Corollary 8.21 Let $p \in [1, \infty]$ and let $\mathcal{F} \subset \mathcal{A}$ be a sub- σ -algebra. Then the map

$$\mathcal{L}^p(\Omega, \mathcal{A}, \mathbf{P}) \rightarrow \mathcal{L}^p(\Omega, \mathcal{F}, \mathbf{P}), \quad X \mapsto \mathbf{E}[X | \mathcal{F}],$$

is a contraction (that is, $\|\mathbf{E}[X | \mathcal{F}]\|_p \leq \|X\|_p$) and thus continuous. Hence, for $X, X_1, X_2, \dots \in \mathcal{L}^p(\Omega, \mathcal{A}, \mathbf{P})$ with $\|X_n - X\|_p \xrightarrow{n \rightarrow \infty} 0$,

$$\|\mathbf{E}[X_n | \mathcal{F}] - \mathbf{E}[X | \mathcal{F}]\|_p \xrightarrow{n \rightarrow \infty} 0.$$

Proof For $p \in [1, \infty)$, use Jensen's inequality with $\varphi(x) = |x|^p$. For $p = \infty$, note that $|\mathbf{E}[X | \mathcal{F}]| \leq \mathbf{E}[|X| | \mathcal{F}] \leq \mathbf{E}[\|X\|_\infty | \mathcal{F}] = \|X\|_\infty$.

Corollary 8.22 Let $(X_i, i \in I)$ be uniformly integrable and let $(\mathcal{F}_j, j \in J)$ be a family of sub- σ -algebras of $\mathcal{A}$. Define $X_{i,j} := \mathbf{E}[X_i | \mathcal{F}_j]$. Then $(X_{i,j}, (i, j) \in I \times J)$ is uniformly integrable. In particular, for $X \in \mathcal{L}^1(\mathbf{P})$, the family $(\mathbf{E}[X | \mathcal{F}_j], j \in J)$ is uniformly integrable.

Proof By Theorem 6.19, there exists a monotone increasing convex function f with the property that $f(x)/x \rightarrow \infty, x \rightarrow \infty$ and $L := \sup_{i \in I} \mathbf{E}[f(|X_i|)] < \infty$. Then $x \mapsto f(|x|)$ is convex; hence, by Jensen's inequality,

$$\mathbf{E}[f(|X_{i,j}|)] = \mathbf{E}[f(|\mathbf{E}[X_i | \mathcal{F}_j]|)] \leq L < \infty$$

Thus $(X_{i,j}, (i, j) \in I \times J)$ is uniformly integrable by Theorem 6.19.

Example 8.23 Let μ and ν be finite measures with $\nu \ll \mu$. Let $f = d\nu/d\mu$ be the Radon-Nikodym derivative and let $I = \{\mathcal{F} \subset \mathcal{A} : \mathcal{F} \text{ is a } \sigma\text{-algebra}\}$. Consider the measures $\mu|_{\mathcal{F}}$ and $\nu|_{\mathcal{F}}$ that are restricted to $\mathcal{F}$. Then $\nu|_{\mathcal{F}} \ll \mu|_{\mathcal{F}}$ (since in $\mathcal{F}$ there are fewer μ -null sets); hence the Radon-Nikodym derivative $f_{\mathcal{F}} := d\nu|_{\mathcal{F}}/d\mu|_{\mathcal{F}}$ exists. Then $(f_{\mathcal{F}} : \mathcal{F} \in I)$ is uniformly integrable (with respect to μ). (For finite σ -algebras $\mathcal{F}$, this was shown in Example 7.39.) Indeed, let $\mathbf{P} = \mu/\mu(\Omega)$ and $\mathbf{Q} = \nu/\mu(\Omega)$. Then $f_{\mathcal{F}} = d\mathbf{Q}|_{\mathcal{F}}/d\mathbf{P}|_{\mathcal{F}}$. For any $F \in \mathcal{F}$, we thus have $\mathbf{E}[f_{\mathcal{F}} \mathbb{1}_F] = \int_F f_{\mathcal{F}} d\mathbf{P} = \mathbf{Q}(F) = \int_F f d\mathbf{P} = \mathbf{E}[f \mathbb{1}_F]$; hence $f_{\mathcal{F}} = \mathbf{E}[f | \mathcal{F}]$. By the preceding corollary, $(f_{\mathcal{F}} : \mathcal{F} \in I)$ is uniformly integrable with respect to $\mathbf{P}$ and thus also with respect to μ .

Exercise 8.2.1 Show the assertions of Remark 8.16.

Exercise 8.2.2 Let $I \subset \mathbb{R}$ be an arbitrary interval and let $X \in \mathcal{L}^1(\Omega, \mathcal{A}, \mathbf{P})$ be a random variable such that $X \in I$ a.s. For $\mathcal{F} \subset \mathcal{A}$, show that $\mathbf{E}[X | \mathcal{F}] \in I$ a.s. Is this statement still true if we require only $X^- \in \mathcal{L}^1(\Omega, \mathcal{A}, \mathbf{P})$ instead of $X \in \mathcal{L}^1(\Omega, \mathcal{A}, \mathbf{P})$?

Exercise 8.2.3 (Bayes' formula) Let $A \in \mathcal{A}$ and $B \in \mathcal{F} \subset \mathcal{A}$. Show that

$$\mathbf{P}[B | A] = \frac{\int_B \mathbf{P}[A | \mathcal{F}] d\mathbf{P}}{\int \mathbf{P}[A | \mathcal{F}] d\mathbf{P}}$$

If $\mathcal{F}$ is generated by pairwise disjoint sets $B_1, B_2, \dots$, then this is exactly Bayes' formula of Theorem 8.7.

Exercise 8.2.4 Give an example for $\mathbf{E}[\mathbf{E}[X | \mathcal{F}] | \mathcal{G}] \neq \mathbf{E}[\mathbf{E}[X | \mathcal{G}] | \mathcal{F}]$.

Exercise 8.2.5 Show the conditional Markov inequality: For monotone increasing $f : [0, \infty) \rightarrow [0, \infty)$ and $\varepsilon > 0$ with $f(\varepsilon) > 0$,

$$\mathbf{P}[|X| \geq \varepsilon | \mathcal{F}] \leq \frac{\mathbf{E}[f(|X|) | \mathcal{F}]}{f(\varepsilon)}$$

Exercise 8.2.6 Show the conditional Cauchy-Schwarz inequality: For square integrable random variables X, Y ,

$$\mathbf{E}[XY | \mathcal{F}]^2 \leq \mathbf{E}[X^2 | \mathcal{F}] \mathbf{E}[Y^2 | \mathcal{F}].$$

Exercise 8.2.7 Let $X_1, \dots, X_n$ be integrable i.i.d. random variables. Let $S_n = X_1 + \dots + X_n$. Show that

$$\mathbf{E}[X_i | S_n] = \frac{1}{n} S_n \quad \text{for every } i = 1, \dots, n$$

Exercise 8.2.8 Let X_1 and X_2 be independent and exponentially distributed with parameter $\theta > 0$. Compute $\mathbf{E}[X_1 \wedge X_2 | X_1]$.

Exercise 8.2.9 Let X and Y be real random variables with joint density f and let $h : \mathbb{R} \rightarrow \mathbb{R}$ be measurable with $\mathbf{E}[|h(X)|] < \infty$. Denote by λ the Lebesgue measure on $\mathbb{R}$.

(i) Show that almost surely

$$\mathbf{E}[h(X) | Y] = \frac{\int h(x)f(x, Y)\lambda(dx)}{\int f(x, Y)\lambda(dx)}$$

(ii) Let X and Y be independent and $\exp_\theta$ -distributed for some $\theta > 0$. Compute $\mathbf{E}[X | X + Y]$ and $\mathbf{P}[X \leq x | X + Y]$ for $x \geq 0$.

5.8.3 8.3 Regular Conditional Distribution

Let X be a random variable with values in a measurable space $(E, \mathcal{E})$. With our machinery, so far we can define the conditional probability $\mathbf{P}[A | X]$ for fixed $A \in \mathcal{A}$ only. However, we would like to define for every $x \in E$ a probability measure $\mathbf{P}[\cdot | X = x]$ such that for any $A \in \mathcal{A}$, we have $\mathbf{P}[A | X] = \mathbf{P}[A | X = x]$ on $\{X = x\}$. In this section, we show how to do this.

For example, we are interested in a two-stage random experiment. At the first stage, we manipulate a coin at random such that the probability of a success (i.e., "head") is X . At the second stage, we toss the coin n times independently with outcomes $Y_1, \dots, Y_n$. Hence the "conditional distribution of $(Y_1, \dots, Y_n)$ given $\{X = x\}$ " should be $(\text{Ber}_x)^{\otimes n}$.

Let X be as above and let Z be a $\sigma(X)$ -measurable real random variable. By the factorization lemma (Corollary 1.97 with $f = X$ and $g = Z$), there is a map $\varphi : E \rightarrow \mathbb{R}$ such that

$$\varphi \text{ is } \mathcal{E} - \mathcal{B}(\mathbb{R})\text{-measurable} \quad \text{and} \quad \varphi(X) = Z. \quad (8.9)$$

If X is surjective, then φ is determined uniquely. In this case, we denote $Z \circ X^{-1} := \varphi$ (even if the inverse map X^{-1} itself does not exist).

Definition 8.24 Let $Y \in \mathcal{L}^1(\mathbf{P})$ and $X : (\Omega, \mathcal{A}) \rightarrow (E, \mathcal{E})$. We define the conditional expectation of Y given $X = x$ by $\mathbf{E}[Y | X = x] := \varphi(x)$, where φ is the function from (8.9) with $Z = \mathbf{E}[Y | X]$.

Analogously, define $\mathbf{P}[A | X = x] = \mathbf{E}[\mathbb{1}_A | X = x]$ for $A \in \mathcal{A}$.

For a fixed set $B \in \mathcal{A}$ with $\mathbf{P}[B] > 0$, the conditional probability $\mathbf{P}[\cdot | B]$ is a probability measure. Is this true also for $\mathbf{P}[\cdot | X = x]$? The question is a bit tricky since for every given $A \in \mathcal{A}$, the expression $\mathbf{P}[A | X = x]$ is defined for almost all x only; that is, up to x in a null set that may, however, depend on A . Since there are uncountably many $A \in \mathcal{A}$ in general, we could not simply unite all the exceptional sets for any A . However, if the σ -algebra $\mathcal{A}$ can be approximated by countably many A sufficiently well, then there is hope.

Our first task is to give precise definitions. Then we present the theorem that justifies our hope.

Definition 8.25 (Transition kernel, Markov kernel) Let $(\Omega_1, \mathcal{A}_1), (\Omega_2, \mathcal{A}_2)$ be measurable spaces. A map $\kappa : \Omega_1 \times \mathcal{A}_2 \rightarrow [0, \infty]$ is called a (σ) -finite transition kernel (from Ω_1 to Ω_2) if:

- (i) $\omega_1 \mapsto \kappa(\omega_1, A_2)$ is $\mathcal{A}_1$ -measurable for any $A_2 \in \mathcal{A}_2$.
- (ii) $A_2 \mapsto \kappa(\omega_1, A_2)$ is a (σ) -finite measure on $(\Omega_2, \mathcal{A}_2)$ for any $\omega_1 \in \Omega_1$.

If in (ii) the measure is a probability measure for all $\omega_1 \in \Omega_1$, then κ is called a stochastic kernel or a Markov kernel. If in (ii) we also have $\kappa(\omega_1, \Omega_2) \leq 1$ for any $\omega_1 \in \Omega_1$, then κ is called sub-Markov or substochastic.

Remark 8.26 It is sufficient to check property (i) in Definition 8.25 for sets A_2 from a π -system $\mathcal{E}$ that generates $\mathcal{A}_2$ and that either contains Ω_2 or a sequence $E_n \uparrow \Omega_2$. Indeed, in this case,

$$\mathcal{D} := \{A_2 \in \mathcal{A}_2 : \omega_1 \mapsto \kappa(\omega_1, A_2) \text{ is } \mathcal{A}_1\text{-measurable}\}$$

is a λ -system (exercise!). Since $\mathcal{E} \subset \mathcal{D}$, by the $\pi - \lambda$ theorem (Theorem 1.19), $\mathcal{D} = \sigma(\mathcal{E}) = \mathcal{A}_2$.

Example 8.27

(i) Let $(\Omega_1, \mathcal{A}_1)$ and $(\Omega_2, \mathcal{A}_2)$ be discrete measurable spaces and let $(K_{ij})_{\substack{i \in \Omega_1 \\ j \in \Omega_2}}$ be a matrix with nonnegative entries and finite row sums

$$K_i := \sum_{j \in \Omega_2} K_{ij} < \infty \quad \text{for } i \in \Omega_1.$$

Then we can define a finite transition kernel from Ω_1 to Ω_2 by $\kappa(i, A) = \sum_{j \in A} K_{ij}$. κ is stochastic if $K_i = 1$ for all $i \in \Omega_1$. It is substochastic if $K_i \leq 1$ for all $i \in \Omega_1$.

(ii) If μ_2 is a finite measure on Ω_2 , then $\kappa(\omega_1, \cdot) \equiv \mu_2$ is a finite transition kernel.

(iii) $\kappa(x, \cdot) = \text{Poi}_x$ is a stochastic kernel from $[0, \infty)$ to $\mathbb{N}_0$ (note that $x \mapsto \text{Poi}_x(A)$ is continuous and hence measurable for all $A \subset \mathbb{N}_0$).

(iv) Let μ be a distribution on $\mathbb{R}^n$ and let X be a random variable with $\mathbf{P}_X = \mu$. Then $\kappa(x, \cdot) = \mathbf{P}[X + x \in \cdot] = \delta_x * \mu$ defines a stochastic kernel from $\mathbb{R}^n$ to $\mathbb{R}^n$. Indeed, the sets $(-\infty, y], y \in \mathbb{R}^n$ form an $\cap$ -stable generator of $\mathcal{B}(\mathbb{R}^n)$ and $x \mapsto \kappa(x, (-\infty, y]) = \mu((-\infty, y - x])$ is left continuous and hence measurable. Hence, by Remark 8.26, $x \mapsto \kappa(x, A)$ is measurable for all $A \in \mathcal{B}(\mathbb{R}^n)$.

Definition 8.28 Let Y be a random variable with values in a measurable space $(E, \mathcal{E})$ and let $\mathcal{F} \subset \mathcal{A}$ be a sub- σ -algebra. A stochastic kernel $\kappa_{Y, \mathcal{F}}$ from $(\Omega, \mathcal{F})$ to $(E, \mathcal{E})$ is called a regular conditional distribution of Y given $\mathcal{F}$ if

$$\kappa_{Y, \mathcal{F}}(\omega, B) = \mathbf{P}[\{Y \in B\} \mid \mathcal{F}](\omega)$$

for $\mathbf{P}$ -almost all $\omega \in \Omega$ and for all $B \in \mathcal{E}$; that is, if

$$\int \mathbb{1}_B(Y) \mathbb{1}_A d\mathbf{P} = \int \kappa_{Y, \mathcal{F}}(\cdot, B) \mathbb{1}_A d\mathbf{P} \quad \text{for all } A \in \mathcal{F}, B \in \mathcal{E} \quad (8.10)$$

Consider the special case where $\mathcal{F} = \sigma(X)$ for a random variable X (with values in an arbitrary measurable space $(E', \mathcal{E}')$). Then the stochastic kernel

$$(x, A) \mapsto \kappa_{Y, X}(x, A) = \mathbf{P}[\{Y \in A\} \mid X = x] = \kappa_{Y, \sigma(X)}(X^{-1}(x), A)$$

(the function from the factorization lemma with an arbitrary value for $x \notin X(\Omega)$) is called a regular conditional distribution of Y given X .

Theorem 8.29 (Regular conditional distributions in $\mathbb{R}$) Let $Y : (\Omega, \mathcal{A}) \rightarrow (\mathbb{R}, \mathcal{B}(\mathbb{R}))$ be real-valued. Then there exists a regular conditional distribution $\kappa_{Y, \mathcal{F}}$ of Y given $\mathcal{F}$.

Proof The strategy of the proof consists in constructing a measurable version of the distribution function of the conditional distribution of Y by first defining it for rational values (up to a null set) and then extending it to the real numbers.

For $r \in \mathbb{Q}$, let $F(r, \cdot)$ be a version of the conditional probability $\mathbf{P}[Y \in (-\infty, r] \mid \mathcal{F}]$. For $r \leq s$, clearly $\mathbb{1}_{\{Y \in (-\infty, r]\}} \leq \mathbb{1}_{\{Y \in (-\infty, s]\}}$. Hence, by Theorem 8.14(ii) (monotonicity of the conditional expectation), there is a null set $A_{r,s} \in \mathcal{F}$ with

$$F(r, \omega) \leq F(s, \omega) \quad \text{for all } \omega \in \Omega \setminus A_{r,s}. \quad (8.11)$$

By Theorem 8.14(viii) (dominated convergence), there are null sets $(B_r)_{r \in \mathbb{Q}} \in \mathcal{F}$ and $C \in \mathcal{F}$ such that

$$\lim_{n \rightarrow \infty} F\left(r + \frac{1}{n}, \omega\right) = F(r, \omega) \quad \text{for all } \omega \in \Omega \setminus B_r \quad (8.12)$$

as well as

$$\inf_{n \in \mathbb{N}} F(-n, \omega) = 0 \quad \text{and} \quad \sup_{n \in \mathbb{N}} F(n, \omega) = 1 \quad \text{for all } \omega \in \Omega \setminus C \quad (8.13)$$

Let $N := \left(\bigcup_{r,s \in \mathbb{Q}} A_{r,s} \right) \cup \left(\bigcup_{r \in \mathbb{Q}} B_r \right) \cup C$. For $\omega \in \Omega \setminus N$, define

$$\tilde{F}(z, \omega) := \inf \{ F(r, \omega) : r \in \mathbb{Q}, r > z \} \quad \text{for all } z \in \mathbb{R}$$

By construction, $\tilde{F}(\cdot, \omega)$ is monotone increasing and right continuous. By (8.11) and (8.12), we have

$$\tilde{F}(z, \omega) = F(z, \omega) \quad \text{for all } z \in \mathbb{Q} \text{ and } \omega \in \Omega \setminus N. \quad (8.14)$$

Therefore, by (8.13), $\tilde{F}(\cdot, \omega)$ is a distribution function for any $\omega \in \Omega \setminus N$. For $\omega \in N$, define $\tilde{F}(\cdot, \omega) = F_0$, where F_0 is an arbitrary but fixed distribution function.

For any $\omega \in \Omega$, let $\kappa(\omega, \cdot)$ be the probability measure on $(\Omega, \mathcal{A})$ with distribution function $\tilde{F}(\cdot, \omega)$. Then, for $r \in \mathbb{Q}$ and $B = (-\infty, r]$,

$$\omega \mapsto \kappa(\omega, B) = F(r, \omega) \mathbb{1}_{N^c}(\omega) + F_0(r) \mathbb{1}_N(\omega) \quad (8.15)$$

is $\mathcal{F}$ -measurable. Now $\{(-\infty, r], r \in \mathbb{Q}\}$ is a π -system that generates $\mathcal{B}(\mathbb{R})$. By Remark 8.26, measurability holds for all $B \in \mathcal{B}(\mathbb{R})$ and hence κ is identified as a stochastic kernel.

We still have to show that κ is a version of the conditional distribution. For $A \in \mathcal{F}$, $r \in \mathbb{Q}$ and $B = (-\infty, r]$, by (8.15),

$$\int_A \kappa(\omega, B) \mathbf{P}[d\omega] = \int_A \mathbf{P}[Y \in B \mid \mathcal{F}] d\mathbf{P} = \mathbf{P}[A \cap \{Y \in B\}]$$

As functions of B , both sides are finite measures on $\mathcal{B}(\mathbb{R})$ that coincide on the $\cap$ stable generator $\{(-\infty, r], r \in \mathbb{Q}\}$. By the uniqueness theorem (Lemma 1.42), we thus have equality for all $B \in \mathcal{B}(\mathbb{R})$. Hence $\mathbf{P}$ -a.s. $\kappa(\cdot, B) = \mathbf{P}[Y \in B \mid \mathcal{F}]$ and thus $\kappa = \kappa_{Y, \mathcal{F}}$.

Example 8.30 Let Z_1, Z_2 be independent Poisson random variables with parameters $\lambda_1, \lambda_2 \geq 0$. One can show (exercise!) that (with $Y = Z_1$ and $X = Z_1 + Z_2$)

$$\mathbf{P}[Z_1 = k \mid Z_1 + Z_2 = n] = b_{n,p}(k) \quad \text{for } k = 0, \dots, n,$$

where $p = \frac{\lambda_1}{\lambda_1 + \lambda_2}$.

This example could still be treated by elementary means. The full strength of the result is displayed in the following examples.

Example 8.31 Let X and Y be real random variables with joint density f (with respect to Lebesgue measure λ^2 on $\mathbb{R}^2$). For $x \in \mathbb{R}$, define

$$f_X(x) = \int_{\mathbb{R}} f(x, y) \lambda(dy)$$

Clearly, $f_X(x) > 0$ for $\mathbf{P}_X$ -a.a. $x \in \mathbb{R}$ and f_X^{-1} is the density of the absolutely continuous part of the Lebesgue measure λ with respect to $\mathbf{P}_X$. The regular conditional distribution of Y given X has density

$$\frac{\mathbf{P}[Y \in dy \mid X = x]}{dy} = f_{Y|X}(x, y) := \frac{f(x, y)}{f_X(x)} \quad \text{for } \mathbf{P}_X[dx]\text{-a.a. } x \in \mathbb{R}. \quad (8.16)$$

Indeed, by Fubini's theorem (Theorem 14.16), the map $x \mapsto \int_B f_{Y|X}(x, y) \lambda(dy)$ is measurable for all $B \in \mathcal{B}(\mathbb{R})$ and for $A, B \in \mathcal{B}(\mathbb{R})$, we have

$$\begin{aligned}
& \int_A \mathbf{P}[X \in dx] \int_B f_{Y|X}(x, y) \lambda(dy) \\
&= \int_A \mathbf{P}[X \in dx] f_X(x)^{-1} \int_B f(x, y) \lambda(dy) \\
&= \int_A \lambda(dx) \int_B f(x, y) \lambda(dy) \\
&= \int_{A \times B} f d\lambda^2 = \mathbf{P}[X \in A, Y \in B]
\end{aligned}$$

Example 8.32 Let $\mu_1, \mu_2 \in \mathbb{R}$, $\sigma_1, \sigma_2 > 0$ and let Z_1, Z_2 be independent and $\mathcal{N}_{\mu_i, \sigma_i^2}$ -distributed ($i = 1, 2$). Then there exists a regular conditional distribution

$$\mathbf{P}[Z_1 \in \cdot \mid Z_1 + Z_2 = x] \quad \text{for } x \in \mathbb{R}.$$

If we define $X = Z_1 + Z_2$ and $Y = Z_1$, then $(X, Y) \sim \mathcal{N}_{\mu, \Sigma}$ is bivariate normally distributed with covariance matrix

$$\Sigma := \begin{pmatrix} \sigma_1^2 + \sigma_2^2 & \sigma_1^2 \\ \sigma_1^2 & \sigma_1^2 \end{pmatrix}$$

and with

$$\mu := \begin{pmatrix} \mu_1 + \mu_2 \\ \mu_1 \end{pmatrix}$$

Note that

$$\Sigma^{-1} = \begin{pmatrix} \sigma_1^2 & \sigma_2^2 \end{pmatrix}^{-1} \begin{pmatrix} \sigma_1^2 & -\sigma_1^2 \\ -\sigma_1^2 & \sigma_1^2 + \sigma_2^2 \end{pmatrix} = \begin{pmatrix} \sigma_1^2 & \sigma_2^2 \end{pmatrix}^{-1} B^T B,$$

where $B = \begin{pmatrix} \sigma_1 & -\sigma_1 \\ 0 & \sigma_2 \end{pmatrix}$. Hence (X, Y) has the density (see Example 1.105(ix))

$$\begin{aligned}
f(x, y) &= \det(2\pi\Sigma)^{-1/2} \exp \left(-\frac{1}{2\sigma_1^2\sigma_2^2} \left\| B \begin{pmatrix} x - (\mu_1 + \mu_2) \\ y - \mu_1 \end{pmatrix} \right\|^2 \right) \\
&= (4\pi^2\sigma_1^2\sigma_2^2)^{-1/2} \exp \left(-\frac{\sigma_1^2(y - (x - \mu_2))^2 + \sigma_2^2(y - \mu_1)^2}{2\sigma_1^2\sigma_2^2} \right) \\
&= C_x \exp \left(-(y - \mu_x)^2 / 2\sigma_x^2 \right)
\end{aligned}$$

Here C_x is a normalising constant and

$$\mu_x = \mu_1 + \frac{\sigma_1^2}{\sigma_1^2 + \sigma_2^2} (x - \mu_1 - \mu_2) \quad \text{and} \quad \sigma_x^2 = \frac{\sigma_1^2\sigma_2^2}{\sigma_1^2 + \sigma_2^2}.$$

By (8.16), $\mathbf{P}[Z_1 \in \cdot \mid Z_1 + Z_2 = x]$ has the density

$$y \mapsto f_{Y|X}(x, y) = \frac{C_x}{f_X(x)} \exp \left(-\frac{(y - \mu_x)^2}{2\sigma_x^2} \right),$$

hence

$$\mathbf{P}[Z_1 \in \cdot \mid Z_1 + Z_2 = x] = \mathcal{N}_{\mu_x, \sigma_x^2} \quad \text{for almost all } x \in \mathbb{R}$$

Example 8.33 If X and Y are independent real random variables, then for $\mathbf{P}_X$ almost all $x \in \mathbb{R}$

$$\mathbf{P}[X + Y \in \cdot \mid X = x] = \delta_x * \mathbf{P}_Y$$

The situation is not completely satisfying as we have made the very restrictive assumption that Y is real-valued. Originally we were also interested in the situation where Y takes values in $\mathbb{R}^n$ or in even more general spaces. We now extend the result to a larger class of ranges for Y .

Definition 8.34 Two measurable spaces $(E, \mathcal{E})$ and $(E', \mathcal{E}')$ are called isomorphic if there exists a bijective map $\varphi : E \rightarrow E'$ such that φ is $\mathcal{E} - \mathcal{E}'$ -measurable and the inverse map φ^{-1} is $\mathcal{E}' - \mathcal{E}$ -measurable. Then we say that φ is an isomorphism of measurable spaces. If in addition μ and μ' are measures on $(E, \mathcal{E})$ and $(E', \mathcal{E}')$ and if $\mu' = \mu \circ \varphi^{-1}$, then φ is an isomorphism of measure spaces, and the measure spaces $(E, \mathcal{E}, \mu)$ and $(E', \mathcal{E}', \mu')$ are called isomorphic.

Definition 8.35 A measurable space $(E, \mathcal{E})$ is called a Borel space if there exists a Borel set $B \in \mathcal{B}(\mathbb{R})$ such that $(E, \mathcal{E})$ and $(B, \mathcal{B}(B))$ are isomorphic.

A separable topological space whose topology is induced by a complete metric is called a Polish space. In particular, $\mathbb{R}^d, \mathbb{Z}^d, \mathbb{R}^{\mathbb{N}}, (C([0, 1]), \|\cdot\|_{\infty})$ and so forth are Polish. Closed subsets of Polish spaces are again Polish. We come back to Polish spaces in the context of convergence of measures in Chapter 13. Without proof, we present the following topological result (see, e.g., [37, Theorem 13.1.1]).

Theorem 8.36 Let E be a Polish space with Borel σ -algebra $\mathcal{E}$. Then $(E, \mathcal{E})$ is a Borel space.

Theorem 8.37 (Regular conditional distribution) Let $\mathcal{F} \subset \mathcal{A}$ be a sub- σ -algebra. Let Y be a random variable with values in a Borel space $(E, \mathcal{E})$ (hence, for example, E Polish, $E = \mathbb{R}^d, E = \mathbb{R}^{\infty}, E = C([0, 1])$, etc.). Then there exists a regular conditional distribution $\kappa_{Y, \mathcal{F}}$ of Y given $\mathcal{F}$.

Proof Let $B \in \mathcal{B}(\mathbb{R})$ and let $\varphi : E \rightarrow B$ be an isomorphism of measurable spaces. By Theorem 8.29, we obtain the regular conditional distribution $\kappa_{Y', \mathcal{F}}$ of the real random variable $Y' = \varphi \circ Y$. Now define $\kappa_{Y, \mathcal{F}}(\omega, A) = \kappa_{Y', \mathcal{F}}(\omega, \varphi(A))$ for $A \in \mathcal{E}$.

To conclude, we pick up again the example with which we started. Now we can drop the quotation marks from the statement and write it down formally. Hence, let X be uniformly distributed on $[0, 1]$. Given $X = x$, let $(Y_1, \dots, Y_n)$ be independent and Ber_x -distributed. Define $Y = (Y_1, \dots, Y_n)$. By Theorem 8.37 (with $E = \{0, 1\}^n \subset \mathbb{R}^n$), a regular conditional distribution exists:

$$\kappa_{Y, X}(x, \cdot) = \mathbf{P}[Y \in \cdot \mid X = x] \quad \text{for } x \in [0, 1].$$

Indeed, for almost all $x \in [0, 1]$,

$$\mathbf{P}[Y \in \cdot \mid X = x] = (\text{Ber}_x)^{\otimes n}$$

Theorem 8.38 Let X be a random variable on $(\Omega, \mathcal{A}, \mathbf{P})$ with values in a Borel space $(E, \mathcal{E})$. Let $\mathcal{F} \subset \mathcal{A}$ be a σ -algebra and let $\kappa_{X, \mathcal{F}}$ be a regular conditional distribution of X given $\mathcal{F}$. Further, let $f : E \rightarrow \mathbb{R}$ be measurable and $\mathbf{E}[|f(X)|] < \infty$. Then

$$\mathbf{E}[f(X) \mid \mathcal{F}](\omega) = \int f(x) \kappa_{X, \mathcal{F}}(\omega, dx) \quad \text{for } \mathbf{P}\text{-almost all } \omega \quad (8.17)$$

Proof We check that the right-hand side in (8.17) has the properties of the conditional expectation.

It is enough to consider the case $f \geq 0$. By approximating f by simple functions, we see that the right-hand side in (8.17) is $\mathcal{F}$ -measurable (see Lemma 14.20 for a formal argument). Hence, by Theorem 1.96, there exist sets $A_1, A_2, \dots \in \mathcal{E}$ and numbers $\alpha_1, \alpha_2, \dots \geq 0$ such that

$$g_n := \sum_{i=1}^n \alpha_i \mathbb{1}_{A_i} \xrightarrow{n \rightarrow \infty} f.$$

Now, for any $n \in \mathbb{N}$ and $B \in \mathcal{F}$,

$$\begin{aligned} \mathbf{E}[g_n(X) \mathbb{1}_B] &= \sum_{i=1}^n \alpha_i \mathbf{P}[\{X \in A_i\} \cap B] \\ &= \sum_{i=1}^n \alpha_i \int_B \mathbf{P}[\{X \in A_i\} \mid \mathcal{F}] \mathbf{P}[d\omega] \\ &= \sum_{i=1}^n \alpha_i \int_B \kappa_{X, \mathcal{F}}(\omega, A_i) \mathbf{P}[d\omega] \\ &= \int_B \sum_{i=1}^n \alpha_i \kappa_{X, \mathcal{F}}(\omega, A_i) \mathbf{P}[d\omega] \\ &= \int_B \left(\int g_n(x) \kappa_{X, \mathcal{F}}(\omega, dx) \right) \mathbf{P}[d\omega] \end{aligned}$$

By the monotone convergence theorem, for almost all ω , the inner integral converges to $\int f(x) \kappa_{X, \mathcal{F}}(\omega, dx)$. Applying the monotone convergence theorem once more, we get

$$\mathbf{E}[f(X) \mathbb{1}_B] = \lim_{n \rightarrow \infty} \mathbf{E}[g_n(X) \mathbb{1}_B] = \int_B \int f(x) \kappa_{X, \mathcal{F}}(\omega, dx) \mathbf{P}[d\omega]$$

Exercise 8.3.1 Let $(E, \mathcal{E})$ be a Borel space and let μ be an atom-free measure (that is, $\mu(\{x\}) = 0$ for any $x \in E$). Show that for any $A \in \mathcal{E}$ and any $n \in \mathbb{N}$, there exist pairwise disjoint sets $A_1, \dots, A_n \in \mathcal{E}$ with $\biguplus_{k=1}^n A_k = A$ and $\mu(A_k) = \mu(A)/n$ for any $k = 1, \dots, n$.

Exercise 8.3.2 Let $p, q \in (1, \infty)$ with $\frac{1}{p} + \frac{1}{q} = 1$ and let $X \in \mathcal{L}^p(\mathbf{P})$ and $Y \in \mathcal{L}^q(\mu)$. Let $\mathcal{F} \subset \mathcal{A}$ be a σ -algebra. Use the preceding theorem to show the conditional version of Hölder's inequality:

$$\mathbf{E}[|XY| \mid \mathcal{F}] \leq \mathbf{E}[|X|^p \mid \mathcal{F}]^{1/p} \mathbf{E}[|Y|^q \mid \mathcal{F}]^{1/q} \quad \text{almost surely.}$$

Exercise 8.3.3 Assume the random variable (X, Y) is uniformly distributed on the disc $B := \{(x, y) \in \mathbb{R}^2 : x^2 + y^2 \leq 1\}$ and on $[-1, 1]^2$, respectively.

(i) In both cases, determine the conditional distribution of Y given $X = x$.

(ii) Let $R := \sqrt{X^2 + Y^2}$ and $\Theta = \arctan(Y/X)$. In both cases, determine the conditional distribution of Θ given $R = r$.

Exercise 8.3.4 Let $A \subset \mathbb{R}^n$ be a Borel measurable set of finite Lebesgue measure $\lambda(A) \in (0, \infty)$ and let X be uniformly distributed on A (see Example 1.75). Let $B \subset A$ be measurable with $\lambda(B) > 0$. Show that the conditional distribution of X given $\{X \in B\}$ is the uniform distribution on B .

Exercise 8.3.5 (Borel's paradox) Consider the Earth as a ball (as widely accepted nowadays). Let X be a random point that is uniformly distributed on the surface. Let Θ be the longitude and let Φ be the latitude of X . A little differently from the usual convention, assume that Θ takes values in $[0, \pi)$ and Φ in $[-\pi, \pi)$. Hence, for fixed Θ , a complete great circle is described when Φ runs through its domain. Now, given Θ , is Φ uniformly distributed on $[-\pi, \pi)$? One could conjecture that any point on the great circle is equally likely. However, this is not the case! If we thicken the great circle slightly such that its longitudes range from Θ to $\Theta + \varepsilon$ (for a small ε), on the equator it is thicker (measured in meters) than at the poles. If we let $\varepsilon \rightarrow 0$, intuitively we should get the conditional probabilities as proportional to the thickness

(in meters).

- (i) Show that $\mathbf{P}[\{\Phi \in \cdot\} \mid \Theta = \theta]$ for almost all θ has the density $\frac{1}{4}|\cos(\phi)|$ for $\phi \in [-\pi, \pi)$.
(ii) Show that $\mathbf{P}[\{\Theta \in \cdot\} \mid \Phi = \phi] = \mathcal{U}_{[0, \pi)}$ for almost all ϕ .

Hint: Show that Θ and Φ are independent, and compute the distributions of Θ and Φ .

Exercise 8.3.6 (Rejection sampling for generating random variables) Let E be a countable set and let P and Q be probability measures on E . Assume there is a $c > 0$ with

$$f(e) := \frac{Q(\{e\})}{P(\{e\})} \leq c \quad \text{for all } e \in E \text{ with } P(\{e\}) > 0$$

Let $X_1, X_2, \dots$ be independent random variables with distribution P . Let $U_1, U_2, \dots$ be i.i.d. random variables that are independent of $X_1, X_2, \dots$ and that are uniformly distributed on $[0, 1]$. Let N be the smallest (random) nonnegative integer n such that $U_n \leq f(X_n)/c$ and define $Y := X_N$.

Show that Y has distribution Q .

Remark. This method for generating random variables with a given distribution Q is called rejection sampling, as it can also be described as follows. The random variable X_1 is a proposal for the value of Y . This proposal is accepted with probability $f(X_1)/c$ and is rejected otherwise. If the first proposal is rejected, the game starts afresh with proposal X_2 and so on.

Exercise 8.3.7 Let E be a Polish space and let $P, Q \in \mathcal{M}_1(\mathbb{R})$. Let $c > 0$ with $f := \frac{dQ}{dP} \leq cP$ -almost surely. Show the statement analogous to Exercise 8.3.6.

Exercise 8.3.8 Show that $(\mathbb{R}, \mathcal{B}(\mathbb{R}))$ and $(\mathbb{R}^n, \mathcal{B}(\mathbb{R}^n))$ are isomorphic. Conclude that every Borel set $B \in \mathcal{B}(\mathbb{R}^n)$ is a Borel space.

5.9 9 Martingales

One of the most important concepts of modern probability theory is the martingale, which formalizes the notion of a fair game. In this chapter, we first lay the foundations for the treatment of general stochastic processes. We then introduce martingales and the discrete stochastic integral. We close with an application to a model from mathematical finance.

5.9.1 9.1 Processes, Filtrations, Stopping Times

We introduce the fundamental technical terms for the investigation of stochastic processes (including martingales). In order to be able to recycle the terms later in a more general context, we go for greater generality than is necessary for the treatment of martingales only.

In the following, let (E, τ) be a Polish space with Borel σ -algebra $\mathcal{E}$. Further, let $(\Omega, \mathcal{F}, \mathbf{P})$ be a probability space and let $I \subset \mathbb{R}$ be arbitrary. We are mostly interested in the cases $I = \mathbb{N}_0, I = \mathbb{Z}, I = [0, \infty)$ and I an interval.

Definition 9.1 (Stochastic process) Let $I \subset \mathbb{R}$. A family of random variables $X = (X_t, t \in I)$ (on $(\Omega, \mathcal{F}, \mathbf{P})$) with values in $(E, \mathcal{E})$ is called a stochastic process with index set (or time set) I and range E .

Remark 9.2 Sometimes families of random variables with more general index sets are called stochastic processes. We come back to this with the Poisson point process in Chapter 24.

Remark 9.3 Following a certain tradition, we will often denote a stochastic process by $X = (X_t)_{t \in I}$ if we want to emphasize the "time evolution" aspect rather than the formal notion of a family of random variables. Formally, both objects are of course the same.

Example 9.4 Let $I = \mathbb{N}_0$ and let $(Y_n, n \in \mathbb{N})$ be a family of i.i.d. $\text{Rad}_{1/2}$ -random variables on a probability space $(\Omega, \mathcal{F}, \mathbf{P})$; that is, random variables with

$$\mathbf{P}[Y_n = 1] = \mathbf{P}[Y_n = -1] = \frac{1}{2}$$

Let $E = \mathbb{Z}$ (with the discrete topology) and let

$$X_t = \sum_{n=1}^t Y_n \quad \text{for all } t \in \mathbb{N}_0.$$

($X_t, t \in \mathbb{N}_0$) is called a symmetric simple random walk on $\mathbb{Z}$.

Example 9.5 The Poisson process $X = (X_t)_{t \geq 0}$ with intensity $\alpha > 0$ (see Section 5.5) is a stochastic process with range $\mathbb{N}_0$.

We introduce some further terms.

Definition 9.6 If X is a random variable (or a stochastic process), we write $\mathcal{L}[X] = \mathbf{P}_X$ for the distribution of X . If $\mathcal{G} \subset \mathcal{F}$ is a σ -algebra, then we write $\mathcal{L}[X \mid \mathcal{G}]$ for the regular conditional distribution of X given $\mathcal{G}$.

Definition 9.7 An E -valued stochastic process $X = (X_t)_{t \in I}$ is called

- (i) real-valued if $E = \mathbb{R}$,
- (ii) a process with independent increments if X is real-valued and for all $n \in \mathbb{N}$ and all $t_0, \dots, t_n \in I$ with $t_0 < t_1 < \dots < t_n$, we have that

$$(X_{t_i} - X_{t_{i-1}})_{i=1, \dots, n} \quad \text{is independent,}$$

- (iii) a Gaussian process if X is real-valued and for all $n \in \mathbb{N}$ and $t_1, \dots, t_n \in I$,

$$(X_{t_1}, \dots, X_{t_n}) \quad \text{is } n\text{-dimensional normally distributed, and}$$

- (iv) integrable (respectively square integrable) if X is real-valued and $\mathbf{E}[|X_t|] < \infty$ (respectively $\mathbf{E}[(X_t)^2] < \infty$) for all $t \in I$.

Now assume that $I \subset \mathbb{R}$ is closed under addition. Then X is called

- (v) stationary if $\mathcal{L}[(X_{s+t})_{t \in I}] = \mathcal{L}[(X_t)_{t \in I}]$ for all $s \in I$, and
- (vi) a process with stationary increments if X is real-valued and

$$\mathcal{L}[X_{s+t+r} - X_{t+r}] = \mathcal{L}[X_{s+r} - X_r] \quad \text{for all } r, s, t \in I$$

(If $0 \in I$, then it is enough to consider $r = 0$.)

Example 9.8

(i) The Poisson process with intensity θ and the random walk on $\mathbb{Z}$ are processes with stationary independent increments.

(ii) If $X_t, t \in I$, are i.i.d. random variables, then $(X_t)_{t \in I}$ is stationary.

(iii) Let $(X_n)_{n \in \mathbb{Z}}$ be real-valued and stationary and let $k \in \mathbb{N}$ and $c_0, \dots, c_k \in \mathbb{R}$. Define

$$Y_n := \sum_{i=0}^k c_i X_{n-i}.$$

Then $Y = (Y_n)_{n \in \mathbb{Z}}$ is a stationary process. If $c_0, \dots, c_k \geq 0$ and $c_0 + \dots + c_k = 1$, then Y is called the moving average of X (with weights $c_0, \dots, c_k$).

The following two definitions make sense also for more general index sets I that are partially ordered. However, we restrict ourselves to the case $I \subset \mathbb{R}$.

Definition 9.9 (Filtration) Let $\mathbb{F} = (\mathcal{F}_t, t \in I)$ be a family of σ -algebras with $\mathcal{F}_t \subset \mathcal{F}$ for all $t \in I$. $\mathbb{F}$ is called a filtration if $\mathcal{F}_s \subset \mathcal{F}_t$ for all $s, t \in I$ with $s \leq t$.

Definition 9.10 A stochastic process $X = (X_t, t \in I)$ is called adapted to the filtration $\mathbb{F}$ if X_t is $\mathcal{F}_t$ -measurable for all $t \in I$. If $\mathcal{F}_t = \sigma(X_s, s \leq t)$ for all $t \in I$, then we denote by $\mathbb{F} = \sigma(X)$ the filtration that is generated by X .

Remark 9.11 Clearly, a stochastic process is always adapted to the filtration it generates. Hence the generated filtration is the smallest filtration to which the process is adapted.

Definition 9.12 (Predictable) A stochastic process $X = (X_n, n \in \mathbb{N}_0)$ is called predictable (or previsible) with respect to the filtration $\mathbb{F} = (\mathcal{F}_n, n \in \mathbb{N}_0)$ if X_0 is constant and if, for every $n \in \mathbb{N}$

$$X_n \text{ is } \mathcal{F}_{n-1}\text{-measurable.}$$

Example 9.13 Let $I = \mathbb{N}_0$ and let $Y_1, Y_2, \dots$ be real random variables. For $n \in \mathbb{N}_0$, define $X_n := \sum_{m=1}^n Y_m$. Let

$$\mathcal{F}_0 = \{\emptyset, \Omega\} \quad \text{and} \quad \mathcal{F}_n = \sigma(Y_1, \dots, Y_n) \quad \text{for } n \in \mathbb{N}.$$

Then $\mathbb{F} = (\mathcal{F}_n, n \in \mathbb{N}_0) = \sigma(Y)$ is the filtration generated by $Y = (Y_n)_{n \in \mathbb{N}}$ and X is adapted to $\mathbb{F}$; hence $\sigma(X) \subset \mathbb{F}$. Clearly, $(Y_1, \dots, Y_n)$ is measurable with respect to $\sigma(X_1, \dots, X_n)$; hence $\sigma(Y) \subset \sigma(X)$, and thus also $\mathbb{F} = \sigma(X)$.

Now let $\tilde{X}_n := \sum_{m=1}^n \mathbb{1}_{[0, \infty)}(Y_m)$. Then $\tilde{X}$ is also adapted to $\mathbb{F}$; however, in general, $\mathbb{F} \not\supseteq \sigma(\tilde{X})$.

Example 9.14 Let $I = \mathbb{N}_0$ and let $D_1, D_2, \dots$ be i.i.d. $\text{Rad}_{1/2}$ -distributed random variables (that is, $\mathbf{P}[D_i = -1] = \mathbf{P}[D_i = 1] = \frac{1}{2}$ for all $i \in \mathbb{N}$). Let $D = (D_i)_{i \in \mathbb{N}}$ and $\mathbb{F} = \sigma(D)$. We interpret D_i as the result of a bet that gives a gain or loss of one euro for every euro we put at stake. Just before each gamble we decide how much money we bet. Let H_n be the number of euros to bet in the n th gamble. Clearly, H_n may only depend on the results of the gambles that happened earlier, but not on D_m for any $m \geq n$. To put it differently, there must be a function $F_n : \{-1, 1\}^{n-1} \rightarrow \mathbb{N}$ such that $H_n = F_n(D_1, \dots, D_{n-1})$. (For example, for the Petersburg game (Example 4.22) we had $F_n(x_1, \dots, x_{n-1}) = 2^{n-1} \mathbb{1}_{\{x_1=x_2=\dots=x_{n-1}=0\}}$.) Hence H is predictable. On the other hand, any predictable H has the form $H_n = F_n(D_1, \dots, D_{n-1})$, $n \in \mathbb{N}$, for certain functions $F_n : \{-1, 1\}^{n-1} \rightarrow \mathbb{N}$. Hence any predictable H is an admissible gambling strategy.

Definition 9.15 (Stopping time) A random variable τ with values in $I \cup \{\infty\}$ is called a stopping time (with respect to $\mathbb{F}$) if for any $t \in I$

$$\{\tau \leq t\} \in \mathcal{F}_t$$

The idea is that $\mathcal{F}_t$ reflects the knowledge of an observer at time t . Whether or not $\{\tau \leq t\}$ is true can thus be determined on the basis of the information available at time t .

Theorem 9.16 Let I be countable. τ is a stopping time if and only if $\{\tau = t\} \in \mathcal{F}_t$ for all $t \in I$.

Proof This is left as an exercise!

Example 9.17 Let $I = \mathbb{N}_0$ (or, more generally, let $I \subset [0, \infty)$ be right-discrete; that is, $t < \inf I \cap (t, \infty)$ for all $t \geq 0$, and hence I in particular is countable) and let $K \subset \mathbb{R}$ be measurable. Let X be an adapted real-valued stochastic process. Consider the first time that X is in K :

$$\tau_K := \inf \{t \in I : X_t \in K\}.$$

It is intuitively clear that τ_K should be a stopping time since we can determine by observation up to time t whether $\{\tau_K \leq t\}$ occurs. Formally, we argue that $\{X_s \in K\} \in \mathcal{F}_s \subset \mathcal{F}_t$ for all $s \leq t$. Hence also the countable union of these sets is in $\mathcal{F}_t$:

$$\{\tau_K \leq t\} = \bigcup_{s \in I \cap [0, t]} \{X_s \in K\} \in \mathcal{F}_t$$

Consider now the random time $\tilde{\tau} := \sup \{t \in I : X_t \in K\}$ of the last visit of X to K . For a fixed time t , on the basis of previous observations, we cannot determine whether X is already in K for the last time. For this we would have to rely on prophecy. Hence, in general, $\tilde{\tau}$ is not a stopping time.

Lemma 9.18 Let $I \subset [0, \infty)$ be closed under addition and let σ and τ be stopping times. Then:

- (i) $\sigma \vee \tau$ and $\sigma \wedge \tau$ are stopping times.
- (ii) If $\sigma, \tau \geq 0$, then $\sigma + \tau$ is also a stopping time.
- (iii) If $s \geq 0$, then $\tau + s$ is a stopping time. However, in general, $\tau - s$ is not.

Before we present the (simple) formal proof, we state that in particular (i) and (iii) are properties we would expect of stopping times. With (i), the interpretation is clear. For (iii), note that $\tau - s$ peeks into the future by s time units (in fact, $\{\tau - s \leq t\} \in \mathcal{F}_{t+s}$), while $\tau + s$ looks back s time units. For stopping times, however, only retrospection is allowed.

Proof (i) For $t \in I$, we have $\{\sigma \vee \tau \leq t\} = \{\sigma \leq t\} \cap \{\tau \leq t\} \in \mathcal{F}_t$ and $\{\sigma \wedge \tau \leq t\} = \{\sigma \leq t\} \cup \{\tau \leq t\} \in \mathcal{F}_t$.

(ii) Let $t \in I$. By (i), $\tau \wedge t$ and $\sigma \wedge t$ are stopping times for any $t \in I$. In particular, $\{\tau \wedge t \leq s\} \in \mathcal{F}_s \subset \mathcal{F}_t$ for any $s \leq t$. On the other hand, we have $\tau \wedge t \leq s$ for $s > t$. Hence $\tau' := (\tau \wedge t) + \mathbb{1}_{\{\tau > t\}}$ and $\sigma' := (\sigma \wedge t) + \mathbb{1}_{\{\sigma > t\}}$ (and thus $\tau' + \sigma'$) are $\mathcal{F}_t$ -measurable. We conclude $\{\tau + \sigma \leq t\} = \{\tau' + \sigma' \leq t\} \in \mathcal{F}_t$.

(iii) For $\tau + s$, this is a consequence of (ii) (with the stopping time $\sigma \equiv s$). For $\tau - s$, since τ is a stopping time, we have $\{\tau - s \leq t\} = \{\tau \leq t + s\} \in \mathcal{F}_{t+s}$. However, in general, $\mathcal{F}_{t+s}$ is a strict superset of $\mathcal{F}_t$; hence $\tau - s$ is not a stopping time. $\square$

Definition 9.19 Let τ be a stopping time. Then

$$\mathcal{F}_\tau := \{A \in \mathcal{F} : A \cap \{\tau \leq t\} \in \mathcal{F}_t \text{ for any } t \in I\}$$

is called the σ -algebra of τ -past.

Example 9.20 Let $I = \mathbb{N}_0$ (or let $I \subset [0, \infty)$ be right-discrete; compare Example 9.17) and let X be an adapted real-valued stochastic process. Let $K \in \mathbb{R}$ and let $\tau = \inf \{t : X_t \geq K\}$ be the stopping time of first entrance in $[K, \infty)$. Consider the events $A = \{\sup \{X_t : t \in I\} > K - 5\}$ and $B = \{\sup \{X_t : t \in I\} > K + 5\}$.

Clearly, $\{\tau \leq t\} \subset A$ for all $t \in I$; hence $A \cap \{\tau \leq t\} = \{\tau \leq t\} \in \mathcal{F}_t$. Thus $A \in \mathcal{F}_\tau$. However, in general, $B \notin \mathcal{F}_\tau$ since up to time τ , we cannot decide whether X will ever exceed $K + 5$. $\square$

Lemma 9.21 If σ and τ are stopping times with $\sigma \leq \tau$, then $\mathcal{F}_\sigma \subset \mathcal{F}_\tau$.

Proof Let $A \in \mathcal{F}_\sigma$ and $t \in I$. Then $A \cap \{\sigma \leq t\} \in \mathcal{F}_t$. Now $\{\tau \leq t\} \in \mathcal{F}_t$ since τ is a stopping time. Since $\sigma \leq \tau$, we thus get

$$A \cap \{\tau \leq t\} = (A \cap \{\sigma \leq t\}) \cap \{\tau \leq t\} \in \mathcal{F}_t.$$

$\square$

Definition 9.22 If $\tau < \infty$ is a stopping time, then we define $X_\tau(\omega) := X_{\tau(\omega)}(\omega)$.

Lemma 9.23 Let I be countable, let X be adapted and let $\tau < \infty$ be a stopping time. Then X_τ is measurable with respect to $\mathcal{F}_\tau$.

Proof Let A be measurable and $t \in I$. Hence $\{\tau = s\} \cap X_s^{-1}(A) \in \mathcal{F}_s \subset \mathcal{F}_t$ for all $s \leq t$. Thus

$$X_\tau^{-1}(A) \cap \{\tau \leq t\} = \bigcup_{\substack{s \in I \\ s \leq t}} (\{\tau = s\} \cap X_s^{-1}(A)) \in \mathcal{F}_t$$

$\square$

For uncountable I and for fixed ω , in general, the map $I \rightarrow E, t \mapsto X_t(\omega)$ is not measurable; hence neither is the composition X_τ always measurable. Here one needs assumptions on the regularity of the paths $t \mapsto X_t(\omega)$; for example, right continuity. We come back to this point in Chapter 21 and leave this as a warning for the time being.

5.9.2 9.2 Martingales

Everyone who does not own a casino would agree without hesitation that the successive payment of gains $Y_1, Y_2, \dots$, such that $Y_1, Y_2, \dots$ are i.i.d. with $\mathbf{E}[Y_1] = 0$, could be considered a fair game consisting of consecutive rounds. In this case, the process X of partial sums $X_n = Y_1 + \dots + Y_n$ is integrable and $\mathbf{E}[X_n | \mathcal{F}_m] = X_m$ if $m < n$ (where $\mathbb{F} = \sigma(X)$). We want to use this equation for the conditional expectations as the defining equation for a fair game that in the following will be called a martingale. Note that, in particular, this definition does not require that the individual payments be independent or identically distributed. This makes the notion quite a bit more flexible. The momentousness of the following concept will become manifest only gradually.

Definition 9.24 Let $(\Omega, \mathcal{F}, \mathbf{P})$ be a probability space, $I \subseteq \mathbb{R}$ a filtration. Let $X = (X_t)_{t \in I}$ be a real-valued, adapted stochastic process. X is called (with respect to $\mathbb{F}$)

- martingale if $\mathbf{E}[X_t | \mathcal{F}_s] = X_s$ for all $s, t \in I$ with $s < t$,
- submartingale if $\mathbf{E}[X_t | \mathcal{F}_s] \geq X_s$ for all $s, t \in I$ with $s < t$,
- supermartingale if $\mathbf{E}[X_t | \mathcal{F}_s] \leq X_s$ for all $s, t \in I$ with $s < t$.

Remark 9.25 Clearly, for a martingale, the map $t \mapsto \mathbf{E}[X_t]$ is constant, for submartingales it is monotone increasing and for supermartingales it is monotone decreasing. $\square$

Remark 9.26 The etymology of the term martingale has not been resolved completely. The French *la martingale* (originally Provençal *martegalo*, named after the town Martiques) in equitation means "a piece of rein used in jumping and cross country riding". Sometimes the ramified shape, in particular of the running martingale (French *la martingale à anneaux*), is considered as emblematic for the doubling strategy in the Petersburg game.

This doubling strategy itself is the second meaning of *la martingale*. Starting here, a shift in the meaning towards the mathematical notion seems plausible. A different derivation, in contrast to the appearance, is based on the function of the rein, which is to "check the upward movement of the horse's head". Thus the notion of a martingale might first have been used for general gambling strategies (checking the movements of chance) and later for the doubling strategy in particular.

Remark 9.27 If $I = \mathbb{N}$, $I = \mathbb{N}_0$ or $I = \mathbb{Z}$, then it is enough to consider at each instant s only $t = s + 1$. In fact, by the tower property of the conditional expectation (Theorem 8.14(iv)), we get

$$\mathbf{E}[X_{s+2} | \mathcal{F}_s] = \mathbf{E}[\mathbf{E}[X_{s+2} | \mathcal{F}_{s+1}] | \mathcal{F}_s].$$

Thus, if the defining equality (or inequality) holds for any time step of size one, by induction it holds for all times. $\square$

Remark 9.28 If we do not explicitly mention the filtration $\mathbb{F}$, we tacitly assume that $\mathbb{F}$ is generated by X ; that is, $\mathcal{F}_t = \sigma(X_s, s \leq t)$. $\square$

Remark 9.29 Let $\mathbb{F}$ and $\mathbb{F}'$ be filtrations with $\mathcal{F}_t \subset \mathcal{F}'_t$ for all t , and let X be an $\mathbb{F}'$ (sub-, super-) martingale that is adapted to $\mathbb{F}$. Then X is also a (sub-, super-) martingale with respect to the smaller filtration $\mathbb{F}$. Indeed, for $s < t$ and for the case of a submartingale,

$$\mathbf{E}[X_t | \mathcal{F}_s] = \mathbf{E}[\mathbf{E}[X_t | \mathcal{F}'_s] | \mathcal{F}_s] \geq \mathbf{E}[X_s | \mathcal{F}_s] = X_s.$$

In particular, an $\mathbb{F}$ -(sub-, super-) martingale X is always a (sub-, super-) martingale with respect to its own filtration $\sigma(X)$. $\square$

Example 9.30 Let $Y_1, \dots, Y_N$ be independent random variables with $\mathbf{E}[Y_t] = 0$ for all $t = 1, \dots, N$. Let $\mathcal{F}_t := \sigma(Y_1, \dots, Y_t)$ and $X_t := \sum_{s=1}^t Y_s$. Then X is adapted and integrable, and $\mathbf{E}[Y_r | \mathcal{F}_s] = 0$ for $r > s$. Hence, for $t > s$,

$$\mathbf{E}[X_t | \mathcal{F}_s] = \mathbf{E}[X_s | \mathcal{F}_s] + \mathbf{E}[X_t - X_s | \mathcal{F}_s] = X_s + \sum_{r=s+1}^t \mathbf{E}[Y_r | \mathcal{F}_s] = X_s$$

Thus, X is an $\mathbb{F}$ -martingale.

Similarly, X is a submartingale if $\mathbf{E}[Y_t] \geq 0$ for all t , and a supermartingale if $\mathbf{E}[Y_t] \leq 0$ for all t . $\square$

Example 9.31 Consider the situation of the preceding example; however, now with $\mathbf{E}[Y_t] = 1$ and $X_t = \prod_{s=1}^t Y_s$ for $t \in \mathbb{N}_0$. By Theorem 5.4, $Y_1 \cdot Y_2$ is integrable.

Inductively, we get $\mathbf{E}[|X_t|] < \infty$ for all $t \in \mathbb{N}_0$. Evidently, X is adapted to $\mathbb{F}$ and for all $s \in \mathbb{N}_0$, we have

$$\mathbf{E}[X_{s+1} | \mathcal{F}_s] = \mathbf{E}[X_s Y_{s+1} | \mathcal{F}_s] = X_s \mathbf{E}[Y_{s+1} | \mathcal{F}_s] = X_s$$

Hence X is an $\mathbb{F}$ -martingale.

Theorem 9.32

- (i) X is a supermartingale if and only if $(-X)$ is a submartingale.
- (ii) Let X and Y be martingales and let $a, b \in \mathbb{R}$. Then $(aX + bY)$ is a martingale.
- (iii) Let X and Y be supermartingales and $a, b \geq 0$. Then $(aX + bY)$ is a supermartingale.
- (iv) Let X and Y be supermartingales. Then $Z := X \wedge Y = (\min(X_t, Y_t))_{t \in I}$ is a supermartingale.
- (v) If $(X_t)_{t \in \mathbb{N}_0}$ is a supermartingale and $\mathbf{E}[X_T] \geq \mathbf{E}[X_0]$ for some $T \in \mathbb{N}_0$, then $(X_t)_{t \in \{0, \dots, T\}}$ is a martingale. If there exists a sequence $T_N \rightarrow \infty$ with $\mathbf{E}[X_{T_N}] \geq \mathbf{E}[X_0]$, then X is a martingale.

Proof (i), (ii) and (iii) These are evident.

(iv) Since $|Z_t| \leq |X_t| + |Y_t|$, we have $\mathbf{E}[|Z_t|] < \infty$ for all $t \in I$. Due to monotonicity of the conditional expectation (Theorem 8.14(ii)), for $t > s$, we have $\mathbf{E}[Z_t | \mathcal{F}_s] \leq \mathbf{E}[Y_t | \mathcal{F}_s] \leq Y_s$ and $\mathbf{E}[Z_t | \mathcal{F}_s] \leq \mathbf{E}[X_t | \mathcal{F}_s] \leq X_s$; hence

$$\mathbf{E}[Z_t | \mathcal{F}_s] \leq X_s \wedge Y_s = Z_s$$

(v) For $t \leq T$, let $Y_t := \mathbf{E}[X_T | \mathcal{F}_t]$. Then Y is a martingale and $Y_t \leq X_t$. Hence

$$\mathbf{E}[X_0] \leq \mathbf{E}[X_T] = \mathbf{E}[Y_T] = \mathbf{E}[Y_t] \leq \mathbf{E}[X_t] \leq \mathbf{E}[X_0]$$

(The first inequality holds by assumption.) We infer that $Y_t = X_t$ almost surely for all t and thus $(X_t)_{t \in \{0, \dots, T\}}$ is a martingale.

Let $T_N \rightarrow \infty$ with $\mathbf{E}[X_{T_N}] \geq \mathbf{E}[X_0]$ for all $N \in \mathbb{N}$. Then, for any $t > s \geq 0$, there is an $N \in \mathbb{N}$ with $T_N > t$. Hence, $\mathbf{E}[X_t | \mathcal{F}_s] = \mathbf{E}[X_s]$ and X is a martingale.

Remark 9.33 Many statements about supermartingales hold mutatis mutandis for submartingales. For example, in the preceding theorem, claim (i) holds with the words "submartingale" and "supermartingale" interchanged, claim (iv) holds for submartingales if the minimum is replaced by a maximum, and so on. We often do not give the statements both for submartingales and for supermartingales. Instead, we choose representatively one case. Note,

however, that those statements that we make explicitly about martingales usually cannot be adapted easily to sub- or supermartingales (such as (ii) in the preceding theorem).

Corollary 9.34 Let X be a submartingale and $a \in \mathbb{R}$. Then $(X - a)^+$ is a submartingale.

Proof Clearly, 0 and $Y = X - a$ are submartingales. By (iv), $(X - a)^+ = Y \vee 0$ is also a submartingale.

Theorem 9.35 Let X be a martingale and let $\varphi : \mathbb{R} \rightarrow \mathbb{R}$ be a convex function.

(i) If

$$\mathbf{E} [\varphi (X_t)^+] < \infty \quad \text{for all } t \in I, \quad (9.1)$$

then $(\varphi (X_t))_{t \in I}$ is a submartingale.

(ii) If $t^* := \sup(I) \in I$, then $\mathbf{E} [\varphi (X_{t^*})^+] < \infty$ implies (9.1).

(iii) In particular, if $p \geq 1$ and $\mathbf{E} [|X_t|^p] < \infty$ for all $t \in I$, then $(|X_t|^p)_{t \in I}$ is a submartingale.

Proof (i) We always have $\mathbf{E} [\varphi (X_t)^-] < \infty$ (Theorem 7.9); hence, by assumption, $\mathbf{E} [|\varphi (X_t)|] < \infty$ for all $t \in I$. Jensen's inequality (Theorem 8.20) then yields, for $t > s$,

$$\mathbf{E} [\varphi (X_t) \mid \mathcal{F}_s] \geq \varphi (\mathbf{E} [X_t \mid \mathcal{F}_s]) = \varphi (X_s)$$

(ii) Since φ is convex, so is $x \mapsto \varphi(x)^+$. Furthermore, by assumption, we have $\mathbf{E} [\varphi (X_{t^*})^+] < \infty$; hence Jensen's inequality implies that, for all $t \in I$,

$$\begin{aligned} \mathbf{E} [\varphi (X_t)^+] &= \mathbf{E} [\varphi (\mathbf{E} [X_{t^*} \mid \mathcal{F}_t])^+] \leq \mathbf{E} [\mathbf{E} [\varphi (X_{t^*})^+ \mid \mathcal{F}_t]] \\ &= \mathbf{E} [\varphi (X_{t^*})^+] < \infty \end{aligned}$$

(iii) This is evident since $x \mapsto |x|^p$ is convex.

Example 9.36 (See Example 9.4.) Symmetric simple random walk X on $\mathbb{Z}$ is a square integrable martingale. Hence $(X_n^2)_{n \in \mathbb{N}_0}$ is a submartingale.

Exercise 9.2.1 Let Y be a random variable with $\mathbf{E}[|Y|] < \infty$ and let $\mathbb{F}$ be a filtration as well as

$$X_t := \mathbf{E}[Y \mid \mathcal{F}_t] \quad \text{for all } t \in I$$

Show that X is an $\mathbb{F}$ -martingale.

Exercise 9.2.2 Let $(X_n)_{n \in \mathbb{N}_0}$ be a predictable $\mathbb{F}$ -martingale. Show that $X_n = X_0$ almost surely for all $n \in \mathbb{N}_0$.

Exercise 9.2.3 Show that the claim of Theorem 9.35 continues to hold if X is only a submartingale but if φ is in addition assumed to be monotone increasing. Give an example that shows that the monotonicity of φ is essential. (Compare Corollary 9.34.)

Exercise 9.2.4 (Azuma's inequality) Show the following.

(i) If X is a random variable with $|X| \leq 1$ a.s., then there is a random variable Y with values in $\{-1, +1\}$ and with $\mathbf{E}[Y \mid X] = X$.

(ii) For X as in (i) with $\mathbf{E}[X] = 0$, infer that (using Jensen's inequality)

$$\mathbf{E} [e^{\lambda X}] \leq \cosh(\lambda) \leq e^{\lambda^2/2} \quad \text{for all } \lambda \in \mathbb{R}.$$

(iii) If $(M_n)_{n \in \mathbb{N}_0}$ is a martingale with $M_0 = 0$ and if there is a sequence $(c_k)_{k \in \mathbb{N}}$ of nonnegative numbers with $|M_n - M_{n-1}| \leq c_n$ a.s. for all $n \in \mathbb{N}$, then

$$\mathbf{E} [e^{\lambda M_n}] \leq \exp \left(\frac{1}{2} \lambda^2 \sum_{k=1}^n c_k^2 \right)$$

(iv) Under the assumptions of (iii), Azuma's inequality holds:

$$\mathbf{P}[|M_n| \geq \lambda] \leq 2 \exp\left(-\frac{\lambda^2}{2 \sum_{k=1}^n c_k^2}\right) \quad \text{for all } \lambda \geq 0$$

Hint: Use Markov's inequality for $f(x) = e^{\gamma x}$ and choose the optimal γ .

5.9.3 9.3 Discrete Stochastic Integral

So far we have encountered a martingale as the process of partial sums of gains of a fair game. This game can also be the price of a stock that is traded at discrete times on a stock exchange. With this interpretation, it is particularly evident that it is natural to construct new stochastic processes by considering investment strategies for the stock. The value of the portfolio, which is the new stochastic process, changes as the stock price changes. It is the price multiplied by the number of stocks in the portfolio. In order to describe such processes formally, we introduce the following notion.

Definition 9.37 (Discrete stochastic integral) Let $(X_n)_{n \in \mathbb{N}_0}$ be an $\mathbb{F}$ -adapted real process and let $(H_n)_{n \in \mathbb{N}}$ be a real-valued and $\mathbb{F}$ -predictable process. The discrete stochastic integral of H with respect to X is the stochastic process $H \cdot X$ defined by

$$(H \cdot X)_n := \sum_{m=1}^n H_m (X_m - X_{m-1}) \quad \text{for } n \in \mathbb{N}_0 \quad (9.2)$$

If X is a martingale, then $H \cdot X$ is also called the martingale transform of X .

Remark 9.38 Clearly, $H \cdot X$ is adapted to $\mathbb{F}$.

Let X be a (possibly unfair) game where $X_n - X_{n-1}$ is the gain per euro in the n th round. We interpret H_n as the number of euros we bet in the n th game. H is then a gambling strategy. Clearly, the value of H_n has to be decided at time $n-1$; that is, before the result of X_n is known. In other words, H must be predictable.

Now assume that X is a fair game (that is, a martingale) and H is locally bounded (that is, each H_n is bounded). Then (since $\mathbf{E}[X_{n+1} - X_n | \mathcal{F}_n] = 0$)

$$\begin{aligned} \mathbf{E}[(H \cdot X)_{n+1} | \mathcal{F}_n] &= \mathbf{E}[(H \cdot X)_n + H_{n+1}(X_{n+1} - X_n) | \mathcal{F}_n] \\ &= (H \cdot X)_n + H_{n+1} \mathbf{E}[X_{n+1} - X_n | \mathcal{F}_n] \\ &= (H \cdot X)_n. \end{aligned}$$

Thus $H \cdot X$ is a martingale. The following theorem says that the converse also holds; that is, X is a martingale if, for sufficiently many predictable processes, the stochastic integral is a martingale.

Theorem 9.39 (Stability theorem) Let $(X_n)_{n \in \mathbb{N}_0}$ be an adapted, real-valued stochastic process with $\mathbf{E}[|X_0|] < \infty$.

(i) X is a martingale if and only if, for any locally bounded predictable process H , the stochastic integral $H \cdot X$ is a martingale.

(ii) X is a submartingale (supermartingale) if and only if $H \cdot X$ is a submartingale (supermartingale) for any locally bounded predictable $H \geq 0$.

Proof (i) " $\implies$ " This has been shown in the discussion above.

" $\implies$ " Fix an $n_0 \in \mathbb{N}$, and let $H_n = \mathbb{1}_{\{n=n_0\}}$. Then $(H \cdot X)_{n_0-1} = 0$; hence

$$0 = \mathbf{E}[(H \cdot X)_{n_0} | \mathcal{F}_{n_0-1}] = \mathbf{E}[X_{n_0} | \mathcal{F}_{n_0-1}] - X_{n_0-1}$$

(ii) This is similar to (i).

The preceding theorem says, in particular, that we cannot find any locally bounded gambling strategy that transforms a martingale (or, if we are bound to nonnegative gambling strategies,

as we are in real life, a supermartingale) into a submartingale. Quite the contrary is suggested by the many invitations to play all kinds of "sure winning systems" in lotteries.

Example 9.40 (Petersburg game) We continue Example 9.14 (see also Example 4.22). Define $X_n := D_1 + \dots + D_n$ for $n \in \mathbb{N}_0$. Then X is a martingale. The gambling strategy $H_n := 2^{n-1} \mathbb{1}_{\{D_1=D_2=\dots=D_{n-1}=-1\}}$ for $n \in \mathbb{N}$ and $H_0 = 1$ is predictable and locally bounded. Let $S_n = \sum_{i=1}^n H_i D_i = (H \cdot X)_n$ be the gain after n rounds. Then S is a martingale by the preceding theorem. In particular, we get (as shown already in Example 4.22) that $\mathbf{E}[S_n] = 0$ for all $n \in \mathbb{N}$. We will come back later to the point that this superficially contrasts with $S_n \xrightarrow{n \rightarrow \infty} 1$ a.s. (see Example 11.6).

For the moment, note that the martingale $S' = (1 - S_n)_{n \in \mathbb{N}_0}$, just like the one in Example 9.31, has the structure of a product of independent random variables with expectation 1. In fact, $S'_n = \prod_{i=1}^n (1 - D_i)$.

5.9.4 9.4 Discrete Martingale Representation Theorem and the Crr Model

By virtue of the stochastic integral, we have transformed a martingale X via a gambling strategy H into a new martingale $H \cdot X$. Let us change the perspective and ask: For fixed X , which are the martingales Y (with $Y_0 = 0$) that can be obtained as discrete stochastic integrals of X with a suitable gambling strategy $H = H(Y)$? Possibly all martingales Y ? This is not the case, in general, as the example below indicates. However, we will see that all martingales can be represented as stochastic integrals if the increments $X_{n+1} - X_n$ can take only two values (given $X_1, \dots, X_n$). In this case, we give a representation theorem and use it to discuss the fair price for a European call option in the stock market model of Cox-Ross-Rubinstein. This model is rather simple and describes an idealized market (no transaction costs, fractional numbers of stocks tradeable and so on). For extensive literature on stochastic aspects of mathematical finance, we refer to the textbooks [9, 42, 48, 57, 86, 102, 121] or [159].

Example 9.41 Consider the very simple martingale $X = (X_n)_{n=0,1}$ with only two time points. Let $X_0 = 0$ almost surely and $\mathbf{P}[X_1 = -1] = \mathbf{P}[X_1 = 0] = \mathbf{P}[X_1 = 1] = \frac{1}{3}$. Let $Y_0 = 0$. Further, let $Y_1 = 2$ if $X_1 = 1$ and $Y_1 = -1$ otherwise. Then Y is manifestly a $\sigma(X)$ -martingale. However, there is no number H_1 such that $H_1 X_1 = Y_1$. $\square$

Let $T \in \mathbb{N}$ be a fixed time. If $(Y_n)_{n=0,1,\dots,T}$ is an $\mathbb{F}$ -martingale, then $Y_n = \mathbf{E}[Y_T | \mathcal{F}_n]$ for all $n \leq T$. An $\mathbb{F}$ -martingale Y is thus determined uniquely by the terminal values Y_T (and vice versa). Let X be a martingale. As $(H \cdot X)$ is a martingale, the representation problem for martingales is thus reduced to the problem of representing an integrable random variable $V := Y_T$ as $v_0 + (H \cdot X)_T$, where $v_0 = \mathbf{E}[Y_T]$.

We saw that, in general, this is not possible if the differences $X_{n+1} - X_n$ take three (or more) different values. Hence we now consider the case where only two values are possible. Here, at each time step, a system of two linear equations with two unknowns has to be solved. In the case where $X_{n+1} - X_n$ takes three values, the system has three equations and is thus overdetermined.

Definition 9.42 (Binary model) A stochastic process $X_0, \dots, X_T$ is called binary splitting or a binary model if there exist random variables $D_1, \dots, D_T$ with values in $\{-1, +1\}$ and functions $f_n : \mathbb{R}^{n-1} \times \{-1, +1\} \rightarrow \mathbb{R}$ for $n = 1, \dots, T$, as well as $x_0 \in \mathbb{R}$ such that $X_0 = x_0$ and

$$X_n = f_n(X_1, \dots, X_{n-1}, D_n) \quad \text{for any } n = 1, \dots, T.$$

By $\mathbb{F} = \sigma(X)$, we denote the filtration generated by X .

Note that X_n depends only on $X_1, \dots, X_{n-1}$ and D_n but not on the full information inherent in the values $D_1, \dots, D_n$. If the latter were the case, a ramification into more than two values in one time step would be possible.

Theorem 9.43 (Representation theorem) Let X be a binary model and let V_T be an $\mathcal{F}_T$ -measurable random variable. Then there exists a bounded predictable process H and $av_0 \in \mathbb{R}$ with $V_T = v_0 + (H \cdot X)_T$.

Note that $\mathbb{F}$ is the filtration generated by X , not the, possibly larger, filtration generated by $D_1, \dots, D_T$. For the latter case, the claim of the theorem would be incorrect since, loosely speaking, with H we can bet on X but not on the D_i .

Proof We show that there exist $\mathcal{F}_{T-1}$ -measurable random variables V_{T-1} and H_T such that $V_T = V_{T-1} + H_T(X_T - X_{T-1})$. By a backward induction, this yields the claim.

Since V_T is $\mathcal{F}_T$ -measurable, by the factorization lemma (Corollary 1.97) there exists a function $g_T : \mathbb{R}^T \rightarrow \mathbb{R}$ with $V_T = g_T(X_1, \dots, X_T)$. Define

$$X_T^\pm = f_T(X_1, \dots, X_{T-1}, \pm 1) \quad \text{and} \quad V_T^\pm = g_T(X_1, \dots, X_{T-1}, X_T^\pm).$$

Each of these four random variables is manifestly $\mathcal{F}_{T-1}$ -measurable. Hence we are looking for solutions V_{T-1} and H_T of the following system of linear equations:

$$\begin{aligned} V_{T-1} + H_T(X_T^- - X_{T-1}) &= V_T^- \\ V_{T-1} + H_T(X_T^+ - X_{T-1}) &= V_T^+ \end{aligned} \tag{9.3}$$

By construction, $X_T^+ - X_T^- \neq 0$ if $V_T^+ - V_T^- \neq 0$. Hence we can solve (9.3) and get

$$H_T := \begin{cases} \frac{V_T^+ - V_T^-}{X_T^+ - X_T^-}, & \text{if } X_T^+ \neq X_T^- \\ 0, & \text{else} \end{cases}$$

and $V_{T-1} = V_T^+ - H_T(X_T^+ - X_{T-1}) = V_T^- - H_T(X_T^- - X_{T-1})$.

We now want to interpret X as the market price of a stock and V_T as the payment of a financial derivative on X , a so-called contingent claim or, briefly, claim. For example, V_T could be a (European) call option with maturity T and strike price $K \geq 0$. In this case, we have $V_T = (X_T - K)^+$. Economically speaking, the European call gives the buyer the right (but not the obligation) to buy one stock at time T at price K (from the issuer of the option). As typically the option is exercised only if the market price at time T is larger than K (and then gives a profit of $X_T - K$ as the stock could be sold at price X_T on the market), the value of the option is indeed $V_T = (X_T - K)^+$.

At the stock exchanges, not only are stocks traded but also derivatives on stocks. Hence, what is the fair price $\pi(V_T)$ for which a trader would offer (and buy) the contingent claim V_T ? If there exists a strategy H and a v_0 such that $V_T = v_0 + (H \cdot X)_T$, then the trader can sell the claim for v_0 (at time 0) and replicate the claim by building a portfolio that follows the trading strategy H . In this case, the claim V_T is called replicable and the strategy H is called a hedging strategy, or briefly a hedge. A market in which every claim can be replicated is called complete. In this sense, the binary model is a complete market.

If there was a second strategy H' and a second v'_0 with $v'_0 + (H' \cdot X)_T = V_T$, then, in particular, $v_0 - v'_0 = ((H' - H) \cdot X)_T$. If we had $v_0 > v'_0$, then the trader could follow the strategy $H' - H$ (which gives a final payment of $V_T - V_T = 0$) and make a sure profit of $v_0 - v'_0$. In the opposite case, $v_0 < v'_0$, the strategy $H - H'$ ensures a risk-free profit. Such a risk-free profit (or free lunch in economic jargon) is called an arbitrage. It is reasonable to assume that a market gives no opportunity for an arbitrage. Hence the fair price $\pi(V_T)$ is determined uniquely once there is one trading strategy H and a v_0 such that $V_T = v_0 + (H \cdot X)_T$.

Until now, we have not assumed that X is a martingale. However, if X is a martingale, then $(H \cdot X)$ is a martingale with $(H \cdot X)_0 = 0$; hence clearly $\mathbf{E}[(H \cdot X)_T] = 0$. Thus

$$\pi(V_T) = v_0 = \mathbf{E}[V_T] \quad (9.4)$$

Since, in this case, v_0 does not depend on the trading strategy and is hence unique, the market is automatically arbitrage-free. A finite market is thus arbitrage-free if and only if there exists an equivalent martingale (to be defined below). In this case, uniqueness of this martingale is equivalent to completeness of the market ("the fundamental theorem of asset pricing" by Harrison-Pliska [68]). In larger markets, equivalence holds only with a somewhat more flexible notion of arbitrage (see [30]).

Now if X is not a martingale, then in some cases, we can replace X by a different process X' that is a martingale and such that the distributions $\mathbf{P}_X$ and $\mathbf{P}_{X'}$ are equivalent; that is, have the same null sets. Such a process is called an equivalent martingale, and $\mathbf{P}_{X'}$ is called an equivalent martingale measure. A trading strategy that replicates V_T with respect to X also replicates V_T with respect to X' . In particular, the fair price does not change if we pass to the equivalent martingale X' . Thus we can compute $\pi(V_T)$ by applying (9.4) to the equivalent martingale.

While here this is only of interest in that it simplifies the computation of fair prices, it has an economic interpretation as a measure for the market prices that we would see if all traders were risk-neutral; that is, for traders who price a future payment by its mean value. Typically, however, traders are risk-averse and thus real market prices include a discount due to the inherent risk.

Now we consider one model in greater detail.

Definition 9.44 Let $T \in \mathbb{N}$, $a \in (-1, 0)$ and $b > 0$ as well as $p \in (0, 1)$. Further, let $D_1, \dots, D_T$ be i.i.d. Rad_p random variables (that is, $\mathbf{P}[D_1 = 1] = 1 - \mathbf{P}[D_1 = -1] = p$). We let $X_0 = x_0 > 0$ and for $n = 1, \dots, T$, define

$$X_n = \begin{cases} (1+b)X_{n-1}, & \text{if } D_n = +1 \\ (1+a)X_{n-1}, & \text{if } D_n = -1 \end{cases}$$

X is called the multi-period binomial model or the Cox-Ross-Rubinstein model (without interest returns).

As we have shown already, the CRR model is complete. Further, with the choice $p = p^* := \frac{a}{a-b}$, we can change X into a martingale. Hence the model is also arbitrage-free (for all $p \in (0, 1)$). Now we want to compute the price of a European call option $V_T := (X_T - K)^+$ explicitly. To this end, we can assume $p = p^*$. Letting $A := \min \{i \in \mathbb{N}_0 : (1+b)^i(1+a)^{T-i}x_0 > K\}$, we get

$$\begin{aligned} \pi(V_T) &= \mathbf{E}_{p^*}[V_T] = \sum_{i=0}^T b_{T,p^*}(\{i\}) [(1+b)^i(1+a)^{T-i}x_0 - K]^+ \\ &= x_0 \sum_{i=A}^T \binom{T}{i} (p^*)^i (1-p^*)^{T-i} [(1+b)^i(1+a)^{T-i}] \\ &\quad - K \sum_{i=A}^T b_{T,p^*}(\{i\}). \end{aligned}$$

If we define $p' = (1+b)p^*$, then $p' \in (0, 1)$ and $1-p' = (1-p^*)(1+a)$. We thus obtain the Cox-Ross-Rubinstein formula

$$\pi(V_T) = x_0 b_{T,p'}(\{A, \dots, T\}) - K b_{T,p^*}(\{A, \dots, T\}). \quad (9.5)$$

This is the discrete analogue of the celebrated Black-Scholes formula for option pricing in certain time-continuous markets.

5.10 10 Optional Sampling Theorems

In Chapter 9 we saw that martingales are transformed into martingales if we apply certain admissible gambling strategies. In this chapter, we establish a similar stability property for martingales that are stopped at a random time. In order also to obtain these results for submartingales and supermartingales, in the first section, we start with a decomposition theorem for adapted processes. We show the optional sampling and optional stopping theorems in the second section. The chapter finishes with the investigation of random stopping times with an infinite time horizon.

5.10.1 10.1 Doob Decomposition and Square Variation

Let $X = (X_n)_{n \in \mathbb{N}_0}$ be an adapted process with $\mathbf{E}[|X_n|] < \infty$ for all $n \in \mathbb{N}_0$. We will decompose X into a sum consisting of a martingale and a predictable process. To this end, for $n \in \mathbb{N}_0$, define

$$M_n := X_0 + \sum_{k=1}^n (X_k - \mathbf{E}[X_k | \mathcal{F}_{k-1}]) \quad (10.1)$$

and

$$A_n := \sum_{k=1}^n (\mathbf{E}[X_k | \mathcal{F}_{k-1}] - X_{k-1}).$$

Evidently, $X_n = M_n + A_n$. By construction, A is predictable with $A_0 = 0$, and M is a martingale since

$$\mathbf{E}[M_n - M_{n-1} | \mathcal{F}_{n-1}] = \mathbf{E}[X_n - \mathbf{E}[X_n | \mathcal{F}_{n-1}] | \mathcal{F}_{n-1}] = 0.$$

Theorem 10.1 (Doob decomposition) Let $X = (X_n)_{n \in \mathbb{N}_0}$ be an adapted integrable process. Then there exists a unique decomposition $X = M + A$, where A is predictable with $A_0 = 0$ and M is a martingale. This representation of X is called the Doob decomposition. X is a submartingale if and only if A is monotone increasing.

Proof We only have to show uniqueness of the decomposition. Hence, let $X = M + A = M' + A'$ be two such decompositions. Then $M - M' = A' - A$ is a predictable martingale; hence (see Exercise 9.2.2) $M_n - M'_n = M_0 - M'_0 = 0$ for all $n \in \mathbb{N}_0$.

Example 10.2 Let $I = \mathbb{N}_0$ or $I = \{0, \dots, N\}$. Let $(X_n)_{n \in I}$ be a square integrable $\mathbb{F}$ -martingale (that is, $\mathbf{E}[X_n^2] < \infty$ for all $n \in I$). By Theorem 9.35, $Y := (X_n^2)_{n \in I}$ is a submartingale. Let $Y = M + A$ be the Doob decomposition of Y . Then $(X_n^2 - A_n)_{n \in I}$ is a martingale. Furthermore, $\mathbf{E}[X_{i-1}X_i | \mathcal{F}_{i-1}] = X_{i-1}\mathbf{E}[X_i | \mathcal{F}_{i-1}] = X_{i-1}^2$; hence (as in (10.1))

$$\begin{aligned} A_n &= \sum_{i=1}^n (\mathbf{E}[X_i^2 | \mathcal{F}_{i-1}] - X_{i-1}^2) \\ &= \sum_{i=1}^n (\mathbf{E}[(X_i - X_{i-1})^2 | \mathcal{F}_{i-1}] - 2X_{i-1}^2 + 2\mathbf{E}[X_{i-1}X_i | \mathcal{F}_{i-1}]) \\ &= \sum_{i=1}^n \mathbf{E}[(X_i - X_{i-1})^2 | \mathcal{F}_{i-1}] \end{aligned}$$

Definition 10.3 Let $(X_n)_{n \in I}$ be a square integrable $\mathbb{F}$ -martingale. The unique predictable process A for which $(X_n^2 - A_n)_{n \in I}$ becomes a martingale is called the square variation process of X and is denoted by $(\langle X \rangle_n)_{n \in I} := A$.

By the preceding example, we conclude the following theorem.

Theorem 10.4 Let X be as in Definition 10.3. Then, for $n \in \mathbb{N}_0$,

$$\langle X \rangle_n = \sum_{i=1}^n \mathbf{E} [(X_i - X_{i-1})^2 \mid \mathcal{F}_{i-1}] \quad (10.2)$$

and

$$\mathbf{E} [\langle X \rangle_n] = \text{Var} [X_n - X_0]. \quad (10.3)$$

Remark 10.5 If Y and A are as in Example 10.2, then A is monotone increasing since $(X_n^2)_{n \in I}$ is a submartingale (see Theorem 10.1). Therefore, A is sometimes called the increasing process of Y .

Example 10.6 Let $Y_1, Y_2, \dots$ be independent, square integrable, centered random variables. Then $X_n := Y_1 + \dots + Y_n$ defines a square integrable martingale with $\langle X \rangle_n = \sum_{i=1}^n \mathbf{E} [Y_i^2]$. In fact, $A_n = \sum_{i=1}^n \mathbf{E} [Y_i^2 \mid Y_1, \dots, Y_{i-1}] = \sum_{i=1}^n \mathbf{E} [Y_i^2]$ (as in Example 10.2).

Note that in order for $\langle X \rangle$ to have the simple form as in Example 10.6, it is not enough for the random variables $Y_1, Y_2, \dots$ to be uncorrelated.

Example 10.7 Let $Y_1, Y_2, \dots$ be independent, square integrable random variables with $\mathbf{E} [Y_n] = 1$ for all $n \in \mathbb{N}$. Let $X_n := \prod_{i=1}^n Y_i$ for $n \in \mathbb{N}_0$. Then $X = (X_n)_{n \in \mathbb{N}_0}$ is a square integrable martingale with respect to $\mathbb{F} = \sigma(X)$ (why?) and

$$\mathbf{E} [(X_n - X_{n-1})^2 \mid \mathcal{F}_{n-1}] = \mathbf{E} [(Y_n - 1)^2 X_{n-1}^2 \mid \mathcal{F}_{n-1}] = \text{Var} [Y_n] X_{n-1}^2.$$

Hence $\langle X \rangle_n = \sum_{i=1}^n \text{Var} [Y_i] X_{i-1}^2$. We see that the square variation process can indeed be a truly random process.

Example 10.8 Let $(X_n)_{n \in \mathbb{N}_0}$ be the one-dimensional symmetric simple random walk

$$X_n = \sum_{i=1}^n R_i \quad \text{for all } n \in \mathbb{N}_0,$$

where $R_1, R_2, R_3, \dots$ are i.i.d. and $\sim \text{Rad}_{1/2}$; that is,

$$\mathbf{P} [R_i = 1] = 1 - \mathbf{P} [R_i = -1] = \frac{1}{2}.$$

Clearly, X is a martingale and hence $|X|$ is a submartingale. Let $|X| = M + A$ be Doob's decomposition of $|X|$. Then

$$A_n = \sum_{i=1}^n (\mathbf{E} [|X_i| \mid \mathcal{F}_{i-1}] - |X_{i-1}|).$$

Now

$$|X_i| = \begin{cases} |X_{i-1}| + R_i, & \text{if } X_{i-1} > 0, \\ |X_{i-1}| - R_i, & \text{if } X_{i-1} < 0, \\ 1, & \text{if } X_{i-1} = 0. \end{cases}$$

Therefore,

$$\mathbf{E} [|X_i| \mid \mathcal{F}_{i-1}] = \begin{cases} |X_{i-1}|, & \text{if } |X_{i-1}| \neq 0 \\ 1, & \text{if } |X_{i-1}| = 0 \end{cases}$$

The process

$$A_n = \# \{i \leq n-1 : |X_i| = 0\}$$

is the so-called local time of X at 0 . We conclude that (since $\mathbf{P}[X_{2j} = 0] = \binom{2j}{j}4^{-j}$ and $\mathbf{P}[X_{2j+1} = 0] = 0$)

$$\begin{aligned} \mathbf{E}[|X_n|] &= \mathbf{E}[\# \{i \leq n-1 : X_i = 0\}] \\ &= \sum_{i=0}^{n-1} \mathbf{P}[X_i = 0] = \sum_{j=0}^{\lfloor (n-1)/2 \rfloor} \binom{2j}{j} 4^{-j}. \end{aligned}$$

Example 10.9 We want to generalize the preceding example further. Evidently, we did not use (except in the last formula) the fact that X is a random walk. Rather, we just used the fact that the differences $(\Delta X)_n := X_n - X_{n-1}$ take only the values -1 and +1 . Hence, now let X be a martingale with $|X_n - X_{n-1}| = 1$ almost surely for all $n \in \mathbb{N}$ and with $X_0 = x_0 \in \mathbb{Z}$ almost surely. Let $f : \mathbb{Z} \rightarrow \mathbb{R}$ be an arbitrary map. Then $Y := (f(X_n))_{n \in \mathbb{N}_0}$ is an integrable adapted process (since $|f(X_n)| \leq \max_{x \in \{x_0-n, \dots, x_0+n\}} |f(x)|$). In order to compute Doob's decomposition of Y , define the first and second discrete derivatives of f :

$$f'(x) := \frac{f(x+1) - f(x-1)}{2}$$

and

$$f''(x) := f(x-1) + f(x+1) - 2f(x).$$

Further, let $F'_n := f'(X_{n-1})$ and $F''_n := f''(X_{n-1})$. By computing the cases $X_n = X_{n-1} - 1$ and $X_n = X_{n-1} + 1$ separately, we see that for all $n \in \mathbb{N}$

$$\begin{aligned} f(X_n) - f(X_{n-1}) &= \frac{f(X_{n-1}+1) - f(X_{n-1}-1)}{2} (X_n - X_{n-1}) \\ &\quad + \frac{1}{2} f(X_{n-1}-1) + \frac{1}{2} f(X_{n-1}+1) - f(X_{n-1}) \\ &= f'(X_{n-1})(X_n - X_{n-1}) + \frac{1}{2} f''(X_{n-1}) \\ &= F'_n \cdot (X_n - X_{n-1}) + \frac{1}{2} F''_n \end{aligned}$$

Summing up, we get the discrete Itô formula:

$$\begin{aligned} f(X_n) &= f(x_0) + \sum_{i=1}^n f'(X_{i-1})(X_i - X_{i-1}) + \sum_{i=1}^n \frac{1}{2} f''(X_{i-1}) \\ &= f(x_0) + (F' \cdot X)_n + \sum_{i=1}^n \frac{1}{2} F''_i \end{aligned} \tag{10.4}$$

Here $F' \cdot X$ is the discrete stochastic integral (see Definition 9.37). Now $M := f(x_0) + F' \cdot X$ is a martingale by Theorem 9.39 since F' is predictable (and since $|F'_n| \leq \max_{x \in \{x_0-n, \dots, x_0+n\}} |f'(x)|$), and $A := (\sum_{i=1}^n \frac{1}{2} F''_i)_{n \in \mathbb{N}_0}$ is predictable. Hence $f(X) := (f(X_n))_{n \in \mathbb{N}_0} = M + A$ is the Doob decomposition of $f(X)$. In particular, $f(X)$ is a submartingale if $f''(x) \geq 0$ for all $x \in \mathbb{Z}$; that is, if f is convex. We knew this already from Theorem 9.35; however, here we could also quantify how much $f(X)$ differs from a martingale.

In the special cases $f(x) = x^2$ and $f(x) = |x|$, the second derivative is $f''(x) = 2$ and $f''(x) = 2 \cdot \mathbb{1}_{\{0\}}(x)$, respectively. Thus, from (10.4), we recover the statements of Theorem 10.4 and Example 10.8.

Later we will derive a formula similar to (10.4) for stochastic processes in continuous time (see Section 25.3).

5.10.2 10.2 Optional Sampling and Optional Stopping

Lemma 10.10 Let $I \subset \mathbb{R}$ be countable, let $(X_t)_{t \in I}$ be a martingale, let $T \in I$ and let τ be a stopping time with $\tau \leq T$. Then $X_\tau = \mathbf{E}[X_T | \mathcal{F}_\tau]$ and, in particular, $\mathbf{E}[X_\tau] = \mathbf{E}[X_0]$.

Proof It is enough to show that $\mathbf{E}[X_T \mathbb{1}_A] = \mathbf{E}[X_\tau \mathbb{1}_A]$ for all $A \in \mathcal{F}_\tau$. By the definition of $\mathcal{F}_\tau$, we have $\{\tau = t\} \cap A \in \mathcal{F}_t$ for all $t \in I$. Hence

$$\begin{aligned} \mathbf{E}[X_\tau \mathbb{1}_A] &= \sum_{t \leq T} \mathbf{E}[X_t \mathbb{1}_{\{\tau=t\} \cap A}] = \sum_{t \leq T} \mathbf{E}[\mathbf{E}[X_T | \mathcal{F}_t] \mathbb{1}_{\{\tau=t\} \cap A}] \\ &= \sum_{t \leq T} \mathbf{E}[X_T \mathbb{1}_A \mathbb{1}_{\{\tau=t\}}] = \mathbf{E}[X_T \mathbb{1}_A] \end{aligned}$$

Theorem 10.11 (Optional sampling theorem) Let $X = (X_n)_{n \in \mathbb{N}_0}$ be a supermartingale and let $\sigma \leq \tau$ be stopping times.

(i) Assume there exists a $T \in \mathbb{N}$ with $\tau \leq T$. Then

$$X_\sigma \geq \mathbf{E}[X_\tau | \mathcal{F}_\sigma]$$

and, in particular, $\mathbf{E}[X_\sigma] \geq \mathbf{E}[X_\tau]$. If X is a martingale, then equality holds in each case.

(ii) If X is nonnegative and if $\tau < \infty$ a.s., then we have $\mathbf{E}[X_\tau] \leq \mathbf{E}[X_0] < \infty$, $\mathbf{E}[X_\sigma] \leq \mathbf{E}[X_0] < \infty$ and $X_\sigma \geq \mathbf{E}[X_\tau | \mathcal{F}_\sigma]$.

(iii) Assume that, more generally, X is only adapted and integrable. Then X is a martingale if and only if $\mathbf{E}[X_\tau] = \mathbf{E}[X_0]$ for any bounded stopping time τ .

Proof (i) Let $X = M + A$ be Doob's decomposition of X . Hence A is predictable and monotone decreasing, $A_0 = 0$, and M is a martingale. Applying Lemma 10.10 to M yields

$$\begin{aligned} X_\sigma &= A_\sigma + M_\sigma = \mathbf{E}[A_\sigma + M_T | \mathcal{F}_\sigma] \\ &\geq \mathbf{E}[A_\tau + M_T | \mathcal{F}_\sigma] = \mathbf{E}[A_\tau + \mathbf{E}[M_T | \mathcal{F}_\tau] | \mathcal{F}_\sigma] \\ &= \mathbf{E}[A_\tau + M_\tau | \mathcal{F}_\sigma] = \mathbf{E}[X_\tau | \mathcal{F}_\sigma] \end{aligned}$$

Here we used $\mathcal{F}_\tau \supset \mathcal{F}_\sigma$, the tower property and the monotonicity of the conditional expectation (see Theorem 8.14).

(ii) We have $X_{\tau \wedge n} \xrightarrow{n \rightarrow \infty} X_\tau$ almost surely. By (i), we get $\mathbf{E}[X_{\tau \wedge n}] \leq \mathbf{E}[X_0]$ for any $n \in \mathbb{N}$. Using Fatou's lemma, we infer

$$\mathbf{E}[X_\tau] \leq \liminf_{n \rightarrow \infty} \mathbf{E}[X_{\tau \wedge n}] \leq \mathbf{E}[X_0] < \infty$$

Similarly, we can show that $\mathbf{E}[X_\sigma] \leq \mathbf{E}[X_0]$.

Now, let $m, n \in \mathbb{N}$ with $m \geq n$. Part (i) applied to the bounded stopping times $\tau \wedge m \geq \sigma \wedge n$ yields

$$X_{\sigma \wedge n} \geq \mathbf{E}[X_{\tau \wedge m} | \mathcal{F}_{\sigma \wedge n}]$$

Now $\{\sigma < n\} \cap A \in \mathcal{F}_{\sigma \wedge n}$ for $A \in \mathcal{F}_\sigma$. Hence

$$\mathbf{E}[X_\sigma \mathbb{1}_{\{\sigma < n\} \cap A}] = \mathbf{E}[X_{\sigma \wedge n} \mathbb{1}_{\{\sigma < n\} \cap A}] \geq \mathbf{E}[X_{\tau \wedge m} \mathbb{1}_{\{\sigma < n\} \cap A}]$$

Using Fatou's lemma, we get

$$\mathbf{E} [X_\tau \mathbb{1}_{\{\sigma < n\} \cap A}] \leq \liminf_{m \rightarrow \infty} \mathbf{E} [X_{\tau \wedge m} \mathbb{1}_{\{\sigma < n\} \cap A}] \leq \mathbf{E} [X_\sigma \mathbb{1}_{\{\sigma < n\} \cap A}].$$

Monotone convergence (for $n \rightarrow \infty$) thus yields $\mathbf{E} [X_\tau \mathbb{1}_A] \leq \mathbf{E} [X_\sigma \mathbb{1}_A]$.

(iii) If X is a martingale, then the claim follows from Lemma 10.10. Now assume that $\mathbf{E} [X_\tau] = \mathbf{E} [X_0]$ for any bounded stopping time τ . Let $t > s$ and $A \in \mathcal{F}_s$. It is enough to show that $\mathbf{E} [X_t \mathbb{1}_A] = \mathbf{E} [X_s \mathbb{1}_A]$. Define $\tau = s \mathbb{1}_A + t \mathbb{1}_{A^c}$. Then τ is a bounded stopping time. However, by assumption,

$$\mathbf{E} [X_t \mathbb{1}_A] = \mathbf{E} [X_t] - \mathbf{E} [X_t \mathbb{1}_{A^c}] = \mathbf{E} [X_0] - \mathbf{E} [X_\tau] + \mathbf{E} [X_s \mathbb{1}_A] = \mathbf{E} [X_s \mathbb{1}_A]$$

Corollary 10.12 Let X be a martingale (respectively a submartingale), and assume $(\tau_N)_{N \in \mathbb{N}}$ is a monotone increasing sequence of bounded stopping times (hence $\tau_N \leq T_N$, $N \in \mathbb{N}$ for some $T_N \in \mathbb{N}$). Then $(X_{\tau_N})_{N \in \mathbb{N}}$ is a martingale (respectively a submartingale) with respect to the filtration $(\mathcal{F}_{\tau_N})_{N \in \mathbb{N}}$.

Definition 10.13 (Stopped process) Let $I \subset \mathbb{R}$ be countable, let $(X_t)_{t \in I}$ be adapted and let τ be a stopping time. We define the stopped process X^τ by

$$X_t^\tau = X_{\tau \wedge t} \quad \text{for any } t \in I.$$

Further, let $\mathbb{F}^\tau$ be the filtration $\mathbb{F}^\tau = (\mathcal{F}_t^\tau)_{t \in I} = (\mathcal{F}_{\tau \wedge t})_{t \in I}$.

Remark 10.14 X^τ is adapted both to $\mathbb{F}$ and to $\mathbb{F}^\tau$.

Theorem 10.15 (Optional stopping) Let $(X_n)_{n \in \mathbb{N}_0}$ be a (sub-, super-) martingale with respect to $\mathbb{F}$ and let τ be a stopping time. Then X^τ is a (sub-, super-) martingale both with respect to $\mathbb{F}$ and with respect to $\mathbb{F}^\tau$.

Proof We give the proof only for the case where X is a submartingale. The other cases are similar since there $(-X)$ is a submartingale.

For each $n \in \mathbb{N}_0$, we have

$$\begin{aligned} \mathbf{E} [|X_n^\tau|] &\leq \mathbf{E} [\max \{|X_m| : m \leq n\}] \\ &\leq \mathbf{E} [|X_0|] + \dots + \mathbf{E} [|X_n|] < \infty. \end{aligned}$$

Hence X^τ is integrable.

Let X be a submartingale. Since $\{\tau > n-1\} \in \mathcal{F}_{n-1}$, we have

$$\begin{aligned} \mathbf{E} [X_n^\tau - X_{n-1}^\tau \mid \mathcal{F}_{n-1}] &= \mathbf{E} [X_{\tau \wedge n} - X_{\tau \wedge (n-1)} \mid \mathcal{F}_{n-1}] \\ &= \mathbf{E} [(X_n - X_{n-1}) \mathbb{1}_{\{\tau > n-1\}} \mid \mathcal{F}_{n-1}] \\ &= \mathbb{1}_{\{\tau > n-1\}} \mathbf{E} [X_n - X_{n-1} \mid \mathcal{F}_{n-1}] \\ &\geq 0, \quad \text{since } X \text{ is an } \mathbb{F}\text{-submartingale.} \end{aligned}$$

Therefore, X^τ is an $\mathbb{F}$ -submartingale. As X^τ is adapted to $\mathbb{F}^\tau$ and since $\mathbb{F}^\tau$ is the smaller filtration, X^τ is also an $\mathbb{F}^\tau$ -submartingale (see Remark 9.29).

Example 10.16 Let X be a symmetric simple random walk on $\mathbb{Z}$ (see Example 10.8). Let $a, b \in \mathbb{Z}$ with $a < 0, b > 0$ and let

$$\begin{aligned} \tau_a &= \inf \{t \geq 0 : X_t = a\}, \quad \tau_b = \inf \{t \geq 0 : X_t = b\} \quad \text{and} \\ \tau_{a,b} &= \tau_a \wedge \tau_b. \end{aligned}$$

$\tau_{a,b}$ is a stopping time by Lemma 9.18. Let $A = \{\tau_{a,b} = \tau_a\}$ be the event where X hits a before hitting b . We want to compute $\mathbf{P}[A]$. By Exercise 2.3.1, almost surely $\limsup_{n \rightarrow \infty} X_n = \infty$ and $\liminf_{n \rightarrow \infty} X_n = -\infty$. Therefore, almost surely $\tau_a < \infty$ and $\tau_b < \infty$. By the optional stopping theorem, $X^{\tau_{a,b}}$ is a martingale. Since $\tau_{a,b} \wedge n \xrightarrow{n \rightarrow \infty} \tau_{a,b}$ almost surely, we

get $X_n \xrightarrow{\tau_{a,b} \rightarrow \infty} X_{\tau_{a,b}}$ almost surely. As $|X_n^{\tau_{a,b}}|$ is bounded by $b - a$, we can infer that $X_n^{\tau_{a,b}} \xrightarrow{n \rightarrow \infty} X_{\tau_{a,b}}$ also in L^1 . Thus

$$\begin{aligned} 0 &= \lim_{n \rightarrow \infty} \mathbf{E} [X_n^{\tau_{a,b}}] = \mathbf{E} [X_{\tau_{a,b}}] = a \cdot \mathbf{P} [\tau_{a,b} = \tau_a] + b \cdot \mathbf{P} [\tau_{a,b} = \tau_b] \\ &= b + (a - b) \mathbf{P} [\tau_{a,b} = \tau_a] \end{aligned}$$

We conclude that $\mathbf{P} [\tau_{a,b} = \tau_a] = \frac{b}{b-a}$.

Example 10.17 Finally, we use our machinery in order to compute $\mathbf{E} [\tau_{a,b}]$ and $\mathbf{E} [\tau_a]$. The square variation process $\langle X \rangle$ (compare Definition 10.3) is given by

$$\langle X \rangle_n = \sum_{i=1}^n \mathbf{E} [(X_i - X_{i-1})^2 \mid \mathcal{F}_{i-1}] = n$$

hence $(X_n^2 - n)_{n \in \mathbb{N}_0}$ is a martingale. By the optional stopping theorem,

$$0 = \mathbf{E} [X_{\tau_{a,b} \wedge n}^2 - (\tau_{a,b} \wedge n)] \quad \text{for all } n \in \mathbb{N}_0$$

Monotone convergence yields

$$\mathbf{E} [\tau_{a,b}] = \mathbf{E} [X_{\tau_{a,b}}^2] = a^2 \mathbf{P} [\tau_{a,b} = \tau_a] + b^2 \mathbf{P} [\tau_{a,b} = \tau_b] = |a| \cdot b.$$

In order to compute $\mathbf{E} [\tau_a]$, note that $\tau_{a,b} \uparrow \tau_a$ almost surely if $b \rightarrow \infty$. The monotone convergence theorem thus yields $\mathbf{E} [\tau_a] = \lim_{b \rightarrow \infty} \mathbf{E} [\tau_{a,b}] = \infty$.

Remark 10.18 Evidently, $X_{\tau_b} = b > 0$. Hence $X_0 < \mathbf{E} [X_{\tau_b} \mid \mathcal{F}_0] = b$. The claim of the optional sampling theorem may thus fail, in general, if the stopping time is unbounded.

Example 10.19 (Gambler's ruin problem) Consider a game of two persons, A and B . In each round, a coin is tossed. Depending on the outcome, either A gets a euro from B or vice versa. The game endures until one of the players is ruined. For simplicity, we assume that in the beginning A has $k_A \in \mathbb{N}$ euros while B has $k_B = N - k_A$ euros, where $N \in \mathbb{N}$, $N \geq k_A$. We want to know the probability of B 's ruin. In Example 10.16 we saw that for a fair coin this probability is k_A/N . Now we allow the coin to be unfair.

Hence, let $Y_1, Y_2, \dots$ be i.i.d. and $\sim \text{Rad}_p$ (that is, $\mathbf{P} [Y_i = 1] = 1 - \mathbf{P} [Y_i = -1] = p$) for some $p \in (0, 1) \setminus \{\frac{1}{2}\}$. Denote by $X_n := k_B + \sum_{i=1}^n Y_i$ the running total for B after n rounds, where formally we assume that the game continues even after one player is ruined. We define as above τ_0, τ_N and $\tau_{0,N}$ as the times of first entrance of X into $\{0\}, \{N\}$ and $\{0, N\}$, respectively. The ruin probability of B thus is $p_B^N := \mathbf{P} [\tau_{0,N} = \tau_0]$. Since X is not a martingale (except for the case $p = \frac{1}{2}$ that was excluded), we use a trick to construct a martingale. Define a new process Z by $Z_n := r^{X_n} = r^{k_B} \prod_{i=1}^n r^{Y_i}$, where $r > 0$ has to be chosen so that Z becomes a martingale. By Example 9.31, this is the case if and only if

$$\mathbf{E} [r^{Y_1}] = pr + (1 - p)r^{-1} = 1;$$

hence, if $r = 1$ or $r = \frac{1-p}{p}$. Evidently, the choice $r = 1$ is useless (as Z does not yield any information on X); hence we assume $r = \frac{1-p}{p}$. We thus get

$$\tau_0 = \inf \{n \in \mathbb{N}_0 : Z_n = 1\} \quad \text{and} \quad \tau_N = \inf \{n \in \mathbb{N}_0 : Z_n = r^N\}.$$

(Note that here we cannot argue as above in order to show that $\tau_0 < \infty$ and $\tau_N < \infty$ almost surely. In fact, for $p \neq \frac{1}{2}$, only one of the statements holds. However, using, for example, the strong law of large numbers, we obtain that $\liminf_{n \rightarrow \infty} X_n = \infty$ (and thus $\tau_N < \infty$) almost surely if $p > \frac{1}{2}$. Similarly, $\tau_0 < \infty$ almost surely if $p < \frac{1}{2}$.) As in Example 10.16, the optional

stopping theorem yields $r^{k_B} = Z_0 = \mathbf{E}[Z_{\tau_0, N}] = p_B^N + (1 - p_B^N) r^N$. Therefore, the probability of B 's ruin is

$$p_B^N = \frac{r^{k_B} - r^N}{1 - r^N} \quad (10.5)$$

If the game is advantageous for B (that is, $p > \frac{1}{2}$), then $r < 1$. In this case, in the limit $N \rightarrow \infty$ (with constant k_B),

$$p_B^\infty := \lim_{N \rightarrow \infty} p_B^N = r^{k_B} \quad (10.6)$$

Exercise 10.2.1 Let X be a square integrable martingale with square variation process $\langle X \rangle$. Let τ be a finite stopping time. Show the following:

(i) If $\mathbf{E}[\langle X \rangle_\tau] < \infty$, then

$$\mathbf{E}[(X_\tau - X_0)^2] = \mathbf{E}[\langle X \rangle_\tau] \quad \text{and} \quad \mathbf{E}[X_\tau] = \mathbf{E}[X_0]. \quad (10.7)$$

(ii) If $\mathbf{E}[\langle X \rangle_\tau] = \infty$, then both equalities in (10.7) may fail.

Exercise 10.2.2 We consider a situation that is more general than the one in the preceding example by assuming only that $Y_1, Y_2, \dots$ are i.i.d. integrable random variables that are not almost surely constant (and $X_n = Y_1 + \dots + Y_n$). We further assume that there is a $\delta > 0$ such that $\mathbf{E}[\exp(\theta Y_1)] < \infty$ for all $\theta \in (-\delta, \delta)$. Define a map $\psi : (-\delta, \delta) \rightarrow \mathbb{R}$ by $\theta \mapsto \log(\mathbf{E}[\exp(\theta Y_1)])$ and the process Z^θ by $Z_n^\theta := \exp(\theta X_n - n\psi(\theta))$ for $n \in \mathbb{N}_0$. Show the following:

(i) Z^θ is a martingale for all $\theta \in (-\delta, \delta)$.

(ii) ψ is strictly convex.

(iii) $\mathbf{E}[\sqrt{Z_n^\theta}] \xrightarrow{n \rightarrow \infty} 0$ for $\theta \neq 0$.

(iv) $Z_n^\theta \xrightarrow{n \rightarrow \infty} 0$ almost surely.

We may interpret Y_n as the difference between the premiums and the payments of an insurance company at time n . If the initial capital of the company is $k_0 > 0$, then $k_0 + X_n$ is the account balance at time n . We are interested in the ruin probability

$$p(k_0) = \mathbf{P}[\inf\{X_n + k_0 : n \in \mathbb{N}_0\} < 0]$$

depending on the initial capital.

It can be assumed that the premiums are calculated such that $\mathbf{E}[Y_1] > 0$. Show that if the equation $\psi(\theta) = 0$ has a solution $\theta^* \neq 0$, then $\theta^* < 0$. Show further that in this case, the Cramér-Lundberg inequality holds:

$$p(k_0) \leq \exp(\theta^* k_0). \quad (10.8)$$

Equality holds if $k_0 \in \mathbb{N}$ and if Y_i assumes only the values -1 and 1. In this case, we get (10.6) with $r = \exp(\theta^*)$.

5.10.3 10.3 Uniform Integrability and Optional Sampling

We extend the optional sampling theorem to unbounded stopping times. We will see that this is possible if the underlying martingale is uniformly integrable (compare Definition 6.16).

Lemma 10.20 Let $(X_n)_{n \in \mathbb{N}_0}$ be a uniformly integrable martingale. Then the family $(X_\tau : \tau \text{ is a finite stopping time})$ is uniformly integrable.

Proof By Theorem 6.19, there exists a monotone increasing, convex function $f : [0, \infty) \rightarrow [0, \infty)$ with

$$\liminf_{x \rightarrow \infty} f(x)/x = \infty \quad \text{and} \quad L := \sup_{n \in \mathbb{N}_0} \mathbf{E}[f(|X_n|)] < \infty$$

If $\tau < \infty$ is a finite stopping time, then by the optional sampling theorem for bounded stopping times (Theorem 10.11 with $\tau = n$ and $\sigma = \tau \wedge n$), $\mathbf{E}[X_n | \mathcal{F}_{\tau \wedge n}] = X_{\tau \wedge n}$. Since $\{\tau \leq n\} \in \mathcal{F}_{\tau \wedge n}$, Jensen's inequality yields

$$\begin{aligned} \mathbf{E}[f(|X_\tau|) \mathbb{1}_{\{\tau \leq n\}}] &= \mathbf{E}[f(|X_{\tau \wedge n}|) \mathbb{1}_{\{\tau \leq n\}}] \\ &\leq \mathbf{E}[\mathbf{E}[f(|X_n|) | \mathcal{F}_{\tau \wedge n}] \mathbb{1}_{\{\tau \leq n\}}] \\ &= \mathbf{E}[f(|X_n|) \mathbb{1}_{\{\tau \leq n\}}] \leq L. \end{aligned}$$

Hence $\mathbf{E}[f(|X_\tau|)] \leq L$. By Theorem 6.19, the family

$$\{X_\tau, \tau \text{ is a finite stopping time}\}$$

is uniformly integrable.

Theorem 10.21 (Optional sampling and uniform integrability) Let $(X_n, n \in \mathbb{N}_0)$ be a uniformly integrable martingale (respectively supermartingale) and let $\sigma \leq \tau$ be finite stopping times. Then $\mathbf{E}[|X_\tau|] < \infty$ and $X_\sigma = \mathbf{E}[X_\tau | \mathcal{F}_\sigma]$ (respectively $X_\sigma \geq \mathbf{E}[X_\tau | \mathcal{F}_\sigma]$).

Proof First let X be a martingale. We have $\{\sigma \leq n\} \cap F \in \mathcal{F}_{\sigma \wedge n}$ for all $F \in \mathcal{F}_\sigma$. Hence, by the optional sampling theorem (Theorem 10.11),

$$\mathbf{E}[X_{\tau \wedge n} \mathbb{1}_{\{\sigma \leq n\} \cap F}] = \mathbf{E}[X_{\sigma \wedge n} \mathbb{1}_{\{\sigma \leq n\} \cap F}].$$

By Lemma 10.20, $(X_{\sigma \wedge n}, n \in \mathbb{N}_0)$ and thus $(X_{\sigma \wedge n} \mathbb{1}_{\{\sigma \leq n\} \cap F}, n \in \mathbb{N}_0)$ are uniformly integrable. Similarly, this holds for X_τ . Therefore, by Theorem 6.25,

$$\begin{aligned} \mathbf{E}[X_\tau \mathbb{1}_F] &= \lim_{n \rightarrow \infty} \mathbf{E}[X_{\tau \wedge n} \mathbb{1}_{\{\sigma \leq n\} \cap F}] = \lim_{n \rightarrow \infty} \mathbf{E}[X_{\sigma \wedge n} \mathbb{1}_{\{\sigma \leq n\} \cap F}] \\ &= \mathbf{E}[X_\sigma \mathbb{1}_F]. \end{aligned}$$

We conclude that $\mathbf{E}[X_\tau | \mathcal{F}_\sigma] = X_\sigma$.

Now let X be a supermartingale and let $X = M + A$ be its Doob decomposition; that is, M is a martingale and $A \leq 0$ is predictable and decreasing. Since

$$\mathbf{E}[|A_n|] = \mathbf{E}[-A_n] \leq \mathbf{E}[|X_n - X_0|] \leq \mathbf{E}[|X_0|] + \sup_{m \in \mathbb{N}_0} \mathbf{E}[|X_m|] < \infty,$$

we have $A_n \downarrow A_\infty$ for some $A_\infty \leq 0$ with $\mathbf{E}[-A_\infty] < \infty$ (by the monotone convergence theorem). Hence A and thus $M = X - A$ are uniformly integrable (Theorem 6.18(ii)). Therefore,

$$\mathbf{E}[|X_\tau|] \leq \mathbf{E}[-A_\tau] + \mathbf{E}[|M_\tau|] \leq \mathbf{E}[-A_\infty] + \mathbf{E}[|M_\tau|] < \infty.$$

Furthermore,

$$\begin{aligned} \mathbf{E}[X_\tau | \mathcal{F}_\sigma] &= \mathbf{E}[M_\tau | \mathcal{F}_\sigma] + \mathbf{E}[A_\tau | \mathcal{F}_\sigma] \\ &= M_\sigma + A_\sigma + \mathbf{E}[(A_\tau - A_\sigma) | \mathcal{F}_\sigma] \\ &\leq M_\sigma + A_\sigma = X_\sigma \end{aligned}$$

Corollary 10.22 Let X be a uniformly integrable martingale (respectively supermartingale) and let $\tau_1 \leq \tau_2 \leq \dots$ be finite stopping times. Then $(X_{\tau_n})_{n \in \mathbb{N}}$ is a martingale (respectively supermartingale).

5.11 11 Martingale Convergence Theorems and Their Applications

We became familiar with martingales $X = (X_n)_{n \in \mathbb{N}_0}$ as fair games and found that under certain transformations (optional stopping, discrete stochastic integral) martingales turn into martingales. In this chapter, we will see that under weak conditions (non-negativity or uniform integrability) martingales converge almost surely. Furthermore, the martingale structure implies L^p -convergence under assumptions that are (formally) weaker than those of Chapter 7. The basic ideas of this chapter are Doob's inequality (Theorem 11.2) and the upcrossing inequality (Lemma 11.3).

5.11.1 11.1 Doob's Inequality

With Kolmogorov's inequality (Theorem 5.28), we became acquainted with an inequality that bounds the probability of large values of the maximum of a square integrable process with independent centered increments. Here we want to improve this inequality in two directions. On the one hand, we replace the independent increments by the assumption that the process of partial sums is a martingale. On the other hand, we can manage with less than second moments; alternatively, we can get better bounds if we have higher moments.

Let $I \subset \mathbb{N}_0$ and let $X = (X_n)_{n \in I}$ be a stochastic process. For $n \in \mathbb{N}$, we denote

$$X_n^* = \sup \{X_k : k \leq n\} \quad \text{and} \quad |X|_n^* = \sup \{|X_k| : k \leq n\}.$$

Lemma 11.1 If X is a submartingale, then, for all $\lambda > 0$,

$$\lambda \mathbf{P}[X_n^* \geq \lambda] \leq \mathbf{E}[X_n \mathbb{1}_{\{X_n^* \geq \lambda\}}] \leq \mathbf{E}[|X_n| \mathbb{1}_{\{X_n^* \geq \lambda\}}].$$

Proof The second inequality is trivial. For the first one, let

$$\tau := \inf \{k \in I : X_k \geq \lambda\} \wedge n.$$

By Theorem 10.11 (optional sampling theorem),

$$\begin{aligned} \mathbf{E}[X_n] &\geq \mathbf{E}[X_\tau] = \mathbf{E}[X_\tau \mathbb{1}_{\{X_n^* \geq \lambda\}}] + \mathbf{E}[X_\tau \mathbb{1}_{\{X_n^* < \lambda\}}] \\ &\geq \lambda \mathbf{P}[X_n^* \geq \lambda] + \mathbf{E}[X_n \mathbb{1}_{\{X_n^* < \lambda\}}]. \end{aligned}$$

(Note that $\tau = n$ if $X_n^* < \lambda$.) Now subtract $\mathbf{E}[X_n \mathbb{1}_{\{X_n^* < \lambda\}}]$.

Theorem 11.2 (Doob's L^p -inequality) Let X be a martingale or a positive submartingale.

(i) For any $p \geq 1$ and $\lambda > 0$,

$$\lambda^p \mathbf{P}[|X|_n^* \geq \lambda] \leq \mathbf{E}[|X_n|^p]$$

(ii) For any $p > 1$,

$$\mathbf{E}[|X_n|^p] \leq \mathbf{E}[(|X|_n^*)^p] \leq \left(\frac{p}{p-1}\right)^p \mathbf{E}[|X_n|^p].$$

Proof We follow the proof in [144].

(i) By Theorem 9.35, $(|X_n|^p)_{n \in I}$ is a submartingale, and the claim follows by Lemma 11.1.

(ii) The first inequality is trivial. For the second inequality, we may assume that $\mathbf{E}[|X_n|^p] < \infty$. Note that, by Lemma 11.1,

$$\lambda \mathbf{P}[|X|_n^* \geq \lambda] \leq \mathbf{E}[|X_n| \mathbb{1}_{\{|X|_n^* \geq \lambda\}}].$$

Hence, for any $K > 0$,

$$\begin{aligned}
\mathbf{E}[(|X|_n^* \wedge K)^p] &= \mathbf{E} \left[\int_0^{|X|_n^* \wedge K} p\lambda^{p-1} d\lambda \right] \\
&= \mathbf{E} \left[\int_0^K p\lambda^{p-1} \mathbb{1}_{\{|X|_n^* \geq \lambda\}} d\lambda \right] \\
&= \int_0^K p\lambda^{p-1} \mathbf{P}[|X|_n^* \geq \lambda] d\lambda \\
&\leq \int_0^K p\lambda^{p-2} \mathbf{E}[|X|_n \mathbb{1}_{\{|X|_n^* \geq \lambda\}}] d\lambda \\
&= p\mathbf{E} \left[|X|_n \int_0^{|X|_n^* \wedge K} \lambda^{p-2} d\lambda \right] \\
&= \frac{p}{p-1} \mathbf{E}[|X|_n \cdot (|X|_n^* \wedge K)^{p-1}]
\end{aligned}$$

Hölder's inequality then yields

$$\mathbf{E}[(|X|_n^* \wedge K)^p] \leq \frac{p}{p-1} \mathbf{E}[(|X|_n^* \wedge K)^p]^{(p-1)/p} \cdot \mathbf{E}[|X|_n^p]^{1/p}.$$

We raise both sides to the p th power and divide by $\mathbf{E}[(|X|_n^* \wedge K)^p]^{p-1}$ (here we need the truncation at K to make sure we divide by a finite number) to obtain

$$\mathbf{E}[(|X|_n^* \wedge K)^p] \leq \left(\frac{p}{p-1} \right)^p \mathbf{E}[|X|_n^p].$$

Finally, let $K \rightarrow \infty$. $\square$

Exercise 11.1.1 Let $(X_n)_{n \in \mathbb{N}_0}$ be a submartingale or a supermartingale. Use Theorem 11.2 and Doob's decomposition to show that, for all $n \in \mathbb{N}$ and $\lambda > 0$,

$$\lambda \mathbf{P}[|X|_n^* \geq \lambda] \leq 12\mathbf{E}[|X_0|] + 9\mathbf{E}[|X_n|].$$

5.11.2 11.2 Martingale Convergence Theorems

In this section, we present the usual martingale convergence theorems and give a few small examples. We start with the core of the martingale convergence theorems, the so-called upcrossing inequality.

Let $\mathbb{F} = (\mathcal{F}_n)_{n \in \mathbb{N}_0}$ be a filtration and $\mathcal{F}_\infty = \sigma(\bigcup_{n \in \mathbb{N}_0} \mathcal{F}_n)$. Let $(X_n)_{n \in \mathbb{N}_0}$ be realvalued and adapted to $\mathbb{F}$. Let $a, b \in \mathbb{R}$ with $a < b$. If we think of X as a stock price, it would be a sensible trading strategy to buy the stock when its price has fallen below a and to sell it when it exceeds b at least if we knew for sure that the price would always rise above the level b again. Each time the price makes such an upcrossing from a to b , we make a profit of at least $b - a$. If we get a bound on the maximal profit we can make, dividing it by $b - a$ gives a bound on the maximal number of such upcrossings. If this number is finite for all $a < b$, then the price has to converge as $n \rightarrow \infty$.

Let us get into the details. Define stopping times $\sigma_0 \equiv 0$ and

$$\begin{aligned}
\tau_k &:= \inf \{n \geq \sigma_{k-1} : X_n \leq a\} \quad \text{for } k \in \mathbb{N}, \\
\sigma_k &:= \inf \{n \geq \tau_k : X_n \geq b\} \quad \text{for } k \in \mathbb{N}.
\end{aligned}$$

Note that $\tau_k = \infty$ if $\sigma_{k-1} = \infty$, and $\sigma_k = \infty$ if $\tau_k = \infty$. We say that X has its k th upcrossing over $[a, b]$ between τ_k and σ_k if $\sigma_k < \infty$. For $n \in \mathbb{N}$, define

$$U_n^{a,b} := \sup \{k \in \mathbb{N}_0 : \sigma_k \leq n\}$$

as the number of upcrossings over $[a, b]$ until time n .

Lemma 11.3 (Upcrossing inequality) Let $(X_n)_{n \in \mathbb{N}_0}$ be a submartingale. Then

$$\mathbf{E} [U_n^{a,b}] \leq \frac{\mathbf{E} [(X_n - a)^+] - \mathbf{E} [(X_0 - a)^+]}{b - a}$$

Proof Recall the discrete stochastic integral $H \cdot X$ from Definition 9.37. Formally, the intimated trading strategy H is described for $m \in \mathbb{N}_0$ by

$$H_m := \begin{cases} 1, & \text{if } m \in \{\tau_k + 1, \dots, \sigma_k\} \text{ for some } k \in \mathbb{N} \\ 0, & \text{else.} \end{cases}$$

H is nonnegative and predictable since, for all $m \in \mathbb{N}$,

$$\{H_m = 1\} = \bigcup_{k=1}^{\infty} (\{\tau_k \leq m-1\} \cap \{\sigma_k > m-1\})$$

and each of the events is in $\mathcal{F}_{m-1}$. Define $Y = \max(X, a)$. If $k \in \mathbb{N}$ and $\sigma_k < \infty$, then clearly $Y_{\sigma_i} - Y_{\tau_i} = Y_{\sigma_i} - a \geq b - a$ for all $i \leq k$; hence

$$(H \cdot Y)_{\sigma_k} = \sum_{i=1}^k \sum_{j=\tau_i+1}^{\sigma_i} (Y_j - Y_{j-1}) = \sum_{i=1}^k (Y_{\sigma_i} - Y_{\tau_i}) \geq k(b - a).$$

For $j \in \{\sigma_k, \dots, \tau_{k+1}\}$, we have $(H \cdot Y)_j = (H \cdot Y)_{\sigma_k}$. On the other hand, for $j \in \{\tau_k + 1, \dots, \sigma_k\}$, we have $(H \cdot Y)_j \geq (H \cdot Y)_{\tau_k} = (H \cdot Y)_{\sigma_{k-1}}$. Hence $(H \cdot Y)_n \geq (b - a)U_n^{a,b}$ for all $n \in \mathbb{N}$.

By Corollary 9.34, Y is a submartingale, and (by Theorem 9.39) so are $H \cdot Y$ and $(1 - H) \cdot Y$. Now $Y_n - Y_0 = (1 \cdot Y)_n = (H \cdot Y)_n + ((1 - H) \cdot Y)_n$; hence

$$\mathbf{E} [Y_n - Y_0] \geq \mathbf{E} [(H \cdot Y)_n] \geq (b - a)\mathbf{E} [U_n^{a,b}].$$

Theorem 11.4 (Martingale convergence theorem) Let $(X_n)_{n \in \mathbb{N}_0}$ be a submartingale with $\sup \{\mathbf{E} [X_n^+] : n \geq 0\} < \infty$. Then there exists an $\mathcal{F}_\infty$ -measurable random variable X_∞ with $\mathbf{E} [|X_\infty|] < \infty$ and $X_n \xrightarrow{n \rightarrow \infty} X_\infty$ almost surely.

Proof Let $a < b$. Since $\mathbf{E} [(X_n - a)^+] \leq |a| + \mathbf{E} [X_n^+]$, by Lemma 11.3,

$$\mathbf{E} [U_n^{a,b}] \leq \frac{|a| + \mathbf{E} [X_n^+]}{b - a}$$

Manifestly, the monotone limit $U^{a,b} := \lim_{n \rightarrow \infty} U_n^{a,b}$ exists. By assumption, we have $\mathbf{E} [U^{a,b}] = \lim_{n \rightarrow \infty} \mathbf{E} [U_n^{a,b}] < \infty$. In particular, $\mathbf{P} [U^{a,b} < \infty] = 1$. Define the $\mathcal{F}_\infty$ -measurable events

$$C^{a,b} = \left\{ \liminf_{n \rightarrow \infty} X_n < a \right\} \cap \left\{ \limsup_{n \rightarrow \infty} X_n > b \right\} \subset \{U^{a,b} = \infty\}$$

and

$$C = \bigcup_{\substack{a, b \in \mathbb{Q} \\ a < b}} C^{a,b}$$

Then $\mathbf{P}[C^{a,b}] = 0$ and thus also $\mathbf{P}[C] = 0$. However, by construction, $(X_n)_{n \in \mathbb{N}}$ is convergent on C^c . Hence there exists the almost sure limit $X_\infty = \lim_{n \rightarrow \infty} X_n$. Each X_n is $\mathcal{F}_\infty$ -measurable; hence X_∞ also is $\mathcal{F}_\infty$ -measurable.

By Fatou's lemma,

$$\mathbf{E}[X_\infty^+] \leq \sup \{ \mathbf{E}[X_n^+] : n \geq 0 \} < \infty$$

On the other hand (since X is a submartingale), again by Fatou's lemma,

$$\begin{aligned} \mathbf{E}[X_\infty^-] &\leq \liminf_{n \rightarrow \infty} \mathbf{E}[X_n^-] = \liminf_{n \rightarrow \infty} (\mathbf{E}[X_n^+] - \mathbf{E}[X_n]) \\ &\leq \sup \{ \mathbf{E}[X_n^+] : n \in \mathbb{N}_0 \} - \mathbf{E}[X_0] < \infty \end{aligned}$$

Corollary 11.5 If X is a nonnegative supermartingale, then there is an $\mathcal{F}_\infty$ -measurable random variable $X_\infty \geq 0$ with $\mathbf{E}[X_\infty] \leq \mathbf{E}[X_0]$ and $X_n \xrightarrow{n \rightarrow \infty} X_\infty$ a.s.

Proof The preceding theorem with $(-X)$ establishes X_∞ as the almost sure limit. Fatou's lemma yields

$$\mathbf{E}[X_\infty] \leq \liminf_{n \rightarrow \infty} \mathbf{E}[X_n] \leq \mathbf{E}[X_0]$$

Example 11.6 Let S_n be the account balance in the Petersburg game after the n th round (see Example 9.40). Then S is a martingale and $S_n \leq 1$ almost surely for any n . Hence the assumptions of Theorem 11.4 are fulfilled and $(S_n)_{n \in \mathbb{N}_0}$ converges to a finite random variable almost surely for $n \rightarrow \infty$. Since the account changes as long as stakes are put up (that is, as long as $S_n < 1$), we get $\lim_{n \rightarrow \infty} S_n = 1$ almost surely.

Since $\mathbf{E}[S_n] = 0$ for all $n \in \mathbb{N}_0$, this convergence cannot hold in L^1 . This observation tallies with the fact that S is not uniformly integrable.

For uniformly integrable martingales, a stronger convergence theorem holds.

Theorem 11.7 (Convergence theorem for uniformly integrable martingales) Let $(X_n)_{n \in \mathbb{N}_0}$ be a uniformly integrable $\mathbb{F}$ - (sub-, super-) martingale. Then there exists an $\mathcal{F}_\infty$ -measurable integrable random variable X_∞ with $X_n \xrightarrow{n \rightarrow \infty} X_\infty$ a.s. and in L^1 . Furthermore:

- $X_n = \mathbf{E}[X_\infty | \mathcal{F}_n]$ for all $n \in \mathbb{N}$ if X is a martingale.
- $X_n \leq \mathbf{E}[X_\infty | \mathcal{F}_n]$ for all $n \in \mathbb{N}$ if X is a submartingale.
- $X_n \geq \mathbf{E}[X_\infty | \mathcal{F}_n]$ for all $n \in \mathbb{N}$ if X is a supermartingale.

Remark 11.8 The statement of Theorem 11.7 can be reformulated as: The process $(X_n)_{n \in \mathbb{N}_0 \cup \{\infty\}}$ is a (sub-, super-) martingale with respect to $(\mathcal{F}_n)_{n \in \mathbb{N}_0 \cup \{\infty\}}$.

Proof We give the proof for the case where X is a submartingale. Uniform integrability implies $\sup \{ \mathbf{E}[X_n^+] : n \geq 0 \} < \infty$. By Theorem 11.4, the almost sure limit X_∞ exists. Hence $\mathbf{E}[|X_n - X_\infty|] \xrightarrow{n \rightarrow \infty} 0$ by Theorem 6.25. By Corollary 8.21, the L^1 convergence of (X_n) implies the L^1 -convergence of the conditional expectations: $\mathbf{E}[|\mathbf{E}[X_n | \mathcal{F}_m] - \mathbf{E}[X_\infty | \mathcal{F}_m]|] \xrightarrow{n \rightarrow \infty} 0$. Thus, by the triangle inequality,

$$\begin{aligned} &|\mathbf{E}[(\mathbf{E}[X_\infty | \mathcal{F}_m] - X_m)^-] - \mathbf{E}[(\mathbf{E}[X_n | \mathcal{F}_m] - X_m)^-]| \\ &\leq \mathbf{E}[|\mathbf{E}[X_\infty | \mathcal{F}_m] - \mathbf{E}[X_n | \mathcal{F}_m]|] \xrightarrow{n \rightarrow \infty} 0 \end{aligned}$$

As X is a submartingale, we have $(\mathbf{E}[X_n | \mathcal{F}_m] - X_m)^- = 0$ for $n \geq m$. Therefore, $\mathbf{E}[(\mathbf{E}[X_\infty | \mathcal{F}_m] - X_m)^-] = 0$ and thus $\mathbf{E}[X_\infty | \mathcal{F}_m] - X_m \geq 0$ almost surely.

Corollary 11.9 Let $X \geq 0$ be a martingale and let $X_\infty = \lim_{n \rightarrow \infty} X_n$. Then $\mathbf{E}[X_\infty] = \mathbf{E}[X_0]$ if and only if X is uniformly integrable.

Proof This is a direct consequence of Theorem 6.25.

Let $p \in [1, \infty)$. A real-valued stochastic process $(X_i)_{i \in I}$ is called L^p -bounded if $\sup_{i \in I} \mathbf{E}[|X_i|^p] < \infty$ (Definition 6.20). In general, for $(|X_i|^p)_{i \in I}$ to be uniformly integrable it is not enough that $(X_i)_{i \in I}$ be L^p -bounded. However, if X is a martingale and if $p > 1$, then Doob's inequality implies that the statements are equivalent. In particular, in this case, almost sure convergence implies convergence in L^p .

Theorem 11.10 (L^p -convergence theorem for martingales) Let $p > 1$ and let $(X_n)_{n \in \mathbb{N}_0}$ be an L^p -bounded martingale. Then there exists an $\mathcal{F}_\infty$ -measurable random variable X_∞ with $\mathbf{E}[|X_\infty|^p] < \infty$ and $X_n \xrightarrow{n \rightarrow \infty} X_\infty$ almost surely and in L^p . In particular, $(|X_n|^p)_{n \in \mathbb{N}_0}$ is uniformly integrable.

Proof By Corollary 6.21, X is uniformly integrable. Hence the almost sure limit X_∞ exists. By Doob's inequality (Theorem 11.2), for all $n \in \mathbb{N}$,

$$\mathbf{E}[\sup\{|X_k|^p : k \leq n\}] \leq \left(\frac{p}{p-1}\right)^p \mathbf{E}[|X_n|^p].$$

Therefore,

$$\mathbf{E}[\sup\{|X_k|^p : k \in \mathbb{N}_0\}] \leq \left(\frac{p}{p-1}\right)^p \sup\{\mathbf{E}[|X_n|^p] : n \in \mathbb{N}_0\} < \infty.$$

Hence, in particular, $(|X_n|^p)_{n \in \mathbb{N}_0}$ is uniformly integrable.

Since $|X_n - X_\infty|^p \leq 2^p \sup\{|X_n|^p : n \in \mathbb{N}_0\}$, dominated convergence yields

$$\mathbf{E}[|X_\infty|^p] < \infty \quad \text{and} \quad \mathbf{E}[|X_n - X_\infty|^p] \xrightarrow{n \rightarrow \infty} 0.$$

For the case of square integrable martingales, there is a convenient criterion for L^2 -boundedness that we record as a corollary (see Definition 10.3).

Corollary 11.11 Let X be a square integrable martingale with square variation process $\langle X \rangle$. Then the following four statements are equivalent:

- (i) $\sup_{n \in \mathbb{N}} \mathbf{E}[X_n^2] < \infty$.
- (ii) $\lim_{n \rightarrow \infty} \mathbf{E}[\langle X \rangle_n] < \infty$.
- (iii) X converges in L^2 .
- (iv) X converges almost surely and in L^2 .

Proof "(i) $\iff$ (ii)" Since $\text{Var}[X_n - X_0] = \mathbf{E}[\langle X \rangle_n]$ (see Theorem 10.4), X is bounded in L^2 if and only if (ii) holds.

"(iv) $\implies$ (iii) $\implies$ (i)" This is trivial.

"(i) $\implies$ (iv)" This is the statement of Theorem 11.10.

Remark 11.12 In general, the statement of Theorem 11.10 fails for $p = 1$. See Exercise 11.2.1.

Lemma 11.13 Let X be a square integrable martingale with square variation process $\langle X \rangle$, and let τ be a stopping time. Then the stopped process X^τ has square variation process $\langle X^\tau \rangle = \langle X \rangle^\tau := (\langle X \rangle_{\tau \wedge n})_{n \in \mathbb{N}_0}$.

Proof This is left as an exercise.

If in Corollary 11.11 we do not assume that the expectations of the square variation are bounded but only that the square variation is almost surely bounded, then we still get that X converges almost surely (albeit not in L^2).

Theorem 11.14 If X is a square integrable martingale with $\sup_{n \in \mathbb{N}} \langle X \rangle_n < \infty$ almost surely, then X converges almost surely.

Proof Without loss of generality, we can assume that $X_0 = 0$, otherwise consider the martingale $(X_n - X_0)_{n \in \mathbb{N}_0}$, which has the same square variation process. For $K > 0$, let

$$\tau_K := \inf\{n \in \mathbb{N} : \langle X \rangle_{n+1} \geq K\}$$

This is a stopping time since $\langle X \rangle$ is predictable. Evidently, $\sup_{n \in \mathbb{N}} \langle X \rangle_{\tau_K \wedge n} \leq K$ almost surely. By Corollary 11.11, the stopped process X^{τ_K} converges almost surely (and in L^2) to a random variable that we denote by $X_\infty^{\tau_K}$. By assumption, $\mathbf{P}[\tau_K = \infty] \rightarrow 1$ for $K \rightarrow \infty$; hence X converges almost surely.

Example 11.15 Let X be a symmetric simple random walk on $\mathbb{Z}$. That is, $X_n = \sum_{k=1}^n R_k$, where $R_1, R_2, \dots$ are i.i.d. and $\sim \text{Rad}_{1/2}$:

$$\mathbf{P}[R_1 = 1] = \mathbf{P}[R_1 = -1] = \frac{1}{2}$$

Then X is a martingale; however, $\limsup_{n \rightarrow \infty} X_n = \infty$ and $\liminf_{n \rightarrow \infty} X_n = -\infty$. Therefore, X does not even converge improperly. By the martingale convergence theorem, this is consonant with the fact that X is not uniformly integrable.

Example 11.16 (Voter model, due to [28, 75]) Consider a simple model that describes the behavior of opportunistic voters who are capable of only one out of two opinions, say 0 and 1. Let $\Lambda \subset \mathbb{Z}^d$ be a set that we interpret as the sites at each of which there is one voter. For simplicity, assume that $\Lambda = \{0, \dots, L-1\}^d$ for some $L \in \mathbb{N}$. Let $x(i) \in \{0, 1\}$ be the opinion of the voter at site $i \in \Lambda$ and denote by $x \in \{0, 1\}^\Lambda$ a generic state of the whole population. We now assume that the individual opinions may change at discrete time steps. At any time $n \in \mathbb{N}_0$, one site I_n out of Λ is chosen at random and the individual at that site reconsiders his or her opinion. To this end, the voter chooses a neighbor $I_n + N_n \in \Lambda$ (with periodic boundary conditions; that is, with addition modulo L in each coordinate) at random and adopts his or her opinion. We thus get a random sequence $(X_n)_{n \in \mathbb{N}_0}$ of states in $\{0, 1\}^\Lambda$ that represents the random evolution of the opinions of the whole colony. See Fig. 11.1 for a computer simulation of the voter model.

For a formal description of this model, let $(I_n)_{n \in \mathbb{N}}$ and $(N_n)_{n \in \mathbb{N}}$ be independent random variables. For any $n \in \mathbb{N}$, I_n is uniformly distributed on Λ and N_n is uniformly distributed on the set $\mathcal{N} := \{i \in \mathbb{Z}^d : \|i\|_2 = 1\}$ of the $2d$ nearest neighbors of the origin. Furthermore, $x = X_0 \in \{0, 1\}^\Lambda$ is the initial state. The states at later times are defined inductively by

$$X_n(i) = \begin{cases} X_{n-1}(i), & \text{if } I_n \neq i \\ X_{n-1}(I_n + N_n), & \text{if } I_n = i \end{cases}$$

Of course, the behavior over small periods of time is determined by the perils of randomness. However, in the long run, we might see certain patterns. To be more specific, the question is: In the long run, will there be a consensus of all individuals or will competing opinions persist?

Let $M_n := \sum_{i \in \Lambda} X_n(i)$ be the total number of individuals of opinion 1 at time n . Let $\mathbb{F}$ be the filtration $\mathbb{F} = (\mathcal{F}_n)_{n \in \mathbb{N}_0}$, where $\mathcal{F}_n = \sigma(I_k, N_k : k \leq n)$ for all $n \in \mathbb{N}_0$. Then M is adapted to $\mathbb{F}$ and

$$\begin{aligned} \mathbf{E}[M_n | \mathcal{F}_{n-1}] &= M_{n-1} - \mathbf{E}[X_{n-1}(I_n) | \mathcal{F}_{n-1}] + \mathbf{E}[X_{n-1}(I_n + N_n) | \mathcal{F}_{n-1}] \\ &= M_{n-1} - \sum_{i \in \Lambda} \mathbf{P}[I_n = i] X_{n-1}(i) + \sum_{i \in \Lambda} \mathbf{P}[I_n + N_n = i] X_{n-1}(i) \\ &= M_{n-1} \end{aligned}$$

since $\mathbf{P}[I_n = i] = \mathbf{P}[I_n + N_n = i] = L^{-d}$ for all $i \in \Lambda$. Hence M is a bounded $\mathbb{F}$ martingale and thus converges almost surely and in L^1 to a random variable M_∞ .

Fig. 11.1 Snapshot of a voter model on an 800×800 torus. The black dots are the Ones

Since M takes only integer values, there is a (random) n_0 such that $M_n = M_{n_0}$ for all $n \geq n_0$. However, then also $X_n = X_{n_0}$ for all $n \geq n_0$. Manifestly, no state x with $x \not\equiv 0$ and $x \not\equiv 1$ is stable. In fact, if x is not constant and if $i, j \in \Lambda$ are neighbors with $x(i) \neq x(j)$, then

$$\mathbf{P}[X_n \neq X_{n-1} \mid X_{n-1} = x] \geq \mathbf{P}[I_{n-1} = i, N_{n-1} = j - i] = L^{-d}(2d)^{-1}.$$

This implies $M_\infty \in \{0, L^d\}$. Now $\mathbf{E}[M_\infty] = M_0$; hence we have

$$\mathbf{P}[M_\infty = L^d] = \frac{M_0}{L^d} \quad \text{and} \quad \mathbf{P}[M_\infty = 0] = 1 - \frac{M_0}{L^d}.$$

Thus, eventually there will be a consensus of all individuals, and the probability that the surviving opinion is $e \in \{0, 1\}$ is the initial frequency of opinion e .

We could argue more formally to show that only the constant states are stable: Let $\langle M \rangle$ be the square variation process of M . Then

$$\begin{aligned} \langle M \rangle_n &= \sum_{k=1}^n \mathbf{E}[\mathbb{1}_{\{M_k \neq M_{k-1}\}} \mid \mathcal{F}_{k-1}] \\ &= \sum_{k=1}^n \mathbf{P}[X_{k-1}(I_k) \neq X_{k-1}(I_k + N_k) \mid \mathcal{F}_{k-1}]. \end{aligned}$$

Hence

$$\begin{aligned} L^{2d} &\geq \text{Var}[M_n] = \mathbf{E}[\langle M \rangle_n] \\ &= \sum_{k=1}^n \mathbf{P}[X_{k-1}(I_k) \neq X_{k-1}(I_k + N_k)] \\ &\geq (2d)^{-1} L^{-d} \sum_{k=1}^n \mathbf{P}[M_{k-1} \notin \{0, L^d\}] \end{aligned}$$

Therefore, $\sum_{k=1}^{\infty} \mathbf{P}[M_{k-1} \notin \{0, L^d\}] \leq 2dL^{3d} < \infty$, and so, by the Borel-Cantelli lemma, $M_\infty \in \{0, L^d\}$.

Example 11.17 (Radon-Nikodym theorem) With the aid of the martingale convergence theorem, we give an alternative proof of the Radon-Nikodym theorem (Corollary 7.34).

Let $(\Omega, \mathcal{F}, \mathbf{P})$ be a probability space and let Q be another probability measure on $(\Omega, \mathcal{A})$. We assume that $\mathcal{F}$ is countably generated; that is, there exist countably many sets $A_1, A_2, \dots \in \mathcal{F}$ such that $\mathcal{F} = \sigma(\{A_1, A_2, \dots\})$. For example, this is the case if $\mathcal{F}$ is the Borel σ -algebra on a Polish space. For the case $\Omega = \mathbb{R}^d$, one could take the open balls with rational radii, centered at points with rational coordinates (compare Remark 1.24).

We construct a filtration $\mathbb{F} = (\mathcal{F}_n)_{n \in \mathbb{N}}$ by letting $\mathcal{F}_n := \sigma(\{A_1, \dots, A_n\})$. Evidently, $\#\mathcal{F}_n < \infty$ for all $n \in \mathbb{N}$. More precisely, there exists a unique finite subset $Z_n \subset \mathcal{F}_n \setminus \{\emptyset\}$ such that $B = \bigsqcup_{\substack{C \in Z_n \\ C \subset B}} C$ for any $B \in \mathcal{F}_n$. Z_n decomposes $\mathcal{F}_n$ into its "atoms". Finally, define a stochastic process $(X_n)_{n \in \mathbb{N}}$ by

$$X_n := \sum_{C \in Z_n: \mathbf{P}[C] > 0} \frac{Q(C)}{\mathbf{P}[C]} \mathbb{1}_C$$

Clearly, X is adapted to $\mathbb{F}$. Let $B \in \mathcal{F}_n$ and $m \geq n$. For any $C \in Z_m$, either $C \cap B = \emptyset$ or $C \subset B$. Hence

$$\mathbf{E}[X_m \mathbb{1}_B] = \sum_{C \in Z_m: \mathbf{P}[C] > 0} \frac{Q(C)}{\mathbf{P}[C]} \mathbf{P}[C \cap B] = \sum_{C \in Z_m: C \subset B} Q(C) = Q(B). \quad (11.1)$$

In particular, X is an $\mathbb{F}$ -martingale.

Now assume that Q is absolutely continuous with respect to P . By Example 7.39, this implies that X is uniformly integrable. By the martingale convergence theorem, X converges $\mathbf{P}$ -almost surely and in $L^1(\mathbf{P})$ to a random variable X_∞ . By (11.1), we have $\mathbf{E}[X_\infty \mathbb{1}_B] = Q(B)$ for all $B \in \bigcup_{n \in \mathbb{N}} \mathcal{F}_n$ and thus also for all $B \in \mathcal{F}$. Therefore, X_∞ is the Radon-Nikodym density of Q with respect to $\mathbf{P}$.

Note that for this proof we did not presume the existence of conditional expectations (rather we constructed them explicitly for finite σ -algebras); that is, we did not resort to the Radon-Nikodym theorem in a hidden way.

It could be objected that this argument works only for probability measures. However, this flaw can easily be remedied. Let μ and ν be arbitrary (but nonzero) σ -finite measures. Then there exist measurable functions $g, h : \Omega \rightarrow (0, \infty)$ with $\int g d\mu = 1$ and $\int h d\nu = 1$. Define $\mathbf{P} = g\mu$ and $Q = h\nu$. Clearly, $Q \ll \mathbf{P}$ if $\nu \ll \mu$. In this case, $\frac{g}{h} X_\infty$ is a version of the Radon-Nikodym derivative $\frac{d\nu}{d\mu}$.

The restriction that $\mathcal{F}$ is countably generated can also be dropped. Using the approximation theorems for measures, it can be shown that there is always a countably generated σ -algebra $\mathcal{G} \subset \mathcal{F}$ such that for any $A \in \mathcal{F}$, there is a $B \in \mathcal{G}$ with $\mathbf{P}[A \Delta B] = 0$. This can be employed to prove the general case. We do not give the details but refer to [169, Chapter 14.13].

Exercise 11.2.1 For $p = 1$, the statement of Theorem 11.10 may fail. Give an example of a nonnegative martingale X with $\mathbf{E}[X_n] = 1$ for all $n \in \mathbb{N}$ but such that $X_n \xrightarrow{n \rightarrow \infty} 0$ almost surely.

Exercise 11.2.2 Let $X_1, X_2, \dots$ be independent, square integrable random variables with $\sum_{n=1}^{\infty} \frac{1}{n^2} \mathbf{Var}[X_n] < \infty$. Use the martingale convergence theorem to show the strong law of large numbers for $(X_n)_{n \in \mathbb{N}}$.

Exercise 11.2.3 Give an example of a square integrable martingale that converges almost surely but not in L^2 .

Exercise 11.2.4 Show that in Theorem 11.14 the converse implication may fail. That is, there exists a square integrable martingale X that converges almost surely but without $\lim_{n \rightarrow \infty} \langle X \rangle_n < \infty$ almost surely.

Exercise 11.2.5 Show the following converse of Theorem 11.14. Let $L > 0$ and let $(X_n)_{n \in \mathbb{N}}$ be a martingale with the property

$$|X_{n+1} - X_n| \leq L \quad \text{a.s.} \quad (11.2)$$

Define the events

$$\begin{aligned} C &:= \{(X_n)_{n \in \mathbb{N}} \text{ converges as } n \rightarrow \infty\}, \\ A^+ &:= \left\{ \limsup_{n \rightarrow \infty} X_n < \infty \right\}, \\ A^- &:= \left\{ \liminf_{n \rightarrow \infty} X_n > -\infty \right\}, \\ F &:= \left\{ \sup_{n \in \mathbb{N}} \langle X \rangle_n < \infty \right\}. \end{aligned}$$

Show that

$$C = A^+ = A^- = F(\text{mod } \mathbf{P}).$$

Here equality of events (mod $\mathbf{P}$) means that the events differ at most by a $\mathbf{P}$ -null set (see Definition 1.68(iii)).

Hint: Use the stopping times $\sigma_K = \inf \{n \in \mathbb{N} : |X_n| \geq K\}$; $\sigma_K^\pm = \inf \{n \in \mathbb{N} : \pm X_n \geq K\}$ and τ_K as in the proof of Theorem 11.14.

Exercise 11.2.6 Let the notation be as in Exercise 11.2.5. However, instead of (11.2) we make the weaker assumption

$$\mathbf{E} \left[\sup_{n \in \mathbb{N}} |X_{n+1} - X_n| \right] < \infty \quad (11.3)$$

Show that

$$C = A^+ = A^-(\text{mod } \mathbf{P})$$

Hint: Use suitable stopping times ϱ_K and apply the martingale convergence theorem (Theorem 11.4) to the stopped process X^{ϱ_K} .

Exercise 11.2.7 (Conditional Borel-Cantelli lemma) Let $(\mathcal{F}_n)_{n \in \mathbb{N}_0}$ be a filtration and let $(A_n)_{n \in \mathbb{N}}$ be events with $A_n \in \mathcal{F}_n$ for all $n \in \mathbb{N}$. Define $A_\infty = \{\sum_{n=1}^\infty \mathbf{P}[A_n | \mathcal{F}_{n-1}] = \infty\}$ and $A^* = \limsup_{n \rightarrow \infty} A_n$. Show the conditional Borel-Cantelli lemma: $\mathbf{P}[A_\infty \triangle A^*] = 0$.

Hint: Apply Exercise 11.2.5 to $X_n = \sum_{i=1}^n (\mathbb{1}_{A_i} - \mathbf{P}[A_i | \mathcal{F}_{i-1}])$.

Exercise 11.2.8 Let $p \in [0, 1]$ and let $X = (X_n)_{n \in \mathbb{N}_0}$ be a stochastic process with values in $[0, 1]$. Assume that for all $n \in \mathbb{N}_0$, given $X_0, \dots, X_n$, we have

$$X_{n+1} = \begin{cases} 1 - p + pX_n & \text{with probability } X_n \\ pX_n & \text{with probability } 1 - X_n \end{cases}$$

Show that X is a martingale that converges almost surely. Compute the distribution of the almost sure limit $\lim_{n \rightarrow \infty} X_n$.

Exercise 11.2.9 Let $f \in \mathcal{L}^1(\lambda)$, where λ is the restriction of the Lebesgue measure to $[0, 1]$. Let $I_{n,k} = [k2^{-n}, (k+1)2^{-n})$ for $n \in \mathbb{N}$ and $k = 0, \dots, 2^n - 1$. Define $f_n : [0, 1] \rightarrow \mathbb{R}$ by

$$f_n(x) = 2^n \int_{I_{k,n}} f d\lambda, \quad \text{if } k \text{ is chosen such that } x \in I_{k,n}$$

Show that $f_n(x) \xrightarrow{n \rightarrow \infty} f(x)$ for λ -almost all $x \in [0, 1]$.

Exercise 11.2.10 Assume that $\mathbb{F} = (\mathcal{F}_n)_{n \in \mathbb{N}}$ is a filtration on the probability space $(\Omega, \mathcal{A}, \mathbf{P})$. Let

$\mathcal{F}_\infty := \sigma(\mathcal{F}_n : n \in \mathbb{N})$, and let $\mathcal{M}$ be the vector space of uniformly integrable $\mathbb{F}$ -martingales. Show that the map $\Phi : \mathcal{L}^1(\mathcal{F}_\infty) \rightarrow \mathcal{M}, X_\infty \mapsto (\mathbf{E}[X_\infty | \mathcal{F}_n])_{n \in \mathbb{N}}$ is an isomorphism of vector spaces.

5.11.3 11.3 Example: Branching Process

Let $p = (p_k)_{k \in \mathbb{N}_0}$ be a probability vector on $\mathbb{N}_0$ and let $(Z_n)_{n \in \mathbb{N}_0}$ be the Galton-Watson process with one ancestor and offspring distribution p (see Definition 3.9). For convenience, we recall the construction of Z . Let $(X_{n,i})_{n \in \mathbb{N}_0, i \in \mathbb{N}}$ be i.i.d. random variables with $\mathbf{P}[X_{1,1} = k] = p_k$ for $k \in \mathbb{N}_0$. Let $Z_0 = 1$ and inductively define

$$Z_{n+1} = \sum_{i=1}^{Z_n} X_{n,i} \quad \text{for } n \in \mathbb{N}_0$$

We interpret Z_n as the size of a population at time n and $X_{n,i}$ as the number of offspring of the i th individual of the n th generation.

Let $m := \mathbf{E}[X_{1,1}] < \infty$ be the expected number of offspring of an individual and let $\sigma^2 := \text{Var}[X_{1,1}] \in (0, \infty)$ be its variance. Let $\mathcal{F}_n := \sigma(X_{k,i} : k < n, i \in \mathbb{N})$. Then Z is adapted to $\mathbb{F}$. Define $W_n = m^{-n} Z_n$.

Lemma 11.18 W is a martingale. In particular, $\mathbf{E}[Z_n] = m^n$ for all $n \in \mathbb{N}$.

Proof We compute the conditional expectation for $n \in \mathbb{N}_0$:

$$\begin{aligned} \mathbf{E}[W_{n+1} | \mathcal{F}_n] &= m^{-(n+1)} \mathbf{E}[Z_{n+1} | \mathcal{F}_n] \\ &= m^{-(n+1)} \mathbf{E}\left[\sum_{i=1}^{Z_n} X_{n,i} \mid \mathcal{F}_n\right] \\ &= m^{-(n+1)} \sum_{k=1}^{\infty} \mathbf{E}[\mathbb{1}_{\{Z_n=k\}} k \cdot X_{n,i} \mid \mathcal{F}_n] \\ &= m^{-n} \sum_{k=1}^{\infty} \mathbf{E}[k \cdot \mathbb{1}_{\{Z_n=k\}} \mid \mathcal{F}_n] \\ &= m^{-n} Z_n = W_n \end{aligned}$$

Theorem 11.19 Let $\text{Var}[X_{1,1}] \in (0, \infty)$. The a.s. limit $W_\infty = \lim_{n \rightarrow \infty} W_n$ exists and

$$m > 1 \iff \mathbf{E}[W_\infty] = 1 \iff \mathbf{E}[W_\infty] > 0.$$

Proof W_∞ exists since $W \geq 0$ is a martingale. If $m \leq 1$, then $(Z_n)_{n \in \mathbb{N}}$ converges a.s. to some random variable Z_∞ . Note that Z_∞ is the only choice since $\sigma^2 > 0$.

Now let $m > 1$. Since $\mathbf{E}[Z_{n-1}] = m^{n-1}$ (Lemma 11.18), by the Blackwell-Girshick formula (Theorem 5.10),

$$\begin{aligned} \text{Var}[W_n] &= m^{-2n} (\sigma^2 \mathbf{E}[Z_{n-1}] + m^2 \text{Var}[Z_{n-1}]) \\ &= \sigma^2 m^{-(n+1)} + \text{Var}[W_{n-1}] \end{aligned}$$

Inductively, we get $\text{Var}[W_n] = \sigma^2 \sum_{k=2}^{n+1} m^{-k} \leq \frac{\sigma^2 m}{m-1} < \infty$. Hence W is bounded in L^2 and Theorem 11.10 yields $W_n \rightarrow W_\infty$ in L^2 and thus in L^1 . In particular, $\mathbf{E}[W_\infty] = \mathbf{E}[W_0] = 1$.

The proof of Theorem 11.19 was simple due to the assumption of finite variance of the offspring distribution. However, there is a much stronger statement that here we can only quote (see [96], and see [110] for a modern proof).

Theorem 11.20 (Kesten-Stigum (1966)) Let $m > 1$. Then

$$\mathbf{E}[W_\infty] = 1 \iff \mathbf{E}[W_\infty] > 0 \iff \mathbf{E}[X_{1,1} \log(X_{1,1})^+] < \infty.$$

5.12 12 Backwards Martingales and Exchangeability

With many data acquisitions, such as telephone surveys, the order in which the data come does not matter. Mathematically, we say that a family of random variables is exchangeable if the joint distribution does not change under finite permutations. De Finetti's structural theorem says that an infinite family of E -valued exchangeable random variables can be described by a two-stage experiment. At the first stage, a probability distribution Ξ on E is drawn at random. At the second stage, i.i.d. random variables with distribution Ξ are implemented.

We first define the notion of exchangeability. Then we consider backwards martingales and prove the convergence theorem for them. This is the cornerstone for the proof of de Finetti's theorem.

5.12.1 12.1 Exchangeable Families of Random Variables

Definition 12.1 Let I be an arbitrary index set and let E be a Polish space. A family $(X_i)_{i \in I}$ of random variables with values in E is called exchangeable if

$$\mathcal{L}[(X_{\varrho(i)})_{i \in I}] = \mathcal{L}[(X_i)_{i \in I}]$$

for any finite permutation $\varrho : I \rightarrow I$.

Recall that a finite permutation is a bijection $\varrho : I \rightarrow I$ that leaves all but finitely many points unchanged.

Remark 12.2 Clearly, the following are equivalent.

- (i) $(X_i)_{i \in I}$ is exchangeable.
- (ii) Let $n \in \mathbb{N}$ and assume $i_1, \dots, i_n \in I$ are pairwise distinct and $j_1, \dots, j_n \in I$ are pairwise distinct. Then we have $\mathcal{L}[(X_{i_1}, \dots, X_{i_n})] = \mathcal{L}[(X_{j_1}, \dots, X_{j_n})]$.

In particular ($n = 1$), exchangeable random variables are identically distributed.

Example 12.3

- (i) If $(X_i)_{i \in I}$ is i.i.d., then $(X_i)_{i \in I}$ is exchangeable.
- (ii) Consider an urn with N balls, M of which are black. Successively draw without replacement all of the balls and define

$$X_n := \begin{cases} 1, & \text{if the } n\text{th ball is black} \\ 0, & \text{else} \end{cases}$$

Then $(X_n)_{n=1, \dots, N}$ is exchangeable. Indeed, this follows by elementary combinatorics since for any choice $x_1, \dots, x_N \in \{0, 1\}$ with $x_1 + \dots + x_N = M$, we have

$$\mathbf{P}[X_1 = x_1, \dots, X_N = x_N] = \frac{1}{\binom{N}{M}}$$

This formula can be derived formally via a small computation with conditional probabilities. As we will need a similar computation for Pólya's urn model in Example 12.29, we give the details here. Let $s_k = x_1 + \dots + x_k$ for $k = 0, \dots, N$ and let

$$g_k(x) = \begin{cases} M - s_k, & \text{if } x = 1, \\ N - M + s_k - k, & \text{if } x = 0 \end{cases}$$

Then $\mathbf{P}[X_1 = x_1] = g_0(x_1)/N$ and
 $\mathbf{P}[X_{k+1} = x_{k+1} \mid X_1 = x_1, \dots, X_k = x_k] = \frac{g_k(x_{k+1})}{N-k}$ for $k = 1, \dots, N-1$.
 Clearly, $g_k(0) = N - M - l$, where $l = \#\{i \leq k : x_i = 0\}$. Therefore,

$$\begin{aligned} \mathbf{P}[X_1 = x_1, \dots, X_N = x_N] &= \mathbf{P}[X_1 = x_1] \prod_{k=1}^{N-1} \mathbf{P}[X_{k+1} = x_{k+1} \mid X_1 = x_1, \dots, X_k = x_k] \\ &= \frac{1}{N!} \prod_{k=0}^{N-1} g_k(x_{k+1}) = \frac{1}{N!} \prod_{k:x_k=1} g_k(1) \prod_{k:x_k=0} g_k(0) \\ &= \frac{1}{N!} \prod_{l=0}^{M-1} (M-l) \prod_{l=0}^{N-1} (N-M-l) = \frac{M!(N-M)!}{N!}. \end{aligned}$$

(iii) Let Y be a random variable with values in $[0, 1]$. Assume that, given Y , the random variables $(X_i)_{i \in I}$ are independent and Ber_Y -distributed. That is, for any finite $J \subset I$,

$$\mathbf{P}[X_j = 1 \text{ for all } j \in J \mid Y] = Y^{\#J}.$$

Then $(X_i)_{i \in I}$ is exchangeable.

Let $X = (X_n)_{n \in \mathbb{N}}$ be a stochastic process with values in a Polish space E . Let $S(n)$ be the set of permutations $\varrho : \{1, \dots, n\} \rightarrow \{1, \dots, n\}$. We consider ϱ also as a map $\mathbb{N} \rightarrow \mathbb{N}$ by defining $\varrho(k) = k$ for $k > n$. For $\varrho \in S(n)$ and $x = (x_1, \dots, x_n) \in E^n$, denote $x^\varrho = (x_{\varrho(1)}, \dots, x_{\varrho(n)})$. Similarly, for $x \in E^\mathbb{N}$, denote $x^\varrho = (x_{\varrho(1)}, x_{\varrho(2)}, \dots) \in E^\mathbb{N}$. Let E' be another Polish space. For measurable maps $f : E^n \rightarrow E'$ and $F : E^\mathbb{N} \rightarrow E'$, define the maps f^ϱ and F^ϱ by $f^\varrho(x) = f(x^\varrho)$ and $F^\varrho(x) = F(x^\varrho)$. Further, we write $f(x) = f(x_1, \dots, x_n)$ for $x \in E^n$ and for $x \in E^\mathbb{N}$.

Definition 12.4 (i) A map $f : E^n \rightarrow E'$ is called symmetric if $f^\varrho = f$ for all $\varrho \in S(n)$.

(ii) A map $F : E^\mathbb{N} \rightarrow E'$ is called n -symmetric if $F^\varrho = F$ for all $\varrho \in S(n)$. F is called symmetric if F is n -symmetric for all $n \in \mathbb{N}$.

Example 12.5

(i) For $x \in \mathbb{R}^\mathbb{N}$, define the n th arithmetic mean by $a_n(x) = \frac{1}{n} \sum_{i=1}^n x_i$. Clearly, a_n is an n -symmetric map (but not m -symmetric for any $m > n$). Furthermore, $\bar{a}(x) := \limsup_{n \rightarrow \infty} a_n(x)$ defines a symmetric map $\mathbb{R}^\mathbb{N} \rightarrow \mathbb{R} \cup \{-\infty, +\infty\}$.

(ii) The map $s : \mathbb{R}^\mathbb{N} \rightarrow [0, \infty]$, $x \mapsto \sum_{i=1}^\infty |x_i|$ is symmetric. Unlike $\bar{a}$, the value of s depends on every coordinate if it is finite.

(iii) For $x \in E^\mathbb{N}$, define the n th empirical distribution by $\xi_n(x) = \frac{1}{n} \sum_{i=1}^n \delta_{x_i}$ (recall that δ_{x_i} is the Dirac measure at the point x_i). Clearly, ξ_n is an n -symmetric map.

(iv) Let $k \in \mathbb{N}$ and let $\varphi : E^k \rightarrow \mathbb{R}$ be a map. The n th symmetrized average

$$A_n(\varphi) : E^\mathbb{N} \rightarrow \mathbb{R}, \quad x \mapsto \frac{1}{n!} \sum_{\varrho \in S(n)} \varphi(x^\varrho) \quad (12.1)$$

is an n -symmetric map.

Definition 12.6 Let $X = (X_n)_{n \in \mathbb{N}}$ be a stochastic process with values in E . For $n \in \mathbb{N}$, define

$$\mathcal{E}'_n := \sigma(F : F : E^\mathbb{N} \rightarrow \mathbb{R} \text{ is measurable and } n\text{-symmetric})$$

and let $\mathcal{E}_n := X^{-1}(\mathcal{E}'_n)$ be the σ -algebra of events that are invariant under all permutations $\varrho \in S(n)$. Further, let

$$\mathcal{E}' := \bigcap_{n=1}^{\infty} \mathcal{E}'_n = \sigma(F : F : E^{\mathbb{N}} \rightarrow \mathbb{R} \text{ is measurable and symmetric})$$

and let $\mathcal{E}_n := \bigcap_{m=1}^{\infty} \mathcal{E}'_m = X^{-1}(\mathcal{E}')$ be the σ -algebra of exchangeable events for X , or briefly the exchangeable σ -algebra.

Remark 12.7 If $A \in \sigma(X_n, n \in \mathbb{N})$ is an event, then there is a measurable $B \subset E^{\mathbb{N}}$ with $A = \{X \in B\}$. If we denote $A^\varrho = \{X^\varrho \in B\}$ for $\varrho \in S(n)$, then $\mathcal{E}_n = \{A : A^\varrho = A \text{ for all } \varrho \in S(n)\}$. This justifies the name "exchangeable event".

Remark 12.8 If we write $\Xi_n(\omega) := \xi_n(X(\omega)) = \frac{1}{n} \sum_{i=1}^n \delta_{X_i(\omega)}$ for the n thempirical distribution, then, by Exercise 12.1.1, $\mathcal{E}_n = \sigma(\Xi_n)$.

Remark 12.9 Denote by $\mathcal{T} = \bigcap_{n \in \mathbb{N}} \sigma(X_{n+1}, X_{n+2}, \dots)$ the tail σ -algebra. Then $\mathcal{T} \subset \mathcal{E}$, and strict inclusion is possible.

Indeed, evidently $\sigma(X_{n+1}, X_{n+2}, \dots) \subset \mathcal{E}_n$ for $n \in \mathbb{N}$; hence $\mathcal{T} \subset \mathcal{E}$. Now let $E = \{0, 1\}$ and let $X_1, X_2, \dots$ be independent random variables with $\mathbf{P}[X_n = 1] \in (0, 1)$ for all $n \in \mathbb{N}$. The random variable $S := \sum_{n=1}^{\infty} X_n$ is measurable with respect to $\mathcal{E}$ but not with respect to $\mathcal{T}$.

Theorem 12.10 Let $X = (X_n)_{n \in \mathbb{N}}$ be exchangeable. If $\varphi : E^{\mathbb{N}} \rightarrow \mathbb{R}$ is measurable and if $\mathbf{E}[|\varphi(X)|] < \infty$, then for all $n \in \mathbb{N}$ and all $\varrho \in S(n)$,

$$\mathbf{E}[\varphi(X) \mid \mathcal{E}_n] = \mathbf{E}[\varphi(X^\varrho) \mid \mathcal{E}_n]. \quad (12.2)$$

In particular,

$$\mathbf{E}[\varphi(X) \mid \mathcal{E}_n] = A_n(\varphi) := \frac{1}{n!} \sum_{\varrho \in S(n)} \varphi(X^\varrho). \quad (12.3)$$

Proof Let $A \in \mathcal{E}_n$. Then there exists a $B \in \mathcal{E}'_n$ such that $A = X^{-1}(B)$. Let $F = \mathbb{1}_B$. Then $F \circ X = \mathbb{1}_A$. By the definition of $\mathcal{E}_n$, the map $F : E^{\mathbb{N}} \rightarrow \mathbb{R}$ is measurable, n -symmetric and bounded. Therefore,

$$\mathbf{E}[\varphi(X)F(X)] = \mathbf{E}[\varphi(X^\varrho)F(X^\varrho)] = \mathbf{E}[\varphi(X^\varrho)F(X)].$$

Here we used the exchangeability of X in the first equality and the symmetry of F in the second equality. From this (12.2) follows. However, $A_n(\varphi)$ is $\mathcal{E}_n$ -measurable and hence

$$\mathbf{E}[\varphi(X) \mid \mathcal{E}_n] = \mathbf{E}\left[\frac{1}{n!} \sum_{\varrho \in S(n)} \varphi(X^\varrho) \mid \mathcal{E}_n\right] = \frac{1}{n!} \sum_{\varrho \in S(n)} \varphi(X^\varrho).$$

Heuristic for the Structure of Exchangeable Families Consider a finite exchangeable family $X_1, \dots, X_N$ of E -valued random variables. For $n \leq N$, what is the conditional distribution of $(X_1, \dots, X_n)$ given Ξ_N ? For any measurable $A \subset E$, $\{X_i \in A\}$ occurs for exactly $N\Xi_N(A)$ of the $i \in \{1, \dots, N\}$, where the order does not change the probability. Hence we are in the situation of

drawing colored balls without replacement. More precisely, let the pairwise distinct points $e_1, \dots, e_k \in E$ be the atoms of Ξ_N and let $N_1, \dots, N_k$ be the corresponding absolute frequencies. Hence $\Xi_N = \sum_{i=1}^k (N_i/N) \delta_{e_i}$. We thus deal with balls of k different colors and with N_i balls of the i th color. We draw n of these balls without replacement but respecting the order. Up to the order, the resulting distribution is thus the generalized hypergeometric distribution (see (1.19) on page 44). Hence, for pairwise disjoint, measurable sets $A_1, \dots, A_k$ with $\bigsqcup_{l=1}^k A_l = E$, for $i_1, \dots, i_n \in \{1, \dots, k\}$, pairwise distinct $j_1, \dots, j_n \in \{1, \dots, N\}$ and with the convention $m_l := \#\{r \in \{1, \dots, n\} : i_r = l\}$ for $l \in \{1, \dots, k\}$, we have

$$\mathbf{P}[X_{j_r} \in A_{i_r} \text{ for all } r = 1, \dots, n \mid \Xi_N] = \frac{1}{(N)_n} \prod_{l=1}^k (N \Xi_N(A_l))^{m_l}. \quad (12.4)$$

Here we defined $(n)_l := n(n-1)\dots(n-l+1)$.

What happens if we let $N \rightarrow \infty$? For simplicity, assume that for all $l = 1, \dots, k$, the limit $\Xi_\infty(A_l) = \lim_{N \rightarrow \infty} \Xi_N(A_l)$ exists in a suitable sense. Then (12.4) formally becomes

$$\mathbf{P}[X_{j_r} \in A_{i_r} \text{ for all } r = 1, \dots, n \mid \Xi_\infty] = \prod_{l=1}^k \Xi_\infty(A_l)^{m_l} \quad (12.5)$$

Drawing without replacements thus asymptotically turns into drawing with replacements. Hence the random variables $X_1, X_2, \dots$ are independent with distribution Ξ_∞ given Ξ_∞ .

For a formal proof along the lines of this heuristic, see Section 13.4.

In order to formulate (and prove) this statement (de Finetti's theorem) rigorously in Section 12.3, we need some more technical tools (e.g., the notion of conditional independence). A further tool will be the convergence theorem for backwards martingales that will be formulated in Section 12.2. For further reading on exchangeable random variables, we refer to [4, 33, 98, 105].

Exercise 12.1.1 Let $n \in \mathbb{N}$. Show that every symmetric function $f : E^n \rightarrow \mathbb{R}$ can be written in the form $f(x) = g(\frac{1}{n} \sum_{i=1}^n \delta_{x_i})$, where g has to be chosen appropriately (depending on f).

Exercise 12.1.2 Derive equation (12.4) formally.

Exercise 12.1.3 Let $X_1, \dots, X_n$ be exchangeable, square integrable random variables. Show that

$$\text{Cov}[X_1, X_2] \geq -\frac{1}{n-1} \text{Var}[X_1] \quad (12.6)$$

For $n \geq 2$, give a nontrivial example for equality in (12.6).

Exercise 12.1.4 Let $X_1, X_2, X_3, \dots$ be exchangeable, square integrable random variables. Show that $\text{Cov}[X_1, X_2] \geq 0$.

Exercise 12.1.5 Show that for all $n \in \mathbb{N} \setminus \{1\}$, there is an exchangeable family of random variables $X_1, \dots, X_n$ that cannot be extended to an infinite exchangeable family $X_1, X_2, \dots$.

5.12.2 12.2 Backwards Martingales

The concepts of filtration and martingale do not require the index set I (interpreted as time) to be a subset of $[0, \infty)$. Hence we can consider the case $I = -\mathbb{N}_0$.

Definition 12.11 (Backwards martingale) Let $\mathbb{F} = (\mathcal{F}_n)_{n \in -\mathbb{N}_0}$ be a filtration and let $X = (X_n)_{n \in -\mathbb{N}_0}$ be an $\mathbb{F}$ -martingale. Then $X = (X_{-n})_{n \in \mathbb{N}_0}$ is called a backwards martingale.

Remark 12.12 A backwards martingale is always uniformly integrable. This follows from Corollary 8.22 and the fact that $X_{-n} = \mathbf{E}[X_0 \mid \mathcal{F}_{-n}]$ for any $n \in \mathbb{N}_0$.

Example 12.13 Let $X_1, X_2, \dots$ be exchangeable real random variables. For $n \in \mathbb{N}$, let $\mathcal{F}_{-n} = \mathcal{E}_n$ and

$$Y_{-n} = \frac{1}{n} \sum_{i=1}^n X_i.$$

We show that $(Y_{-n})_{n \in \mathbb{N}}$ is an $\mathbb{F}$ -backwards martingale. Clearly, Y is adapted. Furthermore, by Theorem 12.10 (with $k = n$ and $\varphi(X_1, \dots, X_n) = \frac{1}{n-1} (X_1 + \dots + X_{n-1})$),

$$\mathbf{E}[Y_{-n+1} \mid \mathcal{F}_{-n}] = \frac{1}{n!} \sum_{\varrho \in S(n)} \frac{1}{n-1} (X_{\varrho(1)} + \dots + X_{\varrho(n-1)}) = Y_{-n}$$

Now replace $\mathbb{F}$ by the smaller filtration $\mathbb{G} = (\mathcal{G}_n)_{n \in -\mathbb{N}}$ that is defined by $\mathcal{G}_{-n} = \sigma(Y_{-n}, X_{n+1}, X_{n+2}, \dots) = \sigma(Y_{-n}, Y_{-n-1}, Y_{-n-2}, \dots)$ for $n \in \mathbb{N}$. This is the filtration generated by Y ; thus Y is also a $\mathbb{G}$ -backwards martingale (see Remark 9.29). $\diamond$

Let $a < b$ and $n \in \mathbb{N}$. Let $U_{-n}^{a,b}$ be the number of upcrossings of X over $[a, b]$ between times $-n$ and 0 . Further, let $U^{a,b} = \lim_{n \rightarrow \infty} U_{-n}^{a,b}$. By the upcrossing inequality (Lemma 11.3), we have $\mathbf{E}[U_{-n}^{a,b}] \leq \frac{1}{b-a} \mathbf{E}[(X_0 - a)^+]$; hence $\mathbf{P}[U^{a,b} < \infty] = 1$. As in the proof of the martingale convergence theorem (Theorem 11.4), we infer the following.

Theorem 12.14 (Convergence theorem for backwards martingales) Let $(X_n)_{n \in -\mathbb{N}_0}$ be a martingale with respect to $\mathbb{F} = (\mathcal{F}_n)_{n \in -\mathbb{N}_0}$. Then there exists $X_{-\infty} = \lim_{n \rightarrow \infty} X_{-n}$ almost surely and in L^1 . Furthermore, $X_{-\infty} = \mathbf{E}[X_0 | \mathcal{F}_{-\infty}]$, where $\mathcal{F}_{-\infty} = \bigcap_{n=1}^{\infty} \mathcal{F}_{-n}$.

Example 12.15 Let $X_1, X_2, \dots$ be exchangeable, integrable random variables. Further, let $\mathcal{T} = \bigcap_{n=1}^{\infty} \sigma(X_m, m \geq n)$ be the tail σ -algebra of $X_1, X_2, \dots$ and let $\mathcal{E}$ be the exchangeable σ -algebra. Then $\mathbf{E}[X_1 | \mathcal{T}] = \mathbf{E}[X_1 | \mathcal{E}]$ a.s. and

$$\frac{1}{n} \sum_{i=1}^n X_i \xrightarrow{n \rightarrow \infty} \mathbf{E}[X_1 | \mathcal{E}] \quad \text{a.s. and in } L^1$$

Indeed, if we let $Y_{-n} := \frac{1}{n} \sum_{i=1}^n X_i$, then (by Example 12.13) $(Y_{-n})_{n \in \mathbb{N}}$ is a backwards martingale with respect to $(\mathcal{F}_n)_{n \in -\mathbb{N}} = (\mathcal{E}_{-n})_{n \in -\mathbb{N}}$ and thus

$$Y_{-n} \xrightarrow{n \rightarrow \infty} Y_{-\infty} = \mathbf{E}[X_1 | \mathcal{E}] \quad \text{a.s. and in } L^1.$$

Now, by Example 2.36(ii), $Y_{-\infty}$ is $\mathcal{T}$ -measurable; hence (since $\mathcal{T} \subset \mathcal{E}$ and by virtue of the tower property of conditional expectation) $Y_{-\infty} = \mathbf{E}[X_1 | \mathcal{T}]$.

Example 12.16 (Strong law of large numbers) If $Z_1, Z_2, \dots$ are real and i.i.d. with $\mathbf{E}[|Z_1|] < \infty$, then

$$\frac{1}{n} \sum_{i=1}^n Z_i \xrightarrow{n \rightarrow \infty} \mathbf{E}[Z_1] \quad \text{almost surely.}$$

By Kolmogorov's 0-1 law (Theorem 2.37), the tail σ -algebra $\mathcal{T}$ is trivial; hence we have

$$\mathbf{E}[Z_1 | \mathcal{T}] = \mathbf{E}[Z_1] \quad \text{almost surely.}$$

In Corollary 12.19, we will see that in the case of independent random variables, $\mathcal{E}$ is also $\mathbf{P}$ -trivial. This implies $\mathbf{E}[Z_1 | \mathcal{E}] = \mathbf{E}[Z_1]$.

We close this section with a generalization of Example 12.15 to mean values of functions of $k \in \mathbb{N}$ variables. This conclusion from the convergence theorem for backwards martingales will be used in an essential way in the next section.

Theorem 12.17 Let $X = (X_n)_{n \in \mathbb{N}}$ be an exchangeable family of random variables with values in E . Assume that $k \in \mathbb{N}$ and let $\varphi : E^k \rightarrow \mathbb{R}$ be measurable with $\mathbf{E}[|\varphi(X_1, \dots, X_k)|] < \infty$. Denote $\varphi(X) = \varphi(X_1, \dots, X_k)$ and let $A_n(\varphi) := \frac{1}{n!} \sum_{\varrho \in S(n)} \varphi(X^{\varrho})$. Then

$$\mathbf{E}[\varphi(X) | \mathcal{E}] = \mathbf{E}[\varphi(X) | \mathcal{T}] = \lim_{n \rightarrow \infty} A_n(\varphi) \quad \text{a.s. and in } L^1. \quad (12.7)$$

Proof By Theorem 12.10, $A_n(\varphi) = \mathbf{E}[\varphi(X) | \mathcal{E}_n]$. Hence $(A_{-n}(\varphi))_{n \geq k}$ is a backwards martingale with respect to $(\mathcal{E}_{-n})_{n \in -\mathbb{N}}$. Hence, by Theorem 12.14,

$$A_n(\varphi) \xrightarrow{n \rightarrow \infty} \mathbf{E}[\varphi(X) | \mathcal{E}] \quad \text{a.s. and in } L^1. \quad (12.8)$$

As for the arithmetic mean (Example 12.16), we can argue that $\lim_{n \rightarrow \infty} A_n(\varphi)$ is $\mathcal{T}$ -measurable. Indeed,

$$\limsup_{n \rightarrow \infty} \frac{\#\{\varrho \in S(n) : \varrho^{-1}(i) \leq l \text{ for some } i \in \{1, \dots, k\}\}}{n!} = 0 \quad \text{for all } l \in \mathbb{N}.$$

Thus, for large n , the dependence of $A_n(\varphi)$ on the first l coordinates is negligible. Together with (12.8), we get (12.7).

Corollary 12.18 Let $X = (X_n)_{n \in \mathbb{N}}$ be exchangeable. Then, for any $A \in \mathcal{E}$ there exists a $B \in \mathcal{T}$ with $\mathbf{P}[A \Delta B] = 0$.

Note that $\mathcal{T} \subset \mathcal{E}$; hence the statement is trivially true if the roles of $\mathcal{E}$ and $\mathcal{T}$ are interchanged.

Proof Since $\mathcal{E} \subset \sigma(X_1, X_2, \dots)$, by the approximation theorem for measures, there exists a sequence of measurable sets $(A_k)_{k \in \mathbb{N}}$ with $A_k \in \sigma(X_1, \dots, X_k)$ and such that $\mathbf{P}[A \Delta A_k] \xrightarrow{k \rightarrow \infty} 0$. Let $C_k \in \mathcal{E}^k$ be measurable with

$$A_k = \{(X_1, \dots, X_k) \in C_k\}$$

for all $k \in \mathbb{N}$. Letting $\varphi_k := \mathbb{1}_{C_k}$, Theorem 12.17 implies that

$$\begin{aligned} \mathbb{1}_A &= \mathbf{E}[\mathbb{1}_A \mid \mathcal{E}] = \mathbf{E}\left[\lim_{k \rightarrow \infty} \varphi_k(X) \mid \mathcal{E}\right] = \lim_{k \rightarrow \infty} \mathbf{E}[\varphi_k(X) \mid \mathcal{E}] \\ &= \lim_{k \rightarrow \infty} \mathbf{E}[\varphi_k(X) \mid \mathcal{T}] =: \psi \quad \text{almost surely} \end{aligned}$$

Hence there is a $\mathcal{T}$ -measurable function ψ with $\psi = \mathbb{1}_A$ almost surely. We can assume that $\psi = \mathbb{1}_B$ for some $B \in \mathcal{T}$.

As a further application, we get the 0-1 law of Hewitt and Savage [72].

Corollary 12.19 (0 – 1 law of Hewitt-Savage) Let $X_1, X_2, \dots$ be i.i.d. random variables. Then the exchangeable σ -algebra is $\mathbf{P}$ -trivial; that is, $\mathbf{P}[A] \in \{0, 1\}$ for all $A \in \mathcal{E}$.

Proof By Kolmogorov's 0-1 law (Theorem 2.37), $\mathcal{T}$ is trivial. Hence the claim follows immediately from Corollary 12.18.

5.12.3 12.3 De Finetti's Theorem

In this section, we show the structural theorem for countably infinite exchangeable families that was heuristically motivated at the end of Section 12.1. Hence we shall show that a countably infinite exchangeable family of random variables is an i.i.d.

family given the exchangeable σ -algebra $\mathcal{E}$. Furthermore, we compute the conditional distribution of the individual random variables. As a first step, we define conditional independence formally (see [25, Chapter 7.3]).

Definition 12.20 (Conditional independence) Let $(\Omega, \mathcal{F}, \mathbf{P})$ be a probability space, let $\mathcal{A} \subset \mathcal{F}$ be a sub- σ -algebra and let $(\mathcal{A}_i)_{i \in I}$ be an arbitrary family of sub- σ -algebras of $\mathcal{F}$. Assume that for any finite $J \subset I$, any choice of $A_j \in \mathcal{A}_j$ and for all $j \in J$,

$$\mathbf{P}\left[\bigcap_{j \in J} A_j \mid \mathcal{A}\right] = \prod_{j \in J} \mathbf{P}[A_j \mid \mathcal{A}] \quad \text{almost surely.} \quad (12.9)$$

Then the family $(\mathcal{A}_i)_{i \in I}$ is called independent given $\mathcal{A}$.

A family $(X_i)_{i \in I}$ of random variables on $(\Omega, \mathcal{F}, \mathbf{P})$ is called independent (and identically distributed) given $\mathcal{A}$ if the generated σ -algebras $(\sigma(X_i))_{i \in I}$ are independent given $\mathcal{A}$ (and the conditional distributions $\mathbf{P}[X_i \in \cdot \mid \mathcal{A}]$ are equal).

Example 12.21 Any family $(\mathcal{A}_i)_{i \in I}$ of sub- σ -algebras of $\mathcal{F}$ is independent given $\mathcal{F}$. Indeed, letting $A = \bigcap_{j \in J} A_j$,

$$\mathbf{P}[A \mid \mathcal{F}] = \mathbb{1}_A = \prod_{j \in J} \mathbb{1}_{A_j} = \prod_{j \in J} \mathbf{P}[A_j \mid \mathcal{F}] \quad \text{almost surely.}$$

□

Example 12.22 If $(\mathcal{A}_i)_{i \in I}$ is an independent family of σ -algebras and if $\mathcal{A}$ is trivial, then $(\mathcal{A}_i)_{i \in I}$ is independent given $\mathcal{A}$. □

Example 12.23 There is no "monotonicity" for conditional independence in the following sense: If $\mathcal{F}_1, \mathcal{F}_2$ and $\mathcal{F}_3$ are σ -algebras with $\mathcal{F}_1 \subset \mathcal{F}_2 \subset \mathcal{F}_3$ and such that $(\mathcal{A}_i)_{i \in I}$ is independent given $\mathcal{F}_1$ as well as given $\mathcal{F}_3$, then this does not imply independence given $\mathcal{F}_2$.

In order to illustrate this, assume that X and Y are nontrivial independent real random variables. Let $\mathcal{F}_1 = \{\emptyset, \Omega\}$, $\mathcal{F}_2 = \sigma(X + Y)$ and $\mathcal{F}_3 = \sigma(X, Y)$. Then $\sigma(X)$ and $\sigma(Y)$ are independent given $\mathcal{F}_1$ as well as given $\mathcal{F}_3$ but not given $\mathcal{F}_2$. □

Let $X = (X_n)_{n \in \mathbb{N}}$ be a stochastic process on a probability space $(\Omega, \mathcal{F}, \mathbf{P})$ with values in a Polish space E . Let $\mathcal{E}$ be the exchangeable σ -algebra and let $\mathcal{T}$ be the tail σ -algebra.

Theorem 12.24 (de Finetti) The family $X = (X_n)_{n \in \mathbb{N}}$ is exchangeable if and only if there exists a σ -algebra $\mathcal{A} \subset \mathcal{F}$ such that $(X_n)_{n \in \mathbb{N}}$ is i.i.d. given $\mathcal{A}$. In this case, $\mathcal{A}$ can be chosen to equal the exchangeable σ -algebra $\mathcal{E}$ or the tail- σ -algebra $\mathcal{T}$.

Proof " $\implies$ " Let X be exchangeable and let $\mathcal{A} = \mathcal{E}$ or $\mathcal{A} = \mathcal{T}$. For any $n \in \mathbb{N}$, let $f_n : E \rightarrow \mathbb{R}$ be a bounded measurable map. Let

$$\varphi_k(x_1, \dots, x_k) = \prod_{i=1}^k f_i(x_i) \quad \text{for any } k \in \mathbb{N}.$$

Let $A_n(\varphi)$ be the symmetrized average from Theorem 12.17. Then

$$\begin{aligned} A_n(\varphi_{k-1}) A_n(f_k) &= \frac{1}{n!} \sum_{\varrho \in S(n)} \varphi_{k-1}(X^{\varrho}) \frac{1}{n} \sum_{i=1}^n f_k(X_i) \\ &= \frac{1}{n!} \sum_{\varrho \in S(n)} \varphi_k(X^{\varrho}) + R_{n,k} = A_n(\varphi_k) + R_{n,k} \end{aligned}$$

where

$$\begin{aligned} |R_{n,k}| &\leq 2 \|\varphi_{k-1}\|_{\infty} \cdot \|f_k\|_{\infty} \cdot \frac{1}{n!} \frac{1}{n} \sum_{\varrho \in S(n)} \sum_{i=1}^n \mathbb{1}_{\{i \in \{\varrho(1), \dots, \varrho(k-1)\}\}} \\ &= 2 \|\varphi_{k-1}\|_{\infty} \cdot \|f_k\|_{\infty} \cdot \frac{k-1}{n} \xrightarrow{n \rightarrow \infty} 0 \end{aligned}$$

Together with Theorem 12.17, we conclude that

$$A_n(\varphi_{k-1}) A_n(f_k) \xrightarrow{n \rightarrow \infty} \mathbf{E}[\varphi_k(X_1, \dots, X_k) \mid \mathcal{A}] \quad \text{a.s. and in } L^1.$$

On the other hand, again by Theorem 12.17,

$$A_n(\varphi_{k-1}) \xrightarrow{n \rightarrow \infty} \mathbf{E}[\varphi_{k-1}(X_1, \dots, X_{k-1}) \mid \mathcal{A}]$$

and

$$A_n(f_k) \xrightarrow{n \rightarrow \infty} \mathbf{E}[f_k(X_1) \mid \mathcal{A}].$$

Hence

$$\mathbf{E}[\varphi_k(X_1, \dots, X_k) \mid \mathcal{A}] = \mathbf{E}[\varphi_{k-1}(X_1, \dots, X_{k-1}) \mid \mathcal{A}] \mathbf{E}[f_k(X_1) \mid \mathcal{A}]$$

Thus we get inductively

$$\mathbf{E} \left[\prod_{i=1}^k f_i(X_i) \mid \mathcal{A} \right] = \prod_{i=1}^k \mathbf{E} [f_i(X_1) \mid \mathcal{A}]$$

Therefore, X is i.i.d. given $\mathcal{A}$.

" $\Leftarrow$ " Now let X be i.i.d. given $\mathcal{A}$ for a suitable σ -algebra $\mathcal{A} \subset \mathcal{F}$. For any bounded measurable function $\varphi : E^n \rightarrow \mathbb{R}$ and for any $\varrho \in S(n)$, we have $\mathbf{E}[\varphi(X) \mid \mathcal{A}] = \mathbf{E}[\varphi(X^\varrho) \mid \mathcal{A}]$. Hence

$$\mathbf{E}[\varphi(X)] = \mathbf{E}[\mathbf{E}[\varphi(X) \mid \mathcal{A}]] = \mathbf{E}[\mathbf{E}[\varphi(X^\varrho) \mid \mathcal{A}]] = \mathbf{E}[\varphi(X^\varrho)],$$

whence X is exchangeable.

Denote by $\mathcal{M}_1(E)$ the set of probability measures on E equipped with the topology of weak convergence (see Definition 13.12 and Remark 13.14). That is, a sequence $(\mu_n)_{n \in \mathbb{N}}$ in $\mathcal{M}_1(E)$ converges weakly to a $\mu \in \mathcal{M}_1(E)$ if and only if $\int f d\mu_n \xrightarrow{n \rightarrow \infty} \int f d\mu$ for any bounded continuous function $f : E \rightarrow \mathbb{R}$. We will study weak convergence in Chapter 13 in greater detail. At this point, we use the topology only to make $\mathcal{M}_1(E)$ a measurable space, namely with the Borel σ -algebra $\mathcal{B}(\mathcal{M}_1(E))$. Now we can study random variables with values in $\mathcal{M}_1(E)$, so-called random measures (compare also Section 24.1). For $x \in E^{\mathbb{N}}$, let $\xi_n(x) = \frac{1}{n} \sum_{i=1}^n \delta_{x_i} \in \mathcal{M}_1(E)$.

Definition 12.25 The random measure

$$\Xi_n := \xi_n(X) := \frac{1}{n} \sum_{i=1}^n \delta_{X_i}$$

is called the empirical distribution of $X_1, \dots, X_n$.

Assume the conditions of Theorem 12.24 are in force.

Theorem 12.26 (de Finetti representation theorem) The family $X = (X_n)_{n \in \mathbb{N}}$ is exchangeable if and only if there is a σ -algebra $\mathcal{A} \subset \mathcal{F}$ and an $\mathcal{A}$ -measurable random variable $\Xi_\infty : \Omega \rightarrow \mathcal{M}_1(E)$ with the property that given Ξ_∞ , $(X_n)_{n \in \mathbb{N}}$ is i.i.d. with $\mathcal{L}[X_1 \mid \Xi_\infty] = \Xi_\infty$. In this case, we can choose $\mathcal{A} = \mathcal{E}$ or $\mathcal{A} = \mathcal{T}$.

Proof " $\Rightarrow$ " This follows as in the proof of Theorem 12.24.

" $\implies$ " Let X be exchangeable. Then, by Theorem 12.24, there exists a σ -algebra $\mathcal{A} \subset \mathcal{F}$ such that $(X_n)_{n \in \mathbb{N}}$ is i.i.d. given $\mathcal{A}$. As E is Polish, there exists a regular conditional distribution (see Theorem 8.37) $\Xi_\infty := \mathcal{L}[X_1 \mid \mathcal{A}]$. For measurable $A_1, \dots, A_n \subset E$, we have $\mathbf{P}[X_i \in A_i \mid \mathcal{A}] = \Xi_\infty(A_i)$ for all $i = 1, \dots, n$; hence

$$\begin{aligned} \mathbf{P} \left[\bigcap_{i=1}^n \{X_i \in A_i\} \mid \Xi_\infty \right] &= \mathbf{E} \left[\mathbf{P} \left[\bigcap_{i=1}^n \{X_i \in A_i\} \mid \mathcal{A} \right] \mid \Xi_\infty \right] \\ &= \mathbf{E} \left[\prod_{i=1}^n \Xi_\infty(A_i) \mid \Xi_\infty \right] = \prod_{i=1}^n \Xi_\infty(A_i) \end{aligned}$$

Therefore, $\mathcal{L}[X \mid \Xi_\infty] = \Xi_\infty^{\otimes \mathbb{N}}$.

Remark 12.27

(i) In the case considered in the previous theorem, by the strong law of large numbers, for any bounded continuous function $f : E \rightarrow \mathbb{R}$,

$$\int f d\Xi_n \xrightarrow{n \rightarrow \infty} \int f d\Xi_\infty \quad \text{almost surely.}$$

If in addition E is locally compact (e.g., $E = \mathbb{R}^d$), then one can even show that

$$\Xi_n \xrightarrow{n \rightarrow \infty} \Xi_\infty \quad \text{almost surely.}$$

(ii) For finite families of random variables there is no perfect analog of de Finetti's theorem. See [33] for a detailed treatment of finite exchangeable families.

Example 12.28 Let $(X_n)_{n \in \mathbb{N}}$ be exchangeable and assume $X_n \in \{0, 1\}$. Then there exists a random variable $Y : \Omega \rightarrow [0, 1]$ such that, for all finite $J \subset \mathbb{N}$,

$$\mathbf{P}[X_j = 1 \text{ for all } j \in J \mid Y] = Y^{\#J}.$$

In other words, $(X_n)_{n \in \mathbb{N}}$ is independent given Y and Ber_Y -distributed. Compare Example 12.3(iii).

Example 12.29 (Pólya's urn model) (See Example 14.38, compare also [17, 58, 135].) Consider an urn with a total of N balls among which M are black and $M - N$ are white. At each step, a ball is drawn and is returned to the urn together with an additional ball of the same color. Let

$$X_n := \begin{cases} 1, & \text{if the } n\text{th ball is black} \\ 0, & \text{else} \end{cases}$$

and let $S_n = \sum_{i=1}^n X_i$. Then

$$\mathbf{P}[X_n = 1 \mid X_1, X_2, \dots, X_{n-1}] = \frac{S_{n-1} + M}{N + n - 1}$$

Inductively, for $x_1, \dots, x_n \in \{0, 1\}$ and $s_k = \sum_{i=1}^k x_i$, we get

$$\begin{aligned} & \mathbf{P}[X_i = x_i \text{ for any } i = 1, \dots, n] \\ &= \prod_{i \leq n: x_i = 1} \frac{M + s_{i-1}}{N + i - 1} \prod_{i \leq n: x_i = 0} \frac{N + i - 1 - M - s_{i-1}}{N + i - 1} \\ &= \frac{(N-1)!}{(N-1+n)!} \cdot \frac{(M + s_n - 1)!}{(M-1)!} \frac{(N - M - 1 + (n - s_n))!}{(N - M - 1)!} \end{aligned}$$

The right-hand side depends on s_n only and not on the order of the $x_1, \dots, x_n$. Hence $(X_n)_{n \in \mathbb{N}}$ is exchangeable. Let

$$Z = \lim_{n \rightarrow \infty} \frac{1}{n} S_n$$

Then $(X_n)_{n \in \mathbb{N}}$ is i.i.d. Ber_Z -distributed given Z . Hence (see Example 12.28)

$$\begin{aligned} \mathbf{E}[Z^n] &= \mathbf{E}[\mathbf{P}[X_1 = \dots = X_n = 1 \mid Z]] \\ &= \mathbf{P}[S_n = n] \\ &= \frac{(N-1)!}{(M-1)!} \frac{(M+n-1)!}{(N+n-1)!} \quad \text{for all } n \in \mathbb{N} \end{aligned}$$

By Exercise 5.1.2, these are the moments of the Beta distribution $\beta_{M, N-M}$ on $[0, 1]$ with parameters $(M, N-M)$ (see Example 1.107(ii)). A distribution on $[0, 1]$ is uniquely characterized by its moments (see Theorem 15.4). Hence $Z \sim \beta_{M, N-M}$.

5.13 13 Convergence of Measures

One focus of probability theory is distributions that are the result of an interplay of a large number of random impacts. Often a useful approximation can be obtained by taking a limit of such distributions, for example, a limit where the number of impacts goes to infinity. With the Poisson distribution, we have encountered such a limit distribution that occurs as the number of very rare events when the number of possibilities goes to infinity (see Theorem 3.7). In many cases, it is necessary to rescale the original distributions in order to capture the behavior of the essential fluctuations, e.g., in the central limit theorem. While these theorems work with real random variables, we will also see limit theorems where the random variables take values in more general spaces such as the space of continuous functions when we model the path of the random motion of a particle.

In this chapter, we provide the abstract framework for the investigation of convergence of measures. We introduce the notion of weak convergence of probability measures on general (mostly Polish) spaces and derive the fundamental properties. The reader will profit from a solid knowledge of point set topology. Thus we start with a short overview of some topological definitions and theorems.

We do not strive for the greatest generality but rather content ourselves with the key theorems for probability theory. For further reading, we recommend [14, 82].

At first reading, the reader might wish to skip this rather analytically flavored chapter. In this case, for the time being it suffices to get acquainted with the definitions of weak convergence and tightness (Definitions 13.12 and 13.26), as well as with the statements of the Portemanteau theorem (Theorem 13.16) and Prohorov's theorem (Theorem 13.29).

5.13.1 13.1 A Topology Primer

Excursively, we present some definitions and facts from point set topology. For details, see, e.g., [90].

In the following, let (E, τ) be a topological space with the Borel σ -algebra $\mathcal{E} = \mathcal{B}(E)$ (compare Definitions 1.20 and 1.21). We will also assume that (E, τ) is a

Hausdorff space; that is, for any two points $x, y \in E$ with $x \neq y$, there exist disjoint open sets U, V such that $x \in U$ and $y \in V$.

For $A \subset E$, we denote by $\bar{A}$ the closure of A , by A° the interior and by ∂A the boundary of A . A set $A \subset E$ is called dense if $\bar{A} = E$.

(E, τ) is called metrizable if there exists a metric d on E such that τ is induced by the open balls $B_\varepsilon(x) := \{y \in E : d(x, y) < \varepsilon\}$. A metric d on E is called complete if any Cauchy sequence with respect to d converges in E . (E, τ) is called completely metrizable if there exists a complete metric on E that induces τ . If (E, d) is a metric space and $A, B \subset E$, then we write $d(A, B) = \inf\{d(x, y) : x \in A, y \in B\}$ and $d(x, B) := d(\{x\}, B)$ for $x \in E$.

A metrizable space (E, τ) is called separable if there exists a countable dense subset of E . Separability in metrizable spaces is equivalent to the existence of a countable base of the topology; that is, a countable set $\mathcal{U} \subset \tau$ with $A = \bigcup_{U \in \mathcal{U}: U \subset A} U$ for all $A \in \tau$. (For example, choose the ε -balls centered at the points of a countable subset and let ε run through the positive rational numbers.) A compact metric space is always separable (simply choose for each $n \in \mathbb{N}$ a finite cover $\mathcal{U}_n \subset \tau$ comprising balls of radius $\frac{1}{n}$ and then take $\mathcal{U} := \bigcup_{n \in \mathbb{N}} \mathcal{U}_n$).

A set $A \subset E$ is called compact if each open cover $\mathcal{U} \subset \tau$ of A (that is, $A \subset \bigcup_{U \in \mathcal{U}} U$) has a finite subcover; that is, a finite $\mathcal{U}' \subset \mathcal{U}$ with $A \subset \bigcup_{U \in \mathcal{U}'} U$. Compact sets are closed. By the Heine-Borel theorem, a subset of $\mathbb{R}^d$ is compact if and only if it is bounded and closed. $A \subset E$ is called relatively compact if $\bar{A}$ is compact. On the other hand, A is called sequentially compact (respectively relatively sequentially compact) if any sequence $(x_n)_{n \in \mathbb{N}}$ with values in A has a subsequence $(x_{n_k})_{k \in \mathbb{N}}$ that converges to some $x \in A$ (respectively $x \in \bar{A}$). In metrizable spaces,

the notions compact and sequentially compact coincide. A set $A \subset E$ is called σ -compact if A is a countable union of compact sets. E is called locally compact if any point $x \in E$ has an open neighborhood whose closure is compact. A locally compact, separable metric space is manifestly σ -compact. If E is a locally compact metric space and if $U \subset E$ is open and $K \subset U$ is compact, then there exists a compact set L with $K \subset L^\circ \subset L \subset U$. (For example, for any $x \in K$, take an open ball $B_{\varepsilon_x}(x)$ of radius $\varepsilon_x > 0$ that is contained in U and that is relatively compact. By making ε_x smaller (if necessary), one can assume that the closure of this ball is contained in U . As K is compact, there are finitely many points $x_1, \dots, x_n \in K$ with $K \subset V := \bigcup_{i=1}^n B_{\varepsilon_{x_i}}(x_i)$. By construction, $L = \bar{V} \subset U$ is compact.)

We present one type of topological space that is of particular importance in probability theory in a separate definition.

Definition 13.1 A topological space (E, τ) is called a Polish space if it is separable and if there exists a complete metric that induces the topology τ .

Examples of Polish spaces are countable discrete spaces (however, not $\mathbb{Q}$ with the usual topology), the Euclidean spaces $\mathbb{R}^n$, and the space $C([0, 1])$ of continuous functions $[0, 1] \rightarrow \mathbb{R}$, equipped with the supremum norm $\|\cdot\|_\infty$. In practice, all spaces that are of importance in probability theory are Polish spaces.

Let (E, d) be a metric space. A set $A \subset E$ is called totally bounded if, for any $\varepsilon > 0$, there exist finitely many points $x_1, \dots, x_n \in A$ such that $A \subset \bigcup_{i=1}^n B_\varepsilon(x_i)$. Evidently, compact sets are totally bounded. In Polish spaces, a partial converse is true.

Lemma 13.2 Let (E, τ) be a Polish space with complete metric d . A subset $A \subset E$ is totally bounded with respect to d if and only if A is relatively compact.

Proof This is left as an exercise. $\square$

In the following, let (E, τ) be a topological space with Borel σ -algebra $\mathcal{E} = \mathcal{B}(E) := \sigma(\tau)$ and with complete metric d . For measures on $(E, \mathcal{E})$, we introduce the following notions of regularity.

Definition 13.3 A σ -finite measure μ on $(E, \mathcal{E})$ is called

- (i) locally finite or a Borel measure if, for any point $x \in E$, there exists an open neighborhood $U \ni x$ such that $\mu(U) < \infty$,
- (ii) inner regular if

$$\mu(A) = \sup\{\mu(K) : K \subset A \text{ is compact}\} \quad \text{for all } A \in \mathcal{E}, \quad (13.1)$$

- (iii) outer regular if

$$\mu(A) = \inf\{\mu(U) : U \supset A \text{ is open}\} \quad \text{for all } A \in \mathcal{E}, \quad (13.2)$$

- (iv) regular if μ is inner and outer regular, and
- (v) a Radon measure if μ is an inner regular Borel measure.

Definition 13.4 We introduce the following spaces of measures on E :

$$\begin{aligned} \mathcal{M}(E) &:= \{ \text{Radon measures on } (E, \mathcal{E}) \}, \\ \mathcal{M}_f(E) &:= \{ \text{finite measures on } (E, \mathcal{E}) \}, \\ \mathcal{M}_1(E) &:= \{ \mu \in \mathcal{M}_f(E) : \mu(E) = 1 \}, \\ \mathcal{M}_{\leq 1}(E) &:= \{ \mu \in \mathcal{M}_f(E) : \mu(E) \leq 1 \}. \end{aligned}$$

The elements of $\mathcal{M}_{\leq 1}(E)$ are called sub-probability measures on E . Further, we agree on the following notation for spaces of continuous functions:

$$\begin{aligned} C(E) &:= \{ f : E \rightarrow \mathbb{R} \text{ is continuous} \}, \\ C_b(E) &:= \{ f \in C(E) \text{ is bounded} \}, \\ C_c(E) &:= \{ f \in C(E) \text{ has compact support} \} \subset C_b(E). \end{aligned}$$

Recall that the support of a real function f is $\overline{f^{-1}(\mathbb{R} \setminus \{0\})}$.

Unless otherwise stated, the vector spaces $C(E)$, $C_b(E)$ and $C_c(E)$ are equipped with the supremum norm.

Lemma 13.5 If E is Polish and $\mu \in \mathcal{M}_f(E)$, then for any $\varepsilon > 0$, there is a compact set $K \subset E$ with $\mu(E \setminus K) < \varepsilon$.

Proof Let $\varepsilon > 0$. For each $n \in \mathbb{N}$, there exists a sequence $x_1^n, x_2^n, \dots \in E$ with $E = \bigcup_{i=1}^{\infty} B_{1/n}(x_i^n)$. Fix $N_n \in \mathbb{N}$ such that $\mu\left(E \setminus \bigcup_{i=1}^{N_n} B_{1/n}(x_i^n)\right) < \frac{\varepsilon}{2^n}$. Define

$$A := \bigcap_{n=1}^{\infty} \bigcup_{i=1}^{N_n} B_{1/n}(x_i^n).$$

By construction, A is totally bounded. Since E is Polish, $\bar{A}$ is compact. Furthermore, it follows that $\mu(E \setminus \bar{A}) \leq \mu(E \setminus A) < \sum_{n=1}^{\infty} \varepsilon 2^{-n} = \varepsilon$.

Theorem 13.6 If E is Polish and if $\mu \in \mathcal{M}_f(E)$, then μ is regular. In particular, in this case, $\mathcal{M}_f(E) \subset \mathcal{M}(E)$.

Proof (Outer regularity) Step 1. Let $B \subset E$ be closed and let $\varepsilon > 0$. Let d be a complete metric on E . For $\delta > 0$, let

$$B_\delta := \{x \in E : d(x, B) < \delta\}$$

be the open δ -neighborhood of B . As B is closed, we have $\bigcap_{\delta>0} B_\delta = B$. Since μ is upper semicontinuous (Theorem 1.36), there is a $\delta > 0$ such that $\mu(B_\delta) \leq \mu(B) + \varepsilon$.

Step 2. Let $B \in \mathcal{E}$ and $\varepsilon > 0$. Consider the class of sets

$$\mathcal{A} := \{V \cap C : V \subset E \text{ open}, C \subset E \text{ closed}\}$$

Clearly, we have $\mathcal{E} = \sigma(\mathcal{A})$. It is easy to check that $\mathcal{A}$ is a semiring. Hence by the approximation theorem for measures (Theorem 1.65), there are mutually disjoint sets $A_n = V_n \cap C_n \in \mathcal{A}$, $n \in \mathbb{N}$, such that $B \subset A := \bigcup_{n=1}^{\infty} A_n$ and $\mu(A) \leq \mu(B) + \varepsilon/2$. As shown in the first step, for any $n \in \mathbb{N}$, there is an open set $W_n \supset C_n$ such that $\mu(W_n) \leq \mu(C_n) + \varepsilon 2^{-n-1}$. Hence also $U_n := V_n \cap W_n$ is open. Let $B \subset U := \bigcup_{n=1}^{\infty} U_n$. We conclude that $\mu(U) \leq \mu(A) + \sum_{n=1}^{\infty} \varepsilon 2^{-n-1} \leq \mu(B) + \varepsilon$.

(Inner regularity) Replacing B by B^c , the outer regularity yields the existence of a closed set $D \subset B$ with $\mu(B \setminus D) < \varepsilon/2$. By Lemma 13.5, there exists a compact set K with $\mu(K^c) < \varepsilon/2$. Define $C = D \cap K$. Then $C \subset B$ is compact and $\mu(B \setminus C) < \varepsilon$. Hence μ is also inner regular.

Corollary 13.7 The Lebesgue measure λ on $\mathbb{R}^d$ is a regular Radon measure. However, not all σ -finite measures on $\mathbb{R}^d$ are regular.

Proof Clearly, $\mathbb{R}^d$ is Polish and λ is locally finite. Let $A \in \mathcal{B}(\mathbb{R}^d)$ and $\varepsilon > 0$. There is an increasing sequence $(K_n)_{n \in \mathbb{N}}$ of compact sets with $K_n \uparrow \mathbb{R}^d$. Since any K_n is bounded, we have $\lambda(K_n) < \infty$. Hence, by the preceding theorem, for any $n \in \mathbb{N}$, there exists an open set $U_n \supset A \cap K_n$ with $\lambda(U_n \setminus A) < \varepsilon/2^n$. Thus $\lambda(U \setminus A) < \varepsilon$ for the open set $U := \bigcup_{n \in \mathbb{N}} U_n$.

If $\lambda(A) < \infty$, then there exists an $n \in \mathbb{N}$ with $\lambda(A \setminus K_n) < \varepsilon/2$. By the preceding theorem, there exists a compact set $C \subset A \cap K_n$ with $\lambda((A \cap K_n) \setminus C) < \varepsilon/2$. Therefore, $\lambda(A \setminus C) < \varepsilon$.

If, on the other hand, $\lambda(A) = \infty$, then for any $L > 0$, we have to find a compact set $C \subset A$ with $\lambda(C) > L$. However, $\lambda(A \cap K_n) \xrightarrow{n \rightarrow \infty} \infty$; hence there exists an $n \in \mathbb{N}$ with $\lambda(A \cap K_n) > L + 1$. By what we have shown already, there exists a compact set $C \subset A \cap K_n$ with $\lambda((A \cap K_n) \setminus C) < 1$; hence $\lambda(C) > L$.

Finally, consider the measure $\mu = \sum_{q \in \mathbb{Q}} \delta_q$. Clearly, this measure is σ -finite; however, it is neither locally finite nor outer regular. $\square$

Definition 13.8 Let (E, d_E) and (F, d_F) be metric spaces. A function $f : E \rightarrow F$ is called Lipschitz continuous if there exists a constant $K < \infty$, the so-called Lipschitz constant, with

$d_F(f(x), f(y)) \leq K \cdot d_E(x, y)$ for all $x, y \in E$. Denote by $\text{Lip}_K(E; F)$ the space of Lipschitz continuous functions with constant K and by $\text{Lip}(E; F) = \bigcup_{K>0} \text{Lip}_K(E; F)$ the space of Lipschitz continuous functions on E .

We abbreviate $\text{Lip}_K(E) := \text{Lip}_K(E; \mathbb{R})$ and $\text{Lip}(E) := \text{Lip}(E; \mathbb{R})$.

Definition 13.9 Let $\mathcal{F} \subset \mathcal{M}(E)$ be a family of Radon measures. A family $\mathcal{C}$ of measurable maps $E \rightarrow \mathbb{R}$ is called a separating family for $\mathcal{F}$ if, for any two measures $\mu, \nu \in \mathcal{F}$, the following holds:

$$\left(\int f d\mu = \int f d\nu \text{ for all } f \in \mathcal{C} \cap \mathcal{L}^1(\mu) \cap \mathcal{L}^1(\nu) \right) \implies \mu = \nu.$$

Lemma 13.10 Let (E, d) be a metric space. For any closed set $A \subset E$ and any $\varepsilon > 0$, there is a Lipschitz continuous map $\rho_{A,\varepsilon} : E \rightarrow [0, 1]$ with

$$\rho_{A,\varepsilon}(x) = \begin{cases} 1, & \text{if } x \in A \\ 0, & \text{if } d(x, A) \geq \varepsilon. \end{cases}$$

Proof Let $\varphi : \mathbb{R} \rightarrow [0, 1]$, $t \mapsto (t \vee 0) \wedge 1$. For $x \in E$, define $\rho_{A,\varepsilon}(x) = 1 - \varphi(\varepsilon^{-1}d(x, A))$. $\square$

Theorem 13.11 Let (E, d) be a metric space.

(i) $\text{Lip}_1(E; [0, 1])$ is separating for $\mathcal{M}(E)$.

(ii) If, in addition, E is locally compact, then $C_c(E) \cap \text{Lip}_1(E; [0, 1])$ is separating for $\mathcal{M}(E)$.

Proof (i) Assume $\mu_1, \mu_2 \in \mathcal{M}(E)$ are measures with $\int f d\mu_1 = \int f d\mu_2$ for all $f \in \text{Lip}_1(E; [0, 1])$. If $A \in \mathcal{E}$, then $\mu_i(A) = \sup \{ \mu_i(K) : K \subset A \text{ is compact} \}$ since the Radon measure μ_i is inner regular ($i = 1, 2$). Hence, it is enough to show that $\mu_1(K) = \mu_2(K)$ for any compact set K .

Now let $K \subset E$ be compact. Since μ_1 and μ_2 are locally finite, for every $x \in K$, there exists an open set $U_x \ni x$ with $\mu_1(U_x) < \infty$ and $\mu_2(U_x) < \infty$. Since K is compact, we can find finitely many points $x_1, \dots, x_n \in K$ such that $K \subset U := \bigcup_{j=1}^n U_{x_j}$. By construction, $\mu_i(U) < \infty$; hence $\mathbb{1}_U \in L^1(\mu_i)$ for $i = 1, 2$. Since U^c is closed and since $U^c \cap K = \emptyset$, we get $\delta := d(U^c, K) > 0$. Let $\rho_{K,\varepsilon}$ be the map from Lemma 13.10. Hence $\mathbb{1}_K \leq \rho_{K,\varepsilon} \leq \mathbb{1}_U \in L^1(\mu_i)$ if $\varepsilon \in (0, \delta)$. Since $\rho_{K,\varepsilon} \xrightarrow{\varepsilon \rightarrow 0} \mathbb{1}_K$, we get by dominated convergence (Corollary 6.26) that $\mu_i(K) = \lim_{\varepsilon \rightarrow 0} \int \rho_{K,\varepsilon} d\mu_i$. However, $\varepsilon \rho_{K,\varepsilon} \in \text{Lip}_1(E; [0, 1])$ for all $\varepsilon > 0$; hence, by assumption,

$$\int \rho_{K,\varepsilon} d\mu_1 = \varepsilon^{-1} \int (\varepsilon \rho_{K,\varepsilon}) d\mu_1 = \varepsilon^{-1} \int (\varepsilon \rho_{K,\varepsilon}) d\mu_2 = \int \rho_{K,\varepsilon} d\mu_2$$

This implies $\mu_1(K) = \mu_2(K)$; hence $\mu_1 = \mu_2$.

(ii) If E is locally compact, then in (i) we can choose the neighborhoods U_x to be relatively compact. Hence U is relatively compact; thus $\rho_{K,\varepsilon}$ has compact support and is thus in $C_c(E)$ for all $\varepsilon \in (0, \delta)$.

Exercise 13.1.1 (i) Show that $C([0, 1])$ has a separable dense subset.

(ii) Show that the space $(C_b([0, \infty)), \|\cdot\|_\infty)$ of bounded continuous functions, equipped with the supremum norm, is not separable.

(iii) Show that the space $C_c([0, \infty))$ of continuous functions with compact support, equipped with the supremum norm, is separable.

Exercise 13.1.2 Let μ be a locally finite measure. Show that $\mu(K) < \infty$ for any compact set K .

Exercise 13.1.3 (Lusin's theorem) Let Ω be a Polish space, let μ be a σ -finite measure on $(\Omega, \mathcal{B}(\Omega))$ and let $f : \Omega \rightarrow \mathbb{R}$ be a map. Show that the following two statements are equivalent:

(i) There is a Borel measurable map $g : \Omega \rightarrow \mathbb{R}$ with $f = g\mu$ -almost everywhere.

(ii) For any $\varepsilon > 0$, there is a compact set K_ε with $\mu(\Omega \setminus K_\varepsilon) < \varepsilon$ such that the restricted function $f|_{K_\varepsilon}$ is continuous.

Exercise 13.1.4 Let $\mathcal{U}$ be a family of intervals in $\mathbb{R}$ such that $W := \bigcup_{U \in \mathcal{U}} U$ has finite Lebesgue measure $\lambda(W)$. Show that for any $\varepsilon > 0$, there exist finitely many pairwise disjoint sets $U_1, \dots, U_n \in \mathcal{U}$ with

$$\sum_{i=1}^n \lambda(U_i) > \frac{1-\varepsilon}{3} \lambda(W).$$

Hint: Choose a finite family $\mathcal{U}' \subset \mathcal{U}$ such that $\bigcup_{U \in \mathcal{U}'} U$ has Lebesgue measure at least $(1-\varepsilon)\lambda(W)$. Choose a maximal sequence $\mathcal{U}''$ (sorted by decreasing lengths) of disjoint intervals and show that each $U \in \mathcal{U}'$ is in $(x-3a, x+3a)$ for some $(x-a, x+a) \in \mathcal{U}''$.

Exercise 13.1.5 Let $C \subset \mathbb{R}^d$ be an open, bounded and convex set and assume that $\mathcal{U} \subset \{x + rC : x \in \mathbb{R}^d, r > 0\}$ is such that $W := \bigcup_{U \in \mathcal{U}} U$ has finite Lebesgue measure $\lambda^d(W)$. Show that for any $\varepsilon > 0$, there exist finitely many pairwise disjoint sets $U_1, \dots, U_n \in \mathcal{U}$ such that

$$\sum_{i=1}^n \lambda^d(U_i) > \frac{1-\varepsilon}{3^d} \lambda(W).$$

Show by a counterexample that the condition of similarity of the open sets in $\mathcal{U}$ is essential.

Exercise 13.1.6 Let μ be a Radon measure on $\mathbb{R}^d$ and let $A \in \mathcal{B}(\mathbb{R}^d)$ be a μ -null set. Let $C \subset \mathbb{R}^d$ be bounded, convex and open with $0 \in C$. Use Exercise 13.1.5 to show that

$$\lim_{r \downarrow 0} \frac{\mu(x + rC)}{r^d} = 0 \quad \text{for } \lambda^d\text{-almost all } x \in A.$$

Conclude that if F is the distribution function of a Stieltjes measure μ on $\mathbb{R}$ and if $A \in \mathcal{B}(\mathbb{R})$ is a μ -null set, then $\frac{d}{dx}F(x) = 0$ for λ -almost all $x \in A$.

Exercise 13.1.7 (Fundamental theorem of calculus) (Compare [37].) Let $f \in \mathcal{L}^1(\mathbb{R}^d)$, $\mu = f\lambda^d$ and let $C \subset \mathbb{R}^d$ be open, convex and bounded with $0 \in C$. Show that

$$\lim_{r \downarrow 0} \frac{\mu(x + rC)}{r^d \lambda^d(C)} = f(x) \quad \text{for } \lambda^d\text{-almost all } x \in \mathbb{R}^d.$$

For the case $d = 1$, conclude the fundamental theorem of calculus:

$$\frac{d}{dx} \int_{[0,x]} f d\lambda = f(x) \quad \text{for } \lambda\text{-almost all } x \in \mathbb{R}$$

Hint: Use Exercise 13.1.6 with

$$\mu_q(dx) = (f(x) - q)^+ \lambda^d(dx) \quad \text{for } q \in \mathbb{Q}$$

as well as the inequality

$$\frac{\mu(x + rC)}{r^d \lambda^d(C)} \leq q + \frac{\mu_q(x + rC)}{r^d \lambda^d(C)}$$

Exercise 13.1.8 Similarly as in Corollary 13.7, show the following: Let E be a σ compact polish space and let μ be a measure on E . Then μ is a Radon measure if and only if $\mu(K) < \infty$ for any compact $K \subset E$.

5.13.2 13.2 Weak and Vague Convergence

In Theorem 13.11, we saw that integrals of bounded continuous functions f determine a Radon measure on a metric space (E, d) . If E is locally compact, it is enough to consider f with compact support. This suggests that we can use $C_b(E)$ and $C_c(E)$ as classes of test functions in order to define the convergence of measures.

Definition 13.12 (Weak and vague convergence) Let E be a metric space.

(i) Let $\mu, \mu_1, \mu_2, \dots \in \mathcal{M}_f(E)$. We say that $(\mu_n)_{n \in \mathbb{N}}$ converges weakly to μ , formally $\mu_n \xrightarrow{n \rightarrow \infty} \mu$ (weakly) or $\mu = w - \lim_{n \rightarrow \infty} \mu_n$, if

$$\int f d\mu_n \xrightarrow{n \rightarrow \infty} \int f d\mu \quad \text{for all } f \in C_b(E)$$

(ii) Let $\mu, \mu_1, \mu_2, \dots \in \mathcal{M}(E)$. We say that $(\mu_n)_{n \in \mathbb{N}}$ converges vaguely to μ , formally $\mu_n \xrightarrow{n \rightarrow \infty} \mu$ (vaguely) or $\mu = v - \lim_{n \rightarrow \infty} \mu_n$, if

$$\int f d\mu_n \xrightarrow{n \rightarrow \infty} \int f d\mu \quad \text{for any } f \in C_c(E)$$

Remark 13.13 If E is Polish, then by Theorems 13.6 and 13.11, the weak limit is unique. The same holds for the vague limit if E is locally compact.

Remark 13.14

(i) In functional analysis the notion of weak convergence is somewhat different. Starting from a normed vector space X (here the space of finite signed measures with the total variation norm), consider the space X' of continuous linear functionals $X \rightarrow \mathbb{R}$. The sequence (μ_n) in X converges weakly to $\mu \in X$, if $\Phi(\mu_n) \xrightarrow{n \rightarrow \infty} \Phi(\mu)$ for every $\Phi \in X'$. In the case of finite signed measures this is equivalent to: (μ_n) is bounded and $\mu_n(A) \xrightarrow{n \rightarrow \infty} \mu(A)$ for any measurable A (see [38, Theorem IV.9.5]). Comparing this to Theorem 13.16(vi), we see that the functional analysis notion of weak convergence is stronger than ours in Definition 13.12.

(ii) Weak convergence (as introduced in Definition 13.12) induces on $\mathcal{M}_f(E)$ the weak topology τ_w . This is the coarsest topology such that for all $f \in C_b(E)$, the map $\mathcal{M}_f(E) \rightarrow \mathbb{R}, \mu \mapsto \int f d\mu$ is continuous. In functional analysis, τ_w corresponds to the so-called weak*-topology. Starting from a normed vector space X (here $X = C_b(E)$ with the norm $\|\cdot\|_\infty$), we define the weak*-topology on the dual space X' by writing $\mu_n \xrightarrow{n \rightarrow \infty} \mu$ if and only if $\mu_n(x) \xrightarrow{n \rightarrow \infty} \mu(x)$ for all $x \in X$. Clearly, each μ defines a continuous linear form on $C_b(E)$ by $f \mapsto \mu(f) := \int f d\mu$. Hence $\mathcal{M}_f(E) \subset C_b(E)'$. This implies that τ_w is the trace of the weak*-topology on $\mathcal{M}_f(E)$.

(iii) If E is separable, then it can be shown that $(\mathcal{M}_f(E), \tau_w)$ is metrizable; for example, by virtue of the so-called Prohorov metric. This is defined by

$$d_P(\mu, \nu) := \max \{d'_P(\mu, \nu), d'_P(\nu, \mu)\} \quad (13.3)$$

where

$$d'_P(\mu, \nu) := \inf \{ \varepsilon > 0 : \mu(B) \leq \nu(B^\varepsilon) + \varepsilon \text{ for any } B \in \mathcal{B}(E) \}, \quad (13.4)$$

and where $B^\varepsilon = \{x : d(x, B) < \varepsilon\}$; see, e.g., [14, Appendix III, Theorem 5]. (It can be shown that $d'_P(\mu, \nu) = d'_P(\nu, \mu)$ if $\mu, \nu \in \mathcal{M}_1(E)$.) If E is locally compact and Polish, then $(\mathcal{M}_f(E), \tau_w)$ is again Polish (see [136, p. 167]).

(iv) Similarly, the vague topology τ_v on $\mathcal{M}(E)$ is the coarsest topology such that for all $f \in C_c(E)$, the map $\mathcal{M}(E) \rightarrow \mathbb{R}, \mu \mapsto \int f d\mu$ is continuous. If E is locally compact, then $(\mathcal{M}(E), \tau_v)$ is a Hausdorff space. If, in addition, E is Polish, then $(\mathcal{M}(E), \tau_v)$ is again Polish (see, e.g., [82, Section 15.7]).

While weak convergence implies convergence of the total masses (since $1 \in C_b(E)$), with vague convergence a mass defect (but not a mass gain) can be experienced in the limit.

Lemma 13.15 Let E be a locally compact Polish space and let $\mu, \mu_1, \mu_2, \dots \in \mathcal{M}(E)$ be measures such that $\mu_n \xrightarrow{n \rightarrow \infty} \mu$ vaguely. Then

$$\mu(E) \leq \liminf_{n \rightarrow \infty} \mu_n(E).$$

Proof Let $(f_N)_{N \in \mathbb{N}}$ be a sequence in $C_c(E; [0, 1])$ with $f_N \uparrow 1$. Then

$$\begin{aligned} \mu(E) &= \sup_{N \in \mathbb{N}} \int f_N d\mu \\ &= \sup_{N \in \mathbb{N}} \lim_{n \rightarrow \infty} \int f_N d\mu_n \\ &\leq \liminf_{n \rightarrow \infty} \sup_{N \in \mathbb{N}} \int f_N d\mu_n \\ &= \liminf_{n \rightarrow \infty} \mu_n(E) \end{aligned}$$

Clearly, the sequence $(\delta_{1/n})_{n \in \mathbb{N}}$ of probability measures on $\mathbb{R}$ converges weakly to δ_0 ; however, not in total variation norm. Indeed, for the closed set $(-\infty, 0]$, we have $\lim_{n \rightarrow \infty} \delta_{1/n}((-\infty, 0]) = 0 < 1 = \delta_0((-\infty, 0])$. Loosely speaking, at the boundaries of closed sets, mass can immigrate but not emigrate. The opposite is true for open sets: $\lim_{n \rightarrow \infty} \delta_{1/n}((0, \infty)) = 1 > 0 = \delta_0((0, \infty))$. Here mass can emigrate but not immigrate. In fact, weak convergence can be characterized by this property. In the following theorem, a whole bunch of such statements will be hung on a coat hanger (French: portemanteau).

For measurable $g : \Omega \rightarrow \mathbb{R}$, let U_g be the set of points of discontinuity of g . Recall from Exercise 1.1.3 that U_g is Borel measurable.

Theorem 13.16 (Portemanteau) Let E be a metric space and let $\mu, \mu_1, \mu_2, \dots \in \mathcal{M}_{\leq 1}(E)$. The following are equivalent.

- (i) $\mu = w - \lim_{n \rightarrow \infty} \mu_n$.
- (ii) $\int f d\mu_n \xrightarrow{n \rightarrow \infty} \int f d\mu$ for all bounded Lipschitz continuous f .
- (iii) $\int f d\mu_n \xrightarrow{n \rightarrow \infty} \int f d\mu$ for all bounded measurable f with $\mu(U_f) = 0$.
- (iv) $\liminf_{n \rightarrow \infty} \mu_n(E) \geq \mu(E)$ and $\limsup_{n \rightarrow \infty} \mu_n(F) \leq \mu(F)$ for all closed $F \subset E$.
- (v) $\limsup_{n \rightarrow \infty} \mu_n(E) \leq \mu(E)$ and $\liminf_{n \rightarrow \infty} \mu_n(G) \geq \mu(G)$ for all open $G \subset E$.
- (vi) $\lim_{n \rightarrow \infty} \mu_n(A) = \mu(A)$ for all measurable A with $\mu(\partial A) = 0$.

If E is locally compact and Polish, then in addition each of the following is equivalent to the previous statements.

- (vii) $\mu = v - \lim_{n \rightarrow \infty} \mu_n$ and $\mu(E) = \lim_{n \rightarrow \infty} \mu_n(E)$.
- (viii) $\mu = v - \lim_{n \rightarrow \infty} \mu_n$ and $\mu(E) \geq \limsup_{n \rightarrow \infty} \mu_n(E)$.

Proof "(iv) $\iff$ (v) $\implies$ (vi)" This is trivial.

"(iii) $\implies$ (i) $\implies$ (ii)" This is trivial.

"(ii) $\implies$ (iv)" Convergence of the total masses follows by using the test function $1 \in \text{Lip}(E; [0, 1])$. Let F be closed and let $\rho_{F, \varepsilon}$ be as in Lemma 13.10. Then

$$\limsup_{n \rightarrow \infty} \mu_n(F) \leq \inf_{\varepsilon > 0} \lim_{n \rightarrow \infty} \int \rho_{F, \varepsilon} d\mu_n = \inf_{\varepsilon > 0} \int \rho_{F, \varepsilon} d\mu = \mu(F)$$

since $\rho_{F, \varepsilon}(x) \xrightarrow{\varepsilon \rightarrow 0} \mathbb{1}_F(x)$ for all $x \in E$.

"(viii) $\implies$ (vii)" This is obvious by Lemma 13.15.

"(i) $\implies$ (vii)" This is clear since $C_c(E) \subset C_b(E)$ and $1 \in C_b(E)$.

"(vii) $\implies$ (v)" Let G be open and $\varepsilon > 0$. Since μ is inner regular (Theorem 13.6), there is a compact set $K \subset G$ with $\mu(G) - \mu(K) < \varepsilon$. As E is locally compact, there is a compact set L with $K \subset L^\circ \subset L \subset G$. Let $\delta := d(K, L^c) > 0$ and let $\rho_{K, \delta}$ be as in Lemma 13.10. Then $\mathbb{1}_K \leq \rho_{K, \delta} \leq \mathbb{1}_L$; hence $\rho_{K, \delta} \in C_c(E)$ and thus

$$\liminf_{n \rightarrow \infty} \mu_n(G) \geq \liminf_{n \rightarrow \infty} \int \rho_{K, \delta} d\mu_n = \int \rho_{K, \delta} d\mu \geq \mu(K) \geq \mu(G) - \varepsilon$$

Letting $\varepsilon \rightarrow 0$, we get (v).

"(vi) $\implies$ (iii)" Let $f : E \rightarrow \mathbb{R}$ be bounded and measurable with $\mu(U_f) = 0$. We make the

elementary observation that for all $D \subset \mathbb{R}$,

$$\partial f^{-1}(D) \subset f^{-1}(\partial D) \cup U_f \quad (13.5)$$

Indeed, if f is continuous at $x \in E$, then for any $\delta > 0$, there is an $\varepsilon(\delta) > 0$ with $f(B_{\varepsilon(\delta)}(x)) \subset B_\delta(f(x))$. If $x \in \partial f^{-1}(D)$, then there are $y \in f^{-1}(D) \cap B_{\varepsilon(\delta)}(x)$ and $z \in f^{-1}(D^c) \cap B_{\varepsilon(\delta)}(x)$. Therefore, $f(y) \in B_\delta(f(x)) \cap D \neq \emptyset$ and $f(z) \in B_\delta(f(x)) \cap D^c \neq \emptyset$; hence $f(x) \in \partial D$.

Let $\varepsilon > 0$. Evidently, the set $A := \{y \in \mathbb{R} : \mu(f^{-1}(\{y\})) > 0\}$ of atoms of the finite measure $\mu \circ f^{-1}$ is at most countable. Hence, there exist $N \in \mathbb{N}$ and $y_0 \leq -\|f\|_\infty < y_1 < \dots < y_{N-1} < \|f\|_\infty$ such that

$$y_i \in \mathbb{R} \setminus A \quad \text{and} \quad |y_{i+1} - y_i| < \varepsilon \quad \text{for all } i.$$

Let $E_i = f^{-1}([y_{i-1}, y_i])$ for $i = 1, \dots, N$. Then $E = \bigsqcup_{i=1}^N E_i$ and by (13.5),

$$\mu(\partial E_i) \leq \mu(f^{-1}(\{y_{i-1}\})) + \mu(f^{-1}(\{y_i\})) + \mu(U_f) = 0.$$

Therefore,

$$\begin{aligned} \limsup_{n \rightarrow \infty} \int f d\mu_n &\leq \limsup_{n \rightarrow \infty} \sum_{i=1}^N \mu_n(E_i) \cdot y_i = \sum_{i=1}^N \mu(E_i) \cdot y_i \\ &\leq \varepsilon + \int f d\mu \end{aligned}$$

We let $\varepsilon \rightarrow 0$ and obtain $\limsup_{n \rightarrow \infty} \int f d\mu_n \leq \int f d\mu$. Finally, consider $(-f)$ to obtain the reverse inequality $\liminf_{n \rightarrow \infty} \int f d\mu_n \geq \int f d\mu$.

Definition 13.17 Let $X, X_1, X_2, \dots$ be random variables with values in E . We say that $(X_n)_{n \in \mathbb{N}}$ converges in distribution to X , formally $X_n \xrightarrow{\mathcal{D}} X$ or $X_n \xrightarrow{n \rightarrow \infty} X$, if the distributions converge weakly and hence if $P_X = \text{w-lim}_{n \rightarrow \infty} \mathbf{P}_{X_n}$. Sometimes we write $X_n \xrightarrow{\mathcal{D}} \mathbf{P}_X$ or $X_n \xrightarrow{n \rightarrow \infty} \mathbf{P}_X$ if we want to specify only the distribution $\mathbf{P}_X$ but not the random variable X .

Theorem 13.18 (Slutzky's theorem) Let $X, X_1, X_2, \dots$ and $Y_1, Y_2, \dots$ be random variables with values in E . Assume $X_n \xrightarrow{\mathcal{D}} X$ and $d(X_n, Y_n) \xrightarrow{n \rightarrow \infty} 0$ in probability. Then $Y_n \xrightarrow{\mathcal{D}} X$.

Proof Let $f : E \rightarrow \mathbb{R}$ be bounded and Lipschitz continuous with constant K . Then

$$|f(x) - f(y)| \leq Kd(x, y) \wedge 2\|f\|_\infty \quad \text{for all } x, y \in E.$$

Dominated convergence yields $\limsup_{n \rightarrow \infty} \mathbf{E}[|f(X_n) - f(Y_n)|] = 0$. Hence we have

$$\begin{aligned} \limsup_{n \rightarrow \infty} |\mathbf{E}[f(Y_n)] - \mathbf{E}[f(X)]| \\ \leq \limsup_{n \rightarrow \infty} |\mathbf{E}[f(X)] - \mathbf{E}[f(X_n)]| + \limsup_{n \rightarrow \infty} |\mathbf{E}[f(X_n) - f(Y_n)]| = 0. \end{aligned}$$

Corollary 13.19 If $X_n \xrightarrow{n \rightarrow \infty} X$ in probability, then $X_n \xrightarrow{\mathcal{D}} X, n \rightarrow \infty$. The converse is false in general.

Example 13.20 If $X, X_1, X_2, \dots$ are i.i.d. (with nontrivial distribution), then trivially $X_n \xrightarrow{\mathcal{D}} X$ but not $X_n \xrightarrow{n \rightarrow \infty} X$ in probability.

Recall the definition of a distribution function of a probability measure from Definition 1.59.

Definition 13.21 Let $F, F_1, F_2, \dots$ be distribution functions of probability measures on $\mathbb{R}$. We say that $(F_n)_{n \in \mathbb{N}}$ converges weakly to F , formally $F_n \xrightarrow{n \rightarrow \infty} F, F_n \xrightarrow{\mathcal{D}} F$ or $F = \text{w-lim}_{n \rightarrow \infty} F_n$, if

$$F(x) = \lim_{n \rightarrow \infty} F_n(x) \quad \text{for all points of continuity } x \text{ of } F. \quad (13.6)$$

If $F, F_1, F_2, \dots$ are distribution functions of sub-probability measures, then we define $F(\infty) := \lim_{x \rightarrow \infty} F(x)$ and for weak convergence require in addition $F(\infty) \geq \limsup_{n \rightarrow \infty} F_n(\infty)$.

Note that (13.6) implies $F(\infty) \leq \liminf_{n \rightarrow \infty} F_n(\infty)$. Hence, if $F_n \xrightarrow{\mathcal{D}} F$, then $F(\infty) = \lim_{n \rightarrow \infty} F_n(\infty)$.

Example 13.22 If F is the distribution function of a probability measure on $\mathbb{R}$ and $F_n(x) := F(x+n)$ for $x \in \mathbb{R}$, then $(F_n)_{n \in \mathbb{N}}$ converges pointwise to 1. However, this is not a distribution function, as 1 does not converge to 0 for $x \rightarrow -\infty$. On the other hand, if $G_n(x) = F(x-n)$, then $(G_n)_{n \in \mathbb{N}}$ converges pointwise to $G \equiv 0$. However, $G(\infty) = 0 < \limsup_{n \rightarrow \infty} G_n(\infty) = 1$; hence we do not have weak convergence here either. Indeed, in each case, there is a mass defect in the limit (in the case of the F_n on the left and in the case of the G_n on the right). However, the definition of weak convergence of distribution functions is constructed so that no mass defect occurs in the limit.

Theorem 13.23 Let $\mu, \mu_1, \mu_2, \dots \in \mathcal{M}_{\leq 1}(\mathbb{R})$ with corresponding distribution functions $F, F_1, F_2, \dots$. The following are equivalent.

(i) $\mu = \text{w-}\lim_{n \rightarrow \infty} \mu_n$.

(ii) $F_n \xrightarrow{\mathcal{D}} F$.

Proof "(i) $\implies$ (ii)" Let F be continuous at x . Then $\mu(\partial(-\infty, x]) = \mu(\{x\}) = 0$. By Theorem 13.16, $F_n(x) = \mu_n((-\infty, x]) \xrightarrow{n \rightarrow \infty} \mu((-\infty, x]) = F(x)$.

"(ii) $\implies$ (i)" Let $f \in \text{Lip}_1(\mathbb{R}; [0, 1])$. By Theorem 13.16, it is enough to show that

$$\int f d\mu_n \xrightarrow{n \rightarrow \infty} \int f d\mu \quad (13.7)$$

Let $\varepsilon > 0$. Fix $N \in \mathbb{N}$ and choose $N+1$ points of continuity $y_0 < y_1 < \dots < y_N$ of F such that $F(y_0) < \varepsilon$, $F(y_N) > F(\infty) - \varepsilon$ and $y_i - y_{i-1} < \varepsilon$ for all i . Then

$$\begin{aligned} \int f d\mu_n &\leq (F_n(y_0) + F_n(\infty) - F_n(y_N)) \\ &\quad + \sum_{i=1}^N (f(y_i) + \varepsilon) (F_n(y_i) - F_n(y_{i-1})). \end{aligned}$$

By assumption, $\lim_{n \rightarrow \infty} F_n(\infty) = F(\infty)$ and $F_n(y_i) \xrightarrow{n \rightarrow \infty} F(y_i)$ for every $i = 0, \dots, N$; hence

$$\limsup_{n \rightarrow \infty} \int f d\mu_n \leq 3\varepsilon + \sum_{i=1}^N f(y_i) (F(y_i) - F(y_{i-1})) \leq 4\varepsilon + \int f d\mu.$$

Therefore,

$$\limsup_{n \rightarrow \infty} \int f d\mu_n \leq \int f d\mu$$

Replacing f by $(1 - f)$, we get (13.7).

Corollary 13.24 Let $X, X_1, X_2, \dots$ be real random variables with distribution functions $F, F_1, F_2, \dots$. Then the following are equivalent.

(i) $X_n \xrightarrow{\mathcal{D}} X$.

(ii) $\mathbf{E}[f(X_n)] \xrightarrow{n \rightarrow \infty} \mathbf{E}[f(X)]$ for all $f \in C_b(\mathbb{R})$.

(iii) $F_n \xrightarrow{\mathcal{D}} F$.

How stable is weak convergence if we pass to image measures under some map φ ? Clearly, we need a certain continuity of φ at least at those points where the limit measure puts mass. The following theorem formalizes this idea and will come in handy in many applications.

Theorem 13.25 (Continuous mapping theorem) Let (E_1, d_1) and (E_2, d_2) be metric spaces and let $\varphi : E_1 \rightarrow E_2$ be measurable. Denote by U_φ the set of points of discontinuity of φ .

(i) If $\mu, \mu_1, \mu_2, \dots \in \mathcal{M}_{\leq 1}(E_1)$ with $\mu(U_\varphi) = 0$ and $\mu_n \xrightarrow{n \rightarrow \infty} \mu$ weakly, then $\mu_n \circ \varphi^{-1} \xrightarrow{n \rightarrow \infty} \mu \circ \varphi^{-1}$ weakly.

(ii) If $X, X_1, X_2, \dots$ are E_1 -valued random variables with $\mathbf{P}[X \in U_\varphi] = 0$ and $X_n \xrightarrow{\mathcal{D}} X$, then $\varphi(X_n) \xrightarrow{\mathcal{D}} \varphi(X)$.

Proof First note that $U_\varphi \subset E_1$ is Borel measurable by Exercise 1.1.3. Hence the conditions make sense.

(i) Let $f \in C_b(E_2)$. Then $f \circ \varphi$ is bounded and measurable and $U_{f \circ \varphi} \subset U_\varphi$; hence $\mu(U_{f \circ \varphi}) = 0$. By Theorem 13.16,

$$\begin{aligned} \lim_{n \rightarrow \infty} \int f d(\mu_n \circ \varphi^{-1}) &= \lim_{n \rightarrow \infty} \int (f \circ \varphi) d\mu_n \\ &= \int (f \circ \varphi) d\mu = \int f d(\mu \circ \varphi^{-1}) \end{aligned}$$

(ii) This is obvious since $\mathbf{P}_{\varphi(X)} = \mathbf{P}_X \circ \varphi^{-1}$.

Exercise 13.2.1 Recall d'_P from (13.4). Show that $d_P(\mu, \nu) = d'_P(\mu, \nu) = d'_P(\nu, \mu)$ for all $\mu, \nu \in \mathcal{M}_1(E)$.

Exercise 13.2.2 Show that the topology of weak convergence on $\mathcal{M}_f(E)$ is coarser than the topology induced on $\mathcal{M}_f(E)$ by the total variation norm (see Corollary 7.45). That is, $\|\mu_n - \mu\|_{TV} \xrightarrow{n \rightarrow \infty} 0$ implies $\mu_n \xrightarrow{n \rightarrow \infty} \mu$ weakly.

Exercise 13.2.3 Let $E = \mathbb{R}$ and $\mu_n = \frac{1}{n} \sum_{k=0}^n \delta_{k/n}$. Let $\mu = \lambda|_{[0,1]}$ be the Lebesgue measure restricted to $[0, 1]$. Show that $\mu = \text{w-}\lim_{n \rightarrow \infty} \mu_n$.

Exercise 13.2.4 Let $E = \mathbb{R}$ and λ be the Lebesgue measure on $\mathbb{R}$. For $n \in \mathbb{N}$, let $\mu_n = \lambda|_{[-n, n]}$. Show that $\lambda = \text{v-}\lim_{n \rightarrow \infty} \mu_n$ but that $(\mu_n)_{n \in \mathbb{N}}$ does not converge weakly.

Exercise 13.2.5 Let $E = \mathbb{R}$ and $\mu_n = \delta_n$ for $n \in \mathbb{N}$. Show that $\text{v-}\lim_{n \rightarrow \infty} \mu_n = 0$ but that $(\mu_n)_{n \in \mathbb{N}}$ does not converge weakly.

Exercise 13.2.6 (Lévy metric) For two probability distribution functions F and G on $\mathbb{R}$, define the Lévy distance by

$$d(F, G) = \inf\{\varepsilon \geq 0 : G(x - \varepsilon) - \varepsilon \leq F(x) \leq G(x + \varepsilon) + \varepsilon \text{ for all } x \in \mathbb{R}\}.$$

Show the following:

(i) d is a metric on the set of distribution functions.

(ii) $F_n \xrightarrow{n \rightarrow \infty} F$ if and only if $d(F_n, F) \xrightarrow{n \rightarrow \infty} 0$.

(iii) For every $P \in \mathcal{M}_1(\mathbb{R})$, there is a sequence $(P_n)_{n \in \mathbb{N}}$ in $\mathcal{M}_1(\mathbb{R})$ such that each P_n has finite support and such that $P_n \xrightarrow{n \rightarrow \infty} P$.

Exercise 13.2.7 We can extend the notions of weak convergence and vague convergence to signed measures; that is, to differences $\varphi := \mu^+ - \mu^-$ of measures from $\mathcal{M}_f(E)$ and $\mathcal{M}(E)$, respectively, by repeating the words of Definition 13.12 for these classes. Show that the topology of weak convergence is not metrizable in general.

Hint: Consider $E = [0, 1]$.

(i) For $n \in \mathbb{N}$, define $\varphi_n = \delta_{1/n} - \delta_{2/n}$. Show that, for any $C > 0$, $(C\varphi_n)_{n \in \mathbb{N}}$ converges weakly to the zero measure.

(ii) Assume there is a metric that induces weak convergence. Show that then there would be a sequence $(C_n)_{n \in \mathbb{N}}$ with $C_n \uparrow \infty$ and $0 = \text{w-}\lim_{n \rightarrow \infty} (C_n \varphi_n)$.

(iii) Choose an $f \in C([0, 1])$ with $f(2^{-n}) = (-1)^n C_n^{-1/2}$ for any $n \in \mathbb{N}$, and show that

$(\int f d(C_n \varphi_n))_{n \in \mathbb{N}}$ does not converge to zero.

(iv) Use this construction to contradict the assumption of metrizable.

Exercise 13.2.8 Show that (13.3) defines a metric on $\mathcal{M}_1(E)$ and that this metric induces the topology of weak convergence.

Exercise 13.2.9 Show the implication "(vi) $\implies$ (iv)" of Theorem 13.16 directly.

Exercise 13.2.10 Let $X, X_1, X_2, \dots$ and $Y_1, Y_2, \dots$ be real random variables. Assume $\mathbf{P}_{Y_n} = \mathcal{N}_{0,1/n}$ for all $n \in \mathbb{N}$. Show that $X_n \xrightarrow{\mathcal{D}} X$ if and only if $X_n + Y_n \xrightarrow{\mathcal{D}} X$.

Exercise 13.2.11 For each $n \in \mathbb{N}$, let X_n be a geometrically distributed random variable with parameter $p_n \in (0, 1)$. How must we choose the sequence $(p_n)_{n \in \mathbb{N}}$ in order that $\mathbf{P}_{X_n/n}$ converges weakly to the exponential distribution with parameter $\alpha > 0$?

Exercise 13.2.12 Let $X, X_1, X_2, \dots$ be real random variables with $X_n \xrightarrow{n \rightarrow \infty} X$. Show the following.

(i) $\mathbf{E}[|X|] \leq \liminf_{n \rightarrow \infty} \mathbf{E}[|X_n|]$.

(ii) Let $r > p > 0$. If $\sup_{n \in \mathbb{N}} \mathbf{E}[|X_n|^r] < \infty$, then $\mathbf{E}[|X|^p] = \lim_{n \rightarrow \infty} \mathbf{E}[|X_n|^p]$.

Exercise 13.2.13 Let $F, F_1, F_2, \dots$ be probability distribution functions on $\mathbb{R}$, and assume $F_n \xrightarrow{n \rightarrow \infty} F$. Let $F^{-1}(u) = \inf\{x \in \mathbb{R} : F(x) \geq u\}$, $u \in (0, 1)$, be the left continuous inverse of F (see the proof of Theorem 1.104). Show that

$$F_n^{-1}(u) \xrightarrow{n \rightarrow \infty} F^{-1}(u) \text{ at every point of continuity } u \text{ of } F^{-1}.$$

Conclude that $F^{-1}(u) \xrightarrow{n \rightarrow \infty} F^{-1}(u)$ for Lebesgue almost all $u \in (0, 1)$.

Exercise 13.2.14 Let $\mu, \mu_1, \mu_2, \dots \in \mathcal{M}_1(\mathbb{R})$ with $\mu_n \xrightarrow{n \rightarrow \infty} \mu$ weakly. Show that there exists a probability space $(\Omega, \mathcal{A}, \mathbf{P})$ and real random variables $X, X_1, X_2, \dots$ on $(\Omega, \mathcal{A}, \mathbf{P})$ with distributions $\mathbf{P}_X = \mu$ and $\mathbf{P}_{X_n} = \mu_n$, $n \in \mathbb{N}$, such that

$$X_n \xrightarrow{n \rightarrow \infty} X \quad \mathbf{P}\text{-a.s.}$$

Hint: Use Exercise 13.2.13.

Exercise 13.2.15 Let (E, d) be a metric space and let $\mu, \mu_1, \mu_2, \dots$ be probability measures on E . A measurable map $f : E \rightarrow \mathbb{R}$ is called uniformly integrable with respect to $(\mu_n)_{n \in \mathbb{N}}$, if

$$\inf_{a > 0} \sup_{n \in \mathbb{N}} \int_{\{|f| > a\}} |f| d\mu_n = 0$$

Let f be continuous and uniformly integrable with respect to $(\mu_n)_{n \in \mathbb{N}}$ and assume that $\mu_n \xrightarrow{n \rightarrow \infty} \mu$ weakly. Show that $\int |f| d\mu < \infty$ and that

$$\int f d\mu_n \xrightarrow{n \rightarrow \infty} \int f d\mu$$

Hint: Apply Exercise 13.2.14 to the image measures $\mu_n \circ f^{-1}$.

5.13.3 13.3 Prohorov's Theorem

In the following, let E be a Polish space with Borel σ -algebra $\mathcal{E}$. A fundamental question is: When does a sequence $(\mu_n)_{n \in \mathbb{N}}$ of measures on $(E, \mathcal{E})$ converge weakly or does at least have a weak limit point? Evidently, a necessary condition is that $(\mu_n(E))_{n \in \mathbb{N}}$ is bounded. Hence, without loss of generality, we will consider only sequences in $\mathcal{M}_{\leq 1}(E)$. However, this condition is not sufficient for the existence of weak limit points, as for example the sequence $(\delta_n)_{n \in \mathbb{N}}$ of probability measures on $\mathbb{R}$ does not have a weak limit point (although it converges vaguely to the zero measure). This example suggests that we also have to make sure that no mass "vanishes at infinity". The idea will be made precise by the notion of tightness.

We start this section by presenting as the main result Prohorov's theorem [136]. We give the proof first for the special case $E = \mathbb{R}$ and then come to a couple of applications. The full proof of the general case is deferred to the end of the section.

Definition 13.26 (Tightness) A family $\mathcal{F} \subset \mathcal{M}_f(E)$ is called tight if, for any $\varepsilon > 0$, there exists a compact set $K \subset E$ such that

$$\sup\{\mu(E \setminus K) : \mu \in \mathcal{F}\} < \varepsilon$$

Remark 13.27 If E is Polish, then by Lemma 13.5, every singleton $\{\mu\} \subset \mathcal{M}_f(E)$ is tight and thus so is every finite family.

Example 13.28

- (i) If E is compact, then $\mathcal{M}_1(E)$ and $\mathcal{M}_{\leq 1}(E)$ are tight.
- (ii) If $(X_i)_{i \in I}$ is an arbitrary family of random variables with

$$C := \sup\{\mathbf{E}[|X_i|] : i \in I\} < \infty,$$

then $\{\mathbf{P}_{X_i} : i \in I\}$ is tight. Indeed, for $\varepsilon > 0$ and $K = [-C/\varepsilon, C/\varepsilon]$, by Markov's inequality, $\mathbf{P}_{X_i}(\mathbb{R} \setminus K) = \mathbf{P}[|X_i| > C/\varepsilon] \leq \varepsilon$.

- (iii) The family $(\delta_n)_{n \in \mathbb{N}}$ of probability measures on $\mathbb{R}$ is not tight.
- (iv) The family $(\mathcal{U}_{[-n, n]})_{n \in \mathbb{N}}$ of uniform distributions on the intervals $[-n, n]$, regarded as measures on $\mathbb{R}$, is not tight.

Recall that a family $\mathcal{F}$ of measures is called weakly relatively sequentially compact if every sequence in $\mathcal{F}$ has a weak limit point (in the closure of $\mathcal{F}$).

Theorem 13.29 (Prohorov's theorem (1956)) Let (E, d) be a metric space and $\mathcal{F} \subset \mathcal{M}_{\leq 1}(E)$. Then:

- (i) $\mathcal{F}$ is tight $\implies \mathcal{F}$ is weakly relatively sequentially compact.
- (ii) If E is Polish, then also the converse holds:

$$\mathcal{F} \text{ is tight} \iff \mathcal{F} \text{ is weakly relatively sequentially compact.}$$

Corollary 13.30 Let E be a compact metric space. Then the sets $\mathcal{M}_{\leq 1}(E)$ and $\mathcal{M}_1(E)$ are weakly sequentially compact.

Corollary 13.31 If E is a locally compact separable metric space, then $\mathcal{M}_{\leq 1}(E)$ is vaguely sequentially compact.

Proof Let $x_1, x_2, \dots$ be dense in E . As E is locally compact, for each $n \in \mathbb{N}$, there exists an open neighborhood $U_n \ni x_n$ whose closure $\bar{U}_n$ is compact. Hence, also $V_n := \bigcup_{i=1}^n V_i$ is relatively compact for each $n \in \mathbb{N}$. This implies that $N(K) := \min\{m : K \subset V_m\}$ is finite for any compact $K \subset E$. Inductively define $W_1 := V_1$ and $W_{n+1} := W_{N(\bar{V}_n)}, n \in \mathbb{N}$. Then W_n is open, $\bar{W}_n$ is compact, and $\bar{W}_n \subset W_{n+1}$ for all $n \in \mathbb{N}$. Furthermore, we have $W_n \uparrow E$.

Applying Prohorov's theorem (i.e., Corollary 13.30) to the measures $(\mu_k \mathbb{1}_{\bar{W}_n})_{k \in \mathbb{N}}$, for each $n \in \mathbb{N}$, we can choose a sequence $(k_l^n)_{l \in \mathbb{N}}$ and a measure $\tilde{\mu}_n := w - \lim_{l \rightarrow \infty} \mu_{k_l^n} \mathbb{1}_{\bar{W}_n}$ whose support lies in $\bar{W}_n$. We may assume that the sequences $(k_l^n)_{l \in \mathbb{N}}$ were chosen successively such that (k_l^{n+1}) is a subsequence of (k_l^n) .

Note that we have $\tilde{\mu}_n(\bar{W}_n) \leq \tilde{\mu}_{n+1}(\bar{W}_n)$, but equality does not hold in general. For $f \in C_c(E)$, there exists an $n_0 \in \mathbb{N}$ such that the support of f is contained in W_{n_0} . Hence, for $m \geq n \geq n_0$, we have

$$\begin{aligned}
\int f d\tilde{\mu}_n &= \lim_{l \rightarrow \infty} \int f \mathbb{1}_{\bar{W}_n} d\mu_{k_l^n} \\
&= \lim_{l \rightarrow \infty} \int f \mathbb{1}_{\bar{W}_n} d\mu_{k_l^m} \\
&= \lim_{l \rightarrow \infty} \int f \mathbb{1}_{\bar{W}_m} d\mu_{k_l^m} = \int f d\tilde{\mu}_m
\end{aligned}$$

and thus

$$\int f d\tilde{\mu}_n = \lim_{m \rightarrow \infty} \int f d\mu_{k_m^m}.$$

This implies that for any measurable relatively compact set $A \subset E$, we have

$$\tilde{\mu}_m(A) = \tilde{\mu}_{N(\bar{A})} \quad \text{for any } m \geq N(\bar{A})$$

For any measurable set $A \subset E$, define

$$\mu(A) := \sup_{n \in \mathbb{N}} \sup_{m > n} \tilde{\mu}_m(A \cap W_n) = \sup_{n \in \mathbb{N}} \tilde{\mu}_{n+1}(A \cap W_n)$$

It is easy to check that μ is a lower semicontinuous content and is hence a measure (see Theorem 1.36). By construction, for any $f \in C_c(E)$, we infer

$$\int f d\mu = \lim_{n \rightarrow \infty} \int f d\mu_{k_n^n}$$

Concluding, we have $\mu = \nu - \lim_{n \rightarrow \infty} \mu_{k_n^n}$.

Remark 13.32 The implication (ii) in Theorem 13.29 is less useful but a lot simpler to prove. Here we need that E is Polish since clearly every singleton is weakly compact but is tight only under additional assumptions; for example, if E is Polish (see Lemma 13.5).

Proof of Theorem 13.29(ii) We start as in the proof of Lemma 13.5. Let $\{x_1, x_2, \dots\} \subset E$ be dense. For $n \in \mathbb{N}$, define $A_{n,N} := \bigcup_{i=1}^N B_{1/n}(x_i)$. Then $A_{n,N} \uparrow E$ for $N \rightarrow \infty$ for all $n \in \mathbb{N}$. Let

$$\delta := \sup_{n \in \mathbb{N}} \inf_{N \in \mathbb{N}} \sup_{\mu \in \mathcal{F}} \mu(A_{n,N}^c)$$

Then there is an $n \in \mathbb{N}$ such that for any $N \in \mathbb{N}$, there is a $\mu_N \in \mathcal{F}$ with $\mu_N(A_{n,N}^c) \geq \delta/2$. As $\mathcal{F}$ is weakly relatively sequentially compact, $(\mu_N)_{N \in \mathbb{N}}$ has a weakly convergent subsequence $(\mu_{N_k})_{k \in \mathbb{N}}$ whose weak limit will be denoted by $\mu \in \mathcal{M}_{\leq 1}(E)$. By the Portemanteau theorem (Theorem 13.16(iv)), for any $N \in \mathbb{N}$,

$$\mu(A_{n,N}^c) \geq \liminf_{k \rightarrow \infty} \mu_{N_k}(A_{n,N}^c) \geq \liminf_{k \rightarrow \infty} \mu_{N_k}(A_{n,N_k}^c) \geq \delta/2.$$

On the other hand, $A_{n,N}^c \downarrow \emptyset$ for $N \rightarrow \infty$; hence $\mu(A_{n,N}^c) \xrightarrow{N \rightarrow \infty} 0$. Thus $\delta = 0$.

Now fix $\varepsilon > 0$. By the above, for any $n \in \mathbb{N}$, we can choose an $N'_n \in \mathbb{N}$ such that $\mu(A_{n,N'_n}^c) < \varepsilon/2^n$ for all $\mu \in \mathcal{F}$. By construction, the set $A := \bigcap_{n=1}^{\infty} A_{n,N'_n}$ is totally bounded and hence relatively compact. Further, for every $\mu \in \mathcal{F}$,

$$\mu((\bar{A})^c) \leq \mu(A^c) \leq \sum_{n=1}^{\infty} \mu(A_{n,N'_n}^c) \leq \varepsilon.$$

Hence $\mathcal{F}$ is tight.

The other implication in Prohorov's theorem is more difficult to prove, especially in the case of a general metric space. For this reason, we first give a proof only for

the case $E = \mathbb{R}$ and come to applications before proving the difficult implication in the general situation.

The problem consists in finding a candidate for a weak limit point. For distributions on $\mathbb{R}$, the problem is equivalent to finding a weak limit point for a sequence of distribution functions. Here Helly's theorem is the tool. It is based on a diagonal sequence argument that will be recycled later in the proof of Prohorov's theorem in the general case.

Let

$$V = \{F : \mathbb{R} \rightarrow \mathbb{R} \text{ is right continuous, monotone increasing and bounded} \}$$

be the set of distribution functions of finite measures on $\mathbb{R}$.

Theorem 13.33 (Helly's theorem) Let $(F_n)_{n \in \mathbb{N}}$ be a uniformly bounded sequence in V . Then there exists an $F \in V$ and a subsequence $(F_{n_k})_{k \in \mathbb{N}}$ with

$$F_{n_k}(x) \xrightarrow{k \rightarrow \infty} F(x) \text{ at all points of continuity of } F.$$

Proof We use a diagonal sequence argument. Choose an enumeration of the rational numbers $\mathbb{Q} = \{q_1, q_2, q_3, \dots\}$. By the Bolzano-Weierstraß theorem, the sequence $(F_n(q_1))_{n \in \mathbb{N}}$ has a convergent subsequence $(F_{n_k^1}(q_1))_{k \in \mathbb{N}}$. Analogously, we find a subsequence $(n_k^2)_{k \in \mathbb{N}}$ of $(n_k^1)_{k \in \mathbb{N}}$ such that $(F_{n_k^2}(q_2))_{k \in \mathbb{N}}$ converges. Inductively, we obtain subsequences $(n_k^1) \supset (n_k^2) \supset (n_k^3) \supset \dots$ such that $(F_{n_k^l}(q_l))_{k \in \mathbb{N}}$ converges for all $l \in \mathbb{N}$. Now define $n_k := n_k^k$. Then $(F_{n_k}(q))_{k \in \mathbb{N}}$ converges for all $q \in \mathbb{Q}$. Define $\tilde{F}(q) = \lim_{k \rightarrow \infty} F_{n_k}(q)$ and

$$F(x) = \inf\{\tilde{F}(q) : q \in \mathbb{Q} \text{ with } q > x\}$$

As $\tilde{F}$ is monotone increasing, F is right continuous and monotone increasing.

If F is continuous at x , then for every $\varepsilon > 0$, there exist numbers $q^-, q^+ \in \mathbb{Q}$, $q^- < x < q^+$ with $\tilde{F}(q^-) \geq F(x) - \varepsilon$ and $\tilde{F}(q^+) \leq F(x) + \varepsilon$. By construction,

$$\limsup_{k \rightarrow \infty} F_{n_k}(x) \leq \lim_{k \rightarrow \infty} F_{n_k}(q^+) = \tilde{F}(q^+) \leq F(x) + \varepsilon$$

Hence $\limsup_{k \rightarrow \infty} F_{n_k}(x) \leq F(x)$. A similar argument for q^- yields $\liminf_{k \rightarrow \infty} F_{n_k}(x) \geq F(x)$.

Proof of Theorem 13.29(i) for the case $E = \mathbb{R}$ Assume $\mathcal{F}$ is tight and $(\mu_n)_{n \in \mathbb{N}}$ is a sequence in $\mathcal{F}$ with distribution functions $F_n : x \mapsto \mu_n((-\infty, x])$. By Helly's theorem, there is a monotone right continuous function $F : \mathbb{R} \rightarrow [0, 1]$ and a subsequence $(F_{n_k})_{k \in \mathbb{N}}$ of $(F_n)_{n \in \mathbb{N}}$ with $F_{n_k}(x) \xrightarrow{k \rightarrow \infty} F(x)$ at all points of continuity x of F . By Theorem 13.23, it is enough to show that $F(\infty) \geq \limsup_{k \rightarrow \infty} F_{n_k}(\infty)$.

As $\mathcal{F}$ is tight, for every $\varepsilon > 0$, there is a $K < \infty$ with $F_n(\infty) - F_n(x) < \varepsilon$ for all $n \in \mathbb{N}$ and $x > K$. If $x > K$ is a point of continuity of F , then $\limsup_{k \rightarrow \infty} F_{n_k}(\infty) \leq \limsup_{k \rightarrow \infty} F_{n_k}(x) + \varepsilon = F(x) + \varepsilon \leq F(\infty) + \varepsilon$.

We come to a first application of Prohorov's theorem. The full strength of that theorem will become manifest when suitable separating classes of functions are at our disposal. We come back to this point in more detail in Chapter 15.

Theorem 13.34 Let E be Polish and let $\mu, \mu_1, \mu_2, \dots \in \mathcal{M}_{\leq 1}(E)$. Then the following are equivalent.

- (i) $\mu = \text{w-lim}_{n \rightarrow \infty} \mu_n$.
- (ii) $(\mu_n)_{n \in \mathbb{N}}$ is tight, and there is a separating family $\mathcal{C} \subset C_b(E)$ such that

$$\int f d\mu = \lim_{n \rightarrow \infty} \int f d\mu_n \quad \text{for all } f \in \mathcal{C} \quad (13.8)$$

Proof "(i) $\implies$ (ii)" By the simple implication in Prohorov's theorem (Theorem 13.29(ii)), weak convergence implies tightness.

"(ii) $\implies$ (i)" Let $(\mu_n)_{n \in \mathbb{N}}$ be tight and let $\mathcal{C} \subset C_b(E)$ be a separating class with (13.8). Assume that $(\mu_n)_{n \in \mathbb{N}}$ does not converge weakly to μ . Then there are $\varepsilon > 0$, $f \in C_b(E)$ and $(n_k)_{k \in \mathbb{N}}$ with $n_k \uparrow \infty$ and such that

$$\left| \int f d\mu_{n_k} - \int f d\mu \right| > \varepsilon \quad \text{for all } k \in \mathbb{N}. \quad (13.9)$$

By Prohorov's theorem, there exists a $\nu \in \mathcal{M}_{\leq 1}(E)$ and a subsequence $(n'_k)_{k \in \mathbb{N}}$ of $(n_k)_{k \in \mathbb{N}}$ with $\mu_{n'_k} \rightarrow \nu$ weakly. Due to (13.9), we have $|\int f d\mu - \int f d\nu| \geq \varepsilon$; hence $\mu \neq \nu$. On the other hand,

$$\int h d\mu = \lim_{k \rightarrow \infty} \int h d\mu_{n'_k} = \int h d\nu \quad \text{for all } h \in \mathcal{C}$$

hence $\mu = \nu$. This contradicts the assumption and thus (i) holds.

We want to shed some more light on the connection between weak and vague convergence.

Theorem 13.35 Let E be a locally compact Polish space and let $\mu, \mu_1, \mu_2, \dots \in \mathcal{M}_f(E)$. Then the following are equivalent.

- (i) $\mu = w - \lim_{n \rightarrow \infty} \mu_n$.
- (ii) $\mu = v - \lim_{n \rightarrow \infty} \mu_n$ and $\mu(E) = \lim_{n \rightarrow \infty} \mu_n(E)$.
- (iii) $\mu = v - \lim_{n \rightarrow \infty} \mu_n$ and $\mu(E) \geq \limsup_{n \rightarrow \infty} \mu_n(E)$.
- (iv) $\mu = v - \lim_{n \rightarrow \infty} \mu_n$ and $\{\mu_n, n \in \mathbb{N}\}$ is tight.

Proof "(i) $\iff$ (ii) $\iff$ (iii)" This follows by the Portemanteau theorem.

"(ii) $\implies$ (iv)" It is enough to show that for any $\varepsilon > 0$, there is a compact set $K \subset E$ with $\limsup_{n \rightarrow \infty} \mu_n(E \setminus K) \leq \varepsilon$. As μ is regular (Theorem 13.6), there is a compact set $L \subset E$ with $\mu(E \setminus L) < \varepsilon$. Since E is locally compact, there exists a compact set $K \subset E$ with $K^\circ \supset L$ and a $\rho_{L,K} \in C_c(E)$ with $\mathbb{1}_L \leq \rho_{L,K}(x) \leq \mathbb{1}_K$. Therefore,

$$\begin{aligned} \limsup_{n \rightarrow \infty} \mu_n(E \setminus K) &\leq \limsup_{n \rightarrow \infty} \left(\mu_n(E) - \int \rho_{L,K} d\mu_n \right) \\ &= \mu(E) - \int \rho_{L,K} d\mu \leq \mu(E \setminus L) < \varepsilon \end{aligned}$$

"(iv) $\implies$ (i)" Let $L \subset E$ be compact with $\mu_n(E \setminus L) \leq 1$ for all $n \in \mathbb{N}$. Let $\rho \in C_c(E)$ with $\rho \geq \mathbb{1}_L$. Since $\int \rho d\mu_n$ converges by assumption, we thus have

$$\sup_{n \in \mathbb{N}} \mu_n(E) \leq 1 + \sup_{n \in \mathbb{N}} \mu_n(L) \leq 1 + \sup_{n \in \mathbb{N}} \int \rho d\mu_n < \infty.$$

Hence also

$$C := \max(\mu(E), \sup \{\mu_n(E) : n \in \mathbb{N}\}) < \infty,$$

and we can pass to μ/C and μ_n/C . Thus, without loss of generality assume that all measures are in $\mathcal{M}_{\leq 1}(E)$. As $C_c(E)$ is a separating class for $\mathcal{M}_{\leq 1}(E)$ (see Theorem 13.11), (i) follows by Theorem 13.34.

Proof of Prohorov's Theorem, Part (i), General Case There are two main routes for proving Prohorov's theorem in the general situation. One possibility is to show the claim first for measures on $\mathbb{R}^d$. (We have done this already for $d = 1$, see Exercise 13.3.4 for $d \geq 2$.) In a second step, the statement is lifted to sequence spaces $\mathbb{R}^{\mathbb{N}}$. Finally, in the third step, an embedding of E into $\mathbb{R}^{\mathbb{N}}$ is constructed. For a detailed description, see [12] or [83].

Here we follow the alternative route as described in [13] (and later [14]) or [44]. The main point of this proof consists in finding a candidate for a weak limit point for the family $\mathcal{F}$. This

candidate will be constructed first as a content on a countable class of sets. From this an outer measure will be derived. Finally, we show that closed sets are measurable with respect to this outer measure. As you see, the argument follows a pattern similar to the proof of Carathéodory's theorem.

Let (E, d) be a metric space and let $\mathcal{F} \subset \mathcal{M}_{\leq 1}(E)$ be tight. Then there exists an increasing sequence $K_1 \subset K_2 \subset K_3 \subset \dots$ of compact sets in E such that $\mu(K_n^c) < \frac{1}{n}$ for all $\mu \in \mathcal{F}$ and all $n \in \mathbb{N}$. Define $E' := \bigcup_{n=1}^{\infty} K_n$. Then E' is a σ -compact metric space and therefore in particular, separable. By construction, $\mu(E \setminus E') = 0$ for all $\mu \in \mathcal{F}$. Thus, any μ can be regarded as a measure on E' . Without loss of generality, we may hence assume that E is σ -compact and thus separable. Hence there exists a countable base $\mathcal{U}$ of the topology $\tau|_E$ on E ; that is, a countable set $\mathcal{U}$ of open sets such that $A = \bigcup_{U \in \mathcal{U}, U \subset A} U$ for any open $A \subset E$. Define

$$\mathcal{C}' := \{\bar{U} \cap K_n : U \in \mathcal{U}, n \in \mathbb{N}\}$$

and

$$\mathcal{C} := \left\{ \bigcup_{n=1}^N C_n : N \in \mathbb{N} \text{ and } C_1, \dots, C_N \in \mathcal{C}' \right\}$$

Clearly, $\mathcal{C}$ is a countable set of compact sets in E , and $\mathcal{C}$ is stable under formation of unions. Any K_n possesses a finite covering with sets from $\mathcal{U}$; hence $K_n \in \mathcal{C}$.

Now let $(\mu_n)_{n \in \mathbb{N}}$ be a sequence in $\mathcal{F}$. By virtue of the diagonal sequence argument (see the proof of Helly's theorem, Theorem 13.33), we can find a subsequence $(\mu_{n_k})_{k \in \mathbb{N}}$ such that for all $C \in \mathcal{C}$, there exists the limit

$$\alpha(C) := \lim_{k \rightarrow \infty} \mu_{n_k}(C). \quad (13.10)$$

Assume that we can show that there is a measure μ on the Borel σ -algebra $\mathcal{E}$ of E such that

$$\mu(A) = \sup\{\alpha(C) : C \in \mathcal{C} \text{ with } C \subset A\} \quad \text{for all } A \subset E \text{ open.} \quad (13.11)$$

Then

$$\begin{aligned} \mu(E) &\geq \sup_{n \in \mathbb{N}} \alpha(K_n) = \sup_{n \in \mathbb{N}} \lim_{k \rightarrow \infty} \mu_{n_k}(K_n) \\ &\geq \sup_{n \in \mathbb{N}} \limsup_{k \rightarrow \infty} \left(\mu_{n_k}(E) - \frac{1}{n} \right) \\ &= \limsup_{k \rightarrow \infty} \mu_{n_k}(E) \end{aligned}$$

Furthermore, for open A and for $C \in \mathcal{C}$ with $C \subset A$,

$$\alpha(C) = \lim_{k \rightarrow \infty} \mu_{n_k}(C) \leq \liminf_{k \rightarrow \infty} \mu_{n_k}(A),$$

hence $\mu(A) \leq \liminf_{k \rightarrow \infty} \mu_{n_k}(A)$. By the Portemanteau theorem (Theorem 13.16), $\mu = w - \lim_{k \rightarrow \infty} \mu_{n_k}$; hence $\mathcal{F}$ is recognized as weakly relatively sequentially compact. It remains to show that there exists a measure μ on $(E, \mathcal{E})$ that satisfies (13.11).

Clearly, the set function α on $\mathcal{C}$ is monotone, additive and subadditive:

$$\begin{aligned} \alpha(C_1) &\leq \alpha(C_2), & \text{if } C_1 \subset C_2, \\ \alpha(C_1 \cup C_2) &= \alpha(C_1) + \alpha(C_2), & \text{if } C_1 \cap C_2 = \emptyset, \\ \alpha(C_1 \cup C_2) &\leq \alpha(C_1) + \alpha(C_2). \end{aligned} \quad (13.12)$$

We define

$$\beta(A) := \sup\{\alpha(C) : C \in \mathcal{C} \text{ with } C \subset A\} \quad \text{for } A \subset E \text{ open}$$

and

$$\mu^*(G) := \inf\{\beta(A) : A \supset G \text{ is open}\} \quad \text{for } G \in 2^E.$$

Manifestly, $\beta(A) = \mu^*(A)$ for any open A . It is enough to show (Steps 1-3 below) that μ^* is an outer measure (see Definition 1.46) and that (Step 4) the σ -algebra of μ^* -measurable sets (see Definition 1.48 and Lemma 1.52) contains the closed sets and thus $\mathcal{E}$. Indeed, Lemma 1.52 would then imply that μ^* is a measure on the σ -algebra of μ^* -measurable sets and the restricted measure $\mu := \mu^*|_{\mathcal{E}}$ fulfills $\mu(A) = \mu^*(A) = \beta(A)$ for all open A . Hence Eq. (13.11) holds.

Evidently, $\mu^*(\emptyset) = 0$ and μ^* is monotone. In order to show that μ^* is an outer measure, it only remains to check that μ^* is σ -subadditive.

Step 1 (Finite subadditivity of β) Let $A_1, A_2 \subset E$ be open and let $C \in \mathcal{C}$ with $C \subset A_1 \cup A_2$. Let $n \in \mathbb{N}$ with $C \subset K_n$. Define two sets

$$\begin{aligned} B_1 &:= \{x \in C : d(x, A_1^c) \geq d(x, A_2^c)\}, \\ B_2 &:= \{x \in C : d(x, A_1^c) \leq d(x, A_2^c)\}. \end{aligned}$$

Evidently, $B_1 \subset A_1$ and $B_2 \subset A_2$. As $x \mapsto d(x, A_i^c)$ is continuous for $i = 1, 2$, the closed subsets B_1 and B_2 of C are compact. Hence $d(B_1, A_1^c) > 0$. Thus there exists an open set D_1 with $B_1 \subset D_1 \subset \bar{D}_1 \subset A_1$. (One could choose D_1 as the union of the sets of a finite covering of B_1 with balls of radius $d(B_1, A_1^c)/2$. These balls, as well as their closures, are subsets of A_1 .) Let $\mathcal{U}_{D_1} := \{U \in \mathcal{U} : U \subset D_1\}$. Then $B_1 \subset D_1 = \bigcup_{U \in \mathcal{U}_{D_1}} U$. Now choose a finite subcovering $\{U_1, \dots, U_N\} \subset \mathcal{U}_{D_1}$ of B_1 and define $C_1 := \bigcup_{i=1}^N \bar{U}_i \cap K_n$. Then $B_1 \subset C_1 \subset A_1$ and $C_1 \in \mathcal{C}$. Similarly, choose $C_2 \in \mathcal{C}$ with $B_2 \subset C_2 \subset A_2$. Thus

$$\alpha(C) \leq \alpha(C_1 \cup C_2) \leq \alpha(C_1) + \alpha(C_2) \leq \beta(A_1) + \beta(A_2).$$

Hence also

$$\begin{aligned} \beta(A_1 \cup A_2) &= \sup\{\alpha(C) : C \in \mathcal{C} \text{ with } C \subset A_1 \cup A_2\} \\ &\leq \beta(A_1) + \beta(A_2). \end{aligned}$$

Step 2 (σ -subadditivity of β) Let $A_1, A_2, \dots$ be open sets and let $C \in \mathcal{C}$ with $C \subset \bigcup_{i=1}^{\infty} A_i$. As C is compact, there exists an $n \in \mathbb{N}$ with $C \subset \bigcup_{i=1}^n A_i$. As shown above, β is subadditive; thus

$$\alpha(C) \leq \beta\left(\bigcup_{i=1}^n A_i\right) \leq \sum_{i=1}^{\infty} \beta(A_i).$$

Taking the supremum over such C yields

$$\beta\left(\bigcup_{i=1}^{\infty} A_i\right) = \sup\left\{\alpha(C) : C \in \mathcal{C} \text{ with } C \subset \bigcup_{i=1}^{\infty} A_i\right\} \leq \sum_{i=1}^{\infty} \beta(A_i).$$

Step 3 (σ -subadditivity of μ^*) Let $G_1, G_2, \dots \in 2^E$. Let $\varepsilon > 0$. For any $n \in \mathbb{N}$ choose an open set $A_n \supset G_n$ with $\beta(A_n) < \mu^*(G_n) + \varepsilon/2^n$. By the σ -subadditivity of β ,

$$\mu^*\left(\bigcup_{n=1}^{\infty} G_n\right) \leq \beta\left(\bigcup_{n=1}^{\infty} A_n\right) \leq \sum_{n=1}^{\infty} \beta(A_n) \leq \varepsilon + \sum_{n=1}^{\infty} \mu^*(G_n).$$

Letting $\varepsilon \downarrow 0$ yields $\mu^*\left(\bigcup_{n=1}^{\infty} G_n\right) \leq \sum_{n=1}^{\infty} \mu^*(G_n)$. Hence μ^* is an outer measure.

Step 4 (Closed sets are μ^* -measurable) By Lemma 1.49, a set $B \subset E$ is μ^* measurable if and only if

$$\mu^*(B \cap G) + \mu^*(B^c \cap G) \leq \mu^*(G) \quad \text{for all } G \in 2^E.$$

Taking the infimum over all open sets $A \supset G$, it is enough to show that for every open B and every open $A \subset E$,

$$\mu^*(B \cap A) + \mu^*(B^c \cap A) \leq \beta(A). \quad (13.13)$$

Let $\varepsilon > 0$. Choose $C_1 \in \mathcal{C}$ with $C_1 \subset A \cap B^c$ and $\alpha(C_1) > \beta(A \cap B^c) - \varepsilon$. Further, let $C_2 \in \mathcal{C}$ with $C_2 \subset A \cap C_1^c$ and $\alpha(C_2) > \beta(A \cap C_1^c) - \varepsilon$. Since $C_1 \cap C_2 = \emptyset$ and $C_1 \cup C_2 \subset A$, we get

$$\begin{aligned} \beta(A) &\geq \alpha(C_1 \cup C_2) \\ &= \alpha(C_1) + \alpha(C_2) \geq \beta(A \cap B^c) + \beta(A \cap C_1^c) - 2\varepsilon \\ &\geq \mu^*(A \cap B^c) + \mu^*(A \cap B) - 2\varepsilon. \end{aligned}$$

Letting $\varepsilon \rightarrow 0$, we get (13.13). This completes the proof of Prohorov's theorem.

Exercise 13.3.1 Show that a family $\mathcal{F} \subset \mathcal{M}_f(\mathbb{R})$ is tight if and only if there exists a measurable map $f : \mathbb{R} \rightarrow [0, \infty)$ such that $f(x) \rightarrow \infty$ for $|x| \rightarrow \infty$ and $\sup_{\mu \in \mathcal{F}} \int f d\mu < \infty$.

Exercise 13.3.2 Let $L \subset \mathbb{R} \times (0, \infty)$ and let $\mathcal{F} = \{\mathcal{N}_{\mu, \sigma^2} : (\mu, \sigma^2) \in L\}$ be a family of normal distributions with parameters in L . Show that $\mathcal{F}$ is tight if and only if L is bounded.

Exercise 13.3.3 If P is a probability measure on $[0, \infty)$ with $m_P := \int xP(dx) \in (0, \infty)$, then we define the size-biased distribution $\hat{P}$ on $[0, \infty)$ by

$$\hat{P}(A) = m_P^{-1} \int_A xP(dx) \quad (13.14)$$

Now let $(X_i)_{i \in I}$ be a family of random variables on $[0, \infty)$ with $\mathbf{E}[X_i] = 1$. Show that $(\widehat{\mathbf{P}}_{X_i})_{i \in I}$ is tight if and only if $(X_i)_{i \in I}$ is uniformly integrable.

Exercise 13.3.4 (Helly's theorem in $\mathbb{R}^d$) Let $x = (x^1, \dots, x^d) \in \mathbb{R}^d$ and $y = (y^1, \dots, y^d) \in \mathbb{R}^d$. Recall the notation $x \leq y$ if $x^i \leq y^i$ for all $i = 1, \dots, d$. A map $F : \mathbb{R}^d \rightarrow \mathbb{R}$ is called monotone increasing if $F(x) \leq F(y)$ whenever $x \leq y$. F is called right continuous if $F(x) = \lim_{n \rightarrow \infty} F(x_n)$ for all $x \in \mathbb{R}^d$ and every sequence $(x_n)_{n \in \mathbb{N}}$ in $\mathbb{R}^d$ with $x_1 \geq x_2 \geq x_3 \geq \dots$ and $x = \lim_{n \rightarrow \infty} x_n$. By V_d denote the set of monotone increasing, bounded right continuous functions on $\mathbb{R}^d$.

(i) Show the validity of Helly's theorem with V replaced by V_d .

(ii) Conclude that Prohorov's theorem holds for $E = \mathbb{R}^d$.

5.13.4 13.4 Application: a Fresh Look at de Finetti's Theorem

(After an idea of Götz Kersting.) Let E be a Polish space and let $X_1, X_2, \dots$ be an exchangeable sequence of random variables with values in E . As an alternative to the backwards martingale argument of Section 12.3, here we give a different proof of de Finetti's theorem (Theorem 12.26). Recall that de Finetti's theorem states that there exists a random probability measure Ξ on E such that, given Ξ , the random variables $X_1, X_2, \dots$ are independent and Ξ -distributed. For $x = (x_1, x_2, \dots) \in E^{\mathbb{N}}$, let $\xi_n(x) := \frac{1}{n} \sum_{l=1}^n \delta_{x_l}$ be the empirical distribution of $x_1, \dots, x_n$. Let

$$\mu_{n,k}(x) := \xi_n(x)^{\otimes k} = n^{-k} \sum_{i_1, \dots, i_k=1}^n \delta_{(x_{i_1}, \dots, x_{i_k})}$$

be the distribution on E^k that describes k -fold independent sampling with replacement (respecting the order) from $(x_1, \dots, x_n)$. Let

$$v_{n,k}(x) := \frac{(n-k)!}{n!} \sum_{\substack{i_1, \dots, i_k=1 \\ \#\{i_1, \dots, i_k\}=k}}^n \delta_{(x_{i_1}, \dots, x_{i_k})}$$

be the distribution on E^k that describes k -fold independent sampling without replacement (respecting the order) from $(x_1, \dots, x_n)$. For all $x \in E^{\mathbb{N}}$,

$$\|\mu_{n,k}(x) - v_{n,k}(x)\|_{TV} \leq R_{n,k} := \frac{k(k-1)}{n}.$$

Indeed, the probability $p_{n,k}$ that we do not see any ball twice when drawing k balls (with replacement) from n different balls is

$$p_{n,k} = \prod_{l=1}^{k-1} (1 - l/n)$$

and thus $R_{n,k} \geq 2(1 - p_{n,k})$. We therefore obtain the rather intuitive statement that as $n \rightarrow \infty$ the distributions of k -samples with replacement and without replacement, respectively, become the same:

$$\lim_{n \rightarrow \infty} \sup_{x \in E^{\mathbb{N}}} \|\mu_{n,k}(x) - v_{n,k}(x)\|_{TV} = 0$$

Now let $f_1, \dots, f_k \in C_b(E)$ and $F(x_1, \dots, x_k) := f_1(x_1) \dots f_k(x_k)$. As the sequence $X_1, X_2, \dots$ is exchangeable, for any choice of pairwise distinct numbers $1 \leq i_1, \dots, i_k \leq n$,

$$\mathbf{E}[F(X_1, \dots, X_k)] = \mathbf{E}[F(X_{i_1}, \dots, X_{i_k})].$$

Averaging over all choices $i_1, \dots, i_k$, we get

$$\mathbf{E}[f_1(X_1) \dots f_k(X_k)] = \mathbf{E}[F(X_1, \dots, X_k)] = \mathbf{E}\left[\int F dv_{n,k}(X)\right].$$

Hence

$$\begin{aligned} & \left| \mathbf{E}[f_1(X_1) \dots f_k(X_k)] - \mathbf{E}\left[\int f_1 d\xi_n(X) \dots \int f_k d\xi_n(X)\right] \right| \\ &= \left| \mathbf{E}\left[\int F dv_{n,k}(X)\right] - \mathbf{E}\left[\int F d\mu_{n,k}(X)\right] \right| \\ &\leq \|F\|_{\infty} R_{n,k} \xrightarrow{n \rightarrow \infty} 0 \end{aligned}$$

We will exploit the following criterion for tightness of subsets of $\mathcal{M}_1(\mathcal{M}_1(E))$.

Exercise 13.4.1 Show that a subset $\mathcal{K} \subset \mathcal{M}_1(\mathcal{M}_1(E))$ is tight if and only if, for any $\varepsilon > 0$, there exists a compact set $K \subset E$ with the property

$$\tilde{\mu}(\{\mu \in \mathcal{M}_1(E) : \mu(K^c) > \varepsilon\}) < \varepsilon \quad \text{for all } \tilde{\mu} \in \mathcal{K}.$$

Since E is Polish, $\mathbf{P}_{X_1}$ is tight. Hence, for any $\varepsilon > 0$, there exists a compact set $K \subset E$ with $\mathbf{P}[X_1 \in K^c] < \varepsilon^2$. Therefore,

$$\mathbf{P}[\xi_n(X)(K^c) > \varepsilon] \leq \varepsilon^{-1} \mathbf{E}[\xi_n(X)(K^c)] = \varepsilon^{-1} \mathbf{P}[X_1 \in K^c] \leq \varepsilon.$$

Hence the family $(\mathbf{P}_{\xi_n(X)})_{n \in \mathbb{N}}$ is tight. Let Ξ_∞ be a random variable (with values in $\mathcal{M}_1(E)$) such that $\mathbf{P}_{\Xi_\infty} = \text{w-lim}_{l \rightarrow \infty} \mathbf{P}_{\xi_{n_l}(X)}$ for a suitable subsequence $(n_l)_{l \in \mathbb{N}}$. The map $\xi \mapsto \int F d\xi = \int f_1 d\xi \dots \int f_k d\xi$ is bounded and (as a product of continuous maps) is continuous with respect to the topology of weak convergence on $\mathcal{M}_1(E)$; hence it is in $C_b(\mathcal{M}_1(E))$. Thus

$$\begin{aligned} \mathbf{E} \left[\int F d\Xi_\infty^{\otimes k} \right] &= \lim_{l \rightarrow \infty} \mathbf{E} \left[\int f_1 d\xi_{n_l}(X) \dots \int f_k d\xi_{n_l}(X) \right] \\ &= \mathbf{E}[f_1(X_1) \dots f_k(X_k)] \end{aligned}$$

Note that the limit does not depend on the choice of the subsequence and is thus unique. Summarising, we have

$$\mathbf{E}[f_1(X_1) \dots f_k(X_k)] = \mathbf{E} \left[\int f_1 d\Xi_\infty \dots \int f_k d\Xi_\infty \right]$$

Since the distribution of $(X_1, \dots, X_k)$ is uniquely determined by integrals of the above type, we conclude that $\mathbf{P}_{(X_1, \dots, X_k)} = \mathbf{P}_{\Xi_\infty^{\otimes k}}$. In other words, $(X_1, \dots, X_k) \stackrel{\mathcal{D}}{=} (Y_1, \dots, Y_k)$, where, given Ξ_∞ , the random variables $Y_1, \dots, Y_k$ are independent with distribution Ξ_∞ .

Exercise 13.4.2 Show that a family $(X_n)_{n \in \mathbb{N}}$ of random variables is exchangeable if and only if, for every choice of natural numbers $1 \leq n_1 < n_2 < n_3 < \dots$, we have

$$(X_1, X_2, \dots) \stackrel{\mathcal{D}}{=} (X_{n_1}, X_{n_2}, \dots)$$

Warning: One of the implications is rather difficult to show.

5.14 14 Probability Measures on Product Spaces

As a motivation, consider the following example. Let X be a random variable that is uniformly distributed on $[0, 1]$. As soon as we know the value of X , we toss n times a coin that has probability X for a success. Denote the results by $Y_1, \dots, Y_n$.

How can we construct a probability space on which all these random variables are defined? One possibility is to construct $n+1$ independent random variables $Z_0, \dots, Z_n$ that are uniformly distributed on $[0, 1]$ (see, e.g., Corollary 2.23 for the construction). Then define $X = Z_0$ and

$$Y_k = \begin{cases} 1, & \text{if } Z_k < X \\ 0, & \text{if } Z_k \geq X \end{cases}$$

Intuitively, this fits well with our idea that the $Y_1, \dots, Y_n$ are independent as soon as we know X and record a success with probability X .

In the above description, we have constructed by hand a two-stage experiment. At the first stage, we determine the value of X . At the second stage, depending on the value of X , the values of $Y = (Y_1, \dots, Y_n)$ are determined. Clearly, this construction makes use of the specific structure

of the problem. However, we now want to develop a systematic framework for the description and construction of multistage experiments. In contrast to Chapter 2, here the random variables need not be independent. In addition, we also want to construct systematically infinite families of random variables with given (joint) distributions.

In the first section, we start with products of measurable spaces. Then we come to finite products of measure spaces and product measures with transition kernels. Finally, we consider infinite products of probability spaces. The main result is Kolmogorov's extension theorem.

5.14.1 14.1 Product Spaces

Definition 14.1 (Product space) Let $(\Omega_i, i \in I)$ be an arbitrary family of sets. Denote by $\Omega = \prod_{i \in I} \Omega_i$ the set of maps $\omega : I \rightarrow \prod_{i \in I} \Omega_i$ such that $\omega(i) \in \Omega_i$ for all $i \in I$. Ω is called the product of the spaces $(\Omega_i, i \in I)$, or briefly the product space. If, in particular, all the Ω_i are equal, say $\Omega_i = \Omega_0$, then we write $\Omega = \times_{i \in I} \Omega_i = \Omega_0^I$.

Example 14.2

(i) If $\Omega_1 = \{1, \dots, 6\}$ and $\Omega_2 = \{1, 2, 3\}$, then

$$\Omega_1 \times \Omega_2 = \{\omega = (\omega_1, \omega_2) : \omega_1 \in \{1, \dots, 6\}, \omega_2 \in \{1, 2, 3\}\}.$$

(ii) If $\Omega_0 = \mathbb{R}$ and $I = \{1, 2, 3\}$, then $\mathbb{R}^{\{1,2,3\}}$ is isomorphic to the customary $\mathbb{R}^3$.

(iii) If $\Omega_0 = \mathbb{R}$ and $I = \mathbb{N}$, then $\mathbb{R}^{\mathbb{N}}$ is the space of sequences $(\omega(n), n \in \mathbb{N})$ in $\mathbb{R}$.

(iv) If $I = \mathbb{R}$ and $\Omega_0 = \mathbb{R}$, then $\mathbb{R}^{\mathbb{R}}$ is the set of maps $\mathbb{R} \rightarrow \mathbb{R}$.

Definition 14.3 (Coordinate maps) If $i \in I$, then $X_i : \Omega \rightarrow \Omega_i, \omega \mapsto \omega(i)$ denotes the i th coordinate map. More generally, for $J \subset J' \subset I$, the restricted map

$$X_J^{J'} : \prod_{j \in J'} \Omega_j \longrightarrow \prod_{j \in J} \Omega_j, \quad \omega' \mapsto \omega'|_J \quad (14.1)$$

is called the canonical projection. In particular, we write $X_J := X_J^I$.

Definition 14.4 (Product- σ -algebra) Let $(\Omega_i, \mathcal{A}_i), i \in I$, be measurable spaces. The product- σ -algebra

$$\mathcal{A} = \bigotimes_{i \in I} \mathcal{A}_i$$

is the smallest σ -algebra on Ω such that for every $i \in I$, the coordinate map X_i is measurable with respect to $\mathcal{A} - \mathcal{A}_i$; that is,

$$\mathcal{A} = \sigma(X_i, i \in I) := \sigma(X_i^{-1}(\mathcal{A}_i), i \in I).$$

If $(\Omega_i, \mathcal{A}_i) = (\Omega_0, \mathcal{A}_0)$ for all $i \in I$, then we also write $\mathcal{A} = \mathcal{A}_0^{\otimes I}$.

For $J \subset I$, let $\Omega_J := \prod_{j \in J} \Omega_j$ and $\mathcal{A}_J = \bigotimes_{j \in J} \mathcal{A}_j$.

Remark 14.5 The concept of the product- σ -algebra is similar to that of the product topology: If $(\Omega_i, \tau_i), i \in I$ are topological spaces, then the product topology τ on $\Omega = \prod_{i \in I} \Omega_i$ is the coarsest topology with respect to which all coordinate maps $X_i : \Omega \rightarrow \Omega_i$ are continuous.

Definition 14.6 Let $I \neq \emptyset$ be an arbitrary index set, let $(E, \mathcal{E})$ be a measurable space, let $(\Omega, \mathcal{A}) = (E^I, \mathcal{E}^{\otimes I})$ and let $X_t : \Omega \rightarrow E$ be the coordinate map for every $t \in I$. Then the family $(X_t)_{t \in I}$ is called the canonical process on $(\Omega, \mathcal{A})$.

Lemma 14.7 Let $\emptyset \neq J \subset I$. Then X_J^I is measurable with respect to $\mathcal{A}_I - \mathcal{A}_J$.

Proof For any $j \in J$, $X_j = X_j^J \circ X_J^I$ is measurable with respect to $\mathcal{A} - \mathcal{A}_j$. Thus, by Corollary 1.82, X_J^I is measurable.

Theorem 14.8 Let I be countable, and for every $i \in I$, let (Ω_i, τ_i) be Polish with Borel σ -algebra $\mathcal{B}_i = \sigma(\tau_i)$. Let τ be the product topology on $\Omega = \prod_{i \in I} \Omega_i$ and $\mathcal{B} = \sigma(\tau)$.

Then (Ω, τ) is Polish and $\mathcal{B} = \bigotimes_{i \in I} \mathcal{B}_i$. In particular, $\mathcal{B}(\mathbb{R}^d) = \mathcal{B}(\mathbb{R})^{\otimes d}$ for $d \in \mathbb{N}$.

Proof Without loss of generality, assume $I = \mathbb{N}$. For $i \in \mathbb{N}$, let d_i be a complete metric that induces τ_i . It is easy to check that

$$d(\omega, \omega') := \sum_{i=1}^{\infty} 2^{-i} \frac{d_i(\omega(i), \omega'(i))}{1 + d_i(\omega(i), \omega'(i))} \quad (14.2)$$

is a complete metric on Ω that induces τ .

Now for any $i \in \mathbb{N}$, let $D_i \subset \Omega_i$ be a countable dense subset and let $y_i \in D_i$ be an arbitrary point. It is easy to see that the set

$$D = \left\{ x \in \prod_{i \in \mathbb{N}} D_i : x_i \neq y_i \text{ only finitely often} \right\}$$

is a countable dense subset of Ω . Hence Ω is separable and thus Polish.

Now, for any $i \in I$, let $\beta_i = \{B_\varepsilon(x_i) : x_i \in D_i, \varepsilon \in \mathbb{Q}^+\}$ be a countable base of the topology of Ω_i consisting of ε -balls. Define

$$\beta := \bigcup_{N=1}^{\infty} \left\{ \bigcap_{i=1}^N X_i^{-1}(B_i) : B_1 \in \beta_1, \dots, B_N \in \beta_N \right\}.$$

Then β is a countable base of the topology τ ; hence any open set $A \subset \Omega$ is a (countable) union of sets in $\beta \subset \bigotimes_{i \in \mathbb{N}} \mathcal{B}_i$. Hence $\tau \subset \bigotimes_{i \in \mathbb{N}} \mathcal{B}_i$ and thus $\mathcal{B} \subset \bigotimes_{i \in \mathbb{N}} \mathcal{B}_i$.

On the other hand, each X_i is continuous and thus measurable with respect to $\mathcal{B} - \mathcal{B}_i$. Therefore, $\mathcal{B} \supset \bigotimes_{i \in \mathbb{N}} \mathcal{B}_i$.

Definition 14.9 (Cylinder sets) For any $i \in I$, let $\mathcal{E}_i \subset \mathcal{A}_i$ be a subclass of the class of measurable sets.

For any $A \in \mathcal{A}_J$, $X_J^{-1}(A) \subset \Omega$ is called a cylinder set with base J . The set of such cylinder sets is denoted by $\mathcal{Z}_J$. In particular, if $A = \times_{j \in J} A_j$ for certain $A_j \in \mathcal{A}_j$, then $X_J^{-1}(A)$ is called a rectangular cylinder with base J . The set of such rectangular cylinders will be denoted by $\mathcal{Z}_J^R$. The set of such rectangular cylinders for which in addition $A_j \in \mathcal{E}_j$ for all $j \in J$ holds will be denoted by $\mathcal{Z}_J^{\mathcal{E}, R}$.

Write

$$\mathcal{Z} = \bigcup_{J \subset I \text{ finite}} \mathcal{Z}_J \quad (14.3)$$

and similarly define $\mathcal{Z}^R$ and $\mathcal{Z}^{\mathcal{E}, R}$. Further, define

$$\mathcal{Z}_*^R = \bigcup_{N=1}^{\infty} \left\{ \bigcup_{n=1}^N A_n : A_1, \dots, A_N \in \mathcal{Z}^R \right\}$$

and similarly $\mathcal{Z}_*^{\mathcal{E}, R}$.

Remark 14.10 Every $\mathcal{Z}_J$ is a σ -algebra, and $\mathcal{Z}$ and $\mathcal{Z}_*^R$ are algebras. Furthermore, $\bigotimes_{i \in I} \mathcal{A}_i = \sigma(\mathcal{Z})$.

Lemma 14.11 If every $\mathcal{E}_i$ is a π -system, then $\mathcal{Z}^{\mathcal{E}, R}$ is a π -system.

Proof This is left as an exercise.

Theorem 14.12 For any $i \in I$, let $\mathcal{E}_i \subset \mathcal{A}_i$ be a generator of $\mathcal{A}_i$.

- (i) $\bigotimes_{j \in J} \mathcal{A}_j = \sigma(\times_{j \in J} E_j : E_j \in \mathcal{E}_j)$ for every finite $J \subset I$.
- (ii) $\bigotimes_{i \in I} \mathcal{A}_i = \sigma(\mathcal{Z}^R) = \sigma(\mathcal{Z}^{\mathcal{E}, R})$.
- (iii) Let μ be a σ -finite measure on $\mathcal{A}$, and assume every $\mathcal{E}_i$ is also a π -system. Furthermore,

assume there is a sequence $(E_n)_{n \in \mathbb{N}}$ in $\mathcal{Z}^{\mathcal{E}, R}$ with $E_n \uparrow \Omega$ and $\mu(E_n) < \infty$ for all $n \in \mathbb{N}$ (this condition is satisfied, for example, if μ is finite and $\Omega_i \in \mathcal{E}_i$ for all $i \in I$). Then μ is uniquely determined by the values $\mu(A)$ for all $A \in \mathcal{Z}^{\mathcal{E}, R}$.

Proof (i) Let $\mathcal{A}'_J = \sigma(X_{j \in J} E_j : E_j \in \mathcal{E}_j \text{ for every } j \in J)$. Note that

$$\times_{j \in J} E_j = \bigcap_{j \in J} (X_j^J)^{-1}(E_j) \in \mathcal{A}_J,$$

hence $\mathcal{A}'_J \subset \mathcal{A}_J$. On the other hand, $(X_j^J)^{-1}(E_j) \in \mathcal{A}'_J$ for all $j \in J$ and $E_j \in \mathcal{E}_j$. Since $\mathcal{E}_i$ is a generator of $\mathcal{A}_i$, we have $(X_j^J)^{-1}(A_j) \in \mathcal{A}'_J$ for all $A_j \in \mathcal{A}_j$, and hence $\mathcal{A}_J \subset \mathcal{A}'_J$.

(ii) Evidently, $\mathcal{Z}^{\mathcal{E}, R} \subset \mathcal{Z}^R \subset \mathcal{A}$; hence also $\sigma(\mathcal{Z}^{\mathcal{E}, R}) \subset \sigma(\mathcal{Z}^R) \subset \mathcal{A}$. By Theorem 1.81, we have $\sigma(\mathcal{Z}_{\{i\}}^{\mathcal{E}, R}) = \sigma(X_i)$ for all $i \in I$; hence $\sigma(X_i) \subset \sigma(\mathcal{Z}^{\mathcal{E}, R})$. Therefore, $\mathcal{A}_I \subset \sigma(\mathcal{Z}^{\mathcal{E}, R})$.

(iii) By (ii) and Lemma 14.11, $\mathcal{Z}^{\mathcal{E}, R}$ is a π -system that generates $\mathcal{A}$. Hence, the claim follows by Lemma 1.42.

Exercise 14.1.1 Show that

$$\bigotimes_{i \in I} \mathcal{A}_i = \bigcup_{J \subset I \text{ countable}} \mathcal{Z}_J \quad (14.4)$$

Hint: Show that the right-hand side is a σ -algebra.

5.14.2 14.2 Finite Products and Transition Kernels

Consider now the situation of finitely many σ -finite measure spaces $(\Omega_i, \mathcal{A}_i, \mu_i)$, $i = 1, \dots, n$, where $n \in \mathbb{N}$.

Lemma 14.13 Let $A \in \mathcal{A}_1 \otimes \mathcal{A}_2$ and let $f : \Omega_1 \times \Omega_2 \rightarrow \overline{\mathbb{R}}$ be an $\mathcal{A}_1 \otimes \mathcal{A}_2$ measurable map. Then, for all $\tilde{\omega}_1 \in \Omega_1$ and $\tilde{\omega}_2 \in \Omega_2$,

$$\begin{aligned} A_{\tilde{\omega}_1} &:= \{\omega_2 \in \Omega_2 : (\tilde{\omega}_1, \omega_2) \in A\} \in \mathcal{A}_2 \\ A_{\tilde{\omega}_2} &:= \{\omega_1 \in \Omega_1 : (\omega_1, \tilde{\omega}_2) \in A\} \in \mathcal{A}_1 \\ f_{\tilde{\omega}_1} : \Omega_2 &\rightarrow \overline{\mathbb{R}}, \quad \omega_2 \mapsto f(\tilde{\omega}_1, \omega_2) \quad \text{is } \mathcal{A}_2\text{-measurable,} \\ f_{\tilde{\omega}_2} : \Omega_1 &\rightarrow \overline{\mathbb{R}}, \quad \omega_1 \mapsto f(\omega_1, \tilde{\omega}_2) \quad \text{is } \mathcal{A}_1\text{-measurable.} \end{aligned}$$

Proof For $\tilde{\omega}_1$, define the embedding map $i : \Omega_2 \rightarrow \Omega_1 \times \Omega_2$ by $i(\omega_2) = (\tilde{\omega}_1, \omega_2)$. Note that $X_1 \circ i$ is constantly $\tilde{\omega}_1$ (and hence $\mathcal{A}_1$ -measurable), and $X_2 \circ i = \text{id}_{\Omega_2}$ (and hence $\mathcal{A}_2$ -measurable). Thus, by Corollary 1.82, the map i is measurable with respect to $\mathcal{A}_2 - (\mathcal{A}_1 \otimes \mathcal{A}_2)$. Hence $A_{\tilde{\omega}_1} = i^{-1}(A) \in \mathcal{A}_2$ and $f_{\tilde{\omega}_1} = f \circ i$ is measurable with respect to $\mathcal{A}_2$.

The following theorem generalizes Theorem 1.61.

Theorem 14.14 (Finite product measures) There exists a unique σ -finite measure μ on $\mathcal{A} := \bigotimes_{i=1}^n \mathcal{A}_i$ such that

$$\mu(A_1 \times \dots \times A_n) = \prod_{i=1}^n \mu_i(A_i) \quad \text{for } A_i \in \mathcal{A}_i, i = 1, \dots, n \quad (14.5)$$

$\bigotimes_{i=1}^n \mu_i := \mu_1 \otimes \dots \otimes \mu_n := \mu$ is called the product measure of the μ_i . If all spaces involved equal $(\Omega_0, \mathcal{A}_0, \mu_0)$, then we write $\mu_0^{\otimes n} := \bigotimes_{i=1}^n \mu_0$.

Proof Let $\tilde{\mu}$ be the restriction of μ to $\mathcal{Z}^R$. Evidently, $\tilde{\mu}(\emptyset) = 0$, and it is simple to check that $\tilde{\mu}$ is σ -finite. Let $A^1, A^2, \dots \in \mathcal{Z}^R$ be pairwise disjoint and let $A \in \mathcal{Z}^R$ with $A \subset \bigcup_{k=1}^{\infty} A^k$. Then, by the monotone convergence theorem,

$$\begin{aligned}\tilde{\mu}(A) &= \int \mu_1(d\omega_1) \dots \int \mu_n(d\omega_n) \mathbb{1}_A((\omega_1, \dots, \omega_n)) \\ &\leq \int \mu_1(d\omega_1) \dots \int \mu_n(d\omega_n) \sum_{k=1}^{\infty} \mathbb{1}_{A^k}((\omega_1, \dots, \omega_n)) = \sum_{k=1}^{\infty} \tilde{\mu}(A^k).\end{aligned}$$

In particular, if $A = A^1 \uplus A^2$, one similarly gets $\tilde{\mu}(A) = \tilde{\mu}(A^1) + \tilde{\mu}(A^2)$. Hence $\tilde{\mu}$ is a σ -finite, additive, σ -subadditive set function on the semiring $\mathcal{Z}^R$ with $\tilde{\mu}(\emptyset) = 0$. By the measure extension theorem (Theorem 1.53), $\tilde{\mu}$ can be uniquely extended to a σ -finite measure on $\mathcal{A} = \sigma(\mathcal{Z}^R)$.

Example 14.15 For $i = 1, \dots, n$, let $(\Omega_i, \mathcal{A}_i, \mathbf{P}_i)$ be a probability space. On the space $(\Omega, \mathcal{A}, \mathbf{P}) := (\times_{i=1}^n \Omega_i, \bigotimes_{i=1}^n \mathcal{A}_i, \bigotimes_{i=1}^n \mathbf{P}_i)$, the coordinate maps $X_i : \Omega \rightarrow \Omega_i$ are independent with distribution $\mathbf{P}_{X_i} = \mathbf{P}_i$.

Theorem 14.16 (Fubini) Let $(\Omega_i, \mathcal{A}_i, \mu_i)$ be σ -finite measure spaces, $i = 1, 2$. Let $f : \Omega_1 \times \Omega_2 \rightarrow \overline{\mathbb{R}}$ be measurable with respect to $\mathcal{A}_1 \otimes \mathcal{A}_2$. If $f \geq 0$ or $f \in \mathcal{L}^1(\mu_1 \otimes \mu_2)$, then

$$\begin{aligned}\omega_1 &\mapsto \int f(\omega_1, \omega_2) \mu_2(d\omega_2) \quad \text{is } \mathcal{A}_1\text{-measurable,} \\ \omega_2 &\mapsto \int f(\omega_1, \omega_2) \mu_1(d\omega_1) \quad \text{is } \mathcal{A}_2\text{-measurable,}\end{aligned}\tag{14.6}$$

and

$$\begin{aligned}\int_{\Omega_1 \times \Omega_2} f d(\mu_1 \otimes \mu_2) &= \int_{\Omega_1} \left(\int_{\Omega_2} f(\omega_1, \omega_2) \mu_2(d\omega_2) \right) \mu_1(d\omega_1) \\ &= \int_{\Omega_2} \left(\int_{\Omega_1} f(\omega_1, \omega_2) \mu_1(d\omega_1) \right) \mu_2(d\omega_2)\end{aligned}\tag{14.7}$$

Proof The proof follows the usual procedure of stepwise approximations, starting with an indicator function.

First let $f = \mathbb{1}_A$ for $A = A_1 \times A_2$ with $A_1 \in \mathcal{A}_1$ and $A_2 \in \mathcal{A}_2$. Then (14.6) and (14.7) hold trivially. Building finite sums, this is also true for $A \in \mathcal{Z}_*^R$ (the algebra of finite unions of rectangles).

Now let $A \in \mathcal{A}_1 \otimes \mathcal{A}_2$. By the approximation theorem (Theorem 1.65), there is a sequence of sets $(A^n)_{n \in \mathbb{N}}$ in $\mathcal{Z}_*^R$ that approximate A in $\mu_1 \otimes \mu_2$ -measure. As limits of measurable functions are again measurable, and since by construction the integrals converge, (14.6) and (14.7) hold also for $f = \mathbb{1}_A$ and $A \in \mathcal{A}_1 \otimes \mathcal{A}_2$. Building finite sums, (14.6) and (14.7) also hold if f is a simple function.

Consider now $f \geq 0$. Then, by Theorem 1.96, there exists a sequence of simple functions $(f_n)_{n \in \mathbb{N}}$ with $f_n \uparrow f$. By the monotone convergence theorem (Theorem 4.20), (14.6) and (14.7) also hold for this f .

Now let $f \in \mathcal{L}^1(\mu_1 \otimes \mu_2)$. Then $f = f^+ - f^-$ with $f^+, f^- \geq 0$ being integrable functions. Since (14.6) and (14.7) hold for f^- and f^+ , they also hold for f .

In Definition 2.32, we defined the convolution of two real probability measures μ and ν as the distribution of the sum of two independent random variables with distributions μ and ν , respectively. As a simple application of Fubini's theorem, we can give a new definition for the convolution of, more generally, finite measures on $\mathbb{R}^n$. Of course, for real probability measures, it coincides with the old definition. If the measures have Lebesgue densities, then we obtain an explicit formula for the density of the convolution.

Let X and Y be $\mathbb{R}^n$ -valued random variables with densities f_X and f_Y . That is, $f_X, f_Y : \mathbb{R}^n \rightarrow [0, \infty]$ are measurable and integrable with respect to n -dimensional Lebesgue measure λ^n and, for all $x \in \mathbb{R}^n$,

$$\mathbf{P}[X \leq x] = \int_{(-\infty, x]} f_X(t) \lambda^n(dt) \quad \text{and} \quad \mathbf{P}[Y \leq x] = \int_{(-\infty, x]} f_Y(t) \lambda^n(dt).$$

Here $(-\infty, x] = \{y \in \mathbb{R}^n : y_i \leq x_i \text{ for } i = 1, \dots, n\}$ (compare (1.5)).

Definition 14.17 Let $n \in \mathbb{N}$. For two Lebesgue integrable maps $f, g : \mathbb{R}^n \rightarrow [0, \infty]$, define the convolution $f * g : \mathbb{R}^n \rightarrow [0, \infty]$ by

$$(f * g)(x) = \int_{\mathbb{R}^n} f(y)g(x - y)\lambda^n(dy)$$

For two finite measures $\mu, \nu \in \mathcal{M}_f(\mathbb{R}^n)$, define the convolution $\mu * \nu \in \mathcal{M}_f(\mathbb{R}^n)$ by

$$(\mu * \nu)((-\infty, x]) = \iint \mathbb{1}_{A_x}(u, v)\mu(du)\nu(dv)$$

where $A_x := \{(u, v) \in \mathbb{R}^n \times \mathbb{R}^n : u + v \leq x\}$.

Lemma 14.18 The map $f * g$ is measurable and we have $f * g = g * f$ and

$$\int_{\mathbb{R}^n} (f * g)d\lambda^n = \left(\int_{\mathbb{R}^n} f d\lambda^n \right) \left(\int_{\mathbb{R}^n} g d\lambda^n \right)$$

Furthermore, $\mu * \nu = \nu * \mu$ and $(\mu * \nu)(\mathbb{R}^n) = \mu(\mathbb{R}^n)\nu(\mathbb{R}^n)$.

Proof The claims follow immediately from Fubini's theorem.

Theorem 14.19 (Convolution of n -dimensional measures)

- (i) If X and Y are independent $\mathbb{R}^n$ -valued random variables with densities f_X and f_Y , then $X + Y$ has density $f_X * f_Y$.
- (ii) If $\mu = f\lambda^n$ and $\nu = g\lambda^n$ are finite measures with Lebesgue densities f and g , then $\mu * \nu = (f * g)\lambda^n$.

Proof (i) Let $x \in \mathbb{R}^n$ and $A := \{(u, v) \in \mathbb{R}^n \times \mathbb{R}^n : u + v \leq x\}$. Repeated application of Fubini's theorem and the translation invariance of λ^n yields

$$\begin{aligned} \mathbf{P}[X + Y \leq x] &= \mathbf{P}[(X, Y) \in A] \\ &= \int_{\mathbb{R}^n \times \mathbb{R}^n} \mathbb{1}_A(u, v) f_X(u) f_Y(v) (\lambda^n)^{\otimes 2}(d(u, v)) \\ &= \int_{\mathbb{R}^n} \left(\int_{\mathbb{R}^n} \mathbb{1}_A(u, v) f_X(u) \lambda^n(du) \right) f_Y(v) \lambda^n(dv) \\ &= \int_{\mathbb{R}^n} \left(\int_{(-\infty, x-v]} f_X(u) \lambda^n(du) \right) f_Y(v) \lambda^n(dv) \\ &= \int_{\mathbb{R}^n} \left(\int_{(-\infty, x]} f_X(u - v) \lambda^n(du) \right) f_Y(v) \lambda^n(dv) \\ &= \int_{(-\infty, x]} \left(\int_{\mathbb{R}^n} f_X(u - v) f_Y(v) \lambda^n(dv) \right) \lambda^n(du) \\ &= \int_{(-\infty, x]} (f_X * f_Y) d\lambda^n \end{aligned}$$

- (ii) In (i), replace μ by $\mathbf{P}_X$ and ν by $\mathbf{P}_Y$. The claim is immediate.

We come next to a concept that generalizes the notion of product measures and points in the direction of the example from the introduction to this chapter.

Recall the definition of a transition kernel from Definition 8.25.

Lemma 14.20 Let κ be a finite transition kernel from $(\Omega_1, \mathcal{A}_1)$ to $(\Omega_2, \mathcal{A}_2)$ and let $f : \Omega_1 \times \Omega_2 \rightarrow [0, \infty]$ be measurable with respect to $\mathcal{A}_1 \otimes \mathcal{A}_2 - \mathcal{B}([0, \infty])$. Then the map

$$I_f : \Omega_1 \rightarrow [0, \infty] \\ \omega_1 \mapsto \int f(\omega_1, \omega_2) \kappa(\omega_1, d\omega_2)$$

is well-defined and $\mathcal{A}_1$ -measurable.

Proof By Lemma 14.13, for every $\omega_1 \in \Omega_1$, the map f_{ω_1} is measurable with respect to $\mathcal{A}_2$; hence $I_f(\omega_1) = \int f_{\omega_1}(\omega_2) \kappa(\omega_1, d\omega_2)$ is well-defined. Hence, it remains to show measurability of I_f .

If $g = \mathbb{1}_{A_1 \times A_2}$ for some $A_1 \in \mathcal{A}_1$ and $A_2 \in \mathcal{A}_2$, then clearly $I_g(\omega_1) = \mathbb{1}_{A_1}(\omega_1) \kappa(\omega_1, A_2)$ is measurable. Now let

$$\mathcal{D} = \{A \in \mathcal{A}_1 \otimes \mathcal{A}_2 : I_{\mathbb{1}_A} \text{ is } \mathcal{A}_1\text{-measurable}\}$$

We show that $\mathcal{D}$ is a λ -system:

- (i) Evidently, $\Omega_1 \times \Omega_2 \in \mathcal{D}$.
- (ii) If $A, B \in \mathcal{D}$ with $A \subset B$, then $I_{\mathbb{1}_{B \setminus A}} = I_{\mathbb{1}_B} - I_{\mathbb{1}_A}$ is measurable, where we used the fact that κ is finite; hence $B \setminus A \in \mathcal{D}$.
- (iii) If $A_1, A_2, \dots \in \mathcal{D}$ are pairwise disjoint and $A := \bigcup_{n=1}^{\infty} A_n$, then $I_{\mathbb{1}_A} = \sum_{n=1}^{\infty} I_{\mathbb{1}_{A_n}}$ is measurable; hence $A \in \mathcal{D}$.

Summarising, $\mathcal{D}$ is a λ -system that contains a π -system that generates $\mathcal{A}_1 \otimes \mathcal{A}_2$ (namely, the rectangles). Hence, by the $\pi - \lambda$ theorem (Theorem 1.19), $\mathcal{D} = \mathcal{A}_1 \otimes \mathcal{A}_2$. Hence $I_{\mathbb{1}_A}$ is measurable for all $A \in \mathcal{A}_1 \otimes \mathcal{A}_2$. We infer that I_g is measurable for any simple function g . Now let $(f_n)_{n \in \mathbb{N}}$ be a sequence of simple functions with $f_n \uparrow f$. For any fixed $\omega_1 \in \Omega_1$, by the monotone convergence theorem, $I_f(\omega_1) = \lim_{n \rightarrow \infty} I_{f_n}(\omega_1)$. As a limit of measurable functions, I_f is measurable.

Remark 14.21 In the following, we often write $\int \kappa(\omega_1, d\omega_2) f(\omega_1, \omega_2)$ instead of $\int f(\omega_1, \omega_2) \kappa(\omega_1, d\omega_2)$ since for multiple integrals this notation allows us to write the integrator closer to the corresponding integral sign.

Theorem 14.22 Let $(\Omega_i, \mathcal{A}_i)$, $i = 0, 1, 2$, be measurable spaces. Let κ_1 be a finite transition kernel from $(\Omega_0, \mathcal{A}_0)$ to $(\Omega_1, \mathcal{A}_1)$ and let κ_2 be a finite transition kernel from $(\Omega_0 \times \Omega_1, \mathcal{A}_0 \otimes \mathcal{A}_1)$ to $(\Omega_2, \mathcal{A}_2)$. Then the map

$$\kappa_1 \otimes \kappa_2 : \Omega_0 \times (\mathcal{A}_1 \otimes \mathcal{A}_2) \rightarrow [0, \infty) \\ (\omega_0, A) \mapsto \int_{\Omega_1} \kappa_1(\omega_0, d\omega_1) \int_{\Omega_2} \kappa_2((\omega_0, \omega_1), d\omega_2) \mathbb{1}_A((\omega_1, \omega_2))$$

is well-defined and is a σ -finite (but not necessarily a finite) transition kernel from $(\Omega_0, \mathcal{A}_0)$ to $(\Omega_1 \times \Omega_2, \mathcal{A}_1 \otimes \mathcal{A}_2)$. If κ_1 and κ_2 are (sub)stochastic, then $\kappa_1 \otimes \kappa_2$ is (sub)stochastic. We call $\kappa_1 \otimes \kappa_2$ the product of κ_1 and κ_2 .

If κ_2 is a kernel from $(\Omega_1, \mathcal{A}_1)$ to $(\Omega_2, \mathcal{A}_2)$, then we define the product $\kappa_1 \otimes \kappa_2$ similarly by formally understanding κ_2 as a kernel from $(\Omega_0 \times \Omega_1, \mathcal{A}_0 \otimes \mathcal{A}_1)$ to $(\Omega_2, \mathcal{A}_2)$ that does not depend on the Ω_0 -coordinate.

Proof Let $A \in \mathcal{A}_1 \otimes \mathcal{A}_2$. By Lemma 14.20, the map

$$g_A : (\omega_0, \omega_1) \mapsto \int \kappa_2((\omega_0, \omega_1), d\omega_2) \mathbb{1}_A(\omega_1, \omega_2)$$

is well-defined and $\mathcal{A}_0 \otimes \mathcal{A}_1$ -measurable. Thus, again by Lemma 14.20, the map

$$\omega_0 \mapsto \kappa_1 \otimes \kappa_2(\omega_0, A) = \int \kappa_1(\omega_0, d\omega_1) g_A(\omega_0, \omega_1)$$

is well-defined and $\mathcal{A}_0$ -measurable. For fixed ω_0 , by the monotone convergence theorem, the map $A \mapsto \kappa_1 \otimes \kappa_2(\omega_0, A)$ is σ -additive and thus a measure.

For $\omega_0 \in \Omega_0$ and $n \in \mathbb{N}$, let $A_{\omega_0, n} := \{\omega_1 \in \Omega_1 : \kappa_2((\omega_0, \omega_1), \Omega_2) < n\}$. Since κ_2 is finite, we have $\bigcup_{n \geq 1} A_{\omega_0, n} = \Omega_1$ for all $\omega_0 \in \Omega_0$. Furthermore, $\kappa_1 \otimes \kappa_2(\omega_0, A_n \times \Omega_2) \leq n \cdot \kappa_1(\omega_0, \bar{A}_n) < \infty$. Hence $\kappa_1 \otimes \kappa_2(\omega_0, \cdot)$ is σ -finite and is thus a transition kernel.

The supplement is trivial.

Corollary 14.23 (Products via kernels) Let $(\Omega_1, \mathcal{A}_1, \mu)$ be a finite measure space, let $(\Omega_2, \mathcal{A}_2)$ be a measurable space and let κ be a finite transition kernel from Ω_1 to Ω_2 . Then there exists a unique σ -finite measure $\mu \otimes \kappa$ on $(\Omega_1 \times \Omega_2, \mathcal{A}_1 \otimes \mathcal{A}_2)$ with

$$\mu \otimes \kappa(A_1 \times A_2) = \int_{A_1} \kappa(\omega_1, A_2) \mu(d\omega_1) \quad \text{for all } A_1 \in \mathcal{A}_1, A_2 \in \mathcal{A}_2$$

If κ is stochastic and if μ is a probability measure, then $\mu \otimes \kappa$ is a probability measure.

Proof Apply Theorem 14.22 with $\kappa_2 = \kappa$ and $\kappa_1(\omega_0, \cdot) = \mu$.

Corollary 14.24 Let $n \in \mathbb{N}$ and let $(\Omega_i, \mathcal{A}_i)$, $i = 0, \dots, n$, be measurable spaces. For $i = 1, \dots, n$, let κ_i be a substochastic kernel from $(\times_{k=0}^{i-1} \Omega_k, \bigotimes_{k=0}^{i-1} \mathcal{A}_k)$ to $(\Omega_i, \mathcal{A}_i)$ or from $(\Omega_{i-1}, \mathcal{A}_{i-1})$ to $(\Omega_i, \mathcal{A}_i)$. Then the recursion $\kappa_1 \otimes \dots \otimes \kappa_i := (\kappa_1 \otimes \dots \otimes \kappa_{i-1}) \otimes \kappa_i$ for any $i = 1, \dots, n$ defines a substochastic kernel $\bigotimes_{k=1}^i \kappa_k := \kappa_1 \otimes \dots \otimes \kappa_i$ from $(\Omega_0, \mathcal{A}_0)$ to $(\times_{k=1}^i \Omega_k, \bigotimes_{k=1}^i \mathcal{A}_k)$. If all κ_k are stochastic, then all $\bigotimes_{k=1}^i \kappa_k$ are stochastic.

If μ is a finite measure on $(\Omega_0, \mathcal{A}_0)$, then $\mu_i := \mu \otimes \bigotimes_{k=1}^i \kappa_k$ is a finite measure on $(\times_{k=0}^i \Omega_k, \bigotimes_{k=0}^i \mathcal{A}_k)$. If μ is a probability measure and if every κ_i is stochastic, then μ_i is a probability measure.

Proof The claims follow inductively by Theorem 14.22.

Definition 14.25 (Composition of kernels) Let $(\Omega_i, \mathcal{A}_i)$ be measurable spaces, $i = 0, 1, 2$, and let κ_i be a substochastic kernel from $(\Omega_{i-1}, \mathcal{A}_{i-1})$ to $(\Omega_i, \mathcal{A}_i)$, $i = 1, 2$. Define the composition of κ_1 and κ_2 by

$$\begin{aligned} \kappa_1 \cdot \kappa_2 : \Omega_0 \times \mathcal{A}_2 &\rightarrow [0, \infty) \\ (\omega_0, A_2) &\mapsto \int_{\Omega_1} \kappa_1(\omega_0, d\omega_1) \kappa_2(\omega_1, A_2) \end{aligned}$$

Theorem 14.26 If we denote by $\pi_2 : \Omega_1 \times \Omega_2 \rightarrow \Omega_2$ the projection to the second coordinate, then

$$(\kappa_1 \cdot \kappa_2)(\omega_0, A_2) = (\kappa_1 \otimes \kappa_2)(\omega_0, \pi_2^{-1}(A_2)) \quad \text{for all } A_2 \in \mathcal{A}_2$$

In particular, the composition $\kappa_1 \cdot \kappa_2$ is a (sub)stochastic kernel from $(\Omega_0, \mathcal{A}_0)$ to $(\Omega_2, \mathcal{A}_2)$.

Proof This is obvious.

Lemma 14.27 (Kernels and convolution) Let μ and ν be probability measures on $\mathbb{R}^d$ and define the kernels $\kappa_i : (\mathbb{R}^d, \mathcal{B}(\mathbb{R}^d)) \rightarrow (\mathbb{R}^d, \mathcal{B}(\mathbb{R}^d))$, $i = 1, 2$, by $\kappa_1(x, dy) = \mu(dy)$ and $\kappa_2(y, dz) = (\delta_y * \nu)(dz)$. Then $\kappa_1 \cdot \kappa_2 = \mu * \nu$.

Proof This is trivial.

Theorem 14.28 (Kernels and convolution) Assume $X_1, X_2, \dots$ are independent $\mathbb{R}^d$ -valued random variables with distributions $\mu_i := \mathbf{P}_{X_i}$, $i = 1, \dots, n$. Let $S_k := X_1 + \dots + X_k$ for $k = 1, \dots, n$, and define stochastic kernels from $\mathbb{R}^d$ to $\mathbb{R}^d$ by $\kappa_k(x, \cdot) = \delta_x * \mu_k$ for $k = 1, \dots, n$. Then

$$\left(\bigotimes_{k=1}^n \kappa_k \right) (0, \cdot) = \mathbf{P}_{(S_1, \dots, S_n)} \quad (14.8)$$

Proof For $k = 1, \dots, n$, define the measurable bijection $\varphi_k : (\mathbb{R}^d)^k \rightarrow (\mathbb{R}^d)^k$ by

$$\varphi_k(x_1, \dots, x_k) = (x_1, x_1 + x_2, \dots, x_1 + \dots + x_k).$$

Evidently, $\mathcal{B}((\mathbb{R}^d)^n) = \sigma(\varphi_n(A_1 \times \dots \times A_n) : A_1, \dots, A_n \in \mathcal{B}(\mathbb{R}^d))$. Hence, it is enough to show (14.8) for sets of this type. That is, it is enough to show that

$$\left(\bigotimes_{k=1}^n \kappa_k \right) (0, \varphi_n(A_1 \times \dots \times A_n)) = \mathbf{P}_{(S_1, \dots, S_n)}(\varphi_n(A_1 \times \dots \times A_n)) = \prod_{k=1}^n \mu_k(A_k).$$

For $n = 1$, this is clear. By definition, $\kappa_n(y_{n-1}, y_{n-1} + A_n) = \mu_n(A_n)$. Inductively, we get

$$\begin{aligned} & \left(\bigotimes_{k=1}^n \kappa_k \right) (0, \varphi_n(A_1 \times \dots \times A_n)) \\ &= \int_{\varphi_{n-1}(A_1 \times \dots \times A_{n-1})} \left(\bigotimes_{k=1}^{n-1} \kappa_k \right) (0, d(y_1, \dots, y_{n-1})) \kappa_n(y_{n-1}, y_{n-1} + A_n) \\ &= \left(\prod_{k=1}^{n-1} \mu_k(A_k) \right) \mu_n(A_n) \end{aligned}$$

□

Theorem 14.29 (Fubini for transition kernels) Let $(\Omega_i, \mathcal{A}_i)$ be measurable spaces, $i = 1, 2$. Let μ be a finite measure on $(\Omega_1, \mathcal{A}_1)$ and let κ be a finite transition kernel from Ω_1 to Ω_2 . Assume that $f : \Omega_1 \times \Omega_2 \rightarrow \overline{\mathbb{R}}$ is measurable with respect to $\mathcal{A}_1 \otimes \mathcal{A}_2$. If $f \geq 0$ or $f \in \mathcal{L}^1(\mu \otimes \kappa)$, then

$$\int_{\Omega_1 \times \Omega_2} f d(\mu \otimes \kappa) = \int_{\Omega_1} \left(\int_{\Omega_2} f(\omega_1, \omega_2) \kappa(\omega_1, d\omega_2) \right) \mu(d\omega_1) \quad (14.9)$$

Proof For $f = \mathbb{1}_{A_1 \times A_2}$ with $A_1 \in \mathcal{A}_1$ and $A_2 \in \mathcal{A}_2$, the statement is true by definition. For general f , apply the usual approximation argument as in Theorem 14.16. □

Example 14.30 We come back to the example from the beginning of this chapter. Let $n \in \mathbb{N}$ and let $(\Omega_2, \mathcal{A}_2) = (\{0, 1\}^n, (2^{\{0, 1\}})^{\otimes n})$ be the space of n -fold coin tossing. For any $p \in [0, 1]$, define

$$P_p = (\text{Ber}_p)^{\otimes n} = ((1 - p)\delta_0 + p\delta_1)^{\otimes n}.$$

P_p is that probability measure on $(\Omega_2, \mathcal{A}_2)$ under which the coordinate maps Y_i are independent Bernoulli random variables with success probability p .

Further, let $\Omega_1 = [0, 1]$, let $\mathcal{A}_1 = \mathcal{B}([0, 1])$ be the Borel σ -algebra on Ω_1 and let $\mu = \mathcal{U}_{[0, 1]}$ be the uniform distribution on $[0, 1]$. Then the identity map $X : \Omega_1 \rightarrow [0, 1]$ is a random variable on $(\Omega_1, \mathcal{A}_1, \mu)$ that is uniformly distributed on $[0, 1]$.

Finally, consider the stochastic kernel κ from Ω_1 to Ω_2 , defined by

$$\kappa(\omega_1, A_2) = P_{\omega_1}(A_2).$$

If we let $\Omega = \Omega_1 \times \Omega_2$, $\mathcal{A} = \mathcal{A}_1 \otimes \mathcal{A}_2$ and $\mathbf{P} = \mu \otimes \kappa$, then X and $Y_1, \dots, Y_n$ describe precisely the random variables on $(\Omega, \mathcal{A}, \mathbf{P})$ from the beginning of this chapter.

Remark 14.31 The procedure can be extended to n -stage experiments. Let $(\Omega_i, \mathcal{A}_i)$ be the measurable space of the i th experiment, $i = 0, \dots, n - 1$. Let P_0 be a probability measure on $(\Omega_0, \mathcal{A}_0)$. Assume that for $i = 1, \dots, n - 1$, the distribution on $(\Omega_i, \mathcal{A}_i)$ depends on $(\omega_1, \dots, \omega_{i-1})$ and is given by a stochastic kernel κ_i from $\Omega_0 \times \dots \times \Omega_{i-1}$ to Ω_i . The whole n -stage experiment is then described by the coordinate maps on the probability space

$$\left(\bigvee_{i=0}^{n-1} \Omega_i, \bigotimes_{i=0}^{n-1} \mathcal{A}_i, \mathbf{P}_0 \otimes \bigotimes_{i=1}^{n-1} \kappa_i \right)$$

Exercise 14.2.1 Show the following convolution formulas.

- (i) Normal distribution: $\mathcal{N}_{\mu_1, \sigma_1^2} * \mathcal{N}_{\mu_2, \sigma_2^2} = \mathcal{N}_{\mu_1 + \mu_2, \sigma_1^2 + \sigma_2^2}$ for all $\mu_1, \mu_2 \in \mathbb{R}$ and $\sigma_1^2, \sigma_2^2 > 0$.
- (ii) Gamma distribution: $\Gamma_{\theta, r} * \Gamma_{\theta, s} = \Gamma_{\theta, r+s}$ for all $\theta, r, s > 0$.
- (iii) Cauchy distribution: $\text{Cau}_r * \text{Cau}_s = \text{Cau}_{r+s}$ for all $r, s > 0$.

Exercise 14.2.2 (Hilbert-Schmidt operator) Let $(\Omega_i, \mathcal{A}_i, \mu_i), i = 1, 2$, be σ -finite measure spaces and let $a : \Omega_1 \times \Omega_2 \rightarrow \mathbb{R}$ be measurable with

$$\int \mu_1(dt_1) \int \mu_2(dt_2) a(t_1, t_2)^2 < \infty$$

For $f \in \mathcal{L}^2(\mu_1)$, define

$$(Af)(t_2) = \int a(t_1, t_2) f(t_1) \mu_1(dt_1)$$

Show that A is a continuous linear operator from $\mathcal{L}^2(\mu_1)$ to $\mathcal{L}^2(\mu_2)$.

Exercise 14.2.3 (Partial integration) Let F_μ and F_ν be the distribution functions of locally finite measures μ and ν on $\mathbb{R}$. For $x \in \mathbb{R}$, define the left-sided limit $F(x-) = \sup_{y < x} F(y)$ and the jump height $\Delta F(x) = F(x) - F(x-)$. Show that, for $a < b$,

$$\begin{aligned} \int_{(a,b]} F_\mu d\nu &= F_\mu(b)F_\nu(b) - F_\mu(a)F_\nu(a) - \int_{(a,b]} F_\nu(x-) \mu(dx) \\ &= F_\mu(b)F_\nu(b) - F_\mu(a)F_\nu(a) - \int_{(a,b]} F_\nu d\mu + \sum_{a < x \leq b} \Delta F_\mu(x) \Delta F_\nu(x) \end{aligned}$$

5.14.3 14.3 Kolmogorov's Extension Theorem

In the previous section, we saw how we can implement n -stage experiments on a probability space. In this section, we first show how to implement countably many successive experiments on one probability space (Ionescu-Tulcea's theorem). Thereafter we also construct probability measures on products of uncountably many spaces (Kolmogorov's extension theorem).

Let $(\Omega_i, \mathcal{A}_i), i \in \mathbb{N}_0$, be measurable spaces and let P_0 be a probability measure on $(\Omega_0, \mathcal{A}_0)$. Let $\Omega^i := \times_{k=0}^i \Omega_k$ and $\mathcal{A}^i = \bigotimes_{k=0}^i \mathcal{A}_k$ and

$$\Omega := \prod_{k=0}^{\infty} \Omega_k \quad \text{and} \quad \mathcal{A} = \bigotimes_{k=0}^{\infty} \mathcal{A}_k$$

For every $i \in \mathbb{N}$, let κ_i be a stochastic kernel from $(\Omega^{i-1}, \mathcal{A}^{i-1})$ to $(\Omega_i, \mathcal{A}_i)$. In Corollary 14.24, we defined inductively probability measures $P_i = P_0 \otimes \bigotimes_{k=1}^i \kappa_k$ on $(\Omega^i, \mathcal{A}^i)$. By construction, for $i, j \geq k$ and $A \in \mathcal{A}^k$, we had

$$P_i(A \times \Omega_{k+1} \times \dots \times \Omega_i) = P_j(A \times \Omega_{k+1} \times \dots \times \Omega_j). \quad (14.10)$$

Now we want to define a probability measure P on $(\Omega, \mathcal{A})$ such that for $k \in \mathbb{N}_0$ and $A \in \mathcal{A}^k$

$$P\left(A \times \prod_{i=k+1}^{\infty} \Omega_i\right) = P_k(A) \quad (14.11)$$

Theorem 14.32 (Ionescu-Tulcea) There is a uniquely determined probability measure on $(\Omega, \mathcal{A})$ such that (14.11) holds.

Proof Uniqueness is clear since the finite-dimensional rectangular cylinders form a π -system that generates $\mathcal{A}$. It remains to show the existence of that measure.

We use (14.11) to define a set function P on cylinder sets. Clearly, P is additive and is hence a content. If we can show that P is $\emptyset$ -continuous, then P is a premeasure (by Theorem 1.36) and thus by Carathéodory's theorem (Theorem 1.41) can be extended uniquely to a measure on $\mathcal{A}$.

Hence, let $A_0 \supset A_1 \supset A_2 \supset \dots$ be a sequence in $\mathcal{Z}$ with $\alpha := \inf_{n \in \mathbb{N}_0} P(A_n) > 0$. It is enough to show that $\bigcap_{n=0}^{\infty} A_n \neq \emptyset$. Without loss of generality, we can assume that $A_n = A'_n \times \times_{k=n+1}^{\infty} \Omega_k$ for certain $A'_n \in \mathcal{A}^n$. For $n \geq m$, define

$$h_{m,n}(\omega_0, \dots, \omega_m) := \left(\delta_{(\omega_0, \dots, \omega_m)} \otimes \bigotimes_{k=m+1}^n \kappa_k \right) (A'_n)$$

and $h_m := \inf_{n \geq m} h_{m,n}$. Inductively, we show that for every $i \in \mathbb{N}_0$, there exists a $\varrho_i \in \Omega_i$ such that

$$h_m(\varrho_0, \dots, \varrho_m) \geq \alpha \quad (14.12)$$

Since $A'_{n+1} \subset A'_n \times \Omega_{n+1}$, we have

$$\begin{aligned} h_{m,n+1}(\omega_0, \dots, \omega_m) &= \left(\delta_{(\omega_0, \dots, \omega_m)} \otimes \bigotimes_{k=m+1}^{n+1} \kappa_k \right) (A'_{n+1}) \\ &\leq \left(\delta_{(\omega_0, \dots, \omega_m)} \otimes \bigotimes_{k=m+1}^{n+1} \kappa_k \right) (A'_n \times \Omega_{n+1}) \\ &= \left(\delta_{(\omega_0, \dots, \omega_m)} \otimes \bigotimes_{k=m+1}^n \kappa_k \right) (A'_n) = h_{m,n}(\omega_0, \dots, \omega_m) \end{aligned}$$

Hence $h_{m,n} \downarrow h_m$ for $n \rightarrow \infty$ and by the monotone convergence theorem,

$$\int h_m dP_m = \inf_{n \geq m} \int h_{m,n} dP_m = \inf_{n \in \mathbb{N}_0} P_n(A'_n) = \alpha$$

whence we have (14.12) for $m = 0$. Now assume that (14.12) holds for $m \in \mathbb{N}_0$. Then

$$\begin{aligned} &\int h_{m+1}(\varrho_0, \dots, \varrho_m, \omega_{m+1}) \kappa_{m+1}((\varrho_0, \dots, \varrho_m), d\omega_{m+1}) \\ &= \inf_{n \geq m+1} \int h_{m+1,n}(\varrho_0, \dots, \varrho_m, \omega_{m+1}) \kappa_{m+1}((\varrho_0, \dots, \varrho_m), d\omega_{m+1}) \\ &= h_m(\varrho_0, \dots, \varrho_m) \geq \alpha \end{aligned}$$

Hence (14.12) holds for $m + 1$.

Let $\varrho := (\varrho_0, \varrho_1, \dots) \in \Omega$. By construction,

$$\alpha \leq h_{m,m}(\varrho_0, \dots, \varrho_m) = \mathbb{1}_{A'_m}(\varrho_0, \dots, \varrho_m)$$

hence $\varrho \in A_m$ for all $m \in \mathbb{N}_0$ and thus $\bigcap_{i=0}^{\infty} A_i \neq \emptyset$.

Corollary 14.33 (Product measure) For every $n \in \mathbb{N}_0$, let P_n be a probability measure on $(\Omega_n, \mathcal{A}_n)$. Then there exists a uniquely determined probability measure P on $(\Omega, \mathcal{A})$ with

$$P\left(A_0 \times \dots \times A_n \times \prod_{i=n+1}^{\infty} \Omega_i\right) = \prod_{k=0}^n P_k(A_k)$$

for $A_i \in \mathcal{A}_i, i = 0, \dots, n$ and $n \in \mathbb{N}_0$.

$\bigotimes_{i=0}^{\infty} P_i := P$ is called the product of the measures $P_0, P_1, \dots$. Under P , the coordinate maps $(X_i)_{i \in \mathbb{N}_0}$ are independent.

Proof This follows by Ionescu-Tulcea's theorem with

$$\kappa_i((\omega_0, \dots, \omega_{i-1}), \cdot) = P_i$$

We want to make a statement similar to that of Ionescu-Tulcea's theorem; however, without the assumption that the measures P_k are defined a priori by kernels. Before we formulate the theorem, we generalize the consistency condition (14.10). Recall that for $L \subset J \subset I, X_L^J : \Omega_J \rightarrow \Omega_L$ denotes the canonical projection.

Definition 14.34 A family $(P_J, J \subset I \text{ finite})$ of probability measures on the space $(\Omega_J, \mathcal{A}_J)$ is called consistent if

$$P_L = P_J \circ (X_L^J)^{-1} \quad \text{for all } L \subset J \subset I \text{ finite.}$$

Recall that $\Omega = \prod_{i \in I} \Omega_i$ and $\mathcal{A} = \bigotimes_{i \in I} \mathcal{A}_i$. Let P be a probability measure on $(\Omega, \mathcal{A})$. Since $X_L = X_L^J \circ X_J$, the family $(P_J := P \circ X_J^{-1}, J \subset I \text{ finite})$ is consistent. Thus, consistency is a necessary condition for the existence of a measure P on the product space with $P_J := P \circ X_J^{-1}$. If all the measurable spaces are Borel spaces (recall Definition 8.35), for example $\mathbb{R}^d, \mathbb{Z}^d, C([0, 1])$ or more general Polish spaces, then this condition is also sufficient. We formulate this statement first for a countable index set.

Theorem 14.35 Let I be countable and let $(\Omega_i, \mathcal{A}_i)$ be Borel spaces for all $i \in I$. Let $(P_J, J \subset I \text{ finite})$ be a consistent family of probability measures. Then there exists a unique probability measure P on $(\Omega, \mathcal{A})$ with $P_J = P \circ X_J^{-1}$ for all finite $J \subset I$.

Proof Without loss of generality, assume $I = \mathbb{N}_0$. Let $P_n := P_{\{0, \dots, n\}}, \Omega^n := \Omega_{\{0, \dots, n\}}$ and $\mathcal{A}^n := \mathcal{A}_{\{0, \dots, n\}}$. It is easy to check that finite products of Borel spaces are again Borel spaces; hence $(\Omega^n, \mathcal{A}^n)$ is Borel for all $n \in \mathbb{N}_0$.

Let $\mathcal{F} := \{A \times \Omega_{n+1} : A \in \mathcal{A}^n\}, Y : \Omega^{n+1} \rightarrow \Omega_{n+1}, (\omega_0, \dots, \omega_{n+1}) \mapsto \omega_{n+1}$ and $Z : \Omega^{n+1} \rightarrow \Omega^n, (\omega_0, \dots, \omega_{n+1}) \mapsto (\omega_0, \dots, \omega_n)$. By Theorem 8.37 (with $\Omega = \Omega^{n+1}, \mathcal{A} = \mathcal{A}^{n+1}$ and $E = \Omega_{n+1}$), there is a stochastic kernel κ'_{n+1} from $(\Omega^{n+1}, \mathcal{F})$ to $(\Omega_{n+1}, \mathcal{A}_{n+1})$ such that κ'_{n+1} is a regular conditional distribution of Y given $\mathcal{F}$ (under the probability measure P_{n+1}). Hence, for $A \in \mathcal{A}^n$ and $B \in \mathcal{A}_{n+1}$, we have (compare (8.10))

$$P_{n+1}(A \times B) = \int \mathbb{1}_B(Y) \mathbb{1}_{A \times \Omega_{n+1}} dP_{n+1} = \int \kappa'_{n+1}(\cdot, B) \mathbb{1}_{A \times \Omega_{n+1}} dP_{n+1}$$

Since $\kappa'_{n+1}(\cdot, B)$ is $\mathcal{F}$ -measurable, there is a stochastic kernel κ_{n+1} from $(\Omega^n, \mathcal{A}^n)$ to $(\Omega_{n+1}, \mathcal{A}_{n+1})$ such that

$$\kappa_{n+1}((\omega_0, \dots, \omega_n), \cdot) = \kappa'_{n+1}((\omega_0, \dots, \omega_{n+1}), \cdot) \quad \text{for all } \omega_0, \dots, \omega_{n+1}.$$

Hence

$$\kappa'_{n+1}(\cdot, B) = \kappa_{n+1}(Z(\cdot), B) \quad \text{and} \quad \mathbb{1}_{A \times \Omega_{n+1}} = \mathbb{1}_A(Z).$$

We infer that

$$\begin{aligned} P_{n+1}(A \times B) &= \int \kappa_{n+1}(Z, B) \mathbb{1}_A(Z) dP_{n+1} \\ &= \int \kappa_{n+1}(\cdot, B) \mathbb{1}_A d(P_{n+1} \circ Z^{-1}) \\ &= \int \kappa_{n+1}(\cdot, B) dP_n \end{aligned}$$

Note that in the last equality we used the fact that $(P_n)_{n \in \mathbb{N}_0}$ is a projective family. By Corollary 14.23, we get $P_{n+1} = P_n \otimes \kappa_{n+1}$. Recursively, we obtain $P_n = P_0 \otimes \bigotimes_{k=1}^n \kappa_k$ for all $n \in \mathbb{N}$. Using Theorem 14.32, this yields the claim.

The last step in our construction is to replace the countable index set I by an arbitrary index set.

Theorem 14.36 (Kolmogorov's extension theorem) Let I be an arbitrary index set and let $(\Omega_i, \mathcal{A}_i)$ be Borel spaces, $i \in I$. Let $(P_J, J \subset I \text{ finite})$ be a consistent family of probability measures. Then there exists a unique probability measure P on $(\Omega, \mathcal{A})$ with $P_J = P \circ X_J^{-1}$ for every finite $J \subset I$. P is called the projective limit and will be denoted by $P =: \lim_{\leftarrow J \uparrow I} P_J$.

Proof For countable $J \subset I$, by Theorem 14.35, there is a unique probability measure P_J on $(\Omega_J, \mathcal{A}_J)$ with $P_J \circ (X_K^J)^{-1} = P_K$ for finite $K \subset J$. By defining $\tilde{P}_J(X_J^{-1}(A_J)) := P_J(A_J)$ for $A_J \in \mathcal{A}_J$, we get a probability measure $\tilde{P}_J$ on $(\Omega, \sigma(X_J))$.

Let $J, J' \subset I$ be countable and let $A \in \sigma(X_J) \cap \sigma(X_{J'}) \cap \mathcal{Z}$ be a $\sigma(X_J) \cap \sigma(X_{J'})$ -measurable cylinder with a finite base. Then there exists a finite $K \subset J \cap J'$ and $A_K \in \mathcal{A}_K$ with $A = X_K^{-1}(A_K)$. Hence $\tilde{P}_J(A) = P_K(A_K) = \tilde{P}_{J'}(A)$. Moreover, by Theorem 14.12, $\tilde{P}_J(A) = P_K(A_K) = \tilde{P}_{J'}(A)$ for all $A \in \sigma(X_J) \cap \sigma(X_{J'})$. Now, by Exercise 14.1.1, for any $A \in \mathcal{A}$, there is a countable $J \subset I$ with $A \in \sigma(X_J)$. Hence, independently of the choice of J , we can uniquely define a set function P on $\mathcal{A}$ by $P(A) = \tilde{P}_J(A)$. It remains to show that P is a probability measure. Evidently, $P(\Omega) = 1$. If $A_1, A_2, \dots \in \mathcal{A}$ are pairwise disjoint and $A := \bigcup_{n=1}^{\infty} A_n$, then for any $n \in \mathbb{N}$, there is a countable $J_n \subset I$ with $A_n \in \sigma(X_{J_n})$. Define $J = \bigcup_{n \in \mathbb{N}} J_n$. Then each A_n is in $\sigma(X_J)$; thus $A \in \sigma(X_J)$. Therefore,

$$P(A) = \tilde{P}_J(A) = \sum_{n=1}^{\infty} \tilde{P}_J(A_n) = \sum_{n=1}^{\infty} P(A_n).$$

This shows that P is a probability measure.

Example 14.37 Let $((\Omega_i, \tau_i), i \in I)$ be an arbitrary family of Polish spaces (recall from Theorem 8.36 that Polish spaces are also Borel spaces). Let $\mathcal{A}_i = \sigma(\tau_i)$ and let

P_i be an arbitrary probability measure on $(\Omega_i, \mathcal{A}_i)$ for every $i \in I$. For finite $J \subset I$, let $P_J := \bigotimes_{j \in J} P_j$ be the product measure of the $P_j, j \in J$. Evidently, the family $(P_J, J \subset I \text{ finite})$ is consistent. We call

$$P = \bigotimes_{i \in I} P_i := \lim_{\leftarrow J \uparrow I} P_J$$

the product measure on $(\Omega, \mathcal{A})$. Under P , all coordinate maps X_j are independent.

Example 14.38 (Pólya's urn model) (Compare Example 12.29.) In an urn there are initially k red and $n - k$ blue balls. At each step, one ball is drawn at random and is returned to the urn with an additional ball of the same color. Hence, at time $i \in \mathbb{N}_0$ there are $n + i$ balls in the urn. The random number of red balls is denoted by X_i .

For a more formal description, let $n \in \mathbb{N}$ and $k \in \{0, \dots, n\}$. Let $I = \mathbb{N}_0, \Omega_i = \{0, \dots, n + i\}, i \in \mathbb{N}$. Let $P_0[\{k\}] = 1$, and define the stochastic kernels κ_i from Ω_i to Ω_{i+1} by

$$\kappa_i(x_i, \{x_{i+1}\}) = \begin{cases} \frac{x_i}{n+i}, & \text{if } x_{i+1} = x_i + 1 \\ 1 - \frac{x_i}{n+i}, & \text{if } x_{i+1} = x_i \\ 0, & \text{else.} \end{cases}$$

Now let $P_{i+1} = P_i \otimes \kappa_i$. Under the measure $\mathbf{P} = \lim_{\leftarrow i \rightarrow \infty} P_i$, the projections $(X_i, i \in \mathbb{N}_0)$ describe Pólya's urn model.

5.14.4 14.4 Markov Semigroups

Definition 14.39 Let E be a Polish space. Let $I \subset \mathbb{R}$ be a nonempty index set and let $(\kappa_{s,t} : s, t \in I, s < t)$ be a family of stochastic kernels from E to E . We say that the family is consistent if $\kappa_{r,s} \cdot \kappa_{s,t} = \kappa_{r,t}$ for any choice of $r, s, t \in I$ with $r < s < t$.

Definition 14.40 Let E be a Polish space. Let $I \subset [0, \infty)$ be an additive semigroup (for example, $I = \mathbb{N}_0$ or $I = [0, \infty)$). A family $(\kappa_t : t \in I)$ of stochastic kernels is called a semigroup of stochastic kernels, or a Markov semigroup, if

$$\kappa_0(\omega, \cdot) = \delta_\omega \quad \text{for all } \omega \in \Omega \quad (14.13)$$

and if it satisfies the Chapman-Kolmogorov equation:

$$\kappa_s \cdot \kappa_t = \kappa_{s+t} \quad \text{for all } s, t \in I \quad (14.14)$$

Indeed, $(\{\kappa_t : t \in I\}, \cdot)$ is a semigroup in the algebraic sense and the map $t \rightarrow \kappa_t$ is a homomorphism of semigroups. In particular, the kernels commute in the sense that $\kappa_s \cdot \kappa_t = \kappa_t \cdot \kappa_s$ for all $s, t \in I$.

Lemma 14.41 If $(\kappa_t : t \in I)$ is a Markov semigroup, then the family of kernels, defined by $\tilde{\kappa}_{s,t} := \kappa_{t-s}$ for $t > s$, is consistent.

Proof This is trivial.

Theorem 14.42 (Kernel via a consistent family of kernels) Let $I \subset [0, \infty)$ with $0 \in I$ and let $(\kappa_{s,t} : s, t \in I, s < t)$ be a consistent family of stochastic kernels on the Polish space E . Then there exists a kernel κ from $(E, \mathcal{B}(E))$ to $(E^I, \mathcal{B}(E)^{\otimes I})$ such that, for all $x \in E$ and for any choice of finitely many numbers $0 = j_0 < j_1 < j_2 < \dots < j_n$ from I , and with the notation $J := \{j_0, \dots, j_n\}$, we have

$$\kappa(x, \cdot) \circ X_J^{-1} = \left(\delta_x \otimes \bigotimes_{k=0}^{n-1} \kappa_{j_k, j_{k+1}} \right) \quad (14.15)$$

Proof First we show that, for fixed $x \in E$, (14.15) defines a probability measure $\kappa(x, \cdot)$. Define the family $(P_J : J \subset I \text{ finite}, 0 \in J)$ by $P_J := \delta_x \otimes \bigotimes_{k=0}^{n-1} \kappa_{j_k, j_{k+1}}$. By Kolmogorov's extension theorem, it is enough to show that this family is consistent. In fact, if for $0 \notin J \subset I$ finite, we define P_J as the projection of $P_{J \cup \{0\}}$ to E^J , then the family $(P_J : J \subset I \text{ finite})$ is projective. Hence, let $0 \in L \subset J \subset I$ with $J \subset I$ finite. We have to show that $P_J \circ (X_L^J)^{-1} = P_L$. We may assume that $L = J \setminus \{j_l\}$ for some $l = 1, \dots, n$. The general case can be inferred inductively.

