = \delta(E' - E)$$

$$C = \left(\frac{2m}{\hbar^2\sqrt{F}}\right)^{\frac{1}{3}}$$

$$\psi_E(x) = \left(\frac{2m}{\hbar^2\sqrt{F}}\right)^{\frac{1}{3}} \mathrm{Ai}\left(\frac{x - E/F}{(\hbar^2/2mF)^{\frac{1}{3}}}\right)$$

$$\int dE \psi_E^*(x')\psi_E(x) = \frac{C^2}{4\pi} \int\limits_{-\infty}^{0} dE \left(e^{\frac{2i}{3}\left((-z')^{\frac{3}{2}} - (-z)^{\frac{3}{2}}\right)} + e^{-\frac{2i}{3}\left((-z')^{\frac{3}{2}} - (-z)^{\frac{3}{2}}\right)}\right) + \mathrm{reg.} =$$

$$= -\frac{FC^2}{4\pi}\left(\frac{\hbar^2}{2mF}\right)^{\frac{1}{3}} \int\limits_{-\infty}^{0} dz \frac{e^{iz^{\frac{1}{2}}\Delta z} + e^{-iz^{\frac{1}{2}}\Delta z}}{z^{\frac{1}{2}}} = FC^2\left(\frac{\hbar^2}{2mF}\right)^{\frac{2}{3}} \delta(x - x') = \delta(x - x')$$

$$\int dE \psi_E^*(x')\psi_E(x) = \delta(x - x')$$

ПТФ-6.з3. Hydrogen atom in 2D

Определите уровни энергии и кратности их вырождения, а также стационарные волновые функции для двумерной частицы, движущейся в притягивающем потенциале $U(\vec{r}) = -\frac{e^2}{r}$.

Указание: задача приводится к вырожденной гипергеометрической функции ${}_1F_1$.

Solution.

Стационарное уравнение Шрёдингера:

$$-\frac{\hbar^2}{2M}\Delta\psi - \frac{e^2}{r}\psi = E\psi$$

$$-\frac{\hbar^2}{2M}\left(\frac{\partial^2\psi}{\partial r^2} + \frac{1}{r}\frac{\partial\psi}{\partial r} + \frac{1}{r^2}\frac{\partial^2\psi}{\partial\varphi^2}\right) - \frac{e^2}{r}\psi = E\psi$$

Разделим переменные:

$$\psi(r,\varphi) = R(r)e^{im\varphi}$$

$\kappa^2 := -\frac{2mE}{\hbar^2}$.

$$\frac{\partial^2 R}{\partial r^2} + \frac{1}{r}\frac{\partial R}{\partial r} - \left(\frac{2Me^2}{\hbar^2 r} + \kappa^2 + \frac{m^2}{r^2}\right)R = 0$$

$x := \kappa r$,

$$R'' + \frac{R'}{x} - \left(1 + \frac{2Me^2}{\hbar^2\kappa x} + \frac{m^2}{x^2}\right)R = 0$$

$R := x^m f$:

$$R' = mx^{m-1}f + x^m f', \quad R'' = m(m-1)x^{m-2}f + 2mx^{m-1}f' + x^m f''$$

$$xf'' + (2m+1)f' - \left(x + \frac{2Me^2}{\hbar^2\kappa}\right)f = 0$$

$$x \to \infty : f'' - f = 0 \to f \sim e^{-x}$$

$f(x) := e^{-x}\chi(x)$.

$$f'(x) = -e^{-x}\chi + e^{-x}\chi', \quad f''(x) = e^{-x}\chi - 2e^{-x}\chi' + e^{-x}\chi''$$

$$x\chi'' + (2m+1-2x)\chi' - \left(2m+1+\frac{2Me^2}{\hbar^2\kappa}\right)\chi = 0$$

$$\chi(x) = C_1 F_1\left(m + \frac{1}{2} - \frac{Me^2}{\hbar^2\kappa}, 2m+1, 2x\right)$$

Второе линейно независимое решение сингулярно в 0.

$$m + \frac{1}{2} - \frac{Me^2}{\hbar^2\kappa} = -n$$

$$E_{n,m} = -\frac{\hbar^2}{2M}\chi^2 = -\frac{Me^2}{2\hbar^2\left(|m| + n + \frac{1}{2}\right)^2}$$

Пусть $N = |m| + n$, тогда кратность вырождения:

$$K = 2N - 1$$

$$\psi(r,\varphi) = Ce^{im\varphi}\left(\frac{\sqrt{-2mE}}{\hbar}r\right)^{|m|} e^{-\frac{\sqrt{-2mE}}{\hbar}r}\,{}_1F_1\left(-n, 2m+1, 2\frac{\sqrt{-2mE}}{\hbar}r\right)$$

ГК-1.10. Волновые функции и спектр в поле $V(x) = V_0\left(\frac{a}{x} - \frac{x}{a}\right)^2$

Найти волновые функции и уровни энергии частицы в поле вида $V(x) = V_0\left(\frac{a}{x} - \frac{x}{a}\right)^2$ $(x > 0)$ (см. рис. 2) и показать, что энергетический спектр совпадает со спектром осциллятора

ГК-1.11. Спектр в $V = -\frac{V_0}{\mathrm{ch}^2\frac{x}{a}}$

Определить уровни энергии для частицы, находящейся в потенциальном поле $V = -\frac{V_0}{\mathrm{ch}^2\frac{x}{a}}$

Solution.

Типично задача решается переходом к гипергеометрической функцией подстановкой, а затем заменой координат.

(еще раз перепишу компактнее потом решение, а также добавлю вычисления. укажу в теории обязательно эти ходы!!!)

Решаем уравнение Шредингера

$$-\frac{\hbar^2}{2\mu}\frac{d^2\psi}{dx^2}-\left(E+\frac{V_0}{\operatorname{ch}^2\frac{x}{a}}\right)\psi=0$$

с помощью подстановки $\psi=\left(\operatorname{ch}\frac{x}{a}\right)^{-2\lambda}u,\quad \lambda=\frac{1}{4}\left(\sqrt{\frac{8\mu V_0a^2}{\hbar^2}+1}-1\right)$

(тут пара промежуточных вычислений)

Уравнение для u примет следующий вид:

$$\frac{d^2u}{dx^2}-\frac{4\lambda}{a}\operatorname{th}\frac{x}{a}\frac{du}{dx}+\frac{4}{a^2}\left(\lambda^2-\varkappa^2\right)u=0,$$

где $\varkappa=\sqrt{-\frac{\mu Ea^2}{2\hbar^2}}$. (рассматриваем дискретный спектр $E<0$). Далее, введем

$$z=-\operatorname{sh}^2\frac{x}{a},$$

и это уравнение сведем к гипергеометрическому уравнению

$$z(1-z)\frac{d^2u}{dz^2}+\left[\frac{1}{2}-(1-2\lambda)z\right]\frac{du}{dz}-\left(\lambda^2-\varkappa^2\right)u=0.$$

Параметры α,β,γ, входящие в гипергеометрическое уравнение общего вида

$$z(1-z)\frac{d^2u}{dz^2}+[\gamma-(\alpha+\beta+1)z]\frac{du}{dz}-\alpha\beta u=0$$

имеют в нашем случае следующие значения:

$$\gamma=\frac{1}{2},\quad \alpha=\varkappa-\lambda,\quad \beta=-\varkappa-\lambda.$$

Два решения, которые дают соответственно четные и нечетные волновые функции ψ; имеют вид

$$u_1=F\left(-\lambda+x,-\lambda-x,\frac{1}{2};z\right)$$
$$u_2=\sqrt{z}F\left(-\lambda+x+\frac{1}{2},-\lambda-x+\frac{1}{2},\frac{3}{2};z\right)$$

Эти решения приводят к ограниченным значениям волновых функций при $x=0(z=0)$.

Для того чтобы волновая функция

$$\zeta=\left(\operatorname{ch}\frac{x}{a}\right)^{-2\lambda}u$$

обращалась в нуль при $x\to\pm\infty(z\to-\infty)$, гипергеометрические функции в выражениях (2) и (3) должны сводиться к полиномам. это условие означает, например, для u_1, что либо $\lambda-x$, либо $\lambda+x$ являются целыми неотрицательными числами. Однако второй случай должен быть отброшен, так как при этом волновая функция при $x\to\pm$ $\pm$ экспоненциально возрастает. Итак, получаем $\lambda-\%=k(k=0,\,1,2,...)$ и уровни энергии

$$E_k=-\frac{t^2}{2\mu\cdot a^2}\left[\frac{1}{2}\sqrt{\frac{8\mu V_0a^2}{\hbar^2}+1}-2k-\frac{1}{2}\right]^2.$$

Аналогично этому для выражения (3) находим, что условие конечности волновой функции при $x\to\pm\infty$ выполняется, если

$$\lambda-x-\frac{1}{2}=l\quad(l=0,1,2,...)$$

откуда

$$E_l=-\frac{\hbar^2}{2\mu a^2}\left[\frac{1}{2}\sqrt{\frac{8\mu V_0a^2}{\hbar^2}+1}-(2l+1)-\frac{1}{2}\right]^2.$$

Объединяя эти выражения, находим:

$$E_n = -\frac{\hbar^2}{2\mu a^2}\left[\frac{1}{2}\sqrt{\frac{8\mu V_0 a^2}{\hbar^2}+1}-\left(n+\frac{1}{2}\right)\right]^2$$

Число дискретных уровней равно наибольшему целому числу N, удовлетворяющему неравенству

$$N < \frac{1}{2}\sqrt{\frac{8\mu V_0 a^2}{\hbar^2}+1}-\frac{1}{2}.$$

Отметим, что полученный спектр энергий совпадает при соответствующем выборе параметров со спектром для потенциала Морза (???).

ПТФ.?. Рассеяние в $V = -\frac{V_0}{\mathrm{ch}^2\frac{x}{a}}$

Определить (???)

Solution.

Решим задачу рассеяния для $E > 0$ в потенциале вида $U(x) = -U_0/\,\mathrm{ch}^2(x/a)$.

Удобно воспользоваться параметризацией $E = k^2/2m$, и решение можно получить из выписанного выше простой заменой $\kappa a = -ika$:

$$\psi(z) = (z(1-z))^{-ika/2}\cdot{}_2F_1(-ika-s,-ika+s+1;-ika+1;z),\quad z=\frac{1}{2}(1-\tanh(x/a))$$

Мы получили какое-то решение непрерывного спектра; однако, ещё не факт что оно соответствует задаче рассеяния.

Тем не менее, даже если и не соответствует - задачу рассеяния мы всё равно сможем построить, выбрав линейную комбинацию с комплексно сопряжённым решением (которое является вторым линейно-независимым).

Чтобы это понять, нам необходимо найти асимптотическое поведение этого решения на бесконечности.

При $x \to +\infty \to y = \tanh\frac{x}{a} \approx 1-2e^{-2x/a} \to z \approx e^{-2x/a} \to 0$, гипергеометрическая функция ${}_2F_1(...,z) \approx 1$. Поэтому:

$$\psi(x \gg a) \approx e^{ikx}$$

Поскольку $z \approx 1$, то в правой части тождества непосредственно гипергеометрические функции раскладываются как ${}_2F_1(...;1-z) \approx 1$, и основная асимптотика определяется выражениями с Гамма-функциями и $(1-z)^{c-a-b} = (1-z)^{ika} \approx e^{2ikx}$ Вспоминая также о префакторе $(z(1-z))^{-ika/2} \approx e^{-ikx}$, мы немедленно получаем асимптотику волновой функции при $x \to -\infty$, которая, следуя общей логике задачи рассеяния, содержит падающую и отражённую волну:

$$\psi(x\to-\infty) = \frac{\Gamma(-ika+1)\Gamma(-ika)}{\Gamma(-ika-s)\Gamma(-ika+s+1)}e^{ikx} + \frac{\Gamma(-ika+1)\Gamma(-ika)}{\Gamma(s+1)\Gamma(-s)}e^{-ikx}$$

Обычно в задаче рассеяния коэффициент при падающей волне e^{ikx} берётся равным единице; тогда остальные коэффициенты отвечают амплитуде отражения и прохождения.

У нас нормировка чуть другая, и амплитуды даются отношением коэффициентов:

$$t = \frac{\Gamma(-ika-s)\Gamma(-ika+s+1)}{\Gamma(-ika+1)\Gamma(-ika)},\quad r = \frac{\Gamma(-ika-s)\Gamma(-ika+s+1)}{\Gamma(s+1)\Gamma(-s)}$$

Это - окончательный ответ, но его можно упросить, используя $\Gamma(z)^* = \Gamma(z^*), \Gamma(z)\Gamma(1-z) = \frac{\pi}{\sin\pi z}, \Gamma(z+1) = z\Gamma(z)$, получим:

$$T = |t|^2 = \frac{\mathrm{sh}^2(\pi ka)}{\mathrm{sh}^2(\pi ka)+\sin^2(\pi s)},\quad R = |r|^2 = \frac{\sin^2(\pi s)}{\mathrm{sh}^2(\pi ka)+\sin^2(\pi s)}$$

Такой ответ уже нам симпатичен.

(???? дальше комментарии???))

Можно проверить, насколько полученный ответ физичен. Во-первых, разумеется, для него выполняется общее соотношение, накладываемое унитарностью квантовой механики $R+T=1$; при большой энергии $ka \gg 1$, коэффициент отражения уменьшается, что разумно -ведь движение с большой

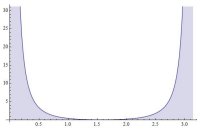
энергией квазиклассично, а в классической механике частица, пролетающая над ямой (или горбом!) совершенно не рассеивается.

Любопытно также, про при целом $s \in \mathbb{Z}$, коэффициент отражения обращается в ноль (на уровне амплитуды отражения это соответствует тому, что у аналитической функции $\Gamma(z)$ имеются полюса первого порядка при $z = -s$) -имеется резонансное безотражательное рассеяние на всех эжергиях! Выше мы получили, что целое s также соответствует ситуации, когда в яме зарождается очередное связанное состояние.

*) Настоящая задача тесно связана со следующей задачей классической механики: дан период колебаний как функция энергии частицы, требуется найти потенциальную энергию (см. Ландау и Пятигорский, «Механика", Гостехиздат, 1940, где даио решение этой задачи)

ГК-1.12. Спектр и волновые функции в $V = V_0 \operatorname{ctg}^2 \frac{\pi}{a}$

Определить энергетические уровни и волновые функции частицы в поле $V = V_0 \operatorname{ctg}^2 \frac{\pi}{a} x (0 < x < a)$



Произвести нормировку волновой функции основного состояния, рассмотреть предельные случаи малых и больших значений V_0.

Solution.

Делаем замену, приходим к гипергеометрической функции, уровни энергии из ее нулей.
(??? как догадаться про это и про конкретные преобразования?? в 1ю позже допишу)

$$-\frac{\hbar^2}{2\mu}\frac{d^2\psi}{dx^2} - \left(E - V_0 \operatorname{ctg}^2 \frac{\pi}{a}x\right)\psi = 0$$

$$\psi \equiv \left(\sin \frac{\pi}{a}x\right)^{-2\lambda} u$$

$$\lambda := \frac{1}{4}\left(\sqrt{\frac{8\mu V_0 a^2}{\pi^2\hbar^2} + 1} - 1\right),$$

$$\nu := \sqrt{\frac{\mu a^2}{2\hbar^2\pi^2}(E + V_0)}$$

(тут вставлю эти вычисления)

$$\frac{d^2u}{dx^2} - 4\frac{\pi}{a}\lambda \operatorname{ctg}\frac{\pi x}{a}\frac{du}{dx} + \frac{4\pi^2}{a^2}\left(\nu^2 - \lambda^2\right)u = 0.$$

$$z := \cos^2 \frac{\pi x}{a}$$

получаем гипергеометрическое уравнение:

$$z(1-z)\frac{d^2u}{dz^2} + \left[\frac{1}{2} - (1-2\lambda)z\right]\frac{du}{dz} + \left(\nu^2 - \lambda^2\right)u = 0.$$

Сравнивая с общим его видом $z(1-z)\frac{d^2u}{dz^2} + [\gamma - (\alpha+\beta+1)z]\frac{du}{dz} - \alpha\beta u = 0$, находим параметры:

$$\gamma = \frac{1}{2}, \quad \alpha = -\nu - \lambda, \quad \beta = \nu - \lambda.$$

Полученное уравнение имеет два решения. Одно из этих решений отлично от нуля и конечно при $z = 0$ (этому значению соответствует $x = a/2$)

$$u_1 = F\left(-\nu - \lambda, \nu - \lambda, \frac{1}{2}; z\right).$$

Другое решение

$$u_2 = \sqrt{z}F\left(-\nu - \lambda + \frac{1}{2}, v - \lambda + \frac{1}{2}, \frac{3}{2}; z\right)$$

обращается в нуль при $z=0\left(x=\frac{a}{2}\right)$. Чтобы определить поведение решений при $z=1$ (это значение соответствует $x=0, x=a$), воспользуемся $F(\alpha,\beta,\gamma;z)=(1-z)^{-\alpha}F\left(\alpha,\gamma-\beta,\gamma;\frac{z}{z-1}\right)$:

$$u_1=(1-z)^{\nu+\lambda}F\left(-\nu-\lambda,-\nu+\lambda+\frac{1}{2},\frac{1}{2};\frac{z}{z-1}\right)$$
$$u_2=\sqrt{z}(1-z)^{v+\lambda-\frac{1}{2}}F\left(-\nu-\lambda+\frac{1}{2},-v+\lambda+1,\frac{3}{2};\frac{z}{z-1}\right)$$

Для того чтобы выполнялось условие обращения в нуль волновой функции ψ при $x=0$ и $x=a$, необходимо, чтобы ряды по степеням $\frac{z}{z-1}$ содержали конечное число членов.

Гипергеометрический ряд для u_1 обрывается, если либо $\nu+\lambda$ - целое положительное число или нуль, либо $\nu-\lambda-\frac{1}{2}$ - целое положительное число или нуль. Однако условию $\psi=0$ при $x=0, x=a$ удовлетворяет только второй случай (??? почему?? видимо, в теории это доказано)

$$\nu-\lambda-\frac{1}{2}=k \qquad (k=0,1,...).$$

$$\sqrt{\frac{\mu a^2}{2\hbar^2\pi^2}(E+V_0)}=\frac{1}{4}\left(\sqrt{\frac{8\mu V_0 a^2}{\pi^2\hbar^2}+1}-1\right)+\frac{1+2k}{2}$$

Возводим в квадрат, сокращаем слева и справа член, обратно вводим λ, получаем:

$$E_k=\left[(2k+1)^2+4(2k+1)\lambda-2\lambda\right]\frac{\pi^2\hbar^2}{2\mu a^2}.$$

Аналогично, гипергеометрический ряд для u_2 обрывается, если

$$\nu-\lambda=l \quad (l=1,2,3,...).$$

Это также будет выполняться, если будет $2k+1=2n$, тогда (??? думаю, у авторов просто ошибка в формуле ниже. или не знаю, нет вариантов, я не понял этот переход тут(???? там в пределе осциллятор по моей логике не выходит, а логику авторов не понимаю пока))

$$E_n=\left(n^2+4n\lambda-2\lambda\right)\frac{\pi^2\hbar^2}{2\mu a^2} \quad (n=1,2,3,...).$$

$$\psi_{n\text{odd}}=c_n\left(\sin\frac{\pi x}{a}\right)^{-2\lambda}F\left(-\frac{n}{2}-2\lambda,\frac{n}{2},\frac{1}{2};\cos^2\frac{\pi x}{a}\right),$$
$$\psi_{n\text{even}}=c_n(\sin\frac{\pi x}{a}\Big)^{-2\lambda}\cos\frac{\pi x}{a}F\left(-\frac{n}{2}-2\lambda+\frac{1}{2},\frac{n}{2}+\frac{1}{2},\frac{3}{2};\cos^2\frac{\pi x}{a}\right).$$

Нормированная волновая функция основного состояния

$$\varphi=\sqrt{\frac{\pi\Gamma(2\lambda+1)}{a\Gamma\left(\frac{1}{2}\right)\Gamma\left(2\lambda+\frac{3}{2}\right)}}\left(\sin\frac{\pi x}{a}\right)^{2\lambda+1},$$

тут $\Gamma\left(\frac{1}{2}\right)=\sqrt{\pi}$. (??? видимо, как-то из свойств гипергеом функции это следует.)

В предельном случае $V_0\to 0$ задача сводится к задаче с частицей в потенциальном ящике. Имеем $\lambda\to 0$ и

$$E_n=\frac{\pi^2\hbar^2}{2\mu a^2}n^2.$$

В противоположном случае $\lambda\gg 1$ для низших уровней ($n\ll\lambda$)

$$E_n=\hbar\omega\left(n+\frac{1}{2}\right) \quad (n=1,2,...),$$

(???? у меня проблема, что получается $E_n=\hbar\omega\left(n-\frac{1}{2}\right)$, не представляю вообще, откуда там плюс???) где $\omega=\frac{\pi}{a}\sqrt{\frac{2V_0}{\mu}}$. Этот же результат можно получить, разлагая потенциальную энергию вблизи точки $x=\frac{a}{2}$ и ограничиваясь квадратичными членами, ибо в этом случае у нас просто осциллятор.

ГК-1.14. Вид уравнения

Написать уравнение Шредингера в «p» представлении для частицы, движущейся в периодическом потенциальном поле $V(x) = V_0 \cos bx$.

Solution.

Оператор Гамильтона при данном потенциале имеет вид

$$\hat{H} = \frac{1}{2\mu}p^2 + \frac{1}{2}V_0 e^{b\hbar\frac{\partial}{\partial p}} + \frac{1}{2}V_0 e^{-b\hbar\frac{\partial}{\partial p}}.$$

Так как

$$e^{b\hbar\frac{\partial}{\partial p}}a(p) = a(p + b\hbar),$$

то уравнение Шредингера будет представлено в виде уравнения в конечных разностях

$$\frac{1}{2\mu}p^2 a(p) + \frac{1}{2}V_0 a(p + b\hbar) + \frac{1}{2}V_0 a(p - b\hbar) = Ea(p).$$

(?? и что с ним делать??)

ГК-1.15. Вид уравнения

Написать уравнение Шредингера в «p» представлении для частицы, движущейся в периодическом потенциальном поле $V(x) = V(x + b)$

Solution.

Это обычное уравнение, только Фурье для потенциала для периодического поля - это ряд:

$$\frac{h^2}{2\mu}k^2 a(k) + \sum_{-\infty}^{+\infty} V_n a\left(k + \frac{2\pi n}{b}\right) = Ea(k)$$

$$\left(k = \frac{p}{b}, V(x) = \sum_{-\infty}^{+\infty} V_n e^{-\frac{2\pi n i x}{b}}, V_n = V_{-n}^*\right)$$

17.1.17 Problems about solutions by special functions 2

ГК-1.16. Потенциалы - стена башенок

Определить зоны разрешенной энергии для частицы, движущейся в периодическом потенциальном поле, изображенном на рис. ниже:

Исследовать предельный случай $V_0 \to \infty$, $b \to 0$ при условии, что $V_0 b = \text{const}$.

Solution.

(??? потом подумаю про это, это почти модель Кронинга-Пенни, итоговый график почти такой же)
Волновая функция в области ямы $0 < x < a$ имеет вид

$$\psi = c_1 e^{ix_1 x} + c_2 e^{-ix_2 x}, \quad x_1 = \frac{\sqrt{2\mu}}{\hbar}$$

а в области барьера $-b < x < 0$

$$\psi = c_3 e^{ix_\beta \mathcal{D}} + c_4 e^{-ix_3 \mathcal{D}}, \quad x_2 = \frac{\sqrt{2\mu\,(E - V_0)}}{b}$$

Так как $\psi(x) = \text{const} \cdot \psi(x + l)$ (const равна по модулю единице, $l = a + b$), то в области следующего барьера $a < x < < a + b$

$$\psi = e^{ikl}\left(c_3 e^{ix_9(x-l)} + c_4 e^{-ix_2(x-l)}\right).$$

Из требования непрерывности волновой функции и ее первой производнои в точках $x = 0, x = a$ получаем четыре уравнения:

$$c_1 + c_2 = c_3 + c_4$$
$$c_1 e^{ix_1 a} + c_2 e^{-ix_1 a} = e^{ikl}\left(c_3 e^{-ix_3 b} + c_4 e^{ix_3 b}\right)$$
$$x_1\,(c_1 - c_2) = x_2\,(c_3 - c_4)$$
$$x_1\left(c_1 e^{ix_1 a} - c_2 e^{-ix_1 a}\right) = x_2\left(c_3 e^{-ix_2 b} - c_4 e^{ix_3 b}\right) e^{ikl}$$

Эта система имеет нетривиальное решение только тогда, когда

$$\cos kl = \cos x_1 a \cdot \cos x_2 b - \frac{x_1^2 + x_2^2}{2x_1 x_2} \sin x_1 a \cdot \sin x_2 b$$

Исследуем два случая: а) $E < V_0, x_2$ - мнимая величина.
Введя обозначение $x_2 = i\gamma,$ перепишем уравнение (1) в виде

$$\cos kl = \cos x_1 a \cdot \operatorname{ch} xb + \frac{x^2 - x_1^2}{2x_1 x} \sin x_1 a \cdot \operatorname{sh} xb.$$

ГК-1.18.б) Спектр в $\operatorname{ctg}^2 \frac{\pi}{a}$

Определить в квазиклассическом приближении спектр энергии частицы в поле:
$V = V_0 \operatorname{ctg}^2 \frac{\pi}{a} x (0 < x < a)$.

Solution.

(Есть пример решенной аналогичной, см. пока его, по идее по аналогии сделать прокатит)

Ответ: $E_n = \frac{\pi^2 h^2}{2\mu a^2}\left[\sqrt{\frac{2\mu a^2 V_0}{\pi^2 h^2}} + \left(n + \frac{1}{2}\right)\right]^2 - V_0$ $(n = 0, 1, 2, ...)$.

ГК-1.19. Средняя кинетическая энергия в квазиклассике

Определить в квазиклассическом приближении среднее значение кинетической энергии стационарного состояния. Система одномерная и имеется некоторая потенциальная яма.

Solution.

(?????)
Среднее значение кинетической энергии в стационарном состоянии ψ_n (волновая функция предполагается вещественной)

$$\bar{T} = -\frac{h^2}{2\mu}\int \psi_n \frac{d^2\psi_n}{dx^2} dx = \frac{\hbar^2}{2\mu}\int \left(\frac{d\psi_n}{dx}\right)^2 dx.$$

В квазиклассическом приближении в классически доступной области $(a < x < b)$ волновая функция имеет вид

$$\psi_n = \frac{A_n}{\sqrt{p}} \cos\left(\frac{1}{\hbar}\int_a^x p dx - \frac{\pi}{4}\right), \quad p = \sqrt{2\mu\,(E_n - V)},$$

откуда

$$\frac{d\psi_n}{dx} = -\frac{\sqrt{p}}{\hbar} A_n \sin\left(\frac{1}{\hbar}\int_a^x p dx - \frac{\pi}{4}\right) - \frac{1}{2}\frac{A_n}{p^{3/2}}\frac{dp}{dx}\cos\left(\frac{1}{\hbar}\int_a^x p dx - \frac{\pi}{4}\right).$$

При подстановке этого выражения в интеграл, определяющий $\bar{T}$, пределы интегрирования можно ограничить классически доступной областью, так как вне этой области ψ_n экспоненциально у бывает. Заменяя квадраты сильно осциллирующих тригонометрических функций на их среднее значение $\frac{1}{2}$ и пренебрегая слагаемым $\sin\left(\frac{1}{\hbar}\int\limits_a^x pdx - \frac{\pi}{4}\right)\cdot\cos\left(\frac{1}{\hbar}\int\limits_a^x pdx - \frac{\pi}{4}\right) = \frac{1}{2}\sin\left(\frac{2}{\hbar}\int\limits_a^x pdx - \frac{\pi}{2}\right)$, потому что оно сильно осциллирует, получаем:

$$\bar{T} = \frac{A_n^2}{4\mu}\int\limits_a^b \left[p + \frac{\hbar^2}{4p^3}\left(\frac{dp}{dx}\right)^2\right]dx$$

Условие применимости квазиклассического приближения $|\frac{d\hbar}{dx}| = \frac{\hbar}{p^2}|\frac{dp}{dx}| \ll 1$ означает, что второй член под знаком интеграла мал по сравнению с первым, поэтому получаем интеграл, который вычисляется условием квантования:

$$\bar{T} = \frac{A_n^2}{4\mu}\int\limits_a^b pdx = \frac{A_n^2}{4\mu}\pi\hbar\left(n+\frac{1}{2}\right).$$

Постоянная A_n определяется из условия нормировки:

$$\int \psi_n^2 dx \approx A_n^2\int\limits_a^b \frac{1}{p}\cos^2\left(\frac{1}{\hbar}\int\limits_a^x pdx - \frac{\pi}{4}\right)dx \approx \frac{A_n^2}{2}\int\limits_a^b \frac{dx}{p} = 1.$$

Тут интеграл вычисляется с помощью условие квантования $\int\limits_a^b pdx \equiv \int\limits_a^b \sqrt{2\mu\left(E_n - V_0\right)}dx = \pi\hbar\left(n+\frac{1}{2}\right)$, для этого дифференцируем его по n, потому что все-таки у нас тут E это гладкая функция от непрерывного n, пусть и подставляем мы дискретные его значения, получаем:

$$\mu\frac{dE_n}{dn}\int\limits_a^b \frac{dx}{\sqrt{2\mu\left(E_n - V\right)}} = \mu\frac{dE_n}{dn}\int\limits_a^b \frac{dx}{p} = \pi\hbar,$$

откуда

$$A_n^2 = \frac{2\mu}{\pi\hbar}\frac{dE_n}{dn}.$$

В итоге получаем:

$$\bar{T} = \frac{1}{2}\frac{dE_n}{dn}\left(n+\frac{1}{2}\right).$$

ГК-1.20. Средняя кинетическая энергия в квазиклассике в примерах

Зная, что средняя кинетическая энергия связанного состояния $\bar{T} = \frac{1}{2}\frac{dE_n}{dn}\left(n+\frac{1}{2}\right)$, найти в квазиклассическом приближении среднюю кинетическую энергию частицы в поле:

а) $V = \frac{\mu\omega^2 x^2}{2}$

б) $V = V_0\operatorname{ctg}^2\frac{\pi x}{a}(0 < x < a)$

Solution.

Для решения задачи нужно лишь знать спектр. Для этого можно просто вспомнить ответ или решить задачу заново, см. соответствующую задачу, где сперт ищется.

Ответ: а) $\bar{T} = \frac{1}{2}\hbar\omega\left(n+\frac{1}{2}\right)$;

Ответ: б) $\bar{T} = \frac{\pi^2\hbar^2}{2\mu a^2}\left[\sqrt{\frac{2\mu a^2 V_0}{\pi^2\hbar^2}} + \left(n+\frac{1}{2}\right)\right]\left(n+\frac{1}{2}\right)$.

ГК-1.21. Произвольная степень потенциала

Определить вид энергетического спектра частицы в поле $V(x) = ax^\nu$, используя квазиклассическое приближение и применяя теорему вириала.

Solution.

Из теоремы вириала следует:

$$2\bar{T} = \nu\bar{V},$$

откуда

$$E = T + V = \frac{2+\nu}{\nu}\bar{T}.$$

Подставляя в это соотношение значение средней кинетической энергии $\bar{T} = \frac{1}{2}\frac{dE_n}{dn}\left(n+\frac{1}{2}\right)$, получаем уравнение

$$E = \frac{2+v}{2v}\frac{dE}{dn}\left(n+\frac{1}{2}\right),$$

решение которого имеет вид

$$E = \text{const}\cdot\left(n+\frac{1}{2}\right)^{\frac{2\cdot\nu}{2+\nu}}.$$

ГК-1.22. Потенциал по спектру (?)

Определить вид потенциальной энергии $V(x)$ по энергетическому спектру E_n в квазиклассическом приближении. $V(x)$ считать четной функцией $V(x) = V(-x)$, монотонно возрастающей при $x > 0$. Прийти к уравнению, из которого ее можно получить.

Solution.

В качестве исходного уравнения возьмем условие квантования Бора

$$\int\limits_{x_1}^{x_2}\sqrt{2\mu[E-V(x)]}dx = \pi\hbar\left(n+\frac{1}{2}\right),$$

определяющее спектр (по крайней мере $n(E)$), если задана потенциальная энергия $V(x)$. Поскольку по условию $V(x)$ - четная функция

$$2\int\limits_{0}^{a}\sqrt{2\mu[E-V(x)]}dx = \pi\hbar\left(n+\frac{1}{2}\right), \qquad a = x_2 \equiv -x_1, \quad E = V(a)$$

Задача, таким образом, сводится к отысканию решения интегрального уравнения

$$x(V) = \frac{\hbar}{\sqrt{2\mu}}\int\limits_{E_0}^{V}\frac{dE}{\frac{dE}{dn}\sqrt{V-E}},$$

(???? вот этот переход не понял, подумал минуты 3, оставил. тут еще под корнем порядок вычитания изменился, почему???? еще раз обратную в механике задачу почитаю) где $x(V)$ - функция, обратная $V(x)$, а $\frac{dE}{dn}$ рассматривается как функция E; E_0 - начало отсчета энергии.

famous. Стационарные волновые функции в $V(x) = -Fx$

Найти волновые функции стационарных состояний одномерного движения частицы массы в однородном поле $V(x) = -Fx$ где $F = \text{const}$.

Solution..

Это известная задача, решается функцией Айри.
В уравнении Шредингера

$$\left(\frac{\hat{p}^2}{2m} - F\hat{x}\right)\Psi = e\Psi$$

оператор $\hat{p}$ возводится в квадрат, а $\hat{x}$ - в первую степень. Поэтому оно в координатном представлении является уравнением второго порядка, а в импульсном представлении - первого, следовательно, задачу удобно решать в импульсном:

$$\left[\frac{p^2}{2m} - \mathrm{i}\hbar F\frac{d}{\mathrm{d}p}\right]\Psi_E(p) = E\Psi_E(p)$$

Поскольку в однородном поле движение всегда инфинитно, энергетический спектр непрерывен.

При заданной энергии E, используя метод разделения переменных, находим решение:

$$\Psi_E(p) = C \exp\left\{\frac{\mathrm{i}p}{\hbar F}\left(E - \frac{p^2}{6m}\right)\right\}.$$

Перейдем к координатному представлению и сделаем замену $z = p/\sqrt[3]{2m\hbar F}$:

$$\begin{aligned}
\psi(x) &\sim \int\limits_{\infty}^{+\infty} \Psi(p) \exp\left(\frac{\mathrm{i}}{\hbar} px\right) \mathrm{d}p = \\
&= \int\limits_{-\infty}^{+\infty} \exp\left\{-\mathrm{i}\left[-\frac{p}{\hbar}\left(x + \frac{E}{F}\right) + \frac{p^3}{6m\hbar F}\right]\right\} \mathrm{d}p \sim \\
&\sim \int\limits_{-\infty}^{+\infty} \exp\left\{-\mathrm{i}z\left[-\sqrt[3]{\frac{2mF}{\hbar^2}}\left(x + \frac{E}{F}\right) + \frac{z^2}{3}\right]\right\} \mathrm{d}z \\
&\sim \mathrm{Ai}\left(-\sqrt[3]{\frac{2mF}{\hbar^2}}\left(x + \frac{E}{F}\right)\right)
\end{aligned}$$

где $\mathrm{Ai}(\xi)$ - функция Эйри, в интегральном представлении $\mathrm{Ai}(\xi) = \frac{1}{\sqrt{\pi}} \int\limits_0^{\infty} \cos\left(z\xi + \frac{z^3}{3}\right) \mathrm{d}z$.

Solution 2.

В рассматриваемом случае имеется только непрерывный энергетический спектр и собственные функции невырождены.

$$-\frac{\hbar^2}{2\mu}\frac{d^2\psi}{dx^2} - [E + Fx]\psi = 0$$

$$\frac{p^2}{2\mu}a(p) - Ea(p) = i\hbar F\frac{d}{dp}a(p).$$

Решение этого уравнения, принадлежащее собственному значению E,

$$a_E(p) = ce^{-\frac{i}{\hbar F}\left(\frac{p^3}{6\mu} - Ep\right)}$$

(???? угадываем его что ли????) представляет собой волновую функцию в импульсном представлении. Произведем нормировку функций $a(p)$ на $\delta\left(E - E'\right)$:

$$\int a_E^*(p) a_{E'}(p) dp = \delta\left(E - E'\right),$$

$$cc^* \int e^{-\frac{ip}{\hbar F}\left(E - E'\right)} dp = cc^* 2\pi\hbar F \delta\left(E - E'\right),$$

откуда

$$c = \frac{1}{\sqrt{2\pi\hbar F}}.$$

Волновая функция в координатном представлении

$$\psi(x) = \frac{\alpha}{2\pi\sqrt{F}} \int\limits_{-\infty}^{+\infty} e^{i\frac{u^3}{3} - iuq} du = \frac{\alpha}{\pi\sqrt{F}} \int\limits_0^{\infty} \cos\left(\frac{u^3}{3} - uq\right) du,$$

$$q := \left(x + \frac{E}{F}\right)\alpha, \qquad \alpha := \left(\frac{2\mu F}{\hbar^2}\right)^{1/3}.$$

этот интеграл можно выразить через функцию Эйри $\Phi(q)$:

$$\Phi(q) = \frac{1}{\sqrt{\pi}} \int\limits_0^{\infty} \cos\left(\frac{u^3}{3} + uq\right) du, \quad \psi(x) = \frac{\alpha}{\sqrt{\pi F}}\Phi(-q).$$

"Угловой" потенциал

Исследовать движение частицы в потенциале:

$$U(x) = \begin{cases} Fx, & x \geq 0 \\ \infty, & x < 0 \end{cases}$$

Solution.

Уравнение Шредингера сводится к уравнению на спецфункцию Айри, нули ее дадут спектр.
УШ есть:

$$-\frac{\hbar^2}{2m}\psi''(x) + Fx\psi(x) = E\psi(x)$$

Обезразмерим подстановкой:

$$z(x) = \frac{x - E/F}{(\hbar^2/2mF)^{1/3}}.$$

Получим уравнение Эйри:

$$\psi''(z) - z\psi(z) = 0.$$

Его общее решение - произвольная линейная комбинация функций Эйри первого и второго рода:

$$\psi(z) = C_1\,\mathrm{Ai}(z) + C_2\,\mathrm{Bi}(z)$$

Поскольку $U(x \to \pm\infty) \to \infty$, то в задаче присутствует только дискретный спектр.

При $x > 0$, уравнение совпадает с уравнением Эйри, в связи с чем его решение даётся затухающей при $x \to \infty$ функцией:

$$\psi(x) = C \cdot \mathrm{Ai}(z(x))$$

Величина $U(0) = \infty$ дает граничное условие $\psi(0) = 0$, из которого получаем корни $z_n(0)$, по ним находим спектр:

$$E_n = -z_n \left(\hbar^2 F^2/2m\right)^{1/3}$$

Список первых нулей функции Эйри $z_n \approx \{-2.3, -4.1, -5.5, ...\}$. А большие нули получим, используя асимптотику для $z \to -\infty$:

$$\sin\left(\frac{2}{3}\left(-z_n\right)^{3/2} + \frac{\pi}{4}\right) = 0 \quad \to z_n \quad \approx -\left(\frac{3\pi}{2}(n - 1/4)\right)^{2/3}$$

К примеру по этой формуле получается $z_{10} \approx -12.8281$, что отличается от численного только в 5 ой значащей цифре. Обратим внимание, что если пренебречь $1/4$ по сравнению с n то для $n = 10$ точность ухудшается в 1000 раз.

Получим

$$E_n \approx \left(\frac{9\pi^2}{8}\frac{\hbar^2 F^2}{m}\right)^{1/3} n^{2/3}$$

ПТФ-? яма $U(x) = a/(a + |x|)$

(потом решу)

Wiki. Модифицированный потенциал Пёшль - Теллера

Найти связные состояния в

$$V(x) = -\frac{\hbar^2}{2m}a^2\frac{\lambda(\lambda - 1)}{\mathrm{ch}^2\, ax}.$$

Solution.

Решаем через гипергеометрические функции, типичная на них задача.
Стационарное уравнение Шрёдингера с модифицированным потенциалом Пёшль - Теллера имеет вид:

$$-\frac{\hbar^2}{2m}\Psi''(x) - \frac{\hbar^2}{2m}a^2\frac{\lambda(\lambda - 1)}{\mathrm{ch}^2\, ax}\Psi(x) = E\Psi(x).$$

Если ввести обозначение $k = \sqrt{2mE/\hbar^2}$, то оно примет вид:

$$\Psi''(x) + \left(k^2 + a^2\frac{\lambda(\lambda-1)}{\mathrm{ch}^2\, ax}\right)\Psi(x) = 0.$$

После замены переменных

$$y = \mathrm{ch}^2\, ax$$

получим

$$y(1-y)\Psi''(y) + \left(\frac{1}{2} - y\right)\Psi'(y) - \left(\frac{k^2}{4a^2} - \frac{\lambda(\lambda-1)}{4y}\right)\Psi(y) = 0$$

Если подставить решение в виде

$$\Psi(y) = y^{\frac{\lambda}{2}}v(y),$$

то уравнение приводится к гипергеометрическому виду

$$y(1-y)v''(y) + \left(\left(\lambda + \frac{1}{2}\right) - (\lambda-1)y\right)v'(y) - \frac{1}{4}\left(\lambda^2 + \frac{k^2}{a^2}\right)v = 0$$

Обозначая

..

(дальше не выгружаю, см вики про задачу.)

Wiki. Потенциал Пёшль - Теллера

Найти стационарные состояния в потенциале Пёшль-Теллера, который имеет вид

$$U(x) = \frac{\hbar^2}{2m}a^2\left(\frac{\varkappa(\varkappa-1)}{\sin^2 ax} + \frac{\lambda(\lambda-1)}{\cos^2 ax}\right)$$

на промежутке $0 \leqslant x \leqslant \pi/(2a)$, на границе которого он обращается в бесконечность. Параметры удовлетворяют условиям $\varkappa > 1$ и $\lambda > 1$.

Solution.

(? порешаю еще раз потом)

Стационарное уравнение Шрёдингера с потенциалом Пёшль - Теллера имеет вид:

$$-\frac{\hbar^2}{2m}\Psi''(x) + \frac{\hbar^2}{2m}a^2\left(\frac{\varkappa(\varkappa-1)}{\sin^2 ax} + \frac{\lambda(\lambda-1)}{\cos^2 ax}\right)\Psi(x) = E\Psi(x)$$

Если ввести обозначение $k = \sqrt{2mE/\hbar^2}$, то оно примет вид:

$$\Psi''(x) + \left(k^2 - a^2\frac{\varkappa(\varkappa-1)}{\sin^2 ax} - a^2\frac{\lambda(\lambda-1)}{\cos^2 ax}\right)\Psi(x) = 0$$

После замены переменных

$$y = \sin^2 ax$$

получим

$$y(1-y)\Psi''(y) + \left(\frac{1}{2} - y\right)\Psi'(y) + \frac{1}{4}\left(\frac{k^2}{a^2} - \frac{\varkappa(\varkappa-1)}{y} - \frac{\lambda(\lambda-1)}{1-y}\right)\Psi(y) = 0.$$

Так как точки 0 и 1 являются особыми, то естественно представить решение в виде:

$$\Psi(y) = y^\mu(1-y)^\nu f(y)$$

Если выбрать

$$\mu = \frac{\varkappa}{2}, \quad \nu = \frac{\lambda}{2},$$

то уравнение приведётся к гипергеометрическому виду:

$$y(1-y)f''(y) + \left(\left(\varkappa + \frac{1}{2}\right) - y(\varkappa+\lambda+1)\right)f'(y) + \frac{1}{4}\left(\frac{\varkappa^2}{a^2} + (\varkappa+\lambda)^2\right)f(y) = 0.$$

Общее решение данного уравнения может быть выражено через гипергеометрические функции:

$$f(y) = C_1\,{}_2F_1(a,b;c;y) + C_2 y^{1-c}\,{}_2F_1(a+1-c, b+1-c; 2-c; y),$$

где введены обозначения:

(дальше не выгружаю, ибо мб это не нужно. мб догружу, если понадобится)

Используется как приближение для энергии двухатомной молекулы, альтернативный потенциалу Морзе.

(в других задачах тоже укажу в конце применения их, если узнаю!)

Я. Частица в треугольнике (????)

Определить уровни энергии частицы в равностороннем треугольнике.

Solution.

(задумался про это, мб почитаю статью про это, все гуглится, просто не до этого. интересная задача!)
(?? мб это в адиабатике решаться должно, там всякая геометрия, пока не уверен, где это стоит решать???)

17.1.18 Problems about radiation

Время жизни частицы на 9м уровне в колодце (???)

Найти время жизни частицы, находящейся на девятом возбужденном уровне в бесконечно глубокой потенциальной яме ширины, $a (0 < \mathrm{x} < a)$.

Solution

(задача это бред, забил на нее и все.)
(?? можно было бы попытаться теорию спонтанного излучения применить для колодца, однако какое одномерное квантовое поле??? или в пространстве какой размерности мы находимся?)
(?? какое вообще квантовое поле при любой размерности??)

Б-2.13.1 Матричные элементы водорода

Вычислить матричные элементы $\langle 2p|\hat{\mathrm{x}}|1s\rangle, \langle 2p|\hat{\mathrm{y}}|1s\rangle$ и $\langle 2p|\hat{\mathrm{z}}|1s\rangle$ для атома водорода. Какие правила отбора они определяют?

Solution

2.13.1. $\langle 210|\hat{x}|100\rangle = 0, \langle 210|\hat{\mathrm{y}}|100\rangle = 0, \langle 210|\hat{\mathrm{z}}|100\rangle = \frac{128\sqrt{2}}{243}$, $\langle 21 \pm 1|\hat{x}|100\rangle = \pm\frac{128}{243}, \langle 21 \pm 1|\hat{y}|100\rangle = i\frac{128}{243}, \langle 21 \pm 1|\hat{\mathrm{z}}|100\rangle = 0$. (Ответы приведены в атомной системе единиц.)

Б-2.13.2 Матричные элементы водорода

Вычислить матричные элементы $\langle 2p|\hat{\mathrm{p}}_x|1s\rangle$, $\langle 2p|\hat{\mathrm{p}}_y|1s\rangle$ и $\langle 2p|\hat{\mathrm{p}}_z|1s\rangle$. Какие правила отбора они определяют?

Solution

2.13.2. $\langle 210|\hat{\mathrm{p}}_x|100\rangle = 0, \langle 210|\hat{\mathrm{p}}_y|100\rangle = 0, \langle 210|\hat{\mathrm{p}}_z|100\rangle = i\frac{16\sqrt{2}}{81}$,
$\langle 21\pm1|\hat{\mathrm{p}}_x|100\rangle = \pm i\frac{16}{81}, \langle 21\pm1|\hat{\mathrm{p}}_y|100\rangle = -\frac{16}{81}, \langle 21\pm1|\hat{\mathrm{p}}_z|100\rangle = 0$. (Ответы приведены в атомной системе единиц.)
(???? что с правилами отбора???)

Б-2.13.3 Угловое распределение излучения водорода

Найти угловое распределение фотонов, излучающихся в переходе $|2p\rangle \to |1s\rangle$ атома водорода, и время жизни $|2p\rangle$ состояния. Выразить это время в атомных единицах времени.

Solution

2.13.3. Уравнение Шредингера, описывающее атом водорода, взаимодействующий с вторично-квантованным полем фотонов, имеет вид

$$\left\{ i\hbar\frac{\partial}{\partial t} - \hat{\mathrm{H}}^{(0)} - \hat{\mathrm{V}} \right\} |\Psi\rangle = 0, \quad \hat{\mathrm{V}} = \frac{e}{mc}(\mathbf{A}\hat{\mathbf{p}}), \quad -e < 0.$$

Здесь $\hat{\mathrm{H}}^{(0)} = \hat{\mathbf{p}}^2/(2m) - e^2/r$ - гамильтониан атома водорода, $\hat{\mathrm{V}}$ - оператор возмущения. Возмущение периодически зависит от времени, потому что вектор-потенциал фотонного поля (11.70) записывается так:

$$\hat{\mathbf{A}}(\mathbf{r},t) = \sum_{\mathbf{k},\lambda} \sqrt{\frac{2\pi\hbar c^2}{\omega L^3}} \left\{ \mathbf{e}_{\mathbf{k},\lambda} \hat{\mathrm{c}}_{\mathbf{k},\lambda} e^{-i(\omega t - \mathrm{kr})} + \mathbf{e}^*_{\mathbf{k},\lambda} \hat{\mathrm{c}}^+_{\mathbf{k},\lambda} e^{i(\omega t - \mathbf{kr})} \right\}$$

где $\hat{c}^+_{\mathbf{k},\lambda}$и $\hat{c}_{\mathbf{k},\lambda}$ - операторы рождения и уничтожения фотона с волновым вектором $\mathbf{k}$ и состоянием поляризации $\lambda = 1, 2$, а $\mathbf{e}_{\mathbf{k},\lambda}$ - единичный вектор поляризации. Вектор-потенциал $\hat{\mathbf{A}}(\mathbf{r},t)$ нормирован на объем $V = L^3$, потому что поле фотонов рассматривается в кубе с длиной ребра L при циклических граничных условиях.

Рассмотрим квантовый переход, совершаемый атомом водорода из состояния $2p$ в состояние $1s$, который сопровождается излучением одного фотона с волновым вектором $\mathbf{k}$ и поляризацией λ. Фотон излучается из вакуума, поэтому мы имеем дело с процессом спонтанного излучения. Начальное и конечное состояния полной квантовой системы, включающей атом и электромагнитное поле, имеют вид $|i\rangle = |2p; 0, 0, ..., 0\rangle$ и $|f\rangle = |1s; \mathbf{1}_{\mathbf{k},\lambda}, 0, ..., 0\rangle$, причем $\mathbf{1}_{\mathbf{k},\lambda}$ - число заполнения, отвечающее наличию одного фотона.

Поскольку $\langle \mathbf{1}_{\mathbf{k},\lambda}, 0, ..., 0|\hat{c}^+_{\mathbf{k},\lambda}|0, 0, ..., 0\rangle = 1$, то в матричный элемент оператора возмущения $\langle f|\hat{V}|i\rangle$, отвечающий нашему процессу, вносит вклад только одно слагаемое из суммы (2), которое включает оператор рождения $\hat{c}^+_{\mathbf{k},\lambda}$и зависит от времени, как $e^{i\omega t}$. Поэтому дифференциальная вероятность нашего квантового перехода в единицу времени запишется следующим образом (см. (II.50)):

$$dw^{\lambda}_{if} = \frac{2\pi}{\hbar} |\langle f|\hat{\mathrm{V}}^+_{\mathbf{k},\lambda}|i\rangle|^2 \delta\left(E_f - E_i + \hbar\omega\right) d\nu_f,$$

$$\hat{\mathrm{V}}^+_{\mathbf{k},\lambda} = \frac{e}{m}\sqrt{\frac{2\pi\hbar}{\omega L^3}} e^{-i\mathbf{kr}} \left(\mathbf{e}^*_{\mathbf{k},\lambda}\hat{\mathbf{p}}\right),$$

где E_i и E_f - начальная и конечная энергия атома водорода (для состояний $2p$ и $1s$). В этой формуле предполагается далее провести интегрирование по энергии конечных фотонов.

Учитываем, что

$$d\nu_f = \frac{d^3k}{(2\pi)^3} L^3 = \frac{k^2 dk d\Omega}{(2\pi)^3} L^3 = \frac{\omega^2 d(\hbar\omega)}{\hbar c^3 (2\pi)^3} L^3 d\Omega,$$

так как энергия фотона $E_{\mathbf{k}} = \hbar\omega = \hbar kc$, и $dk = d\omega/$. Интегрируя в (3)

$$dW^{\lambda}_{ij} = \frac{e^2}{\hbar c}\frac{\omega_{if}}{2\pi} |\frac{\left(\mathbf{e}^*_{\mathbf{k},\lambda}\mathbf{p}_{ii}\right)}{mc}|^2 d\Omega, \quad \text{где} \quad \mathbf{p}_{fi} = \langle 2p|e^{-i\mathbf{kr}}\hat{\mathbf{p}}|1s\rangle$$

и мы ввели обозначение $\omega_{if} = \left(E_i - E_f\right)/\hbar$. Поскольку характерное значение величины $(\mathbf{kr}) \sim ka \sim \hbar\omega a/(\hbar c) \sim e^2/a \cdot a/(\hbar c) \sim \alpha \simeq 1/137 \ll 1$, т. е. является малым для атомных процессов, то можно разложить экспоненту в (4) и пренебречь величиной $(\mathbf{kr})$ по сравнению с единицей [9]. Учитывая, кроме того, что

$$\frac{1}{m}\mathbf{p}_{fi} = -i\omega_{if}\mathbf{r}_{fi},$$

видим, что матричный элемент оператора возмущения сводится к матричному элементу оператора дипольного электрического момента $\hat{\mathbf{d}} = -\hat{\mathbf{r}}$. В итоге мы получаем дифференциальную вероятность перехода в дипольном приближении

$$dW^{\lambda}_{if} = \frac{\omega^3_{ij}}{2\pi\hbar c^3} |\left(\mathbf{e}^*_{\mathbf{k},\lambda}\mathbf{d}_{ii}\right)|^2 d\Omega.$$

В формуле (5) необходимо провести суммирование по поляризациям конечных фотонов при помощи формулы

$$\sum_{\lambda=1,2} \left(\mathbf{e}_{\mathrm{k},\lambda}\right)_i \left(\mathbf{e}^*_{\mathbf{k},\lambda}\right)_j = \delta_{ij} - \frac{k_i k_j}{k^2}$$

В результате получим угловое распределение вероятности излучения:

$$dW_{if} = \frac{\omega^3_{if}}{2\pi\hbar c^3} ||\mathbf{k}^0 \times \mathbf{d}_{it}||^2 d\Omega,$$

где $\mathbf{k}^0 = \mathbf{k}/|\mathbf{k}|$. Интегрируя в (7) по угловым переменным [10], получаем полную вероятность излучения фотонов, сопровождающего переход атома $2p \to 1s$:

$$W_{if} = \frac{4}{3}\frac{\omega^3_{if}}{\hbar c^3} |\mathbf{d}_{fi}|^2.$$

Воспользуемся далее результатами задачи 2.13.1 и увидим, что

$$|\mathbf{d}_{ii}|^2 = e^2|\langle 2p|\hat{\mathbf{r}}|1s\rangle|^2 = e^2\left[|\langle 2p|\hat{x}|1s\rangle|^2 + |\langle 2p|\hat{y}|1s\rangle|^2 + |\langle 2p|\hat{z}|1s\rangle|^2\right] = \left(\frac{128\sqrt{2}}{243}ea\right)^2,$$

независимо от значения квантового числа $m = 0, \pm 1$ начального состояния $\left(a = \hbar^2/(\text{ те } e^2\right)$ - боровский радиус). Имея также в виду, что $\hbar\omega_{if} = E_2 - E_1 = 3e^2/(8a)$, находим из формулы (8)

$$W_{if} = \left(\frac{2}{3}\right)^8 \alpha^4 \frac{c}{a}, \quad \text{где } \alpha = \frac{e^2}{\hbar c} \simeq \frac{1}{137}$$

- постоянная тонкой структуры. Подставляя численные значения физических величин, получаем, что вероятность $W_{if} \simeq 6,35 \cdot 10^8 \text{с}^{-1}$, время жизни $2p$-состояния $\tau \simeq 1,57 \cdot 10^{-9}$ с или $\tau = (3/2)^8 \alpha^{-3} \tau_{\text{ат}}$, где $\tau_{\text{ат}} = \hbar a/e^2 = 2,4 \cdot 10^{-17}$с - атомная единица времени.

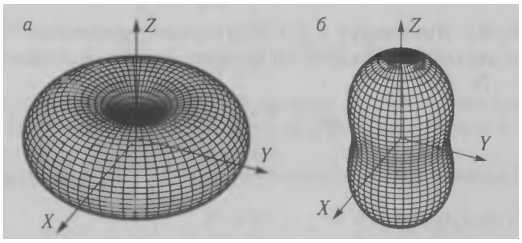
Наконец, проведем анализ углового распределения излученных фотонов. Оно будет различным для начальных состояний атома водорода с квантовыми числами $m = 0$ и $m = \pm 1$ (рисунки 2.17, а и б). Обозначим через φ и θ сферические углы волнового вектора $\mathbf{k}$. Учитывая значения матричных элементов оператора $\hat{\mathbf{d}}$ для начальных состояний $m = 0$ и $m = \pm 1$ (задача 2.13.1), получаем на основе формулы (7)

$$dW_{if}|_{m=0} = W \sin^2\theta d\Omega, \quad dW_{if}|_{m=\pm 1} = W \cdot \frac{1}{2}\left(1 + \cos^2\theta\right) d\Omega,$$

где при помощи W мы обозначили величину

$$W' = \frac{\omega_{if}^3}{2\pi\hbar c^3}|\mathbf{d}_{it}|^2 = \frac{3}{8\pi}W_{if}.$$

Заметим, что для вывода соотношений (9) можно использовать формулу $|\left[\mathbf{k}^0 \times \mathbf{d}_{ii}\right]|^2 = (\mathbf{d}_{ii}^* \mathbf{d}_{ji}) - \left(\mathbf{k}^0 \mathbf{d}_{ji}^*\right)\left(\mathbf{k}^0 \mathbf{d}_{ji}\right)$. Интегрирование по углам в выражениях (9) в обоих случаях дает один и тот же результат (8).



(??? пока это ещё не понимаю.)

Б-2.13.4 Время параллельности спина полю

Нейтрон находится в однородном магнитном поле $\mathcal{H}_0 \| z$. Определить время жизни состояния с проекцией спина на направление поля $m_s = +1/2$. Получить численное значение времени жизни для $\mathcal{H}_0 = 1$ кГс.

Solution

Нейтрон - электрически нейтральная частица со спином 1/2, обладающая собственным магнитным моментом $\mu = -\mu_n = -1,913\mu_8$, где $\mu_{\text{R}} = e\hbar/(2m_p c)$ - ядерный магнетон.

Взаимодействие нейтрона с электромагнитным полем (с классическим внешним и вторично-квантованным полем излучения) имеет вид

$$\hat{\text{V}} = -\hat{\mu}\left(\mathcal{H}_0 + \hat{\mathcal{H}}_{rad}\right),$$

где $\hat{\mu} = -\mu_n \hat{\sigma}$,

$$\hat{\mathcal{H}}_{\text{rad}} = \text{rot}\,\hat{\mathbf{A}}_{\text{rad}} = i\sum_{\mathbf{k},\lambda}\sqrt{\frac{2\pi\hbar c^2}{\omega L^3}}\left\{\left[\mathbf{k} \times \mathbf{e}_{\mathbf{k},\lambda}\right]\hat{c}_{\mathbf{k},\lambda}e^{-i(\omega t - \mathbf{kr})} - \left[\mathbf{k} \times \mathbf{e}_{\mathbf{k},\lambda}^*\right]\hat{c}_{\mathbf{k},\lambda}^+ e^{i(\omega t - \mathbf{kr})}\right\},$$

где мы воспользовались формулой (II.70). Гамильтониан невозмущенной задачи записывается в виде: $\hat{\mathrm{H}}^{(0)} = -\hat{\mu}\mathcal{H}_0 = \mu_n\hat{\sigma}\mathcal{H}_0 = \mu_n\hat{\sigma}_z\mathcal{H}_0$, так как ось z направлена вдоль поля $\mathcal{H}_0$. Волновые функции, собственные для невозмущенного гамильтониана:

$$\chi_1 = \chi_{1/2} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \chi_2 = \chi_{-1/2} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

Эти функции отвечают уровням энергии невозмущенного гамильтониана $E^{(0)}_{1,2} = \pm\mu_n\mathcal{H}_0$. Как видно, энергия нейтрона в магнитном поле зависит от ориентации магнитного момента по отношению к направлению поля. Причем два разных состояния ориентации магнитного момента обладают различной устойчивостью в отношении взаимодействия с полем фотонов. Поэтому оказываются возможными спонтанные переходы нейтрона между состояниями, отличающимися ориентацией магнитного момента. Такие переходы сопровождаются изменением ориентации спина и одновременным испусканием фотона. Это и есть излучение магнитного момента нейтрона во внешнем магнитном поле.

В нашем случае возможен переход нейтрона из состояния $\gamma 1$ в состояние χ_2, которое обладает бóльшей устойчивостью. Проводя начальные преобразования по аналогии с задачей 2.13.3, мы можем записать дифференциальную вероятность излучения фотона с волновым вектором k и поляризацией λ в виде

$$dW^{\lambda}_{12} = \frac{2\pi}{\hbar}|V_{21}|^2 d\nu_f = \frac{\omega_{12}}{2\pi\hbar c}|\left[\mathbf{k}\times\mathbf{e}^*_{\mathbf{k},\lambda}\right]\mu_{21}|^2 d\Omega,$$

где мы ввели обозначения $\omega_{12} = 2\mu_n\mathcal{H}_0, \mu_{21} = \mu_n\langle\chi_2|\hat{\sigma}|\chi_1\rangle$. Выражение dW^{λ}_{12} можно переписать в виде

$$dW^{\lambda}_{12} = \frac{\omega_{12}}{2\pi\hbar c}|\mathbf{e}^*_{\mathbf{k},\lambda}\mathbf{m}_{21}|^2 d\Omega, \quad \text{где} \quad \mathbf{m}_{21} = [\mathbf{k}\times\boldsymbol{\mu}_{21}].$$

Далее суммируем по поляризациям излученных фотонов, как в задаче 2.13.3. В итоге получаем

$$dW_{12} = \frac{\omega^3_{12}}{2\pi\hbar c^3}|\left[\mathbf{k}^0\times\boldsymbol{\mu}_{21}\right]|^2 d\Omega,$$

где $\mathbf{k}^0 = \mathbf{k}/k$, и мы учли, что $\mathbf{k}|\mathbf{k}\times\boldsymbol{\mu}_{21}] = 0$. Интегрируем по углам вылета фотона так же, как и в задаче 2.13.3, и находим полную вероятность излучения в единицу времени:

$$W = \frac{4}{3}\frac{\omega^3_{12}}{\hbar c^3}|\boldsymbol{\mu}_{21}|^2.$$

Очевидно, что излучение имеет магнитно-дипольный характер (ср. (2) и формулу (8) задачи 2.13.3). Вычисляем матричные элементы:

$$(\mu_{21})_x = \mu_n, \quad (\mu_{2\mathrm{I}})_y = i\mu_n, \quad (\mu_{21})_z = 0$$

и получаем окончательное выражение для полной вероятности излучения, сопровождаемого переворотом спина в магнитном поле (так называемый спиновый свет нейтрона):

$$W = \frac{64}{3}\frac{\mu^5_n\mathcal{H}^3_0}{\hbar^4 c^3}.$$

Проведем численные оценки. Для напряженности поля $\mathcal{H}_0 = 1$ кГс получаем время жизни $\tau \simeq 1,9\cdot 10^{28}$с $\simeq 5,9\cdot 10^{20}$ лет. Таким образом, в лабораторных условиях вероятность данного процесса чрезвычайно мала. Однако в сверхсильных полях $\sim 10^{13}$Гс, существующих вблизи астрофизических объектов таких, как нейтронные звезды, вероятность может сильно возрасти, при этом время время жизни τ может составить ~ 10 с.

Б-2.13.5 Фотоэффект в рамках квантовой механики (!??!?!?)

Найти сечение фотоэффекта на атоме водорода под действием плоской монохроматической волны с частотой ω для случая $\hbar\omega \gg I$, где I - потенциал ионизации атома. Сравнить результаты вычислений при классическом и квантовом описаниях падающей электромагнитной волны.

Solution.

Пишем правило Ферми, подставляем начальное и конечное состояния. (??? так просто???)

Фотоэффектом называется реакция “выбивания” электрона из атома падающим фотоном (в задаче речь идет о фотоэффекте на атоме водорода).

В соответствии с условием задачи полагаем, что в начальном состоянии в системе находятся один фотон и атом водорода в основном состоянии, т. е. $|i\rangle = |Is; \mathbf{1}_{\mathbf{k},\lambda}, 0, 0, ..., 0\rangle$, а конкретно

$$E_l = E_1 = -\frac{e^2}{2a}, \quad \psi_i = \psi_{100}(r) = \frac{1}{\sqrt{\pi a^3}} e^{-r/a}$$

- энергия и волновая функция основного состояния атома водорода, $a = \hbar^2/\left(me^2\right)$ - радиус боровской орбиты. Атом взаимодействует с вторично-квантованным полем фотонов, описываемым вектор-потенциалом $\hat{\mathbf{A}}(\mathbf{r}, t)$ (см. (II.70)). Оператор, описывающий взаимодействие, имеет обычный вид:

$$\hat{\mathrm{V}} = \frac{e}{mc}(\hat{\mathbf{A}}\hat{\mathbf{p}})$$

и играет роль оператора возмущения в рассматриваемой задаче ($-e < 0$ - заряд электрона). В результате акта взаимодействия происходит ионизация атома, т. е. атомный электрон переходит в непрерывный спектр. Энергия ионизации в данном случае равна $I = -E_1 = e^2/(2a)$.

Далее мы предположим, что энергия вылетающего из атома электрона велика по сравнению с I, а это значит, что электрон является быстрым, следовательно, можно пренебречь влиянием атома на состояние электрона и выбрать конечное состояние системы в виде $|f\rangle = |\mathbf{p}; 0, 0, ..., 0\rangle$, а конкретно

$$E_f = \frac{\mathbf{p}^2}{2m}, \quad \psi_f = \psi_{\mathbf{p}}(\mathbf{r}) = \frac{1}{\sqrt{L^3}} e^{\frac{i}{\hbar}\mathbf{p}}$$

- энергия и волновая функция свободного электрона. Вероятность процесса в единицу времени, во время которого система поглощает энергию радиационного поля, рассчитывается согласно формуле (см. (II.50))

$$dw_{if} = \frac{2\pi}{\hbar}|V_{fi}|^2 \delta\left(E_i - E_f + \hbar\omega\right) d\nu_f,$$

где E_i и E_l - начальная и конечная энергии электрона, а в матричный элемент $V_{fi} = \langle f|\hat{V}|i\rangle$ вносит вклад только одно слагаемое из суммы (II.70), включающее оператор уничтожения $\hat{c}_{\mathbf{k},\lambda}$, так что $\langle 0, 0, ..., 0|\hat{c}_{\mathbf{k},\lambda}|\mathbf{1}_{\mathbf{k},\lambda}, 0, ..., 0\rangle = 1$. Поэтому $V_{fi} = \langle f|\hat{V}_{\mathbf{k},\lambda}|i\rangle$, где

$$\hat{\mathrm{V}}_{\mathbf{k},\lambda} = \frac{e}{m}\sqrt{\frac{2\pi\hbar}{\omega L^3}} e^{i\mathbf{kr}} \left(\mathbf{e}_{\mathbf{k},\lambda}\hat{\mathbf{p}}\right).$$

Поскольку для волновой функции (1) мы использовали нормировку на объем куба периодичности L^3, то связь дифференциальной вероятности перехода с дифференциальным сечением определяется соотношением

$$d\sigma = \frac{dW}{j} = L^3 \frac{dW}{v} = L^3 \frac{dW}{c},$$

где $\mathbf{j} = \mathbf{v}/L^3$ - плотность потока вероятности при нашем выборе нормировки (для падающих фотонов, очевидно, $v = c$). Запишем матричный элемент:

$$V_{fi} = \frac{e}{mL^3}\sqrt{\frac{2\hbar}{\omega a^3}}\mathbf{e}_{\mathbf{k},\lambda} \int e^{-\frac{i}{\hbar}\mathbf{pr} + i\mathbf{krp}} \hat{\mathbf{p}} e^{-r/a} d^3x.$$

В этом выражении можно пренебречь импульсом фотона по сравнению с импульсом электрона, имея в виду, что из закона сохранения энергии (см. (2)) следует

$$\hbar\omega = I + \frac{\mathrm{p}^2}{2m} \simeq \frac{\mathrm{p}^2}{2m} \ll mc^2,$$

т. е. мы считаем электрон нерелятивистским, а поэтому

$$\frac{\hbar k}{p} \sim \left(\frac{\hbar\omega}{2mc^2}\right)^{1/2} \ll 1.$$

При вычислении интеграла в (5) удобно вначале проинтегрировать по частям, имея в виду, что $\hat{\mathrm{p}} = -i\hbar\nabla$ и перенести действие производной на плоскую волну. Кроме того необходимо учесть, что $\hbar\omega \gg I$, откуда следует, что $pa/\hbar \gg 1$. Расчет интеграла при этом условии дает

$$\frac{8\pi\hbar^4}{ap^4}\mathbf{p}.$$

Для дальнейших вычислений заметим, что

$$d\nu_f = \frac{d^3p}{(2\pi\hbar)^3}L^3 = \frac{L^3p^2dpd\Omega}{(2\pi\hbar)^3} = \frac{L^3pd\left(p^2\right)d\Omega}{2(2\pi\hbar)^3}.$$

Подставляем теперь значение матричного элемента (5) в (2) и, учитывая (4) и (6), интегрируем по энергии конечных электронов при помощи δ-функции (берем интеграл по $d\left(p^2\right)$). В итоге дифференциальное сечение нашего процесса приобретает вид

$$d\sigma = 64\left(\frac{e^2}{\hbar c}\right)\left(\frac{\hbar^2}{me^2}\right)^2\left(\frac{I}{\hbar\omega}\right)^{7/2}|\mathbf{e}_{\mathbf{k},\lambda}\mathbf{n}|^2d\Omega,$$

где $\mathbf{n} = \mathbf{p}/p$ - единичный вектор в направлении вылета электрона. Проводим усреднение по поляризациям начального фотона в выражении (7), используя формулу (6) задачи 2.13.3, разделив результат на два. В результате получаем дифференциальное сечение фотоэффекта для неполяризованных фотонов:

$$d\sigma = 32\alpha a^2\left(\frac{I}{h\omega}\right)^{7/2}|\left[\mathbf{k}^0\times\mathbf{n}\right]|^2d\Omega,$$

где $\alpha = e^2/(\hbar c), \mathbf{k}^0 = \mathbf{k}/k$ - направление волнового вектора падающего фотона. Интегрируя по угловым переменным, получаем окончательный результат - полное сечение фотоэффекта:

$$\sigma = \frac{256}{3}\alpha a^2\left(\frac{l}{\hbar\omega}\right)^{7/2}.$$

В заключение сделаем несколько замечаний относительно полуклассического описания фотоэффекта. При таком подходе электромагнитное поле описывается классически, т. е.

$$\mathbf{A}(\mathbf{r},t) = \mathbf{A}_0e^{-i(\omega t-\mathbf{kr})} + \mathbf{A}_0^*e^{i(\omega t-\mathbf{kr})},$$

а частицы описываются методами квантовой механики. Все, сказанное о выборе начальных и конечных состояний для электрона и о приближениях остается в силе, да и (по большей части) методы решения сохраняются. В основе также лежит формула для вероятности переходов в единицу времени (2). Оператор электромагнитного взаимодействия, очевидно, имеет вид

$$\hat{\mathrm{V}} = -\frac{ie}{mc}(\mathbf{A}\hat{\nabla}).$$

Для определенности будем считать, что плоская волна распространяется вдоль оси z, а вектор электрического поля (т. е. поляризация) направлен вдоль оси x, тогда ось z совпадает с направлением вектора k, а $\mathbf{A}_0 = \{A_0, 0, 0\}$ (A_0 считаем вещественной величиной). Тогда дифференциальная вероятность переходов в единицу времени, проинтегрированная по энергиям конечных электронов, имеет вид

$$dW_{if} = \frac{mpL^3}{4\pi^2\hbar^4}|V_{fi}|^2d\Omega,$$
$$V_{fi} = -\frac{ie\hbar A_0}{mc}\int\frac{1}{L^{3/2}}e^{-\frac{i}{\hbar}\mathrm{pr}}\frac{\partial}{\partial x}\left[\frac{1}{\sqrt{\pi a^3}}e^{-r/a}\right]d^3x.$$

Для вычисления интеграла в (10) тоже нужно вначале проинтегрировать по частям. Сечение процесса равно дифференциальной вероятности, деленной на плотность потока падающих фотонов. Усредненный по времени вектор Пойнтинга направлен вдоль оси z и равен

$$\bar{S} = \frac{c}{4\pi}\overline{|\mathcal{E}\times\mathcal{H}||} = \frac{\omega^2}{2\pi c}A_0^2,$$

а плотность потока фотонов, т. е. число фотонов, падающих в 1 секунду на единичную площадку есть $j = \bar{S}/(\hbar\omega)$. В итоге

$$d\sigma = 32\frac{e^2}{\omega mca^5}\left(\frac{\hbar}{p}\right)^7\left(\frac{p_x}{\hbar}\right)^2, \text{ где } p_x = p\cos\varphi\sin\theta.$$

Интегрирование по углам дает результат, полностью совпадающий с формулой (8).

17.2 Analysis of Typical Models

17.2.1 Problems about Spin, Two-Level Systems, and Their Measurements

ПТФ-1.з1.* Осцилляция Раби (50 б).

На двухуровневую систему накладывается периодическое поле, которое может вызывать переходы между этой парой уровней:

$$\hat{H}(t) = \begin{pmatrix} \varepsilon_1 & Ve^{-i\omega t} \\ Ve^{i\omega t} & \varepsilon_2 \end{pmatrix}$$

В начальный момент времени система находилась в состоянии $|\psi(t=0)\rangle = |\uparrow\rangle$. Определите вероятность обнаружить её в состоянии $|\downarrow\rangle$ через произвольное время t. Что происходит при резонансе, когда отстройка частоты $\delta \equiv \varepsilon_1 - \varepsilon_2 - \hbar\omega$ обращается в нуль?

Указание: покажите, что от зависимости гамильтониана от времени можно избавиться "переходом во вращающуюся систему отсчёта" (rotating wave approximation) – унитарным преобразованием (см. упражнения 2, 3) вида $\hat{U}(t) = e^{i\hat{\sigma}_z\omega_0 t}$. Чему равна соответствующая частота ω_0?

Solution.

(???)
We known that

$$U(t) = e^{i\hat{\sigma}_z\omega_0 t} = \cos\omega_0 t + i\sin\omega_0 t \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} e^{i\omega_0 t} & 0 \\ 0 & e^{-i\omega_0 t} \end{pmatrix}, \qquad U^\dagger(t) = \begin{pmatrix} e^{-i\omega_0 t} & 0 \\ 0 & e^{i\omega_0 t} \end{pmatrix};$$

$$\hat{H}' = \hat{U}\hat{H}\hat{U}^\dagger - i\hbar\hat{U}\partial_t\hat{U}^\dagger$$

thus
(??? what are we doing??)

$$\hat{H}' = \begin{pmatrix} \varepsilon_1 & Ve^{i(2\omega_0-\omega)t} \\ Ve^{-i(2\omega_0-\omega)t} & \varepsilon_2 \end{pmatrix} - \begin{pmatrix} \hbar\omega_0 & 0 \\ 0 & -\hbar\omega_0 \end{pmatrix} = \begin{pmatrix} \varepsilon_1 - \hbar\omega_0 & Ve^{i(2\omega_0-\omega)t} \\ Ve^{-i(2\omega_0-\omega)t} & \varepsilon_2 + \hbar\omega_0 \end{pmatrix}$$

Избавимся от зависимости от времени, подобрав соответствующее ω_0:

$$\omega_0 = \frac{\omega}{2}$$

$$\hat{H}' = \begin{pmatrix} \varepsilon_1 - \frac{\hbar\omega}{2} & V \\ V & \varepsilon_2 + \frac{\hbar\omega}{2} \end{pmatrix}$$

При этом переходе собственные векторы гамильтониана меняются на фазу:

$$\begin{pmatrix} |1'\rangle \\ |2'\rangle \end{pmatrix} = \begin{pmatrix} e^{i\omega_0 t} & 0 \\ 0 & e^{-i\omega_0 t} \end{pmatrix} \begin{pmatrix} |1\rangle \\ |2\rangle \end{pmatrix} = \begin{pmatrix} e^{i\omega_0 t}|1\rangle \\ e^{-i\omega_0 t}|2\rangle \end{pmatrix}$$

Собственные числа дают спектр возможных значений энергии:

$$\left(\varepsilon_1 - \frac{\hbar\omega}{2} - E\right)\left(\varepsilon_2 + \frac{\hbar\omega}{2} - E\right) - V^2 = 0$$

$$E_{1,2} = \frac{\varepsilon_1 + \varepsilon_2 \pm \sqrt{(\varepsilon_2 - \varepsilon_1 + \hbar\omega)^2 + 4V^2}}{2}$$

Соответствующие нормированные собственные состояния системы:

$$|1'\rangle = \frac{1}{C_1}\begin{pmatrix} \frac{\varepsilon_1 - \varepsilon_2 - \hbar\omega + \sqrt{(\varepsilon_2 - \varepsilon_1 + \hbar\omega)^2 + 4V^2}}{2V} \\ 1 \end{pmatrix}, \quad |2'\rangle = \frac{1}{C_2}\begin{pmatrix} \frac{\varepsilon_1 - \varepsilon_2 - \hbar\omega - \sqrt{(\varepsilon_2 - \varepsilon_1 + \hbar\omega)^2 + 4V^2}}{2V} \\ 1 \end{pmatrix}$$

$$|1\rangle = e^{-i\omega_0 t}|1'\rangle = \frac{e^{-i\omega_0 t}}{C_1}\begin{pmatrix} \frac{\varepsilon_1 - \varepsilon_2 - \hbar\omega + \sqrt{(\varepsilon_2 - \varepsilon_1 + \hbar\omega)^2 + 4V^2}}{2V} \\ 1 \end{pmatrix} = \frac{e^{-i\omega_0 t}}{C_1}\begin{pmatrix} a \\ 1 \end{pmatrix} = e^{-i\omega_0 t}\frac{a|\uparrow\rangle + |\downarrow\rangle}{C_1}$$

$$|2\rangle = e^{i\omega_0 t}|2'\rangle = \frac{e^{i\omega_0 t}}{C_2}\begin{pmatrix}\frac{\varepsilon_1-\varepsilon_2-\hbar\omega-\sqrt{(\varepsilon_2-\varepsilon_1+\hbar\omega)^2+4V^2}}{2V}\\1\end{pmatrix} = \frac{e^{i\omega_0 t}}{C_2}\begin{pmatrix}b\\1\end{pmatrix} = e^{i\omega_0 t}\frac{b|\uparrow\rangle+|\downarrow\rangle}{C_2}$$

Разложим начальное условие по стационарным состояниям:

$$|\psi(0)\rangle = |\uparrow\rangle = \frac{C_1 e^{i\omega_0 t}|1\rangle - C_2 e^{-i\omega_0 t}|2\rangle}{a-b}$$

Дальнейшая эволюция:

$$|\psi(t)\rangle = \frac{C_1 e^{i\omega_0 t}e^{-\frac{iE_1 t}{\hbar}}|1\rangle - C_2 e^{-i\omega_0 t}e^{-\frac{iE_2 t}{\hbar}}|2'\rangle}{a-b} = \frac{e^{-\frac{iE_1 t}{\hbar}}(a|\uparrow\rangle+|\downarrow\rangle) - e^{-\frac{iE_2 t}{\hbar}}(b|\uparrow\rangle+|\downarrow\rangle)}{a-b}$$

$$|\psi(t)\rangle = \frac{e^{-\frac{i(\varepsilon_1+\varepsilon_2)t}{2\hbar}}}{a-b}\left(e^{-\frac{i\sqrt{(\varepsilon_2-\varepsilon_1+\hbar\omega)^2+4V^2}t}{2\hbar}}(a|\uparrow\rangle+|\downarrow\rangle) - e^{\frac{i\sqrt{(\varepsilon_2-\varepsilon_1+\hbar\omega)^2+4V^2}t}{2\hbar}}(b|\uparrow\rangle+|\downarrow\rangle)\right)$$

$$\psi_\downarrow(t) = \langle\downarrow|\psi(t)\rangle = \frac{e^{-\frac{i(\varepsilon_1+\varepsilon_2)t}{2\hbar}}}{a-b}\left(e^{-\frac{i\sqrt{(\varepsilon_2-\varepsilon_1+\hbar\omega)^2+4V^2}t}{2\hbar}} - e^{\frac{i\sqrt{(\varepsilon_2-\varepsilon_1+\hbar\omega)^2+4V^2}t}{2\hbar}}\right)$$

Вероятность обнаружить систему в состоянии $|\downarrow\rangle$ через время t:

$$P_\downarrow(t) = |\psi_\downarrow(t)|^2 = \frac{4\sin^2\left(\frac{\sqrt{(\varepsilon_2-\varepsilon_1+\hbar\omega)^2+4V^2}t}{2\hbar}\right)}{(a-b)^2}$$

$$P_\downarrow(t) = \frac{4V^2\sin^2\left(\frac{\sqrt{(\varepsilon_2-\varepsilon_1+\hbar\omega)^2+4V^2}t}{2\hbar}\right)}{(\varepsilon_2-\varepsilon_1+\hbar\omega)^2+4V^2}$$

Случай резонанса:

$$\delta \equiv \varepsilon_1 - \varepsilon_2 - \hbar\omega = 0$$

$$P_\downarrow(t) = \sin^2\frac{Vt}{\hbar}$$

ПТФ-1.з2. Два спина (30 б).

Найдите уровни энергии и собственные состояния для следующего гамильтониана, описывающего систему двух взаимодействующих спинов $1/2$:

$$\hat{H} = -J(\vec{\sigma}_1 \otimes \vec{\sigma}_2) = -J(\hat{\sigma}_1^x \otimes \hat{\sigma}_2^x + \hat{\sigma}_1^y \otimes \hat{\sigma}_2^y + \hat{\sigma}_1^z \otimes \hat{\sigma}_2^z)$$

Solution.

$$\hat{H} = -J\left(\begin{pmatrix}0&0&0&1\\0&0&1&0\\0&1&0&0\\1&0&0&0\end{pmatrix} + \begin{pmatrix}0&0&0&-1\\0&0&1&0\\0&1&0&0\\-1&0&0&0\end{pmatrix} + \begin{pmatrix}1&0&0&0\\0&-1&0&0\\0&0&-1&0\\0&0&0&1\end{pmatrix}\right) = J\begin{pmatrix}1&0&0&0\\0&-1&2&0\\0&2&-1&0\\0&0&0&1\end{pmatrix}$$

Собственные числа дают спектр возможных значений энергии:

$$E_1 = 3J, \quad E_{2,3,4} = -J$$

Соответствующие нормированные собственные состояния системы:

$$|1\rangle = \frac{1}{\sqrt{2}}\begin{pmatrix}0\\-1\\1\\0\end{pmatrix} = \frac{1}{\sqrt{2}}(|\downarrow\uparrow\rangle - |\uparrow\downarrow\rangle), \quad |2\rangle = \begin{pmatrix}0\\0\\0\\1\end{pmatrix} = |\downarrow\downarrow\rangle$$

$$|3\rangle = \frac{1}{\sqrt{2}}\begin{pmatrix}0\\1\\1\\0\end{pmatrix} = \frac{1}{\sqrt{2}}(|\downarrow\uparrow\rangle + |\uparrow\downarrow\rangle), \quad |4\rangle = \begin{pmatrix}1\\0\\0\\0\end{pmatrix} = |\uparrow\uparrow\rangle$$

Solution.

$\hat{\boldsymbol{S}} = (\hbar/2)\hat{\boldsymbol{\sigma}}$
Рассмотрим состояние $|\xi\rangle = \frac{1}{\sqrt{2}}(|\uparrow\rangle + |\downarrow\rangle)$, матрица плотности такого состояния имеет вид:

$$\hat{\rho} = |\psi\rangle\langle\psi| = \frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} = \frac{1}{2}\left(\hat{\mathbb{I}} + \hat{\sigma}_x\right)$$

$$\langle\hat{\boldsymbol{S}}_x\rangle = (\hbar/4)\,\mathrm{Tr}\,(\hat{\rho}\hat{\sigma}_x) = \frac{1}{2}\,\mathrm{Tr}\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} = \hbar/2,$$

$$\langle\hat{\boldsymbol{S}}_y\rangle = (\hbar/2)\frac{i}{2}\,\mathrm{Tr}\begin{pmatrix} 1 & -1 \\ 1 & -1 \end{pmatrix} = 0,$$

$$\langle\hat{\boldsymbol{S}}_z\rangle = (\hbar/2)\frac{1}{2}\,\mathrm{Tr}\begin{pmatrix} 1 & -1 \\ 1 & -1 \end{pmatrix} = 0.$$

Теперь найдем дисперсию $\langle(\boldsymbol{S} - \langle\boldsymbol{S}\rangle)^2\rangle$, (только я так и не понял, как этой формулой пользоваться, ведь для $S_x : 2\times 2$, а $\langle S_x\rangle : 1\times 1$, поэтому) воспользуемся $\sigma_S^2 = \langle S^2\rangle - \langle S\rangle^2$

$$\langle\hat{\boldsymbol{S}}_x^2\rangle = (\hbar/2)^2\frac{1}{2}\,\mathrm{Tr}\left(\hat{\rho}\,\hat{\mathbb{I}}\right) = \frac{1}{2}\,\mathrm{Tr}\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} = (\hbar/2)^2 \equiv \langle\hat{\boldsymbol{S}}_y^2\rangle = \langle\hat{\boldsymbol{S}}_z^2\rangle,$$

$$\sigma_x = \sqrt{(\hbar/2)^2 - (\hbar/2)^2)} = 0; \quad \sigma_y = \sigma_z = (\hbar/2); \quad \sigma_{S_1} = \sqrt{\sigma_x^2 + \sigma_y^2 + \sigma_z^2} = \sqrt{2}(\hbar/2).$$

Теперь рассмотрим состояние $\hat{\rho}_2 = \left(\hat{\mathbb{P}}_\uparrow + \hat{\mathbb{P}}_\downarrow\right)/2$, для которого

$$\hat{\rho}_2 = \frac{1}{2}\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \frac{1}{2}\hat{\mathbb{I}}$$

$$\langle\hat{\boldsymbol{S}}_x\rangle = (\hbar/4)\,\mathrm{Tr}\,(\hat{\rho}_2\hat{\sigma}_x) = \frac{1}{2}\,\mathrm{Tr}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = 0,$$

$$\langle\hat{\boldsymbol{S}}_y\rangle = (\hbar/2)\frac{i}{2}\,\mathrm{Tr}\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} = 0,$$

$$\langle\hat{\boldsymbol{S}}_z\rangle = (\hbar/2)\frac{1}{2}\,\mathrm{Tr}\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = 0.$$

Дисперсию считаем как:

$$\langle\hat{\boldsymbol{S}}_x^2\rangle = (\hbar/2)^2\frac{1}{2}\,\mathrm{Tr}\left(\hat{\rho}\,\hat{\mathbb{I}}\right) = \frac{1}{2}\,\mathrm{Tr}\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = (\hbar/2)^2 \equiv \langle\hat{\boldsymbol{S}}_y^2\rangle = \langle\hat{\boldsymbol{S}}_z^2\rangle,$$

$$\sigma_{S_2} = \sqrt{\sigma_x^2 + \sigma_y^2 + \sigma_z^2} = \sqrt{3}(\hbar/2).$$

ПТФ-2.з1. Блоховское представление двухуровневой системы

1) Покажите, что матрицу плотности произвольной двухуровневой системы самого общего вида можно разложить по матрицам Паули в следующем виде:

$$\hat{\rho} = \frac{1}{2}(\hat{\mathbb{I}} + \hat{\boldsymbol{\sigma}}\cdot\boldsymbol{n})$$

где $\boldsymbol{n}$ – какой-то вектор. При каком условии на $\boldsymbol{n}$ это корректная матрица плотности?
2) При каком условии на $\boldsymbol{n}$, эта матрица плотности описывает чистое состояние?
3) Вычислите средние значения $\langle\hat{\sigma}_{x,y,z}\rangle$ по состоянию, описываемому такой матрицей плотности.

Solution.

Пусть с вероятностью p_α система может быть приготовлена в состоянии $|\alpha\rangle$. Тогда для такого усреднения мы можем записать:

$$\langle\hat{O}\rangle = \sum_\alpha p_\alpha\langle\alpha|\hat{O}|\alpha\rangle = \mathrm{Tr}(|\alpha\rangle p_\alpha\langle\alpha|\hat{O}) \equiv \mathrm{Tr}(\hat{\rho}\hat{O})$$

Матрица плотности:

$$\hat{\rho} = \sum_{\alpha} p_\alpha |\alpha\rangle\langle\alpha|$$

Матрица плотности – эрмитов оператор $\hat{\rho} = \hat{\rho}^\dagger$ с нормировкой $\mathrm{Tr}\hat{\rho} = \sum\limits_{\alpha} p_\alpha = 1$.

Удобно диагонализовать матрицу плотности (любая эрмитова матрица диагонализуема с вещественными собственными числами λ_n):

$$\hat{\rho}|n\rangle = \lambda_n |n\rangle,$$

$$\mathrm{Tr}\hat{\rho} = \sum_n \lambda_n = 1$$

Матрица плотности неотрицательно определена:

$$\langle\psi|\hat{\rho}|\psi\rangle = \sum_\alpha p_\alpha \langle\psi|\alpha\rangle\langle\alpha|\psi\rangle = \sum_\alpha p_\alpha \langle\psi|\alpha\rangle\langle\alpha|\psi\rangle = \sum_\alpha p_\alpha |\langle\alpha|\psi\rangle|^2 \geq 0$$

Следовательно, все $\lambda_n \geq 0$. А поскольку $\sum\limits_n \lambda_n = 1$, то все $\lambda_n \in [0,1]$. Собственные числа λ_n являются вероятностями оказаться в состоянии $|n\rangle$.

• Матрицы Паули совместно с единичной матрицей $\sigma^0 = \hat{\mathbb{I}}_{2\times 2}$ представляют собой базис в пространстве эрмитовых матриц 2×2 (см. упр. 3 недели 1). Поскольку $\mathrm{Tr}\hat{\rho} = 1$ и $\mathrm{Tr}\sigma_i = 0$, то коэффициент перед $\mathbb{I}$ равен $\frac{1}{2}$:

$$\hat{\rho} = \frac{1}{2}(\hat{\mathbb{I}} + \hat{\vec{\sigma}} \cdot \vec{n}) = \frac{1}{2}\begin{pmatrix} 1+n_z & n_x - in_y \\ n_x + in_y & 1-n_z \end{pmatrix}$$

$$\det\hat{\rho} = \frac{1}{2}(1 - n_z^2 - n_x^2 - n_y^2) = \frac{1}{2}(1 - \boldsymbol{n}^2)$$

$$\det\hat{\rho} = \prod_n \lambda_n \geq 0 \to |\boldsymbol{n}| \leq 1$$

Таким образом, конец вектора $\boldsymbol{n}$ лежит в шаре радиуса 1.

• Квантовая система, описываемая какой-то волновой функцией $|\psi\rangle$ (с вероятностью $p = 1$) можно описать на языке матрицы плотности

$$\hat{\rho} = |\psi\rangle\langle\psi|$$

Состояние, описываемое такой матрицей плотности, носит название *чистого*. В противном случае состояние называется *смешанным*.

Матрица плотности чистого состояния является проектором:

$$\hat{\rho}^2 = |\psi\rangle\langle\psi|\psi\rangle\langle\psi| = |\psi\rangle\langle\psi| = \hat{\rho}$$

$$\mathrm{Tr}\hat{\rho}^2 = \mathrm{Tr}\hat{\rho} = 1$$

В общем случае

$$\mathrm{Tr}\hat{\rho}^2 = \sum_\alpha p_\alpha^2 \leq \sum_\alpha p_\alpha = \mathrm{Tr}\hat{\rho} = 1$$

В случае чистого состояния одно из собственных значений равно 1, остальные равны 0.

$$\det\hat{\rho} = \frac{1}{2}(1 - |\boldsymbol{n}|^2) = 0 \to |\boldsymbol{n}| = 1$$

Таким образом, конец вектора $\boldsymbol{n}$ лежит на сфере радиуса 1.

• Среднее значение по состоянию:

$$\langle\sigma_i\rangle = \mathrm{Tr}(\rho\sigma_i) = \frac{1}{2}\mathrm{Tr}(\hat{\sigma}_i + \hat{\sigma}_i{}^2 n_i) = n_i$$

$$\langle\sigma_{x,y,z}\rangle = n_{x,y,z}$$

Solution..

Суть решения в скучных проверках свойств. (???)
Так как матрица плотности двухуровневой системы имеет размерность 2×2, то ее можно всегда разложить по базису в пространстве матриц 2×2, нужно только проверить, чтобы выполнялись ее свойства.
чтобы $\operatorname{Tr}\hat{\rho} = 1$, необходимо, чтобы был член с единичной матрицей, деленной на 2. эрмитовость очевидна из этого разложения положительно определенность дает на компоненты n условие: $n_1^2+n_2^2+n_3^2 \leqslant 1$

$$\hat{\rho}^2 = \hat{\rho}$$

$$\frac{1}{4}\begin{pmatrix} 1+n_3 & n_1-in_2 \\ n_1+in_2 & 1-n_3 \end{pmatrix}^2 = \frac{1}{2}\begin{pmatrix} 1+n_3 & n_1-in_2 \\ n_1+in_2 & 1-n_3 \end{pmatrix}$$

$$((1+n_3)^2+n_1^2+n_2^2)/2 = 1+n_3, \qquad ((1-n_3)^2+n_1^2+n_2^2)/2 = 1-n_3$$

Теперь посчитаем $\langle\hat{\sigma}_{x,y,z}\rangle$:

$$\langle\hat{\sigma}_x\rangle = \operatorname{Tr}(\hat{\rho}\hat{\sigma}_x) = \frac{1}{2}\operatorname{Tr}\begin{pmatrix} n_1-in_2 & 1+n_3 \\ 1-n_3 & n_1+in_2 \end{pmatrix} = \frac{n_1^2+n_2^2}{2},$$
$$\langle\hat{\sigma}_y\rangle = \frac{i}{2}\operatorname{Tr}\begin{pmatrix} n_1-in_2 & -1-n_3 \\ 1-n_3 & -n_1-in_2 \end{pmatrix} = \frac{-n_1^2-n_2^2}{2},$$
$$\langle\hat{\sigma}_z\rangle = \frac{1}{2}\operatorname{Tr}\begin{pmatrix} 1+n_3 & -n_1+in_2 \\ n_1+in_2 & -1+n_3 \end{pmatrix} = \frac{n_3^2-1}{2}$$

ПТФ-2.з2. Термодинамика двухуровневой системы

Двухуровневая система описывается гамильтонианом $\hat{H} = -\boldsymbol{h}\cdot\hat{\boldsymbol{\sigma}}$, где $\boldsymbol{h} = (h_x, h_y, h_z)$, и находится при температуре T. Вычислите средние значения $\hat{\sigma}_{x,y,z}$.

Solution.

Гиббсовский (канонический) ансамбль:

$$\hat{\rho} = \frac{1}{Z}e^{-\beta\hat{H}}, \quad Z = \operatorname{Tr}(e^{-\beta\hat{H}}) = \operatorname{Tr}(e^{\beta\vec{h}\cdot\hat{\vec{\sigma}}})$$

Воспользуемся упр. 3, п. 3 семинара 1 (там был случай $h = 1$, но он очевидным образом обобщается на случай $h \neq 1$):

$$e^{\beta\boldsymbol{h}\cdot\hat{\boldsymbol{\sigma}}} = \mathbb{I}\cosh\beta h + \frac{\sinh\beta h}{h}\boldsymbol{h}\cdot\hat{\boldsymbol{\sigma}}$$

$$Z = \operatorname{Tr}\left(\mathbb{I}\cosh\beta h + \frac{\sinh\beta h}{h}\boldsymbol{h}\cdot\hat{\boldsymbol{\sigma}}\right) = 2\cosh\beta h$$

$$\hat{\rho} = \frac{\mathbb{I}\cosh\beta h + \frac{\sinh\beta h}{h}\boldsymbol{h}\cdot\hat{\boldsymbol{\sigma}}}{2\cosh\beta h} = \frac{1}{2}\mathbb{I} + \frac{1}{2h}\boldsymbol{h}\cdot\hat{\boldsymbol{\sigma}}\tanh\beta h = \frac{1}{2}\begin{pmatrix} 1+\frac{h_z}{h}\tanh\beta h & \frac{h_x-ih_y}{h}\tanh\beta h \\ \frac{h_x+ih_y}{h}\tanh\beta h & 1+\frac{h_z}{h}\tanh\beta h \end{pmatrix}$$

$$\langle\hat{\sigma}_\alpha\rangle = \operatorname{Tr}(\hat{\rho}\sigma_\alpha) = \frac{1}{2}\operatorname{Tr}\left(\hat{\sigma}_\alpha + \frac{h_\alpha\tanh\beta h}{h}\mathbb{I}\right) = \frac{h_\alpha}{h}\tanh\beta h$$

$$\langle\hat{\sigma}_x\rangle = \frac{h_x}{h}\tanh\beta h, \quad \langle\hat{\sigma}_y\rangle = \frac{h_y}{h}\tanh\beta h, \quad \langle\hat{\sigma}_z\rangle = \frac{h_z}{h}\tanh\beta h$$

Solution..

Вероятность состояний определяется распределением Гиббса, т.е. матрицу плотности можно найти так:

$$\hat{\rho} = \frac{1}{Z}e^{-\beta\hat{H}}, \quad Z = \operatorname{Tr}\left(e^{-\hat{H}/T}\right) = \sum_n e^{-E_n/T}$$

$$E_{1,2} = \pm\sqrt{h_1^2+h_2^2+h_3^2}$$

$$Z = e^{\sqrt{h_1^2+h_2^2+h_3^2}/T} + e^{-\sqrt{h_1^2+h_2^2+h_3^2}/T}$$

$$\begin{aligned} e^{-\hat{H}/T} = e^{i\boldsymbol{h}\cdot\hat{\boldsymbol{\sigma}}/iT} &= I\cos(i\cdot(-1/T)) + i(\boldsymbol{h}\cdot\vec{\sigma})\sin(i\cdot(-1/T)) = I\,\mathrm{ch}(-1/T) - (\boldsymbol{h}\cdot\vec{\sigma})\,\mathrm{sh}(-1/T) = \\ &= \begin{pmatrix} \mathrm{ch}(-1/T) & 0 \\ 0 & \mathrm{ch}(-1/T) \end{pmatrix} - \mathrm{sh}(-1/T)\begin{pmatrix} h_3 & h_1 - ih_2 \\ h_1 + ih_2 & h_3 \end{pmatrix} = \\ &= \begin{pmatrix} -\mathrm{sh}(-1/T)h_3 + \mathrm{ch}(-1/T) & -\mathrm{sh}(-1/T)(h_1 - ih_2) \\ -\mathrm{sh}(-1/T)(h_1 + ih_2) & -\mathrm{sh}(-1/T)h_3 + \mathrm{ch}(-1/T) \end{pmatrix} \end{aligned}$$

Теперь можем считать среднее по $\langle\hat{\sigma}_i\rangle = \mathrm{Tr}\,(\hat{\rho}\hat{\sigma}_i)$:

$$\begin{aligned} \langle\hat{\sigma}_x\rangle &= \frac{1}{Z}\,\mathrm{Tr}\begin{pmatrix} -\mathrm{sh}(-1/T)(h_1 - ih_2) & -\mathrm{sh}(-1/T)h_3 + \mathrm{ch}(-1/T) \\ -\mathrm{sh}(-1/T)h_3 + \mathrm{ch}(-1/T) & -\mathrm{sh}(-1/T)(h_1 + ih_2) \end{pmatrix} = \frac{-2\,\mathrm{sh}(-1/T)h_1}{Z}, \\ \langle\hat{\sigma}_y\rangle &= \frac{i}{Z}\,\mathrm{Tr}\begin{pmatrix} -\mathrm{sh}(-1/T)(h_1 - ih_2) & \mathrm{sh}(-1/T)h_3 - \mathrm{ch}(-1/T) \\ -\mathrm{sh}(-1/T)h_3 + \mathrm{ch}(-1/T) & \mathrm{sh}(-1/T)(h_1 + ih_2) \end{pmatrix} = \frac{2i\,\mathrm{sh}(-1/T)h_2}{Z}, \\ \langle\hat{\sigma}_z\rangle &= \frac{1}{Z}\,\mathrm{Tr}\begin{pmatrix} -\mathrm{sh}(-1/T)h_3 + \mathrm{ch}(-1/T) & \mathrm{sh}(-1/T)(h_1 - ih_2) \\ -\mathrm{sh}(-1/T)(h_1 + ih_2) & \mathrm{sh}(-1/T)h_3 - \mathrm{ch}(-1/T) \end{pmatrix} = 0. \end{aligned}$$

ВШЭ-2024.кр.4а Матрица плотности спина после измерения

Спин-1/2 приготовлен в состоянии $\frac{1}{\sqrt{3}}|\uparrow\rangle + \frac{1+i}{\sqrt{3}}|\downarrow\rangle$. Измеряется проекция спина на ось y. Какие значения могут получиться и с какой вероятностью? Найдите матрицу плотности спина после измерения в базисе $|\uparrow\rangle, |\downarrow\rangle$.

Solution.

В общем случае можно получить формулу для проектора вдоль произвольного направления (в качестве упражнения проделайте, исходя из того, что $|n_\uparrow\rangle = \left(\cos\frac{\theta}{2}e^{-i\varphi/2}\sin\frac{\theta}{2}e^{i\varphi/2}\right)$ и $|n_\downarrow\rangle = \left(-\sin\frac{\theta}{2}e^{-i\varphi/2}\cos\frac{\theta}{2}e^{i\varphi/2}\right)$)

$$\mathbb{P}_n = \begin{pmatrix} \frac{1+n_z}{2} & \frac{n_x - in_p}{2} \\ \frac{n_z + in_y}{2} & \frac{1-n_z}{2} \end{pmatrix},$$

где (n_x, n_y, n_z) являются компонентами вектора Блоха. По условию задачи мы проводим измерения вдоль оси y, т.е. в таком случае вектор Блоха $(0, 1, 0)$ направлен вдоль оси y. Тогда проекторы "вверх"и "вниз"

$$\begin{aligned} \mathbb{P}_{y\downarrow} &= \begin{pmatrix} \frac{1}{2} & -\frac{i}{2} \\ \frac{i}{2} & \frac{1}{2} \end{pmatrix}, \\ \mathbb{P}_{y\downarrow} &= \begin{pmatrix} \frac{1}{2} & \frac{i}{2} \\ -\frac{i}{2} & \frac{1}{2} \end{pmatrix}. \end{aligned}$$

Также нам по условию дан спин- 1/2, которому будет соответствовать следующая матрица плотности

$$\rho_i = \frac{1}{3}\begin{pmatrix} 1 & 1-i \\ 1+i & 2 \end{pmatrix}.$$

Матрца плотности после измерения будет классической смесью двух проекций вдоль двух возможный состояний

$$\begin{aligned} \rho_f &= \mathbb{P}_{y\uparrow}\rho_i\mathbb{P}_{y\dagger} + \mathbb{P}_{y\downarrow}\rho_i\mathbb{P}_{y\downarrow} \\ &= \frac{1}{12}\begin{pmatrix} 1 & i \\ -i & 1 \end{pmatrix} + \frac{5}{12}\begin{pmatrix} 1 & -i \\ i & 1 \end{pmatrix} \\ &= \begin{pmatrix} \frac{1}{2} & -\frac{i}{3} \\ \frac{i}{3} & \frac{1}{2} \end{pmatrix} \end{aligned}$$

Вероятность найти спин вдоль оси (или против оси) определяется квадратом скалярного произведения волновых векторов $|\langle y\uparrow|\psi_0\rangle|^2$ (или $|\langle y\downarrow|\psi_0\rangle|^2$), что может быть выражено на языке проектора как

$$\{\text{ вероятность }\} = \langle\psi_0|\,\mathbb{P}_n\,|\psi_0\rangle\,.$$

$$\{\text{ вероятность "вверх" }\} = \langle\psi_0|\,\mathbb{P}_{y\dagger}\,|\psi_0\rangle = \frac{1}{6}$$

$$\{\text{ вероятность "вниз" }\} = \langle\psi_0|\,\mathbb{P}_{y\downarrow}\,|\psi_0\rangle = \frac{5}{6}$$

ВШЭ-2024.кр.4б Матрица плотности спина после измерения

Спин-1/2 приготовили в состоянии вспин вверх». После этого произвели измерение его y-компоненты, затем x-, а затем z-комноненты. Какова матрица плотности спина в конечном состоянии?

Solution.

(сделать по аналогии с прошлой)

ВШЭ-2024.кр.3. Кубит с флуктуирующим напряжением от детектора

В зарядовом кубите (двхуровневой квантовой системе) расстояние межцу уровнями $|0\rangle$ и $|1\rangle$, равное QV_0, определяется поданным затворным напряжением ным напряжением V_0 (коэффициент Q задаётся ёмкостными параметрами кубита). Запишите гамильтониан кубита в базисе $|0\rangle, |1\rangle$.

Дтя измерения состояния кубита к нему подсоединяют квантовый детектор, создающий в процессе работы флуктуирующее напряжение δV, со спектром $\left\langle \delta V_\omega^2 \right\rangle = A\theta(\omega)/\left(\Gamma^2 + \omega^2\right)$. Из-за неидеальности детектора при этом создаётся небольшой матричный элемент перехода между уровнями, равный $q\delta$ V. Найдите зависимость от времени вероятности обнаружить кубит в возбуждённом состоянии $|1\rangle$, если в начальный момент она равна 1.

Solution.

(черт его знает, как эту решать, вроде выше есть похожая задача)

ПТФ-2.з3.* Квантовый парадокс Зенона (30 б).

Рассмотрите двухуровневую систему, описываемую следующим гамильтонианом:

$$\hat{H} = \begin{pmatrix} E_0 & -\Delta \\ -\Delta & E_0 \end{pmatrix}$$

В начальный момент система приготовлена в состоянии $|\psi(0)\rangle = |\uparrow\rangle$. Если бы мы позволили системе эволюционировать самой по себе, то она бы совершала осцилляции Раби; в частности, через время $T = \frac{\pi\hbar}{2\Delta}$ мы бы обнаружили её в состоянии $|\downarrow\rangle$ с вероятностью $P_\downarrow(T) = 1$. Однако теперь вместо этого через каждый промежуток времени $\tau \ll T$ мы проводим измерение наблюдаемой $\hat{\sigma}^z$. Определите вероятность $P_\downarrow(T)$ в таком случае.

Solution.

(??? что делаем???)

$$|\psi(0)\rangle = |\uparrow\rangle$$

$$\hat{\rho}(0) = |\psi(0)\rangle\langle\psi(0)| = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$$

$$\hat{U}(t) = \exp\left(-\frac{i\hat{H}t}{\hbar}\right) = \exp\left(\frac{it}{\hbar}(\Delta\hat{\sigma}_x - E_0\hat{\mathbb{I}})\right) = \exp\left(\frac{it}{\hbar}\Delta\hat{\sigma}_x\right)\exp\left(-\frac{it}{\hbar}E_0\right)$$

$\exp\left(\frac{it}{\hbar}\Delta\hat{\sigma}_x\right) = \hat{\mathbb{I}}\cos\frac{\Delta t}{\hbar} + i\hat{\sigma}_x\sin\frac{\Delta t}{\hbar}$

$$\hat{U}(t) = \begin{pmatrix} \cos\frac{\Delta t}{\hbar} & i\sin\frac{\Delta t}{\hbar} \\ i\sin\frac{\Delta t}{\hbar} & \cos\frac{\Delta t}{\hbar} \end{pmatrix}\exp\left(-\frac{it}{\hbar}E_0\right)$$

Теперь можем записать состояние в любое время:

$$|\psi(t)\rangle = \hat{U}(t)|\psi(0)\rangle, \quad \langle\psi(t)| = \langle\psi(0)|\hat{U}^\dagger(t)$$

$$\hat{\rho}(t) = \hat{U}(t)|\psi(0)\rangle\langle\psi(0)|\hat{U}^\dagger(t) = \hat{U}(t)\hat{\rho}(0)\hat{U}^\dagger(t) =$$
$$= \begin{pmatrix} \cos\frac{\Delta t}{\hbar} & i\sin\frac{\Delta t}{\hbar} \\ i\sin\frac{\Delta t}{\hbar} & \cos\frac{\Delta t}{\hbar} \end{pmatrix}\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}\begin{pmatrix} \cos\frac{\Delta t}{\hbar} & -i\sin\frac{\Delta t}{\hbar} \\ -i\sin\frac{\Delta t}{\hbar} & \cos\frac{\Delta t}{\hbar} \end{pmatrix} = \begin{pmatrix} \cos^2\frac{\Delta t}{\hbar} & -\frac{i}{2}\sin\frac{2\Delta t}{\hbar} \\ \frac{i}{2}\sin\frac{2\Delta t}{\hbar} & \sin^2\frac{\Delta t}{\hbar} \end{pmatrix}$$

После измерения происходит редукция фон-Неймана, приводящая к дефазировке:

$$\hat{\rho}(\tau) = \begin{pmatrix} \cos^2 \frac{\Delta\tau}{\hbar} & 0 \\ 0 & \sin^2 \frac{\Delta\tau}{\hbar} \end{pmatrix}$$

Вероятность направлений спина после 1 измерения:

$$P_\uparrow(\tau) = \rho_{11} = \cos^2 \frac{\Delta\tau}{\hbar}, \quad P_\downarrow(\tau) = \rho_{22} = \sin^2 \frac{\Delta\tau}{\hbar}$$

Те же вероятности были получены в разделе 1.4 без матрицы плотности. Найдём марицу плотности $\hat{\rho}(n\tau)$ через $\hat{\rho}((n-1)\tau)$.

$$\hat{U}(\tau)\hat{\rho}((n-1)\tau)\hat{U}^\dagger(\tau) = \begin{pmatrix} \cos \frac{\Delta t}{\hbar} & i \sin \frac{\Delta t}{\hbar} \\ i \sin \frac{\Delta t}{\hbar} & \cos \frac{\Delta t}{\hbar} \end{pmatrix} \begin{pmatrix} P_\uparrow((n-1)\tau) & 0 \\ 0 & P_\downarrow((n-1)\tau) \end{pmatrix} \begin{pmatrix} \cos \frac{\Delta t}{\hbar} & -i \sin \frac{\Delta t}{\hbar} \\ -i \sin \frac{\Delta t}{\hbar} & \cos \frac{\Delta t}{\hbar} \end{pmatrix} =$$
$$= \begin{pmatrix} P_\uparrow((n-1)\tau) \cos^2 \frac{\Delta t}{\hbar} + P_\downarrow((n-1)\tau) \sin^2 \frac{\Delta t}{\hbar} & -\frac{i}{2}(P_\uparrow((n-1)\tau) - P_\downarrow((n-1)\tau)) \sin \frac{2\Delta t}{\hbar} \\ \frac{i}{2}(P_\uparrow((n-1)\tau) - P_\downarrow((n-1)\tau)) \sin \frac{2\Delta t}{\hbar} & P_\uparrow((n-1)\tau) \sin^2 \frac{\Delta t}{\hbar} + P_\downarrow((n-1)\tau) \cos^2 \frac{\Delta t}{\hbar} \end{pmatrix}$$

После дефазировки:

$$\hat{\rho}(n\tau) = \begin{pmatrix} P_\uparrow((n-1)\tau) \cos^2 \frac{\Delta t}{\hbar} + P_\downarrow((n-1)\tau) \sin^2 \frac{\Delta t}{\hbar} & 0 \\ 0 & P_\uparrow((n-1)\tau) \sin^2 \frac{\Delta t}{\hbar} + P_\downarrow((n-1)\tau) \cos^2 \frac{\Delta t}{\hbar} \end{pmatrix}$$

Вероятность направлений спина после n измерений:

$$P_\uparrow(n\tau) = P_\downarrow((n-1)\tau) \sin^2 \frac{\Delta\tau}{\hbar} + P_\uparrow((n-1)\tau) \cos^2 \frac{\Delta\tau}{\hbar}$$

$$P_\downarrow(n\tau) = P_\downarrow((n-1)\tau) \cos^2 \frac{\Delta\tau}{\hbar} + P_\uparrow((n-1)\tau) \sin^2 \frac{\Delta\tau}{\hbar}$$

Таким образом, нужно решить векторное рекуррентное уравнение (или, что эквивалентно, систему уравнений):

$$\begin{pmatrix} P_\uparrow(n\tau) \\ P_\downarrow(n\tau) \end{pmatrix} = \begin{pmatrix} \cos^2 \frac{\Delta\tau}{\hbar} & \sin^2 \frac{\Delta\tau}{\hbar} \\ \sin^2 \frac{\Delta\tau}{\hbar} & \cos^2 \frac{\Delta\tau}{\hbar} \end{pmatrix} \begin{pmatrix} P_\uparrow((n-1)\tau) \\ P_\downarrow((n-1)\tau) \end{pmatrix}, \quad \begin{pmatrix} P_\uparrow(0) \\ P_\downarrow(0) \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

Решение этого уравнения:

$$\begin{pmatrix} P_\uparrow(n\tau) \\ P_\downarrow(n\tau) \end{pmatrix} = \begin{pmatrix} \cos^2 \frac{\Delta\tau}{\hbar} & \sin^2 \frac{\Delta\tau}{\hbar} \\ \sin^2 \frac{\Delta\tau}{\hbar} & \cos^2 \frac{\Delta\tau}{\hbar} \end{pmatrix}^n \begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

Диагонализуем матрицу:

$$\begin{pmatrix} \cos^2 \frac{\Delta\tau}{\hbar} & \sin^2 \frac{\Delta\tau}{\hbar} \\ \sin^2 \frac{\Delta\tau}{\hbar} & \cos^2 \frac{\Delta\tau}{\hbar} \end{pmatrix} = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & \cos \frac{2\Delta\tau}{\hbar} \end{pmatrix} \frac{1}{2} \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}$$

$$\begin{pmatrix} \cos^2 \frac{\Delta\tau}{\hbar} & \sin^2 \frac{\Delta\tau}{\hbar} \\ \sin^2 \frac{\Delta\tau}{\hbar} & \cos^2 \frac{\Delta\tau}{\hbar} \end{pmatrix}^n = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & \cos^n \frac{2\Delta\tau}{\hbar} \end{pmatrix} \frac{1}{2} \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix} = \frac{1}{2} \begin{pmatrix} 1 + \cos^n \frac{2\Delta\tau}{\hbar} & 1 - \cos^n \frac{2\Delta\tau}{\hbar} \\ 1 - \cos^n \frac{2\Delta\tau}{\hbar} & 1 + \cos^n \frac{2\Delta\tau}{\hbar} \end{pmatrix}$$

$$\begin{pmatrix} P_\uparrow(n\tau) \\ P_\downarrow(n\tau) \end{pmatrix} = \frac{1}{2} \begin{pmatrix} 1 + \cos^n \frac{2\Delta\tau}{\hbar} & 1 - \cos^n \frac{2\Delta\tau}{\hbar} \\ 1 - \cos^n \frac{2\Delta\tau}{\hbar} & 1 + \cos^n \frac{2\Delta\tau}{\hbar} \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \frac{1}{2} \begin{pmatrix} 1 + \cos^n \frac{2\Delta\tau}{\hbar} \\ 1 - \cos^n \frac{2\Delta\tau}{\hbar} \end{pmatrix}$$

Учитывая, что $T = n\tau$, получим

$$P_\downarrow(T) = \frac{1}{2} \left(1 - \cos^{\frac{T}{\tau}} \frac{2\Delta\tau}{\hbar} \right)$$

По формуле Тейлора до 2 порядка:

$$P_\downarrow(T) = \frac{\Delta^2}{\hbar^2} T\tau$$

Выводы и применения парадокса (???)

(пока не знаю.)

ПТФ-2.з4.* Флуктуации магнитного поля и спин (30 б).

Спин-1/2 находится в магнитном поле, направленном вдоль оси z:

$$\hat{H} = -B\hat{\sigma}^z$$

В результате взаимодействия с окружающей средой, магнитное поле испытывает случайные флуктуации: $B \equiv B_0 + \delta B(t)$, которые мы предполагаем гауссовыми с нулевым средним и $\langle \delta B(t)\delta B(t')\rangle = \Gamma\delta(t-t')$. Пусть в начальный момент времени, матрица плотности была самого общего вида:

$$\hat{\rho}(0) = \begin{pmatrix} \rho_{11} & \rho_{12} \\ \rho_{21} & \rho_{22} \end{pmatrix}$$

Определите зависимость усреднённой по таким флуктуациям матрицы плотности от времени $\langle\hat{\rho}(t)\rangle$.

Указание: для средних типа $\langle \exp\left(i\int\limits_{t_1}^{t_2}\delta B(t)dt\right)\rangle$ есть следующие два способа:

• Воспользоваться теоремой Вика, из которой следует, что для любой гауссовой величины с нулевым средним выполнено $\langle e^A\rangle = e^{\frac{1}{2}\langle A^2\rangle}$.

• Дискретизовать время, разбив на маленькие участки $t \in (n\delta t, (n+1)\delta t)$ и предположив $\delta B_n = \text{const}$; тогда такой локальный по времени коррелятор эквивалентен $\langle \delta B_n \delta B_m\rangle = \delta_{nm}\frac{\Gamma}{\delta t}$. В результате вы получите дискретное Гауссово распределение, с которым вы уже умеете работать.

Solution.

Уравнение Гейзенберга для эволюции матрицы плотности $\hat{\rho}(t)$:

$$\frac{\partial\hat{\rho}(t)}{\partial t} = \frac{i}{\hbar}[\hat{\rho}(t), \hat{H}(t)] = -\frac{iB(t)}{\hbar}[\hat{\rho}(t), \hat{\sigma}^z]$$

$$[\hat{\rho}(t),\hat{\sigma}^z] = \left[\begin{pmatrix}\rho_{11}(t) & \rho_{12}(t)\\ \rho_{21}(t) & \rho_{22}(t)\end{pmatrix}, \begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\right] = \begin{pmatrix}\rho_{11}(t) & -\rho_{12}(t)\\ \rho_{21}(t) & -\rho_{22}(t)\end{pmatrix} - \begin{pmatrix}\rho_{11}(t) & \rho_{12}(t)\\ -\rho_{21}(t) & -\rho_{22}(t)\end{pmatrix} = \begin{pmatrix}0 & 2\rho_{12}(t)\\ -2\rho_{21}(t) & 0\end{pmatrix}$$

$$\frac{\partial\hat{\rho}(t)}{\partial t} = \frac{iB(t)}{\hbar}\begin{pmatrix}0 & 2\rho_{12}(t)\\ -2\rho_{21}(t) & 0\end{pmatrix}$$

$$\hat{\rho}(t) = \begin{pmatrix} \hat{\rho}_{11}(t_0) & \hat{\rho}_{12}(t_0)\exp\left(\frac{2i}{\hbar}\int\limits_{t_0}^{t}B(t')dt'\right)\\ \hat{\rho}_{21}(t_0)\exp\left(-\frac{2i}{\hbar}\int\limits_{t_0}^{t}B(t')dt'\right) & \hat{\rho}_{22}(t_0)\end{pmatrix} =$$

$$= \begin{pmatrix} \hat{\rho}_{11}(t_0) & \hat{\rho}_{12}(t_0)\exp\left(\frac{2i}{\hbar}B_0(t-t_0)\right)\exp\left(\frac{2i}{\hbar}\int\limits_{t_0}^{t}\delta B(t')dt'\right)\\ \hat{\rho}_{21}(t_0)\exp\left(-\frac{2i}{\hbar}B_0(t-t_0)\right)\exp\left(-\frac{2i}{\hbar}\int\limits_{t_0}^{t}\delta B(t')dt'\right) & \hat{\rho}_{22}(t_0)\end{pmatrix}$$

Теперь усредним матрицу плотности $\hat{\rho}$ по случайным флуктуациям с помощью теоремы Вика:

$$\left\langle \exp\left(\frac{2i}{\hbar}\int\limits_{t_0}^{t}\delta B(t')dt'\right)\right\rangle = \exp\left(-\frac{2}{\hbar^2}\left\langle\left(\int\limits_{t_0}^{t}\delta B(t')dt'\right)^2\right\rangle\right) =$$

$$= \exp\left(-\frac{2}{\hbar^2}\left\langle\int\limits_{t_0}^{t}\delta B(t')dt'\int\limits_{t_0}^{t}\delta B(t'')dt''\right\rangle\right) = \exp\left(-\frac{2}{\hbar^2}\int\limits_{t_0}^{t}\int\limits_{t_0}^{t}\langle\delta B(t')\delta B(t'')\rangle dt'dt''\right) =$$

$$= \exp\left(-\frac{2}{\hbar^2}\int\limits_{t_0}^{t}\int\limits_{t_0}^{t}\Gamma\delta(t'-t'')dt'dt''\right) = \exp\left(-\frac{2\Gamma}{\hbar^2}\int\limits_{t_0}^{t}dt''\right) = \exp\left(-\frac{2\Gamma}{\hbar^2}(t-t_0)\right)$$

$$\langle\hat{\rho}(t)\rangle = \begin{pmatrix}\hat{\rho}_{11}(t_0) & \hat{\rho}_{12}(t_0)\exp\left(\frac{2(iB_0\hbar-\Gamma)}{\hbar^2}(t-t_0)\right)\\ \hat{\rho}_{21}(t_0)\exp\left(-\frac{2(iB_0\hbar-\Gamma)}{\hbar^2}(t-t_0)\right) & \hat{\rho}_{22}(t_0)\end{pmatrix}$$

Теперь сделаем усреднение другим способом, дискретизуем время:

$$\left\langle \exp\left(\frac{2i}{\hbar}\int\limits_{t_0}^{t}\delta B(t')dt'\right)\right\rangle = \left\langle \exp\left(\frac{2i}{\hbar}\sum_{n=1}^{N}\delta B_n\delta t\right)\right\rangle = \left\langle \prod_{n=1}^{N}\exp\left(\frac{2i\delta t}{\hbar}\delta B_n\right)\right\rangle$$

где $N = \frac{t-t_0}{\delta t}$. Разложим каждую экспоненту по формуле Тейлора до 1 порядка:

$$\exp\left(\frac{2i\delta t}{\hbar}\delta B_n\right) = 1 + \frac{2i\delta t}{\hbar}\delta B_n - \frac{2(\delta t)^2}{\hbar^2}(\delta B_n)^2$$

Поскольку δB_n в каждой экспоненте независимы, то

$$\left\langle \prod_{n=1}^{N}\exp\left(\frac{2i\delta t}{\hbar}\delta B_n\right)\right\rangle = \prod_{n=1}^{N}\left\langle \exp\left(\frac{2i\delta t}{\hbar}\delta B_n\right)\right\rangle = \prod_{n=1}^{N}\left\langle 1 + \frac{2i\delta t}{\hbar}\delta B_n - \frac{2(\delta t)^2}{\hbar^2}(\delta B_n)^2\right\rangle =$$

$$= \prod_{n=1}^{N}\left(1 - \frac{2\delta t}{\hbar^2}\Gamma\right) = \prod_{n=1}^{N}\left(1 - \frac{2\Gamma(t-t_0)}{\hbar^2 N}\right)^N$$

Устремим число слагаемых в разбиении $N \to \infty$ и воспользуемся 2 замечательным пределом:

$$\left\langle \prod_{n=1}^{N}\exp\left(\frac{2i\delta t}{\hbar}\delta B_n\right)\right\rangle = \exp\left(-\frac{2\Gamma}{\hbar^2}(t-t_0)\right)$$

Таким образом, получаем тот же ответ:

$$\langle\hat\rho(t)\rangle = \begin{pmatrix} \hat\rho_{11}(t_0) & \hat\rho_{12}(t_0)\exp\left(\frac{2(iB_0\hbar-\Gamma)}{\hbar^2}(t-t_0)\right) \\ \hat\rho_{21}(t_0)\exp\left(-\frac{2(iB_0\hbar-\Gamma)}{\hbar^2}(t-t_0)\right) & \hat\rho_{22}(t_0)\end{pmatrix}$$

(??? допишу потом, качественно в чем наш результат, который мы получили???)

Моя давняя попытка решения (??)

(??????!!)
если $\hat H = -B\cdot\hat\sigma^z$, где B - магнитное поле, которое флуктуирует так, что $\langle\delta B(t)\delta B\,(t')\rangle = \Gamma\delta\,(t-t')$,
Посмотрим, как будет меняться система с

$$\hat\rho(0) = \begin{pmatrix} \rho_{11} & \rho_{12} \\ \rho_{21} & \rho_{22}\end{pmatrix}.$$

$$\hat H(t) = -B(t)\cdot\hat\sigma^z = -(B_0+\delta B(t))\hat\sigma^z$$

$$\hat\rho(0) = \begin{pmatrix} -\operatorname{sh}(-1/T)(B_0+\delta B(t)) + \operatorname{ch}(-1/T) & 0 \\ 0 & -\operatorname{sh}(-1/T)(B_0+\delta B(t)) + \operatorname{ch}(-1/T)\end{pmatrix}$$

и дальше я не знаю, что делать.
если отталкиваться от распределения Гиббса, то можно прийти к тому, что подсказывается в задаче.

$$\langle\hat\rho(t)\rangle = \langle e^{-\hat{H(t)}/T}\rangle = \langle e^{i(B_0+\int_{t_1}^{t_2}\delta B(t)dt)\hat\sigma^z)/iT}\rangle = \hat\rho(0)\langle e^{\int_{t_1}^{t_2}\delta B(t)dt\hat\sigma^z/(iT)}\rangle$$

Для подсчета этого воспользуемся следствием теоремы Вика $\langle e^A\rangle = e^{\frac12\langle A^2\rangle}$
Поэтому

$$\langle\hat\rho(t)\rangle = \hat\rho(0)e^{\int_{t_1}^{t_2}\langle\delta B(t)^2\rangle dt\hat\sigma^z/(2iT)} = \hat\rho(0)e^{i\int_{t_1}^{t_2}\Gamma dt\hat\sigma^z/(2iT)} = \hat\rho(0)e^{\Gamma\Delta t/(2T)}$$

(?????? потом подумаю.)

17.2.2 Problems about stationary states in potentials 1

1D колодец (?)

Определить волновую функцию в $U(x) = \begin{cases} -U_0, & |x| < a \\ 0, & |x| > a \end{cases}$

Solution.

Волновую функцию находим, решая уравнение Шредингера в двух областях, энергию находим с помощью k, который квантуется из вида волновой функции и граничных условий.

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2} + U(x)\psi = E\psi$$

(???)

$$E_n = \frac{\pi^2\hbar^2}{2ma^2}n^2, \quad n = 1, 2, 3, ...$$

Условие на стационарные состояния можно написать как сравнение характеристик ямы и частицы: (почему?)

$$U_0 a^2 > \frac{\pi^2\hbar^2}{8m}$$

2D циллиндрический колодец

Найти уровни энергии для частицы массы M в двумерном $U(\boldsymbol{r}) = \begin{cases} -U_0, & r < a \\ 0, & r > a \end{cases}$. Рассмотрите предел мелкой ямы.

Solution.

Решаем через функции Бесселя, далее за счет сшивки находим энергию. Для мелкой ямы раскладываем спецфункции до 1-го и следующего порядка и подставляем в условие сшивки.

Запишем уравнение Шрёдингера в цилиндрических координатах $\psi(r, \varphi)$:

$$-\frac{\hbar^2}{2M}\left(\frac{\partial^2\psi}{\partial r^2} + \frac{1}{r}\frac{\partial\psi}{\partial r} + \frac{1}{r^2}\frac{\partial^2\psi}{\partial\varphi^2}\right) + U(r)\psi(r) = E\psi(r)$$

Введём $\varkappa$: $\frac{\hbar^2\varkappa^2}{2M} = -E = |E|$. Подставим $\psi(r, \varphi) = \psi(r)e^{im\varphi}$, получим:

$$\psi''(r) + \frac{1}{r}\psi'(r) - \left(\frac{2MU(r)}{\hbar^2} + \varkappa^2 + \frac{m^2}{r^2}\right)\psi(r) = 0$$

• Вне ямы $U(r) = 0$, введем координату $z = \varkappa r$, получим уравнение:

$$\psi''(z) + \frac{1}{z}\psi'(z) - \left(1 + \frac{m^2}{z^2}\right)\psi(z) = 0.$$

В общем случае двумя линейно-независимыми решениями этого уравнения являются модифицированные функции Бесселя:

$$\psi(z) = A_1 I_m(z) + A_2 K_m(z)$$

Для нашей задачи поиска связанных состояний коэффициент $A_1 \equiv 0$, поскольку волновая функция должна затухать на бесконечности. Значит

$$\psi(r > a) = AK_m(\varkappa r).$$

• Вне ямы $U(r) = U_0$, введём эффективный волновой вектор $k^2 = \frac{2M(U_0 - |E|)}{\hbar^2} = \frac{2MU_0}{\hbar^2} - \varkappa^2$ и сделаем подстановку подстановку $z = kr$. Получаем похожее уравнение, отличающееся лишь знаком единицы (эквивалентно, эти уравнения связаны заменой $z \mapsto iz$):

$$\psi''(z) + \frac{1}{z}\psi'(z) + \left(1 - \frac{m^2}{z^2}\right)\psi(z) = 0$$

В качестве его линейно-независимых решений, как правило, выбирают либо функции Бесселя и Неймана, либо функции Ганкеля:

$$\psi(z) = B_1 J_m(z) + B_2 Y_m(z) = C_1 H_m^{(1)}(z) + C_2 H_m^{(2)}(z)$$

Нас интересует решение, которое в нуле регулярно, поэтому естественный выбор - это функция Бесселя $\psi(x < a) = BJ_m(kr)$.

Для уровней энергии запишем сшивку логарифмической производной $\frac{d}{dz}\ln\psi(a-0) = \frac{d}{dz}\ln\psi(a+0)$:

$$\frac{kaJ'_m(ka)}{J_m(ka)} = \frac{\varkappa a K'_m(\varkappa a)}{K_m(\varkappa a)}$$

Аналитически это уравнение можно решить лишь в разных предельных случаях.

Предел мелкой ямы

Решим это уравнение аналитически в пределе мелкой ямы: $U_0 \ll \frac{\hbar^2}{Ma^2}$. Этот предел соответствует малым $ka \approx \sqrt{\frac{U_0}{\hbar^2/2Ma^2}} \ll 1$ и $\varkappa a = \sqrt{\frac{|E|}{\hbar^2/2Ma^2}} \ll 1$, и мы можем воспользоваться асимптотиками специальных функций.

Основное состояние из общих соображений минимальности энергии должно соответствовать нулевому орбитальному квантовому числу $m = 0$. Чтобы производная не занулилась, нужен следующий член разложения: $J_0(z)|_{z\ll 1} \approx 1 - \frac{z^2}{4}$. Получаем уравнение на сшивку:

$$ka \cdot \left(-\frac{ka}{2}\right) = \frac{\varkappa a\left(-\frac{1}{xa}\right)}{\ln\frac{2e^{-\gamma}}{xa}}$$

получим соотношение

$$\varkappa a = 2e^{-\gamma}\exp\left(-\frac{2}{k^2a^2}\right).$$

Найдем уровни энергии, подставив $\varkappa^2 = \frac{2M|E|}{\hbar^2}$ и принимая, что $k^2|_{|E|\ll 1} \approx \frac{2MU_0}{\hbar^2}$:

$$|E| = C\frac{\hbar^2}{Ma^2}\exp\left(-\frac{2\hbar^2/Ma^2}{U_0}\right),$$

где $C = 2e^{-2\gamma} \approx 0.630$.

Этот ответ в точности совпадает с общим ответом для мелкой ямы даваемый формулой: $|E| = \#\frac{\hbar^2}{Ma^2}\exp\left(-\frac{2\pi\hbar^2}{M}|\int U(\boldsymbol{r})d^2\boldsymbol{r}|^{-1}\right)$, где интеграл $\int U(\boldsymbol{r})d^2\boldsymbol{r} = -U_0\pi a^2$, таким образом, получаем:

$$|E| = \#\frac{\hbar^2}{Ma^2}\exp\left(-\frac{2\hbar^2/Ma^2}{U_0}\right).$$

Однако константу через нее не найти.

ПТФ-3.у2. Прямоугольная яма

Продемонстрируйте, что в случае, когда эта яма — мелкая, точное решение для прямоугольной ямы

$$U(x) = \begin{cases} -U_0, & -\frac{a}{2} \le x \le \frac{a}{2} \\ 0, & \text{otherwise} \end{cases}$$

совпадает с приближённой формулой для мелкой ямы.

Solution.

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2} = (E - U(x))\psi(x)$$

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2} = \begin{cases} E\psi(x), & x \in (-\infty, -\frac{a}{2}) \cup (\frac{a}{2}, \infty) \\ (E+U_0)\psi(x), & -\frac{a}{2} \le x \le \frac{a}{2} \end{cases}$$

$$-U_0 < E < 0$$
$$\kappa^2 := -\frac{2mE}{\hbar^2}, \qquad k^2 := \frac{2m(E+U_0)}{\hbar^2}$$

Поскольку потенциал $U(x)$ – чётная функция, то и гамильтониан $H(x) = \frac{p^2}{2m} + U(x)$ чётный и коммутирует с оператором инверсии. Собственные функции оператора инверсии – чётные и нечётные функции. Будем искать чётные $\psi(x)$. Из $\int\limits_{-\infty}^{\infty} |\psi(x)|^2 dx = 1$ следует, что

$$\psi(x) = \begin{cases} \psi_I(x) = Ae^{\kappa x}, & x < -\frac{a}{2} \\ \psi_{II}(x) = B\cos kx, & -\frac{a}{2} < x < \frac{a}{2} \\ \psi_{III}(x) = Ae^{-\kappa x}, & x > \frac{a}{2} \end{cases}$$

Запишем граничные условия (из чётности достаточно их записать в одной точке $x = \frac{a}{2}$):

$$\psi_{II}\left(\frac{a}{2}\right) = \psi_{III}\left(\frac{a}{2}\right), \quad \psi'_{II}\left(\frac{a}{2}\right) = \psi'_{III}\left(\frac{a}{2}\right)$$

$$Ae^{\frac{-\kappa a}{2}} = B\cos\frac{ka}{2}, \quad -\kappa Ae^{\frac{-\kappa a}{2}} = -\kappa B\sin\frac{ka}{2}$$

$$\tan\frac{ka}{2} = \frac{\kappa}{k} > 0$$

$$\tan\sqrt{\frac{m(E+U_0)}{2}}\frac{a}{\hbar} = \sqrt{-\frac{E}{E+U_0}}$$

В случае мелкой ямы:

$$U_0 \ll \frac{\hbar^2}{ma^2}, \quad |E| < U_0 \ll \frac{\hbar^2}{ma^2}$$

В случае нечётных функций $\tan\frac{ka}{2}$ получился бы отрицательным и условие мелкой ямы выполниться бы не могло. Поскольку $\sqrt{\frac{m(E+U_0)}{2}}\frac{a}{\hbar}$ мало, то и $\sqrt{-\frac{E}{E+U_0}}$ тоже, значит $E \ll U_0$

$$\sqrt{\frac{mU_0}{2}}\frac{a}{\hbar} = \sqrt{-\frac{E}{U_0}}$$

$$E = -\frac{ma^2U_0^2}{2\hbar^2}$$

$$|E_{\text{мелк яма}}| = \frac{m}{2\hbar^2}\left(\int\limits_{-\infty}^{\infty} U(x)dx\right)^2 = \frac{ma^2U_0^2}{2\hbar^2}$$

Формулы совпадают.

Б-2.2.2 1D цилиндрическая яма

Найти уровни энергии и собственные функции частицы в $U(x) = \begin{cases} -U_0, & |x| < a \\ 0, & |x| > a \end{cases}$, используя симметрию потенциала ($U(x) = U(-x)$).

Solution..

Используем оператор инверсии $\hat{I}$. Поскольку в координатном представлении

$$\hat{\mathrm{H}} = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + U(x), \qquad \text{а также } U(x) = U(-x),$$

получаем $[\hat{I}, \hat{\mathrm{H}}] = 0$. Таким образом, волновые функции невырожденного дискретного спектра данной задачи ($E < 0$) обладают определенной четностью

$$\begin{cases} \hat{\mathrm{H}}\psi_E(x) = E\psi_E(x), \\ \hat{I}'\psi_E(x) = \pm\psi_E(x), \end{cases}$$

и данная система уравнений будет заведомо совместна. Обозначая

$$\varkappa^2 = \frac{2m}{\hbar^2}|E|, \quad k^2 = k_0^2 - \varkappa^2, \quad k_0^2 = \frac{2mU_0}{\hbar^2},$$

получим уравнения для определения $\psi_E(x)$ при $|x| < a$:

$$\psi''(x) + k^2\psi_E(x) = 0$$

и при $|x| > a$:

$$\psi''(x) - x^2\psi(x) = 0.$$

Таким образом, для четных состояний получаем $\psi_E{}^{(+)}(x) = A\cos kx$ при $|x| < a$ и $\psi_E^{(+)(x)} = Be^{-x|x|}$ при $|x| > a$. Вследствие явного учета четности функции граничное условие достаточно поставить в одной из точек $x = \pm a$. Из условия непрерывности логарифмической производной $\frac{\psi_E'(a+0)}{\psi_E(a+a)} = \frac{\psi_E'(a-0)}{\psi_E(a-0)}$ получим

$$k\operatorname{tg} ka = \varkappa, \quad k^2 = k_0^2 - \varkappa^2, \text{ или } \left(\frac{k_0}{k}\right)^2 = 1 + \operatorname{tg}^2 ka.$$

На основании этого имеем

$$|\cos ka| = \frac{ka}{k_0 a}$$

при обязательном дополнительном условии $\operatorname{tg} ka > 0$, которое следует из (1). Уровни энергии определяются формулой $E_n = -\hbar^2\varkappa_n^2/(2m)$, где $n = 0, 1, 2, \ldots$ (рис. 2.1).

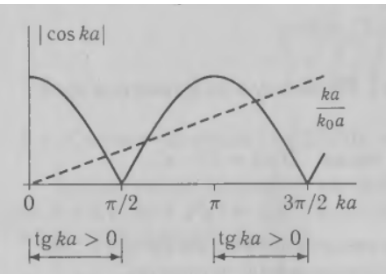


Рис. 2.1. Определение уровней энергии для четных состояний

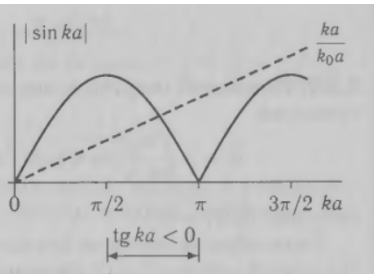

Рис. 2.2. Определение уровней энергии для нечетных состояний

Четное состояние существует при малой глубине U_0 ямы ($k_0 a > 0$). N четных состояний существует при $k_0 a \geqslant (N-1)\pi$. Из условия непрерывности функции

$$\psi(a-0) = \psi(a+0)$$

получаем $B = Ae^{\varkappa a}\cos ka$. Условие нормировки дает

$$1 = 2|A|^2\left(\int_0^a \cos^2 kx dx + \int_a^\infty \cos^2 kae^{-2x(x-a)}dx\right),$$

откуда в результате несложных вычислений имеем

$$A = \frac{1}{\sqrt{a}}\left(1 + \frac{\sin 2ka}{2ka} + \frac{\cos^2 ka}{\varkappa a}\right)^{-1/2}, \quad B = Ae^{\varkappa a}\cos ka.$$

Для нечетных состояний волновая функция должна иметь вид

$$\psi_E^{(-)}(x) = \begin{cases} A\sin kx, & |x| < a, \\ B\operatorname{sign}(x)e^{-x|x|}, & |x| > a. \end{cases}$$

Уровни энергии для нечетных состояний определяются из уравнения $k\operatorname{ctg} ka = -\varkappa$, $k^2 = k_0^2 - \varkappa^2$, Т. е. $\left(\frac{k_0}{k}\right)^2 = 1 + \operatorname{ctg}^2 ka$ или

$$|\sin ka| = \frac{ka}{k_0 a} \quad \text{при } \operatorname{tg} ka < 0.$$

Как видно из рис. 2.2, нечетные дискретные состояния существуют при условии $k_0 a \geqslant \pi/2, (ka/\,(k_0 a) = 1\,,$ когда $k_0 a = \pi/2)$, т. е.

$$U_0 \geqslant \frac{\pi^2}{8}\frac{\hbar^2}{ma^2}.$$

Это и есть условие существования хотя бы одного нечетного состояния в такой яме. N нечетных состояний существует при $k_0 a \geqslant \pi N/2$. Из непрерывности функции $\psi(a+0) = \psi(a-0)$ следует

$$B = Ae^{\varkappa a}\sin ka.$$

Учитываем условие нормировки нашей функции

$$1 = 2|A|^2\left(\int\limits_0^a \sin^2 kx dx + \sin^2 ka\int\limits_a^\infty e^{-2x(x-a)}dx\right)$$

и получаем итоговый результат:

$$A = \frac{1}{\sqrt{a}}\left(1 - \frac{\sin 2ka}{2ka} + \frac{\sin^2 ka}{\varkappa a}\right)^{-1/2}, \quad B = Ae^{\varkappa a}\sin ka.$$

ПТФ-3.2y Мелкая прямоугольная яма (???)

Рассмотрим задачу о частице в прямоугольной яме:

$$U(x) = \begin{cases} -U_0, & -\frac{a}{2} \leq x \leq \frac{a}{2} \\ 0, & \text{otherwise} \end{cases}$$

Продемонстрируйте, что в случае, когда эта яма - мелкая, точное решение совпадает с приближённой формулой для мелкой ямы.

Solution.

(!!! скоро решу, пока просто не особо про нее думал. по идее проблем с решением не должно быть.)

Б-2.2.3 Сила давления на стенку

Используя формулу Фейнмана-Хеллмана $\frac{\partial E_n}{\partial \lambda} = \langle n|\frac{\partial \hat{H}}{\partial \lambda}|n\rangle$, вычислить силу, с которой частица действует на стенку потенциального ящика.

Solution..

Основная идея в том, что мы считаем силу как производную энергии по расстоянию, поэтому формула Фейнмана-Хеллмана как раз сразу и дает ответ.

Сила, действующая на частицу со стороны потенциальной ямы, представляет собой оператор $\hat{\mathrm{F}} = -d\hat{U}/dx = -d\hat{\mathrm{H}}/dx$. Рассмотрим вначале яму конечной глубины U_0, имея в виду дальнейший предельный переход $U_0 \to \infty$. При этом

$$U(x) = U_0(\theta(x-a) + 1 - \theta(x)), \qquad \theta(x) = \begin{cases} 0, & x < 0, \\ 1, & x > 0. \end{cases}$$

Отсюда следует, что

$$\hat{\mathrm{F}} = -\frac{d\hat{\mathrm{U}}}{dx} = U_0(\delta(x) - \delta(x-a)).$$

Используя теорему Фейнмана-Гельмана, находим

$$\langle n|\hat{\mathrm{F}}_{\mathrm{пр}}|n\rangle = \langle n|\frac{\partial\hat{\mathrm{H}}}{\partial a}|n\rangle = \frac{\partial E_n}{\partial a} = -\frac{\pi^2\hbar^2}{ma^3}n^2 = -\frac{2E_n}{a}.$$

Мы нашли среднее значение силы, действующей на частицу со стороны правой стенки потенциального ящика. Сила, которая действует на стенку ящика со стороны частицы, имеет противоположный знак.

Б-2.2.4 Яма рядом со стенкой

Найти уровни энергии и собственные функции частицы в

$$U(x) = \begin{cases} \infty, & x < 0 \\ -U_0, & 0 < x < a \\ 0, & x > a \end{cases}$$

Указать условие существования по крайней мере одного дискретного уровня энергии в такой яме.

Solution..

Можно сразу написать ответ, вспомнив, что если бы не было бесконечной стенки, то были бы известные простые решения, а стенка только дает другую нормировку, потому что с ней другая область пространства свободна для частицы.

(решу заново, без отсылок, это запросто, просто не до нее пока что)

Получим решение задачи о состояниях дискретного спектра в данной потенциальной яме на основании анализа нечетных решений $\psi_E^{(-)}(x)$ задачи 2.2.2. Граничные условия, накладываемые на волновую функцию в точке $x = 0$ и на ψ и ψ' в точке $x = a$, совпадают с соответствующими граничными условиями для $\psi_E^{(-)}(x)$. Однако область, где волновая функция отлична от нуля, уменьшается вдвое. Поэтому $\psi_E^{(-)}(x)$ нужно умножить на $\sqrt{2}$. В итоге получим волновые функции в виде

$$\psi_E(x) = \begin{cases} \sqrt{2}\psi_E^{(-)}(x), & x > 0, \\ 0, & x \leqslant 0. \end{cases}$$

Б-2.2.5 Нахождение вне простой ямы

Пусть в потенциальной яме конечной высоты существует единственный уровень энергии с очень маленькой энергией связи: $|\varepsilon| \ll \hbar^2/\left(2ma^2\right)$ (т. е. $\varkappa := \sqrt{2m|\varepsilon|}/\hbar \ll 1$). Найти вероятность обнаружения частицы вне потенциальной ямы. Можно ли истолковать полученный результат на основе классической механики?

Solution..

Будем считать, что яма мелкая, и тогда, как это следует из анализа задачи о такой яме, в ней присутствует единственный дискретный уровень энергии, отвечающий четной волновой функции. Таким образом, $k_0 a \ll 1$, или $\frac{2mU_0}{\hbar^2}a^2 \ll 1$. Обозначим

$$U_0 = \frac{\hbar^2 k_0^2}{2m}, \quad |\varepsilon| = \frac{\hbar^2 \varkappa^2}{2m}, \quad k^2 = k_0^2 - \varkappa^2.$$

Также будем считать, что энергия связи мала по сравнению с глубиной ямы: $|\varepsilon| \ll U_0$, или $\varkappa \ll k_0$. Оказывается, что при этих предположениях также и $ka \ll 1$, и мы решаем приближенно (с учетом малости ka) трансцендентное уравнение для определения значений энергии:

$$(k_0 a)^2 \cos^2 ka = (ka)^2.$$

В результате имеем

$$\varkappa^2 \approx k_0^4 a^2 \equiv \varkappa_0^2.$$

Получается, что значение энергии связи $|\varepsilon| = |\varepsilon_0|$ гораздо меньше глубины ямы (как и ожидалось):

$$|\varepsilon_0| = \frac{\hbar^2 \varkappa_0^2}{2m} = U_0 \left(k_0 a\right)^2 \ll U_0.$$

Волновая функция в этом приближении имеет вид

$$\psi_0(x) \simeq \begin{cases} B_0 e^{-\varkappa_0 |x|}, & |x| > a, \\ A_0 \cos kx, & |x| \leqslant a, \end{cases}$$

причем $A_0 \simeq B_0 = A|_{ka \to 0} = \sqrt{\varkappa_0}$. Вероятность нахождения частицы в пределах ямы при этом

$$W \simeq \varkappa_0 \int\limits_{-a}^{a} \cos^2 kx dx \simeq 2\varkappa_0 a \ll 1,$$

и, как мы убеждаемся, с подавляющей вероятностью ($\simeq 1$) частица будет находиться вне пределов ямы, т. е. в классически недоступной области. Очевидно, что это существенно квантовое явление, и классическая интерпретация для него невозможна.

Кстати, при $a \to 0, U_0 \to \infty$, но при $U_0 a = \text{const}$, пределом данного потенциала является δ-яма, в которой также имеется всего одно четное состояние дискретного спектра:

$$U(x) = -\frac{h^2}{m}\varkappa_0\delta(x) = \lim_{a\to 0}\left[-\frac{\hbar^2\varkappa_0}{2ma}\theta(a-|x|)\right] = \lim_{a\to 0}\left[-U_0\theta(a-|x|)\right].$$

17.2.3 Problems about stationary states in potentials 2

Б-2.2.17 Показатель преломления света по квантовой механике (!??!?!??!)

На плоскость $z = 0$, разделяющую области пространства с потенциалами

$$U = \begin{cases} U_1, & z < 0 \\ U_2, & z > 0 \end{cases}$$

падает снизу волна де-Бройля, направление которой составляет угол θ_1 с осью z. Найти закон преломления и показатели преломления для обеих сред. Найти коэффициенты отражения и прохождения. При каких условиях будет наблюдаться полное внутреннее отражение? Каково при этом поведение волны во второй среде?

Solution.

(??? решу потом, пока не дошел ещё.)
Вначале введем обозначения

$$E - U_1 = \frac{\hbar^2 k^2}{2m} > 0, \quad E - U_2 = \frac{\hbar^2 q^2}{2m} > 0.$$

Таким образом, мы считаем величины k и q действительными.

В полупространстве $z < 0$ (область 1) волновая функция - решение уравнения Шредингера будет иметь вид

$$\psi_1(\mathbf{r}) = e^{i\mathbf{kr}} + Ae^{i\mathbf{k'r}},$$

где A - амплитуда отраженной волны, $\mathbf{k}$ и $\mathbf{k'}$ - волновые векторы падающей и отраженной волны. В полупространстве $z > 0$ (область 2) волновая функция описывает только прошедшую волну

$$\psi_2(\mathbf{r}) = Be^{i\mathbf{qr}}.$$

Здесь q - волновой вектор прошедшей волны. На плоскости $z = 0$ должны выполняться условия

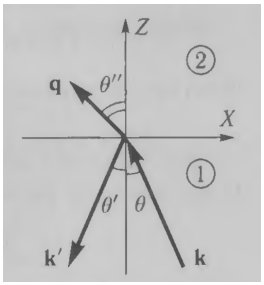
$$\begin{cases} \psi_1(x,y) = \psi_2(x,y), \\ \psi_1'(x,y) = \psi_2'(x,y), \end{cases}$$

откуда следует равенство фаз и амплитуд этих функций. Если направить ось перпендикулярно плоскости падения, то условие равенства фаз запишется совсем просто (рис. 2.7): $k_x x = k'_x x = q_x x$, или $k\sin\theta = k\sin\theta' = q\sin\theta''$, откуда немедленно следует $\theta = \theta'$ (закон отражения) и закон преломления:

$$\frac{\sin\theta''}{\sin\theta} = \frac{q}{k}.$$

По аналогии с оптикой определим показатель преломления:

$$n = \frac{q}{k} = \sqrt{\frac{E-U_2}{E-U_1}}.$$



Это показатель преломления второй "среды» относительно первой. Если же принять $n = 1$ для $U = 0$, то получим показатели преломления обеих «сред» относительно вакуума:

$$n_1 = \sqrt{1 - \frac{U_1}{E}}, \quad n_2 = \sqrt{1 - \frac{U_2}{E}}.$$

Теперь используем условия равенства амплитуд

$$\begin{cases} 1 + A = B, \\ 1 - A = \frac{q_z}{k_z} B. \end{cases}$$

Решаем эту систему и находим коэффициенты прохождения и отражения:

$$D = \frac{|j_z^{\text{прош}}|}{|j_z^{\text{пад}}|} = \frac{q_z}{k_z}|B|^2 = \frac{4q_z k_z}{(k_z + q_z)^2},$$
$$R = \frac{|j_z^{\text{отр}}|}{|j_z^{\text{пад}}|} = |A|^2 = \frac{(k_z - q_z)^2}{(k_z + q_z)^2}.$$

Полное отражение возникает, когда $E < U_2$, и тогда $q = i\varkappa$ - чисто мнимая величина. При этом из равенства (1) следует

$$q_z^2 = q^2 - q_x^2 = -\varkappa^2 - k^2 \sin^2\theta < 0,$$

поэтому и $q_z = i\varkappa_z$ - чисто мнимое. При таких условиях $R = 1$, а плотность потока прошедшей волны равна нулю. Волновая функция в области 2 пропорциональна $e^{-\varkappa_z z}$, т. е. экспоненциально убывает.

ПТФ-3.з4. Регуляризованный кулоновский потенциал (40 б).

Найдите энергию основного состояния в регуляризованном одномерном Кулоновском потенциале $U(x) = -\frac{e^2}{\sqrt{x^2+a^2}}$, считая что регуляризация происходит на масштабах меньше Боровского радиуса $a \ll a_B = \frac{\hbar^2}{me^2}$.

Solution.

$$\bar{U}(p) := \int\limits_{-\infty}^{\infty} U(x) \exp\left(-\frac{ipx}{\hbar}\right) dx = -\int\limits_{-\infty}^{\infty} \frac{e^2 \exp(-\frac{ipx}{\hbar})}{\sqrt{x^2+a^2}} dx$$

В данном случае нельзя приближать выносом $\bar{U}(p)$ за интеграл, ибо $\bar{U}(p)$ меняется быстро ($U(x)$ медленная).

$$-\int\limits_{-\infty}^{\infty} \frac{\bar{U}(p)(dp)}{|E| + \frac{p^2}{2m}} = 1$$

$$\int\limits_{-\infty}^{\infty} \left(\int\limits_{-\infty}^{\infty} \frac{e^2 \exp(-\frac{ipx}{\hbar})}{2\pi\hbar\sqrt{x^2+a^2}(|E| + \frac{p^2}{2m})} dx \right) dp = 1$$

$$\int\limits_{-\infty}^{\infty} \left(\int\limits_{-\infty}^{\infty} \frac{e^2 \exp(-\frac{ipx}{\hbar})}{2\pi\hbar\sqrt{x^2+a^2}(|E| + \frac{p^2}{2m})} dp \right) dx = 1$$

$$\int\limits_{-\infty}^{\infty} \sqrt{\frac{m}{2|E|}} \frac{e^2 \exp(-\frac{\sqrt{2m|E|}|x|}{\hbar})}{\hbar\sqrt{x^2+a^2}} dx = 1$$

$k := a\frac{\sqrt{2m|E|}}{\hbar} = \frac{a}{e}\sqrt{\frac{2|E|}{a_B}}$; $u := \frac{|x|}{a}$, тогда

$$2\int\limits_0^{\infty} \left(\frac{\exp(-ku)}{\sqrt{1+u^2}} \right) du = \frac{ka_B}{a}$$

В пределе малых k экспоненту можно разложить до 1 члена в ряде Тейлора и взять верхний предел $\frac{1}{k}$: (????? не знаю, почему так, но проверил на Вольфраме, действительно примерно выражения совпадают!)

$$\int\limits_0^\infty \left(\frac{\exp(-ku)}{\sqrt{1+u^2}}\right) du \approx \int\limits_0^{1/k} \frac{du}{\sqrt{1+u^2}} = \ln\left[u+\sqrt{1+u^2}\right]\Big|_0^{1/k} = \ln\left(\frac{2}{k}\right)$$

$$2\ln\left(\frac{2}{k}\right) = \frac{ka_B}{a}$$

$$k\exp\left(\frac{ka_B}{2a}\right) = 2$$

$z := \frac{ka_B}{2a}$,

$$\exp(z) = \frac{a_B}{a}\frac{1}{z}$$

$$z^{(0)} = 1$$

$$z^{(1)} = \ln\left(\frac{a_B}{a}\right)$$

$$z = \ln(a_B/a) + \mathcal{O}(\ln\ln(a_B/a)) \qquad \Rightarrow \qquad k \approx \frac{2a\ln(a_B/a)}{a_B}$$

$$E \approx -2\frac{e^2}{a_B}\ln^2\frac{a_B}{a}$$

Еще одно, давнее решение

УШ в импульсной форме, считая $\hbar = 1$, имеет типичное решение

$$\psi(p) = -\frac{1}{p^2/(2m)+|E|}\int\limits_{-\infty}^{\infty}\frac{U_{p-p'}dp'}{2\pi}\psi(p'),$$

где $U_{p-p'} = -\int U(x)e^{-i(p-p')x}dx = -\int \frac{aU_0}{a+|x|}\cos((p-p')x)dx$.

То есть решаем задачу о нахождении E из уравнения:

$$\psi(p) = -\frac{1}{2\pi(p^2/(2m)+|E|)}\int\limits_{-\infty}^{\infty}\int\frac{-aU_0}{a+|x|}e^{-i(p-p')x})dx\psi(p')dp'$$

Преобразуем

$$\int\limits_{-\infty}^{\infty}\psi(p')dp' = -\frac{U_p}{p^2/(2m)+|E|}\int\limits_{-\infty}^{\infty}\frac{dp'}{2\pi}\int\limits_{-\infty}^{\infty}\psi(p')dp'$$

(здесь пренебрегаем p' под косинусом и интегрируем по всему импульсному пространству (одномерному), в итоге справа волновая функция стала 1, слева меняем интегралы местами, потом протаскиваем интеграл до левой волновой функции, и оказывается, что волновая функция тоже уходит)

далее

$$1 = -\int dx\int\frac{dp}{2\pi}\frac{e^{-ipx}}{p^2/(2m)+|E|}\left(\frac{-aU_0}{a+|x|}\right)$$

$$1 = \frac{maU_0}{\pi}\int\frac{dx}{a+|x|}\int\frac{\cos(px)dp}{p^2+2m|E|}$$

(??? преобразование утеряно??)

В итоге

$$\to 1 = \frac{maU_0}{\sqrt{2m|E|}}\int\frac{dxe^{-|x|\sqrt{2m|E|}}}{a+|x|}$$

теперь мы в шаге от нахождения энергии основного состояния, нужно его решить.

введем параметры $t = x\sqrt{2m|E|}$, $\beta = \sqrt{2m|E|}a$.

Считать нужно интеграл с малым β:

$$I = \int \frac{dte^{-|t|}}{\beta + |t|}$$

в нашем случае $\beta \ll |t| \ll 1$, для него решается так:

$$I_2 \approx 2\int\limits_{\beta}^{1} \frac{dt}{\beta + t} \approx 2\ln\frac{1}{\beta}$$

и получаем

$$I \approx 2\ln\frac{1}{\sqrt{2m|E|}a}$$

итог наших действий:

$$1 = \frac{maU_0}{\sqrt{2m|E|}} 2\ln\frac{1}{\sqrt{2m|E|}a} \qquad \leftrightarrow \qquad \frac{a\sqrt{2m|E|}}{ma^2U_0} = -2\ln\sqrt{2m|E|}a$$

короче, хочется сказать, что уровни энергии неявно следуют из этого уравнения.

вообще, так как тут все константы и ищем $|E|$, неплохо бы заменить параметрами и посмотреть просто пересечение графика левой и правой части (как в школе мы делали)

и так как в меня время почти вышло, просто воспользуемся методами, которые советуют математики (это как метод итераций из вычматов):

вводим параметры

$\beta = ma^2U_0 \ll 1$ - константа, $\alpha := a\sqrt{2m|E|}/\beta$ - наша переменная.

уравнение в них $\alpha = -2\ln(\alpha\beta)$

начнем с простейшей зависимости: $\alpha_0 = 1$, тогда на следующем шаге: $\alpha_1 = -2\ln(\beta)$, а потом $\alpha_2 = -2\ln(-2\beta\ln(\beta))$.

если так вообще можно делать, то мы уже с какой-то точностью решили это уравнение.

Добавляя куда нужно $\hbar$, видим:

$$|E| \approx 2U_0 \cdot (ma^2U_0/\hbar)\ln^2(-2ma^2U_0/\hbar\ln(ma^2U_0/\hbar)).$$

Почему самое простейшее решение задачи неверное?

Как известно, задача о трёхмерном Кулоновском потенциале, в частности, при нулевом орбитальном моменте $l = 0$ сводится как раз к одномерной задаче ровно в потенциале $U(x) = -\frac{e^2}{\sqrt{x^2+a^2}}$. Тем самым, казалось бы, ничего не мешает в этом потенциале просто положить $a = 0$ и воспользоваться решением трёхмерной задачи, для которой известно основное состояние $-\psi_{3D}(r) = e^{-r/a_B}$ с энергией $E_0 = -\mathrm{Ry}^{-13} = -me^4/2\hbar^2 = -13.6\mathrm{eV}$

Однако, это рассуждение неверно. Связано это с тем, что переход от трёхмерной задач к одномерной осуществляется подстановкой $\psi_{3D}(r) = \psi_{1D}(r)/r$, и основное состояние трёхмерного Кулона, соответствует одномерной волновой функции $\psi_{1D}(r) = r\exp(-r/a_B)$. У этой волновой функции имеется ровно один узел, $\psi_{1D}(r = 0) = 0$, поэтому по осцилляторной теореме она описывает первое возбуждённое состояние одномерного Кулона! А как же тогда устроено основное?

Оказывается, в одномерии буквально Кулоновский потенциал $U(x) = -\alpha/|x|$ соответствует «падению на центр» и нарушает унитарность - а его основное состояние имеет энергию $E_0 = -\infty$. Для того, чтобы это увидеть, мы и предлагаем ввести «обрезку» потенциала на самых маленьких расстояниях и исследовать поведение энергии основного состояния при $a \to 0$.

(????????? это нужно еще продумать, пока не понял особо глубоко???. в 1ю часть тоже допишу про это)

ФР.? Спектр в экранированном Кулоне

Вычислить, ограничиваясь первым порядком теории возмущений, спектр s-состояний в экранированном кулоновском потенциале $U(r) = -\frac{e^2}{r}e^{-r/\ell}$, при $\ell \gg a_0$. Оценить максимальное n, при котором применима теория возмущений.

Solution.

Обычная теория возмущений дает ответ (????).

Разложим потенциал в ряд по $\frac{1}{\ell}$:

$$U(r) \approx -\frac{e^2}{r}\left(1 - \frac{r}{\ell} + \frac{1}{2}\frac{r^2}{\ell^2}\right) \approx -\frac{e^2}{r} + \frac{e^2}{r}\left(\frac{r}{\ell} - \frac{r^2}{2\ell^2}\right)$$

При $r \ll \ell$ наш потенциал имеет вид $U \approx -e^2/r$. В нулевом приближении искомые уровни нижней части спектра и соответствующие им с.ф. будут такие же, как и в кулоновском поле:

$$E^{(0)}_{n_r l} = -\frac{me^4}{2\hbar^2 n^2}, \quad \Psi^{(0)}_{n_r lm} = \Psi^{\text{кул}}_{n_r lm},$$

При этом отличие рассматриваемых потенциалов от кулоновского играет роль возмущения

$$V(r) = U(r) + e^2/r \approx \frac{e^2}{\ell}$$

Ввиду того что орбитальный момент частицы является интегралом движения и при действии возмущения, с.ф. $\Psi^{(0)}_{n_r lm}$ являются правильными функциями нулевого приближения, поправка первого порядка определяется выражением

$$E^{(1)}_{n_r l} = \int V(r)|\Psi^{(0)}_{n_r lm}|^2 d^3r.$$

Исходя их того, что $\int |\Psi^{(0)}_{n_r lm}|^2 d^3r = 1$, получим:

$$E^{(1)}_{n_r l} = \int \frac{e^2}{\ell}|\Psi^{(0)}_{n_r lm}|^2 d^3r = \frac{e^2}{\ell}.$$

Спектр, то есть энергия состояний, есть:

$$E_n \approx -\frac{me^2}{2\hbar^2 n^2} + \frac{e^2}{\ell}.$$

Определение границ применимости

$$\frac{|V_{kn}|}{\Delta E^{(0)}_{kn}} \ll 1,$$

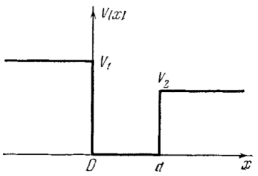
$$\frac{\frac{e^2}{\ell}}{\frac{me^4}{2\hbar^2}\left(-\frac{1}{n^2} + \frac{1}{(n-1)^2}\right)} \approx \frac{2\hbar^2}{m\ell e^2}(n-1)^2 \ll 1,$$

учтено, что $\frac{1}{n^2} \ll \frac{1}{(n-1)^2}$. В итоге получим, что теория возмущений работает для

$$n \ll \sqrt{\frac{m\ell e^2}{2\hbar^2}} + 1$$

ГК-1.4. Несимметричная потенциальная яма

Определить уровни энергии и волновые функции частицы, находящейся в несимметричной потенциальной яме вида



Рассмотреть предельный случай $V_1 = V_2$, и в этом случае предел мелкой ямы.

Solution.

Пишем уравнение Шредингера для каждой области, вводим переменные, подставляем ожидаемые анзацы, сшиваем и получаем выражения для коэффициентов. Для симметричной ямы нужно внимательно посмотреть на имеющиеся уравнения.

$$\begin{aligned}
&\frac{\hbar^2}{2\mu}\frac{d^2\psi}{dx^2} + (E - V_1)\,\psi = 0 \qquad && (x < 0),\\
&\frac{\hbar^2}{2\mu}\frac{d^2\psi}{dx^2} + E\psi = 0 && (0 < x < a),\\
&\frac{\hbar^2}{2\mu}\frac{d^2\psi}{dx^2} + (E - V_2)\,\psi = 0 && (x > a).
\end{aligned}$$

$$\varkappa_1 := \frac{\sqrt{2\mu\,(V_1 - E)}}{\hbar}, \quad \varkappa := \frac{\sqrt{-2\mu E}}{h}, \quad \varkappa_2 := \frac{\sqrt{2\mu\,(V_2 - E)}}{\hbar},$$

$$\begin{aligned}
&\psi = A_1 e^{-\varkappa_2 x} + B_1 e^{\varkappa_1 x} && (x < 0)\\
&\psi = A e^{-\varkappa x} + B e^{\varkappa x} && (0 < x < a),\\
&\psi = A_2 e^{-\varkappa_2 x} + B_2 e^{\varkappa_2 x} && (x > a)
\end{aligned}$$

Рассмотрим дискретный спектр $E < V_2$. Тогда $\varkappa_1$ и $\varkappa_2$-действительные величины. Полагая в средней области $0 < \varkappa < a$, величину $\varkappa = ik$, где k - действительно, поищем решение в виде

$$\psi \sim \sin(kx + \delta) \quad (0 < x < a)$$

В силу конечности волновой функции $A_1 = 0, B_2 = 0$. Из условия непрерывности логарифмической производной $\frac{1}{\psi}\frac{d\psi}{dx}$ получаем

$$\begin{aligned}
\varkappa_1 &= k \operatorname{ctg} \delta\\
-\varkappa_2 &= k \operatorname{ctg}(ka + \delta).
\end{aligned}$$

Перепишем последние два условия, выразив x_1 и x_2 через k

$$\begin{aligned}
&\sqrt{\frac{2\mu V_1}{\hbar^2 k^2} - 1} = \operatorname{ctg} \delta,\\
&-\sqrt{\frac{2\mu V_2}{\hbar^2 k^2} - 1} = \operatorname{ctg}(ka + \delta).
\end{aligned}$$

Запомним сперва, что из этих уравнений следует, что аргументы котангенсов должны находиться в 1-ом или 3-ем и во 2-м и 4-м квадранте соответственно. Возводим в квадрат, переходим к синусу, извлекаем корень, получаем много решений для каждого уравнения, параметризуем их через $n_1, n_2 \in \mathbb{Z}$:

$$\begin{aligned}
\delta &= \arcsin \frac{\hbar k}{\sqrt{2\mu V_1}} + n_1 \pi\\
ka + \delta &= -\arcsin \frac{\hbar k}{\sqrt{2\mu V_2}} + n_2 \pi
\end{aligned}$$

Исключая δ, находим уравнение для определения уровней энергий:

$$ka = n\pi - \arcsin \frac{\hbar k}{\sqrt{2\mu V_1}} - \arcsin \frac{\hbar k}{\sqrt{2\mu V_2}}, \qquad k = \frac{\sqrt{2\mu E}}{\hbar} > 0.$$

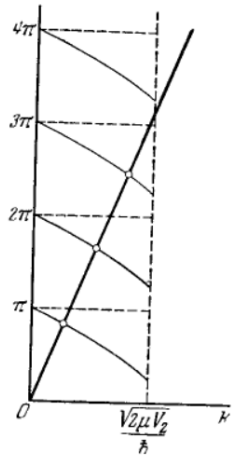
Верность знаков легко проверить, посмотрев на тригонометрическую окружность еще раз. Значения k, удовлетворяющие этому уравнению, можно найти графически. Эти значения определяются точками пересечения прямой

$$y_1(k) = ak$$

и кривыми

$$y_2(k) = n\pi - \arcsin \frac{\hbar k}{\sqrt{2\mu V_1}} - \arcsin \frac{\hbar k}{\sqrt{2\mu V_2}}$$

Имеется конечное число уровней, потому что arcsin вычисляется только для $\sqrt{E} = \frac{\hbar k}{\sqrt{2\mu}} < \sqrt{V_2}$ (ведь $V_2 < V_1$):



Случай симметричной ямы $V_1 = V_2 = V$

Так как $\arcsin \in [-\pi/2, \pi/2]$, то для каждого V и a всегда имеется по крайней мере один k, который удовлетворяет системе уравнений, то есть по крайней мере один уровень.

Для $\frac{\sqrt{2\mu V}}{\hbar}a \ll 1$, находим уровень энергии разложениями:

$$E \approx V - \xi; \qquad k \approx \sqrt{2\mu V}/\hbar$$

$$\sqrt{E/V} \approx 1 - \frac{\xi}{2V},$$

from $\arcsin(1-x) \approx \frac{\pi}{2} - \sqrt{2}x^{1/2}$ (see proof below),

$$\arcsin\sqrt{E/V} \approx \pi/2 - \sqrt{2}\sqrt{\frac{\xi}{2V}}$$

$$\pi - 2\left(\frac{\pi}{2} - \sqrt{\frac{\xi}{V}}\right) = a\sqrt{2\mu V}/\hbar$$

$$\xi = \frac{\mu a^2}{2\hbar^2}V^2.$$

В итоге:

$$E = V - \frac{\mu a^2}{2\hbar^2}V^2.$$

Число уровней N при любых V и найдется из

$$tg\angle = a \equiv N\pi/(\sqrt{2\nu V}/\hbar)$$

т.е. оно определяется соотношением:

$$N > \frac{\sqrt{2\mu V}a}{\pi\hbar} > N - 1$$

(???? я забыл это, переписать нужно решение вообще)

Appendix: derivation of $\arcsin(1-x) \approx \frac{\pi}{2} - \sqrt{2}x^{1/2}$

$$\arcsin x \approx \arcsin(1) + \arcsin'(1)(x-1) = \frac{\pi}{2} + \left(\frac{1}{\sqrt{1-x^2}}\right)\Bigg|_{x=1}(x-1) \overset{\text{Lop. r.}}{=} \frac{\pi}{2} - \frac{\sqrt{1-x^2}}{x} =$$

$$= \frac{\pi}{2} - \frac{\sqrt{1-x^2}}{x}\Bigg|_{x\to 1} = \frac{\pi}{2} - \sqrt{(1-x)(1+x)}\Big|_{x\to 1} = \frac{\pi}{2} - \sqrt{2(1-x)}$$

$$\arcsin x \equiv \arcsin(1-\xi) \qquad \Rightarrow \qquad \xi = 1 - x$$

$$\arcsin(1-\xi) \approx \frac{\pi}{2} - \sqrt{2\xi}$$

Here we have a coefficient $\to \infty$, so we take a limit of a whole term.

Another way:

$$\arcsin(1-\xi) \approx \arcsin(1-0) + \arcsin'(1-\xi)\Big|_{\xi\to 0}\xi = \frac{\pi}{2} - \frac{1}{\sqrt{1-(1-\xi)^2}}\xi \overset{\text{Lop. r.}}{\approx} \frac{\pi}{2} - \sqrt{2\xi}$$

17.2.4 Problems about delta-potentials 1

Б-2.2.6 Уровни энергии в δ-яме

Найти уровень энергии и собственную функцию связанного состояния в δ-яме $U(x) = -\frac{\hbar^2}{m}\varkappa_0\delta(x)$.

Solution..

Это одна из самых известных модельных задач, можно сразу написать ответ.

Положим $E < 0$ и введем

$$\varkappa^2 := \frac{2m|E|}{\hbar^2},$$

$$\psi''(x) - \left(\varkappa^2 - 2\varkappa_0\delta(x)\right)\psi(x) = 0.$$

В точке разрыва потенциала $x = 0$ потребуем непрерывности $\psi(x)$:

$$\psi(+0) = \psi(-0).$$

При этом производная $\psi'(x)$ терпит разрыв, величину которого находим из уравнения Шредингера, интегрируя его в пределах от $-\varepsilon$ до ε при $\varepsilon \to 0$: $\psi'(+0) - \psi'(-0) = -2\varkappa_0\psi(0)$. При этом, как и должно быть, выполняется условие непрерывности плотности потока вероятности: $j(+0) = j(-0)$, где $j(x) = \frac{i\hbar}{2m}\left(\psi(x)\psi'(x)^* - \psi^*(x)\psi'(x)\right)$.

Нормированное решение ищем в виде

$$\psi(x) = \begin{cases} C_1 e^{-\varkappa x}, & x > 0, \\ C_2 e^{\varkappa x}, & x < 0. \end{cases}$$

Из непрерывности ψ при $x = 0$, получаем $C_1 = C_2 = C$. Тогда условие непрерывности производной дает $\varkappa = \varkappa_0$, т. е. при $E < 0$ имеем всего один дискретный уровень с энергией

$$E_0 = -\frac{\hbar^2\varkappa_0^2}{2m}$$

и волновой нормированной функцией

$$\psi_0(x) = \sqrt{\varkappa_0}e^{-\varkappa_0|x|} \equiv \langle x|0\rangle.$$

Б-2.2.7 Средние значения в δ-яме

Для связанного состояния частицы в поле δ-ямы найти $\langle\hat{\mathrm{x}}\rangle, \langle\hat{\mathrm{x}}^2\rangle, \langle\hat{\mathrm{p}}\rangle, \langle\hat{\mathrm{p}}^2\rangle$. Рассмотреть разные способы вычисления $\langle\hat{\mathrm{p}}^2\rangle$. Проверить, выполняется ли соотношение неопределённостей.

Solution..

В импульсном представлении волновая функция дискретного уровня задачи 2.2.6 будет иметь вид

$$\psi_0(p) \equiv \langle p|0\rangle = \int\limits_{-\infty}^{\infty} dx\langle p|x\rangle\langle x|0\rangle = \frac{\sqrt{\varkappa_0}}{(2\pi\hbar)^{1/2}}\int\limits_{-\infty}^{\infty} e^{-\varkappa_0|x| - \frac{ipx}{\hbar}}dx = \sqrt{\frac{2}{\pi}}\frac{(\varkappa_0\hbar)^{3/2}}{(\varkappa_0\hbar)^2 + p^2}.$$

Легко найти $\langle 0|\hat{x}|0\rangle = 0, \langle 0|\hat{\mathrm{p}}|0\rangle = 0$, а также

$$\langle 0|\hat{x}^2|0\rangle = \int\limits_{-\infty}^{\infty} xe^{-2x_0|x|}\hat{x}^2dx = \alpha\int\limits_0^{\infty} e^{-\alpha x}x^2dx = \alpha\frac{d^2}{d\alpha^2}\int\limits_0^{\infty} e^{-\alpha x}dx = \frac{2}{\alpha^2}\Big|_{\alpha=2x_0} = \frac{1}{\varkappa_0^2},$$

и, кроме того,

$$\langle 0|\hat{p}^2|0\rangle = \int\limits_{-\infty}^{\infty} dpp^2 \frac{2}{\pi} \frac{(\varkappa_0\hbar)^3}{\left((\hbar\varkappa_0)^2+p^2\right)^2} = \frac{2}{\pi}(\varkappa_0\hbar)^3 \left(-\frac{d}{d\alpha^2}\right) \int\limits_{-\infty}^{\infty} \frac{p^2dp}{\alpha^2+p^2} =$$
$$= \frac{2}{\pi}(\varkappa_0\hbar)^3 \left(-\frac{d}{d\alpha^2}\right) \frac{2\pi i(i\alpha)^2}{2i\alpha}\bigg|_{\alpha=\varkappa\hbar} = (\varkappa_0\hbar)^2$$

Соотношение неопределённостей для данного состояния имеет вид

$$\langle(\Delta\hat{x})^2\rangle\langle(\Delta\hat{\mathrm{p}})^2\rangle = \frac{1}{2\varkappa_0^2}\varkappa_0^2\hbar^2 = \frac{\hbar^2}{2} > \frac{\hbar^2}{4}$$

- абсолютный минимум для когерентного состояния гармонического осциллятора.

Б-2.2.8 δ-яма в импульсном представлении (!?!?!)

Найти энергию и волновые функции в поле δ-ямы $U(x) = -\frac{\hbar^2}{m}\varkappa_0\delta(x)$ в импульсном представлении.

Solution..

(тут про это хорошие ходы, вот это решить еще раз нужно!)

Фурье-образ потенциала равен константе, и уравнение Шредингера в импульсном представлении принимает простой вид:

$$\frac{p^2}{2m}\varphi(p) + \frac{\hbar\varkappa_0}{2\pi m}\int\limits_{-\infty}^{\infty} dp'\varphi(p') = E\varphi(p)$$

$$E = -\hbar^2\varkappa^2/(2m) < 0 \qquad\qquad C := \int\limits_{-\infty}^{\infty} dp'\varphi(p')\,.$$

$$\varphi(p) = \frac{\hbar\varkappa_0}{\pi}\frac{C}{p^2+\hbar^2\varkappa^2}.$$

Еще раз интегрируем:

$$C = \frac{\hbar\varkappa_0}{\pi}\int\limits_{-\infty}^{+\infty}\frac{C}{(p^2+\hbar^2\varkappa^2)}dp = C\frac{\varkappa_0}{\varkappa},$$

$$E = -\frac{\hbar^2\varkappa_0^2}{2m}.$$

$$\int\limits_{-\infty}^{+\infty}|\varphi(p)|^2dp = 1, \qquad \Rightarrow \qquad |C|^{-2} = \left(\frac{\hbar\varkappa_0}{\pi}\right)^2\int\limits_{-\infty}^{+\infty}\frac{dp}{\left(p^2+\hbar^2\varkappa_0^2\right)^2}.$$

Вычисляем вычетами: следует взять вычет в полюсе второго порядка, например в верхней полуплоскости в точке $z = i\hbar\varkappa_0$, после чего получаем $C = \sqrt{2\pi\hbar\varkappa_0}$. В итоге

$$\psi_\rho = \sqrt{\frac{2}{\pi\hbar\varkappa_0}}\frac{1}{p^2/\hbar^2\varkappa_0^2+1}$$

в полном соответствии с

$$\psi_0(p) \equiv \langle p|0\rangle = \int\limits_{-\infty}^{\infty} dx\langle p|x\rangle\langle x|0\rangle = \frac{\sqrt{\varkappa_0}}{(2\pi\hbar)^{1/2}}\int\limits_{-\infty}^{\infty} e^{-\varkappa_0|x|-\frac{ipx}{\hbar}}dx = \sqrt{\frac{2}{\pi}}\frac{(\varkappa_0\hbar)^{3/2}}{(\varkappa_0\hbar)^2+p^2}$$

Б-2.2.10 Последовательность дельта-потенциалов

Найти разрешенные зоны энергии для частицы, движущейся в одномерном периодическом поле вида

а) $U(x) = \sum\limits_{n=-\infty}^{\infty}\frac{\hbar^2\beta_0}{m}\delta(x-na)$ (модель Кронига-Пенни);

б) $U(x) = -\sum\limits_{n=-\infty}^{\infty}\frac{\hbar^2x_0}{m}\delta(x-na)$.

Рассмотреть предельные случаи $\beta_0 a \gg 1$ (или $\varkappa_0 a \gg 1$, сильная связь) и $\beta_0 a \ll 1$ (или $\varkappa_0 a \ll 1$, слабая связь).

а) Модель Кронига-Пенни

Вследствие инвариантности потенциала относительно трансляций на величину периода одномерной кристаллической решетки a, т. е. $U(x+a)=U(x)$, гамильтониан нашей задачи будет коммутировать с оператором трансляции $\hat{\mathrm{T}}_a$:

$$\left[\hat{\mathrm{H}},\hat{\mathrm{T}}_a\right]=0.$$

Поэтому мы можем искать решение в виде общих собственных функций операторов $\hat{\mathrm{H}}$ и $\hat{\mathrm{T}}_a$:

$$\begin{cases}\hat{\mathrm{H}}\psi(x)=E\psi(x),\\ \hat{\mathrm{T}}_a\psi(x)=\lambda(a)\psi(x),\end{cases}$$

где $\lambda(a)$ (собственное значение оператора трансляции) имеет вид $\lambda(a)=e^{\pm iKa}$, а $\operatorname{Im}K=0$ (квазиимпульс). Собственные функции оператора трансляции согласно теореме Блоха должны удовлетворять условию, которое следует из (1):

$$\psi(x+a)=e^{iKa}\psi(x)$$

Запишем общий вид решения уравнения Шредингера (1) в двух смежных областях:

$0<x<a$ (область 1): $\psi(x)=c_1e^{ikx}+d_1e^{-ikx}$,

$a<x<2a$(область 2) : $\psi(x)=c_2e^{ik(x-a)}+d_2e^{-ik(x-a)}$,

причем $E=\frac{\hbar^2k^2}{2m}>0$.

Условия сшивания в точке $x=a$

$$\psi(a+0)=\psi(a-0),$$
$$\psi'(a+0)-\psi'(a-0)=2\beta_0\psi(0)$$

после элементарных вычислений дают связь между коэффициентами $c_1,\ d_1, c_2, d_2$, которую можно записать в матричном виде:

$$\begin{pmatrix}c_2\\ d_2\end{pmatrix}=A\begin{pmatrix}c_1\\ d_1\end{pmatrix},\qquad A:=\begin{pmatrix}e^{ika}\left(1+\frac{\beta_0}{ik}\right) & e^{-ika}\frac{\beta_0}{ik}\\ -e^{ika}\frac{\beta_0}{ik} & e^{-ika}\left(1-\frac{\beta_0}{ik}\right)\end{pmatrix}.$$

Нетрудно заметить, что $\det A=1$. Далее мы применим формулу (2) и получим

$$\psi(x+a)=c_2e^{ik(x+a-a)}+d_2e^{-ik(x+a-a)}=c_2e^{ikx}+d_2e^{-ikx}=e^{iKa}\psi(x).$$

Таким образом, имеем

$$\begin{pmatrix}c_2\\ d_2\end{pmatrix}=e^{iKa}\begin{pmatrix}c_1\\ d_1\end{pmatrix},$$

и, сравнивая (3) и (4), видим, что задача свелась к проблеме диагонализации матрицы A (матрица сдвига), а $e^{iKa}=\lambda(a)$ - играет роль собственного значения этой матрицы. В результате получаем уравнение на собственные значения

$$\lambda^2(a)-2\rho\lambda(a)+1=0,$$

где $2\rho=\mathrm{Sp}A$ - след матрицы A. Решение уравнения дает

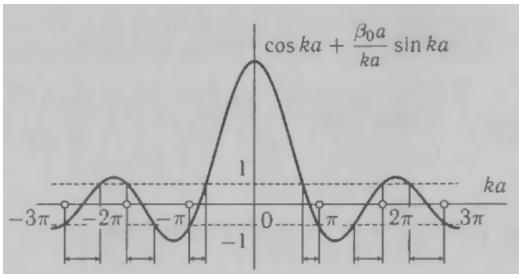
$$\lambda_{1,2}(a)=e^{\pm iKa}=\rho\pm i\sqrt{1-\rho^2},$$

откуда следует, что $\cos Ka=\rho$ или, конкретнее:

$$\cos Ka=\cos ka+\frac{\beta_0}{k}\sin ka.$$

Это и есть так называемое дисперсионное соотношение.

Анализ соотношения (5) показывает, что энергетический спектр частицы в таком поле имеет зонную структуру. В самом деле, задавшись некоторым значением энергии E, мы находим $k=\sqrt{2mE}/\hbar$ и затем из уравнения (5) можем найти значение a (рис. 2.4).



Случай 1. Энергия E такова, что $|\rho| = |\cos Ka| \leqslant 1$. При этом K является вещественным числом, что и требуется для функции Блоха, а сама функция - распространяющаяся модулированная волна. Эти области значений E называются разрешенными зонами энергии.

Случай 2. Энергия E такова, что $|\rho| = |\cos Ka| > 1$. При этом величина K - комплексная, и частицы с такими K не могут распространяться внутри большого кристалла. Эти области значений энергии запрещенные зоны.

Разрешенные зоны чередуются с запрещенными, не перекрываясь между собой. Ширина разрешенных зон увеличивается с ростом $|ka|$. Условие $\beta_0 a \ll 1$ (слабая связь) описывает случай, близкий к свободному. Это значит, что $K \simeq k + 2\pi n/a$, и поэтому зависимость $E(K)$ параболическая. В противоположном предельном случае $\beta_0 a \gg 1$ (сильная связь) интервалы разрешенных значений энергии фактически превращаются в отдельные дискретные уровни $ka \approx \pi n$.

б) Модель Кронига-Пенни с обратным знаком

(?? то же самое, только все со знаком минус будет? потом подумаю.)

Б-2.2.12 Переход из одной дельта-ямы в другую (!?)

Пусть имеется два дельта потенциала с $\varkappa_0 a \gg 1$. Пусть частица в начальный момент времени $t = 0$ находится в левой яме. Найти вероятность обнаружения частицы в правой яме в момент времени t.

Предполагаются следующие приближения:

а) δ-ямы находятся достаточно далеко друг от друга, т. е. в системе ям имеется два дискретных уровня энергии, отвечающих связанным состояниям. Однако ямы не бесконечно далеки, следовательно, $E^{(+)} \neq E^{(-)}$.

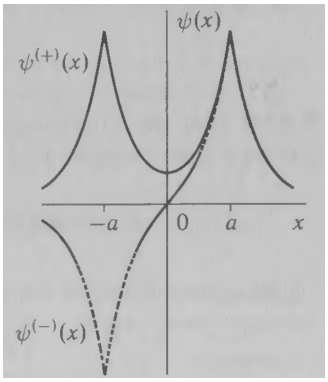
б) Система, рассматриваемая нами, - приближенно двухуровневая, т. е. отброшен весь непрерывный спектр - считается, что частица не выходит из ям.

Solution.

Как это следует из рис. 2.5, в любом из стационарных состояний $\psi^{(+)}(x)$ или $\psi^{(-)}(x)$ выполняется

$$|\psi^{(\pm)}(-x)|^2 = |\psi^{(\pm)}(x)|^2,$$

поэтому вероятность обнаружения частицы вблизи левой и правой ямы одинакова - частица не локализована вблизи ни одной из ям.



С целью построить состояние, в котором частица (хотя бы в начальный момент времени) была бы локализована в окрестности одной из ям, воспользуемся линейной комбинацией функций

$$\Psi(x,t) = C_1 e^{-\frac{iE^{(+)}t}{\hbar}} \psi^{(+)}(x) + C_2 e^{-\frac{iE^{(-)}t}{\hbar}} \psi^{(-)}(x).$$

Очевидно, что в начальный момент времени

$$\Psi(x,0) = C_1 \psi^{(+)}(x) + C_2 \psi^{(-)}(x)$$

Если положить $C_1 = C_2$, то мы получим состояние (рис. 2.5), в котором частица локализована вблизи правой δ-ямы. Обозначим это состояние $\Psi(x,0) = \psi_a(x)$. По аналогии можно построить состояние $\psi_{-a}(x)$ с локализацией частицы вблизи левой δ-ямы. Окончательно

$$\begin{cases} \psi_a(x) = \dfrac{1}{\sqrt{2}}\left(\psi^{(+)}(x) + \psi^{(-)}(x)\right), \\ \psi_{-a}(x) = \dfrac{1}{\sqrt{2}}\left(\psi^{(+)}(x) - \psi^{(-)}(x)\right), \end{cases} \quad \Leftrightarrow \quad \begin{cases} \psi^{(+)}(x) = \dfrac{1}{\sqrt{2}}\left(\psi_a(x) + \psi_{-a}(x)\right), \\ \psi^{(-)}(x) = \dfrac{1}{\sqrt{2}}\left(\psi_a(x) - \psi_{-a}(x)\right). \end{cases}$$

Итак, волновая функция состояния (1), в котором частица в начальный момент времени локализована вблизи правой δ-ямы, имеет вид

$$\Psi(x,t) = \frac{1}{\sqrt{2}}\left\{e^{-\frac{iE^{(+)}t}{\hbar}}\psi^{(+)}(x) + e^{-\frac{iE^{(-)}t}{\hbar}}\psi^{(-)}(x)\right\} = \\ = \frac{1}{2}\left\{\psi_a(x)\left[e^{-\frac{iE^{(+)}t}{\hbar}} + e^{-\frac{iE^{(-)}t}{\hbar}}\right] + \psi_{-a}(x)\left[e^{-\frac{iE^{(+)}t}{\hbar}} - e^{-\frac{iE^{(-)}t}{\hbar}}\right]\right\}.$$

Тогда вероятность обнаружить частицу локализованной вблизи левой ямы, если в начальный момент она была в правой, равна

$$W_{-a} = \frac{1}{4}|e^{-\frac{iE^{(+)}t}{\hbar}} - e^{-\frac{iE^{(-)}t}{\hbar}}|^2 = \frac{1}{2}\left[1 - \cos\left(\frac{E^{(+)} - E^{(-)}}{\hbar}t\right)\right] = \sin^2\left[\frac{E^{(+)} - E^{(-)}}{2\hbar}t\right].$$

ПТФ-3.з3.1/2. Туннельное расщепление

Рассмотрите две мелкие ямы, моделируемые следующим потенциалом:

$$U(x) = -\frac{\hbar^2\kappa}{m}(\delta(x + L/2) + \delta(x - L/2))$$

• Нарисуйте (схематично, но со всеми ключевыми особенностями) зависимость уровней энергии связанных состояний от расстояния между ямами L.
• Пусть расстояние между ямами много больше характерного масштаба волновых функций для каждой из отдельных ям (туннельный режим), $L \gg \kappa^{-1}$. Определите расщепление между связанными состояниями.
• Эта задача может быть рассмотрена как модель ковалентной связи. Считая теперь L классической динамической переменной, определите силу (в туннельном режиме) и характер взаимодействия между ямами, если частица находится в основном состоянии.

Поиск зависимости энергии от расстояния

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2} = (E - U(x))\psi(x) = E\psi(x)$$

$$E < 0$$

$$k^2 := -\frac{2mE}{\hbar^2}.$$

For even states:

$$\psi_{\text{even}}(x) = \begin{cases}\psi_I(x) = Ae^{kx}, & x < -\frac{L}{2} \\ \psi_{II}(x) = B\cosh kx, & -\frac{L}{2} < x < \frac{L}{2} \\ \psi_{III}(x) = Ae^{-kx}, & x > \frac{L}{2}\end{cases}$$

$$\psi_{II}\left(\frac{L}{2}\right) = \psi_{III}\left(\frac{L}{2}\right), \quad \psi'_{III}\left(\frac{L}{2}\right) - \psi'_{II}\left(\frac{L}{2}\right) = -2\varkappa\psi_{III}\left(\frac{L}{2}\right)$$

$$Ae^{-\frac{kL}{2}} = B\cosh\frac{kL}{2}, \quad A(2\kappa - k)e^{-\frac{kL}{2}} = kB\sinh\frac{kL}{2}$$

(я потом допишу вывод там нужно приблизить sh и ch и чуть преобразовать, что ниже и получится)

$$1 + e^{-y} = \frac{y}{\kappa L}, \qquad y := kL$$

Это трансцендентное уравнение.

$$E_{\text{odd}} = -\frac{\hbar^2k^2}{2m} = -\frac{\hbar^2y^2}{2mL^2} \qquad y: \quad 1 + e^{-y} = \frac{y}{\kappa L}$$

Now, for odd states:

$$\psi_{\text{odd}}(x) = \begin{cases}\psi_I(x) = Ae^{kx}, & x < -\frac{L}{2} \\ \psi_{II}(x) = B\sinh kx, & -\frac{L}{2} < x < \frac{L}{2} \\ \psi_{III}(x) = -Ae^{-kx}, & x > \frac{L}{2}\end{cases}$$

Запишем граничные условия (из чётности достаточно их записать в одной точке $x = \frac{L}{2}$):

$$\psi_{II}\left(\frac{L}{2}\right) = \psi_{III}\left(\frac{L}{2}\right), \quad \psi'_{III}\left(\frac{L}{2}\right) - \psi'_{II}\left(\frac{L}{2}\right) = -2\kappa\psi_{III}\left(\frac{L}{2}\right)$$

$$Ae^{-\frac{kL}{2}} = B\sinh\frac{kL}{2}, \quad A(2\kappa - k)e^{-\frac{kL}{2}} = kB\cosh\frac{kL}{2}$$

$$1 - e^{-y} = \frac{y}{\kappa L}, \qquad y := kL$$

Получилось трансцендентное уравнение.

$$E_{\text{odd}} = -\frac{\hbar^2 k^2}{2m} = -\frac{\hbar^2 y^2}{2mL^2} \qquad 1 - e^{-y} = \frac{y}{\kappa L}$$

Графики зависимостей E_1 и E_2 от κL представлены на рис. 1.

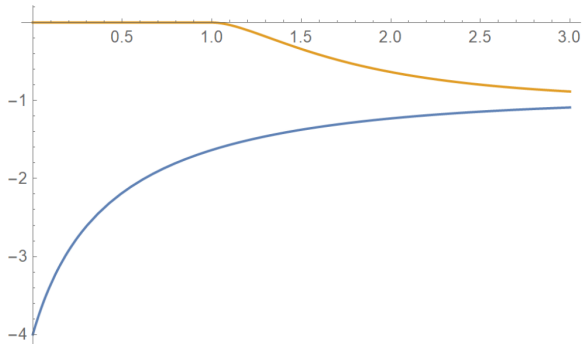


Figure 17.1: Графики зависимостей $E_{\text{even}}(\kappa L)$ (синий график) и $E_{\text{odd}}(\kappa L)$ (жёлтый график)

(надо бы проверить графики, запрограммировать, пока верю. вообще, есть еще другие графики, не уверен, верные ли они. так или иначе, это запросто проверить чуть что можно.)
(??? качественно, почему так и что это значит? у нас только четные в.ф. будут, ибо мин энергия в них?)

Поиск расщепления

• В туннельном режиме (при $\kappa L \gg 1$) решаем методом последовательных приближений (here even→ 1, odd→ 2):

$$y_1^{(0)} = y_2^{(0)} = \kappa L$$

$$y_1^{(1)} = \kappa L(1 + e^{-\kappa L}), \qquad y_2^{(1)} = \kappa L(1 - e^{-\kappa L})$$

$$E_1 = -\frac{\hbar^2\kappa^2}{2m}(1 + 2e^{-\kappa L}) + \mathcal{O}(e^{-2\kappa L}), \qquad E_2 = -\frac{\hbar^2\kappa^2}{2m}(1 - 2e^{-\kappa L}) + \mathcal{O}(e^{-2\kappa L})$$

$$\Delta E = E_2 - E_1 = \frac{2\hbar^2\kappa^2 e^{-\kappa L}}{m} + \mathcal{O}(e^{-2\kappa L})$$

$$\Delta E = \frac{2\hbar^2\kappa_0^2 e^{-\kappa L}}{m} + \mathcal{O}(e^{-2\kappa L})$$

Случай $\kappa L \gg 1$

(тут мое давнее решение, перепишу потом, оно сейчас криво написано, но идея понятна)
Смотря на решения, видим, что они будут почти κ.
Более точно сделаем итерациями:

$$\frac{\kappa_0 l}{L\kappa} = 1 + \exp(-\kappa_0 L)$$
$$(\kappa_0 L)_0 = L\kappa;$$
$$(\kappa_0 L)_1 = (\kappa_0 L)_0 + \epsilon = L\kappa + \epsilon, \quad \epsilon \ll (\kappa_0 L)_0;$$
$$1 + \frac{\epsilon}{L\kappa} = 1 + \exp(-L\kappa)\exp(\epsilon)$$
$$\epsilon = L\kappa\exp(-L\kappa).$$

Короче говоря, мы получили

$$\kappa_0^{e,o} = \kappa(1 \pm \exp(-L\kappa)).$$

Вспоминая, что $\kappa_0 \equiv \sqrt{\frac{2mE_0}{\hbar^2}}$, находим уровни энергии

$$E_0 = -\frac{\hbar^2}{2m}(\kappa(1+e^{-L\kappa}))^2 \approx \frac{\hbar^2}{2m}\kappa^2(1+2e^{-L\kappa})$$

Сила $F = -\frac{\partial}{\partial l}E_0(L) = -\frac{\hbar^2\kappa^2}{m}\kappa e^{-L\kappa} \approx -\frac{\hbar^2\kappa^3}{m}e^{-L\kappa}$.

Случай $\kappa L \ll 1$

Введем $p = \kappa_0/\kappa$ и

$$p = 1 + \exp(-p\kappa L) \approx 1 + 1 - p\kappa Lp = \frac{2}{1+\kappa l} \approx 2(1-\kappa L).$$

в этом случае будет

$$\kappa_0 = 2\kappa(1-\kappa L).$$

(??? перепроверю. это нужно? мб в условие добавить это?)

Поиск силы взаимодействия

Основное состояние – состояние с минимально допустимой энергией. В туннельном режиме (при $\kappa L \gg 1$) минимальная энергия

$$E_1(L) = -\frac{\hbar^2\kappa^2}{2m}(1+2e^{-\kappa L}) + \mathcal{O}(e^{-2\kappa L})$$

$$F = -\frac{\partial E_1}{\partial L} = -\frac{\hbar^2\kappa^3 e^{-\kappa L}}{m} + \mathcal{O}(e^{-2\kappa L})$$

Поскольку $F < 0$, то ямы притягиваются.

ПТФ-3.з3.2/2. Модель сильной связи

Рассмотрите две мелкие ямы, моделируемые следующим потенциалом:

$$U(x) = -\frac{\hbar^2\kappa}{m}(\delta(x+L/2) + \delta(x-L/2))$$

В туннельном данный потенциал может моделировать сильную связь для пары нижних уровней энергии. Все вычисления в этой задаче необходимо проводить в ведущем приближении по параметру $L \gg \kappa^{-1}$.

1. Спроецируйте гамильтониан на линейное подпространство, натянутое на собственные функции каждой из ям по отдельности: $\{|\psi_1\rangle, |\psi_2\rangle\} = \{\psi_0(x+L/2), \psi_0(x-L/2)\}$. Выпишите соответствующую ему матрицу 2×2 в этом базисе.

2. Обратите внимание, что базисные вектора не являются ортогональными. Вычислите матрицу Грама для этого базиса (матрица скалярных произведений $G_{ij} = \langle\psi_i|\psi_j\rangle$).

3. Характеристическое уравнение, определяющее собственные числа для неортонормированного базиса, имеет вид $\det(\hat{H} - E\cdot\hat{G}) = 0$. Найдите собственные уровни энергии в заданном приближении.

Подсказка: обратите внимание: гамильтониан задачи можно записать в виде $\hat{H} = \hat{T} + \hat{U}_1 + \hat{U}_2$, и состояния $|\psi_{1,2}\rangle$ являются собственными для $\hat{H}_{1,2} = \hat{T} + \hat{U}_{1,2}$ соответственно. Это обстоятельство может значительно упростить вычисления. Кроме того, предлагается заметить, что некоторые члены имеет экспоненциальную зависимость $\propto \exp(-\kappa L)$, а часть – зависимость $\propto \exp(-2\kappa L)$, в связи с чем их в ведущем порядке можно положить нулём.

Подготовка к решению

Получим еще раз известные результаты, но в обозначениях данной задачи.

$$\hat{H} = \hat{T} + \hat{U}_1 + \hat{U}_2, \quad \hat{U}_1 = -\frac{\hbar^2\kappa}{m}\delta(x + L/2), \quad \hat{U}_2 = -\frac{\hbar^2\kappa}{m}\delta(x - L/2)$$

$$\hat{H}_1 = \frac{\hat{p}^2}{2m} - \frac{\hbar^2\kappa}{m}\delta(x + L/2), \quad \hat{H}_2 = \frac{\hat{p}^2}{2m} - \frac{\hbar^2\kappa}{m}\delta(x - L/2)$$

$$\hat{H}_i|\psi_i\rangle = E|\psi_i\rangle$$

$$k^2 := -\frac{2mE}{\hbar^2}.$$

$$\hat{H}_1 \qquad \Rightarrow \qquad \left(-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial x^2} - \frac{\hbar^2\kappa}{m}\delta(x + L/2)\right)\psi = E\psi$$

$$\psi(x) = \begin{cases}\psi_I(x) = Ae^{kx}, & x < -\frac{L}{2} \\ \psi_{II}(x) = Be^{-kx}, & x > -\frac{L}{2}\end{cases}$$

$$\psi_I\left(-\frac{L}{2}\right) = \psi_{II}\left(-\frac{L}{2}\right), \quad \psi'_{II}\left(-\frac{L}{2}\right) - \psi'_I\left(-\frac{L}{2}\right) = -2\kappa\psi_{II}\left(-\frac{L}{2}\right)$$

$$Ae^{-\frac{kL}{2}} = Be^{\frac{kL}{2}}, \quad -kBe^{\frac{kL}{2}} - kAe^{-\frac{kL}{2}} = -2\kappa Be^{\frac{kL}{2}}$$

$$B = Ae^{-kL}, \quad k = \kappa$$

$$\psi_1(x) = C_1 e^{-\kappa|x+L/2|}$$

$$\langle\psi_1|\psi_1\rangle = \int\limits_{-\infty}^{\infty} C_1^2 e^{-\kappa|2x+L|}dx = 2C_1^2\int\limits_{0}^{\infty} e^{-2kx}dx = \frac{C_1^2}{k} = 1 \to C_1 = \sqrt{k} = \sqrt{\kappa}$$

$$\psi_1(x) = \sqrt{\kappa}e^{-\kappa|x+L/2|}$$

$$E = -\frac{\hbar^2\kappa^2}{2m}$$

$$\hat{H}_2 \qquad \Rightarrow \qquad \left(-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial x^2} - \frac{\hbar^2\kappa}{m}\delta(x - L/2)\right)\psi = E\psi$$

$$\psi(x) = \begin{cases}\psi_I(x) = Ae^{kx}, & x < \frac{L}{2} \\ \psi_{II}(x) = Be^{-kx}, & x > \frac{L}{2}\end{cases}$$

$$\psi_I\left(\frac{L}{2}\right) = \psi_{II}\left(\frac{L}{2}\right), \quad \psi'_{II}\left(\frac{L}{2}\right) - \psi'_I\left(\frac{L}{2}\right) = -2\kappa\psi_{II}\left(\frac{L}{2}\right)$$

$$Ae^{\frac{kL}{2}} = Be^{-\frac{kL}{2}}, \quad -kBe^{-\frac{kL}{2}} - kAe^{\frac{kL}{2}} = -2\kappa Be^{-\frac{kL}{2}}$$

$$B = Ae^{kL}, \quad k = \kappa$$

$$\psi_2(x) = C_2 e^{-\kappa|x-L/2|}$$

$$\langle\psi_2|\psi_2\rangle = \int\limits_{-\infty}^{\infty} C_2^2 e^{-\kappa|2x-L|}dx = 2C_2^2\int\limits_{0}^{\infty} e^{-2kx}dx = \frac{C_2^2}{k} = 1 \to C_2 = \sqrt{k} = \sqrt{\kappa}$$

$$\psi_2(x) = \sqrt{\kappa}e^{-\kappa|x-L/2|}$$

$$E = -\frac{\hbar^2\kappa^2}{2m}$$

Вычисление проекций

$$\langle\psi_1|\hat{H}|\psi_1\rangle = \langle\psi_1|\hat{H}_1 - \frac{\hbar^2\kappa}{m}\delta(x-L/2)|\psi_1\rangle = E - \frac{\hbar^2\kappa}{m}\langle\psi_1|\delta(x-L/2)|\psi_1\rangle = \\ = -\frac{\hbar^2\kappa^2}{2m}(1+2e^{-2\kappa L}) = -\frac{\hbar^2\kappa^2}{2m}(1+\mathcal{O}(e^{-2\kappa L}))$$

$$\langle\psi_2|\hat{H}|\psi_2\rangle = \langle\psi_2|\hat{H}_2 - \frac{\hbar^2\kappa}{m}\delta(x+L/2)|\psi_2\rangle = E - \frac{\hbar^2\kappa}{m}\langle\psi_2|\delta(x+L/2)|\psi_2\rangle = \\ = -\frac{\hbar^2\kappa^2}{2m}(1+2e^{-2\kappa L}) = -\frac{\hbar^2\kappa^2}{2m}(1+\mathcal{O}(e^{-2\kappa L}))$$

$$\langle\psi_1|\hat{H}|\psi_2\rangle = \langle\psi_1|\hat{H}_2 - \frac{\hbar^2\kappa}{m}\delta(x+L/2)|\psi_2\rangle = \\ = E\langle\psi_1|\psi_2\rangle - \frac{\hbar^2\kappa}{m}\langle\psi_1|\delta(x-L/2)|\psi_2\rangle = \\ = -\frac{\hbar^2\kappa^3}{2m}\int\limits_{-\infty}^{\infty} e^{-\kappa(|x+L/2|+|x-L/2|)}dx - \frac{\hbar^2\kappa^2}{m}e^{-\kappa L} = \\ = -\frac{\hbar^2\kappa^3}{2m}\left(\int\limits_{-\infty}^{-L/2} e^{2\kappa x}dx + \int\limits_{-L/2}^{L/2} e^{-\kappa L}dx + \int\limits_{L/2}^{\infty} e^{-2\kappa x}dx\right) - \frac{\hbar^2\kappa^2}{m}e^{-\kappa L} = \\ = -\frac{3\hbar^2\kappa^2}{2m}e^{-\kappa L} - \frac{\hbar^2\kappa^3 L}{2m}e^{-kL} = \\ = -\frac{\hbar^2\kappa^2}{2m}e^{-\kappa L}(3+\kappa L)$$

$$\langle\psi_2|\hat{H}|\psi_1\rangle = \langle\hat{H}^\dagger\psi_2|\psi_1\rangle = \langle\hat{H}\psi_2|\psi_1\rangle = \langle\psi_1|\hat{H}\psi_2\rangle^\dagger = \langle\psi_1|\hat{H}\psi_2\rangle = -\frac{\hbar^2\kappa^2}{2m}e^{-\kappa L}(3+\kappa L)$$

$$\hat{H} = \begin{pmatrix} -\frac{\hbar^2\kappa^2}{2m}(1+\mathcal{O}(e^{-2\kappa L})) & -\frac{\hbar^2\kappa^2}{2m}e^{-\kappa L}(3+\kappa L) \\ -\frac{\hbar^2\kappa^2}{2m}e^{-\kappa L}(3+\kappa L) & -\frac{\hbar^2\kappa^2}{2m}(1+\mathcal{O}(e^{-2\kappa L})) \end{pmatrix}$$

Let's find the Gram matrix:

$$G_{ii} = \langle\psi_i,\psi_i\rangle = 1$$

$$G_{12} = G_{21} = \langle\psi_1,\psi_2\rangle = \int\limits_{-\infty}^{\infty}\psi_1(x)\psi_2(x)dx = e^{-\kappa L}(1+\kappa L)$$

$$G = \begin{pmatrix} 1 & e^{-\kappa L}(\kappa L+1) \\ e^{-\kappa L}(\kappa L+1) & 1 \end{pmatrix}$$

Поиск собственных уровней

$$\hat{H} - E\hat{G} = \begin{pmatrix} -\frac{\hbar^2\kappa^2}{2m} - E & -e^{-\kappa L}(\frac{\hbar^2\kappa^2}{2m}(3+\kappa L) + E(\kappa L+1)) \\ -e^{-\kappa L}(\frac{\hbar^2\kappa^2}{2m}(3+\kappa L) + E(\kappa L+1)) & -\frac{\hbar^2\kappa^2}{2m} - E \end{pmatrix}$$

$$\det(\hat{H} - E\hat{G}) = 0$$

$$\left(\frac{\hbar^2\kappa^2}{2m} + E\right)^2 - e^{-2\kappa L}\left(\frac{\hbar^2\kappa^2}{2m}(3+\kappa L) + E(\kappa L+1)\right)^2 = 0$$

$$\frac{\hbar^2\kappa^2}{2m} + E = \pm e^{-\kappa L}\left(\frac{\hbar^2\kappa^2}{2m}(3+\kappa L) + E(\kappa L+1)\right)$$

$$E(1 \mp e^{-\kappa L}(\kappa L + 1)) = \frac{\hbar^2\kappa^2}{2m}(\pm e^{-\kappa L}(3 + \kappa L) - 1)$$
$$E = -\frac{\hbar^2\kappa^2}{2m}(1 \pm 2e^{-\kappa L}) + \mathcal{O}(e^{-2\kappa L})$$

Как видно, формулы в туннельном режиме и итоговая тут формула совпадают.

Вычисление проекций более явным способом

Приведу более компактное решение, которое показывает лучше, как делаются вычисления. Смотрим на ямы по отдельности и для них решения:

$$\psi^-(x) = \sqrt{\kappa}\ e^{-\kappa|x-L/2|};$$
$$\psi^+(x) = \sqrt{\kappa}\ e^{-\kappa|x+L/2|}$$

Считаем матрицу Грамма:

$$\langle\psi^+|\psi^+\rangle = \langle\psi^-|\psi^-\rangle = 1;$$
$$\langle\psi^-|\psi^+\rangle = \langle\psi^+|\psi^-\rangle = \kappa\int e^{-\kappa(|x-L/2|-|x+L/2|)}dx = \kappa\left(2\int\limits_{L/2}^{\infty} e^{-2\kappa x}dx + 2\int\limits_{0}^{L/2} e^{-\kappa l}dx\right) = e^{-\kappa l}(\kappa L + 1).$$

$$\hat{G} = \begin{pmatrix} 1 & (\kappa L+1)e^{-\kappa l} \\ (\kappa L+1)e^{-\kappa l} & 1 \end{pmatrix}$$

Считаем гамильтониан в проекциях:

$$\begin{aligned}\langle\psi^-|\hat{H}|\psi^-\rangle &= \frac{-\kappa\hbar^2}{2m}\int e^{-\kappa|x-L/2|}\left(\frac{\partial^2}{\partial x^2} + 2\kappa(\delta(x-L/2)+\delta(x+L/2))\right)e^{-\kappa|x-L/2|}dx = \\ &= -\kappa\frac{\hbar^2}{2m}\left(\left(\int e^{-2\kappa|x-L/2|}(\kappa^2 - \kappa\cdot 2\delta(x-L/2))dx\right) + 2\kappa + 2\kappa e^{-2\kappa l}\right) = \\ &= -\kappa\frac{\hbar^2}{2m}(\kappa - 2\kappa + 2\kappa + 2\kappa e^{-2\kappa l}) = \\ &= \frac{-\kappa^2\hbar^2}{2m}(1 + 2e^{-2\kappa l})\end{aligned}$$

Тут на второй члены в самой внутренней скобке появились за счет второй производной, вне интеграла члены появились от двух дельта функций. Учтено, что производная сигнума - это удвоенная дельта-функция.

$$\begin{aligned}\langle\psi^-|\hat{H}|\psi^+\rangle &= -\kappa\frac{\hbar^2}{2m}\left(\left(\int e^{-\kappa|x-L/2|-\kappa|x+L/2|}(\kappa^2 - \kappa\cdot 2\delta(x-L/2))dx\right) + 4\kappa e^{-\kappa l}\right) = \\ &= -\kappa^2\frac{\hbar^2}{2m}\left(e^{-\kappa l}(\kappa L+1) - 2e^{-\kappa l} + 4e^{-\kappa l}\right) = -\kappa^2\frac{\hbar^2}{2m}\left(e^{-\kappa l}(\kappa L+3)\right)\end{aligned}$$

$$\langle\psi^+|\hat{H}|\psi^-\rangle = -\kappa^2\frac{\hbar^2}{2m}\left(e^{-\kappa l}(\kappa L+3)\right)$$
$$\langle\psi^+|\hat{H}|\psi^+\rangle = \frac{-\kappa^2\hbar^2}{2m}(1 + 2e^{2-\kappa l})$$

В итоге:

$$\hat{H}_P = \frac{-\kappa^2\hbar^2}{2m}\begin{pmatrix} 1+2e^{-2\kappa l} & e^{-\kappa l}(\kappa L+1) \\ e^{-\kappa l}(\kappa L+1) & 1+2e^{-2\kappa l}\end{pmatrix}$$

ищем собственные значения из $\det(\hat{H} - \lambda\hat{G}) = 0$

$$\det\begin{pmatrix} 1+2e^{-2\kappa l} + \lambda\frac{2m}{\kappa^2\hbar^2} & e^{-\kappa l}(3+\kappa L) + \lambda\frac{2m}{\kappa^2\hbar^2}(\kappa L+3)e^{-\kappa l} \\ e^{-\kappa l}(\kappa L+1) + \lambda\frac{2m}{\kappa^2\hbar^2}(\kappa L+1)e^{-\kappa l} & 1+2e^{-2\kappa l} + \lambda\frac{2m}{\kappa^2\hbar^2}\end{pmatrix} = 0$$

долго подумав над решением этого, мы приходим к ответу:

$$\lambda_1 = \frac{-\hbar^2\kappa^2}{2m}(1 + 2e^{-\kappa l}); \lambda_2 = \frac{-\hbar^2\kappa^2}{2m}(1 - 2e^{-\kappa l}).$$

пришли к успеху.