First consider $l = n$. Let $A_{j_0}, \dots, A_{j_{n-1}} \in \mathcal{B}(E)$ and $A := \times_{j \in L} A_j$. Then

$$\begin{aligned} P_J \circ (X_L^J)^{-1}(A) &= P_J(A \times E) = P_L \otimes \kappa_{j_{n-1}, j_n}(A \times E) \\ &= \int_A P_L(d(\omega_0, \dots, \omega_{n-1})) \kappa_{j_{n-1}, j_n}(\omega_{n-1}, E) = P_L(A) \end{aligned}$$

Now let $l \in \{1, \dots, n-1\}$. For all $j \in L$, let $A_j \in \mathcal{B}(E)$ and $A_{j_l} := E$. Define $A := \times_{j \in L} A_j$, and abbreviate $A' = \times_{k=0}^{l-1} A_{j_k}$ and $P' = \delta_x \otimes \bigotimes_{k=0}^{l-2} \kappa_{j_k, j_{k+1}}$. For $i = 0, \dots, n-1$, let

$$f_i(\omega_i) = \left(\bigotimes_{k=i}^{n-1} \kappa_{j_k, j_{k+1}} \right) (\omega_i, A_{j_{i+1}} \times \dots \times A_{j_n})$$

By assumption and using Fubini's theorem, we get

$$\begin{aligned}
f_{l-1}(\omega_{l-1}) &= \int_E \kappa_{j_{l-1}, j_l}(\omega_{l-1}, d\omega_l) \int_{A_{j_{l+1}}} \kappa_{j_l, j_{l+1}}(\omega_l, d\omega_{l+1}) f_{l+1}(\omega_{l+1}) \\
&= \int_{A_{j_{l+1}}} \kappa_{j_{l-1}, j_{l+1}}(\omega_{l-1}, d\omega_{l+1}) f_{l+1}(\omega_{l+1})
\end{aligned}$$

This implies

$$\begin{aligned}
P_J \circ (X_L^J)^{-1}(A) &= \int_{A'} P'(d(\omega_0, \dots, \omega_{l-1})) f_{l-1}(\omega_{l-1}) \\
&= \int_{A'} P'(d(\omega_0, \dots, \omega_{l-1})) \int_{A_{j_{l+1}}} (\kappa_{j_{l-1}, j_{l+1}})(\omega_{l-1}, d\omega_{l+1}) f_{l+1}(\omega_{l+1}) \\
&= P_L(A)
\end{aligned}$$

It remains to show that κ is a stochastic kernel. That is, we have to show that $x \mapsto \kappa(x, A)$ is measurable with respect to $\mathcal{B}(E) - \mathcal{B}(E)^{\otimes I}$. By Remark 8.26, it suffices to check this for rectangular cylinders with a finite base $A \in \mathcal{Z}^R$ since $\mathcal{Z}^R$ is a π system that generates $\mathcal{B}(E)^{\otimes I}$. Hence, let $0 = t_0 < t_1 < \dots < t_n$ and $B_0, \dots, B_n \in \mathcal{B}(E)$ as well as $A = \bigcap_{i=0}^n X_{t_i}^{-1}(B_i)$. However, by Corollary 14.24, the following map is measurable,

$$x \mapsto \mathbf{P}_x[A] = \left(\delta_x \otimes \bigotimes_{i=0}^{n-1} \kappa_{t_i, t_{i+1}} \right) \left(\begin{matrix} n \\ \bigcup_{i=0}^n B_i \end{matrix} \right)$$

Corollary 14.43 (Measures by consistent families of kernels) Under the assumptions of Theorem 14.42, for every probability measure μ on E , there exists a unique probability measure $\mathbf{P}_\mu$ on $(E^I, \mathcal{B}(E)^{\otimes I})$ with the following property: For any choice of finitely many numbers $0 = j_0 < j_1 < j_2 < \dots < j_n$ from I , and letting $J := \{j_0, \dots, j_n\}$, we have $\mathbf{P}_\mu \circ X_J^{-1} = \mu \otimes \bigotimes_{k=0}^{n-1} \kappa_{j_k, j_{k+1}}$.

Proof Take $\mathbf{P}_\mu = \int \mu(dx) \kappa(x, \cdot)$.

As a simple conclusion of Lemma 14.41 and Theorem 14.42, we get the following statement that we formulate separately because it will play a central role later.

Corollary 14.44 (Measures via Markov semigroups) Let $(\kappa_t : t \in I)$ be a Markov semigroup on the Polish space E . Then there exists a unique stochastic kernel κ from $(E, \mathcal{B}(E))$ to $(E^I, \mathcal{B}(E)^{\otimes I})$ with the property: For all $x \in E$ and for any choice of finitely many numbers $0 = t_0 < t_1 < t_2 < \dots < t_n$ from I , and letting $J := \{t_0, \dots, t_n\}$, we have

$$\kappa(x, \cdot) \circ X_J^{-1} = \left(\delta_x \otimes \bigotimes_{k=0}^{n-1} \kappa_{t_{k+1}-t_k} \right) \quad (14.16)$$

For any probability measure μ on E , there exists a unique probability measure $\mathbf{P}_\mu$ on $(E^I, \mathcal{B}(E)^{\otimes I})$ with the property: For any choice of finitely many numbers $0 = t_0 < t_1 < t_2 < \dots < t_n$ from I , and letting $J := \{t_0, \dots, t_n\}$, we have $\mathbf{P}_\mu \circ X_J^{-1} = \mu \otimes \bigotimes_{k=0}^{n-1} \kappa_{t_{k+1}-t_k}$. We denote $\mathbf{P}_x = \mathbf{P}_{\delta_x} = \kappa(x, \cdot)$ for $x \in E$.

Example 14.45 (Independent normally distributed increments) Let $I = [0, \infty)$ and $\Omega_i = \mathbb{R}, i \in [0, \infty)$, equipped with the Borel σ -algebra $\mathcal{B} = \mathcal{B}(\mathbb{R})$. Further, let $\Omega = \mathbb{R}^{[0, \infty)}, \mathcal{A} = \mathcal{B}^{\otimes [0, \infty)}$ and let X_t be the coordinate map for $t \in [0, \infty)$. In the sense of Definition 14.6, $X = (X_t)_{t \geq 0}$ is thus the canonical process on $(\Omega, \mathcal{A})$.

We construct a probability measure $\mathbf{P}$ on $(\Omega, \mathcal{A})$ such that the stochastic process X has independent, stationary, normally distributed increments (recall Definition 9.7). That is, it should hold that

$$(X_{t_i} - X_{t_{i-1}})_{i=1,\dots,n} \text{ is independent for all } 0 =: t_0 < t_1 < \dots < t_n, \quad (14.17)$$

$$\mathbf{P}_{X_t - X_s} = \mathcal{N}_{0,t-s} \quad \text{for all } t > s \quad (14.18)$$

To this end, define stochastic kernels $\kappa_t(x, dy) := \delta_x * \mathcal{N}_{0,t}(dy)$ for $t \in [0, \infty)$ where $\mathcal{N}_{0,0} = \delta_0$. By Lemma 14.27, the Chapman-Kolmogorov equation holds since (compare Exercise 14.2.1(i))

$$\kappa_s \cdot \kappa_t(x, dy) = \delta_x * (\mathcal{N}_{0,s} * \mathcal{N}_{0,t})(dy) = \delta_x * \mathcal{N}_{0,s+t}(dy) = \kappa_{s+t}(x, dy)$$

Let $P_0 = \delta_0$ and let $\mathbf{P}$ be the unique probability measure on Ω corresponding to P_0 and $(\kappa_t : t \geq 0)$ according to Corollary 14.44. By Theorem 14.28, Eqs. (14.17) and (14.18) hold.

With $(X_t)_{t \geq 0}$, we have almost constructed the so-called Brownian motion. In addition to the properties we required here, Brownian motion has continuous paths; that is, the maps $t \mapsto X_t$ are almost surely continuous. Note that at this point it is not even clear that the paths are measurable maps. We will have some work to do to establish continuity of the paths, and we will come back to this in Chapter 21.

The construction in the preceding example does not depend on the details of the normal distribution but only on the validity of the convolution equation

$$\mathcal{N}_{0,s+t} = \mathcal{N}_{0,s} * \mathcal{N}_{0,t}$$

Hence, in (14.18) we can replace the normal distribution by any parameterized family of distributions $(v_t, t \geq 0)$ with the property $v_{t+s} = v_t * v_s$. Examples include the Gamma distribution $v_t = \Gamma_{\theta,t}$ (for fixed parameter $\theta > 0$), the Poisson distribution $v_t = \text{Poi}_t$, the negative binomial distribution $v_t = b_{t,p}^-$ (for fixed $p \in (0, 1]$), the Cauchy distribution $v_t = \text{Cau}_t$ and others (compare Theorem 15.12 and Corollary 15.13). We establish the result in a theorem.

Definition 14.46 (Convolution semigroup) Let $I \subset [0, \infty)$ be a semigroup. A family $v = (v_t : t \in I)$ of probability distributions on $\mathbb{R}^d$ is called a convolution semigroup if $v_{s+t} = v_s * v_t$ holds for all $s, t \in I$.

If $I = [0, \infty)$ and if in addition $v_t \xrightarrow{t \rightarrow 0} \delta_0$, then the convolution semigroup is called continuous (in the sense of weak convergence).

If $d = 1$ and $v_t((-\infty, 0)) = 0$ for all $t \in I$, then v is called a nonnegative convolution semigroup.

For the following theorem, compare Definition 9.7.

Theorem 14.47 For any convolution semigroup $(v_t : t \in I)$ and any $x \in \mathbb{R}^d$, there exists a probability measure $\mathbf{P}_x$ on the product space $(\Omega, \mathcal{A}) = \left((\mathbb{R}^d)^I, \mathcal{B}(\mathbb{R}^d)^{\otimes I} \right)$ such that the canonical process $(X_t)_{t \in I}$ is a stochastic process with $\mathbf{P}_x[X_0 = x] = 1$, with stationary independent increments and with $\mathbf{P}_x \circ (X_t - X_s)^{-1} = v_{t-s}$ for $t > s$. On the other hand, every stochastic process $(X_t)_{t \in I}$ (on an arbitrary probability space $(\Omega, \mathcal{A}, \mathbf{P})$) with stationary independent increments defines a convolution semigroup by $v_t = \mathbf{P} \circ (X_t - X_0)^{-1}$ for all $t \in I$.

Exercise 14.4.1 Assume that $(v_t : t \geq 0)$ is a continuous convolution semigroup. Show that $v_t = \lim_{s \rightarrow t} v_s$ for all $t > 0$.

Exercise 14.4.2 Assume that $(v_t : t \geq 0)$ is a convolution semigroup. Show that $v_{t/n} \xrightarrow{n \rightarrow \infty} \delta_0$.

Exercise 14.4.3 Show that a nonnegative convolution semigroup is continuous.

Exercise 14.4.4 Show that a continuous real convolution semigroup $(v_t : t \geq 0)$ with $v_t((-\infty, 0)) = 0$ for some $t > 0$ is nonnegative.

5.15 15 Characteristic Functions and the Central Limit Theorem

The main goal of this chapter is the central limit theorem (CLT) for sums of independent random variables (Theorem 15.37) and for independent arrays of random variables (Lindeberg-Feller theorem, Theorem 15.43). For the latter, we prove only that one of the two implications (Lindeberg's theorem) that is of interest in the applications.

The ideal tools for the treatment of central limit theorems are so-called characteristic functions; that is, Fourier transforms of probability measures. We start with a more general treatment of classes of test functions that are suitable to characterize weak convergence and then study Fourier transforms in greater detail. The subsequent section proves the CLT for real-valued random variables by means of characteristic functions. In the fifth section, we prove a multidimensional version of the CLT.

5.15.1 15.1 Separating Classes of Functions

Let (E, d) be a metric space with Borel σ -algebra $\mathcal{E} = \mathcal{B}(E)$. Denote by $\mathbb{C} = \{u + iv : u, v \in \mathbb{R}\}$ the field of complex numbers. Let

$$\operatorname{Re}(u + iv) = u \quad \text{and} \quad \operatorname{Im}(u + iv) = v$$

denote the real part and the imaginary part, respectively, of $z = u + iv \in \mathbb{C}$. Let $\bar{z} = u - iv$ be the complex conjugate of z and $|z| = \sqrt{u^2 + v^2}$ its modulus. A prominent role will be played by the complex exponential function $\exp : \mathbb{C} \rightarrow \mathbb{C}$, which can be defined either by Euler's formula $\exp(z) = \exp(u)(\cos(v) + i \sin(v))$ or by the power series $\exp(z) = \sum_{n=0}^{\infty} z^n/n!$. It is well-known that $\exp(z_1 + z_2) = \exp(z_1) \cdot \exp(z_2)$. Note that $\operatorname{Re}(z) = (z + \bar{z})/2$ and $\operatorname{Im}(z) = (z - \bar{z})/2i$ imply

$$\cos(x) = \frac{e^{ix} + e^{-ix}}{2} \quad \text{and} \quad \sin(x) = \frac{e^{ix} - e^{-ix}}{2i} \quad \text{for all } x \in \mathbb{R}$$

A map $f : E \rightarrow \mathbb{C}$ is measurable if and only if $\operatorname{Re}(f)$ and $\operatorname{Im}(f)$ are measurable (see Theorem 1.90 with $\mathbb{C} \cong \mathbb{R}^2$). In particular, any continuous function $E \rightarrow \mathbb{C}$ is measurable. If $\mu \in \mathcal{M}(E)$, then we define

$$\int f d\mu := \int \operatorname{Re}(f) d\mu + i \int \operatorname{Im}(f) d\mu$$

if both integrals exist and are finite. Let $C_b(E; \mathbb{C})$ denote the Banach space of continuous, bounded, complex-valued functions on E equipped with the supremum norm $\|f\|_{\infty} = \sup\{|f(x)| : x \in E\}$. We call $\mathcal{C} \subset C_b(E; \mathbb{C})$ a separating class for $\mathcal{M}_f(E)$ if for any two measures $\mu, \nu \in \mathcal{M}_f(E)$ with $\mu \neq \nu$, there is an $f \in \mathcal{C}$ such that $\int f d\mu \neq \int f d\nu$. The analogue of Theorem 13.34 holds for $\mathcal{C} \subset C_b(E; \mathbb{C})$.

Definition 15.1 Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. A subset $\mathcal{C} \subset C_b(E; \mathbb{K})$ is called an algebra if

- (i) $1 \in \mathcal{C}$,
- (ii) if $f, g \in \mathcal{C}$, then $f \cdot g$ and $f + g$ are in $\mathcal{C}$, and
- (iii) if $f \in \mathcal{C}$ and $\alpha \in \mathbb{K}$, then (αf) is in $\mathcal{C}$.

We say that $\mathcal{C}$ separates points if for any two points $x, y \in E$ with $x \neq y$, there is an $f \in \mathcal{C}$ with $f(x) \neq f(y)$.

Theorem 15.2 (Stone-Weierstraß) Let E be a compact Hausdorff space. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. Let $\mathcal{C} \subset C_b(E; \mathbb{K})$ be an algebra that separates points. If $\mathbb{K} = \mathbb{C}$, then in addition assume that $\mathcal{C}$ is closed under complex conjugation (that is, if $f \in \mathcal{C}$, then the complex conjugate function $\bar{f}$ is also in $\mathcal{C}$).

Then $\mathcal{C}$ is dense in $C_b(E; \mathbb{K})$ with respect to the supremum norm.

Proof We follow the exposition in Dieudonné [34, Chapter VII.3]. First consider the case $\mathbb{K} = \mathbb{R}$. We proceed in several steps.

Step 1. By Weierstraß's approximation theorem (Example 5.15), there is a sequence $(p_n)_{n \in \mathbb{N}}$ of polynomials that approach the map $[0, 1] \rightarrow [0, 1], t \mapsto \sqrt{t}$ uniformly. If $f \in \mathcal{C}$, then also

$$|f| = \|f\|_\infty \lim_{n \rightarrow \infty} p_n(f^2/\|f\|_\infty^2)$$

is in the closure $\bar{\mathcal{C}}$ of $\mathcal{C}$ in $C_b(E; \mathbb{R})$.

Step 2. Applying Step 1 to the algebra $\bar{\mathcal{C}}$ yields that, for all $f, g \in \bar{\mathcal{C}}$,

$$f \vee g = \frac{1}{2}(f + g + |f - g|) \quad \text{and} \quad f \wedge g = \frac{1}{2}(f + g - |f - g|)$$

are also in $\bar{\mathcal{C}}$.

Step 3. For any $f \in C_b(E; \mathbb{R})$, any $x \in E$ and any $\varepsilon > 0$, there exists a $g_x \in \bar{\mathcal{C}}$ with $g_x(x) = f(x)$ and $g_x(y) \leq f(y) + \varepsilon$ for all $y \in E$. As $\mathcal{C}$ separates points, for any $z \in E \setminus \{x\}$, there exists an $H_z \in \mathcal{C}$ with $H_z(z) \neq H_z(x) = 0$. For such z , define $h_z \in \mathcal{C}$ by

$$h_z(y) = f(x) + \frac{f(z) - f(x)}{H_z(z)} H_z(y) \quad \text{for all } y \in E.$$

In addition, define $h_x := f$. Then $h_z(x) = f(x)$ and $h_z(z) = f(z)$ for all $z \in E$. Since f and h_z are continuous, for any $z \in E$, there exists an open neighborhood $U_z \ni z$ with $h(y) \leq f(y) + \varepsilon$ for all $y \in U_z$. We construct a finite covering $U_{z_1}, \dots, U_{z_n}$ of E consisting of such neighborhoods and define $g_x = \min(h_{z_1}, \dots, h_{z_n})$. By Step 2, we have $g_x \in \bar{\mathcal{C}}$.

Step 4. Let $f \in C_b(E; \mathbb{R})$, $\varepsilon > 0$ and, for any $x \in E$, let g_x be as in Step 3. As f and g_x are continuous, for any $x \in E$, there exists an open neighborhood $V_x \ni x$ with $g_x(y) \geq f(y) - \varepsilon$ for any $y \in V_x$. We construct a finite covering $V_{x_1}, \dots, V_{x_n}$ of E and define $g := \max(g_{x_1}, \dots, g_{x_n})$. Then $g \in \bar{\mathcal{C}}$ by Step 2 and $\|g - f\|_\infty < \varepsilon$ by construction. Letting $\varepsilon \downarrow 0$, we get $\bar{\mathcal{C}} = C_b(E; \mathbb{R})$.

Step 5. Now consider $\mathbb{K} = \mathbb{C}$. If $f \in \mathcal{C}$, then by assumption $\operatorname{Re}(f) = (f + \bar{f})/2$ and $\operatorname{Im}(f) = (f - \bar{f})/2i$ are in $\mathcal{C}$. In particular, $\mathcal{C}_0 := \{\operatorname{Re}(f) : f \in \mathcal{C}\} \subset \mathcal{C}$ is a real algebra that, by assumption, separates points and contains the constant functions. Hence $\mathcal{C}_0$ is dense in $C_b(E; \mathbb{R})$. Since $\mathcal{C} = \mathcal{C}_0 + i\mathcal{C}_0$, $\mathcal{C}$ is dense in $C_b(E; \mathbb{C})$.

Corollary 15.3 Let E be a compact metric space. Let $\mathbb{K} = \mathbb{R}$ or $\mathbb{K} = \mathbb{C}$. Let $\mathcal{C} \subset C_b(E; \mathbb{K})$ be a family that separates points; that is, stable under multiplication and that contains 1. If $\mathbb{K} = \mathbb{C}$, then in addition assume that $\mathcal{C}$ is closed under complex conjugation.

Then $\mathcal{C}$ is a separating family for $\mathcal{M}_f(E)$.

Proof Let $\mu_1, \mu_2 \in \mathcal{M}_f(E)$ with $\int g d\mu_1 = \int g d\mu_2$ for all $g \in \mathcal{C}$. Let $\mathcal{C}'$ be the algebra of finite linear combinations of elements of $\mathcal{C}$. By linearity of the integral, $\int g d\mu_1 = \int g d\mu_2$ for all $g \in \mathcal{C}'$.

For any $f \in C_b(E, \mathbb{R})$ and any $\varepsilon > 0$, by the Stone-Weierstraß theorem, there exists a $g \in \mathcal{C}'$ with $\|f - g\|_\infty < \varepsilon$. By the triangle inequality,

$$\begin{aligned} \left| \int f d\mu_1 - \int f d\mu_2 \right| &\leq \left| \int f d\mu_1 - \int g d\mu_1 \right| + \left| \int g d\mu_1 - \int g d\mu_2 \right| \\ &\quad + \left| \int g d\mu_2 - \int f d\mu_2 \right| \\ &\leq \varepsilon (\mu_1(E) + \mu_2(E)). \end{aligned}$$

Letting $\varepsilon \downarrow 0$, we get equality of the integrals and hence $\mu_1 = \mu_2$ (by Theorem 13.11).

The following theorems are simple consequences of Corollary 15.3.

Theorem 15.4 The distribution of a bounded real random variable X is characterized by its moments.

Proof Without loss of generality, we can assume that X takes values in $E := [0, 1]$. For $n \in \mathbb{N}$, define the map $f_n : [0, 1] \rightarrow [0, 1]$ by $f_n : x \mapsto x^n$. Further, let $f_0 \equiv 1$. The family $\mathcal{C} = \{f_n, n \in \mathbb{N}_0\}$ separates points and is closed under multiplication; hence it is a separating class for $\mathcal{M}_f(E)$. Thus $\mathbf{P}_X$ is uniquely determined by its moments $\mathbf{E}[X^n] = \int x^n \mathbf{P}_X(dx), n \in \mathbb{N}$.

Example 15.5 (due to [73]) In the preceding theorem, we cannot simply drop the assumption that X is bounded without making other assumptions (see Corollary 15.32). Even if all moments exist, the distribution of X is, in general, not uniquely determined by its moments. As an example consider $X := \exp(Y)$, where $Y \sim \mathcal{N}_{0,1}$. The distribution of X is called the log-normal distribution. For every $n \in \mathbb{N}$, nY is distributed as the sum of n^2 independent, standard normally distributed random variables $nY \stackrel{\mathcal{D}}{=} Y_1 + \dots + Y_{n^2}$. Hence, for $n \in \mathbb{N}$,

$$\begin{aligned} \mathbf{E}[X^n] &= \mathbf{E}[e^{nY}] = \mathbf{E}[e^{Y_1 + \dots + Y_{n^2}}] = \prod_{i=1}^{n^2} \mathbf{E}[e^{Y_i}] = \mathbf{E}[e^Y]^{n^2} \\ &= \left(\int_{-\infty}^{\infty} (2\pi)^{-1/2} e^y e^{-y^2/2} dy \right)^{n^2} = e^{n^2/2} \end{aligned} \quad (15.1)$$

We construct a whole family of distributions with the same moments as X . By the transformation formula for densities (Theorem 1.101), the distribution of X has the density

$$f(x) = \frac{1}{\sqrt{2\pi}} x^{-1} \exp\left(-\frac{1}{2} \log(x)^2\right) \text{ for } x > 0$$

For $\alpha \in [-1, 1]$, define probability densities f_α on $(0, \infty)$ by

$$f_\alpha(x) = f(x)(1 + \alpha \sin(2\pi \log(x))).$$

In order to show that f_α is a density and has the same moments as f , it is enough to show that, for all $n \in \mathbb{N}_0$,

$$m(n) := \int_0^\infty x^n f(x) \sin(2\pi \log(x)) dx = 0$$

With the substitution $y = \log(x) - n$, we get (note that $\sin(2\pi(y+n)) = \sin(2\pi y)$)

$$\begin{aligned} m(n) &= \int_{-\infty}^{\infty} e^{yn+n^2} (2\pi)^{-1/2} e^{-(y+n)^2/2} \sin(2\pi(y+n)) dy \\ &= (2\pi)^{-1/2} e^{n^2/2} \int_{-\infty}^{\infty} e^{-y^2/2} \sin(2\pi y) dy = 0 \end{aligned}$$

where the last equality holds since the integrand is an odd function.

Theorem 15.6 (Laplace transform) A finite measure μ on $[0, \infty)$ is characterized by its Laplace transform

$$\mathcal{L}_\mu(\lambda) := \int e^{-\lambda x} \mu(dx) \quad \text{for } \lambda \geq 0$$

Proof We face the problem that the space $[0, \infty)$ is not compact by passing to the one-point compactification $E = [0, \infty]$. For $\lambda \geq 0$, define the continuous function $f_\lambda : [0, \infty] \rightarrow [0, 1]$ by $f_\lambda(x) = e^{-\lambda x}$ if $x < \infty$ and $f_\lambda(\infty) = \lim_{x \rightarrow \infty} e^{-\lambda x}$. Then $\mathcal{C} = \{f_\lambda, \lambda \geq 0\}$ separates points, $f_0 = 1 \in \mathcal{C}$ and $f_\mu \cdot f_\lambda = f_{\mu+\lambda} \in \mathcal{C}$. By Corollary 15.3, $\mathcal{C}$ is a separating class for $\mathcal{M}_f([0, \infty])$ and thus also for $\mathcal{M}_f([0, \infty))$.

Definition 15.7 For $\mu \in \mathcal{M}_f(\mathbb{R}^d)$, define the map $\varphi_\mu : \mathbb{R}^d \rightarrow \mathbb{C}$ by

$$\varphi_\mu(t) := \int e^{i\langle t, x \rangle} \mu(dx)$$

φ_μ is called the characteristic function of μ .

Theorem 15.8 (Characteristic function) A finite measure $\mu \in \mathcal{M}_f(\mathbb{R}^d)$ is characterized by its characteristic function.

Proof Let $\mu_1, \mu_2 \in \mathcal{M}_f(\mathbb{R}^d)$ with $\varphi_{\mu_1}(t) = \varphi_{\mu_2}(t)$ for all $t \in \mathbb{R}^d$. By Theorem 13.11(ii), $C_c(\mathbb{R}^d)$ is a separating class for $\mathcal{M}_f(\mathbb{R}^d)$. Hence, it is enough to show that $\int f d\mu_1 = \int f d\mu_2$ for all $f \in C_c(\mathbb{R}^d)$.

Let $f : \mathbb{R}^d \rightarrow \mathbb{R}$ be continuous with compact support and let $\varepsilon > 0$. Assume that $K > 0$ is large enough such that $f(x) = 0$ for $x \notin (-K/2, K/2)^d$ and such that $\mu_i(\mathbb{R}^d \setminus (-K, K)^d) < \varepsilon$, $i = 1, 2$. Consider the torus $E := \mathbb{R}^d / (2K\mathbb{Z}^d)$ and define $\tilde{f} : E \rightarrow \mathbb{R}$ by

$$\tilde{f}(x + 2K\mathbb{Z}^d) = f(x) \quad \text{for } x \in [-K, K]^d.$$

Since the support of f is contained in $(-K, K)^d$, $\tilde{f}$ is continuous. For $m \in \mathbb{Z}^d$ define

$$g_m : \mathbb{R}^d \rightarrow \mathbb{C}, \quad x \mapsto \exp(i\langle \pi m / K, x \rangle).$$

Let $\mathcal{C}$ be the algebra of finite linear combinations of the g_m . For $g \in \mathcal{C}$, we have $g(x) = g(x + 2Kn)$ for all $x \in \mathbb{R}^d$ and $n \in \mathbb{Z}^d$. Hence, the map

$$\tilde{g} : E \rightarrow \mathbb{C}, \quad \tilde{g}(x + 2K\mathbb{Z}^d) = g(x)$$

is well-defined, continuous and bounded. Furthermore, $\tilde{\mathcal{C}} := \{\tilde{g} : g \in \mathcal{C}\} \subset C_b(E; \mathbb{C})$ is an algebra that separates points and is closed under complex conjugation. As E is compact, by the Stone-Weierstraß theorem, there is a $\tilde{g} \in \tilde{\mathcal{C}}$ such that $\|\tilde{g} - \tilde{f}\|_\infty < \varepsilon$. We infer

$$\|(f - g)\mathbb{1}_{[-K, K]^d}\|_\infty < \varepsilon$$

and

$$\|(f - g)\mathbb{1}_{\mathbb{R}^d \setminus [-K, K]^d}\|_\infty \leq \|g\|_\infty = \|\tilde{g}\|_\infty \leq \|\tilde{f}\|_\infty + \varepsilon = \|f\|_\infty + \varepsilon.$$

By assumption of the theorem, $\int g d\mu_1 = \int g d\mu_2$. Hence, using the triangle inequality, we conclude

$$\begin{aligned} \left| \int f d\mu_1 - \int f d\mu_2 \right| &\leq \int |f - g| d\mu_1 + \int |f - g| d\mu_2 \\ &\leq \varepsilon (2\|f\|_\infty + 2\varepsilon + \mu_1(\mathbb{R}^d) + \mu_2(\mathbb{R}^d)) \end{aligned}$$

As $\varepsilon > 0$ was arbitrary, the integrals coincide.

Corollary 15.9 A finite measure μ on $\mathbb{Z}^d$ is uniquely determined by the values

$$\varphi_\mu(t) = \int e^{i\langle t, x \rangle} \mu(dx), \quad t \in [-\pi, \pi]^d$$

Proof This is obvious since $\varphi_\mu(t + 2\pi k) = \varphi_\mu(t)$ for all $k \in \mathbb{Z}^d$.

While the preceding corollary only yields an abstract uniqueness statement, we will profit also from an explicit inversion formula for Fourier transforms.

Theorem 15.10 (Discrete Fourier inversion formula) Let $\mu \in \mathcal{M}_f(\mathbb{Z}^d)$ with characteristic function φ_μ . Then, for every $x \in \mathbb{Z}^d$,

$$\mu(\{x\}) = (2\pi)^{-d} \int_{[-\pi, \pi]^d} e^{-i\langle t, x \rangle} \varphi_\mu(t) dt$$

Proof By the dominated convergence theorem,

$$\begin{aligned} \int_{[-\pi, \pi]^d} e^{-i\langle t, x \rangle} \varphi_\mu(t) dt &= \int_{[-\pi, \pi]^d} e^{-i\langle t, x \rangle} \left(\lim_{n \rightarrow \infty} \sum_{|y| \leq n} e^{i\langle t, y \rangle} \mu(\{y\}) \right) dt \\ &= \lim_{n \rightarrow \infty} \int_{[-\pi, \pi]^d} e^{-i\langle t, x \rangle} \sum_{|y| \leq n} e^{i\langle t, y \rangle} \mu(\{y\}) dt \\ &= \sum_{y \in \mathbb{Z}^d} \mu(\{y\}) \int_{[-\pi, \pi]^d} e^{i\langle t, y-x \rangle} dt \end{aligned}$$

The claim follows since, for $y \in \mathbb{Z}^d$,

$$\int_{[-\pi, \pi]^d} e^{i\langle t, y-x \rangle} dt = \begin{cases} (2\pi)^d, & \text{if } x = y \\ 0, & \text{else.} \end{cases}$$

Similar inversion formulas hold for measures μ on $\mathbb{R}^d$. Particularly simple is the case where μ possesses an integrable density $f := \frac{d\mu}{d\lambda}$ with respect to d -dimensional Lebesgue measure λ . In this case, we have the Fourier inversion formula,

$$f(x) = (2\pi)^{-d} \int_{\mathbb{R}^d} e^{-i\langle t, x \rangle} \varphi_\mu(t) \lambda(dt) \quad (15.2)$$

Furthermore, by Plancherel's theorem, $f \in \mathcal{L}^2(\lambda)$ if and only if $\varphi_\mu \in \mathcal{L}^2(\lambda)$. In this case, $\|f\|_2 = \|\varphi\|_2$.

Since we will not need these statements in the following, we only refer to the standard literature (e.g., [173, Chapter VI.2] or [54, Theorem XV.3.3 and Eq. (XV.3.8)]).

Exercise 15.1.1 Show that, in the Stone-Weierstraß theorem, compactness of E is essential. Hint: Let $E = \mathbb{R}$ and use the fact that $C_b(\mathbb{R}) = C_b(\mathbb{R}; \mathbb{R})$ is not separable. Construct a countable algebra $\mathcal{C} \subset C_b(\mathbb{R})$ that separates points.

Exercise 15.1.2 Let $d \in \mathbb{N}$ and let μ be a finite measure on $[0, \infty)^d$. Show that μ is characterized by its Laplace transform $\mathcal{L}_\mu(\lambda) = \int e^{-\langle \lambda, x \rangle} \mu(dx)$, $\lambda \in [0, \infty)^d$.

Exercise 15.1.3 Show that, under the assumptions of Theorem 15.10, Plancherel's equation holds:

$$\sum_{x \in \mathbb{Z}^d} \mu(\{x\})^2 = (2\pi)^{-d} \int_{[-\pi, \pi]^d} |\varphi_\mu(t)|^2 dt$$

Exercise 15.1.4 (Mellin transform) Let X be a nonnegative real random variable. For $s \geq 0$, define the Mellin transform of $\mathbf{P}_X$ by

$$m_X(s) = \mathbf{E}[X^s]$$

(with values in $[0, \infty]$).

Assume there is an $\varepsilon_0 > 0$ with $m_X(\varepsilon_0) < \infty$ (respectively $m_X(-\varepsilon_0) < \infty$). Show that, for any $\varepsilon > 0$, the distribution $\mathbf{P}_X$ is characterized by the values $m_X(s)$ (respectively $m_X(-s)$), $s \in [0, \varepsilon]$.

Hint: For continuous $f : [0, \infty) \rightarrow [0, \infty)$, let

$$\phi_f(z) = \int_0^\infty t^{z-1} f(t) dt$$

for those $z \in \mathbb{C}$ for which the integral is well-defined. By a standard result of complex analysis if $\phi_f(s) < \infty$ for an $s > 1$, then ϕ_f is holomorphic in $\{z \in \mathbb{C} : \operatorname{Re}(z) \in (1, s)\}$ (and is thus uniquely determined by the values $\phi_f(r), r \in (1, 1 + \varepsilon)$ for any $\varepsilon > 0$). Furthermore, for all $r \in (1, s)$,

$$f(t) = \frac{1}{2\pi i} \int_{-\infty}^{\infty} t^{-(r+i\rho)} \phi_f(r+i\rho) d\rho$$

- (i) Conclude the statement for X with a continuous density.
- (ii) For $\delta > 0$, let $Y_\delta \sim \mathcal{U}_{[1-\delta, 1]}$ be independent of X . Show that XY_δ has a continuous density.
- (iii) Compute m_{XY_δ} , and show that $m_{XY_\delta} \rightarrow m_X$ for $\delta \downarrow 0$.
- (iv) Show that $XY_\delta \implies X$ for $\delta \downarrow 0$.

Exercise 15.1.5 Let X, Y, Z be independent nonnegative random variables such that $\mathbf{P}[Z > 0] > 0$ and such that the Mellin transform $m_{XZ}(s)$ is finite for some $s > 0$.

Show that if $XZ \stackrel{\mathcal{D}}{=} YZ$ holds, then $X \stackrel{\mathcal{D}}{=} Y$.

Exercise 15.1.6 Let μ be a probability measure on $\mathbb{R}$ with integrable characteristic function φ_μ and hence $\varphi_\mu \in \mathcal{L}^1(\lambda)$, where λ is the Lebesgue measure on $\mathbb{R}$. Show that μ is absolutely continuous with bounded continuous density $f = \frac{d\mu}{d\lambda}$ given by

$$f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-itx} \varphi_\mu(t) dt \quad \text{for all } x \in \mathbb{R}$$

Hint: Show this first for the normal distribution $\mathcal{N}_{0,\varepsilon}, \varepsilon > 0$. Then show that $\mu * \mathcal{N}_{0,\varepsilon}$ is absolutely continuous with density f_ε , which converges pointwise to f (as $\varepsilon \rightarrow 0$).

Exercise 15.1.7 Let (Ω, τ) be a separable topological space that satisfies the $T_{3\frac{1}{2}}$ separation axiom: For any closed set $A \subset \Omega$ and any point $x \in \Omega \setminus A$, there exists a continuous function $f : \Omega \rightarrow [0, 1]$ with $f(x) = 0$ and $f(y) = 1$ for all $y \in A$. (Note in particular that every metric space is a $T_{3\frac{1}{2}}$ -space.)

Show that $\sigma(C_b(\Omega)) = \mathcal{B}(\Omega)$; that is, the Borel σ -algebra is generated by the bounded continuous functions $\Omega \rightarrow \mathbb{R}$.

5.15.2 15.2 Characteristic Functions: Examples

Recall that $\operatorname{Re}(z)$ is the real part of $z \in \mathbb{C}$. We collect some simple properties of characteristic functions.

Lemma 15.11 Let X be a random variable with values in $\mathbb{R}^d$ and characteristic function $\varphi_X(t) = \mathbf{E}[e^{i\langle t, X \rangle}]$. Then:

- (i) $|\varphi_X(t)| \leq 1$ for all $t \in \mathbb{R}^d$ and $\varphi_X(0) = 1$.
- (ii) $\varphi_{aX+b}(t) = \varphi_X(at)e^{i\langle b, t \rangle}$ for all $a \in \mathbb{R}$ and $b \in \mathbb{R}^d$.
- (iii) $\mathbf{P}_X = \mathbf{P}_{-X}$ if and only if φ is real-valued.
- (iv) If X and Y are independent, then $\varphi_{X+Y} = \varphi_X \cdot \varphi_Y$.
- (v) $0 \leq 1 - \operatorname{Re}(\varphi_X(2t)) \leq 4(1 - \operatorname{Re}(\varphi_X(t)))$ for all $t \in \mathbb{R}^d$.

Proof (i) and (ii) are trivial.

(iii) $\overline{\varphi_X(t)} = \varphi_X(-t) = \varphi_{-X}(t)$.

(iv) As $e^{i\langle t, X \rangle}$ and $e^{i\langle t, Y \rangle}$ are independent random variables, we have

$$\varphi_{X+Y}(t) = \mathbf{E}[e^{i\langle t, X \rangle} \cdot e^{i\langle t, Y \rangle}] = \mathbf{E}[e^{i\langle t, X \rangle}] \mathbf{E}[e^{i\langle t, Y \rangle}] = \varphi_X(t) \varphi_Y(t).$$

(v) By the addition theorem for trigonometric functions,

$$1 - \cos(\langle 2t, X \rangle) = 2(1 - (\cos(\langle t, X \rangle))^2) \leq 4(1 - \cos(\langle t, X \rangle)).$$

Now take the expectations of both sides.

In the next theorem, we collect the characteristic functions for some of the most important distributions.

Theorem 15.12 (Characteristic functions of some distributions) For some distributions P with density $x \mapsto f(x)$ on $\mathbb{R}$ or weights $P(\{k\}), k \in \mathbb{N}_0$, the characteristic function $\varphi(t)$ is given explicitly in Table 15.1.

Proof (i) (Normal distribution) By Lemma 15.11, it is enough to consider the case $\mu = 0$ and $\sigma^2 = 1$. By virtue of the differentiation lemma (Theorem 6.28) and using partial integration, we get

$$\frac{d}{dt}\varphi(t) = \int_{-\infty}^{\infty} e^{itx} ixe^{-x^2/2} dx = -t\varphi(t)$$

This linear differential equation with initial value $\varphi(0) = 1$ has the unique solution $\varphi(t) = e^{-t^2/2}$.

(ii) (Uniform distribution) This is immediate.

(iii) (Triangle distribution) Note that $\text{Tri}_a = \mathcal{U}_{[-a/2, a/2]} * \mathcal{U}_{[-a/2, a/2]}$; hence

$$\varphi_{\text{Tri}_a}(t) = \varphi_{\mathcal{U}_{[-a/2, a/2]}}(t)^2 = 4 \frac{\sin(at/2)^2}{a^2 t^2} = 2 \frac{1 - \cos(at)}{a^2 t^2}.$$

Here we used the fact that by the addition theorem for trigonometric functions

$$1 - \cos(x) = \sin(x/2)^2 + \cos(x/2)^2 - \cos(x) = 2 \sin(x/2)^2.$$

Table 15.1 Characteristic functions of some distributions

Distribution	Parameter	on	Density / Weights	Char. fct.
Name Symbol				$\varphi(t)$
Normal $\mathcal{N}_{\mu, \sigma^2}$	$\mu \in \mathbb{R}, \sigma^2 > 0$	$\mathbb{R}$	$\frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x-\mu)^2}{2\sigma^2}\right)$	$e^{i\mu t} \cdot e^{-\sigma^2 t^2/2}$
Uniform $\mathcal{U}_{[0, a]}$	$a > 0$	$[0, a]$	$1/a$	$\frac{e^{iat} - 1}{iat}$
Uniform $\mathcal{U}_{[-a, a]}$	$a > 0$	$[-a, a]$	$1/2a$	$\frac{\sin(at)}{at}$
Triangle Tri_a	$a > 0$	$[-a, a]$	$\frac{1}{a}(1 - x /a)^+$	$2 \frac{1 - \cos(at)}{a^2 t^2}$
N.N.	$a > 0$	$\mathbb{R}$	$\frac{1}{a} \frac{1 - \cos(ax)}{ax^2}$	$(1 - t /a)^+$
Gamma $\Gamma_{\theta, r}$	$\theta > 0, r > 0$	$[0, \infty)$	$\frac{\theta^r}{\Gamma(r)} x^{r-1} e^{-\theta x}$	$(1 - it/\theta)^{-r}$
Exponential $\exp_{\theta}$	$\theta > 0$	$[0, \infty)$	$\theta e^{-\theta x}$	$\frac{\theta}{\theta - it}$
Two-sided exponential $\exp_{\theta}^2$	$\theta > 0$	$\mathbb{R}$	$\frac{\theta}{2} e^{-\theta x }$	$\frac{1}{1 + (t/a)^2}$
Cauchy Cau_a	$a > 0$	$\mathbb{R}$	$\frac{1}{a\pi} \frac{1}{1 + (x/a)^2}$	$e^{-a t }$
Binomial $b_{n, p}$	$n \in \mathbb{N}, p \in [0, 1]$	$\{0, \dots, n\}$	$\binom{n}{k} p^k (1-p)^{n-k}$	$((1-p) + pe^{it})^n$
Negative binomial	$r > 0, p \in (0, 1]$	$\mathbb{N}_0$	$\binom{-r}{k} (-1)^k p^r (1-p)^k$	$\left(\frac{p}{1 - (1-p)e^{it}}\right)^r$
$b_{r, p}^-$ Poisson Poi_{λ}	$\lambda > 0$	$\mathbb{N}_0$	$e^{-\lambda} \frac{\lambda^k}{k!}$	$\exp(\lambda(e^{it} - 1))$

(iv) (N.N.) This can either be computed directly or can be deduced from (iii) by using the Fourier inversion formula (Eq. (15.2)).

(v) (Gamma distribution) Again it suffices to consider the case $\theta = 1$. For $0 \leq b < c \leq \infty$ and $t \in \mathbb{R}$, let $\gamma_{b, c, t}$ be the linear path in $\mathbb{C}$ from $b - ibt$ to $c - ict$, let $\delta_{b, t}$ be the linear path from b to $b - ibt$ and let $\epsilon_{c, t}$ be the linear path from $c - ict$ to c . Substituting $z = (1 - it)x$, we get

$$\varphi(t) = \frac{1}{\Gamma(r)} \int_0^\infty x^{r-1} e^{-x} e^{itx} dx = \frac{(1-it)^{-r}}{\Gamma(r)} \int_{\gamma_{0,\infty,t}} z^{r-1} e^{-z} dz.$$

Hence, it suffices to show that $\int_{\gamma_{0,\infty,t}} z^{r-1} \exp(-z) dz = \Gamma(r)$.

The function $z \mapsto z^{r-1} \exp(-z)$ is holomorphic in the right complex plane. Hence, by the residue theorem for $0 < b < c < \infty$,

$$\begin{aligned} \int_b^c x^{r-1} \exp(-x) dx &= \int_{\gamma_{b,c,t}} z^{r-1} \exp(-z) dz \\ &\quad + \int_{\delta_{b,t}} z^{r-1} \exp(-z) dz + \int_{\epsilon_{c,t}} z^{r-1} \exp(-z) dz \end{aligned}$$

Recall that $\int_0^\infty x^{r-1} \exp(-x) dx =: \Gamma(r)$. Hence, it is enough to show that the integrals along $\delta_{b,t}$ and $\epsilon_{c,t}$ vanish if $b \rightarrow 0$ and $c \rightarrow \infty$.

However, $|z^{r-1} \exp(-z)| \leq (1+t^2)^{(r-1)/2} b^{r-1} \exp(-b)$ for $z \in \delta_{b,t}$. As the path $\delta_{b,t}$ has length $b|t|$, we get the estimate

$$\left| \int_{\delta_{b,t}} z^{r-1} e^{-z} dz \right| \leq b^r e^{-b} (1+t^2)^{r/2} \rightarrow 0 \quad \text{for } b \rightarrow 0$$

Similarly,

$$\left| \int_{\epsilon_{c,t}} z^{r-1} e^{-z} dz \right| \leq c^r e^{-c} (1+t^2)^{r/2} \rightarrow 0 \quad \text{for } c \rightarrow \infty$$

(vi) (Exponential distribution) This follows from (v) since $\exp_\theta = \Gamma_{\theta,1}$.

(vii) (Two-sided exponential distribution) If X and Y are independent $\exp_\theta$ distributed random variables, then it is easy to check that $X - Y \sim \exp_\theta^2$. Hence

$$\varphi_{\exp_\theta^2}(t) = \varphi_{\exp_\theta}(t) \varphi_{\exp_\theta}(-t) = \frac{1}{1-it/\theta} \frac{1}{1+it/\theta} = \frac{1}{1+(t/\theta)^2}$$

(viii) (Cauchy distribution) This can either be computed directly using residue calculus or can be inferred from the statement for the two-sided exponential distribution by the Fourier inversion formula (Eq. (15.2)).

(ix) (Binomial distribution) By the binomial theorem,

$$\varphi(t) = \sum_{k=0}^n \binom{n}{k} (1-p)^{n-k} (pe^{it})^k = (1-p+pe^{it})^n.$$

(x) (Negative binomial distribution) By the generalized binomial theorem (Lemma 3.5), for all $x \in \mathbb{C}$ with $|x| < 1$,

$$(1-x)^{-r} = \sum_{k=0}^{\infty} \binom{-r}{k} (-x)^k.$$

Using this formula with $x = (1-p)e^{it}$ gives the claim.

(xi) (Poisson distribution) Clearly,

$$\varphi_{\text{Poi}_\lambda}(t) = \sum_{n=0}^{\infty} e^{-\lambda} \frac{(\lambda e^{it})^n}{n!} = e^{\lambda(e^{it}-1)}.$$

Corollary 15.13 The following convolution formulas hold.

- (i) $\mathcal{N}_{\mu_1, \sigma_1^2} * \mathcal{N}_{\mu_2, \sigma_2^2} = \mathcal{N}_{\mu_1 + \mu_2, \sigma_1^2 + \sigma_2^2}$ for $\mu_1, \mu_2 \in \mathbb{R}$ and $\sigma_1^2, \sigma_2^2 > 0$.
- (ii) $\Gamma_{\theta, r} * \Gamma_{\theta, s} = \Gamma_{\theta, r+s}$ for $\theta, r, s > 0$.
- (iii) $\text{Cau}_a * \text{Cau}_b = \text{Cau}_{a+b}$ for $a, b > 0$.
- (iv) $b_{m,p} * b_{n,p} = b_{m+n,p}$ for $m, n \in \mathbb{N}$ and $p \in [0, 1]$.
- (v) $b_{r,p}^- * b_{s,p}^- = b_{r+s,p}^-$ for $r, s > 0$ and $p \in (0, 1]$.
- (vi) $\text{Poi}_\lambda * \text{Poi}_\mu = \text{Poi}_{\lambda+\mu}$ for $\lambda, \mu \geq 0$.

Proof This follows by Theorem 15.12 and by $\varphi_{\mu * \nu} = \varphi_\mu \varphi_\nu$ (Lemma 15.11).

The following theorem gives two simple procedures for calculating the characteristic functions of compound distributions.

Theorem 15.14

- (i) Let $\mu_1, \mu_2, \dots \in \mathcal{M}_f(\mathbb{R}^d)$ and let $p_1, p_2, \dots$ be nonnegative numbers with $\sum_{n=1}^{\infty} p_n \mu_n(\mathbb{R}^d) < \infty$. Then the measure $\mu := \sum_{n=1}^{\infty} p_n \mu_n \in \mathcal{M}_f(\mathbb{R}^d)$ has characteristic function

$$\varphi_\mu = \sum_{n=1}^{\infty} p_n \varphi_{\mu_n} \quad (15.3)$$

- (ii) Let $N, X_1, X_2, \dots$ be independent random variables. Assume $X_1, X_2, \dots$ are identically distributed on $\mathbb{R}^d$ with characteristic function φ_X . Assume N takes values in $\mathbb{N}_0$ and has the probability generating function f_N . Then $Y := \sum_{n=1}^N X_n$ has the characteristic function $\varphi_Y(t) = f_N(\varphi_X(t))$.

- (iii) In particular, if we let $N \sim \text{Poi}_\lambda$ in (ii), then $\varphi_Y(t) = \exp(\lambda(\varphi_X(t) - 1))$.

Proof (i) Define $\nu_n = \sum_{k=1}^n p_k \mu_k$. By the linearity of the integral, $\varphi_{\nu_n} = \sum_{k=1}^n p_k \varphi_{\mu_k}$. By assumption, $\mu = \text{w-lim}_{n \rightarrow \infty} \nu_n$; hence also $\varphi_\mu(t) = \lim_{n \rightarrow \infty} \varphi_{\nu_n}(t)$.

- (ii) Clearly,

$$\begin{aligned} \varphi_Y(t) &= \sum_{n=0}^{\infty} \mathbf{P}[N = n] \mathbf{E}[e^{i\langle t, X_1 + \dots + X_n \rangle}] \\ &= \sum_{n=0}^{\infty} \mathbf{P}[N = n] \varphi_X(t)^n = f_N(\varphi_X(t)) \end{aligned}$$

- (iii) In this special case, $f_N(z) = e^{\lambda(z-1)}$ for $z \in \mathbb{C}$ with $|z| \leq 1$.

Example 15.15 Let $n \in \mathbb{N}$, and assume that the points $0 = a_0 < a_1 < \dots < a_n$ and $1 = y_0 > y_1 > \dots > y_n = 0$ are given. Let $\varphi : \mathbb{R} \rightarrow [0, \infty)$ have the properties that

- $\varphi(a_k) = y_k$ for all $k = 0, \dots, n$ and φ is linearly interpolated between the points a_k ,

Fig. 15.1 The characteristic function φ from Example 15.15 with $n = 4$

- $\varphi(x) = 0$ for $|x| > a_n$, and
- φ is even (that is, $\varphi(x) = \varphi(-x)$).

Assume in addition that the y_k are chosen such that φ is convex on $[0, \infty)$. This is equivalent to the condition that $m_1 \leq m_2 \leq \dots \leq m_n \leq 0$, where $m_k := \frac{y_k - y_{k-1}}{a_k - a_{k-1}}$ is the slope on the k th interval. We want to show that φ is the characteristic function of a probability measure $\mu \in \mathcal{M}_1(\mathbb{R})$.

Define $p_k = a_k(m_{k+1} - m_k)$ for $k = 1, \dots, n$.

Let $\mu_k \in \mathcal{M}_1(\mathbb{R})$ be the distribution on $\mathbb{R}$ with density $\frac{1}{\pi} \frac{1 - \cos(a_k \pi)}{a_k x^2}$. By Theorem 15.12, μ_k has the characteristic function $\varphi_{\mu_k}(t) = \left(1 - \frac{|t|}{a_k}\right)^+$. The characteristic function φ_μ of $\mu := \sum_{k=1}^n p_k \mu_k$ is then

$$\varphi_\mu(t) = \sum_{k=1}^n p_k (1 - |t|/a_k)^+.$$

This is a continuous, symmetric, real function with $\varphi_\mu(0) = 1$. It is linear on each of the intervals $[a_{k-1}, a_k]$. See Fig. 15.1 for an example with $n = 4$. By partial summation, for all $k = 1, \dots, n$ (since $m_{n+1} = 0$),

$$\begin{aligned} \varphi_\mu(a_l) &= \sum_{k=1}^n a_k (m_{k+1} - m_k) \left(1 - \frac{a_l}{a_k}\right)^+ = \sum_{k=l}^n (a_k - a_l) (m_{k+1} - m_k) \\ &= [(a_n - a_l) m_{n+1} - (a_l - a_l) m_l] - \sum_{k=l+1}^n (a_k - a_{k-1}) m_k \\ &= - \sum_{k=l+1}^n (y_k - y_{k-1}) = y_l = \varphi(a_l) \end{aligned}$$

Hence $\varphi_\mu = \varphi$.

Example 15.16 Define the function $\varphi : \mathbb{R} \rightarrow [0, 1]$ for $t \in [-\pi, \pi)$ by $\varphi(t) = 1 - 2|t|/\pi$, and assume φ is periodic (with period 2π). By the discrete Fourier inversion formula (Theorem 15.10), φ is the characteristic function of the probability measure $\mu \in \mathcal{M}_1(\mathbb{Z})$ with $\mu(\{x\}) = (2\pi)^{-1} \int_{-\pi}^{\pi} \cos(tx) \varphi(t) dt$. In fact, in order that μ be a measure (not only a signed measure), we still have to show that all of the masses $\mu(\{x\})$ are nonnegative. Clearly, $\mu(\{0\}) = 0$. For $x \in \mathbb{Z} \setminus \{0\}$, use partial integration to compute the integral,

$$\begin{aligned} \int_{-\pi}^{\pi} \cos(tx) \varphi(t) dt &= 2 \int_0^{\pi} \cos(tx) (1 - 2t/\pi) dt \\ &= \frac{4}{x} \left(1 - \frac{2}{\pi}\right) \sin(\pi x) - \frac{4}{x} \sin(0) + \frac{4}{\pi x} \int_0^{\pi} \sin(tx) dt \\ &= \frac{4}{\pi x^2} (1 - \cos(\pi x)) \end{aligned}$$

Summing up, we have

$$\mu(\{x\}) = \begin{cases} \frac{4}{\pi^2 x^2}, & \text{if } x \text{ is odd} \\ 0, & \text{else} \end{cases}$$

Since $\mu(\mathbb{Z}) = \varphi(0) = 1$, μ is indeed a probability measure.

Example 15.17 Define the function $\psi : \mathbb{R} \rightarrow [0, 1]$ for $t \in [-\pi/2, \pi/2)$ by $\psi(t) = 1 - 2|t|/\pi$. Assume ψ is periodic with period π . If φ is the characteristic function of the measure μ from

the previous example, then clearly $\psi(t) = |\varphi(t)|$. On the other hand, $\psi(t) = \frac{1}{2} + \frac{1}{2}\varphi(2t)$. By Theorem 15.14 and Lemma 15.11(ii), we infer that ψ is the characteristic function of the measure ν with $\nu(A) = \frac{1}{2}\delta_0(A) + \frac{1}{2}\mu(A/2)$ for $A \subset \mathbb{R}$. Hence,

$$v(\{x\}) = \begin{cases} \frac{1}{2}, & \text{if } x = 0 \\ \frac{8}{\pi^2 x^2}, & \text{if } \frac{x}{2} \in \mathbb{Z} \text{ is odd} \\ 0, & \text{else} \end{cases}$$

Example 15.18 Let $\varphi(t) = (1 - 2|t|/\pi)^+$ be the characteristic function of the distribution "N.N." from Theorem 15.12 (with $a = \pi/2$) and let ψ be the characteristic function from the preceding example. Note that $\varphi(t) = \psi(t)$ for $|t| \leq \pi/2$ and $\varphi(t) = 0$ for $|t| > \pi/2$; hence $\varphi^2 = \varphi \cdot \psi$. Now let X, Y, Z be independent real random variables with characteristic functions $\varphi_X = \varphi_Y = \varphi$ and $\varphi_Z = \psi$. Then $\varphi_X \varphi_Y = \varphi_X \varphi_Z$; hence $X + Y \stackrel{\mathcal{D}}{=} X + Z$. However, the distributions of Y and Z do not coincide.

Exercise 15.2.1 Let φ be the characteristic function of the d -dimensional random variable X . Assume that $\varphi(t) = 1$ for some $t \neq 0$. Show that $\mathbf{P}[X \in H_t] = 1$, where

$$\begin{aligned} H_t &= \{x \in \mathbb{R}^d : \langle x, t \rangle \in 2\pi\mathbb{Z}\} \\ &= \{y + z \cdot (2\pi t / \|t\|_2^2) : z \in \mathbb{Z}, y \in \mathbb{R}^d \text{ with } \langle y, t \rangle = 0\}. \end{aligned}$$

Infer that $\varphi(t + s) = \varphi(s)$ for all $s \in \mathbb{R}^d$.

Exercise 15.2.2 Show that there are real random variables X, X' and Y, Y' with the properties (i) $X \stackrel{\mathcal{D}}{=} X'$ and $Y \stackrel{\mathcal{D}}{=} Y'$, (ii) X' and Y' are independent, (iii) $X + Y \stackrel{\mathcal{D}}{=} X' + Y'$, and (iv) X and Y are not independent.

Exercise 15.2.3 Let X be a real random variable with characteristic function φ . X is called lattice distributed if there are $a, d \in \mathbb{R}$ such that $\mathbf{P}[X \in a + d\mathbb{Z}] = 1$. Show that X is lattice distributed if and only if there exists a $u \neq 0$ such that $|\varphi(u)| = 1$.

Exercise 15.2.4 Let X be a real random variable with characteristic function φ . Assume that there is a sequence $(t_n)_{n \in \mathbb{N}}$ of real numbers such that $|t_n| \downarrow 0$ and $|\varphi(t_n)| = 1$ for any n . Show that there exists a $b \in \mathbb{R}$ such that $X = b$ almost surely. If in addition, $\varphi(t_n) = 1$ for all n , then $X = 0$ almost surely.

5.15.3 15.3 Lévy's Continuity Theorem

The main statement of this section is Lévy's continuity theorem (Theorem 15.23). Roughly speaking, it says that a sequence of characteristic functions converges pointwise to a continuous function if and only if the limiting function is a characteristic function and the corresponding probability measures converge weakly. We prepare for the proof of this theorem by assembling some analytic tools.

Lemma 15.19 Let $\mu \in \mathcal{M}_1(\mathbb{R}^d)$ with characteristic function φ . Then

$$|\varphi(t) - \varphi(s)|^2 \leq 2(1 - \operatorname{Re}(\varphi(t - s))) \quad \text{for all } s, t \in \mathbb{R}^d.$$

Proof By the Cauchy-Schwarz inequality,

$$\begin{aligned}
|\varphi(t) - \varphi(s)|^2 &= \left| \int_{\mathbb{R}^d} e^{i\langle t, x \rangle} - e^{i\langle s, x \rangle} \mu(dx) \right|^2 \\
&= \left| \int_{\mathbb{R}^d} (e^{i\langle t-s, x \rangle} - 1) e^{i\langle s, x \rangle} \mu(dx) \right|^2 \\
&\leq \int_{\mathbb{R}^d} |e^{i\langle t-s, x \rangle} - 1|^2 \mu(dx) \cdot \int_{\mathbb{R}^d} |e^{i\langle s, x \rangle}|^2 \mu(dx) \\
&= \int_{\mathbb{R}^d} (e^{i\langle t-s, x \rangle} - 1) (e^{-i\langle t-s, x \rangle} - 1) \mu(dx) \\
&= 2(1 - \operatorname{Re}(\varphi(t-s)))
\end{aligned}$$

Definition 15.20 Let (E, d) be a metric space. A family $(f_i, i \in I)$ of maps $E \rightarrow \mathbb{R}$ is called uniformly equicontinuous if, for every $\varepsilon > 0$, there exists a $\delta > 0$ such that $|f_i(t) - f_i(s)| < \varepsilon$ for all $i \in I$ and all $s, t \in E$ with $d(s, t) < \delta$.

Theorem 15.21 If $\mathcal{F} \subset \mathcal{M}_1(\mathbb{R}^d)$ is a tight family, then $\{\varphi_\mu : \mu \in \mathcal{F}\}$ is uniformly equicontinuous. In particular, every characteristic function is uniformly continuous.

Proof We have to show that, for every $\varepsilon > 0$, there exists a $\delta > 0$ such that, for all $t \in \mathbb{R}^d$, all $s \in \mathbb{R}^d$ with $|t - s| < \delta$ and all $\mu \in \mathcal{F}$, we have

$$|\varphi_\mu(t) - \varphi_\mu(s)| < \varepsilon.$$

As $\mathcal{F}$ is tight, there exists an $N \in \mathbb{N}$ with $\mu([-N, N]^d) > 1 - \varepsilon^2/6$ for all $\mu \in \mathcal{F}$. Furthermore, there exists a $\delta > 0$ such that, for $x \in [-N, N]^d$ and $u \in \mathbb{R}^d$ with $|u| < \delta$, we have $|1 - e^{i\langle u, x \rangle}| < \varepsilon^2/6$. Hence we get for all $\mu \in \mathcal{F}$

$$\begin{aligned}
1 - \operatorname{Re}(\varphi_\mu(u)) &\leq \int_{\mathbb{R}^d} |1 - e^{i\langle u, x \rangle}| \mu(dx) \\
&\leq \frac{\varepsilon^2}{3} + \int_{[-N, N]^d} |1 - e^{i\langle u, x \rangle}| \mu(dx) \\
&\leq \frac{\varepsilon^2}{3} + \frac{\varepsilon^2}{6} = \frac{\varepsilon^2}{2}.
\end{aligned}$$

Thus, for $|t - s| < \delta$ by Lemma 15.19, $|\varphi_\mu(t) - \varphi_\mu(s)| \leq \varepsilon$.

Lemma 15.22 Let (E, d) be a metric space and let $f, f_1, f_2, \dots$ be maps $E \rightarrow \mathbb{R}$ with $f_n \xrightarrow{n \rightarrow \infty} f$ pointwise. If $(f_n)_{n \in \mathbb{N}}$ is uniformly equicontinuous, then f is uniformly continuous and $(f_n)_{n \in \mathbb{N}}$ converges to f uniformly on compact sets; that is, for every compact set $K \subset E$, we have

$$\sup_{s \in K} |f_n(s) - f(s)| \xrightarrow{n \rightarrow \infty} 0$$

Proof Fix $\varepsilon > 0$, and choose $\delta > 0$ such that $|f_n(t) - f_n(s)| < \varepsilon$ for all $n \in \mathbb{N}$ and all $s, t \in E$ with $d(s, t) < \delta$. For these s, t , we thus have

$$|f(s) - f(t)| = \lim_{n \rightarrow \infty} |f_n(s) - f_n(t)| \leq \varepsilon$$

Hence, f is uniformly continuous.

Now let $K \subset E$ be compact. As compact sets are totally bounded, there exists an $N \in \mathbb{N}$ and points $t_1, \dots, t_N \in K$ with $K \subset \bigcup_{i=1}^N B_\delta(t_i)$. Choose $n_0 \in \mathbb{N}$ large enough that $|f_n(t_i) - f(t_i)| \leq \varepsilon$ for all $i = 1, \dots, N$ and $n \geq n_0$.

Now let $s \in K$ and $n \geq n_0$. Choose a t_i with $d(s, t_i) < \delta$. Then

$$|f_n(s) - f(s)| \leq |f_n(s) - f_n(t_i)| + |f_n(t_i) - f(t_i)| + |f(t_i) - f(s)| \leq 3\varepsilon.$$

As $\varepsilon > 0$ was arbitrary, we infer that $f_n \xrightarrow{n \rightarrow \infty} f$ uniformly on K .

A map $f : \mathbb{R}^d \rightarrow \mathbb{R}$ is called partially continuous at $x = (x_1, \dots, x_d)$ if, for any $i = 1, \dots, d$, the map $y_i \mapsto f(x_1, \dots, x_{i-1}, y_i, x_{i+1}, \dots, x_d)$ is continuous at $y_i = x_i$.

Theorem 15.23 (Lévy's continuity theorem) Let $P, P_1, P_2, \dots \in \mathcal{M}_1(\mathbb{R}^d)$ with characteristic functions $\varphi, \varphi_1, \varphi_2, \dots$.

(i) If $P = w - \lim_{n \rightarrow \infty} P_n$, then $\varphi_n \xrightarrow{n \rightarrow \infty} \varphi$ uniformly on compact sets.

(ii) If $\varphi_n \xrightarrow{n \rightarrow \infty} f$ pointwise for some $f : \mathbb{R}^d \rightarrow \mathbb{C}$ that is partially continuous at 0, then there exists a probability measure Q such that $\varphi_Q = f$ and $Q = w - \lim_{n \rightarrow \infty} P_n$.

Proof (i) By the definition of weak convergence, we have $\varphi_n \xrightarrow{n \rightarrow \infty} \varphi$ pointwise. As the family $(P_n)_{n \in \mathbb{N}}$ is tight, by Theorem 15.21, $(\varphi_n)_{n \in \mathbb{N}}$ is uniformly equicontinuous. By Lemma 15.22, this implies uniform convergence on compact sets.

(ii) By Theorem 13.34, it is enough to show that the sequence $(P_n)_{n \in \mathbb{N}}$ is tight. For this purpose, it suffices to show that, for every $k = 1, \dots, n$, the sequence $(P_n^k)_{n \in \mathbb{N}}$ of k th marginal distributions is tight. (Here $P_n^k := P_n \circ \pi_k^{-1}$, where $\pi_k : \mathbb{R}^d \rightarrow \mathbb{R}$ is the projection on the k th coordinate.) Let e_k be the k th unit vector in $\mathbb{R}^d$. Then $\varphi_{P_n^k}(t) = \varphi_n(t e_k)$ is the characteristic function of P_n^k . By assumption, $\varphi_{P_n^k} \xrightarrow{n \rightarrow \infty} f_k$ pointwise for some function f_k that is continuous at 0. We have thus reduced the problem to the one-dimensional situation and will henceforth assume $d = 1$.

As $\varphi_n(0) = 1$ for all $n \in \mathbb{N}$, we have $f(0) = 1$. Define the map $h : \mathbb{R} \rightarrow [0, \infty)$ by $h(x) = 1 - \sin(x)/x$ for $x \neq 0$ and $h(0) = 0$. Clearly, h is continuously differentiable on $\mathbb{R}$. It is easy to see that $\alpha := \inf\{h(x) : |x| \geq 1\} = 1 - \sin(1) > 0$. Now, for $K > 0$, compute (using Markov's inequality and Fubini's theorem)

$$\begin{aligned} P_n([-K, K]^c) &\leq \alpha^{-1} \int_{[-K, K]^c} h(x/K) P_n(dx) \\ &\leq \alpha^{-1} \int_{\mathbb{R}} h(x/K) P_n(dx) \\ &= \alpha^{-1} \int_{\mathbb{R}} \left(\int_0^1 (1 - \cos(tx/K)) dt \right) P_n(dx) \\ &= \alpha^{-1} \int_0^1 \left(\int_{\mathbb{R}} (1 - \cos(tx/K)) P_n(dx) \right) dt \\ &= \alpha^{-1} \int_0^1 (1 - \operatorname{Re}(\varphi_n(t/K))) dt \end{aligned}$$

Using dominated convergence, we conclude that

$$\begin{aligned} \limsup_{n \rightarrow \infty} P_n([-K, K]^c) &\leq \alpha^{-1} \limsup_{n \rightarrow \infty} \int_0^1 (1 - \operatorname{Re}(\varphi_n(t/K))) dt \\ &= \alpha^{-1} \int_0^1 \left(\lim_{n \rightarrow \infty} (1 - \operatorname{Re}(\varphi_n(t/K))) \right) dt \\ &= \alpha^{-1} \int_0^1 (1 - \operatorname{Re}(f(t/K))) dt \end{aligned}$$

As f is continuous and $f(0) = 1$, the last integral converges to 0 for $K \rightarrow \infty$. Hence $(P_n)_{n \in \mathbb{N}}$ is tight.

Applying Lévy's continuity theorem to Example 15.15, we get a theorem of Pólya.

Theorem 15.24 (Pólya) Let $f : \mathbb{R} \rightarrow [0, 1]$ be continuous and even with $f(0) = 1$. Assume that f is convex on $[0, \infty)$. Then f is the characteristic function of a probability measure.

Proof Define f_n by $f_n(k/n) := f(k/n)$ for $k = 0, \dots, n^2$, and assume f_n is linearly interpolated between these points. Furthermore, let f_n be constant to the right of n and for $x < 0$, define

$f_n(x) = f_n(-x)$. This is an approximation of f on $[0, \infty)$ by convex and piecewise linear functions. By Example 15.15, every f_n is a characteristic function of a probability measure μ_n . Clearly, $f_n \xrightarrow{n \rightarrow \infty} f$ pointwise; hence f is the characteristic function of a probability measure $\mu = w - \lim_{n \rightarrow \infty} \mu_n$ on $\mathbb{R}$.

Corollary 15.25 For every $\alpha \in (0, 1]$ and $r > 0$, $\varphi_{\alpha,r}(t) = e^{-|rt|^\alpha}$ is the characteristic function of a symmetric probability measure $\mu_{\alpha,r}$ on $\mathbb{R}$.

Remark 15.26 In fact, $\varphi_{\alpha,r}$ is a characteristic function for every $\alpha \in (0, 2]$ ($\alpha = 2$ corresponds to the normal distribution), see Section 16.2. The distributions $\mu_{\alpha,r}$ are the so-called α -stable distributions (see Definition 16.20): If $X_1, X_2, \dots, X_n$ are independent and $\mu_{\alpha,a}$ -distributed, then $\varphi_{X_1+\dots+X_n}(t) = \varphi_X(t)^n = \varphi_X(n^{1/\alpha}t)$; hence $X_1 + \dots + X_n \stackrel{\mathcal{D}}{=} n^{1/\alpha}X_1$.

The Stone-Weierstraß theorem implies that a characteristic function determines a probability distribution uniquely. Pólya's theorem gives a sufficient condition for a symmetric real function to be a characteristic function. Clearly, that condition is not necessary, as, for example, the normal distribution does not fulfill it. For general education we present Bochner's theorem that formulates a necessary and sufficient condition for a function $\varphi : \mathbb{R}^d \rightarrow \mathbb{C}$ to be the characteristic function of a probability measure.

Definition 15.27 A function $f : \mathbb{R}^d \rightarrow \mathbb{C}$ is called positive semidefinite if, for all $n \in \mathbb{N}$, all $t_1, \dots, t_n \in \mathbb{R}^d$ and all $y_1, \dots, y_n \in \mathbb{C}$, we have

$$\sum_{k,l=1}^n y_k \bar{y}_l f(t_k - t_l) \geq 0,$$

in other words, if the matrix $(f(t_k - t_l))_{k,l=1,\dots,n}$ is positive semidefinite.

Lemma 15.28 If $\mu \in \mathcal{M}_f(\mathbb{R}^d)$ has characteristic function φ , then φ is positive semidefinite.

Proof We have

$$\begin{aligned} \sum_{k,l=1}^n y_k \bar{y}_l \varphi(t_k - t_l) &= \sum_{k,l=1}^n y_k \bar{y}_l \int e^{ix(t_k - t_l)} \mu(dx) \\ &= \int \sum_{k,l=1}^n y_k e^{ixt_k} \overline{y_l e^{ixt_l}} \mu(dx) \\ &= \int \left| \sum_{k=1}^n y_k e^{ixt_k} \right|^2 \mu(dx) \geq 0 \end{aligned}$$

□

In the case $d = 1$, the following theorem goes back to Bochner (1932) [19].

Theorem 15.29 (Bochner) A continuous function $\varphi : \mathbb{R}^d \rightarrow \mathbb{C}$ is the characteristic function of a probability distribution on $\mathbb{R}^d$ if and only if φ is positive semidefinite and $\varphi(0) = 1$.

The statement still holds if $\mathbb{R}^d$ is replaced by a locally compact Abelian group.

Proof For the case $d = 1$ see [19, Section 20, Theorem 23] or [54, Chapter XIX.2, p. 622]. For the general case, see, e.g., [71, p. 293, Theorem 33.3]. □

Exercise 15.3.1 (Compare [50] and [4]) Show that there exist two exchangeable sequences $X = (X_n)_{n \in \mathbb{N}}$ and $Y = (Y_n)_{n \in \mathbb{N}}$ of real random variables with $\mathbf{P}_X \neq \mathbf{P}_Y$ but such that

$$\sum_{k=1}^n X_k \stackrel{\mathcal{D}}{=} \sum_{k=1}^n Y_k \quad \text{for all } n \in \mathbb{N}. \quad (15.4)$$

Hint:

(i) Define the characteristic functions (see Theorem 15.12) $\varphi_1(t) = \frac{1}{1+t^2}$ and $\varphi_2(t) = (1-t/2)^+$. Use Pólya's theorem to show that

$$\psi_1(t) := \begin{cases} \varphi_1(t), & \text{if } |t| \leq 1, \\ \varphi_2(t), & \text{if } |t| > 1, \end{cases}$$

and

$$\psi_2(t) := \begin{cases} \varphi_2(t), & \text{if } |t| \leq 1, \\ \varphi_1(t), & \text{if } |t| > 1, \end{cases}$$

are characteristic functions of probability distributions on $\mathbb{R}$.

(ii) Define independent random variables $X_{n,i}, Y_{n,i}, n \in \mathbb{N}, i = 1, 2$, and $\Theta_n, n \in \mathbb{N}$ such that $X_{n,i}$ has characteristic function φ_i , $Y_{n,i}$ has characteristic function ψ_i and $\mathbf{P}[\Theta_n = 1] = \mathbf{P}[\Theta_n = -1] = \frac{1}{2}$. Define $X_n = X_{n,\Theta_n}$ and $Y_n = Y_{n,\Theta_n}$. Show that (15.4) holds.

(iii) Determine $\mathbf{E}[e^{it_1 X_1 + it_2 X_2}]$ and $\mathbf{E}[e^{it_1 Y_1 + it_2 Y_2}]$ for $t_1 = \frac{1}{2}$ and $t_2 = 2$. Conclude that $(X_1, X_2) \neq (Y_1, Y_2)$ and thus $\mathbf{P}_X \neq \mathbf{P}_Y$.

Exercise 15.3.2 Show that for any $\delta > 0$ and $\varepsilon > 0$, there is a $C < \infty$ such that for any $\mu \in \mathcal{M}_1(\mathbb{R})$ with characteristic function φ , we have

$$\mu([- \delta, \delta]^c) \leq C \int_0^\varepsilon (1 - \operatorname{Re}(\varphi(t))) dt$$

For $\varepsilon \delta \leq 3$ one can choose $C = 12/\delta^2 \varepsilon^3$.

Hint: Proceed as in the proof of Lévy's continuity theorem.

Exercise 15.3.3 Let $(\mu_n)_{n \in \mathbb{N}}$ be a sequence of probability measures on $\mathbb{R}$ and denote by $(\varphi_n)_{n \in \mathbb{N}}$ the corresponding characteristic functions. Assume that $\varphi_n(t) \xrightarrow{n \rightarrow \infty} 1$ for t in a neighborhood of 0. Use Exercise 15.3.2 to show that $\mu_n \xrightarrow{n \rightarrow \infty} \delta_0$.

5.15.4 15.4 Characteristic Functions and Moments

We want to study the connection between the moments of a real random variable X and the derivatives of its characteristic function φ_X . We start with a simple lemma.

Lemma 15.30 For $t \in \mathbb{R}$ and $n \in \mathbb{N}$, we have

$$\left| e^{it} - 1 - \frac{it}{1!} - \dots - \frac{(it)^{n-1}}{(n-1)!} \right| \leq \frac{|t|^n}{n!}.$$

Proof As the n th derivative of e^{it} has modulus 1, this follows by Taylor's formula. $\square$

Theorem 15.31 (Moments and differentiability) Let X be a real random variable with characteristic function φ .

(i) If $\mathbf{E}[|X|^n] < \infty$, then φ is n -times continuously differentiable with derivatives

$$\varphi^{(k)}(t) = \mathbf{E}[(iX)^k e^{itX}] \text{ for } k = 0, \dots, n.$$

(ii) In particular, if $\mathbf{E}[X^2] < \infty$, then

$$\varphi(t) = 1 + it\mathbf{E}[X] - \frac{1}{2}t^2\mathbf{E}[X^2] + \varepsilon(t)t^2$$

with $\varepsilon(t) \rightarrow 0$ for $t \rightarrow 0$.

(iii) Let $h \in \mathbb{R}$. If $\lim_{n \rightarrow \infty} \frac{|h|^n \mathbf{E}[|X|^n]}{n!} = 0$, then, for every $t \in \mathbb{R}$,

$$\varphi(t+h) = \sum_{k=0}^{\infty} \frac{(ih)^k}{k!} \mathbf{E} [e^{itX} X^k].$$

In particular, this holds if $\mathbf{E} [e^{|hX|}] < \infty$.

Proof (i) For $t \in \mathbb{R}$, $h \in \mathbb{R} \setminus \{0\}$ and $k \in \{1, \dots, n\}$, define

$$Y_k(t, h, x) = k! h^{-k} e^{itx} \left(e^{ihx} - \sum_{l=0}^{k-1} \frac{(ihx)^l}{l!} \right).$$

Then

$$\mathbf{E} [Y_k(t, h, X)] = k! h^{-k} \left(\varphi(t+h) - \varphi(t) - \sum_{l=1}^{k-1} \mathbf{E} [e^{itX} (iX)^l] \frac{h^l}{l!} \right).$$

If the limit $\varphi_k(t) := \lim_{h \rightarrow 0} \mathbf{E} [Y_k(t, h, X)]$ exists, then φ is k -times differentiable at t with $\varphi^{(k)}(t) = \varphi_k(t)$.

However (by Lemma 15.30 with $n = k+1$), $Y_k(t, h, x) \xrightarrow{h \rightarrow 0} (ix)^k e^{itx}$ for all $x \in \mathbb{R}$ and (by Lemma 15.30 with $n = k$) $|Y_k(t, h, x)| \leq |x|^k$. As $\mathbf{E} [|X|^k] < \infty$ by assumption, the dominated convergence theorem implies

$$\mathbf{E} [Y_k(t, h, X)] \xrightarrow{h \rightarrow 0} \mathbf{E} [(iX)^k e^{itX}] = \varphi^{(k)}(t).$$

Applying the continuity lemma (Theorem 6.27) yields that $\varphi^{(k)}$ is continuous.

(ii) This is a direct consequence of (i).

(iii) By assumption,

$$\begin{aligned} \left| \varphi(t+h) - \sum_{k=0}^{n-1} \frac{(ih)^k}{k!} \mathbf{E} [e^{itX} X^k] \right| &= \frac{h^n}{n!} |\mathbf{E} [Y_n(t, h, X)]| \\ &\leq \frac{h^n \mathbf{E} [|X|^n]}{n!} \xrightarrow{n \rightarrow \infty} 0. \end{aligned}$$

Corollary 15.32 (Method of moments) Let X be a real random variable with

$$\alpha := \limsup_{n \rightarrow \infty} \frac{1}{n} \mathbf{E} [|X|^n]^{1/n} < \infty$$

Then the characteristic function φ of X is analytic and the distribution of X is uniquely determined by the moments $\mathbf{E} [X^n]$, $n \in \mathbb{N}$. In particular, this holds if $\mathbf{E} [e^{t|X|}] < \infty$ for some $t > 0$.

Proof By Stirling's formula,

$$\lim_{n \rightarrow \infty} \frac{1}{n!} n^n e^{-n} \sqrt{2\pi n} = 1$$

Thus, for $|h| < 1/(3\alpha)$,

$$\begin{aligned} \limsup_{n \rightarrow \infty} \mathbf{E} [|X|^n] \cdot |h|^n / n! &= \limsup_{n \rightarrow \infty} \sqrt{2\pi n} \left(\mathbf{E} [|X|^n]^{1/n} \cdot |h| \cdot e/n \right)^n \\ &\leq \limsup_{n \rightarrow \infty} \sqrt{2\pi n} (e/3)^n = 0 \end{aligned}$$

Hence the characteristic function can be expanded about any point $t \in \mathbb{R}$ in a power series with radius of convergence at least $1/(3\alpha)$. In particular, it is analytic and is hence determined by the coefficients of its power series about $t = 0$; that is, by the moments of X .

Example 15.33

(i) Let $X \sim \mathcal{N}_{\mu, \sigma^2}$. Then, for every $t \in \mathbb{R}$,

$$\begin{aligned}\mathbf{E}[e^{tX}] &= (2\pi\sigma^2)^{-1/2} \int_{-\infty}^{\infty} e^{tx} e^{-(x-\mu)^2/2\sigma^2} dx \\ &= e^{\mu t + t^2\sigma^2/2} (2\pi\sigma^2)^{-1/2} \int_{-\infty}^{\infty} e^{-(x-\mu-t\sigma^2)^2/2\sigma^2} dx \\ &= e^{\mu t + t^2\sigma^2/2} < \infty\end{aligned}$$

Hence the distribution of X is characterized by its moments. The characteristic function $\varphi(t) = e^{i\mu t} e^{-\sigma^2 t^2/2}$ that we get by the above calculation with t replaced by it is indeed analytic.

(ii) Let X be exponentially distributed with parameter $\theta > 0$. Then, for $t \in (0, \theta)$,

$$\mathbf{E}[e^{tX}] = \theta \int_0^{\infty} e^{tx} e^{-\theta x} dx = \frac{\theta}{\theta - t} < \infty$$

Hence the distribution of X is characterized by its moments. The above calculation with t replaced by it yields $\varphi(t) = \theta/(\theta - it)$, and this function is indeed analytic. The fact that in the complex plane φ has a singularity at $t = -i\theta$ implies that the power series of φ about 0 has radius of convergence θ . In particular, this implies that not all exponential moments are finite. This is reflected by the above calculation that shows that, for $t \geq \theta$, the exponential moments are infinite.

(iii) Let X be log-normally distributed (see Example 15.5). Then $\mathbf{E}[X^n] = e^{n^2/2}$. In particular, here $\alpha = \infty$. In fact, in Example 15.5, we saw that here the moments do not determine the distribution of X .

(iv) If X takes values in $\mathbb{N}_0$ and if $\beta := \limsup_{n \rightarrow \infty} \mathbf{E}[X^n]^{1/n} < 1$, then by Hadamard's criterion $\psi_X(z) := \sum_{k=1}^{\infty} \mathbf{P}[X = k] z^k < \infty$ for $|z| < 1/\beta$. In particular, the probability generating function X is characterized by its derivatives $\psi_X^{(n)}(1)$, $n \in \mathbb{N}$, and thus by the moments of X . Compare Theorem 3.2(iii).

Theorem 15.34 Let X be a real random variable and let φ be its characteristic function. Let $n \in \mathbb{N}$, and assume that φ is $2n$ -times differentiable at 0 with derivative $\varphi^{(2n)}(0)$. Then $\mathbf{E}[X^{2n}] = (-1)^n \varphi^{(2n)}(0) < \infty$.

Proof We carry out the proof by induction on $n \in \mathbb{N}_0$. For $n = 0$, the claim is trivially true. Now, let $n \in \mathbb{N}$, and assume φ is $2n$ -times (not necessarily continuously) differentiable at 0. Define $u(t) = \operatorname{Re}(\varphi(t))$. Then u is also $2n$ -times differentiable at 0 and $u^{(2k-1)}(0) = 0$ for $k = 1, \dots, n$ since u is even. Since $\varphi^{(2n)}(0)$ exists, $\varphi^{(2n-1)}$ is continuous at 0 and $\varphi^{(2n-1)}(t)$ exists for all $t \in (-\varepsilon, \varepsilon)$ for some $\varepsilon > 0$. Furthermore, $\varphi^{(k)}$ exists in $(-\varepsilon, \varepsilon)$ and is continuous on $(-\varepsilon, \varepsilon)$ for any $k = 0, \dots, 2n - 2$. By Taylor's formula, for every $t \in (-\varepsilon, \varepsilon)$,

$$\left| u(t) - \sum_{k=0}^{n-1} u^{(2k)}(0) \frac{t^{2k}}{(2k)!} \right| \leq \frac{|t|^{2n-1}}{(2n-1)!} \sup_{\theta \in (0,1]} |u^{(2n-1)}(\theta t)|. \quad (15.5)$$

Define a continuous function $f_n : \mathbb{R} \rightarrow [0, \infty)$ by $f_n(0) = 1$ and

$$f_n(x) = (-1)^n (2n)! x^{-2n} \left[\cos(x) - \sum_{k=0}^{n-1} (-1)^k \frac{x^{2k}}{(2k)!} \right] \quad \text{for } x \neq 0.$$

By the induction hypothesis, $\mathbf{E}[X^{2k}] = u^{(2k)}(0)$ for all $k = 1, \dots, n-1$. Using (15.5), we infer

$$\begin{aligned}\mathbf{E}[f_n(tX)X^{2n}] &\leq \frac{2n}{|t|} \sup_{\theta \in (0,1]} |u^{(2n-1)}(\theta t)| \leq g_n(t) \\ &:= 2n \sup_{\theta \in (0,1]} \frac{|u^{(2n-1)}(\theta t)|}{\theta|t|}\end{aligned}$$

Now Fatou's lemma implies

$$\begin{aligned}\mathbf{E}[X^{2n}] &= \mathbf{E}[f_n(0)X^{2n}] \leq \liminf_{t \rightarrow 0} \mathbf{E}[f_n(tX)X^{2n}] \\ &\leq \liminf_{t \rightarrow 0} g_n(t) = 2n |u^{(2n)}(0)| < \infty.\end{aligned}$$

By Theorem 15.31, this implies $\mathbf{E}[X^{2n}] = (-1)^n u^{(2n)}(0) = (-1)^n \varphi^{(2n)}(0)$.

Remark 15.35 For odd moments, the statement of the theorem may fail (see, e.g., Exercise 15.4.4 for the first moment). Indeed, φ is differentiable at 0 with derivative im for some $m \in \mathbb{R}$ if and only if $x\mathbf{P}[|X| > x] \xrightarrow{x \rightarrow \infty} 0$ and $\mathbf{E}[X \mathbb{1}_{\{|X| \leq x\}}] \xrightarrow{x \rightarrow \infty} m$. (See [54, Chapter XVII.2a, p.565].)

Exercise 15.4.1 Let X and Y be nonnegative random variables with

$$\limsup_{n \rightarrow \infty} \frac{1}{n} \mathbf{E}[|X|^n]^{1/n} < \infty, \quad \limsup_{n \rightarrow \infty} \frac{1}{n} \mathbf{E}[|Y|^n]^{1/n} < \infty$$

and

$$\mathbf{E}[X^m Y^n] = \mathbf{E}[X^m] \mathbf{E}[Y^n] \quad \text{for all } m, n \in \mathbb{N}_0$$

Show that X and Y are independent.

Hint: Consider the random variable Y with respect to the probability measure $X^m \mathbf{P}[\cdot] / \mathbf{E}[X^m]$, and use Corollary 15.32 to show that

$$\mathbf{E}[X^m \mathbb{1}_A(Y)] / \mathbf{E}[X^m] = \mathbf{P}[Y \in A] \quad \text{for all } A \in \mathcal{B}(R) \text{ and } m \in \mathbb{N}_0$$

Now apply Corollary 15.32 to the random variable X with respect to the probability measure $\mathbf{P}[\cdot | Y \in A]$.

Exercise 15.4.2 Let $r, s > 0$ and let $Z \sim \Gamma_{1,r+s}$ and $B \sim \beta_{r,s}$ be independent (see Example 1.107). Use Exercise 15.4.1 to show that the random variables $X := BZ$ and $Y := (1 - B)Z$ are independent with $X \sim \Gamma_{1,r}$ and $Y \sim \Gamma_{1,s}$.

Exercise 15.4.3 Show that, for $\alpha > 2$, the function $\phi_\alpha(t) = e^{-|t|^\alpha}$ is not a characteristic function.

Hint: Assume the contrary and show that the corresponding random variable would have variance zero.

Exercise 15.4.4 Let $X_1, X_2, \dots$ be i.i.d. real random variables with characteristic function φ . Show the following.

(i) If φ is differentiable at 0, then $\varphi'(0) = im$ for some $m \in \mathbb{R}$.

(ii) φ is differentiable at 0 with $\varphi'(0) = im$ if and only if $(X_1 + \dots + X_n)/n \xrightarrow{n \rightarrow \infty} m$ in probability.

(iii) Assume that φ is differentiable at 0 and that $X_1 \geq 0$ almost surely. Then $\mathbf{E}[X_1] = -i\varphi'(0) < \infty$.

Hint: Use (ii) and the law of large numbers.

(iv) The distribution of X_1 can be chosen such that φ is differentiable at 0 but $\mathbf{E}[|X_1|] = \infty$.

Exercise 15.4.5 Let $X_1, X_2, \dots$ be real random variables. For $r > 0$ let $M_r(X_n) = \mathbf{E}[|X_n|^r]$ be the r th absolute moment. For $k \in \mathbb{N}$ let $m_k(X_n) = \mathbf{E}[X_n^k]$ be the k th moment if $M_k(X_n) < \infty$.

(i) Assume that X is a real random variable and that $(X_{n_l})_{l \in \mathbb{N}}$ is a subsequence such that

$$\mathbf{P}_{X_{n_l}} \xrightarrow{l \rightarrow \infty} \mathbf{P}_X \quad \text{weakly.}$$

Assume further that there is an $r > 0$ such that $\sup_{n \in \mathbb{N}} M_r(X_n) < \infty$. Show that for any $k \in \mathbb{N} \cap (0, r)$ and $s \in (0, r)$ we have $M_s(X) < \infty$ as well as

$$M_s(X_{n_l}) \xrightarrow{l \rightarrow \infty} M_s(X) \quad \text{and} \quad m_k(X_{n_l}) \xrightarrow{l \rightarrow \infty} m_k(X).$$

(ii) Assume that for any $k \in \mathbb{N}$ the limit

$$m_k := \lim_{n \rightarrow \infty} m_k(X_n)$$

exists and is finite (note that finitely many of the $m_k(X_n)$ may be undefined for any k). Show that there exists a real random variable X with $m_k = m_k(X)$ for all $k \in \mathbb{N}$ and a subsequence $(X_{n_l})_{l \in \mathbb{N}}$ such that

$$\mathbf{P}_{X_{n_l}} \xrightarrow{l \rightarrow \infty} \mathbf{P}_X \quad \text{weakly.}$$

(iii) Show the theorem of Fréchet-Shohat: If in (ii) the distribution of X is determined by its moments $m_k(X), k \in \mathbb{N}$ (see Corollary 15.32), then

$$\mathbf{P}_{X_n} \xrightarrow{n \rightarrow \infty} \mathbf{P}_X \quad \text{weakly.}$$

Exercise 15.4.6 Let $X_1, X_2, \dots$ be i.i.d. real random variables with $\mathbf{E}[X_1] = 0$ and $\mathbf{E}[|X_1|^k] < \infty$ for all $k \in \mathbb{N}$.

(i) Show that there exist finite numbers $(d_k)_{k \in \mathbb{N}}$ (depending on the distribution $\mathbf{P}_{X_1}$) such that for any $k, n \in \mathbb{N}$ we have

$$\left| \mathbf{E}[(X_1 + \dots + X_n)^{2k-1}] \right| \leq d_{2k-1} n^{k-1}$$

and

$$\left| \mathbf{E}[(X_1 + \dots + X_n)^{2k}] - \frac{(2k)!}{2^k k!} \mathbf{E}[X_1^2]^k n^k \right| \leq d_{2k} n^{k-1}.$$

Hint: Expand the bracket expression, sort the terms by the different mixed moments and compute by combinatorial means the number of each type of summand. The number of summands of the type $\mathbf{E}[X_{l_1}^2 \dots X_{l_k}^2]$ (for different $l_1, \dots, l_k$) is of particular importance.

(ii) Let $Y \sim \mathcal{N}_{0,1}$. Use Theorem 15.31(i) to show that for any $k \in \mathbb{N}$ we have

$$\mathbf{E}[Y^{2k-1}] = 0 \quad \text{and} \quad \mathbf{E}[Y^{2k}] = \frac{(2k)!}{2^k k!}$$

(iii) Let $S_n^* = (X_1 + \dots + X_n) / \sqrt{n \operatorname{Var}[X_1]}$. Use Exercise 15.4.5 to infer the statement of the central limit theorem (compare Theorem 15.37)

$$\mathbf{P}_{S_n^*} \xrightarrow{n \rightarrow \infty} \mathcal{N}_{0,1} \quad \text{weakly.}$$

5.15.5 15.5 The Central Limit Theorem

In the strong law of large numbers, we saw that, for large n , the order of magnitude of the sum $S_n = X_1 + \dots + X_n$ of i.i.d. integrable random variables is $n \cdot \mathbf{E}[X_1]$. Of course, for any n , the actual value of S_n will sometimes be smaller than $n \cdot \mathbf{E}[X_1]$ and sometimes larger. In the central limit theorem (CLT), we study the size and shape of the typical fluctuations around $n \cdot \mathbf{E}[X_1]$ in the case where the X_i have a finite variance.

We prepare for the proof of the CLT with a lemma.

Lemma 15.36 Let $X_1, X_2, \dots$ be i.i.d. real random variables with $\mathbf{E}[X_1] = \mu$ and $\text{Var}[X_1] = \sigma^2 \in (0, \infty)$. Let

$$S_n^* := \frac{1}{\sqrt{n\sigma^2}} \sum_{k=1}^n (X_k - \mu)$$

be the normalized n th partial sum. Then

$$\lim_{n \rightarrow \infty} \varphi_{S_n^*}(t) = e^{-t^2/2} \quad \text{for all } t \in \mathbb{R}$$

Proof Let $\varphi = \varphi_{X_k - \mu}$. Then, by Theorem 15.31(ii),

$$\varphi(t) = 1 - \frac{\sigma^2}{2}t^2 + \varepsilon(t)t^2$$

where the error term $\varepsilon(t)$ goes to 0 if $t \rightarrow 0$. By Lemma 15.11(iv) and (ii),

$$\varphi_{S_n^*}(t) = \varphi\left(\frac{t}{\sqrt{n\sigma^2}}\right)^n$$

Now $\left(1 - \frac{t^2}{2n}\right)^n \xrightarrow{n \rightarrow \infty} e^{-t^2/2}$ and

$$\begin{aligned} \left| \left(1 - \frac{t^2}{2n}\right)^n - \varphi\left(\frac{t}{\sqrt{n\sigma^2}}\right)^n \right| &\leq n \left| 1 - \frac{t^2}{2n} - \varphi\left(\frac{t}{\sqrt{n\sigma^2}}\right) \right| \\ &\leq n \frac{t^2}{n\sigma^2} \left| \varepsilon\left(\frac{t}{\sqrt{n\sigma^2}}\right) \right| \xrightarrow{n \rightarrow \infty} 0. \end{aligned}$$

(Note that $|u^n - v^n| \leq |u - v| \cdot n \cdot \max(|u|, |v|)^{n-1}$ for all $u, v \in \mathbb{C}$.) $\square$

Theorem 15.37 (Central limit theorem (CLT)) Let $X_1, X_2, \dots$ be i.i.d. real random variables with $\mu := \mathbf{E}[X_1] \in \mathbb{R}$ and $\sigma^2 := \text{Var}[X_1] \in (0, \infty)$. For $n \in \mathbb{N}$, let $S_n^* := \frac{1}{\sqrt{\sigma^2 n}} \sum_{i=1}^n (X_i - \mu)$. Then

$$\mathbf{P}_{S_n^*} \xrightarrow{n \rightarrow \infty} \mathcal{N}_{0,1} \quad \text{weakly.}$$

For $-\infty \leq a < b \leq +\infty$, we have $\lim_{n \rightarrow \infty} \mathbf{P}[S_n^* \in [a, b]] = \frac{1}{\sqrt{2\pi}} \int_a^b e^{-x^2/2} dx$.

Proof By Lemma 15.36 and Lévy's continuity theorem (Theorem 15.23), $(\mathbf{P}_{S_n^*})$ converges to the distribution with characteristic function $\varphi(t) = e^{-t^2/2}$. By Theorem 15.12(i), this is $\mathcal{N}_{0,1}$. The additional claim follows by the Portemanteau theorem (Theorem 13.16) since $\mathcal{N}_{0,1}$ has a density; hence $\mathcal{N}_{0,1}(\partial[a, b]) = 0$. $\square$

Remark 15.38 If we prefer to avoid the continuity theorem, we could argue as follows: For every $K > 0$ and $n \in \mathbb{N}$, we have $\mathbf{P}[|S_n^*| > K] \leq \text{Var}[S_n^*]/K^2 = 1/K^2$; hence the sequence $(\mathbf{P}_{S_n^*})$ is tight. As characteristic functions determine distributions, the claim follows by Theorem 13.34. $\square$

We want to weaken the assumption in Theorem 15.37 that the random variables are identically distributed. In fact, we can even take a different set of summands for every n . The essential assumptions are that the summands are independent, each summand contributes only a little to the sum and the sum is centered and has variance 1.

Definition 15.39 For every $n \in \mathbb{N}$, let $k_n \in \mathbb{N}$ and let $X_{n,1}, \dots, X_{n,k_n}$ be real random variables. We say that $(X_{n,l}) = (X_{n,l}, l = 1, \dots, k_n, n \in \mathbb{N})$ is an array of random variables. Its row sum is denoted by $S_n = X_{n,1} + \dots + X_{n,k_n}$. The array is called

- independent if, for every $n \in \mathbb{N}$, the family $(X_{n,l})_{l=1, \dots, k_n}$ is independent,

- centered if $X_{n,l} \in \mathcal{L}^1(\mathbf{P})$ and $\mathbf{E}[X_{n,l}] = 0$ for all n and l , and
- normed if $X_{n,l} \in \mathcal{L}^2(\mathbf{P})$ and $\sum_{l=1}^{k_n} \text{Var}[X_{n,l}] = 1$ for all $n \in \mathbb{N}$.

A centered array is called a null array if its individual components are asymptotically negligible in the sense that, for all $\varepsilon > 0$,

$$\lim_{n \rightarrow \infty} \max_{1 \leq l \leq k_n} \mathbf{P}[|X_{n,l}| > \varepsilon] = 0.$$

Definition 15.40 A centered array of random variables $(X_{n,l})$ with $X_{n,l} \in \mathcal{L}^2(\mathbf{P})$ for every $n \in \mathbb{N}$ and $l = 1, \dots, k_n$ is said to satisfy the Lindeberg condition if, for all $\varepsilon > 0$,

$$L_n(\varepsilon) := \frac{1}{\text{Var}[S_n]} \sum_{l=1}^{k_n} \mathbf{E} \left[X_{n,l}^2 \mathbb{1}_{\{X_{n,l}^2 > \varepsilon^2 \text{Var}[S_n]\}} \right] \xrightarrow{n \rightarrow \infty} 0. \quad (15.6)$$

The array fulfills the Lyapunov condition if there exists a $\delta > 0$ such that

$$\lim_{n \rightarrow \infty} \frac{1}{\text{Var}[S_n]^{1+(\delta/2)}} \sum_{l=1}^{k_n} \mathbf{E} \left[|X_{n,l}|^{2+\delta} \right] = 0. \quad (15.7)$$

Lemma 15.41 The Lyapunov condition implies the Lindeberg condition.

Proof For $x \in \mathbb{R}$, we have $x^2 \mathbb{1}_{\{|x| > \varepsilon'\}} \leq (\varepsilon')^{-\delta} |x|^{2+\delta} \mathbb{1}_{\{|x| > \varepsilon'\}} \leq (\varepsilon')^{-\delta} |x|^{2+\delta}$. Letting $\varepsilon' := \varepsilon \sqrt{\text{Var}[S_n]}$, we get

$$L_n(\varepsilon) \leq \varepsilon^{-\delta} \frac{1}{\text{Var}[S_n]^{1+(\delta/2)}} \sum_{l=1}^{k_n} \mathbf{E} \left[|X_{n,l}|^{2+\delta} \right].$$

Example 15.42 Let $(Y_n)_{n \in \mathbb{N}}$ be i.i.d. with $\mathbf{E}[Y_n] = 0$ and $\text{Var}[Y_n] = 1$. Let $k_n = n$ and $X_{n,l} = \frac{Y_l}{\sqrt{n}}$. Then $(X_{n,l})$ is independent, centered and normed. Clearly, $\mathbf{P}[|X_{n,l}| > \varepsilon] = \mathbf{P}[|Y_1| > \sqrt{\varepsilon n}] \xrightarrow{n \rightarrow \infty} 0$; hence $(X_{n,l})$ is a null array. Furthermore, $L_n(\varepsilon) = \mathbf{E} \left[Y_1^2 \mathbb{1}_{\{|Y_1| > \varepsilon \sqrt{n}\}} \right] \xrightarrow{n \rightarrow \infty} 0$; hence $(X_{n,l})$ satisfies the Lindeberg condition.

If $Y_1 \in \mathcal{L}^{2+\delta}(\mathbf{P})$ for some $\delta > 0$, then

$$\sum_{l=1}^n \mathbf{E} \left[|X_{n,l}|^{2+\delta} \right] = n^{-(\delta/2)} \mathbf{E} \left[|Y_1|^{2+\delta} \right] \xrightarrow{n \rightarrow \infty} 0.$$

In this case, $(X_{n,l})$ also satisfies the Lyapunov condition.

The following theorem is due to Lindeberg (1922, see [108]) for the implication (i) $\implies$ (ii) and is attributed to Feller (1935 and 1937, see [51, 52]) for the converse implication (ii) $\implies$ (i). As most applications only need (i) $\implies$ (ii), we only prove that implication. For a proof of (ii) $\implies$ (i) see, e.g., [154, Theorem III.4.3].

Theorem 15.43 (Central limit theorem of Lindeberg-Feller) Let $(X_{n,l})$ be an independent centered and normed array of real random variables. For every $n \in \mathbb{N}$, let $S_n = X_{n,1} + \dots + X_{n,k_n}$. Then the following are equivalent.

- The Lindeberg condition holds.
- $(X_{n,l})$ is a null array and $\mathbf{P}_{S_n} \xrightarrow{n \rightarrow \infty} \mathcal{N}_{0,1}$.

We prepare for the proof of Lindeberg's theorem with a couple of lemmas.

Lemma 15.44 If (i) of Theorem 15.43 holds, then $(X_{n,l})$ is a null array.

Proof For $\varepsilon > 0$, by Chebyshev's inequality,

$$\sum_{l=1}^{k_n} \mathbf{P}[|X_{n,l}| > \varepsilon] \leq \varepsilon^{-2} \sum_{l=1}^{k_n} \mathbf{E} \left[X_{n,l}^2 \mathbb{1}_{\{|X_{n,l}| > \varepsilon\}} \right] = L_n(\varepsilon) \xrightarrow{n \rightarrow \infty} 0.$$

In the following, $\varphi_{n,l}$ and φ_n will always denote the characteristic functions of $X_{n,l}$ and S_n .
 Lemma 15.45 For every $n \in \mathbb{N}$ and $t \in \mathbb{R}$, we have

$$\sum_{l=1}^{k_n} |1 - \varphi_{n,l}(t)| \leq \frac{t^2}{2}$$

Proof For every $x \in \mathbb{R}$, we have $|e^{itx} - 1 - itx| \leq \frac{t^2 x^2}{2}$. Since $\mathbf{E}[X_{n,l}] = 0$,

$$\begin{aligned} \sum_{l=1}^{k_n} |\varphi_{n,l}(t) - 1| &= \sum_{l=1}^{k_n} |\mathbf{E}[e^{itX_{n,l}} - 1]| \\ &\leq \sum_{l=1}^{k_n} \mathbf{E}[|e^{itX_{n,l}} - itX_{n,l} - 1|] + |\mathbf{E}[itX_{n,l}]| \\ &\leq \sum_{l=1}^{k_n} \frac{t^2}{2} \mathbf{E}[X_{n,l}^2] = \frac{t^2}{2}. \end{aligned}$$

Lemma 15.46 If (i) of Theorem 15.43 holds, then

$$\lim_{n \rightarrow \infty} \left| \log \varphi_n(t) - \sum_{l=1}^{k_n} \mathbf{E}[e^{itX_{n,l}} - 1] \right| = 0$$

Proof Let $m_n := \max_{l=1, \dots, k_n} |\varphi_{n,l}(t) - 1|$. Note that, for all $\varepsilon > 0$,

$$|e^{itx} - 1| \leq \begin{cases} 2x^2/\varepsilon^2, & \text{if } |x| > \varepsilon, \\ \varepsilon t, & \text{if } |x| \leq \varepsilon. \end{cases}$$

This implies

$$\begin{aligned} |\varphi_{n,l}(t) - 1| &\leq \mathbf{E}[|e^{itX_{n,l}} - 1| \mathbb{1}_{\{|X_{n,l}| \leq \varepsilon\}}] + \mathbf{E}[|e^{itX_{n,l}} - 1| \mathbb{1}_{\{|X_{n,l}| > \varepsilon\}}] \\ &\leq \varepsilon t + 2\varepsilon^{-2} \mathbf{E}[X_{n,l}^2 \mathbb{1}_{\{|X_{n,l}| > \varepsilon\}}]. \end{aligned}$$

Hence, for all $\varepsilon > 0$,

$$\limsup_{n \rightarrow \infty} m_n \leq \limsup_{n \rightarrow \infty} (\varepsilon t + 2\varepsilon^{-2} L_n(\varepsilon)) = \varepsilon t,$$

and thus $\lim_{n \rightarrow \infty} m_n = 0$. Now $|\log(1+x) - x| \leq x^2$ for all $x \in \mathbb{C}$ with $|x| \leq \frac{1}{2}$. If n is sufficiently large that $m_n < \frac{1}{2}$, then

$$\begin{aligned}
\left| \log \varphi_n(t) - \sum_{l=1}^{k_n} \mathbf{E} [e^{itX_{n,l}} - 1] \right| &= \left| \sum_{l=1}^{k_n} \log(\varphi_{n,l}(t)) - \mathbf{E} [e^{itX_{n,l}} - 1] \right| \\
&\leq \sum_{l=1}^{k_n} (\varphi_{n,l}(t) - 1)^2 \\
&\leq m_n \sum_{l=1}^{k_n} |\varphi_{n,l}(t) - 1| \\
&\leq \frac{1}{2} m_n t^2 \quad (\text{by Lemma 15.45}) \\
&\longrightarrow 0 \quad \text{for } n \rightarrow \infty
\end{aligned}$$

The fundamental trick of the proof, which is worth remembering, consists in the introduction of the function

$$f_t(x) := \begin{cases} \frac{1+x^2}{x^2} (e^{itx} - 1 - \frac{itx}{1+x^2}), & \text{if } x \neq 0 \\ -\frac{t^2}{2}, & \text{if } x = 0 \end{cases} \quad (15.8)$$

and the measures $\mu_n, v_n \in \mathcal{M}_f(\mathbb{R}), n \in \mathbb{N}$,

$$v_n(dx) := \sum_{l=1}^{k_n} x^2 \mathbf{P}_{X_{n,l}}(dx) \quad \text{and} \quad \mu_n(dx) := \sum_{l=1}^{k_n} \frac{x^2}{1+x^2} \mathbf{P}_{X_{n,l}}(dx)$$

Lemma 15.47 For every $t \in \mathbb{R}$, we have $f_t \in C_b(\mathbb{R})$.

Proof For all $|x| \geq 1$, we have $\frac{1+x^2}{x^2} \leq 2$; hence

$$|f_t(x)| \leq 2 \left(|e^{itx}| + 1 + \frac{tx}{1+x^2} \right) \leq 4 + 2|t|$$

We have to show that f_t is continuous at 0. By Taylor's formula (Lemma 15.30), we get

$$e^{itx} = 1 + itx - \frac{t^2 x^2}{2} + R(tx)$$

where the error term is bounded by $|R(tx)| \leq \frac{1}{6}|tx|^3$. Hence, for fixed t ,

$$\lim_{0 \neq x \rightarrow 0} f_t(x) = \lim_{0 \neq x \rightarrow 0} \frac{1}{x^2} \left(itx \left(1 - \frac{1}{1+x^2} \right) - \frac{t^2 x^2}{2} + R(tx) \right) = -\frac{t^2}{2}.$$

Lemma 15.48 If (i) of Theorem 15.43 holds, then $v_n \xrightarrow{n \rightarrow \infty} \delta_0$ weakly.

Proof For every $n \in \mathbb{N}$, we have $v_n \in \mathcal{M}_1(\mathbb{R})$ since

$$v_n(\mathbb{R}) = \sum_{l=1}^{k_n} \int x^2 \mathbf{P}_{X_{n,l}}(dx) = \sum_{l=1}^{k_n} \text{Var}[X_{n,l}] = 1$$

However, for $\varepsilon > 0$, we have $v_n((-\varepsilon, \varepsilon)^c) = L_n(\varepsilon) \xrightarrow{n \rightarrow \infty} 0$; hence $v_n \xrightarrow{n \rightarrow \infty} \delta_0$.

Lemma 15.49 If (i) of Theorem 15.43 holds, then

$$\int f_t(x) \mu_n(dx) + it \int \frac{1}{x} \mu_n(dx) \xrightarrow{n \rightarrow \infty} -\frac{t^2}{2}.$$

Proof Since $(x \mapsto f_t(x)/(1+x^2)) \in C_b(\mathbb{R})$, by Lemma 15.48,

$$\int f_t(x) \mu_n(dx) = \int f_t(x) \frac{1}{1+x^2} v_n(dx) \xrightarrow{n \rightarrow \infty} f_t(0) = -\frac{t^2}{2}.$$

Now $(x \mapsto x/(1+x^2)) \in C_b(\mathbb{R})$ and $\mathbf{E}[X_{n,l}] = 0$ for all n and l ; hence

$$\begin{aligned} \int \frac{1}{x} \mu_n(dx) &= \sum_{l=1}^{k_n} \mathbf{E} \left[\frac{X_{n,l}}{1+X_{n,l}^2} \right] = \sum_{l=1}^{k_n} \mathbf{E} \left[\frac{X_{n,l}}{1+X_{n,l}^2} - X_{n,l} \right] \\ &= - \sum_{l=1}^{k_n} \mathbf{E} \left[X_{n,l}^2 \cdot \frac{X_{n,l}}{1+X_{n,l}^2} \right] \\ &= - \int \frac{x}{1+x^2} v_n(dx) \xrightarrow{n \rightarrow \infty} 0 \end{aligned}$$

Proof of Theorem 15.43 "(i) $\implies$ (ii)" We have to show that $\lim_{n \rightarrow \infty} \log \varphi_n(t) = -\frac{t^2}{2}$ for every $t \in \mathbb{R}$. By Lemma 15.46, this is equivalent to

$$\lim_{n \rightarrow \infty} \sum_{l=1}^{k_n} (\varphi_{n,l}(t) - 1) = -\frac{t^2}{2}.$$

Now $f_t(x) \frac{x^2}{1+x^2} = e^{itx} - 1 - \frac{itx}{1+x^2}$. Hence

$$\begin{aligned} \sum_{l=1}^{k_n} (\varphi_{n,l}(t) - 1) &= \sum_{l=1}^{k_n} \int \left(f_t(x) \frac{x^2}{1+x^2} + \frac{itx}{1+x^2} \right) \mathbf{P}_{X_{n,l}}(dx) \\ &= \int f_t d\mu_n + it \int \frac{1}{x} \mu_n(dx) \\ &\xrightarrow{n \rightarrow \infty} -\frac{t^2}{2} \quad (\text{by Lemma 15.49}). \end{aligned}$$

As an application of the Lindeberg-Feller theorem, we give the so-called threeseries theorem, which is due to Kolmogorov.

Theorem 15.50 (Kolmogorov's three-series theorem) Let $X_1, X_2, \dots$ be independent real random variables. Let $K > 0$ and $Y_n := X_n \mathbb{1}_{\{|X_n| \leq K\}}$ for all $n \in \mathbb{N}$.

The series $\sum_{n=1}^{\infty} X_n$ converges almost surely if and only if each of the following three conditions holds:

- (i) $\sum_{n=1}^{\infty} \mathbf{P}[|X_n| > K] < \infty$.
- (ii) $\sum_{n=1}^{\infty} \mathbf{E}[Y_n]$ converges.
- (iii) $\sum_{n=1}^{\infty} \text{Var}[Y_n] < \infty$.

Proof ". Assume that (i), (ii) and (iii) hold. By Exercise 7.1.1, since (iii) holds, the series $\sum_{n=1}^{\infty} (Y_n - \mathbf{E}[Y_n])$ converges a.s. As (ii) holds, $\sum_{n=1}^{\infty} Y_n$ converges almost surely. By the Borel-Cantelli lemma, there exists an $N = N(\omega)$ such that $|X_n| < K$; hence $X_n = Y_n$ for all $n \geq N$. Hence $\sum_{n=1}^{\infty} X_n = \sum_{n=1}^{N-1} X_n + \sum_{n=N}^{\infty} Y_n$ converges a.s.

" $\implies$ " Assume that $\sum_{n=1}^{\infty} X_n$ converges a.s. Clearly, this implies (i) (otherwise, by the Borel-Cantelli lemma, $|X_n| > K$ infinitely often, contradicting the assumption).

We assume that (iii) does not hold and produce a contradiction. To this end, let $\sigma_n^2 = \sum_{k=1}^n \text{Var}[Y_k]$ and define an array $(X_{n,l}; l = 1, \dots, n, n \in \mathbb{N})$ by $X_{n,l} = (Y_l - \mathbf{E}[Y_l])/\sigma_n$. This array is centered and normed. Since $\sigma_n^2 \xrightarrow{n \rightarrow \infty} \infty$, for every $\varepsilon > 0$ and for sufficiently large $n \in \mathbb{N}$, we have $2K < \varepsilon \sigma_n$; thus $|X_{n,l}| \leq \varepsilon$ for all $l = 1, \dots, n$. This implies $L_n(\varepsilon) \xrightarrow{n \rightarrow \infty} 0$, where $L_n(\varepsilon) = \sum_{l=1}^n \mathbf{E} \left[X_{n,l}^2 \mathbb{1}_{\{|X_{n,l}| \geq \varepsilon\}} \right]$ is the quantity of the Lindeberg condition (see (15.6)). By the Lindeberg-Feller theorem, we then get $S_n := X_{n,1} + \dots + X_{n,n} \xrightarrow{n \rightarrow \infty} \mathcal{N}_{0,1}$. As shown in the first part of this proof, almost sure convergence of $\sum_{n=1}^{\infty} X_n$ and (i) imply that

$$\sum_{n=1}^{\infty} Y_n \quad \text{converges almost surely.} \quad (15.9)$$

In particular, $T_n := (Y_1 + \dots + Y_n) / \sigma_n \xrightarrow{n \rightarrow \infty} 0$. Thus, by Slutsky's theorem, we also have $(S_n - T_n) \xrightarrow{n \rightarrow \infty} \mathcal{N}_{0,1}$. On the other hand, for all $n \in \mathbb{N}$, the difference $S_n - T_n$ is deterministic, contradicting the assumption that (iii) does not hold.

Now that we have established (iii), by Exercise 7.1.1, we see that $\sum_{n=1}^{\infty} (Y_n - \mathbf{E}[Y_n])$ converges almost surely. Together with (15.9), we conclude (ii).

As a supplement, we cite a statement about the speed of convergence in the central limit theorem (see, e.g., [154, Chapter III, Section 11] for a proof). With different bounds (instead of 0.8), the statement was found independently by Berry [10] and Esseen [46].

Theorem 15.51 (Berry-Esseen) Let $X_1, X_2, \dots$ be independent and identically distributed with $\mathbf{E}[X_1] = 0$, $\mathbf{E}[X_1^2] = \sigma^2 \in (0, \infty)$ and $\gamma := \mathbf{E}[|X_1|^3] < \infty$. Let $S_n^* := \frac{1}{\sqrt{n\sigma^2}}(X_1 + \dots + X_n)$ and let $\Phi : x \mapsto \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-t^2/2} dt$ be the distribution function of the standard normal distribution. Then, for all $n \in \mathbb{N}$,

$$\sup_{x \in \mathbb{R}} |\mathbf{P}[S_n^* \leq x] - \Phi(x)| \leq \frac{0.8\gamma}{\sigma^3 \sqrt{n}}$$

Example 15.52 Let $\alpha \in (0, 1)$. Consider the distribution μ_α on $\mathbb{R}$ with density

$$f_\alpha(x) = \frac{1}{2\alpha} |x|^{-1-1/\alpha} \mathbb{1}_{\{|x| \geq 1\}}$$

Let $X_1, X_2, \dots$, be i.i.d. random variables with distribution μ_α . Then $\mathbf{E}[X_1] = 0$ and $\sigma^2 := \text{Var}[X_1] = 1/(1 - 2\alpha) < \infty$ if $\alpha < 1/2$. Let F_n denote the distribution function of S_n^* and F_Φ the distribution function of the standard normal distribution.

The closer F_n and F_Φ are, the closer lie the points $(F_\Phi^{-1}(t), F_n^{-1}(t))$ on the diagonal $\{(x, x) : x \in \mathbb{R}\}$. A graphical representation of the points $(F_\Phi^{-1}(t), F_n^{-1}(t))$, $t \in \mathbb{R}$ is called Q-Q-plot or quantile-quantile-plot.

As α approaches $1/2$, the distribution μ_α has less and less moments. Hence we expect the convergence in the central limit theorem to be slower. For fixed n , we expect the deviation of F_n from F_Φ to be larger for larger α . The graphs in Fig. 15.2 illustrate this.

Exercise 15.5.1 The argument of Remark 15.38 is more direct than the argument with Lévy's continuity theorem but is less robust: Give a sequence $X_1, X_2, \dots$ of independent real random variables with $\mathbf{E}[|X_n|] = \infty$ for all $n \in \mathbb{N}$ but such that

$$\frac{X_1 + \dots + X_n}{\sqrt{n}} \xrightarrow{n \rightarrow \infty} \mathcal{N}_{0,1}.$$

Exercise 15.5.2 Let $Y_1, Y_2, \dots$ be i.i.d. with $\mathbf{E}[Y_i] = 0$ and $\mathbf{E}[Y_i^2] = 1$. Let $Z_1, Z_2, \dots$ be independent random variables (and independent of $Y_1, Y_2, \dots$) with

$$\mathbf{P}[Z_i = i] = \mathbf{P}[Z_i = -i] = \frac{1}{2} (1 - \mathbf{P}[Z_i = 0]) = \frac{1}{2} \frac{1}{i^2}$$

For $i, n \in \mathbb{N}$, define $X_i := Y_i + Z_i$ and $S_n = X_1 + \dots + X_n$.

 Fig. 15.2 Q-Q-plots for S_{100}

from Example 15.52 with $\alpha = 0.4$ (left) and $\alpha = 0.48$ (right). The abscissa shows the quantiles of the standard normal distribution. For convenience, also the diagonal is drawn

Show that $n^{-1/2}S_n \xrightarrow{n \rightarrow \infty} \mathcal{N}_{0,1}$ but that $(X_i)_{i \in \mathbb{N}}$ does not satisfy the Lindeberg condition.

Hint: Do not try a direct computation!

Exercise 15.5.3 Let $X_1, X_2, \dots$ be i.i.d. random variables with density

$$f(x) = \frac{1}{|x|^3} \mathbb{1}_{\mathbb{R} \setminus [-1,1]}(x)$$

Then $\mathbf{E}[X_1^2] = \infty$ but there are numbers $A_1, A_2, \dots$, such that

$$\frac{X_1 + \dots + X_n}{A_n} \xrightarrow{n \rightarrow \infty} \mathcal{N}_{0,1}.$$

Determine one such sequence $(A_n)_{n \in \mathbb{N}}$ explicitly.

5.15.6 15.6 Multidimensional Central Limit Theorem

We come to a multidimensional version of the CLT.

Definition 15.53 Let C be a (strictly) positive definite symmetric real $d \times d$ matrix and let $\mu \in \mathbb{R}^d$. A random vector $X = (X_1, \dots, X_d)^T$ is called d -dimensional normally distributed with expectation μ and covariance matrix C if X has the density

$$f_{\mu,C}(x) = \frac{1}{\sqrt{(2\pi)^d \det(C)}} \exp\left(-\frac{1}{2} \langle x - \mu, C^{-1}(x - \mu) \rangle\right) \quad (15.10)$$

for $x \in \mathbb{R}^d$. In this case, we write $X \sim \mathcal{N}_{\mu,C}$.

Theorem 15.54 Let $\mu \in \mathbb{R}^d$ and let C be a real positive definite symmetric $d \times d$ matrix. If $X \sim \mathcal{N}_{\mu,C}$, then the following statements hold.

- (i) $\mathbf{E}[X_i] = \mu_i$ for all $i = 1, \dots, d$.
- (ii) $\text{Cov}[X_i, X_j] = C_{i,j}$ for all $i, j = 1, \dots, d$.
- (iii) $\langle \lambda, X \rangle \sim \mathcal{N}_{\langle \lambda, \mu \rangle, \langle \lambda, C \lambda \rangle}$ for every $\lambda \in \mathbb{R}^d$.
- (iv) $\varphi(t) := \mathbf{E}[e^{i\langle t, X \rangle}] = e^{i\langle t, \mu \rangle} e^{-\frac{1}{2} \langle t, C t \rangle}$ for every $t \in \mathbb{R}^d$.

Moreover, $X \sim \mathcal{N}_{\mu,C} \iff \text{(iii)} \iff \text{(iv)}$.

Proof (i) and (ii) follow by simple computations. The same is true for (iii) and (iv). The implication (iii) $\implies$ (iv) is straightforward. The family

$$\{f_t : x \mapsto e^{i\langle t, x \rangle}, t \in \mathbb{R}^d\}$$

is a separating class for $\mathcal{M}_1(\mathbb{R}^d)$ by the Stone-Weierstraß theorem. Hence φ determines the distribution of X uniquely.

Remark 15.55 For one-dimensional normal distributions, it is natural to define the degenerate normal distribution by $\mathcal{N}_{\mu,0} := \delta_\mu$. For the multidimensional situation, there are various possibilities for degeneracy depending on the size of the kernel of C . If C is only positive semidefinite (and symmetric, of course), we define $\mathcal{N}_{\mu,C}$ as that distribution on $\mathbb{R}^n$ with characteristic function $\varphi(t) = e^{i\langle t, \mu \rangle} e^{-\frac{1}{2}\langle t, Ct \rangle}$.

Theorem 15.56 (Cramér-Wold device) Let $X_n = (X_{n,1}, \dots, X_{n,d})^T \in \mathbb{R}^d, n \in \mathbb{N}$, be random vectors. Then, the following are equivalent:

- (i) There is a random vector X such that $X_n \xrightarrow{n \rightarrow \infty} X$.
- (ii) For any $\lambda \in \mathbb{R}^d$, there is a random variable X^λ such that $\langle \lambda, X_n \rangle \xrightarrow{n \rightarrow \infty} X^\lambda$.

If (i) and (ii) hold, then $X^\lambda \stackrel{\mathcal{D}}{=} \langle \lambda, X \rangle$ for all $\lambda \in \mathbb{R}^d$.

Proof Assume (i). Let $\lambda \in \mathbb{R}^d$ and $s \in \mathbb{R}$. The map $\mathbb{R}^d \rightarrow \mathbb{C}, x \mapsto e^{is\langle \lambda, x \rangle}$ is continuous and bounded; hence we have $\mathbf{E}[e^{is\langle \lambda, X_n \rangle}] \xrightarrow{n \rightarrow \infty} \mathbf{E}[e^{is\langle \lambda, X \rangle}]$. Thus (ii) holds with $X^\lambda := \langle \lambda, X \rangle$.

Now assume (ii). Then $(\mathbf{P}_{X_{n,l}})_{n \in \mathbb{N}}$ is tight for every $l = 1, \dots, d$. Hence $(\mathbf{P}_{X_n})_{n \in \mathbb{N}}$ is tight and thus relatively sequentially compact (Prohorov's theorem). For any weak limit point Q for $(\mathbf{P}_{X_n})_{n \in \mathbb{N}}$ and for any $\lambda \in \mathbb{R}^d$, we have

$$\int Q(dx) e^{i\langle \lambda, x \rangle} = \mathbf{E}[e^{iX^\lambda}]$$

Hence the limit point Q is unique and thus $(\mathbf{P}_{X_n})_{n \in \mathbb{N}}$ converges weakly to Q . That is, (i) holds.

If (ii) holds, then the distributions of the limiting random variables X^λ are uniquely determined and by what we have shown already, $X^\lambda = \langle \lambda, X \rangle$ is one possible choice. Thus $X^\lambda \stackrel{\mathcal{D}}{=} \langle \lambda, X \rangle$.

Theorem 15.57 (Central limit theorem in $\mathbb{R}^d$) Let $(X_n)_{n \in \mathbb{N}}$ be i.i.d. random vectors with $\mathbf{E}[X_{n,i}] = 0$ and $\mathbf{E}[X_{n,i}X_{n,j}] = C_{ij}, i, j = 1, \dots, d$. Let $S_n^* := \frac{X_1 + \dots + X_n}{\sqrt{n}}$. Then

$$\mathbf{P}_{S_n^*} \xrightarrow{n \rightarrow \infty} \mathcal{N}_{0,C} \quad \text{weakly.}$$

Proof Let $\lambda \in \mathbb{R}^d$. Define $X_n^\lambda = \langle \lambda, X_n \rangle, S_n^\lambda = \langle \lambda, S_n^* \rangle$ and $S_\infty \sim \mathcal{N}_{0,C}$. Then $\mathbf{E}[X_n^\lambda] = 0$ and $\text{Var}[X_n^\lambda] = \langle \lambda, C\lambda \rangle$. By the one-dimensional central limit theorem, we have $\mathbf{P}_{S_n^\lambda} \xrightarrow{n \rightarrow \infty} \mathcal{N}_{0, \langle \lambda, C\lambda \rangle} = \mathbf{P}_{\langle \lambda, S_\infty \rangle}$. By Theorem 15.56, this yields the claim.

Exercise 15.6.1 Let $\mu \in \mathbb{R}^d$, let C be a symmetric positive semidefinite real $d \times d$ matrix and let $X \sim \mathcal{N}_{\mu,C}$ (in the sense of Remark 15.55). Show that $AX \sim \mathcal{N}_{A\mu, ACAT}$ for every $m \in \mathbb{N}$ and every real $m \times d$ matrix A .

Exercise 15.6.2 (Cholesky factorization) Let C be a positive definite symmetric real $d \times d$ matrix. Then there exists a real $d \times d$ matrix $A = (a_{kl})$ with $A \cdot A^T = C$. The matrix A can be chosen to be lower triangular. Let $W := (W_1, \dots, W_d)^T$, where $W_1, \dots, W_d$ are independent and $\mathcal{N}_{0,1}$ -distributed. Define $X := AW + \mu$. Show that $X \sim \mathcal{N}_{\mu,C}$.

5.16 16 Infinitely Divisible Distributions

For every n , the normal distribution $\mathcal{N}_{\mu, \sigma^2}$ is the n th convolution power of a probability measure (namely, of $\mathcal{N}_{\mu/n, \sigma^2/n}$). This property is called infinite divisibility and is shared by other probability distributions such as the Poisson distribution and the Gamma distribution. In the first section, we study which probability measures on $\mathbb{R}$ are infinitely divisible and give an exhaustive description of this class of distributions by means of the Lévy-Khinchin formula.

Unlike the Poisson distribution, the normal distribution is the limit of rescaled sums of i.i.d. random variables (central limit theorem). In the second section, we investigate briefly which subclass of the infinitely divisible measures on $\mathbb{R}$ shares this property.

5.16.1 16.1 Lévy-khinchin Formula

For the sake of brevity, in this section, we use the shorthand "CFP" for "characteristic function of a probability measure on $\mathbb{R}$ ".

Definition 16.1 A measure $\mu \in \mathcal{M}_1(\mathbb{R})$ is called infinitely divisible if, for every $n \in \mathbb{N}$, there is a $\mu_n \in \mathcal{M}_1(\mathbb{R})$ such that $\mu_n^{*n} = \mu$. Analogously, a CFP φ is called infinitely divisible if, for every $n \in \mathbb{N}$, there is a CFP φ_n such that $\varphi = \varphi_n^n$. A real random variable X is called infinitely divisible if, for every $n \in \mathbb{N}$, there exist i.i.d. random variables $X_{n,1}, \dots, X_{n,n}$ such that $X \stackrel{D}{=} X_{n,1} + \dots + X_{n,n}$.

Manifestly, all three notions of infinite divisibility are equivalent, and we will use them synonymously. Note that the uniqueness of μ_n and φ_n , respectively, is by no means evident. Indeed, n -fold divisibility alone does not imply uniqueness of the n th convolution root $\mu^{*1/n} := \mu_n$ or of φ_n , respectively. As an example for even n , choose a real-valued CFP φ for which $|\varphi| \neq \varphi$ is also a CFP (see Examples 15.16 and 15.17). Then $\varphi^n = |\varphi|^n$ is n -fold divisible; however, the factors are not unique.

By virtue of Lévy's continuity theorem, one can show that (see Exercise 16.1.1) $\varphi(t) \neq 0$ for all $t \in \mathbb{R}$ if φ is infinitely divisible. The probabilistic meaning of this fact is that as a continuous function $\log(\varphi(t))$ is uniquely defined and thus there exists only one continuous function $\varphi^{1/n} = \exp(\log(\varphi)/n)$. The n th convolution roots are thus unique if the distribution is infinitely divisible.

Example 16.2

- (i) δ_x is infinitely divisible with $\delta_{x/n}^{*n} = \delta_x$ for every $n \in \mathbb{N}$.
- (ii) The normal distribution is infinitely divisible with $\mathcal{N}_{m,\sigma^2} = \mathcal{N}_{m/n,\sigma^2/n}^{*n}$.
- (iii) The Cauchy distribution Cau_a with density $x \mapsto (a\pi)^{-1} (1 + (x/a)^2)^{-1}$ is infinitely divisible with $\text{Cau}_a = \text{Cau}_{a/n}^{*n}$. Indeed, Cau_a has CFP $\varphi_a(t) = e^{-a|t|}$; hence $\varphi_{a/n}^n = \varphi_a$.
- (iv) Every symmetric stable distribution with index $\alpha \in (0, 2]$ and scale parameter $\gamma > 0$ (that is, the distribution with CFP $\varphi_{\alpha,\gamma}(t) = e^{-|\gamma t|^\alpha}$) is infinitely divisible. Indeed, $\varphi_{\alpha,\gamma/n^{1/\alpha}}^n = \varphi_{\alpha,\gamma}$. (To be precise, we have shown only for $\alpha \in (0, 1]$ (in Corollary 15.25) and for $\alpha = 2$ (normal distribution) that $\varphi_{\alpha,\gamma}$ is in fact a CFP. In Section 16.2, we will show that this is true for all $\alpha \in (0, 2]$. For $\alpha > 2$, $\varphi_{\alpha,\gamma}$ is not a CFP, see Exercise 15.4.3.)
- (v) The Gamma distribution $\Gamma_{\theta,r}$ with CFP $\varphi_{\theta,r}(t) = \exp(r\psi_\theta(t))$, where $\psi_\theta(t) = \log(1 - it/\theta)$, is infinitely divisible with $\Gamma_{\theta,r} = \Gamma_{\theta/r,n}^{*n}$.
- (vi) The Poisson distribution is infinitely divisible with $\text{Poi}_\lambda = \text{Poi}_{\lambda/n}^{*n}$.
- (vii) The negative binomial distribution $b_{r,p}^-(\{k\}) = \binom{-r}{k} (-1)^k p^r (1-p)^k$, $k \in \mathbb{N}_0$, with parameters $r > 0$ and $p \in (0, 1)$, is infinitely divisible with $b_{r,p}^- = \left(b_{r/n,p}^-\right)^{*n}$. Indeed, $\varphi_{r,p}(t) = e^{r\psi_p(t)}$, where

$$\psi_p(t) = \log(p) - \log(1 - (1-p)e^{it})$$

(viii) Let X and Y be independent with $X \sim \mathcal{N}_{0,\sigma^2}$ and $Y \sim \Gamma_{\theta,r}$, where $\sigma^2, \theta, r > 0$. It can be shown that the random variable $Z := X/\sqrt{Y}$ is infinitely divisible (see [65] or [131]). In particular, Student's t -distribution with $k \in \mathbb{N}$ degrees of freedom is infinitely divisible (this is the case where $\sigma^2 = 1$ and $\theta = r = k/2$).

(ix) The binomial distribution $b_{n,p}$ with parameters $n \in \mathbb{N}$ and $p \in (0, 1)$ is not infinitely divisible (why?).

(x) Somewhat more generally, there is no nontrivial infinitely divisible distribution that is concentrated on a bounded interval.

A main goal of this section is to show that every infinitely divisible distribution can be composed of three generic ones:

- the Dirac measures δ_x with $x \in \mathbb{R}$,
- the normal distributions $\mathcal{N}_{\mu, \sigma^2}$ with $\mu \in \mathbb{R}$ and $\sigma^2 > 0$, and
- (limits of) convolutions of Poisson distributions.

As convolutions of Poisson distributions play a special role, we will consider them separately.

If $v \in \mathcal{M}_1(\mathbb{R})$ with CFP φ_v and if $\lambda > 0$, then one can easily check that $\varphi(t) = \exp(\lambda(\varphi_v(t) - 1))$ is the CFP of $\mu_\lambda = \sum_{k=0}^{\infty} e^{-\lambda} \frac{\lambda^k}{k!} \nu^{*k}$. Hence, formally we can write $\mu_\lambda = e^{*\lambda(v-\delta_0)}$. Indeed, μ_λ is infinitely divisible with $\mu_\lambda = \mu_{\lambda/n}^{*n}$. We want to combine the two parameters λ and v into one parameter λv . For $v \in \mathcal{M}_f(\mathbb{R})$, we can define $\nu^{*n} = \nu(\mathbb{R})^n (\nu/\nu(\mathbb{R}))^{*n}$ (and $\nu^{*n} = 0$ if $\nu = 0$). In both cases, let $\nu^{*0} := \delta_0$. Hence we make the following definition.

Definition 16.3 The compound Poisson distribution with intensity measure $\nu \in \mathcal{M}_f(\mathbb{R})$ is the following probability measure on $\mathbb{R}$:

$$\text{CPoi}_\nu := e^{*(v-\nu(\mathbb{R})\delta_0)} := e^{-v(\mathbb{R})} \sum_{n=0}^{\infty} \frac{v^{*n}}{n!}.$$

The CFP of CPoi_ν is given by

$$\varphi_\nu(t) = \exp \left(\int (e^{itx} - 1) v(dx) \right) \quad (16.1)$$

In particular, $\text{CPoi}_{\mu+\nu} = \text{CPoi}_\mu * \text{CPoi}_\nu$; hence CPoi_ν is infinitely divisible.

Example 16.4 For every measurable set $A \subset \mathbb{R} \setminus \{0\}$ and every $r > 0$,

$$r^{-1} \text{CPoi}_{rv}(A) = e^{-rv(\mathbb{R})} v(A) + e^{-rv(\mathbb{R})} \sum_{k=2}^{\infty} \frac{r^{k-1} v^{*k}(A)}{k!} \xrightarrow{r \downarrow 0} v(A).$$

We use this in order to show that $b_{r,p}^- = \text{CPoi}_{rv}$ for some $\nu \in \mathcal{M}_f(\mathbb{N})$. To this end, for $k \in \mathbb{N}$, we compute

$$r^{-1} b_{r,p}^-(\{k\}) = \frac{r(r+1) \cdot 3 \cdot (r+k-1)}{rk!} p^r (1-p)^k \xrightarrow{r \downarrow 0} \frac{(1-p)^k}{k}.$$

If we had $b_{r,p}^- = \text{CPoi}_{rv}$ for some $v \in \mathcal{M}_f(\mathbb{N})$, then we would have $v(\{k\}) = (1-p)^k/k$. We compute the CFP of CPoi_{rv} for this v ,

$$\varphi_{rv}(t) = \exp \left(r \sum_{k=1}^{\infty} \frac{((1-p)e^{it})^k - (1-p)^k}{k} \right) = p^r (1 - (1-p)e^{it})^{-r}.$$

However, this is the CFP of $b_{r,p}^-$; hence indeed $b_{r,p}^- = \text{CPoi}_{rv}$.

Not every infinitely divisible distribution is of the type CPoi_ν , however we have the following theorem.

Theorem 16.5 A probability measure μ on $\mathbb{R}$ is infinitely divisible if and only if there is a sequence $(v_n)_{n \in \mathbb{N}}$ in $\mathcal{M}_f(\mathbb{R} \setminus \{0\})$ such that $\text{CPoi}_{v_n} \xrightarrow{n \rightarrow \infty} \mu$.

Since every CPoi_{v_n} is infinitely divisible, on the one hand we have to show that this property is preserved under weak limits. On the other hand, we show that, for infinitely divisible μ , the sequence $v_n = n\mu^{*1/n}$ does the trick. We prepare for the proof of Theorem 16.5 with a further theorem.

Theorem 16.6 Let $(\varphi_n)_{n \in \mathbb{N}}$ be a sequence of CFPs. Then the following are equivalent.

- (i) For every $t \in \mathbb{R}$, the limit $\varphi(t) = \lim_{n \rightarrow \infty} \varphi_n^n(t)$ exists and φ is continuous at 0.
 - (ii) For every $t \in \mathbb{R}$, the limit $\psi(t) = \lim_{n \rightarrow \infty} n(\varphi_n(t) - 1)$ exists and ψ is continuous at 0.
- If (i) and (ii) hold, then $\varphi = e^\psi$ is a CFP.

Proof The proof is based on a Taylor expansion of the logarithm,

$$|\log(z) - (z - 1)| \leq \frac{1}{2}|z - 1|^2 \quad \text{for } z \in \mathbb{C} \text{ with } |z - 1| < \frac{1}{2}$$

In particular, for $(z_n)_{n \in \mathbb{N}}$ in $\mathbb{C}$,

$$\limsup_{n \rightarrow \infty} n|z_n - 1| < \infty \iff \limsup_{n \rightarrow \infty} |n \log(z_n)| < \infty, \quad (16.2)$$

and $\lim_{n \rightarrow \infty} n(z_n - 1) = \lim_{n \rightarrow \infty} n \log(z_n)$ if one of the limits exists.

Applying this to $z_n = \varphi_n(t)$, we see that (ii) implies (i). On the other hand, (i) implies (ii) if $\liminf_{n \rightarrow \infty} n \log(|\varphi_n(t)|) > -\infty$ and hence if $\varphi(t) \neq 0$ for all $t \in \mathbb{R}$.

Since φ is continuous at 0 and since $\varphi(0) = 1$, there is an $\varepsilon > 0$ with $|\varphi(t)| > \frac{1}{2}$ for all $t \in [-\varepsilon, \varepsilon]$. Since φ and φ_n are CFPs, $|\varphi|^2$ and $|\varphi_n|^2$ are also CFPs. Thus, since $|\varphi_n(t)|^{2n}$ converges to $|\varphi(t)|^2$ pointwise, Lévy's continuity theorem implies uniform convergence on compact sets. Now apply (16.2) with $z_n = |\varphi_n(t)|^2$. Thus $(n(1 - |\varphi_n(t)|^2))_{n \in \mathbb{N}}$ is bounded for $t \in [-\varepsilon, \varepsilon]$. Hence, by Lemma 15.11(v), $n(1 - |\varphi_n(2t)|^2) \leq 4n(1 - |\varphi_n(t)|^2)$ also is bounded; thus

$$|\varphi(2t)|^2 \geq \liminf_{n \rightarrow \infty} \exp(4n(|\varphi_n(t)|^2 - 1)) = (|\varphi(t)|^2)^4.$$

Inductively, we get $|\varphi(t)| \geq 2^{-(4^k)}$ for $|t| \leq 2^k \varepsilon$. Hence there is a $\gamma > 0$ such that

$$|\varphi(t)| > \frac{1}{2} e^{-\gamma t^2} \quad \text{for all } t \in \mathbb{R} \quad (16.3)$$

If (i) and (ii) hold, then

$$\log \varphi(t) = \lim_{n \rightarrow \infty} n \log(\varphi_n(t)) = \lim_{n \rightarrow \infty} n(\varphi_n(t) - 1) = \psi(t)$$

By Lévy's continuity theorem, as a continuous limit of CFPs, φ is a CFP.

Corollary 16.7 If the conditions of Theorem 16.6 hold, then φ^r is a CFP for every $r > 0$. In particular, $\varphi = (\varphi^{1/n})^n$ is infinitely divisible.

Proof If φ_n is the CFP of $\mu_n \in \mathcal{M}_1(\mathbb{R})$, then $e^{rn(\varphi_n - 1)}$ is the CFP of $\text{CPoi}_{rn\mu_n}$. Being a limit of CFPs that is continuous at 0, by Lévy's continuity theorem, $\varphi^r = e^{r\psi} = \lim_{n \rightarrow \infty} e^{rn(\varphi_n - 1)}$ is a CFP. Letting $r = \frac{1}{n}$, we get that $\varphi = (\varphi^{1/n})^n$ is infinitely divisible.

Corollary 16.8 Let $\varphi : \mathbb{R} \rightarrow \mathbb{C}$ be continuous at 0. φ is an infinitely divisible CFP if and only if there is a sequence $(\varphi_n)_{n \in \mathbb{N}}$ of CFPs such that $\varphi_n^n(t) \rightarrow \varphi(t)$ for all $t \in \mathbb{R}$.

Proof One implication has been shown already in Corollary 16.7. Hence, let φ be an infinitely divisible CFP. Then $\varphi_n = \varphi^{1/n}$ serves the purpose.

Corollary 16.9 If $(\mu_n)_{n \in \mathbb{N}}$ is a (weakly) convergent sequence of infinitely divisible probability measures on $\mathbb{R}$, then $\mu = \lim_{n \rightarrow \infty} \mu_n$ is infinitely divisible.

Proof Apply Theorem 16.6, where φ_n is the CFP of $\mu_n^{*1/n}$.

Corollary 16.10 If $\mu \in \mathcal{M}_1(\mathbb{R})$ is infinitely divisible, then there exists a continuous convolution semigroup $(\mu_t)_{t \geq 0}$ with $\mu_1 = \mu$ and a stochastic process $(X_t)_{t \geq 0}$ with independent, stationary increments $X_t - X_s \sim \mu_{t-s}$ for $t > s$.

Proof Let φ be the CFP of μ . The existence of the convolution semigroup follows by Corollaries 16.8 and 16.7 if we define μ_r by φ^r . Since $\varphi^r(t) \neq 0$ for all $t \in \mathbb{R}$, we have $\varphi^r \rightarrow 1$ for $r \rightarrow 0$ and thus the semigroup is continuous. Finally, Theorem 14.47 implies the existence of the process X .

Corollary 16.11 If φ is an infinitely divisible CFP, then there exists a $\gamma > 0$ with $|\varphi(t)| \geq \frac{1}{2}e^{-\gamma t^2}$ for all $t \in \mathbb{R}$. In particular, for $\alpha > 2, t \mapsto e^{-|t|^\alpha}$ is not a CFP.

Proof This is a direct consequence of (16.3).

Proof of Theorem 16.5 As every CPoi_{v_n} is infinitely divisible, by Corollary 16.9, the weak limit is also infinitely divisible.

Now let μ be infinitely divisible with CFP φ . Fix probability measures μ_n with CFP φ_n as in Corollary 16.8. By Theorem 16.6, $e^{n(\varphi_n-1)} \xrightarrow{n \rightarrow \infty} \varphi$; hence we have $\text{CPoi}_{n\mu_n} \xrightarrow{n \rightarrow \infty} v$.

Without proof, we quote the following strengthening of Corollary 16.8 that relies on a finer analysis using the arguments from the proof of Theorem 16.6.

Theorem 16.12 Let $(\varphi_{n,l}; l = 1, \dots, k_n, n \in \mathbb{N})$ be an array of CFPs with the property

$$\sup_{L>0} \limsup_{n \rightarrow \infty} \sup_{t \in [-L, L]} \sup_{l=1, \dots, k_n} |\varphi_{n,l}(t) - 1| = 0 \quad (16.4)$$

Assume that, for every $t \in \mathbb{R}$, the limit $\varphi(t) := \lim_{n \rightarrow \infty} \prod_{l=1}^{k_n} \varphi_{n,l}(t)$ exists and that φ is continuous at 0. Then φ is an infinitely divisible CFP.

Proof See, e.g., [54, Chapter Xv.7].

In the special case where for every n , the individual $\varphi_{n,l}$ are equal and where $k_n \xrightarrow{n \rightarrow \infty} \infty$, Eq. (16.4) holds automatically if the product converges to a continuous function. Thus, the theorem is in fact an improvement of Corollary 16.8.

The benefit of this theorem will become clear through the following observation. Let $(X_{n,l}; l = 1, \dots, k_n, n \in \mathbb{N})$ be an array of real random variables with CFPs $\varphi_{n,l}$. This array is a null array if and only if (16.4) holds. In fact, if $\mathbf{P}[|X_{n,l}| > \varepsilon] < \delta$, then we have $|\varphi_{n,l}(t) - 1| \leq 2\varepsilon + \delta$ for all $t \in [-1/\varepsilon, 1/\varepsilon]$. Hence (16.4) holds if the array $(X_{n,l})$ is a null array. On the other hand, (16.4) implies $\varphi_{n,l_n} \xrightarrow{n \rightarrow \infty} 1$ for every sequence (l_n) with $l_n \leq k_n$. Hence $X_{n,l_n} \xrightarrow{n \rightarrow \infty} 0$ in probability.

From these considerations and from Theorem 16.12, we conclude the following theorem.

Theorem 16.13 Let $(X_{n,l}; l = 1, \dots, k_n, n \in \mathbb{N})$ be an independent null array of real random variables. If there exists a random variable S with

$$X_{n,1} + \dots + X_{n,k_n} \xrightarrow{n \rightarrow \infty} S,$$

then S is infinitely divisible.

As a direct application of Theorem 16.5, we give a complete description of the class of infinitely divisible probability measures on $[0, \infty)$ in terms of their Laplace transforms. The following theorem is of independent interest. Here, however, it is primarily used to provide familiarity with the techniques that will be needed for the more challenging classification of the infinitely divisible probability measures on $\mathbb{R}$.

Theorem 16.14 (Lévy-Khinchin formula on $[0, \infty)$) Let $\mu \in \mathcal{M}_1([0, \infty))$ and let $u : [0, \infty) \rightarrow [0, \infty), t \mapsto -\log \int e^{-tx} \mu(dx)$ be the log-Laplace transform μ . μ is infinitely divisible if and only if there exists an $\alpha \geq 0$ and $\alpha\sigma$ -finite measure $v \in \mathcal{M}((0, \infty))$ with

$$\int (1 \wedge x) v(dx) < \infty \quad (16.5)$$

and such that

$$u(t) = \alpha t + \int (1 - e^{-tx}) v(dx) \quad \text{for } t \geq 0 \quad (16.6)$$

In this case, the pair (α, v) is unique. v is called the canonical measure or Lévy measure of μ , and α is called the deterministic part.

Proof " $\implies$ " First assume μ is infinitely divisible. The case $\mu = \delta_0$ is trivial. Now let $\mu \neq \delta_0$; hence $u(1) > 0$.

By Theorem 16.5, there exist $v_1, v_2, \dots \in \mathcal{M}_f(\mathbb{R} \setminus \{0\})$ with $\text{CPoi}_{v_n} \xrightarrow{n \rightarrow \infty} \mu$. Evidently, we can assume $v_n((-\infty, 0)) = 0$. If we define $u_n(t) := \int (1 - e^{-tx}) v_n(dx)$, then (as in (16.1)) $u_n(t) \xrightarrow{n \rightarrow \infty} u(t)$ for all $t \geq 0$. In particular, $u_n(1) > 0$ for sufficiently large n . Define $\tilde{v}_n \in \mathcal{M}_1([0, \infty))$ by $\tilde{v}_n(dx) := \frac{1-e^{-x}}{u_n(1)} v_n(dx)$. Hence, for all $t \geq 0$,

$$\int e^{-tx} \tilde{v}_n(dx) = \frac{u_n(t+1) - u_n(t)}{u_n(1)} \xrightarrow{n \rightarrow \infty} \frac{u(t+1) - u(t)}{u(1)}.$$

Therefore, the weak limit $\tilde{v} := w - \lim \tilde{v}_n$ in $\mathcal{M}_1([0, \infty))$ exists and is uniquely determined by u . Let $\alpha := \tilde{v}(\{0\})u(1)$ and define $v \in \mathcal{M}((0, \infty))$ by

$$v(dx) = u(1) (1 - e^{-x})^{-1} \mathbb{1}_{(0, \infty)}(x) \tilde{v}(dx)$$

Since $1 \wedge x \leq 2(1 - e^{-x})$ for all $x \geq 0$, clearly

$$\int (1 \wedge x) v(dx) \leq 2 \int (1 - e^{-x}) v(dx) \leq 2u(1) < \infty$$

For all $t \geq 0$, the function (compare (15.8))

$$f_t : [0, \infty) \rightarrow [0, \infty), \quad x \mapsto \begin{cases} \frac{1-e^{-tx}}{1-e^{-x}}, & \text{if } x > 0 \\ t, & \text{if } x = 0 \end{cases}$$

is continuous and bounded (by $t \wedge 1$). Hence we have

$$\begin{aligned} u(t) &= \lim_{n \rightarrow \infty} u_n(t) = \lim_{n \rightarrow \infty} u_n(1) \int f_t d\tilde{v}_n \\ &= u(1) \int f_t d\tilde{v} = \alpha t + \int (1 - e^{-tx}) v(dx) \end{aligned}$$

" $\Leftarrow$ " Now assume that α and v are given. Define the intervals $I_0 = [1, \infty)$ and $I_k = [1/(k+1), 1/k)$ for $k \in \mathbb{N}$. Let $X_0, X_1, \dots$ be independent random variables with $\mathbf{P}_{X_k} = \text{CPoi}_{(v|_{I_k})}$ for $k = 0, 1, \dots$, and let $X := \alpha + \sum_{k=0}^{\infty} X_k$. For every $k \in \mathbb{N}$, we have $\mathbf{E}[X_k] = \int_{I_k} xv(dx)$; hence $\sum_{k=1}^{\infty} \mathbf{E}[X_k] = \int_{(0,1)} xv(dx) < \infty$. Thus $X < \infty$ almost surely and $\alpha + \sum_{k=0}^n X_k \xrightarrow{n \rightarrow \infty} X$. Therefore,

$$-\log \mathbf{E}[e^{-tX}] = \alpha t - \sum_{k=0}^{\infty} \log \mathbf{E}[e^{-tX_k}] = \alpha t + \int (1 - e^{-tx}) v(dx)$$

Example 16.15 For an infinitely divisible distribution μ on $[0, \infty)$, we can compute the Lévy measure ν by the vague limit

$$v = v - \lim_{n \rightarrow \infty} n\mu^{*1/n} \Big|_{(0, \infty)} \quad (16.7)$$

Often α is also easy to obtain (e.g., via the representation from Exercise 16.1.3). For example, for the Gamma distribution, we get $\alpha = 0$ and

$$n\Gamma_{\theta, 1/n}(A) = \frac{\theta^{1/n}}{\Gamma(1/n)/n} \int_A x^{(1/n)-1} e^{-\theta x} dx \xrightarrow{n \rightarrow \infty} \int_A x^{-1} e^{-\theta x} dx$$

hence $\nu(dx) = x^{-1} e^{-\theta x} dx$.

For infinitely divisible distributions on $\mathbb{R}$, we would like to obtain a description similar to that in

the preceding theorem. However, an infinitely divisible real random variable X is not simply the difference of two infinitely divisible nonnegative random variables, as the normal distribution shows. In addition, we have more freedom if, as in the last proof, we want to express X as a sum of independent random variables X_k .

Hence we define the real random variable X as the sum of independent random variables,

$$X = b + X^N + X_0 + \sum_{k=1}^{\infty} (X_k - \alpha_k), \quad (16.8)$$

where $b \in \mathbb{R}$, $X^N = \mathcal{N}_{0,\sigma^2}$ for some $\sigma^2 \geq 0$ and $\mathbf{P}_{X_k} = \text{CPoi}_{v_k}$ with intensity measure ν_k that is concentrated on $I_k := (-1/k, -1/(k+1)] \cup [1/(k+1), 1/k)$ (with the convention $1/0 = \infty$), $k \in \mathbb{N}_0$. Furthermore, $\alpha_k = \mathbf{E}[X_k] = \int x \nu_k(dx)$ for $k \geq 1$. In order for the series to converge almost surely, it is sufficient (and also necessary, as a simple application of Kolmogorov's three-series theorem shows) that

$$\sum_{k=1}^{\infty} \text{Var}[X_k] < \infty \quad (16.9)$$

(In contrast to the situation in Theorem 16.14, here it is not necessary to have $\sum_{k=1}^{\infty} \mathbf{E}[|X_k - \alpha_k|] < \infty$. This allows for greater freedom in the choice of v than in the case of nonnegative random variables.) Now $\text{Var}[X_k] = \int x^2 \nu_k(dx)$. Hence, if we let $v = \sum_{k=0}^{\infty} \nu_k$, then (16.9) is equivalent to $\int_{(-1,1)} x^2 v(dx) < \infty$. As v_0 is always finite, this in turn is equivalent to $\int (x^2 \wedge 1) \nu(dx) < \infty$.

Definition 16.16 A σ -finite measure ν on $\mathbb{R}$ is called a canonical measure if $\nu(\{0\}) = 0$ and

$$\int (x^2 \wedge 1) \nu(dx) < \infty \quad (16.10)$$

If $\sigma^2 \geq 0$ and $b \in \mathbb{R}$, then (σ^2, b, ν) is called a canonical triple.

To every canonical triple, by (16.8) there corresponds an infinitely divisible random variable. Define

$$\psi_0(t) = \log \mathbf{E}[e^{itX_0}] = \int_{I_0} (e^{itx} - 1) \nu(dx)$$

For $k \in \mathbb{N}$, let

$$\psi_k(t) = \log \mathbf{E}[e^{it(X_k - \alpha_k)}] = \int_{I_k} (e^{itx} - 1 - itx) \nu(dx)$$

Hence

$$\psi(t) := \log \mathbf{E}[e^{itX}] = -\frac{\sigma^2}{2}t^2 + ibt + \sum_{k=0}^{\infty} \psi_k(t)$$

satisfies the Lévy-Khinchin formula

$$\psi(t) = -\frac{\sigma^2}{2}t^2 + ibt + \int (e^{itx} - 1 - itx \mathbb{1}_{\{|x|<1\}}) \nu(dx) \quad (16.11)$$

Theorem 16.17 (Lévy-Khinchin formula) Let $\mu \in \mathcal{M}_1(\mathbb{R})$ and

$$\psi(t) := \log \int e^{itx} \mu(dx)$$

μ is infinitely divisible if and only if there exists a canonical triple (σ^2, b, ν) such that (16.11) holds. By (16.11), this triple is uniquely determined.

Again, ν is called the Lévy measure of μ , σ^2 is called the Gaussian coefficient and b is called the centering constant.

Proof We have shown already that via (16.11) every canonical triple (σ^2, b, ν) corresponds to an infinitely divisible distribution μ . It remains to show:

- (i) A canonical triple is uniquely determined by (16.11).
 - (ii) For every infinitely divisible distribution, there exists a canonical triple such that (16.11) holds.
- (i) Uniqueness. Define $g_t(x) = e^{itx} - 1 - itx \mathbb{1}_{\{|x| < 1\}}$. For every $x \neq 0$, we have

$$2 \geq \left| \frac{g_t(x)}{t^2 (1 \wedge x^2)} \right| \xrightarrow{t \rightarrow \infty} 0.$$

Since (16.10) holds, by the dominated convergence theorem,

$$\begin{aligned} \lim_{t \rightarrow \infty} \frac{\psi(t)}{t^2} &= -\frac{\sigma^2}{2} + \lim_{t \rightarrow \infty} \frac{ib}{t} + \lim_{t \rightarrow \infty} \int_{-\infty}^{\infty} \left(\frac{g_t(x)}{t^2 (1 \wedge x^2)} \right) (1 \wedge x^2) \nu(dx) \\ &= -\frac{\sigma^2}{2} \end{aligned} \quad (16.12)$$

This implies the uniqueness of σ^2 . Thus we can and will assume $\sigma^2 = 0$ in the following. Define

$$\bar{\psi}(t) = \psi(t) - \frac{1}{2} \int_{t-1}^{t+1} \psi(s) ds \quad (16.13)$$

Then

$$\bar{\psi}(t) = \int_{\mathbb{R}} e^{itx} \left(1 - \frac{1}{2} \int_{-1}^1 e^{isx} ds \right) \nu(dx) = \int e^{itx} h(x) \nu(dx) \quad (16.14)$$

where $h(x) = 1 - \frac{\sin(x)}{x}$ for $x \neq 0$ and $h(0) = 0$. Define $\hat{h}(x) = h(x)/(1 \wedge x^2)$ for $x \neq 0$ and $\hat{h}(0) = 1/6$. Clearly, h and $\hat{h}$ are bounded and continuous and

$$0 < 1 - \sin(1) \leq \hat{h}(x) \leq \frac{3}{2} \quad \text{for all } x \in \mathbb{R}$$

$\bar{\psi}$ is the characteristic function of $\tilde{\nu} \in \mathcal{M}_f(\mathbb{R})$, where $\tilde{\nu}(dx) = h(x)\nu(dx)$. Hence $\tilde{\nu}$ is uniquely determined by ψ . Since $\nu(dx) = (\mathbb{1}_{\{x \neq 0\}}/h(x)) \tilde{\nu}(dx)$, ν is also uniquely determined by ψ . Now the number b is the difference of the remaining terms.

- (ii) Existence of a canonical triple. Let μ be infinitely divisible and let

$$\psi(t) = \log \int e^{itx} \mu(dx)$$

Clearly, $\text{Im}(\psi)$ is odd and $\text{Re}(\psi(t)) \leq 0$ for all $t \in \mathbb{R}$. Hence $\bar{\psi}(0) \geq 0$ (with $\bar{\psi}$ from (16.13)) and $\bar{\psi}(0) = 0$ if $\text{Re} \psi(t) = 0$ for all $t \in [-1, 1]$. By Exercise 15.2.4, this is the case if and only if $\mu = \delta_b$ for some $b \in \mathbb{R}$. In this case, $(0, b, 0)$ is the corresponding canonical triple.

Now assume $\bar{\psi}(0) > 0$. By Theorem 16.5, there exists a sequence $(\nu_n)_{n \in \mathbb{N}}$ in $\mathcal{M}_f(\mathbb{R})$ with $\text{CPoi}_{\nu_n} \xrightarrow{n \rightarrow \infty} \mu$ and $\nu_n(\{0\}) = 0$ for any $n \in \mathbb{N}$. Define

$$b_n = \int x \mathbb{1}_{\{|x| < 1\}} \nu_n(dx)$$

Then, by (16.1) and with g_t from (i),

$$\psi_n(t) := \log \int e^{itx} \text{CPoi}_{v_n}(dx) = \int (e^{itx} - 1) v_n(dx) = \int g_t dv_n + ib_n t$$

As in (16.14), we have

$$\bar{\psi}_n(t) := \psi_n(t) - \frac{1}{2} \int_{t-1}^{t+1} \psi_n(s) ds = \int e^{itx} h(x) v_n(dx)$$

As $\psi_n \xrightarrow{n \rightarrow \infty} \psi$ converges uniformly on compact sets (Theorem 15.23(i)), and since ψ is continuous and thus locally bounded, we have $\bar{\psi}_n \xrightarrow{n \rightarrow \infty} \bar{\psi}$ pointwise. Therefore,

$$\int e^{itx} h(x) v_n(dx) \xrightarrow{n \rightarrow \infty} \bar{\psi}(t) \quad (16.15)$$

In particular, $\bar{\psi}_n(0) > 0$ for large n . If we let $\tilde{v}_n(dx) = (h(x)/\bar{\psi}_n(0)) v_n(dx) \in \mathcal{M}_1(\mathbb{R})$, then $\int e^{itx} \tilde{v}_n(dx) \xrightarrow{n \rightarrow \infty} \bar{\psi}(t)/\bar{\psi}(0)$ and the right-hand side is continuous. Hence, by Lévy's continuity theorem, there is a $\tilde{v} \in \mathcal{M}_1(\mathbb{R})$ with $\tilde{v}_n \xrightarrow{n \rightarrow \infty} \tilde{v}$ and

$$\bar{\psi}(t) = \bar{\psi}(0) \int e^{itx} \tilde{v}(dx)$$

Let $\sigma^2 := -6\bar{\psi}(0)\tilde{v}(\{0\})$ and define a canonical measure ν by

$$v(dx) = \frac{\bar{\psi}(0)}{h(x)} \mathbb{1}_{\{x \neq 0\}} \tilde{v}(dx)$$

The map (compare (15.8))

$$f_t : \mathbb{R} \rightarrow \mathbb{C}, \quad x \mapsto \begin{cases} \frac{g_t(x)}{h(x)}, & \text{if } x \neq 0 \\ -3t^2, & \text{if } x = 0 \end{cases}$$

is bounded and continuous. By construction, we have

$$\int g_t dv_n = \bar{\psi}_n(0) \int f_t d\tilde{v}_n \xrightarrow{n \rightarrow \infty} \bar{\psi}(0) \int f_t d\tilde{v} = -\frac{\sigma^2}{2} t^2 + \int g_t dv$$

Hence also the limit

$$itb := \lim_{n \rightarrow \infty} itb_n = \lim_{n \rightarrow \infty} \left(\psi_n(t) - \int g_t dv_n \right) = \psi(t) + \frac{\sigma^2}{2} t^2 - \int g_t dv$$

exists, and we have

$$\psi(t) = -\frac{\sigma^2}{2} t^2 + ibt + \int g_t dv$$

Remark 16.18 There are many versions of the Lévy-Khinchin formula

$$\psi(t) = -\frac{\sigma^2}{2} t^2 + ibt + \int (e^{itx} - 1 - itf(x)) v(dx)$$

that differ in the function $itf(x)$ that is subtracted for the centering in the integral. We chose $f(x) = x \mathbb{1}_{\{|x| < 1\}}$ since this fits best to the construction with the random variables X_k . However, for a given canonical measure ν , any function $\tilde{f}$ for which $\int |f - \tilde{f}| d\nu < \infty$ holds is possible; that is, every $\tilde{f}$ for which

$|f(x) - \tilde{f}(x)|/(1 \wedge x^2)$ is bounded. One common function is, e.g., $\tilde{f}(x) = \sin(x)$. The Lévy measure and the Gaussian coefficient σ^2 do not change but the b differs:

$$\tilde{b} - b = \int (f - \tilde{f}) d\nu$$

If ν is a measure that is concentrated on $(0, \infty)$ and such that $\int (1 \wedge x) \nu(dx) < \infty$ holds, then this f is integrable with respect to ν and can thus be replaced by $\tilde{f} = 0$. Hence we recover Theorem 16.14 as a special case. However, condition (16.10) is weaker than $\int (1 \wedge x) \nu(dx) < \infty$ and thus describes a larger class of measures than is considered in Theorem 16.14. This implies that to a canonical triple $(b, 0, \nu)$ with $\nu((-\infty, 0)) = 0$ and $\int (1 \wedge x) \nu(dx) = \infty$, there corresponds an infinitely divisible probability distribution μ that is not concentrated on $[0, \infty)$, no matter how b is chosen.

For a given infinitely divisible distribution μ , we can compute the canonical measure ν as the vague limit

$$\nu = v_{n \rightarrow \infty} n \mu^{*1/n} \Big|_{(0, \infty)} \quad (16.16)$$

Example 16.19 For the Cauchy distribution Cau_a with $\psi(t) = -a|t|$, by symmetry, we get $b = 0$ and, by (16.12), $\sigma^2 = -2 \lim_{t \rightarrow \infty} \psi(t)/t^2 = 0$. Finally, if $A \subset \mathbb{R}$ with $(-\varepsilon, \varepsilon) \cap A = \emptyset$ for some $\varepsilon > 0$, then

$$n \text{Cau}_{1/n}(A) = \frac{1}{\pi} \int_A \frac{n^2}{1 + (nx)^2} dx \xrightarrow{n \rightarrow \infty} \frac{1}{\pi} \int_A \frac{1}{x^2} dx$$

Hence Cau_1 has the canonical triple $(0, 0, (\pi x^2)^{-1} dx)$.

Exercise 16.1.1 Use a variance argument to show that an infinitely divisible distribution that is concentrated on a bounded interval is a Dirac measure.

Exercise 16.1.2 Let φ be infinitely divisible, and for every $n \in \mathbb{N}$, let φ_n be a CFP with $\varphi_n^n = \varphi$. Use Lévy's continuity theorem to show that $\varphi_n \xrightarrow{n \rightarrow \infty} 1$ uniformly on compact sets $\varphi_n \xrightarrow{n \rightarrow \infty} 1$. Conclude that $\varphi(t) \neq 0$ for all $t \in \mathbb{R}$.

Exercise 16.1.3 Under the conditions of Theorem 16.14, show that

$$\alpha = \sup\{x \geq 0 : \mu([0, x)) = 0\}$$

5.16.2 16.2 Stable Distributions

A distribution μ on the real numbers is called stable if for any $n \in \mathbb{N}$, the n -fold convolution μ^{*n} equals μ up to an affine linear transformation. Hence stability can be interpreted as self-similarity. We first show that the class of stable distributions is rather simple and can easily be parameterized. Then we quote results which say that stable distributions are exactly those distributions that occur as limits of sums of i.i.d. random variables.

Symmetric Stable Distributions

For $\alpha \in (0, 2)$, let

$$\theta_\alpha := \int_{\mathbb{R}} (1 - \cos(x)) |x|^{-\alpha-1} dx = \begin{cases} -2\Gamma(-\alpha) \cos(\alpha\pi/2), & \text{if } \alpha \neq 1 \\ \pi, & \text{if } \alpha = 1 \end{cases}$$

(Note that the integral diverges for $\alpha \in \mathbb{R} \setminus (0, 2)$.) Then $\nu_\alpha(dx) = \theta_\alpha^{-1} |x|^{-\alpha-1} dx$ is a canonical measure since

$$\int (1 \wedge x^2) v_\alpha(dx) = 2\theta_\alpha^{-1} (\alpha^{-1} + (2 - \alpha)^{-1}) < \infty$$

Let ψ_α be the logarithm of the characteristic function that corresponds to the infinitely divisible measure μ_α with canonical triple $(0, 0, v_\alpha)$. By the Lévy-Khinchin formula, we have

$$\begin{aligned} \psi_\alpha(t) &= \int_{-\infty}^{\infty} (e^{itx} - 1 - itx \mathbb{1}_{\{|x| < 1\}}) \theta_\alpha^{-1} |x|^{-\alpha-1} dx \\ &= -\theta_\alpha^{-1} \int_{-\infty}^{\infty} (1 - \cos(tx)) |x|^{-\alpha-1} dx \\ &= -|t|^\alpha \end{aligned}$$

Hence $\varphi_\alpha(t) := e^{-|t|^\alpha}$ is the characteristic function of the infinitely divisible measure μ_α , which is called the symmetric stable distribution with index α . The name is due to the fact that, for i.i.d. random variables $X_1, X_2, \dots$ that are μ_α -distributed, we have

$$X_1 + \dots + X_n \stackrel{\mathcal{D}}{=} n^{1/\alpha} X_n \quad \text{for all } n \in \mathbb{N} \quad (16.17)$$

General Stable Distributions

Motivated by equation (16.17), we present a somewhat more general notion of stability of a distribution.

Definition 16.20 (Stable distribution) Let $\mu \in \mathcal{M}_1(\mathbb{R})$ be a probability distribution on the real numbers that is not concentrated in one point. Assume that $X_1, X_2, \dots$ are i.i.d. random variables with distribution μ . The distribution μ is said to be stable in the broad sense if there exist nonnegative numbers $a_1, a_2, \dots$ and real numbers $d_1, d_2, \dots$ such that

$$X_1 + \dots + X_n \stackrel{\mathcal{D}}{=} a_n X_1 + d_n \quad \text{for all } n \in \mathbb{N}. \quad (16.18)$$

μ is called stable (in the strict sense), if (16.18) holds with $d_1 = d_2 = \dots = 0$.

μ is called stable in the broad sense with index $\alpha \in (0, 2]$, if (16.18) holds with $a_n = n^{1/\alpha}, n \in \mathbb{N}$. It is called stable (in the strict sense) with index $\alpha \in (0, 2]$, if in addition, we can choose $d_1 = d_2 = \dots = 0$.

Remark 16.21 If μ is stable in the broad sense, then it is infinitely divisible.

Theorem 16.22 Let μ be stable in the broad sense.

- (i) There is an $\alpha \in (0, 2]$ such that μ is stable in the broad sense with index α .
- (ii) If $\alpha = 2$, then μ is a normal distribution.
- (iii) If $\alpha \in (0, 2)$, then the Lévy measure ν of μ has the density

$$\frac{\nu(dx)}{dx} = \begin{cases} c^- (-x)^{-\alpha-1}, & \text{if } x < 0 \\ c^+ x^{-\alpha-1}, & \text{if } x > 0 \end{cases} \quad (16.19)$$

for some $c^-, c^+ \geq 0, c^- + c^+ > 0$.

- (iv) If $\alpha \neq 1$, then there exists a $b \in \mathbb{R}$ such that $\mu * \delta_{-b}$ is stable with index α .
- (v) If $\alpha = 1$, then $d_n = (c^+ - c^-) n \log(n), n \in \mathbb{N}$. If $c^- = c^+$, then μ is a Cauchy distribution.

Remark 16.23 If μ is infinitely divisible with Lévy measure ν given by (16.19), then $\psi(t) := \log \int e^{itx} \mu(dx)$ is given by

$$\psi(t) = \begin{cases} |t|^\alpha \Gamma(-\alpha) \left[(c^+ + c^-) \cos\left(\frac{\pi\alpha}{2}\right) + i(c^+ - c^-) \sin\left(\frac{\pi\alpha}{2}\right) \right], & \alpha \neq 1, \\ -|t| (c^+ + c^-) \left[\frac{\pi}{2} + i \operatorname{sign}(t) (c^+ - c^-) \log(|t|) \right], & \alpha = 1. \end{cases} \quad (16.20)$$

Lemma 16.24 Let μ be infinitely divisible with canonical triple (σ^2, b, ν) ; that is, with log-characteristic function $\psi(t) := \log \left(\int e^{itx} \mu(dx) \right)$ given by

$$\psi(t) = -\frac{\sigma^2}{2}t^2 + ibt + \int (e^{itx} - 1 - itx\mathbb{1}_{\{|x|<1\}}) \nu(dx)$$

Further, let $a > 0, d \in \mathbb{R}, n \in \mathbb{N}$ and let $X, X_1, \dots, X_n$ be i.i.d. random variables with distribution μ .

- (i) The canonical triple of $X_1 + \dots + X_n$ is $(n\sigma^2, nb, n\nu)$.
(ii) The canonical triple of $aX + d$ is $(a^2\sigma^2, \tilde{b}, v \circ m_a^{-1})$, where $m_a : \mathbb{R} \rightarrow \mathbb{R}, x \mapsto ax$ is the multiplication by a and

$$\tilde{b} := ab + d + a \int (\mathbb{1}_{\{|x|<1/a\}} - \mathbb{1}_{\{|x|<1\}}) xv(dx) \quad (16.21)$$

Proof (i) The log-characteristic function of $X_1 + \dots + X_n$ is $n\psi$.

- (ii) The log-characteristic function of $aX + d$ is

$$\begin{aligned} \psi_{aX+d}(t) &= \psi(at) + idt \\ &= -\frac{a^2\sigma^2}{2}t^2 + i(ab + d)t + \int (e^{iatx} - 1 - iatx\mathbb{1}_{\{|x|<1\}}) v(dx) \\ &= -\frac{a^2\sigma^2}{2}t^2 + i\tilde{b}t + \int (e^{iatx} - 1 - iatx\mathbb{1}_{\{|x|<1/a\}}) v(dx) \\ &= -\frac{a^2\sigma^2}{2}t^2 + i\tilde{b}t + \int (e^{itx} - 1 - itx\mathbb{1}_{\{|x|<1\}}) v \circ m_a^{-1}(dx) \end{aligned}$$

Lemma 16.25 (Scaling of the canonical triple) Under the assumptions of Theorem 16.22, let (σ^2, b, v) be the canonical triple of μ .

- (i) We have

$$(a_n^2 - n)\sigma^2 = 0 \quad \text{for all } n \in \mathbb{N} \quad (16.22)$$

and (with m_{a_n} as in Lemma 16.24)

$$nv = v \circ m_{a_n}^{-1} \quad \text{for all } n \in \mathbb{N}. \quad (16.23)$$

- (ii) If $v = 0$, then $a_n = n^{1/2}$ for all $n \in \mathbb{N}$ and

$$d_n = b(n - n^{1/2}). \quad (16.24)$$

- (iii) Assume that $\alpha \in (0, 2)$, $a_n = n^{1/\alpha}$, and that v is given by (16.19). Then we have

$$d_n = \left(b + \frac{c^+ - c^-}{\alpha - 1}\right)(n - n^{1/\alpha}) \quad \text{if } \alpha \neq 1 \quad (16.25)$$

and

$$d_n = (c^+ - c^-)n \log(n) \quad \text{if } \alpha = 1 \quad (16.26)$$

Proof (i) Let $(a_n^2\sigma^2, \tilde{b}_n, v \circ m_{a_n}^{-1})$ be the canonical triple of $a_nX + d_n$ as determined in the preceding lemma and let $(n\sigma^2, nb, n\nu)$ be the canonical triple of $X_1 + \dots + X_n$. By (16.18) and due to the uniqueness of the canonical triple (Theorem 16.17), we infer $a_n^2\sigma^2 = n\sigma^2$, $\tilde{b}_n = nb$ and $v \circ m_{a_n}^{-1} = n\nu$.

- (ii) If $v = 0$, then $\sigma^2 > 0$, since by assumption, μ is not concentrated in one point. Hence, by (16.22), we get $a_n = n^{1/2}$. By virtue of Lemma 16.24(ii), we have $nb = \tilde{b}_n = bn^{1/2} + d_n$ and thus (16.24) holds.

- (iii) Using (16.21), we compute $\tilde{b}_n$ more explicitly:

$$\begin{aligned}
nb &= \tilde{b}_n = bn^{1/\alpha} + d_n - n^{1/\alpha} \int \mathbb{1}_{\{n^{-1/\alpha} \leq |x| < 1\}} xv(dx) \\
&= bn^{1/\alpha} + d_n - n^{1/\alpha} (c^+ - c^-) \int_{n^{-1/\alpha}}^1 x^{-\alpha} dx \\
&= bn^{1/\alpha} + d_n - (c^+ - c^-) \begin{cases} (1 - \alpha)^{-1} (n^{1/\alpha} - n), & \text{if } \alpha \neq 1 \\ n \log(n), & \text{if } \alpha = 1 \end{cases}
\end{aligned}$$

Rearranging terms yields (16.25) and (16.26).

Proof of Theorem 16.22 We distinguish the cases $\liminf_{n \rightarrow \infty} a_n n^{-1/2} < \infty$ and " $= \infty$ ".

Case 1. Assume that $\liminf_{n \rightarrow \infty} a_n n^{-1/2} < \infty$. Let $C \in [1, \infty)$ and let $(n_k)_{k \in \mathbb{N}}$ be a subsequence such that $a_{n_k} n_k^{-1/2} \leq C$ for any $k \in \mathbb{N}$. Then for any $x \in \mathbb{R} \setminus \{0\}$, we have

$$C^2 \geq n_k^{-1} (1 \vee a_{n_k}^2) \geq \frac{n_k^{-1} (1 \wedge a_{n_k}^2 x^2)}{1 \wedge x^2} \xrightarrow{k \rightarrow \infty} 0.$$

Using (16.23) and (16.10), the dominated convergence theorem yields

$$\int_{-\infty}^{\infty} (1 \wedge x^2) v(dx) = \int_{-\infty}^{\infty} \frac{n_k^{-1} (1 \wedge a_{n_k}^2 x^2)}{1 \wedge x^2} (1 \wedge x^2) v(dx) \xrightarrow{k \rightarrow \infty} 0$$

That is, we have $v = 0$. By Lemma 16.25(ii), we see that $\mu * \delta_{-b}$ is stable with index 2. This shows (ii).

Case 2. Assume that

$$a_n n^{-1/2} \xrightarrow{n \rightarrow \infty} \infty. \quad (16.27)$$

By (16.22), we have $\sigma^2 = 0$ and hence $v \neq 0$. We define the function

$$F(x) = \begin{cases} v([x, \infty)), & \text{if } x > 0 \\ v((-\infty, x]), & \text{if } x < 0 \end{cases}$$

Since we have $\nu \neq 0$, there is an $x_0 \in \mathbb{R} \setminus \{0\}$ such that $F(x_0) > 0$. By symmetry, we may assume that $x_0 > 0$. Using (16.23), we infer

$$nF(x) = F(x/a_n) \quad \text{for any } x \in \mathbb{R} \setminus \{0\}, n \in \mathbb{N}$$

and thus

$$F\left(\left(\frac{a_{n+1}}{a_n}\right)^k x_0\right) = \left(\frac{n}{n+1}\right)^k F(x_0) \quad \text{for any } k \in \mathbb{Z}$$

We can rephrase this as

$$F(x) = (x/x_0)^{-\alpha_n} F(x_0) \quad \text{for any } x \in \left\{(a_{n+1}/a_n)^k x_0 : k \in \mathbb{Z}\right\},$$

where $\alpha_n := \log((n+1)/n)/\log(a_{n+1}/a_n)$. Since F is monotone decreasing and since $F(x) \xrightarrow{x \rightarrow \infty} 0$, we have $\alpha_n > 0$ for all $n \in \mathbb{N}$, and

$$\left(\frac{m}{m+1}\right) \left(\frac{x}{x_0}\right)^{-\alpha_m} \leq \frac{F(x)}{F(x_0)} \leq \left(\frac{n+1}{n}\right) \left(\frac{x}{x_0}\right)^{-\alpha_n} \quad \text{for } x > 0, m, n \in \mathbb{N}.$$

Letting $x \rightarrow \infty$, we obtain $\alpha_m \geq \alpha_n$. By symmetry, we also get $\alpha_m \leq \alpha_n$. Hence, we define $\alpha := \alpha_1 > 0$ and get $a_n = n^{1/\alpha}$ for all $n \in \mathbb{N}$ (note that (16.18) implies $a_1 = 1$). By the assumption (16.27), we have $\alpha < 2$. This shows (i).

We have $F(1) = x_0^\alpha F(x_0) > 0$ and $F(x) = x^{-\alpha} F(1)$ for all $x > 0$. Similarly, we get $F(x) = (-x)^{-\alpha} F(-1)$ for $x < 0$ (with the same $\alpha \in (0, 2)$ since it is determined by the sequence $(a_n)_{n \in \mathbb{N}}$). Defining $c^+ = \alpha \nu([1, \infty))$ and $c^- := \alpha \nu((-\infty, -1])$, we get (16.19) and thus (iii) and (i).

The statements (iv) and (v) are immediate consequences of Lemma 16.25.

Convergence to Stable Distributions

To complete the picture, we cite theorems from [54, Chapter XVII.5] (see also [62] and [128]) that state that only stable distributions occur as limiting distributions of rescaled sums of i.i.d. random variables $X_1, X_2, \dots$.

In the following, let $X, X_1, X_2, \dots$ be i.i.d. random variables and for $n \in \mathbb{N}$, let $S_n = X_1 + \dots + X_n$.

Definition 16.26 (Domain of attraction) Let $\mu \in \mathcal{M}_1(\mathbb{R})$ be nontrivial. The domain of attraction $\text{Dom}(\mu) \subset \mathcal{M}_1(\mathbb{R})$ is the set of all distributions $\mathbf{P}_X$ with the property that there exist sequences of numbers $(a_n)_{n \in \mathbb{N}}$ and $(d_n)_{n \in \mathbb{N}}$ with

$$\frac{S_n - d_n}{a_n} \xrightarrow{n \rightarrow \infty} \mu$$

If μ is stable (in the broader sense) with index $\alpha \in (0, 2]$, then $\mathbf{P}_X$ is said to be in the domain of normal attraction if we can choose $a_n = n^{1/\alpha}$.

Theorem 16.27 Let $\mu \in \mathcal{M}_1(\mathbb{R})$ be nontrivial. Then $\text{Dom}(\mu) \neq \emptyset$ if and only if μ is stable (in the broader sense). In this case, $\mu \in \text{Dom}(\mu)$.

In the following, an important role is played by the function

$$U(x) := \mathbf{E} [X^2 \mathbb{1}_{\{|X| \leq x\}}] \quad (16.28)$$

A function $H : (0, \infty) \rightarrow (0, \infty)$ is called slowly varying at ∞ if

$$\lim_{x \rightarrow \infty} \frac{H(\gamma x)}{H(x)} = 1 \quad \text{for all } \gamma > 0$$

In the following, we assume that there exists an $\alpha \in (0, 2]$ such that

$$U(x)x^{\alpha-2} \quad \text{is slowly varying at } \infty \quad (16.29)$$

Theorem 16.28

(i) If $\mathbf{P}_X$ is in the domain of attraction of some distribution, then there exists an $\alpha \in (0, 2]$ such that (16.29) holds.

(ii) In the case $\alpha = 2$, we have: If $\mathbf{P}_X$ is not concentrated at one point, then (16.29) implies that $\mathbf{P}_X$ is in the domain of attraction of some distribution.

(iii) In the case $\alpha \in (0, 2)$, we have: $\mathbf{P}_X$ is in the domain of attraction of some distribution if and only if (16.29) holds and the limit

$$p := \lim_{x \rightarrow \infty} \frac{\mathbf{P}[X \geq x]}{\mathbf{P}[|X| \geq x]} \quad \text{exists.} \quad (16.30)$$

Theorem 16.29 Let $\mathbf{P}_X$ be in the domain of attraction of an α -stable distribution (that is, assume that condition (ii) or (iii) of Theorem 16.28 holds), and assume that $(a_n)_{n \in \mathbb{N}}$ is such that

$$C := \lim_{n \rightarrow \infty} \frac{nU(a_n)}{a_n^2} \in (0, \infty)$$

exists. Further, let μ be the stable distribution with index α whose characteristic function is given by (16.20) with $c^+ = Cp$ and $c^- = C(1-p)$.

- (i) In the case $\alpha \in (0, 1)$, let $b_n \equiv 0$.
- (ii) In the case $\alpha = 2$ and $\text{Var}[X] < \infty$, let $\mathbf{E}[X] = 0$.
- (iii) In the case $\alpha \in (1, 2]$, let $d_n = n\mathbf{E}[X]$ for all $n \in \mathbb{N}$.
- (iv) In the case $\alpha = 1$, let $d_n = na_n\mathbf{E}[\sin(X/a_n)]$ for all $n \in \mathbb{N}$.

Then

$$\frac{S_n - d_n}{a_n} \xrightarrow{n \rightarrow \infty} \mu$$

Corollary 16.30 If $\mathbf{P}_X$ is in the domain of attraction of a stable distribution with index α , then $\mathbf{E}[|X|^\beta] < \infty$ for all $\beta \in (0, \alpha)$ and $\mathbf{E}[|X|^\beta] = \infty$ if $\beta > \alpha$ and $\alpha < 2$.

Exercise 16.2.1 Let μ be an α -stable distribution and let φ be its characteristic function.

- (i) Show by a direct computation using only the definition of stability that $|\varphi(t) - 1| \leq C|t|^\alpha$ for t close to 0 (for some $C < \infty$).
- (ii) Use Exercise 15.3.2 to infer that $\mu = \delta_0$ if $\alpha > 2$.
- (iii) Modify the argument in order to show that for $\alpha > 2$, the α -stable distributions in the broad sense are also necessarily trivial.

Exercise 16.2.2 Show that the distribution on $\mathbb{R}$ with density

$$f(x) = \frac{1 - \cos(x)}{\pi x^2}$$

is not infinitely divisible.

Exercise 16.2.3 Let Φ be the distribution function of the standard normal distribution $\mathcal{N}_{0,1}$ and let $F : \mathbb{R} \rightarrow [0, 1]$ be defined by

$$F(x) = \begin{cases} 2(1 - \Phi(x^{-1/2})), & \text{if } x > 0 \\ 0, & \text{else.} \end{cases}$$

Show the following.

- (i) F is the distribution function of a $\frac{1}{2}$ -stable distribution.
- (ii) If $X_1, X_2, \dots$ are i.i.d. with distribution function F , then $\frac{1}{n} \sum_{k=0}^n X_k$ diverges almost surely for $n \rightarrow \infty$.

Hint: Compute the density of F , and show that the Laplace transform is given by $\lambda \mapsto e^{-\sqrt{2\lambda}}$.

Exercise 16.2.4 Which of the following distributions is in the domain of attraction of a stable distribution and for which parameter?

- (i) The distribution on $\mathbb{R}$ with density

$$f(x) = \begin{cases} \varrho \frac{1}{1+\alpha} |x|^\alpha, & \text{if } x < -1 \\ (1 - \varrho) \frac{1}{1+\beta} x^\beta, & \text{if } x > 1 \\ 0, & \text{else.} \end{cases}$$

Here $\alpha, \beta < -1$ and $\varrho \in [0, 1]$.

- (ii) The exponential distribution $\exp_\theta$ for $\theta > 0$.
- (iii) The distribution on $\mathbb{N}$ with weights cn^α if n is even and cn^β if n is odd. Here $\alpha, \beta < -1$ and $c = (2^\alpha \zeta(-\alpha) + (1 - 2^\beta) \zeta(-\beta))^{-1}$ (ζ is the Riemann zeta function) is the normalization constant.

5.17 17 Markov Chains

In spite of their simplicity, Markov processes with countable state space (and discrete time) are interesting mathematical objects with which a variety of real-world phenomena can be modeled. We give an introduction to the basic concepts and then study certain examples in more detail. The connection with discrete potential theory will be investigated later, in Chapter 19. Some readers might prefer to skip the somewhat technical construction of general Markov processes in Section 17.1.

There is a vast literature on Markov chains. For further reading, see, e.g., [21, 27, 64, 66, 91, 116, 123, 124, 143, 152].

5.17.1 17.1 Definitions and Construction

In the following, E is always a Polish space with Borel σ -algebra $\mathcal{B}(E)$, $I \subset \mathbb{R}$ and $(X_t)_{t \in I}$ is an E -valued stochastic process. We assume that $(\mathcal{F}_t)_{t \in I} = \mathbb{F} = \sigma(X)$ is the filtration generated by X .

Definition 17.1 We say that X has the Markov property (MP) if, for every $A \in \mathcal{B}(E)$ and all $s, t \in I$ with $s \leq t$,

$$\mathbf{P}[X_t \in A \mid \mathcal{F}_s] = \mathbf{P}[X_t \in A \mid X_s]$$

Remark 17.2 If E is a countable space, then X has the Markov property if and only if, for all $n \in \mathbb{N}$, all $s_1 < \dots < s_n < t$ and all $i_1, \dots, i_n, i \in E$ with $\mathbf{P}[X_{s_1} = i_1, \dots, X_{s_n} = i_n] > 0$, we have

$$\mathbf{P}[X_t = i \mid X_{s_1} = i_1, \dots, X_{s_n} = i_n] = \mathbf{P}[X_t = i \mid X_{s_n} = i_n] \quad (17.1)$$

In fact, (17.1) clearly implies the Markov property. On the other hand, if X has the Markov property, then (see(8.6)) $\mathbf{P}[X_t = i \mid \mathcal{F}_{s_n}](\omega) = \mathbf{P}[X_t = i \mid X_{s_n} = i_n]$ for almost all $\omega \in \{X_{s_n} = i_n\}$. Hence, for $A := \{X_{s_1} = i_1, \dots, X_{s_n} = i_n\}$ (using the

Markov property in the second equation),

$$\begin{aligned} & \mathbf{P}[X_t = i, X_{s_1} = i_1, \dots, X_{s_n} = i_n] \\ &= \mathbf{E}[\mathbf{E}[\mathbb{1}_{\{X_t = i\}} \mid \mathcal{F}_{s_n}] \mathbb{1}_A] = \mathbf{E}[\mathbf{E}[\mathbb{1}_{\{X_t = i\}} \mid X_{s_n}] \mathbb{1}_A] \\ &= \mathbf{E}[\mathbf{P}[X_t = i \mid X_{s_n} = i_n] \mathbb{1}_A] = \mathbf{P}[X_t = i \mid X_{s_n} = i_n] \mathbf{P}[A] \end{aligned}$$

Dividing both sides by $\mathbf{P}[A]$ yields (17.1).

Definition 17.3 Let $I \subset [0, \infty)$ be closed under addition and assume $0 \in I$. A stochastic process $X = (X_t)_{t \in I}$ is called a time-homogeneous Markov process with distributions $(\mathbf{P}_x)_{x \in E}$ on the space $(\Omega, \mathcal{A})$ if:

- (i) For every $x \in E$, X is a stochastic process on the probability space $(\Omega, \mathcal{A}, \mathbf{P}_x)$ with $\mathbf{P}_x[X_0 = x] = 1$.
- (ii) The map $\kappa : E \times \mathcal{B}(E)^{\otimes I} \rightarrow [0, 1]$, $(x, B) \mapsto \mathbf{P}_x[X \in B]$ is a stochastic kernel.
- (iii) X has the time-homogeneous Markov property (MP): For every $A \in \mathcal{B}(E)$, every $x \in E$ and all $s, t \in I$, we have

$$\mathbf{P}_x[X_{t+s} \in A \mid \mathcal{F}_s] = \kappa_t(X_s, A) \quad \mathbf{P}_x\text{-a.s.}$$

Here, for every $t \in I$, the transition kernel $\kappa_t : E \times \mathcal{B}(E) \rightarrow [0, 1]$ is the stochastic kernel defined for $x \in E$ and $A \in \mathcal{B}(E)$ by

$$\kappa_t(x, A) := \kappa(x, \{y \in E^I : y(t) \in A\}) = \mathbf{P}_x[X_t \in A]$$

The family $(\kappa_t(x, A), t \in I, x \in E, A \in \mathcal{B}(E))$ is also called the family of transition probabilities of X .

We write $\mathbf{E}_x$ for expectation with respect to $\mathbf{P}_x$, $\mathcal{L}_x[X] = \mathbf{P}_x$ and $\mathcal{L}_x[X | \mathcal{F}] = \mathbf{P}_x[X \in \cdot | \mathcal{F}]$ (for a regular conditional distribution of X given $\mathcal{F}$).

If E is countable, then X is called a discrete Markov process.

In the special case $I = \mathbb{N}_0$, X is called a Markov chain. In this case, κ_n is called the family of n -step transition probabilities.

Remark 17.4 We will see that the existence of the transition kernels (κ_t) implies the existence of the kernel κ . Thus, a time-homogeneous Markov process is simply a stochastic process with the Markov property and for which the transition probabilities are time-homogeneous. Although it is sometimes convenient to allow also timeinhomogeneous Markov processes, for a wide range of applications it is sufficient to consider time-homogeneous Markov processes. We will not go into the details but will henceforth assume that all Markov processes are time-homogeneous.

In the following, we will use the somewhat sloppy notation $\mathbf{P}_{X_s}[X \in \cdot] := \kappa(X_s, \cdot)$. That is, we understand X_s as the initial value of a second Markov process with the same distributions $(\mathbf{P}_x)_{x \in E}$.

Example 17.5 Let $Y_1, Y_2, \dots$ be i.i.d. $\mathbb{R}^d$ -valued random variables and let

$$S_n^x = x + \sum_{i=1}^n Y_i \quad \text{for } x \in \mathbb{R}^d \text{ and } n \in \mathbb{N}_0.$$

Define probability measures $\mathbf{P}_x$ on $((\mathbb{R}^d)^{\mathbb{N}_0}, (\mathcal{B}(\mathbb{R}^d))^{\otimes \mathbb{N}_0})$ by $\mathbf{P}_x = \mathbf{P} \circ (S^x)^{-1}$. Then the canonical process $X_n : (\mathbb{R}^d)^{\mathbb{N}_0} \rightarrow \mathbb{R}^d$ is a Markov chain with distributions $(\mathbf{P}_x)_{x \in \mathbb{R}^d}$. The process X is called a random walk on $\mathbb{R}^d$ with initial value x . $\square$

Example 17.6 In the previous example, it is simple to pass to continuous time; that is, $I = [0, \infty)$. To this end, let $(v_t)_{t \geq 0}$ be a convolution semigroup on $\mathbb{R}^d$ and let $\kappa_t(x, dy) = \delta_x * v_t(dy)$. In Theorem 14.47, for every $x \in \mathbb{R}^d$, we constructed a measure $\mathbf{P}_x$ on $((\mathbb{R}^d)^{[0, \infty)}, \mathcal{B}(\mathbb{R}^d)^{\otimes [0, \infty)})$ with

$$\mathbf{P}_x \circ (X_0, X_{t_1}, \dots, X_{t_n})^{-1} = \delta_x \otimes \bigotimes_{i=0}^{n-1} \kappa_{t_{i+1}-t_i}$$

for any choice of finitely many points $0 = t_0 < t_1 < \dots < t_n$. It is easy to check that the map $\kappa : \mathbb{R}^d \times \mathcal{B}(\mathbb{R}^d)^{\otimes [0, \infty)}, (x, A) \mapsto \mathbf{P}_x[A]$ is a stochastic kernel. The timehomogeneous Markov property is immediate from the fact that the increments are independent and stationary. $\square$

Example 17.7 (See Example 9.5 and Theorem 5.36.) Let $\theta > 0$ and $v_t^\theta(\{k\}) = e^{-\theta t} \frac{t^k \theta^k}{k!}$, $k \in \mathbb{N}_0$, the convolution semigroup of the Poisson distribution. The Markov process X on $\mathbb{N}_0$ with this semigroup is called a Poisson process with (jump) rate θ . $\square$

As in Example 17.6, we will construct a Markov process for a more general Markov semigroup of stochastic kernels.

Theorem 17.8 Let $I \subset [0, \infty)$ be closed under addition and let $(\kappa_t)_{t \in I}$ be a Markov semigroup of stochastic kernels from E to E . Then there is a measurable space $(\Omega, \mathcal{A})$ and a Markov process $((X_t)_{t \in I}, (\mathbf{P}_x)_{x \in E})$ on $(\Omega, \mathcal{A})$ with transition probabilities

$$\mathbf{P}_x[X_t \in A] = \kappa_t(x, A) \quad \text{for all } x \in E, A \in \mathcal{B}(E), t \in I. \quad (17.2)$$

Conversely, for every Markov process X , Eq. (17.2) defines a semigroup of stochastic kernels. By (17.2), the finite-dimensional distributions of X are uniquely determined.

Proof " " We construct X as a canonical process. Let $\Omega = E^{[0, \infty)}$ and $\mathcal{A} = \mathcal{B}(E)^{\otimes [0, \infty)}$. Further, let X_t be the projection on the t th coordinate. For $x \in E$,

define (see Corollary 14.43) on $(\Omega, \mathcal{A})$ the probability measure $\mathbf{P}_x$ such that, for finitely many time points $0 = t_0 < t_1 < \dots < t_n$, we have

$$\mathbf{P}_x \circ (X_{t_0}, \dots, X_{t_n})^{-1} = \delta_x \otimes \bigotimes_{i=0}^{n-1} \kappa_{t_{i+1}-t_i}.$$

Then

$$\begin{aligned} \mathbf{P}_x [X_{t_0} \in A_0, \dots, X_{t_n} \in A_n] \\ = \int_{A_{n-1}} \mathbf{P}_x [X_{t_0} \in A_0, \dots, X_{t_{n-2}} \in A_{n-2}, X_{t_{n-1}} \in dx_{n-1}] \\ \times \kappa_{t_n-t_{n-1}}(x_{n-1}, A_n) \end{aligned}$$

hence $\mathbf{P}_x [X_{t_n} \in A_n \mid \mathcal{F}_{t_{n-1}}] = \kappa_{t_n-t_{n-1}}(X_{t_{n-1}}, A_n)$. Thus X is recognized as a Markov process. Furthermore, we have $\mathbf{P}_x [X_t \in A] = (\delta_x \cdot \kappa_t)(A) = \kappa_t(x, A)$.

" $\Leftarrow$ " Now let $(X, (\mathbf{P}_x)_{x \in E})$ be a Markov process. Then a stochastic kernel κ_t is defined by

$$\kappa_t(x, A) := \mathbf{P}_x [X_t \in A] \quad \text{for all } x \in E, A \in \mathcal{B}(E), t \in I.$$

By the Markov property, we have

$$\begin{aligned} \kappa_{t+s}(x, A) &= \mathbf{P}_x [X_{t+s} \in A] = \mathbf{E}_x [\mathbf{P}_{X_s} [X_t \in A]] \\ &= \int \mathbf{P}_x [X_s \in dy] \mathbf{P}_y [X_t \in A] \\ &= \int \kappa_s(x, dy) \kappa_t(y, A) = (\kappa_s \cdot \kappa_t)(x, A) \end{aligned}$$

Hence $(\kappa_t)_{t \in I}$ is a Markov semigroup.

Theorem 17.9 A stochastic process $X = (X_t)_{t \in I}$ is a Markov process if and only if there exists a stochastic kernel $\kappa : E \times \mathcal{B}(E)^{\otimes I} \rightarrow [0, 1]$ such that, for every bounded $\mathcal{B}(E)^{\otimes I} - \mathcal{B}(\mathbb{R})$ -measurable function $f : E^I \rightarrow \mathbb{R}$ and for every $s \geq 0$ and $x \in E$, we have

$$\mathbf{E}_x [f((X_{t+s})_{t \in I}) \mid \mathcal{F}_s] = \mathbf{E}_{X_s} [f(X)] := \int_{E^I} \kappa(X_s, dy) f(y) \quad (17.3)$$

Proof " $\Rightarrow$ " The time-homogeneous Markov property follows by (17.3) with the function $f(y) = \mathbb{1}_A(y(t))$ since $\mathbf{P}_{X_s} [X_t \in A] = \mathbf{P}_x [X_{t+s} \in A \mid \mathcal{F}_s] = \kappa_t(X_s, A)$.

" $\implies$ " By the usual approximation arguments, it is enough to consider functions f that depend only on finitely many coordinates $0 \leq t_1 \leq t_2 \leq \dots \leq t_n$. We perform the proof by induction on n .

For $n = 1$ and f an indicator function, this is the (time-homogeneous) Markov property. For general measurable f , the statement follows by the usual approximation arguments.

Now assume the claim is proved for $n \in \mathbb{N}$. Again it suffices to assume that f is an indicator function of the type $f(x) = \mathbb{1}_{B_1 \times \dots \times B_{n+1}} l(x_{t_1}, \dots, x_{t_{n+1}})$ (with $B_1, \dots, B_{n+1} \in \mathcal{B}(E)$). Using the Markov property (third and fifth equalities in the following equation) and the induction hypothesis (fourth equality), we get

$$\begin{aligned}
& \mathbf{E}_x [f((X_{t+s})_{t \geq 0}) \mid \mathcal{F}_s] \\
&= \mathbf{E}_x [\mathbf{E}_x [f((X_{t+s})_{t \geq 0}) \mid \mathcal{F}_{t_n+s}] \mid \mathcal{F}_s] \\
&= \mathbf{E}_x \left[\mathbf{E}_x \left[\mathbb{1}_{\{X_{t_{n+1}+s} \in B_{n+1}\}} \mid \mathcal{F}_{t_n+s} \right] \mathbb{1}_{B_1}(X_{t_1+s}) \dots \mathbb{1}_{B_n}(X_{t_n+s}) \mid \mathcal{F}_s \right] \\
&= \mathbf{E}_x [\mathbf{P}_{X_{t_n+s}} [X_{t_{n+1}-t_n} \in B_{n+1}] \mathbb{1}_{B_1}(X_{t_1+s}) \dots \mathbb{1}_{B_n}(X_{t_n+s}) \mid \mathcal{F}_s] \\
&= \mathbf{E}_{X_s} [\mathbf{P}_{X_{t_n}} [X_{t_{n+1}-t_n} \in B_{n+1}] \mathbb{1}_{B_1}(X_{t_1}) \dots \mathbb{1}_{B_n}(X_{t_n})] \\
&= \mathbf{E}_{X_s} [\mathbf{P}_{X_0} [X_{t_{n+1}} \in B_{n+1} \mid \mathcal{F}_{t_n}] \mathbb{1}_{B_1}(X_{t_1}) \dots \mathbb{1}_{B_n}(X_{t_n})] \\
&= \mathbf{E}_{X_s} [\mathbf{P}_{X_0} [X_{t_1} \in B_1, \dots, X_{t_{n+1}} \in B_{n+1} \mid \mathcal{F}_{t_n}]] \\
&= \mathbf{E}_{X_s} [f(X)].
\end{aligned}$$

□

Corollary 17.10 A stochastic process $(X_n)_{n \in \mathbb{N}_0}$ is a Markov chain if and only if

$$\mathcal{L}_x [(X_{n+k})_{n \in \mathbb{N}_0} \mid \mathcal{F}_k] = \mathcal{L}_{X_k} [(X_n)_{n \in \mathbb{N}_0}] \quad \text{for every } k \in \mathbb{N}_0. \quad (17.4)$$

Proof If the conditional distributions exist, then, by Theorem 17.9, the equation (17.4) is equivalent to X being a Markov chain. Hence we only have to show that the conditional distributions exist.

Since E is Polish, $E^{\mathbb{N}_0}$ is also Polish and we have $\mathcal{B}(E^{\mathbb{N}_0}) = \mathcal{B}(E)^{\otimes \mathbb{N}_0}$ (see Theorem 14.8). Hence, by Theorem 8.37, there exists a regular conditional distribution of $(X_{n+k})_{n \in \mathbb{N}_0}$ given $\mathcal{F}_k$.

□

Theorem 17.11 Let $I = \mathbb{N}_0$. If $(X_n)_{n \in \mathbb{N}_0}$ is a stochastic process with distributions $(\mathbf{P}_x, x \in E)$, then the Markov property in Definition 17.3(iii) is implied by the existence of a stochastic kernel $\kappa_1 : E \times \mathcal{B}(E) \rightarrow [0, 1]$ with the property that for every $A \in \mathcal{B}(E)$, every $x \in E$ and every $s \in I$, we have

$$\mathbf{P}_x [X_{s+1} \in A \mid \mathcal{F}_s] = \kappa_1(X_s, A). \quad (17.5)$$

In this case, the n -step transition kernels κ_n can be computed inductively by

$$\kappa_n = \kappa_{n-1} \cdot \kappa_1 = \int_E \kappa_{n-1}(\cdot, dx) \kappa_1(x, \cdot)$$

In particular, the family $(\kappa_n)_{n \in \mathbb{N}}$ is a Markov semigroup and the distribution X is uniquely determined by κ_1 .

Proof In Theorem 17.9, let $t_i = i$ for every $i \in \mathbb{N}_0$. For the proof of that theorem, only (17.5) was needed. □

The (time-homogeneous) Markov property of a process means that, for fixed time t , the future (after t) depends on the past (before t) only via the present (that is, via the value X_t). We can generalize this concept by allowing random times τ instead of fixed times t .

Definition 17.12 Let $I \subset [0, \infty)$ be closed under addition. A Markov process $(X_t)_{t \in I}$ with distributions $(\mathbf{P}_x, x \in E)$ has the strong Markov property if, for every a.s. finite stopping time τ , every bounded $\mathcal{B}(E)^{\otimes I} - \mathcal{B}(\mathbb{R})$ measurable function $f : E^I \rightarrow \mathbb{R}$ and every $x \in E$, we have

$$\mathbf{E}_x [f((X_{\tau+t})_{t \in I}) \mid \mathcal{F}_\tau] = \mathbf{E}_{X_\tau} [f(X)] := \int_{E^I} \kappa(X_\tau, dy) f(y) \quad (17.6)$$

Remark 17.13 If I is countable, then the strong Markov property holds if and only if, for every almost surely finite stopping time τ , we have

$$\mathcal{L}_x [(X_{\tau+t})_{t \in \mathbb{N}_0} \mid \mathcal{F}_\tau] = \mathcal{L}_{X_\tau} [(X_t)_{t \in \mathbb{N}_0}] := \kappa(X_\tau, \cdot) \quad (17.7)$$

This follows just as in Corollary 17.10.

Most Markov processes one encounters have the strong Markov property. In particular, for countable time sets, the strong Markov property follows from the Markov property. For continuous time, however, in general, some work has to be done to establish the strong Markov property.

Theorem 17.14 If $I \subset [0, \infty)$ is countable and closed under addition, then every Markov process $(X_n)_{n \in I}$ with distributions $(\mathbf{P}_x)_{x \in E}$ has the strong Markov property.

Proof Let $f : E^I \rightarrow \mathbb{R}$ be measurable and bounded. Then, for every $s \in I$, the random variable $\mathbb{1}_{\{\tau=s\}} \mathbf{E}_x [f((X_{s+t})_{t \in I}) \mid \mathcal{F}_\tau]$ is measurable with respect to $\mathcal{F}_s$. Using the tower property of the conditional expectation and Theorem 17.9 in the third equality, we thus get

$$\begin{aligned} \mathbf{E}_x [f((X_{\tau+t})_{t \in I}) \mid \mathcal{F}_\tau] &= \sum_{s \in I} \mathbb{1}_{\{\tau=s\}} \mathbf{E}_x [f((X_{s+t})_{t \in I}) \mid \mathcal{F}_\tau] \\ &= \sum_{s \in I} \mathbf{E}_x [\mathbb{1}_{\{\tau=s\}} \mathbf{E}_x [f((X_{s+t})_{t \in I}) \mid \mathcal{F}_s] \mid \mathcal{F}_\tau] \\ &= \sum_{s \in I} \mathbf{E}_x [\mathbb{1}_{\{\tau=s\}} \mathbf{E}_{X_s} [f((X_t)_{t \in I})] \mid \mathcal{F}_\tau] \\ &= \mathbf{E}_{X_\tau} [f((X_t)_{t \in I})] \end{aligned}$$

As a simple application of the strong Markov property, we show the reflection principle for random walks.

Theorem 17.15 (Reflection principle) Let $Y_1, Y_2, \dots$ be i.i.d. real random variables with symmetric distribution $\mathcal{L}[Y_1] = \mathcal{L}[-Y_1]$. Define $X_0 = 0$ and $X_n := Y_1 + \dots + Y_n$ for $n \in \mathbb{N}$. Then, for every $n \in \mathbb{N}_0$ and $a > 0$,

$$\mathbf{P} \left[\sup_{m \leq n} X_m \geq a \right] \leq 2\mathbf{P}[X_n \geq a] - \mathbf{P}[X_n = a] \quad (17.8)$$

If we have $\mathbf{P}[Y_1 \in \{-1, 0, 1\}] = 1$, then for $a \in \mathbb{N}$ equality holds in (17.8).

Proof Let $a > 0$ and $n \in \mathbb{N}$. Define the time of first excess of a (truncated at $(n+1)$),

$$\tau := \inf \{m \geq 0 : X_m \geq a\} \wedge (n+1)$$

Then τ is a bounded stopping time and

$$\sup_{m \leq n} X_m \geq a \iff \tau \leq n.$$

Let $f(m, X) = \mathbb{1}_{\{m \leq n\}} (\mathbb{1}_{\{X_{n-m} > a\}} + \frac{1}{2} \mathbb{1}_{\{X_{n-m} = a\}})$. Then

$$f(\tau, (X_{\tau+m})_{m \in \mathbb{N}_0}) = \mathbb{1}_{\{\tau \leq n\}} \left(\mathbb{1}_{\{X_n > a\}} + \frac{1}{2} \mathbb{1}_{\{X_n = a\}} \right)$$

The strong Markov property of X yields

$$\mathbf{E}_0 [f(\tau, (X_{\tau+m})_{m \geq 0}) \mid \mathcal{F}_\tau] = \varphi(\tau, X_\tau)$$

where $\varphi(m, x) = \mathbf{E}_x[f(m, X)]$. (Recall that $\mathbf{E}_x$ denotes the expectation for X if $X_0 = x$.)

Due to the symmetry of Y_i , we have

$$\varphi(m, x) \begin{cases} \geq \frac{1}{2}, & \text{if } m \leq n \text{ and } x \geq a, \\ = \frac{1}{2}, & \text{if } m \leq n \text{ and } x = a, \\ = 0, & m > n. \end{cases}$$

Hence

$$\begin{aligned}\{\tau \leq n\} &= \{\tau \leq n\} \cap \{X_\tau \geq a\} \subset \left\{ \varphi(\tau, X_\tau) \geq \frac{1}{2} \right\} \cap \{\tau \leq n\} \\ &= \{\varphi(\tau, X_\tau) > 0\} \cap \{\tau \leq n\}\end{aligned}$$

Now (17.8) is implied by

$$\begin{aligned}\mathbf{P}[X_n > a] + \frac{1}{2}\mathbf{P}[X_n = a] &= \mathbf{E}[f(\tau, (X_{\tau+m})_{m \geq 0})] \\ &= \mathbf{E}_0[\varphi(\tau, X_\tau) \mathbb{1}_{\{\tau \leq n\}}] \geq \frac{1}{2}\mathbf{P}_0[\tau \leq n]\end{aligned}\quad (17.9)$$

Now assume $\mathbf{P}[Y_1 \in \{-1, 0, 1\}] = 1$ and $a \in \mathbb{N}$. Then $X_\tau = a$ if $\tau \leq n$. Hence

$$\{\varphi(\tau, X_\tau) > 0\} \cap \{\tau \leq n\} = \left\{ \varphi(\tau, X_\tau) = \frac{1}{2} \right\} \cap \{\tau \leq n\}$$

Thus, in the last step of (17.9), equality holds and hence also in (17.8).

Exercise 17.1.1 Let $I \subset \mathbb{R}$ and let $X = (X_t)_{t \in I}$ be a stochastic process. For $t \in I$, define the σ -algebras that code the past before t and the future beginning with t by

$$\mathcal{F}_{\leq t} := \sigma(X_s : s \in I, s \leq t) \quad \text{and} \quad \mathcal{F}_{\geq t} := \sigma(X_s : s \in I, s \geq t).$$

Show that X has the Markov property if and only if, for every $t \in I$, the σ -algebras $\mathcal{F}_{\leq t}$ and $\mathcal{F}_{\geq t}$ are independent given $\sigma(X_t)$ (compare Definition 12.20).

In other words, a process has the (possibly time-inhomogeneous) Markov property if and only if past and future are independent given the present.

5.17.2 17.2 Discrete Markov Chains: Examples

Let E be countable and $I = \mathbb{N}_0$. By Definition 17.3, a Markov process $X = (X_n)_{n \in \mathbb{N}_0}$ on E is a discrete Markov chain (or Markov chain with discrete state space).

If X is a discrete Markov chain, then $(\mathbf{P}_x)_{x \in E}$ is determined by the transition matrix

$$p = (p(x, y))_{x, y \in E} := (\mathbf{P}_x[X_1 = y])_{x, y \in E}.$$

The n -step transition probabilities

$$p^{(n)}(x, y) := \mathbf{P}_x[X_n = y]$$

can be computed as the n -fold matrix product

$$p^{(n)}(x, y) = p^n(x, y)$$

where

$$p^n(x, y) = \sum_{z \in E} p^{n-1}(x, z)p(z, y)$$

and where $p^0 = I$ is the unit matrix.

By induction, we get the Chapman-Kolmogorov equation (see (14.14)) for all $m, n \in \mathbb{N}_0$ and $x, y \in E$,

$$p^{(m+n)}(x, y) = \sum_{z \in E} p^{(m)}(x, z)p^{(n)}(z, y) \quad (17.10)$$

Definition 17.16 A matrix $(p(x, y))_{x, y \in E}$ with nonnegative entries and with

$$\sum_{y \in E} p(x, y) = 1 \quad \text{for all } x \in E$$

is called a stochastic matrix on E .

A stochastic matrix is essentially a stochastic kernel from E to E . In Theorem 17.8 we saw that, for the semigroup of kernels $(p^n)_{n \in \mathbb{N}}$, there exists a unique discrete Markov chain whose transition probabilities are given by p . The arguments we gave there were rather abstract. Here we give a construction for X that could actually be used to implement a computer simulation of X .

Let $(R_n)_{n \in \mathbb{N}_0}$ be an independent family of random variables with values in E^E and with the property

$$\mathbf{P}[R_n(x) = y] = p(x, y) \quad \text{for all } x, y \in E. \quad (17.11)$$

For example, choose $(R_n(x), x \in E, n \in \mathbb{N})$ as an independent family of random variables with values in E and distributions

$$\mathbf{P}[R_n(x) = y] = p(x, y) \quad \text{for all } x, y \in E \text{ and } n \in \mathbb{N}_0.$$

Note, however, that in (17.11) we have required neither independence of the random variables $(R_n(x), x \in E)$ nor that all R_n had the same distribution. Only the onedimensional marginal distributions are determined. In fact, in many applications it is useful to have subtle dependence structures in order to couple Markov chains with different initial chains. We pick up this thread again in Section 18.2.

For $x \in E$, define

$$X_0^x = x \quad \text{and} \quad X_n^x = R_n(X_{n-1}^x) \quad \text{for } n \in \mathbb{N}.$$

Finally, let $\mathbf{P}_x := \mathcal{L}[X^x]$ be the distribution of X^x . Recall that this is a probability measure on the space of sequences $(E^{\mathbb{N}_0}, \mathcal{B}(E)^{\otimes \mathbb{N}_0})$.

Theorem 17.17

- (i) With respect to the distribution $(\mathbf{P}_x)_{x \in E}$, the canonical process X on $(E^{\mathbb{N}_0}, \mathcal{B}(E)^{\otimes \mathbb{N}_0})$ is a Markov chain with transition matrix p .
- (ii) In particular, to any stochastic matrix p , there corresponds a unique discrete Markov chain X with transition probabilities p .

Proof "(ii)" This follows from (i) since Theorem 17.11 yields uniqueness of X .

"(i)" For $n \in \mathbb{N}_0$ and $x, y, z \in E$, by construction,

$$\begin{aligned} \mathbf{P}_x[X_{n+1} = z \mid \mathcal{F}_n, X_n = y] &= \mathbf{P}[X_{n+1}^x = z \mid \sigma(R_m, m \leq n), X_n^x = y] \\ &= \mathbf{P}[R_{n+1}(X_n^x) = z \mid \sigma(R_m, m \leq n), X_n^x = y] \\ &= \mathbf{P}[R_{n+1}(y) = z] \\ &= p(y, z). \end{aligned}$$

Hence, by Theorem 17.11, X is a Markov chain with transition matrix p .

Example 17.18 (Random walk on $\mathbb{Z}$) Let $E = \mathbb{Z}$, and assume

$$p(x, y) = p(0, y - x) \quad \text{for all } x, y \in \mathbb{Z}.$$

In this case, we say that p is translation invariant. A discrete Markov chain X with transition matrix p is a random walk on $\mathbb{Z}$. Indeed, $X_n \stackrel{D}{=} X_0 + Z_1 + \dots + Z_n$, where $(Z_n)_{n \in \mathbb{N}}$ are i.i.d. with $\mathbf{P}[Z_n = x] = p(0, x)$.

The R_n that we introduced in the explicit construction are given by $R_n(x) := x + Z_n$.

Example 17.19 (Computer simulation) Consider the situation where the state space $E = \{1, \dots, k\}$ is finite. The aim is to simulate a Markov chain X with transition matrix p on a computer. Assume that the computer provides a random number generator that generates an i.i.d. sequence $(U_n)_{n \in \mathbb{N}}$ of random variables that are uniformly distributed on $[0, 1]$. (Of course, this is wishful thinking. But modern random number generators produce sequences that for many purposes are close enough to really random sequences.)

Define $r(i, 0) = 0, r(i, j) = p(i, 1) + \dots + p(i, j)$ for $i, j \in E$, and define Y_n by

$$R_n(i) = j \iff U_n \in [r(i, j-1), r(i, j)).$$

Then, by construction, $\mathbf{P}[R_n(i) = j] = r(i, j) - r(i, j-1) = p(i, j)$.

Example 17.20 (Branching process as a Markov chain) We want to understand the Galton-Watson branching process (see Definition 3.9) as a Markov chain on $E = \mathbb{N}_0$.

To this end, let $(q_k)_{k \in \mathbb{N}_0}$ be a probability vector, the offspring distribution of one individual. Define $q_k^{*0} = \mathbb{1}_{\{0\}}(k)$ and

$$q_k^{*n} = \sum_{l=0}^k q_{k-l}^{*(n-1)} q_l \quad \text{for } n \in \mathbb{N}$$

as the n -fold convolutions of q . Hence, for n individuals, q_k^{*n} is the probability to have exactly k offspring. Finally, define the matrix p by $p(x, y) = q_y^{*x}$ for $x, y \in \mathbb{N}_0$.

Now let $(Y_{n,i}, n \in \mathbb{N}_0, i \in \mathbb{N}_0)$ be i.i.d. with $\mathbf{P}[Y_{n,i} = k] = q_k$. For $x \in \mathbb{N}_0$, define the branching process X with x ancestors and offspring distribution q by $X_0 = x$ and $X_n := \sum_{i=1}^{X_{n-1}} Y_{n-1,i}$. In order to show that X is a Markov chain, we compute

$$\begin{aligned} \mathbf{P}[X_n = x_n \mid X_0 = x, X_1 = x_1, \dots, X_{n-1} = x_{n-1}] \\ &= \mathbf{P}[Y_{n-1,1} + \dots + Y_{n-1,x_{n-1}} = x_n] \\ &= \mathbf{P}_{Y_{1,1}}^{*x_{n-1}}(\{x_n\}) = q_{x_n}^{*x_{n-1}} = p(x_{n-1}, x_n) \end{aligned}$$

Hence X is a Markov chain on $\mathbb{N}_0$ with transition matrix p .

Example 17.21 (Wright's evolution model) In population genetics, Wright's evolution model [171] describes the hereditary transmission of a genetic trait with two possible specifications (say A and B); for example, resistance/no resistance to a specific antibiotic. It is assumed that the population has a constant size of $N \in \mathbb{N}$ individuals and the generations change at discrete times and do not overlap. Furthermore, for simplicity, the individuals are assumed to be haploid; that is, cells bear only one copy of each chromosome (like certain protozoans do) and not two copies (as in mammals).

Here we consider the case where none of the traits is favored by selection. Hence, it is assumed that each individual of the new generation chooses independently and uniformly at random one individual of the preceding generation as ancestor and becomes a perfect clone of that. Thus, if the number of individuals of type A in the current generation is $k \in \{0, \dots, N\}$, then in the new generation it will be random and binomially distributed with parameters N and k/N .

The gene frequencies k/N in this model can be described by a Markov chain X on $E = \{0, 1/N, \dots, (N-1)/N, 1\}$ with transition matrix $p(x, y) = b_{N,x}(\{Ny\})$. Note that X is a (bounded) martingale. Hence, by the martingale convergence theorem (Theorem 11.7), X converges $\mathbf{P}_x$ -almost surely to a random variable X_∞ with $\mathbf{E}_x[X_\infty] = \mathbf{E}_x[X_0] = x$. As with

the voter model (see Example 11.16) that is closely related to Wright's model, we can argue that the limit X_∞ can take only the stable values 0 and 1. That is, $\mathbf{P}_x[\lim_{n \rightarrow \infty} X_n = 1] = x = 1 - \mathbf{P}_x[\lim_{n \rightarrow \infty} X_n = 0]$.

Example 17.22 (Discrete Moran model) In contrast to Wright's model, the Moran model also allows overlapping generations. The situation is similar to that of Wright's model; however, now in each time step, only (exactly) one individual gets replaced by a new one, whose type is chosen at random from the whole population.

As the new and the old types of the replaced individual are independent, as a model for the gene frequencies, we obtain a Markov chain X on $E = \{0, \frac{1}{N}, \dots, 1\}$ with transition matrix

$$p(x, y) = \begin{cases} x(1-x), & \text{if } y = x + 1/N \\ x^2 + (1-x)^2, & \text{if } y = x \\ x(1-x), & \text{if } y = x - 1/N \\ 0, & \text{else.} \end{cases}$$

Here also, X is a bounded martingale and we can compute the square variation process,

$$\langle X \rangle_n = \sum_{i=1}^n \mathbf{E}[(X_i - X_{i-1})^2 \mid X_{i-1}] = \frac{2}{N^2} \sum_{i=0}^{n-1} X_i(1 - X_i). \quad (17.12)$$

Exercise 17.2.1 (Discrete martingale problem) Let $E \subset \mathbb{R}$ be countable and let X be a Markov chain on E with transition matrix p and with the property that, for any x , there are at most three choices for the next step; that is, there exists a set $A_x \subset E$ of cardinality 3 with $p(x, y) = 0$ for all $y \in E \setminus A_x$. Let $d(x) := \sum_{y \in E} (y - x)p(x, y)$ for $x \in E$.

(i) Show that $M_n := X_n - \sum_{k=0}^{n-1} d(X_k)$ defines a martingale M with square variation process $\langle M \rangle_n = \sum_{i=0}^{n-1} f(X_i)$ for a unique function $f : E \rightarrow [0, \infty)$.

(ii) Show that the transition matrix p is uniquely determined by f and d .

(iii) For the Moran model (Example 17.22), use the explicit form (17.12) of the square variation process to compute the transition matrix.

5.17.3 17.3 Discrete Markov Processes in Continuous Time

Let E be countable and let $(X_t)_{t \in [0, \infty)}$ be a Markov process on E with transition probabilities $p_t(x, y) = \mathbf{P}_x[X_t = y]$ (for $x, y \in E$). (Some authors call such a process a Markov chain in continuous time.)

Let $x, y \in E$ with $x \neq y$. We say that X jumps with rate $q(x, y)$ from x to y if the following limit exists:

$$q(x, y) := \lim_{t \downarrow 0} \frac{1}{t} \mathbf{P}_x[X_t = y]$$

Henceforth we assume that the limit $q(x, y)$ exists for all $y \neq x$ and that

$$\sum_{y \neq x} q(x, y) < \infty \quad \text{for all } x \in E \quad (17.13)$$

Then we define

$$q(x, x) = - \sum_{y \neq x} q(x, y) \quad (17.14)$$

Finally we assume that (which is equivalent to exchangeability of the limit and the sum over $y \neq x$ in the display preceding (17.13))

$$\lim_{t \downarrow 0} \frac{1}{t} (\mathbf{P}_x [X_t = y] - \mathbb{1}_{\{x=y\}}) = q(x, y) \quad \text{for all } x, y \in E. \quad (17.15)$$

Definition 17.23 If (17.13), (17.14) and (17.15) hold, then q is called the Q -matrix of X . Sometimes q is also called the generator of the semigroup $(p_t)_{t \geq 0}$.

Example 17.24 (Poisson process) The Poisson process with rate $\alpha > 0$ (compare Section 5.5) has the Q -matrix $q(x, y) = \alpha (\mathbb{1}_{\{y=x+1\}} - \mathbb{1}_{\{y=x\}})$.

Theorem 17.25 Let q be an $E \times E$ matrix such that $q(x, y) \geq 0$ for all $x, y \in E$ with $x \neq y$. Assume that (17.13) and (17.14) hold and that

$$\lambda := \sup_{x \in E} |q(x, x)| < \infty. \quad (17.16)$$

Then q is the Q -matrix of a unique Markov process X .

Intuitively, (17.15) suggests that we define $p_t = e^{tq}$ in a suitable sense. Then, formally, $q = \frac{d}{dt} p_t \big|_{t=0}$. The following proof shows that this formal argument can be made rigorous.

Proof Let I be the unit matrix on E . Define

$$p(x, y) = \frac{1}{\lambda} q(x, y) + I(x, y) \quad \text{for } x, y \in E$$

if $\lambda > 0$ and $p = I$ otherwise. Then p is a stochastic matrix and $q = \lambda(p - I)$. Let $((Y_n)_{n \in \mathbb{N}_0}, (\mathbf{P}_x^Y)_{x \in E})$ be a discrete Markov chain with transition matrix p and let $((T_t)_{t \geq 0}, (\mathbf{P}_n^T)_{n \in \mathbb{N}_0})$ be a Poisson process with rate λ . Let $X_t := Y_{T_t}$ and $\mathbf{P}_x = \mathbf{P}_x^Y \otimes \mathbf{P}_0^T$. Then $\mathfrak{X} := ((X_t)_{t \geq 0}, (\mathbf{P}_x)_{x \in E})$ is a Markov process and

$$\begin{aligned} p_t(x, y) &:= \mathbf{P}_x [X_t = y] = \sum_{n=0}^{\infty} \mathbf{P}_0^T [T_t = n] \mathbf{P}_x^Y [Y_n = y] \\ &= e^{-\lambda t} \sum_{n=0}^{\infty} \frac{\lambda^n t^n}{n!} p^n(x, y) \end{aligned}$$

This power series (in t) converges everywhere (note that as a linear operator, p has finite norm $\|p\|_2 \leq 1$) to the matrix exponential function $e^{\lambda t p}(x, y)$. Furthermore,

$$p_t(x, y) = e^{-\lambda t} e^{\lambda t p}(x, y) = e^{\lambda t(p-I)}(x, y) = e^{tq}(x, y).$$

Differentiating the power series termwise yields $\frac{d}{dt} p_t(x, y) \big|_{t=0} = q(x, y)$. Hence $\mathfrak{X}$ is the required Markov process.

Now assume that $(\tilde{p}_t)_{t \geq 0}$ are the transition probabilities of another Markov process $\tilde{\mathfrak{X}}$ with the same generator q ; that is, with

$$\lim_{s \downarrow 0} \frac{1}{s} (\tilde{p}_s(x, y) - I(x, y)) = q(x, y).$$

It is easy to check that

$$\lim_{s \downarrow 0} \frac{1}{s} (p_{t+s}(x, y) - p_t(x, y)) = (q \cdot p_t)(x, y).$$

That is, we have $(d/dt)p_t(x, y) = qp_t(x, y)$. Similarly, we get $(d/dt)\tilde{p}_t = q\tilde{p}_t(x, y)$. Hence also,

$$p_t(x, y) - \tilde{p}_t(x, y) = \int_0^t (q(p_s - \tilde{p}_s))(x, y) ds$$

If we let $r_s = p_s - \tilde{p}_s$, then $\|r_s\|_2 \leq 2$ and $\|q\|_2 \leq 2\lambda$; hence

$$\sup_{s \leq t} \|r_s\|_2 \leq \sup_{s \leq t} \int_0^s \|qr_u\|_2 du \leq \|q\|_2 \sup_{s \leq t} \int_0^s \|r_u\|_2 du \leq 2\lambda t \sup_{s \leq t} \|r_s\|_2$$

For $t < 1/2\lambda$, this implies $r_t = 0$; hence $\tilde{p}_t = p_t$. For general $t > 0$, choose $n \in \mathbb{N}$ such that $t/n < 1/2\lambda$ to obtain $\tilde{p}_t = (\tilde{p}_{t/n})^n = (p_{t/n})^n = p_t$.

Remark 17.26 The condition (17.16) cannot be dropped easily, as the following example shows. Let $E = \mathbb{N}$ and

$$q(x, y) = \begin{cases} x^2, & \text{if } y = x + 1 \\ -x^2, & \text{if } y = x \\ 0, & \text{else.} \end{cases}$$

We construct explicitly a candidate X for a Markov process with Q -matrix q . Let $T_1, T_2, \dots$ be independent, exponentially distributed random variables with $\mathbf{P}_{T_n} = \exp_{n^2}$. Define $S_n = T_1 + \dots + T_{n-1}$ and $X_t = \sup \{n \in \mathbb{N}_0 : S_n \leq t\}$. Then, at any time, X makes at most one step to the right. Furthermore, due to the lack of memory of the exponential distribution (see Exercise 8.1.1),

$$\begin{aligned} \mathbf{P}[X_{t+s} \geq n+1 \mid X_t = n] &= \mathbf{P}[S_{n+1} \leq t+s \mid S_n \leq t, S_{n+1} > t] \\ &= \mathbf{P}[T_n \leq s+t-S_n \mid S_n \leq t, T_n > t-S_n] = \mathbf{P}[T_n \leq s] \\ &= 1 - \exp(-n^2 s) \end{aligned}$$

Therefore,

$$\lim_{s \downarrow 0} s^{-1} \mathbf{P}[X_{t+s} = n+1 \mid X_t = n] = n^2$$

and

$$\lim_{s \downarrow 0} s^{-1} (\mathbf{P}[X_{t+s} = n \mid X_t = n] - 1) = -n^2;$$

hence

$$\lim_{s \downarrow 0} s^{-1} (\mathbf{P}[X_{t+s} = m \mid X_t = n] - I(m, n)) = q(m, n) \quad \text{for all } m, n \in \mathbb{N}.$$

Let

$$\tau^n = \inf \{t \geq 0 : X_t = n\} = S_n \quad \text{for } n \in \mathbb{N}$$

Then $\mathbf{E}_1[\tau^n] = \sum_{k=1}^{n-1} \frac{1}{k^2}$. By monotone convergence, $\mathbf{E}_1[\sup_{n \in \mathbb{N}} \tau^n] < \infty$. That is, in finite time, X exceeds all levels. We say that X explodes. $\square$

Example 17.27 (A variant of Pólya's urn model) Consider a variant of Pólya's urn model with black and red balls (compare Example 12.29). In contrast to the original model, we do not simply add one ball of the same color as the ball that we return. Rather, the number of balls that we add varies from time to time. More precisely, the k th ball of a given color will be returned together with r_k more balls of the same color. The numbers $r_1, r_2, \dots \in \mathbb{N}$ are parameters of the model. In particular, the case $1 = r_1 = r_2 = \dots$ is the classical Pólya's urn model. Let

$$X_n := \begin{cases} 1, & \text{if the } n\text{th ball is black} \\ 0, & \text{else.} \end{cases}$$

For the classical model, we saw (Example 12.29) that the fraction of black balls in the urn converges a.s. to a Beta-distributed random variable Z . Furthermore, given Z , the sequence $X_1, X_2, \dots$ is independent and Ber_Z -distributed. A similar statement holds for the case where $r = r_1 = r_2 = \dots$ for some $r \in \mathbb{N}$. Indeed, here only the parameters of the Beta distribution change. In particular (as the Beta distribution is continuous and, in particular, does not have atoms at 0 or 1), almost surely we draw infinitely many balls of each color. Formally, $\mathbf{P}[B] = 0$ where B is the event where there is one color of which only finitely many balls are drawn.

The situation changes when the numbers r_k grow quickly as $k \rightarrow \infty$. Assume that in the beginning there is one black and one red ball in the urn. Denote by $w_n = 1 + \sum_{k=1}^n r_k$ the total number of balls of a given color after n balls of that color have been drawn already ($n \in \mathbb{N}_0$).

For illustration, first consider the extreme situation where w_n grows very quickly; for example, $w_n = 2^n$ for every $n \in \mathbb{N}$. Denote by

$$S_n = 2(X_1 + \dots + X_n) - n$$

the number of black balls drawn in the first n steps minus the number of red balls drawn in these steps. Then, for every $n \in \mathbb{N}_0$,

$$\mathbf{P}[X_{n+1} = 1 \mid S_n] = \frac{2^{S_n}}{1 + 2^{S_n}} \quad \text{and} \quad \mathbf{P}[X_{n+1} = 0 \mid S_n] = \frac{2^{-S_n}}{1 + 2^{-S_n}}.$$

We conclude that $(Z_n)_{n \in \mathbb{N}_0} := (|S_n|)_{n \in \mathbb{N}_0}$ is a Markov chain on $\mathbb{N}_0$ with transition matrix

$$p(z, z') = \begin{cases} 2^z / (1 + 2^z), & \text{if } z' = z + 1 > 1, \\ 1, & \text{if } z' = z + 1 = 1, \\ 1 / (1 + 2^z), & \text{if } z' = z - 1, \\ 0, & \text{else.} \end{cases}$$

The event B from above can be written as

$$B = \{Z_{n+1} < Z_n \text{ only finitely often}\}.$$

Let $A = \{Z_{n+1} > Z_n \text{ for all } n \in \mathbb{N}_0\}$ denote the event where Z flees directly to ∞ and let $\tau_z = \inf\{n \in \mathbb{N}_0 : Z_n \geq z\}$. Evidently,

$$\mathbf{P}_z[A] = \prod_{z'=z}^{\infty} p(z', z' + 1) \geq 1 - \sum_{z'=z}^{\infty} \frac{1}{1 + 2^{z'}} \geq 1 - 2^{1-z}$$

It is easy to check that $\mathbf{P}_0[\tau_z < \infty] = 1$ for all $z \in \mathbb{N}_0$. Using the strong Markov property, we get that, for all $z \in \mathbb{N}_0$,

$$\mathbf{P}_0[B] \geq \mathbf{P}_0[Z_{n+1} > Z_n \text{ for all } n \geq \tau_z] = \mathbf{P}_z[A] \geq 1 - 2^{1-z},$$

and thus $\mathbf{P}_0[B] = 1$. In prose, almost surely eventually only balls of one color will be drawn.

This example was a bit extreme. In order to find a necessary and sufficient condition on the growth of (w_n) , we need more subtle methods that appeal to the above example of the explosion of a Markov process.

We will show that $\mathbf{P}[B] = 1$ if and only if $\sum_{n=0}^{\infty} \frac{1}{w_n} < \infty$. To this end, consider independent random variables $T_1^s, T_1^r, T_2^s, T_2^r, \dots$ with $\mathbf{P}_{T_n^r} = \mathbf{P}_{T_n^s} = \exp_{w_{n-1}}$. Let $T_\infty^r = \sum_{n=1}^{\infty} T_n^r$ and $T_\infty^s = \sum_{n=1}^{\infty} T_n^s$. Clearly, $\mathbf{E}[T_\infty^r] = \sum_{n=0}^{\infty} 1/w_n < \infty$; hence, in particular, $\mathbf{P}[T_\infty^r < \infty] = 1$. The corresponding statement holds for T_∞^s . Note that T_∞^r and T_∞^s are independent and have densities (since T_1^r and T_1^s have densities); hence we have $\mathbf{P}[T_\infty^r = T_\infty^s] = 0$.

Now let

$$R_t := \sup \{n \in \mathbb{N} : T_1^r + \dots + T_{n-1}^r \leq t\}$$

and

$$S_t := \sup \{n \in \mathbb{N} : T_1^s + \dots + T_{n-1}^s \leq t\}$$

Let $R := \{T_1^r + \dots + T_n^r, n \in \mathbb{N}\}$ and let $S := \{T_1^s + \dots + T_n^s, n \in \mathbb{N}\}$ be the jump times of (R_t) and (S_t) . Define $U := R \cup S = \{u_1, u_2, \dots\}$, where $u_1 < u_2 < \dots$. Let

$$X_n = \begin{cases} 1, & \text{if } u_n \in S \\ 0, & \text{else} \end{cases}$$

Let $L_n = x_1 + \dots + x_n$. Then

$$\begin{aligned} \mathbf{P}[X_{n+1} = 1 \mid X_1 = x_1, \dots, X_n = x_n] \\ &= \mathbf{P}[u_{n+1} \in S \mid (u_k \in S \iff x_k = 1) \text{ for every } k \leq n] \\ &= \mathbf{P}[T_1^s + \dots + T_{L_n+1}^s < T_1^r + \dots + T_{n-L_n+1}^r \mid \\ &\quad T_1^s + \dots + T_{L_n+1}^s > T_1^r + \dots + T_{n-L_n}^r] \\ &= \mathbf{P}[T_{L_n+1}^s < T_{n-L_n+1}^r] = \frac{w_{L_n}}{w_{L_n} + w_{n-L_n}}. \end{aligned}$$

Hence $(X_n)_{n \in \mathbb{N}_0}$ is our generalized urn model with weights $(w_n)_{n \in \mathbb{N}_0}$. Consider now the event B^c where infinitely many balls of each color are drawn. Evidently, $\{X_n = 1 \text{ infinitely often}\} = \{\sup S = \sup U\}$ and $\{X_n = 0 \text{ infinitely often}\} = \{\sup R = \sup U\}$. Since $\sup S = T_\infty^s$ and $\sup R = T_\infty^r$, we thus have $\mathbf{P}[B^c] = \mathbf{P}[T_\infty^r = T_\infty^s] = 0$.

Exercise 17.3.1 Let $r, s, R, S \in \mathbb{N}$. Consider the generalized version of Pólya's urn model $(X_n)_{n \in \mathbb{N}_0}$ with $r_k = r$ and $s_k = s$ for all $k \in \mathbb{N}$. Assume that in the beginning there are R red balls and S black balls in the urn. Show that the fraction of black balls converges almost surely to a random variable Z with a Beta distribution and determine the parameters. Show that $(X_n)_{n \in \mathbb{N}_0}$ is i.i.d. given Z and $X_i \sim \text{Ber}_Z$ for all $i \in \mathbb{N}_0$.

Exercise 17.3.2 Show that, almost surely, infinitely many balls of each color are drawn if

$$\sum_{n=0}^{\infty} \frac{1}{w_n} = \infty$$

5.17.4 17.4 Discrete Markov Chains: Recurrence and Transience

In the following, let $X = (X_n)_{n \in \mathbb{N}_0}$ be a Markov chain on the countable space E with transition matrix p .

Definition 17.28 For any $x \in E$, let $\tau_x := \tau_x^1 := \inf \{n > 0 : X_n = x\}$ and

$$\tau_x^k = \inf \{n > \tau_x^{k-1} : X_n = x\} \quad \text{for } k \in \mathbb{N}, k \geq 2$$

τ_x^k is the k th entrance time of X for x . For $x, y \in E$, let

$$F(x, y) := \mathbf{P}_x[\tau_y^1 < \infty] = \mathbf{P}_x[\text{there is an } n \geq 1 \text{ with } X_n = y]$$

be the probability of ever going from x to y . In particular, $F(x, x)$ is the return probability (after the first jump) from x to x .

Note that $\tau_x^1 > 0$ even if we start the chain at $X_0 = x$.

Fig. 17.1 Markov chain with eight states. The numbers are the transition probabilities for the corresponding arrows. State 2 is absorbing, the states 1, 3, 4 and 5 are transient and the states 6, 7 and 8 are (positive) recurrent

Theorem 17.29 For all $x, y \in E$ and $k \in \mathbb{N}$, we have

$$\mathbf{P}_x [\tau_y^k < \infty] = F(x, y)F(y, y)^{k-1}.$$

Proof We carry out the proof by induction on k . For $k = 1$, the claim is true by definition. Now let $k \geq 2$. Using the strong Markov property of X (see Theorem 17.14), we get

$$\begin{aligned} \mathbf{P}_x [\tau_y^k < \infty] &= \mathbf{E}_x \left[\mathbf{P}_x [\tau_y^k < \infty \mid \mathcal{F}_{\tau_y^{k-1}}] \mathbb{1}_{\{\tau_y^{k-1} < \infty\}} \right] \\ &= \mathbf{E}_x \left[F(y, y) \cdot \mathbb{1}_{\{\tau_y^{k-1} < \infty\}} \right] \\ &= F(y, y) \cdot F(x, y)F(y, y)^{k-2} = F(x, y)F(y, y)^{k-1}. \end{aligned}$$

□

Definition 17.30 A state $x \in E$ is called

- recurrent if $F(x, x) = 1$,
- positive recurrent if $\mathbf{E}_x [\tau_x^1] < \infty$,
- null recurrent if x is recurrent but not positive recurrent,
- transient if $F(x, x) < 1$, and
- absorbing if $p(x, x) = 1$.

The Markov chain X is called (positive/null) recurrent if every state $x \in E$ is (positive/null) recurrent and is called transient if every recurrent state is absorbing.

Remark 17.31 Clearly, we have:

$$\text{"absorbing"} \implies \text{"positive recurrent"} \implies \text{"recurrent"}.$$

Example 17.32

(i) In Fig. 17.1, the state 2 is absorbing. If it does not get trapped in 2, the chain will eventually jump from 5 to 6 and will not return after that. Hence 1, 3, 4 and 5 are transient. The states 6, 7 and 8 are positive recurrent. One can show (see Exercise 17.6.1) that $\mathbf{E}_6 [\tau_6] = \frac{17}{4}$, $\mathbf{E}_7 [\tau_7] = \frac{17}{5}$ and $\mathbf{E}_8 [\tau_8] = \frac{17}{8}$.

Fig. 17.2 Markov chain on $\mathbb{N}_{-0}$ with parameter $r \in (0, 1)$. The chain is positive recurrent if $r \in (0, 1/2)$, null recurrent if $r = 1/2$ and transient if $r \in (1/2, 1)$

(ii) The chain in Fig. 17.2 has a drift to the right if $r > \frac{1}{2}$. Hence, in this case, every state is transient. On the other hand, if $r \in (0, \frac{1}{2})$, then the chain has a drift to the left (except at the point 0) and hence visits every state again and again. Thus the chain is recurrent. With a little thought, one can show (see Exercise 17.6.4) that in this case, the chain is actually positive recurrent and in the remaining case $r = \frac{1}{2}$ it is null recurrent. $\square$

Definition 17.33 Denote by $N(y) = \sum_{n=0}^{\infty} \mathbb{1}_{\{X_n=y\}}$ the total number of visits of X to y and by

$$G(x, y) = \mathbf{E}_x[N(y)] = \sum_{n=0}^{\infty} p^n(x, y)$$

the Green function of X .

Theorem 17.34

(i) For all $x, y \in E$, we have (with the convention $1/0 := \infty, 0/0 := 0$ and $0 \cdot \infty := 0$)

$$G(x, y) = \begin{cases} \frac{F(x, y)}{1 - F(y, y)}, & \text{if } x \neq y \\ \frac{1}{1 - F(y, y)}, & \text{if } x = y \end{cases} = F(x, y)G(y, y) + \mathbb{1}_{\{x=y\}}. \quad (17.17)$$

(ii) A non-absorbing state $x \in E$ is recurrent if and only if $G(x, x) = \infty$.

Proof (ii) follows by (i). Hence, it remains to show (17.17). By Theorem 17.29, we have

$$\begin{aligned} G(x, y) &= \mathbf{E}_x[N(y)] = \sum_{k=1}^{\infty} \mathbf{P}_x[N(y) \geq k] \\ &= \mathbb{1}_{\{x=y\}} + \sum_{k=1}^{\infty} \mathbf{P}_x[\tau_y^k < \infty] = \mathbb{1}_{\{x=y\}} + \sum_{k=1}^{\infty} F(x, y)F(y, y)^{k-1} \\ &= \begin{cases} \frac{F(x, y)}{1 - F(y, y)}, & \text{if } x \neq y \\ \frac{1}{1 - F(y, y)}, & \text{if } x = y \end{cases} \end{aligned}$$

The second equality in (17.17) is an immediate consequence. $\square$

Theorem 17.35 If x is recurrent and $F(x, y) > 0$, then y is also recurrent, and $F(x, y) = F(y, x) = 1$.

Proof Let $x, y \in E, x \neq y$, be such that $F(x, y) > 0$. Then there is a $k \in \mathbb{N}$ and states $x_1, \dots, x_k \in E$ with $x_k = y$ and $x_i \neq x$ for all $i = 1, \dots, k$ and such that

$$\mathbf{P}_x[X_i = x_i \text{ for all } i = 1, \dots, k] > 0.$$

In particular, $p^k(x, y) > 0$. By the Markov property, we have

$$\begin{aligned} 1 - F(x, x) &= \mathbf{P}_x[\tau_x^1 = \infty] \geq \mathbf{P}_x[X_1 = x_1, \dots, X_k = x_k, \tau_x^1 = \infty] \\ &= \mathbf{P}_x[X_1 = x_1, \dots, X_k = x_k] \cdot \mathbf{P}_y[\tau_x^1 = \infty] \\ &= \mathbf{P}_x[X_1 = x_1, \dots, X_k = x_k] (1 - F(y, x)) \end{aligned}$$

If now $F(x, x) = 1$, then also $F(y, x) = 1$. Since $F(y, x) > 0$, there exists an $l \in \mathbb{N}$ with $p^l(y, x) > 0$. Hence, for $n \in \mathbb{N}_0$,

$$p^{l+n+k}(y, y) \geq p^l(y, x)p^n(x, x)p^k(x, y).$$

If x is recurrent, then we conclude that

$$G(y, y) \geq \sum_{n=0}^{\infty} p^{l+n+k}(y, y) \geq p^l(y, x)p^k(x, y)G(x, x) = \infty$$

and hence also that y is recurrent. Changing the roles of x and y in the above argument, we get $F(x, y) = 1$.

Definition 17.36 A discrete Markov chain is called

- irreducible if $F(x, y) > 0$ for all $x, y \in E$, or equivalently $G(x, y) > 0$, and
- weakly irreducible if $F(x, y) + F(y, x) > 0$ for all $x, y \in E$.

Theorem 17.37 An irreducible discrete Markov chain is either recurrent or transient. If $|E| \geq 2$, then there is no absorbing state.

Proof This follows directly from Theorem 17.35.

Theorem 17.38 If E is finite and X is irreducible, then X is recurrent.

Proof Evidently, for all $x \in E$,

$$\sum_{y \in E} G(x, y) = \sum_{n=0}^{\infty} \sum_{y \in E} p^n(x, y) = \sum_{n=0}^{\infty} 1 = \infty.$$

As E is finite, there is a $y \in E$ with $G(x, y) = \infty$. Since $F(y, x) > 0$, there exists a $k \in \mathbb{N}$ with $p^k(y, x) > 0$. Therefore, since $p^{n+k}(x, x) \geq p^n(x, y)p^k(y, x)$, we have

$$G(x, x) \geq \sum_{n=0}^{\infty} p^n(x, y)p^k(y, x) = p^k(y, x)G(x, y) = \infty.$$

Exercise 17.4.1 Let x be positive recurrent and let $F(x, y) > 0$. Show that y is also positive recurrent.

5.17.5 17.5 Application: Recurrence and Transience of Random Walks

In this section, we study recurrence and transience of random walks on the D dimensional integer lattice $\mathbb{Z}^D$, $D = 1, 2, \dots$. A more exhaustive investigation can be found in Spitzer's book [158].

Consider first the simplest situation of symmetric simple random walk X on $\mathbb{Z}^D$. That is, at each step, X jumps to any of its $2D$ neighbors with the same probability $1/2D$. Hence, in terms of the Markov chain notation, we have $E = \mathbb{Z}^D$ and

$$p(x, y) = \begin{cases} \frac{1}{2D}, & \text{if } |x - y| = 1 \\ 0, & \text{else} \end{cases}$$

Is this random walk recurrent or transient?

The central limit theorem suggests that

$$p^n(0, 0) \approx C_D n^{-D/2} \quad \text{as } n \rightarrow \infty$$

for some constant C_D that depends on the dimension D . However, first we have to exclude the case where n is odd since here clearly $p^n(0, 0) = 0$. Thus let $Y_1, Y_2, \dots$ be independent $\mathbb{Z}^D$ -valued random variables with $\mathbf{P}[Y_i = x] = p^2(0, x)$. Then $X_{2n} \stackrel{\mathcal{D}}{=} S_n := Y_1 + \dots + Y_n$ for $n \in \mathbb{N}_0$; hence $G(0, 0) = \sum_{n=0}^{\infty} \mathbf{P}[S_n = 0]$. Clearly, $Y_1 = (Y_1^1, \dots, Y_1^D)$ has covariance matrix $C_{i,j} := \mathbf{E}[Y_1^i \cdot Y_1^j] = \frac{2}{D} \mathbb{1}_{\{i=j\}}$. By the local central limit theorem (see, e.g., [20, pp. 224ff] for a one-dimensional version of that theorem or Exercise 17.5.1 for an analytic derivation), we have

$$n^{D/2} p^{2n}(0, 0) = n^{D/2} \mathbf{P}[S_n = 0] \xrightarrow{n \rightarrow \infty} 2(4\pi/D)^{-D/2} \quad (17.18)$$

Now $\sum_{n=1}^{\infty} n^{-\alpha} < \infty$ if and only if $\alpha > 1$. Hence $G(0, 0) < \infty$ if and only if $D > 2$. We have thus shown the following theorem of Pólya [134].

Theorem 17.39 (Pólya (1921) [134]) Symmetric simple random walk on $\mathbb{Z}^D$ is recurrent if and only if $D \leq 2$.

The procedure we used here to derive Pólya's theorem has the disadvantage that it relies on the local central limit theorem, which we have not proved (and will not). Hence we will consider different methods of proof that yield further insight into the problem.

Consider first the one-dimensional simple random walk that with probability p jumps one step to the right and with probability $1 - p$ jumps one step to the left.

Then

$$G(0, 0) = \sum_{n=0}^{\infty} \binom{2n}{n} (p(1-p))^n = \sum_{n=0}^{\infty} \binom{-1/2}{n} (-4p(1-p))^n$$

Using the generalized binomial theorem (see Lemma 3.5), we get (since we have $(1 - 4p(1-p))^{1/2} = |2p - 1|$)

$$G(0, 0) = \begin{cases} \frac{1}{|2p-1|}, & \text{if } p \neq \frac{1}{2} \\ \infty, & \text{if } p = \frac{1}{2} \end{cases} \quad (17.19)$$

Thus, simple random walk on $\mathbb{Z}$ is recurrent if and only if it is symmetric; that is, if $p = \frac{1}{2}$.

Of course, transience in the case $p \neq \frac{1}{2}$ could also be deduced directly from the strong law of large numbers since $\lim_{n \rightarrow \infty} \frac{1}{n} X_n = \mathbf{E}_0[X_1] = 2p - 1$ almost surely. In fact, this argument is even more robust since it uses only that the single steps of X have an expectation that is not zero.

Consider now the situation where X does not necessarily jump to one of its nearest neighbors but where we still have $\mathbf{E}_0[|X_1|] < \infty$ and $\mathbf{E}_0[X_1] = 0$. The strong law of large numbers does not yield recurrence immediately and we have to do some work:

By the Markov property, for every $N \in \mathbb{N}$ and every $y \neq x$,

$$G_N(x, y) := \sum_{k=0}^N \mathbf{P}_x[X_k = y] = \sum_{k=0}^N \mathbf{P}_x[\tau_y^1 = k] \sum_{l=0}^{N-k} \mathbf{P}_y[X_l = y] \leq G_N(y, y).$$

This implies for all $L \in \mathbb{N}$

$$\begin{aligned} G_N(0, 0) &\geq \frac{1}{2L+1} \sum_{|y| \leq L} G_N(0, y) \\ &= \frac{1}{2L+1} \sum_{k=0}^N \sum_{|y| \leq L} p^k(0, y) \\ &\geq \frac{1}{2L+1} \sum_{k=1}^N \sum_{y: |y/k| \leq L/N} p^k(0, y) \end{aligned}$$

By the weak law of large numbers, we have $\liminf_{k \rightarrow \infty} \sum_{|y| \leq \varepsilon k} p^k(0, y) = 1$ for every $\varepsilon > 0$. Hence, letting $L = \varepsilon N$, we get

$$\liminf_{N \rightarrow \infty} G_N(0, 0) \geq \frac{1}{2\varepsilon} \quad \text{for every } \varepsilon > 0$$

Thus $G(0, 0) = \infty$, which shows that X is recurrent.

We summarize the discussion in a theorem.

Theorem 17.40 A random walk on $\mathbb{Z}$ with $\sum_{x=-\infty}^{\infty} |x|p(0, x) < \infty$ is recurrent if and only if $\sum_{x=-\infty}^{\infty} xp(0, x) = 0$.

Now what about symmetric simple random walk in dimension $D = 2$ or in higher dimensions? In order that the random walk be at the origin after $2n$ steps, it must perform k_i steps in the i th direction and k_i steps in the opposite direction for some numbers $k_1, \dots, k_D \in \mathbb{N}_0$ with $k_1 + \dots + k_D = n$. We thus get

$$p^{2n}(0, 0) = (2D)^{-2n} \sum_{k_1 + \dots + k_D = n} \binom{2n}{k_1, k_1, \dots, k_D, k_D}, \quad (17.20)$$

where $\binom{N}{l_1, \dots, l_r} = \frac{N!}{l_1! \dots l_r!}$ is the multinomial coefficient. In particular, for $D = 2$,

$$\begin{aligned} p^{2n}(0, 0) &= 4^{-2n} \sum_{k=0}^n \frac{(2n)!}{(k!)^2((n-k)!)^2} \\ &= 4^{-2n} \binom{2n}{n} \sum_{k=0}^n \binom{n}{k} \binom{n}{n-k} = \left(2^{-2n} \binom{2n}{n} \right)^2. \end{aligned}$$

Note that in the last step, we used a simple combinatorial identity that follows, e.g., by the convolution formula $(b_{n,p} * b_{n,p})(\{n\}) = b_{2n,p}(\{n\})$. Now, by Stirling's formula,

$$\lim_{n \rightarrow \infty} \sqrt{n} 2^{-2n} \binom{2n}{n} = \frac{1}{\sqrt{\pi}}$$

hence $\lim_{n \rightarrow \infty} n p^{2n}(0, 0) = \frac{1}{\pi}$. In particular, we have $\sum_{n=1}^{\infty} p^{2n}(0, 0) = \infty$. That is, two-dimensional symmetric simple random walk is recurrent.

For $D \geq 3$, the sum over the multinomial coefficients cannot be computed in a satisfactory way. However, it is not too hard to give an estimate that shows that there exists a $c = c_D$ such that $p^{2n}(0, 0) \leq c n^{-D/2}$, which implies $G(0, 0) \leq c \sum_{n=1}^{\infty} n^{-D/2} < \infty$ (see, e.g., [53, p. 361] or [59, Example 6.31]). Here, however, we follow a different route.

Things would be easy if the individual coordinates of the chain were independent one-dimensional random walks. In this case, the probability that at time $2n$ all coordinates are zero would be the D th power of the probability that the first coordinate is zero. For one coordinate, however, which moves only with probability $1/D$ and thus has variance $1/D$, the probability of being back at the origin at time $2n$ is approximately $(n\pi/D)^{-1/2}$. Up to a factor, we would thus get (17.18) without using the multidimensional local central limit theorem.

An elegant way to decouple the coordinates is to pass from discrete time to continuous time in such a way that the individual coordinates become independent but such that the Green function remains unchanged.

We give the details. Let $(T_t^i)_{t \geq 0}$, $i = 1, \dots, D$ be independent Poisson processes with rate $1/D$. Let $Z^1, \dots, Z^D$ be independent (and independent of the Poisson processes) symmetric simple random walks on $\mathbb{Z}$. Define $T := T^1 + \dots + T^D$, $Y_t^i := Z_{T_t^i}^i$ for $i = 1, \dots, D$ and let $Y_t = (Y_t^1, \dots, Y_t^D)$. Then Y is a Markov chain in continuous time with Q -matrix $q(x, y) = p(x, y) - \mathbb{1}_{\{x=y\}}$. As T is a Poisson process with rate 1, $(X_{T_t})_{t \geq 0}$ is also a Markov process with Q -matrix q . It follows that $(X_{T_t})_{t \geq 0} \stackrel{\mathcal{D}}{=} (Y_t)_{t \geq 0}$. We now compute

$$\begin{aligned}
G_Y &:= \int_0^\infty \mathbf{P}_0[Y_t = 0] dt = \int_0^\infty \sum_{n=0}^\infty \mathbf{P}_0[X_{2n} = 0, T_t = 2n] dt \\
&= \sum_{n=0}^\infty p^{2n}(0, 0) \int_0^\infty e^{-t} \frac{t^{2n}}{(2n)!} dt = G(0, 0)
\end{aligned}$$

The two processes $(X_n)_{n \in \mathbb{N}_0}$ and $(Y_t)_{t \in [0, \infty)}$ thus have the same Green function. As the coordinates of Y are independent, we have

$$G_Y = \int_0^\infty \mathbf{P}_0[Y_t^1 = 0]^D dt$$

Hence we only have to compute the asymptotics of $\mathbf{P}_0[Y_t^1 = 0]$ for large t . We can argue as follows. By the law of large numbers, we have $T_t^1 \approx t/D$ for large t . Furthermore, $\mathbf{P}_0[Y_t^1 \text{ is even}] \approx \frac{1}{2}$. Hence we have, with $n_t = \lfloor t/2D \rfloor$ for $t \rightarrow \infty$ (compare Exercise 17.5.2),

$$\mathbf{P}_0[Y_t^1 = 0] \sim \frac{1}{2} \mathbf{P}[Z_{2n_t}^1 = 0] = \frac{1}{2} \binom{2n_t}{n_t} 4^{-n_t} \sim (2\pi/D)^{-1/2} t^{-1/2}. \quad (17.21)$$

Since $\int_1^\infty t^{-\alpha} dt < \infty$ if and only if $\alpha > 1$, we also have $G_Y < \infty$ if and only if $D > 2$. However, this is the statement of Pólya's theorem.

Finally, we present a third method of studying recurrence and transience of random walks that does not rely on the Euclidean properties of the integer lattice but rather on the Fourier inversion formula.

First consider a general (discrete time) irreducible random walk with transition matrix p on $\mathbb{Z}^D$. By $\phi(t) = \sum_{x \in \mathbb{Z}^D} e^{i\langle t, x \rangle} p(0, x)$ denote the characteristic function of a single transition. The convolution of the transition probabilities translates into powers of the characteristic function; hence

$$\phi^n(t) = \sum_{x \in \mathbb{Z}^D} e^{i\langle t, x \rangle} p^n(0, x)$$

By the Fourier inversion formula (Theorem 15.10), we recover the n -step transition probabilities from ϕ^n by

$$p^n(0, x) = (2\pi)^{-D} \int_{[-\pi, \pi]^D} e^{-i\langle t, x \rangle} \phi^n(t) dt$$

In particular, for $\lambda \in (0, 1)$,

$$\begin{aligned}
R_\lambda &:= \sum_{n=0}^\infty \lambda^n p^n(0, 0) \\
&= (2\pi)^{-D} \sum_{n=0}^\infty \int_{[-\pi, \pi]^D} \lambda^n \phi^n(t) dt \\
&= (2\pi)^{-D} \int_{[-\pi, \pi]^D} \frac{1}{1 - \lambda \phi(t)} dt \\
&= (2\pi)^{-D} \int_{[-\pi, \pi]^D} \operatorname{Re} \left(\frac{1}{1 - \lambda \phi(t)} \right) dt
\end{aligned}$$

Now $G(0, 0) = \lim_{\lambda \uparrow 1} R_\lambda$ and hence

$$X \text{ is recurrent} \iff \lim_{\lambda \uparrow 1} \int_{[-\pi, \pi]^D} \operatorname{Re} \left(\frac{1}{1 - \lambda \phi(t)} \right) dt = \infty \quad (17.22)$$

If we had $\phi(t) = 1$ for some $t \in (-2\pi, 2\pi)^D \setminus \{0\}$, then we would have $\phi^n(t) = 1$ for every $n \in \mathbb{N}$ and hence, by Exercise 15.2.1, $\mathbf{P}_0[\langle X_n, t/(2\pi) \rangle \in \mathbb{Z}] = 1$. Thus X would not be irreducible contradicting the assumption. Due to the continuity of ϕ for all $\varepsilon > 0$, we thus have

$$\inf \{ |\phi(t) - 1| : t \in [-\pi, \pi)^D \setminus (-\varepsilon, \varepsilon)^D \} > 0$$

We summarize the discussion in a theorem due to Chung and Fuchs [26].

Theorem 17.41 (Chung-Fuchs (1951) [26]) An irreducible random walk on $\mathbb{Z}^D$ with characteristic function ϕ is recurrent if and only if, for every $\varepsilon > 0$,

$$\lim_{\lambda \uparrow 1} \int_{(-\varepsilon, \varepsilon)^D} \operatorname{Re} \left(\frac{1}{1 - \lambda \phi(t)} \right) dt = \infty \quad (17.23)$$

Now consider symmetric simple random walk. Here $\phi(t) = \frac{1}{D} \sum_{i=1}^D \cos(t_i)$. Expanding the cosine function in a Taylor series, we get $\cos(t_i) = 1 - \frac{1}{2}t_i^2 + O(t_i^4)$; hence $1 - \phi(t) = \frac{1}{2D} \|t\|_2^2 + O(\|t\|_2^4)$. We infer that X is recurrent if and only if $\int_{\|t\|_2 < \varepsilon} \|t\|_2^{-2} dt = \infty$. We compute this integral in polar coordinates (with C_D the surface of the unit sphere in $\mathbb{R}^D$):

$$\int_{\|t\|_2 < \varepsilon} \|t\|_2^{-2} dt = C_D \int_0^\varepsilon r^{D-1} r^{-2} dr = \infty \iff D \leq 2$$

Hence, X is recurrent if and only if $D \leq 2$.

In Section 19.3, we will encounter a further method of proving Pólya's theorem that has a completely different structure and that is based on the connection between Markov chains and electrical networks.

In fact, the Chung-Fuchs theorem can be used to compute the numerical values of the Green function $G_D(0, 0)$ of symmetric simple random walk on $\mathbb{Z}^D$ if we compute numerically the so-called Watson integral

$$G_D(0, 0) = (2\pi)^{-D} \int_{[-\pi, \pi)^D} \frac{D}{D - (\cos(x_1) + \dots + \cos(x_D))} dx \quad (17.24)$$

For this purpose, we follow [80] (where there are further refinements of the method) to transform the D -fold integral into a double integral. Denote by

$$I_0(t) := \frac{1}{\pi} \int_0^\pi e^{t \cos(\theta)} d\theta$$

the so-called modified Bessel function of the first kind. Using the identity $\frac{1}{\lambda} = \int_0^\infty e^{-\lambda t} dt$ for the integrand and applying Fubini's theorem, we get

$$G_D(0, 0) = \frac{D}{(2\pi)^D} \int_0^\infty e^{-Dt} \left(\int_{[-\pi, \pi)^D} e^{t(\cos(x_1) + \dots + \cos(x_D))} dx \right) dt$$

and thus

$$G_D(0, 0) = D \int_0^\infty e^{-Dt} I_0(t)^D dt \quad (17.25)$$

The right-hand side of (17.25) can quickly be computed numerically with great accuracy (see Table 17.1).

For the case $D = 3$, Watson [168] found the expression

$$G_3(0, 0) = 12 \frac{18 + 12\sqrt{2} - 10\sqrt{3} - 7\sqrt{6}}{\pi^2} K((2 - \sqrt{3})(\sqrt{3} - \sqrt{2}))^2,$$

where $K(m) = \int_0^1 ((1-t^2)(1-mt^2))^{-1/2} dt$ is the complete elliptic integral of the first kind with modulus $m \in (-1, 1)$. This in turn can be expressed as a (quickly convergent) series

$$K(m) = \frac{\pi}{2} \left(1 + \sum_{n=1}^{\infty} \left(\frac{(2n)!}{4^n (n!)^2} \right)^2 m^2 \right)$$

Glasser and Zucker [61] found an expression as a product of four Gamma functions,

$$G_3(0,0) = \frac{\sqrt{6}}{32\pi^3} \Gamma\left(\frac{1}{24}\right) \Gamma\left(\frac{5}{24}\right) \Gamma\left(\frac{7}{24}\right) \Gamma\left(\frac{11}{24}\right) = 1.5163860591519780181\dots$$

Exercise 17.5.1 For $n \in \mathbb{N}_0$, let p^n be the matrix of n -step transition probabilities of simple symmetric random walk on $\mathbb{Z}^D$. For $n \in \mathbb{N}$, derive the formula (see Theorem 15.10)

$$p^{2n}(0,0) = (2\pi)^{-D} \int_{[-\pi,\pi]^D} D^{-2n} (\cos(t_1) + \dots + \cos(t_D))^{2n} dt$$

Table 17.1 Green function $G_D(0,0)$

$(0,0)$ and return probability $F_D(0,0)$ of simple symmetric random walk on $\mathbb{Z}^D$. The numerical computations are based on (17.25)}

By a suitable bound for the integral, conclude the convergence $n^{D/2} p^{2n}(0,0) \xrightarrow{n \rightarrow \infty} 2(4\pi/D)^{-D/2}$ (see (17.18)).

Exercise 17.5.2 Show (17.21) formally.

Exercise 17.5.3 Use Theorem 17.41 to show that a random walk on $\mathbb{Z}^2$ with $\sum_{x \in \mathbb{Z}^2} x p(0,x) = 0$ is recurrent if $\sum_{x \in \mathbb{Z}^2} \|x\|_2^2 p(0,x) < \infty$.

Exercise 17.5.4 Use Theorem 17.41 to show that, for $D \geq 3$ every irreducible random walk on $\mathbb{Z}^D$ is transient.

Exercise 17.5.5 Show (17.25) for $G_D(0,0)$ directly with the $p^{2n}(0,0)$ from (17.20) and using the representation of $I_0(t)$ as the series $I_0(t) = \sum_{k=0}^{\infty} (k!)^{-2} (t/2)^k$.

5.17.6 17.6 Invariant Distributions

In the following, let p be a stochastic matrix on the discrete space E and let $(X_n)_{n \in \mathbb{N}_0}$ be a corresponding Markov chain.

This section is devoted to the question: Which distributions are preserved under the dynamics of the Markov chain? Of course, often the chain will not stay put in a specific state but the distribution of the random state of the chain might nevertheless be the same for all times. If such an invariant distribution exists, we will see in Chapter 18 that under rather weak conditions, the distribution of a Markov chain (started in an arbitrary state) converges in the large time limit to such an invariant distribution.

Definition 17.42 If μ is a measure on E and $f : E \rightarrow \mathbb{R}$ is a map, then we write $\mu p(\{x\}) = \sum_{y \in E} \mu(\{y\})p(y, x)$ and $pf(x) = \sum_{y \in E} p(x, y)f(y)$ if the sums converge.

Definition 17.43 (i) A σ -finite measure μ on E is called an invariant measure if

$$\mu p = \mu.$$

A probability measure that is an invariant measure is called an invariant distribution. Denote by $\mathcal{I}$ the set of invariant distributions.

(ii) A function $f : E \rightarrow \mathbb{R}$ is called subharmonic if pf exists and if $f \leq pf$. f is called superharmonic if $f \geq pf$ and harmonic if $f = pf$.

Remark 17.44 In the terminology of linear algebra, an invariant measure is a left eigenvector of p corresponding to the eigenvalue 1. A harmonic function is a right eigenvector corresponding to the eigenvalue 1.

Lemma 17.45 If f is bounded and (sub-, super-) harmonic, then $(f(X_n))_{n \in \mathbb{N}_0}$ is a (sub-, super-) martingale with respect to the filtration $\mathbb{F} = \sigma(X)$ generated by X .

Proof Let f be bounded and subharmonic. Then

$$\begin{aligned} \mathbf{E}_x[f(X_n) \mid \mathcal{F}_{n-1}] &= \mathbf{E}_{X_{n-1}}[f(X_1)] = \sum_{y \in E} p(X_{n-1}, y) f(y) \\ &= pf(X_{n-1}) \geq f(X_{n-1}) \end{aligned}$$

Theorem 17.46 If any point is transient, then an invariant distribution does not exist.

Proof By assumption, $G(x, y) = \sum_{n=0}^{\infty} p^n(x, y) < \infty$ for all $x, y \in E$; hence $p^n(x, y) \xrightarrow{n \rightarrow \infty} 0$. For every probability measure μ on E , we thus have that $\mu p^n(\{x\}) \xrightarrow{n \rightarrow \infty} 0$. If μ was invariant, however, then we would have $\mu p^n(\{x\}) = \mu(\{x\})$ for all $n \in \mathbb{N}$.

Theorem 17.47 Let x be a recurrent state and let $\tau_x^1 = \inf\{n \geq 1 : X_n = x\}$. Then one invariant measure μ_x is defined by

$$\mu_x(\{y\}) = \mathbf{E}_x \left[\sum_{n=0}^{\tau_x^1 - 1} \mathbb{1}_{\{X_n = y\}} \right] = \sum_{n=0}^{\infty} \mathbf{P}_x[X_n = y, \tau_x^1 > n].$$

Proof First we have to show that $\mu_x(\{y\}) < \infty$ for all $y \in E$. For $y = x$, clearly $\mu_x(\{x\}) = 1$. For $y \neq x$ and $F(x, y) = 0$, we have $\mu_x(\{y\}) = 0$. Now let $y \neq x$ and $F(x, y) > 0$. As x is recurrent, we have $F(x, y) = F(y, x) = 1$ and y is recurrent (Theorem 17.35). Let

$$\hat{F}(x, y) = \mathbf{P}_x[\tau_x^1 > \tau_y^1].$$

Then $\hat{F}(x, y) > 0$ (otherwise y would not be visited). Changing the roles of x and y , we also get $\hat{F}(y, x) > 0$.

By the strong Markov property (Theorem 17.14), we have

$$\begin{aligned}
\mathbf{E}_y \left[\sum_{n=0}^{\tau_x^1-1} \mathbb{1}_{\{X_n=y\}} \right] &= 1 + \mathbf{E}_y \left[\sum_{n=\tau_y^1}^{\tau_x^1-1} \mathbb{1}_{\{X_n=y\}}; \tau_x^1 > \tau_y^1 \right] \\
&= 1 + (1 - \widehat{F}(y, x)) \mathbf{E}_y \left[\sum_{n=0}^{\tau_x^1-1} \mathbb{1}_{\{X_n=y\}} \right].
\end{aligned}$$

Hence,

$$\mathbf{E}_y \left[\sum_{n=0}^{\tau_x^1-1} \mathbb{1}_{\{X_n=y\}} \right] = \frac{1}{\widehat{F}(y, x)}.$$

Therefore,

$$\mu_x(\{y\}) = \mathbf{E}_x \left[\sum_{n=0}^{\tau_x^1-1} \mathbb{1}_{\{X_n=y\}} \right] = \mathbf{E}_x \left[\sum_{n=\tau_y^1}^{\tau_x^1-1} \mathbb{1}_{\{X_n=y\}}; \tau_x^1 > \tau_y^1 \right] = \frac{\widehat{F}(x, y)}{\widehat{F}(y, x)} < \infty.$$

Define $\bar{p}_n(x, y) = \mathbf{P}_x [X_n = y; \tau_x^1 > n]$. Then, for every $z \in E$,

$$\mu_x p(\{z\}) = \sum_{y \in E} \mu_x(\{y\}) p(y, z) = \sum_{n=0}^{\infty} \sum_{y \in E} \bar{p}_n(x, y) p(y, z).$$

Case 1: $x \neq z$. In this case,

$$\begin{aligned}
\sum_{y \in E} \bar{p}_n(x, y) p(y, z) &= \sum_{y \in E} \mathbf{P}_x [X_n = y, \tau_x^1 > n, X_{n+1} = z] \\
&= \mathbf{P}_x [\tau_x^1 > n+1; X_{n+1} = z] = \bar{p}_{n+1}(x, z).
\end{aligned}$$

Hence (since $\bar{p}_0(x, z) = 0$)

$$\mu_x p(\{z\}) = \sum_{n=0}^{\infty} \bar{p}_{n+1}(x, z) = \sum_{n=1}^{\infty} \bar{p}_n(x, z) = \sum_{n=0}^{\infty} \bar{p}_n(x, z) = \mu_x(\{z\})$$

Case 2: $x = z$. In this case, we have

$$\sum_{y \in E} \bar{p}_n(x, y) p(y, x) = \sum_{y \in E} \mathbf{P}_x [X_n = y; \tau_x^1 > n; X_{n+1} = x] = \mathbf{P}_x [\tau_x^1 = n+1]$$

Thus (since $\mathbf{P}_x [\tau_x^1 = 0] = 0$)

$$\mu_x p(\{x\}) = \sum_{n=0}^{\infty} \mathbf{P}_x [\tau_x^1 = n+1] = 1 = \mu_x(\{x\})$$

Corollary 17.48 If X is positive recurrent, then $\pi := \frac{\mu_x}{\mathbf{E}_x[\tau_x^1]}$ is an invariant distribution for any $x \in E$.

Theorem 17.49 If X is irreducible, then X has at most one invariant distribution.

Remark 17.50

(i) One could in fact show that if X is irreducible and recurrent, then an invariant measure of X is unique up to a multiplicative factor. However, the proof is a little more involved. Since we will not need the statement here, we leave its proof as an exercise (compare Exercise 17.6.6; see also [39, Section 6.5]).

(ii) For transient X , there can be more than one invariant measure. For example, consider the asymmetric random walk on $\mathbb{Z}$ that jumps one step to the right with probability r and one step to the left with probability $1 - r$ (for some $r \in (0, 1)$). The invariant measures are the nonnegative linear combinations of the measures μ_1 and μ_2 given by $\mu_1(\{x\}) \equiv 1$ and $\mu_2(\{x\}) = (r/(1 - r))^x$, $x \in \mathbb{Z}$. X is transient if and only if $r \neq 1/2$, in which case we have $\mu_1 \neq \mu_2$. $\diamond$

Proof Let π and ν be invariant distributions. Choose an arbitrary probability vector $(g_n)_{n \in \mathbb{N}}$ with $g_n > 0$ for all $n \in \mathbb{N}$. Define the stochastic matrix $\tilde{p}(x, y) = \sum_{n=1}^{\infty} g_n p^n(x, y)$. Then $\tilde{p}(x, y) > 0$ for all $x, y \in E$ and $\pi \tilde{p} = \pi$ as well as $\nu \tilde{p} = \nu$.

Consider now the signed measure $\mu = \pi - \nu$. We have $\mu \tilde{p} = \mu$. If we had $\mu \neq 0$, then there would exist (since $\mu(E) = 0$) points $x_1, x_2 \in E$ with $\mu(\{x_1\}) > 0$ and $\mu(\{x_2\}) < 0$. Clearly, for every $y \in E$, this would imply $|\mu(\{x_1\}) \tilde{p}(x_1, y) + \mu(\{x_2\}) \tilde{p}(x_2, y)| < |\mu(\{x_1\}) \tilde{p}(x_1, y)| + |\mu(\{x_2\}) \tilde{p}(x_2, y)|$; hence

$$\begin{aligned} \|\mu \tilde{p}\|_{TV} &= \sum_{y \in E} \left| \sum_{x \in E} \mu(\{x\}) \tilde{p}(x, y) \right| \\ &< \sum_{y \in E} \sum_{x \in E} |\mu(\{x\})| \tilde{p}(x, y) = \sum_{x \in E} |\mu(\{x\})| = \|\mu\|_{TV}. \end{aligned}$$

Since this is a contradiction, we conclude that $\mu = 0$.

Recall that $\mathcal{I}$ is the set of invariant distributions of X .

Theorem 17.51 Let X be irreducible. X is positive recurrent if and only if $\mathcal{I} \neq \emptyset$. In this case, $\mathcal{I} = \{\pi\}$ with

$$\pi(\{x\}) = \frac{1}{\mathbf{E}_x[\tau_x^1]} > 0 \quad \text{for all } x \in E$$

Proof If X is positive recurrent, then $\mathcal{I} \neq \emptyset$ by Corollary 17.48. Now let $\mathcal{I} \neq \emptyset$ and $\pi \in \mathcal{I}$. As X is irreducible, we have $\pi(\{x\}) > 0$ for all $x \in E$. Let $\mathbf{P}_\pi = \sum_{x \in E} \pi(\{x\}) \mathbf{P}_x$. Fix an $x \in E$ and for $n \in \mathbb{N}_0$, let

$$\sigma_x^n = \sup \{m \leq n : X_m = x\} \in \mathbb{N}_0 \cup \{-\infty\}$$

be the time of last entrance in x before time n . (Note that this is not a stopping time.) By the Markov property, for all $k \leq n$,

$$\begin{aligned} \mathbf{P}_\pi[\sigma_x^n = k] &= \mathbf{P}_\pi[X_k = x, X_{k+1} \neq x, \dots, X_n \neq x] \\ &= \mathbf{P}_\pi[X_{k+1} \neq x, \dots, X_n \neq x \mid X_k = x] \mathbf{P}_\pi[X_k = x] \\ &= \pi(\{x\}) \mathbf{P}_x[X_1, \dots, X_{n-k} \neq x] \\ &= \pi(\{x\}) \mathbf{P}_x[\tau_x^1 \geq n - k + 1]. \end{aligned}$$

Hence, for every $n \in \mathbb{N}_0$ (since $\mathbf{P}_y[\tau_x^1 < \infty] = 1$ for all $y \in E$),

$$\begin{aligned}
1 &= \sum_{k=0}^n \mathbf{P}_\pi [\sigma_x^n = k] + \mathbf{P}_\pi [\sigma_x^n = -\infty] \\
&= \pi(\{x\}) \sum_{k=0}^n \mathbf{P}_x [\tau_x^1 \geq n - k + 1] + \mathbf{P}_\pi [\tau_x^1 \geq n + 1] \\
&\xrightarrow{n \rightarrow \infty} \pi(\{x\}) \sum_{k=1}^{\infty} \mathbf{P}_x [\tau_x^1 \geq k] = \pi(\{x\}) \mathbf{E}_x [\tau_x^1].
\end{aligned}$$

Therefore, $\mathbf{E}_x [\tau_x^1] = \frac{1}{\pi(\{x\})} < \infty$, and thus X is positive recurrent.

Example 17.52 Let $(p_x)_{x \in \mathbb{N}_0}$ be numbers in $(0, 1]$ and let X be an irreducible Markov chain on $\mathbb{N}_0$ with transition matrix

$$p(x, y) = \begin{cases} p_x, & \text{if } y = x + 1 \\ 1 - p_x, & \text{if } y = 0 \\ 0, & \text{else.} \end{cases}$$

If μ is an invariant measure, then the equations for $\mu p = \mu$ read

$$\begin{aligned}
\mu(\{n\}) &= p_{n-1} \mu(\{n-1\}) \quad \text{for } n \in \mathbb{N}, \\
\mu(\{0\}) &= \sum_{n=0}^{\infty} \mu(\{n\}) (1 - p_n).
\end{aligned}$$

Hence we get

$$\mu(\{n\}) = \mu(\{0\}) \prod_{k=0}^{n-1} p_k$$

and (note that the sum is a telescope sum)

$$\mu(\{0\}) = \mu(\{0\}) \sum_{n=0}^{\infty} (1 - p_n) \prod_{k=0}^{n-1} p_k = \mu(\{0\}) \left(1 - \prod_{n=0}^{\infty} p_n \right).$$

Hence there exists a nontrivial invariant measure μ (that is, $\mu(\{0\})$ can be chosen strictly positive) if and only if $\prod_{n=0}^{\infty} p_n = 0$. This, however, is true if and only if $\sum_{n=0}^{\infty} (1 - p_n) = \infty$. Using a Borel-Cantelli argument, it is not hard to show that this is exactly the condition for recurrence of X .

If $\mu \neq 0$, then μ is a finite measure if and only if

$$M := \sum_{n=0}^{\infty} \prod_{k=0}^{n-1} p_k < \infty$$

Hence X is positive recurrent if and only if $M < \infty$. In fact, it is not hard to show that M is the expected time to return to 0; hence the criterion for positive recurrence could also be deduced by Theorem 17.51.

A necessary condition for $M < \infty$ is of course that the series $\sum_{n=0}^{\infty} (1 - p_n)$ diverge; that is, that X is recurrent. One sufficient condition for $M < \infty$ is

$$\sum_{n=0}^{\infty} \exp \left(- \sum_{k=0}^{n-1} (1 - p_k) \right) < \infty$$

Exercise 17.6.1 Consider the Markov chain from Fig. 17.1 (p. 368). Determine the set of all invariant distributions. Show that the states 6, 7 and 8 are positive recurrent and compute the expected first entrance times

$$\mathbf{E}_6[\tau_6] = \frac{17}{4}, \quad \mathbf{E}_7[\tau_7] = \frac{17}{5} \quad \text{and} \quad \mathbf{E}_8[\tau_8] = \frac{17}{8}$$

Exercise 17.6.2 Let $X = (X_t)_{t \geq 0}$ be a Markov chain on E in continuous time with Q -matrix q . Show that a probability measure π on E is an invariant distribution for X if and only if $\sum_{x \in E} \pi(\{x\})q(x, y) = 0$ for all $y \in E$.

Exercise 17.6.3 Let G be a countable Abelian group and let p be the transition matrix of an irreducible random walk X on G . That is, we have $p(hg, hf) = p(g, f)$ for all $h, g, f \in G$. (This generalizes the notion of a random walk on $\mathbb{Z}^D$.) Use Theorem 17.51 to show that X is positive recurrent if and only if G is finite.

Exercise 17.6.4 Let $r \in [0, 1]$ and let X be the Markov chain on $\mathbb{N}_0$ with transition matrix (see Fig. 17.2 on p. 369)

$$p(x, y) = \begin{cases} 1, & \text{if } x = 0 \text{ and } y = 1, \\ r, & \text{if } y = x + 1 \geq 2, \\ 1 - r, & \text{if } y = x - 1, \\ 0, & \text{else.} \end{cases}$$

Compute the invariant measure and show the following using Theorem 17.51:

(i) If $r \in (0, \frac{1}{2})$, then X is positive recurrent.

(ii) If $r = \frac{1}{2}$, then X is null recurrent.

(iii) If $r \in \{0\} \cup (\frac{1}{2}, 1]$, then X is transient.

Exercise 17.6.5 (i) Use a direct argument to show that the Markov chain in Example 17.52 is recurrent if and only if $\sum_{n=0}^{\infty} (1 - p_n) = \infty$.

(ii) Show that the expected time to return to 0 is M and infer that the chain is positive recurrent if and only if $M < \infty$.

(iii) Give examples of sequences $(p_x)_{x \in \mathbb{N}_0}$ such that the chain is (a) transient, (b) null recurrent, (c) positive recurrent, and (d) positive recurrent but

$$\sum_{n=0}^{\infty} \exp \left(- \sum_{k=0}^{n-1} (1 - p_k) \right) = \infty.$$

Exercise 17.6.6 Let X be irreducible and recurrent. Show that, as claimed in Remark 17.50, the invariant measure is unique up to constant multiples.

Hint: Let $\pi \neq 0$ be an invariant measure for X and abbreviate

$$\mathbf{P}_\pi = \sum_{x \in E} \pi(\{x\}) \mathbf{P}_x$$

(note that, in general, this need not be a finite measure). Let $x, y \in E$ with $x \neq y$ and deduce by induction that

$$\pi(\{y\}) = \mathbf{P}_\pi [\tau_x^1 \geq n, X_0 \neq x, X_n = y] + \sum_{k=1}^n \mathbf{P}_\pi [\tau_x^1 \geq k, X_0 = x, X_k = y].$$

Infer that

$$\pi(\{y\}) \geq \sum_{k=1}^{\infty} \mathbf{P}_\pi [\tau_x^1 \geq k, X_0 = x, X_k = y] = \pi(\{x\})\mu_x(\{y\})$$

where μ_x is the invariant measure defined in Theorem 17.47. Now use the fact that $\pi p^n = \pi$ and $\mu_x p^n = \mu_x$ for all $n \in \mathbb{N}$ to conclude that even $\pi(\{y\}) = \pi(\{x\})\mu_x(\{y\})$ holds.

5.17.7 17.7 Stochastic Ordering and Coupling

In many situations, for the comparison of two distributions, it is helpful to construct a product space such that the two distributions are the marginal distributions but are not necessarily independent. We first introduce the abstract principle of such couplings and then give some examples.

There are many concepts to order probability measures on $\mathbb{R}$ or $\mathbb{R}^d$ such that the "larger" one has a greater preference for large values than the "smaller" one. As one of the most prominent orders we present here the so-called stochastic order and illustrate its connection with couplings. As an excuse for presenting this section in a chapter on Markov chains, we finally use a simple Markov chain in order to prove a theorem on the stochastic order of binomial distributions.

Definition 17.53 Let $(E_1, \mathcal{E}_1, \mu_1)$ and $(E_2, \mathcal{E}_2, \mu_2)$ be probability spaces. A probability measure μ on $(E_1 \times E_2, \mathcal{E}_1 \otimes \mathcal{E}_2)$ with $\mu(\cdot \times E_2) = \mu_1$ and $\mu(E_1 \times \cdot) = \mu_2$ is called a coupling of μ_1 and μ_2 .

Clearly, the product measure $\mu = \mu_1 \otimes \mu_2$ is a coupling, but in many situations there are more interesting ones.

Example 17.54 Let X be a real random variable and let $f, g : \mathbb{R} \rightarrow \mathbb{R}$ be monotone increasing functions with $\mathbf{E}[f(X)^2] < \infty$ and $\mathbf{E}[g(X)^2] < \infty$. We want to show that the random variables $f(X)$ and $g(X)$ are nonnegatively correlated.

To this end, let Y be an independent copy of X ; that is, a random variable with $\mathbf{P}_Y = \mathbf{P}_X$ that is independent of X . Note that $\mathbf{E}[f(X)] = \mathbf{E}[f(Y)]$ and $\mathbf{E}[g(X)] = \mathbf{E}[g(Y)]$. For all numbers $x, y \in \mathbb{R}$, we have $(f(x) - f(y))(g(x) - g(y)) \geq 0$. Hence

$$\begin{aligned} 0 &\leq \mathbf{E}[(f(X) - f(Y))(g(X) - g(Y))] \\ &= \mathbf{E}[f(X)g(X)] - \mathbf{E}[f(X)]\mathbf{E}[g(Y)] + \mathbf{E}[f(Y)g(Y)] - \mathbf{E}[f(Y)]\mathbf{E}[g(X)] \\ &= 2 \operatorname{Cov}[f(X), g(X)] \end{aligned}$$

Example 17.55 Let (E, ϱ) be a Polish space. For two probability measures P and Q on $(E, \mathcal{B}(E))$, denote by $K(P, Q) \subset \mathcal{M}_1(E \times E)$ the set of all couplings of P and Q . The so-called Wasserstein metric on $\mathcal{M}_1(E)$ is defined by

$$d_W(P, Q) := \inf \left\{ \int \varrho(x, y) \varphi(d(x, y)) : \varphi \in K(P, Q) \right\}. \quad (17.26)$$

It can be shown that (this is the Kantorovich-Rubinstein theorem [84]; see also [37, pp. 420ff])

$$d_W(P, Q) = \sup \left\{ \int f d(P - Q) : f \in \operatorname{Lip}_1(E; \mathbb{R}) \right\} \quad (17.27)$$

Compare this representation of the Wasserstein metric with that of the total variation norm,

$$\|P - Q\|_{TV} = \sup \left\{ \int f d(P - Q) : f \in \mathcal{L}^\infty(E) \text{ with } \|f\|_\infty \leq 1 \right\} \quad (17.28)$$

In fact, we can also give a definition for the total variation in terms of a coupling: Let $D := \{(x, x) : x \in E\}$ be the diagonal in $E \times E$. Then

$$\|P - Q\|_{TV} = \inf \{ \varphi((E \times E) \setminus D) : \varphi \in K(P, Q) \}. \quad (17.29)$$

See [60] for a comparison of different metrics on $\mathcal{M}_1(E)$.

As an example of a more involved coupling, we quote the following theorem that is due to Skorohod.

Theorem 17.56 (Skorohod coupling) Let $\mu, \mu_1, \mu_2, \dots$ be probability measures on a Polish space E with $\mu_n \xrightarrow{n \rightarrow \infty} \mu$. Then there exists a probability space $(\Omega, \mathcal{A}, \mathbf{P})$ with random variables $X, X_1, X_2, \dots$ with $\mathbf{P}_X = \mu$ and $\mathbf{P}_{X_n} = \mu_n$ for every $n \in \mathbb{N}$ such that $X_n \xrightarrow{n \rightarrow \infty} X$ almost surely.

Proof See, e.g., [83, p. 79].

We now come to the concept of stochastic order.

Definition 17.57 Let $\mu_1, \mu_2 \in \mathcal{M}_1(\mathbb{R}^d)$. We write $\mu_1 \leq_{st} \mu_2$ if

$$\int f d\mu_1 \leq \int f d\mu_2$$

for every monotone increasing bounded function $f : \mathbb{R}^d \rightarrow \mathbb{R}$. In this case, we say that μ_2 is stochastically larger than μ_1 .

Evidently, $\leq_{st}$ is a partial order on $\mathcal{M}_1(\mathbb{R}^d)$. The stochastic order belongs to the class of so-called integral orders that are defined by the requirement that the integrals with respect to a certain class of functions (here: monotone increasing and bounded) are ordered. Other classes of functions that are often considered are convex functions or indicator functions on lower or upper orthants.

Let F_1 and F_2 be the distribution functions of μ_1 and μ_2 . Clearly, $\mu_1 \leq_{st} \mu_2$ implies $F_1(x) \geq F_2(x)$ for all $x \in \mathbb{R}^d$. If $d = 1$, then both statements are equivalent. However, for $d \geq 2$, the condition $F_1 \geq F_2$ is weaker than $\mu_1 \leq_{st} \mu_2$. For example, consider $d = 2$ and

$$\mu_1 = \frac{1}{2}\delta_{(0,0)} + \frac{1}{2}\delta_{(1,1)} \quad \text{and} \quad \mu_2 = \frac{1}{2}\delta_{(1,0)} + \frac{1}{2}\delta_{(0,1)}.$$

The partial order defined by the comparison of the distribution functions is called (lower) orthant order.

For a survey on different orders of probability measures, see, e.g., [120].

The following theorem was shown by Strassen [160] in larger generality for integral orders.

Theorem 17.58 (Strassen's theorem) Let

$$L := \{(x_1, x_2) \in \mathbb{R}^d \times \mathbb{R}^d : x_1 \leq x_2\}.$$

Then $\mu_1 \leq_{st} \mu_2$ if and only if there is a coupling φ of μ_1 and μ_2 with $\varphi(L) = 1$.

Proof Let φ be such a coupling. For monotone increasing bounded $f : \mathbb{R}^d \rightarrow \mathbb{R}$, we have $f(x_1) - f(x_2) \leq 0$ for every $x = (x_1, x_2) \in L$; hence $\int f d\mu_1 - \int f d\mu_2 = \int_L (f(x_1) - f(x_2)) \varphi(dx) \leq 0$ and thus $\mu_1 \leq_{st} \mu_2$.

Now assume $\mu_1 \leq_{st} \mu_2$. We only consider the case $d = 1$ (see [120, Theorem 3.3.5] for $d \geq 2$). Here $F((x_1, x_2)) := \min(F_1(x_1), F_2(x_2))$ defines a distribution function on $\mathbb{R} \times \mathbb{R}$ (see Exercise 1.5.5) that corresponds to a coupling φ with $\varphi(L) = 1$. A somewhat more explicit representation can be obtained using random variables. Let U be a random variable that is uniformly distributed on $(0, 1)$. Then

$$X_i := F_i^{-1}(U) := \inf \{x \in \mathbb{R} : F_i(x) \geq U\}$$

is a real random variable with distribution μ_i (see proof of Theorem 1.104). Clearly, we have $X_1 \leq X_2$ almost surely; that is, $\mathbf{P}[(X_1, X_2) \in L] = 1$. Evidently, the distribution function of (X_1, X_2) is F .

While Strassen's theorem yields the existence of an abstract coupling, in many examples a natural coupling can be established and used as a tool for proving, e.g., stochastic orders.

Example 17.59 Let $n \in \mathbb{N}$ and $0 \leq p_1 \leq p_2 \leq 1$. Let $Y_1, \dots, Y_n$ be independent random variables that are uniformly distributed on $[0, 1]$. Define $X_i = \#\{k \leq n : Y_k \leq p_i\}$, $i = 1, 2$. Then $X_i \sim b_{n, p_i}$ and $X_1 \leq X_2$ almost surely. This coupling shows that $b_{n, p_1} \leq_{\text{st}} b_{n, p_2}$.

An even simpler coupling can be used to show that $b_{m, p} \leq_{\text{st}} b_{n, p}$ for $m \leq n$ and $p \in [0, 1]$.

Theorem 17.60 Let $n_1, n_2 \in \mathbb{N}$ and $p_1, p_2 \in (0, 1)$. We have $b_{n_1, p_1} \leq_{\text{st}} b_{n_2, p_2}$ if and only if

$$(1 - p_1)^{n_1} \geq (1 - p_2)^{n_2} \quad (17.30)$$

and

$$n_1 \leq n_2. \quad (17.31)$$

Proof (The proof follows the exposition in [100, Section 3].)

Since $b_{n_i, p_i}(\{0\}) = (1 - p_i)^{n_i}$, conditions (17.30) and (17.31) are clearly necessary for $b_{n_1, p_1} \leq_{\text{st}} b_{n_2, p_2}$. Hence we only have to show sufficiency of the two conditions.

Assume that (17.30) and (17.31) hold. By Example 17.59, it is enough to consider the smallest p_2 that fulfills (17.30). Hence we assume $(1 - p_1)^{n_1} = (1 - p_2)^{n_2}$. Define $\lambda := -n_1 \log(1 - p_1) = -n_2 \log(1 - p_2)$. We will construct a binomially distributed random variable by throwing a Poi_λ -distributed number T of balls in n_i boxes and count the number of nonempty boxes. More precisely, let $T \sim \text{Poi}_\lambda$ and let $X_1, X_2, \dots$ be independent and uniformly distributed on $[0, 1]$ and independent of T . For $n \in \mathbb{N}$, $t \in \mathbb{N}_0$ and $l = 1, \dots, n$, define

$$M_{n, t, l} = \#\{s \leq t : X_s \in ((l-1)/n, l/n]\}$$

and the number of nonempty boxes after t balls are thrown:

$$N_{n, t} := \sum_{l=1}^n \mathbb{1}_{\{M_{n, t, l} > 0\}}$$

By Theorem 5.35, the random variables $M_{n, T, 1}, \dots, M_{n, T, n}$ are independent and $\text{Poi}_{\lambda/n}$ -distributed. In particular, we have

$$\mathbf{P}[M_{n_i, T, l} > 0] = 1 - e^{-\lambda/n_i} = p_i$$

and thus $N_{n_i, T} \sim b_{n_i, p_i}$, $i = 1, 2$. Hence it suffices to show that $N_{n_1, T} \leq_{\text{st}} N_{n_2, T}$. For this in turn it is enough to show

$$N_{n_1, t} \leq_{\text{st}} N_{n_2, t} \quad \text{for all } t \in \mathbb{N}_0. \quad (17.32)$$

In fact, let $f : \{0, \dots, n\} \rightarrow \mathbb{R}$ be monotone increasing. Then

$$\begin{aligned} \mathbf{E}[f(N_{n_1, T})] &= \sum_{t=0}^{\infty} \mathbf{E}[f(N_{n_1, t})] \mathbf{P}[T = t] \\ &\leq \sum_{t=0}^{\infty} \mathbf{E}[f(N_{n_2, t})] \mathbf{P}[T = t] = \mathbf{E}[f(N_{n_2, T})] \end{aligned}$$

We use an induction argument to show (17.32). For $t = 0$, the claim holds trivially. Now assume that (17.32) holds for some given $t \in \mathbb{N}_0$. We are now at the point to use a Markov chain. Note that (for fixed n), $(N_{n, t})_{t=0, 1, \dots}$ is a Markov chain with state space $\{0, \dots, n\}$ and transition matrix

$$p_n(k, l) = \begin{cases} k/n, & \text{if } l = k \\ 1 - k/n, & \text{if } l = k + 1 \\ 0, & \text{otherwise} \end{cases}$$

We define for $k, l = 0, \dots, n$

$$h_{n,l}(k) = \sum_{j=l}^n p_n(k, j) = \begin{cases} 0, & \text{if } k < l - 1 \\ 1 - k/n, & \text{if } k = l - 1 \\ 1, & \text{if } k > l - 1 \end{cases}$$

Then $\mathbf{P}[N_{n,t+1} \geq l] = \mathbf{E}[h_{n,l}(N_{n,t})]$ and $h_{n,l}(k)$ is monotone increasing both in k and in n . Hence by the induction hypothesis, we have

$$\begin{aligned} \mathbf{P}[N_{n_1,t+1} \geq l] &= \mathbf{E}[h_{n_1,l}(N_{n_1,t})] \\ &\leq \mathbf{E}[h_{n_1,l}(N_{n_2,t})] \\ &\leq \mathbf{1}(N_{n_2,t}) = \mathbf{P}[N_{n_2,t+1} \geq l]. \end{aligned}$$

We conclude that $N_{n_1,t+1} \leq_{\text{st}} N_{n_2,t+1}$ which completes the induction and the proof of the theorem.

Exercise 17.7.1 Use an elementary direct coupling argument to show the claim of Theorem 17.60 for the case $n_2/n_1 \in \mathbb{N}$.

Exercise 17.7.2 For the Poisson distribution, show that

$$\text{Poi}_{\lambda_1} \leq_{\text{st}} \text{Poi}_{\lambda_2} \iff \lambda_1 \leq \lambda_2.$$

Exercise 17.7.3 Let $n \in \mathbb{N}$, $p \in (0, 1)$ and $\lambda > 0$. Show that

$$b_{n,p} \leq_{\text{st}} \text{Poi}_{\lambda} \iff (1-p)^n \geq e^{-\lambda}.$$

5.18 18 Convergence of Markov Chains

We consider a Markov chain X with invariant distribution π and investigate conditions under which the distribution of X_n converges to π for $n \rightarrow \infty$. Essentially it is necessary and sufficient that the state space of the chain cannot be decomposed into subspaces

- that the chain does not leave
- or that are visited by the chain periodically; e.g., only for odd n or only for even n .

In the first case, the chain would be called reducible, and in the second case, it would be periodic.

We study periodicity of Markov chains in the first section. In the second section, we prove the convergence theorem. The third section is devoted to applications of the convergence theorem to computer simulations with the so-called Monte Carlo method. In the last section, we describe the speed of convergence to the equilibrium by means of the spectrum of the transition matrix.

5.18.1 18.1 Periodicity of Markov Chains

We study the conditions under which a positive recurrent Markov chain X on the countable space E (and with transition matrix p), started in an arbitrary $\mu \in \mathcal{M}_1(E)$, converges in distribution to an invariant distribution π ; that is, $\mu p^n \xrightarrow{n \rightarrow \infty} \pi$. Clearly, it is necessary that π be the unique invariant distribution; that is, up to a factor π it is the unique left eigenvector of p for the eigenvalue 1. As shown in Theorem 17.49, for this uniqueness it is sufficient that the chain be irreducible.

In order for $\mu p^n \xrightarrow{n \rightarrow \infty} \pi$ to hold for every $\mu \in \mathcal{M}_1(E)$, a certain contraction property of p is necessary. Manifestly, 1 is the largest (absolute value of an) eigenvalue of p . However, p is

sufficiently contractive only if the multiplicity of the eigenvalue 1 is exactly 1 and if there are no further (possibly complex-valued) eigenvalues of modulus 1.

For the latter property, it is not sufficient that the chain be irreducible. For example, consider on $E = \{0, \dots, N-1\}$ the Markov chain with transition matrix

Fig. 18.1 The left Markov chain is periodic with period 2, and the right Markov chain is aperiodic

$p(x, y) = \mathbb{1}_{\{y=x+1 \pmod{N}\}}$. The eigenvalue 1 has the multiplicity 1. However, all complex N th roots of unity $e^{2\pi i k/N}$, $k = 0, \dots, N-1$, are eigenvalues of modulus 1. Clearly, the uniform distribution on E is invariant but $\lim_{n \rightarrow \infty} \delta_x p^n$ does not exist for any $x \in E$. In fact, every point is visited periodically after N steps. In order to obtain criteria for the convergence of Markov chains, we thus have to understand periodicity first. Thereafter, for irreducible aperiodic chains, we state the convergence theorem.

If $m, n \in \mathbb{N}$, then write $m \mid n$ if m is a divisor of n ; that is, if $\frac{n}{m} \in \mathbb{N}$. If $M \subset \mathbb{N}$, then denote by $\gcd(M)$ the greatest common divisor of all $n \in M$. In the following, let X be a Markov chain on the countable space E with transition matrix p .

Definition 18.1 (i) For $x, y \in E$, define

$$N(x, y) := \{n \in \mathbb{N}_0 : p^n(x, y) > 0\}.$$

For any $x \in E$, $d_x := \gcd(N(x, x))$ is called the period of the state x .

(ii) If $d_x = d_y$ for all $x, y \in E$, then $d := d_x$ is called the period of X .

(iii) If $d_x = 1$ for all $x \in E$, then X is called aperiodic.

See Figs. 18.1 and 18.2 for illustrations of aperiodic and periodic Markov chains.

Lemma 18.2 For any $x \in E$, there exists an $n_x \in \mathbb{N}$ with

$$p^{nd_x}(x, x) > 0 \quad \text{for all } n \geq n_x. \quad (18.1)$$

Proof Let $k_1, \dots, k_r \in N(x, x)$ with $\gcd(\{k_1, \dots, k_r\}) = d_x$. Then, for all $m_1, \dots, m_r \in \mathbb{N}_0$, we also have $\sum_{i=1}^r k_i m_i \in N(x, x)$. Basic number theory then yields that, for every $n \geq n_x := r \cdot \prod_{i=1}^r (k_i/d_x)$, there are numbers $m_1, \dots, m_r \in \mathbb{N}_0$ with $nd_x = \sum_{i=1}^r k_i m_i$. Hence (18.1) holds. $\square$

The problem of finding the smallest number N such that any $nd_x, n \geq N$ can be written as a nonnegative integer linear combination of $k_1, \dots, k_r$ is called the Frobenius problem. The general solution is unknown; however, for the case $r = 2$,

Fig. 18.2 Here $N(8,8) = \{6, 10, 12, 14, 16, \dots\}$; hence $d_8 := \gcd(\{6, 10, 12, \dots\}) = 2$ and $n_8 = 5$. The chain thus has period 2. However, $n_1 = 2$ and $n_4 = 4$

Sylvester [162] showed that $N = (k_1/d_x - 1)(k_2/d_x - 1)$ is minimal. In the general case, for N , the upper bound $2 \max \{k_i : i = 1, \dots, r\}^2 / (rd_x^2)$ is known; see, e.g., [45].

Lemma 18.3 Let X be irreducible. Then the following statements hold.

- (i) $d := d_x = d_y$ for all $x, y \in E$.
- (ii) For all $x, y \in E$, there exist $n_{x,y} \in \mathbb{N}$ and $L_{x,y} \in \{0, \dots, d - 1\}$ such that

$$nd + L_{x,y} \in N(x, y) \quad \text{for all } n \geq n_{x,y}. \quad (18.2)$$

$L_{x,y}$ is uniquely determined, and we have

$$L_{x,y} + L_{y,z} + L_{z,x} = 0 \pmod{d} \quad \text{for all } x, y, z \in E. \quad (18.3)$$

Proof (i) Let $m, n \in \mathbb{N}_0$ with $p^m(x, y) > 0$ and $p^n(y, z) > 0$. Then

$$p^{m+n}(x, z) \geq p^m(x, y)p^n(y, z) > 0.$$

Hence we have

$$N(x, y) + N(y, z) := \{m + n : m \in N(x, y), n \in N(y, z)\} \subset N(x, z). \quad (18.4)$$

If, in particular, $m \in N(x, y), n \in N(y, x)$ and $k \geq n_y$, then $kd_y \in N(y, y)$; hence $m + kd_y \in N(x, y)$ and $m + n + kd_y \in N(x, x)$. Therefore, $d_x \mid (m + n + kd_y)$ for every $k \geq n_y$; hence $d_x \mid d_y$. Similarly, we get $d_y \mid d_x$; hence $d_x = d_y$.

(ii) Let $m \in N(x, y)$. Then $m + kd \in N(x, y)$ for every $k \geq n_x$. Hence (18.2) holds with

$$n_{x,y} := n_x + \left\lfloor \frac{m}{d} \right\rfloor \quad \text{and} \quad L_{x,y} := m - d \left\lfloor \frac{m}{d} \right\rfloor.$$

Owing to (18.4), we have

$$(n_{x,y} + n_{y,z})d + L_{x,y} + L_{y,z} \in N(x, z).$$

Fig. 18.3 State space decomposition of a Markov chain with period $d = 3$

Together with $z = x$, it follows that $d \mid (L_{x,y} + L_{y,x})$. Hence the value of $L_{x,y}$ is unique in $\{0, \dots, d-1\}$ and $L_{x,y} = -L_{y,x} \pmod{d}$. For general z , we infer that $d \mid (L_{x,y} + L_{y,z} + L_{z,x})$; hence (18.3). $\square$

Theorem 18.4 Let X be irreducible with period d . Then there exists a disjoint decomposition of the state space

$$E = \bigsqcup_{i=0}^{d-1} E_i \quad (18.5)$$

with the property

$$p(x, y) > 0 \quad \text{and} \quad x \in E_i \implies y \in E_{i+1 \pmod{d}}. \quad (18.6)$$

This decomposition is unique up to cyclic permutations.

See Fig. 18.3 for an illustration of the state space decomposition of a periodic Markov chain.

Property (18.6) says that X visits the E_i one after the other (see Fig. 18.3 or Fig. 18.2, where $d = 2$, $E_0 = \{1, 3, 5, 7\}$ and $E_1 = \{2, 4, 6, 8\}$). Somewhat more formally, we could write: If $x \in E_i$ for some i , then $\mathbf{P}_x[X_n \in E_{i+n \pmod{d}}] = 1$.

Proof Existence. Fix an arbitrary $x_0 \in E$ and let

$$E_i := \{y \in E : L_{x_0, y} = i\} \quad \text{for } i = 0, \dots, d-1.$$

Clearly, (18.5) holds. Let $i \in \{0, \dots, d-1\}$ and $x \in E_i$. If $y \in E$ with $p(x, y) > 0$, then $L_{x, y} = 1$ and hence $L_{x_0, y} = L_{x_0, x} + L_{x, y} = i + 1 \pmod{d}$.

Uniqueness. Let $(\tilde{E}_i, i = 0, \dots, d-1)$ be another decomposition that satisfies (18.5) and (18.6). Without loss of generality, assume $E_0 \cap \tilde{E}_0 \neq \emptyset$ (otherwise permute the $\tilde{E}_i$ cyclically until this holds). Fix an arbitrary $x_0 \in E_0 \cap \tilde{E}_0$. By assumption, $p(x_0, y) > 0$ now implies $y \in E_1$ and $y \in \tilde{E}_1$; hence $y \in E_1 \cap \tilde{E}_1$. Inductively, we get that $p^{nd+i}(x_0, y) > 0$ implies $y \in E_i \cap \tilde{E}_i$ (for all $n \in \mathbb{N}$ and $i = 0, \dots, d-1$).

However, since the chain is irreducible, for every $y \in E$, there exist numbers $n(y)$ and $i(y)$ such that $p^{n(y)d+i(y)}(x_0, y) > 0$; hence $y \in E_{i(y)} \cap \tilde{E}_{i(y)}$. Therefore, we have $E_i = \tilde{E}_i$ for every $i = 0, \dots, d-1$.

5.18.2 18.2 Coupling and Convergence Theorem

Our goal is to use a coupling of two discrete Markov chains that are started in different distributions μ and ν in order to show the convergence theorem for Markov chains.

In the following, let E be a countable space and let p be a stochastic matrix on E . Recall the definition of a general coupling of two probability measures from Definition 17.53.

Definition 18.5 A bivariate process $((X_n, Y_n))_{n \in \mathbb{N}_0}$ with values in $E \times E$ is called a coupling if $(X_n)_{n \in \mathbb{N}_0}$ and $(Y_n)_{n \in \mathbb{N}_0}$ are Markov chains, each with transition matrix p .

A coupling is called successful if $\mathbf{P}_{(x,y)} [\bigcup_{m \geq n} \{X_m \neq Y_m\}] \xrightarrow{n \rightarrow \infty} 0$ for all $x, y \in E$.

Of course, two independent chains form a coupling, though maybe not the most interesting one.

Example 18.6 (Independent coalescence) The most important coupling is Markov chains that run independently until they coalesce: Let X and Y be independent chains with transition matrix p until they first meet. After that, the chains run together. We call this coupling the independent coalescent. The transition matrix is

$$\bar{p}((x_1, y_1), (x_2, y_2)) = \begin{cases} p(x_1, x_2) \cdot p(y_1, y_2), & \text{if } x_1 \neq y_1, \\ p(x_1, x_2), & \text{if } x_1 = y_1, x_2 = y_2, \\ 0, & \text{if } x_1 = y_1, x_2 \neq y_2. \end{cases}$$

Denote by $\tau := \inf \{n \in \mathbb{N}_0 : X_n = Y_n\}$ the time of coalescence. We can construct the coupling using two independent chains $\tilde{X}$ and $\tilde{Y}$ by defining $X := \tilde{X}$, $\tilde{\tau} := \inf \{n \in \mathbb{N}_0 : \tilde{X}_n = \tilde{Y}_n\}$ and

$$Y_n := \begin{cases} \tilde{Y}_n, & \text{if } n < \tilde{\tau} \\ X_n, & \text{if } n \geq \tilde{\tau} \end{cases}$$

Instead of checking by a direct computation that this process (X, Y) is indeed a coupling with transition matrix $\bar{p}$, consider the construction of Markov chains from Theorem 17.17: Let $(R_n(x) : n \in \mathbb{N}_0, x \in E)$ be independent random variables with distribution $\mathbf{P}[R_n(x_1) = x_2] = p(x_1, x_2)$, and let $\tilde{R}_n((x_1, y_1)) = (R_n(x_1), R_n(y_1))$. Then $(\tilde{R}_n)_{n \in \mathbb{N}_0}$ is independent and we have

$$\mathbf{P}[\tilde{R}_n((x_1, y_1)) = (x_2, y_2)] = \bar{p}((x_1, y_1), (x_2, y_2))$$

As we saw in Theorem 17.17, by $X_{n+1} := R_n(X_n)$ and $Y_{n+1} := R_n(Y_n)$, two Markov chains X and Y are defined with transition matrix p . On the other hand, we have $(X_{n+1}, Y_{n+1}) = \tilde{R}_n((X_n, Y_n))$. Hence the bivariate process is indeed a coupling with transition matrix $\bar{p}$.

Example 18.7 Let $E = \mathbb{Z}$ and $p(x, y) = 1/3$ if $|x - y| \leq 1$ and 0 otherwise. Clearly, p is the transition matrix of an aperiodic recurrent random walk on $\mathbb{Z}$. We will show that we can obtain a successful coupling by coalescing independent chains.

Accordingly, let $\tilde{X}$ and $\tilde{Y}$ be independent random walks with transition matrix p . Then the difference chain $(Z_n)_{n \in \mathbb{N}_0} := (\tilde{X}_n - \tilde{Y}_n)_{n \in \mathbb{N}_0}$ is a symmetric random walk with finite expectation and hence recurrent. Furthermore, Z is irreducible. For any two points $x, y \in \mathbb{Z}$, we thus have

$$\mathbf{P}_{(x,y)}[\tilde{\tau} < \infty] = \mathbf{P}_{x-y}[Z_n = 0 \text{ for some } n \in \mathbb{N}_0] = 1.$$

Therefore, X and Y coalesce almost surely.

Recurrence, irreducibility and aperiodicity alone are not sufficient for the independent coalescence coupling to be successful. In Exercise 18.2.4, an example is studied that shows that spacial homogeneity cannot easily be dropped if we want to have a successful coupling. Dropping the assumption of recurrence is easier, as the following theorem shows.

Theorem 18.8 Let X be an arbitrary aperiodic and irreducible random walk on $\mathbb{Z}^d$ with transition matrix p . Then there exists a successful coupling (X, Y) .

Proof Step 1. First, consider the case where $p(0, x) = 3^{-d}$ for all $x \in \{-1, 0, 1\}^d$. The individual coordinates $X^{(1)}, \dots, X^{(d)}$ of X are independent random walks on $\mathbb{Z}$ with transition probabilities $\mathbf{P}_0[X_1^{(i)} = x_i] = 1/3$ for $x_i = -1, 0, 1$. By Example 18.7, we can construct independent successful couplings $(X^{(i)}, Y^{(i)})$, $i = 1, \dots, d$, with merging times $\tau^{(i)}$. Define $Y = (Y^{(1)}, \dots, Y^{(d)})$ and $\tau = \max\{\tau^{(1)}, \dots, \tau^{(d)}\} < \infty$. Then (X, Y) is a successful coupling and $X_n = Y_n$ for $n \geq \tau$.

Step 2. Now, consider the case where

$$\lambda := 3^d \min\{p(0, x) : x \in \{-1, 0, 1\}^d\} > 0.$$

If $\lambda = 1$, then the condition of Step 1 is fulfilled and we are done. Hence, we assume that $\lambda \in (0, 1)$. We define the transition matrix $\hat{p}$ on $\mathbb{Z}^d$ by $\hat{p}(x, y) = 3^{-d}$ for $y - x \in \{-1, 0, 1\}^d$. Note that also $\check{p} := (p - \lambda\hat{p})/(1 - \lambda)$ is the transition matrix of a random walk on $\mathbb{Z}^d$ and that

$$p = \lambda\hat{p} + (1 - \lambda)\check{p}.$$

Let $\hat{X}$ and $\check{X}$ be independent random walks with transition matrices $\hat{p}$ and $\check{p}$, respectively. Assume that $\hat{X}_0 = X_0$ and $\check{X}_0 = 0$. Furthermore, let $Z_1, Z_2, \dots$ be i.i.d.

Bernoulli random variables with parameter λ that are independent of $\hat{X}$ and $\check{X}$. Define $S_n := Z_1 + \dots + Z_n$ for $n \in \mathbb{N}$ and

$$X_n := \hat{X}_{S_n} + \check{X}_{n-S_n}.$$

That is, in each time step, a coin flip decides whether X makes a jump according to the matrix $\hat{p}$ or $\check{p}$. Hence X is a random walk with transition matrix p .

By Step 1, there exists a successful coupling $(\hat{X}, \hat{Y})$ such that $\hat{Y}$ is independent of $\check{X}$ and $Z_1, Z_2, \dots$. Consequently,

$$Y_n := \hat{Y}_{S_n} + \check{X}_{n-S_n}, \quad n \in \mathbb{N},$$

is also a random walk with transition matrix p . Since we have $S_n \rightarrow \infty$ almost surely, the coupling (X, Y) is successful.

Step 3. Finally, we consider the general situation. Since X is irreducible and aperiodic, by Lemma 18.3(ii), there exists an $N \in \mathbb{N}$, such that the N -step transition matrix fulfills

$$p^N(0, x) > 0 \quad \text{for all } x \in \{-1, 0, 1\}^d$$

Hence, the random walk $X' = (X'_n)_{n \in \mathbb{N}} := (X_{nN})_{n \in \mathbb{N}}$ fulfills the condition from Step 2. Let (X', Y') be the coupling that was constructed in Step 2 and let

$$\tau := \inf\{n \in \mathbb{N}_0 : X'_m = Y'_m \text{ for all } m \geq n\}.$$

Then Y' is a random walk with transition matrix p^N . For $n \in \mathbb{N}_0$, define $Y_{nN} := Y'_n$. It remains to close the gaps between the points $\{0, N, 2N, \dots\}$ in such a way that Y is a random walk and (X, Y) is a successful coupling.

Let $(U^{x,y,n} : x, y \in \mathbb{Z}^d, n \in \mathbb{N}_0)$ be an independent family of $(\mathbb{Z}^d)^{N-1}$ -valued random variables $U^{x,y,n} = (U_1^{x,y,n}, \dots, U_{N-1}^{x,y,n})$ such that

$$\mathbf{P}[(X_1, \dots, X_{N-1}) \in \cdot \mid X_0 = x, X_N = y] = \mathbf{P}_{U^{x,y,n}}$$

for all $x, y \in \mathbb{Z}^d$ with $p^N(x, y) > 0$ and for all $n \in \mathbb{N}_0$. We further assume that the $U^{x,y,n}$ are independent of X and Y' . For $k \in \{nN + 1, \dots, (n+1)N - 1\}$, define

$$Y_k := \begin{cases} U_{k-nN}^{Y'_n, Y'_{n+1}, n}, & \text{if } n < \tau \\ X_k, & \text{else.} \end{cases}$$

It is easy to check that Y is indeed a random walk with transition matrix p . By construction, the coupling (X, Y) is successful.

Theorem 18.9 Let X be a Markov chain on E with transition matrix p . If there exists a successful coupling, then every bounded harmonic function is constant.

Proof Let $f : E \rightarrow \mathbb{R}$ be bounded and harmonic; hence $pf = f$. Let $x, y \in E$, and let (X, Y) be a successful coupling. By Lemma 17.45, $(f(X_n))_{n \in \mathbb{N}_0}$ and $(f(Y_n))_{n \in \mathbb{N}_0}$ are martingales; hence we have

$$|f(x) - f(y)| = |\mathbf{E}_{(x,y)}[f(X_n) - f(Y_n)]| \leq 2\|f\|_\infty \mathbf{P}_{(x,y)}[X_n \neq Y_n] \xrightarrow{n \rightarrow \infty} 0.$$

□

Corollary 18.10 If X is an irreducible random walk on $\mathbb{Z}^d$, then every bounded harmonic function is constant.

This statement holds more generally if we replace $\mathbb{Z}^d$ by a locally compact Abelian group. In that form, the theorem goes back to Choquet and Deny [24], see also [143].

Proof Let p be the transition matrix of X . Let $\bar{X}$ be a Markov chain with transition matrix $\bar{p}(x, y) = \frac{1}{2}p(x, y) + \frac{1}{2}\mathbb{1}_{\{x\}}(y)$. Clearly, X and $\bar{X}$ have the same harmonic functions. Now $\bar{X}$ is an aperiodic irreducible random walk; hence, by Theorem 18.8, there is a successful coupling for all initial states. □

Theorem 18.11 Let p be the transition matrix of an irreducible, positive recurrent, aperiodic Markov chain on E . Then the independent coalescent chain is a successful coupling.

Proof Let $\tilde{X}$ and $\tilde{Y}$ be two independent Markov chains on E , each with transition matrix p . Then the bivariate Markov chain $Z := \left((\tilde{X}_n, \tilde{Y}_n) \right)_{n \in \mathbb{N}_0}$ has the transition matrix $\tilde{p}$ defined by

$$\tilde{p}((x_1, y_1), (x_2, y_2)) = p(x_1, x_2) \cdot p(y_1, y_2)$$

We first show that the matrix $\tilde{p}$ is irreducible. Only here do we need aperiodicity of p . Accordingly, fix $(x_1, y_1), (x_2, y_2) \in E \times E$. Then, by Lemma 18.2, there exists an $m_0 \in \mathbb{N}$ such that

$$p^n(x_1, x_2) > 0 \quad \text{and} \quad p^n(y_1, y_2) > 0 \quad \text{for all } n \geq m_0.$$

For $n \geq m_0$, we thus have $\tilde{p}^n((x_1, y_1), (x_2, y_2)) > 0$. Hence $\tilde{p}$ is irreducible. Now define the stopping time τ of the first entrance of $(\tilde{X}, \tilde{Y})$ into the diagonal $D := \{(x, x) : x \in E\}$ by $\tau := \inf \{n \in \mathbb{N}_0 : \tilde{X}_n = \tilde{Y}_n\}$. Let π be the invariant distribution of $\tilde{X}$. Then, clearly, the product measure $\pi \otimes \pi \in \mathcal{M}_1(E \times E)$ is an (and then the) invariant distribution of $(\tilde{X}, \tilde{Y})$. Thus $(\tilde{X}, \tilde{Y})$ is positive recurrent (hence, in particular, recurrent) by Theorem 17.51. Therefore, $\mathbf{P}_{(x,y)}[\tau < \infty] = 1$ for all initial points $(x, y) \in E \times E$ of Z . □

Theorem 18.12 Let X be a Markov chain with transition matrix p such that there exists a successful coupling. Then $\|(\mu - v)p^n\|_{TV} \xrightarrow{n \rightarrow \infty} 0$ for all $\mu, v \in \mathcal{M}_1(E)$.

If X is aperiodic and positive recurrent with invariant distribution π , then we have $\|\mathcal{L}_\mu[X_n] - \pi\|_{TV} \xrightarrow{n \rightarrow \infty} 0$ for all $\mu \in \mathcal{M}_1(E)$.

Proof It is enough to consider the case $\mu = \delta_x, v = \delta_y$ for some $x, y \in E$. Summation over x and y yields the general case. Let $(X_n, Y_n)_{n \in \mathbb{N}_0}$ be a successful coupling. Then

$$\|(\delta_x - \delta_y)p^n\|_{TV} \leq 2\mathbf{P}_{(x,y)}[X_n \neq Y_n] \xrightarrow{n \rightarrow \infty} 0.$$

We summarize the connection between aperiodicity and convergence of distributions of X in the following theorem.

Theorem 18.13 (Convergence of Markov chains) Let X be an irreducible, positive recurrent Markov chain on E with invariant distribution π . Then the following are equivalent:

- (i) X is aperiodic.
- (ii) For every $x \in E$, we have

$$\|\mathcal{L}_x[X_n] - \pi\|_{TV} \xrightarrow{n \rightarrow \infty} 0. \quad (18.7)$$

- (iii) Equation (18.7) holds for some $x \in E$.
- (iv) For every $\mu \in \mathcal{M}_1(E)$, we have $\|\mu p^n - \pi\|_{TV} \xrightarrow{n \rightarrow \infty} 0$.

Proof The implications (iv) $\implies$ (ii) $\implies$ (iii) are evident. The implication (i) $\implies$ (ii) was shown in Theorem 18.12. Hence we only show (iii) $\implies$ (i).

"(iii) $\implies$ (i)" Assume that (i) does not hold. If X has period $d \geq 2$, and if $n \in \mathbb{N}$ is not a multiple of d , then, by Theorem 17.51,

$$\|\delta_x p^n - \pi\|_{TV} \geq |p^n(x, x) - \pi(\{x\})| = \pi(\{x\}) > 0.$$

Thus, for every $x \in E$, we have $\limsup_{n \rightarrow \infty} \|\delta_x p^n - \pi\|_{TV} > 0$. Therefore, (iii) does not hold.

Exercise 18.2.1 Let d_P be the Prohorov metric (see (13.3) and Exercise 13.2.1). Show that $d_P(P, Q) \leq \sqrt{d_W(P, Q)}$ for all $P, Q \in \mathcal{M}_1(E)$. If E has a finite diameter $\text{diam}(E)$, then $d_W(P, Q) \leq (\text{diam}(E) + 1)d_P(P, Q)$ for all $P, Q \in \mathcal{M}_1(E)$.

Exercise 18.2.2 Consider the bivariate process (X, Y) that was constructed from $\tilde{X}$ and $\tilde{Y}$ in Example 18.6. Show that (X, Y) is a coupling with transition matrix $\bar{p}$.

Exercise 18.2.3 Let X be an arbitrary aperiodic irreducible recurrent random walk on $\mathbb{Z}^d$. Show that, for any two starting points, the independent coalescent coupling is successful.

Hint: Show that the difference of two independent recurrent random walks is a recurrent random walk.

Exercise 18.2.4 Let X be a Markov chain on $\mathbb{Z}^2$ with transition matrix

$$p((x_1, x_2), (y_1, y_2)) = \begin{cases} \frac{1}{4}, & \text{if } x_1 = 0, \|y - x\|_2 = 1, \\ \frac{1}{4}, & \text{if } x_1 \neq 0 \text{ and } y_1 = x_1 \pm 1, x_2 = y_2, \\ \frac{1}{2}, & \text{if } x_1 \neq 0 \text{ and } y_1 = x_1, x_2 = y_2, \\ 0, & \text{else.} \end{cases}$$

Intuitively, this is the symmetric simple random walk whose vertical transitions are all blocked away from the vertical axis. Show that X is null recurrent, irreducible and aperiodic and that independent coalescence does not give a successful coupling.

5.18.3 18.3 Markov Chain Monte Carlo Method

Let E be a finite set and let $\pi \in \mathcal{M}_1(E)$ with $\pi(x) := \pi(\{x\}) > 0$ for every $x \in E$. We consider the problem of sampling a random variable Y with distribution π on a computer. For example, this is a relevant problem if E is a very large set and if sums of the type $\sum_{x \in E} f(x)\pi(x)$ have to be approximated numerically by the estimator $n^{-1} \sum_{i=1}^n f(Y_i)$ (see Example 5.21).

Assume that our computer has a random number generator that provides realizations of i.i.d. random variables $U_1, U_2, \dots$ that are uniformly distributed on $[0, 1]$. In order for the problem to be interesting, assume also that the distribution π cannot be constructed directly too easily.

Metropolis Algorithm

We have seen already in Example 17.19 how to simulate a Markov chain on a computer. Now the idea is to construct a Markov chain X whose distribution converges to π in the long run. If we simulate such a chain and let it run long enough this should give a sample that is distributed approximately like π . The chain should be designed so that at each step, only a small number of transitions are possible in order to ensure that the procedure described in Example 17.19 works efficiently. (Of course, the chain with transition matrix $p(x, y) = \pi(y)$ converges to π , but this does not help a lot.) This method of producing (approximately) π -distributed samples and using them to estimate expected values of functions of interest is called the Markov chain Monte Carlo method or, briefly, MCMC (see [15, 112, 119]).

Let q be the transition matrix of an arbitrary irreducible Markov chain on E (with $q(x, y) = 0$ for most $y \in E$). We use this to construct the Metropolis matrix (see [70, 114]).

Definition 18.14 Define a stochastic matrix p on E by

$$p(x, y) = \begin{cases} q(x, y) \min \left(1, \frac{\pi(y)q(y, x)}{\pi(x)q(x, y)} \right), & \text{if } x \neq y, q(x, y) > 0, \\ 0, & \text{if } x \neq y, q(x, y) = 0, \\ 1 - \sum_{z \neq x} p(x, z), & \text{if } x = y. \end{cases}$$

p is called the Metropolis matrix of q and π .

Note that p is reversible (see Section 19.2); that is, for all $x, y \in E$, we have

$$\pi(x)p(x, y) = \pi(y)p(y, x). \quad (18.8)$$

In particular, π is invariant (check this!). We thus obtain the following theorem.

Theorem 18.15 Assume that q is irreducible and that for any $x, y \in E$, we have $q(x, y) > 0$ if and only if $q(y, x) > 0$. Then the Metropolis matrix p of q and π is irreducible with unique invariant distribution π . If, in addition, q is aperiodic, or q is not reversible with respect to π , then p is aperiodic.

In order to simulate a chain X that converges to π , we take a reference chain with transition matrix q and use the Metropolis algorithm: If the chain with transition matrix q proposes a transition from the present state x to state y , then we accept this proposal with probability

$$\frac{\pi(y)q(y, x)}{\pi(x)q(x, y)} \wedge 1.$$

Otherwise the chain X stays at x .

In the definition of p , the distribution π appears only in terms of the quotients $\pi(y)/\pi(x)$. In many cases of interest, these quotients are easy to compute even though $\pi(x)$ and $\pi(y)$ are not. We illustrate this with an example.

Example 18.16 (Ising model) The Ising model (pronounced like the English word "easing") is a thermodynamical (and quantum mechanical) model for ferromagnetism in crystals. It makes the following assumptions:

- Atoms are placed at the sites of a lattice Λ (for example, $\Lambda = \{0, \dots, N-1\}^2$).
- Each atom $i \in \Lambda$ has a magnetic spin $x(i) \in \{-1, 1\}$ that either points upwards ($x(i) = +1$) or downwards ($x(i) = -1$).
- Neighboring atoms interact.
- Due to thermic fluctuations, the state of the system is random and distributed according to the so-called Boltzmann distribution π on the state space $E := \{-1, 1\}^\Lambda$. A parameter of this distribution is the inverse temperature $\beta = \frac{1}{T} \geq 0$ (with T the absolute temperature).

Define the local energy that describes the energy level of a single atom at $i \in \Lambda$ as a function H^i of the state x of the whole system,

$$H^i(x) = \frac{1}{2} \sum_{j \in \Lambda: i \sim j} \mathbb{1}_{\{x(i) \neq x(j)\}}$$

Here $i \sim j$ indicates that i and j are neighbors in Λ (that is, coordinate-wise mod N , we also speak of periodic boundary conditions). The total energy (or Hamilton function) of the system in state x is the sum of the individual energies,

$$H(x) = \sum_{i \in \Lambda} H^i(x) = \sum_{i \sim j} \mathbb{1}_{\{x(i) \neq x(j)\}}$$

The Boltzmann distribution π on $E := \{-1, 1\}^\Lambda$ for the inverse temperature $\beta \geq 0$ is defined by

$$\pi(x) = Z_\beta^{-1} \exp(-\beta H(x)),$$

where the partition sum $Z_\beta = \sum_{x \in E} \exp(-\beta H(x))$ is the normalising constant such that π is a probability measure.

Macroscopically, the individual spins cannot be observed but the average magnetization can; that is, the modulus of the average of all spins,

$$m_\Lambda(\beta) = \sum_{x \in E} \pi(x) \left| \frac{1}{\#\Lambda} \sum_{i \in \Lambda} x(i) \right|$$

If we consider a very large system, then we are close to the so-called thermodynamic limit

$$m(\beta) := \lim_{\Lambda \uparrow \mathbb{Z}^d} m_\Lambda(\beta)$$

Using a contour argument, as for percolation (see [127]), one can show that (for $d \geq 2$) there exists a critical value $\beta_c = \beta_c(d) \in (0, \infty)$ such that

$$m(\beta) \begin{cases} > 0, & \text{if } \beta > \beta_c \\ = 0, & \text{if } \beta < \beta_c \end{cases} \quad (18.9)$$

See Fig. 18.4 for a computer simulation of the curve $\beta \mapsto m(\beta)$.

For a similar model, the Weiss ferromagnet, we will prove in Example 23.20 the existence of such a phase transition. In the physical literature, $T_c := 1/\beta_c$ is called the Curie temperature for spontaneous magnetization. This is a material-dependent constant (chromium bromide (CrBr) 37 Kelvin, nickel 645 K, iron 1017 K, cobalt 1404 K). Below the Curie temperature, these materials are magnetic, and above it they are not. Below the critical temperature, the magnetization increases with decreasing temperature. We will see in a computer simulation that the Ising model displays this critical temperature effect.

Fig. 18.4 Computer simulation of the magnetization curve of the Ising model on a 1000×1000 grid. The dashed vertical line indicates the critical inverse temperature

If $x \in E$, then denote by $x^{i,\sigma}$ the state in which at site i the spin is changed to $\sigma \in \{-1, +1\}$; that is,

$$x^{i,\sigma}(j) = \begin{cases} \sigma, & \text{if } j = i, \\ x(j), & \text{if } j \neq i. \end{cases}$$

Furthermore, define the state x^i in which the spin at i is reversed, $x^i := x^{i,-x(i)}$. As reference chain, we choose a chain with transition probabilities

$$q(x, y) = \begin{cases} \frac{1}{\#\Lambda}, & \text{if } y = x^i \text{ for some } i \in \Lambda, \\ 0, & \text{else.} \end{cases}$$

In words, we choose a random site $i \in \Lambda$ (uniformly on Λ) and invert the spin at that site. Clearly, q is irreducible.

The Metropolis algorithm for this chain accepts the proposal of the reference chain with probability 1 if $\pi(x^i) \geq \pi(x)$. Otherwise the proposal is accepted only with probability $\pi(x^i)/\pi(x)$. However, now

$$\begin{aligned} H(x^i) - H(x) &= \sum_{j:j \sim i} \mathbb{1}_{\{x(j) \neq -x(i)\}} - \sum_{j:j \sim i} \mathbb{1}_{\{x(j) \neq x(i)\}} \\ &= -2 \sum_{j:j \sim i} \left(\mathbb{1}_{\{x(j) \neq x(i)\}} - \frac{1}{2} \right) \end{aligned}$$

Fig. 18.5 Equilibrium states of the Ising model on an 800×800 grid (black dot $=$ spin $+1$). Left side: below the critical temperature ($\beta > \beta_c$); Right side: above the critical temperature

Fig. 18.6 Ising model (150×150 grid) below the critical temperature. Even after a long time, the computer simulation does not produce the equilibrium state but rather so-called metastable states, in which the Weiss domains are clearly visible

Hence $\pi(x^i) / \pi(x) = \exp \left(-2\beta \sum_{j \sim i} \left(\mathbb{1}_{\{x(j)=x(i)\}} - \frac{1}{2} \right) \right)$, and this expression is easy to compute as it depends only on the $2d$ neighboring spins and, in particular, does not require knowledge of the value of Z_β . We thus obtain the Metropolis transition matrix

$$p(x, y) = \begin{cases} \frac{1}{\#\Lambda} \left(1 \wedge \exp \left[2\beta \sum_{j: j \sim i} \left(\mathbb{1}_{\{x(j) \neq x(i)\}} - \frac{1}{2} \right) \right] \right), & \text{if } y = x^i \text{ for some } i \in \Lambda, \\ 1 - \sum_{i \in \Lambda} p(x, x^i), & \text{if } x = y, \\ 0, & \text{else.} \end{cases}$$

For a practical simulation use the computer's random number generator to produce independent random variables $I_1, I_2, \dots$ and $U_1, U_2, \dots$ with $I_n \sim \mathcal{U}_\Lambda$ and $U_n \sim \mathcal{U}_{[0,1]}$. Then define

$$F_n(x) = \begin{cases} x^{I_n}, & \text{if } U_n \leq \exp \left[2\beta \sum_{j: j \sim i} \left(\mathbb{1}_{\{x(j) \neq x(i)\}} - \frac{1}{2} \right) \right], \\ x, & \text{else,} \end{cases}$$

and define the Markov chain $(X_n)_{n \in \mathbb{N}}$ by $X_n = F_n(X_{n-1})$ for $n \in \mathbb{N}$. See Figs. 18.5 and 18.6 for computer simulations of equilibrium states and metastable states of the Ising model. $\square$

Gibbs Sampler

We consider a situation where, as in the above example, a state consists of many components $x = (x_i)_{i \in \Lambda} \in E$ and where Λ is a finite set. As an alternative to the Metropolis chain, we consider a different procedure to establish a Markov chain with a given invariant distribution. For the so-called Gibbs sampler or heat bath algorithm, the idea is to adapt the state locally to the stationary distribution. If x is a state and $i \in \Lambda$, then define

$$x_{-i} := \{y \in E : y(j) = x(j) \text{ for } j \neq i\}.$$

Definition 18.17 (Gibbs sampler) Let $q \in \mathcal{M}_1(\Lambda)$ with $q(i) > 0$ for every $i \in \Lambda$. The transition matrix p on E with

$$p(x, y) = \begin{cases} q_i \frac{\pi(x^{i,\sigma})}{\pi(x_{-i})}, & \text{if } y = x^{i,\sigma} \text{ for some } i \in \Lambda, \\ 0, & \text{else,} \end{cases}$$

is called a Gibbs sampler for the invariant distribution π .

Verbally, each step of the chain with transition matrix p can be described by the following instructions.

- (1) Choose a random coordinate I according to some distribution $(q_i)_{i \in \Lambda}$.
- (2) With probability $\pi(x^{I,\sigma}) / \pi(x_{-I})$, replace x by $x^{I,\sigma}$.

If $I = i$, then the new state has the distribution $\mathcal{L}(X \mid X_{-i} = x_{-i})$, where X is a random variable with distribution π . Note that, for the Gibbs sampler also it is enough to know the values of the distribution π only up to the normalising constant. (In a more general framework, the Gibbs sampler and the Metropolis algorithm can be understood as special cases of one and the same method.) For states x and y that differ only in the i th coordinate, we have (since $x_{-i} = y_{-i}$)

$$\pi(x)p(x, y) = \pi(x)q_i \frac{\pi(y)}{\pi(x_{-i})} = \pi(y)q_i \frac{\pi(x)}{\pi(y_{-i})} = \pi(y)p(y, x).$$

Thus the Gibbs sampler is a reversible Markov chain with invariant measure π . Irreducibility of the Gibbs sampler, however, has to be checked for each case.

Example 18.18 (Ising model) In the Ising model described above, we have $x_{-i} = \{x^{i,-1}, x^{i,+1}\}$. Hence, for $i \in \Lambda$ and $\sigma \in \{-1, +1\}$,

$$\begin{aligned} \pi(x^{i,\sigma} \mid x_{-i}) &= \frac{\pi(x^{i,\sigma})}{\pi(\{x^{i,-1}, x^{i,+1}\})} \\ &= \frac{e^{-\beta H(x^{i,\sigma})}}{e^{-\beta H(x^{i,-1})} + e^{-\beta H(x^{i,+1})}} \\ &= (1 + \exp[\beta(H(x^{i,\sigma}) - H(x^{i,-\sigma}))])^{-1} \\ &= \left(1 + \exp\left[2\beta \sum_{j:j \sim i} \left(\mathbb{1}_{\{x(j) \neq \sigma\}} - \frac{1}{2}\right)\right]\right)^{-1} \end{aligned}$$

The Gibbs sampler for the Ising model is thus the Markov chain $(X_n)_{n \in \mathbb{N}_0}$ with values in $E = \{-1, 1\}^\Lambda$ and with transition matrix

$$p(x, y) = \begin{cases} \frac{1}{\#\Lambda} \left(1 + \exp \left[2\beta \sum_{j:j \sim i} (\mathbb{1}_{\{x(j) \neq x(i)\}} - \frac{1}{2}) \right] \right)^{-1}, & \text{if } y = x^i \text{ for some } i \in \Lambda, \\ 0, & \text{otherwise.} \end{cases}$$

Perfect Sampling

The MCMC method as described above is based on hope: We let the chain run for a long time and hope that its distribution is close to the invariant distribution. Even if we can compute the speed of convergence (and in many cases, this is not trivial, we come back to this point in Section 18.4), the distribution will never be exactly the invariant distribution.

Although this flaw might seem inevitable in the MCMC method, it is in fact, at least theoretically, possible to use a very similar method that allows perfect sampling according to the invariant distribution π , even if we do not know anything about the speed of convergence. The idea is simple. Assume that $F_1, F_2, \dots$ are i.i.d. random maps $E \rightarrow E$ with $\mathbf{P}[F(x) = y] = p(x, y)$ for all $x, y \in E$. We have seen how to construct the Markov chain X with initial value $X_0 = x$ by defining $X_n = F_n \circ F_{n-1} \circ \dots \circ F_1(x)$.

Note that $F_1^n(x) := F_1 \circ \dots \circ F_n(x) \stackrel{\mathcal{D}}{=} F_n \circ \dots \circ F_1(x)$. Hence we have

$$\mathbf{P}[F_1^n(x) = y] \xrightarrow{n \rightarrow \infty} \pi(y) \quad \text{for every } y.$$

However, if F_1^n turns out to be a constant map (e.g., $F_1^n \equiv x^*$ for some random x^*), then we will also have $F_1^m \equiv x^*$ for all $m \geq n$. If by some clever choice of the distribution of F_n one can ensure that the stopping time $T := \inf\{n \in \mathbb{N} : F_1^n \text{ is constant}\}$ is almost surely finite (and this is always possible), then we will have $\mathbf{P}[F_1^T(x) = y] = \pi(y)$ for all $x, y \in E$. A simple algorithm for this method is the following.

- (1) Let $F \leftarrow \text{id}_E$ and $n \leftarrow 0$.
- (2) Let $n \leftarrow n + 1$. Generate F_n and let $F \leftarrow F \circ F_n$.
- (3) If F is not a constant map, then go to (2).
- (4) Output $F(*)$.

This method is called coupling from the past and goes back to Propp and Wilson [138] (see also [55, 56, 92, 137, 139, 170]). David Wilson has nice simulations and a survey of the current research on his web site <http://www.dbwilson.com/>. A nice survey on MCMC methods including coupling from the past is [66].

For a practical implementation, there are two main problems: (1) The full map F_n has to be generated and has to be composed with F . The computer time needed for this is at least of the order of the size of the space E . (2) Checking if F is constant needs computer time of the same order of magnitude. Consequently, the method can be efficiently implemented only if there is more structure. For example, assume that E is partially ordered with a smallest element $\underline{0}$ and a largest element $\underline{1}$ (like the Ising model). Further, assume that the maps F_n can be chosen to be almost surely monotone increasing. In this case, it is enough to compute at each step $F(\underline{0})$ and $F(\underline{1})$ since F is constant if the values coincide.

5.18.4 18.4 Speed of Convergence

So far we have ignored the question of the speed of convergence of the distribution $\mathbf{P}_{X_n}$ to π . For practical purposes, however, this is often the most interesting question. We do not intend to go into the details and we only briefly touch upon the topic. Without loss of generality, assume $E = \{1, \dots, N\}$. If p is reversible (Eq. (18.8)), then $f \mapsto pf$ defines a symmetric linear operator on $L^2(E, \pi)$ (exercise!). All eigenvalues $\lambda_1, \dots, \lambda_N$ (listed according to the corresponding multiplicity) are real and have modulus at most 1 since p is stochastic.

Thus we can arrange the eigenvalues by decreasing modulus $\lambda_1 = 1 \geq |\lambda_2| \geq \dots \geq |\lambda_N|$. If p is irreducible and aperiodic, then $|\lambda_2| < 1$. Let $\mu_1 = \pi, \mu_2, \dots, \mu_N$ be an orthonormal basis of left eigenvectors for the eigenvalues $\lambda_1, \dots, \lambda_N$. Then, for every $\mu = \alpha_1 \mu_1 + \dots + \alpha_N \mu_N$, we have $\mu p^n = \sum_{i=1}^N \lambda_i^n \alpha_i \mu_i$ and hence

$$\|\mu p^n - \pi\|_{TV} \leq C |\lambda_2|^n \quad (18.10)$$

for a constant C (that does not depend on μ). A similar formula holds if p is not reversible; however, with a correction term of order at most n^{V-1} . Here, V is the size of the largest Jordan block square matrix for the eigenvalue λ_2 in the Jordan canonical form of p . In particular, V is no larger than the multiplicity of the eigenvalue with second largest modulus.

The speed of convergence is thus exponential with a rate that is determined by the spectral gap $1 - |\lambda_2|$ of the second largest eigenvalue of p . In practice, for a large space E , computing the spectral gap is often extremely difficult.

Example 18.19 Let $r \in (0, 1)$ and $N \in \mathbb{N}, N \geq 2$. Further, let $E = \{0, \dots, N-1\}$. We consider the transition matrix

$$p(i, j) = \begin{cases} r, & \text{if } j = i + 1 \pmod{N} \\ 1 - r, & \text{if } j = i - 1 \pmod{N} \\ 0, & \text{else.} \end{cases}$$

p is the transition matrix of simple (asymmetric) random walk on the discrete torus $\mathbb{Z}/(N)$, which with probability r makes a jump to the right and with probability $1 - r$ makes a jump to the left. Clearly, p is irreducible, and p is aperiodic if and only if N is odd. Furthermore, the uniform distribution $\mathcal{U}_E$ is the unique invariant distribution.

Case 1: N odd. Let $\theta_k = e^{2\pi i k/N}, k = 0, \dots, N-1$, be the N th roots of unity and let the corresponding (right) eigenvectors be

$$x^k := (\theta_k^0, \theta_k^1, \dots, \theta_k^{N-1})$$

It is easy to check that p has the eigenvalues

$$\lambda_k := r\theta_k + (1-r)\bar{\theta}_k = \cos\left(\frac{2\pi k}{N}\right) + (2r-1)i \sin\left(\frac{2\pi k}{N}\right)$$

$$k = 0, \dots, N-1$$

The moduli of the eigenvalues are given by $|\lambda_k| = f(2\pi k/N)$, where

$$f(\vartheta) = \sqrt{1 - 4r(1-r)\sin(\vartheta)^2} \quad \text{for } \vartheta \in \mathbb{R}$$

Since N is odd, $|\lambda_k|$ is maximal (except for $k = 0$) for $k = \frac{N-1}{2}$ and for $k = \frac{N+1}{2}$. For these k , $|\lambda_k|$ equals $\gamma := \sqrt{1 - 4r(1-r)\sin(\pi/N)^2}$. Since all eigenvalues are different, every eigenvalue has multiplicity 1. Hence there is a constant $C < \infty$ such that

$$\|\mu p^n - \mathcal{U}_E\|_{TV} \leq C\gamma^n \quad \text{for all } n \in \mathbb{N}, \mu \in \mathcal{M}_1(E)$$

Case 2: N even. In this case, p is not aperiodic. Nevertheless, the eigenvalues and eigenvectors are of the same form as in Case 1. In order to get an aperiodic chain, for $\varepsilon > 0$, define the transition matrix

$$p_\varepsilon := (1 - \varepsilon)p + \varepsilon I,$$

where I is the unit matrix on E . p_ε describes the random walk on E that with probability ε does not move and with probability $1 - \varepsilon$ makes a jump according to p . Clearly, p_ε is irreducible and aperiodic. The eigenvalues are

$$\lambda_{\varepsilon,k} = (1 - \varepsilon)\lambda_k + \varepsilon, \quad k = 0, \dots, N-1,$$

and the corresponding eigenvectors are the x^k from above. Evidently, $\lambda_{\varepsilon,0} = 1$, and if $\varepsilon > 0$ is very small, then $\lambda_{\varepsilon,N/2} = 2\varepsilon - 1$ is the eigenvalue with the second largest modulus. For larger values of ε , we have $|\lambda_{\varepsilon,1}| > |\lambda_{\varepsilon,N/2}|$. More precisely, if we let

$$\varepsilon_0 := \frac{(1 - (2r - 1)^2) \sin(2\pi/N)^2}{(1 - (2r - 1)^2) \sin(2\pi/N)^2 + 2 \cos(2\pi/N)},$$

then the eigenvalue with the second largest modulus has modulus

$$\gamma_\varepsilon = |\lambda_{\varepsilon,N/2}| = 1 - 2\varepsilon, \quad \text{if } \varepsilon \leq \varepsilon_0,$$

or

$$\begin{aligned} \gamma_\varepsilon &= |\lambda_{\varepsilon,1}| \\ &= \sqrt{\left((1 - \varepsilon) \cos\left(\frac{2\pi}{N}\right) + \varepsilon\right)^2 + \left((1 - \varepsilon)(2r - 1) \sin\left(\frac{2\pi}{N}\right)\right)^2}, \quad \text{if } \varepsilon \geq \varepsilon_0 \end{aligned}$$

It is easy to check that $\varepsilon \mapsto |\lambda_{\varepsilon,N/2}|$ is monotone decreasing and that $\varepsilon \mapsto |\lambda_{\varepsilon,1}|$ is monotone increasing. Hence γ_ε is minimal for $\varepsilon = \varepsilon_0$.

Hence there is a $C < \infty$ with

$$\|\mu p_\varepsilon^n - \mathcal{U}_E\|_{TV} \leq C \gamma_\varepsilon^n \quad \text{for all } n \in \mathbb{N}, \mu \in \mathcal{M}_1(E),$$

and the best speed of convergence (in this class of transition matrices) can be obtained by choosing $\varepsilon = \varepsilon_0$.

Example 18.20 (Gambler's ruin) We consider the gambler's ruin problem from Example 10.19 with the probability of a gain $r \in (0, 1)$. Here the state space is $E = \{0, \dots, N\}$, and the transition matrix is of the form

$$p(i, j) = \begin{cases} r, & \text{if } j = i + 1 \in \{2, \dots, N\}, \\ 1 - r, & \text{if } j = i - 1 \in \{0, \dots, N - 2\}, \\ 1, & \text{if } j = i \in \{0, N\}, \\ 0, & \text{else.} \end{cases}$$

This transition matrix is not irreducible; rather it has two absorbing states 0 and N . In Example 10.19 (Eq. (10.5)) for the case $r \neq \frac{1}{2}$, and Example 10.16 for the case $r = \frac{1}{2}$, it was shown that, for every $\mu \in \mathcal{M}_1(E)$,

$$\mu p^n \xrightarrow{n \rightarrow \infty} (1 - m(\mu))\delta_0 + m(\mu)\delta_N. \quad (18.11)$$

Here $m(\mu) = \int p_N(x)\mu(dx)$, where the probability $p_N(x)$ that the chain, if started at x , hits N is given by

$$p_N(x) = \begin{cases} \frac{1 - \left(\frac{1-r}{r}\right)^x}{1 - \left(\frac{1-r}{r}\right)^N}, & \text{if } r \neq \frac{1}{2} \\ \frac{x}{N}, & \text{if } r = \frac{1}{2} \end{cases}$$

How quick is the convergence in (18.11)? Here also the convergence has exponential speed and the rate is determined by the second largest eigenvalue of p .

Hence we have to compute the spectrum of p . Clearly, $x^0 = (1, 0, \dots, 0)$ and $x^N = (0, \dots, 0, 1)$ are left eigenvectors for the eigenvalue 1. In order for $x = (x_0, \dots, x_N)$ to be a left eigenvector for the eigenvalue λ , the following equations have to hold:

$$\lambda x_k = r x_{k-1} + (1-r)x_{k+1} \quad \text{for } k = 2, \dots, N-2 \quad (18.12)$$

and

$$\lambda x_{N-1} = r x_{N-2} \quad (18.13)$$

If (18.12) and (18.13) hold for $x_1, \dots, x_{N-1}$, then we define $x_0 := \frac{1-p}{\lambda-1}x_1$ and $x_N := \frac{p}{\lambda-1}x_{N-1}$ and get that in fact $xp = \lambda x$. We make the ansatz

$$\lambda = (1-r)\rho(\theta + \bar{\theta}) \quad \text{and} \quad x_k = \varrho^k (\theta^k - \bar{\theta}^k) \quad \text{for } k = 1, \dots, N-1,$$

where

$$\rho = \sqrt{r/(1-r)} \quad \text{and} \quad \theta \in \mathbb{C} \setminus \{-1, +1\} \quad \text{with } |\theta| = 1.$$

Thus we have $\theta\bar{\theta} = 1$ and $(1-r)\rho^{k+1} = r\rho^{k-1}$. Therefore, for every $k = 2, \dots, N-1$,

$$\begin{aligned} \lambda x_k &= (1-r)\rho^{k+1} (\theta^k - \bar{\theta}^k) (\theta + \bar{\theta}) \\ &= (1-r)\rho^{k+1} [(\theta^{k+1} - \bar{\theta}^{k+1}) + \theta\bar{\theta} (\theta^{k-1} - \bar{\theta}^{k-1})] \\ &= r\rho^{k-1} (\theta^{k-1} - \bar{\theta}^{k-1}) + (1-r)\rho^{k+1} (\theta^{k+1} - \bar{\theta}^{k+1}) \\ &= r x_{k-1} + (1-r)x_{k+1} \end{aligned}$$

That is, (18.12) holds. The same computation with $k = N-1$ shows that (18.13) holds if and only if $\theta^N - \bar{\theta}^N = 0$; that is, if $\theta^{2N} = 1$. In all, then, for θ , we get $N-1$ different values (note that the complex conjugates of the values considered here lead to the same values λ_n),

$$\theta_n = e^{(n/N)\pi i} \quad \text{for } n = 1, \dots, N-1$$

The corresponding eigenvalues are

$$\lambda_n = \sigma \cos\left(\frac{n\pi}{N}\right) \quad \text{for } n = 1, \dots, N-1.$$

Here the variance of the individual random walk step is

$$\sigma^2 := 4r(1-r). \quad (18.14)$$

As all eigenvalues are real, the corresponding eigenvectors are given by

$$x_k^n = 2 \left(\frac{r}{1-r} \right)^{n/2} \sin\left(\frac{n\pi}{N}\right), \quad k = 1, \dots, N-1.$$

The second largest modulus of an eigenvalue is $|\lambda_n| = \sigma \cos\left(\frac{\pi}{N}\right)$ if $n = 1$ or $n = N-1$. Thus there exists a $C > 0$ such that, for every $\mu \in \mathcal{M}_1(E)$, we have

$$\mu p^n(\{1, \dots, N-1\}) \leq C \left(\sigma \cos\left(\frac{\pi}{N}\right) \right)^n \quad \text{for every } n \in \mathbb{N}.$$

In other words, the probability that the game has not finished up to the n th round is at most $C(\sigma \cos(\pi/N))^n$.

An alternative approach to the eigenvalues can be made via the roots of the characteristic polynomial

$$\chi_N(x) = \det(p - xI), \quad x \in \mathbb{R}.$$

Clearly, $\chi_1(x) = (1 - x)^2$ and $\chi_2(x) = -x(1 - x)^2$. Using Laplace's expansion formula for the determinant (elimination of rows and columns), we get the recursion

$$\chi_N(x) = -x\chi_{N-1}(x) - r(1 - r)\chi_{N-2}(x). \quad (18.15)$$

The solution is (check this!)

$$\chi_N(x) = (-1)^{N-1}(\sigma/2)^{N-1}(1 - x)^2 U_{N-1}(x/\sigma) \quad (18.16)$$

where

$$U_m(x) := \sum_{k=0}^{\lfloor m/2 \rfloor} (-1)^k \binom{m-k}{k} (2x)^{m-2k}$$

denotes the so-called m th Chebyshev polynomial of the second kind. Using de Moivre's formula, one can show that, for $x \in (-\sigma, \sigma)$,

$$\begin{aligned} \chi_N(x) &= (-1)^{N-1}(\sigma/2)^{N-1}(1 - x)^2 \frac{\sin(N \arccos(x/\sigma))}{\sqrt{1 - (x/\sigma)^2}} \\ &= (1 - x)^2 \prod_{k=1}^{N-1} \left(\sigma \cos\left(\frac{\pi k}{N}\right) - x \right) \end{aligned} \quad (18.17)$$

Apart from the double zero at 1, we get the zeros

$$\sigma \cos(\pi k/N), \quad k = 1, \dots, N - 1.$$

Exercise 18.4.1 Show (18.16).

Exercise 18.4.2 Show (18.17).

Exercise 18.4.3 Let $v(dx) = \frac{2}{\pi} \sqrt{1 - x^2} \mathbb{1}_{[-1,1]}(x) dx$. Show that the Chebyshev polynomials of the second kind are orthonormal with respect to v ; that is,

$$\int U_m U_n dv = \mathbb{1}_{\{m=n\}}$$

Exercise 18.4.4 Let

$$E = \{1, 2, 3\} \quad \text{and} \quad p = \begin{pmatrix} 1/2 & 1/3 & 1/6 \\ 1/3 & 1/3 & 1/3 \\ 0 & 3/4 & 1/4 \end{pmatrix}$$

Compute the invariant distribution and the exponential rate of convergence.

Exercise 18.4.5 Let $E = \{0, \dots, N - 1\}$, $r \in (0, 1)$ and

$$p(i, j) = \begin{cases} r, & \text{if } j = i + 1 \pmod{N} \\ 1 - r, & \text{if } j = i \pmod{N} \\ 0, & \text{else.} \end{cases}$$

Show that p is the transition matrix of an irreducible, aperiodic random walk and compute the invariant distribution and the exponential rate of convergence.

Exercise 18.4.6 Let $N \in \mathbb{N}$ and let $E = \{0, 1\}^N$ denote the N -dimensional hypercube. That is, two points $x, y \in E$ are connected by an edge if they differ in exactly one coordinate. Let p

be the transition matrix of the random walk on E that stays put with probability $\varepsilon > 0$ and that with probability $1 - \varepsilon$ makes a jump to a randomly (uniformly) chosen neighboring site.

Describe p formally and show that p is aperiodic and irreducible. Compute the invariant distribution and the exponential rate of convergence.

5.19 19 Markov Chains and Electrical Networks

We consider symmetric simple random walk on $\mathbb{Z}^2$. By Pólya's theorem (Theorem 17.39), this random walk is recurrent. However, is this still true if we remove a single edge from the lattice $\mathbb{L}^2$ of $\mathbb{Z}^2$? Intuitively, such a small local change should not make a difference for a global phenomenon such as recurrence. However, the computations used in Section 17.5 to prove recurrence are not very robust and would need a substantial improvement in order to cope with even a small change. The situation becomes even more puzzling if we restrict the random walk to, e.g., the upper half plane $\{(x, y) : x \in \mathbb{Z}, y \in \mathbb{N}_0\}$ of $\mathbb{Z}^2$. Is this random walk recurrent? Or consider bond percolation on $\mathbb{Z}^2$. Fix a parameter $p \in [0, 1]$ and independently declare any edge of $\mathbb{L}^2$ open with probability p and closed with probability $1 - p$. At a second stage, start a random walk on the random subgraph of open edges. At each step, the walker chooses one of the adjacent open edges at random (with equal probability) and traverses it. For $p > \frac{1}{2}$, there exists a unique infinite connected component of open edges (Theorem 2.47). The question that we answer at the end of this chapter is: Is a random walk on the infinite open cluster recurrent or transient?

The aim of this chapter is to establish a connection between certain Markov chains and electrical networks. This connection

- in some cases allows us to distinguish between recurrence and transience by means of easily computable quantities, and
- in other cases provides a comparison criterion that says that if a random walk on a graph is recurrent, then a random walk on any connected subgraph is recurrent. Any of the questions raised above can be answered using this comparison technique.

Some of the material of this chapter is taken from [36, 111].

5.19.1 19.1 Harmonic Functions

In this chapter, E is always a countable set and X is a discrete Markov chain on E with transition matrix p and Green function G . Recall that $F(x, y)$ is the probability of hitting y at least once when starting at x . Compare Section 17.4, in particular, Definitions 17.28 and 17.33.

Definition 19.1 Let $A \subset E$. A function $f : E \rightarrow \mathbb{R}$ is called harmonic on $E \setminus A$ if $pf(x) = \sum_{y \in E} p(x, y)f(y)$ exists and if $pf(x) = f(x)$ for all $x \in E \setminus A$.

Theorem 19.2 (Superposition principle) Assume f and g are harmonic on $E \setminus A$ and let $\alpha, \beta \in \mathbb{R}$. Then $\alpha f + \beta g$ is also harmonic on $E \setminus A$.

Proof This is trivial.

Example 19.3 Let X be transient and let $a \in E$ be a transient state (that is, a is not absorbing). Then $f(x) := G(x, a)$ is harmonic on $E \setminus \{a\}$: For $x \neq a$, we have

$$pf(x) = p \sum_{n=0}^{\infty} p^n(x, a) = \sum_{n=1}^{\infty} p^n(x, a) = G(x, a) - \mathbb{1}_{\{a\}}(x) = G(x, a)$$

Example 19.4 For $x \in E$, let $\tau_x := \inf \{n > 0 : X_n = x\}$. For $A \subset E$, let

$$\tau := \tau_A := \inf_{x \in A} \tau_x$$

be the stopping time of the first entrance to A . Assume that A is chosen so that $\mathbf{P}_x[\tau_A < \infty] = 1$ for every $x \in E$. Let $g : A \rightarrow \mathbb{R}$ be a bounded function. Define

$$f(x) := \begin{cases} g(x), & \text{if } x \in A, \\ \mathbf{E}_x[g(X_\tau)], & \text{if } x \in E \setminus A. \end{cases} \quad (19.1)$$

Then f is harmonic on $E \setminus A$. We give two proofs for this statement.

1st Proof By the Markov property, for $x \notin A$ and $y \in E$,

$$\mathbf{E}_x[g(X_\tau) \mid X_1 = y] = \begin{cases} g(y), & \text{if } y \in A \\ \mathbf{E}_y[g(X_\tau)], & \text{if } y \in E \setminus A \end{cases} = f(y).$$

Hence, for $x \in E \setminus A$,

$$\begin{aligned} f(x) &= \mathbf{E}_x[g(X_\tau)] = \sum_{y \in E} \mathbf{E}_x[g(X_\tau); X_1 = y] \\ &= \sum_{y \in E} p(x, y) \mathbf{E}_x[g(X_\tau) \mid X_1 = y] = \sum_{y \in E} p(x, y) f(y) = pf(x). \end{aligned}$$

2nd Proof We change the Markov chain by adjoining a cemetery state Δ . That is, the new state space is $\tilde{E} = E \cup \{\Delta\}$ and the transition matrix is

$$\tilde{p}(x, y) = \begin{cases} p(x, y), & \text{if } x \in E \setminus A, y \neq \Delta, \\ 0, & \text{if } x \in E \setminus A, y = \Delta, \\ 1, & \text{if } x \in A \cup \{\Delta\}, y = \Delta. \end{cases} \quad (19.2)$$

The corresponding Markov chain $\tilde{X}$ is transient, and Δ is the only absorbing state. Furthermore, we have $pf = f$ on $E \setminus A$ if and only if $\tilde{p}f = f$ on $E \setminus A$. Since $\tilde{G}(y, y) = 1$ for all $y \in A$, we have (compare Theorem 17.34)

$$\mathbf{P}_x[X_\tau = y] = \mathbf{P}_x[\tilde{\tau}_y < \infty] = \tilde{F}(x, y) = \tilde{G}(x, y) \quad \text{for all } x \in E \setminus A, y \in A.$$

Now $x \mapsto \tilde{G}(x, y)$ is harmonic on $E \setminus A$. Hence, by the superposition principle,

$$f(x) = \sum_{y \in A} \tilde{G}(x, y) g(y) \quad (19.3)$$

is harmonic on $E \setminus A$. Due to the analogy of (19.3) to Green's formula in continuous space potential theory, the function $\tilde{G}$ is called the Green function for the equation $(p - I)f = 0$ on $E \setminus A$.

Definition 19.5 The system of equations

$$\begin{aligned} (p - I)f(x) &= 0, & \text{for } x \in E \setminus A, \\ f(x) &= g(x), & \text{for } x \in A, \end{aligned} \quad (19.4)$$

is called the Dirichlet problem on $E \setminus A$ with respect to $p - I$ and with boundary value g on A .

We have shown the existence of solutions of the Dirichlet problem in Example 19.4. In order to show uniqueness (under certain conditions) we first derive the maximum principle for harmonic functions.

If $p = I$ then any function f that coincides with g on A is a solution of the Dirichlet problem. However, even in less extreme situations the solution of (19.4) may be ambiguous. This is the case if $E \setminus A$ decomposes into domains between which the chain that is stopped in A cannot change.

In order to describe formally the irreducibility condition that we have to impose, we introduce the transition matrix p_A of the chain stopped upon reaching A by

$$p_A(x, y) := \begin{cases} p(x, y), & \text{if } x \notin A, \\ \mathbb{1}_{\{x=y\}}, & \text{if } x \in A. \end{cases}$$

Further, define F_A for p_A similarly as F was defined for p . Finally, for $x \in E$ let

$$S_A^n(x) = \{y \in E : (p_A)^n(x, y) > 0\}, \quad \text{for } n \in \mathbb{N}_0$$

and

$$S_A(x) = \bigcup_{n=0}^{\infty} S_A^n(x) = \{y \in E : F_A(x, y) > 0\}$$

Theorem 19.6 (Maximum principle) Let f be a harmonic function on $E \setminus A$.

(i) If there exists an $x_0 \in E \setminus A$ such that

$$f(x_0) = \sup f(S_A(x_0)) \quad (19.5)$$

then $f(y) = f(x_0)$ for any $y \in S_A(x_0)$.

(ii) In particular, if $F_A(x, y) > 0$ for all $x, y \in E \setminus A$, and if there is an $x_0 \in E \setminus A$ such that $f(x_0) = \sup f(E)$, then $f(x_0) = f(y)$ for any $y \in E \setminus A$.

Proof (i) Let $m := \sup f(S_A(x_0))$. As f is harmonic on $E \setminus A$, we have $p_A f = f$ on E . Hence, for any $n \in \mathbb{N}$,

$$f(x_0) = (p_A)^n f(x_0) = \sum_{y \in S_A^n(x_0)} p_A^n(x_0, y) f(y) \leq m$$

with equality if and only if $f(y) = m$ for all $y \in S_A^n(x_0)$. Since (19.5) implies equality, we infer $f(x_0) = f(y)$ for all $y \in S_A(x_0)$.

(ii) This is a direct consequence of (i) since $S_A(x) \supset E \setminus A$ for any $x \in E \setminus A$.

Theorem 19.7 (Uniqueness of harmonic functions) Assume that $F(x, y) > 0$ for all $x, y \in E$. Let $A \subset E$ be such that $A \neq \emptyset$ and $E \setminus A$ is finite. Assume that f_1 and f_2 are harmonic on $E \setminus A$. If $f_1 = f_2$ on A , then $f_1 = f_2$.

In other words, the Dirichlet problem (19.4) has a unique solution given by (19.3) (or equivalently by (19.1)).

Proof By the superposition principle, $f := f_1 - f_2$ is harmonic on $E \setminus A$ with $f|_A \equiv 0$.

We will show $f \leq 0$. Then, by symmetry, also $f \geq 0$ and hence $f \equiv 0$. To this end, we assume that there exists an $x \in E$ such that $f(x) > 0$ and deduce a contradiction.

Since $f|_A \equiv 0$ and since $E \setminus A$ is finite, there is an $x_0 \in E \setminus A$ such that $f(x_0) = \max f(E) \geq f(x) > 0$.

Since $F(x, y) > 0$ for all $x, y \in E$, we have

$$n_0 := \min \{n \in \mathbb{N}_0 : p^n(x_0, y) > 0 \text{ for some } y \in A\} < \infty.$$

Clearly, we have $p^{n_0}(x_0, y) = (p_A)^{n_0}(x_0, y)$ for all $y \in A$. Hence, there exists a $y \in A$ such that $(p_A)^{n_0}(x_0, y) > 0$, i.e., $y \in S_A(x_0)$. By Theorem 19.6, this implies $f(x_0) = f(y) = 0$ contradicting the assumption.

Exercise 19.1.1 Let $\bar{p}$ be the substochastic $E \times E$ matrix that is given by $\bar{p}(x, y) = \tilde{p}(x, y)$, $x, y \in E$ (with $\tilde{p}$ as in (19.2)). Hence $\bar{p}(x, y) = p(x, y)\mathbb{1}_{x \in E \setminus A}$. Let I be the unit matrix on E .

(i) Show that $I - \bar{p}$ is invertible.

(ii) Define $\bar{G} := (I - \bar{p})^{-1}$. Show that $\bar{G}(x, y) = \tilde{G}(x, y)$ for all $x, y \in E \setminus A$ and that $\bar{G}(x, y) = \mathbb{1}_{\{x=y\}}$ if $x \in A$. In particular,

$$\bar{G}(x, y) = \mathbf{P}_x[X_{\tau_A} = y] \quad \text{for } x \in E \setminus A \text{ and } y \in A.$$

5.19.2 19.2 Reversible Markov Chains

Definition 19.8 The Markov chain X is called reversible with respect to the measure π if

$$\pi(\{x\})p(x, y) = \pi(\{y\})p(y, x) \quad \text{for all } x, y \in E. \quad (19.6)$$

Equation (19.6) is sometimes called the equation of detailed balance. X is called reversible if there is a π with respect to which X is reversible.

Remark 19.9 If X is reversible with respect to π , then π is an invariant measure for X since

$$\pi p(\{x\}) = \sum_{y \in E} \pi(\{y\})p(y, x) = \sum_{y \in E} \pi(\{x\})p(x, y) = \pi(\{x\}).$$

If X is irreducible and recurrent, then, by Remark 17.50, π is thus unique up to constant multiples.

Example 19.10 Let (E, K) be a graph with vertex set (or set of nodes) E and with edge set K (see p. 65). By $\langle x, y \rangle = \langle y, x \rangle \in K$, denote an (undirected) edge that connects x with y . Let $C := (C(x, y), x, y \in E)$ be a family of weights with $C(x, y) = C(y, x) \geq 0$ for all $x, y \in E$ and

$$C(x) := \sum_{y \in E} C(x, y) < \infty \quad \text{for all } x \in E.$$

If we define $p(x, y) := \frac{C(x, y)}{C(x)}$ for all $x, y \in E$, then X is reversible with respect to $\pi(\{x\}) = C(x)$. In fact,

$$\begin{aligned} \pi(\{x\})p(x, y) &= C(x) \frac{C(x, y)}{C(x)} = C(x, y) \\ &= C(y, x) = C(y) \frac{C(y, x)}{C(y)} = \pi(\{y\})p(y, x) \end{aligned}$$

Definition 19.11 Let (E, K) , C and X be as in Example 19.10. Then X is called a random walk on E with weights C . In particular, if $C(x, y) = \mathbb{1}_{\{\langle x, y \rangle \in K\}}$, then X is called a simple random walk on (E, K) .

Thus the random walk with weights C is reversible. However, the converse is also true.

Theorem 19.12 If X is a reversible Markov chain and if π is an invariant measure, then X is a random walk on E with weights $C(x, y) = p(x, y)\pi(\{x\})$. If X is irreducible and recurrent, then π and hence C are unique up to a factor.

Proof This is obvious.

Exercise 19.2.1 Show that p is reversible with respect to π if and only if the linear map $L^2(\pi) \rightarrow L^2(\pi)$, $f \mapsto pf$ is self-adjoint.

Exercise 19.2.2 Let $\beta > 0$, $K \in \mathbb{N}$ and $W_1, \dots, W_K \in \mathbb{R}$. Define

$$p(i, j) := \frac{1}{Z} \exp(-\beta W_j) \quad \text{for all } i, j = 1, \dots, K,$$

where $Z := \sum_{j=1}^K \exp(-\beta W_j)$ is the normalising constant.

Assume that in K (enumerated) urns there are a total of N indistinguishable balls. At each step, choose one of the N balls uniformly at random. If i is the number of the urn from which the ball is drawn, then with probability $p(i, j)$ move the ball to the urn with number j .

(i) Give a formal description of this process as a Markov chain.

(ii) Determine the invariant distribution π and show that the chain is reversible with respect to π .

5.19.3 19.3 Finite Electrical Networks

An electrical network (E, C) consists of a set E of sites (the electrical contacts) and wires between pairs of sites. The conductance of the wire that connects the points $x \in E$ and $y \in E \setminus \{x\}$ is denoted by $C(x, y) \in [0, \infty)$. If $C(x, y) = 0$, then we could just as well assume that there is no wire connecting x and y . By symmetry, we have $C(x, y) = C(y, x)$ for all x and y . Denote by

$$R(x, y) = \frac{1}{C(x, y)} \in (0, \infty]$$

the resistance of the connection $\langle x, y \rangle$. A particular case is that of a graph (E, K) where all edges have the same conductance, say 1; that is, $C(x, y) = \mathbb{1}_{\{\langle x, y \rangle \in K\}}$. The corresponding network (E, C) will be called the unit network on (E, K) .

In the remainder of this section, assume that (E, C) is a finite electrical network.

Now let $A \subset E$. At the points $x_0 \in A$, we apply the voltages $u(x_0)$ (e.g., using batteries). What is the voltage $u(x)$ at $x \in E \setminus A$?

Definition 19.13 A map $I : E \times E \rightarrow \mathbb{R}$ is called a flow on $E \setminus A$ if it is antisymmetric (that is, $I(x, y) = -I(y, x)$) and if it obeys Kirchhoff's rule:

$$\begin{aligned} I(x) &= 0, \quad \text{for } x \in E \setminus A, \\ I(A) &= 0. \end{aligned} \tag{19.7}$$

Here we denoted

$$I(x) := \sum_{y \in E} I(x, y) \quad \text{and} \quad I(A) := \sum_{x \in A} I(x).$$

Definition 19.14 A flow $I : E \times E \rightarrow \mathbb{R}$ on $E \setminus A$ is called a current flow if there exists a function $u : E \rightarrow \mathbb{R}$ with respect to which Ohm's rule is fulfilled:

$$I(x, y) = \frac{u(x) - u(y)}{R(x, y)} \quad \text{for all } x, y \in E, x \neq y.$$

In this case, $I(x, y)$ is called the flow from x to y and $u(x)$ is called the electrical potential (or voltage) at x .

Theorem 19.15 An electrical potential u in (E, C) is a harmonic function on $E \setminus A$:

$$u(x) = \sum_{y \in E} \frac{1}{C(x, y)} C(x, y) u(y) \quad \text{for all } x \in E \setminus A.$$

In particular, if the network is irreducible, an electrical potential is uniquely determined by the values on A .

Proof By Ohm's rule and Kirchhoff's rule,

$$u(x) - \sum_{y \in E} \frac{C(x, y)}{C(x)} u(y) = \sum_{y \in E} \frac{C(x, y)}{C(x)} (u(x) - u(y)) = \frac{1}{C(x)} \sum_{y \in E} I(x, y) = 0.$$

Hence u is harmonic for the stochastic matrix $p(x, y) = C(x, y)/C(x)$. The claim follows by the uniqueness theorem for harmonic functions (Theorem 19.7).

Corollary 19.16 Let X be a Markov chain on E with edge weights C . Then $u(x) = \mathbf{E}_x[u(X_{\tau_A})]$.

Assume $A = \{x_0, x_1\}$ where $x_0 \neq x_1$, and $u(x_0) = 0, u(x_1) = 1$. Then $I(x_1)$ is the total flow into the network and $-I(x_0)$ is the total flow out of the network. Kirchhoff's rule says that the flow is divergence-free and that the flows into and out of the network are equal. In other words, the net flow is $I(x_0) + I(x_1) = 0$.

Recall that, by Ohm's rule, the resistance of a wire is the quotient of the potential difference and the current flow. Hence we define the effective resistance between x_0 and x_1 as

$$R_{\text{eff}}(x_0 \leftrightarrow x_1) = \frac{u(x_1) - u(x_0)}{I(x_1)} = \frac{1}{I(x_1)} = -\frac{1}{I(x_0)}.$$

Correspondingly, the effective conductance is $C_{\text{eff}}(x_0 \leftrightarrow x_1) = R_{\text{eff}}(x_0 \leftrightarrow x_1)^{-1}$. As I and u are uniquely determined by x_0, x_1 and C , the quantities $C_{\text{eff}}(x_0 \leftrightarrow x_1)$ and $R_{\text{eff}}(x_0 \leftrightarrow x_1)$ are well-defined and can be computed from C .

Consider now two sets $A_0, A_1 \subset E$ with $A_0 \cap A_1 = \emptyset, A_0, A_1 \neq \emptyset$. Define $u(x) = 0$ for every $x \in A_0$ and $u(x) = 1$ for every $x \in A_1$. Let I be the corresponding current flow. In a manner similar to the above, we make the following definition.

Definition 19.17 We call $C_{\text{eff}}(A_0 \leftrightarrow A_1) := I(A_1)$ the effective conductance between A_0 and A_1 and $R_{\text{eff}}(A_0 \leftrightarrow A_1) := \frac{1}{I(A_1)}$ the effective resistance between A_0 and A_1 .

Example 19.18

(i) Let $E = \{0, 1, 2\}$ with $C(0, 2) = 0$, and $A_0 = \{x_0\} = \{0\}, A_1 = \{x_1\} = \{2\}$. Define $u(0) = 0$ and $u(2) = 1$. Then (with $p(x, y) = C(x, y)/C(x)$),

$$\begin{aligned} u(1) &= 1 \cdot p(1, 2) + 0 \cdot p(1, 0) \\ &= \frac{C(1, 2)}{C(1, 2) + C(1, 0)} = \frac{R(1, 0)}{R(1, 0) + R(1, 2)} \\ &= \frac{R_{\text{eff}}(1 \leftrightarrow 0)}{R_{\text{eff}}(1 \leftrightarrow 0) + R_{\text{eff}}(1 \leftrightarrow 2)} \end{aligned}$$

The total current flow is

$$I(\{2\}) = u(1)C(0, 1) = \frac{1}{R(0, 1) + R(1, 2)} = \frac{1}{\frac{1}{C(0, 1)} + \frac{1}{C(1, 2)}}.$$

Hence we have $R_{\text{eff}}(0 \leftrightarrow 2) = \frac{1}{I(\{2\})} = R(0, 1) + R(1, 2)$ and $C_{\text{eff}}(0 \leftrightarrow 2) = (C(0, 1)^{-1} + C(1, 2)^{-1})^{-1}$.

(ii) (Series connection) Let $n \in \mathbb{N}, n \geq 2$ and $E = \{0, \dots, n\}$ with conductances $C(k-1, k) > 0$ and $C(k, l) = 0$ if $|k-l| > 1$. By Kirchhoff's rule, we have $I(l, l+1) = -I(x_1)$ for any $l = 0, \dots, n-1$. By Ohm's rule, we get $u(1) = u(0) + I(x_1)R(0, 1), u(2) = u(1) + I(x_1)R(1, 2)$ and so on, yielding

$$u(k) - u(0) = I(x_1) \sum_{l=0}^{k-1} R(l, l+1)$$

Hence

$$R_{\text{eff}}(0 \leftrightarrow k) = \frac{u(k) - u(0)}{I(x_1)} = \sum_{l=0}^{k-1} R(l, l+1).$$

Fig. 19.1 Series connection of six resistors. The effective resistance is $R_{\text{eff}}(0 \leftrightarrow 6) = R(0,1) + \dots + R(5,6)$

By symmetry, we also have

$$R_{\text{eff}}(k \leftrightarrow n) = \sum_{l=k}^{n-1} R(l, l+1)$$

and thus $R_{\text{eff}}(0 \leftrightarrow n) = R_{\text{eff}}(0 \leftrightarrow k) + R_{\text{eff}}(k \leftrightarrow n)$.

Finally, for $k \in \{1, \dots, n-1\}$, we get

$$u(k) = \frac{R_{\text{eff}}(0 \leftrightarrow k)}{R_{\text{eff}}(0 \leftrightarrow k) + R_{\text{eff}}(k \leftrightarrow n)}.$$

Note that this yields the ruin probability of the corresponding Markov chain X on $\{0, \dots, n\}$,

$$\mathbf{P}_k[\tau_n < \tau_0] = u(k) = \frac{R_{\text{eff}}(0 \leftrightarrow k)}{R_{\text{eff}}(0 \leftrightarrow n)} = \frac{\sum_{l=0}^{k-1} R(l, l+1)}{\sum_{l=0}^{n-1} R(l, l+1)}. \quad (19.8)$$

(iii) (Parallel connection) Let $E = \{0, 1\}$. We extend the model a little by allowing for more than one wire to connect 0 and 1. Denote the conductances of these wires by $C_1, \dots, C_n$. Then, by Ohm's rule, the current flow along the i th wire is $I_i = \frac{u(1) - u(0)}{R_i} = \frac{1}{R_i}$. Hence the total current is $I = \sum_{i=1}^n \frac{1}{R_i}$ and thus we have

$$C_{\text{eff}}(0 \leftrightarrow 1) = \sum_{i=1}^n C_i \quad \text{and} \quad R_{\text{eff}}(0 \leftrightarrow 1) = \left(\sum_{i=1}^n \frac{1}{R_i} \right)^{-1}.$$

Fig. 19.2 Parallel connection of six resistors. The effective resistance is $R_{\text{eff}}(0 \leftrightarrow 1) = \left(R_{\text{eff}}^{-1}(0 \leftrightarrow 1) + \dots + R_{\text{eff}}^{-1}(0 \leftrightarrow 1) \right)^{-1}$

In each of the three preceding examples, the effective resistance is a monotone function of the individual resistances. This is more than just coincidence.

Theorem 19.19 (Rayleigh's monotonicity principle) Let (E, C) and (E, C') be electrical networks with $C(x, y) \geq C'(x, y)$ for all $x, y \in E$.

Then, for $A_0, A_1 \subset E$ with $A_0, A_1 \neq \emptyset$ and $A_0 \cap A_1 = \emptyset$,

$$C_{\text{eff}}(A_0 \leftrightarrow A_1) \geq C'_{\text{eff}}(A_0 \leftrightarrow A_1).$$

The remainder of this section is devoted to the proof of this theorem. We will need a theorem on conservation of energy and Thomson's principle (also called Dirichlet's principle) on the minimization of the energy dissipation.

Theorem 19.20 (Conservation of energy) Let $A = A_0 \cup A_1$, and let I be a flow on $E \setminus A$ (but not necessarily a current flow; that is, Kirchhoff's rule holds but Ohm's rule need not). Further, let $w : E \rightarrow \mathbb{R}$ be a function that is constant both on A_0 and on A_1 : $w|_{A_0} \equiv: w_0$ and $w|_{A_1} \equiv: w_1$. Then

$$(w_1 - w_0) I(A_1) = \frac{1}{2} \sum_{x, y \in E} (w(x) - w(y)) I(x, y)$$

Note that this is a discrete version of Gauß's integral theorem for (wI) . In fact, Kirchhoff's rule says that I is divergence-free on $E \setminus A$.

Proof We compute

$$\begin{aligned} & \sum_{x, y \in E} (w(x) - w(y)) I(x, y) \\ &= \sum_{x \in E} \left(w(x) \sum_{y \in E} I(x, y) \right) - \sum_{y \in E} \left(w(y) \sum_{x \in E} I(x, y) \right) \\ &= \sum_{x \in A} \left(w(x) \sum_{y \in E} I(x, y) \right) - \sum_{y \in A} \left(w(y) \sum_{x \in E} I(x, y) \right) \\ &= w_0 I(A_0) + w_1 I(A_1) - w_0 (-I(A_0)) - w_1 (-I(A_1)) \\ &= 2(w_1 - w_0) I(A_1) \end{aligned}$$

Definition 19.21 Let I be a flow on $E \setminus A$. Denote by

$$L_I := L_I^C := \frac{1}{2} \sum_{x, y \in E} I(x, y)^2 R(x, y)$$

the energy dissipation of I in the network (E, C) .

Theorem 19.22 (Thomson's (or Dirichlet's) principle of minimization of energy dissipation) Let I and J be unit flows from A_1 to A_0 (that is, $I(A_1) = J(A_1) = 1$). Assume in addition that I is a current flow (that is, it satisfies Ohm's rule with some potential u that is constant both on A_0 and on A_1). Then

$$L_I \leq L_J$$

with equality if and only if $I = J$. In particular, the unit current flow is uniquely determined.

Proof Let $D = J - I \neq 0$ be the difference of the flows. Then clearly $D(A_0) = D(A_1) = 0$. We infer

$$\begin{aligned}
& \sum_{x,y \in E} J(x,y)^2 R(x,y) \\
&= \sum_{x,y \in E} (I(x,y) + D(x,y))^2 R(x,y) \\
&= \sum_{x,y \in E} (I(x,y)^2 + D(x,y)^2) R(x,y) + 2 \sum_{x,y \in E} I(x,y) D(x,y) R(x,y) \\
&= \sum_{x,y \in E} (I(x,y)^2 + D(x,y)^2) R(x,y) + 2 \sum_{x,y \in E} (u(x) - u(y)) D(x,y)
\end{aligned}$$

By the principle of conservation of energy, the last term equals

$$2 \sum_{x,y \in E} (u(x) - u(y)) D(x,y) = 4D(A_1)(u_1 - u_0) = 0.$$

Therefore (since $D \not\equiv 0$),

$$L_J = L_I + \frac{1}{2} \sum_{x,y \in E} D(x,y)^2 R(x,y) > L_I.$$

□

Proof (Rayleigh's monotonicity principle, Theorem 19.19) Let I and I' be the unit current flows from A_1 to A_0 with respect to C and C' , respectively. By Thomson's principle, the principle of conservation of energy and the assumption $R(x,y) \leq R'(x,y)$ for all $x,y \in E$, we have

$$\begin{aligned}
R_{\text{eff}}(A_0 \leftrightarrow A_1) &= \frac{u(1) - u(0)}{I(A_1)} = u(1) - u(0) \\
&= \frac{1}{2} \sum_{x,y \in E} I(x,y)^2 R(x,y) \\
&\leq \frac{1}{2} \sum_{x,y \in E} I'(x,y)^2 R(x,y) \leq \frac{1}{2} \sum_{x,y \in E} I'(x,y)^2 R'(x,y) \\
&= u'(1) - u'(0) = R'_{\text{eff}}(A_0 \leftrightarrow A_1)
\end{aligned}$$

□

5.19.4 19.4 Recurrence and Transience

We consider the situation where E is countable and $A_1 = \{x_1\}$ for some $x_1 \in E$. Let X be a random walk on E with weights $C = (C(x,y), x,y \in E)$ and hence with transition probabilities $p(x,y) = C(x,y)/C(x)$ (compare Definition 19.11).

The main goal of this section is to express the probability $1 - F(x_1, x_1)$ that the random walk never returns to x_1 in terms of effective resistances in the network. In order to apply the results on finite electrical networks from the last section, we henceforth assume that $A_0 \subset E$ is such that $E \setminus A_0$ is finite. We will obtain $1 - F(x_1, x_1)$ as the limit of the probability that a random walk started at x_1 hits A_0 before returning to x_1 as $A_0 \downarrow \emptyset$.

Let $u = u_{x_1, A_0}$ be the unique potential function on E with $u(x_1) = 1$ and $u(x) = 0$ for any $x \in A_0$. By Theorem 19.7, u is harmonic and can be written as

$$\begin{aligned}
u_{x_1, A_0}(x) &= \mathbf{E}_x \left[\mathbb{1}_{\{X_{\tau_{A_0} \cup \{x_1\}} = x_1\}} \right] \\
&= \mathbf{P}_x [\tau_{x_1} < \tau_{A_0}] \quad \text{for every } x \in E \setminus (A_0 \cup \{x_1\}).
\end{aligned}$$

Hence the current flow I with respect to u satisfies

$$\begin{aligned}
-I(A_0) &= I(x_1) = \sum_{x \in E} I(x_1, x) = \sum_{x \in E} (u(x_1) - u(x)) C(x_1, x) \\
&= C(x_1) \sum_{x \in E} (1 - u(x)) p(x_1, x) \\
&= C(x_1) \left(\sum_{x \notin A_0 \cup \{x_1\}} p(x_1, x) \mathbf{P}_x[\tau_{A_0} < \tau_{x_1}] + \sum_{x \in A_0} p(x_1, x) \right) \\
&= C(x_1) \mathbf{P}_{x_1}[\tau_{A_0} < \tau_{x_1}].
\end{aligned}$$

Therefore,

$$\begin{aligned}
p_F(x_1, A_0) &:= \mathbf{P}_{x_1}[\tau_{A_0} < \tau_{x_1}] \\
&= \frac{C_{\text{eff}}(x_1 \leftrightarrow A_0)}{C(x_1)} = \frac{1}{C(x_1)} \frac{1}{R_{\text{eff}}(x_1 \leftrightarrow A_0)}.
\end{aligned} \tag{19.9}$$

Definition 19.23 We denote the escape probability

$$p_F(x_1) = \mathbf{P}_{x_1}[\tau_{x_1} = \infty] = 1 - F(x_1, x_1).$$

We denote the effective conductance from x_1 to ∞ by

$$C_{\text{eff}}(x_1 \leftrightarrow \infty) := C(x_1) \inf \{p_F(x_1, A_0) : A_0 \subset E \text{ with } |E \setminus A_0| < \infty, A_0 \notin x_1\}.$$

Lemma 19.24 For any decreasing sequence $A_0^n \downarrow \emptyset$ such that $|E \setminus A_0^n| < \infty$ and $x_1 \notin A_0^n$ for all $n \in \mathbb{N}$, we have

$$C_{\text{eff}}(x_1 \leftrightarrow \infty) = \lim_{n \rightarrow \infty} C_{\text{eff}}(x_1 \leftrightarrow A_0^n).$$

Proof This is obvious since

$$C_{\text{eff}}(x_1 \leftrightarrow \infty) = C(x_1) \inf \{p_F(x_1, A_0) : |E \setminus A_0| < \infty, A_0 \notin x_1\} \tag{19.10}$$

and since $p_F(x_1, A_0)$ is monotone decreasing in A_0 . $\square$

Theorem 19.25 We have

$$p_F(x_1) = \frac{1}{C(x_1)} C_{\text{eff}}(x_1 \leftrightarrow \infty). \tag{19.11}$$

In particular,

$$x_1 \text{ is recurrent} \iff C_{\text{eff}}(x_1 \leftrightarrow \infty) = 0 \iff R_{\text{eff}}(x_1 \leftrightarrow \infty) = \infty.$$

Proof Let $A_0^n \downarrow \emptyset$ be a decreasing sequence such that $|E \setminus A_0^n| < \infty$ and $x_1 \notin A_0^n$ for all $n \in \mathbb{N}$. Define $F_n := \{\tau_{A_0^n} < \tau_{x_1}\}$. For every $M \in \mathbb{N}$, we have

$$\mathbf{P}_{x_1}[\tau_{A_0^n} \leq M] \leq \sum_{k=0}^M \mathbf{P}_{x_1}[X_k \in A_0^n] \xrightarrow{n \rightarrow \infty} 0.$$

Hence $\tau_{A_0^n} \uparrow \infty$ almost surely, and thus $F_n \downarrow \{\tau_{x_1} = \infty\}$ (up to a null set). We conclude

$$\frac{1}{C(x_1)} C_{\text{eff}}(x_1 \leftrightarrow \infty) = \lim_{n \rightarrow \infty} \mathbf{P}_{x_1}[F_n] = \mathbf{P}_{x_1}[\tau_{x_1} = \infty] = p_F(x_1).$$

□

Example 19.26 Symmetric simple random walk on $E = \mathbb{Z}$ is recurrent. Here $C(x, y) = \mathbb{1}_{\{|x-y|=1\}}$. The effective resistance from 0 to ∞ can be computed by the formulas for parallel and sequence connections,

$$R_{\text{eff}}(0 \leftrightarrow \infty) = \frac{1}{2} \sum_{i=0}^{\infty} R(i, i+1) = \infty.$$

□

Example 19.27 Asymmetric simple random walk on $E = \mathbb{Z}$ with $p(x, x+1) = p \in (\frac{1}{2}, 1)$, $p(x, x-1) = 1-p$ is transient. Here one choice (and thus up to multiples the unique choice) for the conductances is

$$C(x, x+1) = \left(\frac{p}{1-p} \right)^x \quad \text{for } x \in \mathbb{Z},$$

and $C(x, y) = 0$ if $|x-y| > 1$. By the monotonicity principle, the effective resistance from 0 to ∞ can be bounded by

$$\begin{aligned} R_{\text{eff}}(0 \leftrightarrow \infty) &= \lim_{n \rightarrow \infty} R_{\text{eff}}(0 \leftrightarrow \{-n, n\}) \\ &\leq \lim_{n \rightarrow \infty} R_{\text{eff}}(0 \leftrightarrow n) \\ &= \sum_{n=0}^{\infty} \left(\frac{1-p}{p} \right)^n = \frac{p}{2p-1} < \infty. \end{aligned}$$

Example 19.28 Symmetric simple random walk on $E = \mathbb{Z}^2$ is recurrent. Here again $C(x, y) = \mathbb{1}_{\{|x-y|=1\}}$. Let $B_n = \{-n, \dots, n\}^2$ and $\partial B_n = B_n \setminus B_{n-1}$. We construct a network C' with greater conductances by adding ring-shaped superconductors along ∂B . (See Figs. 19.3 and 19.4 for illustrations.) That is, we replace $C(x, y)$ by

$$C'(x, y) = \begin{cases} \infty, & \text{if } x, y \in \partial B_n \text{ for some } n \in \mathbb{N}, \\ C(x, y), & \text{else.} \end{cases}$$

Fig. 19.3 Electrical network on $\mathbb{Z}^2$. The bold lines are superconductors. The n th and the $(n + 1)$ th superconductors are connected by $4(2n + 1)$ edges

Fig. 19.4 Effective network after adding superconductors to $\mathbb{Z}^2$. The ring-shaped superconductors have melted down to single points

Then $R'_{\text{eff}}(B_n \leftrightarrow B_n^c) = \frac{1}{4(2n+1)}$ (note that there are $4(2n + 1)$ edges that connect B_n with B_n^c), and thus

$$R'_{\text{eff}}(0 \leftrightarrow \infty) = \sum_{n=0}^{\infty} \frac{1}{4(2n+1)} = \infty$$

By the monotonicity principle, we thus have $R_{\text{eff}}(0 \leftrightarrow \infty) \geq R'_{\text{eff}}(0 \leftrightarrow \infty) = \infty$.

Example 19.29 Let (E, K) be an arbitrary connected subgraph of the square lattice $(\mathbb{Z}^2, \mathbb{L}^2)$. Then simple random walk on (E, K) (see Definition 19.11) is recurrent. Indeed, by the monotonicity principle, we have

$$R_{\text{eff}}^{(E,K)}(0 \leftrightarrow \infty) \geq R_{\text{eff}}^{(\mathbb{Z}^2, \mathbb{L}^2)}(0 \leftrightarrow \infty) = \infty.$$

We formulate the method used in the foregoing examples as a theorem.

Theorem 19.30 Let C and C' be edge weights on E with $C'(x, y) \leq C(x, y)$ for all $x, y \in E$. If the Markov chain X with weights C is recurrent, then the Markov chain X' with weights C' is also recurrent.

In particular, consider a graph (E, K) and a subgraph (E', K') . If simple random walk on (E, K) is recurrent, then so is simple random walk on (E', K') .

Proof This follows from Theorem 19.25 and Rayleigh's monotonicity principle (Theorem 19.19).

Example 19.31 Symmetric simple random walk on $\mathbb{Z}^3$ is transient. In order to prove this, we construct a subgraph for which we can compute $R'_{\text{eff}}(0 \leftrightarrow \infty) < \infty$.

Sketch. We consider the set of all infinite paths starting at 0 and that

- begin by taking one step in the x -direction, the y -direction or the z -direction,
- continue by choosing a possibly different direction x, y or z and make two steps in that direction, and
- at the n th stage choose a direction x, y or z and take 2^{n+1} steps in that direction.

For example, by $xyyxxxxzzzzzzzz...$ we denote the path that starts with one step in direction x , then chooses y , then x , then z and so on. Note that after two paths follow different directions for the first time, they will not have any common edge again, though some of the nodes can be visited by both paths.

Consider the electrical network with unit resistors. Apply a voltage of 1 at the origin and 0 at the endpoints of the paths at the n th stage. By symmetry, the potential at a given node depends only on the distance (length of the shortest path) from the origin. We thus obtain an equivalent network if we replace multiply used nodes by multiple nodes (see Fig. 19.5). Thus we obtain a tree-shaped network: For any $n \in \mathbb{N}_0$, after 2^n steps each path splits into three (see Fig. 19.6). The 3^n paths leading from the nodes of the n th generation to those of the $(n+1)$ th generation are disjoint

Fig. 19.5 Scheme of the first three steps (two stages) of the graph from Example 19.31. The left figure shows the actual edges where, e.g., xyy indicates that the first step is in direction x , the second step is in direction y and then the third step is necessarily also in direction y . In the right figure, the nodes at the ends of $xz/zx, xy/yx$ and yz/zy are split into two nodes and then connected by a superconductor (bold line). If we remove the superconductors from the network, we end up with the network of Fig. 19.6 whose effective resistance $R'_{\text{eff}}(0 \leftrightarrow \infty)$ is not smaller than that of $\mathbb{Z}^3$. (If at the root we apply a voltage of 1 and at the points to the right the voltage 0, then by symmetry no current flows through the superconductors. Thus, in fact, the network is equivalent to that in Fig. 19.6)

paths, each of length 2^{n-1} . If $B(n)$ denotes the set of points up to the n th generation, then

$$R'_{\text{eff}}(0 \leftrightarrow B(n+1)^c) = \sum_{k=0}^{n-1} R'_{\text{eff}}(B(k) \leftrightarrow B(k)^c) = \sum_{k=0}^{n-1} 2^k 3^{-k}.$$

Therefore, $R'_{\text{eff}}(0 \leftrightarrow \infty) = \frac{1}{3} \sum_{k=0}^{\infty} \left(\frac{2}{3}\right)^k = 1 < \infty$. On this tree, random walk is transient. Hence, by Theorem 19.30, random walk on $\mathbb{Z}^3$ is also transient. $\square$

Exercise 19.4.1 Consider the electrical network on $\mathbb{Z}^d$ with unit resistors between neighboring points. Let X be a symmetric simple random walk on $\mathbb{Z}^d$. Finally, fix two arbitrary neighboring points $x_0, x_1 \in \mathbb{Z}^d$. Show the following:

- (i) The effective conductance between x_0 and x_1 is $C_{\text{eff}}(x_0 \leftrightarrow x_1) = d$.
- (ii) If $d \leq 2$, then $\mathbf{P}_{x_0}[\tau_{x_1} < \tau_{x_0}] = \frac{1}{2}$.
- (iii) If $d \geq 3$, then $\mathbf{P}_{x_0}[\tau_{x_1} < \tau_{x_0} \mid \tau_{x_0} \wedge \tau_{x_1} < \infty] = \frac{1}{2}$.

Fig. 19.6 A tree as a subgraph of $\mathbb{Z}^3$ on which random walk is still transient

5.19.5 19.5 Network Reduction

Example 19.32 Consider a random walk on the graph in Fig. 19.7 that starts at x and at each step jumps to one of its neighbors at random with equal probability. What is the probability P that this Markov chain visits 1 before it visits 0?

We can regard the graph as an electrical network with unit resistors at each edge, voltage 0 at 0 and voltage 1 at 1. Then P equals the voltage at point x :

$$P = u(x).$$

In order to compute $u(x)$, we replace the network step by step by simpler networks such that the effective resistances between 0, 1, and x remain unchanged. Hence in each step the voltage $u(x)$ at point x does not change. $\square$

Fig. 19.7 Initial situation

Fig. 19.8 Reduced network with three nodes

Reduced Network

Assume that we have already reduced the network to a network with the three points 0, 1 and x and with resistors between these points $R'(0, 1)$, $R'(0, x)$ and $R'(1, x)$. See Fig. 19.8.

Clearly, we have

$$P = u(x) = \frac{R'(0, x)}{R'(0, x) + R'(1, x)}. \quad (19.12)$$

If we knew the effective resistances $R_{\text{eff}}(0 \leftrightarrow x)$, $R_{\text{eff}}(1 \leftrightarrow x)$ and $R_{\text{eff}}(0 \leftrightarrow 1)$, we could avoid the hassle of reducing the network and we could compute $u(x)$ directly. In order to derive the formula for $u(x)$, we make the following observations. In the reduced network, the effective resistances are easy to compute: If $\{a, b, c\} = \{0, 1, x\}$, then

$$R_{\text{eff}}(a \leftrightarrow b) = \left(\frac{1}{R'(a, b)} + \frac{1}{R'(a, c) + R'(b, c)} \right)^{-1}. \quad (19.13)$$

Solving these three equations for $R'(0, 1)$, $R'(0, x)$ and $R'(1, x)$ and plugging the values into (19.12) yields

$$P = u(x) = \frac{R_{\text{eff}}(0 \leftrightarrow 1) + R_{\text{eff}}(0 \leftrightarrow x) - R_{\text{eff}}(x \leftrightarrow 1)}{2R_{\text{eff}}(0 \leftrightarrow 1)}. \quad (19.14)$$

In particular, in the case $R'(0, 1) = \infty$ (or equivalently $R_{\text{eff}}(0 \leftrightarrow 1) = R_{\text{eff}}(0 \leftrightarrow x) + R_{\text{eff}}(x \leftrightarrow 1)$), we have $R_{\text{eff}}(0 \leftrightarrow x) = R'(0, x)$ and $R_{\text{eff}}(1 \leftrightarrow x) = R'(1, x)$, hence

$$u(x) = \frac{R_{\text{eff}}(0 \leftrightarrow x)}{R_{\text{eff}}(0 \leftrightarrow x) + R_{\text{eff}}(x \leftrightarrow 1)}. \quad (19.15)$$

Since we always have $u(x) \in [0, 1]$, rearranging the terms yields (again in the general situation)

$$R_{\text{eff}}(1 \leftrightarrow x) \leq R_{\text{eff}}(0 \leftrightarrow 1) + R_{\text{eff}}(0 \leftrightarrow x). \quad (19.16)$$

This is the triangle inequality for the effective resistances and it shows that the effective resistance is a metric in any electrical network.

Step-by-step Reduction of the Network

Having seen how to compute $u(x)$ from the effective resistances, we now turn to the systematic computation of these effective resistances. Later we will come back to the introductory example and make the computations explicit.

There are four elementary transformations for the reduction of an electrical network:

1. Deletion of loops. The three points on the very right of the graph form a loop that can be deleted from the network without changing any of the remaining voltages. In particular, any edge that directly connects 0 to 1 can be deleted.
2. Joining serial edges. If two (or more) edges are in a row such that the nodes along them do not have any further adjacent edges, this sequence of edges can be substituted by a single edge whose resistance is the sum of the resistances of the single edges (see Fig. 19.1).
3. Joining parallel edges. Two (or more) edges with resistances $R_1, \dots, R_n$ that connect the same two nodes can be replaced by a single edge with resistance $R = (R_1^{-1} + \dots + R_n^{-1})^{-1}$ (see Fig. 19.2).
4. Star-triangle transformation. (See Exercise 19.5.1.) The star-shaped part of a network (left in Fig. 19.9) is equivalent to the triangle-shaped part (right in Fig. 19.9) if the resistances $R_1, R_2, R_3, \tilde{R}_1, \tilde{R}_2, \tilde{R}_3$ satisfy the condition

$$R_i \tilde{R}_i = \delta \quad \text{for any } i = 1, 2, 3, \quad (19.17)$$

where

$$\delta = R_1 R_2 R_3 (R_1^{-1} + R_2^{-1} + R_3^{-1}) = \frac{\tilde{R}_1 \tilde{R}_2 \tilde{R}_3}{\tilde{R}_1 + \tilde{R}_2 + \tilde{R}_3}.$$

Fig. 19.9 Star-triangle transformation

Application to Example 19.32

With the four transformations at hand, we solve the problem of Example 19.32. Assume that initially all edges have resistance 1. In the figures we label each edge with its resistance if it differs (in the course of the reduction) from 1.

Step 1. Delete the loop at the right-hand side (left in Fig. 19.10).

Step 2. Replace the series on top, bottom and right by edges with resistance 2 (right in Fig. 19.10).

Step 3. Use the star-triangle transformation to remove the lower left node (left in Fig. 19.11). Here $R_1 = 1, R_2 = 2, R_3 = 1, \delta = 5, \tilde{R}_1 = \delta/R_1 = 5, \tilde{R}_2 = \delta/R_2 = 5/2$ and $\tilde{R}_3 = \delta/R_3 = 5$.

Step 4. Replace the parallel edges with resistances $R_1 = 5$ and $R_2 = 1$ by one edge with $R = \left(\frac{1}{5} + 1\right)^{-1} = \frac{5}{6}$ (right in Fig. 19.11).

Step 5. Use the star-triangle transformation to remove the lower right node (left in Fig. 19.12). Here $R_1 = 5, R_2 = 2, R_3 = \frac{5}{6}, \delta = 95/6, \tilde{R}_1 = \delta/R_1 = 19/6, \tilde{R}_2 = \delta/R_2 = 95/12$ and $\tilde{R}_3 = \delta/R_3 = 19$.

Fig. 19.10 Steps 1 and 2

Fig. 19.11 Steps 3 and 4

Fig. 19.12 Steps 5 and 6

Fig. 19.13 Steps 7 and 8

Step 6. Replace the parallel edges by edges with resistances $(\frac{12}{95} + \frac{2}{5})^{-1} = \frac{19}{10}$ and $(\frac{6}{19} + 1)^{-1} = \frac{19}{25}$, respectively (right in Fig. 19.12).

Step 7. Use the star-triangle transformation to remove the lower right node (left in Fig. 19.13). Here $R_1 = \frac{19}{10}, R_2 = \frac{19}{25}, R_3 = 1, \delta = \frac{513}{125}, \tilde{R}_1 = \delta/R_1 = \frac{54}{25}, \tilde{R}_2 = \delta/R_2 = \frac{27}{5}$ and $\tilde{R}_3 = \delta/R_3 = \frac{513}{125}$.

Step 8. Replace the three pairs of parallel edges by single edges with resistances $(\frac{5}{27} + 1)^{-1} = \frac{27}{32}, (\frac{25}{54} + \frac{1}{2})^{-1} = \frac{27}{26}$ and $(\frac{1}{19} + \frac{125}{513})^{-1} = \frac{27}{8}$, respectively.

In the reduced network, we have the resistances

$$R'(0, x) = \frac{27}{32} \quad \text{and} \quad R'(x, 1) = \frac{27}{26}.$$

Using (19.12), the probability that the random walk visits 1 before 0 is

$$P = \frac{\frac{27}{32}}{\frac{27}{32} + \frac{27}{26}} = \frac{13}{29}.$$

Using the values of $R'(0, x), R'(1, x)$ and $R'(0, 1)$ and Eq. (19.13), we compute the effective resistances in the reduced network (and hence in the original network):

$$\begin{aligned} R_{\text{eff}}(0 \leftrightarrow x) &= \left(\frac{32}{27} + \frac{1}{\frac{27}{8} + \frac{27}{26}} \right)^{-1} = \frac{17}{24} \\ R_{\text{eff}}(1 \leftrightarrow x) &= \left(\frac{26}{27} + \frac{1}{\frac{27}{32} + \frac{27}{8}} \right)^{-1} = \frac{5}{6} \\ R_{\text{eff}}(0 \leftrightarrow 1) &= \left(\frac{8}{27} + \frac{1}{\frac{27}{26} + \frac{27}{32}} \right)^{-1} = \frac{29}{24}. \end{aligned}$$

Using (19.14) we can use the values to compute $u(x)$:

$$P = u(x) = \frac{\frac{29}{24} + \frac{17}{24} - \frac{5}{6}}{2 \cdot \frac{29}{24}} = \frac{13}{29}.$$

Clearly, the latter computation is more complicated than using the resistances R' from the reduced network directly. However, it has the advantage that it can be performed without going through all the network reduction steps if, for some reason, we know the effective resistances already. For example, we could buy resistors in an electronic market, solder the network and measure the resistances with a multimeter.

Alternative Solution

A different approach to solving the problem of Example 19.32 is to use linear algebra instead of network reduction. It is a matter of taste as to which solution is preferable. First generate the transition matrix p of the Markov chain. To this end, enumerate the nodes of the graph from 1 to 12 as in Fig. 19.14.

Fig. 19.14 Graph with enumerated nodes

The chain starts at 2, and we want to compute the probability that it visits 3 before 5.

Generate the matrix $\bar{p}$ of the chain that is killed at 3 and at 5 and compute $\bar{G} = (I - \bar{p})^{-1}$. By Exercise 19.1.1 (with $A = \{3, 5\}$, $x = 2$ and $y = 3$), the probability of visiting 3 before 5 is $P = \bar{G}(2, 3) = \frac{13}{29}$.

$$\bar{p} := \begin{pmatrix} 0 & \frac{1}{2} & \frac{1}{2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \frac{1}{3} & 0 & 0 & 0 & \frac{1}{3} & \frac{1}{3} & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{2} & \frac{1}{2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{4} & \frac{1}{4} & 0 & 0 & 0 & 0 & 0 & \frac{1}{4} & \frac{1}{4} & 0 & 0 \\ 0 & 0 & \frac{1}{4} & \frac{1}{4} & 0 & 0 & 0 & 0 & 0 & \frac{1}{4} & \frac{1}{4} & 0 \\ 0 & 0 & 0 & \frac{1}{2} & 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{2} & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{3} & \frac{1}{3} & 0 & 0 & 0 & 0 & 0 & \frac{1}{3} \\ 0 & 0 & 0 & 0 & 0 & \frac{1}{3} & \frac{1}{3} & 0 & 0 & 0 & 0 & \frac{1}{3} \\ 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{2} & \frac{1}{2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{2} & \frac{1}{2} & 0 & 0 \end{pmatrix},$$

$$\bar{G} := (I - \bar{p})^{-1}$$

$$= \begin{pmatrix} \frac{143}{116} & \frac{81}{116} & \frac{21}{29} & \frac{3}{58} & \frac{8}{29} & \frac{19}{58} & \frac{3}{29} & \frac{3}{58} & \frac{15}{116} & \frac{9}{58} & \frac{3}{58} & \frac{11}{116} \\ \frac{116}{27} & \frac{81}{58} & \frac{29}{58} & \frac{58}{29} & \frac{29}{29} & \frac{58}{29} & \frac{29}{29} & \frac{58}{29} & \frac{116}{58} & \frac{58}{29} & \frac{58}{29} & \frac{116}{58} \\ \frac{58}{29} & \frac{58}{29} & \frac{29}{29} & \frac{58}{29} & \frac{29}{29} & \frac{58}{29} & \frac{29}{29} & \frac{58}{29} & \frac{116}{58} & \frac{58}{29} & \frac{58}{29} & \frac{116}{58} \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \frac{3}{58} & \frac{9}{58} & \frac{24}{58} & \frac{165}{58} & \frac{5}{29} & \frac{15}{29} & \frac{78}{29} & \frac{68}{29} & \frac{21}{58} & \frac{30}{29} & \frac{107}{58} & \frac{27}{58} \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ \frac{19}{116} & \frac{57}{116} & \frac{18}{29} & \frac{15}{58} & \frac{11}{29} & \frac{95}{58} & \frac{15}{29} & \frac{15}{58} & \frac{75}{116} & \frac{45}{58} & \frac{15}{58} & \frac{55}{116} \\ \frac{116}{3} & \frac{116}{9} & \frac{29}{24} & \frac{58}{39} & \frac{29}{5} & \frac{58}{15} & \frac{29}{78} & \frac{58}{39} & \frac{116}{21} & \frac{58}{30} & \frac{58}{39} & \frac{116}{27} \\ \frac{58}{3} & \frac{58}{9} & \frac{29}{24} & \frac{29}{68} & \frac{29}{5} & \frac{29}{15} & \frac{29}{78} & \frac{29}{97} & \frac{58}{21} & \frac{29}{30} & \frac{29}{68} & \frac{58}{27} \\ \frac{58}{5} & \frac{58}{15} & \frac{29}{11} & \frac{29}{18} & \frac{29}{25} & \frac{29}{14} & \frac{29}{29} & \frac{58}{93} & \frac{29}{21} & \frac{29}{7} & \frac{29}{45} & \frac{58}{45} \\ \frac{58}{3} & \frac{58}{9} & \frac{29}{19} & \frac{29}{20} & \frac{29}{10} & \frac{29}{30} & \frac{29}{40} & \frac{29}{20} & \frac{58}{21} & \frac{29}{60} & \frac{29}{20} & \frac{58}{27} \\ \frac{29}{3} & \frac{29}{9} & \frac{24}{29} & \frac{107}{29} & \frac{5}{29} & \frac{15}{29} & \frac{78}{29} & \frac{68}{29} & \frac{21}{30} & \frac{30}{165} & \frac{29}{27} & \frac{29}{27} \\ \frac{58}{11} & \frac{58}{33} & \frac{29}{15} & \frac{58}{27} & \frac{29}{14} & \frac{29}{55} & \frac{29}{27} & \frac{29}{135} & \frac{58}{81} & \frac{29}{27} & \frac{58}{215} & \frac{58}{215} \end{pmatrix}.$$

Exercise 19.5.1 Show the validity of the star-triangle transformation.

Exercise 19.5.2 Consider a random walk on the honeycomb graph shown below. Show that if the walk starts at x , then the probability of visiting 1 before 0 is $\frac{8}{17}$ using

- (i) the method of network reduction, and
- (ii) the method of matrix inversion.

Fig. 19.15 Simple ladder graph

Exercise 19.5.3 Consider the graph of Fig. 19.15.

- (i) For the effective conductance between a and z , show that $C_{\text{eff}}(a \longleftrightarrow z) = \sqrt{3}$.
- (ii) For a random walk started at a , show that the probability $\mathbf{P}_a[\tau_z < \tau_a]$ of visiting z before returning to a is $\mathbf{P}_a[\tau_z < \tau_a] = 1/\sqrt{3}$.

Fig. 19.15 Simple ladder graph

Exercise 19.5.4 For the graph of Fig. 19.16, determine $C_{\text{eff}}(a \longleftrightarrow z)$ and $\mathbf{P}_a[\tau_z < \tau_a]$. (This is simpler than in Exercise 19.5.3!)

Fig. 19.16 Crossed ladder graph

Exercise 19.5.5 For a random walk on the graph of Fig. 19.17, determine the probability $\mathbf{P}_a[\tau_z < \tau_a]$.

Fig. 19.17 Random walk on a hypercube

5.19.6 19.6 Random Walk in a Random Environment

(Compare [174], [142] and [76, 77], [93].) Consider a Markov chain X on $\mathbb{Z}$ that at each step makes a jump either to the left (with probability w_i^-) or to the right (with probability w_i^+) if X is at $i \in \mathbb{Z}$. Hence, let $w_i^- \in (0, 1)$ and $w_i^+ := 1 - w_i^-$ for $i \in \mathbb{Z}$. Then X is the Markov chain with transition matrix

$$p_w(i, j) = \begin{cases} w_i^-, & \text{if } j = i - 1 \\ w_i^+, & \text{if } j = i + 1 \\ 0, & \text{else} \end{cases}$$

We consider $(w_i^-)_{i \in \mathbb{Z}}$ as an environment in which X walks and later choose the environment at random.

In order to describe X in terms of conductances of an electrical network, we define $\varrho_i := w_i^- / w_i^+$ for $i \in \mathbb{Z}$. Let $C_w(i, j) := 0$ if $|i - j| \neq 1$ and

$$C_w(i + 1, i) := C_w(i, i + 1) := \begin{cases} \prod_{k=0}^i \varrho_k^{-1}, & \text{if } i \geq 0 \\ \prod_{k=i}^{-1} \varrho_k, & \text{if } i < 0 \end{cases}$$

With this definition,

$$\frac{C_w(i, i + 1)}{C_w(i)} = \frac{1}{\varrho_i + 1} = w_i^+ \quad \text{and} \quad \frac{C_w(i, i - 1)}{C_w(i)} = \frac{\varrho_i}{\varrho_i + 1} = w_i^-.$$

Hence the transition probabilities p_w are indeed described by the C_w . Let

$$R_w^+ := \sum_{i=0}^{\infty} R_w(i, i + 1) = \sum_{i=0}^{\infty} \frac{1}{C_w(i, i + 1)} = \sum_{i=0}^{\infty} \prod_{k=0}^i \varrho_k$$

and

$$R_w^- := \sum_{i=0}^{\infty} R_w(-i, -i - 1) = \sum_{i=0}^{\infty} \frac{1}{C_w(-i, -i - 1)} = \sum_{i=1}^{\infty} \prod_{k=-i}^{-1} \varrho_k^{-1}.$$

Note that R_w^+ and R_w^- are the effective resistances from 0 to $+\infty$ and from 0 to $-\infty$, respectively. Hence

$$R_{w,\text{eff}}(0 \leftrightarrow \infty) = \frac{1}{\frac{1}{R_w^-} + \frac{1}{R_w^+}}$$

is finite if and only if $R_w^- < \infty$ or $R_w^+ < \infty$. Therefore, by Theorem 19.25,

$$X \text{ is transient} \iff R_w^- < \infty \text{ or } R_w^+ < \infty. \quad (19.18)$$

If X is transient, in which direction does it get lost?

Theorem 19.33

(i) If $R_w^- < \infty$ or $R_w^+ < \infty$, then (agreeing on $\frac{\infty}{\infty} = 1$)

$$\mathbf{P}_0 \left[X_n \xrightarrow{n \rightarrow \infty} -\infty \right] = \frac{R_w^+}{R_w^- + R_w^+} \quad \text{and} \quad \mathbf{P}_0 \left[X_n \xrightarrow{n \rightarrow \infty} +\infty \right] = \frac{R_w^-}{R_w^- + R_w^+}.$$

(ii) If $R_w^- = \infty$ and $R_w^+ = \infty$, then $\liminf_{n \rightarrow \infty} X_n = -\infty$ and $\limsup_{n \rightarrow \infty} X_n = \infty$ almost surely.

Proof (i) Let $\tau_N := \inf \{n \in \mathbb{N}_0 : X_n \in \{-N, N\}\}$. As X is transient, we have $\mathbf{P}_0[\tau_N < \infty] = 1$ and (as in (19.8))

$$\mathbf{P}_0[X_{\tau_N} = -N] = \frac{R_{w,\text{eff}}(0 \leftrightarrow N)}{R_{w,\text{eff}}(-N \leftrightarrow N)} = \frac{R_{w,\text{eff}}(0 \leftrightarrow N)}{R_{w,\text{eff}}(0 \leftrightarrow -N) + R_{w,\text{eff}}(0 \leftrightarrow N)}.$$

Again, since X is transient, we infer

$$\begin{aligned} \mathbf{P}_0 \left[X_n \xrightarrow{n \rightarrow \infty} -\infty \right] &= \mathbf{P}[\sup \{X_n : n \in \mathbb{N}_0\} < \infty] \\ &= \lim_{N \rightarrow \infty} \mathbf{P}[\sup \{X_n : n \in \mathbb{N}_0\} < N] \\ &\leq \limsup_{N \rightarrow \infty} \mathbf{P}[X_{\tau_N} = -N] \\ &= \frac{R_w^+}{R_w^- + R_w^+}. \end{aligned}$$

By symmetry (and since X is transient), we get

$$\mathbf{P}_0 \left[X_n \xrightarrow{n \rightarrow \infty} -\infty \right] = 1 - \mathbf{P}_0 \left[X_n \xrightarrow{n \rightarrow \infty} \infty \right] \geq 1 - \frac{R_w^-}{R_w^- + R_w^+} = \frac{R_w^+}{R_w^- + R_w^+}$$

(ii) If $R_w^- = R_w^+ = \infty$, then X is recurrent and hence every point is visited infinitely often. That is, $\limsup_{n \rightarrow \infty} X_n = \infty$ and $\liminf_{n \rightarrow \infty} X_n = -\infty$ a.s.

We now consider the situation where the sequence $w = (w_i^-)_{i \in \mathbb{Z}}$ is also random. That is, we consider a two-stage experiment: At the first stage we choose a realization of i.i.d. random variables $W = (W_i^-)_{i \in \mathbb{Z}}$ on $(0, 1)$ and let $W_i^+ := 1 - W_i^-$. At the second stage, given W , we construct a Markov chain X on $\mathbb{Z}$ with transition matrix

$$p_W(i, j) = \begin{cases} W_i^-, & \text{if } j = i - 1 \\ W_i^+, & \text{if } j = i + 1 \\ 0, & \text{else} \end{cases}$$

Note that X is a Markov chain only given W ; that is, under the probability measure $\mathbf{P}[X \in \cdot \mid W]$. However, it is not a Markov chain with respect to the so-called annealed

measure $\mathbf{P}[X \in \cdot]$. In fact, if W is unknown, observing X gives an increasing amount of information on the true realization of W . This is precisely what memory is and is thus in contrast with the Markov property of X .

Definition 19.34 The process X is called a random walk in the random environment W .

We are now in the position to prove a theorem of Solomon [157]. Let $\varrho_i := W_i^-/W_i^+$ for $i \in \mathbb{Z}$ and R_W^- and R_W^+ be defined as above.

Theorem 19.35 (Solomon (1975)) Assume that $\mathbf{E}[\log(\varrho_0)] < \infty$.

- (i) If $\mathbf{E}[\log(\varrho_0)] < 0$, then $X_n \xrightarrow{n \rightarrow \infty} \infty$ a.s.
- (ii) If $\mathbf{E}[\log(\varrho_0)] > 0$, then $X_n \xrightarrow{n \rightarrow \infty} -\infty$ a.s.
- (iii) If $\mathbf{E}[\log(\varrho_0)] = 0$, then $\liminf_{n \rightarrow \infty} X_n = -\infty$ and $\limsup_{n \rightarrow \infty} X_n = \infty$ a.s.

Proof (i) and (ii) By symmetry, it is enough to show (ii). Hence, let $c := \mathbf{E}[\log(\varrho_0)] > 0$. By the strong law of large numbers, there is an $n_0^- = n_0^-(\omega)$ with

$$\prod_{k=-n}^1 \varrho_k^{-1} = \exp\left(-\sum_{k=-n}^1 \log(\varrho_k)\right) < e^{-cn/2} \quad \text{for all } n \geq n_0^-.$$

Therefore,

$$R_W^- = \sum_{n=1}^{\infty} \prod_{k=-n}^1 \varrho_k^{-1} \leq \sum_{n=1}^{n_0^- - 1} \prod_{k=-n}^1 \varrho_k^{-1} + \sum_{n=n_0^-}^{\infty} e^{-cn/2} < \infty \quad \text{a.s.}$$

Similarly, there is an $n_0^+ = n_0^+(\omega)$ with

$$\prod_{k=0}^n \varrho_k > e^{cn/2} \quad \text{for all } n \geq n_0^+.$$

We conclude

$$R_W^+ = \sum_{n=0}^{\infty} \prod_{k=0}^n \varrho_k \geq \sum_{n=0}^{n_0^+ - 1} \prod_{k=0}^n \varrho_k + \sum_{n=n_0^+}^{\infty} e^{cn/2} = \infty \quad \text{a.s.}$$

Now, by Theorem 19.33, we get $X_n \xrightarrow{n \rightarrow \infty} -\infty$ almost surely.

(iii) In order to show $R_W^- = R_W^+ = \infty$ almost surely, it is enough to show $\limsup_{n \rightarrow \infty} \sum_{k=0}^n \log(\varrho_k) > -\infty$ and $\limsup_{n \rightarrow \infty} \sum_{k=-n}^1 \log(\varrho_k^{-1}) > -\infty$ almost surely if $\mathbf{E}[\log(\varrho_0)] = 0$. If $\log(\varrho_0)$ has a finite variance, this follows by the central limit theorem. In the general case, it follows by Theorem 20.21.

Exercise 19.6.1 Consider the situation of Theorem 19.35 but with the random walk restricted to $\mathbb{N}_0$. To this end, change the walk so that whenever it attempts to make a step from 0 to -1, it simply stays in 0. Show that this random walk in a random environment is

- a.s. transient if $\mathbf{E}[\log(\varrho_0)] < \infty$,
- a.s. null recurrent if $\mathbf{E}[\log(\varrho_0)] = \infty$, and
- a.s. positive recurrent if $\mathbf{E}[\log(\varrho_0)] > \infty$.

5.20 20 Ergodic Theory

Laws of large numbers, e.g., for i.i.d. random variables $X_1, X_2, \dots$, state that the sequence of averages converges a.s. to the expected value, $n^{-1} \sum_{i=1}^n X_i \xrightarrow{n \rightarrow \infty} \mathbf{E}[X_1]$. Hence averaging over one realization of many random variables is equivalent to averaging over all possible realizations

of one random variable. In the terminology of statistical physics this means that the time average, or path (Greek: odos) average, equals the space average. The "space" in "space average" is the probability space in mathematical terminology, and in physics it is considered the space of admissible states with a certain energy (Greek: ergon). Combining the Greek words gives rise to the name ergodic theory, which studies laws of large numbers for possibly dependent, but stationary, random variables.

For further reading, see, for example [103] or [88].

5.20.1 20.1 Definitions

Definition 20.1 Let $I \subset \mathbb{R}$ be a set that is closed under addition (for us the important examples are $I = \mathbb{N}_0, I = \mathbb{N}, I = \mathbb{Z}, I = \mathbb{R}, I = [0, \infty), I = \mathbb{Z}^d$ and so on). A stochastic process $X = (X_t)_{t \in I}$ is called stationary if

$$\mathcal{L}[(X_{t+s})_{t \in I}] = \mathcal{L}[(X_t)_{t \in I}] \quad \text{for all } s \in I. \quad (20.1)$$

Remark 20.2 If $I = \mathbb{N}_0, I = \mathbb{N}$ or $I = \mathbb{Z}$, then (20.1) is equivalent to

$$\mathcal{L}[(X_{n+1})_{n \in I}] = \mathcal{L}[(X_n)_{n \in I}]$$

Example 20.3

- (i) If $X = (X_t)_{t \in I}$ is i.i.d., then X is stationary. If only $\mathbf{P}_{X_t} = \mathbf{P}_{X_0}$ holds for every $t \in I$ (without the independence), then in general X is not stationary. For example, consider $I = \mathbb{N}_0$ and $X_1 = X_2 = X_3 = \dots$ but $X_0 \neq X_1$. Then X is not stationary.
- (ii) Let X be a Markov chain with invariant distribution π . If $\mathcal{L}[X_0] = \pi$, then X is stationary.
- (iii) Let $(Y_n)_{n \in \mathbb{Z}}$ be i.i.d. real random variables and let $c_1, \dots, c_k \in \mathbb{R}$. Then

$$X_n := \sum_{l=1}^k c_l Y_{n-l}, \quad n \in \mathbb{Z},$$

defines a stationary process X that is called the moving average with weights $(c_1, \dots, c_k)$. In fact, X is stationary if only Y is stationary.

Lemma 20.4 If $(X_n)_{n \in \mathbb{N}_0}$ is stationary, then X can be extended to a stationary process $(\tilde{X}_n)_{n \in \mathbb{Z}}$.

Proof Let $\tilde{X}$ be the canonical process on $\Omega = E^{\mathbb{Z}}$. For $n \in \mathbb{N}$, define a probability measure $\tilde{\mathbf{P}}^{\{-n, -n+1, \dots\}} \in \mathcal{M}_1(E^{\{-n, -n+1, \dots\}})$ by

$$\begin{aligned} \tilde{\mathbf{P}}^{\{-n, -n+1, \dots\}} \left[\tilde{X}_{-n} \in A_{-n}, \tilde{X}_{-n+1} \in A_{-n+1}, \dots \right] \\ = \mathbf{P} [X_0 \in A_{-n}, X_1 \in A_{-n+1}, \dots]. \end{aligned}$$

Then $\{-n, -n+1, \dots\} \uparrow \mathbb{Z}$ and $(\tilde{\mathbf{P}}^{\{-n, -n+1, \dots\}}, n \in \mathbb{N})$ is a consistent family. By the Ionescu-Tulcea theorem (Theorem 14.32), the projective limit $\tilde{\mathbf{P}} := \lim_{\leftarrow} \tilde{\mathbf{P}}^{\{-n, -n+1, \dots\}}$ exists. By construction, $\tilde{X}$ is stationary with respect to $\tilde{\mathbf{P}}$ and

$$\tilde{\mathbf{P}} \circ \left(\left(\tilde{X}_n \right)_{n \in \mathbb{N}_0} \right)^{-1} = \mathbf{P} \circ \left((X_n)_{n \in \mathbb{N}_0} \right)^{-1}$$

In the following, assume that $(\Omega, \mathcal{A}, \mathbf{P})$ is a probability space and $\tau : \Omega \rightarrow \Omega$ is a measurable map.

Definition 20.5 An event $A \in \mathcal{A}$ is called invariant if $\tau^{-1}(A) = A$ and quasiinvariant if $\mathbb{1}_{\tau^{-1}(A)} = \mathbb{1}_A$ $\mathbf{P}$ -a.s. Denote the σ -algebra of invariant events by

$$\mathcal{I} = \{A \in \mathcal{A} : \tau^{-1}(A) = A\}$$

Recall that a σ -algebra $\mathcal{I}$ is called $\mathbf{P}$ -trivial if $\mathbf{P}[A] \in \{0, 1\}$ for every $A \in \mathcal{I}$.

Definition 20.6

(i) τ is called measure-preserving if

$$\mathbf{P}[\tau^{-1}(A)] = \mathbf{P}[A] \quad \text{for all } A \in \mathcal{A}$$

In this case, $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ is called a measure-preserving dynamical system.

(ii) If τ is measure-preserving and $\mathcal{I}$ is $\mathbf{P}$ -trivial, then $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ is called ergodic.

Lemma 20.7

(i) A measurable map $f : (\Omega, \mathcal{A}) \rightarrow (\mathbb{R}, \mathcal{B}(\mathbb{R}))$ is $\mathcal{I}$ -measurable if and only if $f \circ \tau = f$.

(ii) $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ is ergodic if and only if any $\mathcal{I}$ -measurable $f : (\Omega, \mathcal{I}) \rightarrow (\mathbb{R}, \mathcal{B}(\mathbb{R}))$ is $\mathbf{P}$ -almost surely constant.

Proof (i) The statement is obvious if $f = \mathbb{1}_A$ is an indicator function. The general case, can be inferred by the usual approximation arguments (see Theorem 1.96(i)).

(ii) " $\implies$ " Assume that $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ is ergodic. Then, for any $c \in \mathbb{R}$, we have $f^{-1}((c, \infty)) \in \mathcal{I}$ and thus $\mathbf{P}[f^{-1}((c, \infty))] \in \{0, 1\}$. We conclude that

$$f = \inf \{c \in \mathbb{R} : \mathbf{P}[f^{-1}((c, \infty))] = 0\} \quad \mathbf{P}\text{-a.s.}$$

" $\Leftarrow$ " Assume any $\mathcal{I}$ -measurable map is $\mathbf{P}$ -a.s. constant. If $A \in \mathcal{I}$, then $\mathbb{1}_A$ is $\mathcal{I}$ -measurable and hence $\mathbf{P}$ -a.s. equals either 0 or 1. Thus $\mathbf{P}[A] \in \{0, 1\}$.

Example 20.8 Let $n \in \mathbb{N} \setminus \{1\}$, let $\Omega = \mathbb{Z}/(n)$, let $\mathcal{A} = 2^\Omega$ and let $\mathbf{P}$ be the uniform distribution on Ω . Let $r \in \{1, \dots, n\}$ and

$$\tau : \Omega \rightarrow \Omega, \quad x \mapsto x + r \pmod{n}.$$

Then τ is measure-preserving. If $d = \gcd(n, r)$ and

$$A_i = \{i, \tau(i), \tau^2(i), \dots, \tau^{n-1}(i)\} = i + \langle r \rangle \quad \text{for } i = 0, \dots, d-1,$$

then $A_0, \dots, A_{d-1}$ are the disjoint coset classes of the normal subgroup $\langle r \rangle \trianglelefteq \Omega$. Hence we have $A_i \in \mathcal{I}$ for $i = 0, \dots, d-1$, and each $A \in \mathcal{I}$ is a union of certain A_i 's. Hence we have

$$(\Omega, \mathcal{A}, \mathbf{P}, \tau) \text{ is ergodic} \iff \gcd(r, n) = 1.$$

Example 20.9 (Rotation) Let $\Omega = [0, 1)$, let $\mathcal{A} = \mathcal{B}(\Omega)$ and let $\mathbf{P} = \lambda$ be the Lebesgue measure. Let $r \in (0, 1)$ and $\tau_r(x) = x + r \pmod{1}$. Clearly, $(\Omega, \mathcal{A}, \mathbf{P}, \tau_r)$ is a measure-preserving dynamical system. We will show

$$(\Omega, \mathcal{A}, \mathbf{P}, \tau_r) \text{ is ergodic} \iff r \text{ is irrational.}$$

Let $f : [0, 1) \rightarrow \mathbb{R}$ be an $\mathcal{I}$ -measurable function. Without loss of generality, we assume that f is bounded and thus square integrable. Hence f can be expanded in a Fourier series

$$f(x) = \sum_{n=-\infty}^{\infty} c_n e^{2\pi i n x} \quad \text{for } \mathbf{P}\text{-a.a. } x.$$

This series converges in L^2 , and the sequence of square summable coefficients $(c_n)_{n \in \mathbb{Z}}$ is unique (compare Exercise 7.3.1 with $c_n = (-i/2)a_n + (1/2)b_n$ and $c_{-n} = (i/2)a_n + (1/2)b_n$ for $n \in \mathbb{N}$ as well as $c_0 = b_0$). Now we compute

$$(f \circ \tau_r)(x) = \sum_{n=-\infty}^{\infty} (c_n e^{2\pi i n r}) e^{2\pi i n x} \quad \text{a.e.}$$

By Lemma 20.7, f is $\mathcal{I}$ -measurable if and only if $f = f \circ \tau_r$; that is, if and only if

$$c_n = c_n e^{2\pi i n r} \quad \text{for all } n \in \mathbb{Z}$$

If r is irrational, this implies $c_n = 0$ for $n \neq 0$, and thus f is almost surely constant. Therefore, $(\Omega, \mathcal{A}, \mathbf{P}, \tau_r)$ is ergodic.

On the other hand, if r is rational, then there exists some $n \in \mathbb{Z} \setminus \{0\}$ with $e^{2\pi i n r} = e^{-2\pi i n r} = 1$. Hence $x \mapsto e^{2\pi i n x} + e^{-2\pi i n x} = 2 \cos(2\pi n x)$ is $\mathcal{I}$ -measurable but not a.s. constant. Thus, in this case $(\Omega, \mathcal{A}, \mathbf{P}, \tau_r)$ is not ergodic.

Example 20.10 Let $X = (X_n)_{n \in \mathbb{N}_0}$ be a stochastic process with values in a Polish space E . Without loss of generality, we may assume that X is the canonical process on the probability space $(\Omega, \mathcal{A}, \mathbf{P}) = (E^{\mathbb{N}_0}, \mathcal{B}(E)^{\otimes \mathbb{N}_0}, \mathbf{P})$. Define the shift operator

$$\tau : \Omega \rightarrow \Omega, \quad (\omega_n)_{n \in \mathbb{N}_0} \mapsto (\omega_{n+1})_{n \in \mathbb{N}_0}$$

Then $X_n(\omega) = X_0(\tau^n(\omega))$. Hence X is stationary if and only if $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ is a measure-preserving dynamical system.

Definition 20.11 The stochastic process X (from Example 20.10) is called ergodic if $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ is ergodic.

Example 20.12 Let $(X_n)_{n \in \mathbb{N}_0}$ be i.i.d. and let $X_n(\omega) = X_0(\tau^n(\omega))$. If $A \in \mathcal{I}$, then, for every $n \in \mathbb{N}$,

$$A = \tau^{-n}(A) = \{\omega : \tau^n(\omega) \in A\} \in \sigma(X_n, X_{n+1}, \dots)$$

Hence, if we let $\mathcal{T}$ be the tail σ -algebra of $(X_n)_{n \in \mathbb{N}}$ (see Definition 2.34), then

$$\mathcal{I} \subset \mathcal{T} = \bigcap_{n=1}^{\infty} \sigma(X_n, X_{n+1}, \dots)$$

By Kolmogorov's 0-1 law (Theorem 2.37), $\mathcal{T}$ is $\mathbf{P}$ -trivial. Hence $\mathcal{I}$ is also $\mathbf{P}$ -trivial and therefore $(X_n)_{n \in \mathbb{N}_0}$ is ergodic.

Exercise 20.1.1 Let G be a finite group of measure-preserving measurable maps on $(\Omega, \mathcal{A}, \mathbf{P})$ and let $\mathcal{A}_0 := \{A \in \mathcal{A} : g(A) = A \text{ for all } g \in G\}$.

Show that, for every $X \in \mathcal{L}^1(\mathbf{P})$, we have

$$\mathbf{E}[X \mid \mathcal{A}_0] = \frac{1}{\#G} \sum_{g \in G} X \circ g.$$

5.20.2 20.2 Ergodic Theorems

In this section, $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ always denotes a measure-preserving dynamical system. Further, let $f : \Omega \rightarrow \mathbb{R}$ be measurable and

$$X_n(\omega) = f \circ \tau^n(\omega) \quad \text{for all } n \in \mathbb{N}_0$$

Hence $X = (X_n)_{n \in \mathbb{N}_0}$ is a stationary real-valued stochastic process. Let

$$S_n = \sum_{k=0}^{n-1} X_k$$

denote the n th partial sum. Ergodic theorems are laws of large numbers for $(S_n)_{n \in \mathbb{N}}$. We start with a preliminary lemma.

Lemma 20.13 (Hopf's maximal-ergodic lemma) Let $X_0 \in \mathcal{L}^1(\mathbf{P})$. Define $M_n = \max \{0, S_1, \dots, S_n\}$, $n \in \mathbb{N}$. Then

$$\mathbf{E} [X_0 \mathbb{1}_{\{M_n > 0\}}] \geq 0 \quad \text{for every } n \in \mathbb{N}.$$

Proof For $k \leq n$, we have $M_n(\tau(\omega)) \geq S_k(\tau(\omega))$. Hence

$$X_0 + M_n \circ \tau \geq X_0 + S_k \circ \tau = S_{k+1}$$

Thus $X_0 \geq S_{k+1} - M_n \circ \tau$ for $k = 1, \dots, n$. Manifestly, $S_1 = X_0$ and $M_n \circ \tau \geq 0$ and hence also (for $k = 0$) $X_0 \geq S_1 - M_n \circ \tau$. Therefore,

$$X_0 \geq \max \{S_1, \dots, S_n\} - M_n \circ \tau \quad (20.2)$$

Furthermore, we have

$$\{M_n > 0\}^c \subset \{M_n = 0\} \cap \{M_n \circ \tau \geq 0\} \subset \{M_n - M_n \circ \tau \leq 0\}. \quad (20.3)$$

By (20.2) and (20.3), and since τ is measure-preserving, we conclude that

$$\begin{aligned} \mathbf{E} [X_0 \mathbb{1}_{\{M_n > 0\}}] &\geq \mathbf{E} [(\max \{S_1, \dots, S_n\} - M_n \circ \tau) \mathbb{1}_{\{M_n > 0\}}] \\ &= \mathbf{E} [(M_n - M_n \circ \tau) \mathbb{1}_{\{M_n > 0\}}] \\ &\geq \mathbf{E} [M_n - M_n \circ \tau] = \mathbf{E} [M_n] - \mathbf{E} [M_n] = 0. \end{aligned}$$

Theorem 20.14 (Individual ergodic theorem, Birkhoff (1931), [16]) Let $f = X_0 \in \mathcal{L}^1(\mathbf{P})$. Then

$$\frac{1}{n} \sum_{k=0}^{n-1} X_k = \frac{1}{n} \sum_{k=0}^{n-1} f \circ \tau^k \xrightarrow{n \rightarrow \infty} \mathbf{E} [X_0 \mid \mathcal{I}] \quad \mathbf{P}\text{-a.s.}$$

In particular, if τ is ergodic, then

$$\frac{1}{n} \sum_{k=0}^{n-1} X_k \xrightarrow{n \rightarrow \infty} \mathbf{E} [X_0] \quad \mathbf{P}\text{-a.s.}$$

Proof If τ is ergodic, then $\mathbf{E} [X_0 \mid \mathcal{I}] = \mathbf{E} [X_0]$ and the supplement is a consequence of the first statement.

Consider now the general case. By Lemma 20.7, we have $\mathbf{E} [X_0 \mid \mathcal{I}] \circ \tau = \mathbf{E} [X_0 \mid \mathcal{I}]$ $\mathbf{P}$ -a.s. Hence, by passing to $\tilde{X}_n := X_n - \mathbf{E} [X_0 \mid \mathcal{I}]$, without loss of generality, we can assume $\mathbf{E} [X_0 \mid \mathcal{I}] = 0$. Define

$$Z := \limsup_{n \rightarrow \infty} \frac{1}{n} S_n$$

Let $\varepsilon > 0$ and $F := \{Z > \varepsilon\}$. We have to show that $\mathbf{P}[F] = 0$. From this we infer $\mathbf{P}[Z > 0] = 0$ and similarly (with $-X$ instead of X) also $\liminf_{n \rightarrow \infty} \frac{1}{n} S_n \geq 0$ almost surely. Hence $\frac{1}{n} S_n \xrightarrow{n \rightarrow \infty} 0$ a.s.

Evidently, $Z \circ \tau = Z$; hence $F \in \mathcal{I}$. Define

$$X_n^\varepsilon := (X_n - \varepsilon) \mathbb{1}_F, \quad S_n^\varepsilon := X_0^\varepsilon + \dots + X_{n-1}^\varepsilon$$

$$M_n^\varepsilon := \max \{0, S_1^\varepsilon, \dots, S_n^\varepsilon\}, \quad F_n := \{M_n^\varepsilon > 0\}$$

Then $F_1 \subset F_2 \subset \dots$ and

$$\bigcup_{n=1}^{\infty} F_n = \left\{ \sup_{k \in \mathbb{N}} \frac{1}{k} S_k^\varepsilon > 0 \right\} = \left\{ \sup_{k \in \mathbb{N}} \frac{1}{k} S_k > \varepsilon \right\} \cap F = F$$

hence $F_n \uparrow F$. Dominated convergence yields $\mathbf{E}[X_0^\varepsilon \mathbb{1}_{F_n}] \xrightarrow{n \rightarrow \infty} \mathbf{E}[X_0^\varepsilon]$.

By the maximal-ergodic lemma (applied to X^ε), we have $\mathbf{E}[X_0^\varepsilon \mathbb{1}_{F_n}] \geq 0$; hence

$$0 \leq \mathbf{E}[X_0^\varepsilon] = \mathbf{E}[(X_0 - \varepsilon) \mathbb{1}_F]$$

$$= \mathbf{E}[\mathbf{E}[X_0 | \mathcal{I}] \mathbb{1}_F] - \varepsilon \mathbf{P}[F] = -\varepsilon \mathbf{P}[F]$$

We conclude that $\mathbf{P}[F] = 0$.

As a consequence, we obtain the statistical ergodic theorem, or L^p -ergodic theorem, that was found by von Neumann in 1931 right before Birkhoff proved his ergodic theorem, but was published only later in [122]. Before we formulate it, we state one more lemma.

Lemma 20.15 Let $p \geq 1$ and let $X_0, X_1, \dots$ be identically distributed, real random variables with $\mathbf{E}[|X_0|^p] < \infty$. Define $Y_n := \left| \frac{1}{n} \sum_{k=0}^{n-1} X_k \right|^p$ for $n \in \mathbb{N}$. Then $(Y_n)_{n \in \mathbb{N}}$ is uniformly integrable.

Proof Evidently, the singleton $\{|X_0|^p\}$ is uniformly integrable. Hence, by Theorem 6.19, there exists a monotone increasing convex map $f : [0, \infty) \rightarrow [0, \infty)$ with $\frac{f(x)}{x} \rightarrow \infty$ for $x \rightarrow \infty$ and $C := \mathbf{E}[f(|X_0|^p)] < \infty$. Again, by Theorem 6.19, it is enough to show that $\mathbf{E}[f(Y_n)] \leq C$ for every $n \in \mathbb{N}$. By Jensen's inequality (for $x \mapsto |x|^p$), we have

$$Y_n \leq \frac{1}{n} \sum_{k=0}^{n-1} |X_k|^p$$

Again, by Jensen's inequality (now applied to f), we get that

$$f(Y_n) \leq f\left(\frac{1}{n} \sum_{k=0}^{n-1} |X_k|^p\right) \leq \frac{1}{n} \sum_{k=0}^{n-1} f(|X_k|^p).$$

Hence $\mathbf{E}[f(Y_n)] \leq \frac{1}{n} \sum_{k=0}^{n-1} \mathbf{E}[f(|X_k|^p)] = C$.

Theorem 20.16 (L^p -ergodic theorem, von Neumann (1931)) Let $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ be a measure-preserving dynamical system, $p \geq 1$, $X_0 \in \mathcal{L}^p(\mathbf{P})$ and $X_n = X_0 \circ \tau^n$. Then

$$\frac{1}{n} \sum_{k=0}^{n-1} X_k \xrightarrow{n \rightarrow \infty} \mathbf{E}[X_0 | \mathcal{I}] \quad \text{in } L^p(\mathbf{P})$$

In particular, if τ is ergodic, then $\frac{1}{n} \sum_{k=0}^{n-1} X_k \xrightarrow{n \rightarrow \infty} \mathbf{E}[X_0]$ in $L^p(\mathbf{P})$.

Proof Define

$$Y_n := \left| \frac{1}{n} \sum_{k=0}^{n-1} X_k - \mathbf{E}[X_0 | \mathcal{I}] \right|^p \quad \text{for every } n \in \mathbb{N}.$$

By Lemma 20.15, $(Y_n)_{n \in \mathbb{N}}$ is uniformly integrable, and by Birkhoff's ergodic theorem, we have $Y_n \xrightarrow{n \rightarrow \infty} 0$ almost surely. By Theorem 6.25, we thus have $\lim_{n \rightarrow \infty} \mathbf{E}[Y_n] = 0$.

If τ is ergodic, then $\mathbf{E}[X_0 | \mathcal{I}] = \mathbf{E}[X_0]$.

5.20.3 20.3 Examples

Example 20.17 Let $(X, (\mathbf{P}_x)_{x \in E})$ be a positive recurrent, irreducible Markov chain on the countable space E . Let π be the invariant distribution of X . Then $\pi(\{x\}) > 0$ for every $x \in E$. Define $\mathbf{P}_\pi = \sum_{x \in E} \pi(\{x\}) \mathbf{P}_x$. Then X is stationary on $(\Omega, \mathcal{A}, \mathbf{P}_\pi)$. Denote the shift by τ ; that is, $X_n = X_0 \circ \tau^n$.

Now let $A \in \mathcal{I}$ be invariant. Then $A \in \mathcal{T} = \bigcap_{n=1}^{\infty} \sigma(X_n, X_{n+1}, \dots)$. By the strong Markov property, for every finite stopping time σ (recall that $\mathcal{F}_\sigma$ is the σ algebra of the σ -past),

$$\mathbf{P}_\pi[X \in A \mid \mathcal{F}_\sigma] = \mathbf{P}_{X_\sigma}[X \in A]. \quad (20.4)$$

Indeed, we have $\{X \in A\} = \{X \in \tau^{-n}(A)\} = \{(X_n, X_{n+1}, \dots) \in A\}$. For $B \in \mathcal{F}_\sigma$, using the Markov property (in the third line), we get

$$\begin{aligned} \mathbf{E}_\pi[\mathbb{1}_{\{X \in B\}} \mathbb{1}_{\{X \in A\}}] &= \sum_{n=0}^{\infty} \sum_{x \in E} \mathbf{P}_\pi[X \in B, \sigma = n, X_n = x, X \in A] \\ &= \sum_{n=0}^{\infty} \sum_{x \in E} \mathbf{P}_\pi[X \in B, \sigma = n, X_n = x, X \circ \tau^n \in A] \\ &= \sum_{n=0}^{\infty} \sum_{x \in E} \mathbf{P}_\pi[X \in B, \sigma = n, X_n = x] \mathbf{P}_x[X \in A] \\ &= \mathbf{E}_\pi[\mathbb{1}_{\{X \in B\}} \mathbf{P}_{X_\sigma}[X \in A]]. \end{aligned}$$

In particular, if $x \in E$ and $\sigma_x = \inf\{n \in \mathbb{N}_0 : X_n = x\}$, then $\sigma_x < \infty$ since X is recurrent and irreducible. By (20.4), we conclude that, for every $x \in E$,

$$\mathbf{P}_\pi[X \in A] = \mathbf{E}_\pi[\mathbf{P}_x[X \in A]] = \mathbf{P}_x[X \in A].$$

Hence $\mathbf{P}_{X_n}[X \in A] = \mathbf{P}_\pi[X \in A]$ almost surely and thus (with $\sigma = n$ in (20.4))

$$\mathbf{P}_\pi[X \in A \mid X_0, \dots, X_n] = \mathbf{P}_{X_n}[X \in A] = \mathbf{P}_\pi[X \in A].$$

Now $A \in \mathcal{I} \subset \sigma(X_1, X_2, \dots)$; hence

$$\mathbf{P}_\pi[X \in A \mid X_0, \dots, X_n] \xrightarrow{n \rightarrow \infty} \mathbf{P}_\pi[X \in A \mid \sigma(X_0, X_1, \dots)] = \mathbb{1}_{\{X \in A\}}.$$

This implies $\mathbf{P}_\pi[X \in A] \in \{0, 1\}$. Hence X is ergodic.

Birkhoff's ergodic theorem now implies that, for every $x \in E$,

$$\frac{1}{n} \sum_{k=0}^{n-1} \mathbb{1}_{\{X_k = x\}} \xrightarrow{n \rightarrow \infty} \pi(\{x\}) \quad \mathbf{P}_\pi - \text{a.s.}$$

In this sense, $\pi(\{x\})$ is the average time X spends in x in the long run.

Example 20.18 Let P and Q be probability measures on the measurable space $(\Omega, \mathcal{A})$, and let $(\Omega, \mathcal{A}, P, \tau)$ and $(\Omega, \mathcal{A}, Q, \tau)$ be ergodic. Then either $P = Q$ or $P \perp Q$. Indeed, if $P \neq Q$, then there exists an f with $|f| \leq 1$ and $\int f dP \neq \int f dQ$. However, by Birkhoff's ergodic theorem,

$$\frac{1}{n} \sum_{k=0}^{n-1} f \circ \tau^k \xrightarrow{n \rightarrow \infty} \begin{cases} \int f dP & P\text{-a.s.} \\ \int f dQ & Q\text{-a.s.} \end{cases}$$

If we define $A := \left\{ \frac{1}{n} \sum_{k=0}^{n-1} f \circ \tau^k \xrightarrow{n \rightarrow \infty} \int f dP \right\}$, then $P(A) = 1$ and $Q(A) = 0$. Thus $P \perp Q$.

Exercise 20.3.1 Let $(\Omega, \mathcal{A})$ be a measurable space and let $\tau : \Omega \rightarrow \Omega$ be a measurable map.

- (i) Show that the set $\mathcal{M} := \{\mu \in \mathcal{M}_1(\Omega) : \mu \circ \tau^{-1} = \mu\}$ of τ -invariant measures is convex.
 (ii) An element μ of $\mathcal{M}$ is called extremal if $\mu = \lambda\mu_1 + (1 - \lambda)\mu_2$ for some $\mu_1, \mu_2 \in \mathcal{M}$ and $\lambda \in (0, 1)$ implies $\mu = \mu_1 = \mu_2$. Show that $\mu \in \mathcal{M}$ is extremal if and only if τ is ergodic with respect to μ .

Exercise 20.3.2 Let $p = 2, 3, 5, 6, 7, 10, \dots$ be square-free (that is, there is no number $r = 2, 3, 4, \dots$, whose square is a divisor of p) and let $q \in \{2, 3, \dots, p-1\}$. For every $n \in \mathbb{N}$, let a_n be the leading digit of the p -adic expansion of q^n .

Show the following version of Benford's law: For every $d \in \{1, \dots, p-1\}$,

$$\frac{1}{n} \# \{i \leq n : a_i = d\} \xrightarrow{n \rightarrow \infty} \frac{\log(d+1) - \log(d)}{\log(p)}$$

5.20.4 20.4 Application: Recurrence of Random Walks

Let $(X_n)_{n \in \mathbb{N}}$ be a stationary process with values in $\mathbb{R}^d$. Define $S_n := \sum_{k=1}^n X_k$ for $n \in \mathbb{N}_0$. Further, let

$$R_n = \# \{S_1, \dots, S_n\}$$

denote the range of S ; that is, the number of distinct points visited by S up to time n . Finally, let $A := \{S_n \neq 0 \text{ for every } n \in \mathbb{N}\}$ be the event of an "escape" from 0.

Theorem 20.19 We have $\lim_{n \rightarrow \infty} \frac{1}{n} R_n = \mathbf{P}[A \mid \mathcal{I}]$ almost surely.

Proof Let X be the canonical process on $(\Omega, \mathcal{A}, \mathbf{P}) = \left((\mathbb{R}^d)^{\mathbb{N}}, \mathcal{B}(\mathbb{R}^d)^{\otimes \mathbb{N}}, \mathbf{P} \right)$ and let $\tau : \Omega \rightarrow \Omega$ be the shift; that is, $X_n = X_0 \circ \tau^n$.

Evidently,

$$\begin{aligned} R_n &= \# \{k \leq n : S_l \neq S_k \text{ for all } l \in \{k+1, \dots, n\}\} \\ &\geq \# \{k \leq n : S_l \neq S_k \text{ for all } l > k\} \\ &= \sum_{k=1}^n \mathbb{1}_A \circ \tau^k \end{aligned}$$

Birkhoff's ergodic theorem yields

$$\liminf_{n \rightarrow \infty} \frac{1}{n} R_n \geq \mathbf{P}[A \mid \mathcal{I}] \quad \text{a.s.} \quad (20.5)$$

For the converse inequality, consider $A_m = \{S_l \neq 0 \text{ for } l = 1, \dots, m\}$. Then, for every $n \geq m$,

$$\begin{aligned} R_n &\leq m + \# \{k \leq n - m : S_l \neq S_k \text{ for all } l \in \{k+1, \dots, n\}\} \\ &\leq m + \# \{k \leq n - m : S_l \neq S_k \text{ for all } l \in \{k+1, \dots, k+m\}\} \\ &= m + \sum_{k=1}^{n-m} \mathbb{1}_{A_m} \circ \tau^k \end{aligned}$$

Again, by the ergodic theorem,

$$\limsup_{n \rightarrow \infty} \frac{1}{n} R_n \leq \mathbf{P}[A_m \mid \mathcal{I}] \quad \text{a.s.} \quad (20.6)$$

Since $A_m \downarrow A$ and $\mathbf{P}[A_m \mid \mathcal{I}] \xrightarrow{n \rightarrow \infty} \mathbf{P}[A \mid \mathcal{I}]$ almost surely (by Theorem 8.14(viii)), the claim follows from (20.5) and (20.6).

Theorem 20.20 Let $X = (X_n)_{n \in \mathbb{N}}$ be an integer-valued, integrable, stationary process with the property $\mathbf{E}[X_1 \mid \mathcal{I}] = 0$ a.s. Let $S_n = X_1 + \dots + X_n$, $n \in \mathbb{N}$. Then

$$\mathbf{P}[S_n = 0 \text{ for infinitely many } n \in \mathbb{N}] = 1.$$

In particular, a random walk on $\mathbb{Z}$ with centered increments is recurrent (ChungFuchs theorem, compare Theorem 17.40).

Proof Define $A = \{S_n \neq 0 \text{ for all } n \in \mathbb{N}\}$.

Step 1. We show $\mathbf{P}[A] = 0$. (If X is i.i.d., then S is a Markov chain, and this implies immediately that 0 is recurrent. Only for the more general case of stationary X do we need an additional argument.) By the ergodic theorem, we have

$\frac{1}{n} S_n \xrightarrow{n \rightarrow \infty} \mathbf{E}[X_1 | \mathcal{I}] = 0$ a.s. Thus, for every $m \in \mathbb{N}$,

$$\begin{aligned} \limsup_{n \rightarrow \infty} \left(\frac{1}{n} \max_{k=1, \dots, n} |S_k| \right) &= \limsup_{n \rightarrow \infty} \left(\frac{1}{n} \max_{k=m, \dots, n} |S_k| \right) \\ &\leq \max_{k \geq m} \frac{|S_k|}{k} \xrightarrow{m \rightarrow \infty} 0 \end{aligned}$$

Therefore,

$$\lim_{n \rightarrow \infty} \left(\frac{1}{n} \max_{k=1, \dots, n} S_k \right) = \lim_{n \rightarrow \infty} \left(\frac{1}{n} \min_{k=1, \dots, n} S_k \right) = 0$$

Now $R_n \leq 1 + (\max_{k=1, \dots, n} S_k) - (\min_{k=1, \dots, n} S_k)$; hence $\frac{1}{n} R_n \xrightarrow{n \rightarrow \infty} 0$. By Theorem 20.19, this implies $\mathbf{P}[A] = 0$.

Step 2. Define $\sigma_n := \inf \{m \in \mathbb{N} : S_{m+n} = S_n\}$, $B_n := \{\sigma_n < \infty\}$ for $n \in \mathbb{N}_0$ and $B := \bigcap_{n=0}^{\infty} B_n$.

Since $\{\sigma_0 = \infty\} = A$, we have $\mathbf{P}[\sigma_0 < \infty] = 1$. By stationarity, $\mathbf{P}[\sigma_n < \infty] = 1$ for every $n \in \mathbb{N}_0$; hence $\mathbf{P}[B] = 1$.

Let $\tau_0 = 0$ and inductively define $\tau_{n+1} = \tau_n + \sigma_{\tau_n}$ for $n \in \mathbb{N}_0$. Then τ_n is the time of the n th return of S to 0. On B we have $\tau_n < \infty$ for every $n \in \mathbb{N}_0$ and hence

$$\mathbf{P}[S_n = 0 \text{ infinitely often}] = \mathbf{P}[\tau_n < \infty \text{ for all } n \in \mathbb{N}] \geq \mathbf{P}[B] = 1.$$

If in Theorem 20.20 the random variables X_n are not integer-valued, then there is no hope that $S_n = 0$ for any $n \in \mathbb{N}$ with positive probability. On the other hand, in this case, there is also some kind of recurrence property, namely $S_n/n \xrightarrow{n \rightarrow \infty} 0$ almost surely by the ergodic theorem. Note, however, that this does not exclude the possibility that $S_n \xrightarrow{n \rightarrow \infty} \infty$ with positive probability; for instance, if S_n grows like $\sqrt{n}$. The next theorem shows that if the X_n are integrable, then the process of partial sums can go to infinity only with a linear speed.

Theorem 20.21 Let $(X_n)_{n \in \mathbb{N}}$ be an integrable ergodic process and define $S_n = X_1 + \dots + X_n$ for $n \in \mathbb{N}_0$. Then the following statements are equivalent.

(i) $S_n \xrightarrow{n \rightarrow \infty} \infty$ almost surely.

(ii) $\mathbf{P}\left[S_n \xrightarrow{n \rightarrow \infty} \infty\right] > 0$.

(iii) $\lim_{n \rightarrow \infty} \frac{S_n}{n} = \mathbf{E}[X_1] > 0$ almost surely.

If the random variables $X_1, X_2, \dots$ are i.i.d. with $\mathbf{E}[X_1] = 0$ and $\mathbf{P}[X_1 = 0] < 1$, then $\liminf_{n \rightarrow \infty} S_n = -\infty$ and $\limsup_{n \rightarrow \infty} S_n = \infty$ almost surely.

Proof "(i) $\iff$ (ii)" Clearly, $\left\{S_n \xrightarrow{n \rightarrow \infty} \infty\right\}$ is an invariant event and thus has probability either 0 or 1.

"(iii) $\implies$ (i)" This is trivial.

"(i) $\implies$ (iii)" The equality follows by the individual ergodic theorem. Hence, it is enough to show that $\liminf_{n \rightarrow \infty} S_n/n > 0$ almost surely.

For $n \in \mathbb{N}_0$ and $\varepsilon > 0$, let

$$A_n^\varepsilon := \{S_m > S_n + \varepsilon \text{ for all } m \geq n+1\}.$$

Let $S^- := \inf \{S_n : n \in \mathbb{N}_0\}$. By assumption (i), we have $S^- > -\infty$ almost surely and $\tau := \sup \{n \in \mathbb{N}_0 : S_n = S^-\}$ is finite almost surely. Hence there is an $N \in \mathbb{N}$ with $\mathbf{P}[\tau < N] \geq \frac{1}{2}$. Therefore,

$$\mathbf{P} \left[\bigcup_{n=0}^{N-1} A_n^0 \right] = \mathbf{P}[\tau < N] \geq \frac{1}{2}$$

Since $A_n^\varepsilon \uparrow A_n^0$ for $\varepsilon \downarrow 0$, there is an $\varepsilon > 0$ with $p := \mathbf{P}[A_0^\varepsilon] \geq \frac{1}{4N} > 0$. As $(X_n)_{n \in \mathbb{N}}$ is ergodic, $(\mathbb{1}_{A_n^\varepsilon})_{n \in \mathbb{N}_0}$ is also ergodic. By the individual ergodic theorem, we conclude that $\frac{1}{n} \sum_{i=0}^{n-1} \mathbb{1}_{A_i^\varepsilon} \xrightarrow{n \rightarrow \infty} p$ almost surely. Hence there exists an $n_0 = n_0(\omega)$ such that $\sum_{i=0}^{n-1} \mathbb{1}_{A_i^\varepsilon} \geq \frac{pn}{2}$ for all $n \geq n_0$. This implies $S_n \geq \frac{pn\varepsilon}{2}$ for $n \geq n_0$ and hence $\liminf_{n \rightarrow \infty} S_n/n \geq \frac{pn\varepsilon}{2} > 0$.

The additional statement follows since $\liminf S_n$ and $\limsup S_n$ cannot assume any finite value and are thus measurable with respect to the tail σ -algebra, which implies that they are constantly $-\infty$ or $+\infty$. By what we have shown, we can exclude $S_n \xrightarrow{n \rightarrow \infty} \infty$; hence we have $\liminf_{n \rightarrow \infty} S_n = -\infty$. Similarly, we get $\limsup_{n \rightarrow \infty} S_n = \infty$.

Remark 20.22 It can be shown that Theorem 20.21 holds also without the assumption that the X_n are integrable. See [94].

5.20.5 20.5 Mixing

Ergodicity provides a weak notion of "independence" or "mixing". At the other end of the scale, the strongest notion is "i.i.d.". Here we are concerned with notions of mixing that lie between these two.

In the following, we always assume that $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ is a measure-preserving dynamical system and that $X_n := X_0 \circ \tau^n$. We start with a simple observation.

Theorem 20.23 $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ is ergodic if and only if, for all $A, B \in \mathcal{A}$,

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{k=0}^{n-1} \mathbf{P}[A \cap \tau^{-k}(B)] = \mathbf{P}[A]\mathbf{P}[B] \quad (20.7)$$

Proof " $\implies$ " Let $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ be ergodic. Define

$$Y_n := \frac{1}{n} \sum_{k=0}^{n-1} \mathbb{1}_{\tau^{-k}(B)} = \frac{1}{n} \sum_{k=0}^{n-1} \mathbb{1}_B \circ \tau^k$$

By Birkhoff's ergodic theorem, we have $Y_n \xrightarrow{n \rightarrow \infty} \mathbf{P}[B]$ almost surely. Hence $Y_n \mathbb{1}_A \xrightarrow{n \rightarrow \infty} \mathbb{1}_A \mathbf{P}[B]$ almost surely. Dominated convergence yields

$$\frac{1}{n} \sum_{k=0}^{n-1} \mathbf{P}[A \cap \tau^{-k}(B)] = \mathbf{E}[Y_n \mathbb{1}_A] \xrightarrow{n \rightarrow \infty} \mathbf{E}[\mathbb{1}_A \mathbf{P}[B]] = \mathbf{P}[A]\mathbf{P}[B]$$

" $\Leftarrow$ " Now assume that (20.7) holds. Let $A \in \mathcal{I}$ (recall that $\mathcal{I}$ is the invariant σ -algebra) and $B = A$. Evidently, $A \cap \tau^{-k}(A) = A$ for every $k \in \mathbb{N}_0$. Hence, by (20.7),

$$\mathbf{P}[A] = \frac{1}{n} \sum_{k=0}^{n-1} \mathbf{P}[A \cap \tau^{-k}(A)] \xrightarrow{n \rightarrow \infty} \mathbf{P}[A]^2$$

Thus $\mathbf{P}[A] \in \{0, 1\}$; hence $\mathcal{I}$ is trivial and therefore τ is ergodic.

We consider a strengthening of (20.7).

Definition 20.24 A measure-preserving dynamical system $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ is called mixing if

$$\lim_{n \rightarrow \infty} \mathbf{P}[A \cap \tau^{-n}(B)] = \mathbf{P}[A]\mathbf{P}[B] \quad \text{for all } A, B \in \mathcal{A} \quad (20.8)$$

Remark 20.25 Sometimes the mixing property of (20.8) is called strongly mixing, in contrast with a weakly mixing system $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$, for which we require only

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=0}^{n-1} |\mathbf{P}[A \cap \tau^{-i}(B)] - \mathbf{P}[A]\mathbf{P}[B]| = 0 \quad \text{for all } A, B \in \mathcal{A}$$

"Strongly mixing" implies "weakly mixing" (see Exercise 20.5.1). On the other hand, there exist weakly mixing systems that are not strongly mixing (see [81]).

Example 20.26 Let $I = \mathbb{N}_0$ or $I = \mathbb{Z}$, and let $(X_n)_{n \in I}$ be an i.i.d. sequence with values in the measurable space $(E, \mathcal{E})$. Hence τ is the shift on the product space $\Omega = E^I$, $\mathbf{P} = (\mathbf{P}_{X_0})^{\otimes I}$. Let $A, B \in \mathcal{E}^{\otimes I}$. For every $\varepsilon > 0$, there exist events A^ε and B^ε that depend on only finitely many coordinates and such that $\mathbf{P}[A \Delta A^\varepsilon] < \varepsilon$ and $\mathbf{P}[B \Delta B^\varepsilon] < \varepsilon$. Clearly, $\mathbf{P}[\tau^{-n}(A \Delta A^\varepsilon)] < \varepsilon$ and $\mathbf{P}[\tau^{-n}(B \Delta B^\varepsilon)] < \varepsilon$ for every $n \in \mathbb{Z}$. For sufficiently large $|n|$, the sets A^ε and $\tau^{-n}(B^\varepsilon)$ depend on different coordinates and are thus independent. This implies

$$\begin{aligned} & \limsup_{|n| \rightarrow \infty} |\mathbf{P}[A \cap \tau^{-n}(B)] - \mathbf{P}[A]\mathbf{P}[B]| \\ & \leq \limsup_{|n| \rightarrow \infty} |\mathbf{P}[A^\varepsilon \cap \tau^{-n}(B^\varepsilon)] - \mathbf{P}[A^\varepsilon]\mathbf{P}[B^\varepsilon]| + 4\varepsilon = 4\varepsilon \end{aligned}$$

Hence τ is mixing. Letting $A = B \in \mathcal{I}$, we obtain the 0-1 law for invariant events: $\mathbf{P}[A] \in \{0, 1\}$.

Remark 20.27 Clearly, (20.8) implies (20.7) and hence "mixing" implies "ergodic". The converse implication is false.

Example 20.28 Let $\Omega = [0, 1)$, $\mathcal{A} = \mathcal{B}([0, 1))$ and let $\mathbf{P} = \lambda$ be the Lebesgue measure on $([0, 1), \mathcal{B}([0, 1)))$. For $r \in [0, 1)$, define $\tau_r : \Omega \rightarrow \Omega$ by

$$\tau_r(x) = x + r - \lfloor x + r \rfloor = x + r \pmod{1}.$$

If r is irrational, then τ_r is ergodic (Example 20.9). However, τ_r is not mixing: Since r is irrational, there exists a sequence $k_n \uparrow \infty$ such that

$$\tau_r^{k_n}(0) \in \left(\frac{1}{4}, \frac{3}{4}\right) \quad \text{for } n \in \mathbb{N}.$$

Hence, for $A = [0, \frac{1}{4}]$, we have $A \cap \tau_r^{-k_n}(A) = \emptyset$. Therefore,

$$\liminf_{n \rightarrow \infty} \mathbf{P}[A \cap \tau_r^{-n}(A)] = 0 \neq \frac{1}{16} = \mathbf{P}[A]^2$$

Theorem 20.29 Let X be an irreducible, positive recurrent Markov chain on the countable space E and let π be its invariant distribution. Let $\mathbf{P}_\pi = \sum_{x \in E} \pi(x) \mathbf{P}_x$. Then:

- (i) X is ergodic (on $(\Omega, \mathcal{A}, \mathbf{P}_\pi)$).
- (ii) X is mixing if and only if X is aperiodic.

Proof (i) This has been shown already in Example 20.17.

(ii) As X is irreducible, by Theorem 17.51, we have $\pi(\{x\}) > 0$ for every $x \in E$.

" $\implies$ " Let X be periodic with period $d \geq 2$. If $n \in \mathbb{N}$ is not a multiple of d , then $p^n(x, x) = 0$. Hence, for $A = B = \{X_0 = x\}$,

$$\begin{aligned}\liminf_{n \rightarrow \infty} \mathbf{P}_\pi [X_0 = x, X_n = x] &= \liminf_{n \rightarrow \infty} \pi(\{x\}) p^n(x, x) \\ &= 0 \neq \pi(\{x\})^2 = \mathbf{P}_\pi [X_0 = x]^2\end{aligned}$$

Thus X is not mixing.

" $\Leftarrow$ " Let X be aperiodic. In order to simplify the notation, we may assume that X is the canonical process on $E^{\mathbb{N}_0}$. Let $A, B \subset \Omega = E^{\mathbb{N}_0}$ be measurable. For every $\varepsilon > 0$, there exists an $N \in \mathbb{N}$ and a $\tilde{A}^\varepsilon \in E^{\{0, \dots, N\}}$ such that, letting $A^\varepsilon = \tilde{A}^\varepsilon \times E^{\{N+1, N+2, \dots\}}$, we have $\mathbf{P}[A \Delta A^\varepsilon] < \varepsilon$. By the Markov property, for every $n \geq N$,

$$\begin{aligned}\mathbf{P}_\pi [A^\varepsilon \cap \tau^{-n}(B)] &= \mathbf{P}_\pi [(X_0, \dots, X_N) \in \tilde{A}^\varepsilon, (X_n, X_{n+1}, \dots) \in B] \\ &= \sum_{x, y \in E} \mathbf{E}_\pi [\mathbb{1}_{A^\varepsilon} \mathbb{1}_{\{X_N=x\}} \mathbb{1}_{\{X_n=y\}} (X_n, X_{n+1}, \dots) \in B] \\ &= \sum_{x, y \in E} \mathbf{E}_\pi [\mathbb{1}_{A^\varepsilon} \mathbb{1}_{\{X_N=x\}}] p^{n-N}(x, y) \mathbf{P}_y[B].\end{aligned}$$

By Theorem 18.13, we have $p^{n-N}(x, y) \xrightarrow{n \rightarrow \infty} \pi(\{y\})$ for all $x, y \in E$. (For periodic X , this is false.) Dominated convergence thus yields

$$\begin{aligned}\lim_{n \rightarrow \infty} \mathbf{P}_\pi [A^\varepsilon \cap \tau^{-n}(B)] &= \sum_{x, y \in E} \mathbf{E}_\pi [\mathbb{1}_{A^\varepsilon} \mathbb{1}_{\{X_N=x\}}] \pi(\{y\}) \mathbf{P}_y[B] \\ &= \mathbf{P}_\pi [A^\varepsilon] \mathbf{P}_\pi [B]\end{aligned}$$

Since $|\mathbf{P}_\pi [A^\varepsilon \cap \tau^{-n}(B)] - \mathbf{P}[A \cap \tau^{-n}(B)]| < \varepsilon$, the statement follows by letting $\varepsilon \rightarrow 0$.

Exercise 20.5.1 Show that "strongly mixing" implies "weakly mixing", which in turn implies "ergodic". Give an example of a measure-preserving dynamical system that is ergodic but not weakly mixing.

5.20.6 20.6 Entropy

The entropy $H(\mathbf{P})$ of a probability distribution $\mathbf{P}$ (see Definition 5.25) measures the amount of randomness in this distribution. In fact, the entropy of a delta distribution is zero and for a distribution on n points, the maximal entropy is achieved by the uniform distribution and equals $\log(n)$ (see Exercise 5.3.3). It is natural to use the entropy in order to quantify also the randomness of a dynamical system.

First we consider the situation of a simple shift: Let $\Omega = E^{\mathbb{N}_0}$, where E is a finite set equipped with the product σ -algebra $\mathcal{A} = (2^E)^{\otimes \mathbb{N}_0}$. Let τ be the shift on Ω and let $\mathbf{P}$ be an invariant probability measure. For $n \in \mathbb{N}$, denote by P_n the projection of $\mathbf{P}$ on $E^n = E^{\{0, \dots, n-1\}}$; that is,

$$P_n(\{(e_0, \dots, e_{n-1})\}) = \mathbf{P}[\{e_0\} \times \dots \times \{e_{n-1}\} \times E^{\{n, n+1, \dots\}}].$$

Denote by h_n the entropy of P_n . By Exercise 5.3.4, the entropy is subadditive:

$$h_{m+n} \leq h_m + h_n \quad \text{for } m, n \in \mathbb{N}.$$

Hence the following limit exists (see Exercise 20.6.2)

$$h := h(\mathbf{P}, \tau) := \lim_{n \rightarrow \infty} \frac{1}{n} h_n = \inf_{n \in \mathbb{N}} \frac{1}{n} h_n$$

Definition 20.30 (Entropy of the simple shift) $h(\mathbf{P}, \tau)$ is called the entropy of the dynamical system $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$.

Example 20.31 Assume that $\mathbf{P}$ is a product measure with marginals π on E . Then

$$h = H(\pi) = - \sum_{e \in E} \pi(\{e\}) \log(\pi(\{e\})).$$

Example 20.32 (Markov chain) Let $(X_n)_{n \in \mathbb{N}_0}$ be a Markov chain on E with transition matrix P and stationary distribution π . Let $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ be the corresponding dynamical system. For $x = (x_0, \dots, x_{n-1})$ and $0 \leq k < n-1$, let

$$p(k, x) = \pi(\{x_k\}) P(x_k, x_{k+1}) \dots P(x_{n-2}, x_{n-1}).$$

Then the entropy of P_n is (using stationarity of π in the third line)

$$\begin{aligned} H(P_n) &= - \sum_{x_0, \dots, x_{n-1} \in E} p(0, x) \log(p(0, x)) \\ &= - \sum_{x_0, \dots, x_{n-1} \in E} p(0, x) \left[\log(\pi(\{x_0\})) + \sum_{k=0}^{n-2} \log(P(x_k, x_{k+1})) \right] \\ &= H(\pi) - \sum_{k=0}^{n-2} \sum_{x_k, \dots, x_{n-1}} p(k, x) \log(P(x_k, x_{k+1})) \\ &= H(\pi) - (n-1) \sum_{x_0, x_1 \in E} \pi(\{x_0\}) P(x_0, x_1) \log(P(x_0, x_1)) \end{aligned}$$

We infer that the entropy of the dynamical system is

$$h(\mathbf{P}, \tau) = - \sum_{x, y \in E} \pi(\{x\}) P(x, y) \log(P(x, y)). \quad (20.9)$$

Example 20.33 (Integer rotation) Consider the rotation of Example 20.8. Let $n \in \mathbb{N} \setminus \{1\}$, $E = \mathbb{Z}/(n)$ and let $\mathbf{P}$ be the uniform distribution on Ω . Let $r \in \{1, \dots, n\}$ and

$$\tau : \Omega \rightarrow \Omega, \quad x \mapsto x + r \pmod{n}.$$

Clearly, $\tau^{(n)}$ is the identity map, hence $h_n = h_{2n} = \dots$ and thus $h(\mathbf{P}, \tau) = 0$.

We now come to the situation of the general dynamical system. Let $\mathcal{P}$ be a finite measurable partition of Ω ; that is, $\mathcal{P} = \{A_1, \dots, A_k\}$ for certain pairwise disjoint non-empty sets $A_1, \dots, A_k \in \mathcal{A}$ with $\Omega = A_1 \cup \dots \cup A_k$. Denote by $\mathcal{P}_n$ the partition that is generated by the sets $\bigcap_{l=0}^{n-1} \tau^{-l}(A_{i_l})$, $i_1, \dots, i_n \in \{1, \dots, k\}$. We define

$$h_n(\mathbf{P}, \tau; \mathcal{P}) = - \sum_{A \in \mathcal{P}_n} \mathbf{P}[A] \log(\mathbf{P}[A])$$

Similarly as in the simple shift case, we obtain the subadditivity of (h_n) and thus the existence of

$$h(\mathbf{P}, \tau; \mathcal{P}) := \lim_{n \rightarrow \infty} \frac{1}{n} h_n(\mathbf{P}, \tau; \mathcal{P}) = \inf_{n \in \mathbb{N}} \frac{1}{n} h_n(\mathbf{P}, \tau; \mathcal{P})$$

Definition 20.34 (Kolmogorov-Sinai entropy) The entropy of a (general) measurepreserving dynamical system $(\Omega, \mathcal{A}, \mathbf{P}, \tau)$ is

$$h(\mathbf{P}, \tau) = \sup_{\mathcal{P}} h(\mathbf{P}, \tau; \mathcal{P})$$

where the supremum is taken over all finite measurable partitions of Ω .

Theorem 20.35 (Kolmogorov-Sinai) Let $\mathcal{P}$ be a generator of $\mathcal{A}$; that is $\mathcal{A} = \sigma\left(\bigcup_{n \in \mathbb{N}_0} \tau^{-n}(\mathcal{P})\right)$. Then

$$h(\mathbf{P}, \tau) = h(\mathbf{P}, \tau; \mathcal{P})$$

Proof See, e.g., [88, Theorem 3.2.18], [167, Theorem 4.17] or [155].

The Kolmogorov-Sinai theorem shows that the entropy that was introduced in Definition 20.30 for simple shifts coincides with the entropy of Definition 20.34; simply take $\mathcal{P} = \{\{e\} \times E^{\mathbb{N}}, e \in E\}$ which generates the product σ -algebra on $\Omega = E^{\mathbb{N}_0}$.

Example 20.36 (Rotation) We come back to the rotation of Example 20.9. Let $\Omega = [0, 1)$, $\mathcal{A} = \mathcal{B}(\Omega)$, $\mathbf{P} = \lambda$ the Lebesgue measure, $r \in (0, 1)$ and $\tau_r(x) = x + r \pmod{1}$.

First assume that r is rational. Let $\mathcal{P}$ be an arbitrary finite measurable partition of Ω . Choose $n \in \mathbb{N}$ such that $rn \in \mathbb{N}_0$. As in Example 20.33 we obtain $h_n(\mathbf{P}, \tau_r; \mathcal{P}) = h_{kn}(\mathbf{P}, \tau_r; \mathcal{P})$ for all $k \in \mathbb{N}$, hence $h(\mathbf{P}, \tau_r, \mathcal{P}) = 0$. Concluding, we get $h(\mathbf{P}, \tau_r) = 0$.

Now assume that r is irrational. Choose the partition $\mathcal{P} = \{[0, 1/2), [1/2, 1)\}$. As r is irrational, it is easy to see that $\mathcal{A}$ is generated by $\bigcup_{n \in \mathbb{N}_0} \tau_r^{-n}(\mathcal{P})$. Hence $h(\mathbf{P}, \tau_r) = h(\mathbf{P}, \tau_r, \mathcal{P})$. In order to compute the latter quantity, we first determine the cardinality $\#\mathcal{P}_n$. To this end, consider the map

$$\begin{aligned} \phi_n : [0, 1) &\rightarrow \{0, 1\}^n \\ x &\mapsto (\mathbb{1}_{[1/2, 1)}(x), \mathbb{1}_{[1/2, 1)}(\tau_r(x)), \dots, \mathbb{1}_{[1/2, 1)}(\tau_r^{n-1}(x))) \end{aligned}$$

Clearly, we have $\#\phi_n([0, 1)) = \#\mathcal{P}_n$. As $x \in [0, 1)$ increases, each coordinate $\mathbb{1}_{[1/2, 1)}(\tau_r^k(x))$, $k = 1, \dots, n-1$, changes its value exactly twice. Only $\mathbb{1}_{[1/2, 1)}(x)$ changes the value exactly once. Summing up, we get $\#\phi_n([0, 1)) \leq 2n$. The maximal entropy of a probability measure on N points is achieved by the uniform distribution and is $\log(N)$. Consequently, $h_n(\mathbf{P}, \tau_r; \mathcal{P}) \leq \log(2n)$. We conclude that

$$h(\mathbf{P}, \tau_r) = h(\mathbf{P}, \tau_r; \mathcal{P}) = 0$$

Exercise 20.6.1 Let $\Omega = [0, 1)$ and $\tau : x \mapsto 2x \pmod{1}$. Let $\mathbf{P}$ be the Lebesgue measure on Ω . Determine $h(\mathbf{P}, \tau)$.

Exercise 20.6.2 Let $(a_n)_{n \in \mathbb{N}}$ be a sequence on nonnegative numbers. The sequence is called subadditive, if $a_{m+n} \leq a_m + a_n$ for all $m, n \in \mathbb{N}$. Show that the limit $\lim_{n \rightarrow \infty} a_n/n$ exists and that

$$\lim_{n \rightarrow \infty} \frac{1}{n} a_n = \inf_{n \in \mathbb{N}} \frac{1}{n} a_n$$

5.21 21 Brownian Motion

In Example 14.45, we constructed a (canonical) process $(X_t)_{t \in [0, \infty)}$ with independent stationary normally distributed increments. For example, such a process can be used to describe the motion of a particle immersed in water or the change of prices in the stock market. We are now interested in properties of this process X that cannot be described in terms of finite-dimensional distributions but reflect the whole path $t \mapsto X_t$. For example, we want to compute the distribution of the functional $F(X) := \sup_{t \in [0, 1]} X_t$. The first problem that has to be resolved is to show that $F(X)$ is a random variable.

In this chapter, we investigate continuity properties of paths of stochastic processes and show how they ensure measurability of some path functionals. Then we construct a version of X that has continuous paths, the so-called Wiener process or Brownian motion. Without exaggeration, it can be stated that Brownian motion is the central object of probability theory.

For further reading, we recommend, e.g., [86, 118, 144, 151].

5.21.1 21.1 Continuous Versions

A priori the paths of a canonical process are of course not continuous since every map $[0, \infty) \rightarrow \mathbb{R}$ is possible. Hence, it will be important to find out which paths are $\mathbf{P}$ -almost surely negligible.

Definition 21.1 Let X and Y be stochastic processes on $(\Omega, \mathcal{A}, \mathbf{P})$ with time set I and state space E . X and Y are called

(i) modifications or versions of each other if, for any $t \in I$, we have

$$X_t = Y_t \quad \mathbf{P}\text{-almost surely ,}$$

(ii) indistinguishable if there exists an $N \in \mathcal{A}$ with $\mathbf{P}[N] = 0$ such that

$$\{X_t \neq Y_t\} \subset N \quad \text{for all } t \in I$$

Clearly, indistinguishable processes are modifications of each other. Under certain assumptions on the continuity of the paths, however, the two notions coincide.

Definition 21.2 Let (E, d) and (E', d') be metric spaces and $\gamma \in (0, 1]$. A map $\varphi : E \rightarrow E'$ is called Hölder-continuous of order γ (briefly, Hölder- γ -continuous) at the point $r \in E$ if there exist $\varepsilon > 0$ and $C < \infty$ such that, for any $s \in E$ with $d(s, r) < \varepsilon$, we have

$$d'(\varphi(r), \varphi(s)) \leq C d(r, s)^\gamma. \quad (21.1)$$

φ is called locally Hölder-continuous of order γ if, for every $t \in E$, there exist $\varepsilon > 0$ and $C = C(t, \varepsilon) > 0$ such that, for all $s, r \in E$ with $d(s, t) < \varepsilon$ and $d(r, t) < \varepsilon$, the inequality (21.1) holds. Finally, φ is called Hölder-continuous of order γ if there exists a C such that (21.1) holds for all $s, r \in E$.

In the case $\gamma = 1$, Hölder continuity is Lipschitz continuity (see Definition 13.8). Furthermore, for $E = \mathbb{R}$ and $\gamma > 1$, every locally Hölder- γ -continuous function is constant. Evidently, a locally Hölder- γ -continuous map is Hölder- γ -continuous at every point. On the other hand, for a function φ that is Hölder- γ -continuous at a given point t , there need not exist an open neighborhood in which φ is continuous. In particular, φ need not be locally Hölder- γ -continuous.

We collect some simple properties of Hölder-continuous functions.

Lemma 21.3 Let $I \subset \mathbb{R}$ and let $f : I \rightarrow \mathbb{R}$ be locally Hölder-continuous of order $\gamma \in (0, 1]$. Then the following statements hold.

- (i) f is locally Hölder-continuous of order γ' for every $\gamma' \in (0, \gamma)$.
- (ii) If I is compact, then f is Hölder-continuous.
- (iii) Let I be a bounded interval of length $T > 0$. Assume that there exists an $\varepsilon > 0$ and an $C(\varepsilon) < \infty$ such that, for all $s, t \in I$ with $|t - s| \leq \varepsilon$, we have

$$|f(t) - f(s)| \leq C(\varepsilon) |t - s|^\gamma$$

Then f is Hölder-continuous of order γ with constant $C := C(\varepsilon) [T/\varepsilon]^{1-\gamma}$.

Proof (i) This is obvious since $|t - s|^\gamma \leq |t - s|^{\gamma'}$ for all $s, t \in I$ with $|t - s| \leq 1$.

(ii) For $t \in I$ and $\varepsilon > 0$, let $U_\varepsilon(t) := \{s \in I : |s - t| < \varepsilon\}$. For every $t \in I$, choose $\varepsilon(t) > 0$ and $C(t) < \infty$ such that

$$|f(r) - f(s)| \leq C(t) \cdot |r - s|^\gamma \quad \text{for all } r, s \in U_t := U_{\varepsilon(t)}(t).$$

There exists a finite subcovering $\mathfrak{U}' = \{U_{t_1}, \dots, U_{t_n}\}$ of the covering $\mathfrak{U} := \{U_t, t \in I\}$ of I . Let $\varrho > 0$ be a Lebesgue number of the covering $\mathfrak{U}'$; that is, $\varrho > 0$ is such that, for every $t \in I$, there exists a $U \in \mathfrak{U}$ such that $U_\varrho(t) \subset U$. Define

$$\bar{C} := \max \{C(t_1), \dots, C(t_n), 2\|f\|_\infty \varrho^{-\gamma}\}.$$

For $s, t \in I$ with $|t - s| < \varrho$, there is an $i \in \{1, \dots, n\}$ with $s, t \in U_{t_i}$. By assumption, we have $|f(t) - f(s)| \leq C(t_i) |t - s|^\gamma \leq \bar{C} |t - s|^\gamma$. Now let $s, t \in I$ with $|s - t| \geq \varrho$. Then

$$|f(t) - f(s)| \leq 2\|f\|_\infty \left(\frac{|t - s|}{\varrho} \right)^\gamma \leq \bar{C} |t - s|^\gamma.$$

Hence f is Hölder-continuous of order γ with constant $\bar{C}$.

(iii) Let $n = \lceil \frac{T}{\varepsilon} \rceil$. For $s, t \in I$, by assumption, $\frac{|t-s|}{n} \leq \varepsilon$ and thus

$$\begin{aligned} |f(t) - f(s)| &\leq \sum_{k=1}^n \left| f\left(s + (t-s)\frac{k}{n}\right) - f\left(s + (t-s)\frac{k-1}{n}\right) \right| \\ &\leq C(\varepsilon) n^{1-\gamma} |t - s|^\gamma = C |t - s|^\gamma \end{aligned}$$

□

Definition 21.4 (Path properties) Let $I \subset \mathbb{R}$ and let $X = (X_t, t \in I)$ be a stochastic process on some probability space $(\Omega, \mathcal{A}, \mathbf{P})$ with values in a metric space (E, d) . Let $\gamma \in (0, 1]$. For every $\omega \in \Omega$, we say that the map $I \rightarrow E, t \mapsto X_t(\omega)$ is a path of X .

We say that X has almost surely continuous paths, or briefly that X is a.s. continuous, if for almost all $\omega \in \Omega$, the path $t \mapsto X_t(\omega)$ is continuous. Similarly, we define locally Hölder- γ -continuous paths and so on.

Lemma 21.5 Let X and Y be modifications of each other. Assume that one of the following conditions holds.

- (i) I is countable.
- (ii) $I \subset \mathbb{R}$ is a (possibly unbounded) interval and X and Y are almost surely right continuous. Then X and Y are indistinguishable.

Proof Define $N_t := \{X_t \neq Y_t\}$ for $t \in I$ and $\bar{N} = \bigcup_{t \in I} N_t$. By assumption, $\mathbf{P}[N_t] = 0$ for every $t \in I$. We have to show that there exists an $N \in \mathcal{A}$ with $\bar{N} \subset N$ and $\mathbf{P}[N] = 0$.

- (i) If I is countable, then $N := \bar{N}$ is measurable and $\mathbf{P}[N] \leq \sum_{t \in I} \mathbf{P}[N_t] = 0$.
- (ii) Now let $I \subset \mathbb{R}$ be an interval and let X and Y be almost surely right continuous. Define

$$\bar{R} := \{X \text{ and } Y \text{ are right continuous}\}$$

and choose an $R \in \mathcal{A}$ with $R \subset \bar{R}$ and $\mathbf{P}[R] = 1$. Define

$$\tilde{I} := \begin{cases} \mathbb{Q} \cap I, & \text{if } I \text{ is open to the right,} \\ (\mathbb{Q} \cap I) \cup \max I, & \text{if } I \text{ is closed to the right,} \end{cases}$$

and $\tilde{N} := \bigcup_{r \in \tilde{I}} N_r$. By (i), we have $\mathbf{P}[\tilde{N}] = 0$. Furthermore, for every $t \in I$,

$$N_t \cap R \subset \bigcup_{r \geq t, r \in \tilde{I}} (N_r \cap R) \subset \tilde{N}.$$

Hence

$$\bar{N} \subset R^c \cup \bigcup_{t \in I} N_t \subset R^c \cup \tilde{N} =: N$$

and thus $\mathbf{P}[N] \leq \mathbf{P}[R^c] + \mathbf{P}[\tilde{N}] = 0$.

We come to the main theorem of this section.

Theorem 21.6 (Kolmogorov-Chentsov) Let $X = (X_t, t \in [0, \infty))$ be a realvalued process. Assume for every $T > 0$, there are numbers $\alpha, \beta, C > 0$ such that

$$\mathbf{E}[|X_t - X_s|^\alpha] \leq C|t - s|^{1+\beta} \quad \text{for all } s, t \in [0, T] \quad (21.2)$$

Then the following statements hold.

- (i) There is a modification $\tilde{X} = (\tilde{X}_t, t \in [0, \infty))$ of X whose paths are locally Hölder-continuous of every order $\gamma \in (0, \frac{\beta}{\alpha})$.
- (ii) Let $\gamma \in (0, \frac{\beta}{\alpha})$. For every $\varepsilon > 0$ and $T < \infty$, there exists a number $K < \infty$ that depends only on $\varepsilon, T, \alpha, \beta, C, \gamma$ such that

$$\mathbf{P}\left[\left|\tilde{X}_t - \tilde{X}_s\right| \leq K|t - s|^\gamma, s, t \in [0, T]\right] \geq 1 - \varepsilon. \quad (21.3)$$

Proof (i) It is enough to show that, for any $T > 0$, the process X on $[0, T]$ has a modification X^T that is locally Hölder-continuous of any order $\gamma \in (0, \beta/\alpha)$. For $S, T > 0$, by Lemma 21.5, two such modifications X^S and X^T are indistinguishable on $[0, S \wedge T]$; hence

$$\Omega_{S,T} := \{ \text{there is a } t \in [0, S \wedge T] \text{ with } X_t^T \neq X_t^S \}$$

is a null set and thus also $\Omega_\infty := \bigcup_{S,T \in \mathbb{N}} \Omega_{S,T}$ is a null set. Therefore, defining $\tilde{X}_t(\omega) := X_t^t(\omega)$, $t \geq 0$, for $\omega \in \Omega \setminus \Omega_\infty$, we get that $\tilde{X}$ is a locally Höldercontinuous modification of X on $[0, \infty)$.

Without loss of generality, assume $T = 1$. We show that X has a continuous modification on $[0, 1]$. By Chebyshev's inequality, for every $\varepsilon > 0$,

$$\mathbf{P}[|X_t - X_s| \geq \varepsilon] \leq C\varepsilon^{-\alpha}|t - s|^{1+\beta} \quad (21.4)$$

Hence

$$X_s \xrightarrow{s \rightarrow t} X_t \quad \text{in probability.} \quad (21.5)$$

The idea is first to construct $\tilde{X}$ on the dyadic rational numbers and then to extend it continuously to $[0, 1]$. To this end, we will need (21.5). In particular, for $\gamma > 0$, $n \in \mathbb{N}$ and $k \in \{1, \dots, 2^n\}$, we have

$$\mathbf{P}[|X_{k2^{-n}} - X_{(k-1)2^{-n}}| \geq 2^{-\gamma n}] \leq C2^{-n(1+\beta-\alpha\gamma)}.$$

Define

$$A_n = A_n(\gamma) := \{ \max \{ |X_{k2^{-n}} - X_{(k-1)2^{-n}}|, k \in \{1, \dots, 2^n\} \} \geq 2^{-\gamma n} \}$$

and

$$B_n := \bigcup_{m=n}^{\infty} A_m \quad \text{and} \quad N := \limsup_{n \rightarrow \infty} A_n = \bigcap_{n=1}^{\infty} B_n.$$

It follows that, for every $n \in \mathbb{N}$,

$$\mathbf{P}[A_n] \leq \sum_{k=1}^{2^n} \mathbf{P}[|X_{k2^{-n}} - X_{(k-1)2^{-n}}| \geq 2^{-\gamma n}] \leq C2^{-n(\beta-\alpha\gamma)}$$

Now fix $\gamma \in (0, \beta/\alpha)$ to obtain

$$\mathbf{P}[B_n] \leq \sum_{m=n}^{\infty} \mathbf{P}[A_m] \leq C \frac{2^{-(\beta-\alpha\gamma)n}}{1-2^{\alpha\gamma-\beta}} \xrightarrow{n \rightarrow \infty} 0 \quad (21.6)$$

hence $\mathbf{P}[N] = 0$. Now fix $\omega \in \Omega \setminus N$ and choose $n_0 = n_0(\omega)$ such that $\omega \notin \bigcup_{n=n_0}^{\infty} A_n$. Hence

$$|X_{k2^{-n}}(\omega) - X_{(k-1)2^{-n}}(\omega)| < 2^{-\gamma n} \quad \text{for } k \in \{1, \dots, 2^n\}, n \geq n_0. \quad (21.7)$$

Define the sets of finite dyadic rationals $D_m = \{k2^{-m}, k = 0, \dots, 2^m\}$, and let $D = \bigcup_{m \in \mathbb{N}} D_m$. Any $t \in D_m$ has a unique dyadic expansion

$$t = \sum_{i=0}^m b_i(t) 2^{-i} \quad \text{for some } b_i(t) \in \{0, 1\}, i = 0, \dots, m$$

Let $m \geq n \geq n_0$ and $s, t \in D_m, s \leq t$ with $|s - t| \leq 2^{-n}$. Let $u := \max(D_n \cap [0, s])$. Then

$$u \leq s < u + 2^{-n} \quad \text{and} \quad u \leq t < u + 2^{1-n}$$

and hence $b_i(t - u) = b_i(s - u) = 0$ for $i < n$. Define

$$t_l = u + \sum_{i=n}^l b_i(t - u) 2^{-i} \quad \text{for } l = n - 1, \dots, m.$$

Then, we have $t_{n-1} = u$ and $t_m = t$. Furthermore, $t_l \in D_l$ for $l = n, \dots, m$ and

$$t_l - t_{l-1} \leq 2^{-l} \quad \text{for } l = n, \dots, m$$

Hence, by (21.7),

$$|X_t(\omega) - X_u(\omega)| \leq \sum_{l=n}^m |X_{t_l}(\omega) - X_{t_{l-1}}(\omega)| \leq \sum_{l=n}^m 2^{-\gamma l} \leq \frac{2^{-\gamma n}}{1 - 2^{-\gamma}}.$$

Analogously, we obtain $|X_s(\omega) - X_u(\omega)| \leq 2^{-\gamma n} (1 - 2^{-\gamma})^{-1}$, and thus

$$|X_t(\omega) - X_s(\omega)| \leq 2 \frac{2^{-\gamma n}}{1 - 2^{-\gamma}} \quad (21.8)$$

Define $C_0 = 2^{1+\gamma} (1 - 2^{-\gamma})^{-1} < \infty$. Let $s, t \in D$ with $|s - t| \leq 2^{-n_0}$. By choosing the minimal $n \geq n_0$ such that $|t - s| \geq 2^{-n}$, we obtain by (21.8),

$$|X_t(\omega) - X_s(\omega)| \leq C_0 |t - s|^\gamma. \quad (21.9)$$

As in the proof of Lemma 21.3(iii), we infer (with $K := C_0 2^{(1-\gamma)n_0}$)

$$|X_t(\omega) - X_s(\omega)| \leq K |t - s|^\gamma \quad \text{for all } s, t \in D. \quad (21.10)$$

In other words, for dyadic rationals D , $X(\omega)$ is (globally) Hölder- γ -continuous. In particular, X is uniformly continuous on D ; hence it can be extended to $[0, 1]$. For $t \in D$, define $\tilde{X}_t := X_t$. For $t \in [0, 1] \setminus D$ and $\{s_n, n \in \mathbb{N}\} \subset D$ with $s_n \rightarrow t$, the sequence $(X_{s_n}(\omega))_{n \in \mathbb{N}}$ is a Cauchy sequence. Hence the limit

$$\tilde{X}_t(\omega) := \lim_{D \ni s \rightarrow t} X_s(\omega) \quad (21.11)$$

exists. Furthermore, the statement analogous to (21.10) holds not only for $s, t \in D$:

$$|\tilde{X}_t(\omega) - \tilde{X}_s(\omega)| \leq K |t - s|^\gamma \quad \text{for all } s, t \in [0, 1]. \quad (21.12)$$

Hence $\tilde{X}$ is locally Hölder-continuous of order γ . By (21.5) and (21.11), we have $\mathbf{P}[X_t \neq \tilde{X}_t] = 0$ for every $t \in [0, 1]$. Hence $\tilde{X}$ is a modification of X .
(ii) Let $\varepsilon > 0$ and choose $n \in \mathbb{N}$ large enough that (see (21.6))

$$\mathbf{P}[B_n] \leq C \frac{2^{-(\beta-\alpha\gamma)n}}{1 - 2^{\alpha\gamma-\beta}} < \varepsilon$$

For $\omega \notin B_n$, we conclude that (21.10) holds. However, this is exactly (21.3) with $T = 1$. For general T , the claim follows by linear scaling.

Remark 21.7 The statement of Theorem 21.6 remains true if X assumes values in some Polish space (E, ϱ) since in the proof we did not make use of the assumption that the range was in $\mathbb{R}$. However, if we change the time set, then the assumptions have to be strengthened: If $(X_t)_{t \in \mathbb{R}^d}$ is a process with values in E , and if, for certain $\alpha, \beta > 0$, all $T > 0$ and some $C < \infty$, we have

$$\mathbf{E}[\varrho(X_t, X_s)^\alpha] \leq C \|t - s\|_2^{d+\beta} \quad \text{for all } s, t \in [-T, T]^d, \quad (21.13)$$

then for every $\gamma \in (0, \beta/\alpha)$, there is a locally Hölder- γ -continuous version of X .

Exercise 21.1.1 Show the claim of Remark 21.7.

Exercise 21.1.2 Let $X = (X_t)_{t \geq 0}$ be a real-valued process with continuous paths. Show that, for all $0 \leq a < b$, the map $\omega \mapsto \int_a^b X_t(\omega) dt$ is measurable.

Exercise 21.1.3 (Optional sampling/stopping) Let $\mathbb{F}$ be a filtration and let $(X_t)_{t \geq 0}$ be an $\mathbb{F}$ -supermartingale with right continuous paths. Let σ and τ be bounded stopping times with $\sigma \leq \tau$. Define $\sigma^n := 2^{-n} \lceil 2^n \sigma \rceil$ and $\tau^n := 2^{-n} \lceil 2^n \tau \rceil$.

(i) Show that $\mathbf{E}[X_{\tau^n} | \mathcal{F}_{\sigma^n}] \xrightarrow{n \rightarrow \infty} \mathbf{E}[X_{\tau^n} | \mathcal{F}_\sigma]$ almost surely and in L^1 as well as $X_{\sigma^n} \xrightarrow{n \rightarrow \infty} X_\sigma$ almost surely and in L^1 .

(ii) Infer the optional sampling theorem for right continuous supermartingales by using the analogous statement for discrete time (Theorem 10.11); that is, $X_\sigma \geq \mathbf{E}[X_\tau | \mathcal{F}_\sigma]$.

(iii) Show that if Y is adapted, integrable and right continuous, then Y is a martingale if and only if $\mathbf{E}[Y_\tau] = \mathbf{E}[Y_0]$ for every bounded stopping time τ .

(iv) Assume that X is uniformly integrable and that $\sigma \leq \tau$ are finite (not necessarily bounded) stopping times. Show that $X_\sigma \geq \mathbf{E}[X_\tau | \mathcal{F}_\sigma]$.

(v) Now let τ be an arbitrary stopping time. Deduce the optional stopping theorem for right continuous supermartingales: $(X_{\tau \wedge t})_{t \geq 0}$ is a right continuous supermartingale.

Exercise 21.1.4 Let $X = (X_t)_{t \geq 0}$ be a stochastic process on $(\Omega, \mathcal{F}, \mathbf{P})$ with values in the Polish space E and with right continuous paths. Show the following.

(i) The map $(\omega, t) \mapsto X_t(\omega)$ is measurable with respect to $\mathcal{F} \otimes \mathcal{B}([0, \infty)) - \mathcal{B}(E)$.

(ii) If in addition X is adapted to the filtration $\mathbb{F}$, then for any $t \geq 0$, the map $\Omega \times [0, t] \rightarrow E, (\omega, s) \mapsto X_s(\omega)$ is $\mathcal{F}_t \otimes \mathcal{B}([0, t]) - \mathcal{B}(E)$ measurable.

(iii) If τ is an $\mathbb{F}$ -stopping time and X is adapted, then X_τ is an $\mathcal{F}_\tau$ -measurable random variable.

5.21.2 21.2 Construction and Path Properties

Definition 21.8 A real-valued stochastic process $B = (B_t, t \in [0, \infty))$ is called a Brownian motion if

- (i) $B_0 = 0$,
- (ii) B has independent, stationary increments (compare Definition 9.7),
- (iii) $B_t \sim \mathcal{N}_{0,t}$ for all $t > 0$, and
- (iv) $t \mapsto B_t$ is $\mathbf{P}$ -almost surely continuous.

Fig. 21.1 Computer simulation of a Brownian motion

See Fig. 21.1 for a computer simulation of a Brownian motion.

Theorem 21.9 There exists a probability space $(\Omega, \mathcal{A}, \mathbf{P})$ and a Brownian motion B on $(\Omega, \mathcal{A}, \mathbf{P})$. The paths of B are a.s. locally Hölder- γ -continuous for every $\gamma < \frac{1}{2}$.

Proof As in Example 14.45 or Corollary 16.10 there exists a stochastic process X that fulfills (i), (ii) and (iii). Evidently, $X_t - X_s \stackrel{\mathcal{D}}{=} \sqrt{t-s}X_1 \sim \mathcal{N}_{0,t-s}$ for all $t > s \geq 0$. Thus, for every $n \in \mathbb{N}$, writing $C_n := \mathbf{E}[X_1^{2n}] = \frac{(2n)!}{2^n n!} < \infty$, we have

$$\mathbf{E}[(X_t - X_s)^{2n}] = \mathbf{E}[(\sqrt{t-s}X_1)^{2n}] = C_n |t-s|^n.$$

Now let $n \geq 2$ and $\gamma \in (0, \frac{n-1}{2n})$. Theorem 21.6 yields the existence of a version B of X that has Hölder- γ -continuous paths. Since all continuous versions of a process are equivalent, B is locally Hölder- γ -continuous for every $\gamma \in (0, \frac{n-1}{2n})$ and every $n \geq 2$ and hence for every $\gamma \in (0, \frac{1}{2})$. $\square$

Recall that a stochastic process $(X_t)_{t \in I}$ is called a Gaussian process if, for every $n \in \mathbb{N}$ and for all $t_1, \dots, t_n \in I$, we have that

$$(X_{t_1}, \dots, X_{t_n}) \quad \text{is } n\text{-dimensional normally distributed.}$$

X is called centered if $\mathbf{E}[X_t] = 0$ for every $t \in I$. The map

$$\Gamma(s, t) := \text{Cov}[X_s, X_t] \quad \text{for } s, t \in I$$

is called the covariance function of X .

Remark 21.10 The covariance function determines the finite-dimensional distributions of a centered Gaussian process since a multidimensional normal distribution is determined by the vector of expectations and by the covariance matrix.

Theorem 21.11 Let $X = (X_t)_{t \in [0, \infty)}$ be a stochastic process. Then the following are equivalent:

- (i) X is a Brownian motion.
- (ii) X is a continuous centered Gaussian process with $\mathbf{Cov}[X_s, X_t] = s \wedge t$ for all $s, t \geq 0$.

Proof By Remark 21.10, X is characterized by (ii). Hence, it is enough to show that, for Brownian motion X , we have $\text{Cov}[X_s, X_t] = \min(s, t)$. This is indeed true since for $t > s$, the random variables X_s and $X_t - X_s$ are independent; hence

$$\text{Cov}[X_s, X_t] = \text{Cov}[X_s, X_t - X_s] + \text{Cov}[X_s, X_s] = \text{Var}[X_s] = s.$$

Corollary 21.12 (Scaling property of Brownian motion) If B is a Brownian motion and if $K \neq 0$, then $(K^{-1}B_{K^2t})_{t \geq 0}$ is also a Brownian motion.

Example 21.13 Another example of a continuous Gaussian process is the so-called Brownian bridge $X = (X_t)_{t \in [0,1]}$ that is defined by the covariance function $\Gamma(s, t) = s \wedge t - st$. We construct the Brownian bridge as follows.

Let $B = (B_t, t \in [0, 1])$ be a Brownian motion and let

$$X_t := B_t - tB_1.$$

Clearly, X is a centered Gaussian process with continuous paths. We compute the covariance function Γ of X ,

$$\begin{aligned} \Gamma(s, t) &= \text{Cov}[X_s, X_t] = \text{Cov}[B_s - sB_1, B_t - tB_1] \\ &= \text{Cov}[B_s, B_t] - s \text{Cov}[B_1, B_t] - t \text{Cov}[B_s, B_1] + st \text{Cov}[B_1, B_1] \\ &= \min(s, t) - st - st + st = \min(s, t) - st \end{aligned}$$

Theorem 21.14 Let $(B_t)_{t \geq 0}$ be a Brownian motion and

$$X_t = \begin{cases} tB_{1/t}, & \text{if } t > 0 \\ 0, & \text{if } t = 0 \end{cases}$$

Then X is a Brownian motion.

Proof Clearly, X is a Gaussian process. For $s, t > 0$, we have

$$\text{Cov}[X_s, X_t] = ts \cdot \text{Cov}[B_{1/s}, B_{1/t}] = ts \min(s^{-1}, t^{-1}) = \min(s, t).$$

Clearly, $t \mapsto X_t$ is continuous at every point $t > 0$. To show continuity at $t = 0$, consider

$$\begin{aligned} \limsup_{t \downarrow 0} X_t &= \limsup_{t \rightarrow \infty} \frac{1}{t} B_t \\ &\leq \limsup_{n \rightarrow \infty} \frac{1}{n} B_n + \limsup_{n \rightarrow \infty} \frac{1}{n} \sup \{B_t - B_n, t \in [n, n+1]\}. \end{aligned}$$

By the strong law of large numbers, we have $\lim_{n \rightarrow \infty} \frac{1}{n} B_n = 0$ a.s. Using a generalization of the reflection principle (Theorem 17.15; see also Theorem 21.19), for $x > 0$, we have (using the abbreviation $B_{[a,b]} := \{B_t : t \in [a, b]\}$)

$$\begin{aligned} \mathbf{P}[\sup B_{[n,n+1]} - B_n > x] &= \mathbf{P}[\sup B_{[0,1]} > x] = 2\mathbf{P}[B_1 > x] \\ &= \frac{2}{\sqrt{2\pi}} \int_x^\infty e^{-u^2/2} du \leq \frac{1}{x} e^{-x^2/2} \end{aligned}$$

In particular, $\sum_{n=1}^\infty \mathbf{P}[\sup B_{[n,n+1]} - B_n > n^\varepsilon] < \infty$ for every $\varepsilon > 0$. By the Borel-Cantelli lemma (Theorem 2.7), we infer

$$\limsup_{n \rightarrow \infty} \frac{1}{n} \sup \{B_t - B_n, t \in [n, n+1]\} = 0 \quad \text{almost surely.}$$

Hence X is also continuous at 0.

Theorem 21.15 (Blumenthal's 0-1 law, see [18]) Let B be a Brownian motion and let $\mathbb{F} = (\mathcal{F}_t)_{t \geq 0} = \sigma(B)$ be the filtration generated by B . Further, let $\mathcal{F}_0^+ = \bigcap_{t > 0} \mathcal{F}_t$. Then $\mathcal{F}_0^+$ is a $\mathbf{P}$ -trivial σ -algebra.

Proof Define $Y^n = (B_{2^{-n}+t} - B_{2^{-n}})_{t \in [0, 2^{-n}]}$, $n \in \mathbb{N}$. Then $(Y^n)_{n \in \mathbb{N}}$ is an independent family of random variables (with values in $C([0, 2^{-n}])$). By Kolmogorov's 0-1 law (Theorem 2.37), the tail σ -algebra $\mathcal{T} = \bigcap_{n \in \mathbb{N}} \sigma(Y^m, m \geq n)$ is $\mathbf{P}$ -trivial. On the other hand, $\sigma(Y^m, m \geq n) = \mathcal{F}_{2^{-n+1}}$; hence

$$\mathcal{F}_0^+ = \bigcap_{t>0} \mathcal{F}_t = \bigcap_{n \in \mathbb{N}} \mathcal{F}_{2^{-n+1}} = \mathcal{T}$$

is $\mathbf{P}$ -trivial.

Example 21.16 Let B be a Brownian motion. For every $K > 0$, we have

$$\mathbf{P} \left[\inf \left\{ t > 0 : B_t \geq K\sqrt{t} \right\} = 0 \right] = 1 \quad (21.14)$$

To check this, define $A_s := \left\{ \inf \left\{ t > 0 : B_t \geq K\sqrt{t} \right\} \leq s \right\}$ and

$$A := \left\{ \inf \left\{ t > 0 : B_t \geq K\sqrt{t} \right\} = 0 \right\} = \bigcap_{s>0} A_s \in \mathcal{F}_0^+$$

Then $\mathbf{P}[A] \in \{0, 1\}$. By the scaling property of Brownian motion,

$$\mathbf{P}[A] = \inf_{s>0} \mathbf{P}[A_s] \geq \mathbf{P}[B_1 \geq K] > 0$$

and thus $\mathbf{P}[A] = 1$.

The preceding example shows that, for every $t \geq 0$, almost surely B is not Hölder- $\frac{1}{2}$ -continuous at t . Note that the order of quantifiers is subtle. We have not shown that almost surely B was not Hölder- $\frac{1}{2}$ -continuous at any $t \geq 0$ (however, see Remark 22.4). However, it is not too hard to show the following theorem, which for the case $\gamma = 1$ is due to Paley, Wiener and Zygmund [126]. The proof presented here goes back to an idea of Dvoretzky, Erdős and Kakutani (see [40]).

Theorem 21.17 (Paley-Wiener-Zygmund (1933)) For every $\gamma > \frac{1}{2}$, almost surely the paths of Brownian motion $(B_t)_{t \geq 0}$ are not Hölder-continuous of order γ at any point. In particular, the paths are almost surely nowhere differentiable.

Proof Let $\gamma > \frac{1}{2}$. It suffices to consider $B = (B_t)_{t \in [0,1]}$. Denote by $H_{\gamma,t}$ the set of maps $[0,1] \rightarrow \mathbb{R}$ that are Hölder- γ -continuous at t and define $H_\gamma := \bigcup_{t \in [0,1]} H_{\gamma,t}$. The aim is to show that almost surely $B \notin H_\gamma$.

If $t \in [0,1)$ and $w \in H_{\gamma,t}$, then for every $\delta > 0$ there exists a $c = c(\delta, w)$ with the property $|w_s - w_t| \leq c|s - t|^\gamma$ for every $s \in [0,1]$ with $|s - t| < \delta$. Choose a $k \in \mathbb{N}$ with $k > \frac{2}{2\gamma-1}$. Then, for $n \in \mathbb{N}$ with $n \geq n_0 := \Gamma(k+1)/\delta$, $i = \lfloor tn \rfloor + 1$ and $l \in \{0, \dots, k-1\}$, we get

$$\begin{aligned} |w_{(i+l+1)/n} - w_{(i+l)/n}| &\leq |w_{(i+l+1)/n} - w_t| + |w_{(i+l)/n} - w_t| \\ &\leq 2c(k+1)^\gamma n^{-\gamma}. \end{aligned}$$

Hence, for $N \geq 2c(k+1)^\gamma$, we have $w \in A_{N,n,i}$, where

$$A_{N,n,i} := \bigcap_{l=0}^{k-1} \left\{ w : |w_{(i+l+1)/n} - w_{(i+l)/n}| \leq Nn^{-\gamma} \right\}.$$

Define $A_{N,n} = \bigcup_{i=1}^n A_{N,n,i}$, $A_N = \liminf_{n \rightarrow \infty} A_{N,n}$ and $A = \bigcup_{N=1}^\infty A_N$. Clearly, $H_\gamma \subset A$. Owing to the independence of increments and since the density of the standard normal distribution is bounded by 1, we get

$$\begin{aligned} \mathbf{P}[B \in A_{N,n,i}] &= \mathbf{P}[|B_{1/n}| \leq Nn^{-\gamma}]^k = \mathbf{P}[|B_1| \leq Nn^{-\gamma+1/2}]^k \\ &\leq N^k n^{k(-\gamma+1/2)} \end{aligned}$$

By the choice of k and since the increments of B are stationary, we have

$$\begin{aligned} \mathbf{P}[B \in A_N] &= \lim_{n \rightarrow \infty} \mathbf{P} \left[\bigcap_{m \geq n} A_{N,m} \right] \leq \limsup_{n \rightarrow \infty} \mathbf{P}[A_{N,n}] \leq \limsup_{n \rightarrow \infty} \sum_{i=1}^n \mathbf{P}[A_{N,n,i}] \\ &\leq \limsup_{n \rightarrow \infty} n \mathbf{P}[B \in A_{N,n,1}] \leq N^k \limsup_{n \rightarrow \infty} n^{1+k(-\gamma+1/2)} = 0 \end{aligned}$$

Thus $\mathbf{P}[B \in A] = 0$. Therefore, we almost surely have $B \notin H_\gamma$.

Exercise 21.2.1 Let B be a Brownian motion and let λ be the Lebesgue measure on $[0, \infty)$.

(i) Compute the expectation and variance of $\int_0^1 B_s ds$. (For the measurability of the integral see Exercise 21.1.2.)

(ii) Show that almost surely $\lambda(\{t : B_t = 0\}) = 0$.

(iii) Compute the expectation and variance of

$$\int_0^1 \left(B_t - \int_0^1 B_s ds \right)^2 dt$$

Exercise 21.2.2 Let B be a Brownian motion. Show that $(B_t^2 - t)_{t \geq 0}$ is a martingale.

Exercise 21.2.3 Let B be a Brownian motion and $\sigma > 0$. Show that the process $\left(\exp \left(\sigma B_t - \frac{\sigma^2}{2} t \right) \right)_{t \geq 0}$ is a martingale.

Exercise 21.2.4 Let B be a Brownian motion, $a < 0 < b$. Define the stopping time $\tau_{a,b} = \inf \{t \geq 0 : B_t \in \{a, b\}\}$.

Show that almost surely $\tau_{a,b} < \infty$ and that $\mathbf{P}[B_{\tau_{a,b}} = b] = -\frac{a}{b-a}$. Furthermore, show (using Exercise 21.2.2) that $\mathbf{E}[\tau_{a,b}] = -ab$.

Exercise 21.2.5 Let B be a Brownian motion, $b > 0$ and $\tau_b = \inf \{t \geq 0 : B_t = b\}$. Show the following.

(i) $\mathbf{E}[e^{-\lambda \tau_b}] = e^{-b\sqrt{2\lambda}}$ for $\lambda \geq 0$.

Hint: Use Exercise 21.2.3 and the optional sampling theorem.

(ii) τ_b has a $\frac{1}{2}$ -stable distribution with Lévy measure

$$v(dx) = (b/(\sqrt{2\pi}))x^{-3/2}\mathbb{1}_{\{x>0\}}dx$$

(iii) The distribution of τ_b has density $f_b(x) = \frac{b}{\sqrt{2\pi}}e^{-b^2/(2x)}x^{-3/2}$.

Exercise 21.2.6 Let B be a Brownian motion, $a \in \mathbb{R}$, $b > 0$ and $\tau = \inf \{t \geq 0 : B_t = at + b\}$. For $\lambda \geq 0$, show that

$$\mathbf{E}[e^{-\lambda \tau}] = \exp \left(-ba - b\sqrt{a^2 + 2\lambda} \right).$$

Conclude that $\mathbf{P}[\tau < \infty] = 1 \wedge e^{-2ba}$.

5.21.3 21.3 Strong Markov Property

Denote by $\mathbf{P}_x$ the probability measure such that $B = (B_t)_{t \geq 0}$ is a Brownian motion started at $x \in \mathbb{R}$. To put it differently, under $\mathbf{P}_x$, the process $(B_t - x)_{t \geq 0}$ is a standard Brownian motion. While the (simple) Markov property of $(B, (\mathbf{P}_x)_{x \in \mathbb{R}})$ is evident, it takes some work to check the strong Markov property.

Theorem 21.18 (Strong Markov property) Brownian motion B with distributions $(\mathbf{P}_x)_{x \in \mathbb{R}}$ has the strong Markov property.

Proof Let $\mathbb{F} = \sigma(B)$ be the filtration generated by B and let $\tau < \infty$ be an $\mathbb{F}$ stopping time. We have to show that, for every bounded measurable $F : \mathbb{R}^{[0, \infty)} \rightarrow \mathbb{R}$, we have:

$$\mathbf{E}_x[F((B_{t+\tau})_{t \geq 0}) \mid \mathcal{F}_\tau] = \mathbf{E}_{B_\tau}[F(B)]. \quad (21.15)$$

It is enough to consider continuous bounded functions F that depend on only finitely many coordinates $t_1, \dots, t_N$ since these functions determine the distribution of $(B_{t+\tau})_{t \geq 0}$. Hence, let $f : \mathbb{R}^N \rightarrow \mathbb{R}$ be continuous and bounded and $F(B) = f(B_{t_1}, \dots, B_{t_N})$. Manifestly, the map $x \mapsto \mathbf{E}_x[F(B)] = \mathbf{E}_0[f(B_{t_1} + x, \dots, B_{t_N} + x)]$ is continuous and bounded. Now let $\tau^n := 2^{-n} \lfloor 2^n \tau + 1 \rfloor$ for $n \in \mathbb{N}$. Then τ^n is a stopping time and $\tau^n \downarrow \tau$; hence $B_{\tau^n} \xrightarrow{n \rightarrow \infty} B_\tau$ almost surely. Now every Markov process with countable time set (here all positive rational linear combinations of $1, t_1, \dots, t_N$) is a strong Markov process (by Theorem 17.14); hence we have

$$\begin{aligned} \mathbf{E}_x[F((B_{\tau^n+t})_{t \geq 0}) \mid \mathcal{F}_{\tau^n}] &= \mathbf{E}_x[f(B_{\tau^n+t_1}, \dots, B_{\tau^n+t_N}) \mid \mathcal{F}_{\tau^n}] \\ &= \mathbf{E}_{B_{\tau^n}}[f(B_{t_1}, \dots, B_{t_N})] \\ &\xrightarrow{n \rightarrow \infty} \mathbf{E}_{B_\tau}[f(B_{t_1}, \dots, B_{t_N})] = \mathbf{E}_{B_\tau}[F(B)]. \end{aligned} \quad (21.16)$$

As B is right continuous, we have $F((B_{\tau^n+t})_{t \geq 0}) \xrightarrow{n \rightarrow \infty} F((B_{\tau+t})_{t \geq 0})$ almost surely and in L^1 and thus

$$\begin{aligned} \mathbf{E}[|\mathbf{E}_x[F((B_{\tau^n+t})_{t \geq 0}) \mid \mathcal{F}_{\tau^n}] - \mathbf{E}_x[F((B_{\tau+t})_{t \geq 0}) \mid \mathcal{F}_{\tau^n}]|] \\ \leq \mathbf{E}_x[|F((B_{\tau^n+t})_{t \geq 0}) - F((B_{\tau+t})_{t \geq 0})|] \xrightarrow{n \rightarrow \infty} 0. \end{aligned} \quad (21.17)$$

Furthermore,

$$\mathcal{F}_{\tau^n} \downarrow \mathcal{F}_{\tau+} := \bigcap_{\sigma > \tau \text{ is a stopping time}} \mathcal{F}_\sigma \supset \mathcal{F}_\tau$$

By (21.16) and (21.17), using the convergence theorem for backwards martingales (Theorem 12.14), we get that in the sense of L^1 -limits

$$\begin{aligned} \mathbf{E}_{B_\tau}[F(B)] &= \lim_{n \rightarrow \infty} \mathbf{E}_x[F((B_{\tau^n+t})_{t \geq 0}) \mid \mathcal{F}_{\tau^n}] \\ &= \lim_{n \rightarrow \infty} \mathbf{E}_x[F((B_{\tau+t})_{t \geq 0}) \mid \mathcal{F}_{\tau^n}] = \mathbf{E}_x[F((B_{\tau+t})_{t \geq 0}) \mid \mathcal{F}_{\tau+}] \end{aligned}$$

The left-hand side is $\mathcal{F}_\tau$ -measurable. The tower property of conditional expectation thus yields (21.15).

Using the strong Markov property, we show the reflection principle for Brownian motion.

Theorem 21.19 (Reflection principle for Brownian motion) For every $a > 0$ and $T > 0$,

$$\mathbf{P}[\sup\{B_t : t \in [0, T]\} > a] = 2\mathbf{P}[B_T > a] \leq \frac{2\sqrt{T}}{\sqrt{2\pi}} \frac{1}{a} e^{-a^2/2T}$$

Proof By the scaling property of Brownian motion (Corollary 21.12), without loss of generality, we may assume $T = 1$. Let $\tau := \inf\{t \geq 0 : B_t \geq a\} \wedge 1$. By symmetry, we have $\mathbf{P}_a[B_{1-\tau} > a] = \frac{1}{2}$ if $\tau < 1$; hence

$$\begin{aligned} \mathbf{P}[B_1 > a] &= \mathbf{P}[B_1 > a \mid \tau < 1] \mathbf{P}[\tau < 1] \\ &= \mathbf{P}_a[B_{1-\tau} > a] \mathbf{P}[\tau < 1] = \frac{1}{2} \mathbf{P}[\tau < 1] \end{aligned}$$

For the inequality compute

$$\begin{aligned} \mathbf{P}[B_1 > a] &= \frac{1}{\sqrt{2\pi}} \int_a^\infty e^{-x^2/2} dx \\ &\leq \frac{1}{\sqrt{2\pi}} \frac{1}{a} \int_a^\infty x e^{-x^2/2} dx = \frac{1}{\sqrt{2\pi}} \frac{1}{a} e^{-a^2/2} \end{aligned}$$

As an application of the reflection principle we derive Paul Lévy's arcsine law [107, p. 216] for the last time a Brownian motion visits zero.

Theorem 21.20 (Lévy's arcsine law) Let $T > 0$ and $\zeta_T := \sup \{t \leq T : B_t = 0\}$. Then, for $t \in [0, T]$,

$$\mathbf{P}[\zeta_T \leq t] = \frac{2}{\pi} \arcsin(\sqrt{t/T})$$

Proof Without loss of generality, assume $T = 1$ and $\zeta = \zeta_1$. Let $\tilde{B}$ be a further, independent Brownian motion. By the reflection principle,

$$\begin{aligned} \mathbf{P}[\zeta \leq t] &= \mathbf{P}[B_s \neq 0 \text{ for all } s \in [t, 1]] \\ &= \int_{-\infty}^{\infty} \mathbf{P}[B_s \neq 0 \text{ for all } s \in [t, 1] \mid B_t = a] \mathbf{P}[B_t \in da] \\ &= \int_{-\infty}^{\infty} \mathbf{P}_{|a|}[\tilde{B}_s > 0 \text{ for all } s \in [0, 1-t]] \mathbf{P}[B_t \in da] \\ &= \int_{-\infty}^{\infty} \mathbf{P}_0[|\tilde{B}_{1-t}| \leq |a|] \mathbf{P}[B_t \in da] \\ &= \mathbf{P}[|\tilde{B}_{1-t}| \leq |B_t|] \end{aligned}$$

If X and Y are independent and $\mathcal{N}_{0,1}$ -distributed, then

$$(B_t, \tilde{B}_{1-t}) \stackrel{\mathcal{D}}{=} (\sqrt{t}X, \sqrt{1-t}Y)$$

Hence

$$\begin{aligned} \mathbf{P}[\zeta \leq t] &= \mathbf{P}[\sqrt{1-t}|Y| \leq \sqrt{t}|X|] \\ &= \mathbf{P}[Y^2 \leq t(X^2 + Y^2)] \\ &= \frac{1}{2\pi} \int_{-\infty}^{\infty} dx \int_{-\infty}^{\infty} dy e^{-(x^2+y^2)/2} \mathbb{1}_{\{y^2 \leq t(x^2+y^2)\}} \end{aligned}$$

Passing to polar coordinates, we obtain

$$\mathbf{P}[\zeta \leq t] = \frac{1}{2\pi} \int_0^{\infty} r dr e^{-r^2/2} \int_0^{2\pi} d\varphi \mathbb{1}_{\{\sin(\varphi)^2 \leq t\}} = \frac{2}{\pi} \arcsin(\sqrt{t})$$

Exercise 21.3.1 (Hard problem!) Let $\mathbf{P}_x$ be the distribution of Brownian motion started at $x \in \mathbb{R}$. Let $a > 0$ and $\tau = \inf \{t \geq 0 : B_t \in \{0, a\}\}$. Use the reflection principle to show that, for every $x \in (0, a)$,

$$\mathbf{P}_x[\tau > T] = \sum_{n=-\infty}^{\infty} (-1)^n \mathbf{P}_x[B_T \in [na, (n+1)a]] \quad (21.18)$$

If f is the density of a probability distribution on $\mathbb{R}$ with characteristic function φ and $\sup_{x \in \mathbb{R}} x^2 f(x) < \infty$, then the Poisson summation formula holds,

$$\sum_{n=-\infty}^{\infty} f(s+n) = \sum_{k=-\infty}^{\infty} \varphi(k) e^{2\pi i s k} \quad \text{for all } s \in \mathbb{R} \quad (21.19)$$

Use (21.18) and (21.19) (compare also (21.37)) to conclude that

$$\mathbf{P}_x[\tau > T] = \frac{4}{\pi} \sum_{k=0}^{\infty} \frac{1}{2k+1} \exp\left(-\frac{(2k+1)^2 \pi^2 T}{2a^2}\right) \sin\left(\frac{(2k+1)\pi x}{a}\right). \quad (21.20)$$

5.21.4 21.4 Supplement: Feller Processes

In many situations, a continuous version of a process would be too much to expect, for instance, the Poisson process is generically discontinuous. However, often there is a version with right continuous paths that have left-sided limits. At this point, we only briefly make plausible the existence theorem for such regular versions of processes in the case of so-called Feller semigroups.

Definition 21.21 Let E be a Polish space. A map $f : [0, \infty) \rightarrow E$ is called *RCLL* (right continuous with left limits) or *càdlàg* (continue à droite, limites à gauche) if $f(t) = f(t+) := \lim_{s \downarrow t} f(s)$ for every $t \geq 0$ and if, for every $t > 0$, the left-sided limit $f(t-) := \lim_{s \uparrow t} f(s)$ exists and is finite.

Definition 21.22 A filtration $\mathbb{F} = (\mathcal{F}_t)_{t \geq 0}$ is called right continuous if $\mathbb{F} = \mathbb{F}^+$, where $\mathcal{F}_t^+ = \bigcap_{s > t} \mathcal{F}_s$. We say that a filtration $\mathbb{F}$ satisfies the usual conditions (from the French conditions habituelles) if $\mathbb{F}$ is right continuous and if $\mathcal{F}_0$ is $\mathbf{P}$ -complete.

Remark 21.23 If $\mathbb{F}$ is an arbitrary filtration and $\mathcal{F}_t^{+,*}$ is the completion of $\mathcal{F}_t^+$, then $\mathbb{F}^{+,*}$ satisfies the usual conditions.

Theorem 21.24 (Doob's regularization) Let $\mathbb{F}$ be a filtration that satisfies the usual conditions and let $X = (X_t)_{t \geq 0}$ be an $\mathbb{F}$ -supermartingale such that $t \mapsto \mathbf{E}[X_t]$ is right continuous. Then there exists a modification $\tilde{X}$ of X with RCLL paths.

Proof For $a, b \in \mathbb{Q}^+$, $a < b$ and $I \subset [0, \infty)$, let $U_I^{a,b}$ be the number of upcrossings of $(X_t)_{t \in I}$ over $[a, b]$. By the upcrossing inequality (Lemma 11.3), for every $N > 0$ and every finite set $I \subset [0, N]$, we have $\mathbf{E}[U_I^{a,b}] \leq (\mathbf{E}[|X_N|] + |a|)/(b - a)$. Define $U_N^{a,b} = U_{\mathbb{Q}^+ \cap [0, N]}^{a,b}$. Then $\mathbf{E}[U_N^{a,b}] \leq (\mathbf{E}[|X_N|] + |a|)/(b - a)$. By Exercise 11.1.1, for $\lambda > 0$, we have

$$\begin{aligned} \lambda \mathbf{P}[\sup\{|X_t| : t \in \mathbb{Q}^+ \cap [0, N]\} > \lambda] \\ &= \lambda \sup\{\mathbf{P}[\sup\{|X_t| : t \in I\} > \lambda] : I \subset \mathbb{Q}^+ \cap [0, N] \text{ finite}\} \\ &\leq 12\mathbf{E}[|X_0|] + 9\mathbf{E}[|X_N|]. \end{aligned}$$

Consider the event

$$A := \bigcap_{N \in \mathbb{N}} \left(\bigcap_{\substack{a, b \in \mathbb{Q}^+ \\ 0 \leq a < b \leq N}} \{U_N^{a,b} < \infty\} \cap \{\sup\{|X_t| : t \in \mathbb{Q}^+ \cap [0, N]\} < \infty\} \right)$$

We have $\mathbf{P}[A] = 1$; hence $A \in \mathcal{F}_t$ for every $t \geq 0$ since $\mathbb{F}$ satisfies the usual conditions. For $\omega \in A$, for every $t \geq 0$, the limit

$$\tilde{X}_t(\omega) := \lim_{\mathbb{Q}^+ \ni s \downarrow t, s > t} X_s(\omega)$$

exists and is RCLL. For $\omega \in A^c$, we define $\tilde{X}_t(\omega) = 0$. As $\mathbb{F}$ satisfies the usual conditions, $\tilde{X}$ is $\mathbb{F}$ -adapted. As X is a supermartingale, for every N , the family $(X_s)_{s \leq N}$ is uniformly integrable. Hence, by assumption,

$$\mathbf{E}[\tilde{X}_t] = \lim_{\mathbb{Q}^+ \ni s \downarrow t, s > t} \mathbf{E}[X_s] = \mathbf{E}[X_t]$$

However, since X is a supermartingale, for every $s > t$, we have

$$X_t \geq \mathbf{E}[X_s | \mathcal{F}_t] \xrightarrow{\mathbb{Q}^+ \ni s \downarrow t, s > t} \mathbf{E}[\tilde{X}_t | \mathcal{F}_t] = \tilde{X}_t \quad \text{in } L^1.$$

Therefore, $X_t = \tilde{X}_t$ almost surely and hence $\tilde{X}$ is a modification of X .

Corollary 21.25 Let $(v_t)_{t \geq 0}$ be a continuous convolution semigroup and assume that $\int |x|v_1(dx) < \infty$. Then there exists a Markov process X with RCLL paths and with independent stationary increments $\mathbf{P}_{X_t - X_s} = v_{t-s}$ for all $t > s$.

Let E be a locally compact Polish space and let $C_0(E)$ be the set of (bounded) continuous functions that vanish at infinity. If κ is a stochastic kernel from E to E and if f is measurable and bounded, then we define $\kappa f(x) = \int \kappa(x, dy)f(y)$.

Definition 21.26 A Markov semigroup $(\kappa_t)_{t \geq 0}$ on E is called a Feller semigroup if

$$f(x) = \lim_{t \rightarrow 0} \kappa_t f(x) \quad \text{for all } x \in E, f \in C_0(E)$$

and $\kappa_t f \in C_0(E)$ for every $f \in C_0(E)$.

Let X be a Markov process with transition kernels $(\kappa_t)_{t \geq 0}$ and with respect to a filtration $\mathbb{F}$ that satisfies the usual conditions.

Let $g \in C_0(E)$, $g \geq 0$. Let $h = \int_0^\infty e^{-t} \kappa_t g dt$. Then

$$e^{-s} \kappa_s h = e^{-s} \int_0^\infty e^{-t} \kappa_s \kappa_t g dt = \int_s^\infty e^{-t} \kappa_t g dt \leq h$$

Hence $X^g := (e^{-t} h(X_t))_{t \geq 0}$ is an $\mathbb{F}$ -supermartingale.

The Feller property and Theorem 21.24 ensure the existence of an RCLL version $\tilde{X}^g$ of X^g . It takes a little more work to show that there exists a countable set $G \subset C_0(E)$ and a process $\tilde{X}$ that is uniquely determined by $\tilde{X}^g, g \in G$, and is an RCLL version of X . See, e.g., [146, Chapter III.7ff].

Let us take a moment's thought and look back at how we derived the strong Markov property of Brownian motion in Section 21.3. Indeed, there we needed only right continuity of the paths and a certain continuity of the distribution as a function of the starting point, which is exactly the Feller property. With a little more work, one can show the following theorem (see, e.g., [146, Chapter III.8ff] or [144, Chapter III, Theorem 2.7]).

Theorem 21.27 Let $(\kappa_t)_{t \geq 0}$ be a Feller semigroup on the locally compact Polish space E . Then there exists a strong Markov process $(X_t)_{t \geq 0}$ with RCLL paths and transition kernels $(\kappa_t)_{t \geq 0}$.

Such a process X is called a Feller process.

Exercise 21.4.1 (Doob's inequality) Let $X = (X_t)_{t \geq 0}$ be a martingale or a nonnegative submartingale with RCLL paths. For $T \geq 0$, let $|X|_T^* = \sup_{t \in [0, T]} |X_t|$. Show Doob's inequalities:

- (i) For any $p \geq 1$ and $\lambda > 0$, we have $\lambda^p \mathbf{P}[|X|_T^* \geq \lambda] \leq \mathbf{E}[|X_T|^p]$.
- (ii) For any $p > 1$, we have $\mathbf{E}[|X_T|^p] \leq \mathbf{E}[(|X|_T^*)^p] \leq \left(\frac{p}{p-1}\right)^p \mathbf{E}[|X_T|^p]$.

Construct a counterexample that shows that right continuity of the paths of X is essential.

Exercise 21.4.2 (Martingale convergence theorems) Let X be a stochastic process with RCLL paths. Use Doob's inequality (Exercise 21.4.1) to show that the martingale convergence theorems (a.s. convergence (Theorem 11.4), a.s. and L^1 convergence for uniformly integrable martingales (Theorem 11.7) and the L^p martingale convergence theorem (Theorem 11.10)) hold for X .

Exercise 21.4.3 Let $p \geq 1$ and let $X^1, X^2, X^3, \dots$ be L^p -integrable martingales. Assume that, for every $t \geq 0$, there exists an $\tilde{X}_t \in \mathcal{L}^p(\mathbf{P})$ such that $X_t^n \xrightarrow{n \rightarrow \infty} \tilde{X}_t$ in L^p .

- (i) Show that $(\tilde{X}_t)_{t \geq 0}$ is a martingale.
- (ii) Use Doob's inequality to show the following. If $p > 1$ and if $X^1, X^2, \dots$ are a.s. continuous, then there is a continuous martingale X with the following properties: X is a modification of $\tilde{X}$ and $X_t^n \xrightarrow{n \rightarrow \infty} X_t$ in L^p for every $t \geq 0$.

Exercise 21.4.4 Let X be a stochastic process with values in a Polish space E and with RCLL paths. Let $\mathbb{F} = \sigma(X)$ be the filtration generated by X and define $\mathbb{F}^+ := (\mathcal{F}_t^+)_{t \geq 0}$ by $\mathcal{F}_t^+ = \bigcap_{s > t} \mathcal{F}_s$. Let $U \subset E$ be open and let $C \subset E$ be closed. For every set $A \subset E$, define $\tau_A := \inf \{t > 0 : X_t \in A\}$. Show the following.

- (i) τ_C is an $\mathbb{F}$ -stopping time (and an $\mathbb{F}^+$ -stopping time).
- (ii) τ_U is an $\mathbb{F}^+$ -stopping time but in general (even for continuous X) is not an $\mathbb{F}$ -stopping time.

Exercise 21.4.5 Show the statement of Remark 21.23. Conclude that if $\mathbb{F}$ is a filtration and if B is a Brownian motion that is an $\mathbb{F}$ -martingale, then B is also an $\mathbb{F}^{+,*}$ -martingale.

5.21.5 21.5 Construction via l^2 -Approximation

We give an alternative construction of Brownian motion by functional analytic means as an L^2 -approximation. For simplicity, as the time interval we take $[0, 1]$ instead of $[0, \infty)$.

Let $H = L^2([0, 1])$ be the Hilbert space of square integrable (with respect to Lebesgue measure λ) functions $[0, 1] \rightarrow \mathbb{R}$ with inner product

$$\langle f, g \rangle = \int_{[0,1]} f(x)g(x)\lambda(dx)$$

and with norm $\|f\| = \sqrt{\langle f, f \rangle}$ (compare Section 7.3). Two functions $f, g \in H$ are considered equal if $f = g$ λ -a.e. Let $(b_n)_{n \in \mathbb{N}}$ be an orthonormal basis (ONB) of H ; that is, $\langle b_m, b_n \rangle = \mathbb{1}_{\{m=n\}}$ and

$$\lim_{n \rightarrow \infty} \left\| f - \sum_{m=1}^n \langle f, b_m \rangle b_m \right\| = 0 \quad \text{for all } f \in H.$$

In particular, for every $f \in H$, Parseval's equation

$$\|f\|^2 = \sum_{m=1}^{\infty} \langle f, b_m \rangle^2 \tag{21.21}$$

holds and for $f, g \in H$

$$\langle f, g \rangle = \sum_{m=1}^{\infty} \langle f, b_m \rangle \langle g, b_m \rangle \tag{21.22}$$

Now consider an i.i.d. sequence $(\xi_n)_{n \in \mathbb{N}}$ of $\mathcal{N}_{0,1}$ -random variables on some probability space $(\Omega, \mathcal{A}, \mathbf{P})$. For $n \in \mathbb{N}$ and $t \in [0, 1]$, define

$$X_t^n = \int \mathbb{1}_{[0,t]}(s) \left(\sum_{m=1}^n \xi_m b_m(s) \right) \lambda(ds) = \sum_{m=1}^n \xi_m \langle \mathbb{1}_{[0,t]}, b_m \rangle.$$

Clearly, for $n \geq m$,

$$\begin{aligned} \mathbf{E} [(X_t^m - X_t^n)^2] &= \mathbf{E} \left[\left(\sum_{k=m+1}^n \xi_k \langle \mathbb{1}_{[0,t]}, b_k \rangle \right) \left(\sum_{l=m+1}^n \xi_l \langle \mathbb{1}_{[0,t]}, b_l \rangle \right) \right] \\ &= \sum_{k=m+1}^n \langle \mathbb{1}_{[0,t]}, b_k \rangle^2 \leq \sum_{k=m+1}^{\infty} \langle \mathbb{1}_{[0,t]}, b_k \rangle^2. \end{aligned}$$

Since $\sum_{k=1}^{\infty} \langle \mathbb{1}_{[0,t]}, b_k \rangle^2 = \|\mathbb{1}_{[0,t]}\|^2 = t < \infty$, we have $X_t^n \in L^2(\mathbf{P})$ and

$$\lim_{m \rightarrow \infty} \sup_{n \geq m} \mathbf{E} [(X_t^m - X_t^n)^2] = 0$$

Hence $(X_t^n)_{n \in \mathbb{N}}$ is a Cauchy sequence in $L^2(\mathbf{P})$ and thus (since $L^2(\mathbf{P})$ is complete, see Theorem 7.3) has an L^2 -limit X_t . Thus, for $N \in \mathbb{N}$ and $0 \leq t_1, \dots, t_N \leq 1$,

$$\lim_{n \rightarrow \infty} \mathbf{E} \left[\sum_{i=1}^N (X_{t_i}^n - X_{t_i})^2 \right] = 0.$$

In particular, $(X_{t_1}^n, \dots, X_{t_N}^n) \xrightarrow{n \rightarrow \infty} (X_{t_1}, \dots, X_{t_N})$ in $\mathbf{P}$ -probability.

Manifestly, $(X_{t_1}^n, \dots, X_{t_N}^n)$ is normally distributed and centered. For $s, t \in [0, 1]$, we have

$$\begin{aligned} \text{Cov}[X_s^n, X_t^n] &= \mathbf{E} \left[\left(\sum_{k=1}^n \xi_k \langle \mathbb{1}_{[0,s]}, b_k \rangle \right) \left(\sum_{l=1}^n \xi_l \langle \mathbb{1}_{[0,t]}, b_l \rangle \right) \right] \\ &= \sum_{k,l=1}^n \mathbf{E} [\xi_k \xi_l] \langle \mathbb{1}_{[0,s]}, b_k \rangle \langle \mathbb{1}_{[0,t]}, b_l \rangle \\ &= \sum_{k=1}^n \langle \mathbb{1}_{[0,s]}, b_k \rangle \langle \mathbb{1}_{[0,t]}, b_k \rangle \\ &\xrightarrow{n \rightarrow \infty} \langle \mathbb{1}_{[0,s]}, \mathbb{1}_{[0,t]} \rangle = \min(s, t) \end{aligned}$$

Hence $(X_t)_{t \in [0,1]}$ is a centered Gaussian process with

$$\text{Cov}[X_s, X_t] = \min(s, t). \quad (21.23)$$

Lévy Construction of Brownian Motion

Up to continuity of paths, X is thus a Brownian motion. A continuous version of X can be obtained via the Kolmogorov-Chentsov theorem (Theorem 21.6). However,

Fig. 21.2 The processes $\{X^n\}_{n=0,1,2,3,10}$ of the Lévy construction of Brownian motion

by a clever choice of the ONB $(b_n)_{n \in \mathbb{N}}$, we can construct X directly as a continuous process. The Haar functions $b_{n,k}$ are one such choice: Let $b_{0,1} \equiv 1$ and for $n \in \mathbb{N}$ and $k = 1, \dots, 2^{n-1}$, let

$$b_{n,k}(t) = \begin{cases} 2^{(n-1)/2}, & \text{if } \frac{2k-2}{2^n} \leq t < \frac{2k-1}{2^n}, \\ -2^{(n-1)/2}, & \text{if } \frac{2k-1}{2^n} \leq t < \frac{2k}{2^n}, \\ 0, & \text{else.} \end{cases}$$

Then $(b_{n,k})$ is an orthonormal system: $\langle b_{m,k}, b_{n,l} \rangle = \mathbb{1}_{\{(m,k)=(n,l)\}}$. It is easy to check that $(b_{n,k})$ is a basis (exercise!). Define the Schauder functions by

$$B_{n,k}(t) = \int_{[0,t]} b_{n,k}(s) \lambda(ds) = \langle \mathbb{1}_{[0,t]}, b_{n,k} \rangle.$$

Let $\xi_{0,1}, (\xi_{n,k})_{n \in \mathbb{N}, k=1, \dots, 2^{n-1}}$ be independent and $\mathcal{N}_{0,1}$ -distributed. Let

$$X^n := \xi_{0,1} B_{0,1} + \sum_{m=1}^n \sum_{k=1}^{2^{m-1}} \xi_{m,k} B_{m,k},$$

and define $\tilde{X}_t$ as the $L^2(\mathbf{P})$ -limit $\tilde{X}_t = L^2 - \lim_{n \rightarrow \infty} X_t^n$. See Fig. 21.2 for a computer simulation of $X^n, n = 0, 1, 2, 3, 10$.

Theorem 21.28 (Brownian motion, L^2 -approximation) There is a continuous version X of $\tilde{X}$. X is a Brownian motion and we have

$$\lim_{n \rightarrow \infty} \|X^n - X\|_\infty = 0 \quad \mathbf{P}\text{-almost surely} \quad (21.24)$$

Proof By (21.24), we have $X_t = \tilde{X}_t$ a.s. for all $t \in [0, 1]$. As uniform limits of continuous functions are continuous, (21.24) implies that X is continuous. Hence, by (21.23) (and Theorem 21.11), X is a Brownian motion. Therefore, it is enough to prove the existence of an X such that (21.24) holds.

Since $(C([0, 1]), \|\cdot\|_\infty)$ is complete, it suffices to show that $\mathbf{P}$ -almost surely (X^n) is a Cauchy sequence in $(C([0, 1]), \|\cdot\|_\infty)$. Note that $\|B_{n,k}\|_\infty \leq 2^{-(n+1)/2}$ if $n \in \mathbb{N}$ and $B_{n,k} B_{n,l} = 0$ if $k \neq l$. Hence

$$\|X^n - X^{n-1}\|_\infty \leq 2^{-(n+1)/2} \max \{|\xi_{n,k}|, k = 1, \dots, 2^{n-1}\}.$$

Therefore,

$$\begin{aligned} \mathbf{P} [\|X^n - X^{n-1}\|_\infty > 2^{-n/4}] &\leq \sum_{k=1}^{2^{n-1}} \mathbf{P} [|\xi_{n,k}| > 2^{(n+2)/4}] \\ &= 2^{n-1} \frac{2}{\sqrt{2\pi}} \int_{2^{(n+2)/4}}^{\infty} e^{-x^2/2} dx \\ &\leq 2^n \exp(-2^{n/2}) \end{aligned}$$

Evidently, $\sum_{n=1}^{\infty} \mathbf{P} [\|X^n - X^{n-1}\|_\infty > 2^{-n/4}] < \infty$; hence, by the Borel-Cantelli lemma,

$$\mathbf{P} [\|X^n - X^{n-1}\|_\infty > 2^{-n/4} \quad \text{only finitely often}] = 1.$$

We conclude that $\lim_{n \rightarrow \infty} \sup_{m \geq n} \|X^m - X^n\|_\infty = 0$ $\mathbf{P}$ -almost surely.

Brownian Motion and White Noise

The construction of Brownian motion via Haar functions has the advantage that continuity of the paths is straightforward. For some applications, however, a decomposition in trigonometric functions is preferable. Here as the orthonormal basis of $L^2([0, 1])$ we use $b_0 = 1$ and

$$b_n(x) = \sqrt{2} \cos(n\pi x) \quad \text{for } n \in \mathbb{N}.$$

For $t \in [0, 1]$ and $n \in \mathbb{N}_0$, define

$$B_n(t) = \int_0^t b_n(s) \lambda(ds)$$

Fig. 21.3 The processes X^n , $n=0,1,4,64,8192$ from the Fourier Construction of Brownian motion

that is, $B_0(t) = t$ and

$$B_n(t) = \frac{\sqrt{2}}{n\pi} \sin(n\pi t) \quad \text{for } n \in \mathbb{N}.$$

Let $\xi_n, n \in \mathbb{N}_0$, be independent standard normally distributed random variables. Define $A_0 = \xi_0$ and

$$A_n := \frac{\sqrt{2}}{\pi n} \xi_n \quad \text{for } n \in \mathbb{N}.$$

Finally, let

$$X^n := \sum_{k=0}^n \xi_k B_k;$$

that is,

$$X^n(t) = \xi_0 t + \sum_{k=1}^n A_k \sin(k\pi t).$$

See Fig. 21.3 for a computer simulation of $X^n, n = 0, 1, 4, 64, 8192$.

As shown above, the sequence (X^n) converges in $L^2([0, 1])$ towards a process X , which (up to continuity of paths) has all properties of Brownian motion:

$$X_t = \xi_0 t + \sum_{n=1}^{\infty} \frac{\sqrt{2}}{n\pi} \xi_n \sin(n\pi t).$$

This representation of the Brownian motions goes back to Paley and Wiener who also show that along a suitable subsequence the series converges uniformly almost surely and hence the limit X is indeed continuous, see [125, Theorem XLIII, p. 148]. The representation is also

sometimes called Karhunen-Loève expansion. More precisely, up to the first summand, it is the Karhunen-Loève expansion of the Brownian bridge $(X_t - tX_1)_{t \in [0,1]}$ (see, e.g., [1, Chapter 3.3]).

Taking the formal derivative

$$\dot{X}_t := \frac{d}{dt}X_t = \xi_0 + \sqrt{2} \sum_{n=1}^{\infty} \xi_n \cos(n\pi t)$$

we get independent identically distributed Fourier coefficients for all frequencies. Hence, the formal object $\dot{X}$ is often referred to as white noise as opposed to colored noise where the coefficients for the different frequencies have different distributions.

The Fourier basis is not too well suited to showing continuity of paths. For example, the sufficient criterion of absolute summability of coefficients (A_n) fails (see Exercise 21.5.5).

Example 21.29 (Stochastic integral à la Paley-Wiener) Assume that $(\xi_n)_{n \in \mathbb{N}}$ is an i.i.d. sequence of $\mathcal{N}_{0,1}$ -distributed random variables. Let $(b_n)_{n \in \mathbb{N}}$ be an orthonormal basis of $L^2([0, 1])$ such that $W_t := \lim_{n \rightarrow \infty} \sum_{k=1}^n \xi_k \langle \mathbb{1}_{[0,t]}, b_k \rangle$, $t \in [0, 1]$, is a Brownian motion. For $f \in L^2([0, 1])$, define

$$I(f) := \sum_{n=1}^{\infty} \xi_n \langle f, b_n \rangle$$

By Parseval's equation and the Bienaymé formula, we have

$$\|f\|_2^2 = \sum_{n=1}^{\infty} \langle f, b_n \rangle^2 = \text{Var}[I(f)] = \mathbf{E} [I(f)^2]$$

Hence

$$I : L^2([0, 1]) \rightarrow L^2(\mathbf{P}), \quad f \mapsto I(f) \quad \text{is an isometry.} \quad (21.25)$$

We call

$$\int_0^t f(s) dW_s := I(f \mathbb{1}_{[0,t]}), \quad t \in [0, 1], f \in L^2([0, 1])$$

the stochastic integral of f with respect to W . In the special case of the Fourier basis $b_0(x) = 1$ and $b_n(x) = \sqrt{2} \cos(n\pi x)$, $n \in \mathbb{N}$, this construction goes back to Paley and Wiener [125, Theorem XLV, p. 154].

The process $X_t := \int_0^t f(s) dW_s$, $t \in [0, 1]$, is centered Gaussian with covariance function

$$\text{Cov}[X_s, X_t] = \int_0^{s \wedge t} f^2(u) du$$

In fact, it is obvious that X is centered and Gaussian (since it is a limit of the Gaussian processes of partial sums) and has the given covariance function. Furthermore, the existence of a continuous version can be obtained as for Brownian motion by employing the fourth moments of the increments, which for normal random variables can be computed from the variances (compare Theorem 21.9). In the following we will assume for the stochastic integral that such a continuous version is chosen.

In the special case, $f = \sum_{i=1}^n \alpha_i \mathbb{1}_{(t_{i-1}, t_i]}$ for some $n \in \mathbb{N}$ and $0 = t_0 < t_1 < \dots < t_n$ and $\alpha_1, \dots, \alpha_n \in \mathbb{R}$, we obtain

$$\int_0^1 f(s) dW_s = \sum_{i=1}^n \alpha_i (W_{t_i} - W_{t_{i-1}})$$

Exercise 21.5.1 Use the representation of Brownian motion $(W_t)_{t \in [0,1]}$ as a random linear combination of the Schauder functions $(B_{n,k})$ to show that the Brownian bridge $Y = (Y_t)_{t \in [0,1]} = (W_t - tW_1)_{t \in [0,1]}$ is a continuous, Gaussian process with covariance function $\text{Cov}[Y_t, Y_s] = (s \wedge t) - st$. Further, show that

$$\mathbf{P}_Y = \lim_{\varepsilon \downarrow 0} \mathbf{P}[W \in \cdot \mid W_1 \in (-\varepsilon, \varepsilon)].$$

Exercise 21.5.2 (Compare Example 8.32) Fix $T \in (0, 1)$. Use an orthonormal basis $b_{0,1}, (c_{n,k}), (d_{n,k})$ of suitably modified Haar functions (such that the $c_{n,k}$ have support $[0, T]$ and the $d_{n,k}$ have support $[T, 1]$) to show that a regular conditional distribution of W_T given W_1 is defined by

$$\mathbf{P}[W_T \in \cdot \mid W_1 = x] = \mathcal{N}_{T,x,T}$$

Exercise 21.5.3 Define $Y := (Y_t)_{t \in [0,1]}$ by $Y_1 = 0$ and

$$Y_t = (1-t) \int_0^t (1-s)^{-1} dW_s \quad \text{for } t \in [0, 1]$$

Show that Y is a Brownian bridge.

Hint: Show that Y is a continuous Gaussian process with the correct covariance function. In particular, it has to be shown that $\lim_{t \uparrow 1} Y_t = 0$ almost surely.

Exercise 21.5.4 Let $d \in \mathbb{N}$. Use a suitable orthonormal basis on $[0, 1]^d$ to show:

(i) There is a Gaussian process $(W_t)_{t \in [0,1]^d}$ with covariance function

$$\text{Cov}[W_t, W_s] = \prod_{i=1}^d (t_i \wedge s_i)$$

(ii) There is a modification of W such that $t \mapsto W_t$ is almost surely continuous (see Remark 21.7).

A process W with properties (i) and (ii) is called a Brownian sheet.

Exercise 21.5.5 Consider the coefficients $(A_n)_{n \in \mathbb{N}_0}$ of the Fourier basis of the construction of Brownian motion. Show the following statements:

- (i) $\sum_{n=0}^{\infty} A_n^2 < \infty$ almost surely.
- (ii) $\sum_{n=0}^{\infty} |A_n| = \infty$ almost surely.
- (iii) $\sum_{k=0}^n A_k, n \in \mathbb{N}$ converges almost surely.

Hint: Kolmogorov's three-series theorem (Theorem 15.50).

Exercise 21.5.6 Let $t \in (0, 1)$ and $f_0(x) := t$ as well as

$$f_n(x) := \frac{2 \sin(n\pi t)}{n\pi} \cos(n\pi x) \quad \text{for } n \in \mathbb{N}, x \in [0, 1]$$

Show that $\sum_{n=0}^{\infty} f_n(x) = \mathbb{1}_{[0,t]}(x)$ for $x \in (0, 1) \setminus \{t\}$.

5.21.6 21.6 The Space $c([0, \infty))$

Are functionals that depend on the whole path of a Brownian motion measurable? For example, is $\sup\{X_t, t \in [0, 1]\}$ measurable? For general stochastic processes, this is false since the supremum depends on more than countably many coordinates. However, for processes with continuous paths, this is true, as we will show in this section in a somewhat more general framework.

We may consider Brownian motion as the canonical process on the space $\Omega := C([0, \infty))$ of continuous paths.

We start by collecting some properties of the space $\Omega = C([0, \infty)) \subset \mathbb{R}^{[0, \infty)}$. Define the evaluation map

$$X_t : \Omega \rightarrow \mathbb{R}, \quad \omega \mapsto \omega(t), \quad (21.26)$$

that is, the restriction of the canonical projection $\mathbb{R}^{[0, \infty)} \rightarrow \mathbb{R}$ to Ω .

For $f, g \in C([0, \infty))$ and $n \in \mathbb{N}$, let $d_n(f, g) := \left\| (f - g)|_{[0, n]} \right\|_\infty \wedge 1$ and

$$d(f, g) = \sum_{n=1}^{\infty} 2^{-n} d_n(f, g). \quad (21.27)$$

Theorem 21.30 d is a complete metric on $\Omega := C([0, \infty))$ that induces the topology of uniform convergence on compact sets. The space (Ω, d) is separable and hence Polish.

Proof Clearly, every d_n is a complete metric on $(C([0, n]), \|\cdot\|_\infty)$. Thus, for every Cauchy sequence (f_N) in (Ω, d) and every $n \in \mathbb{N}$, there exists a $g_n \in \Omega$ with $d_n(f_N, g_n) \xrightarrow{N \rightarrow \infty} 0$. Evidently, $g_n(x) = g_m(x)$ for every $x \leq m \wedge n$; hence there exists a $g \in \Omega$ with $g(x) = g_n(x)$ for every $x \leq n$ for every $n \in \mathbb{N}$. Hence, clearly, $d(f_N, g) \xrightarrow{N \rightarrow \infty} 0$, and thus d is complete.

The set of polynomials with rational coefficients is countable and by the Weierstraß theorem, it is dense in any $(C([0, n]), \|\cdot\|_\infty)$; hence it is dense in (Ω, d) .

Theorem 21.31 With respect to the Borel σ -algebra $\mathcal{B}(\Omega, d)$, the canonical projections $X_t, t \in [0, \infty)$ are measurable. On the other hand, the X_t generate $\mathcal{B}(\Omega, d)$. Hence

$$(\mathcal{B}(\mathbb{R}))^{\otimes [0, \infty)}|_\Omega = \sigma(X_t, t \in [0, \infty)) = \mathcal{B}(\Omega, d)$$

Proof The first equation holds by definition. For the second one, we must show the mutual inclusions.

" $\subset$ " Clearly, every $X_t : \Omega \rightarrow \mathbb{R}$ is continuous and hence $(\mathcal{B}(\Omega, d) - \mathcal{B}(\mathbb{R}))$ measurable. Thus $\sigma(X_t, t \in [0, \infty)) \subset \mathcal{B}(\Omega, d)$.

" $\supset$ " We have to show that open subsets of (Ω, d) are in $\mathcal{A} := (\mathcal{B}(\mathbb{R}))^{\otimes [0, \infty)}$. Since (Ω, d) is separable (Theorem 21.30), every open set is a countable union of ε -balls. Hence it suffices to show that for fixed $\omega_0 \in \Omega$, the map $\omega \mapsto d(\omega_0, \omega)$ is $\mathcal{A}$ -measurable. To this end it is enough to show that for any $n \in \mathbb{N}$, the map $\omega \mapsto Y_n(\omega) := d_n(\omega_0, \omega)$ (see (21.27)) is $\mathcal{A}$ -measurable. However, the map

$$\omega \mapsto Z_t(\omega) := |X_t(\omega) - X_t(\omega_0)| \wedge 1$$

is $\mathcal{A}$ -measurable. Since each ω is continuous, Y_n is a countable supremum

$$Y_n = \sup_{t \in [0, n] \cap \mathbb{Q}} Z_t$$

and is hence $\mathcal{A}$ -measurable.

In the following, let $\mathcal{A} := \sigma(X_t, t \in [0, \infty))$.

Corollary 21.32 The map $F_1 : \Omega \rightarrow [0, \infty), \omega \mapsto \sup\{\omega(t) : t \in [0, 1]\}$ is $\mathcal{A}$ measurable.

Proof F_1 is continuous with respect to d and hence $\mathcal{B}(\Omega, d)$ -measurable.

If B is a Brownian motion (on some probability space $(\tilde{\Omega}, \tilde{\mathcal{A}}, \tilde{\mathbf{P}})$), then there exists an $\bar{\Omega} \in \tilde{\mathcal{A}}$ with $\tilde{\mathbf{P}}[\bar{\Omega}] = 1$ and $B(\omega) \in C([0, \infty))$ for every $\omega \in \bar{\Omega}$. Let $\bar{\mathcal{A}} = \tilde{\mathcal{A}}|_{\bar{\Omega}}$ and $\bar{\mathbf{P}} = \tilde{\mathbf{P}}|_{\bar{\mathcal{A}}}$. Then $B : \bar{\Omega} \rightarrow C([0, \infty))$ is measurable with respect to $(\bar{\mathcal{A}}, \mathcal{A})$. With respect to the image measure $\mathbf{P} = \bar{\mathbf{P}} \circ B^{-1}$ on $\Omega = C([0, \infty))$, the canonical process $X = (X_t, t \in [0, \infty))$ on $C([0, \infty))$ is a Brownian motion.

Definition 21.33 Let $\mathbf{P}$ be the probability measure on $\Omega = C([0, \infty))$ with respect to which the canonical process X is a Brownian motion. Then $\mathbf{P}$ is called the Wiener measure. The

triple $(\Omega, \mathcal{A}, \mathbf{P})$ is called the Wiener space, and X is called the canonical Brownian motion or the Wiener process.

Remark 21.34 Sometimes we want a Brownian motion to start not at $X_0 = 0$ but at an arbitrary point x . Denote by $\mathbf{P}_x$ that measure on $C([0, \infty))$ for which $\tilde{X} = (X_t - x, t \in [0, \infty))$ is a Brownian motion (with $\tilde{X}_0 = 0$).

Exercise 21.6.1 Show that the map

$$F_\infty : \Omega \rightarrow [0, \infty], \quad \omega \mapsto \sup\{\omega(t) : t \in [0, \infty)\}$$

is $\mathcal{A}$ -measurable.

5.21.7 21.7 Convergence of Probability Measures on $C([0, \infty))$

Let X and $(X^n)_{n \in \mathbb{N}}$ be random variables with values in $C([0, \infty))$ (i.e., continuous stochastic processes) with distributions $\mathbf{P}_X$ and $(\mathbf{P}_{X^n})_{n \in \mathbb{N}}$.

Definition 21.35 We say that the finite-dimensional distributions of (X^n) converge to those of X if, for every $k \in \mathbb{N}$ and $t_1, \dots, t_k \in [0, \infty)$, we have

$$(X_{t_1}^n, \dots, X_{t_k}^n) \xrightarrow{n \rightarrow \infty} (X_{t_1}, \dots, X_{t_k}).$$

In this case, we write

$$X^n \xrightarrow[\text{fdd}]{n \rightarrow \infty} X \quad \text{or} \quad \mathbf{P}_{X^n} \xrightarrow[\text{fdd}]{n \rightarrow \infty} \mathbf{P}_X.$$

Lemma 21.36 $P_n \xrightarrow[\text{fdd}]{n \rightarrow \infty} P$ and $P_n \xrightarrow[\text{fdd}]{n \rightarrow \infty} Q$ imply $P = Q$.

Proof By Theorem 14.12(iii), the finite-dimensional distributions determine P uniquely.

Theorem 21.37 Weak convergence in $\mathcal{M}_1(\Omega, d)$ implies fdd-convergence:

$$P_n \xrightarrow{n \rightarrow \infty} P \implies P_n \xrightarrow[\text{fdd}]{n \rightarrow \infty} P.$$

Proof Let $k \in \mathbb{N}$ and $t_1, \dots, t_k \in [0, \infty)$. The map

$$\varphi : C([0, \infty)) \rightarrow \mathbb{R}^k, \quad \omega \mapsto (\omega(t_1), \dots, \omega(t_k))$$

is continuous. By the continuous mapping theorem (Theorem 13.25 on p. 257), we have $P_n \circ \varphi^{-1} \xrightarrow{n \rightarrow \infty} P \circ \varphi^{-1}$; hence $P_n \xrightarrow[\text{fdd}]{n \rightarrow \infty} P$.

The converse statement in the preceding theorem does not hold. However, we still have the following.

Theorem 21.38 Let $(P_n)_{n \in \mathbb{N}}$ and P be probability measures on $C([0, \infty))$. Then the following are equivalent:

- (i) $P_n \xrightarrow{n \rightarrow \infty} P$ and $(P_n)_{n \in \mathbb{N}}$ is tight.
- (ii) $P_n \xrightarrow{\text{fdd}} P$ weakly.

Proof "(ii) $\implies$ (i)" This is a direct consequence of Prohorov's theorem (Theorem 13.29 with $E = C([0, \infty))$).

"(i) $\implies$ (ii)" By Prohorov's theorem, $(P_n)_{n \in \mathbb{N}}$ is relatively sequentially compact. Let Q be a limit point for $(P_{n_k})_{k \in \mathbb{N}}$ along some subsequence (n_k) . Then $P_{n_k} \xrightarrow{\text{fdd}} Q$, $k \rightarrow \infty$. By Lemma 21.36, we have $P = Q$.

Next we derive a useful criterion for tightness of sets $\{P_n\} \subset \mathcal{M}_1(C([0, \infty)))$. We start by recalling the Arzelà-Ascoli characterization of relatively compact sets in $C([0, \infty))$ (see, e.g., [37, Theorem 2.4.7] or [173, Theorem III.3]).

For $N, \delta > 0$ and $\omega \in C([0, \infty))$, let

$$V^N(\omega, \delta) := \sup\{|\omega(t) - \omega(s)| : |t - s| \leq \delta, s, t \leq N\}.$$

Theorem 21.39 (Arzelà-Ascoli) A set $A \subset C([0, \infty))$ is relatively compact if and only if the following two conditions hold.

- (i) $\{\omega(0), \omega \in A\} \subset \mathbb{R}$ is bounded.
- (ii) For every N , we have $\lim_{\delta \downarrow 0} \sup_{\omega \in A} V^N(\omega, \delta) = 0$.

Theorem 21.40 A family $(P_i, i \in I)$ of probability measures on $C([0, \infty))$ is weakly relatively compact if and only if the following two conditions hold.

- (i) $(P_i \circ X_0^{-1}, i \in I)$ is tight; that is, for every $\varepsilon > 0$, there is a $K > 0$ such that

$$P_i(\{\omega : |\omega(0)| > K\}) \leq \varepsilon \quad \text{for all } i \in I. \quad (21.28)$$

- (ii) For all $\eta, \varepsilon > 0$ and $N \in \mathbb{N}$, there is a $\delta > 0$ such that

$$P_i(\{\omega : V^N(\omega, \delta) > \eta\}) \leq \varepsilon \quad \text{for all } i \in I. \quad (21.29)$$

Proof " " By Prohorov's theorem (Theorem 13.29), weak relative compactness of $(P_i, i \in I)$ implies tightness of this family. Thus, for every $\varepsilon > 0$, there exists a compact set $A \subset C([0, \infty))$ with $P_i(A) > 1 - \varepsilon$ for every $i \in I$. Using the Arzelà-Ascoli characterization of the compactness of A , we infer (i) and (ii).

"." Now assume that (i) and (ii) hold. Then, for $\varepsilon > 0$ and $k, N \in \mathbb{N}$, choose numbers K_ε and $\delta_{N,k,\varepsilon}$ such that

$$\sup_{i \in I} P_i(\{\omega : |\omega(0)| > K_\varepsilon\}) \leq \frac{\varepsilon}{2}$$

and

$$\sup_{i \in I} P_i\left(\left\{\omega : V^N(\omega, \delta_{N,k,\varepsilon}) > \frac{1}{k}\right\}\right) \leq 2^{-N-k-1}\varepsilon.$$

Define

$$C_{N,\varepsilon} = \left\{\omega : |\omega(0)| \leq K_\varepsilon, V^N(\omega, \delta_{N,k,\varepsilon}) \leq \frac{1}{k} \text{ for all } k \in \mathbb{N}\right\}.$$

By the Arzelà-Ascoli theorem, $C_\varepsilon := \bigcap_{N \in \mathbb{N}} C_{N,\varepsilon}$ is relatively compact in $C([0, \infty))$ and we have

$$P_i(C_\varepsilon^c) \leq \frac{\varepsilon}{2} + \sum_{k,N=1}^{\infty} P_i(\{\omega : V^N(\omega, \delta_{N,k,\varepsilon}) > 1/k\}) \leq \varepsilon \quad \text{for all } i \in I$$

Hence the claim follows.

Corollary 21.41 Let $(X_i, i \in I)$ and $(Y_i, i \in I)$ be families of random variables in $C([0, \infty))$. Assume that $(\mathbf{P}_{X_i}, i \in I)$ and $(\mathbf{P}_{Y_i}, i \in I)$ are tight. Then $(\mathbf{P}_{X_i+Y_i}, i \in I)$ is tight.

Proof Apply the triangle inequality in order to check (i) and (ii) in the preceding theorem.

The following is an important tool to check weak relative compactness.

Theorem 21.42 (Kolmogorov's criterion for weak relative compactness) Let $(X^i, i \in I)$ be a sequence of continuous stochastic processes. Assume that the following conditions are satisfied.

- (i) The family $(\mathbf{P}[X_0^i \in \cdot], i \in I)$ of initial distributions is tight.
- (ii) For any $N > 0$ there are numbers $C, \alpha, \beta > 0$ such that, for all $s, t \in [0, N]$ and every $i \in I$, we have

$$\mathbf{E}[|X_s^i - X_t^i|^\alpha] \leq C|s - t|^{\beta+1}.$$

Then the family $(\mathbf{P}_{X^i}, i \in I) = (\mathcal{L}[X^i], i \in I)$ of distributions of X^i is weakly relatively compact in $\mathcal{M}_1(C([0, \infty)))$.

Proof We check the conditions of Theorem 21.40. The first condition of Theorem 21.40 is exactly (i).

Let $N > 0$. By the Kolmogorov-Chentsov theorem (Theorem 21.6(ii)), for $\varepsilon > 0$ and $\gamma \in (0, \beta/\alpha)$, there exists a K such that, for every $i \in I$, we have

$$\mathbf{P} [|X_t^i - X_s^i| \leq K|t - s|^\gamma \text{ for all } s, t \in [0, N]] \geq 1 - \varepsilon.$$

This clearly implies (21.29) with $\delta = (\eta/K)^{1/\gamma}$. $\square$

5.21.8 21.8 Donsker's Theorem

Let $Y_1, Y_2, \dots$ be i.i.d. random variables with $\mathbf{E}[Y_1] = 0$ and $\text{Var}[Y_1] = \sigma^2 > 0$. For $t > 0$, let $S_t^n = \sum_{i=1}^{\lfloor nt \rfloor} Y_i$ and $\tilde{S}_t^n = \frac{1}{\sqrt{\sigma^2 n}} S_t^n$. By the central limit theorem, for $t > s \geq 0$, we have $\mathcal{L}[\tilde{S}_t^n - \tilde{S}_s^n] \xrightarrow{n \rightarrow \infty} \mathcal{N}_{0, t-s}$.

Let $B = (B_t, t \geq 0)$ be a Brownian motion. Then

$$\mathcal{L}[\tilde{S}_t^n - \tilde{S}_s^n] \xrightarrow{n \rightarrow \infty} \mathcal{L}[B_t - B_s] \quad \text{for any } t > s \geq 0.$$

For $N \in \mathbb{N}$ and $0 = t_0 < t_1 < \dots < t_N$, the random variables $\tilde{S}_{t_i}^n - \tilde{S}_{t_{i-1}}^n, i = 1, \dots, N$, are independent, and hence, we have

$$\mathcal{L}[(\tilde{S}_{t_1}^n - \tilde{S}_{t_0}^n, \dots, \tilde{S}_{t_N}^n - \tilde{S}_{t_{N-1}}^n)] \xrightarrow{n \rightarrow \infty} \mathcal{L}[(B_{t_1} - B_{t_0}, \dots, B_{t_N} - B_{t_{N-1}})].$$

We infer that

$$\mathcal{L}[(\tilde{S}_{t_1}^n, \dots, \tilde{S}_{t_N}^n)] \xrightarrow{n \rightarrow \infty} \mathcal{L}[(B_{t_1}, \dots, B_{t_N})]. \quad (21.30)$$

We now define $\bar{S}^n$ as $\tilde{S}^n$ but linearly interpolated:

$$\bar{S}_t^n = \frac{1}{\sqrt{\sigma^2 n}} \sum_{i=1}^{\lfloor nt \rfloor} Y_i + \frac{tn - \lfloor tn \rfloor}{\sqrt{\sigma^2 n}} Y_{\lfloor tn \rfloor + 1}. \quad (21.31)$$

Then, for $\varepsilon > 0$,

$$\begin{aligned} \mathbf{P} [|\tilde{S}_t^n - \bar{S}_t^n| > \varepsilon] &\leq \varepsilon^{-2} \mathbf{E} \left[(\tilde{S}_t^n - \bar{S}_t^n)^2 \right] \\ &\leq \frac{1}{\varepsilon^2 n} \frac{1}{\sigma^2} \mathbf{E} [Y_1^2] = \frac{1}{\varepsilon^2 n} \xrightarrow{n \rightarrow \infty} 0. \end{aligned}$$

By Slutsky's theorem (Theorem 13.18), we thus have convergence of the finitedimensional distributions to the Wiener measure $\mathbf{P}_W$:

$$\mathbf{P}_{\bar{S}^n} \xrightarrow[\text{fdd}]{n \rightarrow \infty} \mathbf{P}_W. \quad (21.32)$$

The aim of this section is to strengthen this convergence statement to weak convergence of probability measures on $C([0, \infty))$. The main theorem of this section is the functional central limit theorem, which goes back to Donsker [35]. Theorems

of this type are also called invariance principles since the limiting distribution is the same for all distributions Y_i with expectation 0 and the same variance.

Theorem 21.43 (Donsker's invariance principle) In the sense of weak convergence on $C([0, \infty))$, the distributions of $\bar{S}^n$ converge to the Wiener measure,

$$\mathcal{L}[\bar{S}^n] \xrightarrow{n \rightarrow \infty} \mathbf{P}_W. \quad (21.33)$$

Proof Owing to (21.32) and Theorem 21.38, it is enough to show that $(\mathcal{L}[\bar{S}^n], n \in \mathbb{N})$ is tight. To this end, we want to apply Kolmogorov's moment criterion. However, as in the proof of existence of Brownian motion, second moments are not enough; rather we need fourth moments in order that we can choose $\beta > 0$. Hence the strategy is to truncate the Y_i to obtain fourth moments.

For $K > 0$, define

$$\begin{aligned} Y_i^K &:= Y_i \mathbb{1}_{\{|Y_i| \leq K/2\}} - \mathbf{E}[Y_i \mathbb{1}_{\{|Y_i| \leq K/2\}}] \quad \text{and} \\ Z_i^K &:= Y_i - Y_i^K \quad \text{for } i \in \mathbb{N}. \end{aligned}$$

Then $\mathbf{E}[Y_i^K] = \mathbf{E}[Z_i^K] = 0$ and $\text{Var}[Z_i^K] \xrightarrow{K \rightarrow \infty} 0$ as well as $\text{Var}[Y_i^K] \leq \sigma^2, i \in \mathbb{N}$. Clearly, $|Y_i^K| \leq K$ for every i . Define

$$T_n^K := \sum_{i=1}^n Y_i^K \quad \text{and} \quad U_n^K := \sum_{i=1}^n Z_i^K \quad \text{for } n \in \mathbb{N}.$$

Let $\bar{T}_t^{K,n}$ and $\bar{U}_t^{K,n}$ be the linearly interpolated versions of

$$\tilde{T}_t^{K,n} := \frac{1}{\sqrt{\sigma^2 n}} T_{[nt]}^K \quad \text{and} \quad \tilde{U}_t^{K,n} := \frac{1}{\sqrt{\sigma^2 n}} U_{[nt]}^K \quad \text{for } t \geq 0.$$

Evidently, $\bar{S}^n = \bar{T}^{K,n} + \bar{U}^{K,n}$. By Corollary 21.41, it is enough to show that, for a sequence $(K_n)_{n \in \mathbb{N}}$ (chosen later), the families $(\mathcal{L}[\bar{U}^{K_n,n}], n \in \mathbb{N})$ and $(\mathcal{L}[\bar{T}^{K_n,n}], n \in \mathbb{N})$ are tight.

We consider first the remainder term. As U^K is a martingale, Doob's inequality (Theorem 11.2) yields

$$\mathbf{P} \left[\sup_{l=1, \dots, n} |U_l^K| > \varepsilon \sqrt{n} \right] \leq \varepsilon^{-2} \text{Var}[Z_1^K] \quad \text{for every } \varepsilon > 0.$$

Now, if $K_n \uparrow \infty, n \rightarrow \infty$, then for every $N > 0$, we have

$$\mathbf{P} \left[\sup_{t \in [0, N]} |\bar{U}_t^{K_n,n}| > \varepsilon \right] \leq \frac{N}{\varepsilon^2 \sigma^2} \text{Var}[Z_1^{K_n}] \xrightarrow{n \rightarrow \infty} 0$$

hence $\bar{U}^{K_n,n} \xrightarrow{n \rightarrow \infty} 0$ in $C([0, \infty))$. In particular, $(\mathcal{L}[\bar{U}^{K_n,n}], n \in \mathbb{N})$ is tight.

Next, for $N > 0$ and $s, t \in [0, N]$, we compute the fourth moments of the differences $\bar{T}_{t+s}^{K_n,n} - \bar{T}_s^{K_n,n}$ for the main term. In the following, let $K_n = n^{1/4}$. Fix $n \in \mathbb{N}$. We distinguish two cases:

Case 1: $t < n^{-1}$. Let $k := \lfloor (t+s)n \rfloor$. If $sn \geq k$, then

$$\bar{T}_{t+s}^{K_n,n} - \bar{T}_s^{K_n,n} = \frac{tn}{\sqrt{n\sigma^2}} Y_{k+1}^{K_n}.$$

If $sn < k$, then

$$\bar{T}_{t+s}^{K_n,n} - \bar{T}_s^{K_n,n} = \frac{1}{\sqrt{n\sigma^2}} ((t+s)n - k) Y_{k+1}^{K_n} + (k - sn) Y_k^{K_n}.$$

In either case, we have

$$\left| \bar{T}_{t+s}^{K_n, n} - \bar{T}_s^{K_n, n} \right| \leq \frac{t\sqrt{n}}{\sigma} (|Y_k^{K_n}| + |Y_{k+1}^{K_n}|),$$

hence

$$\begin{aligned} \mathbf{E} \left[\left(\bar{T}_{t+s}^{K_n, n} - \bar{T}_s^{K_n, n} \right)^4 \right] &\leq \frac{n^2 t^4}{\sigma^4} (2K_n)^2 \mathbf{E} \left[(|Y_1^{K_n}| + |Y_2^{K_n}|)^2 \right] \\ &\leq \frac{16n^{5/2} t^4}{\sigma^4} \text{Var} [Y_1^{K_n}] \leq \frac{16}{\sigma^2} t^{3/2} \end{aligned} \quad (21.34)$$

Case 2: $t \geq n^{-1}$. Using the binomial theorem, we get (note that the mixed terms with odd moments vanish since $\mathbf{E} [Y_1^{K_n}] = 0$)

$$\begin{aligned} \mathbf{E} \left[(T_n^{K_n})^4 \right] &= n \mathbf{E} \left[(Y_1^{K_n})^4 \right] + 3n(n-1) \mathbf{E} \left[(Y_1^{K_n})^2 \right]^2 \\ &\leq n K_n^2 \sigma^2 + 3n(n-1) \sigma^4. \end{aligned} \quad (21.35)$$

Note that, for independent real random variables X, Y with $\mathbf{E}[X] = \mathbf{E}[Y] = 0$ and $\mathbf{E}[X^4], \mathbf{E}[Y^4] < \infty$ and for $a \in [-1, 1]$, we have

$$\begin{aligned} \mathbf{E} [(aX + Y)^4] &= a^4 \mathbf{E} [X^4] + 6a^2 \mathbf{E} [X^2] \mathbf{E} [Y^2] + \mathbf{E} [Y^4] \\ &\leq \mathbf{E} [X^4] + 6 \mathbf{E} [X^2] \mathbf{E} [Y^2] + \mathbf{E} [Y^4] = \mathbf{E} [(X + Y)^4]. \end{aligned}$$

We apply this twice (with $a = \lceil (t+s)n \rceil - (t+s)n$ and $a = sn - \lfloor sn \rfloor$) and obtain (using the estimate $\lceil (t+s)n \rceil - \lfloor sn \rfloor \leq tn + 2 \leq 3tn$) from (21.35) (since $t \leq N$)

$$\begin{aligned} \mathbf{E} \left[\left(\bar{T}_{t+s}^{K_n, n} - \bar{T}_s^{K_n, n} \right)^4 \right] &\leq n^{-2} \sigma^{-4} \mathbf{E} \left[\left(T_{\lceil (t+s)n \rceil}^{K_n} - T_{\lfloor sn \rfloor}^{K_n} \right)^4 \right] \\ &= n^{-2} \sigma^{-4} \mathbf{E} \left[\left(T_{\lceil (t+s)n \rceil - \lfloor sn \rfloor}^{K_n} \right)^4 \right] \\ &\leq \frac{3tn K_n^2}{n^2 \sigma^2} + 18t^2 = \frac{3}{\sigma^2} tn^{-1/2} + 18t^2 \\ &\leq \frac{3}{\sigma^2} t^{3/2} + 18t^2 \leq \left(\frac{3}{\sigma^2} + 18\sqrt{N} \right) t^{3/2} \end{aligned} \quad (21.36)$$

By (21.34) and (21.36), for every $N > 0$, there exists a $C = C(N, \sigma^2)$ such that, for every $n \in \mathbb{N}$ and all $s, t \in [0, N]$, we have

$$\mathbf{E} \left[\left(\bar{T}_{t+s}^{K_n, n} - \bar{T}_s^{K_n, n} \right)^4 \right] \leq C t^{3/2}$$

Hence, by Kolmogorov's moment criterion (Theorem 21.42 with $\alpha = 4$ and $\beta = 1/2$), $(\mathcal{L} [\bar{T}^{K_n, n}], n \in \mathbb{N})$ is tight in $\mathcal{M}_1(C([0, \infty)))$.

Exercise 21.8.1 Let $X_1, X_2, \dots$ be i.i.d. random variables with continuous distribution function F . Let $G_n : [0, 1] \rightarrow \mathbb{R}, t \mapsto n^{-1/2} \sum_{i=1}^n (\mathbb{1}_{[0, t]}(F(X_i)) - t)$ and $M_n := \|G_n\|_\infty$. Further, let $M = \sup_{t \in [0, 1]} |B_t|$, where B is a Brownian bridge.

(i) Show that $\mathbf{E} [G_n(t)] = 0$ and $\mathbf{Cov} [G_n(s), G_n(t)] = s \wedge t - st$ for $s, t \in [0, 1]$.

(ii) Show that $\mathbf{E} [(G_n(t) - G_n(s))^4] \leq C((t-s)^2 + |t-s|/n)$ for some $C > 0$.

(iii) Conclude that a suitable continuous version of G_n converges weakly to B . For example, choose

$$H_n(t) = n^{-1/2} \sum_{i=1}^n (h_n(F(X_i) - t) - g_n(t)),$$

where h_n is a suitable smoothed version of $\mathbb{1}_{(-\infty, 0]}$, for example, $h_n(s) = 1 - (s/\varepsilon_n \vee 0) \wedge 1$ for some sequence $\varepsilon_n \downarrow 0$, and $g_n(t) := \int_0^1 h_n(t - u) du$.

(iv) Finally, show that $M_n \xrightarrow{n \rightarrow \infty} M$.

Remark: The distribution of M can be expressed by the Kolmogorov-Smirnov formula ([101] and [156]; see, e.g., [133])

$$\mathbf{P}[M > x] = 2 \sum_{n=1}^{\infty} (-1)^{n-1} e^{-2n^2 x^2} \quad (21.37)$$

Compare (21.20). Using the statistic M_n , one can test if random variables of a known distribution are independent. Let $X_1, X_2, \dots$ and $\tilde{X}_1, \tilde{X}_2, \dots$ be independent random variables with unknown continuous distribution functions F and $\tilde{F}$ and with empirical distribution functions F_n and $\tilde{F}_n$. Further, let

$$D_n := \sup_{t \in \mathbb{R}} |F_n(t) - \tilde{F}_n(t)|$$

Under the assumption that $F = \tilde{F}$ holds, $\sqrt{n/2} D_n$ converges in distribution to M . This fact is the basis for nonparametric tests on the equality of distributions.

5.21.9 21.9 Pathwise Convergence of Branching Processes*

In this section, we investigate the convergence of rescaled Galton-Watson processes (branching processes). As for sums of independent random variables, we first show convergence for a fixed time point to the distribution of a certain limiting process. The next step is to show convergence of finite-dimensional distributions. Finally, using Kolmogorov's moment criterion for tightness, we show convergence in the path space $C([0, \infty))$.

Consider a Galton-Watson process $(Z_n)_{n \in \mathbb{N}_0}$ with geometric offspring distribution

$$p(k) = 2^{-k-1} \quad \text{for } k \in \mathbb{N}_0$$

That is, let $X_{n,i}, n, i \in \mathbb{N}_0$ be i.i.d. random variables on $\mathbb{N}_0$ with $\mathbf{P}[X_{n,i} = k] = p(k), k \in \mathbb{N}_0$, and based on the initial state Z_0 define inductively

$$Z_{n+1} = \sum_{i=1}^{Z_n} X_{n,i}$$

Thus Z is a Markov chain with transition probabilities $p(i, j) = p^{*i}(j)$, where p^{*i} is the i th convolution power of p . In other words, if $Z, Z^1, \dots, Z^i$ are independent copies of our Galton-Watson process, with $Z_0 = i$ and $Z_0^1 = \dots = Z_0^i = 1$, then

$$Z \stackrel{\mathcal{D}}{=} Z^1 + \dots + Z^i \quad (21.38)$$

We consider now the probability generating function of $X_{1,1}, \psi^{(1)}(s) := \psi(s) := \mathbf{E}[s^{X_{1,1}}], s \in [0, 1]$. Denote by $\psi^{(n)} := \psi^{(n-1)} \circ \psi$ its n th iterate for $n \in \mathbb{N}$. Then, by Lemma 3.10,

$$\mathbf{E}_i[s^{Z_n}] = \mathbf{E}_1[s^{Z_n}]^i = (\psi^{(n)}(s))^i.$$

For the geometric offspring distribution, $\psi^{(n)}$ can be computed explicitly.

Lemma 21.44 For the branching process with critical geometric offspring distribution, the n th iterate of the probability generating function is

$$\psi^{(n)}(s) = \frac{n - (n-1)s}{n+1 - ns}.$$

Proof Compute

$$\psi(s) = \sum_{k=0}^{\infty} 2^{-k-1} s^k = \frac{1}{-s+2}$$

In order to compute the iterated function, first consider general linear rational functions of the form $f(x) = \frac{ax+b}{cx+d}$. For such f , define the matrix $M_f = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$. For two linear rational functions f and g , we have $M_{f \circ g} = M_f \cdot M_g$. The powers of M are easy to compute:

$$M_\psi = \begin{pmatrix} 0 & 1 \\ -1 & 2 \end{pmatrix}, \quad M_\psi^2 = \begin{pmatrix} -1 & 2 \\ -2 & 3 \end{pmatrix}, \quad M_\psi^3 = \begin{pmatrix} -2 & 3 \\ -3 & 4 \end{pmatrix},$$

and inductively

$$M_\psi^n = \begin{pmatrix} -(n-1) & n \\ -n & n+1 \end{pmatrix}.$$

If we let $s = e^{-\lambda}$, then we get the Laplace transform of Z_n ,

$$\mathbf{E}_i [e^{-\lambda Z_n}] = \psi^{(n)}(e^{-\lambda})^i.$$

By Example 6.29, we can compute the moments of Z_n by differentiating the Laplace transform. That is, we obtain the following lemma.

Lemma 21.45 The moments of Z_n are

$$\mathbf{E}_i [Z_n^k] = (-1)^k \frac{d^k}{d\lambda^k} \left(\psi^{(n)}(e^{-\lambda})^i \right) \Big|_{\lambda=0}. \quad (21.39)$$

In particular, the first six moments are

$$\begin{aligned} \mathbf{E}_i [Z_n] &= i \\ \mathbf{E}_i [Z_n^2] &= 2in + i^2 \\ \mathbf{E}_i [Z_n^3] &= 6in^2 + 6i^2n + i^3 \\ \mathbf{E}_i [Z_n^4] &= 24in^3 + 36i^2n^2 + (12i^3 + 2i)n + i^4 \\ \mathbf{E}_i [Z_n^5] &= 120in^4 + 240i^2n^3 + (120i^3 + 30i)n^2 + (20i^4 + 10i^2)n + i^5, \\ \mathbf{E}_i [Z_n^6] &= 720in^5 + 1800i^2n^4 + (1200i^3 + 360i)n^3 \\ &\quad + (300i^4 + 240i^2)n^2 + (30i^5 + 30i^3 + 2i)n + i^6. \end{aligned} \quad (21.40)$$

Hence, Z is a martingale, and the first six centered moments are

$$\begin{aligned}
\mathbf{E}_i [(Z_n - i)^2] &= 2in, \\
\mathbf{E}_i [(Z_n - i)^3] &= 6in^2, \\
\mathbf{E}_i [(Z_n - i)^4] &= 24in^3 + 12i^2n^2 + 2in, \\
\mathbf{E}_i [(Z_n - i)^5] &= 120in^4 + 120i^2n^3 + 30in^2, \\
\mathbf{E}_i [(Z_n - i)^6] &= 720in^5 + 1080i^2n^4 + (120i^3 + 360i)n^3 \\
&\quad + 60i^2n^2 + 2in.
\end{aligned} \tag{21.41}$$

Proof The exact formulas for the first six moments are obtained by tenaciously computing the right-hand side of (21.39).

Now consider the following rescaling: Fix $x \geq 0$, start with $Z_0 = \lfloor nx \rfloor$ individuals and consider $\tilde{Z}_t^n := \frac{Z_{\lfloor tn \rfloor}}{n}$ for $t \geq 0$. We abbreviate

$$\mathcal{L}_x [\tilde{Z}^n] := \mathcal{L}_{\lfloor nx \rfloor} \left[(n^{-1} Z_{\lfloor nt \rfloor})_{t \geq 0} \right]. \tag{21.42}$$

Evidently, $\mathbf{E}_x [\tilde{Z}_t^n] = \frac{\lfloor nx \rfloor}{n} \leq x$ for every n ; hence $(\mathcal{L}_x [\tilde{Z}_t^n], n \in \mathbb{N})$ is tight. By considering Laplace transforms, we obtain that, for every $\lambda \geq 0$, the sequence of distributions converges:

$$\begin{aligned}
\lim_{n \rightarrow \infty} \mathbf{E}_x [e^{-\lambda \tilde{Z}_t^n}] &= \lim_{n \rightarrow \infty} (\psi^{(\lfloor tn \rfloor)} (e^{-\lambda/n}))^{nx} \\
&= \lim_{n \rightarrow \infty} \left(\frac{nt - (nt - 1)e^{-\lambda/n}}{nt + 1 - nte^{-\lambda/n}} \right)^{nx} \\
&= \lim_{n \rightarrow \infty} \left(1 - \frac{1 - e^{-\lambda/n}}{n(1 - e^{-\lambda/n})t + 1} \right)^{nx} \\
&= \exp \left(- \lim_{n \rightarrow \infty} \frac{xn(1 - e^{-\lambda/n})}{n(1 - e^{-\lambda/n})t + 1} \right) \\
&= \exp \left(- \frac{\lambda}{\lambda + 1/t} (x/t) \right) := \psi_t(\lambda)^x
\end{aligned} \tag{21.43}$$

However, the function ψ_t^x is the Laplace transform of the compound Poisson distribution $\text{CPoi}_{(x/t)} \exp_{1/t}$ (see Definition 16.3).

Consider the stochastic kernel $\kappa_t(x, dy) := \text{CPoi}_{(x/t)} \exp_{1/t}(dy)$. This is the kernel on $[0, \infty)$ whose Laplace transform is given by

$$\int_0^\infty \kappa_t(x, dy) e^{-\lambda y} = \psi_t(\lambda)^x \tag{21.44}$$

Lemma 21.46 $(\kappa_t)_{t \geq 0}$ is a Markov semigroup and there exists a Markov process $(Y_t)_{t \geq 0}$ with transition kernels $\mathbf{P}_x [Y_t \in dy] = \kappa_t(x, dy)$.

Proof It suffices to check that the Chapman-Kolmogorov equation $\kappa_t \cdot \kappa_s = \kappa_{s+t}$ holds. We compute the Laplace transform for these kernels. For $\lambda \geq 0$, applying (21.44) twice yields

$$\begin{aligned}
\iint \kappa_t(x, dy) \kappa_s(y, dz) e^{-\lambda z} &= \int \kappa_t(x, dy) \exp\left(-\frac{\lambda y}{\lambda s + 1}\right) \\
&= \exp\left(-\frac{\frac{\lambda}{\lambda s + 1} x}{\frac{\lambda}{\lambda s + 1} t + 1}\right) \\
&= \exp\left(-\frac{\lambda x}{\lambda(t + s) + 1}\right) \\
&= \int \kappa_{t+s}(x, dz) e^{-\lambda z}
\end{aligned}$$

Next we show that Y has a continuous version. To this end, we compute some of its moments and then use the Kolmogorov-Chentsov theorem (Theorem 21.6).

Lemma 21.47 The first k moments of Y_t can be computed by differentiating the Laplace transform,

$$\mathbf{E}_x [Y_t^k] = (-1)^k \frac{d^k}{d\lambda^k} (\psi(\lambda)^x) \big|_{\lambda=0}$$

where

$$\psi_t(\lambda) = \exp\left(-\frac{\lambda}{\lambda t + 1}\right).$$

In particular, we have

$$\begin{aligned}
\mathbf{E}_x [Y_t] &= x \\
\mathbf{E}_x [Y_t^2] &= 2xt + x^2 \\
\mathbf{E}_x [Y_t^3] &= 6xt^2 + 6x^2t + x^3 \\
\mathbf{E}_x [Y_t^4] &= 24xt^3 + 36x^2t^2 + 12x^3t + x^4 \\
\mathbf{E}_x [Y_t^5] &= 120xt^4 + 240x^2t^3 + 120x^3t^2 + 20x^4t + x^5 \\
\mathbf{E}_x [Y_t^6] &= 720xt^5 + 1800x^2t^4 + 1200x^3t^3 + 300x^4t^2 + 30x^5t + x^6
\end{aligned} \tag{21.45}$$

Hence Y is a martingale, and the first centered moments are

$$\begin{aligned}
\mathbf{E}_x [(Y_t - x)^2] &= 2xt, \\
\mathbf{E}_x [(Y_t - x)^3] &= 6xt^2, \\
\mathbf{E}_x [(Y_t - x)^4] &= 24xt^3 + 12x^2t^2, \\
\mathbf{E}_x [(Y_t - x)^5] &= 120xt^4 + 120x^2t^3, \\
\mathbf{E}_x [(Y_t - x)^6] &= 720xt^5 + 1080x^2t^4 + 120x^3t^3.
\end{aligned} \tag{21.46}$$

Theorem 21.48 There is a continuous version of the Markov process Y with transition kernels $(\kappa_t)_{t \geq 0}$ given by (21.44). This version is called Feller's (continuous) branching diffusion.

See Fig. 26.4 for a computer simulation of Feller's branching diffusion.

Proof For fixed $N > 0$ and $s, t \in [0, N]$, we have

$$\begin{aligned}
\mathbf{E}_x [(Y_{t+s} - Y_s)^4] &= \mathbf{E}_x [\mathbf{E}_{Y_s} [(Y_t - Y_0)^4]] \\
&= \mathbf{E}_x [24Y_s t^3 + 12Y_s^2 t^2] \\
&= 24xt^3 + 12(2sx + x^2) t^2 \\
&\leq (48Nx + 12x^2) t^2.
\end{aligned}$$

Thus Y satisfies the condition of Theorem 21.6 (Kolmogorov-Chentsov) with $\alpha = 4$ and $\beta = 1$.

Remark 21.49

- (i) By using higher moments, it can be shown that the paths of Y are Höldercontinuous of any order $\gamma \in (0, \frac{1}{2})$.
- (ii) It can be shown that Y is the (unique strong) solution of the stochastic (Itô-) differential equation (see Examples 26.11 and 26.31)

$$dY_t = \sqrt{2Y_t} dW_t, \quad (21.47)$$

where W is a Brownian motion.

Theorem 21.50 We have $\mathcal{L}_x [\tilde{Z}^n] \xrightarrow[\text{fdd}]{n \rightarrow \infty} \mathcal{L}_x[Y]$.

Proof As in (21.43) for $0 \leq t_1 \leq t_2$, $\lambda_1, \lambda_2 \geq 0$ and $x \geq 0$, we get

$$\begin{aligned} & \lim_{n \rightarrow \infty} \mathbf{E}_x \left[e^{-(\lambda_1 \tilde{Z}_{t_1}^n + \lambda_2 \tilde{Z}_{t_2}^n)} \right] \\ &= \lim_{n \rightarrow \infty} \mathbf{E}_x \left[\mathbf{E}_x \left[e^{-\lambda_2 \tilde{Z}_{t_2}^n | \tilde{Z}_{t_1}^n} \right] e^{-\lambda_1 \tilde{Z}_{t_1}^n} \right] \\ &= \lim_{n \rightarrow \infty} \mathbf{E}_x \left[\exp \left(-\frac{\lambda_2}{\lambda_2(t_2 - t_1) + 1} \tilde{Z}_{t_1}^n \right) e^{-\lambda_1 \tilde{Z}_{t_1}^n} \right] \\ &= \exp \left(-\frac{\left(\frac{\lambda_2}{\lambda_2(t_2 - t_1) + 1} + \lambda_1 \right) x}{\left(\frac{\lambda_2}{\lambda_2(t_2 - t_1) + 1} + \lambda_1 \right) t_1 + 1} \right) \\ &= \mathbf{E}_x [\exp(-(\lambda_1 Y_{t_1} + \lambda_2 Y_{t_2}))] \end{aligned}$$

Hence, we obtain

$$\mathcal{L}_x [\lambda_1 \tilde{Z}_{t_1}^n + \lambda_2 \tilde{Z}_{t_2}^n] \xrightarrow{n \rightarrow \infty} \mathcal{L}_x [\lambda_1 Y_{t_1} + \lambda_2 Y_{t_2}].$$

Using the Cramér-Wold device (Theorem 15.56), this implies

$$\mathcal{L}_x \left[\left(\tilde{Z}_{t_1}^n, \tilde{Z}_{t_2}^n \right) \right] \xrightarrow{n \rightarrow \infty} \mathcal{L}_x [(Y_{t_1}, Y_{t_2})].$$

Iterating the argument, for every $k \in \mathbb{N}$ and $0 \leq t_1 \leq t_2 \leq \dots \leq t_k$, we get

$$\mathcal{L}_x \left[\left(\tilde{Z}_{t_i}^n \right)_{i=1, \dots, k} \right] \xrightarrow{n \rightarrow \infty} \mathcal{L}_x [(Y_{t_i})_{i=1, \dots, k}]$$

However, this was the claim.

The final step is to show convergence in path space. To this end, we have to modify the rescaled processes so that they become continuous. Assume that $(Z_i^n)_{i \in \mathbb{N}_0}$, $n \in \mathbb{N}$ is a sequence of Galton-Watson processes with $Z_0^n = \lfloor nx \rfloor$. Define the linearly interpolated processes

$$\bar{Z}_t^n := (t - n^{-1} \lfloor tn \rfloor) (Z_{\lfloor tn \rfloor + 1}^n - Z_{\lfloor tn \rfloor}^n) + \frac{1}{n} Z_{\lfloor tn \rfloor}^n.$$

Theorem 21.51 (Lindvall (1972), see [109]) As $n \rightarrow \infty$, in the sense of weak convergence in $\mathcal{M}_1(C([0, \infty)))$, the rescaled Galton-Watson processes $\bar{Z}^n$ converge to Feller's diffusion Y :

$$\mathcal{L}_x [\bar{Z}^n] \xrightarrow{n \rightarrow \infty} \mathcal{L}_x[Y]$$

Proof We have shown already the convergence of the finite-dimensional distributions. By Theorem 21.38, it is thus enough to show tightness of $(\mathcal{L}_x [\bar{Z}^n], n \in \mathbb{N})$ in $\mathcal{M}_1(C([0, \infty)))$. To this end, we apply Kolmogorov's moment criterion (Theorem 21.42 with $\alpha = 4$ and $\beta = 1$

). Hence, for fixed $N > 0$, we compute the fourth moments $\mathbf{E}_x \left[(\bar{Z}_{t+s}^n - \bar{Z}_s^n)^4 \right]$ for $s, t \in [0, N]$. We distinguish two cases:

Case 1: $t < \frac{1}{n}$. Let $k = \lfloor (t+s)n \rfloor$. First assume that $\lfloor sn \rfloor = k$. Then (by Lemma 21.45)

$$\begin{aligned} \mathbf{E}_x \left[(\bar{Z}_{t+s}^n - \bar{Z}_s^n)^4 \right] &= n^{-4} (tn)^4 \mathbf{E}_{\lfloor nx \rfloor} \left[(Z_{k+1}^n - Z_k^n)^4 \right] \\ &= t^4 \mathbf{E}_{\lfloor nx \rfloor} \left[24Z_k^n + 12(Z_k^n)^2 + 2Z_k^n \right] \\ &= t^4 (26\lfloor nx \rfloor + 24\lfloor nx \rfloor k + \lfloor nx \rfloor^2) \\ &\leq 26xt^3 + 24xst^2 + x^2t^2 \\ &\leq (50Nx + x^2) t^2. \end{aligned}$$

In the case $\lfloor sn \rfloor = k - 1$, we get a similar estimate. Therefore, there is a constant $C = C(N, x)$ such that

$$\mathbf{E}_x \left[(\bar{Z}_{s+t}^n - \bar{Z}_s^n)^4 \right] \leq Ct^2 \quad \text{for all } s, t \in [0, N] \text{ with } t < \frac{1}{n}. \quad (21.48)$$

Case 2: $t \geq \frac{1}{n}$. Define $k := \lceil (t+s)n \rceil - \lfloor sn \rfloor \leq tn + 1 \leq 2tn$. Then (by Lemma 21.45)

$$\begin{aligned} \mathbf{E}_x \left[(\bar{Z}_{t+s}^n - \bar{Z}_s^n)^4 \right] &\leq n^{-4} \mathbf{E}_{\lfloor nx \rfloor} \left[(Z_{\lfloor (t+s)n \rfloor}^n - Z_{\lfloor sn \rfloor}^n)^4 \right] \\ &= n^{-4} \mathbf{E}_{\lfloor nx \rfloor} \left[\mathbf{E}_{Z_{\lfloor sn \rfloor}^n} \left[(Z_k^n - Z_0^n)^4 \right] \right] \\ &= n^{-4} \mathbf{E}_{\lfloor nx \rfloor} \left[24Z_{\lfloor sn \rfloor}^n k^3 + 12(Z_{\lfloor sn \rfloor}^n)^2 k^2 + 2Z_{\lfloor sn \rfloor}^n k \right] \\ &\leq n^{-4} (24xn(2tn)^3 + (24xnsn + 12x^2n^2) (2tn)^2 + 4xtn^2) \\ &\leq 192xt^3 + (96xs + 48x^2) t^2 + 4xn^{-1}t^2 \\ &\leq (292Nx + 48x^2) t^2. \end{aligned} \quad (21.49)$$

Combining the estimates (21.48) and (21.49), the assumptions of Kolmogorov's moment criterion for tightness (Theorem 21.42) are fulfilled with $\alpha = 4$ and $\beta = 1$. Hence the sequence $(\mathcal{L}_x[\bar{Z}^n], n \in \mathbb{N})$ is tight.

5.21.10 21.10 Square Variation and Local Martingales

By the Paley-Wiener-Zygmund theorem (Theorem 21.17), the paths $t \mapsto W_t$ of Brownian motion are almost surely nowhere differentiable and hence have locally infinite variation. In particular, the stochastic integral $\int_0^1 f(s) dW_s$ that we introduced in Example 21.29 cannot be understood as a Lebesgue-Stieltjes integral. However, as a preparation for the construction of integrals of this type for larger classes of integrands and integrators (in Chapter 25), here we investigate the path properties of Brownian motion and, somewhat more generally, of continuous local martingales in more detail.

Definition 21.52 Let $G : [0, \infty) \rightarrow \mathbb{R}$ be a continuous function. For any $t \geq 0$, define the variation up to t by

$$V_t^1(G) := \sup \left\{ \sum_{i=0}^{n-1} |G_{t_{i+1}} - G_{t_i}| : 0 = t_0 \leq t_1 \leq \dots \leq t_n = t, n \in \mathbb{N} \right\}.$$

We say that G has locally finite variation if $V_t^1(G) < \infty$ for all $t \geq 0$. We write $\mathcal{C}_v$ for the vector space of continuous functions G with continuous variation $t \mapsto V_t^1(G)$.

Remark 21.53 Clearly, $V^1(F + G) \leq V^1(F) + V^1(G)$ and $V^1(\alpha G) = |\alpha|V^1(G)$ for all continuous $F, G : [0, \infty) \rightarrow \mathbb{R}$ and for all $\alpha \in \mathbb{R}$. Hence $\mathcal{C}_v$ is indeed a vector space. $\square$

Remark 21.54

(i) If G is of the form $G_t = \int_0^t f(s)ds$ for some locally integrable function f , then we have $G \in \mathcal{C}_v$ with $V_t^1(G) = \int_0^t |f(s)|ds$.

(ii) If $G = G^+ - G^-$ is the difference of two continuous monotone increasing functions G^+ and G^- , then

$$V_t^1(G) - V_s^1(G) \leq (G_t^+ - G_s^+) + (G_t^- - G_s^-) \text{ for all } t > s, \quad (21.50)$$

hence we have $G \in \mathcal{C}_v$. In (21.50), equality holds if G^- and G^+ "do not grow on the same sets"; that is, more formally, if G^- and G^+ are the distribution functions of mutually singular measures μ^- and μ^+ . The measures μ^- and μ^+ are then the Jordan decomposition of the signed measure $\mu = \mu^+ - \mu^-$ whose distribution function is G . Then the Lebesgue-Stieltjes integral is defined by

$$\int_0^t F(s)dG_s := \int_{[0,t]} Fd\mu^+ - \int_{[0,t]} Fd\mu^- \quad (21.51)$$

(iii) If $G \in \mathcal{C}_v$, then clearly

$$G_t^+ := \frac{1}{2} (V_t^1(G) + G_t) \quad \text{and} \quad G_t^- := \frac{1}{2} (V_t^1(G) - G_t)$$

is a decomposition of G as in (ii). $\square$

The fact that the paths of Brownian motion are nowhere differentiable can be used to infer that the paths have infinite variation. However, there is also a simple direct argument.

Theorem 21.55 Let W be a Brownian motion. Then $V_t^1(W) = \infty$ almost surely for every $t > 0$.

Proof It is enough to consider $t = 1$ and to show

$$Y_n := \sum_{i=1}^{2^n} |W_{i2^{-n}} - W_{(i-1)2^{-n}}| \xrightarrow{n \rightarrow \infty} \infty \quad \text{a.s.} \quad (21.52)$$

We have $\mathbf{E}[Y_n] = 2^{n/2} \mathbf{E}[|W_1|] = 2^{n/2} \sqrt{2/\pi}$ and $\text{Var}[Y_n] = 1 - 2/\pi$. By Chebyshev's inequality,

$$\sum_{n=1}^{\infty} \mathbf{P} \left[Y_n \leq \frac{1}{2} 2^{n/2} \sqrt{2/\pi} \right] \leq \sum_{n=1}^{\infty} \frac{2\pi - 4}{2^n} = 2\pi - 4 < \infty$$

Using the Borel-Cantelli lemma, this implies (21.52).

Evidently, the variation is too crude a measure to quantify essential path properties of Brownian motion. Hence, instead of the increments (in the definition of the variation), we will sum up the (smaller) squared increments. For the definition of this square variation, more care is needed than in Definition 21.52 for the variation.

Definition 21.56 A sequence $\mathcal{P} = (\mathcal{P}^n)_{n \in \mathbb{N}}$ of countable subsets of $[0, \infty)$,

$$\mathcal{P}^n := \{t_0, t_1, t_2, \dots\} \quad \text{with } 0 = t_0 < t_1 < t_2 < \dots,$$

is called an admissible partition sequence if

- (i) $\mathcal{P}^1 \subset \mathcal{P}^2 \subset \dots$,
- (ii) $\sup \mathcal{P}^n = \infty$ for every $n \in \mathbb{N}$, and
- (iii) the mesh size

$$|\mathcal{P}^n| := \sup_{t \in \mathcal{P}^n} \min_{s \in \mathcal{P}^n, s \neq t} |s - t|$$

tends to 0 as $n \rightarrow \infty$.

If $0 \leq S < T$, then define

$$\mathcal{P}_{S,T}^n := \mathcal{P}^n \cap [S, T) \quad \text{and} \quad \mathcal{P}_T^n := \mathcal{P}^n \cap [0, T).$$

If $t = t_k \in \mathcal{P}_T^n$, then let $t' := t_{k+1} \wedge T = \min \{s \in \mathcal{P}_T^n \cup \{T\} : s > t\}$.

Example 21.57 $\mathcal{P}^n = \{k2^{-n} : k = 0, 1, 2, \dots\}$.

Definition 21.58 For continuous $F, G : [0, \infty) \rightarrow \mathbb{R}$ and for $p \geq 1$, define the p -variation of G (along $\mathcal{P}$) by

$$V_T^p(G) := V_T^{\mathcal{P},p}(G) := \lim_{n \rightarrow \infty} \sum_{t \in \mathcal{P}_T^n} |G_{t'} - G_t|^p \quad \text{for } T \geq 0$$

if the limit exists. In particular, $\langle G \rangle := V^2(G)$ is called the square variation of G . If $T \mapsto V_T^2(G)$ is continuous, then we write $G \in \mathcal{C}_{\text{qv}} := \mathcal{C}_{\text{qv}}^{\mathcal{P}}$.

If, for every $T \geq 0$, the limit

$$V_T^{\mathcal{P},2}(F, G) := \lim_{n \rightarrow \infty} \sum_{t \in \mathcal{P}_T^n} (F_{t'} - F_t)(G_{t'} - G_t)$$

exists, then we call $\langle F, G \rangle := V^2(F, G) := V^{\mathcal{P},2}(F, G)$ the quadratic covariation of F and G (along $\mathcal{P}$).

Remark 21.59 If $p' > p$ and $V_T^p(G) < \infty$, then $V_T^{p'}(G) = 0$. In particular, we have $\langle G \rangle \equiv 0$ if G has locally finite variation.

Remark 21.60 By the triangle inequality, we have

$$\sum_{t \in \mathcal{P}_T^{n+1}} |G_{t'} - G_t| \geq \sum_{t \in \mathcal{P}_T^n} |G_{t'} - G_t| \quad \text{for all } n \in \mathbb{N}, T \geq 0$$

Hence in the case $p = 1$, the limit always exists and coincides with $V^1(G)$ from Definition 21.52 (and is hence independent of the particular choice of $\mathcal{P}$). A similar inequality does not hold for V^2 and thus the limit need not exist or may depend on the choice of $\mathcal{P}$. In the following, we will, however, show that, for a large class of continuous stochastic processes, V^2 exists almost surely along a suitable subsequence of partitions and is almost surely unique.

Remark 21.61

(i) If $\langle F + G \rangle_T$ and $\langle F - G \rangle_T$ exist, then the covariation $\langle F, G \rangle_T$ exists and the polarization formula holds:

$$\langle F, G \rangle_T = \frac{1}{4} (\langle F + G \rangle_T - \langle F - G \rangle_T).$$

(ii) If $\langle F \rangle_T, \langle G \rangle_T$ and $\langle F, G \rangle_T$ exist, then by the Cauchy-Schwarz inequality, we have for the approximating sums

$$V_T^1(\langle F, G \rangle) \leq \sqrt{\langle F \rangle_T \langle G \rangle_T}$$

Remark 21.62 If $f \in C^1(\mathbb{R})$ and $G \in \mathcal{C}_{qv}$, then (exercise!) in the sense of the Lebesgue-Stieltjes integral

$$\langle f(G) \rangle_T = \int_0^T (f'(G_s))^2 d\langle G \rangle_s$$

Corollary 21.63 If F has locally finite square variation and if $\langle G \rangle \equiv 0$ (hence, in particular, if G has locally finite variation), then $\langle F, G \rangle \equiv 0$ and $\langle F + G \rangle = \langle F \rangle$.

Theorem 21.64 For Brownian motion W and for every admissible sequence of partitions, we have

$$\langle W \rangle_T = T \quad \text{for all } T \geq 0 \quad \text{a.s.}$$

Proof We prove this only for the case where

$$\sum_{n=1}^{\infty} |\mathcal{P}^n| < \infty \quad (21.53)$$

For the general case, we only sketch the argument.

Accordingly, assume (21.53). If $\langle W \rangle$ exists, then $T \mapsto \langle W \rangle_T$ is monotone increasing. Hence, it is enough to show that $\langle W \rangle_T$ exists for every $T \in \mathbb{Q}^+ = \mathbb{Q} \cap [0, \infty)$ and that almost surely $\langle W \rangle_T = T$. Since $(\tilde{W}_t)_{t \geq 0} = (T^{-1/2}W_{tT})_{t \geq 0}$ is a Brownian motion, and since $\langle \tilde{W} \rangle_1 = T^{-1}\langle W \rangle_T$, it is enough to consider the case $T = 1$.

Define

$$Y_n := \sum_{t \in \mathcal{P}_1^n} (W_{t'} - W_t)^2 \quad \text{for all } n \in \mathbb{N}$$

Then $\mathbf{E}[Y_n] = \sum_{t \in \mathcal{P}_1^n} (t' - t) = 1$ and

$$\text{Var}[Y_n] = \sum_{t \in \mathcal{P}_1^n} \text{Var}[(W_{t'} - W_t)^2] = 2 \sum_{t \in \mathcal{P}_1^n} (t' - t)^2 \leq 2|\mathcal{P}^n|.$$

By assumption (21.53), we thus have $\sum_{n=1}^{\infty} \text{Var}[Y_n] \leq 2 \sum_{n=1}^{\infty} |\mathcal{P}^n| < \infty$; hence $Y_n \xrightarrow{n \rightarrow \infty} 1$ almost surely.

If we drop the assumption (21.53), then we still have $\text{Var}[Y_n] \xrightarrow{n \rightarrow \infty} 0$; hence $Y_n \xrightarrow{n \rightarrow \infty} 1$ in probability. However, it is not too hard to show that $(Y_n)_{n \in \mathbb{N}}$ is a backwards martingale (see, e.g., [140, Theorem I.28]) and thus converges almost surely to 1.

Corollary 21.65 If W and $\tilde{W}$ are independent Brownian motions, then we have $\langle W, \tilde{W} \rangle_T = 0$.

Proof The continuous processes $((W + \tilde{W})/\sqrt{2})$ and $((W - \tilde{W})/\sqrt{2})$ have independent normally distributed increments. Hence they are Brownian motions. By Remark 21.61(i), we have

$$\begin{aligned} 4\langle W, \tilde{W} \rangle_T &= \langle W + \tilde{W} \rangle_T - \langle W - \tilde{W} \rangle_T \\ &= 2\langle (W + \tilde{W})/\sqrt{2} \rangle_T - 2\langle (W - \tilde{W})/\sqrt{2} \rangle_T \\ &= 2T - 2T = 0 \end{aligned}$$

Clearly, $(W_t \tilde{W}_t)_{t \geq 0}$ is a continuous martingale. Now, by Exercise 21.4.2, the process $(W_t^2 - t)_{t \geq 0}$ is also a continuous martingale. Thus, as shown above, the processes $W^2 - \langle \bar{W} \rangle$ and $W\tilde{W} - \langle W, \tilde{W} \rangle$ are martingales. We will see (Theorem 21.70) that the square variation $\langle M(\omega) \rangle$ of a square integrable continuous martingale M always exists (for almost all ω) and that the process $\langle M \rangle$ is uniquely determined by the property that $M^2 - \langle M \rangle$ is a martingale.

In order to obtain a similar statement for continuous martingales that are not square integrable, we make the following definition.

Definition 21.66 (Local martingale) Let $\mathbb{F}$ be a filtration on $(\Omega, \mathcal{F}, \mathbf{P})$ and let τ be an $\mathbb{F}$ -stopping time. An adapted real-valued stochastic process $M = (M_t)_{t \geq 0}$ is called a local martingale up to time τ if there exists a sequence $(\tau_n)_{n \in \mathbb{N}}$ of stopping times such that $\tau_n \uparrow \tau$ almost surely and such that, for every $n \in \mathbb{N}$, the stopped process $M^{\tau_n} = (M_{\tau_n \wedge t})_{t \geq 0}$ is a uniformly integrable martingale. Such a sequence $(\tau_n)_{n \in \mathbb{N}}$ is called a localising sequence for M . M is called a local martingale if M is a local martingale up to time $\tau \equiv \infty$. Denote by $\mathcal{M}_{\text{loc}}$ the space of continuous local martingales.

Remark 21.67 Let M be a continuous adapted process and let τ be a stopping time. Then the following are equivalent:

- (i) M is a local martingale up to time τ .
- (ii) There is a sequence $(\tau_n)_{n \in \mathbb{N}}$ of stopping times with $\tau_n \uparrow \tau$ almost surely and such that every M^{τ_n} is a martingale.
- (iii) There is a sequence $(\tau_n)_{n \in \mathbb{N}}$ of stopping times with $\tau_n \uparrow \tau$ almost surely and such that every M^{τ_n} is a bounded martingale.

Indeed, (iii) $\implies$ (i) $\implies$ (ii) is trivial. Hence assume that (ii) holds, and define τ'_n by

$$\tau'_n := \inf \{t \geq 0 : |M_t| \geq n\} \quad \text{for all } n \in \mathbb{N}.$$

Since M is continuous, we have $\tau'_n \uparrow \infty$. Hence $(\sigma_n)_{n \in \mathbb{N}} := (\tau_n \wedge \tau'_n)_{n \in \mathbb{N}}$ is a localising sequence for M such that every M^{σ_n} is a bounded martingale.

Remark 21.68 A bounded local martingale M is a martingale. Indeed, assume that $|M_t| \leq C < \infty$ almost surely for all $t \geq 0$ and that $(\tau_n)_{n \in \mathbb{N}}$ is a localising sequence for M . Let $t > s \geq 0$ and $A \in \mathcal{F}_s$. Then $A \cap \{\tau_n \leq s\} \in \mathcal{F}_{\tau_n \wedge s}$ and hence

$$\mathbf{E} [M_{\tau_n \wedge t} \mathbb{1}_{A \cap \{\tau_n \leq s\}}] = \mathbf{E} [M_{\tau_n \wedge s} \mathbb{1}_{A \cap \{\tau_n \leq s\}}].$$

Since $\tau_n \uparrow \infty$, the dominated convergence theorem (Corollary 6.26) yields

$$\mathbf{E} [M_t \mathbb{1}_A] = \mathbf{E} [M_s \mathbb{1}_A].$$

Hence $\mathbf{E} [M_t | \mathcal{F}_s] = M_s$ and thus M is a martingale.

Example 21.69

- (i) Every martingale is a local martingale.
- (ii) In Remark 21.68, we saw that bounded local martingales are martingales. On the other hand, even a uniformly integrable local martingale need not be a martingale: Let $W = (W^1, W^2, W^3)$ be a three-dimensional Brownian motion (that is, W^1, W^2 and W^3 are independent Brownian motions) that starts at $W_0 = x \in \mathbb{R}^3 \setminus \{0\}$. Let

$$u(y) = \|y\|^{-1} \quad \text{for } y \in \mathbb{R}^3 \setminus \{0\}.$$

It is easy to check that u is harmonic; that is, $\Delta u(y) = 0$ for all $y \neq 0$. We will see later (Corollary 25.34) that this implies that $M := (u(W_t))_{t \geq 0}$ is a local martingale. Define a localising sequence for M by

$$\tau_n := \inf \{t > 0 : M_t \geq n\} = \inf \{t > 0 : \|W_t\| \leq 1/n\}, \quad n \in \mathbb{N}.$$

An explicit computation with the three-dimensional normal distribution shows $\mathbf{E} [M_t] \leq t^{-1/2} \xrightarrow{t \rightarrow \infty} 0$; hence M is integrable but is not a martingale. Since $M_t \xrightarrow{t \rightarrow \infty} 0$ in L^1 , M is uniformly integrable.

Theorem 21.70 Let M be a continuous local martingale.

(i) There exists a unique continuous, monotone increasing, adapted process $\langle M \rangle = (\langle M \rangle_t)_{t \geq 0}$ with $\langle M \rangle_0 = 0$ such that

$$(M_t^2 - \langle M \rangle_t)_{t \geq 0} \quad \text{is a continuous local martingale.}$$

(ii) If M is a continuous square integrable martingale, then $M^2 - \langle M \rangle$ is a martingale.

(iii) For every admissible sequence of partitions $\mathcal{P} = (\mathcal{P}^n)_{n \in \mathbb{N}}$, we have

$$U_T^n := \sum_{t \in \mathcal{P}_T^n} (M_{t'} - M_t)^2 \xrightarrow{n \rightarrow \infty} \langle M \rangle_T \quad \text{in probability for all } T \geq 0.$$

The process $\langle M \rangle$ is called the square variation process of M .

Remark 21.71 By possibly passing in (iii) to a subsequence $\mathcal{P}'$ (that might depend on T), we may assume that $U_T^n \xrightarrow{n \rightarrow \infty} \langle M \rangle_T$ almost surely. Using the diagonal sequence argument, we obtain (as in the proof of Helly's theorem) a sequence of partitions such that $U_T^n \xrightarrow{n \rightarrow \infty} \langle M \rangle_T$ almost surely for all $T \in \mathbb{Q}^+$. Since both $T \mapsto U_T^n$ and $T \mapsto \langle M \rangle_T$ are monotone and continuous, we get $U_T^n \xrightarrow{n \rightarrow \infty} \langle M \rangle_T$ for all $T \geq 0$ almost surely. Hence, for this sequence of partitions, the pathwise square variation almost surely equals the square variation process:

$$\langle M(\omega) \rangle = V^2(M(\omega)) = \langle M \rangle(\omega)$$

Proof of Theorem 21.70 Step 1. First let $|M_t| \leq C$ almost surely for all $t \geq 0$ for some $C < \infty$. Then, in particular, M is a martingale (by Remark 21.68). Write $U_T^n = M_T^2 - M_0^2 - N_T^n$, where

$$N_T^n = 2 \sum_{t \in \mathcal{P}_T^n} M_t (M_{t'} - M_t), \quad T \geq 0,$$

is a continuous martingale. Assume that we can show that, for every $T \geq 0$, $(U_T^n)_{n \in \mathbb{N}}$ is a Cauchy sequence in $\mathcal{L}^2(\mathbf{P})$. Then also $(N_T^n)_{n \in \mathbb{N}}$ is a Cauchy sequence, and we can define $\tilde{N}_T$ as the L^2 -limit of $(N_T^n)_{n \in \mathbb{N}}$. By Exercise 21.4.3, $\tilde{N}$ has a continuous modification N , and we have $N_T^n \xrightarrow{n \rightarrow \infty} N_T$ in L^2 for all $T \geq 0$. Thus there exists a continuous process $\langle M \rangle$ with

$$U_T^n \xrightarrow{n \rightarrow \infty} \langle M \rangle_T \quad \text{in } L^2 \quad \text{for all } T \geq 0, \quad (21.54)$$

and $N = M^2 - M_0^2 - \langle M \rangle$ is a continuous martingale.

It remains to show that, for all $T \geq 0$,

$$(U_T^n)_{n \in \mathbb{N}} \quad \text{is a Cauchy sequence in } L^2. \quad (21.55)$$

For $m \in \mathbb{N}$, let

$$Z_m := \max \{ (M_t - M_s)^2 : s \in \mathcal{P}_T^m, t \in \mathcal{P}_{s,s'}^n, n \geq m \}$$

Since M is almost surely uniformly continuous on $[0, T]$, we have $Z_m \xrightarrow{m \rightarrow \infty} 0$ almost surely. As $Z_m \leq 4C^2$, we infer

$$\mathbf{E} [Z_m^2] \xrightarrow{m \rightarrow \infty} 0. \quad (21.56)$$

For $n \in \mathbb{N}$ and numbers $a_0, \dots, a_n$, we have

$$(a_n - a_0)^2 - \sum_{k=0}^{n-1} (a_{k+1} - a_k)^2 = 2 \sum_{k=0}^{n-1} (a_k - a_0) (a_{k+1} - a_k).$$

In the following computation, we apply this to each summand in the outer sum to obtain for $m \in \mathbb{N}$ and $n \geq m$

$$\begin{aligned} U_T^m - U_T^n &= \sum_{s \in \mathcal{P}_T^m} \left((M_{s'} - M_s)^2 - \sum_{t \in \mathcal{P}_{s,s'}^n} (M_{t'} - M_t)^2 \right) \\ &= 2 \sum_{s \in \mathcal{P}_T^m} \sum_{t \in \mathcal{P}_{s,s'}^n} (M_t - M_s) (M_{t'} - M_t) \end{aligned} \quad (21.57)$$

Since M is a martingale, for $s_1, s_2 \in \mathcal{P}_T^m$ and $t_1 \in \mathcal{P}_{s_1,s'_1}^n, t_2 \in \mathcal{P}_{s_2,s'_2}^n$ with $t_1 < t_2$, we have

$$\begin{aligned} &\mathbf{E} [(M_{t_1} - M_{s_1}) (M_{t'_1} - M_{t_1}) (M_{t_2} - M_{s_2}) (M_{t'_2} - M_{t_2})] \\ &= \mathbf{E} [(M_{t_1} - M_{s_1}) (M_{t'_1} - M_{t_1}) (M_{t_2} - M_{s_2}) \mathbf{E} [M_{t'_2} - M_{t_2} \mid \mathcal{F}_{t_2}]] = 0 \end{aligned}$$

If we use (21.57) to compute the expectation of $(U_T^m - U_T^n)^2$, then the mixed terms vanish and we get (using the Cauchy-Schwarz inequality in the third line)

$$\begin{aligned} \mathbf{E} [(U_T^n - U_T^m)^2] &= 4\mathbf{E} \left[\sum_{s \in \mathcal{P}_T^m} \sum_{t \in \mathcal{P}_{s,s'}^n} (M_t - M_s)^2 (M_{t'} - M_t)^2 \right] \\ &\leq 4\mathbf{E} \left[Z_m \sum_{t \in \mathcal{P}_T^n} (M_{t'} - M_t)^2 \right] \\ &\leq 4\mathbf{E} [Z_m^2]^{1/2} \mathbf{E} \left[\left(\sum_{t \in \mathcal{P}_T^n} (M_{t'} - M_t)^2 \right)^2 \right]^{1/2} \end{aligned} \quad (21.58)$$

For the second factor,

$$\begin{aligned} &\mathbf{E} \left[\left(\sum_{t \in \mathcal{P}_T^n} (M_{t'} - M_t)^2 \right)^2 \right] \\ &= \mathbf{E} \left[\sum_{t \in \mathcal{P}_T^n} (M_{t'} - M_t)^4 \right] \\ &\quad + 2\mathbf{E} \left[\sum_{s \in \mathcal{P}_T^n} (M_{s'} - M_s)^2 \sum_{t \in \mathcal{P}_{s',T}^n} (M_{t'} - M_t)^2 \right] \end{aligned} \quad (21.59)$$

The first summand in (21.59) is bounded by

$$4C^2 \mathbf{E} \left[\sum_{t \in \mathcal{P}_T^n} (M_{t'} - M_t)^2 \right] = 4C^2 \mathbf{E} [(M_T - M_0)^2] \leq 16C^4$$

The second summand in (21.59) equals

$$\begin{aligned}
& 2\mathbf{E} \left[\sum_{s \in \mathcal{P}_T^n} (M_{s'} - M_s)^2 \mathbf{E} \left[\sum_{t \in \mathcal{P}_{s',T}^n} (M_{t'} - M_t)^2 \mid \mathcal{F}_{s'} \right] \right] \\
&= 2\mathbf{E} \left[\sum_{s \in \mathcal{P}_T^n} (M_{s'} - M_s)^2 \mathbf{E} [(M_T - M_{s'})^2 \mid \mathcal{F}_{s'}] \right] \\
&\leq 8C^2 \mathbf{E} [(M_T - M_0)^2] \leq 32C^4
\end{aligned}$$

Together with (21.58) and (21.56), we obtain

$$\sup_{n \geq m} \mathbf{E} [(U_T^n - U_T^m)^2] \leq 16\sqrt{3}C^2 \mathbf{E} [Z_m^2]^{1/2} \xrightarrow{m \rightarrow \infty} 0$$

This shows (21.55).

Step 2. Now let $M \in \mathcal{M}_{\text{loc},c}$ and let $(\tau_N)_{N \in \mathbb{N}}$ be a localising sequence such that every M^{τ_N} is a bounded martingale (see Remark 21.67). By Step 1, for $T \geq 0$ and $N \in \mathbb{N}$, we have

$$U_T^{N,n} := \sum_{t \in \mathcal{P}_T^n} (M_t^{\tau_N} - M_t^{\tau_N})^2 \xrightarrow{n \rightarrow \infty} \langle M^{\tau_N} \rangle_T \text{ in } L^2$$

Since $U_T^{N,n} = U_T^{N+1,n}$ if $T \leq \tau_N$, there is a continuous process U with $U_T^{N,n} \xrightarrow{n \rightarrow \infty} U_T$ in probability if $T \leq \tau_N$. Thus $\langle M^{\tau_N} \rangle_T = \langle M \rangle_T := U_T$ if $T \leq \tau_N$. Since $\tau_N \uparrow \infty$ almost surely, for all $T \geq 0$,

$$U_T^n \xrightarrow{n \rightarrow \infty} \langle M \rangle_T \text{ in probability.}$$

As $((M^{\tau_N})^2 - \langle M^{\tau_N} \rangle_T)_{T \geq 0}$ is a continuous martingale and since $\langle M^{\tau_N} \rangle = \langle M \rangle^{\tau_N}$, we have $M^2 - \langle M \rangle \in \mathcal{M}_{\text{loc},c}$.

Step 3. It remains to show (ii). Let M be a continuous square integrable martingale and let $(\tau_n)_{n \in \mathbb{N}}$ be a localising sequence for the local martingale $M^2 - \langle M \rangle$. Let $T > 0$ and let $\tau \leq T$ be a stopping time. Then $M_{\tau_n \wedge \tau}^2 \leq \mathbf{E} [M_T^2 \mid \mathcal{F}_{\tau_n \wedge \tau}]$ since M^2 is a nonnegative submartingale. Hence $(M_{\tau_n \wedge \tau}^2)_{n \in \mathbb{N}}$ is uniformly integrable and thus (using the monotone convergence theorem in the last step)

$$\begin{aligned}
\mathbf{E} [M_\tau^2] &= \lim_{n \rightarrow \infty} \mathbf{E} [M_{\tau_n \wedge \tau}^2] = \lim_{n \rightarrow \infty} \mathbf{E} [\langle M \rangle_{\tau_n \wedge \tau}] + \mathbf{E} [M_0^2] \\
&= \mathbf{E} [\langle M \rangle_\tau] + \mathbf{E} [M_0^2].
\end{aligned}$$

Thus, by the optional sampling theorem, $M^2 - \langle M \rangle$ is a martingale.

Step 4 (Uniqueness). Let A and A' be continuous, monotone increasing, adapted processes with $A_0 = A'_0$ such that $M^2 - A$ and $M^2 - A'$ are local martingales. Then also $N = A - A'$ is a local martingale, and for almost all ω , the path $N(\omega)$ has locally finite variation. Thus $\langle N \rangle \equiv 0$ and hence $N^2 - \langle N \rangle = N^2$ is a continuous

local martingale with $N_0 = 0$. Let $(\tau_n)_{n \in \mathbb{N}}$ be a localising sequence for N^2 . Then $\mathbf{E} [N_{\tau_n \wedge t}^2] = 0$ for any $n \in \mathbb{N}$ and $t \geq 0$; hence $N_{\tau_n \wedge t}^2 = 0$ almost surely and thus $N_t^2 = \lim_{n \rightarrow \infty} N_{\tau_n \wedge t}^2 = 0$ almost surely. We conclude $A = A'$.

Corollary 21.72 Let M be a continuous local martingale with $\langle M \rangle \equiv 0$. Then $M_t = M_0$ for all $t \geq 0$ almost surely. In particular, this holds if the paths of M have locally finite variation.

Corollary 21.73 Let $M, N \in \mathcal{M}_{\text{loc},c}$. Then there exists a unique continuous adapted process $\langle M, N \rangle$ with almost surely locally finite variation and $\langle M, N \rangle_0 = 0$ such that

$$MN - \langle M, N \rangle \text{ is a continuous local martingale.}$$

$\langle M, N \rangle$ is called the quadratic covariation process of M and N . For every admissible sequence of partitions $\mathcal{P}$ and for every $T \geq 0$, we have

$$\langle M, N \rangle_T = \lim_{n \rightarrow \infty} \sum_{t \in \mathcal{P}_T^n} (M_{t'} - M_t) (N_{t'} - N_t) \quad \text{in probability.} \quad (21.60)$$

Proof Existence. Manifestly, $M + N, M - N \in \mathcal{M}_{\text{loc},c}$. Define

$$\langle M, N \rangle := \frac{1}{4} (\langle M + N \rangle - \langle M - N \rangle).$$

As the difference of two monotone increasing functions, $\langle M, N \rangle$ has locally finite variation. Using Theorem 21.70(iii), we get (21.60). Furthermore,

$$MN - \langle M, N \rangle = \frac{1}{4} ((M + N)^2 - \langle M + N \rangle) - \frac{1}{4} ((M - N)^2 - \langle M - N \rangle)$$

is a local martingale.

Uniqueness. Let A and A' with $A_0 = A'_0 = 0$ be continuous, adapted and with locally finite variation such that $MN - A$ and $MN - A'$ are in $\mathcal{M}_{\text{loc},c}$. Then $A - A' \in \mathcal{M}_{\text{loc},c}$ have locally finite variation; hence $A - A' = 0$.

Corollary 21.74 If $M \in \mathcal{M}_{\text{loc},c}$ and A are continuous and adapted with $\langle A \rangle \equiv 0$, then $\langle M + A \rangle = \langle M \rangle$.

If M is a continuous local martingale up to the stopping time τ , then $M^\tau \in \mathcal{M}_{\text{loc},c}$, and we write $\langle M \rangle_t := \langle M^\tau \rangle_t$ for $t < \tau$.

Theorem 21.75 Let τ be a stopping time, M be a continuous local martingale up to τ and $\tau_0 < \tau$ a stopping time with $\mathbf{E}[\langle M \rangle_{\tau_0}] < \infty$. Then $\mathbf{E}[M_{\tau_0}] = \mathbf{E}[M_0]$, and M^{τ_0} is an L^2 -bounded martingale if $\mathbf{E}[M_0^2] < \infty$.

Proof Let $\tau_n \uparrow \tau$ be a localising sequence of stopping times for M such that every M^{τ_n} is even a bounded martingale (see Remark 21.67). Then $M^{\tau_0 \wedge \tau_n}$ is also a bounded martingale, and for every $t \geq 0$, we have

$$\mathbf{E}[M_{\tau_0 \wedge \tau_n \wedge t}^2] = \mathbf{E}[M_0^2] + \mathbf{E}[\langle M \rangle_{\tau_0 \wedge \tau_n \wedge t}] \leq \mathbf{E}[M_0^2] + \mathbf{E}[\langle M \rangle_{\tau_0}] < \infty. \quad (21.61)$$

Hence $((M_{\tau_0 \wedge \tau_n \wedge t}), n \in \mathbb{N}, t \geq 0)$ is bounded in L^2 and is thus uniformly integrable. Therefore, by the optional sampling theorem for uniformly integrable martingales,

$$\mathbf{E}[M_{\tau_0}] = \lim_{n \rightarrow \infty} \mathbf{E}[M_{\tau_0 \wedge \tau_n}] = \mathbf{E}[M_0]$$

and, for $t > s$,

$$\begin{aligned} \mathbf{E}[M_t^{\tau_0} \mid \mathcal{F}_s] &= \mathbf{E}\left[\lim_{n \rightarrow \infty} M_t^{\tau_0 \wedge \tau_n} \mid \mathcal{F}_s\right] \\ &= \lim_{n \rightarrow \infty} \mathbf{E}[M_t^{\tau_0 \wedge \tau_n} \mid \mathcal{F}_s] \\ &= \lim_{n \rightarrow \infty} M_s^{\tau_0 \wedge \tau_n} = M_s^{\tau_0} \end{aligned}$$

Hence M^{τ_0} is a martingale.

Corollary 21.76 If $M \in \mathcal{M}_{\text{loc},c}$ with $\mathbf{E}[M_0^2] < \infty$ and $\mathbf{E}[\langle M \rangle_t] < \infty$ for every $t \geq 0$, then M is a square integrable martingale.

Exercise 21.10.1 Show that the random variables $(Y_n)_{n \in \mathbb{N}}$ from the proof of Theorem 21.64 form a backwards martingale.

Exercise 21.10.2 Let $f : [0, \infty) \rightarrow \mathbb{R}$ be continuous and let $X \in \mathcal{C}_{\text{qv}}^{\mathcal{P}}$ for the admissible sequence of partitions $\mathcal{P}$. Show that

$$\int_0^T f(s) d\langle X \rangle_s = \lim_{n \rightarrow \infty} \sum_{t \in \mathcal{P}_T^n} f(t) (X_{t'} - X_t)^2 \quad \text{for all } T \geq 0$$

Exercise 21.10.3 Show by a counterexample that if M is a continuous local martingale with $M_0 = 0$ and if τ is a stopping time with $\mathbf{E}[\langle M \rangle_\tau] = \infty$, then this does not necessarily imply $\mathbf{E}[M_\tau^2] = \infty$.

5.22 22 Law of the Iterated Logarithm

For sums of independent random variables we already know two limit theorems: the law of large numbers and the central limit theorem. The law of large numbers describes for large $n \in \mathbb{N}$, the typical behavior, or average value behavior, of sums of n random variables. On the other hand, the central limit theorem quantifies the typical fluctuations about this average value.

In Chapter 23, we will study atypically large deviations from the average value in greater detail. The aim of this chapter is to quantify the typical fluctuations of the whole process as $n \rightarrow \infty$. The main message is: While for fixed time the partial sum S_n deviates by approximately $\sqrt{n}$ from its expected value (central limit theorem), the maximal fluctuation up to time n is of order $\sqrt{n \log \log n}$ (Hartman-Wintner theorem, Theorem 22.11).

We start with the simpler task of computing the fluctuations for Brownian motion (Theorem 22.1). After that, we will see how sums of independent centered random variables (with finite variance) can be embedded in a Brownian motion (Skorohod's theorem, Theorem 22.5). This embedding will be used to prove the Hartman-Wintner theorem.

In this chapter, we follow essentially the exposition of [39, Section 8.8].

5.22.1 22.1 Iterated Logarithm for the Brownian Motion

Let $(B_t)_{t \geq 0}$ be a Brownian motion. In Example 21.16, as an application of Blumenthal's $0-1$ law, we saw that $\limsup_{t \downarrow 0} B_t / \sqrt{t} = \infty$ a.s. Since by Theorem 21.14, $(tB_{1/t})_{t \geq 0}$ also is a Brownian motion, we get

$$\limsup_{t \rightarrow \infty} \frac{B_t}{\sqrt{t}} = \infty \quad \text{a.s.}$$

The aim of this section is to replace $\sqrt{t}$ by a function such that the limes superior is finite and nontrivial.

Theorem 22.1 (Law of the iterated logarithm for Brownian motion)

$$\limsup_{t \rightarrow \infty} \frac{B_t}{\sqrt{2t \log \log(t)}} = 1 \quad \text{a.s.} \quad (22.1)$$

Before proving the theorem, we state an elementary lemma.

Lemma 22.2 Let $X \sim \mathcal{N}_{0,1}$ be standard normally distributed. Then, for any $x > 0$,

$$\frac{1}{\sqrt{2\pi}} \frac{1}{x + \frac{1}{x}} e^{-x^2/2} \leq \mathbf{P}[X \geq x] \leq \frac{1}{\sqrt{2\pi}} \frac{1}{x} e^{-x^2/2} \quad (22.2)$$

Proof Let $\varphi(t) = \frac{1}{\sqrt{2\pi}} e^{-t^2/2}$ be the density of the standard normal distribution. Partial integration yields the second inequality in (22.2),

$$\mathbf{P}[X \geq x] = \int_x^\infty \frac{1}{t} (t\varphi(t)) dt = -\frac{1}{t} \varphi(t) \Big|_x^\infty - \int_x^\infty \frac{1}{t^2} \varphi(t) dt \leq \frac{1}{x} \varphi(x)$$

Similarly, we get

$$\mathbf{P}[X \geq x] \geq \frac{1}{x}\varphi(x) - \frac{1}{x^2} \int_x^\infty \varphi(t)dt = \frac{1}{x}\varphi(x) - \frac{1}{x^2}\mathbf{P}[X \geq x]$$

This implies the first inequality in (22.2).

Proof of Theorem 22.1 Step 1. " $\leq$ " Let $\alpha > 1$, and define $t_n = \alpha^n$ for $n \in \mathbb{N}$. Later, we let $\alpha \downarrow 1$. Define $f(t) = 2\alpha^2 \log \log t$. Then by the reflection principle (Theorem 21.19) and using the abbreviation $B_{[a,b]} := \{B_t : t \in [a,b]\}$, we obtain

$$\begin{aligned} & \mathbf{P}[\sup B_{[t_n, t_{n+1}]} > \sqrt{t_n f(t_n)}] \\ & \leq \mathbf{P}\left[t_{n+1}^{-1/2} \sup B_{[0, t_{n+1}]} > \sqrt{f(t_n)/\alpha}\right] \\ & = \mathbf{P}\left[\sup B_{[0, 1]} > \sqrt{f(t_n)/\alpha}\right] \\ & \leq \sqrt{\frac{\alpha}{f(t_n)}} e^{-f(t_n)/2\alpha} \\ & = (\log \alpha)^{-\alpha} \sqrt{\frac{\alpha}{f(t_n)}} n^{-\alpha} \\ & \leq n^{-\alpha} \quad \text{for large enough } n. \end{aligned} \tag{22.3}$$

In the next to last step, we used

$$\frac{f(t_n)}{2\alpha} = \alpha(\log(n \log \alpha)) = \alpha \log n + \alpha \log \log \alpha$$

Since $\alpha > 1$, the right-hand side of (22.3) is summable in n :

$$\sum_{n=1}^{\infty} \mathbf{P}\left[\sup B_{[t_n, t_{n+1}]} > \sqrt{t_n f(t_n)}\right] < \infty$$

The Borel-Cantelli lemma (Theorem 2.7) then yields (note that $t \mapsto \sqrt{t f(t)}$ is monotone increasing)

$$\limsup_{t \rightarrow \infty} \frac{B_t}{\sqrt{t f(t)}} \leq 1 \quad \text{a.s.}$$

Now let $\alpha \downarrow 1$ to obtain

$$\limsup_{t \rightarrow \infty} \frac{B_t}{\sqrt{2t \log \log t}} \leq 1 \quad \text{a.s.} \tag{22.4}$$

Step 2. " $\geq$ " Here we show the other inequality in (22.1). To this end, we let $\alpha \rightarrow \infty$. Let $\beta := \frac{\alpha}{\alpha-1} > 1$ and $g(t) = \frac{2}{\beta^2} \log \log t$. Choose n_0 large enough that $\beta g(t_n) \geq 1$ for all $n \geq n_0$. Then, by Brownian scaling (note that $t_n - t_{n-1} = \frac{1}{\beta} t_n$) and (22.2) (since $(x + \frac{1}{x})^{-1} \geq \frac{1}{2} \frac{1}{x}$ for $x = (\beta g(t_n))^{1/2} \geq 1$),

$$\begin{aligned} \mathbf{P}\left[B_{t_n} - B_{t_{n-1}} > \sqrt{t_n g(t_n)}\right] &= \mathbf{P}\left[B_1 > \sqrt{\beta g(t_n)}\right] \\ &\geq \frac{1}{\sqrt{2\pi}} \frac{1}{2} \frac{1}{\sqrt{\beta g(t_n)}} e^{-\beta g(t_n)/2} \\ &= \frac{1}{\sqrt{2\pi}} \frac{1}{2} (\log \alpha)^{-1/\beta} \frac{1}{\sqrt{\beta g(t_n)}} n^{-1/\beta}. \end{aligned}$$

If $\varepsilon \in (0, 1 - 1/\beta)$, then, for sufficiently large $n \in \mathbb{N}$, the right-hand side of the above equation is $\geq n^{-\varepsilon} n^{-1/\beta} \geq n^{-1}$. Hence

$$\sum_{n=2}^{\infty} \mathbf{P} \left[B_{t_n} - B_{t_{n-1}} > \sqrt{t_n g(t_n)} \right] = \infty$$

The events are independent and hence the Borel-Cantelli lemma yields

$$\mathbf{P} \left[B_{t_n} - B_{t_{n-1}} > \sqrt{t_n g(t_n)} \text{ for infinitely many } n \right] = 1 \quad (22.5)$$

Since $\frac{t_n \log \log t_n}{t_{n-1} \log \log t_{n-1}} \xrightarrow{n \rightarrow \infty} \alpha$, (22.4) and symmetry of Brownian motion imply that, for $\varepsilon > 0$,

$$B_{t_{n-1}} > -(1 + \varepsilon) \alpha^{-1/2} \sqrt{2t_n \log \log t_n} \quad \text{for almost all } n \in \mathbb{N} \quad \text{a.s.} \quad (22.6)$$

From (22.5) and (22.6), it follows that

$$\limsup_{n \rightarrow \infty} \frac{B_{t_n}}{\sqrt{2t_n \log \log t_n}} \geq \frac{1}{\beta} - (1 + \varepsilon) \alpha^{-1/2} = \frac{\alpha - 1}{\alpha} - (1 + \varepsilon) \alpha^{-1/2} \quad \text{a.s.}$$

Now, letting $\alpha \rightarrow \infty$ gives $\limsup_{t \rightarrow \infty} \frac{B_t}{\sqrt{2t \log \log t}} \geq 1$ a.s. Together with (22.4), this implies the claim of the theorem.

Corollary 22.3 For every $s \geq 0$, a.s. we have

$$\limsup_{t \downarrow 0} \frac{B_{s+t} - B_s}{\sqrt{2t \log \log(1/t)}} = 1$$

Proof Without loss of generality, assume $s = 0$. Apply Theorem 22.1 to the Brownian motion $(tB_{1/t})$ (see Theorem 21.14).

Remark 22.4 The statement of Corollary 22.3 is about the typical points s of Brownian motion B . However, there might be points in which Brownian motion moves faster than $\sqrt{2t \log \log(1/t)}$. The precise statement is due to Paul Lévy [106]: Denote by $h(\delta) := \sqrt{2\delta \log(1/\delta)}$ Lévy's modulus of continuity. Then

$$\mathbf{P} \left[\lim_{\delta \downarrow 0} \sup_{\substack{s, t \in [0, 1] \\ 0 \leq t-s \leq \delta}} |B_t - B_s| / h(\delta) = 1 \right] = 1. \quad (22.7)$$

(See, e.g., [144, Theorem I.2.5] for a proof.) This implies in particular that almost surely B is not locally Hölder- $\frac{1}{2}$ -continuous.

5.22.2 22.2 Skorohod's Embedding Theorem

In order to carry over the result of the previous section to sums of square integrable centered random variables, we use an embedding of such random variables in a Brownian motion that is due to Skorohod. This technique also provides an alternative proof of Donsker's invariance principle (Theorem 21.43).

Theorem 22.5 (Skorohod's embedding theorem) Let X be a real random variable with $\mathbf{E}[X] = 0$ and $\text{Var}[X] < \infty$. Then on a suitable probability space we can construct a random variable Ξ , a Brownian motion B that is independent of Ξ and an $\mathbb{F}$ -stopping time τ such that

$$B_\tau \stackrel{\mathcal{D}}{=} X \quad \text{and} \quad \mathbf{E}[\tau] = \text{Var}[X]$$

Here the filtration $\mathbb{F}$ is given by $\mathcal{F}_t = \sigma(\Xi, (B_s)_{s \leq t})$.

Remark 22.6 In the above theorem we can do without the additional random variable; that is, we can choose $\mathbb{F} = \sigma(B)$. The proof is rather involved, though (see p. 515).

Corollary 22.7 Let $X_1, X_2, \dots$ be i.i.d. real random variables with $\mathbf{E}[X_1] = 0$ and $\text{Var}[X_1] < \infty$. Further, let $S_n = X_1 + \dots + X_n, n \in \mathbb{N}$. Then on a suitable probability space there exists a filtration $\mathbb{F}$, a Brownian motion B and $\mathbb{F}$ -stopping times $0 = \tau_0 \leq \tau_1 \leq \tau_2 \leq \dots$ such that $(\tau_n - \tau_{n-1})_{n \in \mathbb{N}}$ is i.i.d., $\mathbf{E}[\tau_1] = \text{Var}[X_1]$ and $(B_{\tau_n})_{n \in \mathbb{N}} \stackrel{D}{=} (S_n)_{n \in \mathbb{N}}$.

Proof of Corollary 22.7 We only sketch the proof. The details are left to the reader. Choose independent triples $(B^{(n)}, \Xi^{(n)}, \tau^{(n)}), n \in \mathbb{N}$, as in Theorem 22.5. Let $\tau_n = \tau^{(1)} + \dots + \tau^{(n)}$. For $t \leq \tau_1$ let $B_t := B_t^{(1)}$, and define recursively

$$B_t = B_{\tau_n} + B_{t-\tau_n}^{(n+1)}, \quad \text{if } \tau_n < t \leq \tau_{n+1}$$

Using repeatedly the strong Markov property of Brownian motion, we see that B is a Brownian motion. Now let $\mathcal{F}_t = \sigma((\Xi_n)_{n \in \mathbb{N}}, (B_s)_{s \leq t})$.

We prepare for the proof of Theorem 22.5 with a lemma. In order to allow measures as integrands, we use the following notation: If $\mu \in \mathcal{M}(E)$ is a measure and $f \in \mathcal{L}^1(\mu)$ is nonnegative, then define $\int \mu(dx) f(x) \delta_x := f\mu$, where $f\mu$ is the measure with density f with respect to μ . This is consistent since for measurable $A \subset E$, we then have

$$\left(\int \mu(dx) f(x) \delta_x \right) (A) = \int \mu(dx) f(x) \delta_x(A) = \int \mu(dx) f(x) \mathbb{1}_A(x) = f\mu(A)$$

Lemma 22.8 Let $\mu \in \mathcal{M}_1(\mathbb{R})$ with $\int x\mu(dx) = 0$ and $\sigma^2 := \int x^2\mu(dx) < \infty$. Then there exists a probability measure $\theta \in \mathcal{M}_1((-\infty, 0) \times [0, \infty))$ with

$$\mu = \int \theta(d(u, v)) \left(\frac{v}{v-u} \delta_u + \frac{-u}{v-u} \delta_v \right) \quad (22.8)$$

Furthermore, $\sigma^2 = - \int uv\theta(d(u, v))$.

Proof Define $m := \int_{[0, \infty)} v\mu(dv) = - \int_{(-\infty, 0)} u\mu(du)$. If $m = 0$, then $\theta = \delta_{(-1, 0)}$ is a possible choice. Assume now $m > 0$ and define θ by

$$\theta(d(u, v)) := m^{-1}(v-u)\mu(du)\mu(dv) \quad \text{for } u < 0 \text{ and } v \geq 0$$

Then

$$\begin{aligned} \int \theta(d(u, v)) &= m^{-1} \int_{(-\infty, 0)} \mu(du) \int_{[0, \infty)} \mu(dv) (v-u) \\ &= m^{-1} \int_{(-\infty, 0)} \mu(du) [m - u\mu([0, \infty))] \\ &= m^{-1} (m\mu((-\infty, 0)) + m\mu([0, \infty))) = 1 \end{aligned}$$

Hence, θ is in fact a probability measure. Furthermore,

$$\begin{aligned} \int \theta(d(u, v)) \left(\frac{v}{v-u} \delta_u + \frac{-u}{v-u} \delta_v \right) &= m^{-1} \int_{(-\infty, 0)} \mu(du) \int_{[0, \infty)} \mu(dv) (v\delta_u - u\delta_v) \\ &= \int_{(-\infty, 0)} \mu(du) \delta_u + \int_{[0, \infty)} \mu(dv) \delta_v = \mu \end{aligned}$$

By (22.8), we infer

$$\sigma^2 = \int \mu(dx) x^2 = \int \theta(d(u, v)) \left(\frac{v}{v-u} u^2 + \frac{-u}{v-u} v^2 \right) = - \int \theta(d(u, v)) uv$$

Proof Theorem 22.5 First assume that X takes only the two values $u < 0$ and $v \geq 0$: $\mathbf{P}[X = u] = \frac{v}{v-u} = 1 - \mathbf{P}[X = v]$. Let

$$\tau_{u,v} = \inf \{t > 0 : B_t \in \{u, v\}\}.$$

By Exercise 21.2.4, we have $\mathbf{E}[B_{\tau_{u,v}}] = 0$; hence $B_{\tau_{u,v}} \stackrel{\mathcal{D}}{=} X$ and $\mathbf{E}[\tau_{u,v}] = -uv$. Now let X be arbitrary with $\mathbf{E}[X] = 0$ and $\sigma^2 := \mathbf{E}[X^2] < \infty$. Define $\mu = \mathbf{P}_X$ and $\theta = \theta_\mu$ as in Lemma 22.8. Further, let $\Xi = (\Xi_u, \Xi_v)$ be a random variable with values in $(-\infty, 0) \times [0, \infty)$ and with distribution θ .

Let $\mathbb{F} = (\mathcal{F}_t)_{t \geq 0}$ where $\mathcal{F}_t := \sigma(\Xi, B_s : s \in [0, t])$. Define $\tau := \tau_{\Xi_u, \Xi_v}$. By continuity of B , we get

$$\{\tau \leq t\} = \bigcap_{\substack{u, v \in \mathbb{Q} \\ u < 0 \leq v}} (\{\Xi \in (-\infty, u] \times [v, \infty)\} \cap \{\tau_{u,v} \leq t\}) \in \mathcal{F}_t$$

Hence τ is an $\mathbb{F}$ -stopping time (but not a $\sigma(B)$ -stopping time). For $x < 0$,

$$\begin{aligned} \mathbf{P}[X \leq x] &= \int_{(-\infty, x] \times [0, \infty)} \theta(d(u, v)) \frac{v}{v-u} \\ &= \int_{(-\infty, x] \times [0, \infty)} \theta(d(u, v)) \mathbf{P}[B_{\tau_{u,v}} = u] \\ &= \mathbf{P}[B_\tau \leq x] \end{aligned}$$

For $x \geq 0$, we similarly get $\mathbf{P}[X > x] = \mathbf{P}[B_\tau > x]$. Summing up, we have $B_\tau \stackrel{\mathcal{D}}{=} X$. Furthermore,

$$\mathbf{E}[\tau] = -\mathbf{E}[\Xi_u \Xi_v] = - \int \theta(d(u, v)) uv = \sigma^2$$

Supplement: Proof of Remark 22.6

Here we prove that in Skorohod's embedding theorem we can really do without randomized stopping times; that is, we can choose a stopping time with respect to the filtration generated by the Brownian motion B . In other words, the stopping time can be chosen without using additional random variables, such as the Ξ in the proof given above.

An elegant proof that is based on stochastic analysis methods can be found in Azéma and Yor; see [6, 7]. See also [118] for a more elementary version of that proof. Here, however, we follow an elementary route whose basic idea goes back to Dubins.

For $u < 0 < v$, let $\tau_{u,v} = \inf \{t > 0 : B_t \in \{u, v\}\}$. Hence, if X is a centered random variable that takes only the values u and v , then, as shown in the proof of Theorem 22.5, $B_{\tau_{u,v}} \stackrel{\mathcal{D}}{=} X$ and $\mathbf{E}[\tau_{u,v}] = \mathbf{E}[X^2]$.

In a first step, we generalize this statement to binary splitting martingales. (Recall from Definition 9.42 that a binary splitting process at each time step has a choice of just two different values, which may however depend on the history of the process.) In a second step, we show that square integrable centered random variables can be expressed as limits of such martingales.

Theorem 22.9 Let $(X_n)_{n \in \mathbb{N}_0}$ be a binary splitting martingale with $X_0 = 0$. Let B be a Brownian motion and let $\mathbb{F} = \sigma(B)$ be its canonical filtration. Then there exist $\mathbb{F}$ -stopping times $0 = \tau_0 \leq \tau_1 \leq \dots$ such that

$$(X_n)_{n \in \mathbb{N}_0} \stackrel{\mathcal{D}}{=} (B_{\tau_n})_{n \in \mathbb{N}_0}$$

and such that $\mathbf{E}[\tau_n] = \mathbf{E}[X_n^2]$ holds for all $n \in \mathbb{N}_0$.

If $(X_n)_{n \in \mathbb{N}_0}$ is bounded in L^2 and thus converges almost surely and in L^2 to some square integrable X_∞ , then $\tau := \sup_{n \in \mathbb{N}} \tau_n < \infty$ a.s., $\mathbf{E}[\tau] = \text{Var}[X_\infty]$ and $X_\infty \stackrel{\mathcal{D}}{=} B_\tau$.

Proof For $n \in \mathbb{N}$, let $f_n : \mathbb{R}^{n-1} \times \{-1, +1\} \rightarrow \mathbb{R}$ and let D_n be a $\{-1, +1\}$ -valued random variable such that $X_n = f_n(X_1, \dots, X_{n-1}, D_n)$ holds (compare Definition 9.42). Without loss of generality, we may assume that f_n is monotone increasing in D_n . Let $\tau_0 := 0$ and inductively define

$$\tau_n := \inf \{t > \tau_{n-1} : B_t \in \{f_n(B_{\tau_1}, \dots, B_{\tau_{n-1}}, -1), f_n(B_{\tau_1}, \dots, B_{\tau_{n-1}}, +1)\}\}.$$

Let $\tilde{X}_n := B_{\tau_n}$ and

$$\tilde{D}_n := \begin{cases} 1, & \text{if } \tilde{X}_n \geq \tilde{X}_{n-1} \\ -1, & \text{else} \end{cases}$$

By Exercise 21.2.4 and using the strong Markov property (at τ_{n-1}), we get

$$\begin{aligned} \mathbf{P}[\tilde{D}_n = 1 \mid \tilde{X}_1, \dots, \tilde{X}_{n-1}] \\ = \frac{\tilde{X}_{n-1} - f_n(\tilde{X}_1, \dots, \tilde{X}_{n-1}, -1)}{f_n(\tilde{X}_1, \dots, \tilde{X}_{n-1}, +1) - f_n(\tilde{X}_1, \dots, \tilde{X}_{n-1}, -1)} \end{aligned}$$

and $\mathbf{E}[\tau_n - \tau_{n-1}] = \mathbf{E}\left[\left(\tilde{X}_n - \tilde{X}_{n-1}\right)^2\right]$. On the other hand, since $(X_n)_{n \in \mathbb{N}_0}$ is a martingale, we have

$$\begin{aligned} X_{n-1} &= \mathbf{E}[X_n \mid X_0, \dots, X_{n-1}] \\ &= \sum_{i=-1, +1} \mathbf{P}[D_n = i \mid X_0, \dots, X_{n-1}] f_n(X_1, \dots, X_{n-1}, i) \end{aligned}$$

Therefore,

$$\begin{aligned} \mathbf{P}[D_n = 1 \mid X_1, \dots, X_{n-1}] \\ = \frac{X_{n-1} - f_n(X_1, \dots, X_{n-1}, -1)}{f_n(X_1, \dots, X_{n-1}, +1) - f_n(X_1, \dots, X_{n-1}, -1)} \end{aligned}$$

This implies $(X_n)_{n \in \mathbb{N}_0} \stackrel{\mathcal{D}}{=} (\tilde{X}_n)_{n \in \mathbb{N}_0}$. Since $\mathbf{E}[\tau_n - \tau_{n-1}] = \mathbf{E}[(X_n - X_{n-1})^2]$, and since the martingale differences $(X_i - X_{i-1}), i \in \mathbb{N}$, are uncorrelated, we get $\mathbf{E}[\tau_n] = \mathbf{E}[X_n^2]$.

Finally, if (X_n) is bounded in L^2 , then by the martingale convergence theorem there is a square integrable centered random variable X_∞ such that $X_n \xrightarrow{n \rightarrow \infty} X_\infty$ almost surely and in L^2 . In particular, we have $\mathbf{E}[X_n^2] \xrightarrow{n \rightarrow \infty} \mathbf{E}[X_\infty^2]$. Clearly, $(\tau_n)_{n \in \mathbb{N}}$ is monotone increasing and thus converges to some stopping time τ . By the monotone convergence theorem, $\mathbf{E}[\tau] = \lim_{n \rightarrow \infty} \mathbf{E}[\tau_n] = \lim_{n \rightarrow \infty} \mathbf{E}[X_n^2] = \mathbf{E}[X_\infty^2] < \infty$. Hence $\tau < \infty$ a.s. As Brownian motion is continuous, we conclude

$$B_\tau = \lim_{n \rightarrow \infty} B_{\tau_n} = \lim_{n \rightarrow \infty} \tilde{X}_n \stackrel{\mathcal{D}}{=} X_\infty$$

We have shown the statement of Remark 22.6 in the case where the random variable X is the limit of a binary splitting martingale. The general case is now implied by the following theorem.

Theorem 22.10 Let X be a square integrable centered random variable. Then there exists a binary splitting martingale $(X_n)_{n \in \mathbb{N}_0}$ with $X_0 = 0$ and such that $X_n \xrightarrow{n \rightarrow \infty} X$ almost surely and in L^2 .

Proof We follow the idea of the proof in [118]. Let $X_0 := \mathbf{E}[X] = 0$. Inductively, for $n \in \mathbb{N}$, define

$$D_n := \begin{cases} 1, & \text{if } X \geq X_{n-1}, \\ -1, & \text{if } X < X_{n-1}, \end{cases}$$

$$\mathcal{F}_n := \sigma(D_1, \dots, D_n)$$

and

$$X_n := \mathbf{E}[X \mid \mathcal{F}_n]$$

Hence there exists a map $g_n : \{-1, +1\}^n \rightarrow \mathbb{R}$ such that $g_n(D_1, \dots, D_n) = X_n$. Clearly, $\mathbb{1}_{D_k=1} = \mathbb{1}_{X_k \geq X_{k-1}}$ almost surely for all $k \in \mathbb{N}$. Hence the $D_1, \dots, D_k$ can be computed from the $X_1, \dots, X_k$. Thus there exists a map $f_n : \mathbb{R}^{n-1} \times \{-1, +1\} \rightarrow \mathbb{R}$ such that $f_n(X_1, \dots, X_{n-1}, D_n) = X_n$. Therefore, (X_n) is binary splitting.

Manifestly, $(X_n)_{n \in \mathbb{N}_0}$ is a martingale. By Jensen's inequality, we have $\mathbf{E}[X_n^2] \leq \mathbf{E}[X^2] < \infty$ for all $n \in \mathbb{N}$. Hence $(X_n)_{n \in \mathbb{N}_0}$ is bounded in L^2 and thus converges almost surely and in L^2 to some square integrable X_∞ . It remains to show that $X_\infty = X$ holds almost surely. To this end, we first show

$$\lim_{n \rightarrow \infty} D_n(\omega) (X(\omega) - X_n(\omega)) = |X(\omega) - X_\infty(\omega)| \quad \text{for almost all } \omega. \quad (22.9)$$

If $X(\omega) = X_\infty(\omega)$, then (22.9) holds trivially. If $X(\omega) > X_\infty(\omega)$, then $X(\omega) > X_n(\omega)$ and thus $D_n(\omega) = 1$ for all sufficiently large n ; hence (22.9) holds. Similarly, we get (22.9) if $X(\omega) < X_\infty(\omega)$.

Evidently, we have

$$\mathbf{E}[D_n(X - X_n)] = \mathbf{E}[D_n \mathbf{E}[X - X_n \mid \mathcal{F}_n]] = 0$$

As $(D_n(X - X_n))_{n \in \mathbb{N}}$ is bounded in L^2 (and is thus uniformly integrable), we get $\mathbf{E}[|X - X_\infty|] = \lim_{n \rightarrow \infty} \mathbf{E}[D_n(X - X_n)] = 0$; hence $X = X_\infty$ a.s.

5.22.3 22.3 Hartman-wintner Theorem

The goal of this section is to prove the law of the iterated logarithm for i.i.d. centered square integrable random variables $X_n, n \in \mathbb{N}$, that goes back to Hartman and Wintner (1941) (see [69]). For the special case of Rademacher random variables, the upper bound was found earlier by Khinchin in 1923 (see [97]).

Theorem 22.11 (Hartman-Wintner, law of the iterated logarithm) Let $X_1, X_2, \dots$ be i.i.d. real random variables with $\mathbf{E}[X_1] = 0$ and $\text{Var}[X_1] = 1$. Let $S_n = X_1 + \dots + X_n, n \in \mathbb{N}$. Then

$$\limsup_{n \rightarrow \infty} \frac{S_n}{\sqrt{2n \log \log n}} = 1 \quad \text{a.s.} \quad (22.10)$$

The strategy of the proof is to embed the partial sums S_n of the random variables in a Brownian motion and then use the law of the iterated logarithm for Brownian motion. The Skorohod embedding theorem ensures that this works. We follow the exposition in [39, Section 8.8].

Proof By Corollary 22.7, on a suitable probability space there exists a filtration $\mathbb{F}$, a Brownian motion B that is an $\mathbb{F}$ -martingale, and stopping times $\tau_1 \leq \tau_2 \leq \dots$ such that $(S_n)_{n \in \mathbb{N}} \stackrel{\mathcal{D}}{=} (B_{\tau_n})_{n \in \mathbb{N}}$. Furthermore, the $(\tau_n - \tau_{n-1})_{n \in \mathbb{N}}$ are i.i.d. with $\mathbf{E}[\tau_n - \tau_{n-1}] = \text{Var}[X_1] = 1$.

By the law of the iterated logarithm for Brownian motion (see Theorem 22.1), we have

$$\limsup_{t \rightarrow \infty} \frac{B_t}{\sqrt{2t \log \log t}} = 1 \quad \text{a.s.}$$

Hence, it is enough to show that

$$\limsup_{t \rightarrow \infty} \frac{|B_t - B_{\tau_{[t]}}|}{\sqrt{2t \log \log t}} = 0 \quad \text{a.s.}$$

By the strong law of large numbers (Theorem 5.17), we have $\frac{1}{n}\tau_n \xrightarrow{n \rightarrow \infty} 1$ a.s., so let $\varepsilon > 0$ and let $t_0 = t_0(\omega)$ be large enough that

$$\frac{1}{1+\varepsilon} \leq \frac{\tau_{[t]}}{t} \leq 1+\varepsilon \quad \text{for all } t \geq t_0$$

Define

$$M_t := \sup_{s \in [t/(1+\varepsilon), t(1+\varepsilon)]} |B_s - B_t|.$$

It is enough to show that

$$\limsup_{t \rightarrow \infty} \frac{M_t}{\sqrt{2t \log \log t}} = 0$$

Consider the sequence $t_n = (1+\varepsilon)^n$, $n \in \mathbb{N}$, and define

$$M'_n := \sup_{s \in [t_{n-1}, t_{n+2}]} |B_s - B_{t_{n-1}}|.$$

Then (by the triangle inequality), for $t \in [t_n, t_{n+1}]$,

$$M_t \leq 2M'_n.$$

Let $\delta := (1+\varepsilon)^3 - 1$. Then $t_{n+2} - t_{n-1} = \delta t_{n-1}$. Brownian scaling and the reflection principle (Theorem 21.19) now yield

$$\begin{aligned} & \mathbf{P} \left[M'_n > \sqrt{3\delta t_{n-1} \log \log t_{n-1}} \right] \\ &= \mathbf{P} \left[\sup_{s \in [0,1]} |B_s| > \sqrt{3 \log \log t_{n-1}} \right] \\ &\leq 2\mathbf{P} \left[\sup_{s \in [0,1]} B_s > \sqrt{3 \log \log t_{n-1}} \right] \\ &= 4\mathbf{P} \left[B_1 > \sqrt{3 \log \log t_{n-1}} \right] \\ &\leq \frac{2}{\sqrt{3 \log \log t_{n-1}}} \exp \left(-\frac{3}{2} \log \log t_{n-1} \right) \quad (\text{Lemma 22.2}) \\ &\leq n^{-3/2} \text{ for } n \text{ sufficiently large.} \end{aligned}$$

The probabilities can be summed over n ; hence the Borel-Cantelli lemma yields

$$\begin{aligned} \limsup_{t \rightarrow \infty} \frac{M_t}{\sqrt{t \log \log t}} &\leq \limsup_{n \rightarrow \infty} \frac{2M'_n}{\sqrt{t_{n-1} \log \log t_{n-1}}} \\ &\leq 2\sqrt{3\delta} \end{aligned}$$

Letting $\varepsilon \rightarrow 0$, we get $\delta = (1 + \varepsilon)^3 - 1 \rightarrow 0$, and hence the proof is complete. $\square$

5.23 23 Large Deviations

Except for the law of the iterated logarithm, so far we have encountered two types of limit theorems for partial sums $S_n = X_1 + \dots + X_n, n \in \mathbb{N}$, of identically distributed, real random variables $(X_i)_{i \in \mathbb{N}}$ with distribution function F :

(1) (Weak) laws of large numbers state that (under suitable assumptions on the family $(X_i)_{i \in \mathbb{N}}$), for every $x > 0$,

$$\mathbf{P} [|S_n - n\mathbf{E}[X_1]| \geq xn] \xrightarrow{n \rightarrow \infty} 0. \quad (23.1)$$

From this we get immediately that the empirical distribution functions

$$F_n : x \mapsto \frac{1}{n} \sum_{i=1}^n \mathbb{1}_{(-\infty, x]}(X_i)$$

converge in probability; that is, $\|F_n - F\|_\infty \xrightarrow{n \rightarrow \infty} 0$. In other words, for any distribution function $G \neq F$ and any $\varepsilon > 0$ with $\varepsilon < \|F - G\|_\infty$, we have

$$\mathbf{P} [\|F_n - G\|_\infty < \varepsilon] \xrightarrow{n \rightarrow \infty} 0. \quad (23.2)$$

(2) Central limit theorems state that (under different assumptions on the family $(X_i)_{i \in \mathbb{N}}$) for every $x \in \mathbb{R}$

$$\mathbf{P} [S_n - n\mathbf{E}[X_1] \geq x\sqrt{n}] \xrightarrow{n \rightarrow \infty} 1 - \Phi\left(\frac{x}{\sqrt{\text{Var}[X_1]}}\right). \quad (23.3)$$

Here $\Phi : t \mapsto \mathcal{N}_{0,1}((-\infty, t])$ is the distribution function of the standard normal distribution.

In each case, the typical value of S_n is $n\mathbf{E}[X_1]$. Equation (23.3) makes a precise statement about the average size of the deviations (which are of order $\sqrt{n}$) from the typical value. A simple consequence is of course that the probability of large deviations (of order n) from the typical value goes to 0 ; that is, (23.1) holds.

In this chapter, we compute the speed of convergence in (23.1) (Cramér's theorem) and in (23.2) (Sanov's theorem).

We follow in part the expositions in [31, 74].

5.23.1 23.1 Cramér's Theorem

Let $X_1, X_2, \dots$ be i.i.d. with $\mathbf{P}_{X_i} = \mathcal{N}_{0,1}$. Then, for every $x > 0$,

$$\mathbf{P} [S_n \geq xn] = \mathbf{P} [X_1 \geq x\sqrt{n}] = 1 - \Phi(x\sqrt{n}) = (1 + \varepsilon_n) \frac{1}{x\sqrt{2\pi n}} e^{-nx^2/2}$$

where $\varepsilon_n \xrightarrow{n \rightarrow \infty} 0$ (by Lemma 22.2). Taking logarithms, we get

$$\lim_{n \rightarrow \infty} \frac{1}{n} \log \mathbf{P} [S_n \geq xn] = -\frac{x^2}{2} \quad \text{for every } x > 0 \quad (23.4)$$

It might be tempting to believe that a central limit theorem could be used to show (23.4) for all centered i.i.d. sequences (X_i) with finite variance. However, in general, the limit might be infinite or might be a different function of x , as we will show below. The moral is that large deviations depend more subtly on the tails of the distribution of X_i than the average-sized fluctuations do (which are determined by the variance only). The following theorem shows this for Bernoulli random variables.

Theorem 23.1 Let $X_1, X_2, \dots$ be i.i.d. with $\mathbf{P}[X_1 = -1] = \mathbf{P}[X_1 = 1] = \frac{1}{2}$. Then, for every $x \geq 0$,

$$\lim_{n \rightarrow \infty} \frac{1}{n} \log \mathbf{P}[S_n \geq xn] = -I(x) \quad (23.5)$$

where the rate function I is given by

$$I(z) = \begin{cases} \frac{1+z}{2} \log(1+z) + \frac{1-z}{2} \log(1-z), & \text{if } z \in [-1, 1] \\ \infty, & \text{if } |z| > 1 \end{cases} \quad (23.6)$$

Remark 23.2 Here we agree that $0 \log 0 = 0$. This makes the restriction of I to $[-1, 1]$ a continuous function with $I(-1) = I(1) = \log 2$. Note that I is strictly convex on $[-1, 1]$ with $I(0) = 0$ and I is monotone increasing on $[0, 1]$ and is monotone decreasing on $[-1, 0]$.

Proof of Theorem 23.1 For $x = 0$ and $x > 1$, the claim is trivial. For $x = 1$, we have $\mathbf{P}[S_n \geq n] = 2^{-n}$, and thus again (23.5) holds trivially. Hence, it is enough to consider $x \in (0, 1)$. Since $\frac{S_n + n}{2} \sim b_{n, 1/2}$ is binomially distributed, we have

$$\mathbf{P}[S_n \geq xn] = 2^{-n} \sum_{k \geq (1+x)n/2} \binom{n}{k}.$$

Fig. 23.1 Rate function $I(z)$ from (23.6)

Define $a_n(x) = \lceil n(1+x)/2 \rceil$ for $n \in \mathbb{N}$. Since $k \mapsto \binom{n}{k}$ is monotone decreasing for $k \geq \frac{n}{2}$, we get

$$Q_n(x) := \max \left\{ \binom{n}{k} : a_n(x) \leq k \leq n \right\} = \binom{n}{a_n(x)}. \quad (23.7)$$

We make the estimate

$$2^{-n} Q_n(x) \leq \mathbf{P}[S_n \geq xn] \leq (n+1) 2^{-n} Q_n(x). \quad (23.8)$$

By Stirling's formula

$$\lim_{n \rightarrow \infty} \frac{1}{n!} n^n e^{-n} \sqrt{2\pi n} = 1,$$

we obtain

$$\begin{aligned}
& \lim_{n \rightarrow \infty} \frac{1}{n} \log Q_n(x) \\
&= \lim_{n \rightarrow \infty} \frac{1}{n} \log \frac{n!}{a_n(x)! \cdot (n - a_n(x))!} \\
&= \lim_{n \rightarrow \infty} \frac{1}{n} \log \frac{n^n}{a_n(x)^{a_n(x)} \cdot (n - a_n(x))^{n - a_n(x)}} \\
&= \lim_{n \rightarrow \infty} \left[\log(n) - \frac{a_n(x)}{n} \log(a_n(x)) - \frac{n - a_n(x)}{n} \log(n - a_n(x)) \right] \\
&= \lim_{n \rightarrow \infty} \left[\log(n) - \frac{1+x}{2} \left(\log\left(\frac{1+x}{2}\right) + \log(n) \right) \right. \\
&\quad \left. - \frac{1-x}{2} \left(\log\left(\frac{1-x}{2}\right) + \log(n) \right) \right] \\
&= -\frac{1+x}{2} \log\left(\frac{1+x}{2}\right) - \frac{1-x}{2} \log\left(\frac{1-x}{2}\right) = -I(x) + \log 2
\end{aligned}$$

Together with (23.8), this implies (23.5). $\square$

Under certain assumptions on the distribution of X_1 , Cramér's theorem [29] provides a general principle to compute the rate function I .

Theorem 23.3 (Cramér (1938)) Let $X_1, X_2, \dots$ be i.i.d. real random variables with finite logarithmic moment generating function

$$\Lambda(t) := \log \mathbf{E} [e^{tX_1}] < \infty \quad \text{for all } t \in \mathbb{R} \quad (23.9)$$

Let

$$\Lambda^*(x) := \sup_{t \in \mathbb{R}} (tx - \Lambda(t)) \quad \text{for } x \in \mathbb{R}$$

the Legendre transform of Λ . Then, for every $x > \mathbf{E}[X_1]$,

$$\lim_{n \rightarrow \infty} \frac{1}{n} \log \mathbf{P} [S_n \geq xn] = -I(x) := -\Lambda^*(x) \quad (23.10)$$

Proof By passing to $X_i - x$ if necessary, we may assume $\mathbf{E}[X_i] < 0$ and $x = 0$. (In fact, if $\tilde{X}_i := X_i - x$, and $\tilde{\Lambda}$ and $\tilde{\Lambda}^*$ are defined as Λ and Λ^* above but for $\tilde{X}_i$ instead of X_i , then $\tilde{\Lambda}(t) = \Lambda(t) - t \cdot x$ and thus $\tilde{\Lambda}^*(0) = \sup_{t \in \mathbb{R}} (-\tilde{\Lambda}(t)) = \Lambda^*(x)$.)

Define $\varphi(t) := e^{\Lambda(t)}$ and

$$\varrho := e^{-\Lambda^*(0)} = \inf_{t \in \mathbb{R}} \varphi(t)$$

By (23.9) and the differentiation lemma (Theorem 6.28), φ is differentiable infinitely often and the first two derivatives are

$$\varphi'(t) = \mathbf{E} [X_1 e^{tX_1}] \quad \text{and} \quad \varphi''(t) = \mathbf{E} [X_1^2 e^{tX_1}]$$

Hence φ is strictly convex and $\varphi'(0) = \mathbf{E}[X_1] < 0$.

First consider the case $\mathbf{P} [X_1 \leq 0] = 1$. Then $\varphi'(t) < 0$ for every $t \in \mathbb{R}$ and $\varrho = \lim_{t \rightarrow \infty} \varphi(t) = \mathbf{P} [X_1 = 0]$. Therefore,

$$\mathbf{P} [S_n \geq 0] = \mathbf{P} [X_1 = \dots = X_n = 0] = \varrho^n$$

and thus the claim follows.

Now let $\mathbf{P}[X_1 < 0] > 0$ and $\mathbf{P}[X_1 > 0] > 0$. Then $\lim_{t \rightarrow \infty} \varphi(t) = \infty = \lim_{t \rightarrow -\infty} \varphi(t)$. As φ is strictly convex, there is a unique $\tau \in \mathbb{R}$ at which φ assumes its minimum; hence

$$\varphi(\tau) = \varrho \quad \text{and} \quad \varphi'(\tau) = 0$$

Since $\varphi'(0) < 0$, we have $\tau > 0$. Using Markov's inequality (Theorem 5.11), we estimate

$$\mathbf{P}[S_n \geq 0] = \mathbf{P}[e^{\tau S_n} \geq 1] \leq \mathbf{E}[e^{\tau S_n}] = \varphi(\tau)^n = \varrho^n$$

Thus we get the upper bound

$$\limsup_{n \rightarrow \infty} \frac{1}{n} \log \mathbf{P}[S_n \geq 0] \leq \log \varrho = -\Lambda^*(0)$$

The remaining part of the proof is dedicated to verifying the reverse inequality:

$$\liminf_{n \rightarrow \infty} \frac{1}{n} \log \mathbf{P}[S_n \geq 0] \geq \log \varrho \quad (23.11)$$

We use the method of an exponential size-biasing of the distribution $\mu := \mathbf{P}_{X_1}$ of X_1 , which turns the atypical values that are of interest here into typical values. That is, we define the Cramér transform $\hat{\mu} \in \mathcal{M}_1(\mathbb{R})$ of μ by

$$\hat{\mu}(dx) = \varrho^{-1} e^{\tau x} \mu(dx) \quad \text{for } x \in \mathbb{R}$$

Let $\hat{X}_1, \hat{X}_2, \dots$ be independent and identically distributed with $\mathbf{P}_{\hat{X}_i} = \hat{\mu}$. Then

$$\hat{\varphi}(t) := \mathbf{E}[e^{t \hat{X}_1}] = \frac{1}{\varrho} \int_{\mathbb{R}} e^{tx} e^{\tau x} \mu(dx) = \frac{1}{\varrho} \varphi(t + \tau)$$

Hence

$$\begin{aligned} \mathbf{E}[\hat{X}_1] &= \hat{\varphi}'(0) = \frac{1}{\varrho} \varphi'(\tau) = 0 \\ \text{Var}[\hat{X}_1] &= \hat{\varphi}''(0) = \frac{1}{\varrho} \varphi''(\tau) \in (0, \infty) \end{aligned}$$

Defining $\hat{S}_n = \hat{X}_1 + \dots + \hat{X}_n$, we get

$$\begin{aligned} \mathbf{P}[S_n \geq 0] &= \int_{\{x_1 + \dots + x_n \geq 0\}} \mu(dx_1) \dots \mu(dx_n) \\ &= \int_{\{x_1 + \dots + x_n \geq 0\}} (\varrho e^{-\tau x_1}) \hat{\mu}(dx_1) \dots (\varrho e^{-\tau x_n}) \hat{\mu}(dx_n) \\ &= \varrho^n \mathbf{E}[e^{-\tau \hat{S}_n} \mathbb{1}_{\{\hat{S}_n \geq 0\}}] \end{aligned}$$

Thus, in order to show (23.11), it is enough to show

$$\liminf_{n \rightarrow \infty} \frac{1}{n} \log \mathbf{E}[e^{-\tau \hat{S}_n} \mathbb{1}_{\{\hat{S}_n \geq 0\}}] \geq 0 \quad (23.12)$$

However, by the central limit theorem (Theorem 15.37), for every $c > 0$,

$$\begin{aligned}
\frac{1}{n} \log \mathbf{E} \left[e^{-\tau \hat{S}_n} \mathbb{1}_{\{\hat{S}_n \geq 0\}} \right] &\geq \frac{1}{n} \log \mathbf{E} \left[e^{-\tau \hat{S}_n} \mathbb{1}_{\{0 \leq \hat{S}_n \leq c\sqrt{n}\}} \right] \\
&\geq \frac{1}{n} \log \left(e^{-\tau c \sqrt{n}} \mathbf{P} \left[\frac{\hat{S}_n}{\sqrt{n}} \in [0, c] \right] \right) \\
&\xrightarrow{n \rightarrow \infty} \lim_{n \rightarrow \infty} \frac{-\tau c \sqrt{n}}{n} + \lim_{n \rightarrow \infty} \frac{1}{n} \log \left(\mathcal{N}_{0, \text{Var}[\hat{X}_1]}([0, c]) \right) \\
&= 0
\end{aligned}$$

Example 23.4 If $\mathbf{P}_{X_1} = \mathcal{N}_{0,1}$, then

$$\Lambda(t) = \log \left(\mathbf{E} \left[e^{tX_1} \right] \right) = \log \left(\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{tx} e^{-x^2/2} dx \right) = \frac{t^2}{2}$$

Furthermore,

$$\Lambda^*(z) = \sup_{t \in \mathbb{R}} (tz - \Lambda(t)) = \sup_{t \in \mathbb{R}} \left(tz - \frac{t^2}{2} \right) = \frac{z^2}{2}$$

Hence the rate function coincides with that of (23.4).

Example 23.5 If $\mathbf{P}_{X_1} = \frac{1}{2}\delta_{-1} + \frac{1}{2}\delta_1$, then $\Lambda(t) = \log \cosh(t)$. The maximizer $t^* = t^*(z)$ of the variational problem for Λ^* solves the equation $z = \Lambda'(t^*) = \tanh(t^*)$. Hence

$$\Lambda^*(z) = z t^* - \Lambda(t^*) = z \operatorname{arctanh}(z) - \log(\cosh(\operatorname{arctanh}(z))).$$

Now $\operatorname{arctanh}(z) = \frac{1}{2} \log \frac{1+z}{1-z}$ for $z \in (-1, 1)$ and

$$\cosh(\operatorname{arctanh}(z)) = \frac{1}{\sqrt{1-z^2}} = \frac{1}{\sqrt{(1-z)(1+z)}}$$

Therefore,

$$\begin{aligned}
\Lambda^*(z) &= \frac{z}{2} \log(1+z) - \frac{z}{2} \log(1-z) + \frac{1}{2} \log(1-z) + \frac{1}{2} \log(1+z) \\
&= \frac{1+z}{2} \log(1+z) + \frac{1-z}{2} \log(1-z)
\end{aligned}$$

However, this is the rate function from Theorem 23.1.

Exercise 23.1.1 Let X be a real random variable with density

$$f(x) = c^{-1} \frac{e^{-|x|}}{1+|x|^3}$$

where $c = \int_{-\infty}^{\infty} \frac{e^{-|x|}}{1+|x|^3} dx$. Check if the logarithmic moment generating function Λ is continuous and sketch the graph of Λ .

5.23.2 23.2 Large Deviations Principle

The basic idea of Cramér's theorem is to quantify the probabilities of rare events by an exponential rate and a rate function. In this section, we develop a formal framework for the quantification of probabilities of rare events in which the complete theory of large deviations can be developed. For further reading, consult, e.g., [31, 32] or [74].

Let E be a Polish space with complete metric d . Recall that

$$B_\varepsilon(x) = \{y \in E : d(x, y) < \varepsilon\}$$

denotes the open ball of radius $\varepsilon > 0$ that is centered at $x \in E$.

A map $f : E \rightarrow \overline{\mathbb{R}} = [-\infty, \infty]$ is called lower semicontinuous if, for every $a \in \overline{\mathbb{R}}$, the level set $f^{-1}([-\infty, a]) \subset E$ is closed. (In particular, continuous maps are lower semicontinuous. On the other hand, $\mathbb{1}_{(0,1)} : \mathbb{R} \rightarrow \mathbb{R}$ is lower semicontinuous but not continuous.) An equivalent condition for lower semicontinuity is that

$$\liminf_{\varepsilon \downarrow 0} f(B_\varepsilon(x)) = f(x) \quad \text{for all } x \in E$$

(Recall that $\inf f(A) = \inf\{f(x) : x \in A\}$.) If $K \subset E$ is compact and nonempty, then f assumes its infimum on K . Indeed, for the case where $f(x) = \infty$ for all $x \in K$, the statement is trivial. Now assume $\inf f(K) < \infty$. If $a_n \downarrow \inf f(K)$ is strictly monotone decreasing, then $K \cap f^{-1}([-\infty, a_n]) \neq \emptyset$ is compact for every $n \in \mathbb{N}$ and hence the infinite intersection also is nonempty:

$$f^{-1}(\inf f(K)) = K \cap \bigcap_{n=1}^{\infty} f^{-1}([-\infty, a_n]) \neq \emptyset.$$

Definition 23.6 (Rate function) A lower semicontinuous function $I : E \rightarrow [0, \infty]$ is called a rate function. If all level sets $I^{-1}([-\infty, a])$, $a \in [0, \infty)$, are compact, then I is called a good rate function.

Definition 23.7 (Large deviations principle) Let I be a rate function and $(\mu_\varepsilon)_{\varepsilon > 0}$ be a family of probability measures on E . We say that $(\mu_\varepsilon)_{\varepsilon > 0}$ satisfies a large deviations principle (LDP) with rate function I if

(LDP 1) $\liminf_{\varepsilon \rightarrow 0} \varepsilon \log(\mu_\varepsilon(U)) \geq -\inf I(U)$ for every open $U \subset E$,

(LDP 2) $\limsup_{\varepsilon \rightarrow 0} \varepsilon \log(\mu_\varepsilon(C)) \leq -\inf I(C)$ for every closed $C \subset E$.

We say that a family $(P_n)_{n \in \mathbb{N}}$ of probability measures on E satisfies an LDP with rate $r_n \uparrow \infty$ and rate function I if (LDP 1) and (LDP 2) hold with $\varepsilon_n = 1/r_n$ and $\mu_{1/r_n} = P_n$.

Often (LDP 1) and (LDP 2) are referred to as lower bound and upper bound. In many cases, the lower bound is a lot easier to show than the upper bound.

Before we show that Cramér's theorem is essentially an LDP, we make two technical statements.

Theorem 23.8 The rate function in an LDP is unique.

Proof Assume that $(\mu_\varepsilon)_{\varepsilon > 0}$ satisfies an LDP with rate functions I and J . Then, for every $x \in E$ and $\delta > 0$,

$$\begin{aligned} I(x) &\geq \inf I(B_\delta(x)) \\ &\geq -\liminf_{\varepsilon \rightarrow 0} \varepsilon \log(\mu_\varepsilon(B_\delta(x))) \\ &\geq -\limsup_{\varepsilon \rightarrow 0} \varepsilon \log\left(\mu_\varepsilon\left(\overline{B_\delta(x)}\right)\right) \\ &\geq \inf J\left(\overline{B_\delta(x)}\right) \xrightarrow{\delta \rightarrow 0} J(x) \end{aligned}$$

Hence $I(x) \geq J(x)$. Similarly, we get $J(x) \geq I(x)$.

Lemma 23.9 Let $N \in \mathbb{N}$ and let $a_\varepsilon^i, i = 1, \dots, N, \varepsilon > 0$, be nonnegative numbers. Then

$$\limsup_{\varepsilon \rightarrow 0} \varepsilon \log \sum_{i=1}^N a_\varepsilon^i = \max_{i=1, \dots, N} \limsup_{\varepsilon \rightarrow 0} \varepsilon \log(a_\varepsilon^i).$$

Proof The sum and maximum differ at most by a factor N :

$$\max_{i=1, \dots, N} \varepsilon \log(a_\varepsilon^i) \leq \varepsilon \log \sum_{i=1}^N a_\varepsilon^i \leq \varepsilon \log(N) + \max_{i=1, \dots, N} \varepsilon \log(a_\varepsilon^i).$$

The maximum and limit (superior) can be interchanged and hence

$$\begin{aligned}
\max_{i=1,\dots,N} \limsup_{\varepsilon \rightarrow 0} \varepsilon \log(a_\varepsilon^i) &= \limsup_{\varepsilon \rightarrow 0} \varepsilon \log \left(\max_{i=1,\dots,N} a_\varepsilon^i \right) \\
&\leq \limsup_{\varepsilon \rightarrow 0} \varepsilon \log \left(\sum_{i=1}^N a_\varepsilon^i \right) \\
&\leq \limsup_{\varepsilon \rightarrow 0} \varepsilon \log(N) + \max_{i=1,\dots,N} \limsup_{\varepsilon \rightarrow 0} \varepsilon \log(a_\varepsilon^i) \\
&= \max_{i=1,\dots,N} \limsup_{\varepsilon \rightarrow 0} \varepsilon \log(a_\varepsilon^i)
\end{aligned}$$

Example 23.10 Let $X_1, X_2, \dots$ be i.i.d. real random variables that satisfy the condition of Cramér's theorem (Theorem 23.3); i.e., $\Lambda(t) = \log(\mathbf{E}[e^{tX_1}]) < \infty$ for every $t \in \mathbb{R}$. Furthermore, let $S_n = X_1 + \dots + X_n$ for every n . We will show that Cramér's theorem implies that $P_n := \mathbf{P}_{S_n/n}$ satisfies an LDP with rate n and with good rate function $I(x) = \Lambda^*(x) := \sup_{t \in \mathbb{R}} (tx - \Lambda(t))$. Without loss of generality, we can assume that $\mathbf{E}[X_1] = 0$. The function I is lower semicontinuous, strictly convex (in the interval where it is finite) and has its unique minimum at $I(0) = 0$. By convexity, we have $I(y) > I(x)$ whenever $y > x \geq 0$ or $y < x \leq 0$.

Cramér's theorem says that $\lim_{n \rightarrow \infty} \frac{1}{n} \log(P_n([x, \infty))) = -I(x)$ for $x > 0$ and (by symmetry) $\lim_{n \rightarrow \infty} \frac{1}{n} \log(P_n((-\infty, x])) = -I(x)$ for $x < 0$. Clearly, for $x > 0$,

$$\begin{aligned}
-I(x) &\geq \liminf_{n \rightarrow \infty} \frac{1}{n} \log P_n((x, \infty)) \\
&\geq \sup_{y > x} \liminf_{n \rightarrow \infty} \frac{1}{n} \log P_n([y, \infty)) = -\inf_{y > x} I(y)
\end{aligned}$$

Similarly, $\liminf_{n \rightarrow \infty} \frac{1}{n} \log P_n((-\infty, x)) \geq -\inf_{y < x} I(y)$ for $x < 0$. Furthermore, by the law of large numbers, for any $x > 0$, we have

$$\begin{aligned}
\lim_{n \rightarrow \infty} \frac{1}{n} \log P_n((-\infty, x)) &= \lim_{n \rightarrow \infty} \frac{1}{n} \log P_n([-x, \infty)) \\
&= \lim_{n \rightarrow \infty} \frac{1}{n} \log P_n((-\infty, x)) = \lim_{n \rightarrow \infty} \frac{1}{n} \log P_n((-\infty, x]) \\
&= 0 = -I(0)
\end{aligned}$$

The main work has been done by showing that the family $(P_n)_{n \in \mathbb{N}}$ satisfies conditions (LDP 1) and (LDP 2) at least for unbounded intervals. It remains to show by some standard arguments (LDP 1) and (LDP 2) for arbitrary open and closed sets, respectively.

First assume that $C \subset \mathbb{R}$ is closed. Define $x_+ := \inf(C \cap [0, \infty))$ as well as $x_- := \sup(C \cap (-\infty, 0])$. By monotonicity of I , on $(-\infty, 0]$ and $[0, \infty)$, we get $\inf I(C) = I(x_-) \wedge I(x_+)$ (with the convention $I(-\infty) = I(\infty) = \infty$). If $x_- = 0$ or $x_+ = 0$, then $\inf(I(C)) = 0$, and (LDP 2) holds trivially. Now let $x_- < 0 < x_+$.

Using Lemma 23.9, we get

$$\begin{aligned}
&\limsup_{n \rightarrow \infty} \frac{1}{n} \log P_n(C) \\
&\leq \limsup_{n \rightarrow \infty} \frac{1}{n} \log (P_n((-\infty, x_-]) + P_n([x_+, \infty))) \\
&= \max \left\{ \limsup_{n \rightarrow \infty} \frac{1}{n} \log P_n((-\infty, x_-]), \limsup_{n \rightarrow \infty} \frac{1}{n} \log P_n([x_+, \infty)) \right\} \\
&= \max \{-I(x_-), -I(x_+)\} = -\inf I(C)
\end{aligned}$$

This shows (LDP 2).

Now let $U \subset \mathbb{R}$ be open. Let $x \in U \cap [0, \infty)$ with $I(x) < \infty$ (if such an x exists). Then there exists an $\varepsilon > 0$ with $(x - \varepsilon, x + \varepsilon) \subset U$. Now

$$\begin{aligned} \liminf_{n \rightarrow \infty} \frac{1}{n} \log P_n((x - \varepsilon, \infty)) &\geq -I(x) > -I(x + \varepsilon) \\ &= \lim_{n \rightarrow \infty} \frac{1}{n} \log P_n([x + \varepsilon, \infty)) \end{aligned}$$

Therefore,

$$\begin{aligned} \liminf_{n \rightarrow \infty} \frac{1}{n} \log P_n(U) &\geq \liminf_{n \rightarrow \infty} \frac{1}{n} \log P_n((x - \varepsilon, x + \varepsilon)) \\ &= \liminf_{n \rightarrow \infty} \frac{1}{n} \log (P_n((x - \varepsilon, \infty)) - P_n([x + \varepsilon, \infty))) \\ &= \liminf_{n \rightarrow \infty} \frac{1}{n} \log (P_n((x - \varepsilon, \infty))) \geq -I(x) \end{aligned}$$

Similarly, this also holds for $x \in U \cap (-\infty, 0)$ with $I(x) < \infty$; hence

$$\liminf_{n \rightarrow \infty} \frac{1}{n} \log P_n(U) \geq -\inf I(U)$$

This shows the lower bound (LDP 1).

In fact, the condition $\Lambda(t) < \infty$ for all $t \in \mathbb{R}$ can be dropped. Since $\Lambda(0) = 0$, we have $\Lambda^*(x) \geq 0$ for every $x \in \mathbb{R}$. The map Λ^* is a convex rate function but is, in general, not a good rate function. We quote the following strengthening of Cramér's Theorem (see [31, Theorem 2.2.3]).

Theorem 23.11 (Cramér) If $X_1, X_2, \dots$ are i.i.d. real random variables, then $(\mathbf{P}_{S_n/n})_{n \in \mathbb{N}}$ satisfies an LDP with rate function Λ^* .

Exercise 23.2.1 Let $E = \mathbb{R}$. Show that $\mu_\varepsilon := \mathcal{N}_{0,\varepsilon}$ satisfies an LDP with good rate function $I(x) = x^2/2$. Further, show that strict inequality can hold in the upper bound (LDP 2).

Exercise 23.2.2 Let $E = \mathbb{R}$. Show that $\mu_\varepsilon := \mathcal{N}_{0,\varepsilon^2}$ satisfies an LDP with good rate function $I(x) = \infty \cdot \mathbb{1}_{\mathbb{R} \setminus \{0\}}(x)$. Further, show that strict inequality can hold in the lower bound (LDP 1).

Exercise 23.2.3 Let $E = \mathbb{R}$. Show that $\mu_\varepsilon := \frac{1}{2}\mathcal{N}_{-1,\varepsilon} + \frac{1}{2}\mathcal{N}_{1,\varepsilon}$ satisfies an LDP with good rate function $I(x) = \frac{1}{2} \min((x+1)^2, (x-1)^2)$.

Exercise 23.2.4 Compute Λ and Λ^* in the case $X_1 \sim \exp_\theta$ for $\theta > 0$. Interpret the statement of Theorem 23.11 in this case. Check that Λ^* has its unique zero at $\mathbf{E}[X_1]$. (Result: $\Lambda^*(x) = \theta x - \log(\theta x) - 1$ if $x > 0$ and $= \infty$ otherwise.)

Exercise 23.2.5 Compute Λ and Λ^* for the case where X_1 is Cauchy distributed and interpret the statement of Theorem 23.11.

Exercise 23.2.6 Let $X_\lambda \sim \text{Poi}_\lambda$ for every $\lambda > 0$. Show that $\mu_\varepsilon := \mathbf{P}_{\varepsilon X_{1/\varepsilon}}$ satisfies an LDP with good rate function $I(x) = x \log(x/\lambda) + \lambda - x$ for $x \geq 0$ (and $= \infty$ otherwise).

Exercise 23.2.7 Let $(X_t)_{t \geq 0}$ be a random walk on $\mathbb{Z}$ in continuous time that makes a jump to the right with rate $\frac{1}{2}$ and a jump to the left also with rate $\frac{1}{2}$. Show that $(\mathbf{P}_{\varepsilon X_{1/\varepsilon}})_{\varepsilon > 0}$ satisfies an LDP with convex good rate function

$$I(x) = 1 + x \operatorname{arcsinh}(x) - \sqrt{1 + x^2}.$$

5.23.3 23.3 Sanov's Theorem

This section is close to the exposition in [31].

We present a large deviations principle that, unlike Cramér's theorem, is not based on a linear

space. Rather, we consider empirical distributions of independent random variables with values in a finite set Σ , which often is called an alphabet.

Let μ be a probability measure on Σ with $\mu(\{x\}) > 0$ for any $x \in \Sigma$. Further, let $X_1, X_2, \dots$ be i.i.d. random variables with values in Σ and with distribution $\mathbf{P}_{X_1} = \mu$. We will derive a large deviations principle for the empirical measures

$$\xi_n(X) := \frac{1}{n} \sum_{i=1}^n \delta_{X_i}$$

Note that by the law of large numbers, $\mathbf{P}$ -almost surely $\xi_n(X) \xrightarrow{n \rightarrow \infty} \mu$. Hence, as the state space we get $E = \mathcal{M}_1(\Sigma)$, equipped with the metric of total variation $d(\mu, \nu) = \|\mu - \nu\|_{TV}$. (As Σ is finite, in E vague convergence, weak convergence and convergence in total variation coincide.) Further, let

$$E_n := \{\mu \in \mathcal{M}_1(\Sigma) : n\mu(\{x\}) \in \mathbb{N}_0 \text{ for every } x \in \Sigma\}$$

be the range of the random variables $\xi_n(X)$.

Recall that the entropy of μ is defined by

$$H(\mu) := - \int \log(\mu(\{x\})) \mu(dx)$$

If $\nu \in \mathcal{M}_1(\Sigma)$, then we define the relative entropy (or Kullback-Leibler information, see [104]) of ν given μ by

$$H(\nu | \mu) := \int \log \left(\frac{\nu(\{x\})}{\mu(\{x\})} \right) \nu(dx) \quad (23.13)$$

Since $\mu(\{x\}) > 0$ for all $x \in \Sigma$, the integrand ν -a.s. is finite and hence the integral also is finite. A simple application of Jensen's inequality yields $H(\mu) \geq 0$ and $H(\nu | \mu) \geq 0$ (see Lemma 5.26 and Exercise 5.3.3). Furthermore, $H(\nu | \mu) = 0$ if and only if $\nu = \mu$. In addition, clearly,

$$H(\nu | \mu) + H(\nu) = - \int \log(\mu(\{x\})) \nu(dx) \quad (23.14)$$

Since the map $\nu \mapsto I_\mu(\nu) := H(\nu | \mu)$ is continuous, I_μ is a rate function.

Lemma 23.12 For every $n \in \mathbb{N}$ and $\nu \in E_n$, we have

$$(n+1)^{-\#\Sigma} e^{-nH(\nu|\mu)} \leq \mathbf{P}[\xi_n(X) = \nu] \leq e^{-nH(\nu|\mu)} \quad (23.15)$$

Proof We consider the set of possible values for the n -tuple $(X_1, \dots, X_n)$ such that $\xi_n(X) = \nu$:

$$A_n(\nu) := \left\{ k = (k_1, \dots, k_n) \in \Sigma^n : \frac{1}{n} \sum_{i=1}^n \delta_{k_i} = \nu \right\}$$

For every $k \in A_n(\nu)$, we have (compare (23.14))

$$\begin{aligned} \mathbf{P}[\xi_n(X) = \nu] &= \#A_n(\nu) \mathbf{P}[X_1 = k_1, \dots, X_n = k_n] \\ &= \#A_n(\nu) \prod_{x \in \Sigma} \mu(\{x\})^{n\nu(\{x\})} \\ &= \#A_n(\nu) \exp \left(n \int \nu(dx) \log \mu(\{x\}) \right) \\ &= \#A_n(\nu) \exp(-n[H(\nu) + H(\nu | \mu)]) \end{aligned}$$

Now let $Y_1, Y_2, \dots$ be i.i.d. random variables with values in Σ and with distribution $\mathbf{P}_{Y_1} = \nu$. As in the calculation for X , we obtain (since $H(\nu | \nu) = 0$)

$$1 \geq \mathbf{P}[\xi_n(Y) = v] = \#A_n(v)e^{-nH(v)}$$

hence $\#A_n(v) \leq e^{nH(v)}$. This implies the second inequality in (23.15).

The random variable $n\xi_n(Y)$ has the multinomial distribution with parameters $(nv(\{x\}))_{x \in \Sigma}$. Hence the map $E_n \rightarrow [0, 1], v' \mapsto \mathbf{P}[\xi_n(Y) = v']$ is maximal at $v' = v$. Therefore,

$$\#A_n(v) = e^{nH(v)} \mathbf{P}[\xi_n(Y) = v] \geq \frac{e^{nH(v)}}{\#E_n} \geq (n+1)^{-\#\Sigma} e^{nH(v)}$$

This implies the first inequality in (23.15).

We come to the main theorem of this section, Sanov's theorem (see [149, 150]).

Theorem 23.13 (Sanov (1957)) Let $X_1, X_2, \dots$ be i.i.d. random variables with values in the finite set Σ and with distribution μ . Then the family $(\mathbf{P}_{\xi_n(X)})_{n \in \mathbb{N}}$ of distributions of empirical measures satisfies an LDP with rate n and rate function $I_\mu := \bar{H}(\cdot | \mu)$.

Proof By Lemma 23.12, for every $A \subset E$,

$$\begin{aligned} \mathbf{P}[\xi_n(X) \in A] &= \sum_{v \in A \cap E_n} \mathbf{P}[\xi_n(X) = v] \\ &\leq \sum_{v \in A \cap E_n} e^{-nH(v|\mu)} \\ &\leq \#(A \cap E_n) \exp(-n \inf I_\mu(A \cap E_n)) \\ &\leq (n+1)^{\#\Sigma} \exp(-n \inf I_\mu(A)) \end{aligned}$$

Therefore,

$$\limsup_{n \rightarrow \infty} \frac{1}{n} \log \mathbf{P}[\xi_n(X) \in A] \leq -\inf I_\mu(A)$$

Hence the upper bound in the LDP holds (even for arbitrary A).

Similarly, we can use the first inequality in Lemma 23.12 to get

$$\mathbf{P}[\xi_n(X) \in A] \geq (n+1)^{-\#\Sigma} \exp(-n \inf I_\mu(A \cap E_n))$$

and thus

$$\liminf_{n \rightarrow \infty} \frac{1}{n} \log \mathbf{P}[\xi_n(X) \in A] \geq -\limsup_{n \rightarrow \infty} \inf I_\mu(A \cap E_n) \quad (23.16)$$

Note that, in this inequality, in the infimum we cannot simply replace $A \cap E_n$ by A . However, we show that, for open A this can be done at least asymptotically. Hence, let $A \subset E$ be open. For $v \in A$, there is an $\varepsilon > 0$ with $B_\varepsilon(v) \subset A$. For $n \geq (2\#\Sigma)/\varepsilon$, we have $E_n \cap B_\varepsilon(v) \neq \emptyset$ and hence there exists a sequence $v_n \xrightarrow{n \rightarrow \infty} v$ with $v_n \in E_n \cap A$ for large $n \in \mathbb{N}$. As I_μ is continuous, we have

$$\limsup_{n \rightarrow \infty} \inf I_\mu(A \cap E_n) \leq \lim_{n \rightarrow \infty} I_\mu(v_n) = I_\mu(v)$$

Since $v \in A$ is arbitrary, we get $\limsup_{n \rightarrow \infty} \inf I_\mu(A \cap E_n) = \inf I_\mu(A)$.

Example 23.14 Let $\Sigma = \{-1, 1\}$ and let $\mu = \frac{1}{2}\delta_{-1} + \frac{1}{2}\delta_1$ be the uniform distribution on Σ . Define $m = m(v) := v(\{1\}) - v(\{-1\})$. Then the relative entropy of $v \in \mathcal{M}_1(\Sigma)$ is

$$H(v | \mu) = \frac{1+m}{2} \log(1+m) + \frac{1-m}{2} \log(1-m)$$

Note that this is the rate function from Theorem 23.1.

Next we describe formally the connection between the LDPs of Sanov and Cramér that was indicated in the previous example. To this end, we use Sanov's theorem to derive a version of Cramér's theorem for $\mathbb{R}^d$ -valued random variables taking only finitely many different values.

Example 23.15 Let $\Sigma \subset \mathbb{R}^d$ be finite and let μ be a probability measure on Σ . Further, let $X_1, X_2, \dots$ be i.i.d. random variables with values in Σ and distribution $\mathbf{P}_{X_1} = \mu$. Define $S_n = X_1 + \dots + X_n$ for every $n \in \mathbb{N}$. Let $\Lambda(t) = \log \mathbf{E} [e^{\langle t, X_1 \rangle}]$ for $t \in \mathbb{R}^d$ (which is finite since Σ is finite) and $\Lambda^*(x) = \sup_{t \in \mathbb{R}^d} (\langle t, x \rangle - \Lambda(t))$ for $x \in \mathbb{R}^d$.

We show that $(\mathbf{P}_{S_n/n})_{n \in \mathbb{N}}$ satisfies an LDP with rate n and rate function Λ^* . Let $\xi_n(X)$ be the empirical measure of $X_1, \dots, X_n$. Let $E := \mathcal{M}_1(\Sigma)$. Define the map

$$m : E \rightarrow \mathbb{R}^d, \quad v \mapsto \int x v(dx) = \sum_{x \in \Sigma} x v(\{x\})$$

That is, m maps v to its first moment. Clearly, $\frac{1}{n} S_n = m(\xi_n(X))$. For $x \in \mathbb{R}^d$ and $A \subset \mathbb{R}^d$, define

$$E_x := m^{-1}(\{x\}) = \{v \in E : m(v) = x\}$$

and

$$E_A = m^{-1}(A) = \{v \in E : m(v) \in A\}.$$

The map $v \mapsto m(v)$ is continuous; hence E_A is open (respectively closed) if A is open (respectively closed). Let $\tilde{I}(x) := \inf I_\mu(E_x)$ (where $I_\mu(v) = H(v | \mu)$ is the relative entropy). Then, by Sanov's theorem for open $U \subset \mathbb{R}^d$,

$$\begin{aligned} \liminf_{n \rightarrow \infty} \frac{1}{n} \log \mathbf{P}_{S_n/n}(U) &= \liminf_{n \rightarrow \infty} \frac{1}{n} \log \mathbf{P}_{\xi_n(X)}(m^{-1}(U)) \\ &\geq -\inf I_\mu(m^{-1}(U)) = -\inf \tilde{I}(U) \end{aligned}$$

Similarly, for closed $C \subset \mathbb{R}^d$, we have

$$\limsup_{n \rightarrow \infty} \frac{1}{n} \log \mathbf{P}_{S_n/n}(C) \leq -\inf \tilde{I}(C)$$

In other words, $(\mathbf{P}_{S_n/n})_{n \in \mathbb{N}}$ satisfies an LDP with rate n and rate function $\tilde{I}$. Hence, it only remains to show that $\tilde{I} = \Lambda^*$.

Note that $t \mapsto \Lambda(t)$ is differentiable (with derivative Λ') and is strictly convex. Hence the variational problem for $\Lambda^*(x)$ admits a unique maximizer $t^*(x)$. More precisely,

$$\Lambda^*(x) = \langle t^*(x), x \rangle - \Lambda(t^*(x)),$$

$\Lambda^*(x) > \langle t, x \rangle - \Lambda(t)$ for all $t \neq t^*(x)$, and $\Lambda'(t^*(x)) = x$. By Jensen's inequality, for every $v \in \mathcal{M}_1(\Sigma)$,

$$\begin{aligned} \Lambda(t) &= \log \int e^{\langle t, y \rangle} \mu(dy) \\ &= \log \int \left(e^{\langle t, y \rangle} \frac{\mu(\{y\})}{v(\{y\})} \right) v(dy) \\ &\geq \int \log \left(e^{\langle t, y \rangle} \frac{\mu(\{y\})}{v(\{y\})} \right) v(dy) \\ &= \langle t, m(v) \rangle - H(v | \mu) \end{aligned}$$

with equality if and only if $v = v_t$, where $v_t(\{y\}) = \mu(\{y\})e^{\langle t, y \rangle - \Lambda(t)}$. Hence,

$$\langle t, x \rangle - \Lambda(t) \leq \inf_{v \in E_x} H(v \mid \mu)$$

with equality if $v_t \in E_x$. However, we now know that $m(v_t) = \Lambda'(t)$; hence we have $v_{t^*(x)} \in E_x$ and thus

$$\Lambda^*(x) = \langle t^*(x), x \rangle - \Lambda(t^*(x)) = \inf_{v \in E_x} H(v \mid \mu) = \tilde{I}(x)$$

The method of the proof that we applied in the last example to derive the LDP with rate function $\tilde{I}$ is called a contraction principle. We formulate this principle as a theorem.

Theorem 23.16 (Contraction principle) Assume the family $(\mu_\varepsilon)_{\varepsilon > 0}$ of probability measures on E satisfies an LDP with rate function I . If F is a topological space and $m : E \rightarrow F$ is continuous, then the image measures $(\mu_\varepsilon \circ m^{-1})_{\varepsilon > 0}$ satisfy an LDP with rate function $\tilde{I}(x) = \inf I(m^{-1}(\{x\}))$.

5.23.4 23.4 Varadhan's Lemma and Free Energy

Assume that $(\mu_\varepsilon)_{\varepsilon > 0}$ is a family of probability measures that satisfies an LDP with rate function I . In particular, we know that, for small $\varepsilon > 0$, the mass of μ_ε is concentrated around the zeros of I . In statistical physics, one is often interested in integrating with respect to μ_ε (where $1/\varepsilon$ is interpreted as "size of the system") functions that attain their maximal values away from the zeros of I . In addition, these functions are exponentially scaled with $1/\varepsilon$. Hence the aim is to study the asymptotics of $Z_\varepsilon^\phi := \int e^{\phi(x)/\varepsilon} \mu_\varepsilon(dx)$ as $\varepsilon \rightarrow 0$. Under some mild conditions on the continuity of ϕ , the main contribution to the integral comes from those points x that are not too unlikely (for μ_ε) and for which at the same time $\phi(x)$ is large. That is, those x for which $\phi(x) - I(x)$ is close to its maximum. These contributions are quantified in terms of the tilted probability measures $\mu_\varepsilon^\phi(dx) = (Z_\varepsilon^\phi)^{-1} e^{\phi(x)/\varepsilon} \mu_\varepsilon(dx)$, $\varepsilon > 0$, for which we derive an LDP. As an application, we get the statistical physics principle of minimising the free energy. As an example, we analyze the Weiss ferromagnet.

We start with a lemma that is due to Varadhan [166].

Theorem 23.17 (Varadhan's Lemma (1966)) Let I be a good rate function and let $(\mu_\varepsilon)_{\varepsilon > 0}$ be a family of probability measures on E that satisfies an LDP with rate function I . Further, let $\phi : E \rightarrow \mathbb{R}$ be continuous and assume that

$$\inf_{M > 0} \limsup_{\varepsilon \rightarrow 0} \varepsilon \log \int e^{\phi(x)/\varepsilon} \mathbb{1}_{\{\phi(x) \geq M\}} \mu_\varepsilon(dx) = -\infty \quad (23.17)$$

Then

$$\lim_{\varepsilon \rightarrow 0} \varepsilon \log \int e^{\phi(x)/\varepsilon} \mu_\varepsilon(dx) = \sup_{x \in E} (\phi(x) - I(x)). \quad (23.18)$$

Remark 23.18 (Moment condition) The tail condition (23.17) holds if there exists an $\alpha > 1$ such that

$$\limsup_{\varepsilon \rightarrow 0} \varepsilon \log \int e^{\alpha \phi/\varepsilon} d\mu_\varepsilon < \infty \quad (23.19)$$

Indeed, for every $M \in \mathbb{R}$, we have

$$\begin{aligned}
\varepsilon \log \int e^{\phi(x)/\varepsilon} \mathbb{1}_{\{\phi(x) \geq M\}} \mu_\varepsilon(dx) &= M + \varepsilon \log \int e^{(\phi(x)-M)/\varepsilon} \mathbb{1}_{\{\phi(x) \geq M\}} \mu_\varepsilon(dx) \\
&\leq M + \varepsilon \log \int e^{\alpha(\phi(x)-M)/\varepsilon} \mu_\varepsilon(dx) \\
&= -(\alpha-1)M + \varepsilon \log \int e^{\alpha\phi(x)/\varepsilon} \mu_\varepsilon(dx)
\end{aligned}$$

Together with (23.19), this implies (23.17).

Proof We use different arguments to show that the right-hand side of (23.18) is a lower and an upper bound for the left-hand side.

Lower bound. For any $x \in E$ and $r > 0$, we have

$$\begin{aligned}
\liminf_{\varepsilon \rightarrow 0} \varepsilon \log \int e^{\phi/\varepsilon} d\mu_\varepsilon &\geq \liminf_{\varepsilon \rightarrow 0} \varepsilon \log \int_{B_r(x)} e^{\phi/\varepsilon} d\mu_\varepsilon \\
&\geq \inf \phi(B_r(x)) - I(x) \xrightarrow{r \rightarrow 0} \phi(x) - I(x)
\end{aligned}$$

Upper bound. For $M > 0$ and $\varepsilon > 0$, define

$$F_M^\varepsilon := \int_{\{\phi \geq M\}} e^{\phi(x)/\varepsilon} \mu_\varepsilon(dx) \quad \text{and} \quad G_M^\varepsilon := \int_{\{\phi < M\}} e^{\phi(x)/\varepsilon} \mu_\varepsilon(dx)$$

Define

$$F_M := \limsup_{\varepsilon \rightarrow 0} \varepsilon \log F_M^\varepsilon \quad \text{and} \quad G_M := \limsup_{\varepsilon \rightarrow 0} \varepsilon \log G_M^\varepsilon$$

By Lemma 23.9, for any $M > 0$,

$$\limsup_{\varepsilon \rightarrow 0} \varepsilon \log \int e^{\phi(x)/\varepsilon} \mu_\varepsilon(dx) = F_M \vee G_M$$

As by assumption $\inf_{M>0} F_M = -\infty$, it is enough to show that

$$\sup_{M>0} G_M \leq \sup_{x \in E} (\phi(x) - I(x)) \quad (23.20)$$

Let $\delta > 0$. For any $x \in E$ there is an $r(x) > 0$ with

$$\inf I(B_{2r(x)}(x)) \geq I(x) - \delta \quad \text{and} \quad \sup \phi(B_{2r(x)}(x)) \leq \phi(x) + \delta.$$

Let $a \geq 0$. Since I is a good rate function, the level set $K := I^{-1}([0, a])$ is compact. Thus we can find finitely many $x_1, \dots, x_N \in I^{-1}([0, a])$ such that $\bigcup_{i=1}^N B_{r(x_i)}(x_i) \supset K$. Therefore,

$$\begin{aligned}
G_M^\varepsilon &\leq \int_{\{\phi < M\} \cap K^c} e^{\phi(x)/\varepsilon} \mu_\varepsilon(dx) + \sum_{i=1}^N \int_{\{\phi < M\} \cap B_{r(x_i)}(x_i)} e^{\phi(x)/\varepsilon} \mu_\varepsilon(dx) \\
&\leq e^{M/\varepsilon} \mu_\varepsilon(K^c) + \sum_{i=1}^N e^{(\phi(x_i) \wedge M + \delta)/\varepsilon} \mu_\varepsilon(B_{r(x_i)}(x_i)) \\
&= e^{(M + \varepsilon \log(\mu_\varepsilon(K^c)))/\varepsilon} + \sum_{i=1}^N e^{(\phi(x_i) \wedge M + \delta + \varepsilon \log(\mu_\varepsilon(B_{r(x_i)}(x_i))))/\varepsilon}.
\end{aligned}$$

Using Lemma 23.9 and the LDP, we infer

$$\begin{aligned}
G_M &\leq (M - a) \vee \max_{i=1, \dots, N} (\phi(x_i) - I(x_i) + 2\delta) \\
&\leq (M - a) \vee \sup_{x \in E} (\phi(x) - I(x)) + 2\delta.
\end{aligned}$$

By letting first $\delta \downarrow 0$ and then $a \uparrow \infty$, we obtain (23.20).

Theorem 23.19 (Tilted LDP) Assume that $(\mu_\varepsilon)_{\varepsilon>0}$ satisfies an LDP with good rate function I . Further, let $\phi : E \rightarrow \mathbb{R}$ be a continuous function that satisfies condition (23.17). Define $Z_\varepsilon^\phi := \int e^{\phi/\varepsilon} d\mu_\varepsilon$ and $\mu_\varepsilon^\phi \in \mathcal{M}_1(E)$ by

$$\mu_\varepsilon^\phi(dx) = (Z_\varepsilon^\phi)^{-1} e^{\phi(x)/\varepsilon} \mu_\varepsilon(dx)$$

Further, define $I^\phi : E \rightarrow [0, \infty]$ by

$$I^\phi(x) = \sup_{z \in E} (\phi(z) - I(z)) - (\phi(x) - I(x)). \quad (23.21)$$

Then $(\mu_\varepsilon^\phi)_{\varepsilon>0}$ satisfies an LDP with rate function I^ϕ .

Proof This is left as an exercise. (Compare [32, Exercise 2.1.24], see also [43, Section II.7].)

Varadhan's lemma has various applications in statistical physics. Consider a Polish space Σ that is interpreted as the space of possible states of a particle. Further, let $\lambda \in \mathcal{M}_1(\Sigma)$ be a distribution that is understood as the a priori distribution of this particle if the influence of energy could be neglected. If Σ is finite or is a bounded subset of an $\mathbb{R}^d$, then by symmetry, typically λ is the uniform distribution on Σ . If we place n indistinguishable particles independently according to λ on the random positions $z_1, \dots, z_n \in \Sigma$, then the state of this ensemble can be described by $x := \frac{1}{n} \sum_{i=1}^n \delta_{z_i}$. Denote by $\mu_n^0 \in \mathcal{M}_1(\mathcal{M}_1(\Sigma))$ the corresponding a priori distribution of x ; that is, of the n -particle system.

Now we introduce the hypothesis that the energy $U_n(x)$ of a state has the form $U_n(x) = nU(x)$, where $U(x)$ is the average energy of one particle of the ensemble in state x .

Let $T > 0$ be the temperature of the system and let $\beta := 1/T$ be the so-called inverse temperature. In statistical physics, a key quantity is the so-called partition function

$$Z_n^\beta := \int e^{-\beta U_n} d\mu_n^0$$

A postulate of statistical physics is that the distribution of the state x is the Boltzmann distribution:

$$\mu_n^\beta(dx) = (Z_n^\beta)^{-1} e^{-\beta U_n(x)} \mu_n^0(dx) \quad (23.22)$$

Varadhan's lemma (more precisely, the tilted LDP) and Sanov's theorem are the keys to building a connection to the variational principle for the free energy. For simplicity, assume that Σ is a finite set and $\lambda = \mathcal{U}_\Sigma$ is the uniform distribution on Σ . By Sanov's theorem, $(\mu_n^0)_{n \in \mathbb{N}}$ satisfies an LDP with rate n and rate function $I(x) = H(x | \lambda)$, where $H(x | \lambda)$ is the relative entropy of x with respect to λ . By (23.14), we have $H(x | \lambda) = \log(\#\Sigma) - H(x)$, where $H(x)$ is the entropy of x .