Б-2.2.18 Стенка и дельта-потенциал (!!!!!!!)

Частица массы m движется в одномерном потенциальном поле вида:

$$U(x) = \begin{cases} +\infty, & x < 0 \\ -A\delta(x-a), & x > 0 \end{cases}$$

Найти зависимость числа связанных состояний от параметров a и A.

Solution.

(???? давно хотел порешать, скоро сделаю это!!! По идее все, как и выше: назац, сшивка)
2.2.18. Единственное связанное состояние в яме существует при $\frac{mAa}{\hbar^2} > \frac{1}{2}$.

17.2.5 Problems about delta-potentials 2

Б-2.2.14 Вылет из δ-ямы при её внезапном ослаблении

Для частицы, находящейся в связанном состоянии в поле δ-ямы найти вероятность «ионизации» при внезапном изменении параметра ямы от $\varkappa_0$ до $\varkappa_1$.

Solution.

Вероятность остаться дается произведением волновых функций, которые известны, а, зная её, очевидна вероятность улететь.

$\psi(x) = \sqrt{\varkappa}\exp(-\varkappa|x|)$,

$$p = |\psi_{\varkappa_1}(x)\psi_{\varkappa_0}(x)|^2 = \left[\int\limits_{-\infty}^{+\infty} \sqrt{\varkappa_1\varkappa_0}e^{-(\varkappa_1+\varkappa_0)|x|}dx\right]^2 = \frac{4\sqrt{\varkappa_1\varkappa_0}}{\varkappa_1\varkappa_0}$$

Тогда вероятность электрона улететь равна

$$W_i = 1 - \frac{4\varkappa_0\varkappa_1}{(\varkappa_0+\varkappa_1)^2} = \left(\frac{\varkappa_0-\varkappa_1}{\varkappa_0+\varkappa_1}\right)^2.$$

Solution. через нахождение вне ямы (????)

(??? а через вероятности быть вне ямы можно было бы решить??? подумаю когда-то)

Б-2.2.15 Прохождение через δ-потенциал

Частица массы m свободно движется вдоль оси x с энергией E и попадает в область действия δ-потенциала. Найти коэффициенты прохождения и отражения, нарисовать графики.

Solution.

(?? вроде особых проблем не должно быть, потом потренируюсь.)
$R = \frac{\varkappa_0^2}{\varkappa_0^2+k^2}$, $\quad D = \frac{k^2}{\varkappa_0^2+k^2}$, где $E = \frac{\hbar^2k^2}{2m} > 0$.
(??? видимо, обозначения для $\varkappa_0$ из задачи вше.)

Ф1-29. Дираковская потенциальная гребенка

Solution.

(?? мб это про Кронинга-Пенни, открою когда-то еще раз)

МФТИ. Двигающиеся дельта-потенциалы (??)

Solution.

Вроде тут преобразование Галилея используется.
вывод его уже я писал, сюда переставлю

ПТФ-5.пр.1 Ионизация δ-ямы

Рассмотрим мелкую 1D яму под действием периодического электрического поля:

$$H = \frac{p^4}{2m} - \frac{\kappa}{m}\delta(x) + e\mathcal{E}x\cos\omega t.$$

Пусть частица находилась в основном состоянии; найдите частоту переходов в состояния непрерывного спектра в однофотонном приближении.

Solution.

Применяем правило Ферми.

$\hat{V} = \psi_i(x) = \sqrt{\kappa}e^{-\kappa|x|}$, переходы будут только в нечётные состояния непрерывного спектра $\psi_k^{(-)}(x) = \sin kx$,

$$F_{fi} = 2e\mathcal{E}\frac{k\kappa^{3/2}}{\left(\kappa^2+k^2\right)^2}$$

(??? этот ответ в другой задаче получен, допишу потом словами ходы для него!)

С учётом плотности состояний $d\nu_f = dk/\pi$, непосредственное применение золотого правила Ферми в таком случае даёт:

$$\frac{1}{\tau} = \int\limits_0^\infty 2\pi|F_{fi}|^2\delta\left(\frac{k^2+\kappa^2}{2m} - \omega\right)\frac{dk}{\pi} = \frac{2e^2\mathcal{E}^2}{m}\cdot\frac{E_0^{3/2}\sqrt{\omega-E_0}}{\omega^4}$$

(тут учтено, что член $+h\omega$, отвечающий испусканию фотона, отсутствует (???))

Б-2.2.19 δ-потенциал через функцию Грина

Найти функцию Грина $G(x,x')$ уравнения Шредингера для свободной частицы при $E < 0$ в одномерном случае. Используя эту функцию, найти энергию связанного состояния частицы в поле

$$U(x) = -\frac{\hbar^2}{m}\varkappa_0\delta(x).$$

Solution.

Функция Грина известна из теории, в рамках этого формализма для дельта-функции интеграл, дающий волновую функцию решается сразу.

$$G(x,x'): \qquad (\hat{\mathrm{H}} - E)G(x,x') = \left\{-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial x^2} - E\right\}G(x,x') = \delta(x-x').$$

$$\delta(x-x') = \int\frac{dk}{2\pi}e^{ik(x-x')}, \quad G(x,x') = \int\frac{dk}{2\pi}\widetilde{G}(k)e^{ik(x-x')}.$$

Подставляя эти разложения в (1), находим ($p = \hbar k, E = -|E| < 0$)

$$\tilde{G}(k) = \frac{1}{\frac{\hbar^2k^2}{2m} + |E|} = \frac{2m}{\hbar^2}\frac{1}{k^2+\varkappa^2} \qquad \varkappa^2 := 2m|E|/\hbar^2$$

$$G(x,x') = \frac{m}{\pi\hbar^2}\int\limits_{-\infty}^{\infty}dk\frac{e^{ik(x-x')}}{k^2+\varkappa^2} = \frac{m}{\hbar^2\varkappa}e^{-\varkappa|x-x'|}.$$

Интеграл вычисляется вычетами, нужно учитывать, что при $x - x' > 0$ контур интегрирования следует замыкать в верхней, а при $x - x' < 0$ - в нижней полуплоскости.

Общее решение уравнения Шредингера при $U(x) \neq 0, E < 0$ с учетом граничных условий при $x \to \pm\infty$ будет выглядеть так:

$$\psi(x) = -\frac{m}{\hbar^2 \varkappa} \int\limits_{-\infty}^{\infty} e^{-\varkappa|x-x'|} U(x') \psi(x') \, dx',$$

выбор $U(x) = -\hbar^2 \varkappa_0 \delta(x)/m$ приводит к результату задачи 2.2.6.
(напишу его)

17.2.6 Problems about oscillator 1

ПТФ-5.пр.1 Возбуждение осциллятора при $U = -F\hat{x}e^{-t^2}$

Найти вероятность перехода в первое и второе возбуждённые состояния гармонического осциллятора под действием силы, которая действует в течении конечного времени:

$$\hat{H} = \frac{\hat{p}^2}{2m} + \frac{m\omega^2\hat{x}^2}{2} - F\hat{x}e^{-t^2/\tau^2},$$

если, при $t \to -\infty$ мы находились в основном состоянии осциллятора $|i\rangle = |0\rangle$;

Solution. для первого состояния

Решаем через правило Ферми.
Найдем $V_{nm}(t)$:

$$V_{nm}(t) = -Fe^{-t^2/\tau^2}\langle n|\hat{x}|m\rangle = -\frac{Fe^{-t^2/\tau^2}}{\sqrt{2m\omega}} \cdot \begin{cases} \sqrt{n}, & m = n-1 \\ \sqrt{n+1}, & m = n+1, \end{cases}$$

отличны от нуля только переходы между соседними уровнями.

$$w_{0\to1} = |-\frac{F}{\sqrt{2m\omega}} \int\limits_{-\infty}^{\infty} e^{-t^2/\tau^2} e^{i\omega t} dt|^2 = \frac{\pi F^2 \tau^2}{2m\omega} e^{-\omega^2\tau^2/2}$$

где $\omega_{10} = \omega$ - разница энергий.
Требуя малость поправки, мы приходим к выводу, что теория возмущений работает по параметру $F^2\tau^2/m\omega \ll 1$ либо $\omega\tau \gg 1$

Solution. для второго состояния

Чтобы найти вероятность перехода во второе возбуждённое состояние, нужно решить уравнение $i\frac{\partial\psi_n}{\partial t} = \sum\limits_m V_{nm}^{(I)}(t)\psi_m(t)$ точнее, а именно, во 2-м порядке ТВ:

$$\partial_t \psi_2^{(2)}(t) = -i \int\limits_{-\infty}^{t} d\tau_1 V_{21}^{(I)}(\tau_1) \psi_1^{(1)}(\tau_1) = (-i)^2 \int\limits_{-\infty}^{t} d\tau_1 V_{21}^{(I)}(\tau_1) \int\limits_{-\infty}^{\tau_1} d\tau_2 V_{10}^{(I)}(\tau_2)$$

$$w_{0\to2} = |\int\limits_{-\infty}^{\infty} d\tau_1 V_{21}(\tau_1) e^{i\omega\tau_1} \int\limits_{-\infty}^{\tau_1} d\tau_2 V_{10}(\tau_2) e^{i\omega\tau_2}|^2 =$$

$$= \frac{2F^4}{(2m\omega)^2} |\int\limits_{-\infty}^{\infty} d\tau_1 e^{-\tau_1^2/\tau^2 + i\omega\tau_1} \int\limits_{-\infty}^{\tau_1} d\tau_2 e^{-\tau_2^2/\tau^2 + i\omega\tau_2}|^2$$

(?? ниже хз, вообще нет идей, почему это так???)
Можно заметить, что стоящий тут интеграл равен половине такого же интеграла, но с бесконечными пределами $\int\limits_{-\infty}^{\infty} d\tau_1 \int\limits_{-\infty}^{\infty} d\tau_2$ благодаря чему мы можем сразу выписать для него результат:

$$w_{0\to2} = \frac{\pi^2 F^4 \tau^4}{8m^2\omega^2} e^{-\omega^2\tau^2}$$

Полученный результат оказался параметрически меньше $w_{0\to1}$, поскольку он связан со вторым порядком теории возмущений.

ПТФ-6.у2. Квантовый гармонический осциллятор (10 б)

• Вычислите $\langle \hat{x}^4 \rangle$ по произвольному собственному состоянию гармонического осциллятора $|n\rangle$.
• Частица находилась в основном состоянии гармонического осциллятора с частотой ω. Пусть в какой-то момент времени характерная частота осциллятора мгновенно меняется и становится равной ω'. Вычислите вероятность остаться в основном состоянии.

Solution.

• Действие операторов повышения и понижения:

$$\hat{a}|n\rangle = \sqrt{n}|n\rangle, \quad \hat{a}^\dagger|n\rangle = \sqrt{n+1}|n\rangle$$

$$\hat{x} = \sqrt{\frac{\hbar}{2m\omega}}(\hat{a} + \hat{a}^\dagger)$$

$$\langle x^4 \rangle = \langle n|\hat{x}^4|n\rangle = \frac{\hbar^2}{4m^2\omega^2}\langle n|(\hat{a}^2 + \hat{a}\hat{a}^\dagger + \hat{a}^\dagger\hat{a} + (\hat{a}^\dagger)^2)^2|n\rangle = \frac{\hbar^2}{4m^2\omega^2}\langle n|\hat{a}^4 + \hat{a}^3\hat{a}^\dagger + \hat{a}^2\hat{a}^\dagger\hat{a} +$$
$$+ \hat{a}^2(\hat{a}^\dagger)^2 + \hat{a}\hat{a}^\dagger\hat{a}^2 + \hat{a}\hat{a}^\dagger\hat{a}\hat{a}^\dagger + \hat{a}(\hat{a}^\dagger)^2\hat{a} + \hat{a}(\hat{a}^\dagger)^3 + \hat{a}^\dagger\hat{a}^3 + \hat{a}^\dagger\hat{a}^2\hat{a}^\dagger + \hat{a}^\dagger\hat{a}\hat{a}^\dagger\hat{a} + \hat{a}^\dagger\hat{a}(\hat{a}^\dagger)^2 + (\hat{a}^\dagger)^2\hat{a}^2 +$$
$$+ (\hat{a}^\dagger)^2\hat{a}\hat{a}^\dagger + (\hat{a}^\dagger)^3\hat{a} + (\hat{a}^\dagger)^4|n\rangle = \frac{\hbar^2}{4m^2\omega^2}((n+1)(n+2) + (n+1)^2 + n(n+1) + n(n+1) + n^2 + n(n-1))$$

$$\langle x^4 \rangle = \frac{3\hbar^2}{4m^2\omega^2}(2n^2 + 2n + 1)$$

• Волновая функция основного состояния:

$$\psi(x) = \sqrt[4]{\frac{m\omega}{\pi\hbar}} \exp\left(-\frac{m\omega x^2}{2\hbar}\right)$$

$$P = \left|\int_{-\infty}^{\infty} \psi^*(x)\psi'(x)dx\right|^2 = \left|\sqrt[4]{\frac{m^2\omega\omega'}{\pi^2\hbar^2}} \int_{-\infty}^{\infty} \exp\left(-\frac{m(\omega+\omega')x^2}{2\hbar}\right) dx\right|^2$$

$$P = \frac{2\sqrt{\omega\omega'}}{\omega + \omega'}$$

ПТФ-6.у3. Когерентные состояния

Когерентные состояния гармонического осциллятора определяются как собственные состояния для понижающего оператора $\hat{a}$ с собственным комплексным числом $\alpha \in \mathbb{C} : \hat{a}|\alpha\rangle = \alpha|\alpha\rangle$.
• Найдите координатное представление когерентного состояния $\psi_\alpha(x) \equiv \langle x|\alpha\rangle$. Для гамильтониана квантового гармонического осциллятора $\hat{H} = \hbar\omega(\hat{a}^\dagger\hat{a} + \frac{1}{2})$, найдите также $\psi_\alpha(x,t) \equiv \langle x|\alpha(t)\rangle$.
• Выразите когерентное состояние α явно через собственные состояния осциллятора, нормировав его условием $\langle 0|\alpha\rangle = 1$.
• Представьте их в виде $|\alpha\rangle = \hat{C}(\alpha)|0\rangle$; найдите явный вид оператора $\hat{C}(\alpha)$.
• Вычислите перекрытие когерентных состояний $\langle\alpha|\alpha'\rangle$.
• Когерентные состояния образуют *переполненный базис*. Докажите следующую формулу для разложения единицы:

$$\hat{\mathbb{I}} = \int \frac{d\alpha d\alpha^*}{\pi} e^{-|\alpha|^2} |\alpha\rangle\langle\alpha|$$

(мы определили $d\alpha d\alpha^* \equiv d(\mathrm{Re}\alpha)d(\mathrm{Im}\alpha)$).

Solution.

• Оператор уничтожения:

$$\hat{a} = \sqrt{\frac{m\omega}{2\hbar}}\hat{x} + \frac{i}{\sqrt{2\hbar m\omega}}\hat{p}$$
$$\langle x|\hat{a}|\alpha\rangle = \alpha\langle x|\alpha\rangle = \alpha\psi_\alpha(x)$$

$$\left(\sqrt{\frac{m\omega}{2\hbar}}\hat{x}+\frac{i}{\sqrt{2\hbar m\omega}}\hat{p}\right)\psi_\alpha(x)=\alpha\psi_\alpha(x)$$

$$\left(\sqrt{\frac{m\omega}{2\hbar}}x+\sqrt{\frac{\hbar}{2m\omega}}\frac{\partial}{\partial x}\right)\psi_\alpha(x)=\alpha\psi_\alpha(x)$$

$$\sqrt{\frac{\hbar}{2m\omega}}\frac{\partial\psi_\alpha(x)}{\partial x}=\left(\alpha-\sqrt{\frac{m\omega}{2\hbar}}x\right)\psi_\alpha(x)$$

$$\psi_\alpha(x)=e^{\sqrt{\frac{2m\omega}{\hbar}}\alpha x-\frac{m\omega x^2}{2\hbar}}$$

Действие оператора эволюции (воспользуемся п. 2 этой задачи):

$$|\alpha,t\rangle=\hat{U}(t)|\alpha\rangle=\sum_n\frac{\alpha^n}{\sqrt{n!}}e^{-\frac{iE_nt}{\hbar}}|n\rangle$$

$$E_n=\hbar\omega\left(\frac{1}{2}+n\right)$$

$$|\alpha,t\rangle=e^{-\frac{i\omega t}{2}}\sum_n\frac{\alpha^n}{\sqrt{n!}}e^{-i\omega nt}|n\rangle=e^{-\frac{i\omega t}{2}}\sum_n\frac{(\alpha e^{-i\omega t})^n}{\sqrt{n!}}|n\rangle$$

$$\psi_\alpha(x,t)\equiv\langle x|\alpha(t)\rangle=e^{-\frac{i\omega t}{2}}\sum_n\frac{(\alpha e^{-i\omega t})^n}{\sqrt{n!}}\langle x|n\rangle$$

$$\psi_\alpha(x,t)=e^{-\frac{i\omega t}{2}}\sum_n\frac{(\alpha e^{-i\omega t})^n}{\sqrt{2^nn!}}\sqrt[4]{\frac{m\omega}{\pi\hbar}}H_n\left(x\sqrt{\frac{m\omega}{\hbar}}\right)$$

- Разложим когеренстное состояние по базису:

$$|\alpha\rangle=\sum_n C_n(\alpha)|n\rangle,\quad C_n(\alpha)=\langle n|\alpha\rangle=\frac{1}{\alpha}\langle n|\hat{a}\alpha\rangle=\frac{1}{\alpha}\langle\hat{a}^\dagger n|\alpha\rangle$$

$$\hat{a}^\dagger|n\rangle=\sqrt{n+1}|n+1\rangle$$

Получаем рекуррентное соотношение:

$$\alpha C_n(\alpha)=\sqrt{n+1}C_{n+1}(\alpha)\to C_n(\alpha)=\frac{\alpha^n}{\sqrt{n!}}C_0(\alpha)$$

Условие нормировки:

$$C_0(\alpha)=\langle 0|\alpha\rangle=1$$

$$|\alpha\rangle=\sum_n\frac{\alpha^n}{\sqrt{n!}}|n\rangle$$

$$|n\rangle=\frac{(\hat{a}^\dagger)^n}{\sqrt{n!}}|0\rangle$$

$$|\alpha\rangle=\sum_n\frac{(\alpha a^\dagger)^n}{n!}|0\rangle=e^{\alpha\hat{a}^\dagger}|0\rangle=C(\alpha)|0\rangle$$

$$C(\alpha)=e^{\alpha\hat{a}^\dagger}$$

$$\langle\alpha|\alpha'\rangle=\langle 0|\hat{C}^\dagger(\alpha)\hat{C}(\alpha')|0\rangle=\langle 0|e^{\alpha^*\hat{a}}e^{\alpha'\hat{a}^\dagger}|0\rangle=\left\langle 0\left|\sum_{k=0}^\infty\frac{(\alpha^*\hat{a})^k}{k!}\sum_{n=0}^\infty\frac{(\alpha'\hat{a}^\dagger)^n}{n!}\right|0\right\rangle=$$

$$=\left\langle k\left|\sum_{k=0}^\infty\frac{\hat{a}^k}{\sqrt{k!}}\sum_{n=0}^\infty\frac{\alpha'^n}{\sqrt{n!}}\right|n\right\rangle=\sum_{k=0}^\infty\frac{(\alpha^*)^k}{\sqrt{k!}}\sum_{n=0}^\infty\frac{(\alpha')^n}{\sqrt{n!}}\delta_{kn}=\sum_{n=0}^\infty\frac{(\alpha^*\alpha')^n}{n!}=e^{\alpha^*\alpha'}$$

$$\langle\alpha|\alpha'\rangle=e^{\alpha^*\alpha'}$$

- $$\langle m|\hat{\mathbb{I}}|n\rangle=\delta_{mn}$$

$$\left\langle m \left| \int \frac{d\alpha d\alpha^*}{\pi} e^{-|\alpha|^2} |\alpha\rangle\langle\alpha| \right| n \right\rangle = \int \frac{d\alpha d\alpha^*}{\pi} e^{-|\alpha|^2} \langle m|\alpha\rangle\langle\alpha|n\rangle = \int \frac{d\alpha d\alpha^*}{\pi} e^{-|\alpha|^2} \frac{(\alpha^*)^m}{\sqrt{m!}} \frac{\alpha^n}{\sqrt{n!}}$$

$$\alpha = re^{i\varphi}, \qquad d(\mathrm{Re}\alpha)d(\mathrm{Im}\alpha) = rdrd\varphi$$

$$\int_0^\infty \int_0^{2\pi} \frac{drd\varphi}{\pi} re^{-r^2} \frac{r^{m+n}e^{i(n-m)\varphi}}{\sqrt{m!n!}} = \frac{1}{\sqrt{m!n!}} \int_0^\infty drr^{m+n+1}e^{-r^2} \int_0^{2\pi} \frac{d\varphi}{\pi} e^{i(n-m)\varphi} =$$

$$= \frac{2}{\sqrt{m!n!}} \int_0^\infty drr^{m+n+1}e^{-r^2}\delta_{nm} = \frac{1}{m!} \int_0^\infty d(r^2)r^{2m}e^{-r^2}\delta_{mn} = \frac{\Gamma(m+1)}{m!}\delta_{mn} = \delta_{mn}$$

Таким образом,

$$\hat{\mathbb{I}} = \int \frac{d\alpha d\alpha^*}{\pi} e^{-|\alpha|^2} |\alpha\rangle\langle\alpha|$$

ПТФ-6.з1. Теорема Вика

Квантовый гармонический осциллятор находится при температуре T, т.е. описывается матрицей плотности $\hat{\rho} = \frac{1}{Z}e^{-\beta\omega\hat{a}^\dagger\hat{a}}$. Вычислите среднее значение по этому состоянию от оператора $\langle e^{\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger}\rangle$ и докажите следующее соотношение:

$$\langle e^{\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger}\rangle = e^{\frac{1}{2}\langle(\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger)^2\rangle}$$

Указание: вам может пригодиться базис когерентных состояний, а также формула Бейкера-Кэмбелла-Хаусдорфа:

$$e^{\hat{A}+\hat{B}} = e^{\hat{A}}e^{\hat{B}}e^{-\frac{1}{2}[\hat{A},\hat{B}]}, \quad [\hat{A},[\hat{A},\hat{B}]] = [\hat{B},[\hat{A},\hat{B}]] = 0$$

Solution.

Рассмотрим $\hat{O} = e^{\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger}$.

$$\langle\hat{O}\rangle = \mathrm{Tr}(\hat{\rho}\hat{O}) = \mathrm{Tr}\left(\frac{1}{Z}e^{-\beta\omega\hat{a}^\dagger\hat{a}}e^{\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger}\right)$$

$$\langle\hat{O}\rangle = \mathrm{Tr}\left(\frac{1}{Z}e^{-\beta\omega\hat{a}^\dagger\hat{a}}e^{\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger}\right) = \frac{1}{Z}\int \frac{d\alpha d\alpha^*}{\pi} e^{-|\alpha|^2}\langle\alpha|e^{\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger}e^{-\beta\omega\hat{a}^\dagger\hat{a}}|\alpha\rangle$$

$$e^{\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger} = e^{\alpha_1\hat{a}}e^{\alpha_2\hat{a}^\dagger}e^{-\frac{\alpha_1\alpha_2}{2}[\hat{a}^\dagger,\hat{a}]} = e^{\alpha_1\hat{a}}e^{\alpha_2\hat{a}^\dagger}e^{\frac{\alpha_1\alpha_2}{2}}$$

$$\langle\hat{O}\rangle = \frac{1}{Z}\int \frac{d\alpha d\alpha^*}{\pi} e^{-|\alpha|^2}e^{\alpha_2\alpha^*}e^{\frac{\alpha_1\alpha_2}{2}}\langle\alpha|e^{\alpha_1\hat{a}}e^{-\beta\omega\hat{a}^\dagger\hat{a}}|\alpha\rangle$$

$$e^{-\beta\omega\hat{a}^\dagger\hat{a}}|\alpha\rangle = e^{-\beta\omega\hat{a}^\dagger\hat{a}}\sum_{n=0}^\infty \frac{\alpha^n}{\sqrt{n!}}|n\rangle = \sum_{n=0}^\infty \frac{\alpha^n}{\sqrt{n!}}e^{-\beta\omega n}|n\rangle = e^{-\beta\omega}|n\rangle$$

$$\langle\hat{O}\rangle = \frac{e^{\frac{\alpha_1\alpha_2}{2}}}{Z}\int \frac{d\alpha d\alpha^*}{\pi} e^{-|\alpha|^2}e^{\alpha_2\alpha^*}e^{\alpha_1\alpha e^{-\beta\omega}}\langle\alpha|e^{-\beta\omega}|\alpha\rangle =$$

$$= \frac{e^{\frac{\alpha_1\alpha_2}{2}}}{Z}\int \frac{d\alpha d\alpha^*}{\pi} e^{-|\alpha|^2(1-e^{-\beta\omega})}e^{\alpha_2\alpha^*}e^{\alpha_1\alpha e^{-\beta\omega}}$$

$$\langle\hat{O}\rangle = \frac{e^{\frac{\alpha_1\alpha_2}{2}}}{Z}(1-e^{-\beta\omega})\int_{-\infty}^\infty \frac{du}{\sqrt{\pi}} e^{-(u^2-\frac{\alpha_2+\alpha_1e^{-\beta\omega}}{\sqrt{1-e^{-\beta\omega}}}u)} \int_{-\infty}^\infty \frac{du}{\sqrt{\pi}} e^{-(u^2+i\frac{\alpha_2-\alpha_1e^{-\beta\omega}}{\sqrt{1-e^{-\beta\omega}}}u)}$$

$$Z = \mathrm{Tr}(e^{-\beta\omega\hat{a}^\dagger\hat{a}}) = \sum_{n=0}^\infty \langle n|e^{-\beta\omega\hat{a}^\dagger\hat{a}}|n\rangle = \sum_{n=0}^\infty \langle n|e^{-\beta\omega n}|n\rangle = \sum_{n=0}^\infty e^{-\beta\omega n} = \frac{1}{1-e^{-\beta\omega}}$$

$$\langle\hat{O}\rangle = e^{\frac{\alpha_1\alpha_2}{2}}e^{\frac{(\alpha_2+\alpha_1e^{-\beta\omega})^2}{4(1-e^{-\beta\omega})}}e^{-\frac{(\alpha_2-\alpha_1e^{-\beta\omega})^2}{4(1-e^{-\beta\omega})}} = e^{\frac{\alpha_1\alpha_2}{2}\left(\frac{1+e^{-\beta\omega}}{1-e^{-\beta\omega}}\right)}$$

$$\langle e^{\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger}\rangle = e^{\frac{\alpha_1\alpha_2}{2}\coth\frac{\beta\omega}{2}}$$

Рассмотрим $\hat{O} = (\alpha_1\hat{a} + \alpha_2\hat{a}^\dagger)^2$.

$$\begin{aligned}
\langle\hat{O}\rangle &= \mathrm{Tr}(\hat{\rho}\hat{O}) = \mathrm{Tr}\left(\frac{1}{Z}e^{-\beta\omega\hat{a}^\dagger\hat{a}}(\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger)^2\right) = \\
&= \sum_{n=0}^{\infty}\left\langle n\left|\frac{1}{Z}e^{-\beta\omega\hat{a}^\dagger\hat{a}}(\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger)^2\right|n\right\rangle = \\
&= \frac{1}{Z}\sum_{n=0}^{\infty}\left\langle n\left|\frac{1}{Z}e^{-\beta\omega\hat{a}^\dagger\hat{a}}(\alpha_1^2\hat{a}^2+\alpha_1\alpha_2\hat{a}\hat{a}^\dagger+\alpha_1\alpha_2\hat{a}^\dagger\hat{a}+\alpha_2^2\hat{a}^{\dagger 2})\right|n\right\rangle = \\
&= \frac{\alpha_1\alpha_2}{Z}\sum_{n=0}^{\infty}\langle n|e^{-\beta\omega\hat{a}^\dagger\hat{a}}(2n+1)|n\rangle = \\
&= \frac{\alpha_1\alpha_2}{Z}\sum_{n=0}^{\infty}e^{-\beta\omega n}(2n+1) = \frac{\alpha_1\alpha_2}{Z}\frac{1+e^{-\beta\omega}}{(1-e^{-\beta\omega})^2} = \\
&= \alpha_1\alpha_2\frac{1+e^{-\beta\omega}}{1-e^{-\beta\omega}} = \alpha_1\alpha_2\coth\frac{\beta\omega}{2}
\end{aligned}$$

$$e^{\frac{1}{2}\langle(\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger)^2\rangle} = e^{\frac{\alpha_1\alpha_2}{2}\coth\frac{\beta\omega}{2}} = \langle e^{\alpha_1\hat{a}+\alpha_2\hat{a}^\dagger}\rangle$$

Таким образом, теорема Вика доказана.

ПТФ-6.з2. Oscillator in a box

Квантовый гармонический осциллятор помещён в большую коробку размера $2L$ ровно посередине:

$$U(x) = \begin{cases}\frac{m\omega^2x^2}{2}, & |x| < L\\ \infty, & |x| > L\end{cases}$$

Определите *силу*, с которой осциллятор, находясь в одном из низколежащих уровней энергии $n \ll \frac{m\omega L^2}{\hbar}$, действует на эти стенки.

Solution.

Мы знаем общее решение, нужно подставить граничные условия и получить условие на поправку к энергии. (??? как догадаться про матем преобразования тут??? это еще в 1 части указывать буду!)

Общее решение в области $|x| < L$:

$$\psi(y) = C_1{}_1F_1\left(-\frac{\varepsilon}{2},\frac{1}{2},y^2\right)e^{-\frac{y^2}{2}} + C_2y_1F_1\left(-\frac{\varepsilon-1}{2},\frac{3}{2},y^2\right)e^{-\frac{y^2}{2}} = C_1\psi_1(y) + C_2\psi_2(y)$$

$$x_\pm := \pm L \qquad \Rightarrow \qquad y := \pm L\sqrt{\frac{m\omega}{\hbar}}$$

$$\psi\left(\pm L\sqrt{\frac{m\omega}{\hbar}}\right) = 0$$

First we consider the first part of ψ:

$${}_1F_1\left(-\frac{\varepsilon}{2},\frac{1}{2},y^2\right)e^{-\frac{m\omega L^2}{\hbar}} = 0$$

Поскольку $\frac{m\omega L^2}{\hbar} \gg 1$, то воспользуемся ${}_1F_1(a,b,z) \approx \frac{\Gamma(b)}{\Gamma(a)}e^zz^{a-b} + \frac{\Gamma(b)}{\Gamma(b-a)}(-z)^{-a}$:

$$\frac{\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(-\frac{\varepsilon}{2}\right)}e^zz^{-\frac{\varepsilon+1}{2}} + \frac{\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\frac{\varepsilon+1}{2}\right)}(-z)^{\frac{\varepsilon}{2}} = 0$$

$$e^z + \frac{\Gamma(-\frac{\varepsilon}{2})}{\Gamma(\frac{\varepsilon+1}{2})}(-1)^{\frac{\varepsilon}{2}}z^{\varepsilon+\frac{1}{2}} = 0$$

Here we have:

$$\Gamma\left(-\frac{\varepsilon}{2}\right)\Gamma\left(1+\frac{\varepsilon}{2}\right)=\frac{\pi}{\sin\left(-\frac{\pi\varepsilon}{2}\right)}$$

$$\frac{\Gamma\left(-\frac{\varepsilon}{2}\right)}{\Gamma\left(\frac{\varepsilon+1}{2}\right)}=-\frac{\pi}{\sin\frac{\pi\varepsilon}{2}\Gamma\left(1+\frac{\varepsilon}{2}\right)\Gamma\left(\frac{1+\varepsilon}{2}\right)}=-\frac{2^{\varepsilon}\sqrt{\pi}}{\sin\frac{\pi\varepsilon}{2}\Gamma(1+\varepsilon)}=-\frac{2^{\varepsilon}\sqrt{\pi}}{\sin\frac{\pi\varepsilon}{2}\varepsilon\Gamma(\varepsilon)}$$

because $\Gamma(z)\Gamma\left(z+\frac{1}{2}\right)=2^{1-2z}\sqrt{\pi}\Gamma(2z)$;

$$\Gamma(\varepsilon)=\Gamma(n+\delta n)=(n-1+\delta n)...(1+\delta n)\Gamma(1+\delta n)\approx\Gamma(n)$$

(??? почему эпсилон так от н зависит и какой смысл в вариации н?? это важная часть метода!!! впишу в 1ю про это?)

$$\frac{\Gamma\left(-\frac{\varepsilon}{2}\right)}{\Gamma\left(\frac{\varepsilon+1}{2}\right)}=-\frac{2^{n}\sqrt{\pi}}{\sin(\frac{\pi n}{2}+\frac{\pi\delta n}{2})n\Gamma(n)\Gamma(1+\delta n)}\approx\begin{cases}-\frac{(-1)^{k}2^{n}\sqrt{\pi}}{n\Gamma(n)}, & n=2k+1\\ -\frac{(-1)^{k}2^{n+1}}{\sqrt{\pi}n\delta n\Gamma(n)}, & n=2k\end{cases}$$

and we can substitute it:

$$e^{z}-\frac{2^{n+1}\sqrt{\pi}}{\pi\delta nn\Gamma(n)}z^{n+\frac{1}{2}}=0\quad(n=2k)$$

$$\delta n=\frac{e^{-z}2^{n+1}}{\sqrt{\pi}n\Gamma(n)}z^{n+\frac{1}{2}}$$

Now, the second part and apply the same algorithm:

$${}_1F_1\left(-\frac{\varepsilon-1}{2},\frac{3}{2},\frac{m\omega L^2}{\hbar}\right)e^{-\frac{m\omega L^2}{2\hbar}}=0$$

$$\frac{\Gamma\left(\frac{3}{2}\right)}{\Gamma\left(-\frac{\varepsilon-1}{2}\right)}e^{z}z^{-\frac{\varepsilon}{2}-1}+\frac{\Gamma\left(\frac{3}{2}\right)}{\Gamma\left(\frac{\varepsilon+1}{2}\right)}(-z)^{\frac{\varepsilon-1}{2}}=0$$

$$e^{z}+\frac{\Gamma\left(-\frac{\varepsilon-1}{2}\right)}{\Gamma\left(1+\frac{\varepsilon}{2}\right)}(-1)^{\frac{\varepsilon+1}{2}}z^{\varepsilon+\frac{1}{2}}=0$$

$$\Gamma\left(-\frac{\varepsilon-1}{2}\right)\Gamma\left(\frac{\varepsilon+1}{2}\right)=\frac{\pi}{\sin\left(-\frac{\pi(\varepsilon-1)}{2}\right)}$$

$$\frac{\Gamma\left(-\frac{\varepsilon-1}{2}\right)}{\Gamma\left(1+\frac{\varepsilon}{2}\right)}=-\frac{\pi}{\sin\left(\frac{\pi(\varepsilon-1)}{2}\right)\Gamma\left(\frac{\varepsilon}{2}+1\right)\Gamma\left(\frac{1+\varepsilon}{2}\right)}=-\frac{\pi}{\sqrt{\pi}2^{-\varepsilon}\varepsilon\Gamma(\varepsilon)\sin\left(\frac{\pi(\varepsilon-1)}{2}\right)}=$$

$$=-\frac{2^{\varepsilon}\sqrt{\pi}}{\sin\left(\frac{\pi}{2}(n-1)+\frac{\pi}{2}\delta n\right)n\Gamma(n)}\approx\begin{cases}\frac{(-1)^{k}2^{\varepsilon}\sqrt{\pi}}{n\Gamma(n)}, & n=2k+1\\ \frac{(-1)^{k}2^{\varepsilon+1}}{\sqrt{\pi}n\delta n\Gamma(n)}, & n=2k\end{cases}$$

$$e^{z}-\frac{2^{n+1}\sqrt{\pi}}{\pi\delta nn\Gamma(n)}z^{n+\frac{1}{2}}=0\quad(n=2k+1)$$

$$\delta n=\frac{e^{-z}2^{n+1}}{\sqrt{\pi}n\Gamma(n)}z^{n+\frac{1}{2}},$$

which is the same. Таким образом,

$$\forall n\in\mathbb{Z}\quad\delta n=e^{-\frac{m\omega L^2}{\hbar}}\left(\frac{m\omega L^2}{\hbar}\right)^{n+\frac{1}{2}}\frac{2^{n+1}}{\sqrt{\pi}\Gamma(n+1)}.$$

$$E_n=\hbar\omega\left(\frac{1}{2}+n+\frac{2^{n+1}e^{-\frac{m\omega L^2}{\hbar}}\left(\frac{m\omega L^2}{\hbar}\right)^{n+\frac{1}{2}}}{\sqrt{\pi}\Gamma(n+1)}\right)$$

$$F_n=-\frac{\partial E_n}{\partial L}\approx\frac{2^{n+2}m\omega^2Le^{-\frac{m\omega L^2}{\hbar}}\left(\frac{m\omega L^2}{\hbar}\right)^{n+\frac{1}{2}}}{\sqrt{\pi}\Gamma(n+1)}$$

Б-2.3.7.б) Oscillator near a wall

Найти энергетические уровни частицы, движущейся в потенциальном поле вида

$$V(x) = \begin{cases} \infty, & x \leqslant 0 \\ \frac{m\omega^2 x^2}{2}, & x > 0 \end{cases}$$

Solution.

б) $E'_n = E_{2n+1} = \hbar\omega(2n + 1 + 1/2) = 2\hbar\omega(n + 3/4)$.

Б-2.3.1 Импульсы основного состояния (???)

Найти распределение по импульсам для основного состояния гармонического осциллятора.

Solution.

(волновую функцию в импульсном представлении, то есть преобразование фурье сделать от нее в координатном??)

Б-2.3.2 Средние x^2 и p^2

Для одномерного гармонического осциллятора вычислить $\langle n|\hat{\mathrm{x}}^2|n\rangle$, $\langle n|\hat{\mathrm{p}}^2|n\rangle$ и сравнить с классическим результатом для x^2 и p^2.

Solution.

Воспользуемся выражениями

$$\hat{x} = \frac{x_0}{\sqrt{2}}\left(\hat{a}^+ + \hat{a}\right), \quad \hat{\mathrm{p}} = i\frac{p_0}{\sqrt{2}}\left(\hat{a}^+ - \hat{a}\right), \quad x_0 = \sqrt{\frac{\hbar}{m\omega}}, p_0 = \sqrt{\hbar m\omega}.$$

Тогда получим, что

$$\langle\hat{x}^2\rangle = \langle n|\hat{x}^2|n\rangle = \frac{x_0^2}{2}\langle n|\hat{a}^+\hat{a} + \hat{a}\hat{a}^+|n\rangle = x_0^2\left(n + \frac{1}{2}\right) = \frac{E_n}{m\omega^2},$$
$$\langle\hat{\mathrm{p}}^2\rangle = \langle n|\hat{\mathrm{p}}^2|n\rangle = \frac{p_0^2}{2}\langle n|\hat{a}^+\hat{a} + \hat{a}\hat{a}^+|n\rangle = p_0^2\left(n + \frac{1}{2}\right) = mE_n,$$

где $E_n = \hbar\omega(n + 1/2)$ - энергия квантового осциллятора.

Для классического осциллятора общее решение уравнений движения имеет вид

$$x_{\text{кл}} = A\sin(\omega t + \varphi), \quad p_{\text{кл}} = m\omega A\cos(\omega t + \varphi),$$

где A - амплитуда колебаний, а φ - начальная фаза. Нетрудно найти

$$\overline{x^2_{\text{cl}}} = \frac{1}{T}\int\limits_0^T A^2\sin^2(\omega t + \varphi)dt = \frac{A^2}{2} = \frac{E_{\text{K}}}{m\omega^2},$$
$$\overline{p^2_{\text{K}\Omega}} = (m\omega)^2\overline{x^2_{\text{K}}} = mE_{\text{K}\Omega}.$$

Согласно принципу соответствия в пределе $n \to \infty$ выражения для квантовых средних должны переходить в соответствующие выражения для классических средних для одного и того же значения энергии ($E_n = E_{\text{кл}}$). Для гармонического осциллятора данное равенство выполняется не только при $n \to \infty$, но и для любых n.

Б-2.3.3 Средние $\hat{x}^4$ и $\hat{x}^{2k+1}$

Воспользовавшись понижающим и повышающим операторами, $\hat{a}$ и $\hat{a}^+$, найдите средние значения операторов $\hat{x}^4$ и $\hat{x}^{2k+1}$ в n-м стационарном состоянии линейного гармонического осциллятора.

Solution.

(решается прямолинейно, ничего сложного)
Ответ: $\langle\hat{x}^4\rangle = \langle n|\hat{x}^4|n\rangle = \frac{x_0^4}{4}\left(6n^2+6n+3\right)$, $\langle\hat{x}^{2k+1}\rangle = \langle n|\hat{x}^{2k+1}|n\rangle = 0, \quad k = 0, 1, ...$

Б-2.3.4 Дисперсии в осцилляторе

Вычислить произведение дисперсий $\Delta\mathrm{p}\Delta\mathrm{x}$ для n-го состояния осциллятора.

Solution.

Можно дисперсии выразить через среднее значения, которые известно, как посчитать:

$$\Delta\mathrm{p}\Delta\mathrm{x} = \sqrt{\langle\Delta\mathrm{p}^2\rangle}\sqrt{\langle\Delta\mathrm{x}^2\rangle} = E_n/\omega = \hbar(n+1/2),$$

где

$$\langle\hat{x}^2\rangle = \langle n|\hat{x}^2|n\rangle = \frac{x_0^2}{2}\langle n|\hat{a}^+\hat{a}+\hat{a}\hat{a}^+|n\rangle = x_0^2\left(n+\frac{1}{2}\right) = \frac{E_n}{m\omega^2},$$
$$\langle\hat{\mathrm{p}}^2\rangle = \langle n|\hat{\mathrm{p}}^2|n\rangle = \frac{p_0^2}{2}\langle n|\hat{a}^+\hat{a}+\hat{a}\hat{a}^+|n\rangle = p_0^2\left(n+\frac{1}{2}\right) = mE_n,$$

Б-2.3.5

Найти для гармонического осциллятора $\hat{a}$ и $\hat{a}^+$в представлении Гейзенберга.

Solution.

2.3.5. $\hat{a}_H = \hat{a}\exp(-i\omega t), \hat{a}_H^+ = \hat{a}^+\exp(i\omega t)$. Использовать результат задачи 2.1.17.

Б-2.3.6

Вычислить $[\hat{a}, f(\hat{a}^+)]$, если $[\hat{a}, \hat{a}^+] = 1$.

Solution.

17.2.7 Problems about oscillator 2

Leuven.s5. Oscillator in linear potential

We consider a 1D harmonic oscillator perturbed by a small linear potential, i.e.

$$\hat{H} = \frac{\hat{p}^2}{2m} + \frac{1}{2}m\omega^2\hat{x}^2 - \lambda\hat{x}$$

with $0 < \lambda \ll 1$.
(a) Compute the energy shift for a state $|n\rangle$ up to the first non-vanishing order.
(b) Find the exact solution to this problem and compare it to the pertubative solution.

Solution.

The main idea is to use time independent PT, it is an easy problem, can be done in 2-5 minutes.

$$\hat{x} = \sqrt{\frac{\hbar}{2m\omega}}\left(\hat{a}+\hat{a}^\dagger\right), \quad \hat{a}|n\rangle = \sqrt{n}|n-1\rangle, \quad \hat{a}^\dagger|n\rangle = \sqrt{n+1}|n+1\rangle$$

$$V_{kn} = \langle k|\hat{V}|n\rangle = -\lambda\frac{\hbar}{2m\omega}\left(\sqrt{n}\delta_{k,n-1}+\sqrt{n+1}\delta_{k,n+1}\right)$$

$$\Delta_n^{(1)} = V_{nn} = 0,$$

$$\Delta_n^{(2)} = \sum_{k \neq n} \frac{|V_{kn}|^2}{E_n^{(0)} - E_k^{(0)}} = -\frac{\lambda^2}{2m\omega^2}$$

The analytical solution is obtained by $\hat{H} \equiv \frac{\hat{p}^2}{2m} + \frac{1}{2}m\omega^2(\hat{x} - \frac{\lambda}{m\omega^2})^2 - \frac{\lambda^2}{2m\omega^2}$. If we define $\hat{y}_\cdot = \left(\hat{x} - \frac{\lambda}{m\omega^2}\right)$, we see that difference in energy is $-\frac{\lambda^2}{2m\omega^2}$.

Б-2.3.7.а) Вне границ

Частица движется в потенциальном поле $V(x) = \frac{m\omega^2 x^2}{2}$. Определить вероятность нахождения частицы вне классических границ для основного состояния.

Solution.

По смыслу волновой функции сразу пишем ответ, нужно лишь размерности удобные подобрать.
Ответ: $w = \frac{\int_1^\infty e^{-y^2} dy}{\int_0^\infty e^{-y^2} dy} \simeq 0,16$.

Б-2.3.8 Импульсный осциллятор

Написать уравнение Шредингера для осциллятора в p-представлении и определить распределение вероятностей различных значений импульса.

Solution.

(???? тут не уверен, почему именно спецфункция Генкеля решает это? и какой график их???)
2.3.8. $\left(\frac{p^2}{2m} - \frac{m\omega^2\hbar^2}{2}\frac{d^2}{dp^2}\right)\phi_n(p) = E_n\phi_n(p)$

$$|\phi_n(p)|^2 dp = \frac{1}{2^n n!\sqrt{\pi}p_0} \exp\left[-\left(\frac{p}{p_0}\right)^2\right] H_n^2\left(\frac{p}{p_0}\right) dp.$$

Б-2.3.9

Для когерентного состояния осциллятора $|z\rangle$ показать, что

$$\frac{\langle z|\hat{\mathrm{H}}|z\rangle}{\langle z|z\rangle} = \hbar\omega\left(|z|^2 + 1/2\right),$$

где $\hat{\mathrm{H}}$ - гамильтониан гармонического осциллятора с частотой ω.

Solution.

(чет так я хз, как решать, но вроде это у нас как раз энергия, может какая-то теорема Фейнмана-Хеллмана поможет?)
2.3.9. Когерентное состояние $|z\rangle$ является собственным вектором оператора $\hat{a}$, отвечающим собственному значению z (комплексному). На основании этого имеем

$$\frac{\langle z|\hat{\mathrm{H}}|z\rangle}{\langle z|z\rangle} = \frac{\hbar\omega\langle z|\hat{a}^+\hat{a} + \frac{1}{2}|z\rangle}{\langle z|z\rangle} = \frac{\hbar\omega\langle z|z^*z + \frac{1}{2}|z\rangle}{\langle z|z\rangle} = \hbar\omega\left(|z|^2 + \frac{1}{2}\right).$$

Б-2.3.10

Для когерентного состояния осциллятора $|z(t)\rangle$ вычислить среднее значение операторов $\hat{\mathrm{x}}$ и $\hat{\mathrm{p}}$ и сравнить результат с классической траекторией в фазовом пространстве осциллятора.

Solution.

2.3.10. Эволюция во времени когерентного состояния определяется гамильтонианом гармонического осциллятора $\hat{\mathrm{H}} = \hbar\omega\left(\hat{a}^{+}\hat{a} + \frac{1}{2}\right)$, т. е. $|z(t)\rangle = \exp\left(-\frac{i}{\hbar}\hat{\mathrm{H}}t\right)|z(0)\rangle$. Это означает, что

$$\langle\hat{x}\rangle_t = \langle z(t)|\hat{x}|z(t)\rangle = \langle z(0)|e^{\frac{i}{\hbar}\hat{\mathrm{H}}t}\hat{x}e^{-\frac{i}{\hbar}\hat{\mathrm{H}}t}|z(0)\rangle = \langle z(0)|\hat{x}_H|z(0)\rangle,$$
$$\langle\hat{\mathrm{p}}\rangle_t = \langle z(t)|\hat{\mathrm{p}}|z(t)\rangle = \langle z(0)|\hat{\mathrm{p}}_H|z(0)\rangle.$$

где $\hat{x}_H, \hat{\mathrm{p}}_H$ - операторы координаты и импульса в гейзенберговском представлении (см. задачи 2.1.17 и 2.1.23). Несложный расчет приводит к результату $\begin{cases} \langle\hat{x}\rangle_t = \langle\hat{x}\rangle_0\cos\omega t + \frac{\langle\hat{\mathrm{p}}\rangle_0}{m\omega}\sin\omega t, \\ \langle\hat{\mathrm{p}}\rangle_t = \langle\hat{\mathrm{p}}\rangle_0\cos\omega t - m\omega\langle\hat{x}\rangle_0\sin\omega t, \end{cases}$ где $\begin{cases} \langle\hat{x}\rangle_0 = \langle z(0)|\hat{x}|z(0)\rangle, \\ \langle\hat{\mathrm{p}}\rangle_0 = \langle z(0)|\hat{\mathrm{p}}|z(0)\rangle. \end{cases}$

Таким образом, эволюция во времени средних значений координаты и импульса в когерентном состоянии квантового осциллятора в точности соответствует закону изменения координаты и импульса классического осциллятора при движении по классической траектории.

Б-2.3.11 Волновая функция когерентного состояния

Найти волновую функцию для когерентного состояния осциллятора $|z\rangle$ в координатном и импульсном представлении.

Solution.

2.3.11. Основное состояние гармонического осциллятора $|0\rangle$ представляет собой когерентное состояние с $z = 0$. Вектор состояния $|0\rangle$ onределяется из уравнения $\hat{a}|0\rangle = 0$ (см. (II.17)). После перехода к координатному представлению это уравнение принимает вид

$$\left(\xi + \frac{d}{d\xi}\right)\psi_0(\xi) = 0 \qquad \Rightarrow \qquad \psi_0(\xi) = Ce^{-\frac{\xi^2}{2}}.$$

(Использованы обозначения: $\xi = x/x_0, \psi_0(\xi) = \langle\xi|0\rangle$ - волновая функция основного состояния в координатном представлении.)

Уравнение для $\langle\xi|z\rangle$ - волновой функции когерентного состояния

$$\frac{1}{\sqrt{2}}\left(\xi + \frac{d}{d\xi}\right)\langle\xi|z\rangle = z\langle\xi|z\rangle$$

является модификацией предыдущего уравнения с заменой $\xi \to \xi - \sqrt{2}z$. Поэтому искомая функция имеет вид

$$\langle\xi|z\rangle = C\exp\left[-\frac{1}{2}(\xi - \sqrt{2}z)^2\right].$$

В импульсном представлении по аналогии получаем

$$\langle p|z\rangle = C\exp\left[-\frac{1}{2}\left(\frac{p}{p_0} + \sqrt{2}z\right)^2\right].$$

Фактически обе функции являются собственными функциями основного состояния, “сдвинутыми" в комплексной плоскости на чнсло z.

Б-2.3.12

Заряженный гармонический осциллятор находится в основном состоянии в однородном электрическом поле $\mathcal{E}\|x$, которое внезапно выключается в момент времени $t = 0$. Определить вероятность обнаружить осциллятор на n-м возбужденном уровне энергии при $t > 0$.

2.3.12. Гамильтониан заряженного осциллятора в однородном электрическом поле (в системе единиц $m = 1, \hbar = 1$) имеет вид

$$\hat{\mathrm{H}} = \frac{\hat{\mathrm{p}}_x^2}{2} + \frac{\omega^2 x^2}{2} - e\varepsilon x.$$

Волновая функция основного состояния осциллятора с гамильтонианом (1) при $t < 0$ в осцилляторных единицах имеет вид

$$\psi(Q,t)|_{t<0} = e^{-iEt}\frac{1}{\pi^{1/4}}e^{-\frac{1}{2}(Q-e\varepsilon)^2}.$$

Сравнивая с когерентным состоянием (см. задачу 2.3.11), видим что в нашем случае параметр $z = e\mathcal{E}/\sqrt{2}$. Таким образом, вероятность обнаружить осциллятор в момент времени $t > 0$ на n-м возбужденном уровне энергии равна

$$w_{E_n} = \frac{(e\mathcal{E})^{2n}}{n!} e^{-(e\mathcal{E})^2}$$

в соответствии с (II.20).

Б-2.3.13

В когерентном состоянии гармонического осциллятора найти

$$\langle \Delta \hat{\mathrm{x}}^2 \rangle \langle \Delta \hat{\mathrm{p}}^2 \rangle.$$

ЛШ-6 Переходы в осцилляторе

Заряженная частица массы m движется по прямой в параболическом потенциале $U(x) = m\omega^2 x^2/2$. На короткое время τ включают слабое электрическое поле E, а затем выключают.

Какова вероятность перевести частицу в состояние $|n\rangle$, если до включения поля она была в основном состоянии?

а) Решите задачу в представлении взаимодействия. Обратите внимание, что матричные элементы возмущения отличны от нуля только между соседними уровнями. Следовательно, при малом E вероятность перехода в n - состояние дается n-м порядком теории возмущений. При каком соотношении между E, ω и τ теория возмущений работает?

б)* Для произвольных E и τ найдите точную S-матрицу и вероятность перехода из основного в n-е состояние.

Solution. в представлении взаимодействия и теорией возмущений

$$\hat{\mathcal{H}}_{\text{int}} = -eEe^{i\hat{\mathcal{H}}_0 t}\hat{x}^{-i\hat{\mathcal{H}}_0 t},$$

$$\langle m|\hat{\mathcal{H}}_{\text{int}}(t)|n\rangle = -eEe^{i(m-n)\omega t}\langle m|\hat{x}|n\rangle.$$

$$\langle m|\hat{x}|n\rangle := l_0\langle m|a + a^+|n\rangle = l_0\left(\delta_{m,n+1}\sqrt{m} + \delta_{m+1,n}\sqrt{n}\right),$$

$l_0 := \sqrt{h/2m\omega}$.

$$\langle m|\hat{\mathcal{H}}_{\text{int}}(t)|n\rangle = -eEl_0\left(\delta_{m,n+1}\sqrt{m}e^{i\omega t} + \delta_{m+1,n}\sqrt{n}e^{-i\omega t}\right).$$

Далее,

$$i\hbar\dot{\psi} = \hat{\mathcal{H}}_{\text{int}}\psi,$$

$$\psi(t) = \psi(0) - \frac{i}{\hbar}\int_0^t \hat{\mathcal{H}}_{\text{int}}(t')\,\psi(t')\,dt'.$$

Это уравнение говорит, $(n+1)$-я поправка к функции (за счет левой части) определяется функцией в n-ом порядке ТВ и оператором перехода в ближайшие состояния (за счет правой части). Таким образом, в каждом порядке появляется вероятность перехода на больший уровень. Другими словами, проекция $\langle n|\psi(t)\rangle$ отлична от нуля только начиная с n-го порядка теории возмущений:

$$\langle n|\psi^{(n)}(t)\rangle = -i\int_0^t \langle n|\hat{\mathcal{H}}_{\text{int}}(t')\,|\psi^{(n-1)}(t')\rangle dt' = \frac{ieEl_0}{\hbar}\sqrt{n}\int_0^t e^{i\omega t'}\langle n-1|\psi^{(n-1)}(t')\rangle dt',$$

где индекс (n) состояния $\psi^{(n)}(t)$ означает порядок теории возмущений.

$$u_n(t) = \langle n|\psi^{(n)}(t)\rangle, \qquad u_0(t) = 1$$

$$u_n(t) = \frac{ieEl_0}{\hbar}\sqrt{n}\int_0^t e^{i\omega t'}u_{n-1}(t')\,dt',$$

$$u_n(t) = \left(\frac{eEl_0}{\hbar\omega}\right)^n \frac{1}{\sqrt{n!}}\left(e^{i\omega t} - 1\right)^n.$$

$$W_{0\to n} = |u_n(\tau)|^2 = \left(\frac{e^2E^2}{2m\omega^3 h}\right)^n \frac{1}{n!}\left(2\sin\frac{\omega\tau}{2}\right)^{2n} = \frac{1}{n!}\left[\frac{e^2E^2(1-\cos\omega\tau)}{m\omega^3 h}\right]^n.$$

Теория возмущений работает, если $\frac{e^2E^2(1-\cos\omega\tau)}{m\omega^3 h} \ll 1$.

Точная вероятность перехода проекциями

$$\hat{\mathcal{H}} \equiv \hat{\mathcal{H}}_0 + \hat{\mathcal{H}}_{\text{int}}$$
$$\hat{\mathcal{H}}_0 = \hbar\omega\left(a^+a + 1/2\right), \quad \hat{\mathcal{H}}_{\text{int}} = -eE\hat{x} = -eEl_0\left(a + a^+\right),$$

$\left(l_0 = \sqrt{\hbar/2m\omega}\right)$.

Пусть $\hat{\mathcal{H}}_{\text{int}} = 0$:

$$\dot{a} = (i/\hbar)\left[\hat{\mathcal{H}}_0, a\right] = i\omega\left[a^+a, a\right] = -i\omega a, \qquad \dot{a}^+ = i\omega a^+.$$

$$a(t) = ae^{-i\omega t}, \qquad a^+(t) = a^+e^{i\omega t}.$$

Пусть $\hat{\mathcal{H}}_{\text{int}} \neq 0$:

$$\dot{a} = (i/h)\left[\hat{\mathcal{H}}_{\text{int}}, a\right] = ieEl_0e^{-i\omega t}.$$

$$a(\tau) = a(0) - iEl_0\int\limits_0^\tau e^{-i\omega t}dt = a(0) + \mu,$$

$$\mu := \frac{eEl_0}{\hbar\omega}\left(e^{-i\omega\tau} - 1\right)$$

$$|n, t = \tau\rangle = \frac{\left(a^+(\tau)\right)^n}{\sqrt{n!}}|0, t = \tau\rangle = \frac{\left(a^+(0) + \mu^*\right)^n}{\sqrt{n!}}|0, t = \tau\rangle.$$

$$\langle n, t = \tau|0, t = 0\rangle = \langle 0, t = \tau|\frac{(a(0) + \mu)^n}{\sqrt{n!}}|0; t = 0\rangle = \frac{\mu^n}{\sqrt{n!}}\langle 0, t = \tau|0, t = 0\rangle.$$

$$W_{0\to n} = \frac{|\mu|^{2n}}{n!}W_{0\to 0},$$

$$\sum_n W_{0\to n} = 1 \qquad \Rightarrow \qquad W_{0\to 0} = e^{-|\mu|^2}.$$

Получается распределение Пуассона

$$W_{0\to n} = \frac{|\mu|^{2n}}{n!}e^{-|\mu|^2} \qquad |\mu|^2 := e^2E^2/m\hbar\omega^3(1 - \cos\omega\tau)$$

При малых μ ответ совпадает с результатом, полученным по теории возмущений, как и должно быть.

Точная S-матрица переходом к когерентным состояниям (???)

Приведем решение, показывающее связь задачи с когерентными состояниями осциллятора, определяемыми как собственные состояния оператора уничтожения a.

$$\hat{\mathcal{H}} = \hbar\omega\left[a^+a + \frac{1}{2} + \lambda\left(a^+ + a\right)\right], \qquad \lambda := -eEl_0/\hbar\omega$$
$$b := a + \lambda, \qquad b^+ := a^+ + \lambda.$$

Поскольку $[b, b^+] = 1$, переход от a и a^+к b и b^+ определяет каноническое преобразование, при этом гамильтониан становится чисто осцилляторным:

$$\hat{\mathcal{H}} = \hbar\omega\left(b^+b + \frac{1}{2} - \lambda^2\right).$$

Введем собственные состояния оператора уничтожения b:

$$b|\eta\rangle = \eta|\eta\rangle.$$

Здесь η может быть любым комплексным числом. Нетрудно проверить, что

$$|\eta\rangle = e^{-|\eta|^2/2}\sum_{n=0}^{\infty}\frac{\eta^n}{\sqrt{n!}}|n\rangle,$$

где $|n\rangle$ - состояния полученного гамильтониана, отвечающие энергии $E_n = h\omega\left(n + 1/2 - \lambda^2\right)$. Возьмем состояние осцилллтора до включения поля: $a|0_a\rangle = 0$. Используя связь a и b, находим

$$b|0_a\rangle = \lambda|0_a\rangle,$$

$$|0_a\rangle = e^{-\lambda^2/2}\sum_{n=0}^{\infty}\frac{\lambda^n}{\sqrt{n!}}|n_b\rangle.$$

Разложение по состояниям $|n_b\rangle$ позволяет сразу написать зависимость от времени:

$$|0_a\rangle(t) = \exp\left(-\frac{i}{\hbar}\hat{\mathcal{H}}t\right)|0_a\rangle = e^{i\left(\lambda^2-1/2\right)\omega t}e^{-\lambda^2/2}\sum_{n=0}^{\infty}\frac{\left(\lambda e^{-i\omega t}\right)^n}{\sqrt{n!}}|n_b\rangle,$$

т.е.

$$b|0_a\rangle(t) = \lambda e^{-i\omega t}|0_a\rangle(t),$$
$$a|0_a\rangle(t) = \lambda\left(e^{-i\omega t} - 1\right)|0_a\rangle(t).$$

Обозначив $\mu = \lambda\left(e^{-i\omega t} - 1\right)$, получаем

$$|0_a\rangle(t) = S(t)|0_a\rangle = e^{-|\mu|^2/2}\sum_{n=0}^{\infty}\frac{\mu^n}{\sqrt{n!}}|n_a\rangle.$$

Отсюда находим столбец S-матрицы: $\langle n|\hat{S}(t)|0\rangle = e^{-|\mu|^2/2}\mu^n/\sqrt{n!}$. Искомые вероятности переходов есть

$$W_{0\to n} = e^{-|\mu|^2}\frac{|\mu|^{2n}}{n!} = \frac{1}{n!}\left[\frac{e^2E^2(1-\cos\omega t)}{m\omega^3\hbar}\right]^n\exp\left[-\frac{e^2E^2(1-\cos\omega t)}{m\omega^3\hbar}\right]$$

Остальные матричные элементы можно получить из соотношений для зависящих от времени операторов: $\hat{S}b^+ = b^+\hat{S}e^{-i\omega t}, \hat{S}a^+ = a^+\hat{S}e^{-i\omega t} + \mu\hat{S}$. Отсюда

$$\langle n|\hat{S}|k\rangle = \frac{1}{\sqrt{k}}\langle n|\hat{S}a^+|k-1\rangle = \frac{1}{\sqrt{k}}\langle n|a^+\hat{S}e^{-i\omega t} + \mu\hat{S}|k-1\rangle$$

и получается рекуррентная формула:

$$\langle n|\hat{S}|k\rangle = \frac{\sqrt{n}}{\sqrt{k}}e^{-i\omega t}\langle n-1|\hat{S}|k-1\rangle - \frac{\mu}{k}\langle n|\hat{S}|k-1\rangle.$$

Применяя её достаточно много раз, выражаем $\langle n|\hat{S}|k\rangle$ через $\langle 0|\hat{S}|0\rangle = e^{-|\mu|^2/2}$:

$$\langle n|\hat{S}|m\rangle = \frac{e^{-|\mu|^2/2}}{\sqrt{m!n!}}\sum_{k=0}^{\min(m,n)}\frac{n!m!}{k!(n-k)!(m-k)!}\mu^{n+m-2k}e^{-i\omega kt}.$$

ФР.? Линейное появление поля

Для заряженного линейного гармонического осциллятора, находящегося первоначально в основном состоянии, определить вероятности переходов в различные возбужденные состояния под влиянием однородного электрического поля вида

$$\mathcal{E} = \begin{cases} 0, & t < 0, \\ \mathcal{E}_0\frac{t}{\tau}, & 0 \leqslant t \leqslant \tau, \\ \mathcal{E}_0, & t > \tau \end{cases}$$

Solution.

$$\hat{\mathrm{H}} = \frac{\hat{\mathrm{p}}^2}{2m} + \frac{m\omega^2x^2}{2} - e\varepsilon x,$$

последнее слагаемое учтем по теории возмущений.

$$V_{10} = -e\mathcal{E}\langle 1|\hat{x}|0\rangle = -\frac{e\mathcal{E}x_0}{\sqrt{2}}, \quad x_0 = \sqrt{\frac{\hbar}{m\omega}},$$

остальные в 1 порядке нулевые.

$$a_{0n}^{(1)} = \frac{1}{i\hbar}\int\limits_{-\infty}^{+\infty} V_{n0}\left(t'\right) e^{i\omega_{n0}t'}dt' = -\frac{1}{i\hbar}\int\limits_{-\infty}^{+\infty} \mathcal{E}_0\frac{t}{\tau}\frac{ex_0}{\sqrt{2}}e^{i\omega_{n0}t'}dt'$$

Проинтегрируем по частям и отбросим внеинтегральное слагаемое, считая, что оно не вносит вклада в квантовые переходы (??????????????):

$$a_{0n}^{(1)} = -i\int\limits_0^{\tau} \frac{e}{\sqrt{2}}\sqrt{\frac{\hbar}{m\omega}}\frac{\mathcal{E}_0}{\tau}\frac{e^{i\omega_{n0}t'}}{\hbar\omega_{n0}}dt' = \frac{e\mathcal{E}_0}{\sqrt{2\hbar m\omega}\omega\tau}\cdot 2e^{i\omega\tau/2}\sin(\omega\tau/2),$$

since $\mathrm{sh}(ix) = i\sin x$.

$$W_{0\to 1} = W_0\frac{\sin^2\left(\frac{\omega\tau}{2}\right)}{\left(\frac{\omega\tau}{2}\right)^2}, \qquad W_0 = \frac{e^2\mathcal{E}_0^2}{2\hbar m\omega}.$$

В случае мгновенного включения поля ($\omega\tau \ll 1$) имеем $W_{0\to 1} \simeq W_0$. При адиабатически медленном включении поля ($\omega\tau \gg 1$) получим $W_{0\to 1} \simeq 0$, т. е. переходы в возбужденные состояния практически не происходят. Это и ожидаемо.

Теория возмущений применима, если $V_{10} \ll \Delta E_{10}$, т.е.:

$$\frac{e\mathcal{E}_0}{\sqrt{2}}\sqrt{\frac{\hbar}{m\omega}} \ll \hbar\omega$$

17.2.8 Problems about central field 1

Б-2.6.1

Записать уравнение Шредингера для двух частиц с массами m_1 и m_2, взаимодействующих по закону $U\left(\mathbf{r}_1 - \mathbf{r}_2\right)$ в системе центра масс. Какой вид имеет волновая функция $\Psi\left(\mathbf{r}_1, \mathbf{r}_2\right)$?

Solution.

2.6.1. Система двух частиц описывается волновой функцией $\Psi\left(\mathbf{r}_1, \mathbf{r}_2, t\right)$, которая подчиняется уравнению Шредингера

$$i\hbar\frac{\partial}{\partial t}\Psi\left(\mathbf{r}_1, \mathbf{r}_2, t\right) = \hat{\mathrm{H}}\Psi\left(\mathbf{r}_1, \mathbf{r}_2, t\right),$$

причем гамильтониан в координатном представлении имеет вид

$$\hat{\mathrm{H}} = -\frac{\hbar^2}{2m_1}\Delta_1 - \frac{\hbar^2}{2m_2}\Delta_2 + U\left(\mathbf{r}_1 - \mathbf{r}_2\right).$$

Введем координату центра масс $\mathbf{R}$ и относительную координату $\mathbf{r}$:

$$\mathbf{R} = \frac{m_1\mathbf{r}_1 + m_2\mathbf{r}_2}{m_1 + m_2}, \quad \mathbf{r} = \mathbf{r}_1 - \mathbf{r}_2.$$

Проделав далее замену переменных $\mathbf{r}_1, \mathbf{r}_2, \Delta_1, \Delta_2 \to \mathbf{R}, \mathrm{r}, \Delta_{\mathbf{R}}, \Delta_{\mathrm{r}}$ (используя правило дифференцирования сложной функции), приведем гамильтониан к виду

$$\hat{\mathrm{H}} = -\frac{\hbar^2}{2M}\Delta_{\mathbf{R}} - \frac{\hbar^2}{2\mu}\Delta_{\mathbf{r}} + U(\mathbf{r}),$$

где $M = m_1 + m_2, \mu = m_1m_2/M$ - соответственно полная и приведенная массы. Ввиду того, что система стационарна, полагаем, что волновая функция будет иметь вид

$$\Psi\left(\mathbf{r}_1, \mathbf{r}_2, t\right) = e^{-\frac{1}{\hbar}Et}\Phi(\mathbf{R})\psi(\mathbf{r}), \quad E = E_{\text{цм}} + E_{\text{отн.}}\ .$$

Полная энергия складывается из энергии движения центра масс $E_{\text{им и}}$ энергии относительного движения $E_{\text{отн.}}$. Функции $\Phi(\mathbf{R})$ и $\psi(\mathbf{r})$ должны подчиняться уравнениям

$$-\frac{\hbar^2}{2M}\Delta_{\mathbf{R}}\Phi(\mathbf{R}) = E_{\text{цМ}}\ \Phi(\mathbf{R}),$$
$$\left[-\frac{\hbar^2}{2\mu}\Delta_{\mathbf{r}} + U(\mathbf{r})\right]\psi(\mathbf{r}) = E_{\text{отн}}\ \psi(\mathbf{r}).$$

Из уравнения (1) следует, что функция $\Phi(\mathbf{R})$ описывает свободное движение центра масс: $\Phi(\mathbf{R}) = Ce^{\frac{i}{\hbar}\text{PR}}$, характеризуемое полным импульсом $\mathbf{P}$ и энергией $E_{\text{шм}} = \mathbf{P}^2/(2M)$.

Б-2.6.2

Определить интегралы движения для частицы, движущейся в произвольном центральном поле.

Solution.

2.6.2. Операторы $\hat{1}^2, \hat{i}_x, \hat{I}_y, \hat{I}_z, \hat{I}$ коммутируют с гамильтонианом и являются интегралами движения в произвольном центральном поле.

Б-2.6.3

Найти волновую функцию основного состояния атома водорода в импульсном представлении.

Solution.

2.6.3. Используя явный вид волновой функции основного состояния водородоподобного атома в координатном представлении

$$\psi_{100}(\mathbf{r}) = \frac{Z^{3/2}}{\sqrt{\pi}}e^{-Zr},$$

перейдем в импульсное представление:

$$\phi(\mathbf{p}) = \frac{1}{(2\pi)^{3/2}}\int d^3x e^{-i(\mathbf{rp})}\psi_{100}(\mathbf{r}) = \frac{\sqrt{8Z^5}}{\pi}\frac{1}{\left(Z^2+p^2\right)^2}.$$

Б-2.6.4 Средние и теорема вириала в водороде

Найти среднее значение операторов $r^2, 1/r, \hat{\mathbf{p}}^2$ для основного состояния атома водорода. Убедиться в том, что выполняется теорема вириала.

Solution.

2.6.4. Приводим ответы: $\langle r^2\rangle = 3/Z, \langle 1/r\rangle = Z, \langle\hat{\mathbf{p}}^2\rangle = Z^2$. Учитывая, что средняя кинетическая энергия $\langle\hat{\text{T}}\rangle = \langle\hat{\mathbf{p}}^2/2\rangle$, а средняя потенциальная энергия $\langle\hat{\text{U}}\rangle = -\langle Z/r\rangle$, убеждаемся в справедливости теоремы вириала для кулоновских сил:

$$2\langle\hat{\text{T}}\rangle + \langle\hat{\text{U}}\rangle = 0.$$

Б-2.6.5 Средние $\langle 1/r\rangle$ и $\langle 1/r^2\rangle$ в водороде

С помощью теоремы Фейнмана-Гельмана получить $\langle 1/r\rangle$ и $\langle 1/r^2\rangle$ в произвольном состоянии атома водорода. Используя теорему Эренфеста для радиального движения $d\langle\hat{\text{p}}_r\rangle/dt = \langle\hat{\text{F}}_r\rangle$, получить $\langle 1/r^3\rangle$ для состояний атома водорода $cl > 0$.

Solution.

$$\begin{cases} \hat{\mathrm{H}} = \frac{\hat{\mathrm{p}}_r}{2} + \frac{l(l+1)}{2r^2} - \frac{Z}{r}. \\ \varepsilon_n = -\frac{Z^2}{2n^2}. \end{cases}$$

Учитывая теорему Фейнмана-Гельмана (задача 2.1.22), а также очевидные соотношения

$$\frac{\partial \hat{\mathrm{H}}}{\partial Z} = -\frac{1}{r}, \quad \frac{\partial \varepsilon_n}{\partial Z} = -\frac{Z}{n^2}, \quad \text{получаем} \quad \langle \frac{1}{r} \rangle = \frac{Z}{n^2},$$

где угловыми скобками обозначено среднее по произвольному состоянию атома водорода $|n|m\rangle$. Имея в виду далее, что

$$\frac{\partial \hat{\mathrm{H}}}{\partial l} = \frac{l+1/2}{r^2}, \quad \frac{\partial \varepsilon_n}{\partial n} = \frac{Z^2}{n^3}, \quad \text{получаем} \quad \langle \frac{1}{r^2} \rangle = \frac{Z^2}{n^3(l+1/2)}$$

Здесь мы использовали связь квантовых чисел $n = n_r + l + 1$ для атома водорода. При дифференцировании выражений, например, по l, мы считали зависимость от l непрерывной, т. е. вместо реальной дискретной переменной l мы рассматривали некоторую фиктивную непрерывную переменную, равную / в точках, отвечающих целым значениям $l = 0, 1, ...$ Из теоремы Эренфеста для радиального движения

$$\frac{d\langle \hat{\mathrm{p}}_r \rangle}{dt} = \langle \hat{\mathrm{F}}_r \rangle = -\langle \frac{\partial \hat{\mathrm{H}}}{\partial r} \rangle = \frac{i}{\hbar} \langle \left[\hat{\mathrm{H}}, \hat{\mathrm{p}}_r \right] \rangle$$

легко получить, что

$$\langle \hat{\mathrm{H}} \hat{\mathrm{p}}_r - \hat{\mathrm{p}}_r \hat{\mathrm{H}} \rangle = 0, \quad \text{откуда } \langle \frac{\partial \hat{\mathrm{H}}}{\partial \mathrm{r}} \rangle = 0.$$

На основании этого окончательно находим

$$\langle \frac{1}{r^3} \rangle = \frac{Z^3}{n^2(l+1/2)l(l+1)}, \quad l > 0.$$

Б-2.6.6

Записать стационарное уравнение Шредингера для атома водорода в импульсном представлении.

Solution.

Записать-то запросто, а вот про решение много можно думать, но тут не спрашивается эт.

$$\left(\frac{\mathbf{p}^2}{2} - E \right) \phi(\mathbf{p}) = -\int d^3p' W(\mathbf{p} - \mathbf{p}') \phi(\mathbf{p}')$$

$$W(\mathbf{p}) = \frac{1}{(2\pi)^3} \int d^3x e^{-i(\mathbf{r})} U(\mathbf{r})$$

Для $U(r) = -\frac{Z}{r}$ нетрудно получить $W(p) = -\frac{Z}{2\pi^2 p^2}$, и уравнение примет вид

$$\left(p^2 - 2E \right) \phi(\mathbf{p}) = \frac{Z}{\pi^2} \int d^3p' \frac{\phi(\mathbf{p})}{|\mathbf{p} - \mathbf{p}'|^2}$$

Полученное уравнение можно свести к одномерному интегральному уравнению, точное решение которого впервые было найдено В. А. Фоком (1935 г.). (??? потом изучу)

17.2.9 Problems about central field 2

Б-2.6.7 Решение осциллятора в ДСК и СфСК

Найти уровни энергии трехмерного изотропного осциллятора и кратности их вырождения, разделяя переменные:
а) в декартовых координатах;
б) в сферических координатах.
Определить четность состояний. Обсудить связь задачи с моделью ядерных оболочек и получить первые три магических числа: 2, 8, 20.

Solution. а), в ДСК

$$\left\{-\frac{\hbar^2}{2m}\Delta+\frac{m\omega^2\mathbf{r}^2}{2}\right\}\psi(\mathbf{r})=E\psi(\mathbf{r}).$$

$$\hat{\mathrm{H}}=\sum_{i=1}^{3}\left\{-\frac{h^2}{2m}\frac{\partial^2}{\partial x_i^2}+\frac{m\omega^2x_i^2}{2}\right\}.$$

где $x_i=x,y,z$, то очевидно, что решение может быть представлено в виде

$$\psi_{n_1n_2n_3}(\mathbf{r})=u_{n_1}^{\mathrm{ocu}}\,(x)u_{n_2}^{\mathrm{ocul}}\,(y)u_{n_3}^{\mathrm{ocu}}\,(z),\quad n_1,n_2,n_3=0,1,2,...,$$
$$E_n=h\omega\left(n+\frac{3}{2}\right),\quad n=n_1+n_2+n_3,\quad n=0,1,2,...,$$

где $u_{n_i}^{\mathrm{осц}}\,(x_i)$ - собственные функции гамильтониана одномерного осциллятора (II.18):

$$u_{n_i}^{\mathrm{ocu}}\,(x_i)=\frac{1}{\sqrt{2^{n_i}n_i!x_0\sqrt{\pi}}}e^{-\frac{1}{2}\left(\frac{x_i}{x_0}\right)^2}H_{n_i}\left(\frac{x_i}{x_0}\right).$$

Здесь $H_{n_i}\,(x_i)$ - полиномы Эрмита, $x_0=\sqrt{\hbar/(m\omega)}$ - осцилляторная единица длины (II.16). Поскольку четность полиномов Эрмита $H_{n_i}\,(x_i)$ равна $I_{n_i}=(-1)^{n_i}$, то состояния (2) и уровни энергии (3) также характеризуются определенной четностью

$$I_n=(-1)^{n_1+n_2+n_3}=(-1)^n.$$

При вычислении кратности вырождения уровней энергии (3) заметим, что, если задать n_1, то число n_2 будет принимать значения $n_2=0,1,...,n-n_1$, т. е. всего $n-n_1+1$ различных значений. Число n_3 всегда фиксировано соотношением $n_3=n-n_1-n_2$. Поэтому полная кратность вырождения уровня энергии будет равна

$$\sum_{n_1=0}^{n}(n-n_1+1)=\frac{1}{2}(n+1)(n+2).$$

Solution. а), в сферических координатах

(!!!???????!!! впишу про это в 1ю часть!!!)

$$\left\{-\frac{\hbar^2}{2m}\Delta+\frac{m\omega^2\mathbf{r}^2}{2}\right\}\psi(\mathbf{r})=E\psi(\mathbf{r}).$$

$$\psi_{Elm}(\mathbf{r})=R_{El}(r)Y_l^{(m)}(\theta,\varphi),$$

где $Y_l^{(m)}(\theta,\varphi)$ - сферическая функция, а функция $R_{EL}(r)$ должна удовлетворять уравнению

$$R''(r)+\frac{2}{r}R'(r)+\left\{\frac{2mE}{\hbar^2}-\frac{r^2}{r_0^4}-\frac{l(l+1)}{r^2}\right\}R(r)=0.$$

где $r_0=\sqrt{\hbar/(m\omega)}$ - осцилляторная единица длины (II.16). Переходя в уравнении (4) к безразмерным переменным, получим

$$R''(q)+\frac{2}{q}R'(q)+\left\{2\varepsilon-q^2-\frac{l(l+1)}{q^2}\right\}R(q)=0,$$

где $q=r/r_0,\varepsilon=E/(\hbar\omega)$. Исследуем асимптотики функции $R(q)$. При $q\to 0$ имеем следующий асимптотический вид уравнения (5):

$$R_0''+\frac{2}{q}R_0'-\frac{l(l+l)}{q^2}R_0=0.$$

Ищем решение этого уравнения, как обычно, в виде $R_0\sim q^5$ и получаем для s уравнение и его решения в виде

$$s(s-1)+2s-l(l+1)=0,\quad\to s_1=l,\quad s_2=-(l+1).$$

Следовательно, асимптотика радиальной функции при $q \to 0$ имеет вид $R|_{q\to 0} \sim q^l$, поэтому сделаем подстановку $R(q) = q^l u(q)$. Для функции $u(q)$ получим уравнение

$$u'' + \frac{2(l+1)}{q}u' + \left(2\varepsilon - q^2\right)u = 0.$$

Асимптотику функции $u(q)$ при $q \to \infty$ определим из уравнения Подставляя в данное уравнение $u_\infty \sim e^{-\alpha q^2}$, находим $\alpha = 1/2$. Таким образом, радиальную функцию с выделенными асимптотиками можно записать в виде

$$R(q) = e^{-q^2/2} q^l w(q),$$

учитывающем особенности поведения в нуле и на бесконечности. Введем новую переменную согласно $\xi = q^2$, и получим уравнение для функции $w(\xi)$:

$$\xi \frac{d^2 w}{d\xi^2} + \left\{\left(l + \frac{3}{2}\right) - \xi\right\}\frac{dw}{d\xi} - \left\{\frac{1}{2}\left(l + \frac{3}{2}\right) - \frac{\varepsilon}{2}\right\} w = 0.$$

Функцию $w(\xi)$ мы будем далее искать в виде суммы степенного ряда

$$w(\xi) = \sum_{k=0}^{\infty} a_k \xi^k.$$

Подставляя в (7) решение в виде суммы (8) и, группируя члены с одинаковыми степенями ξ, находим

$$\sum_{k=0}^{\infty} \xi^k \left[(k+1)\left(k + l + \frac{3}{2}\right) a_{k+1} - \left(\frac{1}{2}\left(l - \varepsilon + \frac{3}{2}\right) - k\right) a_k\right] = 0.$$

Отсюда, приравнивая нулю коэффициенты при ξ^k, найдем рекуррентные соотношения для коэффициентов a_k:

$$a_{k+1} = a_k \frac{(l + 3/2 - \varepsilon) + 2k}{(k+1)(2(k+l)+3)}.$$

Поскольку в ряде (8) отношение двух последующих коэффициентов в соответствии с (9) при $k \gg 1$ стремится к пределу

$$\left.\frac{a_{k+1}}{a_k}\right|_{k\gg 1} \to \frac{1}{k},$$

то при больших значениях аргумента, т. е. при $\xi \to \infty$ мы получим $w(\xi) \sim e^{\xi}$ или $w(q) \sim e^{q^2}$ (см. Б-2.5.2). Поэтому радиальная функция (6) при $q \to \infty$ будет экспоненциально расти: $R(q)|_{q\to\infty} \sim e^{q^2/2}$. Чтобы избежать данного неограниченного роста, необходимо «оборвать» ряд (8) при некотором $k = n_r$, т. е. свести его к полиному. При этом должно выполняться условие

$$\frac{1}{2}\left(l + \frac{3}{2} - \varepsilon\right) = -n_r, \quad n_r = 0, 1, 2, ...,$$

откуда получаем уровни энергии:

$$E_n = \hbar\omega\left(l + 2n_r + \frac{3}{2}\right) = \hbar\omega\left(n + \frac{3}{2}\right), \quad n = 2n_r + l = 0, 1, 2, ...$$

Здесь n_r - радиальное, l - орбитальное и n - главное квантовое число,

Для функции $w(\xi)$ мы имеем ряд (8), который определяется рекуррентными соотношениями (9) и сводится к вырожденной гипергеометрической функции $F(-n_r, l + 3/2, \xi)$, которая является регулярным при $\xi \to 0$ решением [4)] уравнения (7). При условии (10) гипергеометрическая функция превращается в присоединенный полином Лагерра (см. (Д.24)), т. е.

$$w_{n_r l}(\xi) = a_0\left[1 - \frac{n_r}{(l+3/2)}\frac{\xi}{l} + \frac{n_r(n_r-1)}{(l+3/2)(l+3/2+1)}\frac{\xi^2}{2} + ...\right] =$$
$$= a_0 F(-n_r, l+3/2, \xi) = \frac{a_0\Gamma(l+3/2)}{\Gamma(l+3/2+n_r)} L_{n_r}^{l+1/2}(\xi).$$

Здесь константа a_0 определяется из условия нормировки. Восстанавливая исходные обозначения, запишем общий вид радиальной функции $R(r)$, нормированной условием $\int\limits_0^\infty |R(r)|^2 r^2 dr = 1$:

$$R_{n_r l}(r) = \sqrt{\frac{2}{r_0^3 n_r! \Gamma\left(l+3/2+n_r\right)}} e^{-\frac{1}{2}\left(\frac{r}{r_0}\right)^2} \left(\frac{r}{r_0}\right)^l L_{n_r}^{l+\frac{1}{2}}\left(\left(\frac{r}{r_0}\right)^2\right).$$

Таким образом, полная волновая функция в сферической системе координат

$$\psi_{nlm}(\mathbf{r}) = R_{nl}(r) Y_l^{(m)}(\theta, \varphi)$$

зависит от трех квантовых чисел: n, l и m (функцию (11) можно записать с учетом $n_r = (n-l)/2$), в то время, как уровни энергии определяются только главным квантовым числом n. Поэтому имеется вырождение: уровню энергии с определенным значением числа n отвечают функции с $l = n, n-2, ...0$, если n - четное ($n/2+1$ значений l), или с $l = n, n-2, ..., l$, если n - нечетное ($(n+1)/2$ значений l). Кроме того, для каждого / существует $2l+1$ различных значений магнитного квантового числа m (уровни энергии не зависят от m).

На основании этого заключаем, что уровни энергии имеют определенную четность [5)] $I_n = (-1)^n = (-1)^l$ и полную кратность вырождения (для четного и нечетного n), равную

$$\sum_{l=0,2,...}^{n} (2l+1) = \sum_{l=1,3,...}^{n} (2l+1) = \frac{1}{2}(n+1)(n+2).$$

что полностью соответствует результату п. а). Потенциал изотропного гармонического осциллятора можно использовать в качестве модели самосогласованного поля, которое действует на каждый нуклон в ядре (модель ядерных оболочек). При этом найденные нами уровни энергии (3) представляют собой спектр одночастичных уровней для рассматриваемой модели. Если главное квантовое число принимает значения $n = 0, 1, 3$, то максимальное число нуклонов, которые могут находиться на соответствующих уровнях равно $2, 6, 12$ (удвоение кратности вырождения (12) связано с тем, что нуклоны имеют спин $1/2$). Максимальное число нуклонов, которые можно разместить на всех уровнях, начиная с нулевого и заканчивая рассматриваемым, будет равно $2, 8, 20$. Это и есть значения магических чисел для данной модели оболочек.

Б-2.6.8 Трехмерный колодец

Найти уровни энергии и волновые функции частицы в трехмерном потенциальном ящике:

$$U(x) = \begin{cases} 0, & r < a \\ \infty, & r \geqslant a \end{cases}$$

Сравнить порядок следования уровней энергии в этой задаче и трехмерного изотропного осциллятора.

Solution.

2.6.8. Уравнение Шредингера для данного потенциала допускает разделение переменных в сферической системе координат, и его решение можно представить в виде (см. (II.33))

$$\psi(\mathbf{r}) = R_l(r) Y_l^{(m)}(\theta, \varphi) = \frac{1}{r} \chi_l(r) Y_l^{(m)}(\theta, \varphi).$$

В результате такой подстановки мы получаем для функции $\chi_l(r)$ так называемое «укороченное» радиальное уравнение

$$\chi_l''(r) + \left(k^2 - \frac{l(l+1)}{r^2}\right)\chi_l(r) = 0, \qquad \text{где} \qquad E = \frac{\hbar^2 k^2}{2m}.$$

Функция χ_l удовлетворяет данному уравнению при $0 < r < a$, и должна быть равна нулю при $r = 0$ и при $r \geqslant a$.

Случай $l = 0$.

В этом случае УШ и граничные условия $\chi_l(0) = \chi_l(a) = 0$ имеют точно такой же вид, как и в одномерной задаче (см. задачу 2.2.1). На основании этого сразу получаем решение:

$$E_{n_r 0} = \frac{\pi^2 \hbar^2}{2ma^2} n_r^2, \qquad \psi_{n_r 0} = \begin{cases} \frac{1}{\sqrt{2\pi a r}} \sin \frac{\pi n_r}{a} r, & 0 < r < a \\ 0, & r \geqslant a \end{cases}$$

где $n_r = 1, 2, 3, ...$ - радиальное квантовое число.

Случай $l > 0$.

При помощи замены $\chi_l(r) = \sqrt{r}\varphi(r)$ УШ приводится к виду

$$\varphi'' + \frac{1}{r}\varphi' + \left[k^2 - \frac{(l+1/2)^2}{r^2}\right]\varphi = 0.$$

Решениями данного уравнения являются функции Бесселя полуцелого порядка $J_{\pm(l+1/2)}(kr)$. Поэтому общее решение УШ можно записать в виде

$$\chi_l(r) = C_1 j_l(kr) + C_2 n_l(kr),$$

$$j_l(x) := \sqrt{\frac{\pi x}{2}} J_{l+1/2}(x)$$

$$n_l(x) := \sqrt{\frac{\pi x}{2}} N_{l+1/2}(x) = (-1)^{l+1}\sqrt{\frac{\pi x}{2}} J_{-(l+1/2)}(x).$$

$$j_l(x)|_{x\to 0} \simeq \frac{x^{l+1}}{(2l+1)!!}, \quad n_l(x)|_{x\to 0} \simeq -\frac{(2l-1)!!}{x^l}.$$

Из граничного условия $\chi_l(0) = 0$ и асимптотики следует, что решение УШ необходимо выбрать в виде

$$\chi_l(r) = c j_l(kr).$$

Граничное условие $\chi_l(a) = 0$ определяет значения k и, следовательно, - уровни энергии и собственные функции. Должно выполняться условие

$$j_l(ka) = 0, \quad \text{или} \quad J_{l+1/2}(ka) = 0,$$

поэтому окончательно находим

$$E_{n_r l} = \frac{\pi^2 h^2}{2ma^2}\lambda^2_{n_r l}, \qquad R_{n_r l}(r) = \begin{cases} \frac{c}{r} j_l\left(\frac{\lambda_{n_r l}}{a} r\right), & 0 < r < a, \\ 0, & r \geqslant a, \end{cases}$$

где $\lambda_{n,l}$ - корни функции Бесселя $J_{l+1/2}(x), n_r = 1, 2, \ldots$ - радиальное квантовое число, определяющее номер корня в порядке возрастания его величины. Вырождение по орбитальному квантовому числу отсутствует значение энергии однозначно определяет число l. Вырождение по магнитному квантовому числу m существует, ибо оно обусловлено сферической симметрией задачи.

Используя значения корней $\lambda_{n_r l}$, можно определить порядок расположения уровней энергии, начиная от основного состояния: $1s, 1p, 1d, 2s, 1f, 2p, 1g, 2d, 1h, 3s, 2f, \ldots$, где состояния с $l = 1, 2, 3, 4, 5, \ldots$ обозначаются буквами $s, p, d, f, g, h, \ldots$, число перед буквой нумерует уровни с одинаковым l в порядке возрастания их значений (очевидно, в данном случае это число просто равно n_r). Для сравнения приведем порядок расположения уровней для изотропного пространственного осциллятора (см. задачу 2.6.7, число перед буквой теперь равно $n + 1$) $1s, 1p, [1d, 2s], [1f, 2p], [1g, 2d, 3s], \ldots$. Для уровней энергии осциллятора характерно вырождение по квантовому числу l, поэтому состояния, отвечающие одному и тому же уровню, заключены в скобки. Заметим, что отличия в порядке расположения начинают проявляться лишь для сравнительно высоко лежащих уровней энергии.

Б-2.6.9 Трехмерная яма

Найти уровни энергии состояния частицы в трехмерной потенциальной яме вида

$$U(r) = \begin{cases} -U_0, & r < a, \\ 0, & r \geqslant a. \end{cases}$$

Solution.

Как и в предыдущей задаче, представим решение уравнения Шредингера в виде

$$\psi(\mathbf{r}) = R_l(r) Y_l^{(m)}(\theta, \varphi) = \frac{1}{r}\chi_l(r) Y_l^{(m)}(\theta, \varphi).$$

$$\varkappa^2 := \frac{2m}{\hbar^2}|E|, \qquad k^2 := k_0^2 - \varkappa^2, \qquad k_0^2 := \frac{2mU_0}{\hbar^2},$$

$$\chi_l''(r) + \left(k^2 - \frac{l(l+1)}{r^2}\right)\chi_l(r) = 0 \qquad 0 < r < a,$$
$$\chi_l''(r) + \left(-\varkappa^2 - \frac{l(l+1)}{r^2}\right)\chi_l(r) = 0 \qquad r \geqslant a$$

Решение уравнения (1а), удовлетворяющее граничному условию $\chi_l(0) = 0$, представляет собой сферическую функцию Бесселя $\chi_l(r) = Aj_l(kr)$ при $0 < r < a$. Решением уравнения (1б), экспоненциально убывающим при $r \to \infty$, является сферическая функция Ханкеля мнимого аргумента (см. (Д.17)):

$$\chi_l(r) = Bh_l^{(1)}(i\varkappa r) \quad \text{при } r \geqslant a,$$
$$h_l^{(1)}(x) = j_l(x) + in_l(x).$$

Из условия непрерывности логарифмической производной на границе ямы $r = a$ получим

$$k\frac{j_l'(ka)}{j_1(ka)} = i\varkappa\frac{h_l^{(1)\prime}(i\varkappa a)}{h_l^{(1)}(i\varkappa a)}.$$

Очевидно, что это и есть трансцендентное уравнение, определяющеде уровни энергии связанных состояний в яме.

Для s-состояний ($l = 0$) уравнение (2) приобретает совсем простой вид:

$$k \operatorname{ctg} ka = -\varkappa.$$

Данное уравнение фактически совпадает с уравнением, определяющим уровни энергии для нечетных состояний задачи 2.2.2 (см. также задачу 2.2.4). Обсуждение вопросов о суцществовании связанных состояний и о количестве уровней энергии можно повторить здесь без особых изменений.

Б-2.6.10 Мелкая 2D яма

Найти энергию связанного состояния частицы в мелкой двумерной потенциальной яме. Сравнить с результатом для трехмерной потенциальной ямы.

Solution.

Уравнение Шредингера в импульсном представлении для двумерной потенциальной ямы имеет вид (см. задачу 2.6.6)

$$\left(\frac{\mathbf{p}^2}{2m} - E\right)\phi(\mathbf{p}) = -\int d^2p' W\left(\mathbf{p} - \mathbf{p}'\right)\phi\left(\mathbf{p}'\right) = -\int d^2q W(\mathbf{q})\phi(\mathbf{p} - \mathbf{q}),$$

$$\mathbf{q} := \mathbf{p} - \mathbf{p}',$$
$$W(\mathbf{q}) := \frac{1}{(2\pi\hbar)^2}\int d^2x e^{-i\frac{\mathbf{qr}}{\hbar}}U(\mathbf{r})$$

- фурье-образ потенциала взаимодействия. Полагаем, что потенциал обладает аксиальной симметрией $U(\mathbf{r}) = U(|\mathbf{r}|) = U(r)$, поэтому для фурье-образа будет также $W(\mathbf{q}) = W(q)$.

Не конкретизируя вид потенциала, предположим, что он имеет минимум, равный $-U_0$ и радиус действия a (т. е. при $r < a$ потенциал отличен от нуля). Тогда из очевидных свойств преобразования Фурье следует, что область локализации фурье-образа $W(q)$ в импульсном пространстве ограничена значением $q \lesssim \hbar/a$.

$$W(0) \simeq -\frac{U_0}{(2\pi\hbar)^2}\pi a^2$$

Далее мы полагаем, что яма мелкая, и координатная волновая функция связанного состояния при больших значениях r имеет вид убывающей экспоненты $\psi(r) \sim e^{-\varkappa r}$, причем выполняется условие $\kappa a \ll 1$ (см. также задачу 2.2.5). Поэтому область локализации функции в импульсном представлении, т. е. $\phi(q)$, должна быть $\sim \hbar\varkappa \ll \hbar/a$. Таким образом, при $q \to \infty$ функция $\phi(q)$ убывает значительно быстрее, чем $W(q)$. При этом доминирующую роль в интеграле (1) играет область $|q| \lesssim \hbar/a$, поэтому мы можем вынести $W(q)$ из-под знака интеграла в точке $q \approx 0$. В результате получим

$$\left(\frac{p^2}{2m} - E\right)\phi(p) = -W(0)\int d^2p\phi(p)$$

$$C := \int d^2p\phi(p)$$

$$\phi(p) = -\frac{2mCW(0)}{p^2 + 2m|E|}.$$

$$\left(\frac{p^2}{2m} - E\right)\left(-\frac{2mCW(0)}{p^2 + 2m|E|}\right) = -W(0)\int d^2p\left(-\frac{2mCW(0)}{p^2 + 2m|E|}\right)$$

$$1 = -W(0)\int\limits_0^\infty \frac{2m \cdot 2\pi p dp}{p^2 + 2m|E|} \simeq -W(0)2\pi m \ln\left(\frac{p^2}{2m} + |E|\right)\Big|_0^{\hbar/a}.$$

$W(0) \simeq -\frac{U_0}{(2\pi\hbar)^2}\pi a^2$,

$$\ln\left(\frac{\hbar^2}{2ma^2|E|}\right) \simeq \frac{2\hbar^2}{ma^2U_0},$$

$$E \simeq -\frac{\hbar^2}{2ma^2}\exp\left(-\frac{2\hbar^2}{ma^2U_0}\right).$$

Таким образом, в мелкой двумерной яме, как и в симметричной одномерной, всегда существует одно связанное состояние. Причем, как это видно из (2), глубина залегания соответствующего уровня энергии экспоненциально мала по сравнению с глубиной ямы. В трехмерной же яме связанное состояние есть не всегда (см. задачу 2.6.9).

17.2.10 Problems about motion in a magnetic field 1

(??? потом связи с кл мехом пропишу тоже в теории)
(!! очень скоро в 1 части добавлю формулы основные про это!!! почти готов, еще чуть прорешать задачи нужно)

Б-2.5.1 Частица в магнитном поле в декартовых координатах

Найти волновые функции и спектр энергии для заряженной частицы во внешнем однородном и постоянном магнитном поле, направленном по оси z. (Указание: использовать в качестве векторного потенциала A вектор с компонентами $\mathrm{A}_x = \mathrm{A}_z = 0$, $\mathrm{A}_y = \mathcal{H}x$.)

Определить число состояний, приходящихся на интервал $(p_z \div p_z + \Delta p_z)$ и один дискретный уровень, предполагая, что система заключена в ящик объема V (линейные размеры которого значительно больше ларморовского радиуса).

Solution.

Это известная задача про уровни Ландау, можно сразу написать ответ.

$$\hat{\mathrm{H}} = \frac{1}{2m}\left[\hat{\mathrm{p}}_x^2 + \left(\hat{\mathrm{p}}_y - \frac{e}{c}\mathcal{H}x\right)^2 + \hat{\mathrm{p}}_z^2\right]$$

$$\psi_{Ep_yp_z} = C\exp\left[\frac{i}{\hbar}(p_y y + p_z z)\right] f(x),$$

$$f(x): \qquad f''(x) + \frac{2m}{\hbar^2}\left[\left(E - \frac{p_z^2}{2m}\right) - \frac{m}{2}\omega_H^2(x - x_0)^2\right] f(x) = 0.$$

Здесь $\omega_H = \frac{e\mathcal{H}}{mc}(e > 0)$ и $x_0 = \frac{cp_y}{e\mathcal{H}}$. Решение уравнения (1) выражается через решение уравнения Шредингера для гармонического осциллятора с частотой ω_H (см. (II.18)). В итоге

$$\psi_{np_yp_z}(x, y, z) = C\exp\left[\frac{i}{\hbar}(p_y y + p_z z)\right] u_n^{\mathrm{osc}}\ (x - x_0),$$

$$E_{np_z} = \hbar\omega_H\left(n + \frac{1}{2}\right) + \frac{p_z^2}{2m}, \quad n = 0, 1, ...$$

Первое слагаемое в (2) описывает энергетические уровни поперечного движения (уровни Ландау). Они являются дискретными и нумеруются квантовым числом n. Движение вдоль поля не квантуется, квантовое число p_z может принимать значения $-\infty < p_z < \infty$. Уровни энергии (2) вырождены, ибо они не зависят от квантового числа p_y, которое также может изменяться от $-\infty$ до ∞.

Если ограничить область движения частицы ящиком в виде куба с ребром L, то p_z и p_y становятся дискретными:

$$p_i = \frac{2\pi\hbar}{L}n_i, \quad n_i = 0, \pm 1, ...$$

потому что предполагается граничное условие $\psi(x_i + L) = \psi(x_i)$. Исходя из того, что в классическом пределе на одно квантовое состояние (в одном измерении) приходится фазовый объем $2\pi\hbar$ (см. задачу 2.2.1) получим, что число квантовых состояний в объеме V в расчете на интервал Δp_z и на один дискретный уровень равно

$$\Delta N = \left(\frac{L}{2\pi\hbar}\right)^2 \Delta p_y \Delta p_z.$$

Из условия $0 < x_0 < L$ (центр классической орбиты внутри объема V, и радиус орбиты пренебрежимо мал по сравнению с L) имеем $\Delta p_y = e\mathcal{H}L/c$. Поэтому окончательно

$$\Delta N = \frac{e\mathcal{H}}{c}\frac{V}{(2\pi\hbar)^2}\Delta p_z$$

Б-2.5.2 Частица в магнитном поле в цилиндрических координатах

Найти уровни энергии и волновые функции заряженной бесспиновой частицы в однородном магнитном поле, направленном вдоль оси z, используя цилиндрическую систему координат.

Solution.

Это известная задача теории из книги Ландау, так можно обойти спецфункции, можно сразу написать ответ.

$$\mathbf{A} = \frac{1}{2}[\mathcal{H} \times \mathbf{r}].$$

$z \| \mathcal{H}$

$$\mathrm{A}_z = 0, \quad \mathrm{A}_\rho = 0, \quad \mathrm{A}_\varphi = \frac{1}{2}\mathcal{H}\rho.$$

Гамильтониан частицы массы M с зарядом $e (e > 0)$ имеет вид

$$\hat{\mathrm{H}} = \frac{1}{2M}\left(\hat{\mathcal{P}} - \frac{e}{c}\mathbf{A}\right)^2 = \frac{1}{2M}\hat{\mathcal{P}}^2 - \frac{e\hbar\mathcal{H}}{2Mc}\hat{I}_z + \frac{e^2\mathcal{H}^2}{8Mc^2}\rho^2.$$

$$\omega_H := e\mathcal{H}/(Mc) \qquad \hat{I}_z = -i\partial/\partial\varphi,$$

$$\hat{\mathrm{H}} = -\frac{\hbar^2}{2M}\left(\frac{\partial^2}{\partial z^2} + \frac{1}{\rho}\frac{\partial}{\partial\rho}\rho\frac{\partial}{\partial\rho} + \frac{1}{\rho^2}\frac{\partial^2}{\partial\varphi^2}\right) + \frac{i}{2}\hbar\omega_H\frac{\partial}{\partial\varphi} + \frac{1}{8}M\omega_H^2\rho^2.$$

Гамильтониан (1)-(2) коммутирует с операторами $\hat{l}_z$ и $\hat{\mathrm{p}}_z$, поэтому решение стационарного уравнения Шредингера в цилиндрических координатах

$$\hat{\mathrm{H}}\psi(z,\rho,\varphi) = E\psi(z,\rho,\varphi)$$

следует искать в виде общей собственной функции трех операторов: $\hat{\mathrm{H}}$, $\hat{I}_z$ и $\hat{\mathrm{p}}_z$, т. е.

$$\psi(z,\rho,\varphi) = \psi_z(z)\Phi(\varphi)R(\rho),$$

$$\psi_z(z) \equiv \psi_{p_z}(z) = \frac{1}{\sqrt{2\pi h}}e^{\frac{i}{\hbar}p_z z}, \quad \Phi(\varphi) \equiv \Phi_m(\varphi) = \frac{1}{\sqrt{2\pi}}e^{im\varphi}.$$

$$\psi(z,\rho,\varphi) = \frac{e^{im\varphi}}{\sqrt{2\pi}}\frac{e^{\frac{i}{\hbar}p_x z}}{\sqrt{2\pi\hbar}}R(\rho).$$

Для радиальной функции $R(\rho)$ получаем обыкновенное дифференциальное уравнение

$$-\frac{\hbar^2}{2M}\left(\frac{1}{\rho}\frac{d}{d\rho}\rho\frac{dR}{d\rho} - \frac{m^2}{\rho^2}R\right) - \frac{1}{2}\hbar\omega_H mR + \frac{1}{8}M\omega_H^2\rho^2 R = E_H R.$$

(Мы представили полную энергию в виде суммы $E = E_z + E_H$, где $E_z = p_z^2/(2M)$ - энергия продольного движения частицы.) Потенциальная энергия в (4) зависит квадратично от переменной ρ, как и для гармонического осциллятора, поэтому ее удобно измерять в осцилляторных
единицах: $E_H = \hbar\omega_H\varepsilon$. Поделим уравнение (4) на $\hbar\omega_H$ и введем безразмерную переменную

$$\xi = \frac{\sqrt{2}\rho}{\rho_H} = \sqrt{\frac{2M\omega_H}{\hbar}}\rho,$$

где $\rho_H = \sqrt{\hbar/(M\omega_H)}$ - осцилляторная единица длины (II.16). В безразмерных переменных уравнение принимает вид

$$R'' + \frac{1}{\xi}R' + \left(\varepsilon - \frac{m^2}{\xi^2} + \frac{m}{2} - \frac{\xi^2}{16}\right)R = 0.$$

Выделим его асимптотики. При $\xi \to 0$ имеем

$$R_0'' + \frac{1}{\xi}R_0' - \frac{m^2}{\xi^2}R_0 = 0.$$

Ищем решение, как обычно, в виде степенной функкци $R_0 \sim \xi^s$ и получаем для s уравнение и его решение в виде

$$s(s-1) + s - m^2 = 0, \quad \to \quad s = \pm m.$$

Таким образом, асимптотика радиальной функции при $\xi \to 0$ есть

$$R|_{\xi\to 0} \sim \xi^{|m|}.$$

Для определения асимптотического решения при $\xi \to \infty$ на основании (5) получаем уравнение

$$R_\infty'' - \frac{1}{16}\xi^2 R_\infty = 0.$$

$$R_\infty \sim \mathrm{e}^{-\alpha\xi^2} \qquad \Rightarrow \qquad \alpha = 1/8,$$

$$R|_{\xi\to\infty} \sim e^{-\xi^2/8}.$$

Таким образом, полную радиальную функцию можно представить в виде

$$R(\xi) = e^{-\xi^2/8}\xi^{|m|}w(\xi),$$

учитывающем особенности поведения в нуле и на бесконечности. Подставляя функцию $R(\xi)$ в виде (6) в радиальное уравнение (5) и вводя новую переменную z согласно $z = \xi^2/4$, получим уравнение для функции $w(z)$:

$$z\frac{d^2w}{dz^2} + (|m| + 1 - z)\frac{dw}{dz} + \left[\varepsilon - \frac{|m| - m + 1}{2}\right]w = 0,$$

причем функцию $w(z)$ мы будем далее искать в виде суммы степенного ряда (вообще говоря, бесконечного)

$$\omega(z) = \sum_{k=0}^{\infty} a_k z^k.$$

Подставляя в (7) решение в виде суммы (8) и производя преобразование индекса суммирования таким образом, чтобы сгруппировать члены с одинаковыми степенями z, находим

$$\sum_{k=0}^{\infty} z^k \left[(k+1)(k+1+|m|)a_{k+1} + \left(\varepsilon - k - \frac{|m| - m + 1}{2}\right)a_k\right] = 0.$$

Для того, чтобы левая часть данного уравнения обратилась в ноль, необходимо и достаточно потребовать, чтобы коэффициенты при всех степенях z были бы равны нулю. На основании этого получаем рекуррентные соотношения для коэффициентов a_k:

$$a_{k+1} = a_k \frac{2k + |m| - m + 1 - 2\varepsilon}{2(k+1)(k+1+|m|)}.$$

Заметим, что в ряде (8) отношение двух последующих коэффициентов согласно (9) при $k \gg 1$ стремится к пределу

$$\left.\frac{a_{k+1}}{a_k}\right|_{k\gg 1} \to \frac{1}{k}$$

и будет таким же, как и у функции e^z, разложенной в ряд

$$e^z = \sum_{k=0}^{\infty} \frac{z^k}{k!}.$$

Поэтому при $z \to \infty$ мы получим $w(z) \sim e^z$ или $w(\xi) \sim e^{\xi^2/4}$, т. е. радиальная функция (6) при $\xi \to \infty$ будет экспоненциально расти: $R(\xi)|_{\xi\to\infty} \sim e^{\xi^2/8}$. Единственная возможность избежать данного неограниченного роста "оборвать" ряд (8) при некотором $k = n_\rho$ и превратить его в полином. При этом должно выполняться условие

$$\varepsilon_{n_\rho} = n_\rho + \frac{|m| - m + 1}{2}, \quad n_\rho = 0, 1, 2, ...$$

Число n_ρ, как и обычно, называется радиальным квантовым числом и определяет количество нулей многочлена $w_{n_\rho}(z)$.

Окончательно получаем энергетический спектр заряженной частицы в однородном магнитном поле:

$$E_{np_z} = \hbar\omega_H \left(n + \frac{1}{2}\right) + \frac{p_2^2}{2M}, \quad n = n_\rho + \frac{|m| - m}{2} = 0, 1, 2, ...$$

где мы ввели главное квантовое число n. Данный результат находится в полном согласии с формулой (2) решения задачи 2.5.1.

Уровни энергии (11) вырождены по значению проекции момента на направление магнитного поля: каждому фиксированному значению числа n отвечают состояния с

$$m = -n, -n + 1, ..., 0, 1, ...\infty.$$

(??? бесконечная кратность вырождения, можно что-то сказать про это????)

Для функции $w(z)$ мы получаем ряд (8), определяемый рекуррентными соотношениями (9) и сводящийся к вырожденной гипергеометрической функции $F(-n_\rho, |m| + 1, z)$, которая является регулярным при $z \to 0$ решением уравнения (7). При условии (10) гипергеометрическая функция превращается в присоединенный полнном Лагерра (см. (Д.24)), Т. е.

$$w_{n_\rho m}(z) = a_0 \left[1 - \frac{n_\rho}{(|m| + 1)}\frac{z}{1} + \frac{n_\rho (n_p - 1)}{(|m| + 1)(|m| + 2)}\frac{z^2}{2} + ...\right] =$$
$$= a_0 F(-n_\rho, |m| + 1, z) = \frac{a_0 |m|!}{(|m| + n_\rho)!} L_{n_\rho}^{|m|}(z).$$

Восстанавливая исходные обозначения, запишем общий вид радиальной функции $R(\rho)$, нормированной условием $\int\limits_0^\infty |R(\rho)|^2 \rho d\rho = 1$:

$$R_{n_\rho m}(\rho) = \frac{1}{\rho_H \sqrt{n_\rho! \, (|m| + n_\rho)!}} \exp\left(-\frac{\rho^2}{4\rho_H^2}\right) \left(\frac{\rho}{\sqrt{2}\rho_H}\right)^{|m|} L_{n_\rho}^{|m|}\left(\frac{\rho^2}{2\rho_H^2}\right)$$

Б-2.5.3 Факторизация волновой функции в магнитном поле

Показать, что в однородном магнитном поле, переменном во времени, волновая функция частицы со спином распадается на произведение координатной и спиновой функций.

Solution.

Утверждается, что координатные и спиновые переменные в уравнении Паули разделяются только в случае наличия однородного магнитного поля, возможно, зависящего от времени. Предполагая возможность такого разделения, ищем решение уравнения Паули

$$i\hbar\frac{\partial}{\partial t}\Psi(\mathbf{r}, t) = \left(\hat{\mathrm{H}}^\Psi - \mu_0(\sigma\mathcal{H})\right)\Psi(\mathbf{r}, t),$$

где

$$\hat{\mathrm{H}}^\Psi = \frac{1}{2m}\left(\hat{\mathbf{p}} - \frac{e}{c}\mathbf{A}\right)^2 + \hat{\mathrm{U}}(\mathbf{r}), \qquad \mu_0 = \frac{e\hbar}{2mc}, \quad e > 0,$$

в следующем виде:

$$\Psi(\mathbf{r}, t) = f(\mathbf{r}, t)\chi(t).$$

Здесь $\chi(t)$ - спиновая функция, зависящая только от времени. Подставим (2) в (1) и потребуем, чтобы функция $f(\mathbf{r}, t)$ подчинялась уравнению Шредингера для бесспиновой частицы

$$i\hbar\frac{\partial}{\partial t}f(\mathbf{r}, t) = \hat{\mathrm{H}}^\Psi f(\mathbf{r}, t).$$

Тогда для спиновой функции мы получим

$$i\hbar\frac{\partial}{\partial t}\chi(t) = -\mu_0(\hat{\sigma}\mathcal{H})\chi(t).$$

Уравнения (3) и (4) будут независимыми, если магнитное поле $\mathcal{H}$ - однородное, т. е. не зависит от координат.

Б-2.5.4

Найти зависимость от времени спиновой функции покоящегося мюона, если в начальный момент

$$\chi = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

и включается магнитное поле $\mathcal{H}$, направленное вдоль оси x. Найти $\langle\hat{\sigma}_x\rangle, \langle\hat{\sigma}_y\rangle, \langle\hat{\sigma}_z\rangle$ и убедиться, что магнитный момент мюона совершает прецессию вокруг магнитного поля. Получить вид спиновых операторов в представлении Гейзенберга.

Solution.

Суть решения в том, что 2.5.4. По условию задачи магнитное поле постоянное и однородное, поэтому переменные в уравнении Паули разделяются, и уравнение (4) задачи 2.5.3 принимает вид

$$i\hbar\frac{\partial}{\partial t}\chi(t) = -\hbar\Omega\hat{\sigma}_x\chi(t), \quad \Omega = \frac{e\mathcal{H}}{2mc}.$$

С учетом явного вида матрицы $\hat{\sigma}_x$ уравнение (1) переходит в

$$\frac{\partial}{\partial t}\begin{pmatrix} s_1(t) \\ s_2(t) \end{pmatrix} = i\Omega\begin{pmatrix} s_2(t) \\ s_1(t) \end{pmatrix}; \quad \chi(0) = \begin{pmatrix} s_1(0) \\ s_2(0) \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

- начальное условие. Решаем далее систему дифференциальных уравнений для s_1 и s_2 и получаем

$$\chi(t) = \begin{pmatrix} \cos\Omega t \\ i\sin\Omega t \end{pmatrix}.$$

Используя (2), находим средние значения

$$\langle\hat{\sigma}_x\rangle = \chi^+\hat{\sigma}_x\chi = 0, \quad \langle\hat{\sigma}_y\rangle = \sin 2\Omega t, \quad \langle\hat{\sigma}_z\rangle = \cos 2\Omega t.$$

Поскольку $\langle\hat{\mu}\rangle_\chi = \mu_0\langle\hat{\boldsymbol{\sigma}}\rangle_\chi$, то ясно, что в плоскости yOz, перпендикулярной к направлению магнитного поля, происходят периодические во времени изменения средних значений магнитного момента мюона. Это интерпретируется, как прецессия магнитного момента вокруг направления магнитного поля.

Перейдем к представлению Гейзенберга. Из формулы (1) следует, что гамильтониан $\hat{\mathrm{H}} = -\hbar\Omega\hat{\sigma}_x$ н поэтому

$$\begin{aligned}
(\hat{\sigma}_x)_H &= e^{-i\Omega t\hat{\sigma}_x}\hat{\sigma}_x e^{i\Omega t\hat{\sigma}_x} = \hat{\sigma}_x, \\
(\hat{\sigma}_y)_H &= e^{-i\Omega t\hat{\sigma}_x}\hat{\sigma}_y e^{i\Omega t\hat{\sigma}_x} = \hat{\sigma}_y\cos 2\Omega t + \hat{\sigma}_z\sin 2\Omega t, \\
(\hat{\sigma}_z)_H &= e^{-i\Omega t\hat{\sigma}_x}\hat{\sigma}_z e^{i\Omega t\hat{\sigma}_x} = \hat{\sigma}_z\cos 2\Omega t - \hat{\sigma}_y\sin 2\Omega t.
\end{aligned}$$

При вычислении необходимо использовать соотношение $e^{i\Omega t\hat{\sigma}_x} = \cos\Omega t + i\hat{\sigma}_x\sin\Omega t$, а также свойства матриц Паули. Таким образом, в представлении Гейзенберга матрицы Паули (и спиновые операторы $\hat{\mathrm{s}}_i = \frac{1}{2}\hat{\sigma}_i$) изменяются во времени, как компоненты трехмерного вектора.

Б-2.5.5 Спин электрона в магнитном поле $\mathcal{H}$ в представлении Гейзенберга

Найти оператор спина электрона в однородном магнитном поле $\mathcal{H}$ в представлении Гейзенберга. Считать, что других взаимодействий, изменяющих спиновое состояние электрона, нет.

Solution.

Суть решения в том, что 2.5.5. Данную задачу можно решить двумя способами: 1) используя унитарное преобразование, связывающее представления Шредингера и Гейзенберга (II.11) и 2) непосредственно решая уравнения Гейзенберга (II.10). Первый способ был применен при решении задачи 2.5.4, здесь мы воспользуемся вторым способом.

Направим магнитное поле по оси z, тогда спиновый гамильтониан электрона в однородном магнитном поле примет вид

$$\hat{\mathrm{H}} = 2\mu_0\mathcal{H}\hat{\mathrm{s}}_2.$$

Здесь $\mu_0 = e\hbar/(2mc)$ - магнетон Бора, $-e < 0$ - заряд электрона. Для решения задачи воспользуемся уравнением Гейзенберга (1I.10). Получаем (с учетом $[\hat{\mathrm{s}}_2, \hat{\mathrm{s}}_\pm] = \pm\hat{\mathrm{s}}_\pm$)

$$\frac{d\hat{\mathrm{s}}_z}{dt} = 0, \quad \frac{d\hat{\mathrm{s}}_\pm}{dt} = \pm\frac{i}{h}2\mu_0\mathcal{H}\hat{\mathrm{s}}_\pm.$$

Полученные уравнения легко решаются:

$$\hat{\mathrm{s}}_z(t) = \hat{\mathrm{s}}_z, \quad \hat{\mathrm{s}}_\pm(t) = e^{\pm i\omega t}\hat{\mathrm{s}}_\pm,$$

где $\omega = 2\mu_0\mathcal{H}/\hbar$. Окончательно будем иметь (ср. с задачей 2.5.4)

$$\hat{\mathrm{s}}_x(t) = \hat{\mathrm{s}}_x\cos\omega t - \hat{\mathrm{s}}_y\sin\omega t,$$
$$\hat{\mathrm{s}}_y(t) = \hat{\mathrm{s}}_y\cos\omega t + \hat{\mathrm{s}}_x\sin\omega t.$$

Б-2.5.6, ЛШ-5 Спин во вращающемся поле

Частица со спином $s = 1/2$ и магнитным моментом μ находится в постоянном вертикальном и вращающемся горизонтальном магнитном полях

$$B = (B_1\cos\omega t, B_1\sin\omega t, B_0)$$

1) Запишите уравнение Шредингера в представлении взаимодействия, считая переменную часть поля «возмущением».
2) Решите уравнение и найдите S -матрицу.
3) Пусть при $t = 0$ частица находится в состоянии «спин вверх». Какова вероятность найти ее в состоянии «спин вниз» в момент $t > 0$?
4) Рассмотрите отдельно случай резонанса $\omega = 2\mu B_0$.

Обзор решения

Используем определение представления взаимодействия, а также матричный вид экспоненты от сигма-матриц. Для полученной системы вводим “вращающиеся” переменные, получаем общее решение. S-матрицу находим из определения, зная общее решение.

Уравнение Шредингера и S матрица

$\hat{\mathcal{H}} \equiv \hat{\mathcal{H}}_0 + \hat{\mathcal{H}}_{\text{int}}$,

$$\hat{\mathcal{H}}_0 = \mu B_0\sigma_z = \begin{pmatrix} \mu B_0 & 0 \\ 0 & -\mu B_0 \end{pmatrix},$$
$$\hat{\mathcal{H}}_{\text{int}} = \mu B_1\left(\sigma_x\cos\omega t + \sigma_y\sin\omega t\right) = \begin{pmatrix} 0 & \mu B_1 e^{-i\omega t} \\ \mu B_1 e^{i\omega t} & 0 \end{pmatrix}$$

$$\hat{\mathcal{H}}_{\text{int}}(t) = e^{i\hat{\mathcal{H}}_0 t}\hat{\mathcal{H}}_{\text{int}}\, e^{-i\hat{\mathcal{H}}_0 t} = \begin{pmatrix} e^{i\mu B_0 t} & 0 \\ 0 & e^{-i\mu B_0 t} \end{pmatrix}\hat{\mathcal{H}}_{\text{int}}\begin{pmatrix} e^{-i\mu B_0 t} & 0 \\ 0 & e^{i\mu B_0 t} \end{pmatrix} = \mu B_1\begin{pmatrix} 0 & e^{-2i\Omega t} \\ e^{2i\Omega t} & 0 \end{pmatrix},$$

$\Omega := \omega/2 - \mu B_0$.
$i\dot{\psi} = \hat{\mathcal{H}}_{\text{int}}(t)\psi$,

$$i\dot{\psi}_\uparrow = \mu B_1 e^{-2i\Omega t}\psi_\downarrow,$$
$$i\dot{\psi}_\downarrow = \mu B_1 e^{2i\Omega t}\psi_\uparrow$$

$$\varphi_\uparrow := e^{i\Omega t}\psi_\uparrow,$$
$$\varphi_\downarrow := e^{-i\Omega t}\psi_\downarrow.$$

Уравнения для $\varphi_\alpha(t)$ не содержат явной зависимости от времени:

$$i\dot{\varphi}_\uparrow + \Omega\varphi_\downarrow = \mu B_1\varphi_\uparrow,$$
$$i\dot{\varphi}_\downarrow - \Omega\varphi_\uparrow = \mu B_1\varphi_\downarrow,$$

или

$$i\dot{\varphi} = \begin{pmatrix} -\Omega & \mu B_1 \\ \mu B_1 & \Omega \end{pmatrix}\varphi.$$

Общее решение этих уравнений имеет вид (????)

$$\varphi(t) = c_+\begin{pmatrix} (1+\lambda)^{1/2} \\ -(1-\lambda)^{1/2} \end{pmatrix}e^{i\bar{\omega}t} + c_-\begin{pmatrix} (1-\lambda)^{1/2} \\ (1+\lambda)^{1/2} \end{pmatrix}e^{-i\bar{\omega}t},$$

где $\tilde{\omega} = \sqrt{\Omega^2 + (\mu B_1)^2}, \lambda = \Omega/\tilde{\omega}$, а коэффициенты $c_\pm$ определяются начальными условиями.

$\hat{S}(t):\quad \psi_i(t) \equiv \hat{S}(t)\psi_i(0)$, (???????)

$$\hat{S}(t) = \begin{pmatrix} e^{-i\Omega t} & 0 \\ 0 & e^{i\Omega t} \end{pmatrix} \begin{pmatrix} (1+\lambda)^{1/2} e^{i\tilde{\omega}t} & (1-\lambda)^{1/2} e^{-i\tilde{\omega}t} \\ -(1-\lambda)^{1/2} e^{i\omega\omega t} & (1+\lambda)^{1/2} e^{-i\tilde{\omega}t} \end{pmatrix} \cdot \frac{1}{2} \begin{pmatrix} (1+\lambda)^{1/2} & -(1-\lambda)^{1/2} \\ (1-\lambda)^{1/2} & (1+\lambda)^{1/2} \end{pmatrix} =$$
$$= \begin{pmatrix} W(t)e^{-i\Omega t} & -i\left(1-\lambda^2\right)^{1/2} e^{-i\Omega t} \sin\tilde{\omega}t \\ -i\left(1-\lambda^2\right)^{1/2} e^{i\Omega t} \sin\tilde{\omega}t & W^*(t)e^{i\Omega t} \end{pmatrix},$$

$W(t) := \cos\tilde{\omega}t + i\lambda \sin\tilde{\omega}t$.

(??? по идее тут возня будет с обращением матрицы. ну и по идее подставить просто в эту формулу и нужно, где первый член просто уже найден выше.)

Вероятность поворота спина

Рассмотрим теперь вероятность переворота спина. Ее можно найти с помощью S-матрицы, а можно и прямо из (2.26). Воспользуемся вторым способом. Поскольку при $t = 0$ имеем $\varphi = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$, то коэффициенты $c_\pm$в выражении (2.26) есть $c_+ = (1+\lambda)^{1/2}/2$, $c_- = (1-\lambda)^{1/2}/2$. То есть

$$\varphi_l(t) = \frac{1}{2}\sqrt{1-\lambda^2}\left(e^{-i\tilde{\omega}t} - e^{i\tilde{\omega}t}\right) = \frac{\mu B_1}{i\tilde{\omega}} \sin\tilde{\omega}t.$$

$$p_\downarrow(t) = |\varphi_\downarrow(t)|^2 = \frac{(\mu B_1)^2}{\Omega^2 + (\mu B_1)^2} \sin^2\tilde{\omega}t.$$

Случай резонанса

Если выполнено условие резонанса $\omega = 2\mu B_0$, то $\Omega = 0, \tilde{\omega} = \mu B_1$ и выражение для S-матрицы упрощается:

$$\hat{S}(t) = \begin{pmatrix} \cos\mu B_1 t & -i\sin\mu B_1 t \\ -i\sin\mu B_1 t & \cos\mu B_1 t \end{pmatrix}.$$

Соответственно, в этом случае вероятность переворота спина есть $p_\downarrow(t) = \sin^2\mu B_1 t$.

Solution. по Белоусову

Суть решения в том, что 2.5.6. Уравнение эволюции спина в лабораторной системе координат имеет вид (см. задачу 2.5.3)

$$i\hbar\frac{\partial}{\partial t}\chi(t) = \hat{\mathrm{H}}\chi(t) = -\mu_0(\hat{\sigma}\mathcal{H})\chi(t) = -\gamma(\hat{\mathbf{S}}\mathcal{H})\chi(t),$$

где $\gamma = e/(mc)$ - гиромагнитное отношение для спинового момента, $\hat{\mathbf{S}} = (\hbar/2)\hat{\sigma}$ - оператор спина. Здесь наряду с постоянным полем $\mathcal{H}_0$, направленным по оси z, имеется также поле $\mathcal{H}_1$, вращающееся в плоскости xOy с угловой скоростью $\omega = \omega\mathbf{k}$. Поэтому гамильтониан явно зависит от времени.

Перейдем в систему координат K', вращающуюся относительно лабораторной системы K с угловой скоростью $\boldsymbol{\omega}$. При этом спиновая функция подвергнется преобразованию, отвечающему повороту на угол ωt:

$$\chi' = e^{\frac{i}{2}(\boldsymbol{\omega}\hat{\sigma})t}\chi = e^{\frac{i}{\hbar}(\hat{\mathbf{S}}\boldsymbol{\omega})t}\chi.$$

Функция χ' будет удовлетворять преобразованному уравнению

$$i\hbar\frac{\partial}{\partial t}\chi'(t) = \hat{\mathrm{H}}'_{\mathrm{eli}}\chi'(t), \text{ где } \hat{\mathrm{H}}'_{\mathrm{efI}} = e^{\frac{i}{\hbar}(\hat{\mathbf{S}}\boldsymbol{\omega})t}\hat{\mathrm{H}}e^{-\frac{i}{\hbar}(\hat{\mathbf{S}}\boldsymbol{\omega})t} - (\hat{\mathbf{S}}\boldsymbol{\omega}).$$

С учетом явного вида гамильтониана

$$\hat{\mathrm{H}} = -\gamma\left[\mathcal{H}_1\left(\hat{\mathrm{S}}_x\cos\omega t + \hat{\mathrm{S}}_y\sin\omega t\right) + \mathcal{H}_0\hat{\mathrm{S}}_z\right]$$

$$\hat{\mathrm{H}}'_{\mathrm{eff}} = -\gamma\left(\hat{\mathbf{S}}\mathcal{H}'_{\mathrm{efi}}\right), \quad \mathcal{H}'_{\mathrm{eff}} = \left\{\mathcal{H}_1, 0, \mathcal{H}_0 + \frac{\omega}{\gamma}\right\}.$$

Таким образом, мы перешли к некоторому эффективному полю $\mathcal{H}'_{\text{eff},}$ но зато теперь наш гамильтониан $\hat{\text{H}}'_{\text{elf}}$ не зависит от времени.

В новой системе координат магнитное поле однородно и постоянно во времени. Магнитный момент частицы должен прецессировать вокруг направления магнитного поля (см. задачу 2.5.4). Перейдем теперь в представление Гейзенберга, учитывая, что $\partial\hat{\text{H}}'_{\text{eff}}/\partial t = 0$:

$$\chi_H = \chi'' = e^{\frac{i}{\hbar}\hat{H}'_{e\|'}\chi'} = e^{-\frac{i}{\hbar}\gamma\left(\hat{\mathbf{S}}\mathcal{K}'_{ef11}\right)t}\chi' = e^{\frac{i}{\hbar}(\hat{\mathbf{S}}\Omega)t}\chi'.$$

Как видно, переход к представлению Гейзенберга эквивалентен еще одному повороту - вокруг направления вектора $\Omega = -\gamma\mathcal{H}'_{\text{eff}}$ на угол Ωt. Спиновая функция χ'' не зависит от времени (как и должно быть), ибо новый вид уравнения эволюции:

$$i\hbar\frac{\partial}{\partial t}\chi''(t) = 0, \quad \text{потому что} \quad \hat{\text{H}}''_{\text{eff}} = 0.$$

В итоге решение исходного уравнения $\chi(t)$ записывается при помощи оператора эволюции, представляющего собой два последовательных поворота. Поскольку $\chi''(t) = \chi''(0) = \chi'(0) = \chi(0)$, решение принимает вид

$$\chi(t) = e^{-\frac{i}{\hbar}(\hat{\mathbf{S}}\boldsymbol{\omega})t}e^{-\frac{i}{\hbar}(\hat{\mathbf{S}}\Omega)t}\chi(0).$$

Введем обозначения

$$\begin{cases} \omega_0 = \gamma\mathcal{H}_0, \omega_1 = \gamma\mathcal{H}_1, \\ \Omega = \sqrt{(\omega+\omega_0)^2 + \omega_1^2}, \end{cases} \qquad \begin{cases} \sin\theta = \frac{\mathcal{H}_1}{\mathcal{K}'_{\text{eff}}} = \frac{\omega_1}{\Omega}, \\ \cos\theta = \frac{\mathcal{H}_0+\omega/\gamma}{\mathcal{H}'_{\text{eff}}} = \frac{\omega+\omega_0}{\Omega}, \end{cases}$$

где θ - угол между векторами $\mathcal{H}_0$ и $\mathcal{H}'_{\text{eff.}}$. Тогда

$$(\hat{\mathbf{S}}\omega) = \omega\hat{\text{S}}_z, \quad (\hat{\mathbf{S}}\Omega) = -\Omega\left(\hat{\text{S}}_x\sin\theta + \hat{\text{S}}_z\cos\theta\right).$$

Вероятность переворота спина к моменту t равна

$$W_\chi\left(s_z = -\frac{1}{2}\right) = |\chi^+_{-1/2}\chi(t)|^2 = \sin^2\theta\sin^2\left(\frac{\Omega t}{2}\right) = \frac{\omega_1^2}{(\omega+\omega_0)^2+\omega_1^2}\sin^2\left[\frac{1}{2}\sqrt{(\omega+\omega_0)^2+\omega_1^2}\,t\right].$$

Вероятность переворота спина имеет резонансный характер. При условии $\mathcal{H}_1 \ll \mathcal{H}_0\,(\omega_1 \ll \omega_0)$ она мала при всех значениях частоты ω кроме узкой области вблизи точки резонанса $\omega \to -\omega_0 = -2\mu_0\mathcal{H}_0/\hbar$. В резонансной области вероятность может быть близкой к единице в некоторые моменты времени t.

Б-2.5.7 Измерение магнитного момента по создаваемому им полем (!??!)

Можно ли определить магнитный момент μ свободного электрона на основании измерения напряженности создаваемого им поля? (Использовать соотношение неопределённостей).

Solution.

Суть решения в том, что

2.5.7. Магнитное поле движущегося электрона обусловлено как его собственным магнитным моментом, так и его движением. Поле спинового магнитного момента - поле магнитного диполя $\mathcal{H}_{\text{сп}} \sim \mu/r^3$. Магнитное поле движущегося заряда ($v \ll c$)

$$\mathcal{H}_{\text{оp 6}} \sim |\frac{1}{c}[\mathbf{v}\times\mathcal{E}]| \sim \frac{v}{c}\frac{e}{r^2} \sim \frac{p}{mc}\frac{e}{r^2}.$$

Для реализации эксперимента необходимо выполнение условия

$$\frac{\mathcal{H}_{\text{оp}}}{\mathcal{H}_{\text{сп}}} \ll 1, \quad \text{т. е.} \quad \frac{p}{mc}\frac{e}{\mu} \ll 1.$$

Но импульс движущегося электрона точно не известен. Если считать, что область локализации электрона $\sim \Delta r$, то в соответствии с соотношением неопределённостей $p_{\min} \gtrsim \hbar/\Delta r$, и тогда получим

$$\Delta r \gg \frac{e\hbar}{mc}\frac{r}{\mu}.$$

Если μ - спиновый магнитный момент свободного электрона, то $\mu = \mu_0 = e\hbar/(2mc)$, следовательно $\Delta r \gg r$, что противоречит разумной постановке опыта, ибо для проведения эксперимента требуется $\Delta r \ll r$ - локализация частицы.

Б-2.5.8 Квантование магнитного поля в сверхпроводнике

В сверхпроводнике проделано цилиндрическое отверстие, в котором существует магнитное поле, параллельное оси цилиндра. (В толщу сверхпроводника магнитное поле не проникает). Показать, что поток магнитного поля внутри отверстия должен принимать дискретные значения. Найти квант магнитного потока.

Solution.

Это известная задача сверхпроводимости, можно сразу записать ответ.

$$\psi \equiv \sqrt{n_s} e^{i\varphi},$$

где $n_s(\mathbf{r})$ - плотность сверхпроводящих электронов, $\varphi(\mathbf{r})$ - фаза, общая для всех частиц, находящихся в сверхпроводящем состоянии. Используем выражение для плотности тока вероятности при наличии магнитного поля $\mathcal{H} = \operatorname{rot} \mathbf{A}$:

$$\mathbf{j} = \frac{i\hbar}{2m}\left[(\nabla\psi^*)\,\psi - \psi^*(\nabla\psi)\right] - \frac{e\mathbf{A}}{mc}\psi^*\psi = \left[\frac{\hbar}{m}\nabla\varphi - \frac{e}{mc}\mathbf{A}\right] n_s,$$

где мы учли вид функции (1). Проинтегрируем (2) по замкнутому контуру l, проходящему глубоко внутри сверхпроводника, полагая, что плотность n_s постоянна на контуре интегрирования:

$$\frac{mc}{en_s}\oint_l (\mathbf{j}d\mathbf{l}) = \frac{\hbar c}{e}\oint_l (\nabla\varphi d\mathbf{l}) - \oint_l (\mathbf{A}d\mathbf{l}).$$

Левая часть (3) обращается в нуль, так как в толще сверхпроводника магнитного поля нет, т. е. $\mathcal{H} = 0$, следовательно $\operatorname{rot} \mathcal{H} = \frac{4\pi}{c} j = 0$, поэтому и $\mathbf{j} = 0$. Далее

$$\oint_l (\mathbf{A}d\boldsymbol{l}) = \iint \operatorname{rot} \mathbf{A} d\mathbf{S} = \iint \mathcal{H} d\mathbf{S} = \Phi,$$

где Ф - поток вектора магнитного поля сквозь площадь, окруженную контуром. Н наконец

$$\oint_l (\nabla\varphi dl) = \oint \frac{d\varphi}{dl} dl = \oint d\varphi = 2\pi n, \quad n = 0, \pm 1, ...$$

где использовано условие однозначности волновой функции, вследствие чего изменение фазы должно быть равно $2\pi n$. Окончательно получаем, что

$$\Phi = n\Phi_0, \quad \Phi_0 = \frac{2\pi hc}{e},$$

где Φ_0 - квант магнитного потока.

ГК-4.1.

В однородном магнитном поле электрон, рассматриваемый согласно классической механике, движется по винтовой линии, ось которой направлена вдоль магнитного поля. Движение в плоскости, перпендикулярной магнитному полю, происходит с частотой, равной удвоенной частоте Лармора $\left(\omega = \frac{e\mathscr{E}}{2\mu c}\right)$. Рассмотрим движение волнового пакета на основании квантовой механики. Уравнение Шредингера для частицы в магнитном поле можно записать в сле,іующем виде:

$i\hbar\frac{\partial\Psi}{\partial t} = -\frac{\hbar^2}{2i}\Delta\Psi^* + \frac{\hbar}{i}\omega\left(x\frac{\partial\Psi}{\partial y} - y\frac{\partial\Psi}{\partial x}\right) + \frac{1}{2}u\left(\omega^2\left(x^2+y^2\right)\Psi^*\right.$

Чтобы найти решение задачи, удобно перейти к врашающейся системе координат

$$\left.\begin{array}{rl} x & = x'\cos\omega t' - y'\sin\omega t', \\ y & = x'\sin\omega t' + y'\cos\omega t', \\ z & = z', \\ t & = t', \\ \Psi(x,y,z,t) = & = \Psi'\left(x', y', z', t'\right) \end{array}\right\}$$

Тогда

$$\frac{\partial}{\partial t'} = \frac{\partial}{\partial t} + \omega\left(x\frac{\partial}{\partial y} - y\frac{\partial}{\partial x}\right), \quad \Delta' = \Delta$$

Уравнение Шредингера в новых переменных принимает след ую у ylo форМу:

$$i\hbar\frac{\partial\Psi'}{\partial t'} = -\frac{h^2}{2u'}\Delta'\Psi' + \frac{\mu\omega^2}{2}\left(x'^2 + y'^2\right)\Psi'$$

Решение этого уравнения может быты получено разделением переменных x', y', z'. Уравнение для функции о z') описывает свободное движение вдоль оси z. Решение уравнения, определяющее функцию $\psi(x, y, t)$, имеет вид

$$\psi(x, y, t) = \sum_{nm} A_n \left(x'\sqrt{\frac{\mu\omega\omega}{h}}\right)\gamma m\left(y'\sqrt{\frac{\mu\omega}{\hbar}}\right)e^{-i\omega t(n\div m-1)}$$

Здесь x' и y' функции координат x, y и временн, определяемые из (1), χ_n - собственные функции гармонического осцнліятора, A_{mm} - коэффициенты, подобранные так, чтобы выполнялось начальное условие. Это выражение пля $\psi(x, y, t)$ меняет лишь знак, если t возрастает на период классического движения $T = \frac{\pi}{\omega}$. Действительно, x' и y' при этом меняет знак и, учитывая свойство собственной функции осциллятора

$$\chi_n(-\xi) = (-1)^n\chi_n(\xi),$$

Получим:

$$\psi\left(x, y, t + \frac{\pi}{\omega}\right) = \sum A_{nm}(-1)^n\chi_n\left(x'\sqrt{\frac{\mu\omega}{\hbar}}\right)(-1)^m\chi_m\left(y'\sqrt{\frac{\mu\omega}{\hbar}}\right)e^{-i\omega t(n+m+1)}e^{-i\pi(n+m+1)} = -\psi(x, y, t).$$

Таким образом, в плоскости, перпендикулярной магнитному полю, волновой пакет будет периодически изменять свою форму с периодом, равным периоду классического движения частицы в магнитном поле. В направлении магнитного поля пакет расплывается точно так же, как и для свободного движения. Волновая функция $\psi(x, y, t)$ может быть иайдена в явном виде, если начальная функция задана в форме

$$\psi(x, y, 0) = e^{-\frac{\alpha^2}{2}\left[(x-x_0)^2+(y-y)^2\right]+\frac{ip_{0x}}{\hbar}x+\frac{ip_{0y}}{\hbar}}.$$

Полагая все $A_{nm} = 0$, за исключением $A_{00} = 1$, находим, что такой волновой пакет не расплывается в плоскости xy, а его центр тяжести описывает классическую траекторию.

ГК-4.2

2. Показать, что в случае наличия магнитного поля для операторов компонент скорости имеют место следующие правила коммутации:

$$\hat{v}_x\hat{v}_y - \hat{v}_y\hat{v}_x = \frac{ie\hbar}{\mu^2 c}\mathscr{H}_z;$$
$$\hat{v}_y\hat{v}_z - \hat{v}_z\hat{v}_y = \frac{ie\hbar}{\mu^2 C}\mathscr{H}_x;$$
$$\hat{v}_z\hat{v}_x - \hat{v}_x\hat{v}_z = \frac{\mathrm{ieh}}{\mu^2 c}\mathscr{H}_y.$$

Solution.

Для нахождения оператора $\hat{j}$ надо прокоммутировать вектор $\boldsymbol{r}$ с гамильтонианом

$$\hat{\boldsymbol{v}} = \frac{l}{\hbar}(\hat{H}r - r\hat{H})$$

так как

$$\hat{H} = \frac{1}{2\mu}\left(\hat{p} - \frac{e}{c}A\right)^2 + U(r),$$

то находим:

$$\mu\hat{\mathfrak{v}} = \left(\hat{p} - \frac{e}{c}A\right)$$

Теперь найдем правила коммутации этих операторов

$$\hat{v}_x\hat{v}_y - \hat{v}_y\hat{v}_x = \frac{e}{\mu^2 c}\left[-\left(\hat{p}_x A_y - A_y\hat{p}_x\right) + \left(\hat{p}_y A_x - A_x\hat{p}_y\right)\right] = \frac{ie\hbar}{\mu^2 c}\left(\frac{\partial A_y}{\partial x} - \frac{\partial A_x}{\partial y}\right) = \frac{ie\hbar}{\mu^2 c}\mathscr{H}_z.$$

Путем циклической перестановки получаем остальные два соотношения.

ГК-4.3

3. Основываясь на результатах задач 2 § 6 и 5§1, определить энергию заряженной частицы, движущейся в постоянном магнитном поле.

Solution.

Направим ось z по направлению магнитного поля, напряженность которого обозначим через $\mathscr{H}$. Компоненты скорости частицы удовлетворяют следующим правилам коммутации (см. задачу 2$6):

$$\hat{v}_x\hat{v}_y - \hat{v}_y\hat{v}_x = \frac{ie\hbar}{\mu^2 c}\mathscr{H}, \quad \hat{v}_y\hat{v}_z - \hat{v}_z\hat{v}_y = 0, \quad \hat{v}_z\hat{v}_x - \hat{v}_x\hat{v}_z = 0$$

Оператор энергии равен

$$\hat{H} = \frac{\mu\hat{v}_{\boldsymbol{x}}^2}{2} + \frac{\mu\hat{v}_{\vartheta}^2}{2} + \frac{\mu\hat{v}_z^2}{2}.$$

Представим H в виде суммы двух коммутирующих операторов

$$\hat{H}_1 = \frac{\mu\hat{v}_{\boldsymbol{x}}^2}{2} + \frac{\mu\hat{v}_y^2}{2}, \quad \hat{H}_2 = \frac{\mu\hat{v}_z^2}{2}.$$

Собственные значения $\hat{H}$ равны сумме собственных значений $\hat{H}_1$ и $\hat{H}_2$. Найдем собственные значения $\hat{H}_1$. Для этого введем новые обозначения $\hat{v}_x = \alpha\hat{Q}, \quad \hat{v}_y = \alpha\hat{P}$, где $\alpha = \sqrt{\frac{el\sigma\mathscr{L}}{\mu^2 c}}\cdot B$ переменных $\hat{P}, \hat{Q}$ правило коммутации имеет вид $\hat{P}\hat{Q} - \hat{Q}\hat{P} = -i$, а оператор $\hat{H}_1 = \hbar\frac{e\mathscr{C}}{2\mu c}\times\ \chi\left(\hat{P}^2 + \hat{Q}^2\right)$. На основании задачи 5&1 собственные значения $\hat{H}_1$

$$E_{1n} = \hbar\frac{e\mathscr{O}\mathcal{H}}{\mu c}(n + 1/2) \quad (n = 0, 1, 2, ...).$$

Собственные значения $\hat{H}_2$ образуют непрерывный спектр. Итак, энергия движения в магнитном поле

$$E_{nv_z} = \hbar\frac{e\mathscr{H}}{\mu c}(n + 1/2) + \frac{\mu v_z^2}{2}.$$

ГК-4.4

4. Определить энергетический спектр заряженной частицы, движущейся в однородном электрическом и однородном магнитном полях, направления напряженностей которых взаимно перпендикулярны.

Solution.

Направим ось z по направлению магнитного поля, а ось x вдоль электрического поля. Векторный потенциал магнитного поля возьмем в виде $A_y =$ e $x, A_x = A_z = 0$. Оператор Гамильтона в этом случае запишется следующим образом:

$$\hat{H} = \frac{\hat{p}_x^2}{2\mu} + \frac{\left(\hat{p}_y - \frac{e}{c}\mathscr{H}x\right)^2}{2\mu} + \frac{\hat{p}_z^2}{2\mu} - e\mathscr{E}x.$$

Вводя обозначение

$$\frac{e\mathscr{A}}{c}x - \hat{p}_y - \frac{\mu\cdot\mathcal{E}}{\mathscr{E}} = \hat{\pi},$$

получим для $\hat{H}$ выражение

$$\hat{H} = \frac{\hat{p}_x^2}{2\mu} + \frac{\hat{\pi}^2}{2\mu} - \frac{\hat{p}_y c\mathscr{E}}{\mathscr{C}} - \frac{\mu c^2\mathscr{G}^2}{2\mathscr{E}\mathcal{C}^2} + \frac{\hat{p}_z^2}{2\mu}.$$

Соотношение коммутации между $\hat{p}_x$ и $\hat{\pi}$

$$\hat{p}_{x^\pi} - \hat{\pi}\hat{p}_x = -i\frac{\hbar e_{\mathscr{A}}}{c}.$$

Отсюда находим, чго собственные значения оператора $\hat{H}_1 = \frac{\hat{p}_:^2}{2\mu} + \frac{\hat{\pi}^2}{2\mu}$ совпадают с уровнями энергии осциллятора, колеблющегося с удвоенной частотой Лармора

$$E_{1n} = \hbar\frac{e\mathscr{E}}{\mu c}(n + 1/2).$$

Поскольку операторы $\hat{p}_y$ и $\hat{p}_z$, входящие в последние слагаемые оператора Гамильтона, коммугируют с $\hat{H}_1$, оператор $\hat{H}_2 = \frac{\hat{p}_z^2}{2\mu} - \frac{\hat{p}_y c\mathscr{G}}{\mathscr{E}} - \frac{\mu c^2\mathscr{E}^2}{2\mathscr{C}^2}$ может быть приведен одновременно с $\hat{H}_1$ к диаготальному виду.

Итак, энергетический спектр частицы

$$E_{np_yp_z} = \hbar\frac{e\mathscr{C}}{\mu c}(n + 1/2) + \frac{p_z^2}{2\mu} - \frac{p_y c\mathscr{E}}{\mathscr{E}} - \frac{\mu c^2\mathscr{G}^2}{2\mathscr{C}^2}.$$

Сравнение с результатом предыдущей задачи показывает, что электрическое поле снимает вырождение, которое имеет место в случае одного только магнитного поля: энергетические уровни при наличии электрического поля зависят от трех квантовых чисел.

ГК-4.5

5. Определить волновые функции заряженной частицы при движении во взаимно перпендикулярных однородных магнитном и электрическом полях.

Solution.

$$\psi_{np_yp_z}(x, y, z) = e^{\frac{i}{\hbar}(py^{y+p_z})}e^{-\frac{e\mathscr{H}}{2\hbar c}\left(x-\frac{cp_y}{e\mathscr{C}C}-\frac{\mu c^2\mathscr{E}}{e\mathscr{C}}\right)^2} H_n\left[\sqrt{\frac{egt}{ch}}\left(x - \frac{cp_y}{e^2t} - \frac{\mu c\mathscr{G}}{eg^2}\right)\right].$$

$$E_{nmk} = \hbar\sqrt{\omega^2 + \omega_0^2}(2n + |m| + 1) + \hbar\omega m + \hbar\omega_0(k + 1/2),$$

где

$$\omega = \frac{e\mathscr{C}}{2\mu c} \quad (n = 0, 1, 2, ..., m = 0, \pm1, \pm2, ...,$$
$$k = 0, 1, 2, ...).$$

17.2.11 Problems about motion in a magnetic field 2

ГК-4.7.

Определить зависящие от времени операторы координат $\hat{x}, \hat{y}$ заряженной частицы, движущейся в однородном магнитном поле (векторный потенциал $A_x = -\frac{\mathscr{H}}{2}y$, $A_y = \frac{\mathscr{H}}{2}x$, $A_z = 0$). Найти $\overline{(\hat{x} - \bar{\hat{x}})^2}$ и $\overline{(\hat{y} - \bar{\hat{y}})^2}$ как функции времени.

Solution.

$$\hat{x}(t) = \left(\frac{i\hbar}{\mu\omega}\frac{\partial}{\partial y} + \frac{x}{2}\right)\cos\omega t + \left(-\frac{i\hbar}{\mu\omega}\frac{\partial}{\partial x} + \frac{y}{2}\right)\sin\omega t + \left(-\frac{i\hbar}{\mu\omega}\frac{\partial}{\partial y} + \frac{x}{2}\right).$$

$$\hat{y}(t) = \left(-\frac{i\hbar}{\mu\omega}\frac{\partial}{\partial y} - \frac{x}{2}\right)\sin\omega t + \left(-\frac{i\hbar}{\mu\omega}\frac{\partial}{\partial x} + \frac{y}{2}\right)\cos\omega t + \left(-\frac{i\hbar}{\mu\omega}\frac{\partial}{\partial x} + \frac{y}{2}\right).$$

Здесь $\omega = \frac{eH}{\mu c}$ (удвоенная частота прецессии Лармора).

ГК-4.8

Определить уровни энергии и волновые функции заряженной частицы, движущейся в однородном магнитном поле. Воспользоваться цилиндрической системой координат. Векторный потенциал взять в форме $A_\varphi = \frac{\mathscr{H}}{2}\rho, A_\rho = A_z = 0$.

Solution.

Уравнение Шредингера в цилиндрических координатах ρ, φ, z имеет вид (??????)

$$-\frac{\hbar^2}{2\mu}\left\{\frac{\partial^2\psi}{\partial z^2}+\frac{\partial^2\psi}{\partial\rho^2}+\frac{1}{\rho}\frac{\partial\cdot}{\partial\rho}+\frac{1}{\rho^2}\frac{\partial^2\nu}{\partial\varphi^2}\right\}=\frac{ie\hbar}{2\mu c}e\theta\frac{\partial\psi}{\partial\varphi}+\frac{e^2g\ell^2}{8\mu c^2}\rho^2\Big]=E\psi.$$

Решение ищем в форме

$$\psi(\rho,\varphi,z)=\frac{1}{\sqrt{2\pi}}R(p)e^{ik_zz}e^{im\varphi}.$$

Обозначим через γ и β величины

$$\gamma=\frac{e\mathscr{H}}{2ch},\quad \beta=\frac{2\mu E}{\hbar^2}-k_z^2$$

В уравнение, определяющее радиальную функцию $R(p)$,

$$R''+\frac{1}{\rho}R'+\left(\beta--\gamma^2\rho^2-2\gamma m-\frac{m^2}{\rho^2}\right)R=0$$

введем новую независимую переменную $\xi=\gamma\rho^2$, тогда

$$\xi R''+R'+\left(-\frac{\xi}{4}+\lambda-\frac{m^2}{4\xi}\right)R=0,$$

где $\lambda=\frac{\beta}{4\gamma}-\frac{m}{2}$. Искомая функция при $\xi\to\infty$ ведет себя как $e^{-\xi/2}$, а при малых ξ пропорииональна $\xi^m|/2$. Решение дифференциального уравнения (1) ищем в виде

$$R=e^{-\xi/2\xi|m|/2}w(\xi).$$

Функция $w(\xi)$ находится из уравнения

$$\xi\omega''+(1+|m|-\xi)w'+\left(\lambda-\frac{|m|+1}{2}\right)w=0,$$

решение которого представляет вырожденную гипергеометрическую функцию:

$$w=F\left\{-\left(\lambda-\frac{|m|+1}{2}\right),|m|+1,\xi\right\}.$$

Для того чтобы волновая функция была конечна, величина $\lambda-\frac{|m|+1}{2}$ должна равняться целому неотрицательному числу n. Таким образом, уровни энергии определяются выражением

$$E=h\frac{e\mathscr{H}C}{\mu c}\left(n+\frac{|m|}{2}+\frac{m}{2}+\frac{1}{2}\right)+\frac{l_1^2k_z^2}{2\mu}$$

ГК-4.9

9. Найти компоненты плотности тока для заряженной частицы, движущейся в однородном магнитном поле для состояния, характеризуемого квантовыми числами n, m, k_z (см. предыдущую задачу).

Solution.

В цилиндрических координатах

$$\begin{aligned}J_{\mathrm{p}}&=0,\\ J_\varphi&=\left(\frac{e\hbar m}{\mu\rho}-\frac{e^2\mathscr{H}}{2\mu c}p\right)|\psi_{nmk_z}|^2,\\ J_z&=\frac{e\hbar\bar{k_z}}{\mu}|\psi_{nmk_z}|^2.\end{aligned}$$

ГК-10

10. Найти в квазиклассическом приближении уровни энергии заряженной частицы, находящейся в однородном магнитном поле (цилиндрические координаты).

Solution.

Уравнение для радиальной волновой функции R подстановкой $u = \sqrt{\rho}R$ приводится к виду

$$u'' + \left[\frac{2i}{h^2}E - k_z^2 - \frac{1}{p^2}\left(m + \frac{e\mathscr{H}C}{2\hbar c}p^2\right)^2\right]u = 0,$$

при этом $m^2 - \frac{1}{4}$ заменяется на m^2*. Эта замена аналогична замене $l(l+1) \to (l+1/2)^2$ и может быть обоснована способом, указанным при решении задачи 2$5. (??)

Выражение

$$U_{\text{eff}}(\rho) = \frac{\hbar^2}{2\mu p^2}\left(m + \frac{e\mathscr{H}}{2\hbar c}p^2\right)^2$$

можно рассматривать как эффективную потенциальную энергию при одномерном движении.

Из условия квантования (!!! укажу еще раз этот крутой метод в 1 части!!!!)

$$\int_{p_1}^{\rho_2}\sqrt{\frac{2p}{\hbar^2}E - k_z^2 - \frac{1}{p^2}\left(m + \frac{e^g\mathscr{G}}{2\hbar c}p^2\right)^2}\,dp = \pi(n+1/2)$$

получаем энергетический спектр:

$$E - \frac{\hbar^2 k_z^2}{2\mu} = \frac{e\hbar\mathscr{C}}{\mu c}\left(n + \frac{|m|}{2} + \frac{m}{2} + \frac{1}{2}\right).$$

Энергия, отсчитываемая от минимума $U_{\text{eff}}(p)$ равна

$$E' = \frac{eh\mathscr{H}}{\mu c}(n+1/2)$$

представляет собою энергию радиального движения, а энергия

$$E'' = \frac{e\hbar\mathscr{H}}{2\mu c}(m + |m|)$$

соответствует энергии вращательного движения. Переход к классическим круговым орбитам осуществляется при выполнении условия $E' \ll E''$ или $n \ll \frac{m+|m|}{2}$. Это условие, очевидно, выполняется лишь при положительных m и поэтому может быть записано в виде $n \ll m$.

ГК-4.11

11. Определить классически доступную область радиального движения частицы в магнитном поле (см. предыдущую задачу).

Solution.

Приравнивая нулю подкоренное выражение, получаем для $m > 0$

$$p_{1,2} = \sqrt{\frac{2\hbar c}{e_Q\mathscr{F}}}\left(\sqrt{n + m + \frac{1}{2}} \pm \sqrt{n + \frac{1}{2}}\right).$$

ГК-4.12 Размазанность орбиты (???)

Оценить минимальную «размазанность» орбиты в радиальном направлении для заряженной частицы в магнитном поле.

Solution.

(???)

$$\Delta p \sim \sqrt{\frac{\hbar c}{e\mathscr{H}}}.$$

ГК-4.13 (???)

Уравнение Паули имеет вид

$$i\hbar\frac{\partial}{\partial t}\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix} = \hat{H}_0\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix} - \mu_0(\hat{\sigma}\,\mathcal{H})\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix},$$

где $\hat{H}_0 = \frac{1}{2\mu}\left(p - \frac{e}{c}A\right)^2 + eU,$ а μ_0 - магнитный момент частицы. Будем искать волновую функцию в виде

$$\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix} = \varphi(x,y,z,t)\begin{pmatrix}s_1(t)\\ s_2(t)\end{pmatrix}.$$

где функция φ является решением уравнения $i\hbar\frac{\partial\varphi}{\partial t} = \hat{H}_0\varphi$.

Тогда для спиновой функции $\begin{pmatrix}s_1\\ s_2\end{pmatrix}$ получаем уравнение

$$i\hbar\frac{\partial}{\partial t}\begin{pmatrix}s_1\\ s_2\end{pmatrix} = -\mu_0(\hat{\boldsymbol{\sigma}}\boldsymbol{\mathcal{H}})\begin{pmatrix}s_1\\ s_2\end{pmatrix}.$$

ГК-4.15

Поскольку $\mathscr{H}_x = \mathscr{H}_y = 0$, $\mathscr{H}_z = \mathscr{H}C'(t)$, имеем:

$$i\hbar\frac{\partial s_1}{\partial t} = -\mu_0\mathscr{H}(t)s_1,$$
$$i\hbar\frac{\partial s_2}{\partial t} = \mu_0\mathscr{H}(t)s_2.$$

Решения этих уравнений имеют вид

$$s_2 = c_2 e^{-\frac{i_2,2}{\hbar}\int\limits_0^t \mathscr{H}(t)dt.}$$

Постоянные c_1 и c_2 находим из начальных условий: $c_1 = e^{-i\alpha}\cos\delta, c_2 = e^{i\alpha}\sin\delta$. Из вида функции s_1 и s_2 следует, что вероятность той или иной ориентации спина на ось z не меняется со временем. Среднее значение проекции спина на ось x определяется выражением

$$\bar{\hat{s}}_x = -\frac{\hbar}{2}\sin 2\hat{\delta}\cdot\cos\left\{\frac{2\mu_0}{\hbar}\int\limits_0^t \mathscr{H}(t)dt - 2\alpha\right\}$$

и аналогично

$$\overline{\hat{s}_y} = -\frac{\hbar}{2}\sin 2\hat{o}\cdot\sin\left\{\frac{2\mu_0}{\hbar}\int\limits_0^t \mathscr{H}(t)dt - 2x\right\}.$$

Направление, вдоль которого проекция спина имеет значение $+1/2$, характеризуется полярными координатами $\theta = 2\hat{,}\ \Phi = 2\left(\alpha - \frac{\mu_0}{\hbar}\int\limits_0^t \mathscr{H}(t)dt\right)$. Таким образом, это направление

$$s_1 = c_1 e^{\frac{iw_0}{\hbar}\int\limits_0^t \mathscr{H}(t)dt}$$

описывает с течением времени коническую поверхность. При постоянной напряженности поля прямая, «вдоль которой направлен спин», равномерно вращается вокруг направления магнитного поля частотой $\frac{2\mu_0\mathscr{H}}{h}$.

ГК-4.16

Состояние с произвольной поляризацией падающего пучка всегда может быть представлено как суперпозиция двух состояний, в одном из которых $\begin{pmatrix}1\\0\end{pmatrix}$ спин направлен вдоль оси z, а в другом $\begin{pmatrix}0\\1\end{pmatrix}$ в противоположном направлении. Рассмотрим сначала случай, когда спины нейтронов в падающем пучке направлены по оси z. Тогда падающая, отраженная и преломленная волны будут иметь вид

$$A\begin{pmatrix}1\\0\end{pmatrix}e^{ikr},\quad B\begin{pmatrix}1\\0\end{pmatrix}e^{ik_1r},\quad C\begin{pmatrix}0\\1\end{pmatrix}e^{ik_2r}.$$

Величины $\boldsymbol{k},\boldsymbol{k}_1,\boldsymbol{k}_2$ связаны с полной энергией E и магнитным моментом μ_0 нейтрона соотношениями:

$$\boldsymbol{k}=\frac{\boldsymbol{p}}{h},\quad \frac{\hbar^2k^2}{2\mu}=E,\quad \frac{\hbar^2k_1^2}{2\mu}=E,\quad \frac{\hbar^2k_2^2}{2\mu}=E+\mu_0\Theta^3.$$

Из условия непрерывности на плоскости раздела ($x=0$) вопновой функции и ее производной по x следует:

$$k_y=k_{1y}=k_{2y},\quad k_z=k_{1z}=k_{2z},$$
$$A+B=C,$$
$$k_xA+k_{1x}B=k_{2x}C.$$

Из этих соотношений вытекает, что $k_{1x}=-k_x$, т. е. угол падения ϕ равен углу отражения ϕ_1. Положим для простоты $k_y=0$. Решая уравнения, находим:

$$\left(\frac{B}{A}\right)=\frac{k_x-k_{2x}}{k_x+k_{2x}}\quad\left(\frac{C}{A}\right)=\frac{2k_x}{k_x+k_{2x}},$$
$$k_{2x}=k_x\sqrt{1+\frac{2\mu}{\hbar^2k_x^2}\mu_0\mathcal{A}\mathcal{H}^H}.$$

Таким образом, коэффициент отражения R равен

$$R=\left(\frac{B}{A}\right)^2=\left(\frac{k_x-k_{2x}}{k_x+k_{2x}}\right)^2$$

Если спины нейтронов ориентированы в противоположном оси z направлении, то в этом случае

$$k_{2x}=k_x\sqrt{1-\frac{2\mu}{\hbar^2k_x^2}\mu_0\vartheta^2},$$

а в остальном результаты будут те же. Так как μ_0 для нейтрона отрицательно, то угол преломления $\varphi 2\uparrow>\varphi>\varphi_{2\uparrow}$ (см. рис. 27).

В случае произвольной ориентации спина нейтронов волновая функция в области $x>0$ будет иметь вид

$$C_\uparrow\begin{pmatrix}1\\0\end{pmatrix}e^{-ik_\uparrow\boldsymbol{r}}+C_\downarrow\begin{pmatrix}0\\1\end{pmatrix}e^{ik_\downarrow\boldsymbol{r}},$$

где $C_\uparrow$ и $C_{\mathrm{Im}\dot{a}th}$ - коэффициенты разложения начального спинового состояния по состояниям $\begin{pmatrix}1\\0\end{pmatrix}$ и $\begin{pmatrix}0\\1\end{pmatrix}$.

Простая оценка показывает, что даже при (???) $\sim10^4$ заметное отражение будет иметь место только для очень медленных (тепловых) нейтронов ($\lambda\sim1\text{Å}$) и при угле падения φ, отличающемся от $\frac{\pi}{2}$ на доли градуса.

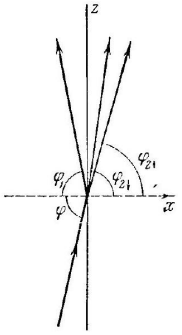

Рис. 27.

ГК-4.17 Вращающееся магнитное поле

Частица со спином 1/2 находится в однородном магнитном поле, постоянном по абсолютной величине и изменяющемся во времени по закону

$$\mathscr{H}_x = \mathscr{H}\sin\vartheta\cos\omega t, \quad \mathscr{H}_y = \mathscr{H}\sin\hat{i}\sin\omega t,$$
$$\mathscr{H}_z = \mathscr{H}\cos\vartheta.$$

В момент времени $t = 0$ проекция спина на направление магнитного поля имела значение $+1/2$. Определить вероятность перехода частицы к моменту времени t в состояние, в котором проекция спина на направление магнитного поля равна - 1/2.

Solution.

$$i\hbar\frac{\partial}{\partial t}\begin{pmatrix}s_1\\ s_2\end{pmatrix} = -\mu\begin{pmatrix}\mathscr{H}_z & \mathscr{H}_x - i\mathscr{H}_y\\ \mathscr{H}_x + i\mathscr{H}_y & -\mathscr{H}z\end{pmatrix}\begin{pmatrix}s_1\\ s_2\end{pmatrix}$$

$$a := \frac{\mu}{\hbar}\cdot\mathscr{H}\cos\theta, \qquad b := \frac{\mu}{h}\mathscr{H}\sin\theta.$$

$$\frac{ds_1}{dt} = ias_1 + ibe^{-i\omega t}s_2,$$
$$\frac{ds_2}{dt} = ibe^{i\omega t}s_1 ias_2$$

$$s_1 = Ae^{ip_1 t} + Be^{ip_2 t},$$
$$s_2 = e^{i\omega t}\left[\frac{-a+p_1}{b}Ae^{ip_1 t} + \frac{-a+p_2}{b}Be^{ip_2 t}\right],$$

$p_1 := \sqrt{\frac{\omega^2}{4} + a^2 + b^2 + \omega a} - \frac{\omega}{2}, \qquad p_2 := -\sqrt{\frac{\omega^2}{4} + a^2 + b^2 + \omega a} - \frac{\omega}{2}.$

Величины A и B определяются из начальных условий и условия нормировки $|s_1|^2 + |s_2|^2 = 1$.

Проделав несложные вычисления, получаем для вероятности перехода следующие значения:

$$P\left(\frac{1}{2}, -\frac{1}{2}\right) = \frac{\sin^2\vartheta}{1+q^2-2q\cos\theta}\sin^2\left[\frac{t}{2}\omega\left(1-2q\cos\theta+q^2\right)^{1/2}\right]$$

где q есть отношение частоты ларморовской прецессии к частоте вращающегося магнитного поля

$$q := -\frac{2\mu\mathscr{H}}{\hbar\omega} \equiv \frac{\omega_0}{\omega}.$$

Величина q положительна, если магнитное поле вращается в направлении прецессии, и отрицательна, если вращение происходит в обратном направлении.

Если угол θ мал, т. е. $\frac{\sqrt{\mathscr{E}_x^2+\ell_y^2}}{\mathscr{E}_z} \ll 1$, то

$$P\left(\frac{1}{2}, -\frac{1}{2}\right) \approx \frac{\vartheta^2}{(1-q)^2+q\vartheta^2}\sin^2\left[\frac{t}{2}\omega\left[(1-q)^2+q\vartheta^2\right]^{1/2}\right].$$

Из этой формулы следует, что при резонансном соотношении $\omega = \omega_0$, т. е. при $q = +1$ вероятность переориентации магнитного момента относительно магнитного поля, равная $P\left(\frac{1}{2}, -\frac{1}{2}\right) \approx \sin^2\frac{t\omega}{2}\theta$, может оказаться близкой к единице при некотором значении t.

Если же в рассматриваемом случае изменить направление вращения магнитного поля (или изменить знак у $\mathscr{H}_z$), то для вероятности перехода получим величину

$$P\left(\frac{1}{2}, -\frac{1}{2}\right) = \frac{\vartheta^2}{4}\sin^2\omega t$$

значительно меньшую единицы. На основании такого резкого качественного различия можно определить знак магнитного момента частицы

ГК-4.18 (????)

Частица, обладающая спином 1/2 и магнитным моментом μ, движется в неоднородном магнитном поле вида

$$\mathscr{E}\mathscr{H}_z = \mathscr{H}_0 + kz, \quad \mathscr{H}_y = -ky, \quad \mathscr{H}_x = 0 \quad (\mathrm{div}\mathscr{H} = 0).$$

а) Найти выражения для зависящих от времени операторов координат x, y, z.

б) Определить средние значения координат и зависимость дисперсии координат от времени, если волновая функция частицы в момент времени $t = 0$ имеет вид

$$\psi = \varphi(x, y, z)e^{\frac{ip_0 x}{\hbar}}\begin{pmatrix} a \\ p \end{pmatrix}.$$

Solution.

а)

$$\hat{x}(t) = \frac{\hat{p}_x}{m}t + x,$$
$$\hat{y}(t) = -\frac{\mu k}{2m}t^2\hat{\sigma}_y + \frac{\hat{p}_y}{m}t + y,$$
$$\hat{z}(t) = -\frac{\mu k}{2m}t^2\hat{\sigma}_z + \frac{\hat{p}_z}{m}t + z,$$

б)

$$\overline{\bar{z}(t)} = \bar{z}(t) = \frac{\mu k}{2m}t_0^2\hat{\sigma}_z + \frac{\mu k}{2m}t^2\left(\alpha\alpha^* - \beta\beta^*\right),$$
$$\overline{\hat{y}(t)} = (\bar{y})_0 - \frac{\mu k}{2m}t^2\left(i\hat{\beta}^*\alpha - i\beta\alpha^*\right),$$
$$\overline{\hat{x}(t)} = (\bar{x})_0 + \frac{p_0}{m}t,$$

$$\overline{(\Delta\hat{z})_t^2} = \overline{(\Delta z)_0^2} + \frac{\mu^2k^2}{4m^2}t^4\left[1 - (\alpha\alpha^* - \beta\beta^*)^2\right] + \frac{h^2t^2}{m^2}\int\left(\frac{\partial\varphi}{\partial z}\right)^2 d\tau,$$
$$\overline{(\Delta\hat{y})_t^2} = \overline{(\Delta y)_0^2} + \frac{\mu^2k^2}{4m^2}t^4\left[1 - (i\beta^*\alpha - i\beta\alpha^*)^2\right] + \frac{h^2t^2}{m^2}\int\left(\frac{\partial\varphi}{\partial y}\right)^2 d\tau,$$
$$\overline{(\Delta\hat{x})_t^2} = \overline{(\Delta x)_0^2} + \frac{h^2t^2}{m^2}\int\left(\frac{\partial\varphi}{\partial x}\right)^2 d\tau,$$

Замечание. Рассмотрим, например, совокупность частиц, у которых проекция спина на ось z при $t = 0$ с достоверностью имеет значение $+1/2$, т. е. $x = 1, \beta = 0$. Как легко видеть из полученных результатов, если на пути таких частиц, движущихся в неоднородном магнитном поле, поставить экран, то на нем этими частицами будет образовано два пятна. z-координаты этих пятен будут одинаковы, а y-е координаты противоположны по знаку.

ГК-4.19

Нейральная частица находится в пространственно-однородном магнитном поле, изменяющемся во времени лишь по направлению, но не по абсолютной величине.

Написать уравнения для спиновой функции в «ξ» представлении, где ось ξ направлена вдоль магнитного поля. Показать, что в случае достаточно медленного изменения направления магнитного поля вероятности тех или иных значений проекций момента на направление поля не изменяются.

Solution.

(?? если нейтральная, то почему она взаимодействует вообще с МП???)

Направление магнитного поля будем характеризовать полярными углами (?), φ. Углы it и φ являются функциями времени. Оператор Гамильтона для нейтральной частицы представим в виде

$$\hat{H} = -\mu\mathscr{H}?\left(\hat{J}_x\sin\theta\cos\varphi + \hat{J}_y\sin\theta\sin\varphi + \hat{J}_z\cos\theta\right)$$

здесь $\mathscr{H}$ - абсолютное значение напряженности магнитного поля. Обозначим через $\hat{J}_\xi$ оператор момента в направлении магнитного поля

$$\hat{J}_\xi = \hat{J}_x\sin\theta\cos\varphi + \hat{J}_y\sin\vartheta\sin\varphi + \hat{J}_z\cos \geqslant$$

и введем функции $\psi_m(t)$, которые являются собственными функциями оператора $\hat{J}_\xi$, т. е.

$$\hat{J}_\xi \psi_m(t) = m\psi_m(t).$$

Будем искать решение уравнения Шредингера

$$i\hbar\frac{\partial\psi}{\partial t} = \hat{H}\psi$$

В виде

$$\psi = \sum a_m(t)\psi_m(t).$$

Как пізвестно (см. задачу 19§4),

$$\psi_m(t) = e^{-i\hat{J}_z^\varphi \cdot e^{-i\hat{J}_y^\vartheta}}\psi_m^{(0)},$$

где $\psi_m^{(0)}$ удовлетворяет соотношению

$$\hat{J}_z\psi_m^{(0)} = m\psi_m^{(0)}$$

Вычислим сперва $\dot{\psi}_m(t)$. Воспользовавшись соотношениями

$$\begin{aligned}
&e^{i\hat{J}_y^\vartheta}\hat{J}_z e^{-i\hat{J}_y^\vartheta} = \hat{J}_z\cos\geqslant -\hat{J}_x\sin\vartheta,\\
&\hat{J}_{x\psi m}\psi_m^{(0)} = \frac{1}{2}\sqrt{(j+m)(j-m+1)}\psi_{m-1}^{(0)} +\\
&+\frac{1}{2}\sqrt{(j+m+1)(j-m)}\psi_{m+1}^{(0)},\\
&\hat{J}_y''\psi_m^{(0)} = \frac{t}{2}\sqrt{(j+m)(j-m+1)}\psi_{m-1}^{(0)} -\\
&-\frac{i}{2}\sqrt{(j+m+1)(j-m)}\psi_{m+1}^{(0)},
\end{aligned}$$

имеем:

$$\begin{aligned}
\dot{\psi}_m(t) =&(-i\dot{\varphi}m\cos i)\psi_m(t) +\\
&+\frac{1}{2}\sqrt{(\dot{j}+m+1)(j-m)}(\dot{i}\varphi\sin i - \dot{i})\psi_{m+1}(t) +\\
&+\frac{1}{2}\sqrt{(j+m)(j-m+1)}(i\varphi\sin\vartheta + \dot{v})\psi_{m-1}(t).
\end{aligned}$$

Подставляя значение $\dot{\psi}_m(t)$ в выражение

$$i\hbar\sum_m\left\{\psi_m(t)\dot{a}_m(t) + a_m(t)\dot{\psi}_m(t)\right\} = -\mu\mathscr{H}\sum_m ma_m(t)\psi_m(t),$$

получаем систему уравнений, определяющих изменение коэффициентов a_m во времени:

$$\begin{aligned}
i\hbar\frac{da_m}{dt} + m\mu\mu_i\mathcal{H}a_m = &-m\hbar\dot{\varphi}\cos\vartheta a_m +\\
&+\frac{1}{2}\hbar(\dot{\varphi}\sin\vartheta + i\dot{\vartheta})\sqrt{(j+m)(j-m+1)}a_{m-1} +\\
&+\frac{1}{2}\hbar(\dot{\varphi}\sin\vartheta - i\dot{0})\sqrt{(j-m)(j+m+1)}a_{m+1}
\end{aligned}$$

Если

$$\dot{\varphi} \ll \frac{\mu\mathcal{H}}{\hbar}, \quad \dot{v} \ll \frac{\mu\mathcal{H}}{\hbar},$$

т. е. угловая скорость изменения направления магнитного поля много меньше частоты прецессии, то в приведенной системе уравнений можно пренебречь правой частью и тогда

$$a_m \sim e^{i\frac{m\mu\cdot\mathscr{F}}{\hbar}t}$$

Таким образом, в этом случае вероятности различных значений проекции момента на изменяющееся во времени направление магнитного поля остаются постоянными.

ФР.?? Проекция спина (????)

Частица со спином 1/2 находится в однородном магнитном поле, направленном по оси z, изменяющемся по абсолютной величине по произвольному закону $\mathscr{H} = \mathscr{H}(t)$. В начальный момент времени ($t = 0$) спиновая функция имела вид $\begin{pmatrix} e^{-i\alpha}\cos\delta \\ e^{i\alpha}\sin\delta \end{pmatrix}$. Определить среднее значение проекции спина на оси x и y, а также на направление, вдоль которого проекция спина имеет определенное значение в момент времени t.

Solution.

$$i\hbar\frac{\partial s_1}{\partial t} = -\mu_0\mathscr{H}(t)s_1,$$
$$i\hbar\frac{\partial s_2}{\partial t} = \mu_0\mathscr{H}(t)s_2.$$

Решения этих уравнений имеют вид

$$s_1 = c_1 e^{\frac{i\mu_0}{\hbar}\int\limits_0^t \mathscr{H}(t)dt},$$
$$s_2 = c_2 e^{-\frac{ix_1}{\hbar}\int\limits_0^t \mathscr{H}(t)dt}$$

Постоянные c_1 и c_2 находим из начальных условий: $c_1 = e^{-i\alpha}\cos\delta, c_2 = e^{i\alpha}\sin\delta$. Из вида функции s_1 и s_2 следует, что вероятность той или иной ориентации спина на ось z не меняется со временем. Среднее значение проекции спина на ось x определяется выражением

$$\bar{\hat{s}}_x = \frac{\hbar}{2}\sin 2\delta\cdot\cos\left\{\frac{2\mu\mu_0}{\hbar}\int\limits_0^t \mathscr{H}(t)dt - 2x\right\}$$

и аналогично этому

$$\overline{\hat{s}_y} = -\frac{\hbar}{2}\sin 2\hat{\partial}\cdot\sin\left\{\frac{2\mu_0}{\hbar}\int\limits_0^t \mathscr{Z}t(t)dt - 2\alpha\right\}.$$

Направление, вдоль которого проекция спина имеет значение $+1/2$, характеризуется полярными координатами $\Theta = 2\hat{,}$, $\Phi = 2\left(\alpha - \frac{\mu_0}{\hbar}\int\limits_0^t \mathscr{H}(t)dt\right)$. Таким образом, это направление описывает с течением времени коническую поверхность. При постоянной напряженности поля прямая, «вдоль которой направлен спин», равномерно вращается вокруг направления магнитного поля с частотой $\frac{2\mu 0\mathscr{A}}{h}$.

17.3 Basic Scatterings

17.3.1 Problems about Passing though a Barrier 1

(задачник Гольдмана Кривченкова, Галицкого 1981, мощные)
(!!!! самое главное - раздел про взятие интегралов для вкб!!! все в это упирается!!! также условия применимости важно выделить!)

Б-2.2.13 Типичные прохождения (!?!?)

Найти коэффициенты прохождения и отражения:
а) для прямоугольной ямы;
б) для прямоугольного потенциального барьера (рассмотреть случаи, когда энергия падающей частицы больше и меньше высоты потенциального барьера).

Solution. а), для ямы

Как всегда: пишем анзацы, сшиваем, получаем коэффициенты, по ним считаем поток, а от потоков - требуемые коэффициенты.

$$U(x) = \begin{cases} -U_0, & |x| < a/2 \\ 0, & |x| > a/2 \end{cases}$$

$$\psi(x) = \begin{cases} e^{ikx} + Ae^{-ikx}, & x < -a/2, \\ Ce^{ik_1 x} + De^{-ik_1 x}, & |x| < a/2, \\ Be^{ikx}, & x > a/2, \end{cases}$$

$$k^2 := \frac{2mE}{\hbar^2} > 0, \quad k_1^2 := \frac{2m\left(E + U_0\right)}{\hbar^2}.$$

Учет условии непрерывности волновой функции ψ и ее производной ψ' в точках $x = \pm a/2$ дает систему из четырех уравнений.

(?? проделаю, по идее всё решит без проблем)

В результате решения этой системы имеем

$$A = \frac{ie^{-ika}\left(k_1^2 - k^2\right)\sin k_1 a}{2kk_1 \cos k_1 a - i\left(k_1^2 + k^2\right)\sin k_1 a},$$

$$B = \frac{2kk_1 e^{-ik_1 a}}{2kk_1 \cos k_1 a - i\left(k_1^2 + k^2\right)\sin k_1 a}.$$

Reflection:

$$R = \frac{|j_x^{\text{refl}}|}{|j_x^{\text{in}}|} = |A|^2 = \frac{\left(k_1^2 - k^2\right)\sin^2 k_1 a}{4k_1^2 k^2 \cos^2 k_1 a + \left(k_1^2 + k^2\right)^2 \sin^2 k_1 a} = \frac{\left(k_1^2 - k^2\right)\sin^2 k_1 a}{4k_1^2 k^2 + \left(k_1^2 - k^2\right)^2 \sin^2 k_1 a}.$$

$R = 0$ при $k_1 a = \frac{a}{\hbar}\sqrt{2m\left(E + U_0\right)} = n\pi, n = 1, 2, ...$, а также, естественно, при $k = k_1, (U_0 = 0)$.

Transmission:

$$D = \frac{|j_x^{\text{прош}}|}{|j_x^{\text{nan}}|} = |B|^2 = \frac{4k_1^2 k^2}{4k_1^2 k^2 \cos^2 k_1 a + \left(k_1^2 + k^2\right)^2 \sin^2 k_1 a} = \frac{4k_1^2 k^2}{4k_1^2 k^2 + \left(k_1^2 - k^2\right)^2 \sin^2 k_1 a}.$$

Также выполняется $D + R = 1$.

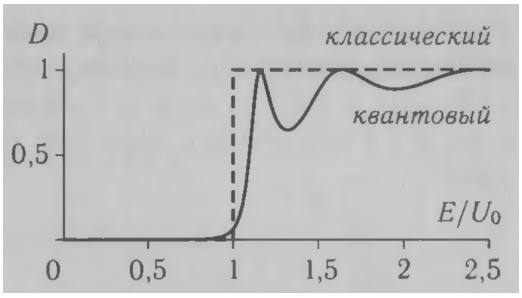
Solution. б), для барьера

Полученные результаты для коэффициентов прохождения и отражения будут справедливы и в случае потенциального барьера

$$U(x) = \begin{cases} 0, & |x| > a/2, \\ U_0, & |x| < a/2, \end{cases}$$

если в формуле $k_1^2 = \frac{2m}{\hbar^2}\left(E + U_0\right)$ осуществить замену $U_0 \to -U_0$. При $0 < E < U_0$ нужно дополнительно положить $k_1 = i\varkappa_1$, где $\varkappa_1^2 = \frac{2m}{\hbar^2}\left(U_0 - E\right)$. В результате получаем

$$R = \frac{\left(\varkappa^2 + k^2\right)\operatorname{sh}^2 \varkappa_1 a}{4\varkappa_1^2 k^2 + \left(\varkappa_1^2 + k^2\right)^2 \operatorname{sh}^2 \varkappa_1 a}, \qquad D = \frac{4\varkappa_1^2 k^2}{4\varkappa_1^2 k^2 + \left(\varkappa_1^2 + k^2\right)^2 \operatorname{sh}^2 \varkappa_1 a}$$



Из рис. видно, что коэффициент прохождения D в квантовом случае достигает максимального значения $D = 1$ (классический предел) лишь при $k_1 a = \pi n, n = 1, 2, ...$ Между этими максимумами находятся минимумы, причем значение D в этих точках растет с ростом величины E/U_0.

Б-2.2.16 Отражение от ямы и стенки

Найти фазу отраженной волны $e^{ikx+i\varphi}$ относительно падающей из бесконечности $-e^{-ikx}$ от потенциала

$$U(x)=\begin{cases}\infty, & x<0\\ -U_0, & 0<x<a\\ 0, & x>a\end{cases}$$

при $|\varepsilon|\ll\hbar^2/\left(2ma^2\right)$. Выразить ее через энергию слабосвязанного уровня ($ka\ll 1$).

Solution.

В соответствии с условием (см. также задачу 2.2.4) выбираем решение в виде

$$\psi(x)=\begin{cases}A\sin k_1x, & 0<x<a,\\ -e^{-ikx}+e^{ikx+i\varphi}=e^{i\varphi/2}2i\sin(kx+\varphi/2), & x\geqslant a.\end{cases}$$

Здесь введены стандартные обозначения:

$$E=\frac{\hbar^2k^2}{2m},\quad U_0=\frac{\hbar^2k_0^2}{2m},\quad k^2+k_0^2=k_1^2.$$

Решение в области $0<x<a$ следует из граничного условия $\psi(0)=0$; φ - дополнительная фаза, приобретенная отраженной волной.

Условие непрерывности логарифмической производной при $x=a$ дает, что

$$ka\operatorname{ctg}(ka+\varphi/2)=k_1a\operatorname{ctg}k_1a.$$

По условию задачи в яме должен быть один слабосвязанный уровень. При глубине ямы

$$U_{0\min}=\frac{\pi^2\hbar^2}{8ma^2}$$

в ней появляется первый дискретный уровень энергии (см. задачу 2.2.4), но его энергия $|\varepsilon|=0$. Поэтому предположим, что глубина ямы $U_0=U_{0\min}(1+\Delta)$, где $\Delta\ll 1$. Раскладывая (2) в предположении $\Delta\ll 1$ и $ka\ll 1$ (омедленные» частицы), получаем условие для определения фазы:

$$\operatorname{ctg}\frac{\varphi}{2}\simeq-\frac{\pi^2\Delta}{8ka}.$$

Величину Δ можно связать с энергией ε слабосвязанного уровня. Для этого в уравнении, определяющем связанные уровни энергии,

$$\operatorname{ctg}Ka=-\frac{\varkappa}{K},\qquad \text{где } |\varepsilon|=\frac{\hbar^2\varkappa^2}{2m}, K^2=k_0^2-\varkappa^2$$

проведем разложение, считая, что $\ll 1, \Delta\ll 1$ (k_0 связано с U_0 обычным соотношением (1)). В результате найдем

$$\varkappa\simeq\frac{\pi^2\Delta}{8a},$$

поэтому окончательно

$$\operatorname{ctg}\frac{\varphi}{2}\simeq-\frac{\varkappa}{k}=-\sqrt{\frac{|\varepsilon|}{E}}.$$

Г.1981-9.26. Сглаженный барьер

Вычислить в квазиклассическом приближении коэффициент прозрачности параболического барьера вида

$$U(x)=\begin{cases}U_0\left(1-x^2/a^2\right), & |x|<a\\ 0, & |x|>a\end{cases}$$

(при этом специально обсудить случай медленных частиц $E\to\to 0$).

Solution.

Г.1981-9.27 Линейный барьер

Оценить в квазиклассическом приближении коэффициент прозрачности барьера вида

$$U(x) = \begin{cases} 0, & x < 0 \\ U_0(1 - x/a), & x > 0 \end{cases}$$

Какова точность полученного результата (сравнить с 9.31 и 9.32)?

Solution.

Стандартная формула для коэффициента прозрачности барьера в квазиклассическом приближении

$$D \approx \exp\left[-\frac{2}{\hbar}\int\limits_{x_1}^{x_1} |p|dx\right] = \exp\left[-\frac{2}{\hbar}\int\limits_{0}^{x_0} \sqrt{2m\,(U_0 - E - U_0 x/a)}dx\right]$$

в рассматриваемой задаче непосредственно не применима, так как в окрестности левой точки поворота $x = 0$ нарушаются условия сшивания квазиклассических решений, использованные при выводе (1) (эти условия приведены в решении предыдущей задачи). Тем не менее формулу (1) можно использовать для оценки коэффициента прозрачности. Элементарное интегрирование дает

$$D \sim \exp\left[-\frac{4a\sqrt{2m}}{3U_0\hbar}\,(U_0 - E)^{3/2}\right].$$

Выражение (2) определяет коэффициент прозрачности лишь по порядку величины (или, как говорят, с точностью до предэкспоненциального множителя, который при $E \sim U_0$ имеет величину порядка единицы; следует, однако, иметь в виду, что при $E \to 0$ этот множитель обращается в нуль -см. 9.32). Однако в случае, когда под знаком экспоненты в этом выражении стоит большое по величине отрицательное число, формула (2) правильно передает основное - экспоненциальную малость коэффициента прозрачности.

Г.1981-9.28.

То же, что и в предыдущей задаче, для барьера вида

$$U(x) = \begin{cases} 0, & x < 0 \\ U_0 \exp(-x/a), & x > 0 \end{cases}$$

(см. также 9.31).

Solution.

Согласно формуле для коэффициента прозрачности барьера в результате элементарного интегрирования находим

$$D \sim \exp\left[\frac{2}{\hbar}\int\limits_{x_1}^{x_2} |p|dx\right] = \exp\left\{-\frac{4a}{\hbar}\sqrt{2mE}\left[\sqrt{\frac{U_0}{E} - 1} - \operatorname{arctg}\sqrt{\frac{U_0}{E} - 1}\right]\right\}.$$

Г.1981-9.30. Гауссов барьер

В квазиклассическом приближении найти коэффициент прозрачности барьера

$$U(x) = \frac{U_0 a^2}{x^2 + a^2}$$

при достаточно малой энергии частиц.

Solution.

9.30. Интеграл в показателе экспоненты в выражении для $D(E)$ заменой переменной $x = a\ \mathrm{sh}\ t$ приводится к виду $\left(\mathrm{sh}\, t_0 = \sqrt{U_0/E - 1} \equiv b^{-1}\right)$

$$\int_{x_1}^{x_2} |p| dx = 2a\sqrt{2m\,(U_0 - E)} \int_0^{t_0} \sqrt{1 - \frac{E}{U_0 - E}\,\mathrm{sh}^2\, t} dt.$$

Инчеграл в выражении (1) представляет собой эллиптический китеграл второго рода. При $E \ll U_0$ этот интеграл легко вычислить приближенно, если учесть, что при этом подкоренное 376 выражение равно единице во всем интервале интегрирования, за исключением узкой области вблизи верхнего иредела интегрирования, в которой $\mathrm{sh}\, t \gg 1$, и поэтому можно положить $\mathrm{sh}^2\, t \approx e^{2t}/4$ (иричем во всем интервале интегрирования!), так что интеграл принимает вид

$$\int_0^t \sqrt{1 - b^2\,\mathrm{sh}^2\, t} dt \approx \int_0^t \sqrt{1 - \frac{b^2}{4} e^{2t}} dt$$

С помощыю замены переменной $(b/2)e^t = \sin z$ интеграл (2) легко вычнсляется и оказывается равным $(b \ll 1)$

$$-1 + \ln\left[4\sqrt{U_0/E}\right].$$

Таким образом,

$$D(E) \approx (E/16U_0)^{\frac{2}{\hbar}}\, a\sqrt{2mU} \cdot \exp\left(\frac{4}{\hbar} a\sqrt{2mU_0}\right).$$

Условиями применимости полученного результата являются

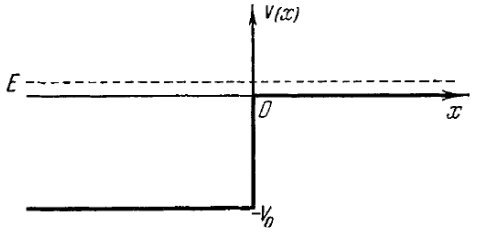
$$\frac{a}{\hbar}\sqrt{2snU_0} \gg 1, \quad E \ll \frac{n}{a}\sqrt{\frac{U_0}{m}},$$

первое из которых обеспечивает применимость квазиклассики. Второе из условий (5) заменяет условие $E \ll U_0$, использованное при вычислении интеграла в выраженни (1). Причина этой замены состоіт в том, что ири приближенном расчете величины f вида $f = e^A$, когда приближеншо вычнсляется значение A, для того чтобы было выполнено условне $f_{\text{точн}}\,/f_{\text{прибл}} \approx 1$, требуется $|A_{\text{точн}} - A_{\text{прибл}}| \ll 1$ (а не просто $A_{\text{точн}}\,/A_{\text{прибл}} \approx 1$, и это обстоятельство следует учитывать в случае $|A| \gg 1$). Внимательный читатель легко убедится в том, что именно второе из условий (5) (а не условие $E \ll U_0$) обеспечивает справедливость полученного значения коэффициента прозрачности.

17.3.2 Problems about Passing though a Barrier 2

ГК-2.1. Отражение электрона от поверхности металла (!?)

При изучении эмиссии электронов металлами необходимо принять во внимание то обстоятельство, что электроны с энергией, достаточной для выхода из металла, согласно квантовой механике, могут отражаться от границы металла. Рассматривая одномерную модель с потенциалом $V = -V_0$ при $x < 0$ (внутри металла) и $V = 0$ при $x > 0$ (вне металла), определить коэффициент отражения электрона с энергией $E > 0$ от поверхности металла.



Solution.

В области металла ($x < 0$) общий вид волновой функции принадлежащей собственному значению E, следующий:

$$\psi_1 = be^{i\varkappa x} + ce^{-i\varkappa x}, \qquad \chi = \frac{\sqrt{2\mu\,(E+V_0)}}{\hbar}.$$

В области $x > 0$ собственная функция имеет вид волны, бегущей из металла

$$\psi_{\mathrm{II}} = ae^{ikx}, \quad \text{где} \quad k = \frac{\sqrt{2\mu E}}{\hbar}.$$

На границе металла волновые функции ψ_{I} и ψ_{II} и их производные должны удовлетворять условию непрерывности

$$\psi_{\mathrm{II}}(0) = \psi_{\mathrm{I}}(0), \quad a = b + c$$
$$\psi'_{\mathrm{II}}(0) = \psi'_{\mathrm{I}}(0), \quad ak = (b - c)\varkappa$$

Отношение плотности потока отраженной волны к плотности потока падающей дает коэффициент отражения

$$R_0 = \left(\frac{\varkappa - k}{\varkappa + k}\right)^2 = \left(\frac{\sqrt{E+V_0} - \sqrt{E}}{\sqrt{E+V_0} + \sqrt{E}}\right)^2 = \frac{V_0^2}{\left(\sqrt{E+V_0} + \sqrt{E}\right)^4}.$$

Если энергия электрона $E = 0$, коэффициент отражения $R_0 = 1$ с возрастанием энергии R_0 быстро уменьшается; при $E \gg V_0$

$$R_0 \approx \frac{V_0^2}{16E^2}.$$

В другом предельном случае $E \ll V_0$

$$R_0 \approx 1 - 4\sqrt{\frac{E}{V_0}}.$$

Для нормальных металлов $V_0 \sim 10$ эв. При этом коэффициент отражения для электронов с энергией $E = 0,1$ эв

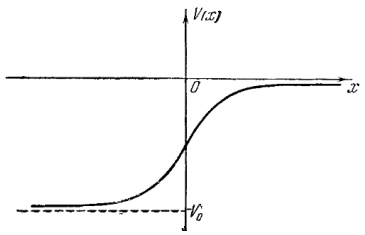
$$R_0 = 0,67.$$

ГК-2.2 Отражение от металла при смытой границе (!?)

В предыдущей задаче предполагалось, что потенциал на границе металла изменяется скачкообразно. В действительности это изменение потенциала прэисходит непрерывно в области, размеры которой порядка междуатомных расстояний в металле. Аппроксимируя потенциал вблизи псверхности металла, с помощью функции

$$V = -\frac{V_0}{e^{\frac{x}{a}} + 1}$$

определить коэффициент отражения электрона с энергией $E > 0$.



Solution.

2. В уравнении Шредингера

$$-\frac{\hbar^2}{2\mu}\psi'' - \left(E + \frac{V_0}{e^{\frac{x}{a}} + 1}\right)\psi = 0$$

произведем подстановку

$$\xi := -e^{-\frac{x}{a}}, \quad \psi := \xi^{-ika}u(\xi), \qquad k := \frac{\sqrt{2\mu E}}{\hbar}.$$

Для функции $u(\xi)$ получим гипергеометрическое уравнение

$$\xi(1-\xi)u'' + (1-2ika)(1-\xi)u' - x_0^2 a^2 u = 0 \quad \left(\varkappa_0 = \frac{\sqrt{2\mu V_0}}{\hbar}\right).$$

Решение уравнения (1), которое при $x \to \infty(\xi \to 0)$ является конечным и асимптотически представляет бегущую волну ce^{ikx}, имеет вид

$$\psi = ce^{ikx} F\left\{i(x-k)a, -i(\varkappa+k)a, 1-2ika, -e^{-\frac{x}{a}}\right\}$$
$$\varkappa := \frac{\sqrt{2\mu\left(E+V_n\right)}}{\hbar}$$

Для того чтобы найти коэффициент отражения, необходимо определить вид волновой функции внутри металла ($x \to -\infty$):

$$\psi \approx c\frac{\Gamma(1-2ika)\Gamma(-2ika)}{\Gamma(-l(x+k)a)\Gamma(1-l(k+\%)a)}e^{i\varkappa x} + c\frac{\Gamma(1-2ika)\Gamma(2ika)}{\Gamma(i(x-k)a)\Gamma(1+i(x-k)a)}e^{-i\varkappa x}.$$

Отсюда находим коэффициент отражения

$$R_a = \left|\frac{\Gamma(2ika)\Gamma(-l(x+k)a)\Gamma(1-i(x+k)a)}{\Gamma'(-2ika)\Gamma^{\top}(i(x-k)a)\Gamma(1+l(x-k)a)}\right|^2 = \frac{\mathrm{sh}^2\,\pi a(\varkappa-k)}{\mathrm{sh}^2\,\pi a(\varkappa+k)}.$$

При вычислении R_a надо воспользоваться соотношениями $\Gamma(z+1) = z\Gamma(z)\Gamma(z)\Gamma(1-z) = \frac{\pi}{\sin\pi z}, \Gamma^*(ix) = \Gamma(-ix)$ при действительном x.

При $a \to 0$ формула для коэффициента отражения переходит в выражение для R_0 в случае прямоугольной потенциальной стенки (см. предыдущую задачу).

Легко убедиться, что имеет место неравенство $R_a < R_0$, т. е. коэффициент отражения в случае плавного изменения потенциала меньше, чем в случае скачкообразного изменения. Для $a = 1\text{Å}, V_0 = 10_B, E = 0,1\text{эВ}$ находим $R_a = 0,235$.

ГК-2.3. Отражение от прямоугольного барьера

Определить коэффициент прохождения частицы через прямоугольный барьер (см. рис. 8 (????)).

Solution.

Рассмотрим поток частиц с энергией $E < V_0$, движущихся слева направо. В области III волновая функция представляет собой прошедшую волну

$$\psi_{\text{III}} = Ce^{ikx}, \quad k = \frac{\sqrt{2\mu E}}{\hbar}.$$

В области I имеется как падающая, так и отраженная волны

$$\psi_I = e^{ikx} + Ae^{-ikx}.$$

В области II общее решение уравнения Шредингера

$$-\frac{\hbar^2}{2\mu}\psi''_{\text{II}} - (E-V_0)\,\psi_{\text{II}} = 0$$

имеет вид

$$\psi_{II} = B_1 e^{\alpha x} + B_2 e^{-xx}, \quad x = \frac{\sqrt{2\mu\left(V_0-E\right)}}{\hbar}.$$

Коэффициенты A, B_1, B_2, C определяются из условий непрерывности волновой функции и ее первой производной.

В точке $x = 0$ эти условия приводят к соотношениям:

$$1 + A = B_1 + B_2$$
$$ik(1-A) = x\left(B_1 - B_2\right).$$

Соответственно в точке $x = a$ имеем:

$$B_1 e^{\times a} + B_2 e^{-xa} = Ce^{ika},$$
$$\times \left(B_1 e^{\times a} - B_2 e^{-xa}\right) = ikCe^{ika}.$$

Из этих уравнений находим: $A = C\frac{k^2+\chi^2}{4lk\pi}e^{ika}\left(e^{\chi a} - e^{-\chi a}\right) = C\frac{2\mu V_0}{\hbar^2}\frac{e^{\chi a}-e^{-\chi a}}{4lk\kappa}e^{ika}$, $B_1 = C\cdot\frac{1}{2}\left(1+\frac{ik}{x}\right)e^{ika-xa}$, $B_2 = C\cdot\frac{1}{2}\left(1-\frac{lk}{x}\right)e^{ika+xa}$, $C = -\frac{4lk}{\%}\frac{e^{-ika}}{e^{\chi a}\left(1-\frac{ik}{\chi}\right)^2 - e^{-xa}\left(1+\frac{ik}{\psi}\right)^2}$. Поскольку принятое выражение для падающей волны в ЧИ имело вид e^{ikx}, коэффициент прохождения

$$D = CC^*.$$

Вычисление дает:

$$D = \frac{4k^2x^2}{\left(k^2+x^2\right)^2 \operatorname{sh}^2 xa + 4k^2x^2}.$$

Отметим, что коэффициент прохождения стремится к нулю при переходе к классической механике, т. е. при $\hbar \to 0$. Если $xa \gg 1$ (т. е. $(V_0 - E) \gg \frac{\hbar^2}{2\mu a^2}$), то выражение для коэффициента прохождения принимает более простой вид

$$D \approx 16\frac{E}{V_0}\left(1-\frac{E}{V_0}\right)e^{-\frac{2\sqrt{2\mu(V_0-E)}}{\hbar}a}.$$

Рассмотрим два конкретных примера: а) Электрон с $E = 1$ эз проходит через потенциальный барьер $V_0 = 2$ яв и $a = 1$ ÅA. Для D получаем значение 0,777. б) Пусть теперь на тот же потенциальный барьер падает протон с той же энергией. В этом случае оказывается, что коэффициент прохождения делается исчезающе малым $D = 3,6 \cdot 10^{-19}$.

ГК-2.4. Отражение от прямоугольного потенциального барьера (?)

Определить коэффициент отражения частицы от прямоугольного барьера в случае $E > V_0$ (надбарьерное отражение).

Solution.

(??? неужели еще не прорешал её???)
4.

$$R = \frac{\left(k^2-\gamma^2\right)\sin^2\gamma a}{4k^2\mu^2 + \left(k^2-\gamma^2\right)\sin^2\gamma a} \quad \left(k = \frac{\sqrt{2\mu E}}{\hbar}, \quad x = \frac{\sqrt{2\mu\left(E-V_0\right)}}{\hbar}\right).$$

ГК-2.5. Коэффициент прохождения через $V(x) = \frac{V_0}{\operatorname{ch}^2\frac{x}{a}}$

Вычислить коэффициент прохождения через потенциальный барьер $V(x) = \frac{V_0}{\operatorname{ch}^2\frac{x}{a}}$ (рис. 9) потока частиц, движущихся с энергией $E < V_0$.

Первое решене (?)

5. Для случая $E < V_0$ волновая функция может быть получена из выражения для волновых функций задачи 11 §1 изменением знака у E и V_0.
Общий вид волновой функции, относящейся к энергии E

$$\psi = c_1\left(\operatorname{ch}\frac{x}{a}\right)^{-2\lambda} F\left(-\lambda+\frac{lka}{2}, -\lambda-\frac{ika}{2}, \frac{1}{2}; -\operatorname{sh}^2\frac{x}{a}\right) + c_2\left(\operatorname{ch}\frac{x}{a}\right)^{-2\lambda}\operatorname{sh}\frac{x}{a}F\left(-\lambda+\frac{lka}{2}+\frac{1}{2}, -\lambda+\frac{tka}{2}+\frac{1}{2}, \frac{3}{2}; -\operatorname{sh}^2\frac{x}{a}\right),$$

где

$$\lambda = \frac{1}{4}\left(\sqrt{1-\frac{8\mu V_0 a^2}{\hbar^2}} - 1\right), \quad k = \frac{\sqrt{2\mu E}}{\hbar}.$$

Коэффициенты c_1 и c_2 определяются из того условия, что при $x \to +\infty$ волновая функция имеет асимптотический вид $\psi \sim e^{ikx}$.

Для нахождения асимптотического вида (1) воспользуемся соотношением

$$F(\alpha,\beta,\gamma;z)=\frac{\Gamma(\gamma)\Gamma(\beta-\alpha)}{\Gamma(\beta)\Gamma(\gamma-1)}(-z)^{-\alpha}F\left(\alpha,\alpha+1-\gamma,\alpha+1-\beta;\frac{1}{z}\right)+ \\ +\frac{\Gamma(\gamma)\Gamma(\alpha-\beta)}{\Gamma(\alpha)\Gamma(\gamma-\beta)}(-z)^{-\beta}F\left(\beta,\beta+1-\gamma,\beta-1-\alpha;\frac{1}{z}\right).$$

Отсюда находим:

$$\psi_{x\to-\infty}\sim(-1)^{2\lambda}\left\{(c_1A_1-c_2A_2)\left(-\frac{1}{2}\right)^{-ika}e^{ikx}+(c_1B_1-c_2B_2)\left(-\frac{1}{2}\right)^{ika}e^{-ikx}\right\}$$
$$\psi_{x\to+\infty}\sim\left\{(c_1A_1+c_2A_2)\left(\frac{1}{2}\right)^{-ika}e^{-ikx}+(c_1B_1+c_2B_2)\left(\frac{1}{2}\right)^{ika}e^{kx}\right\}$$

где для удобства введены обозначения

$$A_1=\frac{\Gamma\left(\frac{1}{2}\right)\Gamma(-ika)}{\Gamma\left(-\lambda-\frac{ika}{2}\right)\Gamma\left(\lambda+\frac{1}{2}-\frac{ika}{2}\right)},$$
$$A_2=\frac{\Gamma\left(\frac{3}{2}\right)\Gamma(-ika)}{\Gamma\left(-\lambda+\frac{1}{2}-\frac{ika}{2}\right)\Gamma\left(\lambda+1-\frac{ika}{2}\right)},$$
$$B_1=\frac{\Gamma\left(\frac{1}{2}\right)\Gamma(ika)}{\Gamma\left(-\lambda+\frac{ika}{2}\right)\Gamma\left(\lambda+\frac{1}{2}+\frac{ika}{2}\right)},$$
$$B_2=\frac{\Gamma\left(\frac{3}{2}\right)\Gamma(ika)}{\Gamma\left(-\lambda+\frac{1}{2}+ika\right)\Gamma\left(\lambda+1+\frac{ika}{2}\right)}.$$

Различие в знаке перед коэффициентом c_2 в выражениях (2) и (3) объясняется тем, что $\operatorname{sh}\frac{x}{a}$ функция нечетная и второй член выражения (1) меняет знак при переходе от положительных к отрицательным значениям x.

Требование того, чтобы на $+\infty$ была только прошедшая волна, приводит к следующей связи коэффициентов c_1 и c_2:

$$c_1A_1+c_2A_2=0.$$

При этом коэффициент прохождения будет иметь вид

$$D=\frac{|c_1B_1+c_2B_2|^2}{|c_1A_1-c_2A_2|^2}.$$

Подставляя в последнее выражение значения коэффициентов A_1,A_2,B_1,B_2 и производя несложные преобразования, получим окончательно:

$$D=\frac{\operatorname{sh}^2\pi ka}{\operatorname{sh}^2\pi ka+\cos^2\left(\frac{\pi}{2}\sqrt{1-\frac{8\mu V_0a^2}{\hbar^2}}\right)},\quad\text{если }\frac{8\mu V_0a^2}{\hbar^2}<1$$

$$D=\frac{\operatorname{sh}^2\pi ka}{\operatorname{sh}^2\pi ka+\operatorname{ch}^2\left(\frac{\pi}{2}\sqrt{\frac{8\mu V_0a^2}{\hbar^2}-1}\right)},\quad\text{если }\frac{8\mu V_0a^2}{\hbar^2}>1.$$

Второе решение

Также эта задача в Галицкий задачник.1981-9.29. Вычислить в квазиклассическом приближении коэффициент прозрачности барьера

$$U(x)=\frac{U_0}{\operatorname{ch}^2(x/a)}.$$

В выражении

$$D=\exp\left[-\frac{2}{\hbar}\int\limits_{x_1}^{x}|p|dx\right]=\exp\left\{-\frac{2\sqrt{2mE}}{\hbar}\int\limits_{-x_3}^{x_1}\sqrt{\frac{U_0}{E\operatorname{ch}^2(x/a)}-1}dx\right\}$$

интеграл заменой переменной

$$\mathrm{sh}(x/a) = x\sin t_3 \quad x = \sqrt{U_0/E - 1},$$

приводится к виду

$$2ax^2 \int\limits_0^{\pi/2} \frac{\cos^2 t dt}{1 + x^2 \sin^2 t} = \pi a \left(\sqrt{1+x^2} - 1\right) = \pi a \left(\sqrt{\frac{U_0}{E}} - 1\right),$$

и коэффициент прозрачности оказывается равным

$$D(E) \approx \exp\left\{-\frac{2\pi a}{\hbar}\sqrt{2m}\left(\sqrt{U_0} - \sqrt{E}\right)\right\}.$$

Условие применимости выражения (2) предполагает $D \ll 1$ (более точно: требуется, чтобы был велик модуль показателя экспоненты), т. е.

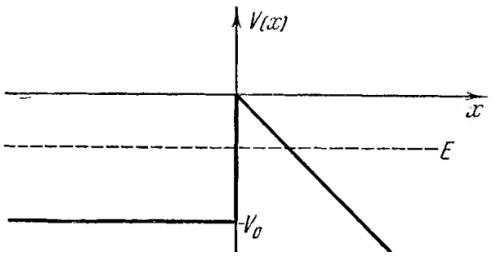
$$\frac{2\pi a}{\hbar}\sqrt{2m}\left(\sqrt{U_0} - \sqrt{E}\right) \gg 1.$$

Кроме этого имеется еще ограничение на энергию частицы E, так как при $E \to 0$ в окрестности точек поворота нарушаются стандартные условия сшивания квазиклассических решений, основанные на линейной аппроксимации потенциала и приводящие к выражению (1) для прозрачности барьера (сравнить с 9.26). Внимательный читатель легко получит, что указанное ограничение имеет вид

$$\sqrt{E} \gg \sqrt{\hbar^2/ma^2}.$$

ГК-2.6. Выход электронов из металла

Вычислить в квазиклассическом приближении коэффициент прохождения электронов через поверхность металла под действием сильного электрического поля напряженности F (рис. нижу). Найти границы применимости расчета.



Solution.

Обычная формула Гамова из квазиклассики решает быстро задачу.

(??? почему если поле есть, то у нас именно так вот меняется потенциал??? это по идее в теории нужно указать.)

Потенциальная энергия электрона имеет вид, изображенный на рис. 10. Коэффициент прохождения

$$D \approx e^{-\frac{2}{\hbar}\int\limits_0^{x_0}\sqrt{2\mu(|E|-Fx)}dx},$$

где точки $x = 0, x = x_0 = \frac{|E|}{F}$ ограничивают область, недоступную частице согласно классической механике. Производя вычисление интеграла в экспоненте, находим:

$$D \approx e^{-\frac{4}{3}\frac{\sqrt{2\mu}}{\hbar F}|E|^{3/2}}.$$

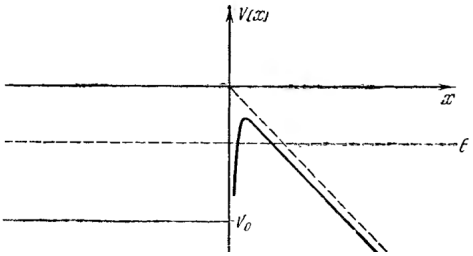
Для выяснений границ применимости этого результата вспомним, что квазиклассическое рассмотрение неприменимо вблизи классической точки поворота x_0 внутри области $x - x_0 \leq \left(\frac{\hbar}{2\mu\cdot F}\right)^{1/3}$. То есть решение применимо в том случае, если область поворота меньше ширины барьера $x_0 = \frac{|E|}{F}$, откуда $\left(\frac{\hbar^2}{2\mu F}\right)^{1/3} \ll \frac{|E|}{F}$ или

$$\frac{\sqrt{2\mu}}{\hbar F}|E|^{3/2} \gg 1.$$

Таким образом, это требование эквивалентно требованию малости коэффициента прохождения $D \ll 1$. Коэффициент прохождения D быстро убывает с ростом $|E|$ и растет с увеличением F.

ГК-2.7. Выход из металла, точнее модель

Рассмотрим модель выхода электронов из металла, в которой изменение потенциала вблизи поверхности происходит непрерывно. Так, например, потенциал электрического изображения $V_{\text{el-im}} = -\frac{e}{4x}$ действует на больших расстояниях от поверхности. Определить коэффициент прохождения D электронов через поверхность металла в электрическом поле с учетом силы электрического изображения (рис. ниже).



Solution..

Используем обычные методы квазиклассики, интеграл сводится к эллиптическому.
(??? что за электрическое изображение тут? буду ЭД смотреть - отвечу про это, пока это просто слова.)
Суммарная потенциальная энергия имеет вид:

$$V = -Fx - \frac{e^2}{4x}.$$

Следует заметить, что это выражение при малых x (порядка атомного расстояния) становится непригодным. Однако для вычисления коэффициента прохождения точный ход потенциала вблизи этой области несущественен. Коэффициент прохождения

$$D \approx \exp\left\{-\frac{2}{\hbar}\int\limits_{x_1}^{x_2}\sqrt{2\mu\left(|E| - Fx - \frac{e^2}{4x}\right)}dx\right\} = \exp\left\{-\frac{2}{\hbar}\int\limits_{x_1}^{x_2} p dx\right\}$$

Причем точки поворота x_1 и x_2 определяются из условия обращения в нуль классического импульса частицы

$$p = \sqrt{2\mu\left(|E| - Fx - \frac{e^3}{4x}\right)} = 0,$$

$$x_{1,2} = \frac{|E| \pm \sqrt{E^4 - e^2F}}{2F}.$$

Тут интеграл

$$\int\limits_{x_1}^{x_2} p dx = \sqrt{2\mu}\int\limits_{x_1}^{x_2}\sqrt{|E| - Fx - \frac{e^2}{4x}}dx$$

представляет собою полный эллиптический интеграл. Заменой независимой переменной $\frac{F}{|E|}x = \xi$ интеграл сводится к функции одного параметра

$$\int\limits_{x_1}^{x_3} p dx = \frac{2}{3}\sqrt{2\mu}\frac{|E|^{3/2}}{F}\varphi(y), y = \frac{\sqrt{e^2F}}{|E|}.$$

Здесь $\varphi(y) := \int\limits_{\xi_1}^{\xi_2}\sqrt{1 - \frac{y^2}{\xi} - \xi}d\xi$, пределы интегрирования ξ_1, ξ_2 определяются из условия обращения в нуль подкоренного выражения. Вводя обозначение $k_0 := \frac{4}{3}\sqrt{2\mu}\frac{|E|^{5/2}}{F}$, получим

$$D = e^{-k_u\varphi(y)}.$$

Отметим, что коэффициент прохождения без учета электрического изображения уже найден ($y = 0$) и равен $D = e^{-k_0}$. Значения $\varphi(y)$ приведены в таблице ниже.

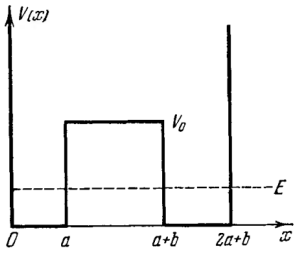
y	0	0,2	0,3	0,4	0,5	0,6	0,7	0,8	0,9	1,0
$\varphi(y)$	1,000	0,951	0,904	0,849	0,781	0,696	0,603	0,494	0,345	0,000

(не нужная таблица на самом деле, но ладно, пусть побудет.)

17.3.3 Problems about Passing though a Barrier 3

ГК-2.8. Колодец с тумбочкой

Определить приближенно уровни энергии и волновые функции частицы в симметричном потенциальном поле вида колодца с тумбочкой (см. рис. ниже), если $E \ll V_0$ и проницаемость барьера мала $\left(\frac{2\mu V_0}{\hbar^2} b^2 \gg 1\right)$.



Solution.

Пишем общий возможный вид волновых функций в трех областях, сшиваем. (все?)
Волновая функция имеет следующий вид:

$$\begin{aligned}
&\psi_{\mathrm{I}} = A\sin kx && 0 < x < a,\\
&\psi_{\mathrm{II}} = B_1 e^{\varkappa} + B_2 e^{-\varkappa x}, && a < x < a+b,\\
&\psi_{\mathrm{III}} = C\sin k(2a+b-x), && a+b < x < 2a+b,
\end{aligned}$$

здесь $k = \frac{\sqrt{2\mu E}}{\hbar}$, $\varkappa = \frac{\sqrt{2\mu(V_0-E)}}{\hbar}$. Условия непрерывности волновой функции и ее произволной приводят к следующим соотношениям:

$$\begin{aligned}
A\sin ka &= B_1 e^{\varkappa a} + B_2 e^{-\varkappa a},\\
Ak\cos ka &= \varkappa\left(B_1 e^{xa} - B_2 e^{-xa}\right),\\
B_1 e^{\varkappa(a+b)} + B_2 e^{-\varkappa(a+b)} &= C\sin ka,\\
\varkappa\left(B_1 e^{\varkappa(a+b)} - B_2 e^{-\varkappa(a+b)}\right) &= -Ck\cos ka.
\end{aligned}$$

Исключая из этих уравнений B_1 и B_2, находим:

$$\begin{aligned}
\left(\frac{\varkappa}{k}\operatorname{tg} ka + 1\right) Ae^{\varkappa b} &= \left(\frac{\varkappa}{k}\operatorname{tg} ka - 1\right) C,\\
\left(\frac{\varkappa}{k}\operatorname{tg} ka - 1\right) Ae^{-\varkappa b} &= \left(\frac{\varkappa}{k}\operatorname{tg} ka + 1\right) C.
\end{aligned}$$

Из условия обращения в нуль детерминанта

$$\begin{vmatrix} \left(\frac{\varkappa}{k}\operatorname{tg} ka + 1\right) e^{\varkappa b} & -\left(\frac{\varkappa}{k}\operatorname{tg} ka - 1\right)\\ \left(\frac{\varkappa}{k}\operatorname{tg} ka - 1\right) e^{-\varkappa b} & -\left(\frac{\varkappa}{k}\operatorname{tg} ka + 1\right) \end{vmatrix} = 0$$

получаем:

$$\left(\frac{\varkappa}{k}\operatorname{tg} ka + 1\right) e^{\varkappa b} = \pm\left(\frac{\varkappa}{k}\operatorname{tg} ka - 1\right).$$

Это уравнение определяет уровни энергии.
Воспользовавшись неравенством

$$xb \gg 1,$$

последнее уравнение можно приближенно представить в следующем виде:

$$\operatorname{tg} ka = -\frac{k}{\varkappa} \mp 2\frac{k}{\varkappa} e^{-\varkappa b}.$$

Правая часть равенства представляет собою малую величину. В нулевом приближении получаем ($k \ll \varkappa$):

$$k_0 = \frac{n\pi}{a}, \quad E_n^{(0)} = \frac{n^2\pi^2\hbar^2}{2\mu a^2}$$

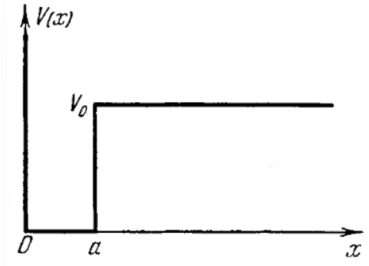
- значения энергии для частицы в потенциальном ящике.

В следующем приближении

$$k = \frac{n\pi}{a} - \frac{k_0}{a\varkappa_0} \mp 2\frac{k_0}{a\varkappa_0} e^{-\varkappa_0 b} \quad (n = 1, 2, 3, ...),$$

$$E_n = E_n^{(0)} - \frac{2E_n^{(0)}}{a\varkappa_0} \mp 4\frac{E_n^{(0)}}{a\varkappa_0} e^{-\varkappa_0 b}, \quad \varkappa_0 = \frac{\sqrt{2\mu\left(V_0 - E_n^{(1)}\right)}}{\hbar}.$$

Первые два члена $E_n^{(1)} = E_n^{(0)} - \frac{2E_n^{(0)}}{a\varkappa_0}$ не зависят от b и дают приближенные значения уровней энергии для частицы в потенциальной яме при $b \to \infty$. См. рис. ниже.



В этом приближении уровни двукратно вырождены; это соответствует возможности нахождения частицы как в области I, так и в области III. Учет конечности b, т. е. возможности прохождения частицы через потенциальный барьер, приводит к расщеплению уровней. Это расщепление экспоненциально мало. Найдем в рассматриваемом приближении коэффициенты A, B_1, B_2 и C. Нижнему уровню

$$E_n^- = E_n^{(1)} - 4\frac{E_n^{(0)}}{a\gamma_0} e^{-\varkappa_0 b}$$

соответствуют

$$B_1 = (-1)^{n-1}\frac{k_0}{\varkappa_0} e^{-\varkappa_0(b+a)} A,$$
$$C = A,$$
$$B_2 = (-1)^{n-1}\frac{k_0}{\varkappa_0} e^{\varkappa_0 a} A.$$

Верхнему уровню

$$E_n^+ = E_n^{(1)} + 4\frac{E_n^{(0)}}{ax_0} e^{-x_v b}$$

соответствуют коэффициенты

$$B_1 = -(-1)^{n-1}\frac{k_0}{\varkappa_0} e^{-\varkappa_0(a+b)} A,$$
$$C = -A,$$
$$B_2 = (-1)^{n-1}\frac{k_0}{\varkappa_0} e^{\varkappa_0 a} A.$$

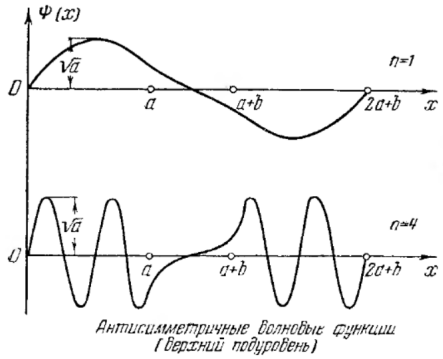
Значение A, определяемое из условия нормировки, равно $\frac{1}{\sqrt{a}}$ (при вычислении нормировочного интеграла долей, вносимой областью II, можно пренебречь).

Таким образом, нижнему уровню соответствует волновая функция

$$\psi_1 = \frac{1}{\sqrt{a}} \sin kx,$$

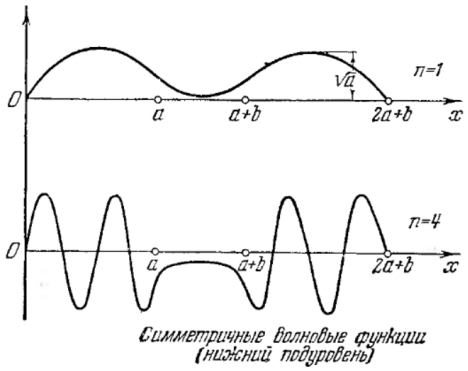
$$\psi_{\text{II}} = (-1)^{n-1}\frac{1}{\sqrt{a}}\frac{k_0}{\varkappa_0}\left\{e^{-\varkappa_0(x-a)} + e^{-\varkappa_0(a+b-x)}\right\},$$

$$\psi_{\text{III}} = \frac{1}{\sqrt{a}} \sin k(2a + b - x).$$



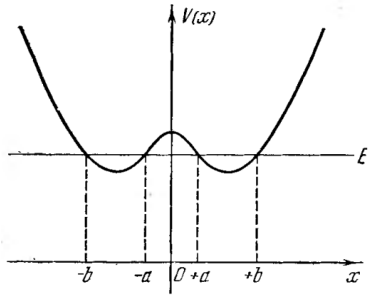
Соответственно для верхнего уровня находим:

$$\psi_{\mathrm{I}} = \frac{1}{\sqrt{a}} \sin kx,$$
$$\psi_{\mathrm{II}} = (-1)^{n-1} \frac{1}{\sqrt{a}} \frac{k_0}{\varkappa_0} \left\{ e^{-\varkappa_0 (x-a)} - e^{-\varkappa_0 (a+b-x)} \right\},$$
$$\psi_{\mathrm{III}} = -\frac{1}{\sqrt{a}} \sin k(2a-b-x).$$



ГК-2.9. Квазиклассика в самбреро (!!!!)

Симметричное поле $V(x)$ представляет собой две потенциальные ямы, разделенные барьером как на рисунке:



Считая выполненным условие квазиклассичности, определить уровни энергии частицы в поле $V(x)$. Сравнить полученный энергетический спектр с энергетическим спектром отдельной ямы. Найти расщепление энергетических уровней отдельной ямы.

Solution.

(?!?!! скоро продумаю, тут типичный метод!)

$$\psi(x<-b)=\frac{c}{\sqrt{|p|}}e^{-\frac{1}{\hbar}\int\limits_{x}^{-b}|p|dx}$$

$$\psi(-b<x<-a)=\frac{c}{\sqrt{p}}e^{-i\frac{\pi}{4}}e^{\frac{i}{\hbar}\int\limits_{-b}^{x}pdx}+\frac{c}{\sqrt{p}}e^{i\frac{\pi}{4}}e^{-\frac{i}{\hbar}\int\limits_{-b}^{x}pdx}=$$
$$=\frac{c}{\sqrt{p}}e^{-i\frac{\pi}{4}}e^{\frac{i}{\hbar}\int\limits_{-b}^{-a}pdx}e^{-\frac{i}{\hbar}\int\limits_{x}^{-a}pdx}+\frac{c}{\sqrt{p}}e^{i\frac{\pi}{4}}e^{-\frac{i}{\hbar}\int\limits_{-b}^{-a}pdx}e^{\frac{i}{\hbar}\int\limits_{x}^{-a}pdx}.$$

$$\psi(-a<x<+a)=ce^{-i\frac{\pi}{4}}e^{\frac{i}{\hbar}\int\limits_{-b}^{-a}pdx}\left\{\frac{e^{-i\frac{\pi}{4}}}{2\sqrt{|p|}}e^{-\frac{1}{\hbar}\int\limits_{-a}^{x}|p|dx}+\frac{e^{i\frac{\pi}{4}}}{\sqrt{|p|}}e^{\frac{1}{\hbar}\int\limits_{-a}^{x}|p|dx}\right\}+$$
$$+ce^{i\frac{\pi}{4}}e^{-\frac{i}{\hbar}\int\limits_{-b}^{-a}pdx}\left\{\frac{e^{i\frac{\pi}{4}}}{2\sqrt{|p|}}e^{-\frac{1}{\hbar}\int\limits_{-a}^{x}|p|dx}+\frac{e^{-i\frac{\pi}{4}}}{\sqrt{|p|}}e^{\frac{1}{\hbar}\int\limits_{-a}^{x}|p|dx}\right\}=$$

$$=\frac{c}{\sqrt{|p|}}\sin\left(\frac{1}{\hbar}\int\limits_{-b}^{-a}pdx\right)e^{-\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}e^{\frac{1}{\hbar}\int\limits_{x}^{+a}|p|dx}+\frac{2c}{\sqrt{|p|}}\cos\left(\frac{1}{\hbar}\int\limits_{-b}^{-a}pdx\right)e^{\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}e^{-\frac{1}{\hbar}\int\limits_{x}^{+a}|p|dx}$$

$$\psi(+a<x<+b)=c\sin\left(\frac{1}{\hbar}\int\limits_{-b}^{-a}pdx\right)e^{-\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}\left\{\frac{e^{-i\frac{\pi}{4}}}{2\sqrt{p}}e^{-\frac{i}{\hbar}\int\limits_{+a}^{x}pdx}+\frac{e^{i\frac{\pi}{4}}}{2\sqrt{p}}e^{\frac{i}{\hbar}\int\limits_{+a}^{x}pdx}\right\}+$$
$$+2c\cos\left(\frac{1}{\hbar}\int\limits_{-b}^{-a}pdx\right)e^{\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}\left\{\frac{e^{-i\frac{\pi}{4}}}{\sqrt{p}}e^{\frac{i}{\hbar}\int\limits_{+a}^{x}pdx}+\frac{e^{i\frac{\pi}{4}}}{\sqrt{p}}e^{-\frac{i}{\hbar}\int\limits_{a}^{x}pdx}\right\}=$$

$$=\frac{c}{\sqrt{p}}\left\{\frac{1}{2}\sin\left(\frac{1}{\hbar}\int\limits_{-b}^{-a}pdx\right)e^{-\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx-i\frac{\pi}{4}}+2\cos\left(\frac{1}{\hbar}\int\limits_{-a}^{+a}pdx\right)e^{\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx+i\frac{\pi}{4}}\right\}e^{-\frac{i}{\hbar}\int\limits_{+a}^{+b}pdx}e^{\frac{i}{\hbar}\int\limits_{x}^{b}pdx}+$$
$$+\frac{c}{\sqrt{p}}\left\{\frac{1}{2}\sin\left(\frac{1}{\hbar}\int\limits_{-b}^{-a}pdx\right)e^{-\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx+i\frac{\pi}{4}}+2\cos\left(\frac{1}{\hbar}\int\limits_{-a}^{+a}pdx\right)e^{\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx-i\frac{\pi}{4}}\right\}e^{\frac{i}{\hbar}\int\limits_{+a}^{+b}pdx}e^{-\frac{i}{\hbar}\int\limits_{x}^{+b}pdx}.$$

(????откуда выр ниже?? видимо, общее правило тут какое-то применено, а выше мы явно делали?)

$$\psi(x>+b)=\frac{c}{\sqrt{|p|}}\left\{\frac{1}{2}\sin\left(\frac{1}{\hbar}\int\limits_{a}^{b}pdx\right)\cos\left(\frac{1}{\hbar}\int\limits_{a}^{b}pdx\right)e^{-\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}+\right.$$
$$\left.+2\cos\left(\frac{1}{\hbar}\int\limits_{a}^{b}pdx\right)\sin\left(\frac{1}{\hbar}\int\limits_{a}^{b}pdx\right)e^{\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}\right\}e^{-\frac{1}{\hbar}\int\limits_{b}^{x}|p|dx}+$$
$$+\frac{c}{\sqrt{|p|}}\left\{-\sin^2\left(\frac{1}{\hbar}\int\limits_{a}^{b}pdx\right)e^{-\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}+4\cos^2\left(\frac{1}{\hbar}\int\limits_{a}^{b}pdx\right)e^{\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}\right\}e^{\frac{1}{\hbar}\int\limits_{b}^{x}|p|dx}.$$

Для того чтобы решение при $x\to+\infty$ стремилось к нулю, необходимо, чтобы коэффициент при $e^{\frac{1}{\hbar}\int\limits_{b}^{x}|p|dx}$ обращался в нуль, т. е.

$$-\sin^2\left(\frac{1}{\hbar}\int\limits_{a}^{b}pdx\right)e^{-\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}+4\cos^2\left(\frac{1}{\hbar}\int\limits_{a}^{b}pdx\right)e^{\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}=0$$

$$\operatorname{ctg}\left(\frac{1}{\hbar}\int\limits_a^b p dx\right) = \pm\frac{1}{2}e^{-\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}.$$

Считая прозрачность барьера малой величиной, получаем условие для определения уровней энергии

$$\frac{1}{\hbar}\int\limits_a^b p dx = \pi\left(n+\frac{1}{2}\right) \pm \frac{1}{2}e^{-\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}.$$

(??? не совсем понял, откуда такие условия? почему не просто было бы πn?)

Обозначим через $E_n^{(0)}$ уровни энергии отдельной потенциальной ямы

$$\frac{1}{\hbar}\int\limits_a^b \sqrt{2\mu\left(E_n^{(0)}-V\right)}dx = \pi\left(n+\frac{1}{2}\right).$$

Уровни энергии в двойной яме $E_n = E_n^{(0)} + \Delta E_n$ найдем из полученного условия квантования, разлагая $\sqrt{2\mu(E_n - V)}$ в ряд по ΔE_n и ограничиваясь линейным членом по ΔE_n

$$\Delta E_n \frac{\mu}{\hbar}\int\limits_a^b \frac{dx}{\sqrt{2\mu\left(E_n^{(0)}-V\right)}} = \pm\frac{1}{2}e^{-\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx}$$

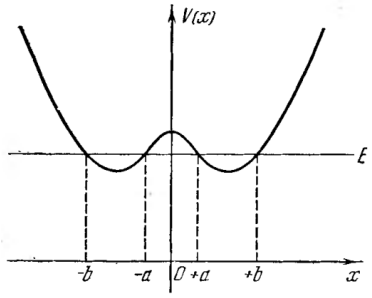
$$\Delta E_n = \pm\frac{\hbar\omega}{2\pi}e^{-\frac{1}{\hbar}\int\limits_{-a}^{+}|p|dx},$$

где ω - циклическая частота классического движения в отдельной яме $\frac{2\pi}{\omega} = 2\mu\int\limits_a^b \frac{dx}{p}$.

Расщепление уровня E_n равно $2|\Delta E_n|$.

ГК-2.10. Переход в самбребо (!?!??!)

Предположим, что до момента времени $t = 0$ между двумя симметричными потенциальными ямами вида



существовала непроницаемая перегородка и частица находилась в левой яме в стационарном состоянии. Определить, по прошествии какого времени τ после удаления перегородки частица окажется в правой яме.

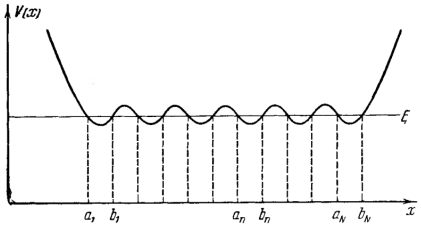
Solution.

(есть только ответ, сам решу потом ее, видимо, решение следует из ответа на пред. задачу)

$$10.\ \tau = -\frac{\pi^2}{\omega}e^{\frac{1}{\hbar}\int\limits_{-a}^{+a}|p|dx},$$

ГК-2.11. Стиральная доска

Поле $V(x)$ представляет собой N одинаковых потенциальных ям, разделенных одинаковыми потенциальными барьерами:



Считая выполненным условие квазиклассичности, определить уровни энергии в поле $V(x)$. Сравнить полученный энергетический спектр с энергетическим спектром отдельной ямы.

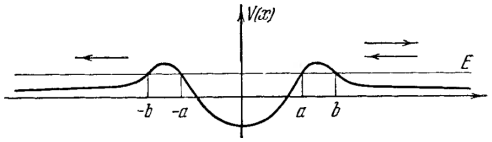
Solution.

Это очень большая задача на страницы 4, когда-то решу.

В области n-го потенциального барьера $b_n < x < < a_{n+1}$ волновую функцию запишем в виде
$\psi = \frac{C_n}{\sqrt{|p|}} e^{-\frac{1}{\hbar}\int_{b_n}^{x}|p|dx} + \frac{D_n}{\sqrt{|p|}} e^{\frac{1}{\hbar}\int_{b_n}^{x}|p|dx} =$
$+\frac{D_n}{\sqrt{|p|}} e^{\frac{1}{\hbar}\int_{b_n}^{a_{n+1}}|p|dx} e^{-\frac{1}{\hbar}\int_{x}^{a_{n+1}}|p|dx};$
продолжая эту функцию в область $(n+1)$-го потенциального барьера $b_{n+1} < x < a_{n+2}$, будем иметь:
(снова формулы на 1 страницу, нет на них сил.)

ГК-2.12. Два холма

Считая выполненными условия квазиклассичности, найти квазистационарные уровни частицы в следующем симметричном поле:



Найти также коэффициент прохождения $D(E)$ для частиц с энергией $E < V_0$.

Solution.

Это очень большая задача на страницы 2, когда-то решу.

ПТФ-12.з1. Отражение методом линий Стокса (40 б).

Найдите с экспоненциальной точностью в рамках квазиклассического приближения вероятность надбарьерного отражения частицы большой энергии E в потенциале $U(x) = -U_0 \frac{x^4}{a^4}$.

1) Идентифицируйте квазиклассические точки остановки; нарисуйте (схематично) линии Стокса и анти-Стокса, соответствующие этой задаче.

2) Выберите любую из интересующих нас линий анти-Стокса, вдоль которых необходимо исследовать решение. Определите условия сшивки амплитуд квазиклассических решений в окрестности необходимых точек остановки. Определите связь амплитуды прохождения и отражения в соответствующей задаче рассеяния.

3) Вычислите необходимые квазиклассические интегралы, найдите ответ.

Solution.

(????)
• Произвольное решение раскладывается по паре линейно независимых:

$$\psi(z) = C_+\psi_+(z) + C_-\psi_-(z)$$

$$\psi_\pm(z) = \frac{1}{\sqrt{p(z)}} e^{\pm iS(z)}, \quad S(z) = \int p(z)dz$$

Идентифицируем точки остановки:

$$p(z_k) = \sqrt{2m\left(E + U_0\frac{z_k^4}{a^4}\right)} = 0$$

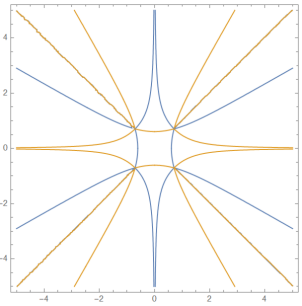
$$z_k = a\sqrt[4]{\frac{E}{U_0}}\exp\left(\frac{i\pi}{4} + \frac{i\pi k}{2}\right), \quad k \in \{0,1,2,3\}$$

$$S(z) = \int\limits_{z_k}^{z} \sqrt{2m\left(E + U_0\frac{z^4}{a^4}\right)}dz$$

Линии Стокса и анти-Стокса задаются соответственно уравнениями:

$$\begin{cases} \mathrm{Re}S(z) = 0, \\ \mathrm{Im}S(z) = 0. \end{cases}$$

Линии Стокса (синие) и анти-Стокса (жёлтые) изображены на рис. ниже



• Задача рассеяния:

$$\psi(x) = \begin{cases} \frac{1}{\sqrt{p(x)}} e^{i\int_0^x p(z)dz} + \frac{r}{\sqrt{p(x)}} e^{-i\int_0^x p(z)dz}, & x < 0 \\ \frac{t}{\sqrt{p(x)}} e^{i\int_0^x p(z)dz}, & x > 0 \end{cases} = \begin{cases} e^{i\int_0^x p(z)dz}\psi_+(x) + re^{-i\int_0^x p(z)dz}\psi_-(x), & \mathrm{Re}\, x < 0 \\ te^{i\int_0^x p(z)dz}\psi_+(x), & \mathrm{Re}\, x > 0 \end{cases}$$

Для нахождения t выберем контур из линий анти-Стокса, приближающихся к действительной оси на бесконечности. При обходе точек остановки дважды пересекается линия Стокса.

Решение между линиями Стокса:

$$\psi(z) = \frac{C'_+}{\sqrt{p(z)}} e^{i\int_{z_0}^z p(z')dz'}$$

Связь между t и C'_+:

$$C'_+ = te^{i\int_0^{z_0} p(z')dz'}$$

Решение после перехода через 2 линию Стокса:

$$\psi(z) = \frac{C''_+}{\sqrt{p(z)}} e^{i\int_{z_1}^z p(z')dz'}$$

Связь между t и C''_+:

$$C''_+ = C'_+ e^{i\int\limits_{z_0}^{z_1} p(z')dz'} = te^{i\int\limits_{0}^{z_0} p(z')dz'} e^{i\int\limits_{z_0}^{z_1} p(z')dz'}$$

Условие сшивки:

$$C''_+ e^{i\int\limits_{z_1}^{0} p(z')dz'} = 1$$

$$te^{i\int\limits_{0}^{z_0} p(z')dz'} e^{i\int\limits_{z_0}^{z_1} p(z')dz'} e^{i\int\limits_{z_1}^{0} p(z')dz'} = 1$$

$$t = e^{-i\left(\int\limits_{0}^{z_0} p(z')dz' + \int\limits_{z_0}^{z_1} p(z')dz' + \int\limits_{z_1}^{0} p(z')dz'\right)}$$

Для нахождения r выберем разрез вдоль линии анти-Стокса. Снизу обходим разрез около точки $z_1 = e^{i\frac{\pi}{4}}$ ($\arg_{z=z_1} z_1 = \frac{13}{12}\pi$) и получим

$$C_- e^{-\frac{i}{4}\frac{13}{12}\pi} e^{-i|\xi|^{3/2}|z_0|^{3/2}\frac{\sqrt{2mU_0}}{3a^2}} + C_+ e^{-\frac{i}{4}\frac{13}{12}\pi} e^{i|\xi|^{3/2}|z_0|^{3/2}\frac{\sqrt{2mU_0}}{3a^2}} =$$

$$= C_- e^{\frac{i}{4}\frac{11}{12}\pi} e^{i|\xi|^{3/2}|z_0|^{3/2}\frac{\sqrt{2mU_0}}{3a^2}} + C_+ e^{\frac{i}{4}\frac{11}{12}\pi} e^{-i|\xi|^{3/2}|z_0|^{3/2}\frac{\sqrt{2mU_0}}{3a^2}}$$

Нижний берег разреза:

$$\psi = t\psi_+ \to C_- = it, \quad C_+ = 0$$

По верхнему берегу разреза вдоль линии анти-Стокса переходим к $z_1 = e^{i\frac{3\pi}{4}}$, и обходим сверху. C_+ остается 0, при пересечении первой линии Стокса из постоянства C_+ следует также сохранение C_-. Вторая линия анти-Стокса с ψ_--доминированием. Пользуемся условие сшивки на действительной оси и получаем

$$r = ite^{-i\sqrt{2mU_0}\left(\int\limits_{z_1}^{0} + \int\limits_{z_0+0}^{z_1+0} + \int\limits_{0}^{z_0}\right)\sqrt{\alpha+\frac{z^4}{a^4}}dz}$$

- Коэффициент прохождения:

$$t = 1$$

$$\sqrt{\alpha + \frac{z^4}{a^4}} = e^{\frac{i}{2}\cdot 2\pi}\sqrt{\alpha + \frac{z^4}{a^4}}$$

$$\left(\int\limits_{z_1-0}^{z_0-0} + \int\limits_{z_0+0}^{z_1+0}\right)\sqrt{\alpha + \frac{z^4}{a^4}}dz = 2\int\limits_{z_1-0}^{z_0-0}\sqrt{\alpha + \frac{z^4}{a^4}}dz$$

Из голоморфности функций:

$$\int\limits_{z_1-0}^{z_0-0}\sqrt{\alpha + \frac{z^4}{a^4}}dz = \int\limits_{z_1}^{0}\sqrt{\alpha + \frac{z^4}{a^4}}dz + \int\limits_{0}^{z_0}\sqrt{\alpha + \frac{z^4}{a^4}}dz$$

$$\left(\int\limits_{z_1-0}^{z_0-0} + \int\limits_{z_0+0}^{z_1+0}\right)\sqrt{\alpha + \frac{z^4}{a^4}}dz = -2i\cos\frac{\pi}{4}a\alpha^{3/4}\int\limits_{0}^{1}\sqrt{1-t^4}dt = -2i\cos\frac{\pi}{4}a\alpha^{3/4}\frac{\Gamma(1/4)^2}{6\sqrt{2\pi}}$$

$$r = i\exp\Big[-2a\sqrt{mE\sqrt{\frac{E}{U_0}}}\frac{\Gamma(1/4)^2}{6\sqrt{2\pi}}\Big]$$

17.3.4 Problems about basic 1D scatterings 1

O3.1-3.12 Scattering over a pot

Найти волновую функцию и уровни энергии стационарных состояний частицы массой m, локализованной в симметричной одномерной потенциальной яме прямоугольной формы, глубина которой равна U_0, а ширина $2a$.

Solution

Примем за начало координат центр дна ямы O (см. рис. 19 к условию задачи). Тогда уравнение Шредингера для связанных состояний внутри ямы будет

$$\frac{d^2\psi}{dx^2} + k^2\psi = 0 \tag{1}$$

а вне ямы

$$\frac{d^2\psi}{dx^2} - \alpha^2\psi = 0 \tag{2}$$

где введены обозначения

$$k = \sqrt{\frac{2m\ell}{\hbar^2}}, \quad \alpha = \sqrt{\frac{2m\,(U_0 - \mathscr{E})}{\hbar^2}} \tag{3}$$

Внутри ямы общее решение имеет вид

$$\psi = A\cos kx + B\sin kx.$$

Вне ямы решение, удовлетворяющее условиям на бесконечности $\Psi(\pm\infty) \to 0$, будет

$$\begin{aligned} \psi &= Ce^{-\alpha x} \quad \text{при} \quad x > a, \\ \psi &= De^{\alpha x} \quad \text{при} \quad x < -a. \end{aligned}$$

Из соображений симметрии следует, что плотность вероятности $|\psi|^2$ должна быть симметричной функцией x относительно начала координат. Следовательно, должно быть $C^2 = D^2$, т. е. возможны два случая: $C = D$ и $C = -D$. Постоянные A, B, C, D надо выбрать так, чтобы на краях ямы функция ψ и ее производная $d\psi/dx$ были непрерывны. На границе $x = +a$ это дает

$$\begin{aligned} A\cos ka + B\sin ka &= Ce^{-\alpha a} \\ -kA\sin ka + kB\cos ka &= -\alpha Ce^{-\alpha a} \end{aligned}$$

а на границе $x = -a$

$$\begin{aligned} A\cos ka - B\sin ka &= De^{-\alpha a} \\ kA\sin ka + kB\cos ka &= \alpha De^{-\alpha a} \end{aligned}$$

Отсюда

$$\begin{aligned} 2A\cos ka &= (C + D)e^{-\alpha a}, \quad 2kA\sin ka = \alpha(C + D)e^{-\alpha a} \\ 2B\sin ka &= (C - D)e^{-\alpha a}, \quad 2kB\cos ka = -\alpha(C - D)e^{-\alpha a} \end{aligned}$$

Если $A \neq 0$ и $C = D$, то

$$k\,\mathrm{tg}\,ka = \alpha \tag{4}$$

Если же $B \neq 0$ и $C = -D$, то

$$k\,\mathrm{ctg}\,ka = -\alpha \tag{5}$$

Эти условия не могут быть удовлетворены одновременно, так как в противном случае получилось бы $k^2 = -\alpha^2$, а это невозможно ввиду вещественности k и α. Решение, когда все коэффициенты A, B, C, D равны нулю, физического смысла не имеет. Таким образом, все возможные решения разделяются на два класса: решения с четной волновой функцией, когда $A \neq 0, B = 0, C = D$ и решения с нечетной волновой функцией, когда $A = 0, B \neq 0, C = -D$.

Уровни энергии найдутся путем графического или численного решения уравнения (4) или уравнения (5), в которых положительные величины k и α определяются выражениями (3). Для графического решения удобно ввести безразмерные величины

$$\xi = ak, \quad \eta = a\alpha \tag{6}$$

Тогда

$$\xi^2 + \eta^2 = \frac{2mU_0a^2}{\hbar^2} \tag{7}$$

причем для решений с четной волновой функцией

$$\eta = \xi\,\mathrm{tg}\,\xi \tag{4a}$$

а для решений с нечетной волновой функцией

$$\eta = -\xi \operatorname{ctg} \xi \tag{5a}$$

На рис. 145a построены кривые $\eta = \xi \operatorname{tg} \xi$, на рис. 145б - кривые $\eta = -\xi \operatorname{ctg} \xi$.

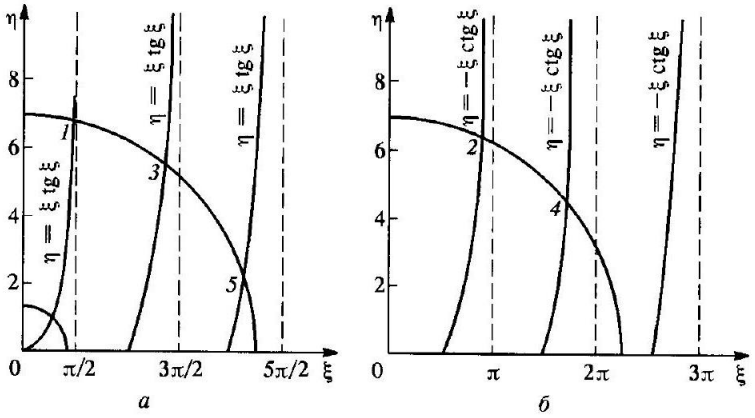


Рис. 145

Вертикальными штриховыми линиями изображены асимптоты этих кривых. Ввиду положительности ξ и η нужны только участки этих кривых, расположенные в положительном квадранте ($\xi > 0, \eta > 0$). Пересечем эти кривые окружностью (7), радиус которой $\sqrt{2mU_0}a/\hbar$ должен

считаться известным. Координаты точек пересечения этой окружности с кривыми (4а) и (5а) дадут возможные значения ξ и η. После этого по формулам (3) легко найти значения $\mathscr{E}$. Число уровней всегда конечно и определяется глубиной U_0 и шириной $2a$ потенциальной ямы. Например, если радиус окружности равен 7, то получается пять уровней. Точкам пересечения $1, 3, 5$ соответствуют четные, а точкам 2 , 4 - нечетные волновые функции. Если $0 \leqslant U_0 a^2 \leqslant \hbar^2\pi^2/8m$, то имеется только одна точка пересечения, которой соответствует четная волновая функция.

Следует еще раз подчеркнуть, что в симметричной одномерной яме при любой ее глубине и ширине всегда есть хотя бь один уровень, отвечающий четной ψ-функции. Аналогично обстоит дело в двумерном случае. Принципиально по-другому обстоит дело в случае трехмерной потенциальной прямоугольной ямы (задача 3.16*), где уровень есть не всегда.

Дадим также другой способ решения уравнений (4) и (5).

Рассмотрим четное решение $k \operatorname{tg} ka = \alpha$, откуда $1 + \operatorname{tg}^2 ka = \frac{\alpha^2+k^2}{k^2}$;

$$\frac{1}{\cos^2 ka} = \frac{2mU_0a^2}{\hbar^2}\frac{1}{(ka)^2}; |\cos ka| = \sqrt{\frac{\hbar^2}{2mU_0a^2}}ka$$

При этом (т.к. $\operatorname{tg} ka > 0$) годятся те четверти, где $\sin ka$ и $\cos ka$ имеют одинаковые знаки.

Для нечетного решения получаем $|\sin ka| = \sqrt{\frac{\hbar^2}{2mU_0a^2}}ka$, и т.к. $\operatorname{ctg} ka < 0$, то годятся те четверти, где $\sin ka$ и $\cos ka$ имеют разные знаки. Графическое решение полученных уравнений изображено на рис. 146 и 147.

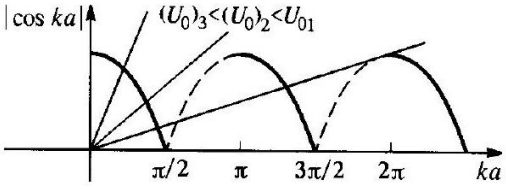

Рис. 146

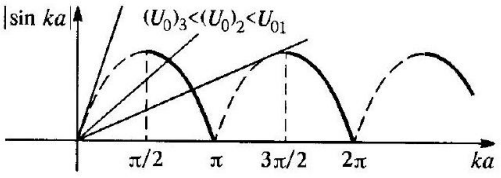

Рис. 147

Видно, что в зависимости от величины U_0 (при данном a) или a (при данном U_0) в случае четной ψ-функции хотя бы одно решение есть всегда! Это будет иметь место при $\sqrt{\frac{\hbar^2}{2mU_0a^2}} > \frac{1}{\pi/2} = \frac{2}{\pi}$, или $U_0 a > \frac{\pi^2\hbar^2}{8m}$. При дальнейшем уменьшении U_0 уровень поднимается к потолку ямы, но частица из ямы не вылетает (рис. 148)!

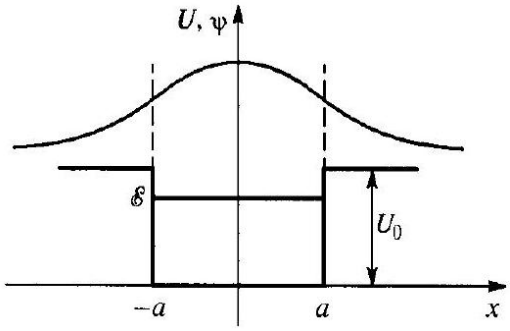

Рис. 148

О3.1-3.1

Найти плотность потока вероятности для:
а) плоской волны $\psi = \exp\left(i\frac{p_z}{\hbar}z\right) = \exp(ikz)$,
б)сферической волны $\psi = \frac{1}{kr}\exp(ikr)$,
в) суммы сходящейся и расходящейся волн $\psi = \frac{1}{2kr}\left(se^{ikr} - e^{-ikr}\right)$.

3.

1. Решение. Плотность потока вероятности вычисляется по формуле

$$\mathbf{j} = \frac{i\hbar}{2m}\left(\psi\nabla\psi^* - \psi^*\nabla\psi\right)$$

или в одномерном случае

$$j_z = \frac{i\hbar}{2m}\left(\psi\frac{\partial\psi^*}{\partial z} - \psi^*\frac{\partial\psi}{\partial z}\right) \qquad (*)$$

а) В случае плоской волны $\psi(z) = \mathrm{e}^{ikz}$ плотность потока вероятности определим прямой подстановкой волновой функции в (*):

$$j_z = \frac{\hbar k}{m} = v$$

т. е. равна скорости частицы v.
б) В случае сферической расходящейся волны $\psi(r) = \frac{1}{kr}\mathrm{e}^{ikr}$, очевидно, вектор плотности потока вероятности $\mathbf{j}$ направлен по радиусу-вектору $\mathbf{r}$. Кроме того будем считать $kr \gg 1$. Поэтому

$$\mathbf{j} = \frac{\hbar k}{m}\frac{1}{(kr)^2}\frac{\mathbf{r}}{r} = \frac{v}{(kr)^2}\frac{\mathbf{r}}{r} = \frac{\mathbf{v}}{(kr)^2}$$

В последнем равенстве учтено, что k || r || v. Можно было бы воспользоваться декартовыми координатами, направив ось z по радиусу-вектору. Естественно, ответ получился бы таким же:

$$j_z = \frac{v_z}{(kr)^2}$$

в) Для суммы сходящейся и расходящейся волновых функций приведем только ответ:

$$\mathbf{j} = \frac{\mathbf{v}}{(2kr)^2}\left(|s|^2 - 1\right)$$

О3.1-3.2

Волновая функция частицы массой m, совершающей одномерное движение, имеет вид $\psi(x) = Ae^{-\alpha x^2}$. Найти потенциал $U(x)$, в котором двигается частица, и ее энергию $\mathcal{E}$ что при $x = 0, U(x) = 0$.

Solution.

$U(x) = \frac{2\alpha^2\hbar^2}{m}x^2$ (гармонический осциллятор), $\mathscr{E} = \frac{\alpha\hbar^2}{m}$.
Указание: в задачах 3,2; 3, 3; 3, 4 предпочтительнее не интегрировать по частям, а наоборот - дифференцировать по параметру α определенный интеграл $\int_0^\infty \mathrm{e}^{-\alpha x}dx = \frac{1}{\alpha}$.

О3.1-3.3

Волновая функция частицы массой m, совершающей одномерное движение в поле с потенциалом $U(x)$, есть

$$\psi(x) = \begin{cases} \Lambda x^2 \exp(-x/a) & \text{при } x > 0 \\ 0 & \text{при } x \leqslant 0 \end{cases}$$

Оценить с помощью соотношения неопределённостей среднюю кинетическую энергию $\langle T \rangle$ частицы и сравнить с результатом точного расчета. Найти $U(x)$ при $x > 0$ и полную энергию частицы $\mathscr{E}$, если известно, что $U(x) \to 0$ при $x \to \infty$.

3.

3. $\langle T \rangle \approx \frac{\hbar^2}{32ma^2}$ (точное значение $\langle T \rangle = \frac{\hbar^2}{6ma^2}\Big)$; $U(x) = \frac{\hbar^2}{m}\left(\frac{1}{x^2} - \frac{2}{ax}\right)$; $\mathscr{E} = -\frac{\hbar^2}{2ma^2}$ (см. указание к задаче 3.2).

О3.1-3.4 Все по волновой функции

Волновая функция частицы массой m, совершающей одномерное движение в поле с потенциалом $U(x)$, есть

$$\psi(x) = \begin{cases} Ax \exp(-x/a) & \text{при } x > 0 \\ 0 & \text{при } x \leqslant 0. \end{cases}$$

Оценить с помощью соотношения неопределённостей среднюю кинетическую энергию $\langle T \rangle$ частицы и сравнить с результатом точного расчета. Найти среднее значение координаты $\langle x \rangle$, а также $U(x)$ при $x > 0$ и полную энергию $\circ$, если известно, что $U(x) \to 0$ при $x \to \infty$.

Solution.

Заметьте, что дана именно волновая функция, а не потенциал!
Плотность вероятности найти частицу:

$$w(x) = \psi^* \psi = A^2 x^2 \exp\left(-\frac{2x}{a}\right) \text{ при } x \geq 0$$

Найдем максимум:

$$\frac{dw(x)}{dx} = 0 \to x_m = a$$

Тогда неопределенность по координате как $2a$ - влево и вправо от максимума. Тогда из соотношения неопределённостей:

$$p \approx \Delta p = \frac{\hbar}{2a} \to \langle T \rangle = \frac{p^2}{2m} = \frac{\hbar^2}{8ma^2}$$

3.4. $\langle T \rangle \approx \frac{\hbar^2}{8ma^2}$ (точное значение $\langle T \rangle = \frac{\hbar^2}{2ma^2}\Big)$; $\langle x \rangle = \frac{3}{2}a; U(x) = -\frac{\hbar^2}{max}$; $\mathscr{E} = -\frac{\hbar^2}{2ma^2}$ (см. указание к задаче 3.2).

О3.1-3.5

Частица массы m находится в одномерном потенциале

$$U(x) = \begin{cases} \infty & \text{при } x < 0, \\ kx & \text{при } x > 0. \end{cases}$$

Оценить энергию основного состояния частицы в этом потенциале, используя в качестве волновой функции $\psi = x\exp(-ax)$. В качестве оценки взять минимальное значение среднего значения полной энергии частицы. Сравнить с задачей 2.39.

3.

5. $\mathscr{E}_0 \approx \left(\frac{9}{4}\frac{\hbar^2 k^2}{m}\right)^{1/3}$, параметр $a = \left(\frac{3mk}{2\hbar^2}\right)^{1/3}$. См. также задачу 2.39. Полученный ответ совпадает с точным решением с точностью 6%.

О3.1-3.6

Используя правило квантования Бора-Зоммерфельда, найти закон квантования энергии частицы массой m при больших значениях главного квантового числа n (в квазиклассическом приближении) в одномерном потенциале

$$U(x) = \begin{cases} \infty & \text{при} \quad x < 0 \\ kx & \text{при} \quad x > 0 \end{cases}$$

У к а з а н и е. Правило квантования Бора-Зоммерфельда: $\oint \mathbf{p} d\mathbf{l} = nh$.

3.

6. $\mathscr{E}_n = \frac{3}{2}\sqrt[3]{\frac{k^2\pi^2\hbar^2}{m}} n^{2/3}$.

(?? заново нужно решать!)

$$dx = \frac{-pdp}{km}$$

$$2\int_{p_0}^{0} \frac{p^2}{km} dp = \frac{2}{3}\frac{p_0^3}{km} = 2\pi\hbar h$$

дальше находим p_0

$$p_0 = [2\pi\hbar k m \frac{2}{3}]^{1/3} n^{1/3}$$

он зависит как корень 3 степени из n????
дальше $E_n \sim n^{2/3}$, $\frac{\Delta E}{E} \sim \frac{\Delta n}{n}\frac{2}{3}$
??????

О3.1-3. 7

В кулоновском поле простейшим сферически симметричным решением уравнения Шрезингера является волновая функция $\psi = A\exp(-ar)$. Какой энергии (в эВ) соответствует это состояние для электрона в кулоновском поле ядра с зарядом $Z = 10$? Чему равна a?

3.

7. $\mathscr{E} = -\frac{mZ^2\mathrm{e}^4}{2\hbar^2} = -1,36\kappa$ В; $a = \frac{\hbar^2}{Zm\mathrm{e}^2} = 0,053$Å.

О3.1-3. 8

Взаимодействие между нуклонами в дейтроне может быть описано потенциалом Юкавы $U(r) = -U_0\frac{\exp(-r/a)}{r/a}$, где r - относительное расстояние, a - радиус взаимодействия ядерных сил, $U_0 = 40$МВ. Если аппроксимировать волновую функцию основного состояния как водородоподобную $\psi(r,\alpha) = \sqrt{\frac{\alpha^3}{8\pi a^3}}\exp\left(-\frac{\alpha r}{2a}\right)$, где a - параметр, при котором достигается минимальная энергия основного состояния, то энергия связи оказывается равной $\mathcal{E}_0 = -1,08$МВ. Определить величину a.

Ук а з а н и е. Уравнение $\frac{x^3(x-1)}{(1+x)^3} = 0,108$ имеет корень $x = 1,5$.

3.

8. $a = \hbar\sqrt{\frac{(1+\alpha)^3}{2\mu U_0\alpha(\alpha+3)}} \approx 1,54\cdot 10^{-13}$ cm.

Решение. Учитывая сферическую симметрию задачи, запишем

$$\langle\mathscr{E}\rangle = \langle T+U\rangle = \int_0^\infty \psi^*\left[\frac{\hat{p}^2}{2\mu} + U(r)\right]\psi dV,$$

где $dV = 4\pi r^2 dr; \mu = m_N/2$ - приведенная масса дейтрона. Оператор

$$\hat{p}^2 = -\hbar^2\Delta_r = -\hbar^2\left(\frac{d^2}{dr^2} + \frac{2}{r}\frac{d}{dr}\right)$$

Вычисляя интегралы, получаем

$$\langle\mathcal{G}\rangle = \frac{\hbar^2\alpha^2}{8\mu a^2} - U_0\frac{a^3}{(1+\alpha)^2}.$$

Основное состояние соответствует минимуму энергии:

$$\frac{d\langle\mathfrak{G}\rangle}{d\alpha} = 0, \text{ откуда } \frac{(1+\alpha)^3}{\alpha(3+\alpha)} = \frac{2\mu a^2 U_0}{\hbar^2}.$$

Далее находим

$$\mathscr{E}_0 = \langle\mathscr{E}\rangle = \frac{\alpha^3(1-\alpha)}{(1+\alpha)^3}\frac{U_0}{4} \text{ или } \frac{\alpha^3(1-\alpha)}{(1+\alpha)^3} = 0,108.$$

Используя указание к задаче, находим, что $\alpha = 1,5$. Таким образом,

$$a = \hbar\sqrt{\frac{(1+\alpha)^3}{2\mu U_0\alpha(\alpha+3)}} \approx 1,54\cdot 10^{-13} \text{ cm}.$$

О3.1-3.9. Энергия связи дейтрона, зная потенциал (???)

Взаимодействие между нуклонами в дейтроне может быть описано потенциалом $U(r) = -U_0\exp\left(-\frac{r}{a}\right)$, где $U_0 = 32,7$ МэВ, $a = 2,2$ фм, r - расстояние между нуклонами. Аппроксимируя волновую функцию основного состояния водородоподобной $\psi(r,\alpha) = \sqrt{\frac{\alpha^3}{8\pi a^3}}\exp\left(-\frac{\alpha r}{2a}\right)$, где α - параметр, при котором достигается минимум энергии основного состояния, найти энергию связи дейтрона.

У к а з а н и е. Уравнение $\frac{(1+x)^4}{x} = 22,6$ имеет корень $x = 1,35$.

3.

9. $\langle E(\alpha)\rangle = \frac{\hbar^2\alpha^2}{8\mu a^2} - U_0\frac{\alpha^3}{(1+\alpha)^3} \approx -2,2$ МэВ, где $\alpha = 1,35$.

О3.1-3.10 Волновая функция трехмерного осциллятора (?)

Волновая функция трехмерного изотропного осциллятора, характеризуемого классической частотой ω и приведенной массой μ, имеет вид $\psi = A\left(1+\alpha r^2\right)e^{-\beta r^2}$, где A, α и β - некоторые константы. Определить величину констант α и β, энергию этого состояния и главное квантовое число. Смотрите также задачу 4.10.

3.

10: 1) $\alpha = -\frac{2}{3}\frac{\mu\omega}{\hbar}; \beta = \frac{\mu\omega}{2\hbar}; \mathscr{E} = \frac{7}{2}\hbar\omega$, поскольку $\mathscr{E}_N = \hbar\omega\left(N+\frac{3}{2}\right)$, то $N = 2$.
2) $\alpha = 0; E = \frac{3}{2}\hbar\omega, N = 0$.

Решение. В трехмерном случае в сферических координатах (r,θ,φ) лапласиан Δ имеет вид

$$\Delta = \Delta_r + \frac{1}{r^2}\Delta_{\theta,\varphi}.$$

Поскольку ψ-функция не зависит от углов (сферически симметричный случай, изотропный осциллятор), то лапласиан в нашей задаче сводится к радиальной части Δ_r

$$\Delta = \Delta_r \equiv \frac{d^2}{dr^2} + \frac{2}{r}\frac{d}{dr}.$$

Дифференцируя исходную ψ-функцию, получим

$$\frac{d\psi}{dr} = 2Ae^{-\beta r^2}\left[(\alpha-\beta)r - \alpha\beta r^3\right]$$
$$\frac{d^2\psi}{dr^2} = 2Ae^{-\beta r^2}\left[2\alpha\beta^2 r^4 - \beta(5\alpha-2\beta)r^2 + (\alpha-\beta)\right]$$

Таким образом, уравнение Шредингера имеет вид

$$-\frac{\hbar^2}{2\mu}\left(\frac{d^2\psi}{dr^2}+\frac{2}{r}\frac{d\psi}{dr}\right)+\frac{\mu\omega^2}{2}r^2\psi=\mathscr{E}\psi,\ \text{или}$$

$$-6\beta+4\beta^2r^2-14\alpha\beta r^2+4\alpha\beta^2r^4+6\alpha-$$
$$-\frac{\mu^2\omega^2}{\hbar^2}r^2-\frac{\mu^2\omega^2}{\hbar^2}r^4\alpha=-\frac{2\mu}{\hbar^2}\S-\frac{2\mu}{\hbar^2}£\alpha r^2.$$

Поскольку энергия $\mathscr{E}=\text{const}$ и не может зависеть от r, то сумма коэффициентов при всех степенях r должна давать 0 .

$$\begin{array}{ll} r^0: & 6(\alpha-\beta)+\frac{2\mu}{\hbar^2}\mathscr{E}=0 \\ r^2: & -14\alpha\beta+4\beta^2-\frac{\mu^2\omega^2}{\hbar^2}+\frac{2\mu\mathscr{E}}{\hbar^2}\alpha=0, \\ r^4: & 4\alpha\beta^2-\frac{\mu^2\omega^2}{\hbar^2}\alpha=0. \end{array}$$

Из этой системы и следуют искомые значения α,β, $\mathscr{E}$ и N, приведенные в ответе.

О3.1-3.11

Найти волновую функцию и уровни энергии стационарных состояний частицы массой m, локализованной в одномерной потенциальной яме прямоугольной формы с бесконечно высокими стенками. Ширина ямы равна $2a$.

3.

11. $\Psi=\begin{cases}\frac{1}{\sqrt{a}}\cos\frac{n\pi x}{2a} & (n=1,3,5,\ldots),\\ \frac{1}{\sqrt{a}}\sin\frac{n\pi x}{2a} & (n=2,4,6,\ldots),\end{cases}\quad \mathscr{E}=\frac{\hbar^2\pi^2}{8ma^2}n^2$ в обоих случаях.

Вследствие симметричности потенциала решения подразделяются на четные и нечетные. В силу граничных условий ($\Psi(\pm a)=0$) на ширине ямы должно укладываться целое число полуволн де Бройля, как это имеет место для электромагнитных волн в случае интерферометра Фабри-Перо или волновода с металлическими стенками.

(типичная элементарная задача, должен решать за 1 минуту, потом потренируюсь, нужно 1ю часть прописать без херни.)

О3.1-3.13 Сила давления и энергия электронов в яме (!!!)

В одномерной потенциальной яме шириной b с бесконечными стенками находятся N электронов. Определить минимальное значение полной энергии $\mathscr{E}_{\min}$ и силу F давления электронов на стенки ямы. Взаимодействием электронов пренебречь.

3.

13. $\mathscr{E}_{\min}=\frac{\pi^2\hbar^2}{4mb^2}\frac{N(N+2)(N+1)}{6}; F=\frac{\pi^2\hbar^2}{2mb^3}\frac{N(N+2)(N+1)}{6}$.

О3.1-3.14

Поток свободно распространяющихся нейтронов падает на непроницаемую стенку толщиной L, в которой имеется канал прямоугольного поперечного сечения с высотой $d=10^{-3}$см и шириной $l\gg d$. Длина канала $L\gg l$ (рис. 20). При каких значениях скорости v нейтронов в падающем пучке нейтроны могут пройти сквозь канал? Чему равна минимальная скорость $v_{\min}$ в случае квадратного сечения канала $d\times d$?

3.

14. Вообще $v>\frac{\pi\hbar}{mdl}\sqrt{d^2+l^2}$. При $d\ll l v_{\min}=\frac{\pi\hbar}{md}\approx 2$ cm/c.
При $d=l$ (квадратное сечение канала) $v_{\min}=\frac{\sqrt{2}\pi\hbar}{md}\approx 2,8$ cm/c.

(такая же, как и следующая задача, только уровни энергии еще по перпендикулярному состоянию)

О3.1-3.15 Пролет нейтронов через щель (???)

Поток нейтронов, летящих со скоростью $V_0 = 25$см/ сек, падает на широкую щель с абсолютно отражающими стенками. Длина щели $l = 1$см, высота $d = 10^{-4}$см. Сколько времени нейтрон будет находиться внутри щели, если он в нее попадет?

3.

15. $t = 0,065$ с.

(?? идейно не очень понимаю, как все тут работает???)
(!!! в 1ю часть добавлю очевидные формулы для этой задачи)
Качественно такое описание. Энергия тратится на отражения, поэтому скорость в этой щели меньше. нулевой уровень:

$$E_0 = \frac{\pi^2\hbar^2}{2md^2}$$

Закон сохранения энергии:

$$\frac{mv_0^2}{2} = \frac{mv^2}{2} + \frac{\pi^2\hbar^2}{2md^2}$$

можно найти

$$v = \sqrt{v_0 - \frac{\pi^2\hbar^2}{2md^2}}$$

ответ: $t = \frac{l}{v} = 0.066$ с.

О строгом описании (???)

(?? почему вообще закон сохранения энергии так выполняется??? что-то сомнительное вроде решение. мб 1ю часть доработаю потом тоже.)

О3.1-3.16

В трехмерной прямоугольной потенциальной яме

$$U(r) = \begin{cases} -U_0 & \text{при} \quad r < a, \\ 0 & \text{при} \quad r > a. \end{cases}$$

Найти волновые функции и энергии стационарных состояний при нулевом моменте импульса.

3.

16. Решение. В сферической системе координат уравнение Шредингера для стационарных состояний с волновыми функциями, зависящими только от r, имеет вид

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{d\psi}{dr}\right) + \frac{2m}{\hbar^2}[\mathscr{E} - U(r)]\psi = 0 \tag{1}$$

Решение этого уравнения должно быть конечным при $r = 0$ и достаточно быстро убывать при $r \to \infty$ (чтобы $\int |\psi|^2 dV$ сходился). Введем новую функцию $\chi = r\psi$. Тогда

$$\frac{d^2\chi}{d^2r} + \frac{2m}{\hbar^2}[\mathscr{E} - U(r)]\chi = 0 \tag{2}$$

Надо найти решения этого уравнения, убывающие при $r \to +\infty$ и обращающиеся в нуль при $r = 0$. Это будут

$$\begin{array}{ll} \chi = B\sin kr & \text{при } r \leqslant a, \\ \chi = Ce^{-\alpha r} & \text{при } r \geqslant a, \end{array}$$

где

$$k = +\sqrt{\frac{2m\,(\mathscr{E} + U_0)}{\hbar^2}}, \quad \alpha = +\sqrt{-\frac{2m\mathscr{E}}{\hbar^2}}. \tag{3}$$

Задача свелась к задаче об одномерной потенциальной яме - уровни энергии определяются точно так же, надо только отбросить состояния с четными и сохранить состояния лишь с нечетными волновыми функциями.

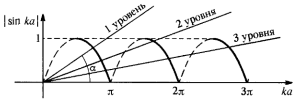
О3.1-3.17 Уровень в 3D кубе (!!!????)

Частица массой m локализована в трехмерной потенциальной яме прямоугольной формы, радиус которой равен . Определить минимальную глубину ямы U_0, при которой появится первый уровень энергии. Чему равна энергия частицы $\mathcal{E}$ на этом уровне?

Solution.

3.17. Решение задачи сводится к решению трансцендентного уравнения $|\sin ka| = \sqrt{\frac{\hbar^2}{2mU_0a^2}}ka$, где $k^2 = \frac{2m(U_0-\varkappa)}{\hbar^2}$, (см. рис. 149).

Минимальная «мощность» U_0a^2 ямы, при которой появляется первый уровень, $U_0a^2 = \pi^2\hbar^2/(8m)$. При этом энергия уровня ($ka = \pi/2$) равна $\mathscr{E} = 0$, т. е. уровень лежит на «потолке» ямы. При увеличении U_0 или a уровень опускается в яму. Из рис. 149 видно, что второй уровень появится при $\operatorname{tg}\alpha = \frac{2}{3\pi}$; третий - при $\operatorname{tg}\alpha = \frac{2}{5\pi}$ и т. д. Итак, $U_0 = \frac{\pi^2\hbar^2}{8ma^2}$.



17.3.5 Problems about basic 1D scatterings 2

О3.1-3.18 Моделирование дейтрона

Дейтрон - это ядро дейтерия, состоящее из протона и нейтрона. Энергия связи дейтрона, измеренная экспериментально, равна $\mathscr{E} = 2,225$ МэВ. Аппроксимируя потенциальную энергию взаимодействия протона с нейтроном с помощью трехмерной прямоугольной потенциальной ямы, определить ее глубину U_0, при которой возможно такое связанное состояние. Радиус потенциальной ямы $a = 1,6 \cdot 10^{-13}$см.

3.

18. $U_0 = \frac{\pi^2\hbar^2}{8\mu a^2} + \mathscr{E} \approx$ 42М ЭВ, где $\mu = \frac{m_p}{2}$. Это довольно грубая оценка. Точное решение трансцендентного уравнения дает $U_0 \approx$ 53М ВВ. Смотрите задачу 3.17 .

О3.1-3.19

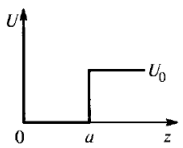
Определить среднее значение квадрата импульса $\langle p^2\rangle$ и среднее значение квадрата координаты $\langle x^2\rangle$ частицы массой m, находящейся в одномерной «мелкой» $\left(U_0 \ll \hbar^2/ma^2\right)$ симметричной потенциальной яме, изображенной на рис. 23. Проверить выполнение соотношения Гайзенберга $\langle p^2\rangle\langle x^2\rangle \geqslant \hbar^2/4$.

3.

19. $\left\langle x^2\right\rangle = \frac{\hbar^4}{8m^2a^2U_0^2}; \left\langle p^2\right\rangle = \frac{4m^2a^2U_0^2}{\hbar^2}; \left\langle x^2\right\rangle\left\langle p^2\right\rangle = \frac{\hbar^2}{2} \Big\rangle \frac{\hbar^4}{2}$.

О3.1-3.20 Средняя координата в яме у стенки

Потенциальную энергию взаимодействия $U(z)$ атома гелия с плоской поверхностью твердого тела $z = 0$ можно аппроксимировать прямоугольной ямой некоторой глубины U_0 и шириной $a = 5$Å, причем $U(z = 0) = +\infty$ (рис. 24). Полагая, что волновая функция адсорбированного атома в основном состоянии достигает максимума при $z = 0,99a$, найти среднее значение координаты $\langle z\rangle$ для адсорбированных атомов в основном состоянии.



Solution.

(??? я уже решал ее из Гольдмана Кривченкова, еще раз допишу суть!)

3.20*. $\langle z\rangle \approx \dfrac{2a}{\pi^2\delta} \approx 20a = 100\text{Å}$, где $\delta = 0,01$ (точное значение $\langle z\rangle =$
$=\dfrac{4a}{\sqrt{2}\pi^2\delta} \approx 140\text{Å}$).

Решение. Разобьем область нахождения атома гелия на две части: I внутри потенциальной ямы $(0 < z \leqslant a)$ и II - вне ее при $z > a$. В области I:
Решение этого дифференциального уравнения очевидно:

$$\psi_1(z) = \sin kz, \quad \text{поскольку при } z = 0 \text{ должно быть } \psi_1(0) = 0.$$

В области I:

$$\psi''_{\text{II}} - \varkappa^2\psi_{\text{II}} = 0, \text{ где } \quad x = \frac{1}{\hbar}\sqrt{2m\,(U_0 - \mathscr{E})}$$

Решение последнего уравнения

$$\psi_{\text{II}}(z) = Ae^{-xz}$$

где A - нормировочная константа. Заметим, что формальным решением этого уравнения могла бы быть положительная экспонента $\propto \exp(xz)$. Но тогда при $z \to \infty, \psi(z) \to \infty$, что не имело бы физического смысла.
На границе областей, т. е. при $z = a$ необходима гладкая сшивка ψ-функций:

$$\psi_{\text{I}}(a) = \psi_{\text{II}}(a), \text{ т. е. } \sin ka = Ae^{-\varkappa a}$$
$$\psi'_{\text{I}}(a) = \psi'_{\text{II}}(a), \text{ т. е. } k\cos ka = -A\varkappa e^{-\varkappa a}$$

Откуда следует

$$\operatorname{ctg} ka = -\frac{x}{k}$$

По условию волновая функция адсорбированного атома в основном состоянии достигает максимума при $z = z^* = 0,99a = (1-\delta)a$, где $\delta = 0,01$. Максимум лежит в области I, т. е.

$$\psi_1(z^*) = \sin kz^* = 1, \text{ откуда } kz^* = \frac{\pi}{2}$$

и откуда определим k:

$$k = \frac{\pi}{2z^*} = \frac{\pi}{2(1-\delta)a} \approx \frac{\pi}{2a}(1+\delta)$$

Вычислим

$$\operatorname{ctg} ka = \frac{\cos\left(\frac{\pi}{2} + \frac{\pi\delta}{2}\right)}{\sin\left(\frac{\pi}{2} + \frac{\pi\delta}{2}\right)} = -\sin\frac{\pi\delta}{2} \approx -\frac{\pi\delta}{2}$$

Из соотношения (3) определим x:

$$x = -k\operatorname{ctg} ka \approx k\frac{\pi\delta}{2} = \frac{\pi^2}{4a}\delta \simeq 5\cdot 10^5 \text{ cm}^{-1}$$

По определению

$$\langle z\rangle = \frac{\int\limits_0^a z\sin^2 kzdz + \int\limits_a^\infty A^2e^{-2xz}zdz}{\int\limits_0^a \sin^2 kzdz + \int\limits_a^\infty A^2e^{-2xz}dz}$$

Но интегралами по области I можно пренебречь в силу их малого вклада, одновременно расширив область интегрирования в области II до 0. Действно, $\frac{\int\limits_0^\infty ze^{-2xz}dz}{\int\limits_0^\infty -2xz} = \frac{1}{2x}$, но $\frac{\int\limits_a^\infty ze^{-2xz}dz}{\int\limits_\infty^\infty -2xz} = \frac{1+2xa}{2x}$. Так как $2xa \approx 10^{-2}$, то

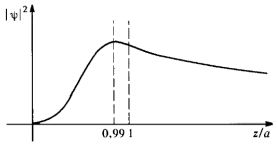
$$\int\limits_0 e^{-2xz}dz \quad \int\limits_a e^{-2xz}dz$$

это очень близкие выражения. Поэтому

$$\langle z\rangle \approx \frac{\int\limits_0^\infty ze^{-2xz}dz}{\int\limits_0^\infty e^{-2xz}dz} = \frac{1}{2x} = \frac{2a}{\pi^2\delta} \approx 20a = 100\text{Å}$$

На рис. 150 приведен график зависимости $|\psi(z)|^2$. Хотя максимум ψ функции и лежит внутри потенциальной ямы, но среднее значение координаты $\langle z\rangle$ - далеко за ее пределами, поскольку ψ-функция крайне медленно спадает при $z > a$. Точное интегрирование дает

$$\langle z\rangle = \frac{2\sqrt{2}a}{\pi^2\delta} \approx 140\text{Å}$$



O3.1-3.21

Энергия взаимодействия $U(z)$ атома водорода с твердой стенкой аппроксимируется прямоугольной потенциальной ямой глубиной U_0, шириной $a = 6$Åи $U(z = 0) = +\infty$ (рис. 25). Энергия адсорбции - это разность наинизших уровней свободного и прилипшего к стенке атома $\mathscr{E} = U_0 - \mathscr{E}_1 = 1$ K. Найти величину U_0 и среднее значение координаты $\langle z\rangle$ адсорбированных атомов.

Указание. $\varphi \operatorname{ctg}\varphi = -1,21$ при $\varphi = 2\pi/3$.

3.

21. $U_0 = 4$ K, $\langle z\rangle \approx \frac{\pi}{2k} + \frac{1}{2x} \approx 7$Å.

Здесь $k = \frac{1}{\hbar}\sqrt{2m\mathscr{E}_1}; x = \frac{1}{\hbar}\sqrt{2m\left(U_0 - \mathscr{E}_1\right)} = \frac{1}{\hbar}\sqrt{2m\mathscr{E}}; \mathscr{E}_1 = U_0 - \mathscr{E}$. Расчет показывает, что $\langle z\rangle \approx 5,4$Å, т. е. «в среднем» атом находится не вне ямы, а все-таки внутри нее.

O3.1-3.22

Электрон находится в одномерной симметричной потенциальной яме размером $2a = 2$Å. Отношение волновой функции основного состояния на границе ямы к ее максимальному значению внутри ямы составляет $\alpha = 1/2$. Найти щегося в основном состоянии в одномерной яме шириной $a = 2$Åс потенциалом $U(0) = \infty, U = -U_0$ при $0 < x <$ и $U = 0$ при $x > a$, если известно, что от- ношение волновой функции на границе ямы ($x = a$) к ее максимальному значению в яме равно $\alpha = \sqrt{3}/2$.

3.

22. $U_0 = \frac{2\pi^2\hbar^2}{9ma^2} = 16,6$ эВ; $\mathscr{E} = \frac{\pi^2\hbar^2}{6ma^2} = 12,45$ эВ .

23

3.

23. $U_0 = \frac{8\pi^2\hbar^2}{27ma^2} = 5,53\ni$ В; $\mathscr{E} = \frac{U_0}{4} = 1,38$ В.

O3.1-3.24

Частица, находящаяся в потенциальной яме с бесконечно высокими стенками, излучает фотон, переходя из состояния с номером $(n + 1)$ в состояние n. Найти связь частоты фотона с периодом колебаний между стенками классической ямы частицы с энергией $\mathscr{E}_n$.

3.

24* Решение. Энергия частицы m, находящейся в одномерной потенциальной яме шириной a, квантуется

$$\mathscr{E}_n = \frac{\pi^2\hbar^2}{2ma^2}n^2$$

При переходе частицы из состояния $n+1$ в состояние n излучается квант энергии с частотой

$$\omega_{n+1,n} = \frac{\mathscr{E}_{n+1} - \mathscr{E}_n}{\hbar} = \frac{\pi^2\hbar}{2ma^2}(2n+1)$$

Классическая частица колеблется в яме с частотой $\omega_{\text{кл}} = 2\pi/T$, где $T = 2a/v$, где в свою очередь v - скорость частицы при движении от стенки к стенке - определяется ее энергией. Для сравнения примем значение энергии равным E_n. Тогда

$$v = \sqrt{\frac{2\S_n}{m}} = \frac{\pi\hbar n}{ma}; \omega_{\text{K}\Omega} = \frac{\pi v}{a} = \frac{\pi^2\hbar n}{ma^2}.$$

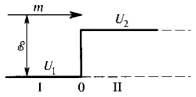
Теперь сравним $\omega_{n+1,n}$ с $\omega_{\text{кл}}$:

$$\frac{\omega_{n+1,n}}{\omega_{\text{kT}}} = 1 + \frac{1}{2n} \to 1 \quad \text{при } n \to \infty.$$

Эта задача является иллюстрацией принципа соответствия Бора. При больших значениях квантовых чисел квантово-механическое поведение системы переходит в классическое.

О3.1-3.25

Свободно движущаяся частица массой m с энергией $\mathscr{E}$ подходит к границе раздела двух областей I и II, на которой потенциальная энергия частицы скачкообразно меняется от постоянного значения U_1 до постоянного значения U_2 (рис. 26).



Определить коэффициенты отражения и пропускания частицы на этой границе по амплитуде (r и d) и по энергии (R и D). Исследовать случаи, когда: 1) $\mathscr{E} > U_2$ и 2) $\mathscr{E} < U_2$. Во втором случае определить среднюю глубину проникновения l частицы во вторую среду.

3.

25* Решение. Запишем уравнение Шредингера в виде

$$\frac{d^2\psi}{dx^2} + k^2\psi = 0 \tag{1}$$

де

$$k^2 = \frac{2m}{\hbar^2}(\mathscr{S} - U) \tag{2}$$

В области I волновая функция частицы состоит из падающей волны

$$\psi_1 = e^{i(k_1x - \omega t)}$$

и отраженной

$$\psi_1' = re^{-i(k_1x + \omega t)}$$

а в области II - из прошедшей волны

$$\psi_2 = de^{i(k_2x - \omega t)}$$

где индексами 1 и 2 отмечены волновые векторы в областях I и II соответственно. Амплитуда падающей волны принята равной единице, что, очевид но, не нарушает общности получаемых ниже результатов. Волновая функция и ее производная по x на границе раздела должны быть непрерывны. Это приводит к соотношениям

$$1 + r = d, \quad k_1 - k_1 r = k_2 d$$

из которых находим

$$r = \frac{k_1 - k_2}{k_1 + k_2}, \quad d = \frac{2k_1}{k_1 + k_2}. \tag{3}$$

1. Если $\mathscr{E} > U_2$, то волна ψ_2 однородна, так же как падающая волна ψ_1 и отраженная ψ_1'. Вычислим плотности потоков вероятностей для отраженной волны

$$j_r = \frac{i\hbar}{2m}\left[\psi_1' \frac{d\psi_1'^*}{dx} - \psi_1'^* \frac{d\psi_1'}{dx}\right] = \frac{i\hbar}{2m}\left[r^2 ik_1 + r^2 ik_1\right] = -r^2 \frac{\hbar k_1}{m}$$

и для прошедшей волны

$$\dot{j}_d = \frac{i\hbar}{2m}\left[\psi_2 \frac{d\psi_2^*}{dx} - \psi_2^* \frac{d\psi_2}{dx}\right] = d^2 \frac{\hbar k_2}{m}$$

Плотность потока вероятностей для падающей волны $j_e = \hbar k_1/m = v_1$ (равна скорости частицы, налетающей на барьер). Вычислим энергетические коэффициенты отражения R и прохождения D:

$$R = \left|\frac{j_r}{j_e}\right| = \left|-r^2\right| = \left|\frac{k_1 - k_2}{k_1 + k_2}\right|^2$$
$$D = \left|\frac{j_d}{j_e}\right| = \frac{k_2}{k_1} d^2 = \frac{4k_1 k_2}{(k_1 + k_2)^2} \tag{4}$$

Величины этих коэффициентов находятся в согласии с законом сохранения энергии: $R + D = 1$.
2) Если $\mathscr{E} < U_2$, то k_2 - чисто мнимое, т. е. волна во второй области неоднородна. В этом случае $R = 1$, т. е. отражение полное. Полагая $k_2 = i\alpha$, для волны во второй области получим

$$\psi_2 = \frac{2k_1}{k_1 + k_2} e^{-\alpha x} e^{-i\omega t}, \tag{5}$$

т. е. амплитуда волны в области II экспоненциально затухает при удалении от границы раздела областей.

Глубина проникновения l определяется как расстояние, на котором плотность потока энергии убывает в e раз. Для нее получаем

$$l = \frac{1}{2}\alpha = \frac{\hbar}{2\sqrt{2m\,(U_2 - \S)}}, \tag{6}$$

О3.1-3.26 Отражения от ямы (???)

Электрон, находящийся в одномерной прямоугольной потенциальной яме шириной несколько сантиметров и глубиной несколько электрон-вольт, поглощает квант света с частотой $v = 1,01 v_0$, где v_0 - предельная частота света, при которой электрон может вылететь из ямы. Определить среднее число отражений N от краев ямы, которые испытывает электрон, прежде чем покинуть ее. Считать, что время радиационного перехода электрона в основное состояние много больше времени вылета электрона из ямы.

3.

26. $N \approx \frac{1}{D} \approx \frac{1}{4}\sqrt{\frac{v_0}{\nu - v_0}} = 2,5$, где D - коэффициент прохождения.

Примечание. Видно, что число ударов очень мало, т. е. здесь состояние «слабо стационарное», и обычно используемое выражение для числа ударов через коэффициент отражения плоской волны от барьера в данном случае является очень грубой оценкой, дающей представление лишь о порядке величины числа отражений.

О3.1-3.27

Электрон, находящийся в основном состоянии в одномерной потенциальной яме шириной $a = 4$ Åи глубиной $U_0 = 10$ эВ (рис. 27) переведен в возбужденное состояние с энергией $\approx 10^{-2}$ эВ (нуль отсчета энергии - состояние покоя вне ямы). Оценить время жизни возбужденного состояния, считая, что оно ограничивается вылетом электрона из ямы, а не переходом в основное состояние.

3.

27. $\tau \approx (nD)^{-1} \approx \frac{a}{4}\sqrt{\frac{m}{2\delta}} \sim 10^{-15}$ с, где $n = \frac{1}{a}\sqrt{\frac{2U_0}{m}}$ - частота ударов о стенки ямы; $D = 4\frac{\sqrt{\mathscr{E}(U_0+\mathscr{E})}}{\left(\sqrt{U_0+\mathscr{E}}+\sqrt{\mathfrak{E}}\right)^2} \approx 4\sqrt{\frac{\mathscr{E}}{U_0}}$ - коэффициент прохождения. См. также примечание к ответу предыдущей задачи.

O3.1-3.28

Электрон, введенный в жидкий гелий, расталкивает атомы жидкости и образует в ней сферическую вакуумную полость, которая является для электрона потенциальной ямой с практически бесконечно высокой стенкой. Вычислить радиус полости, если поверхностное натяжение жидкого гелия равно 0,35 дин/см, а электрон занимает в полости наинизший квантовый уровень. Внешнее давление считать равным нулю.

3.

28. $R = \sqrt[4]{\frac{\pi\hbar^2}{8\sigma m}} \approx 20$Å, см. также решение задачи 3.16 .

O3.1-3.29-46 THEY ARE MISSING, I'LL ADD LATER

SOLUTIONS 3. Уравнение Шредингера. Квантование. Потенциальные барьеры.

3.

29. $l = 0,56$НМ.

3.

30. Решение. В области I $(x < 0)$ $\psi_I = e^{ik_1 x} + re^{-ik_1 x}$, где $k_1^2 = 2m\left(\mathscr{E} - U_1/\hbar^2\right.$. В области барьера $(0 < x < l)\psi = ae^{ikx} + be^{-ikx}$, где $k^2 = 2m(\mathscr{E} - U)/\hbar^2$. В области $II(x > l)\psi_{II} = de^{ik_2 x}$, где $k_2^2 = 2m\left(\mathscr{E} - U_2\right)/\hbar^2$.

Сшивая волновые функции и их производные в точках $x = 0$ и $x = l$, получим систему уравнений относительно r, d, a и b:

$$\begin{array}{ll} 1 + r = a + b; & ae^{ikl} + be^{-ikl} = de^{ik_2 l}; \\ k_1 - k_1 r = ka - kb; & kae^{ikl} - kbe^{-ikl} = k_2 de^{ik_2 l}. \end{array}$$

Отсюда получаем

$$r = \frac{\left(k_1 - k\right)\left(k + k_2\right) + \left(k_1 + k\right)\left(k - k_2\right)e^{2ikl}}{\left(k_1 + k\right)\left(k + k_2\right) + \left(k_1 - k\right)\left(k - k_2\right)e^{2ikl}},$$

$$d = \frac{4k_1 k e^{-ii(k_2 - k)l}}{\left(k_1 + k\right)\left(k + k_2\right) + \left(k_1 - k\right)\left(k - k_2\right)e^{2ikl}}.$$

В случае, когда энергия частицы ниже высоты барьера, т.е. $\mathscr{E} < U$, волновая функция в области барьера имеет вид $\psi = ae^{-xx} + be^{xx}$, где $x^2 = 2m(U - \S)/\hbar^2$, и в этом случае в формулах для r и d нужно провести замену $k \to ix$. Таким образом, поскольку в области II мы по-прежнему имеем прошедшую плоскую волну, то получаем важный вывод - квантово-механическая частица может проходить сквозь барьер даже в том случае, когда ее энергия меньше высоты барьера («туннельный эффект»).

3.

31. Полная энергия $\mathscr{E}$ должна быть больше потенциальной энергии U частицы внутри барьера (ямы). Толщина барьера (ямы) должна быть $l = \lambda/2, \lambda, 3\lambda/2, 2\lambda, 5\lambda/2, ...$, где $\lambda = h/\sqrt{2m(\mathscr{E} - U)}$ - длина волны де Бройля частицы в области барьера (ямы), или, иначе, $l = \pi\hbar p/\sqrt{2m(\mathscr{E} - U)}$ и одновременно

$\mathscr{E} = U + \frac{\pi^2\hbar^2}{2ml^2}p^2$, где $p = 1, 2, ...$, т. е. энергия частицы должна совпадать с одним из собственных значений энергии в бесконечно глубокой потенциальной яме, дно которой расположено на высоте барьера.

3.

32. $\mathscr{E}_n = U + \frac{\pi^2\hbar^2}{2ml^2}n^2, \quad n = 1, 2, 3, ..., \quad$ или в числах $\quad \mathscr{E}_n = \left(5 + 37,62n^2\right)$ эВ.

3.

33. $R \approx \frac{h}{4\sqrt{2m(\text{Å}+U)}} \approx 1,7$Å. (Табличное значение $R = 1,98$Å).

3.

34. $U = \frac{\mathscr{E}}{\sin^2 kd} = 1,64$ эВ, где $k = \frac{1}{\hbar}\sqrt{2m\mathscr{E}} = 6,22 \cdot 10^7$ см$^{-1}$. $D \approx \exp(-18xd) \approx 3,2 \cdot 10^{-5}$, где $x = \frac{1}{\hbar}\sqrt{2m(U-\mathcal{E})} \approx 1,9 \cdot 10^7$ см$^{-1}$; $\tau = \frac{\ln 2}{nD} \approx 1,8 \cdot 10^{-11}$с, где $n = \frac{1}{2d}\sqrt{\frac{2}{m}} \approx 1,22 \cdot 10^{15}$с$^{-1}$.

3.

35. $\tau = \frac{1}{nD} \approx 1,2 \cdot 10^{-11}$с, где $D \approx \exp(-598ax) \approx 8,3 \cdot 10^{-5}$, $x = \sqrt{2m(U-\mathscr{E})}/\hbar \approx 5,08 \cdot 10^5$ см$^{-1}$, $a = 3$Å.

3.

36: Решение. На рис. 151 обозначен подбарьерный переход α-частицы с энергией $\mathfrak{E}$. Так как заряд α-частицы $Z_\alpha = 2$, то оставшаяся часть ядра имеет заряд $Z' = Z - Z_\alpha = Z - 2$. $U(r) = Z'Z_\alpha e^{2/r}$. По условию $\mathscr{E} \ll U(R)$. Вычислим коэффициент прозрачности барьера по известной формуле

$$D \approx \exp\left\{-\frac{2}{\hbar}\int_R^{R_1}\sqrt{2m\left(\frac{z'z_a e^2}{r} - \delta\right)}dr\right\}$$

В подынтегральном выражении можно пренебречь $\mathscr{E}$ в силу указанного в условии неравенства. Вычислим этот интеграл

$$I = -\frac{2}{\hbar}\int_R^{R_1}\sqrt{2m\frac{Z'Z_\alpha e^2}{r}}dr = -\frac{2}{\hbar}\sqrt{2mZ'Z_\alpha e^2}\int_R^{R_1} r^{-1/2}dr =$$
$$= -\frac{4}{\hbar}\sqrt{2mZ'Z_\alpha e^2 R_1}\left(1 - \sqrt{\frac{R_1}{R}}\right)$$

Из рис. 151 видно, что $\frac{Z'Z_\alpha e^2}{R_1} = \mathscr{E}$, откуда $R_1 = \frac{Z'Z_\alpha e^2}{\mathscr{E}}$.

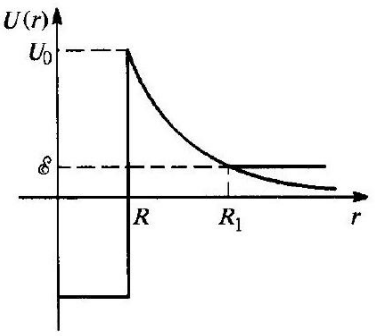


Рис. 151
Подставляя это в формулу для I, получаем

$$I \approx -\frac{4}{\hbar} Z' Z_\alpha e^2 \sqrt{\frac{2m}{\varrho}}$$

где использовано очевидное неравенство $R_1 \gg R$, справедливое в силу заданного условия $\mathscr{E} \ll U(R)$. Таким образом,

$$D \approx \exp\left(-\frac{4}{\hbar} Z' Z_\alpha e^2 \sqrt{\frac{2m}{\mathscr{E}}}\right) = \exp\left(-\frac{A}{\sqrt{\mathfrak{G}}}\right)$$

Для приближенной оценки вероятности распада в единицу времени (постоянной распада) λ необходимо прежде всего оценить число столкновений α-частицы с потенциальной стенкой за 1с : $n \approx v/(2R)$, где v - скорость α-частицы внутри ядра, которую оценим из соотношения неопределенностей:

$$v = \frac{p}{m_a} \approx \frac{\hbar}{m_a R}; \quad n \approx \frac{v}{2R} \approx \frac{\hbar}{2m_a R^2}$$

Вероятность распада в единицу времени

$$\lambda \approx nD \approx \frac{\hbar D}{2m_a R^2}$$

Период полураспада T ядра, как известно, равен

$$T = \frac{\ln 2}{\lambda} \approx \frac{2m_a R^2 \ln 2}{\hbar D} \approx a \exp\left(-\frac{b}{\sqrt{6}}\right)$$

где a и b - очевидные константы. Прологарифмировав это выражение, получим закон Гейгера-Неттола

$$\lg T \approx A + \frac{B}{\sqrt{6}}$$

3.

37* Р ешение.

Оценка изменения туннельного тока может быть проведена при рассмотрении одномерной задачи (рис. 152).

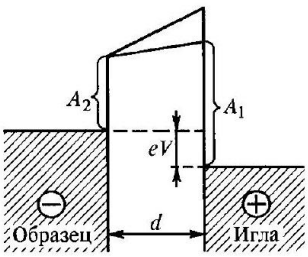

Рис. 152

Обратим внимание, что на такой энергетической диаграмме потенциальная энергия электронов возрастает снизу вверх, а потенциал поля - наоборот.

Очевидно, что туннельный ток пропорционален прозрачности барьера, изображенного на рис. 152.

$$D = D_0 \exp\left[-\frac{2}{\hbar}\int_0^d \sqrt{2m\left(A_2 + eEx\right)}dx\right]$$

где напряженность электрического поля $E = \left(A_1 - A_2 - eV\right)/d$. Интеграл в показателе экспоненты легко вычисляется:

$$\frac{2}{\hbar}\int_0^d \sqrt{2m\left(A_2 + eEx\right)}dx = \frac{4}{3\hbar}\frac{\sqrt{2m}}{eE}\left[\left(A_2 + eEd\right)^{3/2} - A_2^{3/2}\right]$$

Следовательно, прозрачность барьера

$$D = D_0 \exp\left\{-\frac{4}{3\hbar}\frac{\sqrt{2m}d}{\left(A_1 - A_2 - eV\right)}\left[\left(A_1 - eV\right)^{3/2} - A_2^{3/2}\right]\right\}$$

При перемещении иглы над ступенькой высотой b в полученном выражении следует заменить d на $d - b$. Таким образом, ток возрастет в

$$\frac{\mathscr{J}(d-b)}{(d)} = \exp\left\{\frac{4\sqrt{2m}}{3\hbar(A_1 - A_2 - eV)}\left[(A_1 - eV)^{3/2} - A_2^{3/2}\right]b\right\} = e^{2,08} \approx 8 \text{ раз.}$$

3.

38. Ток уменьшится: $\frac{\mathfrak{g}'}{\mathfrak{r}} = e^{-0,82} \approx 0,44$.

3.

39. $\delta_{\mathscr{E}} = 0,27$НА.

3.

40. $D \approx \exp\left(-\frac{4e}{\hbar}\sqrt{2\mu R_2}\right) \approx e^{-234,7} \approx 10^{-102}$, где $\mu = \frac{m_{\text{D}}}{2} = m_{\text{p}}$ - приведенная масса системы из двух дейтронов.

3.

41. $D \approx \exp\left(-\frac{\pi a\sqrt{2m}(U_0-\mathscr{E})}{\hbar\sqrt{U_0}}\right) = \exp\left(-2\pi\frac{U_0-\mathscr{E}}{\hbar\omega}\right)$, где $\mathscr{E}$ - энергия возбуждения ядра, a - координата классической точки поворота.

3.

42. $f = \left|\frac{A_1}{A_2}\right|^2 = \frac{1}{1+(U_0/\mathscr{E})\cos^2 k_1 a}$, где $k_1^2 = \frac{2m}{\hbar^2}(\mathscr{E} + U_0), A_1$ - максимальное значение ψ-функции в области $0 < x \leqslant a; A_2$ - в области $a \leqslant x < b$.

При $U_0 \gg \mathscr{E}$ величина $f \to 0$ при всех $\mathscr{E}$, кроме «резонансных» значений (когда $\cos k_1 a = 0$). При этом $\mathscr{E}_n = \frac{(2n+1)^2\pi^2\hbar^2}{8ma^2} - U_0, n = 0, 1, 2, ...$, а $f = 1$.

3.

43* Решение. Атом гелия участвует во вращательном движении. Момент импульса этого движения квантуется

$$m_{\text{He}}{}^{vr} = n\hbar, \quad n = 1, 2, 3, ...$$

По условию, если v - скорость атомов гелия в вихре, то $vr = K$ - интенсивность вихря. Откуда

$$K = \frac{\hbar}{m_{\text{He}}}n; K_{\min} = \frac{\hbar}{m_{\text{He}}} = 1,6 \cdot 10^{-4} \text{ см}^2/\text{с}$$

3.

44. $v(r) = \frac{n\hbar}{m_{\text{He}}r}$.

3.

45. $L_{\min} = \lambda/4$.

3.

46. $L_{\min} = \lambda/4$.

3.

47. Энергия связи $\mathscr{E} = \frac{\hbar^2\alpha^2}{8ma^2} = 3,8 \cdot 10^{-4}$ В, $U - \mathscr{E} = \frac{\hbar^2\alpha}{4ma^2} = 7,63 \cdot 10^{-3}$ эВ. Глубина потенциальной ямы $U = (U - \mathscr{E}) + \mathscr{E} = \frac{\hbar^2}{4ma^2}\left(\alpha + \frac{\alpha^2}{2}\right) = 8 \cdot 10^{-3}$ В.

3.

48. $\mathscr{E}_{CB} = U_0 - \mathscr{E} = \frac{\hbar^2\alpha^2}{2ma^2} = 123\kappa$ В.

3.

49. $\frac{a}{a'} = \frac{8}{3\sqrt{3}} \approx 1,54$, где a' - ширина «сжатой» ямы.

3.

50. $\frac{U_0}{U_0'} = \frac{9}{2} = 4,5$, где U_0' - измененная высота ямы.

17.3.6 Problems about basic 1D scatterings 3

О3.1-3.47. Свойства электрона в яме

Электрон находится в основном состоянии в одномерной симметричной прямоугольной потенциальной яме **с** шириной $2a = 10$Åс потенциалом $U(\pm\infty) = 0$. Отношение вероятностей обнаружить частицу внутри и вне ямы равно $\alpha = 0,1$. Считая, что изменение волновой функции внутри ямы мало, определить энергию связи электрона и глубину ямы (в эВ).

Solution.

(! решу заново!)
решаем графически равенство:

$$|\cos ka| = \gamma ka$$

подставляем условие задачи:

$$\frac{w_1}{w_2} = \alpha = \frac{2a}{\frac{A^2}{2\kappa}e^{-2\kappa a}}$$

О3.1-3.48

Нейтрон находится в основном состоянии в одномерной прямоугольной потенциальной яме с шириной $a = 1,3{\cdot}10^{-13}$ cm, ограниченной с одной стороны бесконечно высокой стенкой. При этом $U = 0$ при $0 < x < a$, а при $x \geqslant a$ потенциал U равен постоянной конечной величине U_0. Отношение вероятностей обнаружить частицу внутри и вне ямы равно $\alpha = 0,1$. Считая, что максимум волновой функции достигается вблизи границы ямы, определить энергию связи нейтрона.

Solution.

(?? см выше решения, по идее уже метод для этой задачи обсуждался)

3.48. $\mathscr{E}_{\text{СВ}} = U_0 - \mathscr{E} = \frac{\hbar^2\alpha^2}{2ma^2} = 123$ кэВ.

О3.1-3.49. Сжатие ямы

Микрочастица находится в прямоугольной потенциальной яме заданной ширины. Одна стенка бесконечная, а вторая - конечная, высотой U_0. Энергия частицы в яме $\mathscr{E} = 3U_0/4$. Во сколько раз надо квазистатически «сжать» яму при неизменной высоте, чтобы частица стала свободной?

Solution.

Пишем УШ для этого случая, в двух областях:

$$\phi'' + k^2\psi = 0$$
$$\phi'' + \kappa^2\psi = 0,$$

где $k^2 = 2mE/\hbar^2, \kappa^2 = k = 2m(U_0 - E)/\hbar^2$.

Сшивка решений:

$$A\sin ka = Be^{-\kappa a}$$
$$Ak\cos ka = -B\kappa e^{-\kappa a}$$

В итоге:

$$\cot ka = -\frac{\kappa}{k}$$

Распишем

$$\cot^2 ka = -\frac{\kappa^2}{k^2} = \frac{U_0}{E} - 1,$$

отсюда, переходя к синусу по $\cot^2 x + 1 = \sin^{-2} x$, получаем, подставив $E = \hbar^2k^2/2m$

$$|\sin ka| = \sqrt{\frac{\hbar^2k^2}{2mU_0}\cdot\frac{a^2}{a^2}} \equiv \gamma ka,$$

где $\gamma = \sqrt{\frac{\hbar^2}{2mU_0a^2}}$

(?? ничего, что $\gamma = \gamma(a)$???)

(дальше рисуем графически!!)

(вроде уже решал такую задачу, где граф метод, вроде точно для такой же задачи)

Первый уровень появляется при $ka = \pi/2$ (??? имеется в виду, что E это не из условий, а в зависимости от ширины ямы) $U_0 = E$. То есть $\gamma = 22/pi^2$, откуда условие первого уровня:

$$U_0a^2 = \frac{\pi^2\hbar^2}{8m},$$

В нашей задаче при данных энергиях, находим из контангенса

$$ka = \frac{2\pi}{3},$$

подставим $a = a(U_0)$, получим

$$U_0a^2 = \frac{8\pi^2\hbar^2}{27m}$$

(??? это было до сжатия??)

(теперь пишем после сжатия)

В итоге

$$\frac{a}{a_{\text{конечн}}} = \frac{8}{3\sqrt{3}}$$

(паререшаю потом сам!!!.)

Ответ: 3.49. $\frac{a}{a'} = \frac{8}{3\sqrt{3}} \approx 1,54$, где a' - ширина «сжатой» ямы.

О3.1-3.50

Микрочастица находится в одномерной потенциальной яме заданной ширины. Одна ее стенка бесконечно высокая, а вторая конечной высоты U_0. Энергия частицы в яме $\mathscr{E} = U_0/2$. Во сколько раз надо квазистатически изменить высоту ямы при неизменной ширине, чтобы частица стала свободной?

Solution.

(?? см выше решения, по идее уже метод для этой задачи обсуждался)

3.50. $\frac{U_0}{U_0'} = \frac{9}{2} = 4,5$, где U_0' - измененная высота ямы.

О3.1-3.51

Электрон находится в одномерной прямоугольной потенциальной яме с шириной $a = 4$ Å$(U(0) = \infty, U(a) = U_0 = 1$ эВ) в состоянии с энергией $\mathscr{E} = 0,88$ эВ. На яму накладывается постоянное электрическое поле $E = 3 \cdot 10^5$ В/см, направленное в отрицательную сторону оси x. Оценить возникающую при этом ширину уровня энергии. Считать, что энергия уровня не меняется при наложении поля.

3.

51. $\Gamma \simeq \frac{\hbar D}{2a}\sqrt{\frac{2\varepsilon}{m}} = 3,6 \cdot 10^{-5}$эВ, где проницаемость возникающего барьера треугольной формы (рис. 153).

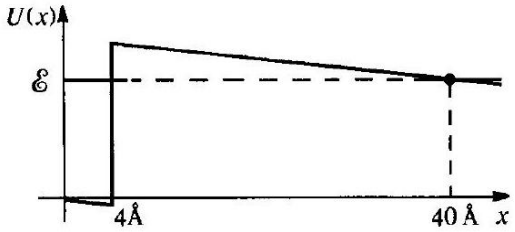

Рис. 153

$D \simeq \exp\left[-\frac{4}{3}\frac{\sqrt{2m(U_0-\mathscr{E})}}{\hbar eE}(U_0-\mathscr{E})\right] \simeq \simeq 7,8 \cdot 10^{-5}$.

Параметры задачи подобраны так, что в яме есть только один уровень: $\sin ka = \sqrt{\frac{\hbar^2}{2mU_0a^2}}ka = 0,488ka$, откуда $ka = 1,92$. Величина $eEa = 0,012$ эВ $\ll U_0 - \delta = 0,12$ эВ.

О3.1-3.52

Электрон находится в одномерной симметричной прямоугольной потенциальной яме с шириной $2a =$ 4 Å$(U(-a) = U(a) = U_0 = 1$ эВ) в состоянии, энергия которого $\mathscr{E} = 0,8$ эВ. На яму накладывается постоянное электрическое поле $E = 3 \cdot 10^5$ В/см, направленное в отрицательную сторону оси x. Оценить время, через которое электрон покинет яму. Считать, что энергия уровня не меняется при наложении поля.

3.

52. $\tau \simeq \frac{4a}{vD} = \frac{4a}{D}\sqrt{\frac{m}{2\S}} \simeq 10^{-6}$ с, где проницаемость возникающего барьера треугольной формы $D \simeq \exp\left[-\frac{4}{3}\frac{\sqrt{2m(U_0-\mathscr{E})}}{\hbar eE}(U_0-\mathscr{E})\right] \simeq 1,45 \cdot 10^{-9}$.

Параметры задачи подобраны так, что в яме есть только один четный уровень: $\cos ka = \sqrt{\frac{\hbar^2}{2mU_0a^2}}ka = 1,94ka$, откуда $ka = 0,46$.

17.3.7 Problems about scattering in Born approximation 1

В этом разделе задачи, которые важно прорешать для понимания рассеяния.

Б-2.12.2 Рассеяние в рамках правила Ферми

С помощью «золотого правила Ферми» получить формулу для дифференциального сечения рассеяния в борновском приближении.

Solution.

(по теории, пропишу скоро)

Б-2.12.3 Формулы для δ_l в борновском приближении (!!!)

Определить фазы рассеяния δ_l в борновском приближении.

Solution.

(по теории, пропишу скоро)

Б-2.12.4 Рассеяние в $1/r^2$

Для модельного потенциала отталкивания

$$V(r) = \frac{\beta}{r^2}, \quad \beta > 0$$

найти фазы рассеяния δ_l. В предельном случае $2m\beta/\hbar^2 \ll 1$ найти приближенное выражение для фаз $\delta_l \ll 1$, и, выполнив суммирование ряда разложения амплитуды рассеяния по парциальным волнам, получить замкнутое выражение для амплитуды $f(\theta)$. Сравнить полученное выражение с борновским приближением.

Solution.

Б-2.12.5 Свойство рассеяния медленных частиц

Показать, что при рассеянии медленных частиц на потенциале с малым радиусом действия a наиболее существенную роль играет рассеяние s-волн ($l = 0$).

Solution.

(по теории, пропишу скоро)

Б-2.12.6 Аппроксимация δ-потенциалом

Показать, что при рассеянии медленной частицы массы m, рассеивающий потенциал может быть заменен контактным псевдопотенциалом

$$V_{\text{eff}} = -\frac{2\pi\hbar^2}{m} a\delta(\mathbf{r}),$$

где a - длина рассеяния (радиус действия потенциала). Данное выражение часто используется для описания рассеяния медленных нейтронов ядрами.

Solution.

GKKG.13.1.a Basic model for Born approximation

Using the Born approximation, find the scattering amplitude and the total scattering cross-section of a particle on the following potentials:

a) $U(r) = \frac{\alpha}{r} e^{-r/R}$

Consider the limiting cases of slow and fast particles. Find the conditions under which the approximations in these limiting cases are valid.

a)

So, we need to just use:

$$f_{3D}^{B}(q) = -\frac{2m}{\hbar^2 q}\int\limits_0^\infty U(r)\sin(qr)rdr \tag{XIII.8}$$

$$\sigma(E) = \int |f|^2 d\Omega = 2\pi\int\limits_0^\pi |f|^2\sin\theta d\theta = \frac{\pi\hbar^2}{2mE}\int\limits_0^{8mE/\hbar^2} f^2(q)dq^2, \tag{1}$$

$q := 2k\sin(\theta/2)$.

$f = -\frac{2m\alpha R^2}{\hbar^2(1+q^2R^2)}$, $\quad \sigma(E) = 16\pi\left(\frac{m\alpha R^2}{\hbar^2}\right)^2\frac{1}{1+4k^2R^2}$.

The first integral here is taken by evaluating integral with $\sin(qr) \to e^{iqr}$ and then by taking imaginary part. The second integral is easy, just one needs to substitute $k = \sqrt{1me/\hbar}$ in the end.

For R finite, the scattering cross-section also has a finite magnitude. However, as $R \to \infty$, the short-range Yukawa potential considered here changes to a long-range Coulomb potential $U = \alpha/r$. For the latter, the differential cross-section is described by the Rutherford formula, $d\sigma/d\Omega = 4m^2\alpha^2/\hbar^4q^4$, and the total scattering cross-section is infinite.

GKKG.13.b Basic model for Born approximation

Using the Born approximation, find the scattering amplitude and the total scattering cross-section of a particle on the following potentials:

b) $U(r) = \alpha\delta(r - R)$;

b)

So, we need to just use:

$$f_{3D}^{B}(q) = -\frac{2m}{\hbar^2 q}\int\limits_0^\infty U(r)\sin(qr)rdr \tag{XIII.8}$$

$$\sigma(E) = \int |f|^2 d\Omega = 2\pi\int\limits_0^\pi |f|^2\sin\theta d\theta = \frac{\pi\hbar^2}{2mE}\int\limits_0^{8mE/\hbar^2} f^2(q)dq^2, \tag{1}$$

$q := 2k\sin(\theta/2)$.

$f = -\frac{2m\alpha R^2}{\hbar^2}\frac{\sin qR}{qR}$, $\qquad \sigma(E) = \frac{4\pi m\alpha^2R^2}{\hbar^2E}\int\limits_0^{\sqrt{8mER^2/\hbar^2}}\frac{\sin^2 x}{x}dx$.

It is obvious how to obtain both integrals.

In the limiting cases, we have

$$\sigma(E)E \underset{\approx}{\to} 0\frac{16\pi\left(m\alpha R^2\right)^2}{\hbar^4}, \quad \sigma(E)E \underset{\approx}{\to} \infty\frac{\pi m\alpha^2R^2}{\hbar^2E}\ln\frac{8mER^2}{\hbar^2}$$

In the $E \to \infty$ limit, the integral in (3) diverges; to calculate this diverging integral we replace the oscillating factor $\sin^2 x$ by its mean value, 1/2.

GKKG.13.1.c Basic model for Born approximation

Using the Born approximation, find the scattering amplitude and the total scattering cross-section of a particle on the following potentials:

c) $U(r) = U_0e^{-r/R}$

Consider the limiting cases of slow and fast particles. Find the conditions under which the approximations in these limiting cases are valid.

c)

So, we need to just use:

$$f_{3D}^{B}(q) = -\frac{2m}{\hbar^2 q}\int\limits_0^\infty U(r)\sin(qr)rdr \tag{XIII.8}$$

$$\sigma(E) = \int |f|^2 d\Omega = 2\pi\int\limits_0^\pi |f|^2 \sin\theta d\theta = \frac{\pi\hbar^2}{2mE}\int\limits_0^{8mE/\hbar^2} f^2(q)dq^2, \tag{1}$$

$q := 2k\sin(\theta/2)$.

$f = -\frac{4mU_0R^3}{\hbar^2(1+q^2R^2)^2}$; $\sigma(E) = \frac{8\pi mR^4U_0^2}{3\hbar^3E}\left[1 - \frac{1}{(1+8mER^2/\hbar^2)^3}\right]$

The first integral is taken by $\sin(qr) \to e^{iqr}$, integration by parts and then by taking imaginary part.

GKKG.13.1.d Basic model for Born approximation

Using the Born approximation, find the scattering amplitude and the total scattering cross-section of a particle on the following potentials:

d) $U(r) = \frac{\alpha}{r^2}$

Consider the limiting cases of slow and fast particles. Find the conditions under which the approximations in these limiting cases are valid.

d)

So, we need to just use:

$$f_{3D}^{B}(q) = -\frac{2m}{\hbar^2 q}\int\limits_0^\infty U(r)\sin(qr)rdr \tag{XIII.8}$$

$$\sigma(E) = \int |f|^2 d\Omega = 2\pi\int\limits_0^\pi |f|^2 \sin\theta d\theta = \frac{\pi\hbar^2}{2mE}\int\limits_0^{8mE/\hbar^2} f^2(q)dq^2, \tag{1}$$

$q := 2k\sin(\theta/2)$.

$f = -\frac{\pi m\alpha}{\hbar^2 q} = -\frac{\pi m\alpha}{2\hbar^2 k\sin(\theta/2)}$.

The integral is just an "integral sine".

The total scattering cross-section is infinite, which is related to a slow decrease of the potential at large distances. For more on scattering from the potential $U = \alpha/r^2$, see Problem 13.19.

GKKG.13.1.e Basic model for Born approximation

Using the Born approximation, find the scattering amplitude and the total scattering cross-section of a particle on the following potentials:

e) $U(r) = \begin{cases} U_0, r < R \\ 0, \quad r > R \end{cases}$

Consider the limiting cases of slow and fast particles. Find the conditions under which the approximations in these limiting cases are valid.

e)

So, we need to just use:

$$f_{3D}^{B}(q) = -\frac{2m}{\hbar^2 q}\int\limits_0^\infty U(r)\sin(qr)rdr \tag{XIII.8}$$

$$\sigma(E) = \int |f|^2 d\Omega = 2\pi\int\limits_0^\pi |f|^2 \sin\theta d\theta = \frac{\pi\hbar^2}{2mE}\int\limits_0^{8mE/\hbar^2} f^2(q)dq^2, \tag{1}$$

$q := 2k\sin(\theta/2)$.

$f = \frac{2mU_0R}{\hbar^2q^2}\left(\cos qR - \frac{\sin qR}{qR}\right)$; $\quad \sigma(E) = \frac{2\pi}{k^2}\left(\frac{mU_0R^2}{\hbar^2}\right)^2\left[1 - \frac{1}{(2kR)^2} + \frac{\sin 4kR}{(2kR)^3} - \frac{\sin^2 2kR}{(2kR)^4}\right]$.

The first integral is evaluated by parts, the second is obvious.

In the limiting cases we have

$$\sigma(E)E \underset{\approx}{\to} 0\frac{16\pi m^2U_0^2R^6}{9\hbar^4}, \quad \sigma(E)E \underset{\approx}{\to} \infty\frac{\pi mU_0^2R^4}{\hbar^2E}$$

The limit $E \to \infty$ is also discussed in Problem 13.2.

GKKG.13.1.f Basic model for Born approximation

Using the Born approximation, find the scattering amplitude and the total scattering cross-section of a particle on the following potentials:

f) $U(r) = U_0e^{-r^2/R^2}$

Consider the limiting cases of slow and fast particles. Find the conditions under which the approximations in these limiting cases are valid.

f)

So, we need to just use:

$$f^B_{3D}(q) = -\frac{2m}{\hbar^2q}\int\limits_0^\infty U(r)\sin(qr)rdr \tag{XIII.8}$$

$$\sigma(E) = \int |f|^2d\Omega = 2\pi\int\limits_0^\pi |f|^2\sin\theta d\theta = \frac{\pi\hbar^2}{2mE}\int\limits_0^{8mE/\hbar^2} f^2(q)dq^2, \tag{1}$$

$q := 2k\sin(\theta/2)$.

$f = -\frac{\sqrt{\pi}mU_0R^3}{2\hbar^2}e^{-q^2R^2/4}$ $\quad \sigma(E) = \frac{\pi^2mU_0^2R^4}{4\hbar^2E}\left(1 - e^{-4mER^2/\hbar^2}\right)$

The first integral is evaluated as follows:

$$V_{\boldsymbol{q}} = V_0\int d\boldsymbol{r}e^{-r^2/a^2 + i\boldsymbol{qr}} = V_0\int d\boldsymbol{r}e^{-\frac{1}{a^2}\left(\boldsymbol{r} - i\boldsymbol{q}a^2/2\right)^2 - q^2a^2/4} = \pi^{3/2}V_0a^3e^{-q^2a^2/4}$$

(by $\int\limits_0^\infty x^2\mathrm{e}^{-\gamma x^2}dx = \frac{1}{4\gamma}\sqrt{\frac{\pi}{\gamma}}$), here $q^2 = 4k^2\sin^2\frac{\theta}{2} = 2k^2(1 - \cos\theta)$;

$$f(\theta) = -\frac{\sqrt{\pi}}{2}V_0ma^3e^{-q^2a^2/4} = -\frac{\sqrt{\pi}}{2}V_0ma^3e^{-k^2a^2(1-\cos\theta)/2}$$

(??? я не понял пока, если мы возьмем $\sin(qr) \to e^{iqr}$ тогда у нас интеграл станет точно каким и был выше, дальше что делать? если так его сразу посчитать, то он вещественный и обратно если взять мнимую часть, получим нуль. Видимо, правильно еще сместить начало отсчета по r, тогда после этой замены от r^2 под интегралом появятся 3 интеграла, по идее они дадут такой же результат, но я не уверен в этом методе. Пока что решение очень компактно, потому что в векторных обозначениях абсолютно очевидно, что можно просто сдвинуть начало координет и избавиться от мнимой части. Другим способом - не понимаю пока, но и не важно, один способ ведь работает.)

Now, the second integral is obtained by:

$\sin\theta d\theta = d(1 - \cos\theta) = \frac{d\left(q^2\right)}{2k^2}$,

$$\sigma = \frac{\pi^2}{4}\frac{m^2a^6V_0^2}{k^2}\int\limits_0^{4k^2} d\left(q^2\right)e^{-q^2a^2/4} = \frac{\pi^2m^2a^4V_0^2}{k^2}\left(1 - e^{-k^2a^2}\right)$$

(??? тоже пока не додумал, у Галицкого 4 в знаменателе есть, по решению ПТФ - нет. где-то в одном из решений ошибка, скорее всего у ПТФ, нужно будет - найду.)

$\sigma_{\text{slow}} \approx \left(\frac{\pi V_0}{1/ma^2}\right)^2a^2 \ll a^2$; $\quad \sigma_{\text{fast}} \approx \left(\frac{\pi V_0}{1/ma^2}\right)^2\frac{1}{k^2} \ll \sigma_{\text{slow}}$ (тут опущена $\hbar$).

Due to the exponential decrease of $f(q)$, the Born approximation is not applicable for large values of q^2 (see Problem 13.13). Therefore, the inclusion of the exponentially small term in the equation for $\sigma(E)$ for $E \to \infty$ is beyond the accuracy of the approximation used.

ПТФ-13.y1.a Basic model for Born approximation

В рамках Борновского приближения, рассмотрите рассеяние на следующих потенциалах:
• $V(\mathbf{r}) = V_0 \frac{a^n}{r^n + a^n}$, $n > 3$, случай медленных частиц $ka \ll 1$. Рассмотрите также предел $n \to \infty$, когда потенциал превращается в сферическую прямоугольную яму.

Решнеие для $V(\mathbf{r}) = V_0 \frac{a^n}{r^n + a^n}$.

$$f(\theta) = -\frac{2ma^n V_0}{2k\hbar^2 \sin\frac{\theta}{2}} \int\limits_0^\infty dr \frac{r \sin\left(2kr \sin\frac{\theta}{2}\right)}{r^n + a^n} \approx -\frac{2ma^n V_0}{2k\hbar^2 \sin\frac{\theta}{2}} \int\limits_0^\infty dr \frac{2kr^2 \sin\frac{\theta}{2}}{r^n + a^n} = -\frac{2\pi m a^3 V_0}{\hbar^2 n \sin\frac{3\pi}{n}}$$

$$\sigma = 2\pi \int\limits_0^\pi |f(\theta)|^2 \sin\theta d\theta = \frac{16\pi^3 m^2 a^6 V_0^2}{\hbar^4 n^2 \sin^2\frac{3\pi}{n}}$$

При $n \to \infty$ (сферическая прямоугольная яма):

$$f(\theta) = -\frac{2ma^3 V_0}{3\hbar^2} \qquad \Rightarrow \qquad \sigma = \frac{16\pi m^2 a^6 V_0^2}{9\hbar^4}$$

ПТФ-13.y1.b Basic model for Born approximation

В рамках Борновского приближения, рассмотрите рассеяние на следующих потенциалах:
• $V(\mathbf{r}) = \frac{\alpha}{r} e^{-\kappa r}$ (потенциал Юкавы). Рассмотрите также предельный переход $\kappa \to 0$ (закон Кулона).

Решнеие для потенциала Юкавы: $V(\mathbf{r}) = \frac{\alpha}{r} e^{-\kappa r}$.

$$f(\theta) = -\frac{2m\alpha}{2k\hbar^2 \sin\frac{\theta}{2}} \int\limits_0^\infty dr \sin\left(2kr \sin\frac{\theta}{2}\right) e^{-\kappa r} = -\frac{2m\alpha}{\hbar^2 (4k^2 \sin^2\frac{\theta}{2} + \kappa^2)}$$

because $\int\limits_0^\infty e^{-\lambda r} \sin(qr) dr = \frac{1}{2i}\left[\int\limits_0^\infty e^{-(\lambda - iq)r} dr - \int\limits_0^\infty e^{-(\lambda + iq)r} dr\right]$

$$\sigma = 2\pi \int\limits_0^\pi |f(\theta)|^2 \sin\theta d\theta = \frac{8\pi m^2 \alpha^2}{\hbar^4} \int\limits_0^\pi \frac{\sin\theta d\theta}{(4k^2 \sin^2\frac{\theta}{2} + \kappa^2)^2} = \frac{16\pi m^2 \alpha^2}{\hbar^4 \kappa^2 (4k^2 + \kappa^2)}$$

(??? тоже нужно пересчитать интеграл!)
Кулоновский потенциал: $\kappa \to 0$:

$$f(\theta) = -\frac{m\alpha}{2\hbar^2 k^2 \sin^2\frac{\theta}{2}} \qquad \Rightarrow \qquad \sigma = \frac{\pi m^2 \alpha^2}{2\hbar^4 k^4} \int\limits_0^\pi \frac{\sin\theta d\theta}{\sin^4\frac{\theta}{2}} \to \infty$$

physicspages.com 1D delta function in Born approximation

The delta function well.

$$V = -\alpha\delta(x)$$

Reminder: one-dimensional Born approximation is

$$R = \left(\frac{m}{\hbar^2 k}\right)^2 \left| \int\limits_{-\infty}^\infty e^{2ikx} V(x) dx \right|^2$$

$$k = \frac{\sqrt{2mE}}{\hbar}$$

Solution

$$\begin{aligned} R &= \left(\frac{m}{\hbar^2 k}\right)^2 \left|-\alpha e^{2ik\times 0}\right|^2 \\ &= \frac{m\alpha^2}{2\hbar^2 E} \\ T &= 1 - R = 1 - \frac{m\alpha^2}{2\hbar^2 E} \end{aligned}$$

The exact values are

$$\begin{aligned} R &= \frac{1}{1 + 2\hbar^2 E/m\alpha^2} \\ T &= \frac{1}{1 + m\alpha^2/2\hbar^2 E} \end{aligned}$$

For a weak potential, α is small, so $2\hbar^2 E/m\alpha^2 \gg 1$ so we can approximate the exact formulas by

$$\begin{aligned} R &\approx \frac{1}{2\hbar^2 E/m\alpha^2} = \frac{m\alpha^2}{2\hbar^2 E} \\ T &\approx 1 - \frac{m\alpha^2}{2\hbar^2 E} \end{aligned}$$

in agreement with the Born approximation.

physicspages.com 1D well in Born approximation

Here

$$V = \begin{cases} -V_0 & -a < x < a \\ 0 & \text{otherwise} \end{cases}$$

Reminder: one-dimensional Born approximation is

$$\begin{aligned} R &= \left(\frac{m}{\hbar^2 k}\right)^2 \left| \int_{-\infty}^{\infty} e^{2ikx} V(x) dx \right|^2 \\ k &= \frac{\sqrt{2mE}}{\hbar} \end{aligned}$$

Solution

$$\int_{-\infty}^{\infty} e^{2ikx} V(x) dx = -V_0 \int_{-a}^{a} e^{2ikx} dx = -V_0 \frac{e^{2ika} - e^{-2ika}}{2ik} = -\frac{V_0}{k} \sin(2ka)$$

$$\begin{aligned} R &= \left(\frac{m}{\hbar^2 k}\right)^2 \left| -\frac{V_0}{k} \sin(2ka) \right|^2 = \frac{V_0^2}{4E^2} \sin^2\left(\frac{2a\sqrt{2mE}}{\hbar}\right) \\ T &= 1 - \frac{V_0^2}{4E^2} \sin^2\left(\frac{2a\sqrt{2mE}}{\hbar}\right) \end{aligned}$$

The exact formula is

$$T^{-1} = 1 + \frac{V_0^2}{4E\,(E + V_0)} \sin^2\left(\frac{2a}{\hbar}\sqrt{2m\,(E + V_0)}\right)$$

For a weak potential (or, equivalently, a high incident energy), $E \gg V_0$ and we get

$$\begin{aligned} T^{-1} &\approx 1 + \frac{V_0^2}{4E^2} \sin^2\left(\frac{2a\sqrt{2mE}}{\hbar}\right) \\ T &\approx 1 - \frac{V_0^2}{4E^2} \sin^2\left(\frac{2a\sqrt{2mE}}{\hbar}\right) \end{aligned}$$

so again, the Born approximation gives a good result.

GKKG.13.2 Cross-sections in the Born approximation

Prove that the total scattering cross-section (in the Born approximation) of a high energy particle in a potential, $U(r)$ with $kR \gg 1$ is described by the expression

$$\sigma(E)|_{E\to\infty} \approx \frac{m}{2\hbar^2 E} \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} \left[\int_{-\infty}^{\infty} U(\rho, z)dz\right]^2 d^2\rho \tag{1}$$

The momentum of the particle before scattering is along the z-axis; $\boldsymbol{\rho}$ is a twodimensional radius-vector lying in the plane perpendicular to the z-axis.

Apply this result to the potential $U(r) = U_0 \exp\left\{-r^2/R^2\right\}$ and to a rectangular potential well (barrier) of strength, U_0, and radius, R. Compare to Problem 13.1.

Prove also that, in this case, the transport scattering cross-section has an asymptotic behavior given by

$$\sigma_{tr} = \int (1-\cos\theta)d\sigma\Big|_{E\to\infty} \approx \frac{1}{8E^2}\iint \left[\int_{-\infty}^{\infty} \frac{\rho}{r}\frac{\partial U(r)}{\partial r}dz\right]^2 d^2\rho \tag{2}$$

State conditions of applicability for these results.

Solution

From Eq. (XIII.6), the scattering amplitude is related to the Fourier transform of the potential, $\tilde{U}(\mathbf{q})$, with

$$f_B(\mathbf{q}) = -\frac{m}{2\pi\hbar^2}\tilde{U}(\mathbf{q}), \quad \tilde{U}(\mathbf{q}) = \int e^{-i\mathbf{q}\cdot\mathbf{r}}U(r)dV$$

From this, it follows that $f_B(q)$ is essentially different from zero only if $qR \lesssim 1$ (where R is the range of the potential); for $qR \gg 1$, this the integral is small due to the fast oscillating integrand. Since $q^2 = 2k^2(1-\cos\theta)$, the two conditions, $kR \gg 1$ and $qR \leq 1$, lead to the known conclusions that the scattering of fast particles occurs primarily into small angles, $\theta \sim 1/kR \ll 1$. From this, it follows that $q \approx k\theta \sim R^{-1}$.

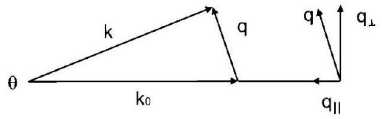

Fig. 13.1

For what follows, we decompose $\mathbf{q}$ into two perpendicular components, $\mathbf{q} = \mathbf{q}_{\|} + \mathbf{q}_{\perp}$, where $\mathbf{q}_{\|}$is directed along the incident momentum, $\hbar\mathbf{k}_0$ (see Fig. 13.1). For $\theta \ll 1$, we have

$$q_{\|} = k(1-\cos\theta) \approx \frac{1}{2}k\theta^2, \quad q_{\perp} = k\sin\theta \approx k\theta$$

so that $q_{\perp} \gg q_{\|}$. It is safe to consider $\mathbf{q} \approx \mathbf{q}_{\perp}$, so that

$$\tilde{U}(\mathbf{q}) \approx \tilde{U}\left(\mathbf{q}_{\perp}\right) = \iiint e^{-i\mathbf{q}_{\perp}\cdot\boldsymbol{\rho}}U(\boldsymbol{\rho}, z)dzd^2\rho \tag{3}$$

To find the scattering cross-section we will carry out the q-integration only in a small region of the 4π-sphere around the z-axis. This region can be considered as approximately flat, so that $k^2 d\Omega \approx dS = dq_{\perp x}dq_{\perp y} = d^2q_{\perp}$. Therefore,

$$\sigma(E) = \int |f_B|^2 d\Omega \approx \frac{m^2}{4\pi^2\hbar^4k^2}\iint \left|\tilde{U}\left(\mathbf{q}_{\perp}\right)\right|^2 d^2q_{\perp}$$

Using expression (3), we have

$$\sigma(E) = \frac{m}{8\pi^2\hbar^2E}\iint \left[\iiint e^{-i\mathbf{q}_{\perp}\cdot\boldsymbol{\rho}}U(\boldsymbol{\rho}, z)dzd^2\rho\right]\left[\iiint e^{i\mathbf{q}_{\perp}\cdot\boldsymbol{\rho}'}U\left(\boldsymbol{\rho}', z'\right)dz'd^2\rho'\right]d^2q_{\perp}$$

After performing the $\mathbf{q}_{\perp}$-integration using

$$\iint \exp\left\{-i\mathbf{q}_{\perp}\cdot\left(\boldsymbol{\rho}-\boldsymbol{\rho}'\right)\right\}d^2q_{\perp} = (2\pi)^2\delta\left(\boldsymbol{\rho}-\boldsymbol{\rho}'\right) \tag{4}$$

and the resulting δ-function integration over ρ', we are immediately led to the following asymptote of the scattering cross-section:

$$\sigma(E)_{E\to\infty} = \frac{m}{2\hbar^2 E}\iint\left[\int\limits_{-\infty}^{\infty} U(\boldsymbol{\rho}, z)dz\right]^2 d^2\rho$$

For the potential $U(r) = U_0 \exp\left\{-r^2/R^2\right\}$ and the rectangular well (barrier), using this expression, we obtain

$$\sigma(E) = \frac{\pi^2 m U_0^2 R^4}{4\hbar^2 E} \quad \text{and} \quad \sigma(E) = \frac{\pi m U_0^2 R^4}{\hbar^2 E}$$

respectively (see Problem 13.1 e, f, they are the same).

2) Finding energy-dependence of the transport cross section for $E \to \infty$

$$\sigma_{tr}(E) = \int(1-\cos\theta)d\sigma\Big|_{E\to\infty} \approx \frac{m}{8\pi^2\hbar^4 k^4}\iint q_\perp^2\left|\tilde{U}\left(q_\perp\right)\right|^2 d^2 q_\perp \tag{5}$$

Now, instead of Eq. (4), we use the integral

$$\iint q^2 e^{-iq\cdot\rho}d^2q = -(2\pi)^2\Delta_\perp\delta(\boldsymbol{\rho})$$

Following some transformations in Eq. (5) for the case of a spherically-symmetric potential, we obtain the desired asymptotic form:

$$\sigma_{tr}(E)|_{E\to\infty} \approx \frac{1}{8E^2}\iint\left[\int\limits_{-\infty}^{\infty}\frac{\rho}{r}\frac{\partial U}{\partial r}dz\right]^2 d^2\rho$$

Note that this expression does not contain Planck's constant, and coincides with σ_{tr} for fast particles ($E \gg U$) in classical mechanics, defined as

$$\sigma_{tr,\ \text{class}}\ (E) = \int\limits_0^\infty[1-\cos\theta(\rho)]\cdot 2\pi\rho d\rho \approx \pi\int\limits_0^\infty\theta^2(\rho)\rho d\rho$$

We have used an equation for small-angle scattering from classical mechanics.
The agreement of the result of Born approximation with the classical result at first sight might appear strange. However, it becomes less surprising if we recall that the same result follows from the quasi-classical eikonal approximation (XIII.18) too; Compare to the Rutherford equation.

In conclusion, we note that expression in Eq. (2) assumes that the differential scattering cross-section at large momenta falls faster than $\propto q^{-2}$, so that the upper limit of the q^2-integration could be set to infinity.

GKKG.13.3 Scattering of exchange potential

Using Born approximation, obtain an expression for the scattering amplitude of a particle in an exchange potential; that is, $\hat{U}_{exc}\psi(\mathbf{r}) \equiv U(r)\psi(-\mathbf{r})$.

Find how the scattering amplitude in this case is related to the scattering amplitude of the particle in a regular garden-variety potential, $U(r)$. Obtain the angular distribution of fast particles.

Solution

Substituting $U\psi^+_{\mathbf{k}_0}$ in Eqs. (XIII.4, 5) by $\hat{U}_{ex}\psi^+_{\mathbf{k}_0}, \psi^+_{\mathbf{k}_0}(\mathbf{r})$ by $e^{i\mathbf{k}_0\cdot\mathbf{r}}$, and taking into account the exchange nature of $\hat{U}_{ex}$, we find

$$f^B_{ex}\left(\mathbf{k}_0, \mathbf{k}\right) = f^B_{ex}(\boldsymbol{\Delta}) = -\frac{m}{2\pi\hbar^2}\int e^{-i\boldsymbol{\Delta}\cdot\mathbf{r}}U(r)dV \tag{1}$$

where $\boldsymbol{\Delta} = \mathbf{k} + \mathbf{k}_0$ and $\Delta^2 = 2k^2(1+\cos\theta)$. Thus,

$$f^B_{ex}(E,\theta) = f^B(E, \pi-\theta)$$

where $f^B(E,\theta)$ is the amplitude of scattering in a regular spherically-symmetric potential, $U(r)$. From this relation, it is clear that for fast particles ($kR \gg 1$), the scattering from the exchange potential occurs primarily "backwards," with the relevant angles, $\pi - \theta \lesssim (kR)^{-1}$. For more on scattering from an exchange potential, see Problem 13.56.

GKKG.13.4;Б-2.12.13 Scattering of electrons and a hydrogen atom

Find the differential and total cross-section of elastic scattering of fast electrons by a hydrogen atom in its ground state. Neglect a polarization of the atom. See also Problem 13.77.

Solution

The scattering potential is of the form:

$$U(r) = -e^2\left(\frac{1}{r} + \frac{1}{a_B}\right)e^{-2r/a_B}$$

(see Problem 4.6). According to Eq. (XIII.8),

```
Integrate[(1/r+1/a) Exp[-2r/a] r Sin[q r],{r,0,Infinity},
Assumptions->{q>0,a>0,Im[a q]==0}]
```

$$f^B(q) = \frac{2\left(8 + q^2a_B^2\right)}{\left(4 + q^2a_B^2\right)^2}a_B \tag{1}$$

The total scattering cross-section $\left(d\Omega = \pi k^{-2}dq^2\right)$:

$$\sigma = \frac{\pi}{k^2}\int\limits_0^{4k^2}\left(f^B\right)^2 dq^2 = \frac{4\pi}{k^2}\left[\frac{7}{12} - \frac{7 + 9k^2a_B^2 + 3k^4a_B^4}{12\left(1 + k^2a_B^2\right)^3}\right] \approx \frac{7\pi a_B^2}{3\left(ka_B\right)^2} \tag{2}$$

Here, we have taken into account the condition of applicability of the Born approximation (XIII.7), viz. $ka_B \gg 1$. (See also Problems 13.77 and 13.78)

Solution. Белоусова

Для описания упругого рассеяния быстрых электронов на атоме (не обязательно на атоме водорода) можно использовать борновское приближение, если скорость налетающего электрона велика по сравнению со скоростями атомных электронов. Поскольку масса атома гораздо больше, чем масса электрона, можно считать, что атом является неподвижным в течение всего процесса рассеяния. Тогда в формуле борновского приближения

$$f(\theta) = -\frac{m}{2\pi\hbar^2}\int e^{-i\mathbf{qr}}V(r)d^3x, \quad \mathbf{q} = \mathbf{k}' - \mathbf{k},$$

как и обычно, $\hbar\mathbf{k}$ и $\hbar\mathbf{k}'$ - импульсы электрона до и после рассеяния, m - масса электрона.

С точки зрения воздействия на электрон, атом представляет собой систему зарядов. Это распределение зарядов создает электрический потенциал, на котором и рассеивается заряженная частица. Потенциал атома создается зарядом ядра и зарядом электронов, распределенным по объему атома, т. е.

$$V(r) = -\frac{Ze^2}{r} + e^2\int\frac{\rho\left(r'\right)}{|\mathbf{r} - \mathbf{r}'|}d^3x',$$

где $-e\rho(r)$ - плотность заряда электронов в атоме. Подставляя $V(r)$ в выражение (1) и учитывая значения интегралов

$$\int\frac{1}{r}e^{-i\mathbf{qr}}d^3x = \frac{4\pi}{q^2}, \int\frac{e^{-iq\boldsymbol{q}}}{|\mathbf{r} - \mathbf{r}'|}d^3x = \frac{4\pi}{q^2}e^{-i\mathbf{q}r'},$$

получаем

$$f(\theta) = \frac{2me^2}{\hbar^2q^2}[Z - F(q)], \quad \text{где} \quad F(q) = \int\rho(r)e^{-iqr}d^3x.$$

Выражение (2) определяет так называемый атомный формфактор. Он зависит от распределения плотности электронов в атоме и от величины q - передаваемого при рассеянии импульса. Если плотность электронов обладает центральной симметрией, то формулу (2) можно упростить:

$$F(q) = \frac{4\pi}{q}\int\limits_0^\infty \sin qr\rho(r)rdr.$$

Для атома водорода ($Z = 1$), находящегося в основном состоянии, электронная плотность $\rho(r)$ определяется очевидным образом:

$$\rho(r) = |\psi_{100}(r)|^2 = \frac{1}{\pi a^2} e^{-2r/a},$$

фактор

$$F(q) = \left[1 + \frac{(qa)^2}{4}\right]^{-2}.$$

Определяем далее дифференциальное сечение рассеяния

$$d\sigma = 4a^2 \frac{\left((qa)^2 + 8\right)^2}{\left((qa)^2 + 4\right)^4} d\Omega.$$

Для вычисления полного сечения заметим, что $d\Omega = 2\pi \sin\theta d\theta = \left(2\pi/k^2\right) qdq$, поскольку $q = 2k \sin\theta/2$. В итоге имеем

$$\sigma = \frac{\pi a^2}{3} \frac{7(ka)^4 + 72(ka)^2 + 192}{\left((ka)^2 + 4\right)^3}\bigg|_{ka \gg 1} \simeq \frac{7\pi}{3k^2}.$$

Критерий применимости борновского приближения (если положить $V_0 \sim e^2/a$) дает условие $ka \gg 1$, поэтому данное приближение применимо лишь для достаточно больших энергий налетающих электронов.

GKKG.13.5 Scattering of electrons and a helium

Find the differential and total cross-section of elastic scattering of fast electrons by a helium atom in its ground state. Neglect a polarization of the atom. Choose the atomic wavefunction using the variational calculation performed in Problem 11.6.

Solution

In the approximation considered in Problem 11.6, we found that the mean electronic density in the ground state of a helium atom is $n = \frac{2}{\pi a^3} e^{-2r/a}$, where $a = a_B/Z_{\text{eff}} = 16a_B/27$. From this, we calculate the form-factor:

$$F(\mathbf{q}) = \int n(\mathbf{r}) e^{-i\mathbf{q}\cdot\mathbf{r}} dV = \frac{2}{\pi a^3} \int e^{-2r/a - i\mathbf{q}\cdot\mathbf{r}} dV = \frac{32}{\left(4 + q^2a^2\right)^2}$$

Here first we evaluate $\int ..d\theta$ and from exponent sine pops up. Later we can integrate by parts of just use:

```
Integrate[Exp[-2r/a] r Sin[q r],{r,0,Infinity},Assumptions->{q>0,a>0,Im[a q]==0}]
```

Using the known equation, (?? maybe it is written in theory of helium in GKKG???)

$$\frac{d\sigma}{d\Omega} = \frac{4[Z - F(q)]^2}{q^4 a_B^2}$$

we find the differential and total cross-section of elastic scattering from the helium atom:

```
Integrate[4 (2 - 32/(4 + qq a^2)^2)^2/(qq^2 a^2), {qq, 0, 4 k},
 Assumptions -> {k > 0, a > 0, Im[a q k] == 0}]
```

(don't even want to think about evaluation of this integral, but maybe it can be done using complex analysis)

$$\sigma = \frac{\pi}{k^2} \int_0^{4k^2} \frac{d\sigma}{d\Omega} dq^2 = \frac{4\pi a^2}{k^2 a_B^2} \frac{7k^6a^6 + 18k^4a^4 + 12k^2a^2}{3\left(1 + k^2a^2\right)^3} \overset{ka_B \gg 1}{\approx} \frac{28\pi a^2}{3\left(ka_B\right)^2}$$

We have $ka_B \gg 1$, and the total cross-section differs from the cross-section for scattering from the hydrogen atom by the factor $4(16/27)^2 \approx 1.40$.

GKKG.13.6 Z-dependance of the cross-section

Find the Z-dependance of the cross-section for the elastic scattering of fast electrons by a neutral atom with $Z \gg 1$; use the Thomas-Fermi model for the interaction potential.

Solution

(!!! I'll add it to the 1st part!)
Under the Thomas-Fermi approximation, the interaction potential between the scattered electrons and the neutral atom (ignoring an atom polarization) is

$$U(r) = -\varphi(r) = -\frac{Z}{r}\chi\left(\frac{rZ^{1/3}}{b}\right)$$

where $\chi(x)$ is the universal function in the Thomas-Fermi model (see Eq. (XI.3). We use the atomic system of units $e = \hbar = m_e = 1$.) The scattering amplitude in the Born approximation is

$$f^B(Z,q) = -2\int\limits_0^\infty U(r)\frac{\sin qr}{q}rdr = Z^{1/3}\Phi\left(\frac{q}{Z^{1/3}}\right) \tag{1}$$

where $\Phi(x)$ is a new universal function (the same for all atoms):

$$\Phi(x) = \frac{2}{x}\int\limits_0^\infty \chi\left(\frac{y}{b}\right)\sin(xy)dy \tag{2}$$

As $x \to \infty$, only a small region of y in the vicinity of the lower limit contributes to the integral (2). Taking into account that $\chi(0) = 1$ and $\int\limits_0^\infty \sin y dy = 1$ (the usual procedure is to introduce a "cutoff" factor $e^{-\alpha y}$ with $\alpha > 0$ in the integrand, and in the final result take the limit $\alpha \to 0$), we find $\Phi(x) \approx 2/x^2$, as $x \to \infty$.
(??? need to practice with it more!!!)
Hence, from Eq. (1), we have

$$f^B_{q\gg Z^{1/3}} \approx 2Z/q^2.$$

It is not unexpected that this corresponds to the amplitude of Rutherford electron scattering in atomic nuclei, since for a large momentum transfer, the screening by atomic electrons can be ignored. As $x \to 0$, the function $\Phi(x)$ takes a finite value.
Eqs. (1) and (2) give the differential cross-section of elastic scattering; the total scattering cross-section is given by

$$\sigma = \frac{\pi}{k^2}\int\limits_0^{4k^2}\left[f^B(q)\right]^2 dq^2 \approx \frac{\pi Z^{2/3}}{k^2}\int\limits_0^\infty \Phi^2\left(\frac{q}{Z^{1/3}}\right)dq^2 = \pi C\frac{Z^{4/3}}{k^2}$$

where $C = 7.14$.
(???? пока нет идей, как последний интеграл взят????)

GKKG.13.7 Collision of identical potentials and diatomic molecules

Using the Born approximation, find the amplitudes for scattering from two identical potential centers that are at some distance, a, from each other (viz., of the form $U(\mathbf{r}) = U_0(r) + U_0(|\mathbf{r} - \mathbf{a}|)$). Express your answer in terms of the scattering amplitude, $f_0^B(q)$, for scattering from $U_0(r)$ alone.
From this expression, determine a relation between the differential cross-sections for scattering of fast electrons from monoatomic and homonuclear diatomic molecules. Note that this quantity should be averaged over the molecular axis orientations, considering all of them to appear with equal probability.
Find a relation between the total scattering cross-sections from one and two centers for the following limiting cases:
a) $ka \ll 1$ (here the quantity $kR - R$ being the range of potential $U_0(r)$ - could be arbitrary);
b) $kR \sim 1$ and $a \gg R$ (i.e., the distance between the centers is much larger than the range of $U_0(r)$).

Solution

(про это отдельно подумаю, в 1ю часть добавлю, там есть раздел про рассеяние на решетке)
The scattering amplitude for two identical force centers separated by a distance, $\mathbf{a}$, is given by

$$f^B_{2c}(\mathbf{q}) = -\frac{m}{2\pi\hbar^2}\int e^{-i\mathbf{q}\cdot\mathbf{r}}\left[U_0(r) + U_0(|\mathbf{r} - \mathbf{a}|)\right]dV = f_0^B(q)\left[1 + e^{-i\mathbf{q}\cdot\mathbf{a}}\right] \tag{1}$$

from which the differential scattering cross-section follows:

$$\frac{d\sigma_{2c}}{d\Omega} = 2(1 + \cos \mathbf{q} \cdot \mathbf{a}) \left[f_0^B(q)\right]^2 \tag{2}$$

Although the form of the potential implies two identical force centers, the expressions in (1) and (2) are also applicable to a diatomic molecule. This is because only the valence electrons participate in the molecular formation, leaving behind two inner cores (nuclei screened by inner electrons) that are essentially the same as those of two isolated atoms. However, Eq. (2) must be averaged over all a. Neglecting nuclear vibrations (see Problem 11.25), it is sufficient to average only over the directions of a. For an isotropic distribution, this means that we perform the averaging using a direction-element $dw = d\Omega_{\rm n}/4\pi$ ($d\Omega_{\rm n}$ is an infinitesimal element of the solid angle that includes the direction of the vector $\mathbf{a} = a\mathbf{n}$). We obtain (choosing the z-axis along $\mathbf{q}$):

$$\overline{\cos \mathbf{a} \cdot \mathbf{q}} = \frac{1}{4\pi} \int \cos \mathbf{a} \cdot \mathbf{q} d\Omega_n = \frac{\sin qa}{qa}$$

Thus,

$$\frac{d\sigma_{mol}}{d\Omega} = 2\left(1 + \frac{\sin qa}{qa}\right) \frac{d\sigma_{at}}{d\Omega}$$

As can be seen, the relation between the atomic and the molecular scattering crosssections changes with the distance between the nuclei, a. (Similar relations can be found for multiatomic molecules, even heterogeneous ones. They form the basis of the diffraction methods used for examining molecular structures.)

Let us discuss the relation between the total scattering cross-sections. For $ka \ll 1$ and $qa \ll 1$, $f_{2c}^B \approx 2f_0^B$, the scattering cross-section on two centers is four times larger than on a single center. In the cases $kR \leq 1$ and $a \gg R$, we have $ka \gg 1$, and hence the quantity qa changes essentially, even for a small change of the scattering angle. So, in the integration (2) over the angles, the term with the fast oscillating factor, $\cos(\mathbf{q} \cdot \mathbf{a})$, is much smaller than the first term, so that in this case the cross-section of scattering on two centers is twice as large as on one center.

GKKG.13.8 Formula for N identical centers

Generalize the result of the previous problem for the case of a system with arbitrary number N of identical centers, located at the points $\mathbf{a}_n, n = 1, 2, ..., N$.

Discuss properties of the angular distribution of the scattered particles for an ordered array of a large number ($N \gg 1$) of centers along a straight line with the same distance, b, between closest neighbors.

Solution

In the Born approximation, the scattering amplitude is described by the expression (compare to the previous problem):

$$f_N^B(\mathbf{q}) = f_0^B(q) G_N(\mathbf{q}), \quad G_N(\mathbf{q}) = \sum_n e^{-i\mathbf{q}\cdot\mathbf{a}_n} \tag{1}$$

Let us emphasize that the factor $G_N(\mathbf{q})$ depends only on the mutual position of the centers and on the vector $\mathbf{q}$ (but not on the form of interaction between the particle and a single center).

In the case of an array of potential centers ordered along a line with the unit vector $\mathbf{j}$ ($\mathbf{a}_n = b(n-1)\mathbf{j}$), we have

$$G_N = \sum_{n=1}^{N} \exp\{-ib(n-1)\mathbf{q} \cdot \mathbf{j}\} = \frac{1 - \exp\{-ibN\mathbf{q} \cdot \mathbf{j}\}}{1 - \exp\{-ib\mathbf{q} \cdot \mathbf{j}\}}$$

$$|G_N(\mathbf{q})|^2 = \left[\frac{\sin(bN\mathbf{q} \cdot \mathbf{j}/2)}{\sin(b\mathbf{q} \cdot \mathbf{j}/2)}\right]^2 \tag{2}$$

In the case of $N \gg 1$, the quantity $|G_N(\mathbf{q})|^2$ is especially large for specific values, $\mathbf{q} = \mathbf{q}_s$ with [316] $b\mathbf{q}_s \cdot \mathbf{j} = 2\pi s$, where $s = 0, \pm 1, \pm 2, ...$ So, the particles are scattered mostly into particular directions, for which

$$\cos \beta_s \approx \frac{\mathbf{k}_0 \cdot \mathbf{j}}{k_0} + \frac{2\pi s}{bk_0}$$

[316] Restriction on $|s|_{\max}$ is determined by the momentum of scattered particles. In the case of $k < \pi/b$, only the value $s = 0$ is possible. In this case, $q = 0$, so that coherent scattering is absent.

where β_s is the angle between the vectors $\mathbf{k}$ and $\mathbf{j}$ (note that $\mathbf{qj} = \mathbf{kj} - \mathbf{k}_0\mathbf{j}$). At maximum, $|G_N|^2 = N^2$. The maxima are sharp; their width is $\Delta\beta_s \propto 1/\sqrt{N}$. The scattering cross-section into such interval of angles is $\propto N$. For other scattering angles, $|G_N|^2 \sim 1$

These results could be obtained by taking advantage of the large- N limit in the expression for $|G_N|^2$. Using the relation

$$\lim_{N\to\infty} \frac{\sin^2 \alpha N}{\pi \alpha^2 N} = \delta(\alpha)$$

and expanding $\sin(b\mathbf{q}\cdot\mathbf{j}/2)$ in expression (2) in the vicinity of $\mathbf{q}_s$, we find

$$|G_N(\mathbf{q})|^2 \approx \frac{2\pi N}{b} \sum_{s=-\infty}^{\infty} \delta\left(\mathbf{k}\cdot\mathbf{j} - \mathbf{k}_0\cdot\mathbf{j} - \frac{2\pi s}{b}\right) \tag{3}$$

Such method allows for an easy generalization to the case of a "crystalline" arrangement of the scattering centers. In particular, for a system of centers with $\mathbf{a}_{\{n\}} = n_1\mathbf{b}_1 + n_2\mathbf{b}_2 + n_3\mathbf{b}_3, n_a = 0, 1, ..., N_a - 1$, we have [317] ([317] Here we have used the relation: $\prod_{a=1}^{3} \delta(\mathbf{q}\cdot\mathbf{b}_a - 2\pi s_a) = \frac{1}{b_1 b_2 b_3}\delta(\mathbf{q} - 2\pi\boldsymbol{\tau})$)

$$|G_N(\mathbf{q})|^2 = \left|\sum_{\{n\}} \exp\left\{-i\mathbf{q}\cdot\mathbf{a}_{\{n\}}\right\}\right|^2 = \frac{(2\pi)^3 N}{b_1 b_2 b_3} \sum_{\tau} \delta\left(\mathbf{k} - \mathbf{k}_0 - 2\pi\boldsymbol{\tau}\right) \tag{4}$$

where $N = N_1 \cdot N_2 \cdot N_3$ is the total number of scattering centers,

$$\boldsymbol{\tau} = s_1\mathbf{a}_1 + s_2\mathbf{a}_2 + s_3\mathbf{a}_3, \quad s_a = 0, \pm 1, ...,$$

$$\mathbf{a}_1 = \frac{1}{\Delta}\left[\mathbf{b}_2 \times \mathbf{b}_3\right], \quad \mathbf{a}_2 = \frac{1}{\Delta}\left[\mathbf{b}_3 \times \mathbf{b}_1\right], \quad \mathbf{a}_3 = \frac{1}{\Delta}\left[\mathbf{b}_1 \times \mathbf{b}_2\right], \quad \Delta = (\mathbf{b}_1 \cdot [\mathbf{b}_2 \times \mathbf{b}_3])$$

(where $\mathbf{a}_1 \cdot \mathbf{b}_1 = \mathbf{a}_2 \cdot \mathbf{b}_2 = \mathbf{a}_3 \cdot \mathbf{b}_3 = 1$).
The δ-function terms in Eq. (4) determine the directions, $\mathbf{k} = \mathbf{k}_0 + 2\pi\boldsymbol{\tau}$, of particle elastic scattering in crystals (Bragg's law).

GKKG.13.9 Collision of extended particles

In the Born approximation, find the scattering amplitude for the collision of two extended (non-point-like) particles, interacting with each other via electrostatic forces. The particles are considered to be extended, which means they are characterized by some charge distribution, $\rho_{1,2}(r)$, that is assumed to be spherically symmetric with respect to the center of mass of the corresponding particle and does not change in the collision process. Express the scattering amplitude in terms of the charge distributions, $\rho_{1,2}(r)$, and the form-factors $F_{1,2}(q)$.

Solution

(тоже строчку в 1ю добавлю про такой случай)
The interaction potential is

$$U(r) = \iint \frac{\rho_1(r_1')\,\rho_2(r_2')}{|\mathbf{r} + \mathbf{r}_1' - \mathbf{r}_2'|} dV_1' dV_2'$$

where $\mathbf{r} = \mathbf{r}_1 - \mathbf{r}_2$, and $\mathbf{r}_{1,2}$ are the radius vectors of the centers of mass of the colliding particles. Taking into account the relation

$$\int \frac{e^{-i\mathbf{q}\cdot\mathbf{r}} dV}{|\mathbf{r} + \mathbf{r}_1' - \mathbf{r}_2'|} = \frac{4\pi}{q^2} e^{i\mathbf{q}\cdot(\mathbf{r}_1' - \mathbf{r}_2')}$$

and according to Eq. (XIII.6), we obtain

$$f^B(q) = -\frac{2m}{\hbar^2 q^2} F_1(q) F_2(q)$$

(where m is the reduced mass of the particles). Here,

$$F_{1,2}(q) = \int e^{-i\mathbf{q}\cdot\mathbf{r}} \rho_{1,2}(r) dV$$

are the form-factors of the corresponding charge distributions. Note that $F_{1,2}(0) = e_{1,2}$ are particle charges. Some properties of the form-factors are considered in Problems 13.80 and 13.84.

By the way, the fact that charge distribution is not point-like denotes the composite character of colliding particles (compare, for example, to Problem 13.4). Since, though, the change of their inner states in a collision process is to be neglected, then the problem is reduced to a common problem of two-body scattering. In connection with this problem, see also Problem 13.80.

17.3.8 Problems about scattering in Born approximation 2

GKKG.13.10 Formula for n-th order of general formula

Obtain an expression for the scattering amplitude in the n-th order of perturbation theory for a potential $U(r)$.

Hint: First, using Eqs. (XIII.5) and (XIII.4), obtain an integral equation for the scattering amplitude (the Lippmann-Schwinger equation).

Solution

Substituting expression (XIII.4) into Eq. (XIII.5), and using the momentum representation for the free-particle Green function,

$$\frac{e^{ik_0|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{2\pi^2}\int \frac{e^{i\boldsymbol{\kappa}\cdot(\mathbf{r}-\mathbf{r}')}}{\kappa^2-k_0^2-i\varepsilon}d^3\kappa$$

($\varepsilon > 0, \varepsilon \to 0$), we obtain the Lippmann-Schwinger equation:

$$f(\mathbf{k},\mathbf{k}_0) = -\frac{m}{2\pi\hbar^2}\left[\tilde{U}(\mathbf{k}-\mathbf{k}_0) + \int \frac{\tilde{U}(\mathbf{k}-\boldsymbol{\kappa})f(\boldsymbol{\kappa},\mathbf{k}_0)}{2\pi^2(\kappa^2-k_0^2-i\varepsilon)}d^3\kappa\right] \tag{1}$$

Let us emphasize that for physical real elastic scattering, $k^2 = k_0^2 = 2mE/\hbar^2$. On the other hand, Eq. (1) connects the scattering amplitudes for values $k^2 \neq k_0^2$ (outside the physical sheet or so-called energy surface; see also Eq. (XIII.5)).

Using Eq. (1), we find a recurrence relation for the terms in the expansion, $f(\mathbf{k},\mathbf{k}_0) = \sum\limits_n f^{(n)}$, of the scattering amplitude in powers of interaction, and then obtain an explicit expression for them ($\mathbf{q} = \mathbf{k}-\mathbf{k}_0$):

$$f^{(1)}(\mathbf{k},\mathbf{k}_0) = f^B(\mathbf{q}) = -\frac{m}{2\pi\hbar^2}\tilde{U}(\mathbf{q}), \quad \tilde{U}(\mathbf{q}) = \int e^{-i\mathbf{q}\cdot\mathbf{r}}U(\mathbf{r})dV$$

$$f^{(n)}(\mathbf{k},\mathbf{k}_0) = \left(-\frac{m}{2\pi\hbar^2}\right)^n \int ... \int \tilde{U}(\mathbf{k}-\boldsymbol{\kappa}_{n-1})\frac{\tilde{U}(\boldsymbol{\kappa}_{n-1}-\boldsymbol{\kappa}_{n-2})\,d^3\kappa_{n-1}}{2\pi^2(\kappa_{n-1}^2-k_0^2-i\varepsilon)} ... \frac{\tilde{U}(\boldsymbol{\kappa}_1-\mathbf{k}_0)\,d^3\kappa_1}{2\pi^2(\kappa_1^2-k_0^2-i\varepsilon)} \tag{2}$$

GKKG.13.11 Connection of Born approximation and optical theorem

In the Born approximation, the forward scattering amplitude (angle $\theta = 0$) is a real quantity and so does not satisfy the optical theorem (XIII.11). Why does this fact not contradict the successful description of differential and total scattering cross-section in the framework of the Born approximation, whenever it applies?

Write an expression for the scattering amplitude in second-order perturbation theory. Find $\operatorname{Im} f^{(2)}(E,\theta=0)$ and explain the result obtained.

Solution

The Born approximation is the first linear term in the expansion of the scattering amplitude in power of the interaction (more specifically, of parameters given in Eq. (XIII.7)). On the other hand, an expansion of the scattering cross-section begins from the term quadratic in interaction, since $\sigma \propto |f|^2$. So, in the relation $4\pi \operatorname{Im} f(E,0) = k\sigma(E)$, the left-hand side must have a second-order interaction term, as the right-hand side does. It follows that necessarily $\operatorname{Im} f^B(\theta=0) = 0$.

In the 2nd order of perturbation theory, the scattering amplitude is described by expression (2) of the previous problem. In particular, for forward scattering ($\theta = 0$, $\mathbf{k} = \mathbf{k}_0$), it gives

$$f^{(2)}(\mathbf{k}_0,\mathbf{k}_0) = \frac{m^2}{8\pi^4\hbar^4}\int \frac{\left|\tilde{U}(\boldsymbol{\kappa}-\mathbf{k}_0)\right|^2}{\kappa^2-k_0^2-i\varepsilon}d^3\kappa \tag{1}$$

We used the fact that $\tilde{U}(\mathbf{q}) = \tilde{U}^*(-\mathbf{q})$. It follows that

$$\operatorname{Im} f^{(2)}(\mathbf{k}_0,\mathbf{k}_0) = \frac{m^2}{8\pi^4\hbar^4}\int \frac{\varepsilon}{(\kappa^2-k_0^2)^2+\varepsilon^2}\left|\tilde{U}(\boldsymbol{\kappa}-\mathbf{k}_0)\right|^2 d^3\kappa \tag{2}$$

If we note that [319] $\varepsilon/\pi\left(x^2+\varepsilon^2\right)=\delta(x)$ (for infinitesimal $\varepsilon>0$), and write $\boldsymbol{\kappa}=\kappa\mathbf{n}$, $d^3\kappa=\frac{1}{2}\kappa d\kappa^2 d\Omega_{\mathrm{n}}$, we transform expression (2) to the form

$$\operatorname{Im} f^{(2)}\left(\mathbf{k}_0,\mathbf{k}_0\right)=\frac{m^2}{16\pi^3\hbar^4}\iint\left|\tilde{U}\left(k\mathbf{n}-\mathbf{k}_0\right)\right|^2\kappa\delta\left(\kappa^2-k_0^2\right)d\kappa^2 d\Omega_{\mathbf{n}}=$$
$$\frac{m^2k_0}{16\pi^3\hbar^4}\int\left|\tilde{U}\left(k_0\mathbf{n}-\mathbf{k}_0\right)\right|^2 d\Omega_n\equiv\frac{k_0}{4\pi}\int\left|f^B\left(\mathbf{k}-\mathbf{k}_0\right)\right|^2 d\Omega_{\mathbf{n}}$$

i.e., $\operatorname{Im} f^{(2)}(E,\theta=0)=k\sigma_B(E)/4\pi$, which expresses the optical theorem in the 2nd order of perturbation theory.

physicspages.com 2nd order scattering on soft sphere

A soft sphere is defined by the potential

$$V(\mathbf{r})=\begin{cases}V_0 & r\le a\\ 0 & r>a\end{cases}$$

where $V_0>0$ is a constant. Griffiths works out the first order Born approximation for the scattering amplitude in his example 11.4, so calculate the second order term.

Reminding of the framework

The first order Born approximation in scattering theory is derived from the integral form of the Schrödinger equation

$$\psi(\mathbf{r})=\psi_0(\mathbf{r})+\int g\left(\mathbf{r}-\mathbf{r}_0\right)V\left(\mathbf{r}_0\right)\psi\left(\mathbf{r}_0\right)d^3\mathbf{r}_0$$

where

$$g\left(\mathbf{r}-\mathbf{r}_0\right)\equiv-\frac{m}{2\pi\hbar^2}\frac{e^{ik|\mathbf{r}-\mathbf{r}_0|}}{|\mathbf{r}-\mathbf{r}_0|}$$

is the Green's function and ψ_0 is a free particle wave function. The first order Born approximation assumes that the wave function isn't changed much by the scattering process, so we can approximate the integral equation by replacing the full wave function ψ in the integrand by the incident wave function:

$$\psi(\mathbf{r})=\psi_0(\mathbf{r})+\int g\left(\mathbf{r}-\mathbf{r}_0\right)V\left(\mathbf{r}_0\right)\psi_0\left(\mathbf{r}_0\right)d^3\mathbf{r}_0$$

We can generate a second order approximation by inserting 3 into the integral in 1 . When we do this, it's important to keep track of the position vectors that apply to each integration. We'll relabel $\mathbf{r}_0$ as $\mathbf{r}_1$ in 1, and then insert 3 into it:

$$\begin{aligned}\psi(\mathbf{r})=&\psi_0(\mathbf{r})+\int g\left(\mathbf{r}-\mathbf{r}_1\right)V\left(\mathbf{r}_1\right)\psi\left(\mathbf{r}_1\right)d^3\mathbf{r}_1\\ \approx&\psi_0(\mathbf{r})+\int g\left(\mathbf{r}-\mathbf{r}_1\right)V\left(\mathbf{r}_1\right)\psi_0\left(\mathbf{r}_1\right)d^3\mathbf{r}_1+\\ &\int g\left(\mathbf{r}-\mathbf{r}_1\right)V\left(\mathbf{r}_1\right)\int g\left(\mathbf{r}_1-\mathbf{r}_0\right)V\left(\mathbf{r}_0\right)\psi_0\left(\mathbf{r}_0\right)d^3\mathbf{r}_0 d^3\mathbf{r}_1\end{aligned}$$

The first two terms just repeat the first order Born approximation, so to calculate the second order approximation we need to work out the third term involving the double integral. Using 2 we have for this term (which we'll call I_2)

$$I_2=\left(\frac{m}{2\pi\hbar^2}\right)^2\iint\frac{e^{ik|\mathbf{r}-\mathbf{r}_1|}}{|\mathbf{r}-\mathbf{r}_1|}\left|\frac{e^{ik|\mathbf{r}_1-\mathbf{r}_0|}}{|\mathbf{r}_1-\mathbf{r}_0|}V\left(\mathbf{r}_1\right)V\left(\mathbf{r}_0\right)\psi_0\left(\mathbf{r}_0\right)d^3\mathbf{r}_0 d^3\mathbf{r}_1\right.$$

In the original derivation, we simplified things by taking $\mathbf{r}$ to point to the detector, which is assumed to be very far from the scattering region. This allows us to approximate the Green's function:

$$g\left(\mathbf{r}-\mathbf{r}_0\right)\approx-\frac{m}{2\pi\hbar^2}\frac{e^{ikr}}{r}e^{-i\mathbf{k}\cdot\mathbf{r}_0}$$

This approximation is still valid for the first factor in the integrand in 6, but not for the second factor, since $\mathbf{r}_0$ and $\mathbf{r}_1$ are position vectors that both refer to locations within the scattering region (that is, where $V\neq0$). Therefore we can write

$$I_2\approx\left(\frac{m}{2\pi\hbar^2}\right)^2\frac{e^{ikr}}{r}\iint e^{-i\mathbf{k}\cdot\mathbf{r}_1}\frac{e^{ik|\mathbf{r}_1-\mathbf{r}_0|}}{|\mathbf{r}_1-\mathbf{r}_0|}V\left(\mathbf{r}_1\right)V\left(\mathbf{r}_0\right)\psi_0\left(\mathbf{r}_0\right)d^3\mathbf{r}_0 d^3\mathbf{r}_1$$

Solution

We'll also consider only the case of low energy scattering, which is defined by the condition $ka \ll 1$. We start by writing out 8 for this case.

$$I_2 \approx \left(\frac{m}{2\pi\hbar^2}\right)^2 \frac{e^{ikr}}{r} V_0^2 \iint e^{-i\mathbf{k}\cdot\mathbf{r}_1} \frac{e^{ik|\mathbf{r}_1-\mathbf{r}_0|}}{|\mathbf{r}_1-\mathbf{r}_0|} \psi_0(\mathbf{r}_0)\, d^3\mathbf{r}_0 d^3\mathbf{r}_1$$

To do the integral, we use an incident plane wave for ψ_0:

$$\psi_0(\mathbf{r}_0) = Ae^{i\mathbf{k}'\cdot\mathbf{r}_0}$$
$$\mathbf{k}' \equiv k\hat{\mathbf{z}}$$

If we do the $\mathbf{r}_0$ integration first, we can take the polar axis to be along $\mathbf{r}_1$. Then

$$|\mathbf{r}_1-\mathbf{r}_0| = \sqrt{r_1^2+r_0^2-2r_0r_1\cos\theta}$$
$$I_2 \approx \left(\frac{m}{2\pi\hbar^2}\right)^2 \frac{Ae^{ikr}}{r} V_0^2 \iint e^{-i\mathbf{k}\cdot\mathbf{r}_1} \frac{e^{ik\sqrt{r_1^2+r_0^2-2r_0r_1\cos\theta}}}{\sqrt{r_1^2+r_0^2-2r_0r_1\cos\theta}} e^{i\mathbf{k}'\cdot\mathbf{r}_0} d^3\mathbf{r}_0 d^3\mathbf{r}_1$$

We can't really make much headway with this integral without invoking the low energy assumption. In that case, all the exponentials are approximately 1, so we get

$$I_2 \approx \left(\frac{m}{2\pi\hbar^2}\right)^2 \frac{Ae^{ikr}}{r} V_0^2 \iint \frac{d^3\mathbf{r}_0 d^3\mathbf{r}_1}{\sqrt{r_1^2+r_0^2-2r_0r_1\cos\theta}}$$

Doing the $\mathbf{r}_0$ integral first, we have

$$\int \frac{d^3\mathbf{r}_0}{\sqrt{r_1^2+r_0^2-2r_0r_1\cos\theta}} = \int_0^a \int_0^\pi \int_0^{2\pi} \frac{r_0^2\sin\theta\, d\phi d\theta dr_0}{\sqrt{r_1^2+r_0^2-2r_0r_1\cos\theta}}$$
$$= 2\pi \int_0^a \int_0^\pi \frac{r_0^2\sin\theta\, d\theta dr_0}{\sqrt{r_1^2+r_0^2-2r_0r_1\cos\theta}}$$
$$= \frac{2\pi}{r_1} \int_0^a r_0\left[r_0+r_1-|r_0-r_1|\right] dr_0$$
$$= \frac{2\pi}{r_1} \int_0^{r_1} r_0\left[r_0+r_1-(r_1-r_0)\right] dr_0 +$$
$$\frac{2\pi}{r_1} \int_{r_1}^a r_0\left[r_0+r_1-(r_0-r_1)\right] dr_0$$
$$= \frac{4}{3}\pi r_1^2 + 2\pi a^2 - 2\pi r_1^2$$
$$= 2\pi a^2 - \frac{2}{3}\pi r_1^2$$

The integral over $\mathbf{r}_1$ is now easy, and we get

$$I_2 \approx \left(\frac{m}{2\pi\hbar^2}\right)^2 \frac{Ae^{ikr}}{r} V_0^2 \int_0^a \int_0^\pi \int_0^{2\pi} \left(2\pi a^2 - \frac{2}{3}\pi r_1^2\right) r_1^2 \sin\theta\, d\phi d\theta dr_1$$
$$= \frac{Ae^{ikr}}{r} \frac{8m^2V_0^2a^5}{15\hbar^4}$$

The second order correction to the scattering amplitude is the coefficient of $\frac{Ae^{ikr}}{r}$ so the correction is

$$f_2 = \frac{8m^2V_0^2a^5}{15\hbar^4}$$

Combining this with the first order correction taken from Griffiths's Example 11.4 we get

$$f(\theta,\phi) \approx -\frac{2ma^3V_0}{3\hbar^2} + \frac{8m^2V_0^2a^5}{15\hbar^4}$$
$$= -\frac{2ma^3V_0}{3\hbar^2}\left(1 - \frac{4mV_0a^2}{5\hbar^2}\right)$$

17.3.9 Second Order Scattering in Yukawa Potential

GKKG.13.12 2nd order scattering on Yukawa potential

In the 2nd order of perturbation theory, find the scattering amplitude of the Yukawa potential, $U(r) = \frac{\alpha}{r}e^{-r/R}$. Compare $f^{(1)}$ to $f^{(2)}$ for different values of energy and scattering angle.

Solution by Suzuki

(???)
We now study the second-order Born approximation for the Yukawa potential

$$f^{(2)} = -\frac{1}{4\pi}\frac{2m}{\hbar^2}(2\pi)^3\langle\mathbf{k}|\hat{V}\hat{G}_0\left(E_\mathbf{k}+i\varepsilon\right)\hat{V}|\mathbf{k}\rangle$$

with

$$\langle\mathbf{k}|\hat{V}\hat{G}_0\left(E_\mathbf{k}+i\delta\right)\hat{V}|\mathbf{k}\rangle = \int d\mathbf{k}''\,\langle\mathbf{k}'|\,\hat{V}\,|\mathbf{k}''\rangle\,\langle\mathbf{k}''|\,\hat{G}_0\left(E_\mathbf{k}+i\delta\right)|\mathbf{k}''\rangle\,\langle\mathbf{k}''|\,\hat{V}|\mathbf{k}\rangle,$$

$$\langle\mathbf{k}"|\hat{G}_0\left(E_\mathbf{k}+i\delta\right)|\mathbf{k}''\rangle = \langle\mathbf{k}"|\frac{1}{E_\mathbf{k}-\hat{H}+i\delta}\,|\mathbf{k}''\rangle$$

$$= \langle\mathbf{k}''|\,\frac{1}{E_\mathbf{k}-E_{\mathbf{k}^-}+i\delta}\,|\mathbf{k}''\rangle$$

$$= \frac{1}{E_\mathrm{k}-E_{\mathbf{k}^-}+i\varepsilon}$$

$$= \frac{2m}{\hbar^2}\frac{1}{\mathbf{k}^2-\mathbf{k}^{m^2}+i\varepsilon}$$

$$\langle\mathbf{k}|\hat{V}|\mathbf{k}\rangle = \frac{1}{(2\pi)^3}\frac{4\pi V_0}{\mu}\frac{1}{\mu^2+(\mathbf{k}^2-\mathbf{k})^2},$$

$$f^{(2)} = -\frac{1}{4\pi}\frac{2m}{\hbar^2}(2\pi)^3\int d\mathbf{Q}\langle\mathbf{k}|\hat{V}|\mathbf{Q}\rangle\langle\mathbf{Q}|\hat{G}_0\left(E_\mathbf{k}+is\right)|\mathbf{Q}\rangle\langle\mathbf{Q}|\hat{V}|\mathbf{k}\rangle$$

$$= -\frac{1}{4\pi}\left(\frac{2m}{\hbar^2}\right)^2(2\pi)^3\frac{1}{(2\pi)^6}\left(\frac{4\pi V_0}{\mu}\right)^2\int d\mathbf{Q}\frac{1}{\mu^2+(\mathbf{Q}-\mathbf{k}')^2}\frac{1}{\mu^2+(\mathbf{Q}-\mathbf{k})^2}\frac{1}{\mathbf{k}^2-\mathbf{Q}^2+i\delta}$$

$$= \frac{\lambda^2\mu^2}{32\pi^4}\int d\mathbf{Q}\frac{1}{\mu^2+(\mathbf{Q}-\mathbf{k}^2)^2}\frac{1}{\mu^2+(\mathbf{Q}-\mathbf{k})^2}\frac{1}{\mathbf{Q}^2-\mathbf{k}^2-i\delta}$$

where E is a positive small constant. We now calculate the integral M (Dalitz integral) defined by

$$M = \int d\mathbf{Q}\frac{1}{\mu^2+(\mathbf{Q}-\mathbf{k}')^2}\frac{1}{\mu^2+(\mathbf{Q}-\mathbf{k})^2}\frac{1}{\mathbf{Q}^2-\mathbf{k}^2-i\varepsilon}.$$

We use the formula (Feynman integral representation)

$$\int_0^1 dz\frac{1}{[az+b(1-z)]^2} = \frac{1}{ab},$$

In general;

$$\frac{1}{a^mb^z} = \frac{(m+n-1)!}{(m-1)!(n-1)!}\int_0^1\frac{t^{m-1}(1-t)^{n-1}}{[at+b(1-t)]^{m+n}}dt$$

(Feynman, 1949)
Here we also use the notations

$$a = \mu^2 + (\mathbf{Q} - \mathbf{k}')^2, \quad b = \mu^2 + (\mathbf{Q} - \mathbf{k})^2$$

and

$$\begin{aligned} az + b(1-z) &= \left[\mu^2 + (\mathbf{Q} - \mathbf{k}')^2\right] z + \left[\mu^2 + (\mathbf{Q} - \mathbf{k})^2\right](1-z) \\ &= \mu^2 + \left(\mathbf{Q}^2 - 2\mathbf{Q}\cdot\mathbf{k} + \mathbf{k}'^2\right) z + \left(\mathbf{Q}^2 - 2\mathbf{Q}\cdot\mathbf{k} + \mathbf{k}^2\right)(1-z) \\ &= \mu^2 + \mathbf{k}'^2 z + \mathbf{k}^2(1-z) + \mathbf{Q}^2 - 2\mathbf{Q}\cdot[\mathbf{k}'z + \mathbf{k}(1-z)] \\ &= \mu^2 + k^2 + \mathbf{Q}^2 - 2\mathbf{Q}\cdot[\mathbf{k}'z + \mathbf{k}(1-z)] \end{aligned}$$

where

$$\begin{aligned} &\mathbf{q} = \mathbf{k}' - \mathbf{k}, \\ &|\mathbf{k}| = |\mathbf{k}| = k, \qquad \mathbf{k}'\cdot\mathbf{k} = k^2\cos\theta \end{aligned}$$

Thus, we have

$$\begin{aligned} az + b(1-z) &= [\mathbf{Q} - \mathbf{k}'z - \mathbf{k}(1-z)]^2 + \mu^2 + k^2 - [\mathbf{k}'z + \mathbf{k}(1-z)]^2 \\ &= [\mathbf{Q} - \mathbf{k}'z - \mathbf{k}(1-z)]^2 + \mu^2 + k^2 - \mathbf{g}^2 \\ &= (\mathbf{Q} - \mathbf{g})^2 + \tau^2 \end{aligned}$$

For convenience, we use the parameters.

$$\begin{aligned} &\mathbf{g} = \mathbf{k}'z + \mathbf{k}(1-z) = \mathbf{q}z + \mathbf{k}, \\ &\tau^2 = \mu^2 + k^2 - g^2. \\ &g^2 = [\mathbf{k}z + \mathbf{k}'(1-z)]\cdot[\mathbf{k}z + \mathbf{k}'(1-z)] \\ &= \mathbf{k}^2 z^2 + \mathbf{k}'^2(1-z)^2 + 2\mathbf{k}\cdot\mathbf{k}'z(1-z) \\ &= k^2\left[2z^2 - 2z + 1 + 2z(1-z)\cos\theta\right] \\ &= k^2\left[1 - 2z(1-z) + 2z(1-z)\left(1 - 2\sin^2\frac{\theta}{2}\right)\right] \\ &= k^2\left[1 - 4z(1-z)\sin^2\frac{\theta}{2}\right] \end{aligned}$$

$$\mathbf{g}^2 + \tau^2 = \mu^2 + k^2$$

So that, M can be rewritten as

$$\begin{aligned} M &= \int_0^1 dz \int d\mathbf{Q} \frac{1}{4\left[(\mathbf{Q} - \mathbf{g})^2 + \tau^2\right]^2} \frac{1}{\mathbf{Q}^2 - \mathbf{k}^2 - i\varepsilon} \\ &= \int_0^1 dz \int d\mathbf{Q} \frac{1}{\left[(\mathbf{Q} - \mathbf{g})^2 + \tau^2\right]^2} \frac{1}{\mathbf{Q}^2 - \mathbf{k}^2 - i\varepsilon} \end{aligned}$$

and

$$M = \int_0^1 dz L(\mathbf{g}, \boldsymbol{\tau})$$

with

$$\begin{aligned} L(\mathbf{g}, \tau) &= \int d\mathbf{Q} \frac{1}{\left[(\mathbf{Q} - \mathbf{g})^2 + \tau^2\right]^2 \left[\mathbf{Q}^2 - k^2 - i\varepsilon\right]} \\ J(\mathbf{g}, \tau) &= \int d\mathbf{Q} \frac{1}{\left[(\mathbf{Q} - \mathbf{g})^2 + \tau^2\right] \left[\mathbf{Q}^2 - k^2 - i\varepsilon\right]} \end{aligned}$$

and

$$M = -\frac{1}{2\tau}\frac{\partial}{\partial\tau} J(\mathbf{g}, \tau)$$

First, we need to calculate $J(\mathbf{g}, \tau)$. Suppose that the vector $\boldsymbol{g}$ is directed along the Q_z axis. When the angle between the vector $\boldsymbol{Q}$ and $\boldsymbol{g}$ is χ, we have a scalar product as

The scalar product:

$$\mathbf{Q}\cdot\mathbf{g} = Qg\cos\chi$$
$$(\mathbf{Q}-\mathbf{g})^2 = \mathbf{Q}^2 - 2\mathbf{Q}\cdot\mathbf{g} + \mathbf{g}^2 = \mathbf{Q}^2 - 2Qg\cos\chi + \mathbf{g}^2$$

16

$$\begin{aligned}
J(\mathbf{g},\tau) &= \int_0^\infty Q^2 dQ \int_0^\pi 2\pi\sin\chi d\chi \frac{1}{[Q^2 - 2Qg\cos\chi + g^2 + \tau^2]\,[Q^2 - k^2 - i\varepsilon]} \\
&= \int_0^\pi 2\pi\sin\chi d\chi \int_0^\infty dQ \frac{Q^2}{[Q^2 - 2Qg\cos\chi + g^2 + \tau^2]\,[Q^2 - k^2 - i\varepsilon]} \\
&= \int_0^\infty \frac{Q^2 dQ}{Q^2 - k^2 - i\delta} \int_0^\pi \frac{2\pi\sin\chi d\chi}{[Q^2 - 2Qg\cos\chi + g^2 + \tau^2]}
\end{aligned}$$

We define the function $F(Q)$ as

$$\begin{aligned}
F(Q) &= \int_0^\pi \frac{2\pi\sin\chi d\chi}{Q^2 + g^2 + \tau^2 - 2Qg\cos\chi} \\
&= \frac{\pi}{gQ}\ln\left(\frac{g^2+\tau^2+2gQ+Q^2}{g^2+\tau^2-2gQ+Q^2}\right)
\end{aligned}$$

$$\begin{aligned}
J(\mathbf{g},\tau) &= \int_0^\pi \frac{Q^2 dQ}{Q^2 - k^2 - i\delta} F(Q) \\
&= \int_0^\infty \frac{Q^2 dQ}{Q^2 - k^2 - i\delta}\left[\frac{\pi}{gQ}\ln\left(\frac{g^2+t^2+2gQ+Q^2}{g^2+t^2-2gQ+Q^2}\right)\right] \\
&= \frac{\pi}{g}\int_0^\infty \frac{QdQ}{Q^2 - k^2 - i\delta}\ln\left(\frac{g^2+t^2+2gQ+Q^2}{g^2+t^2-2gQ+Q^2}\right)
\end{aligned}$$

We note that the integrand of this integral is an even function of Q. This integral can be rewritten as

$$J(\mathbf{g},\tau) = \frac{1}{2}\int_{-\infty}^\infty \frac{Q^2 dQ}{Q^2 - k^2 - i\varepsilon} F(Q).$$

Using the form of $F(Q); F(Q) = \int_0^\pi \frac{2\pi\sin\chi d\chi}{Q^2+g^2+\tau^2-2Qg\cos\chi}$, $J(\mathbf{g},\tau)$ can be obtained as

$$\begin{aligned}
J(\mathbf{g},\tau) &= \frac{1}{2}\int_{-\infty}^\infty \frac{Q^2 dQ}{Q^2 - k^2 - i\delta}\int_0^\pi \frac{2\pi\sin\chi d\chi}{Q^2 + g^2 + t^2 - 2Qg\cos\chi} \\
&= \pi\int_0^\pi \sin\chi d\chi \int_{-\pi}^\infty \frac{Q^2 dQ}{(Q^2 - k^2 - i\delta)\left[(Q - g\cos\chi)^2 + g^2\sin^2\chi + \tau^2\right]}
\end{aligned}$$

Using the Jordan's lemma (the absolute value of the integrand reduces to zero in the limit of $|Q| \to \infty$ in the complex Q-plane), we extend the region of the integral over the upper half of complex plane. Using the Cauchy theorem, we get

$$\begin{aligned}
I &= \int_{-\infty}^\infty \frac{Q^2 dQ}{(Q^2 - k^2 - i\varepsilon)\left[(Q - g\cos\chi)^2 + g^2\sin^2\chi + \tau^2\right]} \\
&= \oint_c \frac{Q^2 dQ}{(Q^2 - k^2 - i\delta)\left[(Q - g\cos\chi)^2 + g^2\sin^2\chi + \tau^2\right]} \\
&= \oint_c \frac{Q^2 dQ}{(Q - Q_1)(Q - Q_2)(Q - Q_3)(Q - Q_4)} \\
&= 2\pi\left[\mathrm{Re}\, s\,(Q = Q_1) + \mathrm{Re}\, s\,(Q = Q_3)\right]
\end{aligned}$$

$$\begin{aligned}
\operatorname{Re} s(Q=Q_1) &= \lim_{Q\to 2} \frac{Q^2\,(Q-Q_1)}{(Q-Q_1)\,(Q-Q_2)\,(Q-Q_3)\,(Q-Q_4)} \\
&= \lim_{Q\to Q} \frac{Q^2}{(Q-Q_2)\,(Q-Q_3)\,(Q-Q_4)} \\
&= \frac{Q_1^2}{(Q_1-Q_2)\,(Q_4-Q_3)\,(Q_4-Q_4)} \\
&= \frac{k^3}{2}\frac{1}{k^2+g^2+\tau^2-2g\cos\chi} \\
&= \frac{k^3}{2}\frac{1}{k^2+\mu^2+k^2-2g\cos\chi}
\end{aligned}$$

where

$$\begin{aligned}
g^2+\tau^2 &= \mu^2+k^2, \\
\operatorname{Re} s(Q=Q_3) &= \lim_{Q\to \varrho} \frac{Q^2\,(Q-Q_3)}{(Q_1-Q_1)\,(Q-Q_2)\,(Q-Q_3)\,(Q-Q_4)} \\
&= \lim_{Q\to \Theta} \frac{Q^2}{(Q-Q_1)\,(Q-Q_2)\,(Q-Q_4)} \\
&= \frac{Q_3^2}{(Q_3-Q_1)\,(Q_3-Q_2)\,(Q_3-Q_4)} \\
&= \frac{(g\cos\chi+i\alpha)^2}{2i\alpha(g\cos\chi+i\alpha+k)(g\cos\chi+i\alpha-k)} \\
&= \frac{(g\cos\chi+i\alpha)^2}{2i\alpha\left[(g\cos\chi+i\alpha)^2-k^2\right]}
\end{aligned}$$

and

$$\begin{aligned}
\operatorname{Re} s(Q=Q_3) &= \frac{k^2}{2k}\frac{1}{(k-g\cos\chi)^2+g^2\sin^2\chi+\tau^2} \\
&= \frac{k}{2}\frac{1}{k^2+g^2+\tau^2-2kg\cos\chi}
\end{aligned}$$

Where we define α as

$$\alpha = \sqrt{g^2\sin^2\chi+\tau^2}$$

We now calculate

$$\begin{aligned}
J(\mathbf{g},\tau) &= 2\pi^2 i \int_0^\pi \sin\chi d\chi \left[\operatorname{Res}(Q=Q_1)+\operatorname{Res}(Q=Q_3)\right. \\
&= J_1+J_3
\end{aligned}$$

where

$$\begin{aligned}
J_1 &= 2\pi^2 i \int_0^\pi \sin\chi d\chi \left[\operatorname{Res}(Q=Q_1)\right] \\
&= 2\pi^2 i \int_0^\pi \sin\chi d\chi \frac{(g\cos\chi+i\alpha)^2}{2i\alpha\left[(g\cos\chi+i\alpha)^2-k^2\right]} \\
&= \pi^2 \int_0^\pi \sin\chi d\chi \frac{(g\cos\chi+i\alpha)^2}{\alpha\left[(g\cos\chi+i\alpha)^2-k^2\right]}
\end{aligned}$$

For simplicity, we choose a variable,

$$x = g\cos\chi+i\alpha = g\cos\chi+i\sqrt{g^2\sin^2\chi+\tau^2}$$

and

$$
\begin{aligned}
dx &= \left[-g\sin\chi + i\frac{g^2\sin\chi\cos\chi}{\sqrt{g^2\sin^2\chi+\tau^2}} \right] d\chi \\
&= \frac{ig\sin\chi}{\sqrt{g^2\sin^2\chi+\tau^2}} \left[i\sqrt{g^2\sin^2\chi+\tau^2} + g\cos\chi \right] d\chi \\
&= \frac{ig\sin\chi}{\sqrt{g^2\sin^2\chi+r^2}} (g\cos\chi + i\alpha) d\chi \\
&= \frac{ig\sin\chi}{\alpha} x d\chi
\end{aligned}
$$

$$
\sin\chi d\chi = \frac{\alpha}{ig}\frac{dx}{x}
$$

Then we have

$$
\begin{aligned}
J_1 &= \pi^2 \int_{g^{+iz}}^{-g+it} \frac{\alpha dx}{igx} \frac{x^2}{\alpha\left(x^2-k^2\right)} \\
&= \frac{i\pi^2}{g} \int_{-g^{+ir}}^{t^{+ir}} \frac{xdx}{x^2-k^2} \\
&= \frac{i\pi^2}{2g} \int_{-g^{+ir}}^{g^{+ir}} \left(\frac{1}{x-k} + \frac{1}{x+k} \right) dx \\
&= \frac{i\pi^2}{2g} \ln \frac{(i\tau-k+g)(i\tau+k+g)}{(i\tau-k-g)(i\tau+k-g)}
\end{aligned}
$$

We also calculate the integral J_3

$$
\begin{aligned}
J_3 &= 2\pi^2 i \int_0^\pi \sin\chi d\chi \left[\mathrm{Res}\left(Q=Q_3\right) \right] \\
&= 2\pi^2 i \int_0^\pi \sin\chi d\chi \frac{k}{2} \frac{1}{k^2+g^2+\tau^2-2kg\cos\chi} \\
&= k\pi^2 i \int_0^\pi \frac{\sin\chi d\chi}{k^2+g^2+\tau^2-2kg\cos\chi} \\
&= \frac{\pi^2 i}{2g} \ln \frac{(k+g)^2+\tau^2}{(k-g)^2+\tau^2}
\end{aligned}
$$

Thus, we have

$$
\begin{aligned}
J &= J_1 + J_3 \\
&= \frac{\pi^2 i}{2g} \left[\ln \frac{(i\tau+k+g)(i\tau-k-g)}{(i\tau+k-g)(i\tau-k+g)} + \ln \frac{(i\tau-k+g)(i\tau+k+g)}{(i\tau-k-g)(i\tau+k-g)} \right] \\
&= \frac{\pi^2 i}{g} \ln \frac{(i\tau+k+g)}{(i\tau+k-g)}
\end{aligned}
$$

M is defined by

$$
M = -\frac{1}{2\tau}\frac{\partial}{\partial\tau} J(\mathbf{g},\tau) = -\frac{\pi^2}{\tau} \frac{1}{k^2-g^2-\tau^2+2i\tau k}.
$$

The scattering amplitude in the second order Born approximation is

$$
\begin{aligned}
f^{(2)} &= \frac{1}{32\pi^2}\lambda^2\mu^2 \int_0^1 M dz \\
&= -\frac{1}{32\pi^2}\lambda^2\mu^2 \int_0^1 \frac{dz}{\tau\left(k^2 - g^2 - \tau^2 + 2i\tau k\right)} \\
&= -\frac{1}{32\pi^2}\lambda^2\mu^2 \int_0^1 \frac{dz}{\tau\left(-\mu^2 + 2i\tau k\right)}
\end{aligned}
$$

where

$$
g^2 + \tau^2 = k^2 + \mu^2,
$$

and

$$
\begin{aligned}
\tau^2 &= \mu^2 + k^2 - g^2 \\
&= \mu^2 + 4k^2 \sin^2\frac{\theta}{2} z(1-z) \\
&= \mu^2 + q^2 z(1-z)
\end{aligned}
$$

Using the separation of the real part and imaginary part of the integrand

$$
\begin{aligned}
\frac{1}{\tau\left(-\mu^2 + 2i\tau k\right)} &= \frac{\left(-\mu^2 - 2i\tau k\right)}{\tau\left(\mu^4 + 4\tau^2 k^2\right)} \\
&= -\frac{\mu^2}{\tau\left(\mu^4 + 4\tau^2 k^2\right)} + \frac{-2ik}{\left(\mu^4 + 4\tau^2 k^2\right)}
\end{aligned}
$$

(a) Imaginary part $\mathrm{Im}\left[f^{(2)}\right]$
We have the imaginary part,

$$
\begin{aligned}
\mathrm{Im}\left[f^{(2)}\right] &= -\frac{1}{32\pi^2}\lambda^2\mu^2 \int_0^1 \frac{-2k dz}{\mu^4 + 4\tau^2 k^2} \\
&= \frac{1}{16\pi^2} k\lambda^2\mu^2 \int_0^1 \frac{dz}{\mu^4 + 4\tau^2 k^2} \\
&= \frac{1}{16\pi^2} k\lambda^2\mu^2 \int_0^1 \frac{dz}{\mu^4 + 4\mu^2 k^2 + 4k^2 q^2 z(1-z)} \\
&= \frac{1}{16\pi^2} k\lambda^2\mu^2 \frac{\ln\left(\frac{\sqrt{\mu^4 + k^2q^2 + 4\mu^2k^2} + kq}{\sqrt{\mu^4 + k^2q^2 + 4\mu^2k^2} - kq}\right)}{2kq\sqrt{\mu^4 + k^2q^2 + 4\mu^2k^2}}
\end{aligned}
$$

or

$$
\mathrm{Im}\left[f^{(2)}\right] = \frac{1}{32\pi^2}\frac{\lambda^2\mu^2}{q}\frac{\ln\left(\frac{\sqrt{\mu^4 + k^2q^2 + 4\mu^2k^2} + kq}{\sqrt{\mu^4 + k^2q^2 + 4\mu^2k^2} - kq}\right)}{\sqrt{\mu^4 + k^2q^2 + 4\mu^2k^2}}
$$

where the integral is calculated by Mathematica

$$
I_{BC} = \int_0^1 \frac{dz}{\mu^4 + 4\mu^2 k^2 + 4k^2 q^2 z(1-z)} = \frac{\ln\left(\frac{\sqrt{\mu^4 + k^2q^2 + 4\mu^2k^2} + kq}{\sqrt{\mu^4 + k^2q^2 + 4\mu^2k^2} - kq}\right)}{2kq\sqrt{\mu^4 + k^2q^2 + 4\mu^2k^2}}
$$

Note that in the limit of $q \to 0$, we get

$$
\lim_{q\to 0} I_{BM} = \frac{1}{\mu^2}\frac{1}{4k^2 + \mu^2},
$$

leading to the relation

$$\mathrm{Im}\left[f^{(2)}(0)\right] = \frac{\lambda^2}{16\pi^2} k \frac{1}{4k^2+\mu^2}$$

(b) Real part $\mathrm{Re}\left[f^{(2)}\right]$
Next, we calculate the real part,

$$\begin{aligned}\mathrm{Re}\left[f^{(2)}\right] &= \frac{1}{32\pi^2}\lambda^2\mu^2 \int_0^1 \frac{\mu^2 dz}{\tau\left(\mu^4+4r^2k^2\right)} \\ &= \frac{1}{32\pi^2}\mu^4\lambda^2 \int_0^1 \frac{dz}{\sqrt{\mu^2+q^2z(1-z)}\left[\mu^4+4\mu^2k^2+4k^2q^2z(1-z)\right]}\end{aligned}$$

where the solution of this integral is also obtained using the Mathematica 26

$$\begin{aligned}I_R &= \int_0^1 \frac{dz}{\sqrt{\mu^2+q^2z(1-z)}\left[\mu^4+4\mu^2k^2+4k^2q^2z(1-z)\right]} \\ &= \frac{1}{q\mu^2\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}\left[\mathrm{Arctan}\,\frac{k\left(q^2+4\mu^2\right)+q\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{2\mu^3}\right. \\ &\left. -\,\mathrm{Arctan}\,\frac{k\left(q^2+4\mu^2\right)-q\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{2\mu^3}\right]\end{aligned}$$

and

$$\lim_{q\to 0} I_n = \frac{1}{\mu^3}\frac{1}{4k^2+\mu^2}.$$

Thus, we have

$$\begin{aligned}\mathrm{Re}\left[f^{(2)}\right] =& \frac{1}{32\pi^2}\mu^4\lambda^2\frac{1}{q\mu^2\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}} \\ &\times \mathrm{Arctan}\,\frac{k\left(q^2+4\mu^2\right)+q\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{2\mu^3} \\ &-\,\mathrm{Arctan}\,\frac{k\left(q^2+4\mu^2\right)-q\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{2\mu^3}\Bigg]\end{aligned}$$

We also have simpler expression as

$$\begin{aligned}\mathrm{Re}\left[f^{(2)}\right] =& \frac{1}{32\pi^2}\frac{\lambda^2\mu^2}{q}\frac{1}{\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}} \\ &\mathrm{Arctan}\left[\frac{q\mu\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{\mu^4+k^2\left(q^2+4\mu^2\right)-\frac{q^2\mu^2}{4}}\right]\end{aligned}$$

(see the note for this derivation)
We note that 27

$$\lim_{q\to 0}\frac{1}{q}\,\mathrm{Arctan}\left[\frac{q\mu}{\sqrt{\mu^4+4k^24\mu^2}}\right] = \frac{\mu}{\sqrt{\mu^2+4k^2}}$$

Using this relation, we have

$$\mathrm{Re}\left[f^{(2)}(0)\right] = \frac{1}{32\pi^2}\lambda^2\mu\frac{1}{\mu^2+4k^2},$$

at $q=0$.
(Note)) Simplification of the expression of $\mathrm{Re}\left[f^{(2)}\right]$ We now simplify the expression of $\mathrm{Re}\left[f^{(2)}\right]$ using simple trigonometry. 29

$$
\begin{aligned}
A &= \operatorname{Arctan} \frac{k\left(q^2+4\mu^2\right)+q\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{2\mu^3} \\
&\quad - \operatorname{Arctan} \frac{k\left(q^2+4\mu^2\right)-q\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{2\mu^3} \\
&= \alpha - \beta
\end{aligned}
$$

where we use α and β as

$$
\begin{aligned}
\tan\alpha &= \frac{k\left(q^2+4\mu^2\right)+q\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{2\mu^3}, \\
\tan\beta &= \frac{k\left(q^2+4\mu^2\right)-q\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{2\mu^3}
\end{aligned}
$$

We note that

$$
\tan(\alpha-\beta) = \frac{\tan\alpha-\tan\beta}{1+\tan\alpha\tan\beta}.
$$

Then, we get

$$
\begin{aligned}
\tan\alpha - \tan\beta &= \frac{q}{\mu^3}\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}, \\
1+\tan\alpha\tan\beta &= 1+\left[\frac{k\left(q^2+4\mu^2\right)+q\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{2\mu^3}\right] \\
&\quad \times \left[\frac{k\left(q^2+4\mu^2\right)-q\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{2\mu^3}\right] \\
&= 1+\frac{1}{4\mu^6}\left[k^2\left(q^2+4\mu^2\right)^2-\left(q^2\mu^4+q^4k^2+4k^2q^2\mu^2\right)\right] \\
&= 1+\frac{1}{4\mu^6}\left[k^2\left(q^4+8q^2\mu^2+16\mu^4\right)-\left(q^2\mu^4+q^4k^2+4k^2q^2\mu^2\right)\right] \\
&= 1+\frac{1}{4\mu^4}\left[4k^2\left(q^2+4\mu^2\right)-q^2\mu^2\right] \\
&= \frac{1}{\mu^4}\left[\mu^4+k^2\left(q^2+4\mu^2\right)\right]-\frac{q^2}{4\mu^2}
\end{aligned}
$$

Thus, we have

$$
\begin{aligned}
\tan(\alpha-\beta) &= \frac{\frac{q}{\mu^3}\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{\frac{1}{\mu^4}\left[\mu^4+k^2\left(q^2+4\mu^2\right)\right]-\frac{q^2}{4\mu^2}} \\
&= \frac{q\mu\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{\left[\mu^4+k^2\left(q^2+4\mu^2\right)\right]-\frac{q^2\mu^2}{4}}
\end{aligned}
$$

or

$$
\alpha-\beta = \operatorname{Arctan}\left[\frac{q\mu\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{\left[\mu^4+k^2\left(q^2+4\mu^2\right)\right]-\frac{q^2\mu^2}{4}}\right]
$$

6. Optical theorem
The scattering amplitude up to the second order, is

$$
f = f^{(1)} + f^{(2)} =
$$

At $q=0$, we get the scattering amplitude as

$$
f^{(1)} = -\frac{\lambda}{4\pi}\mu\frac{1}{\mu^2} = -\frac{\lambda}{4\pi}\frac{1}{\mu}
$$

and

$$\begin{aligned} f^{(2)} &= \frac{\lambda^2}{32\pi^2}\frac{\mu}{\mu^2+4k^2} + i\frac{1}{16}\lambda^2\left(\frac{k}{\mu^2+4k^2}\right) \\ &= \frac{\lambda^2}{32\pi^2}\left(\frac{\mu+2ik}{\mu^2+4k^2}\right) \\ &= \frac{\lambda^2}{32\pi^2}\frac{1}{\mu-2ik} \end{aligned}$$

If the Born approximation is to be reliable, we must certainly have the condition

$$\frac{\left|f^{(2)}\right|}{\left|f^{(1)}\right|} * 1$$

For the forward scattering ($q = 0$), we gave

$$\frac{\left|f^{(2)}\right|}{\left|f^{(1)}\right|} = \frac{\frac{\lambda^2}{32\pi^2}\frac{1}{\sqrt{\mu^2+4k^2}}}{\frac{\lambda}{4\pi\mu}} = \frac{\lambda}{8\pi}\frac{\mu}{\sqrt{\mu^2+4k^2}} * 1$$

When $k > \mu$ (high energy)

$$\frac{\left|f^{(2)}\right|}{\left|f^{(1)}\right|} = \frac{\lambda}{16\pi}\frac{\mu}{k} * 1$$

The condition steadily improved as k increases. When $k\&\mu$ (low energy, $k = 0$),

$$\frac{\left|f^{(2)}\right|}{\left|f^{(1)}\right|} = \frac{\lambda}{8\pi} \approx 1$$

By taking into account of the second order $\operatorname{lm}\left[f^{(2)}(0)\right]$, we confirm that the optical theorem is valid such that

$$\begin{aligned} \frac{4\pi}{k}\operatorname{lm}[f(0)] &= \frac{4\pi}{k}\operatorname{Im}\left[f^{(1)}(0) + f^{(2)}(0)\right] \\ &= \frac{4\pi}{k}\operatorname{Im}\left[f^{(2)}(0)\right] \\ &= \frac{\lambda^2}{4\pi}\frac{1}{\mu^2+4k^2} \\ &= \sigma^{(1)} \end{aligned}$$

where

$$\sigma_{\mathrm{sa}}{}^{(1)} = \frac{\lambda^2}{4\pi}\frac{1}{\mu^2+4k^2}$$

We note that the differential cross section is

$$\begin{aligned} \frac{d\sigma}{d\Omega} &= |f|^2 \\ &= |f^{(1)} + \operatorname{Re}\left[f^{(2)}\right] + \operatorname{Im}\left[f^{(2)}\right|^2 \\ &= \left(f^{(1)} + \operatorname{Re}\left[f^{(2)}\right]\right)^2 + \left(\operatorname{Im}\left[f^{(2)}\right]\right)^2 \\ f^{(1)} &= -\frac{\lambda\mu}{4\pi}\frac{1}{\mu^2+q^2} \\ \operatorname{Re}\left[f^{(2)}\right] &= \frac{1}{32\pi^2}\frac{\lambda^2\mu^2}{q}\frac{1}{\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}} \\ &\quad \operatorname{Arctan}\left[\frac{q\mu\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{\mu^4+k^2\left(q^2+4\mu^2\right)-\frac{q^2\mu^2}{4}}\right] \end{aligned}$$

and

$$\operatorname{Im}\left[f^{22}\right] = \frac{1}{32\pi^2}\frac{\lambda^2\mu^2}{q}\frac{\ln\left(\frac{\sqrt{\mu^4+k^2(q^2+4\mu)}+kq}{\sqrt{\mu^4+k^2(q^2+4\mu^2)}-kq}\right)}{\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}$$

So that, we have the final form

$$\begin{aligned}
f =& f^{(1)} + f^{(2)} \\
=& -\frac{\lambda\mu}{4\pi}\frac{1}{\mu^2+q^2} \\
&+\frac{1}{32\pi^2}\frac{\lambda^2\mu^2}{q}\left[\frac{1}{\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}\operatorname{Arctan}\left[\frac{q\mu\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}{\mu^4+k^2\left(q^2+4\mu^2\right)-\frac{q^2\mu^2}{4}}\right]\right. \\
&\left.+i\frac{\ln\left(\frac{\sqrt{\mu^4+k^2(q^2+4\mu^2)}+kq}{\sqrt{\mu^4+k^2(q^2+4\mu^2)}-kq}\right)}{\sqrt{\mu^4+k^2\left(q^2+4\mu^2\right)}}\right]
\end{aligned}$$

7. Validity of the Born approximation (another approach); direct calculation The validity for the Born approximation is satisfied under the condition

$$\left|\frac{m}{2\pi\hbar^2}\int d\mathbf{r}\frac{e^\star}{r}V(r)\right| \ll 1$$

$$\left|\frac{m}{2\pi\hbar^2}\int d\mathbf{r}\frac{e^*}{r}\frac{V_0}{\mu r}e^{-\mu p}\right| \ll 1$$

We note that

$$\begin{aligned}
\int d\mathbf{r}\frac{e^{dr}}{r}\frac{V_0}{\mu r}e^{-\mu r} &= 4\pi\int_0^\pi dr r^2\frac{e^{jr}}{r}\frac{V_0}{\mu r}e^{-\mu r} \\
&= 4\pi\frac{V_0}{\mu}\int_0^\pi dr e^{(ik-\mu)r} \\
&= 4\pi\frac{V_0}{\mu}\frac{1}{\mu-ik} \\
\left|\frac{m}{2\pi\hbar^2}4\pi\frac{V_0}{\mu}\frac{1}{\mu-ik}\right| &= \frac{2m}{\hbar^2}\frac{V_0}{\mu}\frac{1}{\sqrt{\mu^2+k^2}} \ll 1
\end{aligned}$$

(a) Low energy limit ($k \ll \mu$)

$$\frac{2m}{\hbar^2}\frac{V_0}{\mu^2} \ll 1 \quad |\lambda| \ll 4\pi$$

(b) High energy limit ($k \gg \mu$)

$$\frac{2m}{h^2}\frac{V_0}{\mu k} \ll 1 \quad |\lambda| \ll 4\pi\frac{k}{\mu}$$

The inequality becomes easier to satisfy to satisfy as k increases, implying that the Born approximation becomes much accurate at high incident particle energy. ((Note)) Scattering length a The scattering length a is defined by

$$a = \frac{\beta}{\mu},$$

as will be derived later, with $\beta = \frac{4\pi}{\lambda} = \frac{2mV_0}{\hbar^2\mu^2}$. The condition for the scattering for the high energy limit (as described above) is

$$|\lambda| \ll 4\pi\frac{k}{\mu}$$

This condition can be rewritten as

$$ka > 1$$

The de Broglie wavelength Λ is related as the wave number as

$$\Lambda = \frac{2\pi}{k}$$

So that, the condition is also expressed as

$$a \geqslant \frac{\Lambda}{2\pi}.$$

The de Broglie wavelength Λ is much shorter than the scattering length a. 8. Partial phase shift

The Born approximation is a good approximation for the high energy incident particle, but is not so for the low energy incident particle.

$$f(E,q) = \sum_{i=0}^{\pi}(2l+1)f_i(E)P(\cos\theta)$$

$$f_i(E) = \frac{1}{2}\int_{-1}^{1} dz P_i(z) f(E,q)$$

$$z = \cos\theta$$

$1 - \cos\theta = \frac{q^2}{2k^2} = \frac{\hbar^2 q^2}{4mE}$,

$$\begin{aligned} f^{(1)} &= -\frac{\lambda\mu}{4\pi}\frac{1}{\mu^2+q^2} \\ &= -\frac{\lambda\mu}{4\pi}\frac{1}{\mu^2+2k^2(1-\cos\theta)} \\ &= -\frac{\lambda\mu}{4\pi}\frac{1}{\mu^2+2k^2(1-z)} \\ &= -\frac{\lambda\mu}{4\pi}\frac{1}{\mu^2+\frac{4mE}{\hbar^2}(1-z)} \end{aligned}$$

For $l = 0$ (s-wave)

$$\begin{aligned} f_0(E) &= \frac{1}{2}\int_{-1}^{1} dz f^{(1)}(E,q) \\ &= \frac{-\lambda\mu}{8\pi}\int_{-1}^{1} dz \frac{1}{\mu^2+\frac{4mE}{\hbar^2}(1-z)} \\ &= \frac{-\lambda\mu}{8\pi}\frac{\hbar^2}{4mE}\ln\left[\mu^2+\frac{4mE}{\hbar^2}(1-z)\right]\Big|_{-1}^{1} \\ &= \frac{\lambda\mu\hbar^2}{32\pi mE}\ln\left[\frac{\mu^2}{\mu^2+\frac{8mE}{\hbar^2}}\right] \\ &= \frac{\gamma}{4E}\ln\left[\frac{\mu^2}{\mu^2+\frac{8mE}{\hbar^2}}\right] \end{aligned}$$

where

$$\gamma = \frac{V_0}{\mu}$$

which has the expected branch point at $E = -\frac{\hbar^2\mu^2}{8m}$. Thus, while the scattering amplitude $f^{(1)}$ has no branch points, the partial amplitude does. This illustrates (which is, in fact, true of all partial waves) that the left-hand branch cut is introduced into the partial-wave amplitude in the process of making the projection (Taylor). 9. Phase shift analysis using the Heine expansion

Using the Heine expansion,

$$\frac{1}{x-\cos\theta} = \sum_{l=0}^{\pi}(2l+1)Q_l(x)P_i(\cos\theta)$$

we get the expansion of $f^{(1)}$ as

$$f^{(1)} = -\frac{2mV_0}{\hbar^2\mu}\frac{1}{\mu^2+4k^2\sin^2\frac{\theta}{2}} = -\frac{2mV_0}{\hbar^2\mu}\frac{1}{\mu^2+2k^2(1-\cos\theta)} = -\frac{mV_0}{\hbar^2\mu k^2}\frac{1}{1+\frac{\mu^2}{2k^2}-\cos\theta} \equiv -\frac{mV_0}{\hbar^2\mu k^2}\frac{1}{x-\cos\theta};$$

$x := 1 + \frac{\mu^2}{2k^2}$

$$f^{(1)} = -\frac{mV_0}{\hbar^2\mu k^2}\frac{1}{x-\cos\theta} \qquad = -\frac{mV_0}{\hbar^2\mu k^2}\sum_{l=0}^{\infty}(2l+1)Q_l(x)P_l(\cos\theta) = \sum_{l=0}^{\infty}(2l+1)f_l(k)P_l(\cos\theta)$$

$$f_l(k) = -\frac{mV_0}{\hbar^2\mu k^2}Q_l(x)$$

Solution by GKKG

(ниже компактное решение, над которым нужно думать много, вообще)
For the Yukawa potential,

$$f^{(1)}(q) \equiv f^B(q) = -\frac{2m\alpha R^2}{\hbar^2\left(1+q^2R^2\right)}, \quad \mathbf{q} = \mathbf{k} - \mathbf{k}_0 \tag{1}$$

and according to Eq. (2) from Problem 13.10, in the 2nd order of perturbation theory we have

$$f^{(2)}\left(\mathbf{k}_0, \mathbf{k}_0\right) = \frac{2m^2\alpha^2R^4}{\pi^2\hbar^4}\int \frac{d^3\kappa}{\left[1+R^2\left(\mathbf{k}_0-\boldsymbol{\kappa}\right)^2\right]\left[1+R^2(\mathbf{k}-\boldsymbol{\kappa})^2\right]\left(\kappa^2-k_0^2-i\varepsilon\right)} \tag{2}$$

Using relation (with $k^2 = k_0^2$)

$$\frac{1}{1+R^2\left(\mathbf{k}_0-\boldsymbol{\kappa}\right)^2}\cdot\frac{1}{1+R^2(\mathbf{k}-\boldsymbol{\kappa})^2} = \int_0^1 \frac{d\xi}{\left\{1+k^2R^2+\kappa^2R^2-2R^2\kappa\left[\mathbf{k}_0\xi+(1-\xi)\mathbf{k}\right]\right\}^2}$$

in Eq. (2) it is easy to perform integration over the angles $\left(d^3\kappa = \kappa^2 d\kappa d\Omega\right)$, and obtain

$$f^{(2)}\left(\mathbf{k}_0, \mathbf{k}_0\right) = \frac{4m^2\alpha^2R^4}{\pi\hbar^4}\int_0^1\int_{-\infty}^{\infty}\frac{\kappa^2}{\kappa^2-k^2-i\varepsilon}K(k,q,\kappa,\xi)d\kappa d\xi \tag{3}$$

where

$$K = \left\{\left(1+k^2R^2+\kappa^2R^2\right)^2 - 4\kappa^2R^4\left[k^2-\xi(1-\xi)q^2\right]\right\}^{-1} \tag{4}$$

Taking into account the parity of the function under the integral, the integration over the variable κ may be extended to the entire axis.

Equation (4) for K could be transformed to

$$K = \frac{1}{(\kappa R-\alpha_1)(\kappa R-\alpha_2)(\kappa R-\alpha_3)(\kappa R-\alpha_4)}$$

This function, considered as a function of the complex variable κ, is (as is the entire expression under the integral in Eq. (3)) meromorphic, and has only simple poles at the points $\kappa_n = \alpha_n/R$. We have

$$\alpha_1 \equiv \alpha = \sqrt{k^2R^2-\xi(1-\xi)q^2R^2} + i\sqrt{1+\xi(1-\xi)q^2R^2}$$

(since $0 \le \xi \le 1$ and $q^2 \le 4k^2$, then both radicals are real and positive) and $\alpha_2 = \alpha^*$, $\alpha_3 = -\alpha, \alpha_4 = -\alpha^*$.

Now, in Eq. (3), it is easy to perform an integration over κ using residues, closing the integration contour into the upper half-plane of the complex variable κ.

The positions of the poles are shown in Fig. 13.2. A contribution to the integral in Eq. (3) from the pole at the point $\kappa = k + i\varepsilon$ is

$$I_1(\xi) = \frac{i\pi k}{1+4k^2R^2+4k^2q^2R^4\xi(1-\xi)}$$

This part of the integral is imaginary. The contributions from the poles located at the points $\kappa = \alpha_1/R$ and $\kappa = \alpha_4/R$ are real and equal to

$$I_2(\xi) = \frac{\pi}{2R\sqrt{1+q^2R^2\xi(1-\xi)}\left[1+4k^2R^2\left(1+q^2R^2\xi(1-\xi)\right)\right]}$$

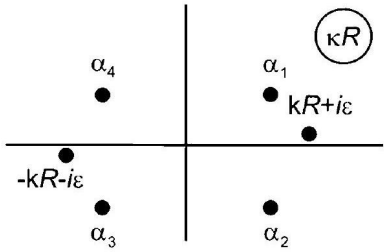

Fig. 13.2
Finally, performing an integration over the variable ξ in

$$f^{(2)}(\mathbf{k},\mathbf{k}_0)=\frac{4m^2\alpha^2R^4}{\pi\hbar^4}\int\limits_0^1\left[I_1(\xi)+I_2(\xi)\right]d\xi$$

we obtain the final expression for the scattering amplitude of the Yukawa potential in second-order perturbation theory:

$$f^{(2)}(\mathbf{k},\mathbf{k}_0)=\frac{2m^2\alpha^2R^3}{\hbar^4}\left\{\frac{2\arctan(qR/2\sqrt{\Delta(k,q)})}{qR\sqrt{\Delta(k,q)}}+\frac{i}{qR\sqrt{\Delta(k,q)}}\ln\frac{\sqrt{\Delta(k,q)}+kqR^2}{\sqrt{\Delta(k,q)}-kqR^2}\right\}\tag{5}$$

where

$$\Delta(k,q)=1+k^2R^2\left(4+q^2R^2\right)$$

Let us discuss these results. We first note that calculating the imaginary part of the amplitude in second-order perturbation theory for $\theta=0$ (here also $q=0$) and using the optical theorem, Eq. (XIII.11), we can find the total scattering cross-section in the Born approximation. The result obtained coincides, of course, with the calculation of cross-section by the equation $\sigma_B=\int\left(f^B\right)^2d\Omega$. See Problem 13.1 a.

It is interesting to compare $\operatorname{Im}f^{(2)}$ and $\operatorname{Re}f^{(2)}$ with each other and with the amplitude of the first approximation for different values of the energy and the scattering angle. In the case of slow particles, when $kR\ll1$, according to Eqs. (5) and (1), we obtain

$$\frac{\operatorname{Im}f^{(2)}}{\operatorname{Re}f^{(2)}}\approx2kR\ll1,\quad\left|\frac{f^{(2)}}{f^{(1)}}\right|\approx\frac{m\alpha R}{\hbar^2}$$

Taking into account the optical theorem, we can conclude that the smallness of the ratio $\operatorname{Im}f^{(2)}/\operatorname{Re}f^{(2)}$ (for $kR\ll1$) is a general result for fairly arbitrary short-range potentials. The smallness of $\left|f^{(2)}/f^{(1)}\right|$ assumes fulfilment of the condition $m\alpha R/\hbar^2\ll1$, which ensures applicability of the Born approximation (see Eq. (XIII.7); for the Yukawa potential, $U_0\sim\alpha/R$). These estimates are also useful for particles of "moderate" energy, $kR\sim1$, but in this case, $\operatorname{Im}f^{(2)}$ and $\operatorname{Re}f^{(2)}$ are quantities of the same order for an arbitrary scattering angle.

Let us consider the case of fast particles, $kR\gg1$. For small scattering angles, when $qR\lesssim1$ (this domain provides a dominant contribution into the total scattering cross-section), we find

$$\frac{\operatorname{Im}f^{(2)}}{\operatorname{Re}f^{(2)}}\sim kR\gg1,\quad\left|\frac{f^{(2)}}{f^{(1)}}\right|\sim\frac{m\alpha}{\hbar^2k}$$

The smallness of $\operatorname{Re}f^{(2)}$ in comparison to $\operatorname{Im}f^{(2)}$ is a general result (see Problem 13.14), while the condition $\left|f^{(2)}/f^{(1)}\right|\ll1$, as expected, assumes that the applicability condition of the Born approximation for fast particles is satisfied, namely the second of conditions (XIII.7). The obtained estimates remain valid for larger value of qR. (Here, some specific properties of the Yukawa potential manifest themselves, in particular, a power-law decrease of $\tilde{U}(q)$ for $q\to\infty$; compare to result of the previous problem.)

Sakurai-6.5 Yukawa scattering

A spinless particle is scattered by a weak Yukawa potential

$$V=\frac{V_0e^{-\mu r}}{\mu r}$$

where $\mu>0$ but V_0 can be positive or negative. It was shown in the text that the first-order Born amplitude is given by

$$f^{(1)}(\theta)=-\frac{2mV_0}{\hbar^2\mu}\frac{1}{[2k^2(1-\cos\theta)+\mu^2]}.$$

(a) Using $f^{(1)}(\theta)$ and assuming $|\delta_l| \ll 1$, obtain an expression for δ_l in terms of a Legendre function of the second kind,

$$Q_l(\zeta) = \frac{1}{2}\int_{-1}^{1} \frac{P_l(\zeta')}{\zeta - \zeta'} d\zeta'$$

(b) Use the expansion formula

$$Q_l(\zeta) = \frac{l!}{1\cdot 3\cdot 5\cdots(2l+1)} \times \left\{ \frac{1}{\zeta^{l+1}} + \frac{(l+1)(l+2)}{2(2l+3)}\frac{1}{\zeta^{l+3}} + \frac{(l+1)(l+2)(l+3)(l+4)}{2\cdot 4\cdot(2l+3)(2l+5)}\frac{1}{\zeta^{l+5}} + \cdots \right\} \quad (|\zeta| > 1)$$

to prove each assertion. (i) δ_l is negative (positive) when the potential is repulsive (attractive). (ii) When the de Broglie wavelength is much longer than the range of the potential, δ_l is proportional to k^{2l+1}. Find the proportionality constant.

Solution by Suzuki

Yukawa potential

$$V(r) = \frac{V_0}{\mu\mu} e^{-\mu r}.$$

The first Born approximation

$$f^{(1)}(\theta) = -\frac{2mV_0}{\hbar^2\mu}\frac{1}{q^2+\mu^2},$$

where

$$\boldsymbol{q} = \boldsymbol{k} - \boldsymbol{k}'$$

$$q^2 = k^2 + k'^2 - 2kk'\cos\theta = 2k^2(1-\cos\theta)$$

where the angle between the vctors $\boldsymbol{k}$ and $\boldsymbol{k}'$ is $\theta.k' = k$ (b)
The scattering amplitude $f(\theta)$ can be expanded in terms of the phase shift δ_l as

$$f(\theta) = \sum_{l'=0}^{\infty} (2l'+1)\, f_{l'}(k) P_{l'}(\cos\theta)$$

Note that

$$I = \int_{-1}^{1} d(\cos\theta) P_l(\cos\theta) f(\theta) = \int_{-1}^{1} d(\cos\theta) \sum_{l'=0}^{\infty} (2l'+1)\, f_{l'}(k) P_l(\cos\theta) P_{l'}(\cos\theta)$$

with the use of formula $\int_{-1}^{1} d(\cos\theta) P_l(\cos\theta) P_{l'}(\cos\theta) = \frac{2}{2l+1}\delta_{l,l'}$.

Then, we get

$$I = \sum_{l=0}^{\infty} (2l'+1)\, f_{l'}(k) \frac{2}{2l+1}\delta_{l,l'} \quad = (2l+1) f_l(k) \frac{2}{2l+1} = 2f_l(k)$$

Thus, we have

$$\begin{aligned} f_l(k) &= \frac{1}{2}\int_{-1}^{1} d(\cos\theta) P_l(\cos\theta) f(\theta) \\ &= \frac{1}{2}\int_{-1}^{1} d(\cos\theta) P_l(\cos\theta) \left(-\frac{2mV_0}{\hbar^2\mu}\right) \frac{1}{2k^2(1-\cos\theta)+\mu^2} \\ &= -\frac{mV_0}{\mu\hbar^2k^2}\frac{1}{2}\int_{-1}^{1} dz \frac{P_l(z)}{1+\frac{\mu^2}{2k^2}-z} \\ &= -\frac{mV_0}{\mu\hbar^2k^2} Q_l\left(1+\frac{\mu^2}{2k^2}\right) \end{aligned}$$

where $Q_l(\varsigma)$ is the Legendre function of the second kind and is defined by

$$Q_l(x) = \frac{1}{2}\int_{-1}^{1} dz \frac{P_l(z)}{x-z}$$

with

$$x = 1 + \frac{\mu^2}{2k^2}.$$

We make a plot of $Q_l(x)$ as a function of x for $x > 1$, where l is changed as a parameter. (numerical integration is done by using the Mathematica).