Fig. 23.2 The shifted free energy $F^{\wedge}(\beta)$ of the Weiss ferromagnet without exterior field ($h = 0$)

Define the free energy (or Helmholtz potential) per particle as

$$F^\beta(x) := U(x) - \beta^{-1}H(x).$$

The theorem on the tilted LDP yields that the sequence of Boltzmann distributions $(\mu_n^\beta)_{n \in \mathbb{N}}$ satisfies an LDP with rate n and rate function

$$I^\beta(x) = F^\beta(x) - \inf_{y \in \mathcal{M}_1(\Sigma)} F^\beta(y).$$

Thus, for large n , the Boltzmann distribution is concentrated on those x that minimize the free energy. For different temperatures (that is, for different values of β) these can be very different states. This is the reason for phase transitions at critical temperatures (e.g., melting ice).

Example 23.20 We consider the Weiss ferromagnet. This is a microscopic model for a magnet that assumes that each of n indistinguishable magnetic particles has one of two possible orientations $\sigma_i \in \Sigma = \{-1, +1\}$. The mean magnetization $m = \frac{1}{n} \sum_{i=1}^n \sigma_i$ describes the state of the system completely (as the particles are indistinguishable). Macroscopically, this is the quantity that can be measured. The basic idea is that it is energetically favorable for particles to be oriented in the same direction. We ignore the spatial structure and assume that any particle interacts with any other particle in the same way. This is often called the mean field assumption. In addition, we assume that there is an exterior magnetic field of strength h . Thus up to constants the average energy of a particle is

$$U(m) = -\frac{1}{2}m^2 - hm.$$

Fig. 23.3 Shifted free energy $F^\beta(m) - F^\beta(0)$ of the Weiss ferromagnet with exterior field $h = 0.04$

The entropy of the state m is

$$H(m) = -\frac{1+m}{2} \log \left(\frac{1+m}{2} \right) - \frac{1-m}{2} \log \left(\frac{1-m}{2} \right)$$

Hence the average free energy of a particle is

$$F^\beta(m) = -\frac{1}{2}m^2 - hm + \beta^{-1} \left[\frac{1+m}{2} \log \left(\frac{1+m}{2} \right) + \frac{1-m}{2} \log \left(\frac{1-m}{2} \right) \right].$$

In order to obtain the minima of F^β , we compute the derivative

$$0 \stackrel{!}{=} \frac{d}{dm} F^\beta(m) = -m - h + \beta^{-1} \operatorname{arctanh}(m).$$

Hence, m solves the equation

$$m = \tanh(\beta(m + h)). \quad (23.23)$$

In the case $h = 0$, $m = 0$ is a solution of (23.23) for any β . If $\beta \leq 1$, then this is the only solution and F^β attains its global minimum at $m = 0$. If $\beta > 1$, then (23.23) has two other solutions, $m_-^{\beta,0} \in (-1, 0)$ and $m_+^{\beta,0} = -m_-^{\beta,0}$, whose values can only be computed numerically.

In this case, F^β has a local maximum at 0 and has global minima $m_\pm^{\beta,0}$. For large n , only those values of m for which F^β is close to its minimal value can be attained and thus the distribution is concentrated around 0 if $\beta \leq 1$ and around $m_\pm^{\beta,0}$ if $\beta > 1$. In the latter case, the absolute value of the mean magnetization is $|m_\pm^{\beta,0}| = m_+^{\beta,0} > 0$. Hence, there is a phase transition between the high temperature phase ($\beta \leq 1$) without magnetization and the low temperature phase ($\beta > 1$) where so-called spontaneous magnetization occurs (that is, magnetization without an exterior field).

Fig. 23.4 Weiss ferromagnet: magnetization $\hat{m}(\beta, h)$ as a function of β

If $h \neq 0$, then F^β does not have a minimum at $m = 0$. Rather, F^β is asymmetric and has a global minimum $m^{\beta,h}$ with the same sign as h . Furthermore, for large β , there is another minimum with the opposite sign. Again, the exact values can only be computed numerically. However, for high temperatures (small β), we can approximate $m^{\beta,h}$ using the approximation $\tanh(\beta(m + h)) \approx \beta(m + h)$. Hence we get

$$m^{\beta,h} \approx \frac{h}{\beta^{-1} - 1} = \frac{h}{T - T_c} \quad \text{for } T \rightarrow \infty, \quad (23.24)$$

where the Curie temperature $T_c = 1$ is the critical temperature for spontaneous magnetization. The relation (23.24) is called the Curie-Weiss law. $\square$

5.24 24 The Poisson Point Process

Poisson point processes can be used as a cornerstone in the construction of very different stochastic objects such as, for example, infinitely divisible distributions, Markov processes with complex dynamics, objects of stochastic geometry and so forth.

In this chapter, we briefly develop the general framework of random measures and construct the Poisson point process and characterize it in terms of its Laplace transform. As an application we construct a certain subordinator and show that the Poisson point process is the invariant measure of systems of independent random walks. Via the connection with subordinators,

in the third section, we construct two distributions that play prominent roles in population genetics: the Poisson-Dirichlet distribution and the GEM distribution.

For a nice exposition including many examples, see also [99].

5.24.1 24.1 Random Measures

In the following, let E be a locally compact Polish space (for example, $E = \mathbb{R}^d$ or $E = \mathbb{Z}^d$) with Borel σ -algebra $\mathcal{B}(E)$. Let

$$\mathcal{B}_b(E) = \{B \in \mathcal{B}(E) : B \text{ is relatively compact}\}$$

be the system of bounded Borel sets and $\mathcal{M}(E)$ the space of Radon measures on E (see Definition 13.3).

Definition 24.1 Denote by $\mathbb{M} = \sigma(I_A : A \in \mathcal{B}_b(E))$ the smallest σ -algebra on $\mathcal{M}(E)$ with respect to which all maps

$$I_A : \mu \mapsto \mu(A), \quad A \in \mathcal{B}_b(E)$$

are measurable.

Denote by $\mathcal{B}^+(E)$ the set of measurable maps $E \rightarrow [0, \infty]$ and by $\mathcal{B}_b^{\mathbb{R}}(E)$ the set of bounded measurable maps $E \rightarrow \mathbb{R}$ with compact support. For every $f \in \mathcal{B}^+(E)$, the integral $I_f(\mu) := \int f d\mu$ is well-defined and for every $f \in \mathcal{B}_b^{\mathbb{R}}(E)$, $I_f(\mu)$ is well-defined and finite.

Theorem 24.2 Let τ_v be the vague topology on $\mathcal{M}(E)$. Then

$$\mathbb{M} = \mathcal{B}(\tau_v) = \sigma(I_f : f \in C_c(E)) = \sigma(I_f : f \in C_c^+(E))$$

Proof This is left as an exercise. (See [82, Lemma 4.1].)

Let $\widetilde{\mathcal{M}}(E)$ be the space of all measures on E endowed with the σ -algebra

$$\widetilde{\mathbb{M}} = \sigma(I_A : A \in \mathcal{B}_b(E)).$$

Choose a countable dense set $F \subset E$, and for any $x \in F$ choose a compact neighborhood K_x . Then we get (compare Exercise 13.1.8)

$$\mathcal{M}(E) = \bigcap_{x \in F} \left\{ \mu \in \widetilde{\mathcal{M}}(E) : \mu(K_x) < \infty \right\}$$

Hence $\mathcal{M}(E) \in \widetilde{\mathbb{M}}$. Clearly, $\mathbb{M} = \widetilde{\mathbb{M}}|_{\mathcal{M}(E)}$ is the trace σ -algebra of $\widetilde{\mathbb{M}}$ on $\mathcal{M}(E)$. Here we need the slightly larger space in order to define random measures in such a way that all almost surely well-defined operations on random measures again yield random measures.

Definition 24.3 A random measure on E is a random variable X on some probability space $(\Omega, \mathcal{A}, \mathbf{P})$ with values in $(\widetilde{\mathcal{M}}(E), \widetilde{\mathbb{M}})$ and with $\mathbf{P}[X \in \mathcal{M}(E)] = 1$.

Theorem 24.4 Let X be a random measure on E . Then the set function $\mathbf{E}[X] : \mathcal{B}(E) \rightarrow [0, \infty]$, $A \mapsto \mathbf{E}[X(A)]$ is a measure. We call $\mathbf{E}[X]$ the intensity measure of X . We say that X is integrable if $\mathbf{E}[X] \in \mathcal{M}(E)$.

Proof Clearly, $\mathbf{E}[X]$ is finitely additive. Let $A, A_1, A_2, \dots \in \mathcal{B}(E)$ with $A_n \uparrow A$. Consider the random variables $Y_n := X(A_n)$ and $Y = X(A)$. Then $Y_n \uparrow Y$ and hence, by monotone convergence, $\mathbf{E}[X](A_n) = \mathbf{E}[Y_n] \xrightarrow{n \rightarrow \infty} \mathbf{E}[Y] = \mathbf{E}[X](A)$. Hence $\mathbf{E}[X]$ is lower semicontinuous and is thus a measure (by Theorem 1.36).

Theorem 24.5 Let $\mathbf{P}_X$ be the distribution of a random measure X . Then $\mathbf{P}_X$ is uniquely determined by the distributions of either of the families

$$((I_{f_1}, \dots, I_{f_n}) : n \in \mathbb{N}; f_1, \dots, f_n \in C_c^+(E)) \quad (24.1)$$

or

$$((I_{A_1}, \dots, I_{A_n}) : n \in \mathbb{N}; A_1, \dots, A_n \in \mathcal{B}_b(E) \text{ pairwise disjoint}) . \quad (24.2)$$

Proof The class of sets

$$\mathcal{I} = \{(I_{f_1}, \dots, I_{f_n})^{-1}(A) : n \in \mathbb{N}; f_1, \dots, f_n \in C_c^+(E), A \in \mathcal{B}([0, \infty)^n)\}$$

is a π -system and by Theorem 24.2 it generates $\mathbb{M}$. Hence the measure $\mathbf{P}_X$ is characterized by its values on $\mathcal{I}$.

Similarly, the claim follows for

$$((I_{A_1}, \dots, I_{A_n}) : n \in \mathbb{N}; A_1, \dots, A_n \in \mathcal{B}_b(E)) .$$

If $A_1, \dots, A_n \in \mathcal{B}_b(E)$ are arbitrary, then there exist $2^n - 1$ pairwise disjoint sets $B_1, \dots, B_{2^n-1}$ with $A_i = \bigcup_{k: B_k \subset A_i} B_k$ for all $i = 1, \dots, n$. The distribution of $(I_{A_1}, \dots, I_{A_n})$ can be computed from that of $(I_{B_1}, \dots, I_{B_{2^n-1}})$.

In the following, let $i = \sqrt{-1}$ be the imaginary unit.

Definition 24.6 Let X be a random measure on E . Denote by

$$\mathcal{L}_X(f) = \mathbf{E} \left[\exp \left(- \int f dX \right) \right], \quad f \in \mathcal{B}^+(E)$$

the Laplace transform of X and by

$$\varphi_X(f) = \mathbf{E} \left[\exp \left(i \int f dX \right) \right], \quad f \in \mathcal{B}_b^{\mathbb{R}}(E)$$

the characteristic function of X .

Theorem 24.7 The distribution $\mathbf{P}_X$ of a random measure X is characterized by its Laplace transform $\mathcal{L}_X(f)$, $f \in C_c^+(E)$, as well as by its characteristic function $\varphi_X(f)$, $f \in C_c(E)$.

Proof This is a consequence of Theorem 24.5 and the uniqueness theorem for characteristic functions (Theorem 15.8) and for Laplace transforms (Exercise 15.1.2) of random variables on $[0, \infty)^n$.

Definition 24.8 We say that a random measure X on E has independent increments if, for any choice of finitely many pairwise disjoint measurable sets $A_1, \dots, A_n$, the random variables $X(A_1), \dots, X(A_n)$ are independent.

Corollary 24.9 The distribution of a random measure X on E with independent increments is uniquely determined by the family $(\mathbf{P}_{X(A)}, A \in \mathcal{B}_b(E))$.

Proof This is an immediate consequence of Theorem 24.5.

Fig. 24.1 Poisson point process on the unit square with intensity measure 50λ

Definition 24.10 Let $\mu \in \mathcal{M}(E)$. A random measure X with independent increments is called a Poisson point process (PPP) with intensity measure μ if, for any $A \in \mathcal{B}_b(E)$, we have $\mathbf{P}_{X(A)} = \text{Poi}_{\mu(A)}$. In this case, we write $\text{PPP}_{\mu} := \mathbf{P}_X \in \mathcal{M}_1(\mathcal{M}(E))$ and say that X is a PPP_{μ} .

See Fig. 24.1 for a simulation of a Poisson point process on the unit square.

Remark 24.11 The definition of the PPP (and its construction in the following theorem) still works if $(E, \mathcal{E}, \mu)$ is only assumed to be a σ -finite measure space. However, the characterization in terms of Laplace transforms is a bit simpler in the case of locally compact Polish spaces considered here.

Theorem 24.12 For every $\mu \in \mathcal{M}(E)$, there exists a Poisson point process X with intensity measure μ .

Proof μ is σ -finite since $\mu \in \mathcal{M}(E)$. Hence there exist $E_n \uparrow E$ with $\mu(E_n) < \infty$ for every $n \in \mathbb{N}$. Define $\mu_1 = \mu(E_1 \cap \cdot)$ and $\mu_n = \mu((E_n \setminus E_{n-1}) \cap \cdot)$ for $n \geq 2$. If $X_1, X_2, \dots$ are independent Poisson point processes with intensity measures $\mu_1, \mu_2, \dots$, then $X = \sum_{n=1}^{\infty} X_n$ has intensity measure $\mathbf{E}[X] = \mu$ and hence X is a random measure (see Exercise 24.1.1). Furthermore, it is easy to see that X has independent increments and that

$$\mathbf{P}_{X(A)} = \mathbf{P}_{X_1(A)} * \mathbf{P}_{X_2(A)} * \dots = \text{Poi}_{\mu_1(A)} * \text{Poi}_{\mu_2(A)} * \dots = \text{Poi}_{\mu(A)}.$$

Hence we have $X \sim \text{PPP}_{\mu}$.

Therefore, it is enough to consider the case $\mu(E) \in (0, \infty)$. Define

$$v = \frac{\mu(\cdot)}{\mu(E)} \in \mathcal{M}_1(E).$$

Let $N, Y_1, Y_2, \dots$ be independent random variables with $N \sim \text{Poi}_{\mu(E)}$ and $\mathbf{P}_{Y_i} = v$ for all $i \in \mathbb{N}$. Define

$$X(A) = \sum_{n=1}^N \mathbb{1}_A(Y_n) \quad \text{for } A \in \mathcal{B}(E)$$

The random variables $\mathbb{1}_A(Y_1), \mathbb{1}_A(Y_2), \dots$ are independent and $\text{Ber}_{v(A)}$ -distributed; hence we have $X(A) \sim \text{Poi}_{\mu(A)}$ (see Theorem 15.14(iii)). Let $n \in \mathbb{N}$ and let $A_1, \dots, A_n \in \mathcal{B}(E)$ be pairwise disjoint. Then

$$\psi(t) := \mathbf{E} \left[\exp \left(i \sum_{l=1}^n t_l \mathbb{1}_{A_l}(Y_1) \right) \right] = 1 + \sum_{l=1}^n v(A_l) (e^{it_l} - 1), \quad t \in \mathbb{R}^n,$$

is the characteristic function of $(\mathbb{1}_{A_1}(Y_1), \dots, \mathbb{1}_{A_n}(Y_1))$. Further, let φ be the characteristic function of $(X(A_1), \dots, X(A_n))$ and let φ_l be the characteristic function of $X(A_l)$ for $l = 1, \dots, n$. Hence

$$\varphi_l(t_l) = \exp(\mu(A_l)(e^{it_l} - 1)).$$

By Theorem 15.14(iii), we have

$$\begin{aligned} \varphi(t) &= \mathbf{E} \left[\exp \left(i \sum_{l=1}^n t_l X(A_l) \right) \right] \\ &= \exp(\mu(E)(\psi(t) - 1)) \\ &= \exp \left(\sum_{l=1}^n \mu(A_l)(e^{it_l} - 1) \right) = \prod_{l=1}^n \varphi_l(t_l). \end{aligned}$$

Thus $X(A_1), \dots, X(A_n)$ are independent. This implies $X \sim \text{PPP}_\mu$.

Exercise 24.1.1 Let $X_1, X_2, \dots$ be random measures and $\lambda_1, \lambda_2, \dots \in [0, \infty)$. Define $X := \sum_{n=1}^\infty \lambda_n X_n$. Show that X is a random measure if and only if we have $\mathbf{P}[X(B) < \infty] = 1$ for all $B \in \mathcal{B}_b(E)$. Infer that if X is a random variable with values in $(\widetilde{\mathcal{M}}(E), \widetilde{\mathbb{M}}(E))$ and $\mathbf{E}[X] \in \mathcal{M}(E)$, then X is a random measure.

Exercise 24.1.2 Let τ_w be the topology of weak convergence on $\mathcal{M}_1(E)$ and let $\sigma(\tau_w)$ be the Borel σ -algebra on $\mathcal{M}_1(E)$. Show that $\mathbb{M}|_{\mathcal{M}_1(E)} = \sigma(\tau_w)$.

5.24.2 24.2 Properties of the Poisson Point Process

Theorem 24.13 Let $\mu \in \mathcal{M}(E)$ be atom-free; that is, $\mu(\{x\}) = 0$ for every $x \in E$. Let X be a random measure on E with $\mathbf{P}[X(A) \in \mathbb{N}_0 \cup \{\infty\}] = 1$ for every $A \in \mathcal{B}(E)$. Then the following are equivalent:

- (i) $X \sim \text{PPP}_\mu$.
- (ii) X almost surely has no double points; that is,

$$\mathbf{P}[X(\{x\}) \geq 2 \quad \text{for some } x \in E] = 0$$

and

$$\mathbf{P}[X(A) = 0] = e^{-\mu(A)} \quad \text{for all } A \in \mathcal{B}_b(E) \quad (24.3)$$

Proof (i) $\implies$ (ii) This is obvious.

(ii) $\implies$ (i) If $A_1, \dots, A_n \in \mathcal{B}_b(E)$ are pairwise disjoint, then

$$\begin{aligned} \mathbf{P}[X(A_1) = 0, \dots, X(A_n) = 0] &= \mathbf{P}[X(A_1 \cup \dots \cup A_n) = 0] \\ &= e^{-\mu(A_1 \cup \dots \cup A_n)} \\ &= \prod_{l=1}^n e^{-\mu(A_l)} = \prod_{l=1}^n \mathbf{P}[X(A_l) = 0]. \end{aligned}$$

Hence the random variables $\widetilde{X}(A) := X(A) \wedge 1$ are independent for disjoint sets A . The rest of the proof is similar to that of Theorem 5.34. Let $A \in \mathcal{B}_b(E)$. Choose an $A_0 \subset A$ with $\mu(A_0) = \mu(A)/2$ (this is possible by Exercise 8.3.1 since μ is atom-free) and define $A_1 = A \setminus A_0$.

Similarly, choose $A_{i,0}, A_{i,1} \subset A_i$ for $i = 0, 1$ and inductively define disjoint sets $A_{i,0}, A_{i,1} \subset A_i$ for $i \in \{0, 1\}^{n-1}$ with $\mu(A_i) = 2^{-n}\mu(A)$ for every $i \in \{0, 1\}^n$. Define

$$N_n(A) := \sum_{i \in \{0,1\}^n} \tilde{X}(A_i).$$

As X does not have double points, we have $N_n(A) \uparrow X(A)$ almost surely. On the other hand, by assumption, $N_n(A) \sim b_{2^n, 1 - \exp(-2^{-n}\mu(A))}$ for $n \in \mathbb{N}$; hence the characteristic functions converge:

$$\varphi_{N_n(A)}(t) = \left(1 + \left(1 - e^{-2^{-n}\mu(A)}\right)(e^{it} - 1)\right)^{2^n} \xrightarrow{n \rightarrow \infty} \exp(\mu(A)(e^{it} - 1)) = \varphi_{\text{Poi}_{\mu(A)}}(t)$$

Therefore, we have $\mathbf{P}_{N_n(A)} \xrightarrow{n \rightarrow \infty} \text{Poi}_{\mu(A)}$ and thus $X(A) \sim \text{Poi}_{\mu(A)}$.

If $A_1, \dots, A_k \in \mathcal{B}_b(E)$ are pairwise disjoint, then the sets $N_n(A_1), \dots, N_n(A_k)$ (constructed in a way similar to that above) are independent. Hence also the limits $X(A_l) = \lim_{n \rightarrow \infty} N_n(A_l)$, $l = 1, \dots, k$ are independent.

Theorem 24.14 Let $\mu \in \mathcal{M}(E)$ and let X be a Poisson point process with intensity measure μ . Then X has Laplace transform

$$\mathcal{L}_X(f) = \exp\left(\int \mu(dx) (e^{-f(x)} - 1)\right), \quad f \in \mathcal{B}^+(E)$$

and characteristic function

$$\varphi_X(f) = \exp\left(\int \mu(dx) (e^{if(x)} - 1)\right), \quad f \in \mathcal{B}_b^{\mathbb{R}}(E)$$

Proof It is enough to show the claim for simple functions $f = \sum_{l=1}^n \alpha_l \mathbb{1}_{A_l}$ with complex numbers $\alpha_1, \dots, \alpha_n$ and with pairwise disjoint sets $A_1, \dots, A_n \in \mathcal{B}_b(E)$. (For general f , the claim follows by the usual approximation arguments.) For such f , however,

$$\begin{aligned} \mathbf{E}[\exp(-I_f(X))] &= \mathbf{E}\left[\prod_{l=1}^n e^{-\alpha_l X(A_l)}\right] = \prod_{l=1}^n \mathbf{E}[e^{-\alpha_l X(A_l)}] \\ &= \prod_{l=1}^n \exp(\mu(A_l)(e^{-\alpha_l} - 1)) \\ &= \exp\left(\sum_{l=1}^n \mu(A_l)(e^{-\alpha_l} - 1)\right) \\ &= \exp\left(\int \mu(dx) (e^{-f(x)} - 1)\right) \end{aligned}$$

Corollary 24.15 (Moments of the PPP) Let $\mu \in \mathcal{M}(E)$ and $X \sim \text{PPP}_{\mu}$.

- (i) If $f \in \mathcal{L}^1(\mu)$, then $\mathbf{E}[\int f dX] = \int f d\mu$.
- (ii) If $f \in \mathcal{L}^2(\mu) \cap \mathcal{L}^1(\mu)$, then $\text{Var}[\int f dX] = \int f^2 d\mu$.

Recall that only for finite μ , we have the inclusion $\mathcal{L}^2(\mu) \subset \mathcal{L}^1(\mu)$.

Proof If $f = f^+ - f^- \in \mathcal{L}^1(\mu)$, then for the characteristic function, integral and differentiation interchange, $\frac{d}{dt}\varphi_X(tf^+) = i\varphi_X(tf^+) \int f(x)e^{itf^+(x)}\mu(dx)$ and hence (by Exercise 15.4.4(iii))

$$\mathbf{E}[I_{f^+}(X)] = \frac{1}{i} \frac{d}{dt} \varphi_X(tf^+) \Big|_{t=0} = \int f^+ d\mu$$

Arguing similarly with f^- and adding up, we get (i).

If $f \in \mathcal{L}^1(\mu) \cap \mathcal{L}^2(\mu)$, then the argument can be iterated (using Theorem 15.34)

$$\frac{d^2}{dt^2} \varphi_X(tf) = -\varphi_X(tf) \left[\int f^2(x) e^{itf(x)} \mu(dx) + \left(\int f(x) e^{itf(x)} \mu(dx) \right)^2 \right]$$

hence we have $\mathbf{E}[I_f(X)^2] = -\frac{d^2}{dt^2} \varphi_X(tf) \Big|_{t=0} = I_{f^2}(\mu) + I_f(\mu)^2$.

Theorem 24.16 (Mapping theorem) Let E and F be locally compact Polish spaces and let $\phi : E \rightarrow F$ be a measurable map. Let $\mu \in \mathcal{M}(E)$ with $\mu \circ \phi^{-1} \in \mathcal{M}(F)$ and let X be a PPP on E with intensity measure μ . Then $X \circ \phi^{-1}$ is a PPP on F with intensity measure $\mu \circ \phi^{-1}$.

Proof For $f \in \mathcal{B}^+(F)$,

$$\begin{aligned} \mathcal{L}_{X \circ \phi^{-1}}(f) &= \mathcal{L}_X(f \circ \phi) = \exp \left(\int (e^{-f(\phi(x))} - 1) \mu(dx) \right) \\ &= \exp \left(\int (e^{-f(y)} - 1) (\mu \circ \phi^{-1})(dy) \right) \end{aligned}$$

Now, Theorem 24.14 and Theorem 24.7 yield the claim.

Theorem 24.17 Let $v \in \mathcal{M}((0, \infty))$ and let $X \sim \text{PPP}_v$ on $(0, \infty)$. Further, define $Y := \int xX(dx)$. Then the following are equivalent.

- (i) $\mathbf{P}[Y < \infty] > 0$.
- (ii) $\mathbf{P}[Y < \infty] = 1$.
- (iii) $\int v(dx)(1 \wedge x) < \infty$.

If (i)-(iii) hold, then Y is an infinitely divisible nonnegative random variable with Lévy measure v .

Proof Let $Y_\infty = \int_{[1, \infty)} xX(dx)$ and $Y_t := \int_{(t, 1)} xX(dx)$ for $t \in [0, 1)$. Evidently, $Y = Y_0 + Y_\infty$. Furthermore, it is clear that

$$\mathbf{P}[Y_\infty < \infty] > 0 \iff \mathbf{P}[Y_\infty < \infty] = 1 \iff v([1, \infty)) < \infty. \quad (24.4)$$

If (iii) holds, then $\mathbf{E}[Y_0] = \int_{(0, 1)} xv(dx) < \infty$; hence $Y_0 < \infty$ a.s. (and thus $Y < \infty$ a.s. by (24.4)). On the other hand, if (iii) does not hold, then $Y_\infty = \infty$ a.s. or $\mathbf{E}[Y_0] = \infty$. While Y_∞ can have infinite expectation even if $Y_\infty < \infty$ a.s., for Y_0 this is impossible since, in contrast with Y_∞ , Y_0 is composed not of a few large contributions but many small ones so that a law of large numbers is in force. More precisely, by Corollary 24.15, we have

$$\text{Var}[Y_t] = \int_{(t, 1)} x^2 v(dx) \leq \int_{(t, 1)} xv(dx) = \mathbf{E}[Y_t] < \infty \quad \text{for all } t \in (0, 1)$$

Hence, by Chebyshev's inequality,

$$\mathbf{P} \left[Y_t < \frac{\mathbf{E}[Y_t]}{2} \right] \leq \frac{4\text{Var}[Y_t]}{\mathbf{E}[Y_t]^2} \xrightarrow{t \rightarrow 0} 0.$$

Thus $Y_0 = \sup_{t \in (0, 1)} Y_t \geq \mathbf{E}[Y_0]/2 = \infty$ almost surely.

Now assume that (i)-(iii) hold. By Theorem 24.14, Y has the Laplace transform

$$\mathbf{E}[e^{-tY}] = \exp \left(\int v(dx) (e^{-tx} - 1) \right)$$

By the Lévy-Khinchin formula (Theorem 16.14), Y is infinitely divisible with Lévy measure ν .

Corollary 24.18 Let $\mu_i \in \mathcal{M}_1([0, \infty))$, $i = 1, 2$, be infinitely divisible distributions with canonical measures $\nu_i \in \mathcal{M}((0, \infty))$ and deterministic parts $\alpha_i \geq 0$ (compare Theorem 16.14). If we have

$$\alpha_1 \leq \alpha_2 \quad \text{and} \quad \nu_1([x, \infty)) \leq \nu_2([x, \infty)) \quad \text{for all } x > 0, \quad (24.5)$$

then μ_1 is stochastically smaller than μ_2 ; i.e., $\mu_1 \leq_{st} \mu_2$.

Proof (The proof follows [100, Proof of Lemma 6.1].) The idea is to use a coupling argument where based on one Poisson point process we construct the two random variables Y_1, Y_2 with $Y_i \sim \mu_i$, $i = 1, 2$, such that $Y_1 \leq Y_2$ almost surely. By Theorem 17.58, this yields the claim.

Let $G_i(x) := \nu_i([x, \infty))$, $i = 1, 2$, $x > 0$, and

$$\phi_i(y) := G_i^{-1}(y) = \inf \{x \geq 0 : G_i(x) \leq y\} \quad \text{for } y > 0.$$

If ν_i is finite, then $\phi_i(y) = 0$ for $y \geq \nu_i((0, \infty))$. Let λ denote the Lebesgue measure on $[0, \infty)$. By construction, for the image measure restricted to the positive reals, we have

$$(\lambda \circ \phi_i^{-1})|_{(0, \infty)} = \nu_i, \quad i = 1, 2$$

Now assume that X is a PPP on $(0, \infty)$ with intensity measure λ . By Theorem 24.16, the random measures

$$X_i := \left(\int \phi_i(x) X(dx) \right) \Big|_{(0, \infty)} = X \circ \phi_i^{-1}$$

are PPPs with intensity measures ν_i , $i = 1, 2$. By Theorem 24.17, we thus have

$$Y_i := \alpha_i + \int \phi_i(x) X(dx) \sim \mu_i \quad \text{for } i = 1, 2$$

However, by assumption, we have $G_1 \geq G_2$ which implies $\phi_1 \leq \phi_2$ and thus $Y_1 \leq Y_2$ a.s.

Example 24.19 By Corollary 16.10, for every nonnegative infinitely divisible distribution μ with Lévy measure ν , there exists a stochastic process $(Y_t)_{t \geq 0}$ with independent stationary increments and $Y_t \sim \mu^{*t}$ (hence with Lévy measure $t\nu$). Here we give a direct construction of this process. Let X be a PPP on $(0, \infty) \times [0, \infty)$ with intensity measure $\nu \otimes \lambda$ (here λ is the Lebesgue measure). Define $Y_0 = 0$ and

$$Y_t := \int_{(0, \infty) \times (0, t]} x X(d(x, s))$$

By the mapping theorem, we have $X(\cdot \times (s, t]) \sim \text{PPP}_{(t-s)\nu}$; hence $Y_t - Y_s$ is infinitely divisible with Lévy measure $(t-s)\nu$. The independence of the increments is evident. Note that $t \mapsto Y_t$ is right continuous and monotone increasing.

The process Y that we have just constructed is called a subordinator with Lévy measure ν .

The procedure in the previous example can be generalized by allowing time sets more general than $[0, \infty)$.

Definition 24.20 A random measure Y is called infinitely divisible if, for any $n \in \mathbb{N}$, there exist i.i.d. random measures $Y_1, \dots, Y_n$ with $Y = Y_1 + \dots + Y_n$.

Theorem 24.21 Let $\nu \in \mathcal{M}((0, \infty) \times E)$ with

$$\int \mathbb{1}_A(t)(1 \wedge x)\nu(d(x, t)) < \infty \quad \text{for all } A \in \mathcal{B}_b(E)$$

and let $\alpha \in \mathcal{M}(E)$. Let X be a PPP_ν and

$$Y(A) := \alpha(A) + \int x \mathbb{1}_A(t) X(d(x, t)) \quad \text{for } A \in \mathcal{B}(E)$$

Then Y is an infinitely divisible random measure with independent increments. For $A \in \mathcal{B}(E)$, $Y(A)$ has the Lévy measure $v(\cdot \times A)$.

We call ν the canonical measure and α the deterministic part of Y .

Proof This is a direct consequence of Theorem 24.16 and Theorem 24.17.

Remark 24.22 We can write Y as $Y = \alpha + \int x \delta_t X(d(x, t))$, where δ_t is the Dirac measure at $t \in E$. If instead of $x \delta_t$, we allow more general measures $\chi \in \mathcal{M}(E)$, then we get a representation

$$Y = \alpha + \int_{\mathcal{M}(E)} \chi X(d\chi)$$

where $X \sim \text{PPP}_\nu$ on $\mathcal{M}(E)$ and $\nu \in \mathcal{M}(\mathcal{M}(E))$ with

$$\int v(d\chi)(\chi(A) \wedge 1) < \infty$$

for any $A \in \mathcal{B}_b(E)$. It can be shown that this is the most general form of an infinitely divisible measure on E . We call ν the canonical measure of Y and α the deterministic part. Y is characterized by its Laplace transform which obeys the Lévy-Khinchin formula:

$$\mathcal{L}_Y(f) = \exp \left(- \int f d\alpha + \int v(d\chi) \left(e^{-\int f d\chi} - 1 \right) \right)$$

Theorem 24.23 (Coloring theorem) Let F be a further locally compact Polish space, let $\mu \in \mathcal{M}(E)$ be atom-free and let $(Y_x)_{x \in E}$ be i.i.d. random variables, independent of X , with values in F and distribution $v \in \mathcal{M}_1(F)$. Then

$$Z(A) := \int \mathbb{1}_A(x, Y_x) X(dx), \quad A \in \mathcal{B}(E \times F)$$

is a $\text{PPP}_{\mu \otimes v}$ on $E \times F$.

Proof This is left as an exercise.

There is an obvious generalization of the coloring theorem: The assumption that μ is atom-free was needed in order that X have no double points. That is, for every unit mass that X produces, there is a different random variable Y_x . However, this can also be achieved by different means and in somewhat greater generality.

Accordingly, let E, F be locally compact Polish spaces, let $\mu \in \mathcal{M}(E)$ and let κ be a stochastic kernel from E to F with $\mu\kappa := \int \mu(dx) \kappa(x, \cdot) \in \mathcal{M}(F)$. Let $(Y_{x,t})_{x \in E, t \in [0,1]}$ be independent random variables with distributions $\mathbf{P}_{Y_{x,t}} = \kappa(x, \cdot)$ for $x \in E$ and $t \in [0, 1]$.

For $X \sim \text{PPP}_\mu$, define the lifting $\tilde{X}$ as that PPP on $E \times [0, 1]$ with intensity measure $\mu \otimes \lambda|_{[0,1]}$, where λ is the Lebesgue measure. Clearly, $X \stackrel{\mathcal{D}}{=} \tilde{X}(\cdot \times [0, 1])$. The random measure $\tilde{X}$ can be understood as a realization of X in which the different points of X are assigned arbitrary $[0, 1]$ -valued labels to distinguish them. Now let

$$X^\kappa(A) := \int \tilde{X}(d(x, t)) \mathbb{1}_A(Y_{x,t}) \quad \text{for } A \in \mathcal{B}(F)$$

Theorem 24.24 X^κ is a random measure with $\mathbf{P}_{X^\kappa} = \text{PPP}_{\mu\kappa}$.

Proof Clearly, almost surely X^κ is a measure. For $A \in \mathcal{B}_b(F)$, we have by assumption

$$\mathbf{E}[X^\kappa(A)] = \mathbf{E} \left[\int \tilde{X}(d(x, t)) \kappa(x, A) \right] = (\mu\kappa)(A) < \infty$$

Hence $X^\kappa(A) < \infty$ almost surely, and thus X^κ is a random measure. We compute the Laplace transform of X^κ . Let $g(x) := -\log \mathbf{E}[e^{-f(Y_{x,t})}]$. Then (since $\tilde{X}$ has no double points)

$$\begin{aligned}
 \mathcal{L}_{X^\kappa}(f) &= \mathbf{E} \left[\exp \left(- \int \tilde{X}(d(x,t)) f(Y_{x,t}) \right) \right] \\
 &= \mathbf{E} \left[\prod_{(x,t): \tilde{X}(\{(x,t)\})=1} e^{-f(Y_{x,t})} \right] \\
 &= \mathbf{E} \left[\prod_{(x,t): \tilde{X}(\{(x,t)\})=1} \mathbf{E}[e^{-f(Y_{x,t})}] \right] \\
 &= \mathbf{E} \left[\prod_{(x,t): \tilde{X}(\{(x,t)\})=1} e^{-g(x)} \right] = \mathcal{L}_X(g) \\
 &= \exp \left(\int \mu(dx) (\mathbf{E}[e^{-f(Y_{x,t})}] - 1) \right) \\
 &= \exp \left(\int \mu(dx) \int \kappa(x, dy) (e^{-f(y)} - 1) \right) \\
 &= \exp \left(\int \mu \kappa(dy) (e^{-f(y)} - 1) \right)
 \end{aligned}$$

Example 24.25 (PPP as invariant distribution) As an application of the previous theorem, consider a stochastic process on $E = \mathbb{Z}^d$ or $E = \mathbb{R}^d$ that consists of a system of independent random walks. Hence assume that we are given i.i.d. random variables $Z_n^i, i, n \in \mathbb{N}$ with distribution $v \in \mathcal{M}_1(E)$. Further, assume that, at time n , the position of the i th particle of our system of random walks is $S_n^i := S_0^i + \sum_{l=1}^n Z_l^i$, where S_0^i is an arbitrary, possibly random, starting point. Assume that the particles are indistinguishable. Hence we simply add the particles at each site:

$$X_n(A) := \sum_{i=1}^{\infty} \mathbb{1}_A(S_n^i) \quad \text{for } A \subset E$$

Each X_n is a measure on E and, if at the beginning the particles are not too concentrated locally, it is a locally finite measure and hence a random measure. Assume that $X_0 \sim \text{PPP}_\mu$ for some $\mu \in \mathcal{M}(E)$. Define $\kappa(x, \cdot) = \delta_x * \nu$, and write κ^n for the n -fold application of κ ; that is, $\kappa^n(x, \cdot) = \delta_x * \nu^{*n}$. We thus get $X_0^\kappa \stackrel{\mathcal{D}}{=} X_1$. Indeed, independence of the motions of the individual particles in the definition of X_0^κ is exactly independence of the random walks. As X_1 is also a PPP, we get inductively $X_n^\kappa \stackrel{\mathcal{D}}{=} X_{n+1}$ and thus $X_n \sim \text{PPP}_{\mu \kappa^n} = \text{PPP}_{\mu * \nu^{*n}}$. In particular, $X_0 \stackrel{\mathcal{D}}{=} X_n$ if and only if $\mu * \nu = \mu$. Clearly, this is true if we have $E = \mathbb{Z}^d$ and μ the counting measure or if $E = \mathbb{R}^d$ and μ is the Lebesgue measure. For example, if $E = \mathbb{Z}^d$, then under rather mild assumptions on ν one can show that the counting measure $\mu = \lambda$ is the unique (up to multiples) solution of $\mu * \nu = \mu$. In this case, every invariant measure is a convex combination of PPPs with different intensity measures $\theta\lambda$.

Exercise 24.2.1 Use an approximation with simple functions in order to show the claim of Corollary 24.15 without using characteristic functions.

Exercise 24.2.2 Prove the coloring theorem (Theorem 24.23).

Exercise 24.2.3 Let $p_1, p_2 \in (0, 1]$ and $r_1, r_2 > 0$. Show the following statement about the stochastic order of negative binomial distributions: $b_{r_1, p_1}^- \leq_{\text{st}} b_{r_2, p_2}^-$ if and only if

$$p_1 \geq p_2 \quad \text{and} \quad p_1^{r_1} \geq p_2^{r_2}$$

5.24.3 24.3 The Poisson-dirichlet Distribution*

The goal of this section is to solve the following problem. Take a stick of length 1. Choose a point of the stick uniformly at random and break the stick at this point. Put the left part of the stick (with length, say, W_1) aside. With the remaining part of the stick proceed just as with the original stick. Break it in two and put the left part (of length W_2) aside. Successively, we thus collect fractions of the stick of lengths $W_1, W_2, W_3, \dots$. What is the joint distribution of $(W_1, W_2, \dots)$? Furthermore, if we order the numbers $W_1, W_2, \dots$ in decreasing order $W_{(1)} \geq W_{(2)} \geq \dots$, what is the distribution of $(W_{(1)}, W_{(2)}, \dots)$? And finally, why do we ask these questions in a chapter on Poisson point processes?

Answering these questions requires some preparation. We saw that the Beta distribution occurs naturally in Pólya's urn model as the limiting distribution of the fraction of balls of a given color. Clearly, Pólya's urn model can be considered for any number $n \geq 2$ of colors. The limiting distribution is then the n -dimensional generalization of the Beta distribution, namely the so-called Dirichlet distribution.

Define the $(n-1)$ -dimensional simplex

$$\Delta_n := \{(x_1, \dots, x_n) \in [0, 1]^n : x_1 + \dots + x_n = 1\}.$$

Definition 24.26 Let $n \in \{2, 3, \dots\}$ and $\theta_1, \dots, \theta_n > 0$. The Dirichlet distribution $\text{Dir}_{\theta_1, \dots, \theta_n}$ is the distribution on Δ_n that is defined for measurable $A \subset \Delta_n$ by

$$\text{Dir}_{\theta_1, \dots, \theta_n}(A) = \int \mathbb{1}_A(x_1, \dots, x_n) f_{\theta_1, \dots, \theta_n}(x_1, \dots, x_n) dx_1 \dots dx_{n-1}$$

Here

$$f_{\theta_1, \dots, \theta_n}(x_1, \dots, x_n) = \frac{\Gamma(\theta_1 + \dots + \theta_n)}{\Gamma(\theta_1) \dots \Gamma(\theta_n)} x_1^{\theta_1-1} \dots x_n^{\theta_n-1}.$$

If the parameters $\theta_1, \dots, \theta_n$ are integer-valued, they correspond to the numbers of balls of the different colors that are originally in the urn. Assume that the colors $n-1$ and n are light green and green and that in the dim light we cannot distinguish them. Then we should still end up with a Dirichlet distribution in the limit but with $n-1$ instead of n and with $\theta_{n-1} + \theta_n$ instead of θ_{n-1} and θ_n ; that is, $\text{Dir}_{\theta_1, \dots, \theta_{n-2}, \theta_{n-1} + \theta_n}$. Let $(M_t)_{t \geq 0}$ be the Moran Gamma subordinator, the stochastic process with right continuous, monotone increasing paths $t \mapsto M_t$ and independent, stationary, Gamma-distributed increments: $M_t - M_s \sim \Gamma_{1, t-s}$ for $t > s \geq 0$. An important connection between M and the Dirichlet distribution is revealed by the corollaries of the following theorem and by Theorem 24.32.

Theorem 24.27 Let $n \in \mathbb{N}$, $\theta_1, \dots, \theta_n > 0$ and $\Theta := \theta_1 + \dots + \theta_n$. Let $X \sim \text{Dir}_{\theta_1, \dots, \theta_n}$ and let $Z \sim \Gamma_{1, \Theta}$ be independent random variables. Then the random variables $S_i := Z \cdot X_i, i = 1, \dots, n$ are independent and $S_i \sim \Gamma_{1, \theta_i}$.

Proof In the following, always let $x_n := 1 - \sum_{i=1}^{n-1} x_i$ and $s = \sum_{j=1}^n s_j$. Let

$$\Delta'_n := \left\{ (x_1, \dots, x_{n-1}) \in (0, 1)^{n-1} : \sum_{i=1}^{n-1} x_i < 1 \right\}$$

For $x \in \Delta'_n$ and $z \geq 0$, the distribution of $(X_1, \dots, X_{n-1}, Z)$ has the density

$$f(x_1, \dots, x_{n-1}, z) = \prod_{j=1}^n \left(x_j^{\theta_j-1} / \Gamma(\theta_j) \right) z^{\Theta-1} e^{-z}$$

Consider the map

$$F : \Delta'_n \times (0, \infty) \rightarrow (0, \infty)^n, \quad (x_1, \dots, x_{n-1}, z) \mapsto (zx_1, \dots, zx_n)$$

This map is invertible with inverse map

$$F^{-1} : (s_1, \dots, s_n) \mapsto (s_1/s, \dots, s_{n-1}/s, s).$$

The Jacobian determinant of F is $\det(F'(x_1, \dots, x_{n-1}, z)) = z^{n-1}$. By the transformation formula for densities (Theorem 1.101), $(S_1, \dots, S_n)$ has density

$$\begin{aligned} g(s_1, \dots, s_n) &= \frac{f(F^{-1}(s_1, \dots, s_n))}{|\det(F'(F^{-1}(s_1, \dots, s_n)))|} \\ &= \frac{s^{\Theta-1} e^{-s}}{s^{n-1}} \prod_{j=1}^n \left((s_j/s)^{\theta_j-1} / \Gamma(\theta_j) \right) \\ &= \prod_{j=1}^n \left(s_j^{\theta_j-1} e^{-s_j} / \Gamma(\theta_j) \right) \end{aligned}$$

However, this is the density for independent Gamma distributions.

Corollary 24.28 If $t_i := \sum_{j=1}^i \theta_j$ for $i = 0, \dots, n$, then the random variables $X = ((M_{t_i} - M_{t_{i-1}}) / M_{t_n}, i = 1, \dots, n)$ and $S := M_{t_n}$ are independent with distributions $X \sim \text{Dir}_{\theta_1, \dots, \theta_n}$ and $S \sim \Gamma_{1, t_n}$.

Corollary 24.29 Let $(X_1, \dots, X_n) \sim \text{Dir}_{\theta_1, \dots, \theta_n}$. Then $X_1 \sim \beta_{\theta_1, \sum_{i=2}^n \theta_i}$ and $(X_2 / (1 - X_1), \dots, X_n / (1 - X_1)) \sim \text{Dir}_{\theta_2, \dots, \theta_n}$ are independent.

Proof Let M be as in Corollary 24.28. Then $X_1 = M_{t_1} / M_{t_n} \sim \beta_{\theta_1, t_n - \theta_1}$. Since $X_1 = \left(\frac{M_{t_n} - M_{t_1}}{M_{t_1}} + 1 \right)^{-1}$, we see that X_1 depend only on M_{t_1} and $M_{t_n} - M_{t_1}$. On the other hand,

$$\left(\frac{X_2}{1 - X_1}, \dots, \frac{X_n}{1 - X_1} \right) = \left(\frac{M_{t_2} - M_{t_1}}{M_{t_n} - M_{t_1}}, \dots, \frac{M_{t_n} - M_{t_{n-1}}}{M_{t_n} - M_{t_1}} \right)$$

is independent of M_{t_1} . By Corollary 24.28, it is also independent of $M_{t_n} - M_{t_1}$ and is $\text{Dir}_{\theta_2, \dots, \theta_n}$ -distributed. $\square$

Corollary 24.30 Let $V_1, \dots, V_{n-1}$ be independent, $V_i \sim \beta_{\theta_i, \theta_{i+1} + \dots + \theta_n}$ and $V_n = 1$. Then

$$\left(V_1, (1 - V_1) V_2, (1 - V_1) (1 - V_2) V_3, \dots, \left(\prod_{i=1}^{n-1} (1 - V_i) \right) V_n \right) \sim \text{Dir}_{\theta_1, \dots, \theta_n}.$$

Proof This follows by iterating the claim of Corollary 24.29. $\square$

It is natural to ask what happens if we distinguish more and more colors (instead of pooling them). For simplicity, consider a symmetric situation where we have $\theta_1 = \dots = \theta_n = \theta/n$ for some $\theta > 0$. Hence we consider

$$\text{Dir}_{\theta; n} := \text{Dir}_{\theta, \dots, \theta} \quad \text{for } \theta > 0.$$

If $X^n = (X_1^n, \dots, X_n^n) \sim \text{Dir}_{\theta/n; n}$, then, by symmetry, we have $\mathbf{E}[X_i^n] = 1/n$ for every $n \in \mathbb{N}$ and $i = 1, \dots, n$. Hence, clearly $(X_1^n, \dots, X_k^n) \xrightarrow{n \rightarrow \infty} 0$ for any $k \in \mathbb{N}$. In order to obtain a nontrivial limit, one possibility is to reorder the values by decreasing size: $X_{(1)}^n \geq X_{(2)}^n \geq \dots$

Definition 24.31 Let $\theta > 0$ and let $(M_t)_{t \in [0, \theta]}$ be a Moran Gamma subordinator. Let $m_1 \geq m_2 \geq \dots \geq 0$ be the jump sizes of M in decreasing order and let $\tilde{m}_i = m_i/M_\theta, i = 1, 2, \dots$. The distribution of the random variables $(\tilde{m}_1, \tilde{m}_2, \dots)$ on $S := \{(x_1 \geq x_2 \geq \dots \geq 0) : x_1 + x_2 + \dots = 1\}$ is called the Poisson-Dirichlet distribution PD_θ with parameter $\theta > 0$.

To be honest, we still have to show that $\sum_{i=1}^{\infty} \tilde{m}_i = 1$. To this end, let Y be a PPP on $(0, \infty) \times (0, \theta]$ with intensity measure $\nu \otimes \lambda$, where λ is the Lebesgue measure and $\nu(dx) = e^{-x}x^{-1}dx$ is the Lévy measure of the $\Gamma_{1,1}$ distribution. We can define M by $M_t := \sum_{(x,s): Y(\{x,s\})=1, s \leq t} x$. Now we have $m_1 = \sup\{x \in (0, \infty) : Y(\{x\} \times (0, \theta]) = 1\}$. Inductively, we get $m_n = \sup\{x < m_{n-1} : Y(\{x\} \times (0, \theta]) = 1\}$ for $n \geq 2$. Interchanging the order of summations, we obtain $M_\theta = \sum_{n=1}^{\infty} m_n$.

Theorem 24.32 If $X^n \sim \text{Dir}_{\theta/n;n}$ for $n \in \mathbb{N}$, then $\mathbf{P}_{(X_{(1)}^n, X_{(2)}^n, \dots)} \xrightarrow{n \rightarrow \infty} \text{PD}_\theta$.

Proof The idea is to express the random variables $X^n, n \in \mathbb{N}$, in terms of the increments of the Moran Gamma subordinator $(M_t)_{t \in [0, \theta]}$ in such a way that convergence of distributions implies almost sure convergence. Hence, let $X_i^n = (M_{\theta i/n} - M_{\theta(i-1)/n})/M_\theta$. By Corollary 24.28, we have $X^n \sim \text{Dir}_{\theta/n;n}$. Let $t_1, t_2, \dots \in (0, \theta]$ be the positions of the jumps $m_1 \geq m_2 \geq \dots$. Evidently, $X_{(1)}^n \geq \tilde{m}_1$ for every n . If n is large enough that $|t_1 - t_2| > \theta/n$, then $X_{(2)}^n \geq \tilde{m}_2$. Inductively, we get

$\liminf_{n \rightarrow \infty} X_{(i)}^n \geq \tilde{m}_i$ almost surely. Using the convention $X_{(i)}^n = 0$ for $i > n$, we have $\sum_{i=1}^{\infty} X_{(i)}^n = 1$ for every $n \in \mathbb{N}$. By Fatou's lemma, we thus get

$$1 = \sum_{i=1}^{\infty} \tilde{m}_i \leq \sum_{i=1}^{\infty} \liminf_{n \rightarrow \infty} X_{(i)}^n \leq \liminf_{n \rightarrow \infty} \sum_{i=1}^{\infty} X_{(i)}^n = 1.$$

Therefore, $\lim_{n \rightarrow \infty} X_{(i)}^n = \tilde{m}_i$ almost surely.

Instead of ordering the values of X^n by their sizes, there is a different way of arranging the terms so that the distributions converge. Think of a biological population in which a certain phenotypical property can be measured with different levels of precision. If we distinguish n different values of this property, then we write X_i^n for the proportion of the population that has type $i \in \{1, \dots, n\}$.

Now successively choose individuals from the population at random. Let I_1^n be the type of the first individual. Denote by I_2^n the type of the first individual that is not of type I_1^n . That is, I_2^n is the second type that we see. Now inductively define I_k^n as the k th type that we see; that is, the type of the first individual that has none of the types $I_1^n, \dots, I_{k-1}^n$. Consider the vector $\hat{X}^n = (\hat{X}_1^n, \dots, \hat{X}_n^n)$, where $\hat{X}_k^n = X_{I_k^n}^n$. Since the probability of the event $\{I_1^n = i\}$ is proportional to the size of the subpopulation of type i , we say that $\hat{X}^n$ is the successively size-biased vector.

The distribution of $\hat{X}^n$ does not change if we change the order of the $X_1^n, \dots, X_n^n$. For example, instead of $X_1^n, \dots, X_n^n$, we can use the order statistics $(X_{(1)}^n, \dots, X_{(n)}^n)$ and again end up with $\hat{X}^n$ as the successively size-biased vector. Hence we can define the successively size-biased vector $\hat{X}$ for the infinite vector $X \sim \text{PD}_\theta$. If $X^n \sim \text{Dir}_{\theta/n;n}$, then by Theorem 24.32, we have $\hat{X}^n \xrightarrow{n \rightarrow \infty} \hat{X}$. Hence we can compute the distribution of $\hat{X}$.

Theorem 24.33 Let $\theta > 0$ and $X^n \sim \text{Dir}_{\theta/n;n}, n \in \mathbb{N}$. Let $X \sim \text{PD}_\theta$. Further, let $V_1, V_2, \dots$ be i.i.d. random variables on $[0, 1]$ with density $x \mapsto \theta(1-x)^{\theta-1}$. Define $Z_1 = V_1$ and $Z_k = \left(\prod_{i=1}^{k-1} (1 - V_i)\right) V_k$ for $k \geq 2$. Then:

- (i) $\hat{X}^n \xrightarrow{n \rightarrow \infty} \hat{X}$.
- (ii) $\hat{X} \stackrel{\mathcal{D}}{=} Z$.

The distribution of Z is called the GEM_θ distribution (Griffiths-Engen-McCloskey).

Proof Statement (i) was shown in the discussion preceding the theorem. In order to show (ii),

we compute the distribution of $\hat{X}^n$ and show that it converges to the distribution of Z .

Let $\hat{X}^{n,1}$ be the vector $X^{n,1} = (X_{I_1^n}^n, X_2, \dots, X_{I_1^n-1}^n, X_{I_1^n+1}^n, \dots, X_n^n)$, in which only the first coordinate is sampled size-biasedly. We show that

$$\hat{X}^{n,1} \sim \text{Dir}_{(\theta/n)+1, \theta/n, \dots, \theta/n}. \quad (24.6)$$

Let $f(x) = (\Gamma(\theta)/\Gamma(\theta/n)^n) \cdot \prod_{k=1}^n x_k^{(\theta/n)-1}$ be the density of $\text{Dir}_{\theta/n; n}$. We compute the density $f^{n,1}$ of $X^{n,1}$ by decomposing according to the value i of I_1^n :

$$\begin{aligned} f^{n,1}(x) &= \sum_{i=1}^n x_1 f(x_2, \dots, x_i, x_1, x_{i+1}, \dots, x_n) = n x_1 f(x) \\ &= \frac{n \Gamma(\theta)}{\Gamma(\theta/n)^n} x_1^{\theta/n} \prod_{i=2}^n x_i^{(\theta/n)-1} \\ &= \frac{\Gamma(\theta+1)}{\Gamma((\theta/n)+1) \Gamma(\theta/n)^{n-1}} x_1^{\theta/n} \prod_{i=2}^n x_i^{(\theta/n)-1}. \end{aligned}$$

However, this is the density of $\text{Dir}_{(\theta/n)+1, \theta/n, \dots, \theta/n}$. By Corollary 24.29, we have

$$\hat{X}^{n,1} \stackrel{\mathcal{D}}{=} (V_1^n, (1 - V_1^n) Y_1, \dots, (1 - V_1^n) Y_{n-1}),$$

where

$$V_1^n \sim \beta_{(\theta/n)+1, \theta(n-1)/n} \quad \text{and} \quad Y = (Y_1, \dots, Y_{n-1}) \sim \text{Dir}_{\theta/n; n-1}$$

are independent. Applying this to Y , we get inductively

$$\hat{X}^n \stackrel{\mathcal{D}}{=} Z^n \quad (24.7)$$

where

$$Z_1^n = V_1^n \quad \text{and} \quad Z_k^n = \left(\prod_{i=1}^{k-1} (1 - V_i^n) \right) V_k^n \quad \text{for } k \geq 2$$

and where $V_1^n, \dots, V_{n-1}^n$ are independent and $V_i^n \sim \beta_{(\theta/n)+1, \theta(n-i)/n}$. Now it is easy to check that $\beta_{(\theta/n)+1, \theta(n-i)/n} \xrightarrow{n \rightarrow \infty} \beta_{1, \theta}$ for every $i \in \mathbb{N}$. Recall that $\beta_{1, \theta}$ has the density $x \mapsto \theta(1-x)^{\theta-1}$. Hence $V_i^n \xrightarrow{n \rightarrow \infty} V_i$ for every i and thus $Z^n \xrightarrow{n \rightarrow \infty} Z$ and $\hat{X}^n \xrightarrow{n \rightarrow \infty} Z$. Together with (i), this proves claim (ii).

At the beginning of this chapter, we raised the question of how the sizes $W_1, W_2, \dots$ of the stick lengths are distributed if at each step, we break the remaining part of the stick at a point chosen uniformly at random. The preceding theorem gives the answer: The vector $(W_{(1)}, W_{(2)}, \dots)$ has distribution PD_1 , and $(W_1, W_2, \dots)$ has distribution GEM_1 .

5.24.4 The Chinese Restaurant Process

We will study a further situation in which the Poisson-Dirichlet distribution arises naturally. As the technical details get a bit tricky, we content ourselves with the description of the problem and with stating (but not proving) two fundamental theorems. An excellent reference for this type of problem is [130].

Consider a Chinese restaurant with countably many enumerated round tables. At each table, there is enough space for arbitrarily many guests. Initially, the restaurant is empty. One by one an infinite number of guests arrive. The first guest sits down at table number one. If

there are already n guests sitting at k tables, then the $(n+1)$ th guest can choose between sitting down at any of the k occupied tables or at the free table with the smallest number (that is, $k+1$). Assume that the guest makes his choice at random (and independently of the previous choices of the other guests). For $l \leq k$, denote by N_l^n the number of guests at the l th table and assume that the probability of choosing the l th table is $(N_l^n - \alpha)/(n + \theta)$. Then the probability of choosing the first free table is $(\theta + k\alpha)/(n + \theta)$. Here $\alpha \in [0, 1]$ and $\theta > -\alpha$ are parameters. We say that $(N^n)_{n \in \mathbb{N}} = (N_1^n, N_2^n, \dots)_{n \in \mathbb{N}}$ is the Chinese restaurant process with parameters (α, θ) .

In the special case $\alpha = 0$, there is a nice interpretation: Assume that the new guest can also choose his seating position at the table (that is, his neighbor to the right). Then, for any of the present guests, the probability of being chosen as a right neighbor is $1/(n + \theta)$. The probability of starting a new table is $\theta/(n + \theta)$.

In order to study the large n behavior of $N^n/n = (N_1^n/n, N_2^n/n, \dots)$, we extend the Poisson-Dirichlet distribution and the GEM distribution by a further parameter.

Definition 24.34 Let $\alpha \in [0, 1]$ and $\theta > -\alpha$. Let $V_1, V_2, \dots$ be independent and $V_i \sim \beta_{1-\alpha, \theta+i\alpha}$. Define $Z = (Z_1, Z_2, \dots)$ by $Z_1 = V_1$ and

$$Z_k = V_k \prod_{i=1}^{k-1} (1 - V_i) \quad \text{for } k \geq 2$$

Then $\text{GEM}_{\alpha, \theta} := \mathbf{P}_Z$ is called the GEM distribution with parameters (α, θ) . The distribution of the size-biased vector $(Z_{(1)}, Z_{(2)}, \dots)$ is called the Poisson-Dirichlet distribution with parameters (α, θ) , or briefly $\text{PD}_{\alpha, \theta}$.

Explicit formulas for the densities of the finite-dimensional marginals of $\text{PD}_{\alpha, \theta}$ can be found in [132]. Note that, for $\alpha = 0$, we recover the classical distributions $\text{GEM}_\theta = \text{GEM}_{0, \theta}$ and $\text{PD}_\theta = \text{PD}_{0, \theta}$.

Theorem 24.35 Let $\alpha \in [0, 1], \theta > -\alpha$ and let $(N^n)_{n \in \mathbb{N}}$ be the Chinese restaurant process with parameters (α, θ) . Then $\mathbf{P}_{N^n/n} \xrightarrow{n \rightarrow \infty} \text{PD}_{\alpha, \theta}$.

Proof See [129] or [130, Theorem 25].

As for the one-parameter Poisson-Dirichlet distribution, there is a representation of $\text{PD}_{\alpha, \theta}$ in terms of the size-ordered jumps of a certain subordinator. In the following, let $\alpha \in (0, 1)$ and let $(M_t)_{t \in [0, 1]}$ be an α -stable subordinator; that is, a subordinator with Lévy measure $v(dx) = x^{-\alpha-1}dx$. Further, let $m_1 \geq m_2 \geq \dots \geq 0$ be the jumps of M , $\tilde{m}_i = m_i/M_1$ for $i \in \mathbb{N}$, and $\tilde{m} = (\tilde{m}_1, \tilde{m}_2, \dots)$. We quote the following theorem from [130, Section 4.2].

Theorem 24.36 Let $\alpha \in (0, 1)$.

- (i) $\tilde{m} \sim \text{PD}_{\alpha, 0}$.
- (ii) If $\theta > -\alpha$, then $\text{PD}_{\alpha, \theta} \ll \text{PD}_{\alpha, 0} = \mathbf{P}[\tilde{m} \in \cdot]$ and the density is

$$\text{PD}_{\alpha, \theta}(dx) = \frac{M_1^{-\theta}}{\mathbf{E}[M_1^{-\theta}]} \mathbf{P}[\tilde{m} \in dx]$$

Exercise 24.3.1 Let $(X, 1 - X) \sim \text{Dir}_{\theta_1, \theta_2}$. Show that $X \sim \beta_{\theta_1, \theta_2}$ is Beta-distributed.

Exercise 24.3.2 Let $X = (X_1, \dots, X_n) \sim \text{Dir}_{\theta_1, \dots, \theta_n}$. Show the following.

- (i) For any permutation σ on $\{1, \dots, n\}$, we have

$$(X_{\sigma(1)}, \dots, X_{\sigma(n)}) \sim \text{Dir}_{\theta_{\sigma(1)}, \dots, \theta_{\sigma(n)}}$$

- (ii) $(X_1, \dots, X_{n-2}, X_{n-1} + X_n) \sim \text{Dir}_{\theta_1, \dots, \theta_{n-2}, \theta_{n-1} + \theta_n}$.

Exercise 24.3.3 Let $(N^n)_{n \in \mathbb{N}}$ be the Chinese restaurant process with parameters $(0, \theta)$.

- (i) Let $\theta = 1$.

- (a) Show that $\mathbf{P}[N_1^n = k] = 1/n$ for any $k = 1, \dots, n$,
 (b) Show that, for $k_l = 1, \dots, n - (k_1 + \dots + k_{l-1})$,

$$\mathbf{P}[N_l^n = k_l \mid N_1^n = k_1, \dots, N_{l-1}^n = k_{l-1}] = \frac{1}{n - (k_1 + \dots + k_{l-1})}.$$

- (c) Infer the claim of Theorem 24.35 in the case $\alpha = 0$ and $\theta = 1$.
 (ii) Let $\theta > 0$.
 (a) Show that $n\mathbf{P}[N_1^n = \lfloor nx \rfloor] \xrightarrow{n \rightarrow \infty} \theta(1-x)^{\theta-1}$ for $x \in (0, 1)$.
 (b) Show that

$$n\mathbf{P}[N_l^n = \lfloor nx_l \rfloor \mid N_1^n = \lfloor nx_1 \rfloor, \dots, N_{l-1}^n = \lfloor nx_{l-1} \rfloor] \xrightarrow{n \rightarrow \infty} (\theta/y_l)(1 - x_l/y_l)^{\theta-1}$$

for $x_1, \dots, x_l \in (0, 1)$ with $y_l = 1 - (x_1 + \dots + x_{l-1}) > x_l$.

- (c) As in (i), infer the claim of Theorem 24.35 for $\alpha = 0$ and $\theta > 0$.

5.25 25 The Itô Integral

The Itô integral allows us to integrate stochastic processes with respect to the increments of a Brownian motion or a somewhat more general stochastic process. We develop the Itô integral first for Brownian motion and then for generalized diffusion processes (so called Itô processes). In the third section, we derive the celebrated Itô formula. This is the chain rule for the Itô integral that enables us to do explicit calculations with the Itô integral. In the fourth section, we use the Itô formula to obtain a stochastic solution of the classical Dirichlet problem. This in turn is used in the fifth section in order to show that like symmetric simple random walk, Brownian motion is recurrent in low dimensions and transient in high dimensions.

5.25.1 25.1 Itô Integral with Respect to Brownian Motion

Let $W = (W_t)_{t \geq 0}$ be a Brownian motion on the space $(\Omega, \mathcal{F}, \mathbf{P})$ with respect to the filtration $\mathbb{F}$ that satisfies the usual conditions (see Definition 21.22). That is, W is a Brownian motion and an $\mathbb{F}$ -martingale. The aim of this section is to construct an integral

$$I_t^W(H) = \int_0^t H_s dW_s$$

for a large class of integrands $H : \Omega \times [0, \infty) \rightarrow \mathbb{R}$, $(\omega, t) \mapsto H_t(\omega)$ in such a way that $(I_t^W(H))_{t \geq 0}$ is a continuous $\mathbb{F}$ -martingale. Since almost all paths $s \mapsto W_s(\omega)$ of Brownian motion are of locally infinite variation, $W(\omega)$ is not the distribution function of a signed Lebesgue-Stieltjes measure on $[0, \infty)$. Hence $I_t^W(H)$ cannot be defined in the framework of classical integration theory. The basic new idea is to establish the integral as an L^2 -limit. We start with an elementary example to illustrate this.

Example 25.1 Assume that $X_1, X_2, \dots$ are i.i.d. $\text{Rad}_{1/2}$ random variables; that is, $\mathbf{P}[X_n = 1] = \mathbf{P}[X_n = -1] = \frac{1}{2}$. Let $(h_n)_{n \in \mathbb{N}}$ be a sequence of real numbers. Under which assumptions on $(h_n)_{n \in \mathbb{N}}$ is the series

$$R := \sum_{n \in \mathbb{N}} h_n X_n \tag{25.1}$$

well-defined? If $\sum_{n \in \mathbb{N}} |h_n| < \infty$, then the series converges absolutely for every ω . In this case, there is no problem. Now assume that only the weaker condition $\sum_{n \in \mathbb{N}} h_n^2 < \infty$ holds. In this case, the series (25.1) does not necessarily converge any more for every ω . However, we have

$\mathbf{E}[h_n X_n] = 0$ for each $n \in \mathbb{N}$ and $\sum_{n=1}^{\infty} \text{Var}[h_n X_n] = \sum_{n=1}^{\infty} h_n^2 < \infty$. Hence $R_N := \sum_{k=1}^N h_k X_k$ converges in L^2 (for $N \rightarrow \infty$). We can thus define the series R in (25.1) as the L^2 -limit of the partial sums R_N . Note that (at least formally) for the approximating sums the order of summation matters. In a sense, we have constructed $\sum_{n=1}^{\infty}$ instead of $\sum_{n \in \mathbb{N}}$.

An equivalent formulation that gives a flavor of what is to come is the following. Denote by ℓ^2 the Hilbert space of square summable sequences of real numbers with inner product $\langle h, g \rangle = \sum_{n=1}^{\infty} h_n g_n$ and norm $\|g\| = \langle g, g \rangle^{1/2}$. Let ℓ^f be the subspace of those sequences with only finitely many nonzero entries. Then $R(h) = \sum_{n \in \mathbb{N}} h_n X_n$ for $h \in \ell^f$ is well-defined (since it is a finite sum). Since

$$\mathbf{E}[R(h)^2] = \text{Var}[R(h)] = \sum_{n \in \mathbb{N}} \text{Var}[h_n X_n] = \sum_{n \in \mathbb{N}} h_n^2 = \|h\|^2,$$

the map $R : \ell^f \rightarrow \mathcal{L}^2(\mathbf{P})$ is an isometry. As $\ell^f \subset \ell^2$ is dense, there is a unique continuous extension of R to ℓ^2 . Hence, if $h \in \ell^2$ and $(h^N)_{N \in \mathbb{N}}$ is a sequence in ℓ^f with $\|h^N - h\| \xrightarrow{N \rightarrow \infty} 0$, then $R(h^N) \xrightarrow{N \rightarrow \infty} R(h)$ in the L^2 sense. In particular, $h_n^N := h_n \mathbb{1}_{\{n \leq N\}}$, $n \in \mathbb{N}$, $N \in \mathbb{N}$, is an approximating sequence for h , and we have $R(h^N) = \sum_{n=1}^N h_n X_n$. Thus the approximation of R with the partial sums R_N that we described above is a special case of this construction.

The programme for the construction of the Itô integral $I_t^W(H)$ is the following. First consider simple functions as integrands H ; that is, the map $t \mapsto H_t(\omega)$ is a step function. For these H , the integral can easily be defined as a finite sum. The next step is to extend the integral, as in Example 25.1, to integrands that can be approximated in a certain L^2 -space by simple integrands.

Definition 25.2 Denote by $\mathcal{E}$ the vector space of maps $H : \Omega \times [0, \infty) \rightarrow \mathbb{R}$ of the form

$$H_t(\omega) = \sum_{i=1}^n h_{i-1}(\omega) \mathbb{1}_{(t_{i-1}, t_i]}$$

where $n \in \mathbb{N}$, $0 = t_0 < t_1 < \dots < t_n$ and h_{i-1} is bounded and $\mathcal{F}_{t_{i-1}}$ -measurable for every $i = 1, \dots, n$. $\mathcal{E}$ is called the vector space of predictable simple processes.

We equip $\mathcal{E}$ with a (pseudo) norm $\|\cdot\|_{\mathcal{E}}$ by defining

$$\|H\|_{\mathcal{E}}^2 = \sum_{i=1}^n \mathbf{E}[h_{i-1}^2] (t_i - t_{i-1}) = \mathbf{E} \left[\int_0^{\infty} H_s^2 ds \right]$$

Definition 25.3 For $H \in \mathcal{E}$ and $t \geq 0$, define

$$I_t^W(H) = \sum_{i=1}^n h_{i-1} (W_{t_i \wedge t} - W_{t_{i-1} \wedge t})$$

and

$$I_{\infty}^W(H) = \sum_{i=1}^n h_{i-1} (W_{t_i} - W_{t_{i-1}})$$

Clearly, for every bounded stopping time τ ,

$$\begin{aligned} \mathbf{E}[I_{\tau}^W(H)] &= \sum_{i=1}^n \mathbf{E} \left[h_{i-1} (W_{t_i}^{\tau} - W_{t_{i-1}}^{\tau}) \right] \\ &= \sum_{i=1}^n \mathbf{E} \left[h_{i-1} \mathbf{E} [W_{t_i}^{\tau} - W_{t_{i-1}}^{\tau} \mid \mathcal{F}_{t_{i-1}}] \right] = 0 \end{aligned}$$

since, by the optional stopping theorem (OST), the stopped Brownian motion W^τ is an $\mathbb{F}$ -martingale. Hence (again by the OST) $(I_t^W(H))_{t \geq 0}$ is an $\mathbb{F}$ -martingale. In particular, we have $\mathbf{E} \left[\left(I_{t_{i+1}}^W(H) - I_{t_i}^W(H) \right) \left(I_{t_{j+1}}^W(H) - I_{t_j}^W(H) \right) \right] = 0$ for $i \neq j$. Therefore,

$$\begin{aligned} \mathbf{E} [I_\infty^W(H)^2] &= \sum_{i=1}^n \mathbf{E} \left[\left(I_{t_i}^W(H) - I_{t_{i-1}}^W(H) \right)^2 \right] \\ &= \sum_{i=1}^n \mathbf{E} \left[h_{i-1}^2 (W_{t_i} - W_{t_{i-1}})^2 \right] \\ &= \sum_{i=1}^n \mathbf{E} [h_{i-1}^2] (t_i - t_{i-1}) = \|H\|_{\mathcal{E}}^2 \end{aligned} \quad (25.2)$$

From these considerations, the following statement is immediate.

Theorem 25.4

- (i) The map $I_\infty^W : \mathcal{E} \rightarrow \mathcal{L}^2(\Omega, \mathcal{F}, \mathbf{P})$ is an isometric linear map (with respect to $\|\cdot\|_{\mathcal{E}}$ and $\|\cdot\|_2$).
- (ii) The process $(I_t^W(H))_{t \geq 0}$ is an L^2 -bounded continuous $\mathbb{F}$ -martingale.

Proof Only the linearity remains to be shown. However, this is trivial.

The idea is to extend the map I_∞^W continuously from $\mathcal{E}$ to a suitable closure $\bar{\mathcal{E}}$ of $\mathcal{E}$. Now as a subspace of what space should we close $\mathcal{E}$? A minimal requirement is that $(\omega, t) \mapsto H_t(\omega)$ be measurable (with respect to $\mathcal{F} \otimes \mathcal{B}([0, \infty))$) and that H be adapted.

Definition 25.5 A stochastic process $X = (X_t)_{t \geq 0}$ with values in a Polish space E is called

- (i) product measurable if $(\omega, t) \mapsto X_t(\omega)$ is measurable with respect to $\mathcal{F} \otimes \mathcal{B}([0, \infty)) - \mathcal{B}(E)$,
- (ii) progressively measurable if, for every $t \geq 0$, the map $\Omega \times [0, t] \rightarrow E, (\omega, s) \mapsto X_s(\omega)$ is measurable with respect to $\mathcal{F}_t \otimes \mathcal{B}([0, t]) - \mathcal{B}(E)$,
- (iii) predictable (or previsible) if $(\omega, t) \mapsto X_t(\omega)$ is measurable with respect to the predictable σ -algebra $\mathcal{P}$ on $\Omega \times [0, \infty)$:

$$\mathcal{P} := \sigma(X : X \text{ is a left continuous adapted process}).$$

Remark 25.6 Any $H \in \mathcal{E}$ is predictable. This property ensures that $I^M(H)$ is a martingale for every (even discontinuous) martingale M . The notion of predictability is important only for integration with respect to discontinuous martingales. As we will not develop that calculus in this book, predictability will not be central for us.

Remark 25.7 If H is progressively measurable, then H is evidently also product measurable and adapted. With a little work, the converse can also be shown: If H is adapted and product measurable, then there is a progressively measurable modification of H (see, e.g., [115, pp. 68ff]).

Theorem 25.8 If H is adapted and right continuous or left continuous, then H is progressively measurable. If H is adapted and a.s. right continuous or left continuous, then there exists a version of H that is progressively measurable.

In particular, every predictable process is progressively measurable.

Proof See Exercise 21.1.4.

We consider $\mathcal{E}$ as a subspace of

$$\mathcal{E}_0 := \left\{ H : \text{product measurable, adapted and } \|H\|^2 := \mathbf{E} \left[\int_0^\infty H_t^2 dt \right] < \infty \right\}$$

Let $\bar{\mathcal{E}}$ denote the closure of $\mathcal{E}$ in $\mathcal{E}_0$.

Theorem 25.9 If H is progressively measurable (for instance, left continuous or right continuous and adapted) and $\mathbf{E} \left[\int_0^\infty H_t^2 dt \right] < \infty$, then $H \in \bar{\mathcal{E}}$.

Proof Let H be progressively measurable and $\mathbf{E} \left[\int_0^\infty H_t^2 dt \right] < \infty$. It is enough to show that, for any $T > 0$, there exists a sequence $(H^n)_{n \in \mathbb{N}}$ in $\mathcal{E}$ such that

$$\mathbf{E} \left[\int_0^T (H_s - H_s^n)^2 ds \right] \xrightarrow{n \rightarrow \infty} 0 \quad (25.3)$$

Step 1. First assume that H is continuous and bounded. Define $H_0^n = 0$ and

$$H_t^n = H_{i2^{-n}T} \quad \text{if } i2^{-n}T < t \leq (i+1)2^{-n}T \text{ for some } i = 0, \dots, 2^n - 1$$

and $H_t^n = 0$ for $t > T$. Then $H^n \in \mathcal{E}$, and we have $H_t^n(\omega) \xrightarrow{n \rightarrow \infty} H_t(\omega)$ for all $t > 0$ and $\omega \in \Omega$. By the dominated convergence theorem, we get (25.3).

Step 2. Now let H be progressively measurable and bounded. It is enough to show that there exist continuous adapted processes $H^n, n \in \mathbb{N}$, for which (25.3) holds. Let

$$H_t^n := n \int_{(t-1/n) \vee 0}^{t \wedge T} H_s ds \quad \text{for } t \geq 0, n \in \mathbb{N}$$

Then H^n is continuous, adapted and bounded by $\|H\|_\infty$. By the fundamental theorem of calculus (see Exercise 13.1.7), we have

$$H_t^n(\omega) \xrightarrow{n \rightarrow \infty} H_t(\omega) \quad \text{for } \lambda\text{-almost all } t \in [0, T] \text{ and for all } \omega \in \Omega. \quad (25.4)$$

By Fubini's theorem and the dominated convergence theorem, we thus conclude that

$$\mathbf{E} \left[\int_0^T (H_s - H_s^n)^2 ds \right] = \int_{\Omega \times [0, T]} (H_s(\omega) - H_s^n(\omega))^2 (\mathbf{P} \otimes \lambda)(d(\omega, s)) \xrightarrow{n \rightarrow \infty} 0$$

Step 3. Now let H be progressively measurable, and assume $\mathbf{E} \left[\int_0^\infty H_t^2 dt \right] < \infty$. It is enough to show that there exists a sequence $(H^n)_{n \in \mathbb{N}}$ of bounded, progressively measurable processes such that (25.3) holds. Manifestly, we can choose $H_t^n = H_t \mathbb{1}_{\{|H_t| < n\}}$.

Definition 25.10 (Itô integral) For $H \in \bar{\mathcal{E}}$, define the Itô integral

$$\int_0^\infty H_s dW_s := I_\infty^W(H)$$

as the continuous extension of the map $I_\infty^W : \mathcal{E} \rightarrow \mathcal{L}^2(\mathbf{P})$ to the closure $\bar{\mathcal{E}}$ of $\mathcal{E}$. In other words, if $(H^n)_{n \in \mathbb{N}}$ is a sequence in $\mathcal{E}$ with $\|H - H^n\| \xrightarrow{n \rightarrow \infty} 0$, then we define $I_\infty^W(H)$ by

$$I_\infty^W(H) := \lim_{n \rightarrow \infty} I_\infty^W(H^n) \quad \text{in } L^2$$

If τ is a stopping time, then in the following we use the abbreviation

$$H_t^{(\tau)} := H_t \mathbb{1}_{\{t \leq \tau\}} \quad \text{for } t \geq 0.$$

(Note that this is not the stopped process $H_t^\tau = H_{\tau \wedge t}$.)

Theorem 25.11

(i) The map $I_\infty^W : \bar{\mathcal{E}} \rightarrow \mathcal{L}^2(\Omega, \mathcal{F}, \mathbf{P})$ is linear and

$$\mathbf{E} [I_\infty^W(H)^2] = \mathbf{E} \left[\int_0^\infty H_s^2 ds \right]$$

(ii) For every $H \in \bar{\mathcal{E}}$, the process $\tilde{I}^W(H)$ defined by $\tilde{I}_t^W(H) := I_\infty^W(H^{(t)})$ is an L^2 -bounded $\mathbb{F}$ -martingale that has a continuous modification $I^W(H)$.

Definition 25.12 (Itô integral as a process) Let $I^W(H)$ be the continuous version of the martingale $(I_\infty^W(H^{(t)}))_{t \geq 0}$ (see Theorem 25.11(ii)). Denote by

$$\int_s^t H_r dW_r := I_t^W(H) - I_s^W(H) \quad \text{for } 0 \leq s \leq t \leq \infty$$

the Itô integral of H with respect to Brownian motion W on the interval $[s, t]$.

Proof of Theorem 25.11 (i) This is a direct consequence of the definition of $I_\infty^W(H)$.

(ii) Let $(H^n)_{n \in \mathbb{N}}$ be a sequence in $\mathcal{E}$ with $\|H^n - H\| \xrightarrow{n \rightarrow \infty} 0$. By Theorem 25.4(ii), we have

$$I_\infty^W((H^n)^{(t)}) = I_t^W(H^n) = \mathbf{E} [I_\infty^W(H^n) | \mathcal{F}_t] \quad \text{for all } t \geq 0, n \in \mathbb{N}.$$

Since $\|(H^n)^{(t)} - H^{(t)}\| \leq \|H^n - H\| \xrightarrow{n \rightarrow \infty} 0$, this implies (using Corollary 8.21)

$$\tilde{I}_t^W(H) = \lim_{n \rightarrow \infty} I_t^W(H^n) = \lim_{n \rightarrow \infty} \mathbf{E} [I_\infty^W(H^n) | \mathcal{F}_t] = \mathbf{E} [I_\infty^W(H) | \mathcal{F}_t]$$

Hence $\tilde{I}^W(H)$ is an L^2 -bounded martingale and $I_t^W(H^n) \xrightarrow{n \rightarrow \infty} \tilde{I}_t^W(H)$ in L^2 for every $t \geq 0$. By Theorem 25.4(ii), $I^W(H^n)$ is continuous for every $n \in \mathbb{N}$. Thus, by Exercise 21.4.3, there exists a continuous modification $I^W(H)$ of $\tilde{I}^W(H)$.

The last step in the construction of the Itô integral is to weaken the strong integrability condition $\mathbf{E} [\int_0^\infty H_s^2 ds] < \infty$. We start with a simple observation.

Let τ be a stopping time and recall that $\int_0^\tau H_s dW_s$ denotes the random variable that for any ω assumes the value $(\int_0^{\tau(\omega)} H_s dW_s)(\omega)$.

Lemma 25.13 Let τ be a stopping time and let $H \in \bar{\mathcal{E}}$.

(i) We have

$$\int_0^\tau H_s dW_s = \int_0^\infty H_s^{(\tau)} dW_s := \int_0^\infty H_s \mathbb{1}_{\{s \leq \tau\}} dW_s \quad \text{a.s.}$$

(ii) In particular, for any $t \geq 0$, on the event $\{\tau \geq t\}$ we have

$$\int_0^t H_s dW_s = \int_0^t H_s^{(\tau)} dW_s \quad \text{a.s.}$$

(iii) Let $G \in \bar{\mathcal{E}}$ be such that $H_s = G_s$ for all $s \leq \tau$. Then

$$\int_0^\tau H_s dW_s = \int_0^\tau G_s dW_s \quad \text{a.s.}$$

Proof (i) Assume first that τ takes values in $\{k/2^n : k \in \mathbb{N}_0\} \cup \{\infty\}$ for some $n \in \mathbb{N}$. Then $\mathbb{1}_{\{k/2^n \leq \tau\}} \mathbb{1}_{\{t \in ((k-1)/2^n, k/2^n]\}} \in \mathcal{E}$ for all $k \in \mathbb{N}$. If, in addition, $H \in \mathcal{E}$, then also $H^{(\tau)} \in \mathcal{E}$ and the claim follows directly from the definition of the Itô integral (Definition 25.3). Now let $H \in \bar{\mathcal{E}}$ and let $(H^k)_{k \in \mathbb{N}}$ be a sequence in $\mathcal{E}$ such that $\|H^k - H\|_{\mathcal{E}} \xrightarrow{k \rightarrow \infty} 0$. Writing $H_t^{k,(\tau)} := H_t^k \mathbb{1}_{\{t \leq \tau\}}$ we get that $\|H^{k,(\tau)} - H^{(\tau)}\|_{\mathcal{E}} \xrightarrow{k \rightarrow \infty} 0$. By choosing a suitable sequence $k_m \uparrow \infty$, we obtain

$$\begin{aligned}\int_0^\tau H_s dW_s &= \lim_{m \rightarrow \infty} \int_0^\tau H_s^{k_m} dW_s \\ &= \lim_{m \rightarrow \infty} \int_0^\infty H_s^{k_m, (\tau)} dW_s = \int_0^\infty H_s^{(\tau)} dW_s \quad \text{a.s.}\end{aligned}$$

Finally, assume that τ is an arbitrary stopping time and define $\tau_n := 2^{-n} \lceil 2^n \tau \rceil$ for $n \in \mathbb{N}$. Then (τ_n) is a sequence of stopping times with $\tau_n \downarrow \tau$. Recall that $I^W(H)$ is continuous and note that $\|H^{(\tau_n)} - H^{(\tau)}\|_{\mathcal{E}} \xrightarrow{n \rightarrow \infty} 0$. Hence by taking a suitable sequence $n(m) \uparrow \infty$, we get

$$\begin{aligned}\int_0^\tau H_s dW_s &= \lim_{m \rightarrow \infty} \int_0^{\tau_{n(m)}} H_s dW_s \\ &= \lim_{m \rightarrow \infty} \int_0^\infty H_s^{(\tau_{n(m)})} dW_s = \int_0^\infty H_s^{(\tau)} dW_s \quad \text{a.s.}\end{aligned}$$

(ii), (iii) These statements are direct consequences of (i).

Definition 25.14 Let $\mathcal{E}_{\text{loc}}$ be the space of progressively measurable stochastic processes H with

$$\int_0^T H_s^2 ds < \infty \quad \text{a.s. for all } T > 0$$

Lemma 25.15 For every $H \in \mathcal{E}_{\text{loc}}$, there exists a sequence $(\tau_n)_{n \in \mathbb{N}}$ of stopping times with $\tau_n \uparrow \infty$ almost surely and $\mathbf{E} \left[\int_0^{\tau_n} H_s^2 ds \right] < \infty$ and hence such that $H^{(\tau_n)} \in \bar{\mathcal{E}}$ for every $n \in \mathbb{N}$.

Proof Define

$$\tau_n := \inf \left\{ t \geq 0 : \int_0^t H_s^2 ds \geq n \right\}$$

By the definition of $\mathcal{E}_{\text{loc}}$, we have $\tau_n \uparrow \infty$ almost surely. By construction, we have $\|H^{(\tau_n)}\|^2 = \mathbf{E} \left[\int_0^{\tau_n} H_s^2 ds \right] \leq n$.

Definition 25.16 Let $H \in \mathcal{E}_{\text{loc}}$ and let $(\tau_n)_{n \in \mathbb{N}}$ be as in Lemma 25.15. For $t \geq 0$, define the Itô integral as the almost sure limit

$$\int_0^t H_s dW_s := \lim_{n \rightarrow \infty} \int_0^t H_s^{(\tau_n)} dW_s \quad (25.5)$$

Theorem 25.17 Let $H \in \mathcal{E}_{\text{loc}}$.

- (i) The limit in (25.5) is well-defined and continuous at t . Up to a.s. equality, it is independent of the choice of the sequence $(\tau_n)_{n \in \mathbb{N}}$.
- (ii) If τ is a stopping time with $\mathbf{E} \left[\int_0^\tau H_s^2 ds \right] < \infty$, then the stopped Itô integral $\left(\int_0^{\tau \wedge t} H_s dW_s \right)_{t \geq 0}$ is an L^2 -bounded, continuous martingale.
- (iii) If $\mathbf{E} \left[\int_0^T H_s^2 ds \right] < \infty$ for all $T > 0$, then $\left(\int_0^t H_s dW_s \right)_{t \geq 0}$ is a square integrable continuous martingale.

Proof (i) By Lemma 25.13(ii), on the event $\{\tau_n \geq t\}$, we have

$$\int_0^t H_s dW_s = \int_0^t H_s^{(\tau_n)} dW_s$$

Hence the limit exists, is continuous and is independent of the choice of the sequence $(\tau_n)_{n \in \mathbb{N}}$.

(ii) This is immediate by Theorem 25.11.

(iii) As we can choose $\tau_n = n$, this follows from (ii).

Theorem 25.18 Let H be progressively measurable and $\mathbf{E} \left[\int_0^T H_s^2 ds \right] < \infty$ for all $T > 0$. Then

$$M_t := \int_0^t H_s dW_s, \quad t \geq 0$$

defines a square integrable continuous martingale, and

$$(N_t)_{t \geq 0} := \left(M_t^2 - \int_0^t H_s^2 ds \right)_{t \geq 0}$$

is a continuous martingale with $N_0 = 0$.

Proof It is enough to show that N is a martingale. Clearly, N is adapted. Let τ be a bounded stopping time. Then

$$\begin{aligned} \mathbf{E}[N_\tau] &= \mathbf{E} \left[M_\tau^2 - \int_0^\tau H_s^2 ds \right] \\ &= \mathbf{E} \left[\left(\int_0^\tau H_s^{(\tau)} dW_s \right)^2 \right] - \mathbf{E} \left[\int_0^\tau (H_s^{(\tau)})^2 ds \right] = 0 \end{aligned}$$

Thus, by the optional stopping theorem (see Exercise 21.1.3(iii)), N is a martingale.

Recall the notions of local martingales and square variation from Section 21.10.

Corollary 25.19 If $H \in \mathcal{E}_{\text{loc}}$, then the Itô integral $M_t = \int_0^t H_s dW_s$ is a continuous local martingale with square variation process $\langle M \rangle_t = \int_0^t H_s^2 ds$.

Example 25.20

(i) $W_t = \int_0^t 1 dW_s$ is a square integrable martingale, and $(W_t^2 - t)_{t \geq 0}$ is a continuous martingale.

(ii) Since $\mathbf{E} \left[\int_0^T W_s^2 ds \right] = \frac{T^2}{2} < \infty$ for all $T \geq 0$, $M_t := \int_0^t W_s dW_s$ is a continuous, square integrable martingale, and $\left(M_t^2 - \int_0^t W_s^2 ds \right)_{t \geq 0}$ is a continuous martingale.

(iii) Assume that H is progressively measurable and bounded, and let $M_t := \int_0^t H_s dW_s$. Then M is progressively measurable (since it is continuous and adapted) and

$$\mathbf{E} \left[\int_0^T M_s^2 ds \right] = \int_0^T \left(\int_0^s \mathbf{E} [H_r^2] dr \right)^2 ds \leq \frac{T^2 \|H\|_\infty^2}{2}$$

Hence $\tilde{M}_t := \int_0^t M_s dW_s$ is a square integrable, continuous martingale and $\left(\tilde{M}_t^2 - \int_0^t M_s^2 dW_s \right)_{t \geq 0}$ is a continuous martingale.

5.25.2 25.2 Itô Integral with Respect to Diffusions

If

$$H = \sum_{i=1}^n h_{i-1} \mathbb{1}_{(t_{i-1}, t_i]} \in \mathcal{E} \quad (25.6)$$

then the elementary integral

$$I_t^M(H) = \sum_{i=1}^n h_{i-1} (M_{t_i \wedge t} - M_{t_{i-1} \wedge t})$$

is a martingale (respectively local martingale) if M is a martingale (respectively local martingale). Furthermore,

$$\begin{aligned}\mathbf{E} \left[(I_{\infty}^M(H))^2 \right] &= \sum_{i=1}^n \mathbf{E} \left[h_{i-1}^2 (M_{t_i} - M_{t_{i-1}})^2 \right] \\ &= \sum_{i=1}^n \mathbf{E} \left[h_{i-1}^2 (\langle M \rangle_{t_i} - \langle M \rangle_{t_{i-1}}) \right] \\ &= \mathbf{E} \left[\int_0^{\infty} H_t^2 d\langle M \rangle_t \right]\end{aligned}$$

if the expression on the right-hand side is finite. Roughly speaking, the procedure in Section 25.1 by which we defined the Itô integral for Brownian motion and integrands $H \in \bar{\mathcal{E}}$ can be repeated to construct a stochastic integral with respect to M for a large class of integrands H . Essentially, in the definition of the norm on $\mathcal{E}$ we have to replace dt (that is, the square variation of Brownian motion) by the square variation $d\langle M \rangle_t$ of M :

$$\|H\|_M^2 := \mathbf{E} \left[\int_0^{\infty} H_t^2 d\langle M \rangle_t \right]$$

Extending the integral to the closure $\bar{\mathcal{E}}$ works just as for Brownian motion. The tricky point is to check whether a given integrand is in $\bar{\mathcal{E}}$. For example, for discontinuous martingales M the integrands have to be predictable in order for the stochastic integral to be a martingale (not to mention the difficulty of establishing for such M , the existence of the square variation process). For the case of discrete time processes, we saw this in Section 9.3. Now if M is a continuous martingale with continuous square variation $\langle M \rangle$, then the following problem occurs. In the proof of Theorem 25.9 in Step 2, in order to show that progressively measurable processes H are in $\bar{\mathcal{E}}$, we used the fact that $H_t^n(\omega) \xrightarrow{n \rightarrow \infty} H_t(\omega)$ for Lebesgue-almost all t and all ω . Now if $d\langle M \rangle_t$ is not absolutely continuous with respect to the Lebesgue measure, then this is not sufficient to infer convergence of the integrals with respect to $d\langle M \rangle_t$. In the case of absolutely continuous square variation, however, that proof works without change. As in Section 25.1, we obtain the following theorem.

Theorem 25.21 Let M be a continuous local martingale with absolutely continuous square variation $\langle M \rangle$ and let H be a progressively measurable process with $\int_0^T H_s^2 d\langle M \rangle_s < \infty$ a.s. for all $T \geq 0$. Then the Itô integral $N_t := \int_0^t H_s dM_s$ is well-defined and is a continuous local martingale with square variation $\langle N \rangle_t = \int_0^t H_s^2 d\langle M \rangle_s$. For any sequence $(\tau_n)_{n \in \mathbb{N}}$ with $\tau_n \uparrow \infty$ and $\|H^{(\tau_n)}\|_M < \infty$, and for any family $(H^{n,m}, n, m \in \mathbb{N}) \subset \mathcal{E}$ with $\|H^{n,m} - H^{(\tau_n)}\|_M \xrightarrow{m \rightarrow \infty} 0$, we have

$$\int_0^t H_s dM_s = \lim_{n \rightarrow \infty} \lim_{m \rightarrow \infty} I_t^M(H^{m,n}) \quad \text{in probability for all } t \geq 0.$$

The following theorem formulates a certain generalization.

Theorem 25.22 Let M^1 and M^2 be continuous local martingales with absolutely continuous square variation. Let H^i be progressively measurable processes with $\int_0^T (H_s^i)^2 d\langle M^i \rangle_s < \infty$ for $i = 1, 2$ and $T < \infty$. Let $N_t^i := \int_0^t H_s^i dM_s^i$ for $i = 1, 2$. Then N^1 and N^2 are continuous local martingales with quadratic covariation $\langle N^i, N^j \rangle_t = \int_0^t H_s^i H_s^j d\langle M^i, M^j \rangle_s$ for $i, j \in \{1, 2\}$. If M^1 and M^2 are independent, then $\langle N^1, N^2 \rangle \equiv 0$.

Proof First assume $H^1, H^2 \in \mathcal{E}$. Then there are numbers $0 = t_0 < t_1 < \dots < t_n$ and $\mathcal{F}_{t_k}$ -measurable bounded maps $h_k^i, i = 1, 2, k = 0, \dots, n-1$ such that

$$H_t^i(\omega) = \sum_{k=1}^n h_{k-1}^i(\omega) \mathbb{1}_{(t_{k-1}, t_k]}(t)$$

Therefore,

$$N_t^i N_t^j = \sum_{k,l=1}^n h_{k-1}^i h_{l-1}^j \left(M_{t_k \wedge t}^i - M_{t_{k-1} \wedge t}^i \right) \left(M_{t_l \wedge t}^j - M_{t_{l-1} \wedge t}^j \right).$$

Those summands with $k \neq l$ are local martingales. For any of the summands with $k = l$,

$$\begin{aligned} & \left(h_{k-1}^i h_{k-1}^j \left(\left(M_{t_k \wedge t}^i - M_{t_{k-1} \wedge t}^i \right) \left(M_{t_k \wedge t}^j - M_{t_{k-1} \wedge t}^j \right) \right. \right. \\ & \quad \left. \left. - \left(\langle M^i, M^j \rangle_{t_k \wedge t} - \langle M^i, M^j \rangle_{t_{k-1} \wedge t} \right) \right) \right)_{t \geq 0} \end{aligned}$$

is a local martingale. Since

$$\sum_{k=1}^n h_{k-1}^i h_{k-1}^j \left(\langle M^i, M^j \rangle_{t_k \wedge t} - \langle M^i, M^j \rangle_{t_{k-1} \wedge t} \right) = \int_0^t H_s^i H_s^j d \langle M^i, M^j \rangle_s$$

$\left(N_t^i N_t^j - \int_0^t H_s^i H_s^j d \langle M^i, M^j \rangle_s \right)_{t \geq 0}$ is a continuous local martingale.

The case of general progressively measurable H^1, H^2 that satisfy an integrability condition follows by the usual L^2 -approximation arguments.

If M^1 and M^2 are independent, then $\langle M^1, M^2 \rangle \equiv 0$.

In the following, we consider processes that can be expressed as Itô integrals with respect to a Brownian motion. For these processes, we give a different and more detailed proof of Theorem 25.21.

Definition 25.23 Let W be a Brownian motion and let σ and b be progressively measurable stochastic processes with $\int_0^t \sigma_s^2 + |b_s| ds < \infty$ almost surely for all $t \geq 0$. Then we say that the process X defined by

$$X_t = \int_0^t \sigma_s dW_s + \int_0^t b_s ds \quad \text{for } t \geq 0$$

is a generalized diffusion process (or, briefly, generalized diffusion) with diffusion coefficient σ and drift b . Often X is called an Itô process.

In particular, if σ and b are of the form $\sigma_s = \tilde{\sigma}(X_s)$ and $b_s = \tilde{b}(X_s)$ for certain maps $\tilde{\sigma} : \mathbb{R} \rightarrow [0, \infty)$ and $\tilde{b} : \mathbb{R} \rightarrow \mathbb{R}$, then X is called a diffusion (in the proper sense).

In contrast with generalized diffusions, we will see that under certain regularity assumptions on the coefficients, diffusions in the proper sense are Markov processes (compare Theorems 26.8, 26.10 and 26.26).

A diffusion X can always be decomposed as $X = M + A$, where $M_t = \int_0^t \sigma_s dW_s$ is a continuous local martingale with square variation $\langle M \rangle_t = \int_0^t \sigma_s^2 ds$ (by Corollary 25.19) and $A_t = \int_0^t b_s ds$ is a continuous process of locally finite variation.

Clearly, for the H in (25.6), we have

$$\begin{aligned} \int_0^t H_s dM_s &= \sum_{i=1}^n h_{i-1} \left(M_{t_i \wedge t} - M_{t_{i-1} \wedge t} \right) \\ &= \sum_{i=1}^n h_{i-1} \int_{t_{i-1} \wedge t}^{t_i \wedge t} \sigma_s dW_s = \int_0^t (H_s \sigma_s) dW_s \end{aligned}$$

For progressively measurable H with $\int_0^T H_s^2 d\langle M \rangle_s = \int_0^T (H_s \sigma_s)^2 ds < \infty$ for all $T \geq 0$, we thus define the Itô integral as

$$\int_0^t H_s dM_s := \int_0^t (H_s \sigma_s) dW_s$$

Without further work, in particular, without relying on Theorem 25.21, we get the following theorem.

Theorem 25.24 Let $X = M + A$ be a generalized diffusion with σ and let b be as in Definition 25.23. Let H be progressively measurable with

$$\int_0^T H_s^2 \sigma_s^2 ds < \infty \quad \text{a.s. for all } T \geq 0 \quad (25.7)$$

and

$$\int_0^T |H_s b_s| ds < \infty \quad \text{a.s. for all } T \geq 0 \quad (25.8)$$

Then the process Y defined by

$$Y_t := \int_0^t H_s dX_s := \int_0^t H_s dM_s + \int_0^t H_s dA_s := \int_0^t H_s \sigma_s dW_s + \int_0^t H_s b_s ds$$

is a generalized diffusion with diffusion coefficient $(H_s \sigma_s)_{s \geq 0}$ and drift $(H_s b_s)_{s \geq 0}$. In particular, $N_t := \int_0^t H_s dM_s$ is a continuous local martingale with square variation process $\langle N \rangle_t = \int_0^t H_s^2 d\langle M \rangle_s = \int_0^t H_s^2 \sigma_s^2 ds$.

Exercise 25.2.1 Let M be a continuous local martingale with absolutely continuous square variation $\langle M \rangle$ (e.g., a generalized diffusion), and let H be progressively measurable and continuous with $\int_0^T H_s^2 d\langle M \rangle_s < \infty$ for all $T \geq 0$. Further, assume that $\mathcal{P} = (\mathcal{P}^{(n)})_{n \in \mathbb{N}}$ is an admissible sequence of partitions (see Definition 21.56).

(i) Show that for all $T \geq 0$, in the sense of stochastic convergence, we have

$$\int_0^T H_s dM_s = \lim_{n \rightarrow \infty} \sum_{t \in \mathcal{P}_T^n} H_t (M_{t'} - M_t) \quad (25.9)$$

(ii) Show that there exists a subsequence of $\mathcal{P}$ such that almost surely, we have (25.9) for all $T \geq 0$.

5.25.3 25.3 The Itô Formula

This and the following two sections are based on lecture notes of Hans Föllmer.

If $t \mapsto X_t$ is a differentiable map with derivative X' and $F \in C^1(\mathbb{R})$ with derivative F' , then we have the classical substitution rule

$$F(X_t) - F(X_0) = \int_0^t F'(X_s) dX_s = \int_0^t F'(X_s) X'_s ds \quad (25.10)$$

This remains true even if X is continuous and has locally finite variation (see Section 21.10); that is, if X is the distribution function of an absolutely continuous signed measure on $[0, \infty)$. In this case, the derivative X' exists as a Radon-Nikodym derivative almost everywhere, and it is easy to show that (25.10) also holds in this case.

The paths of Brownian motion W are nowhere differentiable (Theorem 21.17 due to Paley, Wiener and Zygmund) and thus have everywhere locally infinite variation. Hence a substitution

rule as simple as (25.10) cannot be expected. Indeed, it is easy to see that such a rule must be false: Choose $F(x) = x^2$. Then the right-hand side in (25.10) (with X replaced by W) is $\int_0^t 2W_s dW_s$ and is hence a martingale. The left-hand side, however, equals W_t^2 , which is a submartingale that only becomes a martingale by subtracting t . Indeed, this t is the additional term that shows up in the substitution rule for Itô integrals, the so-called Itô formula. A somewhat bold

heuristic puts us on the right track: For small t , W_t is of order $\sqrt{t}$. If we formally write $dW_t = \sqrt{dt}$ and carry out a Taylor expansion of $F \in C^2(\mathbb{R})$ up to second order, then we obtain

$$dF(W_t) = F'(W_t) dW_t + \frac{1}{2} F''(W_t) (dW_t)^2 = F'(W_t) dW_t + \frac{1}{2} F''(W_t) dt$$

Rewriting this as an integral yields

$$F(W_t) - F(W_0) = \int_0^t F'(W_s) dW_s + \int_0^t \frac{1}{2} F''(W_s) ds \quad (25.11)$$

(For certain discrete martingales, we derived a similar formula in Example 10.9.) The main goal of this section is to show that this so-called Itô formula is indeed correct.

The subsequent discussion in this section does not explicitly rely on the assumption that we integrate with respect to Brownian motion. All that is needed is that the function with respect to which we integrate have continuous square variation (along a suitable admissible sequence of partitions $\mathcal{P} = (\mathcal{P}^n)_{n \in \mathbb{N}}$). In particular, for Brownian motion, $\langle W \rangle_t = t$.

In the following, let $\mathcal{P} = (\mathcal{P}^n)_{n \in \mathbb{N}}$ be an admissible sequence of partitions (recall the definition of $\mathcal{C}_{\text{qv}} = \mathcal{C}_{\text{qv}}^{\mathcal{P}}, \mathcal{P}_T^n, \mathcal{P}_{S,T}^n, t'$ and so on from Definitions 21.56 and 21.58). Let $X \in C([0, \infty))$ with continuous square variation (along $\mathcal{P}$)

$$T \mapsto \langle X \rangle_T = V_T^2(X) = \lim_{n \rightarrow \infty} \sum_{t \in \mathcal{P}_T^n} (X_{t'} - X_t)^2$$

For Brownian motion, we have $W \in \mathcal{C}_{\text{qv}}^{\mathcal{P}}$ almost surely for any admissible sequence of partitions (Theorem 21.64) and $\langle W \rangle_T = T$. For continuous local martingales M passing to a suitable subsequence $\mathcal{P}'$ of $\mathcal{P}$ ensures that $M \in \mathcal{C}_{\text{qv}}^{\mathcal{P}'}$ almost surely (Theorem 21.70).

Now fix $\mathcal{P}$ and let $X \in \mathcal{C}_{\text{qv}}$ be a (deterministic) function.

Theorem 25.25 (Pathwise Itô formula) Let $X \in \mathcal{C}_{\text{qv}}$ and $F \in C^2(\mathbb{R})$. Then, for all $T \geq 0$, there exists the limit

$$\int_0^T F'(X_s) dX_s := \lim_{n \rightarrow \infty} \sum_{t \in \mathcal{P}_T^n} F'(X_t) (X_{t'} - X_t) \quad (25.12)$$

Furthermore, the Itô formula holds:

$$F(X_T) - F(X_0) = \int_0^T F'(X_s) dX_s + \frac{1}{2} \int_0^T F''(X_s) d\langle X \rangle_s \quad (25.13)$$

Here the right integral in (25.13) is understood as a classical (Lebesgue-Stieltjes) integral.

Remark 25.26 If M is a continuous local martingale, then, by Exercise 25.2.1, the Itô integral $\int_0^T F'(M_s) dM_s$ is the stochastic limit of $\sum_{t \in \mathcal{P}_T^n} F'(M_t) (M_{t'} - M_t)$ as $n \rightarrow \infty$. Thus, in fact, for $X = M(\omega)$, the pathwise integral in (25.12) coincides with the Itô integral (a.s.). In particular, for the Itô integral of Brownian motion, the Itô formula (25.11) holds. $\square$

Proof of Theorem 25.25 We have to show that the limit in (25.12) exists and that (25.13) holds.

For $n \in \mathbb{N}$ and $t \in \mathcal{P}_T^n$ (with successor $t' \in \mathcal{P}_T^n$), the Taylor formula yields

$$F(X_{t'}) - F(X_t) = F'(X_t)(X_{t'} - X_t) + \frac{1}{2}F''(X_t) \cdot (X_{t'} - X_t)^2 + R_t^n, \quad (25.14)$$

where the remainder

$$R_t^n = (F''(\xi) - F''(X_t)) \cdot \frac{1}{2}(X_{t'} - X_t)^2$$

(for a suitable ξ between X_t and $X_{t'}$) can be bounded as follows. As X is continuous, $C := \{X_t : t \in [0, T]\}$ is compact and $F''|_C$ is uniformly continuous. Thus, for every $\varepsilon > 0$, there exists a $\delta > 0$ with

$$|F''(X_r) - F''(X_s)| < \varepsilon \quad \text{for all } r, s \in [0, T] \text{ with } |X_r - X_s| < \delta.$$

Since X is uniformly continuous on $[0, T]$ and since the mesh size $|\mathcal{P}^n|$ of the partition goes to 0 as $n \rightarrow \infty$, for every $\delta > 0$, there exists an N_δ such that

$$\sup_{n \geq N_\delta} \sup_{t \in \mathcal{P}_T^n} |X_{t'} - X_t| < \delta.$$

Hence, for $n \geq N_\delta$ and $t \in \mathcal{P}_T^n$,

$$|R_t^n| \leq \frac{1}{2}\varepsilon (X_{t'} - X_t)^2.$$

Summing over $t \in \mathcal{P}_T^n$ in (25.14) yields

$$\sum_{t \in \mathcal{P}_T^n} (F(X_{t'}) - F(X_t)) = F(X_t) - F(X_0)$$

and

$$\sum_{t \in \mathcal{P}_T^n} |R_t^n| \leq \varepsilon \sum_{t \in \mathcal{P}_T^n} (X_{t'} - X_t)^2 \xrightarrow{n \rightarrow \infty} \varepsilon \langle X \rangle_t < \infty.$$

As $\varepsilon > 0$ was arbitrary, we get $\sum_{t \in \mathcal{P}_T^n} |R_t^n| \xrightarrow{n \rightarrow \infty} 0$. We have (see Exercise 21.10.2)

$$\sum_{t \in \mathcal{P}_T^n} \frac{1}{2}F''(X_t)(X_{t'} - X_t)^2 \xrightarrow{n \rightarrow \infty} \frac{1}{2} \int_0^T F''(X_s) d\langle X \rangle_s.$$

Hence, in (25.14) the sum of the remaining terms also has to converge. That is, the limit in (25.12) exists.

As a direct consequence, we obtain the Itô formula for the Itô integral with respect to diffusions.

Theorem 25.27 (Itô formula for diffusions) Let $Y = M + A$ be a (generalized) diffusion (see Definition 25.23), where $M_t = \int_0^t \sigma_s dW_s$ and $A_t = \int_0^t b_s ds$. Let $F \in C^2(\mathbb{R})$. Then we have the Itô formula

$$\begin{aligned} F(Y_t) - F(Y_0) &= \int_0^t F'(Y_s) dM_s + \int_0^t F'(Y_s) dA_s + \frac{1}{2} \int_0^t F''(Y_s) d\langle M \rangle_s \\ &= \int_0^t F'(Y_s) \sigma_s dW_s + \int_0^t \left(F'(Y_s) b_s + \frac{1}{2} F''(Y_s) \sigma_s^2 \right) ds \end{aligned} \quad (25.15)$$

In particular, for Brownian motion,

$$F(W_t) - F(W_0) = \int_0^t F'(W_s) dW_s + \frac{1}{2} \int_0^t F''(W_s) ds \quad (25.16)$$

As an application of the Itô formula, we characterize Brownian motion as a continuous local martingale with a certain square variation process.

Theorem 25.28 (Lévy's characterization of Brownian motion) Let $X \in \mathcal{M}_{\text{loc},c}$ with $X_0 = 0$. Then the following are equivalent.

- (i) $(X_t^2 - t)_{t \geq 0}$ is a local martingale.
- (ii) $\langle X \rangle_t = t$ for all $t \geq 0$.
- (iii) X is a Brownian motion.

Proof (iii) $\implies$ (i) This is obvious.

(i) $\iff$ (ii) This is clear since the square variation process is unique.

(ii) $\implies$ (iii) It is enough to show that $X_t - X_s \sim \mathcal{N}_{0,t-s}$ given $\mathcal{F}_s$ for $t > s \geq 0$.

Employing the uniqueness theorem for characteristic functions, it is enough to show that (with $i = \sqrt{-1}$) for $A \in \mathcal{F}_s$ and $\lambda \in \mathbb{R}$, we have

$$\varphi_{A,\lambda}(t) := \mathbf{E} [e^{i\lambda(X_t - X_s)} \mathbb{1}_A] = \mathbf{P}[A] e^{-\lambda^2(t-s)/2}$$

Applying Itô's formula separately to the real and the imaginary parts, we obtain

$$e^{i\lambda X_t} - e^{i\lambda X_s} = \int_s^t i\lambda e^{i\lambda X_r} dX_r - \frac{1}{2} \int_s^t \lambda^2 e^{i\lambda X_r} dr$$

Therefore,

$$\begin{aligned} & \mathbf{E} [e^{i\lambda(X_t - X_s)} | \mathcal{F}_s] - 1 \\ &= \mathbf{E} \left[\int_s^t i\lambda e^{i\lambda(X_r - X_s)} dX_r | \mathcal{F}_s \right] - \frac{1}{2} \lambda^2 \mathbf{E} \left[\int_s^t e^{i\lambda(X_r - X_s)} dr | \mathcal{F}_s \right] \end{aligned}$$

Now $M_t := \text{Re} \int_s^t i\lambda e^{i\lambda(X_r - X_s)} dX_r$ and $N_t := \text{Im} \int_s^t i\lambda e^{i\lambda(X_r - X_s)} dX_r$, $t \geq s$ are continuous local martingales with

$$\langle M \rangle_t = \int_s^t \lambda^2 \sin(\lambda(X_r - X_s))^2 dr \leq \lambda^2(t-s)$$

and

$$\langle N \rangle_t = \int_s^t \lambda^2 \cos(\lambda(X_r - X_s))^2 dr \leq \lambda^2(t-s)$$

Thus, by Corollary 21.76, M and N are martingales. Hence we have

$$\mathbf{E} \left[\int_s^t i\lambda e^{i\lambda(X_r - X_s)} dX_r | \mathcal{F}_s \right] = 0$$

Since $A \in \mathcal{F}_s$, Fubini's theorem yields

$$\begin{aligned} \varphi_{A,\lambda}(t) - \varphi_{A,\lambda}(s) &= \mathbf{E} [e^{i\lambda(X_t - X_s)} \mathbb{1}_A] - \mathbf{P}[A] \\ &= -\frac{1}{2} \lambda^2 \int_s^t \mathbf{E} [e^{i\lambda(X_r - X_s)} \mathbb{1}_A] dr = -\frac{1}{2} \lambda^2 \int_s^t \varphi_{A,\lambda}(r) dr \end{aligned}$$

That is, $\varphi_{A,\lambda}$ is the solution of the linear differential equation

$$\varphi_{A,\lambda}(s) = \mathbf{P}[A] \quad \text{and} \quad \frac{d}{dt} \varphi_{A,\lambda}(t) = -\frac{1}{2} \lambda^2 \varphi_{A,\lambda}(t)$$

The unique solution is $\varphi_{A,\lambda}(t) = \mathbf{P}[A]e^{-\lambda^2(t-s)/2}$.

As a consequence of this theorem, we get that any continuous local martingale whose square variation process is absolutely continuous (as a function of time) can be expressed as an Itô integral with respect to some Brownian motion.

Theorem 25.29 (Itô's martingale representation theorem) Let M be a continuous local martingale with $M_0 = 0$ and absolutely continuous square variation $t \mapsto \langle M \rangle_t$. Then, on a suitable extension of the underlying probability space, there exists a Brownian motion W with

$$M_t = \int_0^t \sqrt{\frac{d\langle M \rangle_s}{ds}} dW_s \quad \text{for all } t \geq 0$$

Proof Assume that the probability space is rich enough to carry a Brownian motion $\widetilde{W}$ that is independent of M . Let

$$f_t := \lim_{n \rightarrow \infty} n (\langle M \rangle_t - \langle M \rangle_{t-1/n}) \quad \text{for } t > 0$$

Then f is a progressively measurable version of the Radon-Nikodym derivative $\frac{d\langle M \rangle_t}{dt}$. Clearly, $\int_0^T \mathbb{1}_{\{f_t > 0\}} f_t^{-1} d\langle M \rangle_t \leq T < \infty$ for all $T > 0$. Hence the following integrals are well-defined, and furthermore, as a sum of continuous martingales,

$$W_t := \int_0^t \mathbb{1}_{\{f_s > 0\}} f_s^{-1/2} dM_s + \int_0^t \mathbb{1}_{\{f_s = 0\}} d\widetilde{W}_s$$

is a continuous local martingale. By Theorem 25.22, we have

$$\begin{aligned} \langle W \rangle_t &= \int_0^t \mathbb{1}_{\{f_s > 0\}} f_s^{-1} d\langle M \rangle_s + \int_0^t \mathbb{1}_{\{f_s = 0\}} ds \\ &= \int_0^t \mathbb{1}_{\{f_s > 0\}} f_s^{-1} f_s ds + \int_0^t \mathbb{1}_{\{f_s = 0\}} ds = t \end{aligned}$$

Hence, by Theorem 25.28, W is a Brownian motion. On the other hand, we have

$$\begin{aligned} \int_0^t f_s^{1/2} dW_s &= \int_0^t \mathbb{1}_{\{f_s > 0\}} f_s^{1/2} f_s^{-1/2} dM_s + \int_0^t \mathbb{1}_{\{f_s = 0\}} f_s^{1/2} d\widetilde{W}_s \\ &= \int_0^t \mathbb{1}_{\{f_s > 0\}} dM_s \end{aligned}$$

However,

$$M_t - \int_0^t \mathbb{1}_{\{f_s > 0\}} dM_s = \int_0^t \mathbb{1}_{\{f_s = 0\}} dM_s$$

is a continuous local martingale with square variation $\int_0^t \mathbb{1}_{\{f_s = 0\}} d\langle M \rangle_s = 0$ and hence it almost surely equals zero. Therefore, we have $M_t = \int_0^t f_s^{1/2} dW_s$, as claimed.

We come next to a multidimensional version of the pathwise Itô formula. To this end, let $\mathcal{C}_{\text{qv}}^d$ be the space of continuous maps $X : [0, \infty) \rightarrow \mathbb{R}^d$, $t \mapsto X_t = (X_t^1, \dots, X_t^d)$ such that, for $k, l = 1, \dots, d$, the quadratic covariation (see Definition 21.58) $\langle X^k, X^l \rangle$ exists and is continuous. Further, let $C^2(\mathbb{R}^d)$ be the space of twice continuously differentiable functions F on $\mathbb{R}^d$ with partial derivatives $\partial_k F$ and $\partial_k \partial_l F$, $k, l = 1, \dots, d$. Denote by ∇ the gradient and by $\Delta = (\partial_1^2 + \dots + \partial_d^2)$ the Laplace operator.

Theorem 25.30 (Multidimensional pathwise Itô formula) Let $X \in \mathcal{C}_{\text{qv}}^d$ and $F \in C^2(\mathbb{R}^d)$. Then

$$F(X_T) - F(X_0) = \int_0^T \nabla F dX_s + \frac{1}{2} \sum_{k,l=1}^d \int_0^T \partial_k \partial_l F(X_s) d\langle X^k, X^l \rangle_s$$

where

$$\int_0^T \nabla F(X_s) dX_s := \lim_{n \rightarrow \infty} \sum_{t \in \mathcal{P}_T^n} \sum_{k=1}^d \partial_k F(X_t) (X_t^k - X_{t'}^k)$$

Proof This works just as in the one-dimensional case. We leave the details as an exercise.

Remark 25.31 If each of the integrals $\int_0^T \partial_k F(X_s) dX_s^k$ exists, then

$$\int_0^T \nabla F(X_s) dX_s = \sum_{k=1}^d \int_0^T \partial_k F(X_s) dX_s^k$$

Note that existence of the individual integrals does not follow from the existence of the integral $\int_0^T \nabla F(X_s) dX_s$.

Corollary 25.32 (Product rule) If $X, Y, X - Y, X + Y \in \mathcal{C}_{qv}$, then

$$X_T Y_T = X_0 Y_0 + \int_0^T Y_s dX_s + \int_0^T X_s dY_s + \langle X, Y \rangle_T \quad \text{for all } T \geq 0$$

if both integrals exist. In particular, the product rule holds if X and Y are continuous local martingales.

Proof By assumption (and using the polarization formula), the covariation $\langle X, Y \rangle$ exists. Applying Theorem 25.30 with $F(x, y) = xy$, the claim follows.

For continuous local martingales, by Exercise 25.2.1, there exists a suitable sequence of partitions $\mathcal{P}$ such that the integrals exist (pathwise).

Now let $Y = M + A$ be a d -dimensional generalized diffusion. Hence

$$M_t^k = \sum_{l=1}^d \int_0^t \sigma_s^{k,l} dW_s^l \quad \text{and} \quad A_t^k = \int_0^t b_s^k ds \quad \text{for } t \geq 0, k = 1, \dots, d$$

Here $W = (W^1, \dots, W^d)$ is a d -dimensional Brownian motion and $\sigma^{k,l}$ (respectively b^k) are progressively measurable, locally square integrable (respectively locally integrable) stochastic processes for every $k, l = 1, \dots, d$. Since $\langle W^k, W^l \rangle_t = t \cdot \mathbb{1}_{\{k=l\}}$, we have $\langle Y^k, Y^l \rangle_t = \langle M^k, M^l \rangle_t = \int_0^t a_s^{k,l} ds$, where

$$a_s^{k,l} := \sum_{i=1}^d \sigma_s^{k,i} \sigma_s^{i,l}$$

is the covariance matrix of the diffusion M . In particular, we have $M \in \mathcal{C}_{qv}^d$ almost surely. Note that (by Exercise 25.2.1), there exists a partition sequence $\mathcal{P}$ such that the integrals $\int_0^t \sigma_s^{k,l} \partial_k F(Y_s) dW_s^l$ in (25.17) exist in the pathwise sense. As a corollary of the multidimensional pathwise Itô formula (Theorem 25.30 and Remark 25.31), we thus get the following theorem.

Theorem 25.33 (Multidimensional Itô formula) Let Y be as above and let $F \in C^2(\mathbb{R}^d)$. Then

$$\begin{aligned}
F(Y_T) - F(Y_0) &= \int_0^T \nabla F(Y_s) dY_s + \frac{1}{2} \sum_{k,l=1}^d \int_0^T \partial_k \partial_l F(Y_s) d\langle M^k, M^l \rangle_s \\
&= \sum_{k,l=1}^d \int_0^t \sigma_s^{k,l} \partial_k F(Y_s) dW_s^l + \sum_{k=1}^d \int_0^t b_s^k \partial_k F(Y_s) ds \\
&\quad + \frac{1}{2} \sum_{k,l=1}^d \int_0^t a_s^{k,l} \partial_k \partial_l F(Y_s) ds
\end{aligned} \tag{25.17}$$

In particular, for Brownian motion, we have

$$F(W_t) - F(W_0) = \sum_{k=1}^d \int_0^t \partial_k F(W_s) dW_s^k + \frac{1}{2} \int_0^t \Delta F(W_s) ds \tag{25.18}$$

Corollary 25.34 The process $(F(W_t))_{t \geq 0}$ is a continuous local martingale if and only if F is harmonic (that is, $\Delta F \equiv 0$).

Proof If F is harmonic, then as a sum of Itô integrals, $F(W_t) = F(W_0) + \sum_{k=1}^d \int_0^t \partial_k F(W_s) dW_s^k$ is a continuous local martingale.

On the other hand, if F is a continuous local martingale, then as a difference of continuous local martingales, $\int_0^t \Delta F(W_s) ds$ is also a continuous local martingale. As $t \mapsto \int_0^t \Delta F(W_s) ds$ has finite variation, we have $\int_0^t \Delta F(W_s) ds = 0$ for all $t \geq 0$ almost surely (by Corollary 21.72). Hence $\Delta F \equiv 0$.

Corollary 25.35 (Time-dependent Itô formula) If $F \in C^{2,1}(\mathbb{R}^d \times \mathbb{R})$, then

$$\begin{aligned}
&F(W_T, T) - F(W_0, 0) \\
&= \sum_{k=1}^d \int_0^T \partial_k F(W_s, s) dW_s^k + \int_0^T \left(\partial_{d+1} + \frac{1}{2} (\partial_1^2 + \dots + \partial_d^2) \right) F(W_s, s) ds
\end{aligned}$$

Proof Apply Theorem 25.33 to $Y = (W_t^1, \dots, W_t^d, t)_{t \geq 0}$.

Exercise 25.3.1 (Fubini's theorem for Itô integrals) Let $X \in \mathcal{C}_{\text{qv}}$ and assume that $g : [0, \infty)^2 \rightarrow \mathbb{R}$ is continuous and (in the interior) twice continuously differentiable in the second coordinate with derivative $\partial_2 g$. Use the product rule (Corollary 25.32) to show that

$$\int_0^s \left(\int_0^t g(u, v) du \right) dX_v = \int_0^t \left(\int_0^s g(u, v) dX_v \right) du$$

and

$$\int_0^s \left(\int_0^v g(u, v) du \right) dX_v = \int_0^s \left(\int_u^s g(u, v) dX_v \right) du$$

Exercise 25.3.2 (Stratonovich integral) Let $\mathcal{P}$ be an admissible sequence of partitions, $X \in \mathcal{C}_{\text{qv}}^{\mathcal{P}}$ and $F \in C^2(\mathbb{R})$ with derivative $f = F'$. Show that, for every $t \geq 0$, the Stratonovich integral

$$\int_0^T f(X_t) \circ dX_t := \lim_{n \rightarrow \infty} \sum_{t \in \mathcal{P}_T^n} f\left(\frac{X_{t'} + X_t}{2}\right) (X_{t'} - X_t)$$

is well-defined, and that the classical substitution rule

$$F(X_T) - F(X_0) = \int_0^T F'(X_t) \circ dX_t$$

holds. Show that, in contrast with the Itô integral, the Stratonovich integral with respect to a continuous local martingale is, in general, not a local martingale.

5.25.4 25.4 Dirichlet Problem and Brownian Motion

As for discrete Markov chains (compare Section 19.1), the solutions of the Dirichlet problem in a domain $G \subset \mathbb{R}^d$ can be expressed in terms of a d -dimensional Brownian motion that is stopped upon hitting the boundary G .

In the following, let $G \subset \mathbb{R}^d$ be a bounded open set.

Definition 25.36 (Dirichlet problem) Let $f : \partial G \rightarrow \mathbb{R}$ be continuous. A function $u : \bar{G} \rightarrow \mathbb{R}$ is called a solution of the Dirichlet problem on G with boundary value f if u is continuous, twice differentiable in G and

$$\begin{aligned} \Delta u(x) &= 0 \text{ for } x \in G, \\ u(x) &= f(x) \text{ for } x \in \partial G. \end{aligned} \quad (25.19)$$

For sufficiently smooth domains, there always exists a solution of the Dirichlet problem (see, e.g., [79, Section 4.4]). If there is a solution, then as a consequence of Theorem 25.38, it is unique.

In the following, let $W = (W^1, \dots, W^d)$ be a d -dimensional Brownian motion with respect to a filtration $\mathbb{F}$ that satisfies the usual conditions. We write $\mathbf{P}_x$ and $\mathbf{E}_x$ for probabilities and expectations if W is started at $W_0 = x = (x^1, \dots, x^d) \in \mathbb{R}^d$. If $A \subset \mathbb{R}^d$ is open, then

$$\tau_{A^c} := \inf \{t > 0 : W_t \in A^c\}$$

is an $\mathbb{F}$ -stopping time (see Exercise 21.4.4). Since G is bounded, we have $G \subset (-a, a) \times \mathbb{R}^{d-1}$ for some $a > 0$. Thus $\tau_{G^c} \leq \tau_{((-a,a) \times \mathbb{R}^{d-1})^c}$. By Exercise 21.2.4 (applied to W^1), for $x \in G$,

$$\mathbf{E}_x[\tau_{G^c}] \leq \mathbf{E}_x\left[\tau_{((-a,a) \times \mathbb{R}^{d-1})^c}\right] = (a - x^1)(a + x^1) < \infty. \quad (25.20)$$

In particular, $\tau_{G^c} < \infty$ $\mathbf{P}_x$ -almost surely. Hence $W_{\tau_{G^c}}$ is a $\mathbf{P}_x$ -almost surely welldefined random variable with values in ∂G .

Definition 25.37 For $x \in G$, denote by

$$\mu_{x,G} = \mathbf{P}_x \circ W_{\tau_{G^c}}^{-1}$$

the harmonic measure on ∂G .

Theorem 25.38 If u is a solution of the Dirichlet problem on G with boundary value f , then

$$u(x) = \mathbf{E}_x[f(W_{\tau_{G^c}})] = \int_{\partial G} f(y) \mu_{x,G}(dy) \quad \text{for } x \in G \quad (25.21)$$

In particular, the solution of the Dirichlet problem is always unique.

Proof Let $G_1 \subset G_2 \subset \dots$ be a sequence of open sets with $x \in G_1, G_n \uparrow G$ and $\bar{G}_n \subset G$ for every $n \in \mathbb{N}$. Hence, in particular, every $\bar{G}_n$ is compact and thus ∇u is bounded on $\bar{G}_n$. We abbreviate $\tau := \tau_{G^c}$ and $\tau_n := \tau_{G_n^c}$.

As u is harmonic (that is, $\Delta u = 0$), by the Itô formula, for $t < \tau$,

$$u(W_t) = u(W_0) + \int_0^t \nabla u(W_s) dW_s = u(W_0) + \sum_{k=1}^d \int_0^t \partial_k u(W_s) dW_s^k \quad (25.22)$$

In particular, $M := (u(W_t))_{t \in [0, \tau]}$ is a local martingale up to τ (however, in general, it is not a martingale). For $t < \tau_n$, we have

$$(\partial_k u(W_s))^2 \leq C_n := \sup_{y \in \bar{G}_n} \|\nabla u(y)\|_2^2 < \infty \quad \text{for all } k = 1, \dots, d.$$

Hence, by (25.20),

$$\mathbf{E} \left[\int_0^{\tau_n} (\partial_k u(W_s))^2 ds \right] \leq C_n \mathbf{E}_x [\tau_n] \leq C_n \mathbf{E}[\tau] < \infty$$

Thus, by Theorem 25.17(ii), for every $n \in \mathbb{N}$, the stopped process M^{τ_n} is a martingale. Therefore,

$$\mathbf{E}_x [u(W_{\tau_n})] = \mathbf{E}_x [M_{\tau_n}] = \mathbf{E}_x [M_0] = u(x). \quad (25.23)$$

As W is continuous and $\tau_n \uparrow \tau$, we have $W_{\tau_n} \xrightarrow{n \rightarrow \infty} W_\tau \in \partial G$. Since u is continuous, we get

$$u(W_{\tau_n}) \xrightarrow{n \rightarrow \infty} u(W_\tau) = f(W_\tau). \quad (25.24)$$

Again, since u is continuous and $\bar{G}$ is compact, u is bounded. By the dominated convergence theorem, (25.24) implies convergence of the expectations; that is (also using (25.23)),

$$u(x) = \lim_{n \rightarrow \infty} \mathbf{E}_x [u(W_{\tau_n})] = \mathbf{E}_x [f(W_\tau)]$$

Exercise 25.4.1 Let $G = \mathbb{R} \times (0, \infty)$ be the open upper half plane of $\mathbb{R}^2$ and $x = (x_1, x_2) \in G$. Show that $\tau_{G^c} < \infty$ almost surely and that the harmonic measure $\mu_{x,G}$ on $\mathbb{R} \cong \partial G$ is the Cauchy distribution with scale parameter x_2 that is shifted by x_1 : $\mu_{x,G} = \delta_{x_1} * \text{Cau}_{x_2}$.

Exercise 25.4.2 Let $d \geq 3$ and let $G = \mathbb{R}^{d-1} \times (0, \infty)$ be an open half space of $\mathbb{R}^d$. Let $x = (x_1, \dots, x_d) \in G$. Show that $\tau_{G^c} < \infty$ almost surely and that the harmonic measure $\mu_{x,G}$ on $\mathbb{R}^{d-1} \cong \partial G$ has the density

$$\frac{\mu_{x,G}(dy)}{dy} = \frac{\Gamma(d/2)}{\pi^{d/2}} \frac{x_d}{\sqrt{(x_1 - y_1)^2 + \dots + (x_{d-1} - y_{d-1})^2 + x_d^2}}.$$

Exercise 25.4.3 Let $r > 0$ and let $B_r(0) \subset \mathbb{R}^d$ be the open ball with radius r centered at the origin. For $x \in B_r(0)$, determine the harmonic measure $\mu_{x,B_r(0)}$.

5.25.5 25.5 Recurrence and Transience of Brownian Motion

By Pólya's theorem (Theorem 17.39), symmetric simple random walk $(X_n)_{n \in \mathbb{N}}$ on $\mathbb{Z}^d$ is recurrent (that is, it visits every point infinitely often) if and only if $d \leq 2$. If $d > 2$, then the random walk is transient and eventually leaves every bounded set $A \subset \mathbb{Z}^d$. To give a slightly different (though equivalent) formulation of this,

$$\liminf_{n \rightarrow \infty} \|X_n\| = 0 \quad \text{a.s.} \quad \Longleftrightarrow \quad d \leq 2$$

and

$$\lim_{n \rightarrow \infty} \|X_n\| = \infty \quad \text{a.s.} \quad \Longleftrightarrow \quad d > 2.$$

The main result of this section is that a similar dichotomy also holds for Brownian motion.

Theorem 25.39 Let $W = (W^1, \dots, W^d)$ be a d -dimensional Brownian motion.

(i) If $d \leq 2$, then W is recurrent in the sense that

$$\liminf_{t \rightarrow \infty} \|W_t - y\| = 0 \quad \text{a.s.} \quad \text{for every } y \in \mathbb{R}^d$$

In particular, almost surely the path $\{W_t : t \geq 0\}$ is dense in $\mathbb{R}^d$.

(ii) If $d > 2$, then W is transient in the sense that

$$\lim_{t \rightarrow \infty} \|W_t\| = \infty \quad \text{a.s.}$$

and for any $y \in \mathbb{R}^d \setminus \{0\}$, we have $\inf \{\|W_t - y\| : t \geq 0\} > 0$ almost surely.

The basic idea of the proof is to use a suitable Dirichlet problem (and the result of Section 25.4) to compute the probabilities for W to hit certain balls,

$$B_R(x) := \{y \in \mathbb{R}^d : \|x - y\| < R\}.$$

Let $0 < r < R < \infty$ and let $G_{r,R}$ be the annulus

$$G_{r,R} := B_R(0) \setminus \bar{B}_r(0) = \{x \in \mathbb{R}^d : r < \|x\| < R\}$$

Recall that, for closed $A \subset \mathbb{R}^d$, we write $\tau_A = \inf \{t > 0 : W_t \in A\}$ for the stopping time of first entrance into A . We further write

$$\tau_s := \inf \{t > 0 : \|W_t\| = s\} \quad \text{and} \quad \tau_{r,R} = \inf \{t > 0 : W_t \notin G_{r,R}\}.$$

If we start W at $W_0 \in G_{r,R}$, then clearly $\tau_{r,R} = \tau_r \wedge \tau_R$. On the boundary of $G_{r,R}$, define the function f by

$$f(x) = \begin{cases} 1, & \text{if } \|x\| = r \\ 0, & \text{if } \|x\| = R \end{cases} \quad (25.25)$$

Define $u_{r,R} : \bar{G}_{r,R} \rightarrow \mathbb{R}$ by

$$u_{r,R}(x) = \frac{V(\|x\|) - V(R)}{V(r) - V(R)}$$

where $V : (0, \infty) \rightarrow \mathbb{R}$ is Newton's potential function

$$V(s) = V_d(s) = \begin{cases} s, & \text{if } d = 1 \\ \log(s), & \text{if } d = 2 \\ -s^{2-d}, & \text{if } d > 2 \end{cases} \quad (25.26)$$

It is easy to check that $\varphi : \mathbb{R}^d \setminus \{0\} \rightarrow \mathbb{R}, x \mapsto V_d(\|x\|)$ is harmonic (that is, $\Delta \varphi \equiv 0$). Hence $u_{r,R}$ is the solution of the Dirichlet problem on $G_{r,R}$ with boundary value f .

By Theorem 25.38, for $x \in G_{r,R}$,

$$\mathbf{P}_x[\tau_{r,R} = \tau_r] = \mathbf{P}_x[\|W_{\tau_{r,R}}\| = r] = \mathbf{E}_x[f(W_{\tau_{r,R}})] = u_{r,R}(x). \quad (25.27)$$

Theorem 25.40 For $r > 0$ and $x, y \in \mathbb{R}^d$ with $\|x - y\| > r$, we have

$$\mathbf{P}_x[W_t \in B_r(y) \text{ for some } t > 0] = \begin{cases} 1, & \text{if } d \leq 2, \\ \left(\frac{\|x-y\|}{r}\right)^{2-d}, & \text{if } d > 2. \end{cases}$$

Proof Without loss of generality, assume $y = 0$. Then

$$\begin{aligned}\mathbf{P}_x[\tau_r < \infty] &= \lim_{R \rightarrow \infty} \mathbf{P}_x[\tau_{r,R} = \tau_r] = \lim_{R \rightarrow \infty} \frac{V(\|x\|) - V(R)}{V(r) - V(R)} \\ &= \begin{cases} 1, & \text{if } d = 2, \\ \frac{V_d(\|x\|)}{V_d(r)}, & \text{if } d > 2, \end{cases}\end{aligned}$$

since $\lim_{R \rightarrow \infty} V_d(R) = \infty$ if $d \leq 2$ and $= 0$ if $d > 2$.

Proof of Theorem 25.39 Using the strong Markov property of Brownian motion, we get for $r > 0$

$$\begin{aligned}\mathbf{P}_x \left[\liminf_{t \rightarrow \infty} \|W_t\| < s \right] &= \mathbf{P}_x \left[\bigcup_{s \in (0, r)} \bigcap_{R > \|x\|} \{ \|W_t\| < r \text{ for some } t > \tau_R \} \right] \\ &= \sup_{s \in (0, r)} \inf_{R > \|x\|} \mathbf{P}_x [\|W_t\| \leq s \text{ for some } t > \tau_R] \\ &= \sup_{s \in (0, r)} \inf_{R > \|x\|} \mathbf{P}_x [\mathbf{P}_{W_{\tau_R}}[\tau_s < \infty]]\end{aligned}$$

However, by Theorem 25.40 (since $\|W_{\tau_R}\| = R$ for $R > \|x\|$), we have

$$\mathbf{P}_{W_{\tau_R}}[\tau_s < \infty] = \begin{cases} 1, & \text{if } d \leq 2 \\ (s/R)^{d-2}, & \text{if } d > 2 \end{cases}$$

Therefore,

$$\mathbf{P} \left[\liminf_{t \rightarrow \infty} \|W_t\| < r \right] = \begin{cases} 1, & \text{if } d \leq 2 \\ 0, & \text{if } d > 2 \end{cases}$$

This implies the claim.

Definition 25.41 (Polar set) A set $A \subset \mathbb{R}^d$ is called polar if

$$\mathbf{P}_x[W_t \notin A \text{ for all } t > 0] = 1 \quad \text{for all } x \in \mathbb{R}^d.$$

Theorem 25.42 If $d = 1$, then only the empty set is polar. If $d \geq 2$, then $\{y\}$ is polar for every $y \in \mathbb{R}^d$.

Proof For $d = 1$, the statement is obvious since

$$\limsup_{t \rightarrow \infty} W_t = \infty \quad \text{and} \quad \liminf_{t \rightarrow \infty} W_t = -\infty \quad \text{a.s.}$$

Hence, due to the continuity of W , every point $y \in \mathbb{R}$ will be hit (infinitely often).

Now let $d \geq 2$. Without loss of generality, assume $y = 0$. If $x \neq 0$, then

$$\begin{aligned}\mathbf{P}_x[\tau_{\{0\}} < \infty] &= \lim_{R \rightarrow \infty} \mathbf{P}_x[\tau_{\{0\}} < \tau_R] \\ &= \lim_{R \rightarrow \infty} \inf_{r > 0} \mathbf{P}_x[\tau_{r,R} = \tau_r] \\ &= \lim_{R \rightarrow \infty} \inf_{r > 0} u_{r,R}(x) = 0\end{aligned} \tag{25.28}$$

since $V_d(r) \xrightarrow{r \rightarrow 0} -\infty$ if $d \geq 2$.

On the other hand, if $x = 0$, then the strong Markov property of Brownian motion (and the fact that $\mathbf{P}_0[W_t = 0] = 0$ for all $t > 0$) implies

$$\begin{aligned}
\mathbf{P}_0 [\tau_{\{0\}} < \infty] &= \sup_{t>0} \mathbf{P}_0 [W_s = 0 \text{ for some } s \geq t] \\
&= \sup_{t>0} \mathbf{P}_0 [\mathbf{P}_{W_t} [\tau_{\{0\}} < \infty]] = 0
\end{aligned}$$

Note that in the last step, we used (25.28).

5.26 26 Stochastic Differential Equations

Stochastic differential equations describe the time evolution of certain continuous Markov processes with values in $\mathbb{R}^n$. In contrast with classical differential equations, in addition to the derivative of the function, there is a term that describes the random fluctuations that are coded as an Itô integral with respect to a Brownian motion. Depending on how seriously we take the concrete Brownian motion as the driving force of the noise, we speak of strong and weak solutions. In the first section, we develop the theory of strong solutions under Lipschitz conditions for the coefficients. In the second section, we develop the so-called (local) martingale problem as a method of establishing weak solutions. In the third section, we present some examples in which the method of duality can be used to prove weak uniqueness.

As stochastic differential equations are a very broad subject, and since things quickly become very technical, we only excursively touch some of the most important results, partly without proofs, and illustrate them with examples.

5.26.1 26.1 Strong Solutions

Consider a stochastic differential equation (SDE) of the type

$$\begin{aligned}
X_0 &= \xi \\
dX_t &= \sigma(t, X_t) dW_t + b(t, X_t) dt
\end{aligned} \tag{26.1}$$

Here $W = (W^1, \dots, W^m)$ is an m -dimensional Brownian motion, ξ is an $\mathbb{R}^n$ valued random variable with distribution μ that is independent of W , $\sigma(t, x) = (\sigma_{ij}(t, x))_{\substack{i=1, \dots, n \\ j=1, \dots, m}}$ is a real $n \times m$ matrix and $b(t, x) = (b_i(t, x))_{i=1, \dots, n}$ is an n dimensional vector. Assume the maps $(t, x) \mapsto \sigma_{ij}(t, x)$ and $(t, x) \mapsto b_i(t, x)$ are measurable.

By a solution of (26.1) we understand a continuous adapted stochastic process X with values in $\mathbb{R}^n$ that satisfies the integral equation

$$X_t = \xi + \int_0^t \sigma(s, X_s) dW_s + \int_0^t b(s, X_s) ds \quad \mathbf{P}\text{-a.s. for all } t \geq 0 \tag{26.2}$$

Written in full, this is

$$X_t^i = \xi^i + \sum_{j=1}^m \int_0^t \sigma_{ij}(s, X_s) dW_s^j + \int_0^t b_i(s, X_s) ds \quad \text{for all } i = 1, \dots, n$$

Now the following problem arises: To which filtration $\mathbb{F}$ do we wish X to be adapted? Should it be the filtration that is generated by ξ and W , or do we allow $\mathbb{F}$ to be larger? Already for ordinary differential equations, depending on the equation, uniqueness of the solution may fail (although existence is usually not a problem); for example, for $f' = |f|^{1/3}$. If $\mathbb{F}$ is larger than the filtration generated by W , then we can define further random variables that select one out of a variety of possible solutions. We thus have more possibilities for solutions than if $\mathbb{F} = \sigma(W)$. Indeed, it will turn out that in some situations for the existence of a solution, it

is necessary to allow a larger filtration. Roughly speaking, X is a strong solution of (26.1) if (26.2) holds and if X is adapted to $\mathbb{F} = \sigma(W)$. On the other hand, X is a weak solution if X is adapted to a larger filtration $\mathbb{F}$ with respect to which W is still a martingale. Weak solutions will be dealt with in Section 26.2.

Definition 26.1 (Strong solution) We say that the stochastic differential equation (SDE) (26.1) has a strong solution X if there exists a map $F : \mathbb{R}^n \times C([0, \infty); \mathbb{R}^m) \rightarrow C([0, \infty); \mathbb{R}^n)$ with the following properties:

- (i) For every $t \geq 0$, the map $(x, w) \mapsto F(x, w)$ is measurable with respect to $\mathcal{B}(\mathbb{R}^n) \otimes \mathcal{G}_t^m - \mathcal{G}_t^n$, where (for $k = m$ or $k = n$) $\mathcal{G}_t^k := \sigma(\pi_s : s \in [0, t])$ is the σ algebra generated by the coordinate maps $\pi_s : C([0, \infty); \mathbb{R}^k) \rightarrow \mathbb{R}, w \mapsto w(s)$.
- (ii) The process $X = F(\xi, W)$ satisfies (26.2).

Condition (i) says that the path $(X_s)_{s \in [0, t]}$ depends only on ξ and $(W_s)_{s \in [0, t]}$ but not on further information. In particular, X is adapted to $\mathcal{F}_t = \sigma(\xi, W_s : s \in [0, t])$ and is progressively measurable; hence the Itô integral in (26.2) is well-defined if σ and b do not grow too quickly for large x .

Remark 26.2 Clearly, a strong solution of an SDE is a generalized n -dimensional diffusion. If the coefficients σ and b are independent of t , then the solution is an n -dimensional diffusion.

Remark 26.3 Let X be a strong solution and let F be as in Definition 26.1. If W' is an m -dimensional Brownian motion on a space $(\Omega', \mathcal{F}', \mathbf{P}')$ with filtration $\mathbb{F}'$, and if ξ' is independent of W' and is $\mathcal{F}'_0$ -measurable, then $X' = F(\xi', W')$ satisfies the integral equation (26.2). Hence, it is a strong solution of (26.1) with W replaced by W' . Thus the existence of a strong solution does not depend on the actual realization of the Brownian motion or on the filtration $\mathbb{F}$. $\square$

Definition 26.4 We say that the SDE (26.1) has a unique strong solution if there exists an F as in Definition 26.1 such that:

- (i) If W is an m -dimensional Brownian motion on some probability space $(\Omega, \mathcal{F}, \mathbf{P})$ with filtration $\mathbb{F}$ and if ξ is an $\mathcal{F}_0$ -measurable random variable that is independent of W and such that $\mathbf{P} \circ \xi^{-1} = \mu$, then $X := F(\xi, W)$ is a solution of (26.2).
- (ii) For every solution (X, W) of (26.2), we have $X = F(\xi, W)$.

Example 26.5 Let $m = n = 1, b \in \mathbb{R}$ and $\sigma > 0$. The Ornstein-Uhlenbeck process

$$X_t := e^{bt}\xi + \sigma \int_0^t e^{(t-s)b} dW_s, \quad t \geq 0 \quad (26.3)$$

is a strong solution of the SDE $dX_t = \sigma dW_t + bX_t dt$ and

$$dX_t = \sigma dW_t + bX_t dt$$

In the language of Definition 26.1, we have (in the sense of the pathwise Itô integral with respect to w)

$$F(x, w) = \left(t \mapsto e^{bt}x + \int_0^t e^{(t-s)b} dw(s) \right)$$

for all $w \in \mathcal{C}_{\text{qv}}$ (that is, with continuous square variation). Since $\mathbf{P}[W \in \mathcal{C}_{\text{qv}}] = 1$, we can define $F(x, w) = 0$ for $w \in C([0, \infty); \mathbb{R}) \setminus \mathcal{C}_{\text{qv}}$.

Indeed, by Fubini's theorem for Itô integrals, we have (Exercise 25.3.1)

$$\begin{aligned}
& \xi + \int_0^t \sigma dW_s + \int_0^t bX_s ds \\
&= \xi + \sigma W_t + \int_0^t b e^{bs} \xi ds + \int_0^t \sigma b \left(\int_0^s e^{b(s-r)} dW_r \right) ds \\
&= \xi + \sigma W_t + (e^{bt} - 1) \xi + \int_0^t \sigma \left(\int_r^t b e^{b(s-r)} ds \right) dW_r \\
&= e^{bt} \xi + \int_0^t (\sigma + (e^{b(t-r)} - 1) \sigma) dW_r \\
&= X_t
\end{aligned}$$

It can be shown (see Theorem 26.8) that the solution is also (strongly) unique. $\square$

Example 26.6 Let $\alpha, \beta \in \mathbb{R}$. The one-dimensional SDE $X_0 = \xi$ and

$$dX_t = \alpha X_t dW_t + \beta X_t dt \quad (26.4)$$

has the strong solution

$$X_t = \xi \exp \left(\alpha W_t + \left(\beta - \frac{\alpha^2}{2} \right) t \right)$$

In the language of Definition 26.1, we have $\sigma(t, x) = \alpha x$, $b(t, x) = \beta x$ and

$$F(x, w) = \left(t \mapsto x \exp \left(\alpha w(t) + \left(\beta - \frac{\alpha^2}{2} \right) t \right) \right)$$

for all $w \in C([0, \infty); \mathbb{R})$ and $x \in \mathbb{R}$. Indeed, by the time-dependent Itô formula (Corollary 25.35),

$$X_t = \xi + \int_0^t \alpha X_s dW_s + \int_0^t \left(\left(\beta - \frac{\alpha^2}{2} \right) + \frac{1}{2} \alpha^2 \right) X_s ds$$

Also in this case, we have strong uniqueness of the solution (see Theorem 26.8). The process X is called a geometric Brownian motion and, for example, serves in the so-called Black-Scholes model as the process of stock prices.

We give a simple criterion for existence and uniqueness of strong solutions. For an $n \times m$ matrix A , define the Hilbert-Schmidt norm

$$\|A\| = \sqrt{\text{trace}(AA^T)} = \sqrt{\sum_{i=1}^n \sum_{j=1}^m A_{i,j}^2}. \quad (26.5)$$

For $b \in \mathbb{R}^n$, we use the Euclidean norm $\|b\|$. Since all norms on finite-dimensional vector spaces are equivalent, it is not important exactly which norm we use. However, the Hilbert-Schmidt norm simplifies the computations, as the following lemma shows.

Lemma 26.7 Let $t \mapsto H(t) = (H_{ij}(t))_{i=1, \dots, n, j=1, \dots, m}$ be progressively measurable and $\mathbf{E} \left[\int_0^T H_{ij}^2(t) dt \right] < \infty$ for all i, j . Then

$$\mathbf{E} \left[\left\| \int_0^T H(t) dW_t \right\|^2 \right] = \mathbf{E} \left[\int_0^T \|H(t)\|^2 dt \right] \quad (26.6)$$

where $\|H\|$ is the Hilbert-Schmidt norm from (26.5).

Proof For $i = 1, \dots, n$, the process $I_i(t) := \sum_{j=1}^m \int_0^t H_{ij}(s) dW_s^j$ is a continuous martingale with square variation process $\langle I_i \rangle_t = \int_0^t \sum_{j=1}^m H_{ij}^2(s) ds$. Hence

$$\mathbf{E} [(I_i(T))^2] = \mathbf{E} \left[\int_0^T \sum_{j=1}^m H_{ij}^2(s) ds \right]$$

The left-hand side in (26.6) equals

$$\sum_{i=1}^n \mathbf{E} [(I_i(T))^2] = \mathbf{E} \left[\int_0^T \sum_{i=1}^n \sum_{j=1}^m H_{ij}^2(s) ds \right]$$

Hence the claim follows by the definition of $\|H(s)\|^2$.

Theorem 26.8 Let b and σ be Lipschitz continuous in the first coordinate. That is, we assume that there exists a $K > 0$ such that, for all $x, x' \in \mathbb{R}^n$ and $t \geq 0$,

$$\|\sigma(x, t) - \sigma(x', t)\| + \|b(x, t) - b(x', t)\| \leq K \|x - x'\|. \quad (26.7)$$

Further, assume the growth condition

$$\|\sigma(t, x)\|^2 + \|b(t, x)\|^2 \leq K^2 (1 + \|x\|^2) \quad \text{for all } x \in \mathbb{R}^n, t \geq 0. \quad (26.8)$$

Then, for every initial point $X_0 = x \in \mathbb{R}^n$, there exists a unique strong solution X of the SDE (26.1). This solution is a Markov process and in the case where σ and b do not depend on t , it is a strong Markov process.

As the main tool, we need the following lemma.

Lemma 26.9 (Gronwall) Let $f, g : [0, T] \rightarrow \mathbb{R}$ be integrable and let $C > 0$ such that

$$f(t) \leq g(t) + C \int_0^t f(s) ds \quad \text{for all } t \in [0, T] \quad (26.9)$$

Then

$$f(t) \leq g(t) + C \int_0^t e^{C(t-s)} g(s) ds \quad \text{for all } t \in [0, T]$$

In particular, if $g(t) \equiv G$ is constant, then $f(t) \leq Ge^{Ct}$ for all $t \in [0, T]$.

Proof Let $F(t) = \int_0^t f(s) ds$ and $h(t) = F(t)e^{-Ct}$. Then, by (26.9),

$$\frac{d}{dt} h(t) = f(t)e^{-Ct} - CF(t)e^{-Ct} \leq g(t)e^{-Ct}$$

Integration yields

$$F(t) = e^{Ct} h(t) \leq \int_0^t e^{C(t-s)} g(s) ds$$

Substituting this into (26.9) gives

$$f(t) \leq g(t) + CF(t) \leq g(t) + C \int_0^t g(s) e^{C(t-s)} ds$$

Proof of Theorem 26.8 It is enough to show that, for every $T < \infty$, there exists a unique strong solution up to time T .

Uniqueness. We first show uniqueness of the solution. Let X and X' be two solutions of (26.2). Then

$$X_t - X'_t = \int_0^t (b(s, X_s) - b(s, X'_s)) ds + \int_0^t (\sigma(s, X_s) - \sigma(s, X'_s)) dW_s$$

Hence

$$\begin{aligned} \|X_t - X'_t\|^2 &\leq 2 \left\| \int_0^t (b(s, X_s) - b(s, X'_s)) ds \right\|^2 \\ &\quad + 2 \left\| \int_0^t (\sigma(s, X_s) - \sigma(s, X'_s)) dW_s \right\|^2 \end{aligned} \quad (26.10)$$

For the first summand in (26.10), use the Cauchy-Schwarz inequality, and for the second one use Lemma 26.7 to obtain

$$\begin{aligned} \mathbf{E} [\|X_t - X'_t\|^2] &\leq 2t \int_0^t \mathbf{E} [\|b(s, X_s) - b(s, X'_s)\|^2] ds \\ &\quad + 2 \int_0^t \mathbf{E} [\|\sigma(s, X_s) - \sigma(s, X'_s)\|^2] ds \end{aligned}$$

Write $f(t) = \mathbf{E} [\|X_t - X'_t\|^2]$ and $C := 2(T+1)K^2$. Then $f(t) \leq C \int_0^t f(s) ds$. Hence Gronwall's lemma (with $g \equiv 0$) yields $f \equiv 0$.

Existence. We use a version of the Picard iteration scheme. For $N \in \mathbb{N}_0$, recursively define processes X^N by $X^0_t \equiv x$ and

$$X^N_t := x + \int_0^t b(s, X^{N-1}_s) ds + \int_0^t \sigma(s, X^{N-1}_s) dW_s \quad \text{for } N \in \mathbb{N} \quad (26.11)$$

Using the growth condition (26.8), it can be shown inductively that

$$\begin{aligned} \int_0^T \mathbf{E} [\|X^N_t\|^2] dt &\leq 2(T+1)K^2 \left(T + \int_0^T \mathbf{E} [\|X^{N-1}_t\|^2] dt \right) \\ &\leq (2T(T+1)K^2)^N (1 + \|x\|^2) < \infty, \quad N \in \mathbb{N} \end{aligned}$$

Hence, at each step, the Itô integral is well-defined.

Consider now the differences

$$X^{N+1}_t - X^N_t = I_t + J_t$$

where

$$I_t := \int_0^t (\sigma(s, X^N_s) - \sigma(s, X^{N-1}_s)) dW_s$$

and

$$J_t := \int_0^t (b(s, X^N_s) - b(s, X^{N-1}_s)) ds$$

By applying Doob's L^2 -inequality to the nonnegative submartingale $(\|I_t\|^2)_{t \geq 0}$, using Lemma 26.7 and (26.7), we obtain

$$\begin{aligned} \mathbf{E} \left[\sup_{s \leq t} \|I_s\|^2 \right] &\leq 4\mathbf{E} [\|I_t\|^2] \\ &= 4\mathbf{E} \left[\int_0^t \|\sigma(s, X^N_s) - \sigma(s, X^{N-1}_s)\|^2 ds \right] \\ &\leq 4K^2 \int_0^t \mathbf{E} [\|X^N_s - X^{N-1}_s\|^2] ds \end{aligned} \quad (26.12)$$

For J_t , by the Cauchy-Schwarz inequality, we get

$$\|J_t\|^2 \leq t \int_0^t \|b(s, X_s^N) - b(s, X_s^{N-1})\|^2 ds$$

Hence

$$\begin{aligned} \mathbf{E} \left[\sup_{s \leq t} \|J_s\|^2 \right] &\leq t \mathbf{E} \left[\int_0^t \|b(s, X_s^N) - b(s, X_s^{N-1})\|^2 ds \right] \\ &\leq t K^2 \int_0^t \mathbf{E} \left[\|X_s^N - X_s^{N-1}\|^2 \right] ds \end{aligned} \quad (26.13)$$

Defining

$$\Delta^N(t) := \mathbf{E} \left[\sup_{s \leq t} \|X_s^N - X_s^{N-1}\|^2 \right],$$

and $C := 2K^2(4+T) \vee 2(T+1)K^2(1 + \|x\|^2)$, we obtain (using the growth condition (26.8))

$$\Delta^{N+1}(t) \leq C \int_0^t \Delta^N(s) ds \quad \text{for } N \geq 1$$

and

$$\begin{aligned} \Delta^1(t) &\leq 2t \int_0^t \|b(s, x)\|^2 ds + 2 \int_0^t \|\sigma(s, x)\|^2 ds \\ &\leq 2(T+1)K^2(1 + \|x\|^2) \cdot t \leq Ct \end{aligned}$$

Inductively, we get $\Delta^N(t) \leq \frac{(Ct)^N}{N!}$. Thus, by Markov's inequality,

$$\begin{aligned} \sum_{N=1}^{\infty} \mathbf{P} \left[\sup_{s \leq t} \|X_s^N - X_s^{N-1}\|^2 > 2^{-N} \right] &\leq \sum_{N=1}^{\infty} 2^N \Delta^N(t) \\ &\leq \sum_{N=1}^{\infty} \frac{(2Ct)^N}{N!} \leq e^{2Ct} < \infty \end{aligned}$$

Using the Borel-Cantelli lemma, we infer $\sup_{s \leq t} \|X_s^N - X_s^{N-1}\|^2 \xrightarrow{N \rightarrow \infty} 0$ a.s. Hence a.s. $(X^N)_{N \in \mathbb{N}}$ is a Cauchy sequence in the Banach space $(C([0, T]), \|\cdot\|_{\infty})$. Therefore, X^N converges a.s. uniformly to some X . As uniform convergence implies convergence of the integrals, X is a strong solution of (26.2).

Markov property. The strong Markov property follows from the strong Markov property of the Brownian motion that drives the SDE.

We have already seen some important examples of this theorem. Many interesting problems, however, lead to stochastic differential equations with coefficients that are not Lipschitz continuous. In the one-dimensional case, using special comparison methods, one can show that it is sufficient that σ is Hölder-continuous of order $\frac{1}{2}$ in the space variable.

Theorem 26.10 (Yamada-Watanabe) Consider the one-dimensional situation where $m = n = 1$. Assume that there exist $K < \infty$ and $\alpha \in [\frac{1}{2}, 1]$ such that, for all $t \geq 0$ and $x, x' \in \mathbb{R}$, we have

$$|b(t, x) - b(t, x')| \leq K|x - x'| \quad \text{and} \quad |\sigma(t, x) - \sigma(t, x')| \leq |x - x'|^\alpha.$$

Then, for every $X_0 \in \mathbb{R}$, the SDE (26.1) has a unique strong solution X and X is a strong Markov process.

Proof See [172] or [85, Proposition 5.2.13] and [49, Theorem 5.3.11] for existence and uniqueness. The strong Markov property follows from Theorem 26.26.

Example 26.11 Consider the one-dimensional SDE

$$dX_t = \sqrt{\gamma X_t^+} dW_t + a(b - X_t^+) dt \quad (26.14)$$

with initial point $X_0 = x \geq 0$, where $\gamma > 0$ and $a, b \geq 0$ are parameters. The conditions of Theorem 26.10 are fulfilled with $\alpha = \frac{1}{2}$ and $K = \sqrt{\gamma} + a$. Obviously, the unique strong solution X remains nonnegative if $X_0 \geq 0$. (In fact, it can be shown that $X_t > 0$ for all $t > 0$ if $2ab/\gamma \geq 1$, and that X_t hits zero arbitrarily often with probability 1 if $2ab/\gamma < 1$. See, e.g., [78, Example IV.8.2, p. 237]. Compare Example 26.16. See Figs. 26.1 and 26.2 for computer simulations.)

Fig. 26.1 Cox-Ingersoll-Ross diffusion with parameters $\gamma = 1, b = 1$ and $a = 0.3$. The path hits zero again and again since $2ab/\gamma = 0.6 < 1$

Fig. 26.2 Cox-Ingersoll-Ross diffusion with parameters $\gamma = 1, b = 1$ and $a = 2$. The path never hits zero since $2ab/\gamma = 4 \geq 1$

Depending on the context, this process is sometimes called Feller's branching diffusion with immigration or the Cox-Ingersoll-Ross model for the time evolution of interest rates.

For the case $a = b = 0$, use the Itô formula to compute that

$$e^{-\lambda X_t} - e^{-\lambda x} - \gamma \frac{\lambda^2}{2} \int_0^t e^{-\lambda X_s} X_s ds = \lambda \int_0^t e^{-\lambda X_s} \sqrt{\gamma X_s} dW_s$$

is a martingale. Take expectations for the Laplace transform $\varphi(t, \lambda, x) = \mathbf{E}_x [e^{-\lambda X_t}]$ to get the differential equation

$$\frac{d}{dt} \varphi(t, \lambda, x) = \gamma \frac{\lambda^2}{2} \mathbf{E} [X_t e^{-\lambda X_t}] = -\frac{\gamma \lambda^2}{2} \frac{d}{d\lambda} \varphi(t, \lambda, x)$$

With initial value $\varphi(0, \lambda, x) = e^{-\lambda x}$, the unique solution is

$$\varphi(t, \lambda, x) = \exp\left(-\frac{\lambda}{(\gamma/2)\lambda t + 1}x\right)$$

However (for $\gamma = 2$), this is exactly the Laplace transform of the transition probabilities of the Markov process that we defined in Theorem 21.48 and that in Lindvall's theorem (Theorem 21.51) we encountered as the limit of rescaled Galton-Watson branching processes.

Exercise 26.1.1 Let $a, b \in \mathbb{R}$. Show that the stochastic differential equation

$$dX_t = \frac{b - X_t}{1 - t} dt + dW_t$$

with initial value $X_0 = a$ has a unique strong solution for $t \in [0, 1)$ and that $X_1 := \lim_{t \uparrow 1} X_t = b$ almost surely. Furthermore, show that the process $Y = (X_t - a - t(b - a))_{t \in [0, 1]}$ can be described by the Itô integral

$$Y_t = (1 - t) \int_0^t (1 - s)^{-1} dW_s, \quad t \in [0, 1)$$

and is hence a Brownian bridge (compare Exercise 21.5.3).

5.26.2 26.2 Weak Solutions and the Martingale Problem

In the last section, we studied strong solutions of the stochastic differential equation

$$dX_t = \sigma(t, X_t) dW_t + b(t, X_t) dt. \quad (26.15)$$

A strong solution is a solution where any path of the Brownian motion W gets mapped onto a path of the solution X . In this section, we will study the notion of a weak solution where additional information (or additional noise) can be used to construct the solution.

Definition 26.12 (Weak solution of an SDE) A weak solution of (26.15) with initial distribution $\mu \in \mathcal{M}_1(\mathbb{R}^n)$ is a triple

$$L = ((X, W), (\Omega, \mathcal{F}, \mathbf{P}), \mathbb{F}),$$

where

- $(\Omega, \mathcal{F}, \mathbf{P})$ is a probability space,
- $\mathbb{F} = (\mathcal{F}_t)_{t \geq 0}$ is a filtration on $(\Omega, \mathcal{F}, \mathbf{P})$ that satisfies the usual conditions,
- W is a Brownian motion on $(\Omega, \mathcal{F}, \mathbf{P})$ and is a martingale with respect to $\mathbb{F}$,
- X is continuous and adapted (hence progressively measurable),
- $\mathbf{P} \circ (X_0)^{-1} = \mu$, and
- (X, W) satisfies

$$X_t = X_0 + \int_0^t \sigma(s, X_s) dW_s + \int_0^t b(s, X_s) ds \quad \mathbf{P}\text{-a.s.} \quad (26.16)$$

A weak solution L is called (weakly) unique if, for any further solution L' with initial distribution μ , we have $\mathbf{P}' \circ (X')^{-1} = \mathbf{P} \circ X^{-1}$.

Remark 26.13 Clearly, a weak solution of an SDE is a generalized n -dimensional diffusion. If the coefficients σ and b do not depend on t , then the solution is an n -dimensional diffusion.

Remark 26.14 Clearly, every strong solution of (26.15) is a weak solution. The converse is false, as the following example shows.

Example 26.15 Consider the SDE (with initial value $X_0 = 0$)

$$dX_t = \text{sign}(X_t) dW_t, \quad (26.17)$$

where $\text{sign} = \mathbb{1}_{(0,\infty)} - \mathbb{1}_{(-\infty,0)}$ is the sign function. Then

$$X_t = X_0 + \int_0^t \text{sign}(X_s) dW_s \quad \text{for all } t \geq 0 \quad (26.18)$$

if and only if

$$W_t = \int_0^t dW_s = \int_0^t \text{sign}(X_s) dX_s \quad \text{for all } t \geq 0 \quad (26.19)$$

A weak solution of (26.17) is obtained as follows. Let X be a Brownian motion on a probability space $(\Omega, \mathcal{F}, \mathbf{P})$ and $\mathbb{F} = \sigma(X)$. If we define W by (26.19), then W is a continuous $\mathbb{F}$ -martingale with square variation

$$\langle W \rangle_t = \int_0^t (\text{sign}(X_s))^2 ds = t$$

Thus, by Lévy's characterization (Theorem 25.28), W is a Brownian motion. Hence $((X, W), (\Omega, \mathcal{F}, \mathbf{P}), \mathbb{F})$ is a weak solution of (26.17).

In order to show that a strong solution does not exist, take any weak solution and show that X is not adapted to $\sigma(W)$. Since, by (26.18), X is a continuous martingale with square variation $\langle X \rangle_t = t$, X is a Brownian motion.

Let $F_n \in C^2(\mathbb{R})$ be a convex even function with derivatives F'_n and F''_n such that

$$\sup_{x \in \mathbb{R}} |F_n(x) - |x|| \xrightarrow{n \rightarrow \infty} 0$$

$|F'_n(x)| \leq 1$ for all $x \in \mathbb{R}$ and $F'_n(x) = \text{sign}(x)$ for $|x| > \frac{1}{n}$. In particular, we have

$$\int_0^t (F'_n(X_s) - \text{sign}(X_s))^2 ds \xrightarrow{n \rightarrow \infty} 0 \quad \text{a.s.}$$

and thus

$$\int_0^t F'_n(X_s) dX_s \xrightarrow{n \rightarrow \infty} \int_0^t \text{sign}(X_s) dX_s \quad \text{in } L^2 \quad (26.20)$$

By passing to a subsequence, if necessary, we may assume that almost sure convergence holds in (26.20).

Since F''_n is even, we have

$$\begin{aligned} W_t &= \int_0^t \text{sign}(X_s) dX_s = \lim_{n \rightarrow \infty} \int_0^t F'_n(X_s) dX_s \\ &= \lim_{n \rightarrow \infty} \left(F_n(X_t) - F_n(0) - \frac{1}{2} \int_0^t F''_n(X_s) ds \right) \\ &= |X_t| - \lim_{n \rightarrow \infty} \frac{1}{2} \int_0^t F''_n(|X_s|) ds \end{aligned}$$

As the right-hand side depends only on $|X_s|$, $s \in [0, t]$, W is adapted to $\mathbb{G} := (\sigma(|X_s| : s \in [0, t]))$. Hence $\sigma(W) \subset \mathbb{G} \subsetneq \sigma(X)$, and thus X is not adapted to $\sigma(W)$.

Example 26.16 Let $B = (B^1, \dots, B^n)$ be an n -dimensional Brownian motion started at $y \in \mathbb{R}^n$. Let $x := \|y\|^2$, $X_t := \|B_t\|^2 = (B_t^1)^2 + \dots + (B_t^n)^2$ and

$$W_t := \sum_{i=1}^n \int_0^t \frac{1}{\sqrt{X_s}} B_s^i dB_s^i$$

Then W is a continuous local martingale with $\langle W \rangle_t = t$ for every $t \geq 0$ and

$$X_t = x + nt + \int_0^t \sqrt{X_s} dW_s$$

That is, (X, W) is a weak solution of the SDE $dX_t = \sqrt{2X_t} dW_t + n dt$. X is called an n -dimensional Bessel process. By Theorem 25.42, B (and thus X) hits the origin for some $t > 0$ if and only if $n = 1$. Clearly, we can define X also for noninteger $n \geq 0$. One can show that X hits zero if and only if $n \leq 1$. Compare Example 26.11. $\diamond$

For the connection between existence and uniqueness of weak solutions and strong solutions, we only quote here the theorem of Yamada and Watanabe.

Definition 26.17 (Pathwise uniqueness) A solution of the SDE (26.15) with initial distribution μ is said to be pathwise unique if, for every $\mu \in \mathcal{M}_1(\mathbb{R}^n)$ and for any two weak solutions (X, W) and (X', W') on the same space $(\Omega, \mathcal{F}, \mathbf{P})$ with the same filtration $\mathbb{F}$, we have $\mathbf{P}[X_t = X'_t \text{ for all } t \geq 0] = 1$.

Theorem 26.18 (Yamada and Watanabe) The following are equivalent.

- (i) The SDE (26.15) has a unique strong solution.
- (ii) For any $\mu \in \mathcal{M}_1(\mathbb{R}^n)$, (26.15) has a weak solution, and pathwise uniqueness holds.

If (i) and (ii) hold, then the solution is weakly unique.

Proof See [172], [147, pp. 151ff] or [78, pp. 163ff].

Example 26.19 Let X be a weak solution of (26.17). Then $-X$ is also a weak solution; that is, pathwise uniqueness does not hold (although it can be shown that the solution is weakly unique; see Theorem 26.25).

Consider the one-dimensional case $m = n = 1$. If X is a solution (strong or weak) of (26.15), then

$$M_t := X_t - \int_0^t b(s, X_s) ds$$

is a continuous local martingale with square variation

$$\langle M \rangle_t = \int_0^t \sigma^2(s, X_s) ds$$

We will see that this characterizes a weak solution of (26.15) (under some mild growth conditions on σ and b).

Now assume that, for all $t \geq 0$ and $x \in \mathbb{R}^n$, the $n \times n$ matrix $a(t, x)$ is symmetric and nonnegative definite, and let $(t, x) \mapsto a(t, x)$ be measurable.

Definition 26.20 An n -dimensional continuous process X is called a solution of the local martingale problem for a and b with initial condition $\mu \in \mathcal{M}_1(\mathbb{R}^n)$ (briefly, LMP(a, b, μ)) if $\mathbf{P} \circ X_0^{-1} = \mu$ and if, for every $i = 1, \dots, n$,

$$M_t^i := X_t^i - \int_0^t b_i(s, X_s) ds, \quad t \geq 0$$

is a continuous local martingale with quadratic covariation

$$\langle M^i, M^j \rangle_t = \int_0^t a_{ij}(s, X_s) ds \quad \text{for all } t \geq 0, i, j = 1, \dots, n$$

We say that the solution of $\text{LMP}(a, b, \mu)$ is unique if, for any two solutions X and X' , we have $\mathbf{P} \circ X^{-1} = \mathbf{P} \circ (X')^{-1}$.

Denote by σ^T the transposed matrix of σ . Clearly, $a = \sigma\sigma^T$ is a nonnegative semidefinite symmetric $n \times n$ matrix.

Theorem 26.21 X is a solution of $\text{LMP}(\sigma\sigma^T, b, \mu)$ if and only if (on a suitable extension of the probability space) there exists a Brownian motion W such that (X, W) is a weak solution of (26.15).

In particular, there exists a unique weak solution of the SDE (26.15) with initial distribution μ if $\text{LMP}(\sigma\sigma^T, b, \mu)$ is uniquely solvable.

Proof We show the statement only for the case $m = n = 1$. The general case needs some consideration on the roots of nonnegative semidefinite symmetric matrices, which, however, do not yield any further insight into the stochastics of the problem. For this we refer to [85, Proposition 5.4.6].

"." If (X, W) is a weak solution, then, by Corollary 25.19, X solves the local martingale problem.

" $\implies$ " Let X be a solution of $\text{LMP}(\sigma^2, b, \mu)$. By Theorem 25.29, on an extension of the probability space there exists a Brownian motion $\tilde{W}$ such that $M_t = \int_0^t |\sigma(s, X_s)| d\tilde{W}_s$. If we define

$$W_t := \int_0^t \text{sign}(\sigma(s, X_s)) d\tilde{W}_s$$

then $M_t = \int_0^t \sigma(s, X_s) dW_s$ and hence (X, W) is a weak solution of (26.15).

In some sense, a local martingale problem is a very natural way of writing a stochastic differential equation; that is:

X locally has derivative (drift) b and additionally has random normally distributed fluctuations of size σ .

Here, a concrete Brownian motion does not appear. In fact, in most problems its occurrence is rather artificial. Just as Markov chains are described by their transition probabilities and not by a concrete realization of the random transitions (as in Theorem 17.17), many continuous (space and time) processes are most naturally described by the drift and the size of the fluctuations but not by the concrete realization of the random fluctuations.

From a technical point of view, the formulation of a stochastic differential equation as a local martingale problem is very convenient since it makes SDEs accessible to techniques such as martingale inequalities and approximation theorems that can be used to establish existence and uniqueness of solutions. Here we simply quote two important results.

Theorem 26.22 (Existence of solutions) Let $(t, x) \mapsto b(t, x)$ and $(t, x) \mapsto a(t, x)$ be continuous and bounded. Then, for every $\mu \in \mathcal{M}_1(\mathbb{R}^n)$, there exists a solution X of the $\text{LMP}(a, b, \mu)$.

Proof See [147, Theorem V.23.5].

Definition 26.23 The $\text{LMP}(a, b)$ is said to be well-posed if, for every $x \in \mathbb{R}^n$, there exists a unique solution X of $\text{LMP}(a, b, \delta_x)$.

Remark 26.24 If σ and b satisfy the Lipschitz conditions of Theorem 26.8, then the $\text{LMP}(\sigma\sigma^T, b)$ is well-posed. This follows by Theorem 26.8, Theorem 26.18 and Theorem 26.21.

In the following, we assume

$$(t, x) \mapsto \sigma(t, x) \text{ resp. } (t, x) \mapsto a(t, x) \text{ is bounded on compact sets.} \quad (26.21)$$

This condition ensures the equivalence of the local martingale problems to the somewhat more common martingale problem (see [85, Proposition 5.4.11]).

Theorem 26.25 (Uniqueness in the martingale problem) Assume (26.21) and that, for any $x \in \mathbb{R}^n$, there exists a solution X^x of LMP (a, b, δ_x) . The distribution of X^x will be denoted by $\mathbf{P}_x := \mathbf{P} \circ (X^x)^{-1}$.

Assume that, for any two solutions X^x and Y^x of LMP (a, b, δ_x) , we have

$$\mathbf{P} \circ (X_T^x)^{-1} = \mathbf{P} \circ (Y_T^x)^{-1} \quad \text{for any } T \geq 0. \quad (26.22)$$

Then LMP (a, b) is well-posed, and the canonical process X is a strong Markov process with respect to $(\mathbf{P}_x, x \in \mathbb{R}^n)$. If $a = \sigma \sigma^T$, then under $\mathbf{P}_x$, the process X is the unique weak solution of the SDE (26.15).

Proof See [49, Theorem 4.4.2 and Problem 49] and [85, Proposition 5.4.11].

A fundamental strength of this theorem is that we do not need to check the uniqueness of the whole process but only have to check in (26.22) the onedimensional marginal distributions. We will use this in Section 26.3 in some examples.

The existence of solutions of a stochastic differential equation (or equivalently of a local martingale problem) is often easier to show than the uniqueness of solutions. We know already that Lipschitz conditions for the coefficients b and σ (not $\sigma \sigma^T$!) ensure uniqueness (Theorem 26.8 and Theorem 26.18), as here strong uniqueness of the solution holds.

At first glance, it might seem confusing that random fluctuations have a stabilising effect on the solution. That is, there are deterministic differential equations whose solution is unique only after adding random noise terms. For example, consider the following equation:

$$dX_t = \text{sign}(X_t) |X_t|^{1/3} dt + \sigma dW_t, \quad X_0 = 0 \quad (26.23)$$

If $\sigma = 0$, then the deterministic differential equation has a continuum of solutions that can be parameterized by $v \in \{-1, +1\}$ and $T \geq 0$, namely $X_t = v2\sqrt{2}(t - T)^{3/2} \mathbb{1}_{\{t > T\}}$. If $\sigma > 0$, then the noise eliminates the instability of (26.23) at $x = 0$. We quote the following theorem for the time-independent case from [147, Theorem V.24.1] (see also [161, Chapter 10]).

Theorem 26.26 (Stroock-Varadhan) Let $a_{ij} : \mathbb{R}^n \rightarrow \mathbb{R}$ be continuous and let $b_i : \mathbb{R}^n \rightarrow \mathbb{R}$ be measurable for $i, j = 1, \dots, n$. Assume

- (i) $a(x) = (a_{ij}(x))$ is symmetric and strictly positive definite for every $x \in \mathbb{R}^n$,
- (ii) there exists a $C < \infty$ such that, for all $x \in \mathbb{R}^n$ and $i, j = 1, \dots, n$, we have

$$|a_{ij}(x)| \leq C(1 + \|x\|^2) \quad \text{and} \quad |b_i(x)| \leq C(1 + \|x\|).$$

Then the LMP (a, b) is well-posed and the SDE (26.15) has a unique strong solution that is a strong Markov process. The solution X has the Feller property: For every $t > 0$ and every bounded measurable $f : \mathbb{R}^n \rightarrow \mathbb{R}$, the map $x \mapsto \mathbf{E}_x[f(X_t)]$ is continuous.

We will present explicit examples in Section 26.3. Here we just remark that we have developed a particular method in order to construct Markov processes, namely as the solution of a stochastic differential equation or of a local martingale problem. In the framework of models in discrete time, in Section 17.2 and especially in Exercise 17.2.1, we characterized certain Markov chains as solutions of martingale problems. In order for drift and square variation to be sufficient for uniqueness of the Markov chain described by the martingale problem, it was essential that, for any step of the chain, we only allowed three possibilities. Here, however, the decisive restriction is the continuity of the processes.

Exercise 26.2.1 Consider the time-homogeneous one-dimensional case ($m = n = 1$). Let σ and b be such that, for every $X_0 \in \mathbb{R}$, there exists a unique weak solution of

$$dX_t = \sigma(X_t) dW_t + b(X_t) dt$$

that is a strong Markov process. Further, assume that there exists an $x_0 \in \mathbb{R}$ with

$$C := \int_{-\infty}^{\infty} \frac{1}{\sigma^2(x)} \exp \left(\int_{x_0}^x \frac{2b(r)}{\sigma^2(r)} dr \right) dx < \infty$$

(i) Show that the measure $\pi \in \mathcal{M}_1(\mathbb{R})$ with density

$$\frac{\pi(dx)}{dx} = C^{-1} \frac{1}{\sigma^2(x)} \exp \left(\int_{x_0}^x \frac{2b(r)}{\sigma^2(r)} dr \right)$$

is an invariant distribution for X .

(ii) For which values of b does the Ornstein-Uhlenbeck process $dX_t = \sigma dW_t + bX_t dt$ have an invariant distribution? Determine this distribution and compare the result with what could be expected by an explicit computation using the representation in (26.3).

(iii) Compute the invariant distribution of the Cox-Ingersoll-Ross SDE (26.14) (i.e., Feller's branching diffusion).

(iv) Let $\gamma, c > 0$ and $\theta \in (0, 1)$. Show that the invariant distribution of the solution X of the SDE on $[0, 1]$,

$$dX_t = \sqrt{\gamma X_t(1 - X_t)} dW_t + c(\theta - X_t) dt$$

is the Beta distribution $\beta_{2c\gamma/\theta, 2c\gamma/(1-\theta)}$.

Exercise 26.2.2 Let $\gamma > 0$. Let X^1 and X^2 be solutions of $dX_t^i = \sqrt{\gamma X_t^i} dW_t^i$, where W^1 and W^2 are two independent Brownian motions with initial values $X_0^1 = x_0^1 > 0$ and $X_0^2 = x_0^2 > 0$. Show that $Z := X^1 + X^2$ is a weak solution of $Z_0 = 0$ and $dZ_t = \sqrt{\gamma Z_t} dW_t$.

5.26.3 26.3 Weak Uniqueness via Duality

The Stroock-Varadhan theorem provides a strong criterion for existence and uniqueness of solutions of stochastic differential equations. However, in many cases, the condition of locally uniform ellipticity of a (Condition (i) in Theorem 26.26) is not fulfilled. This is the case, in particular, if the solutions are defined only on subsets of $\mathbb{R}^n$.

Here we will study a powerful tool that in many special cases can yield weak uniqueness of solutions.

Definition 26.27 (Duality) Let $X = (X^x, x \in E)$ and $Y = (Y^y, y \in E')$ be families of stochastic processes with values in the spaces E and E' , respectively, and such that $X_0^x = x$ a.s. and $Y_0^y = y$ a.s. for all $x \in E$ and $y \in E'$. We say that X and Y are dual to each other with duality function $H : E \times E' \rightarrow \mathbb{C}$ if, for all $x \in E, y \in E'$ and $t \geq 0$, the expectations $\mathbf{E}[H(X_t^x, y)]$ and $\mathbf{E}[H(x, Y_t^y)]$ exist and are equal:

$$\mathbf{E}[H(X_t^x, y)] = \mathbf{E}[H(x, Y_t^y)].$$

In the following, we assume that $\sigma_{ij} : \mathbb{R}^n \rightarrow \mathbb{R}$ and $b_i : \mathbb{R}^n \rightarrow \mathbb{R}$ are bounded on compact sets for all $i = 1, \dots, n, j = 1, \dots, m$. Consider the time-homogeneous stochastic differential equation

$$dX_t = \sigma(X_t) dW_t + b(X_t) dt \quad (26.24)$$

Theorem 26.28 (Uniqueness via duality) Assume that, for every $x \in \mathbb{R}^n$, there exists a solution of the local martingale problem for $(\sigma \sigma^T, b, \delta_x)$. Further, assume that there exists a family $(Y^y, y \in E')$ of Markov processes with values in the measurable space $(E', \mathcal{E}')$ and a measurable map $H : \mathbb{R}^n \times E' \rightarrow \mathbb{C}$ such that, for every $y \in E', x \in \mathbb{R}^n$ and $t \geq 0$, the expectation $\mathbf{E}[H(x, Y_t^y)]$ exists and is finite. Further, let $(H(\cdot, y), y \in E')$ be a separating class of functions for $\mathcal{M}_1(\mathbb{R}^n)$ (see Definition 13.9).

For every $x \in \mathbb{R}^n$ and every solution X^x of LMP $(\sigma\sigma^T, b, \delta_x)$, assume that the duality equation holds:

$$\mathbf{E}[H(X_t^x, y)] = \mathbf{E}[H(x, Y_t^y)] \quad \text{for all } y \in \mathbf{E}', t \geq 0. \quad (26.25)$$

Then the local martingale problem of $(\sigma\sigma^T, b)$ is well-posed and hence (26.24) has a unique weak solution that is a strong Markov process.

Proof By Theorem 26.25, it is enough to check that, for every $x \in \mathbb{R}^n$, every solution X^x of LMP $(\sigma\sigma^T, b, \delta_x)$ and every $t \geq 0$, the distribution $\mathbf{P} \circ (X_t^x)^{-1}$ is unique. Since $(H(\cdot, y), y \in E')$ is a separating class of functions, this follows from (26.16).

Example 26.29 (Wright-Fisher diffusion) Consider the Wright-Fisher SDE

$$dX_t = \mathbb{1}_{[0,1]}(X_t) \sqrt{\gamma X_t(1-X_t)} dW_t, \quad (26.26)$$

where $\gamma > 0$ is a parameter. See Fig. 26.3 for a computer simulation. By Theorem 26.22, for every $x \in \mathbb{R}$, there exists a weak solution $(\tilde{X}, W)$ of (26.26). $\tilde{X}$ is a continuous local martingale with square variation

$$\langle \tilde{X} \rangle_t = \int_0^t \gamma \tilde{X}_s (1 - \tilde{X}_s) \mathbb{1}_{[0,1]}(\tilde{X}_s) ds$$

Let $\tau := \inf \{t > 0 : \tilde{X}_t \notin [0, 1]\}$ and let $X := \tilde{X}^\tau$ be the process stopped at τ . Then X is a continuous bounded martingale with

$$\langle X \rangle_t = \int_0^t \gamma X_s (1 - X_s) \mathbb{1}_{[0,1]}(X_s) ds$$

Hence, (X, W) is a solution of (26.26). By construction, $X_t \in [0, 1]$ for all $t \geq 0$ if $X_0 = \tilde{X}_0 \in [0, 1]$.

Let $\tau' := \inf \{t > 0 : \tilde{X}_t \in [0, 1]\}$. If $\tilde{X}_0 \notin [0, 1]$, then $\tau' > 0$ since $\tilde{X}$ is continuous. Since $\tilde{X}^{\tau'}$ is a continuous local martingale with $\langle \tilde{X}^{\tau'} \rangle \equiv 0$, we have $\tilde{X}_t^{\tau'} = \tilde{X}_0$ for all $t \geq 0$. However, this implies $\tilde{X}_t = \tilde{X}_0$ for all $t < \tau'$. Again, by continuity of $\tilde{X}$, we get $\tau' = \infty$ and $\tilde{X}_t = \tilde{X}_0$ for all $t \geq 0$.

Hence, it is enough to show uniqueness of the solution for $\tilde{X}_0 = x \in [0, 1]$. To this end, let $Y = (Y_t)_{t \geq 0}$ be the Markov process on $\mathbb{N}$ with Q -matrix

$$q(m, n) = \begin{cases} \gamma \binom{m}{2}, & \text{if } n = m - 1, \\ -\gamma \binom{m}{2}, & \text{if } n = m, \\ 0, & \text{else.} \end{cases}$$

We show duality of X and Y with respect to $H(x, n) = x^n$:

$$\mathbf{E}_x[X_t^n] = \mathbf{E}_n[x^{N_t}] \quad \text{for all } t \geq 0, x \in [0, 1], n \in \mathbb{N}. \quad (26.27)$$

Fig. 26.3 Simulation of a Wright-Fisher diffusion with parameter $\gamma = 1$

Define $m^{x,n}(t) = \mathbf{E}_x[X_t^n]$ and $g^{x,n}(t) = \mathbf{E}_n[x^{N_t}]$. By the Itô formula,

$$X_t^n - x^n - \int_0^t \gamma \binom{n}{2} X_s^{n-1} (1 - X_s) ds = \int_0^t n X_s^{n-1} \sqrt{\gamma X_s (1 - X_s)} dW_s$$

is a martingale.

Taking expectations, we obtain the following recursive equations for the moments of X :

$$\begin{aligned} m^{x,1}(t) &= x \\ m^{x,n}(t) &= x^n + \gamma \binom{n}{2} \int_0^t (m^{x,n-1}(s) - m^{x,n}(s)) ds \quad \text{for } n \geq 2 \end{aligned} \quad (26.28)$$

Clearly, this system of linear differential equations can be uniquely solved recursively in n . Due to the Markov property of Y , for $h > 0$ and $t \geq 0$, we have

$$\begin{aligned} g^{x,n}(t+h) &= \mathbf{E}_n[x^{Y_{t+h}}] = \mathbf{E}_n[\mathbf{E}_{Y_h}[x^{Y_t}]] \\ &= \sum_{m=1}^n \mathbf{P}_n[Y_h = m] \mathbf{E}_m[x^{Y_t}] \\ &= \sum_{m=1}^n \mathbf{P}_n[Y_h = m] g^{x,m}(t) \end{aligned}$$

This implies

$$\begin{aligned} \frac{d}{dt} g^{x,n}(t) &= \lim_{h \downarrow 0} h^{-1} [g^{x,n}(t+h) - g^{x,n}(t)] \\ &= \lim_{h \downarrow 0} h^{-1} \sum_{m=1}^n \mathbf{P}_n[Y_h = m] (g^{x,m}(t) - g^{x,n}(t)) \\ &= \sum_{m=1}^n q(n, m) g^{x,m}(t) \\ &= \gamma \binom{n}{2} (g^{x,n-1}(t) - g^{x,n}(t)). \end{aligned} \quad (26.29)$$

Evidently, $g^{x,1}(t) = x$ for all $x \in [0, 1]$ and $t \geq 0$ and $g^{x,n}(0) = x^n$. That is, $g^{x,n}$ solves (26.28), and thus (26.27) holds.

By Theorem 15.4, the family $(H(\cdot, n), n \in \mathbb{N}) \subset C([0, 1])$ is separating for $\mathcal{M}_1([0, 1])$; hence the conditions of Theorem 26.28 are fulfilled. Therefore, X is the unique weak solution of (26.26) and is a strong Markov process.

Remark 26.30 The martingale problem for the Wright-Fisher diffusion is almost identical to the martingale problem for the Moran model (see Example 17.22) $M^N = (M_n^N)_{n \in \mathbb{N}_0}$ with population size N : M^N is a martingale with values in the set $\{0, 1/N, \dots, (N-1)/N, 1\}$ and with square variation process

$$\langle M^N \rangle_n = \frac{2}{N^2} \sum_{k=0}^{n-1} M_k^N (1 - M_k^N)$$

At each step, M^N can either stay put or increase or decrease by $1/N$. In Exercise 17.2.1, we saw that this determines the process M^N uniquely. Similarly as in Theorem 21.51 for branching processes, it can be shown that the time-rescaled Moran processes $\tilde{M}_t^N = M_{\lfloor N^2 t \rfloor}^N$ converge to the Wright-Fisher diffusion with $\gamma = 2$. The Wright-Fisher diffusion thus occurs as the limiting model of a genealogical model and describes the gene frequency (that is, the fraction) of a certain allele in a population that fluctuates randomly due to resampling.

Example 26.31 (Feller's branching diffusion) Let $(Z_n^N)_{n \in \mathbb{N}_0}$ be a Galton-Watson branching process with critical geometric offspring distribution $p_k = 2^{-k-1}$, $k \in \mathbb{N}_0$ and $Z_0^N = N$ for any $N \in \mathbb{N}$. Then Z^N is a discrete martingale and we have

$$\mathbf{E} \left[(Z_n^N - Z_{n-1}^N)^2 \mid Z_{n-1}^N \right] = Z_{n-1}^N \left(\sum_{k=0}^{\infty} p_k k^2 - 1 \right) = 2Z_{n-1}^N$$

Hence Z^N has square variation

$$\langle Z^N \rangle_n = \sum_{k=0}^{n-1} 2Z_k^N$$

Define the linearly interpolated version

$$Z_t^N := (t - N^{-1} \lfloor tN \rfloor) (Z_{\lfloor tN \rfloor + 1}^N - Z_{\lfloor tN \rfloor}^N) + \frac{1}{n} Z_{\lfloor tN \rfloor}^N$$

Fig. 26.4 Simulation of Feller's branching diffusion with parameter $\gamma = 1$

of $N^{-1}Z_{\lfloor tN \rfloor}^N$. By Lindvall's theorem (Theorem 21.51), there is a continuous Markov process Z such that $Z^N \xrightarrow{N \rightarrow \infty} Z$ in distribution. See Fig. 26.4 for a computer simulation of Z . Since it can be shown that the moments also converge, we have that Z is a continuous martingale with square variation

$$\langle Z \rangle_t = \int_0^t 2Z_s ds$$

In fact, in Example 26.11, we have already shown that Z is the unique solution of the SDE

$$dZ_t = \sqrt{2Z_t} dW_t \quad (26.30)$$

with initial value $Z_0 = 1$. There we also showed that Z is dual to $Y_t^y = \left(\frac{t\gamma}{2} + \frac{1}{y}\right)^{-1}$ with $H(x, y) = e^{-xy}$. This implies uniqueness of the solution of (26.30) and the strong Markov property of Z . $\square$

It could be objected that in Examples 26.29 and 26.31, we considered only onedimensional problems for which the Yamada-Watanabe theorem (Theorem 26.10) yields uniqueness (indeed of a strong solution) anyway. The full strength of the method of duality is displayed only in higher-dimensional problems. As an example, we consider an extension of Example 26.29.

Example 26.32 (Interacting Wright-Fisher diffusions) The Wright-Fisher diffusion from Example 26.29 describes the fluctuations of the gene frequency of an allele in one large population. Now we consider more populations, which live at the points $i \in S := \{1, \dots, N\}$ and interact with each other by a migration that is quantified by migration rates $r(i, j) \geq 0$. As a model for the gene frequencies $X_t(i)$ at site i at time t we use the following N -dimensional SDE for $X = (X(1), \dots, X(N))$:

$$dX_t(i) = \sqrt{\gamma X_t(i)(1 - X_t(i))} dW_t^i + \sum_{j=1}^N r(i, j) (X_t(j) - X_t(i)) dt \quad (26.31)$$

Here $W = (W^1, \dots, W^N)$ is an N -dimensional Brownian motion. By Theorem 26.22, this SDE has weak solutions; however, none of our general criteria for weak uniqueness apply. We will thus show weak uniqueness by virtue of duality.

As in Example 26.29, it is not hard to show that solutions of (26.31), started at $X_0 = x \in E := [0, 1]^S$, remain in $[0, 1]^S$. The diagonal terms $r(i, i)$ do not appear in (26.31). We use our freedom and define these terms as $r(i, i) = -\sum_{j \neq i} r(i, j)$. Let $Y = (Y_t)_{t \geq 0}$ be the Markov process on $E' := (\mathbb{N}_0)^S$ with the following Q -matrix:

$$q(\varphi, \eta) = \begin{cases} \varphi(i)r(i, j), & \text{if } \eta = \varphi - \mathbb{1}_{\{i\}} + \mathbb{1}_{\{j\}} \text{ for} \\ \gamma \binom{\varphi(i)}{2}, & \text{some } i, j \in S, i \neq j, \\ \sum_{i \in S} \left(\varphi(i)r(i, i) - \gamma \binom{\varphi(i)}{2} \right), & \text{if } \eta = \varphi - \mathbb{1}_{\{i\}} \text{ for some } i \in S, \\ 0, & \text{if } \eta = \varphi, \\ \text{else.} & \end{cases}$$

Here $\varphi \in E'$ denotes a generic state with $\varphi(i)$ particles at site $i \in S$, and $\mathbb{1}_{\{i\}} \in E'$ denotes the state with exactly one particle at site i . The process Y describes a system of particles that independently with rate $r(i, j)$ jump from site i to site j . If there is more than one particle at the same site i , then any of the $\binom{\varphi(i)}{2}$ pairs of particles coalesce with the same rate γ to one particle. The common genealogical interpretation of this process is that (in reversed time) it describes the lines of descent of samples of $Y_0(i)$ individuals at each site $i \in S$. By migration, the lines change sites. If two individuals have the same common ancestor, then their lines coalesce. Clearly, for two particles to have the same ancestor at a given time, it is necessary but not sufficient for them to be at the same site.

For $x \in \mathbb{R}^n$ and $\varphi \in E'$, we denote $x^\varphi := \prod_{i \in S} x(i)^{\varphi(i)}$. We show that X and Y are dual to each other with the duality function $H(x, \varphi) = x^\varphi$:

$$\mathbf{E}_x [X_t^\varphi] = \mathbf{E}_\varphi [x^{Y_t}] \quad \text{for all } \varphi \in S^{\mathbb{N}_0}, x \in [0, 1]^S, t \geq 0 \quad (26.32)$$

Let $m^{x,\varphi}(t) := \mathbf{E}_x[X_t^\varphi]$ and $g^{x,\varphi}(t) := \mathbf{E}_\varphi[x^{Y_t}]$. Clearly, H has the derivatives $\partial_i H(\cdot, \varphi)(x) = \varphi(i)x^{\varphi - \mathbb{1}_{\{i\}}}$ and $\partial_i \partial_i H(\cdot, \varphi)(x) = 2 \binom{\varphi(i)}{2} x^{\varphi - 2\mathbb{1}_{\{i\}}}$.

By the Itô formula,

$$\begin{aligned} X_t^\varphi - X_0^\varphi - \int_0^t \sum_{i,j \in S} \varphi(i) r(i, j) (X_s(j) - X_s(i)) X_s^{\varphi - \mathbb{1}_{\{i\}}} ds \\ - \sum_{i \in S} \int_0^t \gamma \binom{\varphi(i)}{2} (X_s(i) (1 - X_s(i))) X_s^{\varphi - 2\mathbb{1}_{\{i\}}} ds \end{aligned}$$

is a martingale. Taking expectations, we get a system of linear integral equations

$$\begin{aligned} m^{x,0}(t) &= 1 \\ m^{x,\varphi}(t) &= x^\varphi + \int_0^t \sum_{i,j \in S} \varphi(i) r(i, j) (m^{x,\varphi + \mathbb{1}_{\{j\}} - \mathbb{1}_{\{i\}}}(s) - m^{x,\varphi}(s)) ds \\ &\quad + \int_0^t \gamma \sum_{i \in S} \binom{\varphi(i)}{2} (m^{x,\varphi - \mathbb{1}_{\{i\}}}(s) - m^{x,\varphi}(s)) ds \end{aligned} \quad (26.33)$$

This system of equations can be solved uniquely by induction on $n = \sum_{i \in I} \varphi(i)$. However, we do not intend to compute this solution explicitly. We show only that it coincides with $g^{x,\varphi}(t)$ by showing that g solves an equivalent system of differential equations.

For g as in (26.29), we obtain

$$\begin{aligned} \frac{d}{dt} g^{x,\varphi}(t) &= \sum_{\eta \in E'} q(\varphi, \eta) g^{x,\varphi}(t) \\ &= \sum_{i,j \in S} r(i, j) (g^{x,\varphi + \mathbb{1}_{\{j\}} - \mathbb{1}_{\{i\}}}(t) - g^{x,\varphi}(t)) \\ &\quad + \sum_{i \in S} \gamma \binom{\varphi(i)}{2} (g^{x,\varphi - \mathbb{1}_{\{i\}}}(t) - g^{x,\varphi}(t)) \end{aligned} \quad (26.34)$$

Together with the initial values $g^{x,0}(t) = 1$ and $g^{x,\varphi}(0) = x^\varphi$, the system (26.34) of differential equations is equivalent to (26.33). Hence the duality (26.32) holds, and thus the SDE (26.31) has a unique weak solution. (In fact, it can be shown that there exists a unique strong solution, even if S is countably infinite, as long as r then satisfies certain regularity conditions such as if it is the Q -matrix of a random walk on $S = \mathbb{Z}^d$; see [153].)

Exercise 26.3.1 (Extinction probability of Feller's branching diffusion) Let $\gamma > 0$ and let Z be the solution of $dZ_t := \sqrt{\gamma Z_t} dW_t$ with initial value $Z_0 = z > 0$. Use the duality to show

$$\mathbf{P}_z[Z_t = 0] = \exp\left(-\frac{2z}{\gamma t}\right) \quad (26.35)$$

Use Lemma 21.44 to compute the probability that a Galton-Watson branching process X with critical geometric offspring distribution and with $X_0 = N \in \mathbb{N}$ is extinct by time $n \in \mathbb{N}$. Compare the result with (26.35).

Part III

Problems

6 Typical tasks

(У Чистякова есть некоторые ответы и решения!!!! тренироваться много еще нужно!!)

6.1 Problems About the Simplest Probabilistic Schemes

6.1.1 Problems About Combinatorial Probability Models (?)

(тут задачи, которые напрямую опираются на комбинаторику)

Ч-1.16

По схеме случайного выбора с возвращением из множества целых чисел $\{0, 1, 2, \dots, 10^n - 1\}$ выбираются числа ξ и η . Обозначим p_m вероятность того, что сумма $\xi + \eta$ будет m -значным натуральным числом в десятичной записи. Найти вероятности $p_{n-k+1}, k = \Rightarrow 0, 1, \dots, n$, и $q_h = \lim_{n \rightarrow \infty} p_{n-k+1}, k = 0, 1, 2, \dots$

Ч-1.17

По схеме случайного выбора с возвратением из множества целых чисел $\{0, 1, 2, \dots, 10^n - 1\}$ выбираются числа ξ и η . Обозначим p_m вероятность того, что произведение $\xi\eta$ будет m -значным натуральным числом в десятичной записи. Найти $q_k = \lim_{n \rightarrow \infty} p_{2n-k} \quad k = 0, 1, 2, \dots$

Количество упаковок для сбора коллекции игрушек в них (????)

В каждую жевачку вложен один из n вкладышей, причем каждый вкладыш встречается с вероятностью $1/n$. Сколько в среднем надо купить жевачек, чтобы собрать полную коллекцию вкладышей?

Пусть у нас уже собрано k вкладышей. Посчитаем, сколько ждать следующего вкладыша. Назовем жевачку новой, если вложенный в нее вкладыш не встречается среди k уже собранных вкладышей. Обозначим M_k среднее количество жевачек, которое нужно купить, чтобы последняя купленная жевачка была новой. Рассмотрим следующую купленную жевачку. Она с вероятностью $\frac{n-k}{n}$ новая (и при этом ожидание $(k+1)$ -ой жевачки в коллекции заканчивается), и с вероятностью $\frac{k}{n}$ она не является новой (в этом случае мы, купив одну жевачку, снова оказываемся в состоянии, когда среднее число жевачек, которые нужно купить до покупки новой, равно M_k). Тем самым, мы приходим к уравнению

$$M_k = \frac{n-k}{n} \cdot 1 + \frac{k}{n} \cdot (M_k + 1),$$

откуда $M_k = \frac{n}{n-k}$. Отсюда получаем, что среднее число жевачек, которое необходимо купить для полной коллекции вкладышей, равно

$$M_0 + M_1 + \dots + M_{n-1} = \frac{n}{n} + \frac{n}{n-1} + \dots + \frac{n}{1} = n \left(1 + \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{n} \right).$$

(??? укажу, почему на самом деле с 0-ля суммируем, важный момент.)

(!! очень крутая задача!! укажу в 1й части суть этих методов!!! очень крутой, очень нетривиальный метод.)

Вероятность совпадения нумераций кубика (??)

Двое человек взяли два кубика, в каждом 6 граней, и произвольного пронумеровали стороны. Какова вероятность того, что с точностью до вращений у них получился один и тот же кубик.

Посчитаем число различных способов, которыми можно пронумеровать грани. 1-ю можно выбрать 6-ю способами, занумеровать 6-ю разными цифрами. 2-ю грань - 5-ю способами, занумеровать 5-ю числами. И т.д. В итоге число различных кубиков будет:

$$N = 6 \cdot 6 \cdot 5 \cdot 5 \cdot 4 \cdot 4 \cdot 3 \cdot 3 \cdot 2 \cdot 2 = (6!)^2$$

Поэтому вероятность совпадения $P = \frac{1}{(6!)^2}$

(?? потом проверю, так ли решил как нужно? пока не уверен, 1я часть слабая.)

Ч-1.18

*. Из множества $\{1, \dots, N\}$ по схеме случайного равновероятного выбора с возвращением выбираются элементы $X'_1, \dots, X'_k$, а по схеме равновероятного выбора для любой совокупности $\mathcal{A} := \{A_1, \dots, A_m\}$, состоящей из попарно различных k -элементных подмножеств $A_i = \{a_{i,1}, \dots, a_{i,k}\} \subset \{1, \dots, N\}$, $0 \leq \mathbf{P}\{\{X''_1, \dots, X''_k\} \in \mathcal{A}\} - \mathbf{P}\{\{X'_1, \dots, X'_k\} \in \mathcal{A}\} \leq \frac{1}{N} C_k^2$.

Ч-1.19

*. По схеме случайного выбора с возвращением из множества натуральных чисел $\{1, 2, \dots, N\}$, $N \geq 4$, выбираются числа X и Y . Что больше: и ли

$$p_2 = \mathbf{P}\{X^2 - Y^2 \text{ делится на } 2\}$$

$$p_3 = \mathbf{P}\{X^2 - Y^2 \text{ делится на } 3\}?$$

Ч-1.22

По схеме случайного выбора с возвращением из множества $\{1, 2, \dots, N\}$ выбираются числа X и Y . Показать, что при $N \geq 4$

$$P\{X^3 + Y^3 = 0 \pmod{3}\} < P\{X^3 + Y^3 = 0 \pmod{7}\}.$$

Ч-1.23

Из совокупности всех подмножеств множества $S = \{1, 2, \dots, N\}$ по схеме выбора с возвращением выбираются множества A_1, A_2 . Найти вероятность того, что $A_1 \cap A_2 = \emptyset$.

Ч-1.24

Из совокупности всех подмножеств множества $S = \{1, 2, \dots, N\}$ по схеме выбора с возвращением выбираются подмножества $A_1, A_2, \dots, A_r$. Найти вероятность того, что множества $A_1, A_2, \dots, A_r$ попарно не пересекаются.

Ч-1.25

*. В урне содержится $(2n+1)^2$ карточек, на каждой из которых написана упорядоченная пара целых чисел (x, y) (x и y принимают значения от $-n$ до n , каждая пара чисел написана ровно на одной карточке). Из урны по схеме выбора без возвращения извлекаются три карточки: $(\xi_1, \eta_1), (\xi_2, \eta_2), (\xi_3, \eta_3)$. Рассмотрим эти пары как координаты случайных точек Ξ_1, Ξ_2, Ξ_3 плоскости в декартовой системе координат. Найти вероят-

Ч-1.26

Брошено 10 игральных костей. Предполагается, что все комбинации выпавших очков равновероятны. Найти вероятности событий:

- а) не выпало ни одной «6»;
- б) выпало ровно три «6»;
- в) выпала хотя бы одна «6»;
- г) выпало хотя бы две «6».

Ч-1.27

Из множества $\{0, 1, \dots, N\}$ по схеме равновероятного выбора с возвращением извлекаются числа

Ч-1.28

Найти вероятность того, что в помете случайно выбранного в большом городе автомобиля сумма первых двух цифр равна сумме двух последних.

Ч-1.29

Некоторые москвичи считают трамвайный, троллейбусный или автобусный билет "счастливым", если сумма первых трех цифр его шестизначного номера совпадает с суммой последних трех цифр (?). Найти вероятность получить «счастливые» билеты.

Ч-1.30

Из карточек разрезной азбуки составлено слово "СТАТИСТИКА". Затем из этих 10 карточек по схеме случайного выбора без возвращения отобрано 5 карточек. Найти вероятность того, что из отобранных карточек можно составить слово «ТАИСИ».

Ч-1.31

Из 30 чисел $(1, 2, \dots, 29, 30)$ случайно отбирается 10 различных чисел. Найти вероятности событий: $A = \{ \text{все числа нечетные} \}$, $B = \{ \text{ровно 5 чисел делится на 3} \}$, $C = \{ \text{5 чисел четных и 5 нечетных, причем ровно одно число делится на 10} \}$.

Ч-1.32

Из урны, содержащей M_1 шаров с номером 1, M_2 шаров с номером 2, ..., M_N шаров с номером N , случайно без возвращения выбирается n шаров. Найти вероятности событий: 1) появилось m_1 шаров с номером 1, m_2 шаров с номером 2, ..., m_N шаров с номером N ; 2) каждый из N номеров появлялся хотя бы один раз.

Ч-1.33

Из множества чисел $\{1, 2, \dots, N\}$ по схеме выбора без возвращения выбираются числа ξ_1 и ξ_2 . Найти $P\{\xi_2 > \xi_1\}$. При выборе трех чисел найти вероятность того, что второе число лежит между первым и третьим.

Ч-1.36

Десять рукописей разложены по 30 папкам (на одну рукопись 3 папки). Найти вероятность того, что в случайно выбранных 6 папках не содержится целиком ни одной рукописи.

Ч-1.37

За круглый стол рассаживаются в случайном порядке $2n$ гостей. Какова вероятность того, что гостей можно разбить на n непересекающихся пар так, чтобы каждая пара состояла из сидящих рядом мужчины и женщины?

Ч-1.38

Участник лотереи «6 из 49» на первой карточке отметил номера $(4, 12, 20, 31, 32, 33)$, а на второй $(4, 12, 20, 41, 42, 43)$. Найти вероятность того, что участник получит ровно два минимальных выигрыша, т. е. что каждый из этих наборов имеет ровно 3 общих элемента с набором номеров $(\alpha_1, \dots, \alpha_6) \subset \{1, 2, \dots, 49\}$, появившихся при розыгрыше тиража.

Ч-1.39

Найти вероятность того, что при случайной расстановке двух ладей на шахматной доске они не будут угрожать друг другу.

Ч-1.40

*. Найти вероятность P_k того, что при случайной расстановке k ($2 \leq k \leq 8$) ладей на шахматной доске никакие две ладьи не будут угрожать друг другу. При каких k эта вероятность меньше $1/2$? Менее $1/100$?

Ч-1.41

Собираясь в путешествие на воздушном шаре, Пончик положил в каждый из 20 карманов своего костюма по прянику. Через каждые 10 минут полета у Пончика возникает желание подкрепиться, и он начинает в случайном порядке просматривать свои карманы до тех пор, пока не найдет очередной пряник. Найти вероятность того, что поиск k -го пряника наталкивается на пустой карман.

Ч-1.50

Равновероятной схемой размещения частиц по ячейкам называют схему размещения, в которой по мере ячейек, последовательно занимаемых частицами, получают посредством случайного выбора с возвращением.

Обозначим $\mu_r = \mu_r(n, N)$ число ячеек, содержащих ровно по r частиц после размещения n частиц по N ячейкам. Найти вероятности следующих событий: 1) $\mu_0(n, N) > 0$ (при $n = N$); 2) $\mu_0(n, N) = 0$ (при $n = N + 1$); 3) $\mu_0(n, N) = 1$ (при $n = N + 1$); 4) найдется ячейка, содержащая хотя бы две частицы (при любых соотношениях между n и N).

Ч-1.51

(см. п.1.50). Найти $P\{\mu_0(n, N) = 0\}$ при произвольных n, N .

Ч-1.52

По N различным ячейкам размещается случайно n неразличимых частиц. (Элементарными событиями являются наборы чисел $(r_1, r_2, \dots, r_N)$, где r_k число частиц в k -й ячейке, $k = 1, 2, \dots, N$.) Найти вероятности событий: 1) $\mu_0(n, N) > 0$; 2) $\mu_0(n, N) = 1$.

Ч-1.53

В первом ряду кинотеатра, состоящем из N кресел, сидит n человек. Предполагая, что все возможные размещения этих n человек в первом ряду равновероятны, найти вероятности следующих событий:

- а) $A_{n,N} = \{\text{никакие 2 человека не сидят рядом}\}$;
- б) $B_{n,N} = \{\text{каждый из } n \text{ человек имеет ровно одного соседа}\}$;
- в) $C_{n,N} = \{\text{из любых двух кресел, расположенных симметрично относительно середины ряда, хотя бы одно свободно}\}$.

Ч-1.54

В зале кинотеатра в первых двух рядах, каждый из которых состоит из N кресел, сидит n человек. Найти вероятности следующих событий:

- а) в первом ряду никакие 2 человека не сидят рядом;
- б) во втором ряду каждый человек имеет ровно одного соседа;
- в) в первом ряду из любых двух кресел, расположенных симметрично относительно середины ряда, хотя бы одно свободно.

Ч-1.55

Из всех отображений множества $\{1, 2, \dots, n\}$ в себя случайно выбирается отображение. Найти вероятности событий: 20

- а) выбранное отображение каждый из n элементов переводит в 1;
- б) элемент i имеет ровно k прообразов;
- в) элемент i переводится в j ;
- г) выбранное отображение элементы $i_1, i_2, \dots, i_k$ ($1 \leq i_1 < i_2 < \dots < i_k \leq n$) переводит в элементы $j_1, j_2, \dots, j_k$ соответственно.

Вероятность попадания при одном выстреле при вероятности попадания хотя бы раз при трех (??)

Вероятность хотя бы одного попадания в цель при трех выстрелах равна 0,973. Найти вероятность попадания в цель при одном выстреле.

Решение: Пусть p - вероятность попадания в цель при одном выстреле. Введем событие $X = \{\text{при трех выстрелах есть хотя бы одно попадание}\}$ и противоположное ему событие $\bar{X} = \{\text{при трех выстрелах нет ни одного попадания}\}$.

Вероятность события $\bar{X}$ равна $P(\bar{X}) = (1-p)^3$, тогда вероятность события X равна $P(X) = 1 - P(\bar{X}) = 1 - (1-p)^3$. По условию эта вероятность равна 0,973, откуда получаем уравнение относительно p :

$$\begin{aligned} 1 - (1-p)^3 &= 0,973, \\ (1-p)^3 &= 0,027, \\ (1-p) &= 0,3, \\ p &= 0,7. \end{aligned}$$

Таким образом, вероятность попадания в цель при одном выстреле равна 0,7.

Ответ: 0,7.

Вероятность, что ладьи на шахматной доске не будут бить друг друга

На шахматную доску 8×8 ставится наудачу две ладьи белого и черного цвета. С какой вероятностью они не будут «бить» друг друга. Решение: Испытание состоит в расположении двух ладей на шахматной доске. Найдем общее число исходов эксперимента. Первую ладью можно поставить 64 способами, после чего вторую ладью можно поставить 63 способами. Общее число исходов равно $64 \cdot 63$.

Событие A - ладьи не будут «бить» друг друга. Очевидно, что проще вычислить вероятность противоположного события $\bar{A}$ - ладьи будут «бить» друг друга.

Найдем благоприятные исходы для события $\bar{A}$. Первую ладью также можно поставить 64 способами, а вторую - только 14-ю (число свободных клеток горизонтали и вертикали, на пересечении которых стоит первая ладья). Общее число благоприятных исходов равно $64 \cdot 14$. Тогда $P(\bar{A}) = \frac{64 \cdot 14}{64 \cdot 63} = \frac{2}{9}$, а $P(A) = 1 - P(\bar{A}) = \frac{7}{9}$.

Тест на заболевание

Заболееваемость некоторым заболеванием X составляет 0,1% (то есть им страдает 0,1% населения). Для выявления этого заболевания был разработан тест. Тест не дает ложноотрицательных результатов (то есть любой, у кого есть заболевание, даст положительный результат на него), но частота ложноположительных результатов составляет 5% (то есть около 5% людей, прошедших тест, получают положительный результат, даже если у них нет этой болезни). Предположим, что случайно выбранный человек проходит тест и у него положительный результат на X . Какова вероятность того, что этот человек действительно болен X ?

Вероятность получить сообщения за меньшее время, чем время, за которое наверняка они придут

(натянута задача, нет такого, хотя отдаленно похожее может быть.)

Володя получает 3 сообщения в час.

- Какова вероятность того, что он получит 5 сообщений в течение двух часов?
- Какова вероятность того, что он получит более двух сообщений в течение двух часов?

$$\lambda = 3 \quad P(X = k) = \frac{(\lambda t)^k}{k!} e^{-\lambda t}$$

X - количество получаемых сообщений

- $P(A) = \frac{(3 \cdot 2)^5}{5!} e^{-6} \approx 0,1606$
- $k > 2 \quad t = 2$

$$P(A) = P(k > 2) = 1 - P(0) - P(1) - P(2) = 1 - \left(\frac{6^2}{2!} + \frac{6^1}{1!} + \frac{6^0}{0!} \right) e^{-6} \approx 0,938$$

(??? причем тут распределение Пуассона!!!!? насколько я плохо это знаю, что вообще не готов к такому??)

Кондратенко-1.

Есть n палок, каждую из которых разломали на 2 части. После этого получившиеся части соединили в пары произвольным образом. Какова вероятность того, что получились в точности исходные палки?

Solution.

Точно исходные палки получатся в единственном из всех случаев сборки. Посчитаем количество вариантов собрать n пар из $2n$ частей. Представим, что мы положили части в определенном порядке и потом соединяем 1 и 2, 3 и 4 и так далее. Тогда способов разложить части будет $(2n)!$. Нам неважно, в каком порядке будут лежать части «внутри палки» - палка получится одинаковая. То есть из одного упорядоченного разложения просто перекалывая части «внутри палки» мы можем получить 2^n эквивалентных сборок. Поэтому делим на 2^n . Кроме того, нас не интересует, в каком порядке будут в итоге лежать получившиеся палки. Способов их переложить $n!$. Значит, искомая вероятность $\frac{n! 2^n}{(2n)!}$.

Кондратенко-2.

У страховой компании 10^4 клиентов, вероятность смерти каждого равна $6 \cdot 10^{-3}$, страховой взнос 12 у.е., выплата в случае смерти - 10^3 \$. Найти вероятность того, что доход компании превысит $4 \cdot 10^4$ и вероятность разорения.

Решение. Подробно рассмотрим случай небывалого дохода, разорение - аналогично. Годовой доход равен $12 \cdot 10^4$, значит, должно произойти не более 80 смертей. Применим теорему Муавра-Лапласа:

$$P\left(a \leq \frac{\mu_n - np}{\sqrt{npq}} \leq b\right) \approx \frac{1}{\sqrt{2\pi}} \int_a^b e^{-\frac{t^2}{2}} dt$$

Подгоним под формулу:

$$\mu_n \leq 80 \Leftrightarrow \frac{\mu_n - 10000 \cdot 0.006}{\sqrt{10000 \cdot 0.006(1 - 0.006)}} \leq \frac{80 - 10000 \cdot 0.006}{\sqrt{10000 \cdot 0.006(1 - 0.006)}} = b$$

В нашем случае $a = -\infty$, поэтому искомая вероятность равна

$$P(\mu_n \leq 80) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^b e^{-\frac{t^2}{2}} dt = \frac{1}{2} + \frac{1}{\sqrt{2\pi}} \int_0^b e^{-\frac{t^2}{2}} dt = \frac{1}{2} + \Phi_0(b)$$

Кондратенко-

3. Вероятность попадания одной пули в бочку с бензином равна p . При одном попадании бочка взрывается с вероятностью p_1 , при двух и более - взрывается наверняка. Найти вероятность того, что бочка рванет при n выстрелах.

Решение. Рассмотрим три случая: не попали ни разу, одно попадание и больше двух попаданий. Обозначим эти события A_0, A_1 и A_2 соответственно. Обозначим событие A - бочка взорвалась. Тогда $P(A) = P(A|A_0)P(A_0) + P(A|A_1)P(A_1) + P(A|A_2)P(A_2)$.

Имеем $P(A_0) = (1-p)^n, P(A_1) = C_n^1 p(1-p)^{n-1}, P(A_2) = 1 - P(A_0) - P(A_1)$.

Из условия $P(A|A_0) = 0, P(A|A_1) = p_1, P(A|A_2) = 1$

Подставляем, $P(A) = np p_1 (1-p)^{n-1} + 1 - np(1-p)^{n-1} - (1-p)^n = 1 + (1-p)^{n-1}(np(p_1 - 1)) - (1-p)^n = 1 + (1-p)^{n-1}(np(p_1 - 1) - (1-p))$

Кондратенко-

4. Завод выпускает изделия с вероятностью брака 0.04. Первый контролер находит брак из брака с вероятностью 0.92, второй - 0.98. Найти вероятность, с которой признанное годным изделие будет бракованным

Решение. Пусть события A_1 - деталь изготовлена с браком, $P(A_1) = 0.04, A_2$ - без брака, $P(A_2) = 0.96, B$ - деталь признана годной. Тогда искомая вероятность

$$P(A_1|B) = \frac{P(B|A_1)P(A_1)}{P(B|A_1)P(A_1) + P(B|A_2)P(A_2)} = \frac{0.04 \cdot P(B|A_1)}{0.04 \cdot P(B|A_1) + 0.96 \cdot 1} = \frac{1}{481}$$

так как $P(B|A_1) = \frac{0.08+0.02}{2} = 0.05$

Кондратенко-

5. Вероятность прихода в бюро k человек равна $e^{-\lambda} \frac{\lambda^k}{k!}$. Вероятность получения отказа p . Найти вероятность ровно m отказов.

Решение. Введем дополнительное обозначение: η - количество деталей.

$$\begin{aligned} P(\xi = m) &= P(\xi = m, (\eta = m) + (\eta = m+1) + \dots) = \sum_{k=m}^{\infty} P(\xi = m|\eta = k)P(\eta = k) = \\ &= \sum_{k=m}^{\infty} e^{-\lambda} \frac{\lambda^k}{k!} p^m q^{k-m} C_k^m = \sum_{k=m}^{\infty} e^{-\lambda} \frac{\lambda^k}{k!} p^m q^{k-m} \frac{k!}{m!(k-m)!} = e^{-\lambda} \frac{p^m}{m!} \sum_{k=m}^{\infty} \frac{\lambda^k}{(k-m)!} q^{k-m} = \\ &= e^{-\lambda} \lambda^m \frac{p^m}{m!} \sum_{k=m}^{\infty} \frac{\lambda^{k-m}}{(k-m)!} q^{k-m} = e^{-\lambda} e^{\lambda(1-p)} \frac{p^m \lambda^m}{m!} = e^{-p\lambda} \frac{(p\lambda)^m}{m!} \end{aligned}$$

Кондратенко-

6. На отрезок $[0, L]$ бросают три точки. Найти вероятность того, что третья окажется между первыми двумя

Решение. По сути требуется найти объем множества $\{(x, y, z) \mid (x < z < y) \vee (y < z < x)\}$. Так как все множества вида $\{(x, y, z) \mid (x < y < z)\}$ $(x, y, z$ идут в определенном порядке) получаются друг из друга движениями, не пересекаются и в сумме покрывают весь куб кроме множества нулевой меры, а всего их 6, то объем каждого из них $1/6$. Значит, объем нашего множества $1/3$.

Кондратенко-

7. Найти мат.ожидание и дисперсию случайной величины:

$$p(x) = \begin{cases} \frac{4x^2}{\alpha^3\sqrt{\pi}} e^{-\frac{x^2}{\alpha^2}}, & x > 0 \\ 0, & x \leq 0 \end{cases}$$

Ответ: $M\xi = \frac{\alpha}{2\sqrt{\pi}}, M\xi^2 = \frac{3}{8}\alpha^2$

Кондратенко-

8. На отрезок бросаются две точки. Найти мат. ожидание и дисперсию расстояния между ними.
Решение. Мат. ожидание:

$$M|\xi - \eta| = \iint_{\substack{0 \leq x \leq 1 \\ 0 \leq y \leq 1}} |x - y| dx dy = 2 \iint_{0 \leq x \leq y \leq 1} (y - x) dx dy = 2 \left(\iint_{0 \leq x \leq y \leq 1} y dx dy - \iint_{0 \leq x \leq y \leq 1} x dx dy \right) = \frac{1}{3}$$

Дисперсия:

$$\begin{aligned} D|\xi - \eta| &= M(\xi - \eta)^2 - \frac{1}{9} = \\ &= \iint_{\substack{0 \leq x \leq 1 \\ 0 \leq y \leq 1}} (x - y)^2 dx dy - \frac{1}{9} = \int_0^1 \left(\frac{1}{3} - y + y^2 \right) dy - \frac{1}{9} = \frac{1}{3} - \frac{1}{2} + \frac{1}{3} - \frac{1}{9} = \frac{1}{18} \end{aligned}$$

Кондратенко-

9. Найти мат. ожидание и дисперсию величины ξ с плотностью $p(x) = \frac{1}{2\alpha} e^{-\frac{|x-a|}{\alpha}}$

Решение. Плотность симметрична относительно точки $x = a$, поэтому $M\xi = a$. Найдём дисперсию:

$$\begin{aligned} D\xi &= \frac{1}{2\alpha} \int_{-\infty}^{\infty} (x - a)^2 e^{-\frac{|x-a|}{\alpha}} dx = \frac{1}{2\alpha} \int_{-\infty}^{\infty} x^2 e^{|x|} \alpha dx = \frac{\alpha^3}{2\alpha} \int_{-\infty}^{\infty} x^2 e^{-|x|} dx = \\ &= \frac{\alpha}{2} \int_{-\infty}^{\infty} x^2 e^{-|x|} dx = \alpha^2 \int_0^{\infty} x^2 e^{-x} dx = \alpha^2 \Gamma(3) = 2\alpha^2 \end{aligned}$$

Кондратенко-

10. Найти мат. ожидание и дисперсию гипергеометрического распределения.

Решение. Гипергеометрическое распределение задается $p_m = \frac{C_M^m C_{N-M}^{n-m}}{C_N^n}$

Его смысл: в урне находится N шаров, из них M белых. Из урны достают без возвращения n шаров, выписана вероятность того, что m из них будут белыми.

Решаем через индикаторы: наша с.в. - количество вынутых белых шаров $\xi = I_1 + \dots + I_n$, где I_i с.в. равная 1, если i -тый вытащенный шар белый, 0 иначе. Индикаторы зависимы, $P(I_i = 1) = \frac{M}{N}$, $P(I_i I_j = 1) = \frac{M(M-1)}{N(N-1)}$ при $i \neq j$. $M I_i = M I_i^2 = \frac{M}{N}$. Поэтому

$$M\xi = \sum_{i=1}^n M I_i = \frac{nM}{N}$$

$$\begin{aligned} M\xi^2 &= M(I_1 + \dots + I_n)^2 = M I_1^2 + \dots + M I_n^2 + 2 \sum_{1 \leq i < j \leq n} M I_i I_j = \\ &= M\xi + 2 \cdot \frac{n!}{(n-2)!2!} \cdot \frac{M}{N} \cdot \frac{M-1}{N-1} = \frac{nM}{N} \left(\frac{(n-1)(M-1)}{N-1} + 1 \right) \end{aligned}$$

Отсюда

$$D\xi = M\xi^2 - M^2\xi = \dots = \frac{nM(N-n)(N-M)}{N^2(N-1)}$$

Кондратенко-

11. Найти мат. ожидание и дисперсию числа смен успеха на неуспех и неуспеха на успех в схеме Бернулли.

Решение. Решим задачу для смен успеха на неуспех. Вероятность смены успеха на неуспех при переходе с i -той позиции на j -тую равна pq . Следовательно, мат. ожидание числа смен успеха на неуспех при этом переходе равно pq . Но мат. ожидание суммы равно сумме мат. ожиданий. Следовательно, $M\xi = (n-1)pq$. Дисперсию сами.

Кондратенко-

12. Пусть ξ_1, ξ_2 - случайные пуассоновские величины с параметрами λ_1 и λ_2 соответственно, причём $\lambda_1 \leq \lambda_2$. Доказать, что $\forall t > 0$ выполняется $P(\xi_1 \leq t) \geq P(\xi_2 \leq t)$.

Решение. Заметим, что

$$P(\xi \leq t) = \sum_{k=0}^{[t]} P(\xi = k) = \sum_{k=0}^{[t]} \frac{\lambda^k}{k!} = e^{-\lambda} Q_{[t]}(\lambda)$$

Найдём производную этой вероятности по λ :

$$P'_\lambda(\xi \leq t) = (e^{-\lambda} Q_{[t]}(\lambda))'_\lambda = -e^{-\lambda} Q_{[t]}(\lambda) + e^{-\lambda} Q'_{[t]}(\lambda) = -e^{-\lambda} (Q_{[t]}(\lambda) - Q_{[t]-1}(\lambda)) = -e^{-\lambda} \frac{\lambda^{[t]}}{[t]!} < 0$$

Из чего следует утверждение задачи.

Кондратенко-

13. Даны ξ_1, ξ_2 - независимые, имеют геометрическое распределение. Найти вероятность того, что $\xi_1 = k$ при условии что $\xi_1 + \xi_2 = n$

Решение. По определению, $P(A|B) = \frac{P(AB)}{P(B)}$

Найдём вероятность того, что $\xi_1 = k$ и $\xi_1 + \xi_2 = n$:

$$P(\xi_1 = k, \xi_1 + \xi_2 = n) = P(\xi_1 = k, \xi_2 = n - k) = p_1 q_1^k p_2 q_2^{n-k}$$

Теперь найдём вероятность того, что $\xi_1 + \xi_2 = n$:

$$P(\xi_1 + \xi_2 = n) = \sum_{k=0}^n P(\xi_1 = k, \xi_1 + \xi_2 = n) = \sum_{k=0}^n p_1 q_1^k p_2 q_2^{n-k} = p_1 p_2 \frac{q_1^{n+1} - q_2^{n+1}}{q_1 - q_2}$$

Осталось поделить одно на другое.

Кондратенко-

14. Пусть ξ - геометрически распределённая случайная величина. Найти распределение величины $\eta = \xi^{1 + \frac{(-1)^\xi}{2}}$.

Решение. Заметим, что $\eta = \xi$, если ξ принимает чётное значение и $\eta = 0$ в противном случае. Значит, $P(\eta = 0) = \sum_{k=0}^{\infty} P(\xi = 2k + 1) = \sum_{k=0}^{\infty} pq^{2k+1} = \frac{pq}{1-q^2}$, $P(\eta = 2k + 1) = 0$, $P(\eta = 2k) = pq^{2k}$

Кондратенко-

15. ξ, η - независимые случайные величины с распределением $\mathcal{N}(0, 1)$. Найти распределение (или плотность) величины $\chi = \xi^2 + \eta^2$

Решение. Найдём функцию распределения. $F_\chi(t) = 0$ при $t \leq 0$, так как $\chi \geq 0$. При $t > 0$:

$$F_\chi(t) = P(\chi \leq t) = \iint_{x^2 + y^2 \leq t} p_{\xi, \eta}(x, y) dx dy = \iint_{x^2 + y^2 \leq t} p_\xi(x) p_\eta(y) dx dy = \frac{1}{2\pi} \iint_{x^2 + y^2 \leq t} e^{-\frac{x^2 + y^2}{2}} dx dy$$

Перейдём к полярным координатам, получим:

$$F_\chi(t) = \frac{1}{2\pi} \int_0^{2\pi} d\varphi \int_0^{\sqrt{t}} e^{-\frac{r^2}{2}} r dr = \int_0^{\sqrt{t}} e^{-\frac{r^2}{2}} d\frac{r^2}{2} = \int_0^{t/2} e^{-u} du = -e^{-u} \Big|_0^{t/2} = 1 - e^{-\frac{t}{2}}$$

Плотность будет

$$p_X(t) = \begin{cases} \frac{1}{2}e^{-\frac{t}{2}}, & t \geq 0 \\ 0, & t < 0 \end{cases}$$

Кондратенко-

16. Пусть ξ, η - нормальные распределения с параметрами $(0, 1)$. Найти распределение $\frac{\xi}{\eta}$

Решение. Зная, что $p_\xi(x) = p_\eta(x) = \frac{1}{\sqrt{2\pi}}e^{-\frac{x^2}{2}}$, найдем распределение

$$F_{\frac{\xi}{\eta}}(t) = \iint_{\frac{y}{x} \leq t} \frac{e^{-\frac{x^2+y^2}{2}}}{2\pi} dx dy = \iint_{\text{tg } \varphi \leq t} \frac{e^{-\frac{r^2}{2}}}{2\pi} r dr d\varphi = 2 \left(\frac{\pi}{2} + \text{arctg } t \right) \cdot \frac{1}{2\pi} \int_0^\infty e^{-u} du = \frac{1}{2} + \frac{\text{arctg } t}{\pi}$$

Получили распределение Коши.

Кондратенко-

17. Даны ξ, η - независимые нормально распределенные величины с параметрами $(0, 1)$. Найти $F_{\frac{\xi}{\eta}, \xi^2 + \eta^2}$

Кондратенко-

18. Пусть η - распределение Коши, $\xi = b\eta + a$, где $b \neq 0$. Найти $p_{\frac{1}{\xi}}(x)$

Кондратенко-

19. Выполняется ли ЗБЧ для такой последовательности случайных величин:

$$P(\xi_n = 2^n) = P(\xi_n = -2^n) = 2^{-2n+1}, P(\xi_n = 0) = 1 - 2^{-2n}?$$

Решение. Да, так как дисперсии $D_{\xi_n} = M\xi_n^2 = 1$ ограничены в совокупности.

Кондратенко-

20. Пусть $M\xi = 0$. Доказать, что $M|\xi| \leq \frac{1}{2}(D\xi + 1)$

Решение. $M\xi = 0$, значит, $D\xi = M\xi^2$. Надо доказать, что $2M|\xi| \leq M(\xi^2 + 1)$, то есть $M(\xi^2 - 2|\xi| + 1) \geq 0$ - правда, так как мат. ожидание неотрицательной величины неотрицательно.

Кондратенко-

21. Дана $\{\xi_n\}_{i=1}^\infty$ - последовательность независимых случайных величин, $M\xi_i = 0, D\xi_i < K \quad \forall i \in \mathbb{N}$

Доказать, что $A_n = \frac{1}{\sqrt{n}} M \left| \sum_{i=1}^n \xi_i \right|$ ограничены в совокупности.

Решение. Обозначим $\eta_n = \frac{\xi_1 + \dots + \xi_n}{\sqrt{n}}$. Так как $M\eta_n = 0$, то $M|\eta_n| \leq \frac{D\eta_n + 1}{2}$. Кроме того, $D\eta_n = \frac{D\xi_1 + \dots + D\xi_n}{n} \leq \frac{Kn}{n} = K$. Значит, $A_n = M|\eta_n| \leq \frac{K+1}{2}$

Кондратенко-

22. Пусть $\xi_1, \dots, \xi_n$ - независимые одинаково распределенные случайные величины, $\eta_n = \xi_1 + \dots + \xi_n$. При этом $M\xi_i = 0$ и $\exists D\xi_i$. Также дано, что $\lim_{n \rightarrow \infty} P(\eta_n > \sqrt{n}) = \frac{1}{3}$. Найти $D\xi_i$ и доказать, что $\forall a, b < \infty \lim_{n \rightarrow \infty} P(\eta_n \in [a, b]) = 0$

Решение. Обозначим $\sigma^2 = D\xi_i$. Применим ЦПТ:

$$\frac{1}{3} = \lim_{n \rightarrow \infty} P(\eta_n > \sqrt{n}) = \lim_{n \rightarrow \infty} P\left(\frac{\eta_n}{\sqrt{n}\sigma} > \frac{1}{\sigma}\right) = 1 - \lim_{n \rightarrow \infty} P\left(\frac{\eta_n}{\sqrt{n}\sigma} < \frac{1}{\sigma}\right) = 1 - \int_{-\infty}^{1/\sigma} e^{-\frac{t^2}{2}} dt = \frac{1}{2} -$$

$$\int_0^{1/\sigma} e^{-\frac{t^2}{2}} dt = \frac{1}{2} - \Phi_0(1/\sigma)$$

Таким образом, $D\xi_i = \sigma^2 = \left(\frac{1}{\Phi_0^{-1}(1/6)}\right)^2$. Посмотрим на второе утверждение:

$$a \leq \eta_n \leq b \Leftrightarrow \frac{a}{\sigma\sqrt{n}} \leq \frac{\eta_n}{\sigma\sqrt{n}} \leq \frac{b}{\sigma\sqrt{n}}$$

Применим ЦПТ:

$$P\left(\frac{a}{\sigma\sqrt{n}} \leq \frac{\eta_n}{\sigma\sqrt{n}} \leq \frac{b}{\sigma\sqrt{n}}\right) \rightarrow \int_{a/(\sigma\sqrt{n})}^{b/(\sigma\sqrt{n})} e^{-\frac{t^2}{2}} dt \rightarrow 0, n \rightarrow \infty$$

Кондратенко-

23. Дана производящая функция Φ . Найти характеристическую.

Решение. По определению,

$$f(t) = Me^{it\xi} = \sum_{k=0}^{\infty} P(\xi = k)e^{itk} = \sum_{k=0}^{\infty} (e^{it})^k = \Phi(e^{it})$$

Кондратенко-

24. Доказать, что $\int_{-\infty}^{\infty} p^2(x)dx = \frac{1}{2\pi} \int_{-\infty}^{\infty} |f(t)|^2 dt$

Решение. Рассмотрим независимые случайные величины ξ_1, ξ_2 с плотностью p . Тогда характеристическая функция их разности будет в точности $f_{\xi_1 - \xi_2}(t) = |f_{\xi}(t)|^2$.

По формуле свёртки $p_{\xi_1 - \xi_2}(x) = \int_{-\infty}^{\infty} p(t-x)p(t)dt$, так как $p_{-\xi}(x) = p_{\xi}(-x)$

Запишем формулу обращения:

$$p_{\xi_1 - \xi_2}(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-itx} |f(t)|^2 dt$$

Приравниваем правые части из обеих формул, подставляем $x = 0$, получаем требуемое утверждение.

Кондратенко-

25. Пусть $(\xi_n - \xi)^2 \xrightarrow{P} 0$. Доказать ¹, что $\xi_n^2 \xrightarrow{P} \xi^2$

Решение. Докажем, что $\xi_n \xrightarrow{P} \xi$. Действительно, $P(|\xi_n - \xi| > \varepsilon) = P((\xi_n - \xi)^2 > \varepsilon^2) \rightarrow 0$ при $n \rightarrow \infty$.

Теперь докажем, что из $\xi_n \xrightarrow{P} \xi$ следует $\xi_n^2 \xrightarrow{P} \xi^2$:

$$P(|\xi_n^2 - \xi^2| > \varepsilon) =$$

$$P(|\xi_n^2 - \xi^2| > \varepsilon, |\xi| > C - 1) + P(|\xi_n^2 - \xi^2| > \varepsilon, |\xi| \leq C - 1, |\xi_n| \leq C) +$$

$$P(|\xi_n^2 - \xi^2| > \varepsilon, |\xi| \leq C - 1, |\xi_n| > C) \leq P(|\xi| > C - 1) + P(|\xi - \xi_n| > \frac{\varepsilon}{2C}) + P(|\xi - \xi_n| > 1)$$

Сначала выберем C так, чтобы первое слагаемое стало маленьким. Потом выберем N так, что при $n > N$ второе и третье слагаемое тоже стали малы.

Кондратенко-

26. Пусть $b > a > 0$, Φ - производящая функция. Доказать, что

$$M \frac{1}{(\xi + a)(\xi + b)} = \int_0^1 z^{b-a-1} \int_0^z u^{a-1} \Phi(u) du dz$$

Решение. По определению,

$$\begin{aligned}
\int_0^1 z^{b-a-1} \int_0^z u^{a-1} \Phi(u) du dz &= \int_0^1 z^{b-a-1} \int_0^z u^{a-1} \sum_{k=0}^{\infty} p_k u^k du dz = \\
\sum_{k=0}^{\infty} p_k \int_0^1 z^{b-a-1} \int_0^z u^{k+a-1} du dz &= \sum_{k=0}^{\infty} p_k \int_0^1 z^{b-a-1} \frac{z^{k+a}}{k+a} dz = \\
\sum_{k=0}^{\infty} p_k \int_0^1 \frac{z^{b+k-1}}{k+a} dz &= \sum_{k=0}^{\infty} p_k \frac{1}{(k+a)(k+b)} = M_{\frac{1}{(k+a)(k+b)}}
\end{aligned}$$

Кондратенко-

27. Пусть ξ_i - независимые одинаково распределенные случайные величины, $M\xi_i = a, D\xi_i = \sigma^2$. Доказать, что последовательность $\frac{\xi_1 + \dots + \xi_n}{\xi_1^2 + \dots + \xi_n^2}$ сходится и найти чему.

Решение. Эта последовательность сходится к $\frac{a}{a^2 + \sigma^2}$. Действительно, $M\xi_i^2 = M^2\xi_i + D\xi_i = a^2 + \sigma^2$. Еще заметим, что $\frac{\xi_1 + \dots + \xi_n}{\xi_1^2 + \dots + \xi_n^2} = \frac{\xi_1 + \dots + \xi_n}{n} \cdot \frac{n}{\xi_1^2 + \dots + \xi_n^2}$. Но первая из дробей, согласно ЗБЧ, сходится к a , а последовательность, обратная второй - к $a^2 + \sigma^2$. Осталось доказать, что предел частного есть частное пределов для сходимости по вероятности.

Кондратенко-

28. Пусть ξ_i - н.о.р.с.в., у которых $M\xi_i = 0, D\xi_i = 1$. Доказать, что величина $\eta_n = \frac{\sqrt{n}(\xi_1 + \dots + \xi_n)}{\xi_1^2 + \dots + \xi_n^2}$ асимптотически нормально распределенная

Решение. Заметим, что по ЦПТ $\frac{\xi_1 + \dots + \xi_n}{\sqrt{n}}$ сходится к нормальному распределению, а $\frac{\xi_1^2 + \dots + \xi_n^2}{n}$ по ЗБЧ сходится к своему мат. ожиданию, в нашем случае к 1. Теперь надо правильно сказать, что частное последовательностей сходится к частному пределов.

Кондратенко-

29. Доказать, что ξ - геометрически распределенная случайная величина тогда и только тогда когда $P(\xi = n + k | \xi \geq k) = P(\xi = n)$.

Решение. Посчитаем для геометрического распределения $P(\xi = n + k | \xi \geq k)$:

$$P(\xi = n + k | \xi \geq k) = \frac{P(\xi = n + k, \xi \geq k)}{P(\xi \geq k)}$$

Если ξ геометрически распределена, то $P(\xi = k) = (1 - q)q^k$, откуда

$$P(\xi \geq k) = \sum_{i=k}^{\infty} P(\xi = i) = (1 - q)q^k (1 + q + q^2 + \dots) = (1 - q) \frac{q^k}{1 - q} = q^k$$

Числитель:

$$P(\xi = n + k, \xi \geq k) = P(\xi = n + k, n + k \geq k) = P(\xi = n + k, n \geq 0) = P(\xi = n + k) = (1 - q)q^{n+k}$$

Значит,

$$P(\xi = n + k | \xi \geq k) = \frac{(1 - q)q^{n+k}}{q^k} = (1 - q)q^n = P(\xi = n)$$

Заметим, что для $n < 0$ числитель будет 0, как и $P(\xi = n)$.

В одну сторону доказали. Теперь докажем, что это свойство и число $p = 1 - q = P(\xi = 0)$ однозначно задает распределение ξ . Действительно, при $n < 0$ числитель нулевой, значит, $P(\xi < 0) = 0$. Подставляя $n = 0$ в свойство, получим:

$$p = P(\xi = 0) = P(\xi = k | \xi \geq k) = \frac{P(\xi = k, \xi \geq k)}{P(\xi \geq k)} = \frac{P(\xi = k)}{P(\xi \geq k)}$$

значит,

⁰¹ Верен и более общий факт, который, кстати, и доказывается более изящно. Именно, если $\xi_i \xrightarrow{P} \xi$, а f непрерывна, то $f(\xi_i) \xrightarrow{P} f(\xi)$. Доказательство смотри М.И.Дьяченко, П.Л.Ульянов. Мера и интеграл, стр. 52-53.

$$P(\xi = k) = p \cdot P(\xi \geq k) = p(1 - P(\xi < k))$$

Зная, что $P(\xi < 0) = 0, P(\xi = 0) = p$ и подставляя в это соотношение $k = 1, 2, \dots$ можно найти все вероятности, то есть распределение определено однозначно. Одно такое мы знаем - геометрическое, значит, это оно и есть.

Кондратенко-

30. Найти свёртку двух нормальных распределений с параметрами (a_1, σ_1^2) и (a_2, σ_2^2)

Решение. Нормальное распределение с произвольными параметрами $\eta \sim \mathcal{N}(a, \sigma^2)$ может быть представлено в виде $\eta = \sigma\xi + a, \xi \sim \mathcal{N}(0, 1)$. Характеристическая функция нормального распределения $f_\xi(t) = e^{-\frac{t^2}{2}}$. Кроме того, $f_{b\xi+a} = e^{ita} f_\xi(bt)$ Значит, $f_\eta = f_{\sigma\xi+a} = e^{ita} e^{-\frac{\sigma^2 t^2}{2}}$. Нашли характеристическую функцию нормального распределения с параметрами (a, σ^2) .

Теперь задача. Пусть $\xi_1 \sim \mathcal{N}(a_1, \sigma_1^2), \xi_2 \sim \mathcal{N}(a_2, \sigma_2^2)$. Тогда

$$f_{\xi_1+\xi_2}(t) = f_{\xi_1}(t)f_{\xi_2}(t) = e^{ita_1} e^{-\frac{\sigma_1^2 t^2}{2}} e^{ita_2} e^{-\frac{\sigma_2^2 t^2}{2}} = e^{it(a_1+a_2)} e^{-\frac{(\sigma_1^2+\sigma_2^2)t^2}{2}}$$

Значит, $\xi_1 + \xi_2 \sim \mathcal{N}(a_1 + a_2, \sigma_1^2 + \sigma_2^2)$

Кондратенко-

31. Найти свёртку двух равномерно распределённых на отрезках $[A, B]$ и $[C, D]$ случайных величин.

Решение. Надо найти распределение суммы. Другими словами, надо найти, какую часть площади прямоугольника с углами (A, C) и (B, D) лежит в полуплоскости $x + y \leq \alpha$. Из геометрии очевидно, что при $\alpha < A + C$ эта площадь равна нулю, при $\alpha \in (A + C, A + D)$ происходит квадратичный рост, при $\alpha \in (A + D, C + B)$ - линейный рост, при $\alpha \in (C + B, B + D)$ - опять квадратичный рост, а при $\alpha > B + D$ доля площади равна единице. Таким образом, плотность сначала равна нулю, потом линейно растёт, потом константа, потом линейно убывает, потом опять ноль.

Кондратенко-

32. Являются ли $\sin x, \cos x$ и $|\cos x|$ характеристическими функциями?

Решение. $\sin x$ не является, так как $\sin 0 = 0 \neq 1$.

$\cos x$ выражается через e^{ix} и e^{-ix} через формулы Эйлера:

$$\begin{cases} e^{ix} = \cos x + i \sin x \\ e^{-ix} = \cos x - i \sin x \end{cases}$$

То есть, $\cos t = 1/2(e^{it} + e^{-it})$, что соответствует характеристической функции дискретного распределения $\xi: P(\xi = 1) = P(\xi = -1) = 1/2$

$|\cos x|$ в окрестности нуля совпадает с просто косинусом и имеет в нуле вторую производную, а значит, если это характеристическая функция какой-то случайной величины, то у этой с.в. должен быть момент второго порядка, но если есть момент k -того порядка, то у характеристической функции всюду существует k -тая производная, но у $|\cos x|$ нет производных в точках $\frac{\pi}{2} + \pi n$. Противоречие.

Кондратенко-

33. Является ли функция

$$f(t) = \begin{cases} 1 - t^2, & |t| \leq 1 \\ 0, & \text{иначе} \end{cases}$$

характеристической, если да, то для какого распределения?

Решение. Не является, так как имеет вторую производную в нуле, но не имеет производной в точках ± 1

Кондратенко-

34. Является ли e^{-t^4} характеристической функцией?

Решение. Не является.

Кратко - по теореме Марцинкевича (если х.ф. представляется в виде экспонента в степени многочлен, то такой многочлен не может быть степени больше 2).

Строго:

При разложении в ряд e^{-t^4} первый член, содержащий t будет иметь степень 4. Это значит, что в нуле у нашей функции первая и вторая (и третья) производные равны 0. Но мы знаем, что $f^{(k)}(0) = i^k \alpha_k$, то

есть, у нашей предполагаемой с.в. первый и второй моменты нулевые. Это значит, что мат. ожидание $M\xi = \alpha_1$ и дисперсия $D\xi = \alpha_2 - \alpha_1^2$ равны 0. Значит, $P(\xi = \text{const}) = 1$, но у константы х.ф. e^{itc} , противоречие.

Кондратенко-

35. Пусть $\sum_{k=1}^n a_k = 1$, будет ли $\sum_{k=1}^n a_k \cos kt$ характеристической функцией?

Решение. Рассмотрим ξ :

$$\begin{pmatrix} -n & -n+1 & \dots & -1 & 1 & \dots & n \\ \frac{a_n}{2} & \frac{a_{n-1}}{2} & \dots & \frac{a_1}{2} & \frac{a_1}{2} & \dots & \frac{a_n}{2} \end{pmatrix}$$

$$\text{Тогда } f_\xi = \sum_{k=1}^n a_k \frac{e^{itk} + e^{-itk}}{2} = \sum_{k=1}^n a_k \cos kt.$$

Кондратенко-

36. Пусть $f(t)$ - характеристическая функция. Является ли $\text{Re } f(t)$ характеристической функцией (а если да, то какого распределения)?

Ответ: Да, является. (Указание: $\text{Re } f(t) = \frac{f(t) + f(-t)}{2}$).

Кондратенко-

37. Найти распределение суммы пуассоновских случайных величин через производящие функции

Решение. Производящая функция для пуассоновского распределения с параметром λ :

$$\xi \sim \Pi(\lambda), \Phi_\xi(x) = \sum_{k=0}^{\infty} e^{-\lambda} \frac{x^k \lambda^k}{k!} = e^{-\lambda} \sum_{k=0}^{\infty} \frac{(\lambda x)^k}{k!} = e^{-\lambda} e^{\lambda x} = e^{\lambda(x-1)}$$

Таким образом, если $\xi_1 \sim \Pi(\lambda_1), \xi_2 \sim \Pi(\lambda_2)$, то

$$\Phi_{\xi_1 + \xi_2}(x) = \Phi_{\xi_1}(x) \Phi_{\xi_2}(x) = e^{\lambda_1(x-1)} e^{\lambda_2(x-1)} = e^{(x-1)(\lambda_1 + \lambda_2)} = \Phi_{\Pi(\lambda_1 + \lambda_2)}$$

То есть $\Pi(\lambda_1) + \Pi(\lambda_2) \sim \Pi(\lambda_1 + \lambda_2)$

Кондратенко-

38. Пусть $\xi_n \xrightarrow{P} 0$. Доказать, что $\forall \varepsilon$, такого, что ξ независимо с любым ξ_n , выполнено $\xi \xi_n \xrightarrow{P} 0$.

Решение. Пусть $\varepsilon > 0$, тогда $P(|\xi_n \xi| \geq \varepsilon) = P\left(|\xi_n| \geq \frac{\varepsilon}{|\xi|}\right) P(|\xi| > 0) + P(0 \geq \varepsilon) P(|\xi| = 0) = P\left(|\xi_n| \geq \frac{\varepsilon}{C}\right) P(0 \leq |\xi| < C) + P\left(|\xi_n| \geq \frac{\varepsilon}{C}\right) P(|\xi| \geq C)$. Тогда $\forall \delta > 0 \exists C > 0 : P\left(|\xi_n| \geq \frac{\varepsilon}{C}\right) P(|\xi| \geq C) < 1 \cdot \delta = \delta$, тогда $\exists N > 0 : \forall n > N$ выполнено $P\left(|\xi_n| \geq \frac{\varepsilon}{C}\right) P(0 \leq |\xi| < C) < \delta \cdot 1 = \delta$. Значит, $\xi_n \xrightarrow{P} 0$.

Кондратенко-

39. Пусть $\xi_n \xrightarrow{d} \xi$, верно ли, что $\xi_n - \xi \xrightarrow{d} 0$?

Ответ: Не верно.

Кондратенко-

40. Пусть $x i_n$ - н.о.р.с.в., $\eta_n = \frac{\xi_1 + \dots + \xi_n}{n}$ и $p_{\xi_n} = \frac{1 - \cos x}{\pi x^2}$ $\xi_n \xrightarrow{d} ?$

Кондратенко-

41. Пусть $x i_n$ - н.о.р.с.в. Доказать, что $\forall k \leq n : M\left(\frac{\xi_1 + \dots + \xi_k}{\xi_1 + \dots + \xi_n} = \frac{k}{n}\right)$

Кондратенко-

42. Доказать формулу Байеса.

Кондратенко-

43. Доказать интегральную теорему Муавра-Лапласа (без использования ЦПТ).

Кондратенко-

44. Доказать эквивалентность сходимости $\xi_i \xrightarrow{d} \xi$ и сходимости их производящих функций.

Кондратенко-

45. Доказать ЗБЧ (в простой форме).

Кондратенко-

46. Доказать ЦПТ (в простой форме).
Решения смотри учебник Севастьянова.

Кондратенко-

47. Доказать, что мощность σ -алгебры не может равняться 130.

Решение. У всякой конечной σ -алгебры есть порождающее множество, т.е. множество таких элементов a_i , что $\forall \omega$ из σ -алгебры пересечение a_i и ω равно либо a_i , либо $\emptyset$, и при этом $\bigcup a_i = \Omega$. Такое множество можно построить: взять элемент A из σ -алгебры, потом взять B и, если A и B пересекаются, то оставить вместо них $A \setminus B, B \setminus A$ и $A \cap B$. Затем берём элемент C и продолжаем данную процедуру. Она оборвётся на некотором шаге в силу конечности алгебры. В итоге получится порождающее множество мощности n . Но тогда можно установить биекцию между n -битными словами и элементами σ -алгебры по следующему принципу: на i -ая буква есть 1, если $a_i \in \omega$, и 0 в противном случае. Так как таких слов 2^n , то и мощность σ -алгебры есть 2^n .

Кондратенко-

48. Доказать, что мощность σ -алгебры не может быть счётной.

Решение. Пусть σ -алгебра счётна, тогда можно построить счётную последовательность непустых непересекающихся её элементов таким образом: возьмём $A \neq \Omega$ за первый элемент и $\bar{A}$ за второй. Очевидно, что они не пересекаются, и хотя бы один из них можно опять поделить (иначе σ алгебра была бы конечной). Будем продолжать этот процесс до тех пор, пока не получим $\aleph_0$ непустых непересекающихся элементов. Но любое счётное объединение элементов из неё будет принадлежать σ -алгебре а если брать объединения различных элементов, то получать будем так же разные. Т.о. в σ -алгебре присутствуют как минимум $2^{\aleph_0} = \mathfrak{c}$ элементов.

Кондратенко-

49. $\xi > 0, \exists M\xi$. Доказать, что $1 \leq M\xi M_{\xi}^{\frac{1}{\xi}}$.

Решение. Нужно доказать, что $1 - M\xi M_{\xi}^{\frac{1}{\xi}} \leq 0$. Посмотрим на это выражение, как на дискриминант некоторого квадратного уравнения:

$$D \leq 0 \Leftrightarrow M\xi x^2 - x + \frac{1}{4}M_{\xi}^{\frac{1}{\xi}} \geq 0 \Leftrightarrow M \left(\frac{1}{\xi} (4x^2\xi^2 - 4x\xi + 1) \right) \geq 0 \Leftrightarrow M \frac{(2x\xi + 1)^2}{\xi} \geq 0$$

что верно при любых x , так как это математическое ожидание неотрицательной функции.

Кондратенко-

50. ξ_i - последовательность независимых неотрицательных целочисленных одинаково распределённых случайных величин, ν - независимая с ними неотрицательная целочисленная случайная величина. Найти $\Phi_{\xi_1 + \dots + \xi_{\nu}}$.

$$\begin{aligned} \text{Решение. } \Phi_{\xi_1+\dots+\xi_\nu} &= Mx^{\xi_1+\dots+\xi_\nu} = \sum_{k=0}^{\infty} x^k P(\xi_1+\dots+\xi_\nu=k) = \sum_{k=0}^{\infty} \sum_{m=0}^{\infty} x^k P(\xi_1+\dots+\xi_m=k|\nu=m) \\ &= \sum_{m=0}^{\infty} \sum_{k=0}^{\infty} x^k P(\xi_1+\dots+\xi_m=k) P(\nu=m) = \sum_{m=0}^{\infty} (\Phi_{\xi_1}(x))^m P(\nu=m) = \Phi_\nu(\Phi_{\xi_1}(x)) \end{aligned}$$

Кондратенко-

51. Доказать, что если ξ и η независимы, то ρ (коэффициент корреляции) равен нулю, но обратное не всегда верно.

Решение. $\Rightarrow$ Если ξ и η независимы, то $\text{cov}(\xi, \eta) = M\xi\eta - M\xi M\eta = 0$, а значит и $\rho = 0$.
 $\Leftarrow$ Рассмотрим величину ξ , принимающие значения $0, \frac{\pi}{2}$ и π с равными вероятностями, и величины $\sin \xi$ и $\cos \xi$. $0 = P(\cos \xi = 1, \sin \xi = 1) \neq P(\cos \xi = 1)P(\sin \xi = 1) = \frac{1}{9}$, значит величины зависимы. При этом $\text{cov}(\cos \xi, \sin \xi) = M \cos \xi \sin \xi - M \cos \xi M \sin \xi = \frac{1}{2} M \sin 2\xi = 0$.

Кондратенко-

52. Доказать, что $|\rho(\xi, \eta)| = 1 \Leftrightarrow \eta = a\xi + b$.

Решение. То, что $|\rho(\xi, \eta)| \leq 1$ следует из неравенства Коши-Буняковского $M^2\xi\eta \leq M\xi^2 M\eta^2$. Вспомним, как мы его доказывали: $M(\xi + \lambda\eta)^2$ неотрицательно как мат. ожидание неотрицательной случайной величины, притом равенство нулю достигается тогда, когда эта случайная величина с вероятностью 1 является константой 0. С другой стороны,

$$M(\xi + \lambda\eta)^2 = M\xi^2 + 2\lambda M\xi\eta + \lambda^2 M\eta^2 \geq 0$$

Это означает, что дискриминант квадратного уравнения на λ меньше либо равен нулю, что и даёт нам неравенство Коши-Буняковского. Пусть он равен нулю (как раз в этом случае $|\rho(\xi, \eta)| = 1$), это значит, что существует такое λ , что $M(\xi + \lambda\eta)^2 = 0$, откуда заключаем, что с вероятностью 1 выполнено $\xi = -\lambda\eta$

Кондратенко-

53. Про производящую функцию $\Phi_\xi(x)$ известно, что $\forall n \geq 0 \Phi_\xi\left(\frac{1}{2^n}\right) = \frac{1}{2^n}$. Найти распределение ξ .

Решение. $\Phi_\xi(0) = \Phi_\xi\left(\lim_{n \rightarrow \infty} \frac{1}{2^n}\right) = \lim_{n \rightarrow \infty} \Phi_\xi\left(\frac{1}{2^n}\right) = 0$, значит $p_0 = 0$. Выпишем два равенства:

$$\begin{aligned} \sum_{k=0}^{\infty} \frac{1}{2^k} p_k &= p_0 + \frac{1}{2} p_1 + \frac{1}{4} p_2 + \dots = \frac{1}{2} \\ \sum_{k=0}^{\infty} \frac{1}{2^{2k}} p_k &= p_0 + \frac{1}{4} p_1 + \frac{1}{16} p_2 + \dots = \frac{1}{4} \end{aligned}$$

Домножим второе равенство на 2 и вычтем из первого, помня, что $p_0 = 0$:

$$0 + 0 + \frac{1}{8} p_2 + \dots = 0$$

Все p_i и коэффициенты перед ними неотрицательны, значит все p_i , кроме p_1 , равны 0. Отсюда $p_1 = 1$.

Кондратенко-

54. Является ли функция $\Phi(x) = \frac{2e}{e^2+1} \text{sh } x$ производящей, и если да, то какого распределения?

Решение. Нужно проверить, чтобы в точке $x = 1$ функция равнялась единице и чтобы все её производные в нуле были неотрицательны. Первое условие выполнено.

$$\begin{aligned} \Phi^{2n+1}(x) &= -\frac{2e}{e^2+1} \text{sh } x \\ \Phi^{2n}(x) &= \Phi(x) \end{aligned}$$

В нуле чётные производные равны $\frac{2e}{e^2+1}$, а нечётные равны 0. Таким образом,

$$p_{2n+1} = 0, p_{2n} = \frac{2e}{(e^2+1)(2n)!}$$

Кондратенко-

55. Верно ли, что сходимость почти всюду равносильна сходимости по вероятности? Решение. Из сходимости почти всюду следует сходимость по вероятности, обратное неверно.

Кондратенко-

56. Известно, что $\xi_n \xrightarrow{P} \xi, \xi_n \xrightarrow{P} \eta$. Доказать, что $P(\xi = \eta) = 1$.

Кондратенко-

57. Известно, что $\xi_n \xrightarrow{P} 0, \eta_n \xrightarrow{P} \eta$. Доказать, что $\xi_n \eta_n \xrightarrow{P} 0$.

Кондратенко-

58. Пусть ξ_i - независимые одинаково распределённые случайные величины, с характеристической функцией

$$f_{\xi_i}(t) = \begin{cases} 1 - |t|, & |t| < 1 \\ 0, & |t| \geq 1 \end{cases}$$

найти $\frac{\xi_1 + \dots + \xi_n}{n} \xrightarrow{d} ?$

Решение. Обозначим $\eta_n = \frac{\xi_1 + \dots + \xi_n}{n}$. Найдём $f_{\eta_n}(t)$:

$$f_{\eta_n}(t) = \left(f_{\xi_1}\left(\frac{t}{n}\right)\right)^n = \left(f_{\xi_1}\left(\frac{t}{n}\right)\right)^n = \left(1 - \frac{|t|}{n}\right)^n$$

отсюда получаем:

$$\lim_{n \rightarrow \infty} f_{\eta_n}(t) = e^{-|t|}$$

Кондратенко-

59. Про события A и B известно, что $P(A) = P(B) = \frac{1}{2}$. Доказать, что $P(AB) = P(\bar{A}\bar{B})$

Решение. Напомню обозначения для событий-множеств: $A \cup B = A + B, A \cap B = AB$. Теперь, имея на руках тождество $P(A + B) = P(A) + P(B) - P(AB)$ и правило де Моргана $\overline{A + B} = \bar{A}\bar{B}$, подгоним искомое равенство:

$$P(AB) = P(A) + P(B) - P(A + B) = 1 - P(\overline{A + B}) = 1 - P(\bar{A}\bar{B}) = 1 - (1 - P(\bar{A}\bar{B})) = P(\bar{A}\bar{B})$$

Кондратенко-

60. Известно, что $\xi_n \xrightarrow{d} \xi$.

Верно ли:

- а) $\forall i \exists M \xi_i \Rightarrow \exists M \xi$
- б) $\exists M \xi \Rightarrow \exists M \xi_i$, начиная с некоторого номера
- в) $\exists M \xi_i, \exists M \xi \Rightarrow M \xi_i \rightarrow M \xi$

Решение. Ничего не верно. Приводим контрпримеры:

- а) Возьмем η - последовательность Коши, а

$$\xi_n = \begin{cases} \eta, & \eta \in [-n, n] \\ 0 & \text{иначе} \end{cases}$$

Вроде это называется обрезкой. Получаем $\xi_i \xrightarrow{d} \eta = \xi$. Из-за того, что плотность у распределения Коши симметрична относительно 0, а интеграл по конечной области можно взять, то $\forall i M \xi_i = 0$, но, как мы знаем, $\nexists M \xi$

- б) Опять с Коши. Возьмем

$$\xi_n = \begin{cases} 0, & \eta \in [-n, n] \\ \eta & \text{иначе} \end{cases}$$

Тогда предельная последовательность будет всюду 0 и мат. ожидание у нее 0, но у любой ξ_i мат. ожидания нет, так как у нее остались от Коши «хвосты» на бесконечности, которые, домноженные на x , дают расходящийся интеграл.

- в) Было на лекции скорее всего. Возьмем дискретную с.в.:

$$\xi_n \left(\begin{array}{cc} 0 & n \\ \frac{n-1}{n} & \frac{1}{n} \end{array} \right)$$

Она опять же стремится к константе 0 с мат. ожиданием 0. Но $M \xi_n = 0 \cdot \frac{n-1}{n} + n \cdot \frac{1}{n} = 1$

Кондратенко-

61. Найти коэффициент корреляции между числом выпадения единицы, и числом выпадения шестёрок при бросании кубика n раз

Решение. Рассмотрим случайные величины $\xi_i =$ числу выпадения грани i . Очевидно, что они распределены одинаково и по сути нет разницы между ξ_1 и ξ_6 . Так же ясно, что при бросании кубика n раз выпадет n граней (n - константа). Таким образом получаем:

$$0 = D(n) = D(\xi_1 + \dots + \xi_6) = D\xi_1 + \dots + D\xi_6 + 2 \sum_{1 \leq i < j \leq 6} \text{cov}(\xi_i, \xi_j) = 6D\xi_1 + 2C_6^2 \text{cov}(\xi_1, \xi_6)$$

$$\text{отсюда следует, что } \rho(\xi_1, \xi_6) = \frac{\text{cov}(\xi_1, \xi_6)}{\sqrt{D\xi_1} \sqrt{D\xi_6}} = \frac{\text{cov}(\xi_1, \xi_6)}{D\xi_1} = -\frac{1}{5}.$$

Кондратенко-

62. Доказать, что если ξ, η имеют совместное нормальное распределение (вектор $(\xi, \eta)^T$ нормально распределен) и их ковариация равна нулю, то ξ и η независимы.

Кондратенко-

63. Двумерная случайная величина (ξ, η) равномерно распределена на прямоугольнике. Что можно сказать о зависимости ξ и η ?

Ответ: Независимы.

Кондратенко-

64. Двумерная случайная величина (ξ, η) равномерно распределена на круге. Что можно сказать о зависимости ξ и η ?

Ответ: Зависимы.

6.1.2 Problems About Geometric Probabilities**МФТИ-Т.14 Бросание иглы**

На плоскость, разлинованную параллельными линиями, расстояние между которыми $L = 1$, бросают иглу длины $l \leq L$. Какова вероятность того, что игла пересечет одну из линий?

Solution

Введем параметр x - расстояние от середины иглы до ближайшей линии. Этим параметром, а также углом α , который составляет игла с линией, определяется однозначно положение иглы. (Мы помещаем центр координат плоскости в центр между линиями, в области, где есть центр иглы). Таким образом, пространство событий это множество из всех x, α : $\Omega = [0, L/2] \times [0, \pi]$. Его можно представить как прямоугольник.

В Ω нам нужны события, соответствующие пересечениям иглы с линией, то есть когда проекция иглы на перпендикуляр $\frac{l}{2} \sin \alpha$ больше расстояния от центра иглы до линии: $x \leq \frac{l}{2} \sin \alpha$. В итоге в прямоугольнике Ω появляется нужная нам область площадью $S = \frac{l}{2} \int_0^\pi \sin \alpha d\alpha = \frac{l}{2} (-\cos(\pi) - (-\cos 0)) = l$.

В итоге по формуле геометрической вероятности

$$P = \frac{l}{\pi L/2} = \frac{2l}{\pi L}$$

Ответ: $\frac{2l}{\pi L}$

Комментарий про решение: Можно было ввести и другой угол, тогда проекция была бы $\sim |\cos \phi_2|$, но так не удобнее.

Комментарий про задачу: это известная задача Бюффона. В прошлом были эксперименты по проверке этого ответа и про вычисление числа π , что сейчас не особо уже интересно и важно.

ФР-2023. Парадокс Бертрана о хорде

В круге радиуса R случайно проводится хорда. Обозначим через ξ ее длину. Найти вероятность $Q_x = P(\xi > x)$. Вычислить вероятности Q_R и $Q_{R\sqrt{3}}$ того, что длина хорды больше стороны правильного вписанного шестиугольника и треугольника соответственно. Рассмотреть следующие случаи:

1. Считать, что слово “случайно” означает, что середина хорды равномерно распределена в круге.
2. Считать, что слово “случайно” означает, что направление хорды фиксировано, а середина равномерно распределена на диаметре окружности.
3. Считать, что слово “случайно” означает, что один из концов хорды закреплён, а другой равномерно распределён на окружности.

Указание: В качестве ответа на каждый из пунктов принимается формула для Q_x , выражающая искомую вероятность через R и параметр x , а также два значения, вычисленные по этой формуле: при $x = R$ и при $x = R\sqrt{3}$.

1. Случай «случайного центра»

Хорда длиннее стороны равностороннего треугольника, если выбранная точка находится внутри круга, вписанного в треугольник. Это можно легко увидеть, представим, что мы вращаем вписанный треугольник, так что его сторона может стать параллельно хорде и очевидно, кто из них больше. Поэтому

$$Q_x = \frac{r_{\text{int}}}{R^2} = \frac{R^2 \cos^2 \frac{\pi}{n}}{R^2} = \cos^2 \frac{\pi}{n}.$$

Рассмотрим случай с треугольником. Площадь вписанного круга есть $1/4$ от площади большего, значит, исходная вероятность равна $\frac{1}{4}$.

Рассмотрим случай с шестиугольником. Аналогично, только площадь вписанного круга есть $\pi R^2 \left(\frac{\sqrt{3}}{2}\right)^2$ от площади большего, значит, исходная вероятность равна $\frac{3}{4}$.

2. Случай «случайного диаметра»

Так как все на диаметр в 2-е больше радиуса и все симметрично, то вероятность выбора случайной точки на диаметре такая же, что и на радиусе. Представим, что n -угольник повернут так, что одна из его сторон перпендикулярна зафиксированному радиусу. Хорда длиннее стороны n -угольника, если её центр ближе к центру, чем точка пересечения треугольника с зафиксированным радиусом. Угол между расстоянием от центра до ребра равен (исходя из равного деления дуги) $\frac{2\pi}{2n}$, поэтому

$$Q_x = \frac{R \cos(\pi/n)}{R}$$

Рассмотрим случай с треугольником. Сторона треугольника делит пополам радиус, следовательно вероятность выбрать хорду длиннее стороны треугольника равна $\frac{1}{2}$.

Рассмотрим случай с шестиугольником. Аналогично, но теперь нужно заметить из геометрии, что от центра шестиугольника до его стороны расстояние $R\frac{\sqrt{3}}{2}$. Ответ: $\frac{\sqrt{3}}{2}$.

3. Случай «случайных концов»

Представим, что n -угольник повернут так, что одна из его вершин совпадает с концом хорды. Нам нужно, чтобы конец хорды лежал на большей дуге между двумя ближайшими вершинами шестиугольника от первого зафиксированного конца.

$$Q_x = \frac{2\pi R(n-2)/n}{2\pi R}$$

Рассмотрим случай с треугольником. Длина рассмотренной дуги равна $1/3$ длины окружности, поэтому искомая вероятность равна $\frac{1}{3}$.

Рассмотрим случай с шестиугольником. Аналогично, но теперь Длина этой дуги равна $2/3$ длины окружности, поэтому искомая вероятность равна $\frac{2}{3}$.

МФТИ-Т.15 Три точки на отрезке

На отрезок наудачу последовательно одну за другой бросают три точки. Какова вероятность того, что третья по счету точка попадет между двумя первыми?

Solution

Пусть три точки уже находятся на отрезке. Между двумя крайними точками находится одна из них. Она могла бы попасть первой, могла бы второй, а могла бы и третьей. Таким образом, из всех способов размещения трех точек только один нужен нам, когда средняя точка попадает последней.

Так как какой бы ни был расклад точек, для каждого расклада только ровно $1/3$ из всех возможных событий успешный, то и в итоге вероятность нужного нам события равна $1/3$.

Ответ $1/3$.

МФТИ-Т.16 Вероятность выполнения неравенства на координаты случайной точки в квадрате

Пусть в единичном квадрате $[0, 1] \times [0, 1]$ выбирается случайно точка $A = (\xi, \eta)$. Докажите, что вероятность, что её координаты удовлетворяют $|\eta - \xi| < \frac{1}{5}$, равна:

$$P\left(|\eta - \xi| < \frac{1}{5}\right) = \frac{9}{25}.$$

Solution

Построим вероятностную модель следующим образом. Пространство элементарных событий будет единичный квадрат $\Omega = [0, 1] \times [0, 1]$. σ -алгеброй F будет совокупность борелевских подмножеств Ω , вероятностной мерой P — мера Лебега на Ω .

На $\Omega = [0, 1] \times [0, 1]$ событию $B = \{|\xi - \eta| < \frac{1}{5}\}$ соответствует полоса S , ограниченной отрезками, которые соединяют точку $(0, \frac{1}{5})$ с точкой $(\frac{4}{5}, 1)$ и точку $(\frac{1}{5}, 0)$ с точкой $(1, \frac{4}{5})$. Дополнение к этой области до квадрата Ω состоит из двух равнобедренных прямоугольных треугольников, с длинами катетов равными $\frac{4}{5}$.

(мб рисунок добавлю)

В итоге вероятность — отношение площади полосы S к площади Ω . Поэтому осталось просто посчитать площадь S , что легко сделать, разбив полосу на прямоугольник и два треугольника.

В итоге $P(|\eta - \xi| < \frac{1}{5}) = \frac{|S|}{|\Omega|} = \frac{9}{25}$.

МФТИ-Т.17 Вероятность составления треугольника из двух точек на отрезке

На отрезке наудачу выбираются две точки. Какова вероятность того, что из получившихся трех отрезков можно составить треугольник?

Solution

Треугольник можно составить если для любых сторон его a, b, c выполняется $a < c + b$. То есть $2c < a + b + c = l$, поэтому любая сторона его должна быть меньше $\frac{l}{2}$. Введем координаты $a = \min(x_1, x_2)$, $b = |x_2 - x_1|$, $c = l - \max(x_1, x_2)$

У нас должно выполняться при $x_1 < x_2$:

$$x_1 < \frac{l}{2}; x_2 > \frac{l}{2}; x_2 - x_1 > \frac{l}{2}$$

А при $x_1 > x_2$:

$$x_1 > \frac{l}{2}; x_2 < \frac{l}{2}; x_2 - x_1 < \frac{l}{2}$$

Изобразим это на рисунке, посчитаем долю площади от всего квадрата, запишем ответ.

Figure 6.1: геометрическая вероятность для двух точек на отрезке

В итоге нужная нам область составляет $\frac{1}{4}$ от площади всех возможных вариантов.

Ответ: $\frac{1}{4}$

Ч-1.61

Случайная точка A равномерно распределена на отрезке $[0, 1]$ и делит этот отрезок на две части. Пусть η_1 - длина большей части и η_2 - длина меньшей части. Найти $P\{\eta_1 \leq x\}$, $P\{\eta_2 \leq x\}$ при любом x .

Solution

Ч-1.62

Случайная точка A имеет равномерное распределение в квадрате со стороной 1. Найти вероятности следующих событий:

- расстояние от точки A до фиксированной стороны квадрата не превосходит x ;
- расстояние от точки A до ближайшей стороны квадрата не превосходит x ;
- расстояние от точки A до центра квадрата не превосходит x ;
- расстояние от точки A до фиксированной вершины квадрата не превосходит x .

Solution

Ч-1.63

Случайная точка A имеет равномерное распределение в прямоугольнике со сторонами 1 и 2. Найти вероятностей следующих событий:

- расстояние от A до ближайшей стороны прямоугольника не превосходит x ;
- расстояние от A до любой стороны прямоугольника не превосходит x ;
- расстояние от A до диагоналей прямоугольника не превосходит x .

Solution

Ч-1.64 Свойства точки в квадрате

Случайная точка A имеет равномерное распределение в квадрате со стороной a . Найти вероятность того, что расстояние от A до ближайшей стороны квадрата меньше, чем расстояние от A до ближайшей диагонали квадрата.

Solution

Ч-1.65

Случайная точка X имеет равномерное распределение в квадрате $A = \{(x, y) : |x| \leq a, |y| \leq a\}$. Найти вероятность того, что квадрат с центром X и сторонами длины b , параллельными осям координат, целиком содержится в квадрате A .

Ч-1.67

Случайная точка X равномерно распределена в правильном треугольнике с вершинами $(a, 0)$, $(-a, 0)$, $(0, a\sqrt{3})$. Найти вероятность того, что квадрат с центром X а сторонами длины b , параллельными осям координат, целиком содержится в этом треугольнике.

Ч-1.68

Случайная точка X равномерно распределена в круге $S = \{(x, y) : x^2 + y^2 \leq R^2\}$. Найти вероятность того, что параллельный оси абсцисс отрезок длины R с серединой в точке X целиком содержится в круге S .

Ч-1.69

Случайная точка A имеет равномерное распределение в правильном n -угольнике. Найти вероятность P_n того, что A находится ближе к границе многоугольника, чем к его диагонали. Найти такие числа C и a , что

$$P_n = Cn^2(1 + o(1)), \quad n \rightarrow \infty.$$

Ч-1.70

Случайная точка (ξ_1, ξ_2) равномерно распределена в единичном квадрате $K = \{(u, v) : 0 \leq u \leq 1, 0 \leq v \leq 1\}$. Обозначим η число действительных корней многочлена

$$f_{\xi_1, \xi_2}(x) = \frac{1}{3}x^3 - \xi_1^2 x + \xi_2.$$

Найти вероятности

$$P\{\eta = k\}, \quad k = 1, 3.$$

Ч-1.71

На паркет, составленный из правильных k -угольников со стороной a , случайно бросается монета радиуса r . Найти вероятность того, что упавшая монета не заденет границу ни одного из k -угольников паркета для:

а) $k = 3$ б) $k = 4$; в) $k = 6$.

Ч-1.73

Парадокс Бертра. В круге радиуса R случайно проводится хорда. Обозначим ξ ее длину. Найти вероятность $Q_x = P\{\xi > x\}$, если середина хорды равномерно распределена в круге. Вычислить вероятности Q_R и $Q_{R\sqrt{3}}$ того, что длина хорды больше стороны правильного вписанного шестиугольника и треугольника соответственно.

Результат зависит от того, как понимать слово «случайно». См. задачи п1.74 и п1.75.

Ч-1.74

Решить задачу п1.73, если направление хорды задано, а ее середина равномерно распределена на диаметре, перпендикулярном ее направлению.

Ч-1.75

Решить задачу п1.73, если один конец хорды закреплен, а другой равномерно распределен на окружности.

Ч-1.76

На плоскость, разную параллельными прямыми (расстояние между соседними прямыми равно $2a$), орошена полуокружность радиуса $r < a$; точка (φ, x) (x - расстояние от центра окружности до ближайшей прямой, $0 \leq x \leq a$; φ - угол между этой прямой и диаметром, соединяющим концы дуги) равномерно распределена в прямоугольнике $[0, a] \times [-\pi/2, \pi/2]$. Найти вероятность пересечений с полуокружностью.

Ч-1.77

В интервале времени $[0, T]$ в случайный момент u появляется сигнал длительности Δ . Приемник включается в случайный момент $v \in [0, T]$ на время t . Предположив, что точка (u, v) равномерно распределена в квадрате $[0, T] \times [0, T]$, найти вероятность обнаружения сигнала.

Ч-1.78

Пассажир может воспользоваться трамваями двух маршрутов, следующих с интервалами T_1, T_2 . Момент прихода пассажира определяет на отрезках $[0, T_1], [0, T_2]$ числа u и v , равные временам, оставшимся до прихода трамваев соответствующего маршрута. Предполагая, что точка (u, v) равномерно распределена на $\Omega = \{(u, v) : 0 \leq u \leq T_1, 0 \leq v \leq T_2\}$, найти вероятность того, что пассажир, пришедший на остановку, будет ждать не дольше t ($0 < t < \min(T_1, T_2)$).

Ч-1.79

Однородный прямой круговой цилиндр случайно бросается на горизонтальную плоскость. Найти вероятность того, что цилиндр упадет на боковую поверхность, если его высота h , а радиус основания r . Вычислить эту вероятность при $h = 2r$. При каких h и r вероятности упасть на основание и на боковую поверхность одинаковы?

Ч-1.80

Неоднородный прямой круговой цилиндр случайно бросается на горизонтальную плоскость. Радиус основания цилиндра r , центр тяжести расположен на оси симметрии цилиндра на расстоянии a от одного основания и $b > a$ от другого основания цилиндра. Найти вероятность того, что цилиндр упадет: а) на основание, расположенное ближе к центру; б) на основание, более удаленное от центра тяжести; в) на боковую поверхность.

Ч-1.81

Однородный прямой круговой конус с высотой h и радиусом основания r случайно бросается на горизонтальную плоскость. а) Найти вероятность того, что он упадет на основание; б) вычислить эту вероятность при $r = h$; в) при каком отношении r/h эта вероятность равна $1/4$?

Ч-1.82

Однородное тело, ограниченное сферой и плоскостью, проходящей через центр сферы (полушар), случайно бросается на горизонтальную плоскость. Найти вероятность того, что полушар упадет на плоскую часть своей границы.

6.1.3 Set Property Tasks

Обсудим другие имеющиеся свойства множеств, использующиеся в теории вероятностей.

(!!! убежусь, чтобы в 1 и 2 части была нужная теория про это!! пока теории нет и я не разобрался нормально.)

Вероятность $p(AB + C|AC + B)$ при условиях на вероятность каждого (!?!???)

Вычислить $P(AB + C|AC + B)$, если известно, что $P(B) = 0.4, P(C) = 0.3, P(A|B) = P(A|C) = 0.7$, B и C - несовместные события.

Как всегда:

$$P(AB + C|AC + B) = \frac{(AB + C)(AC + B)}{AC + B} =$$

Также $P(AB) = P(A|B)P(B) = 0.7 \cdot 0.4 = 0.28$, $P(AC) = P(A|C)P(C) = 0.7 \cdot 0.3 = 0.21$.
(?!?!?! а дальше какое-то преобразование неизвестное мне.)

МФТИ-? Стрелки, начинающие стрелять по жребью (?????)

Два стрелка соревнуются, по очереди стреляя в мишень до первого попадания. Вероятность попадания в мишень стрелка А равна p_1 , а стрелка Б - p_2 . Право первого выстрела определяется жребием, в котором стрелок А побеждает с вероятностью α . Вычислить значение α , при котором шансы на победу у стрелков А и Б равны, если $p_1 = 0.84, p_2 = 0.8$.

Solution

(??? честно, я хз, не отработал еще это.)

МФТИ-Т.1

Пусть A, B - два события. Найти все события X такие, что $\overline{(X \cup A)} \cup \overline{(X \cup \bar{A})} = B$
По правилу де Моргана:

$$\bar{B} = (X \cup A) \cap (X \cup \bar{A})$$

По правилу де Моргана $(X \cup \bar{A}) = \overline{(\bar{X} \cap A)}$, таким образом:

$$(X \cup A) \cap \overline{(\bar{X} \cap A)} = \overline{(\bar{X} \cup \bar{A})} \cup \overline{(\bar{X} \cap A)} = \overline{(\bar{X} \cap \bar{A})} \cup \overline{(\bar{X} \cap A)} = X$$

Ответ $X = \bar{B}$.

МФТИ-Т.2

Пусть A, B - два события. Найти все события X такие, что $AX = AB \iff A \cup X = A \cup B$.

Очевидно, что необходимо, чтобы $X \in A \cap B$. Но также X может содержать любое множество $Y \in X$, которое при $A \cup X$ дало бы ноль, таким образом задача решена.

Ответ $X = Y \cup (A \cap B) \forall Y \in \bar{A}$.

МФТИ-Т.3

Пусть $A_1, \dots, A_n$ - события. Покажите, что

$$\mathbf{P} \left(\bigcup_{k=1}^n A_k \right) + \mathbf{P} \left(\bigcap_{k=1}^n \bar{A}_k \right) = 1$$

Воспользуемся свойству вероятностной меры: $\forall B \quad \mathbf{P}(B) + \mathbf{P}(\bar{B}) = 1$. Возьмем в качестве B выражение: $B = \bigcup_{k=1}^n A_k$, тогда $\bar{B} = \bigcap_{k=1}^n \bar{A}_k$. Подставляя, получаем:

$$\mathbf{P} \left(\bigcup_{k=1}^n A_k \right) + \mathbf{P} \left(\bigcap_{k=1}^n \bar{A}_k \right) = 1$$

МФТИ-Т.4

Пусть $A_1, A_2, \dots$ - последовательность событий и $\mathbf{P}(A_n) = 1$ для всех $n = 1, 2, \dots$. Покажите, что

$$\mathbf{P} \left(\bigcap_{n=1}^{\infty} A_n \right) = 1$$

Первый способ: Пусть $B_n = \bigcap_{i=1}^n A_i$. Заметим, что $B_1 \in B_2 \in \dots$, тогда

$$P(\bar{B}_n) = P \left(\bigcap_{i=1}^n \bar{A}_i \right) \leq \sum_{i=1}^n P(\bar{A}_i) = 0$$

Поэтому в силу положительной определенности $P(\bar{B}_n) = 0$, поэтому $P(B_n) = 1$

Окончательно, заменяя A на B и используя непрерывность вероятностной меры получаем:

$$\mathbf{P} \left(\bigcap_{n=1}^{\infty} A_n \right) = \mathbf{P} \left(\lim_{n \rightarrow \infty} B_n \right) = \lim_{n \rightarrow \infty} \mathbf{P}(B_n)$$

Второй способ: знаем, что на всем вероятностном пространстве Ω выполняется $\mathbf{P}(\Omega) = 1$. Таким образом $A_i = \Omega - A_{i0}$, где $A_{i0} : \mathbf{P}(A_{i0}) = 0$. Таким образом,

$$\mathbf{P} \left(\bigcap_{n=1}^{\infty} A_n \right) = \mathbf{P} \left(\Omega - \bigcap_{n=1}^{\infty} A_{i0} \right) = 1 - \sum_{n=1}^{\infty} 0 = 1$$

МФТИ-Т.5

Пусть $A_1, A_2, \dots$ - последовательность событий. Покажите, что

$$P\left(\lim_{n \rightarrow \infty} A_n\right) \leq \lim_{n \rightarrow \infty} P(A_n) \leq \overline{\lim}_{n \rightarrow \infty} P(A_n) \leq P\left(\overline{\lim}_{n \rightarrow \infty} A_n\right)$$

Вспомним определение:

$$A^* = \overline{\lim}_{n \rightarrow \infty} A_n = \bigcap_{n=1}^{\infty} \bigcup_{k \geq n} A_k, \quad A_* = \lim_{n \rightarrow \infty} A_n = \bigcup_{n=1}^{\infty} \bigcap_{k \geq n} A_k$$

Первое неравенство доказывается с помощью непрерывности вероятностной меры:

$$P\left(\lim_{n \rightarrow \infty} A_n\right) = P\left(\bigcup_{n=1}^{\infty} \bigcap_{k \geq n} A_k\right) \equiv P\left(\bigcup_{n=1}^{\infty} B_n\right) \equiv P(\lim B_n) \stackrel{\substack{\text{т.к. } B_1 \subseteq B_2 \subseteq \dots \\ \text{по непрер. меры}}}{=} \lim P(B_n) \stackrel{\substack{\leq \\ B_n = \bigcup_{N=n}^{\infty} A_n \subset A_n}}{=} \lim_{n \rightarrow \infty} P(A_n)$$

Выражение $\lim_{n \rightarrow \infty} P(A_n) \leq \overline{\lim}_{n \rightarrow \infty} P(A_n)$ очевидно.

И последнее неравенство:

$$P\left(\overline{\lim}_{n \rightarrow \infty} A_n\right) = P\left(\bigcup_{n=1}^{\infty} \bigcap_{k \geq n} A_k\right) \equiv P\left(\bigcup_{n=1}^{\infty} B_n\right) \equiv P(\lim B_n) \stackrel{\substack{\text{т.к. } B_1 \supseteq B_2 \supseteq \dots \\ \text{по непрер. меры}}}{=} \lim P(B_n) \stackrel{\substack{\geq \\ B_n = \bigcup_{N=n}^{\infty} A_n \supset A_n}}{=} P(A_n)$$

МФТИ-Т.6 Неравенство $|P(AB) - P(A)P(B)| \leq \frac{1}{4}$

Покажите, что для любых двух событий A и B выполняется неравенство

$$|P(AB) - P(A)P(B)| \leq \frac{1}{4}$$

Обозначим $AB \equiv c$, $A \setminus B \equiv a$, $B \setminus A \equiv b$, тогда доказать нужно нам, что

$$|c - (a + c)(b + c)| \leq \frac{1}{4}$$

Причем по условию, так как мы работаем с событиями, должно выполняться: $a + b + c \leq 1$. Докажем, что $c - (a + c)(b + c) \geq -\frac{1}{4}$. Действительно, $2\sqrt{ab} \leq a + b \leq 1 \rightarrow ab \leq \frac{1}{4}$.

$$c - (a + c)(b + c) = (1 - \underbrace{a + b + c}_{\leq 0}) - ab \geq -\frac{1}{4}$$

Докажем, что $c - (a + c)(b + c) \leq \frac{1}{4}$. Преобразуем выражение уже в другом виде:

$$c - (a + c)(b + c) \leq c - c^2 = c(1 - c) = (\sqrt{c}\sqrt{1 - c})^2 \stackrel{\substack{\leq \\ \text{неравенство Коши}}}{=} \left(\left(\frac{1}{2}\right)c + (1 - c)\right)^2 \leq \frac{1}{4}$$

Таким образом, уж точно

$$|c - (a + c)(b + c)| \leq \frac{1}{4}$$

6.1.4 Bone and Coin Problems (!!!)

(пока по актуальности собираю)

МФТИ-Т.16 Вероятность, что при подбрасывании двух костей сумма в 5 очков появится раньше, чем сумма в 7 очков

Случайный эксперимент заключается в последовательном подбрасывании двух игральных костей. Найти вероятность того, что сумма в 5 очков появится раньше, чем сумма в 7 очков.

Найдем, чему равна вероятность, что при подбрасывании двух игральных костей выпадет 5: всего таких исходов 4: если выпадает 1,4; 4,1; 2,3; 3,2. Таким образом, $p_5 = 4/36 = 1/9$

Вероятность, что при подбрасывании двух игральных костей выпадет 7: всего таких исходов 4: если выпадает 2,5; 5,2; 2,4; 4,2; 1,6; 6,1. Таким образом, $p_7 = 6/36 = 1/6$

Пусть A - событие, состоящее в выпадении 5 раньше 7. Оно состоит из исхода, при котором на i -м шаге выпадает 5, а на $(i-1)$ -х шагах не выпадало ни 5, ни 7, обозначим его B_i . Запишем событие A в виде

$$A = \bigcup_{i=1}^{\infty} B_i$$

тогда его вероятность:

$$P(A) = \sum_{i=1}^{\infty} P(B_i)$$

Также $P(B_i) = (1 - p_5 - p_7)^{i-1} p_5$, потому что отдельные броски независимы. Таким образом, осталось посчитать ответ:

$$P(A) = \sum_{i=1}^{\infty} (1 - p_5 - p_7)^{i-1} p_5 = \frac{p_5}{1 - (1 - p_5 - p_7)} = \frac{p_5}{p_5 + p_7} = 4/(6 + 4) = 2/5$$

Ответ: $\frac{2}{5}$

МФТИ-Т.? Вероятность первого выпадения герба у каждого из троих подбрасывающих (?!!!!)

Трое игроков по очереди подбрасывают монету. Выигрывает тот, у кого раньше появится герб. Найти вероятности выигрыша каждого игрока

(!! оч крутая задача)

Пусть A_i - вероятность того, что у первого игрока при i -м бросании будет герб. Аналогично, B_i - вероятность того, что у второго игрока при i -м бросании будет герб, C_i - у третьего.

Тогда запишем $A = \bigcup A_i$, $B = \bigcup B_i$, $C = \bigcup C_i$.

И также..

По формуле полной вероятности $P(A) = P(A_1)P(A|A_1) + P(\overline{A_1})P(A|\overline{A_1})$.

И понятно, что $P(A|A_1) = 1$, $P(A_1) = P(\overline{A_1}) = \frac{1}{2}$, поэтому

$$P(A) = \frac{1}{2}(1 + P(A|\overline{A_1}))$$

Дальше заметим, что $P(A|\overline{A_1})$ это вероятность успеха после двух последовательных неудач второго и третьего игрока или после 5 неудач или после 8 неудач и т.п. Это же в точности $P(C)$.

По этой же логике $P(B|\overline{A_1}) = P(A)$

Формула полной вероятности для $P(B)$:

$$P(B) = P(B|A_1)P(A_1) + P(\overline{A_1})P(B|\overline{A_1}) = 0 + \frac{1}{2}P(A)$$

В итоге получается система

$$P(A) + P(B) + P(C) = 1 \quad (6.1)$$

$$P(C) = 2P(A) - 1 \quad (6.2)$$

$$P(B) = \frac{1}{2}P(A) \quad (6.3)$$

Она легко решается.

Ответ: $P(A) = \frac{4}{7}$, $P(B) = \frac{2}{7}$, $P(C) = \frac{1}{7}$.

Одна единица при бросании четырех игральных костей или хотя бы одна пару единиц за один бросок при 24 бросаниях двух костей?

Что вероятнее, получить хотя бы одну единицу при бросании четырех игральных костей или хотя бы одну пару единиц за один бросок при 24 бросаниях двух костей?

Посмотрим на случай четырех костей.

Можно считать количество успешных исходов, но это сделать сложно, так что пойдем от обратного, посчитаем неудачные исходы.

Вероятность невыпадения единицы в одном испытании: $1 - \frac{1}{6} = \frac{5}{6}$, в четырех экспериментах вероятность того, что среди всех выпавших костей нет ни одной единицы равна $(\frac{5}{6})^4$.

Тогда вероятность выпадения единицы равна

$$P_1 = 1 - \left(\frac{5}{6}\right)^4$$

Посмотрим на случай двух костей. При одном бросании двух костей у нас 36 может быть разных исходов, при этом подходит только один. Поэтому аналогично первому пункту, вероятность хотя бы за какой-то бросок получить пару единиц, равна:

$$P_2 = 1 - \left(1 - \frac{1}{36}\right)^{24} = 1 - \left(\frac{35}{36}\right)^{24}$$

Осталось только сравнить эти P_2 и P_1 . Просто посчитаем их на калькуляторе. В итоге

$$P_1 > P_2$$

Ответ: Успех в случае бросания одной кости имеет большую вероятность.

При подбрасывании трёх игральных костей 11 очков выпадают чаще, чем 12

(потренируюсь, сверну скорее всего потом в пару строк, тут всё очевидно, просто подсчетом событий. пока потренироваться еще нужно, научиться на самом деле быстро решать такие задачи.)

Объяснить, почему при подбрасывании трёх игральных костей 11 очков выпадают чаще, чем 12.

Посчитаем количество исходов, которые дадут 11 очков в сумме. По сути это количество целочисленных положительных решений уравнения $x_1 + x_2 + x_3 = 11$ при условии $x_1, x_2, x_3 \leq 6$.

$$P(x_1 + x_2 + x_3 = 11) = \sum_{i=1}^6 P(a = i)P(x_2 + x_3 = 11 - i) = \frac{1}{6} \sum_{i=5}^{10} P(x_2 + x_3 = i)$$

$$P(x_1 + x_2 + x_3 = 12) = \sum_{i=1}^6 P(a = i)P(x_2 + x_3 = 12 - i) = \frac{1}{6} \sum_{i=6}^{11} P(x_2 + x_3 = i)$$

$$P(x_1 + x_2 + x_3 = 11) - P(x_1 + x_2 + x_3 = 12) = P(x_2 + x_3 = 11) - P(x_2 + x_3 = 5)$$

считаем благоприятные $\frac{2}{36} - \frac{4}{36} < 0$
исходы

Поэтому при подбрасывании трёх игральных костей 11 очков выпадают чаще, чем 12.

6.1.5 Map Tasks (!!!)

(потренирую позже!!)

вероятность того, что среди выбранных карт из колоды будут представительницы всех мастей

Из колоды в 52 карты наудачу берется 6 карт. Какова вероятность того, что среди них будут представительницы всех четырех мастей?

Назовем наши масти A, B, C, D. Назовем A_A, A_B, A_C, A_D - исходы, в которых есть масть A, B, C, D соответственно.

Нам нужно событие $X = A_A \cap A_B \cap A_C \cap A_D$ - что есть представители всех мастей.

Посчитаем вероятность события $\bar{X} = \bar{A_A} \cup \bar{A_B} \cup \bar{A_C} \cup \bar{A_D}$ - что нет представителя какой-то из мастей. Для этого воспользуемся формулой включения-исключения:

$$P\left\{\bigcup_{k=1}^n A_k\right\} = \sum_{m=1}^n (-1)^{m-1} \sum_{1 \leq i_1 < \dots < i_m \leq n} P\{A_{i_1} A_{i_2} \dots A_{i_m}\}$$

И так как одной из четырех масти не может быть - 4мя способами, двух мастей - $C_4^2 = 6$ способами, трех - $C_4^3 = 4$ способами, то вторая сумма, учитывая что вероятности наличия разных мастей не зависят от конкретного вида масти, будет иметь вид:

$$P\left\{\bigcup_{k=1}^n A_k\right\} = 4P(\overline{A_1}) - 6P(\overline{A_1 A_2}) + 3P(\overline{A_1 A_2 A_3})$$

Посчитаем вероятности членов в этой сумме, найдя количество благоприятствующих исходов:

$$P(\overline{A_i}) = \frac{C_{52-13}^6}{C_{52}^6}; \quad P(\overline{A_i A_j}) = \frac{C_{52-13-13}^6}{C_{52}^6}; \quad P(\overline{A_i A_j A_k}) = \frac{C_{52-13-13-13}^6}{C_{52}^6};$$

Подставим все в ответ: $P_{\text{искомое}} = 1 - \left(4 \frac{C_{39}^6}{C_{52}^6} - 6 \frac{C_{26}^6}{C_{52}^6} + 4 \frac{C_{13}^6}{C_{52}^6}\right)$
(?? число???)

6.2 Test Sequence Tasks (!!!)

(нужно проработать этот раздел, типичные задачи!)

6.2.1 Problems About Conditional Probabilities

Ч-2.пр.2

Из урны, содержащей 3 белых и 2 черных шара, по схеме случайного выбора без возвращения последовательно извлекаются пары. Найти вероятность p_k того, что черный шар впервые появится при k -м испытании ($k = 1, 2, 3, 4$).

Обозначим C_i событие, состоящее в том, что в i -м испытании появился черный шар. Тогда события $B_k = \{\text{впервые черный шар появился при } k\text{-м испытании}\}$, $k = 1, 2, 3, 4$ можно выразить через C_i и $\bar{C}_i$:

$$B_1 = C_1, \quad B_2 = \bar{C}_1 C_2, \quad B_3 = C_1 C_2 C_3, \quad B_4 = \bar{C}_1 C_2 \bar{C}_3 C_4$$

По формуле (n2.3)

$$\begin{aligned} P(B_1) &= P(C_1), \quad P(B_2) = P(\bar{C}_1) P(C_2|\bar{C}_1), \\ P(B_3) &= P(\bar{C}_1) P(\bar{C}_2|\bar{C}_1) P(C_3|\bar{C}_1 \bar{C}_2) \\ P(B_4) &= P(\bar{C}_1) P(\bar{C}_2|\bar{C}_1) P(\bar{C}_3|\bar{C}_1 \bar{C}_2) P(C_4|\bar{C}_1 \bar{C}_2 \bar{C}_3) \end{aligned}$$

По классическому определению вероятности

$$\begin{aligned} P(C_1) &= \frac{2}{5}, \quad P(\bar{C}_1) = \frac{3}{5}, \quad P(\bar{C}_{i+1}|\bar{C}_1 \dots \bar{C}_i) = \frac{3-i}{5-i} \\ P(C_{i+1}|\bar{C}_1 \dots \bar{C}_i) &= \frac{2}{5-i}, \quad i = 1, 2, 3. \end{aligned}$$

В результате получим

$$\begin{aligned} p_1 &= P(B_1) = \frac{2}{5} = 0,4, \quad p_2 = P(B_2) = \frac{3}{5} \cdot \frac{2}{4} = 0,3, \\ p_3 &= P(B_3) = \frac{3}{5} \cdot \frac{2}{4} \cdot \frac{2}{3} = 0,2 \\ p_4 &= P(B_4) = \frac{3}{5} \cdot \frac{2}{4} \cdot \frac{1}{3} \cdot \frac{2}{2} = 0,1. \end{aligned}$$

Ч-2.пр.3

Найти вероятность того, что среди 10 однозначных случайных чисел ровно 4 четных числа и 2 нечетных числа, кратных 3.

Решен и е. Однозначное случайное число четно с вероятностью $p_1 = \frac{5}{10} = \frac{1}{2}$, нечетно и кратно 3 с вероятностью $p_2 = \frac{2}{10} = \frac{1}{5}$. Вероятность остальных исходов $p_3 = 1 - p_1 - p_2 = \frac{3}{10}$. Если ξ_1 - число четных чисел среди 10 случайных чисел, ξ_2 - число нечетных чисел, кратных 3, то число остальных чисел $\xi_3 = 10 - \xi_1 - \xi_2$, и по формуле (n2.10) с $N = n = 10$ находим $P\{\xi_1 = 4, \xi_2 = 2\} = P\{\xi_1 = 4, \xi_2 = 2, \xi_3 = 5\} =$

$$= \frac{10!}{4!2!4!} \left(\frac{1}{2}\right)^4 \left(\frac{1}{5}\right)^2 \left(\frac{3}{10}\right)^4 = 0,063787...$$

Частный случай полиномиальной схемы с $N = 2$ называют схемой Бернулли. Ниже два исхода каждого испытания в схеме Бернулли будем обозначать символами 1 и 0 или называть успехом и неудачей, а соответствующие им вероятности - буквами p и $q = 1 - p$. Если $\mu_n \rightarrow$ число успехов (или число единиц) в n испытаниях Бернулли, то

$$P\{\mu_n = m\} = P_n(m, p) = C_n^m p^m q^{n-m}, \quad m = 0, 1, \dots, n. \quad (\text{n2.11})$$

Ч-2.пр.4

Проводится n независимых опытов, состоящих в одновременном подбрасывании k монет. Вычислить вероятности событий: $A = \{\text{хотя бы один раз все } k \text{ монет выпали гербами}\}$, $B = \{\text{ровно } m \text{ раз все } k \text{ монет выпали гербами}\}$.

Появление k гербов в одном опыте будем называть успехом. Вероятность успеха $p = \frac{1}{2^k}$. Проще вычислить вероятность противоположного события не выпали гербами. Положим $C_l = \{\text{в } l\text{-м испытании произошел успех}\}$. Тогда $\bar{A} = \bar{C}_1 \bar{C}_2 \dots \bar{C}_n$, и по формуле (n2.6) находим

$$P(\bar{A}) = \prod_{l=1}^n P(\bar{C}_l) = \left(1 - \frac{1}{2^k}\right)^n.$$

Для вычисления $P(\bar{A})$ можно было также воспользоваться формулой (n2.11), положив в ней $m = 0, p = \frac{1}{2^k}, q = 1 - \frac{1}{2^k}$. Таким образом,

$$P(A) = 1 - P(\bar{A}) = 1 - \left(1 - \frac{1}{2^k}\right)^n.$$

Вероятность события B определяем по формуле (n2.11):

$$P(B) = C_n^m \left(\frac{1}{2^k}\right)^m \left(1 - \frac{1}{2^k}\right)^{n-m}$$

Ч-2.пр.5

В партии из $n = 200$ изделий каждое изделие независимо от остальных может быть бракованным с вероятностью $p = 0,01$. Определить вероятность того, что число μ_n бракованных изделий в этой партии равно трем.

Решение. Величина $np^2 = 0,02$ мала. В качестве приближенного значения искомой вероятности можно использовать предельное значение в (n2.12) (теорема Пуассона) с $\lambda = np = 2$: $P\{\mu_n = 3\} \approx \frac{2^3}{3!} e^{-2}$. По табл. 3 (с. 308) находим числовое значение: $P\{\mu_n = 3\} \approx 0,18045\dots$ Точное значение вероятности можно найти по формуле (n2.11):

$$P\{\mu_n = 3\} = C_{200}^3 (0,01)^3 (0,99)^{197} = 0,181355\dots$$

Ч-2.пр.6

В партии из $n = 22500$ изделий, каждое изделие независимо от других может быть бракованным с вероятностью $p = 1/5$. Найти вероятность того, что число μ_n бракованных изделий заключено между 4380 и 4560.

Значение $npq = 3600$ велико, поэтому можно воспользоваться нормальным приближением (n2.14). Вычтем $np = 4500$ из трех частей неравенства $4380 < \mu_n < 4560$ и получившееся неравенство поделим почленно на $-2 < \frac{\mu_n - np}{\sqrt{npq}} < 1$. $P\{4380 < \mu_n < 4560\} = P\left\{-2 < \frac{\mu_n - np}{\sqrt{npq}} < 1\right\} \approx \frac{1}{\sqrt{2\pi}} \int_{-2}^1 e^{-\frac{x^2}{2}} dx$ Так как

$$\frac{1}{\sqrt{2\pi}} \int_{-2}^1 e^{-\frac{x^2}{2}} dx = \frac{1}{\sqrt{2\pi}} \int_0^1 e^{-\frac{x^2}{2}} dx + \frac{1}{\sqrt{2\pi}} \int_0^2 e^{-\frac{x^2}{2}} dx = \Phi_0(1) + \Phi_0(2)_2$$

то (см. табл. 1, с. n306-n307).

$$P\{4380 < \mu_n < 4560\} \approx 0,3413 + 0,4772 = 0,8185.$$

Ч-2.пр.7

Найти вероятность того, что в схеме Бернулли первый успех появится в k -м испытании, если вероятность успеха в отдельном испытании равна p . Реше. $A_k = \{ \text{первый успех появился в } k \text{ - испытании} \}$ определяется исходами в k первых испытаниях. Пусть событие $C_i = \{ \text{в } i \text{ - М испытании наступил успех} \}$. Тогда

$$A_k = \bar{C}_1 \bar{C}_2 \dots \bar{C}_{k-1} C_k,$$

и по формуле (п2.17) находим

$$P(A_k) = P(\bar{C}_1) P(\bar{C}_2) \dots P(\bar{C}_{k-1}) P(C_k) = q^{k-1} p.$$

Приведем еще две формулы, полезные в тех случаях, когда заданы или могут быть легко вычислены условные вероятности. Если события $B_1, B_2, \dots, B_n$ попарно несовместны и $B_1 \cup B_2 \cup \dots \cup B_n = \Omega$, то для любого события A имеем

$$P(A) = \sum_{k=1}^n P(B_k) P(A|B_k)$$

(формула полной вероятности) и

$$P(B_m|A) = \frac{P(B_m) P(A|B_m)}{\sum_{k=1}^n P(B_k) P(A|B_k)}, \quad m = 1, \dots, n_s$$

Ч-2.пр.8

В ящик, содержащий 8 исправных изделий, добавлено 2 изделия, взятых со склада; известно, что доля бракованных изделий на складе равна 5%. Найти вероятность того, что взятое наудачу из пополненного ящика изделие не будет бракованным. Решение. Определим события A, B_0, B_1, B_2 ? A = изделие, взятое из пополненного ящика, $B_k = \{ \text{из двух изделий, добавленных в ящик, } k \text{ бракованных, } k = 0, 1, 2. \}$ Очевидно, что $B_0 \cup B_1 \cup B_2 = \Omega$ и $B_k B_l = \emptyset$ ($k \neq l$). Можно воспользоваться формулой полной вероятности (п2.18):

$$P(A) = P(B_0) P(A|B_0) + P(B_1) P(A|B_1) + P(B_2) P(A|B_2)$$

Если произошло событие B_k , то в ящике из 10 изделий k бракованных, следовательно,

$$P(A|B_k) = \frac{10-k}{10}, \quad k = 0, 1, 2.$$

При выборе малого числа изделий из большой партии схемы выбора без возвращения и с возвращением имеют близкие вероятности исходов (см. задачу п18). Считая поэтому, что каждое из добавленных изделий независимо от другого может быть бракованным с вероятностью 0,05, находим

$$P(B_0) = 0,95^2, \quad P(B_1) = 2 \cdot 0,95 \cdot 0,05, \quad P(B_2) = 0,05^2.$$

Таким образом,

$$P(A) = 0,95^2 \cdot 1 + 2 \cdot 0,95 \cdot 0,05 \cdot \frac{9}{10} + 0,05^2 \cdot \frac{8}{10} = 0,99.$$

Пример

Ч-2.пр.9

Из урны, содержащей 3 белых и 2 черных шара, по схеме выбора без возвращения отобраны 2 шара. Шар, взятый наудачу из этих двух, оказался белым. Какова вероятность того, что второй шар тоже белый? Р. $B_k = \{ \text{среди двух отобранных из урны шаров } k \text{ белых} \}$, $k = 0, 1, 2$, $A = \{ \text{шар, взятый наудачу из двух отобранных, белый} \}$. Условную вероятность $P(B_2|A)$, которую требуется найти, можно вычислить по формуле Байеса (Ч-2.19): $P(B_2|A) = \frac{P(B_2) P(A|B_2)}{P(B_0) P(A|B_0) + P(B_1) P(A|B_1) + P(B_2) P(A|B_2)}$. Вероятности, связанные с извлечением двух шаров из урны, найдем с помощью классического определения вероятности:

$$P(B_0) = \frac{C_2^2}{C_5^2} = 0,1, \quad P(B_1) = \frac{C_3^1 C_2^1}{C_5^2} = 0,6, \quad P(B_2) = \frac{C_3^2}{C_5^2} = 0,3.$$

Так же определяются условные вероятности, связанные с извлечением одного шара из двух отобранных:

$$\text{Значит, } P(A|B_0) = 0, \quad P(A|B_1) = 0,5, \quad P(A|B_2) = 1. \\ P(B_2|A) = \frac{0,3}{0,1 \cdot 0 + 0,6 \cdot 0,5 + 0,3 \cdot 1} = \frac{1}{2}.$$

В задачах п2.1-п2.6 вероятностное пространство считается заданным; Для вычисления условных вероятностей нужно использовать формулу (п2.1).

Ч-2.1

Из множества чисел $\{1, 2, \dots, N\}$ по схеме случайного выбора без возвращения выбираются три числа. Найти условную вероятность того, что третье число попадет в интервал, образованный первыми двумя, если известно, что первое число меньше второго.

Ч-2.2

Брошено две игральные кости. Предполагается, что все комбинации выпавших очков равновероятны. Найти условную вероятность того, что выпали две пятерки, если известно, что сумма выпавших очков делится на пять.

Ч-2.3

Из 100 карточек с числами 00, 01, ..., 98, 99 случайно выбирается одна. Пусть η_1 и η_2 - соответственно сумма и произведение цифр на выбранной карточке. Найти $P\{\eta_1 = i | \eta_2 = 0\}, i = 0, 1, \dots, 18$.

Ч-2.4

Из урны, содержащей M белых и $N - M$ черных шаров, последовательно без возвращения извлекают n шаров. Пусть $A_0^{(i)}(A_1^{(i)})$ - событие, состоящее в том, что i -й шар был черным (белым). Используя классическое определение случайного выбора (гл. 1), найти

$$P\{A_1^{(s+1)} | A_{\varepsilon_1}^{(1)} A_{\varepsilon_2}^{(2)} \dots A_{\varepsilon_s}^{(s)}\}, \quad \varepsilon_i = 0, 1.$$

Ч-2.5

Решить задачу п2.4 в случае выбора с возвращением (см. введение к гл. 1, (п3)).

Ч-2.6

Случайный выбор двух подмножеств A_1 и A_2 из множества $S = \{1, 2, \dots, N\}$ производится так же, как в задаче п2.3. Найти условную вероятность $P\{|A_1| = l_1, |A_2| = l_2 | A_1 \cap A_2 = \emptyset\}$ того, что множества A_1 и A_2 состоят из l_1 и l_2 элементов соответственно при условии, что A_1 и A_2 не пересекаются.

В задачах п2.7-п2.11 предполагаются заданными условные вероятности; при решении используются формулы (п2.2), (п2.3).

Ч-2.7

Среди 25 экзаменационных билетов 5 «хороших». Два студента по очереди берут по одному билету. Найти вероятность того, что:

- первый студент взял «хороший» билет,
- второй студент взял «хороший» билет,
- оба студента взяли «хорошие» билеты.

Ч-2.8

Два игрока поочередно извлекают шары (без возвращения) из урны, содержащей M белых и $N - M$ черных шаров. Выигрывает тот, кто первым вынет белый шар. Используя формулу (п2.3), найти вероятность выигрыша первого участника, если: а) $N = 4, M = 1$; б) $N = 5, M = 1$; в) $N = 7, M = 2$.

Ч-2.9

Из урны, содержащей M белых и $N - M$ черных шаров, по одному без возвращения извлекаются все шары. Используя определение случайного выбора в терминах условных вероятностей, найти вероятности событий $A_k = \{k\text{-й шар белый}\}, B_{h,l} = \{k\text{-й и } l\text{-й шары белые}\}, C_{A_1 1} = \{k\text{-й шар черный, а } l\text{-й белый}\}.$

Ч-2.10

Из урны, содержащей 3 белых шара, 5 черных и 2 красных, два игрока поочередно извлекают по одному шару без возвращения. Выигрывает тот, кто первым вынет белый шар. Если появляется красный шар, то объявляется ничья. Пусть $A_1 = \{\text{выигрывает игрок, начавший игру}\}, A_2 = \{\text{выигрывает второй участник}\}, B = \{\text{игра закончилась вничью}\}.$ Найти $P(A_1), P(A_2), P(B).$

Ч-2.13

Из урны, содержащей a белых и b черных шаров, три игрока извлекают шары по очереди. Выигрывает тот, кому раньше попадается белый шар. Найти вероятности P_1, P_2, P_3 выигрыша 1-го, 2-го, 3-го игроков в случаях, когда шары извлекаются:

а) по схеме равновероятного выбора с возвращением, б) по схеме равновероятного выбора без возвращения.

Ч-2.14

На остановку прибывают автобусы маршрутов $1, 2, \dots, k$. Номера последовательно прибывающих автобусов получаются по схеме равновероятного выбора с возвращением из урны, содержащей шары с номерами $1, 2, \dots, k$. Найти вероятность P_k того, что до появления автобуса маршрута 1 ни на одном из остальных маршрутов не придет более одного автобуса. При каком минимальном $k \geq 2$ эта вероятность меньше $1/2$?

О дорогах (?)

На рисунке изображена схема дорог. Туристы выходят из пункта O , выбирая наугад на разветвлении дорог один из возможных путей. Какова вероятность того, что туристы попадут в пункт M ?

Решение: Путь туристов обязательно проходит через один из промежуточных пунктов B_1, B_2, B_3 .

Пусть H_i - событие, состоящее в том, что при своем движении туристы попадут в пункт B_i ($i = 1, 2, 3$). События H_1, H_2, H_3 по условию несовместны и равновероятны, т. к. путь из точки O выбирается наугад.

Поэтому события H_1, H_2, H_3 образуют полную группу, т. к. $P(H_1) = P(H_2) = P(H_3) = \frac{1}{3}$, и $\sum_{i=1}^3 P(H_i) = 1$.

Если событие A - туристы попадут в пункт M , то $P(A/H_1) = 1/3$, $P(A/H_2) = 1/2$, $P(A/H_3) = 1/4$. Искомую вероятность находим по формуле полной вероятности:

$$\begin{aligned} P(A) &= P(H_1) \cdot P(A/H_1) + P(H_2) \cdot P(A/H_2) + P(H_3) \cdot P(A/H_3) = \\ &= \frac{1}{3} \cdot \frac{1}{3} + \frac{1}{3} \cdot \frac{1}{2} + \frac{1}{3} \cdot \frac{1}{4} = \frac{13}{36}. \end{aligned}$$

Билеты экзамена

Из n -экзаменационных билетов студент знает m («хорошие билеты»). Что лучше: брать на экзамене билет первым или вторым? Решение: Введем событие A - студент взял «хороший» билет. 1. Студент берет билет первым. В этом случае $P(A) = \frac{m}{n}$. 2. Студент берет билет вторым. Введем две гипотезы: H_1 - первый студент взял «хороший» билет, $H_2 = \overline{H_1}$.

События H_1, H_2 образуют полную группу, т. к. $\sum_{i=1}^2 P(H_i) = 1$. $P(A) = P(H_1) P(A/H_1) + P(H_2) P(A/H_2) = \frac{m}{n} \cdot \frac{m-1}{n-1} + (1 - \frac{m}{n}) \cdot \frac{m}{n-1} = \frac{m}{n}$. Вывод: безразлично, брать билет первым или вторым. Пример 3. В первой урне находится 6 белых и 4 черных шара, во второй - 5 белых и 5 черных шаров. Из первой урны наугад берут шар и перекладывают во вторую. Затем из второй урны достают один шар. Какова вероятность того, что он белый? Решение:

$$\begin{aligned} P(A) &= P(H_1) \cdot P(A/H_1) + P(H_2) \cdot P(A/H_2) + P(H_3) \cdot P(A/H_3) = \\ &= \frac{1}{3} \cdot \frac{3}{8} + \frac{1}{3} \cdot \frac{1}{2} + \frac{1}{3} \cdot 0 = \frac{1}{8} + \frac{1}{6} = \frac{7}{24}. \end{aligned}$$

Пример 5.

На фабрике первая машина производит 25%, вторая 35, а третья 40 деталей. Брак в их продукции равен, соответственно, 5, 4 и 3%. Какова вероятность, что случайно выбранная деталь дефектна? Решение: Событие A - выбранная деталь имеет дефект. Обозначим через H_i событие, состоящее в том, что случайно выбранная деталь изготовлена на i -й машине ($i = 1, 2, 3$).

Тогда $P(H_1) = 0,25$; $P(H_2) = 0,35$; $P(H_3) = 0,40$, и события H_1, H_2, H_3 образуют полную группу, если учесть, что других машин на фабрике нет и каждую деталь изготавливает только одна машина. Пусть $P(A)$ - искомая вероятность:

$$P(A) = P(H_1)P(A/H_1) + P(H_2)P(A/H_2) + P(H_3)P(A/H_3) = \\ = 0,25 \cdot 0,05 + 0,35 \cdot 0,04 + 0,4 \cdot 0,03 = 0,0385.$$

Пример 6.

Вам последовательно сдается три карты из колоды в 36 карт. Какова вероятность того, что третья карта по масти не совпадает с первыми двумя? Решение: Обозначим A - третья карта по масти отличается от первых двух. В данной задаче удобно выделить следующие две гипотезы: H_1 - первые две карты одинаковы по масти, H_2 - первые две карты различаются по масти ($H_2 = \overline{H_1}$). События H_1, H_2 образуют полную группу, т. к. $\sum_{i=1}^2 P(H_i) = 1$. Заметим, что

$$H_1 = \text{ЧЧ} + \text{ББ} + \text{ТТ} + \text{ПП},$$

где ЧЧ означает, что две первые карты червы, ББ - они бубны, ТТ - они трефы, ПП - они пики.

Вероятность вытащить две червы равна $P(\text{ЧЧ}) = \frac{C_2^9}{C_2^{36}} = \frac{9 \cdot 8}{36 \cdot 35} = \frac{2}{35}$. Аналогично, $P(\text{ББ}) = P(\text{ТТ}) = P(\text{ПП}) = \frac{2}{35}$. Следовательно,

$$P(H_1) = 4 \cdot \frac{2}{35} = \frac{8}{35}.$$

Если две первые карты одинаковы по масти, то при вытаскивании третьей карты у нас всего 34 карты, а карт, не совпадающих по масти с первыми двумя, 27. Следовательно, $P(A/H_1) = \frac{27}{34}$. Так как $H_2 = \overline{H_1}$, то $P(H_2) = 1 - P(H_1) = \frac{27}{35}$. Если две первые карты различны по масти, то при вытаскивании третьей карты у нас всего 34 карты, а карт, не совпадающих по масти с первыми двумя, 18. Следовательно, $P(A/H_2) = \frac{18}{34}$. По формуле полной вероятности

$$P(A) = P(A/H_1)P(H_1) + P(A/H_2)P(H_2) = \frac{27}{34} \cdot \frac{8}{35} + \frac{18}{34} \cdot \frac{27}{35} = \frac{26}{34} \cdot \frac{27}{35} = 0,59.$$

Пример 7.

По цели произведено три последовательных выстрела. Вероятность попадания при первом выстреле $p_1 = 0,3$; при втором $p_2 = 0,6$; при третьем $p_3 = 0,8$. При одном попадании вероятность поражения цели $r_1 = 0,4$; при двух попаданиях $r_2 = 0,7$; при трех попаданиях $r_3 = 1$. Определить вероятность поражения цели при трех выстрелах. Решение: Пусть событие A - цель поражена. Рассмотрим группу несовместных событий: H_1 - было одно попадание; H_2 - было два попадания; H_3 - было три попадания; H_4 - не было ни одного попадания. Определим вероятность каждого события. По теоремам умножения и сложения вероятностей будем иметь

$$P(H_1) = p_1(1-p_2)(1-p_3) + (1-p_1)p_2(1-p_3) + (1-p_1)(1-p_2)p_3 = 0,332.$$

$$P(H_2) = p_1p_2(1-p_3) + p_1(1-p_2)p_3 + (1-p_1)p_2p_3 = 0,468.$$

$$P(H_3) = p_1p_2p_3 = 0,144.$$

$$P(H_4) = (1-p_1)(1-p_2)(1-p_3) = 0,056.$$

События H_1, H_2, H_3, H_4 образуют полную группу, т. к. $\sum_{i=1}^4 P(H_i) = 1$. Выпишем условные вероятности поражения цели при осуществлении каждого из событий H_1, H_2, H_3 , и H_4 :

$$P(A/H_1) = 0,4, P(A/H_2) = 0,7, P(A/H_3) = 1, P(A/H_4) = 0.$$

Тогда по формуле полной вероятности

$$P(A) = P(H_1)P(A/H_1) + P(H_2)P(A/H_2) + P(H_3)P(A/H_3) + P(H_4)P(A/H_4) = \\ = 0,332 \cdot 0,4 + 0,468 \cdot 0,7 + 0,144 \cdot 1 + 0,056 \cdot 0 = 0,6044.$$

Пример 8.

Известно, что 96 % выпускаемой продукции удовлетворяет стандарту. Упрощенная схема контроля признает пригодной хорошую продукцию с вероятностью 0,98, а бракованную - с вероятностью 0,05. Определить вероятность того, что изделие, прошедшее упрощенный контроль, удовлетворяет стандарту. Решение: Событие A - изделие прошло упрощенный контроль, H_1 - изделие удовлетворяет стандарту, H_2 - изделие бракованное. $P(H_1) = 0,96$; $P(H_2) = 0,04$; и события H_1, H_2 образуют полную группу. $P(A/H_1) = 0,98$; $P(A/H_2) = 0,05$. $P(A) = P(H_1)P(A/H_1) + P(H_2)P(A/H_2) = 0,96 \cdot 0,98 + 0,04 \cdot 0,05 = 0,9428$. $P(H_1/A)$ - изделие удовлетворяет стандарту, если оно прошло упрощенный контроль. По формуле Байеса

$$P(H_1/A) = \frac{P(H_1) \cdot P(A/H_1)}{P(A)} = \frac{0,96 \cdot 0,98}{0,9428} = 0,9979.$$

Пример 9.

В первой урне находится 6 белых и 4 черных шара, во второй - 5 белых и 5 черных шаров. Из первой урны наугад берут шар и перекладывают во вторую. Затем из второй урны достают один шар. Он оказался белым. Какова вероятность того, что из первой урны во вторую переложили белый шар? Решение: Событие A - извлечен белый шар из второй урны. Введем гипотезы H_1 - достали белый шар из первой урны, H_2 - достали черный шар из первой урны. Надо найти $P(H_1/A)$.

$$P(H_1) = \frac{6}{10}, P(A/H_1) = \frac{5+1}{10+1} = \frac{6}{11}, P(H_2) = \frac{4}{10}, P(A/H_2) = \frac{5}{10+1} = \frac{5}{11}, \text{ и}$$

события H_1, H_2 образуют полную группу.

По формуле Байеса

$$P(H_1/A) = \frac{P(A/H_1)P(H_1)}{P(A/H_1)P(H_1) + P(A/H_2)P(H_2)} = \frac{\frac{6}{11} \cdot \frac{6}{10}}{\frac{6}{11} \cdot \frac{6}{10} + \frac{5}{11} \cdot \frac{4}{10}} = \frac{36}{56}.$$

Пример 10.

Один из трех стрелков вызывается на линию огня и производит два выстрела. Вероятность попадания в мишень при одном выстреле для первого стрелка равна 0,3; для второго - 0,5; для третьего - 0,8. Мишень не поражена. Найти вероятность того, что выстрелы произведены первым стрелком. Решение: Возможны три гипотезы: H_1 - «на линию огня вызван первый стрелок», H_2 - «на линию огня вызван второй стрелок», H_3 - «на линию огня вызван третий стрелок». Так как вызов на линию огня любого стрелка равновозможен, то

$$P(H_1) = P(H_2) = P(H_3) = 1/3.$$

В результате опыта наблюдалось событие A - после произведенных выстрелов мишень не поражена.

Условные вероятности этого события при сделанных гипотезах равны

$$P(A/H_1) = 0,7 \cdot 0,7 = 0,49; P(A/H_2) = 0,5 \cdot 0,5 = 0,25; P(A/H_3) = 0,2 \cdot 0,2 = 0,04.$$

По формуле Байеса находим вероятность гипотезы H_1 после опыта:

$$P(H_1/A) = \frac{0,49 \cdot 1/3}{1/3 \cdot 0,49 + 1/3 \cdot 0,25 + 1/3 \cdot 0,04} = \frac{0,49}{0,78} = 0,628.$$

Пример 11.

По линии связи с вероятностями 0,84 и 0,16 соответственно передаются два сигнала A и B . Из-за помех $1/6$ часть переданных сигналов A искажается и принимается как сигнал B , а $1/8$ часть переданных сигналов B принимается как сигнал A . 1) Какова вероятность того, что при приеме появится: а) сигнал A ; б) сигнал B ? 2) Известно, что принят сигнал A . Какова вероятность того, что он же и был передан? Решение: Введем обозначения для событий. H_1 - передан сигнал A , H_2 - передан сигнал B , A - при приеме появится сигнал A , B - при приеме появится сигнал B . Имеем

$$P(H_1) = 0,84; P(H_2) = 0,16; P(A/H_1) = 5/6;$$

$$P(A/H_2) = 1/8; P(B/H_1) = 1/6; P(B/H_2) = 7/8.$$

1. По формуле полной вероятности находим а) $P(A) = P(H_1) \cdot P(A/H_1) + P(H_2) \cdot P(A/H_2) = 0,84 \cdot \frac{5}{6} + 0,16 \cdot \frac{1}{8} = 0,72$;

б) $P(B) = P(H_1) \cdot P(B/H_1) + P(H_2) \cdot P(B/H_2) = 0,84 \cdot \frac{1}{6} + 0,16 \cdot \frac{7}{8} = 0,28$. 2. По формуле Байеса получаем

$$P(H_1/A) = \frac{P(H_1) \cdot P(A/H_1)}{P(A)} = \frac{0,84 \cdot \frac{5}{6}}{0,72} \approx 0,97.$$

Пример 12.

Два из трех независимо работающих элементов вычислительного устройства отказали. Найти вероятность того, что отказали первый и второй элементы, если вероятности отказа первого, второго и третьего элементов соответственно равны $p_1 = 0,2$; $p_2 = 0,4$; $p_3 = 0,3$. Решение: Введем обозначение A для события - отказали два элемента. Рассмотрим следующие гипотезы: H_1 - отказали первый и второй элементы, а третий элемент исправен; H_2 - отказали первый и третий элементы, а второй элемент исправен; H_3 - отказали второй и третий элементы, а первый элемент исправен; H_4 - ни один элемент не отказал; H_5 - отказал только один элемент; H_6 - отказали все три элемента. При этом (поскольку элементы работают независимо, то применима теорема умножения вероятностей):

$$P(H_1) = p_1 p_2 (1 - p_3) = 0,2 \cdot 0,4 \cdot 0,7 = 0,056;$$

$$P(H_2) = p_1 p_3 (1 - p_2) = 0,2 \cdot 0,3 \cdot 0,6 = 0,036;$$

$$P(H_3) = p_2 p_3 (1 - p_1) = 0,4 \cdot 0,3 \cdot 0,8 = 0,096.$$

Вероятности гипотез H_4, H_5, H_6 можно не считать, т. к. из условия задачи следует, что

$$P(A/H_4) = 0, P(A/H_5) = 0, P(A/H_6) = 0,$$

следовательно, равны нулю и произведения $P(H_4) \cdot P(A/H_4), P(H_5) \cdot P(A/H_5), P(H_6) \cdot P(A/H_6)$, входящие в формулу полной вероятности.

При гипотезах H_1, H_2, H_3 событие A достоверно, соответствующие условные вероятности равны единице. По формуле полной вероятности находим вероятность события A :

$$P(A) = \sum_{i=1}^6 P(H_i) \cdot P(A/H_i) = P(H_1) P(A/H_1) + P(H_2) P(A/H_2) + P(H_3) \times \\ \times P(A/H_3) = 0,056 \cdot 1 + 0,036 \cdot 1 + 0,096 \cdot 1 = 0,188.$$

Теперь искомую вероятность вычисляем по формуле Байеса:

$$P(H_1/A) = \frac{P(H_1) \cdot P(A/H_1)}{P(A)} = \frac{0,056 \cdot 1}{0,188} \approx 0,298.$$

6.2.2 Problems About the Independence of Events

- В задачах п2.15-п2.19 предполагается, что задано вероятностное пространство; требуется выяснить, зависимы или независимы некоторые события.

Ч-2.15

Брошены две игральные кости. Положим $A_l = \{ \text{число очков, выпавшее на первой кости, делится на } l \}$, $R_l = \{ \text{число очков, выпавшее на второй кости, делится на } l \}$, $C_l = \{ \text{сумма очков, выпавших на первой и второй костях, делится на } l \}$. Отправляясь от классического определения вероятности, установить, являются ли независимыми следующие пары событий а) A_l, B_k - при любых l, k ; б) A_2, C_2 ; в) A_4, C_4 ?

Ч-2.16

Игральная кость брошена 2 раза, X_1 и X_2 - числа очков, выпавшие при этих испытаниях. Рассмотрим события

$$A_1 = \{X_1 \text{ делится на } 2, X_2 \text{ делится на } 3\},$$

$$A_2 = \{X_1 \text{ делится на } 3, X_2 \text{ делится на } 2\},$$

$$A_3 = \{X_1 \text{ делится на } X_2\},$$

$$A_4 = \{X_2 \text{ делится на } X_1\},$$

$$A_5 = \{X_1 + X_2 \text{ делится на } 2\},$$

$$A_6 = \{X_1 + X_2 \text{ делится на } 3\}.$$

Найти все пары $\{A_i, A_j\}$, тройки $\{A_i, A_j, A_k\}$ и т. д. взаимно независимых событий.

Ч-2.17

Случайная точка (ξ_1, ξ_2) имеет равномерное распределение в квадрате $\{(x_1, x_2) : 0 \leq x_1, x_2 \leq 1\}$. При каких значениях r независимы события $A_r = \{|\xi_1 - \xi_2| \geq r\}$ и $B_r = \{\xi_1 + \xi_2 \leq 3r\}$?

Ч-2.18

События A и B независимы. Являются ли независимыми события: а) A и $\bar{B}$, б) $\bar{A}$ и $\bar{B}$?

Ч-2.19

Случайная точка $\xi = (\xi_1, \xi_2)$ имеет равномерное распределение в квадрате $0 \leq x, y \leq 1$. Пусть

$$A_1 = \left\{ \xi_1 \leq \frac{1}{2} \right\}, \quad A_2 = \left\{ \xi_2 \leq \frac{1}{2} \right\}$$

$$A_3 = \left\{ \left(\xi_1 - \frac{1}{2} \right) \left(\xi_2 - \frac{1}{2} \right) < 0 \right\}$$

Показать, что любые два события из A_1, A_2, A_3 независимы, но все три события A_1, A_2, A_3 зависимы. Являются ли зависимыми события $A_1 A_2$ и A_3 ?

Ч-2.20

(см. п.2.19). Обобщая пример, приведенный в предыдущей задаче, показать, что для любого целого $n \geq 4$ существует совокупность $\{A_1, \dots, A_n\}$ событий, обладающая следующими свойствами:

- события $A_1, \dots, A_n$ не являются независимыми,
- при удалении из $A_1, \dots, A_n$ любого события оставшаяся совокупность состоит из независимых событий.

Ч-2.21

События $A_1, A_2, \dots, A_n$ удовлетворяют условиям

$$P\{A_i\} = p_i, \quad P\left\{\bigcap_{j=1}^i A_j\right\} = p_1 \dots p_i, \quad i = 1, 2, \dots, n.$$

Является ли $\{A_1, \dots, A_n\}$ совокупностью независимых событий?

Ч-2.22

*. Пространство элементарных событий Ω состоит из n элементов. При каких k на подмножествах Ω можно определить вероятность P и события $A_1, \dots, A_n$ так, чтобы события $A_1, \dots, A_k$ были независимыми в совокупности и $0 < P(A_i) < 1$ ($i = 1, 2, \dots, k$)?

Ч-2.23

Пространство элементарных событий Ω состоит из $n \geq 4$ элементов. При каких k можно так определить на подмножествах Ω вероятность P и события $A_1, \dots, A_k$, что $0 < P(A_i) < 1$ ($i = 1, \dots, k$) и события $A_1, \dots, A_k$ попарно независимы?

Ч-2.28

По цели производится n независимых выстрелов. Вероятность попадания при i -м выстреле равна p_i , $i = 1, \dots, n$. Найти вероятность того, что при n выстрелах будет не менее двух попаданий.

6.2.3 Problems About the Total Probability Formula**Ч-2.29**

В первой урне находятся 1 белый и 9 черных шаров. а во второй - 1 черный и 5 белых шаров. Из каждой урны по схеме случайного выбора без возвращения удалили по одному шару, а оставшиеся шары высыпали в третью урну. Найти вероятность того, что шар, вынутый из третьей урны, окажется белым.

Ч-2.30

В первой урне лежит 1 белый шар и 4 красных, а во второй - 1 белый и 7 красных. В первую урну до-

бавляются два шара, случайно выбранных из второй урны.

- Найти вероятность того, что шар, выбранный из пополненной первой урны, будет белым.
- Пусть из пополненной первой урны по схеме случайного выбора с возвращением извлекают k шаров. Найти вероятность того, что все они будут белыми.

Ч-2.31

Из урны, содержащей 2 белых и 3 черных шара, наудачу извлекают 2 шара и добавляют в урну один белый шар.

а) Найти вероятность того, что после этого наудачу выбранный из урны шар окажется белым. б) Пусть из урны по схеме случайного выбора с возвращением извлекают k шаров. Найти вероятность того, что все они белые.

в) Найти ту же вероятность, что в п. б), для схемы выбора без возвращения.

Ч-2.32

В пункте проката имеется 10 телевизоров, для которых вероятность исправной работы в течение месяца равна 0,90, и 5 телевизоров с аналогичной вероятностью, равной 0,95. Найти вероятность того, что два телевизора, взятые наудачу в пункте проката, будут работать исправно в течение месяца.

Ч-2.33

В одной урне содержится 1 белый и 2 черных шара, а в другой урне - 2 белых и 3 черных шара. В третью урну кладут два шара, случайно выбранных из первой урны, и два шара, случайно выбранных из второй.

а) Какова вероятность того, что шар, извлеченный из третьей урны, будет белым?

б) Найти вероятность того, что при выборе с возвращением из третьей урны двух шаров один из них будет белым, а другой - черным.

в) Найти ту же вероятность, что в п. б), для схемы выбора без возвращения.

Ч-2.37

При переливании крови надо учитывать группы крови донора и больного. Человеку, имеющему четвертую группу крови, можно перелить кровь любой группы; человеку со второй или третьей группой крови можно перелить кровь либо той же группы, либо первой; человеку с первой группой крови можно перелить только кровь первой группы. Среди населения 33,7 % имеют первую, 37,5 % - вторую, 20,9 % - третью и 7,9 % - четвертую группы крови.

а) Найти вероятность того, что случайно взятому больному можно перелить кровь случайно взятого донора.

б) Найти вероятность того, что переливание можно осуществить, если имеются два донора; три донора.

Ч-2.38

Во время испытаний было установлено, что вероятность безотказного срабатывания реле при отсутствии помех равна 0,99, при перегреве - 0,95, при вибрации - 0,9, при вибрации и перегреве - 0,8. Найти вероятность P_1 отказа этого реле при работе в жарких странах (вероятность перегрева равна 0,2, вероятность вибрации 0,1) и вероятность P_2 отказа при работе в передвижной лаборатории (вероятность перегрева 0,1, вероятность вибрации 0,3), предполагая перегрев и вибрацию независимыми событиями.

Ч-2.39

(см. п.2.38). Найти границы, в которых могут изменяться вероятности P_1 и P_2 в предыдущей задаче, если отказаться от предположения о независимости перегрева и вибрации.

Ч-2.40

Имеется пять урн. В 1-й, 2-й и 3-й урнах находится по 2 белых и 3 черных шара; в 4-й и 5-й урнах - по 1 белому и 1 черному шару. Случайно выбирается урна и из нее извлекается шар. Какова условная вероятность того, что выбрана 4-я или 5-я урна, если извлеченный шар оказался белым?

6.2.4 Problems About Bernoulli's Scheme (!?!?!?!?)

(очень важно это прорешать будет!)

Пр и м е р 3.

Определить вероятность того, что в семье, имеющей 5 детей, будет не больше трех девочек. Вероятности рождения мальчика и девочки предполагаются одинаковыми. Решение: Вероятность

рождения девочки $p = \frac{1}{2}$, тогда $q = \frac{1}{2}$. Найдём вероятности того, что в семье нет девочек, родилась одна, две или три девочки:

$$P_5(0) = q^5 = \frac{1}{32}, P_5(1) = C_5^1 p^1 q^4 = \frac{5}{32}, \quad P_5(2) = C_5^2 p^2 q^3 = \frac{10}{32},$$

$$P_5(3) = C_5^3 p^3 q^2 = \frac{10}{32}.$$

Следовательно, искомая вероятность

$$P_5(k \leq 3) = P_5(0) + P_5(1) + P_5(2) + P_5(3) = \frac{13}{16}$$

Ч-2.46

Проведено 20 независимых испытаний, каждое из которых заключается в одновременном подбрасывании трех монет. Найти вероятность того, что хотя бы в одном испытании появятся три «герба».

Ч-2.47

При передаче сообщения вероятность искажения одного знака равна $1/10$. Каковы вероятности того, что сообщение из 10 знаков: а) не будет искажено, б) содержит ровно 3 искажения, в) содержит не более трех искажений?

Ч-2.48

Испытание заключается в бросании трех игральных костей. Найти вероятность того, что в пяти независимых испытаниях ровно два раза выпадет по три единицы.

Ч-2.49

Найти вероятность того, что в $2n$ испытаниях схемы Бернулли с вероятностью успеха p и неудачи $q = 1 - p$ появится $m + n$ успехов и все испытания с четными номерами закончатся успехом.

Ч-2.50

Из множества $S = \{1, 2, \dots, N\}$ случайно и независимо выбирают два подмножества A_1 и A_2 так, что каждый элемент из S независимо от других элементов с вероятностью $q = 1 - p$ не включается. Найти вероятность того, что $A_1 \cap A_2 = \emptyset$.

Ч-2.51

. По той же схеме выбора подмножеств на $S = \{1, 2, \dots, N\}$, что в задаче п2.50, независимо выбираются r подмножеств $A_1, A_2, \dots, A_r, r \geq 2$. Найти вероятность того, что выбранные подмножества попарно не пересекаются.

Ч-2.52

(см. п50). Из множества $S = \{1, 2, \dots, N\}$ независимо выбираются r подмножеств $A_1, A_2, \dots, A_r$. Механизм выбора состоит в следующем: любой элемент множества S независимо от других элементов с вероятностью p_i включается в множество A_i и с вероятностью $q_i = 1 - p_i$ не включается ($i = 1, \dots, r$). Найти вероятность того, что подмножества $A_1, A_2, \dots, A_r$ попарно не пересекаются.

Ч-2.55

В одном из матчей на первенство мира по шахматам партии не учитывались, и игра шла до тех пор, пока один из участников матча не набирал 6 очков (выигрыш - 1 очко, проигрыш и ничья - 0 очков). Считая участников матча одинаковыми по силе, а результаты отдельных игр независимыми, найти вероятность того, что при таких правилах в момент окончания матча проигравший набирает k очков, $k = 0, 1, \dots, 5$.

Ч-2.56

Обрабатываемые на станке детали сортируются по размерам на две группы. Каждая очередная деталь независимо от предыдущих с равными вероятностями попадает в первую или вторую группу. Пусть в начал: смены для каждой группы деталей приготовлено по ящику емкости r . Какова вероятность того, что в момент, когда очередную деталь будет некуда класть, в другом ящике будет m деталей?

Бракованные детали в партии

В партии содержатся 50 деталей, из которых 10 бракованных. Из партии наудачу берутся 5 деталей. Найти вероятность того, что:

1) все 5 деталей бракованные; 2) все 5 деталей доброкачественные; 3) в пятерке извлеченных деталей 3 детали бракованные и 2 детали доброкачественные; 4) среди 5-ти извлеченных деталей хотя бы одна бракованная.

Solution

Будем считать, что все детали пронумерованы, т. е. они образуют множество из $n = 50$ различных по номерам объектов, из которых 10 - бракованные, а остальные 40 - доброкачественные. Из этой партии наудачу берутся 5 деталей. В этом состоит эксперимент.

Событие A - все 5 деталей бракованные, событие B - все 5 деталей доброкачественные, событие C - в пятерке извлеченных деталей 3 детали бракованные и 2 - доброкачественные, событие D - в пятерке извлеченных деталей число бракованных деталей от 1 до 5.

Элементарный исход нашего эксперимента определяется номерами пяти взятых деталей, причем порядок указания этих номеров не имеет значения. Общее число таких элементарных событий совпадает с числом различных сочетаний из 50 элементов по 5 и выражается формулой

$$C_{50}^5 = \frac{50!}{5!45!} = \frac{46 \cdot 47 \cdot 48 \cdot 49 \cdot 50}{120} = 2118760.$$

Все эти элементарные исходы образуют полную группу и равновозможны, т. к. 5 деталей берутся наудачу и одна пятерка деталей имеет такие же шансы быть взятой, что и любая другая.

Событию A благоприятствуют лишь те пять деталей, которые взяты из 10 бракованных деталей. Так как порядок взятых 5-ти деталей не играет роли, то их число равно $C_{10}^5 = \frac{10!}{5!5!}$ и, следовательно,

$$P(A) = \frac{\tilde{N}_{10}^5}{\tilde{N}_{50}^5} = \frac{6 \cdot 7 \cdot 8 \cdot 9 \cdot 10}{120 \cdot 2118760} \approx 0,0001.$$

Событию B благоприятствуют лишь пятерки деталей, которые взяты из 40 доброкачественных деталей. Поэтому их число равно C_{40}^5 , и

$$P(B) = \frac{\tilde{N}_{40}^5}{\tilde{N}_{50}^5} = \frac{36 \cdot 37 \cdot 38 \cdot 39 \cdot 40}{120 \cdot 2118760} \approx 0,311.$$

Событию C благоприятствуют лишь те элементарные исходы (пятерки деталей), которые содержат 3 бракованные и 2 доброкачественные детали. Их число (по правилу умножения) равно $C_{10}^3 C_{40}^2$ и, следовательно,

$$P(C) = \frac{C_{10}^3 C_{40}^2}{C_{50}^5} = \frac{8 \cdot 9 \cdot 10 \cdot 39 \cdot 40}{6 \cdot 2 \cdot 2118760} \approx 0,044.$$

Событию $\bar{D}$ благоприятствуют лишь те элементарные исходы (пятерки деталей), которые не содержат бракованные (все доброкачественные детали), т. е. $\bar{D} = B$, поэтому

$$P(D) = 1 - P(\bar{D}) = 1 - P(B) = 1 - 0,311 \approx 0,689$$

Ч-2.57

По каналу связи передаются сообщения из пулей и единиц. Из-за помех вероятность правильной передачи знака равна 0,55. Для повышения вероятности правильной передачи каждый знак сообщения повторяют n раз. Полагают, что последовательности из n принятых знаков в сообщении соответствуют знак, составляющий в ней большинство. Найти вероятность правильной передачи одного знака при n -кратном повторении, если $n = 5$.

Ч-2.58

(см п2.57). Подобрать n так, чтобы вероятность правильной передачи знака была не меньше 0,99.

Ч-2.59

По каналу связи передается 1000 знаков. Каждый аяак может быть искажен независимо от остальных с вероятностью 0,005. Найти приближенное значение вероятности того, что будет искажено не более трех знаков.

Ч-2.61

Пусть ξ_n - число успехов в n независимых испытаниях Бернулли с вероятностью успеха, равной $1/2$.
 а) С помощью теоремы Муавра - Лапласа найти приближенные значения

$$P\left\{\left|\xi_n - \frac{n}{2}\right| \leq \frac{\sqrt{n}}{2}\right\}, P\left\{\left|\xi_n - \frac{n}{2}\right| \geq \frac{\sqrt{n}}{2}\right\}$$

при $n = 100$. 40

б) Вычислить те же вероятности, что в п. а), с погрешностью 10^{-5} , используя уточненную формулу Стирлинга.

Сравнить результаты пп. а) и б) и истолковать их. п2.62*. Решить предыдущую задачу, полагая $n = 128$.

Ч-2.63

Найти приближенное значение вероятности того, что число "девяток" среди 10000 случайных писел заключено между 940 и 1060.

Ч-2.64

Из таблицы случайных чисел отбирают числа, делящиеся на 3, до тех пор, пока не наберется 1025 таких чисел. Найти приближенное значение вероятности того, что потребуется таблица, содержащая не меньше 2500 чисел.

Ч-2.65

Театр, вмещающий 1000 человек, имеет два разных входа. Около каждого из входов имеется свой гардероб. Сколько мест должно быть в каждом из гардеробов для того, чтобы в среднем в 99 случаях из 100 все зрители могли раздеться в гардеробе того входа, через который они вошли? Рассмотреть два случая: а) зрители приходят парами; б) зрители приходят поодиночке. Предположить, что входы зрители выбирают с равными вероятностями.

Ч-2.66

В поселке 2500 жителей. Каждый из них примерно 6 раз в месяц ездит на поезде в город, выбирая для поездок по случайным мотивам независимо от остальных. Какой наименьшей вместимостью должен обладать поезд, чтобы он переполнялся в среднем не чаще одного раза в 100 дней (поезд ходит раз в сутки).

Ч-2.67

Пусть η_N - суммарное число появлений «5» к «6» в N бросаниях игральной кости. При $N = 1800$ найти вероятность того, что $\eta_N \geq 620$.

Ч-2.68

Две монеты подбрасывают 4800 раз. Найти приближенное значение вероятности того, что событие "герб - герб" появится меньше 1140 раз.

Ч-2.69

Вероятность попадания в цель при одном выстреле равна 0,01. Найти приближенное значение вероятности того, что при 100 выстрелах будет не больше трех попаданий.

Ч-2.70

Из урны, содержащей 1 белый и 4 черных шара, по схеме случайного выбора с возвращением проводят 2500 извлечений шаров. Найти приближенное значение вероятности того, что число появлений белого шара заключено между 480 и 540.

Ч-2.71

На одной странице 2400 знаков. При типографском наборе вероятность искажения одного знака равна $1/800$. Найти приближенное значение вероятности того, что на странице не менее двух опечаток.

Ч-2.72

Вероятность успеха в каждом испытании схемы Бернулли равна p . Найти вероятность того, что k -й по порядку успех происходит при l -м испытании.

В задачах с п2.73 по п2.78 рассматриваются бесконечные последовательности испытаний. Воспользоваться частным случаем вероятностного пространства, который определяется формулами (п15) - (п2.17) при $N = 2$.

Ч-2.73

Две игральные кости бросают до выпадения 6 и хотя бы на одной из них. Найти вероятность того, что впервые "6" появляется при k -м бросании, $k = 1, 2, 3, \dots$

Ч-2.74

Двое по очереди бросают монету. Выигрывает тот, кто первым получит «герб». Найти вероятности событий:

- а) игра закончится до 4-го бросания;
- б) выиграет начавший игру (первый игрок);
- в) выиграет второй игрок.

Ч-2.75

В схеме Бернулли p - вероятность исхода 1 и $q = 1 - p$ - вероятность исхода 0. Найти вероятность того, что цепочка 00, состоящая из двух нулей подряд, появится раньше цепочки 01. В частности, вычислить эту вероятность при $p = 1/2$.

Ч-2.76

Пусть выполнены условия задачи п2.75. Найти вероятность того, что цепочка 00 (два нуля подряд) появится раньше цепочки 10. В частности, вычислить эту вероятность при $p \approx 1/2$.

Ч-2.77

Пусть выполнены условия задачи п2.75. Найти вероятность P_{0011} того, что цепочка 00 появится раньше цепочки 111. В частности, вычислить эту вероятность при $p = 1/2$.

6.2.5 Problems About Poisson Events (??)

(мб тут и не про них, посмотрим потом, пока так, выгрузил то, что встречалось.)

Белан-л5.1.

Стрельба по цели ведется до тех пор, пока суммарное число попаданий не достигнет N . Найдите математическое ожидание, дисперсию, а также функцию распределения вероятностей потребовавшегося числа выстрелов k , если выстрелы производятся независимо друг от друга и вероятность попадания в отдельной попытке равна p .

Задача 1

Число выстрелов, требуемое чтобы получить N попаданий можно представить в виде суммы $k = k_1 + k_2 + \dots + k_N$, где k_n - это число выстрелов которое потребовалось для достижения n -го попадания, если отсчитывать от предыдущего попадания (или от начала стрельбы, если речь идет об $n = 1$). В силу отсутствия памяти о процесса Бернулли слагаемые статистически независимы. Каждое из них при этом имеет геометрическую функцию распределения вероятностей, заданную формулой (4). Воспользовавшись результатами, изложенными на третьей лекции и уравнением (5) и (7), запишем для случая произвольной вероятности p успеха в отдельном испытании

$$\mu_k = N\mu_{k_1} = \frac{N}{p},$$

$$\sigma_k^2 = N\sigma_{k_1}^2 = N\frac{1-p}{p^2}.$$

Чтобы получить функцию распределения вероятностей $p(k)$ нужно умножить вероятность получить ровно $N - 1$ попаданий в серии из первых $k - 1$ выстрелов на вероятность попадания в k -м исходе, то есть

$$p(k) = pB(N - 1, k - 1, p) = \frac{(k - 1)!}{(N - 1)!(k - N)!} p^N (1 - p)^{k - N}$$

Этот результат известен как распределение Паскаля.

Белан-л5.2.

Найти среднее число бросков симметричной монетки необходимое чтобы каждая ее сторона выпала хотя бы два раза.

Задача 2 Подбросим монетку три раза. С вероятностью $1/4$ все три исхода будут одинаковы, и тогда среднее оставшееся число попыток, требуемое для накопления двух недостающих исходов, равно $2 + 2 = 4$. С вероятностью $3/4$ не все исходы первых трех попыток одинаковы, и тогда, чтобы получить недостающий исход второй раз, в среднем придется подбросить монетку еще 2 раза. В итоге получаем, что среднее число бросков симметричной монетки необходимое чтобы каждая ее сторона выпала хотя бы два раза равно

$$\frac{1}{4}(3 + 4) + \frac{3}{4}(3 + 2) = \frac{22}{4} = 5.5$$

Белан-л5.3.

Симметричный игральный кубик подбрасывают раз за разом. Найти среднее число попыток $\langle k \rangle$, необходимое, чтобы каждая из шести граней выпала хотя бы один раз. Найти также дисперсию требуемого числа попыток.

Белан-л5.4.

Сколько в среднем раз необходимо подбросить симметричную монетку, чтобы впервые встретить в последовательности исходов реализацию вида "орел, решка"?

Задача 4 Для соответствующей случайной величины справедливо

$$k = k_1^o + k_1^p$$

а значит

$$\langle k \rangle = \langle k_1^o \rangle + \langle k_1^p \rangle = \frac{1}{p} + \frac{1}{1-p} = \frac{1}{p(1-p)}.$$

В частности, для симметричной монетки находим, что для появления пары "орел, решка" необходимо в среднем подкинуть монетку $\langle k \rangle = 4$ раз. Отметим, что среднее число попыток, необходимое для появления пары "орел,орел"равно 6.

Белан-л5.5.

Сколько в среднем раз необходимо подбросить симметричную монетку, чтобы впервые встретить в последовательности исходов реализацию вида "десять орлов подряд"?

Задача 5 Для ответа на поставленный вопрос, рассмотрим схему Бернулли, где единица соответствует выпадению орла, а ноль - выпадению решки. Будем решать задачу в общем случае, когда вероятность выпадения единицы в отдельном испытании равна p , и речь идет об ожидании цепочки исходов из N единиц подряд. Количество попыток, требуемое для реализации первой такой цепочки обозначим через k . Каждая последовательность независимых повторений эксперимента Бернулли характеризуется некоторым количеством нулей, выпавших до первого появления единицы, и количеством единиц, выпавших подряд сразу вслед за этим. Если число идущих подряд единиц в первой встретившейся цепочке единиц меньше чем N , то можно считать, что процесс ожидания цепочки из N единиц подряд начинается заново в том смысле, что оставшееся число попыток k' необходимое для выпадения N единиц подряд имеет ту же статистику, что и k . Сказанное может быть записано в форме уравнения

$$k = k_1^o + (N - 1) \cdot I(k_1^p > N - 1) + (k_1^p + k') I(k_1^p \leq N - 1)$$

где нами были введены следующие обозначения: k_1^o - номер попытки в цепочке независимых испытаний Бернулли, когда впервые выпадает; единица, k_1^p - номер попытки в цепочке независимых испытаний Бернулли, когда впервые выпадает ноль, k' - независимая реализация случайной величины k , $I(\dots)$ - индикаторная функция. Рекурсивное соотношение (43) представляет собой пример того, что называется уравнением обновления.

Произведем статистическое усреднение

$$\langle k \rangle = \langle k_1^o \rangle + (N - 1) \cdot \langle I(k_1^p > N - 1) \rangle + \langle k_1^p I(k_1^p \leq N - 1) \rangle + \langle k' I(k_1^p \leq N - 1) \rangle.$$

Словом, мы приравняли друг другу математические ожидания левой и парвой частей Ур. (43). В силу отсутствия памяти у процесса Бернулли, k_1^p и k' это статистически независимые случайные величины, а значит $\langle k' I(k_1^p \leq N - 1) \rangle = \langle k' \rangle \langle I(k_1^p \leq N - 1) \rangle = \langle k \rangle \langle I(k_1^p \leq N - 1) \rangle$, и мы можем переписать

$$\langle k \rangle = \langle k_1^o \rangle + (N - 1) \cdot \langle I(k_1^p > N - 1) \rangle + \langle k_1^p I(k_1^p \leq N - 1) \rangle + \langle k \rangle \langle I(k_1^p \leq N - 1) \rangle$$

Решая это уравнение относительно $\langle k \rangle$, находим

$$\langle k \rangle = N - 1 + \frac{\langle k_1^o \rangle + \langle k_1^p I(k_1^p \leq N - 1) \rangle}{\langle I(k_1^p > N - 1) \rangle}.$$

Остается лишь вычислить средние значения, входящие в правую часть полученного выражения.

Вспомним, что статистика случайных величин k_1^o и k_1^p описывается геометрическими функциями распределения вероятностей, $P_o(k_1^o) = p(1-p)^{k_1^o-1}$ и $P_p(k_1^p) = (1-p)p^{k_1^p}$ (см п. (4)). Значит

$$\begin{aligned}\langle k_1^o \rangle &= \frac{1}{p}, \\ \langle I(k_1^p > N - 1) \rangle &= \text{Prob}[k_1^p > N - 1] = \sum_{k_1^p=N}^{\infty} (1-p)p^{k_1^p} - 1 = p^{N-1}, \\ \langle k_1^p I(k_1^p \leq N - 1) \rangle &= \sum_{k_1^p=1}^{N-1} k_1^p (1-p)p^{k_1^p} = \frac{1 + (N-1)p^{N-Np^{N-1}}}{1-p}.\end{aligned}$$

Подстановка этих формул в Ур. (46) дает финальный ответ к задаче

$$\langle k \rangle = \frac{1}{1-p} \left(\frac{1}{p^N} - 1 \right).$$

В частности, для симметричной монетки ($p = 1/2$) имеем $\langle k \rangle = 2^{N+1} - 2$. То есть, чтобы встретить десять орлов подряд придется подбросить монетку (в среднем) $2^{11} - 2 = 2046$ раз.

Белан-л5.6.

Крупные метеориты падают на Землю в пуассоновские моменты времени с рейтом λ . Обозначим через t_n время ожидания падения n -го по счету метеорита, отсчитываемое от произвольно выбранного момента начала наблюдений. Какова функция плотности вероятности случайной величины t_n ?

Белан-л5.7.

В области полностью ионизированного водорода начинается происходить рекомбинация электронов с ионами, в результате чего газ постепенно деионизируется. Вероятность того, что электрон рекомбинируется за время dt равна $\rho(t)\beta dt$, где $\rho(t)$ это концентрация ионов в текущий момент времени t , а β - некоторый постоянный коэффициент, характеризующий акт рекомбинации. Известно, что концентрация ионов в начальный момент времени равна ρ_0 , а система в целом электронейтральна. Найдите плотность вероятностей для случайной величины T - времени, прошедшего до момента рекомбинации отдельно взятого электрона. Каково медианное значение времени рекомбинации T ?

6.2.6 Problems About Polynomial Schema

Ч-2.80

При прохождении одного порога байдарка не получает повреждений с вероятностью p_1 , полностью ломается с вероятностью p_2 , получает серьезное повреждение с вероятностью p_3 ($p_1 + p_2 + p_3 = 1$). Два серьезных повреждения приводят к полной поломке. Найти вероятность того, что при прохождении n порогов байдарка не будет полностью сломана.

Ч-2.81

Сообщения, передаваемые по каналу связи, состояются из трех знаков А, В, С. Из-за помех каждый знак принимается правильно с вероятностью 0,6 и принимается ошибочно за любой из двух других знаков с вероятностью 0,2. Для увеличения вероятности правильного приема каждый знак передается 5 раз. За переданный знак принимается знак, который чаще всего встречается в принятой пятерке знаков. Если наиболее частых знаков два, то из них выбирается равновероятно один. Найти вероятность правильного приема знака при указанном способе передачи.

Ч-2.82

Пусть $\xi_{i,\uparrow}$ - число появлений исхода i в n первых испытаниях полиномиальной схемы (см. введение К гл. 2). Найти $P\{\xi_{n,1} = m_1\}$.

Ч-2.83

В схеме, описанной в задаче п2.82, найти условную вероятность

$$P\{\xi_{n,2} = m_2, \dots, \xi_{n,N} = m_n | \xi_{n,1} = m_1\}.$$

Ч-2.84

В N ячейках, разбитых на две группы по N_1 и N_2 ячеек соответственно ($N_1 + N_2 = N$), независимо одну от другой размещают n частиц; пусть p_{ij} ($i = 1, 2; j = 1, 2, \dots, N_1$) - вероятность попадания частицы в j -ю ячейку i -й группы, а $\prod_{ij}^{(n)}$ - число частиц, попавших в j -ю ячейку i -й группы после размещения n частиц. Найти:

- $P\{\eta_{ij}^{(n)} = k_{ij}, i = 1, 2, j = 1, \dots, N\},$
- $P\{\eta_{21}^{(n)} + \dots + \eta_{2N_2}^{(n)} = n_2\},$
- $P\{\eta_{1j} = k_{1j}, j = 1^2, \dots, N_1 | \eta_{21} + \dots + \eta_{2N_2} = n_2\}.$

Ч-2.87

Исходы $\theta_1, \theta_2, \dots$ последовательности испытаний с $N = 3$ возможными исходами 1, 2, 3 и вероятностями исходов p_1, p_2, p_3 объединяются в тройки $(\theta_{3k+1}, \theta_{3k+2}, \theta_{3k+3})$. Из первой тройки $(\theta_{3v+1}, \theta_{3v+2}, \theta_{3v+3})$, в которой все исходы различны, выбирается θ_{3v+1} . Найти $P\{\theta_{3v+1} = i\}$.

Ч-2.88

Испытания в полиномиальной схеме с исходами 1, 2, 3, имеющими вероятности p_1, p_2, p_3 соответственно, заканчиваются, когда впервые не появится исход 3. Найти вероятность того, что испытания закончатся исходом 1.

Ч-2.89

Игрок A подбрасывает 3 игральные кости, а игрок B - 2 кости. Эти испытания они проводят вместе и последовательно до первого выпадения "6" хотя бы на одной кости. Найти вероятности событий:

- $A = \{\text{впервые 6 появилось у игрока } A, \text{ а не } B\};$
- $B = \{\text{впервые 46 и появилось у игрока } B, \text{ а не } A\};$
- $C = \{\text{впервые "6" появилось одновременно у } A \text{ и } B\}.$

6.3 Problems of Probability Theory in Life and Everyday Life

(мб с собеседований тоже сюда буду собирать задачи.)

6.3.1 Problems About Typical Simple Life Tasks (!!!!!)

(тут вот то, что встречается в жизни и буду решать!! заработает теория, если пройду основы нормально!!!)

(другой сборник открыл, лень писать, какой)

Время ремонта и обслуживания автомобиля после одной поездки случайно и имеет экспоненциальный закон распределения. Было замечено, что в текущем сезоне на ремонт и обслуживание автомобиля после одной поездки тратилось в среднем 5 минут. Найти вероятность того, что при очередной поездке это время не превысит 30 минут.

Пусть X - время ремонта и обслуживания автомобиля после одной поездки. По условию задачи $X \sim E(\lambda)$ и $M[X] = 5$. По формуле связи $M[X]$ и λ получаем, что $M[X] = \frac{1}{\lambda} = 5$. Отсюда находим $\lambda = 1/5$. Требуется найти $P\{X \leq 30\}$. Плотность вероятности СВ X имеет вид

$$f(x) = \begin{cases} \frac{1}{5}e^{-x/5}, & x > 0 \\ 0, & x \leq 0 \end{cases}$$

Следовательно, получаем

$$P\{X \leq 30\} = \int_0^{30} \frac{1}{5}e^{-x/5} dx = -e^{-x/5} \Big|_0^{30} = 1 - e^{-6}$$

Ответ. $P\{X \leq 30\} = 1 - e^{-6}$.

Рост взрослого мужчины удовлетворительно описывается нормальным законом распределения. По статистике средний рост составляет 175 см, а среднеквадратическое отклонение равно 7 см. Найти вероятность того, что рост наугад взятого мужчины будет отличаться от среднего роста не больше чем на 7 см.

Решение. Обозначим рост наугад взятого взрослого мужчины через X . По условию задачи $X \sim N(175; 49)$. Требуется найти $P\{|X - M[X]| \leq 7\}$. Так как интервал $(M[X] - 7, M[X] + 7)$ симметричен относительно $M[X]$, то

$$P\{|X - M[X]| \leq 7\} = 2\Phi_0\left(\frac{7}{\sqrt{D[X]}}\right) = 2\Phi_0(1) \approx 2 \cdot 0,3413 = 0,6826.$$

О т в е т. Искомая вероятность приблизительно равна 0,6826.

МФТИ-Т.18 Мячи из ящика (??!!)

В ящике находится 10 теннисных мячей, из которых 6 новые. Для первой игры наугад берут два мяча, которые после игры возвращают в ящик. Для второй игры также наугад берут 2 мяча. Найти вероятность того, что оба мяча, взятые для второй игры, новые.

Посмотрим на первое вытягивание двух мячей. Пусть A_1 - событие изъятия 2х старых мячей; A_2 - событие изъятия одного старого мяча; A_3 событие изъятия только новых мячей. С помощью комбинаторики легко посчитать эту вероятность:

$$P(A_1) = \frac{C_4^2}{C_{10}^2} = \frac{6 \cdot 5}{10 \cdot 9} = \frac{2}{15} \quad (6.4)$$

$$P(A_2) = \frac{C_6^1 C_4^1}{C_{10}^2} = \frac{8}{15} \quad (6.5)$$

$$P(A_3) = \frac{C_6^2}{C_{10}^2} = \frac{1}{3} \quad (6.6)$$

Теперь, зная каждый случай первого доставания, второе доставание - назовем его A - при котором достались два новых мяча можно записать с помощью формулы полной вероятности.

$$P(A) = P(A_1)P(A|A_1) + P(A_2)P(A|A_2) + P(A_3)P(A|A_3)$$

$$P(A) = \frac{2}{15} \frac{C_6^2}{C_{10}^2} + \frac{8}{15} \frac{C_5^2}{C_{10}^2} + \frac{1}{3} \frac{C_4^2}{C_{10}^2} = \frac{2}{45} + \frac{16}{135} + \frac{2}{45} = \frac{12 + 16}{135} = \frac{28}{135}$$

Ответ $\frac{28}{135}$.

МФТИ-Т.19 Вероятность получения букв по каналу

(мб отдельный раздел про такие задачи сделаю.)

По каналу можно передавать одну из трех последовательностей букв: $AAAA, BBBB, CCCC$, причем априорные вероятности равны 0,3, 0,4 и 0,3 соответственно. Известно, что действие шумов на приемное устройство уменьшает вероятность правильного приема каждой из переданных букв до 0,6, а вероятность приема переданной буквы за две другие увеличивается до 0,2 и 0,2. Предполагается, что буквы искажаются независимо друг от друга. Найти вероятность того, что была передана последовательность $AAAA$, если на приемном устройстве получено $ACAB$.

Нам не известно, как считать условную вероятность прошлого при условии будущего, однако есть формула Байеса, которая позволяет перейти к вероятностям будущего при условии прошлого, которые посчитать мы сможем. По формуле Байеса:

$$\begin{aligned} P(AAAA|ACAB) &= \\ &= \frac{P(AAAA)P(ACAB|AAAA)}{P(AAAA)P(ACAB|AAAA) + P(BBBB)P(ACAB|BBBB) + P(CCCC)P(ACAB|CCCC)} = \\ &= \frac{0,3 \cdot (0,6 \cdot 0,2 \cdot 0,6 \cdot 0,2)}{0,3(0,6 \cdot 0,2 \cdot 0,6 \cdot 0,2) + 0,4((0,2)^3 \cdot 0,6) + 0,3((0,2)^3 \cdot 0,6)} = \frac{9}{16} \quad (6.7) \end{aligned}$$

Ответ: $\frac{9}{16}$.

МФТИ-Т.20 автоматы и жетоны

Имеется три телефонных автомата, которые принимают специальные жетоны. Один из них никогда не работает, второй работает всегда, а третий работает с вероятностью $1/2$. Некто имеет три жетона пытается выяснить, какой из автоматов исправный (работает всегда). Он делает попытку на одном из автоматов, которая оказывается неудачной. Затем переходит к другому автомату, на котором две подряд попытки оказываются удачными. Какова вероятность, что этот автомат исправный?

У нас ситуация, когда в первом подходе мог быть или полуробочий или нерабочий автомат. Вероятность неудачи при полуробочем автомате. Так как вероятность работы полуробочего в два раза меньше, чем у рабочего (чья вероятность работы равна 1), то если мы будем подходить к автоматам, то вероятность, что неудача будет на полуробочем должна быть равна половине вероятности на рабочем, а в сумме вероятности равны 1. Из этих соображений следует, что вероятность, что первый автомат был нерабочим равна $\frac{2}{3}$, а что полуробочим - $\frac{1}{3}$.

Дальше, пусть был первый автомат не рабочий. Тогда после ухода из него остались только полуробочий и рабочий автоматы, вероятность успеха на рабочем (по аналогичным рассуждениям) равна $\frac{2}{3}$, а что полуробочим - $\frac{1}{3}$.

А если первый автомат был полуробочий, то остался только рабочий и нерабочий, вероятности успехов на первом равна 1, на втором - 0.

В итоге по формуле полной вероятности получаем (тут сперва вариант: нерабочий, рабочий, рабочий, потом: полуробочий, рабочий, рабочий):

$$P = \frac{2}{3} \frac{2}{3} \frac{2}{3} + \frac{1}{3} \cdot 1 \cdot 1 = \frac{17}{27}$$

Ответ $\frac{17}{27}$

МФТИ-Т.21 Торпеды по кораблю (!?)

(потом еще раз разберу)

Подводная лодка атакует корабль, выпуская по нему последовательно и независимо одну от другой n торпед. Каждая торпеда попадает в корабль с вероятностью p . При попадании торпеды с вероятностью $\frac{1}{m}$ затопляется один из m отсеков корабля. Определить вероятность гибели корабля, если для этого необходимо затопление не менее двух отсеков.

Попробуем просто посчитать число нужных нам событий, и сложить вероятности каждого.

Пусть попало в цель k торпед, нам нужно, чтобы попало $k \in (2, n)$, тогда $(n - k)$ штук промахнулось. Попавшие торпеды могут быть в разной последовательности, последовательностей всего C_n^k . Среди k попавших может быть разное число r пробитых отсеков $r \in (2, k)$, всего возможных последовательностей C_k^r .

Таким образом, нам остается только суммировать наши исходы:

$$P = \sum_{k=2}^n p^k (1-p)^{n-k} \sum_{r=2}^k C_k^r \left(\frac{1}{m}\right)^r \left(1 - \frac{1}{m}\right)^{k-r}$$

Вероятность исхода в первом испытании с вероятностью 60% (?????!!)

Пусть вероятность нужного исхода равна X , сколько нужно сделать испытаний, чтобы получить этот исход с вероятностью 60% (?????)

(прямо очень актуальная жизненная задача, освою теорвер - прорешаю, пока не так владею им)

6.3.2 Service Sector Tasks with Many Customers (!!!)

(это первый раздел, ибо самый прикольный. потом обязательно классификацию додумаю, чтобы прямо с ходу нужные задачи выдавать!!! пока в одном месте всё.)

 n конвертов случайным n адресатам (????)

(?? тут пока слабая теория)

В n конвертов разложено по одному письму n адресатам. На каждом конверте наудачу написан один из n адресов. Найти вероятность того, что хотя бы одно письмо пойдет по назначению.

Пусть A_i - элементарное событие, состоящее в том, что i -е письмо дошло своему адресату. Тогда нужно найти.

$$P\left(\bigcup_{i=1}^n A_i\right) = \sum_{m=1}^n (-1)^{m-1} \sum_{1 \leq i_1 < \dots < i_m \leq n} P(A_{i_1} A_{i_2} \dots A_{i_m})$$

Посмотрим на каждое слагаемое внимательнее. Каждое слагаемое - вероятность того, что у нас будет m попаданий конвертов и писем. Если зафиксировать m писем, то оставшиеся письма можно раскладывать $(n - m)!$ способами. Всего можно n писем по n конвертам разложить $n!$ способами:

$$P(A_{i_1} A_{i_2} \dots A_{i_m}) = \frac{(n - m)!}{n!}$$

при этом при любых перестановках адресатов вероятность такая же, а всего перестановок при фиксированном m будет C_n^m . В итоге формула примет вид:

$$P = \sum_{m=1}^n (-1)^{m-1} C_n^m \frac{(n - m)!}{n!} = \sum_{m=1}^n (-1)^{m-1} \frac{1}{m!}$$

$$\text{Ответ: } P = \sum_{m=1}^n (-1)^{m-1} \frac{1}{m!}$$

Хватит ли сдачи на кассе (!!!)

(!!! вот тут нужно как следует потренироваться и сделать решение быстрым!!)

У билетной кассы стоит очередь в 100 человек. Половина людей в очереди имеет 100-рублевые купюры, а вторая половина - 50-рублевые купюры. Изначально в кассе нет денег и стоимость билета - 50 рублей. Какова вероятность, что никому не придется ждать сдачи?

Для каждого человека, имеющего 100р чтобы нашлась сдача необходимо, чтобы был перед ним человек, пришедший с 50р.

Таким образом, задача эквивалентна задаче о скобочной последовательности, где есть открывающая и закрывающая скобка. и каждая открытая должна иметь после нее закрывающую.

Известно, что число скобочных последовательностей из n открывающих и n закрывающих скобок равно числу Каталана $K_n = \frac{1}{n+1} C_n^{2n}$.

Всего же возможных последовательностей - число сочетаний C_{2n}^n , Поэтому ответ: $P = \frac{1}{n+1}$, для нашего случая, $n = 50$, имеем $P = \frac{1}{51}$

$$\text{Ответ: } P = \frac{1}{51}$$

Вероятность успешной сдачи экзамена при половине подготовки

Студент выучил 50 из 100 экзаменационных вопросов. В экзаменационном билете будет 9 различных вопросов. Вычислить вероятность получения студентом билета, содержащего не более 1 вопроса из числа невыученных.

Поликлиника закреплена за двумя районами города. При этом население первого района в 3 раза больше населения второго района. Известно, что прививку от гриппа в среднем сделали каждые 39 из 100 жителей первого района и каждые 42 из ста жителей второго района. Вычислить вероятность того, что случайным образом выбранный человек проживает в первом районе при условии, что он не сделал прививку от гриппа.

6.3.3 Distance Tasks

Вероятность, что случайно расположенные на дороге три человека находятся не близко друг с другом

Вдоль дороги, длиной в 1 км расположены случайным образом три человека. Найти вероятность того, что никакие два человека не находятся друг от друга на расстоянии, меньшем $1/4$ км.

Обозначим координаты каждого человека x, y, z . Пусть они расположены в порядке $x \rightarrow y \rightarrow z$, тогда благоприятный исход A состоит в следующем:

$$A = \left\{ \begin{array}{l} y - x \geq \frac{1}{4} \\ z - y \geq \frac{1}{4} \\ \frac{1}{4} \leq y \leq \frac{3}{4} \end{array} \right.$$

(?? тут ниже еще кст нормировка какая-то идет, типа чтобы обезразмерить координаты ведь!!!)

$$P(A) = \int_{\frac{1}{4}}^{\frac{3}{4}} dy \int_0^{y-\frac{1}{4}} dx \int_{y+\frac{1}{4}}^1 dz = \int_{\frac{1}{4}}^{\frac{3}{4}} dy \left(y - \frac{1}{4} \right) \left(1 - y - \frac{1}{4} \right) = \frac{1}{48}$$

Порядок трех точек может быть получен $3! = 6$ способами, поэтому ответ есть полученная вероятность, домноженная на 6.

Ответ: $P = \frac{1}{8}$.

6.3.4 Meeting Tasks

Случайный выход пешехода и автобуса (???)

(?? тут путаница много!!!)

(?? что там с геометрией СТО???? мб там какие-то особенности есть, о которых Суслов говорил?? потом подумаю)

Расстояние от пункта А до пункта В автобус проходит за 2 минуты, а пешеход - за 15 минут. Интервал движения автобусов 25 минут. Пешеход в случайный момент времени из пункта А и отправляется в В пешком. Найти вероятность того, что в пути пешехода догонит очередной автобус.

Будем решать графически. Нарисуем 2D пространство-время, как на картинке.

Figure 6.2: для задачи T12. Здесь короткая линия под наклоном - линия движения автобуса. длинные наклонные линии - линии движения человека. заштрихованная область - область всех возможных линий, где мировая линия человека не пересечет мировую линию автобуса. (я рисовал рисунок, решая обратную задачу, поэтому там написано $\frac{12}{25}$)

Несложные соображения показывают, что незаштрихованная область, которая соответствует встрече, может быть такой такой.

Таким образом, вероятность не встречи равна отношению площади этой области к интервалу, в котором мы смотрим движение автобуса. То есть вероятность равна: $\frac{15-2}{25} = \frac{13}{25}$

Ответ: $\frac{13}{25}$

Вероятность прихода на каждую лекцию хотя бы одного студента

В течение учебного семестра проводится 14 лекций по теории вероятностей для потока, на котором учатся 60 студентов. Каждый студент независимо от остальных приходит на лекцию с вероятностью 0.25. Вычислить вероятность того, что на каждую лекцию придёт хотя бы один студент.

Считаем типично как обратная вероятность, потому что так проще. На 1 лекцию 1 студент не придет с вероятностью 0,75. Никто не придет на одну лекцию с вероятностью $0,75^{60}$. На каждую лекцию никто не придет - то есть будет 14 лекций, каждой вероятностью $0,75^{60}$ - с вероятностью $0,75^{60 \cdot 14}$. Таким образом, хотя бы один придет на каждую с вероятностью $1 - 0,75^{60 \cdot 14}$.

6.4 Problems About Random Variables (!!!!)

6.4.1 Problems About the Inequalities of Chebyshev and Markov

(тут очень мощные задачи, соберу потом! ??? куда это лучше вставить, пока не знаю????)

МФТИ-Т.1 Число посетителей салона

Известно, что число посетителей некоторого салона в день является случайной величиной со средним значением 50.

(а) Оценить вероятность того, что число посетителей в конкретный день превысит 75

Решается неравенством Маркова:

$$\mathbf{P}\{|\xi| \geq x\} \leq \frac{\mathbf{M}|\xi|}{x}$$

то

$$P(\xi \geq 75) \leq \frac{50}{75} = \frac{2}{3}$$

(b) При условии, что дисперсия числа посетителей в день равна 25, оценить вероятность того, что в конкретный день их число будет между 40 и 60.

Решается неравенством Чебышева:

$$P(|\xi - 50| \geq 10) \leq \frac{25}{100} = \frac{1}{4}$$

поэтому

$$P(|\xi - 50| < 10) = 1 - P(|\xi - 50| \geq 10) \geq \frac{3}{4}$$

(?? а если бы было между 50 и 60-ю?????)

Самарова-нЧ,збч.1

По известному «правилу трех сигм» вероятность отклонения случайной величины от своего математического ожидания более, чем на три корня из дисперсии, мала. Найти

$$P(|\xi - E\xi| < 3\sqrt{D\xi})$$

если ξ имеет:

1) нормальное распределение с параметрами a, σ ;

2) распределение Пуассона с $E\xi = 0,09$.

Сравнить результат с оценкой, полученной по неравенству Чебышева.

Solution 1.

$$E\xi = a, \quad D\xi = \sigma^2$$

$$p_\xi(x) = \frac{1}{\sigma\sqrt{2\pi}} \cdot e^{-\frac{(x-a)^2}{2\sigma^2}}$$

$$P(|\xi - E\xi| < 3\sqrt{D\xi}) = P(|\xi - a| < 3\sigma) = P(-3\sigma < \xi - a < 3\sigma) =$$

$$= P(a - 3\sigma < \xi < a + 3\sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{a-3\sigma}^{a+3\sigma} e^{-\frac{(x-a)^2}{2\sigma^2}} dx$$

$$y := \frac{x-a}{\sigma}, \quad dy = \frac{dx}{\sigma},$$

$$P(|\xi - E\xi| < 3\sqrt{D\xi}) = \frac{1}{\sqrt{2\pi}} \int_{-3}^3 e^{-\frac{y^2}{2}} dy = \frac{2}{\sqrt{2\pi}} \int_0^3 e^{-\frac{y^2}{2}} dy$$

Используем таблицу значений функции $\Phi_0(x) = \frac{1}{\sqrt{2\pi}} \int_0^x e^{-\frac{t^2}{2}} dt$,

$$P(|\xi - E\xi| < 3\sqrt{D\xi}) = 2\Phi_0(x) = 2 \cdot 0,4987 = 0,9974$$

А по неравенству Чебышева

$$P(|\xi - E\xi| \geq 3\sqrt{D\xi}) \leq \frac{D\xi}{9D\xi} = \frac{1}{9} \approx 0,1111 \quad \Rightarrow \quad P(|\xi - E\xi| < 3\sqrt{D\xi}) \geq 0,8889$$

Результат, полученный с помощью вероятностных таблиц, входит в область, полученную с помощью неравенства Чебышева.

Solution 2

Найдем параметр λ данного распределения. Числовые характеристики случайной величины, распределенной по закону Пуассона с параметром λ , равны

$$E\xi = \lambda, \quad D\xi = \lambda$$

Поэтому

$$\lambda = 0,09; \quad D\xi = E\xi = 0,09$$

Тогда

$$\begin{aligned} P(|\xi - E\xi| < 3\sqrt{D\xi}) &= P(|\xi - 0,09| < 0,9) = P(-0,9 + 0,09 < \xi < 0,9 + 0,09) = \\ &= P(-0,81 < \xi < 0,99) = P(\xi = 0) = e^{-0,09} = 0,9139 \end{aligned}$$

Здесь мы воспользовались формулой для вероятности, с которой случайная величина, распределенная по закону Пуассона, принимает заданное значение

$$P(\xi = k) = \frac{\lambda^k}{k!} e^{-\lambda} \quad (k = 0, 1, 2, 3, \dots)$$

Найдем оценку для требуемой вероятности по неравенству Чебышева:

$$P(|\xi - E\xi| \geq 3\sqrt{D\xi}) \leq \frac{D\xi}{9D\xi} = \frac{1}{9} \approx 0,1111 \quad \Rightarrow \quad P(|\xi - E\xi| < 3\sqrt{D\xi}) \geq 0,8889$$

Видим, что точное значение вероятности входит в интервал оценки, полученный с помощью неравенства Чебышева.

Стоит заметить, что в некоторых случаях улучшить неравенство Чебышева нельзя. Например, в задаче из задания 7 г) приведен пример случайной величины, для которой оценка, полученная по неравенству Чебышева, является точной.

Самарова-нЧ,збч.2

Для случайной величины ξ с распределением

$$P(\xi = 1) = P(\xi = -1) = \frac{1}{18}, \quad P(\xi = 0) = \frac{8}{9}$$

Найти

$$P(|\xi - E\xi| < 3\sqrt{D\xi})$$

и сравнить найденную вероятность с оценкой, полученной по неравенству Чебышева.

Solution

$$E\xi = 1 \cdot \frac{1}{18} + (-1) \cdot \frac{1}{18} + 0 \cdot \frac{8}{9} = 0$$

$$D\xi = E\xi^2 - (E\xi)^2 = E\xi^2 = 1 \cdot \frac{1}{18} + 1 \cdot \frac{1}{18} + 0 \cdot \frac{8}{9} = \frac{1}{9}$$

$$P(|\xi - E\xi| < 3\sqrt{D\xi}) = P(|\xi| < 1) = P(\xi = 0) = \frac{8}{9}$$

Заметим, что неравенство Чебышева в этом случае превращается в равенство

$$P(|\xi - E\xi| \geq 3\sqrt{D\xi}) \leq \frac{D\xi}{9D\xi} = \frac{1}{9} \quad \Rightarrow \quad P(|\xi - E\xi| < 3\sqrt{D\xi}) = 1 - \frac{1}{9} = \frac{8}{9}$$

МФТИ-Т.2 Вероятность нахождения числа выпадений герба в промежутке

С помощью неравенства Чебышева оценить вероятность того, что при 1000 бросаниях монеты число выпадений герба окажется в промежутке $[450, 550]$
Дисперсия в таком эксперименте

$$E(\xi^2) = E\left(\sum_i^n 1_{A_i}\right) + E\left(\sum_{i \neq j}^n\right) = 500 + (1000^2 - 100)/4 =$$

$$D(\xi) = E(\xi^2) - (E(\xi))^2 = 250$$

Неравенство Чебышева даст:

$$P(|\xi - 500| \geq 50) \leq \frac{250}{500}$$

$$P(|\xi - 500| < 50) = 1 - P(|\xi - 500| \geq 50) \geq 0.9$$

МФТИ-Т.3 Объем партии, при котором более всего качественных изделий (!?!?!?)

Вероятность того, что изделие качественное, равна 0,9. Каков должен быть объем партии изделий, чтобы с вероятностью $\geq 0,95$ можно было утверждать, что отклонение (по абсолютной величине) доли качественных изделий от 0,9 не превысит 0,01?

$$P(|\xi - 0,9| < 0,01) = 1 - P(|\xi - 0,9| \geq 0,01) \geq 0,95$$

$$P(|\xi - 0,9| \geq 0,01) \leq 0,05 = \frac{\sigma(\xi)^2}{10^{-4}}$$

но также $\sigma(\xi) = \sqrt{D(\xi)} = \frac{1}{n} \sqrt{n \cdot 0,9 \cdot 0,1} = \frac{0,3}{\sqrt{n}}$, поэтому:

$$0,05 = \frac{0,3^2}{n \cdot 10^{-4}} \rightarrow n = \frac{0,3^2}{0,05 \cdot 10^{-4}} = 18000$$

МФТИ-Т.4 Одностороннее неравенство Чебышева

Пусть случайная величина ξ имеет нулевое среднее и дисперсию σ^2 . Показать, что для $\varepsilon > 0$ выполняется неравенство

$$P(\xi \geq \varepsilon) \leq \frac{\sigma^2}{\sigma^2 + \varepsilon^2}$$

Очевидно, что для $b > 0$

$$P(\xi \geq \varepsilon) \leq P((\xi + b)^2 \geq (\varepsilon + b)^2) \leq \frac{\mathbb{E}((\xi + b)^2)}{(\varepsilon + b)^2} = \frac{\mathbb{E}(\xi^2 + 2\xi b + b^2)}{(\varepsilon + b)^2} = \frac{\mathbb{E}(\xi^2) + b^2}{(\varepsilon + b)^2}$$

Правая часть имеет минимум при $b = \frac{\sigma^2}{\varepsilon}$. Подставляя это значение, приходим к нужному неравенству.

МФТИ-Т5 Неравенство Йенсена

Пусть $\varphi : (a, b) \rightarrow \mathbb{R}$ - дважды непрерывно дифференцируемая функция и $\varphi''(x) \geq 0$ для всех $x \in (a, b)$ (т. е. φ Выпуклая функция, и допускается $a = -\infty$ и $b = \infty$). Допустим также, что ξ - случайная величина, которая принимает значения из (a, b) и $\mathbf{M}\xi = m$, $\mathbf{M}\varphi(\xi)$ конечны. Показать, что тогда

$$\mathbf{M}\varphi(\xi) \geq \varphi(\mathbf{M}\xi) = \varphi(m)$$

$$\varphi(x) \geq \varphi'(x_0)(x - x_0) + \varphi(x_0)$$

Пусть

$$\varphi(\xi) \geq \lambda(\mathbb{E}(\xi))(\xi - \mathbb{E}(\xi)) + \varphi(\mathbb{E}(\xi))$$

Берём матожидание от обеих частей.

$$\mathbb{E}(\varphi(\xi)) \geq \lambda(\mathbb{E}(\xi))(\mathbb{E}(\xi) - \mathbb{E}(\xi)) + \mathbb{E}(\varphi(\mathbb{E}(\xi))) = \varphi(\mathbb{E}(\xi))$$

МФТИ-Т6

Пусть ξ - случайная величина, имеющая нормальное распределение с параметрами (a, σ^2) . Показать, что для $\varepsilon > 0$ выполняется неравенство

$$\begin{aligned} \mathbf{P}(|\xi - a| \geq \varepsilon \sigma) &\leq \frac{1}{\varepsilon} \sqrt{\frac{2}{\pi}} e^{-\varepsilon^2/2} \\ P(|\xi| \geq \varepsilon \sigma) &= \left(\int_{\varepsilon \sigma}^{+\infty} + \int_{-\infty}^{-\varepsilon \sigma} \right) \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{x^2}{2\sigma^2}\right) d(x) = \int_{\varepsilon \sigma}^{+\infty} \frac{\sqrt{2}}{\sqrt{\pi}\sigma} \exp\left(-\frac{x^2}{2\sigma^2}\right) d(x) = \\ &= \sqrt{\frac{2}{\pi}} \int_{\varepsilon}^{+\infty} \exp\left(-\frac{x^2}{2}\right) d(x) \leq \sqrt{\frac{2}{\pi}} \frac{1}{\varepsilon} \exp\left(-\frac{\varepsilon^2}{2}\right) \end{aligned}$$

МФТИ-Т.7 еще неравенство (!?!?)

Пусть $\xi_1, \xi_2, \dots$ - последовательность одинаково распределенных случайных величин такая, что $\mathbf{M}\xi_k = a$, $\mathbf{D}\xi_k = \sigma^2$ и $\text{cov}(\xi_i, \xi_j) = (-1)^{i-j} \sigma^2$ $i \neq j$. Доказать, что для всякого $\varepsilon > 0$ выполняется предельное соотношение

$$\lim_{n \rightarrow \infty} \mathbf{P} \left(\left| \frac{1}{n} \sum_{k=1}^n \xi_k - a \right| \geq \varepsilon \right) = 0$$

МФТИ-Т.8 о чем-то схожим с Збч (???)

Пусть $\{\xi_n\}$ - последовательность неотрицательных случайных величин с конечными математическими ожиданиями и $\xi_n \xrightarrow{\text{п.н.}} \xi$, $\mathbf{M}\xi < \infty$, $\mathbf{M}\xi_n \rightarrow \mathbf{M}\xi$ при $n \rightarrow \infty$.

Покажите, что тогда $\mathbf{M}|\xi_n - \xi| \rightarrow 0$ при $n \rightarrow \infty$ т. е. $\xi_n \xrightarrow{L} \xi$
 $\forall n \in \mathbb{N}$:

$$|\mathbb{E}(\xi_n)| < +\infty, |\mathbb{E}(\xi)| < +\infty \rightarrow \mathbb{E}|\xi_n - \xi| < +\infty$$

$\forall \varepsilon > 0$:

$$\begin{aligned} \mathbb{E}|\xi_n - \xi| &= \mathbb{E}|(\xi_n - \xi) (I(\sup_{k \geq n} (|\xi_k - \xi| > \varepsilon)) + I(\sup_{k \geq n} (|\xi_k - \xi| \leq \varepsilon)))| = \\ &= \mathbb{E}|(\xi_n - \xi) I(\sup_{k \geq n} (|\xi_k - \xi| > \varepsilon))| + \mathbb{E}|(\xi_n - \xi) I(\sup_{k \geq n} (|\xi_k - \xi| \leq \varepsilon))| \end{aligned}$$

Первый индикатор в пределе принимает значение 1 только на множестве меры 0. Второй индикатор в пределе принимает значение 1 почти всюду. Но тогда под вторым математическим ожиданием стоит выражение $|\xi_k - \xi| \leq \varepsilon \rightarrow \mathbb{E}|\xi_k - \xi| \leq \mathbb{E}(\varepsilon) = \varepsilon$

6.4.2 Problems of Probability Distribution of Random Variables (!?!?)

(обязательно прорешаю скоро, просто пока не до этого. уже немного решал, в 1ю часть добавлю потом методы.)

Белан-ВШЭ-л1.1. (!?!?!?)

В диапазоне от 1 до N включительно равновероятным образом выбирается натуральное число. Оцените вероятность того, что это число окажется простым, если $\ln N \gg 1$.

$$\pi(N) \approx \int_2^N \frac{dk}{\ln k} \approx \frac{N}{\ln N}.$$

Solution

(?? тут какой-то гениальный метод, который я пока не понимаю.)

Белан-ВШЭ-л1.2. Первая цифра во времени жизни атома (!?)

Оцените вероятности различных значений, которые может принимать первая значащая цифра в десятичной записи случайного времени жизни радиоактивного атома неизвестного вещества.

Solution

Случайное времени жизни T радиоактивного атома вещества с рейтом распада λ имеет экспоненциальную функцию распределения $p(t) = \lambda \exp(-\lambda t)$. Обозначим первую значащую цифру случайной величины T через a_1 . От нас требуется вычислить вероятности $\Pr[a_1 = d|\lambda]$, где $d = 1, 2, \dots, 9$. Легко сообразить, что

$$\begin{aligned} \Pr[a_1 = d|\lambda] &= \sum_{n=-\infty}^{+\infty} \int_{10^n d}^{10^{n(d+1)}} p(t) dt = \lambda \sum_{n=-\infty}^{+\infty} \int_{10^n d}^{10^{n(d+1)}} \exp(-\lambda t) dt = \\ &= \sum_{n=-\infty}^{+\infty} [1 - \exp(-10^n \lambda)] \exp(-10^n d \lambda) \end{aligned}$$

Отметим, что полученное выражение строго инвариантно относительно замены $\lambda \rightarrow 10\lambda$. Этот факт с необходимостью следует из постановки задачи; ведь если используется именно десятичная запись числа, то умножение случайной величины на любую целочисленную степень десятки не изменит первую значащую цифру. Из Ур. (36) видно, что $\Pr[a_1 = d|\lambda] > \Pr[a_1 = d+1|\lambda]$, ведь $\exp(-10^n d \lambda) > \exp(-10^n (d+1) \lambda)$ для любого n . То есть, значение первой значащей цифры не равнораспределено, как можно было бы подумать. К сожалению, суммирование в формуле (36) невозможно произвести аналитическими методами. Однако, имеется возможность получить приближенный ответ, воспользовавшись подсказками численного анализа. А именно, построение графика выражения (36), рассматриваемого как функция от $\log_{10} \lambda$ показывает, что значение $\Pr[a_1 = d|\lambda]$ достаточно слабо зависит от этого параметра. Это означает, что искомое распределение первой значащей цифры в десятичной записи времени жизни атома практически не зависит от того, в секундах или в годах это время измеряется.

H.-A. Engel, C. Leuenberger / Statistics & Probability Letters 63 (2003) 361–365

Figure 6.3: На этом графике приняты следующие обозначения: $x = \log_{10} \lambda$, $h_d(x) = \Pr[a_1 = d|10^x]$

Так как функция $\Pr[a_1 = d|\lambda]$ периодична по переменной $x = \log_{10} \lambda$ с единичным периодом и слабо меняется, то для целей численной оценки она может быть заменена на амплитуду своей нулевой Фурье-гармоники. Иными словами, можно усреднить по периоду, записав

$$\begin{aligned} \Pr[a_1 = d|\lambda] &\approx \int_0^1 \Pr[a_1 = d|10^x] dx = \int_0^1 \sum_{n=-\infty}^{+\infty} [1 - \exp(-10^{n+x} \lambda)] \exp(-10^{n+x} d \lambda) dx + \text{37} \\ &= \int_{-\infty}^{+\infty} e^{-10^{x'}} d (1 - e^{-10^{x'}}) dx' = \frac{1}{\ln 10} \int_0^{+\infty} \frac{d\lambda}{\lambda} e^{-d\lambda} (1 - e^{-\lambda}) = \\ &= \frac{1}{\ln 10} \lim_{\varepsilon \rightarrow +0} \left[\int_0^{+\infty} d\lambda \lambda^{\varepsilon-1} e^{-d\lambda} - \int_0^{+\infty} d\lambda \lambda^{\varepsilon-1} e^{-(d+1)\lambda} \right] = \\ &= \frac{1}{\ln 10} \lim_{\varepsilon \rightarrow +0} \left[d^{-\varepsilon} \int_0^{+\infty} d\lambda' \lambda'^{\varepsilon-1} e^{-d\lambda'} - (d+1)^{-\varepsilon} \int_0^{+\infty} d\lambda' \lambda'^{\varepsilon-1} e^{-(d+1)\lambda'} \right] = \\ &= \frac{1}{\ln 10} \lim_{\varepsilon \rightarrow +0} [(d^{-\varepsilon} - (d+1)^{-\varepsilon}) \Gamma(\varepsilon)] = \frac{\ln \frac{d+1}{d}}{\ln 10} = \log_{10} \frac{d+1}{d} \end{aligned}$$

где

$$\Gamma(z) \equiv \int_0^{+\infty} t^{z-1} e^{-t} dt,$$

$$d^{-\varepsilon} - (d+1)^{-\varepsilon} = e^{-\varepsilon \ln d} - e^{-\varepsilon \ln(d+1)} \approx \varepsilon \ln \frac{d+1}{d},$$

$\Gamma(\varepsilon) \approx \int_0^{+\delta} t^{\varepsilon-1} dt = \frac{\delta^\varepsilon}{\varepsilon} \approx \frac{1}{\varepsilon}$ (Так как при $\varepsilon \rightarrow +0$ интеграл расходится в точке $t = 0$, то при малом ε можно сказать, что доминирующий вклад набирается в малой области $t \in (0, +\delta)$, где $\delta \ll 1$ и $\delta^\varepsilon \approx 1$)
Полученное распределение называется законом Бенфорда. Очевидно выполнение условия нормировки:
 $\sum_{d=1}^9 \Pr[a_1 = d] = \sum_{d=1}^9 \log_{10} \frac{d+1}{d} = 1.$

оставшиеся вопросы

как так мы численно считаем???? пропишу этот метод, что если период-я функция, то так вот делаем!!!!
это самое гениальное в задаче.

Белан-ВШЭ-л1.3. (!!!!!!)

Рассмотрим случайную величину, равномерно распределенную между 0 и 1. Какова вероятность того, что ровно две из пяти цифр после запятой в десятичной записи этой величины заняты цифрами меньше 6?
(решения нет, я пока хз.)

Solution

Белан-ВШЭ-л1.4. (!!!!!!)

Найдите $\langle \max(X_1, X_2) \rangle$, где X_1 и X_2 - две независимые реализации гауссовой случайной величины, с первым моментом μ и дисперсией σ .

Solution

(решения нет, я пока хз.)

Белан-ВШЭ-л1.5. (!!!!!!)

Найдите $\langle \min(|X|, 1) \rangle$, где X - случайная величина с функцией распределения $p(x) = \frac{1}{\pi} \frac{1}{1+x^2}$.

Solution

$$\begin{aligned} \langle \min(|X|, 1) \rangle &= \langle |X| \cdot I(|X| \leq 1) \rangle + \langle 1 \cdot I(|X| > 1) \rangle = \\ &= \int_{-1}^{+1} dx |x| p(x) + \int_{-\infty}^{-1} dx p(x) + \int_{+1}^{+\infty} dx p(x) = \frac{2}{\pi} \int_0^{+1} \frac{x dx}{1+x^2} + \frac{2}{\pi} \int_{+1}^{+\infty} \frac{dx}{1+x^2} = \\ &= \frac{1}{\pi} \ln(1+x^2) \Big|_0^1 + \frac{2}{\pi} \arctan x \Big|_1^{+\infty} = \frac{\ln 2}{\pi} + \frac{1}{2}. \end{aligned}$$

Белан-ВШЭ-л1.7. (!!!!!!)

Случайная величина X имеет монотонно возрастающую кумулятивную функцию распределения $F(x)$. Найдите функцию распределения случайной величины $Y = F(X)$.

Solution

Обозначим функцию плотности вероятности случайной величины X как $p(x)$. Так как кумулятивная функция распределения $F(x) = \int_0^x dx' p(x')$ является монотонно возрастающей, то функция распределения $\rho(y)$ случайной величины $Y = F(X)$ равна

$$\rho(y) = p(x(y)) \frac{dx(y)}{dy} = p(x) \left(\frac{dF(x)}{dx} \right)^{-1} |_{x=x(y)} = p(x(y)) \frac{1}{p(x(y))} = 1$$

для $0 \leq y \leq 1$

Белан-ВШЭ-л1.8. (?!?!?!?)

Выразите математическое ожидание и дисперсию случайной переменной $Z = aX + bY$, где X и Y - независимые случайные величины с известными первыми двумя статистическими моментами, a и b - некоторые вещественные константы.

Solution**Белан-ВШЭ-л1.9. (?!?!?!?)**

Неотрицательные случайные величины X_1 и X_2 независимы и одинаково распределены с плотностью вероятности $p(x) = a \exp(-ax)$. Найдите функцию плотности вероятности случайной величины $Y = X_1/X_2$.

Solution

Найдем кумулятивную функцию распределения случайной переменной $Y = X_1/X_2$

$$\begin{aligned} F(y) &= \Pr \left[\frac{X_1}{X_2} \leq Y \right] = \Pr [X_1 \leq Y X_2] = \int_0^{+\infty} dx_2 p(x_2) \int_0^{y x_2} dx_1 p(x_1) = \\ &= a^2 \int_0^{+\infty} dx_2 e^{-a x_2} \int_0^{y x_2} dx_1 e^{-a x_1} = a \int_0^{+\infty} dx_2 e^{-a x_2} (1 - e^{-a y x_2}) = \\ &= a \int_0^{+\infty} dx_2 (e^{-a x_2} - e^{-a(y+1)x_2}) = 1 - \frac{1}{y+1} \end{aligned}$$

Значит искомая функция плотности вероятности равна

$$\rho(y) = \frac{dF(y)}{dy} = \frac{1}{(y+1)^2}$$

ФР-2023. Распределение порядковых статистик.

Пусть $\xi_1, \dots, \xi_n$ - независимые случайные величины из одного и того же распределения. В предположении, что распределение каждой из ξ_k - абсолютно непрерывно с функцией распределения $F(x)$ и плотностью $p(x)$, найдите распределение k -той порядковой статистики $\xi_{(k)}$.

Solution**ФР-2023. Интеграл**

Используя результат предыдущей задачи (???), найти в зависимости от n интеграл

$$I(n) = \int_{[0,1]^n} f(x_1, \dots, x_n) d^n x,$$

где $f(x_1, \dots, x_n)$ равно второму по величине сверху из чисел $x_1, \dots, x_n$.

Solution**Показательность для случайной величины без старения (??)**

Докажите, что если X - непрерывная неотрицательная случайная величина, для которой отсутствует старение (т.е. для всех $t, s > 0$ $P(X > t + s | X > t) = P(X > s)$), то она показательно распределена.

(Олег решил, но я еще слишком тупой, чтобы понять решение, так что пропускаю, подрасту - вернусь к ней.)

Распределение $\frac{x}{X-Y}$ от показательных X и Y

Пусть X и Y - независимые случайные величины, показательно распределенные с параметром λ . Найдите распределение величины $\frac{X}{X-Y}$.

(переучу потом, тут разные новые для меня методы есть.)

Solution через интегрирование, грамотно определяя область

Как всегда, в силу независимости $P(XY) = P(X)P(Y)$ делим нужную вероятность на произведение двух:

$$P\left(X; Y = \left(1 - \frac{1}{k}\right)X\right) = P(X)P\left(Y = \left(1 - \frac{1}{k}\right)X\right) = \int_X \int_Y \lambda e^{-\lambda x} \cdot \lambda e^{-\lambda y} dx dy$$

Определим область интегрирования. Оно будет свое для каждого k , который мы повышаем от $-\infty$ до $+\infty$. Наше исходное множество - область $X > 0, Y > 0$, именно по некоторым подмножествам его будут наши интегралы. Прямая $Y = \left(1 - \frac{1}{k}\right)X$ разделяет его на подмножества, если её коэффициент более нуля: $\left(1 - \frac{1}{k}\right) \geq 0$. Это возможно только при $k < 0, k > 1$, именно эти случаи и будем рассматривать.

Пусть $k < 0$. Прямая $Y = \left(1 - \frac{1}{k}\right)X$ при $k < 0$ проходит выше прямой $Y = X$. Рассмотрим подмножество $X > Y$, исходное неравенство $\frac{X}{X-Y} \leq k$ дает область $Y \geq \left(1 - \frac{1}{k}\right)X$, которая не пересекается с подмножеством $X > Y$. Рассмотрим подмножество $X < Y$, исходное неравенство $\frac{X}{X-Y} \leq k$ дает область $Y \leq \left(1 - \frac{1}{k}\right)X$, таким образом, получаем область между прямыми $X = Y$ и $Y = \left(1 - \frac{1}{k}\right)X$:

Считаем:

```
Integrate[L^2 Exp[-L(y+x)], {x,0,Infinity},{y,x,(1-1/k)x}, Assumptions->{Im[L]
==0,L>0,k<0}]

Plot[1/(2 - 4 k), {k, -10, 0}, PlotRange -> {0, 1}]
```

Получаем:

Пусть $k > 1$. Прямая $Y = (1 - \frac{1}{k})X$ проходит ниже прямой $Y = X$. Рассмотрим подмножество $X > Y$, исходное неравенство $\frac{X}{X-Y} \leq k$ дает на нем область $Y \leq (1 - \frac{1}{k})X$, то есть это множество, заключенное между прямой $Y = (1 - \frac{1}{k})X$ и осью X . Рассмотрим подмножество $X < Y$, исходное неравенство $\frac{X}{X-Y} \leq k$ дает на нем область $Y \geq (1 - \frac{1}{k})X$, то есть это вся область $Y > X$. В итоге для $k > 1$ интегрируем по $Y > X$ и $0 < Y \leq (1 - \frac{1}{k})X$:

Считаем:

```
Integrate[L^2 Exp[-L(y+x)], {y,0,Infinity},{x,0,y}, Assumptions->{Im[L] == 0, L > 0}]
+
Integrate[L^2 Exp[-L(y+x)], {x,0,Infinity},{y,0,(1-1/k)x}, Assumptions->{Im[L]
==0,L>0,k>1}]
Plot[3/2 + k/(1 - 2 k), {k, 1, 10}, PlotRange -> {0, 1}]
```

Получаем:

Получаем, что область интегрирования красиво меняется при увеличении k от $-\infty$ до 0 из прямой $Y = X$ до треугольника между осью Y и прямой $Y = X$, а дальше при увеличении k от 1 до $+\infty$, область продолжает увеличиваться, только уже от оси X , и до заполнения всей четверть плоскости $X > 0, Y > 0$.

Ответ: функция распределения имеет вид: $F(k) = \frac{1}{2-4k}$ при $k < 0$, $F(k) = \frac{1}{2}$ при $k \in [0, 1]$, $F(k) = \frac{3}{2} + \frac{k}{1-2k}$ при $k > 1$.

В общем, здесь по типичным методам происходит переход к интегралу от двух функций, а далее самое сложное: четко преобразовать основное неравенство для определения множества интегрирования. Важно понимать, что для каждого k мы должны определить свою область интегрирования, чем мы и занимаемся, аккуратно решая неравенство. Важно тут быть очень внимательным и последовательным! Поэтому эта задача сложная. После определения области интегрирования, важно правильно подставить её границы в интеграл, для этого нужна подготовка по математическому анализу. Также важно решать через вольфрам, без этого может быть огромное количество ошибок.

(мб потом улучшу вольфрамский код, пока прога слабее нужного. как соединить графики в один?? как более компактно записать код?? потом улучшу скорее всего, пока суть итак прекрасно понятна.)
(??? напишу в теорию, что константой можно соединить эти отрезки)

Solution через переход к нужной функции распределения через последовательные шаги

(?!!!! вобщю эти шаблоны и идеи переходы по шагам в теорию. пока на этот метод забил, потому что итак метод есть рабочий.)

Сперва находим распределение Y/X , далее $1 - Y/X$, в итоге $1/(1-Y/X)$

Вот некачественная копия этих рассуждений:

$$\begin{aligned}
 &= \int_0^{+\infty} (1 - e^{-\lambda q t}) \cdot e^{-\lambda q} d(\lambda t) = \left(-e^{-\lambda q} + e^{-\lambda q(1+t)} \cdot \frac{1}{1+t} \right) \Big|_0^{+\infty} = \\
 &= 1 - \frac{1}{1+t} = \frac{t}{1+t}.
 \end{aligned}$$

$$\text{Uow, } F_{\frac{y}{x}}(t) = \begin{cases} 0, & t < 0, \\ \frac{t}{1+t}, & t \geq 0. \end{cases}$$

$$\text{Uak, } F_{\frac{y}{x}}(t) = \begin{cases} 0, & t < 0, \\ \frac{t}{1+t}, & t \geq 0. \end{cases} \text{ Cuyraidear becusuma } 1 - \frac{y}{x} \text{ pacmpegenera:}$$

$$\begin{aligned}
 F_{1-\frac{y}{x}}(t) &= P\left(1 - \frac{y}{x} < t\right) = P\left(\frac{y}{x} > 1 - t\right) = 1 - P\left(\frac{y}{x} \leq 1 - t\right) = \\
 &= 1 - F_{\frac{y}{x}}(1 - t) = \begin{cases} 1 - \frac{1-t}{2-t}, t \leq 1, \\ 1, t > 1 \end{cases} = \begin{cases} \frac{1}{2-t}, t \leq 1, \\ 1, t > 1. \end{cases}
 \end{aligned}$$

$$\frac{\frac{x}{x-y}}{\frac{x}{x-y}} = \frac{1}{1-\frac{y}{x}}. \quad \text{Ocranscs} \quad \text{nomers} \quad \text{coort.} \quad \text{vemgy} \quad \text{cuyracitsodx}$$

$$\begin{aligned}

 &= \begin{cases} F_q(0) - F_q\left(\frac{1}{t}\right), & t < 0, \\ F_q(0), & t = 0, \\ 1 + F_q(0) - F_q\left(\frac{1}{t}\right), & t > 0. \end{cases}
 \end{aligned}$$

$$\text{B ramese ayrae: } \eta = 1 - \frac{y}{x}. \text{ Uak,}$$

$$\begin{aligned}
 F_{\frac{x}{x-y}}(t) &= \begin{cases} \frac{1}{2} - \frac{1}{2-\frac{1}{t}}, t < 0, \\ \frac{1}{2}, t = 0, \\ 1 + \frac{1}{2} - 1, t \in (0; 1), \\ 1 + \frac{1}{2} - \frac{1}{2-\frac{1}{t}}, t \geq 1 \end{cases} = \begin{cases} \frac{1}{2(2t-1)}, t < 0, \\ \frac{1}{2}, t = 0, \\ \frac{1}{2}, t \in (0, 1), \\ \frac{4t-3}{4t-2}, t \geq 1 \end{cases} \\
 &= \begin{cases} -\frac{1}{4t-2}, t < 0, \\ \frac{1}{2} \in [0; 1], \\ 1 - \frac{1}{4t-2}, t > 1. \end{cases}
 \end{aligned}$$

Распределение $x/(x+y)$ от показательных и y (!!!!)

(!!! вобью в 1ю часть, мощные важные методы!!! очень важно отработать и вбить!!!)

Another way

Another way is to do it is to perform the following transformation. Let

$$\begin{aligned}
 U &= \frac{X}{X+Y} \\
 V &= X+Y
 \end{aligned}$$

Then

$$\begin{aligned}
 x(u, v) &= uv \\
 y(u, v) &= v - uv.
 \end{aligned}$$

The determinant of the Jacobian of the transformation is

$$\begin{vmatrix} v & u \\ -v & 1-u \end{vmatrix} = v$$

Then, the joint pdf of U and V is

$$f_{U,V}(u, v) = f_{X,Y}(uv, v - uv)|v| = ve^{-v}, \text{ for } v \geq 0, 0 \leq u \leq 1.$$

Finally, "integrate out" the v to obtain the marginal pdf of $U = X/(X+Y)$ as

$$f_U(u) = \int_0^{\infty} f_{U,V}(u, v) dv = \int_0^{\infty} ve^{-v} dv = 1, \quad \text{for } 0 \leq u \leq 1.$$

Hence, as Michael Hardy showed, $X/(X+Y)$ is uniformly distributed on $[0, 1]$.

1 method

Obviously $X/(X+Y)$ is between 0 and 1. Let (lower-case) w be a number between 0 and 1.

$$\frac{X}{X+Y} \leq w \text{ if and only if } (1-w)X \leq wY$$

We will find this probability. The conditional probability that $Y \geq \frac{(1-w)}{w}X$, given the value of X , is

$$e^{-(1-w)X/w}$$

The probability we seek is then the expected value of that:

$$\begin{aligned} Ee^{-(1-w)X/w} &= \int_0^\infty e^{-(1-w)x/w} (e^{-x} dx) \\ &= \int_0^\infty e^{-x/w} dx \\ &= w \end{aligned}$$

In other words, this random variable is uniformly distributed between 0 and 1.

Second method:

The equality $Y = \frac{1-w}{w}X$ is a straight line through the (X, Y) -plane, passing through $(0, 0)$ and having positive slope. We can let y go from 0 to ∞ and then for any fixed value of y , let x go from 0 to $\frac{wy}{1-w}$

$$\begin{aligned} &\int_0^\infty \left(\int_0^{wy/(1-w)} e^{-y} e^{-x} dx \right) dy \\ &= \int_0^\infty e^{-y} \left(1 - e^{-wy/(1-w)} \right) dy \\ &= \int_0^\infty e^{-y} - e^{-y/(1-w)} dy \\ &= 1 - (1-w) \\ &= w \end{aligned}$$

Распределение $2x/(1-x^2)$, при x по Коши

Пусть X - случайная величина, распределенная по Коши $(0, 1)$. Найдите распределение величины $2X/(1-X^2)$.

(Олег решил, но я еще слишком тупой, чтобы понять решение, так что пропускаю, подрасту - вернусь к ней.)

ВШЭ вероятность первой значащей цифры (!!!)

Задача 2 (7 баллов) Случайная величина X имеет функцию распределения

$$p(x) = \begin{cases} \frac{\alpha-1}{x^\alpha}, & \text{если } x \geq 1, \\ 0, & \text{если } x < 1. \end{cases}$$

где $\alpha > 1$. Найдите вероятности различных значений, которые может принимать первая цифра в десятичной записи величины X . На основе точного ответа отдельно исследуйте случаи $\alpha - 1 \ll 1$ и $\alpha \gg 1$.

$$P(d, a) = \sum_{n=0}^{+\infty} \int_{10^n d}^{10^{n+1} d} p(x) dx$$

(тут потом напишу, почему так, там выше задача похожая, тут очень важная её модификация)

$$P(d, \alpha) = \sum_{n=0}^{+\infty} (-x^{-\alpha+1})_{10^n d}^{107(\alpha+1)} = \sum_{n=0}^{\infty} 10^{n(1-\alpha)} (d^{-\alpha+1} - (d+1)^{-\alpha+1})$$

имеем геом прогрессию с $q = 10^{(1-\alpha)}$

$$p(d, \alpha) = \frac{d^{-\alpha+1} - (d+1)^{-\alpha+1}}{1 - 10^{1-\alpha}}$$

Далее один предел

$$\begin{aligned} 2-1) \text{ ирен } \alpha \gg 1 \\ d^{-\alpha} = d^{-\alpha} \gg (d+1)^{\alpha} \\ 1 > 10^{-\alpha} \\ 1 > 10^{-\alpha} \\ p(d, \alpha) \approx \frac{d^{-\alpha}}{1} = (d^{-\alpha}) \end{aligned}$$

второй предел

2.2)

$$\begin{aligned} P(d, \beta) &= \frac{d^{-\beta} - (d+1)^{-\beta}}{2 - 10^{-\beta}} = \frac{d^{-\beta} \left(1 - \left(\frac{d+1}{d}\right)^{-\beta}\right)}{1 - 10^{-\beta}} = \\ &= \frac{d^{-\beta}(-1) \left(\frac{d+1}{d}\right)^{-\beta} \log\left(\frac{d+1}{d}\right)}{(-1)10^{-\beta} \log 10} = \\ &= \left(\frac{d+1}{10}\right)^{-\beta} \frac{\log\left(\frac{d+1}{d}\right)}{\log 10} \approx \frac{\log \frac{d+1}{d}}{\log 10} = \\ &= \log_{10} \frac{d+1}{d}. \end{aligned}$$

Оставшиеся вопросы (!!!!!)

(почему вольфрам криво считает интеграл???? вообще просто хз, когда-то пороюсь, пока не знаю.)

```
In[92]:= Integrate[(a - 1)/x^a, {x, 10^n d, 10^n (d + 1)},
Assumptions -> {a > 1, d > 0, 10^n >= 0}]

Out[92]
= 10^n (100^n d (1 + d))^-a (- (10^n d)^a (1 + d) +
d (10^n (1 + d))^a)
```

и вот дальше вообще херня пойдет, если эту формулу использовать.

(!!!! впишу, что именно так мы и ищем предельные случаи!!! именно такая гениальная идея находить первую значащую цифру!!! часа 6 ушло на эту задачу, важно прописать этим методы потом!!! просто по сути нужно аккуратно проделать очевидные математические преобразования!!!!!! поэтому эта задача и жесткая!!!)

(!! пропишу методы аппроксимации, что так вот по лопиталю нужно аккуратно брать производные!!! что они через логарифм берутся знать важно. потом когда-то дооформилю.)

ВШЭ вероятность первой значащей цифры в периоде радиоактивного распада

Solution

Основные ходы, которые в 1ю часть добавлю потом!!!

(пока просто слабоватая структура.)

Магистратура Мфти 2019.7.

Случайные величины X и Y независимы. Случайная величина X имеет плотность распределения

$$\rho_X(t) = \begin{cases} e^t, & t < 0 \\ 0, & t \geq 0 \end{cases}$$

Случайная величина Y имеет плотность распределения

$$\rho_Y(t) = \begin{cases} 0, & t < 0, \\ e^{-t}, & t \geq 0. \end{cases}$$

- а) Найти функцию распределения случайной величины $Z = X + Y$.
 б) Вычислить математическое ожидание случайной величины Z .
 в) Вычислить дисперсию случайной величины Z .

Ответ: а) $P(Z < t) = \begin{cases} 1 - \frac{\exp(-t)}{2}, & t > 0, \\ \frac{\exp(t)}{2}, & t \leq 0, \end{cases}$ $\rho_Z(t) = \frac{\exp(-|t|)}{2}$, б) $MZ = 0$, в) $DZ = 2$.

Для любого $t \in \mathbb{R}$ имеем

$$\begin{aligned} P(Z < t) &= \iint_{\substack{\xi + \eta < t \\ \xi < 0, \eta > 0}} e^{\xi - \eta} d\xi d\eta = \int_{-\infty}^{\min\{t, 0\}} e^{\xi} d\xi \int_0^{t-\xi} e^{-\eta} d\eta = \int_{-\infty}^{\min\{t, 0\}} e^{\xi} (1 - e^{\xi-t}) d\xi = \\ &= \exp(\min\{t, 0\}) - \frac{\exp(2 \min\{t, 0\} - t)}{2} = \begin{cases} 1 - \frac{\exp(-t)}{2}, & t > 0, \\ \frac{\exp(t)}{2}, & t \leq 0, \end{cases} \end{aligned}$$

Следовательно, плотность распределения случайной величины Z равна $\rho_Z(t) = \frac{\exp(-|t|)}{2}$.

$$MZ = \int_{-\infty}^{+\infty} t \rho_Z(t) dt = \int_{-\infty}^{+\infty} \frac{t \exp(-|t|)}{2} dt = 0,$$

$$DZ = MZ^2 - (MZ)^2 = \int_{-\infty}^{+\infty} t^2 \rho_Z(t) dt = \int_{-\infty}^{+\infty} \frac{t^2 \exp(-|t|)}{2} dt = \int_0^{+\infty} t^2 \exp(-t) dt = 2.$$

Ч-3.пр.1 Распределение координат точки в квадрате

Пусть точка $A = (u, v)$ равномерно распределена в квадрате $\Omega = \{(u, v) : 0 \leq u \leq 1, 0 \leq v \leq 1\}$. Положим $\xi_1 = \xi_1(u, v) = u$,

$$\xi_2 = \xi_2(u, v) = \begin{cases} 1 & \text{при } u \geq v, \\ -1 & \text{при } u < v. \end{cases}$$

Найти:

- а) функцию распределения и плотность распределения вероятностей случайной величины ξ_1 ;
 б) функцию распределения и вероятности значений дискретной величины ξ_2 .

Событие $\{\xi_1 \leq x\} = \{(u, v) : u \leq x, (u, v) \in \Omega\}$ при $x > 1$ совпадает с Ω , а при $x < 0$ — с $\emptyset$. При $0 < x < 1$ множество точек, определяющих событие $\{\xi_1 \leq x\}$, образует прямоугольник со сторонами 1 и x .

Таким образом,

$$F_{\xi_1}(x) = P\{\xi_1 \leq x\} = \begin{cases} 0 & \text{при } x \leq 0, \\ x & \text{при } 0 < x < 1, \\ 1 & \text{при } x \geq 1. \end{cases}$$

Производная $F'_{\xi_1}(x)$ в ее точках непрерывности совпадает с плотностью распределения:

$$p_{\xi_1}(x) = \begin{cases} 0 & \text{при } x \notin [0, 1], \\ 1 & \text{при } x \in [0, 1]. \end{cases}$$

Функция распределения ξ_2 находится аналогично. Если $x \geq 1$, то $\{\xi_2 \leq x\} = \Omega$; $\{\xi_1 \leq x\} = \emptyset$ при $x < -1$, а при $-1 \leq x < 1$

$$\{\xi_2 \leq x\} = \{(u, v) : u < v, (u, v) \in \Omega\}.$$

Значит,

$$F_{\xi_2}(x) = P(\xi_2 \leq x) = \begin{cases} 0 & \text{при } x < -1, \\ 1/2 & \text{при } -1 \leq x < 1, \\ 1 & \text{при } x \geq 1. \end{cases}$$

Случайная величина ξ_2 дискретна; ее распределение сосредоточено в двух точках: -1 и 1 . Действительно,

$$P\{\xi_2 = 1\} = P\{(u, v) : u > v, (u, v) \in \Omega\} = 1/2,$$

$$P\{\xi_2 = -1\} = P\{(u, v) : u < v, (u, v) \in \Omega\} = 1/2.$$

Ч-3.пр.2 Функция от точки в квадрате

Найти распределение величины $\eta = \xi_1^2$, где случайная величина ξ_1 та же, что в примере п3.1.

Функция распределения η при $0 \leq x \leq 1$ определяется следующей формулой: $F_\eta(x) = P\{\eta \leq x\} = P\{\xi_1^2 \leq x\} = P\{-\sqrt{x} \leq \xi_1 \leq \sqrt{x}\} =$

$$\Rightarrow F_{\xi_1}(\sqrt{x}) - F_{\xi_1}(-\sqrt{x}) = \sqrt{x}.$$

Очевидно, что $F_\eta(x) = 0$ при $x \leq 0$ и $F_\eta(x) = 1$ при $x > 1$. При $0 < x < 1$

$$p_\eta(x) = F'_{\xi_1}\left(\sqrt{x}\right) = \frac{1}{2\sqrt{x}};$$

$p_\eta(x) = 0$ при $x < 0$ и при $x > 1$. Таким образом, величина η абсолютно непрерывна и ее плотность распределения определяется формулой

$$p_\eta(x) = 1/(2\sqrt{x}) \quad \text{при} \quad x \in (0, 1), \\ p_\eta(x) = 0 \quad \text{при} \quad x \notin (0, 1).$$

Ч-3.пр.7

Для случайной величины η , определенной в примере 3.2, найти $M\eta$ и $D\eta$.

Если плотность распределения известна, то для вычисления $M\eta$ удобно воспользоваться формулой

$$D\eta = \int_{-\infty}^{\infty} (x - M\eta)^2 p_\eta(x) dx$$

которая является частным случаем (3.9) с $g(x) \Rightarrow (x - M\eta)^2$. Подставляя в эти формулы плотность распределения $p_\eta(x)$, вычисленную в примере 3.2, получим

$$M_\eta = \int_0^1 x \frac{1}{2\sqrt{x}} dx = \frac{1}{3}, \quad D_\eta = \int_0^1 \left(x - \frac{1}{3}\right)^2 \frac{1}{2\sqrt{x}} dx = \frac{4}{45}.$$

Можно было также воспользоваться формулами (3.9) при $g(x) = x^2$, $g(x) = (x - M\eta)^2$ с заменой $p_4(x)$ на плотность $p_{\xi_1^2}(x)$, определенную в примере 3.1:

$$M_\eta = M_{\xi_1^2}^2 - \int_{-\infty}^{\infty} x^2 p_{\xi_1}(x) dx = \int_0^1 x^2 dx = \frac{1}{3} \\ = \int_0^1 \left(x - \frac{1}{3}\right)^2 dx = \frac{4}{45}.$$

Ч-3.пр.3

Случайная величина ξ имеет плотность распределения $p_\xi(x) = e^{-x}$ ($x > 0$), $p_\xi(x) = 0$ ($x \leq 0$). Найти распределение случайной величины $\eta = \eta(\xi) = [\xi]^2$, где $[\xi]$ обозначает целую часть ξ .

Решение. Так как $\{\eta = k^2\} = \{k \leq \xi < k+1\}$, то вероятность $P\{\eta = k^2\}$ определяется равенствами $P\{\eta = k^2\} = P\{k \leq \xi < k+1\} =$

$$= \int_k^{k+1} p_\xi(x) dx = \int_k^{k+1} e^{-x} dx = e^{-k} (1 - e^{-1}), k = 0, 1, 2, \dots$$

Ч-3.пр.4

Случайная величина ξ_1 принимает значения 0 и 1, а случайная величина ξ_2 - значения -1, 0 и 1. Вероятности $P\{\xi_1 = i, \xi_2 = j\}$ задаются таблицей:

$i \backslash j$	-1	0	1
0	1/16	1/4	1/16
1	1/16	1/4	5/16

Найти распределение случайной величины $\eta = \xi_1 \xi_2$

Произведение $\xi_1 \xi_2$ равно нулю, если равен нулю хотя бы один из сомножителей:

$$\{\eta = 0\} = \{\xi_1 = 0, \xi_2 = -1\} \cup \{\xi_1 = \xi_2 = 0\} \cup \{\xi_1 = 0, \xi_2 = 1\} \cup \{\xi_1 = 1, \xi_2 = 0\},$$

поэтому суммируем нужные ячейки:

$$P\{\eta = 0\} = \frac{1}{16} + \frac{1}{4} + \frac{1}{16} + \frac{1}{4} = \frac{5}{8}.$$

Оставшиеся два значения (1, -1) и (1, 1) пары величин (ξ_1, ξ_2) приводят к двум значениям η : -1 и 1. Следовательно,

$$P\{\eta = -1\} = 1/16, \quad P\{\eta = 1\} = 5/16.$$

Таким образом, величина η дискретна; ее распределение сосредоточено на значениях -1, 0, 1, и вероятности этих значений равны соответственно 1/16, 5/8, 5/16.

Ч-3.пр.5

Случайные величины ξ_1 и ξ_2 независимы; их плотности распределения определяются формулами

$$p_{\xi_1}(x) = \begin{cases} 1 & \text{при } x \in [0, 1], \\ 0 & \text{при } x \notin [0, 1], \end{cases} \quad p_{\xi_2}(x) = \begin{cases} \frac{1}{2} & \text{при } x \in [0, 2], \\ 0 & \text{при } x \notin [0, 2]. \end{cases}$$

Найти функцию распределения и плотность распределения величины $\eta = \xi_1 \xi_2$.

Так как величины ξ_1 и ξ_2 независимы, то двумерная плотность распределения вектора (ξ_1, ξ_2) есть $p_1 \xi_2(u, v) = p_{\xi_1}(u) p_{\xi_2}(v)$. Найдем сначала функцию распределения η :

$$F_n(x) = P\{\eta \leq x\} = P\{\xi_1 \xi_2 \leq x\} = \iint_{D_x} p_{\xi_1}(u) p_{\xi_2}(v) du dv,$$

где $D_x = \{(u, v) : uv \leq x\}$. Отсюда

$$F_n(x) = \frac{1}{2} \iint_{D_x^*} du dv$$

где $D_x^* = D_x \cap \{(u, v) : 0 \leq u \leq 1, 0 \leq v \leq 2\}$.

Эта область в свою очередь $D_x^* \emptyset$ при $x < 0$ и $D_x^* = \{(u, v) : 0 \leq u \leq 1, 0 \leq v \leq 2\}$ при $x \geq 2$; следовательно,

$$P\{\eta \leq x\} = 0 \quad (x \leq 0), \quad P\{\eta \leq x\} = 1 \quad (x \geq 2).$$

При $0 < x < 2$

$$\iint_{D_x^*} dudv = 2 \cdot \frac{x}{2} + \int_{x/2}^1 \frac{x}{u} du = x - x \ln \frac{x}{2}.$$

Таким образом,

$$F_n(x) = \begin{cases} 0 & \text{при } x \leq 0. \\ \frac{x}{2} \left(1 - \ln \frac{x}{2}\right) & \text{при } 0 < x < 2 \\ 1 & \text{при } x \geq 2. \end{cases}$$

56 Отсюда находим плотность распределения

$$p_n(x) = \begin{cases} 0 & \text{при } x \notin (0, 2], \\ -\frac{1}{2} \ln \frac{x}{2} & \text{при } x \in (0, 2]. \end{cases}$$

Ч-3.пр.6.

Найти плотность распределения величины $\eta = \xi_1 + \xi_2$, где ξ_1, ξ_2 независимы и каждая из них равномерно распределена на отрезке $[0, 1]$.

По формуле (3.4)

$$p_\eta(x) = \int_{-\infty}^{\infty} p_{\xi_1}(y) p_{\xi_2}(x-y) dy = \int_0^1 p_{\xi_2}(x-y) dy.$$

Подынтегральная функция $p_{\xi_2}(x-y)$ положительна и равна 1, если $0 \leq x-y \leq 1$. Отрезок интегрирования $[0, 1]$ отрезок $[x-1, x]$ значений y , при которых $p_{\xi_2}(x-y) > 0$, не пересекаются, если $x < 0$ или $x > 2$. В этих слу-

$$p_n(x) = \int_0^x dy = x.$$

Если $1 \leq x \leq 2$, то $[0, 1] \cap [x-1, x] = [x-1, 1]$ и

$$p_n(x) = \int_{x-1}^1 dy = 2 - x.$$

Таким образом,

$$p_\eta(x) = \begin{cases} 0, & \text{если } x < 0 \text{ или } x > 2, \\ x, & \text{если } 0 \leq x \leq 1 \\ 2 - x, & \text{если } 1 \leq x \leq 2. \end{cases}$$

Ч-3.пр.8 (!?!?!?!?) про Бернулли

Пусть η_n - число переходов от успеха к неудаче или обратно в n испытаниях схемы Бернулли, в которой вероятность успеха в отдельном испытании равна p . Найти M_{η_n} и D_{η_n} .

Решение. Представим η_n в виде суммы индикаторов

$$\eta_n = \xi_1 + \xi_2 + \dots + \xi_{n-1},$$

где $\xi_i = 1$, если исходами i -го и $(i+1)$ -го испытаний были соответственно "успех" и "неудача" или "неудача" в «успех». В противном случае $\xi_i = 0$. Тогда

$$M\xi_1 = P\{\xi_i = 1\} = p(1-p) + (1-p)p = 2p(1-p)$$

и, следовательно,

$$M\eta_n = M\xi_1 + \dots + M\xi_{n-1} = 2(n-1)p(1-p).$$

Найдем теперь η_n^2 . Так как

$$\eta_n^2 = \sum_{i=1}^{n-1} \xi_i^2 + \sum_{\substack{i,j=1 \\ i \neq j}}^{n-1} \xi_i \xi_j = \sum_{i=1}^{n-1} \xi_i + 2 \sum_{i=1}^{n-2} \xi_i \xi_{i+1} + \sum_{\substack{i,j=1 \\ |i-j| \geq 2}}^{n-1} \xi_i \xi_j$$

и

$$M\xi_i\xi_{i+1} = p(1-p)p + (1-p)p(1-p) = p(1-p)_3$$

$$M_{\xi_i\xi_j} = M\xi_i M\xi_j = 4p^2(1-p)^2 \quad (|i-j| \geq 2)_s$$

То

$$M\eta_n^2 = 2p(1-p)(n-1) + 2(n-2)p(1-p) + 4p^2(1-p)^2(n^2 - 5n + 6).$$

Отсюда, воспользуя обозначение $q = 1 - p$, получаем

$$D_{\eta_{1n}} = M\eta_n^2 - (M\eta_n)^2 = 4pq(1-3pq)n - 2pq(3-10pq).$$

В задачах п3.1-п3.15 рассматриваются одномерные рас пределения; в п3.16-п3.38 - законы совместного распреде тения нескольких случайных величин; в **3.49–3.53** - случайные величины, связанные с последовательностям пслытаний.

Ч-3.1

Распределение дискретной случайной величинн & опрделается формулами

$$P\{\xi = i\} = \frac{1}{5}, \quad t = -2_s - 1_i 0_s 2.$$

Найти распределения величин $\eta_1 = -\xi, \eta_2 = |\xi|$.**Ч-3.2**

Распределение случайной пеличины ξ определя ется формулами $P\{\xi = k\} = C/k(k+1), k = 1, 2, \dots$
Найти: а) постоянную C ; б) $P\{\xi \leq 3\}$; в) $P\{n_1 \leq \xi \leq n_2\}$.

Ч-3.3

. Распределение дискретной случайной величины ξ определяется формулами: $P\{\xi = k\} = C/k(k+1)(k+2), k = 1, 2, \dots$
Найти: а) постоянную C ; б) $P\{\xi \geq 3\}$;
в) $P\{n_1 \leq \xi \leq n_2\}$.

Ч-3.4Плотность распределения случайной величины ξ задана формулами:

$$p_2(x) = C/x^4 \quad \text{при } x \geq 1;$$

$$p_2(x) = 0 \quad \text{при } x < 1.$$

Найти: а) постоянную C ; б) плотность распределения $\eta = 1/\xi$; в) $P\{0, 1 < \eta < 0, 3\}$.**Ч-3.5**

Случайная величина ξ имеет показательное распределение с параметром $\alpha : P\{\xi \leq x\} = 1 - e^{-\alpha x} (x \geq 0)$.
Найти плотности распределения случайных величин:

- а) $\eta_1 = \sqrt{\xi}$
- б) $\eta_2 = \xi^2$;
- в) $\eta_3 = \frac{1}{\alpha} \ln \xi$.

Ч-3.6

Случайная величина & распределена так же, как в задаче п3.5. Найти плотности распределения величин:

- а) $\eta_1 = \{\xi\}(\{\xi\} - \text{дробная доля } \xi)$; б) $\eta_2 = 1 - e^{-\alpha \xi}$.

Ч-3.7

Случайная величина ξ равномерно распределена на отрезке $[0, 1]$. Найти плотности распределения величин: а) $\eta_1 = 2\xi + 1$; б) $\eta_2 = -\ln(1 - \xi)$.

Ч-3.8

Случайная точка B имеет равномерное распределение на окружности $x^2 + (y - a)^2 = r^2$ с центром в точке $A = (0, a)$, а случайная точка $C = (\xi, 0)$ является пересечением оси абсцисс с прямой, проходящей через A и B . Найти функцию распределения и плотность распределения случайной величины ξ . (Распределение ξ называется распределением Коши.)

Ч-3.9

Случайная величина ξ имеет распределение Коши с плотностью $p_\xi(x) = \frac{1}{\pi} \cdot \frac{1}{1+x^2}$. Найти плотность распределения величин $\eta = \xi^2 / (1 + \xi^2)$, $\xi = 1 / (1 + \xi^2)$.

Ч-3.10

Случайная величина ξ имеет такое же распределение, как в задаче п3.9. Найти плотность распределения случайных величин $\eta = 2\xi / (1 - \xi^2)$, $\zeta = 1/\xi$.

Ч-3.11

Пусть $h(x)$ - плотность распределения случайной величины ξ ; функция $g(x)$ дифференцируема и на интервале $(0, 1)$ монотонно возрастает от $-\infty$ до $+\infty$. Найти: а) такую функцию (x) , что случайная величина $\eta = \varphi(\xi)$ имеет своей плотностью распределения $f(x) = h(g(x))g'(x)$; б) распределение случайной величины $\zeta = g(\eta)$.

Ч-3.12

Случайная величина ξ имеет непрерывную функцию распределения $F(x) = P\{\xi \leq x\}$. Показать, что случайная величина $\eta = F(\xi)$ имеет равномерное распределение на отрезке $[0, 1]$.

Ч-3.13

Пусть η имеет равномерное распределение на $[0, 1]$, а

$$F_{-1}(y) = \sup\{x : F(x) \leq y\}, \quad 0 \leq y \leq 1,$$

- Функция, обратная к функции распределения $F(x)$ (не обязательно непрерывной!). Доказать, что случайная величина $\xi = F_{-1}(\eta)$ имеет функцию распределения $F(x)$.

Ч-3.14

Построить пример такого абсолютно непрерывного распределения случайной величины ξ с плотностью $p_\xi(x)$ и такой непрерывной функции $g(x)$, что распределение случайной величины $\eta = g(\xi)$ не вырождено и дискретно.

Ч-3.15

Функция распределения $F(x)$ непрерывна в каждой точке. Доказать, что она равномерно непрерывна на всей прямой $-\infty < x < \infty$.

Ч-3.17

Случайные величины ξ и η независимы. Найти $P\{\xi = \eta\}$, если: а) ξ и η имеют одно и то же дискретное распределение $P\{\xi = x_k\} = P\{\eta = x_k\} = p_k$, $k = 0, 1, \dots$; б) функция распределения непрерывна.

Ч-3.18

Совместное распределение ξ, η является равномерным в единичном круге $x^2 + y^2 \leq 1$. Найти $P\{|\xi| \leq 3/4, |\eta| \leq 3/4\}$.

Ч-3.19

Плотность совместного распределения величин ξ, η определяется равенствами: $p_{\xi, \eta}(u, v) = 1$ при $(u, v) \in G$, $p_{\xi, \eta}(u, v) = 0$ при $(u, v) \notin G$, где $G = \{(u, v) : 0 \leq u \leq 2, 0 \leq v < 1 - \frac{1}{2}u\}$. Найти плотность распределения $p_\xi(x)$ случайной величины ξ .

Ч-3.20

Плотность совместного распределения $p_{\xi_1, \xi_2}(u, v)$ величин ξ_1, ξ_2 определяется равенствами $p_{\xi_1, \xi_2}(u, v) = -C(u+v)$ при $0 \leq u \leq 1, 0 \leq v \leq 1$ и $p_{\xi_1, \xi_2}(u, v) = 0$, в остальных случаях.

Найти: а) постоянную C ;

б) одномерные плотности распределения ξ_1 и ξ_2 ;

в) плотность распределения $\eta = \max(\xi_1, \xi_2)$.

Ч-3.21

Плотность совместного распределения величин ξ_1, ξ_2 определяется равенствами: $p_{\xi_1, \xi_2}(u, v) = \frac{2}{\pi(u^2+v^2)^3}$ при $u^2 + v^2 \geq 1$ и $p_{\xi_1, \xi_2}(u, v) = 0$ в остальных случаях. Найти плотность распределения $\eta = \sqrt{\xi_1^2 + \xi_2^2}$.

Ч-3.23

Неотрицательные случайные величины ξ_1, ξ_2 независимы и имеют одну и ту же плотность распределения $p(x), x \geq 0$. Найти плотность $q(u, v)$ совместного распределения случайных величин $\eta_1 = \xi_1 - \xi_2, \eta_2 = \sqrt{\xi_1^2 + \xi_2^2}$.

Ч-3.24

Случайные величины ξ_1, ξ_2 независимы и имеют одну и ту же плотность распределения $p(x)$. Найти совместную плотность распределения $q(r, \varphi)$ полярных координат (r, φ) точки (ξ_1, ξ_2) .

Ч-3.25

Случайные величины ξ_1 и ξ_2 независимы и имеют одно и то же показательное распределение: $P\{\xi_i \leq x\} = 1 - e^{-x}, x \geq 0; i = 1, 2$. Найти $P\{|\xi_1 - \xi_2| \leq 1\}$.

Ч-3.26

Случайные величины ξ и η независимы и имеют равномерное распределение на отрезке $[0, a]$. Найти плотности распределения случайных величин: а) $\xi + \eta$; б) $\xi - \eta$; в) $\xi\eta$; г) ξ/η . 69

Ч-3.27

Случайные величины ξ и η независимы и имеют показательное распределение с плотностью $e^{-x} (x \geq 0)$ каждая. Найти плотность распределения: а) $\xi + \eta$; б) $\xi - \eta$; в) $\xi\xi - \eta$; г) ξ/η .

Ч-3.28

Найти плотность распределения суммы $\xi + \eta$, если ξ и η независимы, ξ имеет равномерное распределение в отрезке $[0, 1]$, а η - равномерное распределение в отрезке $[0, 2]$.

Ч-3.29

Найти плотность распределения суммы независимых случайных величин. ξ и η , если ξ равномерно распределена в $[0, 1]$, а η имеет показательное распределение с плотностью $e^{-x} (x \geq 0)$.

Ч-3.30

Случайные величины ξ_1, ξ_2, ξ_3 независимы и имеют равномерное распределение в $[0, 1]$.

Найти плотности распределения сумм: а) $\xi_1 + \xi_2$

б) $\xi_1 + \xi_2 + \xi_3$. Найти $P\{0,5 \leq \xi_1 + \xi_2 + \xi_3 \leq 2,5\}$.

Ч-3.31

Точка (ξ_1, ξ_2) имеет равномерное распределение в квадрате $\{(x, y) : 0 \leq x \leq a, 0 \leq y \leq a\}$. Показать, что распределения случайных величин $|\xi_1 - \xi_2|$ и $\min\{\xi_1, \xi_2\}$ совпадают, т. е. что для любого t

$$P\{|\xi_1 - \xi_2| \leq t\} = P\{\min\{\xi_1, \xi_2\} \leq t\}.$$

Ч-3.32

Найти распределение суммы двух независимых слагаемых ξ_1 и ξ_2 , если слагаемые распределены:

- а) показательно с одним и тем же параметром a ;
 б) по закону Пуассона с параметрами λ_1 и λ_2 .

Ч-3.33

Случайные величины $\xi_1, \dots, \xi_n$ независимы и распределены показательно с одинаковым параметром α .

Найти плотность распределения величин:

- а) $\eta_1 = \max \{\xi_1, \dots, \xi_n\}$ б) $\eta_2 = \min \{\xi_1, \dots, \xi_n\}$.

Ч-3.34

Случайные величины ξ и ξ_2 независимы и имеют гамма-распределения: ξ_1 — с параметрами (λ, α) , ξ_2 — с параметрами (λ, β) . Пользуясь формулой

$$\int_0^1 t^{\alpha-1} (1-t)^{\beta-1} dt = \frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}.$$

найти плотность распределения случайной величины $\xi_1 + \xi_2$.

Ч-3.37

Найти плотность распределения случайной величины $\eta = \frac{\xi_1}{\xi_1 + \xi_2}$, если ξ_1, ξ_2 независимы и равномерно распределены в отрезке $[0, 1]$.

Ч-3.38

Случайные величины $\xi_1, \xi_2, \dots, \xi_n, n \geq 2$, независимы и имеют показательное распределение с плотностью $e^{-x} (x \geq 0)$. Обозначим $\eta = \frac{\xi_1}{\xi_1 + \dots + \xi_n}$. Найти плотность распределения η .

Ч-3.39

Величины ξ_1, ξ_2 независимы; $P\{\xi_1 = 0\} = P\{\xi_1 \Rightarrow 1\} = 1/2$, ξ_2 равномерно распределена на отрезке $[0, 1]$. Найти закон распределения величины $\xi_1 + \xi_2$.

Ч-3.40

Пусть случайные величины ξ и η независимы, ξ имеет функцию распределения $F(x)$, а η равномерно распределена в интервале $[a, b]$. Показать, что $\xi + \eta$ имеет плотность $\frac{F(x-a) - F(x-b)}{b-a}$.

Ч-3.41

Сумму двух независимых равномерно распределенных на $\{0, 1, \dots, 9\}$ случайных однозначных чисел ξ и η можно записать в виде $\xi + \eta = 10\xi_2 + \zeta_1$ ($0 \leq \zeta_i \leq 9$). Найти законы распределения. Зависимы ли ξ_1 и ξ_2 ?

Ч-3.42

Произведение двух независимых равномерно распределенных на $\{0, 1, \dots, 9\}$ однозначных чисел ξ и η можно записать в виде $\xi\eta = 10\xi_2 + \zeta_1$, где ζ_1, ζ_2 — целые числа, принимающие значения от 0 до 9. Зависимы ли ξ_1 и ξ_2 ?

Ч-3.43

Случайная точка $A = (\xi_1, \xi_2, \xi_3) \in R^3$ имеет равномерное распределение на сфере $x^2 + y^2 + z^2 = 1$. Найти распределение проекции (ξ_1, ξ_2) точки A на плоскость (x, y) и проекции ξ точки A на ось x .

Ч-3.44

Ввести на сфере в качестве координат широту и долготу, считая их изменяющимися в отрезках $[-\pi/2, \pi/2]$ и $[-\pi, \pi]$ соответственно. Найти плотность $p_\theta(x)$ распределения широты ξ случайной точки, имеющей равномерное распределение на сфере.

Ч-3.47

В переговорном пункте телефоны-автоматы расположены в t залах: в i -м зале n_i автоматов ($t = 1, 2, 3; n = n_1 + n_2 + n_3$). После перерыва посетители одновременно заняли все автоматы. Введем события $A_i = \{\text{посетитель, закончивший разговор первым, находился в } i\text{-м зале}\}, i = 1, 2, 3$. Найти вероятности событий $A_i, i = 1, 2, 3$, если времена разговора посетителей являются независимыми одинаково распределенными случайными величинами с непрерывной функцией распределения.

Ч-3.48

Случайная величина ξ с равномерным распределением на $[0, 1]$ записывается в виде бесконечной десятичной дроби: $\xi = \sum_{n=1}^{\infty} \xi_n 10^{-n}$, где ξ_n - целые, $0 \leq \xi_n \leq 9$. Доказать, что случайные величины $\xi_1, \xi_2, \dots$ независимы.

Ч-3.49

В схеме Бернулли с вероятностью успеха p обозначим через $v_k (k = 1, 2, \dots)$ номер испытания, при котором происходит k -й успех, и положим $\tau_1 = v_1, \tau_k = v_k - v_{k-1} (k = 2, 3, \dots)$. Найти совместное распределение величин τ_1, τ_2 . Являются ли эти величины независимыми?

Ч-3.50

В полиномиальной схеме с исходами $(1, 2, \dots, N)$ вероятность i -го исхода в каждом испытании равна $p_i, i = 1, 2, \dots, N$. Положим

$$\varepsilon_{s,i} = \begin{cases} 1, & \text{если в } s\text{-м испытании появился } i\text{-й исход} \\ 0 & \text{в противном случае.} \end{cases}$$

Являются ли независимыми случайные величины:

- а) $\varepsilon_{a,i}, \varepsilon_{s,i} \quad (s, i, j - \text{фиксированы});$
 б) $\varepsilon_{a,i}, \varepsilon_{t,j} \quad (s \neq t)$ в) $\varepsilon_{1,i}, \varepsilon_{2,i}, \dots, \varepsilon_{n,i};$
 г) $\sum_{k=1}^N \varepsilon_{1k} c_k, \sum_{k=1}^N \varepsilon_{2k} c_k, \dots, \sum_{k=1}^N \varepsilon_{nk} c_k$, если $c_1, c_2, \dots, c_N$ некоторые постоянные?
 (тут еще задачи были, но я не вставил их)

Ч-3.59

Доказать, что двумерная функция распределения $F_{6,n}(x, y)$ непрерывна в точке (x_0, y_0) , если соответствующие одномерные функции распределения $F_8(x), F_n(y)$ непрерывны в точках x_0 и y_0 соответственно.

Пусть $\xi_1, \xi_2, \dots, \xi_n$ - независимые одинаково распределенные случайные величины. При каждом $\omega \in \Omega$ расположим числа $\xi_n(\omega), k = 1, \dots, n$, в порядке возрастания и перенумеруем их заново: $\xi_{(1)} \leq \xi_{(2)} \leq \dots \leq \xi_{(n)}$. Полученная последовательность случайных величин называется вариационным рядом, а сами случайные величины $\xi_{(k)}$ - членами вариационного ряда. Таким образом, в частности, $\xi_{(1)} = \min_{1 \leq k \leq n} \xi_k, \xi_{(n)} = \max_{1 \leq k \leq n} \xi_k$. Задачи п3.60-п3.66 связаны с вариационным рядом.

Ч-3.60

Случайные величины $\xi_1, \xi_2, \dots, \xi_n (n \geq 2)$ независимы и одинаково распределены с функцией распределения $F(x)$. Найти: а) функцию распределения $\xi_{(1)}$; б) функцию распределения $\xi_{(n)}$; в) двумерную функцию распределения $\xi_{(1)}, \xi_{(n)}$.

Ч-3.61

По независимым одинаково распределенным случайным величинам $\xi_1, \dots, \xi_n$, имеющим функцию распределения $F(x)$ и плотность $p(x)$, построен вариационный ряд $\xi_{(1)} \leq \xi_{(2)} \leq \dots \leq \xi_{(n)}$. Найти: а) плотность распределения $\xi_{(m)}$; б) совместную плотность распределения $\xi_{(h)}$ и $\xi_{(m)} (k < m)$.

Ч-3.62

Случайные величины $\xi_1, \dots, \xi_k, \xi_{k+1}$ независимы и имеют одну и ту же непрерывную функцию распределения. Пусть $\xi_{(1)} \leq \xi_{(2)} \leq \dots \leq \xi_{(k)}$ - вариационный ряд величин $\xi_1, \dots, \xi_k$

$$\begin{aligned} P \{ \xi_{k+1} \in [\xi_{(l)}, \xi_{(l+1)}] \}, \quad l = 1, \dots, k-1, \\ P \{ \xi_{k+1} < \xi_{(1)} \}, \quad P \{ \xi_{k+1} > \xi_{(k)} \}. \end{aligned}$$

Ч-3.63

Случайные величины $\xi_1, \dots, \xi_n$ независимы и имеют одинаковое распределение с плотностью $p(x)$. Найти n -мерную плотность $p_n(x_1, \dots, x_n)$ распределения членов вариационного ряда $\xi_1, \xi_{(2)}, \dots, \xi_{(n)}$.

Ч-3.64

*. Случайные величины $\xi_1, \xi_2, \dots, \xi_n$ независимы и имеют показательное распределение с параметром α :

$$P\{\xi_1 \leq x\} = 1 - e^{-\alpha x}, \quad x \geq 0, \quad i = 1, \dots, n,$$

а $\xi_{(1)} \leq \xi_{(2)} \leq \dots \leq \xi_{(n)}$ - значения $\xi_1, \dots, \xi_n$, расположенные в порядке неубывания (вариационный ряд). Показать, что случайные величины

$$\Delta_1 = \xi_{(1)}, \quad \Delta_i = \xi_{(i)} - \xi_{(i-1)}, \quad i = 2, \dots, n,$$

независимы и что

$$P\{\Delta_1 \leq x\} = 1 - e^{-\alpha(n-i+1)x}, \quad i = 1, \dots, n.$$

Ч-3.65

Случайные величины $\xi_1, \xi_2, \dots, \xi_n$ независимы и имеют одно и то же показательное распределение с параметром λ . Доказать, что случайные величины

$$\max\{\xi_1, \xi_2, \dots, \xi_n\} \text{ и } \xi_1 + \frac{\xi_2}{2} + \frac{\xi_3}{3} + \dots + \frac{\xi_n}{n}$$

одинаково распределены.

Ч-3.66

Пусть $\xi_n = (\xi_{n,1}, \dots, \xi_{n,n})$, $n = 1, 2, \dots$, - последовательность независимых векторов, у которых координаты $\xi_{n,1}, \dots, \xi_{n,h}$ - независимые случайные величины, имеющие одну и ту же непрерывную функцию распределения $F(x)$. Положим

$$A_n = \left\{ \xi_{n,i} < \min_{1 \leq m \leq n} \xi_{m,t}, t = 1, \dots, k \right\}.$$

Доказать, что при $k \geq 2$

$$P\left\{ \bigcup_{n=2}^{\infty} A_n \right\} < \frac{1}{2^{k-3} \cdot g^0}$$

Ч-3.70

Случайная величина ξ_1 распределена по закону Пуассона с параметром λ_1 :

$$P\{\xi_1 = k\} = \frac{\lambda_1^k}{k!} e^{-\lambda_1}, \quad k = 0, 1, 2, \dots$$

а случайная величина ξ_2 распределена по закону Пуассона с параметром $\lambda_2 > \lambda_1$. Доказать, что при любом целом k

$$P\{\xi_1 \leq k\} > P\{\xi_2 \leq k\}.$$

Ч-3.71

Функции распределения $F_1(i)$ и $F_2(t)$ удовлетворяют условию

$$F_1(t) \leq F_2(t) \text{ для любого } t.$$

Показать, что можно так задать на одном вероятностном пространстве случайные величины ξ_1 и ξ_2 с функциями распределения $F_1(t)$ и $F_2(t)$ соответственно, что

$$P\{\xi_1 \geq \xi_2\} = 1.$$

равномерное распределение на отрезке $[0, 1]$, а случайная величина ζ удовлетворяет условиям

$$P\{\zeta = \xi\} = P\{\zeta = \eta\} = 1/2.$$

Найти максимально и минимально возможные значения $P\left\{ \left| \zeta - \frac{1}{2} \right| \leq t \right\}$ и указать, при каких совместных распределениях ξ, η, ζ эти значения достигаются.

6.4.3 Problems About Mathematical Expectations, Covariance, Correlation

(почему-то ватеры не делят на типы эти задачи, я мб потом разделю, посмотрим.)

В задачах п3.75-п3.112 используются прямые способы вычисления математических ожиданий; задачи п3.113-п3.131 иллюстрируют возможности метода индикаторов (см. введение к гл. 3). Задачи п3.132-п3.138 содержат полезные Формулы для математических ожиданий различных функций от случайных величин. Разными методами решаются задачи п3.139-п3.188.

Ч-3.75

Распределение дискретной случайной величины ξ определяется формулами $P\{\xi = i\} = 1/5, i = -2, -1, 0, 1, 2$. Найти математические ожидания величин $\eta_1 = -\xi, \eta_2 = |\xi|$. Распределение дискретной случайной величины ξ определяется формулами $P\{\xi = k\} = \frac{4}{k(k+1)(k+2)}, k = 1, 2, \dots$. Найти математическое ожидание случайной величины ξ .

Ч-3.77

Плотность распределения случайной величины & задана Формулами $p_z(x) = 0$ при $x < 1, p_s(x) = 3/x^4$ при $x \geq 1$. Найти математические ожидания и дисперсии случайных величин ξ и $\eta = 1/\xi$.

Ч-3.78

Найти $M\xi, D\xi, M\xi^{[k]} (k = 1, 2, \dots)$, если:

- $P\{\xi = m\} = \frac{\lambda^m}{m!} e^{-\lambda}, m = 0, 1, 2, \dots;$
- $P\{\xi = m\} = C_n^m p^m q^{n-m}, q = 1 - p, m = 0, 1, 2, \dots, n.$

Ч-3.79

Плотность совместного распределения $p_{\xi_1, \xi_2}(u, v)$ величин ξ_1, ξ_2 определяется равенствами $p_{q_1, z_2}(u, v) = u + v$ при $0 \leq u \leq 1, 0 \leq v \leq 1; p_{\xi_1, \xi_2}(u, v) = 0$ в остальных случаях. Найти $M\xi_1, M\xi_2, D\xi_1, D\xi_2, \text{cov}(\xi_1, \xi_2)$.

Ч-3.80

Совместное распределение ξ_1, ξ_2 определяется условиями $P\{\xi_1 \xi_2 = 0\} = 1, P\{\xi_i = 1\} = P\{\xi_i = -1\} = 1/4, i = 1, 2$. Найти $M\xi_1, M\xi_2, D\xi_1, D\xi_2, \text{cov}(\xi_1, \xi_2)$.

Ч-3.81

Случайная величина ξ равномерно распределена на отрезке $[0, 2\pi]; \eta_1 = \cos \xi, \eta_2 = \sin \xi$. Найти $M, M_2, \text{cov}(\eta_1, \eta_2)$. Являются ли η_1 и η_2 независимыми?

Ч-3.84

Плотность совместного распределения случайных ξ_1, ξ_2 равна $\frac{2}{\pi(u^2 + v^2)^3}$ при $u^2 + v^2 \geq 1$ и $p_{\xi_1, \xi_2}(u, v) = 0$ в остальных случаях. Найти $M\sqrt{\xi_1^2 + \xi_2^2}$.

Ч-3.85

Случайная величина ξ имеет показательное распределение: $P\{\xi > x\} = e^{-x}$ при $x \geq 0$. Найти $M\xi(1 - e^{-\alpha \xi})$.

Ч-3.86

Случайная точка A имеет равномерное распределение в круге радиуса R . Найти математическое ожидание и дисперсию расстояния ξ точки A от центра круга.

Ч-3.87

Случайная величина ζ имеет равномерное распределение на отрезке $[0, 1]$. Найти коэффициент корреляции случайных величин η_1, η_2 , если:

а) $\eta_1 = a\xi, \eta_2 = b\zeta \quad (a, b > 0)$,

б) $\eta_1 = a\zeta, \eta_2 = b\zeta \quad (a < 0 < b)$,

в) $\eta_1 = \zeta, \quad \eta_2 = \zeta^2$, г) $\eta_1 = \zeta - \frac{1}{2}, \quad \eta_2 = \left(\zeta - \frac{1}{2}\right)^2$,

д) $\eta_1 = \sin\left(\frac{\pi}{2}\zeta\right), \quad \eta_2 = \cos\left(\frac{\pi}{2}\zeta\right)$. Имеющей равномерное распределение в области $D \subset R^2$. Найти коэффициент корреляции $\rho(\xi, \eta)$, если:

а) D -часть единичного круга, лежащая в первом квадранте: $x^2 + y^2 \leq 1, x \geq 0, y \geq 0$.

б) D - треугольник: $x + y \leq 1, x \geq 0, y \geq 0$.

Ч-3.89

Пусть $\xi_1, \xi_2, \dots, \xi_n$ - независимые случайные величины, имеющие равномерное распределение на отрезке $[0, 1]$, а $\xi_{(1)} \leq \xi_{(2)} \leq \dots \leq \xi_{(n)}$ - построенный по $\xi_1, \dots, \xi_n$ вариационный ряд, т. е. значения $\xi_1, \dots, \xi_n$ - расположенные в порядке неубывания. Найти плотность $p_i(x)$ распределения $\xi_i, M\xi_{(i)}^h (k = 1, 2, \dots), D_{(i)}$.

Ч-3.91

Доказать, что если случайные величины то $M(\xi + \eta)^3 = M\xi^3 + M\eta^3$.

Ч-3.92

Случайные величины ξ и η некоррелированы. Доказать, что $M\xi\eta = M\xi M\eta$.

Ч-3.93

Случайные величины ξ, η и ξ попарно некоррелированы. Верно ли равенство $M\xi\eta\xi = M\xi M\eta M\xi$?

Ч-3.94

Случайные величины ξ, η, ξ имеют нулевые математические ожидания, дисперсии σ^2 и попарно некоррелированы. Чему равны минимальное и максимальное значения $M\xi\eta(???)$?

Ч-3.95

Найти ковариационную матрицу случайного вектора $\xi = (\xi_1, \xi_2, \xi_3)$, если:

а) ξ_1, ξ_2, ξ_3 независимы и имеют стандартное нормальное распределение;

б) вектор ξ имеет равномерное распределение в кубе $\{(x_1, x_2, x_3) : \max_{1 \leq i \leq 3} |x_i| \leq \sqrt{3}\}$;

в) вектор ξ с вероятностью $1/6$ принимает каждое из 6 значений $(0, 0, \pm\sqrt{3}), (0, \pm\sqrt{3}, 0), (\pm\sqrt{3}, 0, 0)$.

Ч-3.96

Какие из приведенных ниже матриц могут, а какие не могут быть ковариационными для случайного вектора $\xi = (\xi_1, \xi_2, \xi_3)$:

а) $\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$,

б) $\begin{pmatrix} 0 & 1 & 1 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{pmatrix} * \text{В)} \begin{pmatrix} 1 & 1 & 1 \\ -1 & 1 & 1 \\ -1 & -1 & 1 \end{pmatrix}$,

в) $\begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}$,

г) $\begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 4 \\ 3 & 4 & 5 \end{pmatrix}$ е) $\begin{pmatrix} 1 & 1 & -1 \\ 1 & 1 & 1 \\ -1 & 1 & 1 \end{pmatrix}$

Ч-3.98.

Случайный вектор (ξ_1, ξ_2, ξ_3) имеет ковариационную матрицу $\begin{pmatrix} 1 & \rho_{12} & \rho_{13} \\ \rho_{12} & 1 & \rho_{23} \\ \rho_{13} & \rho_{23} & 1 \end{pmatrix}$. Доказать, что

$$|\rho_{13} - \rho_{12}\rho_{23}| \leq \sqrt{(1 - \rho_{12}^2)(1 - \rho_{23}^2)}$$

Ч-3.99

а) Показать, что если распределение случайного вектора (ζ_1, ζ_2) совпадает с распределением вектора $(-\xi_1, -\xi_2)$ и $M\xi_1^2 + M\xi_2^2 < \infty$, то

$$\text{cov}(\zeta_1, \zeta_2) = 2M(\zeta_1 \max(0, \zeta_2)).$$

б) Пусть (ξ_1, η_1) и (ξ_2, η_2) - независимые одинаково распределенные векторы, $M(\xi_1^2 + \eta_1^2) < \infty$. Доказать, что $\text{cov}(\xi_1, \eta_1) = M((\eta_1 - \eta_2) \max(0, \xi_1 - \xi_2))$.

Ч-3.100

Случайные векторы $\xi = (\xi_1, \dots, \xi_n) \in R^n$ и $\xi^* = (\xi_1^*, \dots, \xi_n^*) \in R^n$ независимы, $\xi = (m_1, \dots, m_n) = m$, $M\xi^* = (m_1^*, \dots, m_n^*) = m$, матрицы ковариаций ξ и ξ^* равны $\sigma = \|\sigma_{ij}\|$ и $\sigma^* = \|\sigma_{ij}^*\|$ соответственно.

Найти: а) математическое ожидание и дисперсию случайной величины $\zeta = \xi_1 + \dots + \xi_n$;

б) математическое ожидание и дисперсию случайной величины $\eta = (\xi, a) = a_1\xi_1 + \dots + a_n\xi_n$, где $a = (a_1, \dots, a_n)$ - данный неслучайный вектор;

в) математические ожидания и ковариационные матрицы векторов $\xi + \xi^*, \xi - \xi^*, a\xi + b\xi^*$ (a, b - постоянные).

Ч-3.104

Случайные величины $\xi_1, \xi_2, \dots$ независимы и имеют равномерное распределение на отрезке $[0, 1]$. Найти математическое ожидание случайной величины

$$\eta_n = \sum_{i=1}^n |\xi_{i+1} - \xi_i|.$$

Ч-3.105

Найти дисперсию случайной величины η_n , введенной в задаче

Ч-3.104

Сравнить ее с $nD|\xi_2 - \xi_1| = D(|\xi_2 - \xi_1| + |\xi_4 - \xi_3| + \dots + |\xi_{2n} - \xi_{2n-1}|)$.

Ч-3.106

Случайные величины $\xi_1, \dots, \xi_n, \eta_1, \dots, \eta_n$ независимы. Положим

$$\zeta_n = \xi_1 + \dots + \xi_n, \zeta_n^* = \xi_1\eta_1 + \dots + \xi_n\eta_n.$$

Найти $M\zeta_n, M\zeta_n^*, D\zeta_n, D\zeta_n^*, \text{cov}(\zeta_n, \zeta_n^*)$, если

$$\begin{aligned} M\xi_k &= a, & D\xi_k &= \sigma^2, & P\{\eta_k = 1\} &= p, \\ P\{\eta_k = 0\} &= q = 1 - p & & & (k = 1, 2, \dots, n). \end{aligned}$$

Ч-3.107

В экспедиции, рассчитанной на n дней, ежедневно от запаса продуктов нужно отделять соответствующую часть: в 1-й день - $1/n$ -ю часть, во 2-й день $1/(n-1)$ -ю часть от остатка и т. д. В действительности нужная часть продуктов отделяется с ошибкой. Пусть $\eta_k (k = 1, 2, \dots, n-1)$ - часть от остатка продуктов, которая отделяется в k -й день. Предполагается, что величины η_k независимы, $M_k = a_k = \frac{1}{n-k+1}$. Найти математическое ожидание случайной величины ξ , равной части продуктов, оставшейся к последнему дню:

$$\zeta = (1 - \eta_1)(1 - \eta_2) \dots (1 - \eta_{n-1}).$$

Ч-3.112

Случайные величины $\xi_1, \xi_2, \dots$ независимы $M\xi_i = 0, D\xi_i = \sigma^2 < \infty, i = 1, 2, \dots$. Найти математическое ожидание и дисперсию случайных величин

$$S_n = \xi_1 + \xi_2 + \dots + \xi_n \text{ и } T_n = \xi_{v_1} + \xi_{v_2} + \dots + \xi_{v_n}$$

где $v_1, v_2, \dots$ независимые и все зависящие от $\xi_1, \xi_2, \dots$ случайные величины, имеющие равномерное распределение на множестве $\{1, 2, \dots, k\}$.

Ч-3.113

Обозначим через θ_r число циклов длины r в подстановке, случайно выбранной из множества всех $n!$ подстановок степени n . Найти: а) $M\theta_1, D\theta_1$; б) $M\theta_2$; в) $M\theta_r (r \geq 1)$.

Ч-3.114

В урне содержится M_1 шаров с номером 1, M_2 шаров с номером 2, ..., M_N шаров с номером N . По схеме случайного выбора без возвращения выбирается n шаров. Найти математическое ожидание числа появившихся номеров.

Ч-3.115

Из урны, содержащей M белых и $N - M$ черных шаров, по схеме выбора без возвращения извлекается гипергеометрическое распределение: $P\{\xi = m\} = \frac{C_M^m C_{N-M}^{n-m}}{C_N^n}$. Найти $M\xi$ и D .

Ч-3.116

В N ячейках случайно размещаются n частиц. Каждая частица независимо от остальных с вероятностью $1/N$ может попасть в любую фиксированную ячейку. Обозначим через $\mu_0(n, N)$ число пустых ячеек. Найти $M\mu_0(n, N), D\mu_0(n, N)$ и асимптотические формулы для них при $n, N \rightarrow \infty, n/N \rightarrow \alpha \in (0, \infty)$.

Ч-3.126

В схеме Бернулли задачи

Ч-3.125

найти формулы для математического ожидания и дисперсии числа μ_{111} появлений цепочки 111. (Цепочка 111 появляется при i -м испытании, если исходами $(i-2)$ -го, $(i-1)$ -го и i -го испытаний были единицы.) Сравнить их с формулами для математического ожидания и дисперсии числа μ_1 появлений исхода 1 в $n-2$ независимых испытаниях схемы Бернулли, когда вероятность исхода 1 равна p^3 .

Ч-3.127

Пусть проведено n испытаний по той же схеме Бернулли, что в задачах Ч-3.125 и Ч-3.126. Назовем серией единиц цепочку исходов последовательных испытаний вида 011...110 (при этом считается, что исходами дополнительных испытаний с номерами 0 и $n+1$ были нули). Пусть η_n - число серий единиц. Найти: а) $P\{\eta_n = 0\}$;

Ч-3.128

На бесконечный лист клетчатой бумаги (сторона клеточки равна 1) случайно бросается круг единичного радиуса. Считая, что центр круга равномерно распределен на том единичном квадрате, на который он попал, найти математическое ожидание числа точек с целочисленными координатами (x, y) , покрытых этим кругом.

Ч-3.129

*. Каждую целочисленную точку числовой оси независимо от остальных назовем белой с вероятностью q и черной с вероятностью $p = 1 - q$. Пусть S - множество всех таких целочисленных точек x , что расстояние от x до ближайшей черной точки (включая x , если точка x черная) не меньше расстояния от x до начала координат. Найти математическое ожидание числа $|S|$ элементов множества S .

Ч-3.137

Неотрицательная случайная величина ξ имеет функцию распределения $F(x) = P\{\xi \leq x\}$. Доказать, что для любого действительного $\alpha \neq 0$

$$M\xi^\alpha = |\alpha| \int_0^\infty x^{\alpha-1} (1 - F(x)) dx.$$

Ч-3.138

Случайная величина ξ имеет функцию распределения $F(x) = P\{\xi \leq x\}$. Показать, что если

$$F_{-1}(y) = \sup\{x : F(x) \leq y\}.$$

то для любой интегрируемой функции $h(x)$

$$Mh(\xi) = \int_0^1 h(F_{-1}(y)) dy.$$

Замечание, в 1ю унесу

При решении задач Ч-3.139-Ч-3.143 можно использовать следующее простое замечание.

Если случайные величины $\xi_1, \dots, \xi_n$ независимы и одинаково распределены, а число $k < n$, то набор $\xi_{i_1}, \xi_{i_2}, \dots, \xi_{i_k}$, $1 \leq i_1 < i_2 < \dots < i_k \leq n$, одинаково распределены и для любой измеримой функции $f(x_1, \dots, x_k)$ случайные величины $\eta_{i_1, \dots, i_k} = f(\xi_{i_1}, \dots, \xi_{i_k})$ где $1 \leq i_1, \dots, i_k \leq n, i_r \neq i_s, (r \neq s)$, тоже одинаково распределены.

Ч-3.139

Пусть вероятностное распределение P на плоскости R^2 таково, что если точки $X_1, X_2, X_3 \in R^2$ независимы и имеют распределение P , то

$$P\{X_1, X_2, X_3 \text{ лежат на одной прямой}\} = 0.$$

Найти математическое ожидание угла $X_1 X_2 X_3$.

Ч-3.140

Случайные точки A_1, A_2, A_3, A_4 независимы и имеют равномерное распределение в выпуклой плоской фигуре $C \subset R^2$, площадь которой равна 1. Доказать, что вероятность того, что выпуклая оболочка точек A_1, A_2, A_3, A_4 есть треугольник, в 4 раза больше математического ожидания площади треугольника $A_1 A_2 A_3$.

Ч-3.137

Неотрицательная случайная величина ξ имеет функцию распределения $F(x) = P\{\xi \leq x\}$. Доказать, что для любого действительного $\alpha \neq 0$

$$M\xi^\alpha = |\alpha| \int_0^\infty x^{\alpha-1} (1 - F(x)) dx.$$

Ч-3.138

Случайная величина ξ имеет функцию распределения $F(x) = P\{\xi \leq x\}$. Показать, что если

$$F_{-1}(y) = \sup\{x : F(x) \leq y\}.$$

то для любой интегрируемой функции $h(x)$

$$Mh(\xi) = \int_0^1 h(F_{-1}(y)) dy.$$

При решении задач Ч-3.139-Ч-3.143 можно использовать следующее простое замечание.

Если случайные величины $\xi_1, \dots, \xi_n$ независимы и одинаково распределены, а число $k < n$, то набор $\xi_{i_1}, \xi_{i_2}, \dots, \xi_{i_k}$, $1 \leq i_1 < i_2 < \dots < i_k \leq n$, одинаково распределены и для любой измеримой функции $f(x_1, \dots, x_k)$ случайные величины $\eta_{i_1, \dots, i_k} = f(\xi_{i_1}, \dots, \xi_{i_k})$ где $1 \leq i_1, \dots, i_k \leq n, i_r \neq i_s, (r \neq s)$, тоже одинаково распределены.

Ч-3.139

Пусть вероятностное распределение P на плоскости R^2 таково, что если точки $X_1, X_2, X_3 \in R^2$ независимы и имеют распределение P , то

$$P\{X_1, X_2, X_3 \text{ лежат на одной прямой}\} = 0.$$

Найти математическое ожидание $X_1 X_2 X_3$.

Ч-3.140

Случайные точки A_1, A_2, A_3, A_4 независимы и имеют равномерное распределение в выпуклой плоской фигуре $C \subset R^2$, площадь которой равна 1. Доказать, что вероятность того, что выпуклая оболочка точек A_1, A_2, A_3, A_4 есть треугольник, в 4 раза больше математического ожидания площади треугольника $A_1 A_2 A_3$.

Ч-3.151

Доказать, что если $M|\xi|^h < \infty$, то

$$\lim_{x \rightarrow \infty} x^k P\{|\xi| \geq x\} = 0.$$

Ч-3.152

Показать, что если ξ - действительная случайная величина с конечным математическим ожиданием и $f(x)$ - функция, выпуклая вниз, то

$$Mf(\xi) \geq f(M\xi),$$

в если $f(x)$ выпукла вверх, то

$$Mf(\xi) \leq f(M\xi).$$

Ч-3.153

Показать, что для любых случайных величин $\xi_1, \xi_2, \dots, \xi_h$ с конечными r -ми ($r \geq 1$) моментами справедливо соотношение

$$M|\xi_1 + \dots + \xi_h|^r \leq k^{r-1} (M|\xi_1|^r + \dots + M|\xi_h|^r).$$

Ч-3.154

Доказать, что при $1 \leq r \leq 2$ справедливо неравенство

$$|x+y|^r + |x-y|^r \leq 2(|x|^r + |y|^r), \quad -\infty < x, \quad y < \infty,$$

и с его помощью показать, что если случайные величины ξ и η независимы и распределение η симметрично (т. е. распределения η и $-\eta$ совпадают), то при любом $r, 1 \leq r \leq 2$,

$$M|\xi + \eta|^r \leq M|\xi|^r + M|\eta|^r.$$

Ч-3.155

Показать, что если случайные величины $\xi_1, \dots, \xi_n$ независимы, имеют симметричные распределения и $M|\xi_i|^r < \infty, i = 1, \dots, n$, для некоторого $r \in [1, 2]$, то

$$M|\xi_1 + \dots + \xi_n|^r \leq M|\xi_1|^r + \dots + M|\xi_n|^r.$$

,

Ч-3.158

Случайный вектор $\xi = (\xi_1, \dots, \xi_k)$ принимает значения в R^k , и существует такой набор чисел

$$(\alpha_0, \alpha_1, \dots, \alpha_k) \neq (0, 0, \dots, 0),$$

что $P\{\alpha_1 \xi_1 + \dots + \alpha_k \xi_k + \alpha_0 = 0\} = 1$. Доказать, что если все элементы матрицы ковариаций $B = \|\sigma_{ijl}\|$ компонент вектора ξ конечны, то:

а) $\det B = 0$;

б) $(\alpha_1, \dots, \alpha_k) B = \left(B(\alpha_2, \dots, \alpha_k)^\top \right)^\top = 0_k$ где $^\top$ - знак транспонирования.

Ч-3.159

Случайный вектор $\xi = (\xi_1, \dots, \xi_h)$ принимает значения в R^h имеет математическое ожидание $m \in R^h$ и матрицу ковариаций $B = \|b_{ij}\|$. Доказать, что: а). матрица B неотрицательно определена, т. е.

$$\sum_{i,j=1}^h b_{ij} a_i a_j = (a, B) \geq 0 \text{ для любого } a \in R^h;$$

б)* если ранг матрицы B равен r , то существует r -мерная гиперплоскость $L_r \subset R^h$, для которой $P\{\xi \in L_r\} = 1$, и $P\{\xi \in L_{r-1}\} < 1$ для любой $(r-1)$ -мерной гиперплоскости $L_{r-1} \subset R^h$.

Ч-3.160

Случайные величины $\xi_1, \xi_2, \dots, \xi_n$ независимы и равномерно распределены в отрезке $[0, 1]$. Найти $P\{\xi_1 + \xi_2 + \dots + \xi_n \leq x\}$ при $0 \leq x \leq 1$.

Ч-3.161

Случайные величины $\xi_1, \xi_2, \dots$ независимы и равномерно распределены в отрезке $[0, 1]$. Определим случайную величину v равной тому значению k , при котором впервые сумма $\xi_1 + \xi_2 + \dots + \xi_k$ превзойдет 1. Найти Mv .

Ч-3.162

Случайные величины $\xi_1, \dots, \xi_n$ независимы; $D\xi_i = \sigma_i^2, i = 1, \dots, n$. При каких $c_1, \dots, c_n$, удовлетворяющих условиям $c_k \geq 0, c_1 + \dots + c_n = 1$, случайная величина $\eta_n = c_1 \xi_1 + \dots + c_n \xi_n$ имеет минимальную дисперсию? Найти минимальную дисперсию.

Ч-3.163

По известному «правилу трех сигм» вероятность отклонения случайной величины от своего математического ожидания более чем на три корня из дисперсии мала. Найти $P\{|\xi - \xi| < 3\sqrt{D}\}$, если ξ имеет:

- нормальное распределение;
- показательное распределение;
- равномерное распределение на отрезке $[-1, 1]$;
- $P\{\xi = -1\} = P\{\xi = 1\} = 1/18, P\{\xi = 0\} = 8/9$;
- распределение Пуассона с $M\xi = 0,09$.

Ч-3.164

Вычислить математическое ожидание и дисперсию ξ_{ij} - независимые случайные величины с $M\xi_i^5 = 0$ и $D\xi_{ij} = \sigma^2$.

Ч-3.165

Пусть матрица $\Xi = \|\xi_i \xi_j\|_{i,j=1}^n$, где $\xi_1, \dots, \xi_n$ - независимые случайные величины, имеющие симметричные распределения (т. е. распределение ξ совпадает с распределением $-\xi, i = 1, \dots, n$). Показать, что если $M|\xi_j|^k < \infty, i = 1, \dots, n$, для целого $k \geq 1$, то $M\Xi^k$ - диагональная матрица.

Ч-3.166

Неотрицательная случайная величина ξ имеет монотонно убывающую выпуклую вниз плотность распределения $f(x), f''(x) > 0$. Что можно сказать о вехах величин $M \sin \xi, M \cos \xi$?

Ч-3.167

Обозначим $\eta_n = \max\{\mu_n, n - \mu_n\}$, где μ_n - число успехов в схеме Бернулли с n испытаниями и с вероятностью успеха p . Найти $\lim_{n \rightarrow \infty} n^{-1} M\eta_n$.

Ч-3.171

Координата x случайной точки A на действительной прямой имеет непрерывную функцию распределения. Найти на этой прямой такую точку B , для которой математическое ожидание длины отрезка AB минимально.

Ч-3.172

Случайные величины ξ, η имеют непрерывную двумерную плотность распределения. Как выбрать точку $B = (x, y) \in R^2$, чтобы величина $\varphi(x, y) = M(|\xi - x| + |\eta - y|)$ была минимальной?

Ч-3.173

Случайная величина ξ имеет конечный второй момент $M\xi^2$. Найти $\min_x M(\xi - x)^2$ и то значение x , при котором этот минимум достигается.

Ч-3.174

Математическое ожидание квадрата расстояния случайной точки $X \in R^2$ от начала координат конечно. Для какой точки A минимально $M|AX|^2$?

Ч-3.175

Уровень весеннего паводка на реке является случайной величиной ξ с непрерывной функцией распределения $F(x) = P\{\xi \leq x\}$. Плотина рассчитана так, чтобы выдерживать паводок уровня не выше z . Предполагая, что уровни паводков в разные годы независимы и одинаково распределены, найти:

а) минимальное значение z , при котором математическое ожидание времени до разрушения плотины паводком будет не меньше $T = 100$ лет;

б) минимальное значение z , при котором вероятность разрушения плотины паводком за $T = 100$ лет будет не больше $\alpha = 1/100$.

Ч-3.176

Наблюдения за уровнями весенних паводков в течение T лет дали значения $\xi_1, \dots, \xi_T$. На реке построена плотина, которая может выдержать паводок, если только его уровень не превосходит $\zeta_T = \max\{\xi_1, \dots, \xi_T\}$. Пусть $\tau_T = \min\{t : \hat{J}_{T++} > \zeta_T\}$ - время до разрушения плотины паводком. Предполагая, что случайные величины $\xi_1, \xi_2, \dots$ независимы и имеют одну и ту же для $M\tau_T, P\{\tau_T \leq u\}$ и численные значения этих величин при $T = 100, u = 10$.

Ч-3.177

Случайные величины ξ_1, ξ_2, ξ_3 независимы и имеют одно и то же распределение с конечным математическим ожиданием, $\xi_{(1)} \leq \xi_{(2)} \leq \xi_{(3)}$ - их вариационный ряд (см. задачу 3.60).

а) Доказать, что

$$M(\xi_{(3)} - \xi_{(1)}) = \frac{3}{2}M|\xi_1 - \xi_2|.$$

б) Доказать, что

$$M\{\min(\xi_{(2)} - \xi_{(1)}, \xi_{(3)} - \xi_{(2)})\} \leq \frac{3}{4}M|\xi_1 - \xi_2|.$$

Ч-3.178

Будем говорить, что случайная величина ξ сосредоточена на отрезке $[a, b]$, если $P\{a \leq \xi \leq b\} = 1$ и при любом $\varepsilon > 0$

$$P\{a \leq \xi < a + \varepsilon\} > 0 \text{ и } P\{b - \varepsilon < \xi \leq b\} > 0.$$

Доказать, что дисперсия случайной величины, сосредоточенной на отрезке длины l , не превосходит $l^2/4$.

Ч-3.183

Случайные величины ξ и η заданы на одном вероятностном пространстве. Описать множество возможных значений $P\{\xi \leq \eta\}$ в следующих случаях:

а) $M\xi = 1, M\eta = 10$;

б) ξ и η одинаково распределены; мерно на $[0, a], a \neq 1$. распределение на отрезке $[0, 1]$. Доказать, что при любом характере зависимости между ξ и η

$$M|\xi - \eta| \leq 1/2.$$

Ч-3.185

Случайные величины ξ и η независимы и имеют равномерное распределение на отрезке $[0, 1]$, а случайная величина ζ удовлетворяет условию

$$P\{\xi = \zeta\} = P\{\zeta = \eta\} = 1/2.$$

кажать совместные распределения ξ, η, ζ , при которых достигаются экстремальные значения $M\zeta$, и пайти максимальное и минимальное возможные значения $M\zeta$.

Ч-3.186

Случайная величина ξ имеет непрерывную функцию распределения $F(x)$, случайная величина χ принимает только значения 0 и 1: $P\{\chi = 1\} = a, P\{\chi = 0\} = 1 - a$. Указать совместные распределения ξ и χ , при которых достигаются экстремаль

Ч-3.187

Случайные величины ξ и η независимы и имеют равномерное распределение на отрезке $[0, 1]$, а случайная величина ζ удовлетворяет условию

$$P\{\xi = \zeta\} = p \leq 1/2, \quad P\{\xi = \eta\} = 1 - p.$$

Указать совместные распределения ξ, η, ζ , при которых достигаются экстремальные значения $M\zeta$, и найти эти экстремальные значения.

МФТИ-Т.31.

Игральная кость подбрасывается n раз. Пусть ξ - число появлений единицы, а η - число появлений шестёрки. Найти коэффициент корреляции этих случайных величин.

Обозначим A_i - выпадение на i -м броске единицы, B_i - шестёрки. $\xi = \sum_{i=1}^n \mathbb{1}_{A_i}, \eta = \sum_{i=1}^n \mathbb{1}_{B_i}$;

$$E\mathbb{1}_{A_i} = E\mathbb{1}_{B_i} = \frac{1}{6};$$

$$\text{cov}(\xi, \eta) = E(\xi - E\xi)(\eta - E\eta) = E(\xi\eta) - E\xi E\eta$$

$$E(\xi\eta) = E\left(\sum_{i=1}^n \mathbb{1}_{A_i}\right)\left(\sum_{k=1}^n \mathbb{1}_{B_k}\right) = E\left(\sum_{i=1}^n \mathbb{1}_{A_i} \mathbb{1}_{B_i}\right) + E\left(\sum_{i \neq k} \mathbb{1}_{A_i} \mathbb{1}_{B_k}\right) = \sum_{i \neq k} E\mathbb{1}_{A_i} \mathbb{1}_{B_k} = \frac{n(n-1)}{36}$$

$$\text{cov}(\xi, \eta) = \frac{n(n-1)}{36} - \frac{n^2}{36} = -\frac{n}{36}$$

$$D\xi = \sum_{i=1}^n D\mathbb{1}_{A_i} = \sum_{i=1}^n (E\mathbb{1}_{A_i}^2 - (E\mathbb{1}_{A_i})^2) = n\left(\frac{1}{6} - \frac{1}{6} \cdot \frac{1}{6}\right) = \frac{5}{36}n$$

$$D\eta = \frac{5n}{36}$$

$$\text{cov}(\xi, \eta) = \frac{-\frac{n}{36}}{\frac{5n}{36}} = -\frac{1}{5}$$

МФТИ-Т.32.

Подбрасывают две игральные кости. Пусть ξ_1 - число очков на первой игральной кости, а ξ_2 - на второй. Определим $\eta_1 = \xi_1 + \xi_2$, $\eta_2 = \xi_1 - \xi_2$. Найти $\text{cov}(\eta_1, \eta_2)$ и выяснить, являются ли η_1 и η_2 независимыми.

$$\text{cov}(\eta_1, \eta_2) = E(\eta_1, \eta_2) - E(\eta_1)E(\eta_2) = E(\eta_1^2) - E(\eta_2^2) - (E\eta_1)^2 + (E\eta_2)^2 = D\eta_1 - D\eta_2 = 0$$

Зависимость следует из контрпримера. Из подсчета количества благоприятных успехов, видим, что

$$P(\eta_1 = 2) = \frac{1}{36}; P(\eta_2 = 0) = \frac{1}{6}$$

и в то же время

$$P(\eta_1 = 1, \eta_2 = 0) = P(\eta_1 = 1, \eta_2 = 1) = \frac{1}{36}$$

МФТИ-Т.33.

Доказать, что если случайные величины ξ и η принимают только по два значения каждая, то из некоррелируемости следует их независимость.

$$\xi \in \{a_1, a_2\}; \eta \in \{b_1, b_2\},$$

$$\text{cov}(\xi, \eta) = E\xi\eta - E\xi E\eta = 0$$

$$E\xi\eta = \sum_{i,k=1}^2 a_i b_k E(\mathbb{1}_{A_i} \mathbb{1}_{B_k}) = \sum_{i,k=1}^2 a_i b_k P(A_i, B_k)$$

$$E\xi E\eta = \left(\sum_{i=1}^2 a_i P(A_i)\right) \left(\sum_{k=1}^2 b_k P(B_k)\right) = \sum_{i,k=1}^2 a_i b_k P(A_i)P(B_k)$$

Поэтому

$$\text{cov}(\xi, \eta) = 0 = \sum_{i,k=1}^2 a_i b_k (P(A_i, B_k) - P(A_i)P(B_k)) \rightarrow P(A_i B_k) = P(A_i)P(B_k)$$

МФТИ-Т.34.

Авария происходит в точке X , которая равномерно распределена на дороге длиной L . Во время аварии машина скорой помощи находится в точке Y , которая также равномерно распределена на дороге. Считая, что X и Y независимы, найдите математическое ожидание расстояния между машиной скорой помощи и точкой аварии.

$$E|X - Y| = \int_{[0,L]^2} |x - y| \rho_X(x) \rho_Y(y) dx dy = \int_{[0,L]^2} \frac{|x - y|}{L^2} dx dy = \frac{2}{L} \int_0^L dx \int_x^L (y - x) dy = \frac{2}{L} \frac{L^3}{6} = \frac{L}{3}$$

6.4.4 Problems About Conditional Distributions**Ч-3.189**

Случайные величины ξ и η независимы;

$$P\{\xi = k\} = P\{\eta = k\} = pq^{k-1},$$

Найти: $q = 1 - p$, $0 < p < 1$, $k = 1, 2, \dots$

- а) $P\{\xi = \eta\}$; б) $P\{\xi > \eta\}$; в) $P\{\xi < \eta\}$; г) $P\{\xi = k | \xi > \eta\}$; д) $P\{\xi = k | \xi < \eta\}$; е) $P\{\xi = k | \xi = \eta\}$; ж) $P\{\xi = k | \xi + \eta = l\}$; з) $M(\xi | \xi + \eta = l)$, $l \geq 2$.

Ч-3.190

Найти распределение целочисленной неотрицательной случайной величины ξ , если:

- а) $P\{0 < \xi < \infty\} = 1$, $P\{\xi = k + 1 | \xi > k\} = p$, $k =$

Ч-3.191

Случайные величины ξ , η независимы и одинаково распределены. Найти условную плотность $p_{z|+n=z}(x)$ распределения ξ при условии $\xi + \eta = z$ в следующих случаях: а) ξ и η имеют показательное распределение с плотностью $p(x) = \lambda e^{-\lambda x}$, $x \geq 0$; б) ξ и η равномерно распределены в $[0, 1]$; в) ξ и η имеют распре-

Ч-3.192

Найти условную, $x \geq 0$. случаях а), б), в), определенных в дию $D(\xi | \xi + \eta = z)$ в

Ч-3.193

Случайные величины в предыдущей задаче. паково распределены. Найти $M(\xi | \xi + \eta = z)$. Разобрать отдельно случай, когда ξ имеет дискретное распределение или положительную плотность.

Ч-3.194

Плотность совместного распределения величин ξ, η определяется равенствами: $p_{\xi, \eta}(u, v) = 1$ при $(u, v) \in G$, $p_{\xi, \eta}(u, v) = 0$ при $(u, v) \notin G$, где $G = \{(u, v) : 0 \leq u \leq 2, 0 < v < 1 - \frac{1}{2}u\}$. Найти плотность $p_{\eta|\xi-\varepsilon}(x)$ условного распределения η при условии $\xi = 2$.

Ч-3.195

Пусть $\xi_1, \xi_2, \dots, \xi_n$ - результаты n последовательных испытаний Бернулли, $P\{\xi_i = 1\} = p, P\{\xi_i = 0\} = q = 1 - p$. Доказать, что для любого $k (0 \leq k \leq n)$ условное распределение набора $\xi = (\xi_1, \dots, \xi_n)$ при условии $\xi_1 + \dots + \xi_n = k$ является равномерным на множестве всех C_n^k наборов, состоящих из k единиц и $n - k$ нулей.

Ч-3.196

Случайная величина X_1 имеет биномиальное распределение с параметрами (n, p) , случайная величина X_2 при условии X_1 имеет биномиальное распределение с параметрами (X_1, p) , X_3 - при условии X_2 имеет биномиальное распределение с параметрами (X_2, p) , ..., X_k при условии X_{k-1} имеет биномиальное распределение с параметрами (X_{k-1}, p) . Доказать, что безусловным распределением X_n является биномиальное распределение с параметрами (n, p^k) .

Ч-3.197

Случайные величины $\xi_1, \xi_2, \dots, \xi_N$ независимы и распределены по закону Пуассона с параметрами $\lambda_1, \lambda_2, \dots, \lambda_N$. Найти: а) $P\{\xi_1 + \dots + \xi_k = m | \xi_1 + \dots + \xi_N = n\}$; б) $M\{\xi_1 + \dots + \xi_n | \xi_1 + \dots + \xi_N = n\}$.

Ч-3.19

8. з урны, содержащей M белых и $N - M$ черных шаров, сначала извлекается без возвращения выборка объема n , а затем из этой выборки извлекается без возвращения выборка объема $n_0 < n$. Найти закон распределения числа ξ белых шаров во второй выборке. Зависит ли этот закон от n ?

Ч-3.199

Случайные величины ξ_1, ξ_2, ξ_3 независимы и распределены нормально с одинаковыми параметрами $a = 0, \sigma = 1$; положим $\eta = \frac{\xi_1 + \xi_2 \xi_3}{\sqrt{1 + \xi_3^2}}$. Найти распределение η .

Ч-3.20

2. Пусть $\xi_1, \xi_2, \dots$ последовательность независимых одинаково распределенных случайных величин с математическим ожиданием $a > 0$ и дисперсией $\sigma^2 < \infty$, случайная величина v не зависит от $\xi, \xi, \dots$ и принимает целые положительные значения, $Mv = b, a$

$$\tau = \xi_1 + \xi_2 + \dots + \xi_v.$$

Найти τ и (при дополнительном условии $Dv = \delta^2$) $D\tau$.

Ч-3.20

3. Случайные величины ξ, η независимы. Показать, что для любого x

$$P\{\xi \geq \max(\eta, x)\} \geq P\{\xi \geq \eta\}P\{\xi \geq x\}.$$

Ч-3.204

Случайные величины ξ, η, ζ независимы. Показать, что

$$P\{\xi \geq \max(\eta, \zeta)\} \geq P\{\xi \geq \eta\}P\{\xi \geq \zeta\}.$$

Ч-3.205

Случайные величины $\xi_1, \xi_2, \dots$ независимы и имеют равномерное распределение на отрезке $[0, 1]$. Пусть $\delta_1 = 1$, и если $n \geq 2$, то

$$\delta_n = \begin{cases} 1 & \text{при } \xi_n < \min \{\xi_1, \dots, \xi_{n-1}\}, \\ 0 & \text{в противном случае.} \end{cases}$$

Построим последовательность τ_k моментов появления минимальных значений ξ_n и последовательность их величин η_k , т. е. положим $\tau_0 = 0, \eta_0 = 1, \tau_k \Rightarrow \min \{n : n > \tau_{k-1}, \delta_n = 1\}, \eta_k = \xi_{\tau_k}, k = 1, 2, \dots$

а) Доказать, что при любых $k \geq 1$ и $x \in [0, 1]$ условное распределение η_k при условии $\eta_{k-1} = x$ является равномерным на $[0, x]$.

б) Найти математическое ожидание и дисперсию случайной величины $\xi_h = -\ln \eta_h$.

в) Найти условное распределение, математическое ожидание и дисперсию случайной величины $\Delta_h = \tau_h - \tau_{h-1}$ при условии $\eta_{k-1} = x$.

г) Найти τ_h при $k \geq 1$.

Ч-3.207

Случайная величина ξ имеет нормальное распределение с математическим ожиданием 0 и дисперсией σ^2 . Показать, что при любых $x > 0, C > 0$

$$\mathbf{P} \left\{ \xi - x > \frac{C}{x} \mid \xi > x \right\} < e^{-C/\sigma^2}.$$

Ч-3.20

8. В схеме Бернулли с вероятностью p исхода 1 и вероятностью $q = 1 - p$ исхода 0 найти математическое ожидание числа v_{00} испытаний до первого появления дешифровки из двух нулей. В частности, вычислить $M v_{00}$ при $p = 1/2$.

Ч-3.209

В схеме Бернулли предыдущей задачи найти математическое ожидание числа v_{111} испытаний до первого появления цепочки из трех единиц. В частности, вычислить это математическое ожидание при $p = 1/2$.

Ч-3.210

В схеме Бернулли задачи п3.208 найти математическое ожидание числа v_{01} испытаний до первого появления цепочки 01. В частности, вычислить это математическое ожидание при $p = 1/2$.

Ч-3.211

Точки $A_1, A_2, \dots, A_n$ независимы и имеют равномерное распределение на окружности единичной длины. Найти вероятность того, что длина наименьшей дуги, содержащей все эти точки, не больше $x \leq 1/2$.

Ч-3.212

Точки $A_1, \dots, A_n$ независимы и имеют равномерное распределение на окружности S с центром O . Найти вероятность того, что O лежит внутри выпуклого многоугольника с вершинами $A_1, \dots, A_n$.

Ч-3.213

Точки $A_1, \dots, A_n$ независимы и имеют равномерное распределение на окружности с центром O , а случайная величина v равна наименьшему n , при котором выпуклый многоугольник с вершинами $A_1, \dots, A_n$ содержит O . Найти Mv и Dv .

Ч-3.216

Пусть выполнены условия задачи п3.215 и ξ_i длина дуги $A_{(i)}A_{(i+1)}$. Найти совместное распределение и коэффициент корреляции ξ_1, ξ_2 .

Ч-3.217

Пусть выполнены условия задачи п3.216. Найти закон совместного распределения $\xi_1, \dots, \xi_n$ при $k \leq n$.

Ч-3.21

8. Пусть выполнены условия задачи п3.216. Показать, что совместное распределение $\xi_{i_1}, \xi_{i_2}, \dots, \xi_{i_k}$ с $1 \leq i_1 < i_2 < \dots < i_k \leq n$ совпадает с распределением

Ч-3.219

Пусть выполнены условия задачи п3.216 и v - число дуг $A_{(i)}A_{(i+1)}$ длины больше Δ , $0 \leq \Delta \leq 2\pi r$. Найти Mv , Dv и асимптотические формулы для них при $r = n/2\pi\lambda$, $n \rightarrow \infty$.

Ч-3.220

Пусть выполнены условия задачи п3.216. Найти закон распределения случайной величины

$$\eta_n = \max \{ \xi_1, \dots, \xi_n \}.$$

Ч-3.221

Пусть выполнены условия задачи п3.220. Найти $M\eta_n$ и асимптотическую формулу для η_n при $n \rightarrow \infty$.

Ч-3.222

Точки A, B, C независимы и имеют равномерное распределение на окружности единичного радиуса. Пусть S - площадь $\triangle ABC$, p - его периметр, r - радиус вписанного круга. Найти MS , Mp , Mr .

Ч-3.223

Стороны прямоугольника $ABCD$ параллельны осям координат. Найти математическое ожидание площади S прямоугольника $ABCD$ в следующих случаях:

а) координаты (a_1, a_2) точки A фиксированы, $0 \leq a_1, a_2 \leq 1$, а точка C имеет равномерное распределение на диагонали единичного квадрата, соединяющей его вершины $(0, 0)$ и $(1, 1)$;

б) точки A и C независимы; точка A равномерно распределена в единичном квадрате $[0, 1] \times [0, 1]$, а точка C имеет то же распределение, что в п. а).

МФТИ-Т22 Совместное распределение по заданным вероятностям

Найдем совместное распределение случайных величин ξ и η , принимающих значения $-1, 0, 1$, если известно:

$$P(\xi\eta = 0) = 1; \quad P(\xi = 1) = P(\xi = -1) = P(\eta = 1) = P(\eta = -1) = \frac{1}{4}$$

Из условия следует, что $P(\xi \neq 0) = \frac{1}{2}$, $P(\eta \neq 0) = \frac{1}{2}$, поэтому $P(\xi = 0) \leq \frac{1}{2}$, $P(\eta = 0) \leq \frac{1}{2}$, то есть $P(\xi = 0) + P(\eta = 0) \leq 1$.

В то же время $1 = P(\xi\eta = 0) = P((\xi = 0) \cup (\eta = 0)) \leq P(\xi = 0) + P(\eta = 0)$, поэтому $P(\xi = 0) = \frac{1}{2}$, $P(\eta = 0) = \frac{1}{2}$.

Для плотности распределения получаем таблицу:

$\xi \downarrow; \eta \rightarrow$	-1	0	1
-1	0	1/4	0
0	1/4	1/2	1/4
1	0	1/4	0

Table 9: T22

А плотность распределения имеет вид:

(???)

Она заполняется легко: нули ставятся, так как если бы был не ноль в этих местах, то не было бы $P(\xi\eta = 0) = 1$.

Дальше оставшиеся равенства из условия дают нам заполнение боковых средних ячеек.

Ячейка посередине легко находится.

	$\xi < -1$	$\xi \in [-1; 0)$	$\xi \in [0, 1)$	$\xi \leq 1$
$\eta < -1$	0	0	0	0
$\eta \in [-1; 0)$	0	0	1/4	1/4
$\eta \in [0, 1)$	0	1/4	3/4	1
$\eta \leq 1$	0	1/4	1	1

Table 10: T22

МФТИ-Т23 Закон распределения $\xi + \eta$ при известных плотности ξ и вероятности η (??)

Найти закон распределения случайной величины $\xi + \eta$, если ξ и η независимы; ξ имеет плотность распределения $f_\xi(x)$, а $\eta \in \{-1, 0, 1\}$, $\mathbf{P}(\eta = 0) = \mathbf{P}(\eta = 1) = \mathbf{P}(\eta = -1) = \frac{1}{3}$.

Имеем:

$$\begin{aligned} F_{\xi+\eta}(x) &= P(\xi + \eta \leq x) = \\ &= P(\eta + \xi \leq x | \eta = 0)P(\eta = 0) + P(\eta + \xi \leq x | \eta = 1)P(\eta = 1) + P(\eta + \xi \leq x | \eta = -1)P(\eta = -1) \end{aligned}$$

$$P(\xi \leq x | \eta = 0) = \frac{P(\{\xi \leq x\} \cap (\eta = 0))}{P(\eta = 0)} = \frac{P(\xi \leq x)P(\eta = 0)}{P(\eta = 0)} = P(\xi \leq x)$$

Поэтому

$$\begin{aligned} F_{\xi+\eta}(x) &= 1 \frac{1}{3} (F_\xi(x) + F_\xi(x-1) + F_\xi(x+1)) = \\ &= \frac{1}{3} \left(\int_{-\infty}^x f_\xi(y) dy + \int_{-\infty}^{x-1} f_\xi(y) dy + \int_{-\infty}^{x+1} f_\xi(y) dy \right) \end{aligned}$$

Это и ответ.

МФТИ-Т.24 (?!!!) Функция распределения и плотность суммы координат точки в квадрате

В квадрат $\{(x_1, x_2) : 0 \leq x_i \leq 1; i = 1, 2\}$ наудачу брошена точка. Пусть ξ_1, ξ_2 - ее координаты. Найти функцию распределения и плотность случайной величины $\eta = \xi_1 + \xi_2$

$$F_{\xi_i}(x) = P(\xi_i \leq x) = \begin{cases} 0, & \text{если } x < 0 \\ x, & \text{если } x \in [0, 1) \\ 1 & \text{если } x \in [1, +\infty) \end{cases}$$

$$\rho_{\xi_i} = \begin{cases} x, & \text{если } x \in [0, 1) \\ 1, & \text{иначе} \end{cases}$$

ξ_1, ξ_2 - независимые случайные величины.

$$\rho(\xi_1 + \xi_2) = \rho(\xi_1)\rho(\xi_2)$$

Посчитаем

$$\rho(\xi_1 + \xi_2 \leq x) = \iint_S \rho_{\xi_1 \xi_2}(u, s) du ds$$

где S - площадь, которую пересекает заштрихованная часть на рисунке с единичным квадратом

При $x < 0$ $\rho(\xi_1 + \xi_2 \leq x) = 0$.

При $x > 0$ $\rho(\xi_1 + \xi_2 \leq x) = 1$.

При $x \in [0, 1]$

$$\rho(\xi_1 + \xi_2 \leq x) = \int_0^x d\xi_1 \int_0^{x-\xi_1} d\xi_2 = \int_0^x (x - \xi) d\xi = x^2 - \frac{x^2}{2} = \frac{x^2}{2}$$

При $x \in [1, 2]$ нужно посчитать площадь, заштрихованную розовым, для этого от площади квадрата отнимем оставшуюся площадь, которая легко находится, зная длину сторон этой области.

$$\rho(\xi_1 + \xi_2 \leq x) = 1 - \frac{(2-x)^2}{2} = 2x - \frac{x^2}{2} - 1$$

Figure 6.4: МФТИ-Точка в квадрате

В итоге функция распределения имеет вид:

$$F_{\xi_1+\xi_2}(x) = P(\xi_1 \leq x) = \begin{cases} 0, & \text{если } x < 0 \\ \frac{x^2}{2}, & \text{если } x \in [0, 1) \\ 2x - \frac{x^2}{2} - 1, & \text{если } x \in [1, 2) \\ 1 & \text{если } x \in [2, +\infty) \end{cases}$$

Найдем плотность распределения:

$$f_{\xi_1+\xi_2}(x) = P'(\xi_1 \leq x) = \begin{cases} 0, & \text{если } x < 0 \\ x, & \text{если } x \in [0, 1) \\ 2 - x, & \text{если } x \in [1, 2) \\ 0 & \text{если } x \in [2, +\infty) \end{cases}$$

МФТИ-? (?!?) распределение суммы случайных величин по условному распределению одной и $\xi_1 + \xi_2$

Пусть ξ_1, ξ_2 - независимые случайные величины с распределением Пуассона. Найти распределение их суммы и условное распределение ξ_1 , если известна сумма $\xi_1 + \xi_2$.

$$\begin{aligned} P(\xi_1 + \xi_2 = k) &= \sum_{i=0}^k P(\xi_1 = i; \xi_2 = k - i) \stackrel{\text{независимость}}{=} \sum_{i=0}^k P(\xi_1 = i)P(\xi_2 = k - i) = \\ &= \sum_{i=0}^k \frac{\lambda_1^i \lambda_2^{k-i}}{i!(k-i)!} e^{-\lambda_1 - \lambda_2} = \frac{1}{k!} e^{-\lambda_1 - \lambda_2} \sum_{i=0}^k C_k^i \lambda_1^i \lambda_2^{k-i} = \frac{(\lambda_1 + \lambda_2)^k}{k!} e^{-(\lambda_1 + \lambda_2)} \end{aligned}$$

Теперь найдем

$$P(\xi_1 = k | \eta = n) = \frac{P(\xi_1 = k \cap \xi_2 = n - k)}{P(\eta = n)} = \frac{\xi_1(k) \xi_2(n - k)}{\eta(n)} = C_n^k \frac{(\lambda_1 / \lambda_2)^k}{(\lambda_1 / \lambda_2 + 1)^n}$$

МФТИ-? (?!?) Распределение $\eta = f_\xi(\xi)$

Известно, что случайная величина ξ имеет строго возрастающую непрерывную функцию распределения $F_\xi(x)$. Найти распределение случайной величины $\eta = F_\xi(\xi)$.

Из непрерывности следует, что $\exists F_\xi^{-1}(x)$, поэтому просто преобразуем искомую функцию распределения:

$$F_\eta(x) = P(\eta \leq x) = P(F_\xi(\xi) \leq x) = P(\xi \leq F_\xi^{-1}(x)) = F_\xi(F_\xi^{-1}(x)) = x.$$

В итоге

$$F_\xi(\xi) = \begin{cases} 0, & \text{если } x < 0 \\ x, & \text{если } x \in [0, 1] \\ 1, & x \in [1, +\infty) \end{cases}$$

МФТИ-? Параметры ξ^2 по ξ

Пусть ξ имеет стандартное нормальное распределение. Найти функцию распределения и плотность случайной величины ξ^2

Функция распределения:

$$F_{\xi^2}(x) = P(\xi^2 \leq x) = P(\xi \leq \sqrt{x}) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}x}$$

А ее плотность есть производная $F_{\xi^2}(x)$:

$$f_{\xi^2}(x) = -\frac{1}{2\sqrt{2\pi}} e^{-\frac{1}{2}x}$$

6.4.5 Problems About Normal Distribution**Ч-3.225**

Случайная величина ξ имеет нормальное распределение с математическим ожиданием 0 и дисперсией 1. Какое из двух событий: $\{|\xi| \leq 0,7\}$ или $\{|\xi| \geq 0,7\}$ - имеет большую вероятность?

Ч-3.226

Случайная величина ξ имеет нормальное распределение с параметрами $(0, 1)$. Что больше:

$$P\{-0,5 \leq \xi \leq -0,1\} \text{ или } P\{1 \leq \xi \leq 2\}?$$

Ч-3.227

Случайная величина ξ имеет нормальное распределение с математическим ожиданием 0 и дисперсией σ^2 . Найти $M\xi^k, k = 1, 2, \dots$

Ч-3.228

Случайная величина ξ имеет нормальное распределение с математическим ожиданием 0 и дисперсией σ^2 . Показать, что при любом $x > 0$

$$\frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2\sigma^2}} \left\{ \frac{\sigma}{x} - \frac{\sigma^3}{x^3} \right\} < P\{\xi \geq x\} < \frac{1}{\sqrt{2\pi}} e^{-\frac{x^2}{2\sigma^2}} \frac{\sigma}{x}.$$

Ч-3.229

Случайная величина ξ распределена нормально с параметрами (a, σ^2) . Найти:

- плотность распределения - величины $\eta_1 = \xi^2$ при $a = 0$
- плотность распределения величины $\eta_2 = e^3$ при произвольных $a, 0$.

Ч-3.230

Случайные величины ξ_1 и ξ_2 независимы и имеют нормальное распределение с параметрами $(0, \sigma^2)$. Найти функцию распределения случайной величины $\eta = \xi_1^2 + \xi_2^2$

Ч-3.231

Случайные величины $\xi_1, \dots, \xi_n$ независимы и имеют нормальное распределение с математическим ожиданием 0 и дисперсией 1. Распределение случайной величины $\eta_n = \xi_1^2 + \dots + \xi_n^2$ называется χ^2 -распределением с n степенями свободы. Найти плотность распределения η_n .

Какое из распределений, перечисленных в конце введения к гл. 3, при соответствующем выборе параметров совпадает с распределением η_n ?

Ч-3.232

Случайная величина η_n имеет χ^2 -распределение с n степенями свободы (см. задачу п3.231). Найти $M\eta_n, D\eta_n$

Ч-3.233

Найти $M\xi$ и $D\xi$, если $\ln \xi$ имеет нормальное распределение с параметрами (a, σ^2) (в этом случае говорят, что ξ имеет логарифмически нормальное распределение).

Ч-3.234

Для случайной величины ξ , определенной в задаче **3.233**, найдите точку, в которой максимальна плотность распределения ξ (эта точка называется модой распределения). Найдите отношение математического ожидания ξ к его моде.

Ч-3.235

Некоторая категория людей имеет средний вес m кг и среднее квадратическое отклонение веса 3 кг. Для случаев $m = 60$ и $m = 10$ определить вероятность того, что вес случайно взятого человека отличается от m не более чем на 5 кг; если: а) вес имеет нормальное распределение; б) вес имеет логарифмически нормальное распределение.

Ч-3.236

Для случайных величин η_1, η_2 , определенных в п3.229, найти $M\eta_1^k, M\eta_2^k$.

Ч-3.237

Случайная величина ξ имеет нормальное распределение с нулевым математическим ожиданием и единичной дисперсией. Найти $M\xi \cos \xi$, $M \frac{\xi}{1+\xi^2}$, $M \sin \xi$.

Ч-3.242

Случайная величина η нормально распределена с параметрами $(0, 1)$. Положим

$$\eta = \begin{cases} \xi, & \text{если } |\xi| \leq 1, \\ -\xi, & \text{если } |\xi| > 1. \end{cases}$$

- а) Найти закон распределения η .
б) Имеет ли величина $\xi + \eta$ нормальное распределение?

Ч-3.243

Случайные величины ξ и η независимы и имеют нормальное распределение с математическим ожиданием 0 и дисперсией 1. Найти

$$P\{|\xi - \eta| \leq 1\}.$$

Ч-3.244

Случайные величины ξ_1, ξ_2, ξ_3 независимы и нормально распределены с параметрами $(1, 1)$, $(2, 5)$, $(0, 7)$ соответственно. Найти: а) $P\{2\xi_1 - \xi_2 < 0\}$, б) $P\{-3 < 2\xi_1 - \xi_2 < 5\}$, в) $P\{1 < 2\xi_1 - \xi_2 + \xi_3 < 4\}$.

Ч-3.245

Случайный вектор (ξ_1, ξ_2) имеет сферически симметричное нормальное распределение с $D\xi_1 = D\xi_2 = \sigma^2$. Найти распределение вектора (ζ_1, ζ_2) , если

$$\xi_1 = \zeta_1 \cos \varphi + \zeta_2 \sin \varphi, \quad \xi_2 = -\zeta_1 \sin \varphi + \zeta_2 \cos \varphi.$$

симметричное нормальное распределение с $D_1 = D_2 = 1$. Доказать, что случайные величины $\xi_1 \xi_2$ и $\frac{1}{2}(\xi_1^2 - \xi_2^2)$ одинаково распределены.

Ч-3.247

Случайные величины ξ и η независимы и имеют нормальное распределение с параметрами $(0, 1)$. Найти совместное распределение случайных величин $\zeta_1 = a\xi_1 + b\xi_2$, $\zeta_2 = a\xi_1 - b\xi_2$ при $a, b \neq 0$.

Ч-3.250

Случайные величины ξ_1 и ξ_2 независимы и имеют нормальное распределение с математическим ожиданием 0 и дисперсией σ^2 . Случайные величины η_1 и η_2 определяются соотношением

$$\eta_1 + i\eta_2 = \frac{(\xi_1 + i\xi_2)^k}{(\xi_1^2 + \xi_2^2)^{(k-1)/2}}$$

где $i = \sqrt{-1}$, а $k > 0$ - целое число. Найти совместное распределение величин η_1 и η_2 .

Ч-3.251

Случайные величины ξ_1, ξ_2 независимы и имеют нормальное распределение с параметрами $(0, 1)$. Найти математическое ожидание величины

$$\eta = e^{(\xi_1^2 + \xi_2^2)/2} (1 + \xi_1^2 + \xi_2^2)^{-3/2}$$

Ч-3.252

Случайные величины ξ, η независимы и нормально распределены с параметрами $(0, \sigma_1^2), (0, \sigma_2^2)$ соответственно. Вычислить при $\sigma_1 = 1, \sigma_2 = 2$ вероятность попадания случайной точки $(\xi, \eta) \in R^2$ в следующие области: а) прямоугольник $|x| \leq 1, |y| \leq 2$;

б) прямоугольник $0 \leq y \leq 4$;

г) трапецию $x + y \leq 0, |x| \leq 1, y \geq -2$;

д) область $\frac{x^2}{a^2} + \frac{y^2}{b^2} \leq 1$, ограниченную эллипсом, вписанным в прямоугольник $|x| \leq 1, |y| \leq 2$;

е) область $\frac{x^2}{c^2} + \frac{y^2}{4c^2} \leq 1$, ограниченную эллипсом, описанным около прямоугольника $|x| \leq 1, |y| \leq 2$.

Ч-3.253

Мост через реку представляет собой прямоугольник, координаты которого в декартовой системе координат удовлетворяют неравенствам: $|x| \leq 10, |y| \leq 100$. При артиллерийском обстреле моста точка попадания снаряда (ξ, η) в той же системе координат имеет «вумерное нормальное распределение с независимыми координатами и со средними квадратическими отклонениями $\sigma_\xi = 10, \sigma_\eta = 40$. «Точкой прицеливания» назовем $(M\xi, M\eta)$. Определить вероятность попадания в мост при одном выстреле, если точка прицеливания равна: а) $(0, 0)$; б) $(10, 0)$; в) $(5, 20)$.

Ч-3.257

Случайная точка (ξ, η) имеет сферически симметричное нормальное распределение с $D\xi = D\eta = 1$. Найти вероятность попадания (ξ, η) :

а) в квадрат $C = \{(x, y) : |x| \leq 3, |y| \leq 3\}$;

б) во вписанный в C круг;

в) в описанный около C круг.

Ч-3.258

Случайные величины ξ, η независимы и нормально распределены с $M = M\eta = 0, D\xi = D\eta = 4$. Найти вероятность того, что случайная точка (ξ, η) попадет в:

а) кольцо $\{(x, y) : 2 \leq \sqrt{x^2 + y^2} \leq 3\}$; б) область $\{(x, y) : 2 \leq \min(|x|, |y|), \max(|x|, |y|) \leq 3\}$;

в) область $\{(x, y) : 2 \leq |x| + |y| \leq 3\}$.

Ч-3.259

Случайные точки $A_1 = (\xi_1, \eta_1)$ и $A_2 = (\xi_2, \eta_2)$ на плоскости R^2 независимы и имеют сферически симметричное нормальное распределение с единичной матрицей ковариаций. Найти функцию распределения длины отрезка A_1A_2 .

Ч-3.260

Случайные точки $A_1 = (\xi_1, \eta_1), A_2 = (\xi_2, \eta_2), A_3 = (\xi_3, \eta_3)$ на плоскости R^2 независимы и имеют нормальное распределение с нулевым вектором математических ожиданий и единичной матрицей ковариаций. Найти функцию распределения длины медианы A_1M_1 треугольника $A_1A_2A_3$.

Ч-3.261

Доказать, что в условиях задачи п3.260 длина сторон A_2A_3 и длина медианы A_1M_t треугольника $A_1A_2A_3$ - независимые случайные величины.

Ч-3.262

В условиях задачи п3.260 найти вероятность того, что треугольник $A_1A_2A_3$ - тупоугольный.

Ч-3.264

Случайный вектор $\xi = (\xi_1, \xi_2) \in R^2$ имеет двумерное нормальное распределение с нулевым вектором математических ожиданий, область A - угол с вершиной в начале координат и раствором α . Доказать, что если область A' симметрична области A относительно начала координат, то $P\{\xi \in A'\} = P\{\xi \in A\}$.

Ч-3.265

Случайный вектор $\xi = (\xi_1, \xi_2) \in R^2$ имеет двумерное нормальное распределение с нулевым вектором математических ожиданий и матрицей ковариаций $\begin{pmatrix} \sigma_1^2 & 0 \\ 0 & \sigma_2^2 \end{pmatrix}$. Найти $P\{|\xi_1| > a|\xi_2|\}, a > 0$.

Ч-3.266

Случайный вектор $\xi = (\xi_1, \xi_2) \in R^2$ имеет невырожденное двумерное нормальное распределение с нулевым вектором математических ожиданий и матрицей ковариаций $\|\sigma_{ij}\|_{i,j=1}^2, |\sigma_{12}|^2 < \sigma_{11}\sigma_{22}$. Найти

$$\begin{aligned} p_{00} &= P\{\xi_1 \geq 0, \xi_2 \geq 0\}, & p_{01} &= P\{\xi_1 \geq 0, \xi_2 \leq 0\}, \\ p_{10} &= P\{\xi_1 \leq 0, \xi_2 \geq 0\}, & p_{11} &= P\{\xi_1 \leq 0, \xi_2 \leq 0\}. \end{aligned}$$

Ч-3.267

Случайный вектор $\xi = (\xi_1, \xi_2) \in R^2$ имеет двумерное нормальное распределение с нулевым вектором математических ожиданий и матрицей ковариаций $\begin{pmatrix} \sigma^2 & \alpha \\ \alpha & \sigma^2 \end{pmatrix}$ $\xi \alpha < \sigma^2$. Найти

$$P\{0 \leq \xi_1 \leq x\xi_2\}, \quad x > 0.$$

Ч-3.268

Случайный вектор $\xi = (\xi_1, \xi_2) \in R^2$ имеет невырожденное нормальное распределение с нулевым вектором математических ожиданий и матрицей ковариаций $\begin{pmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{12} & \sigma_{22} \end{pmatrix}$. Найти:

$$\text{а) } P\{\xi_1 > a\xi_2\}, -\infty < a < \infty; \text{ б) } P\{\xi_1 > a\xi_2 + b\}, -\infty < a, b < \infty.$$

Ч-3.271

Случайные величины ξ_1, ξ_2, ξ_3 и $\xi_{(1)}, \xi_{(2)}, \xi_{(3)}$ те же, что в задаче п3.270.

- Найти распределение вектора $(\xi_2 - \xi_1, \xi_3 - \xi_2)$.
- Найти плотность $p(x_1, x_2)$ распределения вектора $(\xi_{(2)} - \xi_{(1)}, \xi_{(3)} - \xi_{(2)})$.
- Найти распределение случайной величины $\xi = (\xi_{(2)} - \xi_{(1)}) / (\xi_{(3)} - \xi_{(2)})$.

Ч-3.272

Случайные величины ξ_1, ξ_2, ζ независимы и имеют стандартное нормальное распределение. Положим

$$\xi_3 = \begin{cases} \zeta, & \text{если } \xi_1\xi_2 = 0, \\ |\zeta| \operatorname{sgn}(\xi_1\xi_2), & \text{если } \xi_1\xi_2 \neq 0, \end{cases}$$

где $\operatorname{sgn}(x) = x/|x|$ при $x \neq 0$.

- Найти вектор математических ожиданий и матрицу ковариаций вектора (ξ_1, ξ_2, ξ_3) .
- Найти распределение ξ_3 и совместные распределения векторов (ξ_1, ξ_3) и (ξ_2, ξ_3) .
- Найти плотность $p(x_1, x_2, x_3)$ распределения вектора (ξ_1, ξ_2, ξ_3) . Н является ли оно нормальным?

Ч-3.273

Используя предыдущую задачу, построить пример случайного вектора $(\xi_1, \xi_2, \dots, \xi_n)$, распределение которого не является нормальным, но любые $n-1$ его координат взаимно независимы и имеют нормальное распределение с математическим ожиданием 0 и дисперсией 1.

Ч-3.274

Случайный вектор $\xi = (\xi_1, \dots, \xi_k)$ имеет сферически симметричное нормальное распределение с нулевым вектором математических ожиданий и единичной ковариационной матрицей. Найти распределение вектора $\eta = \xi A$, где A -действительная матрица с k строками и m столбцами.

Ч-3.277

Случайные величины $\xi_1, \xi_2, \dots, \xi_n$ независимы; ξ_i имеет нормальное распределение с параметрами $(0, \sigma_i^2)$, $i = 1, 2, \dots, n$. Найти распределение вектора

$$\eta = (\xi_1, \xi_1 + \xi_2, \xi_1 + \xi_2 + \xi_3, \dots, \xi_1 + \xi_2 + \dots + \xi_n).$$

Ч-3.278

Случайные величины $\xi_1, \xi_2, \dots$ независимы и имеют нормальное распределение с параметрами $(0, 1)$. Найти минимальное значение k , при котором

$$P\{\max\{|\xi_1|, |\xi_2|, \dots, |\xi_k|\} \geq 2\} \geq \frac{1}{2}.$$

Ч-3.279

Случайный вектор $\xi = (\xi_1, \dots, \xi_k)$ имеет k -мерное нормальное распределение с математическим ожиданием $a \in R^A$ и ковариационной матрицей A . Что больше: $\ln |M\xi_1 \dots \xi_k|$, $M \ln |\xi_1 \dots \xi_k|$ или $\ln M |\xi_1 \dots \xi_k|$?

Ч-3.280

Случайный вектор $\xi = (\xi_1, \xi_2) \in R^2$ имеет двумерное нормальное распределение с нулевым вектором математических ожиданий и ковариационной матрицей $\begin{pmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{pmatrix}$. Найти условное распределение ξ_1 при условии $\xi_2 = x$.

Ч-3.281

Распределение случайного вектора $\xi = (\xi_1, \xi_2) \in R^2$ таково, что при любом $x \in (-\infty, \infty)$ условное распределение ξ_1 при условии $\xi_2 = x$ и условное распределение ξ_2 при условии $\xi_1 = x$ нормальны. Является ли нормальным распределение вектора ξ ?

6.5 Problems About Limit Theorems That Produce and Characteristic Functions

6.5.1 Problems About the law of Large Numbers and the Borel-cantelli Lemma (????)

(уже года 2 как знаю, что такое есть, но только сейчас до задач дошел.)

Ч-4.1

. Пусть функция $g(x), x \geq 0$, неотрицательна и монотонно возрастает. Показать, что для любой действительной случайной величины ξ справедливо неравенство

$$P\{|\xi| \geq x\} \leq \frac{Mg(|\xi|)}{g(x)}.$$

Ч-4.2

. Пусть случайная величина η_n равна сумме очков, появившихся при n бросаниях симметричной игральной кости. Используя неравенство Чебышева, оценить сверху

$$P \left\{ \left| \frac{\eta_n}{n} - 3,5 \right| > \varepsilon \right\}, \quad \varepsilon > 0.$$

Ч-4.3

. Пусть $\xi_1, \xi_2, \dots, \xi_{n+1}$ - результаты $n+1$ испытаний схемы Бернулли ($P\{\xi_i = 1\} = p, P\{\xi_i = 0\} = 1 - p$) и случайная величина η_n равна числу таких $i, 1 \leq i \leq n$, что $\xi_i = \xi_{i+1} = 1$. Используя неравенство Чебышева, оценить сверху

$$P \left\{ \left| \frac{\eta_n}{n} - p^2 \right| > \varepsilon \right\}, \quad \varepsilon > 0.$$

Ч-4.4

Последовательности $\xi_1, \xi_2, \dots$ и $\eta_1, \eta_2, \dots$ образованы одинаково распределенными случайными величинами, независимыми внутри каждой последовательности (случайные величины ξ_i и η_i могут не быть независимы для больших чисел для последовательности $\zeta_1, \zeta_2, \dots$

$$\xi_{2h-1} = \xi_h, \quad \zeta_{2h} = \eta_h, \quad k = 1, 2, \dots$$

Ч-4.5

. Случайные величины $\xi_1, \xi_2, \dots$ независимы и имеют стандартное нормальное распределение,

$$\eta_n = \cos \frac{\varepsilon_n}{\xi_{n+1}}, \quad n = 1, 2, \dots$$

$\bigvee_n$ удовлетворяют ли последовательности $\eta_3, \eta_5, \dots$ и $\eta_1, \eta_2, \eta_3, \dots$ закону больших чисел?

Ч-4.7

Последовательность $\xi_1, \xi_2, \dots$ образована независимыми случайными величинами,

$$M\xi_k = 0, \quad D\xi_k = Ck^\alpha, \quad C > 0, \quad \alpha \geq 0, \quad k = 1, 2, \dots$$

При каких значениях α последовательность $\xi_1, \xi_2, \dots$ может удовлетворять закону больших чисел и при каких значениях α может не удовлетворять ему?

Ч-4.8

Последовательность $\xi_1, \xi_2, \dots$ состоит из независимых одинаково распределенных случайных величин, $M\xi_k = 0, D\xi_k = \sigma^2 < \infty, k = 1, 2, \dots$. Удовлетворяют ли закону больших чисел последовательности случайных величин

$$\zeta_n = \xi_n + \xi_{n+1}, \quad \eta_n = \sum_{k=0}^{\lfloor n/3 \rfloor} \xi_{n+k}, \quad n = 1, 2, \dots?$$

Ч-4.9

Случайные величины $\xi_1, \xi_2, \dots$ независимы, $M\xi_1 = a, D\xi_1 = \sigma^2 < \infty$. Пусть $\zeta_n = \sum_{1 \leq i < j \leq n} \xi_i \xi_j$.

Показать, что последовательность ζ_n удовлетворяет закону больших чисел: для каждого $\varepsilon > 0$

$$\lim_{n \rightarrow \infty} P \left\{ \left| \frac{\zeta_n}{c_n^2} - a^2 \right| > \varepsilon \right\} = 0.$$

Ч-4.10

Показать, что утверждение предыдущей задачи останется справедливым, если в ее формулировке заменить условие независимости $\xi_1, \xi_2, \dots$ условием их некоррелированности:

$$M(\xi_i - a)(\xi_j - a) = 0, \quad 1 \leq i < j < \infty.$$

Ч-4.11

Пусть функция $f(x)$, $0 \leq x \leq 1$, ограничена и интегрируема, а $\xi_1, \xi_2, \dots$ - независимые случайные величины, равномерно распределенные на отрезке $[0, 1]$.

а) Доказать, что для любого $\varepsilon > 0$

$$\lim_{n \rightarrow \infty} P \left\{ \left| \frac{f(\xi_1) + \dots + f(\xi_n)}{n} - \int_0^1 f(x) dx \right| > \varepsilon \right\} = 0.$$

б) Найти

$$\lim_{n \rightarrow \infty} P \left\{ \left| \frac{f(\xi_0) + \dots + f(\xi_n)}{n} - \int_0^1 f(x) dx \right| > \frac{\varepsilon}{\sqrt{n}} \right\}, \quad \varepsilon > 0.$$

114

Ч-4.12

Пусть ограниченная интегрируемая функция $f(x)$, $-\infty < x < \infty$, имеет период 1, а случайные величины ξ и η независимы и равномерно распределены на отрезке $[0, 1]$. Построим последовательность случайных величин

$$\xi_k = f(\xi + k\eta), \quad k = 1, 2, \dots$$

а) Доказать, что случайные величины $\xi_1, \xi_2, \dots$ попарно независимы и одинаково распределены. Найти $M\xi_1, D\xi_1$.

б) Показать, что для любого $\varepsilon > 0$

$$\lim_{n \rightarrow \infty} P \left\{ \left| \frac{\xi_1 + \dots + \xi_n}{n} - \int_0^1 f(x) dx \right| > \varepsilon \right\} = 0.$$

в) Показать, что если $\left| f(y) - \int_0^1 f(x) dx \right| > \varepsilon$ при всех $y \in [a, b] \subset (0, 1)$, то при любом $n = 1, 2, \dots$

$$P \left\{ \left| \frac{\xi_1 + \dots + \xi_n}{n} - \int_0^1 f(x) dx \right| > \varepsilon \right\} \geq 2 \left(\frac{b-a}{n} \right)^2.$$

Ч-4.15

Случайные величины $\xi_1, \xi_2, \dots$ независимы, одинаково распределены, имеют математическое ожидание a и для некоторого ε , $0 < \varepsilon < 1$,

$$m_\varepsilon = M |\xi_1 - a|^{1+\varepsilon} < \infty.$$

Показать, что для любого $\delta > 0$

$$\lim_{n \rightarrow \infty} P \left\{ \left| \frac{\xi_1 + \dots + \xi_n}{n} - a \right| > \delta \right\} = 0.$$

Ч-4.16

Лемма Бореля-Кантелли. Пусть $A_1, A_2, \dots$ - события, заданные на одном вероятностном пространстве, и случайная величина v равна числу одновременно происходящих событий. Показать, что:

а) если $\sum_{n=1}^{\infty} P\{A_n\} < \infty$, то $P\{v < \infty\} = 1$,

б) если события $A_1, A_2, \dots$ попарно независимы и $\sum_{n=1}^{\infty} P\{A_n\} = \infty$, то $P\{v = \infty\} = 1$.

Ч-4.17

Пусть $A_1, A_2, \dots$ события, заданные на одном вероятностном пространстве, и случайная величина v равна числу одновременно происходящих событий. Показать, что если $P\{A_n\} \geq a > 0, n = 1, 2, \dots$ то $P\{v = \infty\} \geq a$.

Ч-4.18

Последовательность чисел c_n удовлетворяет условиям $0 \leq c_n \leq 1, \lim_{n \rightarrow \infty} c_n = 0$. Всегда ли существует такая последовательность событий $A_1, A_2, \dots$, что $P\{A_n\} = c_n$ и для числа v одновременно происходящих событий справедливо соотношение $P\{v < \infty\} = 1$?

Ч-4.21

Случайные величины $\xi_1, \xi_2, \dots$ независимы и имеют одно и то же показательное распределение с параметром λ :

$$P\{\xi_n \leq x\} = 1 - e^{-\lambda x}, \quad x \geq 0, \quad n = 1, 2, \dots$$

Пусть ε - произвольное число из интервала $(0, 1/\lambda)$, случайная величина v_ε равна числу одновременно происходящих событий $A_n^e = \left\{ \frac{\xi_n}{\ln n} > \frac{1}{\lambda} + \varepsilon \right\}$, а μ_ε - числу одновременно происходящих событий

$$B_n^\varepsilon = \left\{ \max_{\sqrt{n} < k < n} \frac{\xi_k}{\ln k} < \frac{1}{\lambda} - \varepsilon \right\}.$$

а) Показать, что $P\{v_e < \infty\} = P\{\mu_e < \infty\} = 1$ при любом $\varepsilon \in (0, 1/\lambda)$.

б) Вывести из результата п. а), что последовательность случайных величин $\xi_n = \frac{\xi_n}{\ln n}$, $n = 1, 2, \dots$, удовлетворяет условию

$$P\left\{\overline{\lim}_{n \rightarrow \infty} \xi_n = \frac{1}{\lambda}\right\} = 1.$$

Ч-4.22

Случайные величины $\xi_1, \xi_2, \dots$ имеют математическое ожидание a и дисперсию $\sigma^2 < \infty$ и все коррелированы:

$$M(\xi_i - a)(\xi_i - a) = 0 \text{ при любых } i \neq 1.$$

Доказать, что

$$p\left\{\lim_{n \rightarrow \infty} \frac{\xi_1 + \dots + \xi_{n^2}}{n^2} = a\right\} = 1.$$

ФР задача на нормальное распределение (!?!?!?)

Two random variables are given: $X \sim \mathcal{N}(0, 9)$ and $Y \sim \mathcal{N}(0, 4)$. $\text{Corr}(X, Y) = -1$. (a) (5 pts) Evaluate $P(X > 1)$ (b) (5 pts) Evaluate $P(2X + Y > 3)$ (c) (5 pts) Evaluate $P(2X + Y > 3 | X = 1)$ (d) (5 pts) Evaluate $P(|X| > 2)$ (e) (5 pts) Evaluate $P((Y + 1)^2 < 2)$

(такую важно решать, но пока плохо понимаю его, не уверен в решениях вообще.)

6.5.2 Limit Theorem Proof Problems**Ч-4.25**

Случайные величины $\xi_1, \xi_2, \dots, \xi_n$ независимы и имеют одно и то же геометрическое распределение с параметром $p, 0 < p < 1$:

$$P\{\xi_1 = k\} = (1-p)p^n, \quad k = 0, 1, 2, \dots$$

а) Показать, что $P\{\xi_1 + \dots + \xi_n = k\} = C_{k+n-1}^{n-1} (1-p)^n p^k$, $k = 0, 1, 2, \dots$

б) Найти

$$q_k^{(n)} = \lim_{m \rightarrow \infty} P\{\xi_1 + \dots + \xi_n - m = k | \xi_1 + \dots + \xi_n \geq m\}_1 = 0, 1, 2, \dots$$

Ч-4.26

(см. задачу п1.53). Первый ряд кинотеатра состоит из N кресел. Зрители один за другим выполняют этот ряд, причем каждый из них может с равной вероятностью занять любое из кресел, свободных в момент его прихода. Пусть $\tau_1(N)$ - порядковый номер первого зрителя, который сел в кресло, находящееся рядом с уже занятым креслом, $\tau_2(N)$ - порядковый номер первого зрителя, который сел в кресло, симметричное относительно середины ряда одному из занятых кресел. Найти законы распределения $\tau_1(N)$ и $\tau_2(N)$ и предельные при $N \rightarrow \infty$ распределения случайных величин $\frac{\tau_i(N)}{VN}, i = 1, 2$, т. е. функции $G_i(x) = \lim_{N \rightarrow \infty} P\left\{\frac{\tau_i(N)}{\sqrt{N}} \leq x\right\}$.

Ч-4.27

. Плотность $p_s(x)$ случайной величины ξ непрерывна и ограничена на отрезке $[a, b]$ и равна 0 вне $[a, b]$. Положим $\eta_n = \{n\xi\}$, где $\{x\}$ - дробная часть числа x . Найти

$$\lim_{n \rightarrow \infty} P\{\eta_n \leq x\}, \quad 0 \leq x \leq 1.$$

Ч-4.28

Показать, что утверждение предыдущей задачи справедливо для случайной величины ξ с кусочно-непрерывной плотностью.

Доказать, что при любом характере зависимости между ξ_n и η_n для каждой точки непрерывности $F(x)$ справедливы равенства:

- а) $\lim_{n \rightarrow \infty} P\{\eta_n + \xi_n \leq x\} = F(x)$;
 б) $\lim_{n \rightarrow \infty} P\{\eta_n(1 + \xi_n) \leq x\} = F(x)$.

Ч-4.34

Случайные величины $\xi_1, \xi_2, \dots$ независимы,

$$P\{\xi_i = 1\} = p, \quad P\{\xi_i = 0\} = 1 - p, \quad i = 1, 2, \dots$$

Положим $\xi_i^{(k)} = \xi_i(1 - \xi_{i+1}\xi_{i+2}\dots\xi_{i+k})$, $\eta_n^{(k)} = \xi_1^{(k)} + \dots + \xi_n^{(k)}$. В случае когда $0 < p < 1$, $\lim_{n \rightarrow \infty} p^{k(n)}\sqrt{n} = 0$ найти

$$\lim_{n \rightarrow \infty} P\left\{\frac{\eta_n^{(h(n))} - np}{\sqrt{np(1-p)}} \leq x\right\}.$$

Ч-4.35

Пусть $\xi_1, \xi_2, \dots$ и $\eta_1, \eta_2, \dots$ - такие последовательности случайных величин, что для некоторых чисел a, b для любого $\varepsilon > 0$

$$\lim_{n \rightarrow \infty} P\{|\xi_n - a| > \varepsilon\} = 0, \quad \lim_{n \rightarrow \infty} P\{|\eta_n - b| > \varepsilon\} = 0.$$

Доказать, что при любом характере зависимости между ξ_n и η_n для любого $\varepsilon > 0$:

- а) $\lim_{n \rightarrow \infty} P\{|\xi_n - a| < \varepsilon, |\eta_n - b| < \varepsilon\} = 1$;
 б) если функция $f(x, y)$ непрерывна в точке (a, b) , то для любого $\varepsilon > 0$

$$\lim_{n \rightarrow \infty} P\{|f(\xi_n, \eta_n) - f(a, b)| < \varepsilon\} = 1.$$

Ч-4.36

Пусть $\xi^{(i)} = (\xi_1^{(i)}, \xi_2^{(i)})$, $i = 1, 2, \dots$, - независимые одинаково распределенные векторы в R^2 ,

$$M\xi_1^{(i)} = a_1 > 0, \quad M\xi_2^{(i)} = a_2 > 0, \quad i = 1, 2, \dots$$

Доказать, что последовательность случайных величин

$$\eta_n = \frac{\xi_1^{(1)} + \xi_1^{(2)} + \dots + \xi_1^{(n)}}{\xi_2^{(1)} + \xi_2^{(2)} + \dots + \xi_2^{(n)}}, \quad n = 1, 2, \dots$$

сходится по распределению к a_1/a_2 , если либо а) $D_{\xi_1^{(i)}} < \infty$ для некоторого $i > 0$.

Ч-4.37

В последовательности случайных величин $\xi_1, \xi_2, \dots$ случайная величина ξ_n при любом $n = 1, 2, \dots$ имеет геометрическое распределение с параметром q_n , $q_n \rightarrow 0$ ($n \rightarrow \infty$). Найти предельное распределение случайных величин

$$\xi_n = q_n \xi_n \text{ при } n \rightarrow \infty.$$

Ч-4.39

Пусть $\xi_1, \xi_2, \dots$ - последовательность независимых одинаково распределенных случайных величин с математическим ожиданием $a > 0$ и дисперсией $\sigma^2 < \infty$, случайная величина v не зависит от $\xi_1, \xi_2, \dots$ и принимает целые положительные значения, $Mv = b$ и

$$\tau = \xi_1 + \xi_2 + \dots + \xi_v.$$

Найти $M\tau$ и предельное распределение случайной величины $\tau/(M\tau)$, когда распределение v изменяется так, что $Mv \rightarrow \infty$ и существует непрерывная функция распределения $F(x)$, удовлетворяющая условиям $F(0) = 0$,

$$\lim P \left\{ \frac{v}{Mv} \leq x \right\} = F(x), \quad 0 \leq x < \infty.$$

Ч-4.40

Время & безотказной работы прибора имеет математическое ожидание $a > 0$ и дисперсию $\sigma^2 < \infty$. Каждый отказ прибора независимо от предыстории и длин Периодов безотказной работы с вероятностью p является несущественным (прибор требует только наладки), а с вероятностью $q = 1 - p$ - существенным (прибор нужно ремонтировать). Пусть τ_q -время от начала работы прибора до его ремонта.

а) Найти $M\tau_q, D\tau_q$.

б) Найти предельное распределение случайной величины $\tau_q/M\tau_q$, когда параметры $a > 0$ и $\sigma^2 < \infty$ фиксированы, а $q \rightarrow 0$.

Ч-4.44

В бункер помещается не более $N = 150$ деталей. Ежеминутно в бункер поступает случайное число деталей, имеющее распределение Пуассона с параметром $\lambda = 2$; числа деталей, поступающих в бункер в непересекающиеся интервалы времени, независимы. Через каждый час все находящиеся в бункере детали перегружаются в тележку и отправляются на дальнейшую обработку. В патальный момент времени бункер свободен. Пользуясь предельными теоремами, указать приближенное значение вероятности того, что 3 время $T = 100$ часов не произойдет ни одного переполнения бункера.

Ч-4.45

Показать, что если последовательность случайных величин $\xi_1, \xi_2, \dots$ сходится к ξ с вероятностью 1 или в среднем квадратичном, то она сходится по вероятности и по распределению. Привести пример последовательности $\xi_1, \xi_2, \dots$, сходящейся к ξ по вероятности, но не сходящейся ни в среднем квадратичном, ни с вероятностью 1.

Ч-4.46

Последовательность случайных величин $\xi_1, \xi_2, \dots$ сходится к ξ по распределению. Показать, что можно задать на одном вероятностном пространстве случайные величины $\xi'_1, \xi'_2, \dots$ и ξ' так, что для всех x

$$P_1 \{ \xi'_1 \leq x \} = P \{ \xi \leq x \}, \quad P \{ \xi'_n \leq x \} = P \{ \xi_n \leq x \}, \\ n = 1, 2, \dots$$

и последовательность $\xi'_1, \xi'_2, \dots$ сходится (??) с вероятностью 1.

Ч-4.48

Последовательность $\xi_1, \xi_2, \dots$ случайных величин удовлетворяет условиям $P \{ \xi_{n+1} \geq \xi_n \} = 1$ для любого $n = 1, 2, \dots$

$$\lim_{n \rightarrow \infty} M\xi_n = a < \infty.$$

Доказать, что существует случайная величина ξ , для которой

$$P \left\{ \lim_{n \rightarrow \infty} \xi_n = \xi \right\} = 1.$$

Верно ли равенство $\xi = a$?

Ч-4.49

Последовательность точек $\xi_1, \xi_2, \dots$ на отрезке $[0, 1]$ строится по следующему правилу: ξ_1 имеет равномерное распределение на $[0, 1]$, и если заданы $\xi_1, \dots, \xi_{k-1}$ ($k \geq 2$) определены, то точка ξ_k имеет равномерное распределение на минимальном по длине из k отрезков, на которые $[0, 1]$ разбивается точками $\xi_1, \dots, \xi_{k-1}$.

а) Доказать, что существует случайная величина ξ , удовлетворяющая условию $P \{ \lim_{n \rightarrow \infty} \xi_n = \xi \} = 1$.

б) Найти $M\xi, D\xi$.

Ч-4.50

Последовательность точек $\xi_0, \xi_1, \xi_2, \dots$ на отрезке $[0, 1]$ строится по следующему правилу: $\xi_0 = 0, \xi_1$ имеет равномерное распределение на $\{0, 1\}$, а ξ_n при любом $n \geq 2$ имеет равномерное распределение на интервале, образованном ξ_{n-1} и ξ_{n-2} .

- Доказать, что существует случайная величина ξ , удовлетворяющая условию $P\{\lim_{n \rightarrow \infty} \xi_n = \xi\} = 1$.
- Найти $M\xi, D$.

Ч-4.51

*. Последовательность случайных величин $\xi, \xi_2, \dots$, последовательности чисел $\{a_n\}, \{b_n\}$ и случайная величина ξ удовлетворяют условиям

$$\lim_{n \rightarrow \infty} a_n = a, \quad |a| < \infty, \quad \lim_{n \rightarrow \infty} b_n = 0, \quad P\{|\xi| < \infty\} = 1$$

$$\lim_{n \rightarrow \infty} P\left\{\frac{\xi_n - a_n}{b_n} \leq x\right\} = P\{\xi \leq x\}$$

в каждой точке непрерывности функции $F(x) = P\{\xi \leq x\}$. Функция $g(x)$ непрерывно дифференцируема в окрестности точки a и $g'(a) \neq 0$. Доказать, что в каждой точке непрерывности $F(x)$

$$\lim_{n \rightarrow \infty} P\left\{\frac{g(\xi_n) - g(a_n)}{b_n g'(a_n)} \leq x\right\} = F(x).$$

Ч-4.52

Последовательность случайных величин $\xi, \xi_2, \dots$, последовательности чисел $\{a_n\}, \{b_n\}$ и случайная величина ξ удовлетворяют тем же условиям, что в задаче Ч-4.51. Функция $g(x)$ имеет $k \geq 2$ непрерывных производных в окрестности точки a

$$g'(a) = g''(a) = \dots = g^{(k-1)}(a) = 0, \quad g^{(k)}(a) \neq 0.$$

оказать, что

$$\lim_{n \rightarrow \infty} P\left\{\frac{g(\xi_n) - g(a_n)}{b_n^k g^{(k)}(a_n)} \leq x\right\} = P\{\xi^k \leq x\}$$

в каждой точке непрерывности функции $F_k(x) = P\{\xi^k \leq x\}$.

Ч-4.53

Случайная величина μ_n равна числу успехов в n независимых испытаниях Бернулли с вероятностью успеха $p, 0 < p < 1$

- Найти $\lim_{n \rightarrow \infty} P\left\{\frac{(\mu_n - np)^2}{np(1-p)} \leq x\right\}$.

6) Пусть $0 < z < 1, z \neq p$. Найти такие последовательности чисел $A_n(z)$ и $B_n(z), n = 1, 2, \dots$, для которых

$$\lim_{n \rightarrow \infty} P\left\{\frac{(\mu_n - ns)^2 - A_n(z)}{B_n(z)} \leq x\right\} = \Phi(x), \quad -\infty < x < \infty.$$

Ч-4.54

". Случайная величина μ_n равна числу успехов в n независимых испытаниях Бернулли с вероятностью успеха p ; функция $g(x)$ определяется соотношениями

$$g(x) = \begin{cases} x \ln x + (1-x) \ln(1-x), & 0 < x < 1, \\ 0, & x = 0 \text{ или } x = 1. \end{cases}$$

- При $p = 1/2$ найти

$$\lim_{n \rightarrow \infty} P\left\{n \left(g\left(\frac{\mu_n}{n}\right) + \ln 2\right) \leq x\right\} \leftarrow x \geq 0.$$

- При $0 < p < 1, p \neq 1/2$, указать такую последовательность $B_n(p), n = 1, 2, \dots$ что

$$\lim_{n \rightarrow \infty} P\left\{B_n(p) \left(g\left(\frac{\mu_n}{n}\right) - g(p)\right) \leq x\right\} = \Phi(x), \quad -\infty < x < \infty.$$

6.5.3 Problems About Characteristic and Producing Functions

В этом параграфе задачи п4.58-п4.83 связаны с вычислением производящих функций, моментов случайных величин и характеристических функций, в задачах п4.84-п4.99 рассматриваются различные свойства характеристических функций, а в задачах п4.100-п4.104 вычисляются характеристические функции специальных распределений и исследуются свойства многомерного нормального распределения.

Ч-4.58

Найти производящие функции целотисленных распределений:

- а) пуассоновского: $P\{\xi = k\} = \frac{\lambda^k}{k!} e^{-\lambda}, \quad k = 0, 1, 2, \dots, 0 < \lambda < \infty$
- б) геометрического: $P\{\xi = k\} = pq^k, k = 0, 1, 2, \dots; p, q > 0, p + q = 1;$
- в) биномиального: $P\{\xi = k\} = C_n^k p^k q^{n-k}, k = 0, 1, \dots, n; p, q > 0, p + q = 1.$

Ч-4.59

Найти производящую функцию $\varphi(z)$ числа ξ_n успехов в n независимых испытаниях, если вероятность успеха в каждом испытании равна p . Используя этот результат, найти формулы для $M\xi_n, M_n^{[k]} (k = 1, 2, \dots)$,

Ч-4.60

Производящая функция распределения случайной величины ξ , принимающей целые неотрицательные значения, равна $\varphi(z) = Mz^\xi$.

- а) Найти $M\xi, D\xi, M(\xi - M\xi)^3$.
- б) Найти производящие функции $\varphi_i(z) = Mz^{\xi_i}$ случайных величин $\xi_1 = \xi/2, \xi_2 = 2\xi, \xi_3 = -\xi$ и $\xi_4 = \xi_1 - \xi_2$ где ξ_1 и ξ_2 - независимые случайные величины, имеющие то же распределение, что ξ .
- в) Доказать, что при $b > a > 0$

$$M \frac{1}{\xi + a} = \int_0^1 z^{a-1} \varphi(z) dz$$

$$M \frac{1}{(\xi + a) \left(\frac{\xi}{b} + 1 \right)} = \int_0^1 z^{b-a-1} \int_0^1 u^{a-1} \varphi(u) du dz.$$

Ч-4.61

Пусть τ_1 - порядковый номер первого из испытаний схемы Бернулли (т. е. последовательности независимых испытаний), которое окончилось успехом, вероятность успеха в каждом испытании равна p , неудачи $-q = 1 - p$. Найти $M\tau_1, D\tau_1, Mz^{\tau_1}$.

Ч-4.62

В схеме Вернулли обозначим через θ_k порядковый номер испытания, в котором появился k -й успех; считая вероятность успеха в каждом испытании равной p , найти: 1) $M\theta_k, D\theta_k$; 2) $\varphi_{\theta_k}(z) = Mz^{\theta_k}$.

Ч-4.63

Закон распределения случайной величины ξ определяется формулой

$$P\{\xi = n\} = C_{n-1}^{m-1} p^m q^{n-m} \quad n = m, m+1, \dots,$$

где m -целое положительное число, $0 < p < 1, q = 1 - p$. Найти производящую функцию распределения суммой m независимых одинаково распределенных случайных величин.

Ч-4.66

Производящая функция совместного распределения величин ξ, ξ_2 равна

$$\varphi_{\xi_1, \xi_2}(z) = e^{\lambda(p_1 z_1 + p_2 z_2 + p_3 z_1 z_2 - 1)}$$

где $p_1 + p_2 + p_3 = 1, p_i \geq 0, i = 1, 2, 3$. Найти:

- а) одномерные распределения ξ и ξ_2 ;
- б) $M\xi_1, M\xi_2, D\xi_1, D\xi_2, \text{cov}(\xi_1, \xi_2)$. Являются ли величины ξ_1 и ξ_2 независимыми?

Ч-4.67

Целочисленная неотрицательная случайная величина ξ имеет производящую функцию $\varphi_{\xi}(z)$. Доказать, что если для целого $k \geq 1$

$$\lim_{u \uparrow 1} \frac{d^k}{dz^k} \varphi_{\xi}(z) \Big|_{z=u} = m_k < \infty$$

то $M\xi^{[k]} = M\xi(\xi-1)\dots(\xi-k+1) = m_k$.

Ч-4.68

Пусть $\xi_{n,i}$ - число появлений i -го исхода в n независимых испытаниях с N несовместными исходами и вероятностью p_j появления j -го исхода в каждом испытании ($j = 1, \dots, N$). Найти

а) $\varphi(z_1, \dots, z_N) = Mz_1^{n,1} \dots z_N^{n,N}$,

Ч-4.69

Пусть выполнены условия предыдущей задачи и $N = 4$,

$$\begin{aligned} \eta_{n,1} &= \xi_{n,1}, & \eta_{n,2} &= \xi_{n,2} + \xi_{n,3}, & \eta_{n,3} &= \xi_{n,4}, \\ \xi_{n,i} &= \xi_{n,1} + \xi_{n,i+1} \quad (i = 1, 2, 3). \end{aligned}$$

Найти производящие функции распределений векторов $(\eta_{n,1}, \eta_{n,2}, \eta_{n,3})$, $(\zeta_{n,1}, \zeta_{n,2}, \zeta_{n,3})$ и коэффициенты корреляции $\rho(\eta_{n,1}, \eta_{n,2})$, $\rho(\zeta_{n,1}, \zeta_{n,2})$.

Ч-4.73

Найти характеристические функции распределений:

- а) пуассоновского: $P\{\xi = m\} = \frac{\lambda^m}{m!} e^{-\lambda}$, $m = 0, 1, \dots$;
 б) биномиального: $P\{\xi = m\} = C_n^m p^m q^{n-m}$, $m = 0, 1, \dots, n$;
 в) показательного: $p_{\lambda}(x) = \alpha e^{-\alpha x}$, $x > 0$.

Ч-4.74

Случайные величины $\xi_1, \xi_2, \dots$ независимы и имеют показательное распределение с параметром α :

$$P\{\xi_i \leq x\} = 1 - e^{-\alpha x}, \quad x \geq 0, \quad i = 1, 2, \dots$$

Найти $M(\xi_1 + \dots + \xi_n)^n$ при любых значениях $k, n = 1, 2, \dots$

Ч-4.75

Случайные величины $\xi_1, \xi_2, \dots$ независимы, одинаково распределены и имеют характеристическую функцию $f(t) = Me^{it_1}$ (производящую функцию $\varphi(s) = Ms^{\xi_1}$), случайная величина v не зависит от $\xi_1, \xi_2, \dots$ принимает только целые неотрицательные значения и имеет производящую функцию $g(s) = Ms^2$. Найти характеристическую функцию (производящую функцию) случайной величины

$$\xi = \begin{cases} \xi_1 + \xi_2 + \dots + \xi_v & \text{при } v \geq 1 \\ 0 & \text{при } v = 0 \end{cases}$$

Ч-4.76

Производящая функция распределения случайной величины ξ_1 принимающей целые неотрицательные значения, равна $\varphi(z) = Mz^{\xi_1}$. Выяснить, при каких условиях следующие выражения являются производящими функциями вероятностных распределений, и если являются, то указать, как соответствующие распределения связаны с распределением ξ :

- а) $\psi(z) = \frac{\varphi'(z)}{\varphi'(1)^r}$ б) $\psi(z) = \frac{1-\varphi(z)}{\varphi'(1)(1-z)^s}$
 в) $\psi(z) = \frac{1-\alpha}{1-\alpha\varphi(z)}$ г) $\psi(z) = 1 - \frac{\ln \varphi(z)}{\ln \varphi(0)^s}$
 а) $\psi(z) = \sqrt{\frac{1-\alpha}{1-\alpha\varphi(z)}}$

Ч-4.80

Случайные величины $\xi_1, \xi_2, \dots, \xi_n$ независимы. Доказать, что для любого действительного λ , удовлетворяющего условиям

$$Me^{\lambda \xi_i} < \infty \quad t = 1, \dots, n$$

справедливо равенство

$$Me^{\lambda(\xi_1 + \dots + \xi_n)} = \prod_{j=1}^n Me^{\lambda \xi_j}.$$

Ч-4.81

Случайная величина принимает действительные значения. Доказать, что для любого действительного x

$$P\{\xi \geq x\} \leq \inf_{\lambda > 0} e^{-\lambda x} Me^{\lambda \xi}$$

$$P\{\xi \leq x\} \leq \inf_{\lambda > 0} e^{\lambda x} Me^{-\lambda \xi}$$

Ч-4.88

Случайная величина ξ имеет нормальное распределение с параметрами $(0, \sigma^2)$. Установив тождество

$$\frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{hx^2} e^{-x^2/2\sigma^2} dx = \frac{1}{\sqrt{1-2h\sigma^2}}, \quad h < \frac{1}{2\sigma^2},$$

$$\eta = \xi e^{h\xi^2}.$$

Ч-4.89

Функция $f(t)$, $-\infty < t < \infty$, обладает следующими свойствами:

- а) $f(0) = 1, f(t) \geq 0$ для любого t ; 6) $f(t) = f(-t)$ для любого t ;
- в) графиком $f(t)$, $0 \leq t < \infty$, является выпуклая вниз ломаная линия, состоящая из конечного числа звеньев. Является ли $f(t)$ характеристической функцией распределения вероятностей?

Ч-4.90

Функция $f(t)$, $-\infty < t < \infty$, обладает следующими свойствами: $f(0) = 1, f(t) \geq 0, f(t) = f(-t)$ для любого t , $f(t)$ непрерывна и $f''(t) \geq 0$ для любого $t \neq 0$. Является ли $f(t)$ характеристической функцией распределения вероятностей?

Ч-4.91

Пусть $a > 0$ и функция $f_1(t)$ имеет период $4a$,

$$f_1(t) = 1 - \frac{|t|}{a}, \quad |t| \leq 2a.$$

- а) Является ли $f_1(t)$ характеристической функцией?
- б) Является ли характеристической функцией функция $f_2(t) = |f_1(t)|$?

Ч-4.92

Случайные величины $\xi_1, \dots, \xi_k$ ($k > 1$) независимы и имеют функцию распределения $F(x)$, случайные величины $\eta_1, \dots, \eta_k$ независимы и имеют функцию распределения $G(x)$. Следует ли из условия

$$P\{\xi_1 + \dots + \xi_k \leq x\} = P\{\eta_1 + \dots + \eta_k \leq x\}$$

для каждого x совпадение функций распределения $F(x)$ и $G(x)$?

Ч-4.96

*. Характеристическая функция $f(t) = Me^{it\xi}$ удовлетворяет условию $|f''(0)| < \infty$. Показать, что

$$M\xi^2 = -f''(0).$$

Ч-4.97

Показать, что если характеристическая функция $f(t) = Me^{it?}$ дважды дифференцируема при $t = 0$ и $|f''(0)| < \infty$, то $|f'(t)| < \sqrt{|f''(0)|}$ при любом t .

Ч-4.9

8. Являются ли характеристическими функциями вероятностных распределений следующие функции:

- а) $e^{2(e^{it}-1)}$; б) $\cos(t^2)$; в) $\frac{\sin t}{t}(t \neq 0), 1 (t = 0)$; г) $\cos^2 t$; д) $e^{-2t}(t \geq 0), \frac{1}{1+t^2} (t \leq 0)$; е) $\cos(|t|^{2/3})$; ж) $e^{-|t|}$?

Ч-4.99

Найти математическое ожидание и дисперсию случайной величины ξ , характеристическая функция $f(t) = Me^{it\xi}$ которой равна:

- а) $\frac{1}{at} \sin at (a \neq 0)$, б) $\frac{4}{t^2} \cos t \sin^2 \frac{t}{2}$, в) $\frac{4}{t^2} e^{it} \sin^2 \frac{t}{2}$, г) $\sqrt{2} e^{-a|t|/2} \sin\left(\frac{\pi}{4} + \frac{a|t|}{\sqrt{2}}\right) (a > 0)$,

Ч-4.10

1. Исходя из формулы для плотности гамма-распределения (см. введения к гл. 3 и 4), проверить, что если случайные величины ξ_1 и ξ_2 независимы, ξ_1 имеет гамма-распределение с параметром α , а ξ_2 - гамма-распределение с параметром β , то $\xi_1 + \xi_2$ имеет гамма-распределение с параметром $\alpha + \beta$. Используя это свойство семейства гамма-распределений, найти характеристическую функцию $f_a(t)$ и формулы для моментов $m_a^{(k)}(k = 1, 2, \dots)$ k -го порядка гамма-распределения с параметром $\alpha > 0$.

Ч-4.10

2. Случайный вектор $(\xi_1, \dots, \xi_k)$ имеет многомерное нормальное распределение в R^k с вектором математических ожиданий $a = (a_1, \dots, a_k)$ и матрицей ковариаций B . Найти распределение случайной величины

$$\zeta = c_1 \xi_1 + \dots + c_k \xi_k,$$

где $c_1, \dots, c_k$ - действительные числа.

Ч-4.10

3. Случайный вектор $(\xi_1, \dots, \xi_m)$ имеет многомерное нормальное распределение в R^k с вектором математических ожиданий $a = (a_1, \dots, a_m)$ и матрицей ковариаций B ; матрица $C = c_{ij}$ ($i = 1, \dots, m; j = 1, \dots, k$) состоит из действительных чисел. Найти распределение случайного вектора $(\xi_1, \dots, \xi_m)$, где

$$\xi_i = c_{i1} \xi_1 + \dots + c_{ik} \xi_k, \quad i = 1, \dots, m.$$

Ч-4.104

Случайный вектор $\xi = (\xi_1, \dots, \xi_k)$ имеет многомерное нормальное распределение в R^k с вектором математических ожиданий $a = (a_1, \dots, a_n)$ и невырожденной матрицей ковариаций B . Показать, что существует такое ортогональное преобразование C пространства R^k в себя, что вектор $\eta = (\eta_1, \dots, \eta_k) = C\xi$ имеет многомерное нормальное распределение с независимыми компонентами.

МФТИ-Т.9

Найти характеристическую функцию распределения Лапласа, которое определяется плотностью

$$f_\xi(x) = \frac{1}{2} e^{-|x|}$$

$$\phi_\xi(t) = \int_{-\infty}^{+\infty} \exp(itx) f_\xi(x) dx = \frac{1}{2} \int_{-\infty}^{+\infty} \exp(itx - |x|) dx$$

$x < 0$

$$\int_{-\infty}^0 \exp(itx - |x|)d(x) = \int_{-\infty}^0 \exp(itx + x)d(x) = \frac{i}{i-t}$$

$$x \geq 0$$

$$\int_0^{+\infty} \exp(itx - |x|)d(x) = \int_0^{+\infty} \exp(itx - x)d(x) = \frac{i}{i+t}$$

$$\phi_{\xi}(t) = \frac{-1}{(-1-t^2)} = \frac{1}{1+t^2}$$

МФТИ-Т.10

Найти характеристическую функцию нормального распределения с параметрами (a, σ^2)

$$\begin{aligned} \phi_{\xi}(t) &= \int_{-\infty}^{+\infty} \exp(itx) \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(x-a)^2}{2\sigma^2}\right) d(x) = \frac{1}{\sqrt{2\pi\sigma^2}} \int_{-\infty}^{+\infty} \exp\left(itx - \frac{(x-a)^2}{2\sigma^2}\right) d(x) = \\ &= \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(ita + \left(\frac{it\sqrt{2}\sigma}{2}\right)^2\right) \int_{-\infty}^{+\infty} \exp\left(-\frac{(x-a)^2}{2\sigma^2} + 2\frac{it\sqrt{2}\sigma}{2} \frac{(x-a)}{\sqrt{2}\sigma} - \left(\frac{it\sqrt{2}\sigma}{2}\right)^2\right) d(x) = \\ &= \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(ita + \left(\frac{it\sqrt{2}\sigma}{2}\right)^2\right) \int_{-\infty}^{+\infty} \exp\left(-\left(\frac{x-a}{\sqrt{2}\sigma} - \frac{it\sqrt{2}\sigma}{2}\right)^2\right) d(x) = \\ &= \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(ita + \left(\frac{it\sqrt{2}\sigma}{2}\right)^2\right) \int_{-\infty}^{+\infty} \exp\left(-\left(\frac{x-a-it\sigma^2}{\sqrt{2}\sigma}\right)^2\right) d(x) = \frac{1}{\sqrt{2\sigma^2}} \exp\left(ita - \frac{t^2\sigma^2}{2}\right) \end{aligned}$$

МФТИ-Т.11

Найти распределения, которым соответствуют следующие характеристические функции:

$$h_1(t) = \cos t; \quad h_2(t) = \frac{1}{2} + \frac{\cos t}{2} + i \frac{\sin t}{6}; \quad h_3(t) = \frac{1}{2 - e^{-it}}$$

для первой:

$$h_1(t) = \cos(t) = \frac{\exp(it) + \exp(-it)}{2} \rightarrow f_1(x) = \frac{1}{2}I(x=1) + \frac{1}{2}I(x=-1)$$

Для второй:

$$h_2(t) = \frac{1}{2} + \frac{\cos(t)}{2} + i \frac{\sin(t)}{6} = \frac{1}{2} \exp(it \cdot 0) + \frac{\exp(it) + \exp(-it)}{4} + i \frac{\exp(it) - \exp(-it)}{12}$$

поэтому

$$f_2(x) = \frac{1}{2}\delta(x) + \frac{1}{4}\delta(x-1) + \frac{1}{4}\delta(x+1) + i \frac{1}{12}\delta(x-1) - i \frac{1}{12}\delta(x+1)$$

для третьей:

$$h_3(t) = \frac{1}{2 - \exp(-it)} = \frac{\frac{1}{2}}{1 - \frac{\exp(-it)}{2}} = \sum_{n=0}^{+\infty} \left(\frac{\exp(itn)}{2^{n+1}} \right)$$

$$f_3(x) = \sum_{n=0}^{+\infty} \left(\frac{1}{2^{n+1}} I(x=n) \right)$$

МФТИ-Т.12 распределение, у которого хар функция $h(t) = e^{-t^2} \cos t$

Найти распределение, которому соответствует характеристическая функция $h(t) = e^{-t^2} \cos t$
(!?!? просто посчитать интеграл?? мб потом упрощу вычисления??!)

$$\begin{aligned}
 f(x) &= \int_{-\infty}^{+\infty} \exp(-t^2) \cos(t) \exp(-itx) d(t) = \\
 &= \int_{-\infty}^{+\infty} \frac{\exp(-t^2 - itx + it) + \exp(-t^2 - itx - it)}{2} d(t) = \\
 &= \int_{-\infty}^{+\infty} \frac{\exp(-t^2 - it(x-1)) + \exp(-t^2 - it(x+1))}{2} d(t) = \\
 &= \int_{-\infty}^{+\infty} \frac{\exp\left(-t^2 - 2t\frac{x-1}{2}i - \left(\frac{x-1}{2}i\right)^2 + \left(\frac{x-1}{2}i\right)^2\right) + \exp\left(-t^2 - 2t\frac{x+1}{2}i - \left(\frac{x+1}{2}i\right)^2 + \left(\frac{x+1}{2}i\right)^2\right)}{2} d(t) = \\
 &= \int_{-\infty}^{+\infty} \frac{\exp\left(-\left(t + \frac{x-1}{2}i\right)^2 + \left(\frac{x-1}{2}i\right)^2\right) + \exp\left(-\left(t + \frac{x+1}{2}i\right)^2 + \left(\frac{x+1}{2}i\right)^2\right)}{2} d(t) = \\
 &= \int_{-\infty}^{+\infty} \frac{\exp\left(-\left(t + \frac{x-1}{2}i\right)^2\right) \exp\left(\left(\frac{x-1}{2}i\right)^2\right) + \exp\left(-\left(t + \frac{x+1}{2}i\right)^2\right) \exp\left(\left(\frac{x+1}{2}i\right)^2\right)}{2} d(t) = \\
 &= \sqrt{\pi} \frac{\exp\left(-\left(\frac{x-1}{2}\right)^2\right) + \exp\left(-\left(\frac{x+1}{2}\right)^2\right)}{2}
 \end{aligned}$$

Вот такому распределению.

МФТИ-Т.13 Характеристическая ли $h(t) = \cos t^2$

Является ли функция $h(t) = \cos t^2$ характеристической?

$\cos(t^2)$ не является равномерно непрерывной на $\mathbb{R}$, а следовательно, и не может быть характеристической функцией.

Докажем это.

Нужно доказать, что

$$\exists \epsilon > 0 : \forall \delta > 0 \exists t_1, t_2 |t_2 - t_1| < \delta \Rightarrow |\cos(t_2^2) - \cos(t_1^2)| \geq \epsilon$$

Найдём решения уравнения $\cos(t^2) = 1$:

$$t^2 = 2\pi n, n \in \mathbb{N} \cup \{0\}$$

Найдём решения уравнения $\cos(t^2) = -1$:

$$t^2 = 2\pi n - \pi, n \in \mathbb{N}$$

Пусть $t_1 = \sqrt{2\pi n}, t_2 = \sqrt{2\pi n - \pi}$. МФТИ-Тогда $|\cos(t_2^2) - \cos(t_1^2)| = 2 = \epsilon$

$$|t_2 - t_1| = |\sqrt{2\pi n} - \sqrt{2\pi n - \pi}| = \frac{\pi}{\sqrt{2\pi n} + \sqrt{2\pi n - \pi}} < \sqrt{\frac{\pi}{n}} \rightarrow n > \frac{\pi}{\delta^2} \rightarrow$$

$$\exists \epsilon = 2 : \forall \delta > 0 \exists t_1 = \sqrt{2\pi n}, t_2 = \sqrt{2\pi n - \pi}, n > \frac{\pi}{\delta^2}, |t_2 - t_1| < \delta \Rightarrow |\cos(t_2^2) - \cos(t_1^2)| \geq \epsilon$$

Доказали.

МФТИ-Т.14 Предел среднего от хар функции (!??!)

Случайная величина ξ_λ распределена по закону Пуассона с параметром λ . Найти

$$\lim_{\lambda \rightarrow \infty} \mathbf{P} \left(\frac{\xi_\lambda - \lambda}{\sqrt{\lambda}} \leq x \right)$$

Рассмотрим, к чему стремится характеристическая функция случайной величины $\eta = \frac{\xi_\lambda - \lambda}{\sqrt{\lambda}}$.

$$\begin{aligned} \phi_\eta(t) &= \mathbb{E} \left(\exp \left(it \frac{\xi_\lambda - \lambda}{\sqrt{\lambda}} \right) \right) = \exp(-it\sqrt{\lambda}) \mathbb{E} \left(\exp \left(it \frac{\xi_\lambda}{\sqrt{\lambda}} \right) \right) = \\ &= \exp(-it\sqrt{\lambda}) \exp \left(\lambda \left(\exp \left(\frac{it}{\sqrt{\lambda}} \right) - 1 \right) \right) = \exp \left(-it\sqrt{\lambda} + \lambda \left(\exp \left(\frac{it}{\sqrt{\lambda}} \right) - 1 \right) \right) \end{aligned}$$

И предел

$$\begin{aligned} \lim_{\lambda \rightarrow +\infty} \phi_\eta(t) &= \lim_{\lambda \rightarrow +\infty} \exp \left(-it\sqrt{\lambda} + \lambda \left(\exp \left(\frac{it}{\sqrt{\lambda}} \right) - 1 \right) \right) = \\ &= \lim_{\lambda \rightarrow +\infty} \exp \left(-it\sqrt{\lambda} + \lambda \left(1 + \frac{it}{\sqrt{\lambda}} + \frac{1}{2} \left(\frac{it}{\sqrt{\lambda}} \right)^2 + o \left(\left(\frac{t}{\sqrt{\lambda}} \right)^2 \right) - 1 \right) \right) = \\ &= \lim_{\lambda \rightarrow +\infty} \exp \left(-it\sqrt{\lambda} + \lambda \left(\frac{it}{\sqrt{\lambda}} - \frac{1}{2} \frac{1}{\lambda} t^2 + o \left(\left(\frac{t}{\sqrt{\lambda}} \right)^2 \right) \right) \right) \\ &= \lim_{\lambda \rightarrow +\infty} \exp \left(-\frac{1}{2} t^2 + o \left(\left(\frac{t}{\sqrt{\lambda}} \right)^2 \right) \right) = \exp \left(-\frac{1}{2} t^2 \right) \\ \lim_{\lambda \rightarrow +\infty} \left(P \left(\frac{\xi_\lambda - \lambda}{\sqrt{\lambda}} \leq x \right) \right) &= \int_{-\infty}^x \exp \left(-\frac{1}{2} t^2 \right) d(t) = \Phi(x) \end{aligned}$$

МФТИ-Т.15

Используя результат предыдущей задачи, найти предел

$$\lim_{n \rightarrow \infty} e^{-n} \sum_{k=n}^n \frac{n^k}{k!}$$

Так как

$$\begin{aligned} \Phi(x) &= \lim_{\lambda \rightarrow +\infty} P \left(\frac{\xi_\lambda - \lambda}{\sqrt{\lambda}} \leq x \right) = \lim_{\lambda \rightarrow +\infty} P \left(\xi_\lambda \leq \sqrt{\lambda}x + \lambda \right) = \\ &= \lim_{\lambda \rightarrow +\infty} \left[\exp(-\lambda) \sum_{k=1}^{\lfloor \sqrt{\lambda}x + \lambda \rfloor} \left(\frac{\lambda^k}{(k)!} \right) \right] = \lim_{\lambda \rightarrow +\infty} \left[\exp(-\lambda) \left(\sum_{k=1}^{\lfloor \lambda \rfloor} \frac{\lambda^k}{(k)!} + \sum_{k=\lfloor \lambda \rfloor + 1}^{\lfloor \sqrt{\lambda}x + \lambda \rfloor} \frac{\lambda^k}{(k)!} \right) \right] \end{aligned}$$

Теперь рассмотрим случай $\lambda \in \mathbb{N}$:

$$\begin{aligned} \Phi(x) &= \lim_{n \rightarrow +\infty} \left(e^{-n} \left(\sum_{k=1}^n \left(\frac{n^k}{(k)!} \right) + \sum_{k=n+1}^{\lfloor \sqrt{n}x + n \rfloor} \frac{n^k}{(k)!} \right) \right) \\ \Phi(x) &= \lim_{n \rightarrow +\infty} \left[\exp(-n) \sum_{k=n+1}^{\lfloor \sqrt{n}x + n \rfloor} \left(\frac{n^k}{(k)!} \right) \right] + \lim_{n \rightarrow +\infty} \left[\exp(-n) \sum_{k=1}^n \left(\frac{n^k}{(k)!} \right) \right] \end{aligned}$$

Возьмём теперь предел $x \rightarrow +\infty$:

$$\Phi(+\infty) = 1 = \lim_{n \rightarrow +\infty} \left(\exp(-n) \sum_{k=1}^n \left(\frac{n^k}{(k)!} \right) \right)$$

6.5.4 Problems About Bonferroni Inequalities and Convergence to the Poisson Distribution (???)

МФТИ-Т.16.

Пусть положительные независимые случайные величины $\xi_{m,n}$ $m = 1, 2, \dots, n$ одинаково распределены с плотностью $\alpha_n e^{-\alpha_n x}$, $x > 0$, где $\alpha_n = \lambda n$ и $\lambda > 0$. Найти предельное при $n \rightarrow \infty$ распределение случайной величины $\xi_n = \sum_{m=1}^n \xi_{m,n}$

$$f(x) = \alpha_n \exp(-\alpha_n x) = \lambda n \exp(-\lambda n x)$$

Найдём характеристическую функцию случайной величины $\xi_{m,n}$:

$$\begin{aligned} \phi_{\xi_{m,n}}(t) &= \mathbb{E}(\exp(itx)) = \int_{\mathbb{R}^+} \lambda n \exp(-\lambda n x) \exp(itx) dx = \lambda n \int_{\mathbb{R}^+} \exp(-\lambda n x) \exp(itx) dx = \\ &= \int_{\mathbb{R}^+} \lambda n \exp(-\lambda n x) \exp(itx) dx = - \int_{\mathbb{R}^+} \frac{\partial}{\partial x} (\exp(-\lambda n x)) \exp(itx) dx = \\ &= it \int_{\mathbb{R}^+} \exp(-\lambda n x) \exp(itx) dx - (\exp(-\lambda n x) \exp(itx))|_{x=0}^{x \rightarrow +\infty} = it \int_{\mathbb{R}^+} \exp(-\lambda n x) \exp(itx) dx + 1 \rightarrow \\ &\rightarrow \phi_{\xi_{m,n}}(t) = \int_{\mathbb{R}^+} \lambda n \exp(-\lambda n x) \exp(itx) dx = \frac{\lambda n}{\lambda n - it} = 1 - \frac{it}{it - \lambda n} \end{aligned}$$

Найдём предел характеристических функций:

$$\begin{aligned} \phi(t) &= \lim_{n \rightarrow +\infty} \left(\phi_{\sum_{m=1}^n \xi_{m,n}}(t) \right) = \lim_{n \rightarrow +\infty} \left(\left(1 - \frac{1}{1 - \frac{\lambda n}{it}} \right)^n \right) = \lim_{n \rightarrow +\infty} \left(\exp \left(n \ln \left(1 - \frac{1}{1 - \frac{\lambda n}{it}} \right) \right) \right) \\ &= \lim_{n \rightarrow +\infty} \left(\exp \left(-\frac{1}{\frac{1}{n} - \frac{\lambda}{it}} \right) \right) = \exp \left(\frac{it}{\lambda} \right) \\ f(x) &= I \left(x = \frac{1}{\lambda} \right) \end{aligned}$$

6.5.4 Problems About Bonferroni Inequalities and Convergence to the Poisson Distribution (???)

(???)

Ч-4.105

Случайные величины $\xi_1^{(n)}, \xi_2^{(n)}, \dots, \xi_n^{(n)}$ независимы, $P\{\xi_k^{(n)} = 1\} = 1 - P\{\xi_k^{(n)} = 0\} = p_k(n)$, $k = 1, 2, \dots, n$. Пусть при $n \rightarrow \infty$ $\max_{1 \leq k \leq n} p_k(n) \rightarrow 0$, $p_1(n) + \dots + p_n(n) \rightarrow \lambda$, $0 < \lambda < \infty$. Используя метод производящих функций, доказать, что

$$\lim_{n \rightarrow \infty} P\{\xi_1^{(n)} + \dots + \xi_n^{(n)} = m\} = \frac{\lambda^m}{m!} e^{-\lambda}, \quad m = 0, 1, 2, \dots$$

ФР Вшэ

1. Стрельба по цели ведется до тех пор, пока суммарное число попаданий не достигнет N . Найдите математическое ожидание, дисперсию, а также функцию распределения вероятностей потребовавшегося числа выстрелов k , если выстрелы производятся независимо друг от друга и вероятность попадания в отдельной попытке равна p .

(!! тут вообще жесткие задачи, про них почти не думал, потом подумаю.)

Число выстрелов, требуемое чтобы получить N попаданий можно представить в виде суммы $k = k_1 + k_2 + \dots + k_N$, где k_n - это число выстрелов которое потребовалось для достижения n -го попадания, если отсчитывать от предыдущего попадания (или от начала стрельбы, если речь идет об $n = 1$). В силу отсутствия памяти о процесса Бернулли слагаемые статистически независимы. Каждое из них при этом

6.5.4 Problems About Bonferroni Inequalities and Convergence to the Poisson Distribution (???)

имеет геометрическую функцию распределения вероятностей, заданную формулой (4). Воспользовавшись результатами, изложенными на третьей лекции и уравнением (5) и (7), запишем для случая произвольной вероятности p успеха в отдельном испытании

$$\mu_k = N\mu_{k_1} = \frac{N}{p},$$
$$\sigma_k^2 = N\sigma_{k_1}^2 = N\frac{1-p}{p^2}.$$

Чтобы получить функцию распределения вероятностей $p(k)$ нужно умножить вероятность получить ровно $N-1$ попаданий в серии из первых $k-1$ выстрелов на вероятность попадания в k -м исходе, то есть

$$p(k) = pB(N-1, k-1, p) = \frac{(k-1)!}{(N-1)!(k-N)!} p^N (1-p)^{k-N}$$

Этот результат известен как распределение Паскаля.

ФР Вшэ

2. Найти среднее число бросков симметричной монетки необходимое чтобы каждая ее сторона выпала хотя бы два раза.

Подбросим монетку три раза. С вероятностью $1/4$ все три исхода будут одинаковы, и тогда среднее оставшееся число попыток, требуемое для накопления двух недостающих исходов, равно $2+2=4$. С вероятностью $3/4$ не все исходы первых трех попыток одинаковы, и тогда, чтобы получить недостающий исход второй раз, в среднем придется подбросить монетку еще 2 раза. В итоге получаем, что среднее число бросков симметричной монетки необходимое чтобы каждая ее сторона выпала хотя бы два раза равно

$$\frac{1}{4}(3+4) + \frac{3}{4}(3+2) = \frac{22}{4} = 5.5$$

ФР Вшэ

3. Симметричный игральный кубик подбрасывают раз за разом. Найти среднее число попыток $\langle k \rangle$, необходимое, чтобы каждая из шести граней выпала хотя бы один раз. Найти также дисперсию требуемого числа попыток.

Обозначим через $k(p)$ число попыток, требуемых, чтобы в серии испытаний Бернулли впервые выпала единица, если вероятность получить единицу в отдельном испытании равна p . На каждом шаге случайного эксперимента с кубиком пространство элементарных исходов можно разделить на две группы: те исходы, которые уже выпадали, и те, что еще не выпадали. Каждый раз, когда в очередном исходе будет выпадать еще не наблюдавшаяся грань кубика, будем добавлять ее к списку уже произошедших исходов, и, соответственно, уменьшать на единицу количество исходов в группе еще ни разу не выпадавших. Тогда, если в текущий момент первая группа состоит из m исходов (неважно каких именно), то в следующем броске с вероятностью $(6-m)/6$ выпадет еще не наблюдавшийся исход, а с вероятностью $m/6$ повторится один из уже нам встречавшихся. Из сказанного становится ясным, что случайную величину k , математическим ожиданием которой мы интересуемся, можно представить в виде суммы

$$k = 1 + k_1\left(\frac{5}{6}\right) + k_1\left(\frac{2}{3}\right) + k_1\left(\frac{1}{2}\right) + k_1\left(\frac{1}{3}\right) + k_1\left(\frac{1}{6}\right)$$

где $k_1(p)$ - это время появления первой единицы в серии испытаний Бернулли с вероятностью получить единицу в отдельном исходе равной p . Усредняя, получаем

$$\langle k \rangle = 1 + \left\langle k_1\left(\frac{5}{6}\right) \right\rangle + \left\langle k_1\left(\frac{2}{3}\right) \right\rangle + \left\langle k_1\left(\frac{1}{2}\right) \right\rangle + \left\langle k_1\left(\frac{1}{3}\right) \right\rangle + \left\langle k_1\left(\frac{1}{6}\right) \right\rangle = 14,7$$

где мы использовали Ур. (5).

ФР Вшэ

4. Сколько в среднем раз необходимо подбросить симметричную монетку, чтобы впервые встретить в последовательности исходов реализацию вида "орел, решка"?

Для соответствующей случайной величины справедливо

$$k = k_1^o + k_1^p,$$

а значит

$$\langle k \rangle = \langle k_1^o \rangle + \langle k_1^p \rangle = \frac{1}{p} + \frac{1}{1-p} = \frac{1}{p(1-p)}.$$

В частности, для симметричной монетки находим, что для появления пары "орел, решка" необходимо в среднем подкинуть монетку $\langle k \rangle = 4$ раз. Отметим, что среднее число попыток, необходимое для появления пары "орел,орел" равно 6.

ФР Вшэ

5. Сколько в среднем раз необходимо подбросить симметричную монетку, чтобы впервые встретить в последовательности исходов реализацию вида "десять орлов подряд"?

Для ответа на поставленный вопрос, рассмотрим схему Бернулли, где единица соответствует выпадению орла, а ноль - выпадению решки. Будем решать задачу в общем случае, когда вероятность выпадения единицы в отдельном испытании равна p , и речь идет об ожидании цепочки исходов из N единиц подряд. Количество попыток, требуемое для реализации первой такой цепочки обозначим через k . Каждая последовательность независимых повторений эксперимента Бернулли характеризуется некоторым количеством нулей, выпавших до первого появления единицы, и количеством единиц, выпавших подряд сразу вслед за этим. Если число идущих подряд единиц в первой встретившейся цепочке единиц меньше чем N , то можно считать, что процесс ожидания цепочки из N единиц подряд начинается заново в том смысле, что оставшееся число попыток k' необходимое для выпадения N единиц подряд имеет ту же статистику, что и k . Сказанное может быть записано в форме уравнения

$$k = k_1^0 + (N - 1) \cdot I(k_1^P > N - 1) + (k_1^P + k') I(k_1^P \leq N - 1)$$

где нами были введены следующие обозначения: k_1^0 - номер попытки в цепочке независимых испытаний Бернулли, когда впервые выпадает единица, k_1^P - номер попытки в цепочке независимых испытаний Бернулли, когда впервые выпадает ноль, k' - независимая реализация случайной величины k , $I(\dots)$ - индикаторная функция. Рекурсивное соотношение (43) представляет собой пример того, что называется уравнением обновления.

Произведем статистическое усреднение

$$\langle k \rangle = \langle k_1^0 \rangle + (N - 1) \cdot \langle I(k_1^P > N - 1) \rangle + \langle k_1^P I(k_1^P \leq N - 1) \rangle + \langle k' I(k_1^P \leq N - 1) \rangle.$$

Словом, мы приравняли друг другу математические ожидания левой и правой частей Ур. (43). В силу отсутствия памяти у процесса Бернулли, k_1^0 и k' это статистически независимые случайные величины, а значит $\langle k' I(k_1^P \leq N - 1) \rangle = \langle k' \rangle \langle I(k_1^P \leq N - 1) \rangle = \langle k \rangle \langle I(k_1^P \leq N - 1) \rangle$, и мы можем переписать

$$\langle k \rangle = \langle k_1^0 \rangle + (N - 1) \cdot \langle I(k_1^P > N - 1) \rangle + \langle k_1^P I(k_1^P \leq N - 1) \rangle + \langle k \rangle \langle I(k_1^P \leq N - 1) \rangle$$

Решая это уравнение относительно $\langle k \rangle$, находим

$$\langle k \rangle = N - 1 + \frac{\langle k_1^0 \rangle + \langle k_1^P I(k_1^P \leq N - 1) \rangle}{\langle I(k_1^P > N - 1) \rangle}$$

Остается лишь вычислить средние значения, входящие в правую часть полученного выражения.

Вспомним, что статистика случайных величин k_1^0 и k_1^P описывается геометрическими функциями распределения вероятностей, $P_0(k_1^0) = p(1-p)^{k_1^0-1}$ и $P_P(k_1^P) = (1-p)p^{k_1^P-1}$ (см Ур. (4)). Значит

$$\begin{aligned} \langle I(k_1^P > N - 1) \rangle &= \text{Prob}[k_1^P > N - 1] = \sum_{k_1^P=N}^{\infty} (1-p)p^{k_1^P-1} = p^{N-1}, \\ \langle k_1^P I(k_1^P \leq N - 1) \rangle &= \sum_{k_1^P=1}^{N-1} k_1^P (1-p)p^{k_1^P-1} = \frac{1 + (N-1)p^N - N^{N-1}}{1-p}. \end{aligned}$$

Подстановка этих формул в Ур. (46) дает финальный ответ к задаче

$$\langle k \rangle = \frac{1}{1-p} \left(\frac{1}{p^N} - 1 \right).$$

В частности, для симметричной монетки ($p = 1/2$) имеем $\langle k \rangle = 2^{N+1} - 2$. То есть, чтобы встретить десять орлов подряд придется подбросить монетку (в среднем) $2^{11} - 2 = 2046$ раз.

ФР Вшэ

6. Крупные метеориты падают на Землю в пуассоновские моменты времени с рейтом λ . Обозначим через t_n время ожидания падения n -го по счету метеорита, отсчитываемое от произвольно выбранного момента начала наблюдений. Какова функция плотности вероятности случайной величины t_n ?
(черновик от другого решателя)

$$\begin{aligned} P(T > t_n) &= P(X = 0) + P(X = 1) + \dots + P(X = n - 1) = \sum_{k=0}^{n-1} \frac{e^{-\lambda t} : (\lambda t)^k}{k!} \Rightarrow \\ \Rightarrow F_n \neq H &= P(T \leq t_n) = 1 - P(T \leq t) = 1 - \sum_{k=0}^{n-1} \frac{e^{-H} (\lambda t)^k}{k!} \end{aligned}$$

$$f_n(t) = F_n(t) = - \sum_{k=0}^{n-1} \frac{\lambda^k}{k!} \cdot \frac{d}{dt} (e^{-\lambda t} \cdot t^k) =$$

$$- \sum_{k=0}^{n-1} \frac{\lambda^k k}{k!} (-\lambda e^{-\lambda t} \cdot t^k + e^{-\lambda t} \cdot t^{k-1}) = \lambda e^{-\lambda t} \sum_{k=0}^{n-1} \frac{14k}{k!} - e^{-\lambda t} \cdot \sum_{k=1}^{n-1} \frac{(\lambda t)}{(k-1)!} =$$

(тут кривая копия, много не так взял матшникс)

$$= \lambda e^{-\lambda t} \sum_{k=0}^{n-1} \frac{(\Delta t)^k}{k!} - \sum_{k=0}^{n-2} \frac{(a+)^{k-1}}{k!} \Bigg) = \frac{\lambda^n \cdot t^{n-1} \cdot e^{-\lambda t}}{(n-1)!}$$

ФР Вшэ

7. В области полностью ионизированного водорода начинает происходить рекомбинация электронов с ионами, в результате чего газ постепенно деионизируется. Вероятность того, что электрон рекомбинируется за время dt равна $\rho(t)\beta dt$, где $\rho(t)$ это концентрация ионов в текущий момент времени t , а β - некоторый постоянный коэффициент, характеризующий акт рекомбинации. Известно, что концентрация ионов в начальный момент времени равна ρ_0 , а система в целом электронейтральна. Найдите плотность вероятностей для случайной величины T - времени, прошедшего до момента рекомбинации отдельно взятого электрона. Каково медианное значение времени рекомбинации T ?
(решения не давалось)

Ч-4.106

Случайная величина ξ принимает значения 1 и 0 с вероятностями p и $q = 1 - p$ соответственно, а случайная величина η имеет распределение Пуассона с параметром p : $P\{\eta = k\} = \frac{p^k}{k!} e^{-p}, k = 0, 1, 2, \dots$. Доказать, что ξ и η можно задать на одном вероятностном пространстве так, что $P\{\xi \neq \eta\} < p^2$.

Ч-4.107

Случайные величины $\xi_1, \xi_2, \dots, \xi_n$ независимы, $P\{\xi_i = 1\} = 1 - P\{\xi_i = 0\} = p_i, i = 1, \dots, n$. Используя результаты задачи п4.106, доказать, что

$$\frac{1}{2} \sum_{k=0}^{\infty} |P\{\xi_1 + \dots + \xi_n = k\} - \frac{(p_1 + \dots + p_n)^k}{k!} e^{-(p_1 + \dots + p_n)}| \leq \sum_{i=1}^n p_i^2.$$

Ч-4.109

Случайная величина ξ принимает только целые неотрицательные значения. Доказать, что если $m_k = M\xi^{[k]} = M\xi(\xi-1)\dots(\xi-k+1), k = 1, 2, \dots$ и для целого $d \geq 1$ величина $m_{2d-1} < \infty$, то

$$\sum_{k=1}^{2d} (-1)^{k-1} \frac{m_k}{k!} \leq P\{\xi > 0\} \leq \sum_{k=1}^{2d-1} (-1)^{k-1} \frac{m_k}{k!}.$$

Ч-4.110

Пусть выполнены условия задачи п4.109. Доказать, что

$$\sum_{k=n}^{n+2d-1} (-1)^{k-n} C_k^n \frac{m_k}{k!} \leq P\{\xi = n\} \leq \sum_{k=n}^{n+2d} (-1)^{k-n} C_k^n \frac{m_k}{k!}$$

если $n = 0, 1, \dots$ и $m_{n+2d-1} < \infty$.

Ч-4.111

Пусть выполнены условия задачи п4.109. Доказать, что при любом $n = 1, 2, \dots$

$$\sum_{k=n}^{n+2d-1} (-1)^{k-n} C_{k-1}^{n-1} \frac{m_k}{k!} \leq P\{\xi \geq n\} \leq \sum_{k=1}^{n+2d} (-1)^{k-n} C_{k-1}^{n-1} \frac{m_k}{k!}$$

если $m_{n+2d-1} < \infty$.

Ч-4.114

Пассажирский поезд состоит из N вагонов по s мест в каждом вагоне. В момент отправления в поезде находилось n пассажиров. Обозначим символом $\mu_i = \mu_i(n, N, s)$ число вагонов, в которых при отправлении поезда находилось ровно i пассажиров, $i = 0, 1, \dots, \varepsilon$. Предполагая, что все $n!C_{Ns}^n = (Ns)^{[n]}$ вариантов размещения пассажиров в поезде равновероятны, найти формулы для факториальных моментов величин $\mu_0, \mu_1, \dots, \mu_s$. Проанализировать поведение математических ожиданий μ_i при изменении n от 0 до Ns .

Ч-4.115

Пусть выполнены условия задачи Ч-4.114. Найти явное выражение для $P\{\mu_i(n, N, s) = k\}$.

Ч-4.116

Пусть выполнены условия задачи Ч-4.114. Показать, что если s и i фиксированы, а $n, N \rightarrow \infty$ так, что $M\mu_i(n, N, s) \rightarrow \lambda \in (0, \infty)$, то при любом $k = 1, 2, \dots$

$$M(\mu_i(n, N, s))^{[k]} \rightarrow \lambda^k.$$

Вывести отсюда, что тогда для любого $m = 0, 1, \dots$

$$P\{\mu_i(n, N, s) = m\} \rightarrow \frac{\lambda^m}{m!} e^{-\lambda}.$$

Ч-4.117

Пусть n частиц размещаются по N ячейкам, причем каждая частица независимо от остальных с одними и теми же вероятностями (равными $1/N$) может попасть в любую из N ячеек. Обозначим через $\mu_r(n, N)$ число ячеек, в которых находится ровно по r частиц. Найти формулу для $M\mu_r(n, N)$ и доказать, что если $r \Rightarrow 0, 1, 2, \dots$ фиксировано, а $n, N \rightarrow \infty$ так, что $M\mu_r(n, N) \rightarrow \lambda_r$, $0 < \lambda < \infty$, то

$$P\left\{\mu_r(n, N) = \{m\} \rightarrow \frac{\lambda^m}{m!} e^{-\lambda}, m = 0, 1, \dots\right.$$

Ч-4.118

Пусть частицы последовательно и независимо друг от друга размещаются по N ячейкам так, что i -я ($i = 1, 2, \dots$) частица попадает в $j - 1$ ($j = 1, \dots, N$) ячейку с вероятностью $1/N$. Положим

$$v_r(N) = \min\{n\mu_r(n, N) > 0\}, \quad r = 2, 3, \dots$$

137 где $\mu_r(n, N)$ - число ячеек, содержащих после размещения n частиц ровно по r частиц. Найти такую последовательность чисел $b_1, b_2, \dots$ что распределения случайных величин $v_r(N)/b_N$ при $N \rightarrow \infty$ и фиксированном r сходятся к невырожденному закону, и сам предельный закон.

Ч-4.119

Пусть n частиц независимо размещаются по N^2 ячейкам, расположенным в виде квадратной таблицы размером $N \times N$. Назовем ячейку свободной, если после размещения n частиц ни в нее, ни в ячейки, находящиеся с ней в одной строке или в одном столбце, не попало ни одной частицы. Найти предельное распределение числа $\chi(n, N)$ свободных ячеек, когда

$$n = N(\ln \lambda N + o(1)), \quad N \rightarrow \infty.$$

6.5.5 Problems About the Central Limit Theorem and the Method of Characteristic Functions (??!!)

(мб это супер нужное??)

(!!!! напишу в 1 часть указания про решения!!!! тут крутые указания должны быть!!!!)

Вероятность прихода более половины студентов на лекции (!?!?!!?)

Обзорную лекцию должны прослушать 100 студентов. Вероятность присутствовать на этой лекции для каждого студента равняется 0,7. Найти вероятность того, что на лекцию придет больше половины студентов.

(??? задача хорошая, но я слишком плохо разобрался, не уверен, что такое решение годное.)

Пусть X - случайная величина, равная числу студентов, пришедших на лекцию. Она равна сумме $n = 100$ независимых одинаково распределённых случайных величин, каждая из которых принимает значение 1 с вероятностью $p = 0,7$ (студент пришёл) и значение 0 с вероятностью $q = 1 - p = 0,3$ (студент не пришёл).

Используем центральную предельную теорему, согласно которой, при больших значениях n случайную величину $Y = (X - MX)/\sqrt{DX}$ можно приближённо считать нормально распределённой с параметрами 0 и 1. Согласно стандартным формулам, $MX = np = 70$, $DX = npq = 21$. Нас интересует вероятность события $X > 50$, что равносильно условию $X - MX > -20$, то есть $Y > -20/\sqrt{21}$. Вероятность этого события находим, интегрируя функцию плотности нормального распределения:

$$P\{Y > -20/\sqrt{21}\} = \frac{1}{\sqrt{2\pi}} \int_{-20/\sqrt{21}}^{\infty} e^{-x^2/2} dx \approx 0,9999936245$$

то есть эта вероятность практически равна единице.

Белан Вшэ (!!!!)

3. Пусть $X_1, X_2, \dots, X_N$ - набор независимых одинаково распределённых неотрицательных случайных величин. Найдите функцию плотности вероятности $P_N(g)$ среднего геометрического $G = \sqrt[N]{\prod_{i=1}^N X_i}$ в случае $N \gg 1$.

(нужно тут прокачаться ещё!!)

Обозначим через $\rho_N(y)$ функцию плотности вероятности случайной величины $Y = \ln G = \frac{1}{N} \sum_{i=1}^N \ln X_i$.

Понятно, что $P_N(G) = \rho_N(Y(G)) \left| \frac{dY(G)}{dG} \right|$, а значит, если мы вычислим $\rho_N(y)$, то и искомую функцию распределения $P_N(g)$ можно будет легко выписать. Заметим, что Y представляет собой среднее арифметическое суммы независимых и одинаково распределённых случайных чисел $Y_1, Y_2, \dots, Y_N$, где $Y_i = \ln X_i$. При этом Y обладает конечным средним значением $\mu_Y = \langle Y \rangle = \langle \ln X \rangle$ и дисперсией $\sigma_Y^2 = \langle Y^2 \rangle - \langle Y \rangle^2 = \langle \ln^2 X \rangle - \langle \ln X \rangle^2$ (данное утверждение справедливо независимо от того, конечны ли $\langle X \rangle$ и $\langle X^2 \rangle$). Таким образом, выполнены условия применимости центральной предельной теоремы, и при $N \gg 1$ величина Y имеет нормальное распределение

$$\rho_N(y) = \mathcal{N}\left(\mu_Y, \frac{\sigma_Y^2}{N}\right) = \frac{\sqrt{N}}{\sqrt{2\pi}\sigma_Y} \exp\left(-\frac{N(y - \mu_Y)^2}{2\sigma_Y^2}\right).$$

Тогда

$$P_N(g) = \rho_N(y(g)) \left| \frac{dy(g)}{dg} \right| = \frac{\sqrt{N}}{\sqrt{2\pi}\sigma_Y g} \exp\left(-\frac{N(\ln g - \mu_Y)^2}{2\sigma_Y^2}\right).$$

В пределе $N \rightarrow \infty$ получаем $P_\infty(g) = \delta(g - e^{\langle \ln X \rangle})$.

Ч-4.120

(см. п4.2).

Случайная величина η_n равна сумме очков, выпавших игри n независимых бросаниях симметричной игральной кости. Используя центральную предельную теорему, выбрать n так, чтобы

$$P\left\{\left|\frac{\mu_n}{n} - 3,5\right| \geq 0,1\right\} \leq 0,1.$$

Ч-4.121

Складывается 10^4 чисел, округленных с точностью до 10^{-m} . Предполагая, что ошибки округления независимы и равномерно распределены в интервале $(-0,5 \cdot 10^{-m}, 0,5 \cdot 10^{-m})$, пайти пределы, в которых с вероятностью, не меньшей 0,99, будет лежать суммарная ошибка.

Ч-4.122

Случайные величины $\xi_1, \xi_2, \dots$ независимы и одинаково распределены:

$$P\{\xi_i = z\} = P\left\{\xi_i = \frac{1}{2}\right\} = \frac{1}{2}, \quad z \neq 1, \quad i = 1, 2, \dots$$

а) Найти пределы математического ожидания и дисперсии $n \rightarrow \infty$.

б) Доказать, что при $n \rightarrow \infty$ распределение η_n сходится к логарифмически нормальному распределению (см. задачу 3.233). Найти параметры a, σ^2 предельного логарифмически нормального распределения.

в) Сравнить найденные в п. а) значения $\lim_{n \rightarrow \infty} M\eta_n$ и $\lim_{n \rightarrow \infty} D\eta_n$ с математическим ожиданием и дисперсией случайной величины η , имеющей логарифмически нормальное распределение из п. б).

Ч-4.123

*. Случайные величины $\xi_1, \xi_2, \dots$ независимы и одинаково распределены:

$$P\{\xi_i = 1, 25\} = P\{\xi_i = 0, 8\} = \frac{1}{2}, \quad i = 1, 2, \dots$$

и $\eta_n = \xi_1 \dots \xi_n$.

а) Найти $M\eta_{1000}, D\eta_{1000}, M \ln \eta_{1000}, D \ln \eta_{1000}$.

б) Пользуясь асимптотической нормальностью $\ln \eta_n$ при $n \rightarrow \infty$, найти приближенные значения $P\{\eta_{1000} \leq 0,001\}, P\{\eta_{1000} < 1\}, P\{\eta_{1000} \leq 1\}, P\{\eta_{1000} \leq 10^4\}$.

в) Пользуясь формулой Стирлинга, найти $P\{\eta_{1000}^4 < 1\}, P\{\eta_{1000} \leq 1\}$.

Ч-4.124

Случайные величины $\xi_1, \xi_2, \dots$ независимы и одинаково распределены:

$$P\{\xi_i = 1, 25\} = P\{\xi_i = 0, 75\} = \frac{1}{2}, \quad i = 1, 2, \dots$$

и $\eta_n = \xi_1 \dots \xi_n$.

а) Найти $M\eta_{1000}, D\eta_{1000}, M \ln \eta_{1000}, D \ln \eta_{1000}$.

б) Пользуясь асимптотической нормальностью $\ln \eta_n$ при $n \rightarrow \infty$, найти приближенные значения

$$\begin{aligned} &P\{\eta_{1000} \leq 10^{-20}\}, \\ &P\{\eta_{1000} < 1, 25^{501} \cdot 0, 75^{499} \approx 1, 6 \cdot 10^{-14}\} \\ &P\{\eta_{1000} \leq 1, 25^{501} \cdot 0, 75^{499}\}, \quad P\{\eta_{1000} \leq 10^{-7}\}. \end{aligned}$$

в) Пользуясь формулой Стирлинга, найти

$$\begin{aligned} &P\{\eta_{1000} < 1, 25^{501} \cdot 0, 75^{499}\} \\ &P\{\eta_{1000} \leq 1, 25^{501} \cdot 0, 75^{499}\} \end{aligned}$$

Ч-4.126

Случайная точка $\xi = (\xi_1, \dots, \xi_n) \in R^n$ имеет равномерное распределение на единичной сфере в R^n , т. е. на множестве точек $S^{n-1} \Rightarrow \{(x_1, \dots, x_n) \in R^n$:

Ч-4.127

Случайный вектор $\xi = (\xi_1, \dots, \xi_n) \in R^n$ имеет сферически симметричное нормальное распределение с нулевым вектором средних и единичной матрицей ковариаций. Равенство

$$\xi = \rho \varepsilon, \quad \rho = |\xi|, \quad \varepsilon = \frac{1}{|\xi|} \xi,$$

где $|\xi| = \sqrt{\xi_1^2 + \dots + \xi_n^2}$ - длина вектора ξ , дает представление ξ в виде произведения скалярной случайной величины ρ и вектора ε . Доказать, что ρ и ε независимы и что ε имеет равномерное распределение на единичной сфере в R^n (см. задачу

Ч-4.126

). Найти распределение, математическое ожидание и дисперсию ρ^2 .

Ч-4.128

Пусть вектор $\varepsilon = (\varepsilon_1, \dots, \varepsilon_n) \in R^n$ имеет равномерное распределение на единичной сфере в R^n . Используя результаты задач 4.127 и 4.125, доказать, что при $n \rightarrow \infty$:

- распределение $\varepsilon_1 \sqrt{n}$ сходится к стандартному нормальному распределению,
- распределение вектора $(\varepsilon_1 \sqrt{n}, \dots, \varepsilon_k \sqrt{n}), k = \text{const}$, сходится к совместному распределению k независимых случайных величин, имеющих стандартное нормальное распределение.

Ч-4.129

Случайные величины $\xi_0, \xi_1, \xi_2, \dots$ независимы и имеют стандартное нормальное распределение. Распределение случайной величины

$$\tau_n = \frac{\xi_0}{\sqrt{(\xi_1^2 + \dots + \xi_n^2)/n}}$$

называется распределением Стьюдента с n степенями свободы. Найти

$$\lim_{n \rightarrow \infty} P\{\tau_n \leq x\} = \Phi(x) \quad -\infty < x < \infty.$$

Ч-4.130

Пусть $\xi_{n,1}$ обозначает число появлений t -го исхода в n независимых испытаниях с N несовместными исходами; вероятности появления этих исходов в каждом из испытаний равны $p_1, p_2, \dots, p_N \geq 0$ соответственно, $p_1 + \dots + p_N = 1$. Далее, пусть $a_1, \dots, a_N$ - действительные числа и

$$\eta_n = a_1 \xi_{n,1} + \dots + a_N \xi_{n,N}.$$

Найти $M\eta_n, D\eta_n$ и предельное распределение $\frac{\eta_n - M\eta_n}{\sqrt{D\eta_n}}$ при $n \rightarrow \infty$.

Ч-4.131

Случайные величины $\xi_1, \xi_2, \dots$ независимы и одинаково распределены; $\xi_a = a, D\xi_a \Rightarrow b^2, k = 1, 2, \dots$. Положим $\eta_k = \xi_n + \xi_{k+1} + \xi_{k+2}, k = 1, 2, \dots$. Найти:

- $M\eta_k, \text{cov}(\eta_k, \eta_c) (k \neq l), D\eta_k$; 6) $\lim_{n \rightarrow \infty} P\left\{\frac{\eta_1 + \dots + \eta_n - 3na}{b\sqrt{3n}} \leq x\right\}$. Пуассона с параметром λ . Найти

$$\lim_{\lambda \rightarrow \infty} P\left\{\frac{\xi_\lambda - \lambda}{\sqrt{\lambda}} \leq x\right\}.$$

Ч-4.134

Последовательность случайных величин $\xi_1, \xi_2, \dots$ такова, что при любом $n = 1, 2, \dots$

$$\xi_n = \xi_{n,1} + \xi_{n,2} + \dots + \xi_{n,n}$$

141 где $\xi_{n,1}, \dots, \xi_{n,n}$ - независимые случайные величины,

$$M\xi_{n,1} = 0, \quad i = 1, \dots, n,$$

$$s_n^2 = \sum_{k=1}^n D\xi_{n,k} < \infty, \quad \lim_{n \rightarrow \infty} \frac{1}{s_n^3} \sum_{k=1}^n M|\xi_{n,k}|^3 = 0.$$

Доказать, что распределения случайных величин ξ_n/s_n при $n \rightarrow \infty$ сходятся к стандартному нормальному распределению.

Ч-4.135

Случайные величины $\xi_1, \xi_2, \dots$ независимы,

$$P\{\xi_n = 1\} = \frac{1}{n^\alpha}, \quad P\{\xi_n = 0\} = \frac{n^\alpha - 1}{n^\alpha},$$

$$n = 1, 2, \dots, 0 < \alpha < 1.$$

Найти предельное распределение случайных величин

$$\xi_n = \frac{\xi_1 + \dots + \xi_n - M(\xi_1 + \dots + \xi_n)}{\sqrt{D(\xi_1 + \dots + \xi_n)}} \quad \text{при } n \rightarrow \infty.$$

Ч-4.138

Случайные величины $\xi_1^{(n)}, \dots, \xi_n^{(n)}$ независимы, $\mathbf{P} \{ \xi_i^{(n)} = 1 \} = p_i^{(n)}$

$$P \{ \xi_i^{(n)} = 0 \} = 1 - p_i^{(n)} \quad (1 \leq i \leq n)_S$$

и $\xi_n = \xi_1^{(n)} + \dots + \xi_n^{(n)}$.

а) Найти $M\xi_n, D\xi_n$.

б) Доказать, что если $D_n \rightarrow \infty$ при $n \rightarrow \infty$, то предельное при $n \rightarrow \infty$ распределение случайной величины $\frac{\xi_n - M\xi_n}{\sqrt{D\xi_n}}$ является стандартным нормальным.

в) Положим $m_n = f(p_1^{(n)}) + \dots + f(p_n^{(n)})$, где $f(x) = 0$ при $x \leq 1/2$ и $f(x) = 1$ при $x > 1/2$. Найти предельное при $n \rightarrow \infty$ распределение случайной величины $\xi_n - m_n$, если

$$\sum_{\substack{1 \leq i \leq n \\ p_i^{(n)} \leq 1/2}} p_i^{(n)} \rightarrow \lambda_{0v} \quad \sum_{\substack{1 \leq i \leq n \\ p_i^{(n)} > 1/2}} p_i^{(n)} \rightarrow \lambda_{1\varepsilon}$$

$$\max_{1 \leq i < n} \min [p_i^{(n)}, 1 - p_i^{(n)}] \rightarrow 0.$$

Ч-4.139

Случайная величина ξ_n имеет распределение - дробно-дирежной производящей функцией $\varphi_n(z) \Rightarrow = \frac{a_n + (1-d_n-a_n)z}{1-d_n z^2}$, $0 \leq a_n \leq 1, 0 \leq d_n < 1$. Какие невырожденные законы распределения $F(x)$ могут быть предельными для последовательности $F_n(x) = \mathbf{P} \left\{ \frac{\xi_n}{A_n} \leq x \right\}$, где $A_n \rightarrow \infty$ - некоторые нормирующие константы? Какие условия надо наложить на последовательности a_n, d_n, A_n , чтобы $\lim_{n \rightarrow \infty} F_n(x) = F(x)$, $x > 0$?

Ч-4.144

Пусть случайная величина v_h та же, что в задаче п4.143. Найти предельное распределение случайной величины $v_k - k$, когда $N \rightarrow \infty, k^2/N \rightarrow \lambda, 0 < \lambda < \infty$.

Ч-4.145

Пусть выполнены условия задачи п4.143. Найти асимптотические формулы для Mv_m, Dv_m и предельное распределение $\frac{v_m - v_m}{\sqrt{Dv_m}}$, когда $N \rightarrow \infty$ и $\alpha_1 N \leq m \leq \alpha_2 N$ при некоторых $\alpha_1, \alpha_2, 0 < \alpha_1 < \alpha_2 < 1$.

Ч-4.146

Производящая функция $\varphi(z) = Mz^2$ случайной величины ξ является многочленом степени N , причем все корни $z_1, \dots, z_N$ уравнения $\varphi(z) = 0$ вещественны. Доказать, что распределение ξ совпадает с распределением суммы $\zeta = \zeta_1 + \dots + \zeta_N$, где случайные величины $\zeta_1, \dots, \zeta_N$ независимы и

$$\mathbf{P} \{ \zeta_i = 1 \} = p_i, \quad \mathbf{P} \{ \zeta_i = 0 \} = 1 - p_i, \quad i = 1, \dots, N.$$

Найти значения $p_1, \dots, p_N$.

Ч-4.147

*. Производящая функция $\varphi(z) = Mz^2$ случайной величины ξ является многочленом степени N , причем все корни $z_1, \dots, z_N$ уравнения $\varphi(z) = 0$ имеют неположительные вещественные части: $\operatorname{Re} z_i \leq 0, i = 1, \dots, N$. Доказать, что распределение ξ совпадает с распределением суммы $\xi = \xi_1 + \dots + \xi_M$, где случайные величины $\xi_1, \dots, \xi_M$ независимы и $\mathbf{P} \{ \zeta_i = 2 \} = r_i, \quad \mathbf{P} \{ \zeta_i = 1 \} = p_i, \quad \mathbf{P} \{ \zeta_i = 0 \} = 1 - p_i - r_i, \quad i = 1, \dots, M$. Найти значения $M, p_i, r_i (i = 1, \dots, M)$.

Ч-4.149

Доказать, что если выполнены условия задачи п4.148, но $Dg_n \rightarrow \lambda < \infty$ при $n \rightarrow \infty$ и, кроме того,

$$\lim_{n \rightarrow \infty} \max_{1 \leq i \leq n} z_{n,i} = -\infty,$$

где $z_{n,1}, \dots, z_{n,n}$ - корни уравнения $\varphi_n(z) = 0$, то распределение ξ_n при $n \rightarrow \infty$ сходится к распределению Пуассона с параметром λ .

Ч-4.150

*. Пусть выполнены условия задач п4.143 и $f_{n,N}(z) = z^{\mu_0(n,N)}$ - производящая функция числа пустых ячеек. Найти рекуррентное уравнение, связывающее многочлены $f_{n,N}(z)$ и $f_{n+1,N}(z)$, и вывести из него, что все $N - 1$ корней уравнения $f_{n,N}(z) = 0$ вещественны при любом $n \geq 1$.

Ч-4.151

Пусть выполнены условия задачи п4.143 и $\mu_0(n, N)$ - число ячеек, оставшихся пустыми после размещения n частиц. Доказать, что если $n, N \rightarrow \infty$ так, что $M\mu_0(n, N) \rightarrow \infty$ и $N - M\mu_0(n, N) \rightarrow \infty$, то предельное распределение случайной величины

$$\frac{\mu_0(n, N) - M_0(n, N)}{\sqrt{D\mu_0(n, N)}}$$

является стандартным нормальным.

Ч-4.152

Случайные величины $\xi_1, \xi_2, \dots$ независимы и имеют одно и то же распределение с характеристической функцией $f(t)$. Доказать, что если при некоторых $C > 0, 0 < \alpha \leq 2$,

$$f(t) = 1 - C|t|^\alpha(1 + o(1)), \quad t \rightarrow 0,$$

то при $n \rightarrow \infty$ существует предельное распределение случайных величин

$$\zeta_n = \frac{\xi_1 + \xi_2 + \dots + \xi_n}{n^{1/\alpha}}.$$

Найти его характеристическую функцию.

Ч-4.157

Случайные величины ξ_1, ξ_2, ξ_3 имеют распределение Коши с параметром a ; при этом ξ_1 и ξ_2 независимы, а $P\{\xi_3 = \xi_1\} = 1$. Сравнить характеристические функции и функции распределения суммы $\xi_1 + \xi_2$ независимых и суммы $\xi_1 + \xi_3$ зависимых одинаково распределенных случайных величин.

Ч-4.158

Используя результат задачи п4.155, вычислить

$$I_{a,b}(x) = \int_{-\infty}^{\infty} \frac{du}{(a^2 + u^2)(b^2 + (x - u)^2)}.$$

(!!! тут могут быть очень крутые задачи.)

ЛШ-9 Возврат назад при случайном блуждании

Рассмотрим частицу, совершающую случайное блуждание по n -мерной кубической решетке. Движение начинается при $t = 0$ из начала координат. Попадая на очередном шаге в какой-то из узлов решетки, частица на следующем шаге с одинаковой вероятностью переходит в любой из $2n$ соседних узлов. Пусть $p(t, \mathbf{x})$ - вероятность того, что частица через t шагов оказалась в узле $\mathbf{x} = (x_1, \dots, x_n)$ решетки. (В этой

задаче время t является дискретным.) В теории вероятностей рассматривают производящую функцию

$$G(z, \mathbf{q}) = \sum_{\mathbf{x}, t} z^t e^{i\mathbf{q}\mathbf{x}} p(t, \mathbf{x}) \quad (t \geq 0, |z| < 1).$$

Свойства этой величины во многом аналогичны свойствам функции Грина. Покажите, что

$$G(z, \mathbf{q}) = \frac{1}{1 - zW(\mathbf{q})}, \quad W(\mathbf{q}) = \frac{1}{n} (\cos q_1 + \dots + \cos q_n).$$

Рассмотрим производящую функцию $\tilde{G}(z, \mathbf{q})$ для блужданий, начинающихся из начала координат, но ни разу не возвращающихся туда на последующих шагах. Величина $\tilde{G}(z, \mathbf{q})$ по своим свойствам похожа на функцию Грина частицы в поле отталкивающего центра (см. задачи 11, 12 и 13). В частности, для нее можно написать такое же интегральное уравнение (напоминающее уравнение Дайсона). Выразите $\tilde{G}(z, \mathbf{q})$ через $G(z, \mathbf{q})$. Найдите вероятность P того, что частица никогда не возвращается в начало координат. Покажите, что

$$P^{-1} = \int G(1, \mathbf{q}) \frac{d^n \mathbf{q}}{(2\pi)^n}.$$

Здесь интеграл берется по зоне Бриллюэна, т. е. по периоду обратной решетки. Вероятность возврата (2.17) имеет нетривиальную зависимость от размерности решетки n . Покажите, что

- а) $P = 0$ при $n \leq 2$;
- б) $0 < P < 1$ при $n > 2$;
- в) $P \rightarrow 1$ при $n \gg 2$.

Поскольку перечисленные свойства чувствительны только к поведению $G(1, \mathbf{q})$ при малых $\mathbf{q}$, т.е. на больших масштабах, они имеют место для произвольного диффузионного движения, а не только для блуждания по решетке. Типичная диффузионная траектория имеет бесконечно много возвратов при $n \leq 2$, и конечное число при $n > 2$.

Solution

(!!! в теории укажу это, пока теория слабее каталога!!!)

Рассмотрим вероятность $p(t, \mathbf{x})$ блуждающей частицы оказаться в узле $\mathbf{x}$ на шаге t . Вероятности на шаге t и $t + 1$ связаны простым соотношением:

$$p(t + 1, \mathbf{x}) = \frac{1}{2n} \sum_{|\mathbf{x}' - \mathbf{x}|=1} p(t, \mathbf{x}')$$

(сумма берется по $2n$ соседям узла $\mathbf{x}$). Перейдем к фурье-образу $p(t, \mathbf{q}) = \sum_{\mathbf{x}} e^{i\mathbf{q}\mathbf{x}} p(t, \mathbf{x})$. Соотношение (2.82) дает

$$p(t + 1, \mathbf{q}) = W(\mathbf{q})p(t, \mathbf{q}), \quad W(\mathbf{q}) = \frac{1}{n} (\cos q_1 + \dots + \cos q_n).$$

Находим производящую функцию

$$G(z, \mathbf{q}) = \sum_{t \geq 0} z^t p(t, \mathbf{q}) = \frac{1}{1 - zW(\mathbf{q})}.$$

Вероятности $p(t, \mathbf{x})$ выражаются через $G(z, \mathbf{q})$ так:

$$p(t, \mathbf{x}) = \frac{-i}{(2\pi)^{n+1}} \oint \frac{dz}{z^{t+1}} \int \frac{d^n q e^{i\mathbf{q}\mathbf{x}}}{1 - zW(\mathbf{q})},$$

где интеграл по $d^n q$ берется по области $-\pi < q_i < \pi (i = 1, \dots, n)$, а интеграл по z - по любому контуру, охватывающему точку $z = 0$.

Теперь, чтобы найти вероятность блужданий без возврата в начало координат, немного модифицируем правила игры. Предположим, что частица блуждает случайно, как и раньше, но, как только она попадает в начало координат, ее «удаляют с поля». В этом случае связь между $p(t+1, \mathbf{x})$ и $p(t, \mathbf{x})$ будет такая:

$$p(t+1, \mathbf{x}) = \begin{cases} \frac{1}{2^n} \sum_{|\mathbf{x}' - \mathbf{x}|=1} p(t, \mathbf{x}') & \text{при } \mathbf{x} \neq 0, \\ 0 & \text{при } \mathbf{x} = 0. \end{cases}$$

Переходя к фурье-образу $p(t, \mathbf{q})$, получаем

$$p(t+1, \mathbf{q}) = W(\mathbf{q})p(t, \mathbf{q}) - \int W(\mathbf{k})p(t, \mathbf{k}) \frac{d^n k}{(2\pi)^n}.$$

Производящая функция $\tilde{G}(z, \mathbf{q}) = \sum_{t \geq 0} z^t p(t, \mathbf{q})$ получается умножением (2.86) на z^{t+1} и суммированием по $t \geq 0$. Находим

$$\tilde{G}(z, \mathbf{q})(1 - zW(\mathbf{q})) = 1 - z \int W(\mathbf{k})\tilde{G}(z, \mathbf{k}) \frac{d^n k}{(2\pi)^n}$$

Это уравнение можно записать в таком виде:

$$\tilde{G}(z, \mathbf{q}) = G(z, \mathbf{q}) + G(z, \mathbf{q}) \int \Sigma(z, \mathbf{k})\tilde{G}(z, \mathbf{k}) \frac{d^n k}{(2\pi)^n},$$

где $\Sigma(z, \mathbf{k}) = G^{-1}(z, \mathbf{k}) - 1$. (Заметим, что по форме уравнение (2.89) напоминает уравнение Дайсона (4.9).) Ищем решение (2.89) в виде

$$\tilde{G}(z, \mathbf{q}) = \lambda(z)G(z, \mathbf{q})$$

где $\lambda(z)$ - некоторая функция z . Подставляя (2.90) в (2.89), находим

$$\lambda(z) = 1 - \lambda(z) \int (G(z, \mathbf{q}) - 1) \frac{d^n q}{(2\pi)^n},$$

откуда

$$\lambda^{-1}(z) = \int G(z, \mathbf{q}) \frac{d^n q}{(2\pi)^n}.$$

Рассмотрим вероятность P_t того, что частица за t шагов ни разу не вернулась в начало координат. Производящая функция $F(z) = \sum_{t \geq 0} z^t P_t$, очевидно, есть

$$F(z) = \tilde{G}(z, \mathbf{q} = 0) = \frac{\lambda(z)}{1 - z}.$$

Находим вероятность

$$P_t = \frac{1}{2\pi i} \oint_{|z|=r} \frac{dz}{z^{t+1}} \frac{\lambda(z)}{1 - z},$$

где $\lambda(z)$ дается (2.92), а радиус контура интегрирования $r < 1$. Для нахождения вероятности того, что частица никогда не вернется в начало координат, необходимо перейти в (2.94) к пределу $t \rightarrow \infty$. Это удобно сделать, рассмотрев

$$P_{a,t} = A_t (P_0 + aP_1 + \dots + a^{t-1}P_{t-1}) = \frac{A_t}{2\pi i} \oint_{|z|=r} \frac{(1 - a^t z^{-t})\lambda(z)}{(1 - z)(z - a)} dz$$

где a - параметр, который $0 < a < r$, а $A_t = (1 + a + \dots + a^{t-1})^{-1} = (1 - a^t)/(1 - a)$. Переходя в (2.95) к пределу $t \rightarrow \infty$, получаем

$$P_a^* = \frac{1 - a}{2\pi i} \oint_{|z|=r} \frac{\lambda(z) dz}{(1 - z)(z - a)},$$

Рассмотрим контурный интеграл (2.96). Функция $\lambda(z)$ аналитична внутри единичного круга, поэтому внутри контура $|z| = r$ подинтегральное выражение в (2.96) имеет один простой полюс $z = a$. Вычет в

точке $z = a$ есть $\lambda(a)$, и поэтому $P_a^* = \lambda(a)$. Искомая вероятность невозвращения, согласно (2.95), есть $\lim_{a \rightarrow 1} P_a^*$. Следовательно,

$$P = \lambda(a)_{a \rightarrow 1} = \left[\int G(1, \mathbf{q}) \frac{d^n q}{(2\pi)^n} \right]^{-1}.$$

При $n \leq 2$ интеграл в (2.97) расходится на малых q , поэтому вероятность невозвращения $P = 0$.

В другом пределе, при $n \rightarrow \infty$, величина суммы косинусов в $W(\mathbf{q})$ порядка $\sqrt{n}$, согласно закону больших чисел. (Это справедливо не для всех $\mathbf{q}$, а только для «типичных», но для оценки интеграла в (2.97) этого достаточно.) Заменяя в $G(1, q)$ величину $1 - W(\mathbf{q})$ на 1, находим, что при больших n вероятность невозвращения $P \rightarrow 1$.

Ч-5.1

Случайные величины $\xi_t (t = 0, \pm 1, \pm 2, \dots)$ независимы, $M\xi_t = a$, $D\xi_t = \sigma^2$. По действительным числам $c_0, c_1, \dots, c_h$, удовлетворяющим условию $c_0 + c_1 + \dots + c_k = 1$, Игостроен случайный процесс

$$\eta_1 = c_0 \xi_t + c_1 \xi_{t-1} + \dots + c_k \xi_{t-k}, \quad t = 0, \pm 1, \pm 2, \dots$$

Найти $M\eta_t, D\eta_t, \text{cov}(\eta_t, \eta_s)$. Показать, что $\text{cov}(\eta_t, \eta_s) = R(|s - t|)$, т. е. зависит только от $|s - t|$.

Ч-5.2

. Пусть выполнены условия задачи н5.1.

а) Доказать, что последовательность случайных величин

$$\zeta_n = \frac{1}{n} (\eta_1 + \dots + \eta_n)$$

при $n \rightarrow \infty$ сходится по вероятности к $a = M \xi_t$.

б) Сходится ли ζ_n к a с вероятностью 1 при $n \rightarrow \infty$?

Ч-5.3

Пусть выполнены условия задачи н5.1 и, кроме того, $a = 0, M\xi_t^4 = c < \infty$.

а) Доказать, что для любого целого $s \geq 0$ последовательность случайных величин

$$\zeta_n^{(s)} = \frac{1}{n} (\eta_1 \eta_{1+s} + \eta_2 \eta_{2+s} + \dots + \eta_n \eta_{n+s})$$

при $n \rightarrow \infty$ сходится по вероятности к $R(s)$.

б) Сходится ли $\zeta_n^{(s)}$ к $R(s)$ с вероятностью 1 при $n \rightarrow \infty$?

Ч-5.4

. Случайный процесс $\xi_t, t = 0, \pm 1, \pm 2, \dots$, определяется формулой

$$\xi_1 = \alpha \sin(At + \beta) + \varepsilon_t,$$

где $\alpha, \beta, \{\varepsilon_t\}_{t=-\infty}^{\infty}$ - независимые случайные величины, $M\alpha = 0, D\alpha = 1, \beta$ имеет равномерное распределение на отрезке $[-\pi, \pi]$, $M\varepsilon_t = 0, D\varepsilon_t = \sigma^2$. Найти $M\xi_t, D\xi_t, \text{cov}(\xi_t, \xi_s)$.

Ч-5.5

Случайный процесс $\xi_1, -\infty < t < \infty$, задан формулой

$$\xi_1 = \sin(t + \pi\eta_1) + \sin \pi(t + \eta_2),$$

где η_1 и η_2 независимы и имеют равномерное распределение на отрезке $[-1, 1]$. Найти $\xi_t, D\xi_t, \text{cov}(\xi_1, \xi_s)$.

Ч-5.6

Случайный процесс $\xi_t, -\infty < t < \infty$, задан формулой

$$\xi_t = \xi_1 \sin t + \xi_2 \sin \pi t$$

где ξ_1 и ξ_2 независимы и имеют равномерное распределение на отрезке $[-1, 1]$. Найти плотность распределения случайной величины $\eta = \sup_t \xi_t$.

Ч-5.7

Случайные величины $\alpha_1, \alpha_2, \dots$ независимы и одинаково распределены, $\alpha_1 = 0$, $D\alpha_1 = 1$. Случайные величины $\beta_1, \beta_2, \dots$ независимы, не зависят от $\alpha_1, \alpha_2, \dots$ и имеют равномерное распределение на отрезке $[-\pi, \pi]$. Последовательность случайных процессов $\eta_1(t), \eta_2(t), \dots$ определяется равенством

$$\eta_n(t) = \frac{1}{\sqrt{n}} \sum_{k=1}^n \alpha_k \cos(t + \beta_k).$$

- а) Найти предельное распределение $\eta_n(t)$ при $n \rightarrow \infty$, $t = \text{const}$.
 б) Доказать, что $\eta_n(t) = \theta_n \cos(t + \gamma_n)$. Найти предельное распределение вектора (γ_n, θ_n) при $n \rightarrow \infty$.

Ч-5.8

Случайный процесс $\varepsilon_t, 0 \leq t < \infty$, с вероятностью 1 имеет непрерывные траектории, $\varepsilon_t \equiv 0$, $D\varepsilon_t < \infty$, $\text{cov}(\varepsilon_t, \varepsilon_s) = R(|t - s|)$ при любых $t, s \geq 0$. Пусть η_t определяется случайная величина

$$\tau_N = \inf \{t \geq 0 : \xi_t \geq N\}.$$

Найти функцию распределения $F_N(x) = P\{\tau_N \leq x\}$ при $N > 0$ в следующих случаях:

- а) $\xi_t = \zeta t$, где $P\{\zeta \leq x\} = 1 - \frac{1}{(1+x)^k}$ ($x \geq 0, k > 0$);
 б) $\xi_t = t^2 - 2t\xi$, где $P\{\xi \leq x\} = 1 - e^{-\lambda x}$ ($x \geq 0$),
 в) $\xi_t = \zeta e^{at}$, где $a > 0$ и $P\{\zeta \leq x\} = 1 - e^{-\lambda x}$ ($x \geq 0$).

Ч-5.10

По последовательности $\xi_0, \xi_1, \dots$ независимых одинаково распределенных случайных величин построен случайный процесс $\eta_k = \xi_{k+1} - \xi_k, k = 0, 1, \dots$. Положим

$$\tau_1 = \inf \{k \geq 0 : \eta_k \leq 0\},$$

$$\tau_2 = \inf \{k \geq 0 : \eta_k < 0\}.$$

Найти $M\tau_1$ и τ_2 в следующих трех случаях:

- а) $P\{\xi_0 = 1\} = P\{\xi_0 = 2\} = 1/2$,
 б) $P\{\xi_0 = 1\} = P\{\xi_0 = 2\} = \dots = P\{\xi_0 = d\} = 1/d$,
 в) ξ_0 имеет равномерное распределение на отрезке $[0, 1]$

Ч-5.11

Найти распределение корня τ случайного уравнения $\xi x + \eta = 0$, где ξ и η - независимые случайные величины, имеющие стандартное нормальное распределение.

Ч-5.12

По последовательности $\xi_1, \xi_2, \dots$ независимых случайных величин, имеющих стандартное нормальное распределение, строится траектория случайного процесса $\xi_t (t \geq 0)$: $\xi_0 = 0, \xi_k = \xi_1 + \dots + \xi_n$ при любом $k \geq 1$, а при $t \in (k, k+1), k = 0, 1, \dots$, графиком траектории ξ_1 является отрезок, соединяющий точки (k, ξ_k) и $(k+1, \xi_{k+1})$, т. е.

$$\xi_t = (k+1-t)\xi_k + (t-k)\xi_{k+1} \text{ при } k < t < k+1.$$

Найти математическое ожидание числа μ_h нулей процесса ξ_1 на полуинтервале $[0, k)$ ($k \geq 1$ -целое) и асимптотику $M\mu_k$ при $k \rightarrow \infty$.

Ч-5.13

Случайный процесс $\xi_n(x), -\infty < x < \infty$, определяется равенством

$$\xi_n(x) = \xi_0 + \xi_1 x + \xi_2 x^2 + \dots + \xi_n x^n,$$

где случайная величина ξ_0 не зависит от случайного вектора $(\xi_1, \dots, \xi_n)$ и имеет непрерывную функцию распределения. Доказать, что при любых фиксированных x и a

$$P\{\xi_n(x) = a\} = 0.$$

Ч-5.14

Доказать, что если выполнены условия задачи п5.13, то с вероятностью 1 все действительные корни многочлена $\xi_n(x)$ - простые.

Ч-5.15

Случайный процесс $\xi_n(x)$, $-\infty < x < \infty$, определяется равенством

$$\xi_n(x) = \zeta_0 + \xi_1 x + \dots + \xi_n x^n,$$

где $\zeta_0, \xi_1, \dots, \xi_n$ - независимые случайные величины, имеющие нулевое математическое ожидание и единичную дисперсию. Найти $M\xi_n(x)$, $D\xi_n(x)$, $\text{cov}(\xi_n(x), \xi_n(y))$.

Ч-5.18

Случайные величины $\xi_1, \xi_2, \dots$ независимы и имеют одно и то же распределение на множестве $\{-1, 0, 1, 2, \dots\}$ с производящей функцией $f(s) = M_s^{k_1}$. По случайному блужданию

$$\rho_0 = 0, \rho_n = \xi_1 + \dots + \xi_n \quad (n \geq 1)$$

построим случайные величины $\tau_1, \tau_2, \dots$:

$$\tau_k = \begin{cases} \min \{n : \rho_n = -k\}, & \text{если } \inf_{n \geq 0} \rho_n \leq -k, \\ \infty & \text{в противном случае.} \end{cases} \quad c > 0$$

а) Доказать, что производящие функции $\varphi_k(s) = M s^{\tau_k}$ связаны соотношениями $\varphi_k(s) = \varphi_1^k(s)$, а производящая функция $\varphi_1(s)$ является решением уравнения $s f(\varphi_1(s)) = 1$.

б) Найти функцию $\varphi_1(s)$, если

$$P\{\xi_1 = k\} = (1-p)p^{k+1}, \quad k = -1, 0, 1, \dots$$

в) Найти функцию $\varphi_1(s)$, если

$$P\{\xi_1 = 1\} = p, \quad P\{\xi_1 = -1\} = 1-p, \quad 0 < p < 1.$$

Ч-5.19

По случайному блужданию ρ_n , определенному в задаче п5.18, построим случайную величину $\mu = \inf_{n \geq 0} \rho_n$. а) Найти распределение μ .

б) Доказать, что $P\{\mu > -\infty\} = 1$ тогда и только тогда, когда $M\xi_1 > 0$ или $P\{\xi_1 = 0\} = 1$.

Ч-5.20

Показать, что если $\rho_0 = 0$, $\rho_n = \xi_1 + \dots + \xi_n$ - случайное блуждание, построенное по независимым одинаково распределенным случайным величинам $\xi_1, \xi_2, \dots$

$$P\{\xi_n = 1\} = P\{\xi_n = -1\} = 1/2, \quad n = 1, 2, \dots,$$

то справедливы следующие соотношения:

$$\text{а) } M\rho_n = 0, \quad D\rho_n = n, \quad P\{\rho_{2n+1} = 0\} = 0, P\{\rho_{2n} = 0\} = C_{2n}^n 2^{-2n} \sim \frac{1}{\sqrt{\pi n}}, \quad n \rightarrow \infty;$$

$$\text{б) } M|\rho_n| = \sum_{k=0}^{n-1} P\{\rho_k = 0\} \sim \sqrt{\frac{2n}{\pi}}, \quad n \rightarrow \infty.$$

Ч-5.21

Случайные векторы $\xi_1, \xi_2, \dots$ в d -мерном евклидовом пространстве независимы и при любом $k = 1, 2, \dots$

$$M\xi_k = 0, \quad M|\xi_k|^2 = \sigma_k^2 < \infty,$$

где $|\xi_k|$ - евклидова длина ξ_k . Построим случайное блуждание $\rho_0 = 0, \rho_n = \xi_1 + \dots + \xi_n (n \geq 1)$. Доказать, что

$$M\rho_n = 0, \quad M|\rho_n|^2 = \sigma_1^2 + \dots + \sigma_n^2.$$

Ч-5.22

Случайные векторы $\xi_n = (\xi_{n,1}, \dots, \xi_{n,d})$ ($k = -1, 2, \dots$) в d -мерном евклидовом пространстве независимы и имеют равномерное распределение на единичной сфере

$$S^{d-1} = \{(x_1, \dots, x_d) \in R^d : x_1^2 + \dots + x_d^2 = 1\}.$$

Пусть $\rho_n = \xi_1 + \dots + \xi_n$ и $|\rho_n|$ - евклидова длина вектора ρ_n . Найти $M|\rho_n|^2$, $D|\rho_n|^2$.

Ч-5.23

Пусть выполнены условия задачи п5.22. Доказать, что при любом $\alpha > 3/2$

$$P\left\{\lim_{n \rightarrow \infty} \frac{|\rho_n|}{n^\alpha} = 0\right\} = 1.$$

Ч-5.24

*. Случайные величины $\xi, \xi_2, \dots$ независимы, принимают значения 1 и -1 с вероятностями p и $q = 1 - p$ соответственно, и $S_0 = 0$, $S_n = \xi_1 + \dots + \xi_n$, $n = 1, 2, \dots$. Обозначим через v число таких n , что $S_n = 0$.

а) Показать, что если $p \neq q$, то $P\{v < \infty\} = 1$; б) показать, что если $p = q = 1/2$, то $P\{v = \infty\} = 1$.

Ч-5.25

Независимые случайные векторы $\xi_n = (\xi_{n,1}, \dots, \xi_{n,s}) \in R^s$, $n = 1, 2, \dots$, имеют независимые компоненты и $P\{\xi_{n,i} = 1\} = P\{\xi_{n,i} = -1\} = \frac{1}{2}$, $1 \leq i \leq s$, $n = 1, 2, \dots$. Положим $S_n = \xi_1 + \dots + \xi_n$, $n = 1, 2, \dots$, и обозначим через v число таких n , что $S_n = (0, \dots, 0)$. Показать, что $P\{v = \infty\} = 1$ при $s = 2$ и что $P\{v < \infty\} = 1$ при $s \geq 3$.

Ч-5.26

(То же, что в В. а. л. д. а.) Пусть случайные величины $\xi_1, \xi_2, \dots$ независимы, $\xi_i = a$, и $|\xi_i| \leq C < \infty$ ($i \geq 1$). Пусть $B_1 \subset R^1, B_2 \subset R^2, B_3 \subset R^3, \dots$ - произвольная последовательность измеримых множеств, и случайная величина v определяется равенством

$$v = \inf\{n : (\xi_1, \dots, \xi_n) \notin B_n\}$$

($v = \infty$, если $(\xi_1, \dots, \xi_n) \in B_n$ при любом $n < \infty$). Используя равенство

$$\sum_{i=1}^v \xi_i = \sum_{i=1}^{\infty} \xi_i \chi\{v \geq i\} = \sum_{i=1}^{\infty} \xi_i (1 - \chi\{v < i\})$$

(где $\chi\{A\}$ - индикатор события A), доказать, что если $Mv < \infty$, то

$$M \sum_{i=1}^v \xi_i = aMv.$$

Ч-5.27

Проверить справедливость установленного в задаче п5.26 равенства в следующих случаях:

а) $P\{\xi_i = 1\} = P\{\xi_i = -1\} = 1/2$, $v = \min\{n \geq 0 : \xi_1 + \dots + \xi_n = 1\}$ б) $P\{\xi_i = 1\} = P\{\xi_i = -2\} = 1/2$, $v = \min\{n \geq 0 : \xi_1 + \dots + \xi_n = 1\}$. Объяснить результаты.

Ч-5.28

Случайные величины $\xi_1, \xi_2, \dots$ независимы и одинаково распределены, $a = M\xi_1 > 0$ и $P\{|\xi_1| \leq C\} = 1$ при некотором $C < \infty$. Пусть $\rho_0 = 0$, $\rho_n = \xi_1 + \dots + \xi_n$ ($n \geq 1$) и $N_1 = \inf\{n > 0 : S_n \geq t\}$. Доказать, что при любом $t > 0$

$$t \leq aMN_t \leq t + C.$$

Ч-5.29

Случайные величины $\rho_1, \rho_2, \dots$ при любом целом $n \geq 1$ удовлетворяют условию

$$M\{\rho_{n+1} | \rho_1, \dots, \rho_n\} \geq \rho_n.$$

Доказать, что при любых целых $k, n \geq 1$

$$M\{\rho_{n+k} | \rho_1, \dots, \rho_n\} \geq \rho_n.$$

Ч-5.30

*. Неотрицательные случайные величины $\rho_1, \rho_2, \dots$ при любом целом $n \geq 1$ удовлетворяют условию

$$M\{\rho_{n+1} | \rho_1, \dots, \rho_n\} \geq \rho_n.$$

Доказать, что для любого $\delta > 0$ и любого целого $n \geq 1$

$$P\{\max\{\rho_1, \dots, \rho_n\} \geq \delta\} \leq \frac{M\rho_n}{\delta}.$$

Ч-5.31

Случайные величины $\xi_1, \xi_2, \dots$ независимы, $M\xi_i = 0, i = 1, 2, \dots$. Доказать, что для любого $\delta > 0$ и любого целого $n \geq 1$

$$P\left\{\max_{1 \leq k \leq n} |\xi_1 + \dots + \xi_k| \geq \delta\right\} \leq \frac{M|\xi_1 + \dots + \xi_n|}{\delta}.$$

МФТИ-Т.17

Население региона делится по некоторому социально-экономическому признаку на три подгруппы. Следующее поколение с вероятностями 0,4; 0,6 и 0,2, соответственно, остается в своей подгруппе, а если не остается, то с равными вероятностями переходит в Любую из остальных подгрупп. Найти:

а) распределение населения по данному социально-экономическому признаку в следующем поколении, если в настоящем поколении в 1-ой подгруппе было 20% населения, во 2-ой подгруппе – 30%, и в 3-ей подгруппе – 50%

Данный процесс описывается марковской цепью с матрицей

$$\begin{pmatrix} 0,4 & 0,3 & 0,3 \\ 0,2 & 0,6 & 0,2 \\ 0,4 & 0,4 & 0,2 \end{pmatrix}$$

По условию начальное распределение было (0,2 0,3 0,5). Тогда распределение в следующем поколении

$$(x \ y \ z) = (0,2 \ 0,3 \ 0,5) \begin{pmatrix} 0,4 & 0,3 & 0,3 \\ 0,2 & 0,6 & 0,2 \\ 0,4 & 0,4 & 0,2 \end{pmatrix} = (0,34 \ 0,44 \ 0,22)$$

Найти б) предельное распределение по данному признаку, которое не меняется при смене поколений.

$$\begin{pmatrix} 0,4 - \lambda & 0,3 & 0,3 \\ 0,2 & 0,6 - \lambda & 0,2 \\ 0,4 & 0,4 & 0,2 - \lambda \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix} \rightarrow \lambda^3 - 1,2\lambda^2 + 0,18\lambda + 0,02 = 0$$

$$\lambda_1 = 1, \lambda_2 = \frac{1 + \sqrt{3}}{10}, \lambda_3 = \frac{1 - \sqrt{3}}{10}$$

$$\begin{pmatrix} 0,4 - \lambda_1 & 0,3 & 0,3 \\ 0,2 & 0,6 - \lambda_1 & 0,2 \\ 0,4 & 0,4 & 0,2 - \lambda_1 \end{pmatrix} \begin{pmatrix} x_1 \\ y_1 \\ z_1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

$$\begin{pmatrix} -2x_1 & y_1 & z_1 \\ x_1 & -2y_1 & z_1 \\ x_1 & y_1 & -2z_1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

$$\begin{pmatrix} x_1 \\ y_1 \\ z_1 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$$

Аналогично получаем:

$$\begin{pmatrix} x_2 \\ y_2 \\ z_2 \end{pmatrix} = \begin{pmatrix} \frac{3}{4}(1 + \sqrt{3}) \\ \frac{1}{2}(-2 - \sqrt{3}) \\ 1 \end{pmatrix}$$

$$\begin{pmatrix} x_3 \\ y_3 \\ z_3 \end{pmatrix} = \begin{pmatrix} \frac{3}{4}(1 - \sqrt{3}) \\ \frac{1}{2}(-2 + \sqrt{3}) \\ 1 \end{pmatrix}$$

Тогда диагонализированная матрица

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1+\sqrt{3}}{10} & 0 \\ 0 & 0 & \frac{1-\sqrt{3}}{10} \end{pmatrix}$$

и

$$\begin{aligned} \begin{pmatrix} 0,4 & 0,3 & 0,3 \\ 0,2 & 0,6 & 0,2 \\ 0,4 & 0,4 & 0,2 \end{pmatrix}^n &= \begin{pmatrix} 1 & \frac{3}{4}(1 + \sqrt{3}) & \frac{3}{4}(1 - \sqrt{3}) \\ 1 & \frac{1}{2}(-2 - \sqrt{3}) & \frac{1}{2}(-2 + \sqrt{3}) \\ 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1+\sqrt{3}}{10} & 0 \\ 0 & 0 & \frac{1-\sqrt{3}}{10} \end{pmatrix}^n \begin{pmatrix} 1 & \frac{3}{4}(1 + \sqrt{3}) & \frac{3}{4}(1 - \sqrt{3}) \\ 1 & \frac{1}{2}(-2 - \sqrt{3}) & \frac{1}{2}(-2 + \sqrt{3}) \\ 1 & 1 & 1 \end{pmatrix}^{-1} = \\ &= \begin{pmatrix} 1 & \frac{3}{4}(1 + \sqrt{3}) & \frac{3}{4}(1 - \sqrt{3}) \\ 1 & \frac{1}{2}(-2 - \sqrt{3}) & \frac{1}{2}(-2 + \sqrt{3}) \\ 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & \left(\frac{1+\sqrt{3}}{10}\right)^n & 0 \\ 0 & 0 & \left(\frac{1-\sqrt{3}}{10}\right)^n \end{pmatrix} \begin{pmatrix} 1 & \frac{3}{4}(1 + \sqrt{3}) & \frac{3}{4}(1 - \sqrt{3}) \\ 1 & \frac{1}{2}(-2 - \sqrt{3}) & \frac{1}{2}(-2 + \sqrt{3}) \\ 1 & 1 & 1 \end{pmatrix}^{-1} = \\ &= \begin{pmatrix} 1 & \frac{3}{4}(1 + \sqrt{3}) & \frac{3}{4}(1 - \sqrt{3}) \\ 1 & \frac{1}{2}(-2 - \sqrt{3}) & \frac{1}{2}(-2 + \sqrt{3}) \\ 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & \left(\frac{1+\sqrt{3}}{10}\right)^n & 0 \\ 0 & 0 & \left(\frac{1-\sqrt{3}}{10}\right)^n \end{pmatrix} \begin{pmatrix} \frac{4}{13} & \frac{6}{13} & \frac{3}{13} \\ -\frac{4(-2+\frac{\sqrt{3}}{2})}{13\sqrt{3}} & -\frac{4(\frac{1}{4}+\frac{3\sqrt{3}}{4})}{13\sqrt{3}} & -\frac{4(\frac{7}{4}-\frac{5\sqrt{3}}{4})}{13\sqrt{3}} \\ -\frac{4(2+\frac{\sqrt{3}}{2})}{13\sqrt{3}} & -\frac{4(-\frac{1}{4}+\frac{3\sqrt{3}}{4})}{13\sqrt{3}} & -\frac{4(-\frac{7}{4}-\frac{5\sqrt{3}}{4})}{13\sqrt{3}} \end{pmatrix} \\ &\lim_{n \rightarrow +\infty} \left(\begin{pmatrix} 0,4 & 0,3 & 0,3 \\ 0,2 & 0,6 & 0,2 \\ 0,4 & 0,4 & 0,2 \end{pmatrix}^n \right) = \\ &= \begin{pmatrix} 1 & \frac{3}{4}(1 + \sqrt{3}) & \frac{3}{4}(1 - \sqrt{3}) \\ 1 & \frac{1}{2}(-2 - \sqrt{3}) & \frac{1}{2}(-2 + \sqrt{3}) \\ 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} \frac{4}{13} & \frac{6}{13} & \frac{3}{13} \\ -\frac{4(-2+\frac{\sqrt{3}}{2})}{13\sqrt{3}} & -\frac{4(\frac{1}{4}+\frac{3\sqrt{3}}{4})}{13\sqrt{3}} & -\frac{4(\frac{7}{4}-\frac{5\sqrt{3}}{4})}{13\sqrt{3}} \\ -\frac{4(2+\frac{\sqrt{3}}{2})}{13\sqrt{3}} & -\frac{4(-\frac{1}{4}+\frac{3\sqrt{3}}{4})}{13\sqrt{3}} & -\frac{4(-\frac{7}{4}-\frac{5\sqrt{3}}{4})}{13\sqrt{3}} \end{pmatrix} \\ &= \begin{pmatrix} \frac{4}{13} & \frac{6}{13} & \frac{3}{13} \\ \frac{4}{13} & \frac{6}{13} & \frac{3}{13} \\ \frac{4}{13} & \frac{6}{13} & \frac{3}{13} \end{pmatrix} \end{aligned}$$

МФТИ-Т.18

Пусть матрица вероятностей перехода за один шаг цепи Маркова с двумя состояниями и имеет вид

$$\begin{pmatrix} 1-\alpha & \alpha \\ \beta & 1-\beta \end{pmatrix}, \quad 0 \leq \alpha, \quad \beta \leq 1$$

Найти вероятности перехода за n шагов и предельные вероятности.

$$\begin{pmatrix} 1-\alpha & \alpha \\ \beta & 1-\beta \end{pmatrix} \begin{pmatrix} x_{\pm} \\ y_{\pm} \end{pmatrix} = \lambda_{\pm} \begin{pmatrix} x_{\pm} \\ y_{\pm} \end{pmatrix} \rightarrow (1-\alpha-\lambda)(1-\beta-\lambda)-\alpha\beta=0 \rightarrow$$

$$\lambda^2 - \lambda(2-\alpha-\beta) + (1-\alpha)(1-\beta) - \alpha\beta = 0$$

$$\begin{aligned}
 \lambda_{\pm} &= \frac{2 - \alpha - \beta \pm \sqrt{(2 - \alpha - \beta)^2 - 4((1 - \alpha)(1 - \beta) - \alpha\beta)}}{2} = \\
 &= \frac{2 - \alpha - \beta \pm \sqrt{(1 - \alpha)^2 - 2(1 - \alpha)(1 - \beta) + (1 - \beta)^2 + 4\alpha\beta}}{2} = \\
 &= \frac{2 - \alpha - \beta \pm \sqrt{(\alpha - \beta)^2 + 4\alpha\beta}}{2} = \frac{2 - \alpha - \beta \pm \sqrt{\alpha^2 + 2\alpha\beta + \beta^2}}{2} = \frac{2 - \alpha - \beta \pm (\alpha + \beta)}{2} \rightarrow \\
 &\begin{cases} \lambda_+ = 1 \\ \lambda_- = 1 - (\alpha + \beta) \end{cases}
 \end{aligned}$$

$$\begin{pmatrix} 1 - \alpha - \lambda_{\pm} & \alpha \\ \beta & 1 - \beta - \lambda_{\pm} \end{pmatrix} \begin{pmatrix} x_{\pm} \\ y_{\pm} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \rightarrow \begin{pmatrix} (1 - \alpha - \lambda_{\pm})x_{\pm} + \alpha y_{\pm} \\ \beta x_{\pm} + (1 - \beta - \lambda_{\pm})y_{\pm} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \rightarrow \\
 \begin{pmatrix} x_{\pm} \\ y_{\pm} \end{pmatrix} = \begin{pmatrix} \alpha \\ -1 + \alpha + \lambda_{\pm} \end{pmatrix}$$

При $\alpha = \beta = 0$ тривиальный случай.

$$\begin{pmatrix} 1 - \alpha & \alpha \\ \beta & 1 - \beta \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \\
 \lim_{n \rightarrow +\infty} \begin{pmatrix} 1 - \alpha & \alpha \\ \beta & 1 - \beta \end{pmatrix}^n = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

При $\alpha, \beta \in (0, 1]$ вырождения нет. Тогда диагонализированная матрица

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 - (\alpha + \beta) \end{pmatrix}$$

и

$$\begin{aligned}
 \begin{pmatrix} 1 - \alpha & \alpha \\ \beta & 1 - \beta \end{pmatrix}^n &= \begin{pmatrix} \alpha & \alpha \\ \alpha & -\beta \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 - (\alpha + \beta) \end{pmatrix}^n \begin{pmatrix} \alpha & \alpha \\ \alpha & -\beta \end{pmatrix}^{-1} = \\
 &= \frac{1}{\alpha(\alpha + \beta)} \begin{pmatrix} \alpha & \alpha \\ \alpha & -\beta \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & (1 - (\alpha + \beta))^n \end{pmatrix} \begin{pmatrix} \beta & \alpha \\ \alpha & -\alpha \end{pmatrix} = \\
 &= \frac{1}{\alpha + \beta} \begin{pmatrix} \alpha(1 - (\alpha + \beta))^n + \beta & \alpha(1 - (1 - (\alpha + \beta))^n) \\ \beta(1 - (1 - (\alpha + \beta))^n) & \alpha + \beta(1 - (\alpha + \beta))^n \end{pmatrix}
 \end{aligned}$$

При $\alpha = 1, \beta = 1$

$$\begin{pmatrix} 1 - \alpha & \alpha \\ \beta & 1 - \beta \end{pmatrix}^n = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

При $\alpha \neq 1, \beta \neq 1$

$$\lim_{n \rightarrow +\infty} \left(\begin{pmatrix} 1 - \alpha & \alpha \\ \beta & 1 - \beta \end{pmatrix}^n \right) = \frac{1}{\alpha + \beta} \begin{pmatrix} \beta & \alpha \\ \beta & \alpha \end{pmatrix}$$

Определение параметров, при котором процесс докритический, критический, надкритический (??)

Для производящей функции процесса Гальтона-Ватсона $f(z) = \frac{1}{m+1-mz}$, $m > 0$ выясним, при каких значениях параметра m процесс является: докритическим, критическим, надкритическим.

Найдём математическое ожидание z :

$$\mathbb{E}(\xi) = \frac{d(f)}{d(z)} \Big|_{z=1} = - \frac{-m}{(m+1-mz)^2} \Big|_{z=1} = m$$

В итоге:

$m < 1$ - процесс докритический,

$m = 1$ - процесс критический,

$m > 1$ - процесс надкритический.

Найти вероятность вырождения процесса в надкритическом случае.

$$\begin{aligned} s = f(s) = \frac{1}{m+1-ms} \rightarrow s(m+1-ms) = ms + s - ms^2 = 1 \rightarrow ms^2 - s(m+1) + 1 = 0 \rightarrow \\ \rightarrow ms(s-1) - (s-1) = 0 \rightarrow (s-1)(ms-1) = 0 \rightarrow \begin{cases} s = 1 \\ s = \frac{1}{m} \end{cases} \end{aligned}$$

Показать, что n -тая итерация производящей функции может быть представлена в виде

$$\begin{aligned} f^n(z) &= \frac{m^n - 1 - m(m^{n-1} - 1)z}{m^{n+1} - 1 - m(m^n - 1)z} \\ \text{при } m \neq 1 \text{ и} \\ f^n(z) &= \frac{n - (n-1)z}{n+1 - nz} \end{aligned}$$

Докажем утверждение по индукции.

База индукции следующая:

$$\begin{aligned} f^2(z) = f(f(z)) = f\left(\frac{1}{m+1-mz}\right) &= \frac{1}{m+1-m\frac{1}{m+1-mz}} = \frac{m+1-mz}{(m+1)(m+1-mz)-m} \\ &= \frac{m+1-mz}{(m+1)^2 - (m+1)mz - m} \end{aligned}$$

при $m \neq 1$ (иначе случай будет ниже)

$$f^2(z) = \frac{(m-1)(m+1-mz)}{(m-1)((m+1)^2 - (m+1)mz - m)} = \frac{m^2 - 1 - m(m-1)z}{m^3 + 1 - m(m^2 - 1)z}$$

Шаг индукции:

$$\begin{aligned} f^{n+1}(z) = f(f^n(z)) &= f\left(\frac{m^n - 1 - m(m^{n-1} - 1)z}{m^{n+1} - 1 - m(m^n - 1)z}\right) = \\ &= \frac{1}{m+1-m\frac{m^n - 1 - m(m^{n-1} - 1)z}{m^{n+1} - 1 - m(m^n - 1)z}} = \\ &= \frac{m^{n+1} - 1 - m(m^n - 1)z}{(m+1)(m^{n+1} - 1 - m(m^n - 1)z) - m(m^n - 1 - m(m^{n-1} - 1)z)} = \\ &= \frac{m^{n+1} - 1 - m(m^n - 1)z}{(m+1)(m^{n+1} - 1) - m(m^n - 1) - m(m+1)(m^n - 1)z + m^2(m^{n-1} - 1)z} = \\ &= \frac{m^{n+1} - 1 - m(m^n - 1)z}{m^{n+2} - 1 - m(m^{n+1} - 1)z} \end{aligned}$$

теперь при $m = 1$ база индукции:

$$f^2(z) = \frac{m+1-mz}{(m+1)^2 - (m+1)mz - m} = \frac{(m+1) - (m)z}{m(m+1) + 1 - (m+1)z} = \frac{2 - (2-1)z}{2 + 1 - 2z}$$

и шаг индукции:

$$\begin{aligned} f^{n+1}(z) = f(f^n(z)) &= f\left(\frac{n - (n-1)z}{n+1 - nz}\right) = \\ &= \frac{1}{2 - \frac{n - (n-1)z}{n+1 - nz}} = \\ &= \frac{n+1 - nz}{2(n+1 - nz) - n + (n-1)z} = \\ &= \frac{n+1 - nz}{n+2 - (n+1)z} \end{aligned}$$

МФТИ-Т.20

Пусть $(W_t, t \geq 0)$ - винеровский процесс. Для $u \in \mathbb{R}$ определяется $\tau_u = \inf \{t : W_t = u\}$ - момент первого достижения уровня u траекторией винеровского процесса. Найти плотность распределения случайной величины τ_u

Если этот процесс впервые пересёк уровень u в точке τ_u , траекторию, исходящую из точки (τ_u, u) можно рассматривать, как самостоятельный винеровский процесс.

Следовательно, вероятность того, что в точке t будет выполнено $W_t \geq u$ равна $\frac{1}{2}$ в силу симметрии.

Заметим с другой стороны, что

$$P(W_t \geq u | \tau_u \leq t) = \frac{P(W_t \geq u)}{P(\tau_u \leq t)} = \frac{1}{2}$$

$$P(\tau_u \leq t) = 2P(W_t \geq u) = 2 \int_u^{+\infty} \frac{1}{\sigma\sqrt{2\pi t}} \exp\left(-\frac{x^2}{2\sigma^2 t}\right) dx = \frac{2}{\sqrt{2\pi}} \int_{\frac{u}{\sqrt{t}\sigma}}^{+\infty} \exp\left(-\frac{x^2}{2}\right) dx$$

$$\frac{\partial}{\partial(t)} (P(\tau_u \leq t)) = \frac{\partial}{\partial(t)} \left(\frac{2}{\sqrt{2\pi}} \int_{\frac{u}{\sqrt{t}\sigma}}^{+\infty} \exp\left(-\frac{x^2}{2}\right) dx \right) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{u^2}{2\sigma^2 t}\right) \frac{u}{t^{\frac{3}{2}}\sigma}$$

МФТИ-Т.21

Пусть

$$M_t = \max_{0 \leq s \leq t} W_s, \quad t > 0$$

где $(W_t, t \geq 0)$ - винеровский процесс.

Найти плотность распределения случайной величины M_t

$$P(M_t \geq x) = P(\tau_x \leq t) = 2 \int_x^{+\infty} \frac{1}{\sigma\sqrt{2\pi t}} \exp\left(-\frac{y^2}{2\sigma^2 t}\right) dy$$

$$P(M_t < x) = 1 - P(M_t \geq x) = 1 - 2 \int_x^{+\infty} \frac{1}{\sigma\sqrt{2\pi t}} \exp\left(-\frac{y^2}{2\sigma^2 t}\right) dy$$

$$1 - \sqrt{\frac{2}{\pi}} \int_{\frac{x}{\sigma\sqrt{t}}}^{+\infty} \exp\left(-\frac{y^2}{2}\right) dy = \sqrt{\frac{2}{\pi}} \int_0^{\frac{x}{\sigma\sqrt{t}}} \exp\left(-\frac{y^2}{2}\right) dy$$

В итоге:

$$\frac{\partial}{\partial(x)} (P(M_t < x)) = \frac{\partial}{\partial(x)} \left(\sqrt{\frac{2}{\pi}} \int_0^{\frac{x}{\sigma\sqrt{t}}} \exp\left(-\frac{y^2}{2}\right) dy \right) = \sqrt{\frac{2}{\pi}} \frac{1}{\sigma\sqrt{t}} \exp\left(-\frac{x^2}{2\sigma^2 t}\right)$$

МФТИ-Т.22.

Пусть $\mathbb{X} = (X_1, \dots, X_n)$ - выборка из пуассоновского распределения с параметром λ .

Найти оценку наибольшего правдоподобия параметра λ

Функция правдоподобия

$$f(\lambda) = \prod_{i=1}^n (P_\lambda(X_i = k_i)) = \prod_{i=1}^n \left(\frac{\lambda^{k_i}}{(k_i)!} \exp(-\lambda) \right) = \prod_{i=1}^n \left(\frac{1}{(k_i)!} \right) \lambda^{\sum_{i=1}^n k_i} \exp(-n\lambda)$$

$$\ln(f(\lambda)) = - \sum_{i=1}^n \ln((k_i)!) + \sum_{i=1}^n (k_i) \ln(\lambda) - n\lambda$$

Найдём максимум этой функции.

$$\frac{\partial}{\partial(\lambda)} (\ln(f(\lambda))) = \sum_{i=1}^n (k_i) \frac{1}{\lambda} - n = 0 \rightarrow \lambda = \frac{1}{n} \sum_{i=1}^n (k_i)$$

убедимся в максимуме с помощью второй производной:

$$\frac{\partial^2}{\partial(\lambda)^2} (\ln(f(\lambda))) = - \sum_{i=1}^n (k_i) \frac{1}{\lambda^2} = - \sum_{i=1}^n (k_i) \left(\frac{1}{n} \sum_{i=1}^n (k_i) \right)^{-2} = -n^2 \left(\sum_{i=1}^n (k_i) \right)^{-1} < 0$$

МФТИ-Т.23.

Пусть $\mathbb{X} = (X_1, \dots, X_n)$ - выборка из нормального распределения $N(a, \sigma^2)$.

Найти оценки наибольшего правдоподобия параметров a и σ^2

Функция правдоподобия:

$$\begin{aligned} f(a, \sigma) &= \prod_{i=1}^n (P_{a, \sigma}(X_i)) = \prod_{i=1}^n \left(\left(\frac{1}{\sqrt{2\pi}\sigma} \right) \exp \left(-\frac{(X_i - a)^2}{2\sigma^2} \right) \right) = \\ &= \left(\frac{1}{\sqrt{2\pi}\sigma} \right)^n \exp \left(-\frac{1}{2\sigma^2} \sum_{i=1}^n ((X_i - a)^2) \right) - \\ \ln(f(a, \sigma)) &= -n(\ln(\sqrt{2\pi}) + \ln(\sigma)) - \frac{1}{2\sigma^2} \sum_{i=1}^n ((X_i - a)^2) \\ \ln(f(a, \sigma)) &= -n(\ln(\sqrt{2\pi}) + \ln(\sigma)) - \frac{1}{2\sigma^2} \sum_{i=1}^n ((X_i - a)^2) \end{aligned}$$

Максимум этой функции:

$$\frac{\partial}{\partial(\sigma)}(\ln(f(a, \sigma))) = -\frac{n}{\sigma} + \frac{1}{\sigma^3} \sum_{i=1}^n ((X_i - a)^2) = 0$$

$$\sigma^2 = \frac{1}{n} \sum_{i=1}^n ((X_i - a)^2)$$

$$\frac{\partial}{\partial(a)}(\ln(f(a, \sigma))) = \frac{1}{\sigma^2} \sum_{i=1}^n (X_i - a) = 0$$

$$a = \frac{1}{n} \sum_{i=1}^n (X_i)$$

$$\frac{\partial^2}{\partial(\sigma)^2}(\ln(f(a, \sigma))) = \frac{n}{\sigma^2} - \frac{3}{\sigma^4} \sum_{i=1}^n ((X_i - a)^2)$$

$$\frac{\partial^2}{\partial(a)^2}(\ln(f(a, \sigma))) = -\frac{n}{\sigma^2}$$

$$\frac{\partial^2}{\partial(a)\partial(\sigma)}(\ln(f(a, \sigma))) = -\frac{2}{\sigma^3} \sum_{i=1}^n (X_i - a)$$

Матрица вторых производных в данной точке

$$\begin{pmatrix} -\frac{2n}{\sigma^2} & 0 \\ 0 & -\frac{n}{\sigma^2} \end{pmatrix} = -\frac{n}{\sigma^2} \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix} < 0 \rightarrow \text{это точка строгого максимума}$$

задача про билеты Птф

(давно хотел прорешать, потом подумаю)

7.1.2 Problems About Poisson Processes**Ч-5.33**

Найти $\text{cov}(\xi_+, \xi_{++\odot})$ при $t, s \geq 0$, если:

- а) ξ_t - пуассоновский процесс на $[0, \infty)$ с интенсивностью λ ,
- б) ξ_t - пуассоновский процесс на $[0, \infty)$ с интенсивностью $\lambda(t)$.

Ч-5.34

Пусть $\{\tau_k\}_{k=1}^\infty$ ($0 < \tau_1 < \tau_2 < \dots$) - положения точек пуассоновского потока на $[0, \infty)$ с интенсивностью λ . Доказать, что при любом $T > 0$

$$\sum_{h=1}^{\infty} P\{\tau_k \leq T\} = \lambda T.$$

Ч-5.35

Пусть выполнены условия задачи п5.34. Найти $M\tau_k$, $D\tau_k$ и плотность $p_k(x)$ распределения τ_k . 160

Ч-5.36

Пусть выполнены условия задачи. п5.34. Найти:

- а) плотность $p(x_1, \dots, x_k)$ совместного распределения случайных величин $\tau_1, \tau_2, \dots, \tau_k$,
 б) $P\{\tau_1 \leq x | \tau_2 > T\}$, $0 \leq x \leq \infty$, в) $P\{\tau_1 \leq x | \tau_1 \leq T < \tau_2\}$, $0 \leq x \leq T$.

Ч-5.37

Пусть выполнены условия задачи п5.34. Найти условную плотность $p_T(x_1, \dots, x_k)$ совместного распределения случайных величин $\tau_1, \dots, \tau_h$ при условии, что $\tau_k \leq T < \tau_{k+1}$. Сравнить $p_T(x_1, \dots, x_k)$ с плотностью $q_T(x_1, \dots, x_h)$ совместного распределения членов варпадионного ряда $\xi_{(1)} \leq \xi_{(2)} \leq \dots \leq \xi_{(h)}$, построенного по независимым случайным величинам $\xi_1, \dots, \xi_k$, имеющим равномерное распределение на отрезке $[0, T]$.

Ч-5.43

Моменты поступления требований в систему массового обслуживания образуют пуассоновский поток на $(-\infty, \infty)$ с интенсивностью λ . Каждое требование независимо от остальных находится в едстве случайное ние числа ξ_1 требований в сиееме в момент t .

Ч-5.44

Для системы массового обслуживания, описанной в задаче п5.43, найти функцию $f(t) = P\{\xi_1 = 0 | \xi_0 = 0\}$. Убедиться в том, что $f(t)$ монотонно возрастает по t .

Ч-5.45

Случайно расположенные на плоскости точки образуют пуассоновское поле с интенсивностью λ , т. е. число точек в любой квадратуемой области S имеет пуассоновское распределение с математическим ожиданием $\lambda|S|$, где $|S|$ площадь области S , и числа точек в непересекающихся областях независимы. Пусть $\rho_1 \leq \rho_2 \leq \dots$ - упорядоченные по возрастанию расстояния от начала координат до точек этого поля.

- а) Как можно описать последовательность $\{\rho_k\}_{k=1}^\infty$?
 б) Найти плотность $p_n(x)$ распределения ρ_n , точную Формулу для ρ_n и асимптотику $M\rho_n$ при $n \rightarrow \infty$.

Ч-5.46

Случайно расположенные в пространстве R^3 точки образуют пуассоновское поле с интенсивностью λ , т. е. число точек в любой измеримой области V имеет пуассоновское распределение с математическим ожиданием $\lambda|V|$, где $|V|$ - объем области V , а числа точек в непересекающихся областях независимы. Ответить на те же вопросы, что в задаче 5.45.

Ч-5.47

Автобусы прибывают на остановку в случайные моменты времени $\tau_1 < \tau_2 < \dots$. Случайные величины $\tau_1, \tau_2, \dots$ независимы и τ_n имеет равномерное распределение в интервале $(n-1, n)$.

- а) Найти плотность $p(x)$ распределения интервала $\delta_n = \tau_{n+1} - \tau_n$ между автобусами.
 б) Найти плотность $p_k(x_1, x_2)$ распределения двумерного вектора $(\delta_n, \delta_{n+\lambda})$ при $k = 1, 2, \dots$
 в) Моменты ξ и ξ прихода двух пассажиров на остановку независимы и имеют равномерное распределение на интервале $(0, 1)$. Найти вероятность того, что они поедут на одном и том же автобусе.
 г) Моменты ξ_1 и ξ_2 прихода двух пассажиров на остановку независимы, ξ_1 имеет равномерное распределение на интервале $(0, 1)$, а ξ_2 - на интервале $(1, 2)$. Найти вероятность того, что эти пассажиры поедут на одном автобусе.
 д) Пассажир приходит на остановку в случайный момент ξ , имеющий равномерное распределение на интервале $(0, 1)$. Найти математическое ожидание, дисперсию и плотность $q(x)$ распределения времени ожидания автобуса.

7.1.3 Problems About Markov Chains (!!!)

(займусь теорвером - в первый же день по ним тренироваться буду)

Белан-ВШЭл5.у1.(3 мин) Последовательность бросаний кубика и монеты

Допустим, берется симметричный кубик и бросается раз за разом до первого выпадения грани с шестью очками. После того как шесть очков выпали, берется симметричная монетка и подбрасывается до тех пор, пока не выпадет первый орел. После того как орел выпал, снова берут кубик и подбрасывают его до первого появления шести очков. И так далее. Вы должны угадать, кубиком или монеткой будет выполнен седьмой бросок в этой игре?

Solution

Решаем самым обычным уравнением для марковских цепей, просто 1 формулой нужно воспользоваться.

Введем цепь Маркова с двумя состояниями и с дискретным временем. Будем говорить, что процесс находится в состоянии 1 в момент времени n , если $n + 1$ -й бросок в описанной игре осуществляется кубиком, и в состоянии 2, если $n + 1$ -й бросок выполняется монеткой. Схема наша как всегда:

Мы имеем $p = 1/6, q = 1/2$. Вероятности нахождения процесса в различных состояниях на n -м шаге даются выведенными формулами из возведения матрицы перехода в n -ю степень а также положить $\pi_1(0) = 1$ и $\pi_2(0) = 0$:

$$\pi_1(n) = \frac{q}{p+q} + \frac{p}{p+q}(1-p-q)^n = \frac{3}{4} + \frac{1}{4 \cdot 3^n},$$

$$\pi_2(n) = \frac{p}{p+q} - \frac{p}{p+q}(1-p-q)^n = \frac{1}{4} - \frac{1}{4 \cdot 3^n}.$$

Итак, $\pi_1(6) > \pi_2(6)$, а значит с большей вероятностью седьмой бросок будет выполняться кубиком.

Задача в 2 строчки решилась цепью Маркова. А иначе и не решить ее вообще! (????? подумаю больше про разные методы для нее.)

Белан-ВШЭл5.у2.(3 мин) Переходы между тремя равновероятными состояниями

Марковский процесс с непрерывным временем может находиться в одном из трех состояний, 1, 2 и 3, причем вероятность перехода между любыми двумя из них равна λ . Найдите вероятности, $\pi_1(t), \pi_2(t)$ и $\pi_3(t)$, найти систему в различных состояниях в произвольный момент времени $t > 0$, если известно, что в нулевой момент времени система находилась в состоянии 1.

Solution

Пишем управляющее уравнение, элементарно его решаем.

Запишем управляющее уравнение на вероятности нахождения марковского процесса в различных состояниях

$$\begin{aligned}\dot{\pi}_1(t) &= -2\lambda\pi_1(t) + \lambda\pi_2(t) + \lambda\pi_3(t), \\ \dot{\pi}_2(t) &= \lambda\pi_1(t) - 2\lambda\pi_2(t) + \lambda\pi_3(t) \\ \dot{\pi}_3(t) &= \lambda\pi_1(t) + \lambda\pi_2(t) - 2\lambda\pi_3(t).\end{aligned}$$

Легко понять, что в силу начального условия ($\pi_1(0) = 1, \pi_2(0) = \pi_3(0) = 0$) и симметрии вероятностей переходов, вероятности нахождения процесса во втором и третьем состояниях одинаковы, то есть $\pi_2(t) = \pi_3(t) = (1 - \pi_1(t))/2$. Отсюда получаем замкнутое уравнение на эволюцию вероятности $\pi_1(t)$

$$\dot{\pi}_1(t) = -3\lambda\pi_1 + \lambda$$

решение которого (с учетом начальных условий) имеет вид

$$\pi_1(t) = \frac{1}{3} + \frac{2}{3}e^{-3\lambda t}$$

и, следовательно,

$$\pi_2(t) = \pi_3(t) = \frac{1}{3} - \frac{1}{3}e^{-3\lambda t}$$

Белан-ВШЭл5.у3. Занятость телефонной линии

Телефонная линия может находиться в одном из двух состояний: (1) линия свободна и (2) линия занята. Длительности интервалов времени между разговорами на линии и длительности самих разговоров статистически независимы друг от друга и имеют экспоненциальные функции распределения, $p_1(\tau) = \lambda e^{-\lambda\tau}$ и $p_2(\tau) = \mu e^{-\mu\tau}$, соответственно.

а) Предположим, что в начальный момент времени линия свободна и мы наблюдаем за ее стохастической динамикой в течении времени T . Обозначим через $r_2(T)$ долю времени, которое линия была занята в течении окна наблюдения. Вычислите математическое ожидание и дисперсию случайной величины $r_2(T)$.

б) Известно, что в нулевой момент времени и спустя время T линия свободна. Найдите вероятность того, что линия занята в промежуточные моменты времени $0 < t < T$.

Solution a)

Рассмотрим стохастическую переменную

$$S(t) = \begin{cases} 1, & \text{если линия свободна в момент } t, \\ 2, & \text{если линия занята в момент } t. \end{cases}$$

Вероятности $\pi_1(t) \equiv \Pr[S(t) = 1]$ и $\pi_2(t) \equiv \Pr[S(t) = 2]$ подчиняются системе уравнений (21) и (22) с начальным условием $\pi_1(0) = 1, \pi_2(0) = 0$. Случайная величина $r_2(T)$, статистикой которой мы интересуемся, может быть представлена как

$$r_2(T) = \frac{\int_0^T I(S(t) = 2) dt}{T}$$

Тогда

$$\langle r_2(T) \rangle = \frac{\int_0^T \langle I(S(t) = 2) \rangle dt}{T} = \frac{\int_0^T \Pr[S(t) = 2 | S(0) = 1] dt}{T},$$

где $\Pr[S(t) = 2 | S(0) = 1]$ это вероятность обнаружить процесс в состоянии 2 в момент времени t при условии, что он находился в состоянии 1 в момент времени 0. Очевидно, $\Pr[S(t) = 2 | S(0) = 1]$ дается решением $\pi_2(t)$ (см формулу (29)) с начальными условиями $\pi_1(0) = 1, \pi_2(0) = 0$. То есть

$$\Pr[S(t) = 2 | S(0) = 1] = \frac{\lambda}{\lambda + \mu} (1 - \exp[-(\lambda + \mu)t])$$

Подставляя Ур. (43) в Ур. (42) и интегрируя, находим

$$\langle r_2(T) \rangle = \frac{\lambda}{\lambda + \mu} - \frac{\lambda}{(\lambda + \mu)^2} \frac{1 - \exp[-(\lambda + \mu)T]}{T}.$$

Итак, в пределе бесконечно большого окна наблюдения, $T \rightarrow \infty$, математическое ожидание доли времени, проведенного процессом в состоянии 2, равно статистически равновесной вероятности π_2^{st} найти процесс в этом состоянии.

Solution б)

Искомая вероятность может быть вычислена при помощи формулы Байеса. Действительно, с учетом марковского свойства вероятность $\Pr[S(t) = 2, S(T) = 1 | S(0) = 1]$ можно представить как

$$\begin{aligned} \Pr[S(t) = 2, S(T) = 1 | S(0) = 1] &= \Pr[S(T) = 1 | S(t) = 2, S(0) = 1] \Pr[S(t) = 2 | S(0) = 1] = \\ &= \Pr[S(T) = 1 | S(t) = 2] \Pr[S(t) = 2 | S(0) = 1] \end{aligned}$$

или как

$$\Pr[S(t) = 2, S(T) = 1 | S(0) = 1] = \Pr[S(t) = 2 | S(0) = 1, S(T) = 1] \Pr[S(T) = 1 | S(0) = 1]$$

Приравнявая эти два представления, получаем

$$\Pr[S(t) = 2 | S(0) = 1, S(T) = 1] = \frac{\Pr[S(T) = 1 | S(t) = 2] \Pr[S(t) = 2 | S(0) = 1]}{\Pr[S(T) = 1 | S(0) = 1]},$$

где

$$\Pr[S(T) = 1 | S(t) = 2] = \frac{\mu}{\lambda + \mu} \left(1 - e^{-(\lambda + \mu)(T-t)} \right),$$

$$\Pr[S(t) = 2 | S(0) = 1] = \frac{\lambda}{\lambda + \mu} (1 - \exp[-(\lambda + \mu)t]),$$

$$\Pr[S(T) = 1 | S(0) = 1] = \frac{\mu}{\lambda + \mu} + \frac{\lambda}{\lambda + \mu} e^{-(\lambda + \mu)T}.$$

Белан-ВШЭ-л3.38 О принципе больших отклонений (??)

Пусть $X_1, X_2, \dots, X_N$ - набор независимых случайных величин, каждая из которых имеет функцию распределения $p(x) = (1-q)\delta(x) + q\delta(x-1)$. Используя теорему Гартнера-Эллиса, выясните, удовлетворяет ли функция плотности вероятности $P_N(a)$ среднего арифметического $A = \frac{1}{N} \sum_{i=1}^N X_i$ принципу больших отклонений. Если да, то найдите соответствующую функцию Крамера $I(a)$.

(?? хз, о чем задача??)

Вычисляем производящую функцию кумулянтов

$$\lambda(\xi) = \langle e^{\xi X} \rangle = \ln \left(\frac{1}{\sqrt{2\pi\sigma^2}} \int_{-\infty}^{+\infty} \exp \left(-\frac{(x-\mu)^2}{2\sigma^2} + \xi x \right) dx \right) = \xi\mu + \frac{\sigma^2 \xi^2}{2}$$

Видим, что она дважды дифференцируема. Тогда согласно теореме Гартнера-Эллиса распределение $P_N(a)$ удовлетворяет принципу больших отклонений с функцией Крамера

$$I(a) = \sup_{\xi \in \mathbb{R}} \{ \xi a - \lambda(\xi) \} = \xi_* a - \lambda(\xi_*) = \frac{(a - \mu)^2}{2\sigma^2}$$

где $\xi_* = \frac{a - \mu}{\sigma^2}$ - точка максимума функции $\xi a - \lambda(\xi)$. Значит

$$P_N(a) \propto e^{-NI(a)} = e^{-\frac{N(a-\mu)^2}{2\sigma^2}}$$

Белан-ВШЭ-л1.дз-9 Энтропии выпадения орлов (???)

Пусть X это случайная величина, которая равна 1, если в эксперименте с подкидыванием монетки выпадает орел, и равна 0 в случае решки. Далее, Y это независимая от X случайная величина, которая равна 1, если в эксперименте с подкидыванием другой монетки выпадает орел, и равна 0 в случае решки. Наконец, Z это случайная величина равная 1, если в результате подкидывания двух вышеупомянутых монеток выпал хотя бы один орел, и ноль в любом другом случае. Найдите (а) частные энтропии, $S(X)$, $S(Y)$ и $S(Z)$, (б) совместные энтропии, $S(X, Y)$, $S(X, Z)$ и $S(Y, Z)$, а также (в) взаимные информации, $I(X, Y)$, $I(X, Z)$ и $I(Y, Z)$

(?? хз, о чем задача??)

Solution

ФР дисперсия 4х подряд орлов

Задача 10 (12 баллов) Монетку подбрасывают до тех пор пока в череде исходов не встретится последовательность из четырех подряд идущих орлов. Найти дисперсию требуемого числа попыток.

(решение другого решателя, тут какая-то копия, оно крупнейшее какое-то. не копирую, потому что все равно не уверен в этом. жесть, а не задача.)

ФР пассажиры на автобусной стоянке

Задача 12 (10 баллов) Пассажиры приходят на автобусную остановку независимо друг от друга со средней частотой λ пассажиров 6 минут. Прибытие автобусов это пуассоновские события со средней частотой μ автобусов в минуту. Будем предполагать, что вместимость автобуса достаточно велика, чтобы всякий раз принять всех скопившихся на остановке пассажиров. Кроме того, будем пренебрегать временем, необходимым для посадки пассажиров в автобус.

(а) Вычислить стационарную вероятность p_n найти на остановке ровно n пассажиров. Каковы условия существования статистически-стационарного режима?

(б) Вычислить среднее количество людей, ожидающих автобус на остановке, в статистически-стационарном режиме.

(6) Каково среднее число пассажиров, которые уедут с остановки в промежутке времени с 14:00 до 16:00, если $\lambda = 2 \text{ мин}^{-1}$ и $\mu = 0.2 \text{ мин}^{-1}$?

(элементарная задача, школой решается)

$$\pi_n(t + \varepsilon t) = (\lambda, \varepsilon_t) \pi_{n-1} + (1 - h\delta t) \pi_n + (1 - \mu dt) \pi_t$$

$$\pi_n = -\alpha \pi_n - \mu \pi_n + h \pi_{n-1}$$

$$6 \text{ в стац случае } \dot{\pi} = 0$$

$$\pi_n = \frac{A}{x + \mu} \pi_{n=1}$$

$$\text{аАа } \pi_0 : \pi_0 = \mu(1 - \pi_0) - \lambda \pi_0 \rightarrow \pi_0 = \frac{\mu}{R + M}$$

$$\pi_h = \left(\frac{h}{L\pi H} \right)^h \frac{\mu}{L + \mu} = \frac{\mu}{L} \left(\frac{\lambda}{L + \mu} \right)^{h+1}$$

$$\langle h \rangle = \mu = \sum_h n \pi_n = \frac{\mu}{\alpha + \mu} \sum_h n \left(\frac{\alpha}{L + \mu} \right)^n = \frac{A}{A}$$

Ч-5.49

Цепь Маркова ξ_t имеет множество состояний $\{-6, -5, \dots, 0, 1, \dots, 6\}$. Переходные вероятности $p_{ij} = P\{\xi_{t+1} = j | \xi_t = i\}$ при $i \neq 0$ определяются соотношениями $p_{ij} = \begin{cases} 1, & \text{если } j = i + 1 \leq 0 \\ 0 & \text{в остальных случаях.} \end{cases}$ или $j = i - 1 \geq 0$. Провести классификацию цепи Маркова и множества ее состояний, если:

а) $p_{0,6} = 1, p_{0,i} = 0 \quad (i \neq 6)$,

б) $p_{0,6} = p_{0,-6} = 1/2, p_{0,1} = 0 \quad (|i| \neq 6)$, в) $p_{0,6} = p_{0,-5} = 1/2, p_{0,4} = 0 \quad (i \neq -5, i \neq 6)$.

Ч-5.50

Матрица вероятностей перехода цепи Маркова имеет вид

$$P = \begin{pmatrix} 0,1 & 0,5 & 0,4 \\ 0,6 & 0,2 & 0,2 \\ 0,3 & 0,4 & 0,3 \end{pmatrix}.$$

Распределение по состояниям в момент времени $t = 0$ определяется вектором $(0, 7; 0, 2; 0, 1)$. Найти: 1) распределение по состояниям в момент $t = 2$; 2) вероятность того, что в моменты $t = 0, 1, 2, 3$ состояниями цепи будут соответственно 1, 3, 3, 2; 3) стационарное распределение.

Ч-5.51

Пусть ξ_t - номер состояния в цепи Маркова в момент времени t ; $P(\xi_0 = 1) = 1$, и матрица вероятностей перехода имеет вид

$$\begin{pmatrix} 3/7 & 3/7 & 1/7 \\ 1/11 & 2/11 & 8/11 \\ 1/11 & 4/11 & 6/11 \end{pmatrix}$$

положим

$$\eta_t = \begin{cases} 1, & \text{если } \xi_t = 1, \\ 2, & \text{если } \xi_t \neq 1. \end{cases}$$

Показать, что последовательность η_t является цепью Маркова. Найти ее матрицу вероятностей перехода.

Ч-5.52

Случайные величины $\xi_i, i = 1, 2, \dots$, независимы и

$$P(\xi_i = 1) = p, \quad P(\xi_i = -1) = 1 - p = q.$$

Положим $\eta_0 = 0; \eta_{t+1} = \eta_t + \xi_{t+1}$. Является ли последовательность η_t цепью Маркова? Найти $P(\eta_t = m), \quad m = 0, 1, 2, \dots$

Ч-5.53

Пусть $\xi_i, i = 1, 2, \dots$, - независимые случайные величины, $P(\xi_i = 1) = 1 - P(\xi_i = -1) = p$ являются ли цепями Маркова последовательности случайных величин:

а) $\eta_t = \xi_t \xi_{t+1}$ б) $\eta_t = \xi_1 \xi_2 \dots \xi_t$;

в) $\eta_t = \varphi(\xi_t, \xi_{t+1})$, где $\varphi(-1, -1) = 1, \varphi(-1, 1) = 2, \varphi(1, -1) = 3, \varphi(1, 1) = 4$?

Для цепей Маркова найти вероятности перехода за один шаг.

Ч-5.54

В N ячейках последовательно независимо друг от друга равновероятно размещают частицы. Пусть $\mu_0(n)$ - число ячеек, оставшихся пустыми после размещения n частиц. Показать, что последовательность $\mu_0(n), n = 1, 2, \dots$, является цепью Маркова. Найти вероятности перехода.

Ч-5.55

В N ячейках независимо друг от друга размещаются комплекты, состоящие из m частиц. Частицы одного комплекта размещаются в ячейках по одной, и все возможные выборы m мест из N имеют одинаковые вероятности. Обозначим через $\mu_0(n)$ число ячеек, оставшихся пустыми после размещения n комплектов. Показать, что последовательность $\mu_0(n), n = 1, 2, \dots$ является цепью Маркова. Найти вероятности перехода.

Ч-5.56

Урна вначале содержит N белых шаров. За 1 шаг из урны по схеме случайного равновероятного выбора вынимают 1 шар и заменяют его новым, который независимо от предыстории процесса - является черным с вероятностью p и белым с вероятностью $q = 1 - p$. Обозначим через ξ_n число белых шаров в урне после n -го шага.

а) Найти $p_{ij} = P\{\xi_{n+1} = j | \xi_n = i\}, i, j \in \{0, 1, \dots, N\}$. Является ли последовательность ξ_n цепью Маркова?

б) Найти $\lim_{n \rightarrow \infty} P\{\xi_n = k\} = \pi_k, \quad k \in \{0, 1, \dots, N\}$.

Ч-5.57

В бесконечной последовательности пронумерованных шаров каждый шар независимо от остальных является черным с вероятностью p и белым с вероятностью $q = 1 - p$. Будем считать, что в момент времени $n \in \{0, 1, \dots\}$ урна содержит шары с номерами $n + 1, n + 2, \dots, n + N$, и обозначим через ξ_n число белых шаров в урне в момент n . Ответить на те же вопросы, что в задаче 5.56.

Ч-5.58

Матрица $P = \|p_{ij}\|_{i,j=1}^N$ с неотрицательными элементами $p_{i2} + \dots + p_{iN} = p_{1i} + p_{2i} + \dots + p_{Ni} = 1$ для любого $i = 1, 2, \dots, N$. Показать, что если цепь Маркова ξ с состояниями $1, \dots, N$ имеет дважды стохастическую матрицу вероятностей перехода $P \rightsquigarrow \|p_{ij}\|_{i,j=1}^N$, то равномерно распределение на множестве $\{1, \dots, N\}$ является стационарным для цепи, ξ_t^n .

Ч-5.59

Пусть $\zeta_0, \zeta_1, \dots$ цепь Маркова с множеством состояний $\{1, 2, 3\}$, матрицей вероятностей перехода $\|p_{ij}\|$ и стационарным распределением π_f . Показать, что если $p_{11} = p_{22} = p_{33} = 0$ и $\pi_1 = \pi_2 = \pi_3 = 1/3$, то $p_{12} = p_{28} = p_{31}$ и $p_{13} = p_{32}$.

Ч-5.60

Пусть $\eta_1; \eta_2, \dots$ - последовательность независимых одинаково распределенных случайных величин, и $f(x, y)$ - функция, принимающая значения в множестве $\{1, \dots, N\}$. Является ли последовательность случайных величин

$$\xi_0 (P(\xi_0 = k) = p_k^{(0)}), \quad \xi_{t+1} = f(\xi_t, \eta_{t+1})_i \\ t = 0, 1, 2, \dots \times$$

цепью Маркова?

Ч-5.61

Пусть $\eta_0, \eta_1, \eta_2, \dots$ последовательность независимых случайных величин, имеющих равномерное распределение на отрезке $[0, 1]$. Показать, что для любого начального распределения $p^{(0)} = (p_1^{(0)}, \dots, p_N^{(0)})$ и для любой матрицы переходных вероятностей $P = \|p_{ij}\|_{i,j=1}^N$ можно указать такие функции $f(x, y)$ и $g(y)$ ($x \in \{1, \dots, N\}$, $y \in [0, 1]$), что последовательность $\varepsilon_0 g(\eta_0)$, $\xi_{t+1} = f(\xi_t, \eta_{t+1})$, $t = 0, 1, \dots$ будет цепью Маркова с начальным распределением $p^{(0)}$ и матрицей вероятностей перехода P .

Ч-5.62

Игральная кость последовательно перекладывается с одной грани равномерно на любую из четырех соседних независимо от предыдущего. К какому пределу стремится при $t \rightarrow \infty$ вероятность того, что при t -м перекладывании кость окажется на грани «6», если сначала она падалась в этом же положении?

Ч-5.63 Свойства цепи Маркова

Цепь Маркова ξ имеет два состояния: 1 и 2 - и матрицу вероятностей перехода $\begin{pmatrix} p_{11} & 1-p_{11} \\ 0 & 1 \end{pmatrix}$.

Пусть $\tau \equiv \min \{t \geq 1 : \xi_t = 2\}$.

- Найти условное распределение τ при условии $\xi_0 = 1$.
- Как изменится ответ, если матрица вероятностей перехода будет равна

$$\begin{pmatrix} p_{11} & 1-p_{11} \\ 1-p_{22} & p_{22} \end{pmatrix}, \quad 0 < p_{22} < 1?$$

Ч-5.64

Матрица вероятностей перехода $\|p_{ij}\|$ цепи Маркова ξ с $n+1$ состояниями имеет вид: $p_{il} = 1 - \alpha$, $l = 1, 2, \dots, n+1$; $p_{ij} = \alpha/n$, $i \neq j$. В процессе, начавшемся из состояния k , $k \neq n+1$, обозначим через τ_n момент первого попадания в состояние $n+1$. Подобрать последовательность A_n ($A_n \rightarrow \infty$ при $n \rightarrow \infty$) так, чтобы существовал предел

$$\lim_{n \rightarrow \infty} P(\tau_n \leq A_n < x)$$

и найти его.

Ч-5.65

Матрица вероятностей перехода цепи Маркова $\xi_n^{(\varepsilon)}$ с множеством состояний $\{1, 2, 3\}$ имеет вид

$$\begin{pmatrix} 1-p & p & 0 \\ 1-p-\varepsilon & p & \varepsilon \\ 0 & \varepsilon^2 & 1-\varepsilon^2 \end{pmatrix}$$

где $0 < p < 1 - \varepsilon \leq 1$. Предполагая, что $\xi_0^{(\varepsilon)} = 1$, рассмотрим случайную величину $\tau_1(\varepsilon) = \min \{n \geq 1 : \xi_n^{(\varepsilon)} = 1\}$ - время возвращения в состояние 1.

- Доказать, что при любом $t = 1, 2, \dots$

$$\lim_{\varepsilon \rightarrow 0} P\{\tau_1(\varepsilon) = t\} = P\{\tau_1(0) = t\}.$$

- Показать, что $M\tau_1(0) < \infty$, но $\lim_{\varepsilon \rightarrow 0} M\tau_1(\varepsilon) = \infty$.
- Найти производящую функцию $\varphi_\varepsilon(s) = M s^{\tau_1(\varepsilon)}$.

Ч-5.66

Цепь Маркова ξ_n имеет начальное состояние $\xi_0 = 0$ и переходные вероятности

$$P\{\xi_{n+1} = k+1 | \xi_n = k\} = p, \quad P\{\xi_{n+1} = k | \xi_n = k\} = 1-p,$$

где $k, n = 0, 1, \dots$ и $0 < p < 1$. Найти распределение ξ_n , математическое ожидание и дисперсию ξ_n . 166

Ч-5.67

По цепи Мартова ξ_n , описанной в задаче

Ч-5.66

, построим последовательность случайных величин

$$\tau_0 = 0, \quad \tau_k = \min\{n : \xi_n = k\}, \quad k = 1, 2, \dots$$

- а) Доказать, что $\{\tau_k\}_{k=0}^\infty$ — тоже цепь Маркова. Найти ее переходные вероятности.
 б) Найти $M\tau_k$, D_{τ_k} , $\varphi_k(s) = Ms^{\tau_k}$.

Ч-5.68

Цепь Маркова ξ_n имеет начальное состояние $\xi_0 = 0$ и переходные вероятности

$$P\{\xi_{n+1} = k+1 | \xi_n = k\} = p, \quad P\{\xi_{n+1} = 0 | \xi_n = k\} = 1-p,$$

где $k, n \in \{0, 1, \dots\}$ и $0 < p < 1$. Положим

$$\tau_0 = 0, \quad \tau_k = \min\{n \geq 1 : \xi_n = k\}, \quad k = 1, 2, \dots$$

- а) Найти производящую функцию $\varphi_k(s) = Ms^{\tau_k}$ и $M\tau_k$.
 б) Найти предельное распределение случайной величины $\eta_h = \frac{\tau_h}{M\tau_h}$ при $k \rightarrow \infty$, пользуясь результатом п. а) и методом характеристических функций.

Ч-5.69

Переходные вероятности цепи Маркова ξ_n при любом $n = 0, 1, \dots$ определяются равенствами

$$\begin{aligned} P\{\xi_{n+1} = 1 | \xi_n = 0\} &= p, \quad P\{\xi_{n+1} = 0 | \xi_n = 0\} = 1-p, \\ P\{\xi_{n+1} = k+1 | \xi_n = k\} &= p, \\ P\{\xi_{n+1} = k-1 | \xi_n = k\} &= 1-p, \quad k = 1, 2, \dots \end{aligned}$$

Пусть $\tau_{i,j}$ — время перехода цепи ξ_n из состояния i в состояние j :

$$P\{\tau_{i,j} = t\} = P\{\min\{n \geq 1 : \xi_n = j\} = t | \xi_0 = i\}, \quad t = 1, 2, \dots$$

- а) Найти производящую функцию $\varphi_{0,1}(s) = Ms^{\tau_{0,1}}$ и $M\tau_{0,1}$.
 б) Найти рекуррентные формулы, связывающие производящие функции $\psi_{k,k+1}(s) = Ms^{\tau_{k,k+1}}$ ($k = 0, 1, \dots$).
 в) Используя результаты п. а) и б), составить и решить рекуррентные уравнения для $\tau_{k,k+1}$, $k = 0, 1, \dots$.
 Найти асимптотические формулы для $M\tau_{0,k}$ при $k \rightarrow \infty$.

Ч-5.70

Пусть $\xi_1, \xi_2, \dots$ — независимые одинаково распределенные случайные величины, $P\{\xi_1 = 1\} = P\{\xi_1 = -1\} = 1/2$; $z_0 = 0$, $z_n = z_{n-1} + \xi_n$, $k = 1, 2, \dots$. Положим $\tau_N = \min\{n \geq 1 : |z_n| = N\}$. Найти $M\tau_1, M\tau_2, M\tau_3$.

Ч-5.71

Пусть последовательность $z_0, z_1, \dots$ определена как в задаче 5.70. Показать, что $M\tau_N = N^2$.

Ч-5.77

Матрица вероятностей перехода P и распределение q по состояниям в момент $t = 0$ цепи Маркова ξ , имеют вид

$$P = \begin{pmatrix} z/12 & 2/12 & 1/12 & 3/12 & 1/12 & 2/12 \\ 1/12 & 1/12 & 8/12 & 1/12 & 4/12 & 2/12 \\ 0 & 0 & 3/4 & 1/4 & 0 & 0 \\ 0 & 0 & 1/2 & 1/2 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1/3 & 2/3 \\ 0 & 0 & 0 & 0 & 2/3 & 1/3 \end{pmatrix},$$

$$q = (1/2, 1/2, 0, 0, 0, 0).$$

Найти:

- несущественные состояния;
- математическое ожидание времени τ до выхода из множества несущественных состояний;
- вероятности $p_i^{(\alpha)}, p_i^{(\beta)}$ попадания в классы состояний $\alpha = \{3, 4\}, \beta = \{5, 6\}$, если начальным состоянием является $i \in \{1, 2\}$;
- предельное при $t \rightarrow \infty$ распределение по состояниям, т. е. величины $\pi_k = \lim_{t \rightarrow \infty} P(\xi_t = k)$.

Ч-5.78

Цепь Маркова ξ имеет начальное состояние $\xi_0 = 0$ и переходные вероятности

$$P\{\xi_{n+1} = k+1 | \xi_n = k\} = \frac{1}{a^k s}$$

$$P\{\xi_{n+1} = k | \xi_n = k\} = 1 - \frac{1}{a^k}$$

где $k, n \in \{0, 1, \dots\}$ и $a > 1$. Составить рекуррентные уравнения для величин $p_k^{(n)} = P\{\xi_n = k\}$ и с их помощью найти Ma^{ξ_n} и D^{ξ_n} .

Ч-5.79

Показать, что если все собственные числа $\lambda_1, \dots, \lambda_n$ матрицы $A = \|a_{ij}\|_{i,j=1}^n$ различны, то элементы матрицы $A^m = \|a_{ij}^{(m)}\|_{i,j=1}^n$ представляются в виде

$$a_{ij}^{(m)} = \sum_{h=1}^n c_{ij}^{(h)} \lambda_h^m, \quad m = 1, 2, \dots$$

Ч-5.80

Показать, что если матрица $A = \|a_{ij}\|_{i,j=1}^n$ имеет собственные числа $\lambda_1, \dots, \lambda_r$, причем кратность λ_s равна $s_i, s_1 + \dots + s_r = n$, то элементы матрицы $A^m = \|a_{ij}^{(m)}\|_{i,j=1}^n$ представляются в виде

$$a_{ij}^{(m)} = \sum_{k=1}^r \lambda_k^m \sum_{l=0}^{s_k-1} c_{ij}^{(k,l)} m^l, \quad m = 1, 2, \dots$$

Ч-5.81

Используя задачи 5.795.80, показать, что получение формулы для вероятности перехода за n шагов из состояния i в состояние j в цепи Маркова с N состояниями может быть сведено к нахождению собственных чисел матрицы $P = \|p_{ij}\|_{i,j=1}^N$ вероятностей перехода за один шаг, вычислению $P, P^2, \dots, P^{N-1}$ и решению системы линейных уравнений.

Ч-5.82

Матрица вероятностей перехода $P = \|p_{ij}\|$ цепи Маркова ξ , с состояний 1 и 2 определяется формулами

$$p_{11} = 1 - \alpha, p_{12} = \alpha, p_{21} = \beta, p_{22} = 1 - \beta.$$

Найти вероятности $p_{ij}(t)$ перехода за время t и стационарные вероятности π .

Ч-5.83

Для цепи Маркова ξ_t , рассмотренной в задаче н5.82, обозначим через $v_1(t)$ число попаданий в состояние 1 за время t . Показать, что для любого $j = 1, 2$ при $t \rightarrow \infty$

$$M\{v_1(t)|\xi_0 = j\} = \frac{\nu\beta}{\alpha + \beta}t(1 + o(1)),$$

$$D\{v_1(t)|\xi_0 = j\} = o(t^2).$$

Ч-5.89

Вероятность того, что атом радиоактивного элемента, существующий в момент t , распадется на интервале $(t, t+h)$, при $h \downarrow 0$ имеет вид $\alpha h + o(h)$ и не зависит от предыстории процесса. Найти:

- вероятность того, что время τ до распада атома будет больше t , $\{ \tau > t \} = 1/2$,
- плотность $p_n(t)$ распределения времени до распада хотя бы одного из n существующих в момент $t = 0$ и независимо ведущих себя атомов.

Ч-5.90

Пусть ξ_t - цепь Маркова с непрерывным временем и множеством состояний $\{1, 2\}$. Вероятности перехода $p_{ij}(h) = P(\xi_{t+h} = j | \xi_t = i)$ удовлетворяют условиям

$$p_{12}(h) = \alpha h + o(h), \quad p_{21}(h) = \beta h + o(h), \quad h \rightarrow 0.$$

Найти $p_{ij}(t)$, $t \geq 0$, $i, j \in \{1, 2\}$.

Ч-5.91

Пусть $p^{(\alpha, \beta)}(t) = \|p_{ij}^{(\alpha, \beta)}(t)\|$ - матрица вероятностей перехода за время t цепи Маркова ξ , описанной в задаче н5.90, а $A = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$ - стохастическая матрица. Доказать, что для любого фиксированного числа $u > 0$ цепь Маркова ξ_t удовлетворяющая условию

$$P^{(\alpha, \beta)}(u) = A,$$

существует тогда, и только тогда, когда $a_{11} + a_{22} > 1$.

Ч-5.92

Для цепи Маркова ξ_i , определенной в задаче н5.90, обозначая через $\tau_k(t)$ ($k = 1, 2$) суммарную длительность пребывания цепи в состоянии k за время t . Найти $m_i(t) = M\{\tau_1(t) | \xi_0 = i\}$ и главный член асимптотической формулы для $t \rightarrow \infty$ $b_i^2(t) = D\{\tau_1(t) | \xi_0 = i\}$ при $t \rightarrow \infty$

Ч-5.95

Цепь Маркова ξ с непрерывным временем имеет множество состояний $\{0, 1, \dots, N\}$, а вероятности $p_{ij}(h) = P\{\xi_{t+h} = j | \xi_t = i\}$ перехода из состояния i в состояние j за время h удовлетворяют при $h \downarrow 0$ условиям

$$p_{00}(h) = 1 - \alpha h + o(h), \quad p_{NN}(h) = 1 - \beta h + o(h),$$

$$p_{ii}(h) = 1 - (\alpha + \beta)h + o(h), \quad 1 \leq i \leq N-1,$$

$$p_{t-1,i}(h) = \alpha h + o(h),$$

$$p_{i,i-1}(h) = \beta h + o(h), \quad 1 \leq i \leq N,$$

$$p_{ij}(h) = o(h), \quad \text{если } |i - j| > 1,$$

а) Составить систему дифференциальных уравнений для $p_{ij}(t)$, $0 \leq i, j \leq N$, $t \geq 0$.

б) Найти $\pi_j^{(N)} = \lim_{t \rightarrow \infty} p_{ij}(t)$, $j = 0, 1, \dots, N$ как функции от $\theta = \alpha/\beta$. Показать что если $\theta = 1$, то $\pi_0^{(N)} = \dots = \pi_N^{(N)} = \frac{1}{N+1}$.

в) В случае $\theta < 1$ найти $\pi_j = \lim_{N \rightarrow \infty} \pi_j^{(N)}$, $j = 0, 1, \dots$, а в случае $\theta > 1$ найти $\pi_j^* = \lim_{N \rightarrow \infty} \pi_{N-1-j}^{(N)} = 0, 1, \dots$

landau-inst-summer-2025.6/8. Случайные блуждания

Пациенту прописали выпивать лекарства в дозировке четверть таблетки раз в день и выдали 10 таблеток в мешочке. Пациент раз в день достает из мешочка случайную таблетку. Если она целая, пациент ломает ее на 4 части, затем выпивает одну, а три четвертинки закидывает обратно в пакет. В противном случае, если он достает четвертинку, то сразу ее выпивает. Сколько в среднем останется целых таблеток через 8 дней?

Указание: задачу разрешается решать численно.

Solution

(???)

7.1.4 Problems About Markov Chains Applications

(!!!??? ну теорию доучить нужно, пока это вообще не продумал еще.)

Белан-ВШЭ-лб.3.4 Стоянка автомобилей

Автомобили приезжают на стоянку бесконечной вместимости независимо друг от друга в случайные моменты времени со средней частотой λ . Каждый автовладелец оставляет свой автомобиль на случайное время, имеющее экспоненциальную функцию плотности вероятности с параметром μ . Найдите среднее число занятых парковочных мест $\langle n(t) \rangle$ как функцию от времени t , если в нулевой момент на стоянке находилось m автомобилей.

Solution

Используя Ур. (48) и (49), можно вывести замкнутое дифференциальное уравнение на эволюцию статистического момента $\langle n(t) \rangle = \sum_{n=0}^{+\infty} n \pi_n(t)$

$$\begin{aligned} \frac{d\langle n(t) \rangle}{dt} &= \sum_{n=0}^{+\infty} n \dot{\pi}_n(t) = \sum_{n=1}^{+\infty} n [\lambda \pi_{n-1}(t) - (\lambda + n\mu) \pi_n(t) + (n+1)\mu \pi_{n+1}(t)] = (62) \\ &= \sum_{n=1}^{+\infty} [\lambda(n-1)\pi_{n-1}(t) + \lambda \pi_{n-1}(t) - \lambda n \pi_n(t) - \mu n^2 \pi_n(t) + \mu(n+1)^2 \pi_{n+1}(t) - \\ &\quad - \mu(n+1)\pi_{n+1}(t)] = \lambda \langle n(t) \rangle + \lambda - \lambda \langle n(t) \rangle - \mu \langle n^2(t) \rangle + \mu \langle n^2(t) \rangle - \mu \pi_1(t) - \\ &\quad - \mu \langle n(t) \rangle + \mu \pi_1(t) = \lambda - \mu \langle n(t) \rangle \end{aligned}$$

решение которого с начальным условием $\langle n(0) \rangle = m$ имеет вид

$$\langle n(t) \rangle = m e^{-\mu t} + \frac{\lambda}{\mu} (1 - e^{-\mu t}).$$

За время порядка μ^{-1} этот ответ релаксирует к стационарному значению $\frac{\lambda}{\mu} (1 - e^{-\mu t})$.

Белан-ВШЭ-лб.3.5 Запросы на сервер (????)

5 Запросы поступают на сервер независимо друг от друга со средней частотой λ . Лист ожидания сервера имеет конечную вместимость N и каждый новый запрос добавляется в очередь, если в момент его прибытия в листе ожидания есть свободное место. Если же лист ожидания оказывается полностью заполненным в момент поступления очередного запроса, то этот запрос отражается. Сервер обслуживает запросы по одному в порядке их поступления. Время обработки одного запроса это случайная величина, имеющая экспоненциальную функцию распределения с параметром μ .

а) Вычислите вероятность p_n обнаружить ровно n задач на сервере в статистически-стационарном режиме его работы.

б) Вычислите среднее число задач в листе ожидания.

(?? не решал)

Белан-ВШЭ-лб.3.6 Автобус и пассажиры (!!?)

Пассажиры приходят на автобусную остановку независимо друг от друга со средней частотой λ пассажиров в минуту. Прибытие автобусов это пуассоновские события со средней частотой μ автобусов в минуту. Будем предполагать, что вместимость автобуса достаточно велика, чтобы всякий раз принять всех скопившихся на остановке пассажиров. Кроме того, будем пренебрегать временем, необходимым для посадки пассажиров в автобус.

(а) Вычислить стационарную вероятность p_n найти на остановке ровно n пассажиров. Каковы условия существования статистически-стационарного режима?

(б) Вычислить среднее количество людей, ожидающих автобус на остановке, в статистически-стационарном режиме.

(в) Каково среднее число пассажиров, которые уедут с остановки за период времени длительностью T в статистически-стационарном режиме?

Solution

(?!?! решал ее, элементарно делается, потом допишу)

Белан-ВШЭ-лб.3.7 Очереди к кассам в магазине

В магазине работают 2 кассы самообслуживания. Обслуживание одного покупателя на любой из касс занимает случайный промежуток времени, имеющий экспоненциальное распределение с параметром μ . Покупатели подходят к кассам в пуассоновские моменты времени со средней частотой λ , выстраиваясь в случае необходимости в единую очередь. Очередной покупатель проходит на ту кассу, которая освобождается первой. Предполагая, что система находится в статистически стационарном режиме, найдите

(а) вероятность того, покупателю, пришедшему на кассы в случайный момент времени, не придется стоять в очереди;

(б) среднее число людей, ожидающих своей очереди.

Будем обозначать через $\pi_n(t)$ вероятность того, что в момент времени t возле касс самообслуживания находятся ровно n покупателей. Эти вероятности подчиняются следующему управляющему уравнению

$$\begin{aligned}\frac{d\pi_0(t)}{dt} &= -\lambda\pi_0(t) + \mu\pi_1(t) \\ \frac{d\pi_1(t)}{dt} &= \lambda\pi_0(t) - (\lambda + \mu)\pi_1(t) + 2\mu\pi_2(t) \\ \frac{d\pi_n(t)}{dt} &= \lambda\pi_{n-1}(t) - (\lambda + 2\mu)\pi_n(t) + 2\mu\pi_{n+1}(t), \quad \text{при } n \geq 2\end{aligned}$$

Отсюда легко находим, что в статистически стационарном режиме $\pi_n^{st} = 2 \left(\frac{\lambda}{2\mu}\right)^n \pi_0^{st}$ для $n \geq 1$. С учетом условия нормировки, $\sum_{n=0}^{+\infty} \pi_n^{st} = 1$, окончательно имеем

$$\begin{aligned}\pi_0^{st} &= \frac{1 - \frac{\lambda}{2\mu}}{1 + \frac{\lambda}{2\mu}} \\ \pi_n^{st} &= 2 \frac{1 - \frac{\lambda}{2\mu}}{1 + \frac{\lambda}{2\mu}} \left(\frac{\lambda}{2\mu}\right)^n, \quad \text{при } n \geq 1\end{aligned}$$

Видим, что стационарное решение существует при условии $\lambda < 2\mu$.

а) Вероятность того, покупателю, пришедшему на кассы в случайный момент времени, не придется стоять в очереди очевидно равна $\pi_0^{st} + \pi_1^{st}$.

б) Среднее число людей, ожидающих своей очереди равно $\sum_{n=3}^{+\infty} (n-2)\pi_n^{st}$.

Белан-ВШЭ-лб.3.8 Очереди на прививки

Пациенты приходят в пункт вакцинации без предварительной записи и независимо друг от друга со средней частотой λ . Каждый пациент, дождавшись своей очереди, сперва попадает в кабинет терапевта, где проводит случайное время, имеющее экспоненциальную функцию распределения с параметром μ_1 , а затем направляется в прививочный кабинет для прохождения процедуры вакцинации, которая длится экспоненциально распределенный с параметром μ_2 случайный промежуток времени.

(а) При каких условиях в такой системе существует статистически стационарное состояние? Предполагая, что система находится в статистически стационарном режиме, определите (б) среднее число пациентов, ожидающих своей очереди в кабинет терапевта;

- (в) среднее число пациентов, ожидающих своей очереди в прививочный кабинет.
 (г) вероятность p_k обнаружить в пункте вакцинации ровно k человек, прийдя туда в случайный момент времени.

Solution

(крутая задача, но не смотрел пока что.)

а) Описанная в условии задачи система массового обслуживания представляет собой тандем из двух последовательных М/М/1 систем. Очевидно, что происходящее во второй системе не оказывает влияния на стохастическую динамику первой системы. Поэтому статистически-стационарная частная функция распределения вероятностей числа пациентов в первой системе имеет вид

$$\pi_n^{(1)} = \left(1 - \frac{\lambda}{\mu_1}\right) \left(\frac{\lambda}{\mu_1}\right)^n$$

а само условие существования стационара дается неравенством $\lambda < \mu_1$. Далее, очевидно, что в статистически стационарном режиме, интенсивность потока пациентов, прибывающих в пункт вакцинации, равна интенсивности потока пациентов, покидающих кабинет терапевта. Словом, на вход второй системы тандема подается поток интенсивности λ . Значит частная функция распределения вероятностей числа пациентов во второй системе дается выражением

$$\pi_m^{(2)} = \left(1 - \frac{\lambda}{\mu_2}\right) \left(\frac{\lambda}{\mu_2}\right)^m$$

при условии, что $\lambda < \mu_2$. Итого получаем, что статистический стационар имеет место, если $\lambda < \min(\mu_1, \mu_2)$. б) Среднее число пациентов, ожидающих своей очереди в кабинет терапевта, равно

$$\sum_{n=1}^{\infty} (n-1) \pi_n^{(1)} = -1 + \pi_0^{(1)} + \left(1 - \frac{\lambda}{\mu_1}\right) \sum_{n=0}^{+\infty} n \left(\frac{\lambda}{\mu_1}\right)^n = \frac{\lambda^2}{\mu_1(\mu_1 - \lambda)}$$

(в) Среднее число пациентов, ожидающих своей очереди в прививочный кабинет: $\frac{\lambda^2}{\mu_2(\mu_2 - \lambda)}$

г) Вероятность p_k обнаружить в пункте вакцинации ровно k человек, прийдя туда в случайный момент времени, может быть записана как

$$p_k = \Pr[n + m = k] = \sum_{n=0}^k \pi_{n, k-n}^{st}$$

где $\pi_{n,m}^{st}$ - совместная функция распределения количеств пациентов в обеих системах. Последняя факторизуется в произведение частных вероятностей

$$\pi_{n,m}^{st} = \pi_n^{(1)} \pi_m^{(2)} = \left(1 - \frac{\lambda}{\mu_1}\right) \left(\frac{\lambda}{\mu_1}\right)^n \left(1 - \frac{\lambda}{\mu_2}\right) \left(\frac{\lambda}{\mu_2}\right)^m$$

в чем легко убедиться подстановкой этого анзаца в систему управляющих уравнений тандема

$$\begin{aligned} \dot{\pi}_{0,0} &= -\lambda \pi_{0,0} + \mu_2 \pi_{0,1} \\ \dot{\pi}_{n,0} &= \lambda \pi_{n-1,0} - (\lambda + \mu_1) \pi_{n,0} + \mu_2 \pi_{n,1}, \quad \text{при } n \geq 1 \\ \dot{\pi}_{0,m} &= \mu_2 \pi_{0,m+1} - (\lambda + \mu_2) \pi_{0,m} + \mu_1 \pi_{1,m-1}, \quad \text{при } m \geq 1, \\ \dot{\pi}_{n,m} &= -(\lambda + \mu_1 + \mu_2) \pi_{n,m} + \mu_1 \pi_{n+1,m-1} + \mu_2 \pi_{n,m+1} + \lambda \pi_{n-1,m}, \quad \text{при } n, m \geq 1 \end{aligned} \quad (78)$$

(780)

Значит

$$p_k = \left(1 - \frac{\lambda}{\mu_1}\right) \left(1 - \frac{\lambda}{\mu_2}\right) \left(\frac{\lambda}{\mu_2}\right)^k \sum_{n=0}^k \left(\frac{\mu_2}{\mu_1}\right)^n = \left(1 - \frac{\lambda}{\mu_1}\right) \left(1 - \frac{\lambda}{\mu_2}\right) \left(\frac{\lambda}{\mu_2}\right)^k \frac{\left(\frac{\mu_2}{\mu_1}\right)^{k+1} - 1}{\frac{\mu_2}{\mu_1} - 1}$$

7.2 Problems of Elementary Mathematical Statistics (????)

(ничего пока не шарю, нужно потом когда-то разобраться.)
 (пока мало что тут есть.)

7.2.1 Problems About the Parameters of Mathematical Statistics

Ч-6.1

Пусть $x_1, x_2, \dots, x_n$ - случайная выборка с $x_k = a$, $Dx_k = \sigma^2$, $M(x_k - a)^4 < \infty$, $k = 1, \dots, n$. Найти математическое ожидание величины

$$s^2 = \frac{1}{n-1} \sum_{k=1}^n (x_k - \bar{x})^2 \quad \left(\bar{x} = \frac{1}{n} \sum_{k=1}^n x_k \right).$$

Является ли s^2 состоятельной оценкой σ^2 ?

Ч-6.2

Найти математическое ожидание и дисперсию эмпирического момента $m_r = \frac{x_1^r + \dots + x_n^r}{n}$ независимой выборки, соответствующей случайной величине ξ с $M\xi^k = a_k$, $1 \leq k \leq 2r$

Ч-6.3

По неоднородной выборке $x_1, \dots, x_{n_1}$ где $x_k, k = 1, \dots, n$, независимы, $x_n = a$, $Dx_k = \sigma_k^2$ (σ_k известны), найти несмещенную линейную относительно x_n ($k = 1, \dots, n$) оценку а параметра a , которая имеет наименьшую возможную дисперсию.

Ч-6.4

*. Пусть $x_{i1}, \dots, x_{in_i}$ ($i = 1, 2, \dots, I$) - независимые нормально распределенные величины с параметрами (a, σ_1^2)

$$\bar{x}_i = \frac{1}{n_i} \sum_{k=1}^{n_i} x_{ik_i} \quad s_i^2 = \frac{1}{n_i - 1} \sum_{k=1}^{n_i} (x_{ik} - \bar{x}_i)^2.$$

Является ли оценка

$$\bar{x} = \sum_{i=1}^I c_i \bar{x}_{iv} \quad c_i = \frac{s_i^2}{s_1^2 + \dots + s_I^2}$$

несмещенной оценкой параметра a ?

Ч-6.5

Пусть $x_1, \dots, x_n$ - независимые одинаково распределенные случайные величины с $Dx_1 > 0$, $Mx_1^4 < \infty$. Положим

$$\bar{x} = \frac{1}{n} \sum_{k=1}^n x_{k\epsilon} \quad s^2 = \frac{1}{n-1} \sum_{k=1}^n (x_k - \bar{x})^2.$$

Найти

$$\lim_{n \rightarrow \infty} P\left(\frac{\bar{x} - Mx_1}{s/\sqrt{n}} \leq x\right)$$

Ч-6.6

Пусть $(x_1, y_1), \dots, (x_n, y_n)$ - независимая выборка, соответствующая случайному вектору. (ξ, η) , Т. θ_0 $P(x_i \leq x, y_1 \leq y) = P(\xi \leq x, \eta \leq y)$. Показать, что величина

$$m = \frac{1}{n-1} \sum_{k=1}^n (x_k - \bar{x})(y_k - \bar{y})_i$$

где

$$\bar{x} = \frac{1}{n} \sum_{k=1}^n x_{k1} \quad \bar{y} = \frac{1}{n} \sum_{k=1}^n y_{ks}$$

является несмещенной и состоятельной оценкой $\text{cov}(\xi, \eta)$.

Ч-6.7

Пусть μ_n - число успехов в n испытаниях схемы Бернулли с вероятностью успеха p в каждом испытании. Найти оценку наибольшего правдоподобия p параметра p . Доказать ее несмещенность и состоятельность.

Ч-6.8

Пусть μ_n - число успехов в n испытаниях схемы Бернулли с вероятностью успеха p в каждом испытании. Построить для p асимптотически доверительный интервал с доверительной вероятностью $1 - 2\alpha$.

Ч-6.9

Используя таблицу случайных чисел, получить реализацию выборки $x_1, \dots, x_n$ где x_k равномерно распределены; $n = 50$). Найти:

а) вариационный ряд $x_{(1)} \leq x_{(2)} \leq \dots \leq x_{(n)}$;
 б) эмпирическую функцию распределения (построить ее график и график теоретической функции распределения);

в) $\bar{x} = \frac{1}{n} (x_1 + \dots + x_n)$ (сравнить с x_k); г) $s^2 = \frac{1}{n-1} \sum_{k=1}^n (x_k - \bar{x})^2$ (сравнить с $D x_k$).

Ч-6.10

Используя таблицу нормально распределенных случайных чисел, получить реализацию выборки $x_1, \dots, x_n$, где x_k имеет нормальное распределение с параметрами $a = Mx_k = 0,5, \sigma^2 = Dx_k = 1; n = 50$. Найти: а) вариационный ряд, б) эмпирическую функцию распределения, в) $\bar{x}, r, s^2$ (см. задачу 6.9).

Ч-6.11

По выборке, полученной в задаче 6.10, построить доверительный интервал для a (считая a и b неизвестными) с доверительной вероятностью 0,95.

Ч-6.12

Используя метод наибольшего правдоподобия, найти по выборке $x_1, \dots, x_n$, где $P(x_k = m) = \frac{\lambda^m}{m!} e^{-\lambda}, m = 0, 1, \dots$, оценку λ параметра λ . Будет ли эта оценка несмещенной и состоятельной? Найти $M\lambda^*, D\lambda^*$.

Ч-6.13

Пусть $x_1, x_2, \dots, x_n$ - выборка, соответствующая показательному распределению с параметром λ . Найти оценку максимального правдоподобия λ для λ . Вычислить $M\frac{1}{\lambda^*}, D\frac{1}{\lambda^*}$.

Ч-6.14

Для оценки параметров a, b, c имеются три независимые выборки $a_1, \dots, a_n; b_1, \dots, b_n; c_1, \dots, c_n$. Известно, что $c = a + b$ и величины a_i, b_i, c_i распределены нормально с $M a_i = a, M b_i = b, M c_i = c$. Дисперсии $D a_i = \sigma_a^2, D b_i = \sigma_b^2, D c_i = \sigma_c^2$ известны. Найти:

а) оценки наибольшего правдоподобия a^*, b^* , с параметров a, b, c используя для каждого параметра только соответствующую ему выборку, а также найти $a^*, M b, M c^*, D a^*, D b^*, D c^*$;

б) оценки наибольшего правдоподобия a^{**}, b^{**}, c^{**} , используя сразу три выборки и связь $c = a + b$, и также найти $M a^{**}, M b^{**}, M c^{**}, D a^{**}, D b^{**}, D c^{**}$.