(b) (i) As is shown in the above figure, we have $Q_l(x) > 0$ for $x > 1$.

$$x = 1 + \frac{\mu^2}{2k^2}$$

(ii) de Broglie wave length $\lambda = \frac{2\pi}{k} \gg \frac{1}{\mu}$ (the range of potential) or

$$\begin{aligned}
\frac{\mu}{k} &\gg 1 \\
f_l(k) &= -\frac{mV_0}{\mu\hbar^2k^2} Q_l\left(1 + \frac{\mu^2}{2k^2}\right) \\
&\approx -\frac{mV_0}{\mu\hbar^2k^2} Q_l\left(\frac{\mu^2}{2k^2}\right) \\
&= -\frac{mV_0}{\mu\hbar^2k^2} \frac{l!}{(2l+1)!!}\left(\frac{2k^2}{\mu^2}\right)^{l+1} \\
&= -\frac{mV_0}{\hbar^2\mu^{2l+3}} \frac{2^{l+1}l!}{(2l+1)!!} k^{2l+1}
\end{aligned}$$

or

$$f_l(k) = -\frac{mV_0}{\hbar^2\mu^2} \frac{2^{l+1}l!}{(2l+1)!!}\left(\frac{k}{\mu}\right)^{2l+1} = -\frac{\lambda}{8\pi} \frac{2^{l+1}l!}{(2l+1)!!}\left(\frac{k}{\mu}\right)^{2l+1}$$

11. The effective range: Phase shift (Capri)

The phase shift for $l = 0$ (s-wave) is given by 44

$$\begin{aligned}
\sin\delta_0 &= -\frac{2m}{\hbar^2} k \int_0^\infty dr r^2 V(r) \left[\frac{\sin(kr)}{kr}\right]^2 \\
&= -\frac{2m}{\hbar^2} k \int_0^\infty dr r^2 \frac{V_0 e^{-\mu}}{\mu r} \left[\frac{\sin(kr)}{kr}\right]^2 \\
&= -\frac{2m}{\hbar^2} \frac{kV_0}{\mu} \int_0^\infty dr^2 \frac{e^{-\mu}}{r} \left[\frac{\sin(kr)}{kr}\right]^2 \\
&= -\frac{\lambda}{16\pi} \frac{\mu}{k} \ln\left(1 + \frac{4k^2}{\mu^2}\right) \\
&= -\frac{\beta}{4} \frac{\mu}{k} \ln\left(1 + \frac{4k^2}{\mu^2}\right)
\end{aligned}$$

where

$$\lambda = 4\pi \frac{2mV_0}{\hbar^2\mu^2}, \quad \beta = \frac{2mV_0}{\hbar^2\mu^2} = \frac{\lambda}{4\pi}$$

and

$$\int_0^\pi dr r^2 \frac{e^{-\mu r}}{r} \left[\frac{\sin(kr)}{kr}\right]^2 = \frac{1}{4k^2} \ln\left(1 + \frac{4k^2}{\mu^2}\right)$$

Thus, we get

$$\begin{aligned}\sin\delta_0 &= -\frac{\beta}{4}\frac{\mu}{k}\ln\left(1+\frac{4k^2}{\mu^2}\right)\\ &= -\frac{\beta}{4}\frac{\mu}{k}\left(\frac{4k^2}{\mu^2}-\frac{8k^4}{\mu^4}\right)\\ &= -\beta\frac{k}{\mu}\left(1-\frac{2k^2}{\mu^2}\right)\end{aligned}$$

Note that

$$k\cot\delta_0 = k\frac{\cos\delta_0}{\sin\delta_0}$$

and

$$\cos\delta_0 = \sqrt{1-\sin^2\delta_0} = \sqrt{1-\frac{\beta^2k^2}{\mu^2}\left(1-\frac{2k^2}{\mu^2}\right)^2} \simeq \sqrt{1-\frac{\beta^2k^2}{\mu^2}} \approx 1-\frac{\beta^2k^2}{2\mu^2}$$

$$k\cot\delta_0 = k\frac{\cos\delta_0}{\sin\delta_0} = -k\frac{\beta^2k^2}{2\mu^2} \simeq -\frac{\mu}{\beta}\left(1-\frac{\beta^2k^2}{2\mu^2}\right)\left(1+\frac{2k^2}{\mu^2}\right) = -\frac{\mu}{\beta}+\frac{1}{2}k^2\left(\beta-\frac{4}{\beta}\right)\frac{1}{\mu} = -\frac{1}{a}+\frac{1}{2}r_0k^2$$

where a is the scattering length and r_0 is the effective range.

$$a = \frac{\beta}{\mu} = \frac{\lambda}{4\pi\mu}, r_0 = \frac{1}{\mu}\left(\beta-\frac{4}{\beta}\right)$$

Note that our result of r_0 is a little different from that reported by Capri. The parameter β is dimensionless. For the low energy limit, the condition for the Born approximation is $\lambda \ll 4\pi$,

leading to $a \ll \frac{1}{\mu}$. For the high energy limit, the condition for the Born approximation is $|\lambda| \ll 4\pi\frac{k}{\mu}$, leading to $a \ll \frac{1}{\mu}\frac{k}{\mu}$.

We note that the total cross section (the first order Born approximation) is given by

$$\sigma^{(1)} = \frac{\lambda^2}{4\pi}\frac{1}{\mu^2+4k^2}$$

In the limit of $k \to 0$, we have

$$\sigma^{(1)}(k=0) = \frac{1}{4\pi}\frac{\lambda^2}{\mu^2} = 4\pi a^2$$

using the scattering length a. Thus, the scattering length determines the low-energy scattering cross section. We see that

$$f_0(k) = S_0(k)-1 \quad = e^{2\delta_0(k)}-1 = \frac{2i}{\cot\delta_0(k)-1} \quad = \frac{2i\sin\delta_0(k)}{\cos\delta_0(k)-\sin\delta_0(k)} = \frac{2i\sin\delta_0(k)}{1-\sin\delta_0(k)} \quad = \frac{2ka}{i-ka}$$

where $\sin[\delta_0(k)] = -k\frac{\beta}{\mu} = -ka$. Thus, $f_0(k)$ has a single pole at $k = \frac{i}{a}$. This pole corresponds to a bound state of energy $E_b = -\frac{\hbar^2\kappa^2}{2m}$ and $\kappa = \frac{1}{a}$. Since the bound state is of the form $\exp(-\kappa r)/r$, its extension is a. ((Mathematica)) Calculation

$$\begin{aligned}&\text{g4} \;=\; \frac{1}{\mu}\frac{e^{-\mu r}}{k^2 r}\sin[kr]^2;\\ &\text{s1} \;=\; \text{Integrate}\,[g4,\{r,0,\infty\},\\ &\text{Assumptions}\;\to\{\mu>0,k>0\}]\\ &\left.\frac{\log\left[1+\frac{4k^2}{\mu^2}\right]}{4k^2\mu}\right|\end{aligned}$$

12. Optical theorem (Capri)

The scattering amplitude for low energy s-waves may be written as

$$\begin{aligned} f_0(k) &= \frac{e^{2i\delta_0}-1}{2ik} \\ &= \frac{1}{2ik}e^{i\delta_0}\left(e^{i\delta_0}-e^{-i\delta_0}\right) \\ &= \frac{1}{2ik}2i\sin\delta_0 e^{i\delta_0} \\ &= \frac{\sin\delta_0}{ke^{-i\delta_0}} \\ &= \frac{\sin\delta_0}{k\cos\delta_0 - ik\sin\delta_0} \\ &= \frac{1}{k\cot\delta_0 - ik} \end{aligned}$$

We note that

$$k\cot\delta_0 = -\frac{1}{a}+\frac{1}{2}r_0k^2,$$

where a is the scattering length and r_0 is the effective range. Thus, we get

$$\begin{aligned} f_0(k) &= \frac{1}{-\frac{1}{a}+\frac{1}{2}r_0k^2-ik} \\ &= -\frac{a}{1+iak-\frac{1}{2}r_0ak^2} \end{aligned}$$

The optical theorem states that the total cross-section σ is given by

$$\begin{aligned} \sigma &= \frac{4\pi}{k}\operatorname{Im}\left[f_0(k)\right] \\ &= \frac{4\pi}{k}\operatorname{Im}\left[\frac{\sin\delta_0}{ke^{-i\delta_0}}\right] \\ &= \frac{4\pi}{k}\frac{1}{k}\sin^2\delta_0 \end{aligned}$$

On the other hand, the total cross section is given by

$$\sigma = \int\frac{d\sigma}{d\Omega}d\Omega \quad = \int\left|f_0(k)\right|^2 d\Omega = 4\pi\left|f_0(k)\right|^2 \quad = 4\pi\left|\frac{\sin\delta_0}{ke^{-i\delta_0}}\right|^2 = \frac{4\pi}{k^2}\sin^2\delta_0$$

So, in this, the optical theorem is proved. We now use the expression of

$$f_0(k) = -\frac{a}{1+iak-\frac{1}{2}r_0ak^2}.$$

Thus, we have

$$\sigma = \frac{4\pi}{k}\operatorname{Im}\left[f_0(k)\right] \quad = \frac{4\pi}{k}\frac{a^2k}{\left(1-\frac{1}{2}r_0ak^2\right)^2+a^2k^2} = \frac{4\pi a^2}{\left(1-\frac{1}{2}r_0ak^2\right)^2+a^2k^2}$$

On the other hands by direct calculation, we find that

$$\sigma = \int\frac{d\sigma}{d\Omega}d\Omega \quad = \int\left|f_0(k)\right|^2 d\Omega = 4\pi\left|f_0(k)\right|^2 \quad = \frac{4\pi a^2}{\left(1-\frac{1}{2}r_0ak^2\right)^2+a^2k^2}$$

Thus, in this case, we also verify the optical theorem.

GKKG.13.13 2nd order scattering on e^{-r^2/R^2}

In the 2nd order of perturbation theory, find the scattering amplitude in the potential $U(r) = U_0e^{-r^2/R^2}$ for large momenta transferred, $qR \gg 1$. Compare the real and imaginary parts of $f^{(2)}$ with each other and with the Born amplitude.

Solution

The Fourier component of the potential is

$$\tilde{U}(q) = \int U_0 \exp\left\{-i\mathbf{q}\cdot\mathbf{r} - \frac{r^2}{R^2}\right\} dV = \pi^{3/2} U_0 R^3 e^{-q^2R^2/4}$$

and according to Eq. (2) from Problem 13.10, the scattering amplitude in the 2nd order of perturbation theory is described by the expression:

$$f^{(2)}(\mathbf{k},\mathbf{k}_0) = \frac{m^2}{8\pi^4\hbar^4}\int \frac{\tilde{U}(\mathbf{k}-\kappa)\tilde{U}(\boldsymbol{\kappa}-\mathbf{k}_0)}{\kappa^2 - k_0^2 - i\varepsilon} d^3\kappa = \frac{m^2U_0^2R^6}{8\pi\hbar^4} e^{-q^2R^2/4} \int \frac{\exp\left\{-\frac{1}{2}R^2\left[\kappa - \frac{1}{2}(\mathbf{k}+\mathbf{k}_0)\right]^2\right\}}{\kappa^2 - k_0^2 - i\varepsilon} d^3\kappa \tag{1}$$

The dominant role in the integral comes from the region of values $\boldsymbol{\kappa}$, where $|\boldsymbol{\kappa}$ - $(\mathbf{k}+\mathbf{k}_0)/2|R \leq 1$ (outside of this domain, the integrand is exponentially small). For large energies, $kR \gg 1$, and large momenta transfered, $qR \gg 1$, in this domain the denominator of the integrand in Eq. (1) changes only slightly, and it can be factored outside the integral sign at the point $\boldsymbol{\kappa} = \mathbf{k} + \mathbf{k}_0/2$. Then, a simple integration gives (for $k^2 = k_0^2$):

$$f^{(2)}(\mathbf{k},\mathbf{k}_0) \approx \mathrm{Re}\, f^{(2)} \approx -\frac{\sqrt{2\pi}m^2U_0^2R^3}{\hbar^4 q^2} \exp\left\{-\frac{1}{8}q^2R^2\right\} \tag{2}$$

In this approximation, amplitude $f^{(2)}$ is a real function. Its imaginary part according to Eq. (1) could be easily found in general if we note that

$$\mathrm{Im}\,\frac{1}{\kappa^2 - k_0^2 - i\varepsilon} = \pi\delta\left(\kappa^2 - k_0^2\right)$$

(compare to Problem 13.11). Writing $d^3\kappa = \kappa d\kappa^2 d\Omega/2$ and integrating first over κ^2 and then over the angles (choosing the polar axis along the vector $\mathbf{k}+\mathbf{k}_0$), we find:

$$\begin{aligned}\mathrm{Im}\, f^{(2)} &= \left(\frac{mU_0R^3}{4\hbar^2}\right)^2 \iint \kappa\delta\left(\kappa^2 - k^2\right) \exp\left\{-\kappa^2R^2 + \frac{1}{2}\boldsymbol{\kappa}\cdot(\mathbf{k}+\mathbf{k}_0)R^2\right\} d\kappa^2 d\Omega = \\ &= \frac{\pi m^2U_0^2R^4}{2\hbar^4|\mathbf{k}+\mathbf{k}_0|} \sinh\left(\frac{1}{2}|\mathbf{k}+\mathbf{k}_0|kR^2\right) e^{-k^2R^2}\end{aligned} \tag{3}$$

(Note that $|\mathbf{k}+\mathbf{k}_0| = \left(4k^2 - q^2\right)^{1/2}$.)
For large energies, $kR \gg 1$, and small scattering angles, when $qR \leq 1$, the scattering amplitude of the 2nd order is determined mainly by the imaginary part of Eq. (3), as is seen from Problem 13.14 (Eq. (2) for $qR \leq 1$ is not applicable). For large changes of momentum, on the contrary, the integral is dominated by the real part of the scattering amplitude, $f^{(2)}$. Moreover, since

$$\mathrm{Re}\, f^{(2)} \propto e^{-q^2R^2/8}, \text{ while } f^{(1)} = f^a \propto \tilde{U}(q) \propto e^{-q^2R^2/4}$$

then for the values of qR large enough, $\left|\mathrm{Re}\, f^{(2)}\right| \gg \left|f^B\right|$. This signal a break-down of the Born approximation, independently of the parameter U_0 that characterizes the interaction strength. [320] Let us emphasize that the discovered properties are characteristic for potentials with an exponential decrease of the Fourier component $\tilde{U}(q) \propto \exp\{-\alpha q^n\}$ with $n \geq 1$ for $q \to \infty$ (compare to Problem 8.29, and also to the case of a power-law decrease of $\tilde{U}(q)$, considered in the previous problem).
In conclusion, let us note that using Eq. (3) and the optical theorem (XIII.11), we can find the scattering cross-section in the Born approximation; the result, of course, coincides with its calculation by the equation $\sigma_B = \int \left(f^B\right)^2 d\Omega$ (see Problem 13.1 f).
[320] It corresponds to the large values of qR (the contribution of which to the total cross-section is small).

17.3.10 Problems about scattering in Born approximation 3

GKKG.13.14 Formula for 2nd order and low momenta transfered

Prove that the scattering amplitude of second-order perturbation theory for large energies, $kR \gg 1$, but for relatively low momenta transfered, $qR \lesssim 1$, is described by (R is the radius of the potential)

$$f^{(2)} \approx i\frac{m^2}{4\pi\hbar^4 k} \iint \left[\int_{-\infty}^{\infty} U(\boldsymbol{\rho}, z)dz\right]^2 \exp\{-i\mathbf{q}_\perp\cdot\boldsymbol{\rho}\}\, d^2\rho$$

Here $|\mathbf{q}_\perp| \approx q$, where $\mathbf{q}_\perp$ is the component of $\mathbf{q}$ perpendicular to the initial momentum $\mathbf{k}_0$ (directed along the axis z).

Apply this result to the potential $U(r) = U_0 e^{-r^2/R^2}$, and compare to Problem 13.13.

Solution

In the 2nd order of perturbation theory, the scattering amplitude is given by

$$f^{(2)}(\mathbf{k}, \mathbf{k}_0) = \frac{m^2}{8\pi^4\hbar^4} \int \frac{\tilde{U}(\mathbf{k}-\boldsymbol{\kappa})\tilde{U}(\boldsymbol{\kappa}-\mathbf{k}_0)}{\kappa^2 - k_0^2 - i\varepsilon} d^3\kappa \tag{1}$$

See Problem 13.10. For a large energy, $kR \gg 1$, and a small scattering angle, $qR \leq 1$, the vector $\boldsymbol{\kappa}$, as well as $\mathbf{k}$, is "close" to $\mathbf{k}_0$. Let us write these vectors in the form:

$$\mathbf{k} = \mathbf{k}_0 + \mathbf{q} = k_\parallel \mathbf{n}_0 + \mathbf{q}_\perp, \quad \kappa = \kappa_\parallel \mathbf{n}_0 + \boldsymbol{\kappa}_\perp$$

where $\mathbf{n}_0 = \mathbf{k}_0/k_0$, while $\mathbf{q}_\perp, \boldsymbol{\kappa}_\perp \perp \mathbf{n}_0$. See that $|\mathbf{q}_\perp| \approx q$ and $k_\parallel = k_0 + q_\parallel, q_\parallel \approx -q^2/2k_0$. Compare to Problem 13.2. After substitution of the explicit expression for Fourier components of the potential (in terms of $U(\mathbf{r})$), the integral in Eq. (1) takes the form:

$$\int \frac{U(\boldsymbol{\rho}_1, z_1) U(\boldsymbol{\rho}_2, z_2) \exp\left\{-i\left[\kappa'_\parallel (z_1 - z_2) + \boldsymbol{\kappa}_\perp \cdot (\boldsymbol{\rho}_1 - \boldsymbol{\rho}_2) + \mathbf{q}_\perp \cdot \boldsymbol{\rho}_2\right]\right\}}{2k_0\kappa'_\parallel + \left(\kappa'_\parallel\right)^2 + \kappa_\perp^2 - i\varepsilon} d^3r_1 d^3r_2 d\kappa'_\parallel d^2\kappa_\perp \tag{2}$$

Here $\boldsymbol{\kappa}'_\parallel = \boldsymbol{\kappa}_\parallel - \mathbf{k}_0$, and the term $-iq_\parallel z_2$ in the exponent is omitted, since $\left|q_\parallel z_2\right| \leq q^2 R/k_0 \ll 1$. Let us note that the terms in the perturbative expansion for the scattering amplitude (see Eq. (2) from Problem 13.10) could be interpreted as describing a number of single-particle collisions with the scattering potential, each accompanied by a momentum change for the particle being scattered. In this sense, the radiusvector $\mathbf{r}_1$ in the corresponding integral corresponds to the point of first collision, after which the particle momentum becomes equal to $\boldsymbol{\kappa}$ (after the second collision, it takes the value $\mathbf{k}$).

Closing the contour in the upper half-plane of the complex variable $\kappa'_\parallel$ in the case of $z_2 > z_1$, and in the lower half-plane for $z_2 < z_1$, we can perform the integration over $\kappa'_\parallel$ in Eq. (2) :

$$\int \frac{\exp\left\{-i\kappa'_\parallel (z_1 - z_2)\right\} d\kappa'_\parallel}{2k_0\kappa'_\parallel + \left(\kappa'_\parallel\right)^2 + \kappa_\perp^2 - i\varepsilon} = \begin{cases} \frac{i\pi}{k_0} \exp\left\{\frac{i\kappa_\perp^2}{2k_0}(z_1 - z_2)\right\}, z_2 > z_1 \\ \frac{i\pi}{k_0} \exp\left\{2ik_0 (z_1 - z_2)\right\}, z_2 < z_1 \end{cases} \tag{3}$$

If $|k_0 z_{1,2}| \sim k_0 R \gg 1$, then in the case of $z_1 > z_2$, the exponent in Eq. (3) is a fast oscillating function. This means that for the subsequent integration over $z_{1,2}$ in Eq. (2),
a contribution of such $z_{1,2}$ would be small, and can be neglected. Thus, Eq. (3) could be considered equal to

$$\frac{i\pi}{k_0} \eta(z_2 - z_1) \exp\left\{i \frac{\kappa_\perp^2 (z_1 - z_2)}{2k_0}\right\} \tag{4}$$

where $\eta(z)$ is a step function, [322] and since typically we have $z_{1,2} \lesssim R$ and $\kappa_\perp \lesssim R^{-1}$, then the exponent can be replaced by 1. The appearance of a step function in Eq. (4) has a physical explanation: for fast particles, each successive "collision" takes place for larger and larger values of z (there is no backward scattering).

Now, in Eq. (2), integration over $\boldsymbol{\kappa}_\perp$ is easily performed, and the δ-function, $\delta(\boldsymbol{\rho}_1 - \boldsymbol{\rho}_2)$, allows integration over $\boldsymbol{\rho}_2$. As a result, we obtain

$$f^{(2)} = i \frac{m^2}{2\pi\hbar^4 k_0} \int \left\{ \int_{-\infty}^{\infty} U(\boldsymbol{\rho}, z_1) dz_1 \int_{z_1}^{\infty} U(\boldsymbol{\rho}, z_2) dz_2 \right\} e^{-i\mathbf{q}_\perp \cdot \boldsymbol{\rho}} d^2\rho$$

Finally, replacing the lower limit of integration over z_2 by $-\infty$ and introducing the coefficient $1/2$, we obtain the expression given in the problem condition. Let us note that for a central potential, the scattering amplitude is purely imaginary (a real part of the amplitude $f^{(2)}$ is much smaller than the imaginary part, and in this approximation it does not appear; compare to Problems 13.12 and 13.13).

For the potential $U = U_0 \exp\left\{-r^2/R^2\right\}$, we obtain

$$f^{(2)} = i \frac{\pi m^2 U_0^2 R^4}{8\hbar^4 k_0} e^{-q^2 R^2/8}$$

which coincides with Eq. (3) from Problem 13.13 for the values $qR \lesssim 1$.

In conclusion, note that taking $q = 0$ in the equation for $f^{(2)}$ and using the optical theorem (XIII.11), we obtain the scattering cross-section in the Born approximation, which coincides with the result of Problem 13.2.

GKKG.13.15 Lippmann-Schwinger equation for special case

From the solution of the Lippmann-Schwinger equation (see Problem 13.10), find the scattering amplitude for a separable potential with the following integral kernel $U(r, r') = \lambda\chi(r)\chi^*(r')$. Find the angular distribution and total scattering cross-section.

Solution

(??? из условия не понятно, что за ядро потенциала?? пока думаю, что это просто такой потенциал, а слова лишние тут. мб изменю потом условие.)

The Lippmann-Schwinger equation (Eq. (1) from Problem 13.10) remains valid for an arbitrary interaction $\hat{U}$, if we replace the potential Fourier component $\tilde{U}(\mathbf{k} - \mathbf{k}')$ by the corresponding kernel $\tilde{U}(\mathbf{k}, \mathbf{k}')$. For the separable potential,

$$\tilde{U}(\mathbf{k}, \mathbf{k}') = \lambda g(k) g^*(k'), \quad g(k) = \int e^{-i\mathbf{k}\cdot\mathbf{r}}\chi(r)dV$$

and the Lippmann-Schwinger equation reads

$$f(\mathbf{k}, \mathbf{k}_0) = -\frac{\lambda m}{2\pi\hbar^2} g(k)\left[g^*(k_0) + \int \frac{g^*(\kappa) f(\mathbf{k}, \mathbf{k}_0)\, d^3\kappa}{2\pi^2(\kappa^2 - k_0^2 - i\varepsilon)}\right] \tag{1}$$

Denoting the integral here by $F(k_0)$, we have

$$f(\mathbf{k}, \mathbf{k}_0) = -\frac{\lambda m}{2\pi\hbar^2} g(k)\left[g^*(k_0) + F(k_0)\right]$$

and after substituting this expression back into the integral, we obtain a self-consistent equation for $F(k_0)$ and determine the scattering amplitude ($k = k_0$):

$$f(\mathbf{k}, \mathbf{k}_0) \equiv f(k) = -\frac{\lambda m}{2\pi\hbar^2}\frac{g^2(k)}{1 + K(k)}$$

where

$$K(k) = \frac{\lambda m}{4\pi^3\hbar^2}\int \frac{|q(\kappa)|^2 d^3\kappa}{\kappa^2 - k^2 - i\varepsilon}$$

One of the notable properties of the scattering amplitude is its independence from the scattering angle, [323] so that the angular distribution of the scattered particles is isotropic, and the total scattering cross-section is simply $\sigma(E) = 4\pi|f|^2$ (it is informative to prove its consistence with the optical theorem). Note that in the largeenergy limit: $\sigma(E) \propto |g(k)|^4$ for $E \to \infty$.

GKKG.13.16 Difference between repulsive potential and an attractive without bound states

For $E = 0$, compare the values of the exact and Born scattering amplitudes in a potential $U(r)$ for
a) a repulsive potential $U(r) \geq 0$;
b) an attractive potential in which there are no bound states (i.e., the potential well is "shallow" enough).

Prove that the Born approximation in case a) overestimates the scattering cross-section, while in case b), it underestimates it.

Solution

For $E = 0$, we have

$$f^B(0) = -\frac{m}{2\pi\hbar^2}\int U(r)dV, \quad f_{ex}(0) = -\frac{m}{2\pi\hbar^2}\int U(r)\psi_0(r)dV \tag{1}$$

where the wavefunction $\psi_0(r)$ satisfies the equation:

$$\psi_0(r) = 1 - \frac{m}{2\pi\hbar^2}\int U(r')\frac{1}{|\mathbf{r} - \mathbf{r}'|}\psi_0(r')\, dV' \tag{2}$$

If there are no bound states in the potential $U(r)$, then the wavefunction for $E = 0$ has no zeros, and since $\psi_0(\infty) = 1$, then $\psi_0(r) > 0$. As follows from Eq. (2), for a repulsive potential, $0 \leq \psi_0(r) \leq 1$, and according to Eq. (1), we have the inequality $\left|f^B(0)\right| > |f_{\text{ex}}(0)|$, i.e., the Born approximation overestimates the

scattering cross-section. In the analogous case of an attractive potential, $U(r) \leq 0$, we obtain $\left|f^B(0)\right| < |f_{ex}(0)|$, so the Born approximation underestimates the scattering cross-section (in the absence of bound states in the potential). Let us emphasize that the relations between the cross-sections do not assume that the potential is weak, as required for the Born approximation to be formally valid. In connection to this problem, see also Problems 13.69 and 13.70.

GKKG.13.17 Scattering by a magnetic field

In the Born approximation, obtain a scattering amplitude for scattering of a charged particle by a magnetic field, $\mathcal{H}(\mathbf{r})$. Prove gauge invariance of the result obtained.

Solution

To first order in the magnetic field, the interaction has the form:

$$\hat{V} = -\frac{e}{2mc}(\hat{\mathbf{p}} \cdot \mathbf{A} + \mathbf{A} \cdot \hat{\mathbf{p}})$$

Substituting this expression into Eq. (XIII.5) instead of $U(r)$, and replacing the wavefunction $\psi^+_{\mathbf{k}_0}$ by a plane wave, we obtain the scattering amplitude

$$f(\mathbf{k}, \mathbf{k}_0) = \frac{e}{4\pi\hbar^2 c}\int e^{-i\mathbf{k}\cdot\mathbf{r}}(\hat{\mathbf{p}} \cdot \mathbf{A} + \mathbf{A} \cdot \hat{\mathbf{p}})e^{i\mathbf{k}_0\cdot\mathbf{r}}d^3r = \frac{e}{4\pi\hbar c}(\mathbf{k} + \mathbf{k}_0) \cdot \tilde{\mathbf{A}}(\mathbf{q})$$

where $\tilde{\mathbf{A}}(\mathbf{q}) = \int e^{-i\mathbf{q}\cdot\mathbf{r}}\mathbf{A}(\mathbf{r})dV$ is the Fourier transform of the vector potential. Under a gauge transformation, a term $\boldsymbol{\nabla}\chi(\mathbf{r})$ is added to $\mathbf{A}(\mathbf{r})$, and consequently $i\mathbf{q}\tilde{\chi}(\mathbf{q})$ to $\tilde{\mathbf{A}}(\mathbf{q})$. But since $\mathbf{q} \cdot (\mathbf{k} + \mathbf{k}_0) = 0$, then the value of f and the value of the differential scattering cross-section do not change, in accordance with gauge invariance.

me. Scattering in 2D in 2nd order of Born approximation (???)

Using the 2nd order of Born approximation, find the scattering amplitude for the two-dimensional space and the total scattering cross-section of a particle on the following potentials:
a) $U(r) = \frac{\alpha}{r}e^{-r/R}$
b) $U(r) = \alpha\delta(r - R)$;
c) $U(r) = U_0 e^{-r/R}$

Solution.

(такое пока что не продумывал. идея взять любой шаблонный и попробовать решить. формулы все есть, потом попробую)

17.3.11 Problems about partial-wave analysis 1

В этом разделе задачи, которые важно прорешать для понимания рассеяния.

Б-2.12.8 Эффект Рамзауэра (!!!!)

Найти сечение рассеяния медленных частиц на сферически-симметричной прямоугольной потенциальной яме. Определить, при каких соотношениях между глубиной V_0 и радиусом ямы a полное сечение намного превышает геометрическое значение πa^2 (резонансное рассеяние) и, наоборот, обращается в ноль (эффект Рамзауэра).
Дополнительный вопрос: а что происходит с быстрыми частицами?

Solution. по Киселеву

(это нужно хорошо продумать!!!)

Потенциал ямы есть $U(r) = \begin{cases} -U_0, & r < a_0 \\ 0, & r > a_0 \end{cases}$

Решение уравнения Шредингера для радиальной волновой функции при $l = 0$ запишется в общем виде как

$$R_{k0}(r) = \begin{cases} A\frac{\sin(k_u r)}{k_u r}, & k_u^2 = \frac{2m(E+U_0)}{\hbar^2}, \quad r < a_0 \\ B\frac{\sin(kr+\delta_0)}{kr}, & k^2 = \frac{2mE}{\hbar^2}, \quad r > a_0 \end{cases}$$

где A, B - константы, которые можно определить исходя из условия непрерывности волновой функции.

$$\left.\frac{R'_{k0}(r)}{R_{k0}(r)}\right|_{r=a_0-0} = \left.\frac{R'_{k0}(r)}{R_{k0}(r)}\right|_{r=a_0+0},$$

для медленных частиц $ka_0 \ll 1$ дифференцирование при $r = a_0 + 0$ дает

$$R'_{k0}(r) \sim k\frac{\cos(\bullet)}{kr} - \frac{\sin(\bullet)}{kr^2} = \frac{1}{kr^2}\{kr\cos(\bullet) - \sin(\bullet)\}$$

а при $r = a_0 - 0$ в глубокой яме $k_u a_0 \gg 1$

$$R'_{k0}(r) \sim k_u\frac{\cos(*)}{k_u r} - \frac{\sin(*)}{k_u r^2} = \frac{1}{k_u r^2}\{k_u r\cos(*) - \sin(*)\}$$

Подставляя, получаем $\tan(ka_0 + \delta_0) = \frac{k}{k_u}\tan(k_u a_0)$, откуда

$$\delta_0 = -ka_0 + \arctan\left[\frac{k}{k_u}\tan(k_u a_0)\right]$$

Если $\tan(k_u a_0) \to \pm\infty$, то вкладом $ka_0 \to 0$ следует пренебречь и $\delta_0 \to \pm\pi/2$, так что имеет место резонанс: сечение рассеяния принимает максимально допустимое значение для парциальной волны $l = 0$, и оно существенно больше геометрического значения $\sigma_0 = 4\pi/k^2 = 4\pi a_0^2/(ka_0)^2 \gg 4\pi a_0^2$ $k \to 0$ в яме $k_u \to k_u^0 = \sqrt{2mU_0}/\hbar$, и фаза

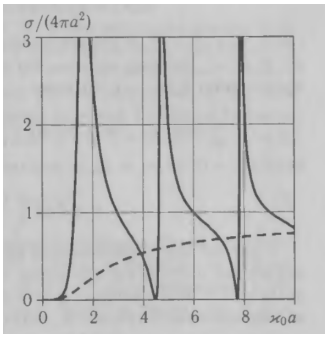
$$\delta_0 \approx k\left\{\frac{1}{k_u^0}\tan\left(k_u^0 a_0\right) - a_0\right\} = \frac{k}{k_u^0}\left\{\tan\left(k_u^0 a_0\right) - k_u^0 a_0\right\}$$

При условии

$$\tan\left(k_u^0 a_0\right) = k_u^0 a_0$$

фаза δ_0, а значит, и длина рассеяния обращаются в нуль, т.е. имеет место эффект Рамзауера: сечение рассеяния определяется высшими парциальными волнами, так что оно аномально мало, зависит от энергии и от углов.

При этом (13.44) совпадает с условием появления в яме связанного состояния.



Описание прохождения быстрых частиц ($ka \gg 1$).

Как мы уже выяснили, для быстрых частиц вклад в полное сечение дают парциальные волны с

$$l \leqslant ka \gg 1$$

При этом, поскольку максимальное значение парциального сечения $\sigma_l^{\max} = 4\pi(2l+1)/k^2$ Достигается при $\sin\delta_l = 1$, полное сечение не превышает величину

$$\sigma < \frac{4\pi}{k^2}\sum_{l=0}^{ka}(2l+1) = \frac{4\pi}{k^2}(ka+1)^2 \approx 4\pi a^2 = \sigma_{\text{geom}}$$

Б-2.12.9 Типичное рассеяние (???)

Найти сечение рассеяния медленных частиц на сферически-симметричном прямоугольном потенциальном барьере.

Solution.

(????!!!!)

Б-2.12.10 Сечение на непроницаемой сфере

Найти сечение рассеяния частиц на непроницаемой сфере радиуса a. Отдельно рассмотреть предельные случаи:
а) медленных частиц ($ka \ll 1$);
б) быстрых частиц ($ka \gg 1$).
Обсудить характер зависимости от угла θ дифференциальных сечений упругого рассеяния.

Solution. по Белоусову

К.? Сечение на непроницаемой сфере по Киселеву

Вклад частиц с $l \gg ka$ в сечение рассеяния пренебрежимо мал.
Для частиц с $l \leqslant ka$, определяющих сечение, радиальные волновые функции при $r > a$ мало отличаются от своих асимптотических выражений, справедливых при $kr \gg l$,

$$R_{kl}(r) \simeq A_l \frac{\sin\left(kr - \frac{\pi}{2}l + \delta_l\right)}{kr}, \quad k^2 = \frac{2mE}{\hbar^2}$$

По непрерывности волновой функции

$$R_{kl}(r)|_{r=a} = 0 \to \sin\left(ka - \frac{\pi}{2}l + \delta_l\right) \approx 0$$

откуда

$$\delta_l \approx -ka + \frac{\pi}{2}l$$

Для вклада парциальной волны

$$\sin^2\delta_l = \frac{1}{2}\left(1 - \cos 2\delta_l\right) = \frac{1}{2}\left\{1 - (-1)^l \cos 2ka\right\}$$

Поэтому в полном сечении

$$\sigma = \frac{4\pi}{k^2}\sum_{l=0}^{ka\gg 1}(2l+1)\sin^2\delta_l$$

можно выделить два вклада: первый дает

$$\frac{2\pi}{k^2}\sum_{l=0}^{ka\gg 1}(2l+1) = 2\pi a^2$$

а второй $-\frac{2\pi}{k^2}\cos(2ka)\sum\limits_{l=0}^{ka\gg 1}(2l+1)(-1)^l$ можно легко оценить согласно разбиению на четные и нечетные l:

$$\sum_{l=0}^{ka\gg 1}(2l+1)(-1)^l = \sum_{n=0}^{\frac{1}{2}ka\gg 1}(4n+1) - \sum_{n=0}^{\frac{1}{2}ka\gg 1}(4n+3) \approx n(2n+1) - n(2n+3)|_{n=\frac{1}{2}ka\gg 1}$$

и

$$-\frac{2\pi}{k^2}\cos(2ka)\sum_{l=0}^{ka\gg 1}(2l+1)(-1)^l \approx 2\pi a^2\frac{\cos(2ka)}{ka}, \quad |\frac{\cos(2ka)}{ka}| \ll 1$$

а значит, этот вклад подавлен по сравнению с первым, и им можно пренебречь.
В итоге, сечение определяется геометрической величиной

$$\sigma \approx 2\pi a^2$$

Б-2.12.11 Сечение рассеяния быстрых частиц на черном шаре

Найти полное сечение рассеяния быстрых частиц ($ka \gg 1$) на черном шаре радиуса a.

Solution.

(??? начало добавлю!)

Падающие на него волны, т.е. оно не отражает волны, достигшие его поверхности.

Как мы видели, центробежные силы создают потенциальный барьер, который непроницаем для волн с $l \gg k$ a.

Поэтому для этих волн отражение происходит также, как и в свободном случае: $S_l = 1$. При $l \leqslant ka$ волны достигают поверхности черного шара, и отражения не прои сходит: $S_l = 0$, а значит, имеет место неупругое рассеяние ($|S_l| < 1$). В этом случае сечение упругого рассеяния

$$\sigma_{\text{el}} = \frac{\pi}{k^2}\sum_{l=0}^{ka}(2l+1)|S_l - 1|^2 = \frac{\pi}{k^2}\sum_{l=0}^{ka}(2l+1) = \pi a^2$$

а неупругого

$$\sigma_{\text{inel.}} = \frac{\pi}{k^2}\sum_{l=0}^{ka}(2l+1)\left(1 - |S_l|^2\right) = \frac{\pi}{k^2}\sum_{l=0}^{ka}(2l+1) = \pi a^2 = \sigma_{\text{el.}}$$

Итак, упругое и неупругое сечения равны друг другу.

Найдем мнимую часть упругого рассеяния в перед

$$\text{Im}\mathfrak{m} f_l(0) = \text{Im}\mathfrak{m}\left[\frac{2l+1}{2\text{i}k}\left(S_l - 1\right)\right] = \frac{2l+1}{2k}$$

В итоге, Для каждого парциального сечения устанавливаем равенство

$$\sigma_l = \sigma_{\text{el}}^l + \sigma_{\text{inel.}}^l = \frac{4\pi}{k}\text{Im}\mathfrak{m} f_l(0) = \frac{2\pi}{k^2}(2l+1)$$

т.е. соотношение оптической теоремы для заданного типа рассеяния.

Б-2.12.12 Рассеяния α-частиц протонов друг на друге

Найти дифференциальное сечение рассеяния:
а) α-частиц на α-частицах;
б) протонов на протонах.

Общий подход к описанию рассеяния

(тут укажу суть решения, пока не вижу его четко. нужно переписать задачу, по сути мы свойства этого решения находим, а не саму величину!)

Волновая функция, описывающая движение двух тождественных частиц в системе центра масс, имеет вид

$$\Psi\left(\mathbf{r}_1, \mathbf{r}_2, s_1, s_2\right) = \Phi(\mathbf{R})\psi(\mathbf{r})\chi\left(s_1, s_2\right).$$

Здесь $\mathbf{R} = \frac{1}{2}\left(\mathbf{r}_1 + \mathbf{r}_2\right)$ - координата центра масс, функция $\Phi(\mathbf{R})$ описывает движение центра масс системы; $\mathbf{r} = \mathbf{r}_1 - \mathbf{r}_2$ - относительная координата, функция $\psi(\mathbf{r})$ описывает движение частицы с приведенной массой $\mu = m/2$; $\chi\left(s_1, s_2\right)$ - спиновая функция двух частиц. Мы предположили, что потенциал взаимодействия не зависит от спинов, поэтому спиновые и координатные переменные разделяются.

Согласно постулату тождественности полная волновая функция Ψ должна быть симметричной или антисимметричной относительно перестановки частиц $1 \leftrightarrow 2$. Координата $\mathbf{R}$ не меняется при указанной перестановке, поэтому симметризации или антисимметризации подлежит только произведение $\psi(\boldsymbol{r})\chi\left(s_1, s_2\right)$.

а) α-частицы.

Спин α-частиц равен нулю, поэтому полная волновая функция должна быть симметричной относительно перестановки $1 \leftrightarrow 2$. При такой перестановке относительная координата меняет знак: $\mathbf{r} \to -\mathbf{r}$, и в сферической системе координат это эквивалентно замене $\theta \to \pi - \theta, \varphi \to \varphi + \pi, r \to r$. В соответствии со сказанным вид функции $\psi(\mathbf{r})$ при больших значениях r должен быть следующим:

$$\psi_s(\mathbf{r})|_{r\to\infty} \sim e^{i\mathbf{kr}} + e^{-i\mathbf{kr}} + (f(\theta) + f(\pi - \theta))\frac{e^{ikr}}{r}.$$

Здесь два первых слагаемых описывают начальное движение частиц в системе центра масс. Первое слагаемое описывает начальное состояние частицы с приведенной массой μ, налетающей на рассеивающий центр из $-\infty$. Второе же слагаемое описывает состояние такой же частицы, летящей из $+\infty$. Третье и четвертое слагаемые учитывают две возможности по рассеянию частицы с массой μ в поле рассеивающего центра. Частица, летящая из $-\infty$, может испытать рассеяние на угол θ и будет зарегистрирована там детектором, ее вероятность так рассеяться отражена в амплитуде $f(\theta)$. В этой же точке вероятность рассеяться второй частице равная определяется $f_2(\pi - \theta)$, ведь она рассеется $\pi - \theta$, и в силу тождественности частиц $f_2(\pi - \theta) = f(\pi - \theta)$.

Дифференциальное сечение рассеяния по определению это отношение числа частиц, рассеявшихся в единицу времени в элемент телесного угла $d\Omega$ в направлении детектора, к плотности потока в каждой из падающих волн, или:

$$d\sigma = |f(\theta) + f(\pi - \theta)|^2 d\Omega$$

б) Протоны.

Так как у протонов спин полуцелый, то полная волновая функция должна быть антисимметричной относительно перестановки частиц. В качестве спиновых функций будут выступать функции $\chi(S, M)$, собственные для операторов квадрата суммарного спина $\hat{\mathbf{S}}^2$ и проекции суммарного спина $\hat{\mathrm{S}}_2$.

(тут укажу решение этой задачи, см. 2.10.1)

Известно, что в состоянии с суммарным спином $S = 0$ спиновая функции антисимметрична, значит координатная функция должна быть симметричной, т. е. она должна быть равна сумме двух начальных вол и двух рассеянных с одинаковыми амплитудами рассеяния:

$$\psi_s(\mathbf{r})|_{r\to\infty} \sim e^{i\mathbf{kr}} + e^{-i\mathbf{kr}} + (f(\theta) + f(\pi - \theta))\frac{e^{ikr}}{r}.$$

В состояниях с $S = 1$ спиновые функции симметричные, поэтому функция $\psi(\mathbf{r})$ должна быть антисимметризована. Подводя итог, можно сказать, что в состояниях с полным спином протонов, равным S, дифференциальное сечение рассеяния равно

$$d\sigma_S = |f(\theta) + (-1)^S f(\pi - \theta)|^2 d\Omega.$$

Если же пучки исходных частиц неполяризованы, то будет наблюдаться среднее значение эффективного сечения. Считая, что все спиновые состояния равновероятны, получим

$$d\sigma = \frac{1}{4} d\sigma_{S=0} + \frac{3}{4} d\sigma_{S=1}.$$

ПТФ-14.з1;LL3-123.1 Фазовая теория в 2D

Постройте фазовую теорию рассеяния в двумерии для случая осесимметричных потенциалов. А именно, выразите через фазовые сдвиги δ_m амплитуду рассеяния $f(\varphi)$, парциальные сечения рассеяния σ_m и полное сечение σ, и выведите оптическую теорему.

Напоминание:

$$\psi_{2D}(\mathbf{r}) = e^{ikr\cos\varphi} + f_{2D}(\varphi)e^{i\frac{\pi}{4}}\frac{e^{ikr}}{\sqrt{r}}$$

Solution.

$$-\frac{\hbar^2}{2M}\left(\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial\psi}{\partial r}\right) + \frac{1}{r^2}\frac{\partial^2\psi}{\partial\phi^2}\right) + V(\mathbf{r})\psi(\mathbf{r}) = E\psi(\mathbf{r})$$

$$e^{ikz} \equiv e^{ikr\cos\varphi} = \sum_{m=-\infty}^{\infty} Q_m^{\text{free}}(r)e^{im\varphi}, \qquad Q_m^{\text{free}}(r) = \frac{1}{2\pi}\int_0^{2\pi} \exp(i(kr\cos\varphi - m\varphi))d\varphi \equiv i^m J_m(kr)$$

(??? откуда такая формула - не знаю, нужно умф дописывать! Однако, можно сослаться на ЛЛ3, там она написана.)

We consider for $r \gg 1$ that $kr \gg 1$, even if k is small,

$$Q_m^{\text{free}}(r; r \gg 1) \approx i^m \sqrt{\frac{2}{\pi kr}} \sin\left(kr - \frac{\pi}{2}\left(m - \frac{1}{2}\right)\right)$$

For $V \neq 0$

$$Q_m(r) \approx i^m \sqrt{\frac{2}{\pi kr}} \sin\left(kr - \frac{\pi}{2}\left(m - \frac{1}{2}\right) + \delta_m\right), \quad \delta_m = \delta_{-m}$$

$$\psi = \sum_{m=-\infty}^{\infty} C_m Q_m(r) e^{im\varphi}, \qquad f(\varphi) = \sum_{m=-\infty}^{\infty} f_m(\varphi) e^{im\varphi}$$

$$C_m Q_m(r) = Q_m^{\text{free}}(r) + f_m(\varphi) e^{i\frac{\pi}{4}} \frac{e^{ikr}}{r}$$

$$C_m \sqrt{\frac{2}{\pi kr}} \sin\left(kr - \frac{\pi}{2}\left(m - \frac{1}{2}\right) + \delta_m\right) = i^m \sqrt{\frac{2}{\pi kr}} \sin\left(kr - \frac{\pi}{2}\left(m - \frac{1}{2}\right)\right) + f_m(\varphi) e^{i\frac{\pi}{4}} \frac{e^{ikr}}{r}$$

$$\frac{C_m}{i} \sqrt{\frac{1}{2\pi kr}} \left(\exp\left(ikr - \frac{i\pi}{2}\left(m - \frac{1}{2}\right) + i\delta_m\right) - \exp\left(-ikr + \frac{i\pi}{2}\left(m - \frac{1}{2}\right) - i\delta_m\right)\right) =$$
$$= i^{m-1} \sqrt{\frac{1}{2\pi kr}} \left(\exp\left(ikr - \frac{i\pi}{2}\left(m - \frac{1}{2}\right)\right) - \exp\left(-ikr + \frac{i\pi}{2}\left(m - \frac{1}{2}\right)\right)\right) + f_m(\varphi) e^{i\frac{\pi}{4}} \frac{e^{ikr}}{\sqrt{r}}$$

$$\begin{cases} e^{-ikr} \\ e^{ikr} \end{cases} \Rightarrow C_m = e^{i\delta_m} i^m \qquad \Rightarrow \qquad \begin{cases} C_m = e^{i\delta_m} i^m, \\ i^{m-1} \sqrt{\frac{1}{2\pi kr}} \exp\left(-\frac{i\pi}{2}\left(m - \frac{1}{2}\right)\right)\left(e^{2i\delta_m} - 1\right) = f_m(\varphi) \frac{e^{i\frac{\pi}{4}}}{\sqrt{r}} \end{cases}$$

$$f_m(\varphi) = \frac{1}{i\sqrt{2\pi k}} (e^{2i\delta_m} - 1)$$

$$f(\varphi) = \sum_{m=-\infty}^{\infty} f_m(\varphi) e^{im\varphi} = \frac{1}{i\sqrt{2\pi k}} \sum_{m=-\infty}^{\infty} (e^{2i\delta_m} - 1) e^{im\varphi}.$$

$$\sigma = \int_0^{2\pi} |f(\varphi)|^2 d\varphi = \frac{1}{2\pi k} \sum_{m=-\infty}^{\infty} 4 \sin^2 \delta_m \cdot 2\pi = \frac{4}{k} \sum_{m=-\infty}^{\infty} \sin^2 \delta_m; \qquad \sigma_m = \frac{4}{k} \sin^2 \delta_m.$$

Here $\int\limits_0^{2\pi} d\varphi e^{i(m_2 - m_2)\varphi} = 0$ since $(m_2 - m_2) \in \mathbb{Z}$.

$$\text{Im} f(0) = \text{Im} \frac{1}{i\sqrt{2\pi k}} \sum_{m=-\infty}^{\infty} (e^{2i\delta_m} - 1) = \text{Im} \frac{1}{i\sqrt{2\pi k}} \sum_{m=-\infty}^{\infty} (\cos(2\delta_m) + i \sin(2\delta_m) - 1) =$$
$$= \frac{1}{\sqrt{2\pi k}} \sum_{m=-\infty}^{\infty} (1 - \cos 2\delta_m) = \sqrt{\frac{2}{\pi k}} \sum_{m=-\infty}^{\infty} \sin^2 \delta_m$$

$$\text{Im} f_{2D}(0) = \sqrt{\frac{k}{8\pi}} \sigma \qquad \text{(optic th 2d)}$$

ПТФ-14.з2. Потенциал $1/r^2$ в 2D

Найдите фазовые сдвиги и сечение рассеяния для двумерного потенциала $V(r) = \frac{\hbar^2 \beta}{2mr^2}$. Исследуйте предел слабого ($\beta \ll 1$, с точностью до членов $O(\beta^2)$) и сильного ($\beta \gg 1$) потенциала.

Reminder:

$$\sigma_{m\ 2D} = \frac{4}{k} \sin^2 \delta_m \qquad \text{Im} f_{2D}(0) = \sqrt{\frac{k}{8\pi}} \sigma$$

Solution.

$$\hat{H} = -\frac{\hbar^2}{2m}\Delta + \frac{\hbar^2\beta}{2mr^2} = -\frac{\hbar^2}{2m}\left(\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial}{\partial r}\right) + \frac{1}{r^2}\frac{\partial^2}{\partial\varphi^2}\right) + \frac{\hbar^2\beta}{2mr^2}$$

$$\psi(\mathbf{r}) \equiv \sum_{l=-\infty}^{\infty} q_l(r)e^{il\varphi}$$

$$\hat{H}\psi(\mathbf{r}) = E\psi(\mathbf{r})$$

$$-\frac{\hbar^2}{2m}\left(q_l''(r) + \frac{q_l'(r)}{r} - \frac{l^2}{r^2}q_l(r)\right) + \frac{\beta\hbar^2 q_l(r)}{2mr^2} = Eq_l(r)$$

$$r^2q_l''(r) + rq_l'(r) + \left(\frac{2mEr^2}{\hbar^2} - l^2 - \beta\right)q_l(r) = 0.$$

$z \equiv \frac{\sqrt{2mE}}{\hbar}r$,

$$z^2q_l''(z) + zq_l'(z) + \left(z^2 - l^2 - \beta\right)q_l(z) = 0 \qquad \text{(Bessel eq.)}$$

$$q_l(z) = J_{\sqrt{l^2+\beta}}(z) \approx \sqrt{\frac{2}{\pi z}}\cos\left(z - \frac{\pi}{2}\sqrt{l^2+\beta} - \frac{\pi}{4}\right)$$

We also know that $Q_m(r) \approx i^m\sqrt{\frac{2}{\pi kr}}\sin\left(kr - \frac{\pi}{2}\left(m - \frac{1}{2}\right) + \delta_m\right); \delta_m = \delta_{-m}$

Мы воспользовались $\sin(x + \pi/2) = \cos(x)$. (??? я так и не понял, что делать с i^m? Если почему-то просто проигнорировать, то у меня получается еще дополнительный (-π), что на ответ не влияет, потому что будем в квадрат синус возводить. Вопрос - что с i делать-то? Модуль - обобщает формулу с учетом $\delta_m = \delta_{-m}$. тоже непонятно, как получить ее, без обобщения, а просто для отрицательных m)

$$\delta_l = \frac{\pi}{2}\left(|l| - \sqrt{l^2+\beta}\right)$$

$$\sigma = \frac{4}{k}\sum_{l=-\infty}^{\infty}\sin^2\left(\frac{\pi}{2}(|l| - \sqrt{l^2+\beta})\right)$$

For $\beta \ll 1 \Rightarrow$ for $l \neq 0$ $\delta_l = \frac{\pi}{2}\left(|l| - |l|\sqrt{1+\frac{\beta}{l^2}}\right) \approx -\frac{\pi\beta}{4|l|}$,

$$\begin{cases}\delta_l = -\frac{\pi\beta}{4|l|}, & l \neq 0\\ \delta_0 = -\frac{\pi\sqrt{\beta}}{2}\end{cases}$$

$$\sigma \approx \frac{4}{k}\left(\sin^2\frac{\pi\sqrt{\beta}}{2} + \sum_{l\neq 0, l=-\infty}^{\infty}\sin^2\frac{\pi\beta}{4|l|}\right) \approx \frac{4}{k}\left(\frac{\pi^2\beta}{4} - \frac{\pi^4\beta^2}{48} + 2\sum_{l=1}^{\infty}\left(\frac{\pi\beta}{4l}\right)^2\right) = \frac{\pi^2\beta}{k}$$

$$\sigma = \frac{\pi^2\beta}{k} + O(\beta^3)$$

Now, for $\beta \gg 1 \qquad \Rightarrow$

$$\delta_l = \frac{\pi}{2}(|l| - \sqrt{l^2+\beta})$$

Сечение рассеяния:

$$\sigma = \frac{4}{k}\sum_{l=-\infty}^{\infty}\sin^2\left(\frac{\pi}{2}(|l| - \sqrt{l^2+\beta})\right) \approx \frac{8}{k}\int_0^{\infty} dl\sin^2\left(\frac{\pi}{2}(l - \sqrt{l^2+\beta})\right)$$

$u := \frac{\pi}{2}(l - \sqrt{l^2+\beta})$, $l = \frac{u}{\pi} - \frac{\beta\pi}{4u}$, $\sqrt{l^2+\beta} = -\frac{u}{\pi} - \frac{\beta\pi}{4u}$, $du = \frac{\pi}{2}dl(1 - l/\sqrt{l^2+\beta}) \Rightarrow$

$$\sigma = \frac{8}{k}\int_{-\sqrt{\beta}}^{0} du\left(\frac{1}{\pi} + \frac{\pi\beta}{4u^2}\right)\sin^2 u \approx \frac{8}{k}\left(\frac{1}{\pi}\frac{\sqrt{\beta}}{2} + \frac{\pi\beta}{4}\frac{\pi}{2} + O(1)\right) = \frac{\pi^2\beta}{k} + O(\sqrt{\beta})$$

since

```
Integrate[Sin[ u ]^2, {u, -a, 0}]
Integrate[Sin[ u ]^2/u^2, {u, -a, 0}, Assumptions -> Re[a] > 0 && Im[a] == 0]
```

and for $\beta \gg 1$ we have $\sqrt{\beta} \gg \sin\beta$, and the sine integral $\approx \pi/2$.

$$\sigma = \frac{\pi^2\beta}{k} + O(\sqrt{\beta})$$

В разных предельных случаях получился одинаковый ответ. Возможно, что при любых β ответ

$$\sigma = \frac{\pi^2\beta}{k}$$

Solution. через формулу Борна (???)

(для меня естественно было просто применить обычный формализм Борна для 2д для этого потенциала. Но я не могу найти примеры этого применения, чтобы сделать так же. Также я не уверен в основной формуле, что там фурье образ берем от потенциала, потому что она выведена для 3д случая. нужно тоже посидеть, проверить вывод. возможно, там чуть другая основная формула будет. также есть статьи про это. Рыться во всем этом - время, пока этим не занимался, итак есть, о чем подумать.)

Что по поводу больших порядков?

(сокращаются ли они там тоже? не знаю, не до этого вообще)

ПТФ-14.з3 Парциальное сечение на твёрдом шаре (30 б).

Найдите точное выражение для произвольного парциального сечения рассеяния на твёрдом шаре σ_l. Исследуйте полученную формулу в следующих предельных случаях:
- Оцените вклад p-канала для рассеяния медленных частиц;
- Определите полное сечение рассеяния для быстрых частиц.

Solution.

Уравнение Шрёдингера для радиальной компоненты волновой функции:

$$R''_{kl}(r) + \frac{2}{r}R'_{kl}(r) + \left(k^2 - \frac{l(l+1)}{r^2}\right)R_{kl}(r) = 0$$

Введём замену $R_{kl}(r) = \frac{Q_{kl}(r)}{\sqrt{r}}$.

$$R'_{kl}(r) = \frac{Q'_{kl}(r)}{\sqrt{r}} - \frac{Q_{kl}(r)}{2r^{\frac{3}{2}}}, \quad R''_{kl}(r) = \frac{Q''_{kl}(r)}{\sqrt{r}} - \frac{Q'_{kl}(r)}{r^{\frac{3}{2}}} + \frac{3Q_{kl}(r)}{4r^{\frac{5}{2}}}$$

$$\frac{Q''_{kl}(r)}{\sqrt{r}} - \frac{Q'_{kl}(r)}{r^{\frac{3}{2}}} + \frac{3Q_{kl}(r)}{4r^{\frac{5}{2}}} + \frac{2Q'_{kl}(r)}{r^{\frac{3}{2}}} - \frac{Q_{kl}(r)}{r^{\frac{5}{2}}} + \left(k^2 - \frac{l(l+1)}{r^2}\right)\frac{Q_{kl}(r)}{\sqrt{r}} = 0$$

$$Q''_{kl}(r) + \frac{Q'_{kl}(r)}{r} - \frac{Q_{kl}(r)}{4r^2} + \left(k^2 - \frac{l(l+1)}{r^2}\right)Q_{kl}(r) = 0$$

$$Q''_{kl}(kr) + \frac{Q'_{kl}(kr)}{kr} + \left(1 - \frac{(l+\frac{1}{2})^2}{(kr)^2}\right)Q_{kl}(kr) = 0$$

Получилось уравнение Бесселя с положительной энергией.

$$Q_{kl}(kr) = C_1 J_{l+\frac{1}{2}}(kr) + C_2 Y_{l+\frac{1}{2}}(kr)$$

Граничное условие:

$$Q_{kl}(ka) = 0 \to \frac{C_2}{C_1} = -\frac{J_{l+\frac{1}{2}}(ka)}{Y_{l+\frac{1}{2}}(ka)}$$

Асимптотика при $kr \gg 1$:

$$J_{l+\frac{1}{2}}(kr) \approx \sqrt{\frac{2}{\pi kr}} \cos\left(kr - \frac{\pi(l+\frac{1}{2})}{2} - \frac{\pi}{4}\right) = \sqrt{\frac{2}{\pi kr}} \sin\left(kr - \frac{\pi l}{2}\right)$$

$$Y_{l+\frac{1}{2}}(kr) \approx \sqrt{\frac{2}{\pi kr}} \sin\left(kr - \frac{\pi(l+\frac{1}{2})}{2} - \frac{\pi}{4}\right) = -\sqrt{\frac{2}{\pi kr}} \cos\left(kr - \frac{\pi l}{2}\right)$$

$$Q_{kl}(kr) \approx C\sqrt{\frac{2}{\pi kr}} \sin\left(kr - \frac{\pi l}{2} + \delta_l\right)$$

$$\tan\delta_l = -\frac{C_2}{C_1} = \frac{J_{l+\frac{1}{2}}(ka)}{Y_{l+\frac{1}{2}}(ka)}$$

$$\sin^2\delta_l = \frac{J^2_{l+\frac{1}{2}}(ka)}{J^2_{l+\frac{1}{2}}(ka) + Y^2_{l+\frac{1}{2}}(ka)}$$

$$\sigma_l = \frac{4\pi}{k^2}(2l+1)\sin^2\delta_l = \frac{4\pi(2l+1)}{k^2} \frac{J^2_{l+\frac{1}{2}}(ka)}{J^2_{l+\frac{1}{2}}(ka) + Y^2_{l+\frac{1}{2}}(ka)}$$

Рассмотрим предельные случаи:

• Медленные частицы $ka \ll 1$.

Асимптотика функций Бесселя и Неймана:

$$J_{l+\frac{1}{2}}(ka) \approx \frac{1}{\Gamma(l+\frac{3}{2})}\left(\frac{ka}{2}\right)^{l+\frac{1}{2}}, \quad Y_{l+\frac{1}{2}}(ka) \approx -\frac{\Gamma(l+\frac{1}{2})}{\pi}\left(\frac{2}{ka}\right)^{l+\frac{1}{2}}$$

Вклад p-канала:

$$\sigma_1 = \frac{12\pi}{k^2} \frac{\frac{1}{\Gamma(\frac{5}{2})^2}\left(\frac{ka}{2}\right)^3}{\frac{1}{\Gamma(\frac{5}{2})^2}\left(\frac{ka}{2}\right)^3 + \frac{\Gamma(\frac{3}{2})^2}{\pi^2}\left(\frac{2}{ka}\right)^3} \approx \frac{12\pi}{k^2} \frac{\pi^2}{\Gamma(\frac{3}{2})^2\Gamma(\frac{5}{2})^2}\left(\frac{ka}{2}\right)^6 = \frac{12\pi}{k^2}\frac{\pi^2}{\frac{\pi}{4}\frac{9\pi}{16}2^6}k^6a^6$$

$$\sigma_1 = \frac{4\pi}{3}k^4a^6$$

• Быстрые частицы $ka \gg 1$.

Граничное условие:

$$Q_{kl}(ka) \approx C\sqrt{\frac{2}{\pi kr}} \sin\left(ka - \frac{\pi l}{2} + \delta_l\right) = 0 \to ka - \frac{\pi l}{2} + \delta_l = 0$$

$$\delta_l = \frac{\pi l}{2} - ka \to \sin^2\delta_l = \frac{1-\cos 2\delta_l}{2} = \frac{1-(-1)^l\cos 2ka}{2}$$

$$\sigma = \frac{4\pi}{k^2}\sum(2l+1)\sin^2\delta_l \approx \frac{4\pi}{k^2}\int\limits_0^{ka} dl(2l+1)\frac{1-\cos 2ka}{2} \approx \frac{2\pi}{k^2}\int\limits_0^{ka} dl(2l+1) =$$

$$= \frac{2\pi}{k^2}(k^2a^2 + ka) \approx 2\pi a^2$$

$$\sigma = 2\pi a^2$$

ПТФ-14.з4 Рассеяние на потенциале $\sim 1/r^3$ (30 б).

Используя фазовую теорию, найдите сечение рассеяния достаточно быстрых частиц ($kL \gg 1$) на потенциале $V(r) = \frac{L}{2m(r^2+a^2)^{\frac{3}{2}}}$ при дополнительных предположениях:

• В случае $kL \ll \frac{L^2}{a^2}$. *Указание*: параметрически главный вклад в сечение приходит с моментов $l \gg (kL)^{1/3}$. Покажите, что вкладом от моментов $l \ll (kL)^{1/3}$ можно пренебречь.

• В случае $kL \gg \frac{L^2}{a^2}$. *Указание*: вычислите вклад моментов $l \gg (kL)^{1/3}$. Сравните результат с ответом, который получается из Борновского приближения. Применимо ли оно в данном случае?

Solution.

• Случай $kL \ll \frac{L^2}{a^2}$.
Квазиклассическое выражение для фазовых сдвигов:

$$\delta_l = \int\limits_{r_0}^{\infty} dr \left(\sqrt{k^2 - \frac{l(l+1)}{r^2} - 2mV(r)} - k \right) - kr_0 + \frac{\pi l}{2} + \frac{\pi}{4}$$

Разложение:

$$\delta_l = -\int\limits_{r_0}^{\infty} dr \frac{mV(r)}{\sqrt{k^2 - \frac{l(l+1)}{r^2}}}, \quad r_0 = \frac{\sqrt{l(l+1)}}{k} \approx \frac{l}{k}$$

В последнем равенстве использвалось, что $l \gg 1$. Это и то, что $r_0 \gg a$ далее будет показано. При $r \gg a$:

$$V(r) \approx \frac{L}{2mr^3}$$

$$\delta_l = \int\limits_{r_0}^{\infty} dr \frac{L}{2r^3\sqrt{k^2 - \frac{l(l+1)}{r^2}}} = \frac{L}{4l(l+1)} \int\limits_{\frac{l}{k}}^{\infty} \frac{d(k^2 - \frac{l(l+1)}{r^2})}{\sqrt{k^2 - \frac{l(l+1)}{r^2}}} = \frac{Lk}{2l(l+1)} \approx \frac{Lk}{2l^2}$$

$\delta_l \sim 1$ при $kL \sim l^2$. Поскольку частицы достаточно быстрые $kL \gg 1$, то и $l \gg 1$.

$$l^3 \sim lkL \gg kL \to l \gg (kL)^{\frac{1}{3}}$$

Покажем, что $r_0 \gg a$.

$$ka^2 \ll L \to (ka)^2 \ll kL \sim l^2 \to \frac{r_0}{a} = \frac{l}{ka} \gg 1$$

Сечение рассеяния:

$$\sigma = \frac{4\pi}{k^2} \sum_{l=-\infty}^{\infty} (2l+1) \sin^2 \delta_l = \frac{4\pi}{k^2} \int\limits_0^{\infty} dl 2l \sin^2 \frac{Lk}{2l^2} = \frac{\pi^2 L}{4k}$$

$$\sigma = \frac{\pi^2 L}{4k}$$

• Случай $kL \gg \frac{L^2}{a^2}$.
Фазовые сдвиги:

$$\delta_l = \int\limits_{r_0}^{\infty} dr \frac{L}{2(r^2+a^2)^{\frac{3}{2}}\sqrt{k^2 - \frac{l(l+1)}{r^2}}} = \frac{L}{2al} \int\limits_1^{\sqrt{1+(\frac{ka}{l})^2}} \frac{udu}{u^3\sqrt{1+(\frac{ka}{l})^2 - u^2}}, \quad u = 1 + \frac{a^2}{r^2}$$

Сделаем замену $v = \frac{1+(\frac{ka}{l})^2}{u^2} - 1$ и получим

$$\delta_l = \frac{L}{4al} \int\limits_0^{\frac{k^2a^2}{l^2}} \frac{dv}{\sqrt{v}} = \frac{kL}{2(l^2 + k^2a^2)}$$

В борновском приближении:

$$f(\theta) = -\frac{m}{2\pi} \tilde{V}_{\mathbf{k}-\mathbf{k}'} = -\frac{m}{k \sin \frac{\theta}{2}} \int\limits_0^{\infty} dr r \sin \left(2kr \sin \frac{\theta}{2} \right) V(r)$$

$$f(\theta) = -\frac{L}{2k \sin \frac{\theta}{2}} \int\limits_0^{\infty} \frac{r \sin 2kr \sin \frac{\theta}{2}}{(a^2+r^2)^{\frac{3}{2}}} dr \approx L\sqrt{\frac{\pi}{ka \sin \frac{\theta}{2}}} e^{-ka \sin \frac{\theta}{2}}$$

Сечение рассеяния:

$$\sigma = 2\pi \int\limits_0^{\pi} |f(\theta)|^2 \sin \theta d\theta = 2\pi \int\limits_0^{\pi} L^2 \frac{\pi e^{-2ka \sin \frac{\theta}{2}}}{ka \sin \frac{\theta}{2}} \sin \theta d\theta \approx \frac{2\pi^2 L^2}{ka} \int\limits_0^{\pi} \frac{e^{-ka\theta}}{\frac{\theta}{2}} \theta d\theta$$

$$\sigma = \frac{4\pi^2 L^2}{k^2 a^2}$$

LL3-34.1 Разложение волны

Разложить плоскую волну по волновым функциям состояний с определенными значениями проекции m момента на ось y и проекцией p_y импульса на ту же ось.

Solution.

По идее математическая подготовка должна быть такой, чтобы это решение было очевидным. (! допишу это!)

Введем цилиндрическую систему координат y, ρ, φ с осью вдоль оси y. Волновые функции указанных состояний будут иметь вид $Q_m(\rho)e^{im\varphi}e^{ip_y y/\hbar}$. Если отсчитывать угол φ от оси z, разложение можно записать в виде:

$$e^{ikz} = e^{ik\rho\cos\varphi} = \sum_{m=-\infty}^{\infty} Q_m(\rho)e^{im\varphi}$$

(в данном случае $p_y = 0$), откуда

$$Q_m(\rho) = \frac{1}{2\pi}\int_0^{2\pi} \exp[i(k\rho\cos\varphi - m\varphi)]d\varphi = i^m J_m(k\rho)$$

где $J_m(x)$ - функция Бесселя. При $k\rho \gg 1$ для Q_m справедливо асимптотическое выражение:

$$Q_m(\rho) \approx i^m\sqrt{\frac{2}{\pi k\rho}}\sin\left[k\rho - \frac{\pi}{2}\left(m - \frac{1}{2}\right)\right]$$

17.3.12 Problems about partial-wave analysis 2

GKKG.13.18 Phase shifts formula

Obtain an expression for phase shifts directly from the partial-wave expansion of the Born scattering amplitude in a spherically-symmetric potential.

Solution

Let us use the expansion:

$$\frac{\sin qr}{qr} = \frac{\sin\sqrt{2k^2r^2 - 2k^2r^2\cos\theta}}{\sqrt{2k^2r^2 - 2k^2r^2\cos\theta}} = \frac{\pi}{2kr}\sum_{l=0}^{\infty}(2l+1)\left[J_{l+1/2}(kr)\right]^2 P_l(\cos\theta)$$

which follows from the addition theorem for cylindrical functions, if we note that $(\sin z)/z = \sqrt{\pi/2z}J_{1/2}(z)$. Substituting this into Eq. (XIII.8), we obtain the Born amplitude in the form of a series:

$$f^B = \sum_{l=0}^{\infty}(2l+1)\left\{-\frac{\pi m}{\hbar^2 k}\int_0^{\infty} U(r)\left[J_{l+1/2}(kr)\right]^2 rdr\right\}P_l(\cos\theta) \tag{1}$$

Comparing this to expansion $f(k,\theta) = \sum\limits_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$ of the scattering amplitude in partial waves, we conclude that the Born approximation corresponds to small scattering phaseshifts, [325] $|\delta_l(k)| \ll 1$, where

$$f = \sum_l (2l+1)\frac{e^{2i\delta_l}-1}{2ik}P_l(\cos\theta) \approx \sum_l (2l+1)\frac{\delta_l(k)}{k}P_l(\cos\theta) \tag{2}$$

From a comparison between Eqs. (1) and (2), we reproduce the known expression for the Born phase shifts - Eq. (XIII.12) - which is a linear-in-the-potential term in the expansion for $\delta_l(k)$.

GKKG.13.19 Phase shifts in $1/r^2$

Find phase shifts in the field $U(r) = \alpha/r^2, \alpha > 0$.

Perform summation of the series $f(k,\theta) = \sum_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$, i.e., of the partial-wave expansion of the scattering amplitude for the following cases:
a) $m\alpha/\hbar^2 \ll 1$ for an arbitrary scattering angle;
b) $m\alpha/\hbar^2 \gtrsim 1$ for small-angle scattering;
c) $m\alpha/\hbar^2 \gg 1$ for the backward scattering ($\theta = \pi$).

Find the differential scattering cross-section and compare it to that in the Born approximation and the scattering cross-section that follows from classical mechanics.

[325] The smallness of all phase shifts is a necessary (but not sufficient) condition for the Born approximation to remain valid. This smallness is responsible for the scattering amplitude being real in this approximation.

Solution

Writing the wavefunctions as $\psi_{klm} = u_{kl}(r)Y_{lm}/\sqrt{r}$, for the function $u_{kl}(r)$ we have the following equation (compare to Eq. (IV.6)):

$$u''_{kl} + \frac{1}{r}u'_{kl} + \left\{k^2 - \frac{1}{r^2}\left[\left(l+\frac{1}{2}\right)^2 + \frac{2m\alpha}{\hbar^2}\right]\right\}u_{kl} = 0$$

Its solution, satisfying the boundary condition $u(0) = 0$, is $u_{kl} = CJ_\nu(kr)$, where J_ν is the Bessel function with the index

$$\nu = \sqrt{\left(l+\frac{1}{2}\right)^2 + \frac{2m\alpha}{\hbar^2}}$$

The asymptote of this solution for $r \to \infty$ is

$$u_{kl} \approx C\sqrt{\frac{2}{\pi kr}}\sin\left[kr - \frac{\pi\nu}{2} + \frac{\pi}{4}\right] \equiv C\sqrt{\frac{2}{\pi kr}}\sin\left[kr - \frac{\pi l}{2} + \delta_l\right]$$

The phase shifts are

$$\delta_l = -\frac{\pi}{2}\left[\sqrt{\left(l+\frac{1}{2}\right)^2 + \frac{2m\alpha}{\hbar^2}} - \left(l+\frac{1}{2}\right)\right] \tag{1}$$

Since δ_l does not depend on k, then according to Eq. $f(k,\theta) = \sum_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$ the scattering amplitude has the form $f(k,\theta) = F(\theta)/k$, and the differential scattering cross-section goes as $d\sigma/d\Omega \propto k^{-2} \propto E^{-1}$. The same energy-dependence [326] (but not a dependence on the scattering angle) occurs in classical mechanics (see Eq. (5)).

Let us consider some special cases where it is possible (approximately) to sum the series $f(k,\theta) = \sum_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$ with phase shifts (1).
a) In the case $m\alpha/\hbar^2 \ll 1$, according to (1) we have

$$\delta_l \approx -\frac{\pi m\alpha}{(2l+1)\hbar^2}$$

where $|\delta_l| \ll 1$. Expanding $e^{2i\delta_l}$ in Eq. $f(k,\theta) = \sum_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$, we obtain [327]

$$f(E,\theta) \approx -\frac{\pi m\alpha}{\hbar^2 k}\sum_{l=0}^{\infty}P_l(\cos\theta) = -\frac{\pi m\alpha}{2\hbar^2 k\sin(\theta/2)} \tag{3}$$

[326] For the potential $U = \alpha/r^2$, the dependence $d\sigma/d\Omega \propto E^{-1}$, both in classical and in quantum mechanics, is easily obtained from a dimensional analysis.

[327] To sum this series, use the generating function of the Legendre polynomials (with $z = \cos\theta$ and $x = 1$):

$$\frac{1}{\sqrt{1-2xz+x^2}} = \sum_{l=0}^{\infty} x^l P_l(z)$$

which coincides with the result of the Born approximation (see Problem 13.1 d). The angular dependence of the differential cross-section,

$$\frac{d\sigma}{d\Omega} = |f|^2 = \frac{\pi^2 m\alpha^2}{8\hbar^2 E \sin^2(\theta/2)} \tag{4}$$

is dissimilar from the corresponding result of classical mechanics:

$$\left(\frac{d\sigma}{d\Omega}\right)_{cl} = \frac{\pi^2\alpha(\pi-\theta)}{E\theta^2(2\pi-\theta)^2\sin\theta} \tag{5}$$

b) In the case $m\alpha/\hbar^2 \gtrsim 1$, it is impossible to perform summation of the partial-wave series for an arbitrary scattering angle. But it is easy to see that for sufficiently small scattering angles, Eqs. (3) and (4) are valid. It is connected to an unbounded increase of the scattering amplitude for $\theta \to 0$. Since each term of series $f(k,\theta) = \sum\limits_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$ is bounded, then such a divergence of the amplitude means that there are a lot of terms with large values of l in the sum (generally, the smaller the scattering angles, the larger the values of l). But for values of l large enough, relation (2) is still valid, from which Eq. (3) and (4) are deduced. The fact that for small scattering angles, the Born approximation is applicable independently of the value of $m\alpha/\hbar^2$, is reasonable: In the conditions of the problem, large distances contribute dominantly to the relevant quantities (due to the aforementioned divergence of the scattering amplitude), where $U = \alpha/r^2 \ll \hbar v/r$, and the potential can be considered as a perturbation.
c) Let us consider backward scattering. In this case, we have:

$$\sum_{l=0}^{\infty}(2l+1)P_l(\cos\theta) = 4\delta(1-\cos\theta)$$

i.e., for $\theta \neq 0$ the sum is equal to zero, and $P_l(-1) = (-1)^l$. Now series $f(k,\theta) = \sum\limits_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$ takes the form:

$$f(E,\theta=\pi) = \frac{1}{2k}\sum_{l=0}^{\infty}(2l+1)\exp\left\{-i\pi\sqrt{\left(l+\frac{1}{2}\right)^2 + \frac{2m\alpha}{\hbar^2}}\right\} \tag{6}$$

In the case of $m\alpha/\hbar^2 \gg 1$, the dominant role in this sum is played by the terms with large angular momenta [328] $l \lesssim \left(m\alpha/\hbar^2\right)^{1/4}$. Here, the neighboring terms differ from one another only slightly, and the summation could be replaced by an integration:
$$

$$f(E,\pi) \approx \frac{1}{k}\int_0^{\infty} l\exp\left\{-i\pi\sqrt{l^2+\frac{2m\alpha}{\hbar^2}}\right\}dl \tag{7}$$

$$
Using the substitution $x = \sqrt{l^2 + 2m\alpha/\hbar^2}$, we finally obtain

$$f(E,\pi) = -i\frac{\sqrt{2m\alpha}}{\pi\hbar k}\exp\left\{-i\pi\sqrt{\frac{2m\alpha}{\hbar^2}}\right\} \tag{8}$$

This differential scattering cross-section for $\theta = \pi$ coincides with result (5) of classical mechanics. This remains so also for the region of scattering angles (which expand with an increase of α), that are close to $\theta = \pi$.

Let us note in conclusion that in the case of an attractive potential, $\alpha < 0$, the phase shifts, (1), could become imaginary. Formally, this coincides with the appearance of "absorption" in the system. This instability can be linked to the classical phenomenon of "fall into the center" (see Problem 9.14). What concerns the small-angle scattering, it is described by Eqs. (3) and (4), independently of the sign of α.

[0] [328] For large values of l, terms of the sum (6) oscillate quickly, and as result of their mutual compensation, the corresponding part of the sum becomes small. Let us note that for the calculation of series (6), as well as for the previous sum with the δ-function, we should introduce a cutoff factor, $e^{-\gamma l}$ with $\gamma > 0$, in integral (7), and then the limit take $\gamma \to 0$ in the final result.

GKKG.13.20 Scattering on a zero-range potential

Find the wavefunction, $\psi^+_{\mathbf{k}_0}(\mathbf{r})$, scattering amplitude, and scattering cross-section of a particle in a zero-range potential (see Problem 4.10). Find the value of effective radius, r_0.

Solution

Since a zero-range potential affects only particles with the angular momentum $l = 0$, then only an s-scattering phase-shift, $\delta_0(k)$, is non-zero, and the scattering amplitude does not depend on the angle θ. The asymptotic form of the wavefunction,

$$\psi^+_{\mathbf{k}}(\mathbf{r}) = e^{i\mathbf{k}\cdot\mathbf{r}} + \frac{f(E)}{r}e^{ikr} \tag{1}$$

determines the exact solution of the Schrdinger equation for all $r > 0$. Comparing the wavefunction expansion for $r \to 0$,

$$\psi^+_{\mathbf{k}} \approx \frac{f}{r} + (1 + ikf)$$

with the boundary condition for the zero-range potential (see Problem 4.10), we find

$$f(E) = -\frac{a_0}{1 + ika_0}, \quad \sigma = 4\pi|f|^2 = \frac{4\pi}{k}\,\mathrm{Im}\, f(E) = \frac{4\pi a_0^2}{1 + k^2a_0^2} \tag{2}$$

Here, $a_0 = 1/\alpha_0$. Note that $f(0) = -a_0$, where a_0 is the scattering length of a z.r.p.

Finally, using the equality $e^{2i\delta} - 1 = 2i/(\cot\delta - i)$, we obtain the s-scatterig phaseshift on the zero-range potential as follows:

$$k\cot\delta_0(k) = -\frac{1}{a_0} \tag{3}$$

Its comparison with the effective-range expansion, (XIII.15), proves that for scattering from a z.r.p., the effective radius of interaction is $r_0 = 0$.

GKKG.13.21 Reconstruct the interaction potential

Reconstruct the interaction potential $U(r)$ from the s-scattering phase-shift $\delta_0(k)$, considering it to be known for all energies, and assuming that $|\delta_0(k)| \ll 1$.

To illustrate applications of this result, consider the following dependencies:

a) $\delta_0(k) = \mathrm{const}$;

b) $\delta_0(k) = \frac{\alpha k}{1+\beta k^2}$.

Solution

(в теории уже раздел создан, по идее им это должно решаться, но пока я)

Since $|\delta_0(k)| \ll 1$ for all energies, we can consider the potential as a perturbation and use expression (XIII.12) for the phase shift of the s-wave:

$$\delta_0(k) = -\frac{2m}{\hbar^2 k}\int\limits_0^\infty U(r)\sin^2 krdr = -\frac{m}{\hbar^2 k}\int\limits_0^\infty U(r)[1 - \cos 2kr]dr \tag{1}$$

Multiplying both parts of this equality by $\left(-\hbar^2 k/2m\right)$ and differentiating by k, we obtain

$$-\frac{\hbar^2}{2m}\frac{d}{dk}\left[k\delta_0(k)\right] = \int\limits_0^\infty rU(r)\sin 2krdr \equiv \frac{i}{2}\int\limits_{-\infty}^\infty rU(|r|)e^{-2ikr}dr \tag{2}$$

Here we have used the even continuation of the potential, $U(-|r|) \equiv U(|r|)$, into the region with negative values of r.

Equation (2) determines the Fourier component of the potential (to be more precise, of the function $rU(|r|)$) and allows us to find the potential using the inverse Fourier transform:

$$rU(|r|) = \frac{i\hbar^2}{\pi m}\int\limits_{-\infty}^\infty e^{2ikr}\frac{d}{dk}\left[k\delta_0(k)\right]dk \tag{3}$$

Since according to Eq. (1), $\delta_0(k)$ is an odd function of the variable k, and so $\delta_0'(k)$ is an even function, then Eq. (3) takes the form:

$$U(r) = -\frac{2\hbar^2}{\pi m r}\int\limits_0^\infty \sin(2kr)\frac{d}{dk}\left[k\delta_0(k)\right]dk \tag{4}$$

Let us consider applications of this general formula.
a) In the case of $\delta_0(k) = \text{const} = C$ (for $k > 0$), according to Eq. (4) we obtain:

$$U(r) = -\frac{2\hbar^2 C}{\pi m r}\int\limits_0^\infty \sin 2kr dk = -\frac{\hbar^2 C}{\pi m r^2} \equiv \frac{\gamma}{r^2} \tag{5}$$

To calculate this integral, introduce the "cutoff" factor $e^{-\lambda k}$ with $\lambda > 0$, and in the final result take $\lambda \to 0$.
b) Substituting $[k\delta_0(k)]' = 2\alpha k/\left(1+\beta k^2\right)^2$ into Eq. (3) and calculating the integral using residues, we find:

$$U(r) = -\frac{2\alpha\hbar^2}{m\sqrt{\beta^3}}\exp\left\{-\frac{2r}{\sqrt{\beta}}\right\} \equiv U_0 e^{-r/R} \tag{6}$$

Note that the condition $|\delta_0(k)| \ll 1$ assumes that $|C| \ll 1$ and $|\alpha| \ll \sqrt{\beta}$. The reconstructed potentials (5) and (6), as expected, are consistent with the applicability condition of the Born approximation for any energy.

GKKG.13.22 Phase shifts for an exchange potential

Obtain phase shifts in the Born approximation for an exchange potential (see Problem 13.3).

Solution

Since the action of the operator $\hat{U}_{ex}$ on the wavefunction of a state with a definite value of angular momentum, l, is reduced to its multiplication by $(-1)^l U(r)$, then the expression for the phase shift, $\delta^B_{ex,l}(k)$, differs from the Born expression, (XIII.12), for a regular potential, $U(r)$, only by the factor $(-1)^l$.

GKKG.13.24 Scattering in symmetric magnetic field

Using the partial-wave decomposition, find the scattering amplitude and differential scattering cross-section of charged particles in an axially symmetric magnetic field, $\mathcal{H}(\rho)$, directed along the z axis and localized at small distances $\rho \le a$ in the vicinity of this axis.
Hint: Consider the limiting case $a \to 0$, and a finite value, Φ_0, of the magnetic flux. It is convenient to choose the vector potential in the form $A_\varphi = \Phi_0/2\pi\rho, A_z = A_\rho = 0$.

Solution

In the polar coordinates, the Hamiltonian of transverse motion in a magnetic field $\hat{H}_\perp = (\hat{\mathbf{p}} - e\mathbf{A}/c)^2/2\mu$, takes the form: [330]

$$\hat{H}_\perp = \frac{\hbar^2}{2\mu}\left\{-\frac{1}{\rho}\frac{\partial}{\partial\rho}\rho\frac{\partial}{\partial\rho} + \frac{1}{\rho^2}\left[\lambda^2 + 2i\lambda\frac{\partial}{\partial\varphi} - \frac{\partial^2}{\partial\varphi^2}\right]\right\} \tag{1}$$

where $\lambda = e\Phi_0/2\pi\hbar c$. Since the operator $\hat{H}_\perp$ commutes with $\hat{l}_z$, the two-dimensional theory of scattering developed in the previous problem is also applicable here. Now, though, the phase shifts, δ_m, depend on the sign of m. The radial functions here, as well as for free motion, are expressed in terms of the Bessel functions, $J_\nu(k\rho)$, but with the index $\nu = |m - \lambda|$. Using their known asymptote, we find

[330] Note that free motion along the field is not particularly interesting and therefore is not being considered. Also note that for to derive Hamiltonian (1), we used the following azimuthal component of the gradient operator, $\rho^{-1}\nabla_\varphi = \partial/\partial\varphi$.

$$\delta_m = -\frac{\pi}{2}(|m-\lambda| - |m|)$$

The scattering amplitude (see Eq. (5) of the previous problem) becomes

$$f(k,\varphi) = \frac{1}{i\sqrt{2\pi k}}\sum_{m=-\infty}^{\infty}\left\{e^{i\pi(m-|m-\lambda|)} - 1\right\}e^{im\varphi} \tag{2}$$

Denoting the minimum value of m (that is still larger than λ) by m_0, and dividing the sum into two pieces: with $m \geq m_0$ and with $m \leq m_0 - 1$, we can calculate the latter summing up a geometrical progression. This yields a closed equation for the amplitude and differential cross-section:

$$f = i\frac{\exp\{i\,(m_0 - 1/2)\,\varphi\}}{\sqrt{2\pi k}}\frac{\sin\pi\lambda}{\sin(\varphi/2)}, \quad \frac{d\sigma}{d\varphi} = \left.\frac{\sin^2(e\Phi_0/2\hbar c)}{2\pi k\sin^2(\varphi/2)}\right|_{\phi\to 0} \propto \phi^{-2}$$

An interesting property of this result is the infinite value of the total scattering cross-section, i.e., particle scattering occurs even for an arbitrarily large impact parameter. From the point of view of classical theory, this conclusion appears counter-intuitive: the magnetic field and the Lorentz force are different from zero only on the axis, and hence have no influence on the particle's classical motion. This paradox is a manifestation of the fact that the phenomenon due to the magnetic flux described in this problem, the Aharonov-Bohm effect, is purely quantum, and disappears in the classical limit; for $\hbar \to 0$ and $k^{-1} = \hbar/p \to 0$, the scattering is indeed absent. In quantum mechanics, the interaction between a charged particle and a magnetic field is characterized by a vector potential: as in the Hamiltonian. [331] In this problem, despite the fact that outside the axis, the field vanishes, $\mathcal{H} = 0$, the vector potential can not be turned off ("gauged away") by any gauge transformation $\left(\oint \mathbf{A}\cdot d\mathbf{l} = \Phi_0\right)$, and its slow, $\propto 1/\rho$, decrease on large distances explains the infinite scattering cross-section.

[331] See also an excellent discussion about whether the vector potential is "real" in The Feynman Lectures on Physics, vol. 6, Ch. 15.

GKKG.13.25 High energy phase shifts

Find the energy dependence of phase shifts, $\delta_l(k)$, with a fixed value of l, in the limit $k \to \infty$. Consider potentials with the following behavior at small distances ($r \to 0$): $U \approx \alpha/r^\nu$ with a) $\nu < 1$; b) $1 < \nu < 2$; c) $\nu = 1$.

Solution

For large energies, the Born approximation is applicable, and we can use expression (XIII.12) for the phase shifts. For $k \to \infty$, the argument of the Bessel function is large, $x = kr \gg 1$, in the entire integration domain, except for a narrow region of small r. Using the known asymptote for $J_\mu(x)$, we obtain

$$\delta_l(k) = -\frac{2m}{\hbar^2 k}\int\limits_0^\infty U(r)\sin^2\left(kr - \frac{\pi l}{2}\right)dr \approx -\frac{m}{\hbar^2 k}\int\limits_0^\infty U(r)dr \propto k^{-1} \tag{1}$$

The fast-oscillating factor $\sin^2(x - \pi l/2)$ was replaced by its mean value, equal to $1/2$. This result is valid in case a), where $rU(r) \to 0$ for $r \to 0$.

For more singular potentials, Eq. (1) is not applicable, due to a divergence of the integral. Such a divergence means that now the region of small r plays a dominant role, and we cannot replace $J_\mu(x)$ by its asymptote. Dividing the integration domain over r in Eq. (XIII.12) into two: from $r = 0$ to some small but finite R, and from $r = R$ to infinity, we see that the second of these integrals is proportional to k^{-1}, as in Eq. (1). A contribution of the first of these integrals is dominant, and we can put there $U = \alpha/r^\nu$. Making substitution $x = kr$, we obtain the [332]

$$\delta_l \approx -\frac{\pi m\alpha}{\hbar^2}k^{\nu-2}\int\limits_0^\infty \frac{J^2_{l+1/2}(x)dx}{x^{\nu-1}} = -\frac{\pi m\alpha}{\hbar^2}\frac{\Gamma(\nu-1)\Gamma(l+(3-\nu)/2)}{2^{\nu-1}\Gamma^2(\nu/2)\Gamma(l+(\nu+1)/2)}k^{\nu-2} \propto k^{\nu-2} \tag{2}$$

Normally, we would replace the upper limit of integration, equal to kR, for $k \to \infty$ by ∞. For $\nu = 1$ however, such a replacement is not valid due to the divergence of the integral (in the upper limit).

Using the asymptote $J_\mu(x)$ for $x \to \infty$, we calculate the divergent part as follows

$$\delta_l \approx -\frac{m\alpha}{\hbar^2 k}\ln kR, \quad \nu = 1 \tag{3}$$

This equation has the logarithmic accuracy in accordance with an uncertainty in the value of R.

Let us note that the ν-dependence of the phase-shifts, $\delta_l(k)$, for $k \to \infty$, affects the scattering of particles with a large momentum transfer. This is connected with the fact that $f^B \propto \tilde{U}(q)$ for large values of q is determined by the singularities of the potential $U(r)$ as a function of r. For singular at $r \to 0$ potentials, $U \approx \alpha/r^\nu$, we have $\tilde{U} \propto q^{\nu-3} \propto k^{\nu-3}$ for $q \to \infty$. But such a difference in the energy dependence of phase-

[332] For $\nu = 2$, the independence of phase-shifts from k holds for any values of α and l, even if the Born approximation is not applicable (see Problem 13.19). Note also that for $\nu > 2$, the Born approximation breaks down.

shifts with fixed values of l does not affect the total scattering cross-section, $\sigma \propto 1/E$, that is determined by angular momenta $l \sim kR \gg 1$.

GKKG.13.26 Born and quasi-classical phase-shifts

Prove that for large values of energy and angular momentum, where $kR \sim l \gg 1$, the Born approximation, (XIII.12), for phase-shifts crosses over to the quasi-classical expression, see Eq. (XIII.14).

Solution

In Eq. (XIII.12) for the values $l \sim kR \gg 1$ (R is the potential radius), we divide the integration domain into two parts: from $r = 0$ to $r = r_0 \equiv (l + 1/2)/k$, and from $r = r_0$ to $r = \infty$. In the second of these integrals, we use the tangent approximation for the Bessel function, i.e., the following asymptote

$$J_\nu\left(\frac{\nu}{\cos\beta}\right) \approx \sqrt{\frac{2}{\pi\nu\tan\beta}}\cos\left(\nu\tan\beta - \beta\nu - \frac{\pi}{4}\right), \quad \nu \gg 1 \tag{1}$$

Here, $\nu = l + 1/2$ and $\nu/\cos\beta = kr$, so that $\nu\tan\beta = k\sqrt{r^2 - r_0^2}$. After replacing the fast-oscillating factor, $\cos^2[\ldots]$, under the integral by its mean value of $1/2$, we find:

$$\delta_l^B(k) \approx -\frac{m}{\hbar^2 k}\int\limits_{r_0}^{\infty}\frac{rU(r)dr}{\sqrt{r^2 - r_0^2}} \tag{2}$$

We restrict ourselves to the second of the integrals mentioned, since the contribution of the first one is small. This smallness is connected to the fact that for $\nu \gg 1$, the function $J_\nu(x)$ decreases exponentially with the decrease of x from the value $x = \nu$. Such a decrease of $J_\nu(x)$ is a manifestation of the common quasiclassical behavior, where the quasiclassical wavefunctions decreases rapidly into a classically-forbidden region, inside a barrier (in this case, the centrifugal barrier).

Equation (2) coincides with the known quasi-classical expression, (XIII.14), for the phase shift in the case of $|U(r)| \ll E$. The use of the Born approximation assumes the fulfilment of a stricter condition, $|U(r)| \ll \hbar v/r$, with $|\delta_l^{B''}| \ll 1$.

According to Eq. (2), a dependence of the phase shift on l and k (in the relevant parameter range) is determined by the expression:

$$\delta_l^B(k) = \frac{g(s)}{k}, \quad s = \frac{l + 1/2}{k} \tag{3}$$

The function $g(s)$ depends on the concrete form of the potential. If the Born approximation applies, by replacing the summation over l with an integration in Eq. $f(k,\theta) = \sum\limits_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$, we obtain the known result, $\sigma \propto 1/E$ for $E \to \infty$ (for a short-range potential).

17.3.13 Advanced different problems about typical scatterings

ЛШ-11 Диаграммный ряд и интегральное уравнение для амплитуды рассеяния

Покажите, что рассеяние частицы в статическом внешнем поле $V(\mathbf{r})$ описывается суммой графиков:

Какие выражения надо сопоставлять графическим элементам? (Используйте импульсное представление.)

Свяжите эти диаграммы с амплитудой рассеяния $f(\mathbf{k}_1, \mathbf{k}_2)$. Получите соотношение

$$f(\mathbf{k}_1, \mathbf{k}_2) = -\frac{m}{2\pi\hbar^2}F(\mathbf{k}_1, \mathbf{k}_2)$$

где $F(\mathbf{k}_1, \mathbf{k}_2)$ удовлетворяет уравнению

$$F(\mathbf{k}_1, \mathbf{k}_2) = V(\mathbf{k}_2 - \mathbf{k}_1) + \int\frac{V(\mathbf{k}_2 - \mathbf{q})F(\mathbf{k}_1, \mathbf{q})}{\varepsilon - \hbar^2\mathbf{q}^2/2m + i\delta}\frac{d^3q}{(2\pi)^3},$$

где $\varepsilon = \hbar^2\mathbf{k}_1^2/(2m) = \hbar^2\mathbf{k}_2^2/(2m)$. Определенную так амплитуду $F(\mathbf{k}_1, \mathbf{k}_2)$ называют амплитудой рассеяния в энергетической нормировке.

Пользоваться ею часто бывает удобнее, чем обычной амплитудой рассеяния. Именно такая амплитуда рассеяния естественно возникает в диаграммной технике (см. другие задачи этой главы, а также задачи глав 9 - 11). (???) По сравнению с обычной квантовомеханической амплитудой рассеяния $f(\mathbf{k}_1, \mathbf{k}_2)$, она менее произвольна, поскольку никак не зависит от выбора нормировки плоских волн.

Solution.

Суть в том, что (?!??!?)
(не задача, а кусок важной теории и определения параметров. впишу в 1ю потом!!!)
Мы будем обращаться с функцией Грина несколько более вольно, чем это принято в учебниках по квантовой механике. Перед тем, как читать решение, полезно вспомнить стандартный вывод интегрального уравнения для амплитуды рассеяния, использующий уравнение Шредингера в импульсном представлении (см. [2], §130).
(???? пока его не полностью выучил, потом доработаю!!!)
Чтобы найти состояние рассеяния (3.3),(3.4), запишем уравнение Шредингера для движения в потенциале $V(\mathbf{r})$ через функцию Грина:

$$\hat{G}^{-1}\psi_{\mathbf{k}}(\mathbf{r}) = 0 \quad \text{или} \quad \left(\hat{G}_0^{-1} - \hat{V}\right)\psi_{\mathbf{k}}(\mathbf{r}) = 0.$$

Будем искать решение в виде $\psi_{\mathbf{k}}(\mathbf{r}) = e^{i\mathbf{kr}} + \chi_{\mathbf{k}}(\mathbf{r})$. На массовой поверхности, при $\varepsilon = k^2/2m$, получаем уравнение для $\chi_{\mathbf{k}}(\mathbf{r})$:

$$\left(\hat{G}_0^{-1} - \hat{V}\right)\chi_{\mathbf{k}}(\mathbf{r}) = V|\mathbf{k}\rangle$$

(???? тоже пока не понял этот переход)
Записываем решение через функцию Грина, $\chi_{\mathbf{k}}(\mathbf{r}) = \langle\mathbf{r}|\hat{G}\hat{V}|\mathbf{k}\rangle$, и разлагаем $\hat{G}$ в ряд по $\hat{V}$:

$$\chi_{\mathbf{k}}(\mathbf{r}) = \langle\mathbf{r}|\hat{G}_0\hat{V} + \hat{G}_0\hat{V}\hat{G}_0\hat{V} + ...|\mathbf{k}\rangle.$$

Удобно переписать это выражение, введя оператор

$$\hat{F} = \hat{V} + \hat{V}\hat{G}_0\hat{V} + \hat{V}\hat{G}_0\hat{V}\hat{G}_0\hat{V} + ...$$

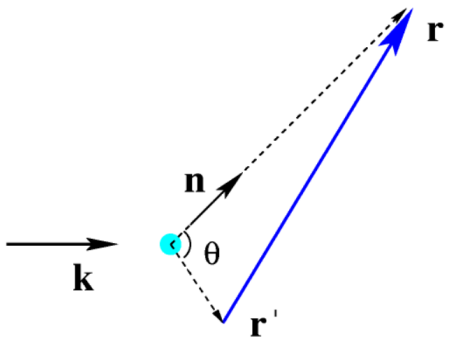
Имеем

$$\chi_{\mathbf{k}}(\mathbf{r}) = \langle\mathbf{r}|\hat{G}_0\hat{F}|\mathbf{k}\rangle.$$

Смысл этой записи в том, что $\hat{F}$ описывает многократное рассеяние падающей волны на потенциале $V(\mathbf{r})$, а $\hat{G}_0$ - свободное движение после последнего рассеяния.
В координатном представлении G_0 имеет вид:

$$G_0(\varepsilon, \mathbf{r}, \mathbf{r}') = \int \frac{e^{i\mathbf{p}(\mathbf{r}-\mathbf{r}')}}{\varepsilon - \mathbf{p}^2/2m + i\delta}\frac{d^3p}{(2\pi)^3} = -\frac{m}{2\pi\hbar^2}\frac{e^{i\varkappa|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|},$$

где $\hbar\varkappa = \sqrt{2m\varepsilon}$. На массовой поверхности $\varkappa = k$. Здесь в знаменателе слагаемое $i\delta$ введено для того, чтобы выбрать запаздывающее решение. С тем же успехом можно было бы выбрать знак $-i\delta$, что привело бы к ряду для $f^*(\mathbf{k}', \mathbf{k})$. Комплексно-сопряженная амплитуда соответствует опережающему решению задачи о рассеянии.
Нас интересует асимптотика $\chi(\mathbf{r})$, поэтому запишем $\mathbf{r} = R\mathbf{n}$ и будем считать R большим. Тогда $|\mathbf{r}-\mathbf{r}'| = R - |\mathbf{r}'|\cos\theta + O(1/R)$, где θ - угол между $\mathbf{n}$ и $\mathbf{r}'$



Подставляем G_0 и разлагаем $|\mathbf{r}-\mathbf{r}'|$:

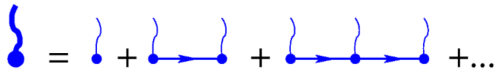
$$\chi(\mathbf{r}) = -\frac{m}{2\pi\hbar^2}\frac{e^{i\varkappa R}}{R}\int e^{-i\varkappa|\mathbf{r}'|\cos\theta}\langle\mathbf{r}'|F|\mathbf{k}\rangle d^3r'.$$

Сравнивая этот ответ с определением амплитуды рассеяния, получаем требуемое соотношение:

$$f(\mathbf{k}_1, \mathbf{k}_2) = -\frac{m}{2\pi\hbar^2}\langle\mathbf{k}_2|\hat{F}|\mathbf{k}_1\rangle$$

где $\mathbf{k}_2 = |k_1|\mathbf{n}$.

Перейдем к выводу интегрального уравнения. Ряд для $\hat{F}$ может быть представлен графически, как показано на рис.



Запишем сумму

$$F = \hat{V} + \hat{V}\hat{G}_0\hat{V} + \hat{V}\hat{G}_0\hat{V}\hat{G}_0\hat{V} + ...$$

в импульсном представлении:

$$F(\mathbf{k}_1, \mathbf{k}_2) = F^{(1)}(\mathbf{k}_1, \mathbf{k}_2) + F^{(2)}(\mathbf{k}_1, \mathbf{k}_2) + ...,$$

где

$$F^{(1)}(\mathbf{k}_1, \mathbf{k}_2) = V(\mathbf{k}_2 - \mathbf{k}_1),$$

$$F^{(2)}(\mathbf{k}_1, \mathbf{k}_2) = \int \frac{V(\mathbf{k}_2 - \mathbf{q})\, V(\mathbf{q} - \mathbf{k}_1)\left(d^3q\right)}{\varepsilon - \mathbf{q}^2/(2m) + i\delta},$$

$$\cdots\cdots\cdots\cdots\cdots\cdots$$

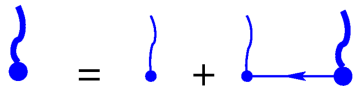
$$F^{(n)}(\mathbf{k}_1, \mathbf{k}_2) = \int ... \int \frac{V(\mathbf{k}_2 - \mathbf{q}_{n-1}) ... V(\mathbf{q}_1 - \mathbf{k}_1)\left(d^3q_{n-1}\right) ... \left(d^3q_1\right)}{\left(\varepsilon - \mathbf{q}_{n-1}^2/(2m) + i\delta\right) ... \left(\varepsilon - \mathbf{q}_1^2/(2m) + i\delta\right)},$$

где $\left(d^3q_i\right) = d^3q_i/(2\pi)^3, \varepsilon = \hbar^2\mathbf{k}_1^2/(2m)$.

Связь этих выражений с рядом выше очевидна: волнистым линиям соответствуют матричные элементы потенциала, прямым линиям — функции Грина. По всем внутренним импульсам надо проинтегрировать, а входящий и выходящий импульсы взять на массовой поверхности. Получаем интегральное уравнение для $\hat{F}$:

$$\begin{aligned}\hat{F} &= \hat{V} + \hat{V}\hat{G}_0\hat{V} + \hat{V}\hat{G}_0\hat{V}\hat{G}_0\hat{V} + ... = \\ &= \hat{V} + \hat{V}\hat{G}_0\left(\hat{V} + \hat{V}\hat{G}_0\hat{V} + ...\right) \\ &= \hat{V} + \hat{V}\hat{G}_0\hat{F}\end{aligned}$$

Графически это можно изобразить так:



В импульсном представлении интегральное уравнение принимает вид

$$F(\mathbf{k}_1, \mathbf{k}_2) = V(\mathbf{k}_2 - \mathbf{k}_1) + \frac{2m}{\hbar^2}\int \frac{V(\mathbf{k}_2 - \mathbf{q})\, F(\mathbf{k}_1, \mathbf{q})}{k_1^2 - q^2 + i\delta}\frac{d^3q}{(2\pi)^3}.$$

Решая это уравнение последовательными приближениями, вновь получаем ряд для $\hat{F}$.

(??? окей, вроде идейно все понятно, нашел уравнения, теперь понять нужно, как их решать???? также пока не готов самостоятельно это вывести, тут еще нужно тренироваться!)

ЛШ-12 Слабо связанное состояние в мелкой яме (!!)

(типичная задача, среди первых перенесу или в теорию)

Мелкая яма - яма, глубина которой $U_0 \ll \hbar^2/2ma^2$, где a - радиус ямы. Размер связанного состояния в такой яме много больше ее радиуса, а энергия связи - много меньше глубины ямы U_0. Рассмотрим мелкую яму в пространстве произвольной размерности D, и выясним, в каких случаях в ней может образоваться связанное состояние.

Решите эту задачу, используя связь амплитуды рассеяния со связанными состояниями $F(\mathbf{k}_1, \mathbf{k}_2) = V(\mathbf{k}_2 - \mathbf{k}_1) + \int \frac{V(\mathbf{k}_2 - \mathbf{q})F(\mathbf{k}_1, \mathbf{q})}{\varepsilon - \hbar^2\mathbf{q}^2/2m + i\delta}\frac{d^3q}{(2\pi)^3}$. Энергия каждого связанного состояния соответствует полюсу амплитуды $F(\mathbf{k}_1, \mathbf{k}_2)$ как функции энергии ε. Покажите, что связанное состояние в мелкой яме существует только при $D \leqslant 2$.

Воспользуйтесь тем, что в пространстве размерности D амплитуда $F(\mathbf{k}_1, \mathbf{k}_2)$ удовлетворяет аналогичному уравнению, только при $d^3q/(2\pi)^3 \to d^Dq/(2\pi)^D$. В уравнении (3.13) замените потенциал ямы на δ-функцию - при этом все интегрирования по импульсам станут независимыми.

Сравните результаты, получающиеся при $D = 1, 2$, с известными квантовомеханическим выражениями (см. задачи в ЛЛ3 пар 45)

(??? кст, почему я их еще не знаю, выпишу их!???)

Смысл и обзор решения 12.

Полюсы функции Грина $\hat{G}(\varepsilon)$ дают спектр системы.
(?? в теории плохо это прописано, не глубоко понимаю это утверждение ещё. допишу в теорию!!)
При этом, поскольку $\hat{G}$ и $\hat{F}$ связаны соотношением $\hat{G} = \hat{G}_0 + \hat{G}_0\hat{F}\hat{G}_0$, каждому связанному состоянию отвечает полюс $\hat{F}(\varepsilon)$.

Размерность $D = 1$

Начнем со случая $D = 1$. Рассмотрим одномерную яму глубины U_0 и ширины a. Заменяя потенциал на δ-функцию $V(x) = -U_0 a\delta(x)$, получаем фурье-компоненту $V(q) = -U_0 a = \text{const}$. При этом уравнение для $F(k, k')$ принимает вид

$$F(k, k') = -U_0 a + U_0 a \int \frac{F(k, q)}{\varepsilon - q^2/2m + i\delta} \frac{dq}{2\pi}.$$

(???? нужно четко прописать свойства этого уравнения, пока только вывел его в задаче выше, по сути в теории нужно это написать нормально!!)
Видим, что $F(k, k')$ не зависит от k', поэтому

$$F(k) = -U_0 a - \frac{U_0 a}{2\pi} F(k) \int\limits_{-\infty}^{+\infty} \frac{2m dq}{q^2 - k^2 - i\delta},$$

что дает

$$F^{-1} + (U_0 a)^{-1} = -im/k = -i\sqrt{m/2\varepsilon},$$

где $\varepsilon = k^2/(2m)$.
(?? интеграл такой еще не считал, вроде не сложно, но потом пересчитаю!)
Получаем

$$F(\varepsilon) = -\frac{U_0 a\sqrt{2(\varepsilon + i\delta)/m}}{\sqrt{2(\varepsilon + i\delta)/m} + iU_0 a}.$$

(?? нужно проделать, пока не проделал все еще!??!)
Амплитуда рассеяния $F(\varepsilon)$ имеет полюс при $\varepsilon_0 = -mU_0^2 a^2/\left(2\hbar^2\right)$, что совпадает с известным ответом для одномерной δ-ямы.

Размерность $D = 2$

Пусть теперь $D = 2$. Снова считаем фурье-компоненту потенциала независящей от $k : V(k) = -U_0 a^2$. Уравнение для F имеет вид

$$F(\varepsilon) = -U_0 a^2 + U_0 a^2 \frac{2m}{\hbar^2} \int F(\varepsilon) \frac{2\pi q}{q^2 - k^2 - i\delta} \frac{dq}{(2\pi)^2},$$

где F снова есть функция только ε.
Интеграл $\int\limits_0^\infty \frac{dq^2}{q^2 - k^2 - i\delta}$ логарифмически расходится на верхнем пределе. Но это не страшно: при $q \geqslant a^{-1}$ фурье-компонента $V(k)$ начинает быстро осциллировать, и интеграл с $V(k)$ сходится. Следовательно, можно пользоваться выражением (3.33), обрезав его “вручную” при $q \approx a^{-1}$:

$$\int\limits_0^{a^{-2}} \frac{dq^2}{q^2 - k^2 - i\delta} = \pi i + \ln \frac{1}{a^2 (k^2 + i\delta)}$$

(!!!! это полный бред, интеграл так не взять. полностью бредовая формула. в теории потом напишу, как делать нормально (пока додумываю))
Итак,

$$F(\varepsilon) \approx -\frac{U_0 a^2}{1 + (2ma^2 U_0/4\pi\hbar^2) \ln(-k^2 a^2)} = -\frac{U_0 a^2}{1 + (mU_0 a^2/2\pi\hbar^2) \ln(-\varepsilon m a^2/\hbar^2)}$$

Дискретный уровень находим как полюс F:

$$\varepsilon_0 \approx -\frac{\hbar^2}{ma^2}\exp\left(-\frac{2\pi h^2}{ma^2U_0}\right).$$

Обратим внимание, что из-за неизвестного множителя порядка единицы, появившегося при обрезании в аргументе логарифма, уровень ε_0 дается выражением (3.36) только по порядку величины.

(??? мы ведь не знаем, где обрезать на самом деле нужно?? почему именно там обрезка идет есть пояснения?)

Размерность $D > 2$

В размерности $D > 2$ интеграл

$$\int_0^{a^{-1}} \frac{q^{D-1}dq}{q^2 - k^2 - i\delta}$$

остается конечным при $k \to 0$. Поэтому для слабого потенциала $F(\varepsilon)$ не имеет полюсов при $|k| \ll a^{-1}$, что означает отсутствие связанного состояния.

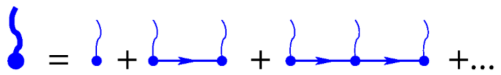
(укажу это в теории. там как-то из каких-то других соображений этот вывод был получен)

ЛШ-13 Двумерное рассеяние: логарифм и ренормгруппа (???)

Рассмотрим подробнее рассеяние в размерности 2 на короткодействующем потенциале. Это может быть яма, причем не обязательно мелкая, или потенциал положительного знака. Определим зависимость амплитуды рассеяния F от энергии в низкоэнергетической области. Нас интересует область энергий много меньших $\varepsilon_a = \hbar^2/2ma^2$, где a - радиус ямы. Ясно, что зависимость от энергии ε возникает от интегрирования по $|q| \ll a^{-1}$.

Для правильного описания низкоэнергетической физики, как и при отыскании связанного состояния, кажется достаточным заменить потенциал на δ-функцию. При этом интегралы по q начинают логарифмически расходиться при $q \to \infty$, и их придется «обрезать руками» при $q \approx a^{-1}$. Такой "ремесленный" подход, хотя и приводит к качественно правильному ответу, является слишком грубым, т.к. полностью игнорирует, например, глубокие уровни в потенциале, если таковые есть.

Более рафинированный метод заключается в следующем. Вычислим производную $\partial F(\varepsilon)/\partial\varepsilon$. Дифференцируя диаграммы рис.



по ε и собирая члены, получим уравнение

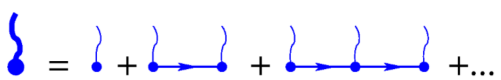
$$\frac{\partial}{\partial\varepsilon}F(\varepsilon) = \frac{m}{2\pi\hbar^2\varepsilon}F^2(\varepsilon),$$

справедливое при $|\varepsilon| \ll \varepsilon_a$. Решив это уравнение, можно связать обрезку логарифма и амплитуду F при большой энергии.

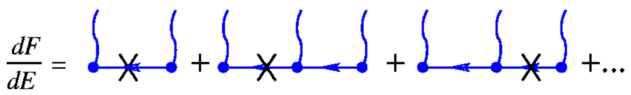
(???? забыли сформулировать, что в задаче то делать? проделать эти вычисления?)

Solution. 13.

Производную $\partial F/\partial\varepsilon$ можно связать с F в общем виде, так, что получится выражение, справедливое при произвольном потенциале. Для этого надо продифференцировать ряд

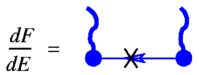


почленно, получим:



$$\text{ } := \frac{\partial}{\partial\varepsilon}G_0 = -\frac{1}{\left(\varepsilon - p^2/2m + i\delta\right)^2} = -G_0^2.$$

Группируя члены графического ряда и пользуясь графическим представлением амплитуды F (жирными линиями), находим:



(??? проверю!)
Отсюда:

$$\frac{\partial}{\partial\varepsilon}F_\varepsilon\left(k_1,k_2\right) = -\int \frac{F_\varepsilon\left(k_1,q\right)F_\varepsilon\left(q,k_2\right)}{\left(\varepsilon - q^2/2m + i\delta\right)^2}\frac{d^2q}{(2\pi)^2},$$

это точный результат, а не приближенный.

Чтобы применить это соотношение в низкоэнергетической области, заметим, что зависимость $F_\varepsilon\left(k_1,k_2\right)$ от k_1 и k_2 имеет характерный масштаб $k_{1,2} \approx a^{-1}$ (??? почему???). Поэтому при малых энергиях $|\varepsilon| \ll \varepsilon_a = \hbar^2/\left(ma^2\right)$ здесь интеграл по q сходится в области, где зависимость F от q несущественна.

$$-\int \frac{F_\varepsilon\left(k_1,q\right)F_\varepsilon\left(q,k_2\right)}{\left(\varepsilon - q^2/2m + i\delta\right)^2}\frac{d^2q}{(2\pi)^2} \approx -\frac{F^2}{4\pi^2}\cdot 2m\int\limits_\varepsilon^{+\infty}\frac{dx}{x^2}$$

$$\frac{\partial}{\partial\varepsilon}F = -\frac{m}{2\pi\hbar^2\varepsilon}F^2.$$

$$F(\varepsilon) = \frac{2\pi\hbar^2}{m\ln\left((\varepsilon+i\delta)/\varepsilon_0\right)},$$

где ε_0 - неизвестная константа. Точка ветвления логарифма при $\varepsilon = 0$ смещена в нижнюю полуплоскость, поскольку вместо ε стоит $\varepsilon + i\delta$. Константа ε_0 вещественна и отрицательна, поскольку при $\varepsilon < 0$ амплитуда F вещественна. Чтобы в этом убедиться, можно записать члены ряда для F, показанные на рис. 3.1, в координатном представлении, где функция Грина имеет вид $G_\varepsilon(r) = -(m/2\pi r)\exp(-\varkappa r)$, $\varkappa^2 = 2m\varepsilon$. Это выражение вещественно при $\varepsilon < 0$. (???)

Если ε_0 находится в низкоэнергетической области, $|\varepsilon_0| \leqslant \varepsilon_a$, то полюс при $\varepsilon = \varepsilon_0$ имеет реальный смысл, и ему соответствует дискретный уровень. В противном случае полюс находится вне области энергий, где применимо сделанное приближение, и поэтому смысла не имеет. Такая ситуация возникает, например, для рассеяния на слабом отталкивающем потенциале, когда ε_0 дается выражением (3.36) с отрицательным U_0.

(?? не, тут не совсем доехал, еще мало понимаю происходящее. плюс 1ю часть дорабатывать нужно про рассеяние, еще не готов к этим темам.)

ЛШ-14 Поляризуемость связанного состояния

Заряженная частица находится в мелкой двумерной яме в основном состоянии. Определим поляризуемость системы в слабом внешнем поле.

а) Используя формализм функции Грина и $F(\varepsilon) = \frac{2\pi\hbar^2}{m\ln((\varepsilon+i\delta)/\varepsilon_0)}$, запишите функцию Грина в импульсном представлении. Сформулируйте правило обхода полюсов, выражающее, что связанное состояние занято, а состояния непрерывного спектра свободны.

б) Выразите дипольный момент системы через точную функцию Грина в импульсном представлении.

в) Рассмотрите поправку к функции Грина, линейную по электрическому полю. Нарисуйте графики, определяющие поляризуемость. Какие из них обращаются в нуль при интегрировании по энергии или импульсам?

Обзор решения

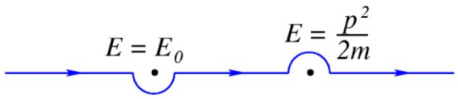
(тут большое решение, потом допишу обзор.)

14.а) определение функции Грина

Согласно формализму функции Грина, $G = G_0 + G_0 F G_0$, где амплитуда $F(\varepsilon) = \frac{2\pi\hbar^2}{m\ln((\varepsilon+i\delta)/\varepsilon_0)}$, что можно получить из дифференцирования диаграмм и решения получившегося уравнения. В импульсном представлении

$$G(\varepsilon, \mathbf{p}, \mathbf{p}') = (2\pi)^2 \frac{\delta^{(2)}(\mathbf{p}-\mathbf{p}')}{\varepsilon - p^2/(2m) + i\delta} + \frac{F(\varepsilon)}{[\varepsilon - p^2/(2m) + i\delta]\,[\varepsilon - p'^2/(2m) + i\delta]}.$$

Положительный знак мнимой части $i\delta$ означает, что состояния непрерывного спектра пусты. При интегрировании по ε эти полюсы надо обходить сверху. Осталось выбрать обход полюса в $F(\varepsilon)$ при $\varepsilon = \varepsilon_0$. Это состояние заполнено, поэтому сдвигаем полюс вверх: $\varepsilon_0 \to \varepsilon_0 + i\delta$. Получаем $F(\varepsilon) = 2\pi\hbar^2/(m\ln(\varepsilon/\varepsilon_0))$, причем обход полюса $\varepsilon = \varepsilon_0$ и точки ветвления $\varepsilon = 0$ такой, как показано на рис. ниже:



14.б) поиск дипольного момента через функцию Грина

$$\begin{aligned}
\mathcal{P} &= e\int \mathbf{r} n(\mathbf{r}) d^2r = -ie\int \lim_{t\to-0} \mathbf{r} G(t,\mathbf{r},\mathbf{r}) d^2r = \\
&= e\iint \left(\int \mathbf{r} e^{i(\mathbf{p}_1-\mathbf{p}_2)\mathbf{r}} d^2r\right)\cdot\left(\lim_{t\to-0}\int e^{-i\omega t} G(\omega,\mathbf{p}_1,\mathbf{p}_2)\frac{d\omega}{2\pi i}\right)\frac{d^2p_1 d^2p_2}{(2\pi)^4} = \\
&= -ie\iint \nabla_1\delta(\mathbf{p}_1-\mathbf{p}_2)\sum \mathrm{Res}_\omega\, G(\omega,\mathbf{p}_1,\mathbf{p}_2)\frac{d^2p_1 d^2p_2}{(2\pi)^2},
\end{aligned}$$

где сумма вычетов берется по всем полюсам ω функции G в верхней полуплоскости ε, что соответствует заполненным уровням. Интегрируя по частям, получаем

$$\mathcal{P} = ie\int \left[\nabla_{\mathbf{p}} \sum \mathrm{Res}_\omega\, G(\omega,\mathbf{p},\mathbf{p}')\right]\Big|_{\mathbf{p}'=\mathbf{p}} \frac{d^2p}{(2\pi)^2}.$$

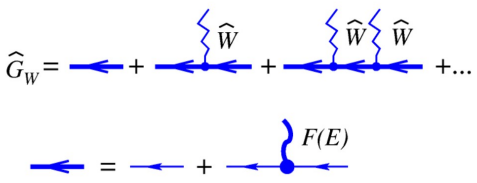
Другую (эквивалентную) форму записи можно получить, если заменить $\nabla_{\mathbf{p}}$ на $\nabla_{\mathbf{p}'}$ и изменить знак.

14.в) Определение поправки и поляризации

Взаимодействие с электрическим полем $W = -eEx$ меняет функцию Грина:

$$\hat{G}_W = \hat{G} + \hat{G}\hat{W}\hat{G} + \hat{G}\hat{W}\hat{W}\hat{G} + \ldots$$

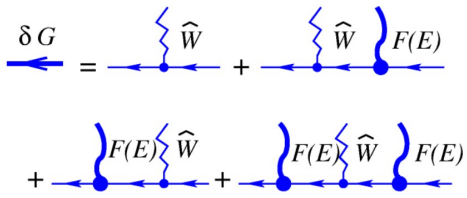
где $\hat{G}$ - точная функция Грина при $E = 0$. Графически это можно представить так:



В импульсном представлении взаимодействию W, линейному по координатам, соответствует производная δ-функции:

$$W(\mathbf{p}) = -\int eEx e^{-i\mathbf{p}\mathbf{r}} d^2r = -ie(2\pi)^2 E\frac{\partial}{\partial p_x}\delta^{(2)}(\mathbf{p}).$$

Для вычисления поляризуемости нужен линейный по полю член ряда (3.45). С учетом структуры G, согласно (3.42), имеем 4 слагаемых (рис. 3.9):



Первое из них есть G_0WG_0. Оно не имеет особенностей над контуром интегрирования по энергии и, поэтому, дает нулевой вклад. Вычислим остальные члены. Выражение $\hat{G}_0W\hat{G}_0\hat{F}\hat{G}_0\,(p,p')$, соответствующее второй диаграмме рис. 3.9, есть:

$$\int \frac{-ieE\partial/\partial p_x\delta^{(2)}\,(\mathbf{p}-\mathbf{p}_1)}{(\varepsilon-p^2/2m+i\delta)}\frac{F(\varepsilon)}{(\varepsilon-p_1^2/2m+i\delta)\,(\varepsilon-p^2/2m+i\delta)}d^2\mathbf{p}_1 =$$
$$= \int \delta\,(\mathbf{p}_1-\mathbf{p})\,\frac{\partial}{\partial p_{1x}}\frac{-ieEF(\varepsilon)}{(\varepsilon-p^2/2m+i\delta)}\times$$
$$\times\frac{1}{(\varepsilon-p_1^2/2m+i\delta)\,(\varepsilon-p^2/2m+i\delta)}d^2\mathbf{p}_1 =$$
$$= -\frac{ieE}{m}F(\varepsilon)\frac{p_x}{(\varepsilon-p^2/2m+i\delta)^3\,(\varepsilon-p^2/2m+i\delta)}.$$

Третье слагаемое получается из второго комплексным сопряжением и перестановкой p и p':

$$\hat{G}_0\hat{F}\hat{G}_0\hat{W}\hat{G}_0\,(\mathbf{p},\mathbf{p}') = \frac{ieEp'_xF(\varepsilon)/m}{(\varepsilon-p^2/2m+i\delta)\,(\varepsilon-p'^2/2m+i\delta)^3}.$$

Последний график $\hat{G}_0\hat{F}\hat{G}_0\hat{W}\hat{G}_0\hat{F}\hat{G}_0\,(p,p')$ равен нулю:

$$ieEF^2(\varepsilon)\iint\frac{d^2p_1d^2p_2}{(2\pi)^2}G_0(\varepsilon,\mathbf{p})G_0\,(\varepsilon,\mathbf{p}_2)\,G_0\,(\varepsilon,\mathbf{p}_1)\,G_0\,(\varepsilon,\mathbf{p}')\,\nabla_{1x}\delta\,(\mathbf{p}_2-\mathbf{p}_1) =$$
$$= -ieEF^2(\varepsilon)G_0(\varepsilon,p)G_0\,(\varepsilon,\mathbf{p}')\int\frac{d^2p_1}{(2\pi)^2}\frac{p_{1,x}/m}{(\varepsilon-p_1^2/2m+i\delta)^3} = 0,$$

как интеграл от нечетной функции. Поэтому

$$\sum_\omega \mathrm{Res}\,G\,(\omega,\mathbf{p},\mathbf{p}') = \mathrm{Res}_{\varepsilon_0}\,F(\varepsilon)\frac{ie}{m}E\left[p'_xG_0\,(\varepsilon_0,\mathbf{p})\,G_0^3\,(\varepsilon_0,\mathbf{p}') - p_xG_0^3\,(\varepsilon_0,\mathbf{p})\,G_0\,(\varepsilon_0,\mathbf{p}')\right].$$

Из-за отмеченной выше симметрии по отношению к перестановке $\mathbf{p}$ и $\mathbf{p}'$ оба слагаемых дают одинаковый вклад в поляризуемость, поскольку и в выражение (3.44) для дипольного момента $\mathcal{P}$ импульсы $\mathbf{p}$ и $\mathbf{p}'$ входят симметрично. Следовательно, достаточно взять только первое слагаемое и удвоить ответ:

$$\mathcal{P}_x = -2\frac{e^2}{m^2}E\int\frac{p_x^2}{(\varepsilon_0-p^2/2m+i\delta)^5}\,\mathrm{Res}_{\varepsilon_0}\,F(\varepsilon)\frac{d^2p}{(2\pi)^2}.$$

Наконец, вычислим поляризуемость

$$\chi_{\alpha\beta} = \frac{2e^2}{m^2}\int\frac{p_\alpha p_\beta(2m)^5}{(p^2+\varkappa^2)^5}\,\mathrm{Res}_{\varepsilon_0}\,F(\varepsilon)\frac{d^2p}{(2\pi)^2},$$

где $\varkappa^2 = 2m|\varepsilon_0|$. Вычислим $\mathrm{Res}_{\varepsilon_0}\,F(\varepsilon)$. Положив $\varepsilon = \varepsilon_0 + z$, разлагаем

$$F(\varepsilon) = \frac{2\pi}{m\ln\,(1+z/\varepsilon_0)} \approx \frac{2\pi\varepsilon_0}{mz}, \qquad \text{откуда} \qquad \mathrm{Res} = \frac{2\pi\varepsilon_0}{m}.$$

Находим

$$\chi_{\alpha\beta} = e^2m^2\varepsilon_0\int\limits_0^{+\infty}\frac{2^6\pi\delta_{\alpha\beta}}{(p^2+\varkappa^2)^5}\frac{p^3dp}{2\pi} = \delta_{\alpha\beta}\frac{16e^2m^2\varepsilon_0}{(2m\varepsilon_0)^3}\int\limits_0^{+\infty}\frac{xdx}{(x+1)^5} = \frac{e^2\delta_{\alpha\beta}}{6m\varepsilon_0^2}.$$

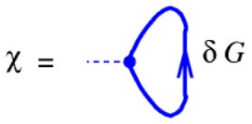
Восстанавливая $\hbar$ по размерности, получаем $\chi = e^2\hbar^2/\left(6m\varepsilon_0^2\right)$.

14.в) Другой способ определения дипольного момента (?????)

К выражению

$$\mathcal{P}_x = -2\frac{e^2}{m^2}E\int \frac{p_x^2}{\left(\varepsilon_0 - p^2/2m + i\delta\right)^5}\,\mathrm{Res}_{\varepsilon_0}\,F(\varepsilon)\frac{d^2p}{(2\pi)^2}.$$

можно прийти несколько быстрее, если заметить, что вершина взаимодействия с электрическим полем устроена точно так же, как и выражение для дипольного момента (3.44). (В координатном представлении (3.50) есть свертка производной δ-функции с функцией Грина по ее аргументам.) Поэтому все вклады в поляризуемость можно представить графически так (рис. 3.10):



Здесь δG дается суммой четырех слагаемых, показанных на рис. 3.9, а штриховая линия обозначает $\nabla\delta(\mathbf{p})$ в импульсном представлении, или $\mathbf{r}$ - в координатном. Первый график на рис. 3.9 дает нуль при интегрировании по энергиям, а четвертый, из-за нечетности $\mathbf{r}$, - обращается в нуль при интегрировании по импульсам. Второй и третий графики отличны от нуля и равны в силу симметрии.

Solution. без диаграмм (????)

(??? можно ли решить эту задачу без диаграмм??? потом попробую. 1D случай для дельта-ямы уже решен.. как этот ответ связан с тем ответом, кстати? пока для меня это два разных значения поляризуемости и всё.)

Пример конкретных мелких 2D ям (????)

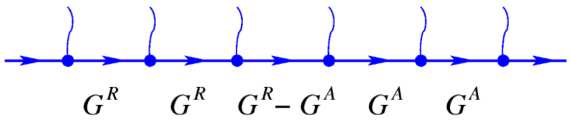
(??? я правильно понимаю, что ε_0 можно запросто определить, зная величину потенциала, а потом подставить сюда???? приведу какой-то пример тут с конкретными значениями!)

ЛШ-15 Теорема унитарности графически

Амплитуда рассеяния $f(\mathbf{k},\mathbf{k}')$ частицы во внешнем поле удовлетворяет теореме унитарности:

$$f(\mathbf{k},\mathbf{k}') - f^*(\mathbf{k}',\mathbf{k}) = \frac{ik}{2\pi}\int f(\mathbf{k},\mathbf{k}'')\,f^*(\mathbf{k}',\mathbf{k}'')\,do''$$

Мы видели, что $F(\mathbf{k},\mathbf{k}') = -\left(2\pi\hbar^2/m\right)f(\mathbf{k},\mathbf{k}')$ дается простой суммой графиков. Поэтому полезно уметь получать соотношение унитарности на графическом языке. Как это сделать? Рассмотрите диаграммы вида

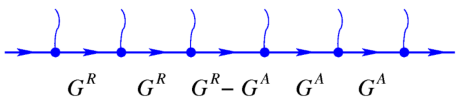


где $G^{R(A)}(\varepsilon,\mathbf{p}) = \frac{1}{\varepsilon - \mathbf{p}^2/2m \pm i\delta}$ — запаздывающая и опережающая функции Грина. Получите левую и правую части равенства теоремы унитарности, просуммировав эти графики двумя разными способами.

Аналогично получите соотношение унитарности в двумерном случае. Какова связь двумерной амплитуды рассеяния $f(\mathbf{k},\mathbf{k}')$ с $F(\mathbf{k},\mathbf{k}')$? Убедитесь, что амплитуда F, найденная в задаче 13, обладает свойством унитарности.

Solution. в 1D

Суммируем диаграммы, изображенные на рис.



С одной стороны, раскрывая по линейности и группируя члены, имеем $F(\mathbf{k},\mathbf{k}')-F^*(\mathbf{k}',\mathbf{k})$, поскольку все остальные члены, содержащие G^R и G^A одновременно, взаимно сокращаются. С другой стороны,

$$G^R-G^A=\frac{1}{\varepsilon-p^2/2m+i\delta}-\frac{1}{\varepsilon-p^2/2m-i\delta}=-2\pi i\delta\left(\varepsilon-p^2/2m\right).$$

И вдобавок, при собирании всех графиков, слева от G^R-G^A возникает выражение $F(\mathbf{k},\mathbf{k}')$, а справа $-F^*(\mathbf{k}',\mathbf{k})$:

$$-2\pi i\int F(\mathbf{k},\mathbf{q})F^*(\mathbf{k}',\mathbf{q})\,\frac{d^3q}{(2\pi)^3}\delta\left(\varepsilon-q^2/2m\right)=-2\pi i\int F(\mathbf{k},\mathbf{q})F^*(\mathbf{k}',\mathbf{q})\,\frac{m}{q}\delta(|\mathbf{q}|-|\mathbf{k}|)do\frac{q^2dq}{(2\pi)^3}=$$
$$=-\frac{imk}{(2\pi)^2}\int F(\mathbf{k},\mathbf{q})F^*(\mathbf{k}',\mathbf{q})\,do.$$

(???? в это пока не въезжаю.)
Сравнивая, получаем теорему унитарности для амплитуды F:

$$F(\mathbf{k},\mathbf{k}')-F^*(\mathbf{k}',\mathbf{k})=-\frac{imk}{(2\pi)^2}\int F(\mathbf{k},\mathbf{q})F^*(\mathbf{k}',\mathbf{q})\,do.$$

Связь с квантовомеханической амплитудой рассеяния, $F=-\left(2\pi\hbar^2/m\right)f$, была найдена в задаче 11.
(??? и какая же она??)
Выражая F через f, приходим к теореме унитарности (3.15).

Solution. в 2D (?)

Повторяя вывод в двумерном случае, получаем

$$F(\mathbf{k},\mathbf{k}')-F^*(\mathbf{k}',\mathbf{k})=-\frac{im}{2\pi}\int F(\mathbf{k},\mathbf{q})F^*(\mathbf{k}',\mathbf{q})\,d\theta$$

В размерности $D=2$ связь F и квантовомеханической амплитуды f другая.
(??? на этом этапе видно, что я вообще не усвоил то, с чем мы работаем.)
Чтобы ее получить, поступим как в задаче 11. Возьмем выражение (3.21) для расходящейся волны, $\chi_{\mathbf{k}}(\mathbf{r})=\langle\mathbf{r}|G_0F|\mathbf{k}\rangle$, верное в любой размерности, и найдем асимптотическое поведение функции G_0:

$$G_0(\varepsilon,\mathbf{r})=\int\frac{e^{i\mathbf{pr}}}{\varepsilon-\hbar^2p^2/2m+i\delta}\frac{d^2p}{(2\pi)^2}\approx-\frac{m}{\hbar^2\sqrt{2\pi k|\mathbf{r}|}}e^{ik|\mathbf{r}|+i\pi/4}$$

при $k|\mathbf{r}|\to\infty$ (см. задачу 6 к §126[2]). Поэтому при $D=2$ амплитуда $f=-\left(m/\hbar^2\sqrt{2\pi k}\right)F$ Поэтому теорема унитарности при $D=2$ гласит:

$$f(\mathbf{k},\mathbf{k}')-f^*(\mathbf{k}',\mathbf{k})=i\sqrt{\frac{k}{2\pi}}\int f(\mathbf{k},\mathbf{q})f^*(\mathbf{k}',\mathbf{q})\,do_q$$

Отметим, что в размерности $D=2$ более удобно включать множитель $e^{i\pi/4}$ в определение расходящейся волны, как это сделано выше, а не в амплитуду рассеяния, как в [2]. При таком определении f, соотношение унитарности принимает наиболее простой вид. Поскольку амплитуда f есть коэффициент при расходящейся волне, включать фазовый множитель в определение f или в выражение для расходящейся волны - дело вкуса.
Воспользуемся случаем, чтобы еще раз отметить существенную разницу между обычной амплитудой f и амплитудой рассеяния в энергетической нормировке F («ужирненной вершиной»). Определение амплитуды F не допускает никакого произвола, поскольку не зависит от выбора выражения для расходящейся волны.

О важности и применимости этой задачи (?????)

Эта задача весьма важна для дальнейшего, поскольку в ней на простейшем примере показан прием, обобщающийся на более сложные случаи. Для любого процесса рассеяния, распада, перехода и т. д. имеется связь между его вероятностью и мнимой частью амплитуды. Эта связь описывается теоремой унитарности. В графическом представлении, мнимая часть какой-либо амплитуды может быть найдена путем разбиения соответствующих диаграмм каким-либо сечением, и заменой функций Грина по одну сторону сечения на комплексно-сопряженные функции. При этом следует просуммировать по всем возможным способам выбора сечения диаграммы. Состояния в сечении имеют смысл конечных состояний распада, рассеяния, и т.п.
(?? не, не знаю, насколько применима она, я не применял, графики - сложно, без них тоже многое решается)

ПТФ.теор Задача Ландау-Зенера методом Лапласа

Задача Ландау - Зенера описывает общий случай «пересечения уровней» (level crossing), и описывается следующим гамильтонианом: $\hat{H} = \begin{pmatrix} \alpha t & \gamma \\ \gamma & -\alpha t \end{pmatrix}$. На $-\infty$ мы имеем волновую функцию $\psi_1 \sim \binom{1}{0}$; Найти вероятность оказаться в каждом из состояний при $t \to \infty$ методом Лапласа.

Напоминание: суть метода Лапласа

(допишу потом)

Solution.

Сводим систему к одному диффуру, делаем преобразование Лапласа, используем метод перевала для двух разных случаев параметра.
(!!!??? решение ниже написано каким-то бездарным человеком, поэтому всё его нужно переписать читабельно. Начать лучше с чтения про эту тему нормальной книги, а не конспекта студентов ПТФ)

$$\begin{cases} i\partial_t \psi_1 = \alpha t \cdot \psi_1 + \gamma \cdot \psi_2 \\ i\partial_t \psi_2 = \gamma \cdot \psi_1 - \alpha t \cdot \psi_2 \end{cases}, \quad |\psi_1(-\infty)|^2 = 1, \quad \psi_2(-\infty) = 0$$

$$z := \alpha^{1/2} t \qquad \beta := \frac{\gamma^2}{2\alpha}$$

$$\psi_1'' + \left(i + 2\beta + z^2\right)\psi_1 = 0$$

$$\psi_1(z) \equiv e^{iz^2/2} f(z)^{17}$$

$$f'' + 2iz \cdot f' + 2(i+\beta) f = 0$$

Применим метод Лапласа:

$$P(t) = t^2 + 2(i+\beta), \qquad Q(t) = 2it, \qquad \int \frac{P}{Q} dt = -\frac{i}{4}t^2 + (-i\beta + 1)\ln t$$

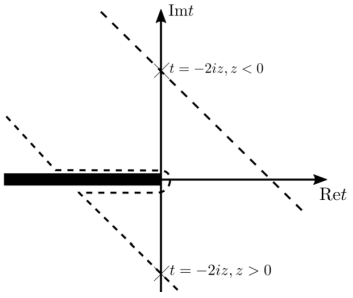
$$f(z) = \int_c dt \cdot t^{-i\beta} \exp\left(-\frac{i}{4}t^2 + zt\right)$$

(?? последнюю формулу нужно прописать, что за формула используется тут??!!!)
Определим седловые точки полученного интеграла:

$$\varphi(t) = -\frac{i}{4}t^2 + zt, \quad \varphi'(t_0) = -\frac{i}{2}t_0 + z = 0 \to t_0 = -2iz, \quad \varphi(t_0) = -iz^2$$

$$\varphi'' = -\frac{i}{2} \to \theta = -\frac{\pi}{4}$$

Таким образом, вклад от седла будет даваться $f(z) \sim e^{-iz^2} \to \psi_1(z) \sim e^{-iz^2/2}$ Кроме этого, для того, чтобы определить многозначную функцию $t^{-i\beta}$, требуется провести разрез.
Вообще говоря, перевальный контур может этот разрез задеть, и в интеграл будет вклад от разреза.



Такой вклад удобно будет оценить, если разрез пустить по вещественной оси влево $t \in (-\infty; 0)$; тогда вдоль разреза функция экспоненциально затухает, и вклад от разреза будет $f \sim 1 \to \psi_1 \sim e^{iz^2/2}$. Исходя

из постановки задачи, мы понимаем, что при $z \to -\infty$ вклад должен быть только от седла, а при $z \to +\infty$ -и от седла, и от разреза.

Это достигается выбором контура, который идёт из 4 четверти во вторую (смотри рисунок).

Случай $z < 0$ Тут имеется только вклад от седла.

При этом многозначная функция $t_0^{-i\beta} = e^{\pi\beta/2} \cdot |t_0|^{-i\beta}$, и получаем (вспоминая, что $\psi_1(z) = e^{-iz^2/2} f(z)\Big)$

$$\psi_1(z \to -\infty) \approx \sqrt{2\pi} e^{\pi\beta/2} e^{-iz^2/2 - i\beta \ln 2|z| - i\pi/4}, \quad |\psi_1(z \to -\infty)|^2 = 2\pi e^{\pi\beta}$$

Воспользуемся первым уравнением, чтобы показать, что $\psi_2(-\infty) = 0$. Подставляя, получаем:

$$\psi_2(z \to -\infty) \approx -\sqrt{\pi\beta} e^{\pi\beta/2} \frac{1}{|z|} e^{-iz^2/2 - i\beta \ln(2|z|) - \frac{i\pi}{4}}, \quad |\psi_2(z \to -\infty)| \approx \frac{\pi\beta e^{\pi\beta}}{z^2} \to 0$$

Тем самым, мы проверили, что найденное решение - ровно то, что мы ищем! Случай $z > 0$ Наша многозначная функция даёт $t_0^{-i\beta} = e^{-\pi\beta/2} |t_0|^{-i\beta}$; тем самым, вклад от седла даётся:

$$\psi_1^{(1)}(z \to +\infty) = \sqrt{2\pi} e^{-\pi\beta/2} e^{-iz^2/2 - i\beta \ln 2z - i\pi/4}, \quad |\psi_1^{(1)}(z \to +\infty)|^2 = 2\pi e^{-\pi\beta/2}$$

Оценим теперь вклад от разреза.

На разных берегах разреза мы имеем:

$$t^{-i\beta} = (-|t|)^{-i\beta} = \begin{cases} e^{\pi\beta} |t|^{-i\beta}, & \operatorname{Im} t = +0 \\ e^{-\pi\beta} |t|^{-i\beta}, & \operatorname{Im} t = -0 \end{cases}$$

Тем самым, вклад от разреза оценивается следующим образом.

На нём затухающая экспонента e^{zt} кважнееэ, чем медленная $e^{-it^2/4}$; получаем:

$$\psi_1^{(2)}(z) = e^{iz^2/2} \left[e^{-\pi\beta} \int\limits_{-\infty}^{0} dt \cdot |t|^{-i\beta} e^{zt} + e^{\pi\beta} \int\limits_{0}^{-\infty} dt |t|^{-i\beta} e^{zt} \right] =$$

$$= e^{iz^2/2} \left(e^{-\pi\beta} - e^{\pi\beta} \right) \int\limits_{0}^{\infty} dt \cdot t^{-i\beta} e^{-zt} = -2 \operatorname{sh} \pi\beta \Gamma(1 - i\beta) \frac{1}{z} e^{i\beta \ln z + iz^2/2},$$

$$|\psi_1^{(2)}(z \to +\infty)|^2 \sim \frac{4\pi\beta \operatorname{sh} \pi\beta}{z^2} \to 0$$

(тут мы воспользовались тем, что $|\Gamma(1 - i\beta)|^2 = \Gamma(1 - i\beta)\Gamma(1 + i\beta) = i\beta \frac{\pi}{\sin(i\pi\beta)} = \frac{\pi\beta}{\operatorname{sh} \pi\beta}\Big)$ Ответ Мы построили все необходимые асимптотики.

Адиабатическое состояние, которое на - ∞ соответствовало в нашем базисе $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$, на $+\infty$ соответствует $\begin{pmatrix} 0 \\ 1 \end{pmatrix}$. Поэтому вероятность адиабатического перехода даётся просто величиной $P = \frac{|\psi_1(t \to +\infty)|^2}{\psi_1(t \to -\infty)|^2} = e^{-2\pi\beta} \equiv e^{-\pi\gamma^2/\alpha}$ (обратим внимание, что вклад от разреза в эту величину, вообще говоря, нулевой). Этот ответ воспроизводит как пертурбативный ответ (при этом $1 - e^{-\pi\gamma^2/\alpha} \approx \pi \frac{\gamma^2}{\alpha}\Big)$, так и адиабатический.

ПТФ-4.y1 Нормировка

Отнормируйте на дельта-функцию от энергии состояния непрерывного спектра, инфинитные в обе стороны для случая потенциала, имеющего различные асимптотики на бесконечностях $U(-\infty) = 0$, $U(+\infty) = U_0$. Для простоты, считайте $E > U_0 > 0$.

Solution.

$$-\frac{\hbar^2}{2m}\psi'' + U(x)\psi = E\psi \to \psi'' + \frac{2m}{\hbar^2}(E - U)\psi = 0$$

$$x \to -\infty \qquad \Rightarrow \qquad \psi'' + \frac{2mE}{\hbar^2}\psi = 0$$

$$\psi(x) = a_L e^{ik_L x} + b_L e^{-ik_L x}, \quad k_L = \frac{\sqrt{2mE}}{\hbar}$$

$$x \to \infty \qquad \Rightarrow \qquad \psi'' + \frac{2m}{\hbar^2}(E - U_0)\psi = 0$$

$$\psi(x) = a_L e^{ik_R x} + b_L e^{-ik_R x}, \quad k_R = \frac{\sqrt{2m(E-U_0)}}{\hbar}$$

$$\psi_k^{(+)}(x) = \begin{cases} e^{ik_L x} + re^{-ik_L x}, & x \to -\infty, \\ te^{ik_R x}, & x \to +\infty, \end{cases} \qquad \psi_k^{(-)}(x) = \begin{cases} t'e^{ik_L x}, & x \to -\infty, \\ e^{ik_R x} + r'e^{-ik_R x}, & x \to +\infty. \end{cases}$$

$$R = |r|^2, \qquad T = \frac{k_R}{k_L}|t|^2, \qquad R + T = 1$$

$$\langle \psi_{k_L}^{(+)} | \psi_{k'_L}^{(+)} \rangle = \int\limits_{-\infty}^{\infty} dx \psi_{k_L}^{(+)*} \psi_{k'_L}^{(+)} = \int\limits_{-\infty}^{\Lambda} dx \psi_{k_L}^{(+)*} \psi_{k'_L}^{(+)} + \int\limits_{\Lambda}^{\infty} dx \psi_{k_L}^{(+)*} \psi_{k'_L}^{(+)} + \int\limits_{-\Lambda}^{\Lambda} dx \psi_{k_L}^{(+)*} \psi_{k'_L}^{(+)}$$

При произвольном значении Λ, последний член конечен при $k = k'$ (а значит и при $E = E'$) и предствляет собой регулярную функцию от k и k'. Поэтому дельта-функциональный вклад возникнуть может только с бесконечности, с первых двух членов. Проводя эти рассуждения для достаточно больших Λ, понимаем, что для нормировки можно пользоваться только асимптотическим представлением волновых функций.

$$\langle \psi_{k_L}^{(+)} | \psi_{k'_L}^{(+)} \rangle = \text{reg.} + \int\limits_{-\infty}^{\Lambda} dx (e^{-ik_L x} + r_k^* e^{ik_L x})(e^{ik'_L x} + r_{k'} e^{-ik'_L x}) + \int\limits_{\Lambda}^{\infty} dx t_k^* e^{-ik_R x} t_{k'} e^{-ik'_R x}$$

Уже в этом выражении заменяя пределы интегрирования на ноль, добавим регулярный вклад, и характер сингулярности не изменится. Поскольку амплитуды являются “медленными огибающими”, то в них мы можем положить $k = k'$.

$$\langle \psi_{k_L}^{(+)} | \psi_{k'_L}^{(+)} \rangle = \text{reg.} + \int\limits_{-\infty}^{0} dx (e^{-i(k_L - k'_L)x} + |r_k|^2 e^{i(k_L - k'_L)x}) + \int\limits_{0}^{\infty} dx |t_k|^2 e^{-i(k_R - k'_R)x}$$

$$k_L^2 - k_L'^2 = \frac{2m(E - E')}{\hbar^2} = k_R^2 - k_R'^2$$

$$k_R - k'_R = \frac{k_R^2 - k_R'^2}{k_R + k'_R} = \frac{k_L^2 - k_L'^2}{k_R + k'_R}$$

$$\int\limits_0^{\infty} dx |t_k|^2 e^{-i(k_R - k'_R)x} = \int\limits_0^{\infty} du \frac{k_R + k'_R}{k_L + k'_L} |t_k|^2 e^{-i(k_L - k'_L)u} = \int\limits_0^{\infty} du \frac{k_R}{k_L} |t_k|^2 e^{-i(k_L - k'_L)u} = \int\limits_0^{\infty} dx T e^{-i(k_L - k'_L)x}$$

$$\langle \psi_{k_L}^{(+)} | \psi_{k'_L}^{(+)} \rangle = \text{reg.} + \int\limits_{-\infty}^{0} dx e^{-i(k_L - k'_L)x} + \int\limits_0^{\infty} R e^{-i(k_L - k'_L)x} + \int\limits_0^{\infty} dx T e^{-i(k_L - k'_L)x} = \int\limits_{-\infty}^{\infty} dx e^{-i(k_L - k'_L)x}$$

$$\langle \psi_{k_L}^{(+)} | \psi_{k'_L}^{(+)} \rangle = \text{reg.} + 2\pi\delta(k_L - k'_L) = \text{reg.} + \frac{2\pi\hbar}{\sqrt{2m}} \delta(\sqrt{E} - \sqrt{E'}) = \text{reg.} + \frac{2\pi\hbar}{\sqrt{2m}} \delta\left(\frac{E - E'}{\sqrt{E} + \sqrt{E'}} \right)$$

$$\langle \psi_E^{(+)} | \psi_{E'}^{(+)} \rangle = \text{reg.} + 2\pi\hbar \sqrt{\frac{2E}{m}} \delta(E - E')$$

ПТФ-4.y2 Полнота состояний в дельта-потенциале

Рассмотрите движение одномерной частицы в поле мелкой ямы, $U(x) = -\frac{\kappa}{m}\delta(x)$. Покажите непосредственным вычислением полноту базиса собственных состояний гамильтониана. Рассмотрите как случай $\kappa > 0$ (когда в яме имеется связанное состояние), так и $\kappa < 0$.

Указание: при проверке условия полноты, $\delta(x - x') = \sum\limits_n \psi_n^*(x)\psi_n(x')$, для простоты можете рассмотреть только случай $x, x' > 0$.

Solution.

(!!! важно дописать основную идею, пока не думал много про это??!!)

$$\psi_k^{(+)}(x) = \begin{cases} e^{ikx} + re^{-ikx}, & x \to -\infty \\ te^{ikx}, & x \to +\infty \end{cases} \quad , \quad \psi_k^{(-)}(x) = \begin{cases} t'e^{ikx}, & x \to -\infty \\ e^{ikx} + r'e^{-ikx}, & x \to +\infty \end{cases}$$

Граничные условия дают:

$$1 + r = t, \qquad ikt - (ik - ikr) = -2\kappa t \qquad \to \qquad t = \frac{ik}{\kappa + ik}, \qquad r = \frac{\kappa}{\kappa + ik}$$

$$t' = t, \qquad r' = -\frac{r^*}{t^*}t = \frac{\kappa}{ik}\frac{-ik}{\kappa + ik} = -\frac{\kappa}{\kappa + ik} = r$$

(???? непонятно, откуда выражение ниже?)

$$f(x, x') = \frac{1}{2\pi}\int\limits_0^\infty dk(e^{ik(x-x')} + |r|^2 e^{-ik(x-x')} + |t|^2 e^{-ik(x-x')} + re^{ik(x+x')} + r^* e^{-ik(x+x')}) =$$

$$= \frac{1}{2\pi}\int\limits_0^\infty dk(e^{ik(x-x')} + e^{-ik(x-x')}) + \frac{1}{2\pi}\int\limits_0^\infty dk\left(\frac{\kappa}{\kappa + ik}e^{ik(x+x')} + \frac{1}{2\pi}\frac{\kappa}{\kappa - ik}e^{-ik(x+x')}\right)$$

$$\int\limits_0^\infty dk(e^{ik(x-x')} + e^{-ik(x-x')}) = \int\limits_{-\infty}^\infty dke^{ik(x-x')} = 2\pi\delta(x - x')$$

$$\int\limits_0^\infty dk\left(\frac{\kappa}{\kappa + ik}e^{ik(x+x')} + \frac{\kappa}{\kappa - ik}e^{-ik(x+x')}\right) = \int\limits_{-\infty}^\infty dk\frac{\kappa}{\kappa + ik}e^{ik(x+x')} \overset{\text{res}}{=} \begin{cases} 2\pi\exp(-\kappa(x + x')), & \kappa > 0 \\ 0, & \kappa < 0 \end{cases}$$

For $\kappa < 0$:

$$f(x, x') = \delta(x - x')$$

For $\kappa > 0$: Добавим к $f(x, x')$ связанное состояние $\psi_0(x)$: $\psi_0^*(x)\psi_0(x') = \kappa e^{-\kappa(|x|+|x'|)}$. Тогда и в этом случае

$$f(x, x') = \delta(x - x')$$

Таким образом, соотношение полноты доказано в обоих случаях.

Давнее вроде неверное решение

Требуется для потенциала вида "ступеньки" отнормировать на δ-функцию состояния непрерывного спектра, то есть найти $c(f)$ в выражении

$$\langle\psi_f|\psi_{f'}\rangle = c(f)\delta\left(f - f'\right)$$

Обозначим $k = \sqrt{2mE}, k' = \sqrt{2m\left(E - U_0\right)}$,
решения УШ имеют вид

$$\Psi_k^+(x) = \begin{cases} e^{ikx} + r(k)e^{-ikx}, & x \longrightarrow -\infty \\ t(k)e^{ik'x}, & x \longrightarrow +\infty \end{cases} .$$

из непрерывности получаем коэффициенты

$$1 + r = t, \quad k(1 - r) = k'r; \quad r(k) = \frac{k - k'}{k + k'}, \quad t(k) = \frac{2k}{k + k'}$$

переписав скалярное произведение подобно тому, как сделано на семинаре:

$$\int\limits_{-\infty}^\infty dx\psi_{f'}^*(x)\psi_f(x) = \int\limits_{-\infty}^{-\lambda} dx\psi_{f'}^*(x)\psi_f(x) + \int\limits_{\lambda}^\infty dx\psi_{f'}^*(x)\psi_f(x) + \int\limits_{-\lambda}^{\lambda} \psi_{f'}^*(x)\psi_f(x)dx$$

придем к

$$\langle\psi_k|\psi_{k'}\rangle = \text{reg}\,. + \int\limits_{-\infty}^{-\lambda} \left(e^{-ikx} + r_k^* e^{ikx}\right)\left(e^{ik'x} + r_{k'}e^{-ik'x}\right)dx + \int\limits_{\lambda}^{\infty} t_k^* e^{-ikx} t_{k'} e^{ik'x} dx$$

и мб я не до конца понимаю что-то, но у нас вроде бы все то же, что в случае

$$\langle\psi_k|\psi_{k'}\rangle = \text{reg} + \int\limits_{-\infty}^{\infty} e^{-i\left(k-k'\right)x} dx = 2\pi\delta\left(k-k'\right)$$

в итоге нормировка такая:

$$\langle\psi_k|\psi_{k'}\rangle = \text{reg} + \int\limits_{-\infty}^{\infty} e^{-i\left(k-k'\right)x} dx = 2\pi\delta\left(k-k'\right)$$

ПТФ-4.з1. Выключение и включение потенциала

1. Частица находится в основном состоянии гармонического осциллятора $U(x) = \frac{m\omega^2 x^2}{2}$. Потенциал выключают на время T, спустя которое его снова включают. Определите вероятность того, что частица окажется в *основном* состоянии.

2. Этот же вопрос, но для $-\frac{\hbar^2\kappa}{m}\delta(x)$ и для случаев малых и больших времён T.

Подсказка: для асимптотической оценки интеграла в пункте 2 для случая малых T вам может пригодиться приём – преобразование Хаббарда-Стратановича (преобразующее экспоненту от квадратом A в выражение экспонентой от просто A):

$$e^{-iA^2} = \frac{e^{\frac{i\pi}{4}}}{\sqrt{\pi}} \int\limits_{-\infty}^{\infty} dz e^{iz^2 - 2izA}$$

Solution. в общем случае

$$-\frac{\hbar^2}{2m}\psi'' + U(x)\psi = E\psi \to \psi'' + \frac{2m}{\hbar^2}\left(E - U(x)\right)\psi = 0$$

$$\Psi(p) = \int\limits_{-\infty}^{\infty} \psi(x) \exp\left(-\frac{ipx}{\hbar}\right) dx$$

$U = 0 \Rightarrow$

$$i\hbar\frac{\partial\Psi(p,t)}{\partial t} = \langle p|\hat{H}(t)|\psi(t)\rangle = \frac{p^2}{2m}\Psi(p,t), \quad \Psi(p,0) = \Psi(p)$$

$$\Psi(p,T) = \Psi(p)\exp\left(-\frac{ip^2}{2m\hbar}T\right)$$

$$P_{\text{gr}\to\text{ gr}} = \left|\int\limits_{-\infty}^{\infty} (dp)\Psi^*(p)\Psi(p,T)\right|^2 = \left|\int\limits_{-\infty}^{\infty} (dp)\Psi^2(p)\exp\left(-\frac{ip^2}{2m\hbar}T\right)\right|^2$$

Solution. для гармонического осциллятора

$$U(x) = \frac{m\omega^2 x^2}{2}$$

$$\psi_0(x) = \left(\frac{m\omega}{\pi\hbar}\right)^{\frac{1}{4}} \exp\left(-\frac{m\omega x^2}{2\hbar}\right)$$

$$\Psi(p) = \int\limits_{-\infty}^{\infty} \psi(x)\exp\left(-\frac{ipx}{\hbar}\right)dx = \sqrt{2}\left(\frac{\pi\hbar}{m\omega^3}\right)^{\frac{1}{4}} \exp\left(-\frac{p^2}{2m\omega^2\hbar}\right)$$

$$\Psi_{U=0}(p,T)=\Psi(p)\exp\left(-\frac{ip^2}{2m\hbar}T\right)$$

$$\begin{aligned}P_{\text{gr}\to\text{ gr}}(T)&=\left|\int\limits_{-\infty}^{\infty}(dp)\Psi^2(p)\exp\left(-\frac{ip^2}{2m\hbar}T\right)\right|^2=\\&=\left|\int\limits_{-\infty}^{\infty}(dp)\left(\sqrt{2}\left(\frac{\pi\hbar}{m\omega^3}\right)^{\frac{1}{4}}\exp\left(-\frac{p^2}{2m\omega^2\hbar}\right)\right)^2\exp\left(-\frac{ip^2}{2m\hbar}T\right)\right|^2=\\&=\frac{1}{\sqrt{1+\frac{\omega^2T^2}{4}}}\end{aligned}$$

Solution. для дельта-потенциала

$$U(x)=-\frac{\hbar^2\kappa}{m}\delta(x)$$

$$\psi(x)=\sqrt{\kappa}\exp(-\kappa|x|)$$

$$\Psi(p)=\int\limits_{-\infty}^{\infty}\psi(x)\exp\left(-\frac{ipx}{\hbar}\right)dx=\frac{2\kappa^{\frac{3}{2}}\hbar^2}{p^2+\kappa^2\hbar^2}$$

Вероятность того, что частица окажется в основном состоянии:

$$P_{\text{gr}\to\text{ gr}}(T)=\left|\int\limits_{-\infty}^{\infty}(dp)\Psi^2(p)\exp\left(-\frac{ip^2}{2m\hbar}T\right)\right|^2=\left|\int\limits_{-\infty}^{\infty}(dp)\left(\frac{2\kappa^{\frac{3}{2}}\hbar^2}{p^2+\kappa^2\hbar^2}\right)^2\exp\left(-\frac{ip^2}{2m\hbar}T\right)\right|^2$$

$A:=p\sqrt{\frac{T}{2m\hbar}}$,

$$e^{-iA^2}=\frac{e^{\frac{i\pi}{4}}}{\sqrt{\pi}}\int\limits_{-\infty}^{\infty}dze^{iz^2-2izA}=\frac{e^{\frac{i\pi}{4}}}{\sqrt{\pi}}\int\limits_{-\infty}^{\infty}dze^{iz^2-2izp\sqrt{\frac{T}{2m\hbar}}}$$

$$P(T)=\left|\int\limits_{-\infty}^{\infty}(dp)\left(\frac{2\kappa^{\frac{3}{2}}\hbar^2}{p^2+\kappa^2\hbar^2}\right)^2\frac{e^{\frac{i\pi}{4}}}{\sqrt{\pi}}\int\limits_{-\infty}^{\infty}dze^{iz^2-2izp\sqrt{\frac{T}{2m\hbar}}}\right|^2$$

Проинтегрируем по p при помощи вычетов (полюсы в $p=\pm i\kappa\hbar$ второго порядка):

(так вроде и получается, еще раз на бумажке проделаю. Пока не досмотрел, вычеты 2го порядка, так ли они получаются как написано?)

$$\begin{aligned}P(T)&=\frac{16\kappa^6\hbar^8}{4\pi^3\hbar^2}\frac{\pi^2}{4\hbar^6\kappa^6}\left|2\int\limits_0^{\infty}dze^{-2\kappa\hbar\sqrt{\frac{T}{2m\hbar}}z}\left(1+2\kappa\hbar\sqrt{\frac{T}{2m\hbar}}z\right)e^{iz^2}\right|^2\\&=\frac{4}{\pi}\left|\int\limits_0^{\infty}dze^{-\kappa\sqrt{\frac{2\hbar T}{m}}z}\left(1+\kappa\sqrt{\frac{2\hbar T}{m}}z\right)e^{iz^2}\right|^2\\&=\frac{4}{\pi}\left|\frac{1}{8}\left(4ia+(1+i)(a^2+2i)e^{i\frac{a^2}{4}}\sqrt{2}\pi(-i-(1-i)\int\limits_0^{a/\sqrt{2}\pi}dt\cos^2t+(1+i)\int\limits_0^{a/\sqrt{2}\pi}dt\sin^2t\right)\right|^2\end{aligned}$$

(????? последний переход нужно сидеть и продумывать. во-первых там скобка пропущена. во-вторых, вообще пока не вижу, как его получили, тут много шагов упущено, нужно вписать их!)

$$\int\limits_0^{a/\sqrt{2}\pi}dt\cos^2t\sim x,\qquad\int\limits_0^{a/\sqrt{2}\pi}dt\sin^2t\sim\frac{x^3}{3}$$

(?? это ужасное решение, нужно переписать, x тут не определен, нужно продумывать с начала)
$a := \sqrt{\frac{2\hbar T}{m}}\kappa \ll 1$,

$$P(T) = \frac{4}{\pi}\left|\frac{1+i}{2}\sqrt{\frac{\pi}{2}} + \frac{\sqrt{\pi}(1-i)}{8\sqrt{2}}a^2 + \mathcal{O}(a^3)\right|^2 = \frac{4}{\pi}\left(\frac{\pi}{4} - \frac{\sqrt{\pi}}{6\sqrt{2}}a^3\right) = 1 - \frac{4\sqrt{\pi}}{6\sqrt{2}\pi}a^3 + \mathcal{O}(a^3)$$

При малых временах T:

$$P(T) = 1 - \frac{4\kappa^3}{3\sqrt{\pi}}\left(\frac{\hbar T}{m}\right)^{\frac{3}{2}} + \mathcal{O}(T^3)$$

При больших временах T: $\int\limits_0^{a/\sqrt{2}\pi} dt \cos^2 t \sim \sqrt{\frac{\pi}{8}} - \frac{\cos x^2}{2x}$, $\int\limits_0^{a/\sqrt{2}\pi} dt \sin^2 t \sim \sqrt{\frac{\pi}{8}} + \frac{\sin x^2}{2x}$,

$$P(T) = \frac{4}{\pi}\left|\frac{2}{a} + \mathcal{O}\left(\frac{1}{a^3}\right)\right| = \frac{16}{\pi a^2} + \mathcal{O}\left(\frac{1}{a^3}\right) = \frac{8m}{\pi\hbar\kappa^2 T} + \mathcal{O}\left(\frac{1}{T^3}\right)$$

Solution. еще одно, давнее

Определим основные состояния при включенном потенциале, то есть решим стационарное УШ:

$$-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial x^2}\psi(x) + \frac{m\omega^2 x^2}{2}\psi(x) = E\psi(x)$$

связное состояние имеет вид:

$$\psi_0(x) = \left(\frac{m\omega}{\pi\hbar}\right)^{1/4} \cdot \exp\left(-\frac{m\omega x^2}{2\hbar}\right)$$

После выключения потенциала эволюция системы будет описываться УШ:

$$i\hbar\frac{\partial\Psi}{\partial t} = \hat{H}\Psi \quad \hat{H} = \frac{\hat{p}^2}{2m}$$

собственные значения энергии: $\frac{p^2}{2m}\varphi = \lambda\varphi$, по итогу эволюция волновой функции происходит: $\hat{U}(t) = e^{-i(p^2/(2m\hbar))T}$

Так как тут имеется только оператор импульса, то представим волновую функцию в импульсном представлении, дальше

$$\psi(p) = \int dx e^{-ipx/\hbar}\psi(x) = \left(\frac{m\omega}{\pi\hbar}\right)^{1/4}\int dx e^{-ipx/\hbar}\cdot e^{\left(-\frac{m\omega x^2}{2\hbar}\right)}$$

(? какие-то преобразования)
и приходим к

$$\psi(p) = \left(\frac{4\pi\hbar}{m\omega}\right)^{1/4}\exp[-p^2/(2m\omega\hbar)]$$

таким образом, эволюция происходит так:

$$\psi_p(T) = \left(\frac{4\pi\hbar}{m\omega}\right)^{1/4}\exp[-p^2/(2m\omega\hbar)]e^{-i(p^2/(2m\hbar))T}$$

$$\psi_x(T) = \frac{1}{2\pi\hbar}\int\limits_{-\infty}^{\infty}\left(\frac{4\pi\hbar}{m\omega}\right)^{1/4}\exp[-p^2/(2m\omega\hbar)]e^{-i(p^2/(2m\hbar))T}e^{ipx/\hbar}$$

Вероятность нахождения опять в основном состоянии определяется ($\hbar = 1$)

$$A = \frac{1}{2\pi}\int\limits_{-\infty}^{\infty}\int\limits_{-\infty}^{\infty}\left(\frac{4\pi\hbar}{m\omega}\right)^{1/4}\exp[-p^2/(2m\omega\hbar)]e^{-i(p^2/(2m\hbar))T}e^{ipx/\hbar}e^{-\kappa|x|}dxdk$$

(??)

Solution. еще одно, давнее

для потенциала $U(x) = -\frac{\kappa}{m}\delta(x)$ решение имеет вид:

$$\psi(x) = \sqrt{\kappa}e^{-\kappa|x|}$$

После отключения потенциала данная волновая функция начнет эволюционировать, а так как она представляется в виде разложения по базису из континуума волн - по спектру оператора импульса, то в импульсном представлении мы знаем, как будет каждая компонента эволюционировать.
(здесь и далее $p \equiv k$)

$$\psi(k) = \int\limits_{-\infty}^{\infty} \psi(x)e^{-ikx}dx = \sqrt{\kappa}\int\limits_{-\infty}^{\infty} e^{-\kappa|x|-ikx}dx \overset{wolfram}{=} \frac{2\kappa^{\frac{3}{2}}}{\kappa^2+k^2}$$

вспоминая $\hat{U}(t) \equiv \exp(-i\hat{H}t/\hbar)$, получаем оператор эволюции ($p \equiv k$):

$$\hat{U}(t) = e^{-i\frac{k^2}{2m}T}$$

Обратно, в координатном представлении эволюция волновой функции происходит так:

$$\psi(x,T) = \frac{1}{2\pi}\int\limits_{-\infty}^{\infty} \frac{2\kappa^{\frac{3}{2}}}{\kappa^2+k^2}e^{-i\frac{k^2}{2m}T}e^{ikx}dk$$

Вероятность прийти в стационарное состояние через время T - проекция на волновую функцию этого состояния:

$$A = \frac{1}{2\pi}\int\limits_{-\infty}^{\infty}\int\limits_{-\infty}^{\infty} \frac{2\kappa^2}{\kappa^2+k^2}e^{-i\frac{k^2}{2m}T}e^{ikx}e^{-\kappa|x|}dxdk$$

Остается привести к понятному виду:

$$A = \frac{1}{2\pi}\int\limits_{-\infty}^{\infty} \frac{2\kappa^2}{\kappa^2+k^2}e^{-i\frac{k^2}{2m}T}\left[\int\limits_{-\infty}^{\infty} e^{ikx}e^{-\kappa|x|}dx\right] = \frac{1}{2\pi}\int\limits_{-\infty}^{\infty} \frac{4\kappa^3}{\left(\kappa^2+k^2\right)^2}e^{-i\frac{k^2}{2m}T}dk$$

Воспользуемся преобразованием Хаббарда-Стратоновича $e^{-iA^2} = \frac{e^{i\pi/4}}{\sqrt{\pi}}\int\limits_{-\infty}^{\infty} dze^{iz^2-2izA}$:

$$A = \frac{e^{i\pi/4}}{\sqrt{\pi}}\frac{1}{2\pi}\int\limits_{-\infty}^{\infty} \frac{4\kappa^3}{\left(\kappa^2+k^2\right)^2}dk\int\limits_{-\infty}^{\infty} dze^{iz^2-2iz\sqrt{\frac{T}{2m}}k} = \frac{-1}{\sqrt{\pi}}e^{i\pi/4}\int\limits_{-\infty}^{\infty} dze^{iz^2-2\kappa\sqrt{\frac{T}{2m}}z}(1+2\kappa\sqrt{\frac{T}{2m}}z)$$

теперь посчитаем то, к чему мы пришли, $c \equiv \sqrt{\frac{2T\kappa^2}{m}}$:

$$\boxed{A = \frac{-e^{i\pi/4}}{\sqrt{\pi}}\int\limits_{-\infty}^{\infty} e^{iz^2-c|z|}(1+c|z|)dz = \frac{-2e^{i\pi/4}}{\sqrt{\pi}}\int\limits_{0}^{\infty} e^{iz^2-cz}(1+cz)dz}$$

для $T \ll 1$
Сделаем замену $z = e^{i\pi/4}x$.
Тогда $a = \frac{-2i}{\sqrt{\pi}}\int\limits_0^{\infty} e^{-x^2-ce^{i\pi/4}x}\left(1+ce^{i\pi/4}x\right)dx$

$$e^{-x^2-ce^{i\pi/4}x} \simeq e^{-x^2}\left(1-ce^{i\pi/4}x+\frac{ic^2x^2}{2}\right)$$

$$e^{-ce^{i\pi/4}x}\left(1+ce^{i\pi/4}x\right) \simeq 1-\frac{ic^2x^2}{2}+\frac{c^3x^3e^{3i\pi/4}}{3}$$

$$a = \frac{-2i}{\sqrt{\pi}}\int\limits_0^{\infty} e^{-x^2}\left[1-\frac{ic^2x^2}{2}+\frac{c^3x^3e^{3i\pi/4}}{3}\right] = -i\left[1-\frac{ic^2}{4}+\frac{c^3(i-1)}{3\sqrt{2\pi}}\right]$$

Для $T \gg 1$ так и хочется применить метод стационарной фазы или метод перевала, но я за 40 мин не разобрался как, так что

ПТФ-4.з2.1. Распад квазистационарного состояния

В этой задаче мы будем исследовать уравнение Шрёдингера в потенциале следующего вида:

$$U(x) = \begin{cases} \infty, & x < 0 \\ \frac{\kappa}{m}\delta(x-a), & x > 0 \end{cases}$$

Рассеивающий потенциал (величину κ) мы будем предполагать сильным. Если заменить этот потенциал на бесконечную стенку, то в этой задаче имеется множество стационарных состояний вида $\psi_n(x) = \sin knx$, $k_n = \frac{\pi n}{a}$ и $E_n^{(0)} = \frac{k_n^2}{2m}$. Возможность туннелирования превращает эти состояния в *квазистационарные* – хоть и не стационарные, но долгоживущие, и на достаточно небольших промежутках времени их можно считать стационарными. Ниже будут изложены три различных точки зрения на такие состояния и показана их эквивалентность.

Указание: хоть дальше и идёт речь об энергетическом представлении – во всех промежуточных вычислениях удобнее пользоваться квантовым числом — импульсом $k = \sqrt{2mE}$.

В начальный момент времени частица была «приготовлена» в одном из квазистационарных состояний, $\psi(x, t = 0) = \psi_0(x)\sqrt{\frac{2}{a}}\sin k_n x$.

• Определите непрерывный спектр исходной задачи, нормированный на дельта-функцию от разницы энергий.

• Рассмотрите разложение исходной волновой функции по этому непрерывному спектру. Обратите внимание, что $|\psi(E)|^2$ вблизи $E_n^{(0)}$ имеет максимум; покажите, что в окрестности этого максимума вероятность устроена как лоренциан:

$$|\psi(E)|^2 \approx c\frac{\Gamma_n}{(E-E_n)^2 + \frac{\Gamma_n^2}{4}}$$

и при этом E_n близка к $E_n^{(0)}$, а $\Gamma_n \ll E_n$. Найдите величины c, E_n, Γ_n.

• Найдите амплитуду того, что через достаточно большое время t частица останется в в этом квазистационарном состоянии $c(t) = \int \psi_0^*(x)\psi(x,t)dx$. Покажите, что на достаточно больших временах соответствующая вероятность $P(t) = |c(t)|^2$ затухает экспоненциально $P(t) \propto \exp(-t/\tau)$. Определите соответствующее «время жизни» τ_n.

Найденное “время жизни” окажется достаточно большим. Это означает, что на временах $t \ll \tau_n$, состояние $|n\rangle$ практически стационарно – волновая функция не меняется, за исключением тривиальной динамической фазы $e^{-iE_n t}$.

Solution.

$$|\psi(E)|^2 = \frac{1}{8\sqrt{2mE}\pi k_n}\frac{\frac{k_n^3}{2m\kappa^2 a}}{(E - E_n^{(0)}(1-\frac{1}{2\kappa a}))^2 + \frac{1}{4}(\frac{k_n^3}{2m\kappa^2 a})^2}$$

$$c = \frac{1}{8\sqrt{2mE}\pi k_n}, \quad E_n = E_n^{(0)}\left(1 - \frac{1}{2\kappa a}\right), \quad \Gamma_n = \frac{k_n^3}{2m\kappa^2 a}$$

Как видно, E_n близко к $E_n^{(0)}$ и $\Gamma_n \ll E_n$.

$$\psi(E) = \sqrt{c}\frac{\sqrt{\Gamma_n}}{(E-E_n) + \frac{i\Gamma_n}{2}}$$

ПТФ-4.з2.2. Задержка волнового пакета

Другой способ смотреть на квазистационарные состояния – это исследовать задачу рассеяния.

• Определите волновые функции исходной задачи, которые соответствуют задаче рассеяния, то есть имеющие асимптотическое поведение $\psi(x \to \infty) = e^{-ikx} + re^{ikx}$. Величина коэффициента отражения $R = |r|^2$ тривиальным образом равна единице, поскольку движение инфинитно только в одну сторону; но вот амплитуда отражения $r(E) \equiv e^{i\delta(E)}$ имеет нетривиальные свойства.

• Покажите, что амплитуда r, как функция *комплексной* энергии ε имеет серию полюсов, близких к вещественной оси $\varepsilon_n = E_n - \frac{i\Gamma_n}{2}$. Покажите, что на вещественной оси в окрестности $E \approx E_n$ амплитуда устроена следующим образом:

$$r(E) \approx e^{i\phi}\frac{E - E_n - \frac{i\Gamma_n}{2}}{E - E_n + \frac{i\Gamma_n}{2}}$$

(с такими же величинами E_n и Γ_n; такой вид связан с условием $|r|^2 = 1$). Как при этом устроена фаза рассеяния $\delta(E)$?

• Рассмотрите нестационарную задачу рассеяния: пусть на такую систему налетает волновой пакет, локализованный по энергии вблизи одного из таких метастабильных состояний, $E \approx E_n$. Определите время задержки такого волнового пакета $\tau = \hbar\frac{\partial\delta}{\partial E}$; и покажите, что непосредственно при резонансе $E = E_n$, время задержки связано с временем жизни метастабильного состояния. Обратите внимание – существенно, что полюса находятся в нижней комплексной полуплоскости; в противном случае мы бы получили $\tau(E_n) < 0$, что очевидным образом противоречит причинности.

С этим эффектом связана иная физическая интерпретация квазистационарных состояний: при рассеянии на резонансе частица «попадает» в метастабильное состояние, где она «застревает» на достаточно продолжительное время, и лишь затем вылетает.

Solution.

•
$$\psi(x \to \infty) = e^{-ikx} + re^{ikx}$$

• Амплитуда отражения:

$$r = \frac{1 - \frac{i\kappa}{k}(1 - e^{-2ika})}{-1 - \frac{i\kappa}{k}(1 - e^{2ika})} = -e^{-2ika}\frac{ke^{ika} - i\kappa e^{ika} + i\kappa e^{-ika}}{ke^{-ika} + i\kappa e^{-ika} - i\kappa e^{ika}} =$$

$$= e^{-2i(k-k_n)a}\frac{ik_n(k-k_n)a + k_n + 2\kappa(k-k_n)a}{ik_n(k-k_n)a - k_n - 2\kappa(k-k_n)a}$$

$$k_n(k-k_n) = \frac{m(E - E_n^{(0)})}{\hbar^2}$$

$$r = e^{-2i(k-k_n)a}\frac{ia\frac{m(E-E_n^{(0)})}{\hbar^2} + k_n + 2\kappa a\frac{m(E-E_n^{(0)})}{k_n\hbar^2}}{ia\frac{m(E-E_n^{(0)})}{\hbar^2} - k_n - 2\kappa a\frac{m(E-E_n^{(0)})}{k_n\hbar^2}}$$

Полюсы:

$$i(E - E_n^{(0)}) - \frac{\hbar^2 k_n}{ma} - \frac{2\kappa}{k_n}(E - E_n^{(0)}) = 0$$

$$(E - E_n^{(0)})\left(i - \frac{2\kappa}{k_n}\right) = \frac{\hbar^2 k_n}{ma}$$

$$E - E_n^{(0)} = \frac{\hbar^2 k_n^2}{2\kappa ma}\frac{1}{\frac{ik_n}{2\kappa} - 1} \approx -\frac{\hbar^2 k_n^2}{2\kappa ma}\left(1 + \frac{ik_n}{2\kappa}\right) = -\frac{\hbar^2 E_n^{(0)}}{\kappa a} - \frac{i\hbar^2 k_n^3}{4\kappa^2 ma}$$

$$E_n = E_n^{(0)}\left(1 - \frac{\hbar^2}{\kappa a}\right) - \frac{i\hbar^2 k_n^3}{4\kappa^2 ma}$$

$$r = \frac{E - E_n - i\frac{\Gamma_n}{2}}{E - E_n + i\frac{\Gamma_n}{2}} = \frac{(E - E_n - i\frac{\Gamma_n}{2})^2}{(E - E_n)^2 + \frac{\Gamma_n^2}{4}} = \frac{(E - E_n)^2 - \frac{\Gamma_n^2}{4} - i\Gamma_n(E - E_n)}{(E - E_n)^2 + \frac{\Gamma_n^2}{4}}$$

$$\delta(E) = -\arctan\frac{\Gamma_n(E - E_n)}{(E - E_n)^2 - \frac{\Gamma_n^2}{4}}$$

• Время задержки:

$$\tau(E) = \hbar\frac{\partial\delta}{\partial E} = \frac{\Gamma_n\hbar}{(E - E_n)^2 + \frac{\Gamma_n^2}{4}}$$

$$\tau(E_n) = \frac{4\hbar}{\Gamma_n}$$

ПТФ-13.y2. Соотношение унитарности

Исходя из соотношения унитарности на языке T-матрицы,

$$\hat{T}_E - \hat{T}_E^\dagger = -2\pi i\hat{T}_E^\dagger\delta(E - \hat{H}_0)\hat{T}_E$$

получите соотношение унитарности на языке амплитуды рассеяния:

$$f(\mathbf{n}, \mathbf{n}') - f^*(\mathbf{n}', \mathbf{n}) = i\frac{k}{2\pi}\int d\mathbf{n}'' f(\mathbf{n}, \mathbf{n}'')f^*(\mathbf{n}', \mathbf{n}'')$$

Solution.

Связь T-матрицы и амплитуды рассеяния:

$$f(\mathbf{n},\mathbf{n}') = -\frac{m}{2\pi}\langle \mathbf{k}'|\hat{T}_E|\mathbf{k}\rangle$$

$$f(\mathbf{n},\mathbf{n}') - f^*(\mathbf{n}',\mathbf{n}) = -\frac{m}{2\pi}(\langle \mathbf{k}'|\hat{T}_E|\mathbf{k}\rangle - \langle \mathbf{k}'|\hat{T}_E^\dagger|\mathbf{k}\rangle) = -\frac{m}{2\pi}\langle \mathbf{k}'|(\hat{T}_E - \hat{T}_E^\dagger)|\mathbf{k}\rangle \quad = im\langle \mathbf{k}'|\hat{T}_E^\dagger\delta(E-\hat{H}_0)\hat{T}_E|\mathbf{k}\rangle =$$
$$= im\int \frac{d^3\mathbf{q}}{(2\pi)^3}\langle \mathbf{k}'|\hat{T}_E^\dagger|\mathbf{q}\rangle\langle \mathbf{q}|\hat{T}_E|\mathbf{k}\rangle\delta(E-E_{\mathbf{q}})$$

$$E = \frac{k^2}{2m} \qquad \Rightarrow \qquad \delta(E-E_{\mathbf{q}}) = \frac{m}{k}\delta(k-|\mathbf{q}|)$$

$$f(\mathbf{n},\mathbf{n}') - f^*(\mathbf{n}',\mathbf{n}) = im\frac{4\pi^2}{(2\pi)^3m^2}\frac{m}{k}k^2\int d\mathbf{n}''f(\mathbf{n},\mathbf{n}'')f^*(\mathbf{n}',\mathbf{n}'') = \frac{ik}{2\pi}\int d\mathbf{n}''f(\mathbf{n},\mathbf{n}'')f^*(\mathbf{n}',\mathbf{n}'')$$

ПТФ-13.з1. Функции Грина и Борновское приближение в 1D и 2D

Одномерие. Выведите формулы Борновского приближения для одномерного пространства. Амплитуда рассеяния определяется согласно:

$$\psi(\mathbf{r}) = e^{i\mathbf{kr}} + f(\mathbf{n},\mathbf{n}')ie^{ik|\mathbf{r}|}$$

Что из себя представляет величина f и как она связана с амплитудами прохождения и отражения t, r? Что из себя представляет сечение рассеяния в одномерии?

Двумерие. Повторите вывод для двумерного пространства. В двумерии амплитуда определяется согласно:

$$\psi(\mathbf{r}) = e^{i\mathbf{kr}} + f(\mathbf{n},\mathbf{n}')e^{\frac{i\pi}{4}}\frac{e^{ikr}}{\sqrt{r}}$$

Указание: функция Грина свободного движения выражается через какие-то из модифицированных функций Бесселя.

Solution. в общем случае

Задача полностью по теории, однако, это очень непростые переходы и задача стоящая.

Пусть $\hat{H}_0 := \frac{\hat{p}^2}{2m}$; $|\mathbf{k}\rangle$ – падающая плоская волна, $|\chi\rangle$ – рассеянная:

$$|\psi\rangle = |\mathbf{k}\rangle + |\chi\rangle, \qquad \hat{H}_0|\mathbf{k}\rangle = E|\mathbf{k}\rangle$$

$$(\hat{H}_0+\hat{V})(|\mathbf{k}\rangle+|\chi\rangle) = E(|\mathbf{k}\rangle+|\chi\rangle) \to (E-\hat{H})|\chi\rangle = \hat{V}|\mathbf{k}\rangle$$
$$|\chi\rangle = (E-\hat{H})^{-1}\hat{V}|\mathbf{k}\rangle$$
$$\hat{G}_E: \qquad (E-\hat{H})\hat{G}_E \equiv \hat{\mathbb{I}}$$

$G_E(\mathbf{r},\mathbf{r}') := \langle \mathbf{r}|\hat{G}_E|\mathbf{r}'\rangle$,

$$(E-\hat{H})G_E(\mathbf{r},\mathbf{r}') = \delta(\mathbf{r}-\mathbf{r}')$$

$\hat{G}_E^{(0)} := (E-\hat{H}_0)^{-1}$,

$$G_E^{(0)}(\mathbf{r},\mathbf{r}') = \int \frac{d^3\mathbf{k}}{(2\pi)^3}\frac{e^{i\mathbf{k}(\mathbf{r}-\mathbf{r}')}}{E-\frac{k^2}{2m}}, \qquad G_E^{(0,R)}(\mathbf{r},\mathbf{r}') = \int \frac{d^3\mathbf{k}}{(2\pi)^3}\frac{e^{i\mathbf{k}(\mathbf{r}-\mathbf{r}')}}{E+i0-\frac{k^2}{2m}}$$

$$\hat{G}_E = (E-\hat{H})^{-1} = (E-\hat{H}_0-\hat{V})^{-1} = \hat{G}_E^{(0)} + \hat{G}_E^{(0)}\hat{V}\hat{G}_E^{(0)} + ...$$

$$|\chi\rangle = (E-\hat{H}+i0)^{-1}\hat{V}|\mathbf{k}\rangle =$$
$$= (\hat{G}_E^{(0,R)}\hat{V} + \hat{G}_E^{(0,R)}\hat{V}\hat{G}_E^{(0,R)}\hat{V} + ...)|\mathbf{k}\rangle =$$
$$= \hat{G}_E^{(0,R)}(\hat{V} + \hat{V}\hat{G}_E^{(0,R)}\hat{V} + ...)|\mathbf{k}\rangle = \hat{G}_E^{(0,R)}\hat{T}_E|\mathbf{k}\rangle$$

$$\hat{T}_E := \hat{V} + \hat{V}\hat{G}_E^{(0,R)}\hat{V} + ... = \hat{V}(1 - \hat{G}_E^{(0,R)}V)^{-1}$$

Finally,

$$\chi_{\mathbf{k}}(\mathbf{r}) = \langle \mathbf{r}|\chi\rangle = \langle \mathbf{r}|\hat{G}_E^{(0,R)}\hat{T}_E|\mathbf{k}\rangle = \int d\mathbf{r}'\frac{d\mathbf{k}'}{(2\pi)^d}\langle \mathbf{r}|\hat{G}_E^{(0,R)}|\mathbf{r}'\rangle\langle \mathbf{r}'|\mathbf{k}'\rangle\langle \mathbf{k}'|\hat{T}_E|\mathbf{k}\rangle =$$
$$= \int d\mathbf{r}'\frac{d\mathbf{k}'}{(2\pi)^d}\hat{G}_E^{(0,R)}(\mathbf{r},\mathbf{r}')e^{i\mathbf{k}'\mathbf{r}'}\hat{T}_E(\mathbf{k},\mathbf{k}')$$

$\hat{T}_{E\text{Brn}} \approx \hat{V}_{\text{Brn}}$,

$$\chi_{\mathbf{k}\text{Brn}}(\mathbf{r}) = \int d\mathbf{r}'\frac{d\mathbf{k}'}{(2\pi)^d}\hat{G}_E^{(0,R)}(\mathbf{r},\mathbf{r}')e^{i\mathbf{k}'\mathbf{r}'}\langle \mathbf{k}'|\hat{V}|\mathbf{k}\rangle$$

Solution. для 1D

$$G_{E\ 1D}^{(0,R)}(x) = \int\frac{dk}{2\pi}\frac{e^{ikx}}{E + i0 - \frac{k^2}{2m}} = \frac{m}{\pi}\int dk\frac{e^{ikx}}{2mE - k^2 + i0} = \frac{m}{\pi}2\pi i\operatorname*{res}_{k=+\sqrt{2mE}}\left(\frac{e^{ikx}}{2mE - k^2}\right) = -i\sqrt{\frac{m}{2E}}e^{i\sqrt{2mE}x}$$

Тут мы сместили контур чуть ниже оси и замкнули сверху. Только один вычет находился сверху над осью, второй после взятия корня попал под ось, ибо он равен $k_- = \sqrt{-2mE - i0}$, он не дает вклад в интеграл (?? да???).

$$G_E^{(0,R)}(x,x') = -\frac{im}{k_E}e^{ik_E|x-x'|}, \quad k_E = \sqrt{2mE} = k$$
$$\chi_k(x) = \int dx'\frac{dk'}{2\pi}\hat{G}_E^{(0,R)}(x,x')e^{ik'x'}\langle k'|\hat{V}|k\rangle = -\frac{im}{k}\int dx'\frac{dk'}{2\pi}e^{ik|x-x'|}e^{ik'x'}\tilde{V}_{k-k'}$$
$$|x - x'| \approx x - n_x x', \quad x \to \infty$$

$$\chi_k(x) = -\frac{im}{k}\int dx'\frac{dk'}{2\pi}e^{ik(x-n_x x')}e^{ik'x'}\tilde{V}_{k-k'} = -\frac{im}{k}\int dx'\delta(x')e^{ik(x-n_x x')}\tilde{V}_{k-k'} = -\frac{im}{k}e^{ikx}\tilde{V}_{k-k'}$$

$$f(n,n') = -\frac{m}{k}\tilde{V}_{k-k'} = \begin{cases} r = -\frac{m}{k}\int V(x)dx, & \mathbf{n}\uparrow\uparrow\mathbf{n}' \\ t = -\frac{m}{k}\int V(x)e^{2kx}dx, & \mathbf{n}\uparrow\downarrow\mathbf{n}' \end{cases}$$
$$\sigma = r^2 + t^2$$

Solution. для 2D (??)

$$G_{E\ 2D}^{(0,R)}(\mathbf{r}) = \int\frac{d^2\mathbf{k}}{(2\pi)^2}\frac{e^{i\mathbf{k}\mathbf{r}}}{E + i0 - \frac{k^2}{2m}} = \int\limits_0^\infty\frac{dkk}{4\pi^2}\frac{1}{E + i0 - \frac{k^2}{2m}}\int\limits_0^{2\pi}d\varphi e^{ikr\cos\varphi}$$

Воспользуемся методом стационарной фазы:

$$\int\limits_0^{2\pi}d\varphi e^{ikr\cos\varphi} \overset{kr\gg 1}{\approx} \sqrt{\frac{2\pi}{kr}}\left(e^{ikr - i\frac{\pi}{4}} + e^{-ikr + i\frac{\pi}{4}}\right) = 2\sqrt{\frac{2\pi}{kr}}\cos\left(kr - \frac{\pi}{4}\right),$$

$$G_{E\ 2D}^{(0,R)}(\mathbf{r}) = \frac{\sqrt{2\pi}}{2\pi^2\sqrt{r}}\int\limits_0^\infty\frac{dk\sqrt{k}\cos\left(kr - \frac{\pi}{4}\right)}{E + i0 - \frac{k^2}{2m}}$$

(!!!! из того, что тут написано не понять никогда переход. заново нужно решить и почитать годное место про это!!!!)

$$G_{E\ 2D}^{(0,R)}(\mathbf{r}) = \frac{m}{\sqrt{2\pi k_E r}}e^{ik_E r + i\frac{\pi}{4}} \qquad \Rightarrow \qquad G_{E\ 2D}^{(0,R)}(\mathbf{r},\mathbf{r}') = \frac{m}{\sqrt{2\pi k_E r}}e^{ik_E|\mathbf{r}-\mathbf{r}'| + i\frac{\pi}{4}}$$

(??? почему косинус стал экспонентой?? не понимаю, почему по большому контуру интеграл ноль, там же экспоненты появляются?)

$$\chi_{\mathbf{k}}(\mathbf{r}) = \int d\mathbf{r}' \frac{d\mathbf{k}'}{(2\pi)^2} G_{E\ 2D}^{(0,R)}(\mathbf{r},\mathbf{r}')\ e^{i\mathbf{k}'\mathbf{r}'}\ \langle \mathbf{k}'|\hat{V}|\mathbf{k}\rangle = \frac{m}{\sqrt{2\pi kr}} \int d\mathbf{r}' \delta(\mathbf{r}') e^{ik|\mathbf{r}-\mathbf{r}'|+i\frac{\pi}{4}} e^{i\mathbf{k}'\mathbf{r}'} \tilde{V}_{\mathbf{k}-\mathbf{k}'} = \frac{m}{\sqrt{2\pi kr}} e^{ikr+i\frac{\pi}{4}} \tilde{V}_{\mathbf{k}-\mathbf{k}'}$$

$$f(\mathbf{n},\mathbf{n}') = \frac{m}{\sqrt{2\pi k}} \tilde{V}_{\mathbf{k}-\mathbf{k}'}$$

$$d\sigma = |f(\mathbf{n},\mathbf{n}')|^2 d\theta$$

ПТФ-13.з2. Рассеяние на $\frac{1}{a+|x|}$

Рассмотрите рассеяние медленных частиц на одномерном потенциале $V(x) = -V_0 \frac{a}{a+|x|}$. Используя

$$f(n,n') = -\frac{m}{k}\tilde{V}_{k-k'} = \begin{cases} r = -\frac{m}{k}\int V(x)dx, & \mathbf{n} \uparrow\uparrow \mathbf{n}', \\ t = -\frac{m}{k}\int V(x)e^{2kx}dx, & \mathbf{n} \uparrow\downarrow \mathbf{n}', \end{cases}$$

вычислите коэффициент прохождения частиц в ведущем Борновском приближении.

Solution.

Если воспользоваться формулой из предыдущей задачи, то

$$t = -\frac{m}{k}\int V(x)dx = -\frac{m}{k}V_0 \int \frac{adx}{a+|x|}$$

Интеграл расходится. Воспользуемся предыдущей формулой, при этом обрезав интеграл по $[-R;R]$, для какого-то $R > 0$.

$$\chi_k(x) = -i\frac{m}{k}\int\limits_{-R}^{R} e^{ik|x-x'|}V(x')e^{ikx'}dx', \quad x > R$$

$$\chi_k(x) \quad = \quad 2iV_0 a e^{ikx}\frac{m}{k}\int\limits_0^R \frac{dx'}{x'+a} \quad = \quad 2iV_0 a e^{ikx}\frac{m}{k}\ln\frac{a+R}{a} \quad = \quad 2iV_0 a e^{ikx}\frac{m}{k}(\ln(ka\ +\ kR)\ -\ \ln ka)$$

k был вставлен в логарифм дополнительно.

Частицы медленные, $ka \ll 1$,

$$R \sim \frac{1}{k} \gg a, \quad \ln(ka+kR) \approx \ln ka$$

(???? почему так????) Мб тут мы говорим, что первый логарифм гораздо больше второго, но тем не менее, почему он зависит только от a по итогу????

$$\chi_k(x) = -2iV_0 a e^{ikx}\frac{m}{k}\ln ka$$

$$t = -2V_0 a\sqrt{\frac{m}{2E}}\ln ka = -\frac{V_0}{E}ka\ln ka$$

Сечение рассеяния в кулоновском поле

Найти в борновском приближении дифференциальное сечение рассеяния частиц кулоновским полем с произвольным зарядом. Указать условия его применимости.

Solution.

Это типичная задача теории (пусть и нетривиальная), можно написать ответ сразу, но ниже короткое решение еще есть.

$$f(\theta) = -\frac{2\mu}{\hbar^2 q}\int\limits_0^\infty r' V\left(r'\right)\sin\left(qr'\right)dr'$$

$$\frac{d\sigma}{d\Omega} = |f(\theta)|^2 = \frac{4\mu^2}{\hbar^4 q^2}\left|\int\limits_0^\infty r' V\left(r'\right)\sin\left(qr'\right)dr'\right|^2$$

$$V(r) = Z_1 Z_2 e^2/r$$

$$\int\limits_0^\infty \sin(qr)dr = \lim_{\lambda\to 0}\int\limits_0^\infty e^{-\lambda r}\sin(qr)dr = \frac{1}{2i}\lim_{\lambda\to 0}\left[\int\limits_0^\infty e^{-(\lambda-iq)r}dr - \int\limits_0^\infty e^{-(\lambda+iq)r}dr\right]$$
$$= \frac{1}{2i}\lim_{\lambda\to 0}\left[\frac{1}{\lambda-iq} - \frac{1}{\lambda+iq}\right] = \frac{1}{q}$$

$q = 2k\sin(\theta/2)$,

$$\frac{d\sigma}{d\Omega} = \left(\frac{2Z_1\mu Z_2 e^2}{\hbar^2 q^2}\right)^2 = \left(\frac{Z_1 Z_2 \mu e^2}{2\hbar^2 k^2}\right)^2 \sin^{-4}\left(\frac{\theta}{2}\right) = \frac{Z_1^2 Z_2^2 e^4}{16E^2}\sin^{-4}\left(\frac{\theta}{2}\right),$$

$E := \hbar^2 k^2/2\mu$ (Rutherford's formula).

Условия применимости борновсокго приближения для Кулона

The first Born approximation is valid whenever the wave function $\Psi(r)$ is only slightly different from the incident plane wave; that is, whenever the second term in (1.23) is very small compared to the first:

$$\psi(\vec{r}) \simeq \phi_{inc}(\vec{r}) - \frac{\mu}{2\pi\hbar^2}\int \frac{e^{ik|\vec{r}-\vec{r}'|}}{|\vec{r}-\vec{r}'|}V\left(\vec{r}'\right)\phi_{inc}\left(\vec{r}'\right)d^3r'.$$
$$|\frac{\mu}{2\pi\hbar^2}\int \frac{e^{ik|\vec{r}-\vec{r}'|}}{|\vec{r}-\vec{r}'|}V\left(r'\right)e^{i\vec{k}_0\cdot\vec{r}'}d^3r'| \ll |\phi_{inc}(\vec{r})|.$$

Since $\phi_{inc} = e^{i\vec{k}_0\cdot\vec{r}}$ we have

$$|\frac{\mu}{2\pi\hbar^2}\int \frac{e^{ik|\vec{r}-\vec{r}'|}}{|\vec{r}-\vec{r}'|}V\left(r'\right)e^{i\vec{k}_0\cdot\vec{r}'}d^3r'| \ll 1.$$

In elastic scattering $k_0 = k$ and assuming that the scattering potential is largest near $r = 0$, we have

$$|\frac{\mu}{\hbar^2}\int\limits_0^\infty r' e^{ik\vec{r}'}V\left(r'\right)dr'\int\limits_0^\pi e^{ikr'\cos\theta'}\sin\theta' d\theta'| \ll 1$$
$$\frac{\mu}{\hbar^2 k}|\int\limits_0^\infty V\left(r'\right)\left(e^{2ikr'}-1\right)dr'| \ll 1.$$

17.4 Specific qeuestions and setups for scattering

17.4.1 Problems about low-energy scattering and resonant scattering 1

GKKG.13.27 Potential $1/r^\nu, 2 < \nu \leq 3$

Find the energy dependence of the scattering cross-section, $\sigma(E)$, in a field that decreases at large distances as $U(r) \approx \alpha/r^\nu, 2 < \nu \leq 3$, and in the low-energy limit, $E \to 0$.

Solution

For potentials with this behavior at large distances, the Born amplitude for $q \to 0$ diverges. Since $q = 2k\sin(\theta/2)$, then for $E \to 0$ in the Born approximation, the total scattering cross-section would diverge as well (here, $q \to 0$ for all scattering angles). The divergence of the scattering cross-section signals the importance of large distances, where conditions (XIII.7) are fulfilled, and therefore the Born approximation does work. Here, according to Eq. (XIII.12), we have:

$$f(q) \approx -\frac{2m\alpha}{\hbar^2 q^{3-\nu}} \int\limits_{qR}^{\infty} \frac{\sin x}{x^{\nu-1}} dx \tag{1}$$

We consider only the diverging part of the amplitude and total scattering cross-section. We do not consider a contribution from distances $r \leq R$, where the potential is not described by its known asymptote.

For $\nu < 3$, in Eq. (1) we set the lower integration limit as $qR = 0$ and obtain:

$$f = \frac{C_\nu}{q^{3-\nu}}, \quad C_\nu = \frac{\pi m\alpha}{\hbar^2 \Gamma(\nu-1)\cos(\pi\nu/2)} \tag{2}$$

using the integral

$$\int\limits_0^{\infty} \frac{\sin x}{x^{\nu-1}} dx = \Gamma(2-\nu)\sin\frac{\pi\nu}{2} = -\frac{\pi\sin(\pi\nu/2)}{\Gamma(\nu-1)\sin\pi\nu}$$

The total scattering cross-section is (for $q^2 = 2k^2(1-\cos\theta)$)

$$\sigma = 2\pi \int\limits_0^{\pi} f^2 \sin\theta d\theta \underset{E\to 0}{\approx} 2\pi C_\nu^2 \left(\frac{\hbar^2}{4mE}\right)^{3-\nu} \int\limits_{-1}^{1} \frac{dz}{(1-z)^{3-\nu}} \propto \frac{1}{E^{3-\nu}} \to \infty \tag{3}$$

If $\nu = 3$, we cannot replace the lower limit of integration in Eq. (1) by zero, due to integral divergence. Since $\sin x \approx x$ for $x \to 0$, the diverging part of the integral is equal to $\ln(1/qR)$, so that

$$f \approx \frac{2m\alpha}{\hbar^2} \ln qR \tag{4}$$

and the total scattering cross-section is

$$\sigma = \int f^2 d\Omega \approx \int \frac{4m^2\alpha^2}{\hbar^4} \ln^2 kR d\Omega = \frac{16\pi m^2\alpha^2}{\hbar^4} \ln^2 kR \to \infty \tag{5}$$

For a calculation of the diverging, $\propto \ln^2 k$, part of the scattering cross-section, we put $\ln qR \approx \ln kR$. An uncertainty in the value of R gives rise to the logarithmic accuracy of Eqs. (4) and (5).

GKKG.13.28

Find the k-dependence of the phase shifts, $\delta_l(k)$, for slow particles, and discuss the effective-range expansion in the Born approximation. What are the constraints on the large-distance asymptotic behavior of the potential that ensure the applicability of the expansion (XIII.15)? Introduce the following parameters of low-energy scattering: scattering length, a_l, and an effective range of the interaction, r_l, with the angular momentum, l.

Solution

For $k \to 0$, the argument, $x = kr$, of the Bessel function in Eq. (XIII.12) is small, and we can use the known expansion of $J_\mu(x)$ for $x \to 0$. We consider only the first two terms of the expansion, [333] and obtain

$$\delta_l^B(k) \approx k^{2l+1}\left[A_l + B_l k^2 + ...\right] \propto k^{2l+1} \tag{1}$$

Here,

$$A_l = c_l \int\limits_0^{\infty} U(r) r^{2l+2} dr, \quad B_l = -\frac{c_l}{2l+3} \int\limits_0^{\infty} U(r) r^{2l+4} dr$$

$$c_l = -\frac{\pi m}{2^{2l+1}\Gamma^2(l+3/2)\hbar^2} \tag{2}$$

Taking into account the effective range expansion, Eq. (XIII.15), and also the smallness of the phase shift in the Born approximation, we find:

$$a_l^B = -A_l, \quad r_l^B = -2B_l A_l^{-2} \tag{3}$$

One of the applicability conditions for these results is a fast decrease of the potential at large distances. This guarantees convergence of the integral in Eq. (2). For an exponential decrease of the potential, no restriction on the values [334] of l appears.

For potentials with a power-law decrease, $U \approx \alpha/r^\nu$, we have a different situation. For the values $l < (\nu-5)/2$, the integrals in Eq. (2) converge in the upper limit, and the notions of the scattering length a_l and effective range r_l are still well-defined.

In the case of $(\nu-5)/2 \le l < (\nu-3)/2$, the second of the integrals in Eq. (2) diverges. Here, the effective range expansion, Eq. (XIII.15), is not valid, but the notion of the scattering length and the dependence $\delta_l \approx -a_l k^{2l+1}$ for slow particles are preserved.

Finally, for the values $l \ge (\nu-3)/2$, the dependence $\delta_l \propto k^{2l+1}$ is broken for $k \to 0$. Low-energy scattering with an arbitrary angular momentum l in potentials with a power "tail" is considered in the following two problems (see Problem 13.27).

GKKG.13.29

For a potential with a power-law decrease at large distances, $U \approx \alpha/r^\nu$ with $\nu > 2$, find the k-dependence of phase-shifts for slow particles with an angular momentum, l.

Solution

For the values $l < (\nu-3)/2, \delta_l = A_l k^{2l+1}$. In the Born approximation, the coefficient A_l in this case is obtained as in the previous problem. In the case $l \ge (\nu-3)/2$, we can not replace the Bessel function, $J_\mu(x)$, in Eq. (XIII.12) by its first, $\propto x^\mu$, expansion term, as it would have led the dependence $\delta_l \propto k^{2l+1}$, and a divergence in the integral. Now, we divide the integration domain in Eq. (XIII.12) into two parts: from $r = 0$ to $r = R$, and from $r = R$ to $r = \infty$ (the value of R is such that for $r > R$, we can use an asymptotic form of the potential), we see that the first integral, proportional to k^{2l+1}, is less important than the second one. We find:

$$\delta_l \approx -\frac{\pi m\alpha}{\hbar^2} k^{\nu-2} \int\limits_{kR}^{\infty} \frac{1}{x^{\nu-1}} J_{l+1/2}^2(x)dx \tag{1}$$

For $l > (\nu-3)/2$, we can replace the lower integration limit by zero and obtain:

$$\delta_l \approx -\frac{\pi m\alpha}{\hbar^2} \frac{\Gamma(\nu-1)\Gamma(l+(3-\nu)/2)}{2^{\nu-1}\Gamma^2(\nu/2)\Gamma(l+(\nu+1)/2)} k^{\nu-2} \tag{2}$$

In the case of $l = (\nu-3)/2$, the integral in Eq. (1) for $k \to 0$ diverges in the lower limit. Using the expansion of $J_\mu(x)$ for $x \to 0$, we find the divergent part of the integral and the phase shift:

$$\delta_l \approx \frac{\pi m\alpha}{2^{2l+1}\Gamma^2(l+3/2)} k^{2l+1} \ln kR \tag{3}$$

Let us make a few remarks:

1. Although the above results are based on the Born approximation, for $\nu > 2$ they apply more broadly. Indeed, in this case, the large distances are essential, where $|U(r)| \ll \hbar^2/mr^2$, so that the potential can be considered as a perturbation.

2. For a potential that is a superposition of a "strong" short-range and a "weak" long-range (with a power-law asymptote) potential, generally speaking, [335] the contributions to the phase shift are additive: $\delta_l \approx \delta_{l,\,\mathrm{shor}} + \delta_{l,long}$. For abnormally small k, the dominant contribution comes from the long-range potential, while for k not too small it comes from the short-range potential. See Problem 13.37, and also Problem 13.42.

[0] [333] These transformations are valid for fixed finite value of k, but $l \gg (kR)^2$, which allows us to make a conclusion for the phase shifts at large values of the angular momentum: $\delta_l \propto (kR/l)^{2l+1}$.

[334] The dependence $\delta_l \propto k^{2l+1}$ is valid for "strong" potentials including those for which the Born approximation is not valid.

GKKG.13.30

For potential with a power-law decrease at large distances, $U \approx \alpha/r^\nu$, discuss how the effective-range expansion, see Eq. (XIII.15), should be modified in order to describe scattering of particles with angular momenta, l, in the range $(\nu-5)/2 \le l < (\nu$ - $3)/2$. As an illustration of this result, consider s-wave scattering of slow particles in a potential with the large-distance asymptote, $U \approx \alpha/r^4$.

Solution

Taking into account the solutions of the two previous problems, it is easy to obtain the following expansions:

$$\delta_l + a_l k^{2l+1} \approx -\frac{\pi m\alpha}{\hbar^2} k^{\nu-2} \int\limits_0^\infty \frac{1}{x^{\nu-1}} \left[J^2_{l+1/2}(x) - \frac{x^{2l+1}}{2^{2l+1}\Gamma^2(l+3/2)} \right] dx$$

$$\frac{\nu-5}{2} < l < \frac{\nu-3}{2} \tag{1}$$

In the case $l = (\nu-5)/2$, we can also obtain Eq. (1), but the lower limit of the integral will be equal to kR. Calculating the divergent part, we find:

$$\delta_l + a_l k^{2l+1} \approx -\frac{\pi m\alpha}{2^{2l+1}(2l+3)\Gamma^2(l+3/2)} k^{2l+3} \ln kR \tag{2}$$

In particular, for a potential that at large distances has the form $U \approx \alpha/r^4$(i.e., $\nu = 4$), and for $l = 0$, we obtain from Eq. (1):

$$\delta_0 + a_0 k \approx -\frac{2m\alpha}{\hbar^2} k^2 \int\limits_0^\infty \frac{1}{x^3} \left[\frac{\sin^2 x}{x} - x \right] dx = \frac{2\pi m\alpha}{3\hbar^2} k^2$$

The generalization of the effective range expansion, Eq. (XIII.15), takes the form:

$$k \cot \delta_0(k) \approx -\frac{1}{a_0} + \frac{2\pi m\alpha}{3\hbar^2 a_0^2} k$$

GKKG.13.31 Catalog of scattering lengths

Find the scattering length, a_0, in the following potentials:

a) $U(r) = \begin{cases} -U_0, & r < R, \\ 0, & r > R \end{cases}$ b) $U(r) = -U_0 R\delta(r-R)$; c) $U(r) = -U_0 e^{-r/R}$

d) $U(r) = -U_0 \left[1 + (r/R)^2\right]^{-2}$; e) $U(r) = U_0(R/r)^4$, $U_0 > 0$.

What is notable about the potential parameters that correspond to a divergent scattering length?

What is the reason behind a non-analytic dependence of $a_0\,(U_0)$ on the parameter U_0, for $U_0 \to 0$ in case e)?

Solution

To calculate the scattering length, a_0, we should find a bounded solution of the radial Schrdinger equation with $E = 0$ and $l = 0$. Its asymptote, [336]

$$R_{l=0,E=0} \approx 1 - \frac{a_0}{r} \quad \text{for} \quad r \to \infty$$

determines the value of a_0. The solutions of the Schrdinger equation for the potentials considered were discussed in Chapter 4, so here we make only several remarks, [337] (below, $\chi = rR_{l=0,E=0}$ and $\lambda = \sqrt{2mU_0R^2/\hbar^2}$).

a) For the square potential well,

$$\chi = \begin{cases} A \sin \frac{\lambda r}{R}, & r < R \\ r - a_0, & r > R \end{cases}$$

From the conditions of χ and χ' continuity at the point $r = R$, we find:

$$a_0 = \left(1 - \frac{1}{\lambda} \tan \lambda\right) R$$

[336] Such an asymptote assumes a decrease of the potential at large distances faster than $\propto 1/r^3$.

[337] Let us reiterate that the boundary condition, $\psi(\infty) = 0$, that is used for states of the discrete spectrum, does not appear here.
b) For the δ-spherical potential,

$$\chi = \begin{cases} Cr, & r < R \\ a_0 - r, r > R \end{cases}$$

Matching the solution at the point $r = R$ (see Problem 4.8) gives

$$a_0 = -\frac{\lambda^2}{1-\lambda^2} R$$

c) For an exponential potential, the solution to the Schrdinger equation is

$$\chi = J_0(2\lambda)N_0(x) - N_0(2\lambda)J_0(x), \text{ where } x = 2\lambda e^{-r/2R}$$

Here, J_0 and N_0 are Bessel and Neumann functions, respectively. We have used the boundary condition $\chi(r = 0) = 0$ (compare to Problem 4.8). Since for $r \to \infty$, we have $x \to 0$, then we can use the expression (with $\mathcal{C} = e^\gamma = 1.781..., \gamma = 0.5772...$ is Euler's constant):

$$J_0(x) \approx 1 - \frac{x^2}{4}, \quad N_0(x) \approx \frac{2}{\pi} J_0(x) \ln \frac{x}{2} + \frac{2\gamma}{\pi} + \frac{1}{2\pi}(1-\gamma)x^2, \quad |x| \ll 1$$

and find the scattering length:

$$a_0 = \frac{\pi R}{J_0(2\lambda)} \left[\frac{2}{\pi} J_0(2\lambda) \ln \gamma\lambda - N_0(2\lambda) \right] \tag{3}$$

d) For the potential given, the Schrdinger equation has the form (compare with Problem 4.25):

$$\psi_{E=0,l=0} = C\sqrt{1 + \frac{R^2}{r^2}} \sin\left(\xi \arctan \frac{r}{R}\right)$$

where $\xi = \sqrt{1+\lambda^2}$. From its asymptote, we find:

$$a_0 = \xi R \cot\left(\frac{1}{2}\pi\xi\right) \tag{4}$$

e) In analogy to the solution to Problem 4.25, we find the wavefunction,

$$\psi_{E=0,l=0} = A \exp\left\{-\frac{\lambda R}{r}\right\}$$

and the scattering length,

$$a_0 = \lambda R \tag{5}$$

Now, we discuss the results obtained. We first mention an essential difference in the dependence of the scattering length, a_0, on the parameter $\lambda \propto \sqrt{U_0}$ for $U_0 \to 0$ in case e) in comparison to the other cases a) -d). According to (1)-(4), a_0 for small λ is expanded into a series in powers of λ^2, and is an analytic function of the parameter
U_0. Depending on the sign of U_0, these expressions give a scattering length in either an attractive potential $U_0 > 0$, or a repulsive one $U_0 < 0$. For example, Eq. (1) for $U_0 < 0$ takes the form:

$$a_0 = \left(1 - \frac{1}{|\lambda|} \tanh|\lambda|\right) R$$

and describes the scattering length of a potential barrier. In the case of the potential $U = \alpha/r^4$, with $\alpha = U_0 R^4$, the dependence of a_0 on the parameter α (or, equivalently, U_0) is non-analytic, since $a_0 \propto \sqrt{\alpha}$. This non-analyticity reflects a qualitatively different way in which the potential affects the particle for small values of $\alpha > 0$ versus $\alpha < 0$, that manifests itself in the "fall into the center" phenomenon in the latter case [338]$\alpha < 0$. Here, Eq. (5) is invalid, since the boundary condition, $\psi(0) = 0$, used for its derivation, could not be fulfilled and requires a modification. Compare to Problem 9.14.

Eqs. (1)-(4) reflect the general nature of the dependence of the scattering length, a_0, on the parameters U_0 and R for a regular potential of a fixed sign and of the form $U(r) = -U_0 f(r/R)$, where $f(|z|) \geq 0$ (attraction

for $U_0 > 0$ and repulsion for $U_0 < 0$). Its qualitative nature is shown in Fig. 13.3.

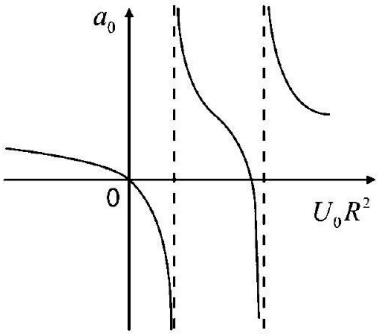


Fig. 13.3

We now list some properties of the solution:

1. For $|\lambda|^2 \ll 1$ (a "weak" potential), the scattering length is also small, since $|a_0| \sim |\lambda|^2 R \ll R$. Writing $a_0 = -\beta\lambda^2 R$ from a) -d), we find that the parameter β, is equal to $1/3, 1, 2, \pi/4$ respectively. These results can be obtained from the Born approximation equation:

$$a_0^B = -f^B(E=0) = \frac{m}{2\pi\hbar^2}\int U(r)dV$$

The sign of the scattering length coincides with the sign of potential.

2) For an increase of $|\lambda|^2$, the value of the scattering length increases. The dependence of a_0 on U_0 is monotonic, except for the unique values, λ_n, of the parameter λ, where, in an attractive potential, the scattering length, a_0, becomes infinite. Such values of λ correspond to the appearance of a new bound state in the potential with the angular momentum $l = 0$.[339] Indeed, the wavefunction's asymptote for $r \to \infty$ at the threshold of emergence of a new bound state is $\psi_{E=0} \propto 1/r$ (but not $C_1 + C_2/r$, as in the general case; compare to Problem 4.25). This corresponds to a divergent scattering length, $a_0 \to \infty$.

Let us prove that the dependence of a_0 on U_0 is monotonous if the potential does not change sign. The two Schrdinger equations for $E = 0$ and $l = 0$ are

$$\chi_0'' = -\frac{2m}{\hbar^2}U_0 f\left(\frac{r}{R}\right)\chi_0, \quad \chi'' = -\frac{2m}{\hbar^2}\left(U_0 + \delta U_0\right) f\left(\frac{r}{R}\right)\chi$$

The boundary conditions take the form $\chi_0(0) = \chi(0) = 0$, while the asymptotes of the solutions for $r \to \infty$ are $\chi_0 \approx a_0 - r$ and $\chi \approx a - r$, with $a = a_0 + \delta a_0$ (where δa_0 is a change in the s-wave scattering length due to a change of the potential by $-\delta U_0 f$). Multiplying the first of these equations by χ and the second one by χ_0, subtracting them term by term, and integrating over r from 0 to ∞, we find:

$$\delta a_0 = -\left(\chi\chi_0' - \chi_0\chi'\right)\Big|_0^\infty \approx -\frac{2m}{\hbar^2}\delta U_0 \int\limits_0^\infty f\left(\frac{r}{R}\right)\chi_0^2(r)dr$$

In the integral, we put $\chi \approx \chi_0$, which is valid due to the assumed smallness of $\delta U_0 \to 0$ and the condition $a_0 \neq \infty$; here, δa_0 is also small and $\delta a_0/\delta U_0 < 0$, which proves the monotonic $a_0\,(U_0)$ dependence.

3) Along with the values of λ close to λ_n, for which the scattering amplitude is anomalously large (resonant scattering), there also exist values $\tilde{\lambda}_n$, where the scattering length on the contrary vanishes. For such values, $\tilde{\lambda}_n$, of the parameters of the potential, the scattering cross-section, $\sigma = 4\pi a_0^2$, of particles with energy $E = 0$ vanishes. So for λ close to $\tilde{\lambda}_n$, the scattering cross-section for slow particles, $kR \ll 1$, can be abnormally small, which manifests itself in the Ramsauer-Townsend effect. Let us emphasize that this smallness of the scattering cross-section, $\sigma \ll \pi R^2$, for slow particles in a "strong" short-range potential of radius R might appear only if the potential is attractive.

Finally, let us mention the following property of the scattering length in the case of a strong potential, with $|\lambda| \gg 1$. If the potential has a well-defined radius, R, as in the case of a rectangular δ-well (or the corresponding barrier), then $a_0 \approx R$, except for narrow regions of λ in the vicinity of the points [340]λ_n (see Eqs. (1) and (2)). This property exists also for rapidly (exponentially) decreasing

[339] In the case of the δ-well, Eq. (2), only one bound state with the angular momentum $l = 0$ appears, as $\lambda \geq \lambda_0 = 1$.

[340] These narrow regions also include the points $\tilde{\lambda}_n$. As is seen from Eqs. (1) and (3), for rapidly decreasing potentials, the points λ_n and $\tilde{\lambda}_n$ move closer as $n \to \infty$; for the step potential (see Eq. (4)) this

[0][338] Compare to the analogous property of the scattering phases δ_l, in the case of an attractive potential $U = -|\alpha|/r^2$, which follows from Eq. (1) of Problem 13.19. For $2m|\alpha|/\hbar^2 = (l + 1/2)^2$, the particle with the angular momentum, l, "falls into the center."

statement is not valid.
potentials. From Eq. (3), for $\ln \gamma\lambda \gg 1$, we have $a_0 \approx R_{eff} \approx 2R \ln \gamma\lambda$, except when the Bessel function, $J_0(2\lambda)$, is close to zero. These exceptional values of λ correspond to the appearance of new bound states. The difference from the previous case lies in the weak, logarithmic dependence of R_{eff} on λ, which is seen from the expression $|U(R_{eff})| \approx \hbar^2/mR_{\text{eff}}^2$. For potentials with a power-law decrease, as seen from Eq. (4), we have a different situation. In this case, $a_0(\lambda)$ is a "lively" function of λ in the entire interval between λ_n and λ_{n+1}.

GKKG.13.32 Scattering by ellipsoid

Find the scattering length and cross-section for slow particles scattered by an impenetrable ellipsoid, i.e., by the potential:

$$U(r) = \begin{cases} \infty, \frac{x^2+y^2}{b^2} + \frac{z^2}{c^2} < 1 \\ 0, \frac{x^2+y^2}{b^2} + \frac{z^2}{c^2} \geq 1 \end{cases}$$

Assume $c \geq b$. Consider specifically two limiting cases: $c \approx b$ and $c \gg b$.

Solution

This problem is reduced to solving the Schrdinger equation with energy $E = 0$, which takes the form $\Delta\psi(\mathbf{r}) = 0$ with the boundary condition $\psi(\mathbf{r}_0) = 0$ on the surface of the ellipsoid and with the asymptote, $\psi \approx 1 - a_0/r$, at large distances. The scattering length is [341] $a_0 = -f(E = 0)$.

For the function $\phi(\mathbf{r}) = 1 - \psi(\mathbf{r})$, the equation, the boundary condition, and the asymptote are:

$$\Delta\varphi = 0, \quad \varphi(\mathbf{r}_0) = 1, \quad \varphi \approx \frac{a_0}{r} \text{ for } r \to \infty \tag{1}$$

According to these relations, the function $\varphi(\mathbf{r})$ can be considered as an electrostatic potential of a charged ellipsoid that on its surface takes the value $\varphi_0 = 1$, and $e = a_0$ is the ellipsoid's total charge. Since $e = C\varphi_0$, where C is the capacitance, the particle's scattering length for an "impenetrable" ellipsoid is formally equivalent to the electrostatic capacitance of a conductor of the same form. [342] The solution of the electrostatic problem, Eq. (1), for an oblong ellipsoid is known and has the form (for $c > b$):

$$\varphi(\mathbf{r}) = \frac{e}{2\sqrt{c^2-b^2}} \ln \frac{z + \sqrt{c^2-b^2} + \left[\left(z + \sqrt{c^2-b^2}\right)^2 + x^2 + y^2\right]^{1/2}}{z - \sqrt{c^2-b^2} + \left[\left(z - \sqrt{c^2-b^2}\right)^2 + x^2 + y^2\right]^{1/2}} \tag{2}$$

[341] Let us emphasize that in the limit of zero energy, particle scattering is isotropic even in the case of a non-spherically-symmetric short-range interaction.

[342] The relation $a_0 = C$ is valid for an "impenetrable" body of an arbitrary form. For example, for particle scattering from an impenetrable disc of radius R, the scattering cross-section is $\sigma(E = 0) = (16/\pi)R^2$ (the disc capacitance is $C = 2R/\pi$).

This result can be obtained by the method of images: the potential created by the ellipsoid coincides with that of a homogeneously-charged segment, whose ends are at the foci of the ellipsoid, with the coordinates $x = y = 0, z = \pm\sqrt{c^2-b^2}$. Determining e from the condition $\varphi(\mathbf{r}_0) = 1$ (here, it is convenient to chose the point on the ellipsoid that lies on the rotation axis, $x = y = 0, z = c$), we find the scattering length:

$$a_0 = e = 2\sqrt{c^2-b^2} \left[\ln \frac{c + \sqrt{c^2-b^2}}{c - \sqrt{c^2-b^2}}\right]^{-1} \tag{3}$$

In the case $c = b$, we have $a_0 = c$ and $\sigma = 4\pi c^2$, the known result for slow particle scattering cross-section for an impenetrable sphere of radius $R = c$. For a strongly prolate ellipsoid, $c \gg b$, Eq. (3) gives:

$$a_0 \approx \frac{c}{\ln(2c/b)}, \quad \sigma(E = 0) \approx \frac{4\pi c^2}{(\ln(2c/b))^2} \tag{4}$$

The generalization to the case of an oblate ellipsoid, $b > c$, can be obtained using analytic continuation of the scattering length (3). Writing $\sqrt{c^2-b^2} = i\sqrt{b^2-c^2} \equiv iv$ and using the relation

$$\ln(c \pm iv) = \frac{1}{2}\ln\left(c^2 + v^2\right) \pm i \arctan\frac{v}{c}$$

we obtain

$$\ln\left(\frac{c+iv}{c-iv}\right) = 2i \arctan\frac{v}{c} = 2i \arctan\frac{\sqrt{b^2-c^2}}{c} = 2i \arccos\frac{c}{b}$$

and for the scattering length, we obtain ($b > c$)

$$a_0 = \frac{\sqrt{b^2 - c^2}}{\arccos(c/b)} \tag{5}$$

If we put here $c = 0$ and $b = R$, we obtain the scattering length, $a_0 = 2R/\pi$, for an impenetrable disc of radius R.

GKKG.13.33

In the quasi-classical approximation, find the scattering length, a_0, for a repulsive potential that has the asymptotic behavior $U \approx \alpha/r^4$ at large distances.

To illustrate the quasi-classical result obtained, apply it to the potentials a) $U = \alpha\left(R^2 + r^2\right)^{-2}$ and, b) $U = \alpha(R + r)^{-4}$, where $R > 0$. Compare these with exact results.

Solution

At finite distances, the quasi-classical solution of Eq. (IV.5) for the function $\chi = rR(r)$ with $E = 0$ and $l = 0$ should be chosen as follows

$$\chi_{quas}(r) = \frac{C}{\sqrt{|p|}} \exp\left\{-\frac{1}{\hbar}\int_r^\infty |p|dr\right\}, \quad |p| = \sqrt{2mU(r)} \tag{1}$$

Here, only the wavefunction that vanishes at the origin is kept. By neglecting the increasing part of the solution, we enforce the boundary condition, [343] $\chi(0) = 0$.

But at large distances, $r \to \infty$, we have $|p(r)| \propto 1/r^2 \to 0$, and the quasiclassical approximation is not applicable. So, we should match solution (1) at large distances, where $U \approx \alpha/r^4$, with the exact solution of the Schrdinger equation, whose asymptote, $\chi(r) \approx a_0 - r$, gives the scattering length. Such an exact solution has the form (see Problem 4.25):

$$\chi = r\left[\frac{a_0}{d}\sinh\frac{d}{r} - \cosh\frac{d}{r}\right]_{r\to\infty} \underset{\sim}{\approx} a_0 - r, \quad d = \sqrt{\frac{2m\alpha}{\hbar^2}} \tag{2}$$

Matching of the solutions (1) and (2) can be performed only if in Eq. (2), as well as in Eq. (1), there exists no term exponentially increasing towards the origin, $r \to 0$. Hence, we find the scattering length in the quasi-classical approximation:

$$a_{0,\ \text{quas}} = d = \sqrt{\frac{2m\alpha}{\hbar^2}} \tag{3}$$

This result for $U = \alpha/r^4$ reproduces the exact one.

For the other potentials from the problem condition, the scattering lengths are (see Problem 13.31d; $\xi = \sqrt{2m\alpha/\hbar^2R^2} = d/R$):

$$\text{a)}\ a_0 = R\sqrt{\xi^2 - 1}\coth\left(\frac{1}{2}\pi\sqrt{\xi^2 - 1}\right),\ \text{b)}\ a_0 = R\xi\left(\coth\xi - \frac{1}{\xi}\right) \tag{4}$$

As expected, for $\xi \to \infty$ they become Eq. (3). Even for the values $\xi \geq 1$, the quasiclassical result is close to the exact one. As an illustration, below is a table showing the ratios, $\eta = a_{0,\ \text{quas}}/a_0$ for several ξ:

ξ	1	2	4	6
$\eta, a)$	1.571	1.145	1.033	1.014
$\eta, b)$	3.202	1.862	1.332	1.200

[343] If $U(r)$ is a bounded potential, $\chi_{quas}(0)$ is different from zero, but is exponentially small. Such a break-down of the boundary condition gives exponentially small errors in the results for relevant observables. More important are corrections connected to the deviation of the potential from its asymptotic form at large distances. See the following problem.

The lower accuracy in case b is due to a larger difference between the potential $U(r)$ and its asymptote, α/r^4, at large distances. See the following problem.

GKKG.13.34

In the conditions of the previous problem, find a quasi-classical correction to the scattering length using the subleading term in the large-distance expansion of the potential: $U = \alpha r^{-4}(1 + b/r + \ldots)$.

Solution

If the potential $U(r)$ differs from α/r^4 only at finite distances, $r \le R$, then for $\xi = \sqrt{2m\alpha/\hbar^2 R^2} \gg 1$, the difference of a_0 from its quasi-classical value $\sqrt{2m\alpha/\hbar^2}$ is exponentially small and is outside the limits of applicability of the quasi-classical approximation.

If the difference, $U(r) - \alpha/r^4$, is different from zero for $r > R$, then power-law corrections in the parameter, $1/\xi \propto \hbar$, appear. To determine the first such correction in the case of $U(r) \approx \left(\alpha/r^4\right)(1 + b/r)$ for $r \to \infty$, it is necessary to find a solution of the Schrdinger equation at large distances, whose accuracy allows to determine correctly a correction in the asymptote of the potential. To do this, we note that within the required accuracy, $U = \alpha/(r - b/4)^4$. For this potential, the Schrdinger equation allows an exact solution, which can be obtained by replacing r by $r - b/4$ in Eq. (2) of the previous problem, and has the form:

$$\chi = -\left(r - \frac{b}{4}\right) \exp\left\{-\frac{\sqrt{2m\alpha}}{\hbar(r - b/4)}\right\} \tag{1}$$

We have omitted here a second independent solution of the Schrdinger equation, which increases exponentially with a decrease in r. From the asymptote of Eq. (1) for $r \to \infty$, we obtain:

$$a_{0,quas} = \sqrt{\frac{2m\alpha}{\hbar^2}}\left(1 + \frac{\hbar b}{\sqrt{32m\alpha}}\right) \tag{2}$$

In the same way, for a potential with the asymptote

$$U(r) = \frac{\alpha}{r^4}\left(1 + \frac{b_1}{r} + \frac{b_2}{r^2} + \ldots\right)$$

we can find a more accurate quasi-classical correction to Eq. (2) if we note that, within the required accuracy, it can be written in the form:

$$U = \frac{\alpha}{\left[(r+b)^2 + R^2\right]^2}, \quad \text{where } b = -\frac{1}{4}b_1, \quad R^2 = \frac{5}{16}b_1^2 - \frac{1}{2}b_2$$

For such a potential, the solution of the Schrdinger equation with $E = 0$ can be obtained as in Problem 4.25, and then we find the following correction to Eq. (2):

$$a_{0,quas} = \sqrt{\frac{2m\alpha}{\hbar^2}}\left[1 + \frac{\hbar b_1}{\sqrt{32m\alpha}} + \frac{\hbar^2}{64m\alpha}\left(8b_2 - 5b_1^2\right)\right] \tag{3}$$

The inclusion of these quasi-classical corrections greatly increases the accuracy of the results. For example, according to Eq. (3) instead of the values given in the table in the previous problem, we now have $0.786, 1.002, 1.0005, 1.0001$ in case a, and $0, 0.931,\ 0.999, 0.99998$ in case b.

In conclusion, we give quasi-classical expressions for the scattering length, a_0, in the case of repulsive potentials with other asymptotic behaviors at infinity, $r \to \infty$.

In the case of a power-law asymptote, $U = (\alpha/r^\nu)(1 + b/r + \ldots)$ with $\nu > 3$, we find:

$$a_{0,\text{ quas}} = \frac{\Gamma[(\nu-3)/(\nu-2)]}{\Gamma[((\nu-1)/(\nu-2))]}\left(\frac{2m\alpha}{(\nu-2)^2\hbar^2}\right)^{1/(\nu-2)} + \frac{b}{\nu} \tag{4}$$

where $\Gamma(z)$ is the Γ-function. For $\nu \to 3, a_{0,\text{ quas}} \to \infty$, which reflects the fact that in the potential $U = \alpha/r^3$, the particle scattering cross-section diverges in the limit $E \to 0$.

For a potential with the exponential decrease, $U \approx U_0 e^{-r/R}$,

$$a_{0,\text{ quas}} = R\left[\ln\left(\frac{2mU_0R^2}{\hbar^2}\right) + 2\gamma\right] \tag{5}$$

where $\gamma = 0.5772\ldots$ is Euler's constant.

GKKG.13.35

For an attractive potential, $U(r) \le 0$, that has a power-law decrease, $U \approx -\alpha/r^\nu$ with $\nu > 3$, at large distances, find the scattering length, a_0, in the quasi-classical approximation. Assume that the potential has the following behavior at small distances, $U \propto r^{-\beta}$ with $0 \le \beta < 2$. What is special about the parameters of the potential that correspond to a divergent scattering length?

Consider applications of this result to the potentials a) $U = -\alpha(r + R)^{-4}$, and b) $U = -\alpha\left(r^2 + R^2\right)^{-2}$, and compare to the exact solution.

Solution

At finite distances, the quasi-classical solution of the Schrdinger Eq. (IV.5) for $E = 0$ and $l = 0$ has the form (compare to Problem 9.9):

$$\chi_{\text{quas}} = rR(r) = \frac{C}{\sqrt{p(r)}} \sin\left(\frac{1}{\hbar}\int_0^r p(r)dr + \gamma_0\right), \quad p = \sqrt{-2mU(r)} \tag{1}$$

where γ_0 depends on the form of the potential at small distances. In the case $U \approx -A/r^\beta$ for $r \to 0$, we have:

$$\gamma_0 = -\frac{\pi\beta}{4(2-\beta)}$$

At large distances, $p(r) \to 0$ and the quasi-classical method is not applicable. Here, though, by taking into account the form of potential, $U \approx -\alpha/r^\nu$, we could find the exact solution of the Schrdinger equation:

$$\chi = \sqrt{r}\left[C_1 J_s\left(2s\sqrt{\tilde{\alpha}}r^{-1/2s}\right) + C_2 J_{-s}\left(2s\sqrt{\tilde{\alpha}}r^{-1/2s}\right)\right] \tag{2}$$

where $s = 1/(\nu-2)$ and $\tilde{\alpha} = 2m\alpha/\hbar^2$. On the other hand at distances, where the argument of the Bessel functions in Eq. (2) is large, the quasi-classical approximation is applicable, and both Eqs. (1) and (2) are valid. Using the asymptote of the Bessel function, $J_\nu(z)$, for $z \to \infty$, solution (2) is transformed to

$$\chi = \sqrt{\frac{\pi s\hbar}{p(r)}}\left[C_1 \sin\left(\frac{1}{\hbar}\int_r^\infty pdr - \frac{\pi s}{2} + \frac{\pi}{4}\right) + C_2 \sin\left(\frac{1}{\hbar}\int_r^\infty pdr + \frac{\pi s}{2} + \frac{\pi}{4}\right)\right] \tag{3}$$

We use $p(r) = \sqrt{2m\alpha/r^\nu}$, and by matching Eqs. (3) and (1) obtain:

$$\frac{C_1}{C_2} = -\frac{\sin(\tau + \pi s/2 + \pi/4)}{\sin(\tau - \pi s/2 + \pi/4)}, \quad \tau = \frac{1}{\hbar}\int_0^\infty \sqrt{-2mU(r)}dr + \gamma_0 \tag{4}$$

Furthermore, using an expansion of $J_{\pm s}(z)$ for $z \to 0$, we find the asymptote of solution (2) at large distances:

$$\chi(r) \approx \frac{C_1}{\Gamma(1+s)}(s\sqrt{\tilde{\alpha}})^s + \frac{C_2}{\Gamma(1-s)}(s\sqrt{\tilde{\alpha}})^{-s}, \quad r \to \infty \tag{5}$$

Since $\chi \propto r - a_0$, and taking into account relation (4), we obtain the quasi-classical scattering amplitude as follows:

$$a^{(0)}_{0,quas} \approx \frac{\Gamma(1-s)}{\Gamma(1+s)}\frac{\sin(\tau + \pi s/2 + \pi/4)}{\sin(\tau - \pi s/2 + \pi/4)}\left(s\sqrt{\frac{2m\alpha}{\hbar^2}}\right)^{2s} \tag{6}$$

The parameters of the potential for which the scattering length becomes infinite correspond to the appearance of a new discrete state, as the well becomes deeper. According to Eqs. (6) and (4), this happens when the following conditions are fulfilled (with $l = 0$):

$$\frac{1}{\hbar}\int_0^\infty \sqrt{-2mU(r)}dr = \pi\left[N + \frac{\beta}{4(2-\beta)} + \frac{1}{2(\nu-2)} - \frac{1}{4}\right] \tag{7}$$

where $N = 1, 2, \ldots$ is the sequence number of the new bound state (compare to Problem 9.9).

For the potentials given in the problem condition, we have $\nu = 4, s = 1/2, \gamma = \beta = 0$. From Eq. (6), we obtain

$$\text{a) } a^{(0)}_{0,quas} = R\xi\cot\xi, \text{ b) } a^{(0)}_{0,quas} = R\xi\cot\left(\frac{\pi}{2}\xi\right) \tag{8}$$

where $\xi = \sqrt{\tilde{\alpha}}/R$. The exact values of the scattering length are equal to, respectively, [344]

$$\text{a) } a_0 = R(\xi\cot\xi - 1), \text{ b) } a_0 = R\sqrt{\xi^2+1}\cot\left(\pi\frac{\sqrt{\xi^2+1}}{2}\right) \tag{9}$$

As is seen, for $\xi \to \infty$ the quasi-classical and exact expressions for the scattering length coincide. Their difference scales as $1/\xi$ for finite values of ξ, and is due to quasi-classical corrections. A calculation of such corrections is more difficult (compare to Problem 13.34), since it is necessary to take into account the next term in $\hbar$ in the phase of the wavefunction at finite distances, i.e., in the quasi-classical region.

17.4.2 Problems about low-energy scattering and resonant scattering 2

GKKG.13.36

Consider a quantum particle moving in the presence of two potentials: a long-range potential, $U_L(r)$, with the radius r_L and a short-range potential, $U_S(r)$, with the radius, $r_S \ll r_L$. Treat the latter short-range potential as a small perturbation and generalize the results of Problem 11.4 for the level shift due to $U_S(r)$ (perturbation theory in terms of the scattering length) for a state with an arbitrary angular momentum, l (as opposed to $l = 0$ in Problem 11.4). Assume that at small distances, $r \lesssim r_S$, the long-range potential is weak $\left(|U_L| \ll \hbar^2/mr_S^2\right)$ and that

$$\left|E_{n_r l}^{(0)}\right| \ll \frac{\hbar^2}{mr_S^2}$$

Solution

We use the method described in Problem 11.4. Using ordinary perturbation theory for the potential $U_S(r)$, we obtain

$$\Delta E_{n_r l} = \overline{U_S(r)} = \int U_S(r) \left|\psi_{n_r lm}^{(0)}(\mathbf{r})\right|^2 dV \tag{1}$$

At the relevant small distances (where the potential, $U_S(r)$, has an effect), we can use the following expression for the unperturbed wavefunction:

$$\psi_{n_r lm}^{(0)}(\mathbf{r}) = R_{n_r l}(r) Y_{lm}(\mathbf{n}), \quad R_{n_r l}(r) \approx Q_{n_r l} r^l \quad \text{for } r \ll r_L$$

Using this, we can express integral (1) in terms of the scattering length with the angular momentum l for the potential $U_S(r)$, in the Born approximation (see Problem 13.28):

$$a_l^B = \frac{\pi m}{2^{2l+1}\Gamma^2(l+3/2)\hbar^2} \int_0^\infty r^{2l+2} U_S(r) dr$$

Finally, by replacing a_l^B with the exact scattering length, a_l^S, in the short-range potential, $U_S(r)$, we obtain the level shift expressed in terms of the scattering length:

$$\Delta E_{n_r l} = \frac{\hbar^2}{2m}[(2l+1)!!]^2 Q_{n_r l}^2 a_l^{(S)} \tag{2}$$

We used the fact that $2^{l+1}\Gamma(l+3/2) = \sqrt{\pi}(2l+1)$!!. Also, note a simplification that occurs for the s-states: $Q_{n0}^2 = 4\pi\psi_{n0}^{(2)}(0)$.

We now discuss the main result - Eq. (2).

1. Since, generally speaking, $a_l^{(S)} \propto r_S^{2l+1}$ while $Q_{n_r l}^2 \propto r_L^{-2l-1}$, then with an increase of l, level shifts decrease fast, $\propto (r_S/r_L)^{2l+1}$. This is connected to a decrease in the penetrability of the centrifugal barrier that divides the regions, where the shortrange and long-range potentials act.

2. If the short-range interaction gives rise to inelastic processes (for example, annihilation into pions due to nuclear interaction for the $p\bar{p}$-hadron atom; see also Problem 11.74), then the scattering length, $a_l^{(S)}$, acquires an imaginary part. In this case, $\Delta E_{n_r l}$ describes not only a shift in energy, but also a widening of the level. The level becomes quasi-stationary and has a finite lifetime.

Let us note that the level width

$$\Gamma_{n_r l} = -2\,\mathrm{Im}\,\Delta E_{n_r l} \propto \mathrm{Im}\, a_l^{(S)}$$

is connected with the inelastic scattering cross-section (the reaction cross-section), $\sigma_{rl}^{(S)}$, in the partial wave with the angular momentum, l due to the short-range interaction of slow particles, since

$$-\operatorname{Im} a_l^{(S)} = \left.\frac{\sigma_{rl}^{(S)}(k)}{4}(2l+1)\pi k^{2l-1}\right|_{k\to 0} \tag{3}$$

Note that the long-range potential can also strongly affect the reaction cross-section for slow particles (see the following problem).

3) As mentioned in Problem 11.4, for the case of angular momentum $l = 0$, if the condition $\left|a_0^{(S)}\right| \ll r_L$ is broken, then Eq. (2) is not applicable. In this case, large shifts of the s-levels are possible in the long-range potential, i.e., a reconstruction of the spectrum occurs (see also Problem 9.3). In the case of $l \neq 0$ we have a different situation and there are no large level shifts, which is due to a low-transparency of the centrifugal barrier. But in the case of a large scattering length, $\left|a_l^{(S)}\right| \gg r_S^{2l+1}$, when there is a shallow level with the angular momentum l in the potential, Eq. (2) does require modification. Here, we note that the solution of the Schrdinger equation in the potential $U_S(r)$ for slow particles, $kr_S \ll 1$, and for the distances $r_s \ll r \ll \left(k^{-1}, r_L\right)$, has the form:

$$R_{kl} \approx C\left[r^l + B_l(k)\frac{1}{r^{l+1}}\right] \tag{4}$$

where

$$B_l^{-1} = \frac{1}{(2l-1)!!(2l+1)!!}k^{2l+1}\cot\delta_l^{(S)}(k)$$

The substitution $k^{2l+1}\cot\delta_l^{(S)} \to -1/a_l^{(S)}$, which leads to Eq. (2) for the level shift (it could be more formally obtained, as in Problem 11.4 for the angular momentum $l = 0$), corresponds to the non-resonant case, where $a_l^{(S)} \leq r_S^{2l+1}$. A generalization of this equation to the resonant case, with the effective range expansion (XIII.15) taken into account, is obtained by replacing $a_l^{(S)}$ with [345]

$$a_l^{(S)} \to \left[\frac{1}{a_l^{(S)}} - r_l^{(S)}E\right]^{-1} \tag{5}$$

Generally speaking, we can put $E = E_{n_r l}^{(0)}$. For $l \neq 0$, the second, singular term in Eq. (4) (which is independent of $a_l^{(S)}$ and scales $\propto 1/r^{l+1}$) is small in the region $r \sim r_L$. This ensures the validity of Eqs. (2) and (5) and yields the corresponding modification of the expression for level shift,

$$\Delta E_{n_r l} = \frac{1}{2}[(2l+1)!!]^2 Q_{n_r l}^2\left(\frac{1}{a_l^{(S)}} - r_l^{(S)}E_{n_r l}^{(0)}\right)^{-1} \tag{6}$$

The importance of the $l \neq 0$ condition to the validity of Eq. (6) in the resonant case is connected to a large effective radius that makes the level shifts small, since

[345] Below in this footnote $\hbar = m = 1$, so that $E = k^2/2$. Note that Eq. (4) can be viewed as a boundary condition for the Schrdinger equation with potential $U_L(r)$ at small distances, which is due to the appearance of the short-range potential $U_S(r)$ (compare to Problem 11.4). But in the case $l \neq 0$, to take the limit $r \to 0$ is impossible due to the divergence of the normalization integral (since it gives $\psi \propto 1/r^{l+1}$ at short distances $r \leq r_s$, the wavefunction coincides with that in the short-range potential). In the case $l = 0$, the limit $r_s = 0$ is possible and corresponds to approximating of the short-range potential by a zero-range potential. See Problem 4.10.

$r_l^{(S)} \propto r_S^{1-2l}$ (see Problem 13.44). The substitution $E = E_{n_r l}^{(0)}$ used in Eqs. (5) and (6) is invalid only if

$$E_S^{(0)} \equiv \frac{1}{a_l^{(S)}}r_l^{(S)} \approx E_{n_r l}^{(0)} \tag{7}$$

This is because $E_S^{(0)}$ describes a level with the angular momentum l that exists in an isolated potential, $U_S(r)$. Condition (7) is fulfilled when there are two close levels, related to both potentials. If we do not substitute $E_{n_r l}^{(0)}$ for E in Eq. (6), we obtain a equation for $\Delta E_{n_r l} = E - E_{n_r l}^{(0)}$, and solve it as follows:

$$E_{1,2} = \frac{1}{2}\left\{E_S^{(0)} + E_{n_r l}^{(0)} \pm \left[\left(E_S^{(0)} - E_{n_r l}^{(0)}\right)^2 + \frac{1}{\left|r_l^{(S)}\right|}((2l+1)!!)^2 Q_{n_r l}^2\right]^{1/2}\right\} \tag{8}$$

This gives the energy of these levels with their interaction taken into account. Note that this equation describes "quasi-crossing" levels. In the case of $E_S^{(0)} > E_{n_r l}^{(0)}$, one of the roots of Eq. (8) describes a shift of the unperturbed level $E_S^{(0)}$ upwards under the influence of the long-range potential, [346] $U_L(r)$, while the second

one describes a level shift downward of $E_{n_r l}^{(0)}$ under the influence of the short-range potential, $U_S(r)$. In the case $E_S^{(0)} < E_{n_r l}^{(0)}$, their roles are switched.
Finally, we discuss the form of wavefunctions in the presence of a level quasicrossing. For a sufficiently large difference between $E_S^{(0)}$ and $E_{n_r l}^{(0)}$, with $E_S^{(0)} > E_{n_r l}^{(0)}$, the wavefunction that corresponds to the first of the levels in Eq. (8) is approximately $\psi_S^{(0)}$, localized at small distances $r \lesssim r_s$, while the wavefunction that corresponds to the second level in Eq. (8) is approximately $\psi_{n_r l}^{(0)}$ localized at large distances, $r \sim r_L$. In the case $E_S^{(0)} < E_{n_r l}^{(0)}$, wavefunctions corresponding to the two levels (in the essential localization domain) change places. In the case of an exact resonance $E_S^{(0)} = E_{n_r l}^{(0)}$, the quantum particle occurs in the two states with an equal probability (equal to 1/2); i.e., has the same probability, 1/2, to be bound in either the localization domains of the potential $U_S(r)$ (for $r \lesssim r_S$) and or that of $U_L(r)$ (for $r \sim r_L$). Wavefunctions of the corresponding states are the same for $r \lesssim r_s$ and differ by a sign in the region $r \gg r_s$, which gives rise to their orthogonality.

[346] Strictly speaking, here we reproduce only the part of the shift that is connected to the action of $U_L(r)$ at large distances, $r \gg r_s$. The influence of U_L on the level shift $E_S^{(0)}$ at short distances manifests itself in a renormalization of the parameters $a_l^{(S)}, r_l^{(S)}$. For example, if $U_L(r) \approx U_0$ for $r \leq r_S$, then it would be more accurate to replace E in Eq. (5) by $E - U_0$. Such a replacement corresponds to a renormalization of the scattering length, i.e., replacing $a^{(S)}$ by $a_l^{(SL)}, 1/a_l^{(SL)} = 1/a_l^{(S)} + r_l^{(S)} U_0$. The effective radius is not renormalized in this case. See also Problem 13.42.

GKKG.13.37

A particle is moving in a combined field of two potentials: a strong short-range potential $U_S(r)$ with the radius r_S and a long-range potential $U_L(r)$ with the radius $r_L \gg r_S$, which is weak at small distances $r \lesssim r_S : |U_L| \ll \hbar^2/m r_S^2$. Assuming that the solution of the Schrdinger equation for the potential $U_L(r)$ is known, find a change of the phase shift, $\Delta\delta_l^{(S)}$, in this potential under the influence of U_S, in the case of slow particles, so that $kr_S \ll 1$. Express $\Delta\delta_l^{(S)}$ in terms of the scattering length $a_l^{(S)}$ in the potential U_S.
Under what conditions is the phase shift in the field $U = U_S + U_L$ approximately equal to the sum of phase shifts in the potentials U_S and U_L separately?
Apply this result to the long-range Coulomb potential.

Solution

We are going to use the methods developed in the previous problem: (1) find a change of the phase shift, $\Delta\delta_l^{(S)}$, by perturbation theory, (2) express it in terms of the scattering length by a short-range potential in the Born approximation, and (3) replace the scattering length by the exact scattering length $a_l^{(S)}$ in the "strong" potential $U_S(r)$. A formal justification of this method is provided in Problem 11.4.

To determine the shift, $\Delta\delta_l^{(S)}$, under the influence of $U_S(r)$ by perturbation theory, we write two Schrdinger equations for the radial wavefunctions, $\psi_{klm} = \chi_{kl} Y_{lm}/r$, of the continuous spectrum:

$$\begin{aligned} \chi_{kl}^{(0)''} + \left[k^2 - \frac{l(l+1)}{r^2} - \frac{2m}{\hbar^2} U_L(r)\right] \chi_{kl}^{(0)} = 0 \\ \chi_{kl}'' + \left[k^2 - \frac{l(l+1)}{r^2} - \frac{2m}{\hbar^2} \left(U_L(r) + U_S(r)\right)\right] \chi_{kl} = 0 \end{aligned} \tag{1}$$

The solutions of these equations, which correspond to the boundary condition $\chi(0) = 0$, have the following asymptotes at large distances:

$$\begin{aligned} \chi_{kl}^{(0)} \approx \sin\left(kr \pm \frac{Z}{k a_B} \ln 2kr - \frac{\pi}{2} l + \delta_l^{(L)}\right) \\ \chi_{kl} \approx \sin\left(kr \pm \frac{Z}{k a_B} \ln 2kr - \frac{\pi}{2} l + \delta_l^{(L)} + \Delta\delta_l^{(S)}\right) \end{aligned} \tag{2}$$

For concreteness, we have considered the case where at large distances: $U_L \approx \mp Z e^2/r$, $a_B = \hbar^2/me^2$.

Multiplying the first of the equations in (1) by χ_{kl} and the second by $\chi_{kl}^{(0)}$, subtracting them term by term, and integrating over r from 0 to ∞, we obtain:

$$k \sin \Delta\delta_l^{(S)} = -\frac{2m}{\hbar^2} \int_0^\infty U_S(r) \chi_{kl}(r) \chi_{kl}^{(0)}(r) dr \tag{3}$$

We can approximate the sine-function by its argument, and χ_{kl} by $\chi_{kl}^{(0)}$. Taking into account the short-range nature of the potential U_S and also the relation $\chi_{kl}^{(0)} \approx Q_{kl} r^{l+1}$ for $r \to 0$, we find:

$$\Delta\delta_l^{(S)} = -\frac{2m}{\hbar^2 k} Q_{kl}^2 \int_0^\infty r^{2l+2} U_S(r) dr \tag{4}$$

The integral here is expressed in terms of the scattering length with angular momentum l in the Born approximation (see the previous problem). Now, we replace it by the exact scattering length, and obtain the desired result:

$$\Delta\delta_l^{(S)}(k) = -[(2l+1)!!]^2 a_l^{(S)} \frac{Q_{kl}^2}{k} \tag{5}$$

We now analyze Eq. (5):

1. Let us first note that in the case $U_L \equiv 0$, we have

$$\chi_{kl}^{(0)} = \sqrt{\frac{\pi k r}{2}} J_{l+1/2}(kr)$$

Here,

$$Q_{kl}^2 = \frac{k^{2l+2}}{[(2l+1)!!]^2}$$

so that

$$\Delta\delta_l^{(S)} = -a_l^{(S)} k^{2l+1} \tag{6}$$

i.e., Eq. (6) coincides with the scattering phase $\delta_l^{(S)}$ from the isolated potential $U_S(r)$, as it should be.
2) The same relation, $\Delta\delta_l^{(S)} = \delta_l^{(S)}$, holds approximately also in the case of a longrange potential $U_L(r)$ that can be considered as perturbation (see conditions (XIII.7)). In this case, the scattering phase in the potential, which is the superposition $U_S(r) + U_L(r)$, is equal to the sum of the scattering phases for each of them separately.
3) Let us finally focus on the case of the long-range Coulomb potential, $U_L = \mp Ze^2/r$. Here,

$$\chi_{kl}^{(0)} = \frac{Zr}{a_B} C_{kl}^{(\mp)} \frac{(2kr)^l}{(2l+1)!} e^{\mp ikr} F\left(i\frac{Z}{ka_B} + l + 1, 2l+2, \pm 2ikr\right)$$

$$\delta_l^{(L)} = \arg \Gamma\left(l + 1 \mp \frac{iZ}{ka_B}\right)$$

$$C_{kl}^{(\mp)} = 2k' e^{\pm\pi/2k'} \left|\Gamma\left(l + 1 \mp \frac{i}{k'}\right)\right| =$$

$$e^{\pm\pi/2k'} \left(\frac{\pi k'}{\sinh \pi k'}\right)^{1/2} \prod_{s=1}^{l} \sqrt{s^2 + \frac{1}{(k')^2}}$$

We let $k' = ka_B/Z$, so that

$$\left(Q_{kl}^{(\mp)}\right)^2 = \frac{\pi Z (2k)^{2l+1}}{[(2l+1)!]^2 a_B} \frac{(\mp 1)}{e^{\mp 2\pi Z/ka_B} - 1} \prod_{s=1}^{l} \left[s^2 + \left(\frac{Z}{ka_B}\right)^2\right] \tag{7}$$

For $l = 0$, the products are replaced by 1.
In the case of "fast" particles, when $ka_B \gg Z$ (but still $kr_s \ll 1$), the Coulomb potential could be considered as a perturbation, and from Eqs. (5) and (7), the results discussed above in 1) and 2) follow.

A completely different situation arises for $ka_B \le Z$. Here, values of $Q_{kl}^{(\mp)}$ differ greatly from the unperturbed values given in 1). Particularly for $ka_B \ll Z$, according to Eqs. (5) and (7), for an s-wave we obtain

$$\text{a) } \Delta\delta_0^{(S)} = \frac{2\pi Z}{ka_B} \delta_0^{(S)}; \quad \text{b) } \Delta\delta_0^{(S)} = \frac{2\pi Z}{ka_B} e^{-2\pi Z/ka_B} \delta_0^{(S)} \tag{8}$$

for the attractive and repulsive Coulomb potential respectively. The essential change of the phase shift value (its increase by $2\pi Z/ka_B \gg 1$ in the case of attraction, and its exponential decrease in the case of repulsion)

has a clear physical underpinning: in the case of slow particles the long-range Coulomb attraction (repulsion) greatly increases (decreases) the probability of finding particles at small distances. This also strongly affects the cross-sections of inelastic processes caused by a short-range interaction, that accompany collisions of slow particles.

In conclusion, let us note that all of this assumes that the scattering from the short-range potential is non-resonant, i.e., there is no "shallow" level in the potential $U_S(r)$. Here $a_l^{(S)} \leq r_S^{2l+1}$ and $\delta_l^{(S)} \approx -a_l^{(S)} k^{2l+1} \ll 1$. However, by substituting the scattering length $a_l^{(S)}$, as in the previous problem, with the expression

$$\left(\frac{1}{a_l^{(S)}} - \frac{1}{2} k^2 r_l^{(S)} \right)^{-1} \tag{9}$$

Eq. (5) could be generalized to include the resonant case. The condition of its applicability is $\Delta\delta_l^{(S)} \ll 1$ (which was used to transform Eq. (3)). Note that for
a repulsive long-range potential, this condition may remain satisfied even if the scattering phase $\delta_l^{(S)}$ for the isolated short-range potential $U_S(r)$ is not small. [347]

GKKG.13.38

How should we modify the Rutherford formula to describe the differential scattering cross-section in the Coulomb potential $U = \pm Ze^2/r$, which is "distorted" at small distances $r \lesssim r_S$? Assume that the conditions $kr_S \ll 1$ and $Ze^2 \ll \hbar v$ are fulfilled. The distortion of the Coulomb field is described by a potential $U_S(r)$, with a known scattering length, $a_0^{(S)}$.

Solution

The scattering amplitude is described by the expression:

$$f \approx f_{\text{Coul}} + f_S; \quad f_{\text{Coul}} = \pm \frac{Ze^2 m}{2\hbar^2 k^2 \sin^2(\theta/2)}, \quad f_S = -a_0^{(S)} \tag{1}$$

This follows from the fact that we only need to consider influence of the short-range potential, $U_S(r)$, on the particles with the angular momentum $l = 0$ (since $kr_s \ll 1$), and that we can consider the Coulomb potential as a perturbation (since $Ze^2 \ll \hbar v$). According to the previous problem, the phase shift in the total potential field (the superposition $U_{\text{Coul}} + U_S$) is approximately equal to the sum of phase shifts for each of the potentials separately.

The differential scattering cross-section is described by

$$\frac{d\sigma}{d\Omega} = \left(\frac{Ze^2}{2mv^2} \right)^2 \frac{1}{\sin^4(\theta/2)} + \left(a_0^{(S)} \right)^2 \mp \frac{Ze^2 a_0^{(S)}}{mv^2 \sin^2(\theta/2)} \tag{2}$$

The last term corresponds to an interference of the scattering amplitudes due to the Coulomb and the short-range interactions. As is seen, its character depends of the sign of the scattering length $a_0^{(S)}$.

GKKG.13.39

Find the scattering length, a_l, of a particle with an arbitrary angular momentum, l for the following potentials:
a) an impenetrable sphere with radius R;
b) $U(r) = -\alpha\delta(r - R)$
c) a square well of radius R and depth U_0.

Compare to the case of $l = 0$ from Problem 13.31.

[347] However, if the scattering length is large, a renormalization of the parameters describing low-energy scattering may become significant. See the previous problem, and also Problem 13.42.

Solution

The scattering length, a_l, could be found from the asymptote of the radial wavefunction, $R_{kl}(r)$, for $E = 0$:

$$R_{0l} \approx r^l - \frac{1}{r^{l+1}} \left\{ (2l-1)!!(2l+1)!! a_l \right\}, \text{ for } r \to \infty$$

This follows, for example, from a comparison of the expression for the wavefunctions of slow particles at distances $d \ll r \ll 1/k$:

$$R_{kl} \approx r^l + B_l(k)\frac{1}{r^{l+1}}, \quad B_l^{-1} = \frac{k^{2l+1}\cot\delta_l}{(2l-1)!!(2l+1)!!}$$

with the effective range expansion (XIII.15).
Below, we present the final results:
a) for scattering from the impenetrable sphere:

$$a_l = \frac{1}{(2l-1)!!(2l+1)!!}R^{2l+1} \equiv a_{sph,l} \tag{1}$$

b) for scattering from the δ-well:

$$a_l = \frac{\xi}{\xi - 2l - 1}a_{sph,l}, \quad \xi = \frac{2m\alpha R}{\hbar^2} \tag{2}$$

c) for scattering from the square potential well:

$$a_l = -\frac{J_{l+3/2}(\lambda)}{J_{l-1/2}(\lambda)}a_{sph,l}, \quad \lambda = \sqrt{\frac{2mU_0R^2}{\hbar^2}} \tag{3}$$

Note that the properties of the scattering length, a_l, as a function of the parameters of the potentials (in cases *b*) and *c*)) are similar to those considered in Problem 13.31 for an s-wave. In particular, when a new bound state appears, the scattering length, a_l, becomes infinite.

GKKG.13.40

Estimate the singlet (i.e., the total electron spin is $S = 0$) electron s-scattering length, $a_0(1)$, for scattering off of an unexcited hydrogen atom. Keep in mind that there exists a weakly-bound state, the ion H^-, with the binding energy $\varepsilon_0 = 0.754\text{eV} = 0.0277$ a.u.
a) Neglect the finite-size effects for both the atomic size and the interaction range of the external electron with the atom.
b) Consider the external electron as weakly bound in a finite-range potential, and use the following asymptotic coefficient $C_{\kappa 0}^2 = 2.65$ (see Problem 11.36).
Compare to the result of a variational calculation: $a_0(1) = 5.97$ a.u.

Solution

a) In this approximation, which corresponds to considering the external electron as in a zero-range potential, we have (see Problems 13.20 and 4.10):

$$a_0 = \kappa_0^{-1} = (2\varepsilon_0)^{-1/2} = 4.25 \tag{1}$$

(in atomic units).
b) Considering the external electron as weakly bound in the potential of finite radius r_S, we first use the relation between the effective interaction radius r_0 and the asymptotic coefficient:

$$r_0 = \frac{C_{\kappa 0}^2 - 1}{\kappa_0 C_{\kappa 0}^2}$$

Now, taking into account the effective-range expansion, Eq. (XIII.15), and the fact that the scattering amplitude, as a function of energy, has a pole at $E = -\varepsilon_0$ (Note that at the pole, $k\cot\delta_0 = ik = -\kappa_0$), we find:

$$a_0 = \frac{2C_{\kappa 0}^2}{\kappa_0\left(1 + C_{\kappa 0}^2\right)} = 6.17 \tag{2}$$

As is seen, the correction to the effective radius strongly affects the value of the scattering length. This is because $\kappa_0 r_s \approx 0.6$ is not that small. In connection to this, let us mention the role of the subleading, $\propto k^4$, term in the effective-range expansion, Eq. (XIII.15). It is usually written as

$$-Pr_0^3k^4 \tag{3}$$

A typical value of this parameter, P, here is small, $|P| \lesssim 0.1$. Taking this into account, we should see that the scattering length (2) is determined to within a few percent accuracy.

GKKG.13.41

In a proton-neutron system, estimate the triplet s-wave scattering length, $a_0(3)$, taking into account the existence of a weakly bound state, the deuteron, with the binding energy $\varepsilon_0 = 2.23\text{MeV}$. Compare to the experimental value, $a_0(3) = 5.39 \cdot 10^{-13}$ cm.

Solution

Neglecting the finiteness of the effective range of the interaction, we have

$$a_0(3) = \kappa_0^{-1} = \left(\frac{\hbar^2}{2\mu\varepsilon_0}\right)^{1/2} = 4.3 \cdot 10^{-13} \text{ cm} \tag{1}$$

where $\mu \approx m_p/2$ is the reduced mass of the pn-system. Since the range of the nuclear forces is $r_s \sim 10^{-13}$ cm, then $\kappa_0 r_s \sim 0.3$, Equation (1) has the same accuracy: about 20%. If we include the term with the effective range $\left(r_0(3) = 1.7 \cdot 10^{-13} \text{ cm}\right)$ in
expansion (XIII.15), we reproduce the experimental value of the triplet scattering length. Compare with the previous problem.

GKKG.13.42

a) Using the experimental value of the singlet s-wave scattering length, $a_0(1) = -23.7 \cdot 10^{-13}$ cm, for a proton-neutron system, estimate the energy of the shallow virtual level [348] in such a system in the state with $S = 0$ and $l = 0$.
b) For a proton-proton system, $a_0(1) = -7.77 \cdot 10^{-13}$ cm. Does the significant difference between the scattering lengths for the pn - and pp-systems contradict the isotopic invariance of the nuclear interaction? The effective range of the interaction $r_0(1)$, is equal to $2.67 \cdot 10^{-13}$ cm and $2.77 \cdot 10^{-13}$ cm, respectively, for the pn - and pp-systems.

Solution

a) Neglecting the effective range of the interaction, we obtain (compare to Problems 13.20 and 4.10, and also Problem 13.40)

$$\varepsilon_{virt} \approx \frac{\hbar^2}{2\mu a_0^2(1)} = 56\text{keV}$$

Here, $\mu = m_p/2$ is the reduced mass of the pn-system.
b) Since the Coulomb interaction at small distances is weaker than the nuclear forces by approximately two orders of magnitude, then navely we might assume that the difference of the low-energy scattering parameters for the pp-system from those for the pn-system should remain to within a few percent. This is indeed so specifically for the effective range of the interaction.

The scattering lengths however do differ noticeably: by a factor of three. But this does not imply that isotopic invariance of nuclear interactions is strongly broken, since the difference could be explained by the Coulomb interaction in the pp-system. In the pn-system there is a shallow virtual level, and the scattering length is large (approximately twenty times larger than the interaction radius!). In such conditions, this function depends sharply on the parameters of the potential (see Problem 13.31), and differs greatly for even a small change of those (in this problem, due to the Coulomb interaction).

Let us provide a simple estimate of the renormalization of the scattering length. We write the pn-interaction in the form $U_{pn} = U_0(r) + \delta U(r)$, where $U_0(r)$ corresponds to the threshold of the appearance of a new bound state, here $\delta U(r) \geq 0$, since the level in the pn-system is virtual. For the pp-system, considering protons to be point-like, we have $U_{pp} = U_0 + \delta U + e^2/r$. Using the result of Problem 4.27 for a shallow s-level depth, we find:

$$\kappa_{pp} = -\frac{2\mu}{\hbar^2} \int_0^d \left(\delta U(r) + \frac{e^2}{r}\right) \chi_0^2(r) dr \tag{1}$$

We use $\chi_0(r)$ as the wavefunction ($\chi = rR$) at the threshold of the appearance of a new bound state, normalized by the condition $\chi_0(r) = 1$ outside of the potential range. The upper integration limit is $d \sim a_B = \hbar^2/m_p e^2 \approx 29 \cdot 10^{-13}$ cm. (At larger distances, a contribution coming from the Coulomb interaction is taken into account independently, and appears in the amplitude of Coulomb scattering of the protons.) The integral of $\delta U(r)$ in Eq. (1) gives κ_{pn} (in both systems $\kappa < 0$, since the levels are virtual). To estimate the integral of the Coulomb potential, we put $\chi_0^2(r) = 1$. Due to a divergence in the lower limit, we introduce a cutoff at $r_s \approx 10^{-13}$ cm (of the order of the nuclear interaction radius). Finally, taking into account the relations $\kappa_{pn} = 1/a_0^{pn}(1)$ and $\kappa_{pp} = 1/a_0^{pp}(1)$, according to Eq. (1), we obtain:

$$\frac{1}{a_0^{pp}(1)} - \frac{1}{a_0^{pn}(1)} \approx -\frac{1}{a_B} \ln\left(\frac{a_B}{r_0}\right) \tag{2}$$

Here, instead of r_s, we put the effective interaction radius, r_0. Let us emphasize that the uncertainty in parameters d and r_s, for which $d/r_s \gg 1$, is "softened" in the final result because of the logarithm. So, we see that accounting for the protons' "weak" Coulomb interaction explains the significant difference of the scattering lengths for the pp - and pn-systems.

GKKG.13.43

Prove the following relation for the effective range of the interaction (see, Eq. (XIII.15)):

$$r_0 = 2\int_0^\infty \left\{\left(-\frac{r}{a_0}+1\right)^2 - \chi_0^2(r)\right\} dr$$

where $\chi_0(r)$ is the radial wavefunction ($\chi_0 = rR_0$) of a state with $l = 0$ and $E = 0$, normalized by the condition $\chi_0(r) = (-r/a_0 + 1)$ for $r \to \infty$ (a_0 is the scattering length).

Find r_0 for an impenetrable sphere of radius R, and also for a δ-well, $U(r) = -\alpha\delta(r - R)$ and a square well of radius R at the threshold for bound state formation ($a_0 = \infty$) in the two latter cases.

Solution

We denote the radial wavefunctions for the values of energy $E = 0$ and $E = \hbar^2k^2/2m$ by χ_0 and χ, respectively. They satisfy the following equations:

$$\chi_0'' - \tilde{U}(r)\chi_0 = 0, \quad \chi'' - \left[\tilde{U}(r) - k^2\right]\chi = 0; \quad \tilde{U} = \frac{2m}{\hbar^2}U(r) \tag{1}$$

To normalize $\chi_0(r)$, use the condition $\chi_0(r) \approx (1 - r/a_0)$ for $r \gg d$ (d is the potential radius). For wavefunction $\chi(r)$ at distances $d \ll r \ll 1/k$, we have

$$\chi(r) = k\cot\delta_0 \cdot r\left[1 + O\left(k^2r^2\right)\right] + \left[1 + O\left(k^2r^2\right)\right] \tag{2}$$

where $O\left(k^2r^2\right)$ corresponds to corrections in the asymptote.

Multiplying the first equation of (1) by χ, the second one by χ_0, subtracting them term by term, and integrating in the region where expansion (2) is valid, we obtain:

$$\int_0^r \frac{d}{dr}\left\{\chi_0'\chi - \chi_0\chi'\right\} dr \equiv -\frac{1}{2}r_0k^2 + O\left(k^2r, k^2\frac{r^2}{a_0}, k^2\frac{r^3}{a_0^2}\right) =$$

$$k^2\int_0^r \chi(r)\chi_0(r)dr \tag{3}$$

Here, we have taken into account the asymptotes given above, the boundary condition $\chi(0) = 0$, and the effective range expansion (XII.15). The integral on the right-hand side of the expression can be cast into the form

$$\int_0^r \chi\chi_0 dr \approx \int_0^r \left[\chi_0^2 \pm \left(-\frac{r}{a_0}+1\right)^2\right] dr =$$

$$= \int_0^r \left[\chi_0^2 - \left(-\frac{r}{a_0}+1\right)^2\right] dr + \frac{r^3}{3a_0^2} - \frac{r^2}{a_0} + r$$

(here we have used $\chi \approx \chi_0$; the notation $\pm(-r/a_0 + 1)^2$ means an addition or subtraction of the corresponding term).

We have used the fact that $\chi \approx \chi_0$. In the last integral we could extend the integration to infinite limits. Then, leaving only r independent terms in Eq. (3), we obtain

$$r_0 = 2\int_0^\infty \left\{\left(-\frac{r}{a_0}+1\right)^2 - \chi_0^2(r)\right\} dr \tag{4}$$

For the scattering from an impenetrable sphere of radius R we have $\chi_0 = 1 - r/R$ for $r > R$ and $\chi_0 = 0$ for $r < R$. In this case, the scattering length is $a_0 = R$, and according to Eq. (4) we find the effective range of the interaction, $r_0 = \frac{2}{3}R$.

For $a_0 = \infty$ from Eq. (4) the well-known result for effective range, r_0, at the threshold of s-level appearance follows. In particular, for the scattering from a δ well with $a_0 = \infty$, we have $\chi_0 = 1$ for $r > R$ and $\chi_0 = r/R$ otherwise. According to Eq. (4) with $a_0 = \infty$, we obtain $r_0 = \frac{4}{3}R$. For the scattering from a square potential well $r_0 = R$, and the effective range is the same whenever a new bound state appears (independently of its sequence number). Here, for $r < R$, the wavefunction is

$$\chi_0 = \sin\left[\pi\left(n_r + \frac{1}{2}\right)\frac{r}{R}\right]$$

where $n_r = 0, 1, 2, ...$ is the sequence number of bound state that appear with a deepening of the well.

Note that both the value $r_0 \sim R$ and the sign $r_0 > 0$ of the "critical" effective range (at the threshold of appearance of a new s-state) are quite general for attractive potentials, $U(r) \leq 0$. Compare to the case of angular momenta $l \neq 0$ in Problem 13.44, and also to the case $l = 0$ for a well surrounded by a potential barrier, in Problem 13.47.

GKKG.13.44

Prove that the effective range of the interaction r_l, in a state with $l \neq 0$ (see Eq. (XIII.15)) and at the threshold of bound-state [349] formation, is

$$r_l = -2[(2l-1)!!]^2 \frac{1}{C_l^2}$$

where C_l is the normalization coefficient in the wavefunction of the zero-energy state ($E = 0$):

$$\chi_l^{(0)}(r) \approx C_l \frac{1}{r^l} \text{ for } r \to \infty \text{ and } \int_0^\infty \left(\chi_l^{(0)}(r)\right)^2 dr = 1$$

Find r_l for a δ-well.

Solution

We will follow the method outlined in the previous problem. Taking into account that the wavefunction when a new bound state is just about to appear has the form $\chi_l^{(0)} = C_l r^{-l}$ for $r \gg d$, and also the relation

$$\chi_{kl} \approx C_l \left[r^{-l} + \frac{k^{2l+1}\cot\delta_l}{(2l-1)!!(2l+1)!!} r^{l+1}\right], \quad d \ll r \ll \frac{1}{k}$$

(compare, for example, to Problem 13.39), we find:

$$-\frac{1}{[(2l-1)!!]^2} C_l^2 k^{2l+1}\cot\delta_l = k^2 \int_0^r \chi_{kl}\chi_l^{(0)}, \quad d \ll r \ll \frac{1}{k}$$

Now, if we replace χ_{kl} by $\chi_l^{(0)}$ in the right-hand side (due to a small value of k^2), extend the integration to infinity (in the case $l = 0$, we cannot do this due to a divergence of

[349] This case is interesting, since in the absence of a shallow level in the potential, the term containing the effective range in Eq. (XIII.15) acts as a small correction.

the integral at the upper limit) and use the relation $k^{2l+1}\cot\delta_l = r_l k^2/2$ (since $a_l = \infty$ at the threshold), then we obtain:

$$r_l = -2[(2l-1)!!]^2 C_l^{-2}, \quad l \geq 1 \tag{1}$$

The value of C_l^2 is uniquely determined by the normalization of the radial wavefunction, $\chi_l^{(0)}$, to 1.

Unlike in the case of s-scattering, the effective range of the interaction is negative, $r_l < 0$, and is of the order of $|r_l| \sim R^{1-2l}$, where R is the radius of the potential (which is of the same magnitude as the localization domain of a zero-energy bound-state with the angular momentum $l \neq 0$).

For a δ-well, the wavefunction at the threshold of appearance of a new bound state with the angular momentum, l, has the form:

$$\chi_l^{(0)} = \begin{cases} C_l r^{-l}, & r > R \\ C_l \frac{r^{l+1}}{R^{2l+1}}, & r < R \end{cases}$$

From the normalization condition, we find C_l^2 and the effective range of the interaction is:

$$r_l = -\frac{4(2l-3)!!(2l+1)!!}{2l+3}R^{1-2l}, \quad l \geq 1$$

In conclusion, note that a change in the effective range as a result of a small change in the potential is also small. So, the "critical" value of r_l at the threshold of bound-state formation is applicable also in the case of a shallow level (real and quasi-discrete).

17.4.3 Problems about low-energy scattering and resonant scattering 3

GKKG.13.45

Find the phase shift, $\delta_0(k)$, and scattering cross-section for scattering of slow particles in the following potentials:
a) an impenetrable sphere of radius R;
b) a δ-well, $U(r) = -\alpha\delta(r-R)$;
c) a square well of radius R and depth U_0.
Use the effective range expansion.

Solution

a) For the radial function $\chi_l = rR_l$ with $l = 0$, the Schrdinger equation and its solution, which corresponds to the boundary condition $\chi_0(R) = 0$, have the form:

$$\chi_0'' + k^2\chi_0 = 0, \quad \chi_0(r) = A\sin[k(r-R)]$$

So, the s-scattering phase shift is $\delta_0(k) = -kR$, and the scattering cross-section for slow particles, when $kR \ll 1$, is described by the expression:

$$\sigma \approx \sigma_{l=0}(k) = \frac{4\pi}{k^2}\sin^2\delta_0 \approx 4\pi R^2\left(1 - \frac{1}{3}k^2R^2\right)$$

Recall that the first correction to the cross-section is connected with p-wave scattering, and is $\propto k^4$. The contribution of higher waves is less important.
In the cases *b*) and *c*), it is also possible to find $\delta_0(k)$ from a exact solution to the Schrdinger equation. But it is easier to consider slow particle scattering using the effective range expansion, Eq. (XIII.15). The parameters of low-energy scattering, a_l and r_l, could be obtained using the zero-energy solution of the Schrdinger equation. See Problems 13.31 and 13.43, specifically for a discussion of the s-wave scattering.
b) The solution of the Schrdinger equation for $E = 0$ and $l = 0$ has the form:

$$\chi_0(r) = \begin{cases} r - a_0, & r > R \\ Cr, & r < R \end{cases}$$

Matching the solution at the point $r = R$ (see Problem 2.6) gives:

$$a_0 = \frac{\tilde{\alpha}R}{\tilde{\alpha}-1}, \quad C = 1 - \frac{a_0}{R}, \quad \tilde{\alpha} = \frac{2m\alpha R}{\hbar^2}$$

If $\tilde{\alpha}$ is not close to 1, then $|a_0| \leq R$, and for slow particles $\sigma \approx 4\pi a_0^2$ (a correction of the order of k^2R^2 to this expression could be found by calculating the effective range, r_0, according to Problem 13.43). However, if $\tilde{\alpha}$ is close to 1, then $|a_0| \gg R$ and the scattering cross-section has a pronounced energy-dependence that is described by resonance equation (XIII.16). For this, the effective range of the interaction for a δ-well at the threshold of s-state formation is $r_0 = \frac{4}{3}R$ (see Problem 13.43). Note that the relation $\sigma \approx 4\pi a_0^2$ needs to be corrected also for values of the parameter $\tilde{\alpha}$ close to $2l+1$ with $l \geq 1$ (when a bound state with the angular momentum l appears in the system), due to the resonant nature of scattering in the l-th partial wave (see Problem 13.46).
c) The parameters of low-energy scattering, a_0 and r_0, for the square potential well were found in Problems 13.31 and 13.43.

GKKG.13.46

Consider scattering of slow particles in the partial wave with the angular momentum, $l \neq 0$, for the potential $U(r) = -\alpha\delta(r-R)$. Consider specifically the case of angular resonant scattering with a quasi-stationary state of small energy, $E_R \ll \hbar^2/mR^2$, and find its width, Γ_R.

Solution

As in the previous problem, we use the effective range expansion, Eq. (XIII.15). The scattering length,

$$a_l = -\frac{1}{(2l-1)!!(2l+1)!!}\frac{\tilde{\alpha}}{2l+1-\tilde{\alpha}}R^{2l+1}, \quad \tilde{\alpha} = \frac{2m\alpha R}{\hbar^2} \tag{1}$$

was calculated in Problem 13.39. When $\tilde{\alpha}$ is not close to $2l+1$, the scattering in l th partial wave is non-resonant. For slow particles,

$$\sigma_l \approx 4\pi(2l+1)a_l^2 k^{4l}$$

and the dominant scattering is s-wave.
If $\tilde{\alpha}$ is close to $2l+1$, then in the potential there exists a shallow real (for $\tilde{\alpha} > 2l+1$) or quasi-discrete [350] (for $\tilde{\alpha} < 2l+1$) level. Scattering has a resonant nature, and the term with the following effective range (according to Problem 13.44)

$$r_l \approx -4(2l-3)!!(2l+1)!!\frac{R^{1-2l}}{2l+3} \tag{2}$$

is essential.
The energy spectrum is determined by the poles of the partial scattering amplitude $f_l(E) = 1/k\,(\cot\delta_l - i)$. At the pole E_l we have $\cot\delta_l(E_l) = i$, and using the effective range expansion, Eq. (XIII.15), we obtain for "shallow" levels:

$$ik_R^{2l+1} = -\frac{1}{a_l} + \frac{1}{2}r_l k_R^2 \tag{3}$$

In the case $l \geq 1$, the left-hand side of this equation is small in comparison to both terms in the right-hand side, so that it could be solved by successive iterations. In the "zeroth" approximation, neglecting the left part in Eq. (3), we obtain:

$$E_R \approx \frac{\hbar^2}{mr_l a_l} \approx \frac{(2l-1)(2l+3)(2l+1-\tilde{\alpha})}{4(2l+1)}\frac{\hbar^2}{mR^2} \tag{4}$$

Since $r_l < 0$ (for $l \geq 1$), then for $a_l > 0$ (i.e., for $\tilde{\alpha} > 2l+1$) we have $E_R < 0$, so that the level corresponds to a bound state in the δ-well (compare to Problem 4.9). For the scattering of slow particles in this case, $f_l \approx (k\cot\delta_l)^{-1}$, while the corresponding partial scattering cross-section is
$$

$$\sigma_l(E) = 4\pi(2l+1)\left|f_l\right|^2 \approx 4\pi(2l+1)\frac{\hbar^4}{m^2 r_l^2}\frac{k^{4l}}{(E+|E_R|)^2} \tag{5}$$

$$
As is seen, $\sigma_l \propto (kR)^{4(l-1)}R^2$, i.e., in this case the resonant cross-section in the l th partial wave has the same order of magnitude as the non-resonant cross-section in the lower partial wave, with the angular momentum equal to $l-1$. So, except for the case $l = 1$, it does not provide a significant contribution to the scattering cross-section.

In the case of $\alpha_l < 0$ (i.e., for the value $\tilde{\alpha} < 2l+1, l \geq 1$), the situation is different. Here, according to Eq. (4), $E_R > 0$ and the left part of Eq. (3) is imaginary. The next iteration allows us to obtain the imaginary part of the amplitude's pole, $E_l = E_R - i\Gamma_R/2$, which determines the width of the quasi-stationary state considered:

$$\Gamma_R \approx \frac{2\hbar^2}{m\left|r_l\right|}k_R^{2l+1} \sim (k_R R)^{2l+1}\frac{\hbar^2}{mR^2}, \quad k_R = \frac{1}{\hbar}\sqrt{2mE_R} \tag{6}$$

The dependence of Γ_R on k_R is determined by the energy-dependence of the transmission coefficient of the centrifugal barrier:

$$\Gamma_R \propto D_l \sim \exp\left\{-2\int_R^b \sqrt{\frac{(l+1/2)^2}{r^2} - k_R^2}dr\right\} \sim$$
$$\exp\left\{-(2l+1)\ln\frac{l+1/2}{k_R R}\right\} \propto (k_R R)^{2l+1}$$

$b = (l+1/2)/k_R$ is the quasi-classical turning point. Compare to Problem 9.30.
Now the partial scattering cross-section, $\sigma_l(E)$, is large for energies in a narrow region of width $\sim \Gamma_R$ around E_R, and is

[0] [350] Since $l \geq 1$, the s-level for $\tilde{\alpha} < 1$ is virtual.

$$\sigma_l(E) \approx \frac{\pi(2l+1)}{k^2} \frac{\Gamma_R^2}{(E-E_R)^2 + \Gamma_R^2/4} \tag{7}$$

It is large, $\sigma_l \sim k_R^{-2} \gg R^2$, and is much larger than the scattering cross-section in the s-wave $\left(\sigma_0 \sim \pi R^2\right)$, so the total cross-section is $\sigma \approx \sigma_l$. Outside this energy region, for $|E - E_R| \gg \Gamma_R$, the cross-section is described analogously to Eq. (5), with the change $(E + |E_R|)^2 \to (E - E_R)^2$. Therefore, the estimate of the scattering cross-section given above for $a_l > 0$ is the same as for $a_l < 0$ considered here.

GKKG.13.47

On the basis of the specific model, including a potential well of strength U_0 and radius R that is surrounded by a δ-barrier $\bar{U}(r) = \alpha\delta(r - R)$ (Fig. 13.4), investigate how
the existence of a weakly-penetrating barrier [351] (in this model, $m\alpha R/\hbar^2 \gg 1$) affects scattering of slow particles int he s-state.

Hint: Use the effective range expansion, paying attention to the effect of the weakly penetrable barrier on the effective range of the interaction, r_0.

Solution

We use the effective range expansion and calculate the parameters of low-energy scattering, a_0 and r_0. The wavefunction $\chi_0 = rR_0(r)$ for $E = 0$ and $l = 0$ has the form:

$$\chi_0(r) = \begin{cases} C \sin \kappa_0 r, r < R, \kappa_0 = \frac{1}{\hbar}\sqrt{2mU_0} \\ 1 - \frac{r}{a_0}, \quad r > R \end{cases}$$

Matching the solution at the point $r = R$ (see Problem 2.6), we obtain:

$$C \sin \lambda = 1 - \frac{R}{a_0}, \quad \frac{R}{a_0} + \lambda C \cos \lambda = \tilde{\alpha}\left(\frac{R}{a_0} - 1\right) \tag{1}$$

where $\lambda = \kappa_0 R$ and $\tilde{\alpha} = 2m\alpha R/\hbar^2$. Hence, we find the scattering length:

$$a_0 = R\left(1 - \frac{1}{\tilde{\alpha} + \lambda \cot \lambda}\right) \tag{2}$$

When the inequality $\tilde{\alpha} \gg 1$ is fulfilled, we generally have $a_0 \approx R$, which corresponds to the scattering length of an impenetrable sphere of radius R (a physically intuitive result due to the small penetrability of the barrier).

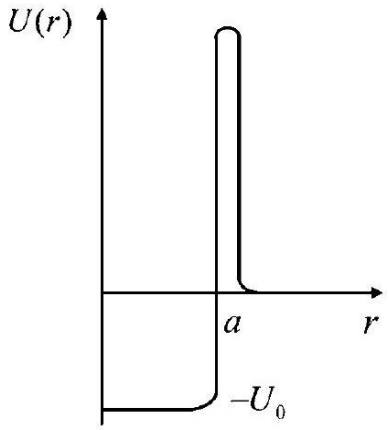

Fig. 13.4

A large difference from the scattering length of an impenetrable sphere appears if λ is close to $n\pi$, with $n = 1, 2, ...$ Writing here $\lambda = n\pi + \gamma$, where $|\gamma| \ll 1$, we obtain:

$$a_0 \approx R\left[1 - \frac{1}{\tilde{\alpha} + n\pi/\gamma}\right] \tag{3}$$

[0] [351] For physical applications, especially interesting is the case where such barrier originates from the Coulomb repulsion of charged particles. But due to the slow decrease of the Coulomb potential, this case needs special consideration.

When $\gamma \approx \gamma_{0,n} = -n\pi/\tilde{\alpha}$, the scattering length is large, $|a_0| \gg R$, and becomes infinite for $\gamma = \gamma_{0,n}$. Such potential parameters correspond to the appearance of a level with energy $E = 0$ (the nth level). In the case of $|a_0| \gg R$, slow particle scattering is resonant.

Now calculate the effective range, r_0. According to Eq. (1), for $a_0 = \infty$ we have $C \approx (-1)^{n+1}\tilde{\alpha}/n\pi$, and from the equation for effective range, r_0, at the threshold of s-level formation,

$$r_0 = 2\int_0^\infty \left(1 - \chi_0^2(r)\right) dr, \quad \chi_0 = 1 \text{ for } r \to \infty$$

(compare Problem 13.43 for the case $a_0 = \infty$), we find:

$$r_0 = R\left(2 - C^2\right) \approx -C^2 R \approx -\left(\frac{\tilde{\alpha}}{n\pi}\right)^2 R \tag{4}$$

Unlike the case of s-scattering by a well without a barrier (where $r_0 \sim R$ and $r_0 > 0$; see Problem 13.43), the effective range at the threshold is large, $|r_0| \gg R$, and negative, $r_0 < 0$. Therefore, the term containing the effective range in Eq. (XIII.15) is essential [352] for description of the resonant s-scattering. The situation is analogous to the one that takes place for scattering of particles with non-zero angular momenta, and the physical reason for this similarity is the existence of the weakly-penetrable δ-barrier that for $l = 0$ plays the same role as the centrifugal potential for $l \neq 0$.

Both the amplitude of resonant scattering,

$$f \approx f_0 = \frac{1}{-\frac{1}{a_0} + \frac{1}{2}r_0 k^2 - ik} \tag{5}$$

and the scattering cross-section, $\sigma \approx 4\pi |f_0|^2$, have a pronounced energy dependence, whose character depends on the relation among the three small parameters $kR \ll 1$, $R/|a_0| \ll 1, R/|r_0| \ll 1$. Let us consider two cases.

1. If $|a_0| \gg |r_0|$, then

$$\sigma \approx \frac{4\pi}{\left(\frac{1}{a_0}\right)^2 + k^2 + \frac{1}{4}r_0^2 k^4} \tag{6}$$

so that the scattering cross-section is almost independent of the sign of the scattering length. In the regime with $k \ll 1/|r_0|$, the term containing the effective range, as in the ordinary s-scattering, acts as a correction. It begins to play an important role for $k > 1/|r_0|$.

[352] Let us note that $|r_0| \gg R$ holds only of there exists a "shallow" level in the system.

2) In the case of $|a_0| \ll |r_0|$, scattering strongly depends on the sign of the scattering length. For $a_0 > 0$, we have (in the denominator of Eq. (5), we could neglect the $-ik$ term):

$$\sigma(E) \approx 4\pi\left(\frac{\hbar^2}{mr_0}\right)^2 \frac{1}{(E+\varepsilon)^2}, \quad \varepsilon = -\frac{\hbar^2}{ma_0 r_0} > 0 \tag{7}$$

The cross-section is also described by an analogous equation (but with $\varepsilon \equiv -E_R < 0$) if $a_0 < 0$, except for a narrow region of energies [353], $|E - E_R| \sim \Gamma_R$, where

$$\sigma(E) \approx \frac{\pi}{k_R^2} \frac{\Gamma_R^2}{(E - E_R)^2 + \Gamma_R^2/4} \tag{8}$$

$$\Gamma_R = \frac{2\hbar^2 k_R}{m|r_0|} = \frac{2(n\pi\hbar)^2 k_R}{m\tilde{\alpha}^2 R} \tag{9}$$

Parameters E_R and Γ_R determine the position and width of the quasi-discrete level; the value of the width is connected to the penetrability of the δ-barrier. Compare to the previous problem, and also with Problem 13.48.

GKKG.13.48

Find the partial amplitude of s-wave scattering in the potential $U(r) = \alpha\delta(r - R)$. In the case of a weakly-penetrable δ-barrier, determine, $E_{R,n}$, and the widths, $\Gamma_{R,n}$, of the lowest quasi-discrete s-levels (with $E_{R,n} \sim \hbar^2/mR^2$).

Compare the scattering cross-section from the δ-sphere and impenetrable sphere. What is the difference, $\Delta\sigma(E)$, between these cross-sections if the energy is close to the energy of the quasi-discrete level?

Solution

The Schrdinger equation and its s-wave solution are

$$\chi'' - \tilde{\alpha}\delta(r-R)\chi + k^2\chi = 0, \quad \tilde{\alpha} = \frac{2m\alpha}{\hbar^2},$$
$$\chi(r) = \begin{cases} A\sin kr, & r < R, \\ \left(S_0 e^{ikr} - e^{-ikr}\right), & r > R. \end{cases}$$

Matching at the point $r = R$ (see Problem 2.6), we find

$$S_0 = e^{2i\delta_0} = e^{-2ikR}\frac{\tilde{\alpha}R\sin kR + kR\cos kR + ikR\sin kR}{\tilde{\alpha}R\sin kR + kR\cos kR - ikR\sin kR} \tag{1}$$

If the conditions $\tilde{\alpha}R \gg 1$ and $kR \sim 1$ (or more precisely, $kR \ll \tilde{\alpha}R$) are fulfilled, then from Eq. (1) we generally have $S_0 \approx e^{-2ikR}$, i.e., $\delta_0 \approx -kR$, which corresponds to the scattering from an impenetrable sphere (see Problem 13.45).

The case of particle energies for which $kR \approx n\pi$ with $n = 1, 2, ...$ needs special consideration, and in Eq. (1) we cannot simply replace the fractional factor by 1. Writing $kR = n\pi + \gamma$, with $|\gamma| \ll 1$, we have

$$\tilde{\alpha}R\sin kR + kR\cos kR - ikR\sin kR \approx (-1)^n(\tilde{\alpha}R\gamma + n\pi - in\pi\gamma) \approx$$
$$(-1)^n(\tilde{\alpha}R - in\pi)\left(kR - n\pi + \lambda + i\lambda^2\right)$$

where $\lambda = n\pi/\tilde{\alpha}R \ll 1$. Equation (1) becomes

$$S_0 \approx e^{-2ikR}\frac{kR - n\pi + \lambda - i\lambda^2}{kR - n\pi + \lambda + i\lambda^2} \tag{2}$$

Multiplying both the numerator and denominator by

$$(kR + n\pi - \lambda)\frac{\hbar^2}{2mR^2} \approx \frac{n\pi\hbar^2}{mR^2}$$

we transform Eq. (2) to a more convenient form,

$$S_0 \approx e^{2i\delta_0^{(0)}}\frac{E - E_{R,n} - i\Gamma_{R,n}/2}{E - E_{R,n} + i\Gamma_{R,n}/2} \tag{3}$$

where $\delta_0^{(0)} = -kR$, and

$$E_{R,n} = \frac{\pi^2 n^2\hbar^2}{2mR^2}\left(1 - \frac{2}{\tilde{\alpha}R}\right)$$
$$\Gamma_{R,n} = \frac{2\pi^2 n^2\hbar^2}{mR^2}\frac{n\pi}{(\tilde{\alpha}R)^2} \ll E_{R,n}$$

Equation (3) has a familiar form for resonant scattering from a quasi-discrete level. $\delta_0^{(0)}$ describes the phase of potential scattering (i.e., phase far from resonance), while $E_{R,n}$ and $\Gamma_{R,n}$ give the position and the width of the quasi-discrete level. Therefore:

1. the phase of potential scattering coincides with the scattering phase for an impenetrable sphere of radius R;

2. the position, $E_{R,n}$, of the quasi-discrete levels almost coincides with the levels in an infinitely deep well of radius R;

3. the level width, which determines the lifetime of the quasi-stationary state, could be written in the form:

$$\Gamma_{R,n} = \frac{\hbar}{\tau_n} \equiv \hbar DN = \hbar \cdot 4\lambda^2 \cdot \frac{\pi n\hbar}{2mR^2}$$

where D is the transmission coefficient (for a single collision) of the δ-barrier for an energy equal to $E_{R,n}$ (see Problem 2.30), while $N = v/2R = \pi n\hbar/2mR^2$ gives the number of times the particle hits the "wall" per unit of time.

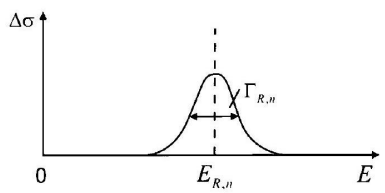

Fig. 13.5

From physical considerations, we should assume that analogous results take place for non-zero values of the angular momentum. So, for $kR \ll \tilde{\alpha}R$, the scattering cross-section on the δ-sphere almost coincides with that on the impenetrable sphere of the same radius, except for narrow regions, ΔE, in the vicinity of quasi-discrete levels. Now, the partial cross-section is described by the expression:

$$\sigma_l = 4\pi(2l+1)\frac{1}{k^2}\left|S_l - 1\right|^2$$

Note that there is no scattering with the angular momentum $l = 0$ from the impenetrable sphere for particles with energy close to the resonant energy $E_{R,n}$ of the s-level (here $\delta_0^{(0)} \approx n\pi$). Hence, we see that the difference between the scattering cross-sections of the δ - and the impenetrable sphere in the vicinity of a quasi-discrete s-level is equal to (Fig. 13.5)

$$\Delta\sigma = \pi R^2 \frac{\Gamma_{R,n}^2}{n^2\pi^2\left[\left(E - E_{R,n}\right)^2 + \Gamma_{R,n}^2/4\right]} > 0$$

GKKG.13.49

Parameters of a potential $U_0(r)$ are chosen so that there exists a zero-energy bound state with the angular momentum l in it (the scattering length is $a_l^{(0)} = \infty$). Find the scattering length, a_l, in this partial wave, for a small change of the potential by $\delta U(r)$.

Using the result obtained, discuss how the dependence of the level position on the perturbation, $\delta U(r)$, differs in the $l = 0$ case from the $l \neq 0$ case. Compare to Problems 4.27 and 4.28.

Solution

Let $\chi_l^{(0)}(r)$ and $\chi_l(r) = rR(r)$ be the zero-energy solutions to the Schrdinger equation with the potentials $U_0(r)$ and $U_0(r) + \delta U(r)$ respectively, normalized by the following conditions (compare to Problem 13.39):

$$\chi_l^{(0)} = r^{-l} \text{ and } \chi_l = r^{-l} - r^{l+1}\left\{(2l-1)!!(2l+1)!!a_l\right\}^{-1} \text{ for } r \to \infty$$

If we write the Schrdinger equation for $\chi_l^{(0)}$ and χ_l, and multiply the first equation by χ_l and the second one by $\chi_l^{(0)}$, then subtract one from the other term by term, and integrate the result over r from 0 to ∞, we find:

$$\frac{\hbar^2}{2[(2l-1)!!]^2 m a_l} = -\int_0^\infty \delta U \chi_l \chi_l^{(0)} dr \approx -\int_0^\infty \delta U \left(\chi_l^{(0)}\right)^2 dr \tag{1}$$

Compare this to the analogous transformation in Problem 13.31. We emphasize that relation (1) is valid for any value of angular momentum.

Using the result obtained and the effective range expansion (XIII.15), from the condition $\cot\delta_l\left(E_l\right) = i$ we can find the position of the pole in the partial scattering amplitude, which determines the change of the level $E_l^{(0)} = 0$ under the influence of the perturbation. If $l = 0$, we have:

$$\kappa_0 = -i\sqrt{\frac{2mE_0}{\hbar^2}} \approx \frac{1}{a_0}$$

and for a positive scattering length $a_0 > 0$ (for $\delta U < 0$), we obtain the known result:

$$E_0 \approx -\frac{2m}{\hbar^2}\left[\int_0^\infty \delta U \left(\chi_0^{(0)}(r)\right)^2 dr\right]^2 \tag{2}$$

Compare to Problem 4.27. In the case $a_0 < 0$, we also have $\kappa_0 < 0$, so that the level E_0 is virtual. We emphasize that the s-wave scattering cross-section depends weakly on the sign of $\delta U(r)$ (see Eq. (XIII.16)).

Now, consider the case with $l \neq 0$. Using Eq. (1) and the result of Problem 13.44 for the effective range of the interaction, r_l, at the threshold where a new bound state appears, we see that the level shift (determined by the poles of the partial amplitude),

$$E_l \approx -\frac{\hbar^2}{m a_l \left|r_l\right|}, \quad l \geq 1 \tag{3}$$

is linear in δU and is described by first-order perturbation theory (compare to Problem 4.28). For $a_l > 0$, the level is real with $E_l < 0$. If $a_l < 0$, then $E_l > 0$ determines the energy of a quasi-stationary state. Its width is

$$\Gamma_l \approx \frac{2\hbar^2}{m\,|r_l|}\left(\frac{2mE_l}{\hbar^2}\right)^{l+1/2} \tag{4}$$

In the case of $l \neq 0$, the nature of resonant scattering depends strongly on the sign of $\delta U(r)$. See, for example, Problem 13.46.

17.4.4 Problems about scattering of fast particles; Eikonal approximation

(углубленный метод, пару задач имеет смысл решить, набивать в них руку не целесообразно.)

GKKG.13.50 Derivation for scattering

Derive Eq. (XIII.18) for the scattering amplitude of fast particles by summing up the non-perturbative series, $f = \sum\limits_n f^{(n)}$, derived in Problem 13.10 (see Eq. (2) there).

Solution

The Fourier components of the potential, $\tilde{U}(\boldsymbol{\kappa})$ are essentially different from zero only for $\kappa R \lesssim 1$(R is the radius of the potential). So, for fast particles, $kR \gg 1$, and small scattering angles, $qR = |\mathbf{k} - \mathbf{k}_0| \lesssim 1$, the integrals over $\boldsymbol{\kappa}_k$ in this equation are dominated by the integration domains where $|\boldsymbol{\kappa}_k - \mathbf{k}_0| \lesssim 1/R$. Writing

$$\boldsymbol{\kappa}_k = \mathbf{k}_0 + \tilde{\kappa}_k^{\parallel}\mathbf{n}_0 + \boldsymbol{\kappa}_k^{\perp}$$

where $\mathbf{n}_0 = \mathbf{k}_0/k_0$ and $\boldsymbol{\kappa}_k^{\perp} \perp \mathbf{n}_0$, then for the energy denominators we have the approximate expression:

$$\kappa_k^2 - k_0^2 - i\varepsilon \approx 2k_0\tilde{\kappa}_k^{\parallel} - i\varepsilon \tag{1}$$

We neglected the terms $\left(\tilde{\kappa}_k^{\parallel}\right)^2$ and $\left(\kappa_k^{\perp}\right)^2$ in comparison to $2k_0\tilde{\kappa}_k^{\parallel}$, which leads to an error $\sim 1/kR$. Now we substitute the Fourier components of the potential into Eq. (2) from Problem 13.10:

$$\tilde{U}\left(\boldsymbol{\kappa}_k - \boldsymbol{\kappa}_{k-1}\right) = \iiint U\left(\boldsymbol{\rho}_k, z_k\right)\exp\left\{-i\left[\left(\tilde{\kappa}_k^{\parallel} - \tilde{\kappa}_{k-1}^{\parallel}\right)z + \left(\tilde{\boldsymbol{\kappa}}_k^{\perp} - \tilde{\boldsymbol{\kappa}}_{k-1}^{\perp}\right)\cdot\boldsymbol{\rho}_k\right]\right\}d^2\rho_k dz_k$$

Recall the following identity for the delta-function:

$$\iint \exp\left\{i\left(\boldsymbol{\rho}_{k+1} - \boldsymbol{\rho}_k\right)\cdot\boldsymbol{\kappa}_k^{\perp}\right\}d^2\kappa_k^{\perp} = (2\pi)^2\delta\left(\boldsymbol{\rho}_{k+1} - \boldsymbol{\rho}_k\right)$$

Now integrating over $\boldsymbol{\kappa}_k^{\perp}$, and using the δ-function to integrate over $\boldsymbol{\rho}_k$, we see that in all factors of $U\left(\boldsymbol{\rho}_k, z_k\right)$, the values $\boldsymbol{\rho}_k$ (with different k) become the same. Finally, using the integral

$$\int \frac{\exp\left\{i\left(z_{k+1} - z_k\right)\kappa_k^{\parallel}\right\}}{2k_0\kappa_k'' - i\varepsilon}d\kappa_k^{\parallel} = \frac{i\pi}{k_0}\eta\left(z_{k+1} - z_k\right)$$

($\eta(z)$ is the step function; see Problem 13.14), we find (for $k = k_0$):

$$f^{(n)} \approx \frac{k}{2\pi i}\left(-\frac{im}{\hbar^2 k}\right)^n \int\limits_{-\infty}^{z_2} dz_1 \int\limits_{-\infty}^{z_3} dz_2 \ldots \int\limits_{-\infty}^{\infty} dz_n \times$$
$$\iint U\left(\boldsymbol{\rho}, z_1\right)\ldots U\left(\boldsymbol{\rho}, z_n\right)e^{-i\mathbf{q}_\perp\cdot\boldsymbol{\rho}}d^2\rho \tag{2}$$

In the exponent we neglected the term $-iq_{\parallel}z_n$, because $q_{\parallel} \ll q_{\perp}$ (compare to Problem 13.2). In this expression we extend integration to infinite limits over all z_k if we introduce the factor $(n!)^{-1}$. As a result, we obtain the scattering amplitude in the eikonal approximation:

$$f \approx \frac{k}{2\pi i} \iint \left\{ \sum_{n=1}^{\infty} \frac{1}{n!} \left(-\frac{im}{\hbar^2 k} \right)^n \left[\int_{-\infty}^{\infty} U(\boldsymbol{\rho}, z) dz \right]^n \right\} e^{-i\mathbf{q}_\perp \cdot \boldsymbol{\rho}} d^2\rho =$$

$$= \frac{ik}{2\pi} \iint \left\{ 1 - \exp\left\{ -\frac{i}{\hbar v} \int_{-\infty}^{\infty} U(\boldsymbol{\rho}, z) dz \right\} \right\} e^{-i\mathbf{q}_\perp \cdot \boldsymbol{\rho}} d^2\rho. \tag{3}$$

In conclusion, we discuss the conditions of applicability of Eq. (3), which follow form the above derivation. Omission of the terms $q_\parallel z \leq q^2 R/k \approx k\theta^2 R \ll 1$ in the exponent of Eq. (2) implies small scattering angles $\theta \ll 1/\sqrt{kR}$. Since $kR \gg 1$, then this region includes scattering angles $\theta \lesssim 1/kR$, which dominate the total cross-section. This, as we noted in the context of Eq. (1), contributes an error $\sim 1/kR$. But the quantity of interest appears in the exponent of Eq. (3). So the condition of its applicability becomes

$$\frac{1}{\hbar v} UR \cdot \frac{1}{kR} \ll 1, \quad \text{i.e.} \quad |U(r)| \ll E.$$

GKKG.13.51

Prove that the total scattering cross-section of fast particles, $kR \gg 1$, in a potential, $U(r)$, of radius R follows from the equation:

$$\sigma(E) = 4\pi \int_0^{\infty} \left\{ 1 - \cos\left[\frac{m}{k\hbar^2} \int_{-\infty}^{\infty} U\left(\sqrt{\rho^2 + z^2} \right) dz \right] \right\} \rho d\rho \tag{1}$$

independently of the relation between particle energy and the characteristic strength of the potential, i.e., the validity of the equation in question does not require that the condition of applicability of the eikonal approximation, $E \gg |U(r)|$, is necessarily satisfied. [354]

Use this result to calculate the scattering cross-section from the potential barrier (or well) with $U = U_0$ for $r < R$ and $U = 0$ for $r > R$.

Solution

Eq. (1) can be derived by combining the optical theorem and the eikonal approximation, Eq. (XIII.18). The condition for its applicability for fast particles is the inequality
$|U(r)| \ll E$, which is valid for a large fraction of scattering angles, $\theta \lesssim 1/kR$ (see the previous problem). In the case of a "strong" potential, for which $|\widetilde{U}(r)| \gtrsim E$ when $r \sim R$, scattering into the angles $\theta \sim 1/kR$ is not described by the eikonal expression. But for forward scattering, corresponding to the angle $\theta = 0$, the amplitude,

$$f(E, \theta = 0) = \frac{1}{2ik} \sum_l (2l+1) \left(e^{2i\delta_l} - 1 \right) \tag{2}$$

still has the eikonal form (the approximation actually remains valid for the region of small scattering angles $\theta \ll 1/kR$, for as long as we can put $P_l \approx 1$ in the amplitude expansion over partial waves, Eq. $f(k,\theta) = \sum_{l=0}^{\infty} (2l+1)\varphi_l(E) P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$ and until the oscillations in the Legendre polynomials with $l \lesssim kR$ begin to play out). To see this, recall that the eikonal equation for the scattering amplitude follows from the quasi-classical expressions for the phase shifts, Eq. (XIII.14). In the case of a "strong" potential, we should use the more general expression, (XIII.13). But this fact is not reflected in the value of the forward scattering amplitude, (2). For the values of l in the sum, Eq. (2), for which $|U(r_0)| \geq E$ (r_0 is the quasi-classical turning point in Eq. (XIII.13)), the phase shifts have the following properties: they are large, $|\delta_l| \gg 1$, and change rapidly with increase in l, $|\delta_{l+1} - \delta_l| \geq 1$. These properties follow both from Eq. (XIII.13) and from [355] Eq. (XIII.14). This leads to the fact that in the corresponding part of sum (2), the contribution of the term with $\exp(2i\delta_l)$ is negligible due to fast oscillations. This happens independently of which expression is used, correct (XIII.13) or "incorrect" Eq. (XIII.14). For values of l such that $|U(r_0)| \ll E$, (XIII.14) is still valid. Therefore the amplitude of forward scattering for fast particles is still described by the eikonal expression, even if the condition $|U(r_0)| \ll E$ breaks down. The statement of the problem follows from the optical theorem. The unitary properties of the scattering amplitude in the eikonal approximation are discussed in Problem 13.76.

In the case of a potential barrier (or a well), we find:

$$\sigma(E) = 4\pi \int_0^R \left[1 - \cos\left(\xi\sqrt{1 - \frac{\rho^2}{R^2}}\right)\right] \rho d\rho =$$
$$2\pi R^2 \left[1 - \frac{2}{\xi^2}(\xi \sin\xi + \cos\xi - 1)\right] \tag{3}$$
$$\xi = \frac{2mU_0 R}{k\hbar^2}$$

This integral is calculated using the substitution $x = \sqrt{1 - \rho^2/R^2}$. For the values $\xi \ll 1$ from Eq. (2), the result of the Born approximation follows

[355] For example, according to Eq. (XIII.14) we have:

$$|\delta_{l+1} - \delta_l| \sim \left|\frac{\partial}{\partial l}\delta_l\right| \sim \frac{m}{\hbar^2 k} |U(r_0)| \frac{l}{k^2 R} \sim \frac{m|U(r_0)|}{\hbar^2 k^2}$$
$$\sigma(E) \approx \pi R^2 \left(\frac{mU_0^2 R^2}{\hbar^2 E}\right) \ll \pi R^2$$

for fast particles (see Problem 13.1), while for $\xi \gg 1$ we have $\sigma \approx 2\pi R^2$, the known result for the scattering cross-section of fast particles from an impenetrable sphere (see Problem 13.57).

GKKG.13.52

Find the total scattering cross-section in the potential $U(r) = \alpha/r^\nu$ with $\nu > 2$ and $\alpha > 0$, for energy $E \to \infty$. Compare to Problem 13.2.

Solution

Let us use the quasi-classical equation for the scattering cross-section from the previous problem. We will also use the integral:

$$\int_{-\infty}^{\infty} U\left(\sqrt{\rho^2 + z^2}\right) dz = 2\alpha\rho^{-\nu+1} \int_0^\infty \frac{du}{(1+u^2)^{\nu/2}} =$$
$$\frac{\sqrt{\pi}\alpha}{\rho^{\nu-1}} \frac{\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}$$

(By the substitution $1 + u^2 = 1/t$, this integral could be transformed to the Euler integral, giving the β-function, $B(x, y)$, with $x = 1/2$ and $y = (\nu - 1)/2$.) We can perform the integration [356] over ρ and obtain

$$\sigma(E) = 2\pi\Gamma(\lambda) \sin\frac{\pi\lambda}{2} \left[\frac{\sqrt{\pi}\alpha}{\hbar v} \frac{\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}\right]^\mu \propto E^{-1/(\nu-1)} \tag{1}$$

where $\lambda = (\nu - 3)/(\nu - 1)$ and $\mu = 2/(\nu - 1)$.
As is seen from Eq. (1), the decrease of the scattering cross-section for $E \to \infty$ is slower than is required for the applicability of the Born approximation, where $\sigma \propto 1/E$. This is because in the scattering of fast particles in the potential $U \propto r^{-\nu}$ with $\nu > 2$, small distances play the dominant role (small impact parameter), and the potential cannot be considered as a perturbation. For large values of energy $E \to \infty$, Eq. (1) is valid for a fairly arbitrary potential, which has the form considered only at small distances. See that for the values $\nu \to 2$, the energy dependence of the cross-section is determined by Eq. (1) and "matches" the result obtained in the Born approximation.

[356] First we make the substitution $x = \rho^2$ and perform integration by parts, which leads to the integral of the form $\int \frac{1}{x^s} \sin\left(\frac{a}{x^s}\right) dx$ with $s = (\nu - 1)/2$. Expressing the sine as a sum of two complex exponentials and making the substitution $v = \pm ia/x^s$, we obtain the integrals that give the Γ-function.

GKKG.13.53

Consider a "potential" of the form $U = g(E)e^{-r/R}$, with the interaction constant, [357] which scales as a power-law with energy, $g(E) = g_0 \left(E/E_0\right)^n$. Prove the inequality

$$\sigma(E) \leq \sigma_0 \ln^2 \left(\frac{E}{E_0}\right)$$

for the energy-dependence of the scattering cross-section in the large-energy limit, $E \to \infty$.

Solution

To calculate the scattering cross-section we use the result of Problem 13.51. The quasiclassical phase shift for large values of the impact parameter $\rho \gg R$ is equal to

$$\delta(\rho) = \frac{g(E)}{2\hbar v} \int\limits_{-\infty}^{\infty} \exp\left\{-\frac{1}{R}\sqrt{\rho^2 + z^2}\right\} dz \approx \frac{g_0}{2\hbar v}\sqrt{2\pi\rho R}\left(\frac{E}{E_0}\right)^n e^{-\rho/R} \tag{1}$$

To calculate this integral, use the expansion: $\sqrt{\rho^2 + z^2} \approx \rho + z^2/2\rho$.
Let us denote by ρ_0 the value of ρ for which the following condition for the phase shift is satisfied: $\delta\left(\rho_0\right) = 1$. In the case $n > 1/2$ and at large energies, we have $\rho_0 \gg R$ (for $E \to \infty, \rho_0 \to \infty$ as well). Now we note that the phase shift is a sharp, rapidly decreasing function of ρ. For calculation of the cross-section using the equation from Problem 13.51, we can completely neglect both the contribution of integration domain $\rho > \rho_0$ (since there, $\delta \approx 0$). On the other hand, in the other domain $\rho < \rho_0$, we can neglect the term corresponding to the fast-oscillating factor, $\cos 2\delta(\rho)$ (because, $\delta \gg 1$). As a result, we obtain $\sigma(E) = 2\pi\rho_0^2(E)$. Thus, using Eq. (1), we find that

$$\sigma(E) \approx \sigma_0 \ln^2 \left(\frac{E}{E_0}\right), \text{ where } \sigma_0 = 2\pi\left(n - \frac{1}{2}\right)^2 R^2 \tag{2}$$

for $n > 1/2$. To calculate approximately $\rho_0(E)$ from the relation $\ln \delta\left(\rho_0\right) = 0$, we neglected the term $\ln\left(\rho_0/R\right)$ in comparison to ρ_0/R. Finally, we mention that for the values $n < 1/2$, the scattering cross-section decreases with the increase of E.

GKKG.13.54

In the eikonal approximation, find the amplitude and differential scattering cross-section for the Coulomb potential, $U = \alpha/r$, in the limiting case opposite to that

[357] Let us note that the spin-orbital interaction, $\hat{U} = \hat{\mathbf{s}} \cdot \hat{\mathbf{l}} f(r)$, increases $\propto \sqrt{E}$ with E. Compare to Problem 13.59. The restriction on the increase of cross-section is known as the Froissart theorem in the theory of strong interactions in elementary particle physics.
required for the validity of the Born approximation: i.e., consider $|\alpha|/\hbar v \gg 1$. Compare to Problem 13.1.
Hint: To calculate the scattering amplitude, introduce a cut-off for the Coulomb potential at some large, but finite, distance R (i.e., put $U = 0$ for $r > R$).

Solution

According to Eq. (XIII.19), for the values $\rho \ll R$, we have

$$\delta(\rho) = -\frac{\alpha}{2\hbar v} \int\limits_{-R}^{R} \frac{dz}{\sqrt{\rho^2 + z^2}} \approx -\frac{\alpha}{\hbar v} \ln \frac{2R}{\rho} \tag{1}$$

and for the $q \neq 0$ scattering amplitude from Eq. (XIII.19), we obtain the relation:

$$f(E, q) = \frac{k}{2\pi i} \int\limits_0^{\infty} \int\limits_0^{2\pi} e^{iS(\rho,\varphi)} \rho d\rho d\varphi$$

where

$$S = \frac{2\alpha}{\hbar v} \ln \frac{\rho}{2R} - q\rho \cos\varphi \tag{2}$$

In the case $|\alpha| \gg \hbar v$, the phase in the exponential is large, and changes rapidly with a change in ρ and φ. Hence, the integral is determined mainly by the integration domains in the vicinity of the saddle points, where the phase reaches extrema as a function of the variables ρ, φ. From this saddle point condition, we find:

$$2\alpha = \hbar v \rho_0 q \cos\varphi_0, \quad q\rho_0 \sin\varphi_0 = 0$$

Thus $\rho_0 = 2|\alpha|/\hbar v q$, and $\varphi_0 = 0$ for $\alpha > 0$ or $\varphi_0 = \pi$ for $\alpha < 0$ (here $|\alpha|/\rho_0 \ll \hbar k v$, i.e., $|U| \ll E$, which allows us to use the eikonal approximation). Expanding $S(\rho, \varphi)$ in the vicinity of the extremum (ρ_0, φ_0) with quadratic accuracy, and using the value of the Poisson integral, we obtain the scattering amplitude:

$$f(E, q) \approx -i \frac{2m|\alpha|}{\hbar^2 q^2} \exp\left\{iS\left(\rho_0, \varphi_0\right)\right\} \tag{3}$$

Therefore, the differential scattering cross-section is

$$\frac{d\sigma}{d\Omega} = \left(\frac{2m\alpha}{\hbar^2 q^2}\right)^2 \approx \frac{\alpha^2}{E^2\theta^4}$$

which coincides with the Rutherford equation (for small scattering angles, $\theta \ll 1$).
Let us note in conclusion that the need to cut off the potential and the absence of a well-defined limit for $R \to \infty$ of the scattering amplitude (but not for the differential cross-section) are connected to the slow decrease of the Coulomb potential. At large
distances, the wavefunction of the Coulomb problem is not the wavefunction of a free particle. The phase of the wavefunction gets "distorted" by the factor,

$$\Delta(r) = -\frac{\alpha}{\hbar v} \ln 2kr$$

due to the cutting off the potential at the distance $r = R$. This distortion is then "inherited" by the scattering amplitude in the form of the factor $\exp\{2i\Delta(R)\}$. Factoring it out from Eq. (3), we obtain the scattering amplitude:

$$\tilde{f}(k, q) = f e^{-2i\Delta(R)} = -\frac{2m\alpha}{\hbar^2 q^2} e^{i\varphi(k,q)}$$
$$\varphi(k, q) = -\frac{2\alpha}{\hbar v} \ln \frac{q}{2k} + \frac{2\alpha}{\hbar v} \ln \frac{|\alpha|}{\hbar v} - \frac{2\alpha}{\hbar v} + \frac{\pi}{2} \frac{\alpha}{|\alpha|} \tag{4}$$

It is now independent of the cutoff radius, and coincides, as expected, with the amplitude of Coulomb scattering: [358]

$$f_{\text{Coul}} = -\frac{\alpha}{2mv^2 \sin^2(\theta/2)} \frac{\Gamma(1 + i\alpha/\hbar v)}{\Gamma(1 - i\alpha/\hbar v)} \exp\left\{-\frac{2i\alpha}{\hbar v} \ln \sin\frac{\theta}{2}\right\}$$

In the quasi-classical case, $|\alpha|/\hbar v \gg 1$ for all scattering angles, while the eikonal approximation is applicable only for angles $\theta \ll \hbar v/|\alpha|$.

GKKG.13.55

In the eikonal approximation, express the scattering amplitude in the field of two identical potentials located at a distance a from one another, i.e., in the potential $U(\mathbf{r}) = U_0(|\mathbf{r} - \mathbf{a}/2|) + U_0(|\mathbf{r} + \mathbf{a}/2|)$, in terms of the amplitude, f_0, of scattering from a single spherically-symmetric potential, $U_0(r)$. What is the connection between the total scattering cross-section in $U(\mathbf{r})$ and that in a single potential, σ_0?

Use the result obtained to calculate the total scattering cross-section for a weakly bound system of two centers (like a deuteron), when its characteristic size is much larger than the interaction radius of a single scattering center.

Solution

In the eikonal approximation, the scattering amplitude is described by the expression:

$$f\left(k, \mathbf{q}_\perp\right) = \frac{ik}{2\pi} \iint \left\{1 - \exp\left\{-\frac{im}{\hbar^2 k} \int\limits_{-\infty}^{\infty} U(\boldsymbol{\rho}, z) dz\right\}\right\} e^{-i\mathbf{q}_\perp \cdot \boldsymbol{\rho}} d^2\rho \tag{1}$$

Using the Fourier transformation, we obtain:

$$\exp\left\{-\frac{im}{\hbar^2 k}\int\limits_{-\infty}^{\infty}U(\boldsymbol{\rho},z)dz\right\}=1+\frac{i}{2\pi k}\iint f\left(k,\boldsymbol{\kappa}_\perp\right)e^{i\boldsymbol{\kappa}_\perp\cdot\boldsymbol{\rho}}d^2\kappa_\perp \tag{2}$$

Now substituting into Eq. (1) the potential

$$U(\mathbf{r})=U_1\left(\mathbf{r}-\frac{\mathbf{a}}{2}\right)+U_2\left(\mathbf{r}+\frac{\mathbf{a}}{2}\right)$$

and transforming potentials $U_{1,2}(\mathbf{r})$ according to Eq. (2), we obtain the scattering amplitude from two centers in the eikonal approximation:

$$f\left(k,\mathbf{q}_\perp\right)=f_1\left(k,\mathbf{q}_\perp\right)\exp\left\{-\frac{i}{2}\mathbf{q}_\perp\cdot\mathbf{a}_\perp\right\}+f_2\left(k,\mathbf{q}_\perp\right)\exp\left\{\frac{i}{2}\mathbf{q}_\perp\cdot\mathbf{a}_\perp\right\}+$$
$$\frac{i}{2\pi k}\int f_1\left(k,\boldsymbol{\kappa}_\perp+\frac{\mathbf{q}_\perp}{2}\right)f_2\left(k,-\boldsymbol{\kappa}_\perp+\frac{\mathbf{q}_\perp}{2}\right)\exp\left\{-i\boldsymbol{\kappa}_\perp\cdot\mathbf{a}_\perp\right\}d^2\kappa_\perp \tag{3}$$

Here, $\mathbf{a}_\perp,\boldsymbol{\kappa}_\perp$ are vectors are perpendicular to the direction of the momentum of the incident particle, $\mathbf{n}_0$; for example, $\mathbf{a}=a_\parallel\mathbf{n}_0+\mathbf{a}_\perp$.

Now, we use Eq. (3) to calculate the elastic scattering amplitude from a bound system of two centers (i.e., on some composite particle), and average the wavefunction $\psi_0(\mathbf{a})$ of the composite system, i.e., $\int d^3a\left|\psi_0(\mathbf{a})\right|^2$ (here it is assumed that the velocity of the target particle is small with respect to the velocity of the incident particle). We also emphasize that $\psi_0(\mathbf{a})$ is the wavefunction of the composite system in its center-of-mass frame (and the target as a whole remains at rest). The radius vectors of the target particles are chosen to be equal to $\pm\mathbf{a}/2$, and it is assumed that they have identical masses (as is the case for the deuteron). The integrals that appear after the averaging are expressed in terms of the form factor of the composite system, equal to

$$F(\mathbf{q})=\int\left|\psi_0(\mathbf{r})\right|^2\exp\left\{-\frac{i}{2}\mathbf{q}\cdot\mathbf{r}\right\}d^3r$$

As a result of averaging, Eq. (3) takes the form:

$$\left\langle f\left(k,\mathbf{q}_\perp\right)\right\rangle=f_1\left(k,\mathbf{q}_\perp\right)F\left(\mathbf{q}_\perp\right)+f_2\left(k,\mathbf{q}_\perp\right)F\left(-\mathbf{q}_\perp\right)+$$
$$\frac{i}{2\pi k}\int f_1\left(k,\boldsymbol{\kappa}_\perp+\frac{\mathbf{q}_\perp}{2}\right)f_2\left(k,-\boldsymbol{\kappa}_\perp+\frac{\mathbf{q}_\perp}{2}\right)F\left(2\boldsymbol{\kappa}_\perp\right)d^2\kappa_\perp \tag{4}$$

Using the optical theorem (XIII.11), the total scattering cross-section can be expressed in terms of the forward scattering amplitude for angle $\theta=0$ (i.e., $\mathbf{q}_\perp=\mathbf{0}$), so that

$$\sigma_{tot}=\sigma_1+\sigma_2+\frac{2}{k^2}\,\mathrm{Re}\int F\left(2\boldsymbol{\kappa}_\perp\right)f_1\left(k,\boldsymbol{\kappa}_\perp\right)f_2\left(k,-\boldsymbol{\kappa}_\perp\right)d^2\kappa_\perp \tag{5}$$

where $\sigma_{1,2}$ are the scattering cross-sections of free particles hitting the target. (We should emphasize that the total scattering cross-section may also include processes, where the initial composite system breaks up).

Notice that the properties of scattering from a weakly-bound system are determined by the fact that the typical momentum, where the form factor begins to noticeably decrease, is of the order of

$$q\sim\frac{1}{R}\sim\left(\frac{\mu\varepsilon_{\mathrm{bind}}}{\hbar^2}\right)^{1/2} \tag{6}$$

where R is the size of a system, $\varepsilon_{\mathrm{bind}}$ and μ are the binding energy and reduced mass of target particles, and R is assumed to be much larger than the interaction radius. Since the characteristic values of q for scattering are of the order of the inverse interaction radius, i.e., are large in comparison to (6), then in Eq. (5) the amplitudes, $f_{1,2}$, can be factored outside of the integral at the point $\boldsymbol{\kappa}_\perp=\mathbf{0}$. Next, we perform the following transformation:

$$\int F\left(2\boldsymbol{\kappa}_\perp\right)d^2\kappa_\perp=\iiint\exp\left\{-i\boldsymbol{\kappa}_\perp\cdot\boldsymbol{\rho}\right\}\left|\psi_0(\boldsymbol{\rho},z)\right|^2d^2\rho dz d^2\kappa_\perp=$$
$$=(2\pi)^2\int\limits_{-\infty}^{\infty}\left|\psi_0(\mathbf{0},z)\right|^2dz=2\pi\int\limits_0^\infty\frac{1}{r^2}\left|\psi_0(r)\right|^2 4\pi r^2dr\equiv 2\pi\left\langle\frac{1}{R^2}\right\rangle$$

We have assumed that the angular momentum of the composite system is equal to zero, so that the wavefunctiom $\psi_0(r)$ is spherically symmetric. $\left\langle R^{-2}\right\rangle$ is the mean value of the inverse distance between the target particles squared. We obtain:

$$\sigma_{tot}=\sigma_1+\sigma_2+\Delta,\quad \Delta=\frac{4\pi}{k^2}\left\langle\frac{1}{R^2}\right\rangle\mathrm{Re}\left(f_1(k,0)f_2(k,0)\right) \tag{7}$$

In particular, if $f_{1,2}(k,0)$ are purely imaginary quantities, then, using the optical theorem for the single center amplitudes, we find:

$$\Delta = -\frac{1}{4\pi}\sigma_1\sigma_2 \left\langle \frac{1}{R^2} \right\rangle \tag{8}$$

Let us note that such a case of imaginary amplitudes corresponds to scattering from impenetrable (or "black") spheres (compare to Problems 13.57 and 13.90). Also, note that the fact that the scattering cross-section from two centers is a little smaller (since $\Delta < 0$) than $\sigma_1 + \sigma_2$, can be thought of as an effect of mutual shading one sphere by the other.

GKKG.13.56

Extend the eikonal approximation to the case of an exchange interaction, $\hat{U}_{\text{ex}}\,\psi(\mathbf{r}) \equiv U(r)\psi(-\mathbf{r})$. What is the connection between the differential and total scattering cross-
sections for the exchange potential and the corresponding ordinary potential? Compare to scattering in the Born approximation, as considered in Problem 13.3.

Solution

We will generalize the derivation of the scattering amplitude in the eikonal approximation based on the quasi-classical expression, Eq. (XIII.14), for the phase shift. If we replace the summation over partial waves by integration over the impact parameters and note that in approximation (XIII.14) for the exchange potential, the phase shift is

$$\delta_{l,ex} = (-1)^l \delta_{l,com} \tag{1}$$

then it is easy to obtain the following results.
In the region of small scattering angles, $\theta \ll 1$, the scattering amplitude for the exchange interaction is described by an equation analogous to (XIII.18), but with $\cos 2\delta_l$ instead of $e^{2i\delta_l}$; i.e.,

$$f_{ex}(k,\theta) \approx \frac{k}{\theta}\iint [\cos 2\delta(\rho) - 1]\exp\{-iq\rho\}d^2\rho = \\ -ik\int_0^\infty [\cos 2\delta(\rho) - 1]J_0(k\rho\theta)\rho d\rho \tag{2}$$

with the same function, $\delta(\rho)$.
Note that the appearance of the factor $(-1)^l$ in Eq. (1) does not change the even-in- δ_l part of the scattering amplitude. For odd functions, $\propto \sin 2\delta_{l,ex}$, a strong mutual compensation of the neighboring terms in the sum over l appears, and this part of the amplitude is negligibly small.

Let us note that amplitude (2) is imaginary and coincides with the imaginary part of the scattering amplitude for the ordinary potential $U(r)$. If we take into account the optical theorem, then their total scattering cross-sections also coincide (the same for partial scattering cross-sections σ_l).

In the case of the exchange potential, the scattering amplitude has a sharp maximum in the region of angles close to π (for scattering backwards, compare to Problem 13.3). Taking into account the relation for the Legendre polynomials $P_1(z) = (-1)^l P_l(-z)$, we find:

$$f_{ex}(k,\theta) \underset{\pi-\theta}{\approx}\underset{1}{\approx} \frac{k}{2\pi}\iint \sin 2\delta(\rho)\exp\{-i\boldsymbol{\Delta}\cdot\boldsymbol{\rho}\}d^2\rho = \\ k\int_0^\infty \sin 2\delta(\rho)J_0(k\rho(\pi-\theta))\rho d\rho \tag{3}$$

where $\boldsymbol{\Delta} = \mathbf{k} + \mathbf{k}_0$. In this region of angles, the amplitude is a real function, and coincides with the real part of the scattering amplitude from the corresponding regular
potential, with the scattering angle $\theta' = \pi - \theta \ll 1$. From Eqs. (2) and (3), we recover the same fact that the total scattering cross-sections are the same for the exchange an the corresponding ordinary potential.

GKKG.13.57

Calculate the scattering amplitude and the differential and total cross-sections for small-angle scattering ($kR\theta \lesssim 1$) of fast particles ($kR \gg 1$) on a hard sphere with radius, R. Use the quasi-classical expression (XIII.13) for the phase shift.

Solution

To calculate the scattering amplitude of fast particles, we use its expansion over partial waves, Eq. $f(k,\theta) = \sum_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$, and the quasi-classical expression (XIII.13) for phase shifts. Since $U = 0$ for $r > R$, then integration by parts in Eq. (XIII.13) gives:

$$\delta_l = \left(l+\frac{1}{2}\right)\arccos\frac{l+1/2}{kR} - \sqrt{k^2R^2 - \left(l+\frac{1}{2}\right)^2}, \quad l \le L \tag{1}$$

where $L = kR - 1/2$ (here $r_0 = R$), while for the values $l > L$ we obtain (here $r_0 = (1+1/2)/k$) :

$$\delta_l = 0, \quad l > L \tag{2}$$

For $l > L$, the exact phase shift is exponentially small. This is beyond quasi-classical approximation, which yields $\delta_l = 0$. Let us also mention that, strictly speaking, we should put an additional term, $-\pi/4$, in Eq. (1). It has the same origin as the modification of the quantization rule considered in Problem 9.2 (for $l < L$ in our problem, the quasi-classical approximation is reliable up to the turning point). Let us also mention that the results obtained for δ_l need correction for values of l that are close to L, since in the vicinity of the point $r = R$, the quasi-classical approximation is not applicable, and the matching conditions require a modification. However, these conditions are not important for further calculations.

Using relations (1) and (2), it is convenient to write the scattering amplitude in the form:

$$f = f_{dif} + f_{cl}$$

where

$$f_{dif} = \frac{i}{2k}\sum_{l=0}^{L}(2l+1)P_l(\cos\theta), \quad f_{cl} = \frac{1}{2ik}\sum_{l=0}^{L}(2l+1)e^{2i\delta_l}P_l(\cos\theta)$$

This partitions the amplitude into "diffractive" and "classical" parts. We will note a few important points about this partition, since it will be important for this and the following few problems. For small scattering angles (i.e., for $\theta \ll (kR)^{-1/3} \ll 1$), we have $|f_{dif}| \gg |f_{cl}|$. The contribution of this region into the total cross-section
is πR^2. Such small-angle scattering is often referred to as diffractive, because it is similar to the diffraction of a plane-parallel light beam falling onto a non-transparent (reflecting or absorptive) screen, Fraunhofer diffraction (see also Problem 13.90). For scattering angles $\theta \gg (kR)^{-1/3}$, the diffractive amplitude f_{dif} is negligibly small. f_{cl} describes the isotropic distribution of scattered particles, $d\sigma/d\Omega \approx |f_{cl}|^2 \approx R^2/4$, so that the scattering cross-section into such angles is also πR^2 (as in classical mechanics). In the region of angles $\theta \sim (kR)^{-1/3}$, the amplitudes f_{dif} and f_{cl} are of the same order. However, the contribution of these angles to scattering is negligibly small in comparison to πR^2. Therefore, the total scattering cross-section is equal to $2\pi R^2$.

For sufficiently small scattering angles, the diffraction part of the scattering amplitude becomes dominant, and $f \approx f_{\text{dif}}$. Indeed, since the phase shifts, (1), are large, $|\delta_l| \gg 1$, and change rapidly, then in the sum for f_{cl}, a mutual compensation appears due to the oscillations of $e^{2i\delta_l}$ in different terms. Using the relation $P_l(\cos\theta) \approx J_0((l+1/2)\theta)$ for $l \gg 1, \theta \ll 1$, and replacing the summation in f_{dif} by an integration over l, we obtain ($L \approx kR$):

$$f_{dif} \approx \frac{i}{2k}\int_0^L (2l+1)J_0\left(\left(l+\frac{1}{2}\right)\theta\right)dl \approx iR\frac{J_1(kR\theta)}{\theta} \tag{4}$$

We have used the equation $\int xJ_0(x)dx = xJ_1(x)$.
Note that the diffractive part of the scattering amplitude is purely imaginary. Using the optical theorem and the relation $J_1 \approx x/2$ for $x \to 0$, we again find that the total scattering cross-section is $\sigma = 2\pi R^2$, which is two times larger than the classical cross-section (compare to Problem 13.51).

In the region of small scattering angles, the differential cross-section, $d\sigma/d\Omega = |f_{dif}|^2$, is an oscillating function of θ, and the distance between the neighboring maxima is of the order of $\Delta\theta \sim 1/kR$. Using known asymptotes of the Bessel functions, according to Eq. (4) we find:

$$\frac{d\sigma_{dif}}{d\Omega} \underset{\theta \ll 1/kR^{\frac{1}{4}}(kR)^2R^2}{\approx} \frac{d\sigma_{dif}}{d\Omega} \underset{1/kR \ll \theta \ll 1}{\approx} \frac{2R\sin^2(kR\theta - \pi/4)}{\pi k\theta^3}$$

The differential scattering cross-section has a maximum in the region $\theta \lesssim 1/kR$, and decreases fast with the increase in θ.

The total cross-section of diffraction scattering is

$$\sigma_{dif} = \int |f_{dif}|^2 \, d\Omega \approx 2\pi R^2 \int\limits_0^\infty \frac{J_1^2(kR\theta)}{\theta} d\theta = \pi R^2$$

i.e., half of the total scattering cross-section.

GKKG.13.58

The same as in the previous problem, but for not necessarily small scattering angles $\theta \gg (kR)^{-1/3}$. Compare to the result of classical mechanics.

Solution

Let us consider the classical part of the scattering amplitude,

$$f_{cl} = \frac{1}{2ik} \sum_{l=0}^{L} (2l+1) e^{2i\delta_l} P_l(\cos\theta), \quad L = kR \tag{1}$$

where δ_l is given by Eq. (1) of the previous problem.
We use a general method of calculating sums such as in Eq. (1) (which involves replacing the sum over l with an integral and using the saddle-point approximation as discussed in great detail in, e.g., the relevant chapter of the Landau and Lifshtiz theoretical physics course) and first write down the equation

$$2 \arccos \frac{l+1/2}{kR} \pm \theta = 0$$

that determines the extremum point l_0 as follows

$$l_0 + \frac{1}{2} = kR \cos\frac{\theta}{2}, \quad \delta_{l_0} = \frac{1}{2}\left(l_0 + \frac{1}{2}\right)\theta - kR \sin\frac{\theta}{2}$$

The final expression [359] for f_{cl} takes the form:

$$f_{cl} = -\frac{i}{2} R \exp\left\{-2ikR \sin\frac{\theta}{2}\right\} \tag{2}$$

Therefore,

$$\frac{d\sigma_{cl}}{d\Omega} = |f_{cl}|^2 = \frac{R^2}{4}, \quad \sigma_{cl} = \pi R^2 \tag{3}$$

which coincides with the result of classical mechanics.
In conclusion, let us refer to Fig. 13.6 for an illustration of a qualitative dependence of the scattering cross-section, $d\sigma/d\Omega$, on the angle θ for scattering of fast particles, $kR \gg 1$ (or, more precisely, for $(kR)^{1/3} \gg 1$), from an impenetrable sphere according to the results of this and the previous problems.

[359] This corresponds to a repulsive potential. The phase factor $e^{-i\pi/4}$, which appears at the transition from the summation over l to an integration, is omitted here (which, however, is not reflected in the value of the differential scattering cross-section.)

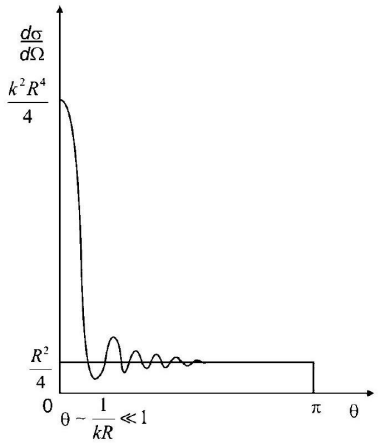

Fig. 13.6

17.4.5 Problems about scattering of particles with spin

(это усложнение, тоже это выходит за рамки минимальной подготовки и если отдельно нет исследования в этом, не вижу смысла заранее разбирать)

GKKG.13.59

The operator describing interaction of a spin-1/2 particle with an external field has the form:

$$\hat{U} = U_0(r) + U_1(r)\hat{\sigma} \cdot \hat{\mathbf{l}}$$

What is the energy dependence of the total scattering cross-section for fast particles in the Born approximation? Compare to the scattering of spinless particles.

Find the spin-dependent part of the electron scattering amplitude in the Coulomb field of a nucleus, $U_0 = -Ze^2/r$, taking into account the spin-orbital interaction, $U_1 = \left(\hbar^2/4m^2c^2r\right)\partial U_0/\partial r$

By the way, a classical analog of the spin-orbital interaction $U(r)\hat{\boldsymbol{\sigma}} \cdot \hat{\mathbf{l}}$ is considered in Problem 13.60. If for a particle with spin $s = 1/2$, we write the magnetic moment in the form $\mu_0 = e\hbar/2mc + \mu'$, where e, m are the charge and mass of a particle and μ' is the anomalous magnetic moment, then the correct quantum-mechanical generalization of the classical result from Problem 13.60 is obtained by substituting the operator $\mu_0'\hat{\sigma}$ with $\mu_0' = e\hbar/4mc + \mu'$ instead of μ. See Problem 15.32.

Solution

Eqs. (XIII.1-XIII.5) are easily generalized to describe scattering of "spinfull" particles. A substitution of the interaction operator $\hat{U}$ (instead of the potential U) and unperturbed wavefunction $\psi^+_{\mathbf{k}_0} = e^{i\mathbf{k}_0\cdot\mathbf{r}}\chi_l$ (χ_l is the spin function of the particle before collision) into Eq. (XIII.5) determines a spinor amplitude of the scattered wave, $F = \hat{f}\chi$, in the Born approximation. Therefore,

$$\begin{aligned}\hat{f}(\mathbf{k}, \mathbf{k}_0) &= -\frac{m}{2\pi\hbar^2}\int e^{-i\mathbf{k}\cdot\mathbf{r}}\left[U_0(r) + U_1(r)\hat{\mathbf{l}}\cdot\hat{\boldsymbol{\sigma}}\right]e^{i\mathbf{k}_0\cdot\mathbf{r}}dV = \\ &= -\frac{m}{2\pi\hbar^2}\left\{\tilde{U}_0(q) - i\left([\mathbf{k}_0 \times \mathbf{k}]\cdot\hat{\boldsymbol{\sigma}}\right)\cdot\frac{1}{q}\frac{\partial}{\partial q}\tilde{U}_1(q)\right\} \qquad (1)\end{aligned}$$

where $\tilde{U}_{0,1}(q) = \int U_{0,1}(r)\exp\{-i\mathbf{q}\cdot\mathbf{r}\}dV$. According to Eqs. (1) and (XIII.23), the total scattering cross-section in the Born approximation is described by the expression (compare to Problem 13.1)

$$\sigma = \frac{m^2}{4\pi\hbar^4k^2}\int\limits_0^{4k^2}\left\{\left|\tilde{U}_0(q)\right|^2 + \left(k^2 - \frac{q^2}{4}\right)\left|\frac{\partial\tilde{U}_1(q)}{\partial q}\right|^2\right\}dq^2 \qquad (2)$$

Let us note that in general, the term in the differential cross-section $\propto \boldsymbol{\nu}\cdot\mathbf{P}_0$ which describes azimuthal asymmetry in scattering (see Eq. (XII.23)) disappears from the calculation of the total scattering cross-section; the cross-section, averaging over the over spin projections, does not depend on the polarization, $\mathbf{P}_0$, of the initial state. So, for fast particles we obtain: [361]

$$\sigma(E) \approx \frac{C_0}{E} + C_1 \qquad (3)$$

where

$$C_0 = \frac{m}{8\pi\hbar^2}\int\limits_0^\infty\left|\tilde{U}_0(q)\right|^2dq^2, \quad C_1 = \frac{m^2}{4\pi\hbar^4}\int\limits_0^\infty\left|\frac{\partial\tilde{U}_1(q)}{\partial q}\right|^2dq^2$$

The terms here correspond to different interactions. For a large but finite energy, they could be of the same order. But in practice, the relativistic origin of the spin-orbit interaction for electrons, yields that the second (non-decreasing with energy) term is less important in the non-relativistic case.

For electron scattering in the Coulomb field, we obtain:

$$\hat{f} = \frac{2mZe^2}{\hbar^2q^2}\left\{1 - i\frac{\hbar^2k^2}{4m^2c^2}\sin\theta(\boldsymbol{\nu}\cdot\hat{\boldsymbol{\sigma}})\right\} \qquad (4)$$

where $\boldsymbol{\nu} = [\mathbf{k}_0 \times \mathbf{k}] / |[\mathbf{k}_0 \times \mathbf{k}]|$. Note that the spin-dependent part of the scattering amplitude is small, $\sim \theta v^2/c^2$.

We now calculate the spin-dependent amplitude in the presence of spin-orbit interaction, $U_1(r) = \frac{\gamma}{r}\frac{\partial}{\partial r}U_0(r)$. Taking into account Eq. (1), let us perform the following transformations

$$\int e^{-i\mathbf{k}\cdot\mathbf{r}} U_1 \hat{\mathbf{l}} e^{i\mathbf{k}_0\cdot\mathbf{r}} dV = \int U_1 \left[\mathbf{r} \times \mathbf{k}_0\right] e^{-i\mathbf{q}\cdot\mathbf{r}} dV = -\gamma \int e^{-i\mathbf{q}\cdot\mathbf{r}} \left[\mathbf{k}_0 \times U_0(r)\right] dV =$$
$$= -i\gamma \left[\mathbf{k}_0 \times \mathbf{q}\right] \tilde{U}_0(q)$$

So, for the considered spin-orbital interaction, the scattering amplitude in the Born approximation is described by the expression:

$$\hat{f} = -\frac{m}{2\pi\hbar^2}\tilde{U}_0(q)\left(1 - i\gamma\left[\mathbf{k}_0 \times \mathbf{k}\right]\cdot\hat{\boldsymbol{\sigma}}\right) \tag{5}$$

Thereafter, using the expression $\tilde{U}_0 = -4\pi Ze^2/q^2$ for the Fourier component of the Coulomb potential and the parameter $\gamma = \hbar^2/4m^2c^2$, we obtain Eq. (4).

GKKG.13.60

Find the Born scattering amplitude and differential cross-section of fast neutrons from the Coulomb field.

Solution

Let us first find the form of the interaction between a moving magnetic dipole and an electric field in classical electrodynamics. In the initial coordinate system, there is only an electric field $\mathcal{E} = -\boldsymbol{\nabla}\phi$ with $\varphi = Ze/r$. To find its interaction with a neutron, moving with the velocity $\mathbf{v} = \mathbf{p}/M$, we pass to the frame of reference moving with the neutron. In this system, a magnetic field $\mathcal{H} \approx [\mathcal{E} \times \mathbf{v}]/c$ appears, and the interaction energy becomes becomes equal to (with $\boldsymbol{\mu}$ being the neutron magnetic moment):

$$U = -\boldsymbol{\mu}\cdot\mathcal{H} = \frac{1}{Mcr}\frac{\partial\varphi}{\partial r}\boldsymbol{\mu}\cdot\mathbf{L}, \quad \mathbf{L} = [\mathbf{r}\times\mathbf{p}] \tag{1}$$

A quantum mechanical generalization of this equation is obtained by substitutions: of $\boldsymbol{\mu}$ by spin magnetic moment operator [362] $\hat{\boldsymbol{\mu}} = \mu_0\hat{\boldsymbol{\sigma}}$, where $\mu_0 = \beta e\hbar/2Mc$ (for the neutron, the experimental value is $\beta = -1.91$), and $\mathbf{L}$ by $\hbar\hat{\mathbf{l}}$. This generalization determines the interaction operator:

$$\hat{U} = \frac{\gamma}{r}\frac{\partial\varphi}{\partial r}\hat{\boldsymbol{\sigma}}\cdot\hat{\mathbf{l}}, \quad \gamma = \frac{\beta e\hbar^2}{2M^2c^2} \tag{2}$$

Using the equations for scattering amplitude with the spin-orbit interaction in the Born approximation, obtained in the previous problem, we find:

$$\hat{f} = i\frac{2Ze^2M\gamma}{\hbar^2q^2}\hat{\boldsymbol{\sigma}}\cdot[\mathbf{k}_0\times\mathbf{q}] = i\frac{\beta Ze^2}{2Mc^2}\cot\frac{\theta}{2}(\hat{\boldsymbol{\sigma}}\cdot\boldsymbol{\nu}) \tag{3}$$

where $\boldsymbol{\nu} = [\mathbf{k}_0 \times \mathbf{k}] / |[\mathbf{k}_0 \times \mathbf{k}]|$ is the unit vector normal to the scattering plane. The differential cross-section, summed over the neutron's spin states, is
$$

$$\frac{d\sigma}{d\Omega} = F^*F = \chi_i^*\hat{f}^+\hat{f}\chi_i = \left(\frac{\beta Ze^2}{2Mc^2}\right)^2\cot^2\frac{\theta}{2} \tag{4}$$

$$

Here, $F = \hat{f}\chi_i$ is the spinor amplitude of the scattered wave. For a small-angle scattering, $\theta \to 0$, we have $d\sigma/d\Omega \propto \theta^{-2}$, so that the total scattering cross-section becomes infinite (this divergence of the cross-section disappears if we take into account screening of the nuclear charge).

[0][361] Note that the applicability conditions of the Born approximation for the spin-orbital interaction involve a restriction on the power law decay of $U_1(r)$ at large distances, which ensures the finiteness of the total scattering cross-section. Let us emphasize that the independence of scattering cross-section from energy for $E \to \infty$ reflects its effective increase with the increase in E, since $l_{\text{eff}} \sim kR \propto \sqrt{E}$.

[0][362] See the footnote of Problem 13.59.

GKKG.13.61

What constraints does the hermiticity property of the Hamiltonian impose on the spin-orbit interaction, $\hat{U} = U_0(r) + U_1(r)\hat{\mathbf{l}} \cdot \hat{\boldsymbol{\sigma}}$, of a spin-1/2 particle with an external field.
(1) Find in the first Born approximation polarization of particles scattered by such a potential, assuming that they were unpolarized initially. (2) Show also that if the particles were, on the contrary, polarized before the collision, the latter can result only in a rotation of the polarization vector.

Solution

The hermiticity of $\hat{U} = U_0(r) + U_1(r)\hat{\mathbf{l}} \cdot \hat{\boldsymbol{\sigma}}$ demands that the functions $U_{0,1}(r)$ are real. Their Fourier components, $\tilde{U}_{0,1}(q)$ are also real, and so are the invariant functions A and B in the expression below for the Born scattering amplitude

$$\hat{f} = A(k,\theta) + iB(k,\theta)\boldsymbol{\nu} \cdot \hat{\boldsymbol{\sigma}} \tag{1}$$

(see Eqs. (1) and (5) from Problem 13.59). So, according to the general equation (XIII.24), we find that the scattered particles remain unpolarized, $\mathbf{P} = \mathbf{0}$, if they were unpolarized initially, $\mathbf{P}_0 = \mathbf{0}$.

For the scattering of polarized particles, the final polarization vector is equal to [363]

$$\mathbf{P} = \frac{\left(|A|^2 - |B|^2\right)\mathbf{P}_0 + 2|B|^2\boldsymbol{\nu}\left(\boldsymbol{\nu}\cdot\mathbf{P}_0\right) - 2\,\mathrm{Re}\,AB^*\left[\boldsymbol{\nu}\times\mathbf{P}_0\right] + 2\,\mathrm{Im}\,AB^*\cdot\boldsymbol{\nu}}{|A|^2 + |B|^2 + 2\,\mathrm{Im}\,AB^*\nu P_0}$$

Since A and B are real functions, then

$$\mathbf{P}_B = \frac{1}{A^2+B^2}\left\{\left(A^2 - B^2\right)\mathbf{P}_0 + 2B^2\boldsymbol{\nu}\left(\boldsymbol{\nu}\cdot\mathbf{P}_0\right) - 2AB\left[\boldsymbol{\nu}\times\mathbf{P}_0\right]\right\}$$

and $\mathbf{P}_B^2 = \mathbf{P}_0^2$. This corresponds to a rotation of the polarization vector around the normal to the scattering plane; here, $\boldsymbol{\nu}\cdot\mathbf{P}_B = \boldsymbol{\nu}\cdot\mathbf{P}_0$.

[363] Note that in Eq. (1), we have adopted a convention, which includes the imaginary constant, i, in front of the coefficient, B (different conventions can be found in the literature).

GKKG.13.62

Find the polarization that appears as a result of scattering of fast $\left(Ze^2/\hbar v \ll 1\right)$ (initially unpolarized) electrons in the Coulomb field of a nucleus. Find also the induced polarization for the Coulomb scattering of initially unpolarized positrons.
Hint: Spin-orbital interaction was discussed in Problem 13.59. To calculate the amplitude in second-order perturbation theory, first consider a screened Coulomb potential, $U_0(r) = -\left(Ze^2/r\right)e^{-r/R}$, and take the $R \to \infty$ in the end of the calculation (compare to Problem 13.54).

Solution

To the first order in interaction

$$\hat{U} = U_0(r) + \frac{\hbar^2}{4m^2c^2r}\frac{\partial U_0(r)}{\partial r}\hat{\boldsymbol{\sigma}}\cdot\hat{\mathbf{l}}, \quad \text{where} \quad U_0(r) = -\frac{Ze^2}{r}e^{-r/R}$$

the scattering amplitude has the form:

$$f^{(1)}(\mathbf{k},\mathbf{k}_0) = \frac{2mZe^2}{\hbar^2\left[\left(\mathbf{k}-\mathbf{k}_0\right)^2 + R^{-2}\right]}\left\{1 - i\frac{\hbar^2}{4m^2c^2}\left[\mathbf{k}_0\times\mathbf{k}\right]\cdot\hat{\boldsymbol{\sigma}}\right\} \equiv$$
$$A^{(1)} + iB^{(1)}\boldsymbol{\nu}\cdot\hat{\boldsymbol{\sigma}}. \tag{1}$$

See Eqs. (4) and (5) from Problem 13.59. Functions $A^{(1)}$ and $B^{(1)}$ are real, and so in the first order of perturbation theory there is no polarization from scattering (see Eq. (XIII.24)).
The general expression for the second-order amplitude, as in the case of spinless particles (see Problem 13.10), is

$$\hat{f}^{(2)}(\mathbf{k},\mathbf{k}_0) = \frac{1}{2\pi^2}\int \hat{f}^{(1)}(\mathbf{k},\boldsymbol{\kappa})\hat{f}^{(1)}(\boldsymbol{\kappa},\mathbf{k}_0)\frac{d^3\kappa}{\kappa^2 - k^2 - i\varepsilon} \tag{2}$$

To calculate a spin-dependent part of the scattering amplitude, $A^{(2)}$, it suffices to retain only the first-order terms in Eq. (2) (including $A^{(2)}$ into both amplitudes $f^{(1)}$ in (2) would result in the additional small relativistic factor $\sim (v/c)^2$, which is beyond the accuracy of the approximation used). Thus $A^{(2)}$ coincides with the scattering amplitude in second-order perturbation theory for the potential, $U_0(r)$. For a Yukawa potential (corresponding to the screened Coulomb interaction), it was calculated in Problem 13.12. Using Eq. (5) of this problem, we obtain (with substitution $\alpha \to -Ze^2$):

$$\operatorname{Im} A^{(2)} = \frac{4\left(Ze^2 m\right)^2}{\hbar^4 k q^2} \ln qR, \quad R \gg \frac{1}{k} \tag{3}$$

For the spin-dependent part of the amplitude, $f^{(2)}$, according to Eqs. (2) and (1) we find:

$$\hat{\boldsymbol{\sigma}} \cdot \boldsymbol{\nu} \operatorname{Im} B^{(2)} = \frac{1}{4\pi} \left(\frac{Ze^2}{\hbar c}\right)^2 \mathbf{k} \cdot \hat{\boldsymbol{\sigma}} \int \frac{[\mathbf{q} \times \boldsymbol{\kappa}] d\Omega_\kappa}{\left[(\mathbf{k}_0 - \boldsymbol{\kappa})^2 + R^{-2}\right] [(\mathbf{k} - \boldsymbol{\kappa})^2 + R^{-2}]} \tag{4}$$

Here, we should put $|\boldsymbol{\kappa}| = |\mathbf{k}| = |\mathbf{k}_0|$ for the calculation of the imaginary part (see, for example, Problem 13.11). The corresponding integral has the form:

$$\int \frac{\boldsymbol{\kappa} d\Omega_\kappa}{\left[(\mathbf{k}_0 - \boldsymbol{\kappa})^2 + R^{-2}\right] [((\mathbf{k} - \boldsymbol{\kappa})^2 + R^{-2}]} = C_1 (\mathbf{k} + \mathbf{k}_0) + C_2 \mathbf{q} \tag{5}$$

After multiplying it by $(\mathbf{k} + \mathbf{k}_0)$, we obtain

$$(\mathbf{k}_0 + \mathbf{k})^2 C_1 = \frac{1}{2} \int d\Omega_\kappa \left\{ -\frac{1}{(\mathbf{k}_0 - \boldsymbol{\kappa})^2 + R^{-2}} - \frac{1}{(\mathbf{k} - \boldsymbol{\kappa})^2 + R^{-2}} + \frac{4k^2 + 2R^{-2}}{\left[(\mathbf{k}_0 - \boldsymbol{\kappa})^2 + R^{-2}\right] [(\mathbf{k} - \boldsymbol{\kappa})^2 + R^{-2}]} \right\}$$

The first two integrals are easily calculated, and the third one could be expressed in terms of the imaginary part of the scattering amplitude for the Yukawa potential (see Problem 13.12). As a result, we obtain for $kR \gg 1$ (remember that $|\boldsymbol{\kappa}| = k$):

$$(\mathbf{k}_0 + \mathbf{k})^2 C_1 = 2\pi \left[-\frac{1}{k^2} \ln 2kR + \frac{4}{q^2} \ln qR \right]$$

Taking into account the fact that $C_2 q$ in Eq. (5) does not contribute to integral (4), and that $(\mathbf{k}_0 + \mathbf{k})^2 = 4k^2 \cos^2(\theta/2)$, we find:

$$\operatorname{Im} B^{(2)} = \frac{1}{4} \left(\frac{Ze^2}{\hbar c}\right)^2 \frac{\sin\theta}{\cos^2(\theta/2)} \left[\frac{\ln 2kR}{k} - \frac{4k \ln qR}{q^2} \right] \tag{6}$$

Now, using Eqs. (1), (3), and (6) along with Eq. (XIII.24), we obtain the electron polarization for scattering in the Coulomb field of the nucleus:

$$\mathbf{P} \approx \frac{2}{\left(A^{(1)}\right)^2} \left\{ \operatorname{Im} A^{(2)} B^{(1)} - A^{(1)} \operatorname{Im} B^{(2)} \right\} \boldsymbol{\nu} =$$
$$2 \frac{Ze^2}{\hbar c} \frac{v}{c} \frac{\sin^3(\theta/2)}{\cos(\theta/2)} \ln\left(\sin\frac{\theta}{2}\right) \boldsymbol{\nu}; \quad \boldsymbol{\nu} = \frac{[\mathbf{k}_0 \times \mathbf{k}]}{|[\mathbf{k}_0 \times \mathbf{k}]|} \tag{7}$$

We emphasize that the cut-off, introduced for regularization purposes, disappears from the final result.

For the scattering of positrons, the polarization vector has the opposite direction (the amplitude $f^{(1)}$ changes sign, while $f^{(2)}$ remains unchanged).

GKKG.13.63

The interaction of particles with spin $s = 1/2$ in an external field has the form $\hat{U} = U_0(r) + U_1(r)\hat{\mathbf{l}} \cdot \hat{\boldsymbol{\sigma}}$. Find the phase shifts $\delta_l^{\pm}$:

a) in the Born approximation;

b) in the quasi-classical approximation.

Calculate also the scattering amplitude in the eikonal approximation, from the partialwave expansion, Eq. (XIII.25).

Solution

The solution of the Schrdinger equation, corresponding to a definite value of the angular momentum squared, $l(l+1)$, the total angular momentum, $j = l \pm 1/2$, and its projection, j_z, has the form:

$$\psi_{kjlj_z} = \tilde{\psi}_{jlj_z} R_{kjl}(r), \quad E = \frac{\hbar^2 k^2}{2m}$$

Here, $\tilde{\psi}_{jlj_z}$ is the spin and angular part of the wavefunction (see Problems 5.24 and 5.25, and note that in this problem its explicit form is not important). Since

$$\hat{\boldsymbol{\sigma}} \cdot \hat{\mathbf{l}} \tilde{\psi}_{jlj_z} = \left[j(j+1) - l(l+1) - \frac{3}{4} \right] \tilde{\psi}_{jlj_z}$$

then we note that the radial Schrdinger equation for R_{kjl} has the same form as in the case of a spinless particle with the angular momentum l in the potential

$$U_1^{\pm}(r) = U_0(r) \pm \left(l + \frac{1}{2} \mp \frac{1}{2} \right) U_1(r)$$

The upper and lower signs correspond to the values $j = l \pm 1/2$. Replacing the potential $U(r)$ by $U_1^{\pm}$in Eqs. (XIII.12-XIII.14) determines the phase shifts, $\delta_l^{\pm}$, in expansions (XIII.25). Therefore the sought-after generalization of Eq. (XIII.14) has the form:

$$\delta_l^{\pm} \approx -\frac{m}{2\hbar v} \int\limits_{-\infty}^{\infty} \left\{ U_0 \left(\sqrt{\rho^2 + z^2} \right) \pm k\rho U_1 \left(\sqrt{\rho^2 + z^2} \right) \right\} dz, \quad l = \rho k \gg 1$$

Using this relation and Eq. (XIII.25), just as in the case of spinless particles, we can obtain expressions for the invariant amplitudes A and B in the eikonal approximation. It is important to remember that

$$\sin\theta P_l'(\cos\theta) \approx -\frac{\partial}{\partial\theta} J_0(l\theta) = l J_1(l\theta); \quad l \gg 1, \quad \theta \ll 1$$

The scattering amplitude operator (i.e., a matrix function in the spin space) in the eikonal approximation has the following simple form:

$$\hat{f} = \frac{ik}{2\pi} \iint \left\{ 1 - \exp\left\{ 2i\hat{\delta}\left(\mathbf{k}_0, \boldsymbol{\rho}\right) \right\} \right\} e^{-i\mathbf{q}\cdot\boldsymbol{\rho}} d^2\rho \tag{1}$$

which becomes physically more transparent if we introduce an operator for the quasiclassical phase-shift (compare to Eq. (XIII.19)):

$$\hat{\delta}\left(\mathbf{k}_0, \boldsymbol{\rho}\right) = -\frac{m}{2\hbar v} \int\limits_{-\infty}^{\infty} \left\{ U_0(\boldsymbol{\rho}, z) + U_1(\boldsymbol{\rho}, z) \left[\boldsymbol{\rho} \times \mathbf{k}_0\right] \cdot \hat{\boldsymbol{\sigma}} \right\} dz \tag{2}$$

Using the identity

$$\exp\{i\alpha\hat{\boldsymbol{\sigma}} \cdot \boldsymbol{\nu}\} = \cos\alpha + i\hat{\boldsymbol{\sigma}} \cdot \boldsymbol{\nu} \sin\alpha, \text{ where } \boldsymbol{\nu}^2 = 1$$

it is easy to obtain the eikonal expressions for amplitudes A and B in Eq. (XIII.22).

GKKG.13.64

In the case of a spin- 1/2 particle colliding with a spinless particle, find a relation between the scattering amplitude in the helicity representation (see Problem 5.20) and the invariant functions A and B in Eq. (XIII.22).

Solution

Let the plane, where the scattering occurs, be the plane (x, z), where the z axis is directed along momentum $\mathbf{p}_0$ of the particle with spin $s = 1/2$ in the center-ofinertia system before the collision. We have $\mathbf{p}_0 = (0, 0, p)$, $\mathbf{p} = (p\sin\theta, 0, p\cos\theta)$, and $\boldsymbol{\nu} = (0, 1, 0)$, so that $\hat{\boldsymbol{\sigma}} \cdot \boldsymbol{\nu} = \hat{\sigma}_y$.

Taking into account the fact that the helical states, φ_λ before the collision and χ_μ after the collision, are described by the spinors (see Problem 5.20):

$$\varphi_{1/2} = \begin{pmatrix}1\\0\end{pmatrix}, \quad \varphi_{-1/2} = \begin{pmatrix}0\\1\end{pmatrix}; \quad \chi_{1/2} = \begin{pmatrix}\cos(\theta/2)\\ \sin(\theta/2)\end{pmatrix}$$
$$\chi_{-1/2} = \begin{pmatrix}-\sin(\theta/2)\\ \cos(\theta/2)\end{pmatrix}$$

we find the helical amplitudes $f_{\lambda\mu} = \chi^*_\mu \hat{f} \varphi_\lambda$:

$$f_{1/2,1/2} = f_{-1/2,-1/2} = \cos(\theta/2)\cdot A - \sin(\theta/2)\cdot B$$
$$f_{1/2,-1/2} = f_{-1/2,1/2} = -\sin(\theta/2)\cdot A - \cos(\theta/2)\cdot B$$

GKKG.13.65

Upon the collision of two spinless particles, a reaction occurs and two particles are created, one of which has spin $s = 1$, and the other $s = 0$. The intrinsic parities of all particles are positive.

Using the vector representation (see Problem 5.26) to describe the spin states of the particle with $s = 1$, prove that the spin structure of the amplitude for the reaction considered is described by the expression:

$$\langle f|\hat{|}|i\rangle = \mathbf{a}^* \cdot [\mathbf{p}_0 \times \mathbf{p}_1]\, f(E,\theta)$$

where $\mathbf{a}$ is the spin function, and $\mathbf{p}_0$ and $\mathbf{p}_1$ are momenta before and after the collision.
Present a partial-wave expansion of $f(E,\theta)$.
Also determine the spin structure of the amplitude in the case, where the particle with spin $s = 1$ has negative intrinsic parity.

Solution

The wavefunction describing the relative motion of the colliding particles at large distances has the form:

$$e^{ikz} \approx \sum_l i^l (2l+1) P_l(\cos\theta) \frac{1}{2kr} \left\{ e^{-i(kr-\pi l/2)} - e^{i(kr-\pi l/2)} \right\}$$

The term $i^l(2l+1)P_l(\cos\theta)e^{-i(kr-\pi l/2)}/2kr$ of this sum describes the state of the colliding particles (before interaction) with angular momentum $l = 1$, parity $I_l = (-1)^l$, and zero projection of the angular momentum onto the z axis (directed along the momentum $\mathbf{p}_0 = \hbar\mathbf{k}$), i.e., $j_z = l_z = 0$. The particles appearing in this reaction channel, are described (when the separation between them, r_1, is large) by the following outgoing wave:

$$\eta_l(E) \mathbf{\Phi}_{j=l,I_l,j_z=0}(\mathbf{n}_1) \frac{1}{r_1} e^{ik_1 r_1}, \quad \mathbf{n}_1 = \frac{\mathbf{r}_1}{r_1} \tag{1}$$

$\mathbf{\Phi}_{jIj_z}(\mathbf{n})$ describes the spin-angular dependence of the escaping particles. The value of the parameter η_l is determined by the intensity of the interaction. To determine the explicit form of $\mathbf{\Phi}(\mathbf{n}_1)$, we note that the angular momentum of the final state coincides with the initial one, l. Indeed, for total angular momentum $j = l$ and spin $s = 1$, the angular momentum could only take the values $l' = l, l \pm 1$. With the parity of the states accounted for, it follows that $l' = l$ (and $l \neq 0$). Thus,

$$\mathbf{\Phi}_{lI_l0}(\mathbf{n}_1) = \sum_{m=0,\pm1} C^{l0}_{lm,1,-m} Y_{lm} Y_{lm}(\mathbf{n}_1) \boldsymbol{\chi}_{-m} \tag{2}$$

Using the explicit form of the spherical functions, Y_{lm}, the components of the vector χ_m (see Problem 3.41), and the Clebsch-Gordan coefficients,

$$Y_{l,\pm1} = \mp i^l \left[\frac{2l+1}{4\pi l(l+1)}\right]^{1/2} \sin\theta P_l'(\cos\theta) e^{\pm i\varphi}$$
$$\chi_{\pm1} = \mp\frac{i}{\sqrt{2}}(1, \pm i, 0); \quad C^{l0}_{l,\pm l,1,\mp1} = \mp(-1)^l \frac{1}{\sqrt{2}}, \quad C^{l0}_{l0,10} = 0$$

we transform Eq. (2) into the form:

$$\mathbf{\Phi}_{lI_l0} = \gamma_l \sin\theta_1 P_l'(\cos\theta_1)(-\sin\varphi_1, \cos\varphi_1, 0)$$

where

$$\gamma_l = (-i)^l \left[\frac{2l+1}{4\pi l(l+1)}\right]^{1/2}$$

Recognizing that the vector with components $\sin\theta_1(-\sin\varphi_1, \cos\varphi_1, 0)$ is equal to $[\mathbf{p}_0 \times \mathbf{p}_1]/p_0 p_1$, and performing a summation over l, we obtain an equation for the vector amplitude of the "scattered" wave, the

coefficient in front of $e^{ik_1 r_1}/r_1$ in the asymptote of the wavefunction for $r_1 \to \infty$ in the reaction channel considered:

$$\mathbf{\Phi}(\mathbf{n}_1) = f(E,\theta)\,[\mathbf{p}_0 \times \mathbf{p}_1]\,, \quad f(E,\theta) = \sum_l \tilde{\eta}_l(E) P_l'(\cos\theta) \tag{3}$$

with $\tilde{\eta}_l(E) = \eta_l(E)\gamma_l/p_0 p_1$. The differential cross-section for this reaction is summed over the spin states, $d\sigma/d\Omega = (v_1/v_B)\,|\mathbf{\Phi}|^2$, where $v_{0,1}$ are the velocities of the particles' relative motion in the initial and final states. The total reaction cross-section is

$$\sigma_r = \sum_l \sigma_{r,l}; \quad \sigma_{r,l} = \frac{v_1}{v_0}\,|\gamma_l|^{-2}\,p_0^2 p_1^2\,|\tilde{\eta}_l|^2 = \frac{v_1}{v_B}\,|\eta_l(E)|^2$$

From the unitarity condition of the S-matrix, a constraint on the partial reaction cross-section follows: $\sigma_{r,l} \le (2l+1)\pi/k_0^2$.

The reaction amplitude for the creation of the particle with $s = 1$ in a specific spin state, described by the polarization vector $\mathbf{a}$, is determined by the expression:

$$\langle f|\hat{f}|i\rangle = (\mathbf{a}^* \cdot \mathbf{\Phi}) = f(E,\theta)\,(\mathbf{a}^* \cdot [\mathbf{p}_0 \times \mathbf{p}_1]) \tag{4}$$

This was evident before (and does not really require the preceding calculation) from the fact that the reaction amplitude is a scalar quantity. Indeed, it is the only possible scalar combination which could be formed from the vectors $\mathbf{p}_0, \mathbf{p}_1$, and $\mathbf{a}$ (due to the superposition principle, the polarization vector must enter linearly). We should take into account that $\mathbf{a}$ is an axial vector (or pseudo-vector), since under inversion, $\hat{I}\mathbf{a} = +\mathbf{a}$, due to the positive intrinsic parity of the particle with $s = 1$. Let us also note that according to Eq. (4), the particle with $s = 1$, that is created in the reaction considered, becomes linearly polarized in the direction perpendicular to the reaction plane (the spin projection on this direction has a definite value, equal to zero).

In the case of a reaction when the particle with spin $s = 1$ has negative intrinsic parity, its polarization vector, $\mathbf{v}$, is a polar vector (since under inversion $\hat{I}\mathbf{v} = -\mathbf{v}$). So now, from the condition that the transition amplitude is a scalar, it follows that its spin structure has the form: [364]

$$\langle f|\hat{f}|i\rangle = \mathbf{v}^* \cdot \{f_1(E,\theta)\mathbf{p}_0 + f_2(E,\theta)\mathbf{p}_1\} \tag{5}$$

The appearance of the two invariant amplitudes, $f_{1,2}$, is connected with the fact that for a given angular momentum, l, of the colliding particles, the angular momentum of the particles in the final state could take two values: $l' = l \pm 1$.

GKKG.13.66

A spinless particle is scattered from a system of identical spin- 1/2 scattering centers, distributed about the space. Interaction with a single center is described by the expression $\hat{U} = U_0(r) + U_1(r)\hat{\mathbf{l}} \cdot \hat{\boldsymbol{\sigma}}$. Analyze the amplitude and differential scattering cross-section in the Born approximation in the case of non-polarized centers ($\mathbf{P}_n = \mathbf{0}$). Compare to the scattering from the same system of spinless particles.

Solution

In the Born approximation, the scattering amplitude is described by the following expression (compare to Problems 13.7 and 13.8)

$$\hat{f} = \sum_n \{A_n(q) + iB_0(q)\hat{\boldsymbol{\sigma}}_n \cdot \boldsymbol{\nu}\} \exp\{-i\mathbf{q} \cdot \mathbf{a}_n\} \tag{1}$$

Here, $\mathbf{a}_n$ is the radius vector of the nth center, and the real functions $A_0(q)$ and $B_0(q)$ were defined in Problem 13.59.

The differential scattering cross-section, averaged over the initial spin states of the scattering centers and summed over their final spin states, has the form:

$$\left\langle \frac{d\sigma}{d\Omega} \right\rangle = A_0^2(q)\left|\sum_n e^{-i\mathbf{q}\cdot\mathbf{a}_n}\right|^2 + 2A_0(q)B_0(q)\sum_{k\ne n}\mathbf{P}_n \cdot \boldsymbol{\nu}\sin[\mathbf{q}\cdot(\mathbf{a}_n - \mathbf{a}_k)] + NB_0^2(q) + B_0^2(q)\sum_{k\ne n}\overline{(\boldsymbol{\sigma}_n \cdot \boldsymbol{\nu})(\boldsymbol{\sigma}_k \cdot \boldsymbol{\nu})}\cos[\mathbf{q}\cdot(\mathbf{a}_n - \mathbf{a}_k)] \tag{2}$$

where the line means averaging over the initial spin states of the centers. If there is no correlation between the states of single centers, then

$$\overline{(\boldsymbol{\sigma}_n \cdot \boldsymbol{\nu})(\boldsymbol{\sigma}_k \cdot \boldsymbol{\nu})} = (\mathbf{P}_n \cdot \boldsymbol{\nu})(\mathbf{P}_k \cdot \boldsymbol{\nu}), \quad n \ne k$$

[364] Here, as well as in the previous problem, it is important that all other spinless particles that take part in the reaction have positive intrinsic parity (or, more precisely, their product must be positive; in the opposite case, then Eqs. (4) and (5) must be exchanged with one another).

In the case of unpolarized centers, $\mathbf{P}_n = \mathbf{0}$, only the first and third terms in Eq. (2) are different from zero. The first of them is determined by the spin-independent part of the interaction, $U_0(r)$, and has the same form as for the scattering from spinless centers (compare to Problem 13.8). The term $NB_0^2(q)$ is determined by the spin-orbital interaction. Its notable property, is its proportionality to the number of scattering centers, which is due to the lack of coherence between them. This term corresponds to scattering involving a spin-flip (so that we can indicate which particular scattering center was involved in the scattering; therefore, there is no interference).

GKKG.13.67

How to generalize the optical theorem to describe scattering of quantum particles with non-zero spin?

Solution

From the unitarity of the S-matrix, the optical theorem is

$$\mathrm{Im}\langle \mathbf{p}, \alpha | \hat{f} | \mathbf{p}, \alpha \rangle = \frac{k}{4\pi} \sigma_{tot}(\mathbf{p}, \alpha)$$

where $\mathbf{p} = \hbar\mathbf{k}$ is the relative momentum of the colliding particles, and α characterizes their spin state. On the left-hand side of the equation is the imaginary part of the elastic forward scattering amplitude, $\theta = 0$, without change of the particle spin state. On the right-hand side is the total scattering cross-section (including inelastic collisions) for the same spin state.

17.4.6 Problems about analytic properties of the scattering amplitude

(Этот раздел интересен тем, кто хочет общее развитие в теории получить, тем кто хочет применять теорию он очень малополезен.)

GKKG.13.68

Analyze the analytical properties and dispersion relation for the scattering amplitude on a zero-range potential (see Problem 13.20). Consider separately the cases with and without a bound state in the potential. Compare to Eq. (XIII.27).

Solution

The scattering amplitude for a zero-range potential is (see Problem 13.20)

$$f(E) = \frac{1}{-1/a_0 - (i/\hbar)\sqrt{2mE}} \tag{1}$$

As an analytical function of the complex variable E, it has branch points at $E = 0$ and $E = \infty$ and a pole at the point E_0, for which $\sqrt{E_0} = i\hbar a_0/\sqrt{2m}$. Making the branch cut along the real semiaxis, as usual (see Fig. 13.7), and choosing the phase on the upper side of the cut to be equal to $\varphi = 0$, we see that for $a_0 > 0$, pole E_0 is located on the physical sheet and corresponds to a bound state in the zero-range potential (compare to Problem 2.30). When $a_0 < 0$, the pole is located on the unphysical Riemann sheet and corresponds to a virtual level.

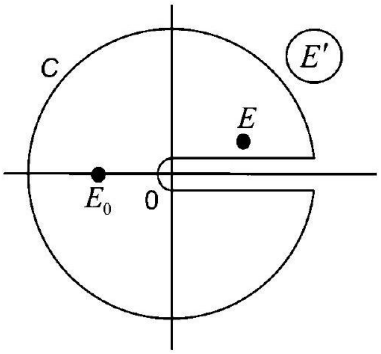

Fig. 13.7

Let us consider the integral over the contour C in Fig. 13.7:

$$\frac{1}{2\pi i}\int\limits_C \frac{f\left(E'\right)dE'}{\left(E'-E\right)} \tag{2}$$

Using Cauchy's theorem, and sending the contour circle radius to infinity, $R_E \to \infty$, in the case of $a_0 > 0$ we obtain:

$$f(E) = -\frac{\hbar^2}{ma_0\left(E-E_0\right)} + \frac{1}{\pi}\int\limits_0^\infty \frac{\operatorname{Im} f\left(E'\right)dE'}{E'-E} \tag{3}$$

We have used the fact that the value of the amplitude jump on the cut (for $E' > 0$) coincides with $2i \operatorname{Im} f\left(E'\right)$ (on the lower side of the cut, $\sqrt{E} = -\sqrt{|E|}$), and that the value of the integral is determined by the contribution of two poles: E and E_0.

In the case $a_0 < 0$, pole E_0 is on the unphysical sheet. It does not contribute to the value of integral (2), and the dispersion relation has a form analogous to (3), but without the pole term.

The dispersion relation in the case of a zero-range potential can be found by direct calculation. Substituting the imaginary part of the scattering amplitude (1), equal to

$$\operatorname{Im} f(E) = \sqrt{\frac{\hbar^2 E}{2m}}\frac{1}{|E_0|+E}, \quad E > 0$$

into the integral in Eq. (3) and integrating, we obtain:

$$\tilde{f}(E) = \frac{1}{\pi}\sqrt{\frac{\hbar^2}{2m}}\int\limits_0^\infty \frac{\sqrt{E'}dE'}{\left(E'-E\right)\left(|E_0|+E'\right)} = \frac{\hbar}{\sqrt{2m}}\frac{1}{\sqrt{|E_0|}-i\sqrt{E}}$$

In the case $a_0 < 0$ (without a bound state), this coincides with the scattering amplitude, Eq. (1). In the case $a_0 > 0$, we obtain the scattering amplitude after adding, according to Eq. (3), the pole term.

The dispersion relations found differ from Eq. (XIII.27) by the absence of the term $f_B \propto \int UdV$. This has a simple explanation. A zero-range potential can be obtained from a potential of finite radius, R, by passage to the limit $R \to 0$ for which $U_0R^2 = \text{const}$, so that we would have $f_B \propto U_0R^3 \to 0$. In a finite-range potential, the scattering amplitude in the limit $E \to \infty$ coincides with the Born one. In order to have a condition as in Eq. (2), we subtract f_B from f on a circle of the finite radius (for a zero-range potential, the scattering amplitude goes to zero for $E \to \infty$).

In conclusion, we note that the residue at the point $E = E_0$ in Eq. (3) is equal to $-\hbar^2/ma_0 = -\hbar^2A^2/2m$. The coefficient $A = \sqrt{2/a_0} = \sqrt{2\kappa_0}$ coincides with the normalization coefficient in the wavefunction,

$$\psi_0 = A\frac{\exp\left\{-\kappa_0 r\right\}}{\sqrt{4\pi}r}$$

of the bound state in the zero-range potential (see Problem 4.10), in accordance with Eqs. (XIII.27) and (XIII.28).

GKKG.13.69

Using the dispersion relation, prove that there is the following restriction on the energy-dependence of the particle-scattering cross-section in a repulsive potential, $U(r) \geq 0$:

$$\int\limits_0^\infty \frac{\sigma(E)}{\sqrt{E}}dE < 4\pi^2\frac{\sqrt{2m}}{\hbar}\int\limits_0^\infty r^2U(r)dr$$

Solution

Since according to the optical theorem, $\operatorname{Im} f(E,0) = k\sigma(E)/4\pi$, then from the dispersion relation, Eq. (XIII.27), for energy $E = 0$, it follows that

$$f(E=0) = -\frac{m}{2\pi\hbar^2}\int U(r)dV + \frac{\sqrt{2m}}{4\pi^2\hbar}\int\limits_0^\infty \frac{\sigma(E)dE}{\sqrt{E}} \tag{1}$$

Here we have also used the fact that in the repulsive potential $U(r) \geq 0$, there are no bound states. Due to the fact that in such a potential we have $f(E=0) < 0$ (see Problems 13.16 and 13.31), we immediately obtain the inequality given in the problem condition.

Let us note that in the case of a "weak" potential, $U_0 \ll \hbar^2/mR^2$, the inequality considered becomes obvious (since $f \propto U_0$, while $\sigma \propto U_0^2$) and is well-fulfilled. But for
a "strong" repulsive potential, [365] $U_0 \gg \hbar^2/mR^2, |f_B| \gg |f(E=0)|$, and the terms of the inequality are approximately the same:

$$\int_0^\infty \frac{\sigma(E)}{\sqrt{E}} dE \approx 4\pi^2 \frac{\sqrt{2m}}{\hbar} \int_0^\infty U(r) r^2 dr \tag{2}$$

In conclusion, we note that from relation (1), obtained in Problem 13.16 by another method, it follows that in a repulsive potential the Born approximation for $E = 0$ greatly overestimates the scattering cross-section.

GKKG.13.70

Prove the relation

$$\int_0^\infty \frac{\sigma(E)}{\sqrt{E}} dE < \pi \sqrt{\frac{2\pi\hbar^2}{m}\sigma(0)}$$

for the scattering in an attractive potential, $U(r) \leq 0$, where there are no bound states (the well is not deep enough). Here $\sigma(0) = 4\pi a_0^2$ is the scattering cross-section for $E = 0$. In what case both sides of the inequality are close?

Solution

Because there are no bound states in the attractive potential, relation (1) from the previous problem is still valid. Now, however, all three terms in it are positive. So in particular, the result from Problem 13.16 follows for the attractive potential. Then the inequality from the problem condition in the case of a "weak" potential must be conservatively valid (compare to the previous problem). When this potential approaches the "critical" one, where a bound state appears, we obtain $f(E = 0) \to \infty$, so that $f(E = 0) \gg f_B$. The values of both inequality parts are close to one another, so that

$$\int_0^\infty \frac{\sigma(E)}{\sqrt{E}} dE \approx \pi \sqrt{\frac{2\pi\hbar^2}{m}\sigma(0)} \tag{1}$$

However, this relation in the case of a "shallow" (real or virtual) s-level in the potential is evident. According to Eq. (XIII.16) in the region of small energies, the scattering cross-section is anomalously large.

$$\sigma(E) \approx \frac{2\pi\hbar^2}{m\,(E + \varepsilon_0)}, \quad \varepsilon_0 \ll \frac{\hbar^2}{mR^2}$$

[365] As an example, for a square potential barrier of radius R, for $U_0 \to \infty$, we also have $|f_B| \to \infty$, but $f(E = 0) = -R = \text{const}$.
This region has the dominant contribution to the value of the integral; by calculating it, we prove relation (1).

GKKG.13.71

Using only the condition of unitary and the dispersion relation (for $q^2 \neq 0$), it is possible to reconstruct [366] the scattering potential in a series over powers of the interaction potential, by the known expression for scattering amplitude in the Born approximation.

As an example, prove that the calculation of the second-order perturbative amplitude for $q^2 = 0$ reproduces the result of perturbation theory over the potential, based on the Schrdinger equation (see Problem 13.10).

Solution

The iteration procedure for the calculation of scattering amplitude $f = \sum_n f^{(n)}$ is the following. First, by the known amplitude of first approximation, $f^{(1)} = f_B$, we can use the unitarity condition, Eq. (XIII.26), to find the imaginary part of the second, order amplitude, [367] $\operatorname{Im} f^{(2)}\left(E, q^2\right)$. Then, using the dispersion relation for $q^2 \neq 0$ (analogous to Eq. (XIII.27)), we can find the entire amplitude, $f^{(2)}$. Higher-order approximation terms are calculated in the same way.

In particular, for the value $q^2 = 0$ we easily find

$$f^{(2)}\left(E, q^2=0\right)=\frac{1}{4\pi}\int\limits_0^\infty \frac{dE'}{\sqrt{E'}\,(E'-E)}\int\limits_0^{4E'} f_B^2(x)dx \tag{1}$$

The imaginary part of the scattering amplitude with the help of the optical theorem is expressed in terms of the scattering cross-section in the Born approximation. For simplicity, we use the system of units $\hbar = 2m = 1$. With this, $E = k^2$. The Born amplitude, f_B, is written in the form $f_B\left(q^2\right)$.

On the other hand, in the 2nd order of perturbation theory according to the result from Problem 13.10, we have:

$$f^{(2)}\left(E, q^2=0\right)=\frac{1}{2\pi^2}\int \frac{f_B^2\left(\left(k_0-\kappa\right)^2\right)}{\kappa^2-E}d^3\kappa = \frac{1}{2\pi}\int\limits_0^\infty \frac{\kappa d\kappa}{\sqrt{E}\,(\kappa^2-E)}\int\limits_{(\kappa-\sqrt{E})^2}^{(\kappa+\sqrt{E})^2} f_B^2(x)dx \tag{2}$$

[366] Let us emphasize that the Schrdinger equation is not used here.

[367] Here, in principle, the relation obtained gives the imaginary part of the amplitude also for the unphysical values of energy $0 < E < \hbar^2 q^2/8m$.

To prove that Eqs. (1) and (2) are actually the same, we make the following transformations (note that their equivalence becomes obvious in the $E \to 0$ limit, if we integrate Eq. (1) by parts): First, we divide the "internal" integral in Eq. (2) into two, with the point $x = 0$ as one of the integration limits. Then, in the first of two terms that appear as a result, use the substitution $2\kappa' = \kappa + \sqrt{E}$, while in the second, use $2\kappa' = \kappa + \sqrt{E}$. In the resulting integrals over κ', again divide the integration domains into two: from 0 to ∞ and from 0 to $\pm\sqrt{E}/2$. The contributions of the latter integration domains cancel each other out, while the sum of the contributions of the former reproduces (after the substitution, $E' = (\kappa')^2$) Eq. (1).

GKKG.13.72 Upper bound for the amplitude

Consider the interaction for partial waves with $l \geq L_0 \equiv kR \gg 1$ to be negligibly small, and obtain the upper bound for the scattering amplitude of spinless particles at high energies for different scattering angles.

Solution

In the scattering amplitude expansion over partial waves, Eq. $f(k,\theta) = \sum\limits_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$, we have the inequality $|\varphi_l| \leq 1/k$, so that in accordance with the problem condition we obtain:

$$|f(k,\theta)| \leq \frac{1}{k}\sum_{l=0}^{L_0}(2l+1)\,|P_l(\cos\theta)| \tag{1}$$

Replacing the summation by integration, for angles $\theta = 0$ and $\theta = \pi$ we find:

$$|f| \leq \frac{L_0^2}{k} = kR^2, \quad \theta = 0;\pi \tag{2}$$

For scattering angles, $\theta \neq 0, \pi$, we have:

$$|P_l(\cos\theta)| \leq \left(\frac{2}{\pi l \sin\theta}\right)^{1/2}$$

and so we obtain:

$$|f(\theta)| \leq \frac{4}{3}\left(\frac{2}{\pi\sin\theta}\right)^{1/2} R(kR)^{1/2} \tag{3}$$

Note that due to the Legendre polynomials oscillation for $\theta \neq 0$, such a restriction for arbitrary scattering angle is too weak and conservatively valid. Indeed, the restriction

[368] In Problems 13.72-13.75, general constraints on the interaction amplitudes and cross-sections for large energies are discussed. These restrictions are connected, basically, with the possibility of neglecting interaction at distances that are larger than the radius of the potential, R. This situation occurs frequently in elementary particle physics. Here, the effective interaction radius increases with energy, but not faster than $\propto \ln(E/E_0)$ (see Problem 13.53). The necessity of using relativistic kinematics is practically not reflected in the results. on the value of total elastic scattering cross-section which follows from inequality (3), $\sigma_{el} = \int |f|^2 d\Omega \leq CR^2 kR$, is uninteresting, since $\sigma_{el} \leq \sigma_{tot} \leq 4\pi R^2$ and $kR \gg 1$.

GKKG.13.73 lower bound on the cross-section

Under the conditions of the previous problem, obtain the lower bound on the value of the elastic scattering cross-section, σ_{el}, of fast particles for a given value, σ_{tot}, of the total collision cross-section.

Solution

From the expressions for partial cross-sections (total and elastic cross-sections),

$$\sigma_{\text{tot}}^{(l)} = 2\pi(2l+1)\frac{1}{k^2}\left(1 - \operatorname{Re} S_l\right)$$
$$\sigma_{el}^{(l)} = \pi(2l+1)\frac{1}{k^2}\left|1 - S_l\right|^2 = \pi(2l+1)\frac{1}{k^2}\left(1 - 2\operatorname{Re} S_l + |S_l|^2\right)$$

it follows that for a given value of $\sigma_{\text{tot}}^{(l)}$, the quantity $\sigma_{el}^{(l)}$ is minimal for $\operatorname{Im} S_1 = 0$. Thus,

$$\sigma_{el} = \sum_l \sigma_{el}^{(l)} \geq \tilde{\sigma}_{el} = \frac{\pi}{k^2}\sum_{l=0}^{L_0}(2l+1)\left(1-\alpha_l\right)^2$$

where $\alpha = \operatorname{Re} S_l$. To find the minimum value of $\tilde{\sigma}_{el}$ as a function of variables α_l for the given $\sigma_{tot} = \sum\limits_l \sigma_{tot}^{(l)}$, we use Lagrange's method of undetermined multipliers and introduce $A(\alpha_l) = \tilde{\sigma}_{el} - \lambda\sigma_{tot}$. From the extremality conditions (now all variables α_l could be varied independently) for $A(\alpha_l)$, we find that $\alpha_l = \text{const} = \alpha$ (no dependence on l). Replacing summation over l by integration and excluding α from the expressions for σ_{el} and σ_{tot}, we obtain the inequality

$$\sigma_{el} \geq \min \tilde{\sigma}_{el} = \frac{1}{4\pi R^2}\sigma_{tot}^2 \tag{1}$$

As mentioned in Problem 13.53, in the theory of strong elementary particle interactions there is a restriction on the possible growth of the interaction radius R with increase in energy:

$$R \leq R_0 \ln\frac{E}{E_0} \text{ for } E \to \infty \tag{2}$$

From this, inequality (1) takes the form:

$$\sigma_{el}(E) \geq C\frac{\sigma_{tot}^2(E)}{\ln^2(E/E_0)} \tag{3}$$

GKKG.13.74 Upper bound for Re(f)

For large energies, find the upper bound for the real part of the amplitude for elastic forward scattering, $\theta = 0$, assuming that the total collision cross-section is known and that particle interaction is negligibly small for distances above R. What is the restriction for $|f(E, \theta = 0)|$?

Solution

Denoting $S_l = |S_l|\, e^{2i\delta_l}$ for the partial amplitudes in Eq. $f(k,\theta) = \sum\limits_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$, we have the following expressions:

$$\operatorname{Im}\varphi_l = \frac{1}{2k}\left(1 - |S_l|\cos 2\delta_l\right), \quad \operatorname{Re}\varphi_l = \frac{1}{2k}|S_l|\sin 2\delta_l$$

For this value of $\operatorname{Im}\varphi_l$, the value of $|\operatorname{Re}\varphi_l|$ is maximum when $|S_l| = 1$. In this case, inelastic scattering is absent and $\sigma_{tot} = \sigma_{el}$. So, writing $\operatorname{Im}\varphi_l = (1-\alpha_l)/2k$, we obtain

$$|\operatorname{Re} f(E,0)| \le \sum_l (2l+1)\,|\operatorname{Re}\varphi_l| \le \frac{1}{2k}\sum_{l=0}^{L_0}(2l+1)\sqrt{1-\alpha_l^2}$$

Using the method from the previous problem, we obtain the following restriction on the real part of the elastic forward scattering amplitude for the total scattering cross-section:

$$|\operatorname{Re} f(E,0)| \le \frac{1}{2\sqrt{\pi}}\sqrt{\sigma_{tot}}kR\left(1-\frac{\sigma_{tot}}{4\pi R^2}\right)^{1/2} \le \frac{1}{2\sqrt{\pi}}\sqrt{\sigma_{tot}}kR \tag{1}$$

So, taking into account the fact that $\sigma_{tot} \le 4\pi R^2$ and the restriction on interaction radius growth with increase in energy (see the previous problem), we obtain

$$|f(E,0)| \le Ck\sqrt{\sigma_{tot}(E)}\ln\frac{E}{E_0} \tag{2}$$

Here, we used the optical theorem.
As mentioned before, restriction (1) suggests the absence of inelastic processes. Analogously (using Lagrange's method of undetermined multipliers), we can obtain a less strict restriction on the scattering amplitude for given values of both total, σ_{tot}, and inelastic, σ_{inel} , collision cross-section.

GKKG.13.75

Prove that for large energies, the derivative with respect to θ at $\theta = 0$ of the imaginary part of the elastic scattering amplitude satisfies the following inequalities:

$$\frac{\sigma_{tot}}{32\pi} \le -\frac{d}{dq^2}\ln \operatorname{Im} f(E,q)\bigg|_{q=0} \le \frac{R^2}{4}, \quad q = 2k\sin\left(\frac{\theta}{2}\right)$$

where σ_{tot} is the total collision cross-section and R is the interaction radius. (At distances larger than R, the interaction is negligibly small.)
Verify explicitly that these inequalities are indeed satisfied by the diffraction scattering amplitude from Problem 13.57.

Solution

Since for the Legendre polynomial, $P_l'(1) = l(l+1)/2$, then using the scattering amplitude expansion over partial waves, Eq. $f(k,\theta) = \sum_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$, for high energies we obtain

$$\frac{d}{d\cos\theta}\operatorname{Im} f(E,\theta)\bigg|_{\theta=0} \approx \sum_l l^3 \operatorname{Im}\varphi_l \tag{1}$$

Using the fact that $\operatorname{Im}\varphi_l \le 1/k$, we see that for a given total scattering cross-section, and so the imaginary part of the scattering amplitude, $\operatorname{Im} f(E,0)$ (due to the optical theorem), the sum (1) takes the minimum value when

$$\operatorname{Im}\varphi_l = \begin{cases} \frac{1}{k}, l \le L_1 \\ 0, l > L_1 \end{cases} \tag{2}$$

The value of L_1 is determined by the total cross-section:

$$\sigma_{tot} = \frac{4\pi}{k}\sum_l (2l+1)\operatorname{Im}\varphi_l \approx \frac{8\pi}{k^2}\sum_{l=0}^{L_1} l$$

Replacing summation over l by integration, we obtain $L_1^2 = k^2\sigma_{tot}/4\pi$ and the following restriction:

$$-\frac{d}{dq^2}\operatorname{Im} f\left(E,q^2\right)\bigg|_{q^2=0} \ge \frac{1}{128\pi^2}k\sigma_{tot}^2(E) \tag{3}$$

We emphasize that relations (2) correspond to the "saturation" of the total scattering cross-section by the lower partial waves. Here $\sigma_{tot} = \sigma_{el}$ (there are no inelastic processes), and moreover, for $l \le L_1$ all of the phases are $\delta_l = \pi/2$, so that restriction (3) must be fulfilled conservatively.
In the same way, we note that the sum in (1) takes the maximum value in the case when total scattering cross-section is saturated by the higher partial waves and

$$\operatorname{Im}\varphi_l = \begin{cases} 0, l < L_2 \\ \frac{1}{k}, L_2 \le l \le L_0 = kR \end{cases}$$

We obtain the following restriction (now from above):

$$-\left.\frac{d}{dq^2}\operatorname{Im} f\left(E,q^2\right)\right|_{q^2=0} \leq \frac{kR^2\sigma_{tot}}{16\pi}\left(1-\frac{\sigma_{tot}}{8\pi R^2}\right) \leq \frac{kR^2\sigma_{tot}}{16\pi} \tag{4}$$

As an example, consider an impenetrable sphere of the radius R (see Problems 13.57 and 13.90). The diffraction scattering amplitude is

$$f_{difr} = i\frac{kR}{q}J_1(qR)$$

The restrictions of the problem condition, which are the direct result of relations (3) and (4), take the form of the following inequality (after cancelling out the factor $R^2/4$): $1/3 < 1/2 < 1$.

In conclusion, we should emphasize that, as mentioned above, restrictions on (3) and (4) assume the absence of inelastic processes. Using the method of Lagrange multipliers, just as in Problem 13.73, we can obtain weaker restrictions when the values of both total and inelastic collision cross-sections are given independently.

GKKG.13.76

Prove unitarity of the scattering amplitude in the eikonal approximation.

Solution

The eikonal approximation assumes that only small scattering angles are important. For these angles, the right-hand part of relation (XIII.26) with the eikonal expression for the amplitude, Eq. (XIII.18), taken into account could be transformed to the form:

$$\frac{ik}{2\pi}\iint \left[S^*(\boldsymbol{\rho})-1\right]\left[S(\boldsymbol{\rho})-1\right]\exp\left\{-i\mathbf{q}_\perp\cdot\boldsymbol{\rho}\right\}d^2\rho \tag{1}$$

To perform the integration over angles which leads to Eq. (1), we use the relations:

$$\mathbf{k}-\mathbf{k}_0 \approx \mathbf{q}_\perp, \quad \mathbf{k}'-\mathbf{k}_0 \approx \mathbf{q}'_\perp, \quad \mathbf{k}'-\mathbf{k} \approx \mathbf{q}'_\perp-\mathbf{q}_\perp, \quad d\Omega' \approx \frac{1}{k^2}d^2q'_\perp$$

Although $q_\perp, q'_\perp \ll k$, due to the fast decrease of the integrand, we can integrate over $q_\perp$ in infinite limits. Using Eq. (XIII.19) for $S(\rho)$, we find the relation:

$$\left[S^*(\boldsymbol{\rho})-1\right]\left[S(\boldsymbol{\rho})-1\right] = \left[1-S(\boldsymbol{\rho})\right]-\left[S^*(\boldsymbol{\rho})-1\right]$$

So now Eq. (1) takes the form $f\left(\mathbf{k},\mathbf{k}_0\right)-f^*\left(\mathbf{k}_0,\mathbf{k}\right)$, which proves the unitarity of the scattering amplitude in the eikonal approximation. In particular, according to the optical theorem, the expression for the scattering cross-section of fast particles, discussed in Problem 13.51, follows.

17.4.7 Problems about scattering on composite particles, inelastic collisions

(тут какая-то очень профессиональная теория, можно не изучать это заранее, потому что это однозначно выходит за рамки минимальной подготовки)

ПТФ-13.з3. Рассеяние на двухатомной молекуле

Смоделируем двухатомную полярную молекулу потенциалом вида $V(\mathbf{r}) = V_0(\mathbf{r}+\frac{\mathbf{R}}{2}) + V_0(\mathbf{r}-\frac{\mathbf{R}}{2})$ (вектор $\mathbf{R}$ соединяет два атома, а $V_0(\mathbf{r})$ представляет собой потенциал рассеяния на отдельном атоме). В рамках Борновского приближения, свяжите дифференциальное сечение рассеяния на такой молекуле с сечением на отдельном атоме. Считая различные ориентации молекулы равновероятными, усредните по ним результат. Как связаны полные сечения рассеяния для случая медленных ($kR \ll 1$) и достаточно быстрых ($ka \sim 1$, но $R \gg a$, где a – характерный масштаб потенциала $V_0(r)$) частиц?

Solution.

$$f(\mathbf{n},\mathbf{n}') = -\frac{m}{2\pi\hbar}\tilde{V}_{\mathbf{k}-\mathbf{k}'} = -\frac{m}{2\pi}\int d^3\mathbf{r}V(\mathbf{r})e^{-i(\mathbf{k}-\mathbf{k}')\mathbf{r}} =$$
$$= -\frac{m}{2\pi}\int d^3\mathbf{r}\left(V_0\left(\mathbf{r}+\frac{\mathbf{R}}{2}\right)+V_0\left(\mathbf{r}-\frac{\mathbf{R}}{2}\right)\right)e^{-i(\mathbf{k}-\mathbf{k}')\mathbf{r}} =$$
$$= -\frac{m}{2\pi}\int d^3\mathbf{r}\left(V_0(\mathbf{r})e^{i(\mathbf{k}-\mathbf{k}')\frac{\mathbf{R}}{2}}+V_0(\mathbf{r})e^{-i(\mathbf{k}-\mathbf{k}')\frac{\mathbf{R}}{2}}\right)e^{-i(\mathbf{k}-\mathbf{k}')\mathbf{r}} =$$
$$= 2f_0(\mathbf{n},\mathbf{n}')\cos\left(\frac{(\mathbf{k}-\mathbf{k}')\mathbf{R}}{2}\right)$$

$f_0(\mathbf{n},\mathbf{n}') := -\frac{m}{2\pi}\tilde{V}_{0\mathbf{k}-\mathbf{k}'} = -\frac{m}{2\pi}\int d^3\mathbf{r}V_0(\mathbf{r})e^{-i(\mathbf{k}-\mathbf{k}')\mathbf{r}}$.

$$d\sigma = |f(\mathbf{n},\mathbf{n}')|^2 d\Omega_{\mathbf{n}'}, \qquad d\sigma_0 = |f_0(\mathbf{n},\mathbf{n}')|^2 d\Omega_{\mathbf{n}'}$$

$$d\sigma = 4\cos^2\left(\frac{(\mathbf{k}-\mathbf{k}')\mathbf{R}}{2}\right)d\sigma_0$$

Усредним величину $\frac{d\sigma}{d\sigma_0}$ по различным ориентациям молекулы.

$$\left\langle\frac{d\sigma}{d\sigma_0}\right\rangle = \frac{1}{4\pi}\int 4\cos^2\left(\frac{(\mathbf{k}-\mathbf{k}')\mathbf{R}}{2}\right)d\Omega = \frac{4\cdot 2\pi}{4\pi}\int\limits_0^\pi \cos^2\left(\frac{|\mathbf{k}-\mathbf{k}'|R\cos\theta}{2}\right)\sin\theta d\theta =$$
$$= \left\langle\frac{d\sigma}{d\sigma_0}\right\rangle = 2\left(1+\frac{\sin(|\mathbf{k}-\mathbf{k}'|R)}{|\mathbf{k}-\mathbf{k}'|R}\right)$$

$|\mathbf{k}| = |\mathbf{k}'| \to |\mathbf{k}-\mathbf{k}'| = \sqrt{k^2+k'^2-2kk'\cos\alpha} = \sqrt{2k^2(1-\cos\alpha)} = 2k\sin\frac{\alpha}{2}$,

$$\left\langle\frac{d\sigma}{d\sigma_0}\right\rangle = 2\left(1+\frac{\sin(2k\sin\frac{\alpha}{2}R)}{2k\sin\frac{\alpha}{2}R}\right)$$

Найдём связь между полными сечениями:

$$\langle\sigma\rangle = \int 2\left(1+\frac{\sin(2k\sin\frac{\alpha}{2}R)}{2k\sin\frac{\alpha}{2}R}\right)|f_0(\mathbf{n},\mathbf{n}')|^2\sin\alpha d\alpha d\varphi = 2\left(\langle\sigma_0\rangle+\int\frac{\sin(2k\sin\frac{\alpha}{2}R)}{2k\sin\frac{\alpha}{2}R}|f_0(\mathbf{n},\mathbf{n}')|^2\sin\alpha d\alpha d\varphi\right)$$

• Случай медленных частиц ($kR \ll 1$).

$$\langle\sigma\rangle \approx 2\left(\langle\sigma_0\rangle+\int|f_0(\mathbf{n},\mathbf{n}')|^2\sin\alpha d\alpha d\varphi\right) = 4\langle\sigma_0\rangle$$

• Случай достаточно быстрых частиц ($ka \sim 1$, $R \gg a$). Подынтегральное выражение быстро осциллирует, поэтому

$$\langle\sigma\rangle \approx 2\langle\sigma_0\rangle$$

GKKG.13.77

Prove that the amplitude of elastic scattering of an electron with an atom (the composite system) in the Born approximation coincides with the amplitude of electron scattering from a static local potential $U(\mathbf{r})$, if we neglect exchange effects. [369] Find its physical meaning. Compare to Problems 13.4-6.

Solution

The interaction between the incident electron and the atom has the form ($\mathbf{r}_a$ are radius vectors of the atomic electrons):

$$U(\mathbf{r},\{\mathbf{r}_a\}) = -\frac{Ze^2}{r}+\sum_a\frac{e^2}{|\mathbf{r}-\mathbf{r}_a|}$$

The electron's elastic scattering amplitude on the atom in the Born approximation, if we neglect exchange effects (which play a role of higher-order corrections) is described by an expression similar to Eq. (XIII.6):

$$f_B = -\frac{m}{2\pi\hbar^2}\int \psi_0^*(\xi_a)\, e^{-i\mathbf{k}\cdot\mathbf{r}} U(\mathbf{r}, \{\mathbf{r}_a\})\, e^{i\mathbf{k}_0\cdot\mathbf{r}}\psi_0(\xi_a)\, dV d\tau\xi \tag{1}$$

Integration over τ_ξ also includes a summation over the spin variables of the atomic electrons. Performing the integration over ξ_a and also examining the "potential",

$$\varphi_{at} = \int\left(\frac{Ze}{r} - \sum_a \frac{e}{|\mathbf{r}-\mathbf{r}_a|}\right)|\psi_0(\xi_a)|^2\, d\tau \tag{2}$$

which gives the mean value of the electrostatic potential maintained by the atom, we see that expression (1) has the form of Eq. (XIII.6) for the scattering amplitude in the Born approximation, with the local potential $U(\mathbf{r}) = -e\varphi_{at}(\mathbf{r})$. Applications are considered in Problems 13.4-13.6.

GKKG.13.78

A polarized electron with $s_z = +1/2$ collides with a hydrogen atom that is in the ground state, where the electron has the opposite value of spin projection, $s_z = -1/2$. In the Born approximation, find the amplitude and cross-section of a spin-flip collision (i.e., the case when $s_z = -1/2$ for a scattered electron, while $s_z = +1/2$ for the atomic
electron), while the atom remains in the ground state. Compare to the case of elastic scattering without spin-flip (see Problem 13.77).

Solution

The system Hamiltonian (with an infinitely heavy proton nucleus) is described by the expression:

$$\hat{H} = \frac{1}{2m}\left(\hat{\mathbf{p}}_1^2 + \hat{\mathbf{p}}_2^2\right) - \frac{e^2}{r_1} - \frac{e^2}{r_2} + \frac{e^2}{|\mathbf{r}_1 - \mathbf{r}_2|}$$

Spin projections, s_z, for each electron are conserved, and the electrons with $s_z = +1/2$ and $s_z = -1/2$ could be considered as distinguishable particles (anti-symmetrization of the wavefunction is not reflected in the results). So, we denote the electron with $s_z = +1/2$ by e_1 and the electron with $s_z = -1/2$ by e_2. Now we see that the process considered is

$$e_1 + (e_2 p) \to e_2 + (e_1 p) \tag{1}$$

where, the symbol $(e_a p)$ corresponds to the hydrogen atom with electron e_a. We see that this process involves a redistribution of particles, where the initial and final channels of the reaction are different.

Amplitudes of such processes are expressed in terms of matrix elements of the corresponding T-operator, which could be written in two different forms:

$$\hat{T}_1 = V_\alpha + V_\beta \frac{1}{E - \hat{H} + i0} V_\alpha \tag{2a}$$

$$\hat{T}_2 = V_\beta + V_\beta \frac{1}{E - \hat{H} + i0} V_\alpha \tag{2b}$$

Here α and β enumerate reaction channels, $V_{\alpha,\beta}$ describes the interaction in the corresponding channels (α initial, β final channels). Note that although $\hat{T}_1 \neq \hat{T}_2$, reaction amplitudes $\langle\beta|\hat{T}_{1,2}|\alpha\rangle$ coincide.

Further, for the plane waves, $\psi = e^{i\mathrm{pr}/\hbar}$, describing relative motion in each of the two-particle channels [370] we use a probability density that is normalized to unity. The differential cross-section of a process is connected to its element of the T-matrix, $\langle\beta|\hat{T}|\alpha\rangle$, by the expression:

$$\frac{d\sigma}{d\Omega} = \frac{\mu_1\mu_2}{(2\pi)^2\hbar^4}\frac{p_2}{p_1}|\left\langle\beta|\hat{T}|\alpha\right\rangle|^2$$

where $p_{1,2}$ and $\mu_{1,2}$ are the momenta, and the reduced masses for colliding particles in channels α, β; $d\Omega$ is an element of the scattering solid angle in the center-ofmass system. The amplitude of elastic scattering commonly used ($\mu_1 = \mu_2, p_1 = p_2$)

[0] [369] In the Born approximation (for fast particles), the neglect of exchange effects is valid. It is important that the spin state of the free electron, as well as the atomic one, is not changed during collision. Compare to Problem 13.78.

[370] These waves (but not the incoming and outgoing waves), in a product involving the wavefunctions of bound states corresponding to composite particles in the channels (compare to Eq. (3)), appear in the matrix elements, $\langle\beta|\hat{T}|\alpha\rangle$, that determine reaction amplitudes.
is connected to the T-matrix by the relation:

$$f = -\frac{\mu}{2\pi\hbar^2}\langle\alpha|\hat{T}|\alpha\rangle$$

The same relation is valid in the case of inelastic collisions, if $\mu_1 \approx \mu_2, p_1 \approx p_2$.
Using Eq. (2a), we can calculate the amplitude of process (1) to the first order of approximation, i.e., restricting ourselves to the term V_α in $\hat{T}_1$. In this case, $V_\alpha = -e^2/r_1 + e^2/|\mathbf{r}_1 - \mathbf{r}_2|$, and the amplitude of the process considered with electron's spin-flip takes the form:

$$f_{\downarrow\uparrow,\uparrow\downarrow} = -\frac{m}{2\pi\hbar^2}\int \psi_0^*(r_1)\, e^{-i\mathbf{p}_2\cdot\mathbf{r}_2/\hbar}\left[\frac{e^2}{|\mathbf{r}_1-\mathbf{r}_2|} - \frac{e^2}{r_1}\right] e^{i\mathbf{p}_1\cdot\mathbf{r}_1/\hbar}\psi_0(r_2)\, dV_1 dV_2 \tag{3}$$

where $\mathbf{p}_{1,2}$ are momenta of the electron becoming bound and of the scattered electron, and $\psi_0(r)$ is the wavefunction of the hydrogen atom in the ground state. In the momentum representation (below we use atomic units $e = \hbar = m = 1$),

$$U(r) = \frac{1}{r} = \int e^{i\boldsymbol{\kappa}\cdot\mathbf{r}}\tilde{U}(\kappa)d^3\kappa, \quad \psi_0(r) = \frac{1}{\sqrt{\pi}}e^{-r} = \frac{1}{(2\pi)^{3/2}}\int e^{i\boldsymbol{\kappa}\cdot\mathbf{r}}\varphi_0(\kappa)d^3\kappa$$

$$\tilde{U}(\kappa) = \frac{1}{2\pi^2\kappa^2}, \quad \varphi_0(\kappa) = \frac{\sqrt{8}}{\pi\left(1+\kappa^2\right)^2}$$

Eq. (3) could be transformed to be

$$f_{\downarrow\uparrow,\uparrow\downarrow} = -(2\pi)^2\left\{\int \varphi_0^*(\mathbf{p}_1+\boldsymbol{\kappa})\,\varphi_0(\mathbf{p}_2+\boldsymbol{\kappa})\,\tilde{U}_{12}(\kappa)d^3\kappa + \right.$$
$$\left.\varphi_0(p_2)\int \varphi_0^*(\mathbf{p}_1+\boldsymbol{\kappa})\,\tilde{U}_m(\kappa)d^3\kappa\right\} \tag{4}$$

We have $p_{1,2} \gg 1$ (the necessary condition for the Born approximation), and we can see that $\varphi_0(p)$ for $p \to \infty$ decreases faster than $\tilde{U}(p)$. Therefore, the integration domains where the argument of one of the wavefunctions, $\varphi_0(\tilde{\kappa})$, is of the order of 1 play the dominant role. In both integrals $\kappa \approx |\mathbf{p}_{1,2}| \equiv p$, and we can factor $\tilde{U}(p)$ outside of the integrals, after which they are easily calculated (compare to Problem 4.17):

$$\int \varphi_0^*(\mathbf{p}_1+\boldsymbol{\kappa})\,\varphi_0(\mathbf{p}_2+\boldsymbol{\kappa})\,d^3\kappa = \int \varphi_0^*(\kappa')\,\varphi_0(\mathbf{q}+\boldsymbol{\kappa}')\,d^3\kappa' =$$
$$= \int \varphi_0^*(\kappa')\,\hat{T}_q\varphi_0(\kappa')\,d^3\kappa' = \int e^{-i\mathbf{q}\cdot\mathbf{r}}\,|\psi_0(r)|^2\,dV =$$
$$= \frac{16}{\left(4+q^2\right)^2}, \quad \mathbf{q} = \mathbf{p}_2 - \mathbf{p}_1$$

(the integral has been reduced to the form factor of the hydrogen atom), and

$$\int \varphi_0^*(\mathbf{p}_1+\boldsymbol{\kappa})\,d^3\kappa = (2\pi)^{3/2}\psi_0^*(0) = \sqrt{8}\pi$$

As a result, we obtain the amplitude of the process considered:

$$f_{\downarrow\uparrow,\uparrow\downarrow}(\mathbf{p}_2,\mathbf{p}_1) = -\frac{32}{p^2}\left\{\frac{1}{\left(4+q^2\right)^2} - \frac{1}{2\left(1+p^2\right)^2}\right\}, \quad \mathbf{q} = \mathbf{p}_2 - \mathbf{p}_1 \tag{5}$$

We can see that the region of values $q \lesssim 1$, i.e., of scattering angles $\theta \lesssim 1/p$, plays the dominant role in scattering. The second term in Eq. (5) is negligibly small, so the differential, $d\sigma/d\Omega = |f|^2$, and total scattering cross-sections become equal to

$$\frac{d\sigma}{d\Omega} = \frac{4}{p^4\left(1+p^2\theta^2/4\right)^4}, \quad \theta \lesssim \frac{1}{p}; \quad \sigma = \frac{16\pi}{3p^6} = \frac{16\pi a_B^2}{3\left(ka_B\right)^6} \tag{6}$$

In conclusion here, note the following:

1. The electron scattering cross-section for a hydrogen atom with spin-flip, which is practically inelastic, for large energies is much lower than the elastic scattering cross-section, $\sigma_{el} = 7\pi/3p^2$. See Problem 13.4.

2. The appearance of the small factor, $\sim 1/(pa_B)^2$, in the amplitude (and $\sim 1/(pa_B)^4$ in the cross-section) compared to the case of elastic scattering (no spin flip) has a simple explanation. To "switch" places, the electrons must be scattered into one another under the angle $\approx 180^\circ$ in the center-of-inertia system. The dependence of the Rutherford scattering amplitude on momentum transferred, $f \sim \tilde{U}(q) \sim 1/(pa_B)^2$, gives rise to this smallness (here $q \approx p$; in the case of elastic scattering $qa_B \sim 1$, the value $q_{\min} \sim 1/a_B$ here is due to screening of the Coulomb potential at the distances $\sim a_B$).

3. It is essential that in the process considered, the two particles (two electrons) receive a large momentum change, and that it could be provided by a single interaction. In other reactions with a particle redistribution of the form $a + (bc) \to b + (ac)$, in the case $m_a \neq m_b$, we have $p_a \neq p_b$ and the large change of the momenta of a and b particles requires an additional large momentum transfer to particle c. This leads to the appearance of an additional small factor in the process amplitude [371] $\sim \tilde{U}(q)/q^2$. Such a situation takes place in process (1) for scattering angles that are not too small, when $q \gg 1$, as is seen from Eq. (5). The additional smallness is connected to the fact that the amplitude of the process includes the hydrogen atom wavefunction (or that of the composite system, in the more general case), $\varphi(p)$, that for large momenta ($p \sim q \gg 1$) has an asymptote of the form $\varphi(p) \sim \tilde{U}(p)/p^2 \sim 1/p^4$ (for s-states, compare to Problems 4.17 and 4.18). The factor mentioned has the same order of magnitude as the second-order terms in the T-operator. In this case, when the change of momentum for all particles is large, calculations of the amplitude and cross-section, using first order of perturbation theory, have only qualitative character. A systematic and reliable calculation of the asymptote needs the inclusion of terms of higher order in the T-operator. For processes with large momentum change for all particles in a three-particle system, as, for example, in the conditions of Problem 13.79, we should take into account terms of at least 2nd order in the interaction, $V_{\alpha,\beta}$.

GKKG.13.79

Evaluate the charge-exchange cross-section for the collision of a fast positron with a hydrogen atom in the ground state (i.e., find the cross-section of positronium formation - a hydrogen-like system with an electron and a positron).

Use the Oppenheimer-Brinkman-Kramers approximation (OBK) for the chargeexchange processes, which neglects the mutual interaction of the nuclei involved (in this case, positron with proton); compare with the previous problem.

Solution

The Oppenheimer-Brinkman-Kramers approximation for the charge-exchange process $e_+ + (e_- p) \to (e_+ e_-) + p$ is based on the following expression for the T-operator [372]

$$\hat{T} \approx V_\alpha \approx U_{e^+e^-} = -\frac{1}{|\mathbf{r}_1 - \mathbf{r}_2|}$$

where $\mathbf{r}_{1,2}$ are the radius vectors of the positron (electron). We will denote the momentum of the incident positron as $\mathbf{p}_1$ (in the rest system of the hydrogen atom, $m_p = \infty$), and the momentum of the positronium as $\mathbf{p}_2$ (with mass $m(e^+e^-) = 2$). From the energy conservation law, it follows that $p_2 = \sqrt{2}p_1$ $\left(E = p_1^2/2 = p_2^2/4\right.$, and we can neglect the binding energy in the hydrogen atom and in the positronium, since $p_{1,2} \gg 1$).

The wavefunctions of the initial (channel α) and final (channel β) states have the form:

$$\psi_\alpha = e^{i\mathbf{p}_1 \cdot \mathbf{r}_1} \psi_{1s}(r_2), \quad \psi_\beta = \exp\left\{\frac{i}{2}\mathbf{p}_2 \cdot (\mathbf{r}_1 + \mathbf{r}_2)\right\} \cdot \frac{1}{\sqrt{8}} \psi_{nlm}\left(\frac{\mathbf{r}_1 - \mathbf{r}_2}{2}\right)$$

Here, $\psi_{nlm}(\mathbf{r})$ is the wavefunction of the hydrogen atom (with mass $m = 1$). Coefficient $1/\sqrt{8}$ and factor $1/2$ in the argument of the wavefunction correspond to the fact that the Bohr radius for positronium is twice that of the hydrogen atom.

The amplitude of the process in the OBK-approximation is described by the expression (after the substitution $\boldsymbol{\rho} = (\mathbf{r}_1 - \mathbf{r}_2)/2$):

$$T_{OBK}(1s \to nlm) = \langle \beta | U_{e^+e^-} | \alpha \rangle = -\sqrt{2} \int \psi_{1s}(r) e^{i(\mathbf{p}_1 - \mathbf{p}_2)\cdot \mathbf{r}} dV \times$$
$$\int \frac{1}{\rho} \psi^*_{nlm}(\boldsymbol{\rho}) e^{-i(\mathbf{p}_2 - 2\mathbf{p}_1)\cdot \boldsymbol{\rho}} d^3\rho \qquad (1)$$

The first integral in this expression is equal to $(2\pi)^{3/2}\varphi_{1s}(q)$ (with $\mathbf{q} = \mathbf{q}_1 - \mathbf{q}_2$), while the second, with the Schrdinger equation taken into account, is

[372] The same results follow also from the choice $T \approx V_\beta \approx U_{e^-p}$. See the previous problem, where we made general statements about processes with a particle redistribution. Let us note that for the charge-exchange

processes, the results of both exact amplitude calculations in the first order of perturbation theory according to $T = V_{\alpha,\beta}$ and in the OBK-approximation have only qualitative character (a reliable calculation necessitates the inclusion of second-order second-order terms).

$$(2\pi)^{3/2}\left(\frac{1}{2}q_1^2 - E_n\right)\boldsymbol{\phi}^*_{nlm}(\mathbf{q}_1), \text{ where } \mathbf{q}_1 = 2\mathbf{p}_1 - \mathbf{p}_2$$

Since $q, q_1 \gg 1$, we can use asymptotes for wavefunctions $\varphi(\mathbf{p})$ in the Coulomb potential, $U = -1/r$ (so $\tilde{U}(p) = -1/2\pi^2 p^2$), for $p \to \infty$. According to Problem 4.18:

$$\varphi_{1s}(p) = \frac{\sqrt{8}}{\pi p^4}, \quad \varphi_{nlm}(\mathbf{p}) = \sqrt{\frac{2}{\pi}}\frac{2(l!)}{p^{l+4}}(-2i)^l \tilde{R}_{nl}(0) Y_{lm}(\mathbf{n}) \tag{2}$$

To obtain this we used a relation for the coordinate Coulomb wavefunctions:

$$\psi_{nlm}(\mathbf{r}) = Y_{lm}(\mathbf{n}) r^l \tilde{R}_{nl}(r), \quad \tilde{R}_{nl}(0) = \frac{2^{l+1}}{(2l+1)! n^{l+2}}\sqrt{\frac{(n+l)!}{(n-l-1)!}}$$

Using these asymptotes, we obtain

$$T_{OBK}(1s \to nlm) = -\frac{16\sqrt{2\pi^3}(\sqrt{2}i)^l \tilde{R}_{nl}(0) l! Y_{lm}(\mathbf{n}_0)}{(3 - 2\sqrt{2}\cos\theta)^{3+l/2} p_1^{6+l}} \tag{3}$$

We have used $\mathbf{n}_0 = (-\mathbf{p}_2 + 2\mathbf{p}_1)/(|\mathbf{p}_2 - 2\mathbf{p}_1|)$, and also that $q_1^2 = 2q^2 = 2(3 - 2\sqrt{2}\cos\theta)p_1^2$, where θ is the angle between vectors $\mathbf{p}_2$ and $\mathbf{p}_1$.

This angular distribution of the emitted positronium, [373] $d\sigma/d\Omega = |T|^2/\sqrt{2}\pi^2$, has several interesting properties. It does not depend on the value of the incident positron's momentum. It is sharply anisotropic (the values of $3 - 2\sqrt{2}\cos\theta$ for angles $\theta = 0$ and π differ by a factor of 35). The polarization state of the positronium created is characterized by a definite projection of its angular momentum onto the direction of vector $\mathbf{n}_0, m_n = 0$, since $Y_{lm}(\theta = 0) = \sqrt{(2l+1)/4\pi}\delta_{m,0}$. For the total chargeexchange cross-section, after summing over the values of the projection of the angular momentum, m, of the positronium created, we obtain

$$\sigma_{OBK}(1s \to nl) = 64\pi a_B^2 \frac{2^l (2l+1)(l!)^2 \tilde{R}^2_{nl}(0)}{(l+5)(3-2\sqrt{2})^{5+l}} \frac{1}{V^{12+2l}} \tag{4}$$

where $V = p_1 a_B/\hbar$ is the relative velocity of the colliding positron and hydrogen atom in atomic units. In particular, we can write the charge-exchange cross-section for the ns-states of the positronium as

$$\sigma_{OBK}(1s \to ns) = \frac{\pi a_B^2}{n^3}\left(\frac{2.89}{V}\right)^{12} \tag{5}$$

Pay attention to the pronounced energy-dependence of the charge-exchange cross-section, $\sigma \propto p^{-12-2l}$ (compare with the result of the previous problem and with the case of elastic scattering; see Problem 13.4). It is explained by the fact that all particles involved experience a large change of momentum. In connection with this, we should note that the charge-exchange cross-section for collisions of fast heavy particles $m \gg m_e$ with a hydrogen atom have a similar energy-dependence. For $m \gg m_e$, the

charge-exchange cross-section does not depend on the mass of the incident particle (for example, proton, muon, etc.). In particular, the charge-exchange cross-section in the ns-state is
$$

$$\sigma_{OBK}(1s \to ns) = \pi a_B^2 \frac{2^{18} Z^5}{5 n^3 V^{12}} \approx \frac{\pi a_B^2}{n^3} Z^5 \left(\frac{2.47}{V}\right)^{12} \tag{6}$$

$$
where Z is the particle charge. From comparison of Eqs. (5) and (6), we see that the charge-exchange cross-section for the collision of the positron and hydrogen atom is ≈ 7 times larger than for the collision with a proton (for the same velocities).

GKKG.13.80

In the Born approximation, express the amplitude of the process $A_i + B_i \to A_f + B_f$ for the collision of fast composite particles A and B, interacting electrostatically, through electric form-factors [374]

$$eF^{A(B)}_{if}(\mathbf{q}) = \left\langle \psi_{A(B)f} \right| \sum_a e_a \exp\{-i\mathbf{q}\cdot\mathbf{r}_a\} \left| \psi_{A(B)i} \right\rangle$$

[0] [373] See Problem 13.78 for amplitude normalization. In this problem, $\mu_1 = 1, \mu_2 = 1, p_2 \approx \sqrt{2}p_1$.

for transitions $i \to f$.
Consider the behavior of the form-factor for $q \to 0$, depending on the quantum numbers of the initial and final states.

Calculate the form-factors for transitions $1s \to 1s, 1s \to 2s, 1s \to 2pm$ in the hydrogen atom. Consider their behavior as $q \to \infty$.

Find the collision cross-section for the following processes:

1. $H(1s) + H(1s) \to H(1s) + H(1s)$, elastic scattering of hydrogen atoms from one another;

2. the collision of a charged, structureless particle (electron, muon, proton, etc., but not an ion) with a hydrogen atom in the ground state, accompanied by the excitation of a) $2s$ state in the atom; b) $2p$ states in the atom.

Solution

Let us denote the radius vectors of the $A(B)$ particles' centers of mass by $\mathbf{R}_{A(B)}$, their masses by $m_{A(B)}$, and the momenta of their relative motion by $\mathbf{p}_{1,2}$ (1) before and (2) after the collision. The wavefunctions of the initial and final states have the form: [375]

[374] Let us emphasize that $\mathbf{r}_a$ is the radius vector of the a th charged particle in the composite system $A(B)$ with respect to the system's center-of-mass.