Ч-6.15

Пусть $y^{(k)} = (y_1^{(k)}, y_2^{(k)})$, $k = 1, \dots, n$, - независимые нормально распределенные случайные векторы, $M y_i^{(k)} = a_i, D y_i^{(k)} = \sigma_i^2, i = 1, 2, \text{cov}(y_1^{(k)}, y_2^{(k)}) = \rho \sigma_1 \sigma_2$. Параметры σ_1, σ_2, ρ известны. Найти:

а) оценку максимального правдоподобия (a_1^*, a_2^*) параметров (a_1, a_2) по выборке $y^{(1)}, \dots, y^{(n)}$;

б) оценку максимального правдоподобия a_i^{**} параметра a_i по выборке $y_i^{(1)}, \dots, y_i^{(n)}$; в) $M a_i^*, D a_i^*, M a_i^{**}, D a_i^{**}$.

Ч-6.16

*. Пусть $y^{(k)} = (y_1^{(k)}, y_2^{(k)})$, $k = 1, \dots, n$, - независимые нормально распределенные случайные векторы, $My_1^{(k)} = a_1$, $My_2^{(k)} = a_2$, $D_i^{(k)} = 1$ ($i = 1, 2$), $\text{cov}(y_1^{(k)}, y_2^{(k)}) = \rho_k$ ($k = 1, \dots, n$). Параметры ρ_k известны. Найти:

- в) оценки максимального правдоподобия a_1^*, a_2 параметров a_1, a_2 по выборке $y^{(1)}, \dots, y^{(n)}$;
 б) оценку максимального правдоподобия a_1^{**} параметра a_1 по выборке $y_1^{(1)}, \dots, y_1^{(n)}$

Ч-6.19

Для величины $A = \alpha + \beta a + \gamma b$ получены оценки

$$A_1^* = \alpha + \beta z_1 + \gamma z_3, \quad A_2^* = \alpha + \beta z_2 + \gamma z_3.$$

где α, β, γ - известные постоянные, z_1, z_2, z_3 - независимые оценки неизвестных параметров: $Mz_3 = b$, $Mz_1 = Mz_2 = a$; $Dz_i = \sigma_i^2$, $i = 1, 2, 3$. Подобрать постоянные c_1, c_2 так, чтобы оценка $A^* = c_1 A_1^* + c_2 A_2^*$ была несмещенной и имела среди несмещенных оценок наименьшую дисперсию.

Ч-6.20

Пусть z_1, z_2, z_3 - несмещенные оценки параметра a ; $Dz_i = 1$ ($i = 1, 2, 3$), $\text{cov}(z_1, z_2) = \rho$, $\text{cov}(z_i, z_3) = 0$ ($i = 1, 2$). Найти несмещенную линейную оценку $z = c_1 z_1 + c_2 z_2 + c_3 z_3$ параметра a с наименьшей возможной дисперсией и дисперсию этой оценки. Рассмотреть случаи: а) $|\rho| < 1$, б) $\rho = -1$, в) $\rho = 1$.

Ч-6.21

Функция $y = Ax$ измерена в точках $x_1, \dots, x_n$. Пусть результаты измерений являются реализацией независимых случайных величин $\tilde{y}_1, \tilde{y}_2, \dots, \tilde{y}_n$, у которых $M\tilde{y}_i = y_i = Ax_i$, $D\tilde{y}_i = \sigma^2 < \infty$ ($i = 1, 2, \dots, n$).

Найти: сумму квадратов, т. е. минимизируя по A выражение $I(A) = \sum_{i=1}^n (\tilde{y}_i - Ax_i)^2$

б) MA_n^*, DA_n^* Доказать, что оценка A_n состоятельна, если $X_n^2 = \sum_{i=1}^n x_i^2 \rightarrow \infty$ при $n \rightarrow \infty$. Пусть результаты измерений являются реализацией n независимых двумерных случайных векторов $(\tilde{x}_i, \tilde{y}_i)$. ($i = 1, \dots, n$), у которых координаты

6.2*. Проведено n измерений значений функций $y =$

измерений являются реализацией n независимых двумерных случайных векторов $(\tilde{x}_i, \tilde{y}_i)$. ($i = 1, \dots, n$), у которых координаты

независимы, $M\tilde{x}_i = x_i$, $M\tilde{y}_i = y_i = Ax_i$, $D\tilde{x}_i = \sigma^2$, $D\tilde{y}_i = \sigma^2$ Найти:

а) оценку A_n параметра A , минимизируя по A и $x_1, \dots, x_n$ выражение

$$I(A, x_1, \dots, x_n) = \sum_{i=1}^n (\tilde{y}_i - Ax_i)^2 + \sum_{i=1}^n (\tilde{x}_i - x_i)^2.$$

б) Показать, что оценка A_n состоятельна, если при

$$X_n^2 = \sum_{i=1}^n x_i^2 \rightarrow \infty, \quad n/X_n^2 \rightarrow 0.$$

Ч-6.23

Функция $y = Ax$ измерена n_1 раз в точке $x_1, \dots, x_{n_1}$ раз в точке x_k . Пусть результаты измерений y_{ij} ($j = 1, \dots, n_i, i = 1, \dots, k$) некоррелированы и имеют вид

$$y_{ij} = Ax_i + \delta_{ij},$$

где $M\delta_{ij} = 0$, $D\delta_{ij} = \sigma^2$.

а) Найти оценку A параметра A , используя метод наименьших квадратов, т. е. минимизируя по A выражение

$$I(A) = \sum_{i=1}^k \sum_{j=1}^{n_i} (y_{ij} - Ax_i)^2.$$

б) Найти MA и DA .

Ч-6.24

В предыдущей задаче обозначим

$$\bar{y}_i = \frac{1}{n_i} \sum_{j=1}^{n_i} y_{ij}, \quad i = 1, \dots, k.$$

Подобрать $c_1, \dots, c_k$ так, чтобы оценка

$$A^* = c_1 \bar{y}_1 + c_2 \bar{y}_2 + \dots + c_k \bar{y}_k$$

была несмещенной и имела наименьшую дисперсию. Найти DA^* при наилучшем выборе $c_1, c_2, \dots, c_k$.

Ч-6.25

Из урны, содержащей N белых и черных шаров, производится выборка объема n с возвращением. Пусть μ_n - число белых шаров в выборке, а M - неизвестное число белых шаров в урне. Для оценки величины $p = M/N$ используется статистика $p_n^* = \mu_n/n$. Найти Mr_n, Dp_n .

Ч-6.26

Из урны, содержащей N белых и черных шаров, производится выборка объема n без возвращения. Пусть μ_n - число белых шаров в выборке, а M - неизвестное начальное число белых шаров в урне. Для оценки величины $p = M/N$ используется статистика $p_n^{**} = \mu_n/n$. Найти Mr_n^{**}, Dp_n^{**} .

Ч-6.27

Для сравнения точности оценок p_n^*, p_n^{**} , определенных в задачах 6.25, 6.26, найти $\lim_{n \rightarrow \infty} (Dp_n^{**}/Dp_n^*)$ в следующих случаях: а) $n \rightarrow \infty, \frac{n}{N} \rightarrow \gamma$ ($0 < \gamma < \infty$); б) $n \rightarrow \infty, n/N \rightarrow 0$.

Ч-6.28

Из урны, содержащей неизвестное число шаров N (шары завуамерены), производится выборка объема n с возвращением. Для оценки числа N используется величина $1/\eta_n$, где

$$\eta_n = \frac{1}{n(n-1)} \sum_{k=1}^N \xi_k (\xi_k - 1),$$

ξ_k - число появлений шара с номером k в выборке. Найти $M\eta_n$ и асимптотическую формулу для $D\eta_n$ при $n, N \rightarrow \infty, n/N \rightarrow \alpha \in (0, \infty)$.

Ч-6.33

Чтобы оценить ширину кольца, образованного двумя окружностями с общим центром, измерялись их радиусы R и r , т. е. была получена выборка $y_1, \dots, y_n, x_1, \dots, x_n$, образованная независимыми случайными величинами, которые имеют нормальные распределения с $My_i = R, \quad Mx_i = r \quad (R > r), \quad Dx_i = Dy_i = \sigma^2, i = 1, 2, \dots, n$. Пусть $\bar{x} = (x_1 + \dots + x_n)/n$ и $\bar{y} = (y_1 + \dots + y_n)/n$. Для оценок $\bar{a} = \bar{y} - \bar{x}, a^* = \max(0, \bar{y} - \bar{x})$ ширины кольца $a = R - r$ найти: $\bar{a}, Ma^*, \sqrt{M(\bar{a} - a)^2}, \sqrt{M(a^* - a)^2}$. Вычислить эти величины при $R = 1001$ м., $r = 1000$ м., $\sigma = 10$ м., $n = 200$.

Ч-6.34

Независимые наблюдения $\theta_1^*, \dots, \theta_n$ имеют не известные математические ожидания $\theta_i^* = \theta_i$ и известные дисперсии $D\theta_i^* = \sigma_i^2, \quad i = 1, \dots, n$. Для оценки линейной комбинации $I = c_1\theta_1 + \dots + c_n\theta_n$ с заданными $c_1, \dots, c_n$ используются статистики

$$I_N = c_1\theta_1^* + \dots + c_N\theta_N^* \quad (1 \leq N \leq n).$$

а) Доказать, что I_n - несмещенная, а I_N при $N < n$ - смещенная оценка I .

б) Найти $M(I_N - I)^2$. При каких условиях среднеквадратическое отклонение смещенной оценки I_{n-1} меньше среднеквадратического отклонения несмещенной оценки I_n ?

Ч-6.35

Используя критерий χ^2 , проверить гипотезу о том, что выборка, полученная в задаче нб.9, соответствует равномерному распределению на отрезке $[0, 1]$. уровень значимости $\alpha = 0,05$.

Ч-6.36

Используя критерий χ^2 , проверить гипотезу о том, что выборка, полученная в задаче нб.10н, соответствует нормальному распределению; параметры a и σ считать неизвестными. Уровень значимости положить равным 0,05. Соотношения для различения по выборке $x_1, \dots, x_n$ гипотез $H_1 : x_h$ распределены нормально с параметрами (a_1, σ^2) , $H_2 : x_k$ распределены нормально с параметрами (a_2, σ^2) .

Ч-6.40

*. Пусть $x_1, \dots, x_n$ - выборка. Гипотеза H_1 состоит в том, что x_i равномерно распределены на интервале $(0, 1)$ и независимы, а гипотеза H_2 - в том, что x_i независимы и имеют непрерывно дифференцируемую плотность распределения $g(x); g(x) \neq 1$ при $0 \leq x \leq 1$, $g(x) = 0$ при $x \notin [0, 1]$. Разобьем $[0, 1]$ на N полуинтервалов $[0, \frac{1}{N}), [\frac{1}{N}, \frac{2}{N}), \dots, [\frac{N-1}{N}, 1)$ и обозначим через μ_a число полуинтервалов, в которые не попало ни одно из наблюдений x_i . При гипотезах H_1 и H_2 найти $a_j = \lim (M_0/N), j = 1, 2$, когда $n/N \rightarrow \gamma \in (0, \infty), n, N \rightarrow \infty$.

Ч-6.41

Пусть $0 < \tau_1 < \tau_2 < \dots$ положения точек пуассоновского потока с неизвестной интенсивностью λ . Найти: а) оценку максимального правдоподобия λ_n параметра λ , построенную по $\tau_1, \dots, \tau_n$; б) $M\lambda_n^*, D\lambda_n$.

Ч-6.42

Пусть $\tau_{12}(t)$ - число переходов в цепи Маркова, определенной в задаче нб.82, из состояния 1 в состояние 2 за время t .

а) Найти $\lim_{t \rightarrow \infty} M \frac{\tau_{12}(t)}{t} \times \lim_{t \rightarrow \infty} D \frac{\tau_{12}(t)}{t}$.

б) Является ли величина $\tau_{12}(t)/t$ состоятельной оценкой параметра $\gamma = \frac{\alpha\beta}{\alpha+\beta}$ при $t \rightarrow \infty$?

7.3 Problems Arising from the Application of Probability Theory

(пока избры, но вообще тут много можно интересного порешать)
(наверное, крутые очень задачи, просто не до них абсолютно. доработаю базу - буду тренироваться, если захочу.)

7.3.1 Problems of Probability Theory in Physics

(тоже такая часть каталога.)

Избры-1 Теорема Вика

На лекции было получено, что

$$\left\langle \exp \left(-ip \frac{\xi}{N} \right) \right\rangle \approx \exp \left(-\frac{p^2 \langle \xi^2 \rangle}{2N^2} \right)$$

1. Для начала найдите моменты случайной величины, т.е. $\langle \xi^n \rangle = M_n$ 2. Рассмотрите усреднение в левой части выражения для случайной величины ξ , распределенной по Гауссу с нулевым средним.

Избры-2

Пусть случайная величина ξ нормально распределена с нулевым матожиданием и дисперсией $\langle \xi^2 \rangle = \sigma^2$. Как распределена случайная величина ξ^2 ? А как распределена ξ^n ?

Избры-3

В этой задаче попробуем проверить корректность нашего понимания вероятности. Пусть мы измеряем величину ξ и провели N измерений, которые дали нам результаты $\{\xi_1, \dots, \xi_N\}$. По этим результатам мы построили плотность вероятности: $\rho_e(\xi) = \frac{1}{N} \sum_{i=1}^N \delta(\xi - \xi_i)$. Мы будем считать, что все ξ_i - независимые случайные величины с плотностью вероятности $\rho(\xi)$. Мы будем обозначать чертой - усреднение по ρ_e т.е. $\overline{f(\xi)} = \int_{-\infty}^{\infty} f(\xi) \rho_e(\xi) d\xi$. Треугольными скобками будем обозначать усреднение по реализации, то есть $\langle \delta(\xi - \xi_i) \rangle = \rho(\xi)$. - Покажите, что функция, полученная с помощью эксперимента в среднем совпадает с истинной функцией распределения: $\langle \rho_e(\xi) \rangle = \rho(\xi)$. Таким образом $\langle \overline{f(\xi)} \rangle = \langle f(\xi) \rangle$ - Вычислим теперь "дисперсию" для экспериментальной функции распределения:

$$\langle \langle \rho_e(\xi') \rho_e(\xi'') \rangle \rangle = \langle \rho_e(\xi') \rho_e(\xi'') \rangle - \langle \rho_e(\xi') \rangle \langle \rho_e(\xi'') \rangle$$

- Предыдущий пункт помогает нам понять во сколько в среднем мы отклоняемся при вычислении различных экспериментальных величин. Выразите следующую величину через $\langle f^2(\xi) \rangle$:

$$\langle \{ \overline{f(\xi)} \}^2 \rangle - \overline{\langle f(\xi) \rangle^2}$$

Избры-4

В этой задаче нам предстоит разобраться с условиями применимости ЦПТ. Нас будет интересовать случайная величина $\xi = \frac{1}{N} \sum_{i=1}^N \xi_i$. Все ξ_i - независимые случайные величины. Нас интересовала производящая функция этой величины:

$$f(p) = \langle e^{-ip\xi} \rangle = \left\langle \prod_i e^{-i\frac{p}{N}\xi_i} \right\rangle$$

Ключевым местом в доказательстве было предположение о малости величины в экспоненте. Попробуем понять применимость этого приближения. Для этого разложим величину $\langle e^{-ip\xi} \rangle$ до 4-го порядка по $1/N$ и выполним усреднение. Наша цель - представить результат этого усреднения в виде $f(p) = \exp(G(-ip/N))$. Где $G(x) = \sum_k \Delta_k \frac{x^k}{k!}$

- Выразите первые 4 коэффициента Δ_k через моменты величины $\xi - M_l = \langle \xi^l \rangle$
- Получите условие на то, что плотность вероятности можно восстановить используя метод перевала
- Воспользуйтесь этим условием для задачи, разобранный на лекции и получите правильное условие применимости ЦПТ

8 Problems from Applications

8.1 Problems From Applications in Physics

8.1.1 Problems From Applications in Statistical Physics

Б-3.1.10 Two Level Systems

(!!! write here the combinatorical part, question exactly about it. remind the formulas for the probability!)
Термодинамическая система представляет собой ансамбль из $N \gg 1$ невзаимодействующих двухуровневых систем с одинаковой энергией возбуждения, равной ε . Кратность основного уровня энергии равна g_1 , а возбужденного уровня - g_2 . Найти энтропию системы:

- а) с помощью статистического определения энтропии;
- б) через распределение Гиббса.

Определить теплоемкость системы и показать, что область отрицательных температур отвечает термодинамически неустойчивым состояниям системы с инверсной заселенностью.

Состояние аморфных веществ (стекол) при низких температурах описывают, как состояние с макроскопически большим набором различных двухуровневых систем, у которых энергия возбуждения ε представляет случайную величину с плотностью распределения $\rho(\varepsilon)$, нормированной на число

двухуровневых систем в единице объема $\int_0^\infty \rho(\varepsilon) d\varepsilon = N$. Предполагая, что плотность распределения двухуровневых систем $\rho(\varepsilon)$ остается конечной и непрерывной при $\varepsilon = 0$, найти поведение теплоемкости аморфных веществ в пределе низких температур.

Solution a)

Суть решения в том, что

Если уровни энергии не вырождены, то число состояний с энергией $E = n\varepsilon$ есть число сочетаний из N по n :

$$\Gamma(E = n\varepsilon) = C_N^n = \frac{N!}{(N-n)!n!}.$$

Если нижний уровень g_1 -кратно вырожденный, а верхний g_2 -кратно вырожденный, то число состояний с энергией $E = n\varepsilon$ будет равно

$$\Gamma(E = n\varepsilon) = g_1^{N-n} g_2^n C_N^n.$$

Соответственно, энтропия системы дается выражением

$$S(E) = \ln \Gamma(E = n\varepsilon) = (N-n) \ln g_1 + n \ln g_2 + \ln \frac{N!}{(N-n)!n!}.$$

11 Random Processes: Basics

Приведем основы описания стохастических систем и покажем, как можно добавлять случайные процессы в любые физические модели.

11.1 Basics of the Theory of Random Processes in a Nutshell

Разберем вкратце переход теории вероятности в теорию случайных процессов.
(по Жуковскому мфти)

11.1.1 Typical Random Processes

(где-то уже писал ведь их, наверное, в случпроцах, там разберу, вставлю сюда)

ветвящиеся процессы Гальтона-Ватсона

В настоящей главе, а также в третьей и четвертых главах мы поговорим о важнейших примерах случайных процессов.

В этой главе речь пойдет о ветвящихся процессах.

Модель ветвящихся процессов была впервые предложена Ф. Гальтоном и Г. Ватсоном в 1873 году в связи с анализом вырождения аристократических фамилий Великобритании.

Физическая модель: в дискретные моменты времени частицы распадаются на случайное количество таких же частиц. Число потомков каждой частицы имеет одно и то же распределение.

Формальная математическая модель выглядит следующим образом.

Математическая модель: пусть ξ - случайная величина со значениями в $\mathbb{Z}_+$, а $\{\xi_k^{(n)}, k, n \in \mathbb{N}\}$ - набор независимых случайных величин с тем же распределением, что и ξ . Положим

$$X_0 = 1, X_n = \sum_{k=1}^{X_{n-1}} \xi_k^{(n)}, n \geq 1$$

Определение

Процесс $(X_n, n \in \mathbb{Z}_+)$ называется ветвящимся процессом Гальтона-Ватсона с законом размножения частиц ξ .

Интерпретация величин модели совершенно ясна: X_n - это

число частиц в n -м поколении, а $\xi_k^{(n)}$ - число потомков k -й частицы из $(n-1)$ -го поколения.

Нас будут интересовать два вопроса относительно ветвящихся процессов. - Какова вероятность вырождения ветвящегося процесса $\mathbf{P}(\exists n : X_n = 0)$? - Каково распределение общего числа частиц в процессе? Ответы на эти вопросы можно найти с помощью метода производящих функций.

А Определение 2.2. Пусть ξ - случайная величина. Тогда ее производящей функцией называется функция

$$\varphi_\xi(z) = \mathbf{M}z^\xi, z \in \mathbb{R}$$

определенная для тех z , для которых конечно данное математическое ожидание. Выделим основные свойства производящих функций.

1. $\varphi_\xi(1) = 1$
2. $\varphi'_\xi(1) = \mathbf{M}\xi$
3. Если ξ и η независимы, то $\varphi_{\xi+\eta}(z) = \varphi_\xi(z) \cdot \varphi_\eta(z)$.

Если ξ принимает значения в $\mathbb{Z}_+$, то имеются дополнительные свойства:

4. $\varphi_\xi(z) = \sum_{k=0}^{\infty} z^k \mathbf{P}(\xi = k)$ - степенной ряд, сходящийся абсолютно и равномерно в области $\{|z| \leq 1\}$
5. $\varphi_\xi(z)$ непрерывно дифференцируема бесконечное число раз в области $\{|z| < 1\}$
6. $\varphi_\xi(0) = \mathbf{P}(\xi = 0)$
7. $\mathbf{P}(\xi = k) = \frac{1}{k!} \left(\frac{d^k}{dz^k} \varphi_\xi(z) \right) \Big|_{z=0}$

Пусть теперь $X = (X_n, n \in \mathbb{N})$ - это ветвящийся процесс Гальтона-Ватсона с законом размножения частиц ξ .

Лемма

2.1. Между производящими функциями элементов процесса X имеют место следующие рекуррентные соотношения:

1. $\varphi_{X_{n+1}}(z) = \varphi_{X_n}(\varphi_\xi(z))$

2. $\varphi_{X_n}(z) = \underbrace{\varphi_\xi(\varphi_\xi(\dots \varphi_\xi(z)))}_{n \text{ раз}};$

3. $\varphi_{X_{n+1}}(z) = \varphi_\xi(\varphi_{X_n}(z)).$

Данная лемма позволяет найти уравнение для вероятности вырождения. Обозначим через q вероятность вырождения, т.е.

$$q = \mathbf{P}(\text{процесс выродился}) = \mathbf{P}(\exists n : X_n = 0)$$

Тогда выполнено следующее утверждение. Лемма 2.2. Вероятность вырождения q ветвящегося процесса с законом размножения частиц ξ является решением уравнения

$$z = \varphi_\xi(z)$$

Уравнение (2) - это первая замечательная формула в теории ветвящихся процессов. Отметим, что

$$z = 1$$

всегда является решением (2). Однако при наличии других корней нам надо уметь отбирать среди них вероятность вырождения. Полную классификацию ситуаций дает

Теорема

о вероятности вырождения.

Теорема 2.1 (0 Вероятности вырождения).

Пусть случайная величина ξ не равна единице тождественно, т.е. $\mathbf{P}(\xi = 1) \neq 1$. Обозначим $\mu = \mathbf{M}\xi$. Если $\mu \leq 1$, то уравнение (2) имеет на $[0, 1]$ только одно решение: $z = 1$. В этом случае $q = 1$. Если $\mu > 1$, то уравнение (2) имеет единственное решение $z_0 \in [0, 1)$. В этом случае $q = z_0$.

Вывод: вероятность вырождения - это наименьший корень уравнения $z = \varphi_\xi(z)$ из отрезка $[0, 1]$.

Отметим, что

Теорема

имеет весьма жизненную интерпретацию: если среднее число потомков в процессе не больше единицы, то процесс обречен на вымирание; в противном случае есть ненулевая вероятность бесконечного существования популяции.

Общее число частиц. Обсудим теперь вопрос об общем

16

числе частиц в ветвящемся процессе. Обозначим общее число частиц в процессе до момента времени n включительно $Y_n = 1 + X_1 + \dots + X_n$. Тогда имеет место следующее рекуррентное соотношение между производящими функциями Y_n и Y_{n-1} , аналогичное соотношениям в лемме 2.1 для самого X_n :

$$\varphi_{Y_{n+1}}(z) = z\varphi_\xi(\varphi_{Y_n}(z))$$

Далее, для каждого $z \in [0, 1)$ существует предел

$$\rho(z) = \lim_{n \rightarrow +\infty} \varphi_{Y_n}(z)$$

который можно интерпретировать как производящую функцию общего числа частиц за все время существования процесса. Пусть Y - общее число частиц в ветвящемся процессе за все время (если процесс не выродился, то, конечно, $Y = +\infty$). Тогда

$$\rho(z) = \mathbf{M}(z^Y I(Y < +\infty)) = \sum_{k=0}^{+\infty} z^k \mathbf{P}(Y = k)$$

Найти $\rho(z)$ можно из второго замечательного уравнения в теории ветвящихся случайных процессов. Лемма 2.3. Функция $\rho(z)$ является решением уравнения

$$\rho(z) = z\varphi_\xi(\rho(z))$$

Понятие времени корреляции

Обозначим случайную бинарную переменную, кодирующую информацию о погодных условиях в n -й день наблюдений, через S_n . Здесь и далее мы будем считать, что случайный процесс S_n является статистически стационарным, то есть частные функции распределения случайных величин S_{n_1} и S_{n_2} одинаковы для любых моментов времени n_1 и n_2 . Можно предложить несколько формальных способов детектирования присутствия корреляций во временном ряду значений такого случайного процесса. - Корреляции в строке значений $s_1, s_2, s_3, \dots$ проявляются, к примеру, в том, что условная вероятность $\Pr[S_{n_2} = s_{n_2} | S_{n_1} = s_{n_1}]$, где $n_2 \geq n_1$, не равна частной вероятности $\Pr[S_2 = s_2]$. Другим способом увидеть статистическую зависимость значений случайной функции S_n в разные моменты времени является основан на анализе автокорреляционной функции, которая определена как

$$C(n_1, n_2) = \langle S_{n_1} S_{n_2} \rangle$$

Очевидно, что при наличии корреляций справедливо $C(n_1, n_2) \neq \langle S_{n_1} \rangle \langle S_{n_2} \rangle = \langle S_n^2 \rangle$. Наконец, вывод о присутствии статистических корреляций можно сделать из факта отличия от нуля взаимной информации $I(S_{n_1}, S_{n_2}) = \left\langle \log_2 \frac{P(S_{n_1}, S_{n_2})}{P_1(S_{n_1})P_2(S_{n_2})} \right\rangle$. Корреляции имеют тенденцию затухать с ростом интервала $n_2 - n_1$ между моментами наблюдений, так что в пределе $n_2 - n_1 \rightarrow +\infty$ переменные S_{n_1} и S_{n_2} становятся статистически

независимыми. Это, в частности, означает, что $\lim_{n_2-n_1 \rightarrow +\infty} C(n_1, n_2) = \lim_{n_2-n_1 \rightarrow +\infty} \langle S_{n_1} S_{n_2} \rangle = \langle S_{n_1} \rangle \langle S_{n_2} \rangle = \langle S_n \rangle^2 \leq \langle S_n^2 \rangle = C(n, n)$. В этой связи удобно ввести масштаб времени τ_c , называемый временем корреляции, на котором корреляционная функция выходит на свое асимптотическое значение. Анализ поведения отношения $\Pr[S_{n_2} = s_{n_2} | S_{n_1} = s_{n_1}] / \Pr[S_{n_2} = s_{n_2}]$ и взаимной информации $I(S_{n_1}, S_{n_2})$ обычно дает ту же оценку по порядку величины для характерного времени корреляции.

11.1.2 Independent Incremental Processes - Poisson Process

Теория по кому-то

Пуассоновский и винеровский процесс являются процессами с независимыми приращениями.

Так что изучим такие процессы.

Определение 3.1.

Процесс $(X_t, t \geq 0)$ называется процессом с независимыми приращениями, если для любого натурального n и любых $t_n > \dots > t_1 \geq 0$ случайные величины $X_{t_n} - X_{t_{n-1}}, \dots, X_{t_2} - X_{t_1}, X_{t_1}$ независимы в совокупности.

Отметим, что в случае дискретного времени процесс с независимыми приращениями является не чем иным, как случайным блужданием.

Тем самым процессы с независимыми приращениями естественно рассматривать как обобщение случайных блужданий для непрерывного времени.

В теории случайных процессов важнейшую роль играют вопросы существования процессов.

Дело в том, что совместные распределения случайных величин X_t не могут быть уж совсем произвольными, а должны быть в определенном роде согласованы.

Для процессов с независимыми приращениями критерий существования звучит следующим образом.

Теорема:

задано $Q_{s,t}$ -распределение вероятностей на $(\mathbb{R}, \mathcal{B}(\mathbb{R}))$ с характеристической функцией $\varphi_{s,t}$ пусть Q_0 -также некоторое распределение вероятностей на $(\mathbb{R}, \mathcal{B}(\mathbb{R}))$. Тогда процесс $(X_t, t \geq 0)$ с независимыми приращениями и условиями

$$X_t - X_s \stackrel{d}{=} Q_{s,t} \quad \forall 0 \leq s < t \text{ и } X_0 \stackrel{d}{=} Q_0$$

существует $\Leftrightarrow \forall 0 \leq s < u < t, \forall \tau \in \mathbb{R}$

$$\varphi_{s,t}(\tau) = \varphi_{s,u}(\tau) \cdot \varphi_{u,t}(\tau)$$

Необходимость условия (4) почти очевидна из свойств характеристических функций, но оказывается, что его достаточно для установления существования процесса.

Первым процессом с независимыми приращениями нашего курса является пуассоновский процесс.

Определение пуассоновского случапроца

Случайный процесс $(N_t, t \geq 0)$ называется пуассоновским процессом интенсивности $\lambda > 0$, если выполнены три условия:

1. $N_0 = 0$ п.н.;
2. N_t имеет независимые приращения;
3. $N_t - N_s \sim \text{Pois}(\lambda(t-s))$ для любых неотрицательных $t > s$.
(ну и дальше куча теории Жуковского, потом мб пойму ее)

Суперпозиция потоков Пуассона

Важным свойством пуассоновского потока является его стабильность относительно сложения. Оказывается, суперпозиция двух независимых пуассоновских потоков с рейтами λ_1 и λ_2 дает пуассоновский поток с рейтом $\lambda_1 + \lambda_2$.

Для доказательства сложим количества событий, n_1 и n_2 , произошедших за один и тот же интервал времени t в двух пуассоновских потоках с рейтами λ_1 и λ_2 , соответственно. Характеристическая функция вероятностного распределения случайной величины $n = n_1 + n_2$ равна

$$\Phi(k) \equiv \langle e^{ik(n_1+n_2)} \rangle = \langle e^{ikn_1} \rangle \langle e^{ikn_2} \rangle = \varphi_1(k) \varphi_2(k),$$

где $\phi_1(k)$ и $\phi_2(k)$ - характеристические функции распределений Пуассона случайных величин n_1 и n_2 , то есть

$$\begin{aligned} \varphi_1(k) &\equiv \langle e^{ikn_1} \rangle = \exp(-\lambda_1 t) \sum_{n_1=0}^{+\infty} e^{ikn_1} \\ &= \exp(\lambda_1 t (e^{ik} - 1)) \\ \varphi_2(k) &\equiv \langle e^{ikn_2} \rangle = \exp(\lambda_2 t (e^{ik} - 1)) \end{aligned}$$

Таким образом, находим

$$\Phi(k) = \varphi_1(k) \varphi_2(k) = \exp((\lambda_1 + \lambda_2) t (e^{ik} - 1))$$

откуда следует что случайная величина n имеет пуассоновское распределение с рейтом $\lambda_1 + \lambda_2$.

Деление потока Пуассона

Аналогично, пуассоновский поток с рейтом λ можно разделить на два независимых пуассоновских подпотока с рейтами λ_1 и $\lambda_2 = \lambda - \lambda_1$. Деление исходного процесса производится посредством подбрасывания монетки с вероятностями орла и решки равными λ_1/λ и $1 - \lambda_1/\lambda$, случайный исход которого определяет, к какому из двух производных процессов будет принадлежать очередное пуассоновское событие. Проще всего указанное свойство можно доказать, показав их справедливость для процесса Бернулли с малой вероятностью единицы, и перейдя затем к континуальному пределу. Упражнение: Посетители прибывают в торговый комплекс в случайные моменты времени и независимо друг от друга со средней частотой λ . В каждом отдельном случае вероятность того, что очередной посетитель будет женского пола равна q . Найдите математическое ожидание и дисперсию числа женщин, прибывших в торговый комплекс за промежуток времени t .

Неоднородный поток Пуассона

Неоднородным потоком Пуассона называется поток событий, в котором вероятность $\lambda(t)dt$ наблюдать событие в промежутке времени $[t, t + dt]$ как и в однородном случае не зависит предшествующей истории наблюдений, но зависит от времени t . Такой процесс можно рассматривать как предельный случай последовательности независимых испытаний Бернулли, в которой вероятность выпадения единицы в очередной попытке зависит от номера этой попытки. К примеру, события распада радиоактивных атомов в образце, состоящим в начальный момент времени из большого их числа $N_0 \gg 1$, представляют собой неоднородный пуассоновский

Распределение числа событий

Пусть n - это число событий, произошедших за время t , отсчитываемое от произвольно выбранного момента начала наблюдений. Найдём функцию распределения вероятностей $p(n; t)$. В случае $n = 0$ получаем

$$P(0; t) = \Pr[qT_1 > t] = \int_t^{+\infty} dT_1 \frac{T_1}{\langle T_1 \rangle} P(T_1) \int_{t/T}^1 dq = \int_t^{+\infty} dT_1 \frac{T_1}{\langle T_1 \rangle} P(T_1) \left(1 - \frac{t}{T}\right)$$

где q - это отношение, в котором точка начала наблюдений делит межсобытийный интервал, на который она попала. Если $n > 0$, то искомое распределение можно записать как

$$\begin{aligned} P(n; t) &= \Pr[(qT_1 + T_2 + \dots + T_n < t) \cap (T_{n+1} > t - qT_1 - T_2 - \dots - T_n)] = (22) \\ &= \int_0^t d\tau \rho(\tau) \int_{t-\tau}^{+\infty} dT_{n+1} P(T_{n+1}) \end{aligned}$$

где $\rho(\tau)$ - плотность вероятности случайной величины $qT_1 + T_2 + \dots + T_n$.

Решение в Лаплас-представлении (!?????)

Из соотношения (23) с учетом теоремы о свертке следует простая связь между Лаплас-образами функциями $p(n; t)$, $\rho(\tau)$ и $P(T)$, а именно

$$\tilde{p}(n; s) = \frac{1 - \tilde{P}(s)}{s} \tilde{\rho}(s),$$

где

$$\begin{aligned} \tilde{\rho}(s) &= \langle e^{-s\tau} \rangle = \langle e^{-s(qT_1 + T_2 + \dots + T_n)} \rangle = \left\langle e^{-sqT_1} \prod_{i=2}^n e^{-sT_i} \right\rangle = \langle e^{-sqT_1} \rangle \prod_{i=2}^n \langle e^{-sT_i} \rangle \quad (25) \\ &= \tilde{P}^{n-1}(s) \int_0^{+\infty} dT_1 \frac{T_1}{\langle T_1 \rangle} P(T_1) \int_0^1 dq e^{-sqT_1} = \tilde{P}^{n-1}(s) \int_0^{+\infty} dT_1 P(T_1) \frac{1 - e^{-sT_1}}{\langle T_1 \rangle s} = (26) \\ &= \frac{\tilde{P}^{n-1}(s)(1 - \tilde{P}(s))}{\langle T \rangle s} \end{aligned}$$

Подставляя этот результат в Ур. (24), находим

$$\tilde{p}(n; s) = \frac{(1 - \tilde{P}(s))^2 \tilde{P}^{n-1}(s)}{\langle T \rangle s^2}$$

Упражнение: Проверьте, что в случае экспоненциального распределения интервала времени между последовательными событиями обратное преобразование Лапласа от выражения (28) дает распределение Пуассона.

Гауссовские процессы.

Винеровский процесс

Марковские моменты

Мартингалы

Большая часть оставшихся глав настоящего учебного пособия посвящена различным классам случайных процессов, наиболее важным с точки зрения приложений. В

предыдущих главах мы уже рассмотрели процессы с независимыми приращениями и гауссовские процессы. В этой главе речь пойдет о мартингалах. **Δ** Определение 6.1. Пусть $T \subset \mathbb{R}$. Процесс $(X_t, t \in T)$ называется мартингалом относительно фильтрации $\mathbb{F} = (\mathcal{F}_t, t \in T)$ если 1. X_t согласован с $\mathbb{F}$; 2. X_t является L^1 -процессом, т.е. для любого $t \in T$ выполнено неравенство $\mathbf{M}|X_t| < +\infty$ 3. $\mathbf{M}(X_t|\mathcal{F}_s) = X_s$ п. н. для любых $s \leq t, s, t \in T$. А Определение 6.2. Если вместо условия 3 выполнено

$$\mathbf{M}(X_t|\mathcal{F}_s) \geq X_s \text{ п. н. } \forall s \leq t, s, t \in T$$

то процесс X_t называется субмартингалом относительно $\mathbb{F}$. Если же вместо условия 3 выполнено

$$\mathbf{M}(X_t|\mathcal{F}_s) \leq X_s \text{ п. н. } \forall s \leq t, s, t \in T$$

то X_t называется супермартингалом относительно $\mathbb{F}$.

Если же вместо условия 3 выполнено

$$\mathbf{M}(X_t|\mathcal{F}_s) \leq X_s \text{ п. н. } \forall s \leq t, s, t \in T$$

то X_t называется супермартингалом относительно $\mathbb{F}$. Субмартингалы и супермартингалы - это мартингалы "наполовину". Для мартингалов условие 3 означает, что функция среднего является постоянной, $\mathbf{M}X_t = \mathbf{M}X_s \forall s, t \in T$. А Определение 6.3. Мартингалами (без указания фильтрации будем называть мартингалы относительно их естественной фильтрации).

Какие же процессы являются мартингалами? Следующая

Теорема

дает критерий мартингальности для процессов с независимыми приращениями.

независимые приращения. Тогда X_t - мартингал $\Leftrightarrow \mathbf{M}X_t = \text{const}$, т.е. функция среднего **по**— стоянна.

Несложно проверить, что если функция среднего не убывает, то процесс с независимыми приращениями является субмартингалом. Если же она не возрастает, то тогда - супермартингалом.

Теорема

6.1 сразу дает нам несколько хороших примеров мартингалов. 1. Винеровский процесс $(W_t, t \geq 0)$ - мартингал. 2. $(S_n, n \in \mathbb{Z}_+)$ - случайное блуждание, $S_n = \xi_1 + \dots + \xi_n, \xi_i$ - независимые случайные величины, $\mathbf{M}|\xi_i| < +\infty$. Тогда S_n - мартингал $\Leftrightarrow$ для любого i $\mathbf{M}\xi_i = 0$. 3. Пуассоновский процесс $(N_t, t \geq 0)$ - субмартингал. 4. Пусть $\xi_n, n \in \mathbb{N}$ - независимые неотрицательные случайные величины, $S_n = \xi_1 \cdot \dots \cdot \xi_n$. Тогда S_n - мартингал $\Leftrightarrow \mathbf{M}\xi_i = 1$ для всех i

Определение

мартингал Леви

Пусть ξ - случайная величина, $\mathbf{M}|\xi| < +\infty$ $\mathbb{F} = (\mathcal{F}_t, t \in T)$ - фильтрация. Докажите, что процесс

$$X_t = \mathbf{M}(\xi|\mathcal{F}_t)$$

Является мартингалом относительно $\mathbb{F}$.

Рассмотрим два важных свойства мартингалов. Первым является разложение Дуба-Мейера для произвольных процессов с дискретным временем. Для его формулировки нам понадобится понятие предсказуемого процесса. А Определение 6.4. Процесс $(X_n, n \in \mathbb{N})$ является предсказуемым относительно фильтрации $(\mathcal{F}_n, n \in \mathbb{Z}_+)$, если X_n измерим относительно $\mathcal{F}_{n-1}$ для всех $n \in \mathbb{N}$.

Теорема

Пусть $(X_n, n \in \mathbb{Z}_+)$ — L^1 -процесс, согласованный с фильтрацией $\mathbb{F} = (\mathcal{F}_n, n \in \mathbb{Z}_+)$. Тогда существует единственное разложение вида

$$X_n = M_n + A_n$$

где M_n — мартингал относительно $\mathbb{F}$, а

$(A_n, n \in \mathbb{N})$ — предсказуемый процесс относи- Заметим в связи с теоремой, что процесс $(X_n, n \in \mathbb{Z}_+)$ является субмартингалом относительно $\mathbb{F}$ тогда и только тогда, когда в его разложении Дуба-Мейера последовательность A_n является п. н. неубывающей.

Второе свойство связывает мартингалы с марковскими моментами и называется теоремой об остановке.

Пусть $(X_n, n \in \mathbb{Z}_+)$ — L^1 -процесс, согласованный с фильтрацией $\mathbb{F} = (\mathcal{F}_n, n \in \mathbb{Z}_+)$. Тогда X_n является мартингалом (субмартингалом) относительно $\mathbb{F} \Leftrightarrow$ для любых τ, σ — ограниченных почти наверное марковских моментов относительно $\mathbb{F}$ таких, что $\tau \leq \sigma$ п. н., выполнено

$$\mathbf{M}X_\tau = (\leq) \mathbf{M}X_\sigma$$

11.1.3 Markov Processes**Марковские процессы в двух словах (?)**

(освоюсь - напишу)

Марковские цепи с дискретным временем

Марковские цепи — это марковские процессы, принимающие не более чем счетное число значений. Пусть x — не более чем счетное множество. Для удобства всегда можно считать, что либо $X = \{1, \dots, N\}$, либо $X = \mathbb{N}$. **Определение 8.1.** Случайный процесс $(X_n, n \in \mathbb{Z}_+)$ со значениями в x называется марковской цепью, если для любого $m \in \mathbb{N}$, для любых $k_1 < \dots < k_m < k < n$ и для любых $a_1, \dots, a_m, i, j \in x$ выполнено (марковское свойство)

$$\mathbf{P}(X_n = j | X_k = i, X_{k_m} = a_m, \dots, X_{k_1} = a_1) = \mathbf{P}(X_n = j | X_k = i)$$

всегда, когда $\mathbf{P}(X_k = i, X_{k_m} = a_m, \dots, X_{k_1} = a_1) > 0$. Определение означает, что «будущее» процесса (X_n) и его «прошлое» $(X_{k_m}, \dots, X_{k_1})$ независимы при фиксированном «настоящем» (X_k) . Также из теоремы 7.1 следует, что марковская Цепь — это марковский процесс с не более чем счетным числом значений. Формальное утверждение, объясняющее обозначенную выше независимость, сформулировано ниже.

Марковские цепи с непрерывным временем

ё

Линейные преобразования в пространстве l^2 **Стационарные случайные процессы****Спектральное представление****Элементы стохастического исчисления Ито****11.1.4 On the use of Markov Processes (?)****О марковских цепях в моделях социального обслуживания (??)**

(такое тоже есть, напишу.)

11.1.5 Random Process Addendums

(всё остальное тут будет, потом буду про структуру думать уже)

11.2 methods for Setting Random Variables

(??)

Случайная величина задается производящим функционалом, который имеет вид:

$$F[\chi(t)] \equiv e^{-W[\chi(t)]} \equiv \left\langle e^{-i \int_0^t dt' \xi(t') \chi(t')} \right\rangle_{\xi}$$

Существует много частных случаев функции $W[\xi(t)]$, например, марковский:

$$W[\chi(t)] = \int_0^t dt' G(\chi(t'))$$

В марковском случае два разных интервала времени статистически независимы, то есть события на одном интервале не влияют на события на другом.

Частный случай марковского процесса является случай с гауссовой силой, когда $G(\chi) = D\chi^2$.

11.2.1 the Probability of Transition in the Presence of Random Processes

Теория

Построим простейшую модель, в которой есть случайность. Пусть у нас есть простейшее уравнение динамики системы: $\dot{x}(t) = -f(x(t))$, добавим к нему случайную величину, то, что получим называется уравнением Ланжевена:

$$\dot{x}(t) = -f(x(t)) + \xi(t).$$

Нашу добавку можно интерпретировать как случайную силу.

Простейшая задача, которую хочется решать, это задача о том, что если мы в момент времени $t = 0$ поместили частицу в точку x_i , с какой вероятностью она перейдет в окрестность точки x_f . (хз, почему, но запишем ее так):

$$P(x_f, x_i; t) = \langle \delta(x_f - x_{\xi}(t)) \rangle_{\xi}$$

Постараемся записать это в форме, которая нас сдвинет дальше. Преобразуем полный переход через сумму переходов за равные промежутки времени $\delta t = t/N$:

$$\delta(x_f - x_{\xi}(t)) = \delta(x_f - x_{n_1}) \delta(x_{n_1} - x_{\xi}(t)) = \dots = \prod_{k=1}^N \delta(x_{n_k} - x_{n_{k-1}}); \quad n_0 = i, \quad n_N = f.$$

Хочется переписать каждый переход с учетом уравнений движения. Для этого посмотрим на дискретную их версию в интегральной форме, которое приближенно

записывается в виде:

$$\begin{aligned} x(t_{k+1}) - x(t_k) &= - \int_{t_k}^{t_{k+1}} dt f(x(t)) + \int_{t_k}^{t_{k+1}} dt \xi(t) \approx \\ &\approx -\frac{1}{2} (t_{k+1} - t_k) (f(x(t_{k+1})) + f(x(t_k))) + \int_{t_k}^{t_{k+1}} dt \xi(t) \quad (11.1) \end{aligned}$$

Введем обозначение $x_k = x(t_k)$, в итоге один переход записывается как:

$$x_{k+1} - x_k = -\frac{\delta t}{2} (f(x_{k+1}) + f(x_k)) + \int_{t_k}^{t_{k+1}} dt \xi(t)$$

Вставка в дельта-функцию производится за счет ее свойства:
 $\delta(x_1 - x_2) = |f'(x_c)| \delta(f(x_c))$, поэтому

$$\begin{aligned} P(x_f, x_i; t) &= \int dx_{N-1} \dots dx_1 \prod_{k=1}^N \left(1 + \frac{\delta t}{2} f'(x_k) \right) \cdot \\ &\cdot \left\langle \delta^{N-1} \left(x_{k+1} - x_k + \frac{\delta t}{2} (f(x_{k+1}) + f(x_k)) - \int_{t_k}^{t_{k+1}} dt \xi(t) \right) \right\rangle_{\xi} \quad (11.2) \end{aligned}$$

Перепишем далее каждую дельта функцию через $\delta(x) = \int \frac{dp}{2\pi} e^{ipx}$, получим:

$$\begin{aligned} P(x_f, x_i; t) &= \frac{1}{(2\pi)^N} \int dx_{N-1} \dots dx_1 dp_N \dots dp_1 \prod_{k=1}^N \left(1 + \frac{\delta t}{2} f'(x_k) \right) \\ &\cdot e^{i \sum_{k=1}^N p_k (x_k - x_{k-1} + \frac{\delta t}{2} (f(x_k) + f(x_{k-1})))} \left\langle e^{-i \sum_{k=1}^N p_k \int_{t_{k-1}}^{t_k} dt \xi(t)} \right\rangle_{\xi} \quad (11.3) \end{aligned}$$

Далее учтем именно свойства самого случайного процесса, за счет добавления производящего функционала для марковского случая:

$$F[\chi(t)] \equiv e^{-W[\chi(t)]} \equiv \left\langle e^{-i \int_0^l dt' G(\chi(t'))} \right\rangle_{\xi}$$

Получим:

$$\begin{aligned} P(x_f, x_i; t) &= \frac{1}{(2\pi)^N} \int dx_{N-1} \dots dx_1 dp_N \dots dp_1 \prod_{k=1}^N \left(1 + \frac{\delta t}{2} f'(x_k) \right) \cdot \\ &\cdot e^{i \sum_{k=1}^N p_k (x_k - x_{k-1} + \frac{\delta t}{2} (f(x_k) + f(x_{k-1})))} \left\langle e^{-\sum_{k=1}^N \delta t G(p_k)} \right\rangle_{\xi} \quad (11.4) \end{aligned}$$

Теперь у нас есть готовое выражение для дискретного времени, которое будем решать. Его можно записать и в случае непрерывных переходов, для этого нужно перейти к непрерывной мере, записав бесконечное произведение в виде члена в экспоненте:

$$P(x_f, x_i; t) = \int_{x(0)=x_i}^{x(t)=x_f} \mathcal{D}x(\tau) \mathcal{D}p(\tau) e^{i \int_0^t d\tau p(\tau)(\dot{x}(\tau) + f(x(\tau))) - \int_0^t d\tau G(p(\tau)) + \frac{1}{2} \int_0^t d\tau f'(x(\tau))}$$

А также в случае гауссовой силы $G(\chi) = D\chi^2$ после интегрирования по импульсу получаем (???)

$$P(x_f, x_i; t) = \int_{x(0)=x_i}^{x(t)=x_f} \mathcal{D}x(\tau) e^{-\frac{1}{4D} \int_0^t d\tau (\dot{x}(\tau) + f(x(\tau)))^2 + \frac{1}{2} \int_0^t d\tau f'(x(\tau))}$$

Или в более понятном виде:

$$P(x_f, x_i; t) = e^{-\frac{1}{2D} \int_{x_i}^{x_f} dy f(y)} \int_{x(0)=x_i}^{x(t)=x_f} \mathcal{D}x(\tau) e^{-\int_0^t d\tau \left(\frac{\dot{x}^2(\tau)}{4D} + \frac{1}{4D} f^2(x(\tau)) - \frac{1}{2} f'(x(\tau)) \right)}.$$

пример: случайные блуждания

Рассмотрим разные задачи случайного блуждания и их решения.

Блуждания с нулевой силой

Рассмотрим случай $f = 0$. Вероятность перейти в конечную точку равна:

$$P(x_f, x_i; t) = \int_{x(0)=x_i}^{x(t)=x_f} \mathcal{D}x(\tau) e^{-\int_0^t d\tau \frac{\dot{x}^2(\tau)}{4D}}$$

Для вычисления данного интеграла заменим:

$$x_{\text{new}} = x + \dot{x} \tau = x_i + \frac{x_f - x_i}{t} \tau$$

После замены у нас выносятся константа:

$$P(x_f, x_i; t) = e^{-\frac{(x_f - x_i)^2}{4Dt}} \int_{x(0)=0}^{x(t)=0} \mathcal{D}x(\tau) e^{-\int_0^t d\tau \frac{\dot{x}^2(\tau)}{4D}}$$

Далее нужно посчитать интеграл по траекториям. Мы его считать не умеем, однако продвинуться нам помогут следующие соображения: во-первых заметим, что он константа; во-вторых так как частица в x_f где-нибудь на координатной оси точно

находится, просуммировав все координаты, то есть проинтегрировав, мы должны получить единицу, так что:

$$\left(\int_{x(0)=0}^{x(t)=0} \mathcal{D}x(\tau) e^{-\int_0^t d\tau \frac{\dot{x}^2(\tau)}{4D}} \right) \int_{-\infty}^{\infty} dx_f e^{-\frac{(x_f - x_i)^2}{4Dt}} = 1,$$

и поэтому

$$\int_{x(0)=0}^{x(t)=0} \mathcal{D}x(\tau) e^{-\int_0^t d\tau \frac{\dot{x}^2(\tau)}{4D}} = \frac{1}{\sqrt{4\pi Dt}}.$$

Окончательно задача решена:

$$P(x_f, x_i; t) = \frac{1}{\sqrt{4\pi Dt}} e^{-\frac{(x_f - x_i)^2}{4Dt}}$$

(место количественных расчетов и на самом деле полезных выводов)

блуждание с силой, не зависящей от времени

$$P(x_f, x_i; t) = \int_{x(0)=x_i}^{x(t)=x_f} \mathcal{D}x(\tau) e^{-\int_0^t d\tau \frac{(t(\tau)+f(\tau))^2}{4D}}$$

$$\ddot{x}_c(\tau) = -\dot{f}(\tau)$$

$$x_c(\tau) = y(\tau) + \frac{x_f - y(t)}{t} \tau \quad y(\tau) = x_i - \int_0^\tau d\tau' f(\tau')$$

$$P(x_f, x_i; t) = \frac{1}{\sqrt{4\pi Dt}} e^{-\frac{(x_f - y(t))^2}{4Dt}}$$

$$P(x_f, x_i; t) = e^{-\frac{\alpha(x^2 - x_i^2)}{4D} + \frac{\alpha t}{2}} \int_{x(0)=x_i}^{x(t)=x_f} \mathcal{D}x(\tau) e^{-\int_0^t d\tau \left(\frac{t^2(\tau)}{10} + \frac{\alpha^2 x^2(\tau)}{4D} \right)}$$

11.2.2 Fundamentals of Brownian Motion

(тут самое основное и суть)

Теория

О применениях (!!?)

(хз, пропишу тут, тоже важно.)

статистика частиц в идеальном газе

(задача с избором)

Пусть у нас есть идеальный газ который содержит N молекул. Каждая молекула может быть равномерно размазана по объёму V всего газа. Выделим в этом газе объём v и зададимся вопросом а какова вероятность того, что в этом объёме ровно m частиц.

нам нужна случайная величина, в данном случае это количество частиц в объёме назовём её ξ

11.3 Sequences of Past-dependent Tests

простейшие такие цепи - цепи маркова
дальше изучим...

11.3.1 Basics of Markov Chains

опишем цепи маркова и покажем их применения.

Теория по Горайнову (??)

Пусть некоторая система меняет свое состояние случайным образом в моменты времени $t = 1, 2, \dots, T$. Множество возможных состояний системы является конечным множеством $E = \{e_1, \dots, e_r\}$ и называется фазовым пространством.

Среди реальных систем важный класс образуют такие, у которых вероятности перехода из одного состояния в другое в данный момент времени не зависят от того, как вела себя система в предыдущие моменты времени.

Такие системы называют марковскими или цепями Маркова.

Эволюция изучаемой системы описывается траекторией $\omega = (\omega_0, \omega_1, \dots, \omega_T)$, где $\omega_t = i$, если система в момент времени t находилась в состоянии e_i . Поэтому под элементарным событием будем понимать $\omega = (\omega_0, \omega_1, \dots, \omega_T)$, т.

е.

последовательность номеров состояний, в которых находилась система в моменты времени $0, 1, \dots, T$. Можно считать, что цепь Маркова является обобщением схемы независимых испытаний, в которой условие независимости заменяется на некоторые другие естественные предположения.

Рассмотрим эти предположения и введем некоторые понятия, связанные с цепями Маркова.

Для вычисления вероятности того, что траектория $\omega = (\omega_0, \omega_1, \dots, \omega_T)$ будет реализована как $i_0, i_1, \dots, i_T$, можно воспользоваться теоремой умножения

$$\begin{aligned} P(\omega_0 = i_0, \dots, \omega_T = i_T) = \\ P(\omega_0 = i_0) P(\omega_1 = i_1 | \omega_0 = i_0) \cdots P(\omega_T = i_T | \omega_0 = i_0, \dots, \omega_{T-1} = i_{T-1}) \end{aligned}$$

Здесь мы считаем, что условная вероятность относительно события с нулевой вероятностью равна нулю.

Условие марковости (независимость от прошлого) выражается в том, что для любых $s < t$ выполняются равенства

$$P(\omega_t = j | \omega_0 = i_0, \dots, \omega_{s-1} = i_{s-1}, \omega_s = i) = P(\omega_t = j | \omega_s = i)$$

$i, j = 1, \dots, r$.

Другими словами, вероятность перехода системы, находившейся в состоянии i в момент времени s , в состояние j в момент времени t не зависит от того, как она себя вела до момента времени s .

Кроме того, мы будем рассматривать однородные марковские цепи, для которых условные вероятности перехода из состояния i в состояние j за время t не зависят от того, в какой момент времени s она находилась в состоянии i .

е.

$$P(\omega_{s+t} = j | \omega_s = i) = P(\omega_t = j | \omega_0 = i) = p_{ij}(t)$$

Вероятности $p_{ij}(t)$ обладают следующими свойствами:

$$1^\circ \cdot p_{ij}(t) \geq 0$$

$$2^\circ \cdot \sum_{j=1}^r p_{ij}(t) = 1$$

$$3^\circ \cdot p_{ij}(0) = \delta_{ij}$$

Матрицу, составленную из вероятностей $p_{ij}(t)$, будем обозначать $\Pi(t)$. Свойства 1° и 2° означают, что $\Pi(t)$ является стохастической матрицей.

Вероятности перехода системы из состояния i в состояние j за единичное время $p_{ij}(1)$ называются переходными вероятностями и обозначаются p_{ij} . Матрица $\Pi(1) = \Pi$ называется матрицей переходных вероятностей.

Однородная марковская цепь вполне определяется вектором-строкой $\vec{p}(0) = (p_1(0), \dots, p_r(0))$ начальных вероятностей ($p_i(0)$ — вероятность того, что в начальный момент времени система находилась в состоянии i) и матрицей переходных вероятностей Π .

Действительно, вероятность $p_j(t)$ того, что система будет находиться в состоянии j в момент времени t определяется равенством

$$p_j(t) = P(\omega_t = j) = \sum_{i=1}^r p_i(0) p_{ij}(t)$$

Если $\vec{p}(t)$ — вектор-строка вероятностей состояний в момент времени t , то

$$\vec{p}(t) = \vec{p}(0)\Pi(t)$$

С другой стороны, матрица $\Pi(t)$ выражается через Π .

Это следует из уравнений Колмогорова-Чепмена

$$p_{ij}(s+t) = \sum_{k=1}^r p_{ik}(s) p_{kj}(t)$$

которые выводятся непосредственно из свойств марковости и однородности

$$\begin{aligned} p_{ij}(s+t) &= P(\omega_{s+t} = j | \omega_0 = i) \\ &= \frac{P(\omega_{s+t} = j, \omega_0 = i)}{P(\omega_0 = i)} \\ &= \sum_{k=1}^r \frac{P(\omega_{s+t} = j, \omega_0 = i, \omega_s = k)}{P(\omega_0 = i)} \\ &= \sum_{k=1}^r \frac{P(\omega_s = k, \omega_0 = i) P(\omega_{s+t} = j | \omega_0 = i, \omega_s = k)}{P(\omega_0 = i)} \\ &= \sum_{k=1}^r p_{ik}(s) p_{kj}(t) \end{aligned}$$

Уравнения (11.1) можно также записать в матричном виде

$$\Pi(s+t) = \Pi(s)\Pi(t)$$

Поскольку $\Pi(1) = \Pi$, то $\Pi(t) = \Pi^t$. Следовательно

$$\vec{p}(t) = \vec{p}(0)\Pi^t$$

Важное значение в теории однородных марковских цепей имеет следующий результат. Тогда для каждого $j = 1, \dots, r$ существует предел

$$p_j = \lim_{t \rightarrow \infty} p_{ij}(t)$$

При этом $p_j > 0, j = 1, \dots, r$, не зависят от i и являются единственным решением системы

$$\sum_{k=1}^r x_k p_{kj} = x_j, \quad \sum_{k=1}^r x_k = 1$$

ДоКАЗАТЕЛЬСТВО.

Введем в рассмотрение

$$M_j(t) = \max_{1 \leq i \leq r} p_{ij}(t), \quad m_j(t) = \min_{1 \leq i \leq r} p_{ij}(t)$$

В силу уравнений (11.1)

$$p_{ij}(1+t) = \sum_{k=1}^r p_{ik} p_{kj}(t)$$

Отсюда и непосредственно из определения $m_j(t)$ и $M_j(t)$ получаем неравенства

$$m_j(t) \leq p_{ij}(t+1) \leq M_j(t)$$

Из этих неравенств, в свою очередь, следуют неравенства

$$m_j(t) \leq m_j(t+1) \leq M_j(t+1) \leq M_j(t)$$

Это означает, что $m_j(t)$ не убывает по t , а $M_j(t)$ не возрастает по t . Обозначим

$$\varepsilon = \min_{1 \leq i, j \leq r} p_{ij}(t_0)$$

По условию теоремы $0 < \varepsilon < 1$. Для $t > 0$, используя уравнения (11.1), получаем

$$\begin{aligned} p_{ij}(t_0+t) &= \sum_{k=1}^r p_{ik}(t_0) p_{kj}(t) \\ &= \sum_{k=1}^r [p_{ik}(t_0) - \varepsilon p_{jk}(t)] p_{kj}(t) + \varepsilon \sum_{k=1}^r p_{jk}(t) p_{kj}(t) \\ &= \sum_{k=1}^r [p_{ik}(t_0) - \varepsilon p_{jk}(t)] p_{kj}(t) + \varepsilon p_{jj}(2t) \end{aligned}$$

Замечая, что выражения в квадратных скобках неотрицательны, получаем неравенство

$$p_{ij}(t_0+t) \leq M_j(t) \sum_{k=1}^r [p_{ik}(t_0) - \varepsilon p_{jk}(t)] + \varepsilon p_{jj}(2t) = (1-\varepsilon)M_j(t) + \varepsilon p_{jj}(2t)$$

из которого следует, что

$$M_j(t_0 + t) \leq (1 - \varepsilon)M_j(t) + \varepsilon p_{jj}(2t)$$

Аналогично получаются неравенства

$$p_{ij}(t_0 + t) \geq (1 - \varepsilon)m_j(t) + \varepsilon p_{jj}(2t)$$

И

$$m_j(t_0 + t) \geq (1 - \varepsilon)m_j(t) + \varepsilon p_{jj}(2t)$$

Сравнивая полученные выше неравенства, приходим к следующему

$$M_j(t_0 + t) - m_j(t_0 + t) \leq (1 - \varepsilon)(M_j(t) - m_j(t))$$

Применяя последовательно k раз последнее неравенство, получаем

$$M_j(kt_0 + t) - m_j(kt_0 + t) \leq (1 - \varepsilon)^k (M_j(t) - m_j(t))$$

Отсюда сразу же следует, что

$$\lim_{k \rightarrow \infty} [M_j(kt_0 + t) - m_j(kt_0 + t)] = 0$$

а поскольку последовательность $\{M_j(t) - m_j(t)\}_{t=1}^{\infty}$ монотонно убывает, то

$$\lim_{t \rightarrow \infty} [M_j(t) - m_j(t)] = 0$$

Таким образом, доказано существование пределов

$$p_j = \lim_{t \rightarrow \infty} M_j(t) = \lim_{t \rightarrow \infty} m_j(t) = \lim_{t \rightarrow \infty} p_{ij}(t)$$

$j = 1, \dots, r$. Заметим также, что поскольку $m_j(t)$ не убывают по t , то

$$p_j \geq m_j(t_0) \geq \varepsilon > 0$$

т.

е.

все p_j строго положительны.

При этом

$$\sum_{j=1}^r p_j = \lim_{t \rightarrow \infty} \sum_{j=1}^r p_{ij}(t) = 1$$

Осуществляя в равенстве

$$p_{ij}(t+1) = \sum_{k=1}^r p_{ik}(t)p_{kj}$$

предельный переход при $t \rightarrow \infty$, получаем

$$p_j = \sum_{k=1}^r p_k p_{kj}$$

т.

е.

$p_1, \dots, p_r$ - решение системы (11.2). Допустим теперь, что $q_1, \dots, q_r$ также является решением этой системы, т.

е.

$$q_j = \sum_{k=1}^r q_k p_{kj}, \quad \sum_{k=1}^r q_k = 1$$

Заметим, что тогда $q_1, \dots, q_r$ будет решением и системы

$$q_j = \sum_{k=1}^r q_k p_{kj}(t)$$

при $t = 1, 2, \dots$. Действительно

$$\sum_{k=1}^r q_k p_{kj}(t) = \sum_{k=1}^r q_k \sum_{l=1}^r p_{kl} p_{lj}(t-1) = \sum_{l=1}^r q_l p_{lj}(t-1) = \dots = \sum_{k=1}^r q_k p_{kj} = q_j$$

Осуществляя в равенстве (11.3) предельный переход при $t \rightarrow \infty$, получаем

$$q_j = \sum_{k=1}^r q_k p_j = p_j$$

и единственность решения системы (11.2) доказана.

Доказанная Теорема относится к так называемым эргодическим теоремам.

Ее смысл состоит в том, что за длительный промежуток времени система как бы забывает, из какого начального состояния она стартовала.

Условие положительности элементов матрицы Π^{t_0} означает, что с положительной вероятностью из любого состояния в любое состояние система может перейти за время t_0 |

Марковское свойство

Простейшей моделью коррелированного случайного процесса является цепь Маркова - случайный процесс с дискретным пространством состояний и дискретным временем, обладающий марковским свойством. Рассмотрим стохастическую переменную S_n , где n играет роль дискретного времени, возможные значения которой принадлежат счетному множеству Ω . Говорят, что стохастический процесс S_n обладает марковским свойством, если условное распределение вероятностей его будущих состояний зависит только от текущего состояния, но не от последовательности более ранних состояний, то есть

$$\Pr [S_{n+1} = s_{n+1} | S_n = s_n, S_{n-1} = s_{n-1}, \dots, S_1 = s_1] = \Pr [S_{n+1} = s_{n+1} | S(n) = s_n]$$

В силу наличия влияния текущего состояния на состояние в сразу следующий за этим момент, в общем случае значения марковской переменной величины в различные моменты времени оказываются скоррелированными друг с другом. Отметим, что следствием Ур. (4) является равенство

$$\Pr [S_n = s_n | S_{n-m} = s_{n-m}, S_{n-k} = s_{n-k}] = \Pr [S_n = s_n | S_{n-m} = s_{n-m}],$$

где $k > m > 0$.

Теория по Вшэ

Управляющее уравнение по ВШЭ

Итак, наш случайный процесс совершает прыжки между двумя состояниями, причем если в момент времени процесс находится в состоянии 1, то $S_n = 1$, а если в состоянии

2, то $S_n = 0$. Обозначим вероятности обнаружить процесс на n -м шаге в состояниях 1 и 2, через $\pi_1(n)$ и $\pi_2(n)$, соответственно. Предполагая марковское свойство стохастической динамики процесса и используя закон полной вероятности, распределение вероятностей на следующем шаге однозначно можно выразить через соответствующее распределение на шаге предыдущем как

$$\begin{aligned}\pi_1(n+1) &= \Pr[S_{n+1} = 1|S_n = 1] \pi_1(n) + \Pr[S_{n+1} = 1|S_n = 2] \pi_2(n) \\ \pi_2(n+1) &= \Pr[S_{n+1} = 2|S_n = 1] \pi_1(n) + \Pr[S_{n+1} = 2|S_n = 2] \pi_2(n)\end{aligned}$$

Условные вероятности переходов между состояниями будем считать не зависящими от времени n и обозначим через $\Pr[S_{n+1} = 2|S_n = 1] = 1 - \Pr[S_{n+1} = 1|S_n = 1] = p$, $\Pr[S_{n+1} = 1|S_n = 2] = 1 - \Pr[S_{n+1} = 2|S_n = 2] = q$. Тогда

$$\begin{aligned}\pi_1(n+1) &= (1-p)\pi_1(n) + q\pi_2(n) \\ \pi_2(n+1) &= p\pi_1(n) + (1-q)\pi_2(n)\end{aligned}$$

Удобно ввести двухкомпонентный вектор вероятностей $\vec{\pi}(n) = (\pi_1(n), \pi_2(n))^T$ и перейти к матричной форме записи

$$\vec{\pi}(n+1) = \hat{P} \cdot \vec{\pi}(n),$$

где матрица $\hat{P}$ называется матрицей вероятностей перехода; ее элементы имеют вид $P_{11} = 1-p$, $P_{12} = q$, $P_{21} = p$, $P_{22} = 1-q$. Уравнение (10) называется управляющим.

Solution управляющего уравнения

Если известно распределение вероятностей $\vec{\pi}(0)$ в начальный момент времени, то решение уравнения (10) записывается как

$$\vec{\pi}(n) = \hat{P}^n \cdot \vec{\pi}(0).$$

Дальнейший анализ требует возведения матрицы $\hat{P}$ в натуральную степень n , что проще всего сделать, представив эту матрицу в виде $\hat{P} = \hat{Q}\hat{D}\hat{Q}^{-1}$, где $\hat{D}$ - диагональная матрица, на диагонали которой стоят собственные числа матрицы $\hat{P}$, $\hat{Q}$ - матрица, составленная из собственных столбцов матрицы $\hat{P}$. Решая уравнение $\det(\hat{P} - \lambda\hat{I}) = 0$ находим пару собственных чисел $\lambda_1 = 1$ и $\lambda_2 = 1-p-q$, которым соответствуют собственные столбцы $\vec{a}_1 = (1/p, 1/q)^T$, $\vec{a}_2 = (1, -1)^T$, по определению удовлетворяющие условию $\hat{P}\vec{a} = \lambda\vec{a}$. Используя эти результаты, запишем

$$\begin{aligned}\hat{P}^n &= \hat{Q}\hat{D}^n\hat{Q}^{-1} = \begin{pmatrix} \frac{1}{p} & 1 \\ \frac{1}{q} & -1 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ 0 & 1-p-q \end{pmatrix}^n \cdot \begin{pmatrix} \frac{pq}{p+q} & \frac{pq}{p+q} \\ \frac{p}{p+q} & -\frac{q}{p+q} \end{pmatrix} \neq (12) \\ &= \begin{pmatrix} \frac{q}{p+q} + \frac{p}{p+q}(1-p-q)^n & \frac{q}{p+q} - \frac{q}{p+q}(1-p-q)^n \\ \frac{p}{p+q} - \frac{p}{p+q}(1-p-q)^n & \frac{p}{p+q} + \frac{q}{p+q}(1-p-q)^n \end{pmatrix}\end{aligned}$$

Подстановка Ур. (13) в Ур. (11) дает

$$\begin{aligned}\pi_1(n) &= \frac{q}{p+q} + \frac{p}{p+q}(1-p-q)^n\pi_1(0) - \frac{q}{p+q}(1-p-q)^n\pi_2(0) \\ \pi_2(n) &= \frac{p}{p+q} - \frac{p}{p+q}(1-p-q)^n\pi_1(0) + \frac{q}{p+q}(1-p-q)^n\pi_2(0)\end{aligned}$$

При выводе этих выражений мы использовали условие нормировки $\pi_1(0) + \pi_2(0) = 1$. Отметим также, что для решения, заданного уравнениями (32) и (33), в любой момент времени справедливо $\pi_1(n) + \pi_2(n) = 1$.

Релаксация к стационарному распределению вероятностей

Из Ур. (32) и (33) видно, что если $0 < p + q < 2$, то любое начальное условие на больших временах релаксирует к стационарному распределению вероятностей

$$\lim_{n \rightarrow +\infty} \pi_1(n) = \bar{\pi}_1^{\text{st}} = \frac{q}{p+q},$$

$$\lim_{n \rightarrow +\infty} \pi_2(n) = \bar{\pi}_2^{\text{st}} = \frac{p}{p+q},$$

которое, как легко проверить, является решением уравнения $\hat{P} \cdot \bar{\pi}^{\text{st}} = 0$. Характерное время релаксации оценивается как $\tau_{\text{relax}} \sim \frac{1}{\ln \frac{1}{|1-p-q|}}$.

Анализ автокорреляций

Продемонстрируем при помощи Ур. (32) и (33) скоррелированность случайного процесса S_n в разные моменты времени. Условная вероятность $\Pr[S_{n_2} = 1 | S_{n_1} = 1]$, где $n_2 \geq n_1$, равна решению π_1 , заданному формулой (32), в которую необходимо подставить $n \rightarrow n_2 - n_1$, $\pi_1(0) = 1$, $\pi_2(0) = 0$. Таким образом, находим

$$\Pr[S_{n_2} = 1 | S_{n_1} = 1] = \frac{q}{p+q} + \frac{p}{p+q}(1-p-q)^{n_2-n_1}$$

Аналогично можно выразить условные вероятности $\Pr[S_{n_2} = 0 | S_{n_1} = 1]$, $\Pr[S_{n_2} = 1 | S_{n_1} = 0]$ и $\Pr[S_{n_2} = 0 | S_{n_1} = 0]$. Из (18) видно, что если $p \neq 1/2$ и $q \neq 1/2$, то $\Pr[S_{n_2} = 1 | S_{n_1} = 1] \neq \Pr[S_{n_2} = 1] = \frac{q}{p+q}$, так что значения случайной функции S_n в различные моменты времени не являются статистически независимыми. Время корреляции, очевидно, дается той же оценкой, что и время релаксации, т.е. $\tau_c \sim \frac{1}{\ln \frac{1}{|1-p-q|}}$. Упражнение: Вычислите парную корреляционную функцию $C(n_1, n_2) = \langle S_{n_1} S_{n_2} \rangle$ для рассмотренного случайного процесса.

Марковские цепи с непрерывным временем

В рассмотренной модели цепи Маркова роль времени выполнял дискретный параметр n - номер наблюдения. Обсудим теперь процесс Маркова с двумя состояниями и непрерывным временем, см. Рис. 1(b). Стохастическая динамика такой цепи по определению подчиняется следующим правилам. Если в момент времени t процесс находится в состоянии 1, то в течении промежутка времени $[t, t+dt]$ с вероятностью λdt он перейдет в состояние 2, а с вероятностью $1 - \lambda dt$ останется в состоянии 1. Если же в момент t процесс находится в состоянии 2, то в течении промежутка времени $[t, t+dt]$ он с вероятностью μdt перейдет в состояние 1, и с вероятностью $1 - \mu dt$ останется в состоянии 2. Марковость процесса означает, что указанные вероятности не зависят от предшествующей истории процесса. С учетом сказанного вероятности $\pi_1(t+dt)$ и $\pi_2(t+dt)$ обнаружить процесс в состояниях 1 и 2 в момент $t+dt$ равны (см. Ур. (6) и (7))

$$\pi_1(t+dt) = (1 - \lambda dt)\pi_1(t) + \mu dt \cdot \pi_2(t)$$

$$\pi_2(t+dt) = \lambda dt \cdot \pi_1(t) + (1 - \mu dt)\pi_2(t)$$

откуда находим систему дифференциальных уравнений

$$\frac{d\pi_1(t)}{dt} = -\lambda\pi_1(t) + \mu\pi_2(t)$$

$$\frac{d\pi_2(t)}{dt} = \lambda\pi_1(t) - \mu\pi_2(t)$$

которую иногда удобно записывать в матричном виде

$$\frac{d\vec{\pi}(t)}{dt} = \hat{Q}\vec{\pi}(t),$$

где $Q_{11} = -Q_{21} = -\lambda$ и $Q_{12} = -Q_{22} = \mu$.

Решение для произвольного начального условия

Решение Ур. (21) и (22) при заданном начальном распределении вероятностей $\pi_1(0)$ и $\pi_2(0)$ может быть построено, к примеру, методом преобразования Лапласа. Умножив обе эти части уравнений на e^{-st} и проинтегрировав их по t от 0 до $+\infty$, получим,

$$\begin{aligned} s\tilde{\pi}_1(s) - \pi_1(0) &= -\lambda\tilde{\pi}_1(s) + \mu\tilde{\pi}_2(s) \\ s\tilde{\pi}_2(s) - \pi_2(0) &= \lambda\tilde{\pi}_1(s) - \mu\tilde{\pi}_2(s) \end{aligned}$$

где $\tilde{\pi}_1(s) = \int_0^{+\infty} dt e^{-st} \pi_1(t)$ и $\tilde{\pi}_2(s) = \int_0^{+\infty} dt e^{-st} \pi_2(t)$. Значит

$$\begin{aligned} \tilde{\pi}_1(s) &= \frac{s + \mu}{s(s + \lambda + \mu)} \pi_1(0) + \frac{\mu}{s(s + \lambda + \mu)} \pi_2(0) \\ \tilde{\pi}_2(s) &= \frac{s + \lambda}{s(s + \lambda + \mu)} \pi_2(0) + \frac{\lambda}{s(s + \lambda + \mu)} \pi_1(0) \end{aligned}$$

Вычисляя обратное преобразование Лапласа, получаем

$$\begin{aligned} \pi_1(t) &= \frac{1}{2\pi i} \int_{\gamma-i\infty}^{\gamma+i\infty} ds e^{st} \tilde{\pi}_1(s) = \frac{\mu}{\lambda + \mu} + \frac{\lambda}{\lambda + \mu} e^{-(\lambda+\mu)t} \pi_1(0) - \frac{\mu}{\lambda + \mu} e^{-(\lambda+\mu)t} \pi_2(0), \\ \pi_2(t) &= \frac{1}{2\pi i} \int_{\gamma-i\infty}^{\gamma+i\infty} ds e^{st} \tilde{\pi}_2(s) = \frac{\lambda}{\lambda + \mu} - \frac{\lambda}{\lambda + \mu} e^{-(\lambda+\mu)t} \pi_1(0) + \frac{\mu}{\lambda + \mu} e^{-(\lambda+\mu)t} \pi_2(0). \end{aligned}$$

Представленный путь вывода, разумеется, не единственный возможный. Заметим, что это решение можно было получить из уравнений (32) и (33), подставив $p = \lambda\Delta t$, $q = \mu\Delta t$ и перейдя к пределу $\Delta t \rightarrow 0$. Кроме того, можно было подставить соотношение $\pi_1(t) = 1 - \pi_2(t)$ в (21) и решить получившееся линейное дифференциальное уравнение первого порядка. Наконец, решение Ур. (23) может быть выписано через матричную экспоненту.

Релаксация к стационарному решению

Из формул (28) и (29) видно, что любое начальное условие экспоненциально быстро релаксирует к стационарному распределению вероятностей

$$\begin{aligned} \lim_{t \rightarrow +\infty} \pi_1(t) &= \bar{\pi}_1^{\text{st}} = \frac{\mu}{\lambda + \mu}, \\ \lim_{t \rightarrow +\infty} \pi_2(t) &= \bar{\pi}_2^{\text{st}} = \frac{\lambda}{\lambda + \mu}, \end{aligned}$$

которое, как легко проверить, является решением уравнения $\hat{Q} \cdot \vec{\pi}^{\text{st}} = 0$. Соответствующее время релаксации оценивается как $(\lambda + \mu)^{-1}$. Этот временной масштаб можно также интерпретировать как время корреляции марковской цепи, то есть время, в течении которого марковский процесс помнит свое исходное состояние.

О моделях социальных сервисов (??)

(типичные задачи на это даются, чуть что буду разбирать эту теорию.)

ВШЭ $M/M/\infty$ парковка

(мб в каталог перенесу потом)

Покажем, как происходит конструирование математической модели системы массового обслуживания на следующем простом примере. Предположим, что перед нами стоит задача обустроить автомобильную стоянку для посетителей нового торгового комплекса. На основании статистических данных мы можем оценить число посетителей, которые будут ежедневно приезжать в торговый комплекс на личных автомобилях, а также среднюю продолжительность визита типичного посетителя. Насколько большой следует сделать стоянку, чтобы быть уверенным, что большинству посетителей хватит парковочных мест?

Для ответа на этот вопрос поступим следующим образом. Оценим статистически-стационарное распределение вероятностей π_n^{st} обнаружить на стоянке ровно n автомобилей, которое имело бы место в том случае, если бы стоянка была неограниченно большой. Тогда для обеспечения большинства посетителей возможностью припарковать свой автомобиль число мест N на проектируемой нами стоянке должно быть таким, чтобы в рамках используемой вероятностной модели выполнялось условие $\Pr[n > N] \ll 1$. Вероятностное распределение π_n^{st} числа занятых парковочных мест может быть вычислено аналитически, если сделать два предположения: (1) автомобили прибывают на стоянку независимо друг от друга в случайные моменты времени со средней частотой λ , (2) каждый автовладелец оставляет свой автомобиль на случайное время, имеющее экспоненциальную функцию плотности вероятности с параметром μ . Значения λ и μ на практике должны оцениваться исходя из статистических данных. Отметим, что указанная модель в англоязычной литературе часто обозначается как $M/M/\infty$, где первая M (от англ. memoryless) обозначает пуассоновскую статистику событий поступления новых клиентов, вторая M обозначает экспоненциальность статистики времени, затрачиваемого на обслуживание одного клиента, и, наконец, знак ∞ соответствует предположению о бесконечно большом числе каналов обслуживания (т.е. парковочных мест в контексте обсуждаемой задачи).

Итак, состояние стоянки в произвольный момент времени t характеризуется числом занятых парковочных мест n . С учетом сделанных предположений, стохастические переходы между этими состояниями описываются марковской цепью, изображенной на Рис. (2). А значит эволюция распределения вероятностей $\pi_n(t)$ подчиняется следующей системе дифференциальных уравнений первого порядка

$$\begin{aligned}\frac{d\pi_0(t)}{dt} &= -\lambda\pi_0(t) + \mu\pi_1(t) \\ \frac{d\pi_n(t)}{dt} &= \lambda\pi_{n-1}(t) - (\lambda + n\mu)\pi_n(t) + (n+1)\mu\pi_{n+1}(t), \quad \text{при } n \geq 1,\end{aligned}$$

Занулив левые части этих уравнений, получим, что стационарные вероятности удовлетворяют соотношению $\pi_n^{\text{st}} = \frac{1}{n!} \left(\frac{\lambda}{\mu}\right)^n \pi_0^{\text{st}}$. Определяя π_0^{st} из условия нормировки $\sum_{n=0}^{+\infty} \pi_n^{\text{st}} = 1$, находим, что искомое стационарное решение дается распределением Пуассона

$$\pi_n^{\text{st}} = \frac{1}{n!} \left(\frac{\lambda}{\mu}\right)^n \exp\left(-\frac{\lambda}{\mu}\right)$$

Математическое ожидание и дисперсия числа автомобилей на стоянке в рамках рассматриваемой модели равны $\langle n \rangle = \frac{\lambda}{\mu}$ и $\sigma_n^2 = \frac{\lambda}{\mu}$, соответственно. Легко видеть, что $\sigma_n \ll \langle n \rangle$ при $\langle n \rangle \gg 1$. Благодаря быстрому затуханию π_n^{st} при неограниченном

возрастании n , можно ожидать, что если на практике N значительно превосходит безразмерное отношение $\frac{\lambda}{\mu}$, то ситуации, когда для очередного посетителя не найдется свободного места на стоянке, будут относительно редки.

ВШЭ M/M/1 Банкомат

Предположим, что клиенты приходят к банкомату независимо друг от друга со средней частотой λ и каждый клиент, дождавшись своей очереди, тратит на проведение банковских операций случайное время, имеющее экспоненциальную функцию плотности вероятности с параметром μ . Какова статистически-стационарная функция распределения π_n^{st} числа клиентов возле банкомата?

Как и в предыдущей задаче, будем характеризовать состояние системы количеством клиентов, в находящихся в ней данный момент. Стохастическая динамика переходов между состояниями представляет собой случайный процесс Маркова, см. Рис. (3). Соответствующая система уравнений на эволюцию распределения вероятностей нахождения системы в различных состояниях выглядит следующим образом

$$\begin{aligned}\frac{d\pi_0(t)}{dt} &= -\lambda\pi_0(t) + \mu\pi_1(t) \\ \frac{d\pi_n(t)}{dt} &= \lambda\pi_{n-1}(t) - (\lambda + \mu)\pi_n(t) + \mu\pi_{n+1}(t), \quad \text{при } n \geq 1.\end{aligned}$$

Отсюда видно, что для стационарных вероятностей имеет место соотношение $\pi_n^{\text{st}} = \left(\frac{\lambda}{\mu}\right)^n \pi_0^{\text{st}}$. С учетом условия нормировки это означает, что стационарное решение дается следующим распределением

$$\pi_n^{\text{st}} = \left(1 - \frac{\lambda}{\mu}\right) \left(\frac{\lambda}{\mu}\right)^n.$$

Отметим, что такое решение существует только, если $\mu > \lambda$. В противном случае среднее время, затрачиваемое на обслуживание одного клиента, превосходит средний интервал времени между прибытием новых клиентов, так что длина очереди неограниченно возрастает с течением времени. Последнее отражается также в том, что среднее число клиентов в системе, $\langle n \rangle = \frac{\lambda}{\mu - \lambda}$, диктуемое распределением (53), становится бесконечно большим при стремлении μ к λ сверху.

Обозначим как T время, которое клиент, пришедший к банкомату в случайный момент времени, потратит на то, чтобы отстоять в очереди и получить услугу. Очевидна, эта случайная величина может быть записана как $T = \sum_{i=0}^n \tau_i$, где n - число человек, обнаруженное возле банкомата новым клиентом, τ_i - время, которое потратит на работу с банкоматом i -й человек в очереди. Так слагаемые в указанной сумме статистически независимы и одинаково распределены с экспоненциальной плотностью вероятности $\mu e^{-\mu\tau}$, то условная плотность вероятности $\rho(T|n)$ дается распределением Эрланга следующего вида

$$\rho(T|n) = \frac{\mu^{n+1} T^n}{n!} e^{-\mu T}$$

Тогда согласно формуле полной вероятности, функция распределения случайного времени T равна

$$\begin{aligned}P(T) &= \sum_{n=0}^{+\infty} \rho(T|n) \pi_n^{\text{st}} = e^{-\mu T} \left(1 - \frac{\lambda}{\mu}\right) \sum_{n=0}^{+\infty} \frac{\mu^{n+1} T^n}{n!} \left(\frac{\lambda}{\mu}\right)^n = \\ &= e^{-\mu T} (\mu - \lambda) \sum_{n=0}^{+\infty} \frac{(\lambda T)^n}{n!} = (\mu - \lambda) e^{-(\mu - \lambda)T}.\end{aligned}$$

Среднее время, которое клиент проведет в системе:

$$\langle T \rangle = \frac{1}{\mu - \lambda}$$

Последний ответ также можно было получить посредством формулы $\langle T \rangle = (\langle n \rangle + 1) \langle \tau \rangle$.

ВШЭ $M/M/N$

Наконец, рассмотрим модель $M/M/N$, характеризуемую произвольным количеством N каналов обслуживания. Предположим, в магазине работают N касс самообслуживания. Каждый покупатель занимает кассу на случайный промежуток времени, имеющий экспоненциальное распределение с параметром μ . Покупатели подходят к кассам в пуассоновские моменты времени со средней частотой λ , выстраиваясь в случае необходимости в единую очередь. Очередной покупатель проходит на ту кассу, которая освобождается первой, либо на любую из свободных, если таковых в момент его прихода несколько. Обозначим через n полное число покупателей в зоне оплаты покупок, включая и тех кто уже стоит на кассе, и тех, кто только ожидает своей очереди. Каково стационарное вероятностное распределение π_n^{st} ? Эволюция распределения вероятностей нахождения системы в состояниях, характеризуемых различным числом покупателей n , описывается следующей системой уравнений

$$\begin{aligned} \frac{d\pi_0(t)}{dt} &= -\lambda\pi_0(t) + \mu\pi_1(t) \\ \frac{d\pi_n(t)}{dt} &= \lambda\pi_{n-1}(t) - (\lambda + n\mu)\pi_n(t) + (n+1)\mu\pi_{n+1}(t), \quad \text{при } 1 \leq n \leq N-1, \\ \frac{d\pi_n(t)}{dt} &= \lambda\pi_{n-1}(t) - (\lambda + N\mu)\pi_n(t) + N\mu\pi_{n+1}(t), \quad \text{при } n \geq N. \end{aligned}$$

Занулив левые части этих уравнений, находим стационарное решение

$$\pi_n^{\text{st}} = \begin{cases} \frac{1}{n!} \left(\frac{\lambda}{\mu}\right)^n \pi_0^{\text{st}}, & \text{при } 0 \leq n \leq N-1 \\ \frac{1}{N!N^{n-N}} \left(\frac{\lambda}{\mu}\right)^n, & \text{при } n \geq N \end{cases}$$

где $\pi_0^{\text{st}} = \left(\frac{1}{N!} \left(\frac{\lambda}{\mu}\right)^N \frac{N\mu}{N\mu - \lambda} + \sum_{n=0}^{N-1} \frac{1}{n!} \left(\frac{\lambda}{\mu}\right)^n \right)^{-1}$ в силу условия нормировки. Легко видеть, что полученное решение переходит в распределения (50) и (53) в случаях $N \rightarrow +\infty$ и $N = 1$, соответственно.

11.3.2 Branching Processes

описание модели

Описание модели.

Первоначально задача формулировалась следующим образом.

Пусть $p_0, p_1, p_2, \dots$ - вероятности того, что отец имеет соответственно 0, 1, 2, ... сыновей, каждый из которых с теми же вероятностями может иметь своих сыновей и т.

д.

Какова вероятность, что мужская линия выродится к n -ому поколению?

В общем случае можно рассматривать однотипные частицы, под которыми могут пониматься люди, животные, бактерии или нейтроны в цепных реакциях.

Вероятности $p_k, k = 0, 1, \dots$, будут связываться с событиями, что одна частица в следующем поколении превращается в k частиц.

Будем считать, что частицы размножаются независимо друг от друга и для каждой из них вероятности $p_k, k = 0, 1, \dots$, одни и те же.

Обозначим через $\xi_0, \xi_1, \xi_2, \dots$ число частиц в нулевом, первом, втором, .

поколениях соответственно.

Другими словами, ξ_n - объем популяции в n -ом поколении.

Будем считать (без особого ограничения общности), что $\xi_0 = 1$, т.

е.

начальное поколение состоит из одной частицы.

Объем последующих поколений $\xi_1, \xi_2, \dots$ будет случайным.

Заметим, что при сделанных предположениях $\{p_0, p_1, \dots\}$ будет распределением вероятностей случайной величины ξ_1 , т.

е.

$P(\xi_1 = k) = p_k, k = 0, 1, \dots$

классификация

Поскольку частицы размножаются независимо друг от друга и число потомков каждой из них имеет одно и то же распределение вероятностей, то распределение случайной величины ξ_n должно определяться из начальных условий.

Важной характеристикой ветвящегося процесса является среднее число непосредственных потомков одной частицы $E\xi_1 = \sum_{k=0}^{\infty} kp_k = m$. В зависимости от значения этой величины ветвящийся процесс называется:

докритическим, если $m < 1$; критическим, если $m = 1$;

- надкритическим, если $m > 1$ (или $m = \infty$).

Через σ^2 будем также обозначать дисперсию $D\xi_1$. Пусть A - событие, которое состоит в том, что процесс $\xi_0 = 1, \xi_1, \xi_2, \dots$ в конце концов вырождается.

Его вероятность $q = P(A)$ будем называть вероятностью вырождения процесса.

Ближайшей нашей целью будет найти зависимость q от начальных данных.

Производящая функция процесса.

Поскольку $\xi_1, \xi_2, \dots$ являются целочисленными случайными величинами, то их распределения вероятностей естественно представлять производящими функциями.

В частности, обозначим

$$f(x) = g_{\xi_1}(x) = \sum_{k=0}^{\infty} p_k x^k$$

и будем называть f производящей функцией процесса.

Для отыскания производящих функций $g_{\xi_n}, n = 2, 3, \dots$, нам потребуется следующий результат.

Теорема

12.1.

Пусть $\eta_1, \eta_2, \dots$ - независимые одинаково распределенные зависимость от них целочисленная случайная величина с производящей функцией $S_\nu = \eta_1 + \dots + \eta_\nu (S_0 = 0)$ определяется равенством

$$g_{S_\nu}(x) = g_\nu \circ g_\eta(x)$$

ДоКАЗАТЕЛЬСТВО.

Непосредственно из определения производящей функции с использованием свойств математического ожидания получаем

$$\begin{aligned} g_{S_\nu}(x) &= E x^{S_\nu} = \sum_{k=0}^{\infty} E (x^{S_\nu} 1_{\{\nu=k\}}) \\ &= \sum_{k=0}^{\infty} E (x^{\eta_1 + \dots + \eta_k} 1_{\{\nu=k\}}) \\ &= \sum_{k=0}^{\infty} (g_\eta(x))^k P(\nu = k) = g_\nu(g_\eta(x)) \end{aligned}$$

ТЕОРЕМА 12.2.

Пусть $\xi_0 = 1, \xi_1, \xi_2, \dots$ — ветвящийся процесс Гальтона-Ватсона с производящей функцией $g_{\xi_1}(x) = f(x)$. Тогда производящая функция $g_{\xi_n}(x)$ представляет собой n -ую итерацию f^n функции f , т.

е.

$$g_{\xi_n}(x) = f^n(x) = f \circ \dots \circ f(x)$$

ДоКАЗАТЕЛЬСТВО.

Представим n -ое поколение частиц в виде $\xi_n = \eta_1 + \dots + \eta_{\xi_{n-1}}$, где η_1 — число потомков от первой частицы, η_2 — от второй, ..., $\eta_{\xi_{n-1}}$ от последней из $(n-1)$ -го поколения.

Тогда по предыдущей теореме

$$g_{\xi_n}(x) = g_{\xi_{n-1}} \circ g_\eta(x) = g_{\xi_{n-1}} \circ f(x)$$

По индукции получаем требуемый результат.

Вероятность вырождения.

Пусть A_n — событие, которое заключается в том, что n -ое поколение отсутствует, т.

е.

$A_n = \{\xi_n = 0\}$. Тогда $A_n \nearrow A = \bigcup_{n=1}^{\infty} A_n$. Поэтому в силу непрерывности вероятностной меры

$$q = P(A) = \lim_{n \rightarrow \infty} P(A_n)$$

Теорема

12.3.

Вероятность q вырождения процесса Гальтона-Ватсона с производящей функцией $f(x)$ определяется равенством

$$q = \lim_{b \rightarrow \infty} f^n(0)$$

и является наименьшим неотрицательным корнем уравнения

$$f(x) = x$$

ДоКАЗАТЕЛЬСТВО.

Поскольку $P(\xi_n = 0) = f^n(0)$, то $f^n(0) \nearrow q$. Осуществляя предельный переход при $n \rightarrow \infty$ в равенстве

$$f(f^n(0)) = f^{n+1}(0)$$

получаем $f(q) = q$, т. е. q — корень уравнения $f(x) = x$. Остается показать, что q — наименьший неотрицательный корень уравнения $f(x) = x$. Допустим противное, т.е.

$f(\alpha) = \alpha$ и $0 \leq \alpha < q$. Тогда в силу монотонности функции f будем иметь

$$f(0) \leq f(\alpha) = \alpha < q = f(q)$$

Снова, используя монотонность функции f , получаем

$$f^2(0) \leq \alpha < q$$

Повторение этого процесса приводит к неравенствам

$$f^n(0) \leq \alpha < q, \quad n = 2, 3, \dots$$

Но тогда

$$\lim_{n \rightarrow \infty} f^n(0) \leq \alpha$$

что противоречит определению q .

процесс Гальтона-Ватсона критический или докритический, то $q = 1$

Теорема

12.4.

Если процесс Гальтона-Ватсона критический или докритический, то $q = 1$.

В случае надкритического процесса $0 \leq q < 1$.

ДоКАЗАТЕЛЬСТВО.

Допустим, что $m = f'(1) \leq 1$. Если процесс невырожденный, то $f'(x) < 1$ при $0 \leq x < 1$. Фиксируем произвольно $x_0 \in [0, 1)$. По теореме о среднем найдется такое $x^* \in (x_0, 1)$, что

$$1 - f(x_0) = f'(x^*)(1 - x_0)$$

Но тогда

$$1 - f(x_0) < 1 - x_0$$

и $f(x_0) > x_0$. Т.

о.

в интервале $[0, 1)$ корней уравнение $f(x) = x$ не имеет.

Если $m = f'(1) > 1$, то найдется такое $x_0 \in (0, 1)$, что $f'(x_0) > 1$. Используя теорему о среднем, получаем

$$1 - f(x_0) > 1 - x_0$$

т.

е.

$f(x_0) - x_0 < 0$. Если $f(0) = 0$, то $q = 0$. В противном случае $f(0) > 0$ и функция $\varphi(x) = f(x) - x$ принимает на концах промежутка $[0, x_0]$ значения разных знаков.

Следовательно, в этом промежутке найдется решение уравнения $f(x) = x$

11.4 Typical Applied Probabilistic Models (!!)

(тут как раз уже такие модели, которые нужны в жизни хотя бы где-то!!)

11.4.1 Particle Walking Models

(написано в разделе про случайпроцы, тут лишь готовые методы с минимумом пояснений)

11.4.2 Fokker-planck Equation

первая тут идея - что нужно перейти к пропагатору, то есть к интегралу от вероятности в прошлом. !!! здесь необходима связка с условной вероятностью, что-то я совсем там не помню никаких таких формул.

12 Mathematical Statistics: Basics

12.1 Fundamentals of Mathematical Statistics in a Nutshell

(сперва пропишу это в части про мат статистику, потом сюда суть переносить буду. пока не до неё, так что позже займусь.)

12.1.1 Some Inequalities in Mathematical Statistics

(просто помню, что их прямо много)

12.1.2 Central Limit Theorem

(хз, чего она именно в мат статистике, но ладно)

Простейший вариант ЦПТ

(из избранных пишу)

Суть ЦПТ (???)

Представим что у нас есть N независимых случайных величин $\xi_1 \dots \xi_N$ с нулевым средним и не сильно разными дисперсиями. Поищем характеристики случайной величины $\xi = \frac{1}{N} \sum_k \xi_k$.

Вычислим её производящую функцию:

$$f(p) = \left\langle e^{-ip \frac{1}{N} \sum_i \xi_i} \right\rangle = \prod_i \left\langle e^{-ip \frac{1}{N} \xi_i} \right\rangle$$

$$f(p) = \prod_i e^{-\frac{\sigma_i^2 p^2}{2N^2}} = e^{-\frac{p^2}{2N^2} \sum_i \sigma_i^2}$$

$$\rho(\xi) = \frac{\sqrt{N}}{\sigma \sqrt{2\pi}} e^{-N \frac{\xi^2}{2\sigma^2}}$$

Получили распределение Гаусса. Видим, что типичное отклонение ξ меньше чем средне-квадратичное отклонение случайных величин в $\sqrt{N}$ раз.

Проверим что наше предположение о малости - верное. При интегрировании $\sqrt{N}$ тогда условие малости верно если $\xi \propto \sqrt{N}$.

Кажется что можно использовать условие $\xi \propto \sqrt{N}$ тогда условие малости переходит в условие $\sqrt{N}$ которое выполнено. В задаче с идеальным газом ξ_i Чтобы перейти к распределению Гаусса нам потребовалось не просто условие как так-то?

Центральная предельная теорема, как следует из её названия, очень важна. Во-первых, Она позволяет понять как ведёт себя случайная величина которая зависит от многих параметров. Хорошим примером такой величины является случайная ошибка в эксперименте. ЦПТ позволяет понять что ошибка распределена Гауссовым образом и зависит всего от одного параметра. Во-вторых,

ЦПТ говорит о том как улучшается ваш результат при повторении измерений.

строгая формулировка и доказательство Цпт

(зубков)

Ранее

Теорема

Муавра-Лапласа о сходимости распределения централизованного и нормированного числа успехов в n независимых испытаниях Бернулли к нормальному распределению была доказана с помощью довольно громоздких вычислений, а результат относился к узкому классу случаев.

С помощью характеристических функций легко доказывать значительно более общие утверждения.

Теорема. (зачем она?)

Если случайные величины $\xi_1, \xi_2, \dots$ независимы, одинаково распределены, $\mathbf{M}\xi_1 = a$, $\mathbf{D}\xi_1 = \sigma^2 \in (0, \infty)$, то

$$\lim_{n \rightarrow \infty} \mathbf{P} \left\{ \frac{\xi_1 + \dots + \xi_n - na}{\sigma\sqrt{n}} \leq x \right\} = \Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-u^2/2} du$$

Доказательство.

Согласно теореме о непрерывности соответствия между функциями распределения и характеристическими функциями, достаточно показать, что характеристические функции $f_n(t) = \mathbf{M}e^{it\zeta_n}$ случайных величин

$$\zeta_n = \frac{\xi_1 + \dots + \xi_n - na}{\sigma\sqrt{n}}$$

при $n \rightarrow \infty$ для каждого $t \in \mathbb{R}$ сходятся к характеристической функции стандартного нормального распределения, равной $\exp\{-t^2/2\}$.

Очевидно,

$$\zeta_n = \frac{\xi_1 + \dots + \xi_1 - na}{\sigma\sqrt{n}} = \frac{1}{\sqrt{n}} \sum_{k=1}^n \frac{\xi_k - a}{\sigma}$$

слагаемые в сумме в правой части независимы и имеют такое же распределение, как ζ_1 .

Поэтому

$$\mathbf{M} \exp \left\{ it \sum_{k=1}^n (\xi_k - a) \right\} = (\mathbf{M} \exp \{ it (\xi_1 - a) \})^n = f_1^n(t).$$

Так как $\mathbf{M} \frac{\xi_1 - a}{\sigma} = 0$ и $\mathbf{D} \frac{\xi_1 - a}{\sigma} = \frac{1}{\sigma^2} \mathbf{D}\xi_1 = 1$, то по свойству 6 характеристических функций

$$f_1(t) = \mathbf{M} \exp \left\{ it \frac{\xi_1 - a}{\sigma} \right\} = 1 - \frac{t^2}{2} + o(t^2), \quad t \rightarrow 0$$

Следовательно, при любом фиксированном $t \in \mathbb{R}$ и $n \rightarrow \infty$

$$\begin{aligned} \mathbf{M} \exp \{ it \zeta_n \} &= \mathbf{M} \exp \left\{ \frac{it}{\sigma\sqrt{n}} \sum_{k=1}^n (\xi_k - a) \right\} = f_1^n \left(\frac{t}{\sqrt{n}} \right) = \\ &= \left(1 - \frac{1}{2} \left(\frac{t}{\sqrt{n}} \right)^2 + o \left(\frac{t^2}{n} \right) \right)^n = \left(1 - \frac{t^2}{2n} + o \left(\frac{t^2}{2n} \right) \right)^n \rightarrow e^{-t^2/2} \end{aligned}$$

Тем самым Теорема доказана.

(и что с этого? кст, суть не понял)

Теорема Ляпунова (????)

Метод характеристических функций позволяет доказывать предельные теоремы и в более общих ситуациях.

В качестве примера рассмотрим теорему Ляпунова.

Теорема Ляпунова.

Пусть при каждом $n = 1, 2, \dots$ случайные величины $\xi_{n,1}, \dots, \xi_{n,n}$ независимы

$$\mathbf{M}\xi_{n,k} = a_{n,k}, \quad \mathbf{D}\xi_{n,k} = \sigma_{n,k}^2, \quad \mathbf{M}|\xi_{n,k} - a_{n,k}|^3 = c_{n,k}^3, \quad n, k = 1, 2, \dots$$

и $S_n = \xi_{n,1} + \dots + \xi_{n,n}$. Если

$$A_n = \sum_{k=1}^n a_{n,k}, \quad B_n^2 = \sum_{k=1}^n \sigma_{n,k}^2, \quad C_n^3 = \sum_{k=1}^n c_{n,k}^3$$

и распределения слагаемых изменяются так, что $\frac{C_n}{B_n} \rightarrow 0, n \rightarrow \infty$, то

$$\lim_{n \rightarrow \infty} \mathbf{P} \left\{ \frac{S_n - A_n}{B_n} \leq x \right\} = \Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-u^2/2} du$$

Доказательство.

Достаточно доказать, что характеристические функции случайных величин $\frac{1}{B_n}(S_n - A_n)$ в каждой точке сходятся к характеристической функции стандартного нормального распределения, равной $\exp\{-t^2/2\}$.

Аналогично случаю, когда слагаемые одинаково распределены, представим характеристическую функцию в виде произведения характеристических функций центрированных и нормированных слагаемых и используем разложения характеристических функций с явной оценкой остаточного члена:

при любом $t \in \mathbb{R}$

$$\begin{aligned} \mathbf{M} \exp \left\{ it \frac{S_n - A_n}{B_n} \right\} &= \mathbf{M} \exp \left\{ it \sum_{k=1}^n \frac{\xi_{n,k} - a_{n,k}}{B_n} \right\} = \\ &= \prod_{k=1}^n \mathbf{M} \exp \left\{ it \frac{\xi_{n,k} - a_{n,k}}{B_n} \right\} = \prod_{k=1}^n \left(1 - \frac{t^2}{2B_n^2} \sigma_{n,k}^2 + \theta_{n,k} \frac{t^3}{B_n^3} c_{n,k}^3 \right) \end{aligned}$$

где $|\theta_{n,k}| \leq \frac{1}{6}$, $k = 1, \dots, n$. Согласно неравенству Ляпунова

$$\sigma_{n,k} = \sqrt{\mathbf{M}(\xi_{n,k} - a_{n,k})^2} \leq (\mathbf{M}|\xi_{n,k} - a_{n,k}|^3)^{1/3} = c_{n,k}, \quad k = 1, \dots, n$$

По условию $\frac{C_n}{B_n} \rightarrow 0$ при $n \rightarrow \infty$, значит,

$$\max_{1 \leq k \leq n} \frac{c_{n,k}^3}{B_n^3} \leq \left(\frac{C_n}{B_n} \right)^3 \rightarrow 0, \quad \text{т. е.} \quad \max_{1 \leq k \leq n} \frac{c_{n,k}}{B_n} \rightarrow 0$$

Следовательно,

$$\max_{1 \leq k \leq n} \frac{\sigma_{n,k}}{B_n} \leq \max_{1 \leq k \leq n} \frac{c_{n,k}}{B_n} \rightarrow 0$$

Таким образом, для каждого фиксированного $t \in \mathbb{R}$

$$\max_{1 \leq k \leq n} \left(\frac{t^2}{2B_n^2} \sigma_{n,k}^2 + \theta_{n,k} \frac{t^3}{B_n^3} c_{n,k}^3 \right) \rightarrow 0 \quad \text{при } n \rightarrow \infty$$

и поэтому при $n \rightarrow \infty$ и $k = 1, \dots, n$

$$\ln \left(1 - \frac{t^2}{2B_n^2} \sigma_{n,k}^2 + \theta_{n,k} \frac{t^3}{B_n^3} c_{n,k}^3 \right) = \left(-\frac{t^2}{2B_n^2} \sigma_{n,k}^2 + \theta_{n,k} \frac{t^3}{B_n^3} c_{n,k}^3 \right) (1 + o(1))$$

где в силу (47) остаточные члены стремятся к 0 при $n \rightarrow \infty$ равномерно по $k \in \{1, \dots, n\}$.

Отсюда следует, что для любого $t \in \mathbb{R}$ при некоторых $\theta = \theta(n, t) \in \left[-\frac{1}{6}, \frac{1}{6}\right]$

$$\begin{aligned} \ln \mathbf{M} \exp \left\{ it \frac{\xi_{n,1} + \dots + \xi_{n,n} - A_n}{B_n} \right\} &= \sum_{k=1}^n \ln \left(1 - \frac{t^2}{2B_n^2} \sigma_{n,k}^2 + \theta_{n,k} \frac{t^3}{B_n^3} c_{n,k}^3 \right) = \\ &= (1 + o(1)) \sum_{k=1}^n \left(-\frac{t^2}{2B_n^2} \sigma_{n,k}^2 + \theta_{n,k} \frac{t^3}{B_n^3} c_{n,k}^3 \right) = \\ &= (1 + o(1)) \left(-t^2 \frac{B_n^2}{2B_n^2} + \theta t^3 \frac{C_n^3}{B_n^3} \right) = -\frac{t^2}{2} (1 + o(1)) \end{aligned}$$

Теорема доказана.

(?? и зачем она??)

применения

12.1.3 Characteristic Functions (?!!!!!)

(чего раньше я не вынесу эту часть?!!!!! почему это мат статика? вынесу скорее всего скоро.)

(тут подробная теория. чет её прямо дохрена. чего кст раньше об этом ничего не было?)

Конструкция характеристической функции

Основные формулы характеристической функции (?)

(пока хз)

Теория

Распространим понятие математического ожидания на комплекснозначные случайные величины. Для комплексной случайной величины $\zeta = \xi + i\eta$, где $\xi = \operatorname{Re} \zeta$ и $\eta = \operatorname{Im} \zeta$ - случайные величины с действительными значениями, причем существуют и конечны $\mathbf{M} \xi$ и $\mathbf{M} \eta$. Тогда по определению полагают

$$\mathbf{M} \zeta = \mathbf{M} \xi + i \mathbf{M} \eta$$

Таким образом, $\operatorname{Re} \mathbf{M} \zeta = \mathbf{M} \operatorname{Re} \zeta$, $\operatorname{Im} \mathbf{M} \zeta = \mathbf{M} \operatorname{Im} \zeta$

Основные свойства математического ожидания (аддитивность, мультипликативность для произведения независимых случайных величин) переносятся на математические ожидания комплекснозначных случайных величин.

Лемма

Если существует математическое ожидание комплекснозначной случайной величины ζ , то

$$|\mathbf{M} \zeta| \leq \mathbf{M} |\zeta|$$

Рассмотрим функцию $m(x + iy) = |x + iy|$, $x, y \in R$, как функцию от двух действительных переменных x и y .

Графиком функции $m(x, y)$ является конус $z = (x^2 + y^2)^{1/2}$.

Для любой точки $(a, b) \in R^2$, плоскость

$$z = z(x, y) = \frac{xa + yb}{(a^2 + b^2)^{1/2}}$$

касается конуса по лучу $(ta, tb, t(a^2 + b^2)^{1/2})$, $t \geq 0$, а для остальных точек плоскости лежит строго ниже конуса, т.е.

$$z(x, y) \leq m(x + iy) \text{ для всех } x, y \in R$$

Пусть теперь ζ - комплекснозначная случайная величина и $M\zeta = a + ib$. Тогда

$$\begin{aligned} M|\zeta| &= Mm(\zeta) \geq Mz(\operatorname{Re} \zeta, \operatorname{Im} \zeta) = \frac{M(a \operatorname{Re} \zeta + ib \operatorname{Im} \zeta)}{(a^2 + b^2)^{1/2}} = \\ &= (a^2 + b^2)^{1/2} = |a + ib| = |M\zeta| \end{aligned}$$

Определение характеристической функции

(зубков)

Характеристической функцией случайной величины ξ , принимающей действительные значения, называется функция

$$f(t) = M \exp\{it\xi\}, \quad -\infty < t < \infty$$

Основные свойства характеристической функции (?)

(!! надо бы посмотреть это!!)

Перечислим несколько простых свойств характеристических функций.

1. $|f(t)| \leq 1$ при всех $t \in R$, $f(0) = 1$

Первое неравенство - простое следствие леммы, так как $|\exp\{it\xi\}| = 1$ и $|f(t)| = M \exp\{it\xi\} \leq M|\exp\{it\xi\}| = 1$. Второе равенство очевидно.

2. Если $\eta = a\xi + b$, где a, b - константы, то

$$f_\eta(t) = e^{itb} f_\xi(at)$$

Действительно,

$$f_\eta(t) = M \exp\{it\eta\} = M \exp\{it(a\xi + b)\} = e^{itb} M \exp\{ita\xi\} = e^{itb} f_\xi(at)$$

3. $f_\gamma(-t) = \overline{f_\gamma(t)}$, где черта - знак комплексного сопряжения.

Действительно: $f_\gamma(-t) = M \exp\{i(-t)\gamma\} = M \exp\{-it\gamma\} = M \exp\{it\gamma\} = \overline{M \exp\{it\gamma\}} = \overline{f_\gamma(t)}$

Следствие.

Если распределение случайной величины γ симметрично, т.е. γ и $-\gamma$ одинаково распределены, то

$$f_\gamma(t) = M \exp\{it\gamma\} = M \exp\{-it\gamma\} = f_\gamma(-t) = \overline{f_\gamma(t)}$$

т. е. характеристическая функция случайной величины с симметричным распределением принимает только действительные значения.

4. Если случайные величины $\gamma_1, \dots, \gamma_n$ независимы, то

$$f_{\gamma_1 + \dots + \gamma_n}(t) = \prod_{k=1}^n f_{\gamma_k}(t)$$

Так как $\gamma_1, \dots, \gamma_n$ независимы, то случайные величины $\exp\{it\gamma_1\}, \dots, \exp\{it\gamma_n\}$ тоже независимы, и поэтому

$$\begin{aligned} f_{\gamma_1 + \dots + \gamma_n}(t) &= \mathbf{M} \exp\{it(\gamma_1 + \dots + \gamma_n)\} = \mathbf{M} \prod_{k=1}^n \exp\{it\gamma_k\} = \\ &= \prod_{k=1}^n \mathbf{M} \exp\{it\gamma_k\} = \prod_{k=1}^n f_{\gamma_k}(t) \end{aligned}$$

свойства характеристических функций

(горяинов)

1°. $|h_{\xi}(t)| \leq 1$ и $h_{\xi}(0) = 1$

2°. $h_{\xi}(-t) = \overline{h_{\xi}(t)}$

3°. $h_{a\xi+b}(t) = e^{itb} h_{\xi}(at)$, $a, b \in \mathbb{R}$

4°. Если $\xi_1, \dots, \xi_n$ - независимые случайные величины и $S_n = \xi_1 + \dots + \xi_n$ то $h_{S_n}(t) = \prod_{k=1}^n h_{\xi_k}(t)$

5°. Функция $h_{\xi}(t)$ равномерно непрерывна на $\mathbb{R}$ и если $\mathbf{M}|\xi|^n < \infty$, то $h_{\xi}(t)$ имеет производные до n -го порядка включительно и

$$\mathbf{M}\xi^n = \frac{1}{i^n} h_{\xi}^{(n)}(0)$$

Свойства 1° – 4° следуют непосредственно из определения характеристической функции и свойств математического ожидания.

Доказательство последнего свойства опирается на теорему Лебега о предельном переходе под знаком интеграла.

Теорема

(Бохнера)

Для того, чтобы непрерывная на $\mathbb{R}$ функция $h(t)$ была характеристической функцией некоторого распределения, необходимо и достаточно, чтобы она была положительно определенной, т. е. для любых $t_1, \dots, t_n$ из $\mathbb{R}$ и $z_1, \dots, z_n$ из $\mathbb{C}$, $n = 1, 2, \dots$, выполнялось условие

$$\sum_{k,l=1}^n h(t_k - t_l) z_k \bar{z}_l \geq 0$$

Доказательство

Необходимость условия следует из простых преобразований.

$$\begin{aligned} \sum_{k,l} h_{\xi}(t_k - t_l) z_k \bar{z}_l &= \mathbf{M} \left(\sum_{k,l} z_k \bar{z}_l e^{i(t_k - t_l)\xi} \right) \\ &= \mathbf{M} \left(\sum_k z_k e^{it_k \xi} \right) \overline{\left(\sum_l z_l e^{it_l \xi} \right)} \\ &= \mathbf{M} \left| \sum_k z_k e^{it_k \xi} \right|^2 \geq 0 \end{aligned}$$

Доказательство достаточности условия теоремы выходит за рамки данного курса.

Характеристические функции для простейших распределений

а) пусть имеет симметричное двухточечное распределение:

$\mathbf{P}\{\xi = a\} = \mathbf{P}\{\xi = -a\} = \frac{1}{2}$. Тогда

$$\mathbf{M} \exp\{it\xi\} = \mathbf{P}\{\xi = a\}e^{ita} + \mathbf{P}\{\xi = -a\}e^{-ita} = \frac{(e^{ita} + e^{-ita})}{2} = \cos(at)$$

б) Пусть ξ имеет равномерное распределение на $[-a, a]$:

$$p_{\xi}(x) = \frac{1}{2a} \text{ при } x \in [-a, a] \text{ и } p_{\xi}(x) = 0 \text{ при } |x| > a$$

Тогда

$$\begin{aligned} \mathbf{M} e^{it\xi} &= \int_{-a}^a e^{itx} \frac{1}{2a} dx = \frac{1}{2a} \int_{-a}^a (\cos(tx) + i \sin(tx)) dx = \\ &= \frac{1}{2a} t (\sin(tx) - i \cos(tx)) \Big|_{-a}^a = \frac{\sin(at)}{at} \end{aligned}$$

в) Пусть ξ имеет стандартное нормальное распределение с плотностью $\varphi(x) = \frac{1}{\sqrt{2\pi}} \left(\frac{-x^2}{2} \right)$. Так как плотность $\varphi(x)$ - четная функция, то

$$\begin{aligned} f(t) &= \mathbf{M} \exp\{it\xi\} = \int_R e^{itx} \varphi(x) dx = \\ &= \int_R (\cos(tx) + i \sin(tx)) \varphi(x) dx = \int_R \varphi(x) \cos(tx) dx \end{aligned}$$

Составим уравнение для производной $f(t)$

$$\begin{aligned} f'(t) &= \frac{d}{dt} \int_R \varphi(x) \cos(tx) dx = -\frac{1}{\sqrt{2\pi}} \int_R x \sin(tx) e^{-x^2/2} dx = \\ &= -\frac{1}{\sqrt{2\pi}} \int_R \sin(tx) d(e^{x^2/2}) = \\ &= -\frac{1}{\sqrt{2\pi}} \left(\sin(tx) e^{-x^2/2} \Big|_{-\infty}^{\infty} - t \int_R \cos(tx) e^{-x^2/2} dx \right) = -tf(t) \end{aligned}$$

Дифференциальное уравнение $f'(t) = -tf(t)$ с начальным условием $f(0) = 1$ решается методом разделения переменных:

$$\frac{f'(t)}{f(t)} = (\ln f(t))' = -t \rightarrow \ln f(t) = \frac{-t^2}{2}$$

Т.е. $f(t) = \exp\left(-\frac{t^2}{2}\right), t \in R$

Если случайная величина ξ имеет стандартное нормальное распределение с математическим ожиданием 0 и дисперсией 1, то случайная величина $\eta = \sigma\xi + a$ имеет нормальное распределение с параметрами (a, σ^2) (математическим ожиданием a и дисперсией σ^2). По свойству 2) получаем:

$$\mathbf{M} \exp(it\eta) = e^{ita} f(\sigma t) = \exp\left(ita - \frac{\sigma^2 t^2}{2}\right)$$

Случайная величина η имеет функцию распределения $\mathbf{P}\{\eta \leq x\} = \Phi\left(\frac{x-a}{\sigma}\right)$ и плотность распределения $\varphi_{a, \sigma^2}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left\{-\frac{(x-a)^2}{2\sigma^2}\right\}$.

дальнейшие свойства

Как и функция распределения, характеристическая функция существует для любой случайной величины с действительными значениями.

Более того, характеристические функции обладают рядом аналитических свойств.

Лемма

2.

Для любых $t \in R$ и целых неотрицательных n

$$\left| e^{it} - \sum_{k=0}^{n-1} \frac{(it)^k}{k!} \right| \leq \frac{|t|^n}{n!}$$

Доказательство проведем индукцией по n . При $n = 0$ имеем

$$|e^{it} - 1| \leq |t| \text{ при всех } t \in R$$

Допустим, что для некоторого целого неотрицательного n утверждение леммы справедливо, и сделаем индуктивный переход. Заметим, что

$$\frac{d}{dt} \left(e^{it} - \sum_{k=0}^n \frac{(it)^k}{k!} \right) = ie^{it} - \sum_{k=0}^n \frac{ik(it)^{k-1}}{k!} = i \left(e^{it} - \sum_{k=0}^{n-1} \frac{(it)^k}{k!} \right)$$

и что при $t = 0$ правая часть равна 0. Поэтому

$$\left| e^{it} - \sum_{k=0}^n \frac{(it)^k}{k!} \right| = \left| i \int_0^t \left(e^{iu} - \sum_{k=0}^{n-1} \frac{(iu)^k}{k!} \right) du \right|$$

Оценивая подынтегральное выражение с помощью индуктивного предположения, находим

$$\left| e^{it} - \sum_{k=0}^n \frac{(it)^k}{k!} \right| = \left| \int_0^t \left(e^{iu} - \sum_{k=0}^{n-1} \frac{(iu)^k}{k!} \right) du \right| \leq \int_0^t \frac{|u|^n}{n!} du = \frac{|t|^{n+1}}{(n+1)!}$$

Лемма доказана.

5.

Лемма

3. Пусть случайная величина ξ имеет функцию распределения $F(x) = \mathbf{P}\{\xi \leq x\}$, $x \in R$. Положим $\mathbf{M}\xi^n = m_n$. Если $|m_n| < \infty$, то существуют производные $f^{(k)}(t)$ при $k = 1, \dots, n$ и

$$f^{(k)}(0) = i^k \mathbf{M}\xi^k = i^k m_k, \quad k = 1, \dots, n$$

более того, имеют место разложения

$$f(t) = \sum_{k=0}^n m_k \frac{(it)^k}{k!} + R_n(t), \quad R_n(t) = o(t^n), \quad t \rightarrow 0$$

$$f(t) = \sum_{k=0}^{n-1} m_k \frac{(it)^k}{k!} + r_n(t), \quad |r_n(t)| \leq \mathbf{M}|\xi|^n \cdot \frac{|t|^n}{n!}$$

Доказательство. Формальным дифференцированием равенства

$$f(t) = \mathbf{M} \exp\{it\xi\} = \int_R e^{itx} dF(x)$$

Получаем:

$$f^{(k)}(t) = \int_R (ix)^k \exp\{itx\} dF(x)$$

законность дифференцирования следует из того, что полученный интеграл сходится абсолютно при любом t :

$$\int_R |(ix)^k \exp\{itx\}| dF(x) = \int_R |x|^k dF(x) = m_k < \infty$$

Полагая $t = 0$ в (46), доказываем первое утверждение:

$$f^{(k)}(0) = \int_R (ix)^k dF(x) = i^k m_k, \quad k = 1, \dots, n$$

После того, как доказана n -кратная дифференцируемость $f(t)$, для доказательства равенства (44) достаточно использовать формулу Тейлора с остаточным членом в форме Пеано. Оценка остаточного члена в (45) следует из разложения

$$\mathbf{M} \exp\{it\xi\} = \mathbf{M} \left[\sum_{k=0}^{n-1} \frac{(it\xi)^k}{k!} + \rho_n(t\xi) \right] = \sum_{k=0}^{n-1} \frac{m_k (it)^k}{k!} + \mathbf{M}\rho_n(t\xi)$$

где $\rho_n(x) = e^{ix} - \sum_{k=0}^{n-1} \frac{(ix)^k}{k!}$ и по лемме $|\rho_n(t\xi)| \leq \frac{|t\xi|^n}{n!}$. Так как для комплекснозначной случайной величины ζ справедлива оценка $|\mathbf{M}\zeta| \leq \mathbf{M}|\zeta|$, то

$$|r_n(t)| = |\mathbf{M}\rho_n(t\xi)| \leq \mathbf{M}|\xi|^n \cdot \frac{|t|^n}{n!}$$

Важными частными случаями соотношения (44) являются

$$f(t) = f(0) + tf'(0) + o(t) = 1 + it\mathbf{M}\xi + o(t)$$

$$f(t) = f(0) + tf'(0) + t^2 \frac{f''(0)}{2!} + o(t) =$$

$$= 1 + it\mathbf{M}\xi - \frac{t^2 \mathbf{M}\xi^2}{2} + o(t^2), \quad t \rightarrow 0$$

если $\mathbf{M}\xi = 0$, то $\mathbf{M}\xi^2 = \mathbf{D}\xi = \sigma^2$ и

$$\begin{aligned} f(t) &= 1 - \frac{t^2\sigma^2}{2} + o(t^2) \quad (t \rightarrow 0) \\ f(t) &= 1 - \frac{t^2\sigma^2}{2} + \Theta t^3 \mathbf{M}|\xi|^3, \quad |\Theta| \leq \frac{1}{6} \end{aligned}$$

Следующие два свойства лежат в основе почти всех применений аппарата характеристических функций в теории вероятностей.

6. Теорема.

Различным распределениям вероятностей соответствуют различные характеристические функции.

Доказательство этой теоремы можно найти в учебниках Б.А.Севастьянова или Боровкова.

Пример. Пусть $\xi_1, \dots, \xi_n$ независимые случайные величины, имеющие нормальные распределения: ξ_k имеет нормальное распределение с параметрами (a_k, σ_k^2) , $k = 1, \dots, n$; им соответствуют характеристические функции

$$f_k(t) = \mathbf{M}e^{it\xi_k} = \exp \left\{ iat - \frac{\sigma_k^2 t^2}{2} \right\}, k = 1, \dots, n$$

Тогда сумма $\zeta = \xi_1 + \dots + \xi_n$ имеет характеристическую функцию

$$f(t) = \mathbf{M}e^{it(\xi_1 + \dots + \xi_n)} = \prod_{k=1}^n \mathbf{M}e^{it\xi_k} = \exp \left\{ i(a_1 + \dots + a_n)t - \frac{1}{2}(\sigma_1^2 + \dots + \sigma_n^2)t^2 \right\}$$

Т. е. ξ имеет нормальное распределение с параметрами $(a_1 + \dots + a_n, \sigma_1^2 + \dots + \sigma_n^2)$. Таким образом, (согласно теореме единственности) сумма независимых случайных величин, имеющих нормальные распределения, имеет нормальное распределение, параметры которого являются суммами параметров слагаемых.

Случайные величины - это функции на пространстве элементарных событий. В математическом анализе рассматриваются разные виды сходимости функций: поточечная, равномерная, почти всюду, в том или ином функциональном пространстве и т.д. В теории вероятностей тоже рассматриваются разные виды сходимости случайных величин. Пока рассмотрим только сходимость распределений (слабую сходимость).

Слабая сходимость. Определение. Последовательность $\xi_1, \xi_2, \dots$ случайных величин с действительными значениями слабо сходится к случайной величине ξ , если функции распределения $F_n(x) = \mathbf{P}\{\xi_n \leq x\}$ сходятся к функции распределения $F(x) = \mathbf{P}\{\xi \leq x\}$ в каждой точке непрерывности $F(x)$

В общем случае последовательность случайных величин $\{\xi_n\}$ со значениями в измеримом пространстве $(B, \mathcal{B})$ с метрикой ρ называют слабо сходящейся к случайной величине ξ , если для любой непрерывной ограниченной функции $g: B \rightarrow \mathbb{R}$

$$\lim_{n \rightarrow \infty} \mathbf{M}g(\xi_n) = \mathbf{M}g(\xi)$$

Пример. При слабой сходимости функции распределения могут не сходить к предельной функции в точках ее разрыва. Пусть случайные величины ξ_n - двухточечные:

$$\mathbf{P}\left\{\xi_n = -\frac{1}{n}\right\} = p_n, \quad \mathbf{P}\left\{\xi_n = \frac{1}{n}\right\} = 1 - p_n, \quad n = 1, 2, \dots$$

а $\mathbf{P}\{\xi = 0\} = 1$. Тогда при любых значениях p_n последовательность функций распределения

$$F_n(x) = \mathbf{P}\{\xi_n \leq x\} = \begin{cases} 0, & x < -\frac{1}{n} \\ p_n, & -\frac{1}{n} \leq x < \frac{1}{n} \\ 1, & x \geq \frac{1}{n} \end{cases}$$

при $n \rightarrow \infty$ сходится к функции распределения $F(x) = 0$ при $x < 0$, $F(x) = 1$ при $x \geq 1$ при каждом $x \neq 0$, но последовательность $F_n(0) = p_n$ может (в зависимости от выбора значений p_n) сходиться к любому числу из отрезка $[0, 1]$, а может не иметь предела.

7.

Теорема

непрерывности. а) Если последовательность F_n распределений случайных величин γ_n слабо сходится при $n \rightarrow \infty$ к распределению F случайной величины $f_n(t) = \mathbf{M}e^{it\gamma_n}$ сходится к характеристической функции $f(t)$ распределения F при каждом t , и эта сходимость равномерна на любом конечном интервале значений t . б) Обратно, если последовательность характеристических функций $f_n(t)$ при каждом t сходится к функции $f(t)$, непрерывной в нуле, то последовательность соответствующих распределений F_n слабо сходится к распределению F и $f(t)$ есть характеристическая функция распределения F .

Доказательство теоремы непрерывности, как и доказательство теоремы единственности, можно найти в учебниках Б.А.Севастьянова и А.А.Боровкова.

Приведем пример, показывающий, что при нарушении условия непрерывности в 0 в п.б) слабой сходимости может не быть. Пусть ξ_n имеет равномерное распределение на отрезке $[-n, n]$: $\mathbf{P}\{\xi_n \leq x\} = \frac{1}{2} + \frac{x}{2n}$, $|x| \leq n$, $n = 1, 2, \dots$; тогда (см. приведенный в начале параграфа пример б))

$$f_n(t) = \mathbf{M}e^{it\xi_n} = \frac{\sin(nt)}{nt}$$

и $f_n(0) = 1$ при всех $n = 1, 2, \dots$, но $f_n(t) \rightarrow 0$ при $n \rightarrow \infty$ для любого $t \neq 0$. Пределом функций распределения $F_n(t) = \mathbf{P}\{\xi_n \leq x\} = \frac{1}{2} + \frac{x}{2n}$ при $n \rightarrow \infty$ является функция, тождественно равная $\frac{1}{2}$, не являющаяся функцией распределения собственной случайной величины (которая с вероятностью 1 принимает конечные значения).

Следствие.

Непрерывная функция, являющаяся поточечным пределом последовательности характеристических функций, сама является характеристической.

Теорема

о непрерывности позволяет сводить доказательство слабой сходимости случайных величин или их функций распределения к доказательству поточечной сходимости характеристических функций. В ряде случаев такое доказательство оказывается проще непосредственного.

примеры

Приведем теперь характеристические функции некоторых часто встречающихся в приложениях распределений.

Врожденное распределение $\mathbf{P}(\xi = a) = 1$. Непосредственно из определения характеристической функции получаем ее вид

$$h_\xi(t) = \mathbf{M}e^{it\xi} = e^{iat}$$

Равномерное на отрезке распределение с плотностью

$$f_\xi(x) = \frac{1}{b-a} \mathbb{1}_{[a,b]}(x)$$

Ее характеристическая функция также получается непосредственно из определения. В случае $t \neq 0$ имеем

$$h_{\xi}(t) = \frac{1}{b-a} \int_a^b e^{itx} dx = \frac{e^{itx}}{it(b-a)} \Big|_{x=a}^{x=b} = \frac{e^{itb} - e^{ita}}{it(b-a)}$$

При $t = 0$ имеем $h_{\xi}(0) = 1$

Экспоненциальное распределение зависит от параметра $\lambda > 0$ и определяется плотностью

$$f_{\xi}(x) \lambda e^{-\lambda x} 1_{[0, \infty)}(x)$$

Здесь снова воспользуемся определением характеристической функции

$$h_{\xi}(t) = \lambda \int_0^{\infty} e^{itx} e^{-\lambda x} dx = \frac{\lambda e^{(it-\lambda)x}}{it-\lambda} \Big|_{x=0}^{x=\infty} = \frac{\lambda}{\lambda - it}$$

Нормальное распределение, определяемое плотностью

$$f_{\xi}(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-a)^2/2\sigma^2}$$

с двумя параметрами $a \in \mathbb{R}$ и $\sigma > 0$, имеет важное значение как в теории, так и в приложениях. Для вычисления характеристической функции нормального распределения вначале рассмотрим случай, когда $a = 0$ и $\sigma = 1$. В этом случае говорят, что случайная величина ξ имеет стандартное нормальное распределение. При этом

$$\begin{aligned} h_{\xi}(t) &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{itx} e^{-x^2/2} dx \\ &= \frac{1}{\sqrt{2\pi}} \left[\int_{-\infty}^{\infty} \cos tx \cdot e^{-x^2/2} dx + i \int_{-\infty}^{\infty} \sin tx \cdot e^{-x^2/2} dx \right] \\ &= \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \cos tx \cdot e^{-x^2/2} dx \end{aligned}$$

поскольку интеграл в мнимой части берется по симметричному промежутку от нечетной функции. Замечая, что выполнены условия дифференцирования несобственного интеграла, зависящего от параметра, получаем

$$\begin{aligned} h'_{\xi}(t) &= -\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} x \sin tx \cdot e^{-x^2/2} dx = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \sin tx \cdot d e^{-x^2/2} \\ &= -\frac{t}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \cos tx \cdot e^{-x^2/2} dx = -t h_{\xi}(t) \end{aligned}$$

Таким образом, характеристическая функция стандартного нормального распределения является решением дифференциального уравнения

$$h'_{\xi}(t) = -t h_{\xi}(t)$$

Это вместе с условием $h_\xi(0) = 1$ приводит к ее виду

$$h_\xi(t) = e^{-t^2/2}$$

Пусть теперь $\sigma > 0$ и $a \in \mathbb{R}$. Случайная величина $\eta = \sigma\xi + a$ будет иметь, в силу свойства 3°, характеристическую функцию

$$h_\eta(t) = e^{iat} e^{-\sigma^2 t^2/2}$$

С другой стороны,

$$F_\eta(x) = \mathbf{P}(\sigma\xi + a \leq x) = \mathbf{P}\left(\xi \leq \frac{x-a}{\sigma}\right) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{(x-a)/\sigma} e^{-u^2/2} du$$

Т. е.

$$f_\eta(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-a)^2}{2\sigma^2}}$$

и η имеет нормальное распределение с параметрами a, σ^2 . Зная вид характеристической функции, легко вычислить математическое ожидание и дисперсию случайной величины с использованием свойства 5°. В частности, если ξ имеет стандартное нормальное распределение, то из равенств

$$h'_\xi(t) = -th_\xi(t), \quad h''_\xi(t) = -h_\xi(t) - th'_\xi(t)$$

следует, что $h'_\xi(0) = 0, h''_\xi(0) = -1$. Отсюда получаем

$$\mathbf{M}\xi = 0, \quad \mathbf{D}\xi = \mathbf{M}\xi^2 = 1$$

Для произвольного нормального распределения, когда $\eta = \sigma\xi + a$, получаем

$$\mathbf{M}\eta = a, \quad \mathbf{D}\eta = \sigma^2$$

Таким образом, параметры нормального распределения имеют вероятностный смысл.

Целочисленная случайная величина с производящей функцией $g_\xi(x)$ имеет характеристическую функцию $h_\xi(t) = g_\xi(e^{it})$. Это следует непосредственно из определений характеристической и производящей функций.

Важным моментом в применении характеристических функций является то, что они вполне определяют распределение случайной величины. Приведем два результата, известные как формулы обращения. Напомним вначале, что распределение случайной величины ξ представляет собой вероятностную меру $\mathbf{P}_\xi$ определенную на σ -алгебре борелевских множеств, т. е. на измеримом пространстве $(\mathbb{R}, \mathcal{B})$. Эта мера связана с функцией распределения F_ξ равенствами

$$F_\xi(x) = \mathbf{P}_\xi((-\infty, x]), \quad \mathbf{P}_\xi((a, b]) = F_\xi(b) - F_\xi(a)$$

$$\begin{aligned} \lim_{R \rightarrow \infty} \frac{1}{2\pi} \int_{-R}^R \frac{e^{-iat} - e^{-ibt}}{it} h_\xi(t) dt &= \frac{1}{2} [\mathbf{P}_\xi([a, b)) + \mathbf{P}_\xi((a, b])] \\ &= \frac{1}{2} [F_\xi(b-0) - F_\xi(a-0) + F_\xi(b) - F_\xi(a)] \end{aligned}$$

Теорема

Пусть характеристическая функция h_ξ абсолютно интегрируема, т. е.

$$\int_{-\infty}^{\infty} |h_\xi(t)| dt < \infty$$

Тогда ξ имеет абсолютно непрерывное распределение, а ее плотность определяется по формуле

$$f_\xi(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-ixt} h_\xi(t) dt$$

Из формулы обращения следует, что между множеством функций распределения F и множеством характеристических функций h имеет место взаимно-однозначное соответствие. Это соответствие является даже непрерывным относительно соответствующих сходимостей.

(!!) Определение слабой сходимости

Будем говорить, что последовательность функций распределения $F_n, n = 1, 2, \dots$, слабо сходится к функции распределения F и писать $F_n \rightarrow F$, если $F_n(x) \rightarrow F(x)$ при $n \rightarrow \infty$ в каждой точке непрерывности функции F .

Теорема

9.4. Пусть $F_1, F_2, \dots$ - функции распределения, а $h_1, h_2, \dots$ - соответствующие им характеристические функции. Тогда имеют место следующие утверждения:

(i) Если $F_n \rightarrow F$ и h - характеристическая функция, соответствующая функции распределения F , то $h_n(t) \rightarrow h(t)$ при $n \rightarrow \infty$ для всех $t \in \mathbb{R}$ (ii) Если $h_n(t) \rightarrow h(t)$ при $n \rightarrow \infty$ для всех $t \in \mathbb{R}$ и функция h непрерывна в точке $t = 0$, то h является характеристической функцией некоторой функции распределения F и $F_n \rightarrow F$.

Важную роль в приложениях играют результаты, утверждающие нормальность распределения сумм независимых случайных величин. Обычно их объединяют в одну группу с названием центральной предельной теоремы. Мы рассмотрим один из вариантов центральной предельной теоремы.

Теорема

9.5. Пусть $\xi_1, \xi_2, \dots$ - последовательность независимых одинаково распределенных случайных величин с конечными $\mathbf{M}\xi = a$ и $\mathbf{D}\xi = \sigma^2$. Тогда для $S_n = \xi_1 + \dots + \xi_n$ выполняется следующее предельное соотношение

$$\lim_{n \rightarrow \infty} \mathbf{P} \left(\frac{S_n - na}{\sigma\sqrt{n}} \leq x \right) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-u^2/2} du$$

для всех $x \in \mathbb{R}$ ДОКАЗАТЕЛЬСТВО. Обозначим $\zeta_n = (S_n - na) / \sigma\sqrt{n}, n = 1, 2, \dots$ Тогда утверждение теоремы эквивалентно тому, что $F_{\zeta_n} \rightarrow \Phi$, где Φ - функция Лапласа, т. е. функция распределения случайной величины η , имеющей стандартное нормальное распределение. В силу теоремы сходимости это эквивалентно условию $h_{\zeta_n}(t) \rightarrow h_\eta(t)$

при $n \rightarrow \infty$ для всех $t \in \mathbb{R}$. Рассмотрим случайные величины $\hat{\xi}_n = (\xi_n - a)/\sigma, n = 1, 2, \dots$. Очевидно, что $\mathbf{M}\hat{\xi}_n = 0$ и $\mathbf{D}\hat{\xi}_n = \mathbf{M}\hat{\xi}_n^2 = 1$. При этом

$$\zeta_n = \frac{\hat{\xi}_1}{\sqrt{n}} + \dots + \frac{\hat{\xi}_n}{\sqrt{n}}$$

Пусть

$$h(t) = h_{\hat{\xi}_n}(t) = \mathbf{M}e^{it\hat{\xi}_n}$$

Поскольку $h(0) = 1, h'(0) = i\mathbf{M}\hat{\xi}_n = 0, h''(0) = -\mathbf{M}\hat{\xi}_n^2 = -1$, То

$$h(t) = 1 - \frac{1}{2}t^2 + o(t^2)$$

Но тогда

$$h_{\zeta_n}(t) = \left(h_{\hat{\xi}_n/\sqrt{n}}(t)\right)^n = \left(h\left(\frac{t}{\sqrt{n}}\right)\right)^n = \left(1 - \frac{1}{2}\frac{t^2}{n} + o\left(\frac{t^2}{n}\right)\right)^n$$

При фиксированном $t \in \mathbb{R}$ имеем $t^2/n \rightarrow 0$ при $n \rightarrow \infty$ и

$$\lim_{n \rightarrow \infty} h_{\zeta_n}(t) = \lim_{n \rightarrow \infty} e^{n \ln\left(1 - \frac{t^2}{2n} + o\left(\frac{t^2}{n}\right)\right)} = e^{-t^2/2}$$

Замечая, что $h_{\eta}(t) = e^{-t^2/2}$, приходим к утверждению теоремы. хов в схеме Бернулли из n независимых испытаний с вероятностью $p, 0 < p < 1$, успеха в отдельном испытании. Тогда для $-\infty < a < b < \infty$ выполняется предельное соотношение

$$\lim_{n \rightarrow \infty} \mathbf{P}\left(a \leq \frac{S_n - np}{\sqrt{npq}} \leq b\right) = \Phi(b) - \Phi(a)$$

где $q = 1 - p$

Доказательство. Заметим, что S_n можно представить как сумму независимых случайных величин ξ_k , которые являются индикаторами успеха в k -ом испытании: $\mathbf{P}(\xi_k = 1) = p, \mathbf{P}(\xi_k = 0) = q, k = 1, 2, \dots$. Тогда $\mathbf{M}\xi_k = p, \mathbf{D}\xi_k = pq$. Применение центральной предельной теоремы дает требуемый результат.

Характеристические функции распределений случайных векторов

(зубков, быстро разберу)

Характеристические функции распределений случайных векторов вводятся аналогично скалярному случаю с заменой произведения аргумента характеристической функции и случайной величины скалярным произведением векторного аргумента характеристической функции и случайного вектора.

Характеристическая функция распределения случайного вектора

Определение.

Характеристической функцией распределения случайного вектора $\bar{\gamma} = (\gamma_1, \dots, \gamma_d)$, принимающего значения в $\mathbb{R}^d$, называется

$$f(t) = \mathbf{M}e^{i(\bar{t}, \bar{\gamma})}, \quad \bar{t} \in \mathbb{R}^d$$

О случаях применения (???)

(?? потом разберу!!)

Свойства

Свойства характеристических функций и их доказательство аналогичны одномерным случайным величинам:

1) $|f(\bar{t})| \leq 1$ при всех $\bar{t} \in R^d$, $f(\bar{0}) = 1$.

Если $d = 1$ и $f(t_0) = \mathbf{M}e^{it_0\gamma} = e^{i\lambda}$ при некоторых $t_0 \neq 0, \lambda \in R$, то в силу выпуклости окружности $\{e^{i\beta}, \beta \in [0, 2\pi)\}$

$$\mathbf{P}\{t_0\gamma \in \{\lambda + 2k\pi, k \in \mathbb{Z}\}\} = 1$$

т. е. распределение γ сосредоточено на арифметической прогрессии $\{t_0^{-1}\lambda + 2kt_0^{-1}\pi, k \in \mathbb{Z}\}$

Аналогично, если $d > 1$ и $f(\bar{t}_0) = \mathbf{M}e^{i(\bar{t}_0, \bar{\gamma})} = e^{i\lambda}$ при некотором $\bar{t}_0 \neq \bar{0}$, то

$$\mathbf{P}\{(\bar{t}_0, \bar{\gamma}) \in \{\lambda + 2\pi k, k \in \mathbb{Z}\}\} = 1$$

т. е. распределение случайного вектора $\bar{\gamma}$ сосредоточено на семействе параллельных гиперплоскостей вида $\{\bar{x} \in \mathbb{R}^d : (\bar{t}_0, \bar{x}) = \lambda + 2\pi k\}, k \in \mathbb{Z}$.

2) Если $\bar{\gamma}$ - случайный вектор (столбец) и $\bar{\kappa} = B\bar{\gamma} + \bar{a}$, где $B = \|b_{ij}\|_{i,j=1}^d, \bar{a} \in R^d$ то

$$f_{\bar{\kappa}}(\bar{t}) = \mathbf{M}e^{i(\bar{t}, \bar{\kappa})} = e^{i(\bar{t}, \bar{a})} f_{\bar{\gamma}}(B^T \bar{t}),$$

где ^{T} - знак транспонирования.

Действительно, так как

$$(\bar{t}, B\bar{\gamma}) = \sum_{i=1}^d t_i \sum_{j=1}^d b_{ij} \gamma_j = \sum_{j=1}^d \left(\sum_{i=1}^d b_{ij} t_i \right) \gamma_j = (B^T \bar{t}, \bar{\gamma})$$

то

$$f_{\bar{\kappa}}(\bar{t}) = \mathbf{M}e^{i(\bar{t}, \bar{\kappa})} = \mathbf{M}e^{i(\bar{t}, B\bar{\gamma} + \bar{a})} = e^{i(\bar{t}, \bar{a})} \mathbf{M}e^{i(\bar{t}, B\bar{\gamma})} = e^{i(\bar{t}, \bar{a})} \mathbf{M}e^{i(B^T \bar{t}, \bar{\gamma})} = e^{i(\bar{t}, \bar{a})} f_{\bar{\gamma}}(B^T \bar{t})$$

Пример

Случайная величина ζ имеет стандартное нормальное распределение с параметрами $(0,1)$, если ее плотность распределения равна $\varphi(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}, -\infty < x < \infty$; функция стандартного нормального распределения есть

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-u^2/2} du$$

а его характеристическая функция

$$\psi(t) = \mathbf{M}e^{it\zeta} = e^{-t^2/2}, \quad -\infty < t < \infty$$

Среди вероятностных распределений в $\mathbb{R}^d$ аналогом стандартного нормального распределения является распределение случайного вектора $\bar{\zeta} = (\zeta_1, \dots, \zeta_d)$, компоненты которого - независимые случайные величины, имеющие стандартное нормальное распределение. Такой случайный вектор имеет нулевой вектор математических ожиданий и единичную матрицу ковариаций:

$$\mathbf{M}\bar{\zeta} = \bar{0}, \quad \text{Cov}(\bar{\zeta}) = \|\text{cov}(\zeta_i, \zeta_j)\| = \begin{vmatrix} 1 & 0 & 0 & \dots & 0 \\ 0 & 1 & 0 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & 0 & \dots & 1 \end{vmatrix}$$

Плотность и характеристическая функция распределения вектора $\bar{\zeta} = (\zeta_1, \dots, \zeta_d)$ имеют вид

$$\varphi(x_1, \dots, x_d) = \prod_{k=1}^d \varphi(x_k) = \frac{1}{(2\pi)^{d/2}} e^{-\frac{x_1^2 + \dots + x_d^2}{2}}$$

$$\psi(t_1, \dots, t_d) = \mathbf{M} e^{i(\bar{t}, \bar{\zeta})} = \mathbf{M} e^{i(t_1 \zeta_1 + \dots + t_d \zeta_d)} = \mathbf{M} \prod_{k=1}^d e^{it_k \zeta_k} = e^{-\frac{t_1^2 + \dots + t_d^2}{2}}$$

Плотность $\varphi(\bar{x})$ распределения $\bar{\zeta}$ зависит только от расстояния точки $\bar{x} = (x_1, \dots, x_d)$ от начала координат, т.е. инвариантна относительно ортогональных преобразований $\mathbb{R}^d$, оставляющих точку $\bar{0}$ на месте. Такие распределения называются сферически симметричными. Если случайный вектор имеет сферически симметричное распределение, то ортогональное преобразование с неподвижной точкой $\bar{0}$ переводит этот случайный вектор в другой случайный вектор, имеющий то же самое распределение.

Согласно определению случайный вектор $\bar{\zeta}$ с $\mathbf{M}\bar{\zeta} = \bar{0}$, $\text{Cov}(\bar{\zeta}) = I$ можно представить в виде $\bar{\zeta} = \zeta_1 \bar{e}_1 + \dots + \zeta_d \bar{e}_d$, где $\zeta_1, \dots, \zeta_d$ - независимые случайные величины, имеющие нормальное распределение с параметрами $(0, 1)$, а $\bar{e}_1, \dots, \bar{e}_d$ - единичные векторы координатных осей. Из сферической симметричности распределения $\bar{\zeta}$ следует, что для любого другого ортонормированного базиса $\bar{e}'_1, \dots, \bar{e}'_d$ в соответствующем разложении $\bar{\zeta} = \zeta'_1 \bar{e}'_1 + \dots + \zeta'_d \bar{e}'_d$ случайные величины $\zeta'_1, \dots, \zeta'_d$ тоже независимы и имеют то же самое нормальное распределение с параметрами $(0, 1)$.

Распределение любого случайного вектора $c\bar{\zeta}$ с математическим ожиданием $\bar{0}$ и матрицей ковариаций $c^2 I$ тоже является нормальным и сферически симметричным. Такое распределение имеет плотность

$$\varphi_{\bar{0}, c^2 I}(x_1, \dots, x_d) = \frac{1}{(2\pi)^{d/2} c^d} e^{-\frac{x_1^2 + \dots + x_d^2}{2c^2}}$$

и характеристическую функцию

$$\psi_{\bar{0}, c^2 I}(t_1, \dots, t_d) = e^{-\frac{(t_1^2 + \dots + t_d^2)c^2}{2}}$$

Определение.

Распределение случайного d -мерного вектора $\bar{\kappa}$ называется многомерным нормальным, если его можно представить в виде линейного преобразования случайного вектора $\bar{\zeta}_{\bar{0}, I}$ с нулевым математическим ожиданием и единичной матрицей ковариаций: $\bar{\kappa} = B\bar{\zeta}_{\bar{0}, I} + \bar{a}$, где $\bar{a} \in \mathbb{R}^d$ - неслучайный вектор и B - $(d \times d)$ -матрица.

Найдем $\mathbf{M}\bar{\kappa}$ и ковариационную матрицу $\text{Cov}(\bar{\kappa})$. Переход от вектора $\bar{\zeta}_{\bar{0}, I}$ к вектору $\bar{\kappa}$ осуществляется преобразованием $g(\bar{x}) = B\bar{x} + \bar{a}$. Значит,

$$\mathbf{M}\bar{\kappa} = \mathbf{M}g(\bar{\zeta}_{\bar{0}, I}) = \mathbf{M}(B\bar{\zeta}_{\bar{0}, I} + \bar{a}) = \bar{a}$$

В силу утверждения 2 из §18

$$\text{Cov}(\bar{\kappa}) = B \text{Cov}(\bar{\zeta}_{\bar{0}, I}) B^T = BB^T$$

В частности, отсюда следует, что $\det C(\bar{\kappa}) = (\det B)^2 \geq 0$.

Согласно утверждению 1 из §24 при невырожденной $d \times d$ -матрице B плотность распределения вектора $\bar{\kappa}$ имеет вид

$$\begin{aligned} \varphi_{\bar{\kappa}}(\bar{x}) &= \frac{\varphi_{\bar{\zeta}_{\bar{0}, I}}(B^{-1}(\bar{x} - \bar{a}))}{|\det B|} = \\ &= \frac{1}{(2\pi)^{d/2} |\det B|} \exp \left\{ -\frac{1}{2} (B^{-1}(\bar{x} - \bar{a}), B^{-1}(\bar{x} - \bar{a})) \right\} = \\ &= \frac{1}{\sqrt{(2\pi)^d \det C(\bar{\kappa})}} \exp \left\{ -\frac{1}{2} (\bar{x} - \bar{a}) C^{-1}(\bar{\kappa}) (\bar{x} - \bar{a})^T \right\} \end{aligned}$$

По теореме из линейной алгебры для любой неотрицательно определенной симметричной матрицы C существует такая матрица B , что $C = BB^\top$. Поэтому для любой симметричной неотрицательно определенной $d \times d$ -матрицы C и любого вектора $\bar{a} \in \mathbb{R}^d$ существует d -мерное нормальное распределение с математическим ожиданием $\bar{a}$ и ковариационной матрицей C .

Так как плотность $\varphi_{\bar{k}}(\bar{x})$ выражается через $\bar{a} = M\zeta$ и $\text{Cov}(\bar{\zeta})$, то многомерное нормальное распределение однозначно определяется вектором математических ожиданий и матрицей ковариаций. В отличие от плотности сферически симметричного нормального распределения, у которой поверхностями уровня являлись сферы с центром в начале координат, для плотности многомерного нормального распределения (48) поверхностями уровня являются эллипсоиды.

Пользуясь свойством 2) характеристических функций, найдем характеристическую функцию многомерного нормального распределения с плотностью (48): так как $\bar{k} = B\bar{\zeta}_{0,I}^\top + \bar{a}$, то

$$\begin{aligned}\psi_{\bar{k}}(\bar{t}) &= M e^{i(\bar{t}, \bar{k})} = e^{i(\bar{t}, \bar{a})} \psi_{\bar{\zeta}}(B^\top \bar{t}) = e^{i(\bar{t}, \bar{a})} e^{-|B^\top \bar{t}|^2/2} = \\ &= e^{i(\bar{t}, \bar{a})} e^{-(B^\top \bar{t}, B^\top \bar{t})/2} = e^{i(\bar{t}, \bar{a})} e^{-(BB^\top \bar{t}, \bar{t})/2} = e^{i(\bar{t}, \bar{a})} e^{-t \text{Cov}(\bar{k}) \bar{t}^\top/2}, \quad \bar{t} \in \mathbb{R}^d\end{aligned}$$

Равенство (49) можно использовать как

определение

многомерного нормального распределения с математическим ожиданием $\bar{a}$ и ковариационной матрицей $C(\bar{k})$. Нужно иметь в виду, что плотность (48) существует только для многомерных нормальных распределений с невырожденными матрицами ковариаций.

Далее для случайного вектора с математическим ожиданием a и матрицей ковариаций C мы будем использовать обозначение $\zeta_{a,C}$. 3) При любом $\bar{t} \in \mathbb{R}^d$ значения $f(-\bar{t}) = M e^{i(-\bar{t}, \gamma)} = M e^{-i(\bar{t}, \gamma)}$ и $f(\bar{t}) = M e^{i(\bar{t}, \gamma)}$ комплексно сопряжены. 4) Если случайные векторы $\bar{\gamma}^{(1)}, \dots, \bar{\gamma}^{(n)}$ независимы, то

$$f_{\bar{\gamma}^{(1)} + \dots + \bar{\gamma}^{(n)}}(\bar{t}) = M e^{i(\bar{t}, \bar{\gamma}^{(1)} + \dots + \bar{\gamma}^{(n)})} = M \prod_{k=1}^n e^{i(\bar{t}, \bar{\gamma}^{(k)})} = \prod_{k=1}^n f_{\bar{\gamma}^{(k)}}(\bar{t})$$

Замечание. Из свойств 3) и 4) следует, что если $f(\bar{t}) = M e^{i(\bar{t}, \bar{\gamma})}$, то $|f(\bar{t})|^2$ - характеристическая функция случайного вектора $\bar{\gamma}_1 - \bar{\gamma}_2$, где $\bar{\gamma}_1$ и $\bar{\gamma}_2$ независимы и имеют такое же распределение, как $\bar{\gamma}$. Распределение разности $\bar{\gamma}_1 - \bar{\gamma}_2$ симметрично:

$-(\bar{\gamma}_1 - \bar{\gamma}_2) = \bar{\gamma}_2 - \bar{\gamma}_1$, и характеристическая функция любого симметричного распределения принимает только действительные неотрицательные значения. 5) Теорема. Различным распределениям вероятностей соответствуют различные характеристические функции. 6)

Теорема

непрерывности. а) Если последовательность F_n распределений случайных векторов $\bar{\gamma}_n$ со значениями в $\mathbb{R}^d$ слабо сходится при $n \rightarrow \infty$ к распределению F при каждом $\bar{t}$. б) Обратно, если последовательность характеристических функций $f_n(\bar{t})$ при каждом $\bar{t}$ сходится к функции $f(\bar{t})$, непрерывной в нуле, то последовательность соответствующих распределений F_n слабо сходится к распределению F и $f(\bar{t})$ есть

характеристическая функция распределения F . Как и в скалярном случае, теоремы единственности и непрерывности в этом курсе приводятся без доказательств.

Следствие. Непрерывная функция, являющаяся поточечным пределом последовательности характеристических функций, сама является характеристической.

7) Лемма 1. Если случайный вектор $\bar{\gamma} = (\gamma_1, \dots, \gamma_d)$ имеет конечные смешанные моменты

$$m_{k_1, \dots, k_d} = \mathbf{M}\gamma_1^{k_1} \dots \gamma_d^{k_d}, \quad k_1, \dots, k_d \in \{0, 1, \dots\}, \quad \sum_{j=1}^d k_j \leq r$$

и характеристическую функцию $f(\bar{t}) = \mathbf{M}e^{i(\bar{t}, \bar{\gamma})}$, $\bar{t} = (t_1, \dots, t_d) \in \mathbb{R}^d$, то существуют частные производные характеристической функции вплоть до r -го порядка и

$$\frac{\partial^{k_1 + \dots + k_d}}{\partial t_1^{k_1} \dots \partial t_d^{k_d}} f(t_1, \dots, t_d) = i^{k_1 + \dots + k_d} \mathbf{M}e^{i(\bar{t}, \bar{\gamma})} \gamma_1^{k_1} \dots \gamma_d^{k_d}, \quad \sum_{j=1}^d k_j \leq r$$

$$m_{k_1, \dots, k_d} = i^{-k} \left. \frac{\partial^k f(\bar{t})}{\partial t_1^{k_1} \dots \partial t_d^{k_d}} \right|_{\bar{t}=\bar{0}}, \quad k = \sum_{j=1}^d k_j \leq r$$

и

$$f(\bar{t}) = 1 + \sum_{k=1}^r i^k \sum_{k_1 + \dots + k_d = k} m_{k_1, \dots, k_d} \frac{t_1^{k_1} \dots t_d^{k_d}}{k_1! \dots k_d!} + R_k(\bar{t})$$

где $R_k(\bar{t}) = o(|\bar{t}|^k)$ при $|\bar{t}| = |t_1| + \dots + |t_d| \rightarrow 0$. Доказательство леммы. Доказательство проводится индукцией. Формула для частной производной первого порядка, например, по t_1 следует из равенства

$$\frac{f(t_1 + h, t_2, \dots, t_d) - f(t_1, t_2, \dots, t_d)}{h} = \mathbf{M}e^{i(\bar{t}, \bar{\gamma})} \frac{e^{ih\gamma_1} - 1}{h}$$

Согласно лемме 2 из §29 дробь под знаком математического ожидания не превосходит $|h|$ по абсолютной величине и стремится к $i\gamma_1$ при $h \rightarrow 0$, поэтому под знаком математического ожидания можно перейти к пределу:

$$\frac{\partial}{\partial t_1} f(t_1, \dots, t_d) = \mathbf{M}e^{i(\bar{t}, \bar{\gamma})} \gamma_1$$

Получив такие формулы для всех частных производных первого порядка, аналогично можно доказывать формулы для производных второго порядка, и по индукции для частных производных всех таких порядков, при которых конечны соответствующие смешанные моменты. Лемма доказана.

Формулы для моментов получаются из формул леммы 1 подстановкой $\bar{t} = \bar{0}$. После того, как доказаны формулы для частных производных, формула (51) становится формулой Тейлора для функции d переменных.

Следствие. Пусть случайный вектор $\bar{\gamma} = (\gamma_1, \dots, \gamma_d)$ имеет конечные математическое ожидание $\bar{a} = (a_1, \dots, a_d) = (\mathbf{M}\gamma_1, \dots, \mathbf{M}\gamma_d)$ и матрицу ковариаций $C(\bar{\gamma})$. Тогда при $|\bar{t}| = |t_1| + \dots + |t_d| \rightarrow 0$

$$f(\bar{t}) = e^{i(\bar{t}, \bar{a})} \left(1 - \frac{1}{2} \bar{t} C(\bar{\gamma}) \bar{t}^T + o(|\bar{t}|^2) \right)$$

Доказательство. Представим вектор $\bar{\gamma}$ в виде $\bar{\gamma} = \bar{a} + (\bar{\gamma} - \bar{a})$. По свойству 2)

$$\mathbf{M}e^{i(\bar{t}, \bar{\gamma})} = e^{i(\bar{t}, \bar{a})} \mathbf{M}e^{i(\bar{t}, \bar{\gamma} - \bar{a})}$$

Далее, $\mathbf{M}(\bar{\gamma} - \bar{a}) = (m_1, \dots, m_d) = 0$ и

$$C(\bar{\gamma}) = \|c_{ij}\| = \|\text{Cov}(\gamma_i, \gamma_j)\| = \|\mathbf{M}(\gamma_i - a_i)(\gamma_j - a_j)\|$$

т.е. ковариации компонент вектора $\bar{\gamma}$ совпадают со смешанными моментами второго порядка вектора $\bar{\gamma} - \bar{a}$; поэтому по свойству 6)

$$\begin{aligned} \text{Me}^{i(\bar{t}, \bar{\gamma} - \bar{a})} &= 1 - \sum_{k_1 + \dots + k_d = 2} m_{k_1, \dots, k_d} \frac{t_1^{k_1} \dots t_d^{k_d}}{k_1! \dots k_d!} + o(|\bar{t}|^2) = \\ &= 1 - \frac{1}{2} \sum_{i,j=1}^d c_{ij} t_i t_j + o(|\bar{t}|^2) \end{aligned}$$

Тем самым следствие доказано. Теперь докажем центральную предельную теорему для сумм независимых одинаково распределенных случайных векторов.

12.1.4 law of Large Numbers

простейший закон больших чисел

(зубков 19)

просто сперва сформулируем и докажем ее.

Закон больших чисел

Пусть случайные величины $\xi_1, \xi_2, \dots$ попарно независимы или попарно некоррелированы и имеют одинаковые математические ожидания и дисперсии: $\mathbf{M}\xi_t = a, \mathbf{D}\xi_t = \sigma^2 < \infty$. Тогда для каждого $\varepsilon > 0$

$$\mathbf{P} \left\{ \left| \frac{1}{n} (\xi_1 + \dots + \xi_n) - a \right| < \varepsilon \right\} \rightarrow 1, \quad n \rightarrow \infty$$

Замечание.

Для случайных величин ξ_t , множество значений которых конечно, условие $\mathbf{D}\xi_t < \infty$ выполняется автоматически.

Закон больших чисел в указанной форме является следствием более общего утверждения.

Теорема.

Пусть случайные величины $\xi_1, \xi_2, \dots$ попарно независимы или попарно некоррелированы и $\sup_t \mathbf{D}\xi_t \leq \sigma^2 < \infty$. Тогда для любого $\varepsilon > 0$

$$\lim_{n \rightarrow \infty} \mathbf{P} \left\{ \left| \frac{1}{n} (\xi_1 + \dots + \xi_n) - \frac{1}{n} (\mathbf{M}\xi_1 + \dots + \mathbf{M}\xi_n) \right| < \varepsilon \right\} = 1$$

Доказательство.

Положим $\zeta_n = \xi_1 + \dots + \xi_n$. Тогда

$$\mathbf{M}\zeta_n = \mathbf{M}\xi_1 + \dots + \mathbf{M}\xi_n, \quad \mathbf{D}\zeta_n = \mathbf{D}\xi_1 + \dots + \mathbf{D}\xi_n \leq n\sigma^2$$

Следовательно,

$$\begin{aligned} \mathbf{M} \left(\frac{1}{n} \zeta_n \right) &= \frac{1}{n} (\mathbf{M}\xi_1 + \dots + \mathbf{M}\xi_n) \\ \mathbf{D} \left(\frac{1}{n} \zeta_n \right) &\leq \frac{1}{n^2} (\mathbf{D}\xi_1 + \dots + \mathbf{D}\xi_n) \leq \left(\frac{1}{n^2} \right) n\sigma^2 = \frac{\sigma^2}{n} \end{aligned}$$

Применим к случайной величине ζ_n/n неравенство Чебышева:

$$\mathbf{P} \left\{ \left| \frac{1}{n} \zeta_n - \mathbf{M} \left(\frac{1}{n} \zeta_n \right) \right| \geq \varepsilon \right\} \leq \frac{\mathbf{D} \left(\frac{1}{n} \zeta_n \right)}{\varepsilon^2} \leq \frac{\sigma^2}{n\varepsilon^2}$$

Правая часть этого неравенства стремится к 0 при $n \rightarrow \infty$. Следовательно, при $n \rightarrow \infty$

$$\mathbf{P} \left\{ \left| \frac{1}{n} \zeta_n - \mathbf{M} \left(\frac{1}{n} \zeta_n \right) \right| < \varepsilon \right\} = 1 - \mathbf{P} \left\{ \left| \frac{1}{n} \zeta_n - \mathbf{M} \left(\frac{1}{n} \zeta_n \right) \right| \geq \varepsilon \right\} \rightarrow 1$$

что завершает доказательство.

Следствие (

Теорема

Бернулли).

(теперь мы можем доказать то, что выглядит максимально очевидно. а когда оно могло бы нарушаться?)

Пусть проводятся испытания по схеме Бернулли с вероятностью успеха $p \in (0, 1)$ и μ_n - число успехов в первых n испытаниях. Тогда при любом $\varepsilon > 0$

$$\mathbf{P} \left\{ \left| \frac{1}{n} \mu_n - p \right| < \varepsilon \right\} \rightarrow 1, \quad n \rightarrow \infty$$

Доказательство.

Свяжем с k -м испытанием Бернулли индикатор $\mathbb{I}_k$, который равен 1, если испытание оканчивается успехом, и равен 0 в противном случае.

Тогда $\mu_n = \mathbb{I}_1 + \dots + \mathbb{I}_n$, случайные величины $\mathbb{I}_1, \mathbb{I}_2, \dots$ независимы в совокупности

$$\mathbf{P} \{ \mathbb{I}_k = 1 \} = p_k, \quad \mathbf{P} \{ \mathbb{I}_k = 0 \} = 1 - p_k, \quad k = 1, 2, \dots$$

и поэтому $\mathbf{M} \mathbb{I}_k = p_k, \mathbf{D} \mathbb{I}_k = \mathbf{M} \mathbb{I}_k^2 - (\mathbf{M} \mathbb{I}_k)^2 = p - p^2 = p(1 - p) \leq \frac{1}{4}$. Теперь для доказательства следствия остается применить закон больших чисел.

усиленный закон больших чисел

(зубков)

Пусть случайные величины $\xi_1, \xi_2, \dots$ независимы, $\mathbf{M} \xi_n \equiv 0, \mathbf{D} \xi_n = \sigma_n^2, S_n = \xi_1 + \dots + \xi_n$ и $\sum_{n \geq 1} \frac{\sigma_n^2}{n^2} < \infty$. тогда

$$\frac{1}{n} S_n \xrightarrow{\text{п.н.}} 0$$

Доказательство.

Согласно утверждению 1 для доказательства того, что последовательность $\frac{1}{n} S_n$ сходится с вероятностью 1, достаточно показать, что при любом $\varepsilon > 0$

$$\lim_{n \rightarrow \infty} \mathbf{P} \left\{ \omega : \sup_{k \geq n} \left| \frac{1}{k} S_k \right| > \varepsilon \right\} = 0$$

Введем события

$$A_m = \left\{ \omega : \max_{2^{m-1} \leq k < 2^m} \left| \frac{1}{k} S_k \right| > \varepsilon \right\}, \quad m = 1, 2, \dots$$

Тогда (54) равносильно тому, что

$$\mathbf{P} \left\{ \bigcup_{m \geq n} A_m \right\} \rightarrow 0, \quad n \rightarrow \infty$$

Вероятность объединения событий не больше суммы вероятностей этих событий:

$$\mathbf{P} \left\{ \bigcup_{m \geq n} A_m \right\} \leq \sum_{m \geq n} \mathbf{P} \{A_m\}$$

поэтому (55) будет доказано, если показать, что ряд $\sum_{m \geq 1} \mathbf{P} \{A_m\}$ сходится.

Оценим члены этого ряда с помощью неравенства Колмогорова:

$$\begin{aligned} \mathbf{P} \{A_m\} &= \mathbf{P} \left\{ \max_{2^{m-1} \leq k < 2^m} \left| \frac{1}{k} S_k \right| > \varepsilon \right\} \leq \mathbf{P} \left\{ \max_{2^{m-1} \leq k < 2^m} |S_k| > 2^{m-1} \varepsilon \right\} \leq \\ &\leq \mathbf{P} \left\{ \max_{1 \leq k < 2^m} |S_k| > 2^{m-1} \varepsilon \right\} \leq \frac{\mathbf{D} S_{2^m}}{(\varepsilon 2^{m-1})^2} = \frac{1}{\varepsilon^2 2^{2(m-1)}} \sum_{k=1}^{2^m} \sigma_k^2 \end{aligned}$$

Из полученных оценок и условия теоремы следует, что

$$\begin{aligned} \sum_{m \geq 1} \mathbf{P} \{A_m\} &\leq \frac{1}{\varepsilon^2} \sum_{m \geq 1} \sum_{k=1}^{2^m} \frac{\sigma_k^2}{2^{2(m-1)}} = \frac{1}{\varepsilon^2} \sum_{k \geq 1} \sigma_k^2 \sum_{m: 2^m \geq k} \frac{1}{2^{2(m-1)}} < \\ &< \frac{1}{\varepsilon^2} \sum_{k \geq 1} \frac{4}{1 - \frac{1}{4}} \frac{\sigma_k^2}{k^2} < \frac{16}{3\varepsilon^2} \sum_{k \geq 1} \frac{\sigma_k^2}{k^2} < \infty \end{aligned}$$

Теорема

доказана.

Следствие

Для числа ν_n успехов в схеме Бернулли с вероятностью успеха p справедливы как слабый закон больших чисел

$$\frac{\nu_n}{n} \xrightarrow{P} p, \quad n \rightarrow \infty$$

так и усиленный закон больших чисел

$$\frac{\nu_n}{n} \xrightarrow{\text{п. н.}} p, \quad n \rightarrow \infty$$

Проведенные рассуждения можно дополнить и доказать, что усиленный закон больших чисел для одинаково распределенных случайных величин верен при тех же условиях, при которых верен слабый закон больших чисел.

Усиленный закон больших чисел Колмогорова.

Пусть случайные величины $\xi_1, \xi_2, \dots$ независимы и одинаково распределены.

Для справедливости усиленного закона больших чисел $\frac{1}{n} S_n \xrightarrow{\text{п. н.}}$ а необходимо и достаточно, чтобы существовало конечное математическое ожидание $\mathbf{M} \xi_k = a$.

12.1.5 types of Convergence of Sequences of Random Variables

(горяйнов. потом укажу применения, пока хз!!! мб в дополнения потом перекину, хз)

В этом параграфе рассматриваются основные виды сходимости последовательностей случайных величин и устанавливается взаимосвязь между ними.

Определение сходимости по вероятности

Будем говорить, что последовательность случайных величин $\xi_1, \xi_2, \dots$ сходится по вероятности к случайной величине ξ , и писать $\xi_n \xrightarrow{P} \xi$, если для всякого $\varepsilon > 0$ выполняется предельное соотношение

$$\lim_{n \rightarrow \infty} P(|\xi_n - \xi| \geq \varepsilon) = 0$$

Именно этот вид сходимости имеет место в законе больших чисел Чебышёва.

Заметим, что из сходимости по вероятности последовательности случайных величин мы ничего не можем сказать о том, как ведет себя последовательность в отдельных экспериментах.

В этом отношении более содержательную информацию дает следующий вид сходимости.

определение сходимости почти наверное

(ну и название...)

Будем говорить, что последовательность случайных величин $\xi_1, \xi_2, \dots$ сходится к случайной величине ξ с вероятностью 1 или почти наверное, и писать $\xi_n \xrightarrow{п.н.} \xi$, если

$$P\left(\left\{\omega : \lim_{n \rightarrow \infty} \xi_n(\omega) = \xi(\omega)\right\}\right) = 1$$

Следующий вид сходимости требует от случайных величин существования средних порядка p .

определение

10.3.

Будем говорить, что последовательность случайных величин $\xi_1, \xi_2, \dots$ сходится к случайной величине ξ в среднем порядка $p, p > 0$ и писать $\xi_n \xrightarrow{L_p} \xi$, если $M|\xi_n - \xi|^p \rightarrow 0$ при $n \rightarrow \infty$. При $p = 2$ эта сходимость называется также в среднем квадратичном.

определение

10.4.

Будем говорить, что последовательность случайных величин $\xi_1, \xi_2, \dots$ сходится к случайной величине ξ по распределению, и писать $\xi_n \xrightarrow{d} \xi$, если $F_{\xi_n} \rightarrow F_\xi$

Теорема

Пусть $\xi_1, \xi_2, \dots$ — последовательность случайных величин. Тогда имеют место следующие утверждения:

- (i) Если $\xi_n \xrightarrow{п.н.} \xi$, то $\xi_n \xrightarrow{P} \xi$
- (ii) Если $\xi_n \xrightarrow{L_p} \xi$, то $\xi_n \xrightarrow{P} \xi$
- (iii) Если $\xi_n \xrightarrow{P} \xi$, то $\xi_n \xrightarrow{d} \xi$.

Доказательство.

- (i) Для $\varepsilon > 0$ введем в рассмотрение последовательность событий

$$A_n^\varepsilon = \{\omega : |\xi_n(\omega) - \xi(\omega)| \geq \varepsilon\}$$

$n = 1, 2, \dots$ Заметим, что условие $\xi_n \xrightarrow{\mathbf{P}} \xi$ эквивалентно тому, что для любого $\varepsilon > 0$ должно выполняться предельное соотношение $\mathbf{P}(A_n^\varepsilon) \rightarrow 0$ при $n \rightarrow \infty$. Также для каждого $\varepsilon > 0$ и $n = 1, 2, \dots$ рассмотрим

$$B_n^\varepsilon = \left\{ \omega : \sup_{k \geq n} |\xi_k(\omega) - \xi(\omega)| \geq \varepsilon \right\}$$

Очевидно, что $A_n^\varepsilon \subset B_n^\varepsilon$ и $\{B_n^\varepsilon\}_{n=1}^\infty$ является монотонно убывающей последовательностью.

Пусть $B^\varepsilon = \bigcap_{n=1}^\infty B_n^\varepsilon$ - предел этой последовательности.

В силу свойства непрерывности вероятностной меры $\mathbf{P}(B_n^\varepsilon) \rightarrow \mathbf{P}(B^\varepsilon)$ при $n \rightarrow \infty$.

С другой стороны, если $\omega \in B^\varepsilon$, то $\xi_n(\omega) \not\xrightarrow{\mathbf{P}} \xi(\omega)$. Это означает, что

$$B^\varepsilon \subset \{\omega : \xi_n(\omega) \not\xrightarrow{\mathbf{P}} \xi(\omega)\}$$

Однако, из условия $\xi_n \xrightarrow{\text{п.н.}} \xi$ следует

$$\mathbf{P}(\{\omega : \xi_n(\omega) \not\xrightarrow{\mathbf{P}} \xi(\omega)\}) = 0$$

Но тогда

$$\lim_{n \rightarrow \infty} \mathbf{P}(B_n^\varepsilon) = \mathbf{P}(B^\varepsilon) = 0$$

Из неравенств

$$0 \leq \mathbf{P}(A_n^\varepsilon) \leq \mathbf{P}(B_n^\varepsilon)$$

следует, что и $\mathbf{P}(A_n^\varepsilon) \rightarrow 0$ при $n \rightarrow \infty$, т.

е.

$$\xi_n \xrightarrow{\mathbf{P}} \xi.$$

(ii) Допустим теперь, что $\xi_n \xrightarrow{L^{\mathcal{R}}} \xi$, т.

е.

$\mathbf{M}|\xi_n - \xi|^p \rightarrow 0$ при $n \rightarrow \infty$. Фиксируем произвольно $\varepsilon > 0$. Используя неравенство (8.1) Маркова, получаем

$$\mathbf{P}(|\xi_n - \xi| \geq \varepsilon) = \mathbf{P}(|\xi_n - \xi|^p \geq \varepsilon^p) \leq \frac{\mathbf{M}|\xi_n - \xi|^p}{\varepsilon^p} \rightarrow 0$$

при $n \rightarrow \infty$, т.

е.

$$\xi_n \xrightarrow{\mathbf{P}} \xi. \quad (\text{iii}) \text{ Пусть } \xi_n \xrightarrow{\mathbf{P}} \xi, \text{ т.}$$

е.

$\mathbf{P}(A_n^\varepsilon) \rightarrow 0$ при $n \rightarrow \infty$ для всех $\varepsilon > 0$. Обозначим $F_n = F_{\xi_n}$ и $F = F_\xi$.

Доказательство $F_n \rightarrow F$ будет следовать из того, что для всех $\varepsilon > 0$ выполняются неравенства

$$F(x - \varepsilon) \leq \liminf_{n \rightarrow \infty} F_n(x) \leq \overline{\lim}_{n \rightarrow \infty} F_n(x) \leq F(x + \varepsilon), \quad x \in \mathbb{R}$$

Эти неравенства, в свою очередь, сразу же следуют из включений

$$\{\xi \leq x - \varepsilon\} \subset \{\xi_n \leq x\} \cup A_n^\varepsilon, \quad \{\xi_n \leq x\} \subset \{\xi \leq x + \varepsilon\} \cup A_n^\varepsilon$$

и того, что $\mathbf{P}(A_n^\varepsilon) \rightarrow 0$ при $n \rightarrow \infty$. В точках непрерывности функции F предельный переход в неравенствах (10.1) при $\varepsilon \rightarrow 0$ дает

$$F(x) \leq \liminf_{n \rightarrow \infty} F_n(x) \leq \overline{\lim}_{n \rightarrow \infty} F_n(x) \leq F(x)$$

что означает $F_n(x) \rightarrow F(x)$ при $n \rightarrow \infty$ и

Теорема доказана.

Пример-контрпример 2 (?)

Следующие два примера показывают, что из сходимости последовательности случайных величин почти наверное не следует сходимость в среднем, а из сходимости в среднем не следует сходимость почти наверное.

Пример 1. Пусть $\Omega = [0, 1]$, $\mathcal{A} = \mathcal{B}([0, 1])$, $\mathbf{P}$ - мера Лебега.

Рассмотрим последовательность

$$\xi_n(\omega) = n^{1/p} \cdot 1_{[0, 1/n]}(\omega)$$

$$n = 1, 2, \dots \text{ Тогда } \xi_n \xrightarrow{\text{п.н.}} \xi, \xi(\omega) \equiv 0, \text{ но } \xi_n \rightarrow \xi \text{ в } L_p, p > 0$$

Пример 2

Пусть $\Omega = \mathbb{T}$ - единичная окружность, $\mathcal{A} = \mathcal{B}(\mathbb{T})$, $\mathbf{P} = \mu/2\pi$ - нормированная мера Лебега.

Для $n = 1, 2, \dots$ рассмотрим

$$E_n = \left\{ \omega = e^{i\theta} : \sum_{k=1}^{n-1} \frac{1}{k} \leq \theta < \sum_{k=1}^n \frac{1}{k} \right\} \subset \mathbb{T}$$

Заметим, что $\mathbf{P}(E_n) = 1/(2\pi n) \rightarrow 0$ при $n \rightarrow \infty$.

Следовательно, для любого $p > 0$ последовательность $\xi_n = 1_{E_n}$ сходится в среднем порядка p и $\xi(\omega) \equiv 0$. С другой стороны, поскольку $\sum_{k=1}^{\infty} 1/k = \infty$, то каждое элементарное событие ω принадлежит бесконечному числу событий из последовательности $\{E_n\}$, т.е.

$\overline{\lim}_{n \rightarrow \infty} E_n = \Omega$. Это означает, что $\xi_n(\omega) \not\xrightarrow{\text{п.н.}} \xi(\omega)$ ни при каком $\omega \in \Omega$, т.е. последовательность ξ_n не сходится почти наверное.

Закон больших чисел Чебышёва касается последовательности независимых случайных величин с равномерно ограниченными дисперсиями.

Метод характеристических функций позволяет снять условие конечности вторых моментов для одинаково распределенных случайных величин.

Теорема Хинчина

(????)

Теорема

(Хинчина)

Пусть $\xi_1, \xi_2, \dots$ - последовательность независимых одинаково распределенных случайных величин с конечным $\xi = a$.

Тогда для $S_n = \xi_1 + \dots + \xi_n$ имеет место предельное соотношение

$$\frac{S_n}{n} \xrightarrow{\mathbf{P}} a \quad \text{при} \quad n \rightarrow \infty$$

Доказательство

ДоКАЗАТЕльСТВО.

Поскольку все $\xi_k, k = 1, 2, \dots$, одинаково распределены, то они имеют одну и ту же характеристическую функцию

$$h(t) = h_{\xi_k}(t) = \mathbf{M}e^{it\xi_k}$$

В силу того, что ξ_k имеет конечное математическое ожидание, характеристическая функция h дифференцируема и

$$h(t) = 1 + iat + o(t) \quad \text{при} \quad t \rightarrow 0$$

По условию $\xi_1, \dots, \xi_n$ независимы.

Поэтому

$$h_{S_n}(t) = (h(t))^n$$

и

$$h_{\frac{S_n}{n}}(t) = \left(h\left(\frac{t}{n}\right) \right)^n = \left(1 + ia\frac{t}{n} + o\left(\frac{t}{n}\right) \right)^n$$

Используя асимптотическую формулу $\ln(1+z) = z + o(|z|)$, при $z \rightarrow 0$, получаем

$$\lim_{n \rightarrow \infty} h_{\frac{S_n}{n}}(t) = \lim_{n \rightarrow \infty} e^{n \ln\left(1 + \frac{iat}{n} + o\left(\frac{t}{n}\right)\right)} = e^{iat}$$

Предельная функция e^{iat} непрерывна и по теореме сходимости она является характеристической функцией некоторой случайной величины η , причем $S_n/n \xrightarrow{d} \eta$. Заметим также, что $h_{\eta}(t) = e^{iat}$ является характеристической функцией вырожденного распределения, сосредоточенного в точке a , т.е.

$$F_{\eta}(x) = \mathbb{1}_{[a, \infty)}(x)$$

Остается показать, что $S_n/n \xrightarrow{\mathbf{P}} \eta$. Для $\varepsilon > 0$ имеем

$$\begin{aligned} \mathbf{P}\left(\left|\frac{S_n}{n} - a\right| \geq \varepsilon\right) &= \mathbf{P}\left(\frac{S_n}{n} \leq a - \varepsilon\right) + \mathbf{P}\left(\frac{S_n}{n} \geq a + \varepsilon\right) \\ &\leq F_n(a - \varepsilon) + \left(1 - F_n\left(a + \frac{\varepsilon}{2}\right)\right) \end{aligned}$$

где F_n - функция распределения случайной величины S_n/n . Поскольку точки $a - \varepsilon$ и $a + \varepsilon/2$ являются точками непрерывности функции F_{η} , то

$$F_n(a - \varepsilon) \rightarrow 0, \quad F_n(a + \varepsilon/2) \rightarrow 1$$

при $n \rightarrow \infty$. Отсюда следует, что

$$\lim_{n \rightarrow \infty} \mathbf{P}\left(\left|\frac{S_n}{n} - a\right| \geq \varepsilon\right) = 0$$

и $S_n/n \xrightarrow{\mathbf{P}} a$.

О применениях теоремы Хинчина

(хз вообще)
и что с этого?

12.1.6 Some Problems About Mathematical Statistics

(потом буду разбирать, пока: раз встретилось, то просто сюда вставлю и всё.)

Равенство для порядковых статистик (???)

(в матстатистике закину и забуду, ибо не до этого)

Пусть $X_1, \dots, X_n$ - независимые одинаково распределенные случайные величины с плотностью $f(x)$. Для каждого элементарного события $\omega \in \Omega$ вектор $(X_1(\omega), \dots, X_n(\omega))$ преобразуем в упорядоченный $(X_{(1)}(\omega), \dots, X_{(n)}(\omega))$, где $X_{(1)}(\omega) \leq \dots \leq X_{(n)}(\omega)$. Упорядоченный вектор $(X_{(1)}, \dots, X_{(n)})$ в математической статистике называют вариационным рядом, а случайные величины $X_{(k)}, k = 1, \dots, n$ - порядковыми статистиками. Плотность совместного распределения порядковых статистик определяется равенством.

$$f_{X_{(1)}, \dots, X_{(n)}}(x_1, \dots, x_n) = n! f(x_1) \cdot \dots \cdot f(x_n) \mathbb{1}_{\{x_1 \leq \dots \leq x_n\}}(x_1, \dots, x_n)$$

Действительно, множество, на котором совпали X_i, X_j $i \neq j$ имеет меру ноль. Для остальных каждому корректному вариационному ряду соответствует $n!$ неупорядоченных векторов. Из независимости $X_1, \dots, X_n$

$$f_{X_1, X_2, \dots, X_n}(x_1, x_2, \dots, x_n) = \prod_{k=1}^n f(x_k)$$

Поэтому $f_{X_{(1)}, \dots, X_{(n)}}(x_1, \dots, x_n) = n! f(x_1) \cdot \dots \cdot f(x_n) \mathbb{1}_{\{x_1 \leq \dots \leq x_n\}}(x_1, \dots, x_n)$.
(также тут укажу приложения)

12.2 Fundamentals of Mathematical Statistics

Разберем основы математической статистики, укажем примеры и приложения.

(пока что еще не дошел, но мб этим буду очень много заниматься.)

(структура по Жуковскому мфти, потом буду развивать нормально)

12.2.1 Confidence Interval

8.2.

12.2.2 Asymptotic Confidence Intervals

12.2.3 Linear Regression

12.2.4 Statistical Hypothesis Testing

12.2.5 Equally Most Powerful Criteria

12.2.6 Testing Simple Hypotheses

12.2.7 Testing Complex Hypotheses

12.2.8 Verification of Linear Hypotheses in the Gaussian Regression Model

12.2.9 Consent Criteria

12.2.10 Kolmogorov's Goodness-of-fit Criterion.

12.2.11 χ^2 Test.

(жуковский)

Пусть $X_1, \dots, X_n$ - выборка из схемы Бернулли с $m \geq 2$ исходами, т.е. $a_1, \dots, a_m$ - исходы и $P(X_i = a_j) = p_j$ для $j = 1, \dots, m$. Построим критерий для проверки гипотезы

$$H_0 : p_j = p_j^0, \quad j \in \{1, \dots, m\}$$

определение

12.3. Статистикой хи-квадрат называется

$$\hat{\chi} = \sum_{j=1}^m \frac{(\mu_j - np_j^0)^2}{np_j^0}$$

где

$$\mu_j = \sum_{i=1}^n I\{X_i = a_j\}$$

Теорема

В предположении верности гипотезы H_0 имеет место сходимость по распределению

$$\hat{\chi} \xrightarrow[n \rightarrow \infty]{d} \chi_{m-1}^2$$

А Критерий хи-квадрат Пирсона записывается следующим образом: $\{\hat{\chi} > u_{1-\alpha}\}$, где $u_{1-\alpha} = (1 - \alpha)$ -Квантиль распределения χ_{m-1}^2 . Из теоремы 12.2 следует, что критерий хи-квадрат является состоятельным. Напоследок заметим, что критерий хи-квадрат принято применять, если $n \geq 50$ и $\mu_j \geq 5$ для всех $j \in \{1, \dots, m\}$.

12.2.12 Other Mathematical Statistics (???)

(там много всего есть, так что тут укажу это, подробнее - в записи по мат статистике)

Коэффициенты корреляции

Коэффициент корреляции Пирсона

Коэффициент корреляции Спирмена

Коэффициент корреляции Кэндалла

Байесовские оценки

12.3 Typical Distributions

Приведем часто встречающиеся распределения.

(в порядке пользы отсортирую потом. укажу, зачем они нужны. графики добавлю потом! удаляю разделы про распределения, которые не так нужны.)

12.3.1 Normal Distribution

Суть нормального распределения

Нормальное (или гауссовское) с плотностью

$$f_{\xi}(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-a)^2/2\sigma^2}, \quad a \in \mathbb{R}, \quad \sigma > 0$$

Случайная величина ζ имеет стандартное нормальное распределение с параметрами $(0,1)$, если ее плотность распределения равна $\varphi(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2}$, $-\infty < x < \infty$; функция стандартного нормального распределения есть

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-u^2/2} du$$

а его характеристическая функция

$$\psi(t) = \mathbf{M}e^{it\zeta} = e^{-t^2/2}, \quad -\infty < t < \infty$$

Свойства (!!!)

(очень часто могут быть задачи про это. мб в разделе выше это напишу, посмотрим.)

Случаи применения

Вывод

12.3.2 Homogeneous Distribution

Конструкция и свойства равномерного распределения

Равномерное на $[a, b]$

$$f_{\xi}(x) = \frac{1}{b-a} \mathbb{1}_{[a,b]}(x)$$

Равномерное распределение на конечном множестве $\{1, \dots, N\}$ определяется равенствами

$$\mathbf{P}\{\xi = m\} = \frac{1}{N}, \quad m = 1, 2, \dots, N$$

Функция распределения $F_{\xi}(x) = \mathbf{P}\{\xi \leq x\}$ такой случайной величины равна 0 при $x < a$, равна 1 при $x > b$ и равна $\frac{x-a}{b-a}$ при $a \leq x \leq b$. Плотность распределения этой случайной величины равна $\frac{1}{b-a}$ при $a \leq x \leq b$ и равна 0 вне отрезка $[a, b]$.

Равномерное распределение не является устойчивым относительно суммирования.

Найдём функцию и плотность распределения суммы двух независимых случайных величин с одинаковым равномерным на отрезке $[0, 1]$ распределением, но не по формуле свёртки, а используя геометрическую вероятность.

Пусть $\xi_1, \xi_2 \in U_{0,1}$ - независимые случайные величины. Пару (ξ_1, ξ_2) можно считать координатой точки, брошенной наудачу в единичный квадрат. Тогда $F_{\xi_1 + \xi_2}(x) = P(\xi_1 + \xi_2 < x)$ равна площади области внутри квадрата под прямой $x_2 = x - x_1$. Эта область - заштрихованный треугольник при $0 < x \leq 1$, и пятиугольник при $1 < x \leq 2$. Окончательно получаем:

$$F_{\xi_1 + \xi_2}(x) = \begin{cases} 0, & x \leq 0 \\ x^2/2, & 0 < x \leq 1 \\ 2x - x^2/2 - 1, & 1 < x \leq 2 \\ 1, & x > 2. \end{cases}$$

Плотность распределения суммы равна

$$f_{\xi_1 + \xi_2}(x) = \begin{cases} 0, & x \notin (0, 2) \\ x, & 0 < x \leq 1 \\ 2 - x, & 1 < x \leq 2 \end{cases}$$

Случаи применения

12.3.3 Demonstrative

Конструкция

Показательное

$$f_{\xi}(x) = \lambda e^{-\lambda x} \mathbb{1}_{[0, \infty)}(x), \quad \lambda > 0$$

Случаи применения

Вывод

12.3.4 Cauchy Distribution

Конструкция

$$f_{\xi}(x) = \frac{1}{\pi} \frac{1}{x^2 + 1}$$

Вырожденное распределение — это распределение случайной величины, которая с вероятностью 1 принимает какое-то одно значение (т. е. как функция на пространстве элементарных событий Ω она равна константе на множестве меры 1)

Случаи применения**Вывод****12.3.5 Binomial (???)****Конструкция**

Пусть $\eta_1, \eta_2, \dots$ - индикаторы успехов в последовательности независимых испытаний Бернулли с вероятностью успеха p :

$$\mathbf{P}\{\eta_k = 1\} = p, \quad \mathbf{P}\{\eta_k = 0\} = 1 - p, k = 1, 2, \dots$$

Биномиальный закон с параметрами (n, p) соответствует распределению числа $\mu_n = \eta_1 + \dots + \eta_n$ успехов в n независимых испытаниях по схеме Бернулли, если в каждом испытании вероятность успеха равна p :

$$\mathbf{P}\{\mu_n = m\} = C_n^m p^m (1 - p)^{n-m}, \quad m = 0, 1, \dots, n$$

Случаи применения**12.3.6 Geometric Distribution****Конструкция**

Геометрическое распределение с параметром p определяется равенствами

$$\mathbf{P}\{\nu = m\} = p(1 - p)^m, \quad m = 0, 1, 2, \dots$$

Одна из интерпретаций случайной величины с геометрическим распределением Число неудач (нулей) до первого успеха (единицы) в последовательности испытаний Бернулли: $\nu = \min\{n \geq 1 : \eta_n = 1\} - 1$, где $\eta_1, \eta_2, \dots$ - те же, что в предыдущем примере.

Случаи применения**Вывод****12.3.7 Hypergeometric Distribution**

Гипергеометрическое распределение имеет вид:

$$\mathbf{P}\{\xi = m\} = \frac{C_M^m C_{N-M}^{n-m}}{C_N^n}, \quad \max\{0, n - N + M\} \leq m \leq \min\{n, M\}$$

(???)

$$\mathbf{P}\{\xi = m\} = \left(\frac{\lambda^m}{m!}\right) e^{-\lambda}, \quad m = 0, 1, 2, \dots$$

Очевидно,

$$\sum_{m \geq 0} \mathbf{P}\{\xi = m\} = \sum_{m \geq 0} \frac{\lambda^m}{m!} e^{-\lambda} = e^{\lambda} e^{-\lambda} = 1$$

Случаи применения

Гипергеометрическое распределение с параметрами n, M и N является распределением числа ξ белых шаров среди n шаров, извлеченных по схеме равновероятного выбора без возвращения урны, содержавшей вначале M белых и $N - M$ черных Шаров:

Вывод**12.3.8 Gamma Distribution****Суть**

Пусть распределение случайной величины X задаётся плотностью вероятности, имеющей вид $f_X(x) = \begin{cases} x^{k-1} \frac{e^{-x/\theta}}{\theta^k \Gamma(k)}, & x \geq 0 \\ 0, & x < 0 \end{cases}$, где $\Gamma(k)$ - гамма-функция Эйлера. Тогда говорят, что случайная величина X имеет гамма-распределение с положительными параметрами θ и k . Пишут $X \sim \Gamma(k, \theta)$.

Замечание. Иногда используют другую параметризацию семейства гаммараспределений. Или вводят третий параметр - сдвиг.

О случаях применения (!?!?!?)**Свойства**

(вики)

Математическое ожидание и дисперсия случайной величины X , имеющей гаммараспределение, имеют вид

$$\begin{aligned}\mathbb{E}[X] &= k\theta, \\ \mathbb{D}[X] &= k\theta^2.\end{aligned}$$

- Если $X_1, \dots, X_n$ - независимые случайные величины, такие что $X_i \sim \Gamma(k_i, \theta)$, $i = 1, \dots, n$, то

$$Y = \sum_{i=1}^n X_i \sim \Gamma\left(\sum_{i=1}^n k_i, \theta\right).$$

- Если $X \sim \Gamma(k, \theta)$, и $a > 0$ - произвольная константа, то $aX \sim \Gamma(k, a\theta)$ - Гамма-распределение бесконечно делимо.

(пока не до этого, чуть что - сюда писать буду)

15.1.1 Visualization of Probabilistic Model Results

Построение распределений на Питоне (??)

(идем по [?] - там отличное введение в приложения.)

как и обещанно в введении, будет много кода и примеров, позже раскидаю многое по другим главам.

выглядит так:

```
from IPython.core.pylabtools import figsize
import numpy as np
from matplotlib import pyplot as plt
figsize(11, 9)

import scipy.stats as stats

dist = stats.beta
n_trials = [0, 1, 2, 3, 4, 5, 8, 15, 50, 500]
data = stats.bernoulli.rvs(0.5, size=n_trials[-1])
x = np.linspace(0, 1, 100)

# For the already prepared, I'm using Binomial's conj. prior.
for k, N in enumerate(n_trials):
    sx = plt.subplot(len(n_trials) / 2, 2, k + 1)
    plt.xlabel("$p$, probability of heads") \
    if k in [0, len(n_trials) - 1] else None
    plt.setp(sx.get_yticklabels(), visible=False)
    heads = data[:N].sum()
    y = dist.pdf(x, 1 + heads, 1 + N - heads)
    plt.plot(x, y, label="observe %d tosses, \n %d heads" % (N, heads))
    plt.fill_between(x, 0, y, color="#348ABD", alpha=0.4)
    plt.vlines(0.5, 0, 4, color="k", linestyle="--", lw=1)

leg = plt.legend()
leg.get_frame().set_alpha(0.4)
plt.autoscale(tight=True)

plt.suptitle("Bayesian updating of posterior probabilities",
y=1.02,
fontsize=14)

plt.tight_layout()
```

и это уже круто. вот - прикладной теорвер!!!

15.2 Machine Learning

часто этим мы и занимаемся, ведь МЛ это круто и полезно.

15.3 Bayesian Machine Learning

обзор

есть курс на ютубе от ВШЭ про это, так что можно посмотреть.

статья.

вообще так или иначе - байесовские темы достойны отдельной подглавы.

степень нашей уверенности в событии A обозначим цифрой $P(A)$.

а далее мы получаем какую-то дополнительную информацию, и с ней наше видение вероятности уже становится другим. обозначим новое видение $P(A|X)$, где X - новое событие. оно называется *условная вероятность (posterior probability)*.

(какие-то рассуждения про величину количества испытаний)

вообще, следует заметить, что тут стиль более программирования и мало физики, мало сути вероятности. для сути вероятности нужно читать другую главу в разделе про квантмех. тут какой-то поверхностный такой метод.

но в этом и его польза.

16 Special constructions

(по идее хватит такой структуры на них, все равно этим почти не занимался.)

16.0.1 Frobenius-perron Theorem

Материал из Википедии — свободной энциклопедии [Перейти к навигации](#)[Перейти к поиску](#) Теорема Фробениуса — Перрона — теорема о наибольшем собственном значении вещественной квадратной матрицы с положительными компонентами. Эта теорема имеет многочисленные приложения в теории вероятностей (эргодичность цепей Маркова); в теории динамических систем; в экономике; в демографии; в социальных сетях; в поисковых системах.

Доказана Оскаром Перроном (1907) и независимо Георгом Фробениусом (1912). Идея использования этой теоремы для определения порядка игроков в турнирах принадлежит Эдмунду Ландау.

Формулировка

Пусть A - квадратная матрица, со строго положительными вещественными элементами, тогда справедливы утверждения: - наибольшее по модулю собственное значение r является вещественным и строго положительным; - это собственное значение является простым корнем характеристического многочлена; - соответствующий r собственной вектор имеет (точнее говоря, может быть выбран таким образом, чтобы иметь) строго положительные координаты, все остальные собственные векторы таким свойством не обладают; - собственное значение r удовлетворяет неравенствам $\min_i \sum_j a_{ij} \leq r \leq \max_i \sum_j a_{ij}$.

Доказательство (??)

16.1 Random Matrices

(почитаю избры, потом впишу)

и да, так как тема сложная, будем излагать просто, без четких определений как в прошлых разделах.

и тут важный взгляд такой: у нас была случайная величина, мы там интегрировали, что-то с ней делали, так же и с матрицами хочется делать, поэтому

Definition 16.1. дифференциальная вероятность от случайной матрицы

Definition 16.2. *дифференциал случайной матрицы*

(пока просто понятно что как-то определяется, потом пойму)

но в сути мы берем тип матриц, закидываем в элементы случайные величины и смотрим характеристики.

Definition 16.3. *гауссовый унитарный ансамбль - GUE - набор эрмитовых матрицы, с такой-то функцией распределения*

функция экспонента на что-то на след квадрата этой матрицы. ну типа напоминает функцию гауссова распределения

Definition 16.4. *среднее от функции от случайной матрицы*

ок, на этом этапе мы поняли, как ставится задача, ввели определения.

нужно еще характеризовать распределения.

(вообще как можно скорее нужно теорию вообще распределений клеить, но это позже обязательно сделаю. здесь как раз вопрос о распределениях)

Definition 16.5. *плотность состояний случайной матрицы*

в общем, на этом этапе мы должны просто понять постановку задачи и все такое и короче говоря мы задачи не умеем на это решать

16.2 diagramming Techniques

здесь типа самое главное эдванст методов

16.3 Quantum Probability

(тут от Амосова прописываю введение в его случпроцы. потом в 1 части также добавлю теорию)

16.4 Special Models and Paradoxes

(пока тут, особо углубляться нет в планах)

16.4.1 Special Patterns of Ordinary Life

Парадокс дней рождений

(должно хватить этого раздела)

Модель

ИнтуИтИвное восприяИе

В группе из 23 человек вероятность совпадения дней рождения у двух человек столь высока, потому что рассматривается вероятность совпадения дней рождения у любых двух человек в группе. Эта вероятность определяется количеством пар людей, которые можно составить из 23 человек. Так как порядок людей в парах не имеет значения, общее число таких пар равно числу сочетаний из 23 по 2, то есть $(23 \times 22)/2 = 253$ пары.

В формулировке парадокса речь идёт именно о совпадении дней рождения у каких-либо двух членов группы. Одно из распространённых заблуждений состоит в том, что этот случай путают с другим случаем, на первый взгляд похожим, когда из группы выбирается

один человек и оценивается вероятность того, что день рождения каких-либо других членов группы совпадёт с днём рождения выбранного человека. В последнем случае вероятность совпадения значительно ниже.

Расчёт вероятности

Требуется определить вероятность того, что в группе из n человек как минимум у двух из них дни рождения совпадут. Пусть дни рождения распределены равномерно, то есть примем, что: - в году 365 дней (нет високосных лет); - в группе нет людей, заведомо родившихся в один день (например, близнецов); - рождаемость не зависит от дня недели, времени года и других факторов. В действительности это не совсем так - в частности, в некоторых странах из-за особенностей работы больниц больше детей рождается в определённые дни недели. Однако неравномерность распределения может лишь увеличить вероятность совпадения дней рождения, но не уменьшить: если бы все люди рождались только в 3 дня из 365, то вероятность совпадения дней рождения была бы очень высокой.

Возьмём наугад одного человека из группы и запомним его день рождения. Затем возьмём наугад второго человека, при этом вероятность того, что у него день рождения не совпадёт с днем рождения первого человека, равна $1 - \frac{1}{365}$. Затем возьмём третьего человека; при этом вероятность того, что его день рождения не совпадёт с днем рождения одного из первых двух, равна $1 - \frac{2}{365}$. Рассуждая по аналогии, мы дойдём до последнего человека, для которого вероятность несовпадения его дня рождения со всеми предыдущими будет равна $1 - \frac{n-1}{365}$. Перемножая все эти вероятности, получаем вероятность того, что все дни рождения в группе будут различными:

$$\bar{p}(n) = \left(1 - \frac{1}{365}\right) \cdot \left(1 - \frac{2}{365}\right) \cdot \dots \cdot \left(1 - \frac{n-1}{365}\right) = \frac{365 \cdot 364 \cdot \dots \cdot (365 - n + 1)}{365^n} = \frac{365!}{365^n (365 - n)!}$$

Тогда вероятность того, что хотя бы у двух человек из n дни рождения совпадут, равна

$$p(n) = 1 - \bar{p}(n).$$

Значение этой функции превосходит 1/2 при $n = 23$, при этом вероятность совпадения равна примерно 50,73 %, а $p(22) \approx 47,57\%$. Список значений n и соответствующих им вероятностей приведён в следующей таблице.

(напишу нормально, на вики куча воды)

Выводы (??)

О применениях (?)

(кст, если группа более 23 человек, то можно найти с одинаковым днем рождения. прикольно ведь)

Вероятность счастливого билета

(пока тут, напишу потом это решение.)

17 Part I Methods by Alon, Spencer

17.1 1 The Basic Method

What you need is that your brain is open.

- Paul Erdős

17.1.1 1.1 The Probabilistic Method

The probabilistic method is a powerful tool for tackling many problems in discrete mathematics. Roughly speaking, the method works as follows: Trying to prove that a structure with certain desired properties exists, one defines an appropriate probability space of structures and then shows that the desired properties hold in this structures and then shows that the desired properties hold in this space with positive probability. The method is best illustrated by examples. Here is a simple one. The Ramsey number $R(k, \ell)$ is the smallest integer n such that in any two-coloring of the edges of a complete graph on n vertices K_n by red and blue, either there is a red K_k (i.e., a complete subgraph on k vertices all of whose edges are colored red) or there is a blue K_ℓ . Ramsey (1929) showed that $R(k, \ell)$ is finite for any two integers k and ℓ . Let us obtain a lower bound for the diagonal Ramsey numbers $R(k, k)$.

Proposition 1.1.1 If $\binom{n}{k} \cdot 2^{1-\binom{k}{2}} < 1$ then $R(k, k) > n$. Thus $R(k, k) > \lfloor 2^{k/2} \rfloor$ for all $k \geq 3$.

Proof. Consider a random two-coloring of the edges of K_n obtained by coloring each edge independently either red or blue, where each color is equally likely. For any fixed set R of k vertices, let A_R be the event that the induced subgraph of K_n on R is monochromatic (i.e., that either all its edges are red or they are all blue). Clearly, $\Pr[A_R] = 2^{1-\binom{k}{2}}$. Since there are $\binom{n}{k}$ possible choices for R , the probability that at least one of the events A_R occurs is at most $\binom{n}{k} 2^{1-\binom{k}{2}} < 1$. Thus, with positive probability, no event A_R occurs and there is a two-coloring of K_n without a monochromatic K_k ; that is, $R(k, k) > n$. Note that if $k \geq 3$ and we take $n = \lfloor 2^{k/2} \rfloor$ then

$$\binom{n}{k} 2^{1-\binom{k}{2}} < \frac{2^{1+\frac{k}{2}}}{k!} \cdot \frac{n^k}{2^{k^2/2}} < 1$$

and hence $R(k, k) > \lfloor 2^{k/2} \rfloor$ for all $k \geq 3$. $\square$

This simple example demonstrates the essence of the probabilistic method. To prove the existence of a good coloring we do not present one explicitly, but rather show, in a nonconstructive way, that it exists. This example appeared in a paper of P. Erdős from 1947. Although Szele had applied the probabilistic method to another combinatorial problem, mentioned in Chapter 2, already in 1943, Erdős was certainly the first one who understood the full power of this method and applied it successfully over the years to numerous problems. One can, of course, claim that the probability is not essential in the proof given above. An equally simple proof can be described by counting; we just check that the total number of two-colorings of K_n is larger than the number of those containing a monochromatic K_k .

Moreover, since the vast majority of the probability spaces considered in the study of combinatorial problems are finite spaces, this claim applies to most of the applications of the probabilistic method in discrete mathematics. Theoretically, this is, indeed, the case. However, in practice, the probability is essential. It would be hopeless to replace the applications of many of the tools appearing in this book, including, for example, the second moment method, the Lovász Local Lemma and the concentration via martingales by counting arguments, even when these are applied to finite probability spaces.

The probabilistic method has an interesting algorithmic aspect. Consider, for example, the proof of Proposition 1.1.1 that shows that there is an edge two-coloring of K_n without a monochromatic $K_{2 \log_2 n}$. Can we actually find such a coloring? This question, as asked, may sound ridiculous; the total number of possible colorings is finite, so we can try them all until we find the desired one. However, such a procedure may require $2^{\binom{n}{2}}$ steps; an amount of time that is exponential in the size $\left[= \binom{n}{2} \right]$ of the problem. Algorithms whose running time is more than polynomial in the size of the problem are usually considered impractical. The class of problems that can be solved in polynomial time, usually denoted by **P** [see, e.g., Aho, Hopcroft and Ullman (1974)], is, in a sense, the class of all solvable problems. In this sense, the exhaustive search approach suggested above for finding a good coloring of K_n is not acceptable, and this is the reason for our remark that the proof of Proposition 1.1.1 is nonconstructive; it does not supply a constructive, efficient and deterministic way of producing a coloring with the desired properties. However, a closer look at the proof shows that, in fact, it can be used to produce, effectively, a coloring that is very likely to be good. This is because for large k , if $n = \lfloor 2^{k/2} \rfloor$ then

$$\binom{n}{k} \cdot 2^{1-\binom{k}{2}} < \frac{2^{1+\frac{k}{2}}}{k!} \left(\frac{n}{2^{k/2}} \right)^k \leq \frac{2^{1+\frac{k}{2}}}{k!} \ll 1.$$

Hence, a random coloring of K_n is very likely not to contain a monochromatic $K_{2 \log n}$. This means that if, for some reason, we must present a two-coloring of the edges of K_{1024} without a monochromatic K_{20} we can simply produce a random two-coloring by flipping a fair coin $\binom{1024}{2}$ times. We can then deliver the resulting coloring safely; the probability that it contains a monochromatic K_{20} is less than $2^{11}/20$!, probably much smaller than our chances of making a mistake in any rigorous proof that a certain coloring is good! Therefore, in some cases the probabilistic, nonconstructive method does supply effective probabilistic algorithms. Moreover, these algorithms can sometimes be converted into deterministic ones. This topic is discussed in some detail in Chapter 16.

The probabilistic method is a powerful tool in Combinatorics and in Graph Theory. It is also extremely useful in Number Theory and in Combinatorial Geometry. More recently, it has been applied in the development of efficient algorithmic techniques and in the study of various computational problems. In the rest of this chapter we present several simple examples that demonstrate some of the broad spectrum of topics in which this method is helpful. More complicated examples, involving various more delicate probabilistic arguments, appear in the

rest of the book.

17.1.2 1.2 Graph Theory

A tournament on a set V of n players is an orientation $T = (V, E)$ of the edges of the complete graph on the set of vertices V . Thus for every two distinct elements x and y of V either (x, y) or (y, x) is in E , but not both. The name "tournament" is natural, since one can think of the set V as a set of players in which each pair participates in a single match, where (x, y) is in the tournament iff x beats y . We say that T has the property S_k if for every set of k players there is one who beats them all. For example, a directed triangle $T_3 = (V, E)$, where $V = \{1, 2, 3\}$ and $E = \{(1, 2), (2, 3), (3, 1)\}$, has S_1 . Is it true that for every finite k there is a tournament T (on more than k vertices) with the property S_k ? As shown by Erdős (1963b), this problem, raised by Schütte, can be solved almost trivially by applying probabilistic arguments. Moreover, these arguments even supply a rather sharp estimate for the minimum possible number of vertices in such a tournament. The basic (and natural) idea is that if n is sufficiently large as a function of k , then a random tournament on the set $V = \{1, \dots, n\}$ of n players is very likely to have property S_k . By a random tournament we mean here a tournament T on V obtained by choosing, for each $1 \leq i < j \leq n$, independently, either the edge (i, j) or the edge (j, i) , where each of these two choices is equally likely. Observe that in this manner, all the $2^{\binom{n}{2}}$ possible tournaments on V are

equally likely; that is, the probability space considered is symmetric. It is worth noting that we often use in applications symmetric probability spaces. In these cases, we shall sometimes refer to an element of the space as a random element, without describing explicitly the probability distribution. Thus, for example, in the proof of Proposition 1.1.1 random two-colorings of K_n were considered; that is, all possible colorings were equally likely. Similarly, in the proof of the next simple result we study random tournaments on V .

Theorem 1.2.1 If $\binom{n}{k} (1 - 2^{-k})^{n-k} < 1$ then there is a tournament on n vertices that has the property S_k .

Proof. Consider a random tournament on the set $V = \{1, \dots, n\}$. For every fixed subset K of size k of V , let A_K be the event that there is no vertex that beats all the members of K . Clearly $\Pr[A_K] = (1 - 2^{-k})^{n-k}$. This is because for each fixed vertex $v \in V - K$, the probability that v does not beat all the members of K is $1 - 2^{-k}$, and all these $n - k$ events corresponding to the various possible choices of v are independent. It follows that

$$\Pr \left[\bigvee_{\substack{K \subset V \\ |K|=k}} A_K \right] \leq \sum_{\substack{K \subset V \\ |K|=k}} \Pr[A_K] = \binom{n}{k} (1 - 2^{-k})^{n-k} < 1.$$

Therefore, with positive probability, no event A_K occurs; that is, there is a tournament on n vertices that has the property S_k .

Let $f(k)$ denote the minimum possible number of vertices of a tournament that has the property S_k . Since $\binom{n}{k} < (en/k)^k$ and $(1 - 2^{-k})^{n-k} < e^{-(n-k)/2^k}$, Theorem 1.2.1 implies that $f(k) \leq k^2 \cdot 2^k \cdot (\ln 2)(1 + o(1))$. It is not too difficult to check that $f(1) = 3$ and $f(2) = 7$. As proved by Szekeres [cf. Moon (1968)], $f(k) \geq c_1 \cdot k \cdot 2^k$.

Can one find an explicit construction of tournaments with at most c_2^k vertices having property S_k ? Such a construction is known but is not trivial; it is described in Chapter 9.

A dominating set of an undirected graph $G = (V, E)$ is a set $U \subseteq V$ such that every vertex $v \in V - U$ has at least one neighbor in U .

Theorem 1.2.2 Let $G = (V, E)$ be a graph on n vertices, with minimum degree $\delta > 1$. Then G has a dominating set of at most $n[1 + \ln(\delta + 1)]/(\delta + 1)$ vertices.

Proof. Let $p \in [0, 1]$ be, for the moment, arbitrary. Let us pick, randomly and independently, each vertex of V with probability p . Let X be the (random) set of all vertices picked and let $Y = Y_X$ be the random set of all vertices in $V - X$ that do not have any neighbor in X . The expected value of $|X|$ is clearly np . For each fixed vertex $v \in V$, $\Pr[v \in Y] = \Pr[v \text{ and its neighbors are not in } X] \leq (1 - p)^{\delta+1}$. Since the expected value of a sum of random variables is the sum of their expectations (even if they are not independent) and since the random variable $|Y|$ can be written as a sum of n indicator random variables $\chi_v (v \in V)$, where $\chi_v = 1$ if $v \in Y$ and $\chi_v = 0$ otherwise, we conclude that the expected value of $|X| + |Y|$ is at most $np + n(1 - p)^{\delta+1}$. Consequently, there is at least one choice of $X \subseteq V$ such that $|X| + |Y_X| \leq np + n(1 - p)^{\delta+1}$. The set $U = X \cup Y_X$ is clearly a dominating set of G whose cardinality is at most this size.

The above argument works for any $p \in [0, 1]$. To optimize the result we use elementary calculus. For convenience we bound $1 - p \leq e^{-p}$ (this holds for all nonnegative p and is a fairly close bound when p is small) to give the simpler bound

$$|U| \leq np + ne^{-p(\delta+1)}$$

Take the derivative of the right-hand side with respect to p and set it equal to zero. The right-hand side is minimized at

$$p = \frac{\ln(\delta + 1)}{\delta + 1}$$

Formally, we set p equal to this value in the first line of the proof. We now have $|U| \leq n[1 + \ln(\delta + 1)]/(\delta + 1)$ as claimed.

Three simple but important ideas are incorporated in the last proof. The first is the linearity of expectation; many applications of this simple, yet powerful principle appear in Chapter 2. The second is perhaps more subtle and is an example of the "alteration" principle that is discussed in Chapter 3. The random choice did not supply the required dominating set U immediately; it only supplied the set X , which has to be altered a little (by adding to it the set Y_X) to provide the required dominating set. The third involves the optimal choice of p . One often wants to make a random choice but is not certain what probability p should be used. The idea is to carry out the proof with p as a parameter giving a result that is a function of p . At the end, that p is selected which gives the optimal result. There is here yet a fourth idea that might be called asymptotic calculus. We wanted the asymptotics of $\min np + n(1 - p)^{\delta+1}$, where p ranges over $[0, 1]$. The actual minimum $p = 1 - (\delta + 1)^{-1/\delta}$ is difficult to deal with and in many similar cases precise minima are impossible to find in closed form. Rather, we give away a little bit, bounding $1 - p \leq e^{-p}$, yielding a clean bound. A good part of the art of the probabilistic method lies in finding suboptimal but clean bounds. Did we give away too much in this case? The answer depends on the emphasis for the original question. For $\delta = 3$ our rough bound gives $|U| \leq 0.596n$ while the more precise calculation gives $|U| \leq 0.496n$, perhaps a substantial difference. For δ large both methods give asymptotically $n \ln \delta / \delta$.

It can easily be deduced from the results in Alon (1990b) that the bound in Theorem 1.2.2 is nearly optimal. A non probabilistic, algorithmic proof of this theorem can be obtained by choosing the vertices for the dominating set one by one, when in each step a vertex that covers the maximum number of yet uncovered vertices is picked. Indeed, for each vertex v denote by $C(v)$ the set consisting of v together with all its neighbors. Suppose that during the process of picking vertices

the number of vertices u that do not lie in the union of the sets $C(v)$ of the vertices chosen so far is r . By the assumption, the sum of the cardinalities of the sets $C(u)$ over all such uncovered vertices u is at least $r(\delta + 1)$, and hence, by averaging, there is a vertex v that belongs to at least $r(\delta + 1)/n$ such sets $C(u)$. Adding this v to the set of chosen vertices we observe that the

number of uncovered vertices is now at most $r(1 - (\delta + 1)/n)$. It follows that in each iteration of the above procedure the number of uncovered vertices decreases by a factor of $1 - (\delta + 1)/n$ and hence after $n \ln(\delta + 1)/(\delta + 1)$ steps there will be at most $n/(\delta + 1)$ yet uncovered vertices that can now be added to the set of chosen vertices to form a dominating set of size at most equal to the one in the conclusion of Theorem 1.2.2.

Combining this with some ideas of Podderyugin and Matula, we can obtain a very efficient algorithm to decide if a given undirected graph on n vertices is, say, $n/2$ edge-connected. A cut in a graph $G = (V, E)$ is a partition of the set of vertices V into two nonempty disjoint sets $V = V_1 \cup V_2$. If $v_1 \in V_1$ and $v_2 \in V_2$ we say that the cut separates v_1 and v_2 . The size of the cut is the number of edges of G having one end in V_1 and another end in V_2 . In fact, we sometimes identify the cut with the set of these edges. The edge connectivity of G is the minimum size of a cut of G . The following lemma is due to Podderyugin and Matula (independently).

Lemma 1.2.3 Let $G = (V, E)$ be a graph with minimum degree δ and let $V = V_1 \cup V_2$ be a cut of size smaller than δ in G . Then every dominating set U of G has vertices in V_1 and in V_2 .

Proof. Suppose this is false and $U \subseteq V_1$. Choose, arbitrarily, a vertex $v \in V_2$ and let $v_1, v_2, \dots, v_\delta$ be δ of its neighbors. For each $i, 1 \leq i \leq \delta$, define an edge e_i of the given cut as follows; if $v_i \in V_1$ then $e_i = \{v, v_i\}$, otherwise, $v_i \in V_2$ and since U is dominating there is at least one vertex $u \in U$ such that $\{u, v_i\}$ is an edge; take such a u and put $e_i = \{u, v_i\}$. The δ edges $e_1, \dots, e_\delta$ are all distinct and all lie in the given cut, contradicting the assumption that its size is less than δ . This completes the proof.

Let $G = (V, E)$ be a graph on n vertices, and suppose we wish to decide if G is $n/2$ edge-connected; that is, if its edge connectivity is at least $n/2$. Matula showed, by applying Lemma 1.2.3, that this can be done in time $O(n^3)$. By the remark following the proof of Theorem 1.2.2, we can slightly improve it and get an $O(n^{8/3} \log n)$ algorithm as follows. We first check if the minimum degree δ of G is at least $n/2$. If not, G is not $n/2$ edge-connected, and the algorithm ends. Otherwise, by Theorem 1.2.2 there is a dominating set $U = \{u_1, \dots, u_k\}$ of G , where $k = O(\log n)$, and it can in fact be found in time $O(n^2)$. We now find, for each $i, 2 \leq i \leq k$, the minimum size s_i of a cut that separates u_1 from u_i . Each of these problems can be solved by solving a standard network flow problem in time $O(n^{8/3})$ [see, e.g., Tarjan (1983)]. By Lemma 1.2.3 the edge connectivity of G is simply the minimum between δ and $\min_{2 \leq i \leq k} s_i$. The total time of the algorithm is $O(n^{8/3} \log n)$, as claimed.

17.1.3 1.3 Combinatorics

A hypergraph is a pair $H = (V, E)$, where V is a finite set whose elements are called vertices and E is a family of subsets of V , called edges. It is n -uniform if each of its edges contains precisely n vertices. We say that H has property B , or that it is two-colorable if there is a two-coloring of V such that no edge is monochromatic. Let $m(n)$ denote the minimum possible number of edges of an n -uniform hypergraph that does not have property B .

Proposition 1.3.1 [Erdős (1963a)] Every n -uniform hypergraph with less than 2^{n-1} edges has property B . Therefore $m(n) \geq 2^{n-1}$.

Proof. Let $H = (V, E)$ be an n -uniform hypergraph with less than 2^{n-1} edges. Color V randomly by two colors. For each edge $e \in E$, let A_e be the event that e is monochromatic. Clearly $\Pr[A_e] = 2^{1-n}$. Therefore

$$\Pr \left[\bigvee_{e \in E} A_e \right] \leq \sum_{e \in E} \Pr[A_e] < 1$$

and there is a two-coloring without monochromatic edges.

In Section 3.5 we present a more delicate argument, due to Radhakrishnan and Srinivasan, and based on an idea of Beck, that shows that

$$m(n) \geq \Omega \left(\left(\frac{n}{\ln n} \right)^{1/2} 2^n \right)$$

The best known upper bound to $m(n)$ is found by turning the probabilistic argument "on its head." Basically, the sets become random and each coloring defines an event. Fix V with v points, where we shall later optimize v . Let χ be a coloring of V with a points in one color, $b = v - a$ points in the other. Let $S \subset V$ be a uniformly selected n -set. Then

$$\Pr[S \text{ is monochromatic under } \chi] = \frac{\binom{a}{n} + \binom{b}{n}}{\binom{v}{n}}$$

Let us assume v is even for convenience. As $\binom{y}{n}$ is convex, this expression is minimized when $a = b$. Thus

$$\Pr[S \text{ is monochromatic under } \chi] \geq p,$$

where we set

$$p = \frac{2\binom{v/2}{n}}{\binom{v}{n}}$$

for notational convenience. Now let $S_1, \dots, S_m$ be uniformly and independently chosen n -sets, m to be determined. For each coloring χ let A_χ be the event that none of the S_i are monochromatic. By the independence of the S_i

$$\Pr[A_\chi] \leq (1 - p)^m.$$

There are 2^v colorings so

$$\Pr \left[\bigvee_{\chi} A_\chi \right] \leq 2^v (1 - p)^m$$

When this quantity is less than 1 there exist $S_1, \dots, S_m$ so that no A_χ holds; that is, $S_1, \dots, S_m$ is not two-colorable and hence $m(n) \leq m$.

The asymptotics provide a fairly typical example of those encountered when employing the probabilistic method. We first use the inequality $1 - p \leq e^{-p}$. This is valid for all positive p and the terms are quite close when p is small. When

$$m = \left\lceil \frac{v \ln 2}{p} \right\rceil$$

then $2^v (1 - p)^m < 2^v e^{-pm} \leq 1$ so $m(n) \leq m$. Now we need to find v to minimize v/p . We may interpret p as twice the probability of picking n white balls from an urn with $v/2$ white and $v/2$ black balls, sampling without replacement. It is tempting to estimate p by 2^{-n+1} , the probability for sampling with replacement. This approximation would yield $m \sim v 2^{n-1} (\ln 2)$. As v gets smaller, however, the approximation becomes less accurate and, as we wish to minimize m , the trade-off becomes essential. We use a second order approximation

$$p = \frac{2\binom{v/2}{n}}{\binom{v}{n}} = 2^{1-n} \prod_{i=0}^{n-1} \frac{v-2i}{v-i} \sim 2^{1-n} e^{-n^2/2v}$$

as long as $v \gg n^{3/2}$, estimating

$$\frac{v-2i}{v-i} = 1 - \frac{i}{v} + O\left(\frac{i^2}{v^2}\right) = e^{-i/v + O(i^2/v^2)}.$$

Elementary calculus gives $v = n^2/2$ for the optimal value. The evenness of v may require a change of at most 2, which turns out to be asymptotically negligible. This yields the following result of Erdős (1964).

Theorem 1.3.2 $m(n) < (1 + o(1)) \frac{e \ln 2}{4} n^2 2^n$.

Let $\mathcal{F} = \{(A_i, B_i)\}_{i=1}^h$ be a family of pairs of subsets of an arbitrary set. We call $\mathcal{F}$ a (k, ℓ) -system if $|A_i| = k$ and $|B_i| = \ell$ for all $1 \leq i \leq h$, $A_i \cap B_i = \emptyset$ and $A_i \cap B_j \neq \emptyset$ for all distinct i, j with $1 \leq i, j \leq h$. Bollobás (1965) proved the following result, which has many interesting extensions and applications.

Theorem 1.3.3 If $\mathcal{F} = \{(A_i, B_i)\}_{i=1}^h$ is a (k, ℓ) -system then $h \leq \binom{k+\ell}{k}$.

Proof. Put $X = \bigcup_{i=1}^h (A_i \cup B_i)$ and consider a random order π of X . For each i , $1 \leq i \leq h$, let X_i be the event that all the elements of A_i precede all those of B_i in this order. Clearly $\Pr[X_i] = 1/\binom{k+\ell}{k}$. It is also easy to check that the events X_i are pairwise disjoint. Indeed, assume this is false and let π be an order in which all the elements of A_i precede those of B_i and all the elements of A_j precede those of B_j . Without loss of generality we may assume that the last element of A_i does not appear after the last element of A_j . But in this case, all elements of A_i precede all those of B_j , contradicting the fact that $A_i \cap B_j \neq \emptyset$. Therefore all the events X_i are pairwise disjoint, as claimed. It follows that

$$1 \geq \Pr\left[\bigvee_{i=1}^h X_i\right] = \sum_{i=1}^h \Pr[X_i] = h/\binom{k+\ell}{k},$$

completing the proof. $\square$

Theorem 1.3.3 is sharp, as shown by the family $\mathcal{F} = \{(A, X \setminus A) : A \subset X, |A| = k\}$, where $X = \{1, 2, \dots, k + \ell\}$.

17.1.4 1.4 Combinatorial Number Theory

A subset A of an abelian group G is called sum-free if $(A + A) \cap A = \emptyset$; that is, if there are no $a_1, a_2, a_3 \in A$ such that $a_1 + a_2 = a_3$.

Theorem 1.4.1 [Erdős (1965a)] Every set $B = \{b_1, \dots, b_n\}$ of n nonzero integers contains a sum-free subset A of size $|A| > \frac{1}{3}n$.

Proof. Let $p = 3k + 2$ be a prime, which satisfies $p > 2 \max\{|b_i|\}_{i=1}^n$ and put $C = \{k + 1, k + 2, \dots, 2k + 1\}$. Observe that C is a sum-free subset of the cyclic group $\mathbb{Z}_p$ and that

$$\frac{|C|}{p-1} = \frac{k+1}{3k+1} > \frac{1}{3}.$$

Let us choose at random an integer x , $1 \leq x < p$, according to a uniform distribution on $\{1, 2, \dots, p-1\}$, and define $d_1, \dots, d_n$ by $d_i \equiv xb_i \pmod{p}$, $0 \leq d_i < p$. Trivially, for every fixed i , $1 \leq i \leq n$, as x ranges over all numbers $1, 2, \dots, p-1$, d_i ranges over all nonzero elements of $\mathbb{Z}_p$ and hence $\Pr[d_i \in C] = |C|/(p-1) > \frac{1}{3}$. Therefore the expected number of elements b_i such that $d_i \in C$ is more than $n/3$. Consequently, there is an x , $1 \leq x < p$ and a subsequence A of B of cardinality $|A| > n/3$, such that $xa \pmod{p} \in C$ for all $a \in A$. This A is clearly sum-free, since if $a_1 + a_2 = a_3$ for some $a_1, a_2, a_3 \in A$ then $xa_1 + xa_2 \equiv xa_3 \pmod{p}$, contradicting the fact that C is a sum-free subset of $\mathbb{Z}_p$. This completes the proof. $\square$

Remark. The above proof works whenever p is a prime that does not divide any of the numbers b_i . This can be used to design an efficient deterministic algorithm for finding a sum-free subset A of size bigger than $|B|/3$ in a given set B as above. In Alon and Kleitman (1990)

it is shown that every set of n nonzero elements of an arbitrary abelian group contains a sum-free subset of more than $2n/7$ elements, and that the constant $2/7$ is best possible. The best possible constant in Theorem 1.4.1 is not known.

17.1.5 1.5 Disjoint Pairs

The probabilistic method is most striking when it is applied to prove theorems whose statement does not seem to suggest at all the need for probability. Most of the examples given in the previous sections are simple instances of such statements. In this section we describe a (slightly) more complicated result, due to Alon and Frankl (1985), which solves a conjecture of Daykin and Erdős.

Let $\mathcal{F}$ be a family of m distinct subsets of $X = \{1, 2, \dots, n\}$. Let $d(\mathcal{F})$ denote the number of disjoint pairs in $\mathcal{F}$; that is,

$$d(\mathcal{F}) = |\{\{F, F'\} : F, F' \in \mathcal{F}, F \cap F' = \emptyset\}|.$$

Daykin and Erdős conjectured that if $m = 2^{(1/2+\delta)n}$, then, for every fixed $\delta > 0$, $d(\mathcal{F}) = o(m^2)$, as n tends to infinity. This result follows from the following theorem, which is a special case of a more general result.

Theorem 1.5.1 Let $\mathcal{F}$ be a family of $m = 2^{(1/2+\delta)n}$ subsets of $X = \{1, 2, \dots, n\}$, where $\delta > 0$. Then

$$d(\mathcal{F}) < m^{2-\delta^2/2} \quad (1.1)$$

Proof. Suppose (1.1) is false and pick independently t members $A_1, A_2, \dots, A_t$ of $\mathcal{F}$ with repetitions at random, where t is a large positive integer, to be chosen later. We will show that with positive probability $|A_1 \cup A_2 \cup \dots \cup A_t| > n/2$ and still this union is disjoint to more than $2^{n/2}$ distinct subsets of X . This contradiction will establish (1.1).

In fact,

$$\begin{aligned} & \Pr[|A_1 \cup A_2 \cup \dots \cup A_t| \leq n/2] \\ & \leq \sum_{\substack{S \subset X \\ |S|=n/2}} \Pr[A_i \subset S, i = 1, \dots, t] \\ & \leq 2^n \left(2^{n/2}/2^{(1/2+\delta)n}\right)^t = 2^{n(1-\delta t)}. \end{aligned} \quad (1.2)$$

Define

$$v(B) = |\{A \in \mathcal{F} : B \cap A = \emptyset\}|.$$

Clearly,

$$\sum_{B \in \mathcal{F}} v(B) = 2d(\mathcal{F}) \geq 2m^{2-\delta^2/2}$$

Let Y be a random variable whose value is the number of members $B \in \mathcal{F}$ that are disjoint to all the A_i ($1 \leq i \leq t$). By the convexity of z^t the expected value of Y satisfies

$$\begin{aligned} \mathbb{E}[Y] &= \sum_{B \in \mathcal{F}} \left(\frac{v(B)}{m}\right)^t = \frac{1}{m^t} \cdot m \left(\sum_{B \in \mathcal{F}} v(B)^t\right) \\ &\geq \frac{1}{m^t} \cdot m \left(\frac{2d(\mathcal{F})}{m}\right)^t \geq 2m^{1-t\delta^2/2} \end{aligned}$$

Since $Y \leq m$ we conclude that

$$\Pr \left[Y \geq m^{1-t\delta^2/2} \right] \geq m^{-t\delta^2/2} \quad (1.3)$$

One can check that for $t = \lceil 1 + 1/\delta \rceil$, $m^{1-t\delta^2/2} > 2^{n/2}$ and the right-hand side of (1.3) is greater than the right-hand side of (1.2). Thus, with positive probability, $|A_1 \cup A_2 \cup \dots \cup A_t| > n/2$ and still this union is disjoint to more than $2^{n/2}$ members of F . This contradiction implies inequality (1.1).

17.1.6 1.6 Exercises

1. Prove that if there is a real p , $0 \leq p \leq 1$ such that

$$\binom{n}{k} p^{\binom{k}{2}} + \binom{n}{t} (1-p)^{\binom{t}{2}} < 1,$$

then the Ramsey number $R(k, t)$ satisfies $R(k, t) > n$. Using this, show that

$$R(4, t) \geq \Omega(t^{3/2}/(\ln t)^{3/2}).$$

2. Suppose $n \geq 4$ and let H be an n -uniform hypergraph with at most $4^{n-1}/3^n$ edges. Prove that there is a coloring of the vertices of H by four colors so that in every edge all four colors are represented.
3. (*) Prove that for every two independent, identically distributed real random variables X and Y ,

$$\Pr[|X - Y| \leq 2] \leq 3 \Pr[|X - Y| \leq 1]$$

4. (*) Let $G = (V, E)$ be a graph with n vertices and minimum degree $\delta > 10$. Prove that there is a partition of V into two disjoint subsets A and B so that $|A| \leq O(n \ln \delta / \delta)$, and each vertex of B has at least one neighbor in A and at least one neighbor in B .
5. (*) Let $G = (V, E)$ be a graph on $n \geq 10$ vertices and suppose that if we add to G any edge not in G then the number of copies of a complete graph on 10 vertices in it increases. Show that the number of edges of G is at least $8n - 36$.
6. (*) Theorem 1.2.1 asserts that for every integer $k > 0$ there is a tournament $T_k = (V, E)$ with $|V| > k$ such that for every set U of at most k vertices of T_k there is a vertex v so that all directed arcs $\{(v, u) : u \in U\}$ are in E . Show that each such tournament contains at least $\Omega(k2^k)$ vertices.
7. Let $\{(A_i, B_i), 1 \leq i \leq h\}$ be a family of pairs of subsets of the set of integers such that $|A_i| = k$ for all i and $|B_i| = l$ for all i , $A_i \cap B_i = \emptyset$ and $(A_i \cap B_j) \cup (A_j \cap B_i) \neq \emptyset$ for all $i \neq j$. Prove that $h \leq (k+l)^{k+l} / (k^k l^l)$.
8. (Prefix-free codes; Kraft Inequality). Let F be a finite collection of binary strings of finite lengths and assume no member of F is a prefix of another one. Let N_i denote the number of strings of length i in F . Prove that

$$\sum_i \frac{N_i}{2^i} \leq 1.$$

9. (*) (Uniquely decipherable codes; Kraft-McMillan Inequality). Let F be a finite collection of binary strings of finite lengths and assume that no two distinct concatenations of two finite sequences of codewords result in the same binary sequence. Let N_i denote the number of strings of length i in F . Prove that

$$\sum_i \frac{N_i}{2^i} \leq 1.$$

10. Prove that there is an absolute constant $c > 0$ with the following property. Let A be an n by n matrix with pairwise distinct entries. Then there is a permutation of the rows of A so that no column in the permuted matrix contains an increasing subsequence of length at least $c\sqrt{n}$.

The Probabilistic Lens: the Erdős-ko-rado Theorem

A family $\mathcal{F}$ of sets is called intersecting if $A, B \in \mathcal{F}$ implies $A \cap B \neq \emptyset$. Suppose $n \geq 2k$ and let $\mathcal{F}$ be an intersecting family of k -element subsets of an n -set, for definiteness $\{0, \dots, n-1\}$. The Erdős-Ko-Rado Theorem is that $|\mathcal{F}| \leq \binom{n-1}{k-1}$. This is achievable by taking the family of k -sets containing a particular point. We give a short proof due to Katona (1972).

Lemma 1 For $0 \leq s \leq n-1$ set $A_s = \{s, s+1, \dots, s+k-1\}$ where addition is modulo n . Then $\mathcal{F}$ can contain at most k of the sets A_s .

Proof. Fix some $A_s \in \mathcal{F}$. All other sets A_t that intersect A_s can be partitioned into $k-1$ pairs $\{A_{s-i}, A_{s+k-i}\}$, ($1 \leq i \leq k-1$), and the members of each such pair are disjoint. The result follows, since $\mathcal{F}$ can contain at most one member of each pair. $\square$

Now we prove the Erdős-Ko-Rado Theorem. Let a permutation σ of $\{0, \dots, n-1\}$ and $i \in \{0, \dots, n-1\}$ be chosen randomly, uniformly and independently and set $A = \{\sigma(i), \sigma(i+1), \dots, \sigma(i+k-1)\}$, addition again modulo n . Conditioning on any choice of σ the lemma gives $\Pr[A \in \mathcal{F}] \leq k/n$. Hence $\Pr[A \in \mathcal{F}] \leq k/n$. But A is uniformly chosen from all k -sets so

$$\frac{k}{n} \geq \Pr[A \in \mathcal{F}] = \frac{|\mathcal{F}|}{\binom{n}{k}}$$

and

$$|\mathcal{F}| \leq \frac{k}{n} \binom{n}{k} = \binom{n-1}{k-1}.$$

17.2 2 Linearity of Expectation

The search for truth is more precious than its possession.

- Albert Einstein

17.2.1 2.1 Basics

Let $X_1, \dots, X_n$ be random variables, $X = c_1X_1 + \dots + c_nX_n$. Linearity of expectation states that

$$E[X] = c_1E[X_1] + \dots + c_nE[X_n].$$

The power of this principle comes from there being no restrictions on the dependence or independence of the X_i . In many instances $E[X]$ can easily be calculated by a judicious decomposition into simple (often indicator) random variables X_i .

Let σ be a random permutation on $\{1, \dots, n\}$, uniformly chosen. Let $X(\sigma)$ be the number of fixed points of σ . To find $E[X]$ we decompose $X = X_1 + \dots + X_n$ where X_i is the indicator random variable of the event $\sigma(i) = i$. Then

$$E[X_i] = \Pr[\sigma(i) = i] = \frac{1}{n}$$

so that

$$E[X] = \frac{1}{n} + \dots + \frac{1}{n} = 1$$

In applications we often use that there is a point in the probability space for which $X \geq E[X]$ and a point for which $X \leq E[X]$. We have selected results with a purpose of describing this basic methodology. The following result of Szele (1943) is oftentimes considered the first use of the probabilistic method.

Theorem 2.1.1 There is a tournament T with n players and at least $n!2^{-(n-1)}$ Hamiltonian paths.

Proof. In the random tournament let X be the number of Hamiltonian paths. For each permutation σ let X_σ be the indicator random variable for σ giving a Hamiltonian path; that is, satisfying $(\sigma(i), \sigma(i+1)) \in T$ for $1 \leq i < n$. Then $X = \sum X_\sigma$ and

$$E[X] = \sum E[X_\sigma] = n!2^{-(n-1)}$$

Thus some tournament has at least $E[X]$ Hamiltonian paths.

Szele conjectured that the maximum possible number of Hamiltonian paths in a tournament on n players is at most $n!/(2 - o(1))^n$. This was proved in Alon (1990a) and is presented in The Probabilistic Lens: Hamiltonian Paths (following Chapter 4).

17.2.2 2.2 Splitting Graphs

Theorem 2.2.1 Let $G = (V, E)$ be a graph with n vertices and e edges. Then G contains a bipartite subgraph with at least $e/2$ edges.

Proof. Let $T \subseteq V$ be a random subset given by $\Pr[x \in T] = 1/2$, these choices being mutually independent. Set $B = V - T$. Call an edge $\{x, y\}$ crossing if exactly one of x, y is in T . Let X be the number of crossing edges. We decompose

$$X = \sum_{\{x, y\} \in E} X_{xy},$$

where X_{xy} is the indicator random variable for $\{x, y\}$ being crossing. Then

$$E[X_{xy}] = \frac{1}{2}$$

as two fair coin flips have probability $1/2$ of being different. Then

$$E[X] = \sum_{\{x,y\} \in E} E[X_{xy}] = \frac{e}{2}$$

Thus $X \geq e/2$ for some choice of T and the set of those crossing edges form a bipartite graph.

A more subtle probability space gives a small improvement (which is tight for complete graphs).

Theorem 2.2.2 If G has $2n$ vertices and e edges then it contains a bipartite subgraph with at least $en/(2n-1)$ edges. If G has $2n+1$ vertices and e edges then it contains a bipartite subgraph with at least $e(n+1)/(2n+1)$ edges.

Proof. When G has $2n$ vertices let T be chosen uniformly from among all n -element subsets of V . Any edge $\{x, y\}$ now has probability $n/(2n-1)$ of being crossing and the proof concludes as before. When G has $2n+1$ vertices choose T uniformly from among all n -element subsets of V and the proof is similar.

Here is a more complicated example in which the choice of distribution requires a preliminary lemma. Let $V = V_1 \cup \dots \cup V_k$, where the V_i are disjoint sets of size n . Let $h : V^k \rightarrow \{\pm 1\}$ be a two-coloring of the k -sets. A k -set E is crossing if it contains precisely one point from each V_i . For $S \subseteq V$ set $h(S) = \sum h(E)$, the sum over all k -sets $E \subseteq S$.

Theorem 2.2.3 Suppose $h(E) = +1$ for all crossing k -sets E . Then there is an $S \subseteq V$ for which

$$|h(S)| \geq c_k n^k$$

Here c_k is a positive constant, independent of n .

Lemma 2.2.4 Let P_k denote the set of all homogeneous polynomials $f(p_1, \dots, p_k)$ of degree k with all coefficients having absolute value at most one and $p_1 p_2 \dots p_k$ having coefficient one. Then for all $f \in P_k$ there exist $p_1, \dots, p_k \in [0, 1]$ with

$$|f(p_1, \dots, p_k)| \geq c_k$$

Here c_k is positive and independent of f .

Proof. Set

$$M(f) = \max_{p_1, \dots, p_k \in [0, 1]} |f(p_1, \dots, p_k)|$$

For $f \in P_k$, $M(f) > 0$ as f is not the zero polynomial. As P_k is compact and $M : P_k \rightarrow R$ is continuous, M must assume its minimum c_k .

Proof [Theorem 2.2.3]. Define a random $S \subseteq V$ by setting

$$\Pr[x \in S] = p_i, \quad x \in V_i$$

these choices being mutually independent, with p_i to be determined. Set $X = h(S)$. For each k -set E set

$$X_E = \begin{cases} h(E) & \text{if } E \subseteq S \\ 0 & \text{otherwise} \end{cases}$$

Say E has type $(a_1, \dots, a_k)$ if $|E \cap V_i| = a_i$, $1 \leq i \leq k$. For these E ,

$$E[X_E] = h(E) \Pr[E \subseteq S] = h(E) p_1^{a_1} \dots p_k^{a_k}$$

Combining terms by type

$$E[X] = \sum_{a_1 + \dots + a_k = k} p_1^{a_1} \dots p_k^{a_k} \sum_{E \text{ of type } (a_1, \dots, a_k)} h(E).$$

When $a_1 = \dots = a_k = 1$ all $h(E) = 1$ by assumption so

$$\sum_{E \text{ of type } (1, \dots, 1)} h(E) = n^k.$$

For any other type there are fewer than n^k terms, each ± 1 , so

$$\left| \sum_{E \text{ of type } (a_1, \dots, a_k)} h(E) \right| \leq n^k.$$

Thus

$$E[X] = n^k f(p_1, \dots, p_k)$$

where $f \in P_k$, as defined by Lemma 2.2.4.

Now select $p_1, \dots, p_k \in [0, 1]$ with $|f(p_1, \dots, p_k)| \geq c_k$. Then

$$E[|X|] \geq |E[X]| \geq c_k n^k.$$

Some particular value of $|X|$ must exceed or equal its expectation. Hence there is a particular set $S \subseteq V$ with $|X| = |h(S)| \geq c_k n^k$.

Theorem 2.2.3 has an interesting application to Ramsey Theory. It is known [see Erdős (1965b)] that given any coloring with two colors of the k -sets of an n -set there exist k disjoint m -sets, $m = \Theta((\ln n)^{1/(k-1)})$, so that all crossing k -sets are the same color. From Theorem 2.2.3 there then exists a set of size $\Theta((\ln n)^{1/(k-1)})$, at least $\frac{1}{2} + \epsilon_k$ of whose k -sets are the same color. This is somewhat surprising since it is known that there are colorings in which the largest monochromatic set has size at most the $k - 2$ -fold logarithm of n .

17.2.3 2.3 Two Quickies

Linearity of expectation sometimes gives very quick results.

Theorem 2.3.1 There is a two-coloring of K_n with at most

$$\binom{n}{a} 2^{1 - \binom{a}{2}}$$

monochromatic K_a .

Proof [Outline]. Take a random coloring. Let X be the number of monochromatic K_a and find $E[X]$. For some coloring the value of X is at most this expectation. $\square$

In Chapter 16 it is shown how such a coloring can be found deterministically and efficiently.

Theorem 2.3.2 There is a two-coloring of $K_{m,n}$ with at most

$$\binom{m}{a} \binom{n}{b} 2^{1 - ab}$$

monochromatic $K_{a,b}$.

Proof [Outline]. Take a random coloring. Let X be the number of monochromatic $K_{a,b}$ and find $E[X]$. For some coloring the value of X is at most this expectation. $\square$

17.2.4 2.4 Balancing Vectors

The next result has an elegant non probabilistic proof, which we defer to the end of this chapter. Here $|v|$ is the usual Euclidean norm.

Theorem 2.4.1 Let $v_1, \dots, v_n \in \mathbb{R}^n$, all $|v_i| = 1$. Then there exist $\epsilon_1, \dots, \epsilon_n = \pm 1$ so that

$$|\epsilon_1 v_1 + \dots + \epsilon_n v_n| \leq \sqrt{n},$$

and also there exist $\epsilon_1, \dots, \epsilon_n = \pm 1$ so that

$$|\epsilon_1 v_1 + \dots + \epsilon_n v_n| \geq \sqrt{n}.$$

Proof. Let $\epsilon_1, \dots, \epsilon_n$ be selected uniformly and independently from $\{-1, +1\}$. Set

$$X = |\epsilon_1 v_1 + \dots + \epsilon_n v_n|^2.$$

Then

$$X = \sum_{i=1}^n \sum_{j=1}^n \epsilon_i \epsilon_j v_i \cdot v_j.$$

Thus

$$\mathbb{E}[X] = \sum_{i=1}^n \sum_{j=1}^n v_i \cdot v_j \mathbb{E}[\epsilon_i \epsilon_j].$$

When $i \neq j$, $\mathbb{E}[\epsilon_i \epsilon_j] = \mathbb{E}[\epsilon_i] \mathbb{E}[\epsilon_j] = 0$. When $i = j$, $\epsilon_i^2 = 1$ so $\mathbb{E}[\epsilon_i^2] = 1$. Thus

$$\mathbb{E}[X] = \sum_{i=1}^n v_i \cdot v_i = n.$$

Hence there exist specific $\epsilon_1, \dots, \epsilon_n = \pm 1$ with $X \geq n$ and with $X \leq n$. Taking square roots gives the theorem.

The next result includes part of Theorem 2.4.1 as a linear translation of the $p_1 = \dots = p_n = 1/2$ case.

Theorem 2.4.2 Let $v_1, \dots, v_n \in \mathbb{R}^n$, all $|v_i| \leq 1$. Let $p_1, \dots, p_n \in [0, 1]$ be arbitrary and set $w = p_1 v_1 + \dots + p_n v_n$. Then there exist $\epsilon_1, \dots, \epsilon_n \in \{0, 1\}$ so that, setting $v = \epsilon_1 v_1 + \dots + \epsilon_n v_n$,

$$|w - v| \leq \frac{\sqrt{n}}{2}$$

Proof. Pick ϵ_i independently with

$$\Pr[\epsilon_i = 1] = p_i, \quad \Pr[\epsilon_i = 0] = 1 - p_i.$$

The random choice of ϵ_i gives a random v and a random variable

$$X = |w - v|^2$$

We expand

$$X = \left| \sum_{i=1}^n (p_i - \epsilon_i) v_i \right|^2 = \sum_{i=1}^n \sum_{j=1}^n v_i \cdot v_j (p_i - \epsilon_i) (p_j - \epsilon_j)$$

so that

$$E[X] = \sum_{i=1}^n \sum_{j=1}^n v_i \cdot v_j E[(p_i - \epsilon_i)(p_j - \epsilon_j)].$$

For $i \neq j$,

$$E[(p_i - \epsilon_i)(p_j - \epsilon_j)] = E[p_i - \epsilon_i] E[p_j - \epsilon_j] = 0.$$

For $i = j$,

$$E[(p_i - \epsilon_i)^2] = p_i(p_i - 1)^2 + (1 - p_i)p_i^2 = p_i(1 - p_i) \leq \frac{1}{4}$$

($E[(p_i - \epsilon_i)^2] = \text{Var}[\epsilon_i]$, the variance to be discussed in Chapter 4.) Thus

$$E[X] = \sum_{i=1}^n p_i(1 - p_i)|v_i|^2 \leq \frac{1}{4} \sum_{i=1}^n |v_i|^2 \leq \frac{n}{4}$$

and the proof concludes as in that of Theorem 2.4.1.

17.2.5 2.5 Unbalancing Lights

Theorem 2.5.1 Let $a_{ij} = \pm 1$ for $1 \leq i, j \leq n$. Then there exist $x_i, y_j = \pm 1$, $1 \leq i, j \leq n$ so that

$$\sum_{i=1}^n \sum_{j=1}^n a_{ij} x_i y_j \geq \left(\sqrt{\frac{2}{\pi}} + o(1) \right) n^{3/2}$$

This result has an amusing interpretation. Let an $n \times n$ array of lights be given, each either on ($a_{ij} = +1$) or off ($a_{ij} = -1$). Suppose for each row and each column there is a switch so that if the switch is pulled ($x_i = -1$ for row i and $y_j = -1$ for column j) all of the lights in that line are "switched": on to off or off to on. Then for any initial configuration it is possible to perform switches so that the number of lights on minus the number of lights off is at least $(\sqrt{2/\pi} + o(1))n^{3/2}$.

Proof. Forget the x 's. Let $y_1, \dots, y_n = \pm 1$ be selected independently and uniformly and set

$$R_i = \sum_{j=1}^n a_{ij} y_j, \quad R = \sum_{i=1}^n |R_i|.$$

Fix i . Regardless of a_{ij} , $a_{ij} y_j$ is ± 1 with probability $1/2$ and their values (over j) are independent; that is, whatever the i th row is initially after random switching it becomes a uniformly distributed row, all 2^n possibilities equally likely. Thus R_i has distribution S_n - the distribution of the sum of n independent uniform $\{-1, 1\}$ random variables - and so

$$E[|R_i|] = E[|S_n|] = \left(\sqrt{\frac{2}{\pi}} + o(1) \right) \sqrt{n}$$

These asymptotics may be found by estimating S_n by $\sqrt{n}N$, where N is standard normal and using elementary calculus. Alternatively, a closed form

$$E[|S_n|] = n2^{1-n} \binom{n-1}{\lfloor (n-1)/2 \rfloor}$$

may be derived combinatorially (a problem in the 1974 Putnam competition!) and the asymptotics follows from Stirling's formula.

Now apply linearity of expectation to R :

$$\mathbb{E}[R] = \sum_{i=1}^n \mathbb{E}[|R_i|] = \left(\sqrt{\frac{2}{\pi}} + o(1) \right) n^{3/2}.$$

There exist $y_1, \dots, y_n = \pm 1$ with R at least this value. Finally, pick x_i with the same sign as R_i so that

$$\sum_{i=1}^n x_i \sum_{j=1}^n a_{ij} y_j = \sum_{i=1}^n x_i R_i = \sum_{i=1}^n |R_i| = R \geq \left(\sqrt{\frac{2}{\pi}} + o(1) \right) n^{3/2}$$

Another result on unbalancing lights appears in The Probabilistic Lens: Unbalancing Lights (following Chapter 13). The existence of Hadamard matrices and the discussion in Section 9.1 show that the estimate in the last theorem cannot be improved to anything bigger than $n^{3/2}$.

17.2.6 2.6 Without Coin Flips

A non probabilistic proof of Theorem 2.2.1 may be given by placing each vertex in either T or B sequentially. At each stage place x in either T or B so that at least half of the edges from x to previous vertices are crossing. With this effective algorithm at least half the edges will be crossing.

There is also a simple sequential algorithm for choosing signs in Theorem 2.4.1. When the sign for v_i is to be chosen, a partial sum $w = \epsilon_1 v_1 + \dots + \epsilon_{i-1} v_{i-1}$ has been calculated. Now if it is desired that the sum be small select $\epsilon_i = \pm 1$ so that $\epsilon_i v_i$ makes an obtuse (or right) angle with w . If the sum need be big make the angle acute or right. In the extreme case when all angles are right angles, Pythagoras and induction give that the final w has norm $\sqrt{n}$, otherwise it is either less than $\sqrt{n}$ or greater than $\sqrt{n}$ as desired.

For Theorem 2.4.2 a greedy algorithm produces the desired ϵ_i . Given $v_1, \dots, v_n \in \mathbb{R}^n, p_1, \dots, p_n \in [0, 1]$ suppose $\epsilon_1, \dots, \epsilon_{s-1} \in \{0, 1\}$ have already been chosen. Set $w_{s-1} = \sum_{i=1}^{s-1} (p_i - \epsilon_i) v_i$, the partial sum. Select ϵ_s so that

$$w_s = w_{s-1} + (p_s - \epsilon_s) v_s = \sum_{i=1}^s (p_i - \epsilon_i) v_i$$

has minimal norm. A random $\epsilon_s \in \{0, 1\}$ chosen with $\Pr[\epsilon_s = 1] = p_s$ gives

$$\begin{aligned} \mathbb{E}[|w_s|^2] &= |w_{s-1}|^2 + 2w_{s-1} \cdot v_s \mathbb{E}[p_s - \epsilon_s] + |v_s|^2 \mathbb{E}[p_s - \epsilon_s]^2 \\ &= |w_{s-1}|^2 + p_s (1 - p_s) |v_s|^2 \end{aligned}$$

so for some choice of $\epsilon_s \in \{0, 1\}$,

$$|w_s|^2 \leq |w_{s-1}|^2 + p_s (1 - p_s) |v_s|^2.$$

As this holds for all $1 \leq s \leq n$ (taking $w_0 = 0$), the final

$$|w_n|^2 \leq \sum_{i=1}^n p_i (1 - p_i) |v_i|^2$$

While the proofs appear similar, a direct implementation of the proof of Theorem 2.4.2 to find $\epsilon_1, \dots, \epsilon_n$ might take an exhaustive search with exponential time. In applying the greedy algorithm at the s th stage one makes two calculations of $|w_s|^2$, depending on whether $\epsilon_s = 0$ or 1 , and picks that ϵ_s giving the smaller value. Hence there are only a linear number of calculations of norms to be made and the entire algorithm takes only quadratic time. In Chapter 16 we discuss several similar examples in a more general setting.

17.2.7 2.7 Exercises

1. Suppose $n \geq 2$ and let $H = (V, E)$ be an n -uniform hypergraph with $|E| = 4^{n-1}$ edges. Show that there is a coloring of V by four colors so that no edge is monochromatic.
2. Prove that there is a positive constant c so that every set A of n nonzero reals contains a subset $B \subset A$ of size $|B| \geq cn$ so that there are no $b_1, b_2, b_3, b_4 \in B$ satisfying

$$b_1 + 2b_2 = 2b_3 + 2b_4$$

3. Prove that every set of n non zero real numbers contains a subset A of strictly more than $n/3$ numbers such that there are no $a_1, a_2, a_3 \in A$ satisfying $a_1 + a_2 = a_3$.
4. Suppose $p > n > 10m^2$, with p prime, and let $0 < a_1 < a_2 < \dots < a_m < p$ be integers. Prove that there is an integer $x, 0 < x < p$ for which the m numbers

$$(xa_i \bmod p) \bmod n, \quad 1 \leq i \leq m$$

are pairwise distinct.

5. Let H be a graph, and let $n > |V(H)|$ be an integer. Suppose there is a graph on n vertices and t edges containing no copy of H , and suppose that $tk > n^2 \log_e n$. Show that there is a coloring of the edges of the complete graph on n vertices by k colors with no monochromatic copy of H .
6. (*) Prove, using the technique shown in The Probabilistic Lens: Hamiltonian Paths, that there is a constant $c > 0$ such that for every even $n \geq 4$ the following holds: For every undirected complete graph K on n vertices whose edges are colored red and blue, the number of alternating Hamiltonian cycles in K (i.e., properly edge-colored cycles of length n) is at most

$$n^c \frac{n!}{2^n}.$$

7. Let $\mathcal{F}$ be a family of subsets of $N = \{1, 2, \dots, n\}$, and suppose there are no $A, B \in \mathcal{F}$ satisfying $A \subset B$. Let $\sigma \in S_n$ be a random permutation of the elements of N and consider the random variable

$$X = |\{i : \{\sigma(1), \sigma(2), \dots, \sigma(i)\} \in \mathcal{F}\}|.$$

By considering the expectation of X prove that $|\mathcal{F}| \leq \binom{n}{\lfloor n/2 \rfloor}$.

8. (*) Let X be a collection of pairwise orthogonal unit vectors in $\mathbb{R}^n$ and suppose the projection of each of these vectors on the first k coordinates is of Euclidean norm at least ϵ . Show that $|X| \leq k/\epsilon^2$, and this is tight for all $\epsilon^2 = k/2^r < 1$.
9. Let $G = (V, E)$ be a bipartite graph with n vertices and a list $S(v)$ of more than $\log_2 n$ colors associated with each vertex $v \in V$. Prove that there is a proper coloring of G assigning to each vertex v a color from its list $S(v)$.

The Probabilistic Lens: Brégman's Theorem

Let $A = [a_{ij}]$ be an $n \times n$ matrix with all $a_{ij} \in \{0, 1\}$. Let $r_i = \sum_{1 \leq j \leq n} a_{ij}$ be the number of ones in the i th row. Let S be the set of permutations $\sigma \in S_n$ with $a_{i, \sigma i} = 1$ for $1 \leq i \leq n$. Then the permanent $\text{per}(A)$ is simply $|S|$. The following result was conjectured by Minc and proved by Brégman (1973). The proof presented here is similar to that of Schrijver (1978).

Theorem 1 [Brégman's Theorem] $\text{per}(A) \leq \prod_{1 \leq i \leq n} (r_i!)^{1/r_i}$.

Pick $\sigma \in S$ and $\tau \in S_n$ independently and uniformly. Set $A^{(1)} = A$. Let $R_{\tau 1}$ be the number of ones in row $\tau 1$ in $A^{(1)}$. Delete row $\tau 1$ and column $\sigma \tau 1$ from $A^{(1)}$ to give $A^{(2)}$. In general, let $A^{(i)}$ denote A with rows $\tau 1, \dots, \tau(i-1)$ and columns $\sigma \tau 1, \dots, \sigma \tau(i-1)$ deleted and let $R_{\tau i}$ denote the number of ones of row τi in $A^{(i)}$. (This is nonzero as the $\sigma \tau i$ th column has a one.) Set

$$L = L(\sigma, \tau) = \prod_{1 \leq i \leq n} R_{\tau i}$$

We think, roughly, of L as Lazyman's permanent calculation. There are $R_{\tau 1}$ choices for a one in row $\tau 1$, each of which leads to a different subpermanent calculation. Instead, Lazyman takes the factor $R_{\tau 1}$, takes the one from permutation σ , and examines $A^{(2)}$. As $\sigma \in S$ is chosen uniformly Lazyman tends toward the high subpermanents and so it should not be surprising that he tends to overestimate the permanent. To make this precise we define the geometric mean $G[Y]$. If $Y > 0$ takes values $a_1, \dots, a_s$ with probabilities $p_1, \dots, p_s$, respectively, then $G[Y] = \prod a_i^{p_i}$. Equivalently, $G[Y] = e^{\mathbb{E}[\ln Y]}$. Linearity of expectation translates into the geometric mean of a product being the product of the geometric means.

Claim 2.7.1 $\text{per}(A) \leq G[L]$.

Proof. We show this for any fixed τ . Set $\tau 1 = 1$ for convenience of notation. We use induction on the size of the matrix. Reorder, for convenience, so that the first row has ones in the first r columns, where $r = r_1$. For $1 \leq j \leq r$ let t_j be the permanent of A with the first row and j th column removed or, equivalently, the number of $\sigma \in S$ with $\sigma 1 = j$. Set

$$t = \frac{t_1 + \dots + t_r}{r}$$

so that $\text{per}(A) = rt$. Conditioning on $\sigma 1 = j$, $R_2 \cdots R_n$ is Lazyman's calculation of $\text{per}(A^{(2)})$, where $A^{(2)}$ is A with the first row and j th column removed. By induction

$$G[R_2 \cdots R_n \mid \sigma 1 = j] \geq t_j$$

and so

$$G[L] \geq \prod_{j=1}^r (rt_j)^{t_j / \text{per}(A)} = r \prod_{j=1}^r t_j^{t_j / rt}$$

Lemma 2 $\left(\prod_{j=1}^r t_j^{t_j} \right)^{1/r} \geq t^t$.

Proof. Taking logarithms, this is equivalent to

$$\frac{1}{r} \sum_{j=1}^r t_j \ln t_j \geq t \ln t$$

which follows from the convexity of the function $f(x) = x \ln x$.

Applying the lemma,

$$G[L] \geq r \prod_{j=1}^r t_j^{t_j / rt} \geq r (t^t)^{1/t} = rt = \text{per}(A)$$

Now we calculate $G[L]$ conditional on a fixed σ . For convenience of notation reorder so that $\sigma i = i$, all i , and assume that the first row has ones in precisely the first r_1 columns. With τ selected uniformly the columns $1, \dots, r_1$ are deleted in order uniform over all $r_1!$ possibilities. R_1 is the number of those columns remaining when the first column is to be deleted. As the first column is equally likely to be in any position among those r_1 columns R_1 is uniformly distributed from 1 to r_1 and $G[R_1] = (r_1!)^{1/r_1}$. "Linearity" then gives

$$G[L] = G\left[\prod_{i=1}^n R_i\right] = \prod_{i=1}^n G[R_i] = \prod_{i=1}^n (r_i!)^{1/r_i}$$

The overall $G[L]$ is the geometric mean of the conditional $G[L]$ and hence has the same value. That is,

$$\text{per}(A) \leq G[L] = \prod_{i=1}^n (r_i!)^{1/r_i}$$

17.3 3 Alterations

Beauty is the first test: there is no permanent place in the world for ugly mathematics.

- G. H. Hardy

The basic probabilistic method was described in Chapter 1 as follows: Trying to prove that a structure with certain desired properties exists, one defines an appropriate probability space of structures and then shows that the desired properties hold in this space with positive probability. In this chapter we consider situations where the "random" structure does not have all the desired properties but may have a few "blemishes." With a small alteration we remove the blemishes, giving the desired structure.

17.3.1 3.1 Ramsey Numbers

Recall from Section 1.1 that $R(k, l) > n$ means there exists a two-coloring of the edges of K_n by red and blue so that there is neither a red K_k nor a blue K_l .

Theorem 3.1.1 For any integer n , $R(k, k) > n - \binom{n}{k} 2^{1-\binom{k}{2}}$.

Proof. Consider a random two-coloring of the edges of K_n obtained by coloring each edge independently either red or blue, where each color is equally likely. For any set R of k vertices let X_R be the indicator random variable for the event that the induced subgraph of K_n on R is monochromatic. Set $X = \sum X_R$, the sum over all such R . By linearity of expectation, $E[X] = \sum E[X_R] = m$ with $m = \binom{n}{k} 2^{1-\binom{k}{2}}$. Thus there exists a two-coloring for which $X \leq m$. Fix such a coloring. Remove from K_n one vertex from each monochromatic k -set. At most m vertices have been removed (we may have "removed" the same vertex more than once but this only helps) so s vertices remain with $s \geq n - m$. This coloring on these s points has no monochromatic k -set.

We are left with the "calculus" problem of finding that n which will optimize the inequality. Some analysis shows that we should take $n \sim e^{-1} k 2^{k/2} (1 + o(1))$ giving

$$R(k, k) > \frac{1}{e} (1 + o(1)) k 2^{k/2}.$$

A careful examination of Proposition 1.1.1 gives the lower bound

$$R(k, k) > \frac{1}{e\sqrt{2}} (1 + o(1)) k 2^{k/2}$$

The more powerful Lovász Local Lemma (see Chapter 5) gives

$$R(k, k) > \frac{\sqrt{2}}{e}(1 + o(1))k2^{k/2}$$

The distinctions between these bounds may be considered inconsequential since the best known upper bound for $R(k, k)$ is $(4 + o(1))^k$. The upper bounds do not involve probabilistic methods and may be found, for example, in Graham, Rothschild and Spencer (1990). We give all three lower bounds in following our philosophy of emphasizing methodologies rather than results.

In dealing with the off-diagonal Ramsey numbers the distinction between the basic method and the alteration is given in the following two results.

Theorem 3.1.2 If there exists $p \in [0, 1]$ with

$$\binom{n}{k}p^{\binom{k}{2}} + \binom{n}{l}(1-p)^{\binom{l}{2}} < 1$$

then $R(k, l) > n$.

Theorem 3.1.3 For all integers n and $p \in [0, 1]$,

$$R(k, l) > n - \binom{n}{k}p^{\binom{k}{2}} - \binom{n}{l}(1-p)^{\binom{l}{2}}.$$

Proof. In both cases we consider a random two-coloring of K_n obtained by coloring each edge independently either red or blue, where each edge is red with probability p . Let X be the number of red k -sets plus the number of blue l -sets. Linearity of expectation gives

$$E[X] = \binom{n}{k}p^{\binom{k}{2}} + \binom{n}{l}(1-p)^{\binom{l}{2}}$$

For Theorem 3.1.2, $E[X] < 1$ so there exists a two-coloring with $X = 0$. For Theorem 3.1.3 there exists a two-coloring with s "bad" sets (either red k -sets or blue l -sets), $s \leq E[X]$. Removing one point from each bad set gives a coloring of at least $n - s$ points with no bad sets.

The asymptotics of Theorems 3.1.2 and 3.1.3 can get fairly complex. Oftentimes Theorem 3.1.3 gives a substantial improvement on Theorem 3.1.2. Even further improvements may be found using the Lovász Local Lemma. These bounds have been analyzed in Spencer (1977).

17.3.2 3.2 Independent Sets

Here is a short and sweet argument that gives roughly half of the celebrated Turán's Theorem. $\alpha(G)$ is the independence number of a graph G ; $\alpha(G) \geq t$ means there exist t vertices with no edges between them.

Theorem 3.2.1 Let $G = (V, E)$ have n vertices and $nd/2$ edges, $d \geq 1$. Then $\alpha(G) \geq n/2d$.

Proof. Let $S \subseteq V$ be a random subset defined by

$$\Pr[v \in S] = p$$

p to be determined, the events $v \in S$ being mutually independent. Let $X = |S|$ and let Y be the number of edges in $G|_S$. For each $e = \{i, j\} \in E$ let Y_e be the indicator random variable for the event $i, j \in S$ so that $Y = \sum_{e \in E} Y_e$. For any such e ,

$$E[Y_e] = \Pr[i, j \in S] = p^2,$$

so by linearity of expectation,

$$E[Y] = \sum_{e \in E} E[Y_e] = \frac{nd}{2} p^2$$

Clearly $E[X] = np$, so, again by linearity of expectation,

$$E[X - Y] = np - \frac{nd}{2} p^2$$

We set $p = 1/d$ (here using $d \geq 1$) to maximize this quantity, giving

$$E[X - Y] = \frac{n}{2d}$$

Thus there exists a specific S for which the number of vertices of S minus the number of edges in S is at least $n/2d$. Select one vertex from each edge of S and delete it. This leaves a set S^* with at least $n/2d$ vertices. All edges having been destroyed, S^* is an independent set.

The full result of Turán is given in The Probabilistic Lens: Turán's Theorem (following Chapter 6).

17.3.3 3.3 Combinatorial Geometry

For a set S of n points in the unit square U , let $T(S)$ be the minimum area of a triangle whose vertices are three distinct points of S . Put $T(n) = \max T(S)$, where S ranges over all sets of n points in U . Heilbronn conjectured that $T(n) = O(1/n^2)$. This conjecture was disproved by Komlós, Pintz and Szemerédi (1982) who showed, by a rather involved probabilistic construction, that there is a set S of n points in U such that $T(S) = \Omega(\log n/n^2)$. As this argument is rather complicated, we only present here a simpler one showing that $T(n) = \Omega(1/n^2)$.

Theorem 3.3.1 There is a set S of n points in the unit square U such that $T(S) \geq 1/(100n^2)$.

Proof. We first make a calculation. Let P, Q, R be independently and uniformly selected from U and let $\mu = \mu(PQR)$ denote the area of the triangle PQR . We bound $\Pr[\mu \leq \epsilon]$ as follows. Let x be the distance from P to Q so that

$$\Pr[b \leq x \leq b + \Delta b] \leq \pi(b + \Delta b)^2 - \pi b^2$$

and in the limit $\Pr[b \leq x \leq b + db] \leq 2\pi b db$. Given P, Q at distance b , the altitude from R to the line PQ must have height $h \leq 2\epsilon/b$ and so R must lie in a strip of width $4\epsilon/b$ and length at most $\sqrt{2}$. This occurs with probability at most $4\sqrt{2}\epsilon/b$. As $0 \leq b \leq \sqrt{2}$ the total probability is bounded by

$$\int_0^{\sqrt{2}} (2\pi b)(4\sqrt{2}\epsilon/b) db = 16\pi\epsilon$$

Now let $P_1, \dots, P_{2n}$ be selected uniformly and independently in U and let X denote the number of triangles $P_i P_j P_k$ with area less than $1/(100n^2)$. For each particular i, j, k the probability of this occurring is less than $0.6n^{-2}$ and so

$$E[X] \leq \binom{2n}{3} (0.6n^{-2}) < n$$

Thus there exists a specific set of $2n$ vertices with fewer than n triangles of area less than $1/(100n^2)$. Delete one vertex from the set from each such triangle. This leaves at least n vertices and now no triangle has area less than $1/(100n^2)$.

We note the following construction of Erdős showing $T(n) \geq 1/(2(n-1)^2)$ with n prime. On $[0, n-1] \times [0, n-1]$ consider the n points (x, x^2) , where x^2 is reduced mod n (more formally,

(x, y) where $y \equiv x^2 \pmod n$ and $0 \leq y < n$). If some three points of this set were collinear they would line on a line $y = mx + b$ and m would be a rational number with denominator less than n . But then in $\mathbb{Z}_n^2$ the parabola $y = x^2$ would intersect the line $y = mx + b$ at three points, so that the quadratic $x^2 - mx - b$ would have three distinct roots, an impossibility. Triangles between lattice points in the plane have as their areas either half-integers or integers, hence the areas must be at least $1/2$. Contracting the plane by an $n - 1$ factor in both coordinates gives the desired set. While this gem does better than Theorem 3.3.1 it does not lead to the improvements of Komlós, Pintz and Szemerédi.

17.3.4 3.4 Packing

Let C be a bounded measurable subset of $\mathbb{R}^d$ and let $B(x)$ denote the cube $[0, x]^d$ of side x . A packing of C into $B(x)$ is a family of mutually disjoint copies of C , all lying inside $B(x)$. Let $f(x)$ denote the largest size of such a family. The packing constant $\delta = \delta(C)$ is defined by

$$\delta(C) = \mu(C) \lim_{x \rightarrow \infty} f(x)x^{-d}$$

where $\mu(C)$ is the measure of C . This is the maximal proportion of space that may be packed by copies of C (this limit can be proved always to exist but even without that result the following result holds with $\lim$ replaced by $\liminf$.)

Theorem 3.4.1 Let C be bounded, convex and centrally symmetric around the origin. Then $\delta(C) \geq 2^{-d-1}$.

Proof. Let P, Q be selected independently and uniformly from $B(x)$ and consider the event $(C + P) \cap (C + Q) \neq \emptyset$. For this to occur we must have, for some $c_1, c_2 \in C$,

$$P - Q = c_1 - c_2 = 2 \frac{c_1 - c_2}{2} \in 2C$$

by central symmetry and convexity. The event $P \in Q + 2C$ has probability at most $\mu(2C)x^{-d}$ for each given Q , hence

$$\Pr[(C + P) \cap (C + Q) \neq \emptyset] \leq \mu(2C)x^{-d} = 2^d x^{-d} \mu(C).$$

Now let $P_1, \dots, P_n$ be selected independently and uniformly from $B(x)$ and let X be the number of $i < j$ with $(C + P_i) \cap (C + P_j) \neq \emptyset$. From linearity of expectation,

$$\mathbb{E}[X] \leq \frac{n^2}{2} 2^d x^{-d} \mu(C)$$

Hence there exists a specific choice of n points with fewer than that many intersecting copies of C . For each P_i, P_j with $(C + P_i) \cap (C + P_j) \neq \emptyset$ remove either P_i or P_j from the set. This leaves at least $n - (n^2/2) 2^d x^{-d} \mu(C)$ nonintersecting copies of C . Set $n = x^d 2^{-d} / \mu(C)$ to maximize this quantity, so that there are at least $x^d 2^{-d-1} / \mu(C)$ nonintersecting copies of C . These do not all lie inside $B(x)$ but, letting w denote an upper bound on the absolute values of the coordinates of the points of C , they do all lie inside a cube of side $x + 2w$. Hence

$$f(x + 2w) \geq x^d 2^{-d-1} / \mu(C)$$

and so $\delta(C) \geq \lim_{x \rightarrow \infty} \mu(C) f(x + 2w)(x + 2w)^{-d} \geq 2^{-d-1}$.

A simple greedy algorithm does somewhat better. Let $P_1, \dots, P_m$ be any maximal subset of $[0, x]^d$ with the property that the sets $C + P_i$ are disjoint. We have seen that $C + P_i$ overlaps $C + P$ if and only if $P \in 2C + P_i$. Hence the sets $2C + P_i$ must cover $[0, x]^d$. As each such set

has measure $\mu(2C) = 2^d \mu(C)$ we must have $m \geq x^d 2^{-d} / \mu(C)$. As before, all sets $C + P_i$ lie in a cube of side $x + 2w$, w a constant, so that

$$f(x + 2w) \geq m \geq x^d 2^{-d} / \mu(C)$$

and so

$$\delta(C) \geq 2^{-d}$$

A still further improvement appears in *The Probabilistic Lens: Efficient Packing* (following Chapter 14).

17.3.5 3.5 Recoloring

Suppose that a random coloring leaves a set of blemishes. Here we apply a random recoloring to the blemishes to remove them. If the recoloring is too weak then not all the blemishes are removed. If the recoloring is too strong then new blemishes are created. The recoloring is given a parameter p and these two possibilities are decreasing and increasing functions of p . Calculus then points us to the optimal p .

We use the notation of Section 1.3 on property B: $m(n) > m$ means that given any n -uniform hypergraph $H = (V, E)$ with m edges there exists a two-coloring of V so that no edge is monochromatic. Beck (1978) improved Erdős' 1963 bound to $m(n) = \Omega(2^n n^{1/3})$. Building on his methods, Radhakrishnan and Srinivasan (2000) proved $m(n) = \Omega(2^n (n/\ln n)^{1/2})$ and it is that proof we shall give. While this proof is neither long nor technically complex it has a number of subtle and beautiful steps and it is not surprising that it took more than thirty-five years to find it. That said, the upper and lower bounds on $m(n)$ remain quite far apart!

Theorem 3.5.1 If there exists $p \in [0, 1]$ with $k(1-p)^n + k^2 p < 1$ then $m(n) > 2^{n-1} k$.

Corollary 3.5.2 $m(n) = \Omega(2^n (n/\ln n)^{1/2})$.

Proof. Bound $1 - p \leq e^{-p}$. The function $ke^{-pn} + k^2 p$ is minimized at $p = \ln(n/k)/n$. Substituting back in, if

$$\frac{k^2}{n}(1 + \ln(n/k)) < 1$$

then the condition of Theorem 3.5.1 holds. This inequality is true when $k = c(n/\ln n)^{1/2}$ for any $c < \sqrt{2}$ with n sufficiently large.

The condition of Theorem 3.5.1 is somewhat typical; one wants the total failure probability to be less than 1 and there are two types of failure. Oftentimes one finds reasonable bounds by requiring the stronger condition that each failure type has probability less than one-half. Here $k^2 p \leq \frac{1}{2}$ gives $p \leq \frac{1}{2} k^{-2}$. Plugging the maximal possible p into the second inequality $k(1-p)^n \leq \frac{1}{2}$ gives $2k^2 \ln(2k) \leq n$. This again holds when $k = c(n/\ln n)^{1/2}$ though now we have the weaker condition $c < 1$. We recommend this rougher approach as a first attempt at a problem, when the approximate range of the parameters is still in doubt. The refinements of calculus can be placed in the published work!

Proof [Theorem 3.5.1]. Fix $H = (V, E)$ with $m = 2^{n-1} k$ edges and p satisfying the condition. We describe a randomized algorithm that yields a coloring of V . It is best to preprocess the randomness: Each $v \in V$ flips a first coin, which comes up heads with probability $\frac{1}{2}$ and a second coin, which comes up heads (representing potential recoloration) with probability p . In addition (and importantly), the vertices of V are ordered randomly.

Step 1. Color each $v \in V$ red if its first coin was heads, otherwise blue. Call this the first coloring. Let D (for dangerous) denote the set of $v \in V$ that lie in some (possibly many) monochromatic $e \in E$.

Step 2. Consider the elements of D sequentially in the (random) order of V . When d is being considered call it still dangerous if there is some (possibly many) $e \in H$ containing d that was monochromatic in the first coloring and for which no vertices have yet changed color. If d is not still dangerous then do nothing. But if it is still dangerous then check its second coin. If it is heads then change the color of d , otherwise do nothing. We call the coloring at the time of termination the final coloring.

We say the algorithm fails if some $e \in H$ is monochromatic in the final coloring. We shall bound the failure probability by $k(1-p)^n + k^2p$. The assumption of Theorem 3.5.1 then assures us that with positive probability the algorithm succeeds. This, by our usual magic, means that there is some running of the algorithm which yields a final coloring with no monochromatic e ; that is, there exists a two-coloring of V with no monochromatic edge. For convenience, we bound the probability that some $e \in H$ is red in the final coloring; the failure probability for the algorithm is at most twice that.

An $e \in E$ can be red in the final coloring in two ways. Either e was red in the first coloring and remained red through to the final coloring or e was not red in the first coloring but was red in the final coloring (the structure of the algorithm assures us that vertices cannot change color more than once). Let A_e be the first event and C_e the second. Then

$$\Pr[A_e] = 2^{-n}(1-p)^n.$$

The first factor is the probability e is red in the first coloring, that all first coins of e came up heads. The second factor is the probability that all second coins came up tails. If they all did, then no $v \in e$ would be recolored in Step 2. Inversely, if any second coins of $v \in e$ came up heads there would be a first v (in the ordering) that came up heads. When it did v was still dangerous as e was still monochromatic and so v does look at its second coin and change its color. We have

$$2 \sum_{e \in H} \Pr[A_e] = k(1-p)^n$$

giving the first addend of our failure probability.

In Beck's 1978 proof, given in our first edition, there was no notion of "still dangerous" - every $d \in D$ changed its color if and only if its second coin was heads. The values $\Pr[A_e] = 2^{-n}(1-p)^n$ are the same in both arguments. Beck's had bounded $\Pr[C_e] \leq k^2pe^{pn}$. The new argument avoids excessive recoloration and leads to a better bound on $\Pr[C_e]$. We turn to the ingenious bounding of $\Pr[C_e]$.

For distinct $e, f \in E$ we say e blames f if:

- e, f overlap in precisely one element. Call it v .
- In the first coloring f was blue and in the final coloring e was red.
- In Step 2 v was the last vertex of e that changed color from blue to red.
- When v changed its color f was still entirely blue.

Suppose C_e holds. Some points of e changed color from blue to red so there is a last point v that did so. But why did v flip its coin? It must have been still dangerous. That is, v must be in some (perhaps many) set f that was blue in the first coloring and was still blue when v was considered. Can e, f overlap in another vertex v' ? No! For such a v' would necessarily have been blue in the first coloring (as $v' \in f$) and red in the final coloring (as $v' \in e$), but then v' changed color before v . Hence f was no longer entirely blue when v was considered,

contradicting the assumption on f . Therefore, when C_e holds, e blames some f . Let B_{ef} be the event that e blames f . Then $\sum_e \Pr[C_e] \leq \sum_{e \neq f} \Pr[B_{ef}]$. As there are less than $(2^{n-1}k)^2$ pairs $e \neq f$ it now suffices to bound $\Pr[B_{ef}] \leq 2^{1-2n}p$.

Let e, f with $e \cap f = \{v\}$ (otherwise B_{ef} cannot occur) be fixed. The random ordering of V induces a random ordering σ of $e \cup f$. Let $i = i(\sigma)$ denote the number of $v' \in e$ coming before v in the ordering and let $j = j(\sigma)$ denote the number of $v' \in f$ coming before v in the ordering. Fixing σ we claim

$$\Pr[B_{ef} \mid \sigma] \leq \frac{p}{2} 2^{-n+1} (1-p)^j 2^{-n+1+i} \left(\frac{1+p}{2} \right)^i$$

Let's take the factors one at a time. First, v itself must start blue and turn red. Second, all other $v' \in f$ must start blue. Third, all $v' \in f$ coming before v must have second coin tails. Fourth, all $v' \in e$ coming after v must start red (since v is the last point of e to change color). Finally, all $v' \in e$ coming before v must either start red or start blue and turn red. [The final factor may well be a substantial overestimate. Those $v' \in e$ coming before v which start blue must not only have second coin heads but must themselves lie in an $e' \in H$ monochromatic under the first coloring. Attempts to further improve bounds on $m(n)$ have often centered on this overestimate but (thus far!) to no avail.]

We can then write

$$\Pr[B_{ef}] \leq 2^{1-2n} p \mathbb{E}[(1+p)^i (1-p)^j],$$

where the expectation is over the uniform choice of σ . The following gem therefore completes the argument.

Lemma 3.5.3 $\mathbb{E}[(1+p)^i (1-p)^j] \leq 1$.

Proof. Fix a matching between $e - \{v\}$ and $f - \{v\}$; think of Mr. & Mrs. Jones, Mr. & Mrs. Smith, and so on. Condition on how many of each pair (two Joneses, one Smith, no Taylors, etc.) come before v . This splits the space into 3^{n-1} parts, and it suffices to show that the conditional expectation in each of them is at most 1. Indeed, the factor contributed to $(1+p)^i (1-p)^j$ from each pair is at most 1, as follows: when there is no Taylor there is no factor. When there are two Joneses there is a factor $(1+p)(1-p) \leq 1$. When there is one Smith the factor is equally likely to be $1+p$ (Brad) or $1-p$ (Angelina), giving a factor of one. Moreover, these factors are independent for different pairs (given the above conditioning). All factors are at most one, and hence so is their product. $\square$

The desired result follows. $\square$

17.3.6 3.6 Continuous Time

Discrete random processes can sometimes be analyzed by placing them in a continuous time framework. This allows the powerful methods of analysis (such as integration!) to be applied. The approach seems most effective when dealing with random orderings. We give two examples.

Property B. We modify the proof that $m(n) = \Omega(2^n n^{1/2} \ln^{-1/2} n)$ of the previous section. We assign to each vertex $v \in V$ a "birth time" x_v . The x_v are independent real variables, each uniform in $[0, 1]$. The ordering of V is then the ordering (under less than) of the x_v . We now claim

$$\Pr[B_{ef}] \leq \sum_{l=0}^{n-1} \binom{n-1}{l} 2^{1-2n} \int_0^1 x^l p^{l+1} (1-xp)^{n-1} dx.$$

For $T \subseteq e - \{v\}$ let B_{efT} be the event that B_{ef} and in the first coloring e had precisely $T \cup \{v\}$ blue. There are $\binom{n-1}{l}$ choices for an l -set T , with l ranging from 0 to $n-1$. The first

coloring on $e \cup f$ is then determined and has probability 2^{1-2n} of occurring. Suppose v has birth time $x_v = x$. All $w \in T \cup \{v\}$ must have second coin flip heads - probability p^{l+1} . All $w \in T$ must be born before v - so that $x_w < x$, which has probability x^l . No $w \in f - \{v\}$ can be born before v and have coin flip heads. Each such w has probability xp of doing that so there is probability $(1 - xp)^{n-1}$ that no w does. As $x_v = x$ was uniform in $[0, 1]$ we integrate over x . Recombining terms,

$$\Pr[B_{ef}] \leq 2^{1-2n} p \int_0^1 (1 + xp)^{n-1} (1 - xp)^{n-1} dx$$

The integrand is always at most one so $\Pr[B_{ef}] \leq 2^{1-2n} p$. The remainder of the proof is unchanged.

Random Greedy Packing. Let H be a $(k + 1)$ -uniform hypergraph on a vertex set V of size N . The $e \in H$, which we call edges, are simply subsets of V of size $k + 1$. We assume:

Degree Condition: Every $v \in V$ is in precisely D edges.

Codegree Condition: Every distinct pair $v, v' \in V$ have only $o(D)$ edges in common.

We think of k fixed ($k = 2$ being an illustrative example) and the asymptotics as $N, D \rightarrow \infty$, with no set relationship between N and D .

A packing is a family P of vertex disjoint edges $e \in H$. Clearly $|P| \leq N/(k + 1)$. We define a randomized algorithm to produce a (not necessarily optimal) packing. Assign to each $e \in H$ uniformly and independently a birth time $x_e \in [0, D)$. [The choice of $[0, D)$ rather than $[0, 1]$ proves to be a technical convenience. Note that as the x_e are real variables with probability one there are no ties.] At time zero $P \leftarrow \emptyset$. As time progresses from 0 to D when an edge e is born it is added to P if possible that is, unless there is already some $e' \in P$ that overlaps e . Let P_c denote the value of P just before time c - when all e with birth times $t_e < c$ have been examined. Set $P^{\text{FINAL}} = P_D$. Note that by time D all edges have been born and their births were in random order. Thus P^{FINAL} is identical to the discrete process - often called the random greedy algorithm - in which H is first randomly ordered and then the $e \in H$ are considered sequentially.

Theorem 3.6.1 [Spencer (1995)] The expected value of $|P^{\text{FINAL}}|$ is asymptotic to $N/(k + 1)$.

We say $v \in V$ survives at time c if no $e \in P_c$ contains v and we let S_c denote the set of $v \in V$ so surviving. Rather than looking at P^{FINAL} we shall examine P_c , where c is an arbitrary fixed nonnegative real. Let

$$f(c) = \lim^* \Pr[v \in S_c],$$

where, formally, we mean here that for all $\epsilon > 0$ there exist D_0, N_0 and $\delta > 0$ so that if H is $(k + 1)$ -uniform on $N > N_0$ vertices with each v in $D > D_0$ edges and every distinct pair $v, v' \in V$ has less than δD , common edges then $|f(c) - \Pr[v \in S_c]| < \epsilon$ for all $v \in V$.

The heart of the argument lies in showing that $f(c)$ exists by defining a continuous time birth process yielding that value. We now describe the birth process, omitting some of the epsilon-delta-manship needed to formally show the limit.

Our birth process starts at time c and time goes backwards to 0. It begins with root Eve, our anthropomorphized v . Eve has births in time interval $[0, c)$. The number of births is given by a Poisson distribution with mean c and given their number their times are uniformly and independently distributed. [This is a standard Poisson process with intensity one. Equivalently, on any infinitesimal time interval $[x, x + dx)$, Eve has probability dx of giving birth and these events are independent over disjoint intervals.] Our fertile Eve always gives birth to k -tuplets. Each child is born fertile under the same rules, so if Alice is born at time x she (in our unisexual model) has a Poisson distribution with mean x of births, uniformly distributed in $[0, x)$.

The resulting random tree $T = T_c$ can be shown to be finite (note the time interval is finite) with probability 1. Given a finite T we say for each vertex Alice that Alice survives or dies according to the following scheme.

Menendez Rule: If Alice has given birth to a set (or possibly several sets) of k -tuplets all of whom survived then she dies; otherwise she survives.

In particular, if Alice is childless she survives. We can then work our way up the tree to determine of each vertex whether she survives or dies.

Example. $c = 10, k = 2$. Eve gives birth to Alice, Barbara at time 8.3 and then to Rachel, Siena at time 4.3. Alice gives birth to Nancy, Olive at time 5.7 and Rachel gives birth to Linda, Mayavati at time 0.4. There are no other births. Leaves Nancy, Olive, Linda, Mayavati, Barbara and Siena then survive. Working up the tree Alice and Rachel die. In neither of Eve's births did both children survive and therefore Eve survives.

We define $f(c)$ to be the probability that the root Eve survives in the random birth tree $T = T_c$.

We outline the equivalence by defining a tree $T = T_c(v)$ for $v \in H$. For each edge e containing v with birth time $t = t_e < c$ we say that $e - \{v\}$ is a set of k -tuplets born to v at time t . We work recursively; if w is born at time t then for each e' containing w with birth time $t' = t_{e'} < t$ we say that $e' - \{w\}$ is a set of k -tuplets born to w at time t' . Possibly this process does not give a tree since the same vertex w may be reached in more than one way - the simplest example is if $v \in e, e'$ where both have birth times less than c and e, e' share another common vertex w . Then the process is stillborn and $T_c(v)$ is not defined. We'll argue that for any particular tree T ,

$$\lim^* \Pr [T_c(v) \cong T] = \Pr [T_c = T] \quad (3.1)$$

As $\sum_T \Pr [T_c = T] = 1$ this gives a rather roundabout argument that the process defining $T_c(v)$ is almost never stillborn.

We find $T_c(v)$ in stages. First consider the D edges e containing v . The number of them with birth time $t_e < c$ has binomial distribution $\text{BIN}[D, c/D]$ which approaches (critically) the Poisson distribution with mean c . Given that there are l such e their birth times t_e are uniformly distributed. There are (by the codegree condition) $o(D^2)$ pairs e, e' containing v and also some other vertex so there is probability $o(1)$ that two such e, e' have birth time less than c . Now suppose $T_c(v)$ has been built out to a certain level and a vertex w has been born at time t . There are only $o(D)$ common edges between w and any of the finite number of w' already born, so there are still about D edges e containing w and no other such w' . We now examine their birth times, the number with $t_e < x$ has binomial distribution $\text{BIN}[D - o(D), x/D]$ which approaches the Poisson distribution with mean x . As above, almost surely no two such e, e' will have a common vertex other than w itself. For any fixed T the calculation of $\Pr [T_c(v) \cong T]$ involves a finite number of these limits, which allows us to conclude (3.1).

With $c < d$ the random tree T_d includes T_c as a subtree by considering only those births of Eve occurring in $[0, c)$. If Eve survives in T_d she must survive in T_c . Hence $f(d) \leq f(c)$. We now claim

$$\lim_{c \rightarrow \infty} f(c) = 0$$

If not, the nondecreasing f would have a limit $L > 0$ and all $f(x) \geq L$. Suppose in T_c Eve had i births. In each birth there would be probability at least L^k that all k children survived. The probability that Eve survived would then be at most $(1 - L^k)^i$. Since the number of Eve's births is Poisson with mean c ,

$$f(c) \leq \sum_{i=0}^{\infty} e^{-c} \frac{c^i}{i!} (1 - L^k)^i = e^{-L^k c}$$

but then $\lim_{c \rightarrow \infty} f(c) = 0$, a contradiction.

By linearity of expectation $E[|S_c|] \rightarrow f(c)n$. As $(k+1)|P_c| + |S_c| = n$, $E[|P_c|] \rightarrow (1 - f(c))n/(k+1)$. But $E[|P^{\text{FINAL}}|] \geq E[|P_c|]$. We make $f(c)$ arbitrarily small by taking c appropriately big, so that $E[|P^{\text{FINAL}}|] \geq (1 - o(1))n/(k+1)$. As $|P^{\text{FINAL}}| \leq n/(k+1)$ always, the theorem follows.

Remark. We can actually say more about $f(c)$. For Δc small, $f(c + \Delta c) - f(c) \sim -(\Delta c)f(c)^{k+1}$ as, roughly, an Eve starting at time $c + \Delta c$ might have a birth in time interval $[c, c + \Delta c)$, all of whose children survive, while Eve has no births in $[0, c)$, all of whose children survive. Letting $\Delta c \rightarrow 0$ yields the differential equation $f'(c) = -f(c)^{k+1}$. The initial value $f(0) = 1$ gives a unique solution $f(c) = (1 + ck)^{-1/k}$. It is intriguing to plug in $c = D$. This is not justified as our limit arguments were for c fixed and $N, D \rightarrow \infty$. Nonetheless, that would yield $E[|S_D|] = O(ND^{-1/k})$, that the random greedy algorithm would leave $O(ND^{-1/k})$ vertices uncovered. Suppose we replace the codegree condition by the stronger condition that every distinct pair $v, v' \in V$ have at most one edge in common. There is computer simulation data that in those cases the random greedy algorithm does leave $O(ND^{-1/k})$ vertices uncovered. This remains an open question, though it is shown in Alon, Kim and Spencer (1997) that this is the case for a modified version of the greedy algorithm.

Corollary 3.6.2 Under the assumptions of the theorem there exists a packing P of size $\sim N/(k+1)$.

Proof. We have defined a random process that gives a packing with expected size $\sim N/(k+1)$ and our usual magic implies such a P must exist.

In particular, this gives an alternate proof to the Erdős-Hanani conjecture, first proved by Rödl as given in Section 4.7. We use the notation of that section and define the packing number $m(n, k, l)$ as the maximal size of a family F of k -element subsets of $[n] = \{1, \dots, n\}$ such that no l -set is contained in more than one k -set. Define a hypergraph $H = H(n, k, l)$ as follows: The vertices of H are the l -element subsets of $[n]$. For each k -element $A \subset [n]$ we define an edge e_A as the set of l -element subsets of A . A family F satisfying the above conditions then corresponds to a packing $P = \{e_A : A \in F\}$ in H . H has $N = \binom{n}{l}$ vertices. Each edge e_A has size $K + 1 = \binom{k}{l}$. Each vertex is in $D = \binom{n-l}{k-l}$ edges. The number of edges containing two vertices v, v' depends on their intersection. It is largest (given $v \neq v'$) when v, v' (considered as l -sets) overlap in $l - 1$ points and then it is $\binom{n-l-1}{k-l-1}$. We assume (as in Section 4.7) that k, l are fixed and $n \rightarrow \infty$ so this number of common edges is $o(D)$. The assumptions of Section 4.7 give $K + 1$ fixed, $N, D \rightarrow \infty$ so that there exists P with

$$m(n, k, l) = |P| \sim N/(K + 1) \sim \binom{n}{l} / \binom{k}{l}.$$

17.3.7 3.7 Exercises

1. As shown in Section 3.1, the Ramsey number $R(k, k)$ satisfies

$$R(k, k) > n - \binom{n}{k} 2^{1 - \binom{k}{2}}$$

for every integer n . Conclude that

$$R(k, k) \geq (1 - o(1)) \frac{k}{e} 2^{k/2}$$

2. Prove that the Ramsey number $R(4, k)$ satisfies

$$R(4, k) \geq \Omega((k/\ln k)^2)$$

3. Prove that every three-uniform hypergraph with n vertices and $m \geq n/3$ edges contains an independent set (i.e., a set of vertices containing no edges) of size at least

$$\frac{2n^{3/2}}{3\sqrt{3}\sqrt{m}}$$

4. (*) Show that there is a finite n_0 such that any directed graph on $n > n_0$ vertices in which each outdegree is at least $\log_2 n - \frac{1}{10} \log_2 \log_2 n$ contains an even simple directed cycle.

The Probabilistic Lens: High Girth and High Chromatic Number

Many consider this one of the most pleasing uses of the probabilistic method, as the result is surprising and does not appear to call for nonconstructive techniques. The girth of a graph G is the size of its shortest cycle, $\alpha(G)$ is the size of the largest independent set in G and $\chi(G)$ denotes its chromatic number.

Theorem 1 [Erdős (1959)] For all k, l there exists a graph G with girth $(G) > l$ and $\chi(G) > k$.

Proof. Fix $\theta < 1/l$ and let $G \sim G(n, p)$ with $p = n^{\theta-1}$; that is, G is a random graph on n vertices chosen by picking each pair of vertices as an edge randomly and independently with probability p . Let X be the number of cycles of size at most l . Then

$$\mathbb{E}[X] = \sum_{i=3}^l \frac{\binom{n}{i}}{2i} p^i \leq \sum_{i=3}^l \frac{n^{\theta i}}{2i} = o(n)$$

as $\theta l < 1$. In particular,

$$\Pr[X \geq n/2] = o(1).$$

Set $x = \lceil (3/p) \ln n \rceil$ so that

$$\Pr[\alpha(G) \geq x] \leq \binom{n}{x} (1-p)^{\binom{x}{2}} < [ne^{-p(x-1)/2}]^x = o(1).$$

Let n be sufficiently large so that both these events have probability less than 0.5. Then there is a specific G with less than $n/2$ cycles of length at most l and with $\alpha(G) < 3n^{1-\theta} \ln n$. Remove from G a vertex from each cycle of length at most l . This gives a graph G^* with at least $n/2$ vertices. G^* has girth greater than l and $\alpha(G^*) \leq \alpha(G)$. Thus

$$\chi(G^*) \geq \frac{|G^*|}{\alpha(G^*)} \geq \frac{n/2}{3n^{1-\theta} \ln n} = \frac{n^\theta}{6 \ln n}.$$

To complete the proof, let n be sufficiently large so that this is greater than k . $\square$

17.4 4 The Second Moment

You don't have to believe in God but you should believe in The Book.

- Paul Erdős

17.4.1 4.1 Basics

After the expectation the most vital statistic for a random variable X is the variance. We denote it $\text{Var}[X]$. It is defined by

$$\text{Var}[X] = \text{E}[(X - \text{E}[X])^2]$$

and measures how spread out X is from its expectation. We shall generally, following standard practice, let μ denote expectation and σ^2 denote variance. The positive square root σ of the variance is called the standard deviation. With this notation, here is our basic tool.

Theorem 4.1.1 [Chebyshev's Inequality] For any positive λ ,

$$\Pr[|X - \mu| \geq \lambda\sigma] \leq \frac{1}{\lambda^2}.$$

Proof. $\sigma^2 = \text{Var}[X] = \text{E}[(X - \mu)^2] \geq \lambda^2\sigma^2 \Pr[|X - \mu| \geq \lambda\sigma]$. $\square$

The use of Chebyshev's Inequality is called the second moment method.

Chebyshev's Inequality is most possible when no additional restrictions are placed on X as X may be $\mu + \lambda\sigma$ and $\mu - \lambda\sigma$ with probability $1/2\lambda^2$ and otherwise μ . Note, however, that when X is a normal distribution with mean μ and standard deviation σ then

$$\Pr[|X - \mu| \geq \lambda\sigma] = 2 \int_{\lambda}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-t^2/2} dt$$

and for λ large this quantity is asymptotically $\sqrt{2/\pi} e^{-\lambda^2/2}/\lambda$, which is significantly smaller than $1/\lambda^2$. In Chapters 7 and 8 we shall see examples where X is the sum of "nearly independent" random variables and these better bounds can apply.

Suppose we have a decomposition

$$X = X_1 + \cdots + X_m.$$

Then $\text{Var}[X]$ may be computed by the formula

$$\text{Var}[X] = \sum_{i=1}^m \text{Var}[X_i] + \sum_{i \neq j} \text{Cov}[X_i, X_j]$$

Here the second sum is over ordered pairs and the covariance $\text{Cov}[Y, Z]$ is defined by

$$\text{Cov}[Y, Z] = \text{E}[YZ] - \text{E}[Y]\text{E}[Z]$$

In general, if Y, Z are independent then $\text{Cov}[Y, Z] = 0$. This often simplifies variance calculations considerably. Now suppose further, as will generally be the case in our applications, that the X_i are indicator random variables; that is, $X_i = 1$ if a certain event A_i holds and otherwise $X_i = 0$. If X_i is one with probability $p_i = \Pr[A_i]$ then

$$\text{Var}[X_i] = p_i(1 - p_i) \leq p_i = \text{E}[X_i],$$

and so

$$\text{Var}[X] \leq \text{E}[X] + \sum_{i \neq j} \text{Cov}[X_i, X_j].$$

17.4.2 4.2 Number Theory

The second moment method is an effective tool in number theory. Let $\nu(n)$ denote the number of primes p dividing n . (We do not count multiplicity though it would make little difference.) The following result says, roughly, that "almost all" n have "very close to" $\ln \ln n$ prime factors. This was first shown by Hardy and Ramanujan in 1920 by a quite complicated argument. We give a remarkably simple proof of Turán (1934), a proof that played a key role in the development of probabilistic methods in number theory.

Theorem 4.2.1 Let $\omega(n) \rightarrow \infty$ arbitrarily slowly. Then the number of x in $\{1, \dots, n\}$ such that

$$|\nu(x) - \ln \ln n| > \omega(n) \sqrt{\ln \ln n}$$

is $o(n)$.

Proof. Let x be randomly chosen from $\{1, \dots, n\}$. For p prime set

$$X_p = \begin{cases} 1 & \text{if } p \mid x \\ 0 & \text{otherwise} \end{cases}$$

Set $M = n^{1/10}$ and set $X = \sum X_p$, the summation over all primes $p \leq M$. As no $x \leq n$ can have more than ten prime factors larger than M we have $\nu(x) - 10 \leq X(x) \leq \nu(x)$ so that large deviation bounds on X will translate into asymptotically similar bounds for ν . [Here 10 could be any (large) constant.] Now

$$\mathbb{E}[X_p] = \frac{\lfloor n/p \rfloor}{n}$$

As $y - 1 < \lfloor y \rfloor \leq y$,

$$\mathbb{E}[X_p] = 1/p + O(1/n)$$

By linearity of expectation,

$$\mathbb{E}[X] = \sum_{p \leq M} \left(\frac{1}{p} + O\left(\frac{1}{n}\right) \right) = \ln \ln n + O(1)$$

where here we used the well-known fact that $\sum_{p \leq x} (1/p) = \ln \ln x + O(1)$, which can be proved by combining Stirling's formula with Abel summation.

Now we find an asymptotic expression for

$$\text{Var}[X] = \sum_{p \leq M} \text{Var}[X_p] + \sum_{p \neq q} \text{Cov}[X_p, X_q].$$

As $\text{Var}[X_p] = (1/p)(1 - 1/p) + O(1/n)$,

$$\sum_{p \leq M} \text{Var}[X_p] = \left(\sum_{p \leq M} \frac{1}{p} \right) + O(1) = \ln \ln n + O(1).$$

With p, q distinct primes, $X_p X_q = 1$ if and only if $p \mid x$ and $q \mid x$, which occurs if and only if $pq \mid x$. Hence

$$\begin{aligned}
\text{Cov}[X_p, X_q] &= E[X_p X_q] - E[X_p] E[X_q] \\
&= \frac{\lfloor n/pq \rfloor}{n} - \frac{\lfloor n/p \rfloor}{n} \frac{\lfloor n/q \rfloor}{n} \\
&\leq \frac{1}{pq} - \left(\frac{1}{p} - \frac{1}{n} \right) \left(\frac{1}{q} - \frac{1}{n} \right) \\
&\leq \frac{1}{n} \left(\frac{1}{p} + \frac{1}{q} \right).
\end{aligned}$$

Thus

$$\sum_{p \neq q} \text{Cov}[X_p, X_q] \leq \frac{1}{n} \sum_{p \neq q} \left(\frac{1}{p} + \frac{1}{q} \right) \leq \frac{2M}{n} \sum \frac{1}{p}.$$

Thus

$$\sum_{p \neq q} \text{Cov}[X_p, X_q] \leq O(n^{-9/10} \ln \ln n) = o(1)$$

and similarly

$$\sum_{p \neq q} \text{Cov}[X_p, X_q] \geq -o(1)$$

That is, the covariances do not affect the variance, $\text{Var}[X] = \ln \ln n + O(1)$ and Chebyshev's Inequality actually gives

$$\Pr[|X - \ln \ln n| > \lambda \sqrt{\ln \ln n}] < \lambda^{-2} + o(1)$$

for any constant $\lambda > 0$. As $|X - \nu| \leq 10$ the same holds for ν .

In a classic paper Erdős and Kac (1940) showed, essentially, that ν does behave like a normal distribution with mean and variance $\ln \ln n$. Here is their precise result.

Theorem 4.2.2 Let λ be fixed, positive, negative or zero. Then

$$\lim_{n \rightarrow \infty} \frac{1}{n} |\{x : 1 \leq x \leq n, \nu(x) \geq \ln \ln n + \lambda \sqrt{\ln \ln n}\}| = \int_{\lambda}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-t^2/2} dt$$

Proof. We outline the argument, emphasizing the similarities to Turán's proof. Fix a function $s(n)$ with $s(n) \rightarrow \infty$ and $s(n) = o((\ln \ln n)^{1/2})$ - for example, $s(n) = \ln \ln \ln n$. Set $M = n^{1/s(n)}$. Set $X = \sum X_p$, the summation over all primes $p \leq M$. As no $x \leq n$ can have more than $s(n)$ prime factors greater than M we have $\nu(x) - s(n) \leq X(x) \leq \nu(x)$ so that it suffices to show Theorem 4.2.2 with ν replaced by X . Let Y_p be independent random variables with $\Pr[Y_p = 1] = 1/p$, $\Pr[Y_p = 0] = 1 - 1/p$ and set $Y = \sum Y_p$, the summation over all primes $p \leq M$. This Y represents an idealized version of X . Set

$$\mu = E[Y] = \sum_{p \leq M} \frac{1}{p} = \ln \ln n + o((\ln \ln n)^{1/2})$$

and

$$\sigma^2 = \text{Var}[Y] = \sum_{p \leq M} \frac{1}{p} \left(1 - \frac{1}{p} \right) \sim \ln \ln n$$

and define the normalized $\tilde{Y} = (Y - \mu)/\sigma$. From the Central Limit Theorem $\tilde{Y}$ approaches the standard normal N and $E[\tilde{Y}^k] \rightarrow E[N^k]$ for every positive integer k . Set $\tilde{X} = (X - \mu)/\sigma$. We compare $\tilde{X}, \tilde{Y}$.

For any distinct primes $p_1, \dots, p_s \leq M$,

$$E[X_{p_1} \cdots X_{p_s}] - E[Y_{p_1} \cdots Y_{p_s}] = \frac{1}{n} \left\lfloor \frac{n}{p_1 \cdots p_s} \right\rfloor - \frac{1}{p_1 \cdots p_s} = O\left(\frac{1}{n}\right)$$

We let k be an arbitrary fixed positive integer and compare $E[\tilde{X}^k]$ and $E[\tilde{Y}^k]$. Expanding, $\tilde{X}^k$ is a polynomial in X with coefficients $n^{o(1)}$. Further expanding each $X^j = (\sum X_p)^j$ - always reducing X_p^a to X_p when $a \geq 2$ - gives the sum of $O(M^k) = n^{o(1)}$ terms of the form $X_{p_1} \cdots X_{p_s}$. The same expansion applies to $\tilde{Y}$. As the corresponding terms have expectations within $O(1/n)$ the total difference

$$E[\tilde{X}^k] - E[\tilde{Y}^k] = n^{-1+o(1)} = o(1)$$

Hence each moment of $\tilde{X}$ approaches that of the standard normal N . A standard, though nontrivial, theorem in probability theory gives that $\tilde{X}$ must therefore approach N in distribution.

We recall the famous quotation of G. H. Hardy:

317 is a prime, not because we think so, or because our minds are shaped in one way rather than another, but because it is so, because mathematical reality is built that way.

How ironic - though not contradictory - that the methods of probability theory can lead to a greater understanding of the prime factorization of integers. Additional results applying information about the moments of a distribution in order to determine it appear in Chapter 8; see also Billingsley (1995).

17.4.3 4.3 More Basics

Let X be a nonnegative integral valued random variable and suppose we want to bound $\Pr[X = 0]$ given the value $\mu = E[X]$. If $\mu < 1$ we may use the inequality

$$\Pr[X > 0] \leq E[X]$$

so that if $E[X] \rightarrow 0$ then $X = 0$ almost always. (Here we are imagining an infinite sequence of X dependent on some parameter n going to infinity.) But now suppose $E[X] \rightarrow \infty$. It does not necessarily follow that $X > 0$ almost always. For example, let X be the number of deaths due to nuclear war in the twelve months after reading this paragraph. Calculation of $E[X]$ can make for lively debate but few would deny that it is quite large. Yet we may believe - or hope - that $\Pr[X \neq 0]$ is very close to zero. We can sometimes deduce $X > 0$ almost always if we have further information about $\text{Var}[X]$.

Theorem 4.3.1 $\Pr[X = 0] \leq \frac{\text{Var}[X]}{E[X]^2}$.

Proof. Set $\lambda = \mu/\sigma$ in Chebyshev's Inequality. Then

$$\Pr[X = 0] \leq \Pr[|X - \mu| \geq \lambda\sigma] \leq \frac{1}{\lambda^2} = \frac{\sigma^2}{\mu^2}$$

We generally apply this result in asymptotic terms.

Corollary 4.3.2 If $\text{Var}[X] = o(E[X]^2)$ then $X > 0$ almost always.

The proof of Theorem 4.3.1 actually gives that, for any $\epsilon > 0$,

$$\Pr[|X - E[X]| \geq \epsilon E[X]] \leq \frac{\text{Var}[X]}{\epsilon^2 E[X]^2}$$

and thus in asymptotic terms we actually have the following stronger assertion.

Corollary 4.3.3 If $\text{Var}[X] = o(E[X]^2)$ then $X \sim E[X]$ almost always.

Suppose again $X = X_1 + \cdots + X_m$, where X_i is the indicator random variable for event A_i . For indices i, j write $i \sim j$ if $i \neq j$ and the events A_i, A_j are not independent. We set (the sum is over ordered pairs)

$$\Delta = \sum_{i \sim j} \Pr[A_i \wedge A_j]$$

Note that when $i \sim j$,

$$\text{Cov}[X_i, X_j] = E[X_i X_j] - E[X_i] E[X_j] \leq E[X_i X_j] = \Pr[A_i \wedge A_j]$$

and that when $i \neq j$ and not $i \sim j$ then $\text{Cov}[X_i, X_j] = 0$. Thus

$$\text{Var}[X] \leq E[X] + \Delta.$$

Corollary 4.3.4 If $E[X] \rightarrow \infty$ and $\Delta = o(E[X]^2)$ then $X > 0$ almost always. Furthermore $X \sim E[X]$ almost always.

Let us say $X_1, \dots, X_m$ are symmetric if for every $i \neq j$ there is a measure preserving mapping of the underlying probability space that sends event A_i to event A_j . Examples will appear in the next section. In this instance we write

$$\Delta = \sum_{i \sim j} \Pr[A_i \wedge A_j] = \sum_i \Pr[A_i] \sum_{j \sim i} \Pr[A_j | A_i]$$

and note that the inner summation is independent of i . We set

$$\Delta^* = \sum_{j \sim i} \Pr[A_j | A_i]$$

where i is any fixed index. Then

$$\Delta = \sum_i \Pr[A_i] \Delta^* = \Delta^* \sum_i \Pr[A_i] = \Delta^* E[X].$$

Corollary 4.3.5 If $E[X] \rightarrow \infty$ and $\Delta^* = o(E[X])$ then $X > 0$ almost always. Furthermore $X \sim E[X]$ almost always.

The condition of Corollary 4.3.5 has the intuitive sense that conditioning on any specific A_i holding does not substantially increase the expected number $E[X]$ of events holding.

17.4.4 4.4 Random Graphs

The random graph $G(n, p)$ is, informally, the graph on n labeled vertices, obtained by selecting each pair of vertices to be an edge, randomly and independently, with probability p . A property of graphs is a family of graphs closed under isomorphism. A function $r(n)$ is a threshold function for some property P , if whenever $p = p(n) \ll r(n)$ then $G(n, p)$ does not satisfy P almost always, and whenever $p \gg r(n)$ then $G(n, p)$ satisfies P almost always. For

more precise definitions of the random graph $G(n, p)$ and of threshold functions, see Section 10.1.

The results of this section are generally surpassed by those of Chapter 10 but they were historically the first results and provide a good illustration of the second moment. We begin with a particular example. By $\omega(G)$ we denote here and in the rest of the book the number of vertices in the maximum clique of the graph G .

Theorem 4.4.1 The property $\omega(G) \geq 4$ has threshold function $n^{-2/3}$.

Proof. For every 4-set S of vertices in $G(n, p)$ let A_S be the event " S is a clique" and X_S its indicator random variable. Then

$$E[X_S] = \Pr[A_S] = p^6$$

as six different edges must all lie in $G(n, p)$. Set

$$X = \sum_{|S|=4} X_S$$

so that X is the number of 4-cliques in G and $\omega(G) \geq 4$ if and only if $X > 0$. Linearity of expectation gives

$$E[X] = \sum_{|S|=4} E[X_S] = \binom{n}{4} p^6 \sim \frac{n^4 p^6}{24}.$$

When $p(n) \ll n^{-2/3}$, $E[X] = o(1)$ and so $X = 0$ almost surely.

Now suppose $p(n) \gg n^{-2/3}$ so that $E[X] \rightarrow \infty$ and consider the Δ^* of Corollary 4.3.5. (All 4-sets "look the same" so that the X_S are symmetric.) Here $S \sim T$ if and only if $S \neq T$ and S, T have common edges; that is, if and only if $|S \cap T| = 2$ or 3 . Fix S . There are $O(n^2)$ sets T with $|S \cap T| = 2$ and for each of these $\Pr[A_T | A_S] = p^5$. There are $O(n)$ sets T with $|S \cap T| = 3$ and for each of these $\Pr[A_T | A_S] = p^3$. Thus

$$\Delta^* = O(n^2 p^5) + O(np^3) = o(n^4 p^6) = o(E[X])$$

since $p \gg n^{-2/3}$. Corollary 4.3.5 therefore applies and $X > 0$; that is, there does exist a clique of size 4, almost always. $\square$

The proof of Theorem 4.4.1 appears to require a fortuitous calculation of Δ^* . The following definitions pave the way for the more general Theorem 4.4.2.

Definition 1 Let H be a graph with v vertices and e edges. We call $\rho(H) = e/v$ the density of H . We call H balanced if every subgraph H' has $\rho(H') \leq \rho(H)$. We call H strictly balanced if every proper subgraph H' has $\rho(H') < \rho(H)$.

Examples. K_4 and, in general, K_k are strictly balanced. The graph

is not balanced as it has density $7/5$ while the subgraph K_4 has density $3/2$. The graph

is balanced but not strictly balanced as it and its subgraph K_4 have density $3/2$.

Theorem 4.4.2 Let H be a balanced graph with v vertices and e edges. Let $A(G)$ be the event that H is a subgraph (not necessarily induced) of G . Then $p = n^{-v/e}$ is the threshold function for A .

Proof. We follow the argument of Theorem 4.4.1. For each v -set S let A_S be the event that $G|_S$ contains H as a subgraph. Then

$$p^e \leq \Pr[A_S] \leq v!p^e$$

(Any particular placement of H has probability p^e of occurring and there are at most $v!$ possible placements. The precise calculation of $\Pr[A_S]$ is, in general, complicated due to the overlapping of potential copies of H .) Let X_S be the indicator random variable for A_S and

$$X = \sum_{|S|=v} X_S$$

so that A holds if and only if $X > 0$. Linearity of expectation gives

$$\mathbb{E}[X] = \sum_{|S|=v} \mathbb{E}[X_S] = \binom{n}{v} \Pr[A_S] = \Theta(n^v p^e).$$

If $p \ll n^{-v/e}$ then $\mathbb{E}[X] = o(1)$, so $X = 0$ almost always.

Now assume $p \gg n^{-v/e}$ so that $\mathbb{E}[X] \rightarrow \infty$ and consider the Δ^* of Corollary 4.3.5. (All v -sets look the same so the X_S are symmetric.) Here $S \sim T$ if and only if $S \neq T$ and S, T have common edges; that is, if and only if $|S \cap T| = i$ with $2 \leq i \leq v-1$. Let S be fixed. We split

$$\Delta^* = \sum_{T \sim S} \Pr[A_T | A_S] = \sum_{i=2}^{v-1} \sum_{|T \cap S|=i} \Pr[A_T | A_S].$$

For each i there are $O(n^{v-i})$ choices of T . Fix S, T and consider $\Pr[A_T | A_S]$. There are $O(1)$ possible copies of H on T . Each has - since, critically, H is balanced - at most ie/v edges with both vertices in S and thus at least $e - (ie/v)$ other edges. Hence

$$\Pr[A_T | A_S] = O(p^{e-(ie/v)})$$

and

$$\begin{aligned} \Delta^* &= \sum_{i=2}^{v-1} O(n^{v-i} p^{e-(ie/v)}) \\ &= \sum_{i=2}^{v-1} O((n^v p^e)^{1-i/v}) \\ &= \sum_{i=2}^{v-1} o(n^v p^e) \\ &= o(\mathbb{E}[X]) \end{aligned}$$

since $n^v p^e \rightarrow \infty$. Hence Corollary 4.3.5 applies. $\square$

Theorem 4.4.3 In the notation of Theorem 4.4.2 if H is not balanced then $p = n^{-v/e}$ is not the threshold function for A .

Proof. Let H_1 be a subgraph of H with v_1 vertices, e_1 edges and $e_1/v_1 > e/v$. Let α satisfy $v_1/e_1 < \alpha < v/e$ and set $p = n^{-\alpha}$. The expected number of copies of H_1 is then $o(1)$ so almost always $G(n, p)$ contains no copy of H_1 . But if it contains no copy of H_1 then it surely can contain no copy of H .

The threshold function for the property of containing a copy of H , for general H , was examined in the original papers of Erdős and Rényi (1960). It still provides an excellent introduction to the theory of random graphs. Let H_1 be that subgraph with maximal density $\rho(H_1) = e_1/v_1$. (When H is balanced we may take $H_1 = H$.) They showed that $p = n^{-v_1/e_1}$ is the threshold function. We do not show this here though it follows fairly straightforwardly from these methods.

We finish this section with two strengthenings of Theorem 4.4.2.

Theorem 4.4.4 Let H be strictly balanced with v vertices, e edges and a automorphisms. Let X be the number of copies of H in $G(n, p)$. Assume $p \gg n^{-v/e}$. Then almost always

$$X \sim \frac{n^v p^e}{a}$$

Proof. Label the vertices of H by $1, \dots, v$. For each ordered $x_1, \dots, x_v$ let $A_{x_1, \dots, x_v}$ be the event that $x_1, \dots, x_v$ provides a copy of H in that order. Specifically we define

$$A_{x_1, \dots, x_v} : \{i, j\} \in E(H) \Rightarrow \{x_i, x_j\} \in E(G).$$

We let $I_{x_1, \dots, x_v}$ be the corresponding indicator random variable. We define an equivalence class on v -tuples by setting $(x_1, \dots, x_v) \equiv (y_1, \dots, y_v)$ if there is an automorphism σ of $V(H)$ so that $y_{\sigma(i)} = x_i$ for $1 \leq i \leq v$. Then

$$X = \sum I_{x_1, \dots, x_v}$$

gives the number of copies of H in G where the sum is taken over one entry from each equivalence class. As there are $(n)_v/a$ terms,

$$E[X] = \frac{(n)_v}{a} E[I_{x_1, \dots, x_v}] = \frac{(n)_v p^e}{a} \sim \frac{n^v p^e}{a}$$

Our assumption $p \gg n^{-v/e}$ implies $E[X] \rightarrow \infty$. It suffices therefore to show $\Delta^* = o(E[X])$. Fixing $x_1, \dots, x_v$,

$$\Delta^* = \sum_{(y_1, \dots, y_v) \sim (x_1, \dots, x_v)} \Pr[A_{(y_1, \dots, y_v)} \mid A_{(x_1, \dots, x_v)}]$$

There are $v!/a = O(1)$ terms with $\{y_1, \dots, y_v\} = \{x_1, \dots, x_v\}$ and for each the conditional probability is at most 1 (actually, at most p), thus contributing $O(1) = o(E[X])$ to Δ^* . When $\{y_1, \dots, y_v\} \cap \{x_1, \dots, x_v\}$ has i elements, $2 \leq i \leq v-1$ the argument of Theorem 4.4.2 gives that the contribution to Δ^* is $o(E[X])$. Altogether $\Delta^* = o(E[X])$ and we apply Corollary 4.3.5.

Theorem 4.4.5 Let H be any fixed graph. For every subgraph H' of H (including H itself) let $X_{H'}$ denote the number of copies of H' in $G(n, p)$. Assume p is such that $E[X_{H'}] \rightarrow \infty$ for every H' . Then

$$X_H \sim E[X_H]$$

almost always.

Proof. Let H have v vertices and e edges. As in Theorem 4.4.4 it suffices to show $\Delta^* = o(\mathbb{E}[X])$. We split Δ^* into a finite number of terms. For each H' with w vertices and f edges we have those $(y_1, \dots, y_v)$ that overlap with the fixed $(x_1, \dots, x_v)$ in a copy of H' . These terms contribute, up to constants,

$$n^{v-w} p^{e-f} = \Theta \left(\frac{\mathbb{E}[X_H]}{\mathbb{E}[X_{H'}]} \right) = o(\mathbb{E}[X_H])$$

to Δ^* . Hence Corollary 4.3.5 does apply.

17.4.5 4.5 Clique Number

Now we fix edge probability $p = \frac{1}{2}$ and consider the clique number $\omega(G)$. We set

$$f(k) = \binom{n}{k} 2^{-\binom{k}{2}},$$

the expected number of k -cliques. The function $f(k)$ drops under one at $k \sim 2 \log_2 n$. [Very roughly, $f(k)$ is like $n^k 2^{-k^2/2}$.]

Theorem 4.5.1 Let $k = k(n)$ satisfy $k \sim 2 \log_2 n$ and $f(k) \rightarrow \infty$. Then almost always $\omega(G) \geq k$.

Proof. For each k -set S let A_S be the event " S is a clique" and X_S the corresponding indicator random variable. We set

$$X = \sum_{|S|=k} X_S$$

so that $\omega(G) \geq k$ if and only if $X > 0$. Then $\mathbb{E}[X] = f(k) \rightarrow \infty$ and we examine the Δ^* of Corollary 4.3.5. Fix S and note that $T \sim S$ if and only if $|T \cap S| = i$, where $2 \leq i \leq k-1$. Hence

$$\Delta^* = \sum_{i=2}^{k-1} \binom{k}{i} \binom{n-k}{k-i} 2^{\binom{i}{2} - \binom{k}{2}}$$

and so

$$\frac{\Delta^*}{\mathbb{E}[X]} = \sum_{i=2}^{k-1} g(i)$$

where we set

$$g(i) = \frac{\binom{k}{i} \binom{n-k}{k-i}}{\binom{n}{k}} 2^{\binom{i}{2}}$$

Observe that $g(i)$ may be thought of as the probability that a randomly chosen T will intersect a fixed S in i points times the factor increase in $\Pr[A_T]$ when it does. Setting $i = 2$,

$$g(2) = 2 \frac{\binom{k}{2} \binom{n-k}{k-2}}{\binom{n}{k}} \sim \frac{k^4}{n^2} \leq o(1/n)$$

At the other extreme $i = k-1$,

$$g(k-1) = \frac{k(n-k) 2^{-\binom{k-1}{2}}}{\binom{n}{k} 2^{-\binom{k}{2}}} \sim \frac{2kn 2^{-k}}{\mathbb{E}[X]}.$$

As $k \sim 2 \log_2 n$, the numerator is $n^{-1+o(1)}$. The denominator approaches infinity and so $g(k-1) \leq o(1/n)$. Some detailed calculation (which we omit) gives that the remaining $g(i)$ and their sum are also negligible so that Corollary 4.3.5 applies.

Theorem 4.5.1 leads to a strong concentration result for $\omega(G)$. For $k \sim 2 \log_2 n$,

$$\frac{f(k+1)}{f(k)} = \frac{n-k}{k+1} 2^{-k} = n^{-1+o(1)} = o(1).$$

Let $k_0 = k_0(n)$ be that value with $f(k_0) \geq 1 > f(k_0+1)$. For "most" n the function $f(k)$ will jump from a large $f(k_0)$ to a small $f(k_0+1)$. The probability that G contains a clique of size k_0+1 is at most $f(k_0+1)$, which will be very small. When $f(k_0)$ is large, Theorem 4.5.1 implies that G contains a clique of size k_0 with probability nearly 1. Together, with very high probability $\omega(G) = k_0$. For some n one of the values $f(k_0), f(k_0+1)$ may be of moderate size so this argument does not apply. Still one may show a strong concentration result found independently by Bollobás and Erdős (1976) and Matula (1976).

Corollary 4.5.2 There exists $k = k(n)$ so that

$$\Pr[\omega(G) = k \text{ or } k+1] \rightarrow 1.$$

We give yet stronger results on the distribution of $\omega(G)$ in Section 10.2.

17.4.6 4.6 Distinct Sums

A set $x_1, \dots, x_k$ of positive integers is said to have distinct sums if all sums

$$\sum_{i \in S} x_i, \quad S \subseteq \{1, \dots, k\}$$

are distinct. Let $f(n)$ denote the maximal k for which there exists a set

$$\{x_1, \dots, x_k\} \subset \{1, \dots, n\}$$

with distinct sums. The simplest example of a set with distinct sums is $\{2^i : i \leq \log_2 n\}$. This example shows

$$f(n) \geq 1 + \lfloor \log_2 n \rfloor$$

Erdős offered \$300 for a proof or disproof that

$$f(n) \leq \log_2 n + C$$

for some constant C . From above, as all $2^{f(n)}$ sums are distinct and less than nk ,

$$2^{f(n)} < nk = nf(n),$$

and so

$$f(n) < \log_2 n + \log_2 \log_2 n + O(1).$$

Examination of the second moment gives a modest improvement. Fix $\{x_1, \dots, x_k\} \subset \{1, \dots, n\}$ with distinct sums. Let $\epsilon_1, \dots, \epsilon_k$ be independent with

$$\Pr[\epsilon_i = 1] = \Pr[\epsilon_i = 0] = 1/2$$

and set

$$X = \epsilon_1 x_1 + \cdots + \epsilon_k x_k.$$

(We may think of X as a random sum.) Set

$$\mu = E[X] = \frac{x_1 + \cdots + x_k}{2}$$

and $\sigma^2 = \text{Var}[X]$. We bound

$$\sigma^2 = \frac{x_1^2 + \cdots + x_k^2}{4} \leq \frac{n^2 k}{4}$$

so that $\sigma \leq n\sqrt{k}/2$. By Chebyshev's Inequality for any $\lambda > 1$,

$$\Pr[|X - \mu| \geq \lambda n\sqrt{k}/2] \leq \lambda^{-2}.$$

Reversing,

$$1 - \frac{1}{\lambda^2} \leq \Pr[|X - \mu| < \lambda n\sqrt{k}/2].$$

But X has any particular value with probability either zero or 2^{-k} since, critically, a sum can be achieved in at most one way. Thus

$$\Pr[|X - \mu| < \lambda n\sqrt{k}/2] \leq 2^{-k}(\lambda n\sqrt{k} + 1)$$

and

$$n \geq \frac{2^k(1 - \lambda^{-2}) - 1}{\sqrt{k}\lambda}.$$

While $\lambda = \sqrt{3}$ gives optimal results any choice of $\lambda > 1$ gives the following.

Theorem 4.6.1 $f(n) \leq \log_2 n + (1/2) \log_2 \log_2 n + O(1)$.

17.4.7 4.7 The Rödl Nibble

For $2 \leq l < k < n$ let $M(n, k, l)$, the covering number, denote the minimal size of a family $\mathcal{K}$ of k -element subsets of $\{1, \dots, n\}$ having the property that every l -element set is contained in at least one $A \in \mathcal{K}$. Clearly $M(n, k, l) \geq \binom{n}{l} / \binom{k}{l}$ since each k -set covers $\binom{k}{l}$ l -sets and every l -set must be covered. Equality holds if and only if the family $\mathcal{K}$ has the property that every l -set is contained in exactly one $A \in \mathcal{K}$. This is called an (n, k, l) tactical configuration (or block design). For example, $(n, 3, 2)$ tactical configurations are better known as Steiner Triple Systems. The question of the existence of tactical configurations is a central one for combinatorics but one for which probabilistic methods (at least so far!) play little role. In 1963 Paul Erdős and Haim Hanani conjectured that for fixed $2 \leq l < k$,

$$\lim_{n \rightarrow \infty} \frac{M(n, k, l)}{\binom{n}{l} / \binom{k}{l}} = 1.$$

Their conjecture was, roughly, that one can get asymptotically close to a tactical configuration. While this conjecture seemed ideal for a probabilistic analysis it was a full generation before Rödl (1985) found the proof, which we describe in this section. [One may similarly define the packing number $m(n, k, l)$ as the maximal size of a family $\mathcal{K}$ of k -element subsets of $\{1, \dots, n\}$ having the property that every l -element set is contained in at most one $A \in \mathcal{K}$. Erdős and Hanani noticed from elementary arguments that

$$\lim_{n \rightarrow \infty} \frac{M(n, k, l)}{\binom{n}{l} / \binom{k}{l}} = 1 \iff \lim_{n \rightarrow \infty} \frac{m(n, k, l)}{\binom{n}{l} / \binom{k}{l}} = 1.$$

While the Rödl result may be formulated in terms of either packing or covering here we deal only with the covering problem.]

Several researchers realized that the Rödl method applies in a much more general setting, dealing with covers in uniform hypergraphs. This was first observed by Frankl and Rödl and has been simplified and extended by Pippenger and Spencer (1989) as well as by Kahn (1996). Our treatment here follows the one in Pippenger and Spencer (1989) and is based on the description of Füredi (1988), where the main tool is the second moment method.

For an r -uniform hypergraph $H = (V, E)$ and for a vertex $x \in V$, we let $d_H(x)$ [or simply $d(x)$, when there is no danger of confusion] denote the degree of x in H , that is, the number of edges containing x . Similarly, for $x, y \in V$, $d(x, y) = d_H(x, y)$ is the number of edges of H containing both x and y . A covering of H is a set of edges whose union contains all vertices. In what follows, whenever we write $\pm\delta$ we mean a quantity between $-\delta$ and δ . The following theorem is due to Pippenger, following Frankl and Rödl.

Theorem 4.7.1 For every integer $r \geq 2$ and reals $k \geq 1$ and $a > 0$, there are $\gamma = \gamma(r, k, a) > 0$ and $d_0 = d_0(r, k, a)$ such that for every $n \geq D \geq d_0$ the following holds.

Every r -uniform hypergraph $H = (V, E)$ on a set V of n vertices in which all vertices have positive degrees and which satisfies the following conditions:

- (1) For all vertices $x \in V$ but at most γn of them, $d(x) = (1 \pm \gamma)D$.
- (2) For all $x \in V$, $d(x) < kD$.
- (3) For any two distinct $x, y \in V$, $d(x, y) < \gamma D$.

contains a cover of at most $(1 + a)(n/r)$ edges.

The basic idea in the proof is simple. Fixing a small $\epsilon > 0$ one shows that a random set of roughly $\epsilon n/r$ edges has, with high probability, only some $O(\epsilon^2 n)$ vertices covered more than once, and hence covers at least $\epsilon n - O(\epsilon^2 n)$ vertices. Moreover, after deleting the vertices covered, the induced hypergraph on the remaining vertices still satisfies the properties described in (1), (2) and (3) above (for some other values of n, γ, k and D). Therefore one can choose again a random set of edges of this hypergraph, covering roughly an ϵ -fraction of its vertices with nearly no overlaps. Proceeding in this way for a large number of times we are finally left with at most ϵn uncovered vertices, and we then cover them trivially, by taking for each of them an arbitrarily chosen edge containing it. Since ϵ is sufficiently small, although this last step is very inefficient, it can be tolerated.

The technical details require a careful application of the second moment method, used several times in the proof of the following lemma.

Lemma 4.7.2 For every integer $r \geq 2$ and reals $K \geq 1$ and $\epsilon > 0$, and for every real $\delta' > 0$, there are $\delta = \delta(r, K, \epsilon, \delta') > 0$ and $D_0 = D_0(r, K, \epsilon, \delta')$ such that for every $n \geq D \geq D_0$ the following holds.

Every r -uniform hypergraph $H = (V, E)$ on a set V of n vertices which satisfies the following conditions:

- (i) For all vertices $x \in V$ but at most δn of them, $d(x) = (1 \pm \delta)D$.
- (ii) For all $x \in V$, $d(x) < KD$.
- (iii) For any two distinct $x, y \in V$, $d(x, y) < \delta D$.

contains a set E' of edges with the following properties:

- (iv) $|E'| = (\epsilon n/r)(1 \pm \delta')$.
- (v) The set $V' = V - \cup_{e \in E'} e$ is of cardinality $|V'| = ne^{-\epsilon}(1 \pm \delta')$.
- (vi) For all vertices $x \in V'$ but at most $\delta'|V'|$ of them, the degree $d'(x)$ of x in the induced hypergraph of H on V' satisfies $d'(x) = De^{-\epsilon(r-1)}(1 \pm \delta')$.

Proof. Throughout the proof we assume, whenever this is needed, that D (and hence n)

is sufficiently large. We denote by $\delta_1, \delta_2, \dots$ positive constants (that can be explicitly estimated) that tend to 0 when δ tends to 0 and D tends to infinity (for fixed r, K, ϵ). Therefore, by choosing δ and D_0 appropriately, we can ensure that each of those will be smaller than δ' .

Let E' be a random subset of E obtained by picking, randomly and independently, each edge in E to be a member of E' with probability $p = \epsilon/D$. We have to show that with positive probability, the properties (iv), (v) and (vi) hold.

The proof that (iv) holds is easy. Note that by the assumptions H has at least $(1 - \delta)n$ vertices of degree at least $(1 - \delta)D$, showing that its number of edges is at least $(1 - \delta)^2 nD/r$. Similarly, the number of edges of H does not exceed $[(1 + \delta)Dn + \delta nKD]/r$. Therefore $|E| = (1 \pm \delta_1) Dn/r$. It follows that the expected value of the size of E' satisfies $E[|E'|] = |E|p = (1 \pm \delta_1)(\epsilon n/r)$ and its variance is $\text{Var}[|E'|] = |E|p(1 - p) \leq (1 \pm \delta_1)(\epsilon n/r)$. Therefore, by Chebyshev's Inequality, for an appropriately chosen $\delta_2 > 0$,

$$\Pr \left[|E'| = (1 \pm \delta_2) \frac{\epsilon n}{r} \right] > 0.99$$

say, giving (iv).

To prove (v), define for each vertex $x \in V$ an indicator random variable I_x , where $I_x = 1$ if $x \notin \cup_{e \in E'} e$ and $I_x = 0$ otherwise. Note that $|V'| = \sum_{x \in V} I_x$. Call a vertex $x \in V$ good if $d(x) = (1 \pm \delta)D$; otherwise call it bad. If x is good, then

$$E[I_x] = \Pr[I_x = 1] = (1 - p)^{d(x)} = \left(1 - \frac{\epsilon}{D}\right)^{(1 \pm \delta)D} = e^{-\epsilon} (1 \pm \delta_3)$$

If x is bad then, clearly, $0 \leq E[I_x] \leq 1$. Since there are at most δn bad vertices it follows, by linearity of expectation, that the expected value of $|V'|$ is $ne^{-\epsilon} (1 \pm \delta_4)$. To compute the variance of $|V'| = \sum_{x \in V} I_x$, note that

$$\begin{aligned} \text{Var}[|V'|] &= \sum_{x \in V} \text{Var}[I_x] + \sum_{x, y \in V, x \neq y} \text{Cov}[I_x, I_y] \\ &\leq E[|V'|] + \sum_{x, y \in V, x \neq y} \text{Cov}[I_x, I_y] \end{aligned}$$

However,

$$\begin{aligned} \text{Cov}[I_x, I_y] &= E[I_x I_y] - E[I_x] E[I_y] \\ &= (1 - p)^{d(x) + d(y) - d(x, y)} - (1 - p)^{d(x) + d(y)} \\ &\leq (1 - p)^{-d(x, y)} - 1 \leq \left(1 - \frac{\epsilon}{D}\right)^{-\delta D} - 1 \leq \delta_5 \end{aligned}$$

It follows that

$$\text{Var}[|V'|] \leq E[|V'|] + \delta_5 n^2 \leq \delta_6 (E[|V'|])^2,$$

which, by Chebyshev, implies that with probability at least 0.99

$$|V'| = (1 \pm \delta_7) E[|V'|] = (1 \pm \delta_8) ne^{-\epsilon},$$

as claimed in (v).

It remains to prove (vi). To do so note, first, that all but at most $\delta_9 n$ vertices x satisfy the following two conditions:

- (A) $d(x) = (1 \pm \delta)D$, and
- (B) all but at most $\delta_{10}D$ edges $e \in E$ with $x \in e$ satisfy

$$|\{f \in E : x \notin f, f \cap e \neq \emptyset\}| = (1 \pm \delta_{11})(r-1)D. \quad (4.1)$$

Indeed, (A) holds for all but $\delta n < \delta_9 n/2$ vertices, by assumption. Moreover, the total number of edges containing vertices whose degrees are not $(1 \pm \delta)D$ is at most $\delta n K D$ and hence the number of vertices contained in more than $\delta_{10} D$ such edges is at most $\delta n K D r / (\delta_{10} D) \leq \delta_9 n/2$ for an appropriate choice of δ_9, δ_{10} . Note, next, that if $x \in e$ and e contains no vertex of degree which is not $(1 \pm \delta)D$ then, since $d(y, z) < \delta D$ for all y, z , the number of edges f not containing x that intersect e is at most $(r-1)(1 \pm \delta)D$ and at least $(r-1)(1 \pm \delta)D - \binom{r-1}{2} \delta D$ and hence e satisfies (4.1).

It thus suffices to show that for most of the vertices x satisfying (A) and (B), $d'(x)$ satisfies (iv). Fix such a vertex x . Call an edge e with $x \in e$ good if it satisfies (4.1). Conditioning on $x \in V'$, the probability that a good edge containing x stays in the hypergraph on V' is $(1-p)^{(1 \pm \delta_{11})(r-1)D}$. Therefore the expected value of $d'(x)$ is

$$\mathbb{E}[d'(x)] = (1 \pm \delta_{10} \pm \delta) D (1-p)^{(1 \pm \delta_{11})(r-1)D} \pm \delta_{10} D = e^{-\epsilon(r-1)} D (1 \pm \delta_{12}).$$

For each edge e containing x , let I_e denote the indicator random variable whose value is 1 iff e is contained in V' . Then, the degree $d'(x)$ is simply the sum of these indicator random variables, conditioned on $x \in V'$. It follows that

$$\begin{aligned} \text{Var}[d'(x)] &\leq \mathbb{E}[d'(x)] + \sum_{x \in e, x \in f} \text{Cov}[I_e, I_f] \\ &\leq \mathbb{E}[d'(x)] + 2\delta_{10} D^2 (1 \pm \delta) + \sum_{x \in e, x \in f, e, f \text{ good}} \text{Cov}[I_e, I_f]. \end{aligned}$$

It remains to bound the sum $\sum_{x \in e, x \in f, e, f \text{ good}} \text{Cov}[I_e, I_f]$. For each fixed good e this sum is a sum of the form $\sum_{x \in f, f \text{ good}} \text{Cov}[I_e, I_f]$. There are at most $(r-1)\delta D$ edges f in the last sum for which $|e \cap f| > 1$, and their contribution to the sum cannot exceed $(r-1)\delta D$. If $e \cap f = \{x\}$ then let $t(e, f)$ denote the number of edges of H that intersect both e and f and do not contain x . Clearly, in this case, $t(e, f) \leq (r-1)^2 \delta D$. It follows that for such e and f , $\text{Cov}[I_e, I_f] \leq (1-p)^{-t(e, f)} - 1 \leq \delta_{13}$, implying that for each fixed good edge e ,

$$\sum_{x \in f, f \text{ good}} \text{Cov}[I_e, I_f] \leq (r-1)\delta D + D(1+\delta)\delta_{13} \leq \delta_{14} D.$$

As the sum $\sum_{x \in e, x \in f, e, f \text{ good}} \text{Cov}[I_e, I_f]$ is the sum of at most $D(1+\delta)$ such quantities, we conclude that

$$\text{Var}[d'(x)] \leq \mathbb{E}[d'(x)] + \delta_{15} D^2 \leq \delta_{16} (\mathbb{E}[d'(x)])^2.$$

It thus follows, by Chebyshev, that with probability at most δ_{17} , $d'(x)$ is not $(1 \pm \delta_{18}) D e^{-\epsilon(r-1)}$, and therefore, by Markov, that with probability at least, say, 0.99, for all but at most $\delta_{19} n$ vertices, $d'(x) = (1 \pm \delta_{18}) D e^{-\epsilon(r-1)}$. This completes the proof of the lemma.

Proof [Theorem 4.7.1]. Fix $\epsilon > 0$ such that

$$\frac{\epsilon}{1 - e^{-\epsilon}} + r\epsilon < 1 + a$$

and fix $1/10 > \delta > 0$ such that

$$(1 + 4\delta) \frac{\epsilon}{1 - e^{-\epsilon}} + r\epsilon < 1 + a$$

Fix an integer t so that $e^{-\epsilon t} < \epsilon$. The theorem is proved by applying the lemma t times. Put $\delta = \delta_t$ and then define, by reverse induction $\delta_t > \delta_{t-1} > \dots > \delta_0$ such that

$\delta_i \leq \delta_{i+1}e^{-\epsilon(r-1)}$, $\prod_{i=0}^t (1 + \delta_i) < 1 + 2\delta$, and for $n \geq D \geq R_i$ one can apply the lemma with $r, K = ke^{\epsilon i(r-1)}$, $\epsilon, \delta' = \delta_{i+1}$ and $\delta = \delta_i$. This will give the assertion of the theorem with $\gamma = \delta_0, d_0 = \max R_i$. Indeed, by applying the lemma repeatedly we obtain a decreasing sequence of sets of vertices $V = V_0, V_1, \dots, V_t$, each contained in the previous one, and a sequence of sets of edges $E_1, E_2, \dots, E_t$, where E_i is the set of edges E' obtained in the application of the lemma to the hypergraph induced on V_{i-1} . Here

$$|V_i| = |V_{i-1}| e^{-\epsilon} (1 \pm \delta_i) \quad (= |V_0| e^{-i\epsilon} (1 \pm 2\delta)),$$

$$|E_i| = \frac{\epsilon |V_{i-1}|}{r} (1 \pm \delta_i) \leq (1 + 4\delta) \frac{\epsilon n}{r} e^{-(i-1)\epsilon},$$

and

$$D_i = D_{i-1}e^{-\epsilon(r-1)} = De^{-\epsilon i(r-1)}$$

By covering each vertex of V_t separately by an edge containing it we conclude that the total number of edges in the cover obtained is at most

$$\begin{aligned} (1 + 4\delta) \sum_{i=0}^{t-1} \frac{\epsilon n}{r} e^{-i\epsilon} + |V_t| &\leq (1 + 4\delta) \frac{\epsilon n}{r} \frac{1}{1 - e^{-\epsilon}} + (1 + 2\delta) n e^{-\epsilon t} \\ &\leq \frac{n}{r} (1 + 4\delta) \left(\frac{\epsilon}{1 - e^{-\epsilon}} + r\epsilon \right) \\ &< (1 + a) \frac{n}{r} \end{aligned}$$

This completes the proof.

We conclude the section by showing how the theorem quickly implies Rödl solution of the Erdős-Hanani problem mentioned at the beginning of the section.

Theorem 4.7.3 [Rödl] For k, l fixed,

$$M(n, k, l) \leq (1 + o(1)) \binom{n}{l} / \binom{k}{l}$$

where the $o(1)$ term tends to zero as n tends to infinity.

Proof. Put $r = \binom{k}{l}$ and let H be the r -uniform hypergraph whose vertices are all l -subsets of $\{1, 2, \dots, n\}$, and whose edges are all collections of $\binom{k}{l} l$ -tuples that lie in a k -set. H has $\binom{n}{l}$ vertices, each of its vertices has degree $D = \binom{n-l}{k-l}$, and every two distinct vertices lie in at most $\binom{n-l-1}{k-l-1} = o(D)$ common edges. Therefore, by Theorem 4.7.1, H has a cover of size at most $(1 + o(1)) \binom{n}{l} / \binom{k}{l}$, as needed.

17.4.8 4.8 Exercises

1. Let X be a random variable taking integral nonnegative values, let $E[X^2]$ denote the expectation of its square, and let $\text{Var}[X]$ denote its variance. Prove that

$$\Pr[X = 0] \leq \frac{\text{Var}[X]}{E[X^2]}$$

2. (*) Show that there is a positive constant c such that the following holds. For any n reals $a_1, a_2, \dots, a_n$ satisfying $\sum_{i=1}^n a_i^2 = 1$, if $(\epsilon_1, \dots, \epsilon_n)$ is a $\{-1, 1\}$ random vector obtained by choosing each ϵ_i randomly and independently with uniform distribution to be either -1 or 1, then

$$\Pr \left[\left| \sum_{i=1}^n \epsilon_i a_i \right| \leq 1 \right] \geq c.$$

3. (*) Show that there is a positive constant c such that the following holds. For any n vectors $a_1, a_2, \dots, a_n \in \mathbb{R}^2$ satisfying $\sum_{i=1}^n \|a_i\|^2 = 1$ and $\|a_i\| \leq 1/10$, where $\|\cdot\|$ denotes the usual Euclidean norm, if $(\epsilon_1, \dots, \epsilon_n)$ is a $\{-1, 1\}$ random vector obtained by choosing each ϵ_i randomly and independently with uniform distribution to be either -1 or 1, then

$$\Pr \left[\left\| \sum_{i=1}^n \epsilon_i a_i \right\| \leq 1/3 \right] \geq c.$$

4. Let X be a random variable with expectation $E[X] = 0$ and variance σ^2 . Prove that for all $\lambda > 0$,

$$\Pr[X \geq \lambda] \leq \frac{\sigma^2}{\sigma^2 + \lambda^2}$$

5. Let $v_1 = (x_1, y_1), \dots, v_n = (x_n, y_n)$ be n two-dimensional vectors, where each x_i and each y_i is an integer whose absolute value does not exceed $2^{n/2}/(100\sqrt{n})$. Show that there are two disjoint sets $I, J \subset \{1, 2, \dots, n\}$ such that

$$\sum_{i \in I} v_i = \sum_{j \in J} v_j.$$

6. (*) Prove that for every set X of at least $4k^2$ distinct residue classes modulo a prime p , there is an integer a such that the set $\{ax \pmod{p} : x \in X\}$ intersects every interval in $\{0, 1, \dots, p-1\}$ of length at least p/k .

The Probabilistic Lens: Hamiltonian Paths

What is the maximum possible number of directed Hamiltonian paths in a tournament on n vertices? Denote this number by $P(n)$. The first application of the probabilistic method in combinatorics is the result of Szele (1943) described in Chapter 2, which states that $P(n) \geq n!/2^{n-1}$. This bound follows immediately from the observation that the right-hand side is the expected number of such paths in a random tournament on n vertices. In the same paper Szele shows that

$$\frac{1}{2} \leq \lim_{n \rightarrow \infty} \left(\frac{P(n)}{n!} \right)^{1/n} \leq \frac{1}{2^{3/4}}$$

proves that this limit does exist, and conjectures that its correct value is $1/2$. This conjecture is proved in Alon (1990a). The proof is given below. The main tool is the Brégman proof of the Minc Conjecture for the permanent of a $(0, 1)$ -matrix, described in The Probabilistic Lens: Brégman Theorem (following Chapter 2).

Theorem 1 There exists a positive constant c such that for every n ,

$$P(n) \leq cn^{3/2} \frac{n!}{2^{n-1}}$$

Proof. For a tournament T , denote by $P(T)$ the number of directed Hamiltonian paths of T . Similarly, $C(T)$ denotes the number of directed Hamiltonian cycles of T , and $F(T)$ denotes the number of spanning subgraphs of T in which the indegree and the outdegree of every vertex is exactly 1. Clearly,

$$C(T) \leq F(T) \quad (1)$$

If $T = (V, E)$ is a tournament on a set $V = \{1, 2, \dots, n\}$ of n vertices, the adjacency matrix of T is the n by n $(0, 1)$ -matrix $A_T = (a_{ij})$ defined by $a_{ij} = 1$ if $(i, j) \in E$ and $a_{ij} = 0$ otherwise. Let r_i denote the number of ones in row i . Clearly,

$$\sum_i^n r_i = \binom{n}{2} \quad (2)$$

By interpreting combinatorially the terms in the expansion of the permanent $\text{per}(A_T)$, it follows that

$$\text{per}(A_T) = F(T) \quad (3)$$

We need the following technical lemma.

Lemma 2 For every two integers a, b satisfying $b \geq a + 2 > a \geq 1$ the inequality

$$(a!)^{1/a} \cdot (b!)^{1/b} < ((a+1)!)^{1/(a+1)} \cdot ((b-1)!)^{1/(b-1)}$$

holds.

Proof. The assertion is simply that $f(a) < f(b-1)$, for the function f defined by $f(a) = (a!)^{1/a} / ((a+1)!)^{1/(a+1)}$. Thus it suffices to show that for every integer $x \geq 2$, $f(x-1) < f(x)$. Substituting the expression for f and raising both sides to the power $x(x-1)(x+1)$ it follows that it suffices to show that for all $x \geq 2$,

$$((x-1)!)^{x(x+1)} \cdot ((x+1)!)^{x(x-1)} < (x!)^{2(x^2-1)}$$

that is,

$$\left(\frac{x^x}{x!}\right)^2 > \left(\frac{x+1}{x}\right)^{x(x-1)}$$

This is certainly true for $x = 2$. For $x \geq 3$ it follows from the facts that $4^x > e^{x+1}$, that $x! < ((x+1)/2)^x$ and that $e^{x-1} > ((x+1)/x)^{x(x-1)}$.

Corollary 3 Define $g(x) = (x!)^{1/x}$. For every integer $S \geq n$ the maximum of the function $\prod_{i=1}^n g(x_i)$ subject to the constraints $\sum_{i=1}^n x_i = S$ and $x_i \geq 1$ are integers, is obtained iff the variables x_i are as equal as possible (i.e., if each x_i is either $\lfloor S/n \rfloor$ or $\lceil S/n \rceil$.)

Proof. If there are indices i and j such that $x_i \geq x_j + 2$ then, by Lemma 2, the value of the product would increase once we add one to x_j and subtract one from x_i .

Returning to our tournament T we observe that the numbers r_i defined above are precisely the outdegrees of the vertices of T . If at least one of these is 0, then clearly $C(T) = F(T) = 0$. Otherwise, by Brégman's Theorem, by Corollary 3 and by (2) and (3), $F(T)$ is at most the value of the function $\prod_{i=1}^n (r_i!)^{1/r_i}$, where the integral variables r_i satisfy (2) and are as equal as possible. By a straightforward (though somewhat tedious) derivation of the asymptotics using Stirling's formula this gives the following.

Proposition 4 For every tournament T on n vertices,

$$C(T) \leq F(T) \leq (1 + o(1)) \frac{\sqrt{\pi}}{\sqrt{2e}} n^{3/2} \frac{(n-1)!}{2^n}$$

To complete the proof of the theorem, we have to derive a bound for the number of Hamiltonian paths in a tournament from the above result. Given a tournament S on n vertices, let T be the random tournament obtained from S by adding to it a new vertex y and by orienting each edge connecting y with one of the vertices of S , randomly and independently. For every fixed Hamiltonian path in S , the probability that it can be extended to a Hamiltonian cycle in T is precisely $1/4$. Thus the expected number of Hamiltonian cycles in T is $\frac{1}{4}P(S)$ and hence there is a specific T for which $C(T) \geq \frac{1}{4}P(S)$. However, by Proposition 4,

$$C(T) \leq (1 + o(1)) \frac{\sqrt{\pi}}{\sqrt{2e}} (n+1)^{3/2} \frac{n!}{2^{n+1}}$$

and thus

$$P(S) \leq O\left(n^{3/2} \frac{n!}{2^{n-1}}\right)$$

completing the proof of Theorem 1.

17.5 5 The Local Lemma

It's a thing that non-mathematicians don't realize. Mathematics is actually an esthetic subject almost entirely.

- John Conway

17.5.1 5.1 The Lemma

In a typical probabilistic proof of a combinatorial result, one usually has to show that the probability of a certain event is positive. However, many of these proofs actually give more and show that the probability of the event considered is not only positive but is large. In fact, most probabilistic proofs deal with events that hold with high probability; that is, a probability that tends to 1 as the dimensions of the problem grow. For example, consider the proof given in Chapter 1 that for each $k \geq 1$ there are tournaments in which for every set of k players there is one who beats them all. The proof actually shows that for every fixed k if the number n of players is sufficiently large then almost all tournaments with n players satisfy this property; that is, the probability that a random tournament with n players has the desired property tends to 1 as n tends to infinity.

On the other hand, there is a trivial case in which one can show that a certain event holds with positive, though very small, probability. Indeed, if we have n mutually independent events and each of them holds with probability at least $p > 0$, then the probability that all events hold simultaneously is at least p^n , which is positive, although it may be exponentially small in n .

It is natural to expect that the case of mutual independence can be generalized to that of rare dependencies and provide a more general way of proving that certain events hold with positive, though small, probability. Such a generalization is, indeed, possible and is stated in the following lemma, known as the Lovász Local Lemma. This simple lemma, first proved in Erdős and Lovász (1975), is an extremely powerful tool, as it supplies a way for dealing with rare events.

Lemma 5.1.1 [The Local Lemma; General Case] Let $A_1, A_2, \dots, A_n$ be events in an arbitrary probability space. A directed graph $D = (V, E)$ on the set of vertices $V = \{1, 2, \dots, n\}$ is called a dependency digraph for the events $A_1, \dots, A_n$ if for each $i, 1 \leq i \leq n$, the event A_i is mutually independent of all the events $\{A_j : (i, j) \notin E\}$. Suppose that $D = (V, E)$ is a dependency

digraph for the above events and suppose there are real numbers $x_1, \dots, x_n$ such that $0 \leq x_i < 1$ and $\Pr[A_i] \leq x_i \prod_{(i,j) \in E} (1 - x_j)$ for all $1 \leq i \leq n$. Then

$$\Pr \left[\bigwedge_{i=1}^n \overline{A_i} \right] \geq \prod_{i=1}^n (1 - x_i)$$

In particular, with positive probability no event A_i holds.

Proof. We first prove, by induction on s , that for any $S \subset \{1, \dots, n\}$, $|S| = s < n$, and any $i \notin S$,

$$\Pr \left[A_i \mid \bigwedge_{j \in S} \overline{A_j} \right] \leq x_i \quad (5.1)$$

This is certainly true for $s = 0$. Assuming it holds for all $s' < s$, we prove it for s . Put $S_1 = \{j \in S : (i, j) \in E\}$, $S_2 = S \setminus S_1$. Then

$$\Pr \left[A_i \mid \bigwedge_{j \in S} \overline{A_j} \right] = \frac{\Pr \left[A_i \wedge \left(\bigwedge_{j \in S_1} \overline{A_j} \right) \mid \bigwedge_{\ell \in S_2} \overline{A_\ell} \right]}{\Pr \left[\bigwedge_{j \in S_1} \overline{A_j} \mid \bigwedge_{\ell \in S_2} \overline{A_\ell} \right]} \quad (5.2)$$

To bound the numerator observe that since A_i is mutually independent of the events $\{A_\ell : \ell \in S_2\}$,

$$\begin{aligned} \Pr \left[A_i \wedge \left(\bigwedge_{j \in S_1} \overline{A_j} \right) \mid \bigwedge_{\ell \in S_2} \overline{A_\ell} \right] &\leq \Pr \left[A_i \mid \bigwedge_{\ell \in S_2} \overline{A_\ell} \right] \\ &= \Pr[A_i] \leq x_i \prod_{(i,j) \in E} (1 - x_j). \end{aligned} \quad (5.3)$$

The denominator, on the other hand, can be bounded by the induction hypothesis. Indeed, suppose $S_1 = \{j_1, j_2, \dots, j_r\}$. If $r = 0$ then the denominator is 1, and (5.1) follows. Otherwise

$$\begin{aligned} &\Pr \left[\overline{A_{j_1}} \wedge \overline{A_{j_2}} \wedge \dots \wedge \overline{A_{j_r}} \mid \bigwedge_{\ell \in S_2} \overline{A_\ell} \right] \\ &= \left(1 - \Pr \left[A_{j_1} \mid \bigwedge_{\ell \in S_2} \overline{A_\ell} \right] \right) \cdot \left(1 - \Pr \left[A_{j_2} \mid \overline{A_{j_1}} \wedge \bigwedge_{\ell \in S_2} \overline{A_\ell} \right] \right) \cdots \\ &\quad \cdots \left(1 - \Pr \left[A_{j_r} \mid \overline{A_{j_1}} \wedge \dots \wedge \overline{A_{j_{r-1}}} \wedge \bigwedge_{\ell \in S_2} \overline{A_\ell} \right] \right) \\ &\geq (1 - x_{j_1}) (1 - x_{j_2}) \cdots (1 - x_{j_r}) \geq \prod_{(i,j) \in E} (1 - x_j) \end{aligned} \quad (5.4)$$

Substituting (5.3) and (5.4) into (5.2) we conclude that $\Pr[A_i \mid \bigwedge_{j \in S} \overline{A_j}] \leq x_i$, completing the proof of the induction.

The assertion of Lemma 5.1.1 now follows easily, as

$$\begin{aligned} \Pr \left[\bigwedge_{i=1}^n \overline{A_i} \right] &= (1 - \Pr[A_1]) \cdot (1 - \Pr[A_2 \mid \overline{A_1}]) \cdots \\ &\quad \cdots \left(1 - \Pr \left[A_n \mid \bigwedge_{i=1}^{n-1} \overline{A_i} \right] \right) \geq \prod_{i=1}^n (1 - x_i), \end{aligned}$$

completing the proof.

Corollary 5.1.2 [The Local Lemma; Symmetric Case] Let $A_1, A_2, \dots, A_n$ be events in an arbitrary probability space. Suppose that each event A_i is mutually independent of a set of all the other events A_j but at most d , and that $\Pr[A_i] \leq p$ for all $1 \leq i \leq n$. If

$$ep(d+1) \leq 1 \quad (5.5)$$

then $\Pr\left[\bigwedge_{i=1}^n \overline{A_i}\right] > 0$.

Proof. If $d = 0$ the result is trivial. Otherwise, by the assumption there is a dependency digraph $D = (V, E)$ for the events $A_1, \dots, A_n$ in which for each i , $|\{j : (i, j) \in E\}| \leq d$. The result now follows from Lemma 5.1.1 by taking $x_i = 1/(d+1) (< 1)$ for all i and using the fact that for any $d \geq 1$,

$$\left(1 - \frac{1}{d+1}\right)^d > \frac{1}{e}.$$

It is worth noting that, as shown by Shearer (1985), the constant " e " is the best possible constant in inequality (5.5). Note also that the proof of Lemma 5.1.1 indicates that the conclusion remains true even when we replace the two assumptions that each A_i is mutually independent of $\{A_j : (i, j) \notin E\}$ and that for each i

$$\Pr[A_i] \leq x_i \prod_{(ij) \in E} (1 - x_j)$$

by the weaker assumption that for each i and each $S_2 \subset \{1, \dots, n\} \setminus \{j : (i, j) \in E\}$,

$$\Pr\left[A_i \mid \bigwedge_{j \in S_2} \overline{A_j}\right] \leq x_i \prod_{(i,j) \in E} (1 - x_j)$$

This turns out to be useful in certain applications.

In the next few sections we present various applications of the Local Lemma for obtaining combinatorial results. There is no known proof of any of these results, which does not use the Local Lemma. Additional applications of the Local Lemma for coloring problems, and much much more, can be found in Molloy and Reed (1999).

17.5.2 5.2 Property b and Multicolored Sets of Real Numbers

Recall that a hypergraph $H = (V, E)$ has property B (i.e., is two-colorable), if there is a coloring of V by two colors so that no edge $f \in E$ is monochromatic.

Theorem 5.2.1 Let $H = (V, E)$ be a hypergraph in which every edge has at least k elements, and suppose that each edge of H intersects at most d other edges. If $e(d+1) \leq 2^{k-1}$ then H has property B .

Proof. Color each vertex v of H , randomly and independently, either blue or red (with equal probability). For each edge $f \in E$, let A_f be the event that f is monochromatic. Clearly $\Pr[A_f] = 2/2^{|f|} \leq 1/2^{k-1}$. Moreover, each event A_f is clearly mutually independent of all the other events $A_{f'}$ for all edges f' that do not intersect f . The result now follows from Corollary 5.1.2.

A special case of Theorem 5.2.1 is that for any $k \geq 9$, any k -uniform k -regular hypergraph H has property B . Indeed, since any edge f of such an H contains k vertices, each of which is incident with k edges (including f), it follows that f intersects at most $d = k(k-1)$ other edges. The desired result follows, since $e(k(k-1)+1) < 2^{k-1}$ for each $k \geq 9$.

The next result we consider, which appeared in the original paper of Erdős and Lovász, deals with k -colorings of the real numbers. For a k -coloring $c : \mathbb{R} \rightarrow \{1, 2, \dots, k\}$ of the real

numbers by the k colors $1, 2, \dots, k$, and for a subset $T \subset \mathbb{R}$, we say that T is multicolored (with respect to c) if $c(T) = \{1, 2, \dots, k\}$; that is, if T contains elements of all colors.