[375] Wavefunctions $\psi_{A(B)}$ of the composite particles describe the states of the particles in the composite system, with respect to its center-of-mass.

$$\psi_i = \exp\left\{\frac{i}{\hbar}\mathbf{p}_1 \cdot \mathbf{R}\right\} \psi_{Ai}\left\{x'_a\right\} \psi_{Bi}\left\{r'_B\right\}, \quad \mathbf{R} = \mathbf{R}_A - \mathbf{R}_B,$$
$$\psi_f = \exp\left\{\frac{i}{\hbar}\mathbf{p}_2 \cdot \mathbf{R}\right\} \psi_{Af}\left\{x'_a\right\} \psi_{Bf}\left\{r'_B\right\}, \quad \hbar\mathbf{q} = \mathbf{p}_2 - \mathbf{p}_1, \tag{1}$$

The amplitude of the process considered in the Born approximation is described by the expression (compare to Problems 13.77 and 13.78):

$$f_{if} = -\frac{\mu}{2\pi\hbar^2} T_{if} = -\frac{\mu}{2\pi\hbar^2} \left\langle \psi_f \right| \sum_{a,b} \frac{e_a e_b}{|\mathbf{x}_a - \mathbf{r}_b|} \left| \psi_i \right\rangle, \quad \frac{d\sigma}{d\Omega} = |f|^2 \tag{2}$$

We use $\mu = m_A m_B / (m_A + m_B)$, the reduced mass of particles A and B. The integration in matrix element (2) is performed both over independent "inner" coordinates $\mathbf{x}'_a$, $\mathbf{r}'_b$ (in the case of atoms, these are the coordinates of all electrons), and over the radius vector, $\mathbf{R}$, of the relative motion. Writing here $\mathbf{x}_a = \mathbf{R}_A + \mathbf{x}'_a$ and $\mathbf{r}_b = \mathbf{R}_B + \mathbf{r}'_b$, using the form of the wavefunctions (1), and using the Fourier transform of the Coulomb potential

$$\frac{1}{|\mathbf{x}_a - \mathbf{r}_b|} = \frac{1}{2\pi^2} \int \exp\left\{i\boldsymbol{\kappa}\left(\mathbf{x}_a - \mathbf{r}_b\right)\right\} \frac{d^3\kappa}{\kappa^2}$$

we obtain

$$T_{if} = \frac{4\pi e^2}{q^2} F_{if}^A(-\mathbf{q}) F_{if}^B(\mathbf{q}) \tag{3}$$

Here

$$eF_{if}^{A(B)}(\mathbf{q}) = \left\langle \psi_{A(B)f} \right| \sum_a e_a \exp\left\{-i\mathbf{q} \cdot \mathbf{r}'_a\right\} \left| \psi_{A(B)i} \right\rangle \tag{4}$$

are the electric form-factors for the corresponding transitions in the composite particles $A(B)$. We can associate the Feynman diagram in Fig. 13.8 with the amplitude, Eq. (3).

It illustrates an important property of the amplitude: it is factorized in terms of the particles, A and B, that take part in the process. In this figure, the wavy line between the vertices corresponds to $4\pi/q^2$, while the form-factors $eF_{if}^{A(B)}(\mp\mathbf{q})$ correspond to the vertices (note that the changes in the momenta of particles A and B differ by a sign).

Let us note some properties of the form-factors:

1. For point (structureless) particles, $F(q) = Z = \text{const}$, where Ze is particle charge.

2. For $q \to 0$, expanding $\exp\{-i\mathbf{q}\cdot\mathbf{r}\}$ in Eq. (4) for $F(\mathbf{q})$ into a series reveals that for a system with charge Ze different from zero, only the elastic (without a change of composite particle's state) form-factor is different from zero, and is equal to $F_{nn}(0) = Z$. In all other cases $F_{if}(0) = 0$ (for a charged particle, due to wavefunction orthogonality). The character of how exactly the form-factor vanishes in the limit $q \to 0$ depends on the quantum numbers, angular momenta, and parity

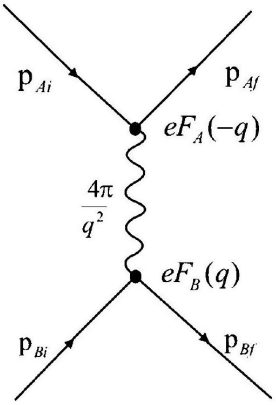

Fig. 13.8

of the initial and final states. The slowest decrease in the form factor is for the dipole transitions: $eF_{if} \approx -i\langle f|\hat{\mathbf{d}}|i\rangle q \propto \mathbf{q}$. For transitions with unchanging values of the angular momentum and parity (for example, for S-states), $F_{if} \propto q^2$. With an increase in the difference between the angular momenta of the initial and final states, the form-factor goes to zero for $q \to 0$ more abruptly.

3) For $q \to \infty$ the form-factor of any composite system vanishes. [376] The power law of this decrease depends strongly on the number of particles in the system and on the specific interaction. From physical considerations, it is evident that the faster $\bar{U}(q)$ decreases and the larger the particle number in the compound system, the faster the form-factor decreases. Compare to Problem 13.84.

For transitions of the hydrogen atom, the form-factors

$$F_{1s\to nlm}(q) = \int \psi^*_{nlm}(\mathbf{r})\left(1 - e^{-i\mathbf{q}\cdot\mathbf{r}}\right)\psi_{1s}(r)dV$$

are easy to calculate. Taking into account the form of the wavefunctions (see Eq. (IV.4)), we can obtain

$$F_{1s\to 1s} = 1 - F_{at}(q) = \frac{8q^2 + q^4}{(4+q^2)^2}, \quad F_{1s\to 2s} = -\frac{4\sqrt{2}q^2}{(9/4+q^2)^3} \tag{5}$$

[376] For an atom in the approximation of an infinite nuclear mass, for $q \to \infty$ the elastic form-factor is $F_{el} = Z$ (it is determined by the contribution from a point-like nucleus).

For the $2p$-states, it is convenient to write the angular part of the wavefunction in the form $\sqrt{3/4\pi}\varepsilon(m)\cdot\mathbf{n}$, where $|\varepsilon(m)|^2 = 1$ (compare Problems 3.41 and 3.42), after which we obtain

$$F_{1s\to 2pm} = -\frac{\varepsilon^*(m)}{4\sqrt{2\pi}}\frac{i\partial}{\partial\mathbf{p}}\int \exp\left\{-\frac{3r}{2} - i\mathbf{q}\cdot\mathbf{r}\right\}dV = \\ = 6\sqrt{2}i\frac{\varepsilon^*(m)\mathbf{q}}{(9/4+q^2)^3} \tag{6}$$

This form-factor is different from zero only for the states with projection of the angular momentum on the direction of the vector $\mathbf{q}$ equal to zero.

For calculating the scattering cross-sections, we first note that

$$q^2 = p_1^2 + p_2^2 - 2p_1p_2\cos\theta, \quad p_2 = \sqrt{p_1^2 - 2\mu(\varepsilon_1 - \varepsilon_2)} \approx \\ \approx p_1 - \frac{\mu(\varepsilon_1 - \varepsilon_2)}{p_1}$$

where $\varepsilon_{1,2} > 0$ are the binding energies of the system before and after the collision. So $d\Omega$ could be replaced by $\pi dq^2/p_1^2$, with the integration over q^2 within limits 0 and ∞ (due to the fast convergence in the upper limit, $q^2_{\max} \approx 4p_1^2$). We cannot always replace the lower integration limit

$$q^2_{\min} = (\mathbf{p}_1 - \mathbf{p}_2)^2 \approx \left(\frac{\mu(\varepsilon_1 - \varepsilon_2)}{p_1}\right)^2$$

by 0, because of a divergence that may appear. This complication however only arises for the inelastic collisions where one of the colliding particles has charge different from zero and its state during the collision

process does not change, so that for it, $F(0) = Z \neq 0$, and for the other particle, the transition is of dipole type. Thus, $eF_{if} \approx -i\mathbf{d}_{if}\mathbf{q}$ for $q \to 0$.

Elementary integration gives the following results:

$$1)\ \sigma(1s1s \to 1s1s) = \frac{4\pi}{V^2}\int\limits_0^\infty F^4_{1s\to 1s}(q)dq^2 = \frac{33\pi}{35V^2} \tag{7}$$

$$2)\ \sigma(1s \to 2s) = \frac{4\pi Z^2}{V^2}\int\limits_0^\infty F^2_{1s\to 2s}(q)dq^2 = \frac{2^{17}\pi Z^2}{5\cdot 3^{10}V^2} \approx 0.444\frac{\pi Z^2}{V^2} \tag{8}$$

where $V = p_1/\mu$ is the relative velocity of the colliding particles, and Ze is the charge of the particle colliding with the hydrogen atom.

Now we calculate the total cross-section for collisions with transitions $1s \to 2p$, by summing over the transitions $1s \to 2pm$:

$$\sigma(1s \to 2p) = 288\pi\left(\frac{Z}{V}\right)^2\left(-\frac{1}{5!}\frac{\partial^5}{\partial a^5}\int\limits_{q^2_{min}}^\infty \frac{dx}{x(a+x)}\right) = \tag{9}$$

$$288\pi\left(\frac{Z}{V}\right)^2\frac{1}{5!}\left[-\frac{\partial^5}{\partial a^5}\left(\frac{1}{a}\ln\frac{a}{q^2_{min}}\right)\right] = \frac{2^{17}\pi Z^2}{3^{10}V^2}\left[\ln\left(16V^2\right) - \frac{137}{60}\right]$$

where $x = q^2, a = 9/4, q^2_{\min} = \left(\varepsilon_{2p} - \varepsilon_{1s}\right)^2/V^2 = 9/64V^2$. Finally,

$$\sigma(1s \to n = 2) = \frac{2^{18}\pi Z^2}{3^{10}V^2}\left(\ln 4V - \frac{25}{24}\right) \approx 4.44\frac{\pi Z^2}{V^2}\left(\ln 4V - \frac{25}{24}\right) \tag{10}$$

is the total cross-section of exciting the states of the hydrogen atom with the principal quantum number $n = 2$ by collision with a charged particle.

Б-2.12.7 Рассеяние нейтрона на молекуле водорода (???)

Записать выражение для эффективного псевдопотенциала, описывающего рассеяние медленного нейтрона на молекуле водорода H_2.

Solution.

GKKG.13.81

Consider the collision between a fast charged particle and a two-atom molecule in its ground state with the dipole moment, d_0. The electron term of the molecule is $^1\Sigma$. Estimate the cross-sections of collisions, which involve excitation of the rotational and oscillation molecular levels. Compare to the case of the collision with an atom (see the previous problem).

Solution

As in the previous problem, the collision cross-section is connected to the electric form-factor of the molecule,

$$eF_{0\to vKM}(\mathbf{q}) = \langle n, \Lambda = 0, vKM|\sum_a e_a e^{i\mathbf{q}\cdot\mathbf{r}_a}|n, 0\rangle \tag{1}$$

In the initial state, the quantum numbers are $\Lambda = v = K = M = 0$, while n characterizes the state of molecular electrons. The wavefunctions of the molecululars states with $\Lambda = 0$, as are in matrix element (1), have the form:

$$\psi_n\Lambda = 0vKM = \psi^{el}_{n\Lambda=0}\left(\xi_a, \mathbf{R}\right)\psi^{osc}_v\left(\mathbf{R} - \mathbf{R}_0\right)Y_{KM}(\mathbf{n}) \tag{2}$$

Here ξ_a are the electron variables (coordinate and spin); $\mathbf{R} = R\mathbf{n} = \mathbf{R}_1 - \mathbf{R}_2$ is the radius vector from one nucleus to the other; the masses are $M_{1,2}$; and the radius vectors in the molecule's center-of-mass system: $\mathbf{R}_1 = M_2\mathbf{R}/\left(M_1 + M_2\right)$ and $\mathbf{R}_2 = -M_1\mathbf{R}/\left(M_1 + M_2\right)$. Summation in Eq. (1) is performed over both the molecular electrons ($\mathbf{r}_a$ denotes the radius vectors relative to the molecular center of mass), and the nuclei, whose contribution is $Z_1e^{-i\mathbf{q}\cdot\mathbf{R}_1} + Z_2e^{-i\mathbf{q}\cdot\mathbf{R}_2}$.

We write the cross-section for the collision between the charged particle and the molecule,

$$\frac{d\sigma_{0\to vKM}}{d\Omega} = \left(\frac{2\mu Ze^2}{\hbar^2 q^2}\right)^2 |F_{0\to vKM}(\mathbf{q})|^2 \tag{3}$$

where Ze is particle charge, and μ is its and the molecule's reduced mass. We note that the easiest way to obtain these cross-sections is to neglect the change in the state of the valence electron states in the molecular formation. In this approximation, the wavefunction of the electron term of the molecule is

$$\psi^{\text{elec}}_{n\Lambda=0} \approx \psi_1(\mathbf{r}_a - \mathbf{R}_1)\,\psi_2(\mathbf{r}_b - \mathbf{R}_2)$$

where $\psi_{1,2}(\mathbf{r}_{a,b})$ is the wavefunction for the electron bound to a single atom of the molecule, and for its form-factor, we obtain

$$F_{0\to\nu KM} \approx \langle \nu KM| \left(e^{-iR_1\mathbf{q}\cdot\mathbf{n}}F_1(q) + e^{iR_2\mathbf{q}\cdot\mathbf{n}}F_2(q)\right)|0\rangle \tag{4}$$

where $F_{1,2}(q)$ are the form-factors of the atoms in the molecule (which also include contributions of the corresponding nuclei). Note that for $q = 0$, the form-factor of the molecule, as of any neutral system, is equal to zero (see a discussion of form-factors in the previous problem).

Due to the smallness of amplitude of nuclear oscillations, we can replace $\mathbf{R}_{1,2}$ by their equilibrium positions. Then, due to wavefunction orthogonality, only the formfactors for transitions with $v = 0$ (i.e., without a change of the molecular oscillation state) are non-zero. For such transitions, we can calculate the differential cross-section, Eq. (3), by summing over the values of the quantum numbers K and M of the molecule's final states. Using approximation (4) and the completeness condition for the spherical functions, according to which

$$\sum_{KM} |\langle KM|\hat{A}|0\rangle|^2 = \sum_{KM}\langle 0|\hat{A}^+|KM\rangle\langle KM|\hat{A}|0\rangle = \langle 0|\hat{A}^+\hat{A}|0\rangle$$

we calculate the differential cross-section:

$$\sum_{KM}\frac{d\sigma_{0\to 0KM}}{d\Omega} = \left(\frac{2\mu Ze^2}{\hbar^2 q^2}\right)^2 \left\langle 0\|F_1(q) + F_2(q)e^{i\mathbf{q}\cdot\mathbf{R}_0}\right|^2|0\right\rangle$$

Compare to Problem 13.7.

Collision cross-sections that do not excite molecular oscillations obey the same rules as the case of a charged particle colliding with an atom (compare to the previous problem). In particular, for collisions that excite a rotational level with the angular momentum $K \neq 1$, the cross-section is

$$\sigma_{0\to 0KM} = \pi a_B^2 Z^2 A_{KM}\left(\frac{V_{at}}{V}\right)^2, \quad K \neq 1 \tag{5}$$

where V is the relative velocity of the colliding particles, and $A_{KM} \sim 1$ for the most important transitions.

For collisions that excite a rotational level with $K = 1$, connected to the ground level by a dipole transition, [377] for $q \to 0$ we have (compare to the previous problem):

$$\frac{d\sigma(0\to 0M)}{dq^2} = \frac{4\pi Z^2 e^2 d_0^2}{3\hbar^2 q^4 V^2}|\varepsilon(M)\mathbf{q}|^2 \tag{6}$$

$\varepsilon(M)$ is the polarization vector that determines a molecular rotational state with $K = 1$, and is connected to the spherical functions by the relation $Y_{1M} = \sqrt{3/4\pi}\varepsilon(M)\mathbf{n}$, where $|\varepsilon|^2 = 1$. Eq. (6) follows from expressions (1) and (3) if we take into account that: 1) for $q \to 0$, the sum in (1) becomes $-i\mathbf{q}\cdot\mathbf{d}$, where $\mathbf{d}$ is the operator of the molecular dipole moment; 2) averaging $\mathbf{d}$ over the electron states of the molecule with $\Lambda = 0$ gives $d(R)\mathbf{n}$; 3) after averaging over the oscillation states with $v = 0$, we can replace $d(R)$ by $d(R_0) \equiv d_0$ due to the smallness of the nuclear oscillation amplitudes (compare to Problem 11.25). The summation in Eq. (6) over M gives $\sum|\varepsilon(M)\mathbf{q}|^2 = q^2$, and the following integration over q^2 with the lower limit of integration (to cut off a divergence) being

$$q^2_{\min} = \left[\frac{\hbar}{\tilde{\mu}R_0^2 V}\right]^2$$

($\tilde{\mu}$ is the reduced mass of the molecular nuclei) allows us to obtain the cross-section of transitions to states with $K = 1$ to logarithmic accuracy: [378]

$$\sigma(0\to v = 0, K = 1) \approx \frac{8\pi Z^2 e^2 d_0^2}{3\hbar^2 q^4 V^2}\ln\frac{\tilde{\mu}}{m_e V_{at}} \tag{7}$$

Let us properties of the collision processes, accompanied by excitation of the molecular oscillation levels. As was mentioned before, replacement of R by is equilibrium value R_0 due to the weak nuclear oscillations is valid only for transitions that do not excite oscillations. For states with $v \neq 0$, in this approximation, the form-factor goes to zero due to wavefunction orthogonality. So for transitions with $v \neq 0$, it is necessary to perform expansion over the small parameter $\Delta R/R_0$, where $\Delta R = R - R_0$ is of the order of the nuclear oscillation

amplitudes. For the linear expansion term, which corresponds to transitions with $\Delta v = 1$, in expression (1) for $v = 1$, as opposed to $v = 0$, a small factor appears, on the order of (see Problems 11.3 and 11.25)

$$\langle v = 1|\frac{R - R_0}{R_0}|v = 0\rangle = \frac{a_{osc}}{\sqrt{2}R_0} \sim \left(\frac{m_e}{\tilde{\mu}}\right)^{1/4}$$

[377] For this transition, approximation (4) for $q \to 0$ is not valid; the dipole moment of the molecule is determined by its valence electrons.

[378] Here as usual, for the upper integration limit we choose the value $q^2_{\max} \sim a_B^{-2}$. We should note that although the argument of the logarithm in Eq. (7) is much larger than in the case of a dipole transition in an atom, due to the small rotational energy, nevertheless the accuracy of Eq. (7) does not increase because of it. Usually, the dipole moment of the molecule, d_0, is much smaller than the value ea_B

This leads to much lower, $\sim (\tilde{\mu}/m_e)^{1/2}$, cross-sections of the transitions with $v = 1$. With an increase of the value v, it is necessary to consider higher orders in $\Delta R/R_0$, which leads to a sharper, $\sim (\mu/m_e)^{v/2}$, suppression of the cross-section for the corresponding molecular transitions.

GKKG.13.82

Find the cross-section of a fast charged particle colliding with a hydrogen atom in a metastable $2s$-state, accompanied by its transition into a $2p$-state.

Comment: In this problem it is necessary to take into account the relativistic splitting of the s - and p-levels (see Problem 11.62).

Solution

For collisions of a charged particle and an atom accompanied by an atomic dipole transition, the region with small values of q^2 plays the dominant role. The cross-section of the collision with transition from the s - to the p-state of the atom to logarithmic accuracy is described by the expression (compare to Problem 13.80):

$$\sigma_{s\to p} = \frac{4\pi Z^2 e^2}{\hbar^2 V^2} \left|\langle l = 1, m = 0|d_z|\, 0\right\rangle|^2 \ln \frac{1}{q^2_{\min} a_B^2} \tag{1}$$

where Ze is the charge of the incident particle and V is the relative velocity of the colliding particles. For a transition $2s \to 2p$ in the hydrogen atom, the matrix element [379] $\langle 1, 0|d_z|0\rangle = 3ea_B$ was calculated in Problem 11.33, in connection with the Stark effect for the states with $n = 2$.

If we neglect relativistic corrections, the states $2s$ and $2p$ of the hydrogen atom are degenerate; here $q^2_{\min} = 0$ and the cross-section, Eq. (1), diverges. Splittings, Δ, of the levels $2s_{1/2}, 2p_{1/2}$ and $2p_{3/2}$, which determine the values of $q^2_{\min} = (\Delta/\hbar V)^2$, were discussed in Problem 11.62. Since here, transitions into the atomic states $2p_{1/2}$ and $2p_{3/2}$ must be considered separately, it is necessary to add the additional factors, equal 1/3 and 2/3, for the $p_{1/2}$- and $p_{3/2}$-states, in Eq. (1). These factors, the squares of the corresponding Clebsch-Gordan coefficients (see, for example, Problem 5.18), reflect the contribution of p-states with $l_z = 0$ to the states [380] $p_{1/2}$ and $p_{3/2}$. If we take into account these facts, we find

$$\sigma(2s \to 2p) = 72\pi a_B^2 \left(\frac{Ze^2}{\hbar V}\right)^2 \ln \frac{\hbar V}{a_B \Delta_0^{1/3} \Delta_1^{2/3}} \tag{2}$$

where $\Delta_0 = E\left(2s_{1/2}\right) - E\left(2p_{1/2}\right)$ and $\Delta_1 = E\left(2p_{3/2}\right) - E\left(2s_{1/2}\right)$, with the numerical value $\Delta_0^{1/3}\Delta_1^{1/3} \approx 8 \cdot 10^{-7}$ (in atomic units).

[379] We emphasize that Eq. (1) describes the cross-section, summed over the projections of the angular momentum of the p-state. Although in Eq. (1) there is a state with $l_z = 0$, we should remember that the choice of a quantization axis z, along the vector $\mathbf{q}$, depends on the scattering angle.

[380] If we take into account relativistic corrections, l_z is not a constant of the motion.

As is seen from Eq. (2), the cross-section $\sigma \gg (V_{at}/V)^2 \sigma_0$, where $\sigma_0 = \pi\overline{r^2} = 40\pi a_B^2$, characterizes the transverse size of the hydrogen atom in states [381] with $n = 2$. This means that in this problem, large impact parameters ($\gg a_B$) are essential. Effective interaction at such distances is $Ze\mathbf{d} \cdot \mathbf{r}/r^3 \sim Zed/r^2$. The applicability condition of perturbation theory (see Eq. (XIII.7)) for such a potential is fulfilled for the distances $r \gg Zed/\hbar V$. Even for values $V \approx 1$, this condition holds true, which proves the applicability of Eq. (2) for such collision velocities.

In conclusion, note that the large value of the transition cross-section, (2), implies that the lifetime of the metastable $2s$-state in a gas could decrease sharply due to collisions (for an isolated hydrogen atom, $\tau(2s) = 1/8$ s; while in the presence of transitions in the $2p$-state, the atom "flashes up" within $\sim 10^{-9}$ s).

GKKG.13.83

Calculate (with logarithmic accuracy) the cross-section of fast deuteron fission in the Coulomb field of a nucleus with charge Ze (for simplicity, consider the nucleus to be point-like and infinitely heavy). Choose the deuteron wavefunction as in the case of a zero-range potential (see 12.1), which is reasonable because of the smallness of the proton-neutron binding energy.

Solution

The differential cross-section of deuteron fission is described by the expression:

$$d\sigma_{fis} = \frac{4Z^2e^4m_d^2}{\hbar^2q^4}\left|\langle \mathbf{p},-|e^{-i\mathbf{q}\cdot\mathbf{r}_p}|\,0\right\rangle|^2\,d^3k d\Omega_f \tag{1}$$

Here, $\hbar\mathbf{q} = \mathbf{P}_f - \mathbf{P}_i, \mathbf{P}_i = m_d\mathbf{V}$ is the deuteron momentum, $\mathbf{P}_f$ is the nucleon's total momentum after the collision, $d\Omega_f$ is the infinitesimal solid angle (which contains vector $\mathbf{P}_f$ direction), and $m, m_d = 2m$ are the nucleon and deuteron masses. The Matrix element

$$F_{0\to\mathbf{p}} = \langle \mathbf{p},-|\exp\{-i\mathbf{q}\cdot\mathbf{r}_p\}|0\rangle$$

could be considered as an inelastic form-factor for transitions into the continuum (compare to Problem 13.80). For the wavefunction of the initial state, we write (see Problems 4.10 and 12.1):

$$\psi_0(r) = \sqrt{\frac{\kappa}{2\pi}}\frac{1}{r}e^{-\kappa r}, \quad \varepsilon_0 = \frac{\hbar^2\kappa^2}{m}$$

where ε_0 is the deuteron binding energy, and $\mathbf{r}_p = \mathbf{r}/2$. For the wavefunctions of the final states, we should choose [382] the wavefunction $\psi^-_{\mathbf{k}}(r)$, that has an asymptote in the form of "a plane wave + a converging wave;" they are normalized to $\delta(\mathbf{k}-\mathbf{k}')$.

[381] For the ns-states of the hydrogen atom, $\overline{r^2} = \frac{1}{2}n^2\left(5n^2+1\right)$.

[382] For an alternative convenient choice of final state wavefunctions, see Problem 11.63.

The dominant input into the fission cross-section comes from small q^2, where transitions to states of the two-nucleon system are important, connected to the deuteron's dipole transition, since for them $d\sigma \propto dq^2/q^2$ (compare to Problem 13.80). For such q, we have

$$\langle \mathbf{p},-|\exp\{-i\mathbf{q}\cdot\mathbf{r}_p\}|0\rangle \approx \langle \mathbf{p},-|\left(-i\mathbf{q}\cdot\mathbf{r}_p\right)|0\rangle \tag{2}$$

and in the last expression we can replace the wavefunction $\psi^-_{\mathbf{k}}$by the plane wave $\psi_{\mathbf{k}} = (2\pi)^{-3/2}e^{i\mathbf{k}\cdot\mathbf{r}}$. This is connected to the fact that in a zero-range potential, wavefunctions $\psi^-_{\mathbf{k}}$and $\psi_{\mathbf{k}}$ differ from one another in s-wave only, which does not contribute to the dipole moment, Eq. (2). A calculation of the corresponding matrix element gives

$$\frac{\sqrt{\kappa}\mathbf{q}}{8\pi^2}\frac{\partial}{\partial\mathbf{k}}\int\frac{1}{r}e^{-\kappa r-i\mathbf{k}\cdot\mathbf{r}}d^3r = \frac{\sqrt{\kappa}\mathbf{q}}{2\pi}\frac{\partial}{\partial\mathbf{k}}\frac{1}{k^2+\kappa^2} = -\frac{\sqrt{\kappa}\mathbf{q}\cdot\mathbf{k}}{\pi\left(k^2+\kappa^2\right)^2} \tag{3}$$

The angular dependence $\propto(\mathbf{q}\cdot\mathbf{k})$ of the vector $\mathbf{k}$ reflects the fact that for a dipole transition, the angular momentum of the nucleon pair in the final state is $l = 1$.

To obtain the differential cross-section, we substitute Eq. (3) in Eq. (1) and perform the integration over the directions of the vector $\mathbf{k}$, using the relations

$$d^3k = k^2dkd\Omega, \quad \int(\mathbf{q}\cdot\mathbf{k})^2d\Omega = \frac{4\pi}{3}q^2k^2$$

After this, $d\Omega_f$ in Eq. (1) could be replaced by $\pi\hbar^2dq^2/P_i^2$. Then the value of P_f that follows from the energy conservation law,

$$\frac{1}{2m_d}P_i^2 - \varepsilon_0 = \frac{1}{2m_d}P_f^2 + \varepsilon$$

where $\varepsilon = \hbar^2k^2/m$ is the energy of the nucleon pair's relative motion after the collision, determines

$$\hbar^2q^2_{\min} = (P_f - P_i)^2 \approx \frac{1}{V^2}(\varepsilon+\varepsilon_0)^2$$

Integrating over q^2 within the limits $q^2_{\min}$ and [383] $q^2_{\max} \approx \kappa^2$, we find

$$d\sigma_{fis} = \frac{8\left(Ze^2\right)^2\left(\varepsilon_0\varepsilon^3\right)^{1/2}}{3m\left(\varepsilon+\varepsilon_0\right)^4V^2}\ln\frac{\hbar^2\kappa^2V^2}{\left(\varepsilon+\varepsilon_0\right)^2}d\varepsilon \tag{4}$$

As is seen, the characteristic value of energy is $\varepsilon \sim \varepsilon_0$. The integration of Eq. (4) over ε gives the total cross-section of deuteron electro-fission. With logarithmic accuracy, we can neglect the dependence on ε under the logarithm and obtain (making the substitution $x = \sqrt{\varepsilon}$; see App.1.5)

[383] Note that for larger values of q it is necessary to take into account the finiteness of nucleon size, whose form-factor decreases fast for $q > 1/R$. Since $q^2_{\max}$ in the final result is inside a logarithm, its detailed value is not so important.

$$\sigma_{fis}(E) \approx \frac{\pi \left(Ze^2\right)^2}{6\varepsilon_0 E} \ln \frac{E}{\varepsilon_0} \tag{5}$$

where $E = m_d V^2/2$ is the deuteron energy.
According to Eq. (5), the value of the cross-section for $E = 200\text{MeV}, \varepsilon_0 = 2.2$ MeV is $\sigma_{\text{fis}} = 1.1 \cdot 10^{-28} Z^2$ cm^2. For all nuclei except for perhaps the heaviest, this quantity is much lower than their geometric size, which shows that the dominant role in the process of deuteron fission is nuclear interaction.

We also note a quasi-classical estimation of the fast deuteron fission cross-section accompanied by the escape of one of the nucleons, a proton or a neutron, for a collision with a nucleus with radius R. Considering the potential to be a hard sphere of radius R:

$$\sigma \sim 2\pi R \Delta R, \quad \Delta R \sim R_d \sim \frac{1}{\kappa} \tag{6}$$

This area is that of a ring with radius R and width of the order of the deuteron size.
In conclusion, we note that each escaping nucleon takes away the energy $E_N \approx E/2$ and moves in the direction of the falling beam with the angle of dispersion $\Delta\theta \sim (\varepsilon_0/E)^{1/2}$ (the transverse component of the nucleon momentum $p_\perp \sim \sqrt{m\varepsilon_0}$ is determined by the binding energy of the deuteron).

GKKG.13.84

Find the asymptotic behavior of the electric form-factor of a two-particle system as $q \to \infty$. It is assumed that the Fourier component of the interaction potential, $\tilde{U}(q)$, that is responsible for the formation of the composite system, has a power-law decay at $q \to \infty : \tilde{U}(q) \propto q^{-n}$ with $n > 1$. Compare to Problem 4.18. Consider applications of the results obtained to the hydrogen atom.

Solution

The electric form-factor for the transition between states ψ_1 and ψ_2 of a twoparticle composite system is described by the following expression (see, for example, Problem 13.80):

$$eF_{1\to 2}(\mathbf{q}) = \langle n_2 l_2 l_{2z}| \, e_1 e^{-i\mathbf{q}\cdot\mathbf{r}_1} + e_2 e^{-i\mathbf{q}\cdot\mathbf{r}_2} \, |n_1 l_1 l_{1z}\rangle \tag{1}$$

where $e_{1,2}$ and $m_{1,2}$ are the charges and masses of the particles, $\hbar\mathbf{q}$ is the momentum transferred between systems, and $\mathbf{r}_{1,2}$ are their radius vectors in the center-of-inertia system. Here,

$$\mathbf{r}_1 = \frac{m_2}{m_1 + m_2}\mathbf{r}, \quad \mathbf{r}_2 = -\frac{m_1}{m_1 + m_2}\mathbf{r}, \quad \mathbf{r} = \mathbf{r}_1 - \mathbf{r}_2$$

Eq. (1) includes two integrals:

$$I\left(\mathbf{q}_{1,2}\right) = \int \psi^*_{n_2 l_2 l_{2z}}(\mathbf{r}) \exp\left\{-i\mathbf{q}_{1,2}\mathbf{r}\right\} \psi_{n_1 l_1 l_{1z}}(\mathbf{r}) d^3 r \tag{2}$$

where $\mathbf{q}_{1,2} = \pm m_{2,1}\mathbf{q}/\left(m_1 + m_2\right)$. The asymptotes of these integrals for $q \to \infty$ are determined by the singular terms of the radial wavefunctions in $\psi_{1,2}$ (see Problem 4.18). Let us write

$$\psi_{nll_z}(\mathbf{r}) = \varepsilon_{i\ldots n}\left(l, l_z\right) x_i \ldots x_n \left\{\tilde{R}_{reg}(r) + \tilde{R}_{sin}(r)\right\}$$

where $\tilde{R}_{reg}(r)$ and $\tilde{R}_{sin}(r)$ are the regular and singular parts of the radial function. Remember that the regular part could be expanded into a series over even, $\left(r^2\right)^s$, powers of the variable r, and $\tilde{R}_{reg}(0) \neq 0$, while $\tilde{R}_{\text{sin}}\left(0\right) = 0$. To obtain the asymptote of integral (2), take one of the radial functions at $r = 0$, and keep the singular part of the other, so that

$$\begin{aligned} & I(\mathbf{q})_{q} \to \infty \\ & \approx \varepsilon^*_{i\ldots n}(2)\varepsilon_{s\ldots l}(1) i\frac{\partial}{\partial q_i} \ldots i\frac{\partial}{\partial q_n} i\frac{\partial}{\partial q_s} \ldots i\frac{\partial}{\partial q_l} \times \\ & \times \left\{\tilde{R}_{2reg}(0) \int e^{-i\mathbf{q}\cdot\mathbf{r}} \tilde{R}_{1\,\text{sin}}(r) d^3 r + \tilde{R}_1(0) \int e^{-i\mathbf{q}\cdot\mathbf{r}} \tilde{R}_2 \sin(r) d^3 r\right\} \end{aligned} \tag{3}$$

The singular part for both radial functions is very small for $r \to 0$, and does not effect the leading asymptotic term of the expansion $I(q)$ for $q \to \infty$. The integrals here are connected to the asymptotes of wavefunctions in the momentum representation. According to Problem 4.18, we have:

$$\frac{\hbar^2 q^2}{2\mu}\hat{D}\int e^{-i\mathbf{q}\cdot\mathbf{r}}\tilde{R}_{sin}(r)d^3r \underset{q\to\infty}{\approx} -\tilde{R}(0)\hat{D}\int e^{-i\mathbf{q}\cdot\mathbf{r}}U(r)d^3r \tag{4}$$

where the differential operator $\hat{D} = \varepsilon_{i\ldots n}\,(l, l_z)\,\partial/\partial q_i \ldots \partial/\partial q_n$, and μ is the reduced mass of the particles.

Eqs. (3) and (4) determine the asymptote of integral (2), and the asymptote of form-factor (1) for $q \to \infty$. In particular, for a transition between the states with the angular momenta $l_1 = 0$ and $l_2 = l$, we find:

$$eF_{0\to 1m} \approx -8(2i)^l \pi^{5/2}\frac{\mu}{\hbar^2}\tilde{R}_1(0)\tilde{R}_2(0)Y^*_{lm}\left(\frac{\mathbf{q}}{q}\right)\times$$
$$\times\left\{e_1\left[q_1^l\frac{\partial^l}{\partial\,(q_1^2)^l}\frac{\tilde{U}\,(q_1)}{q_1^2} + q_1^{l-2}\frac{\partial^l}{\partial\,(q_1^2)^l}\tilde{U}\,(q_1)\right] + (-1)^l e_2\,[q_1 \to q_2]\right\} \tag{5}$$

where the symbol $[q_1 \to q_2]$ means the expression written in the first square bracket, but with q_1 replaced by q_2, and

$$\tilde{U}(q) = \frac{1}{(2\pi)^3}\int U(r)e^{-i\mathbf{q}\cdot\mathbf{r}}d^3r$$

Note that the power-law decrease of the form-factors for $q \to \infty$ is similar to that mentioned in Problem 4.18 in connection with the asymptotes of the wavefunctions
in the momentum representation. In particular, for potentials such that $\tilde{U} \approx -\alpha/q^n$ with $n > 1$, the form-factor is

$$F_{1\to 2} \propto q^{-(2+n+l_1+l_2)} \text{ for } q \to \infty \tag{6}$$

To illustrate the result obtained, we consider the application of Eq. (5) to the hydrogen atom. In the approximation of an infinitely heavy nucleus, Eq. (5) must be slightly revised by simply putting $q_2 \equiv 0$. So, the term $e_2 e^{-i\mathbf{q}\cdot\mathbf{r}_2}$ in Eq. (1), which corresponds to the proton contribution, is now reduced to just its charge e, and inelastic transitions give no contribution to the form-factor due to the wavefunctions' orthogonality. Taking into account that for the Coulomb potential, $\tilde{U} = -e^2/2\pi^2 q^2$, and using the values of the radial functions at zero for this potential (given in Problem 13.79), we find for the transitions $1s \to ns$ and $1s \to np$ with $n \geq 2$:

$$F_{1s\to ns} \approx -\frac{16}{n^{3/2}\,(qa_B)^4}, \quad F_{1s\to npm} \approx \frac{16\sqrt{3}i\sqrt{n^2-1}\,(\varepsilon^*(m)\cdot\mathbf{q}/q)}{n^{5/2}\,(qa_B)^5}$$

These results, of course, coincide with the asymptotes of the exact expression for the form-factor, calculated in Problem 13.80.

GKKG.13.85

Find the differential and total cross-sections of Coulomb excitation of an atomic nucleus (initially in a state with the angular momentum, $J = 0$) by a fast, light, charged particle by a) dipole ($E1-$) and b) monopole ($E0-$) nuclear transition.

Solution

Just as in the previous problems, the sought-after cross-sections could be related to nuclear electric form-factors $F_{i\to f}(\mathbf{q}) = \langle f|\sum_p e^{-i\mathbf{q}\cdot\mathbf{r}_p}|i\rangle$ for the corresponding transitions. Summation is performed over all nuclear protons; $\mathbf{r}_p$ are their radius-vectors with respect to the nucleus' center of mass.

For non-relativistic collisions between the light particle and the nucleus, there holds the inequality $qr_p \leq pR/\hbar \ll 1$ (where R is the nucleus radius, and $p = mV$ is the incident particle momentum), so that in the expression for the form-factor, we can expand the exponent and keep only the first non-zero term. The differential cross-sections of the processes considered are $d\sigma_{E1}/dq^2 \propto q^{-2}$ and $d\sigma_{E0}/dq^2 = \text{const}$, while the total cross-sections are

$$\sigma_{E1} = \frac{8\pi e^2}{\hbar^2 V^2}\left|\langle J = 1, J_z = 0|\,d_z\,|0\right\rangle\right|^2 \ln\frac{p+p'}{p-p'} \tag{1}$$

(the cross-section is summed over projections of the angular momentum of the p-state; though the state has $J_z = 0$, we should take into account that the choice of the

[384] Assume that the (electron, muon) Compton wavelength $\hbar/mc$ is larger than the nuclear size, and the particle charge is $\pm e$.
quantization axis z along the vector $\mathbf{q}$ depends on the scattering angle; compare to Problem 13.80) and

$$\sigma_{E0} \approx \frac{4\pi}{9}\left(\frac{me^2}{\hbar^2}\right)^2 \frac{p'}{p}\,|Q_0|^2\,, \quad Q_0 = \langle f|\sum_p r_p^2|i\rangle \tag{2}$$

(parameter Q_0 also determines the probability of inner conversion for the corresponding nuclear transition; see Problems 11.68 and 11.69). In these relations, p' is the particle momentum after collision.

GKKG.13.86

Find a relation between the amplitudes and differential cross-sections for elastic scattering of a neutron on a proton and of a proton on a hydrogen atom (in the ground state). Neglect the interaction of the neutron magnetic moment with the electron.

Solution

Due to the smallness of the nuclear-force radius, the time of interaction between the proton and neutron is much smaller than the characteristic atomic time. So for the electron, the result of the interaction between the neutron and proton could be considered as a sudden change resulting in the velocity boost $\mathbf{V} = \hbar\mathbf{q}/m_p$ for the proton-nucleus. Therefore, the following relation between the amplitudes of the processes considered follows:

$$f_{nH}(E,q) \approx f_{np}(E,q)a(q) \tag{1}$$

where

$$a(q) = \int |\psi_0(r)|^2 \exp\left\{-\frac{i}{\hbar}m_e\mathbf{V}\cdot\mathbf{q}\right\} d^3r = \frac{1}{\left[1+(qm_e a_B/2m_p)^2\right]^2} \tag{2}$$

is the probability amplitude for the atom to remain in the ground state. (Compare to Problem 11.58; we note that $a(q)$ coincides with the atomic form-factor; see 13.80.)

Since $a(0) = 1$, then, using the optical theorem and relation (1), we conclude that the total cross-sections of the neutron scattering from a proton and from a hydrogen atom are the same. [385] As is seen from Eqs. (1) and (2), the differential cross-sections, $d\sigma/d\Omega = |f|^2$, start to differ only for $qa_B \gtrsim m_p/m_e$, which corresponds to neutron energies that are much larger than atomic (since $\hbar q \le 2p$).

GKKG.13.87

Find the scattering cross-section for heavy charged particles (for example, protons or ions) from neutral atoms with zero angular momentum. The velocities of the scattered particles are assumed to be much lower than the velocities of atomic electrons, but at the same time, $V \gg \hbar/Ma_B$, where M is the particle mass. Use the quasi-classical expression for the scattering cross-section (see Problem 13.51).

Solution

The energy of the interaction between the charged particle and the atom at large distances, $r \gg a_B$, has the form (polarization potential, see Problem 11.49)

$$U(r) = \frac{Ze(\mathbf{d}\cdot\mathbf{r})}{2r^3} = -\frac{1}{2}\beta\frac{(Ze)^2}{r^4} \tag{1}$$

where Ze is the particle charge, and β is the atomic polarizability. The calculation of the scattering cross-section by quasi-classical equation (see Problem 13.51)

$$\sigma = 4\pi\int_0^\infty \left\{1-\cos\left[\frac{1}{\hbar v}\int_{-\infty}^{\infty} U\left(\sqrt{\rho^2+z^2}\right)dz\right]\right\}\rho d\rho \tag{2}$$

for a power-law potential was performed in Problem 13.52. For polarization potential (1), it gives

[0][385] It is important that $m_H \approx m_p$. A completely different situation arises for neutron scattering from a proton bound in a molecule. In the case of a heavy molecule, $M \gg m_p$, the scattering cross-section for small energies from the bound proton is four times larger than the scattering cross-section from a free nucleon.

$$\sigma = \pi\Gamma\left(\frac{1}{3}\right)\left(\frac{\pi\beta Z^2 e^2}{4\hbar v}\right)^{2/3} \tag{3}$$

Let us make several comments about this result. As it follows from (3), distances essential in the scattering process are of the order $\rho_0 \sim \sqrt{\sigma} \sim v^{-1/3}$ (in atomic units), and we put $Z \sim 1$ and $\beta \sim a_B^3$ (such estimation follows from the condition that for $\rho \sim \rho_0$, the argument of the cosine, i.e., the quasi-classical phase, is of order 1 ; let us note that for $r \leq a_B$, Eq. (1) is not applicable, but in the problem conditions such distances do not play an essential role). To be able to use Eq. (1), these distances must be large, $\rho_0 \gg 1$, hence $v^{1/3} \ll 1$. (The condition, $\rho_0/v \gg \omega_{\text{at}}^{-1}$, that ensures the adiabaticity of the atomic electrons, is also fulfilled; when it is broken, dynamic excitation processes become essential for the atom, and the notion of an interaction potential loses its strict meaning.) On the other hand, the quasi-classical condition must also be fulfilled: $l \sim N\rho_0 v \gg 1$, so $v^{2/3} \gg 1/M$(M is the mass of the particle considered). So, Eq.(3) is valid if the conditions

$$\left(\frac{m_e}{M}\right)^{3/2} v_{at} \ll v \ll v_{at} \tag{4}$$

are fulfilled. Hence, the particle must be heavy, $M \gg m_e$ (for electrons, Eq. (3) is not applicable).

GKKG.13.88

Find the charge-exchange cross-section [386] for the collision of a slow, $v \ll v_{at}$, negative ion, A^-, with its atom, A. Consider the atom and ion to be in their S-states, and the ion's valence electron to be weakly bound (see Problem 11.28). The relative motion of atom and ion should be treated quasi-classically.

Solution

The specifics of the situation involving a resonant charge-exchange process, for the relative velocity of colliding particles $1/\sqrt{M} \ll v \ll 1$ (in atomic units, M is mass of atom or ion), is determined by following facts. 1) The charge-exchange cross-section is large, $\sigma_{\text{non-rez}} \gg \pi a_B^2$, i.e., large impact parameters are essential. 2) The atom's and ion's relative motion is quasi-classical, and we can only straight ballistic trajectories, since $Mv^2 \gg 1$.3) States of the "inner" electrons of the atom and ion do not change in the collision process, while the outer-shell electron can be viewed as being in the field of two zero-range potentials. 4) Due to the adiabaticity of the collision process (for the electron subsystem), only transitions between levels that are close in energy matter, that represent, the even (g) and odd (u) states of the quasi-molecular ion. Recall that for $R \to \infty$, these states are degenerate in energy. With decrease of distance, to $R_c = 1/\alpha$, the odd term goes to the continuous spectrum, and ionization becomes possible (see Problem 11.28). But during the process of charge-exchange, distances which are much larger than R_c are essential.

In the conditions mentioned, the wavefunction of the outer-shell electron for large distances $\mathbf{R}(t) = \boldsymbol{\rho} + \mathbf{v}t$ between atoms has the form:

$$\psi(r, \mathbf{R}, t) \approx \frac{1}{\sqrt{2}}\left\{\exp\left\{-i\int\limits_{-\infty}^{t} E_g dt\right\}\psi_g + \exp\left\{-i\int\limits_{-\infty}^{t} E_u dt\right\}\psi_u\right\} \tag{1}$$

where $E_{g,u}(R)$ and

$$\psi_{g,u} \approx \frac{1}{\sqrt{2}}\left\{\psi_0\left(\mathbf{r} - \frac{\mathbf{R}}{2}\right) \pm \psi_0\left(\mathbf{r} + \frac{\mathbf{R}}{2}\right)\right\}$$

are the energy and wavefunction of the even (odd) molecular terms on such distances, while $\psi_0(r)$ is the wavefunction of a bound state in an isolated zero-range potential (see Problem 4.10). Coefficients in the superposition, (1), were chosen so that for $t \to -\infty$, the wavefunction has the form $\psi \approx C(t)\psi_0(\mathbf{r} - \mathbf{R}/2)$, i.e., describes an electron, localized in the vicinity of one atom, which corresponds to the ion before collision. So for $t \to +\infty$, the coefficient in front of the wavefunction $\psi_0(\mathbf{r} + \mathbf{R}/2)$ determines the probability of charge-exchange:

[386] Compare to the charge-exchange cross-section in the collision between a slow proton and a hydrogen atom.

$$W_{ch-ex}(\rho) = \sin^2\left[\int\limits_{-\infty}^{\infty}\left(E_u(R) - E_g(R)\right)\frac{dz}{2v}\right] \tag{2}$$

$\left(R^2 = \rho^2 + z^2, z = vt\right)$; here the charge-exchange cross-section is

$$\sigma_{ch-ex}(v) = \int_0^\infty 2\pi\rho W_{ch-ex}(\rho)d\rho \tag{3}$$

Compare Eqs. (2) and (3) to the expression for the elastic scattering cross-section from a potential, $U(r)$, in the quasi-classical approximation, as considered in Problem 13.51.

According to Problem 11.28, at large distances, $E_u - E_g \approx 2\alpha e^{-\alpha R}/R$, where $\varepsilon_{\text{bind}} = \alpha^2/2$ is the binding energy of an electron in the ion. Writing

$$e^{-\alpha R} \approx \exp\left\{-\alpha\rho\left(1+\frac{z^2}{2\rho^2}\right)\right\}$$

we find that the integral in Eq. (2) in the case $\alpha\rho \gg 1$ is equal to

$$I(\rho) \approx \sqrt{\frac{2\pi\alpha}{\rho}}\frac{1}{v}e^{-\alpha\rho}$$

Due to its pronounced dependence on ρ, the argument of the sine in Eq. (2) decreases rapidly with an increase in ρ. Thus, the dominant contribution to integral (3) is in the region of impact parameter $\rho \leq \rho_0$ (where $I(\rho_0) = 1$), where the rapidly oscillating factor $\sin^2 I(\rho)$ could be replaced by its mean value, equal to 1/2. This gives

$$\sigma_{ch-ex}(v) \approx \frac{1}{2}\pi\rho_0^2 \approx \frac{\pi}{2\alpha^2}\ln^2\left[\frac{\alpha}{v}\sqrt{\frac{2\pi}{\ln\sqrt{2\pi\alpha^2/v^2}}}\right] \tag{4}$$

Note that the value ρ_0 satisfying equation $I(\rho_0) = 1$, which is convenient to write in the form $\ln I(\rho_0) = 0$, can be obtained by successive iterations. The first iteration gives $\alpha\rho_0 = \ln(\sqrt{2\pi}\alpha/v)$

Finally, we emphasize that the large value of the charge-exchange cross-section in Eq. (4) is due to the fact that for a weakly-bound electron, $\alpha \ll 1$.

GKKG.13.89

For the collision of identical atoms, one of which is in the ground state while the other is in an excited state (these states are connected by a dipole transition), estimate the interaction cross-section and, in particular, the excitation transfer cross-section. Consider the atoms' angular momenta to be equal to 0 and 1. The velocity of the atoms' relative motion is assumed to be small in comparison to the characteristic
atomic velocity, while the energy, on the other hand, is assumed to be much larger than atomic. Compare to the previous problem.

Solution

An important property of the process considered, that leads to a large excitation transfer cross-section (as well as to a large elastic scattering cross-section) is the neardegeneracy of the states corresponding to an excitation of one of the identical atoms if the distance between them is large. Therefore, for slow collisions, transitions between the close-in-energy states appear if the impact parameter is large enough. Interaction between the atoms, which has a dipole-dipole nature, was discussed in Problem 11.55. In comparison to the previous problem, here the difficulty arises due to an increase in the number of states: there are three g-terms and three u-terms. These are independent states corresponding to different polarizations of the excited atom (with the angular momentum $l = 1$).

One such state, which corresponds to the projection of the angular momentum $l_z = 0$ of the excited atom with the angular momentum $l = 1$, evolves independently of the other two. Here, as well as in the previous problem, the translational motion of atoms is considered quasi-classically in the approximation of a straight-line trajectory, and axis z is chosen perpendicular to the plane of motion. For this state, $U_{g,u} = \pm d^2/\left(3R^3\right)$ (see Problem 11.55), and calculation of the excitation transfer cross-section could be performed by Eqs. (2) and (3) from Problem 13.88. Calculating the integral

$$\int_{-\infty}^{\infty}\left[U_g(R) - U_u(R)\right]\frac{dz}{2v} = \frac{d^2}{3v}\int_{-\infty}^{\infty}\frac{dz}{\left(\rho^2+z^2\right)^{3/2}} = \frac{2d^2}{3\rho^2 v}$$

just as in the previous problem, we find the excitation transfer cross-section with $l_z = 0$:

$$\sigma_0 = \int_0^\infty 2\pi\rho\sin^2\left(\frac{2d^2}{3\rho^2 v}\right)d\rho = \frac{2\pi d^2}{3v}\int_0^\infty \sin^2 x\frac{dx}{x^2} = \frac{\pi^2 d^2}{3v} \tag{1}$$

As stated in the problem condition, it much exceeds the atomic length-scales (remember that $v \ll 1$).

For the two other polarized states of the excited atom (with $l_z = \pm 1$, or with $l_{x,y} = 0$; see Problem 3.21 and also Problem 3.41), calculation of the excitation transfer cross-section needs to rely on numerical methods. Note that in this case, transitions appear between such states, i.e., in the process of excitation transfer, the atom polarization may change. Diagonalization of the "instantaneous" Hamiltonian (performed in Problem 11.55) is based on the choice of a quantization axis along the direction, which passes through the atoms' centers. But due to their motion, the corresponding "rotating" system is non-inertial. Going to this rotating system gives rise to the following additional term in the Hamiltonian:

$$\hat{V}_{\text{cor}} = -\hat{\mathbf{\Omega}} \cdot \hat{\mathrm{l}} = -\frac{1}{I}\hat{L}_z\hat{l}_z = -\frac{v\rho}{R^2}\hat{l}_z$$

This is the Coriolis interaction, [387] (compare to Problem 6.29). The Coriolis operator does not commute with the operators of the "instantaneous" Hamiltonian, and this leads to transitions between the eigenstates, except for the case of $l_z = 0$ mentioned above. As for the estimation of the excitation transfer cross-section, it is evident that, as in Eq. (1), it is of order $\sigma \sim \pi d^2/v$.

GKKG.13.90 Elastic and inelastic scattering on black sphere

Find the total cross-section σ_{tot}, elastic cross-section σ_{el}, and inelastic cross-section σ_{in}, for the scattering of fast particles, $kR \gg 1$, from an absorbing ("black") sphere of radius R. Find also the differential cross-section of elastic scattering. Compare to Problems 13.57 and 13.58.

Hint: Use quasi-classical ideas to describe particle motion. Assume that all particles that reach the surface of the sphere are absorbed by it.

Solution by Kiselev

(У него это смотрел, возникнет вопрос - в первую очередь его и буду изучать)

Solution

Since we are dealing with a fully-absorbing "black" sphere, all scattering phases in Eq. $f(k,\theta) = \sum_{l=0}^{\infty}(2l+1)\varphi_l(E)P_l(\cos\theta)$; $\varphi_l = \frac{e^{2i\delta_l}-1}{2ik} = \frac{1}{k(\cot\delta_l - i)}$ for the amplitude of elastic scattering are the same: $\delta_l = i\infty\left(e^{2i\delta_l} = 0\right)$ for $l < l_0 = kR$ and $\delta_l = 0$ for $l > l_0$. Such values of δ_l correspond to the following physical picture (particle motion is quasi-classic, since $kR \gg 1$): particles with impact parameter $\rho = l/k < R$ are "absorbed" by the sphere, while those with $\rho > R$ move freely. Elastic scattering by its physical nature is analogous to Fraunhofer diffraction on an opaque screen (in this case, a fully absorbing screen). It is described by the scattering amplitude (compare to Problem 13.57)

$$f_{difr} = \frac{i}{2k}\sum_{l=0}^{l_0}(2l+1)P_l(\cos\theta) \approx \frac{iR}{\theta}J_1(kR\theta), \quad \theta \ll 1 \tag{1}$$

Using the optical theorem, we find total collision cross-section

$$\sigma_{tot} = \frac{4\pi}{k}\,\mathrm{Im}\, f_{difr}(\theta = 0) = 2\pi R^2 \tag{2}$$

The inelastic scattering cross-section (the absorption cross-section) is equal to

$$\sigma_{\text{inel}} = \frac{\pi}{k^2}\sum_{l=0}^{\infty}(2l+1)\left(1 - |S_l|^2\right) = \frac{\pi}{k^2}\sum_{l=0}^{l_0}(2l+1) \approx \pi R^2 \tag{3}$$

while the elastic scattering cross-section is

$$\sigma_{el} = \sigma_{tot} - \sigma_{inel} \approx \pi R^2 \tag{4}$$

of inertia with respect to the center of mass. In the quasi-classical approximation, the operator $\hat{\mathbf{L}}$ could be replaced by the only non-zero component $L_z = \mu\rho v$.

This result is obtained by direct calculation of

$$\sigma_{el} = \int |f_{difr}|^2\, d\Omega = \pi R^2$$

just as in Problem 13.57.

GKKG.13.91

Interaction between an electron and a positron may result in their mutual annihilation, i.e., their conversion into a pair into photons. Because of this, positronium levels have a width, connected to the finite lifetime of the states (see Problem 11.61).

Find a relation between the level width, Γ_{ns}, for the s-states of positronium and the annihilation cross-section of a pair, $\sigma_{an}(v)$.

Hint: Taking into account the fact that the annihilation interaction radius is small, $R_{an} \sim \hbar/m_e c \ll a_B$, use perturbation theory in terms of the scattering length for the level shift and for the phase shift. See Problems 13.36 and 13.37.

Solution

Note that in the non-relativistic case, $kR_{an} \ll 1$. Thus annihilation processes are most important for the s-states. The effect of short-range interaction on an s-state is described by only one parameter: $a_0^{(S)}$, the scattering length (for the angular momentum, $l = 0$) of an isolated center (see Problems 13.36 and 13.37). For inelastic processes, the (annihilation) scattering length has a non-zero imaginary part. So, the level shift (see Problem 13.36) has an imaginary part, which determines the level width:

$$\Gamma_{ns} = -2\,\mathrm{Im}\,\Delta E_{ns} = -\frac{8\pi\hbar^2}{m_e}\left|\psi_{ns}^{(0)}(0)\right|^2 \mathrm{Im}\,a_0^{(S)} \tag{1}$$

Here, we have taken into account that for positronium, the reduced mass is $m = m_e/2$, and $\psi_{ns}^{(0)}(0)$ is the wavefunction at zero for the unperturbed state.

On the other hand, the change of the s-wave phase shift for the Coulomb potential, $U = -e^2/r$, under the influence of a short-range interaction, according to Problem 13.37 is equal to

$$\Delta\delta_0^{(S)}(k) = -\tilde{Q}_{k0}^2 k a_0^{(S)} \tag{2}$$

where

$$\tilde{Q}_{k0}^2 = \frac{\pi}{ka_B\left(1 - \exp\{-\pi/ka_B\}\right)}, \quad \left|\psi_{ns}^{(0)}(0)\right|^2 = \frac{1}{8\pi a_B^3 n^3} \tag{3}$$

and $a_B = \hbar^2/m_e e^2$. (In (3), the fact that the Bohr radius for positronium is twice as large as the atomic Bohr radius has been used.) From the phase shift of the elastic
scattering amplitude (its imaginary part), we find the annihilation cross-section:

$$\sigma_{an} = \frac{\pi}{k^2}\left(1 - |S_0|^2\right) = \frac{\pi}{k^2}\left(1 - \exp\left\{-4\,\mathrm{Im}\,\Delta\delta_0^{(S)}\right\}\right) \approx \frac{4\pi}{k^2}\,\mathrm{Im}\,\Delta\delta_0^{(S)} = \\ = -\frac{4\pi}{k^2}\tilde{Q}_{k0}^2\,\mathrm{Im}\,a_0^{(S)} \tag{4}$$

According to Eqs. (1) and (4), we obtain:

$$\Gamma_{ns} = \hbar\left|\psi_{ns}^{(0)}(0)\right|^2 \frac{1}{\tilde{Q}_{k0}^2}\left(v\sigma_{an}(v)\right) \tag{5}$$

where $v = \hbar k/m = 2\hbar k/m_e$ is the relative velocity of the electron-positron pair. In the case $\hbar v/e^2 \gg 1$, when the Coulomb potential could be considered as a perturbation, relation (5) becomes simpler, since here $\tilde{Q}_{k0}^2 \approx 1$.

In conclusion, we emphasize that both the annihilation cross-section and positronium level widths (and hence their lifetime $\tau = \hbar/\Gamma$) depend strongly on the value of the total electron-positron pair spin (see Problem 11.61), so that the ortho- and para-states of the positronium should be considered separately. Let us also mention that these results could be extended to describe hadron atoms. However, the condition of their applicability assumes that there is no s-level with small binding energy in the strong short-range potential. See Problem 11.4, and also Problem 11.74.

GKKG.13.92

Using the principle of detailed balance, relate the cross-section of neutron radiation capture by a proton, $n + p \to d + \gamma$, and the cross-section of photodisintegration of a deuteron, $d + \gamma \to n + p$

Hint: The relation between cross-sections of mutually inverse two-particle processes, which appear in the principle of detailed balance, is valid in the relativistic region as well. Keep in mind that although the photon spin is equal to 1, it has only two independent polarizations.

Solution

According to the principle of detailed balance for inverse reactions $A \to B$ and $B \to A$, the relation

$$\frac{\bar{\sigma}_{A\to B}}{\bar{\sigma}_{B\to A}} = \frac{g_B p_B^2}{g_A p_A^2} \tag{1}$$

must be satisfied. Here $\bar{\sigma}$ are total cross-sections of the corresponding reactions $A \to B$ and $B \to A$, averaged over the particle spins in the initial state, and summed over the particle spins in the final state; $g_{A,B}$ are the spin statistical weights, and $p_{A,B}$ are the momenta of relative motion in two-particle systems A and B, taken at the same
energy in the center-of-mass system (analogous relations hold not only for the total but also for the differential reaction cross-sections).

In the case of the reactions, $n + p \rightleftharpoons d + \gamma$ we have $\sigma_{A\to B} \equiv \sigma_{\text{cap}}$ (neutron radiation capture cross-section) and $\sigma_{B\to A} \equiv \sigma_{ph}$ (deuteron photodisintegration cross-section). Since the spin (polarization) statistical weight for a particle with spin s is equal to $g_s = (2s+1)$ (except for the photon, for which $g_\gamma = 2$ due to its transverse polarization), then

$$g_A = (2s_p + 1)(2s_n + 1) = 4, \quad g_B = g_\gamma (2s_d + 1) = 6 \tag{2}$$

Momenta $p_{A,B}$ in Eq. (1) are equal to the momenta of the particles in the rest frames of systems A, B. For the reactions considered, $p_A \equiv p_p = p_n$ and $p_0 \equiv p_\gamma = p_d$. Considering all particles to be non-relativistic (except for the photon; for it we have $E_\gamma \ll Mc^2$, where M is the mass of a nucleon), then according to the energy conservation law we obtain

$$E_A = \frac{1}{M} p_A^2 = E_B = E_\gamma + E_d - \varepsilon_0 \approx \hbar\omega - \varepsilon_0$$

We have defined by ε_0 the deuteron binding energy and by ω the photon frequency. We have neglected the value E_d in comparison to E_γ (for a non-relativistic deuteron, $E_d \ll E_\gamma$ for $p_d = p_\gamma$).

Taking into account the fact that $p_\gamma = \hbar\omega/c$, according to Eqs. (1)-(3) we find:

$$\frac{\sigma_{cap}}{\sigma_{ph}} = \frac{3}{2} \frac{\hbar\omega}{Mc^2} \frac{\hbar\omega}{\hbar\omega - \varepsilon_0} \tag{4}$$

Thus, it follows that in the non-relativistic case, $\hbar\omega \ll Mc^2$, we have $\sigma_{ph} \gg \sigma_{\text{cap}}$. The only exception is a narrow region of values $\hbar\omega$ in the vicinity of the reaction $d + \gamma \to n + p$ threshold (here $\hbar\omega \approx \varepsilon_0$), where, conversely, $\sigma_{ph} \ll \sigma_{cap}$.

In conclusion, we emphasize that Eq. (4), as well as Eq. (1), does not rely on any information or assumptions about the mechanism(s) driving the reaction, but is based solely on the symmetry of quantum mechanical equations with respect to time-reversal.

GKKG.13.93

Find the relation between the cross-section of photoelectric effect (a.k.a. "photoeffect") from the ground state of a hydrogen atom and the radiation recombination cross-section of an electron with a proton (the process inverse to photoeffect) into the ground state of a hydrogen atom.

Solution

This problem is solved similarly to the previous one (moreover, the processes considered in these two problems are physically related; see also Problems 14.38 and 14.19). Averaged over the spins, the cross-sections of the photoeffect reaction, $\gamma + H \to e + p$, and the radiation recombination reaction, $e + p \to H + \gamma$, are connected by the relation:

$$\frac{\sigma_{ph}(\omega)}{\sigma_{rec}(\varepsilon_e)} = \frac{p_e^2}{2p_\gamma^2} = \frac{\hbar\omega - |E_0|}{\hbar\omega} \frac{m_e c^2}{\hbar\omega} \tag{1}$$

To prove Eq. (1), we should take into account that first, the center-of-mass frames for these reactions are the rest frames of the hydrogen atom in the ground state [388] or the proton; second, the statistical spin weight is equal to 4 for both the hydrogen atom and the electron-proton system. Finally, the electron and photon energies are connected by the energy conservation law as follows:

$$\hbar\omega + E_0 = \varepsilon_e = \frac{1}{2m_e} p_e^2$$

where E_0 is the energy of the hydrogen atom in the ground state.

[388] Here we neglect the hyperfine structure of the hydrogen atom (see Problem 11.2). Let us also note that for processes involving the hydrogen atom in a state with the angular momentum, l, the "spin" statistical weight is equal to $4(2l + 1)$.

17.5.3 Questions on Understanding Typical Details

Van-Riet. Commutator $[x, p]$ (????)

Let's consider $\langle p|[\hat{p}, \hat{x}]|p\rangle$. If we write

$$\langle p|[\hat{p}, \hat{x}]|p\rangle = \langle p|(\hat{p}\hat{x} - \hat{x}\hat{p})|p\rangle = (\langle p|\hat{p})\hat{x} - \hat{x}(\hat{p}|p\rangle) = p\hat{x} - p\hat{x} = 0$$

But also

$$\langle p|[\hat{p}, \hat{x}]|p\rangle = \langle p|(-i\hbar)|p\rangle = -i\hbar$$

Why?

Solution.

(напишу потом, важно понимать, что с.з. не эрмитовых матриц не переставляются, как в 1 случае. про это же строчка в 1й части.)

me. Bound and not Bound States

In 1D and in 2D, if there is an infinitesimal attraction, there ia a bound state. But in 3D, even though there is an equation for a radial motion, which has only one parameter, there is no bound state if the potential is not large enough. Why?

Solution.

One can say that there is an effective potential, thus for the radial equation there will be a different equation. But for the harmonic $l = 0$, there is no it, so the question remains.

(?? one can somehow use variational theorem, and see that there is not enough potential energy for a kinetic energy. (??? I'll try later. Don't know at the moment, how))

Answer is that the radial 3D Schrodinger equation is written for function $u(x)$, which is a part of the whole wavefunction $\psi(r) = u(r) \cdot r$ (?? check!!). Thus, the wavefunction will have a node in the center and it first grows fast (????), thus, there should ba a strong potential, to make it decreasing.

(point out that it will play an important role in discussing superconductivity)

ПТФ-3.y1 Вероятности по волновой функции (??)

Состояние трёхмерной частицы описывается нормированной волновой функцией $\psi(x, y, z)$. Какова вероятность того, что частица находится в интервале $z_1 < z < z_2$, а её импульс при этом - в интервале $p_1 < p_y < p_2$?

Solution.

$$\Psi(x, p_y, z) = \int\limits_{-\infty}^{\infty} dy e^{-\frac{ip_y y}{\hbar}} \psi(x, y, z)$$

$$\rho = |\Psi(x, p_y, z)|^2 = \left| \int\limits_{-\infty}^{\infty} dy e^{-\frac{ip_y y}{\hbar}} \psi(x, y, z) \right|^2$$

$$P = \int\limits_{-\infty}^{\infty} \int\limits_{p_1}^{p_2} \int\limits_{z_1}^{z_2} dx \frac{dp_y}{2\pi\hbar} dz \rho = \int\limits_{-\infty}^{\infty} \int\limits_{p_1}^{p_2} \int\limits_{z_1}^{z_2} dx \frac{dp_y}{2\pi\hbar} dz \left| \int\limits_{-\infty}^{\infty} dy e^{-\frac{ip_y y}{\hbar}} \psi(x, y, z) \right|^2$$

(?? как это связано с соотношением неопредленности? если так думать про в.ф., то будет ли оно выполняться?)

17.5.4 Typical Problems on Testing Knowledge of Quantum Models

17.5.5 Problems about Understanding States, Entanglement Measurements (???)

(это же в кв теор инфо. тут много всего будет потом)

ПТФ-2.з.? Отличие классической запутанности от квантовой

Есть две системы: $\hat{\rho}_{AB} = |\psi_{AB}\rangle\langle\psi_{AB}| = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$ и $\hat{\rho}_{AB} = \frac{1}{2}\left(\hat{\mathbb{P}}_{\uparrow\downarrow} + \hat{\mathbb{P}}_{\downarrow\uparrow}\right) = \frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$. Придумайте эксперимент, который мог бы их различить, если мы можем наблюдать только A ее часть.

Solution..

(нужно переучивать измерения, пока я не знаю это)
Экспериментатор C должен смотреть на результаты от первой и второй системы, далее посчитать среднее какого-то оператора в случае первой и второй системы.
так как в общем виде оно имеет вид

$$\langle O\rangle = \mathrm{Tr}(\hat{\rho}\hat{O}) = \underbrace{\sum_n \rho_{nn}\langle O\rangle_n}_{\text{classical statistics}} + \underbrace{\sum_{m\neq n} \rho_{nm}\langle m|\hat{O}|n\rangle}_{\text{quantum interference terms}} ,$$

то одина система даст только первое слагаемое, а вторая - что-то большее.
таким образом, система, у которой среднее значение оператора больше - квантовая.

ПТФ-2.у2. (10 б). Отличие запутанности от распутанности

Предположим, наблюдатель C хочет придумать эксперимент, который сможет отличить состояние «ЭПР» от классически запутанного («Носки») (из семинара). Какую наблюдаемую ему нужно придумать? Выразите её через матрицы Паули (и их тензорные произведения)?

Solution.

Наблюдаемая – гамильтониан из задачи 2 семинара 1:

$$\hat{H} = -J(\hat{\sigma}_1^x \otimes \hat{\sigma}_2^x + \hat{\sigma}_1^y \otimes \hat{\sigma}_2^y + \hat{\sigma}_1^z \otimes \hat{\sigma}_2^z)$$

Для “ЭПР”:

$$\mathrm{tr}(\hat{\rho}_{AB}\hat{H}) = \mathrm{tr}\left(\frac{J}{2}\begin{pmatrix}0&0&0&0\\0&1&1&0\\0&1&1&0\\0&0&0&0\end{pmatrix}\begin{pmatrix}1&0&0&0\\0&-1&2&0\\0&2&-1&0\\0&0&0&1\end{pmatrix}\right) = \mathrm{tr}\left(\frac{1}{2}\begin{pmatrix}0&0&0&0\\0&1&1&0\\0&1&1&0\\0&0&0&0\end{pmatrix}\right) = J$$

Для “Носок”:

$$\mathrm{tr}(\hat{\rho}_{AB}\hat{H}) = \mathrm{tr}\left(\frac{J}{2}\begin{pmatrix}0&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&0\end{pmatrix}\begin{pmatrix}1&0&0&0\\0&-1&2&0\\0&2&-1&0\\0&0&0&1\end{pmatrix}\right) = \mathrm{tr}\left(\frac{J}{2}\begin{pmatrix}0&0&0&0\\0&-1&2&0\\0&2&-1&0\\0&0&0&0\end{pmatrix}\right) = -J$$

Как видно, следы не совпадают. Искомая наблюдаемая:

$$\hat{H} = -J(\hat{\sigma}_1^x \otimes \hat{\sigma}_2^x + \hat{\sigma}_1^y \otimes \hat{\sigma}_2^y + \hat{\sigma}_1^z \otimes \hat{\sigma}_2^z)$$

О3.1-1.1(1 мин) Импульс фотона

Найти импульс фотона видимого света ($\lambda = 500$ нм). Сравнить его с импульсом молекулы водорода при комнатной температуре.

1.

1. Импульс фотона $p = \frac{\hbar\omega}{c} = \frac{2\pi\hbar}{\lambda} \approx 1,3 \cdot 10^{-22}\Gamma \cdot \text{с/с}$. Среднеквадратичный импульс молекулы водорода $p = \sqrt{3kTM} \approx 5,4 \cdot 10^{-19}\Gamma \cdot \text{ см/с}$.

О3.1-1.2(1 мин) импульс фотона

При какой длине волны импульс фотона равен импульсу молекулы водорода при комнатной температуре?

1.

2. $\lambda \approx 0,12\text{НМ}$.

О3.1-1.3(2 мин) поток фотонов (!???!?!??!?)

Излучение гелий-неонового лазера мощностью $W = 1$ мВт сосредоточено в пучке диаметром $d = 0,5\text{см}$. Длина волны $\lambda = 0,63$ мкм. Определить плотность потока j фотонов в пучке.

1.

3. $j = \frac{2W\lambda}{\hbar c\pi^2 d^2} \approx 1,7 \cdot 10^{16} \frac{\text{фотон}}{\text{с}^2 \cdot \text{с}}$.

О3.1-1.4 Проверяем ОТО (???)

Согласно общей теории относительности энергия любого объекта в статическом гравитационном поле $\mathscr{E} = \mathscr{E}_0 \left(1 + 2\varphi/c^2\right)^{-1/2}$, где $\mathscr{E}_0$-энергия объекта в «пустом» (т. е. свободном от гравитационных полей) пространстве, а φ - гравитационный потенциал в точке нахождения объекта. Показать на основе этого соотношения, что разница энергий $\Delta\mathscr{E} = \mathscr{E}_2 - \mathscr{E}_1$ между двумя состояниями объекта, расположенного на поверхности Земли и на высоте от нее, оказывается эквивалентной разнице «гравитационных энергий» излученного объектом γ-кванта с энергией $\mathscr{E}_\gamma = \mathscr{E}_2 - \mathscr{E}_1$ и массой $m_\gamma = \mathscr{E}_\gamma/c^2$, как это было показано в опытах Паунда и Ребки с помощью эффекта Мессбауэра.

1.

4*: Решение. Рассмотрим атом (ядро) в статическом гравитационном поле. Согласно условию задачи разность энергий $\Delta\mathscr{E}$ между основным и возбужденным состоянием зависит от положения атома (ядра) в гравитационном поле Земли

$$\Delta\mathscr{E} = \mathscr{E}_2 - \mathscr{E}_1 = \left(\mathscr{S}_2^0 - \mathscr{E}_1^0\right)\left[1 + \frac{\varphi(r)}{c^2}\right]^{-1/2} \tag{1}$$

где $\mathscr{E}_2^0$ и $\mathscr{E}_1^0$ - энергии уровней в «пустом» пространстве. Таким образом, наблюдатель на поверхности Земли обнаружит, что энергия излучения атома (ядра), находящегося на высоте H над поверхностью Земли (радиус R_3), не совпадает с таковой у поверхности, и наоборот. Именно это и было обнаружено в экспериментах Паунда и Ребки. При этом

$$\Delta\mathscr{E}\left(R_3+H\right)=\Delta\mathscr{E}\left(R_3\right)\sqrt{\frac{1+2\varphi\left(R_3\right)/c^2}{1+2\varphi\left(R_3+H\right)/c^2}}\approx$$

$$\approx\Delta\mathscr{F}(\mathscr{R})[+\frac{\varphi(\mathscr{R})-\varphi(\mathscr{R}+\mathscr{H})}{}] \tag{2}$$

Здесь мы учли, что гравитационный потенциал Земли слабый:

$$\frac{2\varphi\left(R_3\right)}{c^2}=\frac{2\gamma M_3}{R_3c^2}=2\cdot10^{-9}\ll1$$

Наивное (но неверное, хотя и часто используемое) объяснение наблюдае мого эффекта смещения уровней состоит в том, что γ-кванту с энергией $\mathscr{E}$ приписывается гравитационная масса $m_\gamma=\mathscr{E}/c^2$, после чего для фотона применяется нерелятивистская формула $\Delta\mathscr{E}=-m_\gamma\Delta\varphi$ (так же, как для какогонибудь камня). Фотон (как и камень) ускоряется; относительное изменение его энергии

$$\frac{\Delta\mathscr{E}}{\mathscr{E}}=-\frac{\Delta\varphi}{c^2} \tag{3}$$

Это полностью совпадает с результатом (2):

$$\frac{\Delta\mathscr{E}}{\mathscr{E}}\approx\frac{\Delta\varphi}{c^2}=\frac{\gamma M_3}{c^2R_3}H=\frac{gH}{c^2}.$$

Следует подчеркнуть, что согласно ОТО ход времени зависит от величи ны гравитационного потенциала. Иначе говоря, если ввести мировое время τ_0, измеряемое часами в отсутствии гравитационных полей, то в точке с по тенциалом $\varphi(r)$ ход часов меняется:

$$\boldsymbol{\tau}=\tau_0\left(1+\frac{2\varphi(r)}{c^2}\right)^{-1/2}$$

Это означает, что наблюдатель в точке с нулевым потенциалом видит, что частота света в любом месте одинакова, а скорость света меняется, и стати ческое гравитационное поле эквивалентно среде с показателем преломления n (см. задачу 1.5). Для наблюдателя, находящегося в ненулевом потенциале, частота (т.е. прошедшее мимо него за единицу времени число «горбов», явля ющееся инвариантом) изменилась. Однако скорость света в его системе равна c.

Отметим, что можно говорить о «красном смещении» фотона по отношению к наблюдателю в точке с нулевым гравитационным потенциалом, если относить это не к частоте, а к длине волны (импульсу) фотона.

О3.1-1.5 Гравитационное отклонение через аналогию с показателем преломления (??)

Как следует из общей теории относительности, статическое гравитационное поле по отношению к своему воздействию на электромагнитные волны эквивалентно неоднородной среде с показателем преломления $n=\left(1+2\varphi/c^2\right)^{-1}$, где φ - гравитационный потенциал. Используя эту аналогию, найти угол отклонения ∂ луча света при прохождении его вблизи края Солнца. Масса Солнца $M=1,99\cdot10^{33}$г, радиус его фотосферы $R=696000$ км.

1.

5. $\delta=\frac{4\gamma M}{Rc^2}\approx0,84\cdot10^{-5}$ рад $=1,75''$.

Гравитационный потенциал Солнца на расстоянии r от него $\varphi(r)=-\gamma M/r$. Если обозначить через α угол падения луча света, т. е. угол между лучом света, упавшим на слой «среды» толщиной dr, и радиальным направлением к центру Солнца, то согласно закону Снеллиуса

$$\frac{\sin(\alpha-d\alpha)}{\sin\alpha}=\frac{n(r-dr)}{n(r)}$$

где $\alpha-d\alpha$ - угол преломления луча света гравитиационным полем. Отсюда следует, что $\operatorname{ctg}\alpha d\alpha=\frac{d}{dr}\ln n(r)$. В силу того, что гравитационный потенциал Солнца мал, легко установить, что $\ln n(r)\approx\frac{2\gamma M}{c^2r}$ и $dr=-\frac{R\cos\alpha}{\sin^2\alpha}d\alpha$. Таким образом, искомый угол поворота луча света δ равен удвоенному углу отклонения на пути из бесконечности ($\alpha=\pi/2$) до $R(\alpha=0)$ (в силу обратимости световых лучей):

$$\delta = -\frac{4\gamma M}{c^2 R}\int_{\pi/2}^{0}\sin\alpha d\alpha$$

откуда и следует ответ.

(????? насколько полезен такой метод показателя преломления????)

О3.1-1.6 Преломление фотонов

Исходя из классического закона преломления света, показать, что при прохождении плоской границы двух прозрачных сред сохраняется тангенциальная компонента импульса фотонов.

О3.1-1.7 Выбивание фотонов

Электромагнитная волна с круговой частотой $\omega = 2\cdot 10^{16}\text{с}^{-1}$ промодулирована по амплитуде синусоидой с круговой частотой $\Omega = 2\cdot 10^{15}\text{с}^{-1}$. Найти энергию фотоэлектронов, выбиваемых этой волной из атомов водорода с энергией ионизации $_{\text{n}} = 13,5$ эВ.

Solution

(?? вспомнить разложение в спектр???)
1.7. $\mathscr{E} = \hbar(\omega+\Omega) - \mathscr{E}_{\text{и}} \approx 0,9$ эВ.

О3.1-1.8 Рентгеновская трубка (???)

Найти напряжение V на рентгеновской трубке, если известно, что в излучаемом ею сплошном спектре нет длин волн, меньших 0,0206 нм.

Solution

(?? вообще хз, что за трубка??? нужна строчка про нее в 1 части.)
1.8. $V = 60\text{кВ}$.

О3.1-1.9

Шарик электроскопа облучается монохроматическим рентгеновским излучением. Листочки электроскопа перестают расходиться, когда потенциал шарика равен 8 кВ. Определить длину волны λ падающего излучения.

1.

9. $\lambda = 0,154$ нм.

О3.1-1.10

В центре посеребренного изнутри вакуумного стеклянного баллона шаровой формы помещен маленький шарик, покрытый никелем. Шарик освещается светом от ртутной лампы с длиной волны $\lambda = 230,2$ нм. Между внутренней поверхностью сферы и шариком приложена задерживающая разность потенциалов. Оказалось, что при увеличении этой разности до $V = 0,75$ В ни один из фотоэлектронов не попадает на посеребренную поверхность сферы. Контактная разность потенциалов между никелем и серебром равна $V_{\mathbb{K}} = 1$ В. Вычислить максимальную скорость фотоэлектронов.

1.

10. $v_{\max} = \sqrt{2e\left(V+V_{\text{K}}\right)/m_{\text{e}}} = 784\text{к/с}$.

О3.1-1.11 Максимальная зарядка шара светом (!)

Уединенный цинковый шарик облучается ультрафиолетовым светом с длиной волны $\lambda = 250$ нм. До какого максимального потенциала зарядится шарик? Работа выхода электрона для цинка $A = 3,74$ эВ.

1.

11. $V = \frac{(hc/\lambda)-A}{e} = 1,23$ В.

Пишем формулу фотоэффекта (????)
(??? подумаю еще про это.)

О3.1-1.12

При каких длинах волн λ облучающего света шарик в условиях предыдущей задачи заряжаться не будет?

1.

12. $\lambda > 2\pi\hbar c/A \approx 331$ нм.

О3.1-1.13 Фотоэлемент с разностью потенциалов (!?!???)

Цинковый электрод вакуумного фотоэлемента освещается монохроматическим светом с длиной волны $\lambda = 250$ нм. При наложении задерживающей разности потенциалов фототок уменьшается и обращается в нуль, когда она достигает значения $V = 2$ В. Определить внешнюю контактную разность потенциалов $V_{\text{к}}$ между цинком и материалом, из которого изготовлен другой электрод фотоэлемента. Работа выхода электрона из цинка $A = 3,74$ эВ.

Solution

(???? думаю, хорошая задача на проверку. лучше по Корявову пока буду решать, я пока тупой, вряд ли правильно решу.)

О3.1-1.16 Электрон только рассеивает (!?!?!??!?!?!?)

Показать, что свободный электрон в вакууме не может ни поглощать, ни излучать фотоны, а лишь рассеивать их.
(!??!? что, почему??)

О3.1-1.17 Максимальный фототок

Какую минимальную длительность импульса фототока можно получить в вакуумном фотоэлементе, между анодом и фотокатодом приложено напряжение $E = 300$ В/см, при освещении фотокатода короткими ($< 10^{-11}$с) импульсами света с длиной волны $\lambda = 500$ нм. Красная граница материала фотокатода $\lambda_{\text{кр}} = 1000$ нм.

Solution

У нас просто по формуле Эйнштейна выбивается электрон, а дальше он ускоряется в постоянном поле. Длительность импульса - длительность во времени, привыкаем к общефизическим словам.
Максимальная скорость выбиваемых электронов

$$\frac{mV_{\max}^2}{2} = h(\omega - \omega_0) = hc\left(\frac{1}{\lambda} - \frac{1}{\lambda_0}\right)$$

$$V_{\max}^2 = \frac{2hc}{m}\left(\frac{1}{\lambda} - \frac{1}{\lambda_0}\right)$$

Кинематическая задачка о времени пролета электронов в трубке длиной I:

$$I = \frac{eEt_1^2}{2m} = V_{\max}t_2 + \frac{eEt_2^2}{2m}$$
$$t_1 = t_2\sqrt{1 + \frac{2mV_{\max}}{eEt_2}} \approx t_2 + \frac{mV_{\max}}{eE}$$

где мы разложили корень, потому что значение добавки мало. В итоге:

$$\Delta t = t_1 - t_2 = \frac{1}{eE}\sqrt{\frac{2hc}{m}\left(\frac{1}{\lambda} - \frac{1}{\lambda_0}\right)} = 1.2 \cdot 10^{-10}\text{с}.$$

(еще раз подумаю про это потом)

О3.1-1.18 Накопление энергии для фотоэффекта (???)

По классической электромагнитной теории света поток световой энергии от источника непрерывно распространяется во все стороны. Через какой промежуток времени, согласно этой теории, отдельный атом танталового катода может накопить столько энергии, чтобы стал возможен вылет фотоэлектрона, если катод находится на расстоянии $L = 10$ м от 25-ваттной лампочки? Работа выхода электрона для тантала составляет $A = 4$ эВ. Считать, что фотоэлектрону передается вся энергия, накапливающаяся в атоме тантала, диаметр которого можно считать равным $d = 0,3$ нм.

Solution

(??? это ведь неверно, так же не происходит??? накопление какое-то???)

О3.1-1.19

Исходя из представления о фотонах как о квантах света, вывести формулу для эффекта Доплера в предположении, что источник света движется с нерелятивистской скоростью.

О3.1-1.20

То же, но для источника, движущегося с релятивистской скоростью.

О3.1-1.22

На рис. 2 (!!?!??!!?!!) изображены результаты, полученные Комптоном при исследовании рассеяния рентгеновских лучей в графите. Наблюдения велись под углом $\theta = 135^\circ$ к направлению падающего пучка. Определить длину волны λ_0 падающего излучения.

О3.1-1.23

Фотон рентгеновского излучения с длиной волны λ в результате комптоновского рассеяния на неподвижном свободном электроне отклонился от первоначального направления на угол θ. Определить кинетическую энергию T_e и импульс p_e электрона отдачи. Дать численный ответ для $\lambda = 0,02$ нм и $\theta = 90^\circ$.

Solution

(?? следствие ур Комптона)

О3.1-1.24

В предыдущей задаче определить угол φ между направлением первичного фотона и направлением движения электрона отдачи.

О3.1-1.25

Определить изменение длины волны при эффекте Комптона, если наблюдение ведется перпендикулярно к направлению первичного пучка излучения.

О3.1-1.26 Возможный угол вылета (???!!!!?)

В результате комптоновского рассеяния фотона на покоящемся электроне последний получил импульс отдачи p. Определить, под какими углами по отношению к направлению падающего фотона мог вылететь электрон с таким импульсом.

Solution

Используя векторную диаграмму рис. 1.8 (вставлю потом) и теорему косинусов, получаем

$$(hv_1/c)^2 = (hv/c)^2 - 2(hv/c)p\cos\varphi + p^2.$$

Вводя кинетическую энергию электрона после соударения $T = E - mc^2$, где E - энергия электрона после соударения, а m - его масса покоя, из закона сохранения энергии имеем $hv_1 = hv - T$. Подставляя это в предыдущее уравнение (исключая hv_1), находим

$$hv = \frac{1}{2}\left(p^2c^2 - T^2\right)/(pc\cos\varphi - T)$$

Используя выражение для T и связь энергии с импульсом $E^2 = p^2c^2 + m^2c^4$, получаем, что числитель - положительная величина. Так как hv также положительная величина, то и знаменатель выражения для hv должен быть положительной величиной:

$$pc\cos\varphi - T > 0,$$

откуда

$$\cos\varphi > T/(pc) = \left[1 + (mc/p)^2\right]^{1/2} - mc/p.$$

Таким образом, диапазон углов, под которыми мог вылететь электрон с заданным импульсом, лежит в пределах

$$0 < \varphi < \arccos\left[\left(1 + m^2c^2/p^2\right)^{1/2} - mc/p\right]$$

О3.1-1.27

В результате комптоновского рассеяния фотона на покоящемся электроне последний вылетел под углом $\alpha = 60°$ к направлению падающего фотона. Какую максимальную кинетическую энергию T может приобрести электрон отдачи в этом случае?

О3.1-1.28

В результате комптоновского рассеяния фотона на покоящемся электроне последний приобрел кинетическую энергию, равную его удвоенной энергии покоя. Под каким углом φ по отношению к направлению падающего фотона мог вылететь электрон?

О3.1-1.29

Фотон ($\lambda_0 = 662$ нм) рассеивается на электроне, летящем перпендикулярно направлению движения фотона. Найти начальный импульс электрона p_0, если длина волны λ_0 при рассеянии не изменяется. Угол рассеяния $\theta = 60°$.

О3.1-1.30 Угол разлета по потере энергии (!?!?)

Фотон с энергией $\mho_\gamma = 2m_ec^2$ (m_e - масса электрона) при рассеянии на покоящемся электроне теряет половину своей энергии. Найти угол разлета α между рассеянным фотоном и электроном отдачи.

Solution

(??? думаю, хорошая задача, но я слишком тупой для нее, основы не усвоены.)

О3.1-1.31 Рассеяние фотона на протоне

Фотон рассеивается на покоящемся протоне. Энергия рассеянного фотона равна кинетической энергии протона отдачи, а угол разлета между рассеянным фотоном и протоном отдачи равен 90°. Найти энергию $\mathcal{E}_\gamma$ падающего фотона.

Solution

О3.1-1.32 Сохранение энергии при рассеянии назад (!?!???!?)

С какой скоростью v должен двигаться электрон, чтобы летящий ему навстречу фотон с длиной волны $\lambda = 0,0024$ нм не изменил свою энергию при 180°-рассеянии?

Solution

Закон сохранения энергии с учетом релятивистской энергии электрона:

$$\hbar\omega + \frac{mc^2}{\sqrt{1+\beta^2}} = \hbar\omega + \frac{mc^2}{\sqrt{1+\beta'^2}}$$

Единственное решением это $\beta = \beta'$, то есть электрон летит назад с той же скоростью назад.

Закон сохранение импульса:

$$\frac{\hbar\omega}{c} - \frac{mc\beta}{\sqrt{1+\beta^2}} = -\frac{\hbar\omega}{c} + \frac{mc\beta}{\sqrt{1+\beta^2}}$$
$$\frac{mc\beta}{\sqrt{1+\beta^2}} = \frac{\hbar\omega}{c} = \frac{h}{\lambda}$$
$$\frac{\beta}{\sqrt{1+\beta^2}} = \frac{h}{mc}\frac{1}{\lambda} = \frac{\Lambda_c}{\lambda} \approx 1$$

Тут Λ_c - комптоновская длина, равная λ. Окончательно решаем уравнение на β и находим, что $v = c/\sqrt{2}$

О3.1-1.33

Оптический фотон с энергией $\hbar\omega_0$ рассеивается назад на электроне, движущемся ему навстречу с полной энергией $\mathscr{E}$ и импульсом p. Какова энергия рассеянного фотона? Рассмотреть два предельных случая:

а) $\frac{\mathscr{E}+pc}{mc^2} \cdot \frac{2\hbar\omega_0}{mc^2} \gg 1$;

б) $\frac{\mathcal{E}+pc}{mc^2} \cdot \frac{2\hbar\omega_0}{mc^2} \ll 1$.

Solution

О3.1-1.34

Определить энергию фотона hv', рассеянного назад покоящимся электроном. Какова эта энергия, если энергия падающего фотона hv удовлетворяет условию $hv \gg m_e c^2$ (m_e – масса электрона)?

Solution

О3.1-1.35 Обратный Комптон-эффект (!?!???!?!??)

Фотон от рубинового лазера ($\lambda = 0,6943$ мкм) испытывает лобовое соударение с электроном, имеющим кинетическую энергию $T = 500$ МэВ. Оценить энергию $\mathcal{E}_\gamma$ фотона, образующегося в результате «обратного комптон-эффекта» (т. е. при 180°-рассеянии фотона на движущемся электроне). См. также задачу 4.51 этого раздела.

Solution

Указание: рассмотреть два последовательных преобразования частоты из-за эффекта Доплера.

(??? подумаю про это, уже очень скоро!!!)

1.35. При условии $T \gg \hbar\omega_0$ ответ имеет вид $\mathscr{E}_\gamma \approx \hbar\omega_0 \frac{2T}{(m_e c^2)^2/(2T)+2\hbar\omega_0}$ (кинетическая энергия электрона $T \gg m_e c^2$, поэтому полная его энергия $\mathscr{E}_0 \approx T$). Здесь возможны два случая:

1) $\hbar\omega_0 \ll m_e c^2 \frac{m_e c^2}{T}$. Тогда $\mathscr{E}_\gamma \approx \hbar\omega_0 \left(\frac{2T}{m_e c^2}\right)^2 \approx 7,2$ МэВ (этот случай и реализуется в задаче).

2) $\hbar\omega_0 \gg m_e c^2 \frac{m_e c^2}{T}$. Тогда $\mathscr{E}_\gamma = \hbar\omega \approx T$. В задаче этот случай не выпол няется.

О3.1-1.36 Удваивание длины волны

Определить длину волны λ рентгеновского излучения, для которого комптоновское рассеяние на электроне на угол 90° удваивает длину волны.

Solution

(хз, с ходу совсем плохо это решаю.)
1.36. $\lambda = 2,4$ пм.

18.1.2 Problems about photons 2

О3.1-1.37

При движении быстрой заряженной частицы в области пространства, заполненной изотропным электромагнитным излучением (например, светом Солнца и звезд), частица теряет энергию в резуль тате взаимодействия с этим излучением. Считая частицу ультрарелятивистской (энергия $\mathscr{E}_0 \gg mc^2$), а ее соударения с фотоном - лобовыми, найти изменение энергии частицы $\Delta\tilde{\sigma} = \sigma_0 - \mathfrak{g}$ и энергию фотона отдачи $\hbar\omega$. Энергию фотонов (до соударения) $\hbar\omega_0$ считать малой по сравнению с $\hbar\omega$. Чему равна энергия $\hbar\omega$, если движущейся частицей является электрон с энергией $\mathscr{E}_0 = 2,5 \cdot 10^9$ эВ и $\hbar\omega_0 = 1$ эВ?

Solution

О3.1-1.38

Электрон с энергией $\mathscr{E}_0 \gg mc^2$ рассеивается на фотоне с энергией $\hbar\omega_0 \ll mc^2$. При каком условии энергия этого фотона в системе отсчета, в которой электрон покоится, удовлетворяет условию $\hbar\omega \ll mc^2$?

Solution

О3.1-1.39* Различение фотоэлектронов от комптоновских электронов (!!!!!!!!!!)

При прохождении γ-квантов через вещество образуются две группы быстрых электронов: одна в результате фотоэффекта, а другая - комптоновского рассеяния. Каково должно быть энергетическое разрешение регистрирующей аппаратуры, чтобы отличать фотоэлектроны от комптоновских электронов с максимальной энергией? Энергия γ-квантов известна: $\mathscr{E}_\gamma = 5$ МэВ.

Solution

(решена в задачнике. Очень нужно разобраться с этим, важная для понимания задача!!!!)

Ответ: $\frac{\Delta T}{T_\phi} = \left(1 + \frac{2\S}{m_e c^2}\right)^{-1} = 0,05$, где T_ϕ и $T_\text{К}$ - кинетические энергии электронов фотоэффекта и эффекта Комптона, $\Delta T = T_\phi - T_\text{К}$.

Р еш е н и е. Запишем закон Эйнштейна для фотоэффекта

$$h\nu = \mathscr{E}_{\text{ион}} + A + T_{\text{ф.}} .$$

где T_ϕ - кинетическая энергия фотоэлектрона, A - работа выхода вещества, $\mathcal{E}_{\text{ион}}$ - энергия ионизации электрона атома. Поскольку для самых глубоких K-электронов $\mathscr{E}_{\text{ион}} \leqslant 13,6 \cdot Z^2$ [эВ], где Z - заряд ядра, то даже для $Z \sim 10^2$ $\mathscr{E}_{\text{ион}} \lesseqgtr 0,136$ МэВ « $h\nu$. Величина работы выхода, как правило, не превышает 10 эВ, поэтому под действием γ-квантов (выокоэнергетичных фотонов) при фотоэффекте $T_\phi \simeq \mathscr{E}_\gamma$.

При Комптон-эффекте $\mathscr{E}_\gamma + m_e c^2 = \mathscr{E}'_\gamma + m_e c^2 + \mathscr{E}_{\text{ион}} + T_\text{К}$. Следовательно,

$$T_{\mathbf{k}} \approx \mathscr{E}_\gamma - \mathscr{E}'_\gamma = \frac{hc}{\lambda} - \frac{hc}{\lambda + \Delta\lambda} = \frac{hc}{\lambda}\frac{\Delta\lambda}{\lambda + \Delta\lambda}.$$

Энергия электрона в эффекте Комптона максимальна, когда фотон рассеивается назад, т. е.

$$\Delta\lambda = \Lambda_e(1 - \cos\varphi); \quad \Delta\lambda_{\max} = 2\Lambda_e = 2\frac{h}{m_e c}.$$

Таким образом,

$$T_\text{К} = \frac{hc}{\lambda}\frac{2h}{m_e c\lambda}\frac{1}{1 + \frac{2h}{m_e c\lambda}} = \mathscr{E}_\gamma \frac{2\mathscr{E}_\gamma}{m_e c^2}\frac{1}{1 + \frac{2E_\gamma}{m_e c^2}}.$$

Введем разрешение аппаратуры по энергии как $\Delta T = T_\phi - T_\text{к}$. Тогда

1.40 Анализ комптоновского рассеяния методом Брэгга-Вульфа

Фотоны с длиной волны $\lambda = 1,4$Å испытывают комптоновское рассеяние на угол $\varphi = 60^\circ$ к первоначальному направлению. Фотоны попадают в рентгеновский спектрограф, работающий по методу интерференционного отражения Брэгга-Вульфа. При какой минимальной толщине D кристаллической пластинки спектрографа можно обнаружить изменение длины волны рассеянного излучения (комптоновское смещение) в первом порядке, если постоянная кристаллической решетки $d = 1$Å?

Solution

Ответ: $D = \frac{\lambda d m_e c}{2\pi\hbar \sin^2(\varphi/2)} = 11,4$ нм.
Требуемая разрешающая способность спектрографа

$$R = \frac{\lambda}{\delta\lambda} = Nm$$

где N - число отражающих слоев, m - порядок интерференции. По формуле Брэгга-Вульфа $m = \frac{2d\sin\theta}{\lambda}$, где θ - угол скольжения; по условию $m = 1$, откуда

$$\sin\theta = \frac{\lambda}{2d}.$$

Изменение длины волны (комптоновское смещение)

$$\Delta\lambda = 2\pi A_e(1-\cos\varphi) = 4\pi \text{Å}_e \sin^2\frac{\varphi}{2}, \quad \text{где Å}_e = \frac{\hbar}{m_e c}3,86\cdot 10^{-11}\text{с}.$$

Таким образом,

$$R = Nm = \frac{D}{d}\frac{2d\cos\theta}{\lambda} = \frac{\lambda}{4\pi \text{Å}_e \sin^2(\varphi/2)}.$$

Отсюда

$$D = \frac{\lambda^2}{4\pi\hbar_e \sin^2(\varphi/2)\sin\theta} = \frac{\lambda d m_e c}{2\pi\hbar\sin^2(\varphi/2)} = 11,4\text{НМ}.$$

О3.1-1.41

Solution

(мб эта аналогичная, проверю потом)
$D_{\min} = \frac{\lambda^2}{4\Lambda_e \sin^2(\theta/2)\sin\varphi} = 2$НМ, $\Lambda_e = 0,0024$ - комптоновская длина волны электрона.

О3.1-1.42

Solution

Решение. Перейдем в систему центра масс пары. На пороге рождения скорость продуктов реакции равна нулю. Но γ-Квант и в этой системе движется со скоростью света, что противоречит закону сохранения импульса. Раз процесс невозможен в системе центра масс, то он невозможен и в других инерциальных системах, т.е. невозможен вообще.

О3.1-1.48. Нулевой сдвиг γ-кванта по энергии

Возбужденное ядро с энергией возбуждения $\Delta\mathscr{E} = 1$М и $A = 100$ движется с кинетической энергией $T = 100$ эВ и испускает гамма-квант. Под каким углом к направлению движения ядра сдвиг γ-кванта по энергии будет равен нулю?

Solution

Допплер уменьшает частоту, изменение скорости увеличивает частоту.
Эффекта Допплера:

$$\omega = \omega_0 \left(1 + \frac{v}{c}\cos\theta\right)$$

При излучении гамма-кванта скорость у ядра тоже меняется существенно. Импульсы ядра и гаммам-кванта в системе покоя ядра одинаковые и посчитаем это сдвиг частот:

$$\Delta\omega = \frac{T_{\text{new}}}{\hbar} = \frac{p^2}{2m\hbar} = \frac{E_\gamma}{2mc^2\hbar}$$
$$\omega = \frac{E_\gamma - T_{\text{new}}}{\hbar} = \frac{E_\gamma}{\hbar}\left(1 - \frac{E^\gamma}{2mc^2}\right)$$

С учетом этих двух сдвигов частот получаем:

$$\omega = \frac{E_\gamma}{\hbar}\left(1 + \frac{v}{c}\cos\theta - \frac{E_\gamma}{2mc^2}\right)$$

Вклады должны скомпенсировать друг друга:

$$\frac{v}{c}\cos\theta = \frac{E^\gamma}{2mc^2} \to \cos\theta = \frac{E_\gamma}{v - 2mc} = \frac{E_\gamma}{\sqrt{8Tmc^2}} \approx 0.116$$

(потом еще раз решу задачу!)

О3.1-1.49.

Рассматривая процесс рождения фотона с энергией $\hbar\omega$ при прохождении в веществе с показателем преломления n релятивистской частицы массой m со скоростью v (эффект Вавилова-Черенкова), показать, что обычно приводимое условие возможности этого процесса $v > v_\phi = c/n$ справедливо только при определенном ограничении на отношение A/λ (- комптоновская длина волны частицы, λ - длина волны фотона). Найти явное выражение этого ограничения в зависимости от релятивистского фактора γ и n.

О3.1-1.50.

По современным представлениям в спектре солнечных нейтрино должна существовать достаточно интенсивная монохроматическая линия с энергией $\mathscr{E}_v = 0,86\text{МВ}$, что обусловлено идущей на Солнце реакцией $^7\text{Be} + \text{e}^- \to {}^7\text{Li} + v_\text{e}$. Для регистрации этих нейтрино был создан детектор BOREXINO с жидким сцинтилятором, в котором регистрируются электроны по реакции рассеяния (ν, e^-). Какова максимальная кинетическая энергия регистрируемых электронов?

О3.1-1.52 высота полета спутника

В системе глобального позиционирования (GPS) используется высокоточный цезиевый генератор, установленный на спутнике. Определить высоту полета спутника, если при прохождении над приемником на Земле регистрируемая частота совпадает с частотой генератора. Учесть, что энергии квантовых уровней любой системы зависят от гравитационного потенциала в месте нахождения системы. Вращение Земли не учитывать. (См. также задачу 1.4 в этом разделе.)

Solution

1.52: $H = \frac{R_3}{2} \simeq 3200\text{КМ}$.
Решени е. Если считать Землю шаром, то гравитационный потенциал на поверхности Земли $\varphi_1 = -\gamma\frac{M}{R_3} = -v_1^2$, где v_1 - первая космическая скорость. На расстоянии r от центра Земли гравитационный потенциал $\varphi_2 = -\gamma\frac{M}{r}$. Фотон, испущенный на спутнике, имеет энергию

$$\hbar\omega_2 = \hbar\omega_0\sqrt{1 + 2\frac{\varphi_2}{c^2}} \approx \hbar\omega_0\left(1 + \frac{\varphi_2}{c^2}\right).$$

где ω_0 - частота генератора в нулевом поле. Из-за движения спутника (вслсдствие поперечного эффекта Доплера) на Земле этот сигнал будет иметь частоту

$$\omega_2' = \omega_2\sqrt{1 - \frac{v^2}{c^2}} \approx \omega_0\left(1 + \frac{\varphi_2}{c^2}\right)\left(1 - \frac{v^2}{2c^2}\right),$$

где $v = \sqrt{\gamma \frac{M}{r}}$ - скорость спутника. Расстояние между энергетическими уровнями приемника на Земле

$$\hbar\omega_1 = \hbar\omega_0 \sqrt{1 + 2\frac{\varphi}{c^2}} \approx \hbar\omega_0 \left(1 + \frac{\varphi_1}{c^2}\right).$$

Сдвига частоты не будет, если $\omega_1 = \omega_2'$, откуда

$$\frac{\varphi_2}{c^2} - \frac{v^2}{2c^2} = \frac{\varphi_1}{c^2} \text{ или } \frac{\varphi_2}{c^2} - \frac{\varphi_1}{c^2} = \frac{v^2}{2c^2}.$$

Подставляя значения, получим $-\gamma\frac{M}{r} + \gamma\frac{M}{R_3} = \gamma\frac{M}{2r}$, откуда $r = \frac{3}{2}R_3$.

(некоторые задачи не выгружал, ибо их слишком много)

1. Фотоны. Фотоэффект. Эффект Комптона SOLUTIONS

1.

13. $V_к = \frac{(2\pi\hbar c/\lambda) - A}{e} - V \approx -0,79$ В. Отрицательный знак означает, что при контакте цинка с материалом второго электрода фотоэлемента потенциал цинка окажется ниже.

1.

14. $\alpha = \sqrt{\frac{e}{WKt}} = 10^{-2}$, где e - заряд электрона.

1.

15. Решение. При «сухом» контакте потери на отражение от границы сцинтиллятор-фотокатод составляют несколько процентов, и ими можно пренебречь. Гораздо большую величину составляют потери на полное отражение при выходе из сцинтиллятора.

При «сухом» контакте на фотокатод попадают фотоны, идущие под углами $\theta_1 < \arcsin(1/n)$. Когда оптический контакт заполнен маслом - под углом $\theta_2 < \operatorname{arctg}(D/2h)$. Поскольку в сцинтилляторе фотоны испускаются изотропно, то отношение потоков равно

$$\frac{\Phi_2}{\Phi_1} = \frac{\int_0^{\theta_2} d\Omega}{\int_0^{\theta_1} d\Omega} = \frac{2\pi \int_0^{\theta_2} I_0 \sin\theta d\theta}{2\pi \int_0^{\theta_1} I_0 \sin\theta d\theta} = \frac{1 - \cos\theta_2}{1 - \cos\theta_1} \approx 3$$

1.

16. Решение. Рассмотрим сначала случай поглощения фотона нерелятивистским электроном. Выберем такую систему отсчета, в которой электрон сначала покоился. Законы сохранения энергии и импульса:

$$\hbar\omega = \frac{mv^2}{2}; \quad \frac{\hbar\omega}{c} = mv$$

Из написанных равенств следует $v = 2c$, что невозможно. Релятивисткое рассмотрение приводит к следующей системе уравнений:

$$\hbar\omega + mc^2 = \frac{mc^2}{\sqrt{1-\beta^2}}; \quad \frac{\hbar\omega}{c} = \frac{m\beta c}{\sqrt{1-\beta^2}}$$

откуда следует $\frac{1-\beta}{\sqrt{1-\beta^2}} = 1$, т. е. либо $\beta = 0$, либо $\beta = 1$. Первое условие означает, что поглощения не произошло, а второе - нереализуемо для массивной частицы. Таким образом показано, что свободный электрон не способен поглотить квант энергии. На частном случае показано, что трехчастичные реакции, т.е. реакции типа a + b $\leftrightarrows$ c невозможны (смотрите также задачу 8.13). Лишь при участиц в реакции четвертой частицы законы сохранения могут быть соблюдены.

Так как процессы поглощения и испускания обратимы по времени, то из невозможности прямого процесса следует невозможность обратного. Конечно, невозможность такого процесса можно показать и прямым вычислением, как это было сделано выше для случая поглощения.

1.

17. Длительность импульса определяется разбросом времени пролета электронов, вылетевших из фотокатода в направлении к аноду с различными направлениями начальной скорости, т. е. с величиной продольной составля-

ющей скорости от нуля до максимально возможной. Если обозначить времсна движения до анода t_1 и t_2, то

$$\Delta t = t_1 - t_2 = \frac{1}{eE}\sqrt{2mhc\left(\frac{1}{\lambda} - \frac{1}{\lambda_{\text{кр}}}\right)} = 1,2 \cdot 10^{-10}\text{с}.$$

1.

18. $t \geqslant 16\frac{A}{N}\frac{L^2}{d^2} = 455$ с, где N - мощность лампочки.

1.

19*. Решение. Пусть M - масса источника, а v - его скорость (рис. 135).

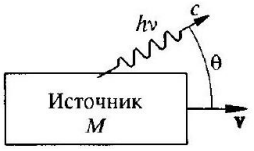

Рис. 135

Энергия источника слагается из кинетической энергии $Mu^2/2$ и внутренней энергии & возбужденных атомов. При испускании одного фотона внутренняя энергия $\mathscr{E}$ изменяется на вполне определенную величину (энергия квантуется!) $\mathscr{E} - \mathscr{E}' = hv_0$, где v_0 - частота фотона, испускаемого неподвижным источником. При испускании фотона тело испытывает отдачу, и его скорость меняется. По закону сохранения энергии

$$\frac{1}{2}Mv^2 + \mathscr{E} = \frac{1}{2}Mv'^2 + \mathscr{E}' + hv$$

где v - частота фотона, излучаемого движущимся источником. Написав закон сохранения импульса и спроектировав его на направление скорости $\mathbf{v}$ и на перпендикулярное направление, получим

$$Mv = Mv'\cos\alpha + \frac{hv}{c}\cos\theta, \quad 0 = Mv'\sin\alpha - \frac{hv}{c}\sin\theta$$

где θ и α - углы между направлением скорости v и направлениями импульсов испущенного фотона и источника после испускания. Исключая v' и α, найдем

$$2Mh\,(v - v_0) - 2Mv\frac{hv}{c}\cos\theta + \frac{h^2v^2}{c^2} = 0$$

Если масса источника M достаточно велика, то можно пренебречь последним членом, и мы получим, учитывая, что по условию $v/c \ll 1$,

$$v = \frac{v_0}{1 - \frac{v}{c}\cos\theta} \simeq v_0\left(1 + \frac{v}{c}\cos\theta\right)$$

1.

20*. Решение. Пусть $\mathscr{E}$ и $\mathscr{E}'$ - полные энергии тела до и после излучения. Соответственно $\mathscr{E}_0$ и $\mathscr{E}_0$ - энергия покоя, а p и p ′ - импульсы. Обозначим также энергию и импульс излученного фотона как ε и $\mathbf{q}$ и запишем законы сохранения

$$\mathscr{E}' = \mathscr{E} - \varepsilon; \quad \mathbf{p} = \mathbf{p}' + \mathbf{q}.$$

Возведем эти уравнения в квадрат и вычтем, предварительно домножив второе соотношение на c^2. Учитывая, что $\varepsilon = qc$, а $\mathscr{E}^2 - p^2c^2 = \mathscr{E}_0^2$ и $\mathscr{E}'^2 - p'^2c^2 = \mathscr{E}_0'^2$, получим

$$\mathscr{E}_0'^2 = \mathscr{E}_0^2 - 2\mathscr{E}\varepsilon + 2c^2pq$$

Релятивистский импульс тела $p = \&\beta/c$, где $\beta = v/c$. Подставляя это в полученное уравнение, находим

$$\mathscr{E}_0 - \mathscr{E}_0' = \frac{2\mathscr{E}}{\mathscr{E}_0 + \mathscr{E}_0'}\varepsilon(1 - \beta\cos\theta),$$

где θ - угол между импульсом тела $\mathbf{p}$ и направлением вылета фотона (рис. 135).
Для массивного тела $Mc^2 \gg h\nu$, откуда $\mathscr{E}_0' \approx \mathscr{E}_0$, и тогда

$$\mathscr{E}_0 - \mathscr{E}_0' \approx \frac{\mathscr{E}}{\mathscr{E}_0}\varepsilon(1 - \beta\cos\theta), \text{ или } (\mathscr{E}_0 - \mathscr{E}_0')\sqrt{1-\beta^2} = \varepsilon(1 - \beta\cos\theta).$$

Поскольку $\mathscr{E}_0 - \mathscr{E}_0' = h\nu$, а $\varepsilon = h\nu'$, то получим искомую связь частот неподвижного и движущегося источников

$$v' = v\frac{\sqrt{1-\beta^2}}{1 - \beta\cos\theta}.$$

При $\theta = \frac{\pi}{2}$ смещение частоты $\Delta v = v_0\frac{v^2}{2c^2}$, а при $\beta \ll 1$ принимаемая частота $\nu \approx \nu_0\left(1 + \frac{v}{c}\cos\theta\right)$ и $\Delta v = \frac{v}{c}\cos\theta$.

1.

21: Решение. При $\theta = 0 \quad \nu(0) = v_0\frac{\sqrt{1-\beta^2}}{1-\beta}$. При $\theta = \frac{\pi}{2}$ эта частота $v(\pi/2) = v_0\sqrt{1-\beta^2}$. Если $\beta \to 1$, то $v(0) \gg v(\pi/2)$. Отсюда ясно, что в узкой окрестности угла $\theta = 0$ частоты излучаемого света особенно велики. Найдем угол θ, для которого $v(\theta) = \alpha\nu(0)$, где $\alpha < 1$. Для этого угла нетрудно получить

$$\cos\theta \approx 1 - \frac{\theta^2}{2} = \frac{1 - (1-\beta)/\alpha}{1 - (1-\beta)} \approx 1 - \frac{1-\alpha}{\alpha}(1-\beta)$$

откуда

$$\theta^2 = 2\frac{1-\alpha}{\alpha}(1-\beta).$$

Так как $\sqrt{1-\beta^2} = mc^2/\mathscr{E}$, где $\mathscr{E}$ - полная энергия частицы, то $1 - \beta \approx \frac{1}{2}\left(\frac{mc^2}{\varrho}\right)^2$. Это дает

$$\theta = \sqrt{\frac{1-\alpha}{\alpha}}\frac{mc^2}{\varrho}.$$

При $\alpha = 1/2$ получаем $\theta = mc^2/\mathscr{E}$, иначе говоря, частота излучения падает вдвое под углом $\theta = mc^2/\mathscr{E} = \sqrt{1-\beta^2} = \gamma^{-1}$.

1.

22. $\Delta\lambda = \Lambda_e(1 - \cos\theta) = \lambda_1 - \lambda_0 = \lambda_0 = 4 \cdot 10^{-3}$ нм.

1.

23. $T_e = \frac{2hc}{\lambda}\frac{\Lambda_e \sin^2(\theta/2)}{\lambda + 2\Lambda_e \sin^2(\theta/2)}, (p_e c)^2 = T_e^2 + 2m_e c^2 T_e$.
Здесь $\Lambda_e = 2,4263 \cdot 10^{-3}$ нм - комптоновская длина волны электрона. При $\theta = 90°$

$$T_e = \frac{hc}{\lambda}\frac{\Lambda_e}{\lambda + \Lambda_e} = 0,108\frac{hc}{\lambda} = 0,67 \cdot 10^4\rho\text{В}, \quad cp_e = 8,3 \cdot 10^4\rho \text{ В},$$

т. е. фотон передал электрону около 10% своей энергии, а импульс электрона отдачи по абсолютной величине оказался больше импульса первичного фотона.

1.

24. Решение. Как видно из рис. 136 , из закона сохранения импульса следует
$p_e \cos\varphi = \frac{h\nu}{c} - \frac{h\nu'}{c}\cos\theta, \quad p_e \sin\varphi = \frac{h\nu'}{c}\sin\theta.$
Почленным делением находим

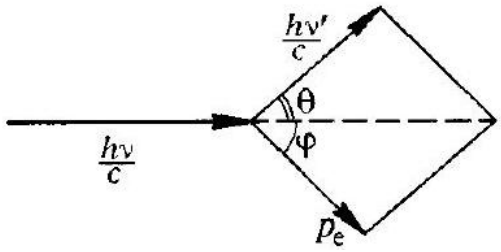

Рис. 136

$$\operatorname{tg}\varphi = \frac{\sin\theta}{\nu/\nu - \cos\theta}$$

Отсюда с учетом соотношения $\frac{v}{v'} - 1 = \frac{2h\nu}{m_e c^2}\sin^2\theta$ легко получить

$$\operatorname{tg}\varphi = \frac{\operatorname{ctg}(\theta/2)}{1 + \frac{h\nu}{m_e c^2}}.$$

При $\theta = 90^\circ$ $\operatorname{tg}\varphi = 0,8916, \varphi = 41^\circ 43'$.

1.

25. $\Delta\lambda = \frac{2h}{m_e c}\sin^2\frac{\theta}{2} = \frac{h}{m_e c} = 2,4263 \cdot 10^{-3}$НМ.

1.

26. $0 \leqslant \varphi < \arccos\left(\sqrt{1 + \left(\frac{mc}{p}\right)^2} - \frac{mc}{p}\right)$.

Решение. Запишем закон сохранения импульса в соответствии с рис. 2: $\mathbf{p}'_\gamma = \mathbf{p}_\gamma - \mathbf{p}$, откуда по теореме косинусов

$$\left(\frac{h\nu'}{c}\right)^2 = \left(\frac{h\nu}{c}\right)^2 - \frac{2h\nu}{c}p\cos\varphi + p^2.$$

Закон сохранения энергии:

$$\mathfrak{E}'_\gamma = \mathscr{E}_\gamma - T = \mathscr{E}_\gamma - \mathscr{E} + mc^2, \text{ т. е.}$$
$$h\nu' = h\nu - \sqrt{(pc)^2 + (mc^2)^2} + mc^2$$

Исключая $h\nu'$, получим

$$h\nu = \frac{(pc)^2 - T^2}{2(pc\cos\varphi - T)}.$$

Определим знак числителя:

$$\begin{aligned}&(pc)^2 - T^2 = \\ &= (pc)^2 - \left[(pc)^2 + \left(mc^2\right)^2 - 2\sqrt{(pc)^2 + (mc^2)^2}\cdot mc^2 + \left(mc^2\right)^2\right] = \\ &= 2mc^2\left(\sqrt{(pc)^2 + (mc^2)^2} - mc^2\right) > 0\end{aligned}$$

всегда. Так как $h\nu > 0$, то и знаменатель полученной дроби тоже положителен: $pc\cos\varphi - T > 0$, откуда $\cos\varphi > \frac{T}{pc} = \sqrt{1 + \left(\frac{mc}{p}\right)^2} - \frac{mc}{p}$. Таким обра-
зом, диапазон углов, под которым мог вылететь электрон с заданным имнульсом, лежит в пределах

$$0 \leqslant \varphi < \arccos\left(\sqrt{1+\frac{m^2c^4}{p^2}}-\frac{mc}{p}\right).$$

1.

27. $T < 2mc^2 \operatorname{ctg}^2\varphi = 0,34$М В В.

1.

28. $0 \leqslant \varphi < 45°$.

1.

29. $p_0 = \frac{2\pi\hbar}{\lambda_0}\operatorname{tg}\frac{\theta}{2} \approx 6\cdot 10^{-23}$Г $\cdot$ см/с.

1.

30. $\alpha = 90°$.

1.

31. $\mathscr{E}_\gamma = 2m_\text{p}c^2 \approx 1,9$ ГэВ, где m_p - масса протона.

1.

32. $v = \frac{c}{\sqrt{1+\lambda/\Lambda_e}} \approx \frac{c}{\sqrt{2}}$, где $\Lambda_\text{e} = \frac{h}{mc} = 0,0024$ нм - комптоновская длина волны электрона.

1.

33. $\hbar\omega' = \hbar\omega_0 \frac{\left(\frac{8+pc}{mc^2}\right)^2}{1+\frac{2\hbar\omega_0}{mc^2}\frac{8+pc}{mc^2}}$, где p - импульс электрона.

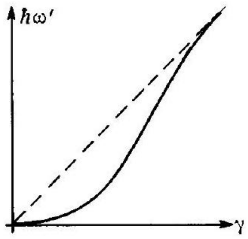

Рис. 137

Случай а) $\hbar\omega' = \frac{\varrho + pc}{2} \approx \mathscr{E}$

Ультрарелятивистский электрон ($\mathfrak{E} \approx pc$) передает фотону всю свою энергию (пунктир на рис. 137).
Случай б) $\hbar\omega' = \hbar\omega_0\left(\frac{\mathscr{E}+pc}{mc^2}\right)^2 \approx 4\gamma^2\hbar\omega_0$, где $\gamma = \frac{1}{\sqrt{1-v^2/c^2}}$.
Таким образом, в этом случае $\hbar\omega' \propto \gamma^2$ (рис. 137).

1.

34.

$$hv' = \frac{hv}{1+\frac{2hv}{m_e c^2}}. \quad \text{Если} \quad hv \gg m_e c^2, \quad \text{то}$$

$hv' \approx m_e c^{2/2}$.

1.

35. При условии $T \gg \hbar\omega_0$ ответ имеет вид $\mathscr{E}_\gamma \approx \hbar\omega_0 \frac{2T}{(m_e c^2)^2/(2T)+2\hbar\omega_0}$ (кинетическая энергия электрона $T \gg m_e c^2$, поэтому полная его энергия $\mathfrak{E}_0 \approx T$). Здесь возможны два случая:

1. $\hbar\omega_0 \ll m_e c^2 \frac{m_e c^2}{T}$. Тогда $\wp_\gamma \approx \hbar\omega_0 \left(\frac{2T}{m_e c^2}\right)^2 \approx 7,2$ МэВ (этот случай и реализуется в задаче).

2. $\hbar\omega_0 \gg m_e c^2 \frac{m_e c^2}{T}$. Тогда $\mathscr{E}_\gamma = \hbar\omega \approx T$. В задаче этот случай не выполь няется.

Указание: рассмотреть два последовательных преобразования частоты из-за эффекта Доплера.

1.

36. $\lambda = 2,4$ пм.

1.

37. $\Delta\delta = \hbar\omega = \left(\frac{2\mathscr{E}}{mc^2}\right)^2 \frac{\hbar\omega_0}{1+4\varrho\hbar\omega_0/(m^2c^4)}$.

Если $\mathscr{E}_0 \ll mc^2\left(mc^2/4\hbar\omega_0\right)$, то $\hbar\omega \approx \left(2\mathscr{E}/mc^2\right)^2 \hbar\omega_0 \ll \mathscr{E}_0$. В противоположном предельном случае $\hbar\omega \approx \mathscr{E}_0$. В приведенном примере $\hbar\omega = 10^8$ эВ.

1.

38. По формуле для эффекта Доплера

$$\omega_0 = \frac{\omega\sqrt{1-v^2/c^2}}{1+v/c}$$

(фотон и электрон считаются движущимися навстречу друг другу, причем скорость электрона равна v). В ультрарелятивистском случае отсюда следует, что $\omega_0 = \omega mc^2/2\varrho_0$, и условие $\hbar\omega \ll mc^2$ принимает вид

$$\mathscr{E}_0 \ll \frac{\left(mc^2\right)^2}{2\hbar\omega_0}$$

1.

39: $\frac{\Delta T}{T_\phi} = \left(1+\frac{2\mathscr{E}}{m_e c^2}\right)^{-1} = 0,05$, где $T_\text{ф}$ и $T_\text{к}$ - кинетические энергии электронов фотоэффекта и эффекта Комптона, $\Delta T = T_\phi - T_\text{к}$.

Решение. Запишем закон Эйнштейна для фотоэффекта

$$hv = \mathfrak{E}_\text{ион} + A + T_\text{ф}$$

где T_ϕ - кинетическая энергия фотоэлектрона, A - работа выхода вещества, $\mathscr{E}_\text{ион}$ - энергия ионизации электрона атома. Поскольку для самых глубоких K-электронов $\mathscr{E}_\text{ион} \leqslant 13,6 \cdot Z^2$[], где Z - заряд ядра, то даже для $Z \sim 10^2$ $\mathscr{E}_\text{ион} \leq 0,136$М ВВ $\ll hv$. Величина работы выхода, как правило, не превышает 10 эВ,

поэтому под действием γ-квантов (выокоэнергетичных фотонов) при фотоэффекте $T_\phi \simeq \mathscr{E}_\gamma$.
При Комптон-эффекте $\mathscr{E}_\gamma + m_\mathrm{e}c^2 = \mathfrak{E}'_\gamma + m_\mathrm{e}c^2 + \mathscr{E}_{\text{ион}} + T_\text{к}$. Следовательно,

$$T_\mathbf{K} \approx \mathscr{E}_\gamma - \mathscr{E}'_\gamma = \frac{hc}{\lambda} - \frac{hc}{\lambda + \Delta\lambda} = \frac{hc}{\lambda}\frac{\Delta\lambda}{\lambda + \Delta\lambda}$$

Энергия электрона в эффекте Комптона максимальна, когда фотон рассеивается назад, т. е.

$$\Delta\lambda = \Lambda_\mathrm{e}(1 - \cos\varphi); \quad \Delta\lambda_\text{max} = 2\Lambda_\mathrm{e} = 2\frac{h}{m_\mathrm{e}c}$$

Таким образом,

$$T_\mathrm{K} = \frac{hc}{\lambda}\frac{2h}{m_\mathrm{e}c\lambda}\frac{1}{1 + \frac{2h}{m_\mathrm{e}c\lambda}} = \mathscr{E}_\gamma\frac{2\mathscr{E}_\gamma}{m_\mathrm{e}c^2}\frac{1}{1 + \frac{2\delta_\gamma}{m_\mathrm{e}c^2}}$$

Введем разрешение аппаратуры по энергии как $\Delta T = T_\Phi - T_\mathrm{k}$. Тогда

$$\frac{\Delta T}{T_\phi} \approx \frac{\varrho_\gamma - T_\mathrm{K}}{\varrho_\gamma} = \frac{1}{1 + \frac{\delta_\gamma}{m_\mathrm{e}c^2}} \simeq 0,05(5\%)$$

1.

40* $D = \frac{\lambda d m_\mathrm{e} c}{2\pi\hbar\sin^2(\varphi/2)} = 11,4\text{НМ}$.
Репение. Требуемая разрешающая способность спектрографа

$$R = \frac{\lambda}{\delta\lambda} = Nm$$

где N - число отражающих слоев, m - порядок интерференции. По формуле Брэгга-Вульфа $m = \frac{2d\sin\theta}{\lambda}$, где θ - угол скольжения; по условию $m = 1$, откуда

$$\sin\theta = \frac{\lambda}{2d}.$$

Изменение длины волны (комптоновское смещение)

$$\Delta\lambda = 2\pi\text{Å}_\mathrm{e}(1 - \cos\varphi) = 4\pi\text{Å}_\mathrm{e}\sin^2\frac{\varphi}{2}, \text{ где } \mathrm{A_e} = \frac{\hbar}{m_\mathrm{e}c}3,86\cdot10^{-11}\text{ cm}.$$

Таким образом,

$$R = Nm = \frac{D}{d}\frac{2d\cos\theta}{\lambda} = \frac{\lambda}{4\pi\star_\mathrm{e}\sin^2(\varphi/2)}.$$

Отсюда

$$D = \frac{\lambda^2}{4\pi\hbar_\mathrm{e}\sin^2(\varphi/2)\sin\theta} = \frac{\lambda d m_\mathrm{e} c}{2\pi\hbar\sin^2(\varphi/2)} = 11,4\text{НМ}.$$

1.

41. $D_\text{min} = \frac{\lambda^2}{4\Lambda_e\sin^2(\theta/2)\sin\varphi} = 2\text{НМ}, \Lambda_\mathrm{e} = 0,0024$ нм - комптоновская длина волны электрона.

1.

42: Решение. Перейдем в систему центра масс пары. На пороге рождения скорость продуктов реакции равна нулю. Но γ-квант и в этой системе движется со скоростью света, что противоречит закону сохранения импульса. Раз процесс невозможен в системе центра масс, то он невозможен и в других инерциальных системах, т. е. невозможен вообще.

1.

44. $\theta_\text{max} = 60°$.

1.

45. $\theta_{12} = 90°; \theta_{13} = \pi - \operatorname{arctg}\frac{4}{3} \approx 127°; \theta_{23} = \pi - \operatorname{arctg}\frac{3}{4} \approx 143°$.

1.

46. $\mathscr{E}_1 = 0,85\mathscr{E}_0 = 432$ кэВ; $\mathscr{E}_2 = \frac{2}{3+\sqrt{3}}\mathscr{E}_0 \approx 216$ кэВ; $\mathscr{E}_3 = \sqrt{3}\mathscr{E}_2 \approx \approx 374$ кэВ.

1.

47. Решение. Преобразование Лоренца для энергии частицы $\mathscr{E}$, импульс которой p,

$$\mathscr{E}' = \frac{\mathscr{E} - vp\cos\theta}{\sqrt{1 - v^2/c^2}}$$

где v - скорость штрихованной (движущейся) системы отсчета, а θ - угол в неподвижной системе между направлением движения фотона и скоростью источника. Энергия фотона $\mathscr{E} = h\nu = pc$, тогда

$$\nu' = \nu\frac{1 - (v/c)\cos\theta}{\sqrt{1 - v^2/c^2}}$$

Здесь ν - частота света в неподвижной системе отсчета, ν' - в движущейся вместе с источником. Переписывая ее в общепринятом виде, получим

$$\nu = \nu'\frac{\sqrt{1 - v^2/c^2}}{1 - (v/c)\cos\theta}$$

1.

48. $\cos\theta = \frac{\Delta\mathscr{E}}{2\sqrt{2Tm_{\text{яд}}\,c^2}} = 0,116, \theta = 83,3°$; где $m_{\text{яд}}\,c^2 = A \cdot 931,5$М ВВ.

1.

49. $\frac{\text{Å}}{\lambda} \leqslant \left(\frac{n\nu}{c} - 1\right)\frac{2\gamma}{n^2-1} < \frac{2\gamma}{n^2-1}$.

1.

50. $T_{\text{e}}^{\max} = \mathscr{E}_\nu\frac{\Delta\lambda^{\max}}{\lambda+\Delta\lambda^{\max}} = 663$ кэВ, где $\Delta\lambda^{\max} = \lambda' - \lambda = 2\Lambda_{\text{e}}$; $\lambda = \frac{hc}{\mathscr{E}_\nu}$ (комптон-эффект нейтрино на электронах).

1.

51: Длина волны гамма-квантов от источника равна $\lambda = 1,88\cdot10^{-10}$ см $\gg R_{\text{яд}}$, поэтому комптоновское рассеяние идет не на нуклонах ядра, а на ядре в целом (но не на молекуле, т.к. $\lambda \ll R_{\text{мол}} \simeq 3$Å для H_2O). Комптон-эффект на протоне $\Delta\lambda_{\text{H}}$ отличается от соответствующего эффекта на дейтроне $\Delta\lambda_{\text{D}}$. Таким образом,

$$\left|\frac{\Delta\varrho}{\varrho}\right| = \frac{|\Delta\lambda_{\text{H}} - \Delta\lambda_{\text{D}}|}{\lambda} = \frac{\varrho}{2m_{\text{p}}c^2} = 3,6\cdot10^{-4}$$

1.

52* $H = \frac{R_3}{2} \simeq 3200$ км.

Решение. Если считать Землю шаром, то гравитационный потенциал на поверхности Земли $\varphi_1 = -\gamma\frac{M}{R_3} = -v_1^2$, где v_1 - первая космическая скорость. На расстоянии r от центра Земли гравитационный потенциал $\varphi_2 = -\gamma\frac{M}{r}$.

Фотон, испущенный на спутнике, имеет энергию

$$\hbar\omega_2 = \hbar\omega_0\sqrt{1+2\frac{\varphi_2}{c^2}} \approx \hbar\omega_0\left(1+\frac{\varphi_2}{c^2}\right)$$

где ω_0 - частота генератора в нулевом поле.

Из-за движения спутника (вследствие поперечного эффекта Доплера) на Земле этот сигнал будет иметь частоту

$$\omega_2' = \omega_2\sqrt{1-\frac{v^2}{c^2}} \approx \omega_0\left(1+\frac{\varphi_2}{c^2}\right)\left(1-\frac{v^2}{2c^2}\right)$$

где $v = \sqrt{\gamma\frac{M}{r}}$ - скорость спутника. Расстояние между энергетическими уровнями приемника на Земле

$$\hbar\omega_1 = \hbar\omega_0\sqrt{1+2\frac{\varphi}{c^2}} \approx \hbar\omega_0\left(1+\frac{\varphi_1}{c^2}\right)$$

Сдвига частоты не будет, если $\omega_1 = \omega_2'$, откуда

$$\frac{\varphi_2}{c^2} - \frac{v^2}{2c^2} = \frac{\varphi_1}{c^2} \text{ или } \frac{\varphi_2}{c^2} - \frac{\varphi_1}{c^2} = \frac{v^2}{2c^2}$$

Подставляя значения, получим $-\gamma\frac{M}{r} + \gamma\frac{M}{R_3} = \gamma\frac{M}{2r}$, откуда $r = \frac{3}{2}R_3$.

18.1.3 Problems about Special Effects in Atoms 1

Б-2.11.1 Конечное ядро водорода

Найти смещение уровня энергии основного состояния атома водорода под влиянием конечных размеров ядра. Ядро считать равномерно заряженным по объему шаром радиуса r_0.

Solution

Считаем поправку по теории возмущений, нужно знать поле от равномерно заряженного шара, что считается элементарными методами электродинамики.

$$H \equiv H_0 + V = \frac{\mathbf{p}^2}{2m} - \frac{e^2}{r} + V(r).$$

$$V(r) \equiv U(r) - \left(-\frac{e^2}{r}\right)$$

$$\psi_{(0)}(\mathbf{r}) = \langle\mathbf{r}|\psi_{(0)}\rangle = R_{10}(r)\cdot Y_{00}(\vartheta,\varphi) = \frac{1}{\sqrt{\pi a^3}}e^{-\frac{r}{a}}.$$

Найдем поправку по теории возмущений. Сперва определим потенциал внутри равномерно заряженного шара.

$$q = e\frac{r^3}{R^3} \qquad \mathcal{E}(r) = e\frac{r}{R^3}, \qquad U(r) = e\int\mathcal{E}(r)dr + c_0 = e^2\frac{r^2}{2R^3} + c_0$$

$U(r)|_{r=R} = -\frac{e^2}{R}$, поэтому $c_0 = -\frac{3e^2}{2R}$. В итоге

$$U(r) = \begin{cases} \dfrac{e^2r^2}{2R^3} - \dfrac{3e^2}{2R}, & r \le R \\ -\dfrac{e^2}{r}, & r \ge R \end{cases}$$

. Поправка к энергии ϵ_1 в первом порядке теории возмущений равна:

$$\epsilon_1 = \langle\psi_{(0)}|V|\psi_{(0)}\rangle = 4\pi\int\limits_0^R dr\frac{r^2}{\pi a^3}\left(\frac{e^2r^2}{2R^3} - \frac{3e^2}{2R} + \frac{e^2}{r}\right)e^{-\frac{2r}{a}} \overset{R\ll a}{\approx}$$

$$\overset{\exp\approx 1}{\approx} = \frac{4}{a^3}\int\limits_0^R dr\left(\frac{e^2r^4}{2R^3} - \frac{3e^2r^2}{2R} + e^2r\right) = \frac{4}{a^3}\frac{e^2R^2}{10} = \frac{2}{5}\frac{e^2R^2}{a^3}$$

Б-2.11.2 Поляризуемость водорода в основном состоянии

Вычислить электрическую поляризуемость атома водорода, находящегося в основном состоянии. Показать, что для нахождения поляризуемости атома, находящегося в основном состоянии, достаточно знать лишь поправку второго порядка $E^{(2)}$.

Solution

Используем обычную теорию возмущений.
Атом водорода в поле $\mathcal{E} = \{0, 0, \mathcal{E}\}$, в атомной системе единиц $h = m = e = 1$ имеет

$$\hat{\mathrm{H}} = \frac{\hat{\mathrm{p}}^2}{2} - \frac{1}{r} + \mathcal{E}r\cos\theta \equiv \hat{\mathrm{H}}^{(0)} + \hat{\mathrm{V}},$$

Здесь $\mathcal{E}$ есть отношение напряженности внешнего электрического поля к внутриатомному $\varepsilon_a = e/a^2 \simeq 5,14\cdot 10^9$ В/см, поэтому практически всегда $\mathcal{E} \ll 1$, т. е. можно использовать теорию возмущений.

В основном состоянии у электрона $\psi^{(0)}(r) = \psi_{100} = \frac{1}{\sqrt{\pi}}e^{-r}$, поэтому поправка первого приближения к энергии $E_0^{(1)} = \langle\psi^{(0)}|\hat{V}|\psi^{(0)}\rangle = 0$ в силу сферической симметрии основного состояния и.

Во втором порядке теории возмущений

$$E_0^{(2)} = -\frac{1}{2}\alpha\mathcal{E}^2,$$

где $\alpha = -\frac{\partial^2 E_0^{(2)}}{\partial\mathcal{E}^2}$- поляризуемость атома.

$$E_0^{(2)} = \langle\psi^{(1)}|\hat{\mathbf{V}}|\psi^{(0)}\rangle = \int\psi^{(1)}(\mathbf{r})\mathcal{E}r\cos\theta\psi^{(0)}(\mathbf{r})d^3x,$$

где поправка первого приближения $\psi^{(1)}$ удовлетворяет уравнению первого приближения теории возмущений:

$$\left(\hat{\mathrm{H}}^{(0)} - E^{(0)}\right)\psi^{(1)}(\mathbf{r}) = -\hat{\mathrm{V}}\psi^{(0)}(\mathbf{r}), \qquad E^{(0)} = -\frac{1}{2},$$

$$\left(-\frac{1}{2}\Delta - \frac{1}{r} + \frac{1}{2}\right)\psi^{(1)}(\mathbf{r}) = -\frac{\varepsilon r\cos\theta}{\sqrt{\pi}}e^{-r} = -\frac{2}{\sqrt{3}}\mathcal{E}re^{-r}Y_1^{(0)}(\theta,\varphi).$$

где $Y_1^{(0)}(\theta,\varphi) = \sqrt{3/4\pi}\cos\theta$.

Подставим анзац $\psi^{(1)}(\mathbf{r}) = f(r)e^{-r}Y_1^{(0)}(\theta,\varphi)$, где $f(r) = a+br+cr^2$, определим коэффициенты, находим окончательно

$$\psi^{(1)}(\mathbf{r}) = -\frac{2\mathcal{E}}{\sqrt{3}}r\left(1+\frac{r}{2}\right)e^{-r}Y_1^{(0)}(\theta,\varphi).$$

В итоге

$$E_0^{(2)} = -\int\frac{2\mathcal{E}}{\sqrt{3}}r\left(1+\frac{r}{2}\right)e^{-r}Y_1^{(0)}(\theta,\varphi)\mathcal{E}r\cos\theta\frac{1}{\sqrt{\pi}}e^{-r}d^3x = -\frac{4}{3}\varepsilon^2\int\limits_0^\infty r^4\left(1+\frac{r}{2}\right)e^{-2r}dr = -\frac{9}{4}\varepsilon^2.$$

Поэтому $\alpha = 9/2$, а в обычной системе единиц

$$\alpha = (9/2)a^3.$$

Б-2.11.3 Эффект Штарка

Найти расщепление в однородном электрическом поле уровня энергии атома водорода с $n = 2$ (эффект Штарка). Найти правильные волновые функции нулевого приближения.

Solution

Решаем обычной теории возмущений для вырожденных уровней.
Атом водорода в поле $\mathcal{E} = \{0, 0, \mathcal{E}\}$, в атомной системе единиц $h = m = e = 1$ имеет

$$\hat{\mathrm{H}} = \frac{\hat{\mathrm{p}}^2}{2} - \frac{1}{r} + \mathcal{E}r\cos\theta \equiv \hat{\mathrm{H}}^{(0)} + \hat{\mathrm{V}},$$

В случае $n = 2$ энергетические поправки оказываются пропорциональны первой степени $\mathcal{E}$ - имеет место линейный эффект Штарка. Причиной этого является случайное вырождение уровней энергии, благодаря которому возбужденные состояния не обладают определенной четностью, и у атома появляется отличный от нуля средний дипольный электрический момент.

Для невозмущенной задачи $E_2^{(0)} = -Z^2/8$, и кратность вырождения $n^2 = 4$, поэтому необходимо применять теорию возмущений для вырожденных уровней энергий. Уровню $E_2^{(0)}$ отвечают четыре собственные функции:

$$\psi_{200} = R_{20}(r)Y_0^{(0)}(\theta,\varphi), \qquad \psi_{210} = R_{21}(r)Y_1^{(0)}(\theta,\varphi), \qquad \psi_{21\pm1} = R_{21}(r)Y_1^{(\pm1)}(\theta,\varphi),$$

где

$$R_{20}(r) = \left(\frac{Z}{2}\right)^{3/2} e^{-\frac{Zr}{2}} 2\left(1 - \frac{Zr}{2}\right), \qquad R_{21}(r) = \left(\frac{Z}{2}\right)^{3/2} e^{-\frac{Zr}{2}\frac{Zr}{\sqrt{3}}},$$

Считаем матричные элементы оператора возмущений. Вычисления показывают, что отличны от нуля лишь следующие:

$$\langle\psi_{200}|\hat{\mathrm{V}}|\psi_{210}\rangle = \langle\psi_{210}|\hat{\mathrm{V}}|\psi_{200}\rangle = -3\frac{\varepsilon}{Z}.$$

Решая секулярное уравнение, получаем поправки к уровню энергии $E_2^{(0)}$:

$$E_{1,4}^{(1)} = \mp 3\frac{\varepsilon}{Z}, \qquad E_{2,3}^{(1)} = 0.$$

Таким образом, исходный уровень энергии $E_2^{(0)}$ под действием электрического поля расщепляется на три уровня с энергиями:

$$E_{1,3} = E_2^{(0)} \pm E_{1,4}^{(1)} = E_2^{(0)} \mp 3\frac{\varepsilon}{Z}, \qquad E_2 = E_2^{(0)}.$$

Уровню энергии E_1 отвечает правильная функция нулевого приближения $\phi_1 = \frac{1}{\sqrt{2}}(\psi_{200} + \psi_{210})$, уровню E_3 соответствует состояние $\phi_4 = \frac{1}{\sqrt{2}}(\psi_{200} - \psi_{210})$, а уровень E_2 двукратно вырожден ему отвечают две линейно независимые функции: ψ_{211} и ψ_{21-1}.

Б-2.11.4 Сверхтонкое расщепление основного состояния водорода

Найти величину сверхтонкого расщепления основного состояния атома водорода.
Напоминание: по определению, под сверхтонким расщеплением имеется в виду изменение энергии при учете взаимодействия между ядром и электроном.

Solution

Считаем добавку к энергии за счет поля от магнитного момента протона методами теории поля, далее по теории возмущений получаем расщепление уровней энергии.
(??? почему квадрупольное вз-е не учитываем тут???)

Ядро атома водорода (протон) обладает собственным магнитным моментом μ_p. Взаимодействие магнитного момента электрона с магнитным полем ядра приводит к расщеплению атомных уровней по значению полного углового момента атома. Поскольку значение ядерного магнитного момента примерно в 10^3 раз меньше, чем значение орбитального магнитного момента электрона, то и соответствующее расщепление примерно в 10^3 раз меньше, чем расщепление тонкой структуры. Поэтому такое расщепление называют сверхтонким расщеплением. Гамильтониан сверхтонкого взаимодействия имеет вид

$$\hat{\mathrm{V}}^{\text{hyp-f}} = -\left(\hat{\mu}\mathcal{H}_{\text{nuc.}}\right),$$

$$\hat{\boldsymbol{\mu}} := -\mu_0\hat{\boldsymbol{\sigma}}; \qquad \mathcal{H}_{\text{nuc.}} := \operatorname{rot}\mathbf{A}; \qquad \mathbf{A} := -\left[\hat{\boldsymbol{\mu}}_p \times \boldsymbol{\nabla}\right]\frac{1}{r},$$

где $\hat{\mu}_p = \mu_p \hat{\sigma}_p$ - оператор магнитного момента протона, $\mu_0 = \frac{e\hbar}{2mc}$ - магнетон Бора. Таким образом,

$$\hat{V}^{\text{hyp-f}} = -\mu_0 \mu_p \hat{\sigma} \left[\nabla \times \left[\hat{\sigma}_p \times \nabla\right]\right] \frac{1}{r} = -\mu_0 \mu_p \hat{\sigma} \left[\hat{\sigma}_p \Delta - \left(\hat{\sigma}_p \nabla\right) \nabla\right] \frac{1}{r}.$$

Тут скалярное произведение опущено, потому что нас интересует просто оценка величины.

Применим теорию возмущений. Имеем:

$$\hat{\mathrm{H}}^{(0)} = \hat{\mathbf{p}}^2/(2m) - e^2/r,$$

$$\psi^{(0)}\left(\mathbf{r}, s, s_p\right) = \psi_{100}(\mathbf{r}) \cdot \chi\left(s, s_p\right), \qquad \psi_{100}(\mathbf{r}) = \frac{1}{\sqrt{\pi a^3}} e^{-r/a}$$

Получаем:

$$E^{(1)}_{\text{hyp-f}} = \int d^3x \chi^+ \psi^*_{100}(\mathbf{r}) \hat{V}^{\text{hyp-f}} \psi_{100}(\mathbf{r}) \chi.$$

$\psi_{100}(\mathbf{r})$ сферически симметрично, поэтому для поправки нужно усреднить по направлениям $\hat{V}^{\text{hyp-f}}$, то есть нужно нужно заменить $\nabla_i \nabla_j \to \delta_{ij}\Delta/3$. Получим:

$$E^{(1)}_{\text{hyp-f}} = \frac{8\pi}{3} \mu_0 \mu_p |\psi_{100}(0)|^2 \chi^+ \cdot \hat{\sigma}\hat{\sigma}_\rho \cdot \chi.$$

Здесь мы отняли два слагаемых и воспользовались тем, что $\Delta(1/r) = -4\pi\delta(\mathbf{r})$.

Поскольку $(\hat{\sigma}\hat{\sigma}_\rho) = 2\hat{S}^2 - 3\cdot\hat{1}$ (???? откуда это???), то правильными функциями нулевого приближения будут собственные функции оператора квадрата суммарного спина $\hat{\mathbf{S}} = \left(\hat{\sigma} + \hat{\sigma}_p\right)/2$ (т. е. ψ_{SM}, см. задачу 2.10.1 (?? там мб пояснения??)). С учетом того, что $|\psi_{100}(0)|^2 = \left(\pi a^3\right)^{-1}$, получим

$$E^{(1)}_{\text{hyp-f}} = \frac{8}{3} \mu_0 \mu_p \frac{1}{a^3} (2S(S+1) - 3) = \begin{cases} \frac{8}{3}\frac{\mu_0\mu_p}{a^3}, & S = 1, \\ -8\frac{\mu_0\mu_p}{a^3}, & S = 0. \end{cases}$$

Таким образом, исходный уровень энергии расщепляется на два в соответствии со значением суммарного спина электрона и протона, причем один из этих уровней трехкратно вырожден по проекции суммарного спина ($S = 1, M = 0, \pm 1$), а второй уровень - невырожденный ($S = 0$).

Численно $\Delta\nu_{\text{теор}} = \frac{E_{S=1} - E_{S=0}}{h} = 1417$МГц. Данное теоретическое значение отличается от экспериментально измеренного $\Delta\nu_{\text{эксп}} = 1420$ МГц. Причина расхождения результатов состоит в том, что в действительности магнитный момент электрона не равен в точности магнетону Бора μ_0, а отличается от него на величину $\Delta\mu\mu_0$, называемую аномальным магнитным моментом.

Б-2.11.5 Водород в магнитном поле с учетом сверхтонкого расщепления (??!!)

Найти уровни энергии атома водорода в основном (1s) состоянии в однородном магнитном поле. Учесть сверхтонкую структуру.

Solution

Суть решения в том, что

(!!! нужно разобраться с эффектами Зеемана !!!??)

В задаче рассматривается эффект Зеемана для основного состояния атома водорода с учетом его сверхтонкой структуры.

Пусть атом водорода в основном состоянии помещен в магнитное поле $\mathcal{H} = \{0, 0, \mathcal{H}\}$. После проведения стандартных преобразований гамильтониан принимает вид

$$\hat{\mathrm{H}} = \frac{\hat{\mathbf{p}}^2}{2m} - \frac{e^2}{r} + \hat{\mathrm{V}}^{\text{свл.}} + h\Omega\left(\hat{I}_z + 2\hat{\mathrm{S}}_z\right).$$

где $\hat{\mathrm{V}}^{\text{свл.}}$ - поправка сверхтонкого взаимодействия,

$$\hat{V}^{\text{hyp-f}} = -\mu_0 \mu_p \hat{\sigma} \left[\nabla \times \left[\hat{\sigma}_p \times \nabla\right]\right] \frac{1}{r} = -\mu_0 \mu_p \hat{\sigma} \left[\hat{\sigma}_p \Delta - \left(\hat{\sigma}_p \nabla\right) \nabla\right] \frac{1}{r}.$$

также $\Omega = e\mathcal{H}/(2mc)$ - ларморова частота, $\hat{I}_z$ и $\hat{\mathrm{s}}_z$ - операторы проекции орбитального момента и спина электрона на ось z. Мы пренебрегли в (1) квадратичным по полю $\mathcal{H}$ членом, считая его вклад в поправку к энергии малым по сравнению с линейным. Это можно сделать при $\mathcal{H} \ll 10^9$ Гс.

В качестве оператора возмущения выберем $\hat{\mathrm{V}}_{\mathscr{H}} = \hbar\Omega\left(\hat{I}_z + 2\hat{\mathrm{s}}_z\right)$. Гамильтониан невозмущенной задачи $\hat{\mathrm{H}}^{(0)}$ включает сверхтонкое взаимодействие $\hat{\mathrm{V}}^{\text{свл.}}$, поэтому в нулевом приближении мы имеем два уровня с энергиями $E_0 + \Delta E_{0,1}$. Здесь $E_0 = -e^2/(2a)$ - энергия основного состояния атома водорода, $\Delta E_{0,1}$ - поправки сверхтонкой структуры

$$E^{(1)}_{\text{hyp-f}} = \frac{8}{3}\mu_0\mu_p\frac{1}{a^3}(2S(S+1)-3) = \begin{cases} \frac{8}{3}\frac{\mu_0\mu_p}{a^3}, & S=1, \\ -8\frac{\mu_0\mu_p}{a^3}, & S=0. \end{cases}$$

Волновые функции невозмущенной задачи имеют вид $\psi^{(0)} = \psi_{100}(\mathbf{r})\psi_{SM}$, где $\psi_{100}(\mathbf{r})$ - координатная волновая функция основного состояния атома водорода, ψ_{SM} - спиновые функции электрона и протона (задачи 2.10.1 и 2.11.4 (!??!?)).

Поскольку $\langle\psi_{100}|\hat{I}_z|\psi_{100}\rangle = 0$, то вся содержательная часть будет касаться вычислений со спиновыми функциями. Обозначим состояния следующим образом: $|1\rangle = |\psi_{00}\rangle, |2\rangle = |\psi_{10}\rangle, |3\rangle = |\psi_{11}\rangle, |4\rangle = |\psi_{1-1}\rangle$. Заметим, что последние три состояния относятся к трехкратно вырожденному уровню с $S = 1$, а состояние $|1\rangle$ - к невырожденному уровню с $S = 0$. Отличные от нуля матричные элементы оператора возмущения равны

$$\langle 1|\hat{\mathrm{V}}_{\mathscr{H}}|2\rangle = \langle 2|\hat{\mathrm{V}}_{\mathscr{H}}|1\rangle = \langle 3|\hat{\mathrm{V}}_{\mathscr{H}}|3\rangle = -\langle 4|\hat{\mathrm{V}}_{\mathscr{H}}|4\rangle = \hbar\Omega.$$

Учитывая малость сверхтонкого расщепления, мы можем считать невозмущенные уровни энергии близкими. Поэтому, записывая секулярное уравнение, включим в него наряду с матричными элементами (2) также и сверхтонкие поправки $\Delta E_{0,1}$:

$$\begin{vmatrix} \Delta E_0 - E^{(1)} & \hbar\Omega & 0 & 0 \\ \hbar\Omega & \Delta E_1 - E^{(1)} & 0 & 0 \\ 0 & 0 & \Delta E_1 + \hbar\Omega - E^{(1)} & 0 \\ 0 & 0 & 0 & \Delta E_1 - \hbar\Omega - E^{(1)} \end{vmatrix} = 0$$

Отсюда получаем (?? пока верю этому.)

$$E^{(1)}_{1,2} = \frac{1}{2}\left\{(\Delta E_0 + \Delta E_1) \mp \sqrt{(\Delta E_1 - \Delta E_0)^2 + 4(\hbar\Omega)^2}\right\}.$$
$$E^{(1)}_{3,4} = \Delta E_1 \pm \hbar\Omega.$$

Проведем анализ результатов. Во-первых, состояния $|3\rangle = |\psi_{11}\rangle$ и $|4\rangle = |\psi_{1-1}\rangle$, относящиеся к уровню сверхтонкой структуры с $S = 1$, получают линейные по полю поправки $\pm\hbar\Omega$. Тем самым снимается вырождение по проекции суммарного спина M, уровень энергии с $S = 1$ расщепляется на три уровня.

В слабом поле, когда вклад магнитного поля много меньше вклада сверхтонкого взаимодействия ($\hbar\Omega \ll \Delta E_{\text{са}\tau} = \Delta E_1 - \Delta E_0$, это справедливо для $\mathcal{H} \ll 10^3$ Гс), поправки получают также состояния $|1\rangle = |\psi 00\rangle$ и $|2\rangle = |\psi_{10}\rangle$. Эти состояния относятся к разным уровням сверхтонкой структуры: $S = 0$ и $S = 1$, но они отвечают одному и тому же значению проекции суммарного спина $M = 0$ (рис. 2.12). Данные поправки квадратичны по полю:

$$E^{(1)}_{1,2} \simeq \Delta E_{0.1} \mp \frac{(\hbar\Omega)^2}{\Delta E_1 - \Delta E_0},$$

но ввиду наличия малого знаменателя $\Delta E_1 - \Delta E_0$ (малости сверхтонкого расщепления) вклад этих поправок может быть существенно больше, чем вклад отброшенного квадратичного по $\mathcal{H}$ члена в гамильтониане.

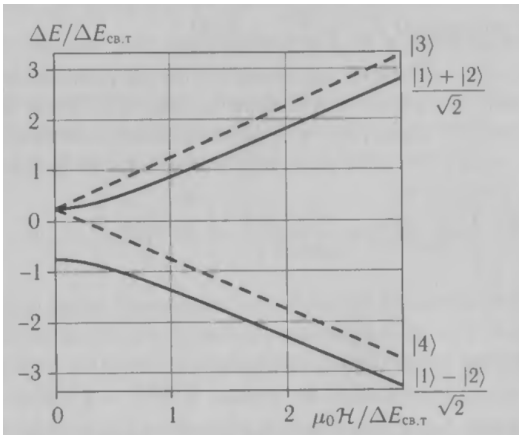

Рис. 2.12. Эффект Зеемана с учетом сверхтонкой структуры для основного состояния атома водорода ($\mu_0\mathscr{H} = \hbar\Omega, \Delta E_{\text{hyp-f}} = \Delta E_1 - \Delta E_0$)

В сильном поле, когда $\hbar\Omega \gg \Delta E_1 - \Delta E_0$, поправки, относящиеся к состояниям $|1\rangle$ и $|2\rangle$, равны

$$E^{(1)}_{1,2} \simeq \mp\hbar\Omega,$$

а правильные функции

$$\tilde{\psi}_{1,2} = \frac{1}{\sqrt{2}}\left(\psi_{00} \mp \psi_{10}\right)$$

описывают состояния, которые характеризуются значениями проекций электронного и протонного спина на направление магнитного поля по отдельности.

Заметим, что в данном приближении состояния $|3\rangle$ и $|4\rangle$ получают поправки

$$E^{(1)}_{3,4} \simeq \pm h\Omega,$$

и при этом в состояниях $|3\rangle = |\psi_{11}\rangle$ и $|4\rangle = |\psi_{1-1}\rangle$ проекции электронного и протонного спина на ось z также имеют определенные значения (как и в состояниях $\widetilde{\psi}_{1,2}$).

Это и понятно, ибо в случае сильного поля можно вначале учесть взаимодействие с полем, а затем, повторно применяя теорию возмущений, - сверхтонкое взаимодействие. Взаимодействие с магнитным полем в (1) влияет только на проекцию спина электрона и не затрагивает спин протона. Поэтому, сопоставляя (4) и (5), мы видим, что в сильном поле (до учета сверхтонкого взаимодействия) мы имеем два двукратно вырожденных (по значениям проекции спина протона) уровня энергии, отвечающие поправкам $E^{(1)}_{1,2} = E^{(1)}_{4,3} \simeq \mp\hbar\Omega$.

Б-2.11.6 Волновые функции с учетом SO-взаимодействия

Для свободного атома водорода написать правильные функции возбужденных состояний с $n = 2$ с учетом спин-орбитального взаимодействия (спин ядра считать равным нулю).

Solution

Суть решения в том, что (???)

Гамильтониан атома водорода с учетом релятивистских и спиновых поправок приведен в решении задачи 2.9.7, см. формулу (11).

Поправки содержат оператор спин-орбитального взаимодействия, который с учетом $U(r) = -Ze^2/r$ может быть записан в виде

$$\hat{\mathrm{V}}^{\mathrm{so}} = \frac{e^2\hbar^2}{2m^2c^2}\frac{(\hat{\mathbf{s}}\hat{\mathbf{i}})}{r^3} = A(r)(\hat{\mathbf{s}}\hat{I}),$$

где $\hat{\mathbf{i}}$ и $\hat{\mathbf{s}}$ - операторы орбитального и спинового моментов электрона. Правильные функции нулевого приближения должны быть собственными функциями операторов, являющихся точными интегралами движения (т. е. коммутирующих не только с $\hat{\mathrm{H}}^{(0)} = \hat{\mathbf{p}}^2/(2m) - e^2/r$, но и с $\hat{\mathrm{V}}^{so}$, играющим роль оператора возмущения). Стандартные решения уравнения Шредингера, пропорциональные сферическим функциям $\psi_{nlm}(\mathbf{r}) = R_{nl}(r)Y^{(m)}_l(\theta,\varphi)$, не подходят для наших целей, ибо эти функции являются собственными для оператора $\hat{I}_z$, а данный оператор, как легко проверить, не коммутирует с $\hat{V}^{\mathrm{co}}$: $\left[(\hat{s}\hat{i}), \hat{I}_z\right] \neq 0$.

Однако оказывается, что $\left[(\hat{\mathbf{s}}\hat{\mathbf{s}}), \hat{\mathrm{j}}_z\right] = 0$, т. е. точным интегралом движения является проекция на ось z полного углового момента $\hat{\mathrm{j}}_z = \hat{I}_z + \hat{\mathrm{s}}_z$. Это значит, что искомые функции должны быть общими собственными функциями для полного набора наблюдаемых $\hat{\mathrm{H}}^{(0)}, \hat{I}^2, \hat{\mathrm{s}}^2, \mathrm{j}^2, \hat{\mathrm{j}}_z$, к которому можно перейти от стандартного набора $\hat{\mathrm{H}}^{(0)}, \hat{I}^2, \hat{\mathrm{s}}^2, \hat{\mathrm{s}}_z, \hat{I}_z$. Эти два набора эквивалентны, ибо по сути данный переход есть не что иное, как задача сложения моментов: $\hat{\mathbf{j}} = \hat{\mathbf{i}} + \hat{\mathbf{s}}$.

Итак, правильный вектор состояния атома водорода должен определяться следующими квантовыми числами: $|nljm_j\rangle$, где мы опустили квантовое число s, потому что оно всегда имеет значение $s = 1/2$. В координатном представлении этим векторам отвечают функции, найденные в решении задачи 2.10.3. Воспользуемся результатами данной задачи и конкретизируем их для $n = 2$.

Для $n = 2$ имеется восемь состояний, из которых в двух состояниях орбитальный момент равен нулю. Поэтому волновые функции этих состояний можно записать в виде

$$\Psi^{\frac{1}{2}}_{2,0,+1/2}(\mathbf{r}) = R_{20}(r)\begin{pmatrix} Y^{(0)}_0 \\ 0 \end{pmatrix}, \quad \Psi^{\frac{1}{2}}_{2,0,-1/2}(\mathbf{r}) = R_{20}(r)\begin{pmatrix} 0 \\ Y^{(0)}_0 \end{pmatrix}.$$

Соответствующие векторы состояний имеют вид

$$|2,0,1/2,\pm 1/2\rangle = |2,0,0\rangle|\pm\rangle,$$

где $|\pm\rangle$ - собственные векторы оператора $\hat{s}_z$, а в представлении, где $\hat{s}_z$ диагонален, им соответствуют функции $\chi_{\pm 1/2}$ (II.26).

Для значения орбитального квантового числа $l = 1$ возможны два состояния с полным моментом $j = 1/2$ и четыре состояния с $j = 3/2$. Используя общие результаты задачи 2.10.3, получаем

$$\Psi^{\frac{1}{2}}_{2,1,+1/2}(\mathbf{r}) = R_{21}(r)\begin{pmatrix} -\frac{1}{\sqrt{3}}Y_1^{(0)} \\ \sqrt{\frac{2}{3}}Y_1^{(1)} \end{pmatrix}, \quad \Psi^{\frac{1}{2}}_{2,1,-1/2}(\mathbf{r}) = R_{21}(r)\begin{pmatrix} -\sqrt{\frac{2}{3}}Y_1^{(-1)} \\ \frac{1}{\sqrt{3}}Y_1^{(0)} \end{pmatrix},$$

или в виде векторов состояний:

$$|2,1,\frac{1}{2},+\frac{1}{2}\rangle = \frac{1}{\sqrt{3}}\Big[\sqrt{2}|2,1,+1\rangle|-\rangle - |2,1,0\rangle|+\rangle\Big].$$

$$|2,1,\frac{1}{2},-\frac{1}{2}\rangle = \frac{1}{\sqrt{3}}\Big[|2,1,0\rangle|-\rangle - \sqrt{2}|2,1,-1\rangle|+\rangle\Big].$$

Соответственно для полного момента $j = 3/2$ мы должны записать четыре состояния. Выпишем только два состояния с положительными проекциями полного момента (остальные два легко написать самостоятельно):

$$\Psi^{(3/2)}_{2,1,+3/2}(\mathbf{r}) = R_{21}(r)\begin{pmatrix} Y_1^{(1)} \\ 0 \end{pmatrix}, \quad \Psi^{(3/2)}_{2,1,+1/2}(\mathbf{r}) = R_{21}(r)\begin{pmatrix} \sqrt{\frac{2}{3}}Y_1^{(0)} \\ \frac{1}{\sqrt{3}}Y_1^{(1)} \end{pmatrix},$$

или в виде векторов состояний:

$$|2,1,3/2,+3/2\rangle = |2,1,+1\rangle|+\rangle$$
$$|2,1,3/2,+1/2\rangle = \frac{1}{\sqrt{3}}(\sqrt{2}|2,1,0\rangle|+\rangle + |2,1,+1\rangle|-\rangle).$$

Б-2.11.7 Тонкое расщепление водорода (!!!)

Найти величину тонкого расщепления состояния атома водорода с главным квантовым числом n и орбитальным квантовым числом l. Выразить величину этого расщепления в атомных единицах энергии. Нарисовать схему расщепленных уровней с $n = 3$.

Solution

Эта задача по теории: берем гамильтониан Дирака для кулоновского поля в нерелятивистском приближении, раскладываем по теории возмущений. Для именно этой задаче и обсуждали мы релятивистскую квантовую механику.

(напишу тут пару ключевых формул)

Получаем в итоге формулу Зоммерфельда для уровней энергии атома водорода с учетом релятивистских поправок:

$$E_{nj} = -\frac{Z^2}{2n^2}\left(\frac{e^2}{a}\right)\left\{1 + \frac{Z^2\alpha^2}{n^2}\left[\frac{n}{j+1/2} - \frac{3}{4}\right]\right\}.$$

где $n = 1, 2, \ldots$ - главное квантовое число, $j = l \pm 1/2$ - внутреннее квантовое число.

(дальше выпишу из теории коротко решение)

(?? это пока не понимаю.) В качестве правильных функций невозмущенной задачи выбрать функции, собственные для следующего набора коммутирующих операторов: $\hat{I}^2, \hat{\mathbf{s}}^2, \hat{\mathrm{j}}^2, \hat{\mathrm{j}}_z$, где $\hat{\mathbf{j}} = \hat{\mathbf{i}} + \hat{\mathbf{s}}$ - полный угловой момент электрона, см. задачу 2.10.3.

18.1.4 Problems about Special Effects in Atoms 2

Б-2.11.11 Основное состояние водорода вариацией

Вычислить энергию основного состояния атома водорода из вариационного принципа. В качестве пробных функций взять:

а) $\psi(r) = \left(\pi a^3\right)^{-1/2}\exp(-r/a)$

б) $\psi(r) = \left(\pi b^2\right)^{-3/4}\exp\left(-r^2/2b^2\right)$.

Определить параметры a и b.

Solution

Суть решения в том, что (?? применяем вар метод и все???)
Параметры функции $\psi(\mathbf{r})$, выбранной для применения вариационного метода, определяются, исходя из того, чтобы вычисленное при помощи этой функции среднее значение гамильтониана

$$\langle\hat{\mathrm{H}}\rangle = \int \psi^*(\mathbf{r})\hat{\mathrm{H}}\psi(\mathbf{r})d^3x, \text{ где } \hat{\mathrm{H}} = -\frac{\hbar^2}{2m}\Delta - \frac{e^2}{r},$$

имело бы минимум при условии, что функция $\psi(\mathbf{r})$ является нормированной. Вычисляя интегралы и находя минимумы для средних значений гамильтониана $\langle\hat{\mathrm{H}}\rangle$, получаем:
(!?!?!? ну вот нужно сесть и сделать это!!!)
случай а) $a = \frac{\hbar^2}{me^2}$, $\quad \langle\hat{\mathrm{H}}\rangle = -\frac{1}{2}\frac{me^4}{\hbar^2}$ (точное решение);
случай б) $b = \frac{3\sqrt{\pi}}{4}\frac{\hbar^2}{me^2}$, $\quad \langle\hat{\mathrm{H}}\rangle = -\frac{4}{3\pi}\frac{me^4}{\hbar^2} \simeq -\frac{1}{2{,}36}\frac{me^4}{\hbar^2}$.

Б-2.11.12 Диамагнитная восприимчивость гелия вариацией

Найти диамагнитную восприимчивость атома гелия в основном состоянии, исходя из волновой функции вида
а) $\psi(r) = \left(\pi a^3\right)^{-1/2}\exp(-\frac{r}{a})$;
б) $\psi(r) = \left(\pi b^2\right)^{-3/4}\exp\left(-\frac{r^2}{2b^2}\right)$.
Определить параметры a и b.

Solution

Суть решения в том, что
2.11.12. Гамильтониан атома гелия, записанный в атомной системе единиц, имеет вид

$$\hat{\mathrm{H}} = -\frac{1}{2}\Delta_1 - \frac{1}{2}\Delta_2 - \frac{Z}{r_1} - \frac{Z}{r_2} + \frac{1}{r_{12}},$$

где $r_{12} = |\mathbf{r}_1 - \mathbf{r}_2|$. В выражении (1) первые два слагаемых описывают кинетическую энергию электронов, третье и четвертое слагаемые притяжение электронов к ядру (для гелия $Z = 2$) и последнее слагаемое описывает кулоновское отталкивание электронов. Первая часть задачи предполагает минимизацию среднего значения гамильтониана (1), найденного при помощи пробной функции $\psi \sim \exp\left[-Z'\left(r_1 + r_2\right)\right]$, и нахождение значения вариационного параметра Z'. Нормируем пробную функцию и получаем

$$\psi = \frac{Z'^3}{\pi}e^{-Z'(r_1+r_2)}.$$

При вычислении среднего значения гамильтониана $\langle\hat{\mathrm{H}}\rangle$ нам встретятся интегралы

$$\langle\frac{1}{r_1}\rangle = \langle\frac{1}{r_2}\rangle = Z',$$

по поводу их вычисления - см. задачу 2.6.4, а также интеграл

$$\langle\frac{1}{r_{12}}\rangle = \left(\frac{Z'^3}{\pi}\right)^2\int dr_1 dr_2\frac{r_1^2 r_2^2 d\Omega_1 d\Omega_2 e^{-2Z'(r_1+r_2)}}{\sqrt{r_1^2 + r_2^2 - 2r_1 r_2\cos\theta}}.$$

В интеграле (3) зафиксируем вначале значение $\mathbf{r}_1$ и проинтегрируем по угловым переменным, относящимся к r_2, совместив ось z с направлением вектора $\mathbf{r}_1$. В результате получим

$$2\pi\int\limits_0^\pi \frac{\sin\theta d\theta}{\sqrt{r_1^2 + r_2^2 - 2r_1 r_2\cos\theta}} = \begin{cases}\frac{4\pi}{r_1}, & r_1 > r_2,\\ \frac{4\pi}{r_2}, & r_2 > r_1.\end{cases}$$

С учетом данного результата приводим интеграл (3) к виду

$$\langle\frac{1}{r_{12}}\rangle = \left(4Z'^3\right)^2\left\{\int\limits_0^\infty r_1 e^{-2Z'r_1}dr_1\int\limits_0^{r_1} r_2^2 e^{-2Z'r_2}dr_2 + \int\limits_0^\infty r_2 e^{-2Z'r_2}dr_2\int\limits_0^{r_2} r_1^2 e^{-2Z'r_1}dr_1\right\} =$$
$$= Z'\left(2 - \frac{11}{8}\right) = \frac{5}{8}Z'.$$

Собирая далее результаты (2) и (4), получаем для среднего значения $\langle\hat{\mathrm{H}}\rangle$ следующее выражение:

$$\langle\hat{\mathrm{H}}\rangle = -2ZZ' + \frac{5}{8}Z' + Z'^2,$$

где мы учли, что $-\langle\Delta_1\rangle = -\langle\Delta_2\rangle = Z'^2$, как это следует из решения задачи 2.6.4. Заметим, что наша пробная функция фактически есть произведение двух функций основного состояния атома водорода с единственным отличием $Z \to Z'$, поэтому использование результатов задачи 2.6.4 является корректным. Минимизируем $\langle\hat{\mathrm{H}}\rangle$ и находим

$$Z' = Z - \frac{5}{16},$$

т. е. для гелия $Z' = 27/16$. Полученное значение Z' имеет прозрачный физический смысл - это значение эффективного заряда ядра, которое «чувствует» электрон при движении в общем кулоновском поле ядра и второго электрона - часть заряда ядра Z экранируется вторым электроном.

Найдем далее диамагнитную восприимчивость основного состояния гелия. Запишем общий вид гамильтониана для атома гелия в однородном внешнем магнитном поле (в обычной системе единиц):

$$\hat{\mathrm{H}} = \hat{\mathrm{H}}_0 + \frac{e\hbar}{2mc}\mathcal{H}(\hat{\mathbf{L}} + 2\hat{\mathbf{S}}) + \frac{e^2}{8mc^2}\sum_{a=1,2}\left[\mathcal{H}\times\mathbf{r}_a\right]^2,$$

обозначения совпадают с обозначениями задачи 2.11.10. Заметим, что в основном состоянии гелия $L = S = 0$, поэтому линейное по $\mathcal{H}$ слагаемое не дает вклада в поправку к энергии. Следовательно,

$$E^{(1)} = \frac{e^2}{8mc^2}\langle\sum_{a=1,2}[\mathcal{H}\times\mathbf{r}_a]^2\rangle = \frac{e^2}{8mc^2}\frac{2}{3}\mathcal{H}^2\sum_{a=1,2}\langle r_a^2\rangle,$$

где угловые скобки $\langle ...\rangle$ означают усреднение по состоянию с пробной функцией с зарядом Z'. Диамагнитная восприимчивость равна

$$\chi = -\frac{\partial^2 E^{(1)}}{\partial\mathcal{H}^2} = -\frac{e^2}{6mc^2}\sum_{a=1,2}\langle r_a^2\rangle = -\frac{e^2}{6mc^2}\frac{a^2}{Z'^2} = -\frac{1}{Z'^2}a^3\alpha^2,$$

где $\alpha = e^2/(\hbar c) \simeq 1/137$ - постоянная тонкой структуры. Численное значение восприимчивости: $\chi = -2,77\cdot 10^{-30}$ см^3.

Б-2.11.13 Парамагнетизм Ван Флека (?)

Показать, что газ атомов, обладающих в основном состоянии полным моментом $J = 0$, но при этом $L = S \neq 0$, парамагнитен (парамагнетизм Ван Флека).

Solution

Суть решения в том, что

В этом случае поправка первого порядка для зеемановского взаимодействия $\hat{V}_Z$ (см. (II.61)) равна нулю. Оценим поправку второго порядка для возмущения $\hat{V}_Z$ к уровню энергии атома с $L = S \neq 0$ и $J = 0$. Поправка второго порядка содержит энергетический знаменатель, равный разности энергии основного терма и соответствующего возбужденного состояния. Среди всех возможных энергетических знаменателей следует учесть только те, которые относятся к одной конфигурации основного терма, поскольку расстояние между уровнями энергии с одной и той же конфигурацией имеет величину порядка $\alpha^2 E_0 \sim A$, где A - эффективная величина спин-орбитального взаимодействия. Таким образом, оценка поправки второго порядка есть

$$\Delta E^{(2)} \approx \sum_{J,M_J}\frac{|\langle L,S,J,M_J|\hat{V}_Z|L,S,0,0\rangle|^2}{E_{LSO} - E_{LSJ}} \sim \frac{\mu_0^2\mathcal{H}^2}{A}.$$

Легко видеть, что $|\Delta E_{\mathrm{Z}}^{(2)}|/|\Delta E_{\mathrm{D}}^{(1)}| > 1$, где $E_{\mathrm{D}}^{(1)}$ - поправка первого приближения для диамагнитного взаимодействия (II.62). Вспомним также, что поправка второго приближения к основному состоянию всегда отрицательна, поэтому газ таких атомов, находящихся в основном состоянии с $J = 0$ и $L = S \neq 0$, будет парамагнитным.

Б-2.11.14 Свойства молекулы водорода (??????)

Определить зависимость вращательного квантового числа молекулы водорода H_2 от суммарного спина S протонов.

Solution

Суть решения в том, что

Б-2.11.15 Спектр двухатомной молекулы, описываемой потенциалом Кратцера (?)

Найти энергетический спектр двухатомной молекулы, считая, что энергия взаимодействия ядер описывается модельным потенциалом Кратцера:

$$U(r) = -2D\left(\frac{b}{r} - \frac{b^2}{2r^2}\right)$$

Solution

Суть решения в том, что

Б-2.11.16 $p\mu$-атом

Отрицательный мюон захватывается протоном, образуя $p\mu$-атом, «боровский радиус» которого в 207 раз меньше соответствующего радиуса атома водорода. На таких расстояниях уже оказываются существенными ядерные силы, и мюон может захватиться протоном. Однако скорость захвата существенно зависит от величины суммарного спина μ-атома $\mathbf{S} = \mathbf{s}_\mu + \mathbf{s}_p$. Таким образом, время жизни отрицательного мюона в среде сильно зависит от величины суммарного спина S. Образовавшийся медленный $p\mu$-атом, как и нейтрон, взаимодействует с ядрами среды контактным образом, однако при этом взаимодействии следует учитывать также магнитное сверхтонкое взаимодействие, которое, как и для атома водорода в s-состоянии имеет изотропный контактный характер. Построить контактный оператор сверхтонкого взаимодействия $p\mu$-атома с ядром, обладающим спином I, при котором изменяется суммарный спин S $p\mu$-атома.
(вроде кривовато задача сформулирована, перепишу потом ее.)

Solution

Суть решения в том, что

18.1.5 Basic Problems about Hydrogen Atoms 1

Мартинсов,Смирнов-5.2. Водорода с массой ядра

Покажите, как изменятся частота излучения атома водорода с учетом конечной величины массы ядра. $m_0 r_e = M r_\mathrm{r}$, аде $m_0 u M$, соответственно, массы электрона и ядра.

Solution

(???)
Из равенства ускорений электрона и ядра вытекает условие равенства их угловых скоростей вращения

$$\frac{\mathrm{v}_e}{r_e} = \frac{\mathrm{v}_\mathrm{B}}{r_\mathrm{a}} = \omega.$$

${}^{2\partial}\mathbf{v}_e{}^{u}\mathbf{v}_\mathrm{g}$ - скорости электрона и ядра, соответственно. С учетом движения ядра, момент импульса атома

$$L = m_0 \mathrm{v}_e r_e + M \mathrm{v}_\pi r_\mathrm{a} = m_0 \omega r_e^2 + M \omega r_\mathrm{a}^2$$

$$\begin{cases} m_0\omega^2 r_e = \frac{e^2}{4\pi\varepsilon_0 (r_e + r_\pi)^2}, \\ m_0 \omega \alpha_e^2 + M\omega r_\pi^2 = n\hbar, \quad n = 1, 2, 3, ... \end{cases}$$

Если расстояние между электроном и ядром обозначить через $r = r_e + r_\mathrm{g} = r_e\,(1 + m_0/M)$, то после преобразований эти соотношения запишутся в виде

$$\begin{cases} \mu\omega^2 r = \frac{e^2}{4\pi\varepsilon_0 r^2}, \\ \mu\omega^2 = n\hbar, \quad n = 1, 2, 3, ... \end{cases}$$

здесь введена приведенная масса системы "электрон-ядро"

$$\mu = \frac{m_0 M}{m_0 + M}$$

$$\mu = \frac{m_0 M}{m_0 + M}$$

Решая полученную систему уравнений, находим для стационарных состояний атома $(n = 1, 2, ...)$

$$r_n = \frac{4\pi\varepsilon_0\hbar^2 n^2}{\mu e^2} \quad \text{и} \quad \omega_n = \frac{\mu e^4}{16\pi^2\varepsilon_0^2\hbar^3 n^3}.$$

Полная энергия атома

$$E = \frac{m_0 \mathrm{v}_e^2}{2} + \frac{M \mathrm{v}_\mathrm{g}^2}{2} - \frac{e^2}{4\pi\varepsilon_0 (r_e + r_\mathrm{a})} = \frac{\mu\omega^2 r}{2} - \frac{e^2}{4\pi\varepsilon_0 r}.$$

Подставляя сюда значения ${r_n}^u\boldsymbol{\omega}_n$, получаем формулу квантования энераии атома

$$E_n = -\frac{\mu e^4}{32\pi^2\varepsilon_0^2\hbar^2} \cdot \frac{1}{n^2}, n = 1, 2, ...$$

Отсюда находим частоты спектральных линий излучения такого атома:

$$\omega_{nk} = \frac{E_k - E_n}{\hbar} = R_\mathrm{M}\left(\frac{1}{n^2} - \frac{1}{k^2}\right)$$

где модифицированная постоянная Ридберга

$$R_\mathrm{M} = \frac{\mu e^4}{32\pi^2\varepsilon_0^2\hbar^3} = \frac{R}{1 + \frac{m_0}{M}}$$

был открыт изотоп тяжелого водорода - дейтерий D, для которого $M_D = 2M_H$

Spaldin-3.1(20 sec) Moment along the field axis

Calculate the allowed values of the magnetic moment along the field axis of an atom which has $J = 1$ and $g = 2$.

Solution

The total magnetic moment of an atom is $m = g\sqrt{J(J+1)}\mu_\mathrm{B}$, and $m_z = -gM_J\mu_\mathrm{B}$.
We have $J = 1$, $\sqrt{J(J+1)} = \sqrt{2}$, $M_J = -1, 0,$ or 1, $g = 2$. So

$$|m| = 2\sqrt{2}\mu_\mathrm{B}, \qquad m_z = -2\mu_\mathrm{B}, \quad 0, \text{ or } +2\mu_\mathrm{B}.$$

Note that in all cases the component along the field direction is less than the total magnetic moment.
(кст, еще 1ю часть доработаю для этой задачи!!!!)

O3.1-4.1

Частица находится в центральном поле силового центра с потенциальной энергией $U = -C/r^s$, где C - положительная постоянная, а r - расстояние от силового центра. Исходя из соотношения неопределённостей, показать, что при $s > 2$ возможны стационарные состояния частицы со сколь угодно большими по абсолютной величине отрицательными собственными значениями полной энергии. Частица при этом условии будет переходить на нижележащие энергетические уровни - произойдет ее «падение» в точку $r = 0$, т.е. на силовой центр. Если же $s < 2$, то наиболее низкий энергетический уровень будет иметь конечное значение полной энергии, Пользуясь этими результатами, объяснить возможность существования атомов, например атома волорода.

4.

1* Решение. Пусть частица локализована вблизи силового центра внутри сферы, радиус которой r. Ее потенциальная энергия будет порядка $-C/r^s$. Неопределенность координаты будет порядка r, а, следовательно, неопределенность импульса - порядка $\hbar/r$. Такого же порядка будет и сам импульс. Следовательно, средняя кинетическая энергия будет порядка $\hbar^2/mr^2$, а полная энергия

$$\mathscr{E} \sim \frac{\hbar^2}{mr^2} - \frac{C}{r^s}.$$

Если $s > 2$, то $\mathfrak{G}$ может принимать сколь угодно большие отрицательные значения. Но в таком случае должны существовать и уровни энергии со

сколь угодно большими по абсолютной величине отрицательными значениями $\mathscr{E}$ - произойдет падение частицы на силовой центр. Если же $s < 2$, то сколь угодно большие по абсолютной величине значения $\mathscr{E}$ невозможны, поэтому невозможно падение на силовой центр и возможно образование связанного состояния с $\mathscr{E} < 0$.

О3.1-4.2

Показать, что в пределе, когда главные числа в атоме водорода стремится к бесконечности, движение электрона переходит в классическое движение по круговой орбите-

(???)

О3.1-4.3 Третий закон Кеплера из квантовой механики (???)

Классические формулы следуют из квантовых в пределе как и в задаче Кеплера, потенццальная энергия $U(r) \propto \frac{1}{r}$. из квантовых формул для уровней энергии $\wp_n = -\mathrm{Ry}/n^2$ и радиусов состояний $r_n = an^2$ электрона в атоме водорода, получить для больших n третий закон Кеплера.

(??? тут кривое скорее всего условие)

4.

3. $\frac{r^3}{T^2} = \frac{e^2}{4\pi^2 m} = \text{const}$. (Классический закон Кеплера в системе Солн-це-Земля $\frac{r^3}{T^2} = \frac{\gamma M_\text{C}}{4\pi^2} = \text{const}$.

О3.1-4.4 Простейшие свойства решения атома водорода (20 секунд)

Показать, что среди сферически симметричных решений уравнения Шредингера для водородоподобного атома, конечных при $r = 0$ и обращающихся в нуль при $r = \infty$, имеется экспоненциальное решение $e^{-\alpha r}$. Найти постоянную α и энергию атома в рассматриваемом состоянии. Что это за состояние?

4.

4. $\psi \propto e^{-\alpha r}$, где $\alpha = \frac{mZe^2}{\hbar^2} = \frac{1}{r_1}, r_1$ - радиус первой боровской орбиты водородоподобного атома, а функция ψ - с точностью до нормировочной константы - описывает основное состояние водородоподобного атома $\left(\psi_1 = \frac{1}{\sqrt{\pi r_1^3}} e^{-r/r_1}\right)$. $\mathscr{E}_1 = -\frac{mz^2e^4}{2\hbar^2}$.

О3.1-4.5

Найти объемную плотность вероятности нахождения электрона в водородоподобном атоме для основного состояния.

4.

5. $|\psi|^2 = \frac{q^2}{4\pi} e^{-qr}$, где $q = \frac{2mZe^2}{\hbar^2}$.

О3.1-4.6(30 sec) Плотность вероятности в атоме водорода

Найти радиальную плотность вероятности нахождения электрона в водородоподобном атоме для основного состояния. При каких значениях r эта величина достигает максимума.

4.

6. $4\pi r^2|\psi|^2 = q^3 r^2 e^{-qr}$, где $q = \frac{2mZe^2}{\hbar^2}$. Эта величина максимальна при $r = \frac{2}{q} = \frac{\hbar^2}{mZe^2} = r_1$, где r_1 - радиус первой боровской орбиты.

(1 строчка тут будет вычисления этого интеграла.)

О3.1-4.7(20 sec) среднее расстояние от ядра в $1s$-состоянии

Найти среднее расстояние $\langle r\rangle$ электрона от ядра в $1s$-состоянии водородоподобного атома.

4.

7. $\langle r\rangle = \frac{3}{2} r_1$.

О3.1-4.8(20 sec) среднее обратное расстояние от ядра в $1s$-состоянии

Найти среднее значение обратного расстояния $\langle 1/r\rangle$ электрона от ядра в основном состоянии водородоподобного атома.
(??? формула Крамерса сразу же говорит ответ??? заготовлю их!!!)

О3.1-4.9(30 sec) $\langle U\rangle$ и $\langle T\rangle$ основного состояния водорода

Найти средние значения потенциальной $\langle U\rangle$ и кинетической $\langle T\rangle$ энергий основного состояния водородоподобного атома.
(чет тут теряюсь, прописать лучше нужно темы эти!!! точно первая часть требует доработку по этому, с ходу формулы не готовы! плохо, а что поделать?)

О3.1-4.10(50 sec) Энергия и константы в водороде по затравочной функции

Волновая функция одного из состояний атома водорода имеет вид $\psi = A(1+\alpha r)e^{-\beta r}$, где A, α, β - некоторые константы. Определить величину констант α и β, энергию этого состояния и его квантовые числа.

О3.1-4.11

Определить разрешающую способность R спектрального прибора, необходимую для наблюдения изотопического сдвига спектральных линий дейтерия относительно линий водорода. Какова должна быть ширина b основания призмы из тяжелого флинта с дисперсией $dn/d\lambda = 1000\text{см}^{-1}$ (в диапазоне красного света) в призменном спектрографе, применяемом для обнаружения изотопического сдвига головной линии серии Бальмера?

О3.1-4.12

Серия Лаймана наблюдается в смеси атомарных водорода и трития (ядро атома трития состоит из протона и двух нейтронов). Определить разрешающую способность спектрального прибора, которая достаточна для разрешения изотопической структуры спектральных линий этой серии. Как меняется требуемая разрешающая способность при переходе к другим сериям (Бальмера, Пашена) той же смеси? Можно ли разрешить изотопическую структуру спектральных линий той же смеси в видимой области спектра с помощью стеклянной призмы с основанием $b = 1$ см и дисперсией показателя преломления $dn/d\lambda = 1000\text{см}^{-1}$? Каково должно быть эффективное разрешить и исследовать ту же структуру с помощью интерферометра Фабри-Перо?

О3.1-4.13

Серия Бальмера наблюдается в смеси атомарных водорода и дейтерия. Определить разрешающую способность и число штрихов N дифракционной решетки, которые необходимы для разрешения во втором порядке изотопической структуры спектральных линий этой серии. Как меняется эта разрешающая способность с увеличением номера линии (т. е. с уменьшением длины волны) указанной серии?

О3.1-4.14

В спектрах некоторых звезд наблюдается $m \approx 30$ линий водородной серии Бальмера. При каком наименьшем числе N штрихов дифракционной решетки можно разрешить эти линии в спектре первого порядка?

О3.1-4.15

Кварцевая пластинка, расположенная между скрещенными поляроидами, образует поляризационный фильтр. Разрешенные направления пластинки составляют угол 45° с главными направлениями поляроидов. Какую минимальную толщину должна иметь пластинка, для того чтобы с помощью такого фильтра можно было от делить наиболее длинноволновую линию серии Бальмера для водорода ($\lambda = 656$ нм) от той же линии дейтерия? Показатели преломления для обыкновенного и необыкновенного лучей в кварце $n_0 = 1,5442, n_\text{e} = 1,5533$. Источником света является газоразрядная водородно-дейтериевая лампа.

О3.1-4.16

Каково должно быть минимальное расстояние между зеркалами в интерферометре Фабри-Перо, чтобы по оптическому спектру установить наличие двух изотопов калия $^{39}_{19}$ К и $^{40}_{19}$ К? Коэффициент отражения зеркал по энергии 0,9, энергия ионизации атома калия $W = 4,3$ эВ.

О3.1-4.17

Отрицательные мюоны могут захватываться атомом и замещать в нем электроны электронной оболочки. Практически может замещаться лищь один электрон. Получающиеся в результате такой замены системы называются мезоатомами. Масса мюона $m_\mu = 207m_\text{e}$. Вычислить по теории Бора радиус первой круговой орбиты (К-орбиты) мюона в мезоатоме. Рассчитать энергетические уровни мезоатома. Какое излучение будет наблюдаться при переходе на К-орбиту мюона с более высоких орбит? Почему исследование такого излучения лрименяется для выявления структуры тяжелых атомных ядер? Массой мюона по сравнению с массой ядра пренебречь.

О3.1-4.18

Позитроний представляет собой связанную систему из электрона и его античастицы - позитрона. Найти уровни энергии, энергию ионизации и соответствующую ей длину волны резонансной линии позитрония. Резонансным называют переход из первого возбужденного состояния в основное.

О3.1-4.19 Энергия ионизации по спектру (????)

Длина волны линии H_α водородной серии Бальмера равна $\lambda = 0,656$ мкм. Определить по этим данным энергии ионизации $\mathscr{E}_\text{и}$ позитрония и мюония, находящихся в основном состоянии. Масса мюона $m_\mu = 207m_\text{e}$ (m_e - масса электрона).

4.

19. $\mathscr{E} = 6,8$ эВ (для позитрония) ; $\mathscr{E}_\text{и} = 2,6$ кэВ (для мюония).

О3.1-4.20

Рассчитать энергию излучения $\Delta\mathscr{E}$, испускаемого в мезоатоме водорода (мюония) при переходе мюона с N- на M-оболочку. Как велик радиус 1-й боровской орбиты в этом случае?

4.

20. $\Delta\mathscr{E} = \frac{\mu e^4}{2\hbar^2}\left(\frac{1}{3^2} - \frac{1}{4^2}\right) \approx 125$ эВ, где $\mu = \frac{m_\mu m_\text{p}}{m_\mu + m_\text{p}}$ - приведенная масса мезоатома; $r_\mu = \frac{m_e}{m_\mu} r_1 = 2,8 \cdot 10^{-11}$ cm, где $r_\text{I} = 0,53$Å - радиус первой боровской орбиты в атоме водорода.

О3.1-4.21

Оценить скорость мюона μ^-в мезоатоме с зарядом ядра $Z = 10$. Найти радиус атома.

4.

21. $v_\mu \approx \frac{Ze^2}{\hbar} = Z\alpha c = 2,3 \cdot 10^9$ cm/c; $r_\mu = \frac{m_e}{Z(m_\mu)_{\text{прив}}} r_1 \approx 2,8 \cdot 10^{-12}$c, где $\alpha = \frac{e^2}{\hbar c} = \frac{1}{137}$ - постоянная тонкой структуры.

О3.1-4.22

При переходе пиона π^-с $4f$-оболочки на $3d$-оболочку мезоатома с ядром фосфора ($Z = 15$) испускается рентгеновский квант с энергией $\mathscr{E} = 40$ кэВ. Определить массу пиона и радиус $3d$-оболочки.

4.

22. $\mu_\pi c^2 \approx 137$МВ, где $\mu_\pi = \frac{m_\pi m}{m_\pi + m_9} \approx m_\pi$ - приведенная масса мезоатома, m_π - масса пиона, m_q - масса ядра. $r_\pi \approx \frac{9m_e}{m_\pi Z} r_1 \approx 1,2 \cdot 10^{-11}$ см.

О3.1-4.23

Какова была бы энергия связи и радиус водородоподобной системы из двух нейтронов при учете только силы гравитационного притяжения между ними?

О3.1-4.24

Какой радиус имела бы $2p$-оболочка атома из нейтрона и электрона, связанных между собой только силой гравитационного взаимодействия?

О3.1-4.25

Найти потенциалы ионизации ионов He^+и Li^{++}.

О3.1-4.26

Определить наименьшую энергию, которую надо сообщить в основном состоянии трижды ионизованному атому бериллия, чтобы возбудить полный спектр этого атома.

О3.1-4.27

Энергия ионизации атома He равна 24,5 эВ. Определить энергию $\mathfrak{g}$, необходимую для получения из нейтрального атома He дважды ионизованного иона He^{++}.

О3.1-4.28

Ядро атома трития, находящееся в основном состоянии, испытывает β^--распад. Считая, что за время вылета распадного электрона состояние атомного электрона не успевает измениться, найти его полную энергию сразу после распада.

О3.1-4.29 Вклад сильного взаимодействия в разность уровней

В 1989 г. в ЦЕРНе при пропускании медленных антипротонов через водородную камеру наблюдалось образование протониума - атома состава ($p\bar{p}$). Энергия излучения, соответствующая переходу протониума из состояния $2p$ в $1s$, оказалась равной 10,1 кэВ. Определить вклад сильного взаимодействия в разность энергий указанных уровней. Для какого из этих уровней вклад сильного взаимодействия оказывается наибольшим?

Solution (???)

4.29*. Вклад сильного взаимодействия $\Delta\mathscr{E} = 0,7$ кэВ.

Решение. Прежде всего, определим энергию излучения протониума, определяемую исключительно кулоновским взаимодействием, возникающим между протоном p и антипротоном $\tilde{p}$. Связанная система ($\tilde{p}$) аналогична позитронию. Поэтому для расчета кулоновского взаимодействия можно использовать результат задачи 4.18 с заменой массы электрона на массу про тона. Это дает уровни энергии протониума

$$\mathscr{E}_n = -\frac{m_\text{p} e^4}{2\hbar^2 n^2} = -\,\text{Ry}\,\frac{m_\text{p}}{m_\text{e}}\frac{1}{2n^2} \approx -12,5\frac{1}{n^2}\ \text{кэВ}.$$

Следовательно, вклад кулоновского взаимодействия в энергию перехода $2p \to 1s$ в атоме протониума составляет

$$\Delta\mathscr{E}_\text{Ку} = 12,5\left(\frac{1}{1^2} - \frac{1}{2^2}\right) \approx 9,4\ \text{кэВ}.$$

Расхождение с экспериментальным значением обусловлено вкладом сильного взаимодействия. Таким образом,

$$\Delta\mathscr{E}_\text{сил} = \Delta\mathscr{E} - \Delta\mathscr{E}_\text{ку} = 10,1 - 9,4 \approx 0,7\ \text{кэВ}.$$

В силу короткодействия ядерных сил их влияние на положение $2p$-состояния незначительно по сравнению с $1s$-состоянием, поскольку в кулоновском потенциале вероятность частице в $2p$-состоянии попасть в окрестность начала координат близка к нулю.

О3.1-4.30

За счет сильного взаимодействия энергия основного состояния протониума (системы $(\text{p}\tilde{\text{p}})$) сдвигается на $\delta E = 0,7$ кэВ относительно его «чисто кулоновского» значения. Считая, что сильное взаимодействие описывается потенциалом Юкавы $U(r) = -\left(g^2/r\right)\exp\left(-r/r_0\right)$, $r_0 = 0,8\cdot 10^{-13}$см, оценить величину константы сильного взаимодействия $g^2/(\hbar c)$ (функция $1s$-состояния протониума $\psi = \left(\pi r_5^3\right)^{-1/2}\exp\left(-r/r_5\right)$, где r_b - боровский радиус протониума.

4.

30. $\frac{g^2}{\hbar_c} = \frac{r_\text{Б}^3\,|\delta\S|}{4\hbar c r_0^2} \approx 0,27$. Сравните с 10.59 и 10.60 .

Маг-МФТИ-вструп.5 возбужденные вращательные уровни в HCl

Оценить количество вращательных уровней молекулы HCl возбуждаемых при комнатной температуре (300K). Межъядерное расстояние у этой молекулы равно d=1.27 Å

Solution

масса HCl $= m_p + 35m_p$ из таблицы менделеева (наверное) ибо у водорода масса - масса протона, а хлор это 35 нуклонов.
Нужно
Энергия вращательного движения:

$$E_\text{вр} = \frac{\hbar^2 l(l+1)}{2\mu d^2}$$

(потом подумаю, как вывести её)
то есть нужно найти максимальное l
В то же время энергия квант тепловой энергии молекулы kT, на одну степень свободы приходится $1/2$ этой энергии. у нас две степени свободы, поэтому есть две половины kT, так что:

$$E_T = kT$$

сравниваем эти выражения.
высчитаем сперва поотдельности каждое, далее условие на l состоит в том, что оно максимальное, при котором энергия меньше возможной при данной температуре:

$$1.3l(l+1) < 25$$

для $l = 4$ это так.
(потом подоказываю, откуда вообще формулы эти)

О3.1-4.31

Фотон головной (наиболее длинноволновой) линии серии Лаймана иона гелия He^+поглощается водородным атомом в основном состоянии и ионизует его. Определить кинетическую энергию T, которую при этом получит электрон.

О3.1-4.32

Атом водорода, вначале находившийся в неподвижном состоянии, излучил квант света, соответствующий головной (наиболее длинноволновой) линии серии Лаймана. Определить относительное изменение частоты фотона $\Delta v/v_0$ из-за отдачи. Какую скорость приобрел атом за счет энергии отдачи?

SOLUTIONS 4. Атом водорода и водородоподобные атомы

4.

8. $\left\langle \frac{1}{r} \right\rangle = \frac{1}{r_I}$.

Примечание. Здесь можно обойтись без интегралов. Достаточно использовать теорему вириала для кулоновского поля

$$2\langle T\rangle = -\langle U\rangle, \text{ откуда:}$$
$$\mathscr{E}_n = \langle T\rangle + \langle U\rangle, \text{ и при } n = 1$$
$$\mathscr{E}_1 = -\frac{e^2}{2r_1} = -\frac{1}{2}\langle U\rangle = e^2\left\langle \frac{1}{r} \right\rangle.$$

Таким образом,

$$\left\langle \frac{1}{r} \right\rangle = \frac{1}{r_1}.$$

4.

9. $\langle U\rangle = -\frac{Ze^2}{r_1}; \langle T\rangle = \frac{Ze^2}{2r_1} = -\frac{\langle U\rangle}{2}$. (См. примечание к ответу задачи 4.8.)

4.

10. $\alpha = -\frac{me^2}{2\hbar^2}; \beta = \frac{me^2}{2\hbar^2}; \mathscr{E} = -\frac{me^4}{8\hbar^2}$, откуда $n = 2$.

Поскольку $\psi = \psi(r)$, то $l = 0$. Это $2s$ - состояние. Если $\alpha = 0$, то это основное состояние $1s$; при этом $\beta = \frac{1}{r_1} = \frac{me^2}{\hbar^2}; n = 1; \mathscr{E} = -\frac{me^4}{2\hbar^2}$. См. также решение задачи 3.10.

4.

11. $R > 2\frac{m_\text{н}}{m_\text{e}} \approx 3700; b > \frac{R}{dn/d\lambda} \approx 3,7$ см.

4.

12. Разрешающая способность должна быть не меньше $\frac{3}{2}\frac{m_\text{p}}{m_\text{e}} \approx 2800$. Она одинакова для всех линий спектральных серий смеси. Разрешающая способность призмы $b\frac{dn}{d\lambda} = 1000$, т. е. недостаточна для разрешения. Для интерферометра Фабри-Перо должны выполняться неравенства:

$$m < \frac{3}{2}\frac{m_\text{p}}{m_\text{e}} < N_\text{Эфф}\, m$$

4.

13. Требуемая разрешающая способность $\frac{\lambda}{\delta\lambda} = \frac{\omega}{\delta\omega} = \frac{2m_\text{p}}{m_\text{e}} \approx 3700$. Она одинакова для всех линий серии, $N > \frac{1}{2}\frac{\lambda}{\delta\lambda} \approx 1850$.

4.

14. $N \approx \frac{m^3}{8} \approx 3400$ штрихов.

4.

15. $d_{\min} = \frac{\lambda_{\text{H}}\lambda_{\text{D}}}{2(\lambda_{\text{D}}-\lambda_{\text{H}})}\frac{1}{n_{\text{e}}-n_{\text{o}}} \approx \frac{\lambda^2}{2\Delta\lambda}\frac{1}{n_{\text{e}}-n_{\text{o}}} = 13,24$ см, $\frac{\lambda}{\Delta\lambda} \simeq \frac{2m_{\text{p}}}{m_{\text{e}}} \approx 3700$.

4.

16. $L_{\min} = \frac{M_1M_2}{(M_2-M_I)m_{\text{e}}}\frac{\hbar c}{W}\frac{1-r}{\sqrt{r}} = 1,37$ см.

4.

17. $r_1 = \frac{\hbar^2}{e^2 m_\mu Z} \approx \frac{1}{Z}\cdot 0,0026\cdot 10^{-8}$ см, что примерно в 200 раз меньше соответствующего значения r_1 для водородоподобного иона с тем же значением заряда ядра Z. Результат получен в предположении, что K-орбита мюона проходит вне ядра. Электронная оболочка практически не оказывает влияния на этот результат, так как из-за сферической симметрии электронного облака создаваемое им электрическое поле в месте нахождения мюона считается равным нулю. В том же предположении

$$\mathscr{E}_n = -\frac{m_\mu e^4}{2\hbar^2}\frac{Z^2}{n^2} \approx -2810\frac{Z^2}{n^2} \ni \text{ В}$$

Отсюда видно, что излучение, возникающее при переходе мюона на K-орбиту с более высоких орбит, будет расположено в рентгеновской области спектра, а при больших Z - в области γ-лучей. При больших ZK-орбита мюона проходит внутри ядра атома. В этом случае приведенные выше формулы становятся неприменимыми. Результаты сильно зависят от распределения электрического заряда в ядре, с чем и связана возможность использования мезоатомов для изучения распределения электрического заряда в атомном ядре.

4.

18. $\mathscr{E}_n = -\frac{hc}{2n^2}R_\infty, \mathscr{E} = -\mathscr{E}_1 = \frac{hc}{2}R_\infty = 6,80 \ni$, $\lambda_{\text{рез}} = \frac{8}{3R_\infty} = 243,0045$ нм, где постоянная Ридберга $R_\infty = 109737,3$ см$^{-1}$.

4.

23. $|\mathscr{E}_1| = \frac{\gamma^2 m_{\text{n}}^2}{4\hbar^2} \sim 10^{-83}$ эрг; $r_1 = \frac{2\hbar^2}{\gamma m_{\text{n}}^3} \sim 10^{28}$с.

Размер «бинейтронного атома» так велик, что неучет действия других масс Вселенной, очевидно, совершенно недопустим.

4.

24. $r_n = n^2\frac{\hbar^2}{m_e^2\gamma m_{\text{n}}}; r_2 \approx 4\cdot 10^{31}$ см, где $n = 1, 2, 3, \ldots$ - главное квантовое число.

4.

25. $V_{\text{He}} = 4V_{\text{H}} = 54,4$ В; $V_{\text{Li}} = 9V_{\text{H}} = 122,4$ В.

4.

26. $\mathscr{E}_{\text{Be}} = Z^2 e V_{\text{H}} = 217,6$ эВ.

4.

27. $\mathscr{E} = 78,9$ эВ.

4.

28. $\langle \delta_2 \rangle = \langle T \rangle + \langle U_2 \rangle = -40,8$ эВ, где $\langle T \rangle = 13,6$ эВ, $\langle U_2 \rangle = -\left\langle \frac{2e^2}{r} \right\rangle = -\frac{2e^2}{r_{\text{S}}} = -54,4$ эВ. Здесь усреднение идет по волновой функции атома трития.

4.

31. $T = 2\mathscr{E}_{\mathbf{n}} = 27,2$ эВ, где $\mathscr{E}_{\mathbf{n}}$ - энергия ионизации атома водорода.

4.

32. $\frac{\nu_0 - v}{v_0} = \frac{h\nu_0}{2m_{\text{a}}c^2} = \frac{3}{16}\frac{m_{\text{e}}}{m_{\text{at}}}\alpha^2 = 5,44 \cdot 10^{-9}$; $v = \frac{3}{8}\frac{m_{\text{e}}}{m_{\text{at}}}\alpha^2 c = 326$ cm/c, где $\alpha = e^2/\hbar c = 1/137$ - постоянная тонкой структуры.

4.

33. Водородная лампа должна удаляться от дейтериевой со скоростью $v \approx 82$ km/c.

4.

34. Угол конуса разлета γ-квантов отличается от развернутого на $\alpha \approx 1,2 \cdot 10^{-2}$ рад.

4.

35. $v_e = v_{\tilde{e}} = \frac{e^2}{2\sqrt{2}\hbar} \approx 8 \cdot 10^7$ cm/c (угол разлета $\approx 180°$).

4.

36. $\Delta\varphi = \frac{m_e e^2 \lambda}{4\pi\hbar^2} \approx 0,15$ рад $\approx 10°$.

Решение. Разброс в углах разлета электронов происходит из-за наличия перпендикулярно направленной импульсу фотона составляющей импульса электрона; ее наличие связано с движением электронов в атоме. Полный импульс электрона $p = \sqrt{p_\parallel^2 + p_\perp^2}$.

Перпендикулярную составляющую $p_\perp$, обеспечивающую максимальное отклонение, легко оценить из сооотношения неопределенностей:

$$\Delta p \Delta r \sim \hbar, \quad \text{где} \quad \Delta p \approx p_\perp, \quad \Delta r = r_1 = \frac{\hbar^2}{me^2}$$

Таким образом,

$$p_\perp \approx \frac{me^2}{\hbar} = m\alpha c$$

где $\alpha = e^2/\hbar c$ - постоянная тонкой структуры. Для нахождения составляющей импульса $p_\parallel$, направленной вдоль движения электрона, достаточно написать закон сохранения импульса:

$$\frac{h}{\lambda} = p_\parallel - \frac{h}{\lambda + \delta\lambda}$$

Величина комптоновского смещения $\delta\lambda$ определяется по известной формуле

$$\delta\lambda = 4\pi\Lambda_\mathrm{e} \approx 0,0485\text{Å} \ll \lambda = 1\text{Å}$$

Таким образом,

$$p_\parallel \approx \frac{2h}{\lambda}$$

Максимальный угол отклонения электрона

$$\operatorname{tg}\varphi = \frac{p_\perp}{p_\parallel} \approx \frac{mc\alpha}{2h/\lambda} = \frac{me^2\lambda}{4\pi\hbar^2} = 0,15, \quad \text{т. е.} \quad \varphi \approx 0,15 \text{ рад } \approx 8,6^\circ$$

Заметим, что для получения ответа можно было бы воспользоваться и законом сохранения энергии.

$$\frac{hc}{\lambda} + \mathscr{E} = \frac{hc}{\lambda + \delta\lambda} + \sqrt{m^2c^4 + p^2c^2}$$

Энергия электрона $\mathscr{E}_{9\mathbf{\Omega}} = mc^2 - |\mathscr{E}_\mathrm{CB}|$. Для водорода очевидно, что $|_{\text{св}}| \ll mc^2$, т. е. $\mathscr{G}_{9\Omega} \approx mc^2$. Энергия рентгеновского кванта $hc/\lambda = 12,4$ кэВ. Поэтому

$$mc^2 \gg \frac{hc}{\lambda} \gg |\mathscr{E}_\mathrm{CB}|$$

Кроме того, $p_\perp \ll p_\parallel$, что выясняется простым подсчетом. Поэтому

$$\sqrt{m^2c^4 + p^2c^2} \approx \sqrt{m^2c^4 + p_\parallel^2c^2} \approx mc^2 + \frac{p_\parallel^2}{2m}.$$

Подставив все это в закон сохранения энергии, получим

$$\frac{hc}{\lambda} \approx \frac{hc}{\lambda + \delta\lambda} + \frac{p_\parallel^2}{2m}, \text{ откуда } p_\parallel \approx \sqrt{\frac{2mhc\delta\lambda}{\lambda^2}} = \frac{2h}{\lambda}, \text{ где } \delta\lambda = \frac{2h}{mc}.$$

4.

37. $\Delta\varphi = \frac{Zm_\mathrm{e}e^2\lambda}{2\pi\hbar^2} \approx 0,25$ рад $\approx 14^\circ$.

4.

38: $T_\mathrm{e} = 10,2$ кэВ.

Решение. Согласно закону Мозли энергия кванта, излученного при переходе электрона с уровня n_2 на уровень n_1 (заряд ядра Z, а σ - поправка на экранирование заряда ядра электронами K-оболочки)

$$\mathscr{E} = \hbar\omega = \mathrm{Ry}(Z - \sigma)^2 \left(\frac{1}{n_1^2} - \frac{1}{n_2^2}\right).$$

Для линии $K_\alpha n_1 = 1, n_2 = 2$. Поскольку энергия такого кванта в спектре излучения серебра известна и равна $\mathscr{E} = 21,6$ кэВ, то из приведенной формулы найдем поправку σ на экранирование заряда ядра электронами на K-оболочке (в обоих случаях $Z < 50$)

$$\sigma = Z_\mathrm{Ag} - \sqrt{\frac{4\mathscr{E}}{3\mathrm{Ry}}} \approx 1$$

Энергия, необходимая для освобождения электрона из K-оболочки атома $_3$Zn (переход с $n = 1$ в $n = \infty$), равна

$$(\hbar\omega)_\mathrm{Zn} = \mathrm{Ry}\left(Z_{Z\mathrm{n}} - 1\right)^2 = 13,6 \cdot 29^2 = 11,4\text{k B}B,$$

а значит, кинетическая энергия T_e вылетевшего оттуда электрона равна

$$T_\mathrm{e} = \mathscr{E} - (\hbar\omega)_\mathrm{Zn} = 21,6 - 11,4 = 10,2\kappa \text{ B}.$$

4.

39. Отличие в $n^4 = 10^4$ раз.

18.1.6 Basic Problems about Hydrogen Atoms 2

O3.1-4.33

С какой скоростью и в каком направ.ении должна двигаться светящаяся газоразрядная лампа, заполненная водородом, чтобы в ней происходило поглощение света, излучаемого неподвижной газоразрядной лампой, заполненной дейтерием? Рассмотреть движение вдоль прямой, соединяющей лампы.

O3.1-4.34

При аннигиляции позитронов с электронами образуются два γ-кванта, уносящие энергию покоя аннигилировавших частиц. Если бы электрон и позитрон перед аннигиляцией покоились, γ - кванты разлетались бы в строго противоположных направлениях. В реальном процессе аннигиляции замедленные в веществе позитроны сталкиваются с движущимися атомными электронами, и угол конуса разлета η-квантов отличается от 180°. Оценить, насколько этот угол отличается от развернутого, если аннигиляция происходит на электронах L-оболочки углерода.

O3.1-4.35

Позитроний поглощает фотон, образовавшийся при переходе атомарного водорода из первого возбужденного состояния в основное. Определить скорости электрона и позитрона в случае их симметричного относительно направления движения фотона разлета. Атом в исходном состоянии считать неподвижным.

O3.1-4.36

При комптоновском рассеянии квантов на атомных электронах явление осложняется тем, что электроны в атомах не находятся в покое. Оценить связанный с этим разброс в углах разлета электронов отдачи, выбиваемых из атомов водорода при рассеянии рентгеновских квантов ($\lambda = 1$Å) строго назад.

O3.1-4.37

Решить предыдущую задачу для электронов отдачи, выбиваемых с K-оботочки атомов свинца при рассеянии гамма-квантов с д.иной волны $\lambda = 0,01$Å строго назад. Для свинца $Z = 82$.

O3.1-4.38

Считая, что поправка на экранирование заряда ядра электронами на K-оболочке одинакова для атомов с $Z < 50$, найти кинетическую энергию T_e фотоэлектронов, вылетающих из K-оболочки атомов ${}_{30}$Zn под действием K_α-излучения серебра ${}_{47}$Ag с энергией 21,6 кэВ.

O3.1-4.39

Во сколько раз отличаются средние длины свободного пробега атома водорода в основном и возбужденном состояниях ($n = 10$) в разреженном одноатомном газе при одинаковой концентрации?

O3.1-4.40

В электрическом поле возможна спонтанная ионизация атомов. Оценить, при какой величине напряженности поля E (в В/см) окажется ионизованным атом водорода в состоянии с $n = 10$. Энергии уровней считать не зависящими от поля.

4.

40. $E = \frac{\text{Ry}^2}{4e^3 n^4} \approx 32$ КВ/cm.

O3.1-4.41

Задача об отыскании уровней энергии атомов обычно решается в предположении, что заряд ядра точечный. На самом деле ядро имеет размер, и радиусы ядер $R_{\text{я}} = 1,3 \cdot 10^{-13} A^{1/3}$см, где A - атомная масса. Определить знак и оценить порядок величины относительной поправки $\Delta\mathscr{E}/\mathcal{E}$ к энергии мюона на K-оболочке в мезоатоме неона ($Z = 10, A = 20$), связанной с тем, что часть времени мюон находится внутри ядра, т. е. в поле с потенциалом, отличным от Ze^2/r. Волновая функция основного состояния электрона в атоме водорода $\psi = \frac{1}{\sqrt{\pi r_1^3}} e^{-r/r_t}$, где r_1 - радиус первой боровской орбиты. Масса мюона $m_\mu = 207 m_{\text{e}}$

4.

41: $\frac{\Delta\mathscr{G}}{\mathscr{G}} = \begin{cases} \frac{4}{3}\left(\frac{R_g}{r_{\mu 1}}\right)^2 = 2,53 \cdot 10^{-2} \text{ (ядро - заряженная сфера)}, \\ \frac{4}{5}\left(\frac{R_g}{r_{\mu 1}}\right)^2 = 1,52 \cdot 10^{-2} \text{ (ядро - однородно заряженный шар)}, \end{cases}$ где $r_{\mu 1} = \frac{\hbar^2}{m_\mu Z e^2}$.

Решение. Считаем, что решение задачи об уровнях энергии в кулоновском поле точечного заряда известно: $\widehat{H}\varphi = \delta \downarrow$, где $\widehat{H} = \frac{\hat{p}^2}{2m} - \frac{Ze^2}{r}$,

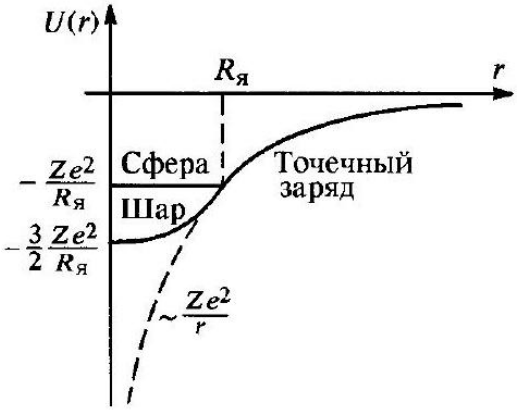

Рис. 154

$\mathscr{E} = -\frac{z^2 m e^4}{2\hbar^2}\frac{1}{n^2}$. Рассмотрим $n = 1$, тогда $\psi_1 = \frac{1}{\sqrt{\pi r_1^3}} e^{-r/r_1}$. Истинный потенциал при $r \geqslant R_{\text{я}}$ совпадает с потенциалом точечного ядра и отличается от него при $r < R_{\text{я}}$. Если считать ядро равномерно заряженной по поверхности сферой, то $U(r < R_{\text{q}}) = -\frac{Ze^2}{R_{\text{я}}}$; если равномерно заряженным шаром, то $U(r < R_{\text{g}}) = -\frac{3}{2}\frac{Ze^2}{R_{\text{я}}}\left(1 - \frac{r^2}{3R_q^2}\right)$, (рис. 154).

Представим истинный гамильтониан в виде

$$\widehat{H} = \frac{\hat{p}^2}{2m} - \frac{Ze^2}{r} + \delta U,$$

где для шара

$$\delta U = \begin{cases} 0, & r \geqslant R_{\text{g}}, \\ \frac{Ze^2}{r} - \frac{3}{2}\frac{Ze^2}{R_{\text{g}}}\left(1 - \frac{r^2}{3R_{\text{g}}^2}\right), & r < R_{\text{g}} \end{cases}$$

и для сферы

$$\delta U = \begin{cases} 0, & r \geqslant R_{\text{g}}, \\ \frac{Ze^2}{r} - \frac{Ze^2}{R_{\text{g}}}, & r < R_{\text{q}}. \end{cases}$$

Так как все отличие проис ходит при $r < R_{\text{g}} \ll r_1$, то рассматриваем δU как поправку. Среднее значение δU в основном состоянии и есть сдвиг уровня:

$$\langle\Psi_1|\,\hat{H}\,|\Psi_1\rangle = \langle\Psi_1|\,\frac{\hat{p}^2}{2m} - \frac{Ze^2}{r}\,|\psi_1\rangle + \langle\psi_1|\,\delta U\,|\psi_1\rangle = -\frac{mZ^2e^4}{2\hbar^2} + \Delta\mathscr{E},$$

$$\Delta\mathscr{E} = \int dV \Psi_1^* \delta U \psi_1 = \frac{1}{\pi r_1^3} 4\pi \int_0^{R_{\text{s}}} e^{-2r/r_1} \left\{ \begin{array}{c} \frac{Ze^2}{r} - \frac{Ze^2}{R_g} \\ \frac{Ze^2}{r} - \frac{3}{2}\frac{Ze^2}{R_g}\left(1 - \frac{r^2}{3R_{\text{A}}^2}\right) \end{array} \right) r^2 dr,$$

т. к. $\frac{R_9}{r_1} \leqslant \frac{3{,}5 \cdot 10^{-13}}{25{,}6 \cdot 10^{-13}} \sim 0,1$, то $e^{-2r/r_1} \simeq 1$. Тогда

$$\Delta\mathscr{E} \approx \frac{4}{r_1^3}\int_0^{R_g}\left\{\begin{array}{c} Ze^2\left(r-\frac{r^2}{R_g}\right) \\ Ze^2\left[r-\frac{3}{2}\frac{r^2}{R}\left(1-\frac{r^2}{3R_g^2}\right)\right]\end{array}\right\}dr = \left\{\begin{array}{l} \frac{2}{3}\frac{Ze^2}{r_1}\left(\frac{R_g}{r_1}\right)^2 - \text{ сфера}, \\ \frac{2}{5}\frac{Ze^2}{r_1}\left(\frac{R_g}{r_1}\right)^2 - \text{ шар.}\end{array}\right.$$

Видно, что поправка положительна, следовательно, уровни сдвигаются вверх. Относительная поправка

$$\delta = \left|\frac{\Delta\mathscr{E}}{\mathscr{Q}_1}\right| = \frac{\Delta\mathscr{E}}{\frac{Ze^2}{2r_1}} = \begin{cases}\frac{4}{3}\left(\frac{R_{\text{g}}}{r_1}\right)^2 & \text{- сфера} \\ \frac{4}{5}\left(\frac{R_{\text{f}}}{r_1}\right)^2 & \text{- шар.}\end{cases}$$

Сделаем вычисления:

$$R_{\text{g}} = 3,53\cdot 10^{-13}\text{c}, r_1 = r_{\mu_1} = \frac{\hbar^2}{m_\mu Ze^2} = \frac{m_{\text{e}}}{m_\mu}\frac{1}{Z}\frac{\hbar^2}{m_{\text{e}}e^2} = 25,6\cdot 10^{-13}\text{c}$$

$$\frac{\Delta\mathscr{E}}{\mathscr{E}} = \left\{\begin{array}{l} 2,53\cdot 10^{-2} - \text{ сфера} \\ 1,52\cdot 10^{-2} - \text{ шар.}\end{array}\right.$$

(остальное скорее всего порешаю потом, итак порешать бы это!)

там много еще хороших задач есть.

4.

42. $\frac{\Delta\mathscr{E}}{\mathscr{G}} = \left\{\begin{array}{l} \frac{4}{3}\left(\frac{R_{\text{Я}}}{a_{\text{Ne}}}\right)^2 = 5,94\cdot 10^{-7} \text{ (ядро - заряженная сфера)}, \\ \frac{4}{5}\left(\frac{R_{\text{я}}}{a_{\text{Ne}}}\right)^2 = 3,56\cdot 10^{-7} \text{ (ядро - однородно заряженный шар)}, \end{array}\right.$ где $a_{\text{Ne}} = \frac{r_1}{Z}$.

4.

43. $\langle T\rangle = \frac{e^2}{2r_1^*} \approx 14,5$ эВ, где $r_1^* = \frac{\hbar^2}{\mu e^2} \approx 0,5\cdot 10^{-8}$ см.

4.

44. $\langle T\rangle = \frac{e^2}{8r_1^*} \approx 3,4$ эВ, где $r_1^* = \frac{\hbar^2}{\mu e^2} \approx 0,5\cdot 10^{-8}$ см.

4.

45. Так как радиус мюонной орбиты $r_\mu = \frac{\hbar^2}{Ze^2 m_\mu} \approx 10^{-11}$ см $\ll r_{\text{Б}}$ - боровского радиуса $(0,53\text{Å})$, то оставшийся электрон фактически движется в поле с зарядом $Z = 1$ (водородоподобный атом). Энергия перехода между уровнями $n = 3$ и $n = 2$ равна (это линия H_α)

$$\frac{1}{\lambda_{32}} = R_\infty\left(\frac{1}{2^2}-\frac{1}{3^2}\right) = \frac{5}{36}R_\infty \approx 1,52\cdot 10^4 \text{ см}^{-1}; \quad \lambda_{32} = 656\text{НМ},$$

где $R_\infty = 109737,3$ см$^{-1}$.

4.

46. Энергия $3p$-состояния находится из условия $\mathscr{E}_{3p} = \mathscr{E}_{3s} + \frac{hc}{\lambda} = -U_0 + \frac{hc}{\lambda} = -3,0$ эВ. Поскольку $\mathscr{E}_{3\text{р}} = -\text{Ry}\frac{Z_{\text{эфф}}^2}{3^2}$, то получаем $Z^2 \approx 2$; $Z_{\text{Эфф}} \approx 1,4$.

4.

47. $v = \frac{3}{4}\frac{z^2 a}{h} Ry = 9 \cdot 10^8$ cm/c.

4.

48: $\mathscr{E}_{\text{осн}} \approx -\frac{e^2}{r} Z\left(Z - \frac{5}{8}\right) = -74,8$ эВ; где обозначено $r = \frac{\hbar^2}{m_e e^2} = 0,529\text{Å}$; $\varrho_{\text{ион}} \approx \frac{m e^4}{2\hbar^2} Z\left(Z - \frac{5}{4}\right) \approx 20,4$ эВ, где $Z = 2$.

Решение. Вычислим энергию кулоновского расталкивания электронов в атоме гелия. Это интеграл

$$\mathscr{E}_{\text{кул}} = e^2 \iint_0^\infty \psi^*(r_1, r_2) \frac{1}{|\mathbf{r}_1 - \mathbf{r}_2|} \psi(r_1, r_2)\, d\mathbf{r}_1 d\mathbf{r}_2 =$$
$$= e^2 \int_0^\infty \int_0^\infty |\psi_0(\mathbf{r}_1)|^2 \cdot |\psi_0(\mathbf{r}_2)|^2 \frac{d\mathbf{r}_1 d\mathbf{r}_2}{|\mathbf{r}_1 - \mathbf{r}_2|}$$

Введем плотности зарядов

$$\rho(\mathbf{r}_1) = e\,|\psi_0(\mathbf{r}_1)|^2 \quad \text{и} \quad \rho(\mathbf{r}_2) = e\,|\psi_0(\mathbf{r}_2)|^2$$

Тогда

$$\mathfrak{E}_{\text{куп}} = 2 \cdot \frac{1}{2} \int_0^\infty \int_0^\infty \frac{\rho(\mathbf{r}_1)\,\rho(\mathbf{r}_2)}{|\mathbf{r}_1 - \mathbf{r}_2|} d\mathbf{r}_1 d\mathbf{r}_2 = 2 \cdot \frac{1}{2} \int_0^\infty \rho(\mathbf{r}_1)\,\varphi(\mathbf{r}_1)\, d\mathbf{r}_1$$

где $\varphi(\mathbf{r}_1) = \int_0^\infty \frac{\rho(\mathbf{r}_2)}{|\mathbf{r}_1 - \mathbf{r}_2|} d\mathbf{r}_2$ - потенциал, создаваемый в точке $\mathbf{r}_1$ распределением заряда $\rho(\mathbf{r}_2)$ - аналог формулы $\frac{1}{2}\sum_i q_i \varphi_i$ (в силу симметрии можно было бы написать $\mathscr{E}_{\text{кул}} = 2 \cdot \frac{1}{2}\int_0^\infty \rho(r_2)\,\varphi(r_2)\, dr_2$).

$$\varphi(\mathbf{r}_1) = \int_0^\infty \frac{\rho(r_2)\, 4\pi r_2^2 dr_2}{|\mathbf{r}_1 - \mathbf{r}_2|}$$

Разобьем область интегрирования на две части $\int_0^\infty = \int_0^{r_1} + \int_{r_1}^\infty$. Тогда первый интеграл есть потенциал, создаваемый сферически симметричным распределением заряда при $r_2 < r_1$. По теореме Гаусса он равен потенциалу точечного заряда, находящегося в центре сферы. То есть

$$\int_0^{r_1} \frac{\rho(r_2)\, 4\pi r_2^2 dr}{|\mathbf{r}_1 - \mathbf{r}_2|} = \frac{1}{r_1}\int_0^{r_1} \rho(\mathbf{r}_2)\, 4\pi r_2^2 dr = \frac{4Z^3}{r_{\text{B}}^3}\frac{e}{r_1}\int_0^{r_1} \exp\left(-\frac{2Zr_2}{r_{\text{B}}}\right) r_2^2 dr_2 =$$
$$= \frac{4e}{r_1}\left(\frac{Z}{r_{\text{E}}}\right)^3 \exp\left[-\frac{r_2^2 r_{\text{B}}}{2Z} - \frac{2r_2 r_{\text{B}}^2}{(2Z)^2} - \frac{2r_{\text{B}}^3}{(2Z)^3}\right] \exp\left(-\frac{2Zr_2}{r_{\text{E}}}\right)\Bigg|_0^{r_1} =$$
$$= 4e\left(\frac{Z}{r_{\text{E}}}\right)^3 \frac{(-1)}{r_1}\left\{\left[\frac{r_1^2 r_{\text{E}}}{2Z} + \frac{r_1 r_{\text{F}}^2}{4Z^2} + \frac{r_{\text{E}}^3}{8Z^3}\right]\exp\left(-\frac{2Zr_1}{r_{\text{B}}}\right) - \frac{r_{\text{B}}^3}{8Z^3}\right\} =$$
$$= -4e\left\{\left[\frac{r_1 Z^2}{2r_{\text{Б}}^2} + \frac{Z}{4r_{\text{Б}}} + \frac{1}{8r_1}\right]\exp\left(-\frac{2Zr_1}{r_{\text{Б}}}\right) - \frac{1}{8}\frac{1}{r_1}\right\}$$

Для вычисления поля, создаваемого распределением заряда при $r_2 > r_1$, разбиваем всю область на вложенные друг в друга сферы толщиной dr с зарядом $dQ = \rho(r_2) \cdot 4\pi r_2^2 dr_2$ (рис. 155).

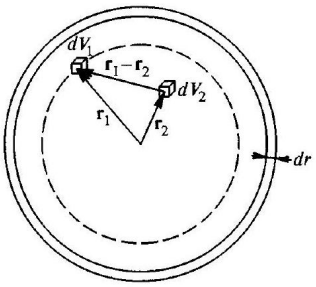

Рис. 155

По теореме Гаусса потенциал внутри сферы равен потенциалу ее поверхности. Таким образом, $\frac{1}{|\mathbf{r}_1 - \mathbf{r}_2|} \to \frac{1}{r_2}$

$$\int_{r_1}^{\mathrm{U}} \to \int_{r_1}^{\infty} \frac{\rho(r_2)\,4\pi r_2^2 dr_2}{r_2} = 4\left(\frac{Z}{r_{\mathrm{E}}}\right)^3 e \int_{r_1}^{\infty} \exp\left(-\frac{2Z}{r_{\mathrm{E}}} r_2\right) r_2 dr_2 =$$
$$= 4\left(\frac{Z}{r_{\mathrm{E}}}\right)^3 e \cdot \exp\left(-\frac{2Z}{r_{\mathrm{E}}} r_2\right) \frac{r_{\mathrm{E}}^2}{(2Z)^2} \left(-\frac{2Z}{r_{\mathrm{E}}} \cdot r_2 - 1\right)_{r_1}^{\infty} =$$
$$= \left(\frac{Z}{r_{\mathrm{E}}}\right)^3 \cdot e \cdot \exp\left(-\frac{2Z}{r_{\mathrm{E}}} r_1\right) \left(\frac{r_{\mathrm{B}}}{Z}\right)^2 \left(2\frac{Z}{r_{\mathrm{E}}} r_1 + 1\right) =$$

$$= \frac{Z}{r_{\mathrm{E}}} \cdot e \cdot \exp\left(-\frac{2Z}{r_{\mathrm{E}}} r_1\right) \left(2\frac{Z}{r_{\mathrm{E}}} r_1 + 1\right).$$

Складывая, получаем

$$\varphi(r_1) = \frac{e}{r_1} - e\left(\frac{Z}{r_{\mathrm{B}}} + \frac{1}{r_1}\right) \exp\left(-\frac{2Z}{r_{\mathrm{B}}} r_1\right)$$

Тогда

$$\mathscr{E}_{\text{ку.}} = \int_0^{\infty} \rho(\boldsymbol{r}_1)\,\varphi(r_1)\,dr_1 = \frac{4\pi Z^3}{\pi r_{\mathrm{B}}^3} e^2 \int_0^{\infty} \exp\left(-\frac{2Z}{r_{\mathrm{Б}}} r_1\right) \times$$
$$\times \left\{\frac{1}{r_1} - \left(\frac{Z}{r_{\mathrm{G}}} + \frac{1}{r_1}\right) \exp\left(-\frac{2Z}{r_{\mathrm{E}}} r_1\right)\right\} r_1^2 dr_1 =$$
$$= 4\left(\frac{Z}{r_{\mathrm{E}}}\right)^3 e^2 \left\{\int_0^{\infty} \exp\left(-\frac{2Z r_1}{r_{\mathrm{E}}} r_1\right) dr_1 -\right.$$
$$\left. -\frac{Z}{r_{\mathrm{E}}} \int_0^{\infty} \exp\left(-\frac{4Z}{r_{\mathrm{E}}} r_1\right) r_1^2 dr_1 - \int_0^{\infty} \exp\left(-\frac{4Z}{r_{\mathrm{E}}} r_1\right) r_1 dr_1 \right\} =$$
$$= 4\left(\frac{Z}{r_{\mathrm{B}}}\right)^3 e^2 \left\{\left(\frac{r_{\mathrm{B}}}{2Z}\right)^2 \int_0^{\infty} e^{-y' y dy - \frac{Z}{r_{\mathrm{B}}}\left(\frac{r_{\mathrm{B}}}{4Z}\right)^3 \int_0^{\infty} e^{-y^2} y^2 dy - \left(\frac{r_{\mathrm{B}}}{4Z}\right)^2 \int_0^{\infty} e^{-y} y dy}\right\} \ldots$$

Так как $\int_0^{\infty} e^{-y} y^n dy = \Gamma(n+1) = n!$, то

$$\mathring{\mathrm{A}}_{\text{ку}} = 4e^2 \left(\frac{Z}{r_{\mathrm{B}}}\right)^3 \left\{\left(\frac{r_{\mathrm{B}}}{2Z}\right)^2 \cdot 1! - \frac{1}{4^3}\left(\frac{r_{\mathrm{B}}}{Z}\right)^2 \cdot 2! - \frac{r_{\mathrm{B}}}{4^2 Z^2} \cdot 1!\right\} =$$
$$= 4e^2 \frac{Z}{r_{\mathrm{E}}} \left\{\frac{1}{4} - \frac{2}{64} - \frac{1}{16}\right\} = 4e^2 \frac{Z}{r_{\mathrm{B}}} \frac{16 - 2 - 4}{64} = \frac{5}{8} \frac{Z e^2}{r_{\mathrm{B}}},$$
$$\mathscr{E}_{\text{осн}} = -2\mathrm{Ry} + \mathrm{E}_{\text{кул}} = -2\frac{Z^2 e^2}{2r_{\mathrm{E}}} + \frac{5}{8}\frac{Z}{r_{\mathrm{B}}} = -Z\left(Z - \frac{5}{8}\right)\frac{e^2}{r_{\mathrm{D}}} = -74{,}8 \text{ В}.$$

После ионизации, т.е. отрыва одного электрона, останется водородоподобный ион с зарядом $+2$. Энергия связи оставшегося электрона есть

$$\mathscr{E}_{\text{СВ}} = -Z^2 \mathrm{Ry} = -Z^2 \frac{e^2}{2r_{\mathrm{B}}}$$
$$\mathscr{E}_{\text{ион}} = \mathscr{E}_{\text{СВ}} - \mathscr{E}_{\text{ОСН}} = Z\left(Z - \frac{5}{8}\right)\frac{e^2}{r_{\mathrm{B}}} - Z^2 \frac{e^2}{2r_{\mathrm{B}}} = Z\left(Z - \frac{5}{4}\right)\frac{e^2}{2r_{\mathrm{B}}} = 20{,}4 \ni \text{ В}$$

4.

49. $3d$-состояние.

4.

50. $2s$-состояние.

4.

51*. $\lambda'' = 3,7$ нм; $T = mc^2\left(\frac{1}{\sqrt{1-v^2/c^2}} - 1\right) \approx 11,6$ ГэВ.

Решение. Частота лазерного излучения в ЛСО $\omega_0 = 2\pi c/\lambda_0$. В системе отсчета ионов (где они неподвижны) эта же частота

$$\omega' = \omega_0\sqrt{\frac{1+\beta}{1-\beta}},\ \text{где}\ \beta = \frac{v}{c}$$

Энергия перехода иона гелия из основного состояния в первое возбужденное $\mathscr{E}_{12} = \text{Ry}\ Z^2\left(\frac{1}{1^2} - \frac{1}{2^2}\right) = 3\text{Ry} = \hbar\omega'$. Поскольку $\frac{\left(\hbar\omega'\right)^2}{(\hbar\omega)^2} = \frac{1+\beta}{1-\beta}$, то $\beta = \frac{(\mathscr{E}_{12}/\hbar\omega_0)^2-1}{(\mathscr{E}_{12}/\hbar\omega_0)^2+1} \approx 0,97$. Здесь $\hbar\omega_0 = \frac{2\pi c\hbar}{\lambda_0} = 5$ эВ .

Частота излучения в ЛСО (см. задачу 1.35)

$$\omega'' = \omega'\sqrt{\frac{1+\beta}{1-\beta}} = \omega_0\frac{1+\beta}{1-\beta} = \left(\frac{\mathscr{E}_{12}}{\hbar\omega_0}\right)^2\omega_0 \approx 66,6\omega_0$$

Эта частота соответствует длине волны

$$\lambda'' = \frac{\lambda_0}{66,6} \approx 3,7\text{НМ}$$

Кинетическая энергия ионов

$$T = mc^2\left(\frac{1}{\sqrt{1-\beta^2}} - 1\right) \approx 11,6\Gamma\ni\ \text{В}$$

4.

52. $\tau \simeq \frac{\hbar\omega}{I} = \frac{3}{2}\frac{Z^2}{n^4}\alpha\hbar\frac{\left(mc^2\right)^2}{(\hbar\omega)^3} = 6,6\cdot 10^{-12}$с, где $\hbar\omega = \frac{3}{4}\text{Ry}Z^2 = 40,8$ В, $Z = 2, n = 2, \alpha = \frac{e^2}{\hbar c} = \frac{1}{137}$.

4.

53. $\text{t} \simeq \frac{\hbar\omega}{I} = \frac{3}{2}\frac{Z^2}{n^4}\alpha\hbar\frac{\left(mc^2\right)^2}{(\hbar\omega)^3} = 0,2\cdot 10^{-7}$с, где $\hbar\omega = \text{Ry}\ Z^2\left(\frac{1}{9^2} - \frac{1}{10^2}\right) = 0,51\rho$ В.

4.

54. $\left(\frac{\Delta\mathscr{E}}{\mathscr{E}}\right)_{\text{Pb}} = \left(\frac{\Delta\mathscr{E}}{\mathscr{E}}\right)_{\text{Ne}}\frac{\left(Z^2R_{\text{я}}^2\right)_{\text{Pb}}}{\left(Z^2R_{\text{яд}}^2\right)_{\text{Ne}}} = 1,92\cdot 10^{-4}$.

4.

55. $R \leqslant 512\frac{\gamma M}{c^2}\left(\frac{Br_1^2}{e}\right)^2 \simeq 6500$ км, где $r_1 = \frac{\hbar^2}{m_e e^2} = \frac{e^2}{2\text{Ry}} \approx 0,53\text{Å} - 60$ - ровский радиус (см. задачу 4.40).

18.1.7 Advanced problems about atoms 1

ГК-5.1 Минимизация

Используя неравенство

$$\int |\nabla\psi + Z\psi\nabla r|^2 d\tau \geqslant 0,$$

найти минимальную энергию одноэлектронного атома и соответствующую этой энергии волновую функцию. Показать, что для основного состояния атома выполняется соотношение $2\bar{T} \geqslant |\bar{v}|$.

ГК-5.2 Средний электростатический потенциал

Электрон в кулоновом поле ядра заряда Z находится в основном состоянии. Показать, что средний электростатический потенциал в пространстве, создаваемый ядром и электроном, равен

$$\varphi = \frac{e(Z-1)}{r} + e\left(\frac{Z}{a} + \frac{1}{r}\right)e^{-\frac{2Zr}{a}}, \quad \left(a = \frac{\hbar^2}{\mu e^2}\right).$$

ГК-5.3 Свойства радиуса орбиты

3. Показать, что в основном состоянии атома водорода:
а) наивероятное значение r равно $a = \frac{\hbar^2}{\mu \cdot e^2}$,
б) среднее значение $\frac{\overline{1}}{r} = \frac{1}{a}$,
в) $\frac{\overline{1}}{r^2} = \frac{2}{a^2}$.

ГК-5.4 Плотность вероятности протона

Волновая функция $\psi(\boldsymbol{r})$ описывает относительное движение двух частиц: протона и электрона. Пусть координаты центра масс атома водорода точно известны и равны

$$X = 0, \quad Y = 0, \quad Z = 0.$$

Показать, что в этом случае плотность вероятности для протона имеет вид

$$w(\boldsymbol{r}) = \left(\frac{m+M}{m}\right)^3 |\psi\left(\frac{m+M}{m}\boldsymbol{r}\right)|^2,$$

где m и M-массы электрона и протона соответственно.

ГК-5.5. Распределение по импульсам

Найти распределение по импульсам электрона в атоме водорода для состояний $1s, 2s$ и $2p$.

ГК-5.6. Среднее квадратичное отклонение расстояния

Вычислить $\overline{r^2} - \bar{r}^2$ среднее квадратичное отклонение расстояния электрона от ядра для электрона в атоме водорода, находящегося в состоянии с квантовыми числами n, l.

ГК-5.7.

Выразить собственную волновую функцию атома водорода в параболических координатах с $n_1 = 1, n_2 = 0$, $m = 0$ через волновые функции в сферических координатах. Показать также, что

$$\psi_{n_1=0,n_2=0,m=n-1}(\xi, \gamma_i, \varphi) = \psi_{n,l=n-1,m=n-1}(r, \vartheta, \varphi).$$

ГК-5.8.

Показать непосредственно, что степень вырождения n-го собственного значения энергии атома водорода при решении уравнения Шредингера в параболических координатах равняется n^2.

ГК-5.9.

Найти поправку к уровням энергии атома водорода за счет релятивистской зависимости массы от скорости (учесть член порядка $\frac{v^2}{c^2}\Big)$.

ГК-5.10.

Из релятивистского уравнения для электрона (уравнения Дирака) следует, что, кроме поправки, учитывающей зависимость массы от скорости $\left(\sim \frac{v^2}{c^2}\right)$, существует еше один член в гамильтониане

$$H_2 = \frac{\hbar^2}{2\mu\mu^2 c^2}\frac{1}{r}\frac{dU}{dr}\hat{\boldsymbol{l}}\hat{\boldsymbol{s}},$$

где $\hat{\boldsymbol{i}}$ - оператор орбитального момента, $\hat{\boldsymbol{s}}$ - оператор спина, $U(r)$ - потенциальная энергия электрона (потенциал предполагается центрально-симметричным). Наглядный смысл этого члена заключается в том, что при движении магнитного момента $\boldsymbol{\mu}$ (связанного со спином электрона) появляется дипольный электрический момент $\boldsymbol{d} = \frac{1}{c}$ [?p], который взаимодействует с полем ядра. Найти поправку к уровням энергии атома водорода, учитывающую член H_2 (так называемое взаимодействие спин-орбита).

ГК-5.11.

Показать, что квадрупольный момент атома водорода равен

$$Q_0 = -\frac{j-\frac{1}{2}}{j+1}\overline{r^2}\left\{\overline{r^2} = \frac{n^2}{2}\left(5n^2+1-3l(l+1)\left(\frac{\hbar^2}{\mu e^2}\right)^2\right\}.\right.$$

ГК-5.12.

Определить суммарную вероятность возбуждения и ионизации атома трития H^3 при β-распаде. Вычислить также вероятности возбуждения n-го уровня.

ГК-5.13.

Найти энергию основного состояния двухэлектронной системы в поле ядра с зарядом Z вариационным методом. В качестве допустимых волновых функций взять произведение водородных функций с эффективным зарядом Z'. Релятивистскими поправками пренебречь.

ГК-5.14.

Волновую функцию атома гелия с достаточной степенью приближения можно положить равной следующему выражению:

$$\psi = \frac{Z'^3}{\pi a^3}e^{-\frac{Z'(r_1+r_2)}{a}}\left(Z' = \frac{27}{16}\right) \text{ (см. задачу 13§7}\Big).$$

Показать, что электростатический потенциал, создаваемый атомом, равен

$$\varphi(r) = 2e\left(\frac{1}{r}+\frac{Z'}{a}\right)e^{-\frac{2Z'r}{a}}.$$

ГК-5.15.

Воспользовавшись приближенной волновой функцией основного состояния атома гелия (см. задачу 13§7), вычислить диамагнитную восприимчивость гелия.

18.1.8 Advanced problems about atoms 2

ГК-5.16.

Определить при помощи вариационного метода энергию основного состояния атома лития с учетом обмена. В качестве собственных волновых функций электронов взять водородные функции для электрона в состоянии $1s$ в виде $\psi_{100} = 2Z_1^{2/2}e^{-Z_1 r}$, для электрона в состоянии $2s$ в виде

$$\psi_{200} = cZ_2^{3/2}e^{-\frac{Z_2 r}{2}}(1-\gamma Z_2 r)$$

Z_1 и Z_2 в этих выражения x являются вариационными параметрами, c определяется из условия нормировки волновой функции ψ_{200}, а γ из условия ортогональности функций ψ_{100}, ψ_{200}. Если бы мы при решении задачи применяли обычную теорию возмущении, то положили бы $Z_1 = Z_2 = 3$. Вводя вариационные параметры Z_1 и Z_2, мы тем самым учитываем экранирующее действие электронов.

ГК-5.17.

Определить смещение энергетических уровней атома вследствие движения ядра. Вычислить величину смещения в атоме гелия для триплетного и синглетного состояний 1 snp, воспользовавшись собственными функциями в форме водородноподобных функций отдельных электронов с эффективным зарядом.

ГК-5.18.

Потенциальная энергия $U(x,y,z)$ является однородной функцией координат с показателем однородности v

$$U(\lambda x, \lambda y, \lambda z) = \lambda^{\nu} U(x,y,z).$$

Доказать, что среднее значение кинетической энергии в состоянии дискретного спектра связано со средним значением потенциальной энергии следующим соотношением $2\bar{T} = \nu\bar{U}$ (теорема вириала).

ГК-5.19. Оценки в рамках модели Томаса-Ферми

Оценить порядок следующих величин согласно модели Томаса-Ферми:
а) среднее расстояние между электроном и ядром; б) средняя энергия кулоновского взаимодействия между двумя электронами в атоме; в) средняя кинетическая энергия электрона; г) энергия, необходимая для полной ионизации атома; д) средняя скорость электронов в атоме; е) средний момент количества движения электрона; ж) среднее радиальное квантовое число электрона.

ГК-5.20.

Выразить приближенно энергию атома через электронную плотность $\rho(\boldsymbol{r})$ согласно модели Томаса-Ферми *).

ГК-5.21.

Показать, что уравнение Томаса-Ферми получается как условие минимума полной энергии при вариации плотности $\rho(\boldsymbol{r})$.
Указание. Воспользоваться результатом предыдущей задачи. При варьировании $E(\rho)$ учесть условие нормировки $\int \rho d\tau = N$ (для нейтрального атома $N = Z$).

ГК-5.22.

Найти вариационным методом наилучшее приближенное выражение для электронной плотности в модели Томаса-Ферми, беря в качестве допустимых функций функции вида $\rho = \frac{Ae^{-x}}{x^3}, x = \sqrt{\frac{r}{\lambda}}$, где A определяется из условия нормировки $\int \rho d\tau = N$ (для нейтрального атома $N = Z$), а λ - параметр, подлежащий варьированию. Определить энергию атома (иона).
Примечание. При выборе вида допустимых функций учтено то обстоятельство, что точное решение в области малых r имеет особенность вида $\rho \sim \frac{\text{const}}{r^{3/2}}$.

ГК-5.23.

Доказать справедливость теоремы вириала для модели Томаса-Ферми.

ГК-5.24.

На основании теоремы вириала доказать, что в модели Томаса-Ферми в нейтральном атоме энергия электростатического взаимодействия электронов составляет $\frac{1}{7}$ от величины взаимодействия электронов с ядром.

ГК-5.25.

Вычислить энергию полной ионизации атома (иона) в приближени,и Томаса-Ферми.

ГК-5.26.

Определить смещение энергетических уровней атома, возникающее вследствие конечности размеров ядра. Потенциал внутри ядра ($r < a$) считать постоянным (физически это означает, что электрический заряд ядра распределен по поверхности сферы радиуса a).

ГК-5.27.

Рассчитать значение $\psi^2(0)$ для валентного s-электрона в атоме с большим Z, используя квазиклассическое приближение.

ГК-5.28.

Определить слагаемое напряженности магнитного поля в центре атома водорода, создаваемое орбитальным движением электрона. Вычислить эту величину для состояния $2p$.

ГК-5.29.

Как изменится выражение для магнитного момента атома водорода в случае учета движения ядра?

ГК-5.30.

Определить расстояние между термами сверхтонкой структуры для s-электрона атома водорода.

ГК-5.31.

Определить энергию сверхтонкой структуры одноэлектронного атома, орбитальный момент количества движения которого не равен нулю.

ГК-5.32. Поле в диамагнитном атоме

Диамагнитный атом находится во внешнем магнитном поле. Определить величину напряженности индуцированного магнитного поля в центре атома.

Solution

В диамагнитных атомах равен нулю не только полный момент, но равны нулю порознь как результирующий орбитальный момент, так и результирующий спиновый момент электронов. Вследствие прецессии электрон приобретает добавочную скорость

$$v' = \frac{e}{2\mu c}[\boldsymbol{\mathcal{H}}, \boldsymbol{r}].$$

Обозначая через A векторный потенциал внешнего магнитного поля $A = \frac{1}{2}[\boldsymbol{\mathcal{H}}, \boldsymbol{r}]$, последнее соотношение можно переписать в виде

$$v' = \frac{e}{\mu c}A.$$

Плотность тока, возникающего вследствие прецессий электронных оболочек, равна

$$J = \frac{e}{\mu C}A\rho(r),$$

где $p(r)$ - плотность заряда в точке r (заряд электрона равен - e). Определим сперва векторный потенциал A' индуцированного магнитного поля

$$A'(r) = \frac{e}{2\mu c^2}\int [\boldsymbol{\mathcal{H}}, \boldsymbol{r}]\frac{\rho\,(r')}{|r - r'|}d\tau'.$$

$$\frac{1}{r_{12}} = \frac{1}{\sqrt{R^2 + r^2 - 2Rr\{\cos\theta\cos\theta + \sin\theta\sin\theta\cos(\Phi - \varphi)}} = \sum_{i,m}\sqrt{\frac{4\pi}{2l+1}}\frac{Y^*_{lm}(\theta,\Phi)Y_{lm}(\vartheta,\varphi)}{Y_{l0}(0)}\begin{cases}\frac{r^l}{R^{l+1}}, & r < R,\\ \frac{R^l}{r^{l+1}}, & r > R,\end{cases}$$

$$A'(r) = \frac{e}{6\mu c^2}[\boldsymbol{\mathcal{H}}, \boldsymbol{r}]\cdot\left\{\frac{1}{r^3}\int\limits_{r'<r} r^2 p\,(r')\,d\tau' + \int\limits_{r>r}\frac{p\,(r')}{r'}d\tau'\right\}.$$

С помощью последнего выражения легко вычислить напряженность магнитного поля в направлении оси z.

Напряженность равна

$$e^{\mathcal{H}'}{}_z = \left(\frac{e_G\ell}{2\mu c^2 r^5}\right)\left(z^2 - \frac{1}{3}r^2\right)_{r'<r}\int^{r^2} p\,(r')\,d\tau' + \frac{e\mathscr{E}}{3\mu c^2}\int\limits_{r'>r}\frac{p\,(r')}{r'}d\tau'.$$

Индуцированное поле в центре атома, т. е. поле, действующее на ядро

$$\mathscr{C}'_z(0) = \frac{e\mathscr{C}}{3\mu c^2}\int\frac{p\,(r')}{r'}d\tau' = \frac{e\mathscr{C}}{3\mu c^2}\,\vartheta\,(0),$$

зависит от электростатического потенциала $\varphi(0)$, производимого электронами.

В модели Томаса-Ферми

$$\varphi(0) = -1,588\frac{Ze}{b}, \quad \text{где} \quad b = 0,858\frac{a}{Z^{1/3}}, \quad a = \frac{h^2}{\mu e^2},$$

и, следовательно,

$$\mathscr{H}'_z(0) = -0,319\cdot 10^{-4}Z^{4/3}\mathscr{H}\mathscr{H}$$

ГК-5.33.

Решить предыдущую задачу в случае гелия.

ГК-5.34.

Указать возможные значения полного момента у состояний ${}^1S, {}^3S, {}^3P, {}^2D, {}^4D$.

18.1.9 Advanced problems about atoms 3

ГК-5.35.

Какие состояния (термы) могут осуществляться для двух электронов а) $nsn's$, б) $nsn'p$, в) $nsn'd$, г) $npn'p$. §71

ГК-5.36. Термы по конфигурации (!!!!!!)

Указать возможные термы следующих конфигурации: а) $(np)^3$, б) $(nd)^2$, в) $ns\,(n'p)^4$,

ГК-5.37. Термы по элементам (!!!)

Определить основные термы следующих элементов: O, Cl, Fe, Co, As, La.

Указание. Для определения необходимо воспользоваться эмпирическими установленными правилами.

1. Наименьшей энергией обладает терм с наибольшим значением S при данной конфигурации электронов и наибольшим (возможным при этом S) значением L (правило Хунда).

2. Для нормального состояния атома $J = |L - S|$, если в не вполне заполненной оболочке находится не более половины максимально возможного для нее числа электронов и $J = L + S$, если оболочка заполнена более чем наполовину.

ГК-5.38.

Определить четность основных термов элементов K, Zn, B, C, N, O, Cl.

39.

Система из N электронов характеризуется N тройками квантовых чисел n, l, m_l. Определить число состоянии, соответствующих данному значению M_S проекции суммарного спина.

40.

Найти число состояний, связанных с конфигурацией nl^x.

41.

Показать, что если $x \leqslant 2l + 1$, то терм с наибольшим значением L для конфигурации nl^x будет синглетным с $L = xl - \frac{1}{4}x(x-2)$, если x четно, или дублетным с $L = xl - \frac{1}{4}(x-1)^2$, если x нечетно.

42.

Из волновых функций одноэлектронной проблемы построить собственные функции, характеризуемые квантовыми числами S, L, M_S, M_L для конфигурации p^3.

Указание. Рассмотреть действие операторов $\left(\hat{L}_x - i\hat{L}_y\right)$ и $\left(\hat{S}_x - i\hat{S}_y\right)$ на антисимметричные функции нулевого приближения.

43.

Получить собственные функции для каждого из двух термов ${}^2D$ конфигурации d^3.

44.

Два электрона движутся в центрально-симметричном поле. Электростатическое взаимодействие электронов будем считать возмущением. Найти энергию возмущения первого порядка для термов конфигурации $npn'p$.

Указание. Сумма корней векового уравнения равна сумме диагональных элементов, входящих в это уравнение.

45.

Показать, что спин-орбитальное возмущение, определяемое формулой $\hat{V}_{SL} = A\hat{\mathbf{S}}\hat{\mathbf{L}}$, обладает тем свойством, что среднее возмущение всех состояний терма (терм характеризуется числами L и S) равно нулю.

46.

Найти расщепление уровней атома в случае слабого магнитного поля, когда $\frac{e\hbar}{2\mu c}\mathscr{H} \ll |\Delta E_{JJ'}|$, где $\Delta E_{JJ'}$ - расстояние между уровнями в мультиплете.

47.

Найти пределы изменения множителя Ланде g при заданных значениях L и S.

48.

Показать, что для термов ${}^4D_{1,2}, {}^5F_1, {}^6G_{3/2}$ отсутствует линейное по полю расщепление.

49.

Определить множитель Ланде для одноэлектронного атома (водород, щелочные металлы) непосредственно при помощи собственных функций Паули (см. задачу 20§4).

50.

Выразить магнитный момент атома через множитель Ланде.

51.

Определить расщепление терма одноэлектронного атома в случае среднего поля $\frac{eh}{2\mu c}\mathscr{E} \sim |\Delta E_{jj}|$.

Решения

1

Из написанного неравенства получаем:

$$\int |\nabla\psi|^2 d\tau + Z\int \left(\nabla|\psi|^2\nabla r\right) d\tau + Z^2\int (\nabla r)^2|\psi|^2 d\tau \geqslant 0$$

Производя во втором члене интегрирование по частям и замечая, что $(\nabla r)^2 = 1$, а $\Delta r = \frac{2}{r}$, имеем:

$$\frac{1}{2}\int |\nabla\psi|^2 d\tau - \int \frac{Z}{r}|\psi|^2 d\tau \geqslant -\frac{Z^2}{2}\int |\psi|^2 d\tau.$$

Левая часть неравенства препставляет среднее значение оператора Гамильтона $*)\hat{H} = -\frac{1}{2}\Delta - \frac{Z}{r}$ в состоянии Ч. Нижнее значэние энергии $-\frac{Z^2}{2}$ достигается в состоянии с волновой функцией (????), удовлетворяющей уравнению первого порядка

$$\nabla\psi_0 + Z\psi_0\nabla r = 0,$$

откуда следует, что

$$\Psi_0 \sim e^{-Zr}$$

5

Вычисляем сначала волновые функции в импульсном представлении по общей формуле

$$\varphi(\boldsymbol{p}) = \frac{1}{(2\pi\hbar)^{3/3}} \iiint e^{-i\frac{pr}{\hbar}} \psi(\boldsymbol{r}) d\tau.$$

Для состояния $1s$ находим:

$$\varphi_{1s}(p) = \frac{1}{\pi} \left(\frac{2a}{\hbar}\right)^{s_i:} \frac{1}{\left(\frac{p^2a^2}{\hbar^2}+1\right)^2}.$$

Аналогично этому для состояния $2s$ получаем:

$$\varphi_{2s}(p) = -\frac{1}{2\pi} \left(\frac{2a}{\hbar}\right)^{s/2} \frac{\frac{p^2a^2}{\hbar^2}-\frac{1}{4}}{\left(\frac{p^2a^2}{\hbar^2}+\frac{1}{4}\right)^3}.$$

Состоянию $2p$ соответствуют 3 собственных функции ($m_2 = -1, 0, +1$)

$$\varphi_{2p}^{(0)}(p) = -i\frac{1}{\pi} \left(\frac{a}{\hbar}\right)^{3/2} \frac{p_z a}{\hbar\left(\frac{p^2a^2}{\hbar^2}+\frac{1}{4}\right)^3},$$

$$\varphi_{2p}^{(\pm1)}(p) = -\frac{i}{\sqrt{2}\pi} \left(\frac{a}{\hbar}\right)^{3/2} \frac{(p_x \pm ip_y)\, a}{\hbar\left(\frac{p^2a^2}{\hbar^2}+\frac{1}{4}\right)^3}.$$

С помощью этих выражений находим распределсние по импульсам (нормированное):

$$\mathfrak{w}(p) = |\varphi(p)|^2.$$

1+5

$\sqrt{r^2 - r^2} = \frac{\sqrt{n^2(n^2+2)-l^2(l+1)^2}}{2}$.
$\to$ В единицах $e = h = \mu = 1$. При заданном n минимальное значение это выражение имеет для «круговых орбит», т. е. при $l = n-1$

$$\sqrt{\overline{r^2} - \overline{r^2}} = \frac{1}{2} n\sqrt{2n+1}, \quad \frac{\sqrt{\overline{r^2} - \bar{r}^2}}{\bar{r}} = \frac{1}{\sqrt{2n+1}}.$$

1+6

При $n_1 = 1, n_2 = 0, m = 0$

$$\psi_{1,0,0}(\xi, \eta, \varphi) = -\frac{1}{\sqrt{2}} R_{20}(r) Y_{00}(i, \varphi) +$$
$$+ + \frac{1}{\sqrt{2}} R_{21}(r) Y_{10}(i, \varphi).$$

1+8

В неквантовой релятивистской механике функция Гамильтона имеет вид

$$H = \sqrt{\mu^2c^4 + p^2c^2} - \mu c^2 + U(r) \approx \frac{p^2}{2\mu} + U(r) + H_1,$$

причем

$$H_1 = -\frac{p^4}{8\mu \cdot c^3}.$$

Будем теперь сиитать p оператором $p = -i\hbar\nabla$, а H_1 рассмотрим как малое возмущение. Тогда в исходном приближении имэем уравнение Шредингера $\left[\frac{\hat{p}^2}{2\mu} + U(r)\right] \circlearrowleft = E\psi$, а искомая поправка к энергии в состоянии n, l, m

$$\Delta E_1 = -\frac{1}{8\mu^3 c^2}\int \psi^* \hat{p}^4 \psi d\tau = -\frac{1}{2\mu c^2}\int \psi^* (E - U(r))^2 \psi d\tau =$$
$$= \frac{3E^2}{2\mu c^2} - \frac{\left(\frac{\mu e^4}{\hbar^2}\right)^2}{n^3 \mu c^2 (2l+1)} = \left[\frac{2}{8n^4} - \frac{1}{(2l+1)n^3}\right]\frac{\mu e^4}{\hbar^2}\left(\frac{e^2}{\hbar c}\right)^2.$$

1+9

Вместо того чтобы исходить из невозмущенных волновых функций определенными l_z и s_z и затем решать секулярное уравнение, удобно выбрать в качестве исходных волновых функций собственные функции с определенным $\boldsymbol{l}^2$ и j^2, где $\hat{\boldsymbol{j}} = \hat{\boldsymbol{l}} + \hat{\boldsymbol{s}}$ — полный момент, коммутирующий, как нетрудно проверить, с H_2. Замечая, что по классу рассматриваемых функций справедливы соотношения

$$\hat{\boldsymbol{j}}^2 = j(j+1) = l(l+1) + s(s+1) + 2\hat{\boldsymbol{l}},$$

находим:

$$\Delta E_2 = \vec{H}_2 = \frac{j(j+1) - l(l+1) - s(s+1)}{4\mu^2 c^2}\hbar^2 \overline{\left(\frac{1}{r}\frac{d\bar{C}}{dr}\right)}$$

Для атома водорода $U = -\frac{e^2}{r}$ и поскольку

$$\frac{\overline{1}}{r^3} = \frac{1}{n^3 (l+1)\left(l+\frac{1}{2}\right) l}\left(\frac{\mu e^2}{\hbar^2}\right)^3,$$

находим окончательно:

$$\Delta E_2 = \frac{\mu e^4}{\hbar^2}\left(\frac{e^2}{\hbar c}\right)^2 \frac{j(j+1) - l(l+1) - s(s+1)}{4n^3 l\left(l+\frac{1}{2}\right)(l+1)}.$$

Эту формулу можно записать короче, так как в нашем случае $s = 1/2$ и возможны два случая $j = l - 1/2$ и $j = l + 1/2$. Как легко проверить, при этом

$$2\hat{\boldsymbol{l}}\hat{\boldsymbol{s}} = j(j+1) - l(l+1) - s(s+1) = \begin{cases} l & \text{при } j = l + \frac{1}{2} \\ -(l+1) & \text{при } j = l - \frac{1}{2}, \end{cases}$$

так что для любых j и l

$$\Delta E_2 = \frac{\mu e^4}{\hbar^2}\left(\frac{e^2}{\hbar c}\right)^2 \frac{1}{2n^3}\left(-\frac{1}{j+\frac{1}{2}} + \frac{1}{l+\frac{1}{2}}\right).$$

Складывая ΔE_2 с пооправкой, учитывающей зависимость массы от скорости ΔE_1 (см. предыдущую задачу), получаем:

$$\Delta E = \frac{\mu e^4}{\hbar^2}\left(\frac{e^2}{\hbar c}\right)\frac{1}{n^3}\left(\frac{3}{8n} - \frac{1}{2j+1}\right).$$

Это выражение не зависит от l, т. е. два уровня с одинаковым j и разными l имеют одинаковую 9 иергию (вырождены).

1+11

При β-распаде япро тритня превращается в ядро изотопа гелия He^3. Влияние β-распада на атомный электрон заключается по существу в том, что за жороткое время $t \ll \frac{j^3}{\mu e^4}$ потенциальная энергия электрона в атоме изменяется и вместо $U = -\frac{e^2}{r}$ становится равной $U = -\frac{2e^2}{r}$. Время t можно оценить как время пролета β-электрона через атом

$$t \sim \frac{a_0}{v},$$

где $a_0 = \frac{\hbar^2}{\mu c^2}$, $\approx$ - скорость β-электрона. Поскольку энергия β-электрона порядка нескольких *кэв*, находим $t \sim 0{,}1\frac{\hbar^3}{\mu e^4}$. Волновая функция электрона не успевает измениться за время t, что следует из уравнения Шредингера:

$$\delta\psi \sim \frac{e^2}{r}\frac{t}{i\hbar}\psi \ll \psi.$$

Разложим волновую функцию электрона по собственным функциям электрона в поле $Z = 2$.

$$\psi = \sum_n c_n\psi_n + \int c_{k_k}\psi_{i_i}d\boldsymbol{k}$$

Козффициенты разложения

$$c_n = \int \psi_n d\tau,$$
$$c_{\boldsymbol{E}} = \int \psi_n \bigcup_{\boldsymbol{s}} d\tau$$

определяют вероятность возбуждения

$$w_n = \sum |c_n|^2$$

и ионизации

$$\mathfrak{W}_{\text{НОН}} = \int |c_{\boldsymbol{l_k}}|^2 d\boldsymbol{k}.$$

Поскольку $\longleftarrow$ - сферически-симметрична, то c_n и c_k отличны от нуля лишь в том случае, когда состояния n, k являются s-состояниями ($l = 0$).

Поскольку

находим:

$$R_{n0}^{(Z)} = 2\left(\frac{Z}{n}\right)^{3/2} e^{-\frac{Z\cdot}{n}} F\left(-n+1, 2, \frac{2Zr}{n}\right),$$

$$c_n = \int_0^\infty R_{n0}^{(Z)} R_{10}^{(Z')} r^2 dr =$$

$$= \frac{8}{\left(Z' + \frac{Z}{n}\right)^3}\left(\frac{ZZ'}{n}\right)^{3/2} F\left(\cdots n+1, 3, 2, \frac{2Z}{nZ'+Z}\right).$$

Полагая $Z = 2, Z' = 1$, получаем для $n = 1$:

$$c_1 = \frac{16\sqrt{2}}{27},$$

т. е. вероятность того, что ион He^3 будет в основном состоянии $w_1 = |c_1|^2 = \left(\frac{8}{9}\right)^3 = 0,70$. Следовательно, суммарная вероятность возбуждения и ионизации будет равна $1 - w_1 = 0,30$. Для $n = 2, c_2 = -\frac{1}{2}, w_2 = 0,25$.

С помощью формулы

$$F(\alpha, \beta, \gamma, x) = (1-x)^{\gamma-\alpha-\beta} F(\gamma-\alpha, \gamma-\beta, \gamma, x)$$

находим:

$$w_n = |c_n|^2 = \frac{2^9 n^5 (n-2)^{2n-4}}{(n+2)^{2n+4}}$$

Приведем значения вероятностей возбуждения, вычисленных с помощью этой формулы, цля нескольких первых уровней:

$$w_1 = \left(\frac{8}{9}\right)^3, \quad w_2 = \frac{1}{4}, \quad w_3 = \frac{2^9 3^j}{5^{10}} = 1,3^{\%}/$$
$$w_4 = \frac{2^{23}}{2^{12}3^{12}} \approx 0,39^{0}\%$$

1+12

Гамильтониан имеет следующий вид (все расчеты будем производить в атомных единицах $e = \hbar = \mu = 1$)

$$\hat{H} = -\frac{1}{2}\Delta_1 - \frac{1}{2}\Delta_2 - \frac{Z}{r_1} - \frac{Z}{r_2} + \frac{1}{r_{12}}.$$

Согласно вариационному принципу надо вычислить интеграл

$$E(Z') = \int \psi^*(r_1, r_2)\, \hat{H}'_{\top}(r_1, r_2)\, d\tau_1 d\tau_2$$

и определить величину Z' из условия $\frac{dE}{dZ'} = 0$.
B нашем случае

$$\psi(r_1, r_2) = ce^{-Z'(r_1 + i_2)},$$

причем нормировочная постоянная $c = \frac{Z'^3}{\pi}$.
Интегралы от первых четырех членов легко вычисляются

$$\int \psi(r_1, r_2) \left\{ -\frac{1}{2}\Delta_1 - \frac{1}{2}\Delta_2 - \frac{Z}{r_1} - \frac{Z}{r_2} \right\} \times$$
$$\times \psi(r_1, r_2)\, d\tau_1 d\tau_2 = Z'^2 - 2ZZ'.$$

Что касается интеграла с $\frac{1}{r_{12}}$, то его удобно вычислить в эллиптических координатах:

$$s = r_1 + r_2, \quad t = r_1 - r_2, \quad u = r_{12},$$
$$d\tau_1 d\tau_2 = \pi^2 \left(s^2 - t^2\right) u ds dt du,$$
$$-u \leqslant t \leqslant u, \quad 0 \leqslant u \leqslant s \leqslant \infty.$$

В результате вычисления имеем:

$$\int \psi^2(r_1, r_2) \frac{1}{r_{12}} d\tau_1 d\tau_2 =$$
$$= \pi^2 c^2 \int_0^{\infty} ds \int_0^{s} du \int_{-u}^{+r} dt e^{-2Z's} \frac{s^2 - t^2}{u} u = \frac{5}{8} Z'.$$

Окончательно получаем:

$$E(Z') = Z'^2 - 2ZZ' + \frac{5}{8} Z'.$$

Из условия минимума $E(Z')$ находим:

$$Z' = Z - \frac{5}{16}.$$

При этом значении Z' энергия основного состояния

$$E = -\left(Z - \frac{5}{16}\right)^2.$$

Чтобы получить представление о точности проведенного расчета, вычислим ионизационный потенциал гелия ($Z = 2$) и сравним результат с экспериментальными данными. Ионизационный потенциал гелия $I_{\text{не}}$ равняется разности энергий однократно ионизированного атома гелия и нейтрального атома гелия в основном состоянии. Значение $I_{\text{не}}$ равно

$$I_{\text{He}} = 0,84 : 6 \text{ ат. ел.} \ = 1,695 Ry *).$$

Экспериментальное значение $I_{\text{He}} = 1,810$.
*) 1 ат. ед. энергии $= 2Ry = 27$ эв. Экспериментально известны также ионизационные потенциалы других двухэлектронных систем $\text{Li}^+, \text{Be}^{++}$и т. д. Сравнивая их с вычисленными, получим:

Элемент	He ($Z = 2$)	Li^+ ($Z = 3$)	Be^{++} ($Z = 4$)	B^{+++} ($Z = 5$)	C^{++++} ($Z = 6$)
Вычисление $I(Ry)$ . . .	1,6952	5,445	11,195	18,945	28,695
Экспериментальное $I(Ry)$	1,810	5,560	11,307	19,061	28,816

Результаты вычисления энергии основного состояния находятся в удовлетворительном согласии с опытом.

1+14

У атома гелия в нормальном состоянии орбитальный и спиновый моменты равны нулю. Вследствие этого гелий обладает диамагнитными свойствами. Диамагнитная восприимчивость, рассчитанная на один грамм-атом, дается следующим выражением:

$$\chi = -\frac{e^2 N_A}{6\mu c^2}\left(\overline{r_1^2} + \overline{r_2^2}\right),$$

где

$$\overline{r_1^2} + \overline{r_2^2} = \int \left(r_1^2 + r_2^2\right)\psi^2 d\tau_1 d\tau_2$$

N_A–число Авогадро. Приближенное выражение для волновой функции основного состояния атома гелия

$$\circlearrowleft (r_1, r_2) = \frac{Z'^3}{\pi a^3} e^{-Z'(r_1+r_2)!a}.$$

Вычисление среднего значения $\overline{r_1^2} + \overline{r_2^2}$ с помощью этой функции приводит к следующему результату:

$$\overline{r_1^2} + \overline{r_2^2} = \frac{2a^2}{Z'^2}.$$

Подставляя это значение в выражение для диамагнитной восприимчивости, находим:

$$\chi = -1,67 \cdot 10^{-6}.$$

Экспериментальное значение диамагнитной восприимчивости

$$x = (1,90 \pm 0,02) \cdot 10^{-6}.$$

1+15

Введем для удобства следующие обозначения:

$$Z_1 = \alpha, \quad Z_2 = 2\beta, \quad 2Z_1^{8/2} = a, \quad cZ_2^{3/2} = b$$

Из условий ортогональности и нормировки находим:

$$\gamma Z_2 = \frac{1}{2}(\alpha + \beta), \quad b^2 = \frac{12\beta^5}{\alpha^2 - \alpha\beta + \beta^2}.$$

В новых обозначениях 1 и ψ_2 будут иметь вид
$\psi_1 = \psi_{100} = ae^{-\alpha r}Y_{00}, \quad \psi_2 = \psi_{200} = b\left[1 - \frac{1}{3}(\alpha + \beta)r\right]e^{-\beta r}Y_{00}$
Приближенная волновая функция атома лития, находящегося в основном состоянии, может быть представлена следующим образом:

$$\Phi = \frac{1}{\sqrt{3!}}\left|\begin{array}{ccc} \psi_1(1)\eta_+(\sigma_1) & \psi_1(2)\eta_+(\sigma_2) & \psi_1(3)\eta_+(\sigma_3) \\ \psi_1(1)\eta_-(\sigma_1) & \psi_1(2)\eta_-(\sigma_2) & \psi_1(3)\eta_-(\sigma_3) \\ \psi_2(1)\eta_+(\sigma_1) & \psi_2(2)\eta_+(\sigma_2) & \psi_2(3)\eta_+(\sigma_3) \end{array}\right|,$$

где $\eta_+\left(\frac{1}{2}\right) = 1, \eta_+\left(-\frac{1}{2}\right) = 0, \eta_-\left(\frac{1}{2}\right) = 0, \eta_-\left(-\frac{1}{2}\right) = 1$. В этом состоянии $S = 1/2, M = 1/2$.
Оператор Гамильтона *) в данном случае имеет вид

$$\hat{H} = \sum_{i=1}^{3}\left\{-\frac{1}{2}\Delta_i - \frac{Z}{r_i}\right\} + \frac{1}{r_{12}} + \frac{1}{r_{23}} + \frac{1}{r_{31}}.$$

Проведем вычисление энергии в состоянии Ф.
Кинетическая энергия электрона в состоянии $1s$ равна

$$T_1 = \int\left\{-\psi_1\frac{1}{2}\Delta\psi_1\right\}d\tau = \int_0^\infty\left(\frac{d\psi_1}{dr}\right)^2 r^2 dr = \frac{1}{2}\alpha^2.$$

*) В атомных единицах $e = \hbar = \mu = 1$. В состоянии $2s$

$$T_2 = \frac{\beta^2}{6} + \frac{\beta^4}{a^2 - \alpha\beta + \beta^2}.$$

Энергия взаимодействия внутреннего электрона с ядром

$$U_1 = -\int \frac{Z\psi_1^2}{r} d\tau = Za^2 \int_0^\infty \frac{e^{-2rr}}{r} r^2 dr = -Z\alpha$$

внешнего электрона с ядром

$$U_2 = -\frac{Z\beta}{2} + \frac{Z\beta^2}{2} \frac{\alpha - 2\beta}{\alpha^2 - \alpha\beta + \beta^2} \text{ (в случае лития } Z = 3)$$

Энергия кулоновского взаимодействия внутренних электронов

$$K_{11} = \iint \frac{1}{r_{12}} |\psi_1(r_1)|^2 |\psi_1(r_2)|^2 d\tau_1 d\tau_2 = \frac{5}{8} a.$$

Энергия взаимодействия внутренних электронов с внешним

$$2K_{12} = 2 \iint \frac{1}{r_{12}} |\psi_1(r_1)|^2 |\psi_2(r_2)|^2 d\tau_1 d\tau_2 =$$
$$= = 2\alpha - \frac{2\alpha^3}{(\alpha+\beta)^2} - \frac{\alpha^4\beta(3\alpha+\beta)}{(\alpha+\beta)^3(\alpha^2-\alpha\beta+\beta^2)}.$$

Энергия обменного взаимодействия двух электронов с параллельными спинами

$$A = 2a^2b^2 \int_0^\infty e^{-(\alpha+\beta)r_2} \left[1 - \frac{1}{3}(\alpha+\beta)r_2\right] r_2^2 dr_2 \times$$
$$\times \int_{r_2}^\infty e^{-(\alpha+\beta)r_1} \left[1 - \frac{1}{3}(\alpha+\beta)r_1\right] r_1 dr_1 =$$
$$= \frac{4\alpha^3\beta^5}{(\alpha+\beta)^5(\alpha^2-\alpha\beta+\beta^2)}.$$

Полагая $\beta = \lambda.\alpha$, получаем:

$$2T_1 + T_2 = T = \alpha^2\varphi_1(\lambda)$$
$$2U_1 + U_2 + K_{11} + 2K_{12} - A = -\alpha\varphi_2(\lambda)$$
$$E = \alpha^2\varphi_1(\lambda) - \alpha\varphi_2(\lambda)$$

Минимум энергии осуществляется при значениях α и λ, удовлетворяющих условиям

$$\frac{\partial E}{\partial \alpha} = 0, \quad \frac{\partial E}{\partial \lambda} = 0$$

Илй

$$2\alpha\varphi_1(\lambda) - \varphi_2(\lambda) = 0, \quad \alpha\varphi_1'(\lambda) - \varphi_2'(\lambda) = 0.$$

Исключая α, получаем:

$$\frac{\varphi_1'(\lambda)}{\varphi_1(\lambda)} - \frac{2\varphi_2'(\lambda)}{\varphi_2(\lambda)} = 0, \quad \lambda = 0,2846.$$

Соответствующие значения α и β равны

$$\alpha = 2,694, \quad \beta = 0,767.$$

Подставляя найденные значения вариационных параметров в E, получаем для энергии нормального состояния атома лития значение

$$E = -7,414 \text{ ат. ед. или } E = -200,8 \text{ эв.}$$

Экспериментальное значение $E = -202,54$ эв. Применяя теорию возмущений, т. е. полагая $\alpha = 3, \beta = 3/2$, мы получим для энергии основного состояния менее точное, чем при вариационном методе, значение $E = -7,05$ или в электрон-вольтах

$$E = -190,84gB.$$

17

Рассмотрим оператор кинетической энергии ядра $\hat{T}$. В системе центра инерции

$$P + \sum p_i = 0,$$

где $\boldsymbol{P}$ - импульс ядра, p_i - импульсы электронов, $\hat{T}$ имеет вид

$$\hat{T} = \frac{\hat{P}^3}{2M} = \frac{\left(\sum \hat{p}_i\right)^2}{2M} = \sum \frac{\hat{p}_i^2}{2M} + \sum_{i>k} \frac{\hat{p}_i \hat{p}_k}{M}.$$

Поскольку отношение массы электрона к массе ядра $\frac{m}{M} \ll 1$ - искомое смещение, можно вычислить по теории возм уцений

$$\Delta E = \int u^* \hat{T} \psi d\tau$$

причем ψ - волновая функция электронов в поле бесконечно тяжелого неподвижного ядра.

Первый член в выражении для $\hat{T}$ отличается лишь множителем $\frac{m}{M}$ от кинетической энергии электронов, которая по теореме вириала равна энергии атома с обратным знаком. Таким образом, ΔE представляется в виде суммы двух членов

$$\Delta E = \Delta E_1 + \Delta E_2,$$

$$\Delta E_1 = -\frac{m}{M} E, \quad \Delta E_2 = \frac{1}{M} \int \psi^* \sum_{i>k}^{\top} \hat{\boldsymbol{p}}_i \hat{p}_k \psi d\tau.$$

Рассмотрим более подробно ΔE_2. Если в качестве у(??) взять произведение волновых функций отдельных электронов, то член ΔE_2 обратился бы в нуль, так как средний импульс электрона в связанном состоянии всегда равен нулю. Однако, если должным образом симметризовать такую волновую функцию, ΔE_2 будет отлично от нуля. Симметризованную собственную функцию атома гелия запишем в виде

$$\psi'(r_1, r_2) = \frac{1}{\sqrt{2}} \left[\psi_1(r_1)\psi_2(r_2) \pm \psi_1(r_2)\psi_2(r_1)\right],$$

причем верхний знак относитсяк парагелию (полный спин $S = 0$), а нижний к ортогелию ($S = 1$).

Представляя это выражение в формулу для ΔE_2, получаем:

$$\Delta E_2 = \pm \frac{1}{M} \left| \int \psi_1^* \hat{p}_1^{\omega_2} d\tau \right|^2.$$

Матричный элемент импульса отличен от нуля, лишь когда $\Delta l = 0, \pm 1$ и, таким образом, ΔE_2 обращается в нуль для состояний 1 snd, 1 snf и т. д.

Беря для $1s$-электрона и для np-электрона водородные функции с эффективным зарядом соответственно Z_1 и Z_2

$$\psi_{1s}(r) = \sqrt{\frac{Z_1^3}{\pi}} e^{-Z_1 r},$$

$$\psi_{np} = Y_{10} \frac{2Z_2^2}{3} \frac{\sqrt{n^2-1}}{n^2} r e^{-\frac{Z_{2^*}}{n}} F\left(-n+2, 4; \frac{2Z_2 r}{n}\right),$$

получим:

$$\Delta E_2 = \pm \frac{m}{M} \frac{64}{3} (Z_1 Z_2)^5 \frac{(Z_1 n - Z_2)^{2n-4}}{(Z_1 n + Z_2)^{2n+4}} n^3 \left(n^2 - 1\right)$$

причем верхний знак относится к паратерму $1\,\mathrm{snp}\,{}^1P$, нижний - К ортотерму $1\,\mathrm{sip}\,{}^3P$.

18

Пусть $\psi(x, y, z)$ является решением уравнения Шредингера, относящимся к дискретному спектру энергии. Рассмотрим однопараметрическое семейство нормированных функций вида $\lambda^{3/2}\psi(\lambda x, \lambda y, \lambda z)$.

Выражение

$$I(\lambda) = \lambda^3 \int \left\{ \frac{\hbar^2}{2\mu} |\nabla \psi(\lambda x, \lambda, y, \lambda z)|^2 + \right.$$

$$\left. + U(x, y, z) |\psi(\lambda x, \lambda y, \lambda z)|^2 \right\} dxdydz,$$

как функция λ, должно иметь экстремум при $\lambda = 1$, т. е.

$$\left(\frac{dI}{d\lambda}\right)_{\lambda=1} = 0.$$

Переходя к новым переменным интегрирования $\lambda x, \lambda y, \lambda z$, получаем:

$$I(\lambda) = \lambda^2 \bar{T} + \lambda^{-v} \bar{U}.$$

Откуда находим:

$$2\bar{T} - \nu \bar{U} = 0.$$

Теорема вириала легко обобщается на случай системы многих частиц.

19

а) $Z^{-1/2} \frac{\hbar^2}{\mu \cdot e^2}$,
б) $Z^{1/s} \frac{\mu e^4}{\hbar^2}$,
в) $Z^{4/\mu} \frac{\mu e^4}{\hbar^2}$,
г) $Z^{7/3} \frac{\mu e^4}{\hbar^2}$,
л) $Z^{2/\frac{e^2}{\hbar}}$,
е) $Z^{1/s}\hbar$
ж) $Z^{1/}$.

20

Полная энергия складывается из трех частей: кинетической энергии электронов T, энергии взаимодействия электронов с ядром U_{ne} и энергии взаимодействия электронов между собой U_{ee}. Два последних слагаемых имеют следующий вид:

$$U_{ne} = -\int \frac{Z}{r} \rho d\tau,$$
$$U_{ee} = \frac{1}{2} \int \frac{\rho(\boldsymbol{r}) \rho(\boldsymbol{r}')}{|\boldsymbol{r} - \boldsymbol{r}'|} d\tau d\tau'.$$

Чтобы вычислить кинетическую энергию, рассмотрим бесконечно-малый элемент объема атома $d\tau$. Число электронов с импульсами, лежащими в пределах $\boldsymbol{p}$ и $\boldsymbol{p} + dp$, пропорционально фазовому объему и равняется

$$dn = \frac{8\pi p^2 dp d\tau}{(2\pi)^3} = \frac{p^2 dp d\tau}{\pi^2}.$$

Плотность электронов получится интегрированием по от 0 до некоторого максимального $p = p_0$.

$$\rho = \frac{p_0^3}{3\pi^2}.$$

Кинетическая энергия электронов в объеме $d\tau$

$$dT = \int_0^{p_0} \frac{p^2}{2} dn = \frac{p_0^5}{10\pi^2} d\tau.$$

Выразив в этой формуле p_0 через и интегрируя по объему атома, находим кинетическую энергию электронов

$$T = \frac{1}{10\pi^2} \left(3\pi^2\right)^{5/3} \int \rho^{5/3} d\tau.$$

Окончательно для полной энергии получаем:

$$E = T + U_{ne} + U_{ee} =$$
$$= \frac{\left(3\pi^2\right)^{5/s}}{10\pi^2} \int \rho^{5/3} d\tau - Z \int_e^2 \frac{\rho}{r} d\tau + \frac{1}{2} \iint \frac{\rho(r) \rho(r')}{|r - r'|} d\tau d\tau'.$$

22

Элемент объема, выраженный через x, имеет вид

$$d\tau = 4\pi r^2 dr = 8\pi\lambda^3 x^5 dx.$$

Вычисляем кинетическую энергию

$$T = \frac{12\left(3\pi^2\right)^{5/3}}{25\pi}\lambda^3 A^{5/3}$$

и энергию взаимодействия электронов с ядром

$$U_{ne} = -8\pi A\lambda^2 Z.$$

Для того чтобы вычислить $U_{ee} = \frac{1}{2}\iint \frac{p(\boldsymbol{r})p(\boldsymbol{r}')}{|\boldsymbol{r}-\boldsymbol{r}'|}d\tau d\tau'$, найдем сначала потенциал, создаваемый электронами φ_e. Решая уравнение Пуассона

$$\Delta\varphi_e = 4\pi\rho_s$$

получим:

$$\varphi_e = -\frac{16\pi A\lambda^2}{x^2}\left[1 - e^{-x}(x+1)\right]$$

Вычисляя теперь U_{ee} с помощью теоремы Грина, находим:

$$U_{ee} = -\frac{1}{2}\int \varphi_e \rho d\tau = 16\pi^2 A^2\lambda^5.$$

Из условия нормировки определяем A

$$\int \rho d\tau = 16\pi A\lambda^3 = N$$

Подставляя $A = \frac{N}{16\pi\lambda^3}$ в выражения для T, U_{ne}, U_e, получим:

$$T = \frac{12}{25\pi}\left(\frac{3\pi N}{16}\right)^{8/3}\frac{1}{\lambda^2},$$
$$U_{ne} = -\frac{ZN}{2\lambda},$$
$$U_{ee} = \frac{N^2}{16\lambda}.$$

Минимум $E = T + U_{ne} + U_{ee}$ достигается при

$$\lambda = \frac{9}{25}\left(\frac{3\pi N}{16}\right)^{2/3}\frac{1}{Z - \frac{N}{8}}$$

и составляет

$$E = \frac{25}{36}\left(\frac{16}{3\pi}\right)^{2/3} N^{1/3}\left(Z - \frac{N}{8}\right)^2 \text{ ат. ед.}$$

Для нейтрального атома

$$E = \frac{25\cdot 49}{36\cdot 64}\left(\frac{16}{3\pi}\right)^{3/3} Z^{7/3} = 0,758Z^{7/3} \text{ ат. ед.}$$

1+22

Пусть $\rho(\boldsymbol{r})$ - выражение для электронной плотности в модели Томаса-ферми. Тогда $\rho(r)$ осуществляет минимум энергии атома

$$E = \frac{\left(3\pi^2\right)^{5/3}}{10\pi^2} \int^{5/3} d\tau - Z \int \frac{p}{r} d\tau + \frac{1}{2} \iint \frac{p(\boldsymbol{r}) p\left(\boldsymbol{r}'\right)}{|\boldsymbol{r} - \boldsymbol{r}'|} d\tau d\tau'.$$

Если в это выражение вместо p подставить функцию $\lambda^3 p(\lambda r)$, удовлетворяющую тому же условию нормировки, что и $\rho(\boldsymbol{r})$, то получим $E(\lambda) = \lambda^2 T + \lambda U$, где T - кинетическая, а U - потенциальная энергия электронов в атоме. Поскольку E ((.) должно иметь минимум при $\lambda = 1$, находим, что должно выполняться равенство

$$2T + U = 0$$

выражающее теорему вириала.

1+23

Энергия взаимодействия между электронами может быть записана в виде

$$U_{ee} = -\frac{1}{2} \int \varphi_e p d\tau = \frac{Z}{2} \int \frac{p}{r} d\tau - \frac{1}{2} \int \varphi p d\tau,$$

где φ_e - потенциал, создаваемый электронами, а φ - потенциал самосогласованного поля, включающий поле ядра

$$\varphi = \varphi_e + \frac{Z}{r}.$$

В модели Томаса-Ферми выполняются соотношения

$$\frac{p_0^2}{2} = \varphi - \varphi_0, \quad \rho = \frac{p_0^3}{3\pi^2},$$

где p_0 - максимальный импульс, φ_0 - потенциал на границе атома. Исключая отсюда p_0 и выражая в формуле (1) φ через р, находим:

$$U_{ee} = \frac{Z}{2} \int \frac{p}{r} d\tau - \frac{\left(3\pi^2\right)^{2/3}}{4} \int p^{5/3} d\tau - \frac{\varphi_0 N}{2}.$$

Первые два члена лишь множителями отличаются от энергии взаимодействия электронов с ядром

$$U_{ne} = -Z \int \frac{p}{r} d\tau$$

и кинетической энергии

$$T = \frac{3\left(3\pi^2\right)^{2/3}}{10} \int p^{5/3} d\tau.$$

Таким образом,

$$U_{ee} = -\frac{1}{2} U_{ne} - \frac{5}{6} T - \frac{\varphi_0 N}{2}.$$

Подставляя сюда значения T из теоремы вириала

$$2T = -U_{ne} - U_{ee}$$

окончательно находим:

$$U_{ee} = -\frac{1}{7} U_{ne} - \frac{6}{7} \varphi_0 N.$$

Для нейтрального атома $(N = Z)\varphi_0 = 0$ и

$$U_{ee} = -\frac{1}{7} U_{ne}.$$

1+24

Энергия полной ионизации равна полной энергии электронов, взятой с обратным знаком. Используя теорему вириала, находим (см. предыдущую задачу):

$$E_{\text{пог}} = -\frac{3}{7}U_{ne} + \frac{3}{7}\varphi_0 N.$$

Преобразуем выражение

$$U_{ne} = -Z\int \frac{p}{r}d\tau$$

следующим образом: введем потенциал φ_e, создаваемый электронами

$$\Delta\varphi_e = 4\pi p$$

и используем теорему Грина

$$U_{ne} = -\frac{Z}{4\pi}\int \frac{\Delta\varphi_e}{r}d\tau = Z\varphi_e(0)$$

(поверхностный интеграл на границе атома равен нулю и $\Delta\frac{1}{r} = -4\pi\delta(r)$).
Итак,

$$E_{\text{ион}} = -\frac{3}{7}Z\varphi_e(0) + \frac{3}{7}N\varphi_0.$$

Переходя к томас-фермиевским единицам

$$r = xbZ^{-1/3}, \quad b = \frac{1}{2}\left(\frac{3\pi}{4}\right)^{2/3}, \varphi - \varphi_0 = \frac{Z^{4/3}}{b}\frac{\chi(x)}{x},$$

находим:

$$\varphi_e(r) = \varphi - \frac{Z}{r} = \varphi_0 - \frac{Z^{4/3}}{b}[1-\chi(x)],$$

и поскольку для малых x

$$\chi(x) = 1 - ax + \frac{4}{3}x^{3/2},$$

где $a = a_0 = 1,58$ для нейтрального атома (для положительного иона $a > a_0$), то окончательно

$$E_{\text{нон}} = \frac{3}{7}\frac{Z^{7/3}}{b}a - \frac{3}{7}\frac{(Z-N)^2 Z^{1/3}}{bx_0},$$

x_0 - радиус $(Z-N)$ - кратного иона.

1+25

Потенциал точечного кулоновского центра совпадает с потенциалом заряженной по поверхности сферы вне этой сферы, поскольку полный заряд в обоих случаях одинаков. Внутри сферы разница двух потенциалов составляет

$$\Delta\varphi = -Ze\left(\frac{1}{r} - \frac{1}{a}\right).$$

Изменение потенциальной энергии электронов атома

$$\Delta U = -Ze^2\sum_{i=1}^{N}\left(\frac{1}{r_i} - \frac{1}{a}\right)\varepsilon(r_i),$$

где введена вспомогательная функция

$$\varepsilon(r) = \begin{cases} 1 & r < a \\ 0 & r > a \end{cases}$$

Смещение уровней энергии в первом приближении теории возмущений

$$\Delta E = -Ze^2\int |\psi|^2 \sum_{i=1}^{N}\left(\frac{1}{r_i} - \frac{1}{a}\right)\varepsilon(r_i)\, d\tau_1 ... d\tau_N.$$

Нтегрирование по всем переменным, кроме одной, дает:

$$\int |\Psi\left(r_1 ... r_N\right)|^2 d\tau_2 ... d\tau_N = \frac{1}{N} p(r)$$

где $p(r)$ - элект ронная плотность.
Таким образом,

$$\Delta E = -Ze^2 \int \rho(r) \left(\frac{1}{r} - \frac{1}{a}\right) \varepsilon(r) d\tau.$$

Воспользуемся тем, что $p(r)$ мало изменяется в области $r < a$. Вынося эту величину за знак интеграла в точке $r = 0$, получаем

$$\Delta E = -Ze^2 p(0) \frac{2\pi}{3} a^2.$$

\section{7. Волновая функция s-электрона

$$\psi_n(r) = \frac{1}{\sqrt{4\pi}} \frac{\chi_n(r)}{r},$$

где χ_n удовлетворяет уравнению

$$\gamma_n'' + \frac{2\mu}{\hbar^2} \left[E_n - U(r)\right] \chi_n = 0$$

и нормировочному условию

$$\int_0^\infty \chi_n^2 dr = 1.$$

Решение уравнения для χ_n в квазиклассическом приближении имеет вид

$$\chi n = \frac{A_n}{\sqrt{p_n}} \cos\left(\frac{1}{\hbar} \int_0^r p_n dr + \varphi\right),$$

где

$$p_n = \sqrt{2\mu \left[E_n - U(r)\right]}.$$

Это решение, однако, непригодно в области малых r. В самом деле, если r мало $\left(r \ll \frac{\hbar^2}{Z^{1/3} \mu e^2}\right)$ то, во-первых, можно пренебречь экранированием поля ядра и положить $U(r) = -\frac{Ze^2}{r}$; во-вторых, можно также пренебречь E_n по сравнению с $U(r)$. Подставляя $p = \sqrt{\frac{2\mu Ze^2}{r}}$ в условие применимости квазиклассическ ого приближения

$$\frac{d\left(\frac{h}{p}\right)}{dr} \ll 1,$$

получаем:

$$Z \gg \frac{h^2}{Z\mu e^2}.$$

Чтобы получить для $/n$ выражение, пригодное в области малых r, вернемся к исходному уравнению и заменим в нем $U(r)$ на $-\frac{Ze^2}{r}$, а также пренебрежем E_n:

$$\gamma_n'' + \frac{2\mu}{n^2} \frac{Ze^2}{r} \gamma_n = 0.$$

Это уравнение имеет решение

$$y_n = C_n \sqrt{r} J_1\left(2\sqrt{\frac{2\mu Ze^2 r}{\hbar^2}}\right).$$

Чтобы найти связь между постоянными C_n и A_n, замечаем, что область применимости квазиклассического решения (1)

$$r \gg \frac{\hbar^2}{Z\mu e^2}$$

и область применимости решения (2), в которой пренебрегается экранированием поля ядра,

$$r \ll \frac{h^2}{Z^{1/s}\mu e^2}$$

при больших Z перекрываются и поэтому решения (1) и (2) в области $\frac{\hbar^2}{Z\mu e^2} \ll r \ll \frac{\hbar^2}{Z^{1/3}\mu e^2}$ должны совпадать.

Покажем, что вид решений (1) и (2) одинаков в общей области применимости. Для этого положим в (1) $p = \sqrt{\frac{2\mu Ze^2}{r}}$. Тогда получаем

$\chi_n = \frac{A_n \sqrt[4]{\cdot \bar{r}}}{\sqrt[4]{2\mu Ze^2}} \cos\left(\frac{2\sqrt{2\mu \cdot Ze^2 r}}{h} + \varphi\right) \frac{\hbar^2}{Z\mu e^2} \ll r \ll \frac{h^2}{Z^{1/3}\mu e^2}$.

Условие $r \gg \frac{\hbar^2}{Z\mu e^2}$ означает, что аргумент бесселевой функции в (2) велик. Но для больших аргументов ($x \gg 1$)

$$J_1(x) \approx \sqrt{\frac{2}{\pi x}} \cos\left(x - \frac{3\pi}{4}\right).$$

Таким образом, решение (2) принимает виль

$$\chi_n = C_n \sqrt{r} \sqrt{\frac{h}{\pi\sqrt{2\mu Ze^{2r}}}} \cos\left(\frac{2\sqrt{2\mu Ze^{3r}}}{h^2} - \frac{3\pi}{4}\right)$$
$$\frac{h^2}{Z\mu e^2} \ll r \ll \frac{h^2}{Z^{1/s\mu e^2}}.$$

Сравнивая эту формулу с (3), найдем:

$$\varphi = -\frac{3\pi}{4}, \quad A_n = C_n\sqrt{\frac{\hbar}{\pi}}.$$

Теперь можно найти $\psi^2(0)$ При $x \ll 1$ имеем $J_1(x) = \frac{x}{2}$ и с помощью формулы находим:

$$\left.\frac{\gamma_n}{r}\right|_{r\to 0} = C_n\sqrt{\frac{2\mu \cdot Ze^2}{\hbar^2}} = \sqrt{\frac{2\pi\mu \cdot Ze^2}{\hbar^3}} A_n.$$

Следовательно,

$$\psi_n^2(0) = \frac{\mu Z c^2}{2h^3} A_n^2.$$

Постоянную A_n определим из условия нормировки

$$\int_0^\infty \gamma_n^2 dr = A_n^2 \int_0^\infty \frac{\cos^2\left(\frac{1}{\hbar}\int_0^r p_n dr - \frac{3\pi}{4}\right)}{\sqrt{2\mu[E_n - U(r)]}} dr \approx$$
$$\approx \frac{A_n^2}{2} \int_0 \frac{dr}{\sqrt{2\mu[E_n - U(r)]}} \quad 1.$$

Дифференцируя по n условие квантования,

$$\int \sqrt{2\mu\left[E_n - U(r)\right]} dr = \pi(n+\gamma)\hbar,$$

которое определяет E_n как функцию от n, находим:

$$\mu \frac{dE_n}{dn} \int \frac{dr}{\sqrt{2\mu\left[E_n - U(r)\right]}} = \pi\hbar.$$

Сравнивая последнее выражение с условием нормировки, получим:

$$A_n^2 = \frac{2\mu}{\pi h} \frac{dE_n}{dn}$$

и окончательно

$$\psi_n^2(0) = \frac{Ze^2\omega^2}{\pi\hbar^4} \frac{dE_n}{dn}.$$

Для неэкранированного кулоновского поля $E_n = -\frac{Z^2}{2n^2}\frac{\mu e^4}{\hbar^2}$ и найденное из формулы (4) $\iota_n^2(0) = \frac{Z^3}{\pi n^3}\left(\frac{\mu e^2}{\hbar^2}\right)^3$ совпадает с полученным из точного расчета. *B* атомной спектроскопии для уровней энергии возбужденных состояний валентного электрона часто используется формула

$$E_n = -\frac{\mu\rho^4}{2!^2}\frac{1}{(n-\sigma)^3},$$

где о-так называемая поправка Ридберга, слабо зависящая от n. Приняв для E_n эту формулу, получаем:

$$\psi^2(0) = \frac{Z}{\pi}\frac{\mu^3 e^6}{\hbar^6}\frac{\left(1-\frac{d\sigma}{dn}\right)}{(n-\sigma)^3}.$$

28

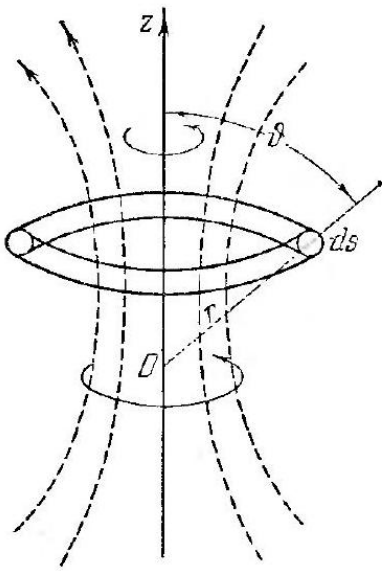
Пусть электрон находится в стационарном состоянии, с определенным значением проекции момента импульса m. Волновая функция такого состояния равна

$$\psi_{nlm}(r,8,\varphi) = R_{nl}(r)P_l^{(m)}(\cos\vartheta)e^{im\varphi}.$$

Плотность электрического тока в состоянии (???) в полярной системе координат $r,\{,\varphi$ имеет вид

$$J_r = J_8 = 0, \quad J_\varphi = -\frac{|e|\hbar m}{\mu r\sin\vartheta}|\psi_{nlm}|^2.$$

Очевидно, что вектор напряженности магнитного поля будет направлен по оси Z.



Рй. 28.

Круговой ток силы dJсо– здает в точке O (см. рис. 28) магнитное поле, напряженность которого равна

$$d\%_z = \frac{dJ}{rc}2\pi\sin^2\vartheta; \quad \text{так как} \quad dJ = J_\varphi r d\vartheta dr$$

ТО

$Q_z = \frac{2\pi|e|hm}{\mu c}\int\limits_0^\infty \frac{R^2}{r}dr\int\limits_0^\pi |P_\eta^{(m)}|^2\sin\vartheta d\vartheta = -\frac{m|e|\hbar}{\mu\cdot c}\int\limits_0^\infty \frac{R^2}{r}dr.$

Этот результат можно получить и иным способом.

Как известно из электродинамики, напряженность магнитного поля, создаваемого при движении заряда, равна (запаздывание не учитывается)

$$\mathscr{H} = \frac{e}{\mu c}\frac{1}{r^3}[rp] = \frac{e}{\mu c}\frac{1}{r^3}l,$$

где r - радиус-вектор, проведенный из точки наблюдения, l - момент количества движения.

В квантовой теории для определения среднего значения на- пряженности магнитного поля нужно вычислить интеграл вида

$$\overline{\mathscr{A}}_z = -\frac{|e|\hbar}{\mu c}\int \psi^* \frac{\hat{l}_z}{r^3}\psi d\tau; \quad \text{так как} \quad \hat{l}_z\psi = m\psi,$$

ТО

$$\overline{\mathscr{A}\mathscr{H}}_z = -m\frac{|e|\hbar}{\mu c}\frac{\overline{1}}{r^3} = -m\frac{|e|\hbar}{\mu c}\left(\frac{\mu e^2}{\hbar^2}\right)^3 \frac{1}{n^3\left(l+\frac{1}{2}\right)(l+1)}.$$

Среднее значение $\mathscr{H}_x, \mathscr{E}_y$ в нашем случае будет равно нулю вследствие того, что

$$\int \psi^*_{nlm}\hat{l}_y\psi_{nlm}\,d\tau = \int \psi^*_{nlm}\hat{l}_x\psi_{nlm}\,d\tau = 0.$$

Для состояния $2p(m=1)$ получаем:

$$\overline{\mathscr{H}}_z = -\frac{1}{12}\frac{|e|\hbar}{2\mu c}\left(\frac{\mu e^2}{\hbar^2}\right)^3, \quad \text{т. е.} \quad \overline{\mathscr{H}}_z \sim 10^4\ \text{гаусс}.$$

29

Магнитный момент частицы равен

$$\mathfrak{M} = \frac{e}{2_1 \cdot c}\int \psi^* \hat{\boldsymbol{l}}\psi d\tau.$$

В случае двух частиц введем новые переменные: координаты центра масс (X, Y, Z) и координаты, характеризующие взаимное расстояние (x, y, z).

Среднее значение магнитного момента, выраженное через новые переменные, будет равно

$$\overline{\mathfrak{M}}_z = \frac{e}{2c}\int \psi^* \left\{\left(\frac{1}{m}+\frac{1}{M}\right)\left(X\frac{\partial}{\partial y} - Y\frac{\partial}{\partial x}\right) + \right.$$
$$\left. + \frac{1}{m+M}\left(x\frac{\partial}{\partial \bar{Y}} - y\frac{\partial}{\partial X}\right) + \frac{m-M}{mM}\left(x\frac{\partial}{\partial y} - y\frac{\partial}{\partial x}\right)\right\}\psi dr,$$

и аналогично для $\bar{\mathfrak{i}}_x$ и $\overline{\mathfrak{M}\mathfrak{i}}_y$.

В стационарном состоянии средние значения координат x, y, z и импульсов $-i\hbar\frac{\partial}{\partial x}, -i\hbar\frac{\partial}{\partial y}, -i\hbar\frac{\partial}{\partial z}$ обращаются в нуль. Вследствие этого последнее выражение упростится и примет вид

$$\overline{\mathfrak{D}}_z = -\frac{e}{2mc}\left(1-\frac{m}{M}\right)\int \psi^* \left\{-i\hbar\left(x\frac{\partial}{\partial y} - y\frac{\partial}{\partial x}\right)\right\}\psi d\tau.$$

В этой задаче m - масса электрона, а M - масса ядра.

30.

$\Delta E = 0,00844 \cdot 2,79\frac{Z^3}{n^3}cM^{-1}$.

Для основного состояния водородного атома $(Z = n = 1)$

$$\Delta E = 0,0235\ \text{см}^{-1}.$$

31

Для определения энергии необходимо найти напряженность магнитного поля, создаваемого электроном. Вследствие орбитального движения электрона в той точке, в которой находится ядро, возникает магнитное поле, напряженность которого по закону Био и Савара равна

$$\mathfrak{H}_l = \frac{1}{c}\frac{[\boldsymbol{r}j]}{r^3},$$

где r - радиус-вектор, направленный от ядра к электрону, а $\boldsymbol{j} = -e\boldsymbol{z}$ (заряд электрона - e). Введем оператор орбитального момента $\hat{\mathrm{Im}}ath$. Тогда для $\hat{\mathscr{H}}_l$ получим:

$$\hat{\mathscr{H}}_l = -\frac{e\hbar}{\mu c}\frac{1}{r^3}\hat{l}.$$

Вследствие того, что электрон, помимо электрического заряда, имеет спиновый магнитный момент, полная напряженность магнитного поля в указанной точке равна

$$\hat{\mathfrak{H}} = \hat{\mathfrak{H}}_l + \hat{\mathfrak{H}}_s = \frac{e\hbar 1}{\mu \cdot r^3}\left\{\hat{\boldsymbol{s}} - \frac{3(\boldsymbol{r}\hat{s})r}{r^2} - \hat{\boldsymbol{i}}\right\}.$$

Таким образом, оператор энергии сверхтонкой структуры мы можем представить следующим образом:

$$\hat{w} = -\beta\hat{i}\hat{\mathfrak{H}},$$

здесь $\hat{\boldsymbol{i}}$-оператор спина ядра, а $\hat{\hat{i}}$ - магнитный момент. Будем рассматривать $\hat{w}$ как малое возмущение. Невозмущенное состояние характеризуется квантовыми числами $n, j(j = l + 1/2, j = l - 1/2), l$ (предполагаем наличие LS связи). Для определения энергии сверхтонкой структуры мы должны усреднить оператор $\hat{\boldsymbol{w}}$ по состоянию с квантовыми числами

$$f, j, l(\hat{f} = \hat{j} + \hat{i}).$$

На основании формулы
имеем:

$$(\hat{A})^{f_m}_{rm}{}^{r} = \frac{\left(\hat{f}\hat{A}\hat{)}^{f}_{f}\right.}{f(f+1)}(\hat{f})^{f'_m}_{fm}$$

$$(g\hat{\mathcal{Q}})^{nljm'_j}_{nljm_j} = -\frac{e\hbar}{\mu c}\left(\frac{1}{r^3}\right)^{nljm_j}_{nljm_j}\frac{l(l+1)}{j(j+1)}(\hat{j})^{jm'_j}_{jm_j}.$$

Используя это соотношение, легко показать, что оператор $\hat{w}$ может быть представлен в виде

$$\hat{w} = \frac{e\hbar}{\mu, c}\beta\frac{1}{r^3}\frac{l(l+1)}{j(j+1)}(\hat{i}\hat{j}).$$

Отсюда следует, что энергия E сверхтонкой структуры определяется выражением

$$E = \frac{e\hbar}{2\mu c}\beta\left(\overline{\frac{1}{r^3}}\right)\frac{l(l+1)}{j(j+1)}\{f(f+1) - j(j+1) - i(i+1)\}.$$

Таким образом, при учете сверхтонкой структуры каждый терм, характеризуемый числами n, l, j, расщепляется на $2i + 1$ компонент (если $j > i$). Совокупность различных значений f дает правило интервалов для сверхтонкой мультиплетной структуры.

Отметим, что путем простого подсчета числа компонент сверхтонкой структуры в спектре данного изотопа можно определить спин ядра. На рис. 29 изображена сверхтонкая мультиплетная структура D-линий натрия.

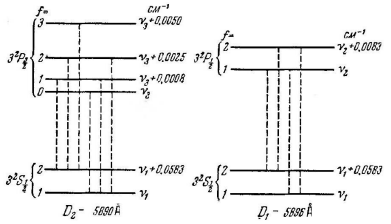


Рис. 29.

Тонкая структура, т. е. наличие дублета (линии $D_1 = 5896$Å, соответствующая переходу $3^2P_{3/2} \to 3^2S_{1/2}$ и $D_2 = 5890$Å, соответствующая переходу $3^2P_{1/2} \to 3^2S_{1/2}$), объясняется спин-орбитальным взаимодействием (см. задачу 10§7).

1+32

$\mathscr{H}_z'(0) = -\frac{27}{24}\frac{e^2\mathscr{G}C}{\mu c^2 a} = -0,599 \cdot 10^{-4}\mathscr{H}$.

г) ${}^1S_0{}^3S^1_1P_1, {}^3P_{012}{}^1D^3_2D_{123}$.

1+35

а) ${}^4S^2P^2D$
б) ${}^1S^3P^1D^3F^1G$
В) ${}^2S^2P^4P^2D$.

1+36

$\mathrm{O}^3P_2, \mathrm{Cl}^2P_{3/2}, \mathrm{Fe}^2D_4, \mathrm{Co}^4F_{9/2}, \mathrm{As}^4S_{3/2}, \mathrm{La}^2D_{8/2}$.
K, Zn, C, O - четные; B, N, Cl - нечетные. 39. Если все тройки квантовых чисел различны, то число состояний равно числу сочетаний из N по $\frac{N}{2} + M_s$, т. е.

$$g\left(M_s\right) = \mathrm{C}_N^{\frac{1}{2}N + M_s}.$$

Если имеется N' пар одинаковых троек квантовых чисел n, l, m_l, то

$$g\left(M_s\right) = \mathrm{C}_{N-2N'}^{\frac{1}{2}\left(N-2N'\right)+M_s}.$$

1+39

Число состояний равно

$$\frac{N_L\left(N_l-1\right)\ldots\left(N_l-x+1\right)}{x!}, \text{ где } N_l = 2(2l+1).$$

42

С целью краткости антисимметричную волновую функцию вида

$$\Phi = \frac{1}{N!}\begin{vmatrix} \psi_{n^1 l^1 m_l^1 m_s^1}(\xi_1) & \psi_{n^1 l^1 m_l^1 m_s^1}(\xi_2) & \cdots & \psi_{n^1 l^1 m_l^1 m_s^1}(\xi_N) \\ \psi_{n^2 l^2 m_l^2 m_s^2}(\xi_1) & \psi_{n^2 l^2 m_l^2 m_s^2}(\xi_2) & \cdots & \psi_{n^2 l^2 m_l^2 m_s^2}(\xi_N) \\ \cdots & \cdots & \cdots & \cdots \\ \psi_{n^N l^N m_l^N m_s^N}(\xi_1) & \psi_{n^N l^N m_l^N m_s^N}(\xi_2) & \cdots & \psi_{n^N l^N m_l^N m_s^N}(\xi_N) \end{vmatrix},$$

составленную из функций одноэлектронной проблемы, будем обозначать следующим образом:

$$\Phi\left(n^1 l^1 m_l^1 m_s^1, n^2 l^2 m_l^2 m_s^2, \ldots, n^N l^N m_l^N m_s^N\right).$$

Рассмотрим действие симметричного онератора

$$\left(\hat{L}_x - i\hat{L}_y\right) = \sum_{i=1}^{N}\left(\hat{l}_x^i - i\hat{l}_y^i\right)$$

na антисимметричную функцию

$$\Phi\left(n^1 l^1 m_l^1 m_s^1, n^2 l^2 m_l^2 m_s^2, \ldots, n^N l^N m_l^N m_s^N\right)$$

Легко видеть, что
$\left(\hat{L}_x - i\hat{L}_y\right)\Phi\left(n^1 l^1 m_l^1 m_s^1, n^2 l^2 m_l^2 m_\varepsilon^2, \ldots\right) =$
$= \sqrt{\left(l^1 + m_l^1\right)\left(l^1 - m_l^1 + 1\right)}\Phi\left(n^1 l^1 m_l^1 - 1m_s', n^2 l^2 m_l^2 m_s^2, \ldots\right) +$
$+\sqrt{\left(l^2 + m_l^2\right)\left(l^2 - m_l^2 + 1\right)}\Phi\left(n^1 l^1 m_l^1 m_s^1, n^2 l^2 m_l^2 - 1m_s^2, \ldots\right) + \ldots$
$\ldots + \sqrt{\left(l^N + m_l^N\right)\left(l^N - m_l^N + 1\right)}\Phi\left(n^1 l^1 m_l^1 m_8^1, \ldots, n^N l^N m_l^N - 1m_j^N\right)$

Результаты действия оператора $\hat{S}_x - i\hat{S}_y$ аналогичны, только вместо m_l понижаются на 1 значения m_s.

Если волновая функция является собственной функцией четырех коммутирующих операторов $\hat{S}^2, \hat{L}^2, \hat{S}_z, \hat{L}_z$, то действие операторов $\left(\hat{L}_x - i\hat{L}_y\right)$ и $\left(\hat{S}_x - i\hat{S}_y\right)$ сводится к следующему:

$$\left(\hat{L}_x - i\hat{L}_y\right)\Phi\left(SLM_SM_L\right) =$$
$$= \sqrt{\left(L + M_L\right)\left(L - M_L + 1\right)}\Phi\left(SLM_SM_L - 1\right),$$
$$\left(\hat{S}_x - i\hat{S}_y\right)\Phi\left(SLM_SM_L\right) =$$
$$= \sqrt{\left(S + M_S\right)\left(S - M_S + 1\right)}\Phi\left(SLM_S - 1M_L\right).\Big)$$

После этих предварительных замечаний приступим непосредственно к решению нашей задачи.

В рассматриваемом случае мы имеем дело с эквивалентными электронами, поэтому квантовые числа nl можно везде опустить. Значение проекции спинового момента будем иногда указывать посредством индексов (????), расположенных над m_l.

Приведем для конфигурации p^3 классификацию состояний по M_S и M_L (ограничиваемся только неотрицательными значениями) и получающиеся в каждом случае термы

$$\begin{array}{l} M_SM_L \\ \frac{3}{2}0\Phi\left(1^+, -1^+, \quad 0^+\right) \quad \left[{}^4S\right] \quad \Phi_1 \\ \left.\begin{array}{llll} \frac{1}{2} & 0 & \Phi\left(1^+, -1^+, \quad 0^-\right) & \\ & & \Phi\left(1^-, -1^+, \quad 0^+\right) & {}^4S \\ & & {}^2P & \\ & & \left(1^+, -1^-, \quad 0^+\right) & \Phi_2 \\ {}^2D & & & \end{array}\right] \begin{array}{l} \Phi_3 \\ \Phi_4 \end{array} \\ \frac{1}{2}2\Phi\left(1^i, 1^-, \quad 0^+\right) \quad \left[{}^2D\right] \quad \Phi_7 \end{array}$$

Затем вычислим действие операторов $\left(\hat{L}_x - i\hat{L}_y\right), \left(\hat{S}_x - i\hat{S}_y\right)$ на некоторые из приведенных выше состояниЙ

$$\left(\dot{L}_x - i\hat{L}_y\right)\Phi_{\tilde{\mathrm{D}}} = \sqrt{2}\left(\Phi_3 - \Phi_2\right)$$
$$\left(\hat{L}_x - i\hat{L}_y\right)\Phi_6 = \sqrt{2}\left(\Phi_2 - \Phi_4\right),$$

$$\begin{array}{llll} \frac{1}{2} & 1 & \Phi(1^+, \quad 1^-, -1^+) & \left[\begin{array}{l} {}^2P \\ {}^2D \end{array}\right] \quad \begin{array}{l} \Phi_5 \\ \Phi_6 \end{array} \\ \cdot & & \Phi(1^+, \quad 0^+, \quad 0^-) & \end{array}$$

$$\left(\hat{L}_x - i\hat{L}_y\right)\Phi_7 = \sqrt{2}\left(\Phi_5 - \Phi_6\right),$$
$$\left(\hat{S}_x - i\hat{S}_y\right)\Phi_1 = \Phi_2 + \Phi_3 + \Phi_4,$$

Φ_1 есть волновая функция состояния ${}^4S$ с $M_S = \frac{3}{2}, M_L = 0$.

Действуя на эту функцию оператором $\left(\hat{S}_x - i\hat{S}_y\right)$, согласно (1) получим:

$$\left(\hat{S}_x - i\hat{S}_y\right)\Phi\left({}^4S, \frac{3}{2}, 0\right) = \sqrt{3}\Phi\left({}^4S, \frac{1}{2}, 0\right),$$

так как

$$\left(\hat{S}_x - i\hat{S}_y\right)\Phi_1 = \Phi_2 + \Phi_3 + \Phi_4,$$

ТО

$$\Phi\left({}^4S, \frac{1}{2}, 0\right) = \frac{1}{\sqrt{3}}\left(\Phi_2 + \Phi_3 + \Phi_4\right)$$

Аналогично для терма ${}^2D$ получим следующие волновые функции:

$$\Phi\left({}^2D,\frac{1}{2},2\right)=\Phi_7,$$
$$\Phi\left({}^2D,\frac{1}{2},1\right)=\frac{1}{\sqrt{2}}\left(\Phi_5-\Phi_6\right),$$
$$\Phi\left({}^2D,\frac{1}{2},0\right)=\frac{1}{\sqrt{6}}\left(\Phi_3-2\Phi_2+\Phi_4\right).$$

Состояние ${}^2P,\frac{1}{2},1\left(M_S=\frac{1}{2},M_L=1\right)$ представляет собой линейную комбинацию состояний Φ_5 и Φ_6, ортогональную к состоянию ${}^2D,\frac{1}{2},1$. Из этих соображений находим:

$$\Phi\left({}^2P,\frac{1}{2},1\right)=\frac{1}{\sqrt{2}}\left(\Phi_5+\Phi_6\right),$$

и далее

$$\Phi\left({}^2P,\frac{1}{2},0\right)=\frac{1}{\sqrt{2}}\left(\Phi_3-\Phi_4\right).$$

Таким же самым способом можно получить волновые функции, соответствующие отрицательным значениям проекции.

43

Как следует из приведенной ниже таблицы для определения собственных функций двух термов ${}^2D$, необходимо вычислить сперва собственные функции термов ${}^2H,{}^2G,{}^4F,{}^2F$.

M_SM_L

$\frac{1}{2}5\Phi\left(2^+,2^-,1^+\right)\quad\Phi_1\quad\left[{}^2H\right]$

$$\begin{array}{cccccc}
 & \frac{1}{2} & 3 & \Phi\left(2^+,2^-, & 1^+\right) & \Phi_4 \quad {}^2H \\
\Phi\left(2^+,1^+,\right. & & 0^-\right) & & \Phi_5 \quad {}^2G & \\
 & \Phi\left(2^+,1^-,\right. & & 0^+\right) & \Phi_6 \quad {}^4F & \\
\Phi\left(2^-,1^+,\right. & & 0^+\right) & & \Phi_7 \quad 2^2F &
\end{array}$$

$$\begin{array}{cccccc}
 & \frac{1}{2}2 & \Phi\left(2^+,2^-, & -2^+\right) & \Phi_8 & {}^2H \\
\Phi\left(2^+,1^+,\right. & -1^-\right) & & \Phi_9 & {}^2G & \\
 & & \Phi\left(2^+,1^-, & -1^+\right) & \Phi_{10} & {}^4F \\
 & & \Phi\left(2^-,1^+, & -1^+\right) & \Phi_{11} & {}^2F \\
 & & \Phi\left(2^+,0^+, & 0^-\right) & \Phi_{12} & {}^2D \\
\Phi\left(1^+,1^-,\right. & 0^+\right) & & \Phi_{13} & {}^2D &
\end{array}$$

$\frac{3}{2}3\Phi\left(2^+,1^+,0^+\right)\Phi_{14}$

$\frac{3}{2}2\Phi\left(2^+,1^+,-1^+\right)\Phi_{1\check{a}}$

Найдем сперва результат действия операторов $\left(\hat{L}_x-i\hat{L}_y\right)$, $\left(\hat{S}_x-i\hat{S}_y\right)$ на некоторые из приведенных выше состояний:

$$\left(\hat{L}_x-i\hat{L}_y\right)\Phi_1=-2\Phi_3+\sqrt{6}\Phi_2$$
$$\left(\hat{L}_x-i\hat{L}_y\right)\Phi_2=-2\Phi_z+2\Phi_6+\sqrt{6}\Phi_4$$
$$\left(\hat{L}_x-i\hat{L}_y\right)\Phi_3=-\sqrt{6}^x+\sqrt{6}\Phi_5$$
$$\left(\hat{S}_x-i\hat{S}_y\right)\Phi_{14}=\Phi_i+\Phi_6+\Phi_5$$
$$\left(\hat{L}_x-i\hat{L}_2\right)\Phi_4=-2\Phi_{11}+2\Phi_{10}+2\Phi_6$$
$$\left(\hat{L}_x-i\hat{L}_y\right)\Phi_5=\sqrt{6}\Phi_{12}+\sqrt{6}\Phi_9$$
$$\left(\dot{S}_x-i\hat{S}_y\right)\Phi_{15}=\Phi_{11}+\Phi_{10}+\Phi_8$$
$$\left(\hat{L}_x-i\hat{L}_y\right)\Phi_6=2\Phi_{13}-\sqrt{6}\Phi_{12}+\sqrt{6}\Phi_{10^*}$$
$$\left(\hat{L}_x-i\hat{L}_y\right)\Phi_7=-2\Phi_{13}+\sqrt{6}\Phi_{11}$$

$$\begin{array}{cccccc} \frac{1}{2} & 4 & \Phi(2^+, & 2^-, & 0^+) & \Phi_2 \\ & & \Phi(2^+, & 1^+, & 1^-) & \Phi_3 \end{array} \quad \begin{bmatrix} ^2H \\ ^2G \end{bmatrix}$$

Волновая функция состояния $^2H, \frac{1}{2}, 5\left(M_S = \frac{1}{2}, M_L = 5\right)$ равна Φ_1, т. е. $\Phi\left(^2H, \frac{1}{2}, 5\right) = \Phi_1$. Применяя оператор $\left(\hat{L}_x - i\hat{L}_y\right)$, получаем:

$$\left(\hat{L}_x - i\hat{L}_y\right)\Phi\left(^2H, \frac{1}{2}, 5\right) = \sqrt{10}\Phi\left(^2H, \frac{1}{2}, 4\right).$$

Так как $\left(\hat{L}_x - i\hat{L}_y\right)\Phi_1 = -2\Phi_3 + \sqrt{6}\Phi_2$, то

$$\Phi\left(^2H, \frac{1}{2}, 4\right) = \frac{1}{\sqrt{10}}\left\{\sqrt{6}\Phi_2 - 2\Phi_3\right\}.$$

Другие, нужные для решения задачи, состояния терма ^2H находим последовательно:

$$\Phi\left(^2H, \frac{1}{2}, 3\right) = \frac{1}{\sqrt{30}}\left\{\sqrt{6}\Phi_4 - 2\Phi_5 + 4\Phi_6 - 2\Phi_3\right\},$$
$$\Phi\left(^2H, \frac{1}{2}, 2\right) = \frac{1}{\sqrt{30}}\left\{\Phi_8 - \Phi_9 + 3\Phi_{10} - 2\Phi_{11} - 3\Phi_{12} + \sqrt{6}\Phi_{13}\right\}.$$

Состояние $\Phi\left(^2G, \frac{1}{2}, 4\right)$ представляет собой линейную комбинацию состояний Φ_2 и Φ_3, ортогональную к состоянию $\Phi\left(^2H, \frac{1}{2}, 4\right)$. Из этих условий определяем волновую функцию $\Phi\left(^2G, \frac{1}{2}, 4\right)$

$$\Phi\left(^2G, \frac{1}{2}, 4\right) = \frac{e^{i\alpha}}{\sqrt{10}}\left\{2\Phi_2 + \sqrt{6}\Phi_3\right\}.$$

Так как состояния разных термов не связаны никакими фазовыми соотношениями, мы можем положить $\alpha = 0$.

Другие состояния терма ^2G получаются посредством последовательного применения оператора $\left(\hat{L}_{sc} - i\hat{L}_y\right)$. Итак, имеем:

$$\Phi\left(^2G, \frac{1}{2}, 4\right) = \frac{1}{\sqrt{10}}\left\{2\Phi_2 + \sqrt{6}\Phi_3\right\},$$
$$\Phi\left(^2G, \frac{1}{2}, 3\right) = \frac{1}{\sqrt{20}}\left\{\sqrt{6}\Phi_4 + 3\Phi_5 - \Phi_6 - 2\Phi_7\right\},$$
$$\Phi\left(^2G, \frac{1}{2}, 2\right) =$$
$$= \sqrt{\frac{3}{140}}\left\{2\Phi_8 + 3\Phi_9 + \Phi_{10} - 4\Phi_{11} + 4\Phi_{12} + \sqrt{\frac{2}{3}}\Phi_{13}\right\}.$$

Для того чтобы решить задачу, нам необходимо еще определить функции $\Phi\left(^4F, \frac{1}{2}, 2\right)$ и $\Phi\left(^2F, \frac{1}{2}, 2\right)$.

Так как $\Phi\left(4F, \frac{3}{2}, 3\right) = \Phi_{14}$, то, действуя оператором $\left(\hat{S}_x - i\hat{S}_y\right)$, получим состояние $\Phi\left(^4F, \frac{1}{2}, 3\right)$:

$\left(\hat{S}_x - i\hat{S}_y\right)\Phi\left(^4F, \frac{3}{2}, 3\right) = \sqrt{3}\Phi\left(^4F, \frac{1}{2}, 3\right) = \left(\hat{S}_x - i\hat{S}_y\right)\Phi_{14}$, $\Phi\left(^4F, \frac{1}{2}, 3\right) = \frac{1}{\sqrt{3}}\left\{\Phi_5 + \Phi_6 + \Phi_7\right\}$

А из состояния $\Phi\left(^4F, \frac{1}{2}, 3\right)$ посредством оператора $\left(\hat{L}_x - i\hat{L}_y\right)$ получаем состояние $\Phi\left(^4F, \frac{1}{2}, 2\right)$:

$$\Phi\left(^4F, \frac{1}{2}, 2\right) = \frac{1}{\sqrt{3}}\left\{\Phi_9 + \Phi_{10} + \Phi_{11}\right\}.$$

Волновая функция $\Phi\left(^2F, \frac{1}{2}, 3\right)$ определится из условия ортогональности ее к трем функциям $\Phi\left(^2H, \frac{1}{2}, 3\right)$, $\Phi\left(^2G, \frac{1}{2}, 3\right), \Phi\left(^4F, \frac{1}{2}, 3\right)$. Нормированная функция $\Phi\left(^2F, \frac{1}{2}, 3\right)$, определенная из этих условий, равна

$$\Phi\left(^2F, \frac{1}{2}, 3\right) = \frac{1}{\sqrt{12}}\left\{-\sqrt{6}\Phi_4 + \Phi_5 + \Phi_6 - 2\Phi_7\right\}.$$

И, наконец,

$$\Phi\left(^2F, \frac{1}{2}, 2\right) = \frac{1}{\sqrt{12}}\left\{-2\Phi_8 + \Phi_9 - \Phi_{10} + \sqrt{6}\Phi_{13}\right\}.$$

Теперь мы имеем четыре состояния с $M_S = \frac{1}{2}$ и $M_L = 2$, $\Phi\left(^2H, \frac{1}{2}, 2\right) =$

$$= \frac{1}{\sqrt{30}} \left\{ \Phi_8 - \Phi_9 + 3\Phi_{10} - 2\Phi_{11} - 3\Phi_{12} + V\overline{6}\Phi_{13} \right\},$$

$\Phi\left({}^2G, \frac{1}{2}, 2\right) =$
$= \sqrt{\frac{3}{140}} \left\{ 2\Phi_8 + 3\Phi_9 + \Phi_{10} - 4\Phi_{11} + 4\Phi_{12} + \sqrt{\frac{2}{3}}\Phi_{13} \right\}$, $\Phi\left({}^4F, \frac{1}{2}, 2\right) = \frac{1}{\sqrt{3}} \{\Phi_9 + \Phi_{10} + \Phi_{11}\}$,
$\Phi\left({}^2F, \frac{1}{2}, 2\right) = \frac{1}{\sqrt{12}} \left\{ -2\Phi_8 + \Phi_9 - \Phi_{10} + \sqrt{6}\Phi_{13} \right\}$.

В эту же группу входят еще два ${}^2D$ состояния. Эти два взаимно ортогональные ${}^2D$ состояния ортогональны также к написанным выше четырем состояниям.

Из условий ортогональности и нормировки получаем следующие ортонормированные функции:

$$\Phi\left(a^2D, \frac{1}{2}, 2\right) = \frac{1}{2} \{-\Phi_8 - \Phi_9 + \Phi_{10} + \Phi_{12}\}$$

$$\Phi\left(b^2D, \frac{1}{2}, 2\right) =$$

$$= \frac{1}{\sqrt{84}} \left\{ -5\Phi_8 + 3\Phi_9 + \Phi_{10} - 4\Phi_{11} - 3\Phi_{12} - 2\sqrt{6\Phi_{13}} \right\}^{\top}$$

Остальные волновые функции ${}^2D$ состояний, соответствующие другим значениям проекции моментов, легко определяются посредством последовательного применения операторов $\left(\hat{L}_x - i\hat{L}_y\right)$ и $\left(\hat{S}_x - i\hat{S}_y\right)$.

44

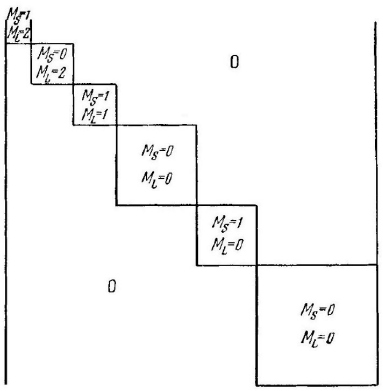
Составим сперва список всех состояний, принадлежащих конфигурации $npn'p$. Ограничимся неотрицательными значениями M_S и M_L

pp		M_S	
		1	0
M_L	2	$\Phi_1(1^+, 1^+)$	$\Phi_2(1^+, 1^-)$ $\Phi_3(1^-, 1^+)$
	1	$\Phi_4(1^+, 0^+)$ $\Phi_5(0^+, 1^+)$	$\Phi_6(1^+, 0^-)$ $\Phi_7(0^+, 1^-)$ $\Phi_8(1^-, 0^+)$ $\Phi_9(0^-, 1^+)$
	0	$\Phi_{10}(1^+, -1^+)\Phi_{11}(0^+, 0^+)$ $\Phi_{12}(-1^+, 1^+)$	$\Phi_{13}(1^+, -1^-)$ $\Phi_{14}(0^+, 0^-)$ $\Phi_{15}(-1^+, 1^-)$ $\Phi_{16}(1^-, -1^+)$ $\Phi_{17}(0^-, 0^+)$ $\Phi_{18}(-1^-, 1^+)$

Из рассмотрения таблицы следует, что данная конфигурация имеет термы ${}^1S, {}^3S, {}^1P, {}^3P, {}^1D$ и ${}^3D$.

При решении задачи в качестве функций нулевого приближения возьмем функции, указанные в таблице.

Так как энергия не зависит от значения проекций M_S и M_L, то матрица возмущения будет представлена в виде субматриц следующим образом:



Обозначим через $\hat{V}$ оператор возмущения. В первой субматрице присутствует только терм ${}^8D$. Следовательно,

$$E^{(1)}\left({}^3D\right) = V_{11}.$$

Во второй субматрице ($M_L = 2, M_S = 0$) комбинируются два терма ${}^3D$ и ${}^1D$,

$$E^{(1)}\left({}^3D\right) + E^{(1)}\left({}^1D\right) = V_{22} + V_{33}.$$

В третьей субматрице ($M_L = 1, M_S = 0$) комбинируются два терма ${}^3D$ и ${}^3P$,

$$E^{(1)}\left({}^3D\right) + E^{(1)}\left({}^3P\right) = V_{44} + V_{65}.$$

В четвертой субматрице ($M_L = 1, M_S = 0$) четыре терма: ${}^3D), {}^1D, {}^3P, {}^1P$

$$E^{(1)}\left({}^3D\right) + E^{(1)}\left({}^1D\right) + E^{(1)}\left({}^3P\right) + E^{(1)}\left({}^1P\right) = V_{66} + V_{77} + V_{88} + V_{99^*}$$

В пятой субматрице ($M_L = 0, M_S = 1$) три терма: ${}^3D, {}^3P, {}^3S$,

$$E^{(1)}\left({}^3D\right) + E^{(1)}\left({}^3P\right) + E^{(1)}\left({}^3S\right) = V_{10,10} + V_{11,11} + V_{12,12}$$

Н, наконец, в шестой ($M_L = 0, M_S = 0$) все термы: ${}^3D, {}^3P$, ${}^3S, {}^1D, {}^1P, {}^1S$

$$\begin{aligned} E^{(1)}\left({}^3D\right) + E^{(1)}\left({}^1D\right) + E^{(1)}\left({}^3P\right) + \\ + E^{(1)}\left({}^1P\right) + E^{(1)}\left({}^3S\right) + E^{(1)}\left({}^1S\right) = \\ = V_{13,13} + V_{14,14} + V_{15,15} + V_{16,16} + V_{17,17} + V_{18,18} \end{aligned}$$

Из этих уравнений легко получить выражение для термов через диагональные матричные элементы:

$$\begin{aligned} E^{(1)}\left({}^3D\right) &= V_{11}, \\ E^{(1)}\left({}^1D\right) &= V_{22} + V_{33} - V_{11}, \\ E^{(1)}\left({}^3P\right) &= V_{44} + V_{55} - V_{11}, \\ E^{(1)}\left({}^1P\right) &= V_{66} + V_{77} + V_{89} + V_{99} + V_{11} - V_{22} - V_{33} - V_{44} - V_{50} \end{aligned}$$

и Т. Д.

1+45

Выражение $\frac{e\hbar}{2\mu c}\left(\hat{L}_z + 2\hat{S}_z\right)$ Эt' является малым возмущением. Рассматриваем рассель-саундеровский тип связи. В этом случае $\hat{H}_0$ коммутирует операторами $\hat{J}^2, \hat{J}_z$, $\hat{\boldsymbol{L}}^2, \hat{\boldsymbol{S}}^2$. Уровни энергии невозмущенного состояния характеризуются квантовыми числами J, L, S. Каждый из этих уровней вырожден по направлению вектора $\hat{\boldsymbol{J}}$, кратность этого вырождения равна $2J + 1$.

Так как недиагональные по $\hat{J}_z$ матричные элементы оператора $\left(\hat{L}_z + 2\hat{S}_z\right)$ равны нулю, то поправка к энергии равна просто среднему значению оператора $\left(\hat{L}_z + 2\hat{S}_z\right)$ в состоянии, характеризуемом квантовыми числами J, JJ_z, L, S. С целью вычисления этого среднего значения положим в формуле (задачи 29§4) $g_1 = 1, g_2 = 2, \hat{J}_1 = \hat{\boldsymbol{L}}, \hat{\boldsymbol{J}}_2 = \hat{\boldsymbol{S}}$. В результате получим:

$$\overline{\hat{L}_z + 2\hat{S}_z} = J_z\left\{\frac{3}{2} + \frac{S(S+1) - L(L+1)}{2J(J+1)}\right\} = J_z g.$$

Согласно сказанному выше искомое расщепление будет равно

$$E^{(1)}_{JLS} = \frac{e\hbar\mathscr{E}}{2\mu c} g J_z.$$

18.1.10 Advanced problems about atoms 4

52.

Найти волновые функции электрона, находящегося в условиях, указанных в предыдущей задаче.

53.

Определить расщепление уровней атома водорода, находящегося в сильном магнитном поле $\left(\frac{e\hbar}{2\mu.c}\mathscr{H} > |E_{nlj} - E_{nlj'}|\right)$. Для применения теории возмущений необходимо потребовать, чтобы энергия атома в магнитном поле была мала по сравнению с разностью энергии различных мультиплетов, т. е.

$$\frac{e\hbar\mathscr{E}}{2\mu c} < |E_{nlj} - E_{n'lj}|.$$

54.

Определить зеемановское расщепление компонент сверхтонкой структуры терма $^2S_{1/2}(j = 1/2, l = 0)$ в случае среднего магнитного поля $\left(\frac{e\hbar}{2\mu c}\mathscr{E} \sim |\Delta E_{ff'}|\right)$. (Расщепление, вызываемое полем одного порядка с интервалами сверхтонкой структуры.)

55.

Показать, что при произвольном значении напряженности магнитного поля сумма изменений энергий, вызванных магнитным полем, по всем состояниям с заданным M_J равна

$$\frac{e\hbar}{2\mu \cdot c}\mathscr{H}M_J \sum \left\{1 + \frac{J(J+1) - L(L+1) + S(S+1)}{2J(J+1)}\right\}.$$

Здесь суммирование производится по J, заключенным в пределах $L + S \leqslant J \leqslant |L - S|, J \geqslant M_J$.

56.

Показать, что при помещении атома водорода в однородное электрическое поле а) энергия состояния с квантовыми числами $l = n - 1$, $m = n - 1$ в линейном по полю приближении не изменяется; б) не меняется положение центра тяжести расщепленного терма; в) состояния, отличающиеся только знаком проекции момента, имеют одну и ту же энергию.

57.

Вычислить расшепление уровней атома водорода в слабом электрическом поле (эффект Штарка мал по сравнению с тонкой структурой).

58.

Найти магнитный момент атома водорода, находящегося в слабом электрическом поле.

59

. Вычислить расщепление терма с $n = 2$ атома водорода, находящегося в среднем (по величине напряженности) электрическом поле (эффект Штарка и тонкая структура одного порядка).

60.

Рассмотрим атом, находящийся под действием возмущающего потенциала $\boldsymbol{u}$. Применяя теорию возмущений, получим для волновои функции ψ в первом приближении выражение следующего вида:

$$\psi = \psi_0 + \sum_{n\neq 0} \frac{u_{n0}}{E_0 - E_n}\psi_n,$$

а для энергии

$$E = E_0 + u_{00} + \sum_{n=0} \frac{(u_{n0})^2}{E_0 - E_n}.$$

Для того чтобы в дальнейшем применить вариационный метод, упростим, насколько это возможно, вид ψ. Так как

$$\sum_{n\neq 0}^{\infty} u_{n0}\psi_n = -u_{00}\psi_0 + \sum_{n=0}^{\infty} u_{n0}\psi_n = \psi_0 (u - u_{00}),$$

то ф приближенно запишем следующим образом:

$$\psi \approx \psi_0 \left(1 + \frac{u - u_{00}}{E'}\right)$$

где E' можно в некоторых случаях считать равным среднему значению $E_0 - E_n$. После того, как вид возмущенной волновой функции приближенно установлен, мы можем для определения энергии применить вариационный метод.

Определить вариационным методом энергию атома, находящегося под действием возмущающего потенциала u. Минимум энергии искать в классе допустимых функций вида $\psi = \psi_0(1 + \lambda u)$, где λ-вариационный параметр.

ГК-5.61.

Исходя из результата предыдущей задачи, найти формулу для поляризуемости атома. Определить численные значения коэффициента поляризуемости для атомов водорода и гелия, находящихся в основных состояниях.

ГК-5.62.

Атом водорода находится в параллельных электрическом и магнитном полях. Найти расщепление в случае а) слабых полей (энергия штарковского и зеемановского расщепления меньше энергии тонкой структуры); б) средних полей, для терма с главным квантовым числом $n = 2$.

ГК-5.63.

Атом водорода в состоянии с главным квантовым числом $n = 2$ находится во взаимно перпендикулярных электрическом и магнитном полях. Определить расщепление, предполагая, что поля сильные (энергия электрона во внешнем электрическом и магнитном поле больше энергии тонкой структуры).

Solutions

1+50

Энергия атома в магнитном поле одного порядка со спин-орбитальным взаимодействием. Поэтому оператор спинорбитального взаимодействия, равный $\varphi(r)\hat{i}\hat{s}$ (см. задачу 10 § 7), объединяем с оператором $\frac{e\hbar}{2\mu c}\left(\hat{l_z} + 2\hat{s_z}\right)$ и их сумму

$$V = \varphi(r)\hat{l}\hat{s} + \frac{e\hbar}{2\mu c}\mathscr{H}\left(\hat{l}_z + 2\hat{s}_z\right)$$

рассматриваем как малое возмущение. В невозмущенном состоянии сохраняющимися величинами будут квадрат и проекция орбитального момента, а также квадрат и проекция спина. Нам удобнее взять другой набор сохраняющихся величин. Будем характеризовать стационарное невозмущенное состояние квантовыми числами $n, \boldsymbol{l}, \dot{j}, m_j$ $\left(\hat{l}^2, j^2, \hat{j}_z\right.$ коммутируют с $\left.H_0\right)$. Степень вырождения в случае кулоновского поля равна $2n^2$, в случае центрально-симметричного произвольного поля $2(2l+1)$. Нам нет необходимости решать секулярное уравнение такой высокой степени. Заметим, что в возмущенном состоянии квадрат орбитального момента и проекция полного момента являются интегралами движения. Вследствие этого волновая функция возмущенной задачи должна быть скомбинирована из функций

$$\psi_{nljm_j}{}^{(0)}$$

относящихся к одним и тем же значениям n, l, m_j, т. е. $\psi = c_1\psi^{(0)}\left(n, l, j = l - \frac{1}{2}, m_j\right) + c_2\psi^{(0)}\left(n, l, j = l + \frac{1}{2}, m_j\right)$ или в другой форме

$$+ c_2\frac{R^{(0)}_{nl}}{\sqrt{2l+1}}\begin{pmatrix} \sqrt{l - m_j + \frac{1}{2}}Y_{l,m_j-1/2} \\ -\sqrt{l + m_j + \frac{1}{2}}Y_{l,m_j+1/2} \end{pmatrix}.$$

Матричные элементы оператора $\hat{V}$ равны

$$(\hat{V})^{nlj=l+1_2m}_{nlj=l+1;2m} j = A\frac{l}{2} + e^{\top}\mu_0\mu_0 m_j\left(1 + \frac{1}{2l-1}\right),$$

$$(\hat{V})^{nlj=l-j_{j2}m_j}_{nlj=l-1/2m_j} = -A\frac{l+1}{2} + \mathscr{F}\mu_0 m_j\left(1 - \frac{1}{2l+1}\right),$$

где

$$A = \int_0^\infty R_{nl}(r)\varphi(r)R_{nl}(r)r^2dr, \quad \text{а} \quad \mu_0 = \frac{e\hbar}{2ic}.$$

Значение энергии E находится из решения секулярного уравнения

$$E_{nl}^0 + A\frac{l}{2} + \mathscr{H}\mu_0 m_j\left(1+\frac{1}{2l+1}\right) - E,$$
$$\frac{\partial \mathscr{A}\mu_0}{2l+1}\sqrt{\left(l+\frac{1}{2}\right)^2 - m_j^2}| = 0.$$
$$\frac{\partial l+1}{\left(l+\frac{1}{2}\right)^2 - m_j^2}$$

Обозначим через E_+и E_-энергию одноэлект ронного атома с учетом спин-орбитаиынго взаимодействия, причем E_+ относится к состоянию с $j = l + 1/2$, а E_-с $j = l - 1/2$.

Как следует из решения задачи 10§7,

$$E_+ = E_{nl}^{(0)} + A\frac{l}{2}, \quad E_- = E_{nl}^{(0)} - A\frac{l+1}{2}.$$

$$\Psi = c_1 \frac{R_{nl}^{(0)}}{\sqrt{2l+1}}\begin{pmatrix}\sqrt{l+m_j+\frac{1}{2}}\,Y_{l,\,m_j-1/2}\\ \sqrt{l-m_j+\frac{1}{2}}\,Y_{l,\,m_j+1/2}\end{pmatrix} +$$

$$(\hat{V})_{nlj=l-1/2 m_j}^{nlj=l-1/2 m_j} = (\hat{V})_{nlj=l+1/2 m_j}^{nlj=l+1/2 m_j} = \frac{\mathscr{H}\mu_0}{2l+1}\sqrt{\left(l+\frac{1}{2}\right)^2 - m_j^2}.$$

Решая секулярное уравнение, находим значение E:

$$E = \frac{1}{2}(E_+ + E_-) + e^{\cdot\cdot}\cdot \mu_0 m_j \pm$$
$$\pm\sqrt{\frac{1}{4}(E_+ - E_-)^2 + \mathscr{H}\mu_0\frac{m_j}{2l+1}(E_+ - E_-) + \frac{1}{4}\mathscr{H}^2\mu_{0^2}{}^*}$$

Рассмотрим предельные случаи.

а) В случае слабых полей, т. е. при ${\mu_0}^7 \ll E_+ - E_-$ для энергии получаем следующие выражения:

$$E = E_+ + \mathscr{H}\theta\mu_0 m_j\frac{2l+2}{2l+1},$$
$$E = E_- - \mathscr{E}\theta\mu_0 m_j\frac{2l}{2l+1}.$$

Первое значение энергии соответствует энергии n-го уровня состояния с $j = l + 1/2$, а второе с $j = l - 1/2$ (см. задачу 46 \$7)

б) В случае сильных полей, т. е. при $\mu_0\mathscr{F} \gg E_+ - E_-$ $E = \frac{1}{2}(E_+ + E_-) + \mathscr{H}\mu_0 m_j \pm \frac{1}{2}\mathscr{H}C\mu_0 \pm \frac{m_j}{2l+1}(E_+ - E_{\ldots})$. Обозначим через E_c энергию центра тяжести уровней в отсутствии поля, т. е.

$$E_c = \frac{E_+(l+1) - E_- l}{2l+1}$$

(статистические веса состояний с E_+и E_-относятся друг к другу как $\left(\frac{2l+1}{2l}\right)$, а через ΔE разность $E_+ - E_-$.В новых обозначениях E будет иметь внд

$$E = E_{\boldsymbol{c}} + \mathscr{H}\mu_0\left(m_j \pm \frac{1}{2}\right) \pm \frac{\Delta E}{2l+1}\left(m_j \mp \frac{1}{2}\right).$$

Это выражение, как легко убедиться, тождественно с выражением задачи 53&7.

Верхний знак соответствует состоянию с $m_l = m_j - 1/2$, $m_s = 1/2$, а нижний-состоянию с $m_l = m_j + 1/2, m_s = 1/2$.

52. $c_1 = \sqrt{\frac{1}{2}(1+\gamma)}$, $c_2 = \sqrt{\frac{1}{2}(1-\gamma)}$ для верхнего

$c_1 = \sqrt{\frac{1}{2}(1-\gamma)}$, $\quad c_2 = -\sqrt{\frac{1}{2}(1+\gamma)}$ для ниж-

где

$$\gamma = \frac{\frac{1}{2}\Delta E + \frac{m_j}{2l+1}\mathscr{H}\mu_0}{\sqrt{\frac{1}{4}(\Delta E)^2 + \frac{m_j}{2l+1}\Delta E\mathscr{H}\mu_0 + \frac{1}{4}\mathscr{H}^2\mu_0^2}}.$$

Нсследуем предельные случаи.

а) Магнитное поле исчезаюие мало, т. е. $\Delta E \gg\gg \mu_0$, тогда $\gamma \approx 1$. Для верхнего уровня будем иметь $c_1 = 1$, $c_2 = 0$, для нижнего $c_1 = 0, c_2 = 1$.

б) Сильное магнитное поле $\triangle E \ll \mathcal{H}_{\mu_0}$ В этом случае $\gamma = \frac{m_j}{l-\frac{1}{2}}$

$$c_1 = \sqrt{\frac{l+m_j+\frac{1}{2}}{2l+1}}, \quad c_2 = \sqrt{\frac{l-m_j+\frac{1}{2}}{2l+1}} \text{ для верхнего}$$

Подставляя полученные значения c_1 и c_2 в выражение пля волновых функций, находим:

$$\psi = R_{nl}^{(0)} \begin{pmatrix} Y_{l,m-1j_2}(\theta,\varphi) \\ 0 \end{pmatrix} \text{ для верхнего уровня,}$$

$$\psi = R_{nl}^{(0)} \begin{pmatrix} 0 \\ Y_{l,m-1,2}(\hat{\varphi},\varphi) \end{pmatrix} \text{ Д.я нижнего уровня.}$$

1+52

Так как энергия в магнитном поле значительно превышает энергию спин-орбитального взаимодействия, то в первом приближении последним взаимодействием пренебрежем.

В этом случае $\hat{l}_z$ и $\hat{s}_z$ - величины сохраняючиеся, и энергия расшепления определяется формулой

$$E^{(1)} = \frac{e\hbar}{2\mu c} e^{\gamma}(m_l + 2m_{\mathrm{s}}).$$

Во втором приближении учтем спин-орбитальное взаимодействие. Мультиплетное расщепление, накладываемое на расщепление в магнитном поле, определится средним значением оператора $\frac{e^2}{2\mu^2c^2}\frac{1}{r^3}(\hat{l}\hat{s})$ (см. задачу 10§7) по состоянию с данными значениями m_l и m_s. При заданном значении одной из компонент момента средние значения двух других равны нулю, поэтому

$$\bar{\vec{l}\hat{s}} = m_l m_s.$$

Таким образом, энергия расщепления уровней с учетом с пин-орбитального взаимодействия имеет вид

$$E^{(1)} = \frac{e\hbar}{2\mu c}\mathscr{H}(m_l + 2m_s) + \frac{e^2\hbar^2}{2\mu^2c^2}\overline{\frac{1}{r^3}} m_l m_{s\circ}$$

Подставим в полученную формулу значение $\overline{\frac{1}{r^3}}$, выраженное через энергию расщепления тонкой структуры в отсутствии поля. Как легко показать (см. задачу 10$7).

$$\frac{e^2\hbar^2}{2\mu^2c^2}\overline{\frac{1}{r^3}} = \frac{E_{n,l,j=l+1,2} - E_{n,l,j=l-1,2}}{l+\frac{1}{2}} = \frac{\Delta E}{l+\frac{1}{2}}.$$

Окончательно для $E^{(1)}$ имеем выражение

$$E^{(1)} = \frac{e\hbar}{2\mu c} e^{\mathcal{H}}(m_l + 2m_s) + \frac{\Delta E}{l+\frac{1}{2}} m_l m_s$$

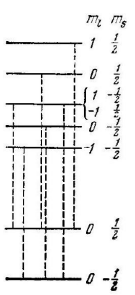


Рис. 30.

На рисунке 30 дана схема расщепления $1s$ и $2p$ термов атома щелочного металла в сильном магнитном поле.

54

Энергия возмущения в данном случае равна

$$\hat{V} = \frac{e\hbar}{\mu c}\beta\frac{1}{r^3}\hat{i}\left\{\frac{3(r\hat{s})r}{r^2} - \hat{s}\right\} + \frac{e\hbar}{\mu c}\mathscr{H}\hat{s}_z + \beta\mathscr{H}\hat{i}_z$$

В этом выражении последним членом пренебрежем ввиду малости магнитного момента ядра по сравнению с магнитным моментом электрона $\left(\beta < \frac{e\hbar}{2\mu c}\right)$. Поступая так же, как и при решении задачи 51&7, находим секулярное уравнение:

$$\begin{vmatrix} E_+ + \frac{\mu_0 \mathscr{H} m_f}{i+\frac{1}{2}} - E & \frac{\mathscr{H}\mu_0}{i+\frac{1}{2}}\sqrt{\left(i+\frac{1}{2}\right)^2 - m_f^2} \\ \frac{\mathscr{H}\mu_0}{i+\frac{1}{2}}\sqrt{\left(i+\frac{1}{2}\right)^2 - m_f^2} & E_- - \frac{\mathscr{H}\mu_0}{i+\frac{1}{2}}m_f - E \end{vmatrix} = 0.$$

Здесь E_+и E_-- энергия терма с учетом сверхтонкой структуры, причем E_+относится к состоянию с $f = i + 1/z$, а E_-с $f = i - 1/2, m_f$ проекция полного момента ($m_f = f,\ f-1, ..., -f$), а $\mu_0 = \frac{e\hbar}{2\mu c}$. Решая секулярное уравнение, находим:

$$E = \frac{E_+ + E_-}{2} \pm \frac{\Delta E}{2}\sqrt{1 + \frac{2\xi}{i+\frac{1}{2}}m_f + \xi^2}$$

где $\Delta E = E_+ \cdots E_-$, а $\xi = \frac{2\mu_0\theta}{\Delta E}$.

Найдем поряпок величины напряженности магнитного поля, в котором будет наблюдаться расщепление, описываемое полученной формулой. По условию $\mathcal{F}' \sim \frac{|\Delta E_{ff'}|}{\mu_0}$. В случае атома натрия $\Delta E_{ff'} = 0,0583cM^{-1} = 1,962 \cdot 10^{-16}\partial p2$; так как $\mu_0 = 0,922 \cdot 10^{-20}$ ааусс $\cdot cM^3$, то напряженность ё по порядку должна быть равна $\mathscr{H} \sim 600$ гаусс.

Рассмотрим предельные случаи.

а) В случае малых полей, т. е. при $\mu_0 \rightleftharpoons \mathcal{H} \ll \Delta E$, пля энергии получаем следующие выражения:

$$E = E_+ + \frac{\mathscr{O}\mu_0}{i+\frac{1}{2}}m_f,$$
$$E = E_- - \frac{\mathscr{H}\mu_0}{i+\frac{1}{2}}m_f.$$

б) В случае больших полей, т. е. при е $\mu_0 \gg \Delta E$,

$$E = \frac{1}{2}(E_+ + E_-) \pm \mathscr{H}\ell\mu_0.$$

57

Собственные нормированные функции атома водорода в невозмущенном состоянии имеют вид (см. задачу 20 §4)

$$\left.\begin{aligned} \psi_{nlj=l+1/2\,m_j} &= \frac{R_{n,j-1/2}}{\sqrt{2j}}\begin{pmatrix}\sqrt{j+m_j}\,Y_{j-1/2,\,m_j-1/2} \\ \sqrt{j-m_j}\,Y_{j-1/2,\,m_j+1/2}\end{pmatrix} = u_-, \\ \psi_{nlj=l-1/2\,m_j} &= \frac{R_{n,j+1/2}}{\sqrt{2j+2}}\begin{pmatrix}\sqrt{j+1-m_j}\,Y_{j+1/2,\,m_j-1/2} \\ -\sqrt{j+1+m_j}\,Y_{j+1/2,\,m_j+1/2}\end{pmatrix} = u_+. \end{aligned}\right\}$$

Энергия определяется двумя квантовыми числами n, j. В присутствии однородного элекгрического поля $(\mathscr{E}_x = \mathscr{E}_y = 0,\ \mathscr{G}_z = \})\,\hat{j}_z$ по-прежнему остается константой движения, а орбитальный момент перестает быть интегралом движения. Матричные элементы оператора возмущения $\hat{V} = e\&z$ для переходов между состояниями с различными значениями m_j равны нулю. Равны нулю также диагональные элементы оператора $\hat{V}$, т. е.

$$\sum_\sigma \int u_+^* z u_+ d\tau = \sum_\sigma \int u_-^* z u_- d\tau.$$

Поэтому для определения расщепления необходимо вычислить матричные элементы $\hat{V}$, соответствующие переходу из состояния $n, j, m_j, l = j + 1/2$ в состояние $n, j, m_j,\ l = j - 1/2$. Искомый матричный элемент равен

$$V_{21} = V_{12} = e\mathscr{G} \sum_{\sigma} \int u_-^* z u_+ d\tau =$$

$$= \int_0^\infty r^8 R_{n,j-1/2}(r) R_{n,j+1/2}(r) dr \frac{1}{2\sqrt{j(j+1)}} \times \left\{ \sqrt{(j+m_j)\,(j-m_j+1)} \times \right.$$

$$\left. \times \int Y^*_{j-1/2,m_j-1/2} Y_{j+1/2,m_j-1/2} \cos\vartheta dQ - \sqrt{(j-m_j)\,(j+m_j+1)} \times \int Y^*_{j-1/2,m_j+1/2} Y_{j+1/2,2,m_j+1/2} \cos\vartheta dQ \right\}.$$

Проинтегрируем сперва по углам. На основании формулы

$$\cos 0 Y_{lm}(i,\varphi) = \sqrt{\frac{(l+m+1)(l-m+1)}{(2l+1)(2l+3)}} Y_{l+1,m}(\theta,\varphi) + \sqrt{\frac{(l+m)(l-m)}{(2l+1)(2l-1)}} Y_{l-1,m}(\theta,\varphi)$$

получаем, что выражение в фигурной скобке в (3) равно

$$\frac{1}{2\sqrt{j(j+1)}} \{(j+m_j)\,(j-m_j+1) - (j+m_j+1)\,(j-m_j)\} = \frac{m_j}{\sqrt{j(j+1)}}.$$

Производя далее интегрирование по r, имеем:

$$-\frac{3}{2} n \sqrt{n^2 - \left(j+\frac{1}{2}\right)^2}.$$

Таким образом, для матричного элемента возмущения (3) окончательно получаем:

$$-\frac{3}{4} n \frac{\sqrt{n^2 - \left(j+\frac{1}{2}\right)^2}}{j(j+1)} m_j e\mathcal{G} = V_{12} = V_{21}.$$

Искомую поправку к энергии находим из решения векового уравнения:

$$\begin{vmatrix} -\varepsilon & V_{12} \\ V_{21} & -\varepsilon \end{vmatrix} = 0, \quad \varepsilon = \pm V_{12},$$

$$\varepsilon = \pm \frac{3}{4} \sqrt{n^2 - \left(j+\frac{1}{2}\right)^2} \frac{n m_j}{j(j+1)} e\varepsilon.$$

При заданном n терм с $j = n - 1/2$ в электрическом поле не расщепляется, так как он не вырожден относительно квантового числа l (l имеет фиксированное значение $l = j - 1/2 = n - 1$). Все остальные термы тонкой структуры распадаются на $2j + 1$ равноотстоящих уровней $m_j = -j, \ldots \cdot \ldots + j$) 58.

$$\mu_0 = \frac{e\hbar}{2\mu c} \frac{\left(j+\frac{1}{2}\right)^2}{j(j+1)} m_j.$$

1+58

В рассматриваемом случае спин-орбитальное взаимодействие V_1, релятивистская поправка на изменение массы V_2 и энергия электрона во внешнем однородном электрическом поле $V_3 = -Fz$ величины одного и того же порядка. Поэтому мы будем рассматривать их сумму как малое возмущение исходной системы. При вычислении исходим из состояний, в которых имеют вполне определенные значения орбитальный момент L, его проекция m_l и проекция спина m_s на направление электрического поля (ось z).

Вычисляя матричные элементы величин V_1, V_2 и V_3, имеем (в ат. ед.):

$$(V_1)^{l'm'_l}_{lm_l} = \begin{cases} \frac{1}{2}\alpha^2 \frac{m_l(m-m_l)}{n^3 l\left(l+\frac{1}{2}\right)(l+1)}\delta_{nl'} & \text{при } m'_l = m_l, \\ \frac{1}{4}\alpha^2 \frac{\sqrt{\left(l+\frac{1}{2}\right)^2 - m^2}}{n^3 l\left(l+\frac{1}{2}\right)(l+1)}\delta_{ll'} & \text{при } m'_l = m + \frac{1}{2}, \\ m_l = m - \frac{1}{2} \text{ или наоборот}, \\ 0 \quad \text{во всех остальных случаях}, \end{cases}$$

$$(V_2)^{i_l m'_l}_{lm_l} = -\frac{1}{2}\frac{a^2}{n^3}\left(\frac{1}{l+\frac{1}{2}} - \frac{3}{4n}\right)\delta_{ll'}\delta_{ml^m l'}{}'$$

$$(V_3)^{l'm'_l}_{lm_l} = -\frac{3n}{2}\sqrt{\frac{\left(n^2-l^2\right)\left(l^2-m_l^2\right)}{4l^2-1}}F\delta_{l',l-1}\delta_{ml''l}.$$

В случае $n = 2$ энергия состояний с квантовыми числами $l = 1, m = m_l + m_s = \pm 3/2 (j = 3/2)$ в электрическом поле не изменяется. Смещение этого уровня вследствие учета V_1 и V_2 равно $\frac{a^2}{128}$ ат. ед. (см. задачу 10§7).

Расщепление уровня, квантовые числа которого $n = 2, m = \pm\frac{1}{2}$, находится из решения секулярного уравнения

$$\begin{vmatrix} -\frac{11}{4}\delta - E^{(1)} & \delta\sqrt{2} & 0 \\ \delta\sqrt{2} & -\frac{7}{4}\delta - E^{(1)} & -3F \\ 0 & -3F & -\frac{15}{4}\delta - E^{(1)} \end{vmatrix} = 0,$$

где $3\delta = \frac{\alpha^2}{32}$ ат. ед. есть расщепление тонкой структуры уровня $n = 2$ в отсутствии внешнего поля. Введем в это уравнение величину ε, связанную с $E^{(1)}$ соотношением $E^{(1)} = \varepsilon - \frac{11}{4}\delta$ $\left(-\frac{11}{4}\delta\right.$ представляет энергию центра тяжести трех энергетических уровней $\left.\frac{E_1^{(1)}+E_2^{(1)}+E_3^{(1)}}{3} = -\frac{11}{4}\delta\right)$, получаем:

$$\begin{vmatrix} -\varepsilon & \delta\sqrt{2} & 0 \\ \delta\sqrt{2} & \delta - \varepsilon & -3F \\ 0 & -3F & -\delta - \varepsilon \end{vmatrix} = 0,$$

или

$$\varepsilon^3 - \varepsilon\left(3\delta^2 + 9F^2\right) - 2\partial^3 = 0.$$

Решаем последнее уравнение в случае слабых полей ($F \ll \delta$) и в случае сильных полей ($F \gg$ о). В первом случае получаем:

Во втором:

$$\varepsilon_1 = -\delta - \sqrt{3}F - \frac{F^2}{\delta}$$
$$\varepsilon_2 = -\delta + \sqrt{3}F - \frac{F^2}{\delta},$$
$$\varepsilon_3 = 2\delta + 2\frac{F^2}{\delta}$$
$$\varepsilon_1 = -3F - \frac{1}{2}\frac{\delta^2}{F} + \frac{1}{9}\frac{\delta^3}{F^2},$$
$$\varepsilon_2 = -\frac{2}{9}\frac{\delta^3}{F^2},$$
$$\varepsilon_3 = 3F + \frac{1}{2}\frac{\delta^2}{F} + \frac{1}{9}\frac{\delta^3}{F^2}$$

1+59

Среднее значение полной энергии равно

$$\hat{H} = \frac{\int \psi_0^*(1+\lambda u)\hat{H}\psi_0(1+\lambda u)d\tau}{\int \psi_0^*\psi_0(1+\lambda u)^2 d\tau}.$$

С помощью интегрирования по частям приведем числитель к более удобной форме.

Оператор кинетической энергии электронов имеет вид

$$\hat{T} = -\frac{1}{2}\sum_{i=1}^{n}\Delta_i,$$

где n-число электронов, а Δ_i - оператор Лапласа, действующий на координаты i-го электрона. (Расчет производим в атомной системе единиц.) Запишем выражение для среднего значения кинетической энергии в симметричной относительно «0 и Чо форме

$$\overline{\hat{T}} = -\frac{1}{2}\sum_{i=1}^{n}\frac{1}{2}\int\{\psi_0^*(1+\lambda u)\Delta_i(1+\lambda u)\psi_0 + \\ +\psi_0(1+\lambda u)\Delta_i(1+\lambda u)\psi_0^*\}\,d\tau.$$

Выполняя дифференцирование под знаком интеграла, получим:

$$\overline{\hat{T}} = -\frac{1}{2}\sum_{i=1}^{n}\frac{1}{2}\int\{\psi_0^*(1+\lambda u)^2\Delta_i\psi_0 + \\ +\psi_0(1+\lambda u)^2\Delta_i\psi_0^* + 2\lambda\psi_\psi\psi_0^*(1+\lambda u)\Delta_i u + \\ +2\lambda(1+\lambda u)\nabla_i\left(\psi_0^*\psi_0\right)\nabla_i u\}\,d\tau.$$

Преобразуем два последние члена. Для этого рассмотрим тождество

$$\nabla_i\{\psi_{0'}^*\langle(1+\lambda u)\nabla_i u\} = \\ = \psi_{\sigma''0}^*(1+\lambda u)\Delta_i u + (1+\lambda a)\nabla_i\left(\psi_0^*\psi_0\right)\nabla_i u + \lambda\psi_0^*\psi_0\left(\nabla_i u\right)^2.$$

При интегрировании тождества (3) по всему конфигурационному пространству имеем:

$$\int\{\psi_0^*\psi_0^*(1+\lambda.u)\Delta_i u + (1+\lambda u)\nabla_i\left(\psi_0^*\psi_0\right)\nabla_i u\}\,d\tau = \\ = -\lambda\int\psi_0^*\left(\nabla_i u\right)^2 d\tau.$$

Подставляя (4) в (2), получим:

$$\overline{\hat{T}} = -\tfrac{1}{2}\sum_{i=1}^{n}\tfrac{1}{2}\int\left\{\psi_0^*(1+\lambda u)^2\Delta_{i\psi_0} + \psi_0(1+\lambda u)^2\Delta_i\psi_0^*\right\}d\tau + \\ +\tfrac{\lambda 2}{2}\sum_{i=1}^{n}\int_0\psi_0^*\psi_0\left(\nabla_i u\right)^2 d\tau.$$

Оператор Гамильтона $\hat{H}$ равен $\hat{H} = \hat{H}_0 + u = \hat{T} + \hat{V} + u$. Учитывая коммутативность $\hat{V}$с$(1+\lambda u)$, выражение (1) представим в следующей форме:

$$\overline{\hat{H}} = E_0 + \frac{\frac{1}{2}\int(1+\lambda u)^2\left(\psi_0^*\hat{H}\Psi_0 + \iota_0\hat{H}_{\iota_0^*}^*\right)d\tau + \frac{\lambda^2}{2}\sum_{i=1}^{n}\int\bigcup_0^*\psi_0\left(\nabla_i u\right)^2 d\tau}{\int(1+\lambda u)^2\iota_0^*\psi_0 d\tau}.$$

Так как $\hat{H}_0\psi_0 = E_0\iota_0$, то
Или

$$\overline{\hat{H}} = E_0 + \frac{\int\psi_0^* u(1+\lambda u)^2\psi_0 d\tau + \frac{\lambda^2}{2}\sum_{i=1}^{n}\int\psi_0^*\psi_0\left(\nabla_i u\right)^2 d\tau}{\int(1+\lambda u)^2\psi_0^*\psi_0 d\tau}$$

$$(u)_{00} + 2\lambda\left(u^2\right)_{00} + \lambda^2\left(u^3\right)_{00} + \frac{\lambda^2}{2}\sum_{i=1}^{n}\left\{\left(\nabla_i u\right)^2\right\}_{00}$$

где $(u)_{00} = \int\psi_0^* u_0 d\tau$, $\left(u^2\right)_{00} = \int\psi_0^* u^2\psi_0 d\tau$ и т. д. Разложим второй член в (5) в ряд, отбросив члены с $\left(u^3\right)_{00}, (u)_{00}^3$ и т. д.
Для добавки к энергии ΔE получим приближенное выражение вида

$$\Delta E \approx (u)_{00} + 2\lambda\left(u^2\right)_{00} - 2\lambda(u)_{00}^2 + \frac{\lambda^2}{2}\sum_{i=1}^{n}\left\{\left(\nabla_i u\right)^2\right\}_{00}.$$

Определим значение вариационного параметра λ из условия

$$\frac{d\Delta E}{d\lambda} = 2\left(u^2\right)_{00} - 2(u)_{00}^2 + \lambda\sum_{i=1}^{n}\left\{\left(\nabla_i u\right)^2\right\}_{00} = 0,$$

$$\bar{\hat{H}} = E_0 + \frac{\overbrace{i=1}}{1 + 2\lambda\,(u)_{00} + \lambda^2\,(u^2)_{00}},$$

откуда для λ получаем значение

$$\lambda = 2\frac{(u)_{00}^2 - \left(u^2\right)_{00}}{\sum\limits_{i=1}^{n}\left\{\left(\nabla_i u\right)^2\right\}_{00}}$$

Подставляя λ в (6), получим искомое соотношение

$$\Delta E \approx (u)_{00} - 2\frac{\left\{(u)_{00}^2 - \left(u^2\right)_0\right\}^2}{\sum\limits_{i=1}^{n}\left\{\left(\nabla_i u\right)^2\right\}_{00}}$$

1+60

Если атом находится в однородном электрическом поле, напряженность которого &, и поле направлено по оси z, то оператор возмущения

$$u = -\& \sum_{i=1}^{n} z_i = -\mathcal{E}z.$$

Матричный элемент $(u)_{00}$ равен нулю.
На основании формулы (7) предыдущей задачи имеем

$$\Delta E \approx -2\xi^2 \frac{\left\{\left(z^2\right)_{00}\right\}}{n},$$

где n-число электронов.
Отсюда следует, что коэффициент поляризуемости равен

$$\alpha = \frac{4\left\{\left(z^2\right)_{00}\right\}^2}{n}.$$

Необходимо отметить, что эта формула, полученная путем введения только одного вариационного параметра λ, представляет удовлетворительное приближение лишь для атома водорода и гелия. В случае атомов с несколькими электронными оболочками деформации оболочек будут не одинаковы. Следовательно, в вариационном методе для получения более удовлетворительного результата мы должны для каждой электронной оболочки ввести свой вариационный параметр λ
Для атома водорода

$$\left(z^2\right)_{00} = \frac{1}{3}\left(r^2\right)_{00} = \frac{1}{3}\frac{4\pi}{\pi}\int_0^\infty e^{-2rr^4}dr = 1$$

и, следовательно, $\alpha = 4$ ат. ед.
В системе CGSE $\alpha = 4\left(\frac{\hbar^2}{\mu e^2}\right)cM^3$.

Для атома гелия волновую функцию основного состояния возьмем в виде

$\psi_0 = \frac{Z_{эфф}^3}{\pi} e^{-Z_{эфф}(r_1+r_2)}$, где $Z_{эфф} = \frac{27}{16}$ (см. задачу 14 § 7).

Произведя вычисления, получим:

$$\alpha = 0,98 \text{ ат. ед. или } \alpha = 0,98\left(\frac{\hbar^2}{\mu e^2}\right)^3 \text{ с. }^3.$$

Для найденного значения α величина диэлектрической постоянной гелия при нормальных условиях будет равна

$$\varepsilon = 1,00049.$$

Экспериментальное значение $\varepsilon_{эксп} = 1{,}00074$.

Сравнительно большое различие между вычисленным значением и экспериментальным объясняется главным образом тем, что мы пользовались грубой аппроксимацией для невозмущенной функции.

1+61

а)

$$E^{(1)} = \frac{m_j}{8j(j+1)} \frac{e\hbar}{\mu c} \{(2j+1)^2 \mathscr{H} \pm$$

$$\pm \sqrt{(2j+1)^2 e^{2c^2} + \frac{36n^2}{\alpha^2} \left\{ n^2 - \left(j + \frac{1}{2} \right)^2 \right\}}]^2$$

$$\left(\alpha = \frac{e^2}{\hbar c} \right)$$

(см. задачи 57, 59$7);
6.

$$E^{(1)} \left(n = 2, m_j = \pm \frac{3}{2} \right) = -\frac{\alpha^2}{128} \left(\frac{\mu e^4}{\hbar^2} \right) \pm \frac{e\hbar}{\mu c} \tilde{f}_t,$$

$$E^{(1)} \left(n = 2, m_j = \pm \frac{1}{2} \right) = \varepsilon - \frac{11}{384} \alpha^2 \left(\frac{\mu e^4}{\hbar^2} \right),$$

где e определяется из решения уравнения третьей степени

$$\varepsilon^3 \mp 2\beta\varepsilon^2 - \varepsilon \left(3\delta^2 + 9F^2 - \beta^2 \right) \pm 2\delta^2\beta - 2\delta^3 = 0.$$

Здесь $\beta = \frac{e\hbar}{2\mu c} \mathscr{H}$, $F = e\mathscr{E} \left(\frac{\hbar^2}{\mu e^3} \right)$, $\delta = \frac{\alpha^2}{96} \left(\frac{\mu e^4}{\hbar^2} \right)$.

В случае сильных полей ($\delta \ll F\delta \ll \beta$)

$$\varepsilon_1 = \pm\beta - 3F - \frac{1}{2} \frac{9F \mp \beta}{9F^2 \mp 3F\beta} \delta^2,$$

$$\varepsilon_2 = \pm \frac{2\beta}{9F^2 - \beta^2} \delta^2,$$

$$\varepsilon_3 = \pm\beta + 3F + \frac{1}{2} \frac{9F \pm \beta}{9F \pm 3F\beta} \delta^2$$

(см. задачу 59§7).

1+62

Направим ось z вдоль направления магнитного поля, а ось x вдоль электрического поля. Тогда для оператора потенциальной энергии электрона в этих полях получим

$$w = \frac{e\hbar}{2\mu c} (\hat{l}_z + 2\hat{s}_z) \mathscr{H} + e\mathscr{E}x.$$

Последнее выражение будем рассматривать как малое возмущение, характеризуя невозмущенное стационарное состояние квантовыми числами $n, l, m, \sigma (m$ и 5 - проекции орбитального и спинового моментов на ось $z)$. Отличные от нуля матричные элементы x имеют вид

$$(x)^{l-1,m}_{l,m-1} = (x)^{l,m-1}_{l-1,m} = \frac{3}{4} n \sqrt{\frac{(n^2 - l^2)(l - m + 1)(l - m)}{(2l+1)(2l-1)}} a,$$

$$(x)^{l,m}_{l-1,m-1} = (x)^{l-1,m-1}_{l,m} = -\frac{3}{4} n \sqrt{\frac{(n^2 - l^2)(l + m - 1)(l + m)}{(2l+1)(2l-1)}} a$$

$$\left(a = \frac{h^2}{\mu, e^2} \right).$$

Рассмотрим случай $n = 2$. Пусть для определенности проекция спина на ось z равна $+1/2$. Введем обозначения $\beta = \frac{eh}{2\mu.c}$ ef, $\gamma = \frac{3}{\sqrt{2}} e\&a$. Матрица оператора возмущения в этих обозначениях имеет следующий вид:

$$\begin{pmatrix} 2\beta & 0 & 0 & -\gamma \\ 0 & \beta & 0 & 0 \\ 0 & 0 & 0 & \gamma \\ -\gamma & 0 & \gamma & \beta \end{pmatrix}.$$

Нумерация состояний производится в порядке убывания l и m. Состояние с квантовыми числами $l = 1, m = 0$ не комбинирует с остальными. Энергия этого состояния равна $E_1^{(1)} =$ з. Остальные три собственные значения матрицы возмущения находятся из решения секулярного уравнения

$$E^3 - 3\beta E^2 + 2\left(\beta^2 - \gamma^2\right) E + 2\gamma^2\beta = 0.$$

Решая его, имеем:

$$E_2^{(1)} = \beta, E_{3,4}^{(1)} = \beta \pm \sqrt{3^2 + 2\gamma^2}$$

или, подставляя значения & и γ,

$$E_2^{(1)} = \frac{e\hbar}{2\mu c}\mathscr{H}, E_{3,4}^{(1)} = \frac{e\hbar}{2\mu c}\left\{\mathscr{H} \pm \sqrt{\mathscr{H}^2 + \frac{36}{\alpha^2}g^2}\right\}.$$

18.1.11 Basic problems about molecules

Б-2.11.8 Основное состояние по правилу Хунда

Пользуясь правилами Хунда, определить значения квантовых чисел L, S и J в основных состояниях следующих атомов:
а) кремния, б) фосфора, в) серы, г) ванадия, д) кобальта, е) церия.
Для случаев а), б) и в) найти все термы. Записать спектроскопические символы полученных состояний.

Solution

Суть решения в том, что
Для первого порядка теории возмущений первое правило Хунда гласит: энергия атома имеет минимальное значения в состояниях с максимально возможным значением полного спина S. Если при этом возможны несколько различных значений полного орбитального момента, минимальную энергию имеют состояния с максимальным значением L.
Для второго порядка теории возмущений формулируется второе правило Хунда: минимальную энергию имеет терм с $J = |L - S|$, если электронная оболочка заполнена меньше, чем наполовину, и с $J = L + S$ в противном случае.
(подумаю потом про это)
Приводим ответы, в электронных конфигурациях указаны только электроны на незаполненных оболочках.

Атом	Конфигурация	Возможные термы	Нормальный терм
$_{14}$Si	$3s^2 3p^2$	${}^1S_0, {}^1D_2, {}^3P_0, {}^3P_1, {}^3P_2$	${}^3P_0$
$_{15}$P	$3s^2 3p^3$	${}^4S_{3/2}, {}^2P_{1/2}, {}^2P_{3/2}, {}^2D_{3/2}, {}^2D_{5/2}$	${}^4S_{3/2}$
$_{16}$ S	$3s^2 3p^4$	${}^1S_0, {}^1D_2, {}^3P_0, {}^3P_1, {}^3P_2$	${}^3P_2$
$_{23}$ V	$3d^3 4s^2$		${}^4F_{3/2}$
$_{27}$Co	$3d^7 4s^2$		${}^4F_{9/2}$
$_{58}$Ce	$4f5d6s^2$		${}^1G_4\left({}^3H_4\right)$

Элемент Ce представляет собой одно из немногих исключений из правила Хунда. В скобках записан терм, определенный согласно правилам Хунда (отличающийся от истинного).

МФТИ.кр-?. Основное состояние углерода, азота, кислорода.

Пользуясь правилами Хунда, определите термы основного состояния атомов:
а) углерода, б) азота, в) кислорода.

Solution

Суть решения в том, что

Б-2.11.9 Взаимодействие атома с ионом и атома с атомом

С помощью второго приближения теории возмущений определить зависимость от расстояния R энергии взаимодействия систем:
а) атом + ион;
б) атом + атом.
В обоих случаях атом находятся в S-состоянии.

Формализм решения

При исследовании взаимодействия составных частиц таких, как атомы, с другими атомами или ионами можно использовать теорию возмущений, рассматривая изолированные атом и ион (или другой атом), как невозмущенную систему, а потенциальную энергию их электростатического взаимодействия - как оператор возмущения. Поскольку скорости относительного движения атомов невелики, мы можем считать, что ядра атомов (ионов) покоятся (приближение Борна-Оппенгеймера).

Считая, что составные частицы находятся на большом расстоянии друг от друга по сравнению с их размерами ($r_a \ll R$), найдем энергию их электрического взаимодействия в виде разложения по степеням $1/R$. Первый неисчезающий член такого разложения (в силу электронейтральности атома) дает оператор возмущения нашей задачи:

$$\hat{\boldsymbol{V}} = -\hat{\boldsymbol{d}}\boldsymbol{E},$$

где $\hat{\mathbf{d}}$ - дипольный момент атома, $\mathcal{E}$ - внешнее электрическое поле (при $r_a \ll R$ его можно считать приблизительно однородным на расстояниях $\sim r_a$).

Применим теорию возмущений.

а) Поиск энергии взаимодействия атома и иона

Поле иона - это поле заряженной частицы $\mathcal{E} = Ze\mathbf{R}/R^3$, где Ze - заряд иона. Поэтому оператор возмущения равен:

$$\hat{\mathrm{V}} = -\frac{Ze}{R^3}(\hat{\mathbf{d}}\mathbf{R}) = -\frac{Ze}{R^2}\hat{\mathrm{d}}_z,$$

где $\hat{\mathbf{d}}_z = \sum\limits_a e_a z_a$, и мы считаем, что $\mathbf{R}||Oz$. Поправка первого приближения теории возмущений

$$E^{(1)} = \langle\psi^{(0)}|\hat{V}|\psi^{(0)}\rangle = 0$$

в силу сферической симметрии S-состояний.

Во втором порядке теории возмущений имеем

$$E^{(2)} = \sum_{n,m\neq 0} \frac{|\langle 00|\hat{\mathrm{V}}|nm\rangle|^2}{E_{00}^{(0)} - E_{nm}^{(0)}},$$

где индексы 00 относятся к S-состояниям атома и иона (наинизшим по энергии), индексы n, m нумеруют их возбужденные состояния. Из формулы для $E^{(2)}$ ясно, что $E^{(2)} < 0$, а также $E^{(2)} \sim 1/R^4$, и в итоге получаем общее выражение для потенциала взаимодействия в виде

$$U(R) = E^{(2)} = -\frac{C}{R^4}, \text{ где } C = \text{ const.}$$

Взаимодействие такого типа называется поляризационным.

б) Поиск энергии взаимодействия атома и атома

В этом случае, учитывая, что напряженность электрического поля для атома с дипольным моментом $\hat{\mathbf{d}}_1$ имеет вид $\mathcal{E} = \left[3\left(\hat{\mathbf{d}}_1\mathbf{n}\right)\mathbf{n} - \hat{\mathbf{d}}_1\right]/R^3$, где $\mathbf{n} = \mathbf{R}/R$, из (1) получаем оператор возмущения

$$\hat{\mathrm{V}} = \frac{\left(\hat{\mathbf{d}}_1\hat{\mathbf{d}}_2\right) - 3\left(\hat{\mathbf{d}}_|\mathbf{n}\right)\left(\hat{\mathbf{d}}_2\mathbf{n}\right)}{R^3} = \frac{1}{R^3}\left(\hat{\mathrm{d}}_{x1}\hat{\mathrm{d}}_{x2} + \hat{\mathrm{d}}_{y1}\hat{\mathrm{d}}_{y2} - 2\hat{\mathrm{d}}_{z1}\hat{\mathrm{d}}_{z2}\right).$$

(см. задачу 1.6.7). Аналогично п. а) имеем $E^{(1)} = 0$, а вычисление поправок второго приближения дает

$$U(R) = -\frac{C}{R^6}, \text{ где } C = \text{ const }.$$

Именно такой зависимостью энергии от расстояния характеризуются силы притяжения Ван-дер-Ваальса.

О решении задачи методами КТП (???)

(??? а если считать атомы полями, то как тогда будет их взаимодействие обобщаться??? мб потом подумаю, когда умным стану.)

Б-2.11.10 Дублет натрия в магнитном поле (!?!??)

Желтый дублет атома натрия соответствует оптическим переходам ${}^2P_{3/2} \to {}^2S_{1/2}$; ${}^2P_{1/2} \to {}^2S_{1/2}$. Определить расщепление этого дублета в слабом и сильном магнитном полях. Сравнить полученные картины расщепления линий натрия с расщеплением синглетной линии кадмия, отвечающей переходу ${}^1D \to {}^1P$.

Суть решения и результаты (!!!)

Формализм решения

Гамильтониан атома, находящегося в однородном магнитном поле $\mathcal{H}$, имеет вид

$$\hat{\mathrm{H}} = \frac{1}{2m}\sum_a \left(\hat{\mathbf{p}}_a + \frac{e}{c}\mathbf{A}\left(\mathbf{r}_a\right)\right)^2 + U + \frac{e\hbar}{mc}\mathcal{H}\hat{\mathbf{S}},$$

где $(-e) < 0$ - заряд электрона, суммирование производится по всем электронам атома, U - энергия взаимодействия электронов с ядром и друг с другом, $\hat{\mathbf{S}} = \sum_a \hat{\mathbf{s}}_a$ - оператор суммарного спина электронов. Проводя стандартные преобразования (в частности, выбирая векторпотенциал в виде $\mathbf{A}_u = \frac{1}{2}\left[\mathcal{H}\times\mathbf{r}_a\right]\big)$, получим

$$\hat{\mathrm{H}} = \hat{\mathrm{H}}_0 + \frac{e\hbar}{2mc}\mathcal{H}(\hat{\mathbf{L}} + 2\hat{\mathbf{S}}) + \frac{e^2}{8mc^2}\sum_a \left[\mathcal{H}\times\mathbf{r}_a\right]^2,$$

где $\hat{\mathbf{L}}$ - полный орбитальный момент атома, $\hat{\mathrm{H}}_0$ - гамильтониан атома в отсутствие поля. (!!! в теории обязательно эту формулу укажу, заготовки про нее пока не усвоены!)

Имея в виду дальнейшее рассмотрение задачи по теории возмущений, сделаем ряд приближений, Во-первых, отбросим в (1) член, квадратичный по напряженности поля $\mathcal{H}$, считая, что в достаточно слабом поле он вносит малый вклад в решение по сравнению с линейным по $\mathcal{H}$ слагаемым. Далее, полагая, что поле направлено по оси z, получим $\hat{\mathrm{H}} = \hat{\mathrm{H}}_0 + \hat{\mathrm{V}}_{\mathscr{H}}$, где $\hat{\mathrm{V}}_{\mathscr{H}} = \hbar\Omega\left(\hat{l}_z + 2\hat{\mathrm{S}}_z\right)$ - оператор взаимодействия с магнитным полем, $\Omega = e\mathcal{H}/(2mc)$ - ларморовская частота.

а) Слабое поле

В этом приближении считается, что поправка, связанная с магнитным полем, т. е. $\Delta E_{\mathscr{H}}$, гораздо меньше тонкого расщепления уровней $\Delta E_{\text{тонк}}$ [8)], и поэтому можно применить теорию возмущений к каждому уровню тонкой структуры. При этом оператором возмущения является $\hat{V}_{\mathscr{F}}$, а невозмущенные уровни - это уровни энергии атома с учетом расщепления тонкой структуры, характеризующиеся определенными значениями квантовых чисел L, S, J (т. е. собственными значениями операторов $\hat{\mathbf{L}}^2, \hat{\mathbf{S}}^2, \hat{\mathbf{J}}^2$, где $\hat{\mathbf{J}} = \hat{\mathbf{L}} + \hat{\mathbf{S}}$). Правильными векторами нулевого приближения в этом случае являются $|L, S, J, M_J\rangle$ (собственные векторы для операторов $\hat{\mathbf{L}}^2, \hat{\mathbf{S}}^2, \hat{\mathbf{J}}^2, \hat{\mathrm{J}}_z$). Расчет в первом порядке теории возмущений дает

$$\Delta E^{(1)}_{\mathcal{H}} = \hbar\Omega g M_J, \quad \text{где} \quad g = 1 + \frac{J(J+1) - L(L+1) + S(S+1)}{2J(J+1)}$$

есть так называемый фактор Ланде. Отсюда следует, что магнитное поле полностью снимает вырождение по магнитному квантовому числу M_J, каждый уровень тонкой структуры расщепляется на $2J+1$ подуровней.

(??? был вопрос о критерии слабости поля, и какой же он????)

Конкретно для атома натрия находим, что уровень ${}^2P_{3/2}$ расщепляется на четыре компоненты:

$$\Delta E^{(1)}_{2P_{3/2}} = \frac{4}{3}\hbar\Omega M_J, \quad M_J = \pm\frac{1}{2}, \pm\frac{3}{2},$$

а каждый из уровней ${}^2P_{1/2}$ и ${}^2S_{1/2}$ расщепляется на две компоненты:

$$\Delta E^{(1)}_{2P_{1/2}} = \tfrac{2}{3}\hbar\Omega M_J, \quad M_J = \pm\tfrac{1}{2};$$
$$\Delta E^{(1)}_{2S_{1/2}} = 2\hbar\Omega M_J, \quad M_J = \pm\tfrac{1}{2}.$$

Спектр наблюдаемых частот, в соответствии с правилом Бора, имеет вид

$$\omega = \frac{E_2^{(0)} - E_1^{(0)}}{\hbar} + \Omega\left(g_2 M_{/2} - g_1 M_{/1}\right) \equiv \omega_0 + \Delta\omega,$$

причем здесь необходимо учитывать правила отбора для дипольного электрического излучения

$$\Delta J = 0, \pm 1, \qquad \Delta M_J = 0, \pm 1, \qquad \Delta L = \pm 1, \qquad \Delta S = 0.$$

Применяя эти правила, видим, что вместо линии ${}^2P_{3/2} \to {}^2S_{1/2}$ в магнитном поле возникают шесть переходов с частотами (см. (2)) $\Delta\omega = \pm\Omega, \pm\frac{1}{3}\Omega, \pm(5/3)\Omega$, а вместо линии ${}^2P_{1/2} \to {}^2S_{1/2}$ - четыре перехода с частотами $\Delta\omega = \pm(2/3)\Omega, \pm(4/3)\Omega$. Таким образом, в слабом магнитном поле вместо резонансного дублета наблюдается спектр, состоящий из 10 близких спектральных линий (аномальный или сложный эффект Зеемана).

6) Сильное поле.

В данном случае считается, что $\Delta E_{\mathcal{H}} \gg \Delta E_{\text{тонк,}}$, т. е. расщепление в магнитном поле велико по сравнению с интервалами тонкой структуры, но по-прежнему настолько мало, что можно пренебречь квадратичным членом в (1). При этом также можно применить теорию возмущений, но необходимо сначала учесть влияние магнитного поля, а затем (если нужно) - спин-орбитальное взаимодействие, ответственное за тонкую структуру.

Правильными векторами нулевого приближения в данном случае являются $|L, S, M_L, M_S\rangle$, т. е. общие собственные векторы для операторов $\hat{\mathbf{L}}^2, \hat{\mathbf{S}}^2, \hat{l}_z, \hat{\mathrm{S}}_z$. В первом приближении теории возмущений получаем поправку к энергии:

$$\Delta E_{2P}^{(1)} = h\Omega\left(M_L + 2M_S\right)$$

и наблюдаемые частоты (с учетом правила отбора $\Delta M_S = 0$):

$$\omega = \omega_0 + \Omega\Delta M_L, \quad \Delta M_L = 0, \pm 1.$$

Таким образом, в сильном поле наблюдается триплет спектральных линий $\omega_0, \omega_0 \pm \Omega$ (простой или нормальный эффект Зеемана).

В случае кадмия термы ${}^1D$ и ${}^1P$ являются синглетными, т. е. для них $S = 0, J = L$ и, следовательно, $g = 1$. Поэтому независимо от величины напряженности магнитного поля будет наблюдаться простой эффект Зеемана.

Киселев-Л.13.1. Термы углерода (????)

Определить термы и основное состояние атома углерода: конфигурация $1s^2 2s^2 2p^2$

Solution

В этой конфигурации две заполненных s-оболочки, которые не участвуют в определении термов. Пара $2p$-электронов может быть распределена по $2(2l+1)$ состояниям с различными проекциями спина и орбитального момента $l = 1$

$$C_6^2 = \frac{6!}{2!4!} = 15$$

способами.

Максимальное значение спина электронов $S = 1$ является симметричным по перестановкам электронов. Сложение орбитальных моментов электронов $1 + 1$ дает $L = 0, 1, 2$, причем максимальное значение $L = 2$ также является симметричным по перестановкам, значит, оно запрещено для $S = 1$, так как в противном случае состояние было бы симметричным, что противоречит статистике Ферми. Состояние с $L = 0$ также является симметричным по перестановке двух электронов, поэтому оно также запрещено для $S = 1$. В итоге получаем единственный триплетный терм

$${}^3P.$$

Число таких состояний $(2S+1)(2L+1) = 3 \cdot 3 = 9$. При $S = 0$ спиновое состояние является антисимметричным по перестановкам, поэтому допустимы только симметричные орбитальные состояния двух электронов, т. е. $L = 0, 2$. Соответствующие термы

$${}^1S, \quad {}^1D$$

имеют вырождение по проекциям спина и момента

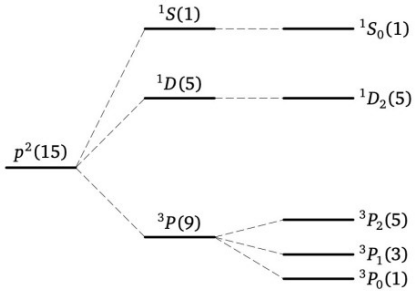
$$1 + 5 = 6.$$

Суммарное число вырождения конфигурации 15 совпадает с суммарным числом состояний термов, которые расщепляются вследствие учета поправок к самосогласованному полю.

Основное состояние согласно правилу Хунда: ${}^3P$.

Приведенное рассуждение является специфическим для двух электронов, поскольку для них за исключением случая заполненной s-оболочки всегда реализуются все состояния, получающиеся сложением орбитальных моментов этих электронов, что, как мы увидим на примере следующей задачи, не имеет места для большего числа эквивалентных электронов, так что приходится использовать наиболее общий метод определения термов.

В атоме углерода основное состояние отвечает терму ${}^3P_0$, а термы ${}^3P_1, {}^3P_2$ находятся последовательно выше согласно правилу интервалов Ланде. Схема расщепления электронной конфигурации углерода при последовательном учете поправок показана на рис. 33.



Киселев-Л.13.2. Термы азота (?????)

Определить термы атома азота: конфигурация $1s^2 2s^2 2p^3$

Solution

Три $2p$-электрона на незаполненной оболочке могут быть распределены по $2(2l+1)$ состояниям с различными проекциями спина и орбитального момента $l = 1$ $C_6^3 = \frac{6!}{3!3!} = 20$ способами.

Максимальное значение спина электронов $S = \frac{3}{2}$ является симметричным по перестановкам электронов, и оно возможно, только если электроны с проекцией полного спина $\frac{3}{2}$ занимают состояния с различными значениями проекции орбитального момента: схема расположения p-электронов с различными проекциями суммарного орбитального момента $m =$ |↑|↑|↑|, а значит, при проекции суммарного орбитального момента только $M = 0$, т. е. исключительно при $L = 0$. Поэтому при максимальном значении спина электронов единственный терм

$${}^4S \mapsto {}^4S_{3/2}.$$

Число таких состояний $(2S+1)(2L+1) = 4 \cdot 1 = 4$.

При $S = \frac{1}{2}$ допустимые значения суммы проекций орбитального момента $M = \pm 2, \pm 1, \pm 0$. Термы с максимальными значениями $|M| = 2$ отвечают $L = 2$:

$${}^2D \mapsto {}^2D_{5/2}, {}^2D_{3/2},$$

и они имеют вырождение по проекциям спина и момента

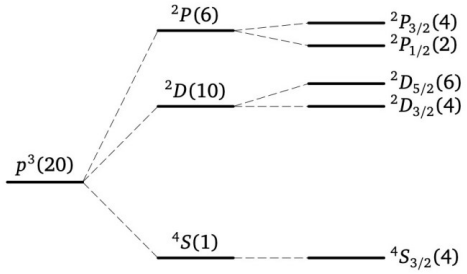
$$2 \cdot 5 = 10, \quad \text{или} \quad \sum_J (2J+1) = 6 + 4 = 10.$$

Состояния с $M_S = +\frac{1}{2}$ и $M = +1$ - это |↑↓| |↑| и |↑|↑↓| |. Одна из суперпозиций отвечает терму с $S = \frac{1}{2}$ и $L = 2$, описанному выше, но просто с другим значением проекции M, а другая, следовательно, терму с $S = \frac{1}{2}$ и $L = 1$. Значит, в конфигурации есть еще и терм

$${}^2P \mapsto {}^2P_{3/2}, {}^2P_{1/2},$$

который имеет вырождение по проекциям спина и орбитального момента $2 \cdot 3 = 6$ или по проекциям полного момента $4 + 2 = 6$.

Состояния с $M_S = +\frac{1}{2}$ и $M = 0$ включают в себя три спин-орбитальных конфигутолько три ортогональных суперпозиции, отвечающих уже найденным нами термам $^2D, ^2P$ и ^4S. Поэтому независимых состояний, отвечающих каким-то новым термам, больше нет. В этом можно убедиться, суммируя количество состояний в термах: $^2D + ^2P + ^4S = 10 + 6 + 4 = 20$, которое исчерпывает степень вырождения конфигурации по проекциям орбитального момента и спина. Основное состояние азота согласно правилам Хунда $-^4S_{3/2}$. Схема расщепления электронной конфигурации азота при последовательном учете поправок показана на рис. 34.



Spaldin-3.2(2 min) Fe^{2+} ion basic properties

In this problem we will calculate the electronic structure and magnetic properties of an important transition-metal ion: Fe^{2+}.

(a) What is the electronic configuration of an Fe^{2+} ion? (Note that the transition metals give up their 4 s electrons before their 3 d electrons on ionization.)

(b) Use Hund's rules to determine the values of S, L, and J in the ground state of an Fe^{2+} ion.

(c) Calculate the Landé g-factor using Eq. (3.28).

(d) Calculate the total magnetic moment of an Fe^{2+} ion, $g\sqrt{J(J+1)}\mu_B$, and the magnetic moment along the field direction, $gM_J\mu_B$. Compare your result with your answer to Exercise 1.3(b).

(e) Try calculating the total magnetic moment using the value of S determined in 3.2(b), but assuming that $L = 0$ (so $J = S$). In fact the measured value is $5.4\mu_B$. More about this later!

(??? задача вроде как простая, да вот нужно подумать про нее еще больше.)

Solution for 3.2(a)

(?????? а я не знаю, откуда это????)

The electronic configuration of an Fe atom is

$$(1s)^2(2s)^2(2p)^6(3s)^2(3p)^6(4s)^2(3d)^6$$

Therefore, because the transition elements give up their 4 s electrons before their 3 d electrons on ionization, the electronic configuration of an Fe^{2+} ion is

$$(1s)^2(2s)^2(2p)^6(3s)^2(3p)^6(3d)^6$$

Solution for 3.2(b)

Hund's first rule tells us that the electrons maximize their total spin, S. Therefore they arrange themselves one electron per d orbital with parallel spins before pairing up with opposite spins in the same orbital. For iron, the resulting configuration looks like:

Therefore the total spin, $S = 4 \times \frac{1}{2} = 2$.

The five d orbitals have m_l values of $-2, -1, 0, 1$, and 2. Depending on which d orbital contains two electrons, the total M_L can be $-2, -1, 0, 1$, or 2. Therefore, since $M_L = -L, -L+1, ..., 0, ..., L-1, L$, the total orbital quantum number, L, must be equal to 2.

Finally, from Hund's third rule, because the shell is more than half full, $J = L + S = 4$.

Solution for 3.2(c)

$$g = 1 + \frac{J(J+1) + S(S+1) - L(L+1)}{2J(J+1)} = 1 + \frac{20 + 6 - 6}{40} = 1.5.$$

Note that, since $S = 2$ and $L = 2$, the g value is exactly halfway between that for the $S = 0$ case ($g = 1$) and the spin-only case ($g = 2$).

Solution for 3.2(d)

The total magnetic moment $M = g\sqrt{J(J+1)}\mu_{\mathrm{B}} = 1.5 \times \sqrt{4 \times 5} = 6.7\mu_{\mathrm{B}}$. Since $J = 4, M_J = -4, -3, -2, -1, 0, 1, 2, 3,$ or 4. Therefore the components of the magnetic moment along the field direction, $-gM_J\mu_{\mathrm{B}}$, can take the values $6\mu_{\mathrm{B}}$,

$$4.5\mu_{\mathrm{B}}, 3\mu_{\mathrm{B}}, 1.5\mu_{\mathrm{B}}, 0, -1.5\mu_{\mathrm{B}}, -3\mu_{\mathrm{B}}, -4.5\mu_{\mathrm{B}}, -6\mu_{\mathrm{B}}.$$

In Solution 1.3(b) we calculated the magnetic moment of a "classical" orbiting electron and obtained a result of $1\mu_{\mathrm{B}}$. This is the same order of magnitude as the results obtained here.

Solution for 3.2(e)

If L were equal to zero, then $J = S = 2$ and $g = 2$. So

$$M = 2\sqrt{6}\mu_{\mathrm{B}} = 4.9\mu_{\mathrm{B}}.$$

This is in good agreement with the measured value of $5.4\mu_{\mathrm{B}}$, whereas the moment we calculated using the total angular momentum ($6.7\mu_{\mathrm{B}}$) does not agree well with the experimental value.

This is a manifestation of a phenomenon known as quenching of the orbital angular momentum, which we discuss in Section 5.3.

(??? не знаю, что такое quenching вообще??? ну и все, внезапно с экспериментом не согласуется, что делать???? вообще к такому не готов.)

Solution 1

Если пренебречь различием между центром тяжести молекулы и центром тяжести ядер и считать, что центр тяжести закреплен в начале координат, то уравнение Шредингера для двухатомной молекулы будет иметь следующий вид:

$$\left\{ -\frac{\hbar^2}{2m} \sum_i \left(\frac{\partial^2}{\partial x_i^2} + \frac{\partial^2}{\partial y_i^2} + \frac{\partial^2}{\partial z_i^2} \right) - \right.$$
$$- \frac{\hbar^2}{2M_p^2} \left[\frac{\partial}{\partial \rho} \left(p^2 \frac{\partial}{\partial p} \right) + \frac{1}{\sin\theta} \frac{\partial}{\partial \theta} \left(\sin\theta \frac{\partial}{\partial \theta} \right) + \frac{1}{\sin^2\theta} \frac{\partial^2}{\partial \rho^2} \right] +$$
$$\left. + V\left(x_i, y_i, z_i; \rho, \theta, \varphi\right) \right\} \psi\left(...x_i, y_i, z_i, ...p, \theta, \varphi\right) = E\psi.$$

Здесь $x_i, y_i, z_i \longrightarrow$ координаты i-го электрона относительно неподвижной системы отсчета, углы θ, φ определяют положение в пространстве прямой, соединяющей ядра, ? - расстояние между ядрами, а M - приведенная масса двух ядер. Недостаток этого уравнения заключается в том, что в потенциальную энергию V электростатического взаимодействия входят углы θ и φ. Для того чтобы придать уравнению Шредингера более удобную форму, введем новую систему координат ξ, τ, вращающуюся вместе с ядрами. Ось: направим вдоль прямой, соединяющей ядра, а ось ξ расположим в плоскости xy. Положительное направление оси (?) выберем таким образом, чтобы оси z, ζ, ξ составляли право- винтовую систему. Соотношения между старыми и новыми координатами имеют следующий вид:

$$\xi_i = -x_i \sin\varphi + y_i \cos\varphi,$$
$$\eta_i = -x_i \cos\theta \cos\varphi - y_i \cos\theta \sin\varphi + z_i \sin\theta,$$
$$\zeta_i = x_i \sin\theta \cos\varphi + y_i \sin\theta \sin\varphi + z_i \cos\theta.$$

Различая дифференцирование при постоянных x_i, y_i, z_i от дифференцирования при постоянных ξ_i, η_i, ζ_i штрихом при ∂ находим:

$$\frac{\partial'}{\partial\theta} = \frac{\partial}{\partial\bar{\theta}} + \sum_i \left(\zeta_i \frac{\partial}{\partial r_{ii}} - \eta_i \frac{\partial}{\partial \vartheta_i} \right)$$
$$\frac{\partial'}{\partial\varphi} = \frac{\partial}{\partial\varphi} - \sum_i \left\{ \sin\theta \left(\xi_i \frac{\partial}{\partial \xi_i} - \xi_i \frac{\partial}{\partial \xi_i} \right) + \cos\theta \left(\xi_i \frac{\partial}{\partial \eta_i} \gamma_i \frac{\partial}{\partial \xi_i} \right) \right\}.$$

Легко видеть, что

$$\sum_i \left(\frac{\partial^2}{\partial x_i^2} + \frac{\partial^2}{\partial y_i^2} + \frac{\partial^2}{\partial z_i^2} \right) = \sum_i^1 \left(\frac{\partial^2}{\partial \xi_i^2} + \frac{\partial^2}{\partial \eta_i^2} + \frac{\partial^2}{\partial \xi_i^2} \right)$$

Потенциальная энергия в новой системе координат будет иметь вид

$$V = \frac{Z_1 Z_2 e^2}{?} + \sum_{i>k} \frac{e^2}{r_{ik}^*} - \sum_{k=1}^{n} \frac{Z_1 e^2}{r_{1k}^*} - \sum_{k=1}^{n} \frac{Z_2 e^2}{r_{2k}^*},$$

где

$$r_{ik}^* = \sqrt{(\xi_i - \xi_i)^2 + (\eta_i - \eta_i)^2 + (_{-i} - _{\ni h})^2}$$

расстояние между i-ым и k-ым электронами в новых координатах:

$$r_{1k}^* = \sqrt{\xi_k^2 + \eta_i^2 + \left(\zeta_k + p \frac{M_2}{M_1 + M_2} \right)^2}$$

расстояние от k-го электрона до первого ядра и

$$r_{2k}^* = \sqrt{\xi_k^2 + r_{ik}^2 + \left(\zeta_k - \frac{\rho M_1}{M_1 + M_2} \right)^2}$$

расстояние между k-м электроном и вторым ядром. Таким образом в новых координатах потенциальная энергия не зависит от углов θ и о. С учетом всех приведенных соотношений уравнение Шредингера примет следующий вид:

$$\left\{ -\frac{hi}{2m} \sum_i \left(\frac{\partial^3}{\partial \epsilon_i^2} + \frac{\partial^3}{\partial \eta_i^2} + \frac{\partial^2}{\partial \varphi_i^2} \right) ... \right.$$

$$-\frac{l^2}{2M} \frac{1}{r^2} \left[\frac{\partial}{\partial r} \left(r^2 \frac{\partial}{\partial r} \right) + \operatorname{ctg} \theta \left(\frac{\partial}{\partial \theta} - i \grave{L}_\xi \right) + \right.$$

$$\left. + \left(\frac{\partial}{\partial \theta} - i \hat{L}_\xi \right)^2 + \frac{1}{\sin^2 \theta} \left(\frac{\partial}{\partial p} - i \sin \theta \hat{L}_{\eta_p} - i \cos \theta \hat{L}_\Gamma \right)^2 \right] +$$

$$\left. + V \left(\xi_i, \eta_i, i_i^i; p \right) - E \right\} \sim (\xi_i, \eta_i, \vartheta_i; p, 0, \varphi) = 0.$$

Здесь $\hat{L}_\xi, \hat{L}_{\mathrm{r_i}}$ и $\hat{L}_v$ представляют измеренные в единицах $\hbar$ операторы компонент орбитального момента электронов в системе координат $\xi, \eta, \not\vdash$.

1+1

Обознатим спиновую переменную i-го электрона относительно неподвижного пространства через s_i', а относительно подвижного через s_i. Функции $\psi(...s_i...)$ со спинами, отнесенными к координатной системе $\xi\vartheta^\circ$, связаны с функциями (?????) $(... \ s_i'..)$ со спинами, отнесенными к координатной системе xyz линейным преобразованием

$\psi(...s_i...) =$

$$= \sum_{s_1', s_i' ...} S(s_1, ..., s_i, ..., s_1', ..., s_i', ...) \psi_i(...s_i'...) =$$

$$= \hat{S}_\top'(..., s_i'...),$$

где

$S(s_1, s_2, ..., s_i, ..., s_1', ..., s_i', ...) =$

причем

$= S(s_1; s_1') S(s_2; s_2') ...S(s_i; s_i') ...$

$$S\left(\frac{1}{2}; \frac{1}{2} \right) = \cos \frac{\theta}{2} e^{\frac{i}{2}(\varphi + \frac{\pi}{2})}.$$

$$S\left(\frac{1}{2}; -\frac{1}{2} \right) = i \sin \frac{\theta}{2} e^{-\frac{i}{2}(\varphi + \frac{\pi}{2})},$$

$$S\left(-\frac{1}{2}; \frac{1}{2} \right) = i \sin \frac{\theta}{2} e^{\frac{i}{2}(\varphi + \frac{\pi}{2})},$$

$$S\left(-\frac{1}{2}; -\frac{1}{2} \right) = \cos \frac{0}{2} e^{-\frac{i}{2}(\varphi + \frac{\pi}{2})}$$

Мскомое уравнение Шредингера будет иметь вид

$$\left[\grave{S}\hat{H}\hat{S}^{-1} - E\right] \circlearrowleft \left(...\xi_i, r_{ii}, \overleftarrow{-i}, s_i ...; p, \theta, \varphi\right) = 0,$$

где $\grave{H}$ - оператор Гамильтона, наЙденный при решении предыдущей задачи.

Производя несложные вычисления окончательно, для уравнения Шредингера получаем следующее выражение:

$$\left\{-\frac{\hbar^2}{2m}\sum\left(\frac{\partial^2}{\partial\xi_i^2}+\frac{\partial^2}{\partial r_i^2}+\frac{\partial^2}{\partial\epsilon_i^2}\right)-\right.$$
$$-\frac{\hbar^2}{2M}\frac{1}{r^2}\left[\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\operatorname{ctg}\theta\left(\frac{\partial}{\partial\theta}-i\grave{M}_\xi\right)+\left(\frac{\partial}{\partial\theta}-iM_\xi\right)^2+\right.$$
$$\left.+\frac{1}{\sin^3\theta}\left(\frac{\partial}{\partial\varphi}-i\sin\theta\grave{M}_r-i\cos\theta\grave{M}_r\right)^2\right]+$$
$$\left.+V-E\right\}\uplus\left(...\xi_i,\eta_i,\overset{\varphi}{-i},s_i...;p,\theta,\varphi\right)=0.$$

Здесь $\hat{M}_\xi, \hat{M}_\eta, \grave{M}$ представляют, в отличие от предыдущей задачи, операторы компонент полного момента электронов (орбитального и спинового).

1+2

Предположим, что задача с неподвижными центрами решена, т. е. известны электронные термы $E^{9.\pi}(\rho)$ и волновая функция $\Phi_{\text{элт}}$ Для определенности рассмотрим тип связи a; пусть в состоянии, описываемом волновой функцией $\Phi_{\text{эл},}$, проекция полного момента (орбитального и спинового) на ось молекулы равна Q. Умножим уравнение Шредингера

$$\hat{H}\Phi_{9,\text{I}}\left(\xi_i,\eta_i,\vartheta_i;\sigma_i;p\right)f(\rho)\Theta((),\varphi)=$$
$$=E\Phi_{9M}\left(\xi_i,\eta_i,\zeta_i;\sigma_i;\rho\right)f(\rho)\theta(\sigma,\varphi)$$

слева на Φ_π^* и проинтегрируем по координатам задачи с неподвижными центрами и просуммируем по σ_i. Замечая, что

$$\int\Phi_{9\pi}^*\hat{M}_\xi\Phi_\pi d\tau=\int\Phi_{9.\text{I}}^*\hat{M}_\eta\Phi_\pi d\tau=0,$$

имеем:

$$\left[B\frac{\partial}{\partial\rho}\left(\rho^2\frac{\partial}{\partial^\rho}\right)-E^{9.T}(\rho)-U(\rho)-E^{\mathbb{B}p}+E\right]f(\rho)=0,$$
$$B\left[\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\left(\frac{\partial}{\partial\varphi}-iQ\cos\theta\right)^2\right]\Theta(\theta,\varphi)+$$
$$+E^{\text{Bp}}\theta(\theta,\varphi)=0.$$

В поспедних двух уравнениях введены спедующие сокращенные обозначения:

$$U(p)=\frac{1}{M}\int\Phi_{\theta\pi}^*\left\{\frac{1}{\rho^3}\left(\hat{M}_5^2+\hat{M}_\eta^2\right)-\frac{\partial^2}{\partial\rho^2}\right\}\Phi_{\partial x}d\tau,$$
$$B=\frac{\hbar^2}{2M}\frac{1}{p^2}.$$

Величина B называется ротационной постоянной.

1+3

Молекула N_2 (атомы в состоянии ^4S): $^1\Sigma_g^+$, $^3\square_u^+$, $^5\Sigma_g^+$, $^7\Sigma_u^+$

Молекула Br_2 (атомы в состоянии ^2P):

$$2^1\Sigma_g^+,\ ^1\Sigma_u-{}^1\Pi_g,{}^1\Pi_u,{}^1\Delta_g;$$
$$2^3\Sigma_u^+,\ ^3\Sigma_g^-,{}^3\Pi_g,{}^3\Pi_u,{}^1\Delta_u.$$

Молекула LiH (атом Li в состоянии ^2S_y, атом H в состоянии $^2S_\S$) : $^1\Sigma^+, 3\Sigma^+$.

Молекула HBr (атом Br в состоянии ${}^2P_u$): $\left[{}^{1\Sigma^+}, {}^3\Sigma^+, Ш^1, 3\right]$. Молекула CN (атом C в сосгоніини ${}^3P_g$, атом N в состоянии ${}^4S_u$) : $2\Sigma^+, 4\Sigma^+, 6\Sigma+, 2\Pi$, ${}^4\Pi, 6\Pi$.

(Число, стоящее перед символом терма, указывает количество термов.)

1+4

Атом гелия в основном состоянии характеризуется тем, что оба его электрона находятся на наиболее низком уровне (парагелий). Полная собственная функция основного состояния атома гелия может быть приближенно представлена в виде

$$\frac{1}{\sqrt{2}}\bigcup_a(1)\bigcup_a(2)\left\{\eta_+\left(\sigma_1\right)\eta_-\left(\sigma_2\right)-\eta_!\left(\sigma_2\right)\eta_-\left(\sigma_1\right)\right\}$$

где $\dot{\psi}_a$ - есть водородная функция.

Атом водорода имеет собственную функцию

$$\bigcup_b(3)\eta_+\left(\sigma_3\right)\ \text{ или }\ \bigcup_0(3)\eta_-\left(\sigma_3\right).$$

Если оба атома находятся на большом расстоянии друг от друга, то волновая функция системы напишется в виде произведения

$\frac{1}{\sqrt{2}}\psi_a(1)\psi_a(2)\bigcup_b(3)\left\{r_1\left(\sigma_1\right)\eta_-\left(\sigma_2\right)-r_{1+}\left(\sigma_2\right)\eta_1\left(\sigma_1\right)\eta_{i!}\left(\sigma_3\right),\right.$ С учетом обмена электронами собственная функция системы должна быть антисимметричной относительно перестановки всех электронов. Существует только одна антисимметричная собственная функция, которая и является собственной функцией нашей системы в нулевом приближении

$$\begin{aligned}\Psi=\frac{1}{\sqrt{6(1-S)}}\{&\psi_a(1)\psi_a(2)\psi_b(3)\left[\eta_+(1)\eta_-(2)-\right.\\&\left.-\eta_+(2)\eta_-(1)\right]\eta_+(3)+\\&+\psi_a(3)\psi_a(1)\psi_b(2)\left[\eta_{i_+}(3)\eta_-(1)-\eta_+(1)\eta_-(3)\right]\eta_+(2)+\\&+\psi_a(2)\psi_a(3)\psi_b(1)\left[\eta_+(2)\eta_-(3)-\eta_+(3)\eta_-(2)\right]\eta_{+-}(1)\}.\end{aligned}$$

В выражении (1) $\frac{1}{\sqrt{6(1-S)}}$ ес ←ь нормировочный множитель, а

$$\begin{aligned}S&=\int\psi_a(1)\psi_a(2)\psi_b(3)\psi_a(2)\dot{\ddots}_a(3)\psi_b(1)d\tau_1d\tau_2d\tau_3=\\&=\int\psi_a(1)\psi_a(2)\psi_b(3)\psi_a(1)\psi_a(3)\psi_b(2)d\tau_1d\tau_2d\tau_3=\\&=\int\psi_a(1)\psi_a(3)\psi_b(2)\psi_a(2)\psi_a(3)\psi_b(1)d\tau_1d\tau_2d\tau_3.\end{aligned}$$

Применяя обычную тсорию возмущения, имеем:

$$\varepsilon=\sum_\sigma\int\Psi\hat{H}\Psi d\tau,$$

гце Ψ - собственная функция в нулевом приближении, $\hat{H}$ - энергия возмущения, суммирование производится по спиновым переменным. Нужно иметь ввнду, что $\grave{H}$ имеет различное выражение для разных составных частей Ч', а именно: для $\psi_a(1)\lhd_a(2)\psi_b(3)$ энергия возмущения равна

$$\hat{H}=e^2\left(\frac{2}{R}-\frac{1}{r_{a3}}-\frac{1}{r_{b1}}-\frac{1}{r_{l2}}+\frac{1}{r_{13}}+\frac{1}{r_{23}}\right),$$

а для $\vartheta_a(1)\psi_a(3)\uplus_b(2)$

$$\hat{H}=e^2\left(\frac{2}{R}-\frac{1}{r_{c2}}-\frac{1}{r_{l1}}-\frac{1}{r_{b3}}+\frac{1}{r_{12}}+\frac{1}{r_{32}}\right).$$

Принимая во внимание то, что интегралы, отличающиеся только нумерацией электронов, идентичны, имеем:

$$\varepsilon=\frac{K-A}{1-S},$$

где

$$K = e^{-2} \int \left(\frac{2}{R} + \frac{1}{r_{13}} + \frac{1}{r_{33}} - \frac{1}{r_{a3}} - \frac{1}{r_{b1}} - \frac{1}{r_{b2}} \right) \times$$
$$X\psi_a^2(1)\psi_a^2(2)\psi_b^2(3)d\tau_1 d\tau_2 d\tau_3$$
$$A = e^2 \int \left(\frac{2}{R} + \frac{1}{r_{13}} + \frac{1}{r_{23}} - \frac{1}{r_{a3}} - \frac{1}{r_{b1}} - \frac{1}{r_{b2}} \right) \times$$
$$X\psi_a\ (1)\ \psi_a(2)\uplus_b(3)\psi_a(1)\psi_a(3)\dot{\psi}_b(2)d\tau_1 d\tau_2 d\tau_3.$$

Нтегралы K, A, S в общем имеют одинаковый характер с соответствующими интегралами проблемы молекулы водорода. Вычисление интегралов показывает, что формула (2) соответствует кривой отталкивания. Это справедливо не только для атома ге.ия, но и для всех благородных газов.

1+5

После отделения движения центра инерции для волновой функции относительного движения ядер получим следующее уравнение:

$$\Delta\psi + \frac{2\mu}{h^2}\left[E + 2D\left(\frac{1}{\rho} - \frac{1}{2p^2}\right)\right]\psi = 0.$$

Разделяя переменные в сферических координатах и полагая

$$\psi = \frac{\chi(\rho)}{\rho} Y_{KM}(\theta, \varphi),$$

находим для γ дифференциальное уравнение:

$$\frac{d^2\gamma_0}{dp^2} + \left[-\lambda^2 + \frac{2\gamma^2}{p} - \frac{\gamma^2 + K(K+1)}{p^2}\right]\chi = 0,$$
$$\lambda = \sqrt{\frac{2\mu a^2 E}{h^2}}, \gamma^2 = \frac{2\mu a^2}{h^3} D.$$

Замена переменных $\chi(p) = p^s e^{-\lambda\rho} u(p)$, где $s = \frac{1}{2} + \ +\sqrt{\gamma^2 + \left(K + \frac{1}{2}\right)^2}$, приводит к гипергеометрическому уравнению

$$\rho u'' + (2s - 2\lambda\rho)u' + \left(-2s\grave{\lambda} + 2\gamma^2\right)u = 0.$$

Решение этого уравнения, конечное при $\rho = 0$, имеет следующий вид:

$$u = cF\left(s - \frac{\gamma^2}{\lambda}, 2s, 2\lambda, p\right).$$

В состояниях дискретного спектра волновая функция χ должна стремиться к нулю при $r \to \infty$. Для этого необходимо, чтобы выражение для u сводилось к полиномам:

$$s - \frac{\gamma^2}{\lambda} = -v,$$

где $\mathfrak{v}$-целое неотрицательное число. Из этого условия получаем энергетические уровни

$$E_{vK} = -\frac{\hbar^2}{2\mu \cdot a^2} \frac{r^4}{\left[v + \frac{1}{2} + \sqrt{\gamma^2 + \left(K + \frac{1}{2}\right)^2}\right]^2}.$$

Безразмерный параметр γ^2 пропорционален приведенной массе ядер μ, так что $\gamma^2 \gg 1$. Если v и K не очен велики

$$\boldsymbol{v} \ll \gamma, \quad K \ll \gamma,$$

выражение $E_{v\ \mathrm{E}}$ принимает следующий вид:

$$E_r K = -D + h\omega_0\left(v + \frac{1}{2}\right) +$$
$$+ \frac{h^2}{2\mu \cdot a^2}\left(K + \frac{1}{2}\right)^2 - \frac{3h^2}{2\mu \cdot a^2}\left(v + \frac{1}{2}\right)^2 - \frac{3h^3\left(K + \frac{1}{2}\right)\left(v + \frac{1}{2}\right)}{2\mu^2 a^4 \omega_0},$$

$$\omega_0 = \sqrt{\frac{2D}{\mu a^2}}.$$

Энергия диссоциации приближенно равна

$$E_0 = D - \frac{\hbar\omega_0}{2}.$$

Второй и третий члены в выражении для $E_{\mathrm{I}mathZZ}$ дают энергию колебательного и вращательного движения. Четвертый член учитывает ангармоничность колебаний и, наконец, пятый член дает поправку к энергии за счет взаимодействия между вращением и колебанием ядер.

Поскольку D есть величина порядка единицы в атомных единицах ($e = m = \hbar = 1$), из полученного выражения следует, что

$$D : \hbar\omega_0 : \frac{h^2}{2\mu, a^2} \sim 1 : \sqrt{\frac{n}{\mu}} : \frac{m}{\mu},$$

где m - масса электрона. Отсюда видно, что разность энергий между двумя квантовыми состояниями с различным движением электронов (величина порядка D) велика по сравнению с разностью энергий различных колебательных состояний, которая в свою очередь велика в сравнении с расстоянием между вращательными уровнями.

1+6

Находим минимум эффективного потенциала

$$W = -2D\left(\frac{1}{\rho} - \frac{1}{2\rho^2}\right) + \frac{A^2}{\rho^2}, \text{ где } \quad A^2 = \frac{\hbar^2 K(K+1)}{2\mu a^2},$$

из условия равенства нулю его производнон:

$$W' = -2D\left(-\frac{1}{\rho_0^2} + \frac{1}{\rho_0^3}\right) - \frac{2A^2}{\rho_0^3} = 0,$$

откуда получаем:

$$P_0 = 1 + \frac{A^2}{D}.$$

Разложим теперь эффективный потенциал вблизи найденного положения равновесия:

$$W(p) \approx -2D\left(\frac{1}{\rho_0} - \frac{1}{p_0^2}\right) + \frac{A^2}{p_0^2} + \frac{D + A^2}{\rho_0^4}\left(p - p_0\right)^2,$$

удерживая здесь члены порядка A^2, получаем:

$$W(p) \approx -D + A^2 + \left(D - 3A^2\right)\left(p - p_0\right)^2.$$

Подставим это выражение в уравнение для %

$$\frac{d^2\chi}{dp^2} + \frac{2\mu a^2}{\hbar^2}\left[E + D - A^2 - \left(D - 3A^2\right)\left(p - p_0\right)^2\right]\chi = 0.$$

Отсюда находим энергетические уровни:

$$E_{vK} = -D + A^2 + \hbar\omega\left(v + \frac{1}{2}\right).$$

Здесь в том же приближении

$$\omega = \omega_0\left(1 - \frac{3}{2}\frac{A^2}{D}\right), \quad \omega_0 = \sqrt{\frac{2\bar{D}}{\mu a^2}}.$$

Окончательно для энергии $E_{\mathrm{I}math\boldsymbol{\kappa}}$ имеем:
$E_{vK} = -D + h\omega_0\left(v + \frac{1}{2}\right) +$

$$+\frac{\hbar^2 K(K+1)}{2\mu a^2} - \frac{3}{2}\frac{\hbar K(K+1)\left(v + \frac{1}{2}\right)}{\mu^2 a^4 \omega_0}.$$

Вследствие того, что при этом вычислении не учитывался эффект ангармоничности, здесь отсутствует член $-\frac{3h^2}{2\mu a^2}\left(v + \frac{1}{2}\right)^2$, полученный при решении предыдущей задачи.

1+7

В инфракрасной полосе мы имеем дело с переходами в основном электронном состоянии, при которых изменяются колебательные и вращательные квантовые числа. Для частоты перехода между двумя состояниями $\tau', J' \to v'', J''$ имеем:

$$\omega = \omega_0 (v' - v'') + \frac{\hbar}{2\mu a^3} \left[J^2 + J' - J'' - J'' \right].$$

Из правил отбора для J следует $J'' = J' \pm 1$. При этом получается совокупность частот

$$\omega = \omega_0 (v' - v'') - \frac{\hbar}{2ua^2} 2 (J' + 1) \quad \left(\begin{array}{l} J'' = J' + 1, \\ J' = 0, 1, 2, \ldots \end{array} \right)$$

и

$$\omega = \omega_0 (v' - v'') + \frac{\hbar}{2\mu a^2} 2J' \quad \left(\begin{array}{l} J'' = J' - 1, \\ J' = 1, 2, \ldots \end{array} \right)$$

Отметим, что эти два' ряда частот в молекулярной спектроскопии называются соответственно P и R ветвью.

Из полученных выражений видно, что разность частот двух соседних линий при фиксированных v' и v'' равна В $C \cdot M^{-1}$

$$\Delta v = \frac{\Delta \omega}{2\pi c} = \frac{\hbar}{2\pi c \mu a^2}.$$

Момент инерции молекулы HCl^{35}

$$I = \mu a^2 = \frac{\hbar}{2\pi c \Delta v} = 2,65 \cdot 10^{-40} 2 \cdot c\mu^2.$$

Используя значение приведенной массы

$$\mu = M_{\mathrm{HI}} \frac{1 \cdot 35}{1 + 35} = 0,972 M_{\mathrm{H}} = 1,61 \cdot 10^{-24} 2,$$

находим расстояние между ядрами в HCl:

$$a = \sqrt{\frac{I}{\mu}} = 1,29 \cdot 10^{-8} \text{см}.$$

Равновесные расстояния a в молекулах DCl и HCl одинаковы, поскольку форма потенциальных кривых определяется состоянием электронов. Отсiода следует, что

$$\frac{\Delta v_{\mathrm{DCI}}}{\Delta v_{\mathrm{HCI}}} = \frac{\mu_{\mathrm{HCI}}}{\mu_{\mathrm{DCI}}}; \quad \Delta v_{\mathrm{DCI}} = 10,7 c\mu^{-1}.$$

1+8

Расстояние между двумя первыми врацательными уровнями

$$\Delta v_{\mathrm{Bp}} = \frac{\hbar}{2\pi c I} = 41,5 \text{см}^{-1}.$$

Отсюда находим:

$$\frac{\Delta v_{\mathrm{Bp}}}{\Delta v_{\mathrm{F0I}}} = 0,0104.$$

1+9

Энергия диссоциации молекулы D_2 равна 4,54 эв.

Переходя К новой переменной $\xi = \frac{r-a}{a}$, запишем уравнение для радиальной функции $\frac{\chi}{r}$:

$$\frac{d^2\chi}{d\xi^3} + \frac{2i^3 a^2}{\hbar^2} (E - V)\% = 0.$$

Полагая $z = \alpha e^{-2\beta \frac{2}{5}}$, получим:

$$\chi'' + \frac{1}{z}\chi' + \left(-\frac{s^2}{z^3} - \frac{1}{4} + \frac{v+s+\frac{1}{2}}{z}\right)\chi = 0$$

где

$$s = \sqrt{\frac{\mu a^2(D-E)}{\beta^2\hbar^2}}, \quad v+s+\frac{1}{2} = \frac{\mu a^2 D}{\alpha\beta^2\hbar^2}, \quad a^2 = \frac{2\mu a^2 D}{\beta^2\hbar^3}.$$

Полученное уравнение заменой $= e^{-\frac{z}{2}} z^s u(z)$ сводится к гигергеометрическому $zu'' + (2s+1-z)u' + nu = 0$, решением которого является вырожденная гипергеометрическая функция $u = F(-v, 2s+1, z)$. Эта функция удовлетворяет условию обращения % в нуль при $r \to +\infty$ при положительных значениях s (дискретный спектр). При $r \to -\infty$ волновая Функция должна обрацаться в нуль. Для выполнения этого условия необходимо, чтобы F сводилось к полиномам, т. е. чтобы v было неотрицательным целым числом. Это условие определяет энергетический спектр

$$E_n = \hbar\omega\left(v+\frac{1}{2}\right) - \frac{\hbar^2\omega^2}{4D}\left(v+\frac{1}{2}\right)^2, \quad \text{где} \quad \omega = 4\beta\sqrt{\frac{D}{2\mu a^2}}.$$

Таким образом, расстояние между колебательными уровнями уменьшается с увеличением квантового числа $\boldsymbol{v}$.