Theorem 5.2.2 Let m and k be two positive integers satisfying

$$e(m(m-1) + 1)k \left(1 - \frac{1}{k}\right)^m \leq 1 \quad (5.6)$$

Then, for any set S of m real numbers there is a k -coloring so that each translation $x + S$ (for $x \in \mathbb{R}$) is multicolored.

Note that (5.6) holds whenever $m > (3 + o(1))k \log k$.

Proof. We first fix a finite subset $X \subseteq \mathbb{R}$ and show the existence of a k -coloring so that each translation $x + S$ (for $x \in X$) is multicolored. This is an easy consequence of the Local Lemma. Indeed, put $Y = \bigcup_{x \in X} (x + S)$ and let $c : Y \rightarrow \{1, 2, \dots, k\}$ be a random k -coloring of Y obtained by choosing, for each $y \in Y$, randomly and independently, $c(y) \in \{1, 2, \dots, k\}$ according to a uniform distribution on $\{1, 2, \dots, k\}$. For each $x \in X$, let A_x be the event that $x + S$ is not multicolored (with respect to c). Clearly $\Pr[A_x] \leq k(1 - 1/k)^m$. Moreover, each event A_x is mutually independent of all the other events $A_{x'}$ but those for which $(x + S) \cap (x' + S) \neq \emptyset$. As there are at most $m(m-1)$ such events, the desired result follows from Corollary 5.1.2.

We can now prove the existence of a coloring of the set of all reals with the desired properties, by a standard compactness argument. Since the discrete space with k points is (trivially) compact, Tikhonov's Theorem (which is equivalent to the axiom of choice) implies that an arbitrary product of such spaces is compact. In particular, the space of all functions from $\mathbb{R}$ to $\{1, 2, \dots, k\}$, with the usual product topology, is compact. In this space for every fixed $x \in \mathbb{R}$, the set C_x of all colorings c , such that $x + S$ is multicolored, is closed. (In fact, it is both open and closed, since a basis to the open sets is the set of all colorings whose values are prescribed in a finite number of places). As we proved above, the intersection of any finite number of sets C_x is nonempty. It thus follows, by compactness, that the intersection of all sets C_x is nonempty. Any coloring in this intersection has the properties in the conclusion of Theorem 5.2.2.

Note that it is impossible, in general, to apply the Local Lemma to an infinite number of events and conclude that in some point of the probability space none of them holds. In fact, there are trivial examples of countably many mutually independent events A_i , satisfying $\Pr[A_i] = 1/2$ and $\bigwedge_{i \geq 1} \overline{A_i} = \emptyset$. Thus the compactness argument is essential in the above proof.

17.5.3 5.3 Lower Bounds for Ramsey Numbers

The derivation of lower bounds for Ramsey numbers by Erdős in 1947 was one of the first applications of the probabilistic method. The Local Lemma provides a simple way of improving these bounds. Let us obtain, first, a lower bound for the diagonal Ramsey number $R(k, k)$. Consider a random two-coloring of the edges of K_n . For each set S of k vertices of K_n , let A_S be the event that the complete graph on S is monochromatic. Clearly $\Pr[A_S] = 2^{1-\binom{k}{2}}$. It is obvious that each event A_S is mutually independent of all the events A_T , but those which satisfy $|S \cap T| \geq 2$, since this is the only case in which the corresponding complete graphs share an edge. We can therefore apply Corollary 5.1.2 with $p = 2^{1-\binom{k}{2}}$ and $d < \binom{k}{2} \binom{n-2}{k-2}$ to conclude the following.

Proposition 5.3.1 If $e \binom{k}{2} \binom{n-2}{k-2} \cdot 2^{1-\binom{k}{2}} < 1$ then $R(k, k) > n$.

A short computation shows that this gives $R(k, k) > (\sqrt{2}/e)(1 + o(1))k2^{k/2}$, only a factor 2 improvement on the bound obtained by the straightforward probabilistic method. Although this minor improvement is somewhat disappointing it is certainly not surprising; the Local Lemma is most powerful when the dependencies between events are rare, and this is not the case here.

Indeed, there is a total number of $K = \binom{n}{k}$ events considered, and the maximum outdegree d in the dependency digraph is roughly $\binom{k}{2} \binom{n}{k-2}$. For large k and much larger n (which is the case of interest for us) we have $d > K^{1-O(1/k)}$, that is, quite a lot of dependencies. On the other hand, if we consider small sets S (e.g., sets of size 3) we observe that out of the total $K = \binom{n}{3}$ of them each shares an edge with only $3(n-3) \approx K^{1/3}$. This suggests that the Local Lemma may be much more significant in improving the off-diagonal Ramsey numbers $R(k, \ell)$, especially if one of the parameters, say, ℓ , is small. Let us consider, for example, following Spencer (1977), the Ramsey number $R(k, 3)$. Here, of course, we have to apply the nonsymmetric form of the Local Lemma. Let us two-color the edges of K_n randomly and independently, where each edge is colored blue with probability p . For each set of three vertices T , let A_T be the event that the triangle on T is blue. Similarly, for each set of k vertices S , let B_S be the event that the complete graph on S is red. Clearly $\Pr[A_T] = p^3$ and $\Pr[B_S] = (1-p)^{\binom{k}{2}}$. Construct a dependency digraph for the events A_T and B_S by joining two vertices by edges (in both directions) iff the corresponding complete graphs share an edge. Clearly each A_T -node of the dependency graph is adjacent to $3(n-3) < 3nA_{T'}$ -nodes and to at most $\binom{n}{k}B_{S'}$ -nodes. Similarly, each B_S -node is adjacent to at most $\binom{k}{2}(n-2) < k^2n/2A_{T'}$ -nodes and to at most $\binom{n}{k}B_{S'}$ -nodes. It follows from the general case of the Local Lemma (Lemma 5.1.1) that if we can find a $0 < p < 1$ and two real numbers $0 \leq x < 1$ and $0 \leq y < 1$ such that

$$p^3 \leq x(1-x)^{3n}(1-y)^{\binom{n}{k}}$$

and

$$(1-p)^{\binom{k}{2}} \leq y(1-x)^{k^2n/2}(1-y)^{\binom{n}{k}}$$

then $R(k, 3) > n$.

Our objective is to find the largest possible $k = k(n)$ for which there is such a choice of p, x and y . An elementary (but tedious) computation shows that the best choice is when $p = c_1n^{-1/2}$, $k = c_2n^{1/2} \log n$, $x = c_3/n^{3/2}$ and y so that $\binom{n}{k}y = c_4$. This gives $R(k, 3) > c_5k^2/\log^2 k$. A similar argument gives $R(k, 4) > k^{5/2+o(1)}$. In both cases the amount of computation required is considerable. However, the hard work does pay; the bound $R(k, 3) > c_5k^2/\log^2 k$ matches a lower bound of Erdős proved in 1961 by a highly complicated probabilistic argument. This was improved to $R(k, 3) > c_6k^2/\log k$ by Kim(1995). The bound above for $R(k, 4)$ is better than any bound for $R(k, 4)$ known to be proved without the Local Lemma.

17.5.4 5.4 A Geometric Result

A family of open unit balls F in the three-dimensional Euclidean space $\mathbb{R}^3$ is called a k -fold covering of $\mathbb{R}^3$ if any point $x \in \mathbb{R}^3$ belongs to at least k balls. In particular, a 1 fold covering is simply called a covering. A k -fold covering $\mathcal{F}$ is called decomposable if there is a partition of $\mathcal{F}$ into two pairwise disjoint families $\mathcal{F}_1$ and $\mathcal{F}_2$, each being a covering of $\mathbb{R}^3$. Mani-Levitska and Pach (1988) constructed, for any integer $k \geq 1$, a non decomposable k -fold covering of $\mathbb{R}^3$ by open unit balls. On the other hand, they proved that any k -fold covering of $\mathbb{R}^3$ in which no point is covered by more than $c2^{k/3}$ balls is decomposable. This reveals a somewhat surprising phenomenon: it is more difficult to decompose coverings that cover some of the points of $\mathbb{R}^3$ too often than to decompose coverings that cover every point about the same number of times. The exact statement of the Mani-Levitska-Pach Theorem is the following.

Theorem 5.4.1 Let $\mathcal{F} = \{B_i\}_{i \in I}$ be a k -fold covering of the three-dimensional Euclidean space by open unit balls. Suppose, further, that no point of $\mathbb{R}^3$ is contained in more than t members of $\mathcal{F}$. If

$$e \cdot t^3 2^{18} / 2^{k-1} \leq 1$$

then $\mathcal{F}$ is decomposable.

Proof. Define an infinite hypergraph $H = (V(H), E(H))$ as follows. The set of vertices of H , $V(H)$, is simply $\mathcal{F} = \{B_i\}_{i \in I}$. For each $x \in \mathbb{R}^3$ let E_x be the set of balls $B_i \in \mathcal{F}$ that contain x . The set of edges of H , $E(H)$, is simply the set of E_x , with the understanding that when $E_x = E_y$ the edge is taken only once. We claim each edge E_x intersects less than $t^3 2^{18}$ other edges E_y of H . If $x \in B_i$ the center of B_i is within distance 1 of x . If now $B_j \cap B_i \neq \emptyset$ the center of B_j is within distance three of x and so B_j lies entirely inside the ball of radius four centered at x . Such a B_j covers precisely $4^{-3} = 2^{-6}$ of the volume of that ball. As no vertex is covered more than t times there can be at most $2^6 t$ such balls. It is not too difficult to check that m balls in $\mathbb{R}^3$ cut $\mathbb{R}^3$ into less than m^3 connected components so that there are at most $(2^6 t)^3$ distinct E_y overlapping E_x .

Consider, now, any finite subhypergraph L of H . Each edge of L has at least k vertices, and it intersects at most $d < t^3 2^{18}$ other edges of L . Since, by assumption, $e(d+1) \leq 2^{k-1}$, Theorem 5.2.1 (which is a simple corollary of the Local Lemma), implies that L is two-colorable. This means that one can color the vertices of L blue and red so that no edge of L is monochromatic. Since this holds for any finite L , a compactness argument, analogous to the one used in the proof of Theorem 5.2.2, shows that H is two-colorable. Given a two-coloring of H with no monochromatic edges, we simply let $\mathcal{F}_1$ be the set of all blue balls, and $\mathcal{F}_2$ be the set of all red ones. Clearly each $\mathcal{F}_i$ is a covering of $\mathbb{R}^3$, completing the proof of the theorem.

It is worth noting that Theorem 5.4.1 can easily be generalized to higher dimensions. We omit the detailed statement of this generalization.

17.5.5 5.5 The Linear Arboricity of Graphs

A linear forest is a forest (i.e., an acyclic simple graph) in which every connected component is a path. The linear arboricity $\text{la}(G)$ of a graph G is the minimum number of linear forests in G , whose union is the set of all edges of G . This notion was introduced by Harary as one of the covering invariants of graphs. The following conjecture, known as the Linear Arboricity Conjecture, was raised in Akiyama, Exoo and Harary (1981).

Conjecture 5.5.1 [The Linear Arboricity Conjecture] The linear arboricity of every d -regular graph is $\lceil (d+1)/2 \rceil$.

Note that since every d -regular graph G on n vertices has $nd/2$ edges, and every linear forest in it has at most $n-1$ edges, the inequality

$$\text{la}(G) \geq \frac{nd}{2(n-1)} > \frac{d}{2}$$

is immediate. Since $\text{la}(G)$ is an integer this gives $\text{la}(G) \geq \lceil (d+1)/2 \rceil$. The difficulty in Conjecture 5.5.1 lies in proving the converse inequality: $\text{la}(G) \leq \lceil (d+1)/2 \rceil$. Note also that since every graph G with maximum degree Δ is a subgraph of a Δ -regular graph (which may have more vertices, as well as more edges than G), the Linear Arboricity Conjecture is equivalent to the statement that the linear arboricity of every graph G with maximum degree Δ is at most $\lceil (\Delta+1)/2 \rceil$.

Although this conjecture received a considerable amount of attention, the best general result concerning it, proved without any probabilistic arguments, is that $\text{la}(G) \leq \lceil 3\Delta/5 \rceil$ for even Δ and that $\text{la}(G) \leq \lceil (3\Delta+2)/5 \rceil$ for odd Δ . In this section we prove that for every $\varepsilon > 0$ there is a $\Delta_0 = \Delta_0(\varepsilon)$ such that for every $\Delta \geq \Delta_0$, the linear arboricity of every graph with maximum degree Δ is less than $(\frac{1}{2} + \varepsilon)\Delta$. This result (with a somewhat more complicated

proof) appears in Alon (1988) and its proof relies heavily on the Local Lemma. We note that this proof is more complicated than the other proofs given in this chapter and requires certain preparations, some of which are of independent interest.

It is convenient to deduce the result for undirected graphs from its directed version. A d -regular digraph is a directed graph in which the indegree and the outdegree of every vertex is precisely d . A linear directed forest is a directed graph in which every connected component is a directed path. The dilinear arboricity $\text{dla}(G)$ of a directed graph G is the minimum number of linear directed forests in G whose union covers all edges of G . The directed version of the Linear Arboricity Conjecture, first stated in Nakayama and Peroche (1987), is the following.

Conjecture 5.5.2 For every d -regular digraph D ,

$$\text{dla}(D) = d + 1.$$

Note that since the edges of any (connected) undirected $2d$ -regular graph G can be oriented along a Euler cycle, so that the resulting oriented digraph is d -regular, the validity of Conjecture 5.5.2 for d implies that of Conjecture 5.5.1 for $2d$.

It is easy to prove that any graph with n vertices and maximum degree d contains an independent set of size at least $n/(d+1)$. The following proposition shows that at the price of decreasing the size of such a set by a constant factor we can guarantee that it has a certain structure.

Proposition 5.5.3 Let $H = (V, E)$ be a graph with maximum degree d , and let $V = V_1 \cup V_2 \cup \dots \cup V_r$ be a partition of V into r pairwise disjoint sets. Suppose each set V_i is of cardinality $|V_i| \geq 2ed$, where e is the basis of the natural logarithm. Then there is an independent set of vertices $W \subseteq V$ that contains a vertex from each V_i .

Proof. Clearly we may assume that each set V_i is of cardinality precisely $g = \lceil 2ed \rceil$ (otherwise, simply replace each V_i by a subset of cardinality g of it, and replace H by its induced subgraph on the union of these r new sets). Let us pick from each set V_i randomly and independently a single vertex according to a uniform distribution. Let W be the random set of the vertices picked. To complete the proof we show that with positive probability W is an independent set of vertices in H .

For each edge f of H , let A_f be the event that W contains both ends of f . Clearly, $\Pr[A_f] \leq 1/g^2$. Moreover, if the endpoints of f are in V_i and in V_j , then the event A_f is mutually independent of all the events corresponding to edges whose endpoints do not lie in $V_i \cup V_j$. Thus there is a dependency digraph for the events in which the maximum degree is less than $2gd$, and since $e \cdot 2gd \cdot 1/g^2 = 2ed/g < 1$ we conclude, by Corollary 5.1.2, that with positive probability none of the events A_f holds. But this means that W is an independent set containing a vertex from each V_i , completing the proof. $\square$

Proposition 5.5.3 suffices to prove Conjecture 5.5.2 for digraphs with no short directed cycle. Recall that the directed girth of a digraph is the minimum length of a directed cycle in it.

Theorem 5.5.4 Let $G = (U, F)$ be a d -regular digraph with directed girth $g \geq 8ed$. Then

$$\text{dla}(G) = d + 1.$$

Proof. As is well known, F can be partitioned into d pairwise disjoint 1-regular spanning subgraphs $F_1, \dots, F_d$ of G . [This is an easy consequence of the HallKönig Theorem; let H be the bipartite graph whose two classes of vertices A and B are copies of U , in which $u \in A$ is joined to $v \in B$ iff $(u, v) \in F$. Since H is d -regular its edges can be decomposed into d perfect matchings, which correspond to d 1-regular spanning subgraphs of G .] Each F_i is a union of vertex disjoint directed cycles $C_{i1}, C_{i2}, \dots, C_{ir_i}$. Let $V_1, V_2, \dots, V_r$ be the sets of edges of all the cycles $\{C_{ij} : 1 \leq i \leq d, 1 \leq j \leq r_i\}$. Clearly $V_1, V_2, \dots, V_r$ is a partition of the set F of all edges

of G , and by the girth condition, $|V_i| \geq g \geq 8ed$ for all $1 \leq i \leq r$. Let H be the line graph of G , that is, the graph whose set of vertices is the set F of edges of G in which two edges are adjacent iff they share a common vertex in G . Clearly H is $4d - 2$ regular. As the cardinality of each V_i is at least $8ed \geq 2e(4d - 2)$, there is, by Proposition 5.5.3, an independent set of H containing a member from each V_i . But this means that there is a matching M in G , containing at least one edge from each cycle C_{ij} of the 1-factors $F_1, \dots, F_d$. Therefore $M, F_1 \setminus M, F_2 \setminus M, \dots, F_d \setminus M$ are $d + 1$ directed forests in G (one of which is a matching) that cover all its edges. Hence

$$\text{dla}(G) \leq d + 1$$

As G has $|U| \cdot d$ edges and each directed linear forest can have at most $|U| - 1$ edges,

$$\text{dla}(G) \geq |U|d / (|U| - 1) > d$$

Thus $\text{dla}(G) = d + 1$, completing the proof.

The last theorem shows that the assertion of Conjecture 5.5.2 holds for digraphs with sufficiently large (directed) girth. In order to deal with digraphs with small girth, we show that most of the edges of each regular digraph can be decomposed into a relatively small number of almost regular digraphs with high girth. To do this, we need the following statement, which is proved using the Local Lemma.

Lemma 5.5.5 Let $G = (V, E)$ be a d -regular directed graph, where d is sufficiently large, and let p be an integer satisfying $10\sqrt{d} \leq p \leq 20\sqrt{d}$. Then, there is a p -coloring of the vertices of G by the colors $0, 1, 2, \dots, p - 1$ with the following property; for each vertex $v \in V$ and each color i , the numbers

$$N^+(v, i) = |\{u \in V : (v, u) \in E \text{ and } u \text{ is colored } i\}|$$

and

$$N^-(v, i) = |\{u \in V : (u, v) \in E \text{ and } u \text{ is colored } i\}|$$

satisfy

$$|N^-(v, i) - d/p|, |N^+(v, i) - d/p| \leq 3\sqrt{d/p} \sqrt{\log d} \quad (5.7)$$

Proof. Let $f : V \rightarrow \{0, 1, \dots, p - 1\}$ be a random vertex coloring of V by p colors, where for each $v \in V$, $f(v) \in \{0, 1, \dots, p - 1\}$ is chosen according to a uniform distribution. For every vertex $v \in V$ and every color i , $0 \leq i < p$, let $A_{v,i}^+$ be the event that the number $N^+(v, i)$ of neighbors of v in G whose color is i does not satisfy inequality (5.7). Clearly $N^+(v, i)$ is a binomial random variable with expectation d/p and standard deviation $\sqrt{(d/p)(1 - 1/p)} < \sqrt{d/p}$. Hence, by the standard estimates for binomial distribution given in Appendix A, for every $v \in V$ and $0 \leq i < p$,

$$\Pr[A_{v,i}^+] < 1/d^4.$$

Similarly, if $A_{v,i}^-$ is the event that the number $N^-(v, i)$ violates (5.7) then

$$\Pr[A_{v,i}^-] < 1/d^4$$

Clearly each of the events $A_{v,i}^+$ or $A_{v,i}^-$ is mutually independent of all the events $A_{u,j}^+$ or $A_{u,j}^-$ for all vertices $u \in V$ that do not have a common neighbor with v in G . Thus there is a dependency digraph for all our events with maximum degree $\leq (2d)^2 \cdot p$. Since $e \cdot (1/d^4) ((2d)^2 p + 1) < 1$, Corollary 5.1.2 (i.e., the symmetric form of the Local Lemma) implies that with positive

probability no event $A_{v,i}^+$ or $A_{v,i}^-$ occurs. Hence there is a coloring f that satisfies (5.7) for all $v \in V$ and $0 \leq i < p$, completing the proof.

We are now ready to deal with general regular digraphs. Let $G = (V, E)$ be an arbitrary d -regular digraph. Throughout the argument we assume, whenever it is needed, that d is sufficiently large. Let p be a prime satisfying $10d^{1/2} \leq p \leq 20d^{1/2}$ (it is well known that for every n there is a prime between n and $2n$). By Lemma 5.5.5 there is a vertex coloring $f : V \rightarrow \{0, 1, \dots, p-1\}$ satisfying (5.7). For each $i, 0 \leq i < p$, let $G_i = (V, E_i)$ be the spanning subdigraph of G defined by $E_i = \{(u, v) \in E : f(v) \equiv f(u) + i \pmod{p}\}$. By inequality (5.7) the maximum indegree Δ_i^- and the maximum outdegree Δ_i^+ in each G_i is at most $(d/p) + 3\sqrt{d/p}\sqrt{\log d}$. Moreover, for each $i > 0$, the length of every directed cycle in G_i is divisible by p . Thus the directed girth g_i of G_i is at least p . Since each G_i can be completed, by adding vertices and edges, to a Δ_i -regular digraph with the same girth g_i and with $\Delta_i = \max(\Delta_i^+, \Delta_i^-)$, and since $g_i > 8e\Delta_i$ (for all sufficiently large d), we conclude, by Theorem 5.5.4, that $\text{dla}(G_i) \leq \Delta_i + 1 \leq (d/p) + 3\sqrt{d/p}\sqrt{\log d} + 1$ for all $1 \leq i < p$. For G_0 , we only apply the trivial inequality

$$\text{dla}(G_0) \leq 2\Delta_0 \leq 2\frac{d}{p} + 6\sqrt{\frac{d}{p}}\sqrt{\log d}$$

obtained, for example, by embedding G_0 as a subgraph of a Δ_0 -regular graph, splitting the edges of this graph into $\Delta_0/2$ -regular spanning subgraphs, and breaking each of these 1 -regular spanning subgraphs into two linear directed forests. The last two inequalities, together with the fact that $10\sqrt{d} \leq p \leq 20\sqrt{d}$, imply

$$\text{dla}(G) \leq d + 2\frac{d}{p} + 3\sqrt{pd}\sqrt{\log d} + 3\sqrt{\frac{d}{p}}\sqrt{\log d} + p - 1 \leq d + c \cdot d^{3/4}(\log d)^{1/2}.$$

We have thus proved the following.

Theorem 5.5.6 There is an absolute constant $c > 0$ such that for every d -regular digraph G

$$\text{dla}(G) \leq d + cd^{3/4}(\log d)^{1/2}$$

We note that by being a little more careful, we can improve the error term to $c'd^{2/3}(\log d)^{1/3}$. Since the edges of any undirected $d = 2f$ -regular graph can be oriented so that the resulting digraph is f -regular, and since any $(2f-1)$ -regular undirected graph is a subgraph of a $2f$ -regular graph, the last theorem implies the following.

Theorem 5.5.7 There is an absolute constant $c > 0$ such that for every undirected d -regular graph G

$$\text{la}(G) \leq \frac{d}{2} + cd^{3/4}(\log d)^{1/2}$$

17.5.6 5.6 Latin Transversals

Following the proof of the Local Lemma we noted that the mutual independency assumption in this lemma can be replaced by the weaker assumption that the conditional probability of each event, given the mutual nonoccurrence of an arbitrary set of events, each nonadjacent to it in the dependency digraph, is sufficiently small. In this section we describe an application, from Erdős and Spencer (1991), of this modified version of the lemma. Let $A = (a_{ij})$ be an $n \times n$ matrix with, say, integer entries. A permutation π is called a Latin transversal (of A) if the entries $a_{i\pi(i)}$ ($1 \leq i \leq n$) are all distinct.

Theorem 5.6.1 Suppose $k \leq (n-1)/(4e)$ and suppose that no integer appears in more than k entries of A . Then A has a Latin transversal.

Proof. Let π be a random permutation of $\{1, 2, \dots, n\}$, chosen according to a uniform distribution among all possible $n!$ permutations. Denote by T the set of all ordered four-tuples

(i, j, i', j') satisfying $i < i', j \neq j'$ and $a_{ij} = a_{i'j'}$. For each $(i, j, i', j') \in T$, let $A_{ijj'i'j'}$ denote the event that $\pi(i) = j$ and $\pi(i') = j'$. The existence of a Latin transversal is equivalent to the statement that with positive probability none of these events hold. Let us define a symmetric digraph (i.e., a graph) G on the vertex set T by making (i, j, i', j') adjacent to (p, q, p', q') if and only if $\{i, i'\} \cap \{p, p'\} \neq \emptyset$ or $\{j, j'\} \cap \{q, q'\} \neq \emptyset$. Thus these two four-tuples are not adjacent iff the four cells $(i, j), (i', j'), (p, q)$ and (p', q') occupy four distinct rows and columns of A . The maximum degree of G is less than $4nk$; indeed, for a given $(i, j, i', j') \in T$ there are at most $4n$ choices of (s, t) with either $s \in \{i, i'\}$ or $t \in \{j, j'\}$, and for each of these choices of (s, t) there are less than k choices for $(s', t') \neq (s, t)$ with $a_{st} = a_{s't'}$. Each such four-tuple (s, t, s', t') can be uniquely represented as (p, q, p', q') with $p < p'$. Since $e \cdot 4nk \cdot [1/n(n-1)] \leq 1$, the desired result follows from the above mentioned strengthening of the symmetric version of the Local Lemma, if we can show that

$$\Pr \left[A_{ijj'i'j'} \mid \bigwedge_S \overline{A_{pp'q'q'}} \right] \leq \frac{1}{n(n-1)} \quad (5.8)$$

for any $(i, j, i', j') \in T$ and any set S of members of T that are nonadjacent in G to (i, j, i', j') . By symmetry, we may assume that $i = j = 1, i' = j' = 2$ and that hence none of the p 's or q 's are either 1 or 2. Let us call a permutation π good if it satisfies $\bigwedge_S \overline{A_{pp'q'q'}}$, and let S_{ij} denote the set of all good permutations π satisfying $\pi(1) = i$ and $\pi(2) = j$. We claim that $|S_{12}| \leq |S_{ij}|$ for all $i \neq j$. Indeed, suppose first that $i, j > 2$. For each good $\pi \in S_{12}$ define a permutation π^* as follows. Suppose $\pi(x) = i, \pi(y) = j$. Then define $\pi^*(1) = i, \pi^*(2) = j, \pi^*(x) = 1, \pi^*(y) = 2$ and $\pi^*(t) = \pi(t)$ for all $t \neq 1, 2, x, y$. One can easily check that π^* is good, since the cells $(1, i), (2, j), (x, 1), (y, 2)$ are not part of any $(p, q, p', q') \in S$. Thus $\pi^* \in S_{ij}$, and since the mapping $\pi \rightarrow \pi^*$ is injective $|S_{12}| \leq |S_{ij}|$, as claimed. Similarly one can define injective mappings showing that $|S_{12}| \leq |S_{ij}|$ even when $\{i, j\} \cap \{1, 2\} \neq \emptyset$. It follows that

$$\Pr \left[A_{1122} \wedge \bigwedge_S \overline{A_{pp'q'q'}} \right] \leq \Pr \left[A_{1i2j} \wedge \bigwedge_S \overline{A_{pp'q'q'}} \right]$$

for all $i \neq j$ and hence that

$$\Pr \left[A_{1122} \mid \bigwedge_S \overline{A_{pp'q'q'}} \right] \leq \frac{1}{n(n-1)}$$

By symmetry, this implies (5.8) and completes the proof.

17.5.7 5.7 The Algorithmic Aspect

When the probabilistic method is applied to prove that a certain event holds with high probability, it often supplies an efficient deterministic, or at least randomized, algorithm for the corresponding problem.

By applying the Local Lemma we often manage to prove that a given event holds with positive probability, although this probability may be exponentially small in the dimensions of the problem. Consequently, it is not clear if any of these proofs can provide polynomial algorithms for the corresponding algorithmic problems. For many years there was no known method of converting the proofs of any of the examples discussed in this chapter into an efficient algorithm. In 1991 J. Beck found such a method that works for some of these examples, with a little loss in the constants.

Beck (1991) demonstrated his method by considering the problem of hypergraph two-coloring. For simplicity we only describe here the case of fixed edge-size in which each edge intersects a fixed number of other edges.

Let n, d be fixed positive integers. By the (n, d) problem we mean the following: Given sets $A_1, \dots, A_N \subseteq \Omega$ with all $|A_i| = n$, such that no set A_i intersects more than d other sets A_j , find a two-coloring of Ω so that no A_i is monochromatic. When $e(d+1) < 2^{n-1}$, Theorem 5.2.1 assures us that this problem always does have a solution. Can we find the coloring in polynomial (in N for fixed n, d) time? Beck has given an affirmative answer under somewhat more restrictive assumptions. We assume Ω is of the form $\Omega = \{1, \dots, m\}$, $m \leq Nn$ and the initial data structure consists of a list of the elements of the sets A_i and a list giving for each element j those i for which $j \in A_i$. We let G denote the dependency graph with vertices the sets A_i and A_i, A_j adjacent if they overlap.

Theorem 5.7.1 Let n, d be such that, setting $D = d(d-1)^3$, there exists a decomposition $n = n_1 + n_2 + n_3$ with

$$16D(1+d) < 2^{n_1}$$

$$16D(1+d) < 2^{n_2}$$

$$2e(1+d) < 2^{n_3}$$

Then there is a randomized algorithm with expected running time $O(N(\ln N)^c)$ for the (n, d) problem, where c is a constant (depending only on n and d).

For $\epsilon < 1/11$, fixed, we note that the above conditions are satisfied, for n sufficiently large, when $d < 2^{n\epsilon}$ by taking $n_1 = n_2 \sim 5n/11$ and $n_3 \sim n/11$. We emphasize again that the algorithmic analysis here is for fixed n, d and N approaching infinity, although the argument can be extended to the nonfixed case as well.

Beck has given a deterministic algorithm for the (n, d) problem. The randomized algorithm we give may be derandomized using the techniques of Chapter 16. The running time remains polynomial but seemingly no longer $N^{1+o(1)}$. Moreover, the algorithm can even be parallelized using some of the techniques in Chapter 16 together with a certain modification in the algorithm.

Proof. The First Pass. During this pass, points will be either red, blue, uncolored or saved. We move through the points $j \in \Omega$ sequentially, coloring them red or blue at random, flipping a fair coin. After each j is colored we check all $A_i \ni j$. If A_i now has n_1 points in one color and no points in the other color we call A_i dangerous. All uncolored $k \in A_i$ are now considered saved. When saved points k are reached in the sequential coloring they are not colored but simply skipped over. At the conclusion of the First Pass points are red, blue or saved. We say a set A_i survives if it does not have both red and blue points. Let $S \subseteq G$ denote the (random) set of surviving sets.

Claim 5.7.2 Almost surely all components C of $G|_S$ have size $O(\ln N)$.

Proof. An $A_i \in S$ may be dangerous or, possibly, many of its points were saved because neighboring (in G) sets were dangerous. The probability of a particular A_i becoming dangerous is at most 2^{1-n_1} since for this to occur the first n_1 coin flips determining colors of $j \in A_i$ must come up the same. (We only have inequality since in addition n_1 points of A_i must be reached before being saved.) Let V be an independent set in G ; that is, the $A_i \in V$ are mutually disjoint. Then the probability that all $A_i \in V$ become dangerous is at most $(2^{1-n_1})^{|V|}$ as the coin flips involve disjoint sets. Now let $V \subseteq G$ be such that all distances between the $A_i \in V$ are at least 4, distance being the length of the shortest path in G . We claim that

$$\Pr[V \subseteq S] \leq (d+1)^{|V|} (2^{1-n_1})^{|V|}$$

This is because for each $A_i \in V$ there are at most $d+1$ choices for a dangerous neighbor $A_{i'}$, giving $(d+1)^{|V|}$ choices for the $A_{i'}$. As the A_i are at least four apart the $A_{i'}$ cannot be adjacent and so the probability that they are all dangerous is at most $(2^{1-n_1})^{|V|}$, as claimed.

Call $T \subseteq G$ a 4-tree if the $A_i \in T$ are such that all their mutual distances in G are at least four and so that, drawing an arc between $A_i, A_j \in T$ if their distance is precisely four, the resulting graph is connected. We first bound the number of 4-trees of size u . The "distance-four" graph defined on T must contain a tree. There are less than 4^j trees (up to isomorphism) on j vertices, now fix one. We can label the tree $1, \dots, u$ so that each $j > 1$ is adjacent to some $i < j$. Now consider the number of $(A^1, \dots, A^u)$ whose distance-four graph corresponds to this tree. There are N choices for A^1 . Having chosen A^i for all $i < j$ the set A^j must be at distance four from A^i in G and there are at most D such points. Hence the number of 4-trees of size u is at most $4^u N D^{u-1} < N(4D)^u$. For any particular 4-tree T we have already that $\Pr[T \subseteq S] \leq [(d+1)2^{1-n_1}]^u$. Hence the expected number of 4-trees $T \subseteq S$ is at most

$$N [8D(d+1)2^{-n_1}]^u$$

As the bracketed term is less than $1/2$ by assumption, for $u = c_1 \ln N$ this term is $o(1)$. Thus almost surely $G|_S$ will contain no 4-tree of size bigger than $c_1 \ln N$. We actually want to bound the size of the components C of $G|_S$. A maximal 4-tree T in a component C must have the property that every $A_i \in C$ lies within three of an $A_j \in T$. There are less than d^3 (a constant) A_i within three of any given A_j so that $c_1 \ln N \geq |T| \geq |C|d^{-3}$ and so (since d is a constant)

$$|C| \leq c_2 \ln N,$$

proving the claim.

If the First Pass leaves components of size larger than $c_2 \ln N$ we simply repeat the entire procedure. In expected linear time the First Pass is successful. The points that are red or blue are now fixed. The sets A_i with both red and blue points can now be ignored. For each surviving A_i fix a subset B_i of $n - n_1$ saved points. It now suffices to color the saved points so that no B_i is monochromatic. B_i are split into components of size $O(\ln N)$ and it suffices to color each component separately. On the Second Pass we apply the method of the First Pass to each component of the B_i . Now we call a set B_i dangerous if it receives n_2 points of one color and none of the other. The Second Pass takes expected time $O(M)$ to color a component of size M ,

hence an expected time $O(N)$ to color all the components. (For success we require that a component of size M is broken into components of size at most $c_2 \ln M$. To avoid trivialities, if $M < \ln \ln N$ we skip the Second Pass for the corresponding component.) At the end of the Second Pass (still in linear time!) there is a family of twice surviving sets $C_i \subset B_i \subset A_i$ of size n_3 , the largest component of which has size $O(\ln \ln N)$.

We still need to color these $O(N)$ components of sets of size n_3 , each component of size $O(\ln \ln N)$. By the Local Lemma (or directly by Theorem 5.2.1), each of these components can be two-colored. We now find the two-coloring by brute force! Examining all two-colorings of a component of size M takes time $O(M2^{n_M})$, which is $O((\ln N)^c)$ in our case. Doing this for all components takes time $O(N(\ln N)^c)$. This completes the coloring.

We note that with slightly more restrictions on n, d , a Third Pass could be made and then the total time would be $O(N(\ln N)^c)$. We note also that a similar technique can be applied for converting several other applications of the Local Lemma into efficient algorithms.

17.5.8 5.8 Exercises

- (*) Prove that for every integer $d > 1$ there is a finite $c(d)$ such that the edges of any bipartite graph with maximum degree d in which every cycle has at least $c(d)$ edges can be colored by $d+1$ colors so that there are no two adjacent edges with the same color and there is no two-colored cycle.

2. (*) Prove that for every $\epsilon > 0$ there is a finite $l_0 = l_0(\epsilon)$ and an infinite sequence of bits $a_1, a_2, a_3, \dots$, where $a_i \in \{0, 1\}$, such that for every $l > l_0$ and every $i \geq 1$ the two binary vectors $u = (a_i, a_{i+1}, \dots, a_{i+l-1})$ and $v = (a_{i+l}, a_{i+l+1}, \dots, a_{i+2l-1})$ differ in at least $(\frac{1}{2} - \epsilon)l$ coordinates.
3. Let $G = (V, E)$ be a simple graph and suppose each $v \in V$ is associated with a set $S(v)$ of colors of size at least $10d$, where $d \geq 1$. Suppose, in addition, that for each $v \in V$ and $c \in S(v)$ there are at most d neighbors u of v such that c lies in $S(u)$. Prove that there is a proper coloring of G assigning to each vertex v a color from its class $S(v)$.
4. Let $G = (V, E)$ be a cycle of length $4n$ and let $V = V_1 \cup V_2 \cup \dots \cup V_n$ be a partition of its $4n$ vertices into n pairwise disjoint subsets, each of cardinality 4. Is it true that there must be an independent set of G containing precisely one vertex from each V_i ? (Prove or supply a counter example.)
5. (*) Prove that there is an absolute constant $c > 0$ such that for every k there is a set S_k of at least $ck \ln k$ integers, such that for every coloring of the integers by k colors there is an integer x for which the set $x + S$ does not intersect all color classes.

The Probabilistic Lens: Directed Cycles

Let $D = (V, E)$ be a simple directed graph with minimum outdegree δ and maximum indegree Δ .

Theorem 1 [Alon and Linial (1989)] If $e(\Delta\delta + 1)(1 - 1/k)^\delta < 1$ then D contains a (directed, simple) cycle of length $0 \pmod k$.

Proof. Clearly we may assume that every outdegree is precisely δ , since otherwise we can consider a subgraph of D with this property.

Let $f : V \rightarrow \{0, 1, \dots, k-1\}$ be a random coloring of V , obtained by choosing, for each $v \in V$, $f(v) \in \{0, \dots, k-1\}$ independently, according to a uniform distribution. For each $v \in V$, let A_v denote the event that there is no $u \in V$, with $(v, u) \in E$ and $f(u) \equiv f(v) + 1 \pmod k$. Clearly $\Pr[A_v] = (1 - 1/k)^\delta$. One can easily check that each event A_v is mutually independent of all the events A_u but those satisfying

$$N^+(v) \cap \left(\{u\} \cup \bigcup N^+(u) \right) \neq \emptyset,$$

where here $N^+(v) = \{w \in V : (v, w) \in E\}$. The number of such u 's is at most $\Delta\delta$ and hence, by our assumption and by the Local Lemma (Corollary 5.1.2), $\Pr[\bigwedge_{v \in V} A_v] > 0$. Thus there is an $f : V \rightarrow \{0, 1, \dots, k-1\}$ such that for every $v \in V$ there is a $u \in V$ with

$$(v, u) \in E \quad \text{and} \quad f(u) \equiv f(v) + 1 \pmod k. \quad (1)$$

Starting at an arbitrary $v = v_0 \in V$ and applying (1) repeatedly we obtain a sequence $v_0, v_1, v_2, \dots$ of vertices of D so that $(v_i, v_{i+1}) \in E$ and $f(v_{i+1}) \equiv f(v_i) + 1 \pmod k$ for all $i \geq 0$. Let j be the minimum integer so that there is an $\ell < j$ with $v_\ell = v_j$. The cycle $v_\ell v_{\ell+1} v_{\ell+2} \dots v_j = v_\ell$ is a directed simple cycle of D whose length is divisible by k .

17.6 6 Correlation Inequalities

Let $G = (V, E)$ be a random graph on the set of vertices $V = \{1, 2, \dots, n\}$ generated by choosing, for each $i, j \in V, i \neq j$ independently, the pair $\{i, j\}$ to be an edge with probability p , where $0 < p < 1$. Let H be the event that G is Hamiltonian and let P be the event that G is planar. Suppose one wants to compare the two quantities $\Pr[P \wedge H]$ and $\Pr[P] \cdot \Pr[H]$.

Intuitively, knowing that G is Hamiltonian suggests that it has many edges and hence seems to indicate that G is less likely to be planar. Therefore it seems natural to expect that $\Pr[P \mid H] \leq \Pr[P]$ implying

$$\Pr[P \wedge H] \leq \Pr[H] \cdot \Pr[P].$$

This inequality, which is, indeed, correct, is a special case of the FKG inequality of Fortuin, Kasteleyn and Ginibre (1971). In this chapter we present the proof of this inequality and several related results, which deal with the correlation between certain events in probability spaces. The proofs of all these results are rather simple, and still they supply many interesting consequences. The first inequality of this type is due to Harris (1960). A result closer to the ones considered here is a lemma of Kleitman (1966a), stating that if $\mathcal{A}$ and $\mathcal{B}$ are two monotone decreasing families of subsets of $\{1, 2, \dots, n\}$ (i.e., $A \in \mathcal{A}$ and $A' \subseteq A \Rightarrow A' \in \mathcal{A}$ and, similarly $B \in \mathcal{B}$ and $B' \subseteq B \Rightarrow B' \in \mathcal{B}$) then

$$|\mathcal{A} \cap \mathcal{B}| \cdot 2^n \geq |\mathcal{A}| \cdot |\mathcal{B}|.$$

This lemma was followed by many extensions and generalizations until Ahlswede and Daykin (1978) obtained a very general result, which implies all these extensions. In the next section we present this result and its proof. Some of its many applications are discussed in the rest of the chapter.

17.6.1 6.1 The Four Functions Theorem of Ahlswede and Daykin

Suppose $n \geq 1$ and put $N = \{1, 2, \dots, n\}$. Let $P(N)$ denote the set of all subsets of N , and let $\mathbb{R}^+$ denote the set of nonnegative real numbers. For a function $\varphi : P(N) \rightarrow \mathbb{R}^+$ and for a family $\mathcal{A}$ of subsets of N denote $\varphi(\mathcal{A}) = \sum_{A \in \mathcal{A}} \varphi(A)$. For two families $\mathcal{A}$ and $\mathcal{B}$ of subsets of N define $\mathcal{A} \cup \mathcal{B} = \{A \cup B : A \in \mathcal{A}, B \in \mathcal{B}\}$ and $\mathcal{A} \cap \mathcal{B} = \{A \cap B : A \in \mathcal{A}, B \in \mathcal{B}\}$.

Theorem 6.1.1 [The Four Functions Theorem] Let $\alpha, \beta, \gamma, \delta : P(N) \rightarrow \mathbb{R}^+$ be four functions from the set of all subsets of N to the nonnegative reals. If, for every two subsets $A, B \subseteq N$ the inequality

$$\alpha(A)\beta(B) \leq \gamma(A \cup B)\delta(A \cap B) \tag{6.1}$$

holds, then, for every two families of subsets $\mathcal{A}, \mathcal{B} \subseteq P(N)$,

$$\alpha(\mathcal{A})\beta(\mathcal{B}) \leq \gamma(\mathcal{A} \cup \mathcal{B})\delta(\mathcal{A} \cap \mathcal{B}). \tag{6.2}$$

Proof. Observe, first, that we may modify the four functions $\alpha, \beta, \gamma, \delta$ by defining $\alpha(A) = 0$ for all $A \notin \mathcal{A}$, $\beta(B) = 0$ for all $B \notin \mathcal{B}$, $\gamma(C) = 0$ for all $C \notin \mathcal{A} \cup \mathcal{B}$, and $\delta(D) = 0$ for all $D \notin \mathcal{A} \cap \mathcal{B}$. Clearly (6.1) still holds for the modified functions and in inequality (6.2) we may assume now that $\mathcal{A} = \mathcal{B} = \mathcal{A} \cup \mathcal{B} = \mathcal{A} \cap \mathcal{B} = P(N)$.

To prove this inequality we apply induction on n . The only step that requires some computation is $n = 1$. In this case $P(N) = \{\emptyset, N\}$. For each function $\varphi \in \{\alpha, \beta, \gamma, \delta\}$ define $\varphi_0 = \varphi(\emptyset)$ and $\varphi_1 = \varphi(N)$. By (6.1) we have

$$\begin{aligned} \alpha_0\beta_0 &\leq \gamma_0\delta_0, \\ \alpha_0\beta_1 &\leq \gamma_1\delta_0, \\ \alpha_1\beta_0 &\leq \gamma_1\delta_0, \\ \alpha_1\beta_1 &\leq \gamma_1\delta_1. \end{aligned} \tag{6.3}$$

By the above paragraph we only have to prove inequality (6.2), where $\mathcal{A} = \mathcal{B} = P(N)$, that is, to prove that

$$(\alpha_0 + \alpha_1)(\beta_0 + \beta_1) \leq (\gamma_0 + \gamma_1)(\delta_0 + \delta_1). \quad (6.4)$$

If either $\gamma_1 = 0$ or $\delta_0 = 0$ this follows immediately from (6.3). Otherwise, by (6.3), $\gamma_0 \geq \alpha_0\beta_0/\delta_0$ and $\delta_1 \geq \alpha_1\beta_1/\gamma_1$. It thus suffices to show that

$$\left(\frac{\alpha_0\beta_0}{\delta_0} + \gamma_1\right) \left(\delta_0 + \frac{\alpha_1\beta_1}{\gamma_1}\right) \geq (\alpha_0 + \alpha_1)(\beta_0 + \beta_1),$$

or, equivalently, that

$$(\alpha_0\beta_0 + \gamma_1\delta_0)(\delta_0\gamma_1 + \alpha_1\beta_1) \geq (\alpha_0 + \alpha_1)(\beta_0 + \beta_1)\delta_0\gamma_1.$$

The last inequality is equivalent to

$$(\gamma_1\delta_0 - \alpha_0\beta_1)(\gamma_1\delta_0 - \alpha_1\beta_0) \geq 0,$$

which follows from (6.3), as both factors on the left-hand side are nonnegative. This completes the proof for $n = 1$.

Suppose, now, that the theorem holds for $n - 1$ and let us prove it for $n (\geq 2)$. Put $N' = N \setminus \{n\}$ and define for each $\varphi \in \{\alpha, \beta, \gamma, \delta\}$ and each $A \subseteq N'$, $\varphi'(A) = \varphi(A) + \varphi(A \cup \{n\})$. Clearly, for each function $\varphi \in \{\alpha, \beta, \gamma, \delta\}$, $\varphi'(P(N')) = \varphi(P(N))$. Therefore the desired inequality (6.3) would follow from applying the induction hypothesis to the functions $\alpha', \beta', \gamma', \delta' : P(N') \rightarrow \mathbb{R}^+$. However, in order to apply this hypothesis we have to check that these new functions satisfy the assumption of Theorem 6.1.1 on N' ; that is, that for every $A', B' \subseteq N'$,

$$\alpha'(A')\beta'(B') \leq \gamma'(A' \cup B')\delta'(A' \cap B'). \quad (6.5)$$

Not surprisingly, this last inequality follows easily from the case $n = 1$, which we have already proved. Indeed, let T be a 1-element set and define

$$\begin{aligned} \bar{\alpha}(\emptyset) &= \alpha(A'), & \bar{\alpha}(T) &= \alpha(A' \cup \{n\}), \\ \bar{\beta}(\emptyset) &= \beta(B'), & \bar{\beta}(T) &= \beta(B' \cup \{n\}), \\ \bar{\gamma}(\emptyset) &= \gamma(A' \cup B'), & \bar{\gamma}(T) &= \gamma(A' \cup B' \cup \{n\}), \\ \bar{\delta}(\emptyset) &= \delta(A' \cap B'), & \bar{\delta}(T) &= \delta((A' \cap B') \cup \{n\}). \end{aligned}$$

By the assumption (6.1), $\bar{\alpha}(S)\bar{\beta}(R) \leq \bar{\gamma}(S \cup R)\bar{\delta}(S \cap R)$ for all $S, R \subseteq T$ and hence, by the case $n = 1$ already proved,

$$\alpha'(A')\beta'(B') = \bar{\alpha}(P(T))\bar{\beta}(P(T)) \leq \bar{\gamma}(P(T))\bar{\delta}(P(T)) = \gamma'(A' \cup B')\delta'(A' \cap B'),$$

which is the desired inequality (6.5). Therefore inequality (6.2) holds, completing the proof. $\square$

The Ahlswede-Daykin Theorem can be extended to arbitrary finite distributive lattices. A lattice is a partially ordered set in which every two elements, x and y , have a unique minimal upper bound, denoted by $x \vee y$ and called the join of x and y and a unique maximal lower bound, denoted by $x \wedge y$ and called the meet of x and y . A lattice L is distributive if for all $x, y, z \in L$,

$$x \wedge (y \vee z) = (x \wedge y) \vee (x \wedge z)$$

or, equivalently if for all $x, y, z \in L$,

$$x \vee (y \wedge z) = (x \vee y) \wedge (x \vee z)$$

For two sets $X, Y \subseteq L$ define

$$X \vee Y = \{x \vee y : x \in X, y \in Y\}$$

and

$$X \wedge Y = \{x \wedge y : x \in X, y \in Y\}$$

Any subset L of $P(N)$, where $N = \{1, 2, \dots, n\}$, ordered by inclusion, which is closed under the union and intersection operations is a distributive lattice. Here, the join of two members $A, B \in L$ is simply their union $A \cup B$ and their meet is the intersection $A \cap B$. It is somewhat more surprising (but easy to check) that every finite distributive lattice L is isomorphic to a sublattice of $P(\{1, 2, \dots, n\})$ for some n . [To see this, call an element $x \in L$ join-irreducible if whenever $x = y \vee z$ then either $x = y$ or $x = z$. Let $x_1, x_2, \dots, x_n$ be the set of all join-irreducible elements in L and associate each element $x \in L$ with the set $A = A(x) \subseteq N$, where $x = \bigvee_{i \in A} x_i$ and $\{x_i : i \in A\}$ are all the join-irreducibles y satisfying $y \leq x$. The mapping $x \rightarrow A(x)$ is the desired isomorphism.] This fact enables us to generalize Theorem 6.1.1 to arbitrary finite distributive lattices as follows.

Corollary 6.1.2 Let L be a finite distributive lattice and let α, β, γ and δ be four functions from L to $\mathbb{R}^+$. If

$$\alpha(x)\beta(y) \leq \gamma(x \vee y)\delta(x \wedge y)$$

for all $x, y \in L$ then for every $X, Y \subseteq L$,

$$\alpha(X)\beta(Y) \leq \gamma(X \vee Y)\delta(X \wedge Y)$$

The simplest case in the last corollary is the case where all the four functions α, β, γ and δ are identically 1, stated below.

Corollary 6.1.3 Let L be a finite distributive lattice and suppose $X, Y \subseteq L$. Then

$$|X| \cdot |Y| \leq |X \vee Y| \cdot |X \wedge Y|.$$

We close this section by presenting a very simple consequence of the last corollary, first proved by Marica and Schonheim (1969).

Corollary 6.1.4 Let $\mathcal{A}$ be a family of subsets of a finite set N and define

$$\mathcal{A} \setminus \mathcal{A} = \{F \setminus F' : F, F' \in \mathcal{A}\}$$

Then $|\mathcal{A} \setminus \mathcal{A}| \geq |\mathcal{A}|$.

Proof. Let L be the distributive lattice of all subsets of N . By applying Corollary 6.1.3 to $\mathcal{A}$ and $\mathcal{B} = \{N \setminus F : F \in \mathcal{A}\}$ we obtain

$$|\mathcal{A}|^2 = |\mathcal{A}| \cdot |\mathcal{B}| \leq |\mathcal{A} \cup \mathcal{B}| \cdot |\mathcal{A} \cap \mathcal{B}| = |\mathcal{A} \setminus \mathcal{A}|^2.$$

The desired result follows.

17.6.2 6.2 The Fkg Inequality

A function $\mu : L \rightarrow \mathbb{R}^+$, where L is a finite distributive lattice, is called logsupermodular if

$$\mu(x)\mu(y) \leq \mu(x \vee y)\mu(x \wedge y)$$

for all $x, y \in L$. A function $f : L \rightarrow \mathbb{R}^+$ is increasing if $f(x) \leq f(y)$ whenever $x \leq y$ and is decreasing if $f(x) \geq f(y)$ whenever $x \leq y$.

Motivated by a problem from statistical mechanics, Fortuin et al. (1971) proved the following useful inequality, which has become known as the FKG Inequality.

Theorem 6.2.1 [The FKG Inequality] Let L be a finite distributive lattice and let $\mu : L \rightarrow \mathbb{R}^+$ be a log-supermodular function. Then, for any two increasing functions $f, g : L \rightarrow \mathbb{R}^+$ we have

$$\left(\sum_{x \in L} \mu(x) f(x) \right) \left(\sum_{x \in L} \mu(x) g(x) \right) \leq \left(\sum_{x \in L} \mu(x) f(x) g(x) \right) \left(\sum_{x \in L} \mu(x) \right). \quad (6.6)$$

Proof. Define four functions $\alpha, \beta, \gamma, \delta : L \rightarrow \mathbb{R}^+$ as follows. For each $x \in L$,

$$\begin{aligned} \alpha(x) &= \mu(x) f(x), & \beta(x) &= \mu(x) g(x), \\ \gamma(x) &= \mu(x) f(x) g(x), & \delta(x) &= \mu(x). \end{aligned}$$

We claim that these functions satisfy the hypothesis of the Ahlswede-Daykin Theorem, stated in Corollary 6.1.2. Indeed, if $x, y \in L$ then, by the supermodularity of μ and since f and g are increasing,

$$\begin{aligned} \alpha(x) \beta(y) &= \mu(x) f(x) \mu(y) g(y) \leq \mu(x \vee y) f(x) g(y) \mu(x \wedge y) \\ &\leq \mu(x \vee y) f(x \vee y) g(x \vee y) \mu(x \wedge y) = \gamma(x \vee y) \delta(x \wedge y) \end{aligned}$$

Therefore by Corollary 6.1.2 (with $X = Y = L$),

$$\alpha(L) \beta(L) \leq \gamma(L) \delta(L)$$

which is the desired result.

Note that the conclusion of Theorem 6.2.1 holds also if both f and g are decreasing (simply interchange γ and δ in the proof). In case f is increasing and g is decreasing (or vice versa) the opposite inequality holds:

$$\left(\sum_{x \in L} \mu(x) f(x) \right) \left(\sum_{x \in L} \mu(x) g(x) \right) \geq \left(\sum_{x \in L} \mu(x) f(x) g(x) \right) \left(\sum_{x \in L} \mu(x) \right).$$

To prove it, simply apply Theorem 6.2.1 to the two increasing functions $f(x)$ and $k - g(x)$, where k is the constant $\max_{x \in L} g(x)$. [This constant is needed to guarantee that $k - g(x) \geq 0$ for all $x \in L$.]

It is helpful to view μ as a measure on L . Assuming μ is not identically zero we can define, for any function $f : L \rightarrow \mathbb{R}^+$, its expectation,

$$\langle f \rangle = \frac{\sum_{x \in L} f(x) \mu(x)}{\sum_{x \in L} \mu(x)}.$$

With this notation, the FKG Inequality asserts that if μ is log-supermodular and $f, g : L \rightarrow \mathbb{R}^+$ are both increasing or both decreasing then

$$\langle fg \rangle \geq \langle f \rangle \langle g \rangle$$

Similarly, if f is increasing and g is decreasing (or vice versa), then

$$\langle fg \rangle \leq \langle f \rangle \langle g \rangle$$

This formulation demonstrates clearly the probabilistic nature of the inequality, some of whose many interesting consequences are presented in the rest of this chapter.

17.6.3 6.3 Monotone Properties

Recall that a family $\mathcal{A}$ of subsets of $N = \{1, 2, \dots, n\}$ is monotone decreasing if $A \in \mathcal{A}$ and $A' \subseteq A \Rightarrow A' \in \mathcal{A}$. Similarly, it is monotone increasing if $A \in \mathcal{A}$ and $A \subseteq A' \Rightarrow A' \in \mathcal{A}$. By considering the power set $P(N)$ as a symmetric probability space, one naturally defines the probability of $\mathcal{A}$ by

$$\Pr[\mathcal{A}] = \frac{|\mathcal{A}|}{2^n}.$$

Thus $\Pr[\mathcal{A}]$ is simply the probability that a randomly chosen subset of N lies in $\mathcal{A}$. Kleitman's Lemma, which was the starting point of all the correlation inequalities considered in this chapter, is the following.

Proposition 6.3.1 Let $\mathcal{A}$ and $\mathcal{B}$ be two monotone increasing families of subsets of $N = \{1, 2, \dots, n\}$ and let $\mathcal{C}$ and $\mathcal{D}$ be two monotone decreasing families of subsets of N . Then

$$\Pr[\mathcal{A} \cap \mathcal{B}] \geq \Pr[\mathcal{A}] \cdot \Pr[\mathcal{B}],$$

$$\Pr[\mathcal{C} \cap \mathcal{D}] \geq \Pr[\mathcal{C}] \cdot \Pr[\mathcal{D}],$$

$$\Pr[\mathcal{A} \cap \mathcal{C}] \leq \Pr[\mathcal{A}] \cdot \Pr[\mathcal{C}].$$

In terms of cardinalities, this can be read as follows:

$$2^n |\mathcal{A} \cap \mathcal{B}| \geq |\mathcal{A}| \cdot |\mathcal{B}|,$$

$$2^n |\mathcal{C} \cap \mathcal{D}| \geq |\mathcal{C}| \cdot |\mathcal{D}|,$$

$$2^n |\mathcal{A} \cap \mathcal{C}| \leq |\mathcal{A}| \cdot |\mathcal{C}|,$$

where here and in what follows, $\mathcal{A} \cap \mathcal{B}$, $\mathcal{C} \cap \mathcal{D}$ and $\mathcal{A} \cap \mathcal{C}$ denote usual intersections of families.

Proof. Let $f : P(N) \rightarrow \mathbb{R}^+$ be the characteristic function of $\mathcal{A}$; that is, $f(A) = 0$ if $A \notin \mathcal{A}$ and $f(A) = 1$ if $A \in \mathcal{A}$. Similarly, let g be the characteristic function of $\mathcal{B}$. By the assumptions, f and g are both increasing. Applying the FKG Inequality with the trivial measure $\mu \equiv 1$ we get

$$\Pr[\mathcal{A} \cap \mathcal{B}] = \langle fg \rangle \geq \langle f \rangle \langle g \rangle = \Pr[\mathcal{A}] \cdot \Pr[\mathcal{B}]$$

The other two inequalities follow similarly from Theorem 6.2.1 and the paragraph following it.

It is worth noting that this proposition can be also derived easily from the Ahlswede-Daykin Theorem or from Corollary 6.1.3.

The last proposition has several interesting combinatorial consequences, some of which appear already in Kleitman's original paper. Since those are direct combinatorial consequences and do not contain any additional probabilistic ideas, we omit their exact statement and turn to a version of Proposition 6.3.1 in a more general probability space.

For a real vector $p = (p_1, \dots, p_n)$, where $0 \leq p_i \leq 1$, consider the probability space whose elements are all members of the power set $P(N)$, where, for each $A \subseteq N$, $\Pr[A] = \prod_{i \in A} p_i \prod_{j \notin A} (1 - p_j)$. Clearly this probability distribution is obtained if we choose a random $A \subseteq N$ by choosing each element $i \in N$, independently, with probability p_i . Let us denote, for each $\mathcal{A} \subseteq P(N)$, its probability in this space by $\Pr_p[\mathcal{A}]$. In particular, if all the probabilities p_i are $1/2$ then $\Pr_p[\mathcal{A}]$ is the quantity denoted as $\Pr[\mathcal{A}]$ in Proposition 6.3.1. Define $\mu = \mu_p : P(N) \rightarrow \mathbb{R}^+$ by $\mu(A) = \prod_{i \in A} p_i \prod_{j \notin A} (1 - p_j)$.

It is easy to check that μ is log-supermodular. This is because for $A, B \subseteq N$, $\mu(A)\mu(B) = \mu(A \cup B)\mu(A \cap B)$, as can be checked by comparing the contribution arising from each $i \in N$ to the left-hand side and to the right-hand side of the last equality. Hence one can apply the FKG Inequality and obtain the following generalization of Proposition 6.3.1.

Theorem 6.3.2 Let $\mathcal{A}$ and $\mathcal{B}$ be two monotone increasing families of subsets of N and let $\mathcal{C}$ and $\mathcal{D}$ be two monotone decreasing families of subsets of N . Then, for any real vector $p = (p_1, \dots, p_n)$, $0 \leq p_i \leq 1$,

$$\begin{aligned}\Pr_p[\mathcal{A} \cap \mathcal{B}] &\geq \Pr_p[\mathcal{A}] \cdot \Pr_p[\mathcal{B}], \\ \Pr_p[\mathcal{C} \cap \mathcal{D}] &\geq \Pr_p[\mathcal{C}] \cdot \Pr_p[\mathcal{D}], \\ \Pr_p[\mathcal{A} \cap \mathcal{C}] &\leq \Pr_p[\mathcal{A}] \cdot \Pr_p[\mathcal{C}].\end{aligned}$$

This theorem can be applied in many cases and will be used in Chapter 8 to derive the Janson Inequalities. As a simple illustration suppose that $A_1, A_2, \dots, A_k$ are arbitrary subsets of N and one chooses a random subset A of N by choosing each $i \in N$, independently, with probability p . Then, Theorem 6.3.2 easily implies that

$$\Pr[A \text{ intersects each } A_i] \geq \prod_{i=1}^k \Pr[A \text{ intersects } A_i]$$

Note that this is false, in general, for other similar probabilistic models. For example, if A is a randomly chosen ℓ -element subset of N then the last inequality may fail.

By viewing the members of N as the $n = \binom{m}{2}$ edges of the complete graph on the set of vertices $V = \{1, 2, \dots, m\}$, we can derive a correlation inequality for random graphs. Let $G = (V, E)$ be a random graph on the set of vertices V generated by choosing, for each $i, j \in V, i \neq j$, independently, the pair $\{i, j\}$ to be an edge with probability p . (This model of random graphs is discussed in detail in Chapter 10.) A property of graphs is a subset of the set of all graphs on V , closed under isomorphism. Thus, for example, connectivity is a property (corresponding to all connected graphs on V) and planarity is another property. A property Q is monotone increasing if whenever G has Q and H is obtained from G by adding edges then H has Q too. A monotone decreasing property is defined in a similar manner. By interpreting the members of N in Theorem 6.3.2 as the $\binom{m}{2}$ pairs $\{i, j\}$ with $i, j \in V, i \neq j$ we obtain the following.

Theorem 6.3.3 Let Q_1, Q_2, Q_3 and Q_4 be graph properties, where Q_1, Q_2 are monotone increasing and Q_3, Q_4 are monotone decreasing. Let $G = (V, E)$ be a random graph on V obtained by picking every edge, independently, with probability p . Then

$$\begin{aligned}\Pr[G \in Q_1 \cap Q_2] &\geq \Pr[G \in Q_1] \cdot \Pr[G \in Q_2], \\ \Pr[G \in Q_3 \cap Q_4] &\geq \Pr[G \in Q_3] \cdot \Pr[G \in Q_4], \\ \Pr[G \in Q_1 \cap Q_3] &\leq \Pr[G \in Q_1] \cdot \Pr[G \in Q_3].\end{aligned}$$

Thus, for example, the probability that G is both Hamiltonian and planar does not exceed the product of the probability that it is Hamiltonian by that it is planar. It seems hopeless to try and prove such a statement directly, without using one of the correlation inequalities.

17.6.4 6.4 Linear Extensions of Partially Ordered Sets

Let $(P, \leq)$ be a partially ordered set with n elements. A linear extension of P is a one to one mapping $\sigma : P \rightarrow \{1, 2, \dots, n\}$, which is order preserving; that is, if $x, y \in P$ and $x \leq y$ then $\sigma(x) \leq \sigma(y)$. Intuitively, σ is a ranking of the elements of P that preserves the partial order of P . Consider the probability space of all linear extensions of P , where each possible extension is equally likely. In this space we can consider events of the form, for example, $x \leq y$ or $(x \leq y) \wedge (x \leq z)$ (for $x, y, z \in P$) and compute their probabilities. It turns out that the FKG Inequality is a very useful tool for studying the correlation between such events. The best known result of this

form was conjectured by Rival and Sands and proved by Shepp (1982). [See also Fishburn

(1992) for a strengthening.] It asserts that for any partially ordered set P and any three elements $x, y, z \in P$: $\Pr[x \leq y \wedge x \leq z] \geq \Pr[x \leq y] \Pr[x \leq z]$.

This result became known as the *XYZ Theorem*. Although it looks intuitively obvious, its proof is nontrivial and contains a clever application of the FKG Inequality. In this section we present this result and its elegant proof.

Theorem 6.4.1 Let P be a partially ordered set with n elements $a_1, a_2, \dots, a_n$. Then

$$\Pr[a_1 \leq a_2 \wedge a_1 \leq a_3] \geq \Pr[a_1 \leq a_2] \Pr[a_1 \leq a_3]$$

Proof. Let m be a large integer (which will later tend to infinity) and let L be the set of all ordered n -tuples $\mathbf{x} = (x_1, \dots, x_n)$, where $x_i \in M = \{1, 2, \dots, m\}$. (Note that we do not assume that the numbers x_i are distinct.) Define an order relation $\leq$ on L as follows. For $\mathbf{y} = (y_1, \dots, y_n) \in L$ and $\mathbf{x}$ as above $\mathbf{x} \leq \mathbf{y}$ iff $x_1 \geq y_1$ and $x_i - x_1 \leq y_i - y_1$ for all $2 \leq i \leq n$. It is not too difficult to check that $(L, \leq)$ is a lattice in which the i th component of the meet $\mathbf{x} \wedge \mathbf{y}$ is $(\mathbf{x} \wedge \mathbf{y})_i = \min\{x_i - x_1, y_i - y_1\} + \max\{x_1, y_1\}$ and the i th component of the join $\mathbf{x} \vee \mathbf{y}$ is $(\mathbf{x} \vee \mathbf{y})_i = \max\{x_i - x_1, y_i - y_1\} + \min\{x_1, y_1\}$.

Moreover, the lattice L is distributive. This follows by an easy computation from the fact that the trivial lattice of integers (with respect to the usual order) is distributive and hence for any three integers a, b and c ,

$$\min\{a, \max\{b, c\}\} = \max\{\min\{a, b\}, \min\{a, c\}\}, \quad (6.7)$$

and

$$\max\{a, \min\{b, c\}\} = \min\{\max\{a, b\}, \max\{a, c\}\}. \quad (6.8)$$

Let us show how this implies that L is distributive. Let $\mathbf{x} = (x_1, \dots, x_n)$, $\mathbf{y} = (y_1, \dots, y_n)$ and $\mathbf{z} = (z_1, \dots, z_n)$ be three elements of L . We must show that

$$\mathbf{x} \wedge (\mathbf{y} \vee \mathbf{z}) = (\mathbf{x} \wedge \mathbf{y}) \vee (\mathbf{x} \wedge \mathbf{z})$$

The i th component of $\mathbf{x} \wedge (\mathbf{y} \vee \mathbf{z})$ is

$$\begin{aligned} (\mathbf{x} \wedge (\mathbf{y} \vee \mathbf{z}))_i &= \min\{x_i - x_1, (\mathbf{y} \vee \mathbf{z})_i - (\mathbf{y} \vee \mathbf{z})_1\} \\ &\quad + \max\{x_1, (\mathbf{y} \vee \mathbf{z})_1\} \\ &= \min\{x_i - x_1, \max\{y_i - y_1, z_i - z_1\}\} \\ &\quad + \max\{x_1, \min\{y_1, z_1\}\} \end{aligned}$$

Similarly, the i th component of $(\mathbf{x} \wedge \mathbf{y}) \vee (\mathbf{x} \wedge \mathbf{z})$ is

$$\begin{aligned} &((\mathbf{x} \wedge \mathbf{y}) \vee (\mathbf{x} \wedge \mathbf{z}))_i \\ &= \max\{(\mathbf{x} \wedge \mathbf{y})_i - (\mathbf{x} \wedge \mathbf{y})_1, (\mathbf{x} \wedge \mathbf{z})_i - (\mathbf{x} \wedge \mathbf{z})_1\} \\ &\quad + \min\{(\mathbf{x} \wedge \mathbf{y})_1, (\mathbf{x} \wedge \mathbf{z})_1\} \\ &= \max\{\min\{x_i - x_1, y_i - y_1\}, \min\{x_i - x_1, z_i - z_1\}\} \\ &\quad + \min\{\max\{x_1, y_1\}, \max\{x_1, z_1\}\}. \end{aligned}$$

These two quantities are equal, as follows by applying (6.7) with $a = x_i - x_1$, $b = y_i - y_1$, $c = z_i - z_1$ and (6.8) with $a = x_1$, $b = y_1$, $c = z_1$.

Thus L is distributive. To apply the FKG Inequality we need the measure function μ and the two functions f and g . Let μ be the characteristic function of P ; that is, for $\mathbf{x} = (x_1, \dots, x_n) \in L$, $\mu(\mathbf{x}) = 1$ if $x_i \leq x_j$ whenever $a_i \leq a_j$ in P and $\mu(\mathbf{x}) = 0$ otherwise. To show that μ is log-supermodular it suffices to check that if $\mu(\mathbf{x}) = \mu(\mathbf{y}) = 1$ then $\mu(\mathbf{x} \vee \mathbf{y}) = \mu(\mathbf{x} \wedge \mathbf{y}) = 1$. However, if $\mu(\mathbf{x}) = \mu(\mathbf{y}) = 1$ and $a_i \leq a_j$ in P then $x_i \leq x_j$ and $y_i \leq y_j$ and hence

$$\begin{aligned}(x \vee y)_i &= \max \{x_i - x_1, y_i - y_1\} + \min \{x_1, y_1\} \\ &\leq \max \{x_j - x_1, y_j - y_1\} + \min \{x_1, y_1\} = (x \vee y)_j,\end{aligned}$$

that is, $\mu(\mathbf{x} \vee \mathbf{y}) = 1$. Similarly, $\mu(\mathbf{x}) = \mu(\mathbf{y}) = 1$ implies $\mu(\mathbf{x} \wedge \mathbf{y}) = 1$ too.

Not surprisingly, we define the functions f and g as the characteristic functions of the two events $x_1 \leq x_2$ and $x_1 \leq x_3$, respectively; that is, $f(\mathbf{x}) = 1$ if $x_1 \leq x_2$ and $f(\mathbf{x}) = 0$ otherwise, and $g(\mathbf{x}) = 1$ if $x_1 \leq x_3$ and $g(\mathbf{x}) = 0$ otherwise. Trivially, both f and g are increasing. Indeed, if $\mathbf{x} \leq \mathbf{y}$ and $f(\mathbf{x}) = 1$ then $0 \leq x_2 - x_1 \leq y_2 - y_1$ and hence $f(\mathbf{y}) = 1$, and similarly for g .

We therefore have all the necessary ingredients for applying the FKG Inequality (Theorem 6.2.1). This gives that in L the probability that an n -tuple $(x_1, \dots, x_n)$ that satisfies the inequalities in P satisfies both $x_1 \leq x_2$ and $x_1 \leq x_3$ is at least as big as the product of the probability that it satisfies $x_1 \leq x_2$ by that it satisfies $x_1 \leq x_3$. Note that this is not yet what we wanted to prove; the n -tuples in L are not n -tuples of distinct integers and thus do not correspond to linear extensions of P . However, as $m \rightarrow \infty$, the probability that $x_i = x_j$ for some $i \neq j$ in a member $\mathbf{x} = (x_1, \dots, x_n)$ of L tends to 0 and the assertion of the theorem follows.

17.6.5 6.5 Exercises

1. Let G be a graph and let P denote the probability that a random subgraph of G obtained by picking each edge of G with probability $1/2$, independently, is connected (and spanning). Let Q denote the probability that in a random two-coloring of G , where each edge is chosen, randomly and independently, to be either red or blue, the red graph and the blue graph are both connected (and spanning). Is $Q \leq P^2$?
2. A family of subsets $\mathcal{G}$ is called intersecting if $G_1 \cap G_2 \neq \emptyset$ for all $G_1, G_2 \in \mathcal{G}$. Let $\mathcal{F}_1, \mathcal{F}_2, \dots, \mathcal{F}_k$ be k intersecting families of subsets of $\{1, 2, \dots, n\}$. Prove that

$$\left| \bigcup_{i=1}^k \mathcal{F}_i \right| \leq 2^n - 2^{n-k}$$

3. Show that the probability that in the random graph $G(2k, 1/2)$ the maximum degree is at most $k-1$ is at least $1/4^k$.

The Probabilistic Lens: Turán's Theorem

In a graph $G = (V, E)$ let d_v denote the degree of a vertex v and let $\alpha(G)$ be the maximal size of an independent set of vertices. The following result was proved by Caro and Wei.

Theorem $1\alpha(G) \geq \sum_{v \in V} \frac{1}{d_v + 1}$.

Proof. Let $<$ be a uniformly chosen total ordering of V . Define

$$I = \{v \in V : \{v, w\} \in E \Rightarrow v < w\}.$$

Let X_v be the indicator random variable for $v \in I$ and $X = \sum_{v \in V} X_v = |I|$. For each v ,

$$\mathbb{E}[X_v] = \Pr[v \in I] = \frac{1}{d_v + 1}$$

since $v \in I$ if and only if v is the least element among v and its neighbors. Hence

$$\mathbb{E}[X] = \sum_{v \in V} \frac{1}{d_v + 1}$$

and so there exists a specific ordering $<$ with

$$|I| \geq \sum_{v \in V} \frac{1}{d_v + 1}$$

But if $x, y \in I$ and $\{x, y\} \in E$ then $x < y$ and $y < x$, a contradiction. Thus I is independent and $\alpha(G) \geq |I|$.

For any $m \leq n$ let q, r satisfy $n = mq + r, 0 \leq r < m$, and let $e = r \binom{q+1}{2} + (m-r) \binom{q}{2}$. Define a graph $G = G_{n,e}$ on n vertices and e edges by splitting the vertex set into m classes as evenly as possible and joining two vertices if and only if they lie in the same class. Clearly $\alpha(G_{n,e}) = m$.

Theorem 2 [Turán (1941)] Let H have n vertices and e edges. Then $\alpha(H) \geq m$ and $\alpha(H) = m \Leftrightarrow H \cong G_{n,e}$.

Proof. $G_{n,e}$ has $\sum_{v \in V} (d_v + 1)^{-1} = m$ since each clique contributes 1 to the sum. Fixing $e = \sum_{v \in V} d_v/2$, $\sum_{v \in V} (d_v + 1)^{-1}$ is minimized with the d_v as close together as possible. Thus for any H ,

$$\alpha(H) \geq \sum_{v \in V} \frac{1}{d_v + 1} \geq m.$$

For $\alpha(H) = m$ we must have equality on both sides above. The second equality implies the d_v must be as close together as possible. Letting $X = |I|$ as in the previous theorem, assume $\alpha(H) = E[X]$. But $\alpha(H) \geq X$ for all values of $<$ so X must be a constant. Suppose H is not a union of cliques. Then, there exist $x, y, z \in V$ with $\{x, y\}, \{x, z\} \in E, \{y, z\} \notin E$. Let $<$ be an ordering that begins x, y, z and $<'$ the same ordering except that it begins y, z, x , and let I, I' be the corresponding sets of vertices all of whose neighbors are "greater." Then I, I' are identical except that $x \in I, y, z \notin I$, whereas $x \notin I', y, z \in I'$. Thus X is not constant. That is, $\alpha(H) = E[X]$ implies that H is the union of cliques and so $H \cong G_{n,e}$.

17.7 7 Martingales and Tight Concentration

Mathematics seems much more real to me than business - in the sense that, well, what's the reality in a McDonald's stand? It's here today and gone tomorrow. Now, the integers - that's reality. When you prove a theorem, you've really done something that has substance to it, to which no business venture can compare for reality.

- Jim Simons

17.7.1 7.1 Definitions

A martingale is a sequence $X_0, \dots, X_m$ of random variables so that for $0 \leq i < m$,

$$E[X_{i+1} \mid X_i, X_{i-1}, \dots, X_0] = X_i$$

Imagine a gambler walking into a casino with X_0 dollars. The casino contains a variety of games of chance. All games are "fair" in that their expectations are zero. The gambler may allow previous history to determine his choice of game and bet. He might employ the gambler's definition of martingale - double the bet until you win. He might play roulette until he wins three times and then switch to keno. Let X_i be the gambler's fortune at time i . Given that $X_i = a$ the conditional expectation of X_{i+1} must be a and so this is a martingale.

A simple but instructive martingale occurs when the gambler plays "flip a coin" for stakes of one dollar each time. Let $Y_1, \dots, Y_m$ be independent coin flips, each $+1$ or -1 with probability

1/2. Normalize so that $X_0 = 0$ is the gambler's initial stake, though he has unlimited credit. Then $X_i = Y_1 + \dots + Y_i$ has distribution S_i .

Our martingales will look quite different, at least from the outside.

The Edge Exposure Martingale. Let the random graph $G(n, p)$ be the underlying probability space. Label the potential edges $\{i, j\} \subseteq [n]$ by $e_1, \dots, e_m$, setting $m = \binom{n}{2}$ for convenience, in any specific manner. Let f be any graph theoretic function. We define a martingale $X_0, \dots, X_m$ by giving the values $X_i(H)$. $X_m(H)$ is simply $f(H)$. $X_0(H)$ is the expected value of $f(G)$ with $G \sim G(n, p)$. Note that X_0 is a constant. In general (including the cases $i = 0$ and $i = m$),

$$X_i(H) = E[f(G) \mid e_j \in G \Leftrightarrow e_j \in H, 1 \leq j \leq i].$$

In words, to find $X_i(H)$ we first expose the first i pairs $e_1, \dots, e_i$ and see if they are in H . The remaining edges are not seen and considered to be random. $X_i(H)$ is then the conditional expectation of $f(G)$ with this partial information. When $i = 0$ nothing is exposed and X_0 is a constant. When $i = m$ all is exposed and X_m is the function f . The martingale moves from no information to full information in small steps.

Fig. 7.1 The edge exposure martingale with $n = m = 3$, f is the chromatic number and the edges exposed in the order "bottom, left, right." The values $X_{\{i\}}$ are given by tracing from the central node to the leaf labeled H .

The figure shows why this is a martingale. The conditional expectation of $f(H)$ knowing the first $i - 1$ edges is the weighted average of the conditional expectations of $f(H)$, where the i th edge has been exposed. More generally - in what is sometimes referred to as a Doob martingale process - X_i may be the conditional expectation of $f(H)$ after certain information is revealed as long as the information known at time i includes the information known at time $i - 1$.

The Vertex Exposure Martingale. Again let $G(n, p)$ be the underlying probability space and f any graph theoretic function. Define $X_1, \dots, X_n$ by

$$X_i(H) = E[f(G) \mid \text{for } x, y \leq i, \{x, y\} \in G \Leftrightarrow \{x, y\} \in H].$$

In words, to find $X_i(H)$ we expose the first i vertices and all their internal edges and take the conditional expectation of $f(G)$ with that partial information. By ordering the edges appropriately the vertex exposure martingale may be considered a subsequence of the edge exposure martingale. Note that $X_1(H) = E[f(G)]$ is constant as no edges have been exposed and $X_n(H) = f(H)$ as all edges have been exposed.

17.7.2 7.2 Large Deviations

Maurey (1979) applied a large deviation inequality for martingales to prove an isoperimetric inequality for the symmetric group S_n . This inequality was useful in the study of normed spaces; see Milman and Schechtman (1986) for many related results. The applications of martingales

in graph theory also all involve the same underlying martingale result used by Maurey, which is the following.

Theorem 7.2.1 [Azuma's Inequality] Let $0 = X_0, \dots, X_m$ be a martingale with

$$|X_{i+1} - X_i| \leq 1$$

for all $0 \leq i < m$. Let $\lambda > 0$ be arbitrary. Then

$$\Pr [X_m > \lambda\sqrt{m}] < e^{-\lambda^2/2}$$

In the "flip a coin" martingale X_m has distribution S_m and this result is Theorem A.1.1. Indeed, the general proof is quite similar.

Proof. Set, with foresight, $\alpha = \lambda/\sqrt{m}$. Set $Y_i = X_i - X_{i-1}$ so that $|Y_i| \leq 1$ and $E[Y_i | X_{i-1}, X_{i-2}, \dots, X_0] = 0$. Then, as in Theorem A.1.16,

$$E[e^{\alpha Y_i} | X_{i-1}, X_{i-2}, \dots, X_0] \leq \cosh(\alpha) \leq e^{\alpha^2/2}$$

Hence

$$\begin{aligned} E[e^{\alpha X_m}] &= E\left[\prod_{i=1}^m e^{\alpha Y_i}\right] \\ &= E\left[\left(\prod_{i=1}^{m-1} e^{\alpha Y_i}\right) E[e^{\alpha Y_m} | X_{m-1}, X_{m-2}, \dots, X_0]\right] \\ &\leq E\left[\prod_{i=1}^{m-1} e^{\alpha^2/2}\right] e^{\alpha^2/2} \leq e^{\alpha^2 m/2} \end{aligned}$$

Therefore

$$\begin{aligned} \Pr [X_m > \lambda\sqrt{m}] &= \Pr [e^{\alpha X_m} > e^{\alpha\lambda\sqrt{m}}] \\ &< E[e^{\alpha X_m}] e^{-\alpha\lambda\sqrt{m}} \\ &\leq e^{\alpha^2 m/2 - \alpha\lambda\sqrt{m}} = e^{-\lambda^2/2} \end{aligned}$$

as needed.

Corollary 7.2.2 Let $c = X_0, \dots, X_m$ be a martingale with

$$|X_{i+1} - X_i| \leq 1$$

for all $0 \leq i < m$. Then

$$\Pr [|X_m - c| > \lambda\sqrt{m}] < 2e^{-\lambda^2/2}$$

A graph theoretic function f is said to satisfy the edge Lipschitz condition if whenever H and H' differ in only one edge then $|f(H) - f(H')| \leq 1$. It satisfies the vertex Lipschitz condition if whenever H and H' differ at only one vertex, $|f(H) - f(H')| \leq 1$.

Theorem 7.2.3 When f satisfies the edge Lipschitz condition the corresponding edge exposure martingale satisfies $|X_{i+1} - X_i| \leq 1$. When f satisfies the vertex Lipschitz condition the corresponding vertex exposure martingale satisfies $|X_{i+1} - X_i| \leq 1$.

We prove these results in a more general context later. They have the intuitive sense that if knowledge of a particular vertex or edge cannot change f by more than one then exposing a vertex or edge should not change the expectation of f by more than one. Now we give a simple application of these results.

Theorem 7.2.4 [Shamir and Spencer (1987)] Let n, p be arbitrary and let $c = E[\chi(G)]$, where $G \sim G(n, p)$. Then

$$\Pr[|\chi(G) - c| > \lambda\sqrt{n-1}] < 2e^{-\lambda^2/2}$$

Proof. Consider the vertex exposure martingale $X_1, \dots, X_n$ on $G(n, p)$ with $f(G) = \chi(G)$. A single vertex can always be given a new color so the vertex Lipschitz condition applies. Now apply Azuma's Inequality in the form of Corollary 7.2.2.

Letting $\lambda \rightarrow \infty$ arbitrarily slowly, this result shows that the distribution of $\chi(G)$ is "tightly concentrated" around its mean. The proof gives no clue as to where the mean is.

17.7.3 7.3 Chromatic Number

In Theorem 10.3.1 we prove that $\chi(G) \sim n/2 \log_2 n$ almost surely, where $G \sim G(n, \frac{1}{2})$. Here we give the original proof of Béla Bollobás using martingales. We follow the notations of Section 10.3, setting $f(k) = \binom{n}{k} 2^{-\binom{k}{2}}$, k_0 so that $f(k_0 - 1) > 1 > f(k_0)$, $k = k_0 - 4$ so that $k \sim 2 \log_2 n$ and $f(k) > n^{3+o(1)}$. Our goal is to show

$$\Pr[\omega(G) < k] = e^{-n^{2+o(1)}},$$

where $\omega(G)$ is the size of the maximum clique of G . We shall actually show in Theorem 7.3.2 a more precise bound. The remainder of the argument is given in Section 10.3.

Let $Y = Y(H)$ be the maximal size of a family of edge disjoint cliques of size k in H . This ingenious and unusual choice of function is key to the martingale proof.

Lemma 7.3.1 $E[Y] \geq (1 + o(1)) (n^2/2k^4)$.

Proof. Let $\mathcal{K}$ denote the family of k -cliques of G so that $f(k) = \mu = E[|\mathcal{K}|]$. Let W denote the number of unordered pairs $\{A, B\}$ of k -cliques of G with $2 \leq |A \cap B| < k$. Then $E[W] = \Delta/2$, with Δ as described in Section 10.3 (see also Section 4.5), $\Delta \sim \mu^2 k^4 n^{-2}$. Let $\mathcal{C}$ be a random subfamily of $\mathcal{K}$ defined by setting, for each $A \in \mathcal{K}$, $\Pr[A \in \mathcal{C}] = q$, q to be determined. Let W' be the number of unordered pairs $\{A, B\}$, $A, B \in \mathcal{C}$ with $2 \leq |A \cap B| < k$. Then

$$E[W'] = E[W]q^2 = \Delta q^2/2.$$

Delete from $\mathcal{C}$ one set from each such pair $\{A, B\}$. This yields a set $\mathcal{C}^*$ of edge disjoint k -cliques of G and

$$E[Y] \geq E[|\mathcal{C}^*|] \geq E[|\mathcal{C}|] - E[W'] = \mu q - \Delta q^2/2 = \mu^2/2\Delta \sim n^2/2k^4,$$

where we choose $q = \mu/\Delta (< 1)$ to minimize the quadratic.

We conjecture that Lemma 7.3.1 may be improved to $E[Y] > cn^2/k^2$. That is, with positive probability there is a family of k -cliques that are edge disjoint and cover a positive proportion of the edges.

Theorem 7.3.2

$$\Pr[\omega(G) < k] < e^{-(c+o(1))(n^2/\ln^8 n)}$$

with c a positive constant.

Proof. Let $Y_0, \dots, Y_m$, $m = \binom{n}{2}$, be the edge exposure martingale on $G(n, \frac{1}{2})$ with the function Y just defined. The function Y satisfies the edge Lipschitz condition as adding a single edge can only add at most one clique to a family of edge disjoint cliques. (Note that the Lipschitz condition would not be satisfied for the number

of k -cliques as a single edge might yield many new cliques.) G has no k -clique if and only if $Y = 0$. Apply Azuma's Inequality with $m = \binom{n}{2} \sim n^2/2$ and $E[Y] \geq (1 + o(1)) (n^2/2k^4)$. Then

$$\begin{aligned} \Pr[\omega(G) < k] &= \Pr[Y = 0] \\ &\leq \Pr[Y - E[Y] \leq -E[Y]] \\ &\leq e^{-E[Y]^2/2\binom{n}{2}} \\ &\leq e^{-(c'+o(1))n^2/k^8} \\ &= e^{-(c+o(1))n^2/\ln^8 n}, \end{aligned}$$

as desired.

Here is another example where the martingale approach requires an inventive choice of graph theoretic function.

Theorem 7.3.3 Let $p = n^{-\alpha}$, where $\alpha > \frac{5}{6}$ is fixed. Let $G = G(n, p)$. Then there exists $u = u(n, p)$ so that almost always

$$u \leq \chi(G) \leq u + 3$$

That is, $\chi(G)$ is concentrated in four values.

We first require a technical lemma that has been well known.

Lemma 7.3.4 Let α, c be fixed, $\alpha > \frac{5}{6}$. Let $p = n^{-\alpha}$. Then almost always every $c\sqrt{n}$ vertices of $G = G(n, p)$ may be three-colored.

Proof. If not, let T be a minimal set that is not three-colorable. As $T - \{x\}$ is three-colorable, x must have internal degree at least 3 in T for all $x \in T$. Thus if T has t vertices it must have at least $3t/2$ edges. The probability of this occurring for some T with at most $c\sqrt{n}$ vertices is bounded from above by

$$\sum_{t=4}^{c\sqrt{n}} \binom{n}{t} \binom{\binom{t}{2}}{3t/2} p^{3t/2}$$

We bound

$$\binom{n}{t} \leq \left(\frac{ne}{t}\right)^t \quad \text{and} \quad \binom{\binom{t}{2}}{3t/2} \leq \left(\frac{te}{3}\right)^{3t/2},$$

so each term is at most

$$\left(\frac{ne}{t} \frac{t^{3/2} e^{3/2}}{3^{3/2}} n^{-3\alpha/2}\right)^t \leq (c_1 n^{1-3\alpha/2} t^{1/2})^t \leq (c_2 n^{1-3\alpha/2} n^{1/4})^t = (c_2 n^{-\epsilon})^t$$

with $\epsilon = \frac{3}{2}\alpha - \frac{5}{4} > 0$ and the sum is therefore $o(1)$.

Proof [Theorem 7.3.3]. Let $\epsilon > 0$ be arbitrarily small and let $u = u(n, p, \epsilon)$ be the least integer so that

$$\Pr[\chi(G) \leq u] > \epsilon.$$

Now define $Y(G)$ to be the minimal size of a set of vertices S for which $G - S$ may be u -colored. This Y satisfies the vertex Lipschitz condition since at worst one could add a vertex to S . Apply the vertex exposure martingale on $G(n, p)$ to Y . Letting $\mu = E[Y]$,

$$\begin{aligned} \Pr[Y \leq \mu - \lambda\sqrt{n-1}] &< e^{-\lambda^2/2} \\ \Pr[Y \geq \mu + \lambda\sqrt{n-1}] &< e^{-\lambda^2/2} \end{aligned}$$

Let λ satisfy $e^{-\lambda^2/2} = \epsilon$ so that these tail events each have probability less than ϵ . We defined u so that, with probability at least ϵ , G would be u -colorable and hence $Y = 0$. That is, $\Pr[Y = 0] > \epsilon$. The first inequality therefore forces $\mu \leq \lambda\sqrt{n-1}$. Now employing the second inequality,

$$\Pr[Y \geq 2\lambda\sqrt{n-1}] \leq \Pr[Y \geq \mu + \lambda\sqrt{n-1}] \leq \epsilon.$$

With probability at least $1 - \epsilon$ there is a u -coloring of all but at most $c'\sqrt{n}$ vertices. By the lemma almost always, and so with probability at least $1 - \epsilon$, these points may be colored with three further colors, giving a $(u + 3)$ -coloring of G . The minimality of u guarantees that with probability at least $1 - \epsilon$ at least u colors are needed for G . Altogether

$$\Pr[u \leq \chi(G) \leq u + 3] \geq 1 - 3\epsilon,$$

and ϵ was arbitrarily small.

Using the same technique, similar results can be achieved for other values of α . Together with some related ideas it can be shown that for any fixed $\alpha > \frac{1}{2}$, $\chi(G)$ is concentrated on at most two values. See Łuczak (1991) and Alon and Krivelevich (1997) for the detailed proofs.

17.7.4 7.4 Two General Settings

The martingales useful in studying random graphs generally can be placed in the following general setting, which is essentially the one considered in Maurey (1979) and in Milman and Schechtman (1986). Let $\Omega = A^B$ denote the set of functions $g : B \rightarrow A$. (With B the set of pairs of vertices on n vertices and $A = \{0, 1\}$ we may identify $g \in A^B$ with a graph on n vertices.) We define a measure by giving values p_{ab} and setting

$$\Pr[g(b) = a] = p_{ab}$$

with the values $g(b)$ assumed mutually independent. [In $G(n, p)$ all $p_{1b} = p, p_{0b} = 1 - p$.] Now fix a gradation

$$\emptyset = B_0 \subset B_1 \subset \cdots \subset B_m = B.$$

Let $L : A^B \rightarrow R$ be a functional (e.g., clique number). We define a martingale $X_0, X_1, \dots, X_m$ by setting

$$X_i(h) = E[L(g) \mid g(b) = h(b) \text{ for all } b \in B_i].$$

X_0 is a constant, the expected value of L of the random g . X_m is L itself. The values $X_i(g)$ approach $L(g)$ as the values of $g(b)$ are "exposed." We say the functional L satisfies the Lipschitz condition relative to the gradation if for all $0 \leq i < m$,

$$h, h' \text{ differ only on } B_{i+1} - B_i \Rightarrow |L(h') - L(h)| \leq 1.$$

Theorem 7.4.1 Let L satisfy the Lipschitz condition. Then the corresponding martingale satisfies

$$|X_{i+1}(h) - X_i(h)| \leq 1$$

for all $0 \leq i < m, h \in A^B$.

Proof. Let H be the family of h' that agree with h on B_{i+1} . Then

$$X_{i+1}(h) = \sum_{h' \in H} L(h') w_{h'},$$

where $w_{h'}$ is the conditional probability that $g = h'$ given that $g = h$ on B_{i+1} . For each $h' \in H$ let $H[h']$ denote the family of h^* that agree with h' on all points except (possibly) $B_{i+1} - B_i$. The $H[h']$ partition the family of h^* agreeing with h on B_i . Thus we may express

$$X_i(h) = \sum_{h' \in H} \sum_{h^* \in H[h']} [L(h^*) q_{h^*}] w_{h'},$$

where q_{h^*} is the conditional probability that g agrees with h^* on B_{i+1} given that it agrees with h on B_i . (This is because for $h^* \in H[h']$, $w_{h'}$ is also the conditional probability that $g = h^*$ given that $g = h^*$ on B_{i+1} .) Thus

$$\begin{aligned} |X_{i+1}(h) - X_i(h)| &= \left| \sum_{h' \in H} w_{h'} \left[L(h') - \sum_{h^* \in H[h']} L(h^*) q_{h^*} \right] \right| \\ &\leq \sum_{h' \in H} w_{h'} \sum_{h^* \in H[h']} |q_{h^*} [L(h') - L(h^*)]| \end{aligned}$$

The Lipschitz condition gives $|L(h') - L(h^*)| \leq 1$ so

$$|X_{i+1}(h) - X_i(h)| \leq \sum_{h' \in H} w_{h'} \sum_{h^* \in H[h']} q_{h^*} = \sum_{h' \in H} w_{h'} = 1.$$

Now we can express Azuma's Inequality in a general form.

Theorem 7.4.2 Let L satisfy the Lipschitz condition relative to a gradation of length m and let $\mu = E[L(g)]$. Then for all $\lambda > 0$,

$$\begin{aligned} \Pr[L(g) \geq \mu + \lambda\sqrt{m}] &< e^{-\lambda^2/2} \\ \Pr[L(g) \leq \mu - \lambda\sqrt{m}] &< e^{-\lambda^2/2} \end{aligned}$$

The second general setting is taken from Alon, Kim and Spencer (1997). We assume our underlying probability space is generated by a finite set of mutually independent Yes/No choices, indexed by $i \in I$. We are given a random variable Y on this space. Let p_i denote the probability that choice i is Yes. Let c_i be such that changing choice i (keeping all else the same) can change Y by at most c_i . We call c_i the effect of i . Let C be an upper bound on all c_i . We call $p_i(1 - p_i)c_i^2$ the variance of choice i .

Now consider a solitaire game in which Paul finds the value of Y by making queries of an always truthful oracle Carole. The queries are always of a choice $i \in I$. Paul's choice of query can depend on Carole's previous responses. A strategy for Paul can then naturally be represented in a decision tree form. A "line of questioning" is a path from the root to a leaf of this tree, a sequence of questions and responses that determine Y . The total variance of a line of questioning is the sum of the variances of the queries in it.

Theorem 7.4.3 For all $\epsilon > 0$ there exists $\delta > 0$ so that the following holds. Suppose Paul has a strategy for finding Y such that every line of questioning has total variance at most σ^2 . Then

$$\Pr[|Y - E[Y]| > \alpha\sigma] \leq 2e^{-\alpha^2/2(1+\epsilon)} \quad (7.1)$$

for all positive α with $\alpha C < \sigma(1 + \epsilon)\delta$.

Applications. For a specific suboptimal bound we may take $\epsilon = \delta = 1$. If $C = O(1)$, $\alpha \rightarrow \infty$ and $\alpha = o(\sigma)$ the upper bound of (7.1) is $\exp[-\Omega(\alpha^2)]$. In many cases Paul queries all $i \in I$. Then we may take σ with $\sigma^2 = \sum_{i \in I} p_i(1 - p_i)c_i^2$. For example, consider an edge Lipschitz Y on $G(n, p)$ with $p = p(n) \rightarrow 0$. I is the set of $m = \binom{n}{2}$ potential edges, all $p_i = p$, $C = 1$ so that $\sigma = \Theta(\sqrt{n^2 p})$. If $\alpha \rightarrow \infty$ with $\alpha = o(\sqrt{n^2 p})$ the upper bound of (7.1) is again $\exp[-\Omega(\alpha^2)]$.

Proof. For simplicity we replace Y by $Y - E[Y]$ so that we shall henceforth assume $E[Y] = 0$. By symmetry we shall bound only the upper tail of Y . We set, with foresight, $\lambda = \alpha/[\sigma(1 + \epsilon)]$. Our side assumption gives that $C\lambda < \delta$. We will show

$$E[e^{\lambda Y}] \leq e^{(1+\epsilon)\lambda^2\sigma^2/2} \quad (7.2)$$

The Martingale Inequality then follows by the Markov bound

$$\Pr[Y > \alpha\sigma] < e^{-\lambda\alpha\sigma} E[e^{\lambda Y}] \leq e^{-\alpha^2/2(1+\epsilon)}$$

We first claim that for all $\epsilon > 0$ there exists $\delta > 0$ so that for $0 \leq p \leq 1$ and $|a| \leq \delta$

$$pe^{(1-p)a} + (1-p)e^{-pa} \leq e^{(1+\epsilon)p(1-p)a^2/2} \quad (7.3)$$

Take the Taylor series in a of the left-hand side. The constant term is 1, the linear term 0, the coefficient of a^2 is $\frac{1}{2}p(1-p)$ and for $j \geq 3$ the coefficient of a^j is at most

$$\frac{1}{j!}p(1-p)(p^{j-1} + (1-p)^{j-1}) \leq \frac{1}{j!}p(1-p).$$

Pick δ so that $|a| \leq \delta$ implies

$$\sum_{j=3}^{\infty} \frac{a^j}{j!} < \epsilon a^2/2.$$

(In particular, this holds for $\epsilon = \delta = 1$.) Then

$$pe^{(1-p)a} + (1-p)e^{-pa} \leq 1 + p(1-p)\frac{a^2}{2}(1+\epsilon)$$

and (7.3) follows from the inequality $1 + x \leq e^x$.

Using this δ we show (7.2) by induction on the depth M of the decision tree. For $M = 0$, Y is constant and (7.2) is immediate. Otherwise, let $p, c, v = p(1-p)c^2$ denote the probability, effect and variance, respectively, of Paul's first query. Let μ_y, μ_n denote the conditional expectations of Y if Carole's response is Yes or No, respectively. Then $0 = E[Y]$ can be split into

$$0 = p\mu_y + (1-p)\mu_n$$

The difference $\mu_y - \mu_n$ is the expected change in Y when all other choices are made independent with their respective probabilities and the root choice is changed from Yes to No. As this always changes Y by at most c ,

$$|\mu_y - \mu_n| \leq c$$

Thus we may parametrize

$$\mu_y = (1-p)b \quad \text{and} \quad \mu_n = -pb$$

with $|b| \leq c$. From (7.3)

$$pe^{\lambda\mu_y} + (1-p)e^{\lambda\mu_n} \leq e^{(1+\epsilon)p(1-p)b^2\lambda^2/2} \leq e^{(1+\epsilon)v\lambda^2/2}$$

Let A_y denote the expectation of $e^{\lambda(Y-\mu_y)}$ conditional on Carole's first response being Yes and let A_n denote the analogous quantity for No. Given Carole's first response Paul has a decision tree (one of the two main subtrees) that determines Y with total variation at most $\sigma^2 - v$ and the tree has depth at most $M - 1$. So by induction $A_y, A_n \leq A^-$, where we set

$$A^- = e^{(1+\epsilon)\lambda^2(\sigma^2-v)/2}$$

Now we split

$$\begin{aligned} E[e^{\lambda Y}] &= pe^{\lambda\mu_y}A_y + (1-p)e^{\lambda\mu_n}A_n \\ &\leq [pe^{\lambda\mu_y} + (1-p)e^{\lambda\mu_n}]A^- \\ &\leq e^{(1+\epsilon)\lambda^2(v+(\sigma^2-v))/2} \end{aligned}$$

completing the proof of (7.2) and hence of Theorem 7.4.3.

We remark that this formal inductive proof somewhat masks the martingale. A martingale $E[Y] = Y_0, \dots, Y_M = Y$ can be defined with Y_t the conditional expectation of Y after the first t queries and responses. Theorem 7.4.3 can be thought of as bounding the tail of Y by that of a normal distribution of greater or equal variance. For very large distances from the mean, large α , this bound fails.

17.7.5 7.5 Four Illustrations

Let g be the random function from $\{1, \dots, n\}$ to itself, all n^n possible functions equally likely. Let $L(g)$ be the number of values not hit, that is, the number of y for which $g(x) = y$ has no solution. By linearity of expectation,

$$E[L(g)] = n \left(1 - \frac{1}{n}\right)^n$$

and this quantity is at most n/e and at least $n(1 - 1/n)^{n-1} \cdot (1 - 1/n) > (n-1)/e$.

Set $B_i = \{1, \dots, i\}$. L satisfies the Lipschitz condition relative to this gradation since changing the value of $g(i)$ can change $L(g)$ by at most 1. Thus we have the following.

Theorem 7.5.1 $\Pr[|L(g) - \frac{n}{e}| > \lambda\sqrt{n} + 1] < 2e^{-\lambda^2/2}$.

Deriving these asymptotic bounds from first principles is quite cumbersome.

As a second illustration let B be any normed space and let $v_1, \dots, v_n \in B$ with all $|v_i| \leq 1$. Let $\epsilon_1, \dots, \epsilon_n$ be independent with $\Pr[\epsilon_i = +1] = \Pr[\epsilon_i = -1] = 1/2$ and set

$$X = |\epsilon_1 v_1 + \dots + \epsilon_n v_n|$$

Theorem 7.5.2

$$\begin{aligned} \Pr[X - E[X] > \lambda\sqrt{n}] &< e^{-\lambda^2/2} \\ \Pr[X - E[X] < -\lambda\sqrt{n}] &< e^{-\lambda^2/2} \end{aligned}$$

Proof. Consider $\{-1, +1\}^n$ as the underlying probability space with all $(\epsilon_1, \dots, \epsilon_n)$ equally likely. Then X is a random variable and we define a martingale $X_0, \dots, X_n = X$ by exposing one ϵ_i at a time. The value of ϵ_i can only change X by 2, so direct application of Theorem 7.4.1 gives $|X_{i+1} - X_i| \leq 2$. But let ϵ, ϵ' be two n -tuples differing only in the i th coordinate:

$$X_i(\epsilon) = (X_{i+1}(\epsilon) + X_{i+1}(\epsilon'))/2$$

so that

$$|X_i(\epsilon) - X_{i+1}(\epsilon)| = |X_{i+1}(\epsilon') - X_{i+1}(\epsilon)|/2 \leq 1.$$

Now apply Azuma's Inequality.

For a third illustration let ρ be the Hamming metric on $\{0, 1\}^n$. For $A \subseteq \{0, 1\}^n$ let $B(A, s)$ denote the set of $y \in \{0, 1\}^n$ so that $\rho(x, y) \leq s$ for some $x \in A$. [$A \subseteq B(A, s)$ as we may take $x = y$.]

Theorem 7.5.3 Let $\epsilon, \lambda > 0$ satisfy $e^{-\lambda^2/2} = \epsilon$. Then

$$|A| \geq \epsilon 2^n \quad \Rightarrow \quad |B(A, 2\lambda\sqrt{n})| \geq (1 - \epsilon)2^n$$

Proof. Consider $\{0, 1\}^n$ as the underlying probability space, all points equally likely. For $y \in \{0, 1\}^n$ set

$$X(y) = \min_{x \in A} \rho(x, y).$$

Let $X_0, X_1, \dots, X_n = X$ be the martingale given by exposing one coordinate of $\{0, 1\}^n$ at a time. The Lipschitz condition holds for X : If y, y' differ in just one coordinate then $|X(y) - X(y')| \leq 1$. Thus, with $\mu = E[X]$,

$$\Pr[X < \mu - \lambda\sqrt{n}] < e^{-\lambda^2/2} = \epsilon,$$

$$\Pr[X > \mu + \lambda\sqrt{n}] < e^{-\lambda^2/2} = \epsilon.$$

But

$$\Pr[X = 0] = |A|2^{-n} \geq \epsilon,$$

so $\mu \leq \lambda\sqrt{n}$. Thus

$$\Pr[X > 2\lambda\sqrt{n}] < \epsilon$$

and

$$|B(A, 2\lambda\sqrt{n})| = 2^n \Pr[X \leq 2\lambda\sqrt{n}] \geq 2^n(1 - \epsilon).$$

Actually, a much stronger result is known. Let $B(s)$ denote the ball of radius s about $(0, \dots, 0)$. The Isoperimetric Inequality proved by Harper (1966) states that

$$|A| \geq |B(r)| \quad \Rightarrow \quad |B(A, s)| \geq |B(r + s)|.$$

One may actually use this inequality as a beginning to give an alternate proof that $\chi(G) \sim n/2 \log_2 n$ and to prove a number of the other results we have shown using martingales.

We illustrate Theorem 7.4.3 with a key technical lemma (in simplified form) from Alon, Kim and Spencer (1997). Let $G = (V, E)$ be a graph on N vertices, each vertex having degree D . Asymptotics will be for $N, D \rightarrow \infty$. Set $p = 1/D$. Define a random subgraph $H \subseteq G$ by placing each edge $e \in E$ in H with independent probability p . Let M (for matching) be the set of isolated edges of H . Let V^* be those $v \in V$ not in any $\{v, w\} \in M$. For $v \in V$ set $\deg^*(v)$ equal to the number of $w \in V^*$ with $\{v, w\} \in E$. As

$$\Pr[w \notin V^*] = \sum_{\{v, w\} \in E} p(1-p)^{2D-1} = e^{-2} + O(D^{-1}),$$

linearity of expectation gives

$$E[\deg^*(v)] = D(1 - e^{-2}) + O(1)$$

We want $\deg^*(v)$ tightly concentrated about its mean.

In the notation of Theorem 7.4.3 the probability space is determined by the choices $e \in H$ for all $e \in E$. All $p_i = p$. Changing $e \in H$ to $e \notin H$ can change $\deg^*(v)$ by at most $C = 4$.

Paul needs to find $\deg^*(v)$ by queries of the form "Is $e \in H$?" For each w with $\{v, w\} \in E$ he determines if $w \in V^*$ by the following line of inquiry. First, for all u with $\{w, u\} \in E$ he queries if $\{w, u\} \in H$. If no $\{w, u\} \in H$ then $w \in V^*$. If two (or more) $\{w, u_1\}, \{w, u_2\} \in H$ then w cannot be in an isolated edge of H so $w \in V^*$. Now suppose $\{w, u\} \in H$ for precisely one u . Paul then asks (using his acquired knowledge!) for each $z \neq w$ with $\{u, z\} \in E$ if $\{u, z\} \in H$. The replies determine if $\{w, u\}$ is an isolated edge of H and hence if $w \in V^*$. Paul has made at most $D + (D - 1)$ queries for each w for a total of at most $D(2D - 1) = O(D^2)$ queries. We deduce

$$\Pr [|\deg^*(v) - D(1 - e^{-2})| > \lambda D^{1/2}] = \exp [-\Omega(\lambda^2)]$$

when $\lambda \rightarrow \infty$ and $\lambda = o(D^{1/2})$.

In application one wishes to iterate this procedure (now applying it to the restriction of G to V^*) in order to find a large matching. This is somewhat akin to the Rödl nibble of Section 4.7. There are numerous further complications but the tight concentration of $\deg^*(v)$ about its mean plays an indispensable role.

17.7.6 7.6 Talagrand's Inequality

Let $\Omega = \prod_{i=1}^n \Omega_i$, where each Ω_i is a probability space and Ω has the product measure. Let $A \subseteq \Omega$ and let $\vec{x} = (x_1, \dots, x_n) \in \Omega$. Talagrand (1996) gives an unusual, subtle and ultimately powerful notion of the distance - denoted $\rho(A, \vec{x})$ - from $\vec{x}$ to A . We imagine moving from $\vec{x}$ to some $\vec{y} = (y_1, \dots, y_n) \in A$ by changing coordinates. $\rho(A, \vec{x})$ will measure the minimal cost of such a move when a suitably restricted adversary sets the cost of each change.

Definition $2\rho(A, \vec{x})$ is the least value such that for any $\vec{\alpha} = (\alpha_1, \dots, \alpha_n) \in \mathbb{R}^n$ with $|\vec{\alpha}| = 1$ there exists $\vec{y} = (y_1, \dots, y_n) \in A$ with

$$\sum_{x_i \neq y_i} \alpha_i \leq \rho(A, \vec{x}).$$

Note that $\vec{y}$ can, and generally will, depend on $\vec{\alpha}$.

We define for any real $t \geq 0$,

$$A_t = \{\vec{x} \in \Omega : \rho(A, \vec{x}) \leq t\}.$$

Note that $A_0 = A$ as when $\vec{x} \in A$ one can select $\vec{y} = \vec{x}$.

Theorem 7.6.1 [talagrand's Inequality]

$$\Pr[A] (1 - \Pr[A_t]) \leq e^{-t^2/4}$$

In particular, if $\Pr[A] \geq \frac{1}{2}$ (or any fixed constant) and t is "very large" then all but a very small proportion of Ω is within "distance" t of A .

Example. Take $\Omega = \{0, 1\}^n$ with the uniform distribution and let τ be the Hamming (L^1) metric. Then $\rho(A, \vec{x}) \geq \min_{\vec{y} \in A} \tau(\vec{x}, \vec{y}) n^{-1/2}$ as the adversary can choose all $\alpha_i = n^{-1/2}$. Suppose to move from $\vec{x}$ to A the values $x_1, \dots, x_l$ (or any particular l coordinates) must be changed. Then $\rho(A, \vec{x}) \geq l^{1/2}$ as the adversary could choose $\alpha_i = l^{-1/2}$ for $1 \leq i \leq l$ and zero elsewhere.

Define $U(A, \vec{x})$ to be the set of $\vec{s} = (s_1, \dots, s_n) \in \{0, 1\}^n$ with the property that there exists $\vec{y} \in A$ such that

$$x_i \neq y_i \Rightarrow s_i = 1$$

We may think of $U(A, \vec{x})$ as representing the possible paths from $\vec{x}$ to A . Note that when $s_i = 1$ we, for somewhat technical reasons, do not require $x_i \neq y_i$. With this notation $\rho(A, \vec{x})$ is the least real so that for all $\vec{\alpha}$ with $|\vec{\alpha}| = 1$ there exists $\vec{s} \in U(A, \vec{x})$ with $\vec{\alpha} \cdot \vec{s} \leq \rho(A, \vec{x})$.

Now define $V(A, \vec{x})$ to be the convex hull of $U(A, \vec{x})$. The following result gives an alternate characterization of ρ that supplies the concept with much of its richness.

Theorem 7.6.2

$$\rho(A, \vec{x}) = \min_{\vec{v} \in V(A, \vec{x})} |\vec{v}|.$$

Proof. Let $\vec{v} \in V(A, \vec{x})$ achieve this minimum. The hyperplane through $\vec{v}$ perpendicular to the line from the origin to $\vec{v}$ then separates $V(A, \vec{x})$ from the origin so that all $\vec{s} \in V(A, \vec{x})$ have $\vec{s} \cdot \vec{v} \geq \vec{v} \cdot \vec{v}$. Set $\vec{\alpha} = \vec{v}/|\vec{v}|$. Then all $\vec{s} \in U(A, \vec{x}) \subseteq V(A, \vec{x})$ have $\vec{s} \cdot \vec{\alpha} \geq \vec{v} \cdot \vec{v}/|\vec{v}| = |\vec{v}|$. Conversely, take any $\vec{\alpha}$ with $|\vec{\alpha}| = 1$. Then $\vec{\alpha} \cdot \vec{v} \leq |\vec{v}|$.

As $\vec{v} \in V(A, \vec{x})$ we may write $\vec{v} = \sum \lambda_i \vec{s}_i$ for some $\vec{s}_i \in U(A, \vec{x})$, with all $\lambda_i \geq 0$ and $\sum \lambda_i = 1$. Then

$$|\vec{v}| \geq \sum \lambda_i (\vec{\alpha} \cdot \vec{s}_i)$$

and hence some $\vec{\alpha} \cdot \vec{s}_i \leq |\vec{v}|$.

The case $\Omega = \{0, 1\}^n$ is particularly important and instructive. There $\rho(A, \vec{x})$ is simply the Euclidean distance from $\vec{x}$ to the convex hull of A .

Theorem 7.6.3

$$\int_{\Omega} \exp \left[\frac{1}{4} \rho^2(A, \vec{x}) \right] d\vec{x} \leq \frac{1}{\Pr[A]}$$

Theorem 7.6.1 is an immediate corollary of the above result. Indeed, fix A and consider the random variable $X = \rho(A, \vec{x})$. Then

$$\Pr[A_t] = \Pr[X \geq t] = \Pr[e^{X^2/4} \geq e^{t^2/4}] \leq \mathbb{E}[e^{X^2/4}] e^{-t^2/4}$$

and the theorem states $\mathbb{E}[e^{X^2/4}] \leq 1/\Pr[A]$.

Proof [Theorem 7.6.3]. We use induction on the dimension n . For $n = 1$, $\rho(A, \vec{x}) = 1$ if $\vec{x} \notin A$, zero otherwise so that

$$\int \exp \left[\frac{1}{4} \rho^2(A, \vec{x}) \right] = \Pr[A] + (1 - \Pr[A])e^{1/4} \leq \frac{1}{\Pr[A]}$$

as the inequality $u + (1 - u)e^{1/4} \leq u^{-1}$ for $0 < u \leq 1$ is a simple calculus exercise.

Assume the result for n . Write $\text{OLD} = \prod_{i=1}^n \Omega_i$, $\text{NEW} = \Omega_{n+1}$ so that $\Omega = \text{OLD} \times \text{NEW}$ and any $z \in \Omega$ can be uniquely written $z = (x, \omega)$ with $x \in \text{OLD}, \omega \in \text{NEW}$. Set

$$B = \{x \in \text{OLD} : (x, \omega) \in A \text{ for some } \omega \in \text{NEW}\}$$

and for any $\omega \in \text{NEW}$ set

$$A_{\omega} = \{x \in \text{OLD} : (x, \omega) \in A\}$$

Given $z = (x, \omega) \in \Omega$ we can move to A in two basic ways - either by changing ω , which reduces the problem to moving from x to B , or by not changing ω , which reduces the problem to moving from x to A_{ω} . Thus

$$\vec{s} \in U(B, x) \Rightarrow (\vec{s}, 1) \in U(A, (x, \omega))$$

and

$$\vec{t} \in U(A_\omega, x) \Rightarrow (\vec{t}, 0) \in U(A, (x, \omega))$$

Taking the convex hulls, if $\vec{s} \in V(B, x)$ and $\vec{t} \in V(A_\omega, x)$ then $(\vec{s}, 1)$ and $(\vec{t}, 0)$ are in $V(A, (x, \omega))$ and hence for any $\lambda \in [0, 1]$,

$$((1 - \lambda)\vec{s} + \lambda\vec{t}, 1 - \lambda) \in V(A, (x, \omega)).$$

Then, by convexity,

$$\rho^2(A, (x, \omega)) \leq (1 - \lambda)^2 + |(1 - \lambda)\vec{s} + \lambda\vec{t}|^2 \leq (1 - \lambda)^2 + (1 - \lambda)|\vec{s}|^2 + \lambda|\vec{t}|^2.$$

Selecting $\vec{s}, \vec{t}$ with minimal norms yields the critical inequality

$$\rho^2(A, (x, \omega)) \leq (1 - \lambda)^2 + \lambda\rho^2(A_\omega, x) + (1 - \lambda)\rho^2(B, x).$$

Quoting from Talagrand, "The main trick of the proof is to resist the temptation to optimize now over λ ." Rather, we first fix ω and bound

$$\begin{aligned} & \int_x \exp \left[\frac{1}{4} \rho^2(A, (x, \omega)) \right] \\ & \leq e^{(1-\lambda)^2/4} \int_x \left(\exp \left[\frac{1}{4} \rho^2(A_\omega, x) \right] \right)^\lambda \left(\exp \left[\frac{1}{4} \rho^2(B, x) \right] \right)^{1-\lambda}. \end{aligned}$$

By Hölder's Inequality this is at most

$$e^{(1-\lambda)^2/4} \left[\int_x \exp \left[\frac{1}{4} \rho^2(A_\omega, x) \right] \right]^\lambda \left[\int_x \exp \left[\frac{1}{4} \rho^2(B, x) \right] \right]^{1-\lambda}$$

which by induction is at most

$$e^{(1-\lambda)^2/4} \left(\frac{1}{\Pr[A_\omega]} \right)^\lambda \left(\frac{1}{\Pr[B]} \right)^{1-\lambda} = \frac{1}{\Pr[B]} e^{(1-\lambda)^2/4} r^{-\lambda}$$

where $r = \Pr[A_\omega] / \Pr[B] \leq 1$. Now we use calculus and minimize $e^{(1-\lambda)^2/4} r^{-\lambda}$ by choosing $\lambda = 1 + 2 \ln r$ for $e^{-1/2} \leq r \leq 1$ and $\lambda = 0$ otherwise. Further (somewhat tedious but simple) calculation shows $e^{(1-\lambda)^2/4} r^{-\lambda} \leq 2 - r$ for this $\lambda = \lambda(r)$. Thus

$$\int_x \exp \left[\frac{1}{4} \rho^2(A, (x, \omega)) \right] \leq \frac{1}{\Pr[B]} \left(2 - \frac{\Pr[A_\omega]}{\Pr[B]} \right)$$

We integrate over ω giving

$$\int_\omega \int_x \exp \left[\frac{1}{4} \rho^2(A, (x, \omega)) \right] \leq \frac{1}{\Pr[B]} \left(2 - \frac{\Pr[A]}{\Pr[B]} \right) = \frac{1}{\Pr[A]} x(2 - x),$$

where $x = \Pr[A] / \Pr[B] \in [0, 1]$. But $x(2 - x) \leq 1$, completing the induction and hence the theorem.

17.7.7 7.7 Applications of Talagrand's Inequality

Let $\Omega = \prod_{i=1}^n \Omega_i$, where each Ω_i is a probability space and Ω has the product measure. Let $h : \Omega \rightarrow R$. Talagrand's Inequality enables us, under certain conditions, to show that the random variable $X = h(\cdot)$ is tightly concentrated. In this sense it can serve the same function Azuma's Inequality does for martingales and there are many cases in which it gives far stronger results.

We call $h : \Omega \rightarrow R$ Lipschitz if $|h(x) - h(y)| \leq 1$ whenever x, y differ in at most one coordinate. Talagrand's Inequality is most effective on those Lipschitz functions with the property that when $h(x) \geq s$ there are a relatively small number of coordinates that will certify that $h(x) \geq s$. We formalize this notion as follows.

Definition 3 Let $f : N \rightarrow N$. h is f -certifiable if whenever $h(x) \geq s$ there exists $I \subseteq \{1, \dots, n\}$ with $|I| \leq f(s)$ so that all $y \in \Omega$ that agree with x on the coordinates I have $h(y) \geq s$.

Example. Consider $G(n, p)$ as the product of $\binom{n}{2}$ coin flips and let $h(G)$ be the number of triangles in G . Then h is f -certifiable with $f(s) = 3s$. For if $h(G) \geq s$ there exist s triangles that together have at most $3s$ edges and any other G' with those $3s$ edges has $h(G') \geq s$. Note that I , here the indices for those $3s$ edges, very much depends on G . Also note that we need certify only lower bounds for h .

Theorem 7.7.1 Under the above assumptions and for all b, t ,

$$\Pr[X \leq b - t\sqrt{f(b)}] \Pr[X \geq b] \leq e^{-t^2/4}.$$

Proof. Set $A = \{x : h(x) < b - t\sqrt{f(b)}\}$. Now suppose $h(y) \geq b$. We claim $y \notin A_t$. Let I be a set of indices of size at most $f(b)$ that certifies $h(y) \geq b$ as given above. Define $\alpha_i = 0$ when $i \notin I$, $\alpha_i = |I|^{-1/2}$ when $i \in I$. If $y \in A_t$ there exists a $z \in A$ that differs from y in at most $t|I|^{1/2} \leq t\sqrt{f(b)}$ coordinates of I though at arbitrary coordinates outside I . Let y' agree with y on I and agree with z outside I . By the certification $h(y') \geq b$. Now y', z differ in at most $t\sqrt{f(b)}$ coordinates and so, by Lipschitz,

$$h(z) \geq h(y') - t\sqrt{f(b)} \geq b - t\sqrt{f(b)},$$

but then $z \notin A$, a contradiction. So $\Pr[X \geq b] \leq \Pr[A_t]$ and from Talagrand's Theorem,

$$\Pr[X < b - t\sqrt{f(b)}] \Pr[X \geq b] \leq e^{-t^2/4}.$$

As the right-hand side is continuous in t we may replace ' $<$ ' by ' $\leq$ ' giving the theorem.

□

A small generalization is sometimes useful. Call $h : \Omega \rightarrow R$ K -Lipschitz if $|h(x) - h(y)| \leq K$ whenever x, y differ in only one coordinate. Applying the above theorem to h/K , which is Lipschitz, we find

$$\Pr[X \leq b - tK\sqrt{f(b)}] \Pr[X \geq b] \leq e^{-t^2/4}$$

In applications one often takes b to be the median so that for t large the probability of being $t\sqrt{f(b)}$ under the median goes sharply to zero. But it works both ways, by parametrizing so that $m = b - t\sqrt{f(b)}$ is the median one usually gets $b \sim m + t\sqrt{f(m)}$ and that the probability of being $t\sqrt{f(b)}$ above the median goes sharply to zero. Martingales, via Azuma's Inequality, generally produce a concentration result around the mean μ of X while Talagrand's Inequality yields a concentration result about the median m . Means tend to be easy to compute, medians notoriously difficult, but a tight concentration result will generally allow us to show that the mean and median are not far away.

Let $x = (x_1, \dots, x_n)$, where the x_i are independently and uniformly chosen from $[0, 1]$. Set $X = h(x)$ to be the length of the longest increasing subsequence of x . Elementary methods

give that $c_1 n^{1/2} < X < c_2 n^{1/2}$ almost surely for some positive constants c_1, c_2 and that the mean μ and median m of X are both in that range. Also X is Lipschitz, as changing one x_i can only change X by at most one. How concentrated is X ? We can apply Azuma's Inequality to deduce that if $s \gg n^{1/2}$ then $|X - \mu| \leq s$ almost surely. This is not particularly good since X itself is only of order $n^{1/2}$. Now consider Talagrand's Inequality. X is f -certifiable with $f(s) = s$ since if x has an increasing subsequence of length s then those s coordinates certify that $X \geq s$. Then $\Pr[X < m - tm^{1/2}] \leq e^{-t^2/4} / \Pr[X \geq m] \leq 2e^{-t^2/4}$ as m is the median value. But $m = \Theta(n^{1/2})$. Thus when $s \gg n^{1/4}$ we have $X > m - s$ almost surely. For the other side suppose $t \rightarrow \infty$ slowly and let b be such that $b - tb^{1/2} = m$. Then $\Pr[X \geq b] \leq e^{-t^2/4} / \Pr[X \leq m] \leq 2e^{-t^2/4}$. Then $X \leq b$ almost surely. But $b = m + (1 + o(1))tm^{1/2}$ so that $X \leq m + tm^{1/2}$ almost surely. Combining, if $s \gg n^{1/4}$ then $|X - m| < s$ almost surely. A much stronger result, determining the precise asymptotic distribution of X , has been obtained by Baik, Deift and Johansson (1999), using deep analytic tools.

Let's reexamine the bound (Theorem 7.3.2) that $G(n, \frac{1}{2})$ has no clique of size k with k as defined there. We let, as there, Y be the maximal number of edge disjoint k -cliques. From the work there $E[Y] = \Omega(n^2 k^{-4})$ and Y is tightly concentrated about $E[Y]$ so that the median m of Y must also have $m = \Omega(n^2 k^{-4})$. As before Y is Lipschitz. Further Y is f -certifiable with $f(s) = \binom{k}{2}s$ as the edges of the s -cliques certify that $Y \geq s$. Hence

$$\Pr\left[Y \leq m - tm^{1/2} \binom{k}{2}^{1/2}\right] \Pr[Y \geq m] < e^{-t^2/4}$$

Set $t = \Theta(m^{1/2}/k)$ so that $m = tm^{1/2} \binom{k}{2}^{1/2}$. Then

$$\Pr[\omega(G) < k] = \Pr[Y \leq 0] < 2e^{-t^2/4} < \exp\left[-\Omega\left(\frac{n^2}{\ln^6 n}\right)\right],$$

which improves the bound of Theorem 7.3.2. Still, we should note that application of the Extended Janson Inequality in Section 10.3 does even better.

17.7.8 7.8 Kim-vu Polynomial Concentration

The approach of Kim and Vu(2000) is often useful. Let $H = (V(H), E(H))$ be a hypergraph and let each edge $e \in E(H)$ have a nonnegative weight w_e . Let $t_i, i \in V(H)$ be mutually independent indicator random variables with $E[t_i] = p_i$. Consider the random variable polynomial

$$Y = \sum_{e \in E(H)} w_e \prod_{i \in e} t_i.$$

We allow $e = \emptyset$ in which case $\prod_{i \in e} t_i$ is by convention 1. We want to show that Y is concentrated about its mean.

Let $S \subseteq V(H)$ be a random set given by $\Pr[i \in S] = p_i$, these events mutually independent over $i \in V(H)$. Then Y is the weighted number of hyperedges e in the restriction of H to S . In applications we generally have all weights equal one so that Y simply counts the hyperedges in the random S . But we may also think abstractly of Y as simply any polynomial over the indicators t_i having all nonnegative coefficients.

We set $n = |V(H)|$, the number of vertices of H (number of variables t_i). Let k be an upper bound on the size of all hyperedges (upper bound on the degree of the polynomial Y).

Let $A \subseteq V(H)$ with $|A| \leq k$. We truncate Y to Y_A as follows: For those terms $\prod_{i \in e} t_i$ with $A \subseteq e$ we set $t_i = 1$ for all $i \in A$, replacing the term by $\prod_{i \in e-A} t_i$. All other terms (where e does not contain A) are deleted. For example, with $A = \{1\}$, $2t_1t_2 + 5t_1t_3t_4 + 7t_2t_4$ becomes

$2t_2 + 5t_3t_4$. Intriguingly, as polynomials in the t_i , Y_A is the partial derivative of Y with respect to the t_i , $i \in A$. Set $E_A = \mathbb{E}[Y_A]$. That is, E_A is the expected number of hyperedges in S that contain A , conditional on all vertices of A being in S . Set E_i equal to the maximal E_A over all $A \subseteq V(H)$ of size i . Set $\mu = \mathbb{E}[Y]$ for convenience and set

$$E' = \max_{1 \leq i \leq k} E_i \quad \text{and} \quad E = \max\{\mu, E'\}$$

Theorem 7.8.1 [Kim-Vu Polynomial Concentration] With the above hypotheses

$$\Pr\left[|Y - \mu| > a_k (EE')^{1/2} \lambda^k\right] < d_k e^{-\lambda} n^{k-1}$$

for any $\lambda > 1$.

Here, for definiteness, we may take $a_k = 8^k k!^{1/2}$ and $d_k = 2e^2$.

We omit the proof, which combines martingale inequalities similar to those of Theorem 7.4.3 with a subtle induction on the degree k . There may well be room for improvement in the a_k, d_k and n^{k-1} terms. In applications one generally has k fixed and $\lambda \gg \ln n$ so that the $e^{-\lambda}$ term dominates the probability bound.

Applications of Kim-Vu polynomial concentration tend to be straightforward. Let $G \sim G(n, p)$ with $p = n^{-\alpha}$ and assume $0 < \alpha < 2/3$. Fix a vertex x of G and let $Y = Y(x)$ be the number of triangles containing x . Set $\mu = \mathbb{E}[Y] = \binom{n-1}{2} p^3 \sim \frac{1}{2} n^{2-3\alpha}$. Let $\delta > 0$ be fixed. We want to bound $\Pr[|Y - \mu| > \delta\mu]$.

The random graph G is defined by the random variables t_{ij} , one for each unordered pair of vertices, which are indicators of the adjacency of the two vertices. In that context

$$Y = \sum_{i,j \neq x} t_{xi} t_{xj} t_{ij}$$

This is a polynomial of degree $k = 3$. When A consists of a single edge $\{x, i\}$ we find $E_A = (n-2)p^2$; when it consists of three edges forming a triangle containing x we find $E_A = 1$. When $A = \emptyset$, $E_A = \mu$. Other cases give smaller E_A . Basically $E' \sim \max\{np^2, 1\}$. Calculation gives $E' \sim c\mu n^{-\epsilon}$ for some positive ϵ (dependent on α) throughout our range. We apply Kim-Vu polynomial concentration with $\lambda = c'n^{\epsilon/6}$, c' a small positive constant, to bound $\Pr[|Y - \mu| > \delta\mu]$ by $\exp[-\Omega(n^{\epsilon/6})]$. Note that the n^{k-1} factor is absorbed by the exponential.

In particular, as this probability is $o(n^{-1})$, we have that almost surely every vertex x is in $\sim \mu$ triangles. This result generalizes. Fix $\alpha \in (0, 1)$ and suppose (R, H) is a rooted graph, safe, in the sense of Section 10.4, with respect to α . Let $G \sim G(n, p)$ with $p = n^{-\alpha}$. For distinct vertices $x_1, \dots, x_r$ let $Y = Y(x_1, \dots, x_r)$ denote the number of extensions in G to H . Set $\mu = \mathbb{E}[Y]$. Kim-Vu polynomial concentration gives an exponentially small upper bound on the probability that Y is not near μ . In particular, this probability is $o(n^{-r})$. Hence almost surely every r vertices have $\sim \mu$ extensions to H .

17.7.9 7.9 Exercises

1. Let $G = (V, E)$ be the graph whose vertices are all 7^n vectors of length n over $\mathbb{Z}_7$, in which two vertices are adjacent iff they differ in precisely one coordinate. Let $U \subset V$ be a set of 7^{n-1} vertices of G , and let W be the set of all vertices of G whose distance from U exceeds $(c+2)\sqrt{n}$, where $c > 0$ is a constant. Prove that $|W| \leq 7^n \cdot e^{-c^2/2}$.
2. (*) Let $G = (V, E)$ be a graph with chromatic number $\chi(G) = 1000$. Let $U \subset V$ be a random subset of V chosen uniformly among all $2^{|V|}$ subsets of V . Let $H = G[U]$ be the induced subgraph of G on U . Prove that

$$\Pr[\chi(H) \leq 400] < 1/100$$

3. Prove that there is an absolute constant c such that for every $n > 1$ there is an interval I_n of at most $c\sqrt{n}/\log n$ consecutive integers such that the probability that the chromatic number of $G(n, 0.5)$ lies in I_n is at least 0.99 .

The Probabilistic Lens: Weierstrass Approximation Theorem

The well-known Weierstrass Approximation Theorem asserts that the set of real polynomials over $[0, 1]$ is dense in the space of all continuous real functions over $[0, 1]$. This is stated in the following theorem.

Theorem 1 [Weierstrass Approximation Theorem] For every continuous real function $f : [0, 1] \rightarrow \mathbb{R}$ and every $\epsilon > 0$, there is a polynomial $p(x)$ such that $|p(x) - f(x)| \leq \epsilon$ for all $x \in [0, 1]$.

Bernstein (1912) gave a charming probabilistic proof of this theorem, based on the properties of the binomial distribution. His proof is the following.

Proof. Since a continuous $f : [0, 1] \rightarrow \mathbb{R}$ is uniformly continuous there is a $\delta > 0$ such that if $x, x' \in [0, 1]$ and $|x - x'| \leq \delta$ then $|f(x) - f(x')| \leq \epsilon/2$. In addition, since f must be bounded there is an $M > 0$ such that $|f(x)| \leq M$ in $[0, 1]$.

Let $B(n, x)$ denote the binomial random variable with n independent trials and probability of success x for each of them. Thus the probability that $B(n, x) = j$ is precisely $\binom{n}{j} x^j (1-x)^{n-j}$. The expectation of $B(n, x)$ is nx and its standard deviation is $\sqrt{nx(1-x)} \leq \sqrt{n}$. Therefore, by Chebyshev's Inequality discussed in Chapter 4, for every integer n , $\Pr[|B(n, x) - nx| > n^{2/3}] \leq 1/n^{1/3}$. It follows that there is an integer n such that

$$\Pr[|B(n, x) - nx| > n^{2/3}] < \frac{\epsilon}{4M}$$

and

$$\frac{1}{n^{1/3}} < \delta.$$

Define

$$P_n(x) = \sum_{i=0}^n \binom{n}{i} x^i (1-x)^{n-i} f(i/n).$$

We claim that for every $x \in [0, 1]$, $|P_n(x) - f(x)| \leq \epsilon$. Indeed, since

$$\sum_{i=0}^n \binom{n}{i} x^i (1-x)^{n-i} = 1$$

we have

$$\begin{aligned}
|P_n(x) - f(x)| &\leq \sum_{i: |i-nx| \leq n^{2/3}} \binom{n}{i} x^i (1-x)^{n-i} |f(i/n) - f(x)| \\
&\quad + \sum_{i: |i-nx| > n^{2/3}} \binom{n}{i} x^i (1-x)^{n-i} [|f(i/n)| + |f(x)|] \\
&\leq \sum_{i: |i/n-x| \leq n^{-1/3} < \delta} \binom{n}{i} x^i (1-x)^{n-i} |f(i/n) - f(x)| \\
&\quad + 2M \Pr[|B(n, x) - nx| > n^{2/3}] \\
&\leq \frac{\epsilon}{2} + 2M \frac{\epsilon}{4M} = \epsilon
\end{aligned}$$

This completes the proof.

17.8 8 The Poisson Paradigm

One of the things that attracts us most when we apply ourselves to a mathematical problem is precisely that within us we always hear the call: here is the problem, search for the solution, you can find it by pure thought, for in mathematics there is no ignorabimus.

- David Hilbert

When X is the sum of many rare indicator "mostly independent" random variables and $\mu = E[X]$, we would like to say that X is close to a Poisson distribution with mean μ and, in particular, that $\Pr[X = 0]$ is nearly $e^{-\mu}$. We call this rough statement the Poisson Paradigm. In this chapter we give a number of situations in which this paradigm may be rigorously proved.

17.8.1 8.1 The Janson Inequalities

In many instances we would like to bound the probability that none of a set of bad events $\{B_i\}_{i \in I}$ occur. If the events are mutually independent then

$$\Pr \left[\bigwedge_{i \in I} \overline{B_i} \right] = \prod_{i \in I} \Pr [\overline{B_i}].$$

When the B_i are "mostly" independent the Janson Inequalities allow us, sometimes, to say that these two quantities are "nearly" equal.

Let Ω be a finite universal set and let R be a random subset of Ω given by

$$\Pr[r \in R] = p_r,$$

these events mutually independent over $r \in \Omega$. Let $\{A_i\}_{i \in I}$ be subsets of Ω , I a finite index set. Let B_i be the event $A_i \subseteq R$. (That is, each point $r \in \Omega$ "flips a coin" to determine if it is in R . B_i is the event that the coins for all $r \in A_i$ came up "heads.") Let X_i be the indicator random variable for B_i and $X = \sum_{i \in I} X_i$ the number of $A_i \subseteq R$. The event $\bigwedge_{i \in I} \overline{B_i}$ and $X = 0$ are then identical. For $i, j \in I$ we write $i \sim j$ if $i \neq j$ and $A_i \cap A_j \neq \emptyset$. Note that when $i \neq j$ and not $i \sim j$ then B_i, B_j are independent events since they involve separate coin flips. Furthermore, and this plays a crucial role in the proofs, if $i \notin J \subset I$ and not $i \sim j$ for all $j \in J$ then B_i is mutually independent of $\{B_j\}_{j \in J}$, that is, independent of any Boolean function of those B_j . This is because the coin flips on A_i and on $\cup_{j \in J} A_j$ are independent. We define

$$\Delta = \sum_{i \sim j} \Pr[B_i \wedge B_j]$$

Here the sum is over ordered pairs so that $\Delta/2$ gives the same sum over unordered pairs. We set

$$M = \prod_{i \in I} \Pr[\overline{B_i}]$$

the value of $\Pr[\bigwedge_{i \in I} \overline{B_i}]$ if the B_i were independent. Finally, we set

$$\mu = \mathbb{E}[X] = \sum_{i \in I} \Pr[B_i]$$

The following results were given in Janson, Łuczak and Ruciński (1990).

Theorem 8.1.1 [The Janson Inequality] Let $\{B_i\}_{i \in I}, \Delta, M, \mu$ be as above and assume all $\Pr[B_i] \leq \epsilon$. Then

$$M \leq \Pr\left[\bigwedge_{i \in I} \overline{B_i}\right] \leq M e^{[1/(1-\epsilon)]\Delta/2}$$

and, further,

$$\Pr\left[\bigwedge_{i \in I} \overline{B_i}\right] \leq e^{-\mu + \Delta/2}$$

For each $i \in I$

$$\Pr[\overline{B_i}] = 1 - \Pr[B_i] \leq e^{-\Pr[B_i]}$$

so, multiplying over $i \in I$,

$$M \leq e^{-\mu}$$

The two upper bounds for Theorem 8.1.1 are generally quite similar; we tend to use the second for convenience. In many asymptotic instances a simple calculation gives $M \sim e^{-\mu}$. In particular, this is always the case when $\epsilon = o(1)$ and $\epsilon\mu = o(1)$.

Perhaps the simplest example of Theorem 8.1.1 is the asymptotic probability that $G(n, c/n)$ is triangle-free, given in Section 10.1. There, as is often the case, $\epsilon = o(1)$, $\Delta = o(1)$ and μ approaches a constant k . In those instances $\Pr[\bigwedge_{i \in I} \overline{B_i}] \rightarrow e^{-k}$. This is no longer the case when Δ becomes large. Indeed, when $\Delta \geq 2\mu$ the upper bound of Theorem 8.1.1 becomes useless. Even for Δ slightly less it is improved by the following result.

Theorem 8.1.2 [The Extended Janson Inequality] Under the assumptions of Theorem 8.1.1 and the further assumption that $\Delta \geq \mu$,

$$\Pr\left[\bigwedge_{i \in I} \overline{B_i}\right] \leq e^{-\mu^2/2\Delta}.$$

Theorem 8.1.2 (when it applies) often gives a much stronger result than Chebyshev's Inequality as used in Chapter 4. In Section 4.3 we saw $\text{Var}[X] \leq \mu + \Delta$ so that

$$\Pr\left[\bigwedge_{i \in I} \overline{B_i}\right] = \Pr[X = 0] \leq \frac{\text{Var}[X]}{\mathbb{E}[X]^2} \leq \frac{\mu + \Delta}{\mu^2}.$$

Suppose $\mu \rightarrow \infty, \mu \ll \Delta$ and $\gamma = \mu^2/\Delta \rightarrow \infty$. Chebyshev's upper bound on $\Pr[X = 0]$ is then roughly γ^{-1} while Janson's upper bound is roughly $e^{-\gamma}$.

17.8.2 8.2 The Proofs

The original proofs of Janson are based on estimates of the Laplace transform of an appropriate random variable. The proof we present here follows that of Boppana and Spencer (1989). We shall use the inequalities

$$\Pr \left[B_i \mid \bigwedge_{j \in J} \overline{B_j} \right] \leq \Pr [B_i],$$

valid for all index sets $J \subset I, i \notin J$ and

$$\Pr \left[B_i \mid B_k \wedge \bigwedge_{j \in J} \overline{B_j} \right] \leq \Pr [B_i \mid B_k],$$

valid for all index sets $J \subset I, i, k \notin J$. The first follows from Theorem 6.3.2. The second is equivalent to the first since conditioning on B_k is the same as assuming $p_r = \Pr[r \in R] = 1$ for all $r \in A_k$.

Proof [Theorem 8.1.1]. The lower bound follows immediately. Order the index set $I = \{1, \dots, m\}$ for convenience. For $1 \leq i \leq m$,

$$\Pr \left[B_i \mid \bigwedge_{1 \leq j < i} \overline{B_j} \right] \leq \Pr [B_i]$$

so

$$\Pr \left[\overline{B_i} \mid \bigwedge_{1 \leq j < i} \overline{B_j} \right] \geq \Pr [\overline{B_i}]$$

and

$$\Pr \left[\bigwedge_{i \in I} \overline{B_i} \right] = \prod_{i=1}^m \Pr \left[\overline{B_i} \mid \bigwedge_{1 \leq j < i} \overline{B_j} \right] \geq \prod_{i=1}^m \Pr [\overline{B_i}].$$

Now the first upper bound. For a given i renumber, for convenience, so that $i \sim j$ for $1 \leq j \leq d$ and not for $d+1 \leq j < i$. We use the inequality $\Pr[A \mid B \wedge C] \geq \Pr[A \wedge B \mid C]$, valid for any A, B, C . With $A = B_i, B = \overline{B_1} \wedge \dots \wedge \overline{B_d}$ and $C = \overline{B_{d+1}} \wedge \dots \wedge \overline{B_{i-1}}$,

$$\begin{aligned} \Pr \left[B_i \mid \bigwedge_{1 \leq j < i} \overline{B_j} \right] &= \Pr[A \mid B \wedge C] \geq \Pr[A \wedge B \mid C] \\ &= \Pr[A \mid C] \Pr[B \mid A \wedge C] \end{aligned}$$

From the mutual independence $\Pr[A \mid C] = \Pr[A]$. We bound

$$\Pr[B \mid A \wedge C] \geq 1 - \sum_{j=1}^d \Pr[B_j \mid B_i \wedge C] \geq 1 - \sum_{j=1}^d \Pr[B_j \mid B_i]$$

from the Correlation Inequality. Thus

$$\Pr \left[B_i \mid \bigwedge_{1 \leq j < i} \overline{B_j} \right] \geq \Pr[B_i] - \sum_{j=1}^d \Pr[B_j \wedge B_i].$$

Reversing

$$\begin{aligned} \Pr \left[\overline{B_i} \mid \bigwedge_{1 \leq j < i} \overline{B_j} \right] &\leq \Pr[\overline{B_i}] + \sum_{j=1}^d \Pr[B_j \wedge B_i] \\ &\leq \Pr[\overline{B_i}] \left(1 + \frac{1}{1-\epsilon} \sum_{j=1}^d \Pr[B_j \wedge B_i] \right) \end{aligned}$$

since $\Pr[\overline{B_i}] \geq 1 - \epsilon$. Employing the inequality $1 + x \leq e^x$,

$$\Pr \left[\overline{B_i} \mid \bigwedge_{1 \leq j < i} \overline{B_j} \right] \leq \Pr[\overline{B_i}] \exp \left(\frac{1}{1-\epsilon} \sum_{j=1}^d \Pr[B_j \wedge B_i] \right).$$

For each $1 \leq i \leq m$ we plug this inequality into

$$\Pr \left[\bigwedge_{i \in I} \overline{B_i} \right] = \prod_{i=1}^m \Pr \left[\overline{B_i} \mid \bigwedge_{1 \leq j < i} \overline{B_j} \right]$$

The terms $\Pr[\overline{B_i}]$ multiply to M . The exponents add: for each $i, j \in I$ with $j < i$ and $j \sim i$ the term $\Pr[B_j \wedge B_i]$ appears once so they add to $\Delta/2$.

For the second upper bound we instead bound

$$\begin{aligned} \Pr \left[\overline{B_i} \mid \bigwedge_{1 \leq j < i} \overline{B_j} \right] &\leq 1 - \Pr[B_i] + \sum_{j=1}^d \Pr[B_j \wedge B_i] \\ &\leq \exp \left(-\Pr[B_i] + \sum_{j=1}^d \Pr[B_j \wedge B_i] \right) \end{aligned}$$

Again, the $\Pr[B_j \wedge B_i]$ terms add to $\Delta/2$ while the $-\Pr[B_i]$ terms add to $-\mu$.

Proof [Theorem 8.1.2]. The second upper bound of Theorem 8.1.1 may be rewritten

$$-\ln \left(\Pr \left[\bigwedge_{i \in I} \overline{B_i} \right] \right) \geq \sum_{i \in I} \Pr[B_i] - \frac{1}{2} \sum_{i \sim j} \Pr[B_i \wedge B_j].$$

For any set of indices $S \subset I$ the same inequality applied only to $\{B_i\}_{i \in S}$ gives

$$-\ln \left(\Pr \left[\bigwedge_{i \in S} \overline{B_i} \right] \right) \geq \sum_{i \in S} \Pr[B_i] - \frac{1}{2} \sum_{i, j \in S, i \sim j} \Pr[B_i \wedge B_j].$$

Let now S be a random subset of I given by

$$\Pr[i \in S] = p$$

with p a constant to be determined, the events mutually independent. (Here we are using probabilistic methods to prove a probability theorem!) Each term $\Pr[B_i]$ then appears with probability p and each term $\Pr[B_i \wedge B_j]$ with probability p^2 so that

$$\begin{aligned} \mathbb{E} \left[-\ln \left(\Pr \left[\bigwedge_{i \in S} \overline{B_i} \right] \right) \right] &\geq \mathbb{E} \left[\sum_{i \in S} \Pr[B_i] \right] - \frac{1}{2} \mathbb{E} \left[\sum_{i, j \in S, i \sim j} \Pr[B_i \wedge B_j] \right] \\ &= p\mu - p^2 \frac{\Delta}{2} \end{aligned}$$

We set

$$p = \frac{\mu}{\Delta}$$

so as to maximize this quantity. The added assumption of Theorem 8.1.2 assures us that the probability p is at most 1. Then

$$\mathbb{E} \left[-\ln \left(\Pr \left[\bigwedge_{i \in S} \overline{B_i} \right] \right) \right] \geq \frac{\mu^2}{2\Delta}$$

Thus there is a specific $S \subset I$ for which

$$-\ln \left(\Pr \left[\bigwedge_{i \in S} \overline{B_i} \right] \right) \geq \frac{\mu^2}{2\Delta}$$

That is,

$$\Pr \left[\bigwedge_{i \in S} \overline{B_i} \right] \leq e^{-\mu^2/2\Delta}$$

But

$$\Pr \left[\bigwedge_{i \in I} \overline{B_i} \right] \leq \Pr \left[\bigwedge_{i \in S} \overline{B_i} \right],$$

completing the proof.

17.8.3 8.3 Brun's Sieve

The more traditional approach to the Poisson Paradigm is called Brun's sieve, for its use by the number theorist T. Brun. Let $B_1, \dots, B_m$ be events, X_i the indicator random variable for B_i and $X = X_1 + \dots + X_m$ the number of B_i that hold. Let there be a hidden parameter n (so that actually $m = m(n)$, $B_i = B_i(n)$, $X = X(n)$), which will define our o, O notation. Define

$$S^{(r)} = \sum \Pr[B_{i_1} \wedge \dots \wedge B_{i_r}]$$

the sum over all sets $\{i_1, \dots, i_r\} \subseteq \{1, \dots, m\}$, and put

$$X^{(r)} = X(X-1) \dots (X-r+1).$$

The inclusion-exclusion principle gives that

$$\Pr[X=0] = \Pr[\overline{B_1} \wedge \dots \wedge \overline{B_m}] = 1 - S^{(1)} + S^{(2)} - \dots + (-1)^r S^{(r)} \dots$$

Theorem 8.3.1 Suppose there is a constant μ so that

$$\mathbb{E}[X] = S^{(1)} \rightarrow \mu$$

and such that for every fixed r ,

$$\mathbb{E} \left[\binom{X}{r} \right] = S^{(r)} \rightarrow \frac{\mu^r}{r!}$$

Then

$$\Pr[X = 0] \rightarrow e^{-\mu}$$

and indeed for every t

$$\Pr[X = t] \rightarrow \frac{\mu^t}{t!} e^{-\mu}$$

Proof. We do only the case $t = 0$. Fix $\epsilon > 0$. Choose s so that

$$\left| \sum_{r=0}^{2s} (-1)^r \frac{\mu^r}{r!} - e^{-\mu} \right| \leq \frac{\epsilon}{2}$$

The Bonferroni Inequalities state that, in general, the inclusion-exclusion formula alternately over- and underestimates $\Pr[X = 0]$. In particular,

$$\Pr[X = 0] \leq \sum_{r=0}^{2s} (-1)^r S^{(r)}$$

Select n_0 (the hidden variable) so that for $n \geq n_0$,

$$\left| S^{(r)} - \frac{\mu^r}{r!} \right| \leq \frac{\epsilon}{2(2s+1)}$$

for $0 \leq r \leq 2s$. For such n

$$\Pr[X = 0] \leq e^{-\mu} + \epsilon$$

Similarly, taking the sum to $2s+1$ we find n_0 so that for $n \geq n_0$,

$$\Pr[X = 0] \geq e^{-\mu} - \epsilon$$

As ϵ was arbitrary $\Pr[X = 0] \rightarrow e^{-\mu}$.

The threshold functions for $G \sim G(n, p)$ to contain a copy of a given graph H , derived in Section 10.1 via the Janson Inequality, were originally found using Brun's sieve. Here is an example where both methods are used. Let $G \sim G(n, p)$, the random graph of Chapter 10. Let EPIT represent the statement that every vertex lies in a triangle.

Theorem 8.3.2 Let $c > 0$ be fixed and let $p = p(n), \mu = \mu(n)$ satisfy

$$\binom{n-1}{2} p^3 = \mu$$

$$e^{-\mu} = \frac{c}{n}$$

Then

$$\lim_{n \rightarrow \infty} \Pr[G(n, p) \text{ satisfies EPIT}] = e^{-c}$$

In Spencer (1990b) threshold functions are found for a very wide class of "extension statements" that every r vertices lie in a copy of some fixed H .

Proof. First fix $x \in V(G)$. For each unordered $y, z \in V(G) - \{x\}$ let B_{xyz} be the event that $\{x, y, z\}$ is a triangle of G . Let C_x be the event $\bigwedge_{y,z} \bar{B}_{xyz}$ and X_x the corresponding indicator random variable. We use Janson's Inequality to bound $E[X_x] = \Pr[C_x]$. Here $p = o(1)$ so $\epsilon = o(1)$. $\sum \Pr[B_{xyz}] = \mu$ as defined above. Dependency $xyz \sim xuv$ occurs if and only if the sets overlap (other than in x). Hence

$$\Delta = \sum_{y,z,z'} \Pr[B_{xyz} \wedge B_{xyz'}] = O(n^3 p^5) = o(1)$$

since $p = n^{-2/3+o(1)}$. Thus

$$E[X_x] \sim e^{-\mu} = \frac{c}{n}$$

Now define

$$X = \sum_{x \in V(G)} X_x$$

the number of vertices x not lying in a triangle. Then from linearity of expectation,

$$E[X] = \sum_{x \in V(G)} E[X_x] \rightarrow c$$

We need to show that the Poisson Paradigm applies to X . Fix r . Then

$$E\left[\binom{X}{r}\right] = S^{(r)} = \sum \Pr[C_{x_1} \wedge \cdots \wedge C_{x_r}],$$

the sum over all sets of vertices $\{x_1, \dots, x_r\}$. All r -sets look alike so

$$E\left[\binom{X}{r}\right] = \binom{n}{r} \Pr[C_{x_1} \wedge \cdots \wedge C_{x_r}] \sim \frac{n^r}{r!} \Pr[C_{x_1} \wedge \cdots \wedge C_{x_r}],$$

where $x_1, \dots, x_r$ are some particular vertices. But

$$C_{x_1} \wedge \cdots \wedge C_{x_r} = \bigwedge \overline{B_{x_i y z}}$$

the conjunction over $1 \leq i \leq r$ and all y, z . We apply Janson's Inequality to this conjunction. Again $\epsilon = p^3 = o(1)$. The number of $\{x_i, y, z\}$ is $r \binom{n-1}{2} - O(n)$, the overcount coming from those triangles containing two (or three) of the x_i . (Here it is crucial that r is fixed.) Thus

$$\sum \Pr[B_{x_i y z}] = p^3 \left(r \binom{n-1}{2} - O(n) \right) = r\mu + O(n^{-1+o(1)})$$

As before Δ is p^5 times the number of pairs $x_i y z \sim x_j y' z'$. There are $O(rn^3) = O(n^3)$ terms with $i = j$ and $O(r^2 n^2) = O(n^2)$ terms with $i \neq j$ so again $\Delta = o(1)$. Therefore

$$\Pr[C_{x_1} \wedge \cdots \wedge C_{x_r}] \sim e^{-r\mu}$$

and

$$E\left[\binom{X}{r}\right] \sim \frac{(ne^{-\mu})^r}{r!} = \frac{c^r}{r!}.$$

Hence the conditions of Theorem 8.3.1 are met for X .

17.8.4 8.4 Large Deviations

We return to the formulation of Section 8.1. Our object is to derive large deviation results on X similar to those in Appendix A. Given a point in the probability space (i.e., a selection of R) we call an index set $J \subseteq I$ a disjoint family (abbreviated disfam) if

- B_j for every $j \in J$.
- For no $j, j' \in J$ is $j \sim j'$.

If, in addition,

- If $j' \notin J$ and $B_{j'}$ then $j \sim j'$ for some $j \in J$,
then we call J a maximal disjoint family (maxdisfam). We give some general results on the possible sizes of maxdisfams. The connection to X must then be done on an ad hoc basis.

Lemma 8.4.1 With the above notation and for any integer s ,

$$\Pr[\text{there exists a disfam } J, |J| = s] \leq \frac{\mu^s}{s!}.$$

Proof. Let $\sum^*$ denote the sum over all s -sets $J \subseteq I$ with no $j \sim j'$. Let $\sum^o$ denote the sum over ordered s -tuples $(j_1, \dots, j_s)$ with $\{j_1, \dots, j_s\}$ forming such a J . Let $\sum^a$ denote the sum over all ordered s -tuples $(j_1, \dots, j_s)$. Then

$$\begin{aligned} \Pr[\text{there exists a disfam } J, |J| = s] &\leq \sum^* \Pr \left[\bigwedge_{j \in J} B_j \right] \\ &= \sum^* \prod_{j \in J} \Pr[B_j] = \frac{1}{s!} \sum^o \Pr[B_{j_1}] \cdots \Pr[B_{j_s}] \\ &\leq \frac{1}{s!} \sum^a \Pr[B_{j_1}] \cdots \Pr[B_{j_s}] \leq \frac{1}{s!} \left(\sum_{i \in I} \Pr[B_i] \right)^s = \frac{\mu^s}{s!}. \end{aligned}$$

Lemma 8.4.1 gives an effective upper bound when $\mu^s \ll s!$ - basically if $s > \mu\alpha$ for $\alpha > e$. For smaller s we look at the further condition of J being a maxdisfam. To that end we let μ_s denote the minimum, over all $j_1, \dots, j_s \in I$ of $\sum \Pr[B_i]$, the sum taken over all $i \in I$ except those i with $i \sim j_l$ for some $1 \leq l \leq s$. In application s will be small (otherwise we use Lemma 8.4.1) and μ_s will be close to μ . For some applications it is convenient to set

$$\nu = \max_{j \in I} \sum_{i \sim j} \Pr[B_i]$$

and note that $\mu_s \geq \mu - s\nu$.

Lemma 8.4.2 With the above notation and for any integer s ,

$$\begin{aligned} \Pr[\text{there exists a maxdisfam } J, |J| = s] &\leq \frac{\mu^s}{s!} e^{-\mu_s} e^{\Delta/2} \\ &\leq \frac{\mu^s}{s!} e^{-\mu} e^{s\nu} e^{\Delta/2} \end{aligned}$$

Proof. As in Lemma 8.4.1 we bound this probability by $\sum^*$ of $J = \{j_1, \dots, j_s\}$ being a maxdisfam. For this to occur J must first be a disfam and then $\bigwedge^* \overline{B_i}$, where $\bigwedge^*$ is the conjunction over all $i \in I$ except those with $i \sim j_l$ for some $1 \leq l \leq s$. We apply Janson's Inequality to give an upper bound to $\Pr[\bigwedge^* \overline{B_i}]$. The associated values μ^*, Δ^* satisfy

$$\begin{aligned}\mu^* &\geq \mu_s \\ \Delta^* &\leq \Delta\end{aligned}$$

the latter since Δ^* has simply fewer addends. Thus

$$\Pr \left[\bigwedge_{i=1}^* \overline{B_i} \right] \leq e^{-\mu_s} e^{\Delta/2}$$

and

$$\begin{aligned}\sum_{j=1}^* \Pr[J \text{ maxdisfam}] &\leq e^{-\mu_s} e^{\Delta/2} \sum_{j=1}^* \Pr \left[\bigwedge_{j \in J} B_j \right] \\ &\leq e^{-\mu_s} e^{\Delta/2} \frac{\mu^s}{s!}\end{aligned}$$

When $\Delta = o(1)$ and $\nu\mu = o(1)$ or, more generally, $\mu_{3\mu} = \mu + o(1)$, then Lemma 8.4.2 gives a close approximation to the Poisson distribution since

$$\Pr[\text{there exists a maxdisfam } J, |J| = s] \leq (1 + o(1)) \frac{\mu^s}{s!} e^{-\mu}$$

for $s \leq 3\mu$ and the probability is quite small for larger s by Lemma 8.4.1.

17.8.5 8.5 Counting Extensions

We begin with a case that uses the basic large deviation results of Appendix A.

Theorem 8.5.1 Set $p = [(\ln n)/n]\omega(n)$, where $\omega(n) \rightarrow \infty$ arbitrarily slowly. Then in $G(n, p)$ almost always

$$\deg(x) \sim (n-1)p$$

for all vertices x .

This is actually a large deviation result. It suffices to show the following.

Theorem 8.5.2 Set $p = [(\ln n)/n]\omega(n)$, where $\omega(n) \rightarrow \infty$ arbitrarily slowly. Let $x \in G$ be fixed. Fix $\epsilon > 0$. Then

$$\Pr[|\deg(x) - (n-1)p| > \epsilon(n-1)p] = o(n^{-1})$$

Proof. As $\deg(x) \sim B(n-1, p)$, that is, it is a binomial random variable with the above parameters, we have from Corollary A.1.14 that

$$\Pr[|\deg(x) - (n-1)p| > \epsilon(n-1)p] < 2e^{-c_\epsilon(n-1)p} = o(n^{-1}),$$

as c_ϵ is fixed and $(n-1)p \gg \ln n$.

This result illustrates why logarithmic terms appear so often in the study of random graphs. We want every x to have a property, hence we try to get the failure probability down to $o(n^{-1})$. When the Poisson Paradigm applies the failure probability is roughly an exponential, and hence we want the exponent to be logarithmic. This often leads to a logarithmic term for the edge probability p .

In Section 8.3 we found the threshold function for every vertex to lie on a triangle. It basically occurred when the expected number of extensions of a given vertex to a triangle reached $\ln n$. Now set $N(x)$ to be the number of triangles containing x . Set $\mu = \binom{n-1}{2}p^3 = E[N(x)]$.

Theorem 8.5.3 Let p be such that $\mu \gg \ln n$. Then almost always

$$N(x) \sim \mu$$

for all $x \in G(n, p)$.

As above, this is actually a large deviation result. We actually show the following.

Theorem 8.5.4 Let p be such that $\mu \gg \ln n$. Let $x \in G$ be fixed. Fix $\epsilon > 0$. Then

$$\Pr[|N(x) - \mu| > \epsilon\mu] = o(n^{-1})$$

Proof. We shall prove this under the further assumption $p = n^{-2/3+o(1)}$ (or equivalently, $\mu = n^{o(1)}$), which could be removed by technical methods. We now have, in the notation of Lemmas 8.4.1 and 8.4.2, $\nu\mu, \Delta = o(1)$. Let P denote the Poisson distribution with mean μ . Then

$$\begin{aligned} & \Pr[\text{there exists a maxdisfam } J, |J| \leq \mu(1 - \epsilon)] \\ & \leq (1 + o(1)) \Pr[P \leq \mu(1 - \epsilon)], \\ & \Pr[\text{there exists a maxdisfam } J, \mu(1 + \epsilon) \leq |J| \leq 3\mu] \\ & \leq (1 + o(1)) \Pr[\mu(1 + \epsilon) \leq P \leq 3\mu], \\ & \Pr[\text{there exists a maxdisfam } J, |J| \geq 3\mu] \\ & \leq \Pr[\text{there exists a disfam } J, |J| \geq 3\mu] \leq \sum_{s=3\mu}^{\infty} \frac{\mu^s}{s!} = O((1 - c)^\mu), \end{aligned}$$

where $c > 0$ is an absolute constant. Since $\mu \gg \ln n$ the third term is $o(n^{-1})$. The first and second terms are $o(n^{-1})$ by Theorem A.1.15. With probability $1 - o(n^{-1})$ every maxdisfam J has size between $(1 - \epsilon)\mu$ and $(1 + \epsilon)\mu$.

Fix one such J . (There always is some maximal disfam - even if no B_i held we could take $J = \emptyset$.) The elements of J are triples xyz that form triangles, hence $N(x) \geq |J| \geq (1 - \epsilon)\mu$. The upper bound is ad hoc. The probability that there exist five triangles of the form $xyz_1, xyz_2, xyz_3, xyz_4, xyz_5$ is at most $n^6 p^{11} = o(n^{-1})$. The probability that there exist triangles $xy_i z_i, xy_i z'_i, 1 \leq i \leq 4$, all vertices distinct, is at most $n^{12} p^{20} = o(n^{-1})$. Consider the graph whose vertices are the triangles xyz , with $\sim$ giving the edge relation. There are $N(x)$ vertices, the maxdisfam J are the maximal independent sets. In this graph, with probability $1 - o(n^{-1})$, each vertex xyz has degree at most nine and there is no set of four disjoint edges. This implies that for any $J, |J| \geq N(x) - 27$ and

$$N(x) \leq (1 + \epsilon)\mu + 27 \leq (1 + \epsilon')\mu.$$

For any graph H with "roots" $x_1, \dots, x_r$ we can examine in $G(n, p)$ the number of extensions $N(x_1, \dots, x_r)$ of a given set of r vertices to a copy of H . In Spencer (1990a) some general results are given that generalize Theorems 8.5.2 and 8.5.4. Under fairly wide assumptions (see Exercise 5, Chapter 10), when the expected number μ of extensions satisfies $\mu \gg \ln n$ then almost always all $N(x_1, \dots, x_r) \sim \mu$.

17.8.6 8.6 Counting Representations

The results of this section shall use the following very basic and very useful result.

Lemma 8.6.1 [The Borel-Cantelli Lemma] Let $\{A_n\}_{n \in \mathbb{N}}$ be events with

$$\sum_{n=1}^{\infty} \Pr[A_n] < \infty$$

Then

$$\Pr \left[\bigwedge_{i=1}^{\infty} \bigvee_{j=i}^{\infty} A_j \right] = 0$$

That is, almost always A_n is false for all sufficiently large n . In application we shall aim for $\Pr[A_n] < n^{-c}$ with $c > 1$ in order to apply this lemma.

Again we begin with a case that involves only the large deviation results of Appendix A. For a given set S of natural numbers let (for every $n \in \mathbb{N}$) $f(n) = f_S(n)$ denote the number of representations $n = x + y, x, y \in S, x < y$.

Theorem 8.6.2 [Erdős (1956)] There is a set S for which $f(n) = \Theta(\ln n)$. That is, there is a set S and constants c_1, c_2 so that for all sufficiently large n

$$c_1 \ln n \leq f(n) \leq c_2 \ln n.$$

Proof. Define S randomly by

$$\Pr[x \in S] = p_x = \min \left\{ 10 \sqrt{\frac{\ln x}{x}}, 1 \right\}$$

Fix n . Now $f(n)$ is a random variable with mean

$$\mu = E[f(n)] = \frac{1}{2} \sum_{\substack{x+y=n \\ x \neq y}} p_x p_y$$

Roughly there are n addends with $p_x p_y > p_n^2 = (100 \ln n)/n$. We have $p_x p_x = \Theta((\ln n)/n)$ except in the regions $x = o(n), y = o(n)$ and care must be taken that those terms don't contribute significantly to μ . Careful asymptotics (and first year calculus!) yield

$$\mu \sim 50 \ln n \int_0^1 \frac{dx}{\sqrt{x(1-x)}} = 50\pi \ln n$$

The negligible effect of the $x = o(n), y = o(n)$ terms reflects the finiteness of the indefinite integral at poles $x = 0$ and $x = 1$. The possible representations $x + y = n$ are mutually independent events so that from Corollary A.1.14,

$$\Pr[|f(n) - \mu| > \epsilon \mu] < 2e^{-\delta \mu}$$

for constants $\epsilon, \delta = \delta(\epsilon)$. To be specific we can take $\epsilon = 0.9, \delta = 0.1$ and

$$\Pr[|f(n) - \mu| > 0.9\mu] < 2e^{-5\pi \ln n} < n^{-1.1}$$

for n sufficiently large. Take $c_1 < 0.1(50\pi)$ and $c_2 > 1.9(50\pi)$.

Let A_n be the event that $c_1 \ln n \leq f(n) \leq c_2 \ln n$ does not hold. We have $\Pr[A_n] < n^{-1.1}$ for n sufficiently large. The Borel-Cantelli Lemma applies, almost always all A_n fail for n sufficiently large. Thus there exists a specific point in the probability space, that is, a specific set S , for which $c_1 \ln n \leq f(n) \leq c_2 \ln n$ for all sufficiently large n .

The development of the infinite probability space used here, and below, has been carefully done in the book Sequences by H. Halberstam and K. F. Roth (1983).

The use of the infinite probability space leaves a number of questions about the existential nature of the proof that go beyond the algorithmic. For example, does there exist a recursive set S having the property of Theorem 8.6.2? An affirmative answer is given in Kolountzakis (1999).

Now for a given set S of natural numbers let $g(n) = g_S(n)$ denote the number of representations $n = x + y + z, x, y, z \in S, x < y < z$. The following result was actually proved for representations of n as the sum of k terms for any fixed k . For simplicity we present here only the proof for $k = 3$.

Theorem 8.6.3 [Erdős and Tetali (1990)] There is a set S for which $g(n) = \Theta(\ln n)$. That is, there is a set S and constants c_1, c_2 so that for all sufficiently large n ,

$$c_1 \ln n \leq g(n) \leq c_2 \ln n.$$

Proof. Define S randomly by

$$\Pr[x \in S] = p_x = \min \left\{ 10 \left(\frac{\ln x}{x^2} \right)^{1/3}, \frac{1}{2} \right\}$$

Fix n . Now $g(n)$ is a random variable and

$$\mu = E[g(n)] = \sum_{x+y+z=n} p_x p_y p_z$$

Careful asymptotics give

$$\mu \sim \frac{10^3}{6} \ln n \int_{x=0}^1 \int_{y=0}^{1-x} \frac{dx dy}{[xy(1-x-y)]^{2/3}} = K \ln n$$

where K is large. (We may make K arbitrarily large by increasing "10.") We apply Lemma 8.4.2. Here

$$\Delta = \sum p_x p_y p_z p_{y'} p_{z'}$$

the sum over all five-tuples with $x+y+z = x+y'+z' = n$. Roughly there are n^3 terms, each $\sim p_n^5 = n^{-10/3+o(1)}$ so that the sum is $o(1)$. Again, care must be taken that those terms with one (or more) small variables don't contribute much to the sum. We bound $s \leq 3\mu = \Theta(\ln n)$ and consider μ_s . This is the minimal possible $\sum p_x p_y p_z$ over all those x, y, z with $x+y+z = n$ that do not intersect a given set of s representations; let us weaken that and say a given set of $3s$ elements. Again one needs that the weight of $\sum_{x+y+z=n} p_x p_y p_z$ is not on the edges but "spread" in

the center and one shows $\mu_s \sim \mu$. Now, as in Section 8.5, let P denote the Poisson distribution with mean μ . The probability that there exists a maxdisfam J of size less than $\mu(1-\epsilon)$ or between $\mu(1+\epsilon)$ and 3μ is asymptotically the probability that P lies in that range. For moderate ϵ , as K is large, these - as well as the probability of having a disfam of size bigger than 3μ - will be $o(n^{-c})$ with $c > 1$. By the Borel-Cantelli Lemma almost always all sufficiently large n will have all maxdisfam J of size between $c_1 \ln n$ and $c_2 \ln n$. Then $g(n) \geq c_1 \ln n$ immediately.

The upper bound is again ad hoc. With this p let $f(n)$ be, as before, the number of representations of n as the sum of two elements of S . We use only that $p_x = x^{-2/3+o(1)}$. We calculate

$$E[f(n)] = \sum_{x+y=n} (xy)^{-2/3+o(1)} = n^{-1/3+o(1)},$$

again watching the "pole" at 0. Here the possible representations are mutually independent so

$$\Pr[f(n) \geq 4] \leq E[f(n)]^4 / 4! = n^{-4/3+o(1)},$$

and by the Borel-Cantelli Lemma almost always $f(n) \leq 3$ for all sufficiently large n . But then almost always there is a C so that $f(n) \leq C$ for all n . For all sufficiently large n there is a maxdisfam (with representations as the sum of three terms) of size less than $c_2 \ln n$. Every triple $x, y, z \in S$ with $x + y + z = n$ must contain at least one of these at most $3c_2 \ln n$ points. The number of triples $x, y, z \in S$ with $x + y + z = n$ for a particular x is simply $f(n - x)$, the number of representations $n - x = y + z$ (possibly one less since $y, z \neq x$), and so is at most C . But then there are at most $C(3c_2 \ln n)$ total representations $n = x + y + z$.

17.8.7 8.7 Further Inequalities

Here we discuss some further results that allow one, sometimes, to apply the Poisson Paradigm. Let $B_i, i \in I$ be events in an arbitrary probability space. As in the Lovász Local Lemma of Chapter 5 we say that a symmetric binary relation ' $\sim$ ' on I is a dependency digraph if for each $i \in I$ the event B_i is mutually independent of $\{B_j : i \not\sim j\}$. [The digraph of Section 5.1 has $E = \{(i, j) : i \sim j\}$.] Suppose the events B_i satisfy the inequalities of Section 8.2:

$$\Pr \left[B_i \mid \bigwedge_{j \in J} \overline{B_j} \right] \leq \Pr [B_i]$$

valid for all index sets $J \subset I, i \notin J$ and

$$\Pr \left[B_i \mid B_k \wedge \bigwedge_{j \in J} \overline{B_j} \right] \leq \Pr [B_i \mid B_k]$$

valid for all index sets $J \subset I, i, k \notin J$. Then the Janson Inequalities in Theorems 8.1.1 and 8.1.2 and also Lemmas 8.4.1 and 8.4.2 hold as stated. The proofs are identical, the above are the only properties of the events B_i that were used.

Suen (1990) [see also Janson (1998) for significant variations] has given a very general result that allows the approximation of $\Pr [\bigwedge_{i \in I} \overline{B_i}]$ by $M = \prod_{i \in I} \Pr [\overline{B_i}]$. Again let $\{B_i\}_{i \in I}$ be events in an arbitrary probability space. We say that a binary relation $\sim$ on I is a superdependency digraph if the following holds: Let $J_1, J_2 \subset I$ be disjoint subsets so that $j_1 \sim j_2$ for no $j_1 \in J_1, j_2 \in J_2$. Let B^1 be any Boolean combination of the events $\{B_j\}_{j \in J_1}$ and let B^2 be any Boolean combination of the events $\{B_j\}_{j \in J_2}$. Then B^1, B^2 are independent. Note that the ' $\sim$ ' of Section 8.1 is indeed a superdependency digraph.

Theorem 8.7.1 [Suen] Under the above conditions,

$$\left| \Pr \left[\bigwedge_{i \in I} \overline{B_i} \right] - M \right| \leq M [e^{\sum_{i \sim j} y(i, j)} - 1]$$

where

$$y(i, j) = (\Pr [B_i \wedge B_j] + \Pr [B_i] \Pr [B_j]) \prod_{l \sim i \text{ or } l \sim j} (1 - \Pr [B_l])^{-1}.$$

We shall not prove Theorem 8.7.1. In many instances the above product is not large. Suppose it is less than two for all $i \sim j$. In that instance

$$\sum_{i \sim j} y(i, j) \leq 2 \left(\Delta + \sum_{i \sim j} \Pr [B_i] \Pr [B_j] \right).$$

In many instances $\sum_{i \sim j} \Pr[B_i] \Pr[B_j]$ is small relative to Δ (as in many instances when $i \sim j$ the events B_i, B_j are positively correlated). When, furthermore, $\Delta = o(1)$, Suen's Theorem gives the approximation of $\Pr[\bigwedge_{i \in I} \overline{B_i}]$ by M . Suen has applied this result to examinations of the number of induced copies of a fixed graph H in the random $G(n, p)$.

Janson (1990) has given a one-way large deviation result on the X of Section 8.1 that is somewhat simpler to apply than Lemmas 8.4.1 and 8.4.2.

Theorem 8.7.2 [Janson] With $\mu = E[X]$ and $\gamma > 0$ arbitrary,

$$\Pr[X \leq (1 - \gamma)\mu] < e^{-\gamma^2 \mu / [2 + (\Delta/\mu)]}$$

When $\Delta = o(\mu)$ this bound on the tail approximates that of the normal curve with mean and standard deviation μ . We shall not prove Theorem 8.7.2 here. The proofs of Theorems 8.7.1 and 8.7.2 as well as the original proofs by Janson of Theorems 8.1.1 and 8.1.2 are based on estimations of the Laplace transform of X , bounding $E[e^{-tX}]$.

17.8.8 8.8 Exercises

1. Prove that for every $\epsilon > 0$ there is some $n_0 = n_0(\epsilon)$ so that for every $n > n_0$ there is a graph on n vertices containing every graph on $k \leq (2 - \epsilon) \log_2 n$ vertices as an induced subgraph.
2. Find a threshold function for the property: $G(n, p)$ contains at least $n/6$ pairwise vertex disjoint triangles.

The Probabilistic Lens: Local Coloring

This result of Erdős (1962) gives further probabilistic evidence that the chromatic number $\chi(G)$ cannot be deduced from local considerations.

Theorem 1 For all k there exists $\epsilon > 0$ so that for all sufficiently large n there exist graphs G on n vertices with $\chi(G) > k$ and yet $\chi(G|_S) \leq 3$ for every set S of vertices of size at most ϵn .

Proof. For a given k let $c, \epsilon > 0$ satisfy (with foresight)

$$\begin{aligned} c &> 2k^2 H(1/k) \ln 2 \\ \epsilon &< e^{-5} 3^3 c^{-3} \end{aligned}$$

where $H(x) = -x \log_2 x - (1 - x) \log_2 (1 - x)$ is the entropy function. Set $p = c/n$ and let $G \sim G(n, p)$. We show that G almost surely satisfies the two conditions of the theorem.

If $\chi(G) \leq k$ there would be an independent set of size n/k . The expected number of such sets is

$$\binom{n}{n/k} (1 - p)^{\binom{n/k}{2}} < 2^{n(H(1/k) + o(1))} e^{-cn/2k^2(1+o(1))},$$

which is $o(1)$ by our condition on c . Hence almost surely $\chi(G) > k$.

Suppose some set S with $t \leq \epsilon n$ vertices required at least four colors. Then as in the proof of Lemma 7.3.4 there would be a minimal such set S . For any $v \in S$ there would be a three-coloring of $S - \{v\}$. If v had two or fewer neighbors in S then this could be extended to a three-coloring of S . Hence every $v \in S$ would have degree

at least three in $G|_S$ and so $G|_S$ would have at least $3t/2$ edges. The probability that some $t \leq \epsilon n$ vertices have at least $3t/2$ edges is less than

$$\sum_{t \leq \epsilon n} \binom{n}{t} \binom{\binom{t}{2}}{3t/2} \left(\frac{c}{n}\right)^{3t/2}$$

We outline the analysis. When $t = O(1)$ the terms are negligible. Otherwise we bound each term from above by

$$\left[\frac{ne}{t} \left(\frac{te}{3}\right)^{3/2} \left(\frac{c}{n}\right)^{3/2} \right]^t \leq \left[e^{5/2} 3^{-3/2} c^{3/2} \sqrt{t/n} \right]^t$$

Now since $t \leq \epsilon n$ the bracketed term is at most $e^{5/2} 3^{-3/2} c^{3/2} \epsilon^{1/2}$, which is less than one by our condition on ϵ . The full sum is $o(1)$; that is, almost surely no such S exists.

Many tempting conjectures are easily disproved by the probabilistic method. If every $n/\ln n$ vertices may be three-colored then can a graph G on n vertices be four-colored? This result shows that the answer is no.

17.9 9 Pseudorandomness

'A knot!', said Alice, always ready to make herself useful, and looking anxiously about her. 'Oh, do let me help to undo it!'

- from Alice in Wonderland, by Lewis Carroll

As shown in the various chapters of this book, the probabilistic method is a powerful tool for establishing the existence of combinatorial structures with certain properties. It is often the case that such an existence proof is not sufficient; we actually prefer an explicit construction. This is not only because an explicit construction may shed more light on the corresponding problem, but also because it often happens that a random-looking structure is useful for a certain algorithmic procedure; in this case we would like to have an algorithm and not merely to prove that it exists.

The problem of finding explicit constructions may look trivial; after all, since we are mainly dealing with finite cases, once we have a probabilistic proof of existence we can find an explicit example by exhaustive search. Moreover, many of the probabilistic proofs of existence actually show that most members of a properly chosen random space have the desired properties. We may thus expect that it would not be too difficult to find one such member. Although this is true in principle, it is certainly not practical to check all possibilities; it is thus common to define an explicit construction of a combinatorial object as one that can be performed efficiently; say, in time that is polynomial in the parameters of the object.

Let us illustrate this notion by one of the best known open problems in the area of explicit constructions, the problem of constructing explicit Ramsey graphs. The first example given in Chapter 1 is the proof of Erdős that for every n there are graphs on n vertices containing neither a clique nor an independent set on $2 \log_2 n$ vertices. This proof is an existence proof; can we actually describe such graphs explicitly? Erdős offered a prize of \$500 for the explicit construction of an infinite family of graphs, in which there is neither a clique nor an independent set of size more than a constant times the logarithm of the number of vertices, for some absolute constant. Of course, we can, in principle, for every fixed n , check all graphs on n vertices until we find a good one, but this does not give an efficient way of producing the desired graphs and hence is not explicit. Although the problem mentioned above received a considerable amount of attention, it is still open. The best known explicit construction is due to Frankl and Wilson (1981), who describe explicit graphs on n vertices which contain neither a clique nor an independent set on more than $2^{c\sqrt{\log n \log \log n}}$ vertices, for some absolute positive constant c .

Although the problem of constructing explicit Ramsey graphs is still open, there are several other problems for which explicit constructions are known. In this chapter we present a few examples and discuss briefly some of their algorithmic applications. We also describe several seemingly unrelated properties of a graph, which all turn out to be equivalent. All these are properties of the random graph and it is thus common to call a graph that satisfies these properties quasirandom. The equivalence of all these properties enables one to show, in several cases, that certain explicit graphs have many pseudorandom properties by merely showing that they possess one of them.

17.9.1 9.1 The Quadratic Residue Tournaments

Recall that a tournament on a set V of n players is an orientation $T = (V, E)$ of the set of edges of the complete graph on the set of vertices V . If (x, y) is a directed edge we say that x beats y . Given a permutation π of the set of players, a (directed) edge (x, y) of the tournament is consistent with π if x precedes y in π . If π is viewed as a ranking of the players, then it is reasonable to try and find rankings with as many consistent arcs as possible. Let $c(\pi, T)$ denote the number of arcs of T which are consistent with π , and define $c(T) = \max c(\pi, T)$, where the maximum is taken over all permutations π of the set of vertices of T . For every tournament T on n players, if $\pi = 1, 2, \dots, n$ and $\pi' = n, n-1, \dots, 1$ then $c(\pi, T) + c(\pi', T) = \binom{n}{2}$. Therefore $c(T) \geq \frac{1}{2} \binom{n}{2}$. In fact, it can be shown that for every such T , $c(T) \geq \frac{1}{2} \binom{n}{2} + \Omega(n^{3/2})$. On the other hand, a simple probabilistic argument shows that there are tournaments T on n players for which $c(T) \leq (1 + o(1)) \frac{1}{2} \binom{n}{2}$. [The best known estimate, which gives the right order of magnitude for the largest possible value of the difference of $c(T) - \frac{1}{2} \binom{n}{2}$ is more complicated and was given by de la Vega (1983), where he showed that there are tournaments T on n players for which $c(T) \leq \frac{1}{2} \binom{n}{2} + O(n^{3/2})$.]

Can we describe explicitly tournaments T on n vertices in which $c(T) \leq (1 + o(1)) \frac{1}{2} \binom{n}{2}$? This problem was mentioned by Erdős and Moon (1965) and by Spencer (1985a). It turns out that several such constructions can be given. Let us describe one.

Let $p \equiv 3 \pmod{4}$ be a prime and let $T = T_p$ be the tournament whose vertices are all elements of the finite field $GF(p)$ in which (i, j) is a directed edge iff $i - j$ is a quadratic residue. [Since $p \equiv 3 \pmod{4}$, -1 is a quadratic nonresidue modulo p and hence T_p is a well-defined tournament.]

Theorem 9.1.1 For the tournaments T_p described above,

$$c(T_p) \leq \frac{1}{2} \binom{p}{2} + O(p^{3/2} \log p)$$

In order to prove this theorem we need some preparations. Let χ be the quadratic residue character defined on the elements of the finite field $GF(p)$ by $\chi(y) = y^{(p-1)/2}$. Equivalently, $\chi(y)$ is 1 if y is a nonzero square, 0 if y is 0 and -1 otherwise. Let $D = (d_{ij})_{i,j=0}^{p-1}$ be the p by p matrix defined by $d_{ij} = \chi(i - j)$.

Fact 1 For every two distinct j and l , $\sum_{i \in GF(p)} d_{ij} d_{il} = -1$.

Proof.

$$\begin{aligned} \sum_i d_{ij} d_{il} &= \sum_i \chi(i - j) \chi(i - l) = \sum_{i \neq j, l} \chi(i - j) \chi(i - l) \\ &= \sum_{i \neq j, l} \chi\left(\frac{i - j}{i - l}\right) = \sum_{i \neq j, l} \chi\left(1 + \frac{l - j}{i - l}\right). \end{aligned}$$

As i ranges over all elements of $GF(p)$ besides j and l the quantity $(1 + (l - j)/(i - l))$ ranges over all elements of $GF(p)$ besides 0 and 1. Since the sum of $\chi(r)$ over all r in $GF(p)$ is 0 this implies that the right-hand side of the last equation is $0 - \chi(0) - \chi(1) = -1$, completing the proof of the fact.

For two subsets A and B of $GF(p)$, let $e(A, B)$ denote the number of directed edges of T_p that start in a vertex of A and end in a vertex of B . By the definition of the matrix D it follows that

$$\sum_{i \in A} \sum_{j \in B} d_{ij} = e(A, B) - e(B, A)$$

The following lemma is proved in Alon (1986b).

Lemma 9.1.2 For any two subsets A and B of $GF(p)$,

$$\left| \sum_{i \in A} \sum_{j \in B} d_{ij} \right| \leq |A|^{1/2} |B|^{1/2} p^{1/2}$$

Proof. By the Cauchy-Schwarz Inequality and by the fact above,

$$\begin{aligned} \left(\sum_{i \in A} \sum_{j \in B} d_{ij} \right)^2 &\leq |A| \sum_{i \in A} \left(\sum_{j \in B} d_{ij} \right)^2 \\ &\leq |A| \sum_{i \in GF(p)} \left(\sum_{j \in B} d_{ij} \right)^2 \\ &= |A| \sum_{i \in GF(p)} \left(|B| + 2 \sum_{j < l \in B} d_{ij} d_{il} \right) \\ &= |A| |B| p + 2 |A| \sum_{j < l \in B} \sum_{i \in GF(p)} d_{ij} d_{il} \\ &\leq |A| |B| p, \end{aligned}$$

completing the proof of the lemma.

Proof [Theorem 9.1.1]. Let r be the smallest integer satisfying $2^r \geq p$. Let $\pi = \pi_1, \dots, \pi_p$ be an arbitrary permutation of the vertices of T_p , and define $\pi' = \pi_p, \dots, \pi_1$. We must show that $c(\pi, T_p) \leq \frac{1}{2} \binom{p}{2} + O(p^{3/2} \log p)$ or, equivalently, that $c(\pi, T_p) - c(\pi', T_p) \leq O(p^{3/2} \log p)$. Let a_1 and a_2 be two integers satisfying $p = a_1 + a_2$ and $a_1 \leq 2^{r-1}, a_2 \leq 2^{r-1}$. Let A_1 be the set of the first a_1 vertices in the permutation π and let A_2 be the set of the last a_2 vertices in π . By Lemma 9.1.2,

$$e(A_1, A_2) - e(A_2, A_1) \leq (a_1 a_2 p)^{1/2} \leq 2^{r-1} p^{1/2}$$

Next, let $a_{11}, a_{12}, a_{21}, a_{22}$ be integers each of which does not exceed 2^{r-2} such that $a_1 = a_{11} + a_{12}$ and $a_2 = a_{21} + a_{22}$. Let A_{11} be the subset of A_1 consisting of those a_{11} elements of A_1 that appear first in π , and let A_{12} be the set of the a_{12} remaining elements of A_1 . The partition of A_2 into the two sets A_{21} and A_{22} is defined similarly. By applying Lemma 9.1.2 we obtain

$$\begin{aligned} &e(A_{11}, A_{12}) - e(A_{12}, A_{11}) + e(A_{21}, A_{22}) - e(A_{22}, A_{21}) \\ &\leq (a_{11} a_{12} p)^{1/2} + (a_{21} a_{22} p)^{1/2} \\ &\leq 2 \cdot 2^{r-2} p^{1/2}. \end{aligned}$$

Continuing in the same manner we obtain, in the i th step, a partition of the set of vertices into 2^i blocks, each consisting of at most 2^{r-i} consecutive elements in the permutation π . This

partition is obtained by splitting each block in the partition corresponding to the previous step into two parts. By applying Lemma 9.1.2 to each such pair $A_{\epsilon_1}, A_{\epsilon_2}$ (where here ϵ is a vector of length $i - 1$ with $\{1, 2\}$ -entries), and by summing we conclude that the sum over all these 2^{i-1} vectors ϵ of the differences $e(A_{\epsilon_1}, A_{\epsilon_2}) - e(A_{\epsilon_2}, A_{\epsilon_1})$ does not exceed

$$2^{i-1}2^{r-i}p^{1/2} \leq 2^{r-1}p^{1/2}$$

Observe that the sum of the left-hand sides of all these inequalities as i ranges from 1 to r is precisely the difference $c(\pi, T_p) - c(\pi', T_p)$. Therefore by summing we obtain

$$c(\pi, T_p) - c(\pi', T_p) \leq 2^{r-1}p^{1/2}r = O(p^{3/2} \log p),$$

completing the proof. $\square$

We note that any antisymmetric matrix with $\{1, -1\}$ -entries in which each two columns are roughly orthogonal can be used to give a construction of a tournament as above. Some related results appear in Frankl, Rödl and Wilson (1988). The tournaments T_p , however, have stronger pseudorandom properties than do some of these other tournaments. For example, for every $k \leq \frac{1}{4} \log p$, and for every set S of k vertices of T_p , the number of vertices of T_p that beat all the members of S is $(1 + o(1))p/2^k$. This was proved by Graham and Spencer (1971) by applying Weil's famous theorem known as the Riemann hypotheses for curves over finite fields [Weil (1948)]. Taking a sufficiently large p this supplies an explicit construction for the Schütte problem mentioned in Chapter 1.

17.9.2 9.2 Eigenvalues and Expanders

A graph $G = (V, E)$ is called an (n, d, c) -expander if it has n vertices, the maximum degree of a vertex is d , and for every set of vertices $W \subset V$ of cardinality $|W| \leq n/2$, the inequality $|N(W)| \geq c|W|$ holds, where $N(W)$ denotes the set of all vertices in $V \setminus W$ adjacent to some vertex in W . We note that sometimes a slightly different definition is used, but the difference is not essential. Expanders share many of the properties of sparse random graphs and are the subject of an extensive literature. A family of linear expanders of density d and expansion c is a sequence $\{G_i\}_{i=1}^\infty$, where G_i is an (n_i, d, c) -expander and n_i tends to infinity as i tends to infinity.

Such a family is the main component of the parallel sorting network of Ajtai, Komlós and Szemerédi (1983) and can be used for constructing certain fault tolerant linear arrays. It also forms the basic building block used in the construction of graphs with special connectivity properties and small number of edges. Some other examples of the numerous applications of these graphs to various problems in theoretical computer science can be found, for example, in Alon (1986b) and its references.

It is not too difficult to prove the existence of a family of linear expanders using probabilistic arguments. This was first done by Pinsker (1973). An explicit construction is much more difficult to find and was first given by Margulis (1973). This construction was later improved by various authors; most known constructions are Cayley graphs of certain groups of matrices, and their expansion properties are proved by estimating the eigenvalues of the adjacency matrices of the graphs and by relying on the close correspondence between the expansion properties of a graph and its spectral properties. This correspondence was first studied, independently, by Tanner (1984) and by Alon and Milman (1984). Since it is somewhat simpler for the case of regular graphs we restrict our attention here to this case.

Let $G = (V, E)$ be a d -regular graph and let $A = A_G = (a_{uv})_{u,v \in V}$ be its adjacency matrix given by $a_{uv} = 1$ if $uv \in E$ and $a_{uv} = 0$ otherwise. Since G is d -regular the largest eigenvalue of A is d , corresponding to the all 1 eigenvector. Let $\lambda = \lambda(G)$ denote the second largest

eigenvalue of G . For two (not necessarily disjoint) subsets B and C of V let $e(B, C)$ denote the number of ordered pairs (u, v) , where $u \in B, v \in C$ and uv is an edge of G . (Note that if B and C are disjoint this is simply the number of edges of G that connect a vertex of B with a vertex of C .)

Theorem 9.2.1 For every partition of the set of vertices V into two disjoint subsets B and C ,

$$e(B, C) \geq \frac{(d - \lambda)|B||C|}{n}$$

Proof. Put $|V| = n, b = |B|$ and $c = |C| = n - b$. Let $D = dI$ be the n by n scalar matrix with the degree of regularity of G on its diagonal. Observe that for any real vector x of length n (considered as a function $x : V \rightarrow \mathbb{R}$) we have

$$\begin{aligned} \langle (D - A)x, x \rangle &= \sum_{u \in V} \left(d(x(u))^2 - \sum_{v: uv \in E} x(v)x(u) \right) \\ &= d \sum_{u \in V} (x(u))^2 - 2 \sum_{uv \in E} x(v)x(u) = \sum_{uv \in E} (x(v) - x(u))^2. \end{aligned}$$

Define, now, a vector x by $x(v) = -c$ if $v \in B$ and $x(v) = b$ if $v \in C$. Note that A and $D - A$ have the same eigenvectors and that the eigenvalues of $D - A$ are precisely $d - \mu$, as μ ranges over all eigenvalues of A . Note, also, that $\sum_{v \in V} x(v) = 0$; that is, x is orthogonal to the constant vector, which is the eigenvector of the smallest eigenvalue of $D - A$. Since $D - A$ is a symmetric matrix, its eigenvectors are orthogonal to each other and form a basis of the n -dimensional space. It follows that x is a linear combination of the other eigenvectors of $D - A$ and hence, by the definition of λ and the fact that $d - \lambda$ is the second smallest eigenvalue of $D - A$, we conclude that

$$\langle (D - A)x, x \rangle \geq (d - \lambda)\langle x, x \rangle = (d - \lambda)(bc^2 + cb^2) = (d - \lambda)bcn.$$

By the second paragraph of the proof the left-hand side of the last inequality is $\sum_{uv \in E} (x(u) - x(v))^2 = e(B, C) \cdot (b + c)^2 = e(B, C) \cdot n^2$. Thus

$$e(B, C) \geq \frac{(d - \lambda)bc}{n}$$

completing the proof.

Corollary 9.2.2 If λ is the second largest eigenvalue of a d -regular graph G with n vertices, then G is an (n, d, c) -expander for $c = (d - \lambda)/2d$.

Proof. Let W be a set of $w \leq n/2$ vertices of G . By Theorem 9.2.1 there are at least $(d - \lambda)w(n - w)/n \geq (d - \lambda)w/2$ edges from W to its complement. Since no vertex in the complement is adjacent to more than d of these edges it follows that $|N(W)| \geq (d - \lambda)w/2d$.

The estimate for c in the last corollary can in fact be improved to $2(d - \lambda)/(3d - 2\lambda)$, as shown by Alon and Milman (1984). Each of these estimates shows that if the second largest eigenvalue of G is far from the first, then G is a good expander. The converse of this is also true, although more complicated. This is given in the following result, proved in Alon (1986a), which we state without its proof.

Theorem 9.2.3 If G is a d -regular graph which is an (n, d, c) -expander then

$$\lambda(G) \leq d - \frac{c^2}{4 + 2c^2}$$

The last two results supply an efficient algorithm for approximating the expanding properties of a d -regular graph; we simply compute (or estimate) its second largest eigenvalue. The larger the difference between this eigenvalue and d is, the better expanding properties of G follow. It is thus natural to ask how far from d this second eigenvalue can be. It is known [see Nilli (1991)] that the second largest eigenvalue of any d -regular graph with diameter k is at least $2\sqrt{d-1}(1 - O(1/k))$. Therefore, in any infinite family of d -regular graphs, the limsup of the second largest eigenvalue is at least $2\sqrt{d-1}$. Lubotzky, Phillips and Sarnak (1986), and independently, Margulis (1988), gave, for every $d = p + 1$ where p is a prime congruent to 1 modulo 4, explicit constructions of infinite families of d -regular graphs G_i with second largest eigenvalues $\lambda(G_i) \leq 2\sqrt{d-1}$. These graphs are Cayley graphs of factor groups of the group of all two by two invertible matrices over a finite field, and their eigenvalues are estimated by applying results of Eichler and Igusa concerning the Ramanujan Conjecture. Eichler's proof relies on Weil's Theorem mentioned in the previous section. The nonbipartite graphs G constructed in this manner satisfy a somewhat stronger assertion than $\lambda(G) \leq 2\sqrt{d-1}$. In fact, besides their largest eigenvalue d , they do not have eigenvalues whose absolute value exceed $2\sqrt{d-1}$. This fact implies some strong pseudorandom properties, as shown in the next results.

Theorem 9.2.4 Let $G = (V, E)$ be a d -regular graph on n vertices, and suppose the absolute value of each of its eigenvalues but the first one is at most λ . For a vertex $v \in V$ and a subset B of V denote by $N(v)$ the set of all neighbors of v in G , and let $N_B(v) = N(v) \cap B$ denote the set of all neighbors of v in B . Then, for every subset B of cardinality bn of V ,

$$\sum_{v \in V} (|N_B(v)| - bd)^2 \leq \lambda^2 b(1-b)n.$$

Observe that in a random d -regular graph each vertex v would tend to have about bd neighbors in each set of size bn . The above theorem shows that if λ is much smaller than d then for most vertices v , $N_B(v)$ is not too far from bd .

Proof. Let A be the adjacency matrix of G and define a vector $f : V \rightarrow \mathbb{R}$ by $f(v) = 1 - b$ for $v \in B$ and $f(v) = -b$ for $v \notin B$. Clearly $\sum_{v \in V} f(v) = 0$; that is, f is orthogonal to the eigenvector of the largest eigenvalue of A . Therefore

$$\langle Af, Af \rangle \leq \lambda^2 \langle f, f \rangle$$

The right-hand side of the last inequality is $\lambda^2 (bn(1-b)^2 + (1-b)nb^2) = \lambda^2 b(1-b)n$. The left-hand side is

$$\sum_{v \in V} ((1-b)|N_B(v)| - b(d - |N_B(v)|))^2 = \sum_{v \in V} (|N_B(v)| - bd)^2.$$

The desired result follows.

Corollary 9.2.5 Let $G = (V, E)$, d, n and λ be as in Theorem 9.2.4. Then for every two sets of vertices B and C of G , where $|B| = bn$ and $|C| = cn$, we have

$$|e(B, C) - cbdn| \leq \lambda \sqrt{bcn}$$

Proof. By Theorem 9.2.4,

$$\sum_{v \in C} (|N_B(v)| - bd)^2 \leq \sum_{v \in V} (|N_B(v)| - bd)^2 \leq \lambda^2 b(1-b)n.$$

Thus, by the Cauchy-Schwarz Inequality,

$$\begin{aligned}
|e(B, C) - cbdn| &\leq \sum_{v \in C} |N_B(v) - bd| \leq \sqrt{cn} \left(\sum_{v \in C} (|N_B(v)| - bd)^2 \right)^{1/2} \\
&\leq \sqrt{cn} \lambda \sqrt{b(1-b)n} \leq \lambda \sqrt{bcn}
\end{aligned}$$

The special case $B = C$ gives the following result. A slightly stronger estimate is proved in a similar way in Alon and Chung (1988).

Corollary 9.2.6 Let $G = (V, E)$, d, n and λ be as in Theorem 9.2.4. Let B be an arbitrary set of vertices of G and let $e(B) = \frac{1}{2}e(B, B)$ be the number of edges in the induced subgraph of G on B . Then

$$\left| e(B) - \frac{1}{2}b^2dn \right| \leq \frac{1}{2}\lambda bn.$$

A walk of length l in a graph G is a sequence $v_0, \dots, v_l$ of vertices of G , where for each $1 \leq i \leq l$, $v_{i-1}v_i$ is an edge of G . Obviously, the total number of walks of length l in a d -regular graph on n vertices is precisely $n \cdot d^l$. Suppose, now, that C is a subset of, say, $n/2$ vertices of G . How many of these walks do not contain any vertex of C ? If G is disconnected it may happen that half of these walks avoid C .

However, as shown by Ajtai, Komlós and Szemerédi (1987), there are many fewer such walks if all the eigenvalues of G but the largest are small. This result and some of its extensions have several applications in theoretical computer science, as shown in the above-mentioned paper [see also Cohen and Wigderson (1989)]. We conclude this section by stating and proving the result and one of its applications.

Theorem 9.2.7 Let $G = (V, E)$ be a d -regular graph on n vertices, and suppose that each of its eigenvalues but the first one is at most λ . Let C be a set of cn vertices of G . Then, for every l , the number of walks of length l in G that avoid C does not exceed $(1-c)n((1-c)d + c\lambda)^l$.

Proof. Let A be the adjacency matrix of G and let A' be the adjacency matrix of its induced subgraph on the complement of C . We claim that the maximum eigenvalue of A' is at most $(1-c)d + c\lambda$. To prove this claim we must show that for every vector $f : V \rightarrow \mathbb{R}$ satisfying $f(v) = 0$ for each $v \in C$ and $\sum_{v \in V} f(v)^2 = 1$, the inequality $\langle Af, f \rangle \leq (1-c)d + c\lambda$ holds. Let $f_1, f_2, \dots, f_n$ be an orthonormal basis of eigenvectors of A , where f_i is the eigenvector of λ_i , $\lambda_1 = d$ and each entry of f_1 is $1/\sqrt{n}$. Then $f = \sum_{i=1}^n c_i f_i$, where $\sum_{i=1}^n c_i^2 = 1$ and

$$\begin{aligned}
c_1 &= \sum_{v \in V} \frac{f(v)}{\sqrt{n}} = \sum_{v \in V \setminus C} \frac{f(v)}{\sqrt{n}} \\
&\leq \left(\sum_{v \in V \setminus C} f(v)^2 \right)^{1/2} \left((1-c)n \frac{1}{n} \right)^{1/2} = \sqrt{1-c},
\end{aligned}$$

where here we used the Cauchy-Schwarz Inequality. Therefore $\sum_{i=2}^n c_i^2 \geq c$ and

$$\langle Af, f \rangle = \sum_{i=1}^n c_i^2 \lambda_i \leq (1-c)d + c\lambda,$$

supplying the desired estimate for the largest eigenvalue of A' .

Let $\gamma_1 \geq \gamma_2 \geq \dots \geq \gamma_m$ be the eigenvalues of A' , where $m = (1-c)n$. By the Perron-Frobenius Theorem it follows that the absolute value of each of them is at most $\gamma_1 \leq (1-c)d + c\lambda$. The total number of walks of length l that avoid C is precisely $(A'^l g, g)$, where g is the all 1-vector indexed by the vertices in $V - C$. By expressing g as a linear combination of the eigenvectors of A' , $g = \sum_{i=1}^m b_i g_i$, where g_i is the eigenvector of γ_i , we conclude that this number is precisely

$$\sum_{i=1}^m b_i^2 \gamma_i^l \leq \gamma_1^l \sum_{i=1}^m b_i^2 = m \gamma_1^l \leq m((1-c)d + c\lambda)^l$$

Substituting $m = (1-c)n$ the desired result follows.

A randomly chosen walk of length l in a graph G is a walk of length l in G chosen according to a uniform distribution among all walks of that length. Note that if G is d -regular such a walk can be chosen by choosing randomly its starting point v_0 , and then by choosing, for each $1 \leq i \leq l$, v_i randomly among the d neighbors of v_{i-1} .

Corollary 9.2.8 Let $G = (V, E)$, d, n, λ, C and c be as in Theorem 9.2.7 and suppose

$$(1-c)d + c\lambda \leq \frac{d}{\sqrt{2}}$$

Then, for every l , the probability that a randomly chosen walk of length l in G avoids C is at most $2^{-l/2}$.

Proof. The number of walks of length l in G that avoid C is at most $(1-c)n((1-c)d + c\lambda)^l \leq nd^l 2^{-l/2}$, by Theorem 9.2.7. Since the total number of walks is nd^l , the desired result follows.

The results above are useful for amplification of probabilities in randomized algorithms. Although such an amplification can be achieved for any Monte Carlo algorithm, we prefer, for simplicity, to consider one representative example: the primality testing algorithm of Rabin (1980).

For an odd integer q , define two integers a and b by $q-1 = 2^a b$, where b is odd. An integer x , $1 \leq x \leq q-1$, is called a witness (for the nonprimality of q) if for the sequence $x_0, \dots, x_a$ defined by $x_0 = x^b \pmod{q}$ and $x_i = x_{i-1}^2 \pmod{q}$ for $1 \leq i \leq a$ either $x_a \neq 1$ or there is an i such that $x_i \neq -1, 1$ and $x_{i+1} = 1$. One can show that if q is a prime then there are no such witnesses for q , whereas if q is an odd nonprime then at least half of the numbers between 1 and $q-1$ are witnesses for q . (In fact, at least $3/4$ are witnesses, as shown by Rabin.) This suggests the following randomized algorithm for testing if an odd integer q is a prime (for even integers there is a simpler algorithm!).

Choose, randomly, an integer x between 1 and $q-1$ and check if it is a witness. If it is, report that q is not a prime. Otherwise, report that q is a prime.

Observe that if q is a prime, the algorithm certainly reports it is a prime, whereas if q is not a prime, the probability that the algorithm makes a mistake and reports it as a prime is at most $1/2$. What if we wish to reduce the probability of making such a mistake? Clearly we can simply repeat the algorithm. If we repeat it l independent times, then the probability of making an error (i.e., reporting a nonprime as a prime) decreases to $1/2^l$. However, the number of random bits required for this procedure is $l \cdot \log(q-1)$.

Suppose we wish to use fewer random bits. By applying the properties of a randomly chosen walk on an appropriate graph, proved in the last two results, we can obtain the same estimate for the error probability by using only $\log(q-1) + O(l)$ random bits. This is done as follows.

Let G be a d -regular graph with $q-1$ vertices, labeled by all integers between 1 and $q-1$. Suppose G has no eigenvalue, but the first one, that exceeds λ and suppose that

$$\frac{d + \lambda}{2} \leq \frac{d}{\sqrt{2}} \tag{9.1}$$

Now choose randomly a walk of length $2l$ in the graph G , and check, for each of the numbers labeling its vertices, if it is a witness. If q is a nonprime, then at least half of the vertices of G are labeled by witnesses. Hence, by Corollary 9.2.8 and by (9.1), the probability that no witness is on the walk is at most $2^{-2l/2} = 2^{-l}$. Thus we obtain the same reduction in the error-probability as the one obtained by choosing l independent witnesses. Let us estimate the number of random bits required for choosing such a random walk.

The known constructions of expanders given by Lubotzky et al. (1986) or by Margulis (1988) give explicit families of graphs with degree d and with $\lambda \leq 2\sqrt{d-1}$, for each $d = p+1$, where p is a prime congruent to 1 modulo 4. [We note that these graphs will not have exactly $q-1$ vertices but this does not cause any real problem as we can take a graph with n vertices, where $q-1 \leq n \leq (1+o(1))(q-1)$, and label its i th vertex by $i \pmod{q-1}$. In this case the number of vertices labeled by witnesses would still be at least $(\frac{1}{2} + o(1))n$.] One can easily check that, for example, $d = 30$ and $\lambda = 2\sqrt{29}$ satisfy (9.1) and thus we can use a 30-regular graph. The number of random bits required for choosing a random walk of length $2l$ in it is less than $\log(q-1) + 10l + 1$, much less than the $l \log(q-1)$ bits that are needed in the repetition procedure.

17.9.3 9.3 Quasirandom Graphs

In this section we describe several pseudorandom properties of graphs, which, somewhat surprisingly, turn out to be all equivalent. All the properties are ones satisfied, almost surely, by a random graph in which every edge is chosen, independently, with probability $1/2$. The equivalence between some of these properties was first proved by several authors; see Thomason (1987), Frankl et al. (1988) and Alon and Chung (1988), but the first paper in which all of them (and some others) appear is the one by Chung, Graham and Wilson (1989). Our presentation here follows that paper, although, in order to simplify the presentation, we consider only the case of regular graphs.

We first need some notation. For two graphs G and H , let $N_G^*(H)$ be the number of labeled occurrences of H as an induced subgraph of G ; that is, the number of adjacency preserving injections $f : V(H) \rightarrow V(G)$ whose image is the set of vertices of an induced copy of H in G . Similarly, $N_G(H)$ denotes the number of labeled copies of H as a (not necessarily induced) subgraph of G . Note that $N_G(H) = \sum_L N_G^*(L)$, where L ranges over all graphs on the set of vertices of H obtained from H by adding to it a (possibly empty) set of edges.

Throughout this section G always denotes a graph with n vertices. We denote the eigenvalues of its adjacency matrix (taken with multiplicities) by $\lambda_1, \dots, \lambda_n$, where $|\lambda_1| \geq \dots \geq |\lambda_n|$. [Since we consider in this section only the eigenvalues of G we simply write λ_1 and not $\lambda_1(G)$.] Recall also the following notation, used in the previous section: for a vertex v of G , $N(v)$ denotes the set of its neighbors in G . If S is a set of vertices of G , $e(S)$ denotes the number of edges in the induced subgraph of G on S . If B and C are two (not necessarily disjoint) subsets of vertices of G ,

$e(B, C)$ denotes the number of ordered pairs (b, c) , where $b \in B, c \in C$ and bc is an edge of G . Thus $e(S) = \frac{1}{2}e(S, S)$.

We can now state the pseudorandom properties considered here. All the properties refer to a graph $G = (V, E)$ with n vertices. Throughout the section, we use the $o(\cdot)$ notation, without mentioning the precise behavior of each $o(\cdot)$. Thus occurrences of two $o(1)$, say, need not mean that both are identical and only mean that if we consider a family of graphs G and let their number of vertices n tend to infinity then each $o(1)$ tends to 0.

Property $P_1(s)$: For every graph $H(s)$ on s vertices

$$N_G^*(H(s)) = (1 + o(1))n^s 2^{-\binom{s}{2}}.$$

Property P_2 : For the cycle $C(4)$ with 4 vertices $N_G(C(4)) \leq (1 + o(1))(n/2)^4$.

Property P_3 : $|\lambda_2| = o(n)$.

Property P_4 : For every set S of vertices of G $e(S) = \frac{1}{4}|S|^2 + o(n^2)$.

Property P_5 : For every two sets of vertices B and C $e(B, C) = \frac{1}{2}|B||C| + o(n^2)$.

Property P_6 : $\sum_{u, v \in V} ||N(u) \cap N(v)| - n/4| = o(n^3)$.

It is easy to check that all the properties above are satisfied, almost surely, by a random graph

on n vertices. In this section we show that all these properties are equivalent for a regular graph with n vertices and degree of regularity about $n/2$. The fact that the innocent-looking property P_2 is strong enough to imply for such graphs $P_1(s)$ for every $s \geq 1$ is one of the interesting special cases of this result.

Graphs that satisfy any (and thus all) of the properties above are called quasirandom. As noted above the assumption that G is regular can be dropped (at the expense of slightly modifying property P_2 and slightly complicating the proofs).

Theorem 9.3.1 Let G be a d -regular graph on n vertices, where $d = (\frac{1}{2} + o(1))n$. If G satisfies any one of the seven properties $P_1(4), P_1(s)$ for all $s \geq 1, P_2, P_3, P_4, P_5, P_6$ then it satisfies all seven.

Proof. We show that

$$P_1(4) \Rightarrow P_2 \Rightarrow P_3 \Rightarrow P_4 \Rightarrow P_5 \Rightarrow P_6 \Rightarrow P_1(s) \text{ for all } s \geq 1 \quad (\Rightarrow P_1(4)).$$

1. $P_1(4) \Rightarrow P_2$.

Suppose G satisfies $P_1(4)$. Then $N_G(C(4)) = \sum_L N_G^*(L)$, as L ranges over the four labeled graphs obtained from a labeled $C(4)$ by adding to it a (possibly empty) set of edges. Since G satisfies $P_1(4)$, $N_G^*(L) = (1 + o(1))n^4 2^{-16}$ for each of these graphs L and hence $N_G(C(4)) = (1 + o(1))n^4 2^{-4}$, showing that G satisfies P_2 .

2. $P_2 \Rightarrow P_3$.

Suppose G satisfies P_2 and let A be its adjacency matrix. The trace of A^4 is precisely $\sum_{i=1}^n \lambda_i^4$. On the other hand it is easy to see that this trace is precisely the number of (labeled) closed walks of length 4 in G , that is, the number of sequences $v_0, v_1, v_2, v_3, v_4 = v_0$ of vertices of G such that $v_i v_{i+1}$ is an edge for each $0 \leq i \leq 3$. This number is $N_G(C(4))$ plus the number of such sequences in which $v_2 = v_0$, which is nd^2 , plus the number of such sequences in which $v_2 \neq v_0$ and $v_3 = v_1$, which is $nd(d-1)$. Thus

$$\begin{aligned} \sum_{i=1}^n \lambda_i^4 &= d^4 + \sum_{i=2}^n \lambda_i^4 = (1 + o(1))(n/2)^4 + \sum_{i=2}^n \lambda_i^4 \\ &= N_G(C(4)) + O(n^3) = (1 + o(1))(n/2)^4 \end{aligned}$$

It follows that $\sum_{i=2}^n \lambda_i^4 = o(n^4)$ and hence that $|\lambda_2| = o(n)$, as needed.

3. $P_3 \Rightarrow P_4$.

This is an immediate consequence of Corollary 9.2.6.

4. $P_4 \Rightarrow P_5$.

Suppose G satisfies P_4 . We first claim that it satisfies property P_5 for disjoint sets of vertices B and C . Indeed, if B and C are disjoint then

$$\begin{aligned} e(B, C) &= e(B \cup C) - e(B) - e(C) \\ &= \frac{1}{4}(|B| + |C|)^2 - \frac{1}{4}|B|^2 - \frac{1}{4}|C|^2 + o(n^2) \\ &= \frac{1}{2}|B||C| + o(n^2), \end{aligned}$$

proving the claim.

In case B and C are not disjoint we have

$$e(B, C) = e(B \setminus C, C \setminus B) + e(B \cap C, C \setminus B) + e(B \cap C, B \setminus C) + 2e(B \cap C).$$

Put $|B| = b, |C| = c$ and $|B \cap C| = x$. By the above expression for $e(B, C)$ and by the fact that G satisfies P_4 and P_5 for disjoint B and C we get

$$\begin{aligned}
e(B, C) &= \frac{1}{2}(b-x)(c-x) + \frac{1}{2}x(c-x) + \frac{1}{2}x(b-x) + \frac{2}{4}x^2 + o(n^2) \\
&= \frac{1}{2}bc + o(n^2) = \frac{1}{2}|B||C| + o(n^2)
\end{aligned}$$

showing that G satisfies P_5 .

5. $P_5 \Rightarrow P_6$.

Suppose that G satisfies P_5 and recall that G is d -regular, where $d = (\frac{1}{2} + o(1))n$. Let v be a fixed vertex of G , and let us estimate the sum

$$\sum_{u \in V, u \neq v} \left| |N(u) \cap N(v)| - \frac{n}{4} \right|.$$

Define

$$B_1 = \left\{ u \in V, u \neq v : |N(u) \cap N(v)| \geq \frac{n}{4} \right\}$$

and similarly

$$B_2 = \left\{ u \in V, u \neq v : |N(u) \cap N(v)| < \frac{n}{4} \right\}.$$

Let C be the set of all neighbors of v in G . Observe that

$$\begin{aligned}
\sum_{u \in B_1} \left| |N(u) \cap N(v)| - \frac{n}{4} \right| &= \sum_{u \in B_1} |N(u) \cap N(v)| - |B_1| \frac{n}{4} \\
&= e(B_1, C) - |B_1| \frac{n}{4}.
\end{aligned}$$

Since G satisfies P_5 and since $d = (\frac{1}{2} + o(1))n$ the last difference is $\frac{1}{2}|B_1|d + o(n^2) - |B_1|n/4 = o(n^2)$.

A similar argument implies that

$$\sum_{u \in B_2} \left| |N(u) \cap N(v)| - \frac{n}{4} \right| = o(n^2).$$

It follows that for every vertex v of G ,

$$\sum_{u \in V, u \neq v} \left| |N(u) \cap N(v)| - \frac{n}{4} \right| = o(n^2),$$

and by summing over all vertices v we conclude that G satisfies property P_6 .

6. $P_6 \Rightarrow P_1(s)$ for all $s \geq 1$.

Suppose $G = (V, E)$ satisfies P_6 . For any two distinct vertices u and v of G let $a(u, v)$ be 1 if $uv \in E$ and 0 otherwise. Also, define $s(u, v) = |\{w \in V : a(u, w) = a(v, w)\}|$. Since G is $d = (\frac{1}{2} + o(1))n$ -regular,

$$s(u, v) = 2|N(u) \cap N(v)| + n - 2d = 2|N(u) \cap N(v)| + o(n).$$

Therefore the fact that G satisfies P_6 implies that

$$\sum_{u, v \in V} \left| s(u, v) - \frac{n}{2} \right| = o(n^3) \quad (9.2)$$

Let $H = H(s)$ be an arbitrary fixed graph on s vertices, and put $N_s = N_G^*(H(s))$. We must show that

$$N_s = (1 + o(1))n^s 2^{-\binom{s}{2}}$$

Denote the vertex set of $H(s)$ by $\{v_1, \dots, v_s\}$. For each $1 \leq r \leq s$, put $V_r = \{v_1, \dots, v_r\}$, and let $H(r)$ be the induced subgraph of H on V_r . We prove, by induction on r , that for $N_r = N_G^*(H(r))$,

$$N_r = (1 + o(1))n_{(r)} 2^{-\binom{r}{2}} \quad (9.3)$$

where $n_{(r)} = n(n-1) \cdots (n-r+1)$.

This is trivial for $r = 1$. Assuming it holds for r , where $1 \leq r < s$, we prove it for $r+1$. For a vector $\alpha = (\alpha_1, \dots, \alpha_r)$ of distinct vertices of G , and for a vector $\epsilon = (\epsilon_1, \dots, \epsilon_r)$ of $(0, 1)$ -entries, define

$$f_r(\alpha, \epsilon) = |\{v \in V : v \neq \alpha_1, \dots, \alpha_r \text{ and } a(v, \alpha_j) = \epsilon_j \text{ for all } 1 \leq j \leq r\}|.$$

Clearly N_{r+1} is the sum of the N_r quantities $f_r(\alpha, \epsilon)$ in which $\epsilon_j = a(v_{r+1}, v_j)$ and α ranges over all N_r induced copies of $H(r)$ in G .

Observe that altogether there are precisely $n_{(r)} 2^r$ quantities $f_r(\alpha, \epsilon)$. It is convenient to view $f_r(\alpha, \epsilon)$ as a random variable defined on a sample space of $n_{(r)} 2^r$ points, each having an equal probability. To complete the proof we compute the expectation and the variance of this random variable. We show that the variance is so small that most of the quantities $f_r(\alpha, \epsilon)$ are very close to the expectation, and thus obtain a sufficiently accurate estimate for N_{r+1} which is the sum of N_r such quantities.

We start with the simple computation of the expectation $E[f_r]$ of $f_r(\alpha, \epsilon)$. We have

$$\begin{aligned} E[f_r] &= \frac{1}{n_{(r)} 2^r} \sum_{\alpha, \epsilon} f_r(\alpha, \epsilon) = \frac{1}{n_{(r)} 2^r} \sum_{\alpha} \sum_{\epsilon} f_r(\alpha, \epsilon) \\ &= \frac{1}{n_{(r)} 2^r} \sum_{\alpha} (n-r) = \frac{n-r}{2^r} \end{aligned}$$

where we used the fact that every vertex $v \neq \alpha_1, \dots, \alpha_r$ defines ϵ uniquely. Next, we estimate the quantity S_r defined by

$$S_r = \sum_{\alpha, \epsilon} f_r(\alpha, \epsilon) (f_r(\alpha, \epsilon) - 1)$$

We claim that

$$S_r = \sum_{u \neq v} s(u, v)_{(r)} \quad (9.4)$$

To prove this claim, observe that S_r can be interpreted as the number of ordered triples $(\alpha, \epsilon, (u, v))$, where $\alpha = (\alpha_1, \dots, \alpha_r)$ is an ordered set of r distinct vertices of G , $\epsilon = (\epsilon_1, \dots, \epsilon_r)$ is a binary vector of length r , and u, v is an ordered pair of additional vertices of G so that

$$a(u, \alpha_k) = a(v, \alpha_k) = \epsilon_k \text{ for all } 1 \leq k \leq r.$$

For each fixed α and ϵ , there are precisely $f_r(\alpha, \epsilon) (f_r(\alpha, \epsilon) - 1)$ choices for the pair (u, v) and hence S_r counts the number of these triples.

Now, let us compute this number by first choosing u and v . Once u, v are chosen, the additional vertices $\alpha_1, \dots, \alpha_r$ must all belong to the set $\{w \in V : a(u, w) = a(v, w)\}$. Since the cardinality of this set is $s(u, v)$ it follows that there are $s(u, v)_{(r)}$ choices for $\alpha_1, \dots, \alpha_r$. Once these are chosen the vector ϵ is determined and thus (9.4) follows.

We next claim that (9.2) implies

$$\sum_{u \neq v} s(u, v)_{(r)} = (1 + o(1))n^{r+2}2^{-r} \quad (9.5)$$

To prove this claim define $\epsilon_{uv} = s(u, v) - n/2$. Observe that, by (9.2), $\sum_{u \neq v} |\epsilon_{uv}| = o(n^3)$ and $|\epsilon_{uv}| \leq n/2 \leq n$ for each u, v . Hence, for every fixed $a \geq 1$,

$$\sum_{u \neq v} |\epsilon_{uv}|^a \leq n^{a-1} \sum_{u \neq v} |\epsilon_{uv}| = o(n^{a+2}).$$

This implies that

$$\begin{aligned} & \sum_{u \neq v} s(u, v)_{(r)} \\ &= \sum_{u \neq v} \left(\frac{n}{2} + \epsilon_{uv} \right)_{(r)} \\ &= \sum_{k=0}^r \sum_{u \neq v} c_k \left(\frac{n}{2} \right)^k \epsilon_{uv}^{r-k} \quad (\text{for appropriate constants } c_k) \\ &= \left(\frac{n}{2} \right)^r n_{(2)} + \sum_{k=0}^{r-1} \sum_{u \neq v} c_k \left(\frac{n}{2} \right)^k \epsilon_{uv}^{r-k} \\ &\leq \left(\frac{n}{2} \right)^r n_{(2)} + \sum_{k=0}^{r-1} \sum_{u \neq v} |c_k| n^k |\epsilon_{uv}|^{r-k} \\ &\leq n^{r+2}2^{-r} + c \sum_{k=0}^{r-1} n^k \sum_{u \neq v} |\epsilon_{uv}|^{r-k} \quad (\text{for an appropriate constant } c) \\ &\leq n^{r+2}2^{-r} + c \sum_{k=0}^{r-1} n^k \cdot o(n^{r-k+2}) \\ &= n^{r+2}2^{-r}(1 + o(1)), \end{aligned}$$

implying (9.5).

By (9.4) and (9.5), $S_r = (1 + o(1))n^{r+2}2^{-r}$. Therefore

$$\begin{aligned} & \sum_{\alpha, \epsilon} (f_r(\alpha, \epsilon) - \mathbb{E}[f_r])^2 \\ &= \sum_{\alpha, \epsilon} f_r^2(\alpha, \epsilon) - \sum_{\alpha, \epsilon} \mathbb{E}[f_r]^2, \\ & \sum_{\alpha, \epsilon} (f_r^2(\alpha, \epsilon) - f_r(\alpha, \epsilon)) + \sum_{\alpha, \epsilon} f_r(\alpha, \epsilon) - n_{(r)}2^r(n-r)^22^{-2r} \\ &= S_r + n_{(r)}2^r \mathbb{E}[f_r] - n_{(r)}2^r(n-r)^22^{-2r} \\ &= S_r + n_{(r+1)} - n_{(r)}2^r(n-r)^22^{-2r} = o(n^{r+2}) \end{aligned}$$

Recall that N_{r+1} is the summation of N_r quantities of the form $f_r(\alpha, \epsilon)$. Thus

$$|N_{r+1} - N_r \mathbb{E}[f_r]|^2 = \left| \sum_{N_r \text{ terms}} (f_r(\alpha, \epsilon) - \mathbb{E}[f_r]) \right|^2.$$

By Cauchy-Schwarz, the last expression is at most

$$\begin{aligned}
N_r \sum_{N_r \text{ terms}} (f_r(\alpha, \epsilon) - E[f_r])^2 &\leq N_r \sum_{\alpha, \epsilon} (f_r(\alpha, \epsilon) - E[f_r])^2 \\
&= N_r \cdot o(n^{r+2}) = o(n^{2r+2})
\end{aligned}$$

It follows that

$$|N_{r+1} - N_r E[f_r]| = o(n^{r+1})$$

and hence, by the induction hypothesis,

$$\begin{aligned}
N_{r+1} &= N_r E[f_r] + o(n^{r+1}) \\
&= (1 + o(1))n_{(r)}2^{-\binom{r}{2}} \cdot (n - r)2^{-r} + o(n^{r+1}) \\
&= (1 + o(1))n_{(r+1)}2^{-\binom{r+1}{2}}
\end{aligned}$$

This completes the proof of the induction step and establishes Theorem 9.3.1.

There are many examples of families of quasirandom graphs. The most widely used is probably the family of Paley graphs G_p defined as follows. For a prime p congruent to 1 modulo 4, let G_p be the graph whose vertices are the integers $0, 1, 2, \dots, p-1$ in which i and j are adjacent if and only if $i - j$ is a quadratic residue modulo p . The graphs G_p , which are the undirected analogues of the quadratic residue tournaments discussed in Section 9.1, are $(p-1)/2$ -regular. For any two distinct vertices i and j of G_p , the number of vertices k that are either adjacent to both i and j or nonadjacent to both is precisely the number of times the quotient $(k-i)/(k-j)$ is a quadratic residue. As k ranges over all numbers between 0 and $p-1$ but i and j , this quotient ranges over all numbers but 1 and 0 and hence it is a quadratic residue precisely $\frac{1}{2}(p-1) - 1$ times. (This is essentially the same assertion as that of the first fact given in the proof of Theorem 9.1.1.) We have thus shown that for every two vertices i and j of G_p , $s(i, j) = (p-3)/2$, and this, together with the fact that G_p is $(p-1)/2$ -regular, easily implies that it satisfies Property P_6 . Therefore it is quasirandom. As is the case with the quadratic residue tournaments, G_p satisfies, in fact, some stronger pseudorandom properties that are not satisfied by every quasirandom graph and that can be proved by applying Weil's Theorem.

17.9.4 9.4 Exercises

1. By considering a random bipartite three-regular graph on $2n$ vertices obtained by picking three random permutations between the two color classes, prove that there is a $c > 0$ such that for every n there exists a $(2n, 3, c)$ -expander.
2. Let $G = (V, E)$ be an (n, d, λ) -graph, suppose n is divisible by k , and let $C : V \rightarrow \{1, 2, \dots, k\}$ be a coloring of V by k colors, so that each color appears precisely n/k times. Prove that there is a vertex of G which has a neighbor of each of the k colors, provided $k\lambda \leq d$.
3. Let $G = (V, E)$ be a graph in which there is at least one edge between any two disjoint sets of size $a+1$. Prove that for every set Y of $5a$ vertices, there is a set X of at most a vertices, such that for every set Z satisfying $Z \cap (X \cup Y) = \emptyset$ and $|Z| \leq a$, the inequality $|N(Z) \cap Y| \geq 2|Z|$ holds.
4. Prove that for every $\epsilon > 0$ there exists an $n_0 = n_0(\epsilon)$ so that for every $(n, n/2, 2\sqrt{n})$ -graph $G = (V, E)$ with $n > n_0$, the number of triangles M in G satisfies $|M - n^3/48| \leq \epsilon n^3$.

The Probabilistic Lens: Random Walks

A vertex-transitive graph is a graph $G = (V, E)$ such that for any two vertices $u, v \in V$ there is an automorphism of G that maps u into v . A random walk of length l in G starting at a vertex v is a randomly chosen sequence $v = v_0, v_1, \dots, v_l$, where each v_{i+1} is chosen, randomly and independently, among the neighbors of v_i ($0 \leq i < l$).

The following theorem states that for every vertex-transitive graph G , the probability that a random walk of even length in G ends at its starting point is at least as big as the probability that it ends at any other vertex. Note that the proof requires almost no computation. We note also that the result does not hold for general regular graphs, and the vertex transitivity assumption is necessary.

Theorem 1 Let $G = (V, E)$ be a vertex-transitive graph. For an integer k and for two (not necessarily distinct) vertices u, v of G , let $P^k(u, v)$ denote the probability that a random walk of length k starting at u ends at v . Then, for every integer k and for every two vertices $u, v \in V$,

$$P^{2k}(u, u) \geq P^{2k}(u, v)$$

Proof. We need the following simple inequality, sometimes attributed to Chebyshev.

Claim 9.4.1 For every sequence $(a_1, \dots, a_n)$ of n reals and for any permutation π of $\{1, \dots, n\}$,

$$\sum_{i=1}^n a_i a_{\pi(i)} \leq \sum_{i=1}^n a_i^2$$

Proof. The inequality follows immediately from the fact that

$$\sum_{i=1}^n a_i^2 - \sum_{i=1}^n a_i a_{\pi(i)} = \frac{1}{2} \sum_{i=1}^n (a_i - a_{\pi(i)})^2 \geq 0.$$

Consider, now, a random walk of length $2k$ starting at u . By summing over all the possibilities of the vertex the walk reaches after k steps we conclude that for every vertex v ,

$$P^{2k}(u, v) = \sum_{w \in V} P^k(u, w) P^k(w, v) = \sum_{w \in V} P^k(u, w) P^k(v, w) \quad (1)$$

where the last equality follows from the fact that G is an undirected regular graph. Since G is vertex-transitive, the two vectors $(P^k(u, w))_{w \in V}$ and $(P^k(v, w))_{w \in V}$ can be obtained from each other by permuting the coordinates. Therefore, by the claim above, the maximum possible value of the sum in the right-hand side of (1) is when $u = v$, completing the proof of the theorem.

18.1 10 Random Graphs

It is six in the morning. The house is asleep. Nice music is playing. I prove and conjecture.

- Paul Erdős, in a letter to Vera Sós

Let n be a positive integer, $0 \leq p \leq 1$. The random graph $G(n, p)$ is a probability space over the set of graphs on the vertex set $\{1, \dots, n\}$ determined by

$$\Pr[\{i, j\} \in G] = p$$

with these events mutually independent. This model is often used in the probabilistic method for proving the existence of certain graphs. In this chapter we study the properties of $G(n, p)$ for their own sake.

Random graphs is an active area of research that combines probability theory and graph theory. The subject began in 1960 with the monumental paper On the Evolution of Random Graphs by Paul Erdős and Alfred Rényi. The book Random Graphs by Bollobás (2001) is the standard source for the field. Another book, also entitled Random Graphs by Janson, Łuczak and Ruciński (2000) is also excellent. In this chapter we explore only a few of the many topics in this fascinating area.

There is a compelling dynamic model for random graphs. For all pairs i, j let $x_{i,j}$ be selected uniformly from $[0, 1]$, the choices mutually independent. Imagine p going from 0 to 1. Originally, all potential edges are "off." The edge from i to j (which we may imagine as a neon light) is turned on when p reaches $x_{i,j}$ and then stays on. At $p = 1$ all edges are "on." At time p the graph of all "on" edges has distribution $G(n, p)$. As p increases $G(n, p)$ evolves from empty to full.

In their original paper, Erdős and Rényi let $G(n, e)$ be the random graph with n vertices and precisely e edges. Again there is a dynamic model: Begin with no edges and add edges randomly one by one until the graph becomes full. Generally $G(n, e)$ will have very similar properties as $G(n, p)$ with $p \sim e/\binom{n}{2}$. We will work on the probability model exclusively.

18.1.1 10.1 Subgraphs

The term "the random graph" is, strictly speaking, a misnomer. $G(n, p)$ is a probability space over graphs. Given any graph theoretic property A there will be a probability that $G(n, p)$ satisfies A , which we write $\Pr[G(n, p) \models A]$. When A is monotone $\Pr[G(n, p) \models A]$ is a monotone function of p . As an instructive example, let A be the event " G is triangle free." Let X be the number of triangles contained in $G(n, p)$. Linearity of expectation gives

$$\mathbb{E}[X] = \binom{n}{3} p^3$$

This suggests the parametrization $p = c/n$. Then

$$\lim_{n \rightarrow \infty} \mathbb{E}[X] = \lim_{n \rightarrow \infty} \binom{n}{3} p^3 = \frac{c^3}{6}$$

It turns out that the distribution of X is asymptotically Poisson. In particular,

$$\lim_{n \rightarrow \infty} \Pr[G(n, p) \models A] = \lim_{n \rightarrow \infty} \Pr[X = 0] = e^{-c^3/6}$$

Note that

$$\begin{aligned} \lim_{c \rightarrow 0} e^{-c^3/6} &= 1 \\ \lim_{c \rightarrow \infty} e^{-c^3/6} &= 0 \end{aligned}$$

When $p = 10^{-6}/n$, $G(n, p)$ is very unlikely to have triangles and when $p = 10^6/n$, $G(n, p)$ is very likely to have triangles. In the dynamic view the first triangles almost always appear at $p = \Theta(1/n)$. If we take a function such as $p(n) = n^{-0.9}$ with $p(n) \gg n^{-1}$ then $G(n, p)$ will almost always have triangles. Occasionally we will abuse notation and say, for example, that $G(n, n^{-0.9})$ contains a triangle - this meaning that the probability that it contains a triangle approaches 1 as n approaches infinity. Similarly, when $p(n) \ll n^{-1}$, for example, $p(n) = 1/(n \ln n)$, then $G(n, p)$ will almost always not contain a triangle and we abuse notation

and say that $G(n, 1/(n \ln n))$ is triangle-free. It was a central observation of Erdős and Rényi that many natural graph theoretic properties become true in a very narrow range of p . They made the following key definition.

Definition 4r(n) is called a threshold function for a graph theoretic property A if

1. When $p(n) \ll r(n)$, $\lim_{n \rightarrow \infty} \Pr[G(n, p) \models A] = 0$,
2. When $p(n) \gg r(n)$, $\lim_{n \rightarrow \infty} \Pr[G(n, p) \models A] = 1$, or vice versa.

In our example, $1/n$ is a threshold function for A . Note that the threshold function, when one exists, is not unique. We could equally have said that $10/n$ is a threshold function for A .

Let's approach the problem of $G(n, c/n)$ being triangle-free once more. For every set S of three vertices let B_S be the event that S is a triangle. Then $\Pr[B_S] = p^3$. Then "triangle-freeness" is precisely the conjunction $\bigwedge \overline{B_S}$ over all S . If the B_S were mutually independent then we would have

$$\Pr \left[\bigwedge \overline{B_S} \right] = \prod \Pr [\overline{B_S}] = (1 - p^3)^{\binom{n}{3}} \sim e^{-\binom{n}{3} p^3} \rightarrow e^{-c^3/6}.$$

The reality is that the B_S are not mutually independent though when $|S \cap T| \leq 1$, B_S and B_T are mutually independent.

We apply Janson's Inequality, Theorem 8.1.1. In the notation of Section 8.1, $I = \{S \subset V(G) : |S| = 3\}$ and $S \sim T$ if and only if $|S \cap T| = 2$. Here $\epsilon = p^3 = o(1)$, $\mu = \binom{n}{3} p^3 \sim c^3/6$ and $M = e^{-\mu(1+o(1))} = e^{-c^3/6+o(1)}$. There are $6\binom{n}{4} = O(n^4)$ pairs S, T of triples with $S \sim T$. For each $\Pr[B_S \wedge B_T] = p^5$. Thus

$$\Delta = O(n^4) p^5 = n^{-1+o(1)} = o(1).$$

When $\Delta = o(1)$ Janson's Inequality sandwiches an asymptotic bound:

$$\lim_{n \rightarrow \infty} \Pr \left[\bigwedge \overline{B_S} \right] = \lim_{n \rightarrow \infty} M = e^{-c^3/6}.$$

Can we duplicate this success with the property A that G contains no (not necessarily induced) copy of a general given graph H ? We use the definitions of balanced and strictly balanced of Section 4.4.

Theorem 10.1.1 Let H be a strictly balanced graph with v vertices, e edges and a automorphisms. Let $c > 0$ be arbitrary. Let A be the property that G contains no copy of H . Then with $p = cn^{-v/e}$,

$$\lim_{n \rightarrow \infty} \Pr[G(n, p) \models A] = \exp[-c^e/a].$$

Proof. Let $A_\alpha, 1 \leq \alpha \leq \binom{n}{v} v!/a$, range over the edge sets of possible copies of H and let B_α be the event $G(n, p) \supseteq A_\alpha$. We apply Janson's Inequality. As

$$\lim_{n \rightarrow \infty} \mu = \lim_{n \rightarrow \infty} \binom{n}{v} v! p^e / a = c^e / a,$$

we find

$$\lim_{n \rightarrow \infty} M = \exp[-c^e/a]$$

Now we examine (as in Theorem 4.4.2)

$$\Delta = \sum_{\alpha \sim \beta} \Pr[B_\alpha \wedge B_\beta]$$

We split the sum according to the number of vertices in the intersection of copies α and β . Suppose they intersect in j vertices. If $j = 0$ or $j = 1$ then $A_\alpha \cap A_\beta = \emptyset$ so that $\alpha \sim \beta$ cannot occur. For $2 \leq j \leq v$ let f_j be the maximal $|A_\alpha \cap A_\beta|$, where $\alpha \sim \beta$ and α, β intersect in j vertices. As $\alpha \neq \beta$, $f_v < e$. When $2 \leq j \leq v - 1$ the critical observation is that $A_\alpha \cap A_\beta$ is a subgraph of H and hence, as H is strictly balanced,

$$\frac{f_j}{j} < \frac{e}{v}$$

There are $O(n^{2v-j})$ choices of α, β intersecting in j points, since α, β are determined, except for order, by $2v - j$ points. For each such α, β ,

$$\Pr[B_\alpha \wedge B_\beta] = p^{|A_\alpha \cup A_\beta|} = p^{2e - |A_\alpha \cap A_\beta|} \leq p^{2e - f_j}.$$

Thus

$$\Delta = \sum_{j=2}^v O(n^{2v-j}) O(n^{-(v/e)(2e-f_j)})$$

But

$$2v - j - \frac{v}{e}(2e - f_j) = \frac{vf_j}{e} - j < 0$$

so each term is $o(1)$ and hence $\Delta = o(1)$. By Janson's Inequality,

$$\lim_{n \rightarrow \infty} \Pr \left[\bigwedge \overline{B_\alpha} \right] = \lim_{n \rightarrow \infty} M = \exp[-c^e/a]$$

completing the proof.

18.1.2 10.2 Clique Number

In this section we fix $p = 1/2$ (other values yield similar results) and consider the clique number $\omega(G(n, p))$. For a fixed $c > 0$ let $n, k \rightarrow \infty$ so that

$$\binom{n}{k} 2^{-\binom{k}{2}} \rightarrow c$$

As a first approximation,

$$n \sim \frac{k}{e\sqrt{2}} \sqrt{2}^k$$

and

$$k \sim \frac{2 \ln n}{\ln 2}.$$

Here $\mu \rightarrow c$ so $M \rightarrow e^{-c}$. The Δ term was examined in Section 4.5. For this k , $\Delta = o(E[X]^2)$ and so $\Delta = o(1)$. Therefore

$$\lim_{n, k \rightarrow \infty} \Pr[\omega(G(n, p)) < k] = \exp[-c].$$

Being more careful, let $n_0(k)$ be the minimum n for which

$$\binom{n}{k} 2^{-\binom{k}{2}} \geq 1.$$

Observe that for this n the left-hand side is $1 + o(1)$. Note that $\binom{n}{k}$ grows, in n , like n^k . For any $\lambda \in (-\infty, +\infty)$ if

$$n = n_0(k) \left[1 + \frac{\lambda + o(1)}{k} \right]$$

then

$$\binom{n}{k} 2^{-\binom{k}{2}} = \left[1 + \frac{\lambda + o(1)}{k} \right]^k = e^\lambda + o(1),$$

and so

$$\Pr[\omega(G(n, p)) < k] = e^{-e^\lambda} + o(1).$$

As λ ranges from $-\infty$ to $+\infty$, e^{-e^λ} ranges from 1 to 0. As $n_0(k+1) \sim \sqrt{2}n_0(k)$ the ranges will not "overlap" for different k . More precisely, let K be arbitrarily large and set

$$I_k = \left[n_0(k) \left[1 - \frac{K}{k} \right], n_0(k) \left[1 + \frac{K}{k} \right] \right].$$

For $k \geq k_0(K)$, $I_{k-1} \cap I_k = \emptyset$. Suppose $n \geq n_0(k_0(K))$. If n lies between the intervals (which occurs for "most" n), which we denote by $I_k < n < I_{k+1}$, then

$$\Pr[\omega(G(n, p)) < k] \leq e^{-e^K} + o(1),$$

nearly zero, and

$$\Pr[\omega(G(n, p)) < k+1] \geq e^{-e^{-K}} + o(1),$$

nearly one, so that

$$\Pr[\omega(G(n, p)) = k] \geq e^{-e^{-K}} - e^{-e^K} + o(1),$$

nearly one. When $n \in I_k$ we still have $I_{k-1} < n < I_{k+1}$ so that

$$\Pr[\omega(G(n, p)) = k \text{ or } k-1] \geq e^{-e^{-k}} - e^{-e^K} + o(1),$$

nearly one. As K may be made arbitrarily large this yields the celebrated twopoint concentration theorem on clique number, Corollary 4.5.2 in Section 4.5. Note, however, that for most n the concentration of $\omega(G(n, \frac{1}{2}))$ is actually on a single value!

18.1.3 10.3 Chromatic Number

In this section we fix $p = 1/2$ (there are similar results for other p) and let G be the random graph $G(n, \frac{1}{2})$. We shall find bounds on the chromatic number $\chi(G)$. A different derivation of the main result of this section is presented in Section 7.3. Set

$$f(k) = \binom{n}{k} 2^{-\binom{k}{2}}$$

Let $k_0 = k_0(n)$ be that value for which

$$f(k_0 - 1) > 1 > f(k_0)$$

Then $n = \sqrt{2}^{k(1+o(1))}$ so for $k \sim k_0$,

$$f(k+1)/f(k) = \frac{n}{k} 2^{-k} (1 + o(1)) = n^{-1+o(1)}$$

Set

$$k = k(n) = k_0(n) - 4$$

so that

$$f(k) > n^{3+o(1)}$$

Now we estimate $\Pr[\omega(G) < k]$ by the Extended Janson Inequality (Theorem 8.1.2). Here $\mu = f(k)$. (Note that Janson's Inequality gives a lower bound of $2^{-f(k)} = 2^{-n^{3+o(1)}}$ to this probability but this is way off the mark since with probability $2^{-\binom{n}{2}}$ the random G is empty!) The value Δ was examined in Section 4.5 where

$$\frac{\Delta}{\mu^2} = \frac{\Delta^*}{\mu} = \sum_{i=2}^{k-1} g(i)$$

There $g(2) \sim k^4/n^2$ and $g(k-1) \sim 2kn2^{-k}/\mu$ were the dominating terms. In our instance $\mu > n^{3+o(1)}$ and $2^{-k} = n^{-2+o(1)}$ so $g(2)$ dominates and

$$\Delta \sim \frac{\mu^2 k^4}{n^2}$$

Hence we bound the clique number probability

$$\Pr[\omega(G) < k] < e^{-\mu^2/2\Delta} = e^{-\Theta(n^2/(\ln n)^4)},$$

as $k = \Theta(\ln n)$. [The possibility that G is empty gives a lower bound so that we may say the probability is $e^{-n^{2+o(1)}}$, though a $o(1)$ in the hyperexponent leaves lots of room.]

Theorem 10.3.1 [Bollobás (1988)] Almost always

$$\chi(G) \sim \frac{n}{2 \log_2 n}$$

Proof. Let $\alpha(G) = \omega(\bar{G})$ denote, as usual, the independence number of G . The complement of G has the same distribution $G(n, \frac{1}{2})$. Hence $\alpha(G) \leq (2 + o(1)) \log_2 n$ almost always. Thus

$$\chi(G) \geq \frac{n}{\alpha(G)} \geq \frac{n}{2 \log_2 n} (1 + o(1))$$

almost always.

The reverse inequality was an open question for a full quarter century! Set $m = \lfloor n/\ln^2 n \rfloor$. For any set S of m vertices the restriction $G|_S$ has the distribution of $G(m, \frac{1}{2})$. Let $k = k(m) = k_0(m) - 4$ as above. Note

$$k \sim 2 \log_2 m \sim 2 \log_2 n$$

Then

$$\Pr[\alpha[G|_S] < k] < e^{-m^{2+o(1)}}$$

There are $\binom{n}{m} < 2^n = 2^{m^{1+o(1)}}$ such sets S . Hence

$$\Pr[\alpha[G] < k \text{ for some } m\text{-set } S] < 2^{m^{1+o(1)}} e^{-m^{2+o(1)}} = o(1)$$

That is, almost always every m vertices contain a k -element independent set. Now suppose G has this property. We pull out k -element independent sets and give each a distinct color until there are less than m vertices left. Then we give each point a distinct color. By this procedure

$$\begin{aligned}\chi(G) &\leq \left\lceil \frac{n-m}{k} \right\rceil + m \leq \frac{n}{k} + m \\ &= \frac{n}{2 \log_2 n} (1 + o(1)) + o\left(\frac{n}{\log_2 n}\right) \\ &= \frac{n}{2 \log_2 n} (1 + o(1))\end{aligned}$$

and this occurs for almost all G .

18.1.4 10.4 Zero-one Laws

In this section we restrict our attention to graph theoretic properties expressible in the first-order theory of graphs. The language of this theory consists of variables $(x, y, z, \dots)$, which always represent vertices of a graph, equality and adjacency $(x = y, x \sim y)$, the usual Boolean connectives $(\wedge, \neg, \dots)$ and universal and existential quantification $(\forall_x, \exists_y)$. Sentences must be finite. As examples, one can express the property of containing a triangle

$$\exists_x \exists_y \exists_z [x \sim y \wedge x \sim z \wedge y \sim z]$$

having no isolated point

$$\forall_x \exists_y [x \sim y]$$

and having radius at most two

$$\exists_x \forall_y [\neg(y = x) \wedge \neg(y \sim x) \longrightarrow \exists_z [z \sim y \wedge y \sim x]].$$

For any property A and any n, p we consider the probability that the random graph $G(n, p)$ satisfies A , denoted

$$\Pr[G(n, p) \models A].$$

Our objects in this section will be the theorem of Glebskii, Kogan, Liagonkii and Talanov (1969) and independently Fagin (1976) (Theorem 10.4.1), and that of Shelah and Spencer (1988) (Theorem 10.4.2).

Theorem 10.4.1 For any fixed $p, 0 < p < 1$ and any first-order A ,

$$\lim_{n \rightarrow \infty} \Pr[G(n, p) \models A] = 0 \text{ or } 1$$

Theorem 10.4.2 For any irrational $\alpha, 0 < \alpha < 1$, setting $p = p(n) = n^{-\alpha}$ and for any first-order A ,

$$\lim_{n \rightarrow \infty} \Pr[G(n, p) \models A] = 0 \text{ or } 1.$$

Both proofs are only outlined.

We shall say that a function $p = p(n)$ satisfies the Zero-One Law if the above equality holds for every first-order A .

The Glebskii-Fagin Theorem has a natural interpretation when $p = 0.5$ as then $G(n, p)$ gives equal weight to every (labeled) graph. It then says that any first-order property A holds

for either almost all graphs or for almost no graphs. The ShelahSpencer Theorem may be interpreted in terms of threshold functions. The general results of Section 10.1 give, as one example, that $p = n^{-2/3}$ is a threshold function for containment of a K_4 . That is, when $p \ll n^{-2/3}$, $G(n, p)$ almost surely does not contain a K_4 whereas when $p \gg n^{-2/3}$ it almost surely does contain a K_4 . In between, say, at $p = n^{-2/3}$, the probability is between 0 and 1, in this case $1 - e^{-1/24}$. The (admittedly rough) notion is that at a threshold function the Zero-One Law will not hold and so to say that $p(n)$ satisfies the Zero-One Law is to say that $p(n)$ is not a threshold function - that it is a boring place in the evolution of the random graph, at least through the spectacles of the first-order language. In stark terms: What happens in the evolution of $G(n, p)$ at $p = n^{-\pi/7}$? The answer: Nothing!

Our approach to Zero-One Laws will be through a variant of the Ehrenfeucht Game, which we now define. Let G, H be two vertex disjoint graphs and t a positive integer. We define a perfect information game, denoted $\text{EHR}[G, H, t]$, with two players, denoted Spoiler and Duplicator. The game has t rounds. Each round has two parts. First the Spoiler selects either a vertex $x \in V(G)$ or a vertex $y \in V(H)$. He chooses which graph to select the vertex from. Then the Duplicator must select a vertex in the other graph. At the end of the t rounds t vertices have been selected from

each graph. Let $x_1, \dots, x_t$ be the vertices selected from $V(G)$ and $y_1, \dots, y_t$ be the vertices selected from $V(H)$, where x_i, y_i are the vertices selected in the i th round. Then Duplicator wins if and only if the induced graphs on the selected vertices are order-isomorphic; that is, if for all $1 \leq i \leq j \leq t$,

$$\{x_i, x_j\} \in E(G) \iff \{y_i, y_j\} \in E(H).$$

As there are no hidden moves and no draws one of the players must have a winning strategy and we will say that that player wins $\text{EHR}[G, H, t]$.

Lemma 10.4.3 For every first-order A there is a $t = t(A)$ so that if G, H are any graphs with $G \models A$ and $H \models \neg A$ then Spoiler wins $\text{EHR}[G, H, t]$.

A detailed proof would require a formal analysis of the first-order language so we give only an example. Let A be the property $\forall x \exists y [x \sim y]$ of not containing an isolated point and set $t = 2$. Spoiler begins by selecting an isolated point $y_1 \in V(H)$, which he can do as $H \models \neg A$. Duplicator must pick $x_1 \in V(G)$. As $G \models A$, x_1 is not isolated so Spoiler may pick $x_2 \in V(G)$ with $x_1 \sim x_2$ and now Duplicator cannot pick a "duplicating" y_2 .

Theorem 10.4.4 A function $p = p(n)$ satisfies the Zero-One Law if and only if for every t , letting $G(n, p(n)), H(m, p(m))$ be independently chosen random graphs on disjoint vertex sets,

$$\lim_{m, n \rightarrow \infty} \Pr[\text{Duplicator wins } \text{EHR}[G(n, p(n)), H(m, p(m)), t]] = 1$$

Remark. For any given choice of G, H somebody must win $\text{EHR}[G, H, t]$. (That is, there is no random play, the play is perfect.) Given this probability distribution over (G, H) there will be a probability that $\text{EHR}[G, H, t]$ will be a win for Duplicator, and this must approach 1.

Proof. We prove only the "if" part. Suppose $p = p(n)$ did not satisfy the Zero-One Law. Let A satisfy

$$\lim_{n \rightarrow \infty} \Pr[G(n, p(n)) \models A] = c,$$

with $0 < c < 1$. Let $t = t(A)$ be as given by the lemma. With limiting probability $2c(1 - c) > 0$ exactly 1 of $G(n, p(n)), H(n, p(n))$ would satisfy A and thus Spoiler would win, contradicting the assumption. This is not a full proof since when the Zero-One Law is not satisfied $\lim_{n \rightarrow \infty} \Pr[G(n, p(n)) \models A]$ might not exist. If there is a subsequence n_i on which the limit is $c \in (0, 1)$ we may use the same argument. Otherwise there will be two subsequences

n_i, m_i on which the limit is zero and one, respectively. Then letting $n, m \rightarrow \infty$ through n_i, m_i respectively, Spoiler will win $\text{EHR}[G, H, t]$ with probability approaching 1.

Theorem 10.4.4 provides a bridge from logic to random graphs. To prove that $p = p(n)$ satisfies the Zero-One Law we now no longer need to know anything about logic - we just have to find a good strategy for the Duplicator.

We say that a graph G has the full level s extension property if for every distinct $u_1, \dots, u_a, v_1, \dots, v_b \in G$ with $a + b \leq s$ there is an $x \in V(G)$ with $\{x, u_i\} \in E(G), 1 \leq i \leq a$ and $\{x, v_j\} \notin E(G), 1 \leq j \leq b$. Suppose that G, H both have the full level $s - 1$ extension property. Then Duplicator wins $\text{EHR}[G, H, s]$ by the following simple strategy. On the i th round, with $x_1, \dots, x_{i-1}, y_1, \dots, y_{i-1}$ already selected, and Spoiler picking, say, x_i , Duplicator simply picks y_i having the same adjacencies to the $y_j, j < i$ as x_i has to the $x_j, j < i$. The full extension property says that such a y_i will surely exist.

Theorem 10.4.5 For any fixed $p, 0 < p < 1$, and any $s, G(n, p)$ almost always has the full level s extension property.

Proof. For every distinct $u_1, \dots, u_a, v_1, \dots, v_b, x \in G$ with $a + b \leq s$ we define $E_{u_1, \dots, u_a, v_1, \dots, v_b, x}$ to be the event that $\{x, u_i\} \in E(G), 1 \leq i \leq a$ and $\{x, v_j\} \notin E(G), 1 \leq j \leq b$. Then

$$\Pr[E_{u_1, \dots, u_a, v_1, \dots, v_b, x}] = p^a(1 - p)^b.$$

Now define

$$E_{u_1, \dots, u_a, v_1, \dots, v_b} = \bigwedge_x \overline{E_{u_1, \dots, u_a, v_1, \dots, v_b, x}}$$

the conjunction over $x \neq u_1, \dots, u_a, v_1, \dots, v_b$. These events are mutually independent over x since they involve different edges. Thus

$$\Pr \left[\bigwedge_x \overline{E_{u_1, \dots, u_a, v_1, \dots, v_b, x}} \right] = [1 - p^a(1 - p)^b]^{n-a-b}.$$

Set $\epsilon = \min\{p, 1 - p\}^s$ so that

$$\Pr \left[\bigwedge_x \overline{E_{u_1, \dots, u_a, v_1, \dots, v_b, x}} \right] \leq (1 - \epsilon)^{n-s}.$$

The key here is that ϵ is a fixed (dependent on p, s) positive number. Set

$$E = \bigvee E_{u_1, \dots, u_a, v_1, \dots, v_b}$$

the disjunction over all distinct $u_1, \dots, u_a, v_1, \dots, v_b \in G$ with $a + b \leq s$. There are less than $s^2 n^s = O(n^s)$ such choices as we can choose a, b and then the vertices. Thus

$$\Pr[E] \leq s^2 n^s (1 - \epsilon)^{n-s}$$

But

$$\lim_{n \rightarrow \infty} s^2 n^s (1 - \epsilon)^{n-s} = 0$$

and so E holds almost never. Thus $\neg E$, which is precisely the statement that $G(n, p)$ has the full level s extension property, holds almost always.

But now we have proved Theorem 10.4.1. For any $p \in (0, 1)$ and any fixed s as $m, n \rightarrow \infty$ with probability approaching one both $G(n, p)$ and $H(m, p)$ will have the full level s extension property and so Duplicator will win $\text{EHR}[G(n, p), H(m, p), s]$.

Why can't Duplicator use this strategy when $p = n^{-\alpha}$? We illustrate the difficulty with a simple example. Let $0.5 < \alpha < 1$ and let Spoiler and Duplicator play a three move game on G, H . Spoiler thinks of a point $z \in G$ but doesn't tell Duplicator about it. Instead he picks $x_1, x_2 \in G$, both adjacent to z . Duplicator simply picks $y_1, y_2 \in H$, either adjacent or not adjacent dependent on whether $x_1 \sim x_2$. But now wily Spoiler picks $x_3 = z.H \sim H(m, m^{-\alpha})$ does not have the full level 2 extension property. In particular, most pairs y_1, y_2 do not have a common neighbor. Unless Duplicator was lucky, or shrewd, he then cannot find $y_3 \sim y_1, y_2$ and so he loses. This example does not say that Duplicator will lose with perfect play - indeed, we will show that he almost always wins with perfect play - it only indicates that the strategy used need be more complex.

We begin our proof of the Zero-One Law, Theorem 10.4.2. Let $\alpha \in (0, 1)$, α irrational, be fixed. A rooted graph is a pair (R, H) where H is a graph on vertex set, say, $V(H) = \{X_1, \dots, X_r, Y_1, \dots, Y_v\}$ and $R = \{X_1, \dots, X_r\}$ is a specified subset of $V(H)$, called the roots. For example, (R, H) might consist of one vertex Y_1 adjacent to the two roots X_1, X_2 . Let $v = v(R, H)$ denote the number of vertices that are not roots and let $e = e(R, H)$ denote the number of edges, excluding those edges between two roots. We say (R, H) is dense if $v - e\alpha < 0$ and sparse if $v - e\alpha > 0$. The irrationality of α assures us that all (R, H) are in one of these categories. We call (R, H) rigid if for all S with $R \subseteq S \subset V(H)$, (S, H) is dense. We call (R, H) safe if for all S with $R \subset S \subseteq V(H)$, $(R, H|_S)$ is sparse. Several elementary properties of these concepts are given as Exercise 4. We sometimes write (R, S) for $(R, H|_S)$ when the graph H is understood.

We think of rooted graphs as on abstract points. In a graph G we say that vertices $y_1, \dots, y_v$ form an (R, H) extension of $x_1, \dots, x_r$ if whenever X_i is adjacent to Y_j in H , x_i is adjacent to y_j in G and also whenever Y_i and Y_j are adjacent in H , y_i and y_j are adjacent in G . Note that we allow G to have more edges than H and that the edges between the roots "don't count."

Lemma 10.4.6 [Generic Extension] Let (R, H) , as given above, be safe. Let $t \geq 0$ be an arbitrary, but fixed, integer. Then in $G \sim G(n, n^{-\alpha})$ almost surely for all $x_1, \dots, x_r$ there exist $y_1, \dots, y_v$ such that

- (i) $y_1, \dots, y_v$ form an (R, H) extension of $x_1, \dots, x_r$.
- (ii) x_i, y_j are adjacent in G if and only if X_i, Y_j are adjacent in H and y_i, y_j are adjacent in G if and only if Y_i, Y_j are adjacent in H .
- (iii) (For $t > 0$) If $z_1, \dots, z_u$ with $u \leq t$ form a rigid (R', H') extension over $x_1, \dots, x_r, y_1, \dots, y_v$ then there are no adjacencies between any pair z_k, y_j .

Example. Let $\alpha \in (\frac{1}{2}, 1)$, $t = 2$, and let (R, H) have root X_1 , nonroot Y_1 and edge $\{X_1, Y_1\}$. Note that (R', H') consisting of two roots X_1, X_2 with a common neighbor Y_1 has $v = 1, e = 2$ and is rigid. Generic Extension in this instance says that every x_1 has a neighbor y_1 such that x_1, y_1 do not have a common neighbor z_1 .

Proof. From Exercise 5 almost surely every $x_1, \dots, x_r$ has $\Theta(n^v p^e)(R, H)$ extensions $y_1, \dots, y_v$. Our rough notion will be that the number of these $y_1, \dots, y_v$ that fail to be generic, in any of the bounded number of ways that could occur, would be bounded by a smaller power of n .

Call y special if $y \in \text{cl}_{t+v}(x_1, \dots, x_r)$ (as defined below), otherwise nonspecial. Let K , from the Finite Closure Lemma 10.4.7 below, be an almost sure bound on the number of special y , uniform over all choices of the x 's. Extend (R, H) to (R^+, H^+) by adding K new roots and no new edges. This is still safe and of the same type as (R, H) so again by Exercise 5 almost surely every $x_1, \dots, x_r, z_1, \dots, z_K$ has $\Theta(n^v p^e)(R^+, H^+)$ extensions $y_1, \dots, y_v$. Letting the z 's include all the special vertices we have that almost surely every $x_1, \dots, x_r$ has $\Theta(n^v p^e)(R, H)$ extensions $y_1, \dots, y_v$ with all y_i nonspecial. Now we bound from above the number of those nonspecial (R, H) extensions that fail condition (ii) or (iii).

Consider those extensions (R, H') with an additional edge y_i, y_j or x_i, y_j . This cannot contain a rigid subextension as that would make some y_i special. Hence by Exercise 4 it must

be a safe extension. Applying Exercise 5 there are $\Theta(n^v p^{e+1}) = o(n^v p^e)$ such extensions.

Consider extensions by $y_1, \dots, y_v$ and $z_1, \dots, z_u$ as in condition (iii) with some z_j, y_k adjacent. We can further assume the z 's form a minimal rigid extension over the x 's and y 's. Let the z 's have type (v_1, e_1) as an extension over the x 's and y 's so that $v_1 - e_1 \alpha$ is negative. If the y 's and z 's together formed a safe extension over the x 's there would be $\Theta(n^{v+v_1} p^{e+e_1}) = o(n^v p^e)$ such extensions and hence at most that many choices for the y 's. Otherwise, by Exercise 4, there would be a rigid subextension. It could not overlap the nonspecial y 's. From the minimality it must be precisely all of the z 's. Given the x 's from the Finite Closure Lemma 10.4.7 there are $O(1)$ choices for the z 's. Then the y 's form a (v, e') extension over the x 's and y 's with $e' > e$. This extension has no rigid subextensions (again as the y 's are nonspecial) and hence is safe. Again applying Exercise 5 there are $\Theta(n^v p^{e'})$ such y 's for each choice of the z 's and so $O(n^v p^{e'}) = o(n^v p^e)$ total choices of such y 's.

In all cases the number of y 's that fail conditions (ii) or (iii) is $o(n^v p^e)$. Hence there exist y 's, indeed most choices of nonspecial y 's, that are (R, H) extensions and satisfy conditions (ii) and (iii).

A rigid t -chain in G is a sequence $X = X_0 \subset X_1 \subset \dots \subset X_K$ with all (X_{i-1}, X_i) rigid and all $|X_{i+1} - X_i| \leq t$. The t -closure of X , denoted by $\text{cl}_t(X)$, is the maximal Y for which there exists a rigid t -chain (of arbitrary length) $X = X_0 \subset X_1 \subset \dots \subset X_K = Y$. When there are no such rigid t -chains we define $\text{cl}_t(X) = X$. To see this is well defined we note (using Exercise 4) that if $X = X_0 \subset X_1 \subset \dots \subset X_K = Z$ and $X = X_0 \subset Y_1 \subset \dots \subset Y_L = Y$ are rigid t -chains then so is $X = X_0 \subset X_1 \subset \dots \subset X_K \subset Z \cup Y_1 \subset \dots \subset Z \cup Y_L = Z \cup Y$. Alternatively, the t -closure $\text{cl}_t(X)$ is the minimal set containing X that has no rigid extensions of $\leq t$ vertices. We say $x_1, \dots, x_r \in G, y_1, \dots, y_r \in H$ have the same t -type if their t -closures are isomorphic as graphs, the isomorphism sending each x_i to the corresponding y_i .

The t -closure is a critical definition, describing the possible special properties of the roots. Suppose, for example, $\alpha \in (\frac{1}{2}, 1)$ and consider $\text{cl}_1(x_1, x_2)$. The only rigid extension with $t = 1$ in this range is a nonroot adjacent to two (or more) roots. A sample 1-type would be: x_1, x_2 have common neighbors y_1, y_2 and then x_1, y_1 have common neighbor y_3 and there are no further edges among these vertices and no pairs have common neighbors other than those described. A randomly chosen x_1, x_2 would have type: x_1, x_2 have no common neighbors and are not adjacent.

We can already describe the nature of Duplicator's strategy. At the end of the r th move, with $x_1, \dots, x_r$ and $y_1, \dots, y_r$ having been selected from the two graphs, Duplicator will assure that these sets have the same a_r -type. We shall call this the $(a_1, \dots, a_t)$ lookahead strategy. Here a_r must depend only on t , the total number of moves in the game and α . We shall set $a_t = 0$ so that at the end of the game, if Duplicator can stick to the $(a_1, \dots, a_t)$ lookahead strategy then he has won. If, however, Spoiler picks, say, x_{r+1} so that there is no corresponding y_{r+1} with $x_1, \dots, x_{r+1}$ and $y_1, \dots, y_{r+1}$ having the same a_{r+1} -type, then the strategy fails and we say that Spoiler wins. The values a_r give the "lookahead" that Duplicator uses but before defining them we need some preliminary results.

Lemma 10.4.7 [Finite Closure] Let $\alpha, r > 0$ be fixed. Set ε equal to the minimal value of $(e\alpha - v)/v$ over all integers v, e with $1 \leq v \leq t$ and $e\alpha - v > 0$. Let K be such that $r - K\varepsilon < 0$. Then in $G(n, n^{-\alpha})$ almost surely,

$$|\text{cl}_t(X)| \leq K + r$$

for all $X \subset G$ with $|X| = r$.

Proof. If not there would be a rigid t -chain $X = X_0 \subset X_1 \subset \dots \subset X_L = Y$ with $K + r < |Y| < K + r + t$. Letting (X_{i-1}, X_i) have type (v_i, e_i) the restriction of G to Y would have $r + \sum v_i$ vertices and at least $\sum e_i$ edges. But

$$\left(r + \sum v_i\right) - \alpha \left(\sum e_i\right) = r + \sum (v_i - \alpha e_i) \leq r - \varepsilon \sum v_i < r - K\varepsilon < 0$$

and G almost surely has no such subgraph.

Remark. The bound on $|\text{cl}_t(X)|$ given by this proof depends strongly on how close α may be approximated by rationals of denominator at most t . This is often the case. If, for example,

$$\frac{1}{2} + \frac{1}{s-1} > \alpha > \frac{1}{2} + \frac{1}{s}$$

then almost surely there will be two points $x_1, x_2 \in G(n, n^{-\alpha})$ having s common neighbors so that $|\text{cl}_1(x_1, x_2)| \geq s + 2$.

Now we define the $a_1, \dots, a_t$ of the lookahead strategy by reverse induction. We set $a_t = 0$. If at the end of the game Duplicator can assure that the 0-types of $x_1, \dots, x_t$ and $y_1, \dots, y_t$ are the same then they have the same induced subgraphs and he has won. Suppose, inductively, that $b = a_{r+1}$ has been defined. We define $a = a_r$ to be any integer satisfying

1. $a \geq b$.
2. Almost surely $|\text{cl}_b(W)| - r \leq a$ for all sets W of size $r + 1$.

Now we need to show that almost surely this strategy works. Let $G_1 \sim G(n, n^{-\alpha})$, $G_2 \sim G(m, m^{-\alpha})$ and Duplicator tries to play the $(a_1, \dots, a_t)$ lookahead strategy on $\text{EHR}(G_1, G_2, t)$.

Consider the $(r + 1)$ st move. We have $b = a_{r+1}, a = a_r$ as above. Points $x_1, \dots, x_r \in G_1, y_1, \dots, y_r \in G_2$ have already been selected. Set, for notational convenience, $X = \{x_1, \dots, x_r\}$ and $Y = \{y_1, \dots, y_r\}$. We assume Duplicator has survived thus far so that $\text{cl}_a(X) \cong \text{cl}_a(Y)$, the isomorphism sending each x_i to the corresponding y_i . Spoiler picks, say, $x = x_{r+1} \in G_1$. Set $X^+ = X \cup \{x\}$ and $Y^+ = Y \cup \{y\}$, where y is Duplicator's as yet undetermined countermove. We distinguish two cases.

We say Spoiler has moved inside if $x \in \text{cl}_a(X)$. Then as $b \leq a$, $\text{cl}_b(X^+) \subseteq \text{cl}_a(X)$. Duplicator looks at the isomorphism $\Psi : \text{cl}_a(X) \rightarrow \text{cl}_a(Y)$ and selects $y = \Psi(x)$.

We say Spoiler has moved outside if $x \notin \text{cl}_a(X)$. Let NEW be those vertices of $\text{cl}_b(X^+)$ that do not lie in $\text{cl}_a(X)$. $NEW \neq \emptyset$ as $x \in NEW$. $|NEW| \leq a$ as $NEW \subseteq \text{cl}_b(X^+) - X$. Consider NEW as an (R, H) extension of $\text{cl}_a(X)$. This extension must be safe as otherwise it would have a rigid subextension NEW^- but that subextension would then be in $\text{cl}_a(X)$. Duplicator now goes to G_2 and, applying the Generic Extension Lemma 10.4.6 with $t = b$, finds an (R, H) extension of $\text{cl}_a(Y)$. That is, he finds an edge preserving injection $\Psi : \text{cl}_a(X) \cup NEW \rightarrow H$ extending the isomorphism between $\text{cl}_a(X)$ and $\text{cl}_a(Y)$. Duplicator selects $y = \Psi(x)$.

Why does this work? Set $NEW' = \Psi(NEW)$ and $CORE = \Psi(\text{cl}_b(X^+))$. We can reach $\text{cl}_b(X^+)$ by a rigid b -chain from X^+ and the isomorphism gives the same chain from Y^+ to $CORE$ so that $\text{cl}_b(Y^+)$ contains $CORE$. But can it have additional vertices? We use the genericity to say no. Suppose there was a rigid extension $MORE$ over $CORE$ with at most b nonroots. We can't have $MORE$ entirely inside $\Psi[\text{cl}_a(X) \cup NEW]$ as then $\Psi^{-1}[MORE]$ would be in $\text{cl}_b(X^+)$ as well. Let $MORE^+$ be the vertices of $MORE$ lying outside $\Psi[\text{cl}_a(X) \cup NEW]$. $MORE^+$ is then a rigid extension of $\Psi[\text{cl}_a(X) \cup NEW]$. By the genericity $MORE^+$ would have no adjacencies to NEW' and so would be a rigid extension of $\Psi[\text{cl}_a(X)] = \text{cl}_a(Y)$. As $a \geq b$ the a -closure of a set cannot have rigid extensions with $\leq b$ vertices. Hence there is no $MORE$.

The first move follows the same pattern but is somewhat simpler. Set $b = a_1$ and let a satisfy $a \geq b$ and $a \geq |\text{cl}_b(x)|$ for any x . Spoiler plays $x \in G_1$. (Effectively, there is no inside move as $X = \emptyset$ is the set of previous moves and $\text{cl}_a(\emptyset) = \emptyset$.) Duplicator calculates the graph

$H = \text{cl}_b(x)$ that has, say, v vertices (including x) and e edges. Since H is a subgraph of G_1 the threshold function for the appearance of H must come before $n^{-\alpha}$. In particular, for every subgraph H' of H with v' vertices

and e' edges we cannot have $v' - \alpha e' < 0$ and therefore must have $v' - \alpha e' > 0$. The conditions of Theorem 4.4.5 then apply and G_2 almost surely has $\Theta(m^{e-v\alpha})$ copies of H . Consider any graph H^+ consisting of H together with a rigid extension of H with at most b vertices. Such H^+ would have $v + v^+$ vertices and $e + e^+$ edges with $v^+ - \alpha e^+ < 0$. The expected number of copies of H^+ is then $\Theta\left(m^{e-v\alpha+(v^+-\alpha e^+)}\right)$, which is $o(m^{e-v\alpha})$. Hence there will be in G_2 a copy of H that is not part of any such H^+ . (Effectively, this is generic extension over the empty set.) Duplicator finds the edge preserving injection $\Psi : \text{cl}_b(x) \rightarrow G_2$ giving such a copy of H and selects $y = \Psi(x)$.

We have shown that the $(a_1, \dots, a_t)$ lookahead strategy almost surely results in a win for Duplicator. By Theorem 10.4.4 this implies the Zero-One Law, Theorem 10.4.2.

18.1.5 10.5 Exercises

1. Show that there is a graph on n vertices with minimum degree at least $n/2$ in which the size of every dominating set is at least $\Omega(\log n)$.
2. Find a threshold function for the property: $G(n, p)$ contains a copy of the graph consisting of a complete graph on four vertices plus an extra vertex joined to one of its vertices.
3. Let X be the number of cycles in the random graph $G(n, p)$ with $p = c/n$. Give an exact formula for $E[X]$. Find the asymptotics of $E[X]$ when $c < 1$. Find the asymptotics of $E[X]$ when $c = 1$.
4. Here we write (R, S) for $(R, H|_S)$, where H is some fixed graph.
 - Let $R \subset S \subset T$. Show that if $(R, S), (S, T)$ are both dense then so is (R, T) . Show that if $(R, S), (S, T)$ are both sparse then so is (R, T) .
 - Let $R \subset S$. Show that if (R, S) is rigid then $(X \cup R, X \cup S)$ is rigid for any X .
 - $R \subset U$ with (R, U) not sparse. Show there is a T with $R \subset T \subset U$ with (R, T) dense. Show further there is an S with $R \subset S \subset T$ with (R, S) rigid.
 - Show that any (R, T) is either rigid or sparse itself or there exists S with $R \subset S \subset T$ such that (R, S) is rigid and (S, T) is sparse.
5. We call (R, H) hinged if it is safe but there is no S with $R \subset S \subset V(H)$ such that (S, H) is safe. For $x_1, \dots, x_r \in G$ let $N(x_1, \dots, x_r)$ denote the number of (R, H) extensions. Set $\mu = E[N] \sim n^v p^e$.
 - Let (R, H) be hinged and fix $x_1, \dots, x_r \in G$. Following the model of Section 8.5, especially Theorem 8.5.4, show that

$$\Pr[|N(x_1, \dots, x_r) - \mu| > \epsilon\mu] = o(n^{-r}).$$

- Deduce that almost surely all $N(x_1, \dots, x_r) \sim \mu$.
- Show that $N(x_1, \dots, x_r) \sim \mu$ holds for any safe (R, H) , by decomposing (R, H) into hinged extensions.

The Probabilistic Lens: Counting Subgraphs

A graph $G = (V, E)$ on n vertices has 2^n induced subgraphs but some will surely be isomorphic. How many different subgraphs can G have? Here we show that there are graphs G with $2^n(1 - o(1))$ different subgraphs. The argument we give is fairly coarse. It is typical of those situations where a probabilistic approach gives fairly quick answers to questions otherwise difficult to approach.

Let G be a random graph on n vertices with edge probability $1/2$. Let $S \subseteq V$, $|S| = t$ be fixed. For any one to one $\rho : S \rightarrow V$, $\rho \neq id$, let A_ρ be the event that ρ gives a graph isomorphism - that is, for $x, y \in S$, $\{x, y\} \in E \Leftrightarrow \{\rho x, \rho y\} \in E$. Set $M_\rho = \{x \in S : \rho x \neq x\}$. We split the set of ρ by $g = g(\rho) = |M_\rho|$.

Consider the $g(t - g) + \binom{g}{2}$ pairs x, y with $x, y \in S$ and at least one of x, y in M . For all but at most $g/2$ of these pairs $\{x, y\} \neq \{\rho x, \rho y\}$. (The exceptions are when $\rho x = y, \rho y = x$.) Let E_ρ be the set of pairs $\{x, y\}$ with $\{x, y\} \neq \{\rho x, \rho y\}$. Define a graph H_ρ with vertices E_ρ and vertex $\{x, y\}$ adjacent to $\{\rho x, \rho y\}$. In H_ρ each vertex has degree at most two ($\{x, y\}$ may also be adjacent to $\{\rho^{-1}x, \rho^{-1}y\}$) and so it decomposes into isolated vertices, paths and circuits. On each such component there is an independent set of size at least one-third the number of elements, the extreme case being a triangle. Thus there is a set $I_\rho \subseteq E_\rho$ with

$$|I_\rho| \geq |E_\rho| \geq \frac{g(t - g) + \binom{g}{2} - g/2}{3},$$

so that the pairs $\{x, y\}, \{\rho x, \rho y\}$ with $\{x, y\} \in I_\rho$ are all distinct.

For each $\{x, y\} \in I_\rho$ the event $\{x, y\} \in E \Leftrightarrow \{\rho x, \rho y\} \in E$ has probability $1/2$. Moreover these events are mutually independent over $\{x, y\} \in I_\rho$ since they involve distinct pairs. Thus we bound

$$\Pr[A_\rho] \leq 2^{-|I_\rho|} \leq 2^{-[g(t-g) + \binom{g}{2} - g/2]/3}.$$

For a given g the function ρ is determined by $\{x : \rho x \neq x\}$ and the values ρx for those x so that there are less than n^{2g} such ρ . We bound

$$\sum_{\rho \neq id} \Pr[A_\rho] = \sum_{g=1}^t \sum_{g(\rho)=g} \Pr[A_\rho] \leq \sum_{g=1}^t n^{2g} 2^{-(g(t-g) + \binom{g}{2} - g/2)/3}.$$

We make the rough bound

$$g(t - g) + \binom{g}{2} - \frac{g}{2} = g \left(t - \frac{g}{2} - 1 \right) \geq g \left(\frac{t}{2} - 1 \right)$$

since $g \leq t$. Then

$$\sum_{\rho \neq id} \Pr[A_\rho] \leq \sum_{g=1}^t \left(n^2 2^{(-t/2+1)/3} \right)^g$$

For, again being rough, $t > 50 \ln n$, $2^{1/2-t/6} < n^{-3}$ and $\sum_{\rho \neq id} \Pr[A_\rho] = o(1)$. That is, almost surely there is no isomorphic copy of $G|_S$.

For all $S \subseteq V$ with $|S| > 50 \ln n$ let I_S be the indicator random variable for there being no other subgraph isomorphic to $G|_S$. Set $X = \sum I_S$. Then $E[I_S] = 1 - o(1)$ so, by linearity of expectation - there being $2^n(1 - o(1))$ such S -

$$E[X] = 2^n(1 - o(1))$$

Hence there is a specific G with $X > 2^n(1 - o(1))$.

18.2 11 The Erdős-rényi Phase Transition

Bach, Mozart, Schubert - they will never fail you. When you perform their work properly it will have the character of the inevitable, as in great mathematics, which seems always to be made of pre-existing truths.

\author{

- E. L. Doctorow
- }

In their great work *On the Evolution of Random Graphs*, Erdős and Rényi (1960) expressed a special interest in the behavior of $\Gamma_{n,N(n)}$, the random graph with n vertices and $N(n)$ edges, when $N(n)$ was near $n/2$:

Thus the situation may be summarized as follows: the largest component of $\Gamma_{n,N(n)}$ is of order $\log n$ for $N(n)/n \rightarrow c < \frac{1}{2}$, of order $n^{2/3}$ for $N(n)/n \rightarrow c \sim \frac{1}{2}$, and of order n for $N(n)/n \rightarrow c > \frac{1}{2}$. This double "jump" of the size of the largest component when $N(n)/n$ passes the value $\frac{1}{2}$ is one of the most striking facts concerning random graphs.

Striking, indeed. The past half century has certainly confirmed the excitement that Erdős and Rényi expressed in their discovery.

18.2.1 11.1 AN Overview

We favor the more modern viewpoint, examining the random graph $G(n, p)$. The behavior of Erdős and Rényi's $\Gamma_{n,N(n)}$ then corresponds to that of $G(n, p)$ with $p = N(n)/\binom{n}{2}$. We shall assume $p = \Theta(n^{-1})$ throughout this chapter.

We shall call

$$p = \frac{c}{n}$$

the coarse parametrization. The value $\frac{1}{2}$ in the Erdős-Rényi formulation corresponds to the value $c = 1$ in our parametrization. Values $c < 1$ and $c > 1$ give $G(n, p)$ that are essentially different. We shall call

$$p = \frac{1}{n} + \lambda n^{-4/3}$$

the fine parametrization. The importance of this parametrization is not a priori at all obvious. Indeed, its "discovery" was one of the great advances in the field. In Section 11.7 we give a heuristic argument why this is the appropriate fine parametrization. Along with the fine parametrization we also define

$$\varepsilon = \lambda n^{-1/3} \text{ so that } p = \frac{1 + \varepsilon}{n}. \quad (11.1)$$

We shall express various results in terms of either λ or ε (or both), whichever best illustrates the result. We shall think of ε, λ as functions of n . To avoid negative numbers we shall sometimes parametrize $p = (1 - \varepsilon)/n$ with $\varepsilon = \lambda n^{-1/3}$. This includes functions such as $p = 1/n - 100n^{0.01}n^{-4/3}$. Of course, for n small this would give $p < 0$ and so would be nonsense. For n sufficiently large we will have $p \in [0, 1]$. As our results are always asymptotic we shall allow this slight abuse of notation and consider $G(n, p)$ defined only for n appropriately large.

In describing the nature of $G(n, p)$ we shall refer to the complexity of components, as defined below. Observe that complexity zero and one correspond to tree components and unicyclic components, respectively.

Definition 5 A connected component of a graph G with v vertices and e edges is said to have complexity $e - v + 1$. Components with complexity zero or one are called simple; components with complexity greater than one are called complex.

Let $C(v)$ denote the component containing a given vertex v . Its size $|C(v)|$ has a distribution. From the symmetry of $G(n, p)$ the distributions of all $|C(v)|$ are the same. We shall be concerned with the sizes of the largest components. We shall let C_i denote the i th largest component and L_i denote its number of vertices. Thus $L_1 = \max_v |C(v)|$. We shall be particularly interested in L_1, L_2 and whether or not they are close together.

The study of $G(n, p)$ when $p = \Theta(n^{-1})$ splits into five regions. We describe them in order of increasing p , thus giving some sense of the evolution.

Very Subcritical. Here we employ the coarse parametrization $p = c/n$ and assume c is a constant with $c < 1$.

Example: $p = 1/2n$.

- All components are simple.
- $L_1 = \Theta(\ln n)$.
- $L_k \sim L_1$ for all fixed k .

Barely Subcritical. Here we employ the fine parametrization: $p = (1 - \varepsilon)/n$ with $\varepsilon = \lambda n^{-1/3}$. We assume $\varepsilon = o(1)$ and $\lambda \rightarrow \infty$.

Example: $p = 1/n - n^{-4/3}n^{0.01}$.

- All components are simple.
- $L_1 = \Theta(\varepsilon^{-2} \ln \lambda) = \Theta(n^{2/3} \lambda^{-2} \ln \lambda)$.
- $L_k \sim L_1$ for all fixed k .

The Critical Window. Here λ is a real constant. The value $\lambda = 0$, perhaps surprisingly, has no special status.

Example: $p = 1/n \pm 2n^{-4/3}$.

- The largest k components (k fixed) all have size $L_k = \Theta(n^{2/3})$.
- Parametrizing $L_k = c_k n^{2/3}$ and letting d_k denote the complexity of C_k there is a nontrivial joint distribution for $c_1, \dots, c_k, d_1, \dots, d_k$.

Barely Supercritical. Here we employ the fine parametrization: $p = (1 + \varepsilon)/n$ with $\varepsilon = \lambda n^{-1/3}$. We assume $\varepsilon = o(1)$ and $\lambda \rightarrow \infty$.

Example: $p = 1/n + n^{-4/3}n^{0.01}$.

- $L_1 \sim 2\varepsilon n = 2\lambda n^{2/3}$.
- The largest component has complexity approaching infinity.
- All other components are simple.
- $L_2 = \Theta(\varepsilon^{-2} \ln \lambda) = \Theta(n^{2/3} \lambda^{-2} \ln \lambda)$.

Note that the ratio L_1/L_2 goes to infinity. For this reason, in this regime we call the largest component the dominant component.

Very Supercritical. We employ the coarse parametrization and assume $c > 1$.

- $L_1 \sim yn$, where $y = y(c)$ is the positive real satisfying

$$e^{-cy} = 1 - y. \quad (11.2)$$

- The largest component has complexity approaching infinity.
- All other components are simple.
- $L_2 = \Theta(\ln n)$.

Following the terminology made famous by Erdős and Rényi, we call the largest component the giant component.

We shall give arguments for only some of the above statements, and then often in limited form. Other results are given in the exercises. Full arguments for these results, and much much more, can be found in the classic texts of Bollobás (2001) and of Janson et al. (2000).

18.2.2 11.2 Three Processes

We place here in concise form three classes of probability spaces that we shall contrast and analyze. Our goal is to analyze the graph branching model. It is estimated by the binomial branching model, and thence by the Poisson branching model, which has a particularly nice analysis.

- The Poisson Branching Model.
- Parameter: Nonnegative real c .
- Underlying Space: An infinite sequence $Z_t, t = 1, 2, \dots$ of independent identically distributed random variables, each having Poisson distribution with mean c .
- Auxiliary $Y_t, t \geq 0$: Given by initial value $Y_0 = 1$ and recursion $Y_t = Y_{t-1} + Z_t - 1$.
- Auxiliary T : T is that minimal t with $Y_t = 0$. If no such t exists we write $T = \infty$.
- Nomenclature: Z_t is the number of nodes born at time t , Y_t is the queue size at time t , T is the total size.
- Interpretation: T is the total size of a Galton-Watson process, as described in Section 11.3, using a Poisson distribution with mean c .
- The Binomial Branching Model
- Parameters: Positive integer m , real $p \in [0, 1]$.
- Underlying Space: An infinite sequence $Z_t, t = 1, 2, \dots$ of independent identically distributed random variables, each having binomial distribution $B(m, p)$.
- Auxiliary $Y_t, t \geq 0$: Given by initial value $Y_0 = 1$ and recursion $Y_t = Y_{t-1} + Z_t - 1$.
- Auxiliary T : T is that minimal t with $Y_t = 0$. If no such t exists we write $T = \infty$.
- Nomenclature: Z_t is the number of nodes born at time t , Y_t is the queue size at time t , T is the total size.

- Interpretation: T is the total size of a Galton-Watson process, as described in Section 11.3 using a binomial distribution with parameters m, p .
- The Graph Branching Model
- Parameters: Positive integer n , real $p \in [0, 1]$.
- Underlying Space: A sequence $Z_1, \dots, Z_n, Z_t$ has binomial distribution with parameters N_{t-1}, p , with N_{t-1} as given below.
- Auxiliary $Y_t, t \geq 0$: Given by initial value $Y_0 = 1$ and recursion $Y_t = Y_{t-1} + Z_t - 1$.
- Auxiliary $N_t, t \geq 0$: Given by initial value $N_0 = n - 1$ and recursion $N_t = N_{t-1} - Z_t$. Equivalently, $N_t = n - t - Y_t$.
- Auxiliary T : T is that minimal t with $Y_t = 0$ or, equivalently, $N_t = n - t$. $1 \leq T \leq n$ always.
- Nomenclature: Z_t is the number of nodes born at time t , Y_t is the queue size at time t , N_t is the number of neutral vertices at time t , T is total size.
- Interpretation: T is the size of the component $C(v)$ of a given vertex v in $G(n, p)$, as found by the Breadth First Search process described in Section 11.5.

We use the superscripts *po* (Poisson), *bin* (binomial) and *gr* (graph) to distinguish these three processes when necessary.

18.2.3 11.3 The Galton-watson Branching Process

Let Z be a distribution over the nonnegative integers. The Galton-Watson process begins with a single root node, we can call her Eve. Eve has Z children. Each of her children (if there are any) now independently has Z children. The process continues, each new offspring having an independent number Z of children. Let T be the total number of nodes (including Eve herself) created in the process. It is possible that the process goes on forever, in which case we write $T = \infty$.

Our analysis of the Galton-Watson process uses fictional continuation. Let $Z_t, t = 1, 2, \dots$, be a countable sequence of independent identically distributed variables, each having distribution Z . This defines our probability space. We think of the children being born in a Breadth First Search manner; that is, Eve has her children, which are ordered in some way. Now the children, in order, have children. Each child's children are ordered in some way and this gives an ordering of Eve's grandchildren. Now the grandchildren have children in order, and the process continues. We count Eve as node number 1, her children have node numbers $2, \dots, 1 + Z_1$ and, more generally, each node is given a distinct positive integer as its node number. We let Z_t be the number of children of the t th node. Since the Z_t are independent and have distribution Z this corresponds to the Galton-Watson process. Imagine the t th node having Z_t children and then dying. By time t we mean the process after the t th node has had her children and died. Let Y_t be the number of living children at time t . We set initial value $Y_0 = 1$, corresponding to the node Eve. We have the recursion

$$Y_t = Y_{t-1} + Z_t - 1 \text{ for all } t \geq 1$$

There are two essentially different cases.

- $Y_t > 0$ for all $t \geq 0$. In this case the Galton-Watson process goes on forever and $T = \infty$.

- $Y_t = 0$ for some $t \geq 0$. In this case let T be the least integer for which $Y_T = 0$. Then the Galton-Watson process stops with the death of the T th node and T is the total number of nodes in the process.

Our fictional continuation enables us to consider the Y_t as an infinite random walk, with step size $Z - 1$. When $c < 1$ the walk has negative drift and so tends to $-\infty$. When $c > 1$ the walk has positive drift and tends to $+\infty$. The process when $c < 1$ is called subcritical and the process when $c > 1$ is called supercritical. When $c = 1$ the walk has zero drift and the situation is especially delicate.

The above is quite general. When Z is Poisson or binomial (the only cases of interest to us) this yields the Poisson branching process and the binomial branching process of Section 11.2.

18.2.4 11.4 Analysis of the Poisson Branching Process

In this section we study $T = T_c^{po}$. We often drop the value c and the superscript po for notational simplicity.

Theorem 11.4.1 If $c < 1$, T is finite with probability one. If $c = 1$, T is finite with probability one. If $c > 1$ then T is infinite with probability $y = y(c)$, where y is that unique positive real satisfying the equation (11.2).

Proof. Suppose $c < 1$. If $T > t$ then $Y_t > 0$ so that $Z_1 + \cdots + Z_t \geq t$. Chernoff bounds give that $\Pr[Y_t > 0] < e^{-kt}$ for a constant k . In particular, $\Pr[Y_t > 0] \rightarrow 0$ so that $\Pr[T > t] \rightarrow 0$ and T is finite with probability one.

Suppose $c \geq 1$. Set $z = 1 - y = \Pr[T < \infty]$. Given that Eve has i children the probability that the branching process is finite is z^i as all i branches must be finite. Thus

$$z = \sum_{i=0}^{\infty} \Pr[Z_1 = i] z^i = \sum_{i=0}^{\infty} e^{-c} \frac{c^i z^i}{i!} = e^{c(z-1)}.$$

Setting $y = 1 - z$ gives the equation (11.2). For $c = 1$, $e^{-y} > 1 - y$ for $y > 0$ so the solution must be $y = 0$. For $c > 1$ the function $f(y) = 1 - y - e^{-cy}$ has $f(0) = 1$, $f(1) < 0$ and $f'(0) = c - 1 > 0$ so there is a $y \in (0, 1)$ with $f(y) = 0$. Furthermore, as f is convex, there is precisely one y . We have shown that either $\Pr[T < \infty] = 1$ or $\Pr[T < \infty] = 1 - y > 0$. The argument that $\Pr[T < \infty] \neq 1$ (not surprising as the walk has positive drift) is left for the exercises.

Theorem 11.4.2 For any positive real c and any integer k , setting $T = T_c^{po}$,

$$\Pr[T = k] = \frac{e^{-ck} (ck)^{k-1}}{k!}.$$

We defer the proof of this classic result to Section 11.6 when we will give a probabilistic proof!

When $c = 1$ Stirling's formula gives

$$\Pr[T_1 = k] = \frac{e^{-k} k^{k-1}}{k!} \sim \frac{1}{\sqrt{2\pi}} k^{-3/2}. \quad (11.3)$$

This perforce approaches zero but it does so only at polynomial speed. In general,

$$\Pr[T_c = k] \sim \frac{1}{\sqrt{2\pi}} k^{-3/2} c^{-1} (ce^{1-c})^k.$$

For any $c \neq 1$ (whether larger or smaller than one) $ce^{1-c} < 1$ and therefore $\Pr[T_c = k]$ approaches zero at exponential speed. This gives a bound on the tail distribution

$$\Pr[T_c \geq u] < e^{-u(\alpha+o(1))}, \quad (11.4)$$

where $\alpha = c - 1 - \ln c > 0$.

We are particularly interested in the Poisson branching process when c is near one. Let us parametrize

$$c = 1 + \varepsilon.$$

When $\varepsilon > 0$, $\Pr[T_{1+\varepsilon} = \infty]$ is the $y = y(\varepsilon) \in (0, 1)$ satisfying $f(y) = 1 - y - e^{-(1+\varepsilon)y} = 0$. Some fun calculus gives

$$\Pr[T_{1+\varepsilon} = \infty] \sim 2\varepsilon \text{ as } \varepsilon \rightarrow 0^+. \quad (11.5)$$

Suppose $c \rightarrow 1^+$ so that $\varepsilon \rightarrow 0^+$. We have

$$\ln(ce^{1-c}) = \ln(1 + \varepsilon) - \varepsilon \sim -\frac{\varepsilon^2}{2}.$$

Thus

$$\Pr[T_{1+\varepsilon} = u] \sim \frac{1}{\sqrt{2\pi}} u^{-3/2} \text{ for } u = o(\varepsilon^{-2}).$$

Note that $\Pr[T_{1+\varepsilon} = u] \sim \Pr[T_1 = u]$ in this range. When u reaches order ε^{-2} there is a change. For $u = A\varepsilon^{-2}$ and fixed A ,

$$\Pr[T_{1+\varepsilon} = A\varepsilon^{-2}] \sim \frac{1}{\sqrt{2\pi}} \varepsilon^3 A^{-3/2} e^{-A/2}.$$

When $A \rightarrow \infty$ we absorb smaller factors into the exponential term:

$$\Pr[T_{1+\varepsilon} = A\varepsilon^{-2}] = \varepsilon^3 e^{-(1+o(1))A/2}.$$

When c is slightly less than one we can write $c = 1 - \varepsilon$, where $\varepsilon \rightarrow 0^+$. We have $\ln(ce^{-c}) \sim -\frac{1}{2}\varepsilon^2$, the same as for $c = 1 + \varepsilon$. Indeed when $u = o(\varepsilon^{-3})$,

$$\Pr[T_{1-\varepsilon} = u] \sim \Pr[T_{1+\varepsilon} = u].$$

For $A \rightarrow \infty$,

$$\Pr[T_{1-\varepsilon} = A\varepsilon^{-2}] = \varepsilon^3 e^{-(1+o(1))A/2}.$$

The Poisson branching processes with means $1 + \varepsilon$ and $1 - \varepsilon$ look almost the same, with the (important!) distinction that the mean $1 + \varepsilon$ process is sometimes infinite while the mean $1 - \varepsilon$ process never is.

In short, the Poisson branching process with mean $1 \pm \varepsilon$ acts as if it had mean 1 until reaching size on the order ε^{-2} . Until then $\Pr[T_{1\pm\varepsilon} = u]$ is dropping at a polynomial rate. Upon reaching order ε^{-2} , $\Pr[T_{1\pm\varepsilon} = u]$ drops exponentially in u .

We are particularly interested in the tail distribution. For $\varepsilon \rightarrow 0^+$ and $A \rightarrow \infty$,

$$\Pr[T_{1-\varepsilon} > A\varepsilon^{-2}] < e^{-(1+o(1))A/2} \varepsilon. \quad (11.6)$$

The same holds for the finite part of $T_{1+\varepsilon}$:

$$\Pr[\infty > T_{1+\varepsilon} > A\varepsilon^{-2}] < e^{-(1+o(1))A/2} \varepsilon$$

When $A \rightarrow \infty$ this quantity is $o(\varepsilon)$ so (11.5) gives

$$\Pr[T_{1+\varepsilon} > A\varepsilon^{-2}] \sim 2\varepsilon \text{ when } \varepsilon \rightarrow 0^+ \text{ and } A \rightarrow \infty. \quad (11.7)$$

18.2.5 11.5 The Graph Branching Model

Abbreviation: We use BFS as an abbreviation for Breadth First Search. BFS algorithms are a mainstay of computer science and central to our approach.

Let $C(v)$ denote the component, in $G(n, p)$, containing a designated vertex v . We generate $C(v)$ using the (standard) BFS algorithm to find $C(v)$. We begin with root v . In this procedure all vertices will be live, dead, or neutral. The live vertices will be contained in a queue. Initially, at time zero, v is live, the queue consists of one vertex, v itself, and all other vertices are neutral. At each time t we remove a live vertex w from the top of the queue (in computer science parlance we "pop the queue") and check all pairs $\{w, w'\}$, w' neutral, for adjacency in G . The popped vertex w is now dead. Those neutral w' (if any) adjacent to w are added to the bottom of the queue and are now live. (They can be placed in any particular order.) The procedure ends when the queue is empty. We let T denote that time. At time T all vertices are neutral or dead and the set of dead vertices is precisely the component $C(v)$. That is, $T = |C(v)|$.

Let Z_t denote the number of vertices added to the queue at time t . Let Y_t denote the size of the queue at the conclusion of time t . We set $Y_0 = 1$, reflecting the initial size of the queue. At time t we remove one vertex and add Z_t vertices to the queue so we have the recursion $Y_t = Y_{t-1} - 1 + Z_t$. Let N_t denote the number of neutral vertices at time t . As Z_t vertices switched from neutral to live at time t , N_t satisfies the recursion $N_0 = n - 1$, $N_t = N_{t-1} - Z_t$. Equivalently, as there are t dead and Y_t live vertices at time t , $N_t = n - t - Y_t$. Z_t is found by checking N_{t-1} pairs for adjacency. As these pairs have not yet been examined they remain adjacent with independent probability p . That is,

$$Z_t \sim B(N_{t-1}, p) \sim B(n - (t - 1) - Y_{t-1}, p) \quad (11.8)$$

The graph branching process of Section 11.2 mirrors the above analysis until time T and then continues until time n . This fictional continuation shall be useful in the analysis of $C(v)$. The graph branching process is similar to a binomial branching process in that the Z_t have binomial distributions but dissimilar in that the parameter N_{t-1} in the graph branching process depends on previous values Z_i .

As $N_t = N_{t-1} - Z_t$, (11.8) yields $N_t \sim B(N_{t-1}, 1 - p)$. By induction we find the distributions

$$N_t \sim B(n - 1, (1 - p)^t) \quad \text{for } 0 \leq t \leq n.$$

If $T = t$ it is necessary (though not sufficient, due to fictitious continuation) that $N_t = n - t$. This yields the useful inequalities.

Theorem 11.5.1 In $G(n, p)$

$$\Pr[|C(v)| = t] \leq \Pr[B(n - 1, (1 - p)^t) = n - t]$$

or, equivalently,

$$\Pr[|C(v)| = t] \leq \Pr[B(n - 1, 1 - (1 - p)^t) = t - 1]. \quad (11.9)$$

An Alternate Analysis. The following analysis of $C(v)$ on $G(n, p)$ has been explored by van der Hofstad and Spencer (2006). Each $w \neq v$ flips a coin, heads with probability p , repeatedly until getting a head. Let X_w denote that flip on which w gets a head. Suppose $X_w = j$. Then w enters the BFS at time j . (However, it may have missed the boat if the BFS has already terminated.) This reverses the usual randomness; we are here imagining the $w \neq v$ trying to get into the BFS tree, rather than the BFS tree trying to expand by finding neutral vertices. Suppose $t = |C(v)|$. Every $w \neq v$ that is in $C(v)$ must have entered by time t so $X_w \leq t$. Every $w \neq v$ that is not in $C(v)$ had t opportunities to enter $C(v)$ and so $X_w > t$. Thus $\Pr[|C(v)| = t]$ is at most the probability that $X_w \leq t$ for precisely $t - 1$ $w \neq v$. For each

$w \neq v$, $\Pr[X_w = t] = 1 - (1 - p)^t$ and these events are independent over w , yielding (11.9). In van der Hofstad and Spencer (2006) this analysis is extended to give more precise bounds on $\Pr[|C(v)| = t]$.

18.2.6 11.6 The Graph and Poisson Processes Compared

Set $p = c/n$. A key observation is that $Z_1 \sim B(n - 1, c/n)$ approaches (in n) the Poisson distribution with mean c . Furthermore, in a more rough sense, the same holds for Z_t as long as $N_{t-1} \sim o(n)$ or, equivalently, the number of live and dead vertices is $o(n)$. That is, the generation of $C(v)$ mimics the Poisson branching process with mean c as long as the number of vertices found is not too large. This allows for a very accurate description in the very subcritical regime $c < 1$. But in the very supercritical regime $c > 1$ the relationship between the generation of $C(v)$ and the Poisson branching process breaks down. As the number N_{t-1} of neutral vertices drops so does the expected number $E[Z_t]$ of vertices added to the queue. Eventually the drift of the walk Y_t lowers from positive to negative, and this eventually causes the process to halt. We call this phenomenon the ecological limitation. Indeed, there must be an ecological limitation. The Poisson branching process becomes infinite with positive probability; the component $C(v)$ tautologically cannot be greater than n .

Theorem 11.6.1 For any positive real c and any fixed integer k

$$\lim_{n \rightarrow \infty} \Pr[|C(v)| = k \text{ in } G(n, c/n)] = \Pr[T_c = k]$$

Proof. Let Z_t^{po}, T^{po} and Z_t^{gr}, T^{gr} denote the values in the Poisson branching process with parameter c and the graph branching process with parameters n, p , respectively. Let Γ denote the set of k -tuples $\vec{z} = (z_1, \dots, z_k)$ of nonnegative integers such that the recursion $y_0 = 1, y_t = y_{t-1} + z_t - 1$ has $y_t > 0$ for $t < k$ and $y_k = 0$. Then

$$\begin{aligned} \Pr[T^{gr} = k] &= \sum \Pr[Z_i^{gr} = z_i, 1 \leq i \leq k], \\ \Pr[T^{po} = k] &= \sum \Pr[Z_i^{po} = z_i, 1 \leq i \leq k], \end{aligned}$$

where both sums are over $\vec{z} \in \Gamma$. Fix such a $\vec{z}$.

$$\Pr[Z_i^{gr} = z_i, 1 \leq i \leq k] = \prod_{i=1}^k \Pr[B(N_{i-1}^{gr}, p) = z_i].$$

As i, y_{i-1}, z_i are fixed $Z_{i-1} = n - O(1)$ and $B(Z_{i-1}, p)$ approaches the Poisson distribution. More precisely,

$$\lim_{n \rightarrow \infty} \Pr[B(Z_{i-1}, p) = z_i] = \Pr[Z_i^{po} = z_i]$$

Furthermore, as the products are of a fixed number of terms,

$$\lim_{n \rightarrow \infty} \Pr[Z_i^{gr} = z_i, 1 \leq i \leq k] = \Pr[Z_i^{po} = z_i, 1 \leq i \leq k]$$

Proof [Theorem 11.4.2]. By Theorem 11.6.1,

$$\Pr[T_c^{po} = k] = \lim_{n \rightarrow \infty} \Pr[|C(v)| = k]$$

where the second probability is in $G(n, p)$ with $p = c/n$ and v is an arbitrary vertex of that graph. There are $\binom{n}{k-1}$ choices for $C(v)$. On any particular such S there is probability $O(p^k) = O(n^{-k})$ that $G(n, p)$ has more than $k - 1$ edges. If $G(n, p)$ has precisely $k - 1$ edges on S they must form a tree. There are k^{k-2} such trees. Each occurs with probability

$p^{k-1}(1-p)^{\binom{k}{2}-k+1} \sim p^{k-1} = c^{k-1}n^{1-k}$. Thus the total probability that $G(n, p)$ restricted to S forms a connected graph is $\sim k^{k-2}c^{k-1}n^{1-k}$. As a connected component, we must further have no edges between $C(v)$ and its complement; this has probability $(1-p)^{k(n-k)} \sim e^{-ck}$. Thus

$$\Pr[C(v) = k] \sim \binom{n}{k-1} k^{k-2} c^{k-1} n^{1-k} e^{-ck} \rightarrow \frac{e^{-ck} (ck)^{k-1}}{k!},$$

as desired.

The graph branching process can be compared to the binomial branching process in both directions. An important cautionary note: the event $T_{n-1,p}^{\text{bin}} \geq u$ in Theorem 11.6.2 (and similarly $T_{n-u,p}^{\text{bin}} \geq u$ in Theorem 11.6.3) includes the possibility that the binomial branching process is infinite. Indeed, in application this will be the critical term.

Theorem 11.6.2 For any u

$$\Pr[T_{n,p}^{\text{gr}} \geq u] \leq \Pr[T_{n-1,p}^{\text{bin}} \geq u]$$

Proof. We modify the graph branching process by constantly replenishing the supply of neutral vertices. That is, when we pop the vertex w and there are $n-1-s$ neutral vertices, we create s fictional vertices w' and allow w, w' to be adjacent with probability p . This gives a component of size $T_{n-1,p}^{\text{bin}}$; the actual $C(v)$ will be a subset of it. Thus $T_{n-1,p}^{\text{bin}}$ dominates $T_{n,p}^{\text{gr}}$.

Theorem 11.6.3 For any u

$$\Pr[T_{n,p}^{\text{gr}} \geq u] \geq \Pr[T_{n-u,p}^{\text{bin}} \geq u]$$

Proof. We halt the graph branching process when the number of found (live plus dead) vertices reaches u . This does not affect the probability of finding at least u vertices. In this truncated graph process we diminish the number of neutral vertices to $n-u$. That is, when we pop the vertex w and there are $n-1-s \geq n-u$ neutral vertices, we select $n-u$ of them and only allow adjacencies w, w' to them. The truncated graph process dominates this truncated binomial $n-u, p$ process and so has a greater or equal probability of reaching u .

The Poisson Approximation. We are working in the range $p = \Theta(n^{-1})$. There the binomial $B(n-1, p)$ distribution and the Poisson distribution with mean np are very close. The Poisson branching process is precisely understood and, we feel, the "purest" branching process. Our goal in this chapter is to give the reader a picture for the "why" of the various regimes. To do this we shall often avoid the technical calculations and simply assume that the binomial $n-1, p$ branching process is very close to the Poisson branching process with mean np .

18.2.7 11.7 The Parametrization Explained

In the parametrization (11.1) for the critical window why is the exponent $-\frac{1}{3}$ as opposed to, say, $-\frac{1}{4}$ or $-\frac{2}{7}$ or something completely different? In the experience of the authors this is the question most frequently asked about the Erdős-Rényi phase transition. Here is a heuristic that may be helpful.

Parametrize $p = (1 + \varepsilon)/n$ with $\varepsilon = \varepsilon(n)$ positive and approaching zero. We look for the following picture. Consider the Poisson branching process $T = T_{1+\varepsilon}^{\text{po}}$. It is infinite with probability $\sim 2\varepsilon$, otherwise its probability of exceeding $A\varepsilon^{-2}$ drops exponentially in A . The graph branching process mimics the Poisson branching process as long as it is not too successful. The cases when the Poisson branching process is finite are mimicked, yielding components of size up to roughly ε^{-2} . The cases when the Poisson branching process is infinite are mimicked by components that "escape" until the ecological limitation sets in. These components all join together. They form a single component, the dominant component, of size $2\varepsilon n$.

In order for the above (admittedly rough) picture to hold there needs to be a distinction between the small components, up to size ε^{-2} , and the dominant component of size $2\varepsilon n$. That is, we need $2\varepsilon n \gg \varepsilon^{-2}$. This heuristic leads us to $\varepsilon = n^{-1/3}$ as the breakpoint. When $\varepsilon \gg n^{-1/3}$ we have the distinction between small and dominant and are in the supercritical regime. When $\varepsilon = O(n^{-1/3})$ there is no effective analogy to the Poisson branching process being infinite, and there is no dominant component.

18.2.8 11.8 The Subcritical Regimes

Let $p = c/n$ with $c < 1$. Theorem 11.6.2 gives

$$\Pr[T_{n,p}^{gr} \geq u] \leq \Pr[T_{n-1,p}^{bin} \geq u]$$

With the Poisson approximation,

$$\Pr[|C(v)| \geq u] \leq (1 + o(1)) \Pr[T_c \geq u].$$

From (11.4) this drops exponentially in u . Taking $u = K \ln n$ for appropriately large K , $\Pr[|C(v)| \geq u] < n^{-1.01}$. As this holds for each of the n vertices v , the probability that any v has $|C(v)| \geq u$ is less than $nn^{-1.01} \rightarrow 0$. That is, $L_1 = O(\ln n)$ with probability tending to one.

Let's push this argument into the barely subcritical regime $p = (1 - \varepsilon)/n$ with $\varepsilon = \lambda n^{-1/3}$. Let I_v be the indicator random variable for $C(v)$ having at least u vertices, u to be determined below. As above Theorem 11.6.2 and our Poisson approximation give the bound

$$\Pr[|C(v)| \geq u] \leq (1 + o(1)) \Pr[T_{1-\varepsilon} \geq u]$$

We now parametrize

$$u = K\varepsilon^{-2} \ln \lambda = Kn^{2/3} \lambda^{-2} \ln \lambda$$

For an appropriately large constant K the bound (11.6) gives

$$\Pr[T_{1-\varepsilon} \geq u] \leq \varepsilon e^{-3.1\lambda} = \varepsilon \lambda^{-3.1}$$

Let $X = \sum_v I_v$ be the number of vertices v in components of size at least u and let Y be the number of components of $G(n, p)$ of size at least u . Linearity of expectation gives

$$\mathbb{E}[X] = n\mathbb{E}[I_v] \leq n\varepsilon \lambda^{-3.1} = n^{2/3} \lambda^{-2.1}$$

As $Y \leq Xu^{-1}$,

$$\mathbb{E}[Y] \leq u^{-1}\mathbb{E}[X] \leq K^{-1} \lambda^{-0.1} \rightarrow 0$$

With probability approaching one, $Y = 0$ and so

$$L_1 \leq u = K\varepsilon^{-2} \ln \lambda = Kn^{2/3} \lambda^{-2} \ln \lambda.$$

18.2.9 11.9 The Supercritical Regimes

In the supercritical regimes there are two salient points about the giant or dominant component; First, it exists. Second, it is unique. Neither is trivial.

The Very Supercritical Phase. We start with the very supercritical region, $p = c/n$, with $c > 1$ constant. The ideas here will carry into the barely supercritical region. Let $y = y(c)$ be

the positive real solution of the equation $e^{-cy} = 1 - y$. Let δ be an arbitrarily small constant and let K be an appropriately large constant. Set $S = K \ln n$, $L^- = (y - \delta)n$ and $L^+ = (y + \delta)n$. Call a component $C(v)$ and its size $|C(v)|$ small if $|C(v)| < S$, giant if $L^- < |C(v)| < L^+$ and awkward otherwise.

No Middle Ground. We claim that the probability of having any awkward component is $o(n^{-20})$. (We could make '20' arbitrarily large by changing K .) There are n choices for v and n choices for $t = |C(v)|$. Thus it suffices to show that for any v and for any awkward t that $\Pr[|C(v)| = t] = o(n^{-18})$. From Theorem 11.5.1 it suffices to bound $\Pr[B(n-1, 1 - (1 - c/n)^t) = t - 1]$. We indicate the technical calculations. When $t = o(n)$, $1 - (1 - c/n)^t \sim cn/t$ and $c > 1$ so $\Pr[B(n-1, 1 - (1 - c/n)^t) \leq t - 1]$ is exponentially small in t . As $t \geq K \ln n$ this is polynomially small in n . When $t \sim xn$, $1 - (1 - c/n)^t \sim 1 - e^{-cx}$. For $x \neq y$, $1 - e^{-cx} \neq x$ so the mean of the binomial is not near t and the probability that it is equal to t is exponentially small in n . In all cases the bounds on $\Pr[|C(v)| = t]$ follow from basic Chernoff bounds.

Escape Probability. Set $\alpha = \Pr[C(v) \text{ is not small}]$. [When this happens we like to think that the BFS on $G(n, p)$ starting with root v has escaped an early death.] Theorems 11.6.2 and 11.6.3 sandwich

$$\Pr[T_{n-S,p}^{\text{bin}} \geq S] \leq \alpha \leq \Pr[T_{n-1,p}^{\text{bin}} \geq S]$$

From our Poisson approximation both $\Pr[T_{n-S,p}^{\text{bin}} \geq S]$ and $\Pr[T_{n-1,p}^{\text{bin}} \geq S]$ are asymptotic to $\Pr[T_c \geq S]$. Thus $\alpha \sim \Pr[T_c \geq S]$. As c is assumed fixed and $S \rightarrow \infty$,

$$\alpha \sim \Pr[T_c \geq S] \sim \Pr[T_c = \infty] = y,$$

with y as in (11.2).

Because there is no middle ground, not small is the same as giant. $C(v)$ is giant with probability $\sim y$. Thus the expected number of vertices in giant components is $\sim yn$. Each giant component has size between $(y - \delta)n$ and $(y + \delta)n$. Our goal is a single giant component of size $\sim yn$. We are almost there - but maybe with probability $\frac{1}{2}$ there are two giant components.

Sprinkling. Set $p_1 = n^{-3/2}$. (Any p_1 with $n^{-2} \ll p_1 \ll n^{-1}$ would do here.) Let $G_1 \sim G(n, p_1)$ be selected independently from $G \sim G(n, p)$ on the same vertex set and let $G^+ = G \cup G_1$ so that $G^+ \sim G(n, p^+)$ with $p^+ = p + p_1 - pp_1$. (We "sprinkle" the relatively few edges of G_1 on G to make G^+ .) Suppose $G(n, p)$ had more than one giant component and let V_1, V_2 be the vertex sets of two of those components. There are $\Omega(n^2)$ pairs $\{v_1, v_2\}$ with $v_1 \in V_1, v_2 \in V_2$. We have selected p_1 large enough so that with probability $1 - o(1)$ at least one of these pairs is in the sprinkling G_1 . Adding this edge merges components V_1, V_2 into a component of size at least $2y(1 - \delta)n$ in G^+ . We have selected p_1 small enough so that $p^+ \sim p = c/n$. The probability that G^+ has a component so large, and hence awkward, is therefore $o(n^{-20})$. Hence the probability that G had more than one giant component is $o(n^{-20})$.

Finally, we make δ arbitrarily small. $G(n, p)$ has an expected number $\sim yn$ of points in giant components and giant components all have size $\sim yn$. Furthermore, by the sprinkling argument, the contribution to this expectation from the possibility of G having more than one giant component is $o(nn^{-20})$, which is negligible. Thus with probability $1 - o(1)$ there is precisely one giant component. This gives the salient features of the very supercritical phase. There is a giant component so $L_1 \sim yn$. There is only one giant component and no middle ground so $L_2 \leq S = O(\ln n)$.

The sprinkling for complexity argument given below in the barely supercritical phase can easily be modified to show that the giant component has high complexity, indeed, complexity $\Omega(n)$.

The Barely Supercritical Phase. Set $p = (1 + \varepsilon)/n$ with $\varepsilon = \lambda n^{-1/3}$ and $\lambda \rightarrow \infty$. Note $\varepsilon^{-2} = \lambda^{-2} n^{2/3} \ll 2\varepsilon n$. The analysis of the barely supercritical region becomes more difficult

as $\lambda = \lambda(n)$ approaches infinity more slowly. We shall add the simplifying assumption that $\lambda \gg \ln n$. Furthermore, we shall find somewhat weaker bounds than stated on L_2 .

Bollobás (1984) showed the existence of the dominant component when $\lambda > K\sqrt{\ln n}$, K constant. That paper was the first indication of the appropriate scaling for the critical window. Łuczak (1990a) tightened the result to "best possible," showing that if $\lambda \rightarrow +\infty$ then the dominant component exists.

Let δ be an arbitrarily small constant and let K be an appropriately large constant. Set $S = K\varepsilon^{-2} \ln n$, $L^- = (1 - \delta)2\varepsilon n$ and $L^+ = (1 + \delta)2\varepsilon n$. Call a component $C(v)$ and its size $|C(v)|$ small if $|C(v)| < S$, dominant if $L^- < |C(v)| < L^+$ and awkward otherwise.

No Middle Ground. We claim that the probability of having any awkward component is $o(n^{-20})$. (We could make '20' arbitrarily large by changing K .) There are n choices for v and n choices for $t = |C(v)|$. Thus it suffices to show that for any v and for any awkward t that $\Pr[|C(v)| = t] = o(n^{-18})$. Again we bound $\Pr[B(n-1, 1 - (1-p)^t) = t-1]$. We indicate the technical calculations. Let μ and σ^2 denote the mean and the variance of the binomial. Then $\mu = (n-1)(1 - (1-p)^t)$ and, in this range, $\sigma^2 \sim \mu$. When $t = o(n\varepsilon)$ we estimate $1 - (1-p)^t$ by $pt = t + t\varepsilon$. Then $\mu - t \sim -t\varepsilon$ and $\sigma^2 \sim t$. This probability is roughly $\exp[-(t\varepsilon)^2/2t] = \exp[-t\varepsilon^2/2]$. As $t \geq S$ the exponent is $o(n^{-18})$ for $K > 36$. [To push S down to $K\varepsilon^{-2} \ln \lambda$ requires a finer bound on $\Pr[|C(v)| = t]$.] Now suppose $t \sim xn\varepsilon$, where $x \neq 2$. The ecological limitation now has an effect and we estimate $1 - (1-p)^t$ by $pt - \frac{1}{2}p^2t^2$ so

$$\mu - t \sim t\varepsilon - \frac{1}{2}t^2n^{-2} \sim (n\varepsilon) \left(x - \frac{1}{2}x^2 \right)$$

[Observe that when $x = 2$ the mean of the binomial is very close to t and so we do not get a small bound on $\Pr[|C(v)| = t]$. This is natural when we consider that there will be a dominant component of size $\sim 2\varepsilon n$.] Again $\sigma^2 \sim t$ so the probability is $\exp[-\Omega((n\varepsilon)^2/t)]$, which is extremely small. When $t \gg n\varepsilon$ the probability is even smaller.

Escape Probability. Set $\alpha = \Pr[C(v) \text{ is not small}]$. Theorems 11.6.2 and 11.6.3 sandwich

$$\Pr[T_{n-S,p}^{\text{bin}} \geq S] \leq \alpha \leq \Pr[T_{n-1,p}^{\text{bin}} \geq S]$$

The Poisson approximation for $T_{n-1,p}^{\text{bin}}$ is $T_{1+\varepsilon}$. As $S \gg \varepsilon^{-2}$, bound (11.7) gives

$$\alpha \leq \Pr[T_{1+\varepsilon} \geq S] \sim \Pr[T_{1+\varepsilon} = \infty] \sim 2\varepsilon.$$

Replacing $n-1$ by $n-S$ lowers the mean by $\sim Sn^{-1}$. But $Sn^{-1}/\varepsilon \sim (\ln n)/(n\varepsilon^3) = \lambda^{-3} \ln n$ and we have made λ large enough that this is $o(1)$. That is, $Sn^{-1} = o(\varepsilon)$. Therefore $T_{n-S,p}^{\text{bin}}$ is approximated by $T_{1+\varepsilon-o(\varepsilon)}$ and

$$\alpha \geq \Pr[T_{1+\varepsilon+o(\varepsilon)} \geq S] \sim \Pr[T_{1+\varepsilon+o(\varepsilon)} = \infty] \sim 2\varepsilon$$

α has been sandwiched and $\alpha \sim 2\varepsilon$.

Because there is no middle ground, not small is the same as dominant. $C(v)$ is dominant with probability $\sim 2\varepsilon$. Thus the expected number of vertices in dominant components is $\sim 2n\varepsilon$. Each dominant component has size between $(1 - \delta)2n\varepsilon$ and $(1 + \delta)2n\varepsilon$. As in the very supercritical case, we need worry about having more than one dominant component.

Sprinkling. Set $p_1 = n^{-4/3}$. Let $G_1 \sim G(n, p_1)$ be selected independently from $G \sim G(n, p)$ on the same vertex set and let $G^+ = G \cup G_1$ so that $G^+ \sim G(n, p^+)$ with $p^+ = p + p_1 - pp_1 = 1 + \varepsilon + o(\varepsilon)$. Suppose $G(n, p)$ had more than one giant component and let V_1, V_2 be the vertex sets of two of those components. There are $\gg n^{4/3}$ pairs $\{v_1, v_2\}$ with $v_1 \in V_1, v_2 \in V_2$. With probability $1 + o(1)$ at least one of these pairs is in the sprinkling G_1 . Adding this edge merges components V_1, V_2 into a component of size at least $(1 - \delta)4\varepsilon n$ in G^+ . The probability G^+ has such a large, and hence awkward, component is $o(n^{-20})$. Thus the probability G had had two

(or more) dominant components is $o(n^{-20})$. Taking δ arbitrarily small, as in the supercritical case, G has with probability $1 - o(1)$ precisely one dominant component. Thus $L_1 \sim 2n\varepsilon$ and, as there is no middle ground, $L_2 \leq K\varepsilon^{-2} \ln n$.

Sprinkling for Complexity. Take $p_1 = (1 + \varepsilon/2)/n$ and $p_2 \sim \varepsilon/2n$ so that $p_1 + p_2 - p_1p_2 = (1 + \varepsilon)/n$. Let $G_1 \sim G(n, p_1)$, $G_2 \sim G(n, p_2)$ and $G_3 = G_1 \cup G_2$ so that $G_3 \sim G(n, (1 + \varepsilon)/n)$. G_1, G_3 will have dominant components V_1, V_3 of sizes $\sim n\varepsilon$ and $\sim 2n\varepsilon$. As G_3 has no middle ground in its component sizes, $V_1 \subseteq V_3$. Now the sprinkling G_2 adds $\sim p_2 \binom{n\varepsilon}{2} \sim n\varepsilon^3/2$ edges internal to V_1 . Thus V_3 will have complexity at least $n\varepsilon^3/2 = \lambda^3/2$, which approaches infinity.

18.2.10 11.10 The Critical Window

We now fix a real λ and set $p = 1/n + \lambda n^{-4/3}$. There has been massive study of this critical window, Łuczak (1990b) and the monumental Janson, Knuth, Łuczak and Pittel (1993) being only two examples. Calculations in this regime are remarkably delicate.

Fix $c > 0$ and let X be the number of tree components of size $k = cn^{2/3}$. Then

$$\mathbb{E}[X] = \binom{n}{k} k^{k-2} p^{k-1} (1-p)^{k(n-k) + \binom{k}{2} - (k-1)}$$

Recall that $\ln(1+x) = x - \frac{1}{2}x^2 + O(x^3)$ and watch the terms cancel!

$$\binom{n}{k} = \frac{(n)_k}{k!} \sim \frac{n^k e^k}{k^k \sqrt{2\pi k}} \prod_{i=1}^{k-1} \left(1 - \frac{i}{n}\right).$$

For $i = 0, \dots, k-1$,

$$-\ln\left(1 - \frac{i}{n}\right) = \frac{i}{n} + \frac{i^2}{2n^2} + O\left(\frac{i^3}{n^3}\right),$$

so that

$$\sum_{i=1}^{k-1} -\ln\left(1 - \frac{i}{n}\right) = \frac{k^2}{2n} + \frac{k^3}{6n^2} + o(1) = \frac{k^2}{2n} + \frac{c^3}{6} + o(1).$$

Considering $p^{k-1} = n^{1-k} (1 + \lambda n^{-1/3})^{k-1}$,

$$(k-1) \ln(1 + \lambda n^{-1/3}) = k\lambda n^{-1/3} - \frac{1}{2}c\lambda^2 + o(1)$$

Last but not least,

$$\ln(1-p) = -p + O(n^{-2}) = -\frac{1}{n} - \frac{\lambda}{n^{4/3}} + O(n^{-2})$$

and

$$k(n-k) + \binom{k}{2} - (k-1) = kn - \frac{k^2}{2} + O(n^{2/3})$$

so that

$$\left[k(n-k) + \binom{k}{2} - (k-1) \right] \ln(1-p) = -k + \frac{k^2}{2n} - \frac{\lambda k}{n^{1/3}} + \frac{\lambda c^2}{2} + o(1)$$

Putting it all together,

$$\mathbb{E}[X] \sim \frac{n^k k^{k-2}}{k^k \sqrt{2\pi k n^{k-1}}} e^A = n k^{-5/2} (2\pi)^{-1/2} e^A$$

where

$$A = k - \frac{k^2}{2n} - \frac{c^3}{6} + \frac{\lambda k}{n^{1/3}} - \frac{\lambda^2 c}{2} - k + \frac{k^2}{2n} - \frac{\lambda k}{n^{1/3}} + \frac{\lambda c^2}{2}.$$

The k and n terms cancel and we can give A the intriguing form

$$A = A(c) = \frac{(\lambda - c)^3 - \lambda^3}{6}$$

Writing k in terms of n then yields

$$\mathbb{E}[X] \sim n^{-2/3} e^{A(c)} c^{-5/2} (2\pi)^{-1/2}$$

For any particular such k , $\mathbb{E}[X] \rightarrow 0$ but if we sum k between $cn^{2/3}$ and $(c + dc)n^{2/3}$ we multiply by $n^{2/3}dc$. Going to the limit gives an integral: For any fixed a, b, λ let X be the number of tree components of size between $an^{2/3}$ and $bn^{2/3}$. Then

$$\lim_{n \rightarrow \infty} \mathbb{E}[X] = \int_a^b e^{A(c)} c^{-5/2} (2\pi)^{-1/2} dc$$

The large components are not all trees. Wright (1977) proved that for fixed $l \geq 0$ there are asymptotically $c_l k^{k-2+(3l/2)}$ connected graphs on k points with $k - 1 + l$ edges, where $c_0 = 1$, $c_1 = \sqrt{\pi/8}$ and c_l was given by a specific recurrence. Asymptotically in l , $c_l = l^{-l/2(1+o(1))}$. The calculation for $X^{(l)}$, the number of such components on k vertices, leads to extra factors of $c_l k^{3l/2}$ and n^{-l} , which gives $c_l c^{3l/2}$. For fixed a, b, λ, l the number $X^{(l)}$ of components of size between $an^{2/3}$ and $bn^{2/3}$ with $l - 1$ more edges than vertices satisfies

$$\lim_{n \rightarrow \infty} \mathbb{E}[X^{(l)}] = \int_a^b e^{A(c)} c^{-5/2} (2\pi)^{-1/2} (c_l c^{3l/2}) dc$$

and letting X^* be the total number of components of size between $an^{2/3}$ and $bn^{2/3}$

$$\lim_{n \rightarrow \infty} \mathbb{E}[X^*] = \int_a^b e^{A(c)} c^{-5/2} (2\pi)^{-1/2} g(c) dc$$

where

$$g(c) = \sum_{l=0}^{\infty} c_l c^{3l/2}$$

a sum convergent for all c . A component of size $\sim cn^{2/3}$ will have probability $c_l c^{3l/2}/g(c)$ of having complexity l , independent of λ . As $\lim_{c \rightarrow 0} g(c) = 1$, most components of size $\epsilon n^{2/3}$, $\epsilon \ll 1$, are trees but as c gets bigger the distribution on l moves inexorably higher.

An Overview. For any fixed λ the sizes of the largest components are of the form $cn^{2/3}$ with a distribution over the constant. This distribution has support the positive reals. Thus, for example, for $\lambda = -4$ there is some positive limiting probability that the largest component is bigger than $10n^{2/3}$ and for $\lambda = +4$ there is some positive limiting probability that the largest component is smaller than $0.1n^{2/3}$, though both these probabilities are miniscule. The $c^{-5/2}$ term dominates the integral as $c \rightarrow 0^+$, reflecting the notion that for any fixed λ there should be many components of size near $\epsilon n^{2/3}$ for $\epsilon = \epsilon(\lambda)$ appropriately small. When λ is large

negative (e.g., $\lambda = -4$) the largest component is likely to be $\epsilon n^{2/3}$, ϵ small, and there will be many components of nearly that size. The nontree components will be a negligible fraction of the tree components. When λ is large positive (e.g., $\lambda = +4$) the dominant component will have begun to emerge. The largest component is likely to be $\sim 2\lambda n^{2/3}$ and of moderately high (not zero or one) complexity and the second largest component will be considerably smaller and simple.

Now consider the evolution of $G(n, p)$ in terms of λ . Suppose that at a given λ there are components of size $c_1 n^{2/3}$ and $c_2 n^{2/3}$. When we move from λ to $\lambda + d\lambda$ there is a probability $c_1 c_2 d\lambda$ that they will merge. Components have a peculiar gravitation in which the probability of merging is proportional to their sizes. With probability $(c_1^2/2) d\lambda$ there will be a new internal edge in a component of size $c_1 n^{2/3}$ so that large components rarely remain trees. Simultaneously, big components are eating up other vertices.

With $\lambda = -4$, say, we have feudalism. Many small components (castles) are each vying to be the largest. As λ increases the components increase in size and a few large components (nations) emerge. An already large France has much better chances of becoming larger than a smaller Andorra. The largest components tend strongly to merge and by $\lambda = +4$ it is very likely that a dominant component, a Roman Empire, has emerged. With high probability this component is nevermore challenged for supremacy but continues absorbing smaller components until full connectivity One World - is achieved.

18.2.11 11.11 Analogies to Classical Percolation Theory

The study of percolation has involved the intense efforts of both mathematicians and physicists for many years. A central object of that study has been bond percolation on $\mathbb{Z}^d$, as described below. Here we explore, without proofs, the fruitful analogies between that percolation and the Erdős-Rényi phase transition. A classic text in this field is Percolation by Grimmett (1999) and we shall follow its treatment.

Let $d \geq 2$. (All parameters below shall depend on the choice of d .) Let $\mathbb{Z}^d$, as usual, represent the set of $\vec{a} = (a_1, \dots, a_d)$ with a_i integers. The d -dimensional cubic lattice, written L^d , is that graph with vertices $\mathbb{Z}^d$, two vertices $\vec{a}, \vec{b}$ being adjacent if they agree on $d - 1$ coordinates and differ by one on the other coordinate. Let $p \in [0, 1]$. The random subgraph $L^d(p)$ contains each edge of L^d (and no others) with independent probability p . We let $C(\vec{a})$ denote the connected component of $L^d(p)$ containing the vertex $\vec{a}$. We generally examine $C(\vec{0})$ as, by symmetry, all $C(\vec{a})$ look the same. [In Grimmett (1999) and elsewhere the edges of L^d are called bonds and they are open with probability p and closed otherwise. The word cluster is used in place of connected component.] Naturally, as p becomes larger $L^d(p)$ will have more adjacencies. There is a critical probability, denoted by p_c , at which $L^d(p)$ undergoes a macroscopic change.

- For $p < p_c$, the subcritical region, all connected components are finite.
- For $p > p_c$, the supercritical region, there is precisely one infinite component.
- For $p = p_c$, at the critical point, the situation is particularly delicate, as discussed below.

The constant probabilities of bond percolation correspond to the parametrized probabilities $p = c/n$ in Erdős-Rényi's $G(n, p)$. The value $c = 1$ is then the critical probability in the Erdős-Rényi model. The infinite component in the bond percolation model is analogous to giant components, components of size $\Omega(n)$, in the Erdős-Rényi model. The finite components in the bond percolation model are analogous to components of size $O(\ln n)$ in the Erdős-Rényi model.

The uniqueness of the infinite component in bond percolation was an open question (though the physicists "knew" it was true!) for many years. It was proved by Aizenman, Kesten and

Newman (1987) and the Book Proof is given by Burton and Keane (1989). This corresponds to the uniqueness of the giant component in $G(n, p)$.

In the bond percolation model there are only three choices for p : it can be less than, greater than, or equal to p_c . The barely subcritical and barely supercritical phases of the Erdős-Rényi model correspond to an asymptotic study of the bond percolation model as p approaches p_c from below and from above, respectively. This study is done through the use of critical exponents as described below.

Set $\theta(p) = \Pr[C(\vec{0}) \text{ is infinite}]$. For $p < p_c$, $\theta(p) = 0$ as with probability one there are no infinite components. For $p > p_c$, $\theta(p) > 0$. This corresponds to the infinite component having positive density, strengthening the analogy to the giant components of the Erdős-Rényi model. When p is barely greater than p_c there will be an infinite component but its density will be very small. The critical exponent β is that real number so that

$$\theta(p) = (p - p_c)^{\beta+o(1)} \text{ as } p \rightarrow p_c^+$$

[As mathematicians, we are aware that $\theta(p)$ could behave erratically as $p \rightarrow p_c^+$ and β might not exist. This holds for all critical exponents we discuss. For a physicist, there is no doubt that the critical exponents do exist, and they can tell you the values to a few decimal places!] Analogously, in the Erdős-Rényi model $\theta(c)$ is the proportion of points in the giant component, that $y = y(c) > 0$ satisfying (11.2). From (11.5), $y(1 + \varepsilon) \sim 2\varepsilon$ as $\varepsilon \rightarrow 0^+$. Therefore $\beta = 1$.

The susceptibility, denoted by $\chi(p)$ (not to be confused with chromatic number), is given by $\chi(p) = E[|C(\vec{0})|]$. For $p > p_c$, $\chi(p) = \infty$ as with positive probability $C(\vec{0})$ is infinite. For $p < p_c$, $\chi(p)$ is finite and $\chi(p) \rightarrow \infty$ as $p \rightarrow p_c^-$. That the susceptibility approaches infinity at the same critical value for which an infinite component appears is not at all obvious and was one of the great developments of the field, due independently to Aizenman and Barsky (1987) and Men'shikov (1986). When p is barely less than p_c , $\chi(p)$ will be finite but large. The critical number γ is that real number so that

$$\chi(p) = (p_c - p)^{-\gamma+o(1)} \text{ as } p \rightarrow p_c^-$$

Analogously, in the Erdős-Rényi model we examine $E[|C(v)|]$ in $G(n, (1 - \varepsilon)/n)$. In the subcritical region this is well mirrored by $T_{1-\varepsilon}$, the total size of a subcritical Poisson branching process. We find $E[T_{1-\varepsilon}]$ by looking at each generation. There is one root Eve, who has an expected number $1 - \varepsilon$ children. They behave similarly and so Eve has an expected number $(1 - \varepsilon)^2$ grandchildren. This continues; there are an expected number $(1 - \varepsilon)^i$ nodes in the i th generation so that

$$E[T_{1-\varepsilon}] = \sum_{i=0}^{\infty} (1 - \varepsilon)^i = \varepsilon^{-1}$$

precisely. Therefore $\gamma = 1$.

While $\chi(p)$ is infinite in the supercritical region we can examine the "finite portion" of $L^d(p)$. The finite susceptibility χ^f is given by

$$\chi^f(p) = E[|C(\vec{0})| \mid C(\vec{0}) \text{ is finite}]$$

When p is barely greater than p_c , $\chi^f(p)$ will be finite but large. The critical number γ' is the real number satisfying

$$\chi^f(p) = (p - p_c)^{-\gamma'+o(1)} \text{ as } p \rightarrow p_c^+$$

The Erdős-Rényi analogue is $E[|C(v)|]$ in $G(n, (1 + \varepsilon)/n)$, conditional on v not being in the giant component. In $G(n, (1 + \varepsilon)/n)$, $|C(v)|$ has basically distribution $T_{1+\varepsilon}^{po}$, with the value

$T_{1+\varepsilon}^{po} = \infty$ corresponding to being in the giant component. The finite analogue then corresponds to $T_{1+\varepsilon}^{po}$, conditional on it being finite. The probability that $T_{1+\varepsilon}^{po}$ is finite approaches one as $\varepsilon \rightarrow 0^+$. The Poisson branching processes $T_{1+\varepsilon}^{po}, T_{1-\varepsilon}^{po}$ have nearly the same finite distribution. Conditioning on v not being in the giant component, $|C(v)|$ then behaves like $T_{1-\varepsilon}^{po}$. Therefore $\gamma' = 1$.

At the critical value $p = p_c$, all components are finite. The distribution of $|C(\vec{0})|$ will have a heavy tail. The critical number δ is that real number so that at $p = p_c$

$$\Pr[|C(\vec{0})| \geq s] = s^{-1/\delta+o(1)} \text{ as } s \rightarrow \infty$$

For the Erdős-Rényi analogue we consider $|C(v)|$ in $G(n, 1/n)$. One needs to be cautious about the double limit. For any fixed s ,

$$\lim_{n \rightarrow \infty} \Pr[|C(v)| \geq s] = \Pr[T_1^{po} \geq s] = \Theta(s^{-1/2})$$

from (11.3). Therefore $\delta = 2$.

We further examine the gap exponent, denoted by Δ . In the subcritical region the distribution of $|C(\vec{0})|$ drops off exponentially. For each $k \geq 1$ it has a finite k th moment. The hypothetical quantity Δ is such that

$$\frac{\mathbb{E}[|C(\vec{0})|^{k+1}]}{\mathbb{E}[|C(\vec{0})|^k]} = (p_c - p)^{-\Delta+o(1)}$$

The belief is that Δ does not depend on the choice of k . In the supercritical region the belief is that the same asymptotics hold when the infinite component is erased. More precisely, the belief is that

$$\frac{\mathbb{E}[|C(\vec{0})|^{k+1} \mid C(\vec{0}) \text{ is finite}]}{\mathbb{E}[|C(\vec{0})|^k \mid C(\vec{0}) \text{ is finite}]} = (p_c - p)^{-\Delta+o(1)}$$

for all $k \geq 1$. In the Erdős-Rényi analogue the distribution of $C(v)$ in $G(n, (1 - \varepsilon)/n)$ mirrors that of $T_{1-\varepsilon}^{po}$. [The supercritical $G(n, (1 + \varepsilon)/n)$, with its giant component erased, behaves similarly.] From Section 11.4, $\Pr[T_{1-\varepsilon}^{po} = s]$ drops like $s^{-3/2}$ until k reaches $\Theta(\varepsilon^{-2})$ when it begins its exponential drop-off. The region of exponential drop-off has negligible effect on the finite moments. The k th moment of $T_{1-\varepsilon}^{po}$ is basically the sum of $s^{-3/2}s^k$ for $s = O(\varepsilon^{-2})$, which is of order $(\varepsilon^{-2})^{k+1/2}$, or ε^{-2k-1} . The ratio of the $(k + 1)$ st and k th moments is then $\Theta(\varepsilon^{-2})$. Therefore $\Delta = 2$.

For bond percolation in $\mathbb{Z}^d$ define the triangle function

$$T(p) = \sum_{\vec{x}, \vec{y} \in \mathbb{Z}^d} \Pr[\vec{0} \leftrightarrow \vec{x}] \Pr[\vec{0} \leftrightarrow \vec{y}] \Pr[\vec{x} \leftrightarrow \vec{y}],$$

where $\vec{x} \leftrightarrow \vec{y}$ means that $\vec{x}, \vec{y}$ lie in the same component. In Aizenman and Newman (1984) the following condition was introduced.

The Triangle Condition: $T(p_c) < \infty$.

They showed that when the triangle condition holds some of the conditions for mean field theory (as discussed below) are valid. For the Erdős-Rényi percolation analogue we fix a vertex v of $G(n, p)$ and define the discrete triangle function

$$T(p) = \sum_{x, y} \Pr[v \leftrightarrow x] \Pr[v \leftrightarrow y] \Pr[x \leftrightarrow y]$$

The critical probability p_c is replaced by $p = n^{-1}$. Finiteness is replaced by the boundedness giving the following.

The Discrete Triangle Condition: $T(p) = O(1)$.

The contribution to $T(p)$ when two or three of v, x, y are equal is easily bounded, leaving the contribution from all triples v, x, y of distinct vertices. As all pairs behave the same and there are $(n-1)(n-2) \sim n^2$ terms,

$$T(p) \sim O(1) + n^2 \Pr[v \leftrightarrow x]^3$$

and

$$\Pr[v \leftrightarrow x] = \sum_t \Pr[|C(v)| = t] \frac{t-1}{n-1} \sim n^{-1} \sum_t t \Pr[|C(v)| = t].$$

We know that $\Pr[|C(v)| = t]$ behaves like $t^{-3/2}$ until t reaches $\Theta(n^{2/3})$ and then drops off exponentially. Ignoring constants,

$$\sum_t t \Pr[|C(v)| = t] = \Theta \left(\sum_{t=\Theta(n^{2/3})} t t^{-3/2} \right) = \Theta \left((n^{2/3})^{1/2} \right)$$

Now $\Pr[v \leftrightarrow x] = \Theta(n^{-2/3})$. [Basically, the main contribution to $\Pr[v \leftrightarrow x]$ comes when v lies in a component of size $\Theta(n^{2/3})$, even though that rarely occurs.] The triangle condition does hold as

$$T(p) = O(1) + O(n^2) \Theta(n^{-2/3})^3 = O(1)$$

The discrete triangle condition does not hold in the barely supercritical region. There $\Pr[v \leftrightarrow x]$ is dominated by the probability that both v, w lie in the dominant component. As the dominant component has size $\gg n^{2/3}$, $\Pr[v \leftrightarrow x] \gg n^{-2/3}$, and $T(p) \gg 1$. This is not mere serendipity. Rather, the boundedness of $T(p)$ provides a natural boundary between the critical window and the barely supercritical region for discrete random structures. This connection is explored in depth in Borgs, Chayes, van der Hofstad, Slade and Spencer (2005) and the recent lecture notes of Slade (2006).

Hara and Slade (1990) [see also the survey by Hara and Slade (1994)] proved that the triangle condition holds in the bond percolation model for sufficiently high dimensions d . [More precisely, they showed that $T(p)$ could be made very small by taking p slightly less than p_c . Their argument works for $d \geq 19$ and for all $d > 6$ with a somewhat different model. It is strongly believed that the condition does hold for all $d > 6$.] Building on that, they found that the critical exponent values $\beta = 1$, $\gamma = \gamma' = 2$, $\delta = 2$ and $\Delta = 2$ hold for those d . Mathematical physicists have a term mean field, which, quoting Grimmett, "permits several interpretations depending on context." A commonly held requirement is that the critical exponents have the values given above. Thus bond percolation for $d \geq 19$ is regarded as exhibiting mean field behavior. Using the analogues described above it seems reasonable to say that the Erdős-Rényi model exhibits mean field behavior.

18.2.12 11.12 Exercises

1. Consider the Poisson branching model with mean $c = 1$ and root Eve. For $n \geq 3$ let A_n be the event that Eve has precisely two children, Dana and Fan, and that the total tree size $T = n$. Let X be the size of the subtree with root Dana. For each $j \geq 1$ find $\lim_{n \rightarrow \infty} \Pr[X = j \mid A_n]$. Find an asymptotic formula for $\Pr[n/3 < X < 2n/3]$.

2. Consider the binomial branching model with parameters m, p and $mp > 1$. Set $y = y(m, p) = \Pr[T = \infty]$. Give an implicit equation for y analogous to (11.2). With m fixed set $mp = (1 + \epsilon)$. Find

$$\lim_{\epsilon \rightarrow 0^+} \frac{y(m, p)}{\epsilon}$$

3. Let $c > 1$. Let $Z_i, i = 1, 2, \dots$ be independent Poisson variables with mean c . For $a > 1$ consider the walk defined by initial condition $Y_1 = a$ and recursion $Y_t = Y_{t-1} + Z_i - 1$ for $t \geq 2$. Use Chernoff bounds to show

$$\lim_{a \rightarrow \infty} \sum_{t \geq 2} \Pr[Y_t \leq 0] = 0$$

Use this to show that the random walk defined by initial condition $Y_0 = 1$ and recursion $Y_t = Y_{t-1} + Z_t - 1$ for $t \geq 1$ has a positive probability of being positive for all t .

4. An Openended Computer Experiment. Begin with vertices $1, \dots, n$ ($n = 10^6$ is very quick when done right) and no edges. Each round pick two random vertices and add an edge between them. Use a Union-Find algorithm to keep track of the components and the component sizes. Parametrize round number E by $E/\binom{n}{2} = 1/n + \lambda n^{-4/3}$ and concentrate on the region $-4 \leq \lambda \leq +4$. Update the ten largest component sizes, noting particularly when two of the ten largest components merge. Watch the barely subcritical picture at $\lambda = -4$

turn into a barely supercritical picture at $\lambda = +4$ as the bulk of the moderate size components merge to form a dominant component.

The Probabilistic Lens: the Rich Get Richer

Consider two bins, each of which initially has one ball. At each time $u = 1, 2, \dots$ we add one ball to one of the bins. The ball is placed randomly, in proportion to the square of the number of balls already in the bin. [For example, if the bins have 5 balls and 3 balls, respectively, the next ball is placed in the bin with 5 balls with probability $25/(25 + 9)$.]

Theorem 1 With probability one, one of the bins will get all but a finite number of the balls.

Proof. We move to a continuous time model. Let X_i be independent random variables, X_i having the exponential distribution with mean i^{-2} . (That is, X_i has density function $i^2 e^{-ti^2}$ for $t \geq 0$.) At time zero the first bin has one ball. It receives its second ball at time X_1 . In general, it receives its i th ball time X_i after receiving its $(i - 1)$ st ball. Let X'_i also be independent exponential distributions with mean i^{-2} , independently chosen from the X_i . The second bin receives its balls according to the X'_i . The process ends when an infinite number of balls have been placed. The fictitious continuation, of defining the X_i, X'_i for all $i \geq 1$, shall be helpful in the analysis.

We use two basic properties of exponential distributions. Both are easy calculus exercises.

Proposition 2 Let X be exponential with mean μ and let $a > 0$. Then $X - a$, conditional on $X \geq a$, is also exponential with mean μ .

This is often called the forgetfulness property.

Proposition 3 Let X, X' be independent exponentials with means μ, ν , respectively. Then

$$\Pr[\min\{X, X'\} = X] = \frac{\mu^{-1}}{\mu^{-1} + \nu^{-1}}$$

The continuous time process mirrors the sequential process. Clearly the first ball is equally likely to go into either of the two bins. Suppose at some time $t > 0$ the first (say) bin has just

received its i th ball and the second bin last received its j th ball at time $t' < t$. (When the second bin has not yet received its second ball set $j = 1$ and $t' = 0$.) The waiting time for the first bin is then X_i . The waiting time for the second was X_j at time t' . By the forgetfulness property its conditional waiting time at time t is X_j^* , exponential with mean j^{-2} . The next ball goes into the first bin if and only if $\min\{X_i, X_j^*\} = X_i$, which occurs with probability $i^2/(i^2 + j^2)$ as desired.

Let $T = \sum_{i=1}^{\infty} X_i, T' = \sum_{i=1}^{\infty} X'_i$ be the total times for the bins to receive (under fictitious continuation) an infinite number of balls. As $E[X_i] = E[X'_i] = i^{-2}$ and (critically!) $\sum_{i=1}^{\infty} i^{-2}$ converges, both T, T' have finite means and so are finite with probability one. As sums of independent continuous distributions $\Pr[T = T'] = 0$. Suppose $T < T'$, the other case being identical. At time T the first bin has received an infinite number of balls. The second bin has not. Therefore the second bin has received only a finite number of balls!

18.3 12 Circuit Complexity

Abstract

It is not knowledge, but the act of learning, not possession but the act of getting there, which grants the greatest enjoyment. When I have clarified and exhausted a subject, then I turn away from it, in order to go into darkness again; the never-satisfied man is so strange - if he has completed a structure then it is not in order to dwell in it peacefully, but in order to begin another. I imagine the world conqueror must feel thus, who, after one kingdom is scarcely conquered, stretches out his arms for another.

- Karl Friedrich Gauss

18.3.1 12.1 Preliminaries

A Boolean function $f = f(x_1, \dots, x_n)$ on the n variables $x_1, x_2, \dots, x_n$ is simply a function $f : \{0, 1\}^n \rightarrow \{0, 1\}$. In particular, $0, 1, x_1 \wedge \dots \wedge x_n, x_1 \vee \dots \vee x_n$ and $x_1 \oplus \dots \oplus x_n$ denote, as usual, the two constant functions, the And function (whose value is 1 iff $x_i = 1$ for all i), the OR function (whose value is 0 iff $x_i = 0$ for all i) and the parity function (whose value is 0 iff an even number of variables x_i is 1), respectively. For a function f , we let $\bar{f} = f \oplus 1$ denote its complement Not f . The functions x_i and $\bar{x}_i$ are called atoms. In this section we consider the problem of computing various Boolean functions efficiently. A circuit is a directed, acyclic graph, with a special vertex with no outgoing edges called the output vertex. Every vertex is labeled by a Boolean function of its immediate parents and the vertices with no parents (i.e., those with no ingoing edges) are labeled either by one of the variables x_i or by a constant 0 or 1. For every assignment of binary values to each variable x_i one can compute, recursively, the corresponding value of each vertex of the circuit by applying the corresponding function labeling it to the already computed values of its parents. We say that the circuit computes the function $f = f(x_1, \dots, x_n)$ if for each $x_i \in \{0, 1\}$, the corresponding value of the output vertex of the circuit equals $f(x_1, \dots, x_n)$. For example, Figure 12.1 presents a circuit computing $f(x_1, x_2, x_3) = (x_1 \oplus (x_2 \wedge x_3)) \wedge x_1$.

Fig. 12.1 A binary circuit for $\left(x_1 \oplus (x_2 \wedge x_3)\right) \wedge x_1$.

If every fanout in a circuit is at most one (i.e., the corresponding graph is a tree) the circuit is called a formula. If every fanin in a circuit is at most two the circuit is called a binary circuit. Therefore the circuit in Figure 12.1 is binary, but it is not a formula. The size of a circuit is the number of vertices in it and its depth is the maximum length (number of edges) of a directed path in it. The binary circuit complexity of a Boolean function is the size of the smallest binary circuit computing it. An easy counting argument shows that for large n the binary circuit complexity of almost all the functions of n variables is at least $(1 + o(1))2^n/n$. This is because the number of binary circuits of size s on n variables can be shown to be less than $(c(s + n))^s$, whereas the total number of Boolean functions on n variables is 2^{2^n} . On the other hand, there is no known nonlinear, not to mention exponential (in n), lower bound for the binary circuit complexity of any "explicit" function. By "explicit" here we mean an NP-function, that is, one of a family $\{f_{n_i}\}_{i \geq 1}$ of Boolean functions, where f_{n_i} has n_i variables, $n_i \rightarrow \infty$, and there is a nondeterministic Turing machine that, given n_i and $x_1, \dots, x_{n_i}$, can decide in (nondeterministic) polynomial time (in n_i) if $f_{n_i}(x_1, \dots, x_{n_i}) = 1$. [An example for such a family is the $(n/2)$ -clique function; here $n_i = \binom{i}{2}$, the n_i variables $x_1, \dots, x_{n_i}$ represent the edges of a graph on i vertices and $f_{n_i}(x_1, \dots, x_{n_i}) = 1$ iff the corresponding graph contains a clique on at least $i/2$ vertices.] Any nonpolynomial lower bound for the binary circuit complexity of an explicit function would imply (among other things) that $\mathbf{P} \neq \mathbf{NP}$ and thus solve the arguably most important open problem in theoretical computer science. Unfortunately, at the moment, the best known lower bound for the binary circuit complexity of an explicit function of n variables is only $3n$ [see Blum (1984), Paul (1977)]. However, several nontrivial lower bounds are known when we impose certain restrictions on the structure of the circuits. Most of the known proofs of these bounds rely heavily on probabilistic methods. In this chapter we describe some of these results. We note that there are many additional beautiful known results about circuit complexity; see, for example, Wegener (1987) and Karchmer and Wigderson (1990), but those included here are not only among the crucial ones, but also represent the elegant methods used in this field. Since most results in this chapter are asymptotic we assume, throughout the chapter, whenever it is needed, that the number of variables we have is sufficiently large.

18.3.2 12.2 Random Restrictions and Bounded-depth Circuits

Let us call a Boolean function G a t -And-Or if it can be written as an And of an arbitrary number of functions, each being an Or of at most t atoms; that is, $G = G_1 \wedge \cdots \wedge G_w$, where $G_i = y_{i1} \vee \cdots \vee y_{ia_i}$, $a_i \leq t$ and each y_{ij} is an atom. Similarly, we call a Boolean function an s -Or-And, if it can be written as an Or of And gates each containing at most s atoms. A minterm of a function is a minimal assignment of values to some of the variables that forces the function to be 1. Its size is the number of variables whose values are set. Note that a function is an s -OrAnd if and only if each of its minterms is of size at most s . A restriction is a map ρ of the set of indices $\{1, \dots, n\}$ to the set $\{0, 1, *\}$. The restriction of the function $G = G(x_1, \dots, x_n)$ by ρ , denoted by $G|_\rho$, is the Boolean function obtained from G by setting the value of each x_i for $i \in \rho^{-1}\{0, 1\}$ to $\rho(i)$, and leaving each x_j for $j \in \rho^{-1}\{*\}$ as a variable. Thus, for example, if $G(x_1, x_2, x_3) = (x_1 \wedge x_2) \vee x_3$ and $\rho(1) = 0, \rho(2) = \rho(3) = *$, then $G|_\rho = x_3$. For $0 \leq p \leq 1$, a random p -restriction is a random restriction ρ defined by choosing for each $1 \leq i \leq n$ independently the value of $\rho(i)$ according to the following distribution:

$$\Pr[\rho(i) = *] = p, \quad \Pr[\rho(i) = 0] = \Pr[\rho(i) = 1] = (1 - p)/2. \quad (12.1)$$

Improving the results of Furst, Saxe and Sipser (1984), Ajtai (1983) and Yao (1985), Håstad (1988) proved the following result, which is very useful in establishing lower bounds for bounded-depth circuits.

Lemma 12.2.1 [The Switching Lemma] Let $G = G(x_1, \dots, x_n)$ be a t -And-Or, that is, $G = G_1 \wedge G_2 \wedge \cdots \wedge G_w$, where each G_i is an Or of at most t atoms. Let ρ be the random restriction defined by (12.1). Then

$$\begin{aligned} & \Pr \left[G|_\rho \text{ is not an } (s-1)\text{-Or-AND} \right] \\ &= \Pr \left[G|_\rho \text{ has a minterm of size } \geq s \right] \leq (5pt)^s. \end{aligned}$$

Proof. Let E_s be the event that $G|_\rho$ has a minterm of size at least s . To bound $\Pr[E_s]$, we prove a stronger result; for any Boolean function F ,

$$\Pr[E_s | F|_\rho \equiv 1] \leq (5pt)^s \quad (12.2)$$

Here we agree that if the condition is unsatisfied then the conditional probability is 0. Lemma 12.2.1 is obtained from (12.2) by taking $F \equiv 1$. We prove (12.2) by induction on w . For $w = 0$, $G \equiv 1$ and there is nothing to prove. Assuming (12.2) holds whenever the number of G_i is less than w , we prove it for w . Put $G = G_1 \wedge G^*$, where $G^* = G_2 \wedge \cdots \wedge G_w$, and let E_s^* be the event that $G^*|_\rho$ has a minterm of size at least s . By interchanging, if necessary, some of the variables with their complements we may assume, for convenience, that $G_1 = \bigvee_{i \in T} x_i$, where $|T| \leq t$. Either $G_1|_\rho \equiv 1$ or $G_1|_\rho \not\equiv 1$. In the former case, E_s holds if and only if E_s^* holds and hence, by induction,

$$\Pr[E_s | F|_\rho \equiv 1, G_1|_\rho \equiv 1] = \Pr[E_s^* | (F \wedge G_1)|_\rho \equiv 1] \leq (5pt)^s \quad (12.3)$$

The case $G_1|_\rho \not\equiv 1$ requires more work. In this case, any minterm of $G|_\rho$ must assign a value 1 to at least one x_i , for $i \in T$. For a nonempty $Y \subseteq T$ and for a function $\sigma : Y \rightarrow \{0, 1\}$ that is not identically 0, let $E_s(Y, \sigma)$ be the event that $G|_\rho$ has a minterm of size at least s which assigns the value $\sigma(i)$ to x_i for each $i \in Y$ and does not assign any additional values to variables x_j with $j \in T$. By the preceding remark,

$$\Pr[E_s | F|_\rho \equiv 1, G_1|_\rho \not\equiv 1] \leq \sum_{Y, \sigma} \Pr[E_s(Y, \sigma) | F|_\rho \equiv 1, G_1|_\rho \not\equiv 1] \quad (12.4)$$

Observe that the condition $G_1|_\rho \not\equiv 1$ means precisely that $\rho(i) \in \{0, *\}$ for all $i \in T$ and hence, for each $i \in T$,

$$\Pr \left[\rho(i) = * | G_1|_\rho \not\equiv 1 \right] = \frac{p}{p + (1-p)/2} = \frac{2p}{1+p}$$

Thus, if $|Y| = y$,

$$\Pr \left[\rho(Y) = * | G_1|_\rho \not\equiv 1 \right] \leq \left(\frac{2p}{1+p} \right)^y$$

The further condition $F|_\rho \equiv 1$ can only decrease this probability. This can be shown using the FKG Inequality (see Chapter 6). It can also be shown directly as follows. For any fixed $\rho' : N - Y \rightarrow \{0, 1, *\}$, where $N = \{1, \dots, n\}$, we claim that

$$\Pr \left[\rho(Y) = * | F|_\rho \equiv 1, G_1|_\rho \not\equiv 1, \rho|_{N-Y} = \rho' \right] \leq \left(\frac{2p}{1+p} \right)^y$$

Indeed, the given ρ' has a unique extension ρ with $\rho(Y) = *$. If that ρ does not satisfy the above conditions, then the conditional probability is zero. If it does, then so do all extensions p with $p(i) \in \{0, *\}$ for $i \in Y$, and so the inequality holds in this case too. As this holds for all fixed ρ' we conclude that indeed

$$\Pr \left[\rho(Y) = * | F|_\rho \equiv 1, G_1|_\rho \not\equiv 1 \right] \leq \left(\frac{2p}{1+p} \right)^y \leq (2p)^y \quad (12.5)$$

Let $\rho' : T \rightarrow \{0, *\}$ satisfy $\rho(Y) = *$ and consider all possible restrictions ρ satisfying $\rho|_T = \rho'$. Under this condition, ρ may be considered as a random restriction on $N - T$. The event $F|_\rho \equiv 1$ reduces to the event $\tilde{F}|_{\rho|_{N-T}} \equiv 1$, where $\tilde{F}$ is the And of all functions obtained from F by substituting the values of x_i according to ρ' for those $i \in T$ with $\rho'(i) = 0$, and by taking all possibilities for all the other variables x_j for $j \in T$. If the event $E_s(Y, \sigma)$ occurs then $G^*|_{\rho\sigma}$ has a minterm of size at least $s - y$ that does not contain any variable x_i with $i \in T - Y$. But this happens if and only if $\tilde{G}|_{\rho|_{N-T}}$ has a minterm of size at least $s - y$, where $\tilde{G}$ is the function obtained from G^* by substituting the values of x_j for $j \in Y$ according to σ , the values of x_i for $i \in T - Y$ and $\rho'(i) = 0$ according to ρ' and by removing all the variables x_k with $k \in T - Y$ and $\rho'(k) = *$. Denoting this event by $\tilde{E}_{s-y}$ we can apply induction and obtain $\Pr \left[E_s(Y, \sigma) | F|_\rho \equiv 1, G_1|_\rho \not\equiv 1, \rho|_T = \rho' \right] \leq \Pr \left[\tilde{E}_{s-y} | \tilde{F}|_\rho \equiv 1 \right] \leq (5pt)^{s-y}$. Since any ρ with $F|_\rho \equiv 1, G_1|_\rho \equiv 1, \rho(Y) = *$ must have $\rho|_T = \rho'$ for some ρ' of this form, and since the event $E_s(Y, \sigma)$ may occur only if $\rho(Y) = *$ we conclude that

$$\Pr \left[E_s(Y, \sigma) | F|_\rho \equiv 1, G_1|_\rho \not\equiv 1, \rho(Y) = * \right] \leq (5pt)^{s-y}$$

and, by (12.5),

$$\begin{aligned} & \Pr \left[E_s(Y, \sigma) | F|_\rho \equiv 1, G_1|_\rho \not\equiv 1 \right] \\ &= \Pr \left[\rho(Y) = * | F|_\rho \equiv 1, G_1|_\rho \not\equiv 1 \right] \\ & \quad \cdot \Pr \left[E_s(Y, \sigma) | F|_\rho \equiv 1, G_1|_\rho \not\equiv 1, \rho(Y) = * \right] \\ & \leq (2p)^y (5pt)^{s-y} \end{aligned}$$

Substituting in (12.4) and using the fact that $|T| \leq t$ and that

$$\sum_{y=1}^t \frac{(2^y - 1) 2^y}{5^y y!} \leq \frac{2}{5} + \sum_{y=2}^{\infty} \frac{(4/5)^y}{y!} = \frac{2}{5} + e^{4/5} - 1 - \frac{4}{5} < 1$$

we obtain

$$\begin{aligned} & \Pr [E_s | F|_{\rho} \equiv 1, G_1|_{\rho} \not\equiv 1] \\ & \leq \sum_{y=1}^{|T|} \binom{|T|}{y} (2^y - 1) (2p)^y (5pt)^{s-y} \leq (5pt)^s \sum_{y=1}^t \frac{t^y}{y!} (2^y - 1) \left(\frac{2}{5t}\right)^y \\ & = (5pt)^s \sum_{y=1}^t (2^y - 1) \cdot \frac{2^y}{5^y \cdot y!} \leq (5pt)^s \end{aligned}$$

This, together with (12.3), gives

$$\Pr [E_s | F|_{\rho} \equiv 1] \leq (5pt)^s$$

completing the induction and the proof.