Энергия диссоциации равна

$$E_0 = D - \frac{\hbar\omega}{2} + \frac{\hbar^2\omega^2}{16D}.$$

1+12

В качестве параметров, характеризующих вращение, возьмем углы Энлера $(\theta, \bigcup, \varphi)$. В этом случае координаты точки x, y, z в неподвижной системе связаны с координатами ξ, η, ζ в подвижноћ системе отсчета следующим образом: $x = \xi(\cos\psi\cos\varphi - \sin\psi\sin\varphi\cos\theta) -$

$$\left.\begin{array}{c} -\eta(\cos\psi\sin\varphi + \sin\psi\cos\varphi\cos\theta) + \zeta\sin\psi\sin\theta, \\ y = \xi(\sin\psi\cos\varphi + \cos\psi\sin\varphi\cos\theta) + \\ +\eta(-\sin\psi\sin\varphi + \cos\psi\cos\varphi\cos\theta) - \gamma\cos\psi\sin\theta, \\ z = \xi\sin\varphi\sin\theta + \eta\cos\varphi\sin\theta + \zeta\cos\theta. \end{array}\right\}$$

Для того чтобы найти вид операторов $\hat{J}_\xi, \hat{J}_\eta, \hat{J}_\zeta$, воспольэуемся тем соображением, что оператор $\hat{J}_\xi$ есть $\hat{J}_\xi = -i\frac{\partial}{\partial\alpha}$, где x угол, отсчитываемыи в плоскости, перпендикулярноћи оси ξ. Так как вследствие поворота системы координат ξ, η, ζ относительно, например, оси ξ на бесконечно малый угол $d\alpha$, значения углов изменятся, то мы можем написать, что $\hat{J}_\xi$, измеренный в единицах $\hbar$, равен

$$\hat{J}_\xi = -i\left(\frac{\partial\theta}{\partial\alpha}\frac{\partial}{\partial\theta} + \frac{\partial\varphi}{\partial\alpha}\frac{\partial}{\partial\varphi} + \frac{\partial\psi}{\partial\alpha}\frac{\partial}{\partial\psi}\right).$$

При бесконечно малом повороте относительно оси ξ на угол $d\alpha$ имеем:

$$\left.\begin{array}{ll} \xi & = \xi', \\ \eta & = \eta' - ?' d\alpha, \\ \zeta & = \eta' d\alpha + \zeta' \end{array}\right\}$$

И

$$z = \xi'\sin(\varphi + d\varphi)\sin(\theta + d\theta) + \\ + \eta'\cos(\varphi + d\varphi)\sin(\theta + d\theta) + \zeta'\cos(\theta + d\theta).$$

С другой стороны, подставляя (2) в (1), получаем:
$z = \xi'\sin\varphi\sin\theta + \eta'(\cos\varphi\sin\theta + \cos\theta d\alpha) +$
$+\zeta'(\cos\theta - \cos\varphi\sin\theta d\alpha)$. Сравнивая (3) и (4), находим:

$$\frac{d\theta}{d\alpha} = \cos\varphi, \quad \frac{d\varphi}{d\alpha} = -\sin\varphi\operatorname{ctg}\theta.$$

Поступая аналогичіо, имеем: $\frac{d\downarrow}{d\alpha} = \frac{\sin\varphi}{\sin\theta}$.

Окончательно для $\hat{J}_\xi$ получаем выражение

$$\hat{J}_\xi = -i\left(\cos\varphi\frac{\partial}{\partial\theta} - \sin\varphi\operatorname{ctg}\theta\frac{\partial}{\partial\varphi} + \frac{\sin\varphi}{\sin\theta}\frac{\partial}{\partial\psi}\right).$$

Таким же образом находятся выражения двух других операгоров

$$\hat{J}_\eta = -i\left(-\sin\varphi\frac{\partial}{\partial\theta} - \cos\varphi\operatorname{ctg}\theta\frac{\partial}{\partial\varphi} + \frac{\cos\varphi}{\sin\theta}\frac{\partial}{\partial\iota}\right),$$
$$\hat{J}_\zeta = -i\frac{\partial}{\partial\varphi}.$$

16.

$$E_J = \frac{h^2}{2A}J(J+1)$$

Каждый уровень вырожден $(2J+1)$ раз по направлениям момента относительно неподвижного пространства и столько же раз по направлениям момента относительно самого тела.

1+16

Так как $\hat{H} = \frac{1}{2A}\hat{J}^2 + \frac{1}{2}\left(\frac{1}{C} - \frac{1}{A}\right)\hat{J}_\zeta^2$, то $E = \frac{1}{2A}J(J+1) + \frac{1}{2}\left(\frac{1}{C} - \frac{1}{A}\right)k^2; J_\zeta = k \quad |k| \leqslant J$.

В этом случае полная кратность вырождения уровня равна $2(2J+1)$. Вырождение по направлениям момента в неподвижном пространстве остается по-прежнему равным $(2J+1)$. 18.

$$-\frac{\hbar^2}{2A}\left\{\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial u}{\partial\theta}\right) + \frac{1}{\sin^2\theta}\left(\frac{\partial^2 u}{\partial\rho^2} + \frac{\partial^2 u}{\partial\psi^2}\right) - \right.$$
$$\left. -2\frac{\cos\theta}{\sin^2\theta}\frac{\partial^2 u}{\partial \Downarrow \partial\varphi}\right\} - \frac{\hbar^2}{2}\left(\frac{1}{C} - \frac{1}{A}\right)\frac{\partial^2 u}{\partial\varphi^2} = Eu.$$

1+18

Поскольку с $\hat{J}^2$ коммутируют операторы $\hat{J}_5 = -i\frac{\partial}{\partial\varphi}$ и $\hat{J}_z = -i\frac{\partial}{\partial}$, то собственную функцию будем искать в виле

$$\Phi_{kJM_J} = \boldsymbol{A}_{kJM_J}(\theta)e^{iM_J\psi}e^{ik\varphi},$$

где M_J, k - проекции момента на неподвижную ось z и подвижную ось ?? соответственно.

Так как & и φ входят в уравнение (14) симметрично, а $|k| \leqslant J$, то $|M_J| \leqslant J$.

Рассмотрим операторы

$$\hat{J}_\xi - i\hat{J}_\eta = -ie^{i\vartheta}\left(\frac{\partial}{\partial\theta} + i\operatorname{ctg}\theta\frac{\partial}{\partial\varphi} - \frac{i}{\sin\theta}\frac{\partial}{\partial\zeta}\right).$$

Легко проверить, что

$$\hat{J}_\xi\left(\hat{J}_\xi - i\hat{J}_\eta\right)\Phi_{kJM_J} = (k+1)\left(\hat{J}_\xi - i\hat{J}_\eta\right)\Phi_{kJM_J},$$

т. е. выражение $\left(\hat{J}_\varepsilon - i\hat{J}_r\right)\Phi_{zJ}M_J$ есть собственная функция, соответствующая значению $(k+1)$ оператора $\hat{j}_\xi$.

Положим $k = J$, тогда имеем:

$$\left(\hat{J}_\xi - i\hat{J}_\eta\right)\Phi_{JJ}M_J \equiv 0.$$

Последнее соотношение можно представить в виде

$$\left(\frac{\partial}{\partial\theta} + i\operatorname{ctg}\theta\frac{\partial}{\partial\rho} - \frac{i}{\sin\theta}\frac{\partial}{\partial\varphi}\right)\Theta_{JJ}M_J(\theta)e^{iU_J\psi}e^{iJ\varphi} \equiv 0.$$

Отсюда найдем обыкновенное дифференциальное уравнение первого порядка для определения Θ_{JJM_J}

$$\frac{d\theta_{JJM_J}}{d\theta} + \frac{M_J - J\cos\theta}{\sin\theta}\theta_{JJM_J} = 0.$$

Общее решение этого уравнения имеет вид

$$\theta^J_{JJM} = c\frac{(\sin\theta)^J}{\left(\operatorname{tg}\frac{\theta}{2}\right)^M}$$

Или

$$\theta(\theta) = c(1-\cos\theta)^{\frac{J-M_J}{2}}(1+\cos\theta)^{\frac{J+\pi N_J}{2}}\cdot\Big)$$

Поскольку функция Θ должна быть конечнойћ, то $|M^J| \leqslant J$.

$$\hat{J}_\xi + i\hat{J}_\eta = -ie^{-i\varphi}\Big(\frac{\partial}{\partial\theta} - i\operatorname{ctg}\theta\frac{\partial}{\partial\varphi} + \frac{i}{\sin\theta}\frac{\partial}{\partial\psi}\Big),$$

Для того чтобы определить функцию Θ_{kJM}, рассмотрим действие на нее оператора $\left(\hat{J}_{\bar{\varepsilon}} + i\hat{J}_{r_1}\right)$. Так как

$$\hat{J}_\xi\left(\hat{J}_\xi + i\hat{J}_\eta\right)\theta_{kJM_J} = (k-1)\left(\hat{J}_\xi + i\hat{J}_\eta\right)\theta_{kJM_J},$$

То

$$\left(\hat{J}_\xi + i\hat{J}_\eta\right)\theta_{kJM_J} = \alpha_k\theta_{k-1JM_J}.$$

Подставляя в (4) явный вид оператора $\left(\hat{J}_\xi + i\hat{J}_\eta\right)$ из (1), приходим к уравнению

$$\frac{d\Theta_{kJM_J}}{d\theta} + \frac{k\cos\theta - M_J}{\sin\theta}(\theta_{kJM_J} = i\alpha_i\Theta_{k-1J}M_J,$$

которое после введения переменнойћ $x = \cos\theta$ принимает вид $\sqrt{1-x^2}\frac{dP_{kJM_J}(x)}{dx} + \frac{M_J - kx}{\sqrt{1-x^2}}P_{kJM_J}(x) = -i\alpha_k P_{k-1JM_J}(x)$, где

$$P_{kJM_J}(x) = \theta_{kJM_J}(\arccos x).$$

Положив

$$P_{\boldsymbol{l}JM_J} = (1-x)^{-\frac{(k-M_J)}{2}}(1+x)^{-\frac{(k+M_JJ)}{2}}\widetilde{}_{kJ}M_J,$$

найдем простое соотношение для опредетения $\boldsymbol{v}_{kJ}\mu_J$

$$\frac{dv_{kJM_J}}{dx} = -i\alpha_k v_{k-1JM}J^\circ$$

Ранее найденные функции $P_{JJ\mu_J}$ (см. (3)), можно переписать в виде (5)

$$P_{JJM_J}(x) = (1-x)^{-\frac{(J-MU_J)}{2}}(1+x)^{-\frac{(J+MJ}{2}}v_{JJM_J},$$

где через блы, мы обозначим выражение

$$v_{JJM_J}(x) = c(1-x)^{J-M_J}(1+x)^{J+M_J}.$$

Из (7) и реккурентного соотношения (6) вытекает, что

$$v_{kJM_J} = c\frac{d^{J-k}}{(dx)^{J-k}}\left\{(1-x)^{J-M_J}(1+x)^{J+M_J}\right\}$$

Следовательно,

$$\Phi_{kJM_J}(\varphi,\psi,\varphi) =$$
$$= ce^{ik\varphi}e^{iM_J\psi}(1-\cos\theta)^{-\frac{k-M_J}{2}}(1-\cos\theta)^{-\frac{k+M_J}{2}}\times$$
$$\chi\left(\frac{d}{d\cos\theta}\right)^{J-R}\left\{(1-\cos\theta)^{J-M_J}(1+\cos\theta)^{J+M}J\right\}$$

при $M_J = 0$ эти обобщенные сферические функции переходят, как и следовало ожидать, в обычные сферические функции и представляют собой волновые функции ротатора:

$$\Phi_{k,J}(\theta,\varphi) = ce^{ik\varphi}\frac{1}{\sin^k\theta}\frac{d^{J-k}}{(d\cos\theta)^{J-k}}\left(\sin^{2J}\theta\right).$$

20.

$$\hat{H}_{kk} = \frac{\hbar^2}{4}\left(\frac{1}{A}+\frac{1}{B}\right)\left\{J(J+1)-k^2\right\} + \frac{\hbar^2k^2}{2c},$$

$\hat{H}_{kk+2} = \grave{H}_{k+2k} =$

$$= \frac{\hbar^2}{8}\left(\frac{1}{A}-\frac{1}{B}\right)\sqrt{(J-k)(J-k-1)(J+k+1)(J+k+2)}.$$

1+20

Для асимметрического волчка вырождение по направлениям момента относительно неподвижного пространства все еще остается. Вырождение относительно квантового числа k полностью снимается, так что данному J соответствует $(2J+1)$ различных уровней. В случае $J=1$ уровни энергии определятся из решения секулярного уравнения вида

$$\begin{vmatrix} H_{11}E & H_{10} & H_{1,-1} \\ H_{10} & H_{00}E & H_{0-1} \\ H_{-11} & H_{-10} & H_{-1,-1}-E \end{vmatrix} = \\ = \begin{vmatrix} H_{11}-E & 0 & H_{1,-1} \\ 0 & H_{00}-E & 0 \\ H_{-1,1} & 0 & H_{-1,-1}-E \end{vmatrix} = 0.$$

Так как $H_{-1,-1}=H_{11}$, то имеем:
откуда

$$(H_{00}-E)\left(H_{11}^2+E^2-2H_{11}E-H_{1,-1}^2\right)=0,$$

$$E_1=\frac{\hbar^2}{2}\left(\frac{1}{A}+\frac{1}{B}\right),\quad E_2=\frac{\hbar^2}{2}\left(\frac{1}{C}+\frac{1}{A}\right),\quad E_3=\frac{h^2}{2}\left(\frac{1}{B}+\frac{1}{C}\right).$$

22.

E		m	
E_1	$\Phi_{k=0,\,m}$	1	$\frac{\sqrt{3}}{4\pi}e^{i\psi}\sin\theta$
		0	$\frac{1}{\pi}\sqrt{\frac{3}{8}}\cos\theta$
		-1	$\frac{\sqrt{3}}{4\pi}e^{-i\psi}\sin\theta$
E_2	$c\,(\Phi_{k=1,\,m}+\Phi_{k=-1,\,m})$	1	$\frac{1}{\pi}\sqrt{\frac{3}{16}}e^{i\psi}(\cos\varphi+i\cos\theta\sin\varphi)$
		0	$\frac{1}{\pi}\sqrt{\frac{3}{8}}\cos\varphi\sin\theta$
		-1	$\frac{1}{\pi}\sqrt{\frac{3}{16}}e^{-i\psi}(\cos\varphi-i\cos\theta\sin\varphi)$
E_3	$c\,(\Phi_{k=1,\,m}-\Phi_{k=-1,\,m})$	1	$\frac{1}{\pi}\sqrt{\frac{3}{16}}e^{i\psi}(\cos\theta\cos\varphi+i\sin\varphi)$
		0	$\frac{1}{\pi}\sqrt{\frac{3}{8}}\sin\theta\sin\varphi$
		-1	$\frac{1}{\pi}\sqrt{\frac{3}{16}}e^{-i\psi}(-\cos\theta\cos\varphi+i\sin\varphi)$

1+23

Расщепление терма обусловлено взаимодействием спин - спин. Для определения искомого расщепления необходимо оператор взаимодействия спин - спин $\alpha(\hat{S}n)^2$ усреднить по вращательному состоянию. При данном K квантовое число J принимает значения

$$J=K+1,K,K-1.$$

Отличные от нуля матричные элементы $(n\hat{S})$ имеют вид

$$(n\hat{S})^{K-1}_{K}{}^{J=K}_{J=K}=(n\hat{S})^{K}_{K-1,J=K}=\sqrt{\frac{K+1}{2K+1}},$$
$$(n\hat{S})^{K}_{K-1}{}^{J=K-1}_{J=K-1}=(n\hat{S})^{K-1}_{K}\overline{\frac{K-1}{J=K-1}}.\sqrt{\frac{K-1}{2K-1}}.$$

Пользуясь последними соотношениями, находим искомое расщепление компонент триплета:
$\Delta E_{J=\boldsymbol{K}+1}=\frac{K+2}{2K+3}\alpha,\quad \Delta E_{J=\boldsymbol{K}}=\alpha,\quad \Delta E_{J=K-1}=\frac{K-1}{2K-1}\alpha$

18.1.12 Advanced problems about molecules

1+24

Найдем прежде всего недиагональные элементы оператора w

$$\{w\}^{n\Delta Qv}_{n\Delta\Omega' vJ'}$$

Легко видеть, что отличны от нуля только матричные элементы, соответствующие $Q' = Q \pm 1, J = J'$. Так как

$$\{\hat{M}_\xi\}^{n\Delta\Omega}_{n\Delta\Omega\pm 1} = \mp i \{\hat{M}_\eta\}^{n\Delta\Omega}_{n\Delta\Omega\pm 1},$$

то

$$\{\tau v\}^{n\Delta 2vJ}_{n\Delta Q\pm 1vJ} = \frac{\hbar^2}{M}\left\{\pm\frac{\partial}{\partial\theta} + \frac{i}{\sin\theta}\frac{\partial}{\partial p} + (Q\pm 1)\operatorname{ctg}\theta\right\}^{\Delta 2J}_{\Delta Q\pm 1J} \times \times \left\{\frac{1}{\rho^2}\hat{M}_{\tau_i}\right\}^{n\Delta Qv}_{n\Delta Q\pm 1v}.$$

Для вычисления матричного элемента

$$\left\{\pm\frac{\partial}{\partial\theta} + \frac{i}{\sin\theta}\frac{\partial}{\partial\dot{\varphi}} + (Q\pm 1)\operatorname{ctg}\theta\right\}^{\Delta QJ}_{\Delta Q\pm 1J},$$

заметим, что если в операторе $(J_\xi + iJ_{r_1})$ (см. задачу 13§ 8) положить угол $\varphi = 0$, а $-i\frac{\partial}{\partial\varphi} \to \hat{M}_\zeta$, то

$$(J_\xi \pm iJ_{r_i})_\xi \to 0$$
$$-i\frac{\partial}{\partial\varphi} \to \mp i\left\{\pm\frac{\partial}{\partial\theta} + \frac{i}{\sin\theta}\frac{\partial}{\partial\varphi} + (Q\pm 1)\operatorname{ctg}\theta\right\}.$$

15 Зак. 1750. И. И. Гольдман, В. Д. Крнвченков

$$(n\hat{S})^{K+1\ J=K}_{K\ \ J=K} = (n\hat{S})^{K\ \ J=K}_{K+1\ J=K} = \sqrt{\frac{K}{2K+1}},$$

$$(n\hat{S})^{K\ \ J=K+1}_{K+1\ J=K+1} = (n\hat{S})^{K-1\ J=K+1}_{K\ \ J=K+1} = \sqrt{\frac{K+2}{2K+3}},$$

Учитывая последнее соотношение, имеем:

$$\left\{\pm\frac{\partial}{\partial\theta} + \frac{i}{\sin\theta}\frac{\partial}{\partial\dot{\rho}} + (Q\pm 1)\operatorname{ctg}\theta\right\}^{\Lambda QJ}_{\Delta Q\pm 1J} =$$
$$= \pm i\sqrt{(J\mp Q)(J\pm Q+1)}.$$

В случае малых колебаний около положения равновесия матричный элемент

$$\left\{\frac{1}{p^2}\hat{M}_\eta\right\}^{n\Delta Qv}_{n\Delta Q\pm 1v}$$

приближенно можно положить равным

$$\frac{1}{p_0^2}\left\{\hat{M}_n\right\}^{n\Lambda\Omega}_{n\Delta\Omega\pm 1},$$

где p_0 - расстояния между ядрами в положении равновесия. Так как
$\left\{\hat{L}_\eta + \hat{S}_n\right\}^{n\Delta\Omega}_{n\Delta Q\pm t} = \left\{\hat{S}_\eta\right\}^{n\Delta Q}_{n\Delta Q\pm 1} = \pm\frac{i}{2}\sqrt{S(S+1) - \sum(\sum\pm 1)}$
то окончательно имеем:

$$\{w^{n\Delta 8}_{n\Delta\varepsilon\pm 1vJ} =$$
$$= B_0\sqrt{S(S+1) - \Sigma(\Sigma\pm 1)}\sqrt{J(J+1) - (\Lambda+\Sigma)(\Lambda+2-1-1.}$$

Здесь $B_0 = \frac{\hbar^2}{2M\rho_0^2}$ представляет собой значение ротационноĥi постоянной для состояния равновесия, отвечающего некоторому $p = P_0$.

В общем случае дублетное расцепление может быть равно по порядку вычисленным маятрнчным элементам. Поэтому д.яя расчета смещения уровней дублетного терма применим теорию возмущения в несколько измененном виде. В качестве исходного нулевого приб.иижения возьмем вместо функций

$$\psi_{n\Delta A+1} \le vJ, \quad i_{n\Delta\Delta-1'_i vJ}$$

их линейную комбинацию

$$\dot{\psi} = c_1\psi i\Delta\Delta\Delta + 1, vJ + c_2\psi_{n\Delta\Delta-1/2v}J.$$

Подставляя это выражение в возмущенное уравнение и поступая стандартным образом, находим секулярное уравнение

$$\begin{vmatrix} E^{(0)}_{n\Delta\Delta+1/2vJ} - E & w^{n\Delta\Delta+1/2vJ}_{n\Delta\Delta-1/2vJ} \\ w^{n\Delta\Delta-1/2vJ}_{n\Delta\Delta+1/2vJ} & E^{(0)}_{n\Delta\Delta-1/2vJ} - E \end{vmatrix} = 0.$$

Из решения секулярного уравнения следует, что

$$E = \frac{1}{2}E^{(0)} \pm \frac{1}{2}\sqrt{\Delta E^{(0)} + 4B_0^2\left\{\left(J+\frac{1}{2}\right)^2 - \Lambda^2\right\}}$$

где

$$E^{(0)} = E^{(0)}_{n\Delta\Delta+1_2v} + E^{(0)}_{n\Delta\Delta-1:vJ}$$
$$\Delta E^{(0)} = E^{(0)}_{n\Delta\Delta\div 1_2vJ} - E^{(0)}_{n\Delta A-1\vdots\Delta vJ}$$

В случае связи a, когда мультиплетное расщепление велико по сравнению с вращением, из соотношения (1) приближенио следует, что

$$E_1 = E^{(0)}_{n\Delta\Delta+1'_2vvJ} + \frac{B_0^2\left\{\left(J+\frac{1}{2}\right)^2 - \Lambda^2\right\}}{\Delta E^{(0)}},$$
$$E_2 = E^{(0)}_{n\Delta\Delta-1!_2vJ} - \frac{B_0^2\left\{\left(J+\frac{1}{2}\right)^2 - \Lambda^2\right\}}{\Delta E^{(0)}}.$$

В случае связи b из (1) получаем:
$E_{1,2} = \frac{1}{2}E^{(0)} \pm B_0\left\{\left(J+\frac{1}{2}\right)^2 - \Lambda^2\right\} \pm \frac{\Delta E^{(0)}}{8B_0\left\{\left(J+\frac{1}{2}\right)^2 - \Lambda^2\right\}}$

1+25

$K = 0, 2, 4, ...$, если суммарный спин $S = 2$ или $S = 0$, $K = 1, 3, 5, ...$, если суммарный спин $S = 1$.
Магнитный момент молекулы равен $\frac{e\hbar}{2mc}(\Lambda + 2\Sigma)n$, где $\boldsymbol{n}$ - единичный вектор, направленный по оси молекулы.
Длля определения энергии расщепления необходимо усреднить величину

$$-\frac{e\hbar}{2mc}(1 + 2\Sigma)ngl$$

по вращательному состоянию, т. е. определить матричные элементы

$$(n)^{JM_j}_{JNI_j}$$

Так как $\hat{J}$ есть единственный сохраняющийся вектор, то очевидно, что матричные элементы вектора $\boldsymbol{n}$ будут пропорциональны матричным элементам вектора $\hat{J}$, т. е.

$$(\boldsymbol{n})^{JMM'_j}_{JM_j} \sim (J_J)^{JM'_j}_{JM_j}.$$

Рассматривая $\boldsymbol{n}$ как оператор, имеем:

$$\hat{\boldsymbol{n}} = \text{ const } \hat{J}.$$

Для определения константы умножим последнее выражение слева и справа на $\hat{\boldsymbol{J}}$. Так как собственные значения $\hat{\boldsymbol{J}}^2$ равны $J(J+1)$, а $\hat{J}\hat{n}$ равны Q, то имеем:

$$\grave{n} = \frac{\Omega}{J(J+1)}\grave{J}.$$

Таким образом, оператор энергии возмущения равен

$$-\frac{e\hbar}{2mc}(\Lambda + 2\Sigma)\cdot\frac{\varrho}{J(J+1)}\mathscr{J}\hat{J}.$$

Вычисляя диагональные матричные элементы, получаем для энергии расщепления выражение следующего вида:

$$\Delta E_{M_j} = -\frac{e\hbar_{\mathcal{H}}}{2mc}(\Lambda + 2\Sigma)\frac{\Omega}{J(J+1)}M_j.$$

1+27

Оператор возмущения, как легко установить, в данном случае имеет следующий вид:

$$-\frac{eh_l}{2m\bar{c}}\mathscr{H}\left\{\frac{\Lambda^2}{K(K+1)}\dot{K} + 2\dot{S}\right\}.$$

Отсюда следует, что зеемановское расщепление равно $\Delta E_{M_j} = -M_j \frac{e\hbar\%\mathcal{C}}{2mc}\times$
$\times\left\{\Lambda^2\frac{J(J+1)-S(S+1)+K(K+1)}{2K(K+1)J(J+1)} + \frac{J(J+1)+S(S+1)-K(K+1)}{J(J+1)}\right\}$.

1+28

Энергия зеемановского расщепления равна

$$\Delta E_{MK^M}M_{\mathrm{S}} = -\frac{e\hbar}{2mc}\mathscr{K}^{2m}\left[\frac{\Lambda^2}{K(K+1)}M_K + 2M_{\mathrm{S}}\right].$$

1+29

Так как энергия взаимодействия магнитного момента с внешним магнитным полем одного порядка с энергией взаимодействия спин- ось, то их надо рассматривать в теории возмущения одновременно. Оператор возмущения имеет В Нд

$$\hat{V} = An\hat{\mathbf{S}} - \mu_0 \Delta n\mathfrak{H} - 2\mu_0\hat{\mathbf{S}}\mathfrak{H}.$$

В качестве волновых функций нулевого приближения возьмем волновые функцни состояний, в которых имеют определенные значения момент K и проекция K и S на направление магнитного поля. Ось z направим по магнитному полю. Так как проекция полного момента на направлени е магнитного поля сохраняется, то в случае дублетного терма мы должны применить теорию возмущения при наличии двухкратного вырождения. Вычисляя матричные элементы оператора возмущения, имеем:

$$\begin{aligned}
&V^{1/K}_{N_K,-1!2}, {}^{-1!} = -M_K\frac{1}{2K(K+1)}A - M_K\frac{\Lambda^2}{K(K+1)}\mu_0\mathscr{H} + \mu_0\mathscr{H},\\
&V^{U_K-1,!_2}_{N_K} = (M_K-1)\frac{1}{2K(K+1)}A -\\
&-(M_K-1)\frac{\Lambda^2}{K(K+1)}\mu_0\mathscr{F} - \mu_0\mathscr{H}O,\\
&V^{M_K^{-1,2}}_{N_K-1,1_{i,2}} = \frac{1}{2}A\frac{1}{K(K+1)}\sqrt{(K-M+1)(K+M)} =\\
&= \frac{1}{2}A\left\{n_x + in_y\right\}^{N_K}_{N_K K^{-1}},\\
&= \frac{1}{2}A\frac{\Lambda}{K(K+1)}\sqrt{(K-M+1)(K+M)}.
\end{aligned}$$

Составляя и решая секулярное уравнение, получим:

$$E^{(1)}_{1,2} = \frac{\lambda^2}{K(K+1)}\left(M_K - \frac{1}{2}\right)\mu_0 A - \frac{A\Lambda}{4K(K+1)} \pm \frac{1}{2K(K+1)}\times$$
$$\times\sqrt{\left\{A\Lambda\left(M-\frac{1}{2}\right) - \Lambda^2\mu_0\mathscr{H} + 2\mu_0\mathscr{O}(K+1)K\right\}^2 + A^2\Lambda^2\left(K+M_K\right)\left(K-M_K+1\right)}.$$

Рассмотрим предельные случаи.
Если $\mu_0 \nrightarrow \gg A$, то для $E^{(1)}_{1,2}$ получаем выражение

$$E_{1,2}^{(1)} = -\frac{\Lambda^2}{K(K+1)}\left\{M_K - \frac{1}{2} \mp \frac{1}{2}\right\}\mu_0\mathscr{H} \leftarrow \mu_0\mathcal{L}?,$$

согласующееся с формулой, полученной в задаче 29§8.

$$V_{M_K,\,-1/2}^{M_K-1,\,1/2} = \frac{1}{2}A\{n_x - in_y\}_{M_K}^{M_K-1} =$$

При $A \gg \mu_0\mathscr{H}$ получается

$$E_1^{(1)} = \frac{A\Lambda}{2(K+1)} - \left(M_K - \frac{1}{2}\right)\left\{\frac{\Lambda^2}{(K+1)\left(K+\frac{1}{2}\right)} + \frac{1}{K+\frac{1}{2}\}}u_0\mathscr{H},$$

$$E_2^{(1)} = -\frac{A\Lambda}{2K} - \left(M_K - \frac{1}{2}\right)\left\{\frac{\Lambda^2}{K\left(K+\frac{1}{2}\right)} - \frac{1}{K+\frac{1}{2}\}\mu_0\mathcal{H}^\circ}.$$

Вторые члены последних формул, т. е. члены, зависящие линейно от ёf, совпадают с соответствующими выражениями, которые получаются при подстановке в формулу, найденную в задаче 28£8,

$$J = K \pm 1/2, \quad S = 1/2 \text{ и } \quad M_j = M_K - 1/2^\circ$$

1+30

В силу аксиальной симметрии дигольный момент молекулы направлен по прямой, соединяющей ядра, т. е.

$$\boldsymbol{p} = p\boldsymbol{n}.$$

Поступая так же, как и при решении задачи 27$8, находим:

$$\Delta E_{M_j} = \ldots_p\frac{\Omega}{J(J+1)}M_j.$$

32.

$$\Delta E_M = -8pM_j\Lambda\frac{J(J+1) - S(S+1) + K(K+1)}{2K(K+1)\cdot J(J+1)}.$$

1+32

Поправка первого приближения к энергии равна нулю. Как известно, поправка второго приближения к энергии в случае вырождения находится из условия совместности однородных линейных уравнений

$$E_n^{(2)}c_{n\xi}^{(0)} = \sum_j c_{nj}^{(0)}\sum_{ma}\frac{V_{ma}^{n\beta}V_{nj}^{ma}}{E_n^{(0)} - E_{ni}^{(0)}}$$

'В нашем случае из последнего соотношения получаем:

$$E_{lmb}^{(2)} = \frac{p^2g^2A}{h^2}\left\{\frac{l^2 - m^2}{(2l+1)(2l-1)l} - \frac{(l+1) - m^2}{(2l+3)(2l+1)(l+1)}\right\}.$$

Таким образом энергия твердого диполя равна

$$E_{lm} = \frac{\hbar^2}{2A}l(l+1) + E_{l,n}^{(2)}; \quad E_{00} = -\frac{1}{3}\frac{Ap^2g^2}{h^2} \quad (l=0).$$

Этот результат до некоторой степени парадоксален. В самом деле, согласно последнему равенству энергия твердого диполя пропорциональна не &, a&^{2}. Следовательно, твердому диполю формально можно приписать определенную «поляризуемость».

Рассмотрим случай, когда $l = 1$. Уровень, соответствующий значению $m = 0$, обладает в электрическом поле большей энергией, чем вне его, так что соответствующая молекула ведет себя так, как будто она обладает отрицательной поляризуемостью.. - Она ведет себя подобно диамагнитному телу в магнитном поле. Молекула в состоянии $m = \pm 1$

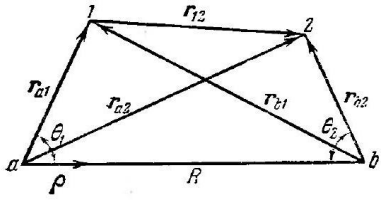


Рис. 31.

ведет себя «нормально». Вырождение в электрическом поле снимается только частично, поскольку энергия зависит только от абсолютного значения проекции момента количества движения.

Отметим, что $\sum_{m=-l}^{m=+l} E_{lm}^{(2)} = 0$.

1+33

При больших значениях R можно пренебречь обменом, т. е. считать, что первый электрон находится при ядре a, а второй электрон - при ядре b (см. рис. 31).

Взаимодействие двух атомов, имеющее вид

$$V = \frac{1}{R} - \frac{1}{r_{a2}} - \frac{1}{r_{b1}} + \frac{1}{r_{12}}$$

будем рассматривать как малое возмущение.

В первом приближении энергия взаимодействия двух атомов равна диагональному матричному элементу V, т. е.

$$\int \psi_0(r_{1a})\,\psi_0(r_{2b})\,V\dot{\zeta}_0(r_{1a})\,\psi_0(r_{2b})\,d\tau_1 d\tau_2,$$

где

$$\psi_0(r_{1a}) = 2e^{-r_{1a}}; \quad \psi_0(r_{2b}) = 2e^{-r_{2b}}.$$

В S-состоянии диагональные матричные элементы, т. е. среднее значение дипольного, квадрупольного и т. д. моментов, равны нулю, поэтому для вычисления энергии взаимодействия необходимо перейти ко второму приближению теории возмущений.

В операторе возмущения (1) ограничимся диполь - дипольным взаимодействием, как наиболее медленно убывающим с расстоянием. ДЛя получения оператора диполь - дипольного взаимодействия разложим потенциал V по убывающим степеням R. Разложение по шаровым функциям дает

$$\frac{1}{r_{l1}} = \frac{1}{|Rp - r_{1a}|} = \sum_{\lambda=0} \frac{r_{a1}^{\lambda}}{R^{\lambda+1}} P_{\lambda}(\cos\theta) =$$

$$= \frac{1}{R} + \frac{\boldsymbol{r}_{a1^p}}{R^2} + \frac{3\,(r_{a1p})^2 - \boldsymbol{r}_{a1}^2}{2R^3} + \cdots$$

$$\frac{1}{r_{12}} = \frac{1}{|Rp + r_{b2} - r_{a1}|} =$$

$$= \frac{1}{R} + \frac{(r_{a1} - r_{b2}, p)}{R^2} + \frac{3\,(r_{a1} - r_{b2}, \rho)^2 - (r_{a1} - r_{b2})^2}{2R^3} + \ldots$$

$$\frac{1}{r_{a2}} = \frac{1}{R} + \frac{(r_{b2}p)}{R^2} + \frac{3\,(r_{b2^p})^2 - r_{b2}^2}{2R^3} + \cdots$$

Подставляя полученные разложения в V, находим выражение для диполь - дипольного взаимодействия

$$V = -\frac{2z_1z_2 - x_1x_2 - y_1y_2}{R^3},$$

причем ось z направлена вдоль линии, соединяющей ядра. Как было уже сказано, среднее значение (2) по невозмущенной собственной функции $\psi = \psi_0(r_{a1})\,\psi_0(r_{b2})$ равно нулю. Недиагональные элементы (2), соответствующие переходам из основного состояния в возбужденные состояния, можно представить в виде

$$V_{00}^{mn} = -\frac{2z_{0m}z_{0n} - x_{0m}x_{0n} - y_{0m}y_{0n}}{R^3}.$$

На основании правила отбора матричные элементы z_{0n}, x_{0n}, y_{0n} отличны от нуля только для переходов из основного состояния в состояния

$$\psi_n(r)\cos\theta, \quad \psi_n(r)\sin\theta\cos\varphi,$$

причем все эти три матричные элемента равны друг другу. Энергия взаимодействия во втором приближении равна

$$E^{(2)} = \sum_{mn} \frac{\left(V_{00}^{mn}\right)^2}{2E_0 - E_m - E_n} = \frac{1}{R^6} \sum_{mn} \frac{4z_{0m}^2 z_{0n}^2 + x_{0m}^2 x_{0n}^2 + y_{0m}^2 y_{0n}^2}{2E_0 - E_m - E_n}$$

И.ПИ

$$E^{(2)} = \frac{6}{R^6} \sum_{mn} \frac{z_{0m}^2 z_{0n}^2}{2E_0 - E_m - E_n}.$$

Так как $E_0 < E_m$ и $E_0 < E_n$, то $E^{(2)}$ отрицательно и, следовательно, два атома в невозбужденном состоянии, находящиеся на большом расстоянии лруг от друга, притягиваются с силой, обратно пропорциональной седьмой степени расстояния. Для приближенного расчета суммы в (3) заметим, что разность энергий между различными верхними уровнями мала по сравнению с разностями энергий между верхними уровнями и основным. Поэтому приближенно (3) можно представить в виде

$$E^{(2)} = \frac{3}{R^6} \sum_m z_{0m}^2 \sum_n \frac{z_{0n}^2}{E_0 - E_n}.$$

Из теории квадратичного эффекта Штарка следует, что $\sum \frac{z_{0n}^2}{E_0 - E_n} = -\frac{1}{2}\alpha$, где α - поляризуемость атома. Для основного состояния атома водорода $x = 4,5$ ат. ед. При вычислении суммы $\sum\limits_{m\pm 0} z_{0m}^2$ воспользуемся правилом умножения матриц
(?)

$$(AB)_{nk} = \sum_m A_{nm} B_{mk}$$

$$\int \psi_n^* (AB)\psi_k d\tau = \sum_m \left\{ \int \psi_n^* A \psi_m^* d\tau \cdot \int \psi_m^* B \psi_k d\tau \right\}.$$

Положив в последнем соотношении $A = B = z, n = k = 0$, получим:

$$\left(z^2\right)_{00} = \sum_m z_{0m} z_{m0} = \sum z_{0nn}^2$$

И. ИИ

$$\sum_{m\neq 0} z_{0m}^2 = \sum_m z_{0m}^2 - z_{00}^2 = \left(z^2\right)_{00} - z_{00}^2.$$

Так как в S-состоянии в силу симметрии $z_{00} = 0$, а $\left(z^2\right)_{00} = \frac{1}{3}\left(r^2\right)_{00}$, то сумма

$$\sum_{m\neq 0} z_{0m}^2 = \frac{1}{3}\left(r^2\right)_{00} = 1$$

Таким образом, для $V(r)$ получаем окончательно выражение

$$V(R) = -\frac{6,75}{R^6}.$$

Для того чтобы уяснить, как могут возникнуть силы взаимодействия между двумя нейтральными сферически-симметричными атомами водорода, рассмотрим волновую функцию системы. Для волновой функции системы в первом приближении получаем выражение

$$\psi = \psi_0(r_{a1})\,\psi_0(r_{b2}) \left[1 + \frac{1}{2E_0 R^8}\left(x_1 x_2 + y_1 y_2 - 2z_1 z_2\right)\right].$$

Плотность вероятности $w(1,2)$, если пренебречь членами, содержащими $\frac{1}{R^6}$ в качестве множителя, имеет вид $w(r_{a1}, r_{b2}) = w_0(r_{a1})\,w_0(r_{b2}) \left[1 + \frac{1}{E_0 R^3}\left(x_1 x_2 + y_1 y_2 - 2z_1 z_2\right)\right]$ Если нет взаимодействия между атомами, плотность вероятности равна просто произведению $w(1)$ на $w(2)$, т. е. меж, положениями электронов в этом случае нет никакой корреляции. В случае же взаимодействия положение первого электрона не независимо от положения второго. Электроны занимают статистически чаще те положения, в которых их взаимная потенциальная энергия имеет по возможности меньшее значение.

Таким образом, силы взаимодействия в первом приближении можно объяснить не деформацией электронных оболочек, а корреляцией между положением электронов.

1+34

Докажем аддитивность для системы, состоящей из трех атомов. Из расчета будет видно, что его можно применить к любому числу атомов. Энергию взаимодействия запишем в следующей форме:

$$V = V(1,2) + V(2,3) + V(3,1),$$

где через $1, 2, 3$ обозначены совокупности координат первого, второго и третьего атомов. Мы рассматриваем взаимо- действие атомов, находящихся на большом расстоянии друг от друга; в этом случае обменные силы не играют никакой роли. Волновую функцию трех атомов при игнорировании обмена в нулевом приближении зададим в форме

$$\because = \bigcup_{ai}(1) \bigcup_{bk}(2) \uplus_{icl} (3),$$

где i, k, l - указывают квантовые состояния атомов a, b, c. Функции а (1), принадлежащие различным значениям i, ортогональны. То же самое можно сказать и про функции $\psi_{bk}(2), \psi_{cl}(3)$.

Энергия возмущения во втором приближении имеет вид

$$\varepsilon = V_{000}^{000} + \sum{}' \frac{|V_{ikl}^{000}|^2}{E_{a0} + E_{b0} + E_{c0} - E_{ai} - E_{bl} - E_{cl}}$$

Штрих у знака суммы означает, что i, k, l не должны одновременно равняться нулю. Первый член представляет классическое взаимодействие мультиполей. В нашем случае он равен нулю. В выражении (1) все члены, у которых одновременно $i \neq 0, k \neq 0, l \neq 0$, исчезают вследствие ортогональности функций.

Т ри частные суммы с $i = k = 0, l \neq 0; i = l = 0, k \neq 0$: $k = l = 0, i \neq 0$ означают поляризационные взаимодействия соответственно l-го, k-го и i-го атомов в результирующем поле двух огтальных атомов. В случае, когда распределение зарядов в атомах обладает шаровой симметрией, эти суммы также исчезают. Необходимо заметить, что эти суммы не могут быть получены путем аддитивного учета энергии взаимодействия каждой пары атомов. Нам остается рассмотреть те члены, в которых два индекса отличны от нуля. Итак, при сделанных предположениях относительно распределения заряда в атомах энергия взаимодействия может быть разложена на три частных суммы:

$$\varepsilon = \sum_{i\neq 0}{}' \frac{|V_{ik0}^{000}|^2}{E_{a0}+E_{b0}-E_{ai}-E_{bk}} + \underbrace{}_{b0}{}^{+E_{c0}-E_{bi}-E_{cl}} \sum_{k\neq 0 l\neq 0} + \sum_{i\neq 0 l\neq 0} \frac{|V_{0kl}^{000}|^2}{E_{a0}+E_{c0}-E_{ai}-E_{cl}}.$$

Вследствие ортогональности и нормированности собственных Функций атома матричный элемент

$$\begin{aligned} V_{ik0}^{000} &= \int \psi_{a0}^*(1)\psi_{b0}^*(2)\psi_{c0}^*(3) \cdot \{V(1,2)+ \\ &+ V(2,3) + V(3,1)\}\psi_{ai}^*(1)\psi_{bk}(2)\psi_{c0}(3)d\tau_1 d\tau_2 = \\ &= \int \psi_{a0}^*(1)\psi_{b0}^*(2)V(1,2)\psi_{ai}(1)\psi_{bk}(2)d\tau_1 d\tau_2 = \{V(1,2)\}_{ik}^{00} \end{aligned}$$

Следовательно, выражение (2) состоит из трех слагаемых, каждое из которых прдставляет дисперсионное взаимодействие пар атомов. Легко видеть, что этот расчет может быть распространен на произвольное число атомов.

В том случае, когда расстояния между атомами невелики, надо принять во внимание переходы электронов от одного атома к другому, т. е. принять во внимание обменныe силы.

18.1.13 Extra Problems about scattering 1

ГК-9.1. Медленное рассеяние притягателем

Найти сечение рассеяния частицы потенциальной ямои при малых скоростях (длина волны де Бройля значительно больше размеров ямы).

Solution

Потенциальная энергия частицы

$$\begin{aligned} U(r) &= -U_0 \quad (r < a), \\ U(r) &= 0 \qquad (r > a). \end{aligned}$$

Необходимо найти фазы рассеяния, т. е. асимптотический вид радиальных функций, удовлетворяющих уравнениям при

$$r > a \quad \chi_l'' + \left[k^2 - \frac{l(l+1)}{r^2}\right]\chi_l = 0, \quad k^2 = \frac{2\mu E}{\hbar^2},$$

при

$$r < a \quad \chi_l'' + \left[k'^2 - \frac{l(l+1)}{r^2}\right]\chi_l = 0, \quad k'^2 = \frac{2\mu\,(E+U_0)}{\hbar^2}$$

с граничным условием $\chi_l(0) = 0$.

В случае, когда длина волны де Бройля значительно больше размеров ямы, основной вклад в рассеяние вносит S-волна. Решение χ_0, удовлетворяющее граничному условию, имеет вид

$$\varkappa_0 = A\sin k'r (r < a),$$
$$\varkappa_0 = \sin\left(kr + \hat{\delta}_0\right)(r > a).$$

Фаза δ_0, также как и коэффициент A, определяется из условия непрерывности волновой функции и ее производной при $r = a$. Эти условия дают:

$$\delta_0 = \operatorname{arctg}\left(\frac{k}{k'}\operatorname{tg} k'a\right) - ka.$$

Итак, парциальное сечение для $l = 0$

$$\sigma_0 = \frac{4\pi}{k^2}\sin^2\delta_0 = \frac{4\pi}{k^2}\sin^2\left[\operatorname{arctg}\left(\frac{k}{k'}\operatorname{tg} k'a\right) - ka\right].$$

При малых скоростях падающих частиц ($k \to 0$) фаза рассеяния δ_0 пропорциональна k:

$$\delta_0 \approx k\left(\frac{\operatorname{tg} k_0 a}{k_0 a} - 1\right), \quad k_0^2 = \frac{2\mu U_0}{\hbar^2},$$

но благодаря множителю $\frac{1}{k^2}$ сечение σ_0 оказывается конечным

$$\sigma \approx 4\pi a^2\left(\frac{\operatorname{tg} k_0 a}{k_0 a} - 1\right)^2$$

(малые k).

Рассмотрим сечение 5_0 как функцию глубины ямы, которая характеризуется k_0. Если яма неглубока ($k_0 a \ll 1$), то

$$\sigma_0 = 4\pi a^2\frac{k_0^4 a^4}{9} = \frac{16\pi}{9}\frac{a^6 U_0^2\mu^2}{\hbar^4}.$$

Отметим, что согласно теории возмущений

$$f(\text{th}) = -\frac{1}{4\pi}\frac{2\mu}{\hbar^2}\int U(r)d\tau = \frac{2\mu}{\hbar^2}U_0\frac{a^3}{3}$$

и, следовательно,

$$\sigma = 4\pi|f(\vartheta)|^2 = \frac{16\pi}{9}\frac{a^6 U_0^2\mu^2}{\hbar^4}.$$

По мере возрастания U_0 сечение возрастает и при $k_0 a = \frac{\pi}{2}$ становится неограниченно большим. Условие $k_0 a = \frac{\pi}{2}$ совпадает с условием появления в яме первого уровня. По мере углубления ямы сечение затем начинает уменьшаться и обращается в нуль при $\operatorname{tg} k_0 a = k_0 a$. При дальнейшем увеличении U_0 сечение продолжает колебаться между 0 и ∞, причем обращение сечения в ∞ наступает при появлении нового уровня в яме. Резкие колебания сечения при рассеянии медленных частиц качественно объясняет тот факт, что при рассеянии медленных электронов атомом сечение может значительно отличаться от геометрического.

Отметим, что если значение $k_0 a$ близко к целому кратному $\frac{\pi}{2}$, то формулы (2) и (3) необходимо видоизменить. Действительно, в этом случае $\operatorname{tg} \boldsymbol{k}'a$ оказывается большим числом и в формуле (1) нельзя произвести разложения, приводящего к формуле (7). В этом случае по-прежнему однако можно пренебречь слагаемым $ka \ll 1$ в квадратных скобках формулы (1). Тогда

$$\delta_0 = \operatorname{arctg}\left[\frac{k}{k'}\operatorname{tg} k'a\right]$$

и отсюда для сечения σ_0 получаем:

$$\sigma_0 = \frac{4\pi(1+O(xa))}{x^2+k^2},$$

где по условию

$$x = \frac{k'}{\operatorname{tg} k'a} \ll \frac{1}{a}.$$

Эта формула для «резонансного» рассеяния дает зависимость сечения от $\boldsymbol{k}$ при малых k, если потенциальная яма такова, что малым изменением ее глубины (или размера) можнодобиться появления или исчезновения дискретного уровня.

ГК-9.2. Медленное рассеяние отталкивателем

Определить сечение рассеяния медленных частиц в поле отталкивания

$$\begin{array}{ll} U(r) = U_0 & (r < a), \\ U(r) = 0 & (r > a). \end{array}$$

Solution

(??? по идее аналогично тому, что выше, понимал бы я это только!)

1+1

$0 = 4\pi a^2 \left(\frac{\operatorname{th} xa}{xa} - 1\right)^2$, где $\quad x = \frac{\sqrt{2\mu U_0}}{\hbar}$.

При $U_0 \to \infty \sigma = 4\pi a^2$, т. е. в 4 раза больше, чем сечение упругого рассеяния на непроницаемой сфере в классической механике.

ГК-9.3.

Выразить через фазы рассеяния первые три коэффициента разложения сечения упругого рассеяния $\frac{d\sigma}{d\Omega}$ по полиномам Лежандра.

Solution

3.
$$\begin{aligned} \frac{ds}{dQ} &= \frac{1}{k^2}\sum_{l=0}^{\infty}(2l+1)\sin^2\partial_l + \\ &+ \frac{6\cos\theta}{k^2}\sum_{l=0}^{\infty}(l+1)\sin\delta_l\sin\delta_{l+1}\cos(\delta_{l+1}-\delta_l) + \\ &+ \frac{5}{k^2}\frac{3\cos^2\vartheta-1}{2}\sum_{l=0}^{\infty}\left\{\frac{l(l+1)(2l+1)}{(2l-1)(2l+3)}\sin^2\delta_l + \right. \\ &\left. + \frac{3(l+1)(l+2)}{2l+3}\sin\delta_l\sin\delta_{l+2}\cos(\delta_{l+2}-\delta_l)\right\} + \ldots \end{aligned}$$

или

$$\int_0^{\pi} ds = \frac{4\pi}{k^2}\sum_{i=0}^{\infty}(2l+1)\sin^2 0_i$$

$$\int_0^{\pi}\cos\hat{\theta}d\sigma = \frac{8\pi}{k^2}\sum_{l=0}^{\infty}(l+1)\sin\hat{c}_l\sin\delta_{l+1}\cos(\delta_{l+1}-\delta_l)$$

$$\int_0^{\pi}\frac{3\cos^2\theta-1}{2}d\sigma = \frac{4\pi}{k^2}\sum_{l=0}^{\infty}\frac{l(l+1)(2l+l)}{(2l+1)(2l+3)}\sin^2\delta_l +$$

$$+ \frac{12\pi}{k^2}\sum_{l=0}^{\infty}\frac{(l+1)(l+2)}{2l+3}\sin\delta_l\sin\delta_{l+2}\cos(\delta_{l+2}-\delta_l)$$

ГК-9.4.

Найти фазы рассеяния в поле $U = \frac{A}{r^2}$. Определить сечение рассеяния на малые углы.

Solution

1+3

Радиальные функции подчиняются уравнению

$$\chi_l'' + \left[k^2 - \frac{l(l+1)}{r^2} - \frac{2\mu A}{\hbar^2 r^2}\right]\chi = 0$$

и должны удовлетворять условиям $\chi_l(0) = 0$ и конечности при $r \to \infty$. Удовлетворяющее этим условиям решение имеет следующий вид:

$$\chi_{-l} = \sqrt{r} J_\lambda(kr),$$

где

$$\lambda = \sqrt{\left(l + \frac{1}{2}\right)^2 + \frac{2\mu \cdot A}{\hbar^2}}.$$

Из формул для асимптотического поведения $J_\lambda(kr)$ находим фазы:
$\delta_t = -\frac{\pi}{2}\left(\lambda - l - \frac{1}{2}\right) = -\frac{\pi}{2}\left\{\sqrt{\left(l+\frac{1}{2}\right)^2 + \frac{2\mu A}{\hbar^2}} - \left(l + \frac{1}{2}\right)\right\}$.
Независимость $\delta_{\mathrm{I}math}$ от k означает, что амплитуда рассеяния

$$f(\vartheta, k) = \frac{1}{k} f_0(\theta),$$

где $f_0(\vartheta)$ не зависит от энергии рассеиваемых частиц. Сечение рассеяния

$$d\tau = \frac{1}{k^2}|f_0(\ (?)\ |^2 dQ$$

обратно пропорционально энергии и характеризуется универсальным угловым распределением. Поскольку при $\to 0$ сумма, определяющая амплитуду рассеяния

$$f(i) = \frac{1}{2ik}\sum_{l=0}^{\infty}(2l+1)P_l(\cos\vartheta)\left[e^{2i}l - 1\right],$$

расходится, ясно, что для вычисления $f(\vartheta)$ при малых \$ существенны большие l. Для больших l имеем:

$$-\delta_l \approx -\frac{\pi\mu A}{(2l+1)\hbar^2} \ll 1,$$

юткуда

$$f(i) \approx \frac{1}{k}\sum_{l=0}^{\infty}(2l+1)P_l(\cos\vartheta)c_l \approx$$

$$\approx -\frac{\pi u \cdot A}{\hbar^2 k}\sum_{l=0}^{\infty}P_l(\cos i) = -\frac{\pi i \cdot A}{k\hbar^2}\frac{1}{2\sin\frac{\theta}{2}}.$$

В том случае, когда

$$\frac{8\mu A}{\hbar^2} \ll 1$$

выражение (1) для δ_l справедливо при любых l и таким образом для всех

$$f(\ \mathrm{ii}\ ) \approx -\frac{\pi\mu A}{k\hbar^2}\frac{1}{2\sin\frac{\vartheta}{2}},$$

$$ds = \frac{\pi^3 A^2}{2h^2 E}\operatorname{ctg}\frac{\vartheta}{2}d!$$

ГК-9.5.

Рассчитать дифференциальное сечение рассеяния в поле отталкивания $U = \frac{A}{r^2}$ в борновском приближении и согласно классической механике. Определить пределы применимости полученных формул.

Solution

Амплитуда рассеяния в борновском приближении имеет вид

$$f_{60_{\text{iA}}}(\hat{i}) = -\frac{\mu}{2\pi\hbar^2}\int e^{iqr}U(r)d\tau = -\frac{\pi_i A}{h^2 q},$$

где

$$\boldsymbol{q} = \boldsymbol{k}' - \boldsymbol{k}, \quad q = 2\boldsymbol{k}\sin\frac{\vartheta}{2}.$$

Отсюда

$$d\sigma_{\text{born}} = |f(\text{th})^2|d\Omega = \frac{\pi^3\mu A^3}{2\hbar^2 E}\operatorname{ctg}\frac{\text{th}}{2}d\,\text{th}$$

В классической механике связь между углом рассеяния и прицельным параметром имеет вид

$$\int\limits_{i_0}^{\infty}\frac{\mu\nu p dr}{r^2\sqrt{2\mu(E-U)-\left(\frac{\mu\nu p}{r}\right)^2}} = \frac{\pi-\vartheta}{2},$$

где r_0 - корень подкоренного выражения. Производя интегрирование, находим:

$$p^2 = \frac{A}{E}\frac{1}{v}\frac{(\pi-\vartheta)^2}{2\pi-\vartheta},$$

откуда

$$d\tau = -2\pi\rho\frac{d\rho}{d\vartheta}d\theta = \frac{2\pi^3 A}{E}\frac{\pi-\vartheta}{\vartheta^2(2\pi-\vartheta)^2}d\theta.$$

При выполнении условия

$$\frac{8\mu A}{h^2} \ll 1$$

борновское приближение применимо для всех углов (ср. с предыдущей задачей).

В обратном предельном случае, если $\frac{8\mu A}{\hbar^2} \gg 1$ классическое выражение применимо для не слишком малых углов

$$0 \geqslant \frac{h^2}{8\mu A},$$

а для меньших углов

$$0 \leqslant \frac{\hbar^2}{8\mu A},$$

справедливы результаты расчета в борновском приближении.

ГК-9.6.

Найти дискретные уровни для частицы в поле притяжения $U(r) = -U_0 e^{-\frac{r}{a}}$ при $l = 0$. Определить фазу рассеяния δ_0 для этого потенциала и проанализировать связь между δ_0 и дискретным спектром.

Solution

1+5

Для радиальной функции имеем уравнение

$$\chi'' + \frac{2\mu}{\hbar^2}\left(E + U_0 e^{-\frac{r}{a}}\right)\chi = 0$$

Введем обозначения $k^2 = \frac{2\mu E}{\hbar^2}, x^2 = \frac{2\mu U_0}{\hbar^2}$ и в качестве независимой переменной выберем $\xi = e^{-\frac{r}{2a}}$. Решениями получающегося при этом уравнения

$$\chi'' + \frac{1}{\xi}\chi' + 4a^2\left(\frac{k^2}{\xi^2} + x^2\right)\chi = 0$$

являются бесселевы функции мнимого порядка $\chi = J_{\pm 2aki}(2a\chi\xi)$. Условие обращения χ в нуль при $r = 0$, т. е. при $\xi = 1$, приводит с точностью до нормировочной постоянной К выражению

$$\chi = J_{-2aki}(2ax)J_{2aki}\left(2ax^{\xi}\right) - J_{2aki}(2ax)J_{-2aki}\left(2ax^{\xi}\right).$$

Асимптотический вид Функции χ при $r \to \infty(\xi \to 0)$
$\chi = J_{-2aki}(2ax)\frac{e^{2aki\ln ax}}{\Gamma(2aki+1)}e^{-ikr} - J_{2aki}(2ax)\frac{e^{-2aki\ln ax}}{\Gamma(-2aki+1)}e^{ikr}$.

Коэффициенты при e^{-ikr} и e^{ikr} можно рассматривать как функции комплексного k. Если их обозначить через $a(k)$ и $b(k)$, то, как нетрудно убедиться, выполняются соотношения

$$a(-k) = -b(k),$$
$$a^*(k) = -b(k)$$

(при взятии комплексно-сопряженной величины k не заменяется на k^*).
Запишем асимптотическое выражение γ в виде

$$\chi = A\left(e^{-ikr - i\delta_0} - e^{ikr + i\delta_0}\right) = -2iA\sin(kr + \delta_0).$$

Фаза рассеяния δ_0 определяется из соотношения

$$e^{2i\delta_0} = \frac{J_{2aki}(2ax)}{J_{-2aki}(2ax)}\frac{\Gamma(2aki+1)}{\Gamma(-2aki+1)}e^{-4aki\ln ax}.$$

Связанному состоянию соответствует чисто мнимое значение $k = ik_n$ (в этом случае энергия отрицательна).

Для $k_n > 0$ коэффициент при $e^{-ikr} = e^k n^r$ в первом слагаемом асимптотического выражения для % должен обращаться в нуль. Таким образом, либо $J_{2ak_n}(2ax) = 0$, либо $\frac{1}{1(2ak_n+1)} = 0$. 11з второго условия следует:

$$2ak_n + 1 = -n \quad (n = 0, 1, 2, ...),$$

Т. е.

$$E = -\frac{\hbar^2 k_n^2}{2\mu} = -\frac{\hbar^2(n+1)^2}{8\mu a^2},$$

однако при этом индексы бесселевых функций становятся цельми чисіами и, так как $J_n(x) = (-1)^n J_{-n}(x)$, два реше- ния оказываются линейно зависимыми и волновая функция (1) обращается тождественно в нуль. Поэтому полученные уровни энергии являются фиктивными. Первое условие дает истинный дискретный спектр задачи:

$$J_{2ak}(2ax) = 0, \quad E_n = -\frac{\hbar^2 k_n^2}{2\mu}$$

Таким образом, нули выражения $e^{2i\delta_0(k)}$ лежат на мнимой оси и, помимо значений ik_n, соответствующих дискретным уровням (2), содержат лишние нули.

1+7

а) $d\sigma = \left(\frac{g^2}{2E}\right)^2 \frac{dQ}{\left(\sin^2\frac{\vartheta}{2} + \frac{\hbar^2\alpha^2}{2\mu E}\right)^2}$; $\quad \sigma = \frac{\pi\mu^2 g^4}{\hbar^2 a^2(2\mu E + \hbar^2 a^2)}$;
б) $d\sigma = \frac{\pi\mu^2 U_0}{4\hbar^4\alpha^6}e^{-\frac{4\mu\cdot E}{\hbar^2\alpha^2}\sin^2\frac{\theta}{2}}d\Omega$
$J = \frac{\pi^2 U_0^2\mu}{4\hbar^2\alpha^4 E}\left(1 - e^{-\frac{4\mu\cdot E}{\hbar^2\alpha^2}}\right)$
В) $ds = \frac{16\mu^2 U_0^2}{h^4}\frac{a^2}{(\alpha^2+q^3)^4}dQ$ $\sigma = \frac{64\pi}{3}\frac{\mu^2 U_0}{\hbar^4}\frac{16k^4+12k^2\alpha^2+3\alpha^4}{\alpha^4(\alpha^4+4k^2)^3}$

ГК-9.7.

Показать, что для кулоновского поля имеется однозначное соответствие между полюсами амплитуды рассеяния и уровнями дискретного спектра.

Указание. Воспользоваться формулой

$$e^{2i\grave{\partial}}l = \frac{\Gamma\left(l+1+\frac{l}{k}\right)}{\Gamma\left(l+1-\frac{i}{k}\right)}.$$

Solution

(решений нет, думай сам, или тупой.)

ГК-9.8.

Определить в борновском приближении дифференциальное и полное сечение рассеяния в поле а) $U(r) = g^2\frac{e^{-\alpha r}}{r}$, б) $U(r) = U_0 e^{-a^2 r^2}$, В) $U(r) = U_0 e^{-\alpha r}$.

Solution

ГК-9.9. Сечения на водороде и на гелии

Используя борновское приближение, найти дифференциальное и полное сечение упругого рассеяния быстрых электронов а) атомом водорода; б) атомом гелия.

9а)

(???? хорошая задача, подумаю потом!!)

Вычисляем атомный формфактор для водорода $F(q) = \int e^{iqv} n(r) d\tau = \frac{1}{\pi a^3}\int e^{iqr-\frac{2r}{a}} d\tau = \frac{1}{\left(1+\frac{q^2 a^i}{4}\right)^2}$ $\left(a = \frac{\hbar^2}{\mu e^2} -\right.$ боровский радиус).

Отсюда находим дифференциальное сечение

$$d\sigma = \frac{4a^2\left(8+q^2a^2\right)^2}{\left(4+q^2a^2\right)^4} d\Theta \quad \left(q = 2k\sin\frac{\theta}{2}\right)$$

и полное сечение

$$s = \frac{\pi a^2}{3}\frac{7k^4a^4+18k^2a^2+12}{\left(k^2a^2+1\right)^3}.$$

Условие применимости борновского приближения принимает в данном случае вид

$$ka \gg 1,$$

поэтому последняя формула упрощается

$$\sigma = \frac{7\pi}{3k^2}.$$

9 б)

Для атома гелия распределение плотности электронов, найденное с помощью вариационного расчета, имеет следующий вид:

$$n(r) = \frac{2}{\pi b^3} e^{-\frac{2r}{b}}, \quad b = \frac{16}{27}a.$$

Дифференциальное и полное сечение упругого рассеяния на атоме гелия в этом приближении имеет тот же вид, что и для рассеяния на атоме водорода. Нужно лишь в формулах (1) и (2) заменить a на b и ввести общий множитель $Z^2 = 4$. В частности,

$$\sigma = \frac{28\pi}{3k^3}.$$

ГК-9.10.

Рассмотреть столкновения одинаковых частиц с энергией взаимодействия $U(r)$. Найти эффективное сечение рассеяния медленных одинаковых частиц в случае короткодействующих сил.

Solution

ГК-9.11.

Рассчитать сечение упругого рассеяния электрона на электроне и α-частицы на α-частице.

Solution

ГК-9.12. Рассеяние нейтронов

Рассеяние нейтронов на протонах зависит от суммарного спина нейтрона и протона. При малых энергиях сечение в случае триплетного соотношения ($S = 1$) равно $\sigma^{\tau\ \text{трпл}} = 4\pi|f_3|^2 \approx 2 \cdot 10^{-24} c^2$, а в случае синглетного ($S = 0$)$\sigma^{\text{curl}} = 4\pi|f_1|^2 \approx 78 \cdot 10^{-24} cM^2$. Введем оператор

$$\hat{f} = \frac{f_1 + 3f_3}{4} + \frac{f_8 - f_1}{4} \left(\hat{\sigma}_n \hat{\sigma}_p\right).$$

Как легко видеть, в случаях триплетного и синглетного состояний его собственные значения равны f_3 и f_1 соответственно. Для того чтобы определить сечение рассеяния при произвольной поляризации нейтронов, необходимо усреднить оператор $\hat{f}^2$:

$$\sigma = 4\pi\overline{\hat{f}^2}.$$

Пусть спиновое состояние падающих нейтронов описывается функцией $\begin{pmatrix} e^{-ia}\cos\beta \\ e^{i\alpha}\sin\beta \end{pmatrix}$ (направление спина нейтрона задается полярными углами $A = 2\beta, \Phi = 2\alpha + \frac{\pi}{2}$; см. задачу 11§4), а спиновое состояние протонов функцией $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$ (спины протонов направлены по оси z). Определить для этого случая сечение рассеяния нейтронов на протонах.

Solution

ГК-9.13.

Найти вероятность того, что рассеянный на протоне медленный нейтрон изменит ориентацию своего спина, если до столкновения спины нейтронов были направлены по оси z, а спины протонов - в противоположном направлении.

Solution

ГК-9.14.

Амплитуда рассеяния медленных нейтронов с энергиями заметно меньше тепловых $\left(\lambda > 10^{-8} c\mu\right.$, т. е. длина волны падающих нейтронов велика по сравнениго с взаимными расстояниями протонов в молекуле) на молекуле водорода равна сумме амплитуд для обоих протонов. Таким образом,

$$\hat{f} = \frac{f_1 + 3f_3}{2} + \frac{f_3 + f_1}{4} \left\{\hat{\sigma}_n \left(\hat{\sigma}_{p_1} + \hat{\sigma}_{p_v}\right)\right\}.$$

Протоны в молекуле водорода могут находиться как в состоянии с параллельными спинами (ортоводород), так и в состоянии с антипараллельными спинами (пароводород). Определить сечение рассеяния нейтронов на пароводороде и ортоводороде. 15. Определить полное сечение упругого рассеяния непроницаемоИ сферой радиуса a для быстрых частиц (длина волны де Бронля $\ll a$).

Solution

ГК-9.16.

Доказать следующие свойства амплитуды рассеяния при энергии $E \to 0$ (длины рассеяния): а) в поле отталкивания длина рассеяния отрицательна; б) в поле притяжения, если нет дискретных уровней, длина рассеяния положительна; в) длина рассеяния обращается в ∞, если при углублении потенциальной ямы появляется новый уровень. к эквивалентному интегральному уравнению ($E = 0$) то для асимптотического вида ψ получаем

$$\psi = 1 + \frac{a}{r},$$

где длина рассеяния

$$a = -\frac{\mu}{2\pi\hbar^2}\int \psi U d\tau$$

выражена через потенциальную энергию и $\psi_{E=0}$.

Solution

ГК-9.17.

Рассмотреть упругое рассеяние частиц со спином 1/2 на скалярной (спин равен нулю) частице. Найти дифференциальное сечение рассеяния с переориентацией спина. Рассмотреть рассеяние S и P волн.

18.1.14 Extra Problems about scattering 2

ГК-9.18. Известное разложение сечения в сумму двух (?????)

Доказать, что в общем случае неупругого рассеяния имеет место следующая формула, связывающая величину полсеяния при $0 = 0$

$$\sigma = \frac{4\pi}{k}\operatorname{Im} f(0).$$

Указание. Воспользоваться разложениями этих величин в ряды по орбитальному моменту:

$$f(i) = \frac{1}{2lk}\sum_{l=0}^{\infty}(2l+1)\left(\eta_l - 1\right)P_l(\cos i),$$

$$\sigma_{\text{ym}_\text{F}} = \frac{\pi}{k^2}\sum_{l=0}^{\infty}(2l+1)|1-\eta_l|^2,$$

$$\sigma_{\text{неупр}} = \frac{\pi}{k^2}\sum_{l=1}^{\infty}(2l+1)\left(1-|\Upsilon_l|^2\right).$$

Solution

ГК-9.19.

Рассмотрим предельный случай так называемого «черного» ядра. Радиус ядра R пусть будет велик в сравнении с де-бройлевской длиной волны нейтронов. Будем считать, что все нейтроны, попадающие в ядро, поглощаются. Определить полные сечения рассеяния и поглощения.

Solution

ГК-9.20.

Рассмотрим ядерную реакцию

$$A + a \to C \to B + b.$$

Как будет выглядеть угловое распределение продуктов ядерной реакции в системе центра инерции или, что то же саиое, в системе промежуточного ядра C в нижеперечисленшых случаях. Если равен нулю: а) спин промежуточного ядра; б) орбитальный момент относительного движения процуктов реакции; в) орбитальный момент относительного движения сталкивающихся тастиц (спин промежуточного ядра не равен чулю).

Solution

ГК-9.21.

Найти собственные функции операторэв квадрата и проекции полного изотопического спина I^2 и I_z системы нуклон—мезон *).

Solution

ГК-9.22.

В системе центра инерции рассеяние мезонов на нуклонах сводится к рассеянию частиц на неподвижном рассеивающем центре. Тогда вдали от центра падающая волна с определенным значением проекции спина S_z и проекции 'изотопического спина τ_z запишется в виде

$$e^{ikz}\begin{pmatrix}1\\0\end{pmatrix}\text{ò}\ (\pi-\pi_i)\,\delta\,(n-\tau_z)\,.$$

Здесь π_i принимает значения:

$$\begin{array}{ll}\pi_i=1 \text{ для } \pi^+\text{-мезона}, & \delta(\pi-1)=\varphi_+,\\ \pi_i=0 \text{ для } \pi^0\text{-мезона}, & \delta(\pi)=\varphi_0,\\ \pi_i=-1 \text{ для } \pi^-\text{-мезона}, & \delta(\pi+1)=\varphi_-,\end{array}$$

τ_z принимает значения:

$$\tau_z=\frac{1}{2}\text{ для протона}, \qquad \delta\left(n-\frac{1}{2}\right)=\psi_p,$$

$$\tau_z=-\frac{1}{2}\text{ для нейтрона}, \qquad \delta\left(n+\frac{1}{2}\right)=\psi_n.$$

Разложить падающую волну по собственным функциям операторов J^2, J_z, I^2, I_z.

Указание. В системе мезон-нуклон интегралами движения являются четн зсть $(-1)^l$, полный момент J, изотопический спин I.

Так как полный спин в такой системе равен $\frac{1}{2}$, то сохраняется также и орбитальный момент l. ПJэтому при разложении палающей волны по собственным функциям операторов сохраняющихся величин можно вместо суммирования по J, I суммировать по l, I.

Solution

ГК-9.23. Сечения пи мезонов на протонах через фазы

Найти амплитуды рассеяния π-мезонов на нуклонах, выраженные через фазы, для следующих реакции:

$$\pi^+ + p \to \pi^+ + p,$$
$$\pi^- + p \to \pi^- + p,$$
$$\pi^- + p \to \pi^0 + n.$$

Solution

ГК-9.24. Амплитуды для разных реакций (??????)

Показать, что амплитуды рассеяния для всех возможных реакций мезона с нуклоном выражаются через написанные в задаче 23 в силу гипотезы об изотопической инвариантности.

Выразить их через амплитуды рассеяния для состояний с изотопическим спином 3/2 и 1/2.

Solution

ГК-9.25. Полные сечения пи мезонов на протонах через фазы

Выразить через фазы полные сечения реакций:

$$\pi^+ + p \to \pi^+ + p,$$
$$\pi^- + p \to \pi^- + p,$$
$$\pi^- + p \to \pi^0 + n.$$

(???? в чем отличие от просто 9.23, не то же самое там???)

Solution

ГК-9.26.

В области малых энергий, когда длина волны мезона значительно больше радиуса сил взаимодействия между мезоном и нуклоном, основной вклад в рассеяние вносят лишь S и P-волны.

Найти дифференциальное сечение рассеяния, выраженное через фазы, для реакций:

$$\pi^+ + p \to \pi^+ + p,$$
$$\pi^- + p \to \pi^- + p,$$
$$\pi^- + p \to \pi^0 + n.$$

Solution

ГК-9.27. π-мезоны на поляризованных протонах

Пучок π-мезонов рассеивается на неполяризованной мишени из протонов, т. е. в мишени число протонов с $S_z = 1/2$ равно числу протонов с $S_z = -1/2$. Оказывается, что при рассеянии неполяризованные вначале протоны поляризуются. Определить величину поляризации протонов, учитывая только S - и P-волны.

Solution

10

1+9

Волновая функция системы из двух одинаковых частиц имеет вид произведения орбитальной и спиновой функций: Независимо от того, является ли спин частиц целым или полущелым, четному суммарному спину соответствует симметричная орбитальная волновая функция, а нечетному-антисимметричная.

После перехода к системе центра инерции и отделения переменной центра тяжести орбитальная волновая функция принимает вид.

$$\Psi\left(r_1, r_2\right) = \varphi(R)\psi(p),$$

где

$$R = \frac{\boldsymbol{r}_1 + \boldsymbol{r}_2}{2}, \quad p = \boldsymbol{r}_1 - \boldsymbol{r}_2.$$

При замене $\boldsymbol{r}_1$ на $\boldsymbol{r}_2$ функция $\varphi(R)$, опигывающая движение центра тяжести, очевидно, не меняется. Таким образом, волновая функция отногительного движения двух частиц должна быть четной

$$\psi(p) = \psi(-p)$$

в том случае, если суммарный спин S четен, и нечетной

$$\psi(p) = -\psi(-p),$$

если спин S нечетен.

Невозмущенную волновую функцию можно записать в виде

$$\psi(\rho) = e^{i\pi_{0p}} + e^{-ik_{op}p},$$

если S - четное, и

$$\psi(\rho) = e^{ik_0\rho} - e^{-ik_0\rho},$$

если S - нечетное. В результате взаимодействия частиц возникает рассеянная волна $\frac{F(\vartheta)}{\rho}e^{ikp}$, где ϑ-угол между $\boldsymbol{k}_0$ и направлением, в котором разлетаются частицы в системе центра инерции. Амплитуду рассеяния можно выразить через амплитуду рассеяния частицы с массой, равной приведенной массе обеих частиц в поле $U(r)$. Действительно, $\psi(\rho)$ удовлетворяет уравнению

$$\left\{-\frac{\hbar^2}{\mu}\left(\Delta_p + k^2\right) - U(p)\right\} \backsim (p) = 0.$$

Если падающей волне $e^{ik_p\rho}$ соответствует рассеянная $\frac{f(\vartheta)}{r}e^{ik\rho}$, то для падающей волны (1)

$$F_0(i) = f(i) + f(\pi -) \quad \text{(спин четен)},$$

а для (2)

$$F_1(\vartheta) = f(\vartheta) - f(\pi - \vartheta) \text{ (спин нечетен)}.$$

Вероятность рассеяния одной из частиц в телесном угле dQ (при этом другая частица движется в противоположном направлении), отнесенная к плотности падающего потока:

$$d\tau_0 = |f(9) + f(\pi - \vartheta)|^2,$$
$$d\sigma_1 = |f(\vartheta) - f(\pi - \vartheta)|^2.$$

Амплитуда $f(0)$ выражается через фазы рассеяния δ_l по формуле

$$f(\vartheta) = \frac{1}{2lk}\sum_{l=0}^{\infty}(2l+1)P_l(\cos\vartheta)\left[e^{2i\hbar}l - 1\right].$$

Принимая во внимание, что

$$P_l(\cos(\pi - \vartheta)) = P_l(-\cos\vartheta) = (-1)^l P_l(\cos\vartheta),$$

Находим:

$$F_0(i) = \frac{1}{lk}\sum_{\text{четные } l}(2l+1)P_{\text{Im}ath}(\cos i)\left[e^{2\dot{i}}l - 1\right],$$
$$F_1(i) = \frac{1}{ik}\sum_{\text{нечетные Im}ath}(2l+1)P_l(\cos i)\left[e^{2i\delta}l - 1\right].$$

Для медленных частиц наибольший вклад в рассеяние вносят малые l. В случае четного суммарного спина сечение (как и при рассеянии различных частиц) сферически симметрично и не обращается в нуль при $k \to 0$.

Если же суммарный спин нечетный, то сечение определяется членом с $l = 1$. Поскольку $\delta_l \sim k^{2l+1}$ для малых волновых чисел k, сечение обращается в нуль как E^2 (при $E \to 0$) и имеет угловую зависимость $\sim \cos^2\vartheta$.

11

В случае кулоновского поля амплитуда рассеяния

$$f(\vartheta) = -\frac{1}{2k^2\sin^2\frac{\vartheta}{2}}e^{-\frac{2i}{k}\ln\sin\frac{\theta}{2}\Gamma\left(1+\frac{l}{k}\right)}\frac{\Gamma\left(1+\frac{l}{k}\right)}{\Gamma\left(1-\frac{l}{k}\right)}.$$

Воспользовавшись результатом предыдущей задачи, находим дифференциальное сечение рассеяния в случае четного спина

$$d\sigma_0 = |f(n) + f(\pi - n)|^2 dQ = \frac{1}{4k^4}\left\{\frac{1}{\sin^4\frac{\theta}{2}} + \frac{1}{\cos^4\frac{\theta}{2}} + \frac{2\cos\left(\frac{2}{k}\ln\text{tg}\frac{\theta}{2}\right)}{\sin^2\frac{9}{2}\cos^2\frac{8}{2}}\right\}d\Omega.$$

Эта формула дает сечение рассеяния α-частиц, у которых спин равен нулю.

В случае двух электронов возможно состояние с суммарным спином 1. Тогда дифференциальное сечение

$$d\sigma_1 = |f(7) - f(\pi - \vartheta)|^2 = \frac{1}{4k^4}\left\{\frac{1}{\sin^4\frac{7}{2}} + \frac{1}{\cos^4\frac{\pi}{2}} - \frac{2\cos\left(\frac{2}{k}\ln\text{tg}\frac{\theta}{2}\right)}{\sin^2\frac{9}{2}\cos^2\frac{8}{2}}\right\}d\Omega.$$

Если рассеивающиеся электроны не поляризованы, то возможны три значения проекции суммарного спина вдоль некоторого направления $z : S_z = 0, S_z = 1, S_z = -1$ и два значения полного спина $S = 0$ и $S = 1$. Вероятность каждого из значений проекций $W_{-1} = \frac{1}{4}, W_0 = \frac{1}{2}, W_{+1} = \frac{1}{4}$. Значения $S_z = +1$ или $S_z = -1$ соответствуют непременно полному спину $S = 1$. Поскольку различные значения проекции для $S = 1$ равновероятны, то вероятность $S_z = 0$ при полном спине 1, так же как и для $S_z = \pm 1$, равна $\frac{1}{4}$. Таким образом, вероятность того, что полный спин $S = 0$, равна $w_0 - \frac{1}{4} = \frac{1}{4}$, а вероятность $S = 1$ равна $\frac{3}{4}$. Поэтому для неполяризованных пучков электронов

$$ds = \frac{1}{4}d\sigma_0 + \frac{3}{4}ds_1 = \\ = \frac{1}{4k^4}\left\{\frac{1}{\sin^4\frac{\theta}{2}} + \frac{1}{\cos^4\frac{\theta}{2}} - \frac{\cos\left(\frac{2}{k}\ln\mathrm{tg}\,\frac{\theta}{2}\right)}{\sin^2\frac{\theta}{2}\cos^2\frac{\theta}{2}}\right\}dQ.$$

Последний интерференционный член в фигурных скобках характерен для рассеяния тождественных частиц. При $\hbar \to 0$ формула для $d\sigma$ должна переходить в классическую формулу Резерфорда, которая для системы центра инерции имеет вид

$$ds = \frac{1}{4k^4}\left\{\frac{1}{\sin^4\frac{\%}{2}} + \frac{1}{\cos^4\frac{9}{2}}\right\}d\Omega.$$

Переход этой формуле происходит необычно. При выполнении условия $\frac{e^2}{\hbar v} \gg 1$, когда применимо классическое рассмотрение, интерференционный член, имеющий в обычных единицах вид

$$\frac{\cos\left(\frac{2e^2}{\hbar v}\ln\mathrm{tg}\,\frac{\vartheta}{2}\right)}{\sin^2\frac{\theta}{2}\cos^2\frac{\vartheta}{2}}$$

быстро осциллирует. Таким образом, квантовое дифференциальное сечение для строго фиксированного 7 существенно отличается от классического даже для больших значений $\frac{e^2}{\hbar\bar{v}}$. Однако при усреднении по небольшому интервалу углов $\Delta i \sim \frac{\hbar v}{e^2}$ интерференционный член обращается в нуль и квантовая формула переходит в классическую.

12.

$$\hat{f}^2 = \frac{3}{4}f_3^2 + \frac{1}{4}f_1^2 + \frac{1}{4}\left(f_3^2 - f_1^2\right)\left(\hat{\sigma}_n\hat{\sigma}_p\right).$$

Среднее значение оператора $(\hat{\sigma}_n\hat{\sigma}_p)$ в состоянии, характеризуемом спиновой Фуункцией равно

$$\begin{pmatrix} e^{-i\alpha}\cos\beta \\ e^{i\alpha}\sin\beta \end{pmatrix}_n \begin{pmatrix} 1 \\ 0 \end{pmatrix}_p,$$

$$\overline{\left(\hat{\sigma}_n\hat{\sigma}_p\right)} = \cos^2\beta - \sin^2\beta.$$

Таким образом, для сечения рассеяния находим выражение

$$\sigma = \pi\left\{3f_3^2 + f_1^2 - \left(f_3^2 - f_1^2\right)\cos 2\beta\right\}$$

HI

$$\sigma = \left\{\frac{3}{4}\sigma^{\text{трипл}} + \frac{1}{4}\sigma^{\text{сингл}} - \frac{\cos 2\beta}{4}\left(\sigma^{\text{Ti ипл}} - \sigma^{\text{сингл}}\right)\right\}.$$

В случае неполяризованного пучка нейтронов сечение равно

$$\sigma = \frac{3}{4}\sigma^{\text{ti ипл}} + \frac{1}{4}\sigma^{\text{сингл}},$$

поскольку $\overline{\cos 2\beta} = 0$.

13

Спиновое состояние нейтрона и протона до взаимодействия описывается Функцией

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}_n \begin{pmatrix} 0 \\ 1 \end{pmatrix}_p.$$

Эту функцию разложим по спиновым функциям синглетного и триплетного состояний

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}_n \begin{pmatrix} 0 \\ 1 \end{pmatrix}_p = \frac{1}{\sqrt{2}}\left[\frac{1}{\sqrt{2}}\left\{\begin{pmatrix} 1 \\ 0 \end{pmatrix}_n \begin{pmatrix} 0 \\ 1 \end{pmatrix}_p + \begin{pmatrix} 0 \\ 1 \end{pmatrix}_n \begin{pmatrix} 1 \\ 0 \end{pmatrix}_p\right\} + \right.$$

$$\left. + \frac{1}{\sqrt{2}}\left\{\begin{pmatrix} 1 \\ 0 \end{pmatrix}_n \begin{pmatrix} 0 \\ 1 \end{pmatrix}_p - \begin{pmatrix} 0 \\ 1 \end{pmatrix}_n \begin{pmatrix} 1 \\ 0 \end{pmatrix}_p\right\}\right].$$

Рассеянная волна имеет вид
или

$$\frac{e^{ikr}}{r}\frac{1}{\sqrt{2}}\left[f_3\frac{1}{\sqrt{2}}\left\{\begin{pmatrix}1\\0\end{pmatrix}_n\begin{pmatrix}0\\1\end{pmatrix}_p+\begin{pmatrix}0\\1\end{pmatrix}_n\begin{pmatrix}1\\0\end{pmatrix}_p\right\}+\right.$$
$$\left.+f_1\frac{1}{\sqrt{2}}\left\{\begin{pmatrix}1\\0\end{pmatrix}_n\begin{pmatrix}0\\1\end{pmatrix}_p-\begin{pmatrix}0\\1\end{pmatrix}_n\begin{pmatrix}1\\0\end{pmatrix}_p\right\}\right]$$
$$\frac{e^{ikr}}{r}\left\{\frac{f_3+f_1}{2}\begin{pmatrix}1\\0\end{pmatrix}_n\begin{pmatrix}0\\1\end{pmatrix}_p+\frac{f_3-f_1}{2}\begin{pmatrix}0\\1\end{pmatrix}_n\begin{pmatrix}1\\0\end{pmatrix}_p\right\}$$

отсюда следует, что вероятность переориентации равна

$$\frac{1}{2}\frac{(f_3-f_1)^2}{f_3^2+f_1^2}.$$

14

Введем оператор суммарного спина двух протонов

$$\frac{1}{2}\left(\hat{\sigma}_{p_1}+\hat{\sigma}_{p_2}\right)=\hat{\boldsymbol{S}}.$$

Как пегко показать,

$$\left(\hat{\sigma}_n\hat{S}^2=\hat{S}^2-\left(\hat{\sigma}_n\hat{S}\right).\right.$$

С. учетом последнего соотношения выражение для $\hat{f}^2$ примет вид
$\hat{f}^2=\frac{1}{4}\left\{(f_1+3f_3)^2+\left(5f_3^2-2f_3f_1-3f_1^2\right)\left(\hat{\sigma}_n\hat{\boldsymbol{S}}\right)+(f_3-f_1)^2\hat{\boldsymbol{S}}^2\right\}$
В случае рассеяния на параводороде сечение равно

$$\sigma^{\text{papa}}=\pi\left(f_1+3f_3\right)^2.$$

Естественно, что это сечение не зависит от поляризации падающих нейтронов, поскольку нет физически выделенного направления в пространстве.
Сечение рассеяния на ортоводороде равно
$\sigma^{\text{or ro}}=\pi\left\{(f_1+3f_3)^2+\right.$

$$\left.+\left(5f_3^2-2f_3f_1-3f_1^2\right)\cos 2\beta+2\left(f_3-f_1\right)^2\right\}$$

где 2β - угол между направлениями суммарного спина двух протинов и спина нейтрона.
Если пучок нейтронов не поляризован, то среднее значение $\cos 2\beta$ по смешанному ансамблю равно нулю и σ° примет вид

$$\sigma^{\text{орто}}=\pi\left\{(f_1+3f_3)^2+2\left(f_3-f_1\right)^2\right\},$$

а отношение сечений будет равно

$$\frac{\sigma^{\text{орто}}}{\sigma^{\text{пог'}}}=1+2\left(\frac{f_3-f_1}{f_1+3f_3}\right)^2$$

15

1+14

Радиальные функции, удовлетворяющие граничному условию $\chi_l(a)=0$, выражаются следующим образом через бесселевы функции:

$$\chi_l=\sqrt{r}\left\{J_{-l-1/2}(ka)J_{l+1/2}(kr)-J_{l+1/2}(ka)J_{-l-1/2}(kr)\right\}$$

Из формул для асимптотического поведения бесселевых Функций находим фазы рассеяния

$$\operatorname{ctg}\delta_l=(-1)^{\mathrm{Im}ath+1}\frac{J_{-l-1/2}(ka)}{J_{l+1/2}(ka)}.$$

Отсюда полное сечение упругого рассеяния

$$\sigma = \frac{4\pi}{k^2}\sum_{l=0}^{\infty}(2l-1)\frac{J^2_{l+l_{i,2}}(ka)}{J^2_{l+1,2}(ka)+J^2_{-l-1,2}(ka)} \approx 2\pi a^2.$$

17

1+16

На больших расстояниях от мишени (мишень состоит из скалярных частиц) волновая функция падающих частиц имеет вид

$$e^{ikz}\begin{pmatrix}1\\0\end{pmatrix} = \frac{1}{2kr}\sum_{l=0}^{\infty} i^{l+1}(2l+1)\begin{pmatrix}1\\0\end{pmatrix}P_l(\cos v)\times$$
$$\times\left\{e^{-i\left(kr-\frac{\pi l}{2}\right)} - e^{i\left(kr-\frac{\pi l}{2}\right)}\right\}.$$

Разложим функцию $\begin{pmatrix}1\\0\end{pmatrix}P_l(\cos\vartheta)$ по собственным функциям оператора $\hat{J}^2$. В результате разложения получим:

$$\begin{pmatrix}1\\0\end{pmatrix}P_l(\cos\theta) = \frac{2\sqrt{\pi}}{\sqrt{2l+1}}\begin{pmatrix}1\\0\end{pmatrix}Y_{l0}(\theta) =$$
$$= \frac{2\sqrt{\pi}}{2l+1}\left\{\sqrt{l+1}\Psi_l^+ + \sqrt{l}\Psi_l^-\right\}.$$

Здесь через Ψ_l^+и Ψ_l^-мы обозначили функции Паули

$$\Psi_l^+ = \frac{1}{\sqrt{2l+1}}\begin{pmatrix}\sqrt{l+1}Y_{l0}\\ \sqrt{l}Y_{l1}\end{pmatrix}\quad\left(j=l+\frac{1}{2},l,j_z=\frac{1}{2}\right),$$
$$\Psi_l^- = \frac{1}{\sqrt{2l+1}}\begin{pmatrix}\sqrt{lY_{l0}}\\ -\sqrt{l+1}Y_{21}\end{pmatrix}\quad\left(j=l-\frac{1}{2},l,j_z=\frac{1}{2}\right)$$

(см. задачу 20§4).
Подставляя (2) в (1), имеем:

$$e^{ikz}\begin{pmatrix}1\\0\end{pmatrix} \approx \frac{\sqrt{\pi}}{kr}\sum_{l=0}^{\infty} i^{l+1}\left\{\sqrt{l+1}\Psi_l^+ + \sqrt{l}\Psi_l^-\right\}\times$$
$$\times\left\{e^{-\left(kr-\frac{\pi l}{2}\right)} - e^{i\left(kr-\frac{\pi l}{2}\right)}\right\}.$$

В результате взаимодействия изменится только расходящаяся волна $\frac{e^{ikr}}{r}$.

Так как при любом законе взаимодействия этих частиц $\hat{j}^2, \hat{l}^2$ и $\hat{j}_z$ будут интегралами движения (см. задачу 39§4), то изменение в общем случае будет различно для состояний с различными квантовыми числами j, l. Для рассеянной волны получим выражение следующего вида:

$$\Psi_s \approx \frac{e^{ikr}}{r}\frac{\sqrt{\pi}}{ik}\sum_{l=0}^{\infty}\left\{\sqrt{l+1}\left(\eta_l^+ - 1\right)\Psi_l^+ + \sqrt{l}\left(\eta_l - -1\right)\Psi_l^-\right\},$$
$$\eta_l^+ = \eta\left(j=l+\frac{1}{2},l\right),$$
$$\eta_l^- = \eta\left(j=l-\frac{1}{2},l\right)$$

или $\Psi_8 \approx \frac{e^{ikr}}{r}\frac{\sqrt{\pi}}{ik}\sum\limits_{l=0}^{\infty}\frac{1}{\sqrt{2l+1}}\times$
$X\left\{\begin{pmatrix}1\\0\end{pmatrix}Y_{l0}\left[(l+1)\left(\eta_l^+-1\right)+l\left(\eta_i--1\right)\right]+\begin{pmatrix}0\\1\end{pmatrix}Y_{l1}\left(\eta_l+-\eta_l-\right)\right\}$

Отсюда видно, что переориентация спина частицы может произойти в том случае, когда $r_l^+ \neq \eta_i^-$. Выразим сечение рассеяния через η_i^+и η_i^-.

Дифференциальное сечение рассеяния с изменением поляризации $d\sigma_1$ равно

$$d\sigma_1 = \frac{\pi}{k^2}|\sum_{l=0}^{\infty}\sqrt{\frac{l(l+1)}{2l+1}}\left(\eta_l + ...\eta_l^-\right)Y_{l1}|^2 dQ,$$

а сечение $d\sigma_2$ без изменения поляризации равно $d\sigma_2 = \frac{\pi}{k^2}|\sum\limits_{l=0}^{\infty}\frac{1}{\sqrt{2l+1}}Y_{l0}\left\{(l+1)\left(\eta_l^+ - 1\right) + l\left(\eta_l^- - 1\right)\right\}|^2 dQ$.

Когда относительная скорость частиц не велика, нужно принимать во внимание рассеяния только S - и P-волн

$$\left(|\eta_l^+ - 1| \ll 1, \quad |\eta_l^- - 1| \ll 1, \quad \text{если} \quad l > 1\right).$$

В этом случае

$$d\sigma_1 \approx \frac{1}{4k^2}\left(\eta_1^+ - \eta_1\right)\sin^2\theta d\Omega,$$
$$d\sigma_2 \approx \frac{1}{4k^2}|\cos\vartheta\left(2\eta_1^+ + \eta_1^- - 1\right) + \eta_0^+ - 1|^2 d\Omega.$$

Из выражения для $d\sigma_1$ видно, что частицы, изменившие ориентацию спина, рассеиваются главным образом в направлении, перпендикулярном оси z.

19

1+18

Поскольку $R \gg \lambda$, то можно применять квазиклассические соображения. В ядро попадают все частицы с $l \leqslant \frac{R}{\pi}$, следовательно,

$$\eta_l = 0 \text{ для} \quad l < \frac{R}{\lambda},$$
$$r_{il} = 1 \quad \text{для} \quad l > \frac{R}{\lambda}.$$

Подставляя значение η_l в выражение для полных сечений $\sigma_r = \pi\lambda^2\sum(2l+1)\left(1 - |\eta_l|^2\right)$, $\sigma_s = \pi\lambda^2\sum(2l+1)|1-\eta_{il}|^2$, имеем:

$$\sigma_r = \sigma_s = \pi\lambda\sum_{l=0}^{\frac{R}{\lambda}}(2l+1) \approx \pi R^2.$$

Таким образом, полное сечение $\sigma = \sigma_r + \sigma_s$ равно удвоенному геометрическому сечению ядра.

20

Во всех трех случаях распределение изотропно.

21

Собственные функции оператора I_z для системы мезон - нуклон записываются как всевозможные произведения функций φ и (???). При этом, φ относится различным зарядовым состояниям мезона $(\varphi_+, \varphi_0, \varphi_-)$, а у нуклона $\left(\bigsqcup_p, \iota_n\right)$. Всего таких фуикций будет шесть:

$(p^+) = \varphi_+\psi_p$ $I_z = \frac{3}{2}$	$(p^0) = \varphi_0\psi_p$ $I_z = \frac{1}{2}$	$(p^-) = \varphi_-\psi_p$ $I_z = -\frac{1}{2}$
$(n^+) = \varphi_+\psi_n$ $I_z = \frac{1}{2}$	$(n^0) = \varphi_0\psi_n$ $I_z = -\frac{1}{2}$	$(n^-) = \varphi_-\psi_n$ $I_z = -\frac{3}{2}$

Здесь (p^+)обозначает функцию системы, составленной из π^+-мезона и протона; (n^+)- функцию, составленную из π^+-мезона и нейтрона и т. д. Эти функции, вообще говоря, не являются собственными функциями оператора квадрата полного изотопического спина системы I^2.

Собственные функции I^2, одновременно принадлежащие заданному I_z, будут линейными комбинациями из вышенаписанных функций, взятых с коэффициентами Клебша - Жордана. Коэффициенты Клебша – Кордана для $m' = \pm 1/2$ имеют вид (см. задачу 20§4)

	$m'=\frac{1}{2}$	$m'=-\frac{1}{2}$
$I=j+\frac{1}{2}$	$\sqrt{\frac{j+M+\frac{1}{2}}{2j+1}}$	$\sqrt{\frac{j-M+\frac{1}{2}}{2j+1}}$
$I=j-\frac{1}{2}$	$-\sqrt{\frac{j-M+\frac{1}{2}}{2j+1}}$	$\sqrt{\frac{j+M+\frac{1}{2}}{2j+1}}$

В нашем случае $M=I_z, j=1, m'=\tau_z$.
Пользуясь этой таблицей, получаем собственные функции $\Phi^I_{I_z}$ операторов I^2 и I_z:

$$\Phi^{3/2}_{3/2}=\left(p^+\right),$$
$$\Phi^{3/2}_{1/2}=\sqrt{\frac{2}{3}}\left(p^0\right)+\sqrt{\frac{1}{3}}\left(n^+\right)$$
$$\Phi^{3/2}_{-1/2}=\sqrt{\frac{1}{3}}\left(p^-\right)+\sqrt{\frac{2}{3}}\left(n^0\right),$$
$$\Phi^{3/2}_{-3/2}=\left(n^-\right),$$
$$\Phi^{1/2}_{1/2}=-\sqrt{\frac{1}{3}}\left(p^0\right)+\sqrt{\frac{2}{3}}\left(n^{-1}\right),$$
$$\Phi^{1/2}_{-1/2}=-\sqrt{\frac{2}{3}}\left(p^-\right)+\sqrt{\frac{1}{3}}\left(n^0\right).$$

Отсюда легко выразить собственные функции системы мезон - нуклон через собственные функции I^2 и I_z. Они оказываются равными:
$(p^+)=\Phi^{3/2}_{2/2}, \quad (n^+)=\sqrt{\frac{1}{3}}\Phi^{3/3}_{1/2}+\sqrt{\frac{2}{3}}\Phi^{1/2}_{1,2},$
$\left(p^0\right)=\sqrt{\frac{2}{3}}\Phi^{3/2}_{1/2}-\sqrt{\frac{1}{3}}\Phi^{1/2}_{1/2}, \left(n^0\right)=\sqrt{\frac{2}{3}}\Phi^{3/2}_{-1/2}+\sqrt{\frac{1}{3}}\Phi^{1/2}_{-1/2},$
$(p^-)=\sqrt{\frac{1}{3}}\Phi^{3/2}_{-1/2}\cdots\sqrt{\frac{2}{3}}\Phi^{1/2}_{-1/2}, \quad (n^-)=\Phi^{3/2}_{-3/,\cdot}$

22

Разложение падающей волны имеет вид

$$\psi=e^{ikz}\begin{pmatrix}1\\0\end{pmatrix}\delta\left(\pi-\pi_i\right)\delta\left(n-\tau_z\right)=$$
$$=\sum_{l=0}^{\infty}il(2l+1)P_l(\cos\theta)\begin{pmatrix}1\\0\end{pmatrix}\delta\left(\pi-\pi_i\right)\delta\left(n-\tau_z\right)\frac{\sin\left(kr-\frac{\pi l}{2}\right)}{kr}=$$
$$=2\sqrt{\pi}\sum_{l=0}^{\infty}\sum_{I}^{\infty}C^{I\tau}_{I}\Phi^I_z I_z i^l\sqrt{2l+1}Y_{l0}\begin{pmatrix}1\\0\end{pmatrix}\frac{\sin\left(kr-\frac{\pi l}{2}\right)}{kr}$$

где $C^{I\tau}_{I^I_z}$ - коэффициенты Клебша - Жордана, определяемые из таблицы

	$\tau_z=\frac{1}{2}$	$\tau_z=-\frac{1}{2}$
$C^{3/2}_{I^3_z}$	$\sqrt{\frac{1}{2}+\frac{I_z}{3}}$	$\sqrt{\frac{1}{2}-\frac{I_z}{3}}$
$C^{1/2}_{\frac{1}{z}}$	$-\sqrt{\frac{1}{2}-\frac{I_z}{3}}$	$\sqrt{\frac{1}{2}+\frac{I_z}{3}}$

Здесь мы учли, чго (см. задачу 21)

$$\delta\left(\pi-\pi_i\right)\delta\left(n-\tau_z\right)=\sum_I C^{I\tau_z}_I\Phi^I_{I_z}$$

Введем функции Паули для $m_j=1/2$ (см. задачу 17 §9):

$$Y^+_l=\begin{pmatrix}\sqrt{\frac{l+1}{2l+1}}Y_{l0}\\ \sqrt{\frac{l}{2l+1}}Y_{l1}\end{pmatrix}; \quad Y^-_l=\begin{pmatrix}\sqrt{\frac{l}{2l+1}}Y_{l0}\\ \sqrt{\frac{l+1}{2l+1}}Y_{l1}\end{pmatrix}$$

и разложим по ним $Y_{l0}\begin{pmatrix}1\\0\end{pmatrix}$:

$$Y_{l0}\begin{pmatrix}1\\0\end{pmatrix}=\frac{1}{\sqrt{2l+1}}\left(\sqrt{l+1}Y_l^+ + \sqrt{l}Y_l^-\right).$$

Подставляя (3) в (1), получаем:

$$\bigcup = \frac{2\sqrt{\pi}}{kr}\sum_{l=0}^{\infty}\sum_I il\left(\sqrt{l+1}Y_l^+ + \sqrt{l}Y_l\right)\times$$
$$X\sin\left(kr-\frac{\pi l}{2}\right)C_z^{It}z\Phi_z^I =$$
$$= \frac{\sqrt{\pi}}{lkr}\sum_{l=0}^{\infty}\sum_I\left(\sqrt{l+1}Y_l^+ + \sqrt{l}Y_l\right)\times$$
$$XC_I^{I\tau}z\Phi_z^I\left(e^{ikr}-(-1)^l e^{-ikr}\right) =$$
$$= \frac{\sqrt{\pi}}{ik}\sum_{l=0}^{\infty}\sum_I C_I^{I\tau}z\Phi_z^I\left(\sqrt{l+1}Y_l^+ + \sqrt{l}Y_l^-\right)\frac{e^{ikr}}{r}-$$
$$-\frac{\sqrt{\pi}}{ik}\sum_{l=0}^{\infty}\sum_I C_I^{I\tau}z\Phi_I^I\left(\sqrt{l+1}Y_l^+ + \sqrt{l}Y_l\right)\times$$

23

1+22

Воспользуемся разложением падающей волны по собственным функциям сохраняющихся операторов (см. формулу (4) предыдущей задачи).

Каждый член этой суммы, соответствующий определенным значениям (l, J, I), будет рассеиваться независимо от других.

Следовательно, число частиц, обладающих (l, J, I), в процессе упругого рассеяния не меняется, поэтому влияние рассеивающего центра сводится к умножению на некоторый фазовый множитель $e^{2i\delta_{l\pm}^I}$. Здесь $\delta_{l\pm}^I = \delta_{l,J=1\pm\frac{1}{2}}^I$ зависит от l, J, I и не зависит от I_z вследствие гипотезы об изотопической инвариантности.

Следует заметить, что рассеивающий центр не влияет на сходящиеся волны, а влияет только на расходящиеся. Тогда волновая функция системы с учетом рассеяния запишется

$$\times(\quad -1)^l\frac{e^{-ikr}}{r}.$$

В ВиДе

$$\psi = \frac{\sqrt{\pi}}{lk}\sum_I\sum_{l=0}^{\infty}C_{I_z}^{I_z}z\times$$
$$\times\Phi_{I_z}^I\left(\sqrt{l+1}Y_l^+e^{2ii_l^l} + \sqrt{l}Y_l e^{2ii_{l-}^I}\right)\frac{e^{ikr}}{r}-$$
$$-\frac{\sqrt{\pi}}{ik}\sum_I\sum_{l=0}^{\infty}C_{I_z}^{I\tau}\Phi_I^I\left(\sqrt{l+1}Y_l^+ + \sqrt{l}Y_l^-\right)\frac{e^{-lkr}}{r}.$$

На больших расстояниях от рассеивающего центра ее можно представить в виде

$$\dot{\varphi} = \bigcup_{\text{пад}} + f\frac{e^{ikr}}{r}.$$

Здесь f-амплитуда рассеяния. Отсюда, вычитая из (1) выражение для (???)тал (см. формулу (4) задачи 22 § 9), получим:

$$f = \frac{\sqrt{\pi}}{ik}\sum_I\sum_{l=0}^{\infty}C_{I_z}^{I_z z}\times$$
$$\times\Phi_{I_z}^I\left\{\sqrt{l+1}Y_l^+\left(e^{2ii_{l+}^I}-1\right)+\sqrt{l}Y_l^-\left(e^{2ii_l^I}-1\right)\right\}.$$

Ф Фукций $\Phi_{I_z}^I$ разложим по собственным функциям оператора I_z

$$\Phi^I_{I_z} = C^{I_z}_{z}\delta(\pi - \pi_i)\delta(n-\tau_z) + C^{I_z - \tau_z}_{I_z}\delta(\pi-\pi_k)\delta(n+\tau_z),$$

где коэффициенты Клебша - Жордана $C_{I_z^I \tau_z}$ определяются из таблицы (2) задачи 22, а $\pi_k = \pi_i + 2\tau_z$. Подставляя (3) в (2), получим:

$$f = \frac{\sqrt{\pi}}{ik}\sum_I \sum_{l=0}^{\infty}\left\{G^{I\tau_z}_{I_z z_z}\delta(\pi-\pi_i)\,\hat{\delta}(n-\tau_z) + G^{I_{\bar{h}}}_{I_{z'}-\tau_z}\delta(\pi-\pi_k)\,\delta(n+\tau_z)\right\}\times$$
$$\times\left\{\sqrt{l+1}Y_l^+\left(e^{2ii^I_{l+}}-1\right)+\sqrt{l}Y_l^-\left(e^{2ii^I_{l-}}-1\right)\right\},$$

где

$$O^{I\tau_z}_{I_z\tau_z} = C^{I\tau_z}_z C^{I\tau'_z}_{I_z}$$

и z'_z обозначает конечное состояние нукпона.
Тогда, полагая:

$$f = f^{\tau_z}_{\tau_z}\hat{0}(\pi-\pi_i)\,\delta(n+\tau_z) +$$
$$-1 - f^{\tau}_z\delta(\pi-\pi_k)\,\delta(n+\tau_z)$$

Получим:

$$f^{\tau_z}_z = \frac{\sqrt{\pi}}{ik}\sum_I\sum_{i=0}^{\infty}C^{I\tau_z}_{z_z},\sqrt{l+1Y_l^+}\left(e^{2i\delta^I_l}+(1)+1\right.$$
$$\left.+\sqrt{lY_l-\left(e^{2i\delta^I_l}-1\right)}\right\}$$

где $G^{I\tau_z}_z$ для требуемых в задаче реакций даны в следующей таблице:

Реакция	$p^+ \to p^+$	$p^- \to p^-$	$p^- \to n^0$
$G^{3/2\,\tau_z}_{I_z\tau_z}$	1	$\frac{1}{3}$	$\frac{\sqrt{2}}{3}$
$G^{1/2\,\tau_z}_{I_z\tau_z}$	0	$\frac{2}{3}$	$-\frac{\sqrt{2}}{3}$

Подставляя эти значения $G^{It_z}_{I_z;}$ в (4), окончательно получаем:

$$f(p^+,p^+) = \frac{\sqrt{\pi}}{lk}\sum_{l=0}^{\infty}\left\{\sqrt{l+1}Y_l^+\left(e^{2ii_l^{8/2}}-1\right)+\right.$$
$$\left.+\sqrt{l}Y_l-\left(e^{2i\delta^2/2}-1\right)\right\},$$
$$f(p^-,p^-) = \frac{\sqrt{\pi}}{3ik}\sum_{i=0}^{\infty}\left\{\sqrt{l+1}Y_l^+\left(e^{2ii_l^2/2}+2e^{2ii^2/2}+3\right)+\right.$$

24

1+23

Таблица коэффициентов $G^{I_z}_{r_z\tau'_z}$ для все возможных реакций мезонов с нуклонами имеет вид

№ п/п	Реакция	I_z	$G^{3/2\,\tau_z}_{I_z\tau_z}$	$G^{1/2\,\tau_z}_{I_z\tau_z}$
1	$p^+ \to p^+$	3/2	1	0
2	$p^0 \to p^0$	1/2	2/3	1/3
3	$p^0 \to n^+$	1/2	$\sqrt{2}/3$	$-\sqrt{2}/3$
4	$p^- \to n^0$	$-1/2$	$\sqrt{2}/3$	$-\sqrt{2}/3$
5	$p^- \to p^-$	$-1/2$	1/3	2/3
6	$n^+ \to n^+$	1/2	1/3	2/3
7	$n^0 \to p^-$	$-1/2$	$\sqrt{2}/3$	$-\sqrt{2}/3$
8	$n^+ \to p^0$	1/2	$\sqrt{2}/3$	$-\sqrt{2}/3$
9	$n^0 \to n^0$	$-1/2$	2/3	1/3
10	$n^- \to n^-$	$-3/2$	1	0

$$f(p^-,\ n_0)=\frac{\sqrt{2\pi}}{3ik}\sum_{l=0}^{\infty}\Big[\sqrt{l+1}Y_l^+\left(e^{2i\delta_{l+}^{3/}}-e^{2i\delta_{l+}^{1/}}\right)+\sqrt{l}Y_l^-\left(e^{2i\delta_{l-}^{3/}}-e^{2i\delta_{l-}^{1/}}\right)\Big].$$

Так как фазы не зависят от I_z в силу гипотезы об изотопической инвариантности, то из таблицы (1) и формулы (4) задачи 23§9 непосредственно следует:
$f\left(p^+,p^+\right)=f\left(n^-,n^-\right)$,
$f\left(p^-,p^-\right)=f\left(n^{\div},n^+\right)$,
$f\left(p^0,n^+\right)=f\left(n^+,p^0\right)=f\left(p^-,n^0\right)=f\left(n^0,p^-\right)$,
$f\left(p^0,p^0\right)=f\left(n^0,n^0\right)$.
Выражения для первых трех амплитуд даны в задаче 23. Из таблицы (1) легко видеть, что

$$f\left(p^0,p^0\right)=\frac{1}{2}\left[f\left(p^+,p^+\right)+f\left(p^-,p^-\right)\right]$$

Пользуясь таблицей (1), получаем:
$f\left(p^+,p^+\right)=f\left(n^-,n^-\right)=f^{3/2}$
$f\left(p^-,p^-\right)=f\left(n+,^4n+\right)=\frac{1}{3}\left[f^3+2+2f^{i_i'}\right]$,
$f\left(p^0,n^+\right)=f\left(n^+,p^0\right)=$

$$=f\left(p^-,n^0\right)=f\left(n^0,p^-\right)=\frac{\sqrt{2}}{3}|f''...f^1!\Bigg]$$

1+3

$f\left(p^0,p^0\right)=f\left(n^0,n^0\right)=\frac{1}{3}\left[2f^{3/2}+f^{1/2}\right]$

1+24

Дифференциальное сечение рассеяния:

$$\frac{d\sigma}{d\Delta 2}=|f|^2,\ \text{где } dQ=\sin\theta d\theta d\varphi.$$

Полное сечение рассеяния:

$$\sigma=\int_0^{2\pi}\int_0^{\pi}|f|^2\sin\theta dtd\varphi_0.$$

Подставляя сюда амплитуды рассеяния указанных реакций, найденные в задаче 23 и учтя ортонормированность функций Паули

$$\iint\left(Y_l^+\right)^+\left(Y_{l'}^+\right)dQ=\iint\left(Y_l^-\right)^+\left(Y_{l'}^-\right)dQ=\delta l_{l'},$$
$$\iint\left(Y_l^+\right)^+\left(Y_{l'}^-\right)dQ=\iint\left(Y_l^-\right)^+\left(Y_{l'}^+\right)dQ=0,$$

получаем:

$$\sigma\left(p^+,p^+\right)=\frac{4\pi}{k^2}\sum_{l=0}^{\infty}\left\{(l+1)\sin^2\delta_{l+}^{3//+}+l\sin^2\delta_{l-}^{3/4}\right\},$$

$$\sigma\left(p^-,p^-\right)=\frac{4\pi}{3k^2}\sum_{l=0}^{\infty}\{(l+1)\times$$
$$\times\left[\sin^2\delta_{l+}^{8/2}+2\sin^2\delta_{l++}^{1/2}-\frac{2}{3}\sin^2\left(\delta_{l+}^{3/2}-\delta_{l+/2}^{1/2}\right)\right]+$$
$$+l\left[\sin^2\delta_{l-}^{3/2}+2\sin^2\delta_{l-}^{1/2}-\frac{2}{3}\sin^2\left(\delta_{l-}^{8/2}-\delta_{l-}^{1/2}\right)\right]\Bigg\},$$

$$\sigma\left(p^-,n^0\right)=\frac{8\pi}{9k^2}\sum_{l=0}^{\infty}\left\{(l+1)\sin^2\left(\delta_{l+}^{8/2}-\delta_{l+}^{1/2}\right)+l\sin^2\left(\delta_{l+}^{8/2}-\delta_{l-}^{1/2}\right)\right\}.$$

1+25

Дадим подробное решение для реакции (p^+, p^+). Амплитуда рассеяния для S - и P-волн имеет вид (см. задачу 23§9):

$$f\left(p^+, p^+\right) = \frac{\sqrt{\pi}}{lk}\left\{\alpha_0 Y_0^+ + \sqrt{2}\alpha_1 Y_1^+ + \beta_1 Y_1^-\right\},$$

rge

$$\alpha_0 = e^{2i\delta_0^{8/2}} - 1; \quad \alpha_1 = e^{2i\delta_1^{8}/\frac{2}{+}} - 1; \quad \beta_1 = e^{2ii_1^{2/2}-} - 1.$$

Тогда дифференциальное сечение рассеяния для S - и P-волн равно (здесь учтены явные выражения для функций Паули (см. задачу 22§9))

$$\begin{aligned}
&\frac{k^2}{\pi}\frac{d\sigma}{d\underline{Q}} = |Y_{00}|^2|\alpha_0|^2 + \\
&+ \frac{1}{\sqrt{3}}|Y_{00}||Y_{10}|\left\{2\left(\alpha_0\alpha_1^* + \alpha_0^*\alpha_1\right) + \left(a_0, 3_1^* + \alpha_{0,\beta_1}^*\right)\right\} + \\
&+ \frac{1}{3}|Y_{10}|^2\left\{4|\alpha_1|^2 + |3_1|^2 + 2\left(\alpha_1\beta_1^* + \alpha_1^*\beta_1\right)\right\} + \\
&+ \frac{2}{3}|Y_{11}|^2\left\{|\alpha_1|^2 + |\beta_1|^2 - \left(\alpha_1\beta_1^* + \alpha_1^*\beta_1\right)\right\}.
\end{aligned}$$

Так как шаровые функции Y_{lm} равны

$$Y_{00} = \frac{1}{\sqrt{4\pi}}; \quad Y_{10} = \sqrt{\frac{3}{4\pi}}\cos\theta; \quad Y_{11} = \sqrt{\frac{3}{8\pi}}\sin\theta e^{i\varphi},$$

то дифференциальное сечение запишется в виде

$$k^2\frac{d\sigma}{d\theta} = A + B\cos\theta + C\cos^2\theta,$$

где коэффициенты A, B, C равны

$$\begin{aligned}
A &= \frac{1}{4}\left\{|\alpha_0|^2 + |\alpha_1|^2 + |\beta_1|^2 - \left(\alpha_1\beta_1^* + \alpha_1^*\beta_1\right)\right\}; \\
B &= \frac{1}{4}\left\{2\left(\alpha_0\alpha_1^* + \alpha_0^*\alpha_1\right) + \left(\alpha_{01}^* + \alpha_0^*\beta_1\right)\right\}; \\
C &= \frac{3}{4}\left\{|\alpha_1|^2 + \left(\alpha_1\beta_1^* + \alpha_1^*\beta_1\right)\right\}.
\end{aligned}$$

Чтобы выразить коэффициенты A, B, C через фазы, воспользуемся тождествами

$$\begin{aligned}
&|e^{2i\cdot x} - 1|^2 = 4\,\mathrm{sit}^2\, x; \\
&\left(e^{2ix} - 1\right)\left(e^{-2iy} - 1\right) + \left(e^{-2ix} - 1\right)\left(e^{2iy} - 1\right) = \\
&= 4\left[\sin^2 x + \sin^2 y - \sin^2(x - y)\right].
\end{aligned}$$

Тогда:

$$\left.\begin{aligned}
A\left(p^+, p^+\right) = &\quad \sin^2\delta_0^{3/2} + \sin^2\left(\delta_{1+}^{3/2} - \delta_1^{3/2}\right); \\
B\left(p^+, p^+\right) = &\quad 3\sin^2\delta_0^{33/2} + 2\sin^2\delta_{1+}^{3/2} + \sin^2\delta_1^{3/2} - \\
&\quad -2\sin^2\left(\delta_0^{3/2} - \delta_{1+}^{3/2}\right) - \sin^2\left(\delta_0^{3/2} - \delta_{1-}^{3/2}\right); \\
C\left(p^+, p^+\right) = &\quad 3\left\{2\sin^2\delta_{1+}^{3/4} + \sin^2\delta_{1-}^{3/2} - \sin^2\left(\delta_{1+}^{8/2} - \delta_{1-}^{3/2}\right)\right\}.
\end{aligned}\right\}$$

Указанным способом легко подсчитать коэффициенты A, B, C для реакций (p^-, p^-)и $\left(p^-, n^0\right)$. Приведем лишь окончательные результаты:

$$\begin{aligned}
A\left(p^-\ p^-\right) = &\frac{1}{3}\sin^2\delta_0^{2/2} + \frac{2}{3}\sin^2\delta_0^{1/2} - \frac{2}{9}\sin^2\left(\delta_0^{3/2} - \delta_0^{1/2}\right) + \\
&+ \frac{1}{9}\sin^2\left(\delta_{1+}^{3/2} - \delta_{1-}^{3/2}\right) - \frac{2}{9}\sin^2\left(\delta_{1-}^{3/2} - \delta_{1-}^{1/2}\right) + \\
&+ \frac{2}{9}\sin^2\left(\delta_{1-}^{3/2} - \delta_{1+}^{1/2}\right) + \frac{2}{9}\sin^2\left(\delta_{1+}^{3/2} - \delta_1^{1/2}\right) + \\
&+ \frac{4}{9}\sin^2\left(\delta_{1-}^{1/2} - \delta_{1+}^{1/2}\right) - \frac{2}{9}\sin^2\left(\delta_{1+}^{3/4} - \delta_{1+}^{1/2}\right)
\end{aligned}$$

$$B\left(p^-,p^-\right)=\sin^2\delta_0^{3/2}+2\sin^2\delta_0^{1/2}+\frac{2}{3}\sin^2\delta_{1+}^{s/2}+$$
$$+\frac{4}{3}\sin^2\delta_{1+}^{2/s}+\frac{1}{3}\sin^2\delta_{1-}^{3/2}+\frac{2}{3}\sin^2\delta_{1-}^{1/2}-\frac{2}{9}\sin^2\left(\delta_0^{8/2}-\delta_{1+}^{3/2}\right)-$$
$$-\frac{4}{9}\sin^2\left(\delta_0^{3/3}-\delta_1^3/2\right)-\frac{1}{9}\sin^2\left(\delta_0^{3/2}-\delta_{1-}^{8/4}\right)-$$
$$-\frac{2}{9}\sin^2\left(\delta_0^{3/2}-\delta_1^{1/2}\right)-\frac{4}{9}\sin^2\left(\delta_0^{1/2}-\delta_{1+}^{2/2}\right)-\frac{8}{9}\sin^2\left(\delta_0^{1/2}-\delta_{1+}^{1/2}\right)-$$
$$-\frac{2}{9}\sin^2\left(\delta_0^{1/2}-\delta_1^{3/3}\right)-\frac{4}{9}\sin^2\left(\delta_0^{7/2}-\delta_1^{2/2}\right);$$

$$C\left(p^-,p^-\right)=2\sin^2\delta_{1+}^{3/2}+4\sin^2\delta_{1+}^{1/2}+\sin^2\delta_{1-}^{3/2}+\qquad+2\sin^2\delta_{1-}^{1/2}-\frac{2}{3}\sin^2\left(\delta_{1-+}^{2//}-\delta_{1+}^{1/2}\right)-$$
$$-\frac{1}{3}\sin^2\left(\delta_{1+}^{3/4}-\delta_{1-}^{3/2}\right)-\frac{2}{3}\sin^2\left(\delta_{1+}^2/\frac{2}{-2}\delta_{1-}^{1/2}\right)-$$
$$-\frac{2}{3}\sin^2\left(\delta_{1+}^{3/2}-\delta_{1-}^{3/2}\right)-\frac{2}{3}\sin^2\left(\delta_{1+}^{1/2}-\delta_{1-}^{3/2}\right);$$
$$A\left(p^-,n^0\right)=\frac{2}{9}\left\{\sin^2\left(\delta_0^{3/2}-\delta_0^{1/2}\right)+\sin^2\left(\delta_{1+}^{3/2}-\delta_{1+}^{1/2}\right)+\right.$$
$$+\sin^2\left(\delta_{1+}^{3/2}-\delta_{1-}^{3/2}\right)-\sin^2\left(\delta_{1+}^{3/2}-\delta_1^{2/2}\right).$$
$$-\sin^2\left(\delta_{1+}^{1/2}-\delta_{1-}^{2/2}\right)+\sin^2\left(\delta_{1+}^{1/2}-\delta_{1-}^{1/2}\right)+$$
$$\left.+\sin^2\left(\delta_1^{3/2}-\delta_{1-}^{1/2}\right)\right\};$$

$$B\left(p^-,n^0\right)=\frac{2}{9}\left\{-2\sin^2\left(\delta_0^{8/2}-\delta_{1+}^{3/2}\right)+2\sin^2\left(\delta_0^{3/2}-\delta_{+_+}^{1/2}\right)-\right.$$
$$-\sin^2\left(\delta_0^{s/4}-\delta_{1-}^{3/9}\right)+\sin^2\left(\delta_0^{8/3}-\delta_1^{1/2}\right)+$$
$$+2\sin^2\left(\delta_0^{1/2}-\delta_{1+}^{8/4}\right)-2\sin^2\left(\delta_0^{1/2}-\delta_{1+}^{1/2}\right)+$$
$$\left.+\sin^2\left(\delta_0^{1/2}-\delta_1^{3/2}\right)-\sin^2\left(\delta_0^{1/2}-\delta_1^{1/2}\right)\right\};$$
$$C\left(p^-,n^0\right)=\frac{2}{3}\left\{\sin^2\left(\delta_{1+}^{2/2}-\delta_{1+}^{z_1^{2/2}}\right)+\sin^2\left(\delta_{1+}^{8/2}-\delta_{1-}^{1/2}\right)-\right.$$
$$\left.-\sin^2\left(\delta_{1+}^{2/2}-\delta_{1-}^{3/2}\right)+\sin^2\left(\delta_{1+}^{2/2}-\delta_{1-}^{2/2}\right)-\sin^2\left(\delta_{1+}^{2/2}-\delta_{1-}^{1/2}\right)\right\}.$$

Полученные результаты имеют большое значение при изучении углового распределения рассеяния π-мезонов на протонах. Экспериментально можно проверить формулу (1) и определить коэффициенты A, B, C для реакций (p^+,p^+), (p^-,p^-), $\left(p^-,n^0\right)$. Тогда шесть неизвестных фаз $\delta_0^{3/2}, \delta_3^{1/2}, \delta_{1-1}^{2/3}, \delta_{1-}^{3/2}, \delta_{1+}^{1/9}, \delta_{1-}^{1/2}$ определяются из девяти уравнений (2), (3), (4), которые оказываются совместными.

Однако вычисленные фазы обладают неоднозначностью двоякого рода: во-первых, вследствие того, что в уравнения (2), (3), (4) входят квадраты синусов фаз и разностей фаз, последние определяются с точностью до знака; во-вторых, имеется несколько различных наборов фаз, удовлетворяющих опытным данным. Из них лучше других согласуется с экспериментом решение Ферми, в котором наибольший вклад в рассеяние вносит фаза $\delta_{1-1}^{3/,}$, проходящая через 90° при энергии мезона $E\approx 195$ Мэв в лабораторной системе координат, а фазы $\delta_{1-}^{3/3}, \delta_{1+}^{1/2}, \delta_{1-}^{1/2}$ малы.

Имеется ряд дополнительных критериев, позволяющих устранить указанные неоднозначности. Знаки фаз можно определить из соображений, основывающихся на принципе причинности, а также из опытов, специально учитывающих кулоновское взаимодействие. В выборе правильного решения могли бы помочь опыты по поляризации нуклонов отдачи, но в настоящее время они еще не поставлены. Ожидаемые величины поляризаций для реакций (p^+,p^+), (p^-,p^-), $\left(p^-,n^0\right)$ определяются в следующей задаче.

1+26

Рассмотрим подробно реакцию (p^+,p^+). Пусть спиновые функции протона:

$$\alpha=\begin{pmatrix}1\\0\end{pmatrix}\text{ для }\quad s_z=1/2;$$
$$\beta=\begin{pmatrix}0\\1\end{pmatrix}\text{ для }\quad s_z=-1/2.$$

Если вначале протон имел $s_z = 1/2$, то амплитуда рассеяния запишется в виде

$$f_{t_{i/2}} = f_{\alpha u}\alpha + f_{\alpha\beta,3}$$

и если вначале $\varsigma_z = -1/2$, то амплитуда рассеяния

$$f_{-1/2} = f_{\beta\alpha\alpha}\alpha + f_{\beta\beta\beta}3.$$

Здесь $f_{\alpha a}, f_{\beta\beta}$ - амплитуды рассеяния без переориентации спина и $f_{\alpha\beta}, f_{\beta\alpha}$ - с переориентацией спина. Амплитуды $f_{\alpha\alpha}$ и $f_{\alpha\beta}$ определяются из формул (5) задачи 23§9 как коэффициенты при столбцах $\begin{pmatrix} 1 \\ 0 \end{pmatrix}$ и $\begin{pmatrix} 0 \\ 1 \end{pmatrix}$, причем берутся только S и P-волны

$$f_{o\alpha} = \frac{\sqrt{\pi}}{tk}\left\{\alpha_0 Y_{00} + \frac{1}{\sqrt{3}}\left[2\alpha_1 + \beta_1\right]Y_{10}\right\},$$
$$f_{\theta\beta} = \frac{\sqrt{\pi}}{ik}\sqrt{\frac{2}{3}}\left(\beta_1 - \alpha_1\right)Y_{11},$$

где $\alpha_0, \alpha_1, \beta_1$ даны в задаче 26§9. Пользуясь выражениями для функций Паули при $m_j = 1/2$, легко получить:

$$f_{\beta\alpha} = \frac{\sqrt{\pi}}{ik}\sqrt{\frac{2}{3}}\left(\alpha_1 - \beta_1\right)Y_{1,-1};$$
$$f_{\beta\beta} = f_{\alpha\alpha}.$$

Если считать, что π-мезоны рассеиваются в плоскости xz, то полярный угол $\varphi = 0$, и следовательно:

$$f_{\alpha,3} = -f_{\beta\alpha}.$$

Тогда амплитуда рассеяния на протоне с $s_z = -1/2$ (см. (2))

$$f_{-1/2} = -f_{\beta\alpha}\alpha + f_{\alpha a i}3.$$

Так как вначале протоны не были поляризованы, то из формул (1) и (5) слелует, что и после рассеяния они останутся неполяризованными вдоль оси z.

Можно показать, что после рассеянииия поляризация протонов в плоскости xz отсутствует. Действительно, спиновые функции протона γ_θ и δ_0, соответствующие проекциям спина $1/2$ и $-1/2$ на ось z', проведенную в плоскости xz под углом θ к оси z, имеют вид

$$\begin{pmatrix} \gamma_\theta \\ \delta_\theta \end{pmatrix} = e^{-i\hat{y}_y\theta}\begin{pmatrix} \alpha \\ \beta \end{pmatrix} = \begin{pmatrix} \cos\frac{\theta}{2} & -\sin\frac{\theta}{2} \\ \sin\frac{\theta}{2} & \cos\frac{\theta}{2} \end{pmatrix}\begin{pmatrix} \alpha \\ \beta \end{pmatrix}$$

(см. задачу 19§4), Тогда

$$\begin{aligned} f_{1/2} =& f_{\alpha\alpha}\alpha + f_{\alpha\beta}\beta = \\ &= \left(f_{\alpha\alpha}\cos\frac{\theta}{2} - f_{\alpha\beta}\sin\frac{\theta}{2}\right)\gamma_\theta + \left(f_{\alpha\alpha}\sin\frac{\theta}{2} + f_{z\beta}\cos\frac{\theta}{2}\right)\delta_0; \\ f_{-1/2} =& -f_{\sigma\beta}\alpha + f_{\alpha\alpha}\beta = \\ &= -\left(f_{\alpha\alpha}\sin\frac{\theta}{2} + f_{\sigma\beta}\cos\frac{\theta}{2}\right)\gamma_\theta + \left(f_{\alpha\alpha}\cos\frac{\theta}{2} - f_{\alpha\beta}\sin\frac{\theta}{2}\right)\delta_0, \end{aligned}$$

т. е. поляризации в любом направлении в плоскости xz нет.

Однако протоны будут поляризованы вдоль оси y, перпендикулярной плоскости рассеяния. Чтобы найти величину поляризации, выразим $f_{1/2}$ и $f_{-1/2}$ через спиновые собственные функции

$$\gamma = \frac{\alpha + i\beta}{\sqrt{2}}; \quad \delta = \frac{\alpha - i\beta}{\sqrt{2}},$$

соответствующие направлению спина вдоль и против оси y. Тогда

$$f_{1/2} = \frac{1}{\sqrt{2}}\left(f_{\alpha\alpha} - if_{\alpha\beta}\right)\gamma + \frac{1}{\sqrt{2}}\left(f_{\alpha\alpha} + if_{\alpha\beta}\right)\delta,$$
$$f_{-1/2} = \frac{-i}{\sqrt{2}}\left(f_{\alpha\alpha} - if_{\alpha\beta}\right)\gamma + \frac{i}{\sqrt{2}}\left(f_{\alpha\alpha} + if_{\alpha\beta}\right)\delta.$$

Отсюда получаем:

$$W_+ \sim |f_{\alpha\alpha} - if_{\alpha\beta}|^2; \quad W_- \sim |f_{\alpha 2} + if_{\alpha\beta}|^2,$$

где W_+и W_-−вероятности того, чго спин после рассеяния будет направлен соответственно параллельно или антипараллельно оси y. Заметим, что формулы (6) справедливы независимо от первоначального значения s_z протона. Подставляя в (6) выражения (3) и (4) для $f_{\alpha\alpha}$ и $f_{\alpha,3}$, получим:

$$W_\pm \sim |\alpha_0 + (2\alpha_1 + \beta_1)\cos\theta \mp i\,(\beta_1 - \alpha_1)\sin\theta|_1^2,$$

или

$$W_\pm \sim |\left(e^{2ii_0^{3/2}} - 1\right) + \left(2e^{2ii_1^{3/2}+-3} + e^{2ii_1^{3/2}}\right)\cos\theta\pm$$
$$\pm i\left(e^{2i\hbar_1^{3/2}+} - e^{2ii_1^{3/2}}\right)\sin\theta|^3.$$

Iодобным же образом получим для реакций (p^-, p^-)и $\left(p^-, n^0\right)$:

$$W_\pm\left(p^-, p^-\right) \sim |\left(e^{2i\delta_0^{3/2}} - 3 + 2e^{2i\delta_0^{1/2}}\right) +$$
$$+\left(2e^{2i\delta_1^{3/2}} - 9 + 4e^{2ii_1^{1/2}} + +e^{2i\delta_1^{8/2}} + 2e^{2ii_1^{1/2}}\right)\cos\theta\pm$$
$$\pm\, i\left(e^{2i\delta_1^{3/2}} + 2e^{2ii_1^{1/2}+} - e^{2i\delta_1^{3/s}} - 2e^{2i\delta_i^{1/2}}\right)\cos\theta\Big|^2$$
$$W_\pm\left(p^-, n^0\right) \sim |\left(e^{2i\hbar_0^{3/2}} - e^{2i6^1\dot{0}'^2}\right) +$$
$$+\left(2e^{2i\delta_{11}^{32}} + -2e^{2i\delta_1^{1/2}} + e^{2i\delta_1^{3/3}} - -e^{2i\delta_1^{1/2}}\right)\cos\theta+$$
$$\pm\, i\left(e^{2i\delta_1^{3/2}} + e^{2i\delta_1^{1/2}} + -e^{2i\delta_1^{3/2}} + e^{2i\hat{\delta}_1^{1/2}}\right)\sin\theta|^2.$$

18.1.15 General problems about of uncertainty and matter waves 1

(maybe I'll move all it to the .tex file before, but currently they are not so important, so they are here)

О3.1-2.1 Волны размером протона

При каких кинетических энергиях электрона и протона их длины волн де Бройля близки к размеру протона $r_\text{p} \approx 0,8 \cdot 10^{-13}$см.

Solution

(?? просто сравнить формулы нужно?)
2.1. $T_\text{p} \approx 880$МэВ; $T_\text{e} \approx pc \approx 1550$МэВ.

О3.1-2.2;Иродов-6.57. Дебройлевская и комптоновская волны

Определить кинетическую энергию T электрона, при которой его дебройлевская и комптоновская длины волн равны между собой.

Solution

Просто сравниваем величины и пользуемся законами релятивистской механики. Мы помним, что $\lambda = \frac{h}{p}$ $\lambda_c = \frac{h}{m_e c}$ По условию $p = m_e c$, поэтому из $p^2c^2 = E^2 - \left(mc^2\right)^2$, деля на m^2c^4 и добавляя единицу, имеем $2 = \left(\frac{E_k}{m_e c^2} + 1\right)^2$. В итоге

$$E_k = (\sqrt{2} - 1)m_e c^2$$

$T = mc^2(\sqrt{2} - 1) = 0,212$МэВ

О3.1-2.3 Рассеяние протона

Протон с дебройлевской длиной волны $\lambda = 0,001$ нм упруго рассеялся под углом $\pi/2$ на первоначально покоившейся α-частице. Определить дебройлевскую длину волны λ' рассеянного протона.

Solution

(? по идее ф Комтона сразу дает ответ. но в ответах какой-то другой метод, его пока не понял, ответ какой-то с корнем, вообще пока нет идей, откуда это???)

2.3. $\lambda' = \sqrt{5/3}\lambda = 0,00129$НМ.

О3.1-2.4 Масса фотона

В опытах по распространению радиоволн с длиной волны $\lambda = 300$ м было установлено, что скорость v их распространения в вакууме совпадает со скоростью света c с точностью до $0,05\%$. Оценить на основе этих результатов верхнюю границу массы фотона.

Solution

Допустим, что фотон имеет энергию покоя $m_\gamma c^2$, тогда

$$\mathscr{E} = \sqrt{p^2c^2 + m_\gamma^2 c^4}$$

$$u = \frac{d\mathscr{E}}{d\rho} = \frac{pc}{\sqrt{p^2 + m_\gamma^2 c^2}} = \frac{c}{\sqrt{1 + (m_\gamma c\lambda/h)^2}}; \qquad \frac{u}{c} = \left[1 + \left(\frac{m_\gamma c\lambda}{h}\right)^2\right]^{-1/2} \geqslant 1 - \delta.$$

Тут $\lambda = h/p$ - дебройлевская длина волны фотона. Заметим что скорость фотона, в вакууме зависит от длины волны λ, т. е. в этом случае должна наблюдаться дисперсия электромагнитных волн в вакууме. По условию задачи $\delta = 5 \cdot 10^{-4}$, поэтому $m_\gamma \leqslant \frac{2h^2\delta}{c^2\lambda^2}$.

Ответ: $m_\gamma \leqslant 2 \cdot 10^{-43}$г; $\quad m_\gamma c^2 \leqslant 1,1 \cdot 10^{-10}$эВ.

О3.1-2.5 Ненулевая масса и расстояния

В опытах при измерении расстояния между Землей и Луной $\left(L = 3,8 \cdot 10^5\right)$ методом радиолокации оказалось, что результаты в оптическом и радиодиапазоне ($\lambda_1 = 20$см) не совпадают. Отличие в результатах измерений объяснялось попаданием излучения в разные точки лунной поверхности, которые могли отличаться по высоте на $\Delta L = \pm 100$ м. С другой стороны, этот результат можно интерпретировать как результат отражения фотона с ненулевой массой от ровной поверхности. Принимая это, оценить возможную верхнюю границу массы фотона m_γ (в эВ).

Solution

$$\mathscr{E} = \sqrt{p^2c^2 + m_\gamma^2 c^4}$$

$$u = \frac{d\mathscr{E}}{d\rho} = \frac{pc}{\sqrt{p^2 + m_\gamma^2 c^2}} = \frac{c}{\sqrt{1 + (m_\gamma c\lambda/h)^2}}; \qquad \frac{u}{c} = \left[1 + \left(\frac{m_\gamma c\lambda}{h}\right)^2\right]^{-1/2} \geqslant 1 - \delta.$$

$$m_\gamma \leqslant \frac{2h^2\delta}{c^2\lambda^2} = \frac{2hc}{\lambda_1}\sqrt{\frac{\Delta L}{L}} \approx 0,6 \cdot 10^{-8}\text{эВ}.$$

О3.1-2.6 Показатель преломления и работа выхода

Найти выражение для показателя преломления n электронных волн через работу выхода $A_0 = eV_0$ (V_0 - внутренний потенциал кристалла).

Solution

(??? я забыл начальные формулы фотоэффекта, тут длина волны через частоту выражается, а та почему через корень???? также, перепишу условие, там V нужно тоже задать)

$n = \frac{\lambda_0}{\lambda'} = \sqrt{\frac{\mathscr{E}+A_0}{\mathscr{E}}} = \sqrt{1 + \frac{V_0}{V}}$

$\mathscr{E}$ и V соответственно энергия электрона в вакууме и разность потенциалов, пройденная им).

О3.1-2.7 Закон преломления

Показать, что при преломлении электронной волны соблюдается закон преломления $\sin\varphi/\sin\varphi' = n$.
Указание. При проникновении в кристалл меняется лишь нормальная компонента скорости электрона.

Solution

(?? надо теорию перечитать)

О3.1-2.8 Модификация ф. Брэгга-Вульфа

Как нужно изменить формулу Брэгга-Вульфа, чтобы учесть преломление волн на поверхности кристалла? Считать, что отражающая плоскость параллельна поверхности кристалла.

Solution

(??? тоже пока это не понимаю. я условие не понял, мы изначально не учитываем что ли преломление?)
2.8. $2d\sqrt{n^2 - \cos^2\theta} = m\lambda_0$, где λ_0 - длина волны в вакууме, n - показатель преломления волн де Бройля, θ - угол скольжения.

О3.1-2.9 Показатель преломления электронных волн

Пучок электронов, ускоренный разностью потенциалов $V = 150$ В, падает на поверхность серебра, внутренний потенциал которого $V_0 = 15$ В. Найти показатель преломления электронных волн в серебре.

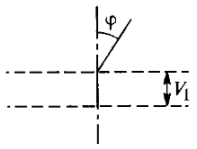
Solution

(??? как и в 2.6 не знаю, почему корень?)

$$n = \frac{\lambda_0}{\lambda'} = \sqrt{\frac{\mathscr{G} + A_0}{\mathscr{G}}} = \sqrt{1 + \frac{V_0}{V}} = 1,05$$

О3.1-2.10 Две сетки

Электроны с кинетической энергией $T = 100$ эВ падают под углом $\varphi = 30^\circ$ к нормали на систему, состоящую из двух параллельных сеток, между которыми создана разность потенциалов $V_1 = 36$ В:



Полагая, что потенциал нижней сетки выше, чем верхней, найти относительный показатель преломления n сред, расположенных по обе стороны от сеток. При какой разности потенциалов V_2 произойдет полное отражение электронов от второй сетки?

Solution

(???)
Очевидно, что полная энергия электрона, преодолевающего потенциальный барьер, сохраняется: $\mathscr{E} = T + U = \text{const}$, откуда $T = T_1 + eV_1$, где T и T_1 - кинетическая энергия до и после барьера. При этом

$$T = \frac{p^2}{2m} = \frac{p_\perp^2 + p_\parallel^2}{2m}$$

$p_\perp$ и $p_\parallel$- нормальная и касательная к границе раздела компоненты импульса. Поскольку скачок U связан с силами, действующими перпендикулярно к границе (электрического поля), то $p_\parallel$ =const. Откуда $p\sin\varphi = p_1\sin\varphi_1$. Относительным коэффициентом преломления сред является величина

$$n = \frac{\lambda}{\lambda_1} = \frac{h/p}{h/p_1} = \frac{p_1}{p} = \frac{\sin\varphi}{\sin\varphi_1} = \sqrt{\frac{T - eV_1}{T}} = \sqrt{1 + \frac{|e|V_1}{T}}.$$

210

Полное отражение электронов произойдет, когда $\sin\varphi_1 = 1$ (при этом разность потенциалов равна V_2), т. е.

$$\sin\varphi_1 = \frac{\sin\varphi}{\sqrt{1 + (|e|V_2)/T}} = 1 \text{ или } \frac{1}{4} = 1 + \frac{|e|V_2}{T}$$

откуда и следует второй ответ.

Ответ: $n = \sqrt{\frac{T+|e|V_1}{T}} = 1,17; V_2 = -\frac{3}{4}\frac{T}{|e|} = -75$ В, где e - заряд электрона.

О3.1-2.11

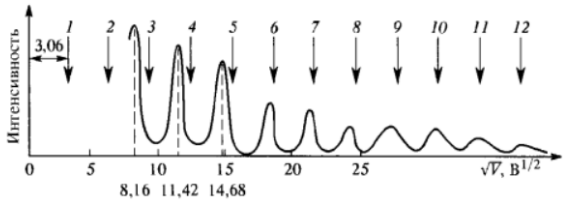
Пучок электронов падает перпендикулярно на поликристаллическую пластинку из хлористого натрия, постоянная решетки которого $a = 0,56$ нм. В результате брэгговского рассеяния пучка на фотопластинке Ф, расположенной на расстоянии $L = 25$см от пластинки , возникают концентрические дифракционные кольца (рис. 4). Определить энергию электронов, зная, что радиус первого кольша равен $R = 0.5$см.

2.

11. $\mathscr{E} = \frac{h^2}{2m}\left(\frac{L}{Ra}\right)^2 \approx 1,2 \cdot 10^4$ эВ.

О3.1-2.12 Опыт Дэвиссона и Джермера

На рис. ниже приведена кривая, полученная в опытах Дэвиссона и Джермера по рассеянию электронов от монокристалла никеля, падающих под углом скольжения 80°. По оси абсцисс отложено значение $\sqrt{V}$, где V - энергия электронов в вольтах, по оси ординат - относительная интенсивность рассеянных электронов. При больших порядках отражения m максимумы эквидистантны (расстояние между ними $3,06$ В$^{1/2}$), а при малых эта закономерность, показанная стрелками, нарушается. Оценить немонохроматичность используемых электронов и показатель преломления никеля для волны де Бройля электронов, соответствующих 3-му, 4-му и 5 -му максимумам, которые наблюдаются при $\sqrt{V}$, равном соответственно $8,16, 11,42$ и 14,68 В $^{1/2}$. Найти межплоскостное расстояние d никеля.



2.

12*: Решение. Для нерелятивистского электрона $\mathscr{E} = \frac{p^2}{2m} = \frac{h^2}{2m\lambda^2} \propto \frac{1}{\lambda^2}$. Поэтому искомую немонохроматичность электронов $\Delta\mathscr{E}/\mathscr{E}$ легко оценить по числу наблюдаемых отражений $m_{\max} = 12$, откуда следует $\Delta\lambda = \frac{\lambda}{m_{\max}} \approx \frac{\lambda}{12}$. И далее $\left|\frac{\Delta\mathscr{E}}{\mathscr{E}}\right| = 2\left|\frac{\Delta\lambda}{\lambda}\right| = \frac{1}{6}$.

Вне металла скорость электрона $v_1 \propto \sqrt{V}$, внутри металла $v_2 \propto \propto \sqrt{V_0 + V}$, где V_0 - внутренний потенциал металла. Таким образом, показатель преломления металла

$$n = \frac{\boldsymbol{v}_2}{\boldsymbol{v}_1} = \sqrt{1 + \frac{V_0}{V}}$$

Эквидистантное расположение максимумов интенсивности отраженных электронов наблюдается, когда внутренний потенциал металла

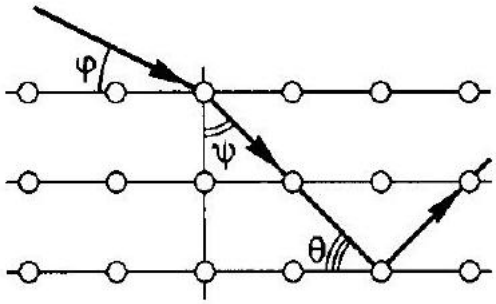


Рис. 138 $V_0 \ll V$. Это соответствует показателю преломления кристалла $n = 1$ (для $m \geqslant 6$). В этом случае в соответствии с формулой Брэгга-Вульфа (рис. 138)

$$2d\sin\varphi = m\lambda; \quad \lambda = \frac{2\pi\hbar}{\sqrt{2meV}}; \quad \sqrt{V} = \frac{2\pi\hbar}{\lambda\sqrt{2me}}$$

Последнее соотношение обычно записывают так

$$\sqrt{V} = \frac{12,26}{\lambda\,[\lambda]} = \frac{12,26m}{2d\sin\varphi}$$

где d следует подставлять в ангстремах [Å], а результат $\sqrt{V}$ получается в $\text{В}^{1/2}$. В нашем случае при $m = 1\sqrt{V} = 3,06\ \text{В}^{1/2}$, и поэтому межплоскостное расстояние $d = 2,03$Å. Из рис. 5 и условия задачи следует, что при $m < 6$ максимумы интенсивности неэквидистантны. Это означает, что при соответствующих энергиях показатель преломления отличается от 1 .

Закон преломления волн де Бройля идентичен классическому закону Снеллиуса:

$$\frac{\cos\varphi}{\sin\psi} = n; \cos\psi = \sqrt{1-\sin^2\psi} = \frac{1}{n}\sqrt{n^2-\cos^2\varphi}$$

По формуле Брэгга-Вульфа $n\cdot 2d\sin\theta = m\lambda$ или $n\cdot 2d\cos\psi = m\lambda$, откуда следует

$$2d\sqrt{n^2-\cos^2\varphi} = m\lambda$$

Обозначим через V' ускоряющий потенциал, соответствующий энергиям электронов, когда $n \neq 1$. Тогда

$$\sqrt{V'} = \frac{12,26}{\lambda[\text{Å}]} = \frac{12,26m}{2d\sqrt{n^2-\cos^2\varphi}}$$

Из соотношения $\sqrt{\frac{V}{V'}}$ мы и определим n : $\sqrt{\frac{V}{V'}} = \frac{\sqrt{n^2-\cos^2\varphi}}{\sin\varphi}$, откуда $n = \left(\frac{V}{V'}\sin^2\varphi + \cos^2\varphi\right)^{1/2}$.

Для $m = 5; \sqrt{V'} = 14,68\ \text{В}^{1/2}; \sqrt{V} = 15,3\ \text{В}^{1/2}; \quad n = 1,04.$
Для $m = 4; \sqrt{V'} = 11,42\ \text{В}^{1/2}; \sqrt{V} = 12,24\ \text{В}^{1/2}; n = 1,07.$
Для $m = 3; \sqrt{V'} = 8,16\ \text{В}^{1/2}; \sqrt{V} = 9,18\ \text{В}^{1/2}; \quad n = 1,12.$

О3.1-2.13 Падение электронов на движущейся кристалл

Параллельный пучок моноэнергетических нерелятивистских нейтронов, движущихся со скоростью v, падает на плоскую поверхность кристалла под углом скольжения θ_0 и испытывает на ней брэгговское отражение n-го порядка. Кристалл приводят в движение с постоянной скоростью u в направлении нормали к отражающей плоскости (рис. 6). Под каким углом θ к отражающей плоскости надо направить пучок таких же нейтронов, чтобы наблюдалось брэгговское отражение их от движущегося кристалла в прежнем порядке n? При какой скорости такое отражение возможно?

О3.1-2.15 Брэгговское отражение нейтронов

Чтобы получить пучок нейтронов, обладающих заданной энергией $\mathscr{E} = 1$ эВ, используют брэгговское отражение первого порядка от кристалла LiF, для которого расстояние между плоскостями кристаллической решетки $d = 2,32$Å. На кристалл падает пучок нейтронов с различными энергиями. 1) Оценить разброс нейтронов по энергиям $\Delta\mathscr{E}$ в отраженном пучке, если угловая ширина этого пучка $\Delta\varphi = 0,1^\circ$. 2) Какую толщину кристалла D следует выбирать в этом эксперименте? Кристалл вырезан так, что отражающие плоскости параллельны поверхности кристалла.

Solution

Условие Брэгга-Вульфа и масштаб бедствия по углам отклонения:

$$\sin\varphi = \frac{\lambda}{2d}$$

$$\lambda = \frac{h}{p} = \frac{h}{\sqrt{2mE}} \approx 0.287\text{Å}; \sin\varphi \approx \varphi \approx 0.06$$

Из закономерности: $\lambda \sim \varphi \sim E^{-1/2}$:

$$\frac{\Delta\lambda}{\lambda} = \frac{\Delta\varphi}{\varphi} = \frac{\Delta E}{2E}$$

Выражаем отсюда $\Delta E = 2E\frac{\Delta\varphi}{\varphi} \approx 0.58$ эВ

Вопрос с толщиной. Дифракционная решетка с разрешающей способностью:

$$\frac{\Delta\lambda}{\lambda} \leq R = mN = 1 \cdot \frac{D}{d}$$

окончательно $D = \frac{\lambda}{2\Delta\varphi} = 82$Å

(!! подумаю про это еще раз)

О3.1-2.18

Один из способов монохроматизации медленных нейтронов состоит в следующем: в цилиндре радиусом $R = 10$ см и длиной $L = 1,0$ м делается винтовой паз шириной $b = 1$см с поворотом на угол $\varphi = 30°$ (рис. 10). Цилиндр вращается с частотой $n = 3000$ об/мин. Определить длину волны λ нейтронов, пропускаемых таким монохроматором, и оценить степень их монохроматизации $\Delta\lambda/\lambda$. Пучок нейтронов направлен вдоль оси цилиндра. Оценить оптимальную ширину паза, при которой достигается максимальная монохроматичность пучка.

О3.1-2.19 Брегговский интерферометр и предельный заряд нейтрона (!??!?)

Нейтроны со скоростью $v_0 = 5 \cdot 10^5$см/с падают на брэгговский интерферометр, состоящий из трех тонких монокристаллических пластинок, вырезанных перпендикулярно главным кристаллическим плоскостям. На каждой из пластинок волна де Бройля разделяется на прошедшую и отраженную (рис. 11). Результат интерференции фиксируется счетчиком нейтронов C, скорость счета которого зависит от разности фаз в плечах интерферометра. В од ном из плеч с помощью электродов (не показанных на рис. 11) на участке длиной $l = 1$ см создается электрическое поле с разностью потенциалов $V = 300$ В. Если бы у нейтрона был электрический заряд, то включение поля изменило бы скорость счета счетчика C. Найти, какой предельный заряд q нейтрона может быть обнаружен в таком опыте, если чувствительность интерферометра к сдвигу фаз составляет $\Delta\varphi = 0,1$ рад.

18.1.16 General problems about of uncertainty and matter waves 2

О3.1-2.20

Нейтроны со скоростью $v_0 = 5 \cdot 10^5$см/ с падают на брэгговский интерферометр, описанный в задаче 2.19. В одном из плеч ин терферометра с помощью электродов (не показанных на рис. 11) на участке длиной $l = 1$ см создается электрическое поле $E = 3 \cdot 10^4$ В/cm. Если бы у нейтрона был электрический дипольный момент d, то включение поля повлияло бы на скорость счета счетчика. Найти, какая предельная величина d может быть обнаружена в таком опыте, если поле E параллельно предполагаемому направлению дипольного момента, а чувствительность интерферометра к сдвигу фаз $\Delta\varphi$ составляет 0,1 рад.

О3.1-2.21 Электроны проходят через лазер

Коллимированный пучок электронов с кинетической энергией $T = 1,65$ кэВ пропускается через резонатор лазера, работающего на длине волны $\lambda = 0,63$ мкм. При некоторых углах падения пучка относительно оси резонатора, близких к прямому, может наблюдаться брэгговское рассеяние электронов на стоячей электромагнитной волне (эффект Капицы-Дирака). Оценить возможные углы отклонения электронов.

Solution

(интересный эффект, в доп теории раздел про него создам, пока не совсем готов решать задачу)

О3.1-2.22

Исходя из требования, чтобы групповая скорость и волн де Бройля равнялась скорости движения v частицы, и пользуясь формулой Рэлея, связывающей фазовую и групповую скорости, определить фазовую скорость ш этих волн, а также найти связь между энергией частицы $\mathcal{E}$ и частотой v.

О3.1-2.23

Движение электрона описывается плоской монохроматической волной де Бройля. Электрон в таком состоянии обладает вполне определенным импульсом, но его координата совершенно не определена. Для определения x-координаты электрона на пути волны перпендикулярно к направлению ее распространения ставится непрозрачный экран со щелью. Пусть координатная плоскость XY расположена в плоскости экрана, причем ось X направлена перпендикулярно к щели. Показать, что в результате дифракции на щели возникает состояние электрона, в котором неопределённостей координаты электрона x и импульса p_x удовлетворяют соотношению Гейзенберга.

О3.1-2.24

В мысленном опыте Гейзенберга положение электрона определяется с помощью микроскопа при освещении электрона светом. Показать, что при таком методе измерения координата x и импульс p_x Электрона не могут быть определены более точно, чем требует соотношение неопределённостей Гейзенберга.

О3.1-2.25*

Скорость макроскопического тела измеряется по доплеровскому изменению частоты световой волны при отражении от этого тела (зеркала). Показать, что соответствующие неточности измерений импульса и положения тела удовлетворяют соотношению неопределённостей Гейзенберга.

О3.1-2.26

Какова должна быть кинетическая энергия T электронов (протонов) для исследования распределения заряда и ядерной материи внутри ядра с точностью $l \sim 1$ фм $\left(10^{-13}\text{см}\right)$, и структур с линейными размерами $l \sim 10^{-4}$ фм, что соответствует радиусу слабого взаимодействия?

О3.1-2.27

Из ускорителя через щель выводится короткий сгусток протонов с энергией $\mathcal{G} = 100$ кэВ. Оценить минимально достижимую ширину пучка протонов на расстоянии $L = 100$ м от выходной щели.

О3.1-2.28

Пучок протонов из ускорителя выводится через отверстие диаметром d. Используя соотношение неопределённостей, найти минимальный размер пучка на экране, расположенном на расстоянии $L = 1$ м от отверстия, если радиус орбиты в ускорителе $r = 10$ см, а величина магнитного поля в момент вывода $B = 300\Gamma c$.

О3.1-2.29

Оценить минимальный диаметр d пятна, создаваемого на экране пучком электронов, если время пролета от коллиматора до экрана равно 10^{-8}с.

О3.1-2.30

Оценить минимально достижимый диаметр d гятна, которое можно создать на детекторе пучком атомов серебра, испускаемых печью с температурой $t^\circ = 1200^\circ$с. Расстояние от выходной щели печи до детектора равно $L = 1$ м. Расчет произвести: 1) исхоая из волновой природы частиц (радиус первой зоны Френеля); 2) исходя из соотношения неопределённостей. Убедиться в эквивалентности обоих подходов.

О3.1-2.31 Радиус действия ядерных сил

Предполагая, что ядерные силы между нуклонами обусловлены обменом квантами ядерного поля - виртуальными пионами, оценить радиус Δr действия ядерных сил, если известно, что энергия покоя пионов $m_\pi c^2 \approx 140$ МэВ.

Solution

О3.1-2. 32

Оценить кинетическую энергию 8 электрона, локализованного в области пространства, радиус которого $r \sim 10^{-8}$см (атом) и $r \sim 10^{-12}$см (атомное ядро).

О3.1-2. 33

Оценить, при какой напряженности E электрического поля лазерного излучения может произойти пробой вакуума, т. е. разрыв виртуальных электрон-позитронных пар. См. также задачу 6.260 из второй части задачника.

О3.1-2.34 Минимальное видимое расстояние электронным микроскопом (??)

Определить теоретическое минимально разрешимое расстояние d электронным микроскопом при ускоряющем напряжении $V = 100$ кВ и числовой апертуре $A = 0,1$.

О3.1-2.35

Мезоатомы водорода (связанные состояния протона и мюона) исследуются с помощью электронного микроскопа с ускоряющим напряжением $V = 3$МВ. При какой числовой апертуре микроскопа можно определить размер мезоатома? Энергия покоя электрона $\oint_0 = 0,511$МВ, масса мюона $m_\mu \approx 200 m_\text{e}$.

О3.1-2.36

В новых сверхпроводящих материалах расстояние d между соседними атомами около 4Å. Определить, какую апертуру должен иметь электронный микроскоп с ускоряющим напряжением $V = 50$ кВ, чтобы можно было получить изображение кристаллической решетки этих материалов.

18.1.17 General problems about of uncertainty and matter waves 3

О3.1-2.37

У оптического микроскопа угловая апертура порядка 1, а у электронного она равна 10^{-4}. При каком напряжении, ускоряющем электроны, разрешающая сила этих приборов будет одинакова?

О3.1-2.38.

Электрон притягивается к поверхности жидкого гелия электростатическими силами изображения, гютенциальная энергия которых, как известно, равна

$$U(x) = \frac{e^2}{4x}\frac{\varepsilon - 1}{\varepsilon + 1}$$

где x - кратчайшее расстояние от электрона до поверхности, e - заряд электрона, $\varepsilon = 1,057$ - диэлектрическая проницаемость гелия (рис. 12). В то же время медленный электрон не может проникнуть внутрь гелия из-за отталкивания (так называемое отрицательное сродство гелия к электрону). Поэтому можно считать, что на поверхности ($x = 0$) потенциальная энергия испытывает бесконечный скачок и электрон оказывается в потенциальной яме (рис. 12, там просто типичный потенциал атома, падаем из бесконечности в нуле к минимуму, далее выпукло поднимаемся). Пользуясь этой моделью и соотношением неопределённостей, оценить по порядку величины среднее расстояние x электрона от поверхности гелия в основном состоянии и энергию связи $\mathscr{E}_\text{cs}$ Электрона вблизи поверхности гелия.

(дальше не выгружал, потому что их слишком много.)

О3.1-2.43. Оценки водорода и двухатомной молекулы

Оценить на основании соотношения неопределённостей радиус атома водорода в основном состоянии и энергию связи электрона в том же состоянии.

Определить на основании таких же оценок размер двухатомной молекулы и энергию её основного состояния,рассматривая молекулу как одномерный гармонический осциллятор с собственной частотой ω_0 и приведенной массой μ.

Solution. Атом водорода

(мб выше поставлю, хорошая по идее задача)
неопределённостей: $\Delta x \sim r; \Delta p \sim p \to p \cdot r = \hbar$. Полная энергия электрона в атоме водорода:

$$E = \frac{p^2}{2m} - \frac{e^2}{r} = \frac{\hbar^2}{2mr^2} - \frac{e^2}{r}$$

Атом находится в основном состоянии, значит, в состоянии с минимальной энергией. Найдем минимум через производную энергии по времени.

$$\frac{dE}{dt} = -\frac{\hbar^2 2r}{2mr^4} + \frac{e^2}{r^2} = 0 \to = \frac{\hbar^2}{me^2} = 0.53\text{Å}$$

Тогда энергия основного состояния:

$$E = \frac{\hbar^2}{2mr^2} - \frac{e^2}{r} = -\frac{me^4}{2\hbar^2} = -13.6 \text{ В}$$

Что интересно, эта оценка дает точно совпадающий с теорией Бора результат.

2. SOLUTIONS Волны де Бройля. Соотношение неопределенностей

2.

13. $\sin\theta = \sin\theta_0 \pm (u/v)$, где знак $\pm$ определяет направление движения кристалла ($/+$ - вниз, «-» - вверх). Отражение возможно при скоростях u, удовлетворяющих соотношению $|\sin\theta_0 \pm (u/v)| \leqslant 1$.

2.

14. $T = \frac{h^2}{3mk\lambda^2} = 14$ K, $d = \frac{\lambda}{2} = 0,335$.

2.

15: $D \geqslant \frac{\lambda}{2\Delta\varphi} = 82$Å.
Решение. Согласно условию Брэгга-Вульфа первый порядок ($m = 1$) отражения соответствуют углу

$$\sin\varphi = \frac{\lambda}{2d}$$

Длина волны, соответствующая энергии нейтрона Å $= 1$ эВ, равна $0,287$Å, поэтому $\lambda/(2d) \approx 0,06$. Это означает, что $\sin\varphi \approx \varphi \approx 0,06$. Очевидно, что $\frac{\Delta\varphi}{\varphi} = \frac{\Delta\lambda}{\lambda}$. Дебройлевская длина волны $\lambda = \frac{h}{p} = \frac{h}{\sqrt{2m\xi}} \propto \mathscr{E}^{-1/2}$. Поэтому $\left|\frac{\Delta\lambda}{\lambda}\right| = \frac{1}{2}\left|\frac{\Delta\mathscr{E}}{\varepsilon}\right|$. Откуда

$$\Delta\mathscr{E} = 2\mathscr{E}\frac{\Delta\lambda}{\lambda} = 2\mathscr{E}\frac{\Delta\varphi}{\varphi} \approx 0,58 \text{ эВ}$$

Толщину кристалла D выберем из тех соображений, что разрешающая способность такой системы $R = mN \geqslant \lambda/\Delta\lambda$, т. е. при $m = 1$ и числе интерферирующих пучков, равном числу слоев, $N = D/d$:

$$\frac{D}{d} \geqslant \frac{\lambda}{\Delta\lambda} = \frac{\varphi}{\Delta\varphi} = \frac{\lambda}{2d\Delta\varphi}$$

откуда

$$D \geqslant \frac{\lambda}{2\Delta\varphi} \approx 82\text{Å}.$$

Приведем другое решение этой задачи. Рассмотрим бесконечную решетку в направлении оси X (рис. 139). Волновая функция всей решетки представляет собой плоскую волну $A\exp\left(i\frac{p_x x}{\hbar}\right)$, где p_x - импульс решетки в направ-
лении оси X. При смещении всей решетки вдоль X на период d волновая функция умножается на $\exp\left(i\frac{p_x d}{\hbar}\right)$ и переходит сама в себя. Отсюда $p_x d = 2\pi m\hbar$, т. е. импульс, передаваемый решетке, квантован!

При

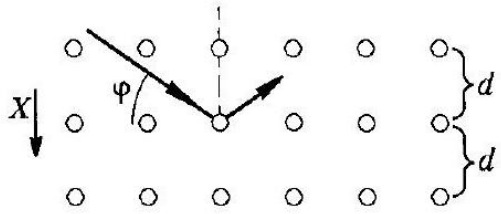

Рис. 139 упругом отражении $p_x = 2p\sin\varphi$, откуда следует $2d\sin\varphi = m(h/p) = m\lambda$. Таким образом, мы получили условие Брэг-га-Вульфа.

Если же решетка ограничена по x, то передаваемый по X решетке импульс приобретает неопределенность $\delta p_x \gtrsim h/D$. С другой стороны, $\delta p_x = 2p\delta(\sin\varphi) = 2p\cos\varphi\delta\varphi$. Поскольку $\cos\varphi \approx 1$, то

$$\delta\varphi = \frac{\delta p_x}{2p} \geqslant \frac{h}{D2p} \approx \frac{\lambda}{2D}.$$

Таким образом, искомая толщина кристалла $D \geqslant \frac{\lambda}{2\delta\varphi}$. Полагая $\delta\varphi \approx \Delta\varphi = 0,1°$, получим ответ.

2.

16: $T \approx \frac{\pi^2\hbar^2}{5kmd^2\theta^2} \approx 470$ K.

Решение. Под интенсивностью пучка молекул понимается плотность потока молекул с размерностью $\left[1/\left(\mathrm{cm}^2\cdot\mathrm{c}\right)\right]$. Плотность потока молекул, если считать их распределение по скоростям максвелловским, в интервале скоростей от v до $v + dv$ с точностью до известных констант равна

$$dj(v) \propto v\exp\left(-\frac{mv^2}{2kT}\right)v^2dv \qquad (*)$$

Далее пучок молекул испытывает рассеяние на кристаллических плоскостях LiCl. По условию Брэгта-Вульфа $2d\sin\theta = \lambda = 2\pi\hbar/(mv)$, где согласно графику порядок интерференции равен 1 , а m - масса молекулы водорода. Отсюда следует $v = \frac{\pi\hbar}{md\sin\theta}$. Из пучка шириной $d\theta$ дифракционное рассеяние испытывают молекулы из интервала скоростей dv, при этом

$$2d\cos\theta d\theta = -\frac{2\pi\hbar}{mv^2}dv$$

откуда $dv \propto v^2\cos\theta(v)d\theta$ с точностью до очевидных констант. Подставляя dv в (*), получим выражение для полного числа актов рассеяния молекул (плотность потока) в угол $d\theta$, имеющих скорость из заданного интервала скоростей, с точностью до известных констант

$$dN_{v,\theta} \propto v^3\exp\left(-\frac{mv^2}{2kT}\right)mv^2\cos\theta(v)d\theta.$$

Полагая, что $\cos\theta \approx 1$ (около 10°), $d\theta = \mathrm{const}$, найдем экстремум этой функции:

$$\frac{d}{dv}\left[v^5\exp\left(-\frac{mv^2}{2kT}\right)\right] = 0, \quad \text{откуда} \quad mv_{\max}^2 = 5kT$$

Таким образом,

$$T = \frac{m}{5k}\left(\frac{\pi\hbar}{md\sin\theta}\right)^2 \approx \frac{\pi^2\hbar^2}{5kmd^2\theta^2} \approx 470 \text{ K}.$$

При вычислениях из графика взято $\theta \approx 11°$.

2.

17. $\lambda = \frac{h\varphi}{m\Omega R} = 0,92$НМ, $\frac{\Delta\lambda}{\lambda} = \frac{a}{l\varphi} = 0,072$.

2.

18. $\frac{\hbar\varphi}{mLn} = 0,6$ нм; $\frac{\Delta\lambda}{\lambda} = \frac{b}{R\varphi} = 0,2$; $b_{\text{оптим}} = \sqrt{\lambda L} = 2,6 \cdot 10^{-3}$с (заметим, что этот численный ответ зависит от того, в какой форме взять соотношение неопределенностей: $\Delta p b \approx \hbar$ или h).

2.

19. $q < \frac{\Delta\varphi\hbar v_0}{Vl} \approx 5 \cdot 10^{-23}$ ед. СГСЭ.

2.

20* $d < \frac{\Delta\varphi\hbar v_0}{lE} \approx 5 \cdot 10^{-25}$ ед. СГСЭ или $d < e \cdot 10^{-15}$с, где e - заряд электрона в ед. СГСЭ.

Решение. Без поля сдвиг фаз на участке длиной l (разность хода!) $\varphi_0 2\pi l/h = lp_0/\hbar$, где p_0 - импульс частицы. При включенном поле импульс нейтрона должен измениться на Δp, и появится сдвиг фаз $\varphi_1 = l\left(p_0 + \Delta p\right)/\hbar$. Разность сдвигов фаз $\varphi_1 - \varphi_0 = \Delta\varphi = l\Delta p/\hbar$. Изменение импульса найдем из закона сохранения энергии: работа поля равна изменению кинетической энергии -

$$\frac{\left(p_0 + \Delta p\right)^2}{2m} - \frac{p_0^2}{2m} = Ed.$$

Из этого уравнения следует, что $\Delta p > Ed/v_0$. Отсюда получим $\Delta\varphi > \frac{l}{\hbar}\frac{Ed}{v_0}$ и дипольный момент $d < \frac{\Delta\varphi\hbar v_0}{lE}$.

2.

21*:

$$\theta \approx m\frac{2h}{\sqrt{2m_e T\lambda}} \approx m \cdot 10^{-4} \text{ рад, где } m = 1, 2, 3, \ldots$$

Решение. В резонаторе лазера устанавливается стоячая волна типа $E(x,t) \propto \sin kx e^{-i\omega t}$ (рис. 140). Электронная дебройлевская волна рассеивается на пучностях поля **E** стоячей волны, которые отстоят друг от друга на $\lambda/2$. Это и есть период структуры. От этих «плоскостей» происходит зеркаль ное отражение. Условие Брэгга-Вульфа (рис. 141) $2d\sin\varphi = m\lambda_{\text{дБ}}$;

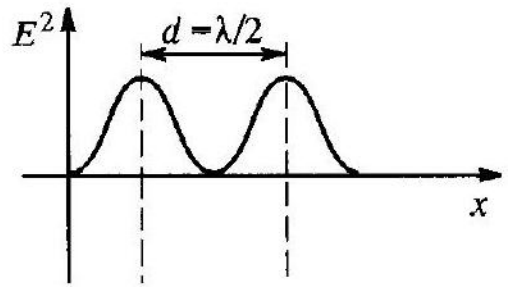

Рис. 140

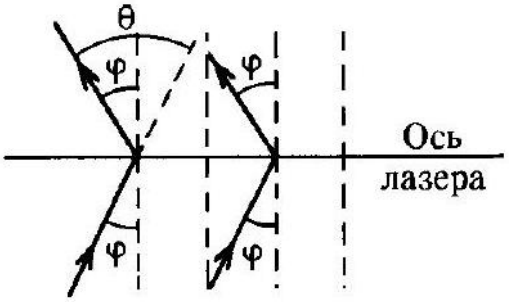

Рис. 141

$\lambda_{\text{дБ}} = h/p$. Поскольку кинетическая энергия электронов $T \ll m_e c^2$, то их можно считать нерелятивистскими. Поэтому $T = p^2/\left(2m_e\right)$ и $p = \sqrt{2m_e T}$. По условию угол скольжения $\varphi \ll 1$, таким образом,

$$\varphi \approx \dot{m}\frac{\lambda_{\text{ab}}}{2d} = m\frac{h}{\lambda\sqrt{2m_e T}}$$

Искомые углы отклонения

$$\theta = 2\varphi = m\frac{2h}{\lambda\sqrt{2m_e T}} \approx m \cdot 10^{-4} \text{ рад.}$$

2.

22*: $w = \frac{v}{2} + \frac{\text{const}}{v}, hv = \frac{1}{2}mv^2 + \text{const}$.

Решение. По формуле Рэлея групповая скорость $u = w - \lambda dw/d\lambda$. Полагая здесь $\lambda = h/p = h/(mv), u = v$ и рассматривая движение с нерелятивистскими скоростями, получим

$$v = w + v\frac{dw}{dv} = \frac{d}{dv}(wv),$$

откуда

$$w = \frac{v^2}{2} + \text{ const }, w = \frac{v}{2} + \frac{\text{const}}{v}.$$

Далее,

$$v = \frac{w}{\lambda} = \frac{v/2 + \text{ const }/v}{h/(mv)} = \frac{mv^2/2 + \text{ const}}{h}.$$

Во всех явлениях произвольные постоянные, входящие в выражения для v и w, не играют роли. Их можно положить равными нулю.

Разумеется, решение можно распространить и на движения с релятивистскими скоростями. Тогда, если отбросить не играющие роли постоянные интегрирования, формулы примут вид

$$w = \frac{c^2}{v}, hv = \frac{m_0 c^2}{\sqrt{1 - v^2/c^2}}$$

2.

23* Решение. Если электрон прошел через щель, то в плоскости самой щели координата x будет фиксирована с точностью $\Delta x \sim d$, где d - ширина щели. Однако в результате дифракции на щели волновая функция электрона ψ будет иметь максимумы и минимумы. Элек трон может быть обнаружен в любом месте, где $\psi \neq 0$. Наиболее интенсивным получится максимум нулевого порядка. Его угловая ширина равна 2θ, причем $d\sin\theta = \lambda$. Практически достаточно принять во внимание именно такой максимум. В этом приближении после прохождения через щель неопределенность Δp_x импульса электрона получится порядка $\Delta p_x = p\sin\theta = (h/\lambda)\sin\theta = h/d$. Таким образом, $\Delta x \Delta p_x \sim h$. Более определенное неравенство, которому должны удовлетворять Δx и Δp_x, с помощью этих соображений указать нельзя, поскольку не указан точный смысл самих величин Δx и Δp_x.

2.

24: При рассеянии фотона на электроне рассеянный фотон может попасть в любую точку плоскости изображения. Дифракционная картина в этой плоскости состоит из концентрических светлых и темных колец с центральным светлым кружком, называемым кружком Эйри, радиус которого равен $R \approx \lambda/\beta$ (рис. 142).

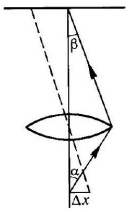

Рис. 142

Практически, рассеянный фотон может быть зафиксирован только внутри кружка, поскольку интенсивность там наибольшая. В этом приближении положение точки попадания фотона в плоскости изображения может быть определено с точностью порядка R. Неточность положения Δx электрона в предметной плоскости найдется из условия синусов Аббе $R\beta = \Delta x \sin\alpha$, т. е. $\lambda = \Delta x \sin\alpha$. При рассеянии фотона на электроне последний испытывает отдачу, в результате чего импульс электрона получает неконтролируемое приращение $\Delta p_x \sim \frac{h}{\lambda}\sin\alpha$. Таким образом, $\Delta x \Delta p_x \sim h$.

2.

25*. Решение. Пусть телом является идеально отражающее зеркало, а свет падает нормально на его поверхность. На основании законов сохранения энергии и импульса

$$\hbar\omega_0 + \frac{1}{2}Mv_0^2 = \hbar\omega + \frac{1}{2}Mv^2, \frac{\hbar\omega_0}{c} + Mv_0 = -\frac{\hbar\omega}{c} + Mv,$$

где M - масса тела, v_0 и v - его скорости до и после отражения света, ω_0 и ω - частоты падающего и отраженного фотонов. Переписав эти уравнения в виде

$$M\left(v^2 - v_0^2\right) = 2\hbar\left(\omega - \omega_0\right), M\left(v - v_0\right) = \frac{\hbar}{c}\left(\omega + \omega_0\right) \qquad (*)$$

почленным делением находим

$$v + v_0 = 2c\frac{\omega_0 - \omega}{\omega_0 + \omega}. \qquad ()$$

Для массивного зеркала $Mv^2/2 \gg \hbar\omega$. Поэтому $v \simeq v_0$, и тогда

$$v \simeq v_0 = c\frac{\omega_0 - \omega}{\omega_0 + \omega}.$$

Измерив частоты ω_0 и ω, можно по этой формуле вычислить скорость зеркала v. Частоту ω_0 можно считать измеренной точно. Тогда ошибка Δv в значении скорости будет определяться неточностью измерения частоты ω. Чтобы измерить ω с точностью $\Delta\omega$, надо производить измерение в течение времени Δt, удовлетворяющего условию $\Delta\omega\Delta t \sim 2\pi$. На основании $(^{**})$

$$\Delta v = -c\frac{2\omega_0\Delta\omega}{\left(\omega_0 + \omega\right)^2} \approx -c\frac{\Delta\omega}{2\omega_0}.$$

Так как моменты отражения фотона известны с ошибкой Δt, то неточность в значении скорости v поведет к ошибке Δx в определении координаты зеркала:

$$\Delta x \sim |\Delta v\Delta t| \sim \frac{c}{2\omega_0}|\Delta\omega\Delta t| \sim \frac{\pi c}{\omega_0}.$$

Согласно (*) при взаимодействии с фотоном зеркало получает неконтролируемое изменение импульса $\Delta p \sim 2\omega_0\hbar/$. Следовательно, $\Delta x\Delta p \sim 2\pi\hbar/c$ и

$$\Delta x\Delta p \sim 2\pi\hbar = h.$$

2.

26. $T > mv^2\sqrt{1 + (\Lambda/l)^2} - mc^2$, где $\Lambda = h/(mc)$ - комптоновская длина волны электрона (протона).

Для электрона $T > m_{\text{e}}c^2\Lambda_{\text{e}}/l_{\text{эл}} \approx 720$М или 7200 ГэВ во втором случае.

Для протона $T > m_{\text{p}}\text{c}^2\sqrt{1 + \left(\Lambda_{\text{p}}/l\right)^2} - m_{\text{p}}\text{c}^2 \approx 600$М или 8,2 ГэВ во втором случае.

2.

27. $d_{\min} = 2\sqrt{\frac{2Lh}{\sqrt{2m_{\text{p}}\varepsilon}}} \approx 8,5$mkM.

2.

28. $b = d + \frac{2hcl}{derB}$, откуда $b_{\min} = 2\sqrt{\frac{2hcl}{\text{er } B}} \approx 3,3 \cdot 10^{-4}$ cm.

2.

29. $d_{\min} = 2\sqrt{\frac{2h\tau}{m_e}} = 7,6$МКМ.

2.

30. $d \approx 2\sqrt{\frac{2hL}{\sqrt{3mkT}}} \approx 7,5$ мкм.

2.

31: $\Delta r \approx 2 \cdot 10^{-13}$ cm

Решение. Обмен «виртуальными» частицами - основной язык описания взаимодействия между реальными частицами в квантовой теории поля. Виртуальная частица - это частица, время жизни которой определяется соотношением неопределенностей, а не какими-либо другими физическими процессами. У виртуальной частицы есть энергия $\mathscr{E}$, импульс p, масса m. Однако для нее не выполняется обычное релятивисткое соотношение, и поэтому $\mathscr{E} \neq \sqrt{(pc)^2 + (mc^2)^2}$. Например, виртуальный фотон может обладать энергией и покоиться! Одна и та же частица, в зависимости от ситуации, может быть либо реальной, либо виртуальной. В связи с возникновением такой частицы в системе возникает неопределенность энергии $\Delta\mathcal{E}$, которая и определяет время жизни частицы $\boldsymbol{\tau} \sim \frac{\hbar}{\Delta}$. Через время $\tau \sim \frac{\hbar}{\Delta}$ поглащается либо самой испустившей ее реальной частицей или другой реальной частицей, и энергетический баланс в системе восстанавливается. В процессах испускания и поглощения выполняется закон сохранения импульса (хотя и направление импульса может и не совпадать с классическим).

При рассмотрении низкоэнергетических процессов, когда $^2 - p^2c^2 \ll \ll \left(mc^2\right)^2$, можно считать, что $\Delta\mathscr{E} \approx mc^2$, и тогда $\tau \sim \frac{\hbar}{mc^2}$. За это время частица может пройти расстояние $l \approx c\tau \sim \frac{\hbar}{mc} = \text{Å}_\text{K}$ - т. е. расстояние, равное комптоновской длине волны частицы. Это и есть радиус взаимодействия, обусловленный обменом виртуальными квантами.

2.

32. $\mathscr{E} \geq \hbar^2/8mr^2$. Для электрона в атоме $\mathscr{E} \geq 1 \ni$ В, для электрона в атомном ядре $\mathscr{E} \geq 10^{10}$ эВ $= 10^4$ МэВ. Электрон, будучи лептоном, может быть удержан в ядре только кулоновскими силами. Однако энергия взаимодействия $\sim Ze^2/R_{\text{яд}} \sim 1\text{М ВВ} \ll \mathscr{E} \sim 10^4$ МэВ.

2.

33: Решение. В полях такой напряженности из-за рождения виртуальных пар вакуум становится «поляризованной средой», а уравнения Максвелла теряют свойство линейности. Виртуальная пара живет время $\tau \sim \frac{\hbar}{\Delta\S} \sim \frac{\hbar}{2mc^2}$. Чтобы виртуальные частицы стали реальными, на длине $c\tau$ (на комптоновской длине волны) за счет работы электрического поля E дол-

жна набираться энергия, большая, чем $2mc^2$, т. е. $2mc^2 \approx eEc\tau \sim \frac{eE\hbar}{2mc}$, откуда $E \sim \frac{4m^2c^3}{e\hbar} \approx 2 \cdot 10^{14}$ ед. СГСЭ $= 6 \cdot 10^{16}$ В/с.

2.

34. $d = 0,61\frac{h}{A\sqrt{2meV}} = 0,024\text{НМ}$.

2.

35. $A = 0,83$ (в нерелятивистском приближении, $A = 1,73$). Числовая апертура A определяется из соотношения для минимально разрешаемого микроскопом расстояния $l \geqslant 0,61\frac{\lambda_e}{A}$, где $l = \frac{\hbar^2}{m_\mu e^2}$ - размер мезоатома, $\lambda_\text{e} = \frac{h}{p} = \frac{h}{\sqrt{(eV)^2 - (m_e c^2)^2}}$ - дебройлевская длина волны электрона.

2.

36. $A \approx \frac{h}{d\sqrt{2meV}} = 1,37 \cdot 10^{-2}$.

2.

37. $V = \frac{h^2}{2m_e e} \frac{1}{\lambda_{\text{опт}}^2} \left(\frac{\sin u_{\text{опт}}}{\sin u_{\text{эл}}} \right)^2 \approx 450$ В, где u - угловая апертура.

2.

38. $\bar{x} \approx \frac{4(\varepsilon+1)}{\varepsilon-1} r_1 \approx 76$Å, где $r_1 = \frac{\hbar^2}{me^2} = 0,53 \cdot 10^{-8}$ см - радиус первой боровской орбиты в атоме водорода. Энергия связи

$$\mathscr{E}_{\text{СВ}} \approx -\frac{me^4}{32\hbar^2} \left(\frac{\varepsilon-1}{\varepsilon+1} \right)^2 = \mathscr{E}_{\text{НОН}} \frac{1}{16} \left(\frac{\varepsilon-1}{\varepsilon+1} \right)^2 \approx -6,5 \cdot 10^{-4} \ni \text{ В}$$

где $\mathscr{E}_{\text{ион}} = \frac{me^4}{2\hbar^2} == 13,6$ эВ - энергия ионизации атома водорода.

2.

39: $\mathscr{E}_0 \approx 1,5 \left(\frac{k^2\hbar^2}{m} \right)^{1/3}, l \approx \sqrt[3]{\frac{\hbar^2}{km}}$.

Решение. В n-м стационарном состоянии квантовой системы, как следует из уравнений Шредингера, средние значения кинетической и потенциальной энергии удовлетворяют соотношению

$$\left\langle \widehat{T}_n \right\rangle + \left\langle \widehat{U}_n \right\rangle = \mathscr{E}_n$$

где $\widehat{T} = \frac{\hat{p}^2}{2m} = -\frac{\hbar^2}{2m} \frac{d^2}{dx^2}; \hat{U} = U(x); \mathscr{E}_n$ - полная энергия системы, а угловые скобки означают квантово-механическое среднее. Таким образом, $\frac{\langle \hat{p}^2 \rangle}{2m} + k\langle x \rangle = \mathscr{E}_n$. Для оценки энергии основного сос тояния воспользуемся тем, что в основном состоянии ($n = 0$) неопределенность координаты $\delta x \sim \langle x \rangle$, а неопределенность импульса $\delta p \sim \langle \hat{p} \rangle$ и $\langle \hat{p} \rangle^2 \sim \langle \hat{p}^2 \rangle$. Согласно соотношению неопределенностей получаем $\langle \hat{p} \rangle \langle x \rangle \sim \hbar$, откуда выражая, например $\langle x \rangle$ через $\langle p \rangle$, получим

$$\frac{\langle \hat{p} \rangle^2}{2m} + \frac{k\hbar}{\langle p \rangle} = {}_0$$

В основном состоянии энергия системы минимальна. Поэтому $\partial \mathscr{E}_0 / \partial \langle \hat{p} \rangle = 0$, т. е.

$$\frac{\langle \hat{p} \rangle}{m} - \frac{kh}{\langle \hat{p} \rangle^2} = 0$$

откуда $\langle \widehat{p} \rangle = p_0 = \sqrt[3]{km\hbar}$, а размер области локализации частицы в данной яме $l = \langle x \rangle = \frac{\hbar}{p_0} = \sqrt[3]{\frac{\hbar^2}{km}}$. Для энергии основного состояния получаем

$$\mathscr{E}_0 = \frac{3}{2m} (km\hbar)^{2/3} = 1,5 \left(\frac{k^2\hbar^2}{m} \right)^{1/3}$$

Приведем для сравнения точный результат, полученный из решения у равнения Шредингера для данного потенциала $\mathscr{E}_0 = 1,856 \left(\frac{k^2\hbar^2}{m} \right)^{1/3}$. Видно, что точность нашего приближенного подхода составляет примерно 20%.

2.

40*: Решение. Угол φ между направлением полета частиц и направлением излучения определяется из равенства

$$\cos\varphi = \frac{c}{nv}$$

Дифференцируем это выражение и заменяем дифференциалы конечными приращениями

$$\sin\varphi\Delta\varphi = \frac{c}{nv^2}\Delta v = \frac{c}{nm_e v^2}\Delta p$$

Электрон, находясь в слое вещества толщиной d, имеет неопределенность импульса $\Delta p \approx \hbar/d$, откуда следует неопределенность угла

$$\Delta\varphi \approx \frac{c\hbar}{dnm_e v^2 \sin\varphi}$$

2.

41: Решение. Чтобы имело смысл представление о классическом движении электрона по первой боровской орбите, необходимо выполнение соотношения $\Delta r \ll r_1$, где $r_1 = \hbar^2/me^2$ - радиус этой орбиты, а Δr - неопределенность положения электрона по радуису. Но тогда по соотношению неопределенностей соответствующая неопределенность в импульсе будет

$$\Delta p \approx \frac{\hbar}{\Delta r} \gg \frac{\hbar}{r_1} = \frac{me^2}{\hbar}$$

т. е. равна самому импульсу электрона $p = me^2/\hbar$. Однако по мере увеличения орбиты (увеличения квантового числа n), движение становится все более «классическим», что и постулируется принципом соответствия Бора.

2.

42. $\frac{l_n}{\lambda} = n, \lambda = \frac{h^2 n}{2\pi m e^2 Z} = 3,32 \cdot 10^{-8} \cdot \frac{n}{Z}$ cm.

2.

43: Решение. В стационарном состоянии квантово-механические средние значения кинетической и потенциальной энергий системы связаны соотношен ием

$$\langle T\rangle + \langle U\rangle = \mathscr{E}$$

где $\mathscr{E}$ - полная энергия системы.
B случае атома водорода $U = -\frac{e^2}{r}, T = \frac{p^2}{2\mu}$.

Если атом находится в основном состоянии, то $\Delta p \sim p; \Delta r \sim r$. Т.к. $\Delta p \Delta r \sim \hbar$, то $\mathscr{E} z \frac{\hbar}{2\mu r^2} - \frac{e^2}{r}$. Правая часть достигает минимума при

$$r = \frac{\hbar^2}{\mu e^2}$$

чем и определяется порядок величины размера атома водорода в основном состоянии. Соответствующая энергия

$$\mathscr{E} \geqq -\frac{\mu e^4}{2\hbar^2}$$

В случае двухатомной молекулья (если не учитывать ее вращения)

$$\langle T\rangle = \frac{\overline{p_x^2}}{2\mu}, \langle U\rangle = \frac{1}{2}\mu\omega_0^2\overline{x^2},$$

причем в силу соотношения неопределенностей в форме Вейля

$$\left(\overline{p_x^2} - \overline{p_x}^2\right)\left(\overline{x^2} - \bar{x}^2\right) \geqslant \frac{\hbar^2}{4}$$

В силу симметрии потенциальной ямы $\overline{p_x} = \bar{x} = 0$ и тогда
Таким образом,

$$\overline{p_x^2 x^2} \geqslant \frac{\hbar^2}{4}.$$

$$\frac{1}{2}\mu\omega_0^2\overline{x^2} + \frac{\hbar^2}{8\mu\overline{x^2}} \leqslant \mathscr{E}$$

Левая часть достигает минимума при $\overline{x^2} = \hbar/\left(2\mu\omega_0\right)$. Следовательно,

$$\mathcal{E} \geqslant \frac{1}{2}\hbar\omega_0.$$

Основное состояние - это состояние с минимально возможной энергией, и для него

$$\mathscr{E} = \frac{1}{2}\hbar\omega_0, \quad \overline{x^2} = \frac{\hbar}{2\mu\omega_0}.$$

Размер молекулы порядка $\sqrt{\frac{\hbar}{2\mu\omega_0}}$.

2.

44: $F \geqslant \sqrt{\frac{4\hbar m}{\tau^3}}$.

Решение. Минимальная сила, действие которой может быть определено по отклику свободной частицы (пробного тела) определяется квантово-механическими особенностями пробного тела и временем действия силы. При обнаружении малого внешнего воздействия на пробную квантово-механическую частицу требуется как минимум два измерения: начальной координаты и конечной (через время т). При этом мы не рассматриваем «снос» частицы $x = v_0\tau$ где v_0 - скорость свободной частицы, поскольку он не влияет на ответ.

Под действием силы частица движется с ускорением a, и за время т переместится на расстояние $l = \frac{a\tau^2}{2} = \frac{F_\tau^2}{2m}$. Этот результат справедлив и в квантовой механике. Зная координату частицы $x(0)$, т. е. в момент $t = 0$, мы могли бы знать положение частицы в момент $t = \boldsymbol{\tau} : x(\tau) = x(0) + l$. Следовательно, по крайней мере одно измерение координаты нам было бы необходимо.

Согласно основным представлениям квантовой механики при измерении вносится неконтролируемая неопределенность $\left\langle \Delta x_0^2 \right\rangle = \left\langle x^2 \right\rangle - \langle x \rangle^2$. В результате после измерения координаты возникает разброс в значении импульса $\left\langle \Delta p_x^2 \right\rangle$, который можно найти из соотношения неопределенностей в форме Вейля

$$\left\langle \Delta x_0^2 \right\rangle \left\langle \Delta p_x^2 \right\rangle \geqslant \frac{\hbar^2}{4}, \quad \text{откуда} \quad \left\langle \Delta p_x^2 \right\rangle \geqslant \frac{\hbar^2}{4\left\langle \Delta x_0^2 \right\rangle}$$

Через время т это приводит к неопределенности в пройденном расстоянии (конечную координату мы можем измерить сколь угодно точно).

$$\left\langle \Delta x_\tau^2 \right\rangle = \frac{\left\langle \Delta p_\lambda^2 \right\rangle \tau^2}{m^2} \geqslant \frac{\hbar^{22}_\tau}{4m^2\left\langle \Delta x_0^2 \right\rangle}.$$

Складывая обе дисперсии, в силу их статистической независимости получим

$$\left\langle \Delta x^2 \right\rangle = \left\langle \Delta x_0^2 \right\rangle + \left\langle \Delta x_\tau^2 \right\rangle \geqslant \left\langle \Delta x_0^2 \right\rangle + \frac{\hbar^{22}}{4m^2\left\langle \Delta x_0^2 \right\rangle}$$

Минимизируя полученное выражение по $\left\langle \Delta x_0^2 \right\rangle$, определяем неопределенность первого измерения координаты, которая обеспечит минимальную неопределенность пройденного за время т пути $\left\langle \Delta x_0^2 \right\rangle_{\min} = \hbar\tau/2m$. Это соответствует $\left\langle \Delta x^2 \right\rangle_{\min} = \hbar\tau/m$.

Силу можно будет зарегистрировать, если смещение l под действием силы окажется больше неопределенности пути

$$\frac{F\tau^2}{2m} \geqslant \sqrt{\frac{\hbar\tau}{m}}$$

откуда

$$F_{\min} = \frac{2m}{\tau^2}\sqrt{\frac{\hbar\tau}{m}} = \sqrt{\frac{4m\hbar}{\tau^3}}$$

2.

45: $F_{\min} = \sqrt{\frac{8\hbar^2 m}{\mathscr{E}_0 \tau^4}}$.

Решение. В этом случае мы измеряем энергию частицы до действия си лы и после. Первое измерение дает значение начальной энергии. Точность $\Delta\mathscr{E}$ такого измерения зависит от длительности измерения τ_1, т. е. $\Delta\mathscr{E} = \hbar/\tau_1$ (в принципе при достаточно большом τ_1 она может быть сделана сколь угодно малой). Поскольку полное время наблюдения ограничено величиной τ, то часть этого времени должна быть затрачена на измерение начальной энергии, а в оставшуюся часть времени $\tau - \tau_1$ будет происходить изменение энергии за счет работы силы F.

За время $\tau - \tau_1$ при условии $F\tau_1 \ll p_0$ изменение энергии

$$\Delta\mathscr{E}_0 = \frac{p_0 \Delta p}{m} = p_0 \frac{F(\tau - \tau_1)}{m}$$

Это изменение энергии можно обнаружить, если $\Delta\mathscr{E}_0 > \Delta\mathscr{E} = \hbar/\tau_1$, откуда

$$F \geqslant \frac{\hbar m}{p_0 \tau_1 (\tau - \tau_1)}.$$

Вводя $\mathscr{E}_0 = \frac{p_0^2}{2m}$ и минимизируя по τ_1, получаем

$$\tau_1 = \frac{\tau}{2} \quad \text{и} \quad F_{\min} = \frac{\hbar}{\tau^2}\sqrt{\frac{8m}{\varrho_0}}.$$

Заметим, что при подобных измерениях необходимо уменьшить все флуктуации энергии неквантовой природы (например, тепловые) до уровня меньше квантовых.

2.

46: Пороговая энергия рождения пары $\varrho = 2m_e c^2$. Эта энергия «появля-

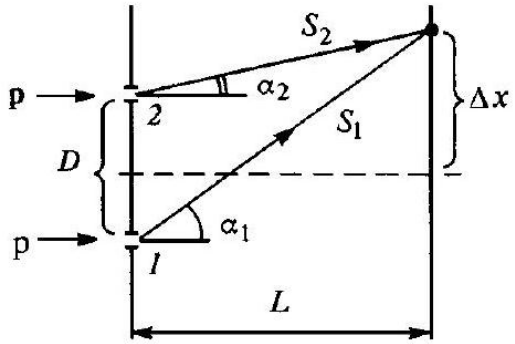

Рис. 143

ется» при попытке локализовать электрон в размере $\text{Å}_e/2$, где Å_e - комптоновская длина волны электрона. Действительно, при $\Delta x \simeq \frac{\Lambda_e}{2} = \frac{\hbar}{2m_e c}$ возникает неопределенность в энергии $\Delta\mathscr{E} = \frac{\hbar^2}{2m_e(\Delta x)^2}$, которая равна $2m_e c^2$. Таким образом в области $\sim \Lambda_e/2$ электрон не может рассматриваться как «точечный» объект.

2.

47. $t_{\text{изм}} \approx \frac{\hbar}{\mathscr{E}_\gamma} = 4 \cdot 10^{-20}\text{с}; \Delta\varrho \approx \frac{\hbar}{t_{\text{изм}}} = 15$ кэВ.

2.

48. Решение. Условие возникновения первого максимума $S_1 - S_2 = \lambda_{\text{дб}}$. Из геометрии разность хода (рис. 143)

$$S_1 - S_2 = \sqrt{\left(\frac{D}{2} + \Delta x\right)^2 + L^2} - \sqrt{\left(\Delta x - \frac{D}{2}\right)^2 + L^2} \approx \frac{D\Delta x}{L}$$

где использовано обычное условие эксперимента $L \gg D, \Delta x$.
Если электрон прошел через щель I, то изменение импульса экрана

$$|\Delta p_{x1}| = p\frac{\Delta x + D/2}{\sqrt{(\Delta x + D/2)^2 + L^2}}$$

а если через щель 2 , то

$$|\Delta p_{x2}| = p\frac{\Delta x - D/2}{\sqrt{(\Delta x - D/2)^2 + L^2}}$$

Чтобы определить по измерению импульса, через которую щель прошел электрон, нужно суметь различить по величине $|\Delta p_{x1}|$ и $|\Delta p_{x2}|$, т. е. точность измерений импульса должна быть лучше, чем

$$\Delta p_x = |\Delta p_{x1}| - |\Delta p_{x2}| \approx p\frac{\Delta x + D/2}{L} - p\frac{\Delta x - D/2}{2} = p\frac{D}{L}$$

Согласно соотношению неопределенностей

$$\delta x \delta p_x \sim h, \quad \text{откуда} \quad \delta x \sim \frac{h}{\delta p_x} \geqslant \frac{h}{\Delta p_x} = \frac{hL}{pD} = \frac{\lambda_{\text{ББ}}\, L}{D}.$$

Так как $\lambda_{\text{дБ}} = \frac{D\Delta x}{L}$, то $\delta x \geqslant \Delta x$. Тем самым неопределенность в положении щелей (обе щели смещаются как целое вместе с экраном) будет больше, чсм масштаб интерференционного расщепления, и картина размоется.

2.

49*: Решение. Пока расстояние d между расщепленными пучками меньше $0,61\lambda_{\text{ф}}$ (результат, хорошо известный в оптике как предельное разрешение двух светящихся точек), определить, каким путем движется атом, невозможно. Поэтому первое размытие картины произойдет при $d = 0,61\lambda_{\text{ф}}$. Так как угол дифракции мал, то, как следует из рис. 144 , размытие интерференционной картины произойдет при расстоянии между пучками

$$d \approx z\theta = z\frac{\lambda_{a\ \text{В}}}{a} = \frac{z}{a}\frac{h}{p}.$$

Поэтому

$$z = 0,61\lambda_{\Phi}\frac{a}{\lambda_{\text{дБ}}} = \frac{0,61\lambda_{\phi} aMv}{h} = 6 \text{ mm}.$$

Следует отметить, что при таком способе измерения координат атомов изза их большой массы $\Delta p_{\perp}$, возникающее из соотношения неопределенностей, очень мало.

2.

50. $F = \frac{n_0 h}{4d^2}\left(\lambda_2^2 - \lambda_1^2\right) \approx 5 \cdot 10^{-21}$ дин, где $\lambda_2 = 4\text{Å}$ и $\lambda_1 = 2\text{Å}$ (упруго рассеиваться будут все нейтроны с длиной волны $\lambda \leqslant 4\text{Å}$).

2.

51. $v = \frac{h}{M\lambda} = 2,77 \cdot 10^4$ cm/c, где $\lambda = \frac{d\Delta}{l}$ - длина волны фуллеренов.

2.

52. Скорость тримеров и димеров одинакова: $v = \frac{h}{\theta MNd} = 1,8 \cdot 10^6$ cm/c, где N - число ато-

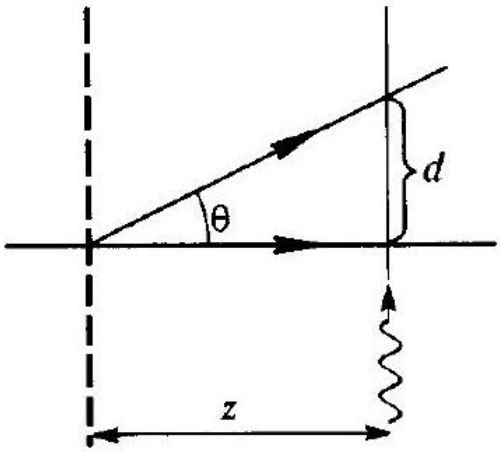

Рис. 144 мов гелия в кластере.

2.

53. $\Delta\varphi \simeq \sqrt[4]{\frac{\hbar^2}{m^2 l^3 g}}; \Delta L \simeq \left(\hbar^2 m^2 g l^3\right)^{1/4}$. Легко проверить, что $\Delta\varphi\Delta L \simeq \hbar$.

2.

54*: Решение. Флуктуация энергии в системе осцилляторов $\Delta\mathscr{E} = \Delta N\hbar\omega$; в свою очередь, $\Delta t = \frac{\Delta\varphi}{\omega}$. Поэтому $\frac{\Delta\mathscr{E}\Delta t}{\hbar} = \Delta N\Delta\varphi = 1$.

18.1.18 Basic problems about atoms in fields 1

(первые отсюда задачи в оптику скорее всего перенесу)

О3.1-6.1 Вращение диска светом

Пучок циркулярно поляризованного света с длиной волны $\lambda = 0,5$ мкм падает на зачерненный диск, подвешенный на тонкой нити так, что он может совершать крутильные колебания относительно оси. Измеряется установившийся угол поворота. Диск имеет массу $m = 1$ г и радиус $r = 5$см. Найти период собственных колебаний диска T, если при мощности светового потока $N = 10$ Вт угол поворота диска составил $\alpha = 1''$.

6.

1. $T = 2\pi r\sqrt{\frac{\pi amc}{N\lambda}} = 5$ мин.

(??? непонятно, почему в разделе про магнетизм задача. По идее через давление света все решается. нужно переучивать)

О3.1-6.2 Вращение пластины светом

Абсолютно черная пластинка площадью $S = 10$ см ^{2} освещается монохроматическим светом с длиной волны $\lambda = 600$, поляризованным по кругу. Интенсивность света равна $\vartheta = 30\text{Br/cm}^2$. Какой вращающий момент M испытывает пластинка? Зависит ли M от распределения интенсивности в пучке? Как изменится вращающий момент, если черную пластинку заменить на кристаллическую пластинку в $\lambda/4$? Какую надо взять кристаллическую пластинку, чтобы вращающий момент M удвоился?

6.

2. $M = \frac{\mathscr{I} S \lambda}{2\pi c} = 0,95 \cdot 10^{-6}$ дин $\cdot$ см. От распределения интенсивности в пучке M не зависит. Для пластинки в $\lambda/4$ вращающий момент такой же, как и для поглощающей пластинки. Вращающий момент удвоится, если взять пластинку в $\lambda/2$.

О3.1-6.3 Вращательный момент

Эллиптически поляризованный параллельный световой поток с длиной волны $\lambda = 600$ нм и интенсивностью $\mathscr{I} = 30\text{В}/\text{см}^2$ падает перпендикулярно на абсолютно черную пластинку. Площадь поперечного сечения светового потока $S = 10\text{см}^2$. Отношение длин главных полуосей эллипса поляризации в световом пучке составляет $a/b = 2$. Найти вращающий момент M, который испытывает пластинка при поглощении света.

6.

3. $M = \frac{gS\lambda}{2\pi c} \frac{2ab}{a+b} = 0,76 \cdot 10^{-6}$ дин $\cdot$.

О3.1-6.4 Двоякопреломляющая пластинка

Поляризованный по правому кругу световой поток с длиной волны $\lambda = 500$ нм, интенсивность которого составляет $\mathscr{I} = 1,4 \cdot 10^6 \text{pr}/\left(\text{с} \cdot \text{см}^2\right)$ (такой интенсивностью обладает солнечное излучение на границе земной атмосферы), падает на двоякопреломляющую пластинку в $\lambda/2$. Как будет поляризован свет после прохождения пластинки? Определить вращающий момент на единицу площади (M/S) такой пластинки.

6.

4. Свет будет поляризован по левому кругу.

$$\frac{M}{S} = \frac{g\lambda}{\pi c} = 7,7 \cdot 10^{-9} \text{ дин } /$$

О3.1-6.5 Вращательный момент

На кварцевую пластинку в $\lambda/4$ перпендикулярно падает пучок линейно поляризованного света с длиной волны $\lambda = 628$ нм и мощностью $N = 3\text{В}$. При каких условиях пластинка будет испытывать вращающий момент и каковы его значение и направление?

6.

5. Максимальный вращающий момент возникает, когда главные направления пластинки ориентированны под углом 45° к плоскости поляризации света.

$$M = \frac{N\lambda}{2\pi c} = 10^{-8} \text{ дин } \cdot .$$

О3.1-6.6 Вращающийся момент по максимумам и минимумам

Некогерентная смесь естественного и линейно поляризованного света с длиной волны $\lambda = 500$ нм и интенсивностью $\mathscr{J} = 1,4 \cdot 10^6$ эрг/ $\left(\text{с}^2\text{см}^2\right)$ (такой интенсивностью обладает солнечное излучение на границе земной атмосферы) падает на двоякопреломляющую пластинку в $\lambda/4$. Определить вращающий момент на единицу площади (M/S) такой пластинки, если направление колебаний в линейно поляризованном свете составляет угол 45° с главными направлениями пластинки. Известно, что при анализе падающего из тучения с помощью поляризатора соотношение $\tau_{\max}/\mathscr{E}_{\min} = 3$.

6.

6. Из условий $_{\max}/\mathscr{C}_{\min} = 3$ следует, что линейно поляризованный свет переносит половину всей мощности.

$$\frac{M}{S} = \frac{g\lambda}{4\pi c} = 1,9 \cdot 10^{-9} \text{ дин } /.$$

О3.1-6.7 Вращение решетки

Параллельный пучок монохроматического излучения (длина волны в вакууме $\lambda = 496$ мкм), поляризованного по кругу, падает нормально на решетку, изготовленную в виде натянутых проволочек с расстоянием между ними $d \ll \lambda$. При таких условиях решетка полностью пропускает излучение, поляризованное так, что электрический вектор направлен перпендикулярно проволочкам, и отражает излучение с поляризацией, повернутой на 90°. Найти вращающий момент M и силу F, действующих на решетку, если интенсивность потока в пучке $\vartheta = 10\text{В/см}^2$, а облучаемая поверхность решетки $S = 10\text{см}^2$.

6.

7* $M = \frac{\mathscr{J} S\lambda}{2\pi c} \approx 3 \cdot 10^{-4}$ дин ·; $F = \frac{\mathscr{J} S}{c} \approx 0,03$ дин.

Решение. Момент импульса проходящей и отраженной волн равен нулю в силу линейной поляризации. Согласно закону сохранения момента импульса $\Delta L_{\text{реш}} = -\Delta L_{\text{фот}}$ (изменению момента импульса фотонов).

Вращающий момент $M = \frac{\Delta L_{\text{dx}}}{\Delta t} = \frac{\hbar \mathscr{J} S \Delta t}{\hbar\omega \Delta t} = \frac{\mathscr{J}\mathscr{S}}{\omega} = \frac{\mathscr{S}\mathscr{S}}{2\pi c} \approx 3 \cdot 10^{-4}$ дин ·с.
Сила давления F обусловлена изменением импульса той части потока, которая испытывает отражение. Поэтому

$$F = 2\frac{\hbar\omega}{c}\frac{\mathscr{A} S}{2\hbar\omega} = \frac{S}{c} \approx 0,03 \text{ дин.}$$

О3.1-6.8 Вращение цилиндра Фарадея

Пучок продольно поляризованных по спину электронов с током 100 А и кинетической энергией 100 кэВ поглощается цилиндром Фарадея. Определить силу и крутящий момент, действующие на цилиндр. Пучок электронов направлен параллельно оси цилиндра.

6.

8. $F = p\frac{g}{e} = 1,12 \cdot 10^4$ дин, где $p = \frac{1}{c}\sqrt{T\left(T + 2mc^2\right)} = 1,78 \cdot 10^{-17}\Gamma \cdot \text{с}/; M = \frac{\hbar}{2e} = 3,3 \cdot 10^{-7}$ дин · см.

О3.1-6.9 Вращение цилиндра

С какой угловой скоростью ω и в каком направлении должен начать вращаться цилиндр, подвешенный в магнитном поле B, направленном параллельно его оси вертикально вверх, если изменить направление поля на обратное? Считать, что цилиндр намагничивается до насыщения. (Момент импульса электрона в атоме равен l, число атомов в цилиндре N, момент инерции цилиндра I.)

6.

9. $\omega = \frac{2Nl}{I}$, цилиндр закрутится против часовой стрелки (вектор ω направлен вверх).

О3.1-6.10 Вращение цилиндра

Какое значение для ω следует ожидать в упрощенном опыте Эйнштейна-де Гааза (предыдущая задача), если длина цилиндра $L = 1$см, его масса $m = 1$, цилиндр сделан из железа и если предположить, что момент импульса каждого атома равен таковому для электрона на первой боровской орбите?

6.

10. $\omega = \frac{2N_A h}{Am} Lp = 1,1 \cdot 10^{-3}\text{с}^{-1}$, где N_A - число Авогадро, A - атомная масса железа [г/моль], ρ - его плотность.

О3.1-6.11 Опыт Штерна-Герлаха с водородом

На сколько компонент расщепится при проведении опыта Штерна-Герлаха пучок атомов водорода?

6.

11. На два ($2S + 1 = 2$).

О3.1-6.12 Опыт Штерна-Герлаха с натрием

Пучок атомов натрия, находящихся в основном состоянии, вылетает из печи, температура которой $T = 350$ К. Пучок расщепляется в поперечном неоднородном магнитном поле с градиентом $dB/dx = 50$ Тл/м на пути $l = 1$ см. Детектор удален от магнита на расстояние $L = 6,5$ м. Найти расстояние s между пятнами на экране.

6.

12* $s = 2\mu_\text{б} \frac{dB}{dx} \frac{l(L+l/2)}{3kT} \approx 0,4$ см.
Решение. В области магнита на атом действует постоянная сила

$$F_x = \mu_B \frac{dB}{dx}$$

где μ_B - проекция магнитного момента атома на направление поля B

$$\mu_B = m_J g \mu_\text{Б}$$

где $g = \frac{3}{2} + \frac{S(S+1)-L(L+1)}{2J(J+1)}$ - фактор Ланде. В основном состоянии атома Na $L = 0, S = 1/2, J = 1/2, g = 2$, и $F_x = \pm\mu_\text{б} \frac{dB}{dx}$. За время $t = \frac{l}{v}$ смещение частицы $x_1 = \frac{at^2}{2} = \frac{F_x}{2m} \frac{l^2}{v^2}$, а скорость на выходе $v_x = \frac{F_x}{m} \frac{l}{v}$ ($v_x \ll v$, в чем убедимся ниже). Вне магнита атом движется по инерции и $x_2 = x_1 + v_x \frac{L}{v} = \frac{F_x}{mv^2} l \left(\frac{l}{2} + L\right)$.
За время $t = l/v$ атомы приобретают скорость

$$v_x = \pm\mu \frac{dB}{dx} \frac{l}{mv} \approx \pm 20\text{с/с}$$

приводящую к смещению пучков на детекторе

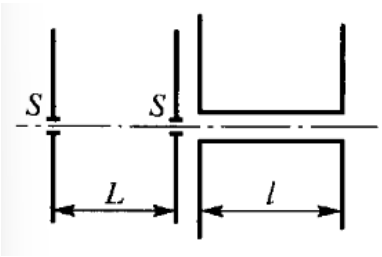
$$x_2 = \pm\mu_\text{Б} \frac{dB}{dx} \frac{l(l/2 + L)}{mv^2}$$

Средняя кинетическая энергия атомов в пучке равна $\overline{\frac{mv^2}{2}} = \frac{3}{2}kT$, откуда $v \simeq 600$ м/с $\gg v_x$, а искомое расстояние между пятнами на детекторе

$$s = 2x_2 = 2\mu_\text{Б} \frac{dB}{dx} \frac{l(l/2 + L)}{3kT} \approx 4 \text{ mm}$$

О3.1-6.13 Магнит Штерна-Герлаха и диафрагмы

Пучок атомов лития в основном состоянии с максимальной кинетической энергией $T = 0,1$ эВ проходит через магнит типа Штерна-Герлаха длиной $l = 6$см с градиентом поля $dB/dx = 5 \cdot 10^4$Гс/cm. Сразу за магнитом расположена система из двух одинаковых диафрагм S диаметром d, находящихся на расстоянии $L = 1$ м одна от другой



При какой минимальной величине диаметра $d_{\min}$ компоненты разделенного пучка пройдут через систему диафрагм?

Solution

(???)

О3.1-6.14

Пучок атомов ванадия ($A = 50$), находящихся в состоянии ${}^4F_{3/2}$, пропускается через сильное неоднородное магнитное поле. На сколько компонент разобьется такой пучок?

На какой угол разойдутся соседние компоненты пучка, если участок с неоднородным полем имеет протяженность $l = 25$см, градиент поля в нем $dB/dx = 5 \cdot 10^4$Гс/cm, а скорость атомов $v = 500$ м/с?

Solution

(???)

О3.1-6.15 Коллиматор и магнит

Параллельный пучок нейтронов с энергией $T = 0,025$ эВ проходит через коллимирующую щель шириной $d = 0,1$ мм и затем через зазор в магните Штерна-Герлаха длиной $L = 1$ м. Оценить значение градиента поля dB/dx, при котором угол магнитного отклонения компонент пучка равен углу дифракционного уширения. Магнитный момент нейтрона $\mu_{\text{n}} = 9,66 \cdot 10^{-24}$ эрг/Гс.

Solution

(???)

О3.1-6.16 Расщепление пучка нейтронов

В опытах Шалла (1968 г.) наблюдалось расщепление пучка нейтронов на два пучка при преломлении на границе однородного магнитного поля. Найти малый угол θ между направлениями преломления пучков. Однородное магнитное поле имеет индукцию $B = 2,5$ Тл. Нейтроны с дебройлевской длиной волны $\lambda = 0,5$ нм падают под углом $\varphi = 30^\circ$ к достаточно резкой границе магнитного поля.

Solution

(???)

О3.1-6.17 Мультиплетность

Определить возможную мультиплетность атомов H, He, Li, Mg, Fe, Hg, U, Cl.

Solution

(???)

О3.1-6.18 Мультиплетность

Какова возможная мультиплетность Sr^+, Li^+, Ca^+, c^{++}, O^{4+}?

Solution

(???)

О3.1-6.1 Мультиплетность

Какова наивысшая мультиплетность атомов элементов третьей группы?

Solution

(???)

О3.1-6.20 Дублет натрия (!!!!!)

Желтый дублет Na возникает при переходе электронов $3^2P \to 3^2S$ и соответствует длинам волн $\lambda_1 = 5896$Å и $\lambda_2 = 5890$Å. Найти энергетическое расстояние $\Delta\S$ между соответствующими подуровнями терма 3^2P (мультиплетное расщепление). Оценить среднюю величину магнитного поля B, действующего на «оптический» электрон.

Solution

(???)

О3.1-6.21 Переход $P \to S$

При переходе $P \to S$ из возбужденного состояния атома в основное испускается дублет $\lambda_1 = 455,1$ нм и $\lambda_2 = 458,9$ нм. Какие линии, соответствующие переходу ${}^2S_{1/2} \to {}^2P_{3/2}$, будут наблюдаться в спектре поглощения газа, состоящего из таких атомов, при наложении магнитного поля 50κ при температуре $T = 0,5$ К?

Solution

(?? про Зеемана тут???? пока не очень вижу)

Решение Первое, с чем определимся это то какой это эффект Зеемана - в сильном или слабом поле? Считаем характерные энергии спин-орбитального взаимодействия и взаимодействия с магнитным полем:

$$U_{LS} = \frac{hc}{\lambda^2}\Delta\lambda = 2 \cdot 10^{-2\text{В}}\text{В}$$
$$U_B = \mu B = 3 \cdot 10^{-4\ni}\text{В}$$