By taking the complement of the function G in Lemma 12.2.1 and applying De Morgan's rules one clearly obtains its dual form: If G is a t -OR-AND and ρ is the random restriction given by (12.1) then

$$\Pr [G|_{\rho} \text{ is not an } (s-1)\text{-AND-OR}] \leq (5pt)^s$$

We now describe an application of the switching lemma that supplies a lower bound to the size of circuits of small depth that compute the parity function $x_1 \oplus \cdots \oplus x_n$. We consider circuits in which the vertices are arranged in levels; those in the first level are atoms (i.e., variables or their complements) and each other gate is either an Or or an AND of an arbitrary number of vertices from the previous level. We assume that the gates in each level are either all And gates or all Or gates, and that the levels alternate between And levels and Or levels. A circuit of this form is called a $C(s, s', d, t)$ -circuit if it contains at most s gates, at most s' of which are above the second level, its depth is at most d and the fanin of each gate in its second level is at most t . Thus, for example, the circuit that computes the parity function by computing an Or of the 2^{n-1} terms $x_1^{\varepsilon_1} \wedge \cdots \wedge x_n^{\varepsilon_n}$, where $(\varepsilon_1, \dots, \varepsilon_n)$ ranges over all even binary vectors and $x_i^{\varepsilon_i} = x_i \oplus \varepsilon_i$, is a $C(2^{n-1} + 1, 1, 2, n)$ -circuit.

Theorem 12.2.2 Let $f = f(x_1, \dots, x_n)$ be a function and let C be a $C(\infty, s, d, t)$ circuit computing f , where $s(1/2)^t \leq 0.5$. Then either f or its complement $\bar{f}$ has a minterm of size at most $n - n / \lceil 2(10t)^{d-2} \rceil + t$.

Proof. Let us apply to C , repeatedly, $d-2$ times a random $(1/10t)$ -restriction. Each of these random restrictions, when applied to any bottom subcircuit of depth 2, transforms it by Lemma 12.2.1 with probability at least $1 - (1/2)^t$ from a t -Or-And to a t -And-OR (or conversely). If all these transformations succeed we can merge the new And gates with these from the level above them and obtain a circuit with a smaller depth. As the total size of the circuit is at most s and $s(1/2)^t \leq 0.5$, we conclude that with probability at least $\frac{1}{2}$, all transformations succeed and C is transformed into a $C(\infty, 1, 2, t)$ -circuit. Each variable x_i , independently, is still a variable (i.e., has not been assigned a value) with probability $1/(10t)^{d-2}$. Thus the number of remaining variables is a binomial random variable with expectation $n/(10t)^{d-2}$ and a little smaller variance. By the standard estimates for binomial distributions (see Appendix A) the probability that at least $n/2(10t)^{d-2}$ variables are still variables is more than $\frac{1}{2}$. Therefore, with positive probability, at most $n - n/2(10t)^{d-2}$ of the variables have been fixed and the resulting

restriction of f has a $C(\infty, 1, 2, t)$ -circuit; that is, its value can be fixed by assigning values to at most t additional variables. This completes the proof.

Corollary 12.2.3 For any $d \geq 2$, there is no

$$C\left(\infty, \frac{1}{2} \cdot 2^{(1/10)n^{1/(d-1)}}, d, \frac{1}{10}n^{1/(d-1)}\right)\text{-circuit}$$

that computes the parity function $f(x_1, \dots, x_n) = x_1 \oplus \dots \oplus x_n$.

Proof. Assuming there is such a circuit we obtain, by Theorem 12.2.2, that the value of f can be fixed by assigning values to at most $n - \frac{1}{2}n^{1/(d-1)} + \frac{1}{10}n^{1/(d-1)} < n$ variables. This is false, and hence there is no such circuit.

The estimate in Corollary 12.2.3 is, in fact, nearly the best possible. Since every $C(s, s', d, t)$ -circuit can be transformed into a $C((t+1)s, s, d+1, 2)$ -circuit (by replacing each atom by an Or or And of two copies of itself), Corollary 12.2.3 easily implies that the depth d of any $C(s, s', d, t)$ -circuit of polynomial size that computes the parity of n bits is at least $\Omega(\log n / \log \log n)$. This lower bound is also optimal.

18.3.3 12.3 More on Bounded-depth Circuits

In the previous section we saw that the parity function is hard to compute in small depth using And, Or and Not gates. It turns out that even if we allow the use of parity gates (in addition to the And, Or and Not gates) there are still some relatively simple functions that are hard to compute. Such a result was first proved by Razborov (1987). His method was modified and strengthened by Smolensky (1987). For an integer $k \geq 2$, let $\text{Mod}_k(x_1, x_2, \dots, x_n)$ be the Boolean function whose value is 1 iff $\sum x_i \not\equiv 0 \pmod{k}$. Smolensky showed that for every two powers p and q of distinct primes, the function Mod_p cannot be computed in a bounded-depth polynomial-size circuit that uses And, Or, Not and Mod_q gates. Here we present the special case of this result in which $q = 3$ and $p = 2$.

Let C be an arbitrary circuit of depth d and size s consisting of And, Or, Not and Mod_3 gates. A crucial fact, due to Razborov, is the assertion that the output of C can be approximated quite well (depending on d and s) by a polynomial of relatively small degree over $GF(3)$. This is proved by applying the probabilistic method as follows. Let us replace each gate of the circuit C by an approximate polynomial operation, according to the following rules, which guarantee that in each vertex in the new circuit we compute a polynomial over $GF(3)$, whose values are all 0 or 1 (whenever the input is a 0–1 input).

- (i) Each NOT gate $\bar{y}$ is replaced by the polynomial gate $(1 - y)$.
- (ii) Each Mod_3 gate $\text{Mod}_3(y_1, \dots, y_m)$ is replaced by the polynomial gate $(y_1 + y_2 + \dots + y_m)^2$.

The rule for replacement of Or and And gates is a little more complicated. Observe that in the two previous cases (i) and (ii) there was no approximation; the new gates compute precisely what the old ones did, for all possible Boolean values of the variables. This can, in principle, be done here too. An And gate $y_1 \wedge \dots \wedge y_m$ should simply be replaced by the product $y_1 \dots y_m$. An Or gate $y_1 \vee \dots \vee y_m$ can then be computed by De Morgan's rules. Since $y_1 \vee \dots \vee y_m = \overline{(\bar{y}_1 \wedge \dots \wedge \bar{y}_m)}$ and $\bar{y}$ is realized by $(1 - y)$, this would give

$$1 - (1 - y_1)(1 - y_2) \dots (1 - y_m) \quad (12.6)$$

The trouble is that this procedure would increase the degree of our polynomials too much. Hence we need to be a little more tricky. Let ℓ be an integer, to be chosen later. Given an Or gate $y_1 \vee \dots \vee y_m$, we choose ℓ random subsets $I_1, \dots, I_\ell$ of $\{1, \dots, m\}$, where for each $1 \leq i \leq \ell$ and for each $1 \leq j \leq m$ independently $\Pr[j \in I_i] = 1/2$. Observe that for each fixed i , $1 \leq i \leq \ell$,

the sum $\left(\sum_{j \in I_i} y_j\right)^2$ over $GF(3)$ is certainly 0 if $y_1 \vee \cdots \vee y_m = 0$ and is 1 with probability at least $1/2$ if $y_1 \vee \cdots \vee y_m = 1$. Hence, if we compute the OR function of the ℓ expressions $\left(\sum_{j \in I_i} y_j\right)^2$, $1 \leq i \leq \ell$, this function is 0 if $y_1 \vee \cdots \vee y_m = 0$ and is 1 with probability at least $1 - (1/2)^\ell$ if $y_1 \vee \cdots \vee y_m = 1$. We thus compute the Or and write it as a polynomial, in the way explained in equation (12.6). This gives

$$1 - \prod_{i=1}^{\ell} \left(1 - \left(\sum_{j \in I_i} y_j\right)^2\right). \quad (12.7)$$

Therefore in our new circuit we replace each Or gate by an approximation polynomial gate of the form described in (12.7). Once we have an approximation to an Or gate we can obtain the corresponding one for an And gate by applying De Morgan's rules. Since $y_1 \wedge \cdots \wedge y_m = (\overline{y_1} \vee \cdots \vee \overline{y_m})$ we replace each AND gate of the form $y_1 \wedge \cdots \wedge y_m$ by

$$\prod_{i=1}^{\ell} \left(1 - \left[\sum_{j \in I_i} (1 - y_j)\right]^2\right). \quad (12.8)$$

Observe that the polynomials in (12.7) and (12.8) are both of degree at most 2ℓ . Given the original circuit C of depth d and size s , we can now replace all its gates by our approximative polynomial gates and get a new circuit CP , which depends on all the random choices made in each replacement of each of the And/Or gates. The new circuit CP computes a polynomial $P(x_1, \dots, x_n)$ of degree at most $(2\ell)^d$. Moreover, for every fixed Boolean assignment to $x_1, x_2, \dots, x_n$, the probability that all the new gates compute exactly what the corresponding gates in C computed is at least $1 - s/2^\ell$. Therefore the expected number of inputs on which $P(x_1, \dots, x_n)$ is equal to the output of C is at least $2^n (1 - s/2^\ell)$. We have thus proved the following.

Lemma 12.3.1 For any circuit C of depth d and size s on n Boolean variables that uses Not, Or, And and Mod₃ gates and for any integer ℓ , there is a polynomial $P = P(x_1, \dots, x_n)$ of degree at most $(2\ell)^d$ over $GF(3)$ whose value is equal to the output of C on at least $2^n (1 - s/2^\ell)$ inputs.

In order to apply this lemma for obtaining lower bounds for the size of any circuit of the above type that computes the parity function, we need the following additional combinatorial result.

Lemma 12.3.2 For $n \geq 20$, there is no polynomial $P(x_1, \dots, x_n)$ over $GF(3)$ of degree at most $\sqrt{n}$ which is equal to the parity of $x_1, \dots, x_n$ for a set S of at least $0.9 \cdot 2^n$ distinct binary vectors $(x_1, \dots, x_n)$.

Proof. Suppose this is false, and suppose $S \subset \{0, 1\}^n$, $|S| \geq 0.9 \cdot 2^n$ and $P(x_1, \dots, x_n) = x_1 \oplus \cdots \oplus x_n$ for all $(x_1, \dots, x_n) \in S$. Define a polynomial $Q = Q(y_1, \dots, y_n)$ by

$$Q(y_1, \dots, y_n) = P(y_1 + 2, \dots, y_n + 2) - 2$$

and let

$$T = \{(y_1, \dots, y_n) \in \{1, -1\}^n : (y_1 + 2, \dots, y_n + 2) \in S\},$$

where all additions are in $GF(3)$. Clearly Q has degree at most $\sqrt{n}$ and satisfies $Q(y_1, \dots, y_n) = \prod_{i=1}^n y_i$ for all $(y_1, \dots, y_n) \in T$. Let now $G = G(y_1, \dots, y_n)$ be an arbitrary function from T to $GF(3)$. Extend it in an arbitrary way to a function from $(GF(3))^n$ to $GF(3)$ and write this function as a polynomial in n variables. [Trivially, any function from $(GF(3))^n$ to $GF(3)$ is a polynomial. This follows from the fact that it is a linear combination

of functions of the form $\prod_{i=1}^n (y_i - \varepsilon_i)(y_i - \varepsilon_i - 1)$, where $\varepsilon_i \in GF(3)$.] Replace each occurrence of y_i^2 in this polynomial by 1 to obtain a multilinear polynomial $\tilde{G}$ that agrees with G on T . Now replace each monomial $\prod_{i \in U} y_i$, where $|U| > n/2 + \sqrt{n}/2$ by $\prod_{i \notin U} y_i \cdot Q(y_1, \dots, y_n)$ and replace this new polynomial by a multilinear one, $\tilde{G}'$, again by replacing each y_i^2 by 1. Since for $y_i \in \{\pm 1\}$, $\prod_{i \notin U} y_i \cdot \prod_{i=1}^n y_i = \prod_{i \in U} y_i$, $\tilde{G}'$ is equal to G on T and its degree is at most $n/2 + \sqrt{n}/2$. However, the number of possible $\tilde{G}'$ is $3^{\sum_{i=0}^{n/2+\sqrt{n}/2} \binom{n}{i}} < 3^{0.88 \cdot 2^n}$, whereas the number of possible G is $3^{|T|} \geq 3^{0.9 \cdot 2^n}$. This is impossible, and hence the assertion of the lemma holds.

Corollary 12.3.3 There is no circuit of depth d and size $s \leq 0.1 \cdot 2^{(1/2)n^{1/2d}}$ computing the parity of $x_1, x_2, \dots, x_n$ using Not, And, Or and Mod 3 gates.

Proof. Suppose this is false and let C be such a circuit. Put $\ell = \frac{1}{2}n^{1/2d}$. By Lemma 12.3.1 there is a polynomial $P = P(x_1, \dots, x_n)$ over $GF(3)$, whose degree is at most $(2\ell)^d = \sqrt{n}$, which is equal to the parity of $x_1, \dots, x_n$ on at least $2^n \left(1 - s/2^{(1/2)n^{1/2d}}\right) \geq 0.9 \cdot 2^n$ inputs. This contradicts Lemma 12.3.2 and hence completes the proof.

18.3.4 12.4 Monotone Circuits

A Boolean function $f = f(x_1, \dots, x_n)$ is monotone if $f(x_1, \dots, x_n) = 1$ and $x_i \leq y_i$ imply $f(y_1, \dots, y_n) = 1$. A binary monotone circuit is a binary circuit that contains only binary And and Or gates. It is easy to see that a function is monotone if and only if there is a binary monotone circuit that computes it. The monotone complexity of a monotone function is the smallest size of a binary monotone circuit that computes it. Until 1985, the largest known lower bound for the monotone complexity of a monotone NP-function of n variables was $4n$. This was considerably improved in the fundamental paper of Razborov (1985), where a bound of $n^{\Omega(\log n)}$ to the k -clique function (which is 1 iff a given graph contains a clique of size k) is established. Shortly afterwards, Andreev (1985) used similar methods to obtain an exponential lower bound to a somewhat unnatural NP-function. Alon and Boppana (1987) strengthened the combinatorial arguments of Razborov and proved an exponential lower bound for the monotone circuit complexity of the clique function. In this section we describe a special case of this bound by showing that there are no linear size monotone circuits that decide if a given graph contains a triangle. Although this result is much weaker than the ones stated above, it illustrates nicely all the probabilistic considerations in the more complicated proofs and avoids some of the combinatorial subtleties, whose detailed proofs can be found in the above mentioned papers.

Put $n = \binom{m}{2}$, and let $x_1, x_2, \dots, x_n$ be n Boolean variables representing the edges of a graph on the set of vertices $\{1, 2, \dots, m\}$. Let $T = T(x_1, \dots, x_n)$ be the monotone Boolean function whose value is 1 if the corresponding graph contains a triangle. Clearly there is a binary monotone circuit of size $O(m^3)$ computing T . Thus the following theorem is tight, up to a polylogarithmic factor.

Theorem 12.4.1 The monotone circuit complexity of T is at least $\Omega(m^3 / \log^4 m)$.

Before we present the proof of this theorem we introduce some notation and prove a simple lemma. For any Boolean function $f = f(x_1, \dots, x_n)$ define

$$A(f) = \{(x_1, \dots, x_n) \in \{0, 1\}^n : f(x_1, \dots, x_n) = 1\}.$$

Clearly $A(f \vee g) = A(f) \cup A(g)$ and $A(f \wedge g) = A(f) \cap A(g)$. Let C be a monotone circuit of size s computing the function $f = f(x_1, \dots, x_n)$. Clearly C supplies a monotone straight-line program of length s computing f ; that is, a sequence of functions $x_1, x_2, \dots, x_n, f_1, \dots, f_s$, where $f_s = f$ and each f_i , for $1 \leq i \leq s$, is either an OR or an AND of two of the previous functions. By applying the operation A we obtain a sequence $A(C)$ of subsets of $\{0, 1\}^n$: $A_{-n} = A_{x_n}, \dots, A_{-1} = A_{x_1}, A_1, \dots, A_s$, where $A_{x_i} = A(x_i)$, $A_s = A(f)$ and each A_i for $1 \leq i \leq s$ is either

a union or an intersection of two of the previous subsets. Let us replace the sequence $A(C)$ by an approximating sequence $M(C) : M_{-n} = M_{x_n} = A_{x_n}, \dots, M_{-1} = M_{x_1} = A_{x_1}, M_1, \dots, M_s$ defined by replacing the union and intersection operations in $A(C)$ by the approximating operations $\sqcup$ and $\sqcap$, respectively. The exact definition of these two operations will be given later, in such a way that for all admissible M and L the inclusions

$$M \sqcup L \supseteq M \cup L \quad \text{and} \quad M \sqcap L \subseteq M \cap L \quad (12.9)$$

will hold. Thus $M_{x_i} = A_{x_i}$ for all $1 \leq i \leq n$ and if for some $1 \leq j \leq s$ we have $A_j = A_\ell \cup A_k$ then $M_j = M_\ell \sqcup M_k$, whereas if $A_j = A_\ell \cap A_k$ then $M_j = M_\ell \sqcap M_k$. In the former case put $\delta_\sqcup^j = M_j - (M_\ell \cup M_k)$ and $\delta_\sqcap^j = \emptyset$, and in the latter case put $\delta_\sqcap^j = (M_\ell \cap M_k) - M_j$ and $\delta_\sqcup^j = \emptyset$.

Lemma 12.4.2 For all members M_i of $M(C)$,

$$A_i \setminus \bigcup_{j \leq i} \delta_\sqcap^j \subseteq M_i \subseteq A_i \cup \bigcup_{j \leq i} \delta_\sqcup^j. \quad (12.10)$$

Proof. We apply induction on i . For $i < 0$, $M_i = A_i$ and thus (12.10) holds. Assuming (12.10) holds for all M_j with $j < i$ we prove it for i . If $A_i = A_\ell \cup A_k$, then, by the induction hypothesis,

$$M_i = M_\ell \cup M_k \cup \delta_\sqcup^i \subseteq A_\ell \cup A_k \cup \bigcup_{j \leq i} \delta_\sqcup^j = A_i \cup \bigcup_{j \leq i} \delta_\sqcup^j$$

and

$$\begin{aligned} M_i &= M_\ell \sqcup M_k \supseteq M_\ell \cup M_k \\ &\supseteq \left(A_\ell \setminus \bigcup_{j \leq \ell} \delta_\sqcap^j \right) \cup \left(A_k \setminus \bigcup_{j \leq k} \delta_\sqcap^j \right) \supseteq A_i \setminus \bigcup_{j \leq i} \delta_\sqcap^j \end{aligned}$$

as needed. If $A_i = A_\ell \cap A_k$ the proof is similar.

Lemma 12.4.2 holds for any choice of the operations $\sqcup$ and $\sqcap$ that satisfies (12.9). In order to prove Theorem 12.4.1 we define these operations as follows. Put $r = 100 \log^2 m$. For any set R of at most r edges on $V = \{1, 2, \dots, m\}$, let $\lceil R \rceil$ denote the set of all graphs on V containing at least one edge of R . In particular, $\lceil \emptyset \rceil$ is the empty set. We also let $\lceil * \rceil$ denote the set of all graphs. The elements of $M(C)$ will all have the form $\lceil R \rceil$ or $\lceil * \rceil$. Note that $A_{x_i} = M_{x_i}$ is simply the set $\lceil R \rceil$, where R is a singleton containing the appropriate single edge. For two sets R_1 and R_2 of at most r edges each, we define $\lceil R_1 \rceil \sqcap \lceil R_2 \rceil = \lceil R_1 \cap R_2 \rceil$, $\lceil R_1 \rceil \sqcap \lceil * \rceil = \lceil R_1 \rceil$ and $\lceil * \rceil \sqcap \lceil * \rceil = \lceil * \rceil$. Similarly, if $|R_1 \cup R_2| \leq r$ we define $\lceil R_1 \rceil \sqcup \lceil R_2 \rceil = \lceil R_1 \cup R_2 \rceil$, whereas if $|R_1 \cup R_2| > r$ then $\lceil R_1 \rceil \sqcup \lceil R_2 \rceil = \lceil * \rceil$. Finally $\lceil * \rceil \sqcup \lceil R_1 \rceil = \lceil * \rceil \sqcup \lceil * \rceil = \lceil * \rceil$.

Proof [Theorem 12.4.1]. We now prove Theorem 12.4.1 by showing that there is no monotone circuit of size $s < \binom{m}{3}/2r^2$ computing the function T . Indeed, suppose this is false and let C be such a circuit. Let $M(C) = M_{x_n}, \dots, M_{x_1}, M_1, \dots, M_s$ be an approximating sequence of length s obtained from C as described above. By Lemma 12.4.2,

$$A(T) \setminus \bigcup_{j \leq s} \delta_\sqcap^j \subseteq M_s \subseteq A(T) \cup \bigcup_{j \leq s} \delta_\sqcup^j \quad (12.11)$$

We consider two possible cases.

1. $M_s = \lceil R \rceil$, where $|R| \leq r$.

Let us choose a random triangle Δ on $\{1, 2, \dots, m\}$. Clearly

$$\Pr [\Delta \in M_s] \leq \frac{r(m-2)}{\binom{m}{3}} < \frac{1}{2}$$

Moreover, for each fixed $j \leq s$,

$$\Pr [\Delta \in \delta_{\square}^j] \leq \frac{r^2}{\binom{m}{3}}$$

This is because if $\delta_{\square}^j \neq \emptyset$, then $\delta_{\square}^j = ([R_1] \cap [R_2]) \setminus [R_1 \cap R_2]$ for some two sets of edges R_1, R_2 , each of cardinality at most r . The only triangles in this difference are those containing an edge from R_1 and another edge from R_2 (and no edge of both). Since there are at most r^2 such triangles the last inequality follows. Since $s < \binom{m}{3}/2r^2$ the last two inequalities imply that $\Pr [\Delta \notin M_s \text{ and } \Delta \notin \bigcup_{j \leq s} \delta_{\square}^j] > 0$ and thus there is such a triangle Δ . Since this triangle belongs to $A(T)$ this contradicts (12.11), showing that this case is impossible.

2. $M_s = [*]$.

Let B be a random spanning complete bipartite graph on $V = \{1, 2, \dots, m\}$ obtained by coloring each vertex in V randomly and independently by 0 or 1 and taking all edges connecting vertices with distinct colors. Since M_s is the set of all graphs, $B \in M_s$. Also $B \notin A(T)$, as it contains no triangle. We claim that for every fixed $j, j \leq s$,

$$\Pr [B \in \delta_{\square}^j] \leq 2^{-\sqrt{r}/2} < \frac{1}{m^5}. \quad (12.12)$$

Indeed, if $\delta_{\square}^j \neq \emptyset$, then $\delta_{\square}^j = [*] \setminus ([R_1] \cup [R_2])$, where $|R_1 \cup R_2| > r$. Consider the graph whose set of edges is $R_1 \cup R_2$. Let d be its maximum degree. By Vizing's Theorem the set of its edges can be partitioned into at most $d + 1$ matchings. Thus either $d > \sqrt{r}/2$ or the size of the maximum matching in this graph is at least $\sqrt{r}/2$. It follows that our graph contains a set of $k = \sqrt{r}/2$ edges $e_1, \dots, e_k$ that form either a star or a matching. In each of these two cases $\Pr [e_i \in B] = \frac{1}{2}$ and these events are mutually independent. Hence

$$\Pr [B \notin [R_1] \cup [R_2]] \leq 2^{-\sqrt{r}/2},$$

implying (12.12). Note that a similar estimate can be established without Vizing's Theorem by observing that B does not belong to $[R_1] \cup [R_2]$ if and only if the vertices in any connected component of the graph whose edges are $R_1 \cup R_2$ belong to the same color class of B .

Since $s < \binom{m}{3}/2r^2 < m^5$, inequality (12.12) implies that there is a bipartite B such that $B \in M_s$, $B \notin A(T)$ and $B \notin \bigcup_{j \leq s} \delta_{\square}^j$. This contradicts (12.11), shows that this case is impossible as well and hence completes the proof of Theorem 12.4.1. $\square$

18.3.5 12.5 Formulae

Recall that a formula is a circuit in which every fanout is at most 1. Unlike in the case of circuits, there are known superlinear lower bounds for the minimum size of formulae computing various explicit NP-functions over the full binary basis. For a Boolean function $f = f(x_1, \dots, x_n)$, let us denote by $L(f)$ the minimum number of And and Or gates in a formula that uses And, Or and Not gates and computes f . By De Morgan's rules we may assume that all Not gates appear in the first level of this formula. We conclude this chapter with a simple result of Subbotovskaya (1961), which implies that for the parity function $f = x_1 \oplus \dots \oplus x_n$, $L(f) \geq \Omega(n^{3/2})$. This bound was improved later by Khrapchenko (1971) to $L(f) = n^2 - 1$. However, we present here only the weaker $\Omega(n^{3/2})$ lower bound, not only because it demonstrates, once more, the power of relatively simple probabilistic arguments, but also because a modification of this proof

enabled Andreev (1987) to obtain an $\Omega(n^{5/2}/(\log n)^{O(1)})$ lower bound for $L(g)$ for another NP-function $g = g(x_1, \dots, x_n)$. Håstad (1998) later improved this lower bound to $\Omega(n^{3-o(1)})$. This is at present the largest known lower bound for the formula complexity of an NP-function of n variables over a complete basis.

The method of Subbotovskaya is based on random restrictions similar to the ones used in Section 12.2. The main lemma is the following.

Lemma 12.5.1 Let $f = f(x_1, \dots, x_n)$ be a nonatom Boolean function of n variables. Then there is an i , $1 \leq i \leq n$, and an $\varepsilon \in \{0, 1\}$ such that for the function $g = f(x_1, \dots, x_{i-1}, \varepsilon, x_{i+1}, \dots, x_n)$ of $n - 1$ variables obtained from f by substituting $x_i = \varepsilon$, the following inequality holds:

$$(L(g) + 1) \leq \left(1 - \frac{3}{2n}\right) (L(f) + 1) \leq \left(1 - \frac{1}{n}\right)^{3/2} (L(f) + 1).$$

Proof. Fix a formula F computing f with $l = L(f)$ And and Or gates. F can be represented by a binary tree each of whose $l+1$ leaves is labeled by an atom x_i or $\bar{x}_i$. Let us choose, randomly, a variable x_i , $1 \leq i \leq n$, according to a uniform distribution, and assign to it a random binary value $\varepsilon \in \{0, 1\}$. When we substitute the values ε and $1 - \varepsilon$ to x_i and $\bar{x}_i$, respectively, the number of leaves in F is reduced; the expected number of leaves omitted in this manner is $(l+1)/n$. However, further reduction may occur.

Indeed, suppose a leaf is labeled x_i and it feeds, say, an And gate $x_i \wedge H$ in F . Observe that we may assume that the variable x_i does not appear in the subformula H , as otherwise F can be simplified by substituting $x_i = 1$ in H . If $x_i = \varepsilon = 0$, then H can be deleted once we substitute the value for x_i , thus further decreasing the number of leaves.

Since the behavior of this effect is similar for an Or gate (and also for $\bar{x}_i$ instead of x_i), it follows that the expected number of additional leaves omitted is at least $(l+1)/2n$. Hence the expected number of remaining leaves in the simplified formula is at most $(l+1)(1 - 3/2n)$, as claimed.

By repeatedly applying Lemma 12.5.1 we obtain the following.

Corollary 12.5.2 If $f = f(x_1, \dots, x_n)$ and $L(f) \leq (n/k)^{3/2} - 1$, then one can assign values to $n - k$ variables so that the resulting function g is an atom.

Proof. Repeated application of Lemma 12.5.1 $n - k$ times yields a g with

$$(L(g) + 1) \leq \prod_{i=k+1}^n \left(1 - \frac{1}{i}\right)^{3/2} (L(f) + 1) = (k/n)^{3/2} (L(f) + 1) \leq 1$$

Hence g is either x_i or $\bar{x}_i$ for some i .

Corollary 12.5.3 For the parity function $f = x_1 \oplus \dots \oplus x_n$,

$$L(f) > \left(\frac{n}{2}\right)^{3/2} - 1$$

18.3.6 12.6 Exercises

1. Show that there exists a constant c such that the number of binary Boolean circuits of size s on n variables is at most $(c(s+n))^s$.
2. Let f be a Boolean formula in the n variables $x_1, x_2, \dots, x_n$, where f is an AND of an arbitrary (finite) number of clauses; each clause is an Or of 10 literals, where each literal is either a variable or its negation, and suppose each variable appears (negated or unnegated) in at most 10 clauses. Prove that f is satisfiable.

3. (*) Prove that there is a bounded-depth, polynomial-size, monotone circuit of n Boolean inputs $x_1, x_2, \dots, x_n$ computing a function f whose value is 1 if $\sum_{i=1}^n x_i \geq n/2 + n/\log n$ and is 0 if $\sum_{i=1}^n x_i \leq n/2 - n/\log n$.

The Probabilistic Lens: Maximal Antichains

A family $\mathcal{F}$ of subsets of $\{1, \dots, n\}$ is called an antichain if no set of $\mathcal{F}$ is contained in another.

Theorem 1 Let $\mathcal{F}$ be an antichain. Then

$$\sum_{A \in \mathcal{F}} \frac{1}{\binom{n}{|A|}} \leq 1.$$

Proof. Let σ be a uniformly chosen permutation of $\{1, \dots, n\}$ and set

$$\mathcal{C}_\sigma = \{\{\sigma(j) : 1 \leq j \leq i\} : 0 \leq i \leq n\}$$

(The cases $i = 0$ and $i = n$ give $\emptyset \in \mathcal{C}_\sigma$ and $\{1, \dots, n\} \in \mathcal{C}_\sigma$, respectively.) Define a random variable

$$X = |\mathcal{F} \cap \mathcal{C}_\sigma|$$

We decompose

$$X = \sum_{A \in \mathcal{F}} X_A,$$

where X_A is the indicator random variable for $A \in \mathcal{C}$. Then

$$\mathbb{E}[X_A] = \Pr[A \in \mathcal{C}_\sigma] = \frac{1}{\binom{n}{|A|}}$$

since $\mathcal{C}_\sigma$ contains precisely one set of size $|A|$, which is distributed uniformly among the $|A|$ -sets. By linearity of expectation,

$$\mathbb{E}[X] = \sum_{A \in \mathcal{F}} \frac{1}{\binom{n}{|A|}}$$

For any σ , $\mathcal{C}_\sigma$ forms a chain - every pair of sets is comparable. Since $\mathcal{F}$ is an antichain we must have $X = |\mathcal{F} \cap \mathcal{C}_\sigma| \leq 1$. Thus $\mathbb{E}[X] \leq 1$.

Corollary 2 [Sperner's Theorem] Let $\mathcal{F}$ be an antichain. Then

$$|\mathcal{F}| \leq \binom{n}{\lfloor n/2 \rfloor}.$$

Proof. The function $\binom{n}{x}$ is maximized at $x = \lfloor n/2 \rfloor$ so that

$$1 \geq \sum_{A \in \mathcal{F}} \frac{1}{\binom{n}{|A|}} \geq \frac{|\mathcal{F}|}{\binom{n}{\lfloor n/2 \rfloor}}$$

18.4 13 Discrepancy

The mystery, as well as the glory, of mathematics lies not so much in the fact that abstract theories do turn out to be useful in solving problems but in that wonder of wonders, the fact that a theory meant for solving one type of problem is often the only way of solving problems of entirely different kinds, problems for which the

theory was not intended. These coincidences occur so frequently that they must belong to the essence of mathematics.

18.4.1 13.1 Basics

Suppose we are given a finite family of finite sets. Our object is to color the underlying points red and blue so that all of the sets have nearly the same number of red and blue points. It may be that our cause is hopeless - if the family consists of all subsets of a given set Ω then regardless of the coloring some set, either the red or the blue points, will have size at least half that of Ω and be monochromatic. In the other extreme, should the sets of the family be disjoint then it is trivial to color so that all sets have the same number of red and blue points or, at worst if the cardinality is odd, the number of red and blue points differ by only one. The discrepancy will measure how good a coloring we may find.

To be formal, let a family $\mathcal{A}$ of subsets of Ω be given. Rather than using red and blue we consider colorings as maps

$$\chi : \Omega \rightarrow \{-1, +1\}.$$

For any $A \subset \Omega$ we set

$$\chi(A) = \sum_{a \in A} \chi(a).$$

Define the discrepancy of $\mathcal{A}$ with respect to χ by

$$\text{disc}(\mathcal{A}, \chi) = \max_{A \in \mathcal{A}} |\chi(A)|$$

and the discrepancy of $\mathcal{A}$ by

$$\text{disc}(\mathcal{A}) = \min_{\chi: \Omega \rightarrow \{-1, +1\}} \text{disc}(\mathcal{A}, \chi)$$

Other equivalent definitions of discrepancy reveal its geometric aspects. Let $\mathcal{A} = \{S_1, \dots, S_m\}$, $\Omega = \{1, \dots, n\}$ and let $B = [b_{ij}]$ be the $m \times n$ incidence matrix: $b_{ij} = 1$ if $j \in S_i$, otherwise $b_{ij} = 0$. A coloring χ may be associated with the vector $u = (\chi(1), \dots, \chi(n)) \in \{-1, +1\}^n$ so that $Bu^T = (\chi(S_1), \dots, \chi(S_m))$ and

$$\text{disc}(\mathcal{A}) = \min_{u \in \{-1, +1\}^n} \|Bu^T\|_{\infty},$$

where $\|v\|_{\infty}$ is the L^{∞} -norm, the maximal absolute value of the coordinates. Similarly, letting v_j denote the j th column vector of B (the profile of point j)

$$\text{disc}(\mathcal{A}) = \min |\pm v_1 \pm \dots \pm v_n|_{\infty},$$

where the minimum ranges over all 2^n choices of sign.

We will generally be concerned with upper bounds to the discrepancy. Unraveling the definitions, $\text{disc}(\mathcal{A}) \leq K$ if and only if there exists a coloring χ for which $|\chi(A)| \leq K$ for all $A \in \mathcal{A}$. Naturally, we try the random coloring.

Theorem 13.1.1 Let $\mathcal{A}$ be a family of n subsets of an m -set Ω . Then

$$\text{disc}(\mathcal{A}) \leq \sqrt{2m \ln(2n)}$$

Proof. Let $\chi : \Omega \rightarrow \{-1, +1\}$ be random. For $A \subset \Omega$ let X_A be the indicator random variable for $|\chi(A)| > \alpha$, where we set $\alpha = \sqrt{2m \ln(2n)}$. If $|A| = a$ then $\chi(A)$ has distribution S_a , so by Theorem A.1.1

$$\mathbb{E}[X_A] = \Pr[|\chi(A)| > \alpha] < 2e^{-\alpha^2/2a} \leq 2e^{-\alpha^2/2m} = 1/n$$

by our propitious choice of α . Let X be the number of $A \in \mathcal{A}$ with $|\chi(A)| > \alpha$ so that

$$X = \sum_{A \in \mathcal{A}} X_A$$

and linearity of expectation gives

$$\mathbb{E}[X] = \sum_{A \in \mathcal{A}} \mathbb{E}[X_A] < |\mathcal{A}|(1/n) = 1$$

Thus for some χ we must have $X = 0$. This means $\text{disc}(\mathcal{A}, \chi) \leq \alpha$ and therefore $\text{disc}(\mathcal{A}) \leq \alpha$.

18.4.2 13.2 SIX Standard Deviations Suffice

When $\mathcal{A}$ has both n sets and n points Theorem 13.1.1 gives

$$\text{disc}(\mathcal{A}) = O(\sqrt{n \ln(n)})$$

This is improved by the following result. Its proof resembles that of the main result of Beck (1981). The approach via entropy was suggested by R. Boppana.

Theorem 13.2.1 [Spencer (1985b)] Let $\mathcal{A}$ be a family of n subsets of an n -element set Ω . Then

$$\text{disc}(\mathcal{A}) < 6\sqrt{n}$$

With $\chi : \Omega \rightarrow \{-1, +1\}$ random, $A \in \mathcal{A}$, $\chi(A)$ has zero mean and variance at most $\sqrt{n}$. If $|\chi(A)| > 6\sqrt{n}$ then $\chi(A)$ is at least six standard deviations off the mean. The probability of this occurring is very small but a fixed positive constant and the number of sets $A \in \mathcal{A}$ is going to infinity. In fact, a random χ almost always will not work. The specific constant 6 (actually 5.32) was the result of specific calculations that could certainly be further improved and will not concern us here. Rather, we show Theorem 13.2.1 with the constant 11.

A map $\chi : \Omega \rightarrow \{-1, 0, +1\}$ will be called a partial coloring. When $\chi(a) = 0$ we say a is uncolored. We define $\chi(A)$ as before.

Lemma 13.2.2 Let $\mathcal{A}$ be a family of n subsets of an n -set Ω . Then there is a partial coloring χ with at most $10^{-9}n$ points uncolored such that

$$|\chi(A)| \leq 10\sqrt{n}$$

for all $A \in \mathcal{A}$.

Here the values 10 and 10^{-9} are not the best possible. The significant point is that they are absolute constants. Label the sets of $\mathcal{A}$ by $A_1, \dots, A_n$ for convenience. Let

$$\chi : \Omega \rightarrow \{-1, +1\}$$

be random. For $1 \leq i \leq n$ define

$$b_i = \text{nearest integer to } \frac{\chi(A_i)}{20\sqrt{n}}$$

For example, $b_i = 0$ when $-10\sqrt{n} < \chi(A_i) < 10\sqrt{n}$ and $b_i = -3$ when $-70\sqrt{n} < \chi(A_i) < -50\sqrt{n}$. From Theorem A.1.1 (as in Theorem 13.1.1),

$$\begin{aligned}\Pr[b_i = 0] &> 1 - 2e^{-50} \\ \Pr[b_i = 1] &= \Pr[b_i = -1] < e^{-50} \\ \Pr[b_i = 2] &= \Pr[b_i = -2] < e^{-450}\end{aligned}$$

and, in general,

$$\Pr[b_i = s] = \Pr[b_i = -s] < e^{-50(2s-1)^2}$$

Now we bound the entropy $H(b_i)$. This important concept is explored more fully in Section 15.7. Letting $p_j = \Pr[b_i = j]$,

$$\begin{aligned}H(b_i) &= \sum_{j=-\infty}^{+\infty} -p_j \log_2(p_j) \\ &\leq (1 - 2e^{-50}) [-\log_2(1 - 2e^{-50})] + 2e^{-50} [-\log_2 e^{-50}] \\ &\quad + 2e^{-450} [-\log_2 e^{-450}] + \dots\end{aligned}$$

The infinite sum clearly converges and is strongly dominated by the second term. Calculation gives

$$H(b_i) \leq \epsilon = 3 \times 10^{-20}.$$

Now consider the n -tuple $(b_1, \dots, b_n)$. Of course, there may be correlation among the b_i . Indeed, if S_i and S_j are nearly equal then b_i and b_j will usually be equal. But by Proposition 15.7.2 entropy is subadditive. Hence

$$H((b_1, \dots, b_n)) \leq \sum_{i=1}^n H(b_i) \leq \epsilon n$$

If a random variable Z assumes no value with probability greater than 2^{-t} then $H(Z) \geq t$. In contrapositive form, there is a particular n -tuple $(s_1, \dots, s_n)$ so that

$$\Pr[(b_1, \dots, b_n) = (s_1, \dots, s_n)] \geq 2^{-\epsilon n}$$

Our probability space was composed of the 2^n possible colorings χ , all equally likely. Thus, shifting to counting, there is a set $\mathcal{C}'$ consisting of at least $2^{(1-\epsilon)n}$ colorings $\chi : \Omega \rightarrow \{-1, +1\}$, all having the same value $(b_1, \dots, b_n)$.

Let us think of the class $\mathcal{C}$ of all colorings $\chi : \Omega \rightarrow \{-1, +1\}$ as the Hamming cube $\{-1, +1\}^n$ endowed with the Hamming metric

$$\rho(\chi, \chi') = |\{a : \chi(a) \neq \chi'(a)\}|.$$

Kleitman (1966b) has proved that if $\mathcal{D} \subset \mathcal{C}$ and

$$|\mathcal{D}| \geq \sum_{i \leq r} \binom{n}{i}$$

with $r \leq n/2$ then $\mathcal{D}$ has diameter at least $2r$. That is, the set of a given size with minimal diameter is the ball. ($\mathcal{D}$ has diameter at least r trivially, which would suffice to prove Lemma

13.2.2 and Theorem 13.2.1 with weaker values for the constants.)

Proof. In our case we may take $r = \alpha n$ as long as $\alpha < \frac{1}{2}$ and

$$2^{H(\alpha)} \leq 2^{1-\epsilon}$$

Calculation gives that we may take $\alpha = \frac{1}{2}(1 - 10^{-9})$ with room to spare. [The Taylor series expansion give

$$H\left(\frac{1}{2} - x\right) \sim 1 - \frac{2}{\ln 2}x^2$$

for x small.] Thus $\mathcal{C}'$ has diameter at least $n(1 - 10^{-9})$. Let $\chi_1, \chi_2 \in \mathcal{C}'$ be at maximal distance. We set

$$\chi = \frac{\chi_1 - \chi_2}{2}$$

χ is a partial coloring of Ω . $\chi(a) = 0$ if and only if $\chi_1(a) = \chi_2(a)$, which occurs for $n - \rho(\chi_1, \chi_2) \leq 10^{-9}n$ coordinates a . Finally, and crucially, for each $1 \leq i \leq n$ the colorings χ_1, χ_2 yield the same value b_i , which means that $\chi_1(A_i)$ and $\chi_2(A_i)$ lie on a common interval of length $20\sqrt{n}$. Thus

$$|\chi(A_i)| = \left| \frac{\chi_1(A_i) - \chi_2(A_i)}{2} \right| \leq 10\sqrt{n},$$

as desired.

Theorem 13.2.1 requires a coloring of all points whereas Lemma 13.2.2 leaves $10^{-9}n$ points uncolored. The idea now is to iterate the procedure of Lemma 13.2.2, coloring all but, say, $10^{-18}n$ of the uncolored points on the second coloration. We cannot apply Lemma 13.2.2 directly since we have an asymmetric situation with n sets and only $10^{-9}n$ points.

Lemma 13.2.3 Let $\mathcal{A}$ be a family of n subsets of an r -set Ω with $r \leq 10^{-9}n$. Then there is a partial coloring χ of Ω with at most $10^{-40}r$ points uncolored so that

$$|\chi(A)| < 10\sqrt{r}\sqrt{\ln(n/r)}$$

for all $A \in \mathcal{A}$.

Proof. We outline the argument which leaves room to spare. Let $A_1, \dots, A_n$ denote the sets of $\mathcal{A}$. Let $\chi : \Omega \rightarrow \{\pm 1\}$ be random. For $1 \leq i \leq n$ define

$$b_i = \text{nearest integer to } \frac{\chi(A_i)}{20\sqrt{r}\sqrt{\ln(n/r)}}$$

Now the probability that $b_i = 1$ is less than $(r/n)^{50}$. The entropy $H(b_i)$ is dominated by this term and is less than

$$3\left(\frac{r}{n}\right)^{50} \left[-\log_2 \left(\left(\frac{r}{n}\right)^{50} \right) \right] < 10^{-100} \frac{r}{n}$$

The entropy of $(b_1, \dots, b_n)$ is then less than $10^{-100}r$; one finds nearly antipodal χ_1, χ_2 with the same b 's and takes $\chi = (\chi_1 - \chi_2)/2$ as before.

Proof [Theorem 13.2.1]. Apply Lemma 13.2.2 to find a partial coloring χ^1 and then apply Lemma 13.2.3 repeatedly on the remaining uncolored points giving $\chi^2, \chi^3, \dots$ until all points have been colored. Let χ denote the final coloring. For any $A \in \mathcal{A}$,

$$\chi(A) = \chi^1(A) + \chi^2(A) + \dots$$

so that

$$|\chi(A)| \leq 10\sqrt{n} + 10\sqrt{10^{-9}n}\sqrt{\ln 10^9} \\ + 10\sqrt{10^{-49}n}\sqrt{\ln 10^{49}} + 10\sqrt{10^{-89}n}\sqrt{\ln 10^{89}} + \dots$$

Removing the common $\sqrt{n}$ term gives a clearly convergent infinite series, strongly dominated by the first term so that

$$|\chi(A)| \leq 11\sqrt{n}$$

with room to spare.

Suppose that $\mathcal{A}$ consists of n sets on r points and $r < n$. We can apply Lemma 13.2.3 repeatedly (first applying Lemma 13.2.2 if $r > 10^{-9}n$) to give a coloring χ with

$$\text{disc}(\mathcal{A}, \chi) < K\sqrt{r}\sqrt{\ln(n/r)}$$

where K is an absolute constant. As long as $r = n^{1-o(1)}$ this improves the random coloring result of Theorem 13.1.1.

18.4.3 13.3 Linear and Hereditary Discrepancy

We now suppose that $\mathcal{A}$ has more points than sets. We write $\mathcal{A} = \{A_1, \dots, A_n\}$ and $\Omega = \{1, \dots, m\}$ and assume $m > n$. Note that $\text{disc}(\mathcal{A}) \leq K$ is equivalent to the existence of a set S ; namely, $S = \{j : \chi(j) = +1\}$, with $|S \cap A|$ within $K/2$ of $|A|/2$ for all $A \in \mathcal{A}$. We define the linear discrepancy $\text{lindisc}(\mathcal{A})$ by

$$\text{lindisc}(\mathcal{A}) = \max_{p_1, \dots, p_m \in [0,1]} \min_{\epsilon_1, \dots, \epsilon_m \in \{0,1\}} \max_{A \in \mathcal{A}} \left| \sum_{i \in A} (\epsilon_i - p_i) \right|.$$

The upper bound $\text{lindisc}(\mathcal{A}) \leq K$ means that given any $p_1, \dots, p_m$ there is a "simultaneous roundoff" $\epsilon_1, \dots, \epsilon_m$ so that, with $S = \{j : \epsilon_j = 1\}$, $|S \cap A|$ is within K of the weighted sum $\sum_{j \in A} p_j$ for all $A \in \mathcal{A}$. Taking all $p_j = \frac{1}{2}$, the upper bound implies $\text{disc}(\mathcal{A}) \leq 2K$. But $\text{lindisc}(\mathcal{A}) \leq K$ is much stronger. It implies, taking all $p_j = \frac{1}{3}$, the existence of an S with all $|S \cap A|$ within K of $|A|/3$, and much more. Linear discrepancy and its companion hereditary discrepancy defined below have been developed in Lovász, Spencer and Vesztergombi (1986). For $X \subset \Omega$ let $\mathcal{A}|_X$ denote the restriction of $\mathcal{A}$ to X , that is, the family $\{A \cap X : A \in \mathcal{A}\}$. The next result "reduces" the bounding of $\text{disc}(\mathcal{A})$ when there are more points than sets to the bounding of $\text{lindisc}(\mathcal{A})$ when the points do not outnumber the sets.

Theorem 13.3.1 Let $\mathcal{A}$ be a family of n sets on m points with $m \geq n$. Suppose that $\text{lindisc}(\mathcal{A}|_X) \leq K$ for every subset X of at most n points. Then $\text{lindisc}(\mathcal{A}) \leq K$.

Proof. Let $p_1, \dots, p_m \in [0, 1]$ be given. We define a reduction process. Call index j fixed if $p_j \in \{0, 1\}$, otherwise call it floating, and let F denote the set of floating indices. If $|F| \leq n$ then halt. Otherwise, let $y_j, j \in F$, be a nonzero solution to the homogeneous system

$$\sum_{j \in A \cap F} y_j = 0, \quad A \in \mathcal{A}.$$

Such a solution exists since there are more variables ($|F|$) than equations (n) and may be found by standard techniques of linear algebra. Now set

$$p'_j = \begin{cases} p_j + \lambda y_j, & j \in F, \\ p_j, & j \notin F, \end{cases}$$

where we let λ be the real number of least absolute value so that for some $j \in F$ the value p'_j becomes zero or one. Critically,

$$\sum_{j \in A} p'_j = \sum_{j \in A} p_j + \lambda \sum_{j \in A \cap F} y_j = \sum_{j \in A} p_j \quad (13.1)$$

for all $A \in \mathcal{A}$. Now iterate this process with the new p'_j . At each iteration at least one floating j becomes fixed and so the process eventually halts at some $p_1^*, \dots, p_m^*$. Let X be the set of floating j at this point. Then $|X| \leq n$. By assumption there exist $\epsilon_j, j \in X$ so that

$$\left| \sum_{j \in A \cap X} p_j^* - \epsilon_j \right| \leq K, \quad A \in \mathcal{A}.$$

For $j \notin X$ set $\epsilon_j = p_j^*$. As (13.1) holds at each iteration,

$$\sum_{j \in A} p_j^* = \sum_{j \in A} p_j$$

and hence

$$\left| \sum_{j \in A} (p_j - \epsilon_j) \right| = \left| \sum_{j \in A} (p_j - p_j^*) + \sum_{j \in A \cap X} (p_j^* - \epsilon_j) \right| \leq K$$

for all $A \in \mathcal{A}$.

We now define the hereditary discrepancy $\text{herdisc}(\mathcal{A})$ by

$$\text{herdisc}(\mathcal{A}) = \max_{X \subseteq \Omega} \text{disc}(\mathcal{A}|_X)$$

Example. Let $\Omega = \{1, \dots, n\}$ and let $\mathcal{A}$ consist of all intervals $[i, j] = \{i, i+1, \dots, j\}$ with $1 \leq i \leq j \leq n$. Then $\text{disc}(\mathcal{A}) = 1$ as we may color Ω alternately $+1$ and -1 . But also $\text{herdisc}(\mathcal{A}) = 1$. For given any $X \subseteq \Omega$, say, with elements $x_1 < x_2 < \dots < x_r$, we may color X alternately by $\chi(x_k) = (-1)^k$. For any set $[i, j] \in \mathcal{A}$ the elements of $[i, j] \cap X$ are alternately colored.

Theorem 13.3.2 $\text{lindisc}(\mathcal{A}) \leq \text{herdisc}(\mathcal{A})$.

Proof. Set $K = \text{herdisc}(\mathcal{A})$. Let $\mathcal{A}$ be defined on $\Omega = \{1, \dots, m\}$ and let $p_1, \dots, p_m \in [0, 1]$ be given. First let us assume that all p_i have finite expansions when written in base two. Let T be the minimal integer so that all $p_i 2^T \in \mathbb{Z}$. Let J be the set of i for which p_i has a one in the T th digit of its binary expansion, that is, for which $p_i 2^{T-1} \notin \mathbb{Z}$. As $\text{disc}(\mathcal{A}|_J) \leq K$ there exist $\epsilon_j \in \{-1, +1\}$, so that

$$\left| \sum_{j \in J \cap A} \epsilon_j \right| \leq K$$

for all $A \in \mathcal{A}$. Write $p_j = p_j^{(T)}$. Now set

$$p_j^{(T-1)} = \begin{cases} p_j^{(T)} & \text{if } j \notin J \\ p_j^{(T)} + \epsilon_j 2^{-T} & \text{if } j \in J \end{cases}$$

That is, the $p_j^{(T-1)}$ are the "roundoffs" of the $p_j^{(T)}$ in the T th place. Note that all $p_j^{(T-1)} 2^{-(T-1)} \in \mathbb{Z}$. For any $A \in \mathcal{A}$,

$$\left| \sum_{j \in A} p_j^{(T-1)} - p_j^{(T)} \right| = \left| \sum_{j \in J \cap A} 2^{-T} \epsilon_j \right| \leq 2^{-T} K$$

Iterate this procedure, finding $p_j^{(T-2)}, \dots, p_j^{(1)}, p_j^{(0)}$. All $p_j^{(0)} 2^{-0} \in \mathbb{Z}$ so all $p_j^{(0)} \in \{0, 1\}$ and

$$\left| \sum_{j \in A} p_j^{(0)} - p_j^{(T)} \right| \leq \sum_{i=1}^T \left| \sum_{j \in A} p_j^{(i-1)} - p_j^{(i)} \right| \leq \sum_{i=1}^T 2^{-i} K \leq K,$$

as desired.

What about general $p_1, \dots, p_m \in [0, 1]$? We can flip and say that, at least to a computer scientist, all real numbers have finite binary expansions. More rigorously, the function

$$f(p_1, \dots, p_m) = \min_{\epsilon_1, \dots, \epsilon_m \in \{0, 1\}} \max_{A \in \mathcal{A}} \left| \sum_{i \in A} (\epsilon_i - p_i) \right|$$

is the finite minimum of finite maxima of continuous functions and thus is continuous. The set of $(p_1, \dots, p_m) \in [0, 1]^m$ with all $p_i 2^T \in \mathbb{Z}$ for some T is a dense subset of $[0, 1]^m$. As $f \leq K$ on this dense set, $f \leq K$ for all $(p_1, \dots, p_m) \in [0, 1]^m$.

Corollary 13.3.3 Let $\mathcal{A}$ be a family of n sets on m points. Suppose $\text{disc}(\mathcal{A}|_X) \leq K$ for every subset X with at most n points. Then $\text{disc}(\mathcal{A}) \leq 2K$.

Proof. For every $X \subseteq \Omega$ with $|X| \leq n$, $\text{herdisc}(\mathcal{A}|_X) \leq K$ so by Theorem 13.3.2 $\text{lindisc}(\mathcal{A}|_X) \leq K$. By Theorem 13.3.1 $\text{lindisc}(\mathcal{A}) \leq K$. But

$$\text{disc}(\mathcal{A}) \leq 2 \text{lindisc}(\mathcal{A}) \leq 2K.$$

Corollary 13.3.4 For any family $\mathcal{A}$ of n sets of arbitrary size

$$\text{disc}(\mathcal{A}) \leq 12\sqrt{n}$$

Proof. Apply Theorem 13.2.1 and Corollary 13.3.3.

18.4.4 13.4 Lower Bounds

We now give two quite different proofs that, up to a constant factor, Corollary 13.3.4 is the best possible. A Hadamard matrix is a square matrix $H = (h_{ij})$ with all $h_{ij} \in \{-1, +1\}$ and with row vectors mutually orthogonal (and hence with column vectors mutually orthogonal). Let H be a Hadamard matrix of order n and let $v = (v_1, \dots, v_n)$, $v_i \in \{-1, +1\}$. Then

$$Hv = v_1 c_1 + \dots + v_n c_n$$

where c_i denotes the i th column vector of H . Writing $Hv = (L_1, \dots, L_n)$ and letting $|\cdot|$ denote the usual Euclidean norm,

$$L_1^2 + \dots + L_n^2 = |Hv|^2 = v_1^2 |c_1|^2 + \dots + v_n^2 |c_n|^2 = n + \dots + n = n^2$$

since the c_i are mutually orthogonal. Hence some $L_i^2 \geq n$ and thus

$$|Hv|_\infty = \max\{|L_1|, \dots, |L_n|\} \geq \sqrt{n}$$

Now we transfer this result to one on families of sets. Let H be a Hadamard matrix of order n with first row and first column all ones. (Any Hadamard matrix can be so "normalized" by multiplying appropriate rows and columns by -1.) Let J denote the all ones matrix of order n . Let $v_1, \dots, L_1, \dots$ be as above. Then

$$L_1 + \dots + L_n = \sum_{i,j=1}^n v_j h_{ij} = \sum_{j=1}^n v_j \sum_{i=1}^n h_{ij} = nv_1 = \pm n,$$

since the first column sums to n but the other columns, being orthogonal to it, sum to zero. Set $\lambda = v_1 + \dots + v_n$ so that $Jv = (\lambda, \dots, \lambda)$ and

$$(H + J)v = (L_1 + \lambda, \dots, L_n + \lambda).$$

We calculate

$$|(H + J)v|^2 = \sum_{i=1}^n (L_i + \lambda)^2 = \sum_{i=1}^n (L_i^2 + 2\lambda L_i + \lambda^2) = n^2 \pm 2n\lambda + n\lambda^2.$$

Assume n is even. (Hadamard matrices don't exist for odd n , except $n = 1$.) Then λ is an even integer. The quadratic (in λ) $n^2 \pm 2n\lambda + n\lambda^2$ has a minimum at ∓ 1 and so under the restriction of being an even integer its minimum is at $\lambda = 0, \mp 2$ and so

$$|(H + J)v|^2 \geq n^2$$

Again, some coordinate must be at least $\sqrt{n}$. Setting $H^* = (H + J)/2$,

$$|H^*v|_\infty \geq \sqrt{n}/2$$

Let $\mathcal{A} = \{A_1, \dots, A_m\}$ be any family of subsets of $\Omega = \{1, \dots, n\}$ and let M denote the corresponding $m \times n$ incidence matrix. A coloring $\chi : \Omega \rightarrow \{-1, +1\}$ corresponds to a vector $v = (\chi(1), \dots, \chi(n)) \in \{-1, +1\}^n$. Then

$$\text{disc}(\mathcal{A}, \chi) = |Mv|_\infty$$

and

$$\text{disc}(\mathcal{A}) = \min_{v \in \{-1, +1\}^n} |Mv|_\infty$$

In our case H^* has entries 0,1. Thus we have the following theorem.

Theorem 13.4.1 If a Hadamard matrix exists of order $n > 1$ then there exists a family $\mathcal{A}$ consisting of n subsets of an n -set with

$$\text{disc}(\mathcal{A}) \geq \sqrt{n}/2$$

While it is not known precisely for which n a Hadamard matrix exists [the Hadamard conjecture is that they exist for $n = 1, 2$ and all multiples of 4; see, for example, Hall (1986)], it is known that the orders of Hadamard matrices are dense in the sense that for all ϵ if n is sufficiently large there will exist a Hadamard matrix of order between n and $n(1 - \epsilon)$. This result suffices to extend Theorem 13.4.1 to an asymptotic result on all n .

Our second argument for the existence of $\mathcal{A}$ with high discrepancy involves turning the probabilistic argument "on its head." Let M be a random 0,1 matrix of order n . Let $v = (v_1, \dots, v_n)$, $v_j = \pm 1$ be fixed and set $Mv = (L_1, \dots, L_n)$. Suppose half of the $v_j = +1$ and half are -1. Then

$$L_i \sim B\left(\frac{n}{2}, \frac{1}{2}\right) - B\left(\frac{n}{2}, \frac{1}{2}\right)$$

which has roughly the normal distribution $N(0, \sqrt{n}/2)$. Pick $\lambda > 0$ so that

$$\int_{-\lambda}^{\lambda} \frac{1}{\sqrt{2\pi}} e^{-t^2/2} dt < \frac{1}{2}$$

Then

$$\Pr [|L_i| < \lambda\sqrt{n}/2] < \frac{1}{2}$$

When v is imbalanced the same inequality holds; we omit the details. Now, crucially, the L_i are mutually independent as each entry of M was independently chosen. Thus

$$\Pr [|L_i| < \lambda\sqrt{n}/2 \text{ for all } 1 \leq i \leq n] < \left(\frac{1}{2}\right)^n$$

There are "only" 2^n possible v . Thus the expected number of v for which $|Mv|_\infty < \lambda\sqrt{n}/2$ is less than $2^n 2^{-n} = 1$. For some M this value must be zero, there are no such v . The corresponding family $\mathcal{A}$ thus has

$$\text{disc}(\mathcal{A}) > \lambda\sqrt{n}/2.$$

18.4.5 13.5 The Beck-fiala Theorem

For any family $\mathcal{A}$ let $\deg(\mathcal{A})$ denote the maximal number of sets containing any particular point. The following result due to Beck and Fiala (1981) uses only methods from linear algebra and thus is technically outside the scope we have set for this book. We include it both for the sheer beauty of the proof and because the result itself is very much in the spirit of this chapter.

Theorem 13.5.1 Let $\mathcal{A}$ be a finite family of finite sets, no restriction on either the number of sets or on the cardinality of the sets, with $\deg(\mathcal{A}) \leq t$. Then

$$\text{disc}(\mathcal{A}) \leq 2t - 1$$

Proof. For convenience write $\mathcal{A} = \{A_1, \dots, A_m\}$ with all $A_i \subseteq \Omega = \{1, \dots, n\}$. To each $j \in \Omega$ there is assigned a value x_j that will change as the proof progresses. Initially all $x_j = 0$. At the end all $x_j = \pm 1$. We will have $-1 \leq x_j \leq +1$ at all times and once $x_j = \pm 1$ it "sticks" there and that becomes its final value. A set S_i has value $\sum_{j \in S_i} x_j$. At any time j is called fixed if $x_j = \pm 1$; otherwise it is floating. A set S_i is safe if it has fewer than t floating points; otherwise it is active. Note, crucially, that as points are in at most t sets and active sets contain more than t floating points there must be fewer active sets than floating points.

We insist at all times that all active sets have value zero. This holds initially since all sets have value zero. Suppose this condition holds at some stage. Consider x_j a variable for each floating j and a constant for each fixed j . The condition that S_i has value zero then becomes a linear equation in these variables. This is an underdetermined system: there are fewer linear conditions (active sets) than variables (floating points). Hence we may find a line, parametrized

$$x'_j = x_j + \lambda y_j, j \text{ floating,}$$

on which the active sets retain value zero. Let λ be the smallest value for which some x'_j becomes ± 1 and replace each x_j by x'_j . (Geometrically, follow the line until reaching the boundary of the cube in the space over the floating variables.) This process has left fixed variables fixed and so safe sets stayed safe sets (though active sets may have become safe) and so the condition still holds. In addition, at least one previously floating j has become fixed.

We iterate the above procedure until all j have become fixed. (Toward the end we may have no active sets at which time we may simply set the floating x_j to ± 1 arbitrarily.) Now consider any set S_i . Initially it had value zero and it retained value zero while it contained at least t floating points. Consider the time when it first becomes safe, say, $1, \dots, l$ were its floating points. At this moment its value is zero. The variables $y_1, \dots, y_l$ can now change less than two to their final value since all values are in $[-1, +1]$. Thus, in total, they may change less than $2t$. Hence the final value of S_i is less than $2t$ and, as it is an integer, it is at most $2t - 1$.

Conjecture 13.5.2 If $\deg(\mathcal{A}) \leq t$ then $\text{disc}(\mathcal{A}) \leq K\sqrt{t}$, K an absolute constant.

This conjecture seems to call for a melding of probabilistic methods and linear algebra. The constructions of t sets on t points, described in Section 13.4, show that, if true, this conjecture would be the best possible.

18.4.6 13.6 Exercises

1. Let $\mathcal{A}$ be a family of n subsets of $\Omega = \{1, \dots, m\}$ with m even. Let $\chi(i)$, $1 \leq i \leq m/2$ be independent and uniform in $\{-1, +1\}$ and set $\chi(i+m/2) = -\chi(i)$ for $1 \leq i \leq m/2$. Using this notion of random coloring, improve Theorem 13.1.1 by showing $\text{disc}(\mathcal{A}) \leq \sqrt{m \ln(2n)}$. Show that this can be improved even further by splitting Ω randomly into $m/2$ disjoint pairs.
2. Let $\vec{v}_1, \dots, \vec{v}_s \in \mathbb{R}^n$. Let $x_1, \dots, x_s \in [-1, +1]$ such that $\sum_{i=1}^s x_i \vec{v}_i = \vec{0}$ and such that $x_i \in \{-1, +1\}$ for all but at most n values of i . Let $\vec{v}_{s+1} \in \mathbb{R}^n$. Use the linear ideas of Section 13.5 to find $x'_1, \dots, x'_s, x'_{s+1}$ with the following properties:
 - $\sum_{i=1}^{s+1} x'_i \vec{v}_i = \vec{0}$.
 - All $x'_i \in [-1, +1]$.
 - $x'_i \in \{-1, +1\}$ for all but at most n values of i .
 - $x'_i = x_i$ whenever $x_i \in \{-1, +1\}$.

Use the above to prove the following result of Barány and Grinberg: Let $|\cdot|$ be an arbitrary norm in $\mathbb{R}^n$. Let $\vec{v}_1, \dots, \vec{v}_s \in \mathbb{R}^n$ with all $|\vec{v}_i| \leq 1$. Then there exist $x_1, \dots, x_s \in \{-1, +1\}$ such that

$$\left| \sum_{i=1}^t x_i \vec{v}_i \right| \leq 2n$$

for all $1 \leq t \leq s$.

3. Let $A_1, \dots, A_n \subset \Omega = \{1, \dots, m\}$ with $m \sim n \ln n$. Assume further that all $|A_i| \leq n$. Use the methods of Theorem 13.2.1, including Kleitman's Theorem, to prove that there exists $\chi : \{1, \dots, m\} \rightarrow \{-1, 0, +1\}$ such that all $\chi(A_i) = O(\sqrt{n \ln \ln n})$ and $\chi(x) = 0$ for at most n vertices x . Use Theorem 13.2.1 to deduce the existence of $\chi : \{1, \dots, m\} \rightarrow \{-1, +1\}$ such that all $\chi(A_i) = O(\sqrt{n \ln \ln n})$.

The Probabilistic Lens: Unbalancing Lights

For any $m \times n$ matrix $B = (b_{ij})$ with coefficients $b_{ij} = \pm 1$ set

$$F[B] = \max_{x_i, y_j = \pm 1} \sum_{i=1}^m \sum_{j=1}^n x_i y_j b_{ij}.$$

As in Section 2.5 we may interpret B as an $m \times n$ array of lights, each either on ($b_{ij} = +1$) or off ($b_{ij} = -1$). For each row and each column there is a switch that, when pulled, changes all lights in that line from on to off or from off to on. Then $F[B]$ gives the maximal achievable number of lights on minus lights off. In Section 2.5 we found a lower bound for $F[B]$ when $m = n$. Here we set $n = 2^m$ and find the precise best possible lower bound.

With $n = 2^m$ let A be an $m \times n$ matrix with coefficients ± 1 containing every possible column vector precisely once. We claim $F[A]$ is the minimal value of $F[B]$ over all $m \times n$ matrices B .

For any given B let $x_1, \dots, x_m = \pm 1$ be independently and uniformly chosen and set

$$X_j = \sum_{i=1}^m x_i b_{ij},$$

$$X = |X_1| + \dots + |X_n|,$$

so that

$$F[B] = \max_{y_j = \pm 1} \max_{x_i = \pm 1} \sum_{j=1}^n y_j X_j = \max_{x_i = \pm 1} \sum_{j=1}^n |X_j| = \max X.$$

Regardless of the b_{ij} , X_i has distribution S_m so that $E[|X_i|] = E[|S_m|]$ and, by linearity of expectation,

$$E[X] = nE[|S_m|].$$

With $B = A$, any choices of $x_1, \dots, x_m = \pm 1$ have the effect of permuting the columns - the matrix $(x_i a_{ij})$ also has every column vector precisely once - so that $X = |X_1| + \dots + |X_m|$ is a constant. Note that $E[X]$ is independent of B . In general, fixing $E[X] = \mu$, the minimal possible value for $\max X$ is achieved when X is the constant μ . Thus $F[B]$ is minimized with $B = A$.

18.5 14 Geometry

Few people think more than two or three times a year. I have made an international reputation for myself by thinking once or twice a week.
-George Bernard Shaw

Suppose we choose randomly n points $P_1, \dots, P_n$ on the unit circle, according to a uniform distribution. What is the probability that the origin lies in the convex hull of these points? There is a surprisingly simple (yet clever) way to compute this probability. Let us first choose n random pairs of antipodal points $Q_1, Q_{n+1} = -Q_1, Q_2, Q_{n+2} = -Q_2, \dots, Q_n, Q_{2n} = -Q_n$ according to a uniform distribution. Note that with probability 1 these pairs are all distinct. Next we choose each P_i to be either Q_i or its antipodal $Q_{n+i} = -Q_i$, where each choice is equally likely. Clearly this corresponds to a random choice of the points P_i . The probability that the origin does not belong to the convex hull of the points P_i , given the (distinct) points Q_j , is precisely $x/2^n$, where x is the number of subsets of the points Q_j contained in an open half-plane determined by a line through the origin, which does not pass through any of the points Q_j . It is easy to see that $x = 2n$. This is because if we renumber the points Q_j so that their cyclic order on the circle is $Q_1, \dots, Q_n, Q_{n+1}, \dots, Q_{2n}$ and $Q_{n+i} = -Q_i$ then the subsets contained in such half-planes are precisely $\{Q_i, \dots, Q_{n+i-1}\}$, where the indices are reduced modulo $2n$. Therefore the probability that the origin is in the convex hull of n randomly chosen points on the unit circle is precisely $1 - 2n/2^n$. Observe that the same result holds if we replace the unit circle by any centrally symmetric bounded planar domain with center 0 and that the argument can easily be generalized to higher dimensions.

This result, due to Wendel (1962), shows how in some cases a clever idea can replace a tedious computation. It also demonstrates the connection between probability and geometry. The probabilistic method has recently been used extensively for deriving results in discrete and computational geometry. Some of these results are described in this chapter.

18.5.1 14.1 The Greatest Angle Among Points in Euclidean Spaces

There are several striking examples, in different areas of combinatorics, where the probabilistic method supplies very simple counter examples to long standing conjectures. Here is an example, due to Erdős and Füredi (1983).

Theorem 14.1.1 For every $d \geq 1$ there is a set of at least $\lfloor \frac{1}{2}(2/\sqrt{3})^d \rfloor$ points in the d -dimensional Euclidean space $\mathbb{R}^d$, such that all angles determined by three points from the set are strictly less than $\pi/2$.

This theorem disproves an old conjecture of Danzer and Grünbaum (1962) that the maximum cardinality of such a set is at most $2d - 1$. We note that as proved by Danzer and Grünbaum the maximum cardinality of a set of points in $\mathbb{R}^d$ in which all angles are at most $\pi/2$ is 2^d .

Proof. We select the points of a set $X \subset \mathbb{R}^d$ from the vertices of the d -dimensional cube. As usual, we view the vertices of the cube, which are 0,1 -vectors of length d , as the characteristic vectors of subsets of a d -element set; that is, each 0,1 -vector a of length d is associated with the set $A = \{i : 1 \leq i \leq d, a_i = 1\}$. A simple consequence of Pythagoras' Theorem gives that the three vertices a, b and c of the d -cube, corresponding to the sets A, B and C , respectively, determine a right angle at c if and only if

$$A \cap B \subset C \subset A \cup B \quad (14.1)$$

As the angles determined by triples of points of the d -cube are always at most $\pi/2$, it suffices to construct a set X of cardinality at least the one stated in the theorem, no three distinct members of which satisfy (14.1).

Define $m = \lfloor \frac{1}{2}(2/\sqrt{3})^d \rfloor$, and choose, randomly and independently, $2md$ dimensional $\{0, 1\}$ -vectors $a_1, \dots, a_{2m}$, where each coordinate of each of the vectors independently is chosen to be either 0 or 1 with equal probability. For every fixed triple a, b and c of the chosen points, the probability that the corresponding sets satisfy equation (14.1) is precisely $(3/4)^d$. This is because (14.1) simply means that for each $i, 1 \leq i \leq d$, neither $a_i = b_i = 0, c_i = 1$ nor $a_i = b_i = 1, c_i = 0$ hold. Therefore the probability that, for three fixed indices i, j and k , our chosen points a_i, a_j, a_k form a right angle at a_k is $(3/4)^d$. Since there are $\binom{2m}{3}3$ possible triples that can produce such angles, the expected number of right angles is

$$\binom{2m}{3}3(3/4)^d \leq m,$$

where the last inequality follows from the choice of m . Thus there is a choice of a set X of $2m$ points in which the number of right angles is at most m . By deleting one point from each such angle we obtain a set of at least $2m - m = m$ points in which all angles are strictly less than $\pi/2$. Note that the remaining points are all distinct since (14.1) is trivially satisfied if $A = C$. This completes the proof.

It is worth noting that, as observed by Erdős and Füredi, the proof above can be easily modified to give the following.

Theorem 14.1.2 For every $\epsilon > 0$ there is a $\delta > 0$ such that for every $d \geq 1$ there is a set of at least $(1 + \delta)^d$ points in $\mathbb{R}^d$ so that all the angles determined by three distinct points from the set are at most $\pi/3 + \epsilon$.

We omit the detailed proof of this result.

18.5.2 14.2 Empty Triangles Determined by Points in the Plane

For a finite set X of points in general position in the plane, let $f(X)$ denote the number of empty triangles determined by triples of points of X ; that is, the number of triangles, determined by points of X , that contain no other point of X . Katchalski and Meir (1988) studied the minimum possible value of $f(X)$ for a set X of n points. Define $f(n) = \min f(X)$, where X ranges over all planar sets of n points in general position (i.e., containing no three collinear points). They proved that

$$\binom{n-1}{2} \leq f(n) < 200n^2.$$

These bounds were improved by Barány and Füredi (1987), who showed that as n grows

$$(1 + o(1))n^2 \leq f(n) \leq (1 + o(1))2n^2$$

The construction that establishes the upper bound is probabilistic and is given in the following theorem. See also Valtr (1995) for a slightly better result.

Theorem 14.2.1 Let $I_1, I_2, \dots, I_n$ be parallel unit intervals in the plane, where

$$I_i = \{(x, y) : x = i, 0 \leq y \leq 1\}.$$

For each i let us choose a point p_i randomly and independently from I_i according to a uniform distribution. Let X be the set consisting of these n randomly chosen points. Then the expected number of empty triangles in X is at most $2n^2 + O(n \log n)$.

Clearly, with probability 1, X is a set of points in general position and hence the above theorem shows that $f(n) \leq 2n^2 + O(n \log n)$.

Proof. We first estimate the probability that the triangle determined by the points p_i, p_{i+a} and p_{i+k} is empty, for some fixed i, a and $k = a + b \geq 3$. Let $A = (i, x)$, $B = (i + a, y)$ and $C = (i + k, z)$ be the points p_i, p_{i+a} and p_{i+k} , respectively. Let m be the distance between B and the intersection point of the segment AC with the interval I_{i+a} . Since each of the points p_j for $i < j < i + k$ are chosen randomly according to a uniform distribution on I_j , it follows that the probability that the triangle determined by A, B and C is empty is precisely

$$\begin{aligned} & \left(1 - \frac{m}{a}\right) \left(1 - 2\frac{m}{a}\right) \cdots \left(1 - (a-1)\frac{m}{a}\right) \left(1 - (b-1)\frac{m}{b}\right) \cdots \left(1 - \frac{m}{b}\right) \\ & \leq \exp\left(-\frac{m}{a} - 2\frac{m}{a} \cdots - (a-1)\frac{m}{a} - (b-1)\frac{m}{b} \cdots - \frac{m}{b}\right) \\ & = \exp\left(-\binom{a}{2}\frac{m}{a} - \binom{b}{2}\frac{m}{b}\right) = \exp\left(-\binom{k-2}{2}\frac{m}{2}\right) \end{aligned}$$

For every fixed choice of A and C , when the point $p_{i+a} = B$ is chosen randomly, the probability that its distance m from the intersection of the segment AC with the interval I_{i+a} is at most d is clearly at most $2d$, for all $d \geq 0$. Therefore the probability that the triangle determined by p_i, p_{i+a} and p_{i+k} is empty is at most

$$2 \int_0^\infty e^{-\frac{1}{2}(k-2)m} dm = \frac{4}{k-2}$$

It follows that the expected value of the total number of empty triangles is at most

$$\begin{aligned}
 & n - 2 + \sum_{i=1}^{n-3} \sum_{k=3}^{n-i} \sum_{a=1}^{k-1} \frac{4}{k-2} \\
 &= n - 2 + \sum_{k=3}^{n-1} (n-k)(k-1) \frac{4}{k-2} \\
 &= n - 2 + \sum_{k=3}^{n-1} (n-k) \frac{4}{k-2} + 4 \sum_{k=3}^{n-1} (n-k) \\
 &= 2n^2 + O(n \log n).
 \end{aligned}$$

This completes the proof.

The result above can be extended to higher dimensions by applying a similar probabilistic construction. A set X of n points in the d -dimensional Euclidean space is called independent if no $d+1$ of the points lie on a hyperplane. A simplex determined by $d+1$ of the points is called empty if it contains no other point of X . Let $f_d(X)$ denote the number of empty simplices of X , and define $f_d(n) = \min f_d(X)$, where X ranges over all independent sets of n points in $\mathbb{R}^d$. Katchalski and Meir (1988) showed that $f_d(n) \geq \binom{n-1}{d}$. The following theorem of Bárány and Füredi

shows that here, again, a probabilistic construction gives a matching upper bound, up to a constant factor (that depends on the dimension). We omit the detailed proof.

Theorem 14.2.2 There exists a constant $K = K(d)$, such that for every convex, bounded set $A \subset \mathbb{R}^d$ with nonempty interior, if X is a random set of n points obtained by n random and independent choices of points of A picked with uniform distribution, then the expected number of empty simplices of X is at most $K \binom{n}{d}$.

18.5.3 14.3 Geometrical Realizations of Sign Matrices

Let $A = (a_{i,j})$ be an m by n matrix with ± 1 entries. We say that A is realizable in $\mathbb{R}^d$ if there are m hyperplanes $H_1, \dots, H_m$ in $\mathbb{R}^d$ passing through the origin and n points $P_1, \dots, P_n$ in $\mathbb{R}^d$, so that for all i and j , P_j lies on the positive side of H_i if $a_{i,j} = +1$, and on the negative side if $a_{i,j} = -1$. Let $d(A)$ denote the minimum dimension d such that A is realizable in $\mathbb{R}^d$, and define $d(m, n) = \max d(A)$, where A ranges over all m by n matrices with ± 1 entries. Since $d(m, n) = d(n, m)$ we can consider only the case $m \geq n$.

The problem of determining or estimating $d(m, n)$ and, in particular, $d(n, n)$ was raised by Paturi and Simon (1984). This problem was motivated by an attempt to estimate the maximum possible "unbounded-error probabilistic communication complexity" of Boolean functions. Alon, Frankl and Rödl (1985) proved that as n grows $\frac{1}{32}n \leq d(n, n) \leq (\frac{1}{2} + o(1))n$. Both the upper and the lower bounds are proved by combining probabilistic arguments with certain other ideas. In the next theorem we prove the upper bound, which is probably closer to the truth.

Theorem 14.3.1 For all $m \geq n$,

$$d(m, n) \leq \frac{n+1}{2} + \sqrt{\frac{n-1}{2} \log m}.$$

For the proof, we need a definition and two lemmas. For a vector $\vec{a} = (a_1, \dots, a_n)$ of ± 1 entries, the number of sign changes in $\vec{a}$ is the number of indices $i, 1 \leq i \leq n-1$ such that $a_i = -a_{i+1}$. For a matrix A of ± 1 entries, denote by $s(A)$ the maximum number of sign changes in a row of A .

Lemma 14.3.2 For any matrix A of ± 1 entries, $d(A) \leq s(A) + 1$.

Proof. Let $A = (a_{i,j})$ be an m by n matrix of ± 1 entries and suppose $s = s(A)$. Let $t_1 < t_2 < \dots < t_n$ be arbitrary reals, and define n points $P_1, P_2, \dots, P_n$ in $\mathbb{R}^{s+1}$ by $P_j = (1, t_j, t_j^2, \dots, t_j^s)$.

These points, whose last s coordinates represent points on the d -dimensional moment curve, will be the points used in the realization of A . To complete the proof we have to show that each row of A can be realized by a suitable hyperplane through the origin. This is proved by applying some of the known properties of the moment curve as follows. Consider the sign vector representing an arbitrary row of A . Suppose this vector has r sign changes, where, of course,

$r \leq s$. Suppose the sign changes in this vector occur between the coordinates i_j and $i_j + 1$, for $1 \leq j \leq r$. Choose arbitrary reals $y_1, \dots, y_r$, where $t_{i_j} < y_j < t_{i_{j+1}}$ for $1 \leq j \leq r$. Consider the polynomial $P(t) = \prod_{j=1}^r (t - y_j)$. Since its degree is at most s there are real numbers a_j such that $P(t) = \sum_{j=0}^s a_j t^j$. Let H be the hyperplane in $\mathbb{R}^{s+1}$ defined by $H = \{(x_0, x_1, \dots, x_s) \in \mathbb{R}^{s+1} : \sum_{j=0}^s a_j x_j = 0\}$. Clearly the point $P_j = (1, t_j, \dots, t_j^s)$ is on the positive side of this hyperplane if $P(t_j) > 0$, and is on its negative side if $P(t_j) < 0$. Since the polynomial P changes sign only in the values y_j , it follows that the hyperplane H separates the points $P_1, \dots, P_n$ according to the sign pattern of the corresponding row of A . Hence, by choosing the orientation of H appropriately, we conclude that A is realizable in $\mathbb{R}^{s+1}$, completing the proof of the lemma.

Lemma 14.3.3 For every m by n matrix A of ± 1 entries there is a matrix B obtained from A by multiplying some of the columns of A by -1 , such that

$$s(B) \leq \frac{n-1}{2} + \sqrt{\frac{n-1}{2} \log m}.$$

Proof. For each column of A , randomly and independently, choose a number $\epsilon \in \{\pm 1\}$, where each of the two choices is equally likely, and multiply this column by ϵ . Let B be the random sign matrix obtained in this way. Consider an arbitrary fixed row of B . One can easily check that the random variable describing the number of sign changes in this row is a binomial random variable with parameters $n-1$ and $p = 1/2$. This is because no matter what the entries of A in this row are, the row of B is a totally random row of ± 1 entries. By the standard estimates for binomial distributions, described in Appendix A, the probability that this number is greater than $\frac{1}{2}(n-1) + \sqrt{\frac{1}{2}(n-1) \log m}$ is smaller than $1/m$. Therefore with positive probability the number of sign changes in each of the m rows is at most that large, completing the proof.

Proof [Theorem 14.3.1]. Let A be an arbitrary m by n matrix of ± 1 entries. By Lemma 14.3.3 there is a matrix B obtained from A by replacing some of its columns by their inverses, such that $s(B) \leq \frac{1}{2}(n-1) + \sqrt{\frac{1}{2}(n-1) \log m}$. Observe that $d(A) = d(B)$, since any realization of one of these matrices by points and hyperplanes through the origin gives a realization of the other one by replacing the points corresponding to the altered columns by their antipodal points. Therefore, by Lemma 14.3.2,

$$d(A) = d(B) \leq s(B) + 1 \leq \frac{n+1}{2} + \sqrt{\frac{n-1}{2} \log m}.$$

This completes the proof.

It is worth noting that by applying the (general) six standard deviations theorem stated at the end of Section 13.2, the estimate in Lemma 14.3.3 (and hence in Theorem 14.3.1) can be improved to $\frac{1}{2}n + O(\sqrt{n \log(m/n)})$. It can also be shown that if n and m grow so that m/n^2 tends to infinity and $(\log_2 m)/n$ tends to 0 then for almost all m by n matrices A of ± 1 entries $d(A) = (\frac{1}{2} + o(1))n$.

18.5.4 14.4 ϵ -nets and Vc-dimensions of Range Spaces

What is the minimum number $f = f(n, \epsilon)$ such that every set X of n points in the plane contains a subset S of at most f points such that every triangle containing at least ϵn points of X contains at least one point of S ? As we shall see in this section, there is an absolute constant c such that $f(n, \epsilon) \leq (c/\epsilon) \log(1/\epsilon)$ and this estimate holds for every n . This somewhat surprising result is a very special case of a general theorem of Vapnik and Chervonenkis (1971), which has been extended by Haussler and Welzl (1987), and which has many interesting applications in computational geometry and in statistics.

In order to describe this result we need a few definitions. A range space S is a pair (X, R) , where X is a (finite or infinite) set and R is a (finite or infinite) family of subsets of X . The members of X are called points and those of R are called ranges. If A is a subset of X then $P_R(A) = \{r \cap A : r \in R\}$ is the projection of R on A . In case this projection contains all subsets of A we say that A is shattered. The Vapnik-Chervonenkis dimension (or VC-dimension) of S , denoted by $VC(S)$, is the maximum cardinality of a shattered subset of X . If there are arbitrarily large shattered subsets then $VC(S) = \infty$.

The number of ranges in any finite range space with a given number of points and a given VC-dimension cannot be too large. For integers $n \geq 0$ and $d \geq 0$, define a function $g(d, n)$ by $g(d, n) = \sum_{i=0}^d \binom{n}{i}$. Observe that for all $n, d \geq 1$, $g(d, n) = g(d, n-1) + g(d-1, n-1)$. The following combinatorial lemma was proved, independently, by Sauer (1972), by Perles and Shelah and, in a slightly weaker form, by Vapnik and Chervonenkis.

Lemma 14.4.1 If (X, R) is a range space of VC-dimension d with $|X| = n$ points then $|R| \leq g(d, n)$.

Proof. We apply induction on $n + d$. The assertion is trivially true for $d = 0$ and $n = 0$. Assuming it holds for n and $d-1$ and for $n-1$ and $d-1$ we prove it for n and d . Let $S = (X, R)$ be a range space of VC-dimension d on n points. Suppose $x \in X$, and consider the two range spaces $S - x$ and $S \setminus x$ defined as follows.

$$\begin{aligned} S - x &= (X - \{x\}, R - x), \text{ where } R - x = \{r \setminus \{x\} : r \in R\}, \\ S \setminus x &= (X - \{x\}, R \setminus x), \text{ where } R \setminus x = \{r \in R : x \notin r, r \cup \{x\} \in R\}. \end{aligned}$$

Clearly the VC-dimension of $S - x$ is at most d . It is also easy to see that the VC-dimension of $S \setminus x$ is at most $d-1$. Therefore, by the induction hypothesis,

$$|R| = |R - x| + |R \setminus x| \leq g(d, n-1) + g(d-1, n-1) = g(d, n),$$

completing the proof.

It is easy to check that the estimate given in the above lemma is sharp for all possible values of n and d . If (X, R) is a range space of VC-dimension d and $A \subset X$, then the VC-dimension of $(A, P_R(A))$ is clearly at most d . Therefore the last lemma implies the following.

Corollary 14.4.2 If (X, R) is a range space of VC-dimension d then for every finite subset A of X , $|P_R(A)| \leq g(d, |A|)$.

There are many range spaces with finite VC-dimension that arise naturally in discrete and computational geometry. One such example is the space $S = (\mathbb{R}^d, H)$, whose points are all the points in the d -dimensional Euclidean space, and whose set of ranges is the set of all (open) half-spaces. Any set of $d+1$ affinely independent points is shattered in this space, and, by Radon's Theorem, no set of $d+2$ points is shattered. Therefore $VC(S) = d+1$. As shown by Dudley (1978), if (X, R) has finite VC-dimension, so does (X, R_k) , where R_k is the set of all Boolean combinations formed from at most k ranges in R . In particular, the following statement is a simple consequence of Corollary 14.4.2.

Corollary 14.4.3 Let (X, R) be a range space of VC-dimension $d \geq 2$ and let (X, R_h) be the range space on X in which $R_h = \{(r_1 \cap \dots \cap r_h) : r_1, \dots, r_h \in R\}$. Then $VC(X, R_h) \leq$

$2dh \log(dh)$.

Proof. Let A be an arbitrary subset of cardinality n of X . By Corollary 14.4.2 $|P_R(A)| \leq g(d, n) \leq n^d$. Since each member of $P_{R_h}(A)$ is an intersection of h members of $P_R(A)$, it follows that $|P_{R_h}(A)| \leq \binom{g(d, n)}{h} \leq n^{dh}$. Therefore, if $n^{dh} < 2^n$, then A cannot be shattered. But this inequality holds for $n \geq 2dh \log(dh)$, since $dh \geq 4$.

As shown above, the range space whose set of points is $\mathbb{R}^d$ and whose set of ranges is the set of all half-spaces has VC-dimension $d + 1$. This and the last corollary imply that the range space $(\mathbb{R}^d, C_h)$, where C_h is the set of all convex d -polytopes with h facets, has a VC-dimension that does not exceed $2(d + 1)h \log((d + 1)h)$.

An interesting property of range spaces with a finite VC-dimension is the fact that each finite subset of such a set contains relatively small good samples in the sense described below. Let (X, R) be a range space and let A be a finite subset of X . For $0 \leq \epsilon \leq 1$, a subset $B \subset A$ is an ϵ -sample for A if for any range $r \in R$ the inequality

$$\left| \frac{|A \cap r|}{|A|} - \frac{|B \cap r|}{|B|} \right| \leq \epsilon$$

holds. Similarly, a subset $N \subset A$ is an ϵ -net for A if any range $r \in R$ satisfying $|r \cap A| > \epsilon|A|$ contains at least one point of N .

Note that every ϵ -sample for A is also an ϵ -net and that the converse is not true. However, both notions define subsets of A that represent approximately some of the behavior of A with respect to the ranges. Our objective is to show the existence of small ϵ -nets or ϵ -samples for finite sets in some range spaces. Observe that if (X, R) is a range space with an infinite VC-dimension then for every n there is a shattered subset A of X of cardinality n . It is obvious that any ϵ -net (and hence certainly any ϵ -sample) for such an A must contain at least $(1 - \epsilon)n$ points; that is, it must contain almost all points of A . Therefore in infinite VC-dimension there are no small nets or samples. However, it turns out that in finite VC-dimension there are always very small nets and samples. The following theorem was proved by Vapnik and Chervonenkis (1971).

Theorem 14.4.4 There is a positive constant c such that if (X, R) is any range space of VC-dimension at most d , $A \subset X$ is a finite subset and $\epsilon, \delta > 0$, then a random subset B of cardinality s of A , where s is at least the minimum between $|A|$ and

$$\frac{c}{\epsilon^2} \left(d \log \frac{d}{\epsilon} + \log \frac{1}{\delta} \right)$$

is an ϵ -sample for A with probability at least $1 - \delta$.

Using similar ideas, Haussler and Welzl (1987) proved the following theorem.

Theorem 14.4.5 Let (X, R) be a range space of VC-dimension d , let A be a finite subset of X and suppose $0 < \epsilon, \delta < 1$. Let N be a set obtained by m random independent draws from A , where

$$m \geq \max \left\{ \frac{4}{\epsilon} \log \frac{2}{\delta}, \frac{8d}{\epsilon} \log \frac{8d}{\epsilon} \right\}. \quad (14.2)$$

Then N is an ϵ -net for A with probability at least $1 - \delta$.

Therefore, if A is a finite subset of a range space of finite VC-dimension d , then for any $\epsilon > 0$, A contains ϵ -nets as well as ϵ -samples whose size is at most some function of ϵ and d , independent of the cardinality of A ! The result about the triangles mentioned in the first paragraph of this section thus follows from Theorem 14.4.5, together with the observation following Corollary 14.4.3 that implies that the range space whose ranges are all triangles in the plane has a finite VC-dimension. We note that, as shown by Pach and Woeginger (1990), there are cases in which, for fixed δ , the dependence of m in $1/\epsilon$ cannot be linear, but there is no known natural

geometric example demonstrating this phenomenon. See also Komlós, Pach and Woeginger (1992) for a tight form of the last theorem.

The proofs of Theorems 14.4.4 and 14.4.5 are very similar. Since the computation in the proof of Theorem 14.4.5 is simpler, we describe here only the proof of this theorem and encourage the reader to try and make the required modifications that yield a proof for Theorem 14.4.4.

Proof [Theorem 14.4.5]. Let (X, R) be a range space with VC-dimension d and let A be a subset of X of cardinality $|A| = n$. Suppose m satisfies (14.2), and let $N = (x_1, \dots, x_m)$ be obtained by m independent random choices of elements of A . (The elements in N are not necessarily distinct, of course.) Let E_1 be the following event:

$$E_1 = \{\exists r \in R : |r \cap A| > \epsilon n, r \cap N = \emptyset\}.$$

To complete the proof we must show that the probability of E_1 is at most δ . To this end, we make an additional random choice and define another event as follows. Independently of our previous choice, we let $T = (y_1, \dots, y_m)$ be obtained by m independent random choices of elements of A . Let E_2 be the event defined by

$$E_2 = \left\{ \exists r \in R : |r \cap A| > \epsilon n, r \cap N = \emptyset, |r \cap T| \geq \frac{\epsilon m}{2} \right\}.$$

[Since the elements of T are not necessarily distinct, the notation $|r \cap T|$ means here $|\{i : 1 \leq i \leq m, y_i \in r\}|$. The quantities $|r \cap N|$ and $|r \cap (N \cup T)|$ are similarly defined.]

Claim 14.4.6 $\Pr[E_2] \geq \frac{1}{2} \Pr[E_1]$.

Proof. It suffices to prove that the conditional probability $\Pr[E_2 \mid E_1]$ is at least $\frac{1}{2}$. Suppose that the event E_1 occurs. Then there is an $r \in R$ such that $|r \cap A| > \epsilon n$ and $r \cap N = \emptyset$. The conditional probability above is clearly at least the probability that for this specific r , $|r \cap T| \geq \frac{1}{2}\epsilon m$. However, $|r \cap T|$ is a binomial random variable with expectation pm and variance $(1-p)pm \leq pm$, where $p = |r \cap A|/|A| \geq \epsilon$. Hence, by Chebyshev's Inequality,

$$\Pr\left[|r \cap T| < \frac{\epsilon m}{2}\right] \leq \Pr\left[|r \cap T| < \frac{pm}{2}\right] \leq \frac{pm}{(pm/2)^2} \leq \frac{4}{\epsilon m} \leq \frac{1}{2},$$

where the last inequality follows from (14.2). Thus the assertion of Claim 14.4.6 is correct.

Claim 14.4.7 $\Pr[E_2] \leq g(d, 2m)2^{-\epsilon m/2}$.

Proof. The random choice of N and T can be described in the following way, which is equivalent to the previous one. First one chooses $N \cup T = (z_1, \dots, z_{2m})$ by making $2m$ random independent choices of elements of A , and then one chooses randomly precisely m of the elements z_i to be the set N (the remaining elements z_j form the set T , of course). For each range $r \in R$ satisfying $|r \cap A| > \epsilon n$, let E_r be the event that $|r \cap T| > \frac{1}{2}\epsilon m$ and $r \cap N = \emptyset$. A crucial fact is that if $r, r' \in R$ are two ranges, $|r \cap A| > \epsilon n$ and $|r' \cap A| > \epsilon n$ and if $r \cap (N \cup T) = r' \cap (N \cup T)$, then the two events E_r and $E_{r'}$, when both are conditioned on the choice of $N \cup T$, are identical. This is because the occurrence of E_r depends only on the intersection $r \cap (N \cup T)$. Therefore, for any fixed choice of $N \cup T$, the number of distinct events E_r does not exceed the number of different sets in the projection $P_{N \cup T}(R)$.

Since the VC-dimension of X is d , Corollary 14.4.2 implies that this number does not exceed $g(d, 2m)$.

Let us now estimate the probability of a fixed event of the form E_r given the choice of $N \cup T$. This probability is at most

$$\Pr\left[r \cap N = \emptyset \mid |r \cap (N \cup T)| > \frac{\epsilon m}{2}\right].$$

Define $s = |r \cap (N \cup T)|$. Since the choice of N among the elements of $N \cup T$ is independent of the choice of $N \cup T$, the last conditional probability is precisely

$$\begin{aligned} & \frac{(2m-s)(2m-s-1)\cdots(m-s+1)}{2m(2m-1)\cdots(m+1)} \\ &= \frac{m(m-1)\cdots(m-s+1)}{2m(2m-1)\cdots(2m-s+1)} \leq 2^{-s} \leq 2^{-\epsilon m/2} \end{aligned}$$

Since there are at most $g(d, 2m)$ potential distinct events E_r , it follows that the probability that at least one of them occurs given the choice of $N \cup T$ is at most $g(d, 2m)2^{-\epsilon m/2}$. Since this estimate holds conditioned on every possible choice of $N \cup T$ it follows that the probability of the event E_2 is at most $g(d, 2m)2^{-\epsilon m/2}$. This establishes Claim 14.4.7

By Claims 14.4.6 and 14.4.7, $\Pr[E_1] \leq 2g(d, 2m)2^{-\epsilon m/2}$. To complete the proof of the theorem it remains to show that if m satisfies inequality (14.2) then

$$2g(d, 2m)2^{-\epsilon m/2} \leq \delta$$

We describe the proof for $d \geq 2$. The computation for $d = 1$ is easier. Since $g(d, 2m) \leq (2m)^d$ it suffices to show that $2(2m)^d \leq \delta 2^{\epsilon m/2}$; that is,

$$\frac{\epsilon m}{2} \geq d \log(2m) + \log \frac{2}{\delta}$$

From (14.2) it follows that

$$\frac{\epsilon m}{4} \geq \log \frac{2}{\delta}$$

and hence it suffices to show that $\frac{1}{4}\epsilon m \geq d \log(2m)$.

The validity of the last inequality for some value of m implies its validity for any larger m and hence it suffices to check that it is satisfied for $m = (8d/\epsilon) \log(8d/\epsilon)$; that is,

$$2d \log \frac{8d}{\epsilon} \geq d \log \left(\frac{16d}{\epsilon} \log \frac{8d}{\epsilon} \right)$$

The last inequality is equivalent to $4d/\epsilon \geq \log(8d/\epsilon)$, which is certainly true. This completes the proof of the theorem.

Theorems 14.4.4 and 14.4.5 have been used for constructing efficient data structures for various problems in computational geometry. A trivial example is just the observation that Theorem 14.4.4 implies the following: For every $\epsilon > 0$ there is a constant $c = c(\epsilon)$ such that for every n and every set A of n points in the plane there is a data structure of size $c(\epsilon)$ that enables us to estimate, given any triangle in the plane, the number of points of A in this triangle up to an additive error of ϵn . This is done simply by storing the coordinates of a set of points that form an ϵ -sample for A considered as a subset of the range space whose ranges are all planar triangles. More sophisticated data structures whose construction relies on the above two theorems can be found in the paper of Haussler and Welzl (1987).

18.5.5 14.5 Dual Shatter Functions and Discrepancy

The dual shatter function h of a range space $S = (X, R)$ is the function h mapping integers to integers, defined by letting $h(g)$ denote the maximum, over all possible choices of g members of R , of the number of atoms in the Venn diagram of these members. It is not too difficult to prove that if the VC-dimension of S is d , then $h(g) \leq O\left(g^{2^{d+1}-1}\right)$, but in geometric applications it is usually better to bound this function directly.

In Matoušek, Welzl and Wernisch (1993) it is proved that if the dual shatter function of a range space $S = (X, R)$ satisfies $h(g) \leq O(g^t)$, A is any set of n points in the range space and $\mathcal{F}$ is the projection $P_R(A)$ of R on A , then the discrepancy of $\mathcal{F}$ satisfies

$$\text{disc}(\mathcal{F}) \leq O\left(n^{1/2-1/2t}\sqrt{\log n}\right) \quad (14.3)$$

This supplies nontrivial estimates in various geometric situations, improving the trivial bound that follows from Theorem 13.1.1 of Chapter 13. In most of these geometric applications it is widely believed that the $\sqrt{\log n}$ factor can be omitted. In the abstract setting, however, this factor cannot be omitted, as proved for $t = 2, 3$ in Matoušek (1997) and later for all t in Alon, Rónyai and Szabó (1999).

The proof of (14.3) is based on a beautiful result of Chazelle and Welzl (1989) and its improvement by Haussler (1995). It is somewhat simpler to prove the result with an extra logarithmic factor, and this is the proof we present here. See Pach and Agarwal (1995) for some additional information.

Let $\mathcal{F}$ be a family of subsets of a finite set A . In what follows we consider graphs whose edges are (unordered) pairs of points of A . For $F \in \mathcal{F}$ and $x, y \in A$, the edge xy stabs F if F contains exactly one of the two points x and y . The following theorem is proved in Chazelle and Welzl (1989). An improvement by a logarithmic factor appears in Haussler (1995).

Theorem 14.5.1 Let $(A, \mathcal{F})$ be a finite range space, where $|A| = n$, and suppose that its dual shatter function h satisfies $h(g) \leq cg^t$ for some fixed $c, t > 0$. Then, there is a $C = C(c, t)$ and a Hamiltonian path on A , such that each member F of $\mathcal{F}$ is stabbed by at most $Cn^{1-1/t} \log n$ edges of the path.

To prove the above theorem, we need the following lemma.

Lemma 14.5.2 Let $(A, \mathcal{F}), n, h, t$ and c be as above, let B be a finite subset of $p > 1$ points of A , and let $\mathcal{G}$ be a collection of m (not necessarily distinct) members of $\mathcal{F}$. Then there are two distinct points x, y in B , such that the edge xy stabs at most $(bm \log p)/p^{1/t}$ members of $\mathcal{G}$, where $b = b(c)$.

Proof. We may and will assume that p is larger than $c + 1$. Let g be the largest integer such that $cg^t \leq p - 1$, that is, $g = \lfloor ((p - 1)/c)^{1/t} \rfloor$. Let L be a random collection of g members of $\mathcal{G}$, each picked, randomly and independently (with possible repetitions), among all m members of $\mathcal{G}$ with uniform distribution. The Venn diagram of all members of L partition B into at most $h(g) \leq cg^t < p$ atoms and hence there are two distinct points x, y of B that lie in the same atom.

To complete the proof it suffices to show that with positive probability, for each pair of points of B that stabs more than $(bm \log p)/p^{1/t}$ members of $\mathcal{G}$, at least one of these members lies in L (and hence the pair does not lie in an atom of the corresponding Venn diagram.) There are $\binom{p}{2}$ such pairs and for each of them the probability that L contains no member of $\mathcal{G}$ it stabs is at most

$$\left(1 - \frac{b \log p}{p^{1/t}}\right)^g \leq \exp\left(-\frac{b \log p}{p^{1/t}} \left\lfloor \left(\frac{p-1}{c}\right)^{1/t} \right\rfloor\right),$$

which is less than $1/p^2$ for an appropriately chosen constant $b = b(c)$. This completes the proof.

Proof [Theorem 14.5.1]. Note first that if d is the VC-dimension of the given space, then there is a shattered set D of size d . It is not difficult to see that there are $g = \lceil \log_2 d \rceil$ sets among those shattering D , so that no two points of D lie in the same atom of their Venn diagram. Therefore $d \leq c(\lceil \log_2 d \rceil)^t$, implying that $d \leq 2^{c't \log t}$, where $c' = c'(c)$. By Lemma 14.4.1 this implies that the total number of ranges in R is at most $n^{2^{c't \log t}}$.

We next prove that there is a spanning tree of A satisfying the assertion of Theorem 14.5.1, and then show how to replace it by a Hamiltonian path. By Lemma 14.5.2 with $B_0 = A, p_0 = n$ and $\mathcal{G}_0 = \mathcal{F}, m_0 = |\mathcal{G}_0| \left(\leq n^{2^{c't \log t}}\right)$, we conclude that there is a pair x_0, y_0 of points in A

such that the edge x_0y_0 does not stab more than $m_0(b \log n)/n^{1/t}$ members of $\mathcal{G}$. Let $\mathcal{G}_1$ be the collection obtained from $\mathcal{G}$ by duplicating all members of $\mathcal{G}$ that are stabbed by x_0y_0 , and define $B_1 = B - x_0, p_1 = n - 1, m_1 = |\mathcal{G}_1| \leq m_0 [1 + (b \log n)/n^{1/t}]$. Applying Lemma 14.5.2 again, this time to B_1 and $\mathcal{G}_1$, we obtain another pair x_1, y_1 , define $B_2 = B_1 - x_1, p_2 = p_1 - 1 = n - 2$, and let $\mathcal{G}_2$ be the collection obtained from $\mathcal{G}_1$ by duplicating all members of $\mathcal{G}_1$ stabbed by $x_1y_1, m_2 = |\mathcal{G}_2|$. By the assertion of the lemma, $m_2 \leq m_1 [1 + (b \log n)/(n - 1)^{1/t}]$. Proceeding in this manner we get a sequence $x_0y_0, x_1y_1, \dots, x_{n-1}y_{n-1}$ of edges of a graph on A , a sequence of subsets $B_0 = A, B_1, \dots, B_{n-1}$, where each B_i is obtained from the previous one by omitting the point x_{i-1} , and a sequence of collections $\mathcal{G}_0, \mathcal{G}_1, \dots, \mathcal{G}_{n-1}$, where

$$\begin{aligned} |\mathcal{G}_{n-1}| &\leq m_0 \prod_{i=0}^{n-1} \left(1 + \frac{b \log n}{(n-i)^{1/t}} \right) \\ &\leq n^{2^{c't \log t}} \exp \left(b \log n \sum_{i=0}^{n-1} (n-i)^{-1/t} \right) \leq 2^{b'n^{1-1/t} \log n}, \end{aligned}$$

for an appropriate $b' = b'(c, t)$.

Note, now, that the edges x_iy_i form a spanning tree on the set A . The crucial observation is the fact that if a member of $\mathcal{F}$ is stabbed by s of the edges, then it is being duplicated s times during the above process that generates $\mathcal{G}_{n-1}$, implying that $2^s \leq |\mathcal{G}_{n-1}|$ and hence that $s \leq b'n^{1-1/t} \log n$. It remains to replace the spanning tree by a Hamiltonian path. To do so, replace each edge of the tree by two parallel edges and take a Euler tour in the resulting graph (in which all degrees are even). This is a sequence $x_0, x_1, x_2, \dots, x_{2n-2} = x_0$ of points of A such that each adjacent pair of elements of the sequence is an edge of the tree, and each edge appears twice this way. The subsequence of the above one obtained by keeping only the first appearance of each point of A is a Hamiltonian path; it is easy to check that each member of $\mathcal{F}$ is stabbed by at most $2b'n^{1-1/t} \log n$ of its edges, completing the proof.

The following result is a simple consequence of Theorem 14.5.1. As mentioned above, its assertion can be improved by a factor of $\sqrt{\log n}$.

Theorem 14.5.3 Let $(A, \mathcal{F})$ be a finite range space, where $|A| = n$, and suppose that its dual shatter function h satisfies $h(g) \leq cg^t$ for some fixed $c, t > 0$. Then, there is a $C' = C'(c, t)$ such that the discrepancy of $\mathcal{F}$ satisfies

$$\text{disc}(\mathcal{F}) \leq C'n^{1/2-1/2t} \log n.$$

Proof. Without loss of generality, assume that the number of points of A is even (otherwise, simply omit a point). By Theorem 14.5.1 there is a Hamiltonian path $x_1x_2 \cdots x_n$ on these points such that each member of $\mathcal{F}$ is stabbed by at most $Cn^{1-1/t} \log n$ edges of the path. Let $f : A \rightarrow \{-1, 1\}$ be a random coloring of A , where for each $i, 1 \leq i \leq n/2$, randomly and independently, either $f(x_{2i-1}) = 1, f(x_{2i}) = -1$ or $f(x_{2i-1}) = -1, f(x_{2i}) = 1$, the two choices being equally likely. Fix a member $F \in \mathcal{F}$, and note that the contribution of each pair $x_{2i-1}x_{2i}$ to the sum $\sum_{x_j \in F} f(x_j)$ is zero, if the edge $x_{2i-1}x_{2i}$ does not stab F , and is either $+1$ or -1 otherwise. It thus follows that this sum has, in the notation of Theorem A.1.1, the distribution S_r for some $r \leq Cn^{1-1/t} \log n$. Thus the probability it is at least α in absolute value can be bounded by $2e^{-\alpha^2/2r}$. As shown in the first paragraph of the proof of Theorem 14.5.1, the total number of members of $\mathcal{F}$ does not exceed $n^{2^{c't \log t}}$, and thus the probability that there exists a member $F \in \mathcal{F}$ for which the sum $\sum_{x_j \in F} f(x_j)$ exceeds $C'n^{1/2-1/2t} \log n$ is less than 1 for an appropriately chosen constant $C' = C'(c, t)$.

The range space whose set of points is an arbitrary set of points in the plane, and whose ranges are all discs in the plane, has dual shatter function $O(g^2)$. The above theorem thus

shows that it is possible to color any set of n points in the plane red and blue, such that the absolute value of the difference between the number of red points and the number of blue points inside any disc would not exceed $n^{1/4+o(1)}$. Similar results can be proved for many other geometric range spaces.

18.5.6 14.6 Exercises

1. Let A be a set of n points in the plane, and let $\mathcal{F}$ be the set of all intersections of A with an open triangle in the plane. Prove that the discrepancy of $\mathcal{F}$ does not exceed $n^{1/4+o(1)}$.
2. Prove that n distinct points in the plane determine at most $O(n^{4/3})$ unit distances.

The Probabilistic Lens: Efficient Packing

Let $C \subset \mathbb{R}^n$ be bounded with Riemann measure $\mu = \mu(C) > 0$. Let $N(C, x)$ denote the maximal number of disjoint translates of C that may be packed in a cube of side x and define the packing constant

$$\delta(C) = \mu(C) \lim_{x \rightarrow \infty} N(C, x) x^{-n},$$

the maximal proportion of space that may be packed by copies of C . The following result improves the one described in Section 3.4.

Theorem 1 Let C be bounded, convex and centrally symmetric about the origin. Then

$$\delta(C) \geq 2^{-(n-1)}.$$

Proof. Fix $\epsilon > 0$. Normalize so $\mu = \mu(C) = 2 - \epsilon$. For any real z let C_z denote the "slab" of $(z_1, \dots, z_{n-1}) \in \mathbb{R}^{n-1}$ such that $(z_1, \dots, z_{n-1}, z) \in C$ and let $\mu(C_z)$ be the usual $(n-1)$ -dimensional measure of C_z . Riemann measurability implies

$$\lim_{\gamma \rightarrow 0} \sum_{m \in \mathbb{Z}} \mu(C_{m\gamma}) \gamma = \mu(C).$$

Let K be an integer sufficiently large so that

$$\sum_{m \in \mathbb{Z}} \mu(C_{mK^{-(n-1)}}) K^{-(n-1)} < 2$$

and further that all points of C have all coordinates less than $K/2$.

For $1 \leq i \leq n-1$ let $v_i \in \mathbb{R}^n$ be that vector with all coordinates zero except K as the i th coordinate. Let

$$v = (z_1, \dots, z_{n-1}, K^{-(n-1)})$$

where $z_1, \dots, z_{n-1}$ are chosen uniformly and independently from the real interval $[0, K)$. Let Λ_v denote the lattice generated by the v 's; that is,

$$\begin{aligned} \Lambda_v &= \{m_1 v_1 + \dots + m_{n-1} v_{n-1} + m v : m_1, \dots, m_{n-1}, m \in \mathbb{Z}\} \\ &= \{(m z_1 + m_1 K, \dots, m z_{n-1} + m_{n-1} K, m K^{-(n-1)}) : \\ &\quad m_1, \dots, m_{n-1}, m \in \mathbb{Z}\}. \end{aligned}$$

Let $\theta(x)$ denote that unique $x' \in (-\frac{1}{2}K, \frac{1}{2}K]$ so that $x - mK = x'$ for some $m \in \mathbb{Z}$. For $m \in \mathbb{Z}$ let A_m be the event that some $m_1 v_1 + \dots + m_{n-1} v_{n-1} + m v \in C$. Since all coordinates of all points of C are less than $K/2$, A_m occurs if and only if

$$(\theta(mz_1), \dots, \theta(mz_{n-1}), mK^{-(n-1)}) \in C$$

which occurs if and only if $(\theta(mz_1), \dots, \theta(mz_{n-1})) \in C_{mK^{-(n-1)}}$. The independence and uniformity of the z_i over $[0, K)$ implies the independence and uniformity of the $\theta(z_i)$ over $(-\frac{1}{2}K, \frac{1}{2}K]$ and so

$$\Pr[A_m] = K^{-(n-1)} \mu(C_{mK^{-(n-1)}})$$

Summing over positive m , and employing the central symmetry,

$$\sum_{m>0} \Pr[A_m] < \frac{1}{2} \sum_{m \in \mathbb{Z}} K^{-(n-1)} \mu(C_{mK^{-(n-1)}}) < \frac{1}{2} \cdot 2 = 1$$

Hence there exists v with all $\{A_m\}_{m>0}$ not holding. By the central symmetry A_m and A_{-m} are the same event so no $\{A_m\}_{m \neq 0}$ holds. When $m = 0$ the points $m_1v_1 + \dots + m_{n-1}v_{n-1} = K(m_1, \dots, m_{n-1}, 0)$ all lie outside C except the origin. For this v

$$\Lambda_v \cap C = \{0\}$$

Consider the set of translates $C + 2w, w \in \Lambda_v$. Suppose

$$z = c_1 + 2w_1 = c_2 + 2w_2 \text{ with } c_1, c_2 \in C, w_1, w_2 \in \Lambda_v$$

Then $\frac{1}{2}(c_1 - c_2) = w_2 - w_1$. From convexity and central symmetry $\frac{1}{2}(c_1 - c_2) \in C$. As $w_2 - w_1 \in \Lambda_v$, it is zero and hence $c_1 = c_2$ and $w_1 = w_2$. That is, the translates form a packing of $\mathbb{R}^n$. As $\det(2\Lambda_v) = 2^n \det(\Lambda_v) = 2^n$ this packing has density $2^{-n}\mu = 2^{-n}(2 - \epsilon)$. As $\epsilon > 0$ was arbitrary, $\delta(C) \geq 2^{-(n-1)}$.

18.6 15 Codes, Games and Entropy

18.6.1 15.1 Codes

Suppose we want to send a message, here considered a string of bits, across a noisy channel. There is a probability p that any bit sent will be received incorrectly. The value p is a parameter of the channel and cannot be changed. We assume that p is both the probability that a sent zero is received as a one and that a sent one is received as a zero. Sent bits are always received, but perhaps incorrectly. We further assume that the events that the bits are received incorrectly are mutually independent. The case $p = 0.1$ will provide a typical example.

How can we improve the reliability of the system? One simple way is to send each bit three times. When the three bits are received we use majority rule to decode. The probability of incorrect decoding is then $3p^2 + p^3 = 0.031$ in our instance. We have sacrificed speed - the rate of transmission of this method

is $\frac{1}{3}$ - and gained accuracy in return. If we send each bit five times and use majority rule to decode, the probability of incorrect decoding drops to 0.01051 but the rate of transmission also drops to $\frac{1}{5}$. Clearly we may make the probability of incorrect decoding as low as needed, but seemingly with the trade-off that the rate of transmission tends to zero. It is the fundamental theorem of Information Theory due to Claude Shannon - that this trade-off is not necessary: there are codes with rate of transmission approaching a positive constant (dependent on p) with probability of incorrect transmission approaching zero.

A coding scheme consists of positive integers m, n , a function $f : \{0, 1\}^m \rightarrow \{0, 1\}^n$ called the encoding function, and a function $g : \{0, 1\}^n \rightarrow \{0, 1\}^m$ called the decoding function. The notion is that a message (or segment of message) $x \in \{0, 1\}^m$ will be encoded and sent as $f(x)$

and a received message $y \in \{0, 1\}^n$ will be decoded as $g(y)$. The rate of transmission of such a scheme is defined as m/n . Let $E = (e_1, \dots, e_n)$ be a random string defined by $\Pr[e_i = 1] = p$, $\Pr[e_i = 0] = 1 - p$, the values e_i mutually independent. We define the probability of correct transmission as $\Pr[g(f(x) + E) = x]$. Here x is assumed to be uniformly distributed over $\{0, 1\}^m$ and independent of E ; '+' here is mod2 vector addition.

A crucial role is played by the entropy function

$$H(p) = -p \log_2 p - (1 - p) \log_2 (1 - p)$$

defined for $0 < p < 1$. For any fixed p the entropy function appears in the asymptotic formula

$$\binom{n}{pn} = \frac{n^n e^{-n}}{(pn)^{pn} e^{-pn} ((1-p)n)^{(1-p)n} e^{-(1-p)n}} (1 + o(1))^n = 2^{n(H(p) + o(1))}.$$

For $0 < p < \frac{1}{2}$ we further bound

$$\sum_{i \leq pn} \binom{n}{i} \leq (1 + pn) \binom{n}{pn} = 2^{n(H(p) + o(1))}.$$

Theorem 15.1.1 [Shannon's Theorem] Let $0 < p < \frac{1}{2}$ be fixed. For $\epsilon > 0$ arbitrarily small there exists a coding scheme with rate of transmission greater than $1 - H(p) - \epsilon$ and probability of incorrect transmission less than ϵ .

Remark. It is not difficult to show that, for every such p , any coding scheme whose rate of transmission exceeds $1 - H(p) + \epsilon$ must have a significant error probability. Indeed, if $f(x)$, the image of x , is transmitted, then with high probability, the obtained output, y , is of distance $(1 + o(1))pn$ from $f(x)$. Hence, if there are 2^m input words, the total size of all typical outputs is about $2^m \cdot \binom{n}{pn} = 2^{m + (1 + o(1))H(p)n}$. If this quantity is much larger than 2^n , then there must be significant overlaps between the output sets of different input words, making the decoding likely to err.

Proof. Let $\delta > 0$ be such that $p + \delta < \frac{1}{2}$ and $H(p + \delta) < H(p) + \epsilon/2$. For n large set $m = n(1 - H(p) - \epsilon)$, guaranteeing the rate of transmission. Let $f : \{0, 1\}^m \rightarrow \{0, 1\}^n$ be a random function - each $f(x)$ uniformly and independently chosen. Given f define the decoding function $g : \{0, 1\}^n \rightarrow \{0, 1\}^m$ by setting $g(y) = x$ if x is the unique vector in $\{0, 1\}^m$ whose image, $f(x)$, is within $n(p + \delta)$ of y . We measure distance by the Hamming metric $\rho : \rho(y, y')$ is the number of coordinates in which y, y' differ. If there is no such x , or more than one such x , then we shall consider decoding to be incorrect.

There are two ways decoding can be incorrect. Possibly $f(x) + E$ is not within $n(p + \delta)$ of $f(x)$. The distance from $f(x) + E$ to $f(x)$ is simply the number of ones in E , which has a binomial distribution $B(n, p)$ and so this occurs with probability $o(1)$ (in fact, with exponentially small probability.) The only other possibility is that there is some $x' \neq x$ with $f(x') \in S$, where S is the set of y' within $n(p + \delta)$ of $f(x) + E$. Conditioning on the values $f(x)$ and E , $f(x')$ is still uniformly distributed over $\{0, 1\}^n$ and hence this occurs with probability $|S|2^{-n}$ for any particular x' and thus with total probability at most

$$2^m |S| 2^{-n} < 2^{-n(\epsilon/2 + o(1))} = o(1).$$

The total probability for incorrect decoding from both sources is thus $o(1)$ and, in fact, exponentially small. For n sufficiently large this is less than ϵ .

The average over all choices of f, x of the probability of incorrect decoding is less than ϵ . Thus there exists a specific f (hence a specific coding scheme) with probability of incorrect coding less than ϵ .

Shannon's Theorem, dealing with the intensely practical subject of communications, puts the shortcomings of the probabilistic approach in sharp contrast. Where is the coding scheme? Supposing that a coding scheme may be found, how can encoding and decoding be rapidly processed?

A group code is a coding scheme in which the map $f : \{0, 1\}^m \rightarrow \{0, 1\}^n$ is linear; that is, $f(0) = 0$ and $f(x + x') = f(x) + f(x')$, all calculations done mod 2. Group codes are of particular interest, in part because of the ease of encoding.

Theorem 15.1.2 Let $0 < p < \frac{1}{2}$ be fixed. For $\epsilon > 0$ arbitrarily small there exists a group code with rate of transmission greater than $1 - H(p) - \epsilon$ and probability of incorrect transmission less than ϵ .

Proof. For $1 \leq i \leq m$ let $u_i \in \{0, 1\}^m$ be that vector with a one in position i , all other entries zero. Let $f(u_1), \dots, f(u_m)$ be chosen randomly and independently and then extend f by setting

$$f(\epsilon_1 u_1 + \dots + \epsilon_m u_m) = \epsilon_1 f(u_1) + \dots + \epsilon_m f(u_m).$$

We follow the proof of Shannon's Theorem until bounding the probability that $f(x) + E$ lies within $n(p + \delta)$ of $f(x)$. Set $z = x - x' = \epsilon_1 u_1 + \dots + \epsilon_m u_m$, again all mod 2. As $x \neq x', z \neq 0$. Reorder for convenience so that $\epsilon_m = 1$.

By linearity $f(z) = f(x) - f(x')$ so we bound $\Pr[f(z) \in S]$, where S is the set of vectors within $n(p + \delta)$ of E . Fixing E and the $f(u_i), i < m, f(z)$ still has an additive term $f(u_m)$ that is uniform and independent. Hence $f(z)$ is distributed uniformly. Thus $\Pr[f(z) \in S] = |S|2^{-n}$ and the remainder of the proof is as in Shannon's Theorem.

18.6.2 15.2 Liar Game

Paul is trying to find a number $x \in \{1, \dots, n\}$ from a recalcitrant and mendacious Carole. He may ask q questions of the form "Is $x \in S$?", where S can be any subset of the possibilities. The questions are asked sequentially and Paul's choice of his i th question can depend on previous responses. Carole is allowed to lie - but she can lie at most k times. For which n, q, k can Paul determine the number?

When $k = 0$ Paul can win exactly when $n \leq 2^q$. The values $n = 100, q = 10, k = 1$ make for an amusing parlor game. Carole is hardly a passive observer; she may play an adversary strategy. By that we mean that she does not select an x in advance but answers consistently with at least one x . At the end of the game if her answers were consistent with more than one x then she has won. The game, called the (n, q, k) -Liar Game, is now a perfect information game with no hidden move and no draws. Hence either Paul or Carole has a perfect winning strategy. But who?

We describe an equivalent game, the Chip-Liar Game. There is a board with positions $0, 1, \dots, k$. There are n chips labeled $1, \dots, n$ which are initially at position k . There are q rounds. On each round Paul selects a set S of the chips. Carole can either move every chip not in S one position to the left or move every chip in S one position to the left. (Here position $i - 1$ is one position to the left of position i . Chips moved one position to the left from position 0 are removed from the board.) At the end of the q rounds Carole wins if there is more than one chip remaining on the board and Paul wins if there is one or zero chip remaining on the board. Basically, chip i at position j represents that the answer $x = i$ has already received $k - j$ lies; Paul selecting S represents his asking if $x \in S$; Carole moving the chips not in S represents a Yes answer, moving the chips in S represents a No answer. (In the Chip-Liar Game Carole can remove all chips from the board while in the Liar Game Carole must play consistently with at least one x . But when Carole removes all chips from the board she automatically has lost and hence this difference does not affect the determination of the winner.)

In the Chip-Liar Game there is no reason to place all chips at position k at the start. More generally, for $x_0, \dots, x_k \geq 0$, we define the $(x_0, \dots, x_k)$, q -Chip-Liar Game to be the above q round game with initial position consisting of x_i chips at position i . This, in turn, corresponds to a Liar Game in which there are x_i possibilities for which Carole is constrained to lie at most i times.

Let us define $B(q, j)$ as the probability that in q flips of a fair coin there are at most j heads. Of course, we have the exact formula

$$B(q, j) = 2^{-q} \sum_{i=0}^j \binom{q}{i}.$$

Theorem 15.2.1 If

$$\sum_{i=0}^k x_i B(q, i) > 1$$

then Carole wins the $(x_0, \dots, x_k)$, q -Chip-Liar Game.

Corollary 15.2.2 If

$$n > \frac{2^q}{\sum_{i=0}^k \binom{q}{i}}$$

then Carole wins the (n, q, k) -Liar Game.

Proof [Theorem 15.2.1]. Fix a strategy for Paul. Now Carole plays randomly! That is, at each round, after Paul has selected a set S of chips Carole flips a coin - if it comes up heads she moves every chip not in S one position to the left and if it comes up tails she moves every chip in S one position to the left. For each chip c let I_c be the indicator random variable for c remaining on the board at the end of the game. Set $X = \sum I_c$, the number of chips remaining on the board at the end of the game. Consider a single chip c . Each round Paul may have chosen $c \in S$ or $c \notin S$ but in either case c is moved to the left with probability $\frac{1}{2}$. Suppose c starts at position i . It remains on the board at the end of the game if and only if in the q rounds it has been moved to the left at most i times. Then $E[I_c]$, the probability of this occurring, is precisely $B(q, i)$. By linearity of expectation $E[X] = \sum_{i=0}^k x_i B(q, i)$. The assumption of the theorem gives $E[X] > 1$. But then $X > 1$ must occur with positive probability. That is, Carole must win with positive probability.

No strategy of Paul allows him to always win. But this is a perfect information game with no draws so someone has a perfect strategy that always wins. That someone isn't Paul, so it must be Carole.

The above proof certainly illustrated the magical element of the probabilistic method. Carole has a winning strategy but what is it? The general notion of moving from a probabilistic existence proof to an explicit construction is called derandomization and will be dealt with in detail in the next chapter. Here we can give an explicit strategy. With l moves remaining in the game and y_i chips on position i define the weight of the position as $\sum_i y_i B(l, i)$ - note this is $E[Y]$, where Y is the number of chips that would remain on the board should Carole play the rest of the game randomly. Carole's explicit strategy is to always move so as to maximize the weight.

Consider any position with weight W and any move S by Paul. Let W^y, W^n be the new weights should Carole move all chips not in S or all chips in S , respectively. We claim $W = \frac{1}{2}(W^y + W^n)$. One argument is that by linearity this identity reduces to the case of one chip and it then follows from the identity $B(l, j) = \frac{1}{2}(B(l-1, j) + B(l-1, j-1))$. But we needn't actually do any calculation. Carole's playing randomly can be thought of as first flipping a coin

to decide on her first move and then playing randomly so that $E[Y]$ is the average of the two conditional expectations.

At the start of the game, by assumption, the weight is larger than one. Carole's explicit strategy assures that the weight does not decrease so at the end of the game the weight is larger than one. But at the end of the game the weight is the number of chips remaining. Being larger than one, Carole has won the game.

The converse of the theorem, and even the corollary, is false. Consider the Liar Game with $n = 5, q = 5$ questions and $k = 1$ possible lie. In the Chip-Liar version this is the $(0, 5)$, 5-Chip-Liar Game. Here $B(5, 1) = \frac{6}{32}$ and $5 \cdot \frac{6}{32} \leq 1$. Still, Carole wins with perfect play. The problem is that Paul has no good first move. Suppose he selects two chips as S (asks "Is $x \leq 2$?" in the Liar Game). Then Carole moves the two chips one to the left (responds Yes) leaving the position $(2, 3)$ with four questions remaining. As $2B(4, 0) + 3B(4, 1) = \frac{17}{16} > 1$, Carole will now win. It is easy to check that all other moves of Paul fail. The difficulty here is that Paul was in a position with weight $W \leq 1$ but was unable to find a move such that $W^y \leq 1$ and $W^n \leq 1$.

18.6.3 15.3 Tenure Game

Paul, Chair of Department, is trying to promote one of his faculty to tenure but standing in his way is a recalcitrant and meanspirited Carole, the Provost. There are k pretenure levels, labeled $1, \dots, k$, level 1 the highest, and a level 0, representing tenure. For our purposes each faculty member is represented by a chip. The $(x_1, \dots, x_k)$ -Tenure Game begins with x_i chips at level i for $1 \leq i \leq k$ and no chips on level zero. Each year Paul presents a set S of chips to Carole. Carole may either:

- Promote all chips in S and fire the others or
- Promote all chips not in S and fire those in S .

Promote, as used above, means to move from level i to level $i - 1$. Fired means just that: removing the chip from the game. If a chip reaches level 0 then Paul is the winner. The draconian promotion or perish provision ensures that the game will end within k years with either Paul winning or Carole having successfully eliminated all chips.

Theorem 15.3.1 If $\sum_i x_i 2^{-i} < 1$ then Carole wins the $(x_1, \dots, x_k)$ -Tenure Game.

Proof. Fix a strategy for Paul. Now Carole plays randomly! That is, at each round, after Paul has selected a set S of chips Carole flips a coin - if it comes up heads she moves every chip not in S one position to the left and if it comes up tails she moves every chip in S one position to the left. For each chip c let I_c be the indicator random variable for c reaching level 0. Set $X = \sum I_c$, the number of chips reaching level 0 at the end of the game. Consider a single chip c . Each round Paul may have chosen $c \in S$ or $c \notin S$ but in either case c is moved to the left with probability $\frac{1}{2}$. Suppose c starts at position i . It remains on the board at the end of the game if and only if the first i coin flips of Carole led to promotions for c . Then $E[I_c]$, the probability

of this occurring, is precisely 2^{-i} . By linearity of expectation $E[X] = \sum_{i=1}^k x_i 2^{-i}$. The assumption of the theorem gives $E[X] < 1$. But then $X < 1$ must occur with positive probability. That is, Carole must win with positive probability.

No strategy of Paul allows him to always win. But this is a perfect information game with no draws so someone has a perfect strategy that always wins. That someone isn't Paul, so it must be Carole.

As with the Liar Game we may derandomize the above argument to give an explicit strategy for Carole. With y_i chips on position i define the weight of the position as $\sum_i y_i 2^{-i}$ - note this is $E[Y]$, where Y is the number of chips that would reach level 0 should Carole play the rest

of the game randomly. Carole's explicit strategy is to always move so as to minimize the weight. Consider any position with weight W and any move S by Paul. Let W^y, W^n be the new weights should Carole move all chips not in S or all chips in S , respectively. As in the Liar Game $W = \frac{1}{2}(W^y + W^n)$. At the start of the game, by assumption, the weight is less than one. Carole's explicit strategy assures that the weight does not increase so at all times the weight is smaller than one. A chip at level 0 would add one to the weight by itself so that this never occurs and hence Carole wins.

In the Liar Game the sufficient condition for Carole to win was not necessary because Paul did not always have an appropriately splitting move. Here, however, we have an amusing lemma.

Lemma 15.3.2 If a set of chips has weight at least one it may be split into two parts, each of weight at least $\frac{1}{2}$.

Proof. There must be two chips at some position i , otherwise the weight is less than one. If there are two chips at position 1 simply split them. If there are two chips at position $i > 1$ glue them together, and consider them as one superchip at position $i - 1$. Then the proof follows by induction on the number of chips.

Theorem 15.3.3 If $\sum x_i 2^{-i} \geq 1$ then Paul wins the $(x_1, \dots, x_k)$ -Tenure Game.

Proof. The initial weight is at least one. Applying the lemma Paul splits the chips into two parts, each of weight at least $\frac{1}{2}$, and sets S equal to one of the parts. Carole moves all chips in one part one position to the left, doubling their weight, leaving a new position of weight at least one. Thus the weight never goes below one. Therefore the game cannot end with all chips having been removed (which would have weight zero) and so it must end with a win for Paul.

18.6.4 15.4 Balancing Vector Game

The balancing vector game is a perfect information game with two players, Pusher and Chooser. There is a parameter $n \geq 1$, and we shall be concerned with asymptotics in n . There are n rounds, each involving vectors in $\mathbb{Z}^n$. There is a position vector $P \in \mathbb{Z}^n$, initially set at 0. Each round has two parts. First Pusher picks $v \in \{-1, +1\}^n$. Then Chooser either resets P to $P + v$ or to $P - v$. At the end of the n th round the payoff to Pusher is $|P|_\infty$, the maximal absolute value of the coordinates of P . Let $\text{VAL}(n)$ denote the value of this game to Pusher, that is, the maximum payoff Pusher can ensure when both players play optimally. Let S_n denote, as usual, the sum of n independent uniform ± 1 random variables.

Theorem 15.4.1 If $\Pr[|S_n| > \alpha] < n^{-1}$ then $\text{VAL}(n) \leq \alpha$.

Proof. Consider the game a win for Pusher if the final $|P|_\infty > \alpha$. Suppose Chooser announces that she will flip a fair coin each round to determine whether to reset P as $P + v$ or $P - v$. Let x_i be the i th coordinate for the final value of the position vector P . Let W_i be the event $|x_i| > \alpha$ and $W = \bigvee_{i=1}^n W_i$ so that W is the event of Pusher winning. Regardless of Pusher's strategy x_i has distribution S_n so that

$$\Pr[W] \leq \sum_{i=1}^n \Pr[|S_n| > \alpha] < 1$$

Pusher cannot always win so Chooser always wins.

Corollary 15.4.2 $\text{VAL}(n) = O(\sqrt{n \ln n})$.

To give a lower bound on $\text{VAL}(n)$ one wants to find a strategy for Pusher that wins against any Chooser. It is not sufficient to find a strategy that does well against a randomly playing Chooser - the Chooser is an adversary. Still, the notion of a randomly playing Chooser motivates the following result.

Theorem 15.4.3 If $\Pr[|S_n| > \alpha] > cn^{-1/2}$, where c is an absolute constant, then $\text{VAL}(n) > \alpha$.

Corollary 15.4.4 $\text{VAL}(n) = \Omega(\sqrt{n \ln n})$ and hence $\text{VAL}(n) = \Theta(\sqrt{n \ln n})$.

Proof [Theorem 15.4.3]. Define, for $x \in \mathbb{Z}, 0 \leq i \leq n$,

$$w_i(x) = \Pr [|x + S_{n-i}| > \alpha].$$

For $P = (x_1, \dots, x_n)$ set $w_i(P) = \sum_{j=1}^n w_i(x_j)$. When P is the position vector at the end of the i th round, $w_i(P)$ may be interpreted as the expected number of coordinates with absolute value greater than α at the end of the game, assuming random play by Chooser. At the beginning of the game $w_0(P) = w_0(0) > c\sqrt{n}$ by assumption. Given position P at the end of round i , Pusher's strategy will be to select $v \in \{-1, +1\}^n$ so that $w_{i+1}(P - v)$ and $w_{i+1}(P + v)$ are close together.

The distribution $x + S_{n-i}$ splits into $x + 1 + S_{n-i-1}$ and $x - 1 + S_{n-i-1}$ depending on the first coin flip so that for any i, x ,

$$w_i(x) = \frac{1}{2} (w_{i+1}(x + 1) + w_{i+1}(x - 1)).$$

Set $P = (x_1, \dots, x_n), v = (v_1, \dots, v_n)$. For $1 \leq j \leq n$ set

$$\Delta_j = w_{i+1}(x_j + 1) - w_{i+1}(x_j - 1)$$

so that

$$w_{i+1}(P + v) - w_{i+1}(P - v) = \sum_{j=1}^n v_j \Delta_j$$

and, for $\epsilon = \pm 1$,

$$w_{i+1}(P + \epsilon v) = w_i(P) + \frac{1}{2} \epsilon \sum_{j=1}^n v_j \Delta_j.$$

Now we bound $|\Delta_j|$. Observe that

$$\Delta_j = \Pr [S_{n-i-1} = y] - \Pr [S_{n-i-1} = z]$$

where y is the unique integer of the same parity as $n - i - 1$ in the interval $(\alpha - (x_j + 1), \alpha - (x_j - 1)]$ and z is the same in $[-\alpha - (x_j + 1), -\alpha - (x_j - 1))$. Let us set

$$g(m) = \max_s \Pr [S_m = s] = \binom{m}{\lfloor m/2 \rfloor} 2^{-m} \sim \sqrt{\frac{2}{\pi m}}$$

so that $|\Delta_j| \leq g(n - i - 1)$ for all j .

A simple strategy for Pusher is then to reorder the coordinates so that $|\Delta_1| \geq \dots \geq |\Delta_n|$ and then select $v_1, \dots, v_n \in \{-1, +1\}$ sequentially, giving $v_i \Delta_i$ the opposite sign of $v_1 \Delta_1 + \dots + v_{i-1} \Delta_{i-1}$. (When $i = 1$ or the sum is zero, choose v_i arbitrarily.) This assures

$$|v_1 \Delta_1 + \dots + v_n \Delta_n| \leq |\Delta_1| \leq g(n - i - 1).$$

Let P^i denote the position vector at the end of the i th round and v Pusher's choice for the $(i + 1)$ st round. Then regardless of Chooser's choice of $\epsilon = \pm 1$,

$$w_{i+1}(P^{i+1}) = w_{i+1}(P^i + \epsilon v) \geq w_i(P^i) - \frac{1}{2} \left| \sum_{j=1}^n v_j \Delta_j \right| \geq w_i(P^i) - \frac{1}{2} g(n - i - 1).$$

Thus

$$w_n(P^n) \geq w_0(P^0) - \frac{1}{2} \sum_{i=0}^{n-1} g(n - i - 1).$$

Simple asymptotics give that the above sum is asymptotic to $(8n/\pi)^{1/2}$. Choosing $c > (2/\pi)^{1/2}$, $w_n(P^n) > 0$. But $w_n(P^n)$ is simply the number of coordinates with absolute value greater than α in the final $P = P^n$. This Pusher strategy assures there is more than zero, hence at least one such coordinate and therefore Pusher wins.

18.6.5 15.5 Nonadaptive Algorithms

Let us modify the balancing game of Section 15.4 by requiring the vectors selected by Pusher to have coordinates zero and one rather than plus and minus one. Let $\text{VAL}^*(n)$ denote the value of the modified game. One can use the bounds on $\text{VAL}(n)$ to show $\text{VAL}^*(n) = \Theta(\sqrt{n \ln n})$.

In Chapter 13 we showed that any family of n sets $S_1, \dots, S_n$ on n points $1, \dots, n$ has discrepancy $O(\sqrt{n})$; that is, there is a coloring $\chi : \{1, \dots, n\} \rightarrow \{-1, +1\}$ so that all $|\chi(S_i)| \leq c\sqrt{n}$. The proof of this result does not yield an effective algorithm for finding such a coloring and indeed it is not known if there is a polynomial time algorithm to do so. Suppose one asks for a nonadaptive or on-line algorithm in the following sense. Instead of being presented the entire data of $S_1, \dots, S_n$ at once, one is presented with the points sequentially. At the j th "round" the algorithm looks at point j - more specifically, at which sets S_i contain j or, equivalently, at the j th column of the incidence matrix. At that stage the algorithm must decide how to color j and, once colored, the coloring cannot be changed. How small can we assure $\max |\chi(S_i)|$ with such an algorithm? We may think of the points as being presented by an adversary. Thinking of the points as their associated column vectors, Pusher as the worst case adversary and Chooser as the algorithm, the best such an algorithm can do is precisely $\text{VAL}^*(n)$.

The requirement that an algorithm be nonadaptive is both stronger and weaker than the requirement that an algorithm take polynomial time. Still, this lends support to the conjecture that there is no polynomial time algorithm for finding a coloring with all $|\chi(S_i)| \leq c\sqrt{n}$.

18.6.6 15.6 Half Liar Game

We modify the Liar Game of Section 15.2 by limiting Carole's mendacity. If the correct answer is Yes then Carole is now required to answer Yes. She may answer Yes when the correct answer is No, and that would count as one of her k lies. Let $A_k(q)$ denote the maximal n for which Paul wins the Half Liar Game with n values, q queries, and a maximum of k lies.

Theorem 15.6.1 [Dumitriu and Spencer (2004)] For each fixed $k \geq 1$,

$$A_k(q) \sim 2^{q+k} / \binom{q}{k}$$

While the methods below extend to arbitrary k , we give the proof only for the case $k = 1$. This case was first given by Cicalese and Mundici (2000).

Proof. Let us fix a winning strategy for Paul with $n = A_1(q)$. This may be described by a binary decision tree of depth q . For each value i , $1 \leq i \leq n$, let $\sigma_i = (x_{i1}, \dots, x_{iq}) \in \{Y, N\}^q$ be the string of truthful responses to Paul's queries with that value. Let T_i be the set of possible response strings given by Carole with that value. For each $x_{ij} = N$ Carole may lie on the j th question, otherwise responding truthfully. Thus $|T_i| = W(\sigma_i)$, where we define the weight $W(\sigma)$ to be one plus the number of N 's in the string σ . We cannot have any common $\sigma \in T_i \cap T_j$ as then Carole could respond with σ and Paul would not be able to distinguish i, j . Thus

$$\sum_{i=1}^n W(\sigma_i) \leq 2^q. \quad (15.1)$$

For a given u , call σ Carole friendly if $W(\sigma) \leq 1 + \frac{1}{2}(q - u)$, otherwise Paul friendly. There are at most $2^q \Pr[S_q \leq -u]$ Carole friendly σ 's, where S_q is the sum of q independent ± 1 random variables. By (15.1) there are at most $2^{q+1}/(q - u)$ Paul friendly σ 's. Thus

$$n \leq 2^q \Pr[S_q \leq -u] + \frac{2^{q+1}}{q - u}$$

The optimization of u is left as an exercise but even taking a suboptimal $u = \lfloor q^{2/3} \rfloor$ gives

$$A_1(q) = n \leq (1 + o(1)) \frac{2^{q+1}}{q}.$$

For larger n Paul cannot have a winning strategy and thus Carole must have a winning adversary strategy. Intriguingly, this argument does not yield an explicit strategy for Carole.

In the other direction let $\epsilon > 0$ be fixed and small and set $n = \lfloor (1 - \epsilon)2^{q+1}/q \rfloor$. We will give a strategy for Paul. For $r \geq 1$ let M_r denote those $\sigma \in \{Y, N\}^r$ with at least $\frac{1}{2}(r - u)N$'s and let $f(r) = |M_r|$. For definiteness, take $u = \lfloor r^{2/3} \rfloor$. Then $f(r) \sim 2^r$. We first message n . Pick r with, say, $10/\epsilon \leq n/f(r) \leq 21/\epsilon$, set $A = \lceil n/f(r) \rceil$, and boost n to $n = Af(r)$. As the boost (which makes things only harder for Paul) was by a factor less than $1 + (\epsilon/10)$ the new n still has $n \leq (1 - \epsilon/2)2^{q+1}/q$.

Paul associates the $n = f(r)A$ values with pairs (σ, j) , $\sigma \in M_r$, $1 \leq j \leq A$. For his first r queries he asks for the coordinates of σ . Carole responds τ , which can differ from the truthful σ in at most one coordinate. Thus τ has at most $\frac{1}{2}(r + u) + 1Y$'s. (Basically, these r queries are nearly even splits and force Carole to answer No nearly half the time.) What does Paul know at this moment? If Carole has not lied the answer must be one of the A values (τ, j) . If Carole has lied the answer must be one of the at most $\frac{1}{2}A(r + u + 2)$ values (τ^+, j) , where τ^+ is derived from τ by shifting a Y to a N .

Set $s = q - r$, the number of remaining queries. As A is bounded and $2^r A \sim f(r)A = n = \Theta(2^q/q)$, we have $r = q - \log_2 q - O(1)$. In particular, $r \sim q$, the first r queries were the preponderance of the queries. Then

$$A \leq (1 + o(1))n2^{-r} \leq \left(1 - \frac{\epsilon}{2} + o(1)\right) 2^{q+1-r}r$$

and

$$A \frac{r + u + 2}{2} \sim A \frac{r}{2} \leq \left(1 - \frac{\epsilon}{2} + o(1)\right) 2^s$$

Paul may now give further ground and allow Carole to lie in either direction for the remaining s questions. This is the (x_0, x_1) , s -Chip-Liar Game with $x_0 = A$ and $x_1 \leq (1 - \epsilon/2 + o(1))2^s$. The endgame strategy required at this point is given in the exercises.

18.6.7 15.7 Entropy

Let X be a random variable taking values in some range S , and let $P(X = x)$ denote the probability that the value of X is x . The binary entropy of X , denoted by $H(X)$, is defined by

$$H(X) = \sum_{x \in S} P(X = x) \log_2 \frac{1}{P(X = x)}$$

If Y is another random variable, taking values in T , and (X, Y) is the random variable taking values in $S \times T$ according to the joint distribution of X and Y , then the conditional entropy of X given Y is

$$H(X | Y) = H(X, Y) - H(Y)$$

In this section we prove some simple properties of the entropy function and describe several surprising combinatorial and geometric applications. Intuitively, the entropy of a random variable measures the amount of information it encodes. This provides an intuitive explanation to the four parts of the next simple lemma. The formal proof, given below, uses the properties of the functions $\log z$ and $z \log z$, where here, and in the rest of this section, all logarithms are in base 2.

Lemma 15.7.1 Let X, Y and Z be three random variables taking values in S, T and U , respectively. Then

- (i) $H(X) \leq \log |S|$.
- (ii) $H(X, Y) \geq H(X)$.
- (iii) $H(X, Y) \leq H(X) + H(Y)$.
- (iv) $H(X | Y, Z) \leq H(X | Y)$.

Proof.

- (i) Since the function $\log z$ is concave it follows, by Jensen's Inequality, that

$$\begin{aligned} H(X) &= \sum_{i \in S} P(X = i) \log \frac{1}{P(X = i)} \\ &\leq \log \left[\sum_{i \in S} P(X = i) \frac{1}{P(X = i)} \right] = \log |S|. \end{aligned}$$

- (ii) By the monotonicity of $\log z$ for all $z > 0$,

$$\begin{aligned} H(X, Y) &= \sum_{i \in S} \sum_{j \in T} P(X = i, Y = j) \log \frac{1}{P(X = i, Y = j)} \\ &\geq \sum_{i \in S} \sum_{j \in T} P(X = i, Y = j) \log \frac{1}{P(X = i)} \\ &= \sum_{i \in S} P(X = i) \log \frac{1}{P(X = i)} = H(X) \end{aligned}$$

- (iii) By definition

$$\begin{aligned} &H(X) + H(Y) - H(X, Y) \\ &= \sum_{i \in S} \sum_{j \in T} P(X = i, Y = j) \log \frac{P(X = i, Y = j)}{P(X = i)P(Y = j)} \\ &= \sum_{i \in S} \sum_{j \in T} P(X = i)P(Y = j)f(z_{ij}) \end{aligned}$$

where $f(z) = z \log z$ and $z_{ij} = P(X = i, Y = j)/[P(X = i)P(Y = j)]$. Since $f(z)$ is convex it follows, by Jensen's Inequality, that the last quantity is at least

$$f \left(\sum_{i \in S} \sum_{j \in T} P(X = i)P(Y = j)z_{ij} \right) = f(1) = 0.$$

- (iv) Note that

$$\begin{aligned}
H(X | Y) &= H(X, Y) - H(Y) \\
&= \sum_{i \in S} \sum_{j \in T} P(X = i, Y = j) \log \frac{P(Y = j)}{P(X = i, Y = j)}.
\end{aligned}$$

Similarly

$$\begin{aligned}
&H(X | Y, Z) \\
&= \sum_{i \in S} \sum_{j \in T} \sum_{k \in U} P(X = i, Y = j, Z = k) \log \frac{P(Y = j, Z = k)}{P(X = i, Y = j, Z = k)}.
\end{aligned}$$

Therefore

$$\begin{aligned}
&H(X | Y) - H(X | Y, Z) \\
&= \sum_{i \in S} \sum_{j \in T} \sum_{k \in U} P(X = i, Y = j, Z = k) \\
&\quad \cdot \log \frac{P(Y = j)P(X = i, Y = j, Z = k)}{P(X = i, Y = j)P(Y = j, Z = k)} \\
&= \sum_{i \in S} \sum_{j \in T} \sum_{k \in U} \frac{P(X = i, Y = j)P(Y = j, Z = k)}{P(Y = j)} f(z_{ijk}),
\end{aligned}$$

where $f(z) = z \log z$ and

$$z_{ijk} = \frac{P(Y = j)P(X = i, Y = j, Z = k)}{P(X = i, Y = j)P(Y = j, Z = k)}$$

By the convexity of $f(z)$ and since

$$\sum_{i \in S} \sum_{j \in T} \sum_{k \in U} \frac{P(X = i, Y = j)P(Y = j, Z = k)}{P(Y = j)} = 1,$$

it follows that the above quantity is at least

$$f \left(\sum_{i \in S} \sum_{j \in T} \sum_{k \in U} \frac{P(X = i, Y = j)P(Y = j, Z = k)}{P(Y = j)} z_{ijk} \right) = f(1) = 0.$$

The following simple but useful fact that the entropy is subadditive has already been applied in Section 13.2.

Proposition 15.7.2 Let $X = (X_1, \dots, X_n)$ be a random variable taking values in the set $S = S_1 \times S_2 \times \dots \times S_n$, where each of the coordinates X_i of X is a random variable taking values in S_i . Then

$$H(X) \leq \sum_{i=1}^n H(X_i).$$

Proof. This follows by induction from Lemma 15.7.1, part (iii).

The above proposition is used in Kleitman, Shearer and Sturtevant (1981) to derive several interesting applications in Extremal Finite Set Theory, including an upper estimate for the maximum possible cardinality of a family of k -sets in which the intersection of no two is contained in a third. The basic idea in Kleitman et al. (1981) can be illustrated by the following very simple corollary of the last proposition.

Corollary 15.7.3 Let $\mathcal{F}$ be a family of subsets of $\{1, 2, \dots, n\}$ and let p_i denote the fraction of sets in $\mathcal{F}$ that contain i . Then

$$|\mathcal{F}| \leq 2^{\sum_{i=1}^n H(p_i)},$$

where $H(p) = -p \log_2 p - (1-p) \log_2 (1-p)$.

Proof. Associate each set $F \in \mathcal{F}$ with its characteristic vector $v(F)$, which is a binary vector of length n . Let $X = (X_1, \dots, X_n)$ be the random variable taking values in $\{0, 1\}^n$, where $P(X = v(F)) = 1/|\mathcal{F}|$ for all $F \in \mathcal{F}$. Clearly $H(X) = |\mathcal{F}| \cdot (1/|\mathcal{F}|) \log |\mathcal{F}| = \log |\mathcal{F}|$ and since here $H(X_i) = H(p_i)$ for all $1 \leq i \leq n$, the result follows from Proposition 15.7.2.

The following interesting extension of Proposition 15.7.2 has been proved by Shearer; see Chung, Frankl, Graham and Shearer (1986). As in that proposition, let $X = (X_1, \dots, X_n)$ be a random variable taking values in the set $S = S_1 \times S_2 \times \dots \times S_n$, where each X_i is a random variable taking values in S_i . For a subset I of $\{1, 2, \dots, n\}$, let $X(I)$ denote the random variable $(X_i)_{i \in I}$.

Proposition 15.7.4 Let $X = (X_1, \dots, X_n)$ and S be as above. If $\mathcal{G}$ is a family of subsets of $\{1, \dots, n\}$ and each $i \in \{1, \dots, n\}$ belongs to at least k members of $\mathcal{G}$ then

$$kH(X) \leq \sum_{G \in \mathcal{G}} H(X(G)).$$

Proof. We apply induction on k . For $k = 1$, replace each set $G \in \mathcal{G}$ by a subset of it to obtain a family $\mathcal{G}'$ whose members form a partition of $\{1, \dots, n\}$. By Lemma 15.7.1, part (ii), $\sum_{G \in \mathcal{G}} H(X(G)) \geq \sum_{G' \in \mathcal{G}'} H(X(G'))$ and by Lemma 15.7.1, part (iii), $\sum_{G' \in \mathcal{G}'} H(X(G')) \geq H(X)$, supplying the desired result for $k = 1$.

Assuming the result holds for $k - 1$, we prove it for $k (\geq 2)$. If there is a $G \in \mathcal{G}$ with $G = \{1, \dots, n\}$, the result follows from the induction hypothesis. Otherwise, let G, G' be two members of $\mathcal{G}$. By applying Lemma 15.7.1, part (iv), we conclude that

$$H(X(G \setminus G') \mid X(G \cap G'), X(G' \setminus G)) \leq H(X(G \setminus G') \mid X(G \cap G')),$$

implying that

$$H(X(G \cup G')) - H(X(G')) \leq H(X(G)) - H(X(G \cap G')).$$

Therefore $H(X(G \cup G')) + H(X(G \cap G')) \leq H(X(G)) + H(X(G'))$. It follows that if we modify $\mathcal{G}$ by replacing G and G' by their union and intersection, then the sum $\sum_{G \in \mathcal{G}} H(X(G))$ can only decrease. After a finite number of such modifications we can reach the case in which one of the sets in $\mathcal{G}$ is $\{1, \dots, n\}$, and as this case has already been proved, this completes the proof.

Corollary 15.7.5 Let $\mathcal{F}$ be a family of vectors in $S_1 \times S_2 \times \dots \times S_n$. Let $\mathcal{G} = \{G_1, G_2, \dots, G_m\}$ be a collection of subsets of $N = \{1, 2, \dots, n\}$, and suppose that each element $i \in N$ belongs to at least k members of $\mathcal{G}$. For each $1 \leq i \leq m$ let $\mathcal{F}_i$ be the set of all projections of the members of $\mathcal{F}$ on G_i . Then

$$|\mathcal{F}|^k \leq \prod_{i=1}^m |\mathcal{F}_i|$$

Proof. Let $X = (X_1, \dots, X_n)$ be the random variable taking values in $\mathcal{F}$, where $P(X = F) = 1/|\mathcal{F}|$ for all $F \in \mathcal{F}$. By Proposition 15.7.4,

$$kH(X) \leq \sum_{i=1}^m H(X(G_i))$$

But $H(X) = \log_2 |\mathcal{F}|$, whereas by Lemma 15.7.1, part (i), $H(X(G_i)) \leq \log_2 |\mathcal{F}_i|$, implying the desired result.

Since the volume of every d -dimensional measurable set in $\mathbb{R}^n$ can be approximated by the volume of an appropriate approximation of it by standard aligned boxes in a fine enough grid, the last result has the following geometric application, proved in Loomis and Whitney (1949) in a different manner.

Corollary 15.7.6 Let B be a measurable body in the n -dimensional Euclidean space, let $\text{Vol}(B)$ denote its (n -dimensional) volume, and let $\text{Vol}(B_i)$ denote the ($n-1$)-dimensional volume of the projection of B on the hyperplane spanned by all coordinates besides the i th one. Then

$$(\text{Vol}(B))^{n-1} \leq \prod_{i=1}^n \text{Vol}(B_i)$$

If $S_i = \{0, 1\}$ for all i in Corollary 15.7.5, we get the following statement about set systems.

Corollary 15.7.7 [Chung et al. (1986)] Let N be a finite set, and let $\mathcal{F}$ be a family of subsets of N . Let $\mathcal{G} = \{G_1, \dots, G_m\}$ be a collection of subsets of N , and suppose that each element of S belongs to at least k members of $\mathcal{G}$. For each $1 \leq i \leq m$ define $\mathcal{F}_i = \{F \cap G_i : F \in \mathcal{F}\}$. Then

$$|\mathcal{F}|^k \leq \prod_{i=1}^m |\mathcal{F}_i|$$

We close the section with the following application of the last result, given in Chung et al. (1986).

Corollary 15.7.8 Let $\mathcal{F}$ be a family of graphs on the labeled set of vertices $\{1, \dots, t\}$, and suppose that for any two members of $\mathcal{F}$ there is a triangle contained in both of them. Then

$$|\mathcal{F}| < \frac{1}{4} 2^{\binom{t}{2}}.$$

Proof. Let N be the set of all $\binom{t}{2}$ unordered pairs of vertices in $T = \{1, 2, \dots, t\}$, and consider $\mathcal{F}$ as a family of subsets of N . Let $\mathcal{G}$ be the family of all subsets of N consisting of the edge sets of unions of two vertex disjoint nearly equal complete graphs in T . Let

$$s = \binom{\lceil t/2 \rceil}{2} + \binom{\lfloor t/2 \rfloor}{2}$$

denote the number of edges of such a union, and let m denote the total number of members in $\mathcal{G}$. By symmetry, each edge in N lies in precisely $k = sm / \binom{t}{2}$ members of $\mathcal{G}$. The crucial point is that every two graphs in $\mathcal{F}$ must have at least one common edge in each $G \in \mathcal{G}$, since their intersection contains a triangle (and there are no triangles in the complement of G .) Therefore, in the notation of Corollary 15.7.7, the cardinality of each $\mathcal{F}_i$ is at most 2^{s-1} . We thus conclude that

$$|\mathcal{F}|^{sm / \binom{t}{2}} \leq (2^{s-1})^m,$$

implying that

$$|\mathcal{F}| \leq 2^{\binom{t}{2} - \binom{t}{2}/s},$$

and the desired result follows, as $s < \frac{1}{2} \binom{t}{2}$.

Simonovits and Sós conjectured that if $\mathcal{F}$ satisfies the assumptions of the last corollary, then, in fact,

$$|\mathcal{F}| \leq \frac{1}{8} 2^{\binom{t}{2}},$$

which, if true, is tight. This remains open. It seems plausible to conjecture that there is some absolute constant $\epsilon > 0$, such that for any fixed graph H that is not a star-forest (i.e., a forest each connected component of which is a star), the following holds. Let $\mathcal{F}$ be a family of graphs on the labeled set of vertices $\{1, 2, \dots, t\}$, and suppose that for any two members of $\mathcal{F}$ there is a copy of H contained in both of them. Then

$$|\mathcal{F}| < \left(\frac{1}{2} - \epsilon\right) 2^{\binom{t}{2}}.$$

This is also open, though it is not difficult to show that it is true for every H of chromatic number at least 3, and that the conclusion fails for every star-forest H .

18.6.8 15.8 Exercises

1. Suppose that in the $(x_1, \dots, x_k)$ -Tenure Game of Section 15.3 the object of Paul is to maximize the number of faculty receiving tenure while the object of Carole is to minimize that number. Let v be that number with perfect play. Prove $v = \left\lfloor \sum_{i=1}^k x_i 2^{-i} \right\rfloor$.
2. Let $A_1, \dots, A_n \subseteq \{1, \dots, m\}$ with $\sum_{i=1}^n 2^{-|A_i|} < 1$. Paul and Carole alternately select distinct vertices from $\{1, \dots, m\}$, Paul having the first move, until all vertices have been selected. Carole wins if she has selected all the vertices of some A_i . Paul wins if Carole does not win. Give a winning strategy for Paul.
3. Let $\mathcal{F}$ be a family of graphs on the labeled set of vertices $\{1, 2, \dots, 2t\}$, and suppose that for any two members of $\mathcal{F}$ there is a perfect matching of t edges contained in both of them. Prove that

$$|\mathcal{F}| \leq 2^{\binom{2t}{2} - t}$$

4. (Han's Inequality.) Let $X = (X_1, \dots, X_m)$ be a random variable and let $H(X)$ denote its entropy. For a subset I of $\{1, 2, \dots, m\}$, let $X(I)$ denote the random variable $(X_i)_{i \in I}$. For $1 \leq q \leq m$, define

$$H_q(X) = \frac{1}{\binom{m-1}{q-1}} \sum_{Q \subset \{1, \dots, m\}, |Q|=q} H(X(Q))$$

Prove that

$$H_1(X) \geq H_2(X) \geq \dots \geq H_m(X) = H(X)$$

5. Let $X_i = \pm 1, 1 \leq i \leq n$, be uniform and independent and let $S_n = \sum_{i=1}^n X_i$. Let $0 \leq p \leq \frac{1}{2}$. Prove

$$\Pr[S_n \geq (1 - 2p)n] \leq 2^{H(p)n} 2^{-n}$$

by computing precisely the Chernoff bound $\min_{\lambda \geq 0} \mathbb{E}[e^{\lambda S_n}] e^{-\lambda(1-2p)n}$. (The case $p = 0$ will require a slight adjustment in the method though the end result is the same.)

6. (Parameter optimization in the Half Liar Game.) Find, asymptotically, the $u = u(q)$ that

minimizes $2^q \Pr[S_q \leq -u] + 2^{q+1}/(q-u)$ and express the minimal value in the form $2^{q+1}/q + (1+o(1))g(q)$ for some function g .

7. Show that for A fixed and r sufficiently large Paul wins the $(2^r - (r+1)A, A), r$ Chip Liar Game.

The Probabilistic Lens: an Extremal Graph

Let T (top) and B (bottom) be disjoint sets of size m and let G be a bipartite graph, all edges between T and B . Suppose G contains no 4-cycle. How many edges can G have? This is a question from Extremal Graph Theory. Surprisingly, for some m , we may give the precise answer.

Suppose $m = n^2 + n + 1$ and that a projective plane P of order n (and hence containing m points) exists. Identify T with the points of P and B with the lines of P and define $G = G_P$ by letting $t \in T$ be adjacent to $b \in B$ if and only if point t is on line b in P . As two points cannot lie on two lines, G_P contains no 4-cycle. We claim that such a G_P has the largest number of edges of any G containing no 4-cycle and further that any G containing no 4-cycle and having that many edges can be written in the form $G = G_P$.

Suppose G contains no 4-cycle. Let $b_1, b_2 \in B$ be a uniformly selected pair of distinct elements. For $t \in T$ let $D(t)$ be the set of $b \in B$ adjacent to t and $d(t) = |D(t)|$, the degree of t . Let I_t be the indicator random variable for t being adjacent to b_1, b_2 . Then

$$\mathbb{E}[I_t] = \Pr[b_1, b_2 \in D(t)] = \binom{d(t)}{2} / \binom{m}{2}.$$

Now set

$$X = \sum_{t \in T} I_t,$$

the number of $t \in T$ adjacent to b_1, b_2 . Then $X \leq 1$; that is, all b_1, b_2 have at most one common neighbor. ($X \leq 1$ is actually equivalent to G containing no 4-cycle.)

Linearity of expectation gives

$$\mathbb{E}[X] = \sum_{t \in T} \mathbb{E}[I_t] = \sum_{t \in T} \binom{d(t)}{2} / \binom{m}{2}.$$

Let $\hat{d} = m^{-1} \sum_{t \in T} d(t)$ be the average degree. Convexity of the function $\binom{y}{2}$ gives

$$\sum_{t \in T} \binom{d(t)}{2} / \binom{m}{2} \geq m \binom{\hat{d}}{2} / \binom{m}{2}$$

with equality if and only if all $t \in T$ have the same degree. Now

$$1 \geq \max X \geq \mathbb{E}[X] \geq m \binom{\hat{d}}{2} / \binom{m}{2}$$

When $G = G_P$ all $d(x) = \hat{d}$ (every line has $n+1$ points) and X is identically 1 (two points determine precisely one line) so that the above inequalities are all equalities and

$$1 = m \binom{\hat{d}}{2} / \binom{m}{2}.$$

Any graph with more edges would have a strictly larger $\hat{d}$ so that $1 \geq m \binom{\hat{d}}{2} / \binom{m}{2}$ would fail and the graph would contain a 4-cycle.

Suppose further G has the same number of edges as G_P and contains no 4-cycle. The inequalities then must be equalities and so $X = 1$ always. Define a geometry with points T and lines given by the neighbor sets of $b \in B$. As $X = 1$ any two points determine a unique line. Reversing the roles of T, B one also has that any two lines must determine a unique point. Thus G is generated from a projective plane.

18.7 16 Derandomization

Math is natural. Nobody could have invented the mathematical universe. It was there, waiting to be discovered, and it's crazy; it's bizarre.

- John Conway

As mentioned in Chapter 1, the probabilistic method supplies, in many cases, effective randomized algorithms for various algorithmic problems. In some cases, these algorithms can be derandomized and converted into deterministic ones. In this chapter we discuss some examples.

18.7.1 16.1 The Method of Conditional Probabilities

An easy application of the basic probabilistic method implies the following statement, which is a special case of Theorem 2.3.1.

Proposition 16.1.1 For every integer n there exists a coloring of the edges of the complete graph K_n by two colors so that the total number of monochromatic copies of K_4 is at most $\binom{n}{4} \cdot 2^{-5}$.

Indeed, $\binom{n}{4} \cdot 2^{-5}$ is the expected number of monochromatic copies of K_4 in a random 2-edge-coloring of K_n , and hence a coloring as above exists.

Can we actually find deterministically such a coloring in time which is polynomial in n ? Let us describe a procedure that does, which is a special case of a general technique called the method of conditional probabilities.

We first need to define a weight function for any partially colored K_n . Given a coloring of some of the edges of K_n by red and blue, we define, for each copy K of K_4 in K_n , a weight $w(K)$ as follows. If at least one edge of K is colored red and at least one edge is colored blue then $w(K) = 0$. If no edge of K is colored, then $w(K) = 2^{-5}$, and if $r \geq 1$ edges of K are colored, all with the same color, then $w(K) = 2^{r-6}$. Also define the total weight W of the partially colored K_n as the sum $\sum w(K)$, as K ranges over all copies of K_4 in K_n . Observe that the weight of each copy K of K_4 is precisely the probability that it will be monochromatic, if all the presently uncolored edges of K_n will be assigned randomly and independently one of the two colors red and blue. Hence, by linearity of expectation, the total weight W is simply the expected number of monochromatic copies of K_4 in such a random extension of the partial coloring of K_n to a full coloring.

We can now describe the procedure for finding a coloring as in Proposition 16.1.1. Order the $\binom{n}{2}$ edges of K_n arbitrarily, and construct the desired two-coloring by coloring each edge either red or blue in its turn. Suppose $e_1, \dots, e_{i-1}$ have already been colored, and we now have to color e_i . Let W be the weight of K_n , as defined above, with respect to the given partial coloring c of $e_1, \dots, e_{i-1}$. Similarly, let W_{red} be the weight of K_n with respect to the partial coloring obtained from c by coloring e_i red, and let W_{blue} be the weight of K_n with respect to the partial coloring obtained from c by coloring e_i blue. By the definition of W (and as follows from its interpretation as an expected value),

$$W = \frac{W_{\text{red}} + W_{\text{blue}}}{2}$$

The color of e_i is now chosen so as to minimize the resulting weight; that is, if $W_{\text{red}} \leq W_{\text{blue}}$ then we color e_i red, otherwise, we color it blue. By the above inequality, the weight function never increases during the algorithm. Since at the beginning its value is exactly $\binom{n}{4}2^{-5}$, its value at the end is at most this quantity. However, at the end all edges are colored, and the weight is precisely the number of monochromatic copies of K_4 . Thus the procedure above produces, deterministically and in polynomial time, a 2-edge-coloring of K_n satisfying the conclusion of Proposition 16.1.1.

Let us describe, now, the method of conditional probabilities in a more general setting. An instance of this method is due, implicitly, to Erdős and Selfridge (1973) and more explicit examples appear in Spencer (1987) and in Raghavan (1988). Suppose we have a probability space, and assume, for simplicity, that it is symmetric and contains 2^l points, denoted by the binary vectors of length l . Let $A_1, \dots, A_s$ be a collection of events and suppose that $\sum_{i=1}^s \Pr[A_i] = k$. Thus k is the expected value of the number of events A_i that hold, and hence there is a point $(\epsilon_1, \dots, \epsilon_l)$ in the space in which at most k events hold. Our objective is to find such a point deterministically.

For each choice of $(\epsilon_1, \dots, \epsilon_{j-1})$ and for each event A_i , the conditional probability

$$\Pr[A_i \mid \epsilon_1, \dots, \epsilon_{j-1}]$$

of the event A_i given the values of $\epsilon_1, \dots, \epsilon_{j-1}$ is clearly the average of the two conditional probabilities corresponding to the two possible choices for ϵ_j . That is,

$$\Pr[A_i \mid \epsilon_1, \dots, \epsilon_{j-1}] = \frac{\Pr[A_i \mid \epsilon_1, \dots, \epsilon_{j-1}, 0] + \Pr[A_i \mid \epsilon_1, \dots, \epsilon_{j-1}, 1]}{2}.$$

Consequently,

$$\begin{aligned} & \sum_{i=1}^s \Pr[A_i \mid \epsilon_1, \dots, \epsilon_{j-1}] \\ &= \frac{1}{2} \sum_{i=1}^s \Pr[A_i \mid \epsilon_1, \dots, \epsilon_{j-1}, 0] + \frac{1}{2} \sum_{i=1}^s \Pr[A_i \mid \epsilon_1, \dots, \epsilon_{j-1}, 1] \\ &\geq \min \left\{ \sum_{i=1}^s \Pr[A_i \mid \epsilon_1, \dots, \epsilon_{j-1}, 0], \sum_{i=1}^s \Pr[A_i \mid \epsilon_1, \dots, \epsilon_{j-1}, 1] \right\}. \end{aligned}$$

Therefore, if the values of ϵ_j are chosen, each one in its turn, so as to minimize the value of $\sum_{i=1}^s \Pr[A_i \mid \epsilon_1, \dots, \epsilon_j]$, then the value of this sum cannot increase. Since this sum is k at the beginning, it follows that it is at most k at the end. But at the end each ϵ_j is fixed, and hence the value of this sum is precisely the number of events A_i that hold at the point $(\epsilon_1, \dots, \epsilon_l)$, showing that our procedure works.

Note that the assumptions that the probability space is symmetric and that it has 2^l points can be relaxed. The procedure above is efficient provided l is not too large (as is usually the case in combinatorial examples), and, more importantly, provided the conditional probabilities $\Pr[A_i \mid \epsilon_1, \dots, \epsilon_j]$ can be computed efficiently for each of the events A_i and for each possible value of $\epsilon_1, \dots, \epsilon_j$. This is, indeed, the case in the example considered in Proposition 16.1.1. However, there are many interesting examples where this is not the case. A trick that can be useful in such cases is the introduction of pessimistic estimators, introduced by Raghavan (1988). Consider, again, the symmetric probability space with 2^l points described above, and the events $A_1, \dots, A_s$ in it. Suppose that for each event A_i and for each $0 \leq j \leq l$ we have a function $f_j^i(\epsilon_1, \dots, \epsilon_j)$ that can be efficiently computed. Assume also that

$$f_{j-1}^i(\epsilon_1, \dots, \epsilon_{j-1}) \geq \frac{f_j^i(\epsilon_1, \dots, \epsilon_{j-1}, 0) + f_j^i(\epsilon_1, \dots, \epsilon_{j-1}, 1)}{2}, \quad (16.1)$$

and that f_j^i is an upper bound on the conditional probabilities for the event A_i ; that is,

$$f_j^i(\epsilon_1, \dots, \epsilon_j) \geq \Pr[A_i \mid \epsilon_1, \dots, \epsilon_j]. \quad (16.2)$$

Clearly the same inequalities hold for the sums over i . In this case, if in the beginning $\sum_{i=1}^s f_0^i \leq t$, and we choose the values of the ϵ_j so as to minimize the sum $\sum_{i=1}^s f_j^i(\epsilon_1, \dots, \epsilon_j)$ in each step, we get in the end a point $(\epsilon_1, \dots, \epsilon_l)$ for which the sum $\sum_{i=1}^s f_l^i(\epsilon_1, \dots, \epsilon_l) \leq t$. The number of events A_i that hold in this point is at most t . The functions f_j^i in the argument above are called pessimistic estimators.

This enables us to obtain efficient algorithms in some cases where there is no known efficient way of computing the required conditional probabilities. The following theorem is an example; it is related to some of the results in Chapters 13 and 15.

Theorem 16.1.2 Let $(a_{ij})_{i,j=1}^n$ be an n by n matrix of reals, where $-1 \leq a_{ij} \leq 1$ for all i, j . Then one can find, in polynomial time, $\epsilon_1, \dots, \epsilon_n \in \{-1, 1\}$ such that for every i , $1 \leq i \leq n$,

$$\left| \sum_{j=1}^n \epsilon_j a_{ij} \right| \leq \sqrt{2n \ln(2n)}$$

Proof. Consider the symmetric probability space on the 2^n points corresponding to the 2^n possible vectors $(\epsilon_1, \dots, \epsilon_n) \in \{-1, 1\}^n$. Define $\beta = \sqrt{2n \ln(2n)}$ and let A_i be the event $\left| \sum_{j=1}^n \epsilon_j a_{ij} \right| > \beta$. We next show that the method of conditional probabilities with appropriate pessimistic estimators enables us to find efficiently a point of the space in which no event A_i holds.

Define $\alpha = \beta/n$ and let $G(x)$ be the function

$$G(x) = \cosh(\alpha x) = \frac{e^{\alpha x} + e^{-\alpha x}}{2}$$

By comparing the terms of the corresponding Taylor series it is easy to see that, for every real x ,

$$G(x) \leq e^{\alpha^2 x^2 / 2}$$

with strict inequality if neither x nor α are 0. It is also simple to check that for every real x and y ,

$$G(x)G(y) = \frac{G(x+y) + G(x-y)}{2}.$$

We can now define the functions f_p^i that will form our pessimistic estimators. For each $1 \leq i \leq n$ and for each $\epsilon_1, \dots, \epsilon_p \in \{-1, 1\}$ we define

$$f_p^i(\epsilon_1, \dots, \epsilon_p) = 2e^{-\alpha\beta} G\left(\sum_{j=1}^p \epsilon_j a_{ij}\right) \prod_{j=p+1}^n G(a_{ij}).$$

Obviously, these functions can be efficiently computed. It remains to check that they satisfy the conditions described in equations (16.1) and (16.2), and that the sum $\sum_{i=1}^n f_0^i$ is less than 1. This is proved in the following claims.

Claim 16.1.3 For every $1 \leq i \leq n$ and every $\epsilon_1, \dots, \epsilon_{p-1} \in \{-1, 1\}$,

$$f_{p-1}^i(\epsilon_1, \dots, \epsilon_{p-1}) = \frac{f_p^i(\epsilon_1, \dots, \epsilon_{p-1}, -1) + f_p^i(\epsilon_1, \dots, \epsilon_{p-1}, 1)}{2}.$$

Proof. Put $v = \sum_{j=1}^{p-1} \epsilon_j a_{ij}$. By the definition of f_p^i and by the properties of G ,

$$\begin{aligned}
 f_{p-1}^i(\epsilon_1, \dots, \epsilon_{p-1}) &= 2e^{-\alpha\beta} G(v) G(a_{ip}) \prod_{j=p+1}^n G(a_{ij}) \\
 &= 2e^{-\alpha\beta} \frac{G(v - a_{ip}) + G(v + a_{ip})}{2} \prod_{j=p+1}^n G(a_{ij}) \\
 &= \frac{f_p^i(\epsilon_1, \dots, \epsilon_{p-1}, -1) + f_p^i(\epsilon_1, \dots, \epsilon_{p-1}, 1)}{2}
 \end{aligned}$$

completing the proof of the claim.

Claim 16.1.4 For every $1 \leq i \leq n$ and every $\epsilon_1, \dots, \epsilon_{p-1} \in \{-1, 1\}$,

$$f_{p-1}^i(\epsilon_1, \dots, \epsilon_{p-1}) \geq \Pr[A_i \mid \epsilon_1, \dots, \epsilon_{p-1}].$$

Proof. Define v as in the proof of Claim 16.1.3. Then

$$\begin{aligned}
 &\Pr[A_i \mid \epsilon_1, \dots, \epsilon_{p-1}] \\
 &= \Pr\left[v + \sum_{j \geq p} \epsilon_j a_{ij} > \beta\right] + \Pr\left[-v - \sum_{j \geq p} \epsilon_j a_{ij} > \beta\right] \\
 &= \Pr\left[e^{\alpha(v + \sum_{j \geq p} \epsilon_j a_{ij})} > e^{\alpha\beta}\right] + \Pr\left[e^{-\alpha(v + \sum_{j \geq p} \epsilon_j a_{ij})} > e^{\alpha\beta}\right] \\
 &\leq e^{\alpha v} e^{-\alpha\beta} \mathbb{E}\left[\exp\left(\alpha \sum_{j \geq p} \epsilon_j a_{ij}\right)\right] + e^{-\alpha v} e^{-\alpha\beta} \mathbb{E}\left[\exp\left(-\alpha \sum_{j \geq p} \epsilon_j a_{ij}\right)\right] \\
 &= 2e^{-\alpha\beta} G(v) \prod_{j \geq p} G(a_{ij}) = f_{p-1}^i(\epsilon_1, \dots, \epsilon_{p-1})
 \end{aligned}$$

This completes the proof of Claim 16.1.4.

To establish the theorem it remains to show that $\sum_{i=1}^n f_0^i < 1$. Indeed, by the properties of G and by the choice of α and β :

$$\begin{aligned}
 \sum_{i=1}^n f_0^i &= \sum_{i=1}^n 2e^{-\alpha\beta} \prod_{j=1}^n G(a_{ij}) \leq \sum_{i=1}^n 2e^{-\alpha\beta} \prod_{j=1}^n e^{\alpha^2 a_{ij}^2 / 2} \\
 &\leq \sum_{i=1}^n 2e^{-\alpha\beta} e^{\alpha^2 n / 2} = 2ne^{\alpha^2 n / 2 - \alpha\beta} = 2ne^{-\alpha^2 n / 2} = 1.
 \end{aligned}$$

Moreover, the first inequality is strict unless $a_{ij} = 0$ for all i, j , whereas the second is strict unless $a_{ij}^2 = 1$ for all i, j . This completes the proof of the theorem.

18.7.2 16.2D-wise Independent Random Variables in Small Sample Spaces

The complexity class **NC** is, roughly speaking, the class of all problems that can be solved in time that is polylogarithmic (in the size of the input) using a polynomial number of parallel processors. Several models of computation, which are a theoretical abstraction of the parallel computer, have been used in considering this class. The most common one is the EREW (Exclusive Read, Exclusive Write) PRAM, in which different processors are not allowed to read from or write into the same memory cell simultaneously. See Karp and Ramachandran (1990) for more details.

Let n denote the size of the input. There are several simple tasks that can easily be performed in NC. For example, it is possible to copy the content of a cell c into $m = n^{O(1)}$ cells in

time $O(\log n)$, using, say, m processors. To do so, consider a complete binary tree with m leaves and associate each of its internal vertices with a processor. At first, the processor corresponding to the root of the tree reads from c and writes its content in two cells, corresponding to its two children. Next, each of these two, in parallel, reads from its cell and writes its content in two cells corresponding to its two children. In general, at the i th step all the processors whose distance from the root of the tree is $i - 1$, in parallel, read the content of c previously stored in their cells and write it twice. The procedure clearly ends in time $O(\log m)$, as claimed. [In fact, it can be shown that $O(m/\log m)$ processors suffice for this task but we do not try to optimize this number here.]

A similar technique can be used for computing the sum of m numbers with m processors in time $O(\log m)$. We consider the numbers as if they lie on the leaves of a complete binary tree with m leaves, and in the i th step each one of the processors whose distance from the leaves is i computes, in parallel, the sum of the two numbers previously computed by its children. The root will clearly have, in such a way, the desired sum in time $O(\log m)$.

Let us now return to the edge-coloring problem of the complete graph K_n discussed in Proposition 16.1.1. By the remarks above, the problem of checking if in a given edge-coloring there are at most $\binom{n}{4}2^{-5}$ monochromatic copies of K_4 is in NC; that is, this checking can be done in time $(\log n)^{O(1)}$ - in fact, in time $O(\log n)$ - using $n^{O(1)}$ processors. Indeed, we can first copy the given coloring $\binom{n}{4}$ times. Then we assign a processor for each copy of K_4 in K_n , and this processor checks if its copy is monochromatic or not (all these checkings can be done in parallel, since we have enough copies of the coloring). Finally, we sum the number of processors whose copies are monochromatic. Clearly we can complete the work in time $O(\log n)$ using $n^{O(1)}$ parallel processors.

Thus we can check, in NC, if a given coloring of K_n satisfies the assertion of Proposition 16.1.1. Can we find such a coloring deterministically in NC? The method described in the previous section does not suffice, as the edges have been colored one by one, so the procedure is sequential and requires time $\Omega(n^2)$. However, it turns out that in fact we can find, in NC, a coloring with the desired properties by applying a method that relies on a technique first suggested by Joffe (1974), and later

developed by many researchers. This method is a general technique for converting randomized algorithms whose analysis only depends on d -wise rather than fully independent random choices (for some constant d) into deterministic (and in many cases also parallel) ones. Our approach here follows the one of Alon, Babai and Itai (1986), but for simplicity we only consider here the case of random variables that take the two values 0,1 with equal probability.

The basic idea is to replace an exponentially large sample space by one of polynomial size. If a random variable on such a space takes a certain value with positive probability, then we can find a point in the sample space in which this happens simply by deterministically checking all the points. This can be done with no loss of time by using a polynomial number of parallel processors. Note that for the edge-coloring problem considered in Proposition 16.1.1, 6-wise independence of the random variables corresponding to the colors of the edges suffice, since this already gives a probability of 2^{-5} for each copy of K_4 to be monochromatic, and hence gives the required expected value of monochromatic copies. Therefore, for this specific example, it suffices to construct a sample space of size $n^{O(1)}$ and $\binom{n}{2}$ random variables in it, each taking the values 0 and 1 with probability $\frac{1}{2}$, such that each 6 of the random variables are independent.

Small sample spaces with many d -wise independent 0,1 random variables in them can be constructed from any linear error correcting code with appropriate parameters. The construction we describe here is based on the binary BCH codes [see, e.g., MacWilliams and Sloane (1977)].

Theorem 16.2.1 Suppose $n = 2^k - 1$ and $d = 2t + 1$. Then there exists a symmetric probability space Ω of size $2(n + 1)^t$ and d -wise independent random variables $y_1, \dots, y_n$ over Ω

each of which takes the values 0 and 1 with probability $\frac{1}{2}$.

The space and the variables are explicitly constructed, given a representation of the field $F = GF(2^k)$ as a k -dimensional algebra over $GF(2)$.

Proof. Let $x_1, \dots, x_n$ be the n nonzero elements of F , represented as column vectors of length k over $GF(2)$. Let H be the following $1 + kt$ by n matrix over $GF(2)$.

$$H = \begin{pmatrix} 1 & 1 & \cdots & 1 \\ x_1 & x_2 & \cdots & x_n \\ x_1^3 & x_2^3 & \cdots & x_n^3 \\ \vdots & \vdots & \ddots & \vdots \\ x_1^{2t-1} & x_2^{2t-1} & \cdots & x_n^{2t-1} \end{pmatrix}$$

This is the parity check matrix of the extended binary BCH code of length n and designed distance $2t + 2$. It is well known that any $d = 2t + 1$ columns of H are linearly independent over $GF(2)$. For completeness, we present the proof in the next lemma.

Lemma 16.2.2 Any set of $d = 2t + 1$ columns of H is linearly independent over $GF(2)$.

Proof. Let $J \subset \{1, 2, \dots, n\}$ be a subset of cardinality $|J| = 2t + 1$ of the set of indices of the columns of H . Suppose that $\sum_{j \in J} z_j H_j = 0$, where H_j denotes the j th column of H and $z_j \in GF(2)$. To complete the proof we must show that $z_j = 0$ for all $j \in J$. By the assumption,

$$\sum_{j \in J} z_j x_j^i = 0 \quad (16.3)$$

for $i = 0$ and for every odd i satisfying $1 \leq i \leq 2t - 1$. Suppose, now, that $a = 2^b \cdot l$, where $l \leq 2t - 1$ is an odd number. By squaring the equation (16.3) b times, where $i = l$, using the fact that $(u + v)^2 = u^2 + v^2 \pmod{2}$ and the fact that since each z_j is either 0 or 1, the equality $z_j = z_j^2$ holds for all j , we conclude that equation (16.3) holds for $i = a$. Consequently, (16.3) holds for all $i, 0 \leq i \leq 2t$. This is a homogeneous system of $2t + 1$ linear equations in $2t + 1$ variables. The matrix of the coefficients is a Vandermonde matrix, which is nonsingular. Thus the only solution is the trivial one $z_j = 0$ for all $j \in J$, completing the proof of the lemma.

Returning to the proof of the theorem, we define $\Omega = \{1, 2, \dots, 2(n + 1)^t\}$, and let $A = (a_{ij}), i \in \Omega, 1 \leq j \leq n$ be the $(0, 1)$ -matrix whose $2(n + 1)^t = 2^{kt+1}$ rows are all the linear combinations (over $GF(2)$) of the rows of H . The sample space Ω is now endowed with the uniform probability measure, and the random variable y_j is defined by the formula $y_j(i) = a_{ij}$ for all $i \in \Omega, 1 \leq j \leq n$.

It remains to show that the variables y_j are d -wise independent, and that each of them takes the values 0 and 1 with equal probability. For this we have to show that for every set J of up to d columns of A , the rows of the $|\Omega|$ by $|J|$ submatrix $A_J = (a_{ij}), i \in \Omega, j \in J$ take on each of the $2^{|J|}$ $(0, 1)$ -vectors of length $|J|$ equally often. However, by Lemma 16.2.2 the columns of the corresponding submatrix H_J of H are linearly independent. The number of rows of A_J that are equal to any given vector is precisely the number of linear combinations of the rows of H_J that are equal to this vector. This number is the number of solutions of a system of $|J|$ linearly independent linear equations in $kt + 1$ variables, which is, of course, $2^{kt+1-|J|}$, independent of the vector of free coefficients. This completes the proof of the theorem.

Theorem 16.2.1 supplies an efficient way of constructing, for every fixed d and every n , a sample space of size $O(n^{\lceil d/2 \rceil})$ and nd -wise independent random variables in it, each taking the values 0 and 1 with equal probability. In particular, we can use such a space of size $O\left(\binom{n}{2}^3\right) = O(n^6)$ for finding a coloring as in Proposition 16.1.1 in NC. Several other applications of Theorem 16.2.1 appear in the paper of Alon et al. (1986).

It is natural to ask if the size $O(n^{\lceil d/2 \rceil})$ can be improved. We next show that this size is optimal, up to a constant factor (depending on d).

Let us call a random variable almost constant if it attains a single value with probability 1. Let $m(n, d)$ denote the function defined by

$$m(n, d) = \sum_{j=0}^{d/2} \binom{n}{j} \text{ if } d \text{ is even}$$

and

$$m(n, d) = \sum_{j=0}^{(d-1)/2} \binom{n}{j} + \binom{n-1}{(d-1)/2} \text{ if } d \text{ is odd.}$$

Observe that for every fixed d , $m(n, d) = \Omega(n^{\lfloor d/2 \rfloor})$.

Proposition 16.2.3 If the random variables $y_1, \dots, y_n$ over the sample space Ω are d -wise independent and none of them is almost constant then $|\Omega| \geq m(n, d)$.

Note that we assume here neither that Ω is a symmetric space nor that the variables y_j are $(0, 1)$ -variables.

Proof. Clearly we may assume that the expected value of each y_j is 0 [since otherwise we can replace y_j by $y_j - E[y_j]$.] For each subset S of $\{1, \dots, n\}$, define $\alpha_S = \prod_{j \in S} y_j$. Observe that since no y_j is almost constant and since the variables are d -wise independent,

$$E[\alpha_S \alpha_S] = \prod_{j \in S} \text{Var}[y_j] > 0 \quad (16.4)$$

for all S satisfying $|S| \leq d$. Similarly, for all S and T satisfying $|S \cup T| \leq d$ and $S \neq T$ we have

$$E[\alpha_S \alpha_T] = \prod_{j \in S \cap T} \text{Var}[y_j] \prod_{j \in S \cup T \setminus (S \cap T)} E[y_j] = 0. \quad (16.5)$$

Let $S_1, \dots, S_m$, where $m = m(n, d)$, be subsets of $\{1, \dots, n\}$ such that the union of each two is of size at most d . [Take all subsets of size at most $d/2$, and if d is odd add all the subsets of size $(d+1)/2$ containing 1.]

To complete the proof, we show that the m functions α_{S_j} (considered as real vectors of length $|\Omega|$) are linearly independent. This implies that $|\Omega| \geq m = m(n, d)$, as stated in the proposition.

To prove linear independence, suppose $\sum_{j=1}^m c_j \alpha_{S_j} = 0$. Multiplying by α_{S_i} and computing expected values we obtain, by (16.5),

$$0 = \sum_{j=1}^m c_j E[\alpha_{S_j} \alpha_{S_i}] = c_i E[\alpha_{S_i} \alpha_{S_i}]$$

This implies, by (16.4), that $c_i = 0$ for all i . The required linear independence follows, completing the proof.

The last proposition shows that the size of a sample space with nd -wise independent non-trivial random variables can be polynomial in n only when d is fixed. However, as shown by Naor and Naor (1990), if we only require the random variables to be almost d -wise independent, the size can be polynomial even when $d = \Omega(\log n)$. Such sample spaces and random variables, which can be constructed explicitly in several ways, have various interesting applications in which almost d -wise independence suffices. More details appear in Naor and Naor (1990) and in Alon, Goldreich, Håstad and Peralta (1990).

18.7.3 16.3 Exercises

1. Let $A_1, \dots, A_n \subseteq \{1, \dots, m\}$ with $\sum_{i=1}^n 2^{1-|A_i|} < 1$. Prove there exists a two-coloring $\chi : \{1, \dots, m\} \rightarrow \{0, 1\}$ with no A_i monochromatic. With $m = n$ give a deterministic algorithm to find such a χ in polynomial time.
2. Describe a deterministic algorithm that, given n , constructs, in time polynomial in n , a family $\mathcal{F}$ of n^{10} subsets of the set $N = \{1, 2, \dots, n\}$, where each $F \in \mathcal{F}$ is of size at most $10 \log n$ and for every family $\mathcal{G}$ of n subsets each of cardinality $n/2$ of N , there is an $F \in \mathcal{F}$ that intersects all members of $\mathcal{G}$.

The Probabilistic Lens: Crossing Numbers, Incidences, Sums and Products

In this lens we start with a simple result in graph theory, whose proof is probabilistic, and then describe some of its fascinating consequences in combinatorial geometry and combinatorial number theory. Some versions of most of these seemingly unrelated consequences have been proved before, in a far more complicated manner. Before the discovery of the new proofs shown here, the only clue that there might be a connection between all of them has been the fact that Endre Szemerédi is one of the coauthors of each of the papers providing the first proofs.

An embedding of a graph $G = (V, E)$ in the plane is a planar representation of it, where each vertex is represented by a point in the plane, and each edge uv is represented by a curve connecting the points corresponding to the vertices u and v . The crossing number of such an embedding is the number of pairs of intersecting curves that correspond to pairs of edges with no common endpoints. The crossing number $\text{cr}(G)$ of G is the minimum possible crossing number in an embedding of it in the plane. The following theorem was proved by Ajtai, Chvátal, Newborn and Szemerédi (1982) and, independently, by Leighton. Here we describe a very short probabilistic proof.

Theorem 1 The crossing number of any simple graph $G = (V, E)$ with $|E| \geq 4|V|$ is at least $|E|^3/64|V|^2$.

Proof. By Euler's formula any simple planar graph with $n \geq 3$ vertices has at most $3n - 6$ edges, implying that any simple planar graph with n vertices has at most $3n$ edges. Therefore the crossing number of any simple graph with n vertices and m edges is at least $m - 3n$. Let $G = (V, E)$ be a graph with $|E| \geq 4|V|$ embedded in the plane with $t = \text{cr}(G)$ crossings. Let H be the random induced subgraph of G obtained by picking each vertex of G , randomly and independently, to be a vertex of H with probability p (where p will be chosen later). The expected number of vertices of H is $p|V|$, the expected number of its edges is $p^2|E|$, and the expected number of crossings in its given embedding is p^4t , implying that the expected value of its crossing number is at most p^4t . Therefore $p^4t \geq p^2|E| - 3p|V|$, implying that

$$\text{cr}(G) = t \geq \frac{|E|}{p^2} - 3\frac{|V|}{p^3}.$$

Without trying to optimize the constant factor, substitute $p = 4|V|/|E| (\leq 1)$, to get the desired result.

Székely (1997) noticed that this result can be applied to obtain a surprisingly simple proof of a result of Szemerédi and Trotter in combinatorial geometry. The original proof is far more complicated.

Theorem 2 Let P be a set of n distinct points in the plane, and let L be a set of m distinct lines. Then the number of incidences between the members of P and those of L (i.e., the number of pairs (p, l) with $p \in P, l \in L$ and $p \in l$) is at most $c(m^{2/3}n^{2/3} + m + n)$, for some absolute constant c .

Proof. We may and will assume that every line in L is incident with at least one of the points of P . Denote the number of incidences by I . Let $G = (V, E)$ be the graph whose vertices are all members of P , where two are adjacent if and only if they are consecutive points of P on some line in L . Clearly $|V| = n$ and $|E| = I - m$. Note that G is already given embedded in the plane, where the edges are represented by segments of the corresponding lines in L . In this embedding, every crossing is an intersection point of two members of L , implying that $\text{cr}(G) \leq \binom{m}{2} \leq \frac{1}{2}m^2$. By Theorem 1, either $I - m = |E| < 4|V| = 4n$, that is, $I \leq m + 4n$, or

$$\frac{m^2}{2} \geq \text{cr}(G) \geq \frac{(I - m)^3}{64n^2}$$

implying that $I \leq (32)^{1/3}m^{2/3}n^{2/3} + m$. In both cases $I \leq 4(m^{2/3}n^{2/3} + m + n)$, completing the proof.

An analogous argument shows that the maximum possible number of incidences between a set of n points and a set of m unit circles in the plane does not exceed $O(m^{2/3}n^{2/3} + m + n)$ and this implies that the number of unit distances determined by a set of n points in the plane is at most $O(n^{4/3})$. While the above upper bound for the number of incidences of points and lines is sharp, up to a constant factor, an old conjecture of Erdős asserts that the maximum possible number of unit distances determined by a set of n points in the plane is at most $c_\epsilon n^{1+\epsilon}$ for any $\epsilon > 0$. The

$O(n^{4/3})$ estimate is, however, the best known upper bound and was first proved by Spencer, Szemerédi and Trotter in a far more complicated way.

Elekes (1997) found several applications of Theorem 2 in additive number theory. Here, too, the proofs are amazingly simple. Here is a representative result.

Theorem 3 For any three sets A, B and C of s real numbers each,

$$|A \cdot B + C| = |\{ab + c : a \in A, b \in B, c \in C\}| \geq \Omega(s^{3/2}).$$

Proof. Put $R = A \cdot B + C$, $|R| = r$ and define

$$P = \{(a, t) : a \in A, t \in R\}, \quad L = \{y = bx + c : b \in B, c \in C\}$$

Thus P is a set of $n = sr$ points in the plane, L is a set of $m = s^2$ lines in the plane, and each line $y = bx + c$ in L is incident with s points of P , that is, with all the points $\{(a, ab + c) : a \in A\}$. Therefore, by Theorem 2, $s^3 \leq 4(s^{4/3}(sr)^{2/3} + sr + s^2)$, implying that $r \geq \Omega(s^{3/2})$, as needed.

The same method implies that for every set A of n reals, either $|A + A| \geq \Omega(n^{5/4})$ or $|A \cdot A| \geq n^{5/4}$, greatly improving and simplifying a result of Erdős and Szemerédi.

18.8 17 Graph Property Testing

'Call the first witness,' said the King; and the White Rabbit blew three blasts on the trumpet, and called out, 'First witness!'

- from Alice in Wonderland, by Lewis Carroll

18.8.1 17.1 Property Testing

Property testers are fast randomized algorithms for distinguishing between combinatorial structures that satisfy a certain property, and ones that are far from satisfying it. The basic algorithmic task in this area is to design a randomized algorithm that, given a combinatorial structure S , can distinguish with high probability between the case that S satisfies a prescribed property $\mathcal{P}$ and the case that S is ϵ -far from satisfying $\mathcal{P}$. Here S is said to be ϵ -far from

satisfying $\mathcal{P}$ if an ε -fraction of its representation should be modified in order to turn it to a structure that satisfies $\mathcal{P}$. The main objective is to design randomized algorithms, which look at a very small portion of the input, and using this information distinguish with high probability between the above two cases. Such algorithms are called testers for the property $\mathcal{P}$.

Preferably, a tester should look at a portion of the input whose size is a function of ε only. The general notion of property testing was first formulated by Rubinfeld and Sudan (1996), who were motivated by the study of various algebraic properties such as linearity of functions. Property testing is also motivated by questions in program checking, computational learning, approximation algorithms and probabilistically checkable proofs, as well as by the need to access large data sets, like the graph of the Internet. The investigation of the subject relies heavily on probabilistic methods.

The main focus of this chapter is in testing properties of graphs. In this case a graph G on n vertices is said to be ε -far from satisfying a property $\mathcal{P}$, if one needs to add to or delete from G at least εn^2 edges in order to turn it into a graph satisfying $\mathcal{P}$. Here we assume that the tester can query an oracle whether a pair of vertices, i and j , are adjacent in the input graph G . If the graph satisfies the property, then the tester has to accept with probability at least, say, $\frac{2}{3}$, and if it is ε -far from satisfying it, then the algorithm has to reject with probability at least $\frac{2}{3}$.

The study of the notion of testability for combinatorial structures, and mainly for labeled graphs, was introduced by Goldreich, Goldwasser and Ron (1998). They showed that many natural graph properties such as k -colorability, having a large clique or having a large cut, admit a tester, whose query complexity [i.e., the number of oracle queries of type "does (i, j) belong to $E(G)$ "] as well as their total running time can be upper bounded by a function of ε that is independent of the size of the input. We call properties having such efficient testers, that is, testers whose query complexity is a function of ε only, testable. In general, a property tester may have a small probability of accepting graphs that are ε -far from satisfying the tested property, as well as a small probability of rejecting graphs satisfying the property. In this case the tester is said to have two-sided error. If the tester accepts graphs satisfying the property with probability 1, then the tester is said to have one-sided error.

It is worth noting that the model of graph property testing described here is often referred to as the dense graph model. Other models of graph property testing have also been investigated; see, for example, Goldreich and Ron (2002). For further reading and pointers on testing properties of graphs and other combinatorial structures the reader is referred to the surveys by Goldreich (1999), Fischer (2001), Ron (2001), Alon and Shapira (2006) and their references.

18.8.2 17.2 Testing Colorability

Although the computational problem of deciding whether a given graph is k -colorable is NP-complete for every fixed $k \geq 3$, it turns out that, somewhat surprisingly, for every fixed $\varepsilon > 0$ there is an efficient algorithm for distinguishing between graphs on n vertices that are k -colorable, and graphs from which one has to delete at least εn^2 edges to make them k -colorable. This result, mentioned already in Alon, Duke, Lefmann, Rödl and Yuster (1994), follows from the fact that the property of being k -colorable is testable, as proved implicitly in Rödl and Duke (1985) and explicitly (with a far better dependence on the parameter ε) in Goldreich et al. (1998). Indeed, as we show in this subsection, if a graph $G = (V, E)$ is ε -far from being k -colorable, then an induced subgraph of it on a randomly chosen set of $c(k)/\varepsilon^2$ vertices is not k -colorable with high probability. This is proved in Alon and Krivelevich (2002), with $c(k) = 36k \ln k$, building on the work of Goldreich et al. (1998), who showed that a random set of $O(k^2 \ln k / \varepsilon^3)$ vertices suffices. Note that the above supplies a very simple tester with one-sided error for testing k -colorability; consider the induced subgraph

on a randomly chosen set of $36k \ln k / \varepsilon^2$ vertices, and accept iff this subgraph is k -colorable. Obviously, every k -colorable graph is accepted by this procedure, and graphs that are ε -far from being k -colorable are likely to be rejected. Note also that the validity of this statement implies the nontrivial fact that every graph that is ε -far from being k -colorable contains a small witness (for being non k colorable), that is, a subgraph on only $c(\varepsilon, k) \leq O(k \ln k / \varepsilon^2)$ vertices which is not k -colorable. The existence of some such function $c(\varepsilon, k)$ has been conjectured by Erdős and first proved by Rödl and Duke [for some extremely fast growing function $c(\varepsilon, k)$ of ε and k - see Rödl and Duke (1985).] In this section we describe the improved $c(k)/\varepsilon^2$ bound. For simplicity, we present the proof only for $k = 3$; the proof for the general case is essentially identical. Throughout the proof we omit all floor and ceiling signs whenever these are not crucial.

Theorem 17.2.1 Suppose $0 < \varepsilon < \frac{1}{10}$, let $G = (V, E)$ be a graph on $n > 400/\varepsilon^3$ vertices, and suppose that one has to delete from G at least εn^2 edges to make it 3-colorable. Then the probability that an induced subgraph of G on a randomly chosen set of $s = 40/\varepsilon^2$ vertices is 3-colorable does not exceed $\frac{1}{10}$.

We start with an outline of the proof. Given $G = (V, E)$ as in the theorem, pick a random subset $R \subset V$ of size $|R| = s = 40/\varepsilon^2$ in s rounds, each time choosing uniformly at random a single vertex r_j among the vertices not selected so far.

Suppose that some subset $S \subset R$ has already been 3-colored by $\phi : S \rightarrow C$, where $C = \{1, 2, 3\}$. The objective is to show that with high probability there is a witness showing that this partial coloring cannot be extended to a proper coloring of the induced subgraph on R . If a proper 3-coloring $c : V \rightarrow C$ of G is to coincide with ϕ on S , then for every vertex $v \in V \setminus S$, the colors of the neighbors of v in S under ϕ are forbidden for v in c . The rest of the colors are still feasible for v . It could be that v has no feasible colors left at all. Such a vertex will be called colorless with respect to S and ϕ . If the number of colorless vertices is large, then there is a decent chance that among the next few randomly chosen vertices of R there will be one such colorless vertex v^* . Obviously, adding v^* to S provides the desired witness for non extendibility of ϕ .

If the set of colorless vertices is small, then one can show that, as G is ε -far from being 3-colorable, there is a relatively large subset W of vertices (which will be called restricting) such that adding any vertex $v \in W$ to S and coloring it by any feasible color excludes this color from the lists of feasible colors of at least εn neighbors of v . If such a vertex v is found among the next few vertices of the random sample R , then adding v to S and coloring it by any of its feasible colors reduces substantially the total size of the lists of feasible colors for the remaining vertices of V , which helps to approach the first situation, that is, the case when there are many colorless vertices. This process can be represented by a tree in which every internal node corresponds to a restricting vertex v , and every edge from v to a child corresponds to a feasible color for v . The tree will not be very large. Indeed, each of its internal vertices has at most 3 children, and its depth cannot exceed $3/\varepsilon$, as the total size of the lists of feasible colors at the beginning is $3n$, and this size is reduced by at least εn in each step. It thus suffices to show that with high probability the construction of the whole tree (until no feasible colors are left to any of its leaves) can be completed using the vertices in our random set R .

We proceed with the formal proof. For a subset $S \subseteq V$, a 3-coloring of it $\phi : S \rightarrow C$, and a vertex $v \in V \setminus S$ let $L_\phi(v)$ be the set of all colors in C besides those that appear already on some neighbor of v . This is the set of feasible colors for v . Clearly, for $S = \emptyset$, $L_\phi(v) = C$ for every $v \in V$. A vertex $v \in V \setminus S$ is called colorless if $L_\phi(v) = \emptyset$. Let U denote the set of all colorless vertices under (S, ϕ) .

For every vertex $v \in V \setminus (S \cup U)$ define

$$\delta_\phi(v) = \min_{i \in L_\phi(v)} |\{u \in N(v) \setminus (S \cup U) : i \in L(u)\}|.$$

Therefore coloring v by any one of the colors from $L_\phi(v)$ and then adding it to S will result in deleting this color and thus shortening the lists of feasible colors of at least $\delta_\phi(v)$ neighbors of v outside S .

Claim 17.2.2 For every set $S \subset V$ and every 3-coloring ϕ of S , the graph G is at most

$$(n-1)|S \cup U| + \frac{1}{2} \sum_{v \in V \setminus (S \cup U)} \delta_\phi(v)$$

edges far from being k -colorable.

Proof. Consider the following coloring of G : Every $v \in S$ is colored by $\phi(v)$, every $v \in U$ is colored by an arbitrary color and every $v \in V \setminus (S \cup U)$ is colored by a color $i \in L_\phi(v)$ for which $\delta_\phi(v) = |\{u \in N(v) \setminus (S \cup U) : i \in L(u)\}|$. The number of monochromatic edges incident with $S \cup U$ is at most $(n-1)|S \cup U|$. Every vertex $v \in V \setminus (S \cup U)$ has exactly $\delta_\phi(v)$ neighbors $u \in V \setminus (S \cup U)$, whose color list $L_\phi(v)$ contains the color chosen for v . Therefore v will have at most $\delta_\phi(v)$ neighbors in $V \setminus (S \cup U)$ colored in the same color as v itself. Hence the total number of monochromatic edges is at most

$$(n-1)|S \cup U| + \frac{1}{2} \sum_{v \in V \setminus (S \cup U)} \delta_\phi(v),$$

as claimed.

Given a pair (S, ϕ) , a vertex $v \in V \setminus (S \cup U)$ is called restricting if $\delta_\phi(v) \geq \varepsilon n$. We denote by W the set of all restricting vertices.

Claim 17.2.3 For every pair (S, ϕ) , where $S \subset V$ and $\phi : S \rightarrow C$,

$$|U \cup S \cup W| \geq \varepsilon n / 2.$$

Proof. By the previous claim, and since G is ε -far from being 3-colorable,

$$\begin{aligned} \varepsilon n^2 &< n(|S| + |U|) + \frac{1}{2} \sum_{v \in V \setminus (S \cup U)} \delta_\phi(v) \\ &\leq n(|S| + |U|) + \frac{1}{2}|W|(n-1) + \frac{1}{2} \sum_{v \in V \setminus (S \cup U \cup W)} \delta_\phi(v) \\ &< n(|S| + |U| + |W|) + \frac{1}{2}\varepsilon n^2. \end{aligned}$$

□

Returning to our randomly chosen vertices $r_1, \dots, r_s$ of R , construct an auxiliary ternary tree T . To distinguish between the vertices of G and those of T we call the latter nodes. Each node of T is labeled either by a vertex of G or by the special symbol $\#$, whose meaning will be explained in what follows. If a node t of T is labeled by $\#$, then t is called a terminal node. The edges of T are labeled by integers from C .

Let t be a node of T . Consider the path from the root of T to t , not including t itself. The labels of the nodes along this path form a subset $S(t)$ of V . The labels of the edges along the path define a 3-coloring $\phi(t)$ of $S(t)$ in a natural way: the label of the edge following a node t' in the path determines the color of its label $v(t')$. The labeling of the nodes and edges of T will have the following property: If t is labeled by v and v has a neighbor in $S(t)$ whose color in $\phi(t)$ is i , then the son of v along the edge labeled by i is labeled by $\#$. This label indicates the fact that in this case color i is infeasible for v , given $(S(t), \phi(t))$.

At each step of the construction of T we will maintain the following: All leafs of T are either unlabeled or are labeled by $\#$. Also, only leafs of T can be labeled by $\#$. We start the construction of T from an unlabeled single node, the root of T .

Suppose that $j - 1$ vertices of T have already been chosen, and we are about to choose vertex r_j of R . Consider a leaf t of T . If t is labeled by $\#$, we do nothing for this leaf. (That is the reason such a t is called a terminal node; nothing will ever grow out of it.) Assume now that t is unlabeled. Define the pair $(S(t), \phi(t))$ as described above. Now, for the pair $(S(t), \phi(t))$ we define the set $U(t)$ of colorless vertices and the set $W(t)$ of restricting vertices as described before. Round j is called successful for the node t if the random vertex r_j satisfies $r_j \in U(t) \cup W(t)$. If round j is indeed successful for t , then we label t by r_j , create 3 sons of t and label the corresponding edges by 1, 2, 3. Now, if color i is infeasible for r_j , given $(S(t), \phi(t))$, we label the son of t along the edge with label i by $\#$, otherwise we leave this son unlabeled. Note that if $r_j \in U(t)$, then none of the colors from C is feasible for r_j , and thus all the sons of t will be labeled by $\#$. This completes the description of the process of constructing T . As each edge along a path from a root to a leaf of the tree corresponds to a restricting vertex, and the total size of all lists starts with $3n$ and is reduced by at least εn with each coloring of a restricting vertex, we have the following.

Claim 17.2.4 The depth of T is at most $3/\varepsilon$.

Our construction also implies that if a leaf t^* of T is labeled by $\#$, then $\phi(t^*)$ is not a proper 3-coloring of $S(t^*)$. We thus have the following.

Claim 17.2.5 If after round j all leafs of the tree T are terminal nodes, then the induced subgraph of G on $\{r_1, \dots, r_j\}$ is not 3-colorable.

To complete the proof it thus suffices to show the following.

Claim 17.2.6 After $s = 40/\varepsilon^2$ rounds, with probability at least $\frac{9}{10}$ all leaves of T are terminal nodes.

Proof. As every non leaf node of T has at most 3 sons and by Claim 17.2.4 the depth of T is at most $3/\varepsilon$, it can be embedded naturally in the ternary tree $T_{3,3/\varepsilon}$ of depth $3/\varepsilon$. Moreover, this embedding can be prefixed even before exposing R and T . Note that the number of vertices of $T_{3,3/\varepsilon}$ is $1 + 3 + \dots + 3^{3/\varepsilon} < 3^{1+3/\varepsilon}$.

Recall that during the construction of the random sample R and the tree T , a successful round for a leaf t of T results in creating 3 sons of T . Fix a node t of $T_{3,3/\varepsilon}$. If after $40/\varepsilon^2$ rounds t is a leaf of T , then the total number of successful rounds for the path from the root of T to t is equal to the depth of t . As $S(t) \subseteq R$ and thus $|S(t)| \leq 40/\varepsilon^2 \leq \varepsilon n/10$, by Claim 17.2.3 each round has probability of success at least 0.4ε . Therefore, the probability that t is a non terminal leaf of T after $40/\varepsilon^2$ steps can be bounded from above by the probability that the binomial random variable $B(40/\varepsilon^2, 0.4\varepsilon)$ is at most $3/\varepsilon$. The latter probability is at most

$$\exp\left(-\frac{(16/\varepsilon - 3/\varepsilon)^2}{2 \cdot 16/\varepsilon}\right) = \exp\left(-\frac{169}{32\varepsilon}\right).$$

Thus by the union bound we conclude that the probability that some node of $T(3, 3/\varepsilon)$ is a leaf of T , not labeled by $\#$, is at most

$$|V(T_{3,3/\varepsilon})| \exp\left(-\frac{169}{32\varepsilon}\right) < \frac{1}{10}$$

The assertion of Theorem 17.2.1 follows from Claims 17.2.5 and 17.2.6.

18.8.3 17.3 Szemerédi's Regularity Lemma

In this section we describe a fundamental result, the Regularity Lemma, proved by Endre Szemerédi in the 1970s. The original motivation for proving it was an application in combinato-

rial number theory, leading, together with several additional deep ideas, to a complete solution of the Erdős-Turán conjecture discussed in Appendix B.2: Every set of integers of positive upper density contains arbitrarily long arithmetic progressions. It took some time to realize that the lemma is an extremely powerful

tool in extremal graph theory, combinatorics and theoretical computer science. Stated informally, the Regularity Lemma asserts that the vertices of every large graph can be decomposed into a finite number of parts, so that the edges between almost every pair of parts form a random-looking graph. The power of the lemma is in the fact it deals with an arbitrary graph, making no assumptions, and yet it supplies much useful information about its structure. It should be stressed that the impact of the Regularity Lemma goes far beyond its applications in property testing, which is our focus in this chapter. A detailed survey of the lemma and some of its many variants and fascinating consequences can be found in Komlós and Simonovits (1996).

Let $G = (V, E)$ be a graph. For two disjoint nonempty subsets of vertices $A, B \subset V$, let $e(A, B)$ denote the number of edges of G with one end in A and one in B , and let

$$d(A, B) = \frac{e(A, B)}{|A||B|}$$

denote the density of the pair (A, B) . For a real $\varepsilon > 0$, a pair (A, B) as above is called ε -regular if for every $X \subset A$ and $Y \subset B$ that satisfy $|X| \geq \varepsilon|A|, |Y| \geq \varepsilon|B|$ the inequality $|d(A, B) - d(X, Y)| \leq \varepsilon$ holds. It is not difficult to see that for every fixed positive ε, p a fixed pair of two sufficiently large disjoint subsets A and B of a random graph $G = G(n, p)$ are very likely to be ε -regular of density roughly p . (This is stated in one of the exercises at the end of the chapter.) Conversely, an ε -regular pair A, B with a sufficiently small positive ε is random-looking in the sense that it shares many properties satisfied by random (bipartite) graphs.

A partition $V = V_0 \cup V_1 \cup \dots \cup V_k$ of V into pairwise disjoint sets in which V_0 is called the exceptional set is an equipartition if $|V_1| = |V_2| = \dots = |V_k|$. We view the exceptional set as $|V_0|$ distinct parts, each consisting of a single vertex. For two partitions $\mathcal{P}$ and $\mathcal{P}'$ as above, $\mathcal{P}'$ is a refinement of $\mathcal{P}$, if every part in $\mathcal{P}$ is a union of some of the parts of $\mathcal{P}'$. By the last comment on the exceptional set this means, in particular, that if $\mathcal{P}'$ is obtained from $\mathcal{P}$ by shifting vertices from the other sets in the partition to the exceptional set, then $\mathcal{P}'$ is a refinement of $\mathcal{P}$. An equipartition is called ε -regular if $|V_0| \leq \varepsilon|V|$ and all pairs (V_i, V_j) with $1 \leq i < j \leq k$, except at most εk^2 of them, are ε -regular.

Theorem 17.3.1 [The Regularity Lemma, Szemerédi (1978)] For every $\varepsilon > 0$ and every integer t there exists an integer $T = T(\varepsilon, t)$ so that every graph with at least T vertices has an ε -regular partition $(V_0, V_1, \dots, V_k)$, where $t \leq k \leq T$.

The basic idea in the proof is simple. Start with an arbitrary partition of the set of vertices into t disjoint classes of equal sizes (with a few vertices in the exceptional set, if needed, to ensure divisibility by t). Proceed by showing that as long as the existing partition is not ε -regular, it can be refined in a way that increases the weighted average of the square of the density between a pair of classes of the partition by at least a constant depending only on ε . As this average cannot exceed 1, the process has to terminate after a bounded number of refinement steps. Since in each step we control the growth in the number of parts as well as the number of extra vertices thrown to the exceptional set, the desired result follows. The precise details require some care and are given in what follows.

Let $G = (V, E)$ be a graph on $|V| = n$ vertices. For two disjoint subsets $U, W \subset V$, define $q(U, W) = (|U||W|/n^2) d^2(U, W)$. For partitions $\mathcal{U}$ of U and $\mathcal{W}$ of W , define

$$q(\mathcal{U}, \mathcal{W}) = \sum_{\substack{U' \in \mathcal{U} \\ W' \in \mathcal{W}}} q(U', W')$$

Finally, for a partition $\mathcal{P}$ of V , with an exceptional set V_0 , define $q(\mathcal{P}) = \sum q(U, W)$, where the sum ranges over all unordered pairs of distinct parts U, W in the partition, with each vertex of the exceptional set V_0 forming a singleton part in its own. Therefore $q(\mathcal{P})$ is a sum of $\binom{k+|V_0|}{2}$ terms of the form $q(U, W)$. The quantity $q(\mathcal{P})$ is called the index of the partition $\mathcal{P}$. Since $d^2(U, W) \leq 1$ for all U, W , and since the sum $\sum |U||W|$ over all unordered pairs of distinct parts U, W is at most the number of unordered pairs of vertices, it follows that the index of any partition is smaller than $\frac{1}{2}$.

Lemma 17.3.2

- (i) Let U, W be disjoint nonempty subsets of V ; let $\mathcal{U}$ be a partition of U and $\mathcal{W}$ a partition of W . Then $q(\mathcal{U}, \mathcal{W}) \geq q(U, W)$.
- (ii) If $\mathcal{P}'$ and $\mathcal{P}$ are partitions of V and $\mathcal{P}'$ is a refinement of $\mathcal{P}$, then $q(\mathcal{P}') \geq q(\mathcal{P})$.
- (iii) Suppose $\varepsilon > 0$, and suppose U, W are disjoint nonempty subsets of V and the pair (U, W) is not ε -regular. Then there are partitions $\mathcal{U} = \{U_1, U_2\}$ of U and $\mathcal{W} = \{W_1, W_2\}$ of W so that $q(\mathcal{U}, \mathcal{W}) > q(U, W) + \varepsilon^4 |U||W|/n^2$.

Proof.

(i) Define a random variable Z as follows. Let u be a uniformly chosen random element of U , and let w be a uniformly chosen random element of W . Let $U' \in \mathcal{U}$ and $W' \in \mathcal{W}$ be those members of the partition so that $u \in U', w \in W'$. Then $Z = d(U', W')$. The expectation of Z is

$$\sum_{\substack{U' \in \mathcal{U} \\ W' \in \mathcal{W}}} \frac{|U'| |W'|}{|U||W|} d(U', W') = \sum_{\substack{U' \in \mathcal{U} \\ W' \in \mathcal{W}}} \frac{|U'| |W'|}{|U||W|} \cdot \frac{e(U', W')}{|U'| |W'|} = d(U, W).$$

By Jensen's Inequality, $E[Z^2] \geq (E[Z])^2$ and the desired result follows, as

$$E[Z^2] = \frac{n^2}{|U||W|} q(\mathcal{U}, \mathcal{W}) \text{ and } (E[Z])^2 = d^2(U, W) = \frac{n^2}{|U||W|} q(U, W)$$

(ii) This is an immediate consequence of (i).

(iii) Since the pair (U, W) is not ε -regular, there are subsets $U_1 \subset U, W_1 \subset W$ so that $|U_1| \geq \varepsilon |U|, |W_1| \geq \varepsilon |W|$ and $|d(U_1, W_1) - d(U, W)| > \varepsilon$. Put $U_2 = U \setminus U_1, W_2 = W \setminus W_1$ and define the partitions $\mathcal{U} = \{U_1, U_2\}, \mathcal{W} = \{W_1, W_2\}$. Let Z be the random variable defined in the proof of part (i). Then, as shown in that proof,

$$\text{Var}[Z] = E[Z^2] - (E[Z])^2 = \frac{n^2}{|U||W|} (q(\mathcal{U}, \mathcal{W}) - q(U, W))$$

However, as $E[Z] = d(U, W)$ it follows that Z deviates from $E[Z]$ by more than ε with probability $|U_1| |W_1| / |U||W|$, implying that

$$\text{Var}[Z] > \frac{|U_1| |W_1|}{|U||W|} \varepsilon^2 \geq \varepsilon^4$$

This provides the desired result.

Proposition 17.3.3 Suppose $0 < \varepsilon \leq \frac{1}{4}$, let $\mathcal{P} = \{V_0, V_1, \dots, V_k\}$ be an equipartition of V , where V_0 is the exceptional set, $|V_0| \leq \varepsilon n$, and $|V_i| = c$ for all $1 \leq i \leq k$. If $\mathcal{P}$ is not ε -regular

then there exists a refinement $\mathcal{P}' = \{V'_0, V'_1, \dots, V'_\ell\}$ of $\mathcal{P}$, in which $k \leq \ell \leq k4^k$, $|V'_0| \leq |V_0| + n/2^k$, all other sets V_i are of the same size and $q(\mathcal{P}') \geq q(\mathcal{P}) + \frac{1}{2}\varepsilon^5$.

Proof. For every pair $1 \leq i < j \leq k$ define a partition $\mathcal{V}_{ij}$ of V_i and $\mathcal{V}_{ji}$ of V_j as follows. If the pair (V_i, V_j) is ε -regular, then the two partitions are trivial. Otherwise, each partition consists of two parts, chosen according to Lemma 17.3.2, part (iii). For each $1 \leq i \leq k$, let $\mathcal{V}_i$ be the partition of V_i obtained by the Venn diagram of all $(k-1)$ -partitions $\mathcal{V}_{ij}$. Thus each $\mathcal{V}_i$ has at most 2^{k-1} parts. Let $\mathcal{Q}$ be the partition of V consisting of all parts of the partitions $\mathcal{V}_i$ together with the original exceptional set V_0 . By Lemma 17.3.2, parts (ii) and (iii), and since $\mathcal{P}$ is not ε -regular, we conclude that the index of $\mathcal{Q}$ satisfies

$$q(\mathcal{Q}) \geq q(\mathcal{P}) + \varepsilon k^2 \varepsilon^4 \frac{c^2}{n^2} = q(\mathcal{P}) + \varepsilon^5 \frac{(kc)^2}{n^2} > q(\mathcal{P}) + \frac{\varepsilon^5}{2}$$

where here we used the fact that $kc \geq (1-\varepsilon)n \geq \frac{3}{4}n$. Note that $\mathcal{Q}$ has at most $k2^{k-1}$ parts (besides the exceptional set), but those are not necessarily of equal sizes. Define $b = \lfloor c/4^k \rfloor$ and split every part of $\mathcal{Q}$ arbitrarily into disjoint sets of size b , throwing the remaining vertices in each part, if any, to the exceptional set. This process creates a partition $\mathcal{P}'$ with at most $k4^k$ non exceptional parts of equal size, and a new exceptional set V'_0 of size smaller than $|V_0| + k2^{k-1}b < |V_0| + kc/2^k \leq |V_0| + n/2^k$. Moreover, by Lemma 17.3.2, part (ii), the index $q(\mathcal{P}')$ of $\mathcal{P}'$ is at least $q(\mathcal{Q}) > q(\mathcal{P}) + \frac{1}{2}\varepsilon^5$, completing the proof.

Proof [Theorem 17.3.1]. It suffices to prove the lemma for $\varepsilon \leq \frac{1}{4}$ and t satisfying $2^{t-2} > 1/\varepsilon^6$; hence we assume that these inequalities hold. Put $s = \lceil 1/\varepsilon^5 \rceil$ and note that for this choice $1/2^k \leq \varepsilon/2s$ for all $k \geq t$. Define $k_0 = t$ and $k_{i+1} = k_i 4^{k_i}$ for all $i \geq 0$. We prove the lemma with $T = k_s$.

Let $G = (V, E)$ be a graph with $|V| = n \geq T$ vertices. Start with an arbitrary partition $\mathcal{P} = \mathcal{P}_0$ of its vertices into $k = k_0 = t$ pairwise disjoint parts, each of size $\lfloor n/t \rfloor$, and let the exceptional set consist of the remaining vertices, if any. Note that their number is less than t , which is (much) smaller than $\frac{1}{2}\varepsilon n$. As long as the partition $\mathcal{P}$ we have already defined is not ε -regular, apply Proposition 17.3.3 to refine it to a new equipartition $\mathcal{P}'$ with at most $k4^k$ non exceptional parts, whose index exceeds that of $\mathcal{P}$ by at least $\frac{1}{2}\varepsilon^5$, while the size of the exceptional set increases by at most $n/2^k < \varepsilon n/2s$. As the initial index is nonnegative, and the index never exceeds $\frac{1}{2}$, the process must terminate in at most s steps, yielding an ε -regular partition with at most T non exceptional parts, and an exceptional set of size smaller than εn .

Remark. The proof shows that $T(\varepsilon, \lceil 1/\varepsilon \rceil)$ is bounded by a tower of exponents of height roughly $1/\varepsilon^5$. Surprisingly, as shown by Gowers (1997), this tower-type behavior is indeed necessary.

18.8.4 17.4 Testing Triangle-freeness

The relevance of the Regularity Lemma to property testing is nicely illustrated in the proof that the property of containing no triangle is testable with one-sided error. The required combinatorial lemma here is the (intuitive, yet nontrivial) fact that if one has to delete at least εn^2 edges of an n -vertex graph to destroy all triangles in it, then the graph must contain at least δn^3 triangles, where $\delta = \delta(\varepsilon) > 0$. As shown in the exercises, following Ruzsa and Szemerédi (1978), this fact implies that any set of integers with positive upper density contains a three-term arithmetic progression.

Lemma 17.4.1 For any positive $\varepsilon < 1$ there is a $\delta = \delta(\varepsilon) > 0$ so that if $G = (V, E)$ is a graph on $|V| = n$ vertices that is ε -far from being triangle-free, then it contains at least δn^3 triangles.

Proof. We prove the lemma with

$$\delta = \frac{\varepsilon^3}{2^9 T^3 (\varepsilon/4, \lceil 4/\varepsilon \rceil)},$$

where T is as in Theorem 17.3.1. Let $G = (V, E)$ satisfy the assumption. Note, first, that if $n < T(\varepsilon/4, \lceil 4/\varepsilon \rceil)$ then the assertion is trivial, as in this case δn^3 is less than 1, and it is trivial that if G is ε -far from being triangle-free then it contains a triangle. We thus assume that n is at least $T(\varepsilon, t)$, where $t = \lceil 4/\varepsilon \rceil$. By Theorem 17.3.1 there is an $(\varepsilon/4)$ -regular partition $(V_0, V_1, \dots, V_k)$ of G , where $t \leq k \leq T = T(\varepsilon, t)$. Put $c = |V_1| = |V_2| = \dots = |V_k|$. Let G' be the graph obtained from G by deleting the following edges:

- All edges of G that are incident with a vertex of the exceptional set V_0 (there are less than $\frac{1}{4}\varepsilon n^2$ such edges.)
- All edges of G that lie inside some set V_i (there are less than $\frac{1}{8}\varepsilon n^2$ such edges.)
- All edges of G that lie in irregular pairs [there are at most $\frac{1}{4}\varepsilon k^2 c^2 \leq \varepsilon \frac{1}{4}n^2$ such edges.]
- All edges of G that lie in regular pairs (V_i, V_j) , where the density $d(V_i, V_j)$ is smaller than $\frac{1}{2}\varepsilon$ [there are less than $\binom{k}{2} \frac{1}{2}\varepsilon c^2 < \frac{1}{4}\varepsilon n^2$ such edges.]

Since G' is obtained from G by deleting less than εn^2 edges, it contains a triangle, as G is ε -far from being triangle-free. By the definition of G' , the vertices of this triangle must lie in three distinct sets V_i , any two of which form a regular pair of density at least $\frac{1}{2}\varepsilon$. Without loss of generality assume that these sets are V_1, V_2, V_3 . Call a vertex $v_1 \in V_1$ typical if it has at least $\frac{1}{4}\varepsilon c$ neighbors in V_2 and at least $\frac{1}{4}\varepsilon c$ neighbors in V_3 . We claim that all vertices of V_1 but at most $2 \cdot \frac{1}{4}\varepsilon c < \frac{1}{2}c$ are typical. Indeed, if X_1 is the set of all vertices of V_1 that have less than $\frac{1}{4}\varepsilon c$ neighbors in V_2 then its cardinality must be smaller than $\frac{1}{4}\varepsilon c$, since otherwise the pair X_1 and $X_2 = V_2$, together with the fact that $d(V_1, V_2) \geq \frac{1}{2}\varepsilon$, would violate the $(\varepsilon/4)$ -regularity of this pair. Similarly, there are less than $\frac{1}{4}\varepsilon c$ vertices of V_1 that have less than $\frac{1}{4}\varepsilon c$ neighbors in V_3 , proving the claim.

Fix a typical vertex $v_1 \in V_1$, and let N_2, N_3 denote the sets of all its neighbors in V_2 and V_3 , respectively. Thus $|N_2|, |N_3| \geq \frac{1}{4}\varepsilon c$, and hence, by the $(\varepsilon/4)$ -regularity of the pair (V_2, V_3) and the fact that its density is at least $\frac{1}{2}\varepsilon$, there are at least $\frac{1}{4}\varepsilon |N_2| |N_3| \geq (\varepsilon/4)^3 c^2$ edges between N_2 and N_3 . We conclude that v_1 lies in at least $(\varepsilon/4)^3 c^2$ triangles. As there are at least $\frac{1}{2}c$ typical vertices in V_1 , and since

$$c^3 \geq \left(1 - \frac{\varepsilon}{4}\right)^3 n^3 / T^3 > \frac{n^3}{4T^3},$$

the desired result follows. $\square$

Corollary 17.4.2 The property of being triangle-free is testable with one-sided error.

Proof. For $\varepsilon > 0$, let $\delta = \delta(\varepsilon)$ be as in Lemma 17.4.1. Given a graph $G = (V, E)$ on n vertices, consider the following randomized algorithm for testing if G is triangle-free. Let s be a confidence parameter. Pick randomly and independently s/δ triples of vertices of the graph, and check if at least one of them forms a triangle. If so, then report that the graph is not triangle-free, otherwise, report that the graph is triangle-free. Clearly, if G is triangle-free, the algorithm will decide so. If it is ε -far from being triangle-free, then by Lemma 17.4.1, the probability that the algorithm will err and report that G is triangle-free does not exceed $(1 - 6\delta)^{s/\delta} \leq e^{-6s}$. This completes the proof. $\square$

18.8.5 17.5 Characterizing the Testable Graph Properties

In this section we describe several recent results on graph property testing. The proofs of these results apply a strong variant of the Regularity Lemma, proved in Alon, Fischer, Krivelevich and Szegedy (2000). The detailed proofs are somewhat technical and will not be given here.

A graph property is monotone if it is closed under removing vertices and edges. Thus being k -colorable or triangle-free is a monotone property. A property is hereditary if it is closed under removal of vertices (and not necessarily under removal of edges). Clearly every monotone graph property is also hereditary, but there are also many well-studied hereditary properties that are not monotone. Examples are being a perfect graph, a chordal graph, an interval graph and many more. The results discussed in the previous subsections deal with two special cases of hereditary properties that are also monotone, namely, being triangle-free and being k -colorable. Handling hereditary non-monotone graph properties, such as being perfect or not containing an induced cycle of length 4, is more involved than handling monotone properties.

For a (possibly infinite) family of graphs $\mathcal{F}$, a graph G is said to be induced $\mathcal{F}$ -free if it contains no $F \in \mathcal{F}$ as an induced subgraph. The following lemma is not difficult.

Lemma 17.5.1 Let $\mathcal{F}$ be a (possibly infinite) family of graphs, and suppose there are functions $f_{\mathcal{F}}(\varepsilon)$ and $\delta_{\mathcal{F}}(\varepsilon)$ such that the following holds for every $\varepsilon > 0$. Every graph G on n vertices that is ε -far from being induced $\mathcal{F}$ -free contains at least $\delta_{\mathcal{F}}(\varepsilon)n^{f_{\mathcal{F}}}$ induced copies of a graph $F \in \mathcal{F}$ of size $f \leq f_{\mathcal{F}}(\varepsilon)$. Then, being induced $\mathcal{F}$ -free is testable with one-sided error.

The following general result is proved in Alon and Shapira (2005). A subsequent different, elegant, but non effective proof can be found in Lovász and Szegedy (to appear).

Theorem 17.5.2 [Alon and Shapira (2005)] For any (possibly infinite) family of graphs $\mathcal{F}$ there are functions $f_{\mathcal{F}}(\varepsilon)$ and $\delta_{\mathcal{F}}(\varepsilon)$ satisfying the conditions of Lemma 17.5.1.

It is easy to see that one can define for any hereditary property $\mathcal{P}$, a (possibly infinite) family of graphs $\mathcal{F}_{\mathcal{P}}$ such that satisfying $\mathcal{P}$ is equivalent to being induced $\mathcal{F}_{\mathcal{P}}$ -free. Indeed, we simply put a graph F in $\mathcal{F}_{\mathcal{P}}$ if and only if F does not satisfy $\mathcal{P}$. It thus follows that Theorem 17.5.2, combined with Lemma 17.5.1, implies the following.

Theorem 17.5.3 Every hereditary graph property is testable with one-sided error.

An easy consequence of Theorem 17.5.2 is the following.

Corollary 17.5.4 For every hereditary graph property $\mathcal{P}$, there is a function $W_{\mathcal{P}}(\varepsilon)$ with the following property: If G is ε -far from satisfying $\mathcal{P}$, then G contains an induced subgraph of size at most $W_{\mathcal{P}}(\varepsilon)$ that does not satisfy $\mathcal{P}$.

Using Theorem 17.5.3 one can obtain a characterization of the "natural" graph properties, which are testable with one-sided error.

A tester (one-sided or two-sided) is said to be oblivious if it works as follows: Given ε the tester computes an integer $Q = Q(\varepsilon)$ and asks an oracle for a subgraph induced by a set of vertices S of size Q , where the oracle chooses S randomly and uniformly from the vertices of the input graph. If Q is larger than the size of the input graph then the oracle returns the entire graph. The tester then accepts or rejects according to the graph induced by S .

In some sense, oblivious testers capture the essence of property testing as essentially all the testers that have been analyzed in the literature are in fact oblivious, or could easily be turned into oblivious testers. Clearly some properties cannot have oblivious testers; however, these properties are not natural. An example is the property of not containing an induced cycle of length 4 if the number of vertices is even, and not containing an induced cycle of length 5 if the number of vertices is odd.

Using Theorem 17.5.3 it can be shown that if one considers only oblivious testers, then it is possible to precisely characterize the graph properties, which are testable with one-sided error. To state this characterization we need the following definition.

A graph property $\mathcal{P}$ is called semi-hereditary if there exists a hereditary graph property $\mathcal{H}$ such that the following holds.

1. Any graph satisfying $\mathcal{P}$ also satisfies $\mathcal{H}$.
2. For any $\varepsilon > 0$ there is an $M(\varepsilon)$ such that any graph of size at least $M(\varepsilon)$ that is ε -far from satisfying $\mathcal{P}$ does not satisfy $\mathcal{H}$.

Clearly any hereditary graph property $\mathcal{P}$ is also semi-hereditary because we can take $\mathcal{H}$ in the above definition to be $\mathcal{P}$ itself. In simple words, a semi-hereditary $\mathcal{P}$ is obtained by taking a hereditary graph property $\mathcal{H}$ and removing from it a (possibly infinite, carefully chosen) set of graphs. This means that the first item in the definition above is satisfied. The only restriction, which is needed to get item 2 in the definition, is that $\mathcal{P}$ will be such that for any $\varepsilon > 0$ there will be only finitely many graphs that are ε -far from satisfying it, and yet satisfy $\mathcal{H}$. We are now ready to state the characterization.

Theorem 17.5.5 A graph property $\mathcal{P}$ has an oblivious one-sided tester if and only if $\mathcal{P}$ is semi-hereditary.

The proof can be found in Alon and Shapira (2005). The Regularity Lemma and its strong variant mentioned in the beginning of this subsection play a crucial role in this proof. This is not a coincidence. In Alon, Fischer, Newman and Shapira (2006) it is shown that the property defined by having any given Szemerédi-partition is testable with a constant number of queries. This leads to a combinatorial characterization of the graph properties that are testable with a constant number of queries. This characterization (roughly) says that a graph property $\mathcal{P}$ can be tested by a two-sided error tester with a constant number of queries if and only if testing $\mathcal{P}$ can be reduced to testing the property of satisfying one of finitely many Szemerédi-partitions. See Alon et al. (2006) for the precise formulation and detailed proof.

18.8.6 17.6 Exercises

1. Show that for every fixed $\varepsilon > 0$ and $0 < p < 1$ there is an $m_0 = m_0(\varepsilon, p)$ so that for every $n > 2m > m_0$, the probability that two fixed disjoint sets A and B , each of size m , of the random graph $G(n, p)$ do not form an ε -regular pair is smaller than ε .
2. (Removal Lemma.) Show that for any fixed graph H on h vertices and for any $\varepsilon > 0$ there is a $\delta = \delta(\varepsilon, H) > 0$ so that if one has to delete at least εn^2 edges from an n -vertex graph G to destroy all copies of H , then G contains at least δn^h copies of H .
3. (*) Using Lemma 17.4.1 prove that for any $\varepsilon > 0$ there is an n_0 so that if $n > n_0$ then every subset $A \subset \{1, 2, \dots, n\}$ of size $|A| \geq \varepsilon n$ contains a three-term arithmetic progression.
4. Combine Turán's Theorem with the Regularity Lemma to prove the following result, due to Erdős, Simonovits and Stone: For every fixed graph H of chromatic number $r > 1$ and every $\varepsilon > 0$, there is an $n_0 = n_0(H, \varepsilon)$ so that if $n > n_0$ then any simple graph with n vertices and at least

$$\left(1 - \frac{1}{r-1} + \varepsilon\right) \binom{n}{2}$$

edges contains a copy of H .

5. A graph is chordal if any cycle of length at least 4 in it has a chord. Apply Corollary 17.5.4 to show that for every $\varepsilon > 0$ there is a $k = k(\varepsilon)$ so that every graph on n vertices in which every cycle of length at least 4 and at most k has a chord can be transformed into a chordal graph by adding and/or deleting at most εn^2 edges.
6. (*) A construction of Behrend (1946) gives a subset X of $\{1, 2, \dots, m\}$ of size $|X| \geq m/e^{c\sqrt{\log m}}$ with no three-term arithmetic progression. Show how to construct from such an X a graph on n vertices, which is ε -far from being triangle-free, and yet contains only $\varepsilon^{b \log(1/\varepsilon)} n^3$ triangles.
7. Prove that the property of being triangle-free is not testable with a one-sided error tester whose query complexity is polynomial in $1/\varepsilon$.
8. A graph G is H -free if it contains no copy of H . Prove that for every bipartite graph H

with h vertices, there is a $c = c(h) > 0$ so that any graph G on n vertices that is ε -far from being H -free contains at least $\varepsilon^c n^h$ copies of H .

The Probabilistic Lens: Turán Numbers and Dependent Random Choice

For a graph H and an integer n , the Turán number $\text{ex}(n, H)$ is the maximum possible number of edges in a simple graph on n vertices that contains no copy of H . The asymptotic behavior of these numbers for graphs of chromatic number at least 3 is well known; see, for example, Exercise 4 in Chapter 17. For bipartite graphs H , however, the situation is considerably more complicated, and there are relatively few nontrivial bipartite graphs H for which the order of magnitude of $\text{ex}(n, H)$ is known. Here we prove that for every fixed bipartite graph H in which the degrees of all vertices in one color class are at most r , there is a constant $c = c(H)$ so that $\text{ex}(n, H) \leq cn^{2-1/r}$. This is tight for all values of r , as it is known that for every r and $t > (r-1)!$, there is a simple graph with n vertices and at least $c_{r,t} n^{2-1/r}$ edges, containing no copy of the complete bipartite graph $K_{r,t}$.

The basic tool in the proof is a simple and yet surprisingly powerful method, whose probabilistic proof may be called "dependent random choice," as it involves a random selection of a set of vertices, where the choices are dependent in a way that increases the probability that r -tuples of selected vertices will have many common neighbors. An early variant of this lemma was first proved in Kostochka and Rödl (2004) and Gowers (1998). The proof given here is from Alon, Krivelevich and Sudakov (2003).

Lemma 1 Let a, b, n, r be positive integers. Let $G = (V, E)$ be a graph on $|V| = n$ vertices with average degree $d = 2|E|/n$. If

$$\frac{d^r}{n^{r-1}} - \binom{n}{r} \left(\frac{b-1}{n} \right)^r > a - 1, \quad (1)$$

then G contains a subset A_0 of at least a vertices so that every r vertices of A_0 have at least b common neighbors.

Proof. Let T be a (multi)-set of r random vertices of G , chosen uniformly with repetitions. Set

$$A = \{v \in V : T \subseteq N(v)\},$$

where $N(v)$ denotes the set of all neighbors of v . Denote by X the cardinality of A . By linearity of expectation,

$$\begin{aligned} \mathbb{E}[X] &= \sum_{v \in V} \left(\frac{|N(v)|}{n} \right)^r = \frac{1}{n^r} \sum_{v \in V} |N(v)|^r \\ &\geq \frac{1}{n^r} n \left(\frac{\sum_{v \in V} |N(v)|}{n} \right)^r = \frac{1}{n^{r-1}} \left(\frac{2|E|}{n} \right)^r = \frac{d^r}{n^{r-1}}, \end{aligned}$$

where the inequality follows from the convexity of $f(x) = x^r$.

Let Y denote the random variable counting the number of r -tuples in A with fewer than b common neighbors. For a given r -tuple $R \subseteq V$, the probability that R will be a subset of A is precisely $(|N^*(R)|/n)^r$, where $N^*(R)$ denotes the set of all common neighbors of the vertices in R . As there are at most $\binom{n}{r}$ subsets R of cardinality $|R| = r$ for which $|N^*(R)| \leq b-1$, it follows that

$$\mathbb{E}[Y] \leq \binom{n}{r} \left(\frac{b-1}{n} \right)^r$$

Applying linearity of expectation once again, we conclude by (1) that

$$\mathbb{E}[X - Y] \geq \frac{d^r}{n^{r-1}} - \binom{n}{r} \left(\frac{b-1}{n} \right)^r > a - 1$$

Hence there exists a choice for T so that for the corresponding set A we get $X - Y \geq a$. Pick such a set, and omit a point from every r -tuple in it with fewer than b common neighbors. This gives a set A_0 of at least a vertices so that every r vertices in it have at least b common neighbors.

Theorem 2 Let H be a bipartite graph with maximum degree r on one side. Then there exists a constant $c = c(H) > 0$ such that

$$ex(n, H) < cn^{2-1/r}.$$

Proof. Let A and B be the vertex classes of H , and suppose $|A| = a$, $|A| + |B| = b$, where the degree of every vertex $b \in B$ in H does not exceed r . Let $G = (V, E)$ be a graph on $|V| = n$ vertices with average degree $d = 2|E|/n \geq cn^{1-1/r}$, where c satisfies $c^r > (b-1)^r/r! + a - 1$. It is easy to check that (1) holds. To complete the proof, it suffices to show that G must contain a copy of H . By Lemma 1 there is

a subset $A_0 \subset V$ of cardinality $|A_0| = a$ so that every r -subset of A_0 has at least b common neighbors in G . It is now an easy matter to embed H in G . To do so, start by embedding the vertices of A by an arbitrary injective function from A to A_0 . Proceed by embedding the vertices of B one by one in an arbitrary order, making sure that in each step the image of the new embedded vertex is connected to the images of its neighbors in H and is different from the images of all previously embedded vertices. Since every set of (at most) r vertices of A_0 has at least b common neighbors in G , this process can be performed until the images of all b vertices of H are found. This completes the proof.

18.8.7 Appendix A: Bounding of Large Deviations

A. 1 Chernoff Bounds

We give here some basic bounds on large deviations that are useful when employing the probabilistic method. Our treatment is self-contained. Most of the results may be found in, or immediately derived from, the seminal paper of Chernoff (1952). While we are guided by asymptotic considerations the inequalities are proved for all values of the parameters in the specified region. The first result, while specialized, contains basic ideas found throughout the appendix.

Theorem A.1.1 Let $X_i, 1 \leq i \leq n$, be mutually independent random variables with

$$\Pr[X_i = +1] = \Pr[X_i = -1] = \frac{1}{2}$$

and set, following the usual convention,

$$S_n = X_1 + \cdots + X_n.$$

Let $a > 0$. Then

$$\Pr[S_n > a] < e^{-a^2/2n}$$

We require Markov's Inequality, which states: Suppose that Y is an arbitrary nonnegative random variable, $\alpha > 0$. Then

$$\Pr[Y > \alpha \mathbb{E}[Y]] < \frac{1}{\alpha}$$

Proof. Fix n, a and let, for the moment, $\lambda > 0$ be arbitrary. For $1 \leq i \leq n$,

$$\mathbb{E} [e^{\lambda X_i}] = \frac{e^\lambda + e^{-\lambda}}{2} = \cosh(\lambda)$$

We require the inequality $\cosh(\lambda) \leq e^{\lambda^2/2}$, valid for all $\lambda > 0$, the special case $\alpha = 0$ of Lemma A.1.5 below. (The inequality may be shown more easily by comparing the Taylor series of the two functions termwise.)

$$e^{\lambda S_n} = \prod_{i=1}^n e^{\lambda X_i}$$

Since the X_i are mutually independent so are the $e^{\lambda X_i}$; expectations multiply and

$$\mathbb{E} [e^{\lambda S_n}] = \prod_{i=1}^n \mathbb{E} [e^{\lambda X_i}] = \cosh^n(\lambda) < e^{\lambda^2 n/2}$$

We note that $S_n > a$ if and only if $e^{\lambda S_n} > e^{\lambda a}$ and apply Markov's Inequality so that

$$\Pr[S_n > a] = \Pr[e^{\lambda S_n} > e^{\lambda a}] < \mathbb{E} [e^{\lambda S_n}] / e^{\lambda a} \leq e^{\lambda^2 n/2 - \lambda a}.$$

We set $\lambda = a/n$ to optimize the inequality, $\Pr[S_n > a] < e^{-a^2/2n}$ as claimed.

By symmetry we immediately have the following.

Corollary A.1.2 Under the assumptions of Theorem A.1.1,

$$\Pr[|S_n| > a] < 2e^{-a^2/2n}.$$

The proof of Theorem A.1.1 illustrates the basic idea of the Chernoff bounds. We wish to bound $\Pr[X > a]$ for some random variable X . For any positive λ we bound

$$\Pr[X > a] = \Pr[e^{\lambda X} > e^{\lambda a}] \leq \mathbb{E} [e^{\lambda X}] e^{-\lambda a} \quad (\text{A.1})$$

The core idea of the Chernoff bounds is to select that λ that minimizes $\mathbb{E} [e^{\lambda X}] e^{-\lambda a}$. The art to the Chernoff bounds is to select a λ that is reasonably close to optimal and easy to work with, yielding upper bounds on $\Pr[X > a]$ that are, one hopes, good enough for our purposes. Bounds on $\Pr[X < a]$ are similar. For any positive λ we bound

$$\Pr[X < a] = \Pr[e^{-\lambda X} > e^{-\lambda a}] \leq \mathbb{E} [e^{-\lambda X}] e^{\lambda a}.$$

Chernoff bound arguments tend to be cleaner when $\mathbb{E}[X] = 0$. A simple translation, replacing X by $X - \mu$ where $\mu = \mathbb{E}[X]$, is often quite helpful.

It is instructive to examine the case when N is the standard normal distribution and a is positive. In this instance $\mathbb{E} [e^{\lambda N}] = e^{\lambda^2/2}$ and so

$$\Pr[N > a] = \Pr[e^{\lambda N} > e^{\lambda a}] \leq \mathbb{E} [e^{\lambda N}] e^{-\lambda a} = e^{\lambda^2/2 - \lambda a}.$$

Elementary calculus leads to the optimal choice $\lambda = a$ so that

$$\Pr[N > a] < e^{-a^2/2}$$

This compares well, as $a \rightarrow \infty$, with the actual asymptotics

$$\Pr[N > a] = \frac{1}{\sqrt{2\pi}} \int_a^\infty e^{-t^2/2} dt \sim \frac{1}{\sqrt{2\pi}a} e^{-a^2/2}$$

Results with N being normal with mean μ and variance σ^2 are similarly good. This explains, to some extent, the efficacy of the Chernoff bounds. When a random variable X is "roughly" normal the Chernoff bounds on $\Pr[X > a]$ should be quite close to the actual values for a large. In practice, however, precise calculations of $E[e^{\lambda X}]$ can be difficult or impossible to achieve and there can be considerable art in finding approximations for $E[e^{\lambda X}]$ that will allow for good bounds on $\Pr[X > a]$.

Many of our remaining results will deal with distributions X of the following prescribed type.

Assumptions A.1.3

- $p_1, \dots, p_n \in [0, 1]$,
- $X_1, \dots, X_n$ are mutually independent with
 $\Pr[X_i = 1 - p_i] = p_i$ and $\Pr[X_i = -p_i] = 1 - p_i$,
- $p = (p_1 + \dots + p_n)/n$ and $X = X_1 + \dots + X_n$.

Remark. Clearly $E[X] = E[X_i] = 0$. When all $p_i = 1/2$, X has distribution $S_n/2$. When all $p_i = p$, X has distribution $B(n, p) - np$, where $B(n, p)$ is the usual binomial distribution.

Theorem A.1.4 Under Assumptions A.1.3 and with $a > 0$,

$$\Pr[X > a] < e^{-2a^2/n}$$

Lemma A.1.5 For all reals α, β with $|\alpha| \leq 1$,

$$\cosh(\beta) + \alpha \sinh(\beta) \leq e^{\beta^2/2 + \alpha\beta}$$

Proof. This is immediate if $\alpha = \pm 1$ or $|\beta| \geq 100$. If the lemma were false the function $f(\alpha, \beta) = \cosh(\beta) + \alpha \sinh(\beta) - e^{\beta^2/2 + \alpha\beta}$ would assume a positive global maximum in the interior of the rectangle $R = \{(\alpha, \beta) : |\alpha| \leq 1, |\beta| \leq 100\}$.

Setting partial derivatives equal to zero we find

$$\begin{aligned} \sinh(\beta) + \alpha \cosh(\beta) &= (\alpha + \beta)e^{\beta^2/2 + \alpha\beta}, \\ \sinh(\beta) &= \beta e^{\beta^2/2 + \alpha\beta}, \end{aligned}$$

and thus $\tanh(\beta) = \beta$, which implies $\beta = 0$. But $f(\alpha, 0) = 0$ for all α , a contradiction.

Lemma A.1.6 For all $\theta \in [0, 1]$ and all $\lambda, \theta e^{\lambda(1-\theta)} + (1-\theta)e^{-\lambda\theta} \leq e^{\lambda^2/8}$.

Proof. Setting $\theta = \frac{1}{2}(1 + \alpha)$ and $\lambda = 2\beta$, this lemma reduces to Lemma A.1.5.

Proof [Theorem A.1.4]. Let, for the moment, $\lambda > 0$ be arbitrary.

$$E[e^{\lambda X_i}] = p_i e^{\lambda(1-p_i)} + (1-p_i)e^{-\lambda p_i} \leq e^{\lambda^2/8}$$

by Lemma A.1.6. Then

$$E[e^{\lambda X}] = \prod_{i=1}^n E[e^{\lambda X_i}] \leq e^{\lambda^2 n/8}$$

Applying Markov's Inequality,

$$\Pr[X > a] = \Pr[e^{\lambda X} > e^{\lambda a}] < E[e^{\lambda X}] / e^{\lambda a} \leq e^{\lambda^2 n/8 - \lambda a}.$$

We set $\lambda = 4a/n$ to optimize the inequality: $\Pr[X > a] < e^{-2a^2/n}$, as claimed.

Again by symmetry we immediately have the following.

Corollary A.1.7 Under Assumptions A.1.3 and with $a > 0$,

$$\Pr[|X| > a] < 2e^{-2a^2/n}$$

Under Assumptions A.1.3 with λ arbitrary,

$$\begin{aligned} \mathbb{E}[e^{\lambda X}] &= \prod_{i=1}^n \mathbb{E}[e^{\lambda X_i}] = \prod_{i=1}^n (p_i e^{\lambda(1-p_i)} + (1-p_i) e^{-\lambda p_i}) \\ &= e^{-\lambda p n} \prod_{i=1}^n (p_i e^{\lambda} + (1-p_i)) \end{aligned}$$

With λ fixed, the function

$$f(x) = \ln(xe^{\lambda} + 1 - x) = \ln(Bx + 1) \text{ with } B = e^{\lambda} - 1$$

is concave and hence $\sum_{i=1}^n f(p_i) \leq n f(p)$ (Jensen's Inequality). Exponentiating both sides,

$$\prod_{i=1}^n (p_i e^{\lambda} + (1-p_i)) \leq (p e^{\lambda} + (1-p))^n,$$

so that we have the following.

Lemma A.1.8 Under the Assumptions A.1.3,

$$\mathbb{E}[e^{\lambda X}] < e^{-\lambda p n} (p e^{\lambda} + (1-p))^n.$$

Applying this lemma with inequality (A.1) yields the following.

Theorem A.1.9 Under the Assumptions A.1.3 and with $a > 0$,

$$\Pr[X > a] < e^{-\lambda p n} (p e^{\lambda} + (1-p))^n e^{-\lambda a}$$

for all $\lambda > 0$.

Remark. For given p, n, a , an optimal assignment of λ in Theorem A.1.9 is found by elementary calculus to be

$$\lambda = \ln \left[\left(\frac{1-p}{p} \right) \left(\frac{a + np}{n - (a + np)} \right) \right].$$

This value is oftentimes too cumbersome to be useful. We employ suboptimal λ to achieve more convenient results.

Setting $\lambda = \ln(1 + a/pn)$ and using the fact that $(1 + u/n)^n \leq e^u$, Theorem A.1.9 implies the following.

$$\text{Corollary A.1.10 } \Pr[X > a] < e^{a - pn \ln(1 + a/pn) - a \ln(1 + a/pn)}.$$

To simplify further, apply the inequality $\ln(1 + u) \geq u - u^2/2$, valid for all $u \geq 0$, to Corollary A. 1.10 with $u = a/pn$. This gives the following.

$$\text{Theorem A.1.11 } \Pr[X > a] < e^{-a^2/2pn + a^3/2(pn)^2}.$$

When all $p_i = p$, X has variance $np(1-p)$. With $p = o(1)$ and $a = o(pn)$ this bound reflects the approximation of X by a normal distribution with variance $\sim np$. The bound of Theorem A.1.11 hits a minimum at $a = 2pn/3$. For $a > 2pn/3$ we have the simple bound

$$\Pr[X > a] \leq \Pr[X > 2pn/3] < e^{-2pn/27}.$$

This is improved by the following.

Theorem A.1.12 For $\beta > 1$,

$$\Pr[X > (\beta - 1)pn] < [e^{\beta-1} \beta^{-\beta}]^{pn}$$

Proof. Direct "plug in" to Corollary A.1.10.

$X + pn$ may be interpreted as the number of successes in n independent trials when the probability of success in the i th trial is p_i .

Theorem A.1.13 Under Assumptions A.1.3 and with $a > 0$,

$$\Pr[X < -a] < e^{-a^2/2pn}$$

Note that one cannot simply employ "symmetry" as then the roles of p and $1 - p$ are interchanged.

Proof. Let $\lambda > 0$ be, for the moment, arbitrary. Then by the argument preceding Lemma A.1.8,

$$\mathbb{E}[e^{-\lambda X}] \leq e^{\lambda pn} (pe^{-\lambda} + (1 - p))^n$$

Thus

$$\Pr[X < -a] = \Pr[e^{-\lambda X} > e^{\lambda a}] < e^{\lambda pn} (pe^{-\lambda} + (1 - p))^n e^{-\lambda a},$$

analogous to Theorem A.1.9. We employ the inequality $1 + u \leq e^u$, valid for all u , so that

$$pe^{-\lambda} + (1 - p) = 1 + (e^{-\lambda} - 1)p < e^{p(e^{-\lambda} - 1)}$$

and

$$\Pr[X < -a] \leq e^{\lambda pn + np(e^{-\lambda} - 1) - \lambda a} = e^{np(e^{-\lambda} - 1 + \lambda) - \lambda a}$$

We employ the inequality

$$e^{-\lambda} \leq 1 - \lambda + \lambda^2/2$$

valid for all $\lambda > 0$. (Note: The analogous inequality $e^\lambda \leq 1 + \lambda + \lambda^2/2$ is not valid for $\lambda > 0$ and so this method, when applied to $\Pr[X > a]$, requires an "error" term as the one found in Theorem A.1.11.) Now

$$\Pr[X < -a] \leq e^{np\lambda^2/2 - \lambda a}$$

Set $\lambda = a/np$ to optimize the inequality: $\Pr[X < -a] < e^{-a^2/2pn}$, as claimed.

For clarity the following result is often useful.

Corollary A.1.14 Let Y be the sum of mutually independent indicator random variables, $\mu = \mathbb{E}[Y]$. For all $\epsilon > 0$,

$$\Pr[|Y - \mu| > \epsilon\mu] < 2e^{-c_\epsilon\mu},$$

where $c_\epsilon > 0$ depends only on ϵ .

Proof. Apply Theorems A.1.12 and A.1.13 with $Y = X + pn$ and

$$c_\epsilon = \min \left\{ -\ln(e^\epsilon(1 + \epsilon)^{-(1+\epsilon)}), \epsilon^2/2 \right\}.$$

The asymmetry between $\Pr[X < a]$ and $\Pr[X > a]$ given by Theorems A.1.12 and A.1.13 is real. The estimation of X by a normal distribution with zero mean and variance np is roughly valid for estimating $\Pr[X < a]$ for any a and for estimating $\Pr[X > a]$ while $a = o(np)$. But when a and np are comparable or when $a \gg np$ the Poisson behavior "takes over" and $\Pr[X > a]$ cannot be accurately estimated by using the normal distribution.

We conclude with several large deviation results involving distributions other than sums of indicator random variables.

Theorem A.1.15 Let P have Poisson distribution with mean μ . For $\epsilon > 0$

$$\begin{aligned}\Pr[P \leq \mu(1 - \epsilon)] &\leq e^{-\epsilon^2 \mu/2} \\ \Pr[P \geq \mu(1 + \epsilon)] &\leq [e^\epsilon(1 + \epsilon)^{-(1+\epsilon)}]^\mu\end{aligned}$$

Proof. For any s

$$\Pr[P = s] = \lim_{n \rightarrow \infty} \Pr\left[B\left(n, \frac{\mu}{n}\right) = s\right]$$

Apply Theorems A.1.12 and A.1.13.

Theorem A.1.16 Let $X_i, 1 \leq i \leq n$, be mutually independent with all $E[X_i] = 0$ and all $|X_i| \leq 1$. Set $S = X_1 + \cdots + X_n$. Then

$$\Pr[S > a] < e^{-a^2/2n}$$

Proof. Set, as in the proof of Theorem A.1.1, $\lambda = a/n$. Set

$$h(x) = \frac{e^\lambda + e^{-\lambda}}{2} + \frac{e^\lambda - e^{-\lambda}}{2}x$$

For $x \in [-1, 1]$, $e^{\lambda x} \leq h(x)$. [$y = h(x)$ is the chord through the points $x = \pm 1$ of the convex curve $y = e^{\lambda x}$.] Thus

$$E[e^{\lambda X_i}] \leq E[h(X_i)] = h(E[X_i]) = h(0) = \cosh \lambda.$$

The remainder of the proof follows as in Theorem A.1.1.

Theorem A.1.17 Suppose $E[X] = 0$ and no two values of X are ever more than one apart. Then for all $\lambda \geq 0$,

$$E[e^{\lambda X}] \leq e^{\lambda^2/8}.$$

Proof. Fix $b \in [-\frac{1}{2}, \frac{1}{2}]$ with $X \in [\frac{1}{2}(-1 + b), \frac{1}{2}(+1 + b)]$. Let $y = h(x)$ be the straight line intersecting the curve $y = e^{\lambda x}$ at the points $\frac{1}{2}(\pm 1 + b)$. As $e^{\lambda x}$ is a convex function, $e^{\lambda x} \leq h(x)$ for all $x \in [\frac{1}{2}(-1 + b), \frac{1}{2}(+1 + b)]$. Thus

$$E[e^{\lambda X}] \leq E[h(X)] = h(E[X]) = h(0).$$

We calculate $h(0) = e^{\lambda b/2}[\cosh(\lambda/2) - b \sinh(\lambda/2)]$, which is at most $e^{\lambda^2/8}$ by Lemma A.1.5.

Theorem A.1.18 Let $X_i, 1 \leq i \leq n$, be independent random variables with each $E[X_i] = 0$ and no two values of any X_i ever more than one apart. (We allow, however, values of different X_i, X_j to be further apart.) Set $S = X_1 + \cdots + X_n$. Then

$$\Pr[S > a] < e^{-2a^2/n}$$

Proof. $E[e^{\lambda S}] = \prod_{i=1}^n E[e^{\lambda X_i}] \leq e^{n\lambda^2/8}$ by Theorem A.1.17. Then for $\lambda \geq 0$,

$$\Pr[S > a] = \Pr[e^{\lambda S} \geq e^{\lambda a}] \leq \exp\left[\frac{n\lambda^2}{8} - \lambda a\right]$$

and we set $\lambda = 4a/n$.

We have been roughly guided by the notion that if X has mean zero and variance σ^2 then $\Pr[X \geq a\sigma]$ should go like $e^{-a^2/2}$. There are times when this idea is very wrong. Consider Assumptions A.1.3 with all $p_i = 1/n$ so that $X = P_n - 1$, where P_n has the binomial distribution $B(n, 1/n)$, which is asymptotically P , the Poisson distribution with mean one. Then $E[X] = 0$ and $\text{Var}[X] \sim 1$. For a fixed $\Pr[X = a] \rightarrow 1/e(a+1)!$, which is far bigger than $e^{-a^2/2}$. With

this cautionary preamble, we give a general situation for which the notion is asymptotically correct when a is not too large.

Theorem A.1.19 For every $C > 0$ and $\varepsilon > 0$ there exists $\delta > 0$ so that the following holds: Let $\{X_i\}_{i=1}^n$, n arbitrary, be independent random variables with $E[X_i] = 0$, $|X_i| \leq C$ and $\text{Var}[X_i] = \sigma_i^2$. Set $X = \sum_{i=1}^n X_i$ and $\sigma^2 = \sum_{i=1}^n \sigma_i^2$ so that $\text{Var}[X] = \sigma^2$. Then for $0 < a \leq \delta\sigma$,

$$\Pr[X > a\sigma] < e^{-\frac{1}{2}a^2(1-\varepsilon)}.$$

Proof. We set $\lambda = a/\sigma$ so that $0 \leq \lambda \leq \delta$. Then

$$E[e^{\lambda X_i}] = \sum_{k=0}^{\infty} E\left[\frac{\lambda^k}{k!} X_i^k\right] = 1 + \frac{\lambda^2}{2} \sigma_i^2 + \sum_{k=3}^{\infty} \frac{\lambda^k}{k!} E[X_i^k].$$

As $|X_i^k| \leq C^{k-2} X_i^2$ we bound

$$E[X_i^k] \leq E[|X_i^k|] \leq C^{k-2} E[X_i^2] = C^{k-2} \sigma_i^2$$

For $k \geq 3$ we bound $2/k! \leq 1/(k-2)!$ so that

$$E[e^{\lambda X_i}] \leq 1 + \frac{\lambda^2}{2} \sigma_i^2 \left[1 + \sum_{k=3}^{\infty} \frac{(C\lambda)^{k-2}}{(k-2)!} \right] = 1 + \frac{\lambda^2}{2} \sigma_i^2 e^{\lambda C}.$$

We choose δ to satisfy $e^{C\delta} \leq 1 + \varepsilon$. As $\lambda \leq \delta$,

$$E[e^{\lambda X_i}] \leq 1 + \frac{\lambda^2}{2} \sigma_i^2 (1 + \varepsilon) < \exp\left[\frac{\lambda^2}{2} \sigma_i^2 (1 + \varepsilon)\right].$$

This inequality has held for all X_i so

$$E[e^{\lambda X}] = \prod_{i=1}^n E[e^{\lambda X_i}] < \exp\left[\frac{\lambda^2}{2} \sigma^2 (1 + \varepsilon)\right]$$

and

$$\Pr[X > a\sigma] \leq E[e^{\lambda X}] e^{-\lambda a\sigma} < e^{-\frac{1}{2}a^2(1-\varepsilon)}$$

A. 2 LOWER BOUNDS

The Chernoff bounds of the previous section give upper bounds for $\Pr[X > a]$ by examining one value (albeit, the right one!) of the Laplace transform $E[e^{\lambda X}]$. Here we use three values of the Laplace transform to give lower bounds for $\Pr[X > a]$. We shall set

$$\begin{aligned} f(\lambda) &= E[e^{\lambda X}] \\ g_a(\lambda) &= f(\lambda) e^{-\lambda a} \end{aligned}$$

With this notation $\Pr[X > a] \leq g_a(\lambda)$ and the Chernoff bound is achieved by taking that λ minimizing $g_a(\lambda)$. For any positive u and ε ,

$$\begin{aligned} X \geq a + u &\Rightarrow \lambda X \leq (\lambda + \varepsilon)X - \varepsilon a - \varepsilon u, \\ X \leq a - u &\Rightarrow \lambda X \leq (\lambda - \varepsilon)X + \varepsilon a - \varepsilon u, \end{aligned}$$

so that

$$\begin{aligned} E[e^{\lambda X} \chi(X \geq a + u)] &\leq f(\lambda + \varepsilon) e^{-\varepsilon a} e^{-\varepsilon u} \\ E[e^{\lambda X} \chi(X \leq a - u)] &\leq f(\lambda - \varepsilon) e^{\varepsilon a} e^{-\varepsilon u} \end{aligned}$$

Subtracting these from $E[e^{\lambda X}]$ yields

$$E[e^{\lambda X} \chi(|X - a| < u)] \geq f(\lambda) - e^{-\varepsilon u} [f(\lambda + \varepsilon)e^{-\varepsilon a} + f(\lambda - \varepsilon)e^{\varepsilon a}]$$

When $|X - a| < u$, $e^{\lambda X} \leq e^{\lambda u} e^{\lambda a}$ so

$$\Pr[|X - a| < u] \geq e^{-\lambda u} e^{-\lambda a} E[e^{\lambda X} \chi(|X - a| < u)]$$

But $\Pr[X > a - u] \geq \Pr[|X - a| < u]$, giving our general result as follows.

Theorem A.2.1 For any $a, u, \lambda, \varepsilon$ with $u, \lambda, \varepsilon, \lambda - \varepsilon$ all positive,

$$\Pr[X > a - u] \geq e^{-\lambda u} [g_a(\lambda) - e^{-\varepsilon u} [g_a(\lambda + \varepsilon) + g_a(\lambda - \varepsilon)]] .$$

We note that this bound has used only three values of the Laplace transform: $f(\lambda), f(\lambda - \varepsilon), f(\lambda + \varepsilon)$.

It is instructive to examine the case when N is the standard normal distribution. We assume a is positive and are interested in the asymptotics as $a \rightarrow +\infty$. We set $\lambda = a$ so that $g_a(\lambda) = e^{-a^2/2}$. Now

$$g_a(\lambda \pm \varepsilon) = e^{(\lambda \pm \varepsilon)^2/2 - a(\lambda \pm \varepsilon)} = g_a(\lambda) e^{\varepsilon^2/2}$$

The cancellation of the linear (in ε) terms was not serendipity, but rather reflected the critical choice of λ to minimize $\ln(g_a(\lambda))$. Now

$$\Pr[N > a - u] \geq g_a(a) e^{-au} [1 - 2e^{-\varepsilon u} e^{\varepsilon^2/2}]$$

Suppose we take $\varepsilon = u = 2$. This gives

$$\Pr[N > a - 2] \geq e^{-a^2/2} e^{-2a} [1 - 2e^{-2}]$$

Rescaling: $\Pr[N > a] = \Omega(e^{-a^2/2} e^{-4a})$. In contrast we have the upper bound $\Pr[N > a] \leq e^{-a^2/2}$.

In many applications one does not have the precise values of the Laplace transform $f(\lambda)$. Suppose, however, that we have reasonably good estimates in both directions on $f(\lambda)$. Then Theorem A.2.1 will give a lower bound for $\Pr[X > a - u]$ by using a lower bound for $g_a(\lambda)$ and upper bounds for $g_a(\lambda \pm \varepsilon)$. Our goal will be less ambitious than the estimate achieved for the standard normal N . We shall be content to find the asymptotics of the logarithm of $\Pr[X > a]$. In the next result, the X_n may be imagined to be near the normal distribution. The interval for λ could easily be replaced by $[(1 - \gamma)a_n, (1 + \gamma)a_n]$ for any fixed positive γ .

Theorem A.2.2 Let X_n be a sequence of random variables and a_n a sequence of positive reals with $\lim_{n \rightarrow \infty} a_n = \infty$. Assume

$$E[e^{\lambda X_n}] = e^{\frac{1}{2}\lambda^2(1+o(1))}$$

uniformly for $\frac{1}{2}a_n \leq \lambda \leq \frac{3}{2}a_n$. Then

$$\ln \Pr[X_n > a_n] \sim -\frac{a_n^2}{2}$$

Remark. For $X_n = S_n n^{-1/2}$, $E[e^{\lambda X_n}] = \cosh^n(\lambda n^{-1/2})$. When $u \rightarrow 0$, $\ln \cosh(u) \sim \frac{1}{2}u^2$. The conditions of Theorem A.2.2 therefore hold when $a_n = o(\sqrt{n})$ and $a_n \rightarrow +\infty$. That is, $\ln \Pr[S_n > b_n] \sim -b_n^2/2n$ when $\sqrt{n} \ll b_n \ll n$.

Proof. The upper bound is the Chernoff bound with $\lambda = a_n$.

$$\Pr[X_n > a_n] \leq E[e^{\lambda X_n}] e^{-a_n \lambda} = e^{-\frac{1}{2}a_n^2(1+o(1))}$$

For the lower bound we first let $\delta \in (0, 0.01)$ be fixed. We set $\lambda = a = a_n(1 + \delta)$, $u = a_n\delta$, $\varepsilon = \lambda\delta/10$. Applying Theorem A.2.1

$$\Pr[X > a_n] \geq e^{-\lambda u} B$$

with

$$B = g_a(a) - e^{-\varepsilon u} [g_a(a + \varepsilon) + g_a(a - \varepsilon)]$$

But $\ln[g_a(a)] \sim -\frac{1}{2}a^2$ and, analogous to our result for the standard normal,

$$\ln[g_a(a \pm \varepsilon)] \sim \frac{a^2}{2} \left(1 \pm \frac{\delta}{10}\right)^2 - a^2 \left(1 \pm \frac{\delta}{10}\right) = \frac{a^2}{2} \left(-1 + \frac{\delta^2}{100}\right).$$

As $\varepsilon u = a^2\delta^2/10(1 + \delta)$ we have $e^{-\varepsilon u}g_a(a \pm \varepsilon) \ll g_a(a)$. Now B is dominated by its initial term and

$$\Pr[X > a_n] \geq e^{-\lambda u} g_a(a)(1 - o(1))$$

Taking logarithms:

$$\ln[\Pr[X > a_n]] \geq -a_n^2\delta(1 + \delta) - \frac{a_n^2}{2}(1 + \delta)^2(1 + o(1)) - o(1)$$

As this holds for any fixed $\delta \in (0, 0.01)$

$$\ln[\Pr[X > a_n]] \geq -\frac{a_n^2}{2}(1 + o(1))$$

We have seen that $\Pr[S_n > b_n]$ can be well approximated by $\Pr[\sqrt{n}N > b_n]$ as long as $\sqrt{n} \ll b_n \ll n$. For $b_n = \Theta(n)$ this approximation by the normal distribution is no longer valid. Still, we shall see that the Chernoff bounds continue to give the right asymptotic value for $\ln \Pr[S_n > b_n]$. We place this in a somewhat wider context. Ellis (1984) has given far more general results.

Theorem A.2.3 Let Z_n be a sequence of random variables. Let a be a fixed positive real. Set

$$F(\lambda) = \lim_{n \rightarrow \infty} \frac{1}{n} \ln \mathbf{E}[e^{\lambda Z_n}]$$

Suppose that there exists $\lambda > 0$ and an open interval I containing λ such that

1. $F(s)$ exists and has a first and second derivative for all $s \in I$.
2. $F'(\lambda) = a$.
3. F' is a strictly increasing function in I .
4. There is a K so that $|F''(s)| \leq K$ for all $s \in I$.

Then

$$\lim_{n \rightarrow \infty} \frac{1}{n} \ln \Pr[Z_n > an] = F(\lambda) - a\lambda$$

Remark. Let X be a random variable whose Laplace transform is well defined. Let Z_n denote the sum of n independent copies of X . Then $F(\lambda) = \ln \mathbf{E}[e^{\lambda X}]$. In particular, suppose $\Pr[X = 1] = \Pr[X = -1] = \frac{1}{2}$ so that $Z_n = S_n$. Then $F(\lambda) = \ln \cosh(\lambda)$. For any $a \in (0, 1)$

there is a positive λ for which $a = F'(\lambda) = \tanh(\lambda)$. The conditions of Theorem A.2.3 hold and give the asymptotics of $\ln(S_n > an)$.

Proof. The upper bound is the Chernoff bound as

$$\Pr[Z_n > an] \leq \mathbb{E}[e^{\lambda Z_n}] e^{-a\lambda n} = e^{n(F(\lambda) - a\lambda + o(1))}$$

For the lower bound we will apply Theorem A.2.1. First note that since F' is continuous and monotone over I it has a continuous inverse H defined over some interval J containing a . Note $H(a) = \lambda$. Let u be positive and sufficiently small so that $H(a + u) \pm u/k \in I$. As

$$\lim_{u \rightarrow 0} H(a + u) \pm \frac{u}{K} = H(a) = \lambda$$

all sufficiently small u satisfy this criterion.

Set $a^* = a + u$ and $\lambda^* = H(a^*)$ so that $F'(\lambda^*) = a^*$. We define

$$g_n(s) = \mathbb{E}[e^{sZ_n}] e^{-sa^*}$$

Theorem A.2.1 (noting that $an = a^*n - un$) states

$$\Pr[Z_n > an] \geq e^{-\lambda^* a^* n} [g_n(\lambda^*) - e^{-\varepsilon un} [g_n(\lambda^* + \varepsilon) + g_n(\lambda^* - \varepsilon)]]$$

We select $\varepsilon = u/K$. Our selection of u assures us that $\lambda^* \pm \varepsilon$ belong to I . We have

$$\lim_{n \rightarrow \infty} \frac{1}{n} \ln \left(\frac{e^{-\varepsilon un} g_n(\lambda^* + \varepsilon)}{g_n(\lambda^*)} \right) = -\varepsilon u + F(\lambda^* + \varepsilon) - F(\lambda^*) - \varepsilon a^*.$$

We have selected λ^* so that $F'(\lambda^*) = a^*$. Since $|F''(s)| \leq K$ in the interval I Taylor series bounds

$$|F(\lambda^* + \varepsilon) - F(\lambda^*) - \varepsilon a^*| \leq \frac{K}{2} \varepsilon^2.$$

Our choice of ε (chosen to minimize the quadratic though any sufficiently small ε would do) gives that

$$-\varepsilon u + F(\lambda^* + \varepsilon) - F(\lambda^*) - \varepsilon a^* \leq -\frac{u^2}{2K}.$$

Thus $e^{-\varepsilon n} g_n(\lambda^* + \varepsilon) / g_n(\lambda^*)$ drops exponentially quickly. We only use that for n sufficiently large the ratio is less than 0.25. The same argument shows that for n sufficiently large $e^{-\varepsilon n} g_n(\lambda^* - \varepsilon) / g_n(\lambda^*) < 0.25$. For such n we then have

$$\Pr[Z_n > an] \geq \frac{1}{2} e^{-\lambda^* a^* n} g_n(\lambda^*).$$

This lower bound is $\exp[n(F(\lambda^*) - \lambda^* a^* + o(1))]$. Now consider $F(\lambda^*) - \lambda^* a^*$ as a function of u . As $u \rightarrow 0$, $\lambda^* = H(a + u) \rightarrow H(a) = \lambda$. As F is continuous $F(\lambda^*) \rightarrow F(\lambda)$. Clearly $a^* = a + u \rightarrow a$ and therefore $\lambda^* a^* \rightarrow \lambda a$. Thus

$$F(\lambda^*) - \lambda^* a^* \rightarrow F(\lambda) - \lambda a$$

so

$$\Pr[Z_n > an] \geq e^{n(F(\lambda) - \lambda a + o(1))}$$

Remark. Let Z_n be a sequence of random variables with mean and variance μ_n and σ_n^2 , respectively. The analysis of $\Pr[Z_n > \mu_n + \lambda_n \sigma_n]$ frequently (S_n being the premier example) splits into three parts:

1. Small Deviations. $\lambda_n \rightarrow \lambda$, a positive constant. One hopes to prove asymptotic normality so that $\Pr[Z_n > \mu_n + \lambda_n \sigma_n] \rightarrow \Pr[N > \lambda]$. There is a huge literature on asymptotic normality but, for the most part, asymptotic normality is not covered in this work.
2. Large Deviations. $\lambda_n \rightarrow +\infty$ and $\lambda_n = o(\sigma_n)$. One hopes to show that Z_n is approximately normal in the sense that $\ln \Pr[Z_n > \mu_n + \lambda_n \sigma_n] \sim -\lambda_n^2/2$.
3. Very Large Deviations. $\lambda_n \rightarrow +\infty$ and $\lambda_n = \Omega(\sigma_n)$. Here the approximation of Z_n by the normal distribution generally fails but one hopes that the asymptotics of $\ln \Pr[Z_n > \mu_n + \lambda_n \sigma_n]$ may still be found by the methods we have given.

A. 3 EXERCISES

1. The Hajós number of a graph G is the maximum number k such that there are k vertices in G with a path between each pair so that all the $\binom{k}{2}$ paths are internally pairwise vertex disjoint (and no vertex is an internal vertex of a path and an endpoint of another). Is there a graph whose chromatic number exceeds twice its Hajós number?
2. For two subsets A and B of the set $\mathbb{Z}_m$ of integers modulo m and for $g \in \mathbb{Z}_m$, denote

$$s(A, B, g) = |\{(a, b) : a \in A, b \in B, a + b = g\}|.$$

For a partition of $\mathbb{Z}_m$ into two disjoint sets $\mathbb{Z}_m = A \cup B, A \cap B = \emptyset$ denote

$$c(A, B) = \max_{x \in \mathbb{Z}_m} |s(A, A, x) + s(B, B, x) - 2s(A, B, x)|.$$

Prove that for every odd m there is a partition of $\mathbb{Z}_m$ into two disjoint sets A and B such that $c(A, B) = O(\sqrt{m \log m})$.

3. For $a \in (0, 1)$ apply Theorem A.2.3 to find $\lim_n (1/n) \ln \Pr[S_n > an]$ explicitly. Express $\Pr[S_n > an]$ combinatorially as 2^{-n} times the sum of binomial coefficients. Use Stirling's formula to asymptotically evaluate this sum and show that you get the same result for $\lim_n (1/n) \ln \Pr[S_n > an]$.
4. More generally, for $p \in (0, 1)$ fixed, apply Theorem A.2.3 to find the asymptotics of $\ln \Pr[B(n, p) > an]$ for $p < a < 1$ and of $\ln \Pr[B(n, p) < an]$ for $0 < a < p$. Show that an application of Stirling's formula gives the same answer.
5. Let $\{X_i\}_{i=1}^n$ be independent random variables, each chosen uniformly from $\{+1, +2, -3\}$. Set $Y_n = \sum_{i=1}^n X_i$. Let $f(n)$ be the minimal value so that $\Pr[Y_n > f(n)] < 1/n$. Find the asymptotics of $f(n)$. Redo with $1/n$ replaced by n^{-50} . (Note that it doesn't change the answer much!)

The Probabilistic Lens: Triangle-free Graphs Have Large Independence Numbers

Let $\alpha(G)$ denote the independence number of a graph G . It is easy and well known that for every graph G on n vertices with maximum degree d , $\alpha(G) \geq n/(d+1)$. Ajtai, Komlós and Szemerédi (1980) showed that in case G is triangle-free, this can be improved by a logarithmic factor and in fact $\alpha(G) \geq (cn \log d)/d$, where c is an absolute positive constant. Shearer (1983) simplified the proof and improved the constant factor to $c = 1 + o(1)$. Here is a very short proof, without any attempt to optimize c , which is based on a different technique of Shearer (1995) and its modification in Alon (1996).

Proposition 1 Let $G = (V, E)$ be a triangle-free graph on n vertices with maximum degree at most $d \geq 1$. Then $\alpha(G) \geq (n \log d)/8d$, where the logarithm here and in what follows is in base 2.

Proof. If, say, $d < 16$ the result follows from the trivial bound $\alpha(G) \geq n/(d+1)$ and hence we may and will assume that $d \geq 16$. Let W be a random independent set of vertices in G , chosen uniformly among all independent sets in G . For each vertex $v \in V$ define a random variable $X_v = d|\{v\} \cap W| + |N(v) \cap W|$, where $N(v)$ denotes the set of all neighbors of v . We claim that the expectation of X_v satisfies $E[X_v] \geq \frac{1}{4} \log d$.

To prove this claim, let H denote the induced subgraph of G on $V - (N(v) \cup \{v\})$, fix an independent set S in H and let X denote the set of all non neighbors of S in the set $N(v)$, $|X| = x$. It suffices to show that the conditional expectation

$$E[X_v \mid W \cap V(H) = S] \geq \frac{\log d}{4} \quad (1)$$

for each possible S . Conditioning on the intersection $W \cap V(H) = S$ there are precisely $2^x + 1$ possibilities for W : one in which $W = S \cup \{v\}$ and 2^x in which $v \notin W$ and W is the union of S with a subset of X . It follows that the conditional expectation considered in (1) is precisely

$$\frac{d}{2^x + 1} + \frac{x2^{x-1}}{2^x + 1}$$

To check that the last quantity is at least $\frac{1}{4} \log d$ observe that the assumption that this is false implies that $x \geq 1$ and $2^x(\log d - 2x) > 4d - \log d$, showing that $\log d > 2x \geq 2$ and hence $4d - \log d < \sqrt{d}(\log d - 2)$, which is false for all $d \geq 16$. Therefore

$$E[X_v \mid W \cap V(H) = S] \geq \frac{\log d}{4}$$

establishing the claim.

By linearity of expectation we conclude that the expected value of the sum $\sum_{v \in V} X_v$ is at least $\frac{1}{4}n \log d$. On the other hand, this sum is clearly at most $2d|W|$, since each vertex $u \in W$ contributes d to the term X_u in this sum, and its degree in G , which is at most d , to the sum of all other terms X_v . It follows that the expected size of W is at least $(n \log d)/8d$, and hence there is an independent set of size at least this expectation, completing the proof.

The Ramsey number $R(3, k)$ is the minimum number r such that any graph with at least r vertices contains either a triangle or an independent set of size k . The asymptotic behavior of this function has been studied for over fifty years. It turns out that $R(3, k) = \Theta(k^2/\log k)$. The lower bound is a recent result of Kim(1995), based on a delicate probabilistic construction together with some thirty pages of computation. There is no known explicit construction of such a graph, and the largest known explicit triangle-free graph with no independent set of size k , described in Alon (1994), has only $\Theta(k^{3/2})$ vertices. The tight upper bound for $R(3, k)$, proved in Ajtai et al. (1980), is a very easy consequence of the above proposition.

Theorem 2 [Ajtai et al. (1980)] There exists an absolute constant b such that $R(3, k) \leq bk^2/\log k$ for every $k > 1$.

Proof. Let $G = (V, E)$ be a triangle-free graph on $8k^2/\log k$ vertices. If G has a vertex of degree at least k then its neighborhood contains an independent set of size k . Otherwise, by Proposition 1 above, G contains an independent set of size at least

$$\frac{8k^2}{\log k} \frac{\log k}{8k} = k$$

Therefore, in any case $\alpha(G) \geq k$, completing the proof.

18.9 Appendix B Paul Erdős

Working with Paul Erdős was like taking a walk in the hills. Every time when I thought that we had achieved our goal and deserved a rest, Paul pointed to the top of another hill and off we would go.

- Fan Chung

B. 1 PAPERS

Paul Erdős was the most prolific mathematician of the twentieth century, with over 1500 written papers and more than 490 collaborators. This highly subjective list gives only some of the papers that created and shaped the subject matter of this volume. MR and Zbl. refer to reviews in Math Reviews and Zentralblatt, respectively. Chapter and section reference are to pertinent areas of this volume.

- A combinatorial problem in geometry, *Compositio Math* 2 (1935), 463-470 (with George Szekeres); Zbl. 12, 270.
Written when Erdős was still a teenager this gem contains a rediscovery of Ramsey's Theorem and the Monotone Subsequence Theorem. Many authors have written that this paper played a key role in moving Erdős toward a more combinatorial view of mathematics.
- Some remarks on the theory of graphs, *Bull. Am. Math. Soc.* 53 (1947), 292-294, MR 8# 479d; Zbl 32, 192.
The three-page paper that "started" the probabilistic method, giving an exponential lower bound on the Ramsey number $R(k, k)$. Section 1.1.
- The Gaussian law of errors in the theory of additive number theoretic functions, *Am. J. Math.* 62 (1940), 738-742 (with Mark Kac); MR 2# 42c; Zbl. 24, 102. Showing that the number of prime factors of x chosen uniformly from 1 to n has an asymptotically normal distribution. A connection between probability and number theory that was extraordinary for its time. Section 4.2.
- Problems and results in additive number theory, *Colloque sur la Théorie des Nombres*, Bruxelles, 1955, 127-137, George Thone, Liège; Masson and Cie, Paris, 1956; MR 18# 18a; Zbl. 73, 31.
Using random subsets to prove the existence of a set of integers such that every n is represented $n = x + y$ at least once but at most $c \ln n$ times. Resolving a problem Sidon posed to Erdős in the 1930s. This problem continued to fascinate Erdős: see, e.g., Erdős and Tetali (1990). Section 8.6.
- On a combinatorial problem, *Nordisk Mat. Tidsskr.* 11 (1963), 220-223; MR 28# 4068; Zbl. 122, 248.
On a combinatorial problem II, *Acta Math. Acad. Sci. Hung.* 15 (1964), 445-447; MR 29# 4700; Zbl. 201, 337.
Property B . Probabilistic proofs that any $m < 2^{n-1}n$ -sets can be two-colored with no set monochromatic yet there exist $cn^2 2^n n$ -sets that cannot be so colored. Section 1.3.
- On the evolution of random graphs, *Magyar. Tud. Akad. Mat. Kutató Int. Közl.* 5 (1960), 17-61 (with Alfred Rényi); MR 23# A2338; Zbl. 103, 163. Rarely in mathematics can an entire subject be traced to one paper. For random graphs this is the paper. Chapter 10.

- Graph theory and probability, Can. J. Math. 11 (1959), 34-38; MR 21# 876; Zbl. 84, 396.

Proving by probabilistic methods the existence of graphs with arbitrarily high girth and chromatic number. This paper convinced many of the power of the methodology, as the problem had received much attention but no construction had been found. The Probabilistic Lens: High Girth and High Chromatic Number, following Chapter 3.

- Graph theory and probability II, Can. J. Math. 13 (1961), 346-352; MR 22# 10925; Zbl. 97, 391.

Showing the existence of a triangle-free graph on n vertices with no independent set of size $cn^{1/2} \ln n$ vertices, and hence that the Ramsey number $R(3, k) = \Omega(k^2 \ln^{-2} k)$. A technical tour de force that uses probabilistic methods in a very subtle way, particularly considering the early date of publication.

- On circuits and subgraphs of chromatic graphs, Mathematika 9 (1962), 170-175; MR 25 # 3035; Zbl. 109, 165.

Destroying the notion that chromatic number is necessarily a local property, Erdős proves the existence of a graph on n vertices that cannot be k -colored but for which every εn vertices can be three-colored. The Probabilistic Lens: Local Coloring, following Chapter 8.

- On a combinatorial game, J. Combin. Theory, Ser. A 14 (1973), 298-301 (with John Selfridge); MR 48# 5655; Zbl. 293, 05004.

Players alternate turns selecting vertices and the second player tries to stop the first from getting a winning set. The weight function method used was basically probabilistic and was an early use of derandomization. Section 16.1.

B. 2 CONJECTURES

Conjectures were always an essential part of the mathematical life of Paul Erdős. Here are some of our favorites.

- Do sets of integers of positive density necessarily contain arithmetic progressions of arbitrary length? In finite form, is there for all k and all $\varepsilon > 0$, an n_0 so that if $n \geq n_0$ and S is a subset of the first n integers of size at least εn then S necessarily contains an arithmetic progression of length k ? This conjecture was first made by Paul Erdős and Paul Turán in the 1930s. It was solved (positively) by Szemerédi in the 1970s. Let $F(k, \varepsilon)$ denote the minimal n_0 that suffices above. The growth rate of F remains an intriguing question with very recent results due to Gowers.
- Call distinct S, T, U a Δ -system if $S \cap T = S \cap U = T \cap U$. Let $F(n)$ be the minimal m such that given any mn -sets some three form a Δ -system. Erdős and Rado showed that $F(n)$ exists and gave the upper bound $F(n) \leq 2^n n!$. Erdős conjectured that $F(n) < C^n$ for some constant C .
- What are the asymptotics of the Ramsey function $R(k, k)$? In particular, what is the value c (if it exists) of $\lim_k R(k, k)^{1/k}$? The classic 1947 paper of Erdős gives $c \geq \sqrt{2}$ and $c \leq 4$ follows from the proof of Ramsey's Theorem but a half-century has seen no further improvements in c , though there have been some results on lower order terms.
- Write $r_S(n)$ for the number of solutions to the equation $n = x + y$ with $x, y \in S$. Does there exist a set S of positive integers such that $r_S(n) > 0$ for all but finitely many n yet $r_S(n)$ is bounded by some constant K ? The 1955 paper of Erdős referenced above gives S with $r_S(n) = \Theta(\ln n)$.

- Let $m(n)$, as defined in Section 1.3, denote the minimal size of a family of n sets that cannot be two-colored without forming a monochromatic set. What are the asymptotics of $m(n)$? In 1963 and 1964 Erdős found the bounds $\Omega(2^n) \leq m(n) = O(2^{n/2})$ and the lower bound of Radhakrishnan and Srinivasan, shown in Section 3.5, is now $\Omega(2^{n/2})$.
- Given $2^{n-2} + 1$ points in the plane, no three on a line, must some n of them form a convex set? This conjecture dates back to the 1935 paper of Erdős and Szekeres referenced above.
- Let $m(n, k, l)$ denote the size of the largest family of k -element subsets of an n -set such that no l -set is contained in more than one of them. Simple counting gives $m(n, k, l) \leq \binom{n}{l} / \binom{k}{l}$. Erdős and Hanani conjectured in 1963 that for fixed $l < k$ this bound is asymptotically correct; that is, the ratio of $m(n, k, l)$ to $\binom{n}{l} / \binom{k}{l}$ goes to one as $n \rightarrow \infty$. Erdős had a remarkable ability to select problems that were very difficult but not impossible. This conjecture was settled affirmatively by Vojtech Rödl in 1985, as discussed in Section 4.7. The asymptotics of the difference $\binom{n}{l} / \binom{k}{l} - m(n, k, l)$ remains open.

B. 3 ON ERDŐS

There have been numerous books and papers written about the life and mathematics of Paul Erdős. Three deserving particular mention are:

- The Mathematics of Paul Erdős (Ron Graham and Jarik Nešetřil, eds.), Springer-Verlag, Berlin, 1996 (Vols. I and II).
- Combinatorics, Paul Erdős Is Eighty (D. Miklós, V. T. Sós, T. Szönyi, eds.), Bolyai Soc. Math. Studies, Vol. I (1990) and Vol. II (1993).
- Erdős on Graphs - His Legacy of Unsolved Problems, Fan Chung and Ron Graham, A.K. Peters, 1998.

Of the many papers by mathematicians we note the following:

- László Babai, In and out of Hungary: Paul Erdős, his friends, and times. In Combinatorics, Paul Erdős Is Eighty (listed above), Vol. II, 7-93.
- Béla Bollobás, Paul Erdős - Life and work, in The Mathematics of Paul Erdős (listed above), Vol. II, 1-42.
- A. Hajnal, Paul Erdős' Set theory, in The Mathematics of Paul Erdős (listed above), Vol. II, 352-393.
- János Pach, Two places at once: a remembrance of Paul Erdős, Math Intelligencer, Vol. 19 (1997), no. 2, 38-48.

Two popular biographies of Erdős have appeared:

- The Man Who Loved Only Numbers, Paul Hoffman, Hyperion, New York, 1998.
- My Brain Is Open - The Mathematical Journeys of Paul Erdős, Bruce Schechter, Simon & Schuster, New York, 1998.

Finally, George Csicsery has made a documentary film, *N Is a Number, A Portrait of Paul Erdős*, available from the publishers A. K. Peters, which allows one to see and hear Erdős in lecture and among friends, proving and conjecturing.

B. 4 UNCLE PAUL

Paul Erdős died in September 1996 at the age of 83. His theorems and conjectures permeate this volume. This tribute,¹ given by Joel Spencer at the National Meeting of the American Mathematical Society in January 1997, attempts to convey some of the special spirit that we and countless others took from this extraordinary man.

Paul Erdős was a searcher, a searcher for mathematical truth.

Paul's place in the mathematical pantheon will be a matter of strong debate for in that rarefied atmosphere he had a unique style. The late Ernst Straus said it best, in a commemoration of Erdős' seventieth birthday.

In our century, in which mathematics is so strongly dominated by "theory constructors" he has remained the prince of problem solvers and the absolute monarch of problem posers. One of my friends - a great mathematician in his own right - complained to me that "Erdős only gives us corollaries of the great metatheorems which remain unformulated in the back of his mind." I think there is much truth to that observation but I don't agree that it would have been either feasible or desirable for Erdős to stop producing corollaries and concentrate on the formulation of his metatheorems. In many ways Paul Erdős is the Euler of our times. Just as the "special" problems that Euler solved pointed the way to analytic and algebraic number theory, topology, combinatorics, function spaces, etc.; so the methods and results of Erdős' work already let us see the outline of great new disciplines, such as combinatorial and probabilistic number theory, combinatorial geometry, probabilistic and transfinite combinatorics and graph theory, as well as many more yet to arise from his ideas.

Straus, who worked as an assistant to Albert Einstein, noted that Einstein chose physics over mathematics because he feared that one would waste one's powers in pursuing the many beautiful and attractive questions of mathematics without finding the central questions. Straus goes on,

Erdős has consistently and successfully violated every one of Einstein's prescriptions. He has succumbed to the seduction of every beautiful problem he has encountered - and a great many have succumbed to him. This just proves to me that in the search for truth there is room for Don Juans like Erdős and Sir Galahads like Einstein.

I believe, and I'm certainly most prejudiced on this score, that Paul's legacy will be strongest in Discrete Math. Paul's interest in this area dates back to a marvellous paper with George Szekeres in 1935 but it was after World War II that it really flourished. The rise of the Discrete over the past half century has, I feel, two main causes. The first was The Computer, how wonderful that this physical object has led to such intriguing mathematical questions. The second, with due respect to the many others, was the constant attention of Paul Erdős with his famous admonition "Prove and Conjecture!" Ramsey Theory, Extremal Graph Theory, Random Graphs, how many turrets in our mathematical castle were built one brick at a time with Paul's theorems and, equally important, his frequent and always penetrating conjectures.

My own research specialty, The Probabilistic Method, could surely be called The Erdős Method. It was begun in 1947 with a three page paper in the Bulletin of the American Math Society. Paul proved the existence of a graph having certain Ramsey property without actually constructing it. In modern language he showed that an appropriately defined random graph would have the property with positive probability and hence there must exist a graph with the property. For the next twenty years Paul was a "voice in the wilderness," his colleagues admired his amazing results but adaption of the methodology was slow. But Paul persevered -

⁰¹ Reprinted with permission from the Bulletin of the American Mathematical Society.

he was always driven by his personal sense of mathematical aesthetics in which he had supreme confidence - and today the method is widely used in both Discrete Math and in Theoretical Computer Science.

There is no dispute over Paul's contribution to the spirit of mathematics. Paul Erdős was the most inspirational man I have ever met. I began working with Paul in the late 1960s, a tumultuous time when "do your own thing" was the admonition that resonated so powerfully. But while others spoke of it, this was Paul's *modus operandi*. He had no job; he worked constantly. He had no home; the world was his home. Possessions were a nuisance, money a bore. He lived on a web of trust, travelling ceaselessly from Center to Center, spreading his mathematical pollen.

What drew so many of us into his circle? What explains the joy we have in speaking of this gentle man? Why do we love to tell Erdős stories? I've thought a great deal about this and I think it comes down to a matter of belief, or faith. We mathematicians know the beauties of our subject and we hold a belief in its transcendent quality. God created the integers, the rest is the work of Man. Mathematical truth is immutable, it lies outside physical reality. When we show, for example, that two n th powers never add to an n th power for $n \geq 3$ we have discovered a Truth. This is our belief, this is our core motivating force. Yet our attempts to describe this belief to our nonmathematical friends are akin to describing the Almighty to an atheist. Paul embodied this belief in mathematical truth. His enormous talents and energies were given entirely to the Temple of Mathematics. He harbored no doubts about the importance, the absoluteness, of his quest. To see his faith was to be given faith. The religious world might better have understood Paul's special personal qualities. We knew him as Uncle Paul.

I do hope that one cornerstone of Paul's, if you will, theology will long survive. I refer to The Book. The Book consists of all the theorems of mathematics. For each theorem there is in The Book just one proof. It is the most aesthetic proof, the most insightful proof, what Paul called The Book Proof. And when one of Paul's myriad conjectures was resolved in an "ugly" way Paul would be very happy in congratulating the prover but would add, "Now, let's look for The Book Proof." This platonic ideal spoke strongly to those of us in his circle. The mathematics was there, we had only to discover it.

The intensity and the selflessness of the search for truth were described by the writer Jorge Luis Borges in his story "The Library of Babel." The narrator is a worker in this library which contains on its infinite shelves all wisdom. He wanders its infinite corridors in search of what Paul Erdős might have called The Book. He cries out,

To me, it does not seem unlikely that on some shelf of the universe there lies a total book. I pray the unknown gods that some man - even if only one man, and though it have been thousands of years ago! - may have examined and read it. If honor and wisdom and happiness are not for me, let them be for others. May heaven exist though my place be in hell. Let me be outraged and annihilated but may Thy enormous Library be justified, for one instant, in one being.

In the summer of 1985 I drove Paul to what many of us fondly remember as Yellow Pig Camp - a mathematics camp for talented high school students at Hampshire College. It was a beautiful day - the students loved Uncle Paul and Paul enjoyed nothing more than the company of eager young minds. In my introduction to his lecture I discussed The Book but I made the mistake of describing it as being "held by God." Paul began his lecture with a gentle correction that I shall never forget. "You don't have to believe in God," he said, "but you should believe in The Book."

Part VI

Appendix

A Introduction and Overview

Приведем соображения о подходе к теории вероятностей.

A.1 Extra Motivation

(?? write later)

Востребованность в аналитических работах (?)

(про то, что на собеседованиях нужно, а также аналитики её по идее используют)

Множество приложений

(? пока хз, каких, потом пропишу)

Множество приложений в программировании

(? пока хз, каких, потом пропишу)

Удивительные факты

(позже пропишу)

Результаты теории вероятности

Обсудим, какие способности и знания дает нам теория вероятности.
(позже пропишу)

Мотивация к разделам теории вероятностей

(потом пропишу, пока не так вижу их, да и тут разделов не столько много, сколько в других записях)

A.2 The Mindset of Professionals

A.2.1 Attitude to Probability Theory

об использовании теории вероятностей в жизни

(?? пока не знаю, насколько на самом деле теория вероятностей используется в жизненных задачах, ибо её знаю пока плохо)

О важности алгебры и теории меры

(??? я хз, насколько она нужна, пока изучаю, потом пойму и пропишу. мб нужна, мб и нет.)

Способы догадаться до главных идей теории вероятностей

незаменимая часть нормального понимания теории вероятностей.
хз

Наиболее прикладные темы теории вероятностей (?)

обсудим, какие темы используются более всего.

О взгляде, что теория вероятностей большая и глубокая

(действительно, много книг про неё написано, так что я придерживаюсь такого взгляда. но потом обсудим.)

О взгляде, что теория вероятностей проста и поверхностна

(так некоторые думают, обсудим этот подход. пока хз, мне и в ней хватает работы)

A.2.2 Features of Effective Learning

Необходимые темы для изучения теории вероятностей

Необходимо хорошее знакомство с математическим анализом

(потому что очень много и теорем из него и в целом предмет берется ровно так же, как и матан. потом распишу подробнее, пока еще сам не освоил кучу лем и кучу переходов.)

Необходимо хорошее знакомство с теорией меры

Тоже без минимальных заготовок на неё отлетишь. Однако если нужно будет, её по ходу дела доделывать правильнее, чем готовить изначально.

способы изучения теории вероятностей

важно собрать основы теории, потому что они постоянно нужны

и это не так много, мб даже страниц 50 только - самые основы.
но они не простые.
хотя и не сложные.
сесть просто нужно, и сделать их.
а дальше всё и заживет.

как можно скорее на задачи выходим

в основах можно долго тормозить, поэтому важно скорее выйти на задачи.
а с задачами - есть устойчивость и база, там уже дело техники - выйти на приложения.

A.3 Acknowledgements

Currently, no one except me has worked on the sections of this note (with the exception of sections taken from books).

A.4 Literature

Литературы аж навалом, так что важно понимать основную и не урываться в неё вечно.

A.4.1 Main Literature

Basic Educational Literature

Самарова С.С. Учебные пособие для студентов МФТИ по теории вероятностей.
Прекрасные пособия, для начала даже не думаю, что еще что-то нужно. Гуглятся.

В. А. Колемаев, В. Н. Калинина и др. Теория Вероятностей В Примерах И Задачах
Крутая книга, где компактно всё написано,

[1] Зубков А. М. Конспект лекций по теории вероятностей

Небольшой сборник лекций, где достаточно теории, чтобы с неё начать. Однако правильнее вообще забыть на это, потому что куда полезнее начать задачи решать.

[4] Горяйнов

добавка в помощь для Зубкова

С.Е. Демин, Е.Л. Демина Теория вероятностей в трех частях. Часть 1. Случайные события

Хорошая книга с многими хорошими задачами разобрана, посмотрю потом.

М.Е. Жуковский Теория вероятностей. Конспект лекций (записал Александр Марков, 30.01.2017)

60 страниц компактного конспекта, но похоже, что там больше бесполезная теория, чем полезные методы. Гуглится, чуть смотрел.

Books With Many Solved Problems

Чистяков Сборник задач

Типичный задачник, можно месяц о нем думать.

Кондратенко А. Е. задачи с зачетов по теории вероятностей

13 страниц задач-решений, полезный файл.

Математическая помощь

[5] Гусев мера

справочник по теории меры. не уверен, насколько она нужна.

A.4.2 Extra Literature

Другая обучающая

<https://www.maths.ed.ac.uk/~jmf/Teaching/mi4a.html> José Figuerola-O’Farrill 21
Lectures on Probability and Random Processes

Nice great lectures, nice summary of typical topics.

Особо профессиональная и подробная литература

[3] Гнеденко Б. В. курс теории вероятностей
(!!!!) вроде хороший вмеру подробный курс. Уже завершаю по Зубкову и Горяйнову, так что его скоро и начну и он очень сильно повлияет на мою структуру!!! Пока еще пара шагов до него остается.

Феллер Введение в теорию вероятностей

Амосов сказал, что хорошая большая книга.

Статьи при интересные модели теории вероятностей

[6] Семенов А. Г. О случайном блуждании «пьяной компании»
помню, что это интересная статья о континуальном интеграле и случайных блужданиях, соберу эти теории - прочитаю её, ибо интересно очень.

По отдельным конструкциям

(пока их не смотрел, но помню, что супер интересная, чуть что посмотрю)

[2] Алон Н. Спенсер Дж. Вероятностный метод
топ книга, но сперва азы нормально прописать нужно!! профессиональные тут всякие теоремы и подходы. Мне не до этого пока.

Про квантовую теорию вероятностей

(просто знаю, что такое есть, курс Амосова ни о чем был, так что забить можно на копание в этом. чуть что - здесь укажу эти книги.)

По основам случайных процессов

Жуковский МФТИ лекции по случайным процессам
помню, что такая есть, потом добавлю тоже мб ей, пока что не актуально.
Лекции по случайным процессам Под редакцией А. В. Гасникова
нашел в интернете, хотелось бы тоже взять их, но уже после многих других книг, что выше я писал, начну их.

По основам математической статистики

Боровков математическая статистика
помню такую книгу, отдельная большая история. мб когда-то добавлю какие-то основы из неё в раздел про основы мат статистики, но пока не до неё.

A.4.3 Literature About Applications

Про жизненные применения теории вероятностей

Существует множество популярных или упрощенно прикладных книг по теорверу, многие из которых обсудим ниже, они же вписаны в многие части (будут).

(Каждое приложение - отдельная запись, здесь основную литературу по ним приведем.)

Тарасов Закономерности окружающего мира. Случайность, необходимость, вероятность

наверное, такая о жизни книга. как основы сделаю - дополню ей много баланса. Очень круто она в помощь для прикладного понимания теорвера.

Мандельброт Фракталы случай и финансы

очень наверное крутые связки там раскрыты. прямо очень интересно, и как раз куча приложений будет начато рассматриваться. так что очень крутая книга, дойти бы!

По приложениям в программировании и анализе данных

тоже много книг в таком направлении, так что обсудим и их тут.

A.4.4 History in a Nutshell

A.5 Puzzles for Different Situations

Обсудим в порядке интересности задачки и вопросы

A.5.1 Puzzles for Interesting Discussion

A.5.2 Puzzles About Everyday Life

(???? what fun questions can arise about this subject in everyday life?)

A.5.3 Selected Fun Typical Problems

(all this should also be in the problem-solution section!)

B Mathematics for Probability Theory

Обсудим все математические конструкции, применяющиеся в теории вероятностей.
(Многое потом добавлю, пока не успел. по актуальности соберу)

B.1 Another Mathematics for Probability Theory

(странно, что до сих пор ничего про нее не написано)

B.1.1 Constructions of the Theory of Measure

(по потребности буду их добавлять)

B.1.2 Convergence Theorems

При доказательстве различных теорем теории вероятностей часто используются два утверждения, фактически относящиеся к математическому анализу: теоремы о монотонной и мажорируемой сходимости. (в отдельный раздел потом перенесу)

Теорема о монотонной сходимости

Если последовательность $\{\xi_n\}$ случайных величин такова, что $0 \leq \xi_n \uparrow \xi$ при $n \uparrow \infty$, то

$$\lim_{n \rightarrow \infty} M\xi_n = M\xi$$

Эта теорема отличается от аналогичного утверждения при обосновании корректности определения математического ожидания тем, что случайные величины ξ_n не предполагаются простыми.

Доказательство. В силу свойства монотонности математического ожидания из условия $0 \leq \xi_n \leq \xi$ следует, что $0 \leq M\xi_n \leq M\xi$ и

$$\lim_{n \rightarrow \infty} M\xi_n \leq M\xi$$

Введем монотонные последовательности простых случайных величин $\{\xi_{nk}\}$ так, что $0 \leq \xi_{nk} \uparrow \xi_n$ при $k \uparrow \infty$. Случайные величины

$$\eta_k = \max_{1 \leq n \leq k} \xi_{nk} \leq \max_{1 \leq n \leq k} \xi_n = \xi_k$$

тоже являются простыми, причем последовательность η_k не убывает:

$$0 \leq \eta_k = \max \{\xi_{1k}, \xi_{2k}, \dots, \xi_{kk}\} \leq \max \{\xi_{1k+1}, \xi_{2k+1}, \dots, \xi_{k+1k+1}\} = \eta_{k+1}$$

Значит, для всех $\omega \in \Omega$ существует $\lim_{k \rightarrow \infty} \eta_k = \eta$. Так как $\eta_k \leq \xi_k$ при всех k и η_k - простые случайные величины, то

$$\lim_{k \rightarrow \infty} \eta_k = M\eta \leq \lim_{k \rightarrow \infty} M\xi_k$$

С другой стороны, $\xi_{nk} \leq \eta_k \leq \eta$; переходя к пределу по $k \rightarrow \infty$, находим: $\xi_n \leq \eta$ при всех n , откуда $\xi \leq \eta$ и $M\xi \leq M\eta$. Таким образом,

$$M\xi \leq M\eta \leq \lim_{k \rightarrow \infty} M\xi_k \leq M\xi$$

и Теорема доказана.

Без условия монотонного возрастания монотонной сходимости может не быть (?????)

Без условия монотонного возрастания утверждение теоремы может быть неправильным.

пример монотонно убывающей последовательности неотрицательных случайных величин с бесконечными математическими ожиданиями, сходящейся к случайной величине, тождественно равной 0.

(ХЗ, сказали построить, но я тупой)

Следствия теоремы о монотонной сходимости

Если случайные величины ξ_n неотрицательны, то

$$M \sum_{n \geq 1} \xi_n = \sum_{n \geq 1} M\xi_n$$

Для доказательства достаточно рассмотреть монотонно не убывающую последовательность случайных величин $\eta_k = \sum_{n=1}^k \xi_n$ и применить теорему о монотонной сходимости.

Следствие 2. Если M η конечно и последовательность событий $A_n \downarrow \emptyset$ при $n \uparrow \infty$, то

$$\lim_{n \rightarrow \infty} M\eta I \{A_n\} = 0$$

Доказательство. По условию $M|\eta| < \infty$. Представим $|\eta|$ в виде $|\eta| = \eta_n + \eta'_n$, где $\eta_n = |\eta| I \{A_n\}$, $\eta'_n = |\eta| I \{\overline{A_n}\}$. Тогда

$$M|\eta| = M\eta_n + M\eta'_n$$

Так как $\overline{A_n} \uparrow \Omega$, то $0 \leq \eta'_n \uparrow |\eta|$ и по теореме о монотонной сходимости

$$M\eta'_n \uparrow M|\eta|, \text{ значит } M\eta_n \rightarrow 0 \text{ при } n \rightarrow \infty$$

Но тогда $|M\eta I \{A_n\}| \leq M|\eta I \{A_n\}| = M\eta_n \rightarrow 0$.

Теорема Лебега о мажорируемой сходимости

(?? зачем она вообще в мат ожидании??)

Если $\lim_{n \rightarrow \infty} \xi_n(\omega) = \xi(\omega)$ и $|\xi_n(\omega)| \leq \eta$ при всех $\omega \in \Omega$, причем $M\eta < \infty$, то

$$\lim_{n \rightarrow \infty} M\xi_n = M\xi$$

Доказательство.

Выберем произвольно $\varepsilon > 0$ и рассмотрим последовательность событий

$$A_n = \left\{ \omega \in \Omega : \sup_{m > n} |\xi_m(\omega) - \xi(\omega)| < \varepsilon \right\}, \quad n = 1, 2, \dots$$

Из условия теоремы следует, что $\overline{A_n} \downarrow \emptyset$ при $n \uparrow \infty$ для любого $\varepsilon > 0$. Тогда, как в следствии 2,

$$\xi_n = \xi_n I\{A_n\} + \xi_n I\{\overline{A_n}\}$$

И

$$\begin{aligned} \xi I\{A_n\} - \varepsilon &\leq \xi_n I\{A_n\} \leq \xi I\{A_n\} + \varepsilon \\ -\eta I\{\overline{A_n}\} &\leq \xi_n I\{\overline{A_n}\} \leq \eta I\{A_n\} \end{aligned}$$

Складывая почленно эти неравенства с учетом равенства $\xi I\{A_n\} = \xi - \xi I\{\overline{A_n}\}$ получаем

$$\xi - \xi I\{\overline{A_n}\} - \varepsilon - \eta I\{\overline{A_n}\} \leq \xi_n \leq \xi - \xi I\{\overline{A_n}\} + \varepsilon + \eta I\{\overline{A_n}\}$$

далее вычислим математическое ожидание от всех частей неравенства:

$$M\xi - \varepsilon - 2M\eta I\{\overline{A_n}\} \leq \xi_n \leq M\xi + \varepsilon + 2M\eta I\{\overline{A_n}\}$$

Переходя здесь к пределу по $n \rightarrow \infty$ и учитывая следствие 2, получим:

$$M\xi - \varepsilon \leq \liminf_{n \rightarrow \infty} \xi_n \leq \limsup_{n \rightarrow \infty} \xi_n \leq M\xi + \varepsilon$$

Ввиду того, что $\varepsilon > 0$ можно выбирать произвольно малым, теорема доказана.

B.1.3 Calculation of Integrals

(?? с этим могут быть проблемы или особенности)

B.2 Elements of Discrete Mathematics**B.2.1 Math.-phys.**

остановимся на леммах теории множеств, которые часто нужны в задачах про вероятность. Укажем также, где они нужны.

B.2.2 Combinatorics

запишем подробно разные методы комбинаторики, которые нам нужны для задач на теорию вероятностей.

размещения это...

сочетания это..

типа там для каждого набора из k элементов с учетом порядка можно получить $k!$ разных наборов, меняя элементы местами. !! кстати, тут уже интересный момент, сколько перестановок? их $A_n^n = n!$. тут-то и пригождаются наши рассуждения.

круто, теперь с возвращением с учетом порядка: n^k . тоже

(место где рассуждаем про возвращение и без учета порядка) честно - пока пофиг, потом добыю, пока просто понимаю, что это есть.

B.3 Programming for Probability Theory (!!???)

(тоже часто нужно какие-то посчитать вещи, напишу тут эти методы потом.)

B.4 Math

B.4.1 A. 1 Sets

A set is a Many that allows itself to be thought of as a One.

- Georg Cantor

A set is a collection of objects. The objects can be anything: numbers, people, cats, courses, even other sets! The language of sets allows us to talk precisely about events. If S is a set, then the notation $x \in S$ indicates that x is an element or member of the set S (and $x \notin S$ indicates that x is not in S). We can think of the set as a club, with precisely defined criteria for membership. For example:

1. $\{1, 3, 5, 7, \dots\}$ is the set of all odd numbers;
2. $\mathbb{R}$ is the set of all real numbers;
3. $\{\text{Worf, Jack, Tobey}\}$ is the set of Joe's cats;
4. $[3, 7]$ is the closed interval consisting of all real numbers between 3 and 7;
5. $\{HH, HT, TH, TT\}$ is the set of all possible outcomes if a coin is flipped twice (where, for example, HT means the first flip lands Heads and the second lands Tails).

To describe a set (when it's tedious or impossible to list out its elements), we can give a rule that says whether each possible object is or isn't in the set. For example, $\{(x, y) \in \mathbb{R}^2 : x^2 + y^2 \leq 1\}$ is the disk of radius 1 in the plane $\mathbb{R}^2$, centered at the origin. In this expression, the ":" is read as "such that".

A.1.1 The Empty set

The smallest set, which is both subtle and important, is the empty set, which is the set that has no elements whatsoever. It is denoted by $\emptyset$ or by $\{\}$. Make sure not to confuse $\emptyset$ with $\{\emptyset\}$. The former has no elements, while the latter has one element. If we visualize the empty set as an empty paper bag, then we can visualize $\{\emptyset\}$ as a paper bag inside of a paper bag.

A.1.2 Subsets

If A and B are sets, then we say A is a subset of B (and write $A \subseteq B$) if every element of A is also an element of B . For example, the set of all integers is a subset of the set of all real numbers. It is always true that $\emptyset$ and A itself are subsets of A ; these are the extreme cases for subsets. A general strategy for showing that $A \subseteq B$ is to let x be an arbitrary element of A , and then show that x must also be an element of B . A general strategy for showing that $A = B$ for two sets A and B is to show that each is a subset of the other.

A.1.3 Unions, Intersections, and Complements

The union of two sets A and B , written as $A \cup B$, is the set of all objects that are in A or B (or both). The intersection of A and B , written as $A \cap B$, is the set of all objects that are in both A and B . We say that A and B are disjoint if $A \cap B = \emptyset$. For n sets $A_1, \dots, A_n$, the union $A_1 \cup A_2 \cup \dots \cup A_n$ is the set of all objects that are in at least one of the A_j 's, while the intersection $A_1 \cap A_2 \cap \dots \cap A_n$ is the set of all objects that are in all of the A_j 's.

In many applications, all the sets we're working with are subsets of some set S (in probability, this may be the set of all possible outcomes of some experiment). When S is clear from the context, we define the complement of a set A to be the set of all objects in S that are not in A ; this is denoted by A^c .

Unions, intersections, and complements can be visualized easily using Venn diagrams, such as the one shown below. The union is the entire shaded region, while the intersection is the football-shaped region of points that are in both A and B . The complement of A is all points in the rectangle that are outside of A .

FIGURE A. 1

A Venn diagram. Note that the area of the region $A \cup B$ is the area of A plus the area of B , minus the area of $A \cap B$ (this is a basic form of the inclusion-exclusion principle).

De Morgan's laws give an elegant, useful duality between unions and intersections:

$$\begin{aligned}(A_1 \cup A_2 \cup \dots \cup A_n)^c &= A_1^c \cap A_2^c \cap \dots \cap A_n^c \\ (A_1 \cap A_2 \cap \dots \cap A_n)^c &= A_1^c \cup A_2^c \cup \dots \cup A_n^c\end{aligned}$$

It is much more important to understand De Morgan's laws than to memorize them! The first law says that not being in at least one of the A_j is the same thing as not being in A_1 , nor being in A_2 , nor being in A_3 , etc.

For example, let A_j be the set of people who like the j th Star Wars prequel, for $j \in \{1, 2, 3\}$. Then $(A_1 \cup A_2 \cup A_3)^c$ is the set of people for whom it is not the case that they like at least one of the prequels, but that is the same as $A_1^c \cap A_2^c \cap A_3^c$, the set of people who don't like The Phantom Menace, don't like Attack of the Clones, and don't like Revenge of the Sith.

The second law says that not being in all of the A_j is the same thing as being outside at least one of the A_j . For example, let the A_j be defined as in the previous paragraph. If it is not the case that you like all of the Star Wars prequels (making you a member of the set $(A_1 \cap A_2 \cap A_3)^c$), then there must be at least one prequel that you don't like (making you a member of the set $A_1^c \cup A_2^c \cup A_3^c$), and vice versa.

Proving the following facts about sets (not just drawing Venn diagrams, though they are very helpful for building intuition) is good practice:

1. $A \cap B$ and $A \cap B^c$ are disjoint, with $(A \cap B) \cup (A \cap B^c) = A$.
2. $A \cap B = A$ if and only if $A \subseteq B$.

3. $A \subseteq B$ if and only if $B^c \subseteq A^c$.

A.1.4 Partitions

A collection of subsets $A_1, \dots, A_n$ of a set S is a partition of S if $A_1 \cup \dots \cup A_n = S$ and $A_i \cap A_j = \emptyset$ for all $i \neq j$. In words, a partition of a set is a collection of disjoint subsets whose union is the entire set. For example, the set of even numbers $\{0, 2, 4, \dots\}$ and the set of odd numbers $\{1, 3, 5, \dots\}$ form a partition of the set of nonnegative integers.

A.1.5 Cardinality

A set may be finite or infinite. If A is a finite set, we write $|A|$ for the number of elements in A , which is called its size or cardinality. For example, $|\{2, 4, 6, 8, 10\}| = 5$ since there are 5 elements in this set. A very useful fact is that A and B are finite sets, then

$$|A \cup B| = |A| + |B| - |A \cap B|.$$

This is a form of the inclusion-exclusion theorem from Chapter 1. It says that to count how many elements are in the union of A and B , we can add the separate counts for each, and then adjust for the fact that we have double-counted the elements (if any) that are in both A and B .

Two sets A and B are said to have the same size or same cardinality if they can be put into one-to-one correspondence, i.e., if each element of A can be paired up with exactly one element of B , with no unpaired elements in either set. We say that A is smaller than B if there is not a one-to-one correspondence between A and B , but there is a one-to-one correspondence between A and some subset of B .

For example, suppose that we want to count the number of people in a movie theater with 100 seats. Assume that no one in the theater is standing, and no seat has more than one person in it. The obvious thing to do is to go around counting people one by one (though it's surprisingly easy to miss someone or accidentally count someone twice). But if every seat is occupied, then a much easier method is to note that there must be 100 people, since there are 100 seats and there is a one-to-one correspondence between people and seats. If some seats are empty, then there must be fewer than 100 people there.

This idea of looking at one-to-one correspondences makes sense both for finite and for infinite sets. Consider the perfect squares $1^2, 2^2, 3^2, \dots$. Galileo pointed out the paradoxical result that on the one hand it seems like there are fewer perfect squares than positive integers (since every perfect square is a positive integer, but lots of positive integers aren't perfect squares), but on the other hand it seems like these two sets have the same size since they can be put into one-to-one correspondence: pair 1^2 with 1, pair 2^2 with 2, pair 3^2 with 3, etc.

The resolution of Galileo's paradox is to realize that intuitions about finite sets don't necessarily carry over to infinite sets. By definition, the set of all perfect squares and the set of all positive integers do have the same size. Another famous example of this is Hilbert's hotel. For any hotel in the real world the number of rooms is finite. If every room is occupied, there is no way to accommodate more guests, other than by cramming more people into already occupied rooms.

Now consider an imaginary hotel with an infinite sequence of rooms, numbered $1, 2, 3, \dots$. Assume that all the rooms are occupied, and that a weary traveler arrives, looking for a room. Can the hotel give the traveler a room, without leaving any of the current guests without a room? Yes, one way is to have the guest in room n move to room $n + 1$, for all $n = 1, 2, 3, \dots$. This frees up room 1, so the traveler can stay there.

What if infinitely many travelers arrive at the same time, such that their cardinality is the same as that of the positive integers (so we can label the travelers as traveler 1, traveler 2, ...) ?

The hotel could fit them in one by one by repeating the above procedure over and over again, but it would take forever (infinitely many moves) to accommodate everyone, and it would be bad for business to make the current guests keep moving over and over again. Can the room assignments be updated just once

so that everyone has a room? Yes, one way is to have the guest in room n move to room $2n$ for all $n = 1, 2, 3, \dots$, and then have traveler n move into room $2n - 1$. In this way, the current guests occupy all the even-numbered rooms, and the new guests occupy all the odd-numbered rooms.

An infinite set is called countably infinite if it has the same cardinality as the set of all positive integers. A set is called countable if it is finite or countably infinite, and uncountable otherwise. The mathematician Cantor showed that not all infinite sets are the same size. In particular, the set of all real numbers is uncountable, as is any interval in the real line of positive length.

A.1.6 Cartesian Product

The Cartesian product of two sets A and B is the set

$$A \times B = \{(a, b) : a \in A, b \in B\}.$$

For example, $[0, 1] \times [0, 1]$ is the square $\{(x, y) : x, y \in [0, 1]\}$, and $\mathbb{R} \times \mathbb{R} = \mathbb{R}^2$ is two-dimensional Euclidean space.

B.4.2 A. 2 Functions

Let A and B be sets. A function from A to B is a deterministic rule that, given an element of A as input, provides an element of B as an output. That is, a function from A to B is a machine that takes an x in A and "maps" it to some y in B . Different x 's can map to the same y , but each x only maps to one y . Here A is called the domain and B is called the target. The notation $f : A \rightarrow B$ says that f is a function mapping A into B . The range of f is $\{y \in B : f(x) = y \text{ for some } x \in A\}$.

It is important to distinguish between f (the function) and $f(x)$ (the value of the function when evaluated at x). That is, f is a rule, while $f(x)$ is a number for each number x . The function g given by $g(x) = e^{-x^2/2}$ is exactly the same as the function g given by $g(t) = e^{-t^2/2}$; what matters is the rule, not the name we use for the input. For this example, the rule is that x gets mapped to $e^{-x^2/2}$; this rule is also denoted by $x \mapsto e^{-x^2/2}$.

A function f from the real line to the real line is continuous if $f(x) \rightarrow f(a)$ as $x \rightarrow a$, for any value of a . It is called right-continuous if this is true when approaching from the right, i.e., $f(x) \rightarrow f(a)$ as $x \rightarrow a$ while ranging over values with $x > a$.

The set A may not be a set of numbers. In probability, it is extremely common and useful to consider functions whose domains are the set of all possible outcomes of some experiment. It may be difficult to write down a formula for the function, but the function is still valid as long as it's defined unambiguously.

A.2.1 One-to-one Functions

Let f be a function from A to B . Then f is a one-to-one function if $f(x) \neq f(y)$ whenever $x \neq y$. That is, any two distinct inputs in A get mapped to two distinct outputs in B ; for each y in B , there can be at most one x in A that maps to it.

Let f be a one-to-one function from A to B , and let C be the range of f , i.e.,

$$C = \{b \in B : f(a) = b \text{ for some } a \in A\}.$$

Then there is an inverse function $f^{-1} : C \rightarrow A$, defined by letting $f^{-1}(y)$ be the unique element $x \in A$ such that $f(x) = y$. A function that has an inverse is called an invertible function.

For example, let $f(x) = x^2$ for all real x . This is not a one-to-one function since, for example, $f(3) = f(-3)$. But now assume instead that the domain of f is chosen to be $[0, \infty)$, so we are defining f as a function from $[0, \infty)$ to $[0, \infty)$. Then f is one-to-one, and its inverse function is given by $f^{-1}(y) = \sqrt{y}$ for all $y \in [0, \infty)$.

The pigeonhole principle says that if A and B are finite sets with $|A| > |B|$, then there does not exist a one-to-one function from A to B . In other words, if k objects are placed into n boxes, where $k > n$, then there must be at least one box that contains more than one object.

For example, in the birthday problem from Chapter 1 (assuming there are 365 days in a year), with 366 or more people there is guaranteed to be at least one birthday match. There is no one-to-one function assigning a birthday to each of the people, when there are more people than there are days in a year.

A.2.2 Increasing and Decreasing Functions

Let $f : A \rightarrow \mathbb{R}$, where A is a set of real numbers. Then f is an increasing function if $x \leq y$ implies $f(x) \leq f(y)$ (for all $x, y \in A$). Note that this definition allows there to be regions where f is flat, e.g., the constant function that is equal to 42 everywhere is an increasing function, and any CDF (see Section 3.6) is an increasing function. We say that f is strictly increasing if $x < y$ implies $f(x) < f(y)$. For example, $f : \mathbb{R} \rightarrow \mathbb{R}$ with $f(x) = x^3$ is a strictly increasing function.

Similarly, f is a decreasing function if $x \leq y$ implies $f(x) \geq f(y)$, and is a strictly decreasing function if $x < y$ implies $f(x) > f(y)$. For example, $f : (0, \infty) \rightarrow (0, \infty)$ with $f(x) = 1/x$ is a strictly decreasing function.

A monotone function is a function that is either increasing or decreasing. A strictly monotone function is a function that is either strictly increasing or strictly decreasing. Note that any strictly monotone function is one-to-one.

A.2.3 Even and odd Functions

Let f be a function from $\mathbb{R}$ to $\mathbb{R}$. We say f is an even function if $f(x) = f(-x)$ for all x , and we say f is an odd function if $-f(x) = f(-x)$ for all x . If neither of these conditions is satisfied, then f is neither even nor odd. Figure A. 2 shows the graphs of two even functions and two odd functions.

FIGURE A. 2

Even and odd functions. The graphs on the left are even functions: $f(x) = x^2$ on the top and $f(x) = e^{-x^2/2}$ on the bottom. The graphs on the right are odd functions: $f(x) = x^3$ on the top and $f(x) = xe^{-x^2/2}$ on the bottom.

Even and odd functions have nice symmetry properties. The graph of an even function remains the same if you reflect it about the vertical axis, and the graph of an odd function remains the same if you rotate it 180 degrees around the origin.

Even functions have the property that for any a ,

$$\int_{-a}^a f(x)dx = 2 \int_0^a f(x)dx,$$

assuming the integral exists. This is because the area under the function from $-a$ to 0 is equal to the area under the function from 0 to a . Odd functions have the property that for any a ,

$$\int_{-a}^a f(x)dx = 0,$$

again assuming the integral exists. This is because the area under the function from $-a$ to 0 cancels the area under the function from 0 to a .

A.2.4 Convex and Concave Functions

A function g whose domain is an interval I is convex if

$$g(px_1 + (1-p)x_2) \leq pg(x_1) + (1-p)g(x_2)$$

for all $x_1, x_2 \in I$ and $p \in (0, 1)$. Geometrically, this says that if we draw a line segment connecting two points on the graph of g , then the line segment lies above the graph of g . If the derivative g' exists, then an equivalent definition is that every tangent line to the graph of g lies below the graph. If g'' exists, then an equivalent definition is that $g''(x) \geq 0$ for all $x \in I$. An example is shown in Figure A.3. A simple example is $g(x) = x^2$, whose second derivative is

$$g''(x) = 2 > 0.$$

FIGURE A. 3 Graph of a convex function g . We have $g''(x) \geq 0$. Any line segment connecting two points on the curve lies above the curve. Any tangent line lies below the curve.

A function g is concave if $-g$ is convex. If g'' exists, then g is concave if and only if $g''(x) \leq 0$ for all x in the domain. For example, $g(x) = \log(x)$ defines a concave function on $(0, \infty)$ since $g''(x) = -1/x^2 < 0$ for all $x \in (0, \infty)$.

A.2.5 Exponential and Logarithmic Functions

An exponential function is a function of the form $f(x) = a^x$ for some number $a > 0$. If $a > 1$, the function is increasing, and if $0 < a < 1$, the function is decreasing. The most common exponential function we'll work with is $f(x) = e^x$, and a very useful limit result to know is that

$$\left(1 + \frac{x}{n}\right)^n \rightarrow e^x$$

as $n \rightarrow \infty$, for any real number x . This has an interpretation in terms of a bank paying compound interest on a deposit: as compounding occurs more and more times per year, the growth rate approaches exponential growth.

Here are some properties of exponential functions:

1. $a^x a^y = a^{x+y}$.
2. $a^x b^x = (ab)^x$.
3. $(a^x)^y = a^{xy}$.

The inverse of an exponential function is a logarithmic function: for positive y , $\log_a y$ is defined to be the number x such that $a^x = y$. Throughout this book, when we write $\log y$ without explicitly specifying the base, we are referring to the natural logarithm (base e).

Here are some properties of logarithms:

1. $\log_a x + \log_a y = \log_a xy$.
2. $\log_a x^n = n \log_a x$.
3. $\log_a x = \frac{\log x}{\log a}$.

A.2.6 Floor Function and Ceiling Function

The floor function is defined by letting $\lfloor x \rfloor$ be the greatest integer less than or equal to x . That is, it says to round down to an integer. For example, $\lfloor 3.14 \rfloor = 3$, $\lfloor -1.3 \rfloor = -2$, and $\lfloor 5 \rfloor = 5$. (Some books denote the floor function by $[x]$ but this is bad notation since it does not suggest a corresponding notation for the ceiling function, and since square brackets are also used for other purposes.)

The ceiling function is defined by letting $\lceil x \rceil$ be the smallest integer greater than or equal to x . For example, $\lceil 3.14 \rceil = 4$, $\lceil -1.3 \rceil = -1$, and $\lceil 5 \rceil = 5$.

A.2.7 Factorial Function and Gamma Function

The factorial function takes a positive integer n and returns the product of the integers from 1 to n , denoted $n!$ and read " n factorial":

$$n! = n(n-1)(n-2) \cdots 1$$

Also, we define $0! = 1$. This convention makes sense since if we think of $n!$ as the number of ways in which n people can line up, there is 1 way for $n = 0$ (this just means there is no one there, so the line is empty). It is also very helpful since, for example, we can then say that $n!/(n-1)! = n$ for all positive integers n without running into trouble when $n = 1$.

The factorial function grows extremely quickly as n grows. A famous, useful approximation for factorials is Stirling's formula,

$$n! \approx \sqrt{2\pi n} \left(\frac{n}{e}\right)^n$$

The ratio of the two sides converges to 1 as $n \rightarrow \infty$. For example, direct calculation gives $52! \approx 8.066 \times 10^{67}$, while Stirling's formula says $52! \approx 8.053 \times 10^{67}$.

The gamma function Γ generalizes the factorial function to positive real numbers; it is defined by

$$\Gamma(a) = \int_0^\infty x^a e^{-x} \frac{dx}{x}, \quad a > 0$$

and has the property that

$$\Gamma(n) = (n-1)!$$

for all positive integers n . Also, $\Gamma(1/2) = \sqrt{\pi}$.

An important property of the gamma function, which generalizes the fact that $n! = n \cdot (n-1)!$, is that

$$\Gamma(a+1) = a\Gamma(a)$$

for all $a > 0$. See Chapter 8 for more about the gamma function.

B.4.3 A. 3 Matrices

Neo: What is the Matrix?

Trinity: The answer is out there, Neo, and it's looking for you, and it will find you if you want it to.

- The Matrix (film from 1999)

A matrix is a rectangular array of numbers, such as $\begin{pmatrix} 3 & 1/e \\ 2\pi & 1 \end{pmatrix}$ or $\begin{pmatrix} 1 & 1 & 0 \\ 1 & 2 & 3 \end{pmatrix}$. We say that the dimensions of a matrix are m by n (also written $m \times n$) if it has m rows and n columns (so the former example is 2 by 2, while the latter is 2 by 3). The matrix is called square if $m = n$. If $m = 1$, we have a row vector; if $n = 1$, we have a column vector. We write $A = (a_{ij})$ to indicate that the row i , column j entry of A is a_{ij} .

A.3.1 Matrix Addition and Multiplication

To add two matrices A and B with the same dimensions, just add the corresponding entries, e.g.,

$$\begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \end{pmatrix} + \begin{pmatrix} 1 & 0 & 0 \\ 1 & 1 & 0 \end{pmatrix} = \begin{pmatrix} 2 & 1 & 0 \\ 2 & 2 & 1 \end{pmatrix}.$$

When we multiply an $m \times n$ matrix A by an $n \times r$ matrix B , we obtain an $m \times r$ matrix AB . The product AB is undefined if the number of columns of A does not equal the number of rows of B .

The row i , column j entry of AB is $\sum_{k=1}^n a_{ik}b_{kj}$, where a_{ij} and b_{ij} are the row i , column j entries of A and B , respectively. For example, here is how to multiply a 2×3 matrix by a 3×1 vector:

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix} \begin{pmatrix} 7 \\ 8 \\ 9 \end{pmatrix} = \begin{pmatrix} 1 \cdot 7 + 2 \cdot 8 + 3 \cdot 9 \\ 4 \cdot 7 + 5 \cdot 8 + 6 \cdot 9 \end{pmatrix} = \begin{pmatrix} 50 \\ 122 \end{pmatrix}$$

Note that AB may not equal BA , even if both are defined. To multiply a matrix A by a scalar, just multiply each entry by that scalar.

The transpose of a matrix A is the matrix whose row i , column j entry is the row j , column i entry of A . It is denoted by A' and read as " A transpose". The rows of A are the columns of A' , and the columns of A are the rows of A' . A square matrix A is symmetric if $A' = A$. A useful property of transposes is that if A and B are matrices such that the product AB is defined, then $(AB)' = B'A'$.

The determinant of a 2×2 matrix is defined by

$$\begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc$$

Determinants can also be defined for $n \times n$ matrices, in a recursive manner not reviewed here.

A.3.2 Eigenvalues and Eigenvectors

An eigenvalue of an $n \times n$ matrix A is a number λ such that

$$A\mathbf{v} = \lambda\mathbf{v}$$

for some $n \times 1$ column vector $\mathbf{v}$, where the elements of $\mathbf{v}$ are not all zero. The vector $\mathbf{v}$ is called an eigenvector of A , or a right eigenvector. (Similarly, a left eigenvector of A is a row vector $\mathbf{w}$ satisfying $\mathbf{w}A = \lambda\mathbf{w}$ for some λ .) This definition says that when A and $\mathbf{v}$ are multiplied, $\mathbf{v}$ just gets stretched by the constant λ .

Some matrices have no real eigenvalues, but the Perron-Frobenius theorem tells us that in a special case that is of particular interest to us in Chapter 11, eigenvalues exist and have nice properties. Let A be a square matrix whose entries are nonnegative and whose rows sum to 1

. Further assume that for all i and j , there exists $k \geq 1$ such that the row i , column j entry of A^k is positive. Then the Perron-Frobenius theorem says that 1 is an eigenvalue of A , which is in fact the largest eigenvalue of A , and there is a corresponding eigenvector whose entries are all positive.

B.4.4 A. 4 Difference Equations

A difference equation describes a sequence of numbers recursively in terms of earlier terms in the sequence. For example, $a_0, a_1, \dots$ is a Fibonacci sequence if

$$a_i = a_{i-1} + a_{i-2}$$

for all $i \geq 2$. There are infinitely many Fibonacci sequences, but such a sequence is uniquely determined after a_0 and a_1 are specified (these are called the initial conditions or boundary conditions). For example, $a_0 = 0, a_1 = 1$ yields the Fibonacci sequence 0, 1, 1, 2, 3, 5, 8, 13, ...

Difference equations often arise in probability, especially when applying LOTP. In this section, we will show how to solve difference equations of the form

$$p_i = p \cdot p_{i+1} + q \cdot p_{i-1}$$

where $p \neq 0$ and $q = 1 - p$. (This equation comes up in the gambler's ruin problem.) The first step is to guess a solution of the form $p_i = x^i$. Plugging this into the above, we have

$$x^i = p \cdot x^{i+1} + q \cdot x^{i-1}$$

which reduces to $px^2 - x + q = 0$. This is called the characteristic equation, and the solution to the difference equation depends on whether the characteristic equation has one or two distinct roots. If there are two distinct roots r_1 and r_2 , then the solution is of the form

$$p_i = ar_1^i + br_2^i$$

for some constants a and b . If there is only one distinct root r , then the solution is of the form

$$p_i = ar^i + bir^i$$

In our case, the characteristic equation has roots 1 and q/p , since

$$\frac{1 \pm \sqrt{1 - 4p(1 - p)}}{2p} = \frac{1 \pm \sqrt{(2p - 1)^2}}{2p} = \frac{1 \pm |2p - 1|}{2p}$$

is $(1 + 2p - 1)/(2p) = 1$ or $(2 - 2p)/(2p) = q/p$. The roots are distinct if $p \neq q$ and are both equal to 1 if $p = q$. So we have

$$p_i = \begin{cases} a + b \left(\frac{q}{p}\right)^i, & p \neq q \\ a + bi, & p = q \end{cases}$$

This is called the general solution of the difference equation, since we have not yet specified the constants a and b . To get a specific solution, we need to know two points in the sequence in order to solve for a and b .

B.4.5 A. 5 Differential Equations

Differential equations are the continuous version of difference equations. A differential equation uses derivatives to describe a function or collection of functions. For example, the differential equation

$$\frac{dy}{dx} = 3y$$

describes a collection of functions that have the following property: the instantaneous rate of change of the function at any point (x, y) is equal to $3y$. This is an example of a separable differential equation because we can separate the x 's and y 's, putting them on opposite sides of the equation:

$$\frac{dy}{y} = 3dx$$

Now we can integrate both sides, giving $\log y = 3x + c$, or equivalently,

$$y = Ce^{3x}$$

where C is any constant. This is called the general solution of the differential equation, and it tells us that all functions satisfying the differential equation are of the form $y = Ce^{3x}$ for some C . To get a specific solution, we need to specify one point on the graph, which allows us to solve for C .

B.4.6 A. 6 Partial Derivatives

If you can do ordinary derivatives, you can do partial derivatives: just hold all the other input variables constant except for the one you're differentiating with respect to. For example, let $f(x, y) = y \sin(x^2 + y^3)$. Then the partial derivative with respect to x is

$$\frac{\partial f(x, y)}{\partial x} = 2xy \cos(x^2 + y^3),$$

and the partial derivative with respect to y is

$$\frac{\partial f(x, y)}{\partial y} = \sin(x^2 + y^3) + 3y^3 \cos(x^2 + y^3).$$

These are first order partial derivatives. If we take a partial derivative of a first order partial derivative, we get a second order partial derivative, such as

$$\frac{\partial^2 f(x, y)}{\partial y \partial x} = \frac{\partial}{\partial y} \left(\frac{\partial f(x, y)}{\partial x} \right) = 2x (\cos(x^2 + y^3) - 3y^3 \sin(x^2 + y^3)).$$

We get the same result if we take the partial derivatives in the opposite order (with respect to y and then with respect to x):

$$\frac{\partial^2 f(x, y)}{\partial x \partial y} = \frac{\partial}{\partial x} \left(\frac{\partial f(x, y)}{\partial y} \right) = 2x (\cos(x^2 + y^3) - 3y^3 \sin(x^2 + y^3)).$$

Under mild technical assumptions, it is also true for general f that

$$\frac{\partial^2 f(x, y)}{\partial x \partial y} = \frac{\partial^2 f(x, y)}{\partial y \partial x}.$$

The Jacobian of a transformation which maps $(x_1, \dots, x_n)$ to $(y_1, \dots, y_n)$ is the $n \times n$ matrix of all possible first order partial derivatives, given by

$$\frac{\partial \mathbf{y}}{\partial \mathbf{x}} = \begin{pmatrix} \frac{\partial y_1}{\partial x_1} & \frac{\partial y_1}{\partial x_2} & \cdots & \frac{\partial y_1}{\partial x_n} \\ \vdots & \vdots & & \vdots \\ \frac{\partial y_n}{\partial x_1} & \frac{\partial y_n}{\partial x_2} & \cdots & \frac{\partial y_n}{\partial x_n} \end{pmatrix}$$

B.4.7 A. 7 Multiple Integrals

If you can do single integrals, you can do multiple integrals: just do more than one integral, holding variables other than the current variable of integration constant.

For example,

$$\begin{aligned} \int_0^1 \int_0^y (x-y)^2 dx dy &= \int_0^1 \int_0^y (x^2 - 2xy + y^2) dx dy \\ &= \int_0^1 \left((x^3/3 - x^2y + xy^2) \Big|_0^y \right) dy \\ &= \int_0^1 (y^3/3 - y^3 + y^3) dy \\ &= \frac{1}{12} \end{aligned}$$

A.7.1 Change of Order of Integration

We can also integrate in the other order, $dydx$ rather than $dx dy$, as long as we are careful about the limits of integration. Since we're integrating over all (x, y) with x and y between 0 and 1 such that $x \leq y$, to integrate the other way we write

$$\begin{aligned} \int_0^1 \int_x^1 (x-y)^2 dy dx &= \int_0^1 \int_x^1 (x^2 - 2xy + y^2) dy dx \\ &= \int_0^1 \left((x^2y - xy^2 + y^3/3) \Big|_x^1 \right) dx \\ &= \int_0^1 (x^2 - x + 1/3 - x^3 + x^3 - x^3/3) dx \\ &= \frac{1}{12} \end{aligned}$$

A.7.2 Change of Variables

In making a change of variables with multiple integrals, a Jacobian is needed. To simplify notation, we will discuss the two-dimensional version; the n -dimensional version is analogous. Suppose we make an invertible transformation from (x, y) to (u, v) , where the inverse transformation is given by

$$x = g(u, v), y = h(u, v)$$

Let A be a region in the (x, y) -plane and B be the corresponding region in the (u, v) -plane. Then the change of variables formulas says that

$$\iint_A f(x, y) dx dy = \iint_B f(g(u, v), h(u, v)) \cdot \left\| \frac{\partial(x, y)}{\partial(u, v)} \right\| du dv$$

where $\left| \left| \frac{\partial(x,y)}{\partial(u,v)} \right| \right|$ is the absolute value of the determinant of the Jacobian matrix. A few technical assumptions are needed for this result, such as that the partial derivatives that appear in the Jacobian matrix exist and are continuous, and that the determinant of the Jacobian matrix is never 0 .

For example, let's find the area of a circle of radius 1 . To find the area of a region, we just need to integrate 1 over that region (so the part that may be tricky is the limits of integration; the integrand is just 1). So the area is

$$\iint_{x^2+y^2 \leq 1} 1 dx dy = \int_{-1}^1 \int_{-\sqrt{1-y^2}}^{\sqrt{1-y^2}} 1 dx dy = 2 \int_{-1}^1 \sqrt{1-y^2} dy$$

Note that the limits for the inner variable (x) of the double integral can depend on the outer variable (y), while the outer limits are constants. The last integral can be done with a trigonometric substitution, but instead let's simplify the problem by transforming to polar coordinates: let

$$x = r \cos \theta, y = r \sin \theta,$$

where r is the distance from (x, y) to the origin and $\theta \in [0, 2\pi)$ is the angle. The Jacobian matrix of this transformation is

$$\frac{\partial(x,y)}{\partial(r,\theta)} = \begin{pmatrix} \cos \theta & -r \sin \theta \\ \sin \theta & r \cos \theta \end{pmatrix}$$

so the absolute value of the determinant of the Jacobian is $r (\cos^2 \theta + \sin^2 \theta) = r$. That is, $dx dy$ becomes $r dr d\theta$. So the area of the circle is

$$\int_0^{2\pi} \int_0^1 r dr d\theta = \int_0^{2\pi} \frac{1}{2} d\theta = \pi$$

For a circle of radius r , it follows immediately that the area is πr^2 since we can convert our units of measurement to the unit for which the radius is 1 .

This may seem like a lot of work just to get such a familiar result, but it served as illustration and with similar methods we can get the volume of a ball in any number of dimensions! It turns out that the volume of a ball of radius 1 in $\mathbb{R}^n$ is

$$V_n = \frac{\pi^{n/2}}{\Gamma(n/2 + 1)},$$

where Γ is the gamma function (see Section A.2.7).

B.4.8 A. 8 Sums

There are several kinds of sums that come up frequently in probability.

A.8.1 Binomial Theorem

The binomial theorem states that

$$(x + y)^n = \sum_{k=0}^n \binom{n}{k} x^k y^{n-k}$$

for any nonnegative integer n . Here $\binom{n}{k}$ is a binomial coefficient, defined as the number of ways to choose k objects out of n , with order not mattering. An explicit formula for $\binom{n}{k}$ in terms of factorials for $0 \leq k \leq n$ is

$$\binom{n}{k} = \frac{n!}{(n-k)!k!}$$

A proof of the binomial theorem is given in Example 1.4.19.

Sometimes 0^0 is said to be undefined, but there are several strong arguments for defining it to be 1, and we will take $0^0 = 1$ in this book. For one simple reason for doing so, consider the case $x = 0, y = 1$ in the binomial theorem. Then the left-hand side is $1^n = 1$, and we need to have $0^0 = 1$ in order to make the right-hand side also equal to 1.

A.8.2 Geometric Series

A series of the form $\sum_{n=0}^{\infty} x^n$ is called a geometric series. For $|x| < 1$, the series converges and we have

$$\sum_{n=0}^{\infty} x^n = \frac{1}{1-x}$$

The series diverges if $|x| \geq 1$. A series of the same form except with finitely many terms is called a finite geometric series. For $x \neq 1$, the sum is

$$\sum_{k=0}^n x^k = \frac{1-x^{n+1}}{1-x}$$

Note that the $n+1$ in the exponent is the number of terms in the sum. If the sum starts at $k = m$ rather than $k = 0$ (where m is an integer with $0 \leq m \leq n$), then we can easily reduce to the case where the sum starts at 0. Making the substitution $j = k - m$, we have

$$\sum_{k=m}^n x^k = \sum_{j=0}^{n-m} x^{j+m} = x^m \sum_{j=0}^{n-m} x^j = x^m \cdot \frac{1-x^{n-m+1}}{1-x}.$$

A.8.3 Taylor Series for e^x

The Taylor series for e^x is

$$\sum_{n=0}^{\infty} \frac{x^n}{n!} = e^x, \text{ for all } x$$

A.8.4 Harmonic Series and Other Sums with a Fixed Exponent

It is also useful to know that $\sum_{n=1}^{\infty} 1/n^c$ converges for $c > 1$ and diverges for $c \leq 1$. For $c = 1$, this is called the harmonic series. The sum of the first n terms of the harmonic series can be approximated using

$$\sum_{k=1}^n \frac{1}{k} \approx \log(n) + \gamma$$

for n large, where $\gamma \approx 0.577$ is the Euler-Mascheroni constant.

The sum of the first n positive integers is

$$\sum_{k=1}^n k = n(n+1)/2 = \binom{n+1}{2}.$$

It follows from this identity, for example, that the sum of the first n odd positive integers is

$$\sum_{k=1}^n (2k-1) = 2 \sum_{k=1}^n k - \sum_{k=1}^n 1 = n(n+1) - n = n^2.$$

For squares of integers, we have

$$\sum_{k=1}^n k^2 = n(n+1)(2n+1)/6.$$

For cubes of integers, amazingly, the sum is the square of the sum of the first n positive integers! That is,

$$\sum_{k=1}^n k^3 = (n(n+1)/2)^2$$

Exercise 22 from Chapter 1 asks for a story proof of this result.

B.4.9 A. 9 Pattern Recognition

Much of math and statistics is really about pattern recognition: seeing the essential structure of a problem, recognizing when one problem is essentially the same as another problem (just in a different guise), noticing symmetry, and so on. We will see many examples of this kind of thinking in this book. For example, suppose we have the series $\sum_{k=0}^{\infty} e^{tk} e^{-\lambda} \lambda^k / k!$, with λ a positive constant. The $e^{-\lambda}$ can be taken out from the sum, and then the structure of the series exactly matches up with the structure of the Taylor series for e^x . Therefore

$$\sum_{k=0}^{\infty} \frac{e^{tk} e^{-\lambda} \lambda^k}{k!} = e^{-\lambda} \sum_{k=0}^{\infty} \frac{(\lambda e^t)^k}{k!} = e^{-\lambda} e^{\lambda e^t} = e^{\lambda(e^t-1)},$$

valid for all real t .

Similarly, suppose we want the Taylor series for $1/(1-x^3)$ about $x=0$. It would be tedious to start taking derivatives of this function. Instead, note that this function is reminiscent of the result of summing a geometric series. Therefore

$$\frac{1}{1-x^3} = \sum_{n=0}^{\infty} x^{3n}$$

for $|x^3| < 1$ (which is equivalent to $|x| < 1$). What matters is the structure, not what names we use for variables!

B.4.10 A. 10 Common Sense and Checking Answers

It is very easy to make mistakes in probability, so checking answers is especially important. Some useful strategies for checking answers are:

- seeing whether the answer makes sense intuitively (though as we have often seen in this book, probability has many results that seem counterintuitive at first);
- making sure your answer isn't a category error;
- making sure you're avoiding biohazards;
- trying out simple cases;

- trying out extreme cases;
- looking for alternative methods to solve the problem (including methods that may only give a bound or approximation, such as applying one of the inequalities from Chapter 10 or using R to run a simulation).

B.5 R

B.5.1 B. 1 Vectors

Command	What it does
<code>c(1,1,0,2.7,3.1)</code>	creates the vector (1, 1, 0, 2.7, 3.1)
<code>1:100</code>	creates the vector (1, 2, ..., 100)
<code>(1 : 100)^3</code>	creates the vector (1 ³ , 2 ³ , ..., 100 ³)
<code>rep(0,50)</code>	creates the vector (0, 0, ..., 0) of length 50
<code>seq (0, 99, 3)</code>	creates the vector (0, 3, 6, 9, ..., 99)
<code>v [5]</code>	5 th entry of vector v (index starts at 1)
<code>v [-5]</code>	all but the 5th entry of v
<code>v[c(3,1,4)]</code>	3rd, 1st, 4th entries of vector v
<code>v[v > 2]</code>	entries of v that exceed 2
<code>which(v>2)</code>	indices of v such that entry exceeds 2
<code>which(v == 7)</code>	indices of v such that entry equals 7
<code>min (v)</code>	minimum of v
<code>max (v)</code>	maximum of v
<code>which.max(v)</code>	indices where $\max(v)$ is achieved
<code>sum (v)</code>	sum of the entries in v
<code>cumsum(v)</code>	cumulative sums of the entries in v
<code>prod(v)</code>	product of the entries in v
<code>rank(v)</code>	ranks of the entries in v
<code>length(v)</code>	length of vector v
<code>sort(v)</code>	sorts vector v (in increasing order)
<code>unique(v)</code>	lists each element of v once, without duplicates
<code>tabulate(v)</code>	tallies how many times each element of v occurs
<code>table(v)</code>	same as <code>tabulate(v)</code> , except in table format
<code>c(v,w)</code>	concatenates vectors v and w
<code>union (v , w)</code>	union of v and w as sets
<code>intersect(v,w)</code>	intersection of v and w as sets
<code>v+w</code>	adds v and w entrywise (recycling if needed)
<code>v*w</code>	multiplies v and w entrywise (recycling if needed)

B.5.2 B. 2 Matrices

Command	What it does
<code>matrix (c(1, 3, 5, 7), nrow = 2, ncol = 2)</code>	binds vectors u, v, w into a matrix, as rows binds vectors u row 2, column 3 entry of matrix A row 2 of matrix A (as a submatrix of A , keeping rows 1,3 and columns 2,4 row sum eigenvalues and eigenvectors of matrix A A^{-1} solves $A\mathbf{x} = \mathbf{b}$ for $\mathbf{x}$ (where $\mathbf{b}$ is a column vector) matrix m

B.5.3 B. 3 Math

Command	What it does
abs(x)	$ x $
exp(x)	e^x
log (x)	$\log(n)$
log(x, b)	$\log_b(n)$
sqrt(x)	$\sqrt{x}$
floor(x)	$\lfloor x \rfloor$
ceiling(x)	$\lceil x \rceil$
factorial(n)	$n!$
lfactorial(n)	$\log(n!)$ (helps prevent overflow)
gamma(a)	$\Gamma(a)$
lgamma(a)	$\log(\Gamma(a))$ (helps prevent overflow)
choose(n,k)	binomial coefficient $\binom{n}{k}$
pbirthday(k)	solves birthday problem for k people
if (x > 0)x^2 else x^3	x^2 if $x > 0$, x^3 otherwise (piecewise)
f <- function(x) exp(-x)	defines the function f by $f(x) = e^{-x}$
integrate(f, lower=0, upper=Inf)	finds $\int_0^\infty f(x)dx$ numerically
optimize(f , lower = 0, upper = 5, maximum=TRUE)	maximizes f numerically on $[0, 5]$
uniroot(f, lower = 0, upper = 5)	searches numerically for a zero of f in $[0, 5]$

B.5.4 B. 4 Sampling and Simulation

Command	What it does
sample(7)	random permutation of 1, 2, ..., 7
sample (52, 5)	picks 5 times from 1, 2, ..., 52 (don't replace)
sample(letters,5)	picks 5 random letters of the alphabet (don't replace)
sample(3,5, replace = TRUE , prob=p)	picks 5 times from 1, 2, 3 with probabilities p (replace)
replicate(10^4, experiment)	simulates 10^4 runs of experiment

B.5.5 B. 5 Plotting

Command	What it does
curve (f, from=a, to=b)	graphs the function f from a to b
plot(x,y)	creates scatter plot of the points (x_i, y_i)
plot(x,y,type="l")	creates line plot of the points (x_i, y_i)
points(x, y)	adds the points (x_i, y_i) to the plot
abline(a,b)	adds line segments through the (x_i, y_i) to the plot
hist(x, breaks=b, col="blue")	blue histogram of the values in x , with b bins suggested
par(new=TRUE)	tells R not to clear the palette when we make our next plot
par(mfrow=c(1,2))	tells R we want 2 side-by-side plots (a 1 by 2 array of plots)

B.5.6 B. 6 Programming

Command	What it does
<code>x <- pi</code>	sets x equal to π
<code>x > 3 && x < 5</code>	Is $x > 3$ and $x < 5$? (TRUE/FALSE)
<code>x > 3 x < 5</code>	Is $x > 3$ or $x < 5$? (TRUE/FALSE)
<code>if (n > 3)x <- -x + 1</code>	adds 1 to x if $n > 3$
<code>if (n == 0) x <- -x + 1 else x <- -x + 2</code>	adds 1 to x if $n = 0$, else adds 2
<code>v <- rep(0, 50); for (k in 1:50) v[k]<-rbinom(1, 50, 0.5)</code>	solves birthday problem up to 50 people

B.5.7 B. 7 Summary Statistics

Command	What it does
<code>mean (v)</code>	sample mean of vector v
<code>var(v)</code>	sample variance of vector v
<code>sd(v)</code>	sample standard deviation of vector v
<code>median(v)</code>	sample median of vector v
<code>summary(v)</code>	min, 1st quartile, median, mean, 3rd quartile, max of v
<code>quantile(v,p)</code>	p th sample quantile of vector v
<code>cov (v,w)</code>	sample covariance of vectors v and w
<code>cor(v, w)</code>	sample correlation of vectors v and w

B.5.8 B. 8 Distributions

Command	What it does
<code>help(distributions)</code>	shows documentation on distributions
<code>dbinom(k,n,p)</code>	PMF $P(X = k)$ for $X \sim \text{Bin}(n, p)$
<code>pbinom(x,n,p)</code>	CDF $P(X \leq x)$ for $X \sim \text{Bin}(n, p)$
<code>qbinom(a,n,p)</code>	quantile $\min\{x : P(X \leq x) \geq a\}$ for $X \sim \text{Bin}(n, p)$
<code>rbinom(r,n,p)</code>	vector of r i.i.d. $\text{Bin}(n, p)$ r.v.s
<code>dgeom(k,p)</code>	PMF $P(X = k)$ for $X \sim \text{Geom}(p)$
<code>dhyper(k,w,b,n)</code>	PMF $P(X = k)$ for $X \sim \text{HGeom}(w, b, n)$
<code>dnbinom(k,r,p)</code>	PMF $P(X = k)$ for $X \sim \text{NBin}(r, p)$
<code>dpois(k,r)</code>	PMF $P(X = k)$ for $X \sim \text{Pois}(r)$
<code>dbeta(x,a,b)</code>	PDF $f(x)$ for $X \sim \text{Beta}(a, b)$
<code>dcauchy(x)</code>	PDF $f(x)$ for $X \sim \text{Cauchy}$
<code>dchisq(x,n)</code>	PDF $f(x)$ for $X \sim \chi_n^2$
<code>dexp(x,r)</code>	PDF $f(x)$ for $X \sim \text{Expo}(r)$
<code>dgamma(x,a,r)</code>	PDF $f(x)$ for $X \sim \text{Gamma}(a, r)$
<code>dlnorm(x,m,s)</code>	PDF $f(x)$ for $X \sim \mathcal{LN}(m, s^2)$
<code>dnorm(x,m,s)</code>	PDF $f(x)$ for $X \sim \mathcal{N}(m, s^2)$
<code>dt(x, n)</code>	PDF $f(x)$ for $X \sim t_n$
<code>dunif(x,a,b)</code>	PDF $f(x)$ for $X \sim \text{Unif}(a, b)$
<code>dweibull(x,a,b)</code>	PDF $f(x)$ for $X \sim \text{Weibull}(b^{-a}, a)$

There are commands that are completely analogous to `pbinom`, `qbinom`, and `rbinom` for the other distributions appearing in the above table. For example, `pnorm`, `qnorm`, and `rnorm` can be used to get the CDF, the quantiles, and random generation for the Normal (note that the mean and standard deviation need to be provided as the parameters, rather than the mean and variance).

For the Multinomial, `dmultinom` can be used for calculating the joint PMF and `rmultinom` can be used for generating random vectors. For the Multivariate Normal, after installing and

loading the mvtnorm package, dmvnorm can be used for calculating the joint PDF and rmvnorm can be used for random generation.

B.6 Table of Distributions

Name	Param.	PMF or PDF	Mean	Variance
Bernoulli	p	$P(X = 1) = p, P(X = 0) = q$	p	pq
Binomial	n, p	$\binom{n}{k} p^k q^{n-k}, k \in \{0, 1, \dots, n\}$	np	npq
FS	p	$pq^{k-1}, k \in \{1, 2, \dots\}$	$1/p$	q/p^2
Geom	p	$pq^k, k \in \{0, 1, 2, \dots\}$	q/p	q/p^2
NBin	r, p	$\binom{r+k-1}{r-1} p^r q^k, k \in \{0, 1, 2, \dots\}$	rq/p	rq/p^2
HGeom	w, b, n	$\frac{\binom{w}{k} \binom{b}{n-k}}{\binom{w+b}{n}}, k \in \{0, 1, \dots, n\}$	$\mu = \frac{nw}{w+b}$	$\left(\frac{w+b-n}{w+b-1}\right) \mu \left(1 - \frac{\mu}{n}\right)$
NHGeom	w, b, r	$\frac{\binom{r+k-1}{r-1} \binom{w+b-r-k}{w-r}}{\binom{w+b}{w}}, k \in \{0, 1, \dots, b\}$	$\frac{rb}{w+1}$	$\frac{rb(w+b+1)(w-r+1)}{(w+1)^2(w+2)}$
Poisson	λ	$\frac{e^{-\lambda} \lambda^k}{k!}, k \in \{0, 1, 2, \dots\}$	λ	λ
Uniform	$a < b$	$\frac{1}{b-a}, x \in (a, b)$	$\frac{a+b}{2}$	$\frac{(b-a)^2}{12}$
Normal	μ, σ^2	$\frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\mu)^2/(2\sigma^2)}$	μ	σ^2
Log-Normal	μ, σ^2	$\frac{1}{x\sigma\sqrt{2\pi}} e^{-(\log x - \mu)^2/(2\sigma^2)}, x > 0$	$\theta = e^{\mu + \sigma^2/2}$	$\theta^2 (e^{\sigma^2} - 1)$
Expo	λ	$\lambda e^{-\lambda x}, x > 0$	$1/\lambda$	$1/\lambda^2$
Weibull	λ, γ	$\gamma \lambda e^{-\lambda x^\gamma} x^{\gamma-1}, x > 0$	$\mu = \frac{\Gamma(1+1/\gamma)}{\lambda^{1/\gamma}}$	$\frac{\Gamma(1+2/\gamma)}{\lambda^{2/\gamma}} - \mu^2$
Gamma	a, λ	$\Gamma(a)^{-1} (\lambda x)^a e^{-\lambda x} x^{-1}, x > 0$	a/λ	a/λ^2
Beta	a, b	$\frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} x^{a-1} (1-x)^{b-1}, 0 < x < 1$	$\mu = \frac{a}{a+b}$	$\frac{\mu(1-\mu)}{a+b+1}$
Chi-Square	n	$\frac{1}{2^{n/2} \Gamma(n/2)} x^{n/2-1} e^{-x/2}, x > 0$	n	$2n$
Student- t	n	$\frac{\Gamma((n+1)/2)}{\sqrt{n\pi} \Gamma(n/2)} (1 + x^2/n)^{-(n+1)/2}$	0 if $n > 1$	$\frac{n}{n-2}$ if $n > 2$
